Structure Solution and Refinement. The structure of **1** was first solved by the Patterson-Fourier method. The structure solution of **2** was straightforward because the **1** and **2** structures are isomorphous. The refinement of the structures was carried out by the use of the block-diagonal least-squares method. The function minimized was $\sum w(F_o-|F_c|)^2$, where $w=1/\sigma^2(F_o)$ was used. The neutral atomic scattering factors for the Mo, S, O, N, and C atoms were taken from Ref. 5, with an anomalous dispersion corrections ($\Delta f'$) for the Mo and S atoms. The final R values were 0.041 for **1** and 0.064 for **2**. No attempt was made to locate hydrogen atoms. The N atom of the pyridinium ion could not be identified in either crystal. The positions of the N atoms were detemined on the basis of short contact distances (Table 4), because the N–H group of the pyridinium ion is expected to form a hydrogen bond. No chemically significant peaks were observed on the final difference Fourier maps for **1** and **2**. The maximum peaks were 0.6 e Å^{-3} for **1** and 0.6 e Å^{-3} for **2**. No water of crystallization was found in **1**. The F_o-F_c tables for **1** and **2** and the anisotropic temperature factors are preserved by the Chemical Society of Japan (Document No. 8340). The final atomic coordinates are given in Tables 2 and 3. The figures were drawn by the use of ORTEP.[6] The computations were performed by the use of a FACOM 230-60 computer at Osaka City University and an ACOS-900 computer at the Crystallographic Research Center, Institute for Protein Research, Osaka University, using Programs in the UNICS.[7]

Results and Discussion

Perspective views of the complex ions in **1** and **2** are given in Figs. 1 and 2. Each complex contains a crystallographic mirror plane through the two bridging atoms. Therefore, both complexes have the *cis*-dioxo structure. Each structure consists of two distorted octahedra sharing as SS or OS edge. The geometries and dimensions of $Mo_2O_2S_2$ and Mo_2O_3S cores do not significantly differ from those of the corresponding cores in the other binuclear Mo(V) complexes. The deviation of the Mo atom from the mean plane defined by the S_2N_2 plane to O1 is 0.28 Å in **1**, while that from the OSN_2 plane to O1 is 0.28 Å in **2**. The bond distances and angles are listed in Table 4, while important interatomic distances and dihedral angles are compared in Table 5. The Mo–Mo and O1–O1 distances are larger in **1** than in **2**, in

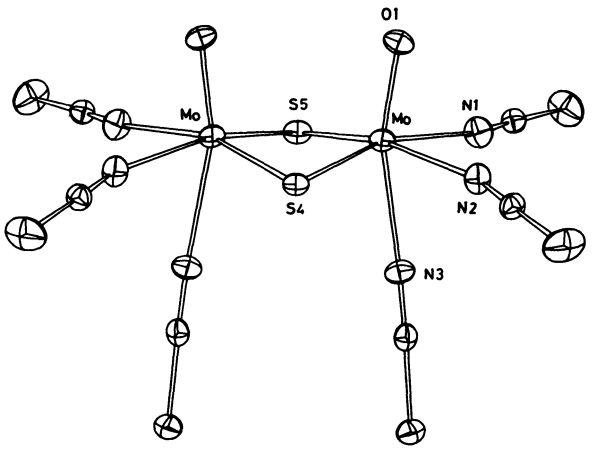

Fig. 1. A perspective view of $[Mo_2O_2S_2(NCS)_6]^{4-}$. The thermal ellipsoid was drawn at the 40% probability level.

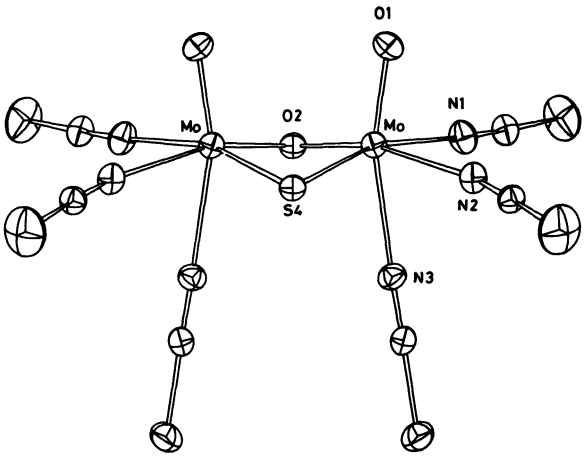

Fig. 2. A perspective view of $[Mo_2O_3S(NCS)_6]^{4-}$.

accordance with the larger size of the sulfur compared to that of the oxygen in the bridge. On the other hand, the S_b–Mo–O1 (S_b: bridging sulfido) and O_b–Mo–O1 (O_b : bridging oxo) angles in the cores in **1** and **2** have similar values. The angle between the two MoS_2 planes in **1** is very close to that between the two MoOS planes in **2**. The MoS_2–MoS_2 dihedral angle of 153.4° and the MoOS–MoOS dihedral angle of 153.8° are similar to those in $Ba[Mo_2O_4(ox)_2(H_2O)_2]\cdot 10H_2O$[8] and $Cs_2[Mo_2O_2S_2(ox)_2(H_2O)_2]\cdot 2H_2O$,[9] but smaller than those in $K_6[\{Mo_2O_3S(ox)_2\}_2(ox)]\cdot 10H_2O$[3] and $K_6[\{Mo_2O_4(mal)_2\}_2(mal)]\cdot 4H_2O$.[10] The Mo–O1 distance in **1** is 1.683 Å and that in **2**, 1.669 Å. These values are in agreement with those previously reported.[11] The Mo–S (bridging sulfido) distances in **1** and **2** range from 2.301 to 2.313 Å, and the Mo–O (bridging oxo) distance in **2** is 1.950 Å. The S–Mo–S, O–Mo–S, Mo–S–Mo, and Mo–O–Mo angles in the bridges agree well with those in $Na_2[Mo_2S_2O_2(R\text{-pdta})]\cdot 4H_2O$,[12] and $Na_2[Mo_2O_3S(R\text{-pdta})]\cdot 4H_2O$.[12] The bond lengths and angles for the $Mo_2S_2O_2$ core in **1** are similar to those in $Na_2[Mo_2O_2S_2(R\text{-pdta})]\cdot 4H_2O$, and the bond lengths and angles for the Mo_2O_3S core in **2** are similar to those in $Na_2[Mo_2O_3S(R\text{-pdta})]\cdot 4H_2O$. The large trans effect of terminal oxo (O_t=O1) was observed in these cases,

Retention Behavior of Iron(III) Chelates with Amine-*N*-carboxylic Acids on Silica-gel and Octadecyl-silica Columns

Akihiro YAMAGUCHI, Atsuko TODA, Kunio OHZEKI,* and Tomihito KAMBARA
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received March 31, 1983)

The separation of iron(III)–edta, –methyl-edta, –dtpa, and –cdta was investigated by high performance liquid chromatography on silica-gel (ZORBAX SIL) and octadecyl-silica (ZORBAX ODS) columns. The chelates were retained on both columns from phosphate buffer mobile phase of pH 3, while the baseline separation was not achieved on the ODS column. The degree of increase in retention caused by the addition of tetrabutylammonium bromide to the eluent was greater on the ODS column than on the silica-gel column, and well separated chelates were eluted in the order, iron(III)–edta, –methyl-edta, –dtpa, and –cdta on both columns.

The application of reversed-phase high performance liquid chromatography (RPHPLC) to analysis of metal chelates has become of interest in recent years.[1,2] The mobile phase containing hydrophobic counter ions has been used to enhance retention and resolution of charged metal complexes on alkyl-bonded silica gel[1] and silica-gel columns.[3]

We have recently shown[4] that iron(III) complexes with EDTA and the analogous compounds were retained from phosphate buffer mobile phase on a silica-gel column, and that the retention increased either with increasing buffer concentration or with increasing amount of sodium sulfate added to the eluent. The purpose of this paper is to show the effect of a tetra-alkylammonium ion on the retention behavior of the chelates on the silica-gel column, and to compare the results with those observed on the octadecyl-silica column.

Experimental

Apparatus. A Shimadzu Model LC-3A chromatograph equipped with a Model SIL-1A syringe injector and a Model SPD-2A variable wavelength UV-detector was used in combination with a Chromatopac C-R1A recorder. The pre-packed columns of ZORBAX SIL and ZORBAX ODS, (DuPont Co.) were used. Both columns were 25 cm × 4.6 mm i.d. A Horiba Model F-7C pH meter was used.

Reagents. The chelating agents were obtained from Dojin Laboratory. The compounds and their abbreviations are disodium salt of ethylenediamine-*N,N,N',N'*-tetraacetic acid (EDTA), 1,2-propanediamine-*N,N,N',N'*-tetraacetic acid (Methyl-EDTA), diethylenetriamine-*N,N,N',N'',N''*-pentaacetic acid (DTPA), and 1,2-cyclohexanediamine-*N,N,N',N'*,-tetraacetic acid (CDTA). Inorganic salts used were of analytical reagent grade. Iron(III) standard solution was prepared from ammonium iron(III) sulfate dodecahydrate. Tetrabutylammonium bromide (TBAB) and chromatographic grade acetonitrile were obtained from Wako Pure Chemicals Co. Deionized and redistilled water was used.

Procedure. Sample solutions were prepared by mixing standard iron(III) and chelating agent solutions in the stoichiometric ratio. The final concentration of each chelate was 20 μmol dm^{-3}. The 10-μl portions were injected. All experiments were carried out at room temperature. The capacity factors were calculated in the usual way.[5] The retention time of a nonretained component was evaluated from the first detectable peak on the chromatogram.

Results and Discussion

Effect of TBAB on Silica-gel Column. The retention of iron(III)–edta, –methyl-edta, –dtpa, and –cdta complexes on the silica-gel column was remarkably enhanced by the addition of TBAB to the phosphate buffer mobile phase. In the presence of 0.1 mmol dm^{-3} TBAB in 2.3 mmol dm^{-3} phosphate buffer eluent of pH 3, the retention time increased from 3.4 to 12.7 min for iron(III)–edta, and 12.6 to 107 min for iron(III)–cdta complexes, respectively, at a flow rate of 1 ml min^{-1}. The capacity factor of each chelate increased with increasing concentration of TBAB in the mobile phase, as generally occurs in reversed-phase chromatography. Among mechanisms which were reviewed[6] to describe the effect of lipophilic alkyl ions in RPHPLC the ion-exchange model[7] seems to be most familiar.

Effect of Electrolyte. The effect of electrolyte added to the phosphate buffer mobile phase was studied in the

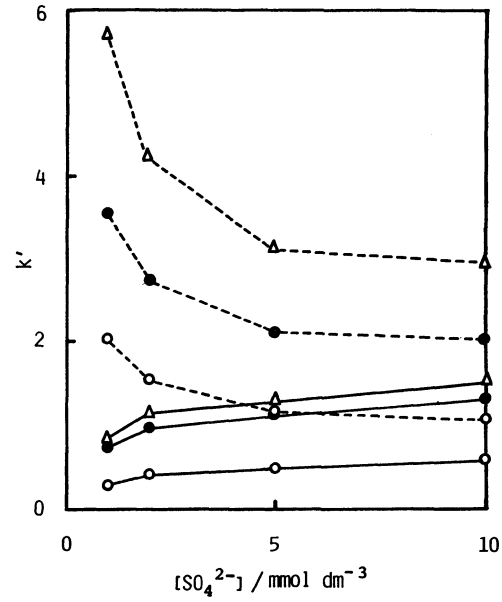

Fig. 1. Effect of sodium sulfate concentration in 2.3 mmol dm^{-3} phosphate buffer eluent (pH 3) on the capacity factor in the absence (solid line) and in the presence (dashed line) of 0.1 mmol dm^{-3} TBAB. Column: ZORBAX SIL, 25 cm × 4.6 mm i.d.; sample: (○) Fe^{III}–edta, (●) Fe^{III}–methyl-edta, (△) Fe^{III}–dtpa.

TABLE 1. THE CAPACITY FACTORS OF IRON(III) CHELATES ON ZORBAX SIL AND ODS

	ZORBAX SIL			ZORBAX ODS		
	k'_1	k'_2	k'_2/k'_1	k'_1	k'_2	k'_2/k'_1

Eluent: 0.012 mol dm^{-3} phosphate buffer solution, 5% (V/V) acetonitrile, pH 3. k'_1: Capacity factor in the absence of TBAB. k'_2: Capacity factor in the presence of 0.1 mmol dm^{-3} TBAB.

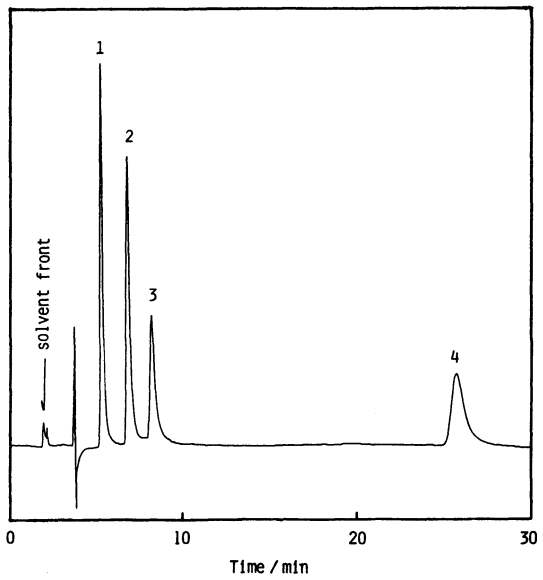

Fig. 2. Separation of iron(III) chelates on ZORBAX ODS in the presence of TBAB. Eluent: 12.0 mmol dm^{-3} phosphate buffer solution containing 0.1 mmol dm^{-3} TBAB and 5% (V/V) acetonitrile, pH 3; flow rate: 1 ml min^{-1}; detection at 260 nm, 0.01 a.u.f.s.; sample: 10 μl containing each chelate in 20 μmol dm^{-3}; peak 1, Fe^{III}-edta; peak 2, Fe^{III}-methyl-edta; peak 3, Fe^{III}-dtpa; peak 4, Fe^{III}-cdta.

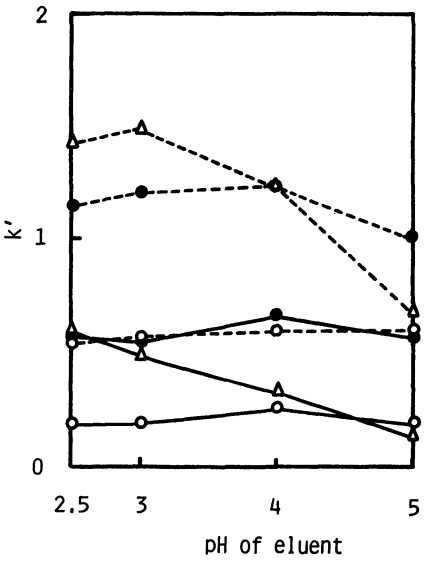

Fig. 3. Effect of pH on the capacity factor. Column: ZORBAX ODS (solid line), ZORBAX SIL (dashed line); eluent: phosphate buffer solution containing 10 mmol dm^{-3} sodium sulfate; sample: (○) Fe^{III}-edta, (●) Fe^{III}-methyl-edta, (△) Fe^{III}-dtpa.

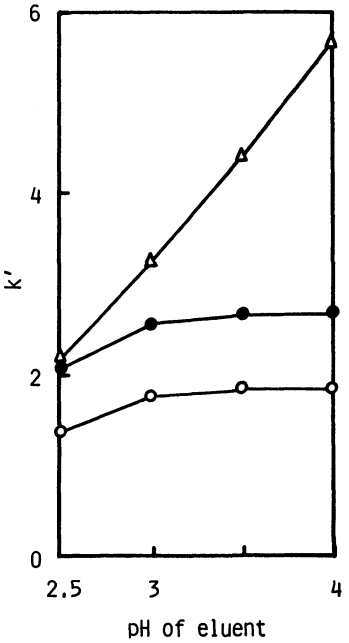

Fig. 4. Effect of pH on the capacity factor in the presence of TBAB. Column: ZORBAX ODS; eluent: phosphate buffer solution containing 0.1 mmol dm^{-3} TBAB and 5% acetonitrile; sample: (○) Fe^{III}-edta, (●) Fe^{III}-methyl-edta, (△) Fe^{III}-dtpa.

presence and absence of TBAB (Fig. 1). In the absence of TBAB, the retention of each complex increased gradually with increasing concentration of sodium sulfate in the mobile phase. The increase in retention is caused by the salting-out effect[8] of the electrolyte, the hydrophobic interaction[4] between the solute and stationary phase being facilitated. On the other hand, in the presence of TBAB, the retention decreased with increasing concentration of sodium sulfate, and reached almost constant value for each chelate in the concentration range of 5 to 10 mmol dm^{-3} of sodium sulfate. It is clearly concluded that the retention observed in the presence of TBAB is governed by at least two factors, namely, ion-exchange and salting-out effects. With increasing concentration of electrolyte in the eluent, the retention due to ion-exchange decreases and the retention caused by salting-out effect becomes predominant.

Separation of Chelates. The capacity factors of the chelates on silica-gel and ODS columns obtained by using mobile phase of the same composition were summarized in Table 1. The acetonitrile was used to reduce the retention time. The degree of increase in retention

caused by the addition of TBAB to the mobile phase was much greater on the ODS column than on the silica-gel column. The results suggested that the hydrophobic tetrabutylammonium ion is more feasibly adsorbed on the hydrocarbonaceous silica gel than on the original silica gel. The typical chromatogram was shown in Fig. 2. In the absence of TBAB, baseline separation of the iron(III) chelates were not achieved on the ODS column, even though the retention and resolution of the chelates were enhanced with increasing buffer concentration. The iron(III)–dtpa complex eluted between EDTA and Methyl–EDTA complexes on the ODS column, while the compound was eluted after the Methyl–EDTA complex on the silica-gel column. In the presence of TBAB, the chelates were well separated and eluted in the following order, iron(III)–edta, –methyl-edta, –dtpa, and –cdta on both columns. The elution sequence depends on the hydrophobicity of the chelates[4] and the pH of mobile phase as described below.

The Effect of Eluent pH. The effect of eluent pH was examined on the silica-gel and alkyl-modified silica-gel columns. On both columns, the retention of iron(III)–dtpa decreased with increasing pH of the mobile phase (Fig. 3). The DTPA complex has two carboxyl groups which do not participate in the complexation.[9] The dissociation of one or two uncoordinated carboxyl groups will reduce the hydrophobicity of the complex. The retention of DTPA complex begins to decrease at lower pH on the ODS column than on the silica-gel column. The silanol groups on the silica-gel surface will suppress the dissociation of carboxyl groups. The effect of pH on the ODS column was also studied in the presence of TBAB (Fig. 4). The retention of iron(III)–dtpa increased with increasing pH, which suggested also the dissociation of uncoordinated carboxyl groups.

(Received April 21, 1983)

The normal pulse polarographic behavior of the Cu(II)–EDTA and –HEDTA complexes was examined in a wide range of pH values to elucidate the mechanisms of their electrode reactions and to evaluate the relevant electrochemical kinetic parameters. From analysis of the dependence of the half-wave potentials on the sampling time and the hydrogen ion concentration, it was shown that the reduction wave of the Cu(II)–EDTA complexes observed in the pH range of 2.0 to 9.5 at −0.1 to −0.5 V *vs.* SCE corresponds to the simultaneous reduction of four complex species, CuH_3L^+, CuH_2L^0, $CuHL^-$, and CuL^{2-}, where $CuH_pL^{(p-2)+}$ and L^{4-} denote the protonated complex species with p protons and the unprotonated EDTA ion, respectively. The reduction wave of the Cu(II)–HEDTA complexes in the pH range of 3.0 to 9.0 at −0.25 to −0.4 V *vs.* SCE corresponds to the simultaneous reduction of two complex species, $CuHL^0$ and CuL^-, where L^{3-} denotes the unprotonated HEDTA ion. The kinetic parameters of the corresponding complex species (*i.e.* the cathodic transfer coefficient and the standard rate constant of electrode reaction) were evaluated.

In a series of papers,[1-3] we have examined the electrode reaction mechanism of the Cd(II) and Pb(II) complexes with ethylenediamine-*N*,*N*,*N*′,*N*′-tetraacetic acid (EDTA) and *N*-(2-hydroxyethyl)ethylenediamine-*N*,*N*′,*N*′-triacetic acid (HEDTA) and it has been shown that many protonated complex species of the type MH_pL (p=1,2,3 for the EDTA complex and p=1,2 for the HEDTA complex) complex species, as well as the ordinary unprotonated complex species can participate directly in the charge transfer processes. The relevant electrochemical kinetic parameters have been evaluated therein.

Our careful analysis of the d.c. polarograms for the Cu(II) complexes with EDTA and HEDTA confirmed that the electrode reactions are the quasi-reversible[4] in the range of pH=1.0 to 11.0, although their electrode processes have been considered to be reversible in the polarographic time scale.[5-8] It has been recognized that in the case of the quasi-reversible processes less reliable data regarding the electrochemical kinetic parameters are obtained from the analysis of the d.c. polarograms.

Normal pulse polarography (NPP) among the numerous pulse techniques is most suitable for the examination of the kinetics of polarographically quasi-reversibel electrode processes, because the current measuring time in NPP can be widely varied from 10^{-4} to a few seconds and the shape of normal pulse polarograms is similar to that of d.c. polarograms, so that the analysis of the normal pulse polarograms can be easily carried out by using the procedure similar to that of the analysis of the d.c. polarograms.[9] However, NPP has been ever applied to the examination of the electrode kinetics in only a few examples.[10-13] In general many pulse techniques[14] have been used for the microanalysis so far, since they were proposed by Barker[15,16] in 1957.

In this paper, we demonstrate that NPP is the powerful method to elucidate in detail the mechanism of the electrode processes of Cu(II)–EDTA and –HEDTA complexes and determine the values of the kinetic parameters of many protonated complexes and the unprotonated complexes being participating in the electrode reactions. Previously,[4] we have performed the examination of complex equilibrium of the Cu(II) aqua ion with EDTA and HEDTA by potentiometric titration measurements and reported the values of the formation constants of many protonated complexes and hydroxo complexes, being newly found.

Experimental

Instrumentation. Current-potential curves were measured by home-made instruments with multifunctions (d.c. polarography, differential pulse polarography, and normal pulse polarography). The program controlling potentials was generated by CMOS logic IC and programmable timer counter IC (Intersil ICM 7250) with a quartz oscillator, which acted through a 12-bit D/A converter driving the potentiostat. The current response, which was converted to the voltage at the current follower of the potentiostat, was fed through a sample-hold circuits (Intersil IH 5110) into two integrator-type sample-hold circuits (using Analog Devies AD515k) with very small drift rate (<1 μV s^{-1}) at the hold-mode. Individual storing information was recorded with a two-pen X-Y-Y recorder. The sampling times of normal pulse polarography can be set at two arbitrary values from 0.1 ms to 9.9 s. The magnitude of the increase in the potential pulse height, ΔE, at each mercury drop can be changed from 1 to 99 mV. As an another current sampling method, we also used the following method: the current was integrated over a time interval, which is shorter than one-tenth of the pulse width, near the end of the pulse and the average value of the integrated current was taken as the current sampled. In order to increase the signal-to-noise ratio, especially when the faradic current is small,

A spike-like pulse which is generated between a dropping mercury electrode and a counter electrode at the moment of mercury drop fall is employed as a signal indicating the drop birth.[17] A chatter-free wetting mercury relay was employed to remove the counter electrode from potentiostatic control after measuring the current.

In the differential pulse polarographic mode operation, the dual slope integrating technique reported by Kalvoda and Trojanek[18,19] was employed.

Procedure. An electrolytic cell which was specially designed to be able to monitor continuously the concentration of hydrogen ion during the polarographic measurements, was a seven-neck vesel which was set with a dropping mercury electrode (DME), an 1.0 M (1 M=1 mol dm^{-3}) NaCl agar-agar bridge for connection with a saturated calomel electrode (SCE), a Pt wire counter electrode, a glass electrode, an Ag–AgCl reference electrode and two burets. A digital pH/mV meter (Orion Research, model 801) was used for pH measurements, in combination with a Beckman 40495 glass electrode and an Ag/AgCl electrode. The determination of the pH values was carried out in a similar manner as reported previously.[1,20] The flow rate of the mercury of the DME was $m=0.97$ mg s^{-1} and the drop time 6 s at the height of mercury head $h=60$ cm in 1 M $NaClO_4$ solution.

All measurements were performed in a parafine oil thermostat at (25.0±0.1) °C. The hydrogen ion concentration of the test solution was varied and measured before and after the recording of each polarogram. The difference in these pH values was within 0.01 pH unit as a rule. The composition of the test solution was 4.00×10^{-4} M of Cu(II) aqua ion, 8.00×10^{-3} M of EDTA or 2.00×10^{-2} M for HEDTA, and 1.0 M $NaClO_4$, unless otherwise noted. No buffer was added in the pH ranges 1.0—3.5 and 5.5—10.0 because the ligands are expected to have a large buffer capacity in these pH ranges. In the pH range 3.5—5.5, the acetate buffer was used at three different concentrations, 20, 40, and 80 mM CH_3COONa. The acetate ion did not show any influence on the shape and the position of the polarograms obtained. No maximum suppressor was added, since no polarographic maximum appeared in the pH range 1.0—11.5. The test solution was deaerated for 30 min with argon gas before each measurement of the polarograms.

Reagents. Ethylenediaminetetraacetic acid (disodium salt) (reagent grade, Dojindo Lab.) was recrystallized twice, dried and stored over silica gel in a desiccator. *N*-(2-Hydroxyethyl)-ethylenediamine-*N*,*N*′,*N*′-triacetic acid (Dojindo Lab.) was recrystallized from distilled water and dried under a reduced pressure. Copper(II) perchlorate was prepared by dissolving $CuCO_3$ in a $HClO_4$ solution and purified by recrystallizing three times from distilled water. The stock solution contained a small amount of $HClO_4$ to prevent hydrolysis of Cu(II) aqua ion. The concentration of Cu(II) aqua ion in the stock solution was determined by electrogravimetry.

Sodium perchlorate, sodium hydroxide and perchloric acid stock solutions were prepared by the methods described previously.[20]

Results

The Cu(II)–EDTA Complexes. Normal pulse polarograms for the reduction of the Cu(II) complexes were measured in the pH range from 1.0 to 11.0. Typical normal pulse polarograms are shown in Fig. 1. The half-wave potential of reduction waves shifted to cathodic direction with increasing the pH value and with decreasing sampling time, θ. Their limiting current was diffusion-controlled, as proved from the fact that the product of the limiting current and $\theta^{1/2}$ is always constant.

As has been described previously,[4] a number of protonated complex species of the MH_pL type (p= 1,2,3) for the EDTA complex are formed in the bulk of the solution and any possibility of the formation of polynuclear or polyligand complexes can be disregarded, when the solution contains an excess of EDTA ligand relative to the Cu(II) aqua ion. Since no Cu(II) aqua ion is present above pH=1.0[4] and no its kinetic behavior was observed in the normal pulse polarograms in the pH range 1.0 to 11.0, it seems reasonable to assume that the mechanism of the electrode processes under consideration can generally be expressed by

$$\begin{array}{l} CuH_NL + 2e \rightleftarrows Cu(Hg) + H_NL \\ \quad\updownarrow \qquad\quad \alpha_N, k_N^\circ \\ \cdots\cdots\cdots\cdots\cdots\cdots \\ \quad\updownarrow \\ CuH_pL + 2e \rightleftarrows Cu(Hg) + H_pL \\ \quad\updownarrow \qquad\quad \alpha_p, k_p^\circ \\ \cdots\cdots\cdots\cdots\cdots\cdots \\ \quad\updownarrow \\ CuL + 2e \rightleftarrows Cu(Hg) + L \\ \qquad\quad \alpha_0, k_0^\circ \end{array} \qquad (1)$$

We have previously reported the d.c. polarographic current-potential relationship for the similar mechanism of the electrode processes and its application to the analysis of the polarograms for the reduction of the Cd(II) and Pb(II) complexes with EDTA and HEDTA.[1-3] The current-potential relationship for normal pulse polarograms of the electrode process, assuming that the CuH_pL complex predominantly participates in the charge transfer process, is given by Eq. 2 which can be derived from the modification of the general current-potential relationship for normal pulse polarograms of the simple electrode process, $Ox+ne \rightleftarrows Red$.[9,13,21]

$$E = E^* - \frac{2.3RT}{2a_pF}\log\left[\frac{\sqrt{3x}}{4\sqrt{\theta}}\left\{\frac{1.75+x^2(1+\exp\zeta)^2}{1-x(1+\exp\zeta)}\right\}^{1/2}\right] \qquad (2)$$

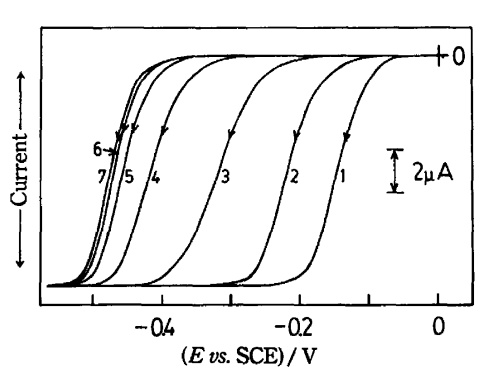

Fig. 1. Typical normal pulse polarograms for the reduction of the Cu(II)–EDTA complexes in 1.0 M $NaClO_4$ solution containing 0.4 mM Cu(II) aqua ion and 8 mM EDTA.
Sampling time θ=27 ms, drop time of DME τ=4.0 s and rate of the increase in potential pulse height ΔE=5 mV/drop.

with

$$E^* = E^r_{1/2.p} + \frac{2.3RT}{2a_pF} \log\left[\frac{k^\circ_p(\beta_{0p1})^{a_p}(\beta_{1p1})^{1-a_p}[H^+]^p\{F([H^+])+G([H^+])/C_L\}^{1+a_p}}{\{D_C^{1-a_p}D^{a_p}_{Cu(Hg)}\}^{1/2}\{G([H^+])/C_L\}^{a_p}F([H^+])^2}\right], \quad (3)$$

$$X = i/(i_d)_{Cott}, \quad (4)$$

$$\zeta = (2F/RT)(E-E^r_{1/2.p}), \quad (5)$$

$$E^r_{1/2.p} = E^\circ_p + \frac{2.3RT}{2F} \log\left[\left(1+\frac{F([H^+])}{G([H^+])/C_L}\right)\frac{\beta_{0p1}}{\beta_{1p1}}\right] + \frac{2.3RT}{2F}\log\frac{D_C}{D_{Cu(Hg)}}, \quad (6)$$

$$F([H^+]) = \sum_{p=0}^{N}\beta_{1p1}[H^+]^p, \quad (7)$$

$$G([H^+]) = \sum_{p=0}^{N}\beta_{0p1}[H^+]^p, \quad (8)$$

$$\beta_{qpr} = [Cu_qH_pL_r^{2q+p-nr}]/[Cu^{2+}]^q[H^+]^p[L^{n-}]^r, \quad (9)$$

$$C_c = \sum_{p=0}^{N}[CuH_pL^{2+p-n}], \quad (10)$$

$$D_c = \sum_{p=0}^{N}\beta_{1p1}[H^+]^pD_p/F([H^+]). \quad (11)$$

In these equation, E is the electrode potential; i is the normal pulse polarographic current; θ is the sampling time; E°_p, $E^r_{1/2.p}$, k°_p, and α_p are the standard potential, the reversible half-wave potential, the standard rate constant and the cathodic transfer coefficient, respectively, of the electrode reaction: $CuH_pL^{2+p-n}+2e \rightleftarrows Cu(Hg)+H_pL^{p-n}$; D_p and $D_{Cu(Hg)}$ are the diffusion coefficients of the complex species CuH_pL^{2+p-n} in the solution and of the copper atoms Cu(Hg) in the amalgam, respectively; β_{qpr} which is designated by Eq. 9 is the equilibrium constant for the reaction: $qCu^{2+}+pH^++rL^{n-} \rightleftarrows Cu_qH_pL_r^{2q+p-nr}$; C_L is the total concentration of the ligand; $[H^+]$ is the concentration of hydrogen ion; $[Cu^{2+}]$ and $[CuH_pL^{2+p-n}]$ are the concentrations of the Cu(II) aqua ion and the complex species CuH_pL^{2+p-n}, respectively; $[L^{n-}]$ is the concentration of the free ligand; $(i_d)_{Cott}$ denotes the diffusion current expressed by the Cottrell equation.[22]

D.c. polarograms of Cu(II)–EDTA complexes were measured in the same solutions as used in NPP. The reversible half-wave potentials, $E^r_{1/2.p}$, were evaluated from these d.c. polarograms by means of extrapolation method.[23] Thus, the values of the logarithmic term of r.h.s. of Eq. 2 and ζ can be calculated by using Eqs. 2 and 5, respectively, at any electrode potential. The modified log-plots of the normal pulse polarograms, in which the log-term on r.h.s. of Eq. 2 is plotted against E, gave straight lines for the reduction of the Cu(II)–EDTA complexes over the whole pH range examined (Fig. 2). These straight lines have constant slopes, the values of which are equal to $-2a_pF/2.3RT$, in the range of pH 1.0—2.5, 3.0—4.5, 5.5—7.5, and 8.0—10.0 within experimental errors. The cathodic transfer coefficients were evaluated from their reciprocal slopes. The values obtained are given in Table 1. The constant value of α_p obtained in each pH range seems to permit us to assume that only one species predominantly participates in the charge transfer process in limited pH ranges. Thus we can apply Eq. 3 to the determination of the composition of the discharging species.

After some rearrangements of Eq. 3, we obtain

$$Z_p \equiv \frac{2a_pF}{2.3RT}(E^*-E^r_{1/2.p}) + \log\left[\frac{\{G([H^+])/C_L\}^{a_p}F([H^+])^2}{\{F([H^+])+G([H^+])/C_L\}^{1+a_p}}\right], \quad (12)$$

$$= \log[k^\circ_p(\beta_{0p1})^{a_p}(\beta_{1p1})^{1-a_p}] - \frac{1}{2}\log[D_c^{1-a_p}D_{Cu(Hg)}{}^{a_p}] + p\log[H^+]. \quad (13)$$

The values of the function Z_p, defined by Eq. 12, were calculated as a function of $[H^+]$ for each pH range. Hence, the composition of the discharging complex species, *i.e.*, p can be determined from the dependence of the function, $-Z_p$, upon $-\log[H^+]$. In Fig. 3, the values of $-Z_p$ are plotted against $-\log[H^+]$. As can readily be seen from Fig. 3, a linear relationship is obtained with $p=3$ in the pH range 1.0—2.5, indicating that the discharging species is the species CuH_3L^+. Similarly, the discharging species is primarily CuH_2L^0 in the pH range 3.0—4.5, $CuHL^-$ in 5.5—7.5 and CuL^{2-} in pH 8.0—10.0, respectively. Thus, it can be concluded

Experimental conditions are the same as in Fig. 1.

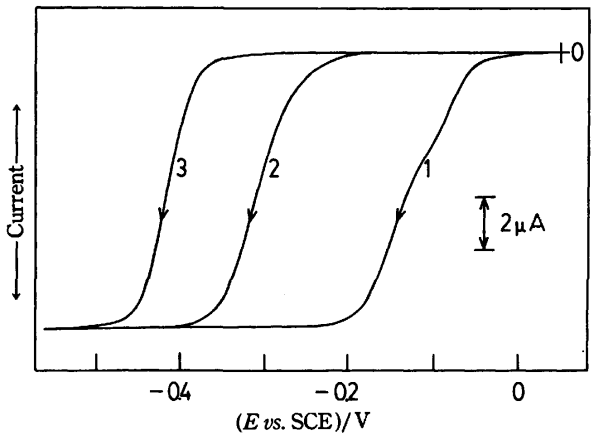

Fig. 4. Normal pulse polarograms for the reduction of the Cu(II)–HEDTA complexes.
Solution composition: 0.4 mM Cu(II) aqua ion, 20 mM HEDTA and 1.0 M $NaClO_4$. Sampling time $\theta=27$ ms, drop time of DME $\tau=4.0$ s and rate of the increase in potential pulse height $\Delta E=5$ mV/drop.
$-\log[H^+]$: (1) 1.91 (2) 4.63, (3) 9.21.

that the normal pulse polarographic wave for the reduction of the Cu(II)–EDTA complexes is composed of the four charge transfer processes, $CuH_pL^{p-2}+2e \rightleftarrows Cu(Hg)+H_pL^{p-4}$ ($p=3, 2, 1, 0$). The standard rate constant, k_p°, of each charge transfer process can be evaluated from the value of the intercept of the plots shown in Fig. 3 and by introducing the experimental data into Eq. 13, where the values of D_p and $D_{Cu(Hg)}$ were 5.4×10^{-6} cm^2 s^{-1} and 1.06×10^{-5} cm^2 s^{-1},[24] respectively. The above value of D_p was obtained from the cathodic limiting currents of d.c. polarograms by using the Ilkovic equation.[14] The kinetic parameters obtained are given in Table 1.

The Cu(II)–HEDTA Complexes. Figure 4 shows a set of normal pulse polarograms for the reduction of the system of the Cu(II)–HEDTA complexes in the solution of various pH. Figure 5 shows the modified log-plots of the normal pulse polarograms. These log-plots satisfied the straight lines and their slopes were constants in the range of pH 3.0—6.0 and 7.5—9.5, respectively. The cathodic transfer coefficients were evaluated from their reciprocal slopes. In Fig. 6, the values of $-Z_p$, calculated from Eq. 12, are plotted against $-\log[H^+]$. It is apparent from this figure that the discharging species is primarily $CuHL'^0$ and CuL'^- ($L'=hedta^{3-}$) in the pH range 3.0—6.0 and 7.5—9.5, respectively. The standard rate constants for these discharging species were evaluated by means of the same method as described in the previous section. The values obtained are summarized in Table 1.

In the acidic solution below pH 3.0, the modified log-plots of the normal pulse polarograms deviated from the straight line, as shown in Fig. 5, when the value of the logarithmic term of r.h.s. of Eq. 2 is below zero. The deviation seems to result from that the

polarogram probably consists of the overlap of two waves for the reduction of Cu(II) aqua ion and the protonated Cu(II) complexes, as seen from polarogram 1 in Fig. 4. By the differential pulse polarography the two humps in polarogram were observed. However, since two waves closely overlapped, the waves could not be satisfctorily separated by using the non-linear least-squares method.[25]

Discussion

The results obtained above demonstrate that normal pulse polarography is one of the most useful pulse techniques for the examination of the electrode kinetics in d.c. polarographically quasi-reversible electrode processes. The kinetic parameters obtained are summarized in Table 1 together with the values of the standard rate constants, $(k_p^\circ)_{corr}$, corrected for the double layer effect by means of the Frumkin theory,[26] in which the values of ϕ_2 were taken from Russell's tables.[27] The values of the standard rate constants, $(k_p^\circ)_{corr}$ increase in the following order: $CuL^{2-} \ll CuH_2L^0 < CuHL^- < CuH_3L^+$ (L=edta^{4-}) for the Cu-(II)–EDTA complexes and $CuL'^- < CuHL'^0$ (L'=hedta^{3-}) for the Cu(II)–HEDTA complexes. In both systems, the values of k_p° ($p \geqq 1$) for the protonated complex species are larger than those for the ordinary unprotonated complex species. The corrected rate constant, $(k_p^\circ)_{corr}$, of the Cu(II)–EDTA and –HEDTA complexes except CuH(hedta)^0 and Cu(edta)$^{2-}$ were almost the same order of magnitude ($\approx 10^{-2}$ cm s^{-1}) as that of the Cu(II) aqua ion.[28] The values of the cathodic transfer coefficients for the species under consideration were in the range of 0.47 to 0.59, as summarized in Table 1.

Previously[1-3] we have found that the linear relation between the cathodic rate constants at some reference

potential and the corresponding standard potentials holds for the Cd(II) and Pb(II) complexes with EDTA and related compounds and further suggested that the protonation of acetate groups of these ligands, leading to the cleavage of the metal-oxygen bonds within the complex species, accelerates the rate of charge transfer process. We examined whether such a correlation prevails for the present series of the Cu(II) complexes. In Fig. 7 the logarithms of $(k_p^\circ)_{ref}$'s are plotted against $E_p^\circ - E_{Cu}^\circ (= -2.3(RT/2F)\log(\beta_{1p1}/\beta_{0p1}))$, where E_p° is the standard potential of the couple $CuH_pL/Cu(Hg)$ or $CuH_pL'/Cu(Hg)$ and E_{Cu}° is the standard potential of Cu(II) aqua ion. As can readily be seen from this figure, a linear relationship between the cathodic rate constants and the corresponding standard potentials could not be obtained. We have no idea to explain such a different behavior at present, but this may probably be associated with the difference between the ordinary octahedral structure of the Cd(II) and Pb(II) complexes and the pseudo octahedral structure of the Cu(II) complex.[29-31]

Preparation, Racemization, and Deuteration of 2-(Methylthio)propionato-*S,O* and 2-Sulfinatopropionato-*S,O* Complexes of Cobalt(III)

Masaaki Kojima and Junnosuke Fujita*
Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464
(Received April 28, 1983)

$(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]$^+$, $(-)_{589}$-[Co{CH_3SCH(CH_3)COO}(tren)]$^{2+}$, and $(+)_{589}$-[Co{$S(O)_2$-CH(CH_3)COO}(tren)]$^+$ (tren=tris(2-aminoethyl)amine) were prepared and assigned to the trans (*tertiary amine nitrogen, S*) isomer with the *R* carbon atom on the basis of the absorption, CD, and ^{1}H NMR spectra. Racemization of the complexes was studied in aqueous solutions with ionic strength of 0.1, 0.2, or 1.0 ($NaClO_4$) in the pH and temperature ranges of 5.96—6.86 and 19.9—49.5 °C, respectively. The $CH_3SCH(CH_3)COO^-$ and $^-O_2SCH(CH_3)$-COO^- complexes follow the rate law, $R=k_r[OH^-][complex]$. The second-order rate constants (k_r) for the former and the latter complexes are 4.6×10^3 (35.3 °C) and 7.8×10^3 (35.2 °C) mol^{-1} dm^3 s^{-1}, respectively. The $^-SCH(CH_3)COO^-$ complex did not racemize under these conditions. Deuteration of the methine protons in the complexes was found to proceed simultaneously with the racemization. The differences in reactivity to racemization and proton exchange among three complexes were accounted for by the difference in electron-withdrawing effect of the $^-S-$, $S(CH_3)-$, and $^-S(O)_2-$ groups, and by the difference in net charge of the complex ions.

It is known that methine or methylene groups of α-amino acids become reactive on chelation to metals. The activation leads to such reactions as deuteration of the methine or methylene protons,[1-3] racemization at the α-carbon atom,[2] and condensation with aldehydes to afford α-substituted amino acids.[4] Activation of methylene groups of ethylenediaminetetraacetato[1] and malonato[5,6] metal chelates has also been demonstrated. All these reactions are base-catalyzed and occur at methine or methylene groups located between two electron-withdrawing groups. 2-(Methylthio)propionato-*S,O* and 2-sulfinatopropionato-*S,O* chelates both of which contain two electron-withdrawing groups are also expected to have similar reactivity. Recently Adzamli *et al.*[7] reported that the methylene protons of *S,O* chelates in [Co{$S(O)_nCH_2COO$}$(en)_2$]$^+$ (n=0, 1, 2; en: ethylenediamine) undergo deuterium exchange in basic D_2O solutions. However, no kinetic studies have been done. It is of interest to compare quantitatively the activity of methylene groups of such *S,O* chelates with that of amino acidato-*N,O* and dicarboxylato-*O,O* chelates.

This paper reports kinetic studies on racemization and deuteration of optically active $CH_3SCH(CH_3)$-COO^- and $^-O_2SCH(CH_3)COO^-$ chelates in tris(2-aminoethyl)amine(tren) cobalt(III) complexes as well as deuteration of $CH_3SCH_2COO^-$ and $^-O_2SCH_2COO^-$ chelates in some related complexes. Preparation, stereochemistry, and circular dichroism (CD) spectra of these tren complexes are also described in this paper.

Experimental

$(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]ClO_4. To an aqueous solution (30 cm^3) of [$CoCl_2$(tren)]Cl[8] (1.24 g, 4 mmol) was added an aqueous solution (30 cm^3) of 2-mercaptopropionic acid (0.24 g, 4 mmol). The pH of the solution was adjusted to *ca.* 9 with Na_2CO_3, and the mixture was stirred for 1 h at 65 °C. The color of the solution changed from violet to dark brown. The solution was cooled and then mixed with $NaClO_4$ to yield brown crystals of the complex perchlorate, which were filtered and washed with ethanol. Yield: 1.1 g. No evidence indicative of the presence of the other isomer was obtained in both the ^{1}H NMR spectrum of the isolated complex and chromatography (SP-Sephadex C-25, 0.1 mol dm^{-3} NaBr) of the reaction mixture. The sparingly soluble perchlorate was converted into chloride by use of Dowex 1×8 (Cl^- form). Brown crystals were obtained by adding ethanol to the concentrate of the complex chloride. Yield: 85%. The complex was resolved as follows: To an aqueous solution (9 cm^3) of the complex chloride (2.68 g, 7.78 mmol) was added an aqueous solution (9 cm^3) of $(+)_{546}$-$Na[Co(C_2O_4)_2(en)]\cdot3.5H_2O$[9] (1.48 g, 3.89 mmol). The solution was mixed with 10 cm^3 of ethanol and allowed to stand overnight at room temperature. The dark purple crystals precipitated were collected by filtration and recrystallized six times from water–ethanol. Yield: 0.72 g. The crystals were dissolved in water, and the solution was passed through a column (ϕ1.5 cm×5 cm) of SP-Sephadex C-25 (Na^+ form). After washing the column with water the complex adsorbed was eluted with 0.5 mol dm^{-3} $NaClO_4$. The crystalline $(+)_{589}$-isomer was obtained by further addition of $NaClO_4$ to the effluent, filtered, and washed with ethanol. Yield: 0.37 g. Found: C, 26.30; H, 5.44; N, 13.73%. Calcd for $C_9H_{22}N_4ClCoO_6S$: C, 26.45; H, 5.42; N, 13.71%.

$(-)_{589}$-[Co{CH_3SCH(CH_3)COO}(tren)]$(ClO_4)_2\cdot H_2O$. To a stirred suspension of $(+)_{589}$-[Co{SCH(CH_3)COO}-(tren)]ClO_4 (0.80 g, 1.96 mmol) in dimethyl sulfoxide (20 cm^3) was added CH_3I (2.78 g, 19.6 mmol) in dimethyl sulfoxide (20 cm^3). An orange solution was obtained within a few minutes. After a day the solution was diluted with 0.01 mol dm^{-3} HCl (200 cm^3), excess CH_3I was extracted with $CHCl_3$ (300 cm^3), and the orange aqueous phase was passed through a column (ϕ1.5 cm×3 cm) of SP-Sephadex C-25. The Sephadex charged with the product was placed on the top of a column (ϕ6 cm×30 cm) of SP-Sephadex C-25, and the product was eluted with 0.2 mol dm^{-3} NaCl adjusted to pH 2 with HCl. The column showed only one band. The effluent was diluted twenty times with 0.01 mol dm^{-3} HCl and passed again through an SP-Sephadex C-25 column (ϕ1.5 cm×3 cm). After washing the column with 0.01 mol dm^{-3} $HClO_4$, the complex adsorbed was eluted with 0.7 mol dm^{-3} $NaClO_4$ adjusted to pH 2 with $HClO_4$. The effluent was evaporated to a small volume under reduced pressure to yield orange crystals of the $(-)_{589}$-isomer, which were filtered, washed with ethanol, and recrystallized from 0.01 mol dm^{-3} $HClO_4$. Yield: 0.65 g. Found: C, 22.24; H, 4.68; N, 10.59%. Calcd for $C_{10}H_{27}N_4Cl_2CoO_{11}S$: C, 22.19; H, 5.03; N, 10.35%.

$(+)_{589}$-[Co{$S(O)_2$CH(CH_3)COO}(tren)]$ClO_4\cdot H_2O$. To

a suspension of $(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]ClO_4 (0.82 g, 2 mmol) in 0.1 mol dm^{-3} $HClO_4$ (20 cm^3) was added 35% aqueous H_2O_2 (1.94 g, 20 mmol) in 0.1 mol dm^{-3} $HClO_4$ (30 cm^3) with stirring. The color of the mixture changed from purple to orange, and the starting material dissolved completely in 10 min. After a day $NaClO_4$ was added to the resulting solution to yield yellow crystals, which were filtered and washed with ethanol. No other complex was formed. Yield: 0.53 g. Found: C, 23.57; H, 5.16; N, 12.44%. Calcd for $C_9H_{24}N_4ClCoO_9S$: C, 23.56; H, 5.27; N, 12.21%.

$(-)_{589}$-[Co{S(O)CH(CH_3)COO}(tren)]$^+$. This complex was less stable than the above sulfinato complex and could not be isolated as the pure solid. To a solution of $(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]ClO_4 (8.2 mg, 0.02 mmol) in 0.01 mol dm^{-3} $HClO_4$ (10 cm^3) was added 35% aqueous H_2O_2 (2.1 mg, 0.022 mmol) in 0.01 mol dm^{-3} $HClO_4$ (25 cm^3). The color of the solution changed immediately from purple to orange. After 30 min the solution showed an absorption band at 365 nm characteristic of the S-bonded sulfenato moiety.[7] The solution was used for CD measurements without isolating the complex.

[Co(SCH_2COO)(tren)]ClO_4, [Co(CH_3SCH_2COO)(tren)]$(ClO_4)_2$, and [Co{S(O)$_2CH_2COO$}(tren)]ClO_4. These complexes were prepared by the same methods as those for the corresponding 2-mercaptopropionate, and its derivative complexes. Found: C, 24.32; H, 5.13; N, 14.22%. Calcd for $C_8H_{20}N_4ClCoO_6S$=[Co(SCH_2COO)(tren)]ClO_4: C,24.34; H, 5.11; N, 14.19%. Found: C, 21.17; H, 4.55; N, 10.95%. Calcd for $C_9H_{23}N_4Cl_2CoO_{10}S$=[Co($CH_3SCH_2COO$)(tren)]$(ClO_4)_2$: C, 21.23; H, 4.55; N, 11.00%. Found: C, 22.81; H, 4.85; N, 13.14%. Calcd for $C_8H_{20}N_4ClCoO_8S$=[Co{S(O)$_2$-CH_2COO}(tren)]ClO_4: C, 22.52; H, 4.72; N, 13.13%. Each complex was confirmed to yield only one isomer by column chromatography on SP-Sephadex and ^1H NMR spectra.

p- and t-[Co($CH_3SCH_2CH_2NH_2$)(tren)]$(ClO_4)_3\cdot H_2O$. These complexes were prepared from CH_3I and the corresponding isomers of [Co($SCH_2CH_2NH_2$)(tren)]$ZnCl_4$[10] by a method similar to that for $(-)_{589}$-[Co{CH_3SCH(CH_3)COO}(tren)]$(ClO_4)_2\cdot H_2O$. Found for the *p*-isomer: C, 17.56; H, 4.51; N, 11.39%. Found for the *t*-isomer: C, 17.58; H, 4.70; N, 11.57%. Calcd for $C_9H_{29}N_5Cl_3CoO_{13}S$: C, 17.64; H, 4.77; N, 11.43%.

[Co(SCH_2COO)$(en)_2$]ClO_4, [Co(CH_3SCH_2COO)$(en)_2$]$(ClO_4)_2$, and [Co{S(O)$_2CH_2COO$}$(en)_2$]$Cl\cdot H_2O$. These complexes were prepared by literature procedures.[7,11-13]

[Co{S(O)$_2$C(CH_2OH)$_2COO$}$(en)_2$]$ClO_4\cdot 0.5CH_3OH$. To a mixture of [Co{S(O)$_2CH_2COO$}$(en)_2$]$Cl\cdot H_2O$ (0.68 g, 2 mmol) and Na_2CO_3 (0.12 g, 1 mmol) in water (25 cm^3) was added an aqueous solution (25 cm^3) containing 8 mmol of formaldehyde. The mixture was stirred for a day at room temperature and filtered to remove a small amount of precipitate. The filtrate was chromatographed using a column (ϕ3 cm×40 cm) of SP-Sephadex C-25 and an eluent of 0.2 mol dm^{-3} $NaClO_4$. The effluent of the fast-moving main band was collected and evaporated to a small volume under reduced pressure. On addition of methanol the concentrate gave large orange crystals, which were filtered, washed with methanol, and recrystallized from water–methanol. Yield: 0.13 g. The presence of 0.5 mol of methanol in the complex salt was confirmed by the ^1H NMR spectrum. Found: C, 21.22; H, 5.06; N, 11.86%. Calcd for $C_{8.5}H_{24}N_4ClCoO_{10.5}S$: C, 21.41; H, 5.07; N, 11.75%.

Measurements. Absorption and CD spectra were recorded on a Hitachi 323 spectrophotometer and a JASCO J-40CS spectropolarimeter, respectively. Optical rotations at 589 nm were measured with a JASCO DIP-4 polarimeter. ^1H NMR spectra were obtained in D_2O or DCl–D_2O solutions with a JEOL PMX-60 spectrometer using sodium 3-(trimethylsilyl)propionate-d_4 or sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) as an internal reference.

Racemization Studies. Racemization rates were followed by monitoring CD strength changes at 465 nm ([Co{CH_3SCH(CH_3)COO}(tren)]$^{2+}$) or at 420 nm ([Co{S(O)$_2$CH(CH_3)COO}(tren)]$^+$) as a function of reaction time. All experiments were carried out in aqueous solutions with ionic strength of 0.1, 0.2, or 1.0 ($NaClO_4$) in the pH and temperature ranges of 5.96—6.86 ($NaCH_3COO$–HCl) and 19.9—49.5 °C, respectively. The complex concentrations were in the range of (2.5—9.6)×10^{-3} mol dm^{-3}. The absorption spectra were also measured to check the stability of the complexes toward decomposition.

Deuteration Studies. Deuteration rates were followed by monitoring signal changes in ^1H NMR spectra. The complex perchlorates were converted into chlorides with a Dowex 1×8 anion exchanger in the chloride form in order to increase the solubility. The complex concentrations were 0.21—0.25 mol dm^{-3}, and no attempt was made to keep ionic strength constant. The samples in NMR tubes were placed in a thermostat at 34.5 °C, and the spectra were recorded at timed intervals at 34.5 °C. The peak areas of signals were determined by weighing paper cutouts maching the peak areas. The pD=pH+0.4,[14] and $[OD^-]=2.89\times10^{-15}$ $[D^+]^{-1}$ [15] formulae were used to evaluate $[D^+]$ and $[OD^-]$, respectively.

Results and Discussion

Preparation and Characterization of the Complexes. The thiolato complexes, [Co{SCH(CH_3)COO}(tren)]$^+$ and [Co(SCH_2COO)(tren)]$^+$ were prepared from [$CoCl_2$(tren)]$^+$ and the thiolate ligands in fairly good yields (60—70%). A number of thiolatobis(ethylenediamine)cobalt(III) complexes have been prepared by oxidizing bis(ethylenediamine)cobalt(II) ions with the disulfide derivative of a thiol in the absence of air.[16] However, this method was not effective for the tren complex, no redox reaction taking place between tren-cobalt(II) ions and either disulfide, ($^-OOCCH_2S$–)$_2$ or (^-OOCCH-(CH_3)S–)$_2$. On the other hand, analogous ligands, ($^-OOCCH_2Se$–)$_2$ and ($NH_2CH_2CH_2S$–)$_2$ oxidize tren-cobalt(II) ions to yield [Co($SeCH_2COO$)(tren)]$^+$[19] and [Co($NH_2CH_2CH_2S$)(tren)]$^{2+}$,[10] respectively, although the reaction with the latter ligand is slow. Such differences in reactivity may be related with oxidizing strength of these ligands toward the tren-cobalt(II) ion.

Two geometrical (*p*- and *t*-) isomers[18] are possible for

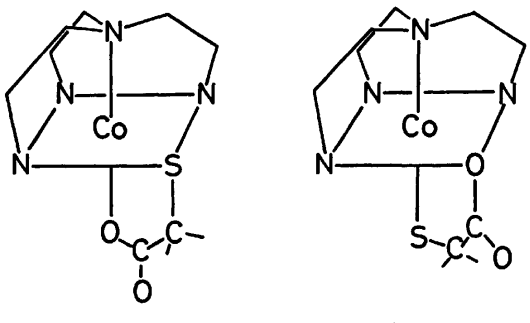

Fig. 1. Two geometrical isomers of [Co(*S,O* chelate)(tren)]$^{n+}$.

a) Measured in 10^{-2} mol dm^{-3} $HClO_4$. b) Shoulder.

$[Co(SCHRCOO)(tren)]^+$ (R=H, CH_3; Fig. 1). These thiolatocarboxylato complexes form only one geometrical isomer as confirmed by column chromatography and ^1H NMR spectra. The absorption spectra of both complexes are quite similar and the complexes will have the same geometrical configuration. The spectra show a shoulder around 17000 cm^{-1} on the low energy side of the first absorption band, and an intense sulfur-to-cobalt(III) charge-transfer band around 34700 cm^{-1} (Table 1 and Fig. 2). The spectral pattern is characteristic of cobalt(III)-thiolato complexes.[19]

The $[Co(NH_2CH_2CH_2S)(tren)]^{2+}$ complex forms both *p*- and *t*-isomers. The isomers give the first absorption band at nearly the same position, but the patterns differ remarkably from each other. The spectral pattern of the $^-SCHRCOO^-$ complexes is very similar to that of the *t*-isomer of the $NH_2CH_2CH_2S^-$ complex, showing strong shoulder absorption on the low energy side of the first absorption band (Fig. 2). The *p*-isomer exhibits only weak shoulder in this region. Thus both thiolatocarboxylato complexes can be assigned to the *t*-isomer. This assignment agrees with that obtained from absorption spectra of methylthio complexes derived from the present $^-SCHRCOO^-$ complexes described below.

The sulfenato-, sulfinato-, and methylthio-carboxylato complexes were prepared from the $^-SCHRCOO^-$ complexes by stoichiometric oxidation with H_2O_2,[7,20] by oxidation with excess H_2O_2,[7,20] and by methylation with CH_3I in dimethyl sulfoxide,[10,11,21,22] respectively. These reactions do not involve Co–S cleavage, and geometrical structures of the complexes should be retained.[23,24] The $[Co(CH_3SCH_2COO)(tren)]^{2+}$ complex thus obtained gives the first absorption band (20620 cm^{-1}) between those of *p*-(20530 cm^{-1}) and *t*-(20790

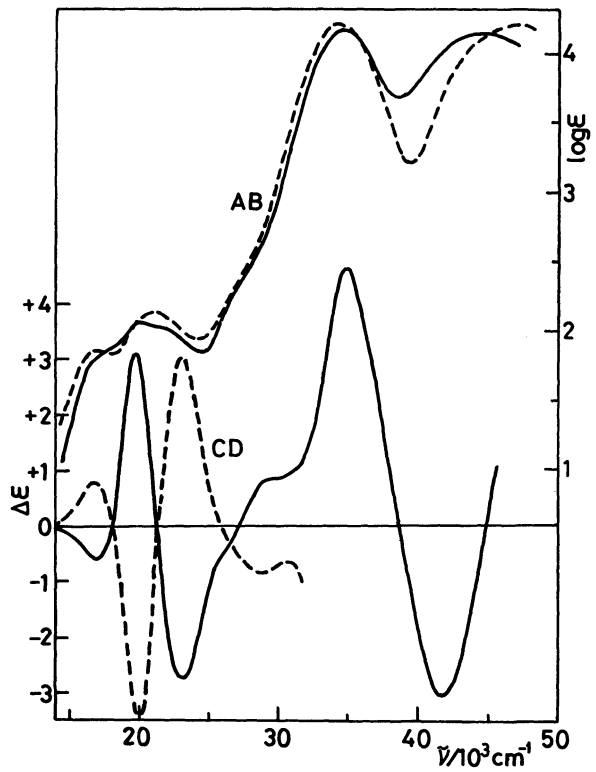

Fig. 2. Absorption and CD spectra of $(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]$^+$ (——) and *t*-[Co{(*S*)-SCH(CH_3)-CH_2NH_2}(tren)]$^{2+}$ (------)[26] in water.

cm^{-1}) isomers of [Co($CH_3SCH_2CH_2NH_2$)(tren)]$^{3+}$ (Table 1). Since $CH_3SCH_2COO^-$ will exert a weaker ligand field than $CH_3SCH_2CH_2NH_2$, the CH_3SCH_2-COO^- complex will show the d-d absorption bands at lower energy than those of the $CH_3SCH_2CH_2NH_2$ complex with the same geometrical configuration. Thus [Co(CH_3SCH_2COO)(tren)]$^{2+}$ and all the *S,O* chelate complexes obtained in this study can be assigned to the *t*-isomer.

The difference in absorption maxima of the d-d bands between *t*- and *p*-[Co($CH_3SCH_2CH_2NH_2$)-(tren)]$^{3+}$ may partly be ascribed to the difference in strain involved in the isomers. Molecular models indicate that the *p*-isomer will be strained by steric hindrance between the methyl group and the tren ligand. On the other hand, the *t*-isomer has no such hindrance around the methyl group. Accordingly the strained *p*-isomer will show the first absorption band at lower energy than that of the *t*-isomer. When the methyl group in the *p*-isomer is replaced by a small hydrogen atom, the hindrance with the tren ligand will be diminished, and the energy difference between the first absorption bands of the *p*- and *t*-isomers will be decreased. In concd H_2SO_4, where the thiolato chelates will be completely protonated,[25] both isomers show the first absorption band at the same position (20640 cm^{-1}). Thus the position of the first absorption band of [Co-($RSCH_2CH_2NH_2$)(tren)]$^{3+}$ seems to depend strongly on the steric conditions.

The ^1H NMR spectrum of [Co(CH_3SCH_2COO)-(tren)]$^{2+}$ in DCl–D_2O (pD *ca.* 2) gives an AB quartet (3.53—4.22 ppm, J=18 Hz, $\Delta\nu$=14 Hz) attributable to the methylene protons of the (methylthio)acetate ligand. The result demonstrates that the inversion at the sulfur atom is slow on the NMR time scale. However, attempts to resolve the complex by column chromatography were unsuccessful, suggesting that the inversion is not so slow as to be resolved by conventional techniques. The ^1H NMR spectrum of [Co{CH_3SCH-(CH_3)COO}(tren)]$^{2+}$ shows only one kind of quartet (4.07 ppm) and doublet (1.65 ppm) assignable to the methine and methyl protons of the –$CH(CH_3)$– group, respectively. From a comparison with the above (methylthio)acetato complex, it is unlikely that the spectrum is brought about by rapid inversion at sulfur (coalesced spectrum) or accidental degeneracies. Thus it is concluded that the disposition of the S–CH_3 group is stereospecific in the (methylthio)propionato complex (*vide post*). In general, sulfur atoms in cobalt(III)-sulfide complexes are labile toward inversion, although the rate is slow on the NMR time scale.[10]

Figure 2 compares the absorption and CD spectra of $(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]$^+$, which has been assigned to the *t*-isomer, with those of *t*-[Co{(*S*)-SCH-(CH_3)CH_2NH_2}(tren)]$^{2+}$.[26] The absorption spectra of both complexes are similar, but the CD spectra are almost enantiomeric to each other in the d-d absorption band region. Thus the carbon atom of $(+)_{589}$-[Co-{SCH(CH_3)COO}(tren)]$^+$ can be assigned to *R* configuration. The absolute configuration of the sulfur atom in $(-)_{589}$-[Co{S(O)CH(CH_3)COO}(tren)]$^+$ which was derived from $(+)_{589}$-[Co{SCH(CH_3)COO}-(tren)]$^+$ can be assigned by comparing the CD spectrum with that of *Λ*-[Co{*S*(S), *R*(C)-cysO}$(en)_2$]$^{+}$[23] whose absolute configuration has been determined by the X-ray method[27] (*S*(S), *R*(C)-cysO=(*S*(S), *R*(C))-2-amino-3-sulfenatopropionate-*N,S*). In the Co–S charge-transfer band region (25000—39000 cm^{-1}) the CD pattern of $(-)_{589}$-[Co{S(O)CH(CH_3)COO}(tren)]$^+$ is almost enantiomeric to that of the *Λ*[*S*(S), *R*(C)]-cysO complex, and very similar to that of the *Λ*[*R*(S), *R*(C)]-cysO complex.[23] Thus the sulfur atom in $(-)_{589}$-[Co{S(O)CH(CH_3)COO}(tren)]$^+$ can be assigned to *R* configuration. The oxidation of the sulfur atom in the $^-SCH(CH_3)COO^-$ complex will occur selectively at the *anti* position to the methyl group to afford the (*R*(S), *R*(*C*))- or (*S*(S), *S*(C))-$^-S(O)CH(CH_3)COO^-$ complex, since the incoming oxidant to this position has less steric interaction with the methyl group (Fig. 3). Thus the carbon atom in $(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]$^+$ which gives the (*R*(S))-$^-S(O)CH(CH_3)COO^-$ complex should have *R* configuration. This conclusion for the carbon atom agrees with the previous one obtained on the basis of the CD spectrum of the (*S*)-SCH(CH_3)-CH_2NH_2 complex.

Very recently, the structure of $(-)_{589}$-[Co{CH_3SCH-(CH_3)COO}(tren)]$^{2+}$ which was derived from $(+)_{589}$-[Co{SCH(CH_3)COO}(tren)]$^+$ has been determined by X-ray analysis to have *S*(S), *R*(C) configuration.[28] The disposition of the methyl group on the sulfur atom in this complex is the same as that of the oxygen atom in the above *R*(S), *R*(C)-sulfenato complex, the notation, *R* and *S* for the chiral sulfur atom being reversed between the methylthio and sulfenato complexes.

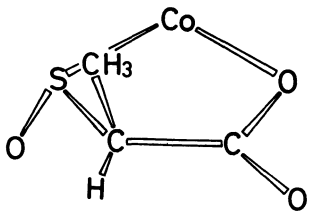

Fig. 3. Proposed structure of the $^{-}OSCH(CH_3)COO^{-}$ chelate.

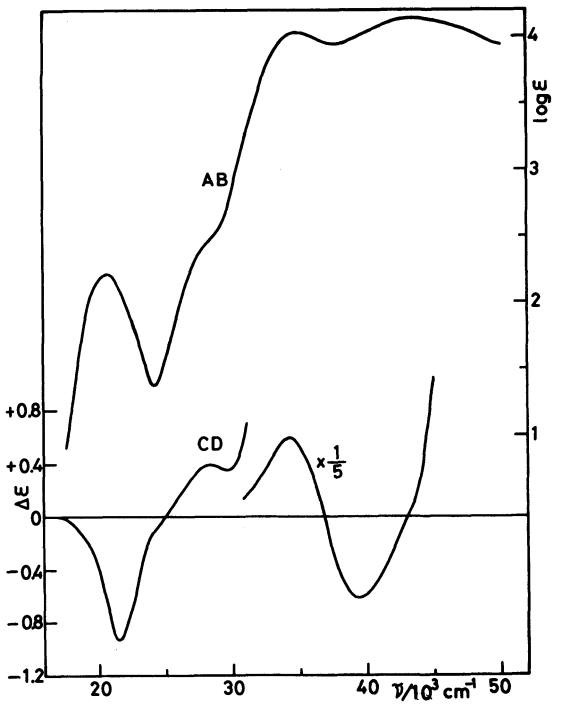

Fig. 4. Absorption and CD spectra of $(-)_{589}$-$[Co\{CH_3SCH(CH_3)COO\}(tren)]^{2+}$ in 10^{-2} mol dm^{-3} $HClO_4$.

Kinetics of Racemization and Deuteration Reactions. Absorption and CD spectra of $(-)_{589}$-$[Co\{CH_3SCH(CH_3)COO\}(tren)]^{2+}$ in acidic water are given in Fig. 4. The complex which was prepared from $(+)_{589}$-$[Co\{SCH(CH_3)COO\}(tren)]^{+}$ gives a CD extreme at 465 nm (21510 cm^{-1}), and this wavelength was used to follow the racemization rates. Measurements were carried out over the temperature range of 20.0 to 45.3 °C in the pH region of 5.96 to 6.86. In every kinetic run the plot of $\log(\Delta\varepsilon_{465})$ *vs.* time at a constant pH gave a straight line for at least two half-lives. Thus the racemization rate at a constant pH can be expressed as $-d[complex]/dt=k_{r(obsd)}[complex]$, where $k_{r(obsd)}$ is the pseudo-first-order rate constant for racemization at a constant pH. The $k_{r(obsd)}/[OH^-]$ $(=k_r)$ values are constant at a given temperature, indicating that the reaction is first-order in $[OH^-]$. The values of $k_{r(obsd)}$ and k_r are listed in Table 2, where the variation of ionic product of water, $k_w=[H^+][OH^-]$ with change in temperature[29] was taken into consideration. The average value of k_r is $(4.6\pm0.1)\times10^3$ mol^{-1} dm^3 s^{-1} at 35.3 °C (Table 3). No detectable change in the absorption spectrum was observed during the measurements. The rate was independent of ionic strength in the range of 0.1 to 1.0 ($NaClO_4$). Eyring treatments of $\log(k_r/T)$ *vs.* T^{-1} yielded an activation enthalpy of 46 ± 1 kJ mol^{-1} and an activation entropy of -26 ± 4 J mol^{-1} K^{-1}. The sulfur atom in the complex is also chiral, but racemizes more rapidly than does the carbon atom as stated previously. Thus the racemization observed should be for the carbon atom.

Table 2. Rate constants for the racemization of $(-)_{589}$-$[Co\{CH_3SCH(CH_3)COO\}(tren)]^{2+}$ and $(+)_{589}$-$[Co\{S(O)_2CH(CH_3)COO\}(tren)]^{+}$ $(I=0.2)$

Table 3. Rate constants for racemization and deuteration

Complex	k/mol^{-1} dm^3 s^{-1} (t/°C)
Racemization	
$[Co\{CH_3SCH(CH_3)COO\}(tren)]^{2+}$	$(4.6\pm0.1)\times10^3$ (35.3)
$[Co\{S(O)_2CH(CH_3)COO\}(tren)]^{+}$	$(7.8\pm0.2)\times10^3$ (35.2)
Deuteration	
$[Co\{CH_3SCH(CH_3)COO\}(tren)]^{2+}$	$(1.5\pm0.3)\times10^4$ (34.5)
$[Co\{S(O)_2CH(CH_3)COO\}(tren)]^{+}$	$(4.5\pm0.9)\times10^4$ (34.5)
$[Co\{S(O)_2CH_2COO\}(tren)]^{+}$	$(3.0\pm0.6)\times10^5$ (34.5)
$[Co\{S(O)_2CH_2COO\}(en)_2]^{+}$	$(4.3\pm0.9)\times10^5$ (34.5)

The absorption and CD spectra of $(+)_{589}$-$[Co\{S(O)_2CH(CH_3)COO\}(tren)]^{+}$ in 0.01 mol dm^{-3} $HClO_4$ are given in Fig. 5. The complex was also prepared from $(+)_{589}$-$[Co\{SCH(CH_3)COO\}(tren)]^{+}$, and the racemization was studied by the same procedure as the above. The decrease in CD strength also obeyed second-order kinetics; first-order in each of the concentrations of complex and OH^- ions. The results are given in Table 2. The second-order rate constant (k_r) is $(7.8\pm$

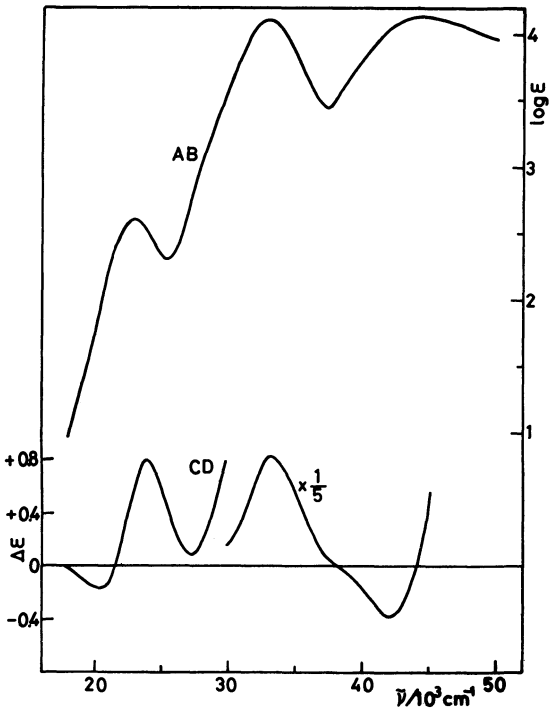

Fig. 5. Absorption and CD spectra of $(+)_{589}$-$[Co\{S(O)_2CH(CH_3)COO\}(tren)]^+$ in 10^{-2} mol dm^{-3} $HClO_4$.

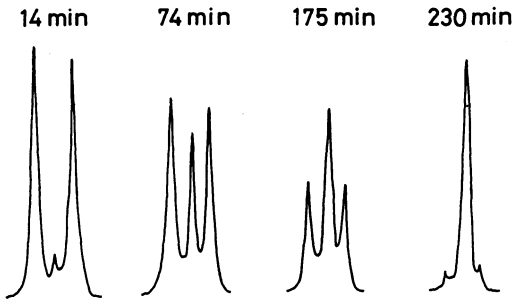

Fig. 6. Signal change of the C–CH_3 of $[Co\{S(O)_2CH(CH_3)COO\}(tren)]^+$ in D_2O (pD 5.75, 34.5 °C).

$0.2)\times10^3$ mol^{-1} dm^3 s^{-1} at 35.2 °C, and the values of activation enthalpy and entropy are 40 ± 1 kJ mol^{-1} and -40 ± 4 J mol^{-1} K^{-1}, respectively.

Deuteration rates of the methine protons of *S,O* chelates in $[Co\{CH_3SCH(CH_3)COO\}(tren)]Cl_2$ and $[Co\{S(O)_2CH(CH_3)COO\}(tren)]Cl$ were obtained by monitoring signal changes in the ^1H NMR spectra. The C–CH_3 doublet signals become a singlet by the proton-deuteron exchange (Fig. 6). For both complexes, the plot of log(peak area of the doublet) *vs.* time was linear, from which the pseudo-first-order rate constant for the deuteration $k_{D(obsd)}$ was obtained. The rates for the $CH_3SCH(CH_3)COO^-$ and $^-S(O)_2CH(CH_3)COO^-$ complexes were $(7.3\pm0.5)\times10^{-5}$ s^{-1} (pD 5.75, 34.5 °C) and $(6.4\pm0.4)\times10^{-5}$ s^{-1} (pD 6.16, 34.5 °C), respectively. The deuteration was completed in 1 h at pD 7.5 and 34.5 °C for both complexes. The rates are 10^5—10^6-fold greater than that for the methine proton in $[Co(alaninate)(en)_2]^{2+}$ (8.5×10^{-11} s^{-1} at pD 5.75 and 34.3 °C, and 2.2×10^{-10} s^{-1} at pD 6.16 and 34.3 °C).[30]

Table 4. ^1H NMR spectral data for S–CH and S–CH_2 protons in $[CoN_4OS]^{n+}$-type complexes in D_2O, δ[a]

Complex	S–CH	S–CH_2
$[Co\{SCH(CH_3)COO\}(tren)]^+$	3.5(q)[b]	
$[Co\{CH_3SCH(CH_3)COO\}(tren)]^{2+}$	4.07(q)	
$[Co\{S(O)_2CH(CH_3)COO\}(tren)]^+$	4.38(q)	
$[Co(SCH_2COO)(en)_2]^+$		3.21(s)
$[Co(CH_3SCH_2COO)(en)_2]^{2+}$		3.85(q_{AB})
$[Co\{S(O)_2CH_2COO\}(en)_2]^+$		4.45(q_{AB})

a) The complexes of which methine or methylene protons are susceptible to deuterium exchange were measured in DCl–D_2O. b) The signal overlapped with those of tren-CH_2, and the chemical shift was determined by the spin decoupling technique. s: singlet, q: quartet, q_{AB}: AB quartet.

As shown previously, the racemization rates of $CH_3SCH(CH_3)COO^-$ and $^-S(O)_2CH(CH_3)COO^-$ chelates in the tren complex are proportional to the concentration of OH^-. The results support that the reactions proceed with a mechanism analogous to that for racemization of α-amino acidato chelates,[2] where the rate-determining step is release of the methine proton by the nucleophilic attack of OH^-. If the proton exchange and the racemization take place simultaneously and there is no isotopic effect between H and D, the ratio of k_D to k_r (k_D/k_r) should be 2. The observed ratios are 3.2 and 5.7 for $[Co\{CH_3SCH(CH_3)COO\}(tren)]^+$ and $[Co\{S(O)_2CH(CH_3)COO\}(tren)]^+$, respectively, at 35 °C, the k_D values being obtained by the formula $k_D = k_{D(obsd)}[D^+]/2.89\times10^{-15}$.[15] Although the reliability of these values is uncertain because of difficulty in determining accurate $[D^+]$ values,[14] we assume that both reactions of the proton exchange and the racemization in these tren complexes proceed simultaneously, forming carbanions as intermediate.

Table 4 shows that the NMR signals of the methine or methylene protons adjacent to sulfur shift remarkably to a lower magnetic field in the order of the $^-SCHRCOO^-$, $CH_3SCHRCOO^-$, and $^-S(O)_2CHRCOO^-$ (R=H and CH_3) complexes. Such large lower shifts may be brought about by the increasing electron-withdrawing effect of $^-S-$, $S(CH_3)-$, and $^-S(O)_2-$ groups. When the electron-withdrawing effect is small, the methine or methylene group will require larger energy in forming a carbanion and will have less reactivity to proton exchange or racemization. In fact, $[Co\{SCH(CH_3)COO\}(tren)]^+$ which has two lone pairs of electrons on the sulfur atom and gives the methine proton signal at 3.5 ppm does not racemize over 6 days at pH 9.22 and 25 °C. The methylene protons of $^-SCH_2COO^-$ in $[Co(SCH_2COO)(tren)]^+$ do not either undergo deuterium exchange over at least a day at pD 10.4 and 30 °C, although Adzamli *et al.*[7] reported that the deuteration occured in basic D_2O solution. The complex decomposes at higher pH. The sulfinato complex is expected to be more labile than the methylthio complex in deuteration or racemization reactions, since the sulfinato group is more electronegative than the methylthio group. However, the rates of $[Co\{S(O)_2CH(CH_3)-$

COO}(tren)]$^+$ in these reactions are similar to those of [Co{$CH_3SCH(CH_3)COO$}(tren)]$^{2+}$. The result may be accounted for by a difference in net charge of the complex ions. It has been reported that reactivity of glycine chelates in cobalt(III) complexes toward base-catalyzed condensation with acetaldehyde decreases with a decreasing positive net charge of the complex ion.[2,31,32]

The [Co{$S(O)_2CH_2COO$}$(en)_2$]$^+$ complex easily reacts with formaldehyde under basic conditions to afford [Co{$S(O)_2C(CH_2OH)_2COO$}$(en)_2$]$^+$ (Experimental). A similar condensation reaction has been reported to occur between [Co(glycinate)$(en)_2$]$^{2+}$ and formaldehyde in aqueous solution saturated with Li_2CO_3.[33]

The free $CH_3SCHRCOO^-$ (R=H, CH_3) ligand is stable to proton exchange. For example, $CH_3SCH(CH_3)COO^-$ does not undergo deuterium exchange for 4 d at pD *ca.* 9 and 30 °C. Thus the cobalt(III) ion activates the methine or methylene protons of these *S,O* chelate ligands. The activity of the protons seems to be much higher than that of the corresponding protons of amino acidato chelates as indicated by the proton exchange or racemization reactions.

Immunoassay Using a Metal-complex Compound as a Chemiluminescent Catalyst. II. An Improvement of the Analytical Method for Practical Use

Tadashi HARA,* Motohiro TORIYAMA, and Kazuhiko TSUKAGOSHI
Dapartment of Chemical Engineering, Faculty of Engineering, Doshisha University, Karasuma Imadegawa, Kamigyo-ku, Kyoto 602
(Received April 30, 1983)

Immunoassay using a synthesized metal-complex compound as a labeling reagent has been investigated. Iron(III) 2,9,16,23-tetrakis(chlorocarbonyl)phthalocyanine, which showed a marked catalytic action in the chemiluminescence reaction between luminol and H_2O_2, was synthesized, and albumin was labeled with it. Albumin in the range from 50 ng/tube to 50 μg/tube could be determined by measuring the chemiluminescence intensity in a competitive immunoassay using glass beads immobilized with an antibody. The present method became about 40 time as sensitive as the previous method by optimizing the labeling procedure, the chemiluminescence reaction, and the immune reaction.

A chemiluminescence complex catalyst immunoassay (CLCCIA), in which a synthesized metal-complex compound acting as a catalyst for chemiluminescence reaction was used as a labeling reagent, was previously reported by the authors for the determination of human serum albumin(HSA) as a model compound for the protein.[1] Since the CLCCIA was carried out by measuring the catalyst effect of conjugated iron(III) 2,9,16,23-tetracarboxyphthalocyanine(TCP–Fe(III)) on the chemiluminescence reaction between 5-amino-2,3-dihydro-1,4-phthalazinedione(luminol) and hydrogen peroxide(H_2O_2), CLCCIA was expected to have the following advantages: 1) A sensitive and rapid analysis can be made by the use of a simple and inexpensive apparatus; 2) the TCP–Fe(III) used as a labeling reagent is more stable and cheaper than a radioactive isotope and enzyme; 3) no steric hindrance of the immune reaction is caused by TCP–Fe(III) because its molecular weight is very small as compared with that of enzyme, and 4) no counterplan is necessary for hazards of radioactivity. These advantages were almost all verified in the previous work, but its sensitivity was still unsatisfactory for practical use in immunoassay.

In order to make the CLCCIA a practical method of immunoassay, the following were examined: 1) The carboxyl group in TCP–Fe(III) used as a labeling reagent in the previous work was converted into acyl chloride, and the product, iron(III) 2,9,16,23-tetrakis-(chlorocarbonyl)phthalocyanine(TCCP–Fe(III)), was used as a labeling reagent in the present work. Labeled HSA was easily obtained by only adding TCCP–Fe(III) to a HSA solution; it was more homogeneous than that obtained by the tedious and complicated carbodiimide method. 2) Optimization for chemiluminescence reaction was made with regard to the experimental conditions, such as the luminol concentration, the H_2O_2 concentration, and the total volume of the mixed solution. 3) Optimization was also made for the amounts of labeled HSA and the sample which were used for the competitive immunoassay. As a result, an improved CLCCIA was found to be about 40 times as sensitive as the previous method. This sensitivity enabled an improved CLCCIA to determine HSA on a picomole level which corresponded to the practical sensitivity in a common immunoassay.

Experimental

Reagents. TCCP–Fe(III) was synthesized by the acyl chlorination of TCP–Fe(III).[2] The labeling of HSA with TCCP–Fe(III) was made by the following method: Thirty milligrams of HSA (Sigma, Fraction V) was dissolved in 10 cm^3 of a potassium dihydrogenphosphate-disodium hydrogenphosphate buffer solution (pH 7.2), a 5-mg portion of TCCP–Fe(III) was added to it, and the mixed solution was incubated for 48 h at 4 °C. After the reaction, the mixture was centrifuged at 10000 *g*, and the precipitate was removed. To the supernatant we then added 10 cm^3 of a saturated ammonium sulfate solution ,and the mixed solution was held at 4 °C overnight. The supernatant was removed by centrifugation at 10000 *g*, and the precipitate thus obtained was dissolved in 1 cm^3 of a phosphate buffer solution (pH 7.0), after which the solution was dialyzed to remove the ammonium sulfate. After dialysis, the precipitate was removed by centrifugation, and the supernatant was submitted to gel chromatography on a TOYOPEARL HW-50 (TOYO SODA) column (150 cm^3), using a phosphate buffer solution (pH 7.0) as an eluent. Twenty cubic centimeters of an albumin fraction containing HSA labeled with TCCP–Fe(III) were thus obtained.

The glass beads immobilized with the antibody (Ab-bead) were prepared by the previously reported method.[1] The other reagents used were of a commercially available analytical grade.

Apparatus. The same apparatus as in the previous paper was used for the measurement of the chemiluminescence intensity (CL intensity).[1]

Procedure. Seventy cubic millimeters of a phosphate buffer solution (pH 7.2), containing a definite amount of HSA as an analyte and 30 mm^3 of a labeled HSA solution (containing about 200 ng of conjugated TCCP–Fe(III)), were placed in a 50×6 mm diam. test tube, and one particle of the Ab-beads was soaked in its solution. Thus, the labeled HSA and the free HSA used as an analyte were made to react competitively overnight at 4 °C with the antibody immobilized on the Ab-beads. After the immune reaction, the Ab-beads were twice washed with a phosphate buffer solution (pH 7.2). On the other hand, 0.5 cm^3 of a 1.0×10^{-3} mol/dm^3 luminol solution (pH 10.2; a boric acid–potassium hydroxide buffer solution) and 0.5 cm^3 of a 7.5×10^{-3} mol/dm^3 H_2O_2 solution were mixed in a 90×10 mm diam. test tube; the mixture was then allowed to stand for 30 min before measurement to stabilize

the chemiluminescence background. The above Ab-beads were put into the mixed solution, and the CL intensity was immediately measured by means of the photon counter.

Results and Discussion

Labeling with TCCP-Fe(III). The labeling of HSA with TCP-Fe(III) in the previous paper was carried out by allowing the carboxyl group of TCP-Fe(III) to combine covalently with the amino group of HSA by the use of the water-soluble carbodiimide reagent. However, this labeling method resulted in lowering the homogeneity of labeled HSA because in HSA containing both carboxyl and amino groups the two groups easily combined with each other.

The labeling of HSA with TCCP-Fe(III) in the present work was easily carried out by adding TCCP-Fe(III) as an acyl chloride to a HSA solution, and no linkage was produced between one HSA molecule and others. The absorption spectra of HSA, TCP-Fe(III), TCCP-Fe(III), HSA labeled with TCP-Fe(III) by the carbodiimide method, and HSA labeled with TCCP-Fe(III) by the present method were measured by the use of their respective phosphate buffer solutions (pH 7.0); the results are shown in Fig. 1. Each albumin fraction prepared by gel chromatography was used for the respective HSA labeled with TCP-Fe(III) and TCCP-Fe(III) (*cf.* Fig. 1). The spectrum of TCCP-Fe(III) was obtained after TCCP-Fe(III) had been dissolved in a phosphate buffer solution (pH 7.0) and the solution kept at 4 °C for 48 h. As can be seen from Fig. 1, the spectrum of TCCP-Fe(III) agreed well with that of TCP-Fe(III). Each shoulder at 675 nm, which was not quite observed for TCP-Fe(III) and TCCP-Fe(III) alone, was newly found for HSA labeled with TCP-Fe(III) and TCCP-Fe(III) respectively. In addition, slight peak shifts at 325 and 639 nm were also observed for both labeled HSA's. It still remains to be determined if the above-mentioned phenomena are based on either the formation of a covalent bond between HSA and a labeling reagent or the formation of a coordination linkage between the functional group of HSA and the residual coordination sites of the iron(III) complex as a labeling reagent. The absorption spectrum of HSA labeled with TCCP-Fe(III) was rather more similar to that of TCP-Fe(III) than to that of HSA labeled with TCP-Fe(III). By assuming that the molar absorptivity of HSA at 280 nm and of TCCP-Fe(III) and TCP-Fe(III) at 639 nm do not change upon labeling, the approximate mole ratio of a labeling reagent to HSA was obtained by the use of the calibration curves for TCCP-Fe(III), TCP-Fe(III), and HSA, the results being TCCP-Fe(III) : HSA=1 : 1 and TCP-Fe(III) : HSA=1 : 5. It is concluded from the amount of the conjugated iron(III) complex that the present method using TCCP-Fe(III) as a labeling reagent is superior to the carbodiimide method using TCP-Fe(III) as a labeling reagent.

Optimum Conditions for the Measurement of the CL Intensity. To find out the optimum conditions for the measurement of the CL intensity, the effects of the concentrations of H_2O_2 and luminol and of the total volume of a H_2O_2–luminol mixed solution on the CL intensity were examined. The CL intensity was measured by the use of Ab-beads which had been submitted to an immune reaction overnight at 4 °C in 100 mm³ of a phosphate buffer solution (pH 7.2) containing 30

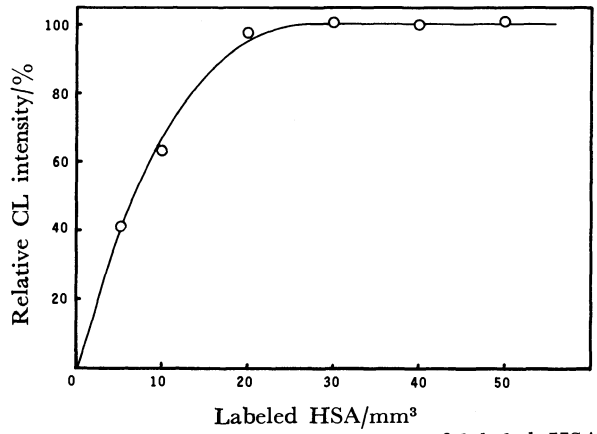
Volume of immune reaction solution/cm^3

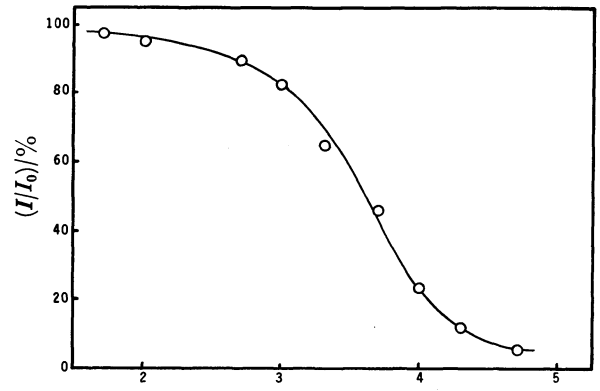
Fig. 5. Relationship between total aqueous volume in immune reaction and relative CL intensity in a mixed solution of luminol (0.5 cm^3, 1.0×10^{-3} mol/dm^3) and H_2O_2 (0.5 cm^3, 7.5×10^{-3} mol/dm^3).



Labeled HSA/mm^3

Fig. 6. Relationship between volume of labeled HSA and relative CL intensity.

mm^3 of a labeled HSA solution. The results are shown in Figs. 2, 3, and 4. The CL intensity increased proportionally with an increase in the concentration of H_2O_2 and gave a maximum value at 7.5×10^{-3} mol/dm^3 H_2O_2, followed by its decrease. The maximum CL intensity was also obtained at 1.0×10^{-3} mol/dm^3 luminol. The total volume of a luminol–H_2O_2 mixed



log(HSA/ng tube^{-1})

Fig. 7. Standard curve for HSA.
I, I_0: CL intensity of the sample in the presence or absence of HSA.

solution did not affect the CL intensity.

On the basis of these results, 0.5 cm^3 of a 7.5×10^{-3} mol/dm^3 H_2O_2 solution and 0.5 cm^3 of a 1.0×10^{-3} mol/dm^3 luminol solution were mixed to obtain an optimum result.

Optimum Conditions for a Competitive Immune Reaction. The relationship between the CL intensity and the total aqueous volume for an immune reaction is shown in Fig. 5. A definite concentration of labeled HSA was allowed to react with the antibody on Ab-beads at a total aqueous volume of from 0.1 to 1 cm^3. After the immune reaction, each Ab-bead showed approximately the same CL intensity. Since a minimum aqueous volume of 0.1 cm^3 was necessary to keep an Ab-bead in a solution, a total aqueous volume of 0.1 cm^3 was recommended for practical use.

The amount of labeled HSA required for a competitive immune reaction with HSA was examined by changing the amount of labeled HSA in a 0.1 cm^3 aqueous solution and by measuring the CL intensities, the results are shown in Fig. 6. As can be seen from Fig. 6, the active site of an antibody on an Ab-bead was completely saturated with more than 30 mm^3 of labeled HSA. To satisfy the requirements that 1) the total amount of antigen and labeled antigen has to surpass the corresponding amount of the immobilized antibody in a competitive immunoassay and 2) the sensitivity for a competitive immunoassay has to be enhanced as much as possible, 30 mm^3 of labeled HSA was chosen for the immunoassay.

Immunoassay. The immunoassay of HSA was carried out by the use of HSA labeled with TCCP–Fe(III), and a standard curve was obtained for HSA of from 50 ng/tube to 50 μg/tube (Fig. 7). For the preparation of the standard curve for HSA, the CL intensities of five equal amounts of HSA were separately measured, and their mean value(I) was obtained. The relative CL intensity(I/I_0) was represented as the ratio of I to the CL intensity(I_0) of a labeled HSA alone. The CL intensity of a HSA of more than 50 ng/tube was always smaller than the I_0 value, while the CL intensity of a HSA of less than 50 ng/tube was often larger than the I_0 value. Therefore, 50 ng/tube of HSA was defined

TABLE 1. IMMUNOASSAY USING A METAL COMPLEX COMPOUND AS A LABELING REAGENT

Immunoassay	Method		Chemical amplification[a)]	Detection limit	Sample	Analyte
	Component	Measurement				
CLCCIA	Catalytic activity	Chemiluminescence	+	50 ng/tube (7.6×10^{-9} mol/dm^3)	70 mm^3	HSA
VIA	In	Differential pulse anodic stripping voltammetry	−	5.0 μg/cm^3 (7.6×10^{-8} mol/dm^3)	5000 mm^3	HSA
MIA	Fe, Mn	Atomic-absorption spectrometry	−	0.1 μg/cm^3 (3.5×10^{-7} mol/dm^3)	30 mm^3	Oestrogen steroids (hapten)

a) +, −: Shows the presence or absence of chemical amplification.

as the detection limit. Judging from the detection limit for the previous and the present methods, the present method was about 40 times as sensitive as the previous method. This enhancement is attributed to 1) the optimization of the chemiluminescence reaction and the immune reaction, and 2) the use of HSA labeled sufficiently with TCCP–Fe(III). Voltammetric immunoassay (VIA)[3] and metalloimmunoassay (MIA)[4,5] have previously been reported as immunoassays using a metal-complex compound as a labeling reagent. In Table 1 they are compared with the present method. According to the present method, the picomole level of albumin can be determined; this sensitivity satisfies the sensitivity required for a practical immunoassay. Since the present method makes use of the catalytic action of a metal-complex compound as a labeling reagent, its sensitivity would be much more improved by using a sandwich method or some other such method. Further study is now in progress.

Synthesis of Mesoionic Triazolopyridine. II. *N*-Acylation of 1,2,4-Triazolo[4,3-*a*]pyridin-3(2*H*)-one

Akio SAITO* and Bunji SHIMIZU
Chemical Research Laboratories, Sankyo Co., Ltd., Hiromachi, Shinagawa-ku, Tokyo 140
(Received December 25, 1982)

N-Acyl and *N*-alkoxycarbonyl mesoionic triazolopyridines were synthesized by selective *N*-acylation of 1,2,4-triazolo[4,3-*a*]pyridin-3(2*H*)-one. Some properties of these new-type azolides were also investigated.

In a previous work[1] in this series, we reported a novel approach for the synthesis of mesoionic triazolopyridines (**2**) by the selective alkylation of 1,2,4-triazolo[4,3-*a*]-pyridin-3(2*H*)-one (**1**). The interesting properties of *N*-alkyl mesoionic triazolopyridines (**2**) have called our attention to mesoionic *N*-acyl derivatives (**3**). These compounds (**3**) are characterized by combination of *N*-acyl azole(azolide) with mesoionic ring. Hence, a term "mesoionic azolide" will be used for these compounds. Only one example of this class of compounds has so far been reported.[2]

N-Acyl azoles, such as imidazolides (**4**) or triazolides (**5**) have been known as active amides, and widely used as acylating reagents.[3-8] The remarkable reactivity of these azolides has been attributed[7] to their resonance structures. Hence, it is thought that the reactivity of the acyl group of **3** reflects the particular resonance structure of the mesoionic ring. Possible use of the compounds (**3**) as acylating reagents would also be expected. Therefore, we have studied *N*-acylation of **1**. In this paper, we wish to report the selective *N*-acylation of **1** and some properties of the *N*-acyl mesoionic triazolopyridines.

Results and Discussion

The followings are typical known preparative methods of *N*-acyl azoles(azolides): 1) direct acylation of parent azoles with acid halides,[5,9,10] 2) acylation of *N*-(trimethylsilyl)azoles with acid halides,[11] 3) reaction of carbonyl(diazolide)s with carboxylic acids.[5,12] We attempted several methods for the preparation of the mesoionic azolides (Fig. 2).

Almost all attempts to obtained the *N*-acyl mesoionic triazolopyridinones (**3**) by the reaction of **1** with acid chloride failed. Thus, heating of **1** with acid chloride in boiling chloroform resulted in the exclusive formation of

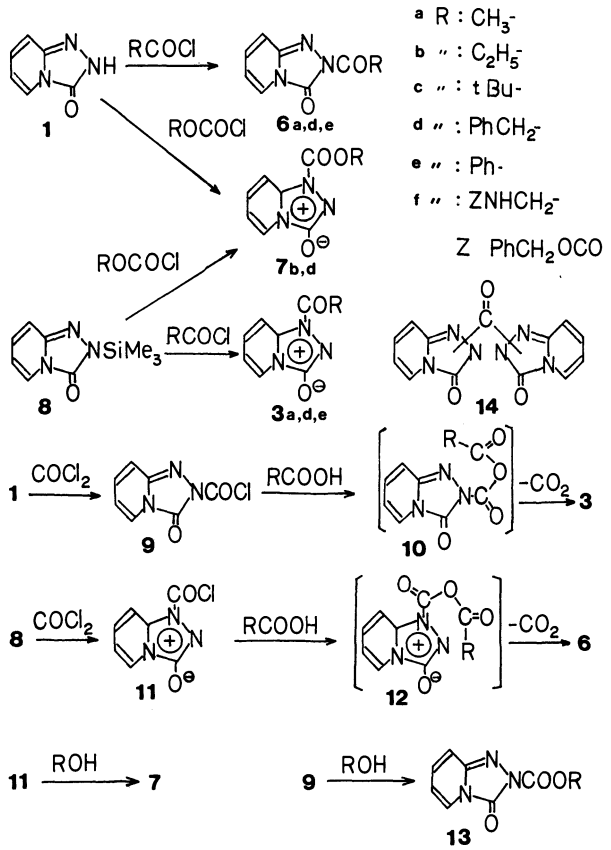

Fig. 2.

nonmesoionic compounds, which were assigned to N^2-acyltriazolopyridinones (**6**) based on their physical data. Details on the structural assignment are described in the following section. On the other hand, reaction of **1** with alkokycarbonyl chlorides gave mesoionic compounds (**7**) in moderate yields. For example, heating **1** with benzyl chloroformate gave a pale yellowish crystalline product which showed strong fluorescence when it was dissolved in an aprotic solvent. By comparing its IR, UV, and NMR spectra with those of *N*-alkyl mesoionic triazolopyridinones (**2**), this compound was found to have a mesoionic structure (**7d**) as shown in Table 1. *N*-acyl mesoionic triazolopyridinones (**3**) were obtained by using 2-(trimethylsilyl)triazolopyridine (**8**)[1] instead of **1**. Reaction of **8** with acid chlorides proceeded smoothly to give the desired mesoionic compounds (**3**) even at low temperature. When the reaction is carried out in a nonpolar solvent, such as benzene, the product is easily isolated by filtration, because it precipitates during reaction in most cases. Reaction of

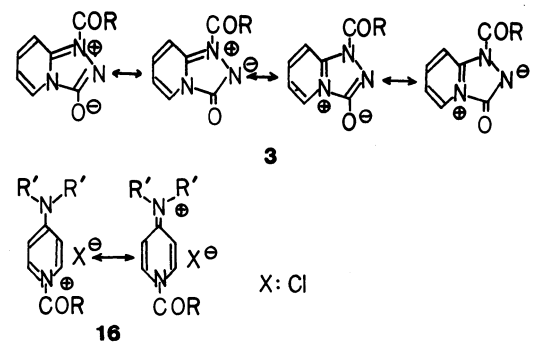

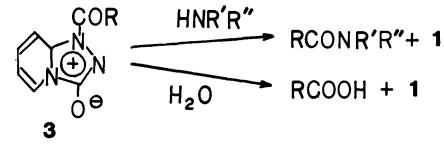

Fig. 4.

8 with alkoxycarbonyl chlorides gave the urethane-type mesoionic triazolopyridines (**7**) in the same manner.

When phosgene was used as the acylating reagent for the reaction of **1** or **8**, the N-chloroformyl derivative, **9** or **11** respectively, was obtained instead of the expected[4] carbonyldi(triazolopyridine) (**14**).

Structure of **9** and **11** were assigned on the basis of their UV spectra. It became clear that these compounds were useful reagents for the preparation of N-acyltriazolopyridines, similar to the carbonyldi(azole) for the preparation of N-acyl azoles[5,12] Thus, reaction of **9** with a variety of carboxylic acids proceeded in the presence of one equivalent-molar bases to give the mesoionic azolides (**3**) accompanying evolution of carbon dioxide. Since **3** was the sole product in this reaction, it was supposed that intramolecular transacylation of the intermediate mixed anhydride (**10**) occurred exclusively on the N^1-atom of the triazolopyridine ring. Similar transacylation was assumed in the reaction of **11** with a carboxylic acid, in this case **6** was the sole product. Reactions of these reagents, **9** and **11**, with alcohols in the presence of pyridine gave urethane-type mesoionic and nonmesoionic triazolopyridines, **7** and **13**, respectively. Thus, it became possible to obtain these mesoionic azolides (**3** and **7**) from appropriate carboxylic acids or alcohols by using these reagents (**9** or **11**). Both reagents are stable crystalline masses and may be stored in a desiccator at room temperature for a few months, but preferably in a refrigerator for longer storage.

Some Properties of the Mesoionic Azolides (3 and 7).
A comparison of physical data of the mesoionic azolides (**3d** and **7d**) with those of N-alkyl and N^2-acyl analogs (Fig. 3) is shown in Table 1. It can be seen that the spectra of the N-acyl mesoionic triazolopyridines (**3d** and **7d**) are closely related to those of N-benzyl mesoionic triazolopyridine (**2d**). In an aprotic solvent, mesoionic triazolopyridines (**2**, **3**, and **7**) showed characteristic UV absorption in the region from 360 to 400 nm with intensity (ε 5500—10000) and large hypsochromic shifts (35—40 nm) of the maxima were observed when the solvents were changed to a protic solvent. In the case of nonmesoionic triazolopyridines (**6**, **13**, and **15**), these maxima were found in the region from 350 to 360 nm in an aprotic solvent with relatively low intensity (ε 3500—4500), and small hypsochromic shifts (*ca.* 10 nm) were observed. In the IR spectra, absorption bands for ring carbonyl of these mesoionic compounds (**3**, **7**, and **2**) were found in a lower frequency region than those of the corresponding nonmesoionic N^2-analogs (**6**, **13**, and **15**). In the NMR spectra, the chemical shifts of the pyridine-ring protons of the mesoionic compounds (**3**, **7**, and **2**) were always found at a lower field than those of the nonmesoionic analogs (**6**, **13**, and **15**). Thus, UV absorption and chemical shift of the pyridine-ring protons are effective in discriminating mesoionic compounds from their nonmesoionic analogs.

The mesoionic azolides (**3**) were found to have a tendency to transform to the thermodynamically more stable N^2-acyl analogs (**6**) under the conditions described below.

On heating in boiling 1,2-dichloroethane, slow conversion of **3d** to **6d** was found. In a previous paper,[1]

it was found that benzyl bromide acted as an effective catalyst for the N^1—N^2 benzyl migration on the triazolopyridine ring. Conversion of **3d** to **6d** was accelerated by addition of phenylacetyl chloride. The exclusive formation of **6** in the reaction of **1** with acyl chloride may be explained by the finding described above. Tertiary amine was found to be a more efficient catalyst for the conversion. When triethylamine was used as a catalyst, conversion of **3d** to **6d** took place even at room temperature, and completed within 3 h. The resonance structure of the mesoionic ring is illustrated in Fig. 4, which is very close to that of 1-acyl-4-dialkylaminopyridinium chloride (**16**),[13,14] a very reactive acylating reagent (Fig. 4). This similarity indicates that these acyl azolides (**3** or **7**) should act as powerful acylating agents. In fact, a reaction of **3d** with aniline in dichloromethane at room temperature completed within 2 h, yielding phenylacetanilide in nearly quantitative yield.

Relative reactivity of the mesoionic azolide (**3**) was determined on the reaction of **3a** with diethylamine or water, according to the method of Staab.[3] The mesoionic azolide (**3a**) was found to be 4 times more reactive than *N*-acetylimidazole[3] toward diethylamine in THF. On the other hand, hydrolytic decomposition of **3a** was found to proceed fairly slowly in spite of the high reactivity to an amine. The half life of the mesoionic azolide (**3a**) in water was found to be 380 min as determined by the change of the UV absorption at 25 °C. In the literature, the half lives of *N*-acetylimidazole,[3] *N*-acetyltriazole,[3] and 1-acetyl-4-dimethylaminopyridinium chloride were reported as 33—45, 6.6, and 3.9 min respectively under the same conditions. From these facts it appears that *N*-acyl mesoionic triazolopyridines (**3**) should be quite stable against water but very reactive toward amines. Although the relationship between the mesoionic structure and the selective reactivity of the mesoionic azolide against different nucleophiles is still uncertain, the stability toward hydrolytic decomposition makes the reagent (**3**) easy to handle. These findings together with their easy preparation suggest the usefulness of these mesoionic azolides (**3** and **7**) as acylating reagent. Details of their applications as acylating reagents will be reported in a subsequent paper.

Experimental

Melting points were determined on a Yazawa hot-stage apparatus and are uncorrected. IR, UV, and NMR spectra were recorded on JASCO A-102, Hitachi 200-20 and Varian EM 360L spectrometers, respectively. Triazolopyridine (**1**) was prepared by the method of Potts and Burton.[16]

1-Ethoxycarbonyl-1,2,4-triazolo[4,3-a]pyridinium-3-olate (7b). *a)*: A mixture of 5.4 g (40 mmol) of 1,2,4-triazolo[4,3-*a*]-pyridin-3(2*H*)-one (**1**) and ethyl chloroformate (100 ml) was heated under reflux for 3 h, cooled, and evaporated *in vacuo*. The residue was crystallized from methanol to give yellow fine needles, mp 144—145 °C. Yield 5.87 g (71%). UV (THF) λ_{max}: 378 nm (ε 5500). IR (Nujol): 1735, 1720 cm^{-1} (C=O). NMR ($CDCl_3$–DMSO-d_6); δ=8.57 (m, 1, H-5), 8.40 (m, 1, H-8), 8.16 (m, 1, H-7), 7.54 (m, 1, H-6), 4.51 (q, J=7 Hz, 2, COOC$\underline{H}_2$), 1.47 (t, J=7 Hz, 3, COOCH$_2$C$\underline{H}_3$). Found: C, 51.96; H, 4.23; N, 20.16%. Calcd for $C_9H_9N_3O_3$: C, 52.17; H, 4.23; N, 20.27%.

b): To a solution of 2.07 g (10 mmol) of 2-trimethylsilyl-1,2,4-triazolo[4,3-*a*]pyridin-3(2*H*)-one (**8**)[11] in dry benzene(20 ml) was added ethyl chloroformate (1.19 g, 11 mmol) with stirring. After the mixture had been stirred for 1 h, the crystalline precipitate was collected by filtration, washed with dry benzene and recrystallized from methanol to give pure **7b** (1.81 g, 87%). This product was identical with the sample prepared by route *a)*.

1-Benzyloxycarbonyl-1,2,4-triazolo[4,3-a]pyridinium-3-olate (7d). *a)*: A mixture of **1** (3.95 g, 2.93 mmol) and benzyl chloroformate (50 ml) was stirred at 90 °c for 1 h, and evaporated *in vacuo*. The residue was crystallized from ethanol to give **7d** as fine needles, mp 140°C. Yield 4.10 g (52%). UV (THF) λ_{max}: 224 (ε 4800), 254 (4300), 314 (3300), 377 nm (6100). IR (Nujol): 1745, 1710 cm^{-1} (C=O). NMR ($CDCl_3$–DMSO-d_6); δ=8.55 (m, 1, H-5), 8.4—8.0 (m, 2, H-7 and H-8), 7.42 (m, 1, H-6), 7.41 (s, 5, C$_6\underline{H}_5$), 5.48 (s, 2, PhC$\underline{H}_2$). Found: C, 62.48; H, 4.09; N, 15.81%. Calcd for $C_{14}H_{11}N_3O_3$: C, 62.45; H, 4.12; N, 15.61%.

b): To a solution of **8** (2.07 g, 10 mmol) in dry benzene (20 ml) was added benzyl chloroformate (1.82 g, 10.7 mmol) with stirring. After the mixture had been stirred for 1 h at room temperature, the crystalline precipitate was collected, recrystallized from ethanol to give **7d** (2.48 g, 92%). This product was identical with the sample prepared by route *a)*.

1-Acetyl-1,2,4-triazolo[4,3-a]pyridinium-3-olate (3a). To a solution of **8** (2.07 g, 10.0 mmol) in dry THF (20 ml) was added 0.80 g (10.2 mmol) of acetyl chloride with stirring. The reaction was slightly exothermic, and yellow crystals precipitated off immediately from the solution. After the mixture had been stirred for 1 h at room temperature, the product was collected by filtration, washed with dry THF and dried *in vacuo*: 1.29 g (73%) of **3a** was obtained, mp 150—153°C. UV (THF) λ_{max}: 374 nm (ε 6220). IR (Nujol): 1720 cm^{-1} (C=O). Found: C, 53.97; H, 4.00; N, 23.76%. Calcd for $C_8H_7N_3O_2$: C, 54.24; H. 3.98; N, 23.72%.

Reactions of 1 with Acid Chlorides. *a) With Acetyl Chloride*: A mixture of **1** (1.35 g, 10 mmol) and acetyl chloride (1.57 g, 20 mmol) in chloroform (15 ml) was boiled under reflux for 4 h, then, cooled to room temperature. A small amount of solid was filtered off, and the filtrate was evaporated *in vacuo* to dryness. The residue was crystallized from chloroform–hexane to give 1.63 g (92%) of 2-acetyl-1,2,4-triazolo[4,3-*a*]pyridin-3-(2*H*)-one (**6a**), mp 176 °C. UV (THF) λ_{max}: 351 nm (ε 3750). IR (Nujol): 1720 cm^{-1} (C=O). NMR ($CDCl_3$); δ=7.79 (m, 1, H-5), 7.4—7.1 (m, 2, H-7 and H-8), 6.55 (m, 1, H-6), 2.72 (s, 3, C$\underline{H}_3$CO). Found: C, 54.34; H. 3.86; N, 23.83%. Calcd for $C_8H_7N_3O_2$: C, 54.24; H, 3.98; N, 23.72%.

b) With Phenylacetyl Chloride: A mixture of **1** (1.35 g, 10 mmol) and phenylacetyl chloride (1.57 g, 20 mmol) in chloroform (15 ml) was boiled under refiux, and the reaction mixture was worked up in the manner described above expt; 2.43 g (96%) of 2-phenylacetyl-1,2,4-triazolo[4,3-*a*]pyridin-3(2*H*)-one (**6d**) was obtained, mp 142—143 °C. UV (THF) λ_{max}: 257 (ε 4300), 266 (4100), 350 nm (4000). IR (Nujol): 1740 cm^{-1} (C=O). NMR ($CDCl_3$); δ=7.75 (m, 1, H-5), 7.40 (s, 5, C$_6\underline{H}_5$), 7.5—7.0 (m, 2, H-7 and H-8), 6.50 (m, 1, H-6), 4.45 (s, 2, PhCH_2). Found: C, 66.56; H, 4.22; N, 16.71%. Calcd for $C_{14}H_{11}N_3O_2$: C, 66.39; H, 4.38; N, 16.59%.

c) With Benzoyl Chloride: A mixture of **1** (1.35 g, 10 mmol) and benzoyl chloride (2.81 g, 20 mmol) in chloroform (15 ml) was boiled under reflux for 96 h and the reaction mixture was worked up in the manner described above to give 1.78 g (74%) of 2-benzoyl-1,2,4-triazolo[4,3-*a*]pyridin-3(2*H*)-

one (**6e**), mp 145 °C. UV (THF) λ_{max}: 358 nm (ε 4300). IR (Nujol): 1730, 1695 cm^{-1}. NMR (DMSO-d_6): δ=8.03 (m, 1, H-5), 8.0—7.0 (m, 7, H-7, H-8 and $C_6\underline{H}_5$), 6.66 (m, 1, H-6). Found: C, 65.28; H, 3.59; N, 17.70%. Calcd for $C_{13}H_9N_3O_2$: C, 65.27; H, 3.79; N, 17.57%.

*2-Chloroformyl-1,2,4-triazolo[4,3-a]pyridin-3(2H)-one (**9**).* To a suspension of **1** (27 g, 200 mmol) in dry THF (600 ml) was introduced phosgene (40 g) with stirring. The resulting mixture was boiled under reflux for 2 h to afford a clear soln and then cooled to room temperature. The resulting crystalline product was collected by filtration, washed with a small amount of dry THF, and dried *in vacuo* to give **9**. The filtrate was combined with the washing, concentrared *in vacuo*, giving a second crop of **9**. Mp 230 °C. Yield 36.78 g (93%). UV (CH_2Cl_2) λ_{max}: 262, 272, 283, 356 nm. Found: C, 42.30; H, 2.33; N, 21.26; Cl, 17.99%. Calcd for $C_7H_4N_3O_2Cl$: C, 42.55; H, 2.04; N, 21.27; Cl, 17.95%.

*1-Chloroformyl-1,2,4-triazolo[4,3-a]pyridinium-3-olate (**11**).* To a solution of **8** (20.7 g, 100 mmol) in dry benzene was slowly added a solution of phosgene (9.90 g, 100 mmol) in dry THF (50 ml) at a temperature between 4 °C and 10 °C with stirring. After the mixture had been stirred at room temperature for 1 h, the crystalline precipitate was collected by filtration, washed with dry benzene, and dried *in vacuo* to give **11**, mp 320 °C (decomp). UV (CH_2Cl_2) λ_{max}: 247, 375 nm. Found: C, 42.56; H, 2.14; N, 21.54; Cl, 17.72%. Calcd for $C_7H_4N_3O_2Cl$: C, 42.55; H, 2.04; N, 21.27; Cl, 17.95%.

*Reaction of **9** with Carboxylic Acids.* *a) With Acetic Acid*: To a solution of acetic acid (0.48 g, 10 mmol) in dichloromethane (40 ml) was added triethylamine (1.40 ml, 10 mmol). The mixture was cooled to 4 °C and 1.98 g (10 mmol) of **9** was added. With evolution of gas, the solution became yellow-green. After 1 h-stirring at 4 °C, the solution was washed twice with cold water, dried over anhydrous sodium sulfate, and concentrated *in vacuo* to *ca.* 10 ml. Ether was added to give a crystalline product of 1-acetyl-1,2,4-triazolo[4,3-*a*]-pyridinium-3-olate (**3a**), mp 167 °C. Yield 1.10 g (62%). The physical properties of this product agreed with those of the sample obtained in the above expt.

b) With Phenylacetic Acid: By treating phenylacetic acid (1.36 g, 10 mmol) with **9** (1.98 g, 10 mmol) as in the previous experiment, 2.26 g (89%) of 1-phenylacetyl-1,2,4-triazolo[4,3-*a*]pyridinium-3-olate (**3d**) was obtained, mp 155—157 °C. UV (THF) λ_{max}: 232 (ε 8150), 258 (3100), 384 nm (7550). IR (Nujol): 1720, 1700 cm^{-1} (C=O). NMR ($CDCl_3$); δ=8.16 (m, 1, H-5), 8.0—7.3 (m, 7, H-7, H-8, and $C_6\underline{H}_5$), 7.25 (m, 1, H-6), 4.42 (s, 2, $PhCH_2$). Found: C, 66.50; H, 4.28; N, 16.65%. Calcd for $C_{14}H_{11}N_3O_2$: C, 66.39; H, 4.38; N, 16.59%.

c) With Benzoic Acid: By treating benzoic acid (1.22 g, 10 mmol) with **9** (1.98 g, 10 mmol) in the manner described above, 1-benzoyl-1,2,4-triazolo[4,3-*a*]pyridinium-3-olate (**3e**) was obtained, mp 134—136 °C. Yield 2.06 g (86%). UV (THF) λ_{max}: 398 nm (ε 9950). IR (Nujol): 1730, 1695 cm^{-1} (C=O). NMR ($CDCl_3$); δ=8.8—7.3 (m, triazolopyridine ring and benzene ring protons). Found: C, 65.22; H, 3.63; N, 17.74%. Calcd for $C_{13}H_9N_3O_2$: C, 65.27; H, 3.79; N, 17.57%.

d) With N-(Benzyloxycarbonyl)glycine: By treating *N*-*Z*-glycine (2.09 g, 10 mmol) with **9** (1.98 g, 10 mmol) in the manner described above, 1-[*N*-(benzyloxycarbonyl)glycyl]-1,2,4-triazolo[4,3-*a*]pyridinium-3-olate (**3f**) was obtained, mp 173—176 °C. Yield 2.87 g (88%). UV (THF) λ_{max}: 375 nm. IR (Nujol): 1720, 1695 cm^{-1} (C=O). Found: C, 58.69; H, 4.23; N, 17.34%. Calcd for $C_{16}H_{14}N_4O_4$: C, 58.89; H, 4.32; N, 17.17%.

*Reaction of **11** with Phenylacetic Acid.* To a solution of phenylacetic acid (0.68 g, 5 mmol) in dichloromethane (20 ml) was added triethylamine (0.70 ml, 5 mmol), and the mixture was cooled to 4 °C, then, **11** (0.985 g, 5 mmol) was added. After stirring at room temperature for 1 h, the reaction mixture was washed twice with cold water, dried over anhydrous sodium sulfate, and evaporated *in vacuo* to dryness. The residue was crystallized from chloroform–hexane to give 1.18 g (93%) of **6d**. The physical properties of this product agreed with those of the sample obtained in the above expt.

*Reaction of **11** with Alcohols.* *a) With Benzyl Alcohol*: A suspension of **11** (1.98 g, 10 mmol) in ethanol–free chloroform (50 ml) prepared by passing through an alumina column before use was cooled to 4 °C, and 1.05 ml of pyridine was added. After the mixture had been stirred at 4 °C for 1 h, benzyl alcohol (1.19 g, 11 mmol) was added. The reaction mixture became a clear solution, and soon after yellow crystals separated out from the solution. After the mixture had been stirred at room temperature for 30 min, the product was collected by filtration, washed with chloroform, and dried *in vacuo* to give **7d**. The filtrate and washings were combined, washed twice with water, dried over anhydrous sodium sulfate, and concentrated *in vacuo*, giving a second crop of **7d**. The total yield of **7d** was 2.50 g (94%). The physical properties of this product were identical to those of the sample in the above expt.

b) With t-Butyl Alcohol: A suspension of **11** (1.98 g, 10 mmol) in ethanol–free chloroform was cooled to 4 °C, dry pyridine (1.05 ml) was added, and the mixture was stirred at 4 °C for 40 min then, anhydrous *t*-butyl alcohol (2 ml) was added. On stirring at room temperature, the reaction mixture became a clear solution within 20 min. After a further 1 h-stirring, the solution was washed twice with cold water, dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from chloroform–ether to give 2.04 g (69%) of 1-(*t*-butoxycarbonyl)-1,2,4-triazolo-[4,3-*a*]pyridinium-3-olate (**7c**) as a chloroform adduct, mp 119—121 °C. UV (THF) λ_{max} 374 nm. IR (Nujol): 1757, 1722 cm^{-1} (C=O). Found: C, 46.95; H, 4.62; N, 14.47%. Calcd for $C_{11}H_{13}N_3O_3 \cdot 1/2CHCl_3$: C, 46.82; H, 4.61; N, 14.25 %.

*2-Benzyloxycarbonyl-1,2,4-triazolo[4,3-a]pyridin-3(2H)-one (**13d**).* To a suspension of **9** (1.0 g) in dichloromethane were added pyridine (0.40 g) and benzyl alcohol (0.65 g), and the mixture was stirred for 1 h at room temperature. The resulting solution was washed twice with water, dried over anhydrous sodium sulfate, and evastallized *in vacuo* to dryness. The residue was crystallized from ether to give **13d** (1.257 g, 93%), mp 138 °C. UV (THF)λ_{max}: 254 (ε 3500), 264 (3500), 276 (2200), 347 nm (3600). IR (Nujol): 1730 cm^{-1} (C=O). NMR (DMSO-d_6); δ=7.88 (m, 1, H-5), 7.7—7.0 (m, 2, H-7 and H-8), 7.51 (s, 5, C_6H_5), 6.64 (m, 1, H-6), 5.47 (s, 2, $PhC\underline{H}_2$). Found: C, 62.24; H, 4.00; N, 15.60%. Calcd for $C_{14}H_{11}N_3O_3$: C, 62.45; H, 4.12; N, 15.61%.

*Conversion of **3d** to **6d**.* *a) Thermal Conversion*: A solution of **3d** (100 mg) in 5 ml of 1,2-dichloroethane was heated under reflux for 20 h, then, the solvent was removed by evaporation *in vacuo*. The NMR spectrum of the residue in $CDCl_3$ showed that it consisted of **3d** and **6d** (43 : 57).

b) Conversion Catalyzed by Acid Chloride: A mixture of **3d** (253 mg, 1 mmol) and phenylacetyl chloride (155 mg, 1 mmol) in 1,2-dichloroethane (2.5 ml) was stirred at 80 °C for 45 min; TLC on silica gel in 40% ethyl acetate in benzene showed disappearance of the starting material (**3d**) within 40 min. The reaction mixture was evaporated *in vacuo*, and the residue was crystallized from chloroform–hexane to give 232 mg of **6d**.

c) Conversion Catalyzed by Triethylamine: To a solution of

3d (100 mg) in 1,2-dichloroethane (5 ml) was added triethylamine (0.04 ml), and the mixture was stirred at room temperature. TLC on silica gel showed that **3d** was almost completely converted to **6d** within 3 h.

Reaction of Mesoionic Azolide (3d) with Aniline. A mixture of **3d** (1.27 g, 5 mmol) and aniline (0.49 g, 5.25 mmol) in dichloromethane (10 ml) was stirred at room temperature for 2 h, filtered, and the filtrate was washed successively with 0.5 M citric acid, water, 4% sodium hydrogencarbonate, and water. The dichloromethane solution was dried over anhydrous sodium sulfate, and evaporated *in vacuo* to give crystalline phenylacetanilide (1.02 g, 97%), mp 117—118 °C. The physical properties of this product agreed with those of authentic phenylacetanilide.

Measurement of the Reactivities of 3a. The rates of aminolysis and hydrolysis were measured at 25 °C according to the direction of Staab.[3] The rate of the aminolysis of **3a** (1.830×10^{-4} mmol/ml) in THF containing 5% diethylamine was measured by observing the decrease in its UV absorption maximum at 389 nm. The rate of the hydrolysis of **3a** in water (2.25×10^{-4} mmol/ml) was also measured by means of the change of the maximum at 340 nm. Pseudo-first order rate constants of the amonolysis in 5% diethylamine–THF was 3.84×10^{-2} and that of hydrolytic decomposition was 1.8×10^{-3}.

The authors wish to thank Dr. Genshun Sunagawa, Dr. Keisuke Murayama, and Dr. Hideo Nakao for their continuing interest and encouragement and Dr. Masakatsu Kaneko for his helpful comments.

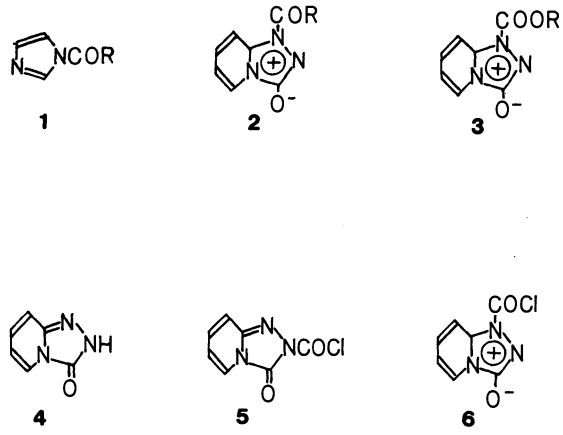
Synthesis of Mesoionic Triazolopyridine. III. Applications of *N*-Acyl Mesoionic Triazolopyridines as Acylating Reagents

Akio SAITO* and Bunji SHIMIZU
Chemical Research Laboratories, Sankyo Co., Ltd., Hiromachi, Shinagawa-ku, Tokyo 140
(Received September 11, 1982)

Utility of *N*-acyl mesoionic triazolopyridines as acylating reagents was investigated concerning with peptide synthesis. Several dipeptides and *N*-alkoxycarbonyl amino acids were prepared by use of these reagents.

N-Acylimidazoles(imidazolides, **1**) are widely used for organic synthesis[1] as acylating reagents because of their easy preparation and appropriate reactivity. Thus, imidazolides are readily prepared[2] from carboxylic acids under very mild conditions, and are utilized in a wide variety of synthetic processes, *e.g.*, amides[1,2] esters,[3] aldehydes,[4] ketones,[1] and C–C bond formations.[5] However, the instability of imidazolides on hydrolytic decomposition requires careful handling and delineates their appricatons. To remove this defect, other types of active amides are being developed.[6–8]

In the preceding paper[9] of this series, we described the synthesis and some properties of *N*-acyl and *N*-alkoxycarbonyl mesoionic triazolopyridines† (**2** and **3**). These compounds are readily synthesized from carboxylic acids or alcohols by using *N*-(chloroformyl)-triazolopyridines (**5** and **6**) under the very mild conditions. Preliminary study[9] revealed that the active amide of these types (**2** and **3**) was relatively stable toward hydrolytic decomposition but more active than corresponding imidazolide in the reaction with amines. These properties of the mesoionic azolide have indicated the potential of these compounds as acylating reagents. To examine the utility of the mesoionic azolides as acylating reagents, we have first applied them for a synthesis of amides. In this paper, we wish to describe the applications of these mesoionic azolides (**2** and **3**) for peptide synthesis including both of peptide-bond formation and introduction of urethane-type protecting groups to amine moieties of amino acids.



1 2 3 4 5 6

Fig. 1.

† Both classes of compounds are characterized by combination of *N*-acylazole(azolide)[1] with mosoionic ring. Hence, we wish to use a term "mesoionic azolide" for the compounds (**2** and **3**) in this paper.

Results and Discussion

The *N*-acyl mesoionic azolides (**2**) were applied for peptide-bond formation, and the urethane-type mesoionic azolides (**3**) were utilized for the introduction of amineprotecting groups.

Peptide-bond Formation. One of the major problem in peptide synthesis is racemization, which proceeds[10] *via* 5(4*H*)-oxazolone (**8**) formation at the activated carboxyl group of an *N*-acyl amino acid or acyl peptide (Scheme 1). To avoid this problem, the *N*-blocked amino acids (**9**) by urethane-type protecting groups, which suppress the oxazolone formation, are usually used for the coupling reactions of amino acids.

N^{α}-Benzyloxycarbonyl (Z) or N^{α}-(*t*-butoxycalbonyl) (Boc) amino acids reacted rapidly with **5** in the presence of one equimolor of tertiary amines in an aprotic solvent with evolution of gas. The reactions completed within 10 min at 4—25 °C, and the reaction mixture turned fluorescent yellow-green, indicating the formation of the mesoionic azolides (**2**). The products (**10**) were isolated easily by washing the reaction mixture with water, followed by removing the solvent *in vacuo*. However, in most cases, the reaction mixtures were used to the following coupling reactions without isolation of the mesoionic azolides. Reactions of the mesoionic azolides, such as **10**, with amino acid esters (**11**, R^3=alkyl) took place smoothly and generally completed within 1—3 h; in the case of sterically hindered amino acids, *e.g.*, isoleucine or valine, longer time (—15 h) was required to complete the reaction. According to the progress of the reaction, disappearance of the fluorescence of the reaction mixture and precipitation of the by-product (**4**) were found. These changes can be used to monitor the reaction. The by-product (**4**) is only slightly soluble in most of solvents. Therefore, it was almost separated by filtration, and the small amount of **4** remaining in the filtrate was completely removed by washing with 4% sodium hydrogencarbonate or 0.5 M copper(II) sulfate buffered with sodium citrate. Thus, desired dipeptide esters (**12**, R^3= alkyl) were isolated from the reaction mixture without any difficulties. The yields of the products were good.

When the mesoionic azolide (**10a**) was treated with sodium salts of amino acids (**11**, R^3=Na) in aqueous solution, dipeptides (**12**, R^3=H) were obtained in good yield. The yield of 93% for *N*-Z-glycylphenylalanine is obviously superior than those of other methods including imidazolide method; the yields of 55—66% were reported.[2,8,11] It seemed that this good yield could be ascribed to the stability of the mesoionic azolide toward hydrolytic decomposition. The conditions of the coupl-

TABLE 1. PREPARATION OF DIPEPTIDES. REACTION CONDITIONS AND YIELDS

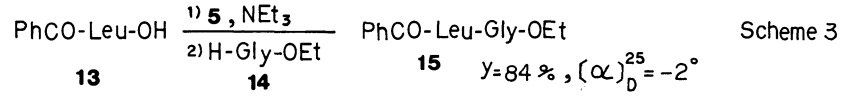

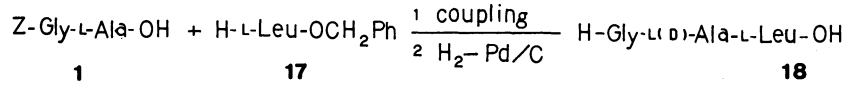

Fig. 3.

ing reaction and the yields of dipeptides are summarized in Table 1. The physical properties of the dipeptides are in agreement with those of the samples reported in literature.[2,24-26]

When *N*-benzoyl-L-leucine (**13**) was treated with **5**, instead of *N*-Boc or *N*-*Z* amino acid, relatively weak fluorescence of the reaction mixture and precipitation of **4** were found. These facts suggest the formation of oxazolone (**8**) instead of mesoionic azolide such as **10**. The following treatment of this reaction mixture with glycine ethyl ester (**14**) gave the dipeptide (**15**) with loss of optical activity. This peptide-bond formation seemed to proceed via oxazolone, which causes the racemization. To determine exact degree of the racemization in this method, Izumiya test[12] was achieved. The results are shown in Table 2. The racemization was minimized to 6.7% when the reaction was carried out in THF and in lower temperature (−20 °C). Further attempts to overcome the racemization were not achieved, since polypeptides are generally synthesized by stepwise condensation using an N^{α}-protected amino acid with a urethane-type protecting group, and practical methods[13,14] for fragment condensation now became available.

TABLE 2. IZUMIYA TEST

Run	Activation conditions			Tripeptide	
	Temp °C	Time min	Solvent	Yield %	Extent of racemization %
1	0	20	$CHCl_3$	90	16.3
2	−20	10	THF	97	6.7

Protection of Amino Function by Using the Mesoionic Azolide (3). Since benzyloxycarbonyl fragment was introduced as an amino-protecting group in peptide synthesis, a number of analogous groups with a variety of

the deblocking conditions have been utilized, *e.g.*, *t*-butoxycarbonyl (Boc),[15] *p*-methoxybenzyloxycarbonyl (PMZ),[15,16] *p*-nitrobenzyloxycarbonyl (PNZ),[17] benzhydryloxycarbonyl (Bhoc),[18] trichloroethoxycarbonyl (Troc),[19] and the others. Introduction of these blocking groups to amino acids has been done by using corresponding chloride or azide. However, the former procedure suffers from the instability of the reagents and the later cases have a fear of explosion in the synthesis of the reagent. To overcome these defects, some of reagents[20,21] have been developed in connection with the synthesis of *N*-Boc amino acid, which are most widely used for peptide synthesis.

Table 3. Urethane-type mesoionic azolides (3)

	R	Yield/%	Mp θ_m/°C
3a	*t*-Bu-	87	112—114
3b	$PhCH_2$-	90	140
3c	*p*-$MeOC_6H_4CH_2$-	82	127—130
3d	*p*-$NO_2C_6H_4CH_2$-	92	230
3e	Ph_2CH-	95	147—149
3f	Cl_3CCH_2-	88	140

The urethane-type mesoionic azolides (**3**) are obtained in good yield from a variety of alcohols by using **6**, or more conveniently by subsequent treatment of **4** with phosgene, pyridine and appropriate alcohols, (Fig. 4) and (Table 3). These mesoionic azolides were highly crystalline solids and could be stored in the air at room temperature for several months without any practical decomposition. It was found these reagents are applicable to the introduction of a variety of urethane-type *N*-protecting groups. Reactions of mesoionic *N*-Boc triazolopyridine (**3a**) with sodium salts of amino acids in aqueous acetone took place smoothly at room temperature, and generally completed in about 1—5 h, and the yields of the *N*-Boc amino acids were good (80—100%) (Table 4). The other urethane-type protecting groups were also easily introduced by using corresponding mesoionic azolide (**3**). For example mesoionic *N*-*Z*-triazolopyridine (**3b**) reacted with glycine sodium salt under the same conditions to give *N*-(benzyloxycarbonyl)glycine in 86% yield. In case of amino acid, like phenylglycine which has low solubility in aqueous solution, precipitation of the amino acid frequently occurred during the course of the eraction. This causes lowering the yields of the products. This problem was overcome by controlling the pH (10.2—10.5) of the reaction mixture or by exchanging the solvent from aqueous acetone to aqueous pyridine. Another problem in this procedure is the competitive conversion of the mesoionic azolide (**3**) into less reactive nonmesoionic N^2-acyl analogs.[9] However, this problem was overcome using excess of the reagent (1.2—2.0 molar equivalent). By using these conditions, several *N*-(alkoxycarbonyl)-

a) Each of amino acids (10 mmol) was dissolved in 10 ml of 1 M sodium hydroxide, then organic solvents were added. A: Acetone (10 ml)-pyridine (2 ml), B: no additive, C: dioxane (10 ml)-pyridine (2 ml).

phenylglycines (**22a**, **c**, **f**) were obtained in satisfactory yields. These results show that the mesoionic azolides (**3**) are useful reagents for the introduction of a variety of urethane-type protecting groups. These reactions of **3** with amino acids proceed in aqueous solution under mild conditions, and the yields of the *N*-protected amino acids are satisfactory. These good results are probably attributed to the feature of the mesoionic azolide. Thus, both of polar structure of the mesoionic ring and higher reactivity toward amines compared with water are favorable for reaction in aqueous solution. Alternative example of the highly selective reactivity of the mesoionic azolide were found in the following experiments. The reaction of **3e** with 2-aminoethanol (**23**) gave *N*-Boc-2-aminoethanol (**24**) in 96% yield (Scheme 8). More interesting result was obtained in the case of 2-aminoethanethiol (**25**). The reaction of **3d** with **25** gave *N*-protected product (**26**) in good yield (Scheme 9). It was reported[22] that **26** was hardly prepared by direct *N*-acylation of **25** since *N*- and *S*-acylations compete in the reaction.

As described above, *N*-Boc and *N*-*Z* amino acids were converted readily to the mesoionic azolide (**2**) under very mild conditions by using the reagent (**5**). Coupling reactions of these mesoionic azolides with amino acid esters or amino acid salts proceeded smoothly yielding dipeptides. The yields were satisfactory even in the reaction being conducted in aqueous solution. A variety of urethane-type mesoionic azolides were also utilized successfully for the specific introduction of urethane-type protecting groups to the amino moieties of several amines having another functional groups. Remarkable selective reactivity of these mesoionic azolides (**2** and **3**) toward amino moiety was found in the experiments described above. The results revealed the utility of these mesoionic azolides (**2** and **3**) as acylating reagents, and indicate possible use for the acylation of complicated molecules.

Experimental

Melting points were determined on a Yazawa hot-stage apparatus and were uncorrected. IR, UV, and NMR spectra were recorded on JASCO A102, Hitachi 200-20 and Varian EM 360L spectrometers respectively.

N-(Chloroformyl)triazolopyridines (**5** and **6**) were prepared in the manner previously reported.[9]

*1-[N-(Benzyloxycarbonyl)glycyl]-1,2,4-triazolo[4,3-a]pyridinium-3-olate (**10a**).* To a solution of *N*-(benzyloxycarbonyl)-glycine (6.27 g, 30 mmol) in chloroform (80 ml) were successively added triethylamine (4.20 ml, 30 mmol) and 5.91 g (30 mmol) of 2-chloroformyl-1,2,4-triazolo[4,3-*a*]pyridin-3(2*H*)-one (**5**). After the mixture had been stirred at room temperature for 1 h, the precipitate formed was collected by filtration to give 8.23 g (84%) of **10a**. The filtrate was washed twice with cold water, dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from chloroform–ether to give second crop of **10a** (328 mg, 3.3%); mp 173—176 °C. UV (THF) λ_{max}: 375 nm. IR (Nujol): 1720, 1695 cm^{-1} (C=O). Found: C, 58.65; H, 4.13; N, 17.05%. Calcd for $C_{16}H_{14}N_4O_4$: C, 58.89; H, 4.32; N, 17.17%.

*1-(N-Benzyloxycarbonyl-L-isoleucyl)-1,2,4-triazolo[4,3-a]pyridinium-3-olate (**10b**).* To a solution of *N*-benzyloxycarbonyl-L-isoleucine (7.96 g, 30 mmol) in chloroform (100 ml) was added triethylamine (4.2 ml, 30 mmol), and the mixture was cooled to 4 °C, then 5.91 g (30 mmol) of **5** was added. After having been stirred for 1 h, at room temperature, the reaction mixture was washed twice with cold water, dried over anhydro us sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from chloroform–ether giving pure **10b** (10.83 g, 95%); mp 165—170 °C. UV (THF) λ_{max}: 374 nm. Found: C, 62.92; H, 5.84; N, 14.65%. Calcd for $C_{20}H_{22}N_4O_4$: C, 62.81; H, 5.80; N, 14.65%.

*1-(N^a-Benzyloxycarbonyl-N^g-nitro-L-arginyl)-1,2,4-triazolo[4,3-a]pyridinium-3-olate (**10c**).* A solution of N^a-benzyloxycarbonyl-N^g-nitro-L-arginine (7.06 g, 20 mmol) and triethylamine (2.80 ml, 20 mmol) in dichloromethane (30 ml) was added dropwise into a suspension of **5** (4.00 g, 20 mmol) in dichloromethane (50 ml) at a temperature between 4 °C to 7 °C with stirring. The mixture was stirred for 1 h at 4 °C, then allowed to stand at room temperature for 2 h. The crystalline precipitate was collected by filtration, washed with chloroform, dried *in vacuo* to give **10c** (8.08 g, 85.5%). The filtrate and the washing were combined, washed twice with cold water, dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from chloroform–ether to give second crop of **10c** (1.381 g, 14.5%); mp 120 °C. UV (CH_2Cl_2) λ_{max}: 378 nm. Found: C, 49.24; H, 4.96; N, 22.68%. Calcd for $C_{20}H_{22}N_8O_6 \cdot H_2O$: C, 49.16; H, 4.95; N, 22.95%.

*Reaction of **10b** with H–Gly–OEt.* To a solution of glycine ethyl ester (356 mg, 3.15 mmol) in chloroform (10 ml) was added **10b** (1.15 g, 3 mmol), and the mixture was stirred at room temperature for 3 h. The reaction mixture was filtered to remove the by-product (**4**), and the filtrate was washed successively with 2% hydrochloric acid, water, 4% sodium hydrogencarbonate, and water, then dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from methanol to give *N*-benzyloxycarbonyl-L-isoleucylglycine ethyl ester (1.01 g, 96%); mp 155—156 °C; $[\alpha]_D^{25}$ −27° (c 0.9, CH_3OH). Lit[24] mp 155 °C; $[\alpha]_D$ −26° (*c* 1, CH_3OH). Found: C, 61.67; H, 7.63; N, 8.26%. Calcd for $C_{18}H_{26}N_2O_5$: C, 61.70; H, 7.48; N, 7.99%.

*Reaction of **10b** with H-L-Leu-OEt.* Triethylamine (0.70 ml, 5 mmol) was added to a solution of leucine ethyl ester hydrochloride (1.00 g, 5 mmol) in chloroform (10 ml), then **10b** (1.91 g, 5 mmol) was added. After having been stirred at room temperature for 15 h, the reaction mixture was worked up in the same manner as described in the preceding experiment. Crystallization from ether gave *N*-benzyloxycarbonyl-L-isoleucyl-L-leucine ethyl ester (1.433 g, 71%); mp 116—117 °C; $[\alpha]_D^{25}$ −43.5° (*c* 0.8, CH_3OH). Found: C, 64.69; H, 8.44; N, 6.72%. Calcd for $C_{22}H_{34}N_2O_5$: C, 64.99; H, 8.43; N, 6.89%.

*Reaction of **10c** with H-L-Pro-OBzl.* To a suspension of L-proline benzyl ester hydrochloride (2.64 g, 11 mmol) in chloroform (20 ml) was added triethylamine (1.54 ml, 11 mmol), and the mixture was stirred for 10 min, then **10c** (4.88 g, 10 mmol) was added. After having been stirred at room temperature for 2 h, the reaction mixture was worked up in the same manner as described in the preceding experiment. Crystallization from ethanol–ether gave N^a-benzyloxycarbonyl-N^g-nitro-L-arginyl-L-proline benzyl ester (4.33 g, 82%); mp 145—146 °C; $[\alpha]_D^{22}$ −59° (*c* 1, CH_3OH). Lit,[25] $[\alpha]_D$ −61° (*c* 1.1, CH_3OH). Found: C, 57.49; H, 6.09; N, 15.46%. Calcd for $C_{26}H_{32}N_6O_7$: C, 57.77; H, 5.97; N, 15.55%.

*Coupling of Z-L-pyro-Glu-OH with H-L-His-OBzl by Use of **5**.* To a solution of *N*-benzyloxycarbonyl-L-pyroglutamic acid (526 mg, 2 mmol) in chloroform (10 ml) were added triethylamine (0.28 ml, 2 mmol) and **5** (396 mg, 2 mmol), and the

mixture was stirred at room temperature for 30 min, then L-histidine benzyl ester (490 mg, 2 mmol) was added. After having been stirred at room temperature for 2 h, the reaction mixture was filtered to remove the by-product (**4**). The filtrate was washed successively with water, 2% hydrochloric acid, 4% sodium hydrogencarbonate and water, then dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from ethyl acetate to give *N*-benzyloxycarbonyl-L-pyroglutamyl-L-histidine benzyl ester (852 mg, 87%); mp 125—126 °C; $[\alpha]_D^{22}$ −40° (*c* 1.2, CH_3OH). Found: C, 63.40; H, 5.33; N, 11.33%. Calcd for $C_{19}H_{22}N_4O_5$: C, 63.68; H, 5.34; N, 11.42%.

Coupling of Boc-L-Pro-OH with H-Gly-OEt by Use of ***5***. To a stirred solution of Boc-L-proline (5.37 g, 25 mmol) in chloroform (50 ml) were added successively *N*-methylmorpholine (2.74 ml, 25 mmol) and **5** (4.95 g, 25 mmol) at a temperature below 10 °C, and the mixture was stirred at room temperature for 40 min, then glycine ethyl ester (2.83 g, 27.5 mmol) was added. After having been stirred at room temperature for 30 min, the reaction mixture was filtered to remove the by-product (**4**). The filtrate was washed successively with water, 0.5 M citric acid, water, 4% sodium hydrogencarbonate and water, then dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The oily residue was chromatographically pure *N*-Boc-L-prolylglycine ethyl ester (7.43 g, 99%). Found: C, 56.23; H, 8.22; N, 9.15%. Calcd for $C_{14}H_{24}N_2O_5$: C, 55.97; H, 8.05; N, 9.32%.

Reaction of ***10a*** *with H-Ala-OH.* To a solution of L-alanine (1.60 g, 18 mmol) in a mixture of 1 M sodium hydroxide (18 ml) and acetone (18 ml) was added **10a** (4.89 g, 15 mmol) at 4 °C. The mixture was stirred at 4 °C for 3 h, evaporated *in vacuo* to remove the acetone, and filtered to remove by-product. The filtrate was washed with ethyl acetate, acidified by adding 1 M hydrochloric acid, and extracted with ethyl acetate (×2). The ethyl acetate solution was washed successively with a 1 : 1 mixture of 0.5 M copper(II) sulfate and 1/6 M sodium citrate, and with water, dried over anhydrous sodium sulfate, and concentrated *in vacuo* giving a crystalline product. The product was collected by filtration, washed with small amount of ethyl acetate, and dried. *N*-(Benzyloxycarbonyl)glycyl-L-alanine (3.864 g, 91%) was obtained: mp 117 °C; $[\alpha]_D^{22}$ −9.7° (*c* 3, C_2H_5OH). Lit,[26]: mp 119.5 °C; $[\alpha]_D$ −9.8° (*c* 2.8, C_2H_5OH). found: C, 55.98; H, 5.60; N, 9.97%. Calcd for $C_{13}H_{16}N_2O_5$: C, 55.68; H, 5.75; N, 9.99%.

Reaction of ***10a*** *with H-L-Phe-OH.* To a solution of L-phenylalanine (2.48 g, 15 mmol) in a mixture of 1 M sodium hydroxide (15 ml) and acetone (15 ml) was added **10a** (4.89 g, 10 mmol). The mixture was stirred at room temperature for 30 min, then allowed to stand overnight in a refrigerator. The crystalline by-product (**4**) was removed by filtration. Sodium hydrogencarbonate (4%, 10 ml) was added to the filtrate. The mixture was washed with ethyl acetate, acidified by adding 1 M hydrochloric acid (17 ml), and then extracted with ethyl acetate. The ethyl acetate extract was washed with 1 : 1 mixture of 0.5 M copper(II) sulfate and 1/6 M sodium citrate, and with water, then dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from ether to give *N*-(benzyloxycarbonyl)glycyl-L-phenylalanine (5.02 g, 93%): mp 124—125.5 °C; $[\alpha]_D^{22}$ +40° (*c* 1, C_2H_5OH). Lit,[2]: mp 126.5 °C; $[\alpha]_D$ +40° (C_2H_5OH). Found: C, 64.11; H, 5.55; N, 7.96%. Calcd for $C_{19}H_{20}N_2O_5$: C, 64.03; H, 5.66; N, 7.86%.

Coupling of Bz-Leu-OH with H-Gly-OEt by Use of ***5***. A solution of *N*-benzoyl-L-leucine (1.175 g, 5 mmol) and triethylamine (1.40 g, 5 mmol) in chloroform (5 ml) was added dropwise with stirring into a suspension of **5** (1.0 g, 5 mmol) in chloroform at −15 °C. Gas evolution, followed by precipitation of insoluble material was found. The mixture was stirred at −10 °C for 1 h, and glycine ethyl ester (515 mg, 5 mmol) was added. After having been stirred at −10 °C for 30 min, then at 4 °C for 3 h, the reaction mixture was filtered. The filtrate was washed with water, dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from ether to give *N*-(benzoyl) leucylglycine ethyl ester (1.342 g, 84%); mp 144—147 °C; $[\alpha]_D^{22}$ −2° (*c* 1, C_2H_5OH): the value of $[\alpha]_D^{20}$ −34.0° (*c* 3.1, C_2H_5OH) was reported[10] for *N*-benzoyl-L-leucylglycine ethyl ester. Found: C, 63.88; H, 7.41; N, 9.03%. Calcd for $C_{17}H_{24}N_2O_4$: C, 63.73; H, 7.55; N, 8.75%.

Izumiya Test. Z-Gly-L-Ala-OH and authentic samples of H-Gly-L-Ala-L-Leu-OH and H-Gly-D-Ala-L-Leu-OH were prepared by the methods in the literature.[12] The dipeptide (Z-Gly-L-Ala-OH) was treated with **5** under the condotions summarized in Table 2, and then allowed to react with L-leucine benzyl ester at room temperature overnight to give tripeptide. After hydrogenation to remove the protecting group, the tripeptide (**18**) were analyzed according to the procedure in the literature.[12]

General Procedure for Synthesis of the Urethane-type Mesoionic Azolide (3). *Synthesis of* ***3a***: Finely powdered 1,2,4-triazolo[4,3-*a*]pyridin-3(2*H*)-one[23] (40.5 g, 0.3 mol) was suspended in ethanol-free chloroform (1.2 l) prepared by passing through an alumina column, and a solution of phosgene (33 g, 0.33 mol) in THF (150 ml) was added with stirring at a temperature below 10 °C. The mixture was stirred at 4 °C for 45 min, pyridine (53.5 ml, 0.66 mol) was added. After the mixture had been stirred for 30 min at 4 °C, *t*-butyl alcohol (50 ml) was added, and resultant mixture was stirred at room temperature for 40 min. The reaction mixture was washed with cold water (×3), dried over anhydrous sodium sulfate, and concentrated *in vacuo* giving crystalline product, and ether was added slowly to complete the crystallization. The product (**3a**) was collected by filtration, washed with ether, and dried *in vacuo*. Yield; 77.0 g (87% as a one-half molar chloroform adduct). UV (CH_2Cl_2) λ_{max}: 363 nm. IR (Nujol): 1757, 1722 cm^{-1} (C=O). Found: C, 46.75; H, 4.52; N, 14.52%. Calcd for $C_{11}H_{13}N_3O_3 \cdot 1/2\ CHCl_3$: C, 46.82; H, 4.61; N, 14.25%.

Other mesoionic azolides (**3**) were prepared in the same manner by using appropriate alcohols instead of *t*-butyl alcohol. In some cases, the products were crystallized off from the reaction mixture during the course of the reaction, hence they could be collected by filtration. Result was summarized in Table 3. The physical data of **3** were as follows:

a) **3b**; mp 140 °C, Physical properties of this compound were identical to those of authentic samples.[9]

b) **3c**; mp 127—130 °C. UV (CH_2Cl_2) λ_{max} 363 nm. NMR ($CDCl_3$–CD_3OD); δ=8.53 (m, 1, H-5), 8.5—7.9 (m, 2, H-7 and H-8), 7.45 (m, 1, H-6), 7.42 (d, J=9 Hz, 2, aromatic H), 6.88 (d, J=9 Hz, 2, aromatic H), 5.42 (s, 2, $PhC\underline{H}_2$), 3.81 (s, 3, OCH_3). Found: C, 59.93; H, 4.54; N, 14.31%. Calcd for $C_{15}H_{13}N_3O_4$: C, 60.20; H, 4.38; N, 14.04%.

c) **3d**; mp 230 °C (decomp). UV (CH_2Cl_2) λ_{max} 363 nm. Found: C, 56.65; H, 3.01; N, 16.38%. Calcd for $C_{16}H_{10}N_4O_5$: C, 56.80; H, 2.98; N, 16.56%.

d) **3e**; mp 147—149 °C. UV (CH_2Cl_2)λ_{max} 263, 363 nm. Found: C, 68.59; H, 4.56; N, 12.23%. Calcd for $C_{20}H_{15}N_3O_3$ 1/4 H_2O: C, 68.65; H, 4.46; N, 12.01%.

e) **3f**; mp 140 °C. UV (CH_2Cl_2) λ_{max} 364 nm. NMR ($CDCl_3$–CD_3OD); δ=8.67 (m, 1, H-5), 8.6—8.1 (m, 2, H-7 and H-8), 7.61 (m, 1, H-6), 5.18 (s, 2, $Cl_3CC\underline{H}_2$). Found: C, 35.03; H, 1.99; N, 13.66; Cl, 34.13%. Calcd for $C_9H_6N_3$-

O_3Cl_3: C, 34.82; H, 1.95; N, 13.53; Cl, 34.25%.

General Procedure of Synthesis of N-*Boc Amino Acids.* *a) A Typical Procedure*: To a solution of L-tryptophan (2.04 g, 10 mmol) in a mixture of 1 M sodium hydroxide (10 ml), acetone (10 ml) and pyridine (2 ml), **3a** (4.14 g, 14 mmol as 1/2 $CHCl_3$ adduct) was added, and the mixture was stirred at room temperature for 3 h then evaporated *in vacuo* to remove the acetone, and the residual aqueous solution was allowed to stand overnight in a refrigerator. Crystalline by-product (**4**) was removed by filtration, and the filtrate was acidified with 0.5 M citric acid to pH 3, then extracted with ethyl acetate. The ethyl acetate solution was washed with a 1 : 1 mixture of 0.5 M copper(II) sulfate and 1/6 M sodium citrate, and with water, then dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from ethyl acetate–hexane to give *N*-Boc-L-tryptophan (2.74 g, 90%); mp 137—139 °C. Found: C, 62.97; H, 6.40; N, 9.35%. Calcd for $C_{16}H_{20}N_2O_4$: C, 63.14; H, 6.62; N, 9.20%. Other *N*-Boc amino acids were synthesized in the almost same manner, under the conditions summarized in Table 4; *N*-Boc-glutamic acid was extracted with 1-butanol instead of ethyl acetate.

b) By pH Control: To a solution of D-phenylglycine (3.03 g, 20 mmol) in a mixture of 1 M sodium hydroxide (20 ml) and acetone (20 ml) was added **3a** (11.80 g, 40 mmol as 1/2 $CHCl_3$ adduct), and the mixture was stirred at room temperature for 30 min. pH of the reaction mixture was kept around 10.5 by adding 2 M sodium hydroxide. The reaction mixture was stirred for additional 1.5 h without the pH control, and then evaporated *in vacuo* to remove the acetone. The resultant aqueous solution was allowed to stand for 1 h in a refrigerator, then filtered to remove the by-product (**4**). The filtrate was worked up in the same manner as described in preceding experiment. Crystallization from hexane gave *N*-Boc-D-phenylglycine (4.21 g, 84%); mp 86—88 °C; lit,[21] 87—89.5 °C. $[\alpha]_D^{22}$ −148° (*c* 1, C_2H_5OH); lit,[23] $[\alpha]_D$ +150° (*c* 1, C_2H_5OH) for *N*-Boc-L-phenylglycine.

N-*(p-Methoxybenzyloxycarbonyl)-D-phenylglycine.* D-Phenylglycine (3.03 g, 20 mmol) was treated with **3c** (8.95 g, 30 mmol) in the same manner as described before in the preparation of *N*-Boc-D-phenylglycine. Crystallization of the crude product from ethyl acetate–hexane gave desired product (5.16 g, 82%); mp 130—132 °C; $[\alpha]_D^{22}$ −102° (*c* 1, CH_3OH). NMR (DMSO-d_6–$CDCl_3$); δ=7.92 (d, J=8 Hz, 1, NH), 7.34 (s, 5, C_6H_5), 7.25 (d, J=9 Hz, 2, aromatic H), 6.84 (d, J=9 Hz, 2, aromatic H), 5.13 (d, J=8 Hz, 1, PhC<u>H</u>), 4.94 (s, 2, PhC<u>H</u>$_2$), 3.72 (s, 3, OCH_3). Found: C, 43.22; H, 8.91; N, 7.23%. Calcd for $C_{17}H_{17}NO_5$: C, 43.06; H, 8.78; N, 7.18%.

N-*(Benzyloxycarbonyl)glycine.* To a solution of glycine (375 mg, 5 mmol) in 1 M sodium hydroxide (5 ml) was added **3b** (1.48 g, 5.5 mmol), and the mixture was stirred at room temperature for 1 h and then allowed to stand for 3 h in a refrigerator. The reaction solution was filtered to remove the by-product (**4**). The filtrate was washed twice with ethyl acetate, acidified by adding 1 M hydrochloric acid (6 ml) and extracted with ethyl acetate. The ethyl acetate solution was washed twice water, dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was extracted with ether, and the extract was evaporated *in vacuo*. The residue was crystallized from ether–petroleum ether to give desired compound (898 mg, 86%); mp 120—121 °C. Found: C, 57.25; H, 5.34; N, 6.75%. Calcd for $C_{10}H_{11}NO_4$: C, 57.40; H, 5.30; N, 6.70%.

N-*Trichloroethoxycarbonyl-D-phenylglycine (22f).* To a solution of D-phenylglycine (1.51 g, 10 mmol) in a mixture of 1 M sodium hydroxide (10 ml), acetone (10 ml) and pyridine (2 ml) was added **3f** (3.5 g, 11 mmol), and the mixture was stirred at 4 °C for 2 h, then evaporated *in vacuo* to remove the acetone. The residual aqueous solution was allowed to stand overnight in a refrigerator, and then filtered to remove the by-product. The filtrate was washed with ethyl acetate, acidified with 1 M hydrochloric acid to pH 2.5, and extracted with ethyl acetate. The ethyl acetate solution was washed with a 1 : 1 mixture of 0.5 M copper(II) sulfate and 1/6 M sodium citrate, and with water, then dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was crystallized from ether–petroleum ether to give desired product (3.10 g, 93%); mp 140—141.5 °C; $[\alpha]_D^{22}$ −105° (*c* 1.2, CH_3OH). Lit[21]: mp 141—143 °C. Found: C, 40.43; H, 3.15; N, 4.36; Cl, 31.91%. Calcd for $C_{11}H_{10}NO_4Cl_3$: C, 40.45; H, 3.09; N, 4.29; Cl; 32.56%.

Reaction of 3e with 2-Aminoethanol. To a solution of 2-aminoethanol (1.22 g, 20 mmol) in dichloromethane (30 ml) was added **3e** (6.0 g, 17.4 mmol), and the mixture was stirred at room temperature for 20 min, then filtered to remove the by-product (**4**). The filtrate was washed successively with 0.5 M citric acid, water, 5% sodium hydrogencarbonate, and water, then dried over anhydrous sodium sulfate, and concentrated giving crystalline product which was collected by filtration. 4.50 g (95.6%) of 2-(benzhydryloxycarbonylamino)ethanol was collected; mp 66—67 °C. NMR ($CDCl_3$); δ=7.36 (s, 10, C_6H_5), 6.84 (s, 1, $Ph_2C\underline{H}$), 5.68 (t, J=5 Hz, 1, NH), 3.5—3.0 (m, 5, CH_2 and OH). Found: C, 71.25; H, 6.36; N, 5.25%. Calcd for $C_{16}H_{17}NO_3$: C, 70.83; H, 6.32; N, 5.16%.

Reaction of 3d with 2-Aminoethanethiol. To a suspension of 2-aminoethanethiol hydrochloride (1.25 g, 11 mmol) in dichloromethane was added triethylamine (1.4 ml, 10 mmol), and the mixture was stirred at room temperature for 30 min under nitrogen atmosphere, then **3d** (3.14 g, 10 mmol) was added. After having been stirred at room temperature for 30 min, the reaction mixture was filtered, and the filtrate was washed successively with water, 0.5 M citric acid, water, 4% sodium hydrogencarbonate and water. The chloroform solution was dried over anhydrous sodium sulfate, and evaporated *in vacuo* to give a solid, which was washed with diisopropyl ether to give 2-(*p*-nitrobenzyloxycarbonylamino)ethanethiol (1.950 g, 81%); mp 66—68 °C. NMR ($CDCl_3$); δ=8.14 (d, J=8.5 Hz, 2, aromatic H), 7.47 (d, J=8.5 Hz, 2, aromatic H), 5.61 (broad-s, 1, NH), 5.19 (s, 2, PhC<u>H</u>$_2$), 3.46 (t, J=7 Hz, 2, NC<u>H</u>$_2$), 2.68 (m, 2, SC<u>H</u>$_2$), 1.44 (t, J=8 Hz, 1, SH).

Revision of Structure of Anhydronellionol Triacetate

Takashi MATSUMOTO,* Sachihiko IMAI, Masanori MITSUKI, and Seiji MAETA
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730
(Received January 27, 1983)

The structure of anhydronellionol triacetate was revised to 11,12,16-triacetoxy-6-hydroxyabieta-5,8,11,13-tetraen-7-one (**18**) by the following syntheses. Acetylation of 16-acetoxyabieta-8,11,13-trien-12-ol, followed by oxidation with chromium trioxide, afforded 12,16-diacetoxyabieta-8,11,13-trien-7-one. This was converted into 6,12,16-triacetoxyabieta-5,8,11,13-tetraen-7-one (**17**) *via* 12,16-diacetoxyabieta-8,11,13-trien-6-one. Oxidation of 11,12,16-triacetoxyabieta-8,11,13-trien-6-one with Jones reagent gave **18**, whose ^{1}H NMR spectrum was in good agreement with that of natural anhydronellionol triacetate. 11,12,16-Triacetoxyabieta-5,8,11,13-tetraen-7-one (**28**) was also synthesized from 11,12,16-triacetoxyabieta-8,11,13-trien-7-one. The ^{1}H NMR spectra of **17** and **28** were different from that of natural anhydronellionol triacetate. Since the revised structure **18** corresponds to dehydronellionol triacetate, the name of anhydronellionol should now be dropped from the list of natural diterpenes.

Recently three tricyclic aromatic diterpenes, nellionol, dehydronellionol, and anhydronellionol, have been isolated from the root bark of *Premna latifolia* Roxb. by Rao *et al.*[1] On the basis of chemical and spectroscopic studies, they deduced the structures of nellionol, dehydronellionol, and anhydronellionol to be 6α,11,14,16-tetrahydroxyabieta-8,11,13-trien-7-one (**1**), 6,11,14,16-tetrahydroxyabieta-5,8,11,13-tetraen-7-one (**2**), and 11,14,16-trihydroxyabieta-5,8,11,13-tetraen-7-one (**3**), respectively. The isolation of several abietane type diterpenes possessing two oxygen functions in the C-ring have already been reported. In these natural products oxygen functions are usually present at the C-11 and C-12 positions such as cryptojaponol (**4**),[2] fuerstione (**5**),[3] taxodione (**6**),[4] and carnosolone (**7**).[5] However, the proposed structures (**1**, **2**, and **3**) are unique because they possess two oxygen functions at the C-11 and C-14 positions and no oxygen function at the C-12 position. In the previous paper[6] we have reported the revised structures of nellionol and dehydronellionol to be respectively 6α,11,12,16-tetrahydroxyabieta-8,11,13-trien-7-one (**8**) and 6,11,12,16-tetrahydroxyabieta-5,8,11,13-tetraen-7-one (**9**); these possess two oxygen functions in the C-ring at the C-11 and C-12 positions. As an extension of the previous work,[6] we have now examined the published spectral data[1] of natural anhydronellionol triacetate to confirm the validity of the proposed structure **3**. The ^{1}H NMR spectrum of anhydronellionol triacetate showed singlet signals at δ 7.11 and 8.16 which were assigned respectively to the C-6 olefinic proton and the C-12 aromatic proton in the proposed structure (**10**). However, the chemical shift (δ 8.16) of the aromatic proton is different from those (δ 7.04 and 7.09) of the C-12 aromatic protons in methyl 11,14-diacetoxy-7-oxoabieta-8,11,13-trien-18-oate (**11**)[6] and 11,14-diacetoxy-13-(acetoxymethyl) podocarpa-8,11,13-trien-7-one (**12**),[7] but very similar to those (δ 8.15, 8.13, and 8.23) of the C-14 aromatic protons in methyl 11,12-diacetoxy-7-oxoabieta-5,8,11,13-tetraen-20-oate (**13**),[8] 12-acetoxyabieta-5,8,11,13-tetraen-7-one (**14**),[9] and carnosolone diacetate (**15**).[5] These spectral data strongly suggested that the aromatic proton in anhydronellionol triacetate is located at the C-14 position ortho to a carbonyl group. Furthermore the assignment of the signal at δ 7.11 to the C-6 olefinic proton was also unusual, because the olefinic protons in the same moiety of **13** and **14** were observed as singlets at δ 6.57 and 6.50 respectively. On the other hand, the ^{1}H NMR spectrum of **14** showed a singlet signal at δ 7.20 due to the C-11 aromatic proton and that of 6-hydroxyabieta-5,8,11,13-tetraen-7-one (**16**)[10] showed a singlet signal due to an enolic hydroxyl group at δ 7.08. From these spectral analyses, together with consideration of the other spectral data, we deduced a preferable structure of anhydronellionol triacetate to be 6,12,16-triacetoxyabieta-5,8,11,13-tetraen-7-one (**17**) or 11,12,16-triacetoxy-6-hydroxyabieta-5,8,11,13-tetraen-7-one (**18**). To obtain final confirmation of the structure of anhydronellionol triacetate, syntheses of **17** and **18** have been attempted.

Acetylation of 16-acetoxyabieta-8,11,13-trien-12-ol (**19**)[6,11] with acetic anhydride in pyridine, followed by oxidation of the resulting acetate (**20**: 91%) with chromium trioxide in acetic acid at room temperature, afforded 12,16-diacetoxyabieta-8,11,13-trien-7-one (**21**:

65%). The ketone **21** was reduced with sodium borohydride in methanol and the resulting mixture of epimeric 7-hydroxy compounds was immediately subjected to dehydration with dilute hydrochloric acid in refluxing methanol. Under these conditions, the acetoxyl groups were hydrolyzed. Therefore, the crude product was acetylated with acetic anhydride in pyridine to give 12,16-diacetoxyabieta-6,8,11,13-tetraene (**22**). This was treated with *m*-chloroperbenzoic acid in dichloromethane at room temperature. The resulting crude epoxide (**23**) was refluxed with dilute hydrochloric acid in methanol and then acetylated[12] with acetic anhydride in pyridine to afford 12,16-diacetoxyabieta-8,11,13-trien-6-one (**24**: 48% from **21**). The structure of **24** was supported by its ^{1}H NMR spectrum which showed singlet signals at δ 2.39 (1H) due to the $C_{5\alpha}$ proton and at δ 3.61 (2H) due to the C-7 methylene protons. Oxidation of **24** with Jones reagent at room temperature, followed by treatment with anhydrous sodium acetate in refluxing acetic anhydride, afforded the desired **17** (55%). The ^{1}H NMR spectrum of synthetic **17** showed singlet signals due to three acetoxyl groups at δ 2.01 (3H) and 2.36 (6H), and due to two aromatic protons at δ 7.21 (1H) and 8.08 (1H). However, the spectrum of **17** was different from that of natural anhydronellionol triacetate.

Subsequently, 11,12,16-triacetoxyabieta-8,11,13-trien-6-one (**25**)[6,11] was oxidized with Jones reagent and the resulting crude product purified by column chromatography on silica gel to give the desired **18** (49%). The ^{1}H NMR spectrum of synthetic **18** showed singlet signals due to three acetoxyl groups at δ 2.01 (3H), 2.32 (3H), and 2.35 (3H), due to an enolic hydroxyl group at δ 7.05 (1H), and due to an aromatic proton at δ 8.15 (1H). The spectrum of **18** was in good agreement with that of natural anhydronellionol triacetate.

For comparison, 11,12,16-triacetoxyabieta-5,8,11,13-tetraen-7-one (**28**) was also synthesized as follows. Bromination of 11,12,16-triacetoxyabieta-8,11,13-trien-7-one (**26**)[6,11] with pyridinium tribromide in a mixture of chloroform and ethanol (2 : 1) at room temperature produced 11,12,16-triacetoxy-6β-bromoabieta-8,11,13-trien-7-one (**27**). The β-configuration of the bromine atom in **27** was supported by its ^{1}H NMR spectrum, which showed a signal due to the C-10 methyl group in low field (δ 1.75), owing to the 1,3-diaxial interaction between the bromine atom and the C-10 methyl group. Dehydrobromination of the crude bromide **27** with 1,5 diazabicyclo[4.3.0]non-5-ene in refluxing benzene, followed by acetylation,[12] afforded **28** (37% from **26**). The ^{1}H NMR spectrum of **28** showed signals due to the C-6 olefinic proton at δ 6.53 (1H) and due to an aromatic proton at δ 8.13 (1H), which were different from those of natural anhydronellionol triacetate.

From the present study, the proposed structure[1] of natural anhydronellionol triacetate must be revised to **18**, which corresponds to dehydronellionol 11,12,16-triacetate.[6] Therefore, the name of anhydronellionol should now be dropped from the list of natural diterpenes.

Experimental

The IR spectra were measured in chloroform, and the ^{1}H NMR spectra in deuterochloroform at 60 MHz, with tetramethylsilane as an internal standard, unless otherwise stated. The chemical shifts are reported in terms of δ values; s: singlet, d: doublet, bd: broad doublet, m: multiplet. Column chromatography was performed using Merck silica gel.

*12,16-Diacetoxyabieta-8,11,13-triene (**20**).* A solution of

16-acetoxyabieta-8,11,13-trien-12-ol (**19**)[6,11] (678 mg) and acetic anhydride (1.5 ml) in pyridine (2.0 ml) was heated at 75—85 °C for 2 h. After the usual work-up, the crude product was chromatographed on silica gel (20 g), using ether–benzene (3 : 97) as the eluent, to give **20** (690 mg: 91%). IR: 1750, 1730 cm^{-1}; ^1H NMR (CCl_4): δ=0.95 (6H, s, $-C(CH_3)_2$), 1.18 (3H, d, J=7 Hz, C_{15}–CH_3), 1.19 (3H, s, C_{10}–CH_3), 1.95 (3H, s, C_{16}–$OCOCH_3$), 2.24 (3H, s, C_{12}–$OCOCH_3$), 3.97 (d, J=7 Hz) and 4.01 (d, J=7 Hz) (2H, $-CH_2OCOCH_3$), 6.78 (1H, s) and 6.85 (1H, s) (C_{11}–H and C_{14}–H).

*12,16-Diacetoxyabieta-8,11,13-trien-7-one (**21**).* Anhydrous chromium trioxide (416 mg) was added to a solution of **20** (913 mg) in acetic acid (10 ml) with cooling in an ice–water bath. The mixture was stirred at this temperature for 15 min and then at room temperature for 22 h. The mixture was diluted with water and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (40 g), using ether–benzene (4 : 96) as the eluent, to give the starting **20** (103 mg: 11%). Further elution with ether–benzene (7 : 93) gave **21** (615 mg: 65%). IR: 1750, 1730, 1673, 1607 cm^{-1}; ^1H NMR: δ=0.95 (3H, s) and 1.02 (3H, s) ($-C(CH_3)_2$), 1.26 (3H, d, J=7 Hz, C_{15}–CH_3), 1.27 (3H, s, C_{10}–CH_3), 2.04 (3H, s, C_{16}–$OCOCH_3$), 2.38 (3H, s, C_{12}–$OCOCH_3$), 4.13 (2H, d, J=7 Hz, $-CH_2OCOCH_3$), 7.07 (1H, s, C_{11}–H), 8.03 (1H, s, C_{14}–H).

*12,16-Diacetoxyabieta-8,11,13-trien-6-one (**24**).* A mixture of **21** (767 mg) and sodium borohydride (150 mg) in methanol (10 ml) was stirred at 0—5 °C for 30 min and then at room temperature for 1 h. The mixture was acidified with dilute hydrochloric acid (10%: 2.0 ml), refluxed for 1 h, and evaporated *in vacuo*. The residue was extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residual oil was acetylated with acetic anhydride (2.0 ml) in pyridine (2.0 ml) at 75—85 °C for 2 h to give the crude 12,16-diacetoxyabieta-6,8,11,13-tetraene (**22**) (743 mg) which was used without purification in the next reaction.

A mixture of the crude tetraene **22** (743 mg) and *m*-chloroperbenzoic acid (590 mg) in dichloromethane (10 ml) was stirred at 0—5 °C for 1 h and then at room temperature for 14 h. The mixture was diluted with ether and washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The ether solution was dried over sodium sulfate and evaporated *in vacuo* to give a crude epoxide (**23**) (871 mg) which was used without purification in the next reaction.

A mixture of the crude epoxide **23** (871 mg) and dilute hydrochloric acid (10%: 2.0 ml) in methanol (10 ml) was refluxed for 1 h. The mixture was evaporated *in vacuo*, diluted with water, and extracted with ether. The ether extract was washed with water, dried over sodium sulfate, and evaporated *in vacuo* to give an oil (784 mg). This was acetylated with acetic anhydride (2.0 ml) in pyridine (2.0 ml) at 75—85 °C for 2 h. After the usual work-up, the crude product was purified by column chromatography on silica gel (40 g), using ether–benzene (3 : 97) as the eluent, to give **24** (368 mg: 48% from **21**). IR: 1750sh, 1732, 1710 cm^{-1}; ^1H NMR: δ=1.09 (3H, s), 1.18 (3H, s), and 1.34 (3H, s) ($-C(CH_3)_2$ and C_{10}–CH_3), 1.23 (3H, d, J=7 Hz, C_{15}–CH_3), 2.05 (3H, s, C_{16}–$OCOCH_3$), 2.36 (3H, s, C_{12}–$OCOCH_3$), 2.39 (1H, s, $C_{5\alpha}$–H), 3.61 (2H, s, $-COCH_2-$), 4.12 (2H, d, J=7 Hz, $-CH_2OCOCH_3$), 7.01 (2H, s, C_{11}–H and C_{14}–H).

*6,12,16-Triacetoxyabieta-5,8,11,13-tetraen-7-one (**17**).* A solution of **24** (368 mg) in acetone (8.0 ml) was oxidized with Jones reagent [2.5 M (1 M=1 mol dm^{-3}): 1.2 ml] at 0—5 °C for 10 min and then at room temperature for 2.5 h. The mixture was diluted with water and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give a crude 6,7-dioxo compound. This was immediately refluxed with acetic anhydride (15 ml) in the presence of anhydrous sodium acetate (900 mg) for 2.5 h with stirring. The mixture was diluted with water and benzene, evaporated *in vacuo* to remove the excess acetic anhydride, and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (20 g), using ether–benzene (5 : 95) as the eluent, to give **17** (229 mg: 55%). IR: 1760, 1735sh, 1660, 1615 cm^{-1}; ^1H NMR (90 MHz): δ=1.27 (d, J=7 Hz) and 1.30 (d, J=7 Hz) (3H, C_{15}–CH_3), 1.33 (3H, s) and 1.40 (3H, s) ($-C(CH_3)_2$), 1.59 (3H, s, C_{10}–CH_3), 2.01 (3H, s, C_{16}–$OCOCH_3$), 2.36 (6H, s, C_6 –$OCOCH_3$ and C_{12}–$OCOCH_3$), 4.04—4.18 (2H, m, $-CH_2-OCOCH_3$), 7.21 (1H, s, C_{11}–H), 8.08 (1H, s, C_{14}–H). The ^1H NMR spectrum of **17** was different from that of natural anhydronellionol triacetate. Found: C, 68.12; H, 7.17%. Calcd for $C_{26}H_{32}O_7$: C, 68.40; H, 7.07%.

*11,12,16-Triacetoxy-6-hydroxyabieta-5,8,11,13-tetraen-7-one (Dehydronellionol 11,12,16-Triacetate) (**18**).* A solution of 11,12,16-triacetoxyabieta-8,11,13-trien-6-one (**25**)[6,11] (71 mg) in acetone (2.0 ml) was oxidized with Jones reagent (2.5 M: 0.1 ml) at 0—5 °C for 10 min and then at room temperature for 2 h. The mixture was diluted with water and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (7.0 g), using ether–benzene (3 : 97) as the eluent, to give **18** (36 mg: 49%). IR: 3405, 1775, 1730, 1631, 1605 cm^{-1}; ^1H NMR (90 MHz): δ=1.30 (d, J=7 Hz) and 1.32 (d, J=7 Hz) (3H, C_{15}–CH_3), 1.46 (3H, s) and 1.48 (3H, s) ($-C(CH_3)_2$), 1.59 (3H, s, C_{10}–CH_3), 2.01 (3H, s, C_{16}–$OCOCH_3$), 2.32 (3H, s) and 2.35 (3H, s) (C_{11} –$OCOCH_3$ and C_{12}–$OCOCH_3$), 4.10 (d, J=7 Hz) and 4.13 (d, J=7 Hz) (2H, $-CH_2OCOCH_3$), 7.05 (1H, s, –OH), 8.15 (1H, s, C_{14}–H). The ^1H NMR spectrum of **18** was compatible with that of natural anhydronellionol triacetate, except for the signals due to the corresponding C-15 epimer.

*11,12,16-Triacetoxy-6β-bromoabieta-8,11,13-trien-7-one (**27**).* A mixture of 11,12,16-triacetoxyabieta-8,11,13-trien-7-one (**26**)[6,11] (68 mg) and 80% pyridinium tribromide (120 mg) in chloroform (1.0 ml) and ethanol (0.5 ml) was stirred at room temperature for 2 h. The mixture was diluted with water and extracted with ether. The ether extract was washed successively with water, aqueous sodium thiosulfate, and brine. The dried solution was evaporated *in vacuo* to give a crude bromide (**27**) (87 mg). ^1H NMR (CCl_4): δ=1.42 (6H, s, $-C(CH_3)_2$), 1.75 (3H, s, C_{10}–CH_3), 1.98 (3H, s, C_{16}–$OCOCH_3$), 2.39 (6H, s, C_{11}–$OCOCH_3$ and C_{12}–$OCOCH_3$), 4.80 (1H, bd, J=2.5 Hz, $W_{1/2}$=4 Hz, $C_{6\alpha}$–H), 8.05 (1H, s, C_{14}–H).

*11,12,16-Triacetoxyabieta-5,8,11,13-tetraen-7-one (**28**).* A mixture of the crude bromide **27** (87 mg) and 1,5-diazabicyclo-[4.3.0]non-5-ene (0.1 ml) in dry benzene (2.0 ml) was refluxed for 2 h in a stream of nitrogen. The mixture was cooled, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was washed with aqueous sodium thiosulfate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was immediately acetylated[12] with acetic anhydride (0.5 ml) in pyridine (0.5 ml) at room temperature for 20 h. After the usual work-up, the crude product was chromatographed on silica gel (7.0 g), using ether–benzene (3 : 97) as the eluent, to give **26** (18 mg: 26%). Further elution with ether–benzene (5 : 95) afforded **28** (25 mg: 37% from **26**). IR: 1772, 1727, 1650, 1605 cm^{-1}; ^1H

NMR (90 MHz): $\delta=1.30$ (3H, s) and 1.38 (3H, s) ($-\dot{C}(CH_3)_2$), 1.31 (3H, d, $J=7$ Hz, C_{15}–CH_3), 1.59 (3H, s, C_{10}–CH_3), 2.01 (s) and 2.02 (s) (3H, C_{16}–$OCOCH_3$), 2.33 (3H, s) and 2.34 (3H, s) (C_{11}–$OCOCH_3$ and C_{12}–$OCOCH_3$), 3.25 (1H, m, C_{15}–H), 4.09 (d, $J=7$ Hz) and 4.12 (d, $J=7$ Hz) (2H, $-C\underline{H}_2OCOCH_3$), 6.53 (1H, s, C_6–H), 8.13 (1H, s, C_{14}–H). The ^{1}H NMR spectrum of **28** was different from that of natural anhydronellionol triacetate.

The authors are grateful to Professor Ch. B. Rao for kindly supplying the spectral data of the natural product.

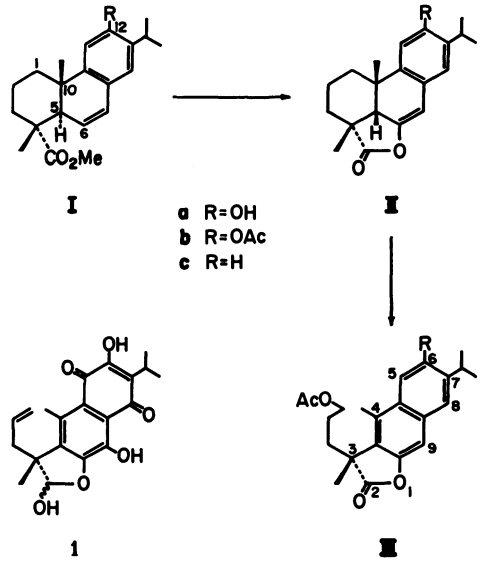
Functionalization of (*R*)-3-(3-Acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one and Some Related Compounds

Takashi MATSUMOTO,* Sachihiko IMAI,* Kenji ONDO, Hideo KATAOKA, and Kyoko KATO
Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730
(Received February 7, 1983)

Oxidation of (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one with Fremy's radical afforded the corresponding *o*-quinone, which was converted into (*R*)-5,6,8-triacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one and its 5,6,9-triacetoxy isomer. (*R*)-3-(3-Acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one was also converted into (*R*)-9-acetoxy- and (*R*)-5,8,9-triacetoxy-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]-furan-2-one. Transformation of (*R*)-2,3-dihydro-6-hydroxy-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho-[2,3-*b*]furan-2-one into (*R*)-6-acetoxy-3-allyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one was also achieved.

In previous papers,[1,2] we have reported the conversion of methyl abieta-6,8,11,13-tetraen-18-oate derivatives (**Ia**, **b**, **c**) into (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one derivatives (**IIIa**, **b**, **c**) *via* the corresponding 6-hydroxy-5β*H*-abieta-6,8,11,13-tetraen-18-oic acid 18,6-lactones (**IIa**, **b**, **c**). These naphthalene derivatives (**III**) seem to be useful intermediates for the synthesis of coleon A (**1**),[3,4] a rare highly oxygenated 1,10-secoabietane derivative isolated from the leaves of *Coleus igniarius* Schweinf. (Labiatae) by Eugster *et al.*[5] In order to devise an efficient synthetic route for coleon A, we have now attempted, as a preliminary experiment, to introduce oxygen functions into the naphthalene skeleton of **III** and to transform an acetoxypropyl side chain into an allyl group. This paper describes the syntheses of (*R*)-5,6,8-triacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**2**) and its 5,6,9-triacetoxy isomer (**3**), and some related compounds, starting from **IIIa**, **b**, **c**.

Oxidation of (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**IIIa**)[2] in aqueous acetone with Fremy's radical[6] in the presence of potassium dihydrogenphosphate at room temperature afforded a hydroxy-*p*-quinone (IR: 3355, 1645 cm^{-1}), (*R*)-3-(3-acetoxypropyl)-2,3,5,8-tetrahydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,8-trione (**4**: 5%), and an *o*-quinone (IR: 1678, 1661 cm^{-1}),[7] (*R*)-3-(3-acetoxypropyl)-2,3,5,6-tetrahydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]-furan-2,5,6-trione (**5**: 40%), together with the starting **IIIa** (22%). The *o*-quinone **5** was then submitted to Thiele-Winter acetoxylation[8] with acetic anhydride and concentrated sulfuric acid at room temperature to give an acetoxy-*p*-quinone (IR: 1775, 1735, 1667 cm^{-1}), (*R*)-6-acetoxy-3-(3-acetoxypropyl)-2,3,5,8-tetrahydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,8-trione (**6**: 7%), and **2** (43%). The *p*-quinones **4** and **6** were each converted into **2** in quantitative yield by reductive acetylation with zinc and acetic anhydride in pyridine at room temperature. Similar treatment of **5** with zinc and acetic anhydride in pyridine afforded (*R*)-5,6-diacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**7**: 89%). The structure of **2** was supported by its ^1H NMR spectrum, which showed a doublet signal due to isopropyl methyls at δ 1.25 (6H) and singlet signals due to two methyls at δ 1.53 and 2.62 (each 3H), four acetoxyls at δ 1.89 (3H), 2.26 (6H), and 2.33 (3H), and an aromatic proton at δ 7.08 (1H). (*R*)-2,3-dihydro-6-hydroxy-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**8**), prepared from (*R*)-6-acetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**IIIb**)[2] by hydrolysis with dilute hydrochloric acid in refluxing methanol, was similarly oxidized with Fremy's radical to give the corresponding *o*-quinone (**9**) (IR: 1673, 1658 cm^{-1}), which was converted into **7** (63% from **IIIb**) by reductive acetylation with zinc and acetic anhydride in pyridine. Attempts to introduce an acetyl group at C-9 in **2** and at C-8 or C-9 in **7** by Friedel-Crafts acylation with acetyl chloride and anhydrous aluminium chloride in refluxing carbon disulfide were unsuccessful, giving the starting **2** and **7**. However, nitration of **2** with fuming nitric acid in acetic anhydride at 0 °C and then at room temperature afforded a nitro compound (IR: 1547, 1340 cm^{-1}), (*R*)-5,6,8-triacetoxy-3-(3-acetoxypropyl)-



2,3-dihydro-7-isopropyl-3,4-dimethyl-9-nitronaphtho-[2,3-*b*]furan-2-one (**10**: 41%), together with **6** (18%) and an acetoxy-*o*-quinone (IR: 1778, 1735, 1672, 1659 cm^{-1}), (*R*)-8-acetoxy-3-(3-acetoxypropyl)-2,3,5,6-tetrahydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,6-trione (**11**: 17%). Reductive acetylation of **11** with zinc and acetic anhydride in pyridine produced **2** in quantitative yield. For conversion of the nitro group into the hydroxyl group *via* the corresponding amine (**12**), the nitro compound **10** in ethanol was submitted to catalytic hydrogenation over PtO_2 at room temperature under an atmosphere of hydrogen. The IR spectrum of the product (**13**: 51%) showed absorption bands at 1809 (γ-lactone), 1774 and 1736 (acetoxyls), 1660 cm^{-1} (C=N), and no absorption band at 3500—3400 cm^{-1} (NH_2). The ^1H NMR spectrum of **13** showed a doublet signal at δ 1.30 (6H) due to isopropyl methyls and singlet signals at δ 1.56, 1.92, 2.23, 2.24, 2.26, and 2.50 (each 3H) due to three methyls and three acetoxyls. From these spectral data, the structure of **13** was tentatively assigned to be (*R*)-5,6-diacetoxy-8-(3-acetoxypropyl)-8,9-dihydro-4-isopropyl-2,7,8-trimethylfuro-[2′,3′ : 2,3]naphtho[1,8-*de*][1,3]oxazin-9-one. Since the desired amine **12** could not be obtained, the following approach was adopted. Nitration of **7** in acetic anhydride with fuming nitric acid at −10 °C and then at 0—5 °C afforded, in addition to **5** (10%), **6** (4%), and the starting **7** (11%), three nitro compounds **14** (21%) **15** (1%), and **16** (38%). The IR spectrum of **14** showed absorption bands at 1823 (γ-lactone), 1737 (acetoxyl), 1680 and 1658 (*o*-quinone), 1548 and 1309 cm^{-1} (NO_2), and its ^1H NMR spectrum showed a multiplet signal due to an isopropyl methine at very high field (δ 2.66), compared with that (δ 2.98) of **5**. From these spectral data, the structure of **14** was assigned to be (*R*)-3-(3-acetoxypropyl)-2,3,5,6-tetrahydro-7-isopropyl-3,4-dimethyl-8-nitronaphtho[2,3-*b*]furan-2,5,6-trione. The ^1H NMR spectrum of **16** showed signals at δ 1.29 (6H) and 3.02 (1H) due to an isopropyl, at δ 1.63 and 2.70 (each 3H) due to two methyls, at δ 1.91, 2.30, and 2.31 (each 3H) due to three acetoxyls, and at δ 7.74 (1H) due to an aromatic proton. Since the long-range coupling between the isopropyl methine at δ 3.02 and the aromatic proton at δ 7.74 was observed,[9] the structure of **16** was assigned to be (*R*)-5,6-diacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethyl-9-nitronaphtho[2,3-*b*]furan-2-one. The IR and ^1H NMR spectra of **15** were very similar to those of **16**, except for a singlet NMR signal at δ 7.02 (1H) due to an aromatic proton. Therefore, both compounds **15** and **16** should be position-isomers with regard to the nitro group. The compound **15** was also obtained by reductive acetylation of **14** with zinc and acetic anhydride in pyridine. Thus, the structure of **15** was assigned to be (*R*)-5,6-diacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethyl-8-nitronaphtho[2,3-*b*]furan-2-one. Catalytic hydrogenation of **16** with PtO_2 in acetic acid afforded the corresponding amine (**17**: 80%), which was converted into **3** (20%) and **7** (25%) by successive treatments with sodium nitrite and dilute hydrochloric acid in acetic acid at 0—5 °C, with dilute sulfuric acid at 80 °C, and then with zinc and acetic anhydride in pyridine. The structure of **3** was supported by its ^1H NMR spectrum, which showed signals at δ 1.31 (6H, doublet) and 3.02 (1H, multiplet) due to an isopropyl, at δ 1.64 and 2.66 (each 3H and singlet) due to two methyls, at δ 1.93 (3H), 2.29 (6H), and 2.44 (3H) (each singlet) due to four acetoxyls, and at δ 7.60 (1H, singlet) due to an aromatic proton. Friedel-Crafts acylation of **3** with acetyl chloride and anhydrous aluminium chloride in refluxing carbon disulfide afforded only the starting compound, as in the case of **2**. However nitration of **3** with fuming nitric acid or dilute nitric acid gave a complex mixture. Since functionalization of C-8 in **3** was also unsuccessful, the following experiments were carried out for the introduction of a functional group at C-9 of the naphthalene skeleton.

Reduction of (*R*)-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan-2-one (**18**)[2] with lithium aluminium hydride in refluxing ether afforded (*R*)-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylna-

phtho[2,3-*b*]furan (**19**: 29%) and an epimeric mixture at C-2 of 2,3-dihydro-2-hydroxy-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan (**20**: 60%) which gave the corresponding acetate (**21**: 90%) with acetic anhydride in pyridine. The compound **20** was also obtained in quantitative yield by reduction of **18** with sodium borohydride in methanol. Oxidation of **20** with Jones reagent at 0—5 °C gave **18** (93%). Treatment of **21** in acetic anhydride with boron trifluoride etherate at room temperature afforded the corresponding 9-acetyl (**22**: 58%) and 9-acetoacetyl (**23**: 29%) derivatives. Both compounds **22** and **23** were also obtained by the same treatment of **20** in 58% and 20% yields, respectively. The ^{1}H NMR spectrum of **22** showed an acetyl signal at δ 2.58 (3H, singlet) and three aromatic proton signals at δ 7.21 (1H, double doublet, J=2 and 9 Hz), 7.81 (1H, doublet, J=9 Hz), and 8.15 (1H, doublet, J=2 Hz). These chemical shifts and coupling pattern of the aromatic protons suggested the presence of the acetyl group at C-9. The ^{1}H NMR spectrum of **23** also showed similar signals due to three aromatic protons at δ 7.22 (1H, double doublet, J=2 and 9 Hz), 7.82 (1H, doublet, J=9 Hz), and 8.13 (1H, doublet, J=2 Hz), and signals due to an acetoacetyl at δ 2.13 (3H, singlet), 5.93 (1H, singlet), and 15.95 (1H, broad). These spectral data also suggested that the acetoacetyl group was present at C-9 as its enol form. Acetylation of **19** in acetic anhydride with boron trifluoride etherate also gave the corresponding 9-acetyl derivative (**24**: 77%). It is noteworthy that the compounds **19**, **20**, and **21** were each acetylated at C-9 with acetic anhydride and boron trifluoride etherate, because when the lactone **18** was treated in the same manner only the starting material was recovered. In contrast to the above results, acetylation of (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**IIIc**)[2] with acetyl chloride and anhydrous aluminium chloride in refluxing carbon disulfide afforded the corresponding 8-acetyl derivative (**25**: 54%). The structure of **25** was supported by its ^{1}H NMR spectrum, which showed an acetyl signal at δ 2.54 (3H, singlet) and three aromatic proton signals at δ 7.01 (1H, broad singlet), 7.36 (1H, doublet, J=9 Hz), and 7.91 (1H, doublet, J=9 Hz). Hydrolysis of **IIIc** with concentrated hydrochloric acid in refluxing methanol quantitatively produced the corresponding alcohol (**26**), which was methylated with diazomethane in the presence of boron trifluoride etherate to give (*R*)-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho [2,3-*b*] furan-2-one (**27**: 85%). In order to introduce an acetyl group at C-9, the lactone **27** was reduced with sodium borohydride in ethanol and the resulting hemiacetal (**28**) was treated with acetic anhydride and boron trifluoride etherate to give an epimeric mixture at C-2 of 2-acetoxy-9-acetyl-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]furan (**29**: 70% from **27**). Hydrolysis of **29** with dilute hydrochloric acid in refluxing methanol afforded the corresponding hemiacetal (**30**), which was oxidized with Jones reagent at 0—5 °C to give (*R*)-9-acetyl-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**31**: 69% from **29**). Treatment of **31** in refluxing dichloromethane with *m*-chloroperbenzoic acid in the presence of *p*-toluenesulfonic acid monohydrate afforded, after column chromatography on silica gel, the corresponding 9-acetoxy derivative (**32**: 11%), together with an acetoxy-*p*-quinone (**33**: 4%) and a mixture of **32** and the starting **31**. The mixture of **31** and **32** was hydrolyzed with dilute hydrochloric acid in refluxing methanol and then purified by column chromatography on silica gel to give **31** (16%) and the 9-hydroxy derivative (**34**: 22% from **31**). Acetylation of **34** with acetic anhydride in pyridine afforded **32** (87%). The structure of **32** was supported by its ^{1}H NMR spectrum, which showed signals due to an acetoxyl at δ 2.45 (3H, singlet) and

three aromatic protons at δ 7.37 (1H, double doublet, J=2 and 9 Hz), 7.62 (1H, broad singlet), and 7.94 (1H, doublet, J=9 Hz). The IR spectrum of **33** showed absorption bands at 1821 (γ-lactone), 1779 (acetoxyl), 1659 cm^{-1} (p-quinone), and its ^{1}H NMR spectrum showed signals due to an acetoxyl at δ 2.42 (3H, singlet), an olefinic proton at δ 6.55 (1H, doublet, J=1.5 Hz), and no aromatic proton. From these spectral data, the structure of **33** was assigned to be (*R*)-9-acetoxy-2,3,5,8-tetrahydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,8-trione. Reductive acetylation of **33** with zinc and acetic anhydride in pyridine afforded the corresponding triacetate (**35**: 45%). It is of interest that the oxygen functions were introduced to C-5, C-8, and C-9 of **31** in one stage by oxidation with *m*-chloroperbenzoic acid, although the yield was low. Therefore if the yield is improved, the 9-acetyl derivatives seem to be useful intermediates for the synthesis of coleon A (**1**).

Finally, transformation of a hydroxypropyl side chain into an allyl group was also carried out as follows. Treatment[10] of **8** with *o*-nitrophenyl selenocyanate and tributylphosphine in pyridine at room temperature under a stream of nitrogen yielded a selenide (**36**), which was immediately acetylated with acetic anhydride in pyridine to give the corresponding 6-acetoxy selenide (**37**: 56% from **8**). Oxidation of **37** with 50% hydrogen peroxide in tetrahydrofuran at room temperature afforded the desired (*R*)-6-acetoxy-3-allyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**38**: 89%). The structure of **38** was supported by its ^{1}H NMR spectrum, which showed signals due to an acetoxyl at δ 2.32 (3H, singlet), an allyl at δ 2.76 (2H, doublet, J=6.5 Hz) and 4.7—5.6 (3H, multiplet), and three aromatic protons at δ 7.20, 7.50, and 7.58 (each 1H and singlet). Application of the present results for the synthesis of coleon A (**1**) will describe in the succeeding paper.

Experimental

All melting points are uncorrected. The IR spectra and optical rotations were measured in chloroform, and the ^{1}H NMR spectra in carbon tetrachloride at 90 MHz, with tetramethylsilane as an internal standard, unless otherwise stated. The chemical shifts are presented in terms of δ values; s: singlet, bs: broad singlet, d: doublet, bd: broad doublet, dd: double doublet, t: triplet, m: multiplet. The column chromatography was performed using Merck silica gel.

Oxidation of (R)-3-(3-Acetoxypropyl)-2,3-dihydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (IIIa) with Fremy's Reagent. A solution of freshly prepared Fremy's reagent [potassium nitrosodisulfonate (4.2 g) and aqueous potassium dihydrogenphosphate (0.17 M:† 150 ml) in water (300 ml)] was added to a stirred solution of **IIIa** (1522 mg) in acetone (260 ml) at room temperature. After being stirred for 3 h and then 2 h more, additional Fremy's reagent [potassium nitrosodisulfonate (2.8 g) and aqueous potassium dihydrogenphosphate (0.17 M: 100 ml) in water (200 ml)] was added twice. The mixture was further stirred for 24 h, diluted with brine, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (150 g), using ether–benzene (5 : 95) as the eluent, to give (*R*)-3-(3-acetoxypropyl)-2,3,5,8-tetrahydro-6-hydroxy-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,8-trione (**4**) (85 mg: 5.2 %). IR: 3355, 1817, 1732, 1645, 1598, 1585 cm^{-1}; ^{1}H NMR: δ=1.30 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.61 (3H, s, C_3-CH_3), 1.94 (3H, s, -OCOCH_3), 2.72 (3H, s, C_4-CH_3), 3.32 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 3.88 (2H, t, J=6.5 Hz, -C$\underline{H}_2$OAc), 7.70 (1H, s, C_6-OH, disappeared with D_2O), 7.75 (1H, s, C_9-H).

Subsequent elution gave (*R*)-3-(3-acetoxypropyl)-2,3,5,6-tetrahydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,6-trione (**5**) (637 mg: 40.3%). $[\alpha]_D$ +125° (*c* 5.36); IR: 1815, 1735, 1678, 1661, 1598, 1580 cm^{-1}; ^{1}H NMR: δ=1.17 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.60 (3H, s, C_3-CH_3), 1.94 (3H, s, -OCOCH_3), 2.63 (3H, s, C_4-CH_3), 2.98 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 3.87 (2H, t, J=6 Hz, -C$\underline{H}_2$OAc), 6.89 (1H, s, C_9-H), 6.99 (1H, bs, C_8-H); UV: λ_{max}^{EtOH} 265 nm (log ε 4.38), 358 (3.63). Found: C, 68.56; H, 6.29%. Calcd for $C_{22}H_{24}O_6$: C, 68.73; H, 6.29%.

Further elution gave the recovered **IIIa** (332 mg: 21.8%).

Thiele-Winter Reaction of 5. Concentrated sulfuric acid (0.08 ml) was added to a stirred solution of **5** (802 mg) in acetic anhydride (8.0 ml) at 0—5 °C. The solution was stirred at room temperature for 4 h, poured into aqueous sodium hydrogencarbonate, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (85 g), using ether–benzene (5 : 95) as the eluent, to give (*R*)-6-acetoxy-3-(3-acetoxypropyl)-2,3,5,8-tetrahydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,8-trione (**6**) (63 mg: 6.8%). $[\alpha]_D$ +10° (*c* 0.77); IR: 1816, 1775, 1735, 1667, 1603, 1588 cm^{-1}; ^{1}H NMR: δ=1.27 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.61 (3H, s, C_3-CH_3), 1.93 (3H, s, -CH_2-OCOC$\underline{H}_3$), 2.36 (3H, s, C_6-OCOCH_3), 2.68 (3H, s, C_4-CH_3), 3.21 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 3.86 (2H, t, J=6.5 Hz, -C$\underline{H}_2$OAc), 7.71 (1H, s, C_9-H); UV: λ_{max}^{EtOH} 252 nm (log ε 4.31), 353 (3.45). Found: C, 64.91; H, 6.15%. Calcd for $C_{24}H_{26}O_8$: C, 65.15; H, 5.92%.

Further elution with ether–benzene (15 : 85) afforded (*R*)-5,6,8-triacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**2**) (478 mg: 43.3%). $[\alpha]_D$ +13° (*c* 1.13); IR: 1807, 1778, 1733, 1641, 1617 cm^{-1}; ^{1}H NMR: δ=1.25 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.53 (3H, s, C_3-CH_3), 1.89 (3H, s, -CH_2OCOC$\underline{H}_3$), 2.26 (6H, s) and 2.33 (3H, s) (C_5-OCOCH_3, C_6-OCOCH_3, and C_8-OCOCH_3), 2.62 (3H, s, C_4-CH_3), 3.10 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 3.77 (2H, t, J=6 Hz, -C$\underline{H}_2$OAc), 7.08 (1H, s, C_9-H); UV: λ_{max}^{EtOH} 241.5 nm (log ε 5.00), 274 (3.81), 285.5 (3.86), 296.5 (3.77), 320.5 (3.17), 335 (3.25). Found: C, 63.91; H, 6.27%. Calcd for $C_{28}H_{32}O_{10}$: C, 63.62; H, 6.10%.

Reductive Acetylation of 5. Zinc powder (0.1 g) was added to a stirred solution of **5** (470 mg) and acetic anhydride (2.0 ml) in pyridine (2.0 ml) with cooling in an ice–water bath. The mixture was stirred at this temperature for 5 min and then at room temperature for 1 h, poured into aqueous sodium hydrogencarbonate, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (60 g), using ether–benzene (1 : 9) as the eluent, to give (*R*)-5,6-diacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**7**) (512 mg: 89.0%). $[\alpha]_D$ +23° (*c* 1.92); IR: 1798, 1769, 1729, 1638 cm^{-1}; ^{1}H NMR: δ=1.30 (6H, d, J=7 Hz, -CH(C$\underline{H}_3$)$_2$), 1.60 (3H, s, C_3-CH_3), 1.92 (3H, s, -CH_2OCOC$\underline{H}_3$), 2.28 (6H, s, C_5-OCOCH_3 and C_6-OCOCH_3), 2.66 (3H, s, C_4-CH_3), 2.99 (1H, m, -C$\underline{H}$(CH$_3$)$_2$), 3.84 (2H, t, J=6 Hz, -C$\underline{H}_2$OAc), 7.24 (1H, s, C_9-H), 7.50 (1H, s, C_8-H); UV: λ_{max}^{EtOH} 239 nm (log ε

† 1 M=1 mol dm^{-3}.

4.94), 272 (3.78), 283 (3.83), 294 (3.71), 318.5 (3.03), 332.5 (3.11). Found: C, 66.29; H, 6.58%. Calcd for $C_{26}H_{30}O_8$: C, 66.37; H, 6.43%.

Nitration of **2**. A solution of fuming nitric acid ($d=1.50$, 0.62 ml) in acetic anhydride (1.24 ml) was added dropwise over a period of 5 min to a stirred solution of **2** (410 mg) in acetic anhydride (4.1 ml) with cooling in an ice–water bath. The mixture was stirred at room temperature for 30 min, poured into brine, and extracted with ether. The ether extract was washed successively with brine, aqueous sodium hydrogencarbonate, and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (40 g), using ether–benzene (5 : 95) as the eluent, to give a diacetoxy-*p*-quinone (60 mg: 17.5%), whose IR and ^{1}H NMR spectra were identical with those of the authentic **6**.

Subsequent elution gave (*R*)-8-acetoxy-3-(3-acetoxypropyl)-2,3,5,6-tetrahydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]-furan-2,5,6-trione (**11**) (59 mg: 17.2%). $[\alpha]_D$ +45° (*c* 0.31); IR: 1818, 1778, 1735, 1690, 1672, 1659, 1622, 1600, 1583 cm^{-1}; ^{1}H NMR: $\delta=1.23$ (6H, d, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3-CH_3), 1.94 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.44 (3H, s, $C_8-OCOCH_3$), 2.64 (3H, s, C_4-CH_3), 2.80 (1H, m, $-C\underline{H}(CH_3)_2$), 3.86 (2H, t, $J=6$ Hz, $-C\underline{H}_2OAc$), 6.91 (1H, s, C_9-H); UV: λ_{max}^{EtOH} 241.5 nm (log ε 4.61), 290sh (3.74), 298sh (3.71), 302sh (3.71), 335.5 (3.53). Found: C, 65.45; H, 6.21%. Calcd for $C_{24}H_{26}O_8$: C, 65.15; H, 5.92%.

Further elution with ether–benzene (15 : 85) gave (*R*)-5,6,8-triacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethyl-9-nitronaphtho[2,3-*b*]furan-2-one (**10**) 181 mg: (40.7%). This was crystallized from ethanol, mp 171.5—172.5 °C, $[\alpha]_D$ +7° (*c* 1.04); IR: 1827, 1787, 1737, 1650, 1614, 1547, 1340 cm^{-1}; ^{1}H NMR: $\delta=1.23$ (6H, bd, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3-CH_3), 1.92 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.27 (9H, s, $C_5-OCOCH_3$, $C_6-OCOCH_3$, and $C_8-OCOCH_3$), 2.56 (3H, s, C_4-CH_3), 3.00 (1H, m, $-C\underline{H}(CH_3)_2$), 3.82 (2H, t, $J=6$ Hz, $-C\underline{H}_2OAc$). Found: C, 58.88; H, 5.74; N, 2.38%. Calcd for $C_{28}H_{31}O_{12}N$: C, 58.63; H, 5.45; N, 2.44%.

Reductive Acetylation of **4**, **6**, *and* **11**. *a)*: A solution of **4** (80 mg) and acetic anhydride (0.4 ml) in pyridine (0.4 ml) was treated with zinc powder (26 mg) in the same manner as described for the preparation of **7**. The crude product was purified by column chromatography on silica gel (10 g) to give **2** (104 mg: 98%), whose IR and ^{1}H NMR spectra were identical with those of an authentic sample.

b): A solution of **6** (113 mg) and acetic anhydride (0.6 ml) in pyridine (0.6 ml) was treated with zinc powder (33 mg) to give **2** (129 mg: 96%).

c): A solution of **11** (50 mg) and acetic anhydride (0.3 ml) in pyridine (0.3 ml) was treated with zinc powder (15 mg) to give **2** (58 mg: 97%).

*Conversion of (*R*)-6-Acetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**IIIb**) into* **7**. A solution of **IIIb**[2] (4120 mg) and dilute hydrochloric acid (6 M: 83 ml) in methanol (412 ml) was refluxed for 1 h, and then evaporated *in vacuo*. The residue was diluted with brine and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give the crude (*R*)-2,3-dihydro-6-hydroxy-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**8**) which, without purification, was used in the next reaction. IR: 3575, 3325br, 1785, 1621 cm^{-1}; ^{1}H NMR (60 MHz, $CDCl_3$): $\delta=1.33$ (6H, d, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3-CH_3), 2.50 (3H, s, C_4-CH_3), 3.35 (1H, m, $-C\underline{H}(CH_3)_2$), 3.46 (2H, t, $J=6$ Hz, $-C\underline{H}_2OH$), 6.70 (1H, br, C_6-OH), 7.20 (2H, s, C_5-H and C_9-H), 7.51 (1H, s, C_8-H).

A stirred solution of the above crude **8** in acetone (656 ml) was oxidized with Fremy's reagent [potassium nitrosodisulfonate (13.42 g) and aqueous potassium dihydrogenphosphate (0.17 M: 300 ml) in water (600 ml)] at room temperature. After being stirred for 5 h, additional Fremy's reagent [potassium nitrosodisulfonate (5.36 g) and aqueous potassium dihydrogenphosphate (0.17 M: 120 ml) in water (240 ml)] was added. The mixture was further stirred for 14 h, diluted with brine, and extracted with chloroform. The chloroform extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give the crude (*R*)-2,3,5,6-tetrahydro-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]-furan-2,5,6-trione (**9**) which, without purification, was used in the next reaction. IR: 3580sh, 3490, 3370sh, 1808, 1673, 1658, 1596, 1577 cm^{-1}; ^{1}H NMR (60 MHz, $CDCl_3$): $\delta=1.19$ (6H, d, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.63 (3H, s, C_3-CH_3), 2.68 (3H, s, C_4-CH_3), 3.55 (2H, t, $J=6$ Hz, $-C\underline{H}_2OH$), 6.99 (1H, s, C_9-H), 7.09 (1H, bs, C_8-H).

Zinc powder (650 mg) was added to a stirred solution of the above crude **9** and acetic anhydride (17 ml) in pyridine (17 ml) at 0—5 °C. After being stirred at 0—5 °C for 5 min and then at room temperature for 1 h, the mixture was filtered and the filtrate was extracted with chloroform. The chloroform extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (220 g), using ether–benzene (5 : 95) as the eluent, to give the starting **IIIb** (640 mg: 15.5%) and **7** (2940 mg: 62.6%). Further elution with ether–benzene (2 : 8) gave **2** (60 mg: 1.1%). The IR and ^{1}H NMR spectra of **2** and **7** were identical with those of authentic samples.

Catalytic Hydrogenation of **10**. A mixture of **10** (57 mg) and PtO_2 (12 mg) in ethanol (5.7 ml) was submitted to catalytic hydrogenation at room temperature for 34 h. After the usual work-up, the crude product was chromatographed on silica gel (5.0 g), using ether–benzene (1 : 3) as the eluent, to give an oxazine derivative (**13**) (27 mg: 51%). IR: 1809, 1774, 1736, 1660, 1623 cm^{-1}; ^{1}H NMR: $\delta=1.30$ (6H, d, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.56 (3H, s, C_3-CH_3), 1.92 (3H, s, $-CH_2-OCOC\underline{H}_3$), 2.23, 2.24, and 2.26 (each 3H and s, $C_5-OCOCH_3$, $C_6-OCOCH_3$, and $-N=CCH_3$), 2.50 (3H, s, C_4-CH_3), 3.04 (1H, m, $-C\underline{H}(CH_3)_2$), 3.84 (2H, t, $J=6$ Hz, $-C\underline{H}_2OAc$).

Nitration of **7**. A solution of fuming nitric acid ($d=1.50$, 0.94 ml) in acetic anhydride (4.7 ml) was added dropwise to a stirred solution of **7** (2350 mg) in acetic anhydride (35 ml) at −10 °C over a period of 30 min. After being stirred at −10—−5 °C for 1 h and then at 0—5 °C for 50 h, the mixture was poured into aqueous sodium hydrogencarbonate and extracted with chloroform. The extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (260 g), using ether–benzene (5 : 95) as the eluent, to give **6** (85 mg: 3.8%) and (*R*)-3-(3-acetoxypropyl)-2,3,5,6-tetrahydro-7-isopropyl-3,4-dimethyl-8-nitronaphtho[2,3-*b*]furan-2,5,6-trione (**14**) (459 mg: 21.4%). IR: 1823, 1737, 1680, 1658, 1629, 1601, 1583, 1548, 1309 cm^{-1}; ^{1}H NMR: $\delta=1.29$ (6H, d, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.61 (3H, s, C_3-CH_3), 1.92 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.66 (1H, m, $-C\underline{H}(CH_3)_2$), 2.67 (3H, s, C_4-CH_3), 3.86 (2H, t, $J=6$ Hz, $-C\underline{H}_2OAc$), 6.69 (1H, s, C_9-H).

Subsequent elution gave **5** (187 mg: 9.7%), the starting **7** (253 mg: 10.8%), and (*R*)-5,6-diacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethyl-8-nitronaphtho[2,3-*b*]-furan-2-one (**15**) (25 mg: 1.0%). This was recrystallized from ether, mp 153—154.5 °C, $[\alpha]_D$ +18° (*c* 0.55); IR: 1810, 1780, 1732, 1642, 1532, 1331 cm^{-1}; ^{1}H NMR (60 MHz): $\delta=$ 1.32 (6H, d, $J=7$ Hz, $-CH(C\underline{H}_3)_2$), 1.58 (3H, s, C_3-CH_3), 1.91 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.33 (6H, s, $C_5-OCOCH_3$ and $C_6-OCOCH_3$), 2.70 (3H, s, C_4-CH_3), 3.06 (1H, m, $-C\underline{H}-(CH_3)_2$), 3.85 (2H, t, $J=6$ Hz, $-C\underline{H}_2OAc$), 7.02 (1H, s, C_9-H).

Found: C, 60.54; H, 5.69; N, 2.72%. Calcd for $C_{26}H_{29}O_{10}N$: C, 60.57; H, 5.67; N, 2.72%.

Further elution gave (*R*)-5,6-diacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethyl-9-nitronaphtho[2,3-*b*]-furan-2-one (**16**) (970 mg: 37.7%). This was recrystallized from chloroform-carbon tetrachloride, mp 181—182 °C, $[\alpha]_D$ +6° (*c* 0.71); IR: 1820, 1774, 1729, 1642, 1530, 1327 cm^{-1}; ^1H NMR: δ=1.29 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.63 (3H, s, C_3-CH_3), 1.91 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.30 and 2.31 (each 3H and s, $C_5-OCOCH_3$ and $C_6-OCOCH_3$), 2.70 (3H, s, C_4-CH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 3.83 (2H, t, J=6 Hz, $-C\underline{H}_2OAc$), 7.74 (1H, s, C_8-H); UV: λ_{max}^{EtOH} 236 nm (log ε 4.86), 265sh (3.98), 322sh (3.47), 335 (3.52). Found: C, 60.86; H, 5.76; N, 2.55%. Calcd for $C_{26}H_{29}O_{10}N$: C, 60.57; H, 5.67; N, 2.72%. The IR and ^1H NMR spectra of **5**, **6**, and **7** were identical with those of authentic samples.

Reductive Acetylation of ***14***. Zinc powder (17 mg) was added to a stirred solution of **14** (108 mg) and acetic anhydride (0.5 ml) in pyridine (0.5 ml) at 0—5 °C. After being stirred at 0—5 °C for 5 min and then at room temperature for 1 h, the mixture was diluted with ether. The ether solution was washed successively with aqueous sodium hydrogencarbonate, dilute hydrochloric acid, and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (10 g), using ether–benzene (1 : 4) as the eluent, to give **15** (53 mg: 40.9%). The IR and ^1H NMR spectra of **15** were identical with those of an authentic sample.

*(R)-5,6-Diacetoxy-3-(3-acetoxypropyl)-9-amino-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (**17**).* A mixture of **16** (515 mg) and PtO_2 (103 mg) in acetic acid (10 ml) was submitted to catalytic hydrogenation with 1 atm hydrogen pressure at room temperature for 3.5 h. After the usual work-up, the crude product was recrystallized from ethanol to give **17** (388 mg: 80.0%), mp 192.5—193 °C, $[\alpha]_D$ +23° (*c* 0.52); IR: 3440, 3370, 1792, 1770, 1732, 1658, 1625 cm^{-1}; ^1H NMR ($CDCl_3$): δ=1.31 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.62 (3H, s, C_3-CH_3), 1.98 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.36 (6H, s, $C_5-OCOCH_3$ and $C_6-OCOCH_3$), 2.60 (3H, s, C_4-CH_3), 3.07 (1H, m, $-C\underline{H}(CH_3)_2$), *ca.* 3.7—4.3 (2H, br, $-NH_2$), 3.91 (2H, t, J=6 Hz, $-C\underline{H}_2OAc$), 7.62(1H, s, C_8-H). Found: C, 64.01; H, 6.39; N, 2.84%. Calcd for $C_{26}H_{31}O_8N$: C, 64.31; H, 6.44; N, 2.89%.

*(R)-5,6,9-Triacetoxy-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (**3**).* A solution of sodium nitrite (522 mg) in water (10.5 ml) was added dropwise at 0—5 °C to a stirred solution of **17** (1440 mg) and dilute hydrochloric acid (4 M: 18.6 ml) in acetic acid (30 ml). After being stirred at 0—5 °C for 20 min, urea (900 mg) was added. The mixture was stirred for 10 min more, diluted with dilute sulfuric acid (3 M: 500 ml), and then heated at 80 °C for 1 h. After standing overnight at room temperature, the mixture was extracted with chloroform. The extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*.

The above residue was treated with zinc powder (390 mg) and acetic anhydride (6.5 ml) in pyridine (6.5 ml) at room temperature for 1 h. After the same work-up as described for the preparation of **7**, the crude product was chromatographed on silica gel (170 g), using ether–benzene (7 : 93) as the eluent, to give **7** (342 mg: 24.5%) and **3** (315 mg: 20.1%), $[\alpha]_D$ +15° (*c* 2.50); IR: 1802, 1770, 1729, 1653 cm^{-1}; ^1H NMR: δ=1.31 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.64 (3H, s, C_3-CH_3), 1.93 (3H, s, $-CH_2OCOC\underline{H}_3$), 2.29 (6H, s, $C_5-OCOCH_3$ and $C_6-OCOCH_3$), 2.44 (3H, s, $C_9-OCOCH_3$), 2.66 (3H, s, C_4-CH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 3.87 (2H, t, J=6 Hz, $-C\underline{H}_2OAc$), 7.60 (1H, s, C_8-H). Found: C, 63.90; H, 6.10%. Calcd for $C_{28}H_{32}O_{10}$: C, 63.62; H, 6.10%.

*Reduction of (R)-2,3-Dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-b]furan-2-one (**18**) with Lithium Aluminium Hydride.* A mixture of **18**[2] (300 mg) and lithium aluminium hydride (80 mg) in dry ether (12 ml) was refluxed for 4 h with stirring. The mixture was poured into ice-dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (50 g), using hexane–benzene (9 : 1) as the eluent, to give (*R*)-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan (**19**) (84 mg: 29%), $[\alpha]_D$ +28° (*c* 4.02); IR: 1635, 1583 cm^{-1}; ^1H NMR (60 MHz): δ=1.31 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.47 (3H, s, C_3-CH_3), 2.60 (3H, s, C_4-CH_3), 3.00 (1H, m, $-C\underline{H}(CH_3)_2$), 4.14 (2H, ABq, δ_{AB}=14.5 Hz, J_{AB}=8.5 Hz, C_2-H_2), 6.77 (1H, s, C_9-H), 7.05 (1H, dd, J=2 and 9 Hz, C_6-H), 7.31 (1H, d, J=2 Hz, C_8-H), 7.70 (1H, d, J=9 Hz, C_5-H). Found: C, 85.26; H, 9.39%. Calcd for $C_{20}H_{26}O$: C, 85.05; H, 9.28%.

Further elution with ether–benzene (2 : 98) gave an epimeric mixture at C-2 of 2,3-dihydro-2-hydroxy-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan (**20**) (*ca.* 4 : 1 mixture, 180 mg: 59.6%), IR: 3590, 3400br, 1633, 1591 cm^{-1}; ^1H NMR (60 MHz): δ=1.29 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.35 and 1.43 (3H, each s, *ca.* 1: 4, C_3-CH_3), 2.58 (3H, s, C_4-CH_3), 2.99 (1H, m, $-C\underline{H}(CH_3)_2$), 5.39 and 5.48 (1H, each bs, *ca.* 1 :4, C_2-H), 6.82 (1H, s, C_9-H), 7.09 (1H, dd, J=2 and 8.5 Hz, C_6-H), 7.33 (1H, d, J=2 Hz, C_8-H), 7.71 (1H, d, J=8.5 Hz, C_5-H). Found: C, 80.64; H, 8.81%. Calcd for $C_{20}H_{26}O_2$: C, 80.49; H, 8.78%.

Reduction of ***18*** *with Sodium Borohydride.* A mixture of **18** (444 mg) and sodium borohydride (114 mg) in methanol (22.2 ml) was stirred at 0—5 °C for 1 h and then allowed to stand overnight at room temperature. The mixture was evaporated *in vacuo*, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give a product (*ca.* 4 : 1 mixture, 423 mg: 94.6%), whose IR and ^1H NMR spectra were identical with those of authentic **20**.

A stirred solution of **20** (31.4 mg) in acetone (2.0 ml) was oxidized with four drops of Jones reagent (2M) at 0—5 °C for 15 min. The mixture was diluted with water and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give a lactone (29.1 mg: 93.0%), whose IR and ^1H NMR spectra were identical with those of authentic **18**.

A mixture of **20** (182 mg) and acetic anhydride (1.0 ml) in pyridine (0.5 ml) was allowed to stand overnight at room temperature. After the usual work-up, the crude product was chromatographed on silica gel (20 g), using benzene as the eluent, to give an acetate (**21**) (187 mg: 90.1%). IR: 1735, 1633, 1587 cm^{-1}; ^1H NMR (60 MHz): δ=1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.41 and 1.49 (3H, each s, *ca.* 1 : 4, C_3-CH_3), 2.01 (3H, s, $-OCOCH_3$), 2.62 (3H, s, C_4-CH_3), 3.00 (1H, m, $-C\underline{H}(CH_3)_2$), 6.34 and 6.44 (1H, each s, *ca.* 1 : 4, C_2-H), 6.92 (1H, s, C_9-H), 7.14 (1H, dd, J=2 and 8.5 Hz, C_6-H), 7.40 (1H, d, J=2 Hz, C_8-H), 7.78 (1H, d, J=8.5 Hz, C_5-H). Found: C, 77.73; H, 8.31%. Calcd for $C_{22}H_{28}O_3$: C, 77.61; H, 8.29%.

Acetylation of ***19***, ***20***, *and* ***21***. *a)*: Boron trifluoride etherate (0.09 ml) was added to a stirred solution of **19** (84 mg) in acetic anhydride (1.8 ml) with cooling in an ice-water bath. The mixture was stirred at room temperature for 3 min, poured into a mixture of ice and aqueous sodium hydrogencarbonate, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (10 g), using benzene as the eluent, to give (*R*)-9-acetyl-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan (**24**)

(74 mg: 77%), $[\alpha]_D$ +7.3° (*c* 3.01); IR: 1661, 1613, 1585 cm^{-1}; ^1H NMR: δ=1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.45 (3H, s, C_3-CH_3), 2.57 (6H, s, C_4-CH_3 and C_9-COCH_3), 3.00 (1H, m, $-C\underline{H}(CH_3)_2$), 4.24 (2H, ABq, δ_{AB}=22.5 Hz, J_{AB}= 8.5 Hz, C_2-H_2), 7.16 (1H, dd, J=2 and 8.5 Hz, C_6-H), 7.75 (1H, d, J=8.5 Hz, C_5-H), 8.15 (1H, d, J=2 Hz, C_8-H). Found: C, 81.20; H, 8.78%. Calcd for $C_{22}H_{28}O_2$: C, 81.44; H, 8.70%.

b): A solution of **20** (99.8 mg) in acetic anhydride (2.0 ml) was treated with boron trifluoride etherate (0.1 ml) as described for the preparation of **24**. The crude product was chromatographed on silica gel (20 g), using ether–benzene (2 : 98) as the eluent, to give an epimeric mixture at C-2 of 2-acetoxy-9-acetyl-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan (**22**) (74.0 mg: 57.9%); IR: 1740, 1665, 1613, 1587 cm^{-1}; ^1H NMR: δ=1.31 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.44 and 1.50 (3H, each s, C_3-CH_3), 2.04 and 2.06 (3H, each s, *ca.* 4 : 1, $C_2-OCOCH_3$), 2.58 (3H, s, C_9-COCH_3), 2.63 (3H, s, C_4-CH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 6.40 and 6.51 (1H, each s, *ca.* 1 : 4, C_2-H), 7.21 (1H, dd, J=2 and 9 Hz, C_6-H), 7.81 (1H, d, J=9 Hz, C_5-H), 8.15 (1H, d, J=2 Hz, C_8-H). Found: C, 75.22; H, 7.91%. Calcd for $C_{24}H_{30}O_4$: C, 75.36; H, 7.91%.

Further elution with ether–benzene (1 : 9) gave an epimeric mixture at C-2 of 9-acetoacetyl-2-acetoxy-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-propylnaphtho[2,3-*b*]furan (**23**) (28.4 mg: 20.0%), whose acetoacetyl group existed only in the enol form. IR: 1737, 1640—1530br cm^{-1}; ^1H NMR: δ=1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.49 (3H, s, C_3-CH_3), 2.05 (3H, s, $-OCOCH_3$), 2.13 (3H, s, $-COCH=C(OH)C\underline{H}_3$), 2.63 (3H, s, C_4-CH_3), 3.03 (1H, m, $-C\underline{H}(CH_3)_2$), 5.93 (1H, s, $-COC\underline{H}=C(OH)CH_3$), 6.52 (1H, s, C_2-H), 7.22 (1H, dd, J=2 and 9 Hz, C_6-H), 7.82 (1H, d, J=9 Hz, C_5-H), 8.13 (1H, d, J=2 Hz, C_8-H), 15.95 (1H, br, $-COCH=C(O\underline{H})CH_3$). Found: C, 73.54; H, 7.69%. Calcd for $C_{26}H_{32}O_5$: C, 73.56; H, 7.60%.

c): A solution of **21** (84.5 mg) in acetic anhydride (1.8 ml) was treated with boron trifluoride etherate (0.09 ml) as described for the preparation of **24**. The crude product was chromatographed on silica gel (10 g) to give **22** (55.0 mg, 57.9%) and **23** (31.0 mg: 29.4%).

(R)-3-(3-Acetoxypropyl)-8-acetyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (25). A solution of (*R*)-3-(3-acetoxypropyl)-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**IIIc**)[2] (71.0 mg) and acetyl chloride (160 mg) in carbon disulfide (1.4 ml) was added dropwise to a stirred solution of anhydrous aluminium chloride (266 mg) in carbon disulfide (2.7 ml) over a period of 15 min. The mixture was refluxed for 4 h and evaporated *in vacuo*. The residue was decomposed with a mixture of ice and dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The crude product was purified by column chromatography on silica gel (7.0 g), using ether–benzene (3 : 97) as the eluent, to give **25** (43.0 mg: 54.1%). IR: 1802, 1735, 1697, 1642 cm^{-1}; ^1H NMR: δ=1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.62 (3H, s, C_3-CH_3), 1.92 (3H, s, $-OCOCH_3$), 2.54 (3H, s, $-COCH_3$), 2.64 (3H, s, C_4-CH_3), 2.94 (1H, m, $-C\underline{H}(CH_3)_2$), 3.86 (2H, t, J=6.5 Hz, $-C\underline{H}_2OAc$), 7.01 (1H, bs, C_9-H), 7.36 (1H, d, J=9 Hz, C_6-H), 7.91 (1H, d, J=9 Hz, C_5-H). Found: C, 72.98; H, 7.16%. Calcd for $C_{24}H_{28}O_5$: C, 72.70; H, 7.12%.

(R)-2,3-Dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-b]furan-2-one (27). The diazomethane ether solution (600 ml) was prepared from *N*-methyl-*N*-nitrosourea (60 g) by the known procedure and it was then dried over potassium hydroxide. To a stirred solution of (*R*)-2,3-dihydro-3-(3-hydroxypropyl)-7-isopropyl-3,4-dimethylnaphtho[2,3-*b*]-furan-2-one (**26**)[2] (9.94 g) in ether (500 ml) was added successively boron trifluoride etherate (1.9 ml) and the above diazomethane ether solution (600 ml). The mixture was allowed to stand at room temperature for 30 min and then filtered to remove a resinous material. The filtrate was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (300 g), using benzene as the eluent, to give **27** (8.87 g: 85.4%). $[\alpha]_D$ +27° (*c* 1.71); IR: 1792, 1637, 1592 cm^{-1}; ^1H NMR: δ=1.32 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3-CH_3), 2.62 (3H, s, C_4-CH_3), 3.01 (1H, m, $-C\underline{H}(CH_3)_2$), 3.12 (3H, s, $-OCH_3$), 3.13 (2H, t, J=6 Hz, $-C\underline{H}_2OMe$), 7.18 (1H, s, C_9-H), 7.24 (1H, dd, J=2 and 8.5 Hz, C_6-H), 7.48 (1H, d, J=2 Hz, C_8-H), 7.82 (1H, d, J=8.5 Hz, C_5-H). Found: C, 77.28; H, 7.97%. Calcd for $C_{21}H_{26}O_3$: C, 77.27; H, 8.03%.

(3R)-2ξ-Acetoxy-9-acetyl-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-b]furan (29). A mixture of **27** (699 mg) and sodium borohydride (163 mg) in ethanol (35 ml) was stirred at room temperature for 20 h. The mixture was evaporated *in vacuo*, acidified with dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo* to give an epimeric mixture at C-2 of the corresponding alcohol (**28**) (713 mg) which, without purification, was used in the next reaction. IR: 3600, 3350br, 1635, 1593 cm^{-1}; ^1H NMR (60 MHz): δ=1.31 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.37 and 1.44 (3H, each s, C_3-CH_3), 2.59 (3H, s, C_4-CH_3), 2.99 (1H, m, $-C\underline{H}(CH_3)_2$), 3.19 and 3.26 (3H, each s, $-OCH_3$), *ca.* 3.1—3.4 (2H, m, $-C\underline{H}_2OMe$), 4.1 (1H, br, -OH), 5.37 and 5.50 (1H, each bs, *ca.* 1 : 3, C_2-H), 6.84 (1H, s, C_9-H), 7.11 (1H, bd, J=9 Hz, C_6-H), 7.36 (1H, bs, C_8-H), 7.76 (1H, d, J=9 Hz, C_5-H).

Boron trifluoride etherate (0.71 ml) was added to a stirred solution of the above crude **28** (713 mg) in acetic anhydride (14.2 ml) at 0—5 °C. The mixture was stirred at this temperature for 4 min and then treated as described for the preparation of **24**. The crude product was chromatographed on silica gel (90 g), using ether–benzene (5 : 95) as the eluent, to give **29** (618 mg: 70.0% from **27**). IR: 1748, 1675, 1621, 1597 cm^{-1}; ^1H NMR (60 MHz): δ=1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.45 and 1.52 (3H, each s, C_3-CH_3), 2.04 and 2.07 (3H, each s, $C_2-OCOCH_3$), 2.60 (3H, s, C_9-COCH_3), 2.64 (3H, s, C_4-CH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 3.17 and 3.24 (3H, each s, $-OCH_3$), *ca.* 3.1—3.4 (2H, m, $-C\underline{H}_2OMe$), 6.40 and 6.50 (1H, each s, *ca.* 1 : 3, C_2-H), 7.20 (1H, dd, J= 2.5 and 9 Hz, C_6-H), 7.77 (1H, d, J=9 Hz, C_5-H), 8.11 (1H, d, J=2.5 Hz, C_8-H). Found: C, 72.62; H, 7.83%. Calcd for $C_{25}H_{32}O_5$: C, 72.79; H, 7.82%.

(R)-9-Acetyl-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-b]furan-2-one (31). A mixture of **29** (484 mg) and dilute hydrochloric acid (6M: 0.6 ml) in methanol (20 ml) was refluxed for 1 h. The mixture was evaporated *in vacuo* and extracted with ether. The ether extract was washed successively with aqueous sodium hydrogencarbonate and brine, dried over sodium sulfate, and evaporated *in vacuo* to give an epimeric mixture at C-2 of the corresponding alcohol (**30**) (436 mg) which, without purification, was used in the next reaction. IR: 3600, 3325br, 1667, 1619, 1591 cm^{-1}; ^1H NMR (60 MHz): δ=1.33 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.38 and 1.43 (3H, each s, C_3-CH_3), 2.60 (3H, s, C_4-CH_3), 2.63 (3H, s, C_9-COCH_3), 3.02 (1H, m, $-C\underline{H}(CH_3)_2$), 3.17 and 3.24 (3H, each s, $-OCH_3$), *ca.* 3.05—3.35 (2H, m, $-C\underline{H}_2OMe$), 5.49 (1H, bs, C_2-H), 7.16 (1H, dd, J=2 and 9 Hz, C_6-H), 7.78 (1H, d, J=9 Hz, C_5-H), 8.07 (1H, d, J=2 Hz, C_8-H).

A solution of the above crude **30** (436 mg) in acetone (20 ml) was oxidized with Jones' reagent (2 M: 0.8 ml) at 0—5 °C

for 45 min. After the usual work-up, the crude product was chromatographed on silica gel (45 g), using ether–benzene (3 : 97) as the eluent, to give **31** (300 mg: 69.4% from **29**). $[\alpha]_D$ +11° (*c* 4.76); IR: 1805, 1685, 1627, 1597 cm^{-1}; ^1H NMR (60 MHz): δ=1.33 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.63 (3H, s, C_3-CH_3), 2.65 (3H, s, C_4-CH_3), 2.71 (3H, s, C_9-COCH_3), 3.03 (1H, m, $-C\underline{H}(CH_3)_2$), 3.13 (3H, s, $-OCH_3$), 3.15 (2H, t, J=6 Hz, $-C\underline{H}_2OMe$), 7.32 (1H, dd, J=2 and 9 Hz, C_6–H), 7.84 (1H, d, J=9 Hz, C_5–H), 8.07 (1H, d, J=2 Hz, C_8–H). Found: C, 74.77; H, 7.90%. Calcd for $C_{23}H_{28}O_4$: C, 74.97; H, 7.66%.

*Oxidation of **31** with* m-*Chloroperbenzoic Acid.* A mixture of **31** (3490 mg), *m*-chloroperbenzoic acid (85%: 8170 mg), and *p*-toluenesulfonic acid monohydrate (175 mg) in dichloromethane (240 ml) was refluxed for 30 h and then diluted with ether. The ether solution was washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (130 g), using ether–benzene (2 : 98) as the eluent, to give (*R*)-9-acetoxy-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]-furan-2-one (**32**) (395 mg: 10.8%). $[\alpha]_D$ +16° (*c* 1.40); IR: 1807, 1773, 1655, 1623 cm^{-1}; ^1H NMR (60 MHz): δ=1.34 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.64 (3H, s, C_3-CH_3), 2.45 (3H, s, $-OCOCH_3$), 2.62 (3H, s, C_4-CH_3), 2.98 (1H, m, $-C\underline{H}(CH_3)_2$), 3.15 (3H, s, $-OCH_3$), 3.16 (2H, t, J=6 Hz, $-C\underline{H}_2OMe$), 7.37 (1H, dd, J=2 and 9 Hz, C_6–H), 7.62 (1H, bs, C_8–H), 7.94 (1H, d, J=9 Hz, C_5–H). Found: C, 72.12; H, 7.37%. Calcd for $C_{23}H_{28}O_5$: C, 71.85; H, 7.34%. Subsequent elution gave a mixture of **32** and the starting **31** (1320 mg), whose purification is described later. Further elution gave (*R*)-9-acetoxy-2,3,5,8-tetrahydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]furan-2,5,8-trione (**33**) (162 mg: 4.1%). $[\alpha]_D$ +25° (*c* 1.01); IR: 1821, 1779, 1659, 1633, 1607, 1562 cm^{-1}; ^1H NMR (60 MHz): δ=1.20 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.63 (3H, s, C_3-CH_3), 2.42 (3H, s, $-OCOCH_3$), 2.68 (3H, s, C_4-CH_3), 3.04 (1H, m, $-C\underline{H}(CH_3)_2$), 3.16 (3H, s, $-OCH_3$), 3.20 (2H, t, J=6 Hz, $-C\underline{H}_2OMe$), 6.55 (1H, d, J=1.5 Hz, C_6–H). Found: C, 66.83; H, 6.38%. Calcd for $C_{23}H_{26}O_7$: C, 66.65; H, 6.32%.

The above mixture (1320 mg) of **31** and **32** was treated with dilute hydrochloric acid (6 M: 8.0 ml) in refluxing methanol (50 ml) for 1 h. The mixture was concentrated *in vacuo*, diluted with brine, and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (120 g), using ether–benzene (5 : 95) as the eluent, to give the starting **31** (541 mg: 15.5%) and (*R*)-2,3-dihydro-9-hydroxy-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-*b*]furan-2-one (**34**) (706 mg: 21.8%); IR: 3570, 3340br, 1793, 1653, 1620, 1603 cm^{-1}; ^1H NMR (60 MHz): δ=1.33 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3-CH_3), 2.48 (3H, s, C_4-CH_3), 3.18 (3H, s, $-OCH_3$), 7.21 (1H, bd, J=9 Hz, C_6–H), 7.30 (1H, br, –OH), 7.63 (1H, d, J=9 Hz, C_5–H), 7.98 (1H, bs, C_8–H).

A solution of **34** (2.01 g) and acetic anhydride (2.0 ml) in pyridine (2.0 ml) was allowed to stand at room temperature for 1 h. After the usual work-up, the crude product was chromatographed on silica gel (100 g) to give **32** (1.96 g: 86.9%).

*(R)-5,8,9-Triacetoxy-2,3-dihydro-7-isopropyl-3-(3-methoxypropyl)-3,4-dimethylnaphtho[2,3-b]furan-2-one (**35**).* Zinc powder (65 mg) was added to a stirred solution of **33** (85 mg) and acetic anhydride (0.4 ml) in pyridine (0.4 ml) at 0—5 °C. The mixture was stirred at room temperature for 1 h and then treated as described for the preparation of **7**. The crude product was chromatographed on silica gel (30 g), using ether–benzene (1 : 9) as the eluent, to give **35** (46 mg: 45%). $[\alpha]_D$ +18° (*c* 2.33); IR: 1818, 1767, 1654,1628 cm^{-1}; ^1H NMR: δ=1.22 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.59 (3H, s, C_3-CH_3), 2.29, 2.30, and 2.32 (each 3H and s, $C_5-OCOCH_3$, $C_8-OCOCH_3$, and $C_9-OCOCH_3$), 2.67 (3H, s, C_4-CH_3), 3.07 (2H, t, J=6 Hz, $-C\underline{H}_2OMe$), 3.07 (1H, m, $-C\underline{H}(CH_3)_2$), 3.09 (3H, s, $-OCH_3$), 6.96 (1H, s, C_6–H). Found: C, 65.02; H, 6.48%. Calcd for $C_{27}H_{32}O_9$: C, 64.79; H, 6.44%.

*(R)-6-Acetoxy-2,3-dihydro-7-isopropyl-3,4-dimethyl-3-[3-(o-nitrophenylseleno)propyl]naphtho[2,3-b]furan-2-one (**37**).* Tributylphosphine (0.75 ml) was added to a stirred mixture of **8** (242 mg) and *o*-nitrophenyl selenocyanate (665 mg) in pyridine (6.0 ml) at room temperature under a stream of nitrogen. The mixture was stirred at room temperature for 1 h, diluted with ether, and then filtered to remove yellow precipitates. The filtrate was evaporated *in vacuo* to give a crude selenide (**36**), which was immediately acetylated with acetic anhydride (1.0 ml) in pyridine (1.0 ml) at room temperature for 1 h. After the usual work-up, the product was purified by column chromatography on silica gel (150 g), using benzene as the eluent, to give **37** (229 mg: 56.0%). $[\alpha]_D$ +47° (*c* 2.83); IR: 1793, 1752, 1638, 1600, 1588, 1567, 1507, 1330 cm^{-1}; ^1H NMR ($CDCl_3$): δ=1.32 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.64 (3H, s, C_3-CH_3), 2.40 (3H, s, $-OCOCH_3$), 2.55 (3H, s, C_4-CH_3), *ca.* 2.5—3.0 (2H, m, $-C\underline{H}_2SeC_6H_4-$), 3.11 (1H, m, $-C\underline{H}(CH_3)_2$) *ca.* 7.0—7.2 (3H, m) and *ca.* 8.0—8.25 (1H, m) ($-SeC_6\underline{H}_4-$), 7.29 (1H, s, C_9–H), 7.56 (1H, s, C_5–H), 7.66 (1H, s, C_8–H).

*(R)-6-Acetoxy-3-allyl-2,3-dihydro-7-isopropyl-3,4-dimethylnaphtho[2,3-b]furan-2-one (**38**).* A mixture of **37** (229 mg) and 50% hydrogen peroxide (0.26 ml) in tetrahydrofuran (9.2 ml) was stirred at room temperature for 19 h. The mixture was diluted with brine and extracted with ether. The ether extract was washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine, dried over sodium sulfate, and evaporated *in vacuo*. The residue was chromatographed on silica gel (15 g), using benzene as the eluent, to give **38** (129 mg: 88.6%). $[\alpha]_D$ +105° (*c* 2.82); IR: 1794, 1753, 1640, 1622 cm^{-1}; ^1H NMR: δ=1.30 (6H, d, J=7 Hz, $-CH(C\underline{H}_3)_2$), 1.61 (3H, s, C_3-CH_3), 2.32 (3H, s, $-OCOCH_3$), 2.62 (3H, s, C_4-CH_3), 2.76 (2H, d, J=6.5 Hz, $C_3-C\underline{H}_2CH=CH_2$), *ca.* 4.7—5.6 (3H, m, $C_3-CH_2C\underline{H}=C\underline{H}_2$), 7.20 (1H, s, C_9–H), 7.50 (1H, s, C_5–H), 7.58 (1H, s, C_8–H). Found: C, 75.27; H, 7.07%. Calcd for $C_{22}H_{24}O_4$: C, 74.97; H, 6.86%.

The authors are grateful to Messrs. Tatsuo Arioka, Shuji Takauchi, and Yutaka Fukuda for their technical assistance.

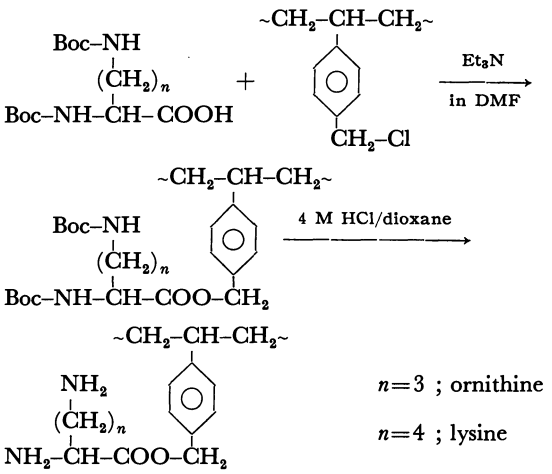
(Received March 9, 1983)

A series of experiments on column chromatography of the optically active resin containing L-lysine or L-ornithine were carried out with pyridinium acetate and ammonium acetate solvent systems as the eluents. *threo*-β-Hydroxy-DL-aspartic acid was found to be resolved on the optically active resin containing L-lysine with ammonium acetate solvent system; *erythro*-β-hydroxy-DL-aspartic acid could be resolved on that containing L-ornithine with pyridinium acetate solvent system. The *threo* or *erythro* racemate was resolved on a preparative scale, and the resolution including the complete characterization of enantiomers resolved was first accomplished.

Resolution of racemic compounds on the optically active resin has become familiar. In the initial stage, the resolution was carried out using naturally occurring adsorbent materials such as wool,[3] (+)-quartz,[4] and cellulose,[5-7] but the optical purity of the enantiomers obtained was low. The possibility of using synthetic optically active polymers as agents for the resolution was first studied by Bunnett and Marks in 1952.[8] The application of this principle to the resolution of racemic amino acids was first reported by Losse *et al.*[9] They attempted to resolve eight kinds of racemic amino acids on three types of copolymers composed by L-tyrosine and some suitable crosslinking agents. Roberts and Haigh also reported the synthesis of polymer of *S*-(*o*- and *p*-vinylbenzyl)-L-cysteine and its use in the partial resolution of DL-methionine.[10] Yamashita and Nakamura synthesized three types of optically active polymers by the homogeneous copolymerization of *N*-acryloylated α-amino acids with *N*,*N*′-dimethacryloyl-1,6-hexanediamine, and then partially resolved several kinds of DL-amino acid anilides by the use of these copolymers.[11] Snyder *et al.* resolved DL-valine, DL-isoleucine, DL-norvaline, DL-α-aminobutyric acid, DL-alanine, and DL-proline on styrene–divinylbenzene copolymers containing (*N*-carboxymethyl-L-valine)copper(II) at 40—70% optical purity.[12] These authors suggested that the degree of resolution increased with an increase in the bulkiness of the side chain on the α-carbon of the amino acid. Davankov *et al.* reported that DL-proline was resolved at 100% optical purity using an asymmetric resin containing optically active L-proline in the Cu^{2+} form.[13] In all cases mentioned above, however, there has been no work on the resolution involving the complete characterization of enantiomers resolved.

One of the present authors has previously reported the resolution of *threo*- or *erythro*-β-hydroxy-DL-aspartic acid by the fractional crystallization of diastereomeric salt.[14] Although the *threo* racemate has been most satisfactorily resolved with L-lysine, and the *erythro* racemate with L-ornitine, these resolutions have required a highly skilled experimental technique. The resolutions of β-hydroxyaspartic acid were expected to become technically easier by the application of these resolutions to column chromatography. So the authors have tried to resolve *threo*- or *erythro*-β-hydroxy-DL-aspartic acid on the optically active resin containing L-lysine or L-ornithine. In this paper, we deal with the preparations of the optically active resins and their use in the resolutions.

The optically active resins were prepared by the modification of the solid phase peptide synthesis by Merrifield.[15,16] N^{α}, N^{ϵ}-Bis(*t*-butoxycarbonyl)-L-lysine and chloromethylated styrene–divinylbenzene copolymer (PS–DVB) (DVB 2%, 200—400 Mesh, 1.32 mmol of Cl/g-resin) were coupled in *N*,*N*-dimethylformamide containing triethylamine for 72 h at 50 °C. The desired resin was afforded by the removal of the *t*-butoxycarbonyl group from the resin mentioned above by treatment with hydrogen chloride in dioxane for 90 min at room temperature. After the acidic hydrolysis



of the prepared resin, L-lysine content was determined by amino acid analysis and found to be 0.58 mmol/g-resin (correspond to 44% yield). L-Ornithylstyrene–divinylbenzene copolymer (Orn-PS–DVB) was prepared in the same manner as described for the preparation of L-lysylstyrene–divinylbenzene copolymer (Lys-PS–DVB) ;the L-ornithine content was 0.97 mmol/g-resin (yield 73%). The chromatography was carried out as follows: The aqueous solution of an aliquot of the racemate was applied to a column (1.2×10 cm) and eluted with various solvent systems at room temperature and

a flow rate of *ca.* 5 ml h^{-1}.

The elution patterns of *threo*-β-hydroxy-DL-aspartic acid with 0.1 M (1 M=1 mol dm^{-3}) pyridinium acetate solvent system are shown in Fig. 1. The effect of variation of pH was examined on Lys-PS–DVB and Orn-PS–DVB; in no cases was any *threo* racemate resolved. A similar experiment was run by the use of 0.1 M ammonium acetate instead of 0.1 M pyridinium acetate as an eluent. The elution patterns of the *threo* racemate are shown in Fig. 2. The *threo* racemate was successfully resolved with the column of Lys-PS–DVB using 0.1 M ammonium acetate of pH 8.0. It was confirmed that D-isomer eluted faster than L-isomer by separately eluting each enantiomer under the conditions described above. The effect of variation in concentration of ammonium acetate in the solvent system was also examined on Lys-PS–DVB; 0.1 M concentration proved to be the optimal condition for the resolution of the *threo* racemate (Fig. 3).

The resolution of *erythro*-β-hydroxy-DL-aspartic acid was carried out with column of Lys-PS–DVB and Orn-PS–DVB using 0.1 M pyridinium acetate of pH 4.0, 6.0, and 8.0. The elution patterns of the *erythro* racemate are shown in Fig. 4. The *erythro* racemate was found

to be successfully resolved with the column of Orn-PS–DVB using 0.1 M pyridinium acetate of pH 8.0. The faster peak was eluted easily, as shown in Fig. 4, whereas 2.0 M acetic acid was required for the elution of the slower peak. The faster peak proved to be L-isomer, and the slower peak was D-isomer.

As an experiment on a preparative scale, we attempted to resolve the *threo* racemate with the column (1.8×40 cm) of Lys-PS–DVB, and the *erythro* racemate with the column of Orn-PS–DVB, under the optimal conditions which had been found previously for the resolutions on a smaller scale. Two hundred milligrams of *threo*-β-hydroxy-DL-aspartic acid was resolved, and the eluate containing each enantiomer was collected. The resolution was repeated five times, and each faster (or slower) peak was combined. We observed the presence of a small amount of lysine in the collected eluates, which seemed to be attributable to the liberation of lysine from the resin. After the removal of lysine by ion-exchange chromatography with an appropriate eluent,

a) The yields are based on Cl content (1.32 mmol/g-resin) of chloromethylated PS-DVB (DVB 2%, 200—400 Mesh).
b) The amounts of liberated amino acids below 0.01 mmol/g-resin are described as <0.01, and the percentages of liberation below 1% as <1.

the faster fraction (containing D-isomer) or the slower fraction (containing L-isomer) was concentrated *in vacuo*; optically pure *threo*-β-hydroxy-D-aspartic acid or *threo*-β-hydroxy-L-aspartic acid was obtained, in a good yield. *erythro*-β-Hydroxy-DL-aspartic acid was resolved by the elution of 500 mg of the racemate. Each enantiomer was obtained in the same manner as described for the resolution of the *threo* racemate. The specific rotations and yields of the four optical isomers so obtained are summarized in Table 1, together with those obtained by the fractional crystallization. As shown in Table 1, it was obvious that the *threo* or *erythro* racemate was completely resolved. This chromatographic procedure was far more useful than the resolution by the fractional crystallization: Such as could be obtained both a high yield and high optical purity, in a chemical procedure, were given by a facile operation.

In order to estimate the degree of the above-mentioned spontaneous degradation in PS-DVB substituted with amino acids, the authors prepared twelve kinds of resins, including Lys-PS-DVB and Orn-PS-DVB, and compared the liberations of amino acids from resins. They were prepared in the same manner as described for the preparations of Lys-PS-DVB and Orn-PS-DVB. Amino acid contents of resins are shown in Table 2. An aliquot of each resin so obtained was immersed in 0.1 M pyridinium acetate of pH 4.0, 6.0, and 8.0 for 7 d at room temperature, and the liberated amino acid in the supernatant was determined by amino acid analysis (Table 2). Table 2 revealed the liberations of amino acids from resins, whereas amino acid benzyl esters in liquid phase were not entirely hydrolyzed under such mild conditions. The percentage of the liberated amino acid based on each amino acid content varied with the kinds of bonded amino acid. Gly-, Ala-, Pro-, and Lys-PS-DVB were unstable, while the resins containing amino acids possessing hydrophobic side chains were relatively stable. The variation of pH in the solvent also affected the liberation. The degree of liberation was greater under the acidic conditions than under the neutral and basic conditions, but only Lys-PS-DVB was unstable under the neutral conditions. These phenomena were greatly different from the commonly known propensity of hydrolysis of amino acids benzyl ester in aqueous acidic or basic solution. It seemed that an amino acid benzyl ester fixed on the stationary phase behaved in different ways from that in the liquid phase.

There have been some reports on successful resolutions of racemic amino acid derivatives by gas chromatography on optically active stationary phases,[17,18] but they have been used only on the analytical scale for the determination of configurations and optical purity and have restricted the variation of the racemates. For the resolutions of various kinds of racemic amino acids on a preparative scale, liquid-chromatographic resolutions have been more effective than gas-chromatographic resolutions. This report is the first on the complete resolution of a racemic amino acid on the

optically active stationary phase. It will be possible to apply the principles of this procedure to the resolutions of other racemic amino acids.

Experimental

All the melting points were uncorrected. The optical rotations were measured on a Union PM-101 Polarimeter. The quantitative analyses of amino acids were run with the high-performance liquid chromatography (HPLC) apparatus composed of; Toyo soda HLC-805, Toyo soda solvent feeder, Toyo soda sequence controller, Toyo soda reactor, Shimadzu fluorescence spectromonitor RF-500LC (for phthalaldehyde as fluorogenic reagent), Toyo soda visible spectrophotometer (for ninhydrin as color-developing reagent), and TSK pen recorder. The amounts of color developed were determined by an Atago AG-4 densitometer (slit 1 × 18 mm, 610 nm).

Syntheses of N-*(t-Butoxycarbonyl) Amino Acid Derivatives.* All the *N*-(*t*-butoxycarbonyl) amino acid derivatives were synthesized by the ordinary manner. *N*-(*t*-Butoxycarbonyl) derivatives of lysine, ornithine, valine, isoleucine, phenylalanine, tyrosine, serine, and threonine were stored as a DCHA salt, and that of leucine as the hemihydrate. Boc–Lys(Boc)–OH·DCHA: mp 134—136 °C; $[\alpha]_D^{20}$ −4° (*c* 3, AcOH). Boc–Orn(Boc)–OH·DCHA: mp 164—166 °C; $[\alpha]_D^{20}$ +2° (*c* 4, AcOH). Boc–Gly–OH: mp 93—94 °C (lit,[19] 94—95 °C). Boc–Ala–OH: mp 81–83 °C (lit,[20] 83—84 °C); $[\alpha]_D^{20}$ −22° (*c* 1, AcOH) (lit,[20] −24° (*c* 1, AcOH)). Boc–Val–OH·DCHA: mp 138—140 °C; $[\alpha]_D^{20}$ −1° (*c* 4, AcOH). Boc–Leu–OH·1/2 H_2O: mp 80—82 °C (lit,[19] 78—81 °C); $[\alpha]_D^{20}$ −21° (*c* 2, AcOH). Boc–Ile–OH·DCHA: mp 125—127 °C (lit,[21] 127—128 °C); $[\alpha]_D^{20}$ +7° (*c* 1.5, DMF) (lit,[21] +6° (*c* 1.5, DMF)). Boc–Phe–OH·DCHA: mp 213—214 °C (lit,[22] 210—212 °C); $[\alpha]_D^{20}$ +30° (*c* 1, methanol) (lit,[22] +29.2° (*c* 1.025, methanol at 23 °C)). Boc–Tyr–OH·DCHA: mp 208—210 °C (lit,[20] 205—208 °C); $[\alpha]_D^{20}$ +4° (*c* 1, AcOH) (lit,[20] +3.8° (*c* 1, AcOH)). Boc–Pro–OH: mp 133—134 °C (lit,[23] 133—134 °C); $[\alpha]_D^{20}$ −59° (*c* 2, AcOH) (lit,[23] −60.8° (*c* 2.04, AcOH at 25 °C)). Boc–Ser–OH·DCHA: mp 140—142 °C (lit,[24] 142—144 °C); $[\alpha]_D^{20}$ +13° (*c* 3, methanol) (lit,[24] +13.3° (*c* 3.044, methanol at 25.5 °C)). Boc–Thr–OH·DCHA: mp 148—151 °C; $[\alpha]_D^{20}$ −2° (*c* 4, AcOH). Elemental analyses of these compounds also agreed with the theoretical values.

Preparations of Optically Active Resins. L-*Lysylstyrene–divinylbenzene Copolymer (Lys-PS–DVB)*: The chloromethylated PS–DVB (DVB 2%, 200—400 Mesh, 1.32 mmol of Cl/g-resin) (10.0 g) was suspended in DMF (80 ml). The suspension was degassed for 1 h *in vacuo*. The solvent was decanted and the residual resin was washed three times with DMF by decantation. Boc–Lys(Boc)–OH which was released from its DCHA salt (13.9 g, 26.4 mmol) with 1 M sulfuric acid in the usual manner was dissolved in DMF (80 ml). The solution and triethylamine (3.3 ml, 23.8 mmol) were added to the residual resin and the mixture was shaken for 72 h at 50 °C. Then the resin was filtered, washed throughly with DMF, acetic acid, methanol, DMF, and methanol by gradual changes of solvent composition and sucked dry. The resin was kept overnight in a vacuum desiccator: yield 12.8 g. The resulting resin was suspended in dioxane (80 ml) and the suspension was degassed for 1 h *in vacuo*. The solvent was decanted and the residual resin was washed three times with dioxane by decantation. To the residual resin, 4 M hydrogen chloride in dioxane (50 ml) was added. After shaking for 90 min at room temperature, the resin was filtered, washed with dioxane, 1 M acetic acid, water and finally methanol and sucked dry. The resin was kept overnight in a vacuum desiccator: yield 11.0 g. Lys-PS–DVB (41 mg) weighed out precisely was introduced into a tube and hydrolyzed with a mixture of 6 M HCl (0.5 ml) and propionic acid (0.5 ml) at 110 °C in a sealed tube for 24 h. Lys-PS–DVB was filtered and the filtrate was evaporated to dryness *in vacuo*. The residue was dissolved in water (1.0 ml) and the solution was diluted with water. Lysine content was determined by applying a part of the dilute solution on HPLC and found to be 0.58 mmol/g-resin. The PS–DVB substituted with ornithine, glycine, alanine, valine, leucine, isoleucine, phenylalanine, tyrosine, proline, serine, and threonine were prepared in the same manner as described for the preparation of Lys-PS–DVB. *N*-(*t*-Butoxycarbonyl) derivatives of glycine, alanine and proline were used for the coupling directly, and Boc–Leu–OH·1/2 H_2O was used after dehydration. The amino acid content of each resin is presented in Table 2.

Resolution of threo- *or* erythro-DL-*Hyasp on Optically Active Resin.* *Resolution of* threo-DL-*Hyasp*: Lys-PS–DVB or Orn-PS–DVB (7.5 g) was packed into a column (1.2 × 10 cm); each column was equilibrated by washing with an eluent. 0.1 M ammonium acetate was prepared in the following manner. Ammonium acetate (7.7 g) was dissolved in water (500 ml), and the pH of the solution was adjusted with acetic acid. The solution was made up to 1 L with water, and adjusted again to the desired pH by acetic acid or aqueous ammonia. 0.1 M Pyridinium acetate was also prepared in the same manner by using pyridine (8.1 ml) instead of ammonium acetate. The solution of *threo*-DL-Hyasp[14] (20 mg/1 ml water) was put on the column and eluted with the appropriate solvent system at room temperature and a flow rate of *ca.* 5 ml h^{-1}. The volume of each fraction was one milliliter. When the elution volume exceeded 90 ml, 2.0 M acetic acid was used as an eluent. The color development, the determination of the developed color, and the plotting on a graph were run according to the manner by H. Okai *et al.*[14] The elution patterns are shown in Fig. 1—3.

Resolution of erythro-DL-*Hyasp*: *erythro*-DL-Hyasp[14] (20 mg) was treated in the same manner as has been described for the resolution of *threo*-DL-Hyasp. For the elution of the slower peak, 2.0 M acetic acid was used as an eluent. The elution patterns are shown in Fig. 4.

Preparative Resolution of threo-DL-*Hyasp*: A solution of *threo*-DL-Hyasp[14] (0.2 g) in a suitable volume (*ca.* 10 ml) of 0.1 M ammonium acetate solvent of pH 8.0 was put on a column (1.8 × 40 cm) of Lys-PS–DVB (70 g, 0.63 mmol of Lys/g-resin), and eluted with the same solvent at a flow rate of *ca.* 10 ml h^{-1}. Each fraction (2 ml) was tested on a paper strip with ninhydrin, and then the ninhydrin-positive fractions were applied on paper chromatography (developing solvent, 1-butanol–acetic acid–pyridine–water (4 : 1 : 1 : 2, v/v)) to find the fractions containing hydroxyaspartic acid. The resolution of 0.2 g of the racemate was repeated five times in the above-mentioned manner. The faster eluting fractions were combined and then evaporated to dryness *in vacuo*. Most of the ammonium acetate was removed by sublimation *in vacuo* for *ca.* 1 h at 100 °C. To remove the contaminated lysine, the residue was treated with Dowex 1 (acetate form). A column (1.8 × 12 cm) of Dowex 1 was washed with 0.5 M acetic acid (30 ml) and then with 2.0 M acetic acid (70 ml) to elute hydroxyaspartic acid. The residue obtained by the evaporation of the eluate was crystallized from water–ethanol: yield of *threo*-D-Hyasp 0.42 g (84%).

Found: C, 31.99; H, 4.88; N, 9.32%. Calcd for $C_4H_7O_5N$: C, 32.22; H, 4.73; N, 9.40%. The slower eluting fractions were combined and then treated in the manner described above: yield of *threo*-L-Hyasp 0.40 g (80%).

Found: C, 31.96; H, 4.90; N, 9.28%. The specific rotations of each enantiomer are presented in Table 1.

Preparative Resolution of erythro-DL-*Hyasp*: A solution of *erythro*-DL-Hyasp[14] (0.5 g) in a suitable volume (*ca.* 20 ml) of 0.1 M pyridinium acetate of pH 8.0 was put on a column (1.8×40 cm) of Orn-PS–DVB (70 g, 0.91 mmol of Orn/g-resin), and eluted with the same solvent at a flow rate of *ca.* 10 ml h^{-1}. After the faster eluting fractions containing hydroxyaspartic acid were found in the above-mentioned manner, 2.0 M acetic acid was used as an eluent. The resolution was repeated twice, and *erythro*-L-Hyasp was obtained from the faster eluting fractions by the method described for the separation of *threo*-D-Hyasp: yield of *erythro*-L-Hyasp 0.46 g (92%).

Found: C, 32.02; H, 4.82; N, 9.35%. The slower eluting fractions were combined and then treated as in the separation of *threo*-D-Hyasp: yield of *erythro*-D-Hyasp 0.45 g (90%).

Found: C, 32.18; H, 4.77; N, 9.42%. The specific rotations of each enantiomer are presented in Table 1.

Spontaneous Degradation. Determination of Liberated Amino Acid: The prepared resin (*ca.* 300 mg) was weighed out precisely and introduced into three test tubes. To the tubes 6.0 ml of 0.1 M pyridinium acetate (pH 4.0, 6.0, and 8.0) were added; the tubes were then sealed and allowed to stand at room temperature. The time-course of the spontaneous degradation was followed by determining the amino acid in the supernatant at daily intervals. The supernatant (0.5 ml) was withdrawn and evaporated to dryness *in vacuo*, and an aliquot of the residue was applied on HPLC. The amounts of the amino acids in the supernatant at each time were derived by correcting the experimental values, and those at zero time were subtracted from those at each time. The amounts of the liberated amino acids after 7 d are presented in Table 2.

We wish to express our thanks to Professor Nobuo Izumiya of Kyushu University and Professor Sakuzo Fukui of Hiroshima University for their helpful discussions.

Synthetic Studies on the Validamycins. IX. Synthesis of Some Racemic Isomers of Validoxylamine A[1]

Tatsushi Toyokuni, Seiichiro Ogawa, and Tetsuo Suami*
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Kohoku-ku, Yokohama 223
(Received March 23, 1983)

Two racemic isomers of validoxylamine A have been synthesized by use of coupling reactions of the protected DL-validamine and the allyl bromides, the precursors of the unsaturated branched-chain cyclitol moiety. The racemic diastereomers thus formed can be separated by chromatography on silica gel. It indicates that optically pure validoxylamine A analogs should be obtained if chiral validamine derivative is used in place of the racemate.

The validamycins,[2] isolated from the culture filtrate of *Streptomyces hygroscopicus* var. *limoneous*, is a complex mixture of novel aminocyclitol antibiotics[3] containing a single amino group linked to two separate branched-chain cyclitols. The antibiotics are widely used for the treatment of sheath blight disease of rice plants. Among them, validamycin A (**1**) is the major and most active component.[4]

Hydrolysis of **1** with 1 M (=1 mol dm^{-3}) sulfuric acid gave validoxylamine A (**2**)[5,6] and D-glucose. Compound **2** was assigned as *N*-[(1*S*)-(1,4,6/5)-3-hydroxymethyl-4,5,6-trihydroxycyclohex-2-enyl]-(1*S*)-(1,2,4/3,5)-2,3,4-trihydroxy-5-(hydroxymethyl)cyclohexylamine, and was also found in the validamycin producing culture.[4b] It is not only an aglycon part of **1** but also a common structural unit of other validamycins (C, D, E, and F),[7] except for validamycin B which has validoxylamine B,[8] the C-6 hydroxy analog of **2**, as an aglycon. Although **2** showed a low activity compared with validamycin A in the "dendroid-test method," it exhibits a considerable activity in the green house test.[4b]

Validoxylamine A octa-O-acetate (3)	Ac	Ac

As a part of the study directed toward the total synthesis of **1** and the related substances,[9] we now wish to describe the stereoselective synthesis of two racemic isomers of **2**, that is, "reversed" validoxylamine A (**18a** and **18b**) and 1′-epivalidoxylamine A (**23a** and **23b**), in order to elucidate the structure activity relationships of this type of pseudo-disaccharides. For the synthesis of the validoxylamine A analogs, we have undertaken a coupling reaction of the protected DL-validamine (**11**) and appropriate allyl bromides (**15** and **19**),[10] the precursors of the unsaturated branched-chain cyclitol moiety.

Results and Discussion

Preparation of Protected DL-*Validamine.* Di-*O*-isopropylidene derivative **11** of DL-validamine was prepared from readily available DL-1,2,3-tri-*O*-acetyl-(1,3/2,4,6)-4-bromo-6-acetoxymethyl-1,2,3-cyclohexanetriol (**4**).[11]

Hydrolysis of **4** with 2 M hydrochloric acid yielded the hydroxy compound **5**, which was then treated with 2,2-dimethoxypropane in *N*,*N*-dimethylformamide (DMF) in the presence of a small amount of *p*-toluenesulfonic acid at 60 °C to give the di-*O*-isopropylidene derivative **9** in 77% overall yield. When **9** was allowed to react with sodium azide in dimethyl sulfoxide at 110 °C, the azido compound **10** was produced in 78% yield. In agreement with the inversion of the configuration at C-4, the ^{1}H NMR spectrum of **10** showed a quartet (J= 3 Hz) at δ=4.26, assignable to the C-4 equatorial proton.

Alternatively, **10** was provided, in less satisfactory yield, from DL-1,2,3-tri-*O*-acetyl-(1,3,4/2,6)-6-acetoxymethyl-4-azido-1,2,3-cyclohexanetriol (**6**),[11] which was obtained by treatment of **4** with sodium azide. Thus, *O*-deacetylation of **6** with methanolic sodium methoxide gave the hydroxy compound **7** in 52% yield, together with elimination product, DL-(1,3/2,4)-4-hydroxymethyl-5-cyclohexene-1,2,3-triol (**8**) in 12% yield. Similar isopropylidenation of **7** afforded **10** in 83% yield.

The IR spectrum and the elemental analysis supported the assigned structure of **8**.[12] As far as we are aware, such an elimination of an azido function as hydrazoic acid under basic conditions have not hitherto been encountered in the literature except for the report by Uryu *et al.*[13]

Catalytic hydrogenation of **10** with Raney nickel T-4[14] in ethanol gave the protected validamine **11** in 76% yield, which was further characterized as the *N*-acetyl derivative **12**. As it is well known that introduction of the electron-withdrawing group into an amino group increases the nucleophilicity of the nitrogen atom,[15] the *N*-(*p*-tolysulfonyl) **13** and *N*-(trifluoroacetyl) derivatives

14 were prepared as the nucleophiles for the allyl bromides.

Synthesis of Racemic Reversed Validoxylamine A. The allyl bromide, DL-1,3,4-tri-*O*-acetyl-(1,2,4/3)-5-bromomethyl-5-cyclohexene-1,2,3,4-tetrol (**15**), was prepared according to the procedure described previously.[10] The coupling reaction of **11** with **15** in chloroform in the presence of *N,N*-diisopropylethylamine under reflux for 3 d, followed by the conventional acetylation, gave the expected two racemic isomers **16a** and **16b** in 80% yield. Isolation of the diastereomeric mixture by use of a silica-gel column eluting with 1 : 3 2-butanone–toluene gave **16a** (19%) and **16b** (27%). In agreement with the postulated structures, the ^{1}H NMR spectra of **16a** and **16b** showed the presence of four acetoxyl and two isopropylidene groups. The splitting pattern of the signals due to the ring protons of the unsaturated cyclitol moiety appeared to be somewhat different each other. The elemental analyses were also consistent with their structures.

Removal of the isopropylidene groups of **16a** and **16b**, followed by acetylation, gave the corresponding octa-*O*-acetyl derivatives **17a** and **17b**, respectively. The ^{1}H NMR spectra of **17a** and **17b** were very similar and the C-2′ olefinic proton of **17b** resonated at higher field (0.07 ppm) than that of **17a**. It is noteworthy that acetylation, even under the forcing conditions, gave no *N*-acetylated compound.

O-Deacetylation of **17a** and **17b** was effected by treatment with methanolic sodium methoxide in methanol to give the racemic "reversed" validoxylamine A (**18a** and **18b**), respectively. They showed the similar chromatographic behaviors (R_f 0.11) on TLC [4 : 1 : 1 1-propanol–acetic acid–water, *cf.* validoxylamine A (**2**):[16] R_f 0.33]. In the present stage, it is not possible to determine which diastereomer is which, for instance, on

the basis of ^{1}H NMR spectroscopy.

Synthesis of Racemic 1'-Epivalidoxylamine A. Next the synthesis of the racemic 1'-epivalidoxylamine A (**23a** and **23b**) was carried out by a coupling of **11** with DL-1,2,3-tri-*O*-acetyl-(1,3,6/2)-4-acetoxymethyl-6-bromo-4-cyclohexene-1,2,3-triol (**19**).[10]

When molar equivalent of **11** and **19** were allowed to react in DMF in the presence of *N,N*-diisopropylethylamine at room temperature for 20 d, the pseudo-disaccharide **21a** and **21b** were obtained mainly, after chromatography on silica gel, as a homogeneous mixture in 40% yield, together with a mixture of pentaacetate **24** and **25**[10] (7%), a mixture of tetraacetate **26** and **27**[10] (23%), the *N*-acetyl derivative **12** (18%) of **11**, and recovered **11** (17%). These compounds were identified with authentic samples by comparing the ^{1}H NMR spectra. In the ^{1}H NMR spectrum of the mixture of **21a** and **21b**, the signals for the isopropylidene and acetoxymethyl groups appeared at δ=1.36—1.56 and 1.92—2.20, respectively, and that of the olefinic proton at δ=5.83.

For the synthesis of validoxylamine A, the C-6 epimer **20** of **19** would be a desirable substrate, if the nucleophilic substitution reaction with **11** proceeds *via* an S_N2 mechanism. As **20** had not been available as a pure compound, a 3.5 : 1 mixture of **19** and **20** was used in the coupling reaction with **11**. However, the reaction gave no desired products at all but the same mixture of products as was obtained from **19**. This facts indicate that the reaction pathway might be independent of the configuration of the allylic bromine atom, and the reaction mechanism may be speculated as follows: Due to a low nucleophilicity of **11**, **20** is likely to be converted into the 1,6-cyclic acetoxonium ion, by neighboring group participation of the C-1 acetoxyl group, which is cleaved by moisture or a back-side attack of **11** at C-6. On the other hand, **19** may suffer an S_N2 attack by **11** and/or by a bromide ion generated from the initial reaction of **19** with **11**, giving rise to an equilibrium mixture of **19** and **20**.

	X	Y
24	H	OAc
25	OAc	H

	R^1	R^2
26	H	Ac
27	Ac	H

The similar reaction was carried out by using **13** or **14** instead of **11**. However, desired secondary amines were not obtained at all, presumably due to the steric hindrance.

When the coupling reaction was conducted at elevated temperature (60 °C), the formation of the side-products became preferable.

Separation of the mixture of **21a** and **21b** was not possible because of their similar chromatographic behaviors. Removal of the isopropylidene groups, followed by the conventional acetylation, gave the diastereomeric mixture (**22a** and **22b**) of 1'-epivalidoxylamine A octaacetate, which were fractionated by a silica-gel column with 1 : 2 ethyl acetate–toluene to give **22a** and **22b** in 23 and 41% isolated yields, respectively. Their elemental analyses and ^{1}H NMR spectral data were consistent with the structures proposed. In both ^{1}H NMR spectra, the signals due to the acetoxymethyl protons of the saturated cyclitol moiety and those of the unsaturated cyclitol moiety could be assignable.

Compounds **22a** and **22b** showed R_f 0.40 and 0.35, respectively on TLC in 1 : 1 ethyl acetate–toluene, while validoxylamine A octaacetate (**3**)[17] R_f 0.32. The ^{1}H NMR spectrum of **3** revealed a doublet (J=5.3 Hz) at δ=5.95, ascribable to the C-2 olefinic proton, whereas those of **22a** and **22b** have a broad singlet at δ=5.70 and 5.65, respectively, indicative of the pseudoequatorial orientation of the imino group.

It is interesting to note that, in the ^{1}H NMR spectrum of **22b**, the chemical shifts and the splitting pattern of the signals due to the ring protons of the saturated cyclitol part as well as the acetoxylmethyl protons resemble those of **3**, suggesting that **22b** adopts more similar conformation to that of **3** in chloroform than does **22a**. Similar to the case of the reversed validoxylamine A, the *N*-acetyl derivatives of 1'-epivalidoxylamine A could not be prepared.

O-Deacetylation of **22a** and **22b** with sodium methoxide in methanol afforded the racemic 1'-epivalidoxylamine A (**23a**) and (**23b**), respectively, which showed almost similar mobilities (*Rf* 0.28) on TLC in 4 : 1 : 1 1-propanol–acetic acid–water [*cf.* validoxylamine A (**2**): R_f 0.31].

The present results indicate that resolution of the coupling products should be possible by using optically active validamine[18] instead of the racemate. Biological and biochemical studies on the isomers of validoxylamine A obtained here are on the way.

Experimental

Melting points were determined on a Büchi 510 capillary melting point apparatus and are uncorrected. ^{1}H NMR spectra were recorded on a Varian EM-390 (90 MHz) spectrometer in chloroform-*d*. Chemical shifts were reported as ppm relative to tetramethylsilane as an internal standard. TLC was performed on precoated silica gel 60 F-254 plates (Merck, Darmstadt; 0.25 mm thickness), and the spots were visualized by concd sulfuric acid spray (heating at 120 °C) or ninhydrin spray. Conventional chromatography was carried out with Wakogel C-300 (silica gel, Wako Pure Chemical Industries, Ltd.). Solutions were dried over anhydrous sodium sulfate and concentrated below 50 °C under reduced pressure. Catalytic hydrogenation was carried out in a Parr shaker type apparatus in the initial hydrogen pressure of 3.5 kg/cm^2 at room temperature.

DL-*(1,3/2,4,6)-4-Bromo-6-hydroxymethyl-1,2,3-cyclohexanetriol (5).* To a solution of DL-1,2,3-tri-*O*-acetyl-(1,3/2,4,6)-6-acetoxymethyl-4-bromo-1,2,3-cyclohexanetriol (**4**)[11] (2.84 g) in ethanol (18 ml) was added 2 M hydrochloric acid (17 ml), and the mixture was heated for 3 h at 80 °C. The mixture was evaporated and then coevaporated with ethanol several times to give a crystalline residue, which was recrystallized from ethanol giving **5** (1.5 g, 90%): mp 155.5—156 °C.

Found: C, 34.97; H, 5.26; Br, 33.28%. Calcd for $C_7H_{13}BrO_4$: C, 35.09; H, 5.43; Br, 33.15%.

DL-*1,7:2,3-Di-O-isopropylidene-(1,3/2,4,6)-4-bromo-6-hydroxymethyl-1,2,3-cyclohexanetriol (9).* A mixture of **5** (1.40 g), 2,2-dimethoxypropane (DMP) (21 ml), *p*-toluenesulfonic acid monohydrate (TsOH) (35 mg), and *N,N*-dimethylformamide (DMF) (30 ml) was heated for 3 h at 60 °C. The mixture was then neutralized with Amberlite IRA-400 (OH^-) and concentrated to dryness. Recrystallization of the crude product from ethanol gave **9** (1.56 g, 86%) as feathers: mp 148—149 °C; ^{1}H NMR (60 MHz)[19] δ=1.45 (6H, s) and 1.68 (6H, s) (isopropylidene), 1.71—2.31 (3H, m, H-5, H-5', and H-6), and 3.30—4.20 (6H, m, H-1, H-2, H-3, H-4, and C$\underline{H}_2$O).

Found: C, 48.59; H, 6.51; Br, 24.79%. Calcd for $C_{13}H_{21}BrO_4$: C, 48.61; H, 6.59; Br, 24.88%.

DL-*(1,3,4/2,6)-4-Azido-6-hydroxymethyl-1,2,3-cyclohexanetriol(7) and* DL-*(1,3/2,4)-4-Hydroxymethyl-5-cyclohexene-1,2,3-triol (8).* To a solution of DL-1,2,3-tri-*O*-acetyl-(1,3,4/2,6)-4-azido-6-acetoxymethyl-1,2,3-cyclohexanetriol (**6**)[11] (1.36 g) in methanol (80 ml) was added 1 M methanolic sodium methoxide (2.0 ml), and the mixture was allowed to stand at room temperature overnight. After treatment with Amberlite IR-120 (H^+) resin, the mixture was concentrated to a syrup, which was shown by TLC to contain two components (R_f 0.42 and 0.33, 3 : 1 chloroform–methanol). The products were fractionated on a silica-gel column (30 g) with 3 : 1 chloroform–methanol as an eluent. The first fraction gave **7** (378 mg, 52%) as feathers: mp 112.5—113 °C.

Found: C, 41.13; H, 6.33; N, 20.41%. Calcd for $C_7H_{13}N_3O_4$: C, 41.38; H, 6.45; N, 20.68%.

The second fraction gave **8** (70 mg, 12%): mp 136—138 °C; ^{1}H NMR (90 MHz)[20] δ=2.13—2.47 (1H, m, H-4), 3.39—4.15 (5H, H-1, H-2, H-3, and C$\underline{H}_2$OH), and 5.60 (2H, s, H-5 and H-6), identical with the compound obtained by the different route.[12]

DL-*1,7 : 2,3-Di-O-isopropylidene-(1,3,4/2,6)-4-azido-6-hydroxymethyl-1,2,3-cyclohexanetriol (10).* *a)*: A mixture of **7** (284 mg), DMP (5 ml), TsOH (8 mg), and DMF (9 ml) was heated for 3 h at 60 °C. After neutralization with Amberlite IRA-400 (OH^-) resin, the mixture was concentrated, and the residue was crystallized from ethanol giving **10** (329 mg, 83%) as needles: mp 109—110.5 °C; ^{1}H NMR (90 MHz) δ=1.45 (6H, s) and 1.50 (6H, s) (isopropylidene), 3.51 (1H, dd, J=3 and 9 Hz, H-3), 3.60—3.87 (3H, m, H-1 and C$\underline{H}_2$O), 3.98 (1H, t, J=9 Hz, H-2), and 4.26 (1H, q, J=3 Hz, H-4).

Found: C, 55.33; H, 7.46; N, 14.71%. Calcd for $C_{13}H_{21}N_3O_4$: C, 55.11; H, 7.47; N, 14.83%.

b): A mixture of **9** (1.40 g), sodium azide (1.47 g, 4 molar equivalent), and dimethyl sulfoxide (30 ml) was heated at 110 °C for 15 h. The mixture was then diluted with ethyl acetate and washed with water thoroughly. The organic layer was dried and concentrated, and the residue was recrystallized from ethanol giving **10** (960 mg, 78%), identical with the compound obtained from **9**.

DL-*1,7:2,3-Di-O-isopropylidene-(1,3,4/2,6)-4-amino-6-hydroxymethyl-1,2,3-cyclohexanetriol*[DL-*Di-O-(isopropylidene)validamine*] *(11).* A solution of **10** (946 mg) in ethanol (30 ml) was hydrogenated in the presence of Raney nickel T-4[14] (one spoonful) at room temperature overnight. The catalyst was removed by filtration and the filtrate was concentrated to give a crystalline residue, which was recrystallized from ethanol giving **11** (653 mg, 76%) as needles: mp 153—154 °C; ^{1}H NMR (90 MHz) δ=1.43 (9H, s) and 1.50 (3H, s) (isopropylidene), 3.42 (1H, dd, J=3 and 9 Hz, H-3), 3.53—3.81 (4H, m, H-1, H-4, and C$\underline{H}_2$O), and 3.97 (1H, t, J=9 Hz, H-2).

Found: C, 60.59; H, 8.72; N, 5.65%. Calcd for $C_{13}H_{23}NO_4$: C, 60.67; H, 9.00; N, 5.44%.

DL-*1,7: 2,3-Di-O-isopropylidene-(1,3,4/2,6)-4-acetamido-1,2,3-cyclohexanetriol (12).* Compound **11** (30 mg) was treated with acetic anhydride (1 ml) in pyridine (1 ml) at room temperature overnight. The mixture was concentrated to a syrup, which was purified by passage through a short column of alumina with chloroform. The eluate was concentrated and the residue was crystallized from ethanol giving **12** (29 mg, 84%) as prisms: mp 231—232 °C; ^{1}H NMR (90 MHz) δ=1.43 (3H, s), 1.47 (6H, s), and 1.51 (3H, s) (isopropylidene), 2.00 (3H, s, NAc), 3.37—3.83 (5H, m, H-1, H-2, H-3, and C$\underline{H}_2$O), 4.33—4.57 (1H, m, H-4), and 6.04 (1H, m, N$\underline{H}$).

Found: C, 60.30; H, 8.28; N, 4.68%. Calcd for $C_{15}H_{25}NO_5$: C, 60.17; H, 8.43; N, 4.68%.

DL-*1,7: 2,3-Di-O-isopropylidene-(1,3,4/2,6)-6-hydroxymethyl-4-(p-toluenesulfonamido)-1,2,3-cyclohexanetriol (13).* To a solution of **11** (100 mg) in pyridine (3 ml) was added *p*-toluenesulfonyl chloride (173 mg), and the mixture was

stirred at room temperature for 3 h. The reaction mixture was poured into ice–water (10 ml) and extracted with chloroform. The extracts were washed successively with saturated hydrogencarbonate solution and water, and concentrated. The residue was recrystallized from ethanol giving **13** (140 mg, 87%): mp 190—191 °C; ^{1}H NMR (90 MHz) δ=1.39 (6H, s), 1.41 (3H, s), and 1.46 (3H, s) (isopropylidene), 2.42 (3H, s, tosyl C$\underline{H}_3$), 3.30—3.83 (6H, m, H-1, H-2, H-3, H-4, and C$\underline{H}_2$O), and 7.27 (2H, d, J=12 Hz) and 7.54 (2H, d, J=12 Hz) (phenyl).

Found: C, 58.10; H, 6.99; N, 3.17; S, 7.62%. Calcd for $C_{20}H_{29}NO_6S$: C, 58.36; H, 7.12; N, 3.40; S, 7.79%.

DL-*1,7 : 2,3-Di-O-isopropylidene-(1,3,4/2,6)-6-hydroxymethyl-4-trifluoroacetamido-1,2,3-cyclohexanetriol (**14**).* To a stirred solution of **11** (100 mg) in pyridine (3 ml) was added dropwise trifluoroacetic anhydride (0.25 ml) under ice cooling, and the mixture was stirred at room temperature overnight. The mixture was diluted with chloroform (10 ml) and washed with water. The solution was dried and concentrated to a syrup, which was solidified upon standing in a desiccator giving **14** (129 mg, 94%): ^{1}H NMR (90 MHz) δ=1.47 (9H, s) and 1.53 (3H, s) (isopropylidene), 3.47—3.90 (6H, m, H-1, H-2, H-3, and C$\underline{H}_2$O), 4.30—4.51 (1H, m, H-4), and 6.17—6.40 (1H, m, N$\underline{H}$).

Found: C, 51.20; H, 6.39; N, 3.96%. Calcd for $C_{15}H_{22}F_3NO_5$: C, 50.98; H, 6.29; N, 3.96%.

DL-N-[*(3,4,6/5)-3,4,5,6-Tetraacetoxy-1-cyclohexenylmethyl*]-*2,3:4,7-di-O-isopropylidene-(1,2,4/3,5)-2,3,4-trihydroxy-5-(hydroxymethyl)cyclohexylamine (**16a** and **16b**).* A mixture of **11** (73 mg, 0.28 mmol), DL-1,3,4-tri-*O*-acetyl-(1,2,4/3)-5-bromomethyl-5-cyclohexene-1,2,3,4-tetrol (**15**)[10] (103 mg, 0.28 mmol)- and *N,N*-diisopropylethylamine (0.10 ml, 0.28 mmol) in chloroform (4 ml) was refluxed for 3 d. The mixture was evaporated and the residue was acetylated in the usual way. The product was shown to consist of two components (TLC: R_f 0.29 and 0.23, 1 : 3 2-butanone–toluene). It was fractionated on a silica-gel column (10 g) with 1 : 3 2-butanone–toluene as an eluent. The first fraction gave, after crystallization from ethanol, **16a** (32 mg, 19%): mp 176—177 °C; ^{1}H NMR (90 MHz) δ=1.43 (9H, s) and 1.50 (3H, s) (isopropylidene), 1.99 (3H, s), 2.02 (3H, s), 2.07 (3H, s), and 2.10 (3H, s) (OAc), 3.16—3.35 (3H, m, H-1 and C=CC$\underline{H}_2$), 3.47 (1H, dd, J=3.3 and 9 Hz, H-2), 3.55—3.83 (3H, m, H-4 and CC$\underline{H}_2$O), 3.99 (1H, t, J=9 Hz, H-3), 5.08 (1H, ddd, J=1.8, 3.8, and 9 Hz, H-4′), 5.36—5.71 (3H, m, H-3′, H-5′, and H-6′), and 5.96 (1H, br d, J=*ca.* 7 Hz, H-2′).

Found: C, 57.68; H, 7.00; N, 2.28%. Calcd for $C_{28}H_{41}NO_{12}$: C, 57.62; H, 7.08; N, 2.40%.

The second fraction gave **16b** (45 mg, 27%) as a syrup: ^{1}H NMR (90 MHz) δ=1.46 (9H, s) and 1.49 (3H, s) (isopropylidene), 2.00 (3H, s), 2.02 (3H, s), 2.07 (3H, s), and 2.10 (3H, s) (OAc), 3.12—3.32 (3H, m, H-1 and C=CC$\underline{H}_2$), 3.47 (1H, dd, J=3.3 and 9 Hz, H-2), 3.56—3.82 (3H, m, H-4 and CC$\underline{H}_2$O), 3.94 (1H, t, J=9 Hz, H-3), 5.09 (1H, dd, J=3.8 and 10 Hz, H-4′), 5.51 (1H, dd, J=6.8 and 10 Hz, H-5′), 5.47—5.65 (1H, m, H-3′), 5.74 (1H, br d, J=6.8 Hz, H-6′), and 5.85 (1H, br d, J=6 Hz, H-2′).

Found: C, 57.65; H, 6.95; N, 2.26%. Calcd for $C_{28}H_{41}NO_{12}$: C, 57.62; H, 7.08; N, 2.40%.

The fraction containing unresolved mixture of **16a** and **16b** weighed 58 mg (34%).

DL-N-[*(3,4,6/5)-3,4,5,6-Tetrahydroxy-1-cyclohexenylmethyl*]-*(1,2,4/3,5)-2,3,4-triacetoxy-5-(acetoxymethyl)cyclohexylamine (**17a** and **17b**).* Compound **16a** (21 mg) was treated with 70% aqueous acetic acid (2 ml) at room temperature overnight. The mixture was concentrated to a syrup, which was acetylated in the usual way. The product was purified by a silica-gel column with 1 : 3 2-butanone–toluene as an eluent, giving **17a** (16 mg, 65%) as a syrup: ^{1}H NMR (90 MHz) δ=1.93 (3H, s), 1.97 (6H, s), 1.98 (3H, s), 2.00 (3H, s), 2.05 (6H, s), and 2.07 (3H, s) (OAc), 2.08—3.18 (3H, m, H-1 and C=CC$\underline{H}_2$), 3.79 (1H, br dd, J=3.8 and 11 Hz) and 4.00 (1H, br dd, J=4 and 11 Hz) (CC$\underline{H}_2$OAc), 4.75—5.12 (3H, m, H-2, H-3, and H-4), 5.19—5.63 (4H, m, H-3′, H-4′, H-5′, and H-6′), and 5.81 (1H, br d, J=*ca.* 6 Hz, H-2′).

Found: C, 53.77; H, 6.03; N, 1.94%. Calcd for $C_{30}H_{41}NO_{16}$: C, 53.65; H, 6.15; N, 2.09%.

Similarly, *O*-deisopropylidenation of **16b** followed by acetylation gave **17b** (37 mg, 71%) as a syrup: ^{1}H NMR (90 MHz) δ=1.94 (3H, s), 1.97 (6H, s), 2.00 (6H, s), 2.04 (6H, s), and 2.06 (3H, s) (OAc), 2.85—3.32 (3H, m, H-1 and C=CC$\underline{H}_2$), 3.78 (1H, br dd, J=3.2 and 12 Hz) and 4.02 (1H, br dd, J=4.5 and 12 Hz) (CC$\underline{H}_2$OAc), 4.69—5.07 (3H, m, H-2, H-3, and H-4), 5.16—5.54 (4H, m, H-3′, H-4′, H-5, and H-6′), and 5.74 (1H, br d, J=5 Hz, H-2′).

Found: C, 53.64; H, 6.00; N, 1.97%. Calcd for $C_{30}H_{41}NO_{16}$: C, 53.65; H, 6.15; N, 2.09%.

DL-N-[*(3,4,6/5)-3,4,5,6-Tetrahydroxy-1-cyclohexenylmethyl*]-*(1,2,4/3,5)-2,3,4-trihydroxy-5-(hydroxymethyl)cyclohexylamine (Racemic Reversed Validoxylamine A) (**18a** and **18b**).* De-*O*-acetylation of **17a** and **17b** was carried out by treatment with 1 M methanolic sodium methoxide in methanol at room temperature overnight giving **18a** and **18b**, respectively, in quantitative yields. Both **18a** and **18b** showed the same R_f value (0.11) on TLC (4 : 1 : 1 1-propanol–acetic acid–water, *cf.* validoxylamine A,[16] R_f 0.33).

DL-N-[*(1,5/4,6)-4,5,6-Triacetoxy-3-acetoxymethyl-2-cyclohexenyl*]-*2,3: 4,7-di-O-isopropylidene-(1,2,4/3,5)-2,3,4-trihydroxy-5-(hydroxymethyl)cyclohexylamine (**21a** and **21b**).* A mixture of **11** (368 mg, 1.43 mmol), DL-1,2,3-tri-*O*-acetyl-(1,3,6/2)-4-acetoxymethyl-6-bromo-4-cyclohexene-1,2,3-triol (**19**)[10] (582 mg, 1.43 mmol), and *N,N*-diisopropylethylamine (0.80 ml, 4.58 mmol) in DMF (15 ml) was stirred at room temperature for 20 d. At this time, TLC indicated the formation of many components (R_f 0.50, 0.41, 0.30, 0.27, and 0.16, 1 : 8 ethanol–toluene). The mixture was concentrated to a syrup, which was fractionated on a silica-gel column (50 g) with 1 : 5 2-butanone–toluene as an eluent. The first fraction (R_f 0.50) gave a syrupy mixture (39 mg, 7%) of DL-1,2,3,4-tetra-*O*-acetyl-(1,2,4/3)- (**24**) and -(1,3/2,4)-5-acetoxymethyl-5-cyclohexene-1,2,3,4-tetrol (**25**), identical with authentic samples.[10]

The second fraction (R_f 0.41) gave a mixture (334 mg, 40%) of **21a** and **21b** as a glass: ^{1}H NMR (90 MHz) δ=1.36—1.56 (12H, m, isopropylidene), 1.92—2.20 (12H, m, OAc), and 5.83 (1H, br s, H-2′).

Found: C, 57.39; H, 6.92; N, 2.35%. Calcd for $C_{28}H_{41}NO_{12}$: C, 57.62; H, 7.08; N, 2.40%.

The third fraction (R_f 0.30) gave a mixture (113 mg, 23%) of DL-1,3,4-tri-*O*-acetyl-(1,2,4/3)-5-acetoxymethyl-5-cyclohexene-1,2,3,4-tetrol (**26**) and DL-2,3,4-tri-*O*-acetyl-(1,2,4/3)-5-acetoxymethyl-5-cyclohexene-1,2,3,4-tetrol (**27**), identical with authentic samples.[10]

The fourth fraction (R_f 0.27) gave **12** (77 mg, 18%): mp 229—230.5 °C, identical with the compound prepared above.

The fifth fraction gave recovered **11** (63 mg, 17%).

DL-N-[*(1,5/4,6)-4,5,6-Triacetoxy-3-acetoxymethyl-2-cyclohexenyl*]-*(1,2,4/3,5)-2,3,4-triacetoxy-5-(acetoxymethyl)cyclohexylamine (**22a** and **22b**).* The syrupy mixture of **21a** and **21b** (189 mg) was treated with a small amount of *p*-toluenesulfonic acid in ethanol (5 ml) at room temperature for 1 d, and then the mixture was neutralized with Amberlite IRA-400 (OH^-). The mixture was concentrated and the residue was acetylated in the usual way. The product was shown by TLC to consist of two components (R_f 0.40 and 0.35, 1 : 1 ethyl acetate–toluene).

The mixture was fractionated on a silica-gel column (10 g) with 1 : 2 acetone–toluene as eluent. The first fraction (R_f 0.40) gave **22a** (89 mg, 41%) as a syrup: ^{1}H NMR (90 MHz) δ=1.89—2.06 (24H, m, OAc), 3.30—3.52 (2H, m, H-1 and H-1′), 3.83 (1H, dd, J=4.2 and 12 Hz) and 4.03 (1H, dd, J=4.7 and 12 Hz) (CC$\underline{H}_2$OAc), 4.24 (1H, d, J=13 Hz) and 4.60 (1H, br d, J=13 Hz) (C=C$\underline{H}_2$OAc), 4.67—5.10 (3H, m, H-2, H-3, and H-4), 5.11—5.49 (2H, m, H-5′ and H-6′), 5.53—5.69 (1H, m, H-4′), and 5.70 (1H, br s, H-2′).

Found: C, 53.74; H, 6.09; N, 2.06%. Calcd for $C_{30}H_{41}NO_{16}$: C, 53.65; H, 6.15; N, 2.09%.

The fraction (R_f 0.35) gave **22b** (50 mg, 23%) as a syrup: ^{1}H NMR (90 MHz) δ=1.90—2.07 (24H, m, OAc), 3.18—3.41 (2H, m, H-1 and H-1′), 3.79 (1H, dd, J=3.2 and 12 Hz) and 4.01 (1H, dd, J=4.5 and 12 Hz) (CC$\underline{H}_2$OAc), 4.26 (1H, d, J=14 Hz) and 4.52 (1H, br d, J=14 Hz) (C=CC$\underline{H}_2$OAc), 4.70—5.15 (3H, m, H-2, H-3, and H-4), 5.15—5.39 (2H, m, H-5′ and H-6′), 5.58 (1H, m, H-4′), and 5.65 (1H, br s, H-2′).

Found: C, 53.78; H, 6.07; N, 2.17%. Calcd for $C_{30}H_{41}NO_{16}$: C, 53.65; H, 6.15; N, 2.09%.

The fraction containing unresolved mixture of **22a** and **22b** weighed 50 mg (23%).

DL-N-[*(1,5/4,6)-3-Hydroxymethyl-4,5,6-trihydroxy-2-cyclohexenyl*]-*(1,2,4/3,5)-2,3,4-trihydroxy-5-(hydroxymethyl)cyclohexylamine (Racemic 1′-Epivalidoxylamine A) (**23a** and **23b**).* O-Deacetylation of **22a** and **22b** in the usual way gave **23a** and **23b**, respectively, in quantitative yields. Both showed the same R_f value (0.28) on TLC (4 : 1 : 1 1-propanol–acetic acid–water, *cf.* validoxylamine A:[16] R_f 0.31).

This work was supported in part by a Grant-in-Aid for Scientific Research No. 56550617 from the Ministry of Education, Science and Culture. We wish to thank Mr. Saburo Nakada for elemental analyses and Dr. Satoshi Horii of Takeda Chemical Industries, Ltd. (Osaka) for a gift of validoxylamine A. We also thank Messrs. Yasuo Abe, Masayuki Oya, and Yoshikazu Iwasawa for their assistance in some preparative work.

Studies on the β-Turn of Peptides. V.[1] Turn Preference of Peptide Sequences Analyzed by Conformational Energy Calculation on Dipeptide Models and by CD Spectra of Chromophoric Derivatives

Masao KAWAI,*,† Kazuki SATO, Rika SUGAWARA, and Ukon NAGAI
Mitsubishi-Kasei Institute of Life Sciences, Minamiooya 11, Machida, Tokyo 194
†*Department of Synthetic Chemistry, Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466*
(Received April 8, 1983)

Empirical conformational energy calculations were performed on Ac–L-Pro–D-Ala–$NHCH_3$ and Ac–D-Ala–L-Pro–$NHCH_3$. In order to study the turn tendency of the dipeptide sequences turn probabilities and average interterminal distances were calculated. Much larger turn preference of D-Ala containing sequences was indicated compared with the corresponding L-Ala containing sequences. The turn tendency of the dipeptide sequences were shown to be in the order: L-Pro–D-Ala>D-Ala–L-Pro>L-Pro–L-Ala>L-Ala–L-Pro. This order coincides with the order of the magnitude of the Cotton effects in the CD spectra of the chromophoric derivatives having 2,4-dinitrophenylglycyl and glycine-*p*-nitroanilide at the *N*- and the *C*-termini, respectively, of the corresponding dipeptide sequences. This agreement supports the validity of the chiroptical method to study the turn tendency of the peptide sequences using chromophoric derivatives reported earlier.

CD spectra of *N*-(2,4-dinitrophenyl)tetrapeptide *p*-nitroanilides (Dnp–tetrapeptide–pNA)[2] exhibit characteristic Cotton effects when they take β-turn conformation. Exciton coupling of the electric transition moments of the two chromophores were assumed to explain the spectra and the mgnitude of the Cotton effects around 310 and 350 nm were shown to reflect the β-turn preference of the derivatives.[3] A question was raised, however, whether such chiroptical method using chromophoric derivatives as mentioned above reveals well the conformational characteristics of the original peptide sequences lacking those chromophoric groups. For the purpose of answering the question we have attempted empirical conformational energy calculations on model peptides having acetyl and *N*-methylamide groups at the *N*- and the *C*-termini, respectively. In this paper the conformational energy studies on model dipeptides are described and the results are compared with the CD spectral data of tetrapeptide derivatives having Dnp–Gly and Gly–pNA moieties at the *N*- and the *C*-termini, respectively.

Results and Discussion

The CD spectra of Dnp–Gly–X–Y–Gly–pNA are shown in Fig. 1 where X–Y represents a dipeptide sequence consisting of L- or D-Ala and L-Pro residues. Marked difference in the magnitude of the Cotton effects observed for this series of tetrapeptide derivatives can be attributed to the divergent β-turn tendency of the central dipeptide sequences X–Y. Theoretical study has been attempted to elucidate the turn preference of the X–Y sequences by means of empirical conformational energy calculation on the model dipeptides Ac–X–Y–$NHCH_3$. Computations were carried out using the program ECEPP[4] with the Powell's minimization subroutine.[5] The conformational properties of Ac–L-Pro–L-Ala–$NHCH_3$ and Ac–L-Ala–L-Pro–$NHCH_3$ had been already elucidated by Zimmerman and Scheraga[6] by use of ECEPP. Essentially same procedure as reported by them was followed for the calculation of Ac–L-Pro–D-Ala–$NHCH_3$ and Ac–D-Ala–L-Pro–$NHCH_3$ except that

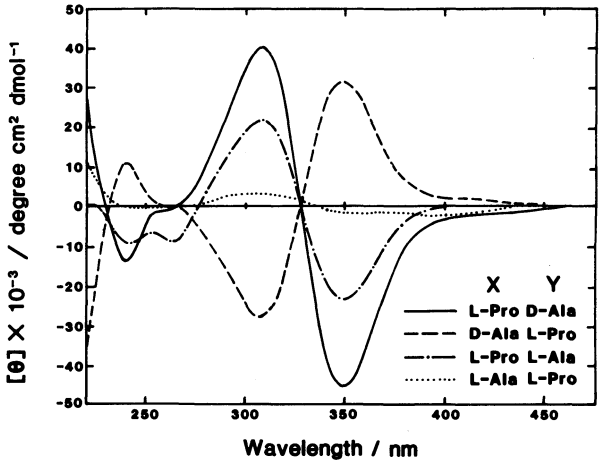

Fig. 1. CD spectra of Dnp–Gly–X–Y–Gly–pNA in methanol.

the contribution of librational entropy is not included in our calculation.

For the calculation of Ac–L-Pro–D-Ala–$NHCH_3$ all combination of low energy conformations of Ac–L-Pro–$NHCH_3$[7] (C −75°, −79°; F −75°, 159°; A −75°, 48°; A −75°, −23°)[8] and of Ac–D-Ala–$NHCH_3$[7] (C* 84°, −79°; E* 154°; −153°; D* 150°, −72°; F* 75°, −145°; A* 74°, 45°; G* 158°, 85°; A −54°, −57°)[8] were used as the starting conformations for energy minimization. All ω values were fixed to 180°. In Table 1 are listed 19 low-energy conformations obtained through energy minimization of Ac–L-Pro–D-Ala–$NHCH_3$. The interatomic distance *R*, defined as the distance between the methyl carbons of the acetyl and the *N*-methylamide groups, and the O(Ac)···N($NHCH_3$) distance *h* are given along with the relative conformational energy ΔE and the normalized statistical weight *v* of each conformation. For each conformation with the *R* value less than 7.0 Å the bend type is given according to the classification by Zimmerman and Scheraga.[6] In the case of energy minimization of Ac–D-Ala–L-Pro–$NHCH_3$ some starting conformations having *cis* peptide linkage which were taken from the minimum energy conforma-

tions with *cis* Ac-Pro bond of Ac-L-Pro-$NHCH_3$[7] (A −75°, −48°; F −75°, 162°)[8] were also included. The results of energy minimization are given in Table 2.

In order to evaluate the turn tendency of the dipeptide sequences the bend probability P_b and the averaged interterminal distance $\langle R \rangle$ were calculated for each model peptide. As defined by Zimmerman and Scheraga[6] the quantity P_b is the probability of occurrence (or mole fraction) of bend conformations ($R < 7$ Å) in a particular dipeptide and the quantity $\langle R \rangle$ is the statistical average of the interterminal distance R.[6] In Table 3 are shown the calculated P_b and $\langle R \rangle$ values for the D-Ala containing model peptides along with the reported values[6] for Ac-L-Pro-L-Ala-$NHCH_3$ and Ac-L-Ala-L-Pro-$NHCH_3$. The larger P_b values and the smaller $\langle R \rangle$ values for the D-Ala containing dipeptides compared with the corresponding L-Ala derivatives indicated the larger turn tendency of D-Ala containing sequences. Stability of turn conformation of LL and LD sequences and the role of proline in the formation of the LL and the LD bends were studied by Chandrasekaran *et al.*[9] Our results afforded semiquantitative evaluation of turn tendency of these sequences.

As can be seen from Table 3 theoretical conforma-

tional study clearly demonstrated the turn tendency of the dipeptide sequences to be in the order: L-Pro–D-Ala>D-Ala–L-Pro>L-Pro–L-Ala>L-Ala–L-Pro. This order coincides with the order of the magmitude of the Cotton effects in the CD spectra of Dnp–Gly–X–Y–Gly–pNA as summarized in Table 3. In other words turn preference of dipeptide sequences studied by the chiroptical approach has been shown to agree with the results of theoretical conformational analysis, indicating the usefulness of the chiroptical method. Though librational entropy was not calculated in our study, the sequence dependence of turn tendency obtained in this study is assumed to be valid since the deviation of the $\langle R \rangle$ and P_b values due to neglection of librational entropy is at most 0.36 Å and 0.14, respectively, among the 12 proline containing dipeptides.[6]

Conformational properties of the tetrapeptide derivatives studied by their CD spectra were discussed with relation to the intrinsic turn tendency of the central dipeptide units disclosed by theoretical study. Conformational energy calculations were performed on the dipeptide models which contain acetyl and *N*-methylamide groups in place of Dnp–Gly and Gly–pNA moieties, respectively, of the tetrapeptide derivatives. These achiral terminal moieties in the chromophoric tetrapeptide derivatives, however, make some contribution to the absolute turn tendency of these molecules. Acetyl and *N*-methylamide groups of the dipeptide models correspond to the CH_2CO group of the 1st Gly residue and the $NHCH_2$ group of the 4th Gly residue, respectively, but Dnp–NH and CO–pNA groups were not included in the calculation. It was shown that intramolecular interaction between the two chromophoric groups stabilizes turn conformers without changing relative turn prefernce of the peptide sequences of the same series of compounds.[10] Replacement of the 1st and the 4th Gly residues of Dnp–Gly–X–Y–Gly–pNA by chiral amino acids markedly changes the turn tendency,[11] which is not dealt with in this paper.

In summary intrinsic turn tendency of proline containing dipeptide sequences were estimated semiquantitatively by means of empirical conformational energy calculation on model peptides. Calculation on Ac–L-Pro–D-Ala–NHCH$_3$ and Ac–D-Ala–L-Pro–NHCH$_3$ demonstrated the larger turn tendency of these D-Ala containing dipeptides than the corresponding L-Ala analogs, which is consistent with the CD spectral data of the tetrapeptide derivatives having Dnp–Gly and Gly–pNA groups. We consider that the results described here proved the validity of the chiroptical method using Dnp,pNA derivatives.[3] NMR study of acetyltetrapeptide *N*-methylamide also supported the chiroptical analysis as described elsewhere.[10]

Experimental

Materials. Synthesis of Dnp–Gly–L-Pro–L-Ala–Gly–pNA,[12] Dnp–Gly–L-Pro–D-Ala–Gly–pNA,[12] and Dnp–Gly–D-Ala–L-Pro–Gly–pNA[13] were already described.

Synthesis of Dnp–Gly–L-Ala–L-Pro–Gly–pNA. All the melting points were measured on a Yanagimoto micromelting point apparatus and were uncorrected. TLC's were carried out on Merck silica gel 60 F_{254} plates with the following solvent systems: R_f^1, $CHCl_3$–MeOH (5 : 1, v/v); R_f^2, $CHCl_3$–MeOH–AcOH (95 : 5 : 1, v/v); R_f^3, *n*-BuOH–AcOH–pyridine–H_2O (4 : 1 : 1 : 2, v/v). Optical rotations were measured on an Union automatic polarimeter PM-201.

Boc-L-Pro–Gly–pNA. To a chilled solution of Boc-L-Pro–OH (1.075 g, 5 mmol) and H–Gly–pNA (0.975 g, 5 mmol) in DMF (20 ml) was added EDC·HCl (0.959 g, 5 mmol). The mixture was stirred at 0 °C for 1 h and at room temperature overnight and evaporated under reduced pressure. The residue was dissolved in EtOAc, and the solution was washed successively with 10% citric acid, 4% $NaHCO_3$, and water, dried (Na_2SO_4), and evaporated. The residue was solidified by addition of ether and petroleum ether, and the product was recrystallized from EtOAc–ether–petroleum ether; yield, 1.523 g (77%); mp 204—205 °C; $[\alpha]_D^{22}$ −18.8° (*c* 0.5, MeOH); R_f^1 0.70, R_f^2 0.41, R_f^3 0.83.

Found: C, 55.34; H, 6.23%; N, 14.20%. Calcd for $C_{18}H_{24}O_6N_4$: C, 55.09; H, 6.17%; N, 14.28%.

H–L-Pro–Gly–pNA·HCl. Boc-L-Pro–Gly–pNA (785 mg, 2 mmol) was dissolved in 0.1 M (1 M=1 mol dm^{-3}) hydrogen chloride in formic acid (24 ml). The solution was allowed to stand at room temperature for 30 min and evaporated under reduced pressure to leave crystals, which were collected by filtration with the aid of ether; yield, 651 mg (99%); mp 217—219 °C; $[\alpha]_D^{22}$ −25.6° (*c* 1, MeOH); R_f^1 0.13, R_f^3 0.53.

Found: C, 47.40; H, 5.15; N, 17.12%. Calcd for $C_{13}H_{17}O_4N_4Cl$: C, 47.49; H, 5.21; N, 17.05%.

Boc–L-Ala–L-Pro–Gly–pNA. To a chilled solution of H–L-Pro–Gly–pNA·HCl (625 mg, 1.9 mmol) were added TEA (0.27 ml, 1.9 mmol) and Boc–L-Ala–ONSu (653 mg, 2.3 mmol). The mixture was treated as described for the synthesis of Boc–L-Pro–Gly–pNA. The product was recrystallized from MeOH–ether; yield, 511 mg (59%); mp 220—222 °C; $[\alpha]_D^{22}$ −12.6° (*c* 1, MeOH); R_f^1 0.64, R_f^3 0.23, R_f^3 0.76.

Found: C, 54.31; H, 6.25; N, 15.11%. Calcd for $C_{21}H_{29}O_7N_5$: C, 54.42; H, 6.31; N, 15.11%.

H–L-Ala–L-Pro–Gly–pNA·HCl. Boc–L-Ala–L-Pro–Gly–pNA (278 mg, 0.6 mmol) was treated with 0.1 M hydrogen chloride in formic acid (7 ml) as described for H–L-Pro–Gly–pNA·HCl. The product was highly hygroscopic crystals; yield, 240 mg (100%); $[\alpha]_D^{22}$ −11.0° (*c* 1, MeOH); R_f^1 0.07, R_f^3 0.54.

Found: C, 45.84; H, 5.84; N, 16.56%. Calcd for $C_{16}H_{22}O_5N_5Cl \cdot H_2O$: C, 45.99; H, 5.79; N, 16.76%.

Boc–Gly–L-Ala–L-Pro–Gly–pNA. This compound was prepared from H–L-Ala–L-Pro–Gly–pNA·HCl (200 mg, 0.5 mmol) and Boc–Gly–ONSu (163 mg, 0.6 mmol) as described for Boc–L-Ala–L-Pro–Gly–pNA; yield, 151 mg (58%); mp 135—138 °C; $[\alpha]_D^{22}$ −34.2° (*c* 1, MeOH); R_f^1 0.52, R_f^2 0.09, R_f^3 0.77.

Found: C, 52.47; H, 6.04; N, 15.82%. Calcd for $C_{23}H_{32}O_8N_6 \cdot 1/2\ H_2O$: C, 52.17; H, 6.28; N, 15.87%.

H–Gly–L-Ala–L-Pro–Gly–pNA·HCl. Boc–Gly–L-Ala–L-Pro–Gly–pNA (78 mg, 0.15 mmol) was dissolved in 0.1 M hydrogen chloride in formic acid (1.8 ml). After 30 min, the solution was evaporated to leave an oil, which was used for the next reaction without further treatment; yield was quantitative; R_f^1 0.02, R_f^3 0.51.

Dnp–Gly–L-Ala–L-Pro–Gly–pNA. To a solution of H–Gly–L-Ala–L-Pro–Gly–pNA·HCl (69 mg, 0.15 mmol) in DMF (1 ml) were added TEA (0.063 ml, 0.45 mmol) and N_2ph–F (56 mg, 0.3 mmol). The reaction mixture was stirred at room temperature for 3 h and evaporated *in vacuo*. The residue dissolved in $CHCl_3$ (10 ml) was applied to a column (1.8×18 cm) of silica gel 60 (Merck) and the column was washed with $CHCl_3$. The desired product was eluted with a mixture of $CHCl_3$ and MeOH (5 : 1, v/v). The fractions containing the desired product were evaporated to leave an oil, which was crystallized by addition of ether and recrystallized from MeOH–ether; yield, 73 mg (83%); mp 162—163 °C; $[\alpha]_D^{22}$ −26.2° (*c* 1, DMF); R_f^1 0.54, R_f^2 0.09, R_f^3 0.74.

Found: C, 48.31; H, 4.59; N, 18.56%. Calcd for $C_{24}H_{26}O_{10}N_8 \cdot 1/2\ H_2O$: C, 48.40; H, 4.57; N, 18.82%.

Measurements. CD spectra were recorded in methanol solution on JASCO J-40 spectropolarimeter.

Computation. ECEPP program and minimization subroutine VA04A were obtained from Quantum Chemistry Program Exchange, Indiana University. Computations were performed with FACOM 260F computer. All bond lengths and bond angles were taken from the standard ECEPP data for residues and end groups. The proline ring was taken in the puckered down position ($\phi = -75°$).

The authors are grateful to Dr. Tadakazu Maeda in our Institute and the members of System Center, Mitsubishi-Kasei Industries, Ltd. for their assistance during computation and also to the members of System Engineering Laboratory, Mitsubishi-Kasei Industries, Ltd., for performing elemental analyses.

Conversion of Disilanes to Functional Monosilanes. XIII.[1] The Palladium Catalyzed Reductive Coupling of Benzylidene Dichlorides and Benzylidyne Trichlorides Using Disilanes as Reducing Agents

Hideyuki MATSUMOTO,* Takeshi ARAI, Masatoshi TAKAHASHI, Toshiyuki ASHIZAWA, Taichi NAKANO, and Yoichiro NAGAI*

Department of Chemistry, Gunma University, Kiryu, Gunma 376

(Received April 11, 1983)

The reaction of benzylidene dichlorides or benzylidyne trichlorides with 1,2-dichloro-1,1,2,2-tetramethyldisilane or hexamethyldisilane proceeded smoothly in the presence of a catalytic amount of $Pd(PPh_3)_4$ to give (*E*)-stilbenes or (*E*)- and (*Z*)-α,β-dichlorostilbenes in high yields, respectively. Also, in the presence of the palladium(0) catalyst, α,α-dichlorobenzyltrimethylsilanes reacted with hexamethyldisilane yielding (*E*)-α,β-bis(trimethylsilyl)stilbenes in quantitative yield.

The reductive coupling of benzylidene dichlorides and benzylidyne trichlorides has been studied extensively and previous work employed active metal agents in low-oxidation state such as zero-valent titanium, iron, cobalt, and nickel compounds or slurries[2] as well as copper(I), titanium(II), vanadium(II), chromium(II), iron(II), cobalt(I), and cobalt(II) species.[3]

In connection with our continuing interest in the Si–Si cleavage of disilanes by organic halides,[1,4] we examined the interaction of benzylidene dichloride with methylchlorodisilanes, *e.g.*, 1,2-dichloro-1,1,2,2-tetramethyldisilane, in the presence of $Pd(PPh_3)_4$.[5] The reaction afforded the coupling products of the *gem*-dichlorides, stilbenes, in good yields. The result in this preliminary investigation demonstrates that such methylchlorodisilanes, formally tetravalent silicon species, can be effectively used for the coupling reaction as reducing agents. We have now extended this approach to use of other active *gem*-polychloro compounds such as benzylidyne trichlorides and α,α-dichlorobenzyltrimethylsilanes. The present paper is intended to summarize our work on this palladium(0) complex-catalyzed reductive coupling reaction.

Results and Discussion

Results for the reaction of benzylidene dichloride and benzylidyne trichloride with methylchlorodisilanes, $Me_{6-n}Si_2Cl_n$ (n=0, 2, 4), are given in Tables 1 and 2.

As shown in the tables, both hexamethyldisilane and 1,2-dichloro-1,1,2,2-tetramethyldisilane can bring about the coupling reaction. However, there is somewhat a puzzling difference in the effectiveness of these disilanes and choice of disilane depends upon the nature of the polychloromethylbenzene. The dichlorotetramethyldisilane is much more effective for converting benzylidene dichloride to (*E*)-stilbene than hexamethyldisilane, and optimum yield is obtained at initial disilane/substrate molar ratio of 2. On the other hand, the coupling of benzylidyne trichloride can be achieved smoothly with the permethyldisilane rather than with the dichlorotetramethyldisilane. The observed trend seems to reflect a compromise of the controlling factors in the sequence of the steps involved in the present catalytic reaction.

These reactions were run at 130 °C in a refluxing system. However, we note that the coupling can be also achieved at lower temperatures. For example, benzylidyne trichloride reacted with the permethyldisilane at 100 °C to give α,β-dichlorostilbene in 97% yield after 10 h.

In contrast with the case of these disilanes, the reaction of 1,1,2,2-tetrachloro-1,2-dimethyldisilane with benzylidene dichloride and benzylidyne trichloride afforded a complex mixture of products involving polysilanes due to the competitive disproportionation of the disilane itself.

The fact that the product ratio [PhCClXCClXPh: PhCX=CXPh (X=H, Cl)] is markedly affected by the ratio of the reactants (Tables 1 and 2) suggests that the formation of PhCX=CXPh occurs by a two-step process, Eqs. 1 and 2. This is further confirmed by the time-concentration profiles for the coupling of $PhCCl_2X$, indicating the initial formation of the dichlorodiphenylethane (**2**) followed by conversion of **2** to the

corresponding stilbenes (Figs. 1 and 2).

Under optimum conditions, the coupling of substituted benzylidene dichlorides and benzylidyne trichlorides was achieved in high yields by the reaction with the dichloroteramethyldisilane or with the permethyldisilane. As shown in Table 3, (*E*)-stilbenes are only coupled products obtained by the reaction with the dichlorides, whereas a mixture of (*E*)- and (*Z*)-isomers is obtained from the trichlorides.[6)] The geometrical isomerism for previously unreported stilbenes, *e.g.*, α,β,-2,2′-tetrachlorostilbene and α,β,2,2′,4,4′-hexachlorostilbene, was assigned based on differences in the physical properties of these isomers: (i) in ^1H NMR spectra, the phenyl proton signals in the (*E*)-isomers appear at lower fields compared to those on the (*Z*)-isomers. ii) In IR spectra, the C=C stretching frequences around 1600 cm^{-1} of the (*E*)-isomers are very weak and broad, due to their symmetrical structures, while those of the (*Z*)-isomers are relatively strong and sharp. (iii) The conjugation bands of the UV spectra for the (*E*)-isomers occur at shorter wave length than those of the (*Z*)-isomers. (iv) The melting points of the (*E*)-isomers are

higher than those of the (*Z*)-isomers. Similar observations have been made in such pairs of the geometrical isomers of α,β-dichlorostilbene and α,β,4,4′-tetrachlorostilbene.[2,3,7]

The data accumulated in Tables 1-3 clearly reveal that the present system provides a workable procedure for the selective coupling of these polychloromethylbenzenes to the stilbenes. This has advantages: (i) the methylchlorodisilanes employed are readily available in large quantities.[8] (ii) Removal of the counter products, Me_2SiCl_2 (bp 70 °C) and Me_3SiCl (bp 57 °C), can be easily achieved by evaporation. The formation of large amounts of nonvolatile and solid inorganic salts as oxidation products is the drawback of the conventional methods using stoichiometric amount of low-valent metals as reducing agents.[2,3] Further, the fact that only catalytic amounts of the palladium(0) complex are required in the present reaction also increases the potential synthetic utility of our method.

Catalytic efficiency was tested briefly for other common group VIII metal–phosphine complexes using the reaction of benzylidene dichloride with 1,2-dichloro-1,1,2,2-tetramethyldisilane as a standard. As shown in Table 4, $PdCl_2(PPh_3)_2$ showed the catalytic activity for the coupling. However, the reaction was less selective compared to that in the presence of the palladium(0) complex and gave a considerable amount of $PhCH(SiMe_2Cl)_2$ as well as (*E*)-stilbene. The complexes $Pt(PPh_3)_4$, $PtCl_2(PPh_3)_2$, and $RhCl(PPh_3)_3$ also induced the reaction, but their catalytic ability was much lower. $NiCl_2(PPh_3)_2$ failed to effect the expected reaction to any appreciable extent.

$$\xrightarrow{d:\ \Delta}$$
$$(E)\text{-}ArCH{=}CHAr + Me_2SiCl_2$$

Scheme 1.

Mechanistically, the coupling reaction perhaps consists of several steps as shown in Scheme 1. This involves the palladium-catalyzed dechlorinative silylation of a benzylidene dichloride $ArCHCl_2$ with 1,2-dichloro-1,1,2,2-tetramethyldisilane to give the α-chlorobenzyldimethylchlorosilane (**3**) (path a), followed by the metathesis between **3** and $ArCHCl_2$ yielding a coupling product ArCHClCHClAr (path b). Support for the transient intermediate **3** was found in the reaction of $PhCHCl_2$ with excess of the dichlorotetramethyldisilane. The reaction afforded $PhCH(SiMe_2Cl)_2$, as a by-product, which should arise from **3** (Ar=Ph) by the reaction with the disilane (Table 1). Path b is the reminiscent of the palladium-catalyzed metathesis of allyltrimethylsilane with allyl bromide that gives 1,5-hexadiene together with trimethylbromosilane.[4c] The reaction of ArCHClCHClAr with the dichlorotetramethyldisilane to give the 1-chloro-2-(dimethylchlorosilyl)-1,2-diarylethane **4** (path c), which releases spontaneously dimethyldichlorosilane *via* β-elimination[9] resulting in the formation of (*E*)-ArCH=CHAr (path d), should be also involved. A similar mechanism may be given for the coupling of benzylidyne trichlorides.

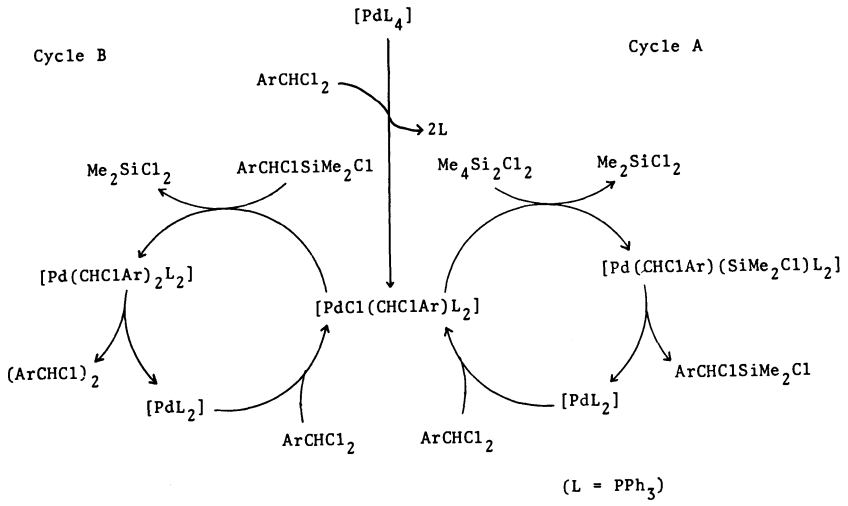
Alternatively, a scheme might be proposed whereby the dichlorotetramethyldisilane as well as the permethyldisilane acts as reducing agents to regenerate the palladium(0) from the palladium(II) formed upon the coupling (Eqs. 3 and 4). This scheme, however, seems

$$ArCCl_2X + Pd(PPh_3)_4 \longrightarrow ArCClXCClXAr + PdCl_2(PPh_3)_2 + 2PPh_3 \quad (3)$$

$$PdCl_2(PPh_3)_2 + YMe_2SiSiMe_2Y \longrightarrow Pd(PPh_3)_2 + 2MeSiClY \quad (4)$$

to be unlikely, since vigorous conditions (*e.g.*, 160—200 °C) are generally required to bring about reduction of this type.[10] Moreover, the recent finding by Stille and Lau,[11] and Eaborn *et al.*[12] that trimethylchlorosilane reacts with $Pd(PPh_3)_4$ to give hexamethyldisilane and $PdCl_2(PPh_3)_2$ strongly indicates that reaction 4 is much less favorable.

In consideration of the catalytic cycles for paths a and b in Scheme 1, it is likely that the cycles are initiated by the reaction of $ArCHCl_2$ with $Pd(PPh_3)_4$, since we found that such a reaction occurs rapidly at a room temperature, although an attempt to isolate the expected oxidative adduct, *e.g.*, $PdCl(CHClPh)(PPh_3)_2$, failed due to the instability of this complex. On the other hand, 1,2-dichloro-1,1,2,2-tetramethyldisilane is much less reactive toward the palladium(0) complex under comparable conditions.[1] Thus, plausible catalytic cycles are shown in Scheme 2. Cycle A was inferred from the mechanism proposed for the palladium(0)-catalyzed metathesis between benzyl chlorides and the dichlorotetramethyldisilane to give benzyldimethylchlorosilanes.[1] Cycle B involves the transmetallation of the palladium(II) complex, $PdCl(CHClAr)(PPh_3)_2$, with the α-chlorobenzyldimethylchlorosilane (**3**). Analogous transmetallation process has been proposed for the cleavage of silicon-alkyl and silicon-aryl bonds by palladium(II) compounds which takes places at 60—120 °C[13] and also for the palladium-catalyzed coupling



Scheme 2.

of tetraorganotin compounds with aryl and benzyl halides.[14] Further, it has been found by Pitt *et al.*[15] that silicon-benzyl bond is cleaved by palladium under certain conditions.

In view of this proposed mechanism, it is expected that α,α-dichlorobenzyltrimethylsilanes could be readily enter into the coupling and this was found to be the case (Table 5). For example, $PhCCl_2SiMe_3$ reacted very smoothly with hexamethyldisilane in the presence of the palladium(0) catalyst to give (*E*)-α,β-bis(trimethylsilyl)stilbene together with α-chloro-β-(trimethylsilyl)-stilbene (presumably, (*E*)-isomer). Further, the bis-(trimethylsilyl)stilbene could be obtained in quatitative yield by continuing the reaction until virtual disappearance of the monosilylstilbene. The formation of the bis(silyl)stilbene can be rationalized in terms of the palladium-catalyzed metathesis between the monosilylstilbene and the permethyldisilane (Eq. 5).[16] The results in the table again emphasize the utility of our

$$PhCCl{=}C(SiMe_3)Ph + Me_3SiSiMe_3 \xrightarrow{[Pd]} Me_3Si(Ph)C{=}C(SiMe_3)Ph + Me_3SiCl \quad (5)$$

procedure as a selective route (*E*)-α,β-bis(trimethylsilyl)-stilbenes which would be of interest for the study of physico-chemical properties.[17]

Experimental

Melting points were uncorrected. IR spectra were taken on a JASCO A102 spectrophotometer. ^1H NMR spectra were obtained with a Varian EM-360 spectrometer using tetramethylsilane as an internal standard. UV spectra were taken on a Hitachi 200-10 spectrophotomter. Mass spectra were obtained with a JEOL JMS-07 spectrometer. GLC analyses were performed on an Ohkura GC-103 instrument with thermal conductivity detector using 0.4×100-200 cm Teflon and Pyrex glass columns packed with 10%SE-30, 10% DCQF-1, 10%KF-96, and 10%Carbowax 20M on Celite 545 (80—100 mesh). Corrections were made thermal conductivity of the various components.

Materials. Benzylidene dichloride was commercially available and used as received. Substituted benzylidene dichlorides were prepared by the benzoyl peroxide-catalyzed chlorination of the corresponding benzyl chlorides with sulfuryl chloride.[18] Benzylidyne trichlorides were commercially available and used as received. α,α-Dichlorobenzyltrimethylsilanes were prepared according to literature directions.[19] Hexamethyldisilane was commercially available and purified by distillation prior to use. 1,2-Dichloro-1,1,2,2-tetramethyldisilane[8f] and 1,1,2,2-tetrachloro-1,2-dimethyldisilane[8e] were prepared according to published procedures.

The complexes $Pd(PPh_3)_4$,[20] $PdCl_2(PPh_3)_2$,[21] $Pt(PPh_3)_4$,[22] $PtCl_2(PPh_3)_2$,[23] $RhCl(PPh_3)_3$,[24] and $NiCl_2(PPh_3)_2$[25] were prepared according to literature procedures.

Other organic reagents and solvents were commercially available and purified according to standard procedures.

Procedure for the Coupling of Benzylidene Dichlorides and Benzylidyne Trichlorides. All the reactions were carried out under nitrogen in a refluxing system and typical examples are described below.

(a) Reaction of 2-Chlorobenzylidene Dichloride with 1,2-Dichloro-1,1,2,2-tetramethyldisilane: A mixture of 1.98 g (10.2 mmol) of the dichloride, 3.75 g (20.0 mmol) of the disilane, 0.12 g (0.1 mmol) of $Pd(PPh_3)_4$, and 3 ml of mesitylene was heated at 130 °C for 0.5 h with stirring. GLC analysis showed that the dichloride had been completely consumed and that 2,2′-dichlorostilbene (4.7 mmol, 94% yield) had been produced. The reaction mixture was then diluted with 30 ml of pentanes to precipitate the catalyst which was removed by filtration. The filtrate was concentrated to yield 1.03 g (85% yield) of

stilbene as colorless crystals.

(b) Reaction of Benzylidyne Trichloride with Hexamethyldisilane: A mixture of 1.95 g (10.0 mmol) of the trichloride, 2.90 g (19.8 mmol) of the disilane, 0.12 g (0.1 mmol) of the palladium(0) complex, and 5 ml of mesitylene was heated at 130 °C for 2 h with stirring. GLC analysis showed that the reaction had given 5.0 mmol (100% yield) of α,β-dichlorostilbene as a 30 : 70 mixture of the (*E*)- and (*Z*)-isomers. Work-up as described above afforded 1.20 g (97% yield) of the product as colorless crystals.

The physical data of the products obtained are given below. PhCHClCHClPh: mp 176—190 °C (lit,[3a] *meso*, mp 191—193 °C; *dl*, 93—94 °C); NMR (CCl_4) δ=5.05 (s, 2H) and 7.31 (s, 10H). (*E*)-PhCH=CHPh: mp 123—124 °C (lit,[26] 124 °C); NMR (CCl_4) δ=7.10 (s, 2H) and 7.50 (m, 10H). $PhCH(SiMe_2Cl)_2$: IR (neat) 1255 (s) cm^{-1}; NMR (CCl_4) δ=0.46 (s, 12H); 1.88 (s, 1H) and 7.12 (s, 5H); MS (30 eV), *m/e*, 276 (M^+). This compound gave a poor analytical result due to high susceptibility to hydrolysis. (*E*)-2-ClC_6H_4CH=CHC_6H_4-2-Cl: mp 97—98 °C (lit,[26] 98—99 °C); NMR (CCl_4) δ=6.98 (s, 2H) and 7.53 (s, 8H). 4-ClC_6H_4CH=CHC_6H_4-4-Cl: mp 174—176 °C (lit,[26] 176—176.5 °C); NMR (CCl_4) δ=6.92 (s, 2H) and 7.30 (s, 8H). Time-concentration Profiles for the Coupling of Benzylidene Dichloride and Benzylidyne Trichloride. Typically, a mixture of 1.61 g (10.0 mmol) of benzylidene dichloride, 3.75 g (20.0 mmol) of 1,2-dichloro-1,1,2,2-tetramethyldisilane, 0.12 g (0.1 mmol) of the palladium(0) complex, 3 ml of mesitylene, and 0.488 g (2.00 mmol) of triphenylmethane as an internal standard was heated at 130 °C under nitrogen with stirring. The course of the reaction was monitored by GLC.

Effect of Some Common Group VIII Metal Complex on the Reaction of Benzylidene Dichloride with 1,2-Dichloro-1,1,2,2-tetramethyldisilane. A mixture of 1.61 g (10.0 mmol) of the dichloride, 3.75 g (20.0 mmol) of the disilane, 0.1 mmol of a complex, and 3 ml of mesitylene was heated at 130 °C under nitrogen with stirring. After 2—5 h, the resulting mixture was subjected to GLC analysis.

Reaction of α,α-Dichlorobenzyltrimethylsilane with Hexamethyldisilane. Typical examples are described below. *i)* A mixture of 2.34 g (10.0 mmol) of $PhCCl_2SiMe_3$, 2.93 g (20.0 mmol) of hexamethyldisilane, 0.12 g (0.1 mmol) of the palladium(0) complex, and 5 ml of mesitylene was heated at 130 °C under nitrogen for 2 h. GLC analysis showed that the reaction had given α,β-bis(trimethylsilyl)stilbene in 44% yield together with a 42% yield of α-chloro-β-(trimethylsilyl)-stilbene.

ii) A mixture of 1.34 g (5.0 mmol) of α,α,4-trichlorobenzyltrimethylsilane, 1.50 g (10.3 mmol) of the permethyldisilane, 0.058 g (0.05 mmol) of the palladium(0) complex, and 3 ml of mesitylene was heated at 130 °C for 24 h under nitrogen. The resulting mixture was diluted with 50 ml of pentanes and the precipitated catalyst was removed by filtration. The filtrate was concentrated to dryness under reduced pressure to yield 1.05 g (100% yield) of (*E*)-α,β-bis(trimethylsilyl)-4,4′-dichlorostilbene.

The physical data of the products obtained are given below. (*E*)-$Ph(Me_3Si)C$=$C(SiMe_3)Ph$: mp 112 °C (lit,[17] 116 °C); IR (KBr disk) 1600 (vw) and 1248 (s) cm^{-1}; NMR (CCl_4) δ=7.22 (m, 10H) and −0.38 (s, 18H). $PhCCl$=$C(SiMe_3)Ph$: mp 52—53 °C; IR (KBr disk) 1600 (vw) and 1250 (s) cm^{-1}; NMR (CCl_4) δ=7.02 (m, 10H) and 0.18 (s, 9H); MS (30 eV), *m/e* 286 (M^+). Found: C, 71.67; H, 6.25%. Calcd for $C_{17}H_{19}ClSi$: C, 71.18; H, 6.68%. (*E*)-4-$ClC_6H_4(Me_3Si)C$=$C(SiMe_3)C_6H_4$-4-Cl: mp 178—181 °C; IR (KBr disk) 1600 (vw) and 1252 (s) cm^{-1}; NMR (CCl_4) δ=6.98 (d, 2H, J=7 Hz), 7.12 (d, 2H, J=7 Hz) and −0.08 (s, 18H); MS (30 eV), *m/e*, 392 (M^+). Found: C, 60.89; H, 6.15%. Calcd for $C_{20}H_{26}Cl_2Si_2$: C, 61.05; H, 6.61%.

Reaction of Benzylidene Dichloride with $Pd(PPh_3)_4$. To a solution of 0.23 g (0.20 mmol) of the palladium(0) complex in 5 ml of benzene was added 0.064 g (0.40 mmol) of the dichloride under nitrogen. The reaction mixture was stirred at a room temperature for 5 h and then diluted with 20 ml of pentanes. The yellow microcrystals that separated were filtered, washed with ether and dried *in vacuo*. IR spectrum of this product was in complete agreement with that of the complex $PdCl_2(PPh_3)_2$; 0.083 g (64% yield). Further, GLC analysis of the filtrate showed the formation of (*E*)-stilbene (0.07 mmol) and 1,2-dichloro-1,2-diphenylethane (0.02mmol).

6) The formation of silylated products, *e.g.*, α-chloro-β-(trimethylsilyl)stilbenes, was virtually negligible in each run shown in Tables 2 and 3. It may be thus concluded that the reaction of the resulting α,β-dichlorostilbenes with hexamethyldisilane did not take place under the conditions employed. This is further confirmed by a control experiment in which α,β-dichlorostilbene [30%(*E*)- and 70%(*Z*)-isomers] was allowed to react with excess (10 equiv) of the permethyldisilane in the presence of 1 mol% of the palladium(0) complex at 130 °C for 5 h. The reaction resulted in the complete recovery of the starting dichlorostilbene.

16) The results seem to demonstrate that the reactivity of the chlorine atom in α-chloro-β-(trimethylsilyl)stilbenes toward hexamethyldisilane is substantially increased by β-trimethylsilyl substituent, when compared with those of the α,β-dichlorostilbenes, coupling products from benzylidyne trichlorides (see Ref. 6). Such an anchimeric effect of β-silicon will be discussed in future.

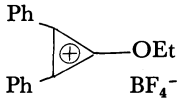
(Received April 19, 1983)

Reaction of methylthio-, ethylthio-, and benzylthiodiphenylcyclopropenium salts with 2,4-pentanedione (**3a**) and ethyl acetoacetate (**3b**) yielded the cyclopentadienol derivatives (**4**) by ring expansion. One of the products **4a** was shown to be 4-acetyl-5-hydroxy-5-methyl-1-methylthio-2,3-diphenyl-1,3-cyclopentadiene by X-ray crystallography. Chemical transformation of the products yielded some cyclopentenones. Triphenylcyclopropenium perchlorate reacted with **3a** and **3b** affording the ketocyclopropene in good yields.

Cyclopropenium ions with phenyl, amino, and alkylthio groups as substituents condense with nitrogenous nucleophiles such as hydrazine, aliphatic amines, and azides to give 5- or 6-membered nitrogen heterocycles,[1-4] whereas 1,2-diphenyl-3-ethoxycyclopropenium tetrafluoroborate (**1**) reacts with 1,3-diketones yielding fulvenes.[5,6] In the course of our studies on the chemistry of some cyclopropenone derivatives[7,8] we found a novel cyclization reaction of 3-alkylthio-1,2-diphenylcyclopropenium salts (**2**) with 2,4-pentanedione (**3a**) or ethyl acetoacetate (**3b**).



1

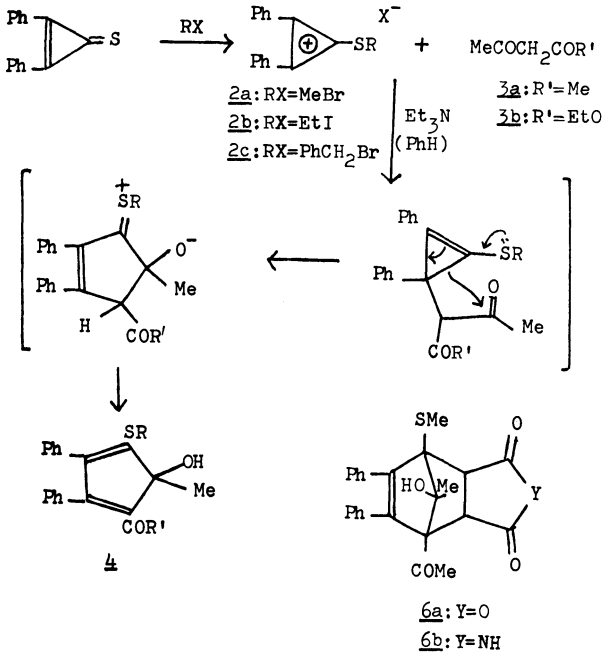
Diphenylcyclopropenethione reacted easily with alkyl halides, such as methyl bromide, ethyl iodide, or benzyl bromide, to give the corresponding cyclopropenium salts (**2a—c**) in good yields. A mixture of **2**, **3**, and triethylamine in approximately 1 : 1.2 : 2 molar ratio was stirred in benzene at room temperature for 20 min. Column chromatography of the products on silica gel afforded pale yellow crystals of the cyclopentadienols (**4**) (Table 1). The use of acetonitrile as reaction solvent or diisopropylamine as base lowered the yield of **4a**. Although many isomeric structures are mechanistically possible for the products, the ^{1}H- and ^{13}C-NMR, and mass spectra did not permit clear choice to be made.

Table 1. Reactions of cyclopropenium salts **2** or **11** with carbonyl compounds **3**.

Product	Reactant		R	R′	Yield/%[a]
4a	**2a**	**3a**	Me	Me	73, 59,[b] 61[c]
4b	**2a**	**3b**	Me	EtO	36
4c	**2b**	**3a**	Et	Me	71
4d	**2b**	**3b**	Et	EtO	45
4e	**2c**	**3a**	$PhCH_2$	Me	65
4f	**2c**	**3b**	$PhCH_2$	EtO	14
12a	**11**	**3a**	—	Me	73
12b	**11**	**3b**	—	EtO	61

Tertiary amine and solvent used: a) triethylamine in benzene, b) triethylamine in acetonitrile, c) diisopropylamine in acetonitrile.

The structure of 4-acetyl-5-hydroxy-5-methyl-1-methylthio-2,3-diphenylcyclopentadiene (**4a**) was ascertained by an X-ray crystal structure determination. There are two molecules of **4a** in the asymmetric unit and their relationship is shown in the stereo diagram, Fig. 1. Thermal ellipsoid plots of both molecules are shown in Fig. 2 and some of the more interesting bond lengths and angles are presented in Tables 2 and 3. There are no significant differences between the parameters for the two molecules. The two phenyl groups make angles of ≈58° (range 55.6—61°) in the same sense with the best plane through the respective cyclopentadiene ring. The bond length data suggests that there is electron delocalization from the sulfur atom through the butadiene system and into the acetyl group. In particular the S(1)–C(1) and C(2)–C(3) single bonds are shortened and the carbon-carbon and carbon-oxygen double bonds lengthened. The *S*-methyl carbons lie almost in the plane of their respective cyclopentadiene rings (deviation from plane: C(6)-0.307, C(6A)-0.211 Å)



Scheme 1.

TABLE 2. BOND LENGTHS FOR **4a** WITH e.s.d.'s IN PARENTHESES

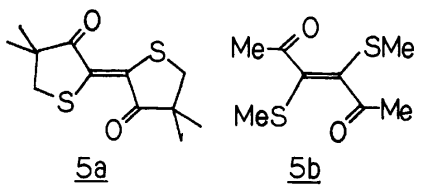
Bond length	l/Å	
	Molecule 1	Molecule 1A
S(1)–C(1)	1.744(6)	1.732(7)
S(1)–C(6)	1.769(8)	1.747(9)
O(1)–C(19)	1.235(7)	1.234(7)
O(2)–C(5)	1.440(7)	1.450(8)
C(1)–C(2)	1.359(8)	1.355(8)
C(1)–C(5)	1.504(8)	1.513(9)
C(2)–C(3)	1.389(8)	1.468(8)
C(2)–C(7)	1.481(8)	1.478(8)
C(3)–C(4)	1.351(8)	1.354(8)
C(3)–C(13)	1.484(8)	1.491(8)
C(4)–C(5)	1.523(8)	1.517(9)
C(4)–C(19)	1.456(8)	1.461(9)
C(5)–C(21)	1.525(9)	1.502(9)
C(19)–C(20)	1.502(9)	1.491(9)

Carbon-carbon bond lengths in the phenyl rings range between 1.361 and 1.397 Å with e.s.d.'s ranging from 0.008 to 0.011 Å.

TABLE 3. BOND ANGLES FOR **4a** WITH e.s.d.'s IN PARENTHESES

Bond angle	ϕ/°	
	Molecule 1	Molecule 1A
C(1)–S(1)–C(6)	107.4(4)	109.4(4)
S(1)–C(1)–C(2)	122.1(5)	124.0(5)
S(1)–C(1)–C(5)	126.4(5)	126.0(5)
C(2)–C(1)–C(5)	110.7(5)	109.6(6)
C(1)–C(2)–C(3)	107.3(5)	109.2(5)
C(1)–C(2)–C(7)	127.6(6)	126.0(6)
C(3)–C(2)–C(7)	125.2(5)	124.8(5)
C(2)–C(3)–C(4)	110.3(5)	109.3(5)
C(2)–C(3)–C(13)	119.7(5)	122.0(5)
C(4)–C(3)–C(13)	129.9(5)	128.8(6)
C(3)–C(4)–C(5)	108.6(5)	109.4(6)
C(3)–C(4)–C(19)	132.0(6)	132.1(6)
C(5)–C(4)–C(19)	119.3(6)	118.4(6)
O(2)–C(5)–C(1)	109.7(5)	109.5(6)
O(2)–C(5)–C(4)	111.7(5)	113.3(6)
O(2)–C(5)–C(21)	110.6(5)	110.5(5)
C(1)–C(5)–C(4)	102.6(5)	102.3(5)
C(1)–C(5)–C(21)	112.1(6)	111.3(6)
C(4)–C(5)–C(21)	110.0(5)	109.8(6)
O(1)–C(19)–C(4)	119.4(6)	118.4(7)
O(1)–C(19)–C(20)	117.9(6)	119.0(7)
C(4)–C(19)–C(20)	122.7(6)	122.4(6)

C–C–C bond angles at the phenyl ring carbons vary between 118.2 and 121.3° with e.s.d.'s ranging between 0.6 and 0.8°.



5a 5b

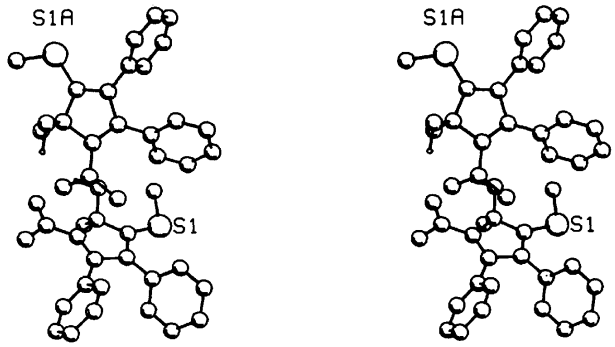


Fig. 1. A stereo view of the contents of the asymmetric unit of the crystal structure of **4a** drawn with SNOOPI.[10]

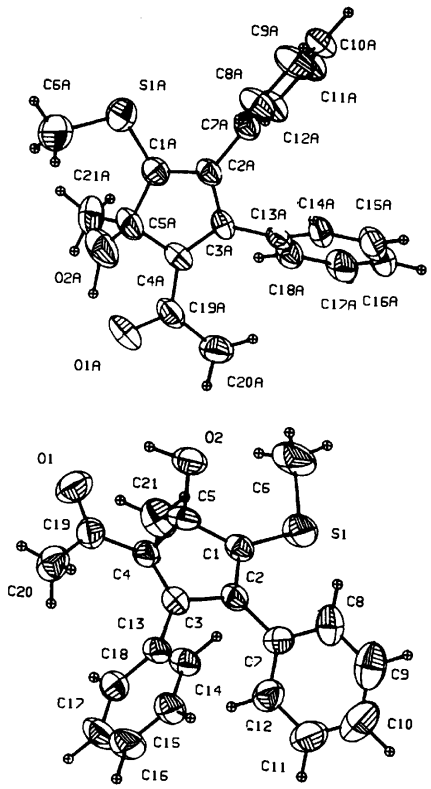

Fig. 2. Thermal ellipsoid plots, drawn at the 50% level of the two independent molecules of **4a** drawn with SNOOPI.[10]

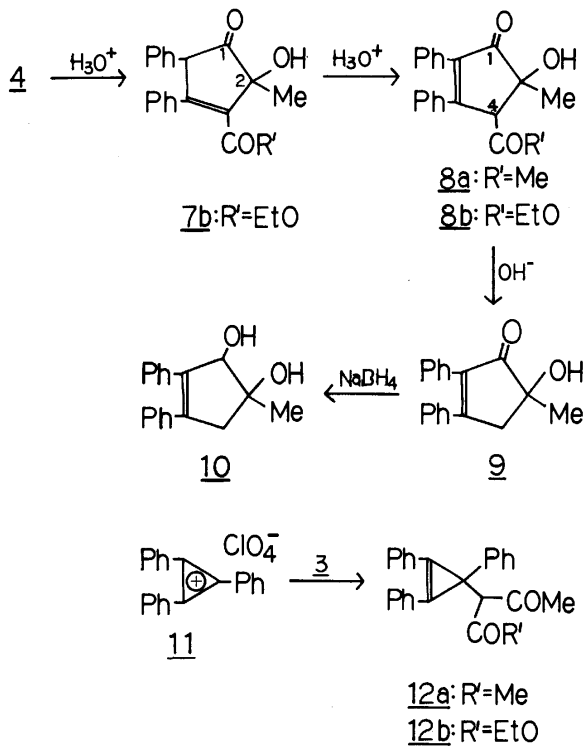
suggesting that the conjugated sulfur lone pair is in an essentially p-type orbital. From a comparison with the accurately measured[9] bond length data for *trans*-$\Delta^{2,2'}$-bis(4,4-dimethylthiolan-3-one) (**5a**) and *trans*-3,4-bis-(methylthio)-3-hexene-2,5-dione (**5b**) it would appear that electron delocalization from sulfur into an acetys group through a butadiene system was more effectivel than through just one carbon-carbon double bond. Thus the average C(1)–S(1) bond and the average C(4)–C(19) bond in **4a** are both shorter (by 0.010 and 0.028 Å respectively) while all the double bonds are longer than the equivalent bonds in **5a** and **5b**. However this may be misleading since further shortening of the bonds



joining the sulfur and acetyl moieties to the double bond in **5a, b** would further reduce the distance between the sulfur and carbonyl oxygen which is already (2.8 Å) within the sum of the van der Waals radii for these two atoms (3.2 Å).

The other compounds listed in Table 1 and given similar structures have similar spectra. In agreement with the dienol structure, **4a** underwent Diels-Alder reactions with maleic anhydride and maleimide at room temperature in benzene to give the adducts **6a** and **6b** in 81 and 66% yields and both showed characteristic AB quartets due to the two methine protons in their ^{1}H-NMR spectra.

Chemical transformation of **4** yielded some new cyclopentene derivatives **7**—**10**, the structures of which are based on their spectra and the reagents employed. Raney nickel (W1 and W5) desulfurization of **4a** and **4b** gave only tarry mixtures.

On hydrolysis with a mixture of trifluoroacetic acid–mercury(II) chloride–water–chloroform, both **4a** and **4c** gave the cyclopentenone (**8a**) in 88 and 81% yield respectively. In the absence of the mercury(II) chloride the product was a tarry mixture. In contrast, **4b** and **4d** were hydrolyzed easily with hydrochloric acid in ethanol to give β,γ-unsaturated cyclic ketone **7b**, which isomerized to **8b** under further acid treatment.

On heating in aqueous sodium hydroxide **8a** and **8b** smoothly cleaved to yield the cyclopentenone (**9**) in good yields. This type of cleavage of vinylogous β-keto esters or diketones has been studied.[11]

Reduction of **9** with sodium borohydride gave the cyclic glycol **10** quantitatively. The structure of **7**—**10** are consistent with their ^{1}H- and ^{13}C-NMR, IR, and mass spectra. The mass spectra of **8**—**9** showed peaks at *m/e* 178, corresponding to PhC≡CPh, indicaing that the PhC=CPh grouping splits out intact; **7b** showed no such peak. Since ^{1}H- and ^{13}C-NMR spectra indicated that only one isomer was obtained for **8a**, **8b**, and **10**, their structures were not settled.

Eicher and his coworkers have reported reactions of **1**, with various carbon nucleophiles,[12] at position 1 or 3 of the cyclopropene ring depending on the conditions and reactant used.

Although the reactions of **2** with **3** were expected to give similar products to those obtained from **1**, several attempts (careful column chromatography or varieties of reaction conditions) to isolate products other than **4** were unsaccessful.

In contrast to the behavior of **2**, triphenylcyclopropenium perchlorate (**11**) with **3** in the presence of triethylamine in benzene produced the triphenylcyclopropenes (**12**) (Table 1). Their structures are clear from their ^{1}H-NMR (one proton exchanged by NaOD) and IR (2000—1700 cm^{-1} due to the cyclopropene ring) spectra. These cyclopropenes **12** were stable at 100 °C in the presence or absence of triethylamine.

The marked difference in reaction between **2** and **11** may be ascribed to electron-releasing properties of the alkylthio group.[13] The exact mechanism for the formation of **4** is not clear but most probably involves the formation of an intermediate corresponding to **12**, ring expansion, and proton movement as shown in Scheme 1.

Experimental

General. Melting points are uncorrected. The ^{13}C FT NMR spectra were recorded on a JEOL JNM FX-60 spectrometer (15.04 MHz), and ^{1}H-NMR spectra, on a Hitachi-Perkin Elmer R-24 (60 MHz). The IR spectra were recorded on a JASCO A-3 spectrometer.

Preparation of Alkylthiodiphenylcyclopropenium Salts (2a—c). The alkyl halide (25 mmol) was added in one portion to a solution of diphenylcyclopropenthione (4.3 g) in benzene (50 ml), and after 2 d at room temperature the precipitated salt **2** was collected, washed with dry benzene, and all solvent removed under reduced pressure. The following were prepared: *methylthiodiphenylcyclopropenium bromide (2a)*: yield 88%; mp 131—132 °C; ^{1}H-NMR ($CDCl_3$–10% CF_3CO_2H) δ=3.24 (3H, s, MeS) and 7.1—8.3 (10H, m, Ph). *Ethylthiocyclopropenium iodide (2b)*: yield 62%; mp 130—132 °C; ^{1}H-NMR ($CDCl_3$–10% CF_3CO_2H) δ=1.52 (3H, t, J=7.5 Hz, $\underline{Me}CH_2$), 3.66 (2H, q, CH_2), and 7.1—8.3 (10H, m, Ph). *Benzylthiodiphenylcyclopropenium bromide (2c)*: yield 79%; mp 131—134 °C; ^{1}H-NMR ($CDCl_3$–10% CF_3CO_2H) 5.09 (2H, s, $Ph\underline{C}H_2$) and 7.1—8.3 (15H, m, Ph).

The Reactions of Alkylthiodiphenylcyclopropenium Ions (2) with 2,4-Pentanedione (3a) or Ethyl Acetoacetate (3b). (a): Methylthiodiphenylcyclopropenium bromide with **3a**. A mixture of **2a** (10 mmol), **3a** (12 mmol), and triethylamine (20 mmol) in dry benzene (100 cm^3) was stirred for 20 min. After filtration from the precipitate, the benzene solution was concentrated and chromatographed over silica gel (petroleum ether : benzene : ethyl acetate, 10 : 2 : 1 v/v) to give *4-acetyl-5-hydroxy-5-methyl-1-methylthio-2,3-diphenyl-1,3-cyclopentadiene (4a)*, yellow crystals (73%): mp 105—106 °C; IR (KBr) 3300—3500 (OH) and 1615 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$) δ=1.79 (3H, s, MeCO), 1.82 (3H, s, $\underline{Me}COH$), 2.39 (3H, s, MeS), 4.36 (1H, s, OH), and 6.9—7.5 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=15.0 (q, MeS), 27.1 (q, $\underline{Me}COH$), 29.7 (g, $\underline{Me}CO$) 87.2 (s, COH), 127.7 (d), 128.2 (d), 128.6 (d),

129.7 (d), 133.4 (s), 134.7 (s), 139.6 (s), 143.6 (s), 154.0 (s), 155.4 (s), and 196.0 (s, C=O); MS (*m/e*) 336 (M^+); Found: C, 74.73; H, 5.91%. Calcd for $C_{21}H_{20}O_2S$: C, 74.97; H, 5.99%.

Acetonitrile as reaction solvent gave 61% of **4a**, and replacing the triethylamine by diisorpylamine as well reduced the yield to 59%.

The subsequent reactions were carried out in benzene as described above. (*b*): Methylthiodiphenylcyclopropenium bromide (**2a**) with ethyl acetoacetate (**3b**) yielded *4-ethoxycarbonyl-5-hydroxy-5-methyl-1-methylthio-2,3-diphenyl-1,3-cyclopentadiene* (***4b***) (36%): mp 96—97 °C; IR (KBr) 3300—3500 (OH) and 1670 cm^{-1} (C=O); ^{1}H-NMR ($CDCl_3$) δ=0.99 (3H, t, J=7.5 Hz, MeCH$_2$), 1.78 (3H, s, MeCO), 2.31 (3H, s, MeS) 3.88 (1H, s, OH), 4.06 (2H, q, MeCH$_2$), and 7.0—7.6 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=13.6 (q, MeS), 15.1 (q, MeCH$_2$O), 21.6 (q, MeCOH), 59.9 (t, CH$_2$O), 86.1 (s, COH), 127.1 (d), 127.5 (d), 128.1 (d), 129.7 (d), 133.5 (s), 134.2 (s), 134.7 (s), 139.9 (s), 154.2 (s), 155.1 (s), and 164.1 (s, CO$_2$); MS (*m/e*) 366 (M^+); Found: C, 71.74; H, 5.98%. Calcd for $C_{22}H_{22}O_3S$: C, 72.12; H, 6.05%. (*c*): Ethylthiodiphenylcyclopropenium iodide (**2b**) with 2,4-pentanedione (**3a**) yielded *4-acetyl-1-ethylthio-5-hydroxy-5-methyl-2,3-diphenyl-1,3-cyclopentadiene* (***4c***) (71%): mp 107—107.5 °C; IR (KBr) 3300—3500 (OH) and 1610 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$) δ=1.13 (3H, t, J=7.5 Hz, MeCH$_2$), 1.74 (3H, s, MeC=O), 1.78 (3H, s, MeCOH), 2.4—3.6 (2H, m, CH$_2$), 4.05 (1H, s, OH), and 6.8—7.4 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=15.1 (q, MeCH$_2$), 25.8 (t, CH$_2$S), 27.5 (q, MeCOH), 29.4 (q, MeC=O), 87.2 (s, COH), 127.7 (d), 128.2 (d), 128.6(d), 129.6(d), 133.6 (s), 134.8 (s), 140.6 (s), 144.0 (s), 153.4 (s), 155.2 (s), and 195.9 (s, C=O); MS (*m/e*) 350 (M^+); Found: C, 75.50; H, 6.28%. Calcd for $C_{22}H_{22}O_2S$: C, 75.40; H, 6.23%. (*d*) Ethylthiodiphenylphenylcyclopropenium iodide (**2b**) with ethyl acetoacetate (**3b**) yielded *4-ethoxycarbonyl-1-ethylthio-5-hydroxy-5-methyl-2,3-diphenyl-1,3-cyclopentadiene* (***4d***) (45%): mp 62—63 °C; IR (KBr) 3300—3500 (OH) and 1660 cm^{-1} (CO): ^{1}H-NMR ($CDCl_3$) δ=0.98 (3H, t, J=7.5 Hz, MeCH$_2$O), 1.15 (3H, t, J=7.5 Hz, MeCH$_2$S), 1.77 (3H, s, MeCOH), 2.4—3.6 (2H, m, CH$_2$), 4.08 (2H, q, J=7.5 Hz, CH$_2$O), and 6.8—7.4 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=13.7 (q, MeCH$_2$S), 15.2 (q, MeCH$_2$O), 25.8 (t, CH$_2$S), 26.4 (q, MeCOH), 59.9 (t, CH$_2$O), 86.1 (s, COH), 127.0 (d), 127.3 (d), 127.6 (d), 127.7 (d), 128.9 (d), 129.6 (d), 133.7 (s), 134.2 (s), 135.2 (s), 141.1 (s), 150.5 (s), 154.1 (s), and 164.2 (s, CO$_2$); MS (*m/e*) 380 (M^+); Found: C, 72.50; H, 6.48%. Calcd for $C_{23}H_{24}O_3S$: C, 72.60; H, 6.36%. (*e*): Benzylthiodiphenylcyclopropenium bromide (**2c**) with 2,4-pentanedione (**3a**) yielded *4-acetyl-1-benzylthio-5-hydroxy-5-methyl-2,3-diphenyl-1,3-cyclopentadiene* (***4e***) (65%): mp 116—117 °C; IR (KBr) 3300—3500 (OH) and 1620 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$) δ=1.76 (3H, s, MeCO), 1.99 (3H, s, MeCOH), 4.04 and 4.30 (2H, ABq, J=13 Hz, CH$_2$), 4.16 (1H, s, OH), and 6.7—7.4 (15H, m, Ph); MS (*m/e*) 412 (M^+); Found: C, 78.61; H, 5.97%. Calcd for $C_{27}H_{24}O_2S$: C, 78.61; H, 6.06%. (*f*): Benzylthiodiphenylcyclopropenium bromide (**2c**) with ethyl acetoacetate (**3b**) gave *1-benzylthio-4-ethoxycarbonyl-5-hydroxy-5-methyl-2,3-diphenyl-1,3-cyclopentadiene* (***4f***) (14%): mp 120—121 °C; IR (KBr) 3300—3500 (OH) and 1675 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$) δ=0.98 (3H, t, J=7.5 Hz, MeCH$_2$), 1.76 (3H, s, MeCOH), 4.08 (2H, q, CH$_2$O), 4.08 (1H, s, OH), 4.13 (2H, s, PhCH$_2$) and 6.6—7.7 (15H, m, Ph); MS (*m/e*) 442 (M^+); Found; C, 76.28; H, 6.09%. Calcd for $C_{28}H_{26}O_3S$: C, 75.99; H, 5.92%.

Diels-Alder Reaction of ***4a***. (*a*): A solution of **4a** (1 mmol) and maleic anhydride (2 mmol) in benzene (25 cm^3) was stirred at room temperature for 3 h. The precipitate of needles was collected, washed with small amount of benzene, and dried to give *the adduct* **6a** (81%): mp 151—165 °C; IR (KBr) 3450 (OH), 1855, 1770, and 1690 cm^{-1}; ^{1}H-NMR ($CDCl_3$–DMSO-d_6 1/1) δ=1.63 (3H, s, MeCOH), 2.03 (3H, s, MeCO), 2.22 (3H, s, MeS), 3.10 (1H, bs, OH), 4.33 (1H, d, J=9 Hz, CH), 4.83 (1H, d, CH), and 6.6—7.6 (10H, m, Ph) MS (*m/e*) 434 (M^+); Found: C, 68.54; H, 5.01%. Calcd for $C_{25}H_{20}O_5S$: C, 69.11; H, 5.10%. (b) A solution of **4a** (1 mmol) and maleimide (1 mmol) in ethanol (50 cm^3) was left at room temperature for 3 h. The solvent was removed *in vacuo* and the residual crystalline mass washed with benzene and hot ethanol to yield *the adduct* **6b** (66%): mp 234—238 °C; IR (KBr) 3475 (OH), 1860, 1780, and 1700 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$: DMSO-d_6, 1 : 1) δ=1.06 (3H, s, MeCOH), 2.14 (3H, s, MeCO), 2.16 (3H, s, MeS), 3.24 (1H, s, OH), 3.86 (1H, d, J=7.5 Hz, CH), 4.52 (1H, d, CH), 5.91 (1H, s, NH), and 6.6—7.3 (10H, m, Ph); MS (*m/e*) 443 (M^+); Found: C, 68.44; H, 5.12; N, 3.10%. Calcd for $C_{25}H_{21}NO_4S$: C, 69.26; H, 5.35; N, 3.23%.

Hydrolysis of ***4a***. A mixture of **4a** (160 mg, 0.48 mmol), mercury(II) chloride (260 mg, 0.96 mmol), trifluoroacetic acid (0.56 cm^3, 48 mmol), water (0.4 cm^3), and chloroform (15 cm^3) was vigorously stirred at room temperature for 3 d. Water (15 cm^3) was added and the organic layer separated. Removal of the solvent and chromatography of the residue over silica gel (chloroform: ethyl acetate, 3 : 1, v/v) yielded *4-acetyl-5-hydroxy-5-methyl-2,3-diphenyl-2-cyclopentenone* (**8a**) (88 %): mp 184—185 °C (2-propanol); IR (KBr) 3450 (OH), 1700, 1690 (sh) (CO), and 1620 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=1.60 (3H, s, MeCOH), 2.20 (3H, s, MeCO), 2.92 (1H, OH, D_2O exchangeable), 4.28 (1H, s, CH), and 7.28—7.31 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=27.3 (q, MeCOH), 30.5 (q, MeCO), 67.7 (d, C_4H), 78.4 (s, C_5), 128.3 (d), 128.6 (d), 128.8 (d), 129.2 (d), 129.5 (d), 130.5 (d), 131.2 (s), 134.2 (s), 138.0 (s), 163.2 (s), 204.9 (s, MeC=O), and 206.8 (s, C_1=O); MS (*m/e*) 304 (M^+); Found: C, 78.28; H, 5.83%. Calcd for $C_{20}H_{18}O_3$: C, 78.41; H, 5.92%.

Hydrolysis of ***4b*** *to* ***7b***. A solution of **4b** (270 mg, 0.55 mmol) and concentrated hydrochloric acid (0.4 cm^3) in ethanol (10 cm^3) was stirred at 10 °C for 2 d. The mixture was quenched with water and the product was extracted with chloroform. The extract was dried and evaporated under reduced pressure to give colorless crystals of *3-ethoxycarbonyl-2-hydroxy-2-methyl-4,5-diphenyl-3-cyclopentenone* (***7b***) (86% crude yield) which after recrystallization from 2-propanol (48%) has mp 150—151 °C: IR (KBr) 3450 (OH), 1730, 1710 (CO), and 1630 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=1.16 (3H, t, J=7 Hz, MeCH$_2$), 1.60 (3H, s, MeC$_2$), 3.01 (1H, s, OH), 4.06 (1H, s, CH), 4.07 (2H, q, CH$_2$), and 7.0—7.4 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=13.7 (q, MeCH$_2$), 26.4 (q, MeCOH), 61.0 (d, C_5H), 61.7 (t, CH$_2$), 78.1 (s, C_2), 128.3 (d), 128.5 (d), 129.2 (d), 130.0 (d), 130.3 (d), 131.3 (s), 134.1 (s), 137.9 (s), 161.0 (s), 169.6 (s, CO$_2$), and 206.2 (s, C_1=O); MS (*m/e*) 396 (M^+); Found: C, 75.08; H, 5.83%. Calcd for $C_{21}H_{20}O_4$: C, 74.98; H, 5.99%.

Similar treatment of **4d** yielded **7b** in 83% yield.

Isomerization of ***4b*** *to* ***8b***. A solution of **4b** (0.5 mmol) and concentrated HCl (1 cm^3) in ethanol (10 cm^3) was left at 25 °C for 2 d. The mixture was quenched with water, extracted with chloroform and the dried extracts evapolated *in vacuo* to yield a crystalline mass of *4-ethoxy-5-hydroxy-5-methyl-2,3-diphenylcyclopent-2-enone* (***8b***) (83%) mp: 158—159 °C (benzene–petroleum ether); IR (KBr) 3470 (OH), 1730, and 1710 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$) δ=1.06 (3H, t, J=7.5 Hz, MeCH$_2$), 1.46 (3H, s, MeC$_5$), 3.13 (1H, s, OH, D_2O exchangeable), 4.08 (2H, q, CH$_2$), 4.27 (1H, s, CH), and 7.0—7.5 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=14.0 (q, MeCH$_2$), 21.7 (q, Me), 60.0 (t, CH$_2$), 61.2 (d, CH), 77.2 (s,

MeCOH), 128.4 (d), 128.4 (d), 129.5 (d), 130.1 (d), 130.9 (s), 134.3 (s), 137.3 (s), 163.5 (s), 169.8 (s, CO_2), and 206.3 (s, C=O); MS (*m/e*) 396 (M^+) and 178 (PhC≡CPh); Found: C, 74.75; H, 5.85%. Calcd for $C_{21}H_{20}O_4$: C, 74.98; H, 5.99%.

The compound **8b** was prepared in the same way from **7b** in 96% yield.

*Preparation of 2,3-Diphenyl-5-hydroxy-5-methylcyclopent-2-en-1-one (**9**).* A suspension of **8a** (272 mg, 0.89 mmol) in 20% aqueous hydroxide (15 cm^3) was refluxed for 20 min. The first formed red solution precipitated crystals. After cooling these were collected and purified by chromatography over silica gel (ethyl acetate : chloroform, 1 : 3, v/v) to give **9** (60%): mp 146—147 °C (benzene); IR (KBr) 3425 (OH) and 1690 cm^{-1} (CO); ^{1}H-NMR ($CDCl_3$) δ=1.53 (3H, s, Me), 2.68 (1H, s, OH), 2.94 and 3.31 (2H, d, J=18 Hz, CH_2), and 7.1—7.4 (10H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=24.1 (q, Me), 44.2 (t, CH_2), 73.2 (COH), 126.4 (d), 126.8 (d), 127.7 (d), 128.6 (d), 130.4 (s), 133.4 (s), 134.2 (s), 163.5 (s), and 207.2 (s, C=O); MS (*m/e*) 264 (M^+) and 178 (PhC≡CPh); Found: C, 81.55; H, 6.00%. Calcd for $C_{18}H_{16}O_2$: C, 81.79; H, 6.10%. similar treatment of **8b** with aqueous sodium hydroxide yielded **9** in a 74% yield.

*Reduction of **9** with Sodium Borohydride.* A solution of **9** (1 mmol) and sodium borohydride (1 mmol) in ethanol (25 cm^3) was stirred at room temperature for 1 d, quenched with water and extracted with chloroform. The extract was chromatographed over silica gel (chloroform : ethyl acetate, 3 : 1, v/v) to yield *3,4-diphenyl-1-methyl-3-cyclopentene-1,2-diol (**10**)* (75%): mp 110—111 °C; IR (KBr) 3100—3700 cm^{-1} (OH); ^{1}H-NMR ($CDCl_3$) δ=1.45 (3H, s, Me), 2.20 (2H, s, OH), 2.58 and 3.20 (2H, d, J=16 Hz, CH_2), 4.07 (1H, s, CH), and 7.1—7.3 (10H, m, Ph); MS (*m/e*) 266 (M^+) and 178 (PhC≡CPh); Found: C, 80.58; H, 6.84%. Calcd for $C_{18}H_{18}O_2$: C, 81.17; H, 6.81%.

*Reactions of Triphenylcyclopropenium Perchlorate (**11**). (a) With 2,5-Pentanedione (**3a**)*: A mixture of **11** (0.5 mmol), **3a** (0.6 mmol), and triethylamine (1.0 mmol) in benzene (10 cm^3) was stirred for 20 min. The solution was concentrated and chromatographed over silica gel (petroleum ether : ethyl acetate, 4 : 1, v/v). Evaporation of the elute gave a solid which recrystallized from 2-propanol to give *3-(1,2,3-triphenyl-2-cyclopropenyl)-2,4-pentanedione (**12a**)* (73%): mp 135—137 °C; IR (KBr) 1810, 1730, and 1700 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=2.07 (6H, s, MeCO), 5.22 (1H, s, CH), and 7.0—8.1 (15H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=31.2 (q, Me), 33.0 (s, C_3), 72.1 (d, CH), 116.9 (s), 125.9 (d), 126.2 (d), 128.0 (d), 128.2 (s), 128.3 (d), 128.6 (d), 128.9 (d), 129.7 (d), 144.3 (s), and 204.2 (C=O); MS (*m/e*) 366 (M^+); Found: C, 85.28; H, 6.00%. Calcd for $C_{26}H_{22}O_2$: C, 85.22; H, 6.05%. *(b) With Ethyl Acetoacetate **3b***: A mixture of **11** (0.5 mmol), ethyl acetoacetate **3b** (0.6 mmol), and triethylamine (1 mmol) in benzene yielded *ethyl 2-(1,2,3-triphenyl-2-cyclopropenyl)-3-oxobutyrate (**12b**)* (61%): mp 133—134 °C; IR (KBr) 1950, 1890, 1730, and 1710 cm^{-1}; ^{1}H-NMR ($CDCl_3$) δ=0.94 (3H, t, J=7 Hz, MeCH$_2$) 2.12 (s, MeCO), 3.98 (2H, q, CH_2O), 4.96 (1H, CH), and 7.1—8.0 (15H, m, Ph); ^{13}C-NMR ($CDCl_3$) δ=13.6 (q, MeCH$_2$), 30.3 (q, MeCO), 32.5 (s, C_3), 61.1 (t, CH_2O), 64.6 (d, CH), 116.0 (s), 116.3 (s), 125.8 (d), 126.2 (s), 128.0 (s), 128.2 (d), 128.7 (d), 129.0 (d), 129.7 (d), 129.8 (d), 144.2 (s), 169.1 (s, CO_2), and 202.5 (s, COMe); MS (*m/e*) 396(M^+); Found: C, 81.99; H, 6.28%. Calcd for $C_{27}H_{24}O_3$: C, 81.79; H, 6.10%.

Crystal Structure Determination. Crystal Data: $C_{21}H_{20}O_2S$, M_r 336.5, monoclinic, $P2_1/n$, a=10.365(4), b=24.659(8), c=14.394(5) Å, β=101.63(3)°, U=3603.4 Å, Z=8, D_c=1.25 g cm^{-3}, μ=0.19 mm^{-1} (Mo $K\alpha$), R=0.053 for 2225 observed reflections.

A crystal of **4a** mounted on a glass fibre, was transferred to a CAD-4F four-circle diffractometer. Cell dimensions were determined from the positions of strong reflections located by the SEARCH routine and intensity data was collected by $\omega/2\theta$ scans out to 2θ=44° with periodic checking of the intensity and orientation of three standered reflections. After the application of Lorentz and polarization corrections, elimination of systematic absences and the merging of equivalent reflections, 3520 structure amplitudes were derived. The structure was solved using MULTAN 80[14] whic hlocated all but one of the non-hydrogen atoms. The structure was refined by blocked-matrix least squares with isotropic temperature factors and with Waser constrains[15] applied to the phenyl ring (bond lengths: 1.40 Å, e.s.d. 0.01 Å, bond angles: 120°, e.s.d. 0.5°). The missing atom was located by a difference Fourier synthesis and refinement continued with anisotropic temperature factors. The hydroxyl hydrogen atoms were placed from a difference Fourier synthesis but all the other hydrogens were placed geometrically and all were assigned an isotropic temperature factor of 0.075 and excluded from the refinement. The constrains on the phenyl ring were removed and weights for the final rounds of refinement were computed from Chebyshev series $w=[19.33t_0(x)+25.87t_1(x)+8.733t_2(x)]^{-1}$, where $(x)=F_o/F_{max}$.[16] The structure converged at an R-value of 0.053. All calculations were performed with the CRYSTALS[17] package on a VAX 11/750 computer.

Stereoselective Syntheses of 3-Acetyl-1,2-dimethyl-1-cyclopentanols. Syntheses of *dl*-Plinols A, B, and C

Takeshi IMAGAWA, Kazuyuki MATSUURA, Nobuyuki MURAI, Tetsuo AKIYAMA, and Mituyosi KAWANISI*

Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

(Received May 9, 1983)

c- and *t*-3-Acetyl-1,*c*-2-dimethyl-*r*-1-cyclopentanols and *c*-3-acetyl-1,*t*-2-dimethyl-*r*-1-cyclopentanol are synthesized stereoselectively and *dl*-plinols A, B, and C are prepared therefrom.

Isomeric 3-acetyl-1,2-dimethyl-1-cyclopentanols have been obtained by ozonolysis of four isomeric plinols separated gas-chromatographically from a mixture of A, B, C, and D, which was derived from linalool by ene reaction.[1] Meanwhile, the title cyclopentanols have been recognized[2] as the key substance for synthesis of a variety of terpenoids. For instance, cyclonerodiol, a biogenetically important fungal metabolite, has been synthesized from an isomer of the cyclopentanols.[3] However, procurement of the aforementioned plinols in stereochemically pure state is not necessarily easy task. Therefore, facile preparation of each cyclopentanol isomer seems highly desirable.

In this report we wish to describe a streoselective synthesis of *c*- and *t*-acetyl-1,*c*-2-dimethyl-*r*-1-cyclopentanols (**1** and **2**, respectively) and *c*-3-acetyl-1,*t*-2-dimethyl-*r*-1-cyclopentanol (**3**) by a methodology based on Wagner-Meerwein rearrangement of 7-oxabicyclo[2.2.1]hept-2-yl cation to 2-oxabicyclo[2.2.1]hept-3-yl cation employing anodic oxidative decarboxylation.[4]

Additionally the transformation of the cyclopentanols into *dl*-plinols A, B, and C is described.

6 ; R = CH_2 4 : R = CH_2 5 : R = CH_2

Results and Discussion

The anhydride **8**,[5] obtained from the Diels-Alder adduct (**7**) of maleic anhydride and 2,5-dimethylfuran followed by hydrogenation, was reduced by sodium borohydride to give lactone **9**. Lactone **9** was treated with benzenethiolate anion to afford carboxylic acid **10**. Raney nickel desulfurization of **10** gave *exo*-methyl carboxylic acid **11** in 31% overall yield from **7**.

Acid **11** was electrolyzed in methanolic solution with addition of sodium methanolate using graphite electrodes to give cyclic acetal **12**.[4] Addition of aqueous acetic acid to this mixture gave ketone **1** in 84% yield. The configuration of this compound was obvious from consideration of the reaction course as well as from comparison with the reported data.[1] It was further established by transformation into *dl*-plinol C (**6**) as follows.

Methylenation of **1** with dibromomethane–zinc–titanium tetrachloride[6] gave exclusively *dl*-plinol C (**6**) in 50% yield. Its structure was confirmed by comparison with the reported spectral data.[1]

Alternatively the methyl ketone **1** was efficiently epimerized[1,3] to isomeric ketone **2** which was a synthetic intermediate for cyclonerodiol.[3] Methylenation of ketone **2** in the same manner yielded *dl*-plinol A (**4**) in 66% yield.

The *endo*-anhydride **17** obtained from the Diels-Alder adduct (**13**) of 2,5-dimethylfuran and dimethyl acetylenedicarboxylate gave lactone **18** by sodium borohydride reduction. Cleavage of lactone **18** by benzenethiolate anion, followed by desulfurization gave *endo*-methyl carboxylic acid **20** isomeric to **11** in 77% yield.

Similarly, electrolysis of **20** followed by hydrolysis gave stereoselectively *trans*-methyl ketone **3** in 63% yield. Methylenation of **3** gave *dl*-plinol B (**5**) in 51% yield.

In summary three isomeric 3-acetyl-1,2-dimethyl-1-cyclopentanols were prepared in stereochemically pure form and it was demonstrated that they are useful starting materials for synthesis of natural products.

Experimental

All mp's were uncorrected. Distillation was performed on a Buchi Kugelrohr apparatus. ^{1}H-NMR spectra were obtained with a Varian EM-360 or EM-390 spectrometer using tetramethylsilane as an internal standard. ^{13}C-NMR spectra were obtained with a Varian CFT-20 spectrometer in $CDCl_3$ solution unless otherwise noted, using tetramethylsilane as an internal standard. IR spectra were recorded with a Shimazu IR-27 spectrophotometer as Nujol mull.

Synthesis of c-*3-Acetyl-1,*c-*2-dimethyl-*r-*1-cyclopentanol (1).*

(a) Hydrogenation of 7: Hydrogenation of 5.23 g (26.9 mmol) of **7** in 30 ml of ethyl acetate using palladium black catalyst (0.5 g) gave 5.03 g (95%) of the product **8** after filtration, removal of the solvent and distillation; mp 126.2—126.7 °C (lit,[5] 121.5 °C); ^{1}H-NMR ($CDCl_3$): δ=3.16 (s, 2H), 1.81 (s, 4H), 1.64 (s, 6H).

(b) exo-*3-Hydroxymethyl-1,4-dimethyl-7-oxabicyclo[2.2.1]heptane-*exo-*2-carboxylic Lactone (9)*: To an ice-cooled and stirred solution of 2.8 g (73.7 mmol) of $NaBH_4$ in 100 ml of dry EtOH 9.03 g (46.0 mmol) of the anhydride **8** was added slowly. After the evolution of the reaction heat subsided, the reaction mixture was kept for 3 h at room temp and 35 ml of 5 M hydrochloric acid (1 M=1 mol dm^{-3}) was added with cooling in an ice bath. The solution was diluted with water and extracted with dichloromethane. The organic layer was dried over anhydrous Na_2SO_4 and concentrated *in vacuo*. Distillation gave 7.41 g (88%) of **9**; bp 116—117 °C/3 kPa; ^{1}H-NMR ($CDCl_3$): δ=4.5—4.1 (m, 2H), 2.2—2.9 (2H), 1.74 (m, 4H), 1.59 (s, 3H), 1.47 (s, 3H); ^{13}C-NMR: δ=176.6 (s), 85.8 (s),

85.0 (s), 68.7 (t), 52.7 (d), 48.0 (d), 38.7 (t), 37.5 (t), 18.0 (q), 17.4 (q); MS: *m/e* 182 (M^+, 1), 124, 98 (100), 97, 43. Found: C, 66.20; H, 7.83%. Calcd for $C_{10}H_{14}O_3$: C, 65.92; H, 7.74%.

*(c) 1,4-Dimethyl-*exo*-3-phenylthiomethyl-7-oxabicyclo[2.2.1]-heptane-*exo*-2-carboxylic Acid (**10**)*: Sodium benzenethiolate, freshly prepared from 0.74 g (32 mmol) of Na and 3.5 ml (34 mmol) of benzenethiol by stirring overnight at room temp. and evaporation of the solvent (THF), and 2.374 g (13.03 mmol) of **9** were dissolved in 25 ml of DMF. The solution was heated at 130 °C for 16 h. After having been cooled to room temp, the reaction mixture was acidified with 20 ml of 2 M hydrochloric acid and extracted with dichloromethane. The organic layer was extracted with 2% aq NaOH four times (30 ml×2, 20 ml×2). The combined aqueous layer was acidified and extracted with diethyl ether. The organic layer was dried over anhydrous Na_2SO_4 and concentrated *in vacuo*. Crude crystals thus obtained were recrystallized from benzene to give 2.468 g (65%) of pure **10**; mp 122.0—124.0 °C; ^{1}H-NMR ($CDCl_3$): δ=7.4 (m, 5H), 3.3—2.9 (3H), 2.42 (m, 1H), 1.70 (bs, 4H), 1.52 (s, 3H), 1.48 (s, 3H); ^{13}C-NMR: δ 177.4 (s), 135.7 (s), 129.9 (d), 128.9 (d), 126.3 (d), 85.2 (s), 84.9 (s), 56.1 (d), 49.8 (d), 39.3 (t), 38.7 (t), 33.0 (t), 18.3 (q), 17.8 (q) Found: C, 65.57; H, 6.98; S, 11.13%. Calcd for $C_{16}H_{20}O_3S$: C, 65.73; H, 6.89; S, 10.96%.

*(d) 1,*exo*-3,4-Trimethyl-7-oxabicyclo[2.2.1]heptane-*exo*-2-carboxylic Acid (**11**)*: To a solution of 6.04 g of NaOH and 612 mg (2.093 mmol) of **10** in 40 ml of water, 3.06 g of Ni–Al alloy was added slowly with cooling with running water. After addition of the alloy the suspension was stirred for 1 h and refluxed for 2.5 h. The Raney nickel was removed by filtration and the filtrate was acidified with hydrochloric acid. Extraction with diethyl ether, drying over Na_2SO_4, removal of the solvent, and distillation gave 364 mg (94%) of **11**; mp 67.5—68.5 °C; ^{1}H-NMR ($CDCl_3$): δ=9.1 (COOH), 2.95 (d, 1H), 2.3 (m, 1H), 1.70 (bs, 4H), 1.54 (s, 3H), 1.37 (s, 3H), 0.98 (d), 3H); ^{13}C-NMR: δ=174.6 (s), 85.8(s), 84.5 (s), 58.4 (d), 44.0 (d), 39.3 (t), 38.4 (t), 18.6 (q), 17.4 (q), 13.3 (q); MS: *m/e* 184 (M^+, 15), 169, 139, 123, 109, 97 (100). Found: C, 64.93; H, 8.79%. Calcd for $C_{10}H_{16}O_3$: C, 65.19; H, 8.75%.

*(e) Electrolysis of **11***: A solution of 351 mg (1.906 mmol) of **11** and 30 mg of NaOMe in 25 ml of dry MeOH was electrolyzed using graphite electrode in an undivided cell with ice cooling. After **11** had been consumed, 4 ml of water and 1 ml of AcOH were added to the reaction mixture. The solution was kept overnight at room temp. and concentrated *in vacuo*. The residue was diluted with water, neutralized with $NaHCO_3$ and extracted with dichloromethane. The organic layer was washed with sat. aq NaCl, dried over Na_2SO_4, concentrated, and distilled to give 250 mg (84%) of **1**; ^{13}C-NMR: δ=216.4 (s), 79.3 (s), 54.9 (d), 46.4 (d), 41.6 (t), 32.4 (q), 26.6 (t), 24.8 (q), 9.1 (q); other spectral data of **1** were in accord with those previously reported.[1]

Synthesis of dl-*Plinol C (**6**)*. To a suspension of 779 mg (11.9 mmol) of zinc powder in 10 ml of dry THF, 756 mg (4.35 mmol) of CH_2Br_2 was added under argon atmosphere. At 0 °C 3.0 ml of 1 M solution of $TiCl_4$ in CH_2Cl_2 was added and stirring was continued for 20 min. A solution of 44.4 mg of **1** in 2 ml of THF was added to this solution. After having been stirred overnight at r.t., the mixture was diluted with 10 ml of diethyl ether and 20 ml of 1 M hydrochloric acid and stirring was continued for an additional hour. Ether extract of the solution was washed with sat. aq NaCl, dried over Na_2SO_4, concentrated, and distilled to give 21.9 mg (50%) of *dl*-plinol C (**6**); ^{13}C-NMR: δ=148.2 (s), 110.6 (t), 80.3 (s), 48.9 (d), 45.7 (d), 39.5 (t), 29.4 (q), 25.5 (t), 23.3 (q), 9.3 (q); other spectra were identical with the reported full spectra.[1] (−)-Plinols C and B are reported to be crystals[1] but *dl*-plinols C and B were obtained as oils.

Preparation of t-*3-Acetyl-1,*c-*2-dimethyl-*r-*1-cyclopentanol (**2**)*. Isomerization of **1** (123 mg; 0.787 mmol) was performed by the published procedure[3] to give 107 mg (87%) of **2**; ^{13}C-NMR: δ=211.3 (s), 80.7 (s), 57.8 (d), 46.2 (d), 40.2 (t), 29.8 (q), 25.8 (q), 11.6 (q); other spectral data were consistent with those previously reported.[1]

Synthesis of dl-*Plinol A (**4**)*. *dl*-Plinol A (**4**) was prepared from **2** (31.6 mg; 0.203 mg) according to the method described above for plinol C as a liquid (20.7 mg; 66%); ^{13}C-NMR: δ=147.2 (s), 110.3 (t), 80.4 (s), 52.9 (d), 47.2 (d), 40.2 (t), 27.6 (t), 26.6 (q), 19.1 (q), 10.6 (q); other spectra were identical with the reported full spectra.[1]

Synthesis of c-*3-Acetyl-1,*t-*2-dimethyl-*r-*1-cyclopentanol (**3**)*.

*(a) 1,4-Dimethyl-7-oxabicyclo[2.2.1]heptane-*endo*-2,3-dicarboxylic Anhydride (**17**)*: A mixture of 3.34 g (34.8 mmol) of 2,5-dimethylfuran and 4.47 g (31.5 mmol) of dimethyl acetylenedicarboxylate was heated in a pressure bottle at 100 °C

for 21 h. The reaction mixture was dissolved in 30 ml of acetone and hydrogenated over 0.82 g of 10% Pd/C. Removal of the catalyst and of the solvent gave **14** in quantitative yield; mp 158—160 °C; ^{1}H-NMR ($CDCl_3$): δ=3.81 (s, 6H), 1.76 (bs, 4H), 1.68 (s, 6H).

To a solution of 3.461 g (14.4 mmol) of **14** in 2.5 ml of THF, 6 ml of 20 M KOH solution was added . After stirring for 2 h at r.t., the reaction mixture was acidified to pH 1 and concentrated. The residue was extracted with diethyl ether. Drying over Na_2SO_4 and removal of the solvent gave 3.003 g (98%) of **15**; mp 158—160 °C; ^{1}H-NMR (CD_3COCD_3): δ=1.72 (bs, 4H), 1.68 (s, 6H).

Hydrogenation of **15** (1.156 g; 5.45 mmol) (Pd black; EtOH) gave quantitiatively **16**; mp 155—158 °C; ^{1}H-NMR (CD_3COCD_3): δ=3.00 (s, 2H), ≈1.5 (4H), 1.47 (s, 6H).

A solution of 656 mg (3.06 mmol) of **16** in 8 ml of acetyl chloride was heated under reflux for 3 h. Removal of the volatile material by evaporation and washing the residue with ligroine gave 549 mg (92%) of **17**; mp 140—143 °C; ^{1}H-NMR (CD_3COCD_3): δ=3.62 (s, 2H), 1.82 (s, 4H), 1.59 (s, 6H). Found: C, 60.98; H, 5.87%. Calcd for $C_{10}H_{12}O_4$: C, 61.21; H, 6.17%.

endo-*3-Hydroxymethyl-1,4-dimethyl-7-oxabicyclo*[*2.2.1*]*heptane*-endo-**2**-*carboxylic Lactone* (**18**). According to the procedure for the reduction of **8**, 278 mg (1.42 mmol) of **17** was reduced to the lactone **18** (246 mg; 95%); mp 103.0—104.5 °C. ^{1}H-NMR (CD_3COCD_3): δ=4.21 (m, 2H), 2.97 (m, 2H), ≈1.7 (4H), 1.46 (s, 3H), 1.37 (s, 3H); ^{13}C-NMR (CD_3COCD_3): δ=177.1 (s), 87.3 (s), 86.6 (s), 67.6 (t), 56.3 (d), 52.4 (d), 35.2 (t), 31.4 (t), 21.4 (q), 21.0 (q); MS: *m/e* 182 (M^+, 9), 125. 124, 108 (100), 107; IR: 1760 cm^{-1}. Found: C, 65.74; H, 7.78%. Calcd for $C_{10}H_{14}O_3$: C, 65.92; H, 7.74%.

1,4-Dimethyl-endo-*3-phenylthiomethyl-7-oxabicyclo*[*2.2.1*]*heptane*-endo-*2-carboxylic Acid* (**19**). As described above, 545 mg (2.99 mmol) of **18** yielded 777 mg (89%) of **19**; ^{1}H-NMR ($CDCl_3$): δ=7.2 (5H), 2.7—3.5 (3H), 1.5—2.5 (5H), 1.42 (s, 3H), 1.32 (s, 3H); ^{13}C-NMR: δ=177.2 (s), 135.8 (s), 130.0 (d), 129.0 (d), 126.4 (d), 87.1 (s), 86.4 (s), 54.1 (d), 49.8 (d), 33.2 (t), 31.7 (t), 31.7 (t), 21.2 (q), 20.4 (q). IR: 3000, 1725, 1580, 1450 cm^{-1}. Found: C, 65.46; H, 6.61; S, 11.13%. Calcd for $C_{16}H_{20}O_3S$: C, 65.73; H, 6.89; S, 10.96%.

1,endo-*3,4-Trimethyl-7-oxabicyclo*[*2.2.1*]*heptane*-endo-*2-carboxylic Acid* (**20**). As described above, 145 mg (0.496 mmol) of **19** gave 82 mg (90%) of **20**; mp 102.9—104.2 °C; ^{1}H-NMR ($CDCl_3$): δ=9.6 (COOH), 2.93 (d, 1H), 2.6—1.8 (5H), 1.51 (s, 3H), 1.40 (s, 3H), 1.05 (d, 3H); ^{13}C-NMR: δ=177.2 (s), 87.8 (s), 85.7 (s), 55.4 (d), 44.2 (d), 32.7 (t), 31.2 (t), 21.4 (q), 20.1 (q), 12.5 (q); MS: *m/e* 184 (M^+), 166, 139, 97 (100); IR: 2900, 1740 cm^{-1}. Found: C, 65.38; H, 9.01%. Calcd for $C_{10}H_{16}O_3$; C, 65.19; H, 8.75%.

Electrolysis of **20** (114 mg; 0.619 mmol) gave 61 mg (63%) of **3** after hydrolysis; ^{13}C-NMR: δ=211.8 (s), 81.2 (s), 58.8 (d), 47.4 (d), 40.0 (t), 29.4 (q), 25.6 (t), 23.1 (q), 16.4 (q); other spectral characteristics were consistent with those previously reported.[1]

Synthesis of dl-*Plinol B* (**5**). Similar methylenation of 50.2 mg (0.321 mmol) of **3** gave 25.4 mg (51%) of *dl*-plinol B (**5**): ^{13}C-NMR: δ=135.4 (s), 110.2 (t), 80.4 (s), 53.3 (d), 48.0 (d), 40.6 (t), 27.0 (t), 23.5 (q), 19.0 (q), 12.8 (q); other spectra were in accord with the reported full spectra.[1]

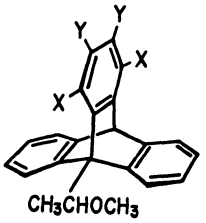
Restricted Rotation Involving the Tetrahedral Carbon. L. Rotamer Distributions and Rotational Barriers in Some 9-(1-Methoxyethyl)triptycene Derivatives[1]

Yoshiyuki TANAKA, Gaku YAMAMOTO, and Michinori ŌKI*
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received April 22, 1983)

1,4-Dimethyl- and 1,2,3,4-tetrahalo-9-(1-methoxyethyl)triptycenes (halogen=F, Cl, and Br) were synthesized by reactions of 9-(1-methoxyethyl)anthracene with appropriate benzynes. Rotamer distributions and rotational barriers about the bridgehead-to-substituent bond were studied by NMR spectroscopy. Rotamer distributions are governed mainly by the steric effect; the major rotamer is assigned to *sc**(*S**), the minor one to *ap*, and the third one found only in the tetrafluoro derivative to *sc**(*R**). Rotational barriers are 21—23 kcal mol^{-1} which are slightly lower than those for the corresponding 9-isopropyltriptycenes.

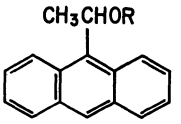
We have reported on the energy barriers to rotation about the bridgehead-to-substituent bond in triptycene derivatives carrying several types of secondary alkyl groups at the bridgehead position and on the dependence of the barriers upon *peri*-substituents. Among the compounds investigated are 9-isopropyl-,[2] 9-(2-methoxy-1-methylethyl)-,[3] and 9-(1-methyl-2-propenyl)triptycenes.[4] These compounds have rather similar barrier heights irrespective of the type of 9-alkyl groups. These findings allured us to study the rotational barriers in 9-(1-methoxyethyl)triptycenes which carry an oxygen function in the α-position of the 9-substituent and to compare the behavior with that exhibited by the 9-*s*-alkyltriptycenes mentioned above. We also found that singly *peri*-substituted 9-(1-hydroxy or methoxy-1-methylethyl)triptycenes have strong preference for the $\pm sc$ rotamers over the *ap* because of the smaller bulkiness of an oxy group than a methyl.[5] Therefore, the rotamer distributions in 9-(1-methoxyethyl)triptycenes are of interest because they are determined by the differential steric interactions of the methoxyl and methyl groups with the *peri*-substituent. Furthermore, the populations of rotamers may be affected by other factors than the steric because of the polar nature of a methoxyl group.

In this paper we report the syntheses of 9-(1-methoxyethyl)triptycenes **1**—**4** and the studies of the rotational equilibria and the rotational barriers measured by means of NMR spectroscopy.



1: X = Y = F
2: X = Y = Cl
3: X = Y = Br
4: X = CH_3, Y = H

The compounds studied were prepared as follows. 9-(1-Hydroxyethyl)anthracene (**5**) obtained by reduction of 9-acetylanthracene was methylated to give 9-(1-methoxyethyl)anthracene (**6**). Reactions of **6** with appropriate benzynes afforded the desired triptycene derivatives **1**—**4**. Tetrafluorobenzyne was generated by lithiation of bromopentafluorobenzene followed by *in situ* elimination of lithium fluoride. The other benzynes were generated by aprotic diazotization of the corresponding anthranilic acids followed by *in situ* pyrolysis of the resulting 2-diazoniobenzoates.



5: R = H
6: R = CH_3

Experimental

Melting points are not corrected. ^{1}H and ^{19}F NMR spectra at ambient temperature (*ca.* 35 °C) were obtained on a Varian EM 390 spectrometer at 90.0 and 84.67 MHz, respectively. ^{1}H NMR spectra were obtained also on a Hitachi R-20B spectrometer at 60.0 MHz. ^{1}H NMR data for **1**—**4** are compiled in Table 1. ^{19}F chemical shifts are shown in ppm downfield from internal hexafluorobenzene.

9-(1-Hydroxyethyl)anthracene (5). To a solution of 5.0 g (23 mmol) of 9-acetylanthracene[6] in 250 mL of diethyl ether was added 500 mg (13 mmol) of lithium tetrahydridoaluminate and the mixture was heated under reflux for 4 h with stirring. The reaction mixture was treated with 10 mL of ethyl acetate and then with 50 mL of water. The ether layer was washed with water and dried over magnesium sulfate. After the solvent was evaporated, the residue was recrystallized from dichloromethane-hexane to afford 4.3 g (85%) of the desired compound, mp 122—123 °C (lit,[7]: 125—126 °C). ^{1}H NMR ($CDCl_3$, δ): 1.85 (3H, d, J=6.3 Hz), 2.1 (1H, br s), 6.35 (1H, q, J=6.3 Hz), 7.3—7.6 (4H, m), 7.8—8.1 (2H, m), 8.30 (1H, s), 8.5—8.7 (2H, m).

9-(1-Methoxyethyl)anthracene (6). To a solution of 2.2 g (10 mmol) of **5** in 70 mL of tetrahydrofuran was added 10 mL of 1.5 mol L^{-1} solution of butyllithium in hexane and the mixture was stirred for 1 h at room temperature. To this solution was added dropwise 10 mL of methyl iodide and the mixture was stirred for 2 h. After evaporation of the volatile part of the reaction mixture, the residue was taken up in ether. The ether layer was washed with water and dried over magnesium sulfate. Evaporation of the solvent followed by recrystallization from dichloromethane–pentane gave 1.85 g (78%) of **6** as yellow crystals, mp 94—95 °C. Found: C, 86.41; H, 6.82%. Calcd for $C_{17}H_{16}O$: C, 86.48; H, 6.81%. ^{1}H NMR ($CDCl_3$, δ): 1.84 (3H, d, J=6.3 Hz), 3.19 (3H, s), 5.89 (1H, q, J=6.3 Hz), 7.3—7.6 (4H, m), 7.8—8.1 (2H, m), 8.37 (1H, s), 8.5—8.8 (2H, m).

1,2,3,4-Tetrafluoro-9-(1-methoxyethyl)triptycene (1). To a solution of 908 mg (3.8 mmol) of **6** and 1.1 g (4.5 mmol) of bromopentafluorobenzene in 100 mL of diethyl ether was

TABLE 1. ^{1}H NMR DATA AND POPULATION OF THE ROTAMERS IN $CDCl_3$ AT *ca.* 35°C[a]

a) Refers to the *sc*(S*)*→*ap* process. In parentheses are the data for the *ap*→*sc*(S*)* process. b) $K=[ap]/[sc^*(S^*)]$. c) The temperature at which the rate constant was obtained by simulation.

added 3.0 mL of 1.5 mol L^{-1} solution of butyllithium in hexane at −78 °C.[8] The mixture was stirred at this temperature for 1 h, allowed to warm up to room temperature and then heated under reflux for 40 h. The reaction mixture was treated with dilute hydrochloric acid. The organic layer was washed with water and dried over magnesium sulfate. Column chromatography of the product on silica gel with hexane–dichloromethane as the eluent followed by recrystallization from dichloromethane–hexane gave 180 mg (12%) of **1** as colorless crystals, mp 193—195 °C. Found: C, 71.84; H, 4.19%. Calcd for $C_{23}H_{16}F_4O$: C, 71.87; H, 4.20%. ^{19}F NMR ($CDCl_3$): 2.0—4.0 (m, 2- and 3-F of the three rotamers), 12.0—14.0 (m, 4-F of the three rotamers), 19.6 (apparent quintet, 1-F of *sc*(S*)*), 25.3 (br, 1-F of *ap*) 33.5 (br, 1-F *sc*(R*)*).

1,2,3,4-Tetrachloro-9-(1-methoxyethyl)triptycene (2). To a boiling solution of 498 mg (2.1 mmol) of **6** and 1 mL of isopently nitrite in 40 mL of 1,2-dimethoxyethane (DME) was added a solution of 1.1 g (4.1 mmol) of tetrachloroanthranilic acid[9] in 50 mL of DMF during the course of 3 h. The mixture was heated under reflux for 1 h. Evaporation of the solvent followed by column chromatography of the residue on silica gel with hexane–dichloromethane as the eluent and recrystallization from dichloromethane–hexane gave 84 mg (9%) of **2**, mp 264.5—266 °C. Found: C, 61.22; H, 3.50; Cl, 31.63%. Calcd for $C_{23}H_{16}Cl_4O$: C, 61.36; H, 3.58; Cl, 31.50%.

1,2,3,4-Tetrabromo-9-(1-methoxyethyl)triptycene (3), mp 288—289 °C, was synthesized similarly as **2** from **6** and tetrabromoanthranilic acid[10] in 8% yield. Found: C, 44.13; H, 2.64; Br, 50.75%. Calcd for $C_{23}H_{16}Br_4O$: C, 43.99; H, 2.57; Br, 50.89%.

9-(1-Methoxyethyl)-1,4-dimethyltriptycene (4), mp 219—220 °C, was synthesized similarly as **2** from **6** and 3,6-dimethylanthranilic acid[11] in 25% yield. Found: C, 88.18; H, 7.00%. Calcd for $C_{25}H_{24}O$: C, 88.20; H, 7.10%.

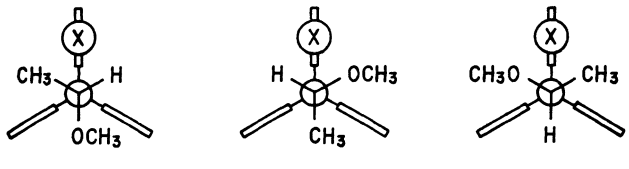
Dynamic NMR Studies. Variable temperature NMR spectra were recorded on a Hitachi R-20B spectrometer at 60.0 MHz as solutions in chlorobenzene or 1-chloronaphthalene. Temperatures were calibrated using an ethylene glycol sample.[12] Chemical shift differences ($\Delta\nu_c$) at the coalescence temperatures (T_c) were obtained by linearly extrapolating the chemical shift differences at low tempera-

tures. Equilibrium constants (K_c) at T_c were calculated using the van't Hoff parameters shown in Table 2 which were obtained from the equilibrium constants at low temperatures. Rate constants (k_c) at T_c of the methoxyl signals were obtained by two methods: graphically following Jaeschke *et al.*[13] and by computer simulation of the spectra. Values obtained by the two methods agreed quite well. As for the coalescence of the methyl doublets, it was difficult to define T_c and the rate constants were obtained by simulating the spectra at a temperature which was estimated to be close to T_c.

Computer Simulation of the NMR Spectra. The calculations of the theoretical spectra were carried out on a Hitachi M280H computer at the Computer Center of the University of Tokyo, using a modified version of the DNMR 3 program by Binsch.[14] Spectra of **2**—**4** at or near T_c were simulated using the parameters obtained as described in the preceding section and modifying them if necessary to give the rate constants shown in Table 2. The methyl proton signal of **1** at ambient temperature was also simulated putting the exchange rates as zero. As our version of the program can not accommodate a three-site exchange problem of a five-spin system (AM_3X with a methine and methyl protons and a fluorine nucleus), we treated the system as a three-spin system regarding the methyl group as a single nucleus. The fluorine chemical shifts were assumed to be 9000 Hz upfield of the methyl protons, because the computation failed if the actual chemical shift differences between the proton and fluorine were used. Attempt at rigorous simulation of the variable temperature spectra of **1** was abandoned because of too many variable parameters: three independent rate constants, and temperature dependent chemical shifts and rotamer populations. Instead, the theoretical spectra were calculated using the parameters at ambient temperatures and assuming $k_{ap\rightarrow sc^*(S^*)} = 10\ k_{ap\rightarrow sc^*(R^*)} = 10\ k_{sc^*(S^*)\rightarrow sc^*(R^*)}$. Those with $k_{ap\rightarrow sc^*(S^*)}$ of 10—20 s^{-1} gave the best resemblance with the experimental spectrum at 122 °C, which gives a rough estimate of $\Delta G^{\ddagger}$ of 20.5—21.5 kcal mol^{-1} for the $ap\rightarrow sc^*(S^*)$ process.

Results and Discussion

Rotamer Assignments and Equilibria. The compounds examined have high rotational barriers on the NMR time scale and the rotamers about the bridgehead-to-substituent bond are separately observed at room temperature by NMR spectroscopy. Three racemic rotamers, *ap*, *sc**(*S**), and *sc**(*R**),[15] are possible and the Newman projections along the bond in question for those with *R*-configuration are shown in Scheme 1.



ap *sc*(S*)* *sc*(R*)*

Scheme 1.

It is shown that all the three rotamers are present in chloroform-*d* solution of the tetrafluoro derivative (**1**). In the ^{19}F NMR spectrum, three separate signals due to 1-F are observed at 19.6, 25.3, and 33.5 ppm downfield from internal hexafluorobenzene with an intensity ratio of 55 : 39 : 6, besides the signals due to 2-, 3-, and 4-F. The least abundant rotamer with the lowest-field 1-F signal can be assigned to *sc**(*R**) because the *sc**(*R**) rotamer should be least stable on the steric ground and the 1-F in this rotamer should be most deshielded: a downfield shift known as the van der Waals (steric compression) shift. Similarly from the standpoint of steric compression, the most abundant rotamer with the highest-field 1-F signal can be assigned to *sc**(*S**) and thus the remainder to *ap*.

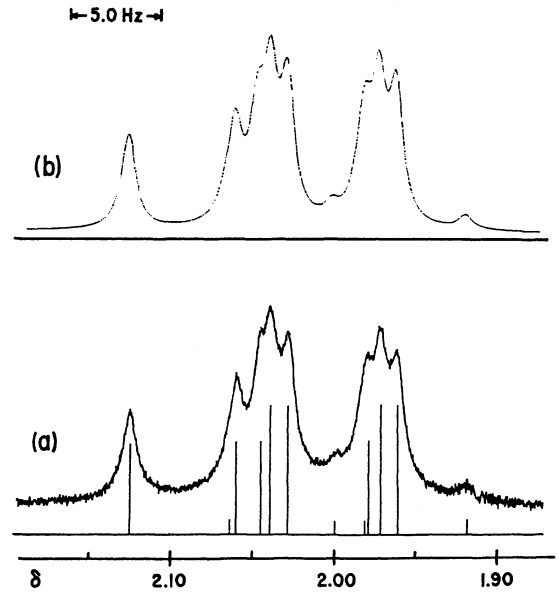


Fig. 1. (a) Observed 90 MHz ^1H NMR spectrum of the methyl region of compound **1** in chloroform-*d* at *ca.* 35 °C. (b) Calculated spectrum using the parameter values given in Table 1.

These assignments are supported by the analysis of the ^1H NMR spectrum of **1**. As found in our previous studies on 1-fluoro-9-(1,1-dimethyl-2-phenylethyl)triptycene atropisomers[16] and on 1-fluoro-9-isopropyltriptycene,[2] the methyl group in a $\pm sc$ site to the *peri*-fluoro substituent shows a large long-range spin-spin coupling with 1-F with a magnitude of 6—9 Hz, while the methyl in an *ap* site which is remote from the *peri*-fluoro group shows only a small coupling, if any, reflecting the through-space nature of the coupling.[17]

The methyl proton signal of **1** looks very complex consisting of three overlapping sets of double doublets due to the coupling with the methine proton and with the 1-F nucleus. The spectrum at 90.0 MHz is shown in Fig. 1. The analysis of the signals is almost unambiguously made by comparing the spectra obtained at 60 and 90 MHz. Furthere, the calculated spectrum (Fig. 1b) using the chemical shifts, the coupling constants and the rotamer populations, given in Table 1, properly reproduces the experimental spectrum.

The methyl signal due to the most abundant rotamer shows a small coupling with 1-F (1.0 Hz) indicating that the methyl group is in the *ap* site and therefore the rotamer is *sc**(*S**). The second abundant rotamer has a large ^1H–^{19}F coupling of 7.1 Hz which is consistent with the *ap* rotamer. The least abundant rotamer also gives a large coupling of 7.4 Hz.

The chemical shifts of the methyl protons in **1** fall in a

narrow range of δ 1.99—2.05 and are not helpful in rotamer assignments but those of the methine proton are shown to be clearly site dependent: the protons in the *ap* and *sc**(*S**) rotamers have nearly identical chemical shifts and the proton in the *sc**(*R**) rotamer appears at a higher field by more than 0.15 ppm than the others. A methine proton synclinal to the *peri*-fluorine is deshielded due probably to the steric compression and/or anisotropy effect exerted by the *peri*-substituent.[18]

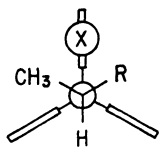
The tetrachloro compound **2** shows the presence of only two rotamers in equilibrium in a ratio of 76 : 24. It is reasonable to deduce that the absent rotamer is *sc**(*R**), because the population of the *sc**(*R**) rotamer of **1** is only 6% and the *peri*-chloro substituent in **2** is bulkier than the *peri*-fluoro one in **1**. The methine proton signals of the two rotamers have nearly the same chemical shifts of δ 5.77 and 5.75 and this supports that the two rotamers have their methine protons in similar environments, *i.e.* $\pm sc$ sites to the *peri*-substituent and that they are the *ap* and *sc**(*S**) rotamers.

Differentiation between the *ap* and *sc**(*S**) rotamers is made by consideration of the chemical shifts of the methyl proton signals. As was shown in our previous studies on 9-*t*-alkyl-[16] and 9-*s*-alkyltriptycenes[2-4] carrying a single *peri*-substituent, a methyl group located synclinal to the *peri*-substituent gives its signal at a considerably lower field than the one antiperiplanar to the *peri*-group probably because of the steric compression effect of the flanking *peri*-substituent. *peri*-Fluoro compounds behave exceptionally as mentioned above. Assuming that this generalization applies to compound **2**, we can assign *sc**(*S**) to the major rotamer because the methyl doublet at a higher field is more intense than that at a lower field (Table 1).

The same arguments apply to compounds **3** and **4**, both of which reside as two rotamers in a ratio of 78 : 22 in chloroform-*d*. In either of the compounds the more intense doublet for the methyl group appears at a higher field, and thus the *sc**(*S**) conformation is assigned to the major rotamer.

It becomes clear from the discussion above that the rotamer distribution in **1**—**4** is principally governed by the steric factor, the electrostatic effect being insignificant. A methoxyl group is less bulky than a methyl and is more confortably accommodated in a $\pm sc$ site, resulting in the predominance of the *sc**(*S**) rotamers. Operation of other factors than the steric one, *i.e.* electrostatic and hydrogen bonding effects, was observed in several 1-oxy-substituted 9-(1-methoxyethyl)triptycenes, which will be discussed in the following paper.[19]

The absence of the *sc**(*R**) rotamer in **2**—**4** may be in accordance with the absence of the corresponding rotamers **7** in 9-*s*-alkyltriptycenes hitherto examined.[2-4] The



R = CH_3, CH_2OCH_3, $CH{=}CH_2$

7

presence of a small amount of the *sc**(*R**) rotamer in **1** corresponds to the existence of the *ap* rotamer (**7**: R=CH_3, X=F) in 1-fluoro-9-isopropyltriptycene.[2b]

Rotational Barriers. Dynamic NMR behavior of **2**—**4** were studied in solutions of chlorobenzene or 1-chloronaphthalene by observing the methyl and/or methoxyl proton signals. These compounds reside as two rotamers, *ap* and *sc**(*S**), in these solvents as well as in chloroform-*d*, although the rotamer ratios are slightly different from those shown in Table 1. Rate constants for the $ap \rightleftharpoons sc^*(S^*)$ interconversion at or near the coalescence temperatures were evaluated by a graphical method or by computer simulation. These data and the free energies of activation therefrom are given in Table 2. The barriers for **2**—**4** are lower than those for the corresponding 9-isopropyltriptycenes[2] by 0.2—0.8 kcal mol^{-1} (1 cal=4.184 J). This may be due to the smaller bulkiness of a methoxyl than a methyl group. The higher barriers for **2** and **3** than for **4** may be ascribed to the operation of the positive buttressing effect in **2** and **3**[2,20] and also to the effective raise of the ground state in **4** due to the bulkiness of the *peri*-substituent as found in 9-isopropyltriptycenes.[2] The barrier for **1** is roughly estimated to be 20.5—21.5 kcal mol^{-1} as described in the Experimental section and this is evidently lower than the barriers for **2** and **3**.

Conformation in Crystalline States. Many compounds reside as only one of the possible rotamers in the crystalline states and this fact constituted a basis for the assignment of rotational isomers in the pioneering spectroscopic studies.[21] There are however some examples in which a crystal contains more than one rotamer.[22] Therefore it is interesting to see whether the crystals obtained here contain one or more rotamers. Although the rotational barriers found in **2**—**4** are too low for the rotamers to be separately isolated at room temperature, they are high enough for the rotamer composition in the crystalline state to be retained on dissolution in a solvent at low temperatures.

Crystals of compound **4** were dissolved in chloroform-*d* at *ca.* −50 °C and the ^1H NMR spectrum of the solution was taken at −40 °C. The sample was shown to be rotamerically homogeneous under these conditions and the rotamer was the one to which we have assigned *sc**(*S**) in the discussion above. The ^1H NMR spectra of **2** and **3** taken at −10——40 °C after dissolving the crystalline compounds at *ca.* −50 °C showed the presence of a small amount of the *ap* rotamer in addition to the *sc**(*S**). This may have been caused by the elevation of the sample temperature in the dissolution process. The crystals of **2**—**4** are therefore inferred to consist solely of the *sc**(*S**) rotameric state which is the major rotamer in solution. X-ray crystallographic studies on these compounds will afford an unambiguous evidence for the rotamer assignments in solution and are now in progress.

Restricted Rotation Involving the Tetrahedral Carbon. LI. Electrostatic and Hydrogen Bonding Effects on the Rotamer Distribution in 1-Oxy-substituted 9-(1-Methoxyethyl)triptycenes[1)]

Gaku YAMAMOTO, Yoshiyuki TANAKA, and Michinori ŌKI*
Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received April 22, 1983)

1-Hydroxy-4-methoxy- (**5**) and 1,4-dimethoxy-9-(1-methoxyethyl)triptycenes (**6**) were obtained by the reaction of 9-(1-methoxyethyl)anthracene with *p*-benzoquinone followed by enolization and methylation. Rotamer equilibrium in **6** is principally governed by the electrostatic effects favoring the *ap* rotamer. In weakly proton-accepting chloroform-*d*, **5** exists as *sc**(*R**) and *sc**(*S**) rotamers with the former predominating, both of which contain a strong intramolecular hydrogen bonding between the 1-hydroxyl and the methoxyl group in the 9-substituent. In strongly proton-accepting dimethyl-d_6 sulfoxide, all the three rotamers exist with the *ap* rotamer predominating. It is noteworthy that the *sc**(*R**) rotamer, which is present in 20% ratio in dimethyl sulfoxide, still retains the intramolecular hydrogen bonding in this solvent.

In the preceding paper[1)] we reported that the rotamer equilibrium in 9-(1-methoxyethyl)triptycenes **1**—**4** carrying a halogen or a methyl substitutent in a *peri*-position is principally governed by steric effects, the less crowded *sc**(*S**) rotamer being favored. We report here on the dynamic behavior of 1-oxy-substituted 9-(1-methoxyethyl)triptycenes **5** and **6** in which electrostatic and hydrogen bonding effects are the crucial factors governing the rotamer distribution.

Results and Discussion

Syntheses. Reaction of 9-(1-methoxyethyl)anthracene (**7**) with *p*-benzoquinone in acetonitrile gave a 9,10-adduct (**8**) which essentially consists of one diastereomer. In our previous studies on several 9-*s*-alkyl systems,[3)] enolization followed by methylation of a *p*-benzoquinone-anthracene adduct to give a 1,4-dimethoxytriptycene derivative was carried out in one pot under base-catalysis conditions. However, this method was unsatisfactory in the present case and thus the enolization of **8** was effected with acid and the 1,4-dihydroxy compound **9** was once isolated. Action of dimethyl sulfate on **9** in the presence of an aqueous base and a phase-transfer catalyst afforded a monomethylated compound **5**, which was then converted to the dimethylated derivative **6** by action of butyllithium and methyl iodide.

That the monomethylated compound is actually the 1-hydroxy-4-methoxy derivative **5** comes from the following observations. ^{1}H NMR spectrum of the hydroquinone **9** in chloroform-*d* exhibits two types of hydroxyl proton signals. One is a broad signal at δ 5.6 and the other consists of two sharp singlets at δ 9.12 and 9.27 with an intensity ratio of 3 : 1 which is identical with the rotamer ratio of **9** obtained by integration of the methyl and methoxyl signals. The former is assigned to the 4-hydroxyl proton because the chemical shift is in the normal region of phenolic hydroxyl protons.[4)] The latter is ascribed to the 1-hydroxyl group which forms a strong intramolecular hydrogen bonding with the methoxyl group in the bridgehead substituent, as is discussed in detail in the later section. The monomethylated compound **5** in chloroform-*d* shows only the latter type of hydroxyl proton signals, *i.e.* two sharp singlets at δ 9.06 and 9.16 in 3 : 1 ratio, consistent with the presence of the 1-hydroxyl group.

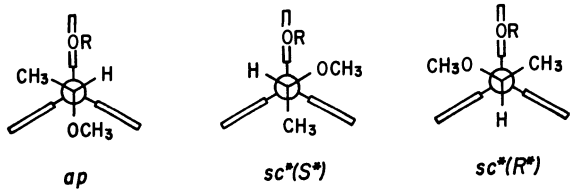
a) Chemical shifts are given in δ. Signals are singlets unless otherwise noted. d: doublet, q: quartet, m: multiplet, br: broad signal. In parentheses are coupling constants in Hz. b) For the rotamer assignments, see text. c) Assignments are unambiguously made by comparing the spectrum of 1-hydroxy-4-trideuteriomethoxy-9-(1-methoxyethyl) triptycene. d) Assignments of the methoxyl signals are not made.

1,4-dimethoxy compound **6** in chloroform-*d* shows that it exists as two rotamers about the bridgehead-to-substituent bond in a ratio of 3 : 1. A criterion for making rotamer assignments is the chemical shifts of the methyl and methine protons in the bridgehead substituent as discussed in the preceding paper.[1)] We rely on the general tendency that either the methyl group or the methine proton gives its signal at a lower field when it is synclinal to the *peri*-substituent than when it is antiperiplanar due mainly to the steric compression effect exerted by the *peri*-substituent.[5)]

From the fact that the methine signals for the two rotamers have very similar chemical shifts (Table 1), it is inferred that the two rotamers are *ap* and *sc**(*S**) because the methine protons in these rotamers are in similar environments, *i.e.* are flanked by the *peri*-methoxyl group. The absence of the *sc**(*R**) rotamer is reasonable because this rotamer should be least stable of the three on both steric and electrostatic grounds.



Differentiation between *ap* and *sc**(*S**) comes from the inspection of the methyl signals. The doublet at a low field is more intense than that at a high field, and thus the major rotamer should be *ap* from the criterion. Although similar assignments were made for the rotamers in **2**—**4**,[1)] the one in the present case may be less reliable because the chemical shift difference between the methyl doublets is far smaller in **6** (0.07 ppm) than in **2**—**4** (0.20—0.23 ppm).

In order to confirm the assignment, we studied the effect of solvent polarity on the rotamer ratio. Upon changing the solvent from chloroform-*d* to more polar dimethyl-d_6 sulfoxide (DMSO-d_6), the more abundant rotamer increased its population (75→78%), whereas the less abundant decreased. As is clearly shown by molecular model consideration, *ap*-**6** is more polar than *sc**(*S**)-**6**, and the major rotamer is reasonably assigned to *ap* because a more polar isomer is stabilized in a more polar solvent.

The predominance of the *ap* rotamer in **6** is in sharp contrast with the behavior exhibited by the *peri*-halo compounds **1**—**3** and the *peri*-methyl one **4** where the *sc**(*S**) rotamer is predominant. As shown in the preceding paper, steric effect is the major factor governing the rotamer distribution in **1**—**4**.[1)] The findings here indicate that the electrostatic effect overweighs the steric effect in **6**: the electrostatic repulsion between the oxygen lone pairs in the 1-methoxyl and the 9-(1-methoxyethyl) groups destabilizes the *sc**(*S**) rotamer. An alternative explanation may be possible which includes a hypothetical C–H···O hydrogen bonding.[3,9)] We prefer to attribute the phenomenon to the electrostatic effect until afirm basis of the C–H···O hydrogen bonding is laid.

Compounds **5** and **9**, carrying a hydroxyl group at a *peri*-position, behaved very similarly with each other in ^{1}H NMR spectra, and a detailed study was carried out mainly on **5** because of the low solubility of **9**. ^{1}H NMR spectrum of **5** in chloroform-*d* shows the presence of two rotamers in a ratio of 3 : 1 (Table 1). The most distinguished feature of the spectrum is the appearance of the *peri*-hydroxyl proton signal as two sharp singlets at δ 9.06 and 9.16 in an intensity ratio of 3 : 1. This clearly indicates that the hydroxyl group in each of the rotamers forms a strong intramolecular hydrogen bonding and thus the two are *sc**(*R**) and *sc*(*S**), in both of which the methoxyl group in the 9-substituent flanks the *peri*-hydroxyl. The hydroxyl group in the *ap* rotamer, if present, would appear at a far higher field.[4]

This situation is also evidenced by IR spectroscopy.[10] A dilute solution (*ca.* 2×10^{-3} mol L^{-1}) of **5** in chloroform shows an absorption at 3220 cm^{-1} ($\varepsilon\approx150$) with a half band width of *ca.* 200 cm^{-1} as the only one ascribable to O–H stretching. This frequency is lower by nearly 400 cm^{-1} than the normal one of 3610 cm^{-1} for a phenolic hydroxyl group, suggesting the occurence of an unusually strong intramolecular hydrogen bonding. Such a large shift as found here is unprecedented in an intramolecular hydrogen bonding between a hydroxyl and an alkoxyl group although several examples of large shifts have been reported on *o*-nitrophenol derivatives.[10b]

This spectral feature is retained in a more concentrated solution of **5** (*ca.* 8×10^{-2} mol L^{-1}) in chloroform-*d*, which is the same sample as is used in the ^{1}H NMR measurement.[11] Therefore IR spectroscopy also indicates that **5** in chloroform resides only as the rotamers capable of intramolecular hydrogen bonding: *sc**(*R**) and/or *sc**(*S**).

Conformational assignments of the two rotamers present in chloroform-*d* come again from the chemical shifts of the methyl and methine proton signals. As the lower-field methyl signal and the higher-field methine signal are more intense than their respective counterparts, the major rotamer is deduced to be *sc**(*R**), and thus the minor *sc**(*S**). This assignment looks quite unusual from the standpoint of steric effect because the *sc**(*R**) rotamer is apparently more crowded. The explanation for this still remains unknown.

Although **5** was shown to exist solely as intramolecularly hydrogen-bonded rotamers in chloroform which is very weak as a proton acceptor, the compound was expected to behave differently in a strongly proton-accepting solvent. Actually, ^{1}H NMR spectrum of **5** in DMSO-d_6 disclosed the presence of three rotamers in a ratio of 62 : 20 : 18. As the direct comparison of the spectrum with that in chloroform-*d* did not allow an unambiguous assignment of the rotamers, the change of the rotamer distribution was followed by gradually varying the solvent composition in a mixture of chloroform-*d* and DMSO-d_6. The results, as shown in Fig. 1, clearly reveal that the most abundant rotamer in DMSO is the one which is absent in chloroform, namely *ap*. The major rotamer in chloroform, *sc**(*R**), becomes less and less populous with the increasing content of DMSO, and the minor one in chloroform, *sc**(*S**), does not significantly change its population by the solvent composition.

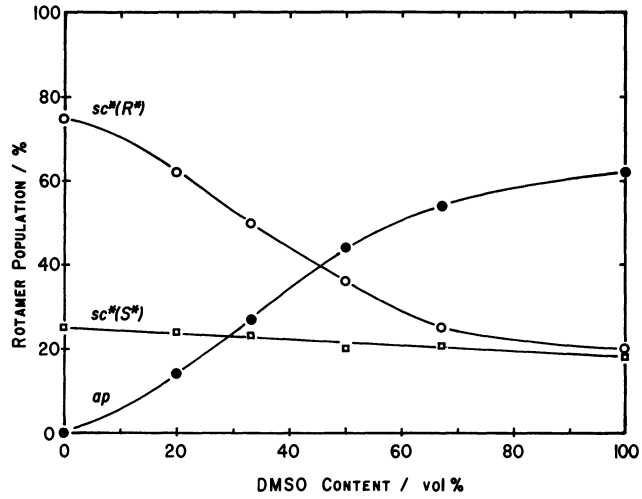


Fig. 1. Dependence of the rotamer populations in **5** upon the solvent composition in $CDCl_3$–DMSO-d_6. ●: *ap*, ○: *sc**(*R**), □: *sc**(*S**).

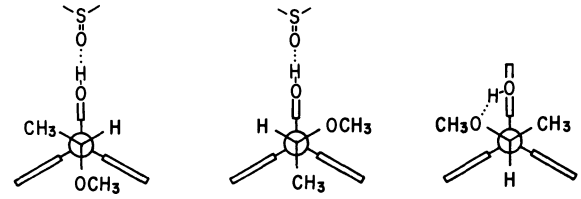
In a fraction of molecules of **5**, intramolecular hydrogen bonding in chloroform switches to intermolecular hydrogen bonding with a solvent molecule in DMSO. In intermolecularly hydrogen-bonded species the attractive interaction between the *peri*-hydroxyl group and the methoxyl in the side chain disappears, rendering the electrostatic repulsion between the lone pairs a ruling factor. This results in the destabilization of *sc**(*S**)-**5** and the predominance of *ap*-**5** (Scheme 1).



ap-**5** *sc**(*S**)-**5** *sc**(*R**)-**5**

Scheme 1.

It is noticed that the population ratio of the *ap* and *sc**(*S**) rotamers of **5** in DMSO is identical with that of **6** in DMSO within the experimental error (3.4 *vs.* 3.5). This suggests that the same factor dominates in controlling the distribution between the *ap* and *sc**(*S**) rotamers, *i.e.* the electrostatic repulsion between the lone pair electrons, and that the 1-hydroxyl group in the *sc**(*S**) rotamer forms an intermolecular hydrogen bonding with a DMSO molecule.

The fact that the *sc**(*R**) rotamer of **5** still exists in 20% population in DMSO, in contrast with the absence of the corresponding *sc**(*R**) rotamer of **6**, suggests that *sc**(*R**)-**5** is stabilized by a special factor which is absent in **6**, *i.e.* an intramolecular hydrogen bonding (Scheme 1).

Intra- and intermolecularity of the hydrogen bonding in **5** is also reflected in the chemical shifts, especially of the hydroxyl and methoxyl proton signals. The dependence of the chemical shifts of these signals upon the solvent composition is shown in Fig. 2. The hydroxyl

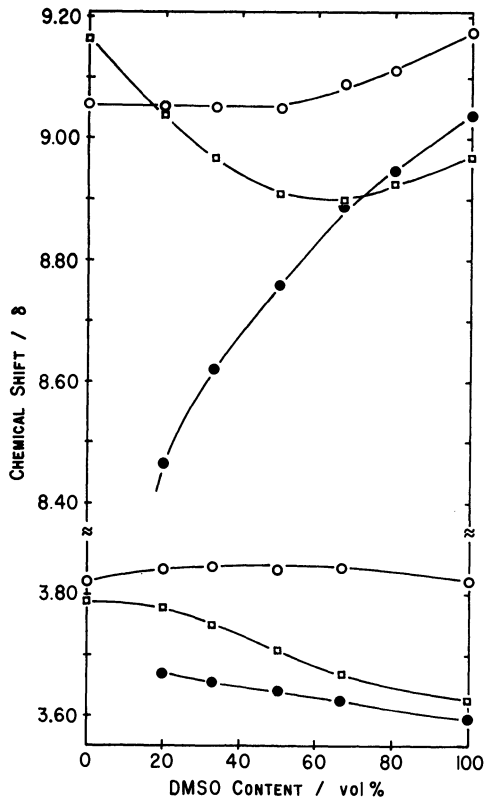


Fig. 2. Dependence of the chemical shifts of the 1-hydroxyl proton and the methoxyl protons in the 9-substituent in rotamers of **5** upon the solvent composition in $CDCl_3$–DMSO-d_6. ●: *ap*, ○: *sc**(*R**), □: *sc**(*S**).

proton signal of the *sc**(*R**) rotamer stays at the initial position of δ 9.06 and then gradually shifts downfield as the DMSO content increases. The signal retains its sharpness (a half-band width of less than 1.7 Hz) irrespective of the solvent composition reflecting the intramolecularity of the hydrogen bonding throughout the solvent range. The hydroxyl proton signal of the *sc**(*S**) rotamer, which appears at δ 9.16 in chloroform-*d*, rapidly shifts upfield and broadens as the DMSO content increases up to 50 vol%. It then moves downfield and resharpens. Appearance of the broad signal at the intermediate region of the DMSO content should be due to exchange between the intramolecular hydrogen-bonded species and the intermolecularly hydrogen-bonded ones. A small broad signal due to *ap*-**5** is observed at δ 8.45 when the DMSO content is *ca.* 20 vol%, which increases in its intensity, sharpens and shifts downfield as the DMSO content increases until it appears at δ 9.04 as a sharp singlet in DMSO.[12]

Dependence of the chemical shifts of the methoxyl protons of the 9-substituent upon the solvent composition also seems to reflect whether the methoxyl group participates in the hydrogen bonding. Although the chemical shifts of the methoxyl protons depend on several other factors, their contributions would be rather small in view of the fact that the chemical shift differences of the methoxyl protons between the rotamers in **1**—**4** is at most 0.06 ppm. The methoxyl group of *sc**(*R**)-**5** which forms the hydrogen bonding with the hydroxyl group gives its signal at a low field of δ 3.82—3.85, while that of *ap*-**5** which does not participate in hydrogen bonding appears at a high field of δ 3.59—3.67. The methoxyl proton signal due to *sc**(*S**)-**5** is located near that due to *sc**(*R**)-**5** in chloroform-*d* but it shifts upfield with the increasing content of DMSO and appears closely to that due to *ap*-**5** in DMSO, suggesting that the hydrogen bonding in *sc**(*S**)-**5** switches from intramolecular in chloroform to intermolecular in DMSO.

^{1}H NMR spectrum of **5** obtained in acetone-d_6 indicates the presence of three rotamers in a ratio of 66 : 22 : 12. The behavior of the chemical shifts and populations in mixtures of chloroform-*d* and acetone-d_6 reveals that the most abundant rotamer in acetone-d_6 is *sc**(*R**), the second abundant *sc**(*S**) and the least abundant *ap*. This ratio is almost identical with the rotamer ratio of **5** in chloroform-*d* containing 15 vol% of DMSO-d_6 (Fig. 1). Therefore the rotamer distribution in **5** may serve as a measure of the proton accepting ability of a solvent system. In benzene-d_6, **5** exists as two rotamers, *sc**(*R**) and *sc**(*S**), in a ratio of 3 : 1 just as in chloroform-*d*, indicating that benzene is as weak a proton acceptor as chloroform.

Rotational Barriers. Variable temperature ^{1}H NMR spectra of **5** and **6** were obtained in chlorobenzene. Both of them showed the presence of two rotamers in this solvent. As there is no reason to assume that the rotamer distributions significantly alter by changing the solvent from chloroform-*d* to chlorobenzene, the existing rotamers of **5** are assigned to *sc**(*R**) and *sc**(*S**) and those of **6** to *ap* and *sc**(*S**), the former predominating in each compound. Rate constants for the interconversion between the two rotamers at or near the coalescence temperatures (T_c) and the free energies of activation therefrom are given in Table 2. The barrier to the $ap \rightleftarrows sc^*(S^*)$ process in **6** is a little lower than that to the $+sc \rightleftarrows -sc$ process in 1,4-dimethoxy-9-isopropyltriptycene ($\Delta G_c^{\ddagger}$=23.0 kcal mol^{-1} at 140 °C),[7] both occurring through similar transition states in which the methine hydrogen in the 9-substituent eclipses the *peri*-

Table 2. Dynamic NMR data in chlorobenzene

Compound	Obsd signal	Process	T_c / °C	$\Delta\nu_c$ / Hz	k_c / s^{-1}	$\Delta G_c^{\ddagger}$ / kcal mol^{-1}	K_c
5	OCH_3	*sc**(*R**)→*sc**(*S**)	112	5.5	9.3	21.0±0.1	3.0
		*sc**(*S**)→*sc**(*R**)			3.1	21.9±0.1	
6	CH_3	*ap*→*sc**(*S**)	114	9.2	13.2	20.9±0.1	2.2
		*sc**(*S**)±*ap*			6.0	21.5±0.1	

methoxyl group. The barrier difference may be ascribed to the smaller bulkiness of a methoxyl than a methyl. The barriers in the *peri*-methoxy compound **6** are almost the same as those in the *peri*-methyl one **4**.[1] In the 9-isopropyl series, the *peri*-methoxy compound has a higher barrier than the *peri*-methyl one (ΔG_c^*: 23.0 *vs.* 22.0 kcal mol^{-1}), which was ascribed to the destabilization of the ground state in the latter due to molecular deformation. The destabilization of the ground state in **4** may be less significant because of the smaller congestion in the 9-(1-methoxyethyl) series.

Observation of the *sc**(*R**)⇌*sc**(*S**) process in **5** is unique in the point that the methoxyl group in the 9-substituent eclipses the *peri*-hydroxyl group in the transition state, because every barrier heigen hitherto examined in 9-*s*-alkyl- and 9-(1-methoxylethyl)-triptycenes has referred to the process in which the methine hydrogen eclipses the *peri*-substituent in the transition state.

Experimental

Melting points are not corrected. ^{1}H NMR spectra were obatined on a Hitachi R-20B (60 MHz) or a Varian EM-390 (90 MHz) spectrometer at *ca.* 35 °C. IR spectra were recorded on a Hitachi 260-30 or a Hitachi 260-50 spectrophotometer using a 0.1 mm KRS-5 cell for samples of *ca.* 0.1 mol L^{-1} and a 5.0 mm quartz cell for samples of *ca.* 10^{-3} mol L^{-1}.

1,4-Dihydroxy-9-(1-methoxyethyl)triptycene (9). A mixture of 944 mg (4.0 mmol) of 9-(1-methoxyethyl)anthracene (**7**)[1] and 2.1 g (20 mmol) of *p*-benzoquinone in 7 mL of acetonitrile was heated under reflux for 3 h with stirring. The mixture was cooled and the precipitate was collected by filtration. The solid was washed with diethyl ether to remove the unreacted *p*-benzoquinone. The 9,10-adduct (**8**) was obtained in 99% yield, mp 177—179 °C (decomp), which was shown by ^{1}H NMR to consist of a single diastereomer. ^{1}H NMR ($CDCl_3$, δ): 1.79 (3H, d, J=6.0 Hz), 2.97 (1H, dd, J=8.5 and 2.5 Hz), 3.45 (1H, d, J=8.5 Hz), 3.67 (3H, s), 4.43 (1H, q, J=6.0 Hz), 4.58 (1H, d, J=2.5 Hz), 5.99 (2H, s), 7.0—7.4 (7H, m), 7.95 (1H, m). A suspension of 500 mg of the adduct **8** in 50 mL of acetic acid containing 2 mL of concentrated hydrochloric acid was stirred overnight at room temperature. The solid was collected by filtration, washed with water and dried in air. Recrystallization from dichloromethane–hexane gave 475 mg (95%) of **9**, mp 166 °C (decomp). This compound was directly used for the next reaction.

1-Hydroxy-4-methoxy-9-(1-methoxyethyl)triptycene (5). A solution of 500 mg (1.45 mmol) of **9**, 3 mL (32 mmol) of dimethyl sulfate and 100 mg of benzyltrimethylammonium chloride in 50 mL of dichloromethane was stirred overnight at room temperature with 30 mL of a 1 mol L^{-1} aqueous solution of potassium hydroxide. The excess of dimethyl sulfate was decomposed by warming the organic layer with 10 mL of a 1 mol L^{-1} aqueous solution of potassium hydroxide. The organic layer was separated and concentrated by evaporation. The residue was taken up in ether. The ethereal solution was washed successively with dilute hydrochloric acid, aqueous sodium hydrogencarbonate and water, and dried over magnesium sulfate. Recrystallization of the product from chloroform–hexane gave 260 mg (50%) of **5**, mp 265—266 °C. Found: C, 80.16; H, 6.22%. Calcd for $C_{24}H_{22}O_3$: C, 80.42; H, 6.19%.

1,4-Dimethoxy-9-(1-methoxyethyl)triptycene (6). To a solution of 113 mg (0.32 mmol) of the monomethylated compound **5** in 30 mL of tetrahydrofuran was added dropwise 0.3 mL of 1.5 mol L^{-1} butyllithium in hexane and the mixture was stirred for 3 h at room temperature. To the solution was added dropwise 10 mL (160 mmol) of methyl iodide and the mixture was stirred for 24 h at room temperature. The mixture was taken up in ether and the ethereal solution was washed successively with dilute hydrochloric acid, aqueous sodium hydrogencarbonate and water. The ether layer was dried over magnesium sulfate and the solvent was evaporated. The residue was recrystallized from dichloromethane–hexane to give 62 mg (53%) of **6**, mp 204—205 °C. Found: C, 80.83; H, 6.23%. Calcd for $C_{25}H_{24}O_3$: C, 80.62; H, 6.49%.

DNMR Studies. Variable temperature ^{1}H NMR spectra were recorded on the Hitachi R-20B spectrometer. Temperatures were calibrated with the use of an ethylene glycol sample.[13] Rate constants at or near T_c were evaluated by simulating the spectra using a modified version of the DNMR 3 program by Binsch.[14] While T_c for the methoxyl proton signal in **6** was easily defined, that for the methyl signal in **5** was not definitely identified and a spectrum obtained at a temperature which was estimated to be close to T_c was simulated.

Production of $C_2(d^3\Pi_g)$ by Controlled Electron Impact on Acetylene, Ethylene, and Ethane

Teiichiro OGAWA,* Yasuhiro UEDA,† and Morihide HIGO††
Department of Molecular Science and Technology, Kyushu University 39, Kasuga, Fukuoka 816
(Received January 20, 1983)

The emission spectra produced by controlled electron impact on C_2H_2, C_2H_4, and C_2H_6 have been analyzed to gain insight into the production mechanisms of $C_2(d^3\Pi_g)$ from the three molecules. There are four thresholds on the excitation function of $C_2(d^3\Pi_g)$ from C_2H_2. Its vibrational temperatures are 22000 K for C_2H_2, 30000 K for C_2H_4 and 56000 K for C_2H_6 at an electron energy of 100 eV. Doubly-excited states are involved in the dissociative excitation of C_2H_2.

The observation of the diatomic C_2 radicals can be traced back to the nineteenth century. The intense emission bands of C_2 are prominent in all kinds of flames and electrical discharges of carbon compounds. Laser photolysis combined with laser-induced fluorescence detection is an efficient method to produce and to monitor this radical, and has been applied for studying elementary processes of C_2.[1] The mechanism of C_2 production in the infrared multiphoton dissociation has been investigated under collisionless conditions.[2,3] This radical has been produced by excimer laser photolysis;[4,5] the vibrational and the rotational temperatures of $C_2(d^3\Pi_g)$ from acrylonitrile have been determined to be 7150 and 4960 K, respectively.[5]

The molecular excitation process by electrons is somewhat different from that by photons; excitation into a triplet state and into a doubly-excited state is more feasible for the former. The $C_2(d^3\Pi_g)$ radical has been observed by controlled electron impact on acetylene,[6,7] ethylene,[8] and benzene;[9] however, no detailed discussion on their production mechanism has been carried out.

In the present paper, the emission spectra of C_2H_2, C_2H_4, and C_2H_6 produced by controlled electron impact have been measured under higher resolution than those in the previous papers, and the vibrational distributions and excitation functions of $C_2(d^3\Pi_g)$ have been analyzed to elucidate its production mechanisms.

Experimental

The details of the apparatus have been described.[10,11] In brief, the sample gas jet (10^{-4} Torr, 1 Torr≈133.322 Pa) was made to collide with an electron beam and the photoemission was measured with a Spex 1269 monochromator. The photons were detected with an HTV R585 photomultiplier and were counted with an NF PC545A photoncounter. The wavelength response was corrected with an Ushio JC-24-150 halogen lamp.[12] All the spectra were measured in a region where the intensity was proportional to both the electron-beam current and to the gas pressure. The sample gases were used as supplied (C_2H_2, Fuji Gas Ind.; C_2H_4, Seitetsu Chemicals; C_2H_6, Takachiho Chemicals); bulb-to-bulb distillation did not induce any change on the spectrum.

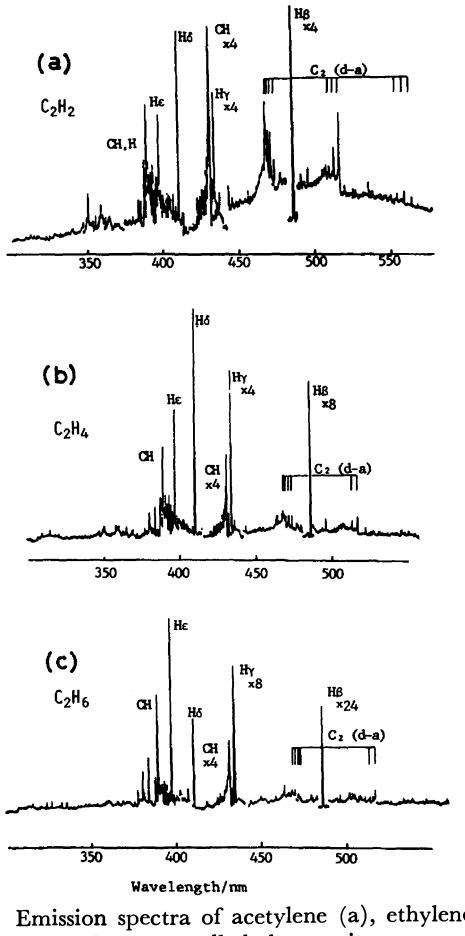

Fig. 1. Emission spectra of acetylene (a), ethylene (b), and ethane (c) by controlled electron impact.
Electron energy 100 eV; electron-beam current 100 μA (a, b), 1000 μA (c); gas pressure 3×10^{-4} Torr; optical resolution 3.2 Å.

Results and Discussion

Spectra. The emission spectra of acetylene, ethylene, and ethane by controlled electron impact show the Balmer lines of the excited hydrogen atom and bands of the CH radical (the A–X and B–X transition) and of the C_2 radical (the Swan system: the d–a transition),[13] as are shown in Fig. 1. The detailed spectra of the Swan system of C_2 from acetylene are shown in Fig. 2. The weak intensity of this system, especially for ethane, makes a quantitative analysis difficult. The band shape was independent of pressure

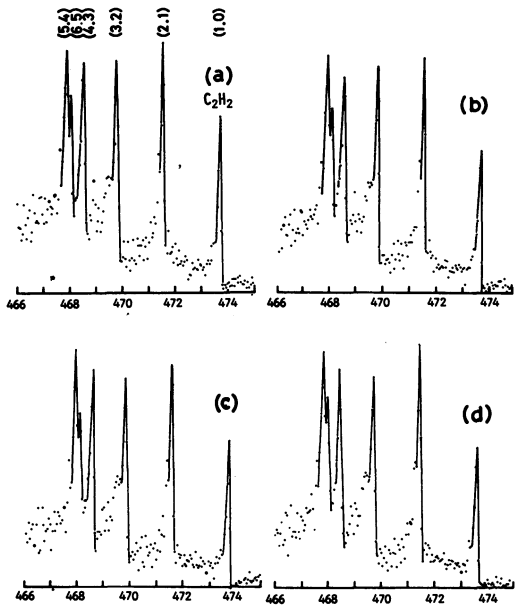

Fig. 2. The detailed spectra of the Swan system of acetylene at 100 eV (a), 50 eV (b), 30 eV (c), and 20 eV (d).
Electron-beam current 200—400 μA; optical resolution 0.8 Å.

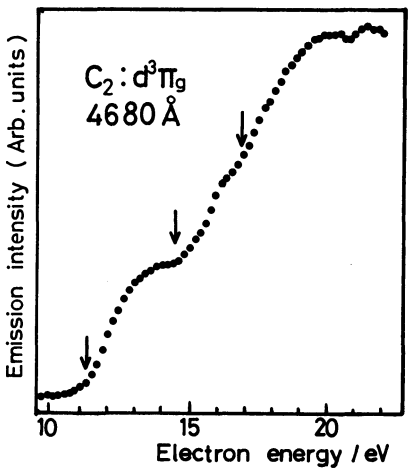

Fig. 3. The excitation function of $C_2(d^3\Pi_g)$ from acetylene at 4680 Å.
Electron-beam current 2 μA; electron energy resolution 0.6 eV; gas pressure 3×10^{-4} Torr.

$(6—50)\times10^{-5}$ Torr. The Swan bands are slightly polarized (1—2%) for electron energies from the threshold to 100 eV: this finding indicates that direct dissociation processes are involved in the dissociative excitation of the three molecules.

The excitation function of $C_2(d^3\Pi_g)$ from acetylene is shown in Fig. 2. There are four thresholds; their values are 11.2 ± 0.8, 14.5 ± 1.1, 16.9 ± 0.8, and 24.0 ± 1.0 eV. Those of ethylene and probably of ethane also have four thresholds.[14] These findings indicate that there are four major processes for the formation of C_2 from acetylene and ethylene, and probably also from ethane. The existence of two or more processes for dissociative excitation is usual for electron impact dissociations.[15]

Vibrational Population. The Vibrational distribution of the fragments produced in a collision process has much to do with the kinematics. The intensity of each vibrational band of the $\Delta v=+1$ transition of $C_2(d^3\Pi_g)$ has been obtained from its peak intensity, following the method of Danylewych and Nicholls.[16] The vibrational population thus obtained are shown in Fig. 3 for the three molecules excited by an electron beams of 100 eV. The values are relative to that $v'=0$, which is set to 1.0. The error bars shown are due to random experimental fluctuations. The observed distribution represents the nascent one, since the pressure is so low that the collisional deactivation can be ignored over the lifetime of the emitting level ($\approx$119 ns[4]).

The vibrational population of C_2 decreased as v' increased. If the excess energy of the primarily excited species are distributed randomly over various freedoms of motions, the vibrational population may be a Poisson distribution. This is not the case, as is shown in Fig. 4.

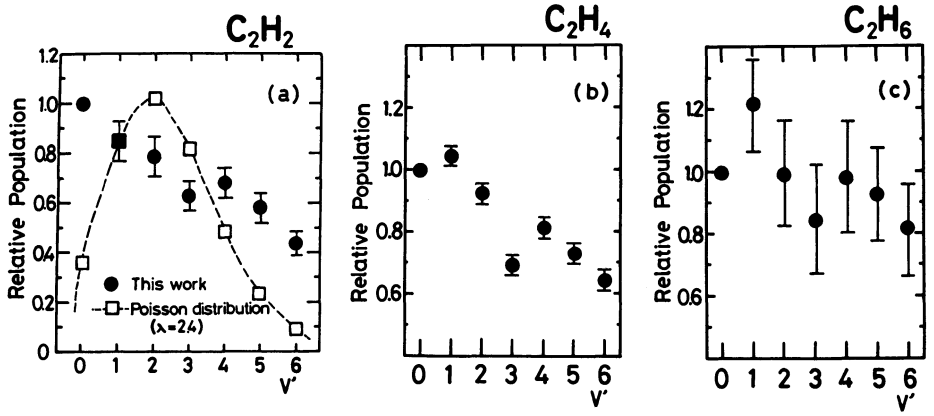

Fig. 4. Vibrational populations of $C_2(d^3\Pi_g)$ from C_2H_2 (a), C_2H_4 (b), and C_2H_6 (c) at an excitation energy of 100 eV.
The error bars represent random scatterings. A poisson distribution is shown for the case of C_2H_2, where λ is determined as a parameter for the least-square fitting with the observed values.

Table 1. Vibrational temperature ($T_{vib.}$) of C_2 at various electron energies (E_{el})

C_2H_2		C_2H_4		C_2H_6

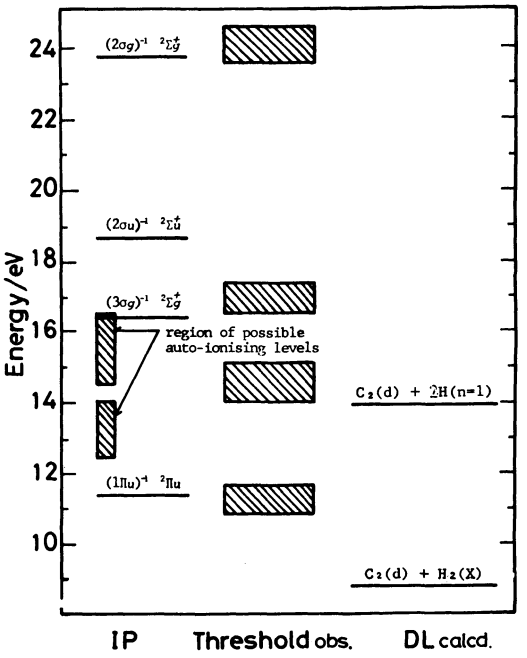

Fig. 5. Energy diagram of acetylene.
The ionization potentials, the observed threshold energies and the calculated dissociation limits are shown. The width of the threshold energy represents its uncertainty.

The vibrational distributions of C_2 are rather similar to a Boltzmann distribution. Semi-logarithmic plots of the vibrational populations give the vibrational temperatures of $C_2(d^3\Pi_g)$, as are shown in Table 1. The vibrational temperatures tend to increase for a larger parent molecule. This finding seems to be inconsistent with a statistical prediction,[17] which has been successfully applied to multiphoton dissociation of benzene.[18] This means either that the three molecules are too simple to be treated statistically or that there are some predominant processes.

Assignments for Acetylene. The core-ion model of molecular dissociation may be extended to the low-Rydberg fragments.[15] If this is also the case for the production of C_2, dissociative ionization to produce C_2^+ should be correlated with dissociative excitation. The electron configuration of acetylene is $KK(2\sigma_g)^2(2\sigma_u)^2(3\sigma_g)^2(1\pi_u)^4$. The energy diagram for dissociation is shown in Fig. 5.

The first component of C_2, which has the threshold at 11.2 eV, is assigned to be produced from dissociative excitation through Rydberg states converging to the $(1\pi_u)^{-1}$ ionized state, which lies in this region.[19] The final state should be $C_2(d^3\Pi_g)+H_2(X)$ from energy considerations. The excess energy of this process is about 2.6 eV and is almost equal to the vibrational energy of C_2 excited at 13 eV (30000 K=2.6 eV); thus, the excess energy mostly goes into the vibrational freedom of C_2 in this process.

There are auto-ionizing levels[20] near the second threshold (14.5 eV), Rydberg states converging to the $(2\sigma_u)^{-1}$ and $(3\sigma_g)^{-1}$ ionized states[19] near the third threshold (16.9 eV), and Rydberg states converging to the $(2\sigma_g)^{-1}$ ionized state[19] near the fourth threshold (24.0 eV). The $(3\sigma_g)^{-1}$ state dissociates into C_2H^+ and then into C_2^+ quickly.[21] The $(2\sigma_u)$ orbital is strongly bonding for the C–H bonds and the $(2\sigma_u)^{-1}$ state is expected to dissociate into C_2^+. Thus, these states are expected to be important for the formation of $C_2(d^3\Pi_g)$ in the respective energy regions.

Assignments of C_2 production mechanism may be carried out similarly for ethylene and ethane; however, insufficient information on their highly-excited states and larger experimental fluctuations made any detailed discussion difficult.

Concluding Remarks. An electron is a very efficient source for molecular excitation in the 10—1000 eV range, and an electron source is much easily operated than a synchrotron orbital radiation facility. Furthermore, the electron has a distinct advantage; it is able to excite optically forbidden processes, which are often important in the dissociation dynamics.[15] The vibrational distributions of $C_2(d^3\Pi_g)$ produced by IR multiphoton dissociation of C_2H_3CN concentrate in the lower vibrational level,[3] whereas those produced by UV multiphoton dissociation of C_2H_3CN have a vibrational temperature of 7150 K.[5] These results disclose differences in the excitation mechanisms. Recent demands for the dynamics and kinetics of C_2 from combustion engineering, atmospheric and environmental sciences warrant further investigation on this subject.

The authors thank Professor Nobuhiko Ishibashi for his encouragement. The present study was partially supported by a Grant-in-Aid from the Ministry of Education, Science and Culture.

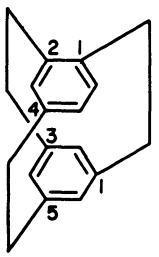
The Crystal Structure of 2,11,20-Trithia[3.3.3](1,2,4)(1,3,5)cyclophane and Molecular Structures of Unsymmertically Tris-bridged [2.2.2](1,2,4)(1,3,5) and [2.2.2](1,2,4)(1,2,5)Cyclophanes, Estimated by Molecular Conformational Analysis†

Yasushi KAI, Takashi MIZUMA,†† Noritake YASUOKA,††† and Nobutami KASAI*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received January 24, 1983)

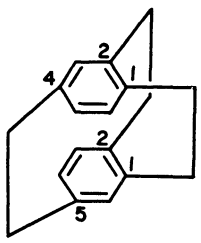
The crystal structure of 2,11,20-trithia[3.3.3](1,2,4)(1,3,5)cyclophane has been determined by the X-ray diffraction method and compared with the molecular structures of unsymmetrically tris-bridged [2.2.2](1,2,4)(1,3,5) and [2.2.2](1,2,4)(1,2,5)cyclophanes, estimated by molecular conformational analysis.

In a series of recent synthetic studies of layered cyclophane compounds with more than two ethano bridges holding two benzene rings,[1-4] a new type of unsymmetrically tris-bridged [2.2.2]cyclophanes (**1** and **2**) has been reported by Nakazaki and his co-workers.[5]

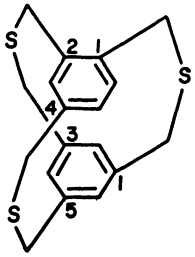
The molecular structures of **1** and **2** are expected to have unusually deformed benzene rings with a new mode of overlapping structures among the various kinds of layered cyclophane compounds. In the synthetic paths to **1** and **2**, trithia[3.3.3]cyclophanes (**3** and **4**) are the intermediate products, followed by the preparation of trisulfones and their pyrolysis.



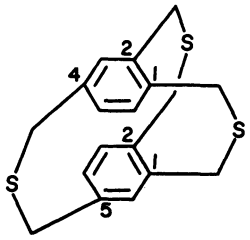
1



2



3



4

As a first step in structural studies of these unsymmetrically tris-bridged [2.2.2]cyclophanes, the crystal structure of **3** has been determined by the X-ray diffraction method. The crystals of **1** and **2** were of a poor quality for the X-ray experiment. The molecular structures of **1** and **2**, therefore, have been estimated by the intramolecular-strain-energy-minimization method with semi-empirical potential functions by Boyd,[6] and have been compared with the molecular structure of **3**.

Experimental

Crystal Data. $C_{18}H_{18}S_3$, *F.W.* 330.5, monoclinic, space group $P2_1/c$, $a=15.466(4)$, $b=13.068(5)$, $c=8.409(2)$ Å, $\beta=115.39(2)°$, $V=1535.4(8)$ Å^3, $D_m=1.43$ (by flotation), $D_c=1.430$ g cm^{-3}, $Z=4$.

The three-dimensional X-ray data were collected using a crystal with dimensions of $0.3\times0.3\times0.35$ mm by the use of Zr-filtered Mo $K\alpha$ radiation on a Rigaku automated four-circle diffractometer. The θ-2θ scan method was employed at a rate of 4° min^{-1}. The backgrounds were measured for 5 s before and after each scan. A total of 3384 (2513 non-zero) reflections was collected up to $2\theta=54°$. Usual *Lp* corrections were made but no absorption correction was employed [μ(Mo $K\alpha$) = 4.5 cm^{-1}].

The structure was solved by the direct method (*MULTAN* 74)[7] and refined anisotropically by the block-diagonal least-squares procedure (*HBLS*-V).[8] After the *R* value had converged to 0.113, all the H atoms located on the difference Fourier map were included in the refinement with the isotropic temperature factors. The weighting scheme used was $w=[\sigma^2(F_o)+a|F_o|+b|F_o|^2]^{-1}$ and $w=c$ for non-zero and zero reflections respectively. The final *R* value was 0.098 for non-zero reflections (0.149 for all), and $R_w=0.138$, with $a=0.0796$, $b=0.0017$, and $c=0.1320$. The atomic scattering factors for the S and C atoms were taken from the "International Tables for X-Ray Crystallography," Vol. IV,[9] and those for the H atom from Stewart *et al.*[10] The final atomic coordinates are listed in Table 1.††††

Results and Discussion

Molecular Structure of 2,11,20-Trithia[3.3.3](1,2,4)-(1,3,5)cyclophane (3). The perspective view of the molecule are shown in Fig. 1 by the *ORTEP* drawings,[12] together with the atomic numberings. The bond distances and angles are listed in Table 2.

In the crystal structure of **3**, no conformational disorder of the sulfide bridges is found, in contrast with the crystal structures of related compounds, 2,11,20-trithia[3.3.3](1,3,5)cyclophane (**5**),[13] and *syn*-2,11-dithia-9,18-dimethyl[3.3]cyclophane (**6**).[14] The conformational disorder observed in **5** and **6** was inter-

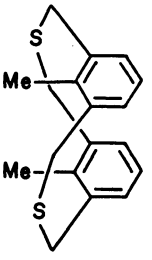
5



6

preted in terms of a temperature-modulated flipping of the sulfide bridges[13] between two positions related by the local 2-fold symmetry. The lack of local 2-fold symmetry in **3** may be an important factor in preventing the sulfide bridges from flipping in the crystal structure.

The structures of the two benzene rings in this molecule are different from each other. The benzene ring with three sulfide bridges symmetrically on its 1, 3, and 5 positions [abbreviated as (1,3,5)benzene hereafter] is planar within a maximum deviation of 0.015 Å. On the other hand, the other benzene ring, with three sulfide bridges unsymmetrically on its 1, 2, and 4 positions [(1,2,4)benzene], deviates from a plane to boat structure. The C(14), C(15), C(17), and C(18) atoms make a base plane within a 0.003 Å deviation, with the C(13) and C(16) atoms as the bow and/or stern atoms. The dihedral angles between the base plane and the bow and/or stern planes [C(14), C(13), and C(18)] and [C(15), C(16), and C(17)] are both 6.4°, a value of which is much smaller than the corresponding angles (12—14°) of the boat-form benzene rings in [2.2]paracyclophane[15] and its derivatives.[16,17] In the **5** molecule, the two benzene rings are both planar and are parallel to each other within a 1° deviation. In the **3** molecule, the mean plane of the (1,3,5)benzene ring makes an angle of 6.8° with the base plane of the (1,2,4)-benzene ring. The distances of the carbon atoms in (1,3,5)benzene from the base plane of (1,2,4)benzene lie between 2.902 and 3.238 Å, the average of which [3.077 Å] is shorter than the corresponding distance of **5**, 3.192 Å.

The C–S–C angles about the S(2), S(11), and S(20) atoms are 103.9(3), 103.1(3), and 103.5(3)° respectively. The C–S distances range from 1.817(8) to 1.840(8) Å [av. 1.827 Å]. The S–C–C angles, distributed in the

S–C–H 96—116 (5—8), av. 106(6)			
C–C(sp^3)–H 104—118 (5—8), av. 110(6)			
C–C(sp^2)–H 116—122 (4—8), av. 119(6)			
H–C(sp^3)–H 90—117 (7—9), av. 107(8)			

range from 111.1(5) to 118.7(5)° [av. 114.8°], are greater than the tetrahedral angle of 109.5°.

The angular deviation of the C(3)–C(4) bond from the plane defined by the C(4), C(5), and C(9) atoms, that of the C(6)–C(21) bond from the plane defined by the C(5), C(6), and C(7) atoms, and that of the C(8)–C(10) bond from the plane defined by the C(7), C(8), and C(9) atoms are 5.9, 9.5, and 3.4° respectively. The corresponding angular deviations of the C(1)–C(16), C(17)–C(19), and C(12)–C(13) bonds are 2.7, 0.2, and 4.1° respectively. These angles are much smaller than the corresponding angles (11—15°) in [2.2]paracyclophane[15] and related compounds.[16,17]

The above results suggest that the intramolecular strain of the **3** molecule may be much smaller than the layered cyclophanes with ethano bridges and a little greater than those of the symmetrically tris-bridged analogue (**5**) and the di-bridged related compound (**6**).

Estimated Molecular Structures of Unsymmetrically Tris-bridged [2.2.2](1,2,4)(1,3,5) and [2.2.2](1,2,4)(1,2,5)-Cyclophanes. The molecular structures of [2.2.2](1,2,4)(1,3,5)cyclophane (**1**) and [2.2.2](1,2,4)(1,2,5)-cyclophane (**2**) were obtained by the conformational analysis of Boyd's *MOLBD*-3 program.[6] The starting molecular models were generated by Mansfield's *MOLGEN* program[18] using the standard structural parameters. The starting molecular models were refined through the energy-minimization procedure by means of the *MOLBD*-3 program to converged structures with strain energies of 39.1 (**1**) and 28.3 kcal mol^{-1} (**2**).†††† The calculated molecular structures of **1** and **2** are shown in Fig. 2. The molecular structures thus obtained give quite reasonable results, with a significantly greater strain energy in **1** than in **2**. The strain energy of [2.2]-paracyclophane was reported by Boyd to be 35.1 kcal mol^{-1}.[6]

The additional strain energy in **1** compared with that in **2** is based on the difference in bridging positions between the facing benzene rings. In the **2** molecule, the bridging from the 1, 2, and 4 positions of one benzene ring to the 1, 2, and 5 positions of the other benzene ring is done by sliding and rotating two benzene

Fig. 2. Molecular structures of **1** and **2** estimated by the molecular conformational analysis by the use of *MOLBD*-3 program. a) Side views of the molecules projected along the C(13)–C(11) bond. b) Projections of the molecules onto the least-squares planes of (1, 3, 5)benzene for **1** and (1, 2, 5) benzene for **2**, respectively.

rings from the eclipsed position without adding an extra strain energy to its molecular structure. In the **1** molecule, however, the deviation of the two benzene rings from the eclipsed position is smaller than that of **2** because of the more constrained bridging positions of 1, 3, and 5 of the second benzene ring. This causes the rather large deformations of the structural parameters from the standard values. Almost all of the difference between the intramolecular strain energies of **1** and **2** [10.2 kcal mol^{-1}] is due to the difference in the strain energies of the angular deformations about C(benzene) connecting to the ethano bridges [2.7 kcal mol^{-1}] and out-of-plane deformations of C(benzene)–C(bridge) from the C(benzene) plane [6.5 kcal mol^{-1}] between **1** and **2**.

In the **1** molecule, the (1,2,4)benzene ring takes an approximately boat form, with the base plane including C(4), C(5), C(7), and C(8) atoms, while the (1,3,5)-benzene ring is roughly planar. The structures of these benzene rings in **1** are similar to those found in trithia-[3.3.3]cyclophane, which has the same bridging structure (**3**). In the **2** molecule, the (1,2,4)benzene ring also takes a boat form, with the base plane including C(4), C(5), C(7), and C(8), while the planality of the (1,2,5)-benzene ring is lower than that of the (1,3,5)benzene ring in **1**. The distances of the atoms in the (1,3,5)-benzene ring from the base plane of the (1,2,4)-benzene ring in **1** range from 2.57 to 3.02 Å [av. 2.82 Å], while

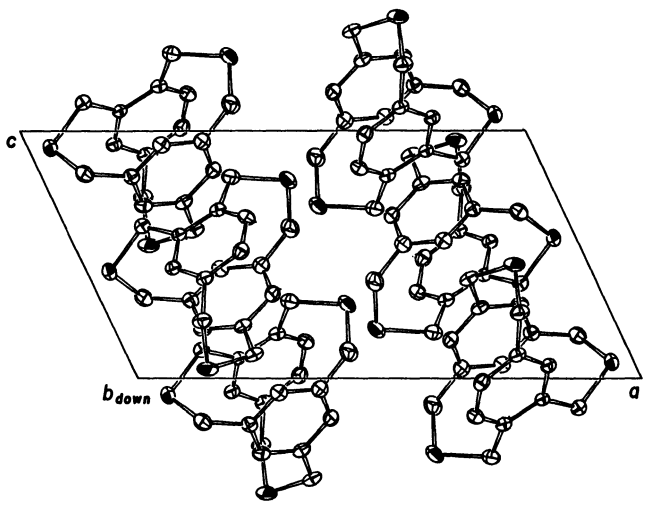

Fig. 3. Crystal structure of **3** projected along the b axis.

the corresponding values in **2** range from 2.52 to 3.01 Å [av. 2.81 Å]. It is noteworthy that the projection of **3** onto the mean plane of (1,3,5)benzene (Fig. 1), which shows an overlapping structure of two benzene rings, is essentially the same as the projection of **1** in Fig. 2.

Crystal Structure of 2,11,20-Trithia[3.3.3](1,3,5)cyclophane (3). The crystal structure of the **3** molecule is shown in Fig. 3. No unusually short contacts were found, the shortest ones being as follows: S(11)–C(13)

[x, 1/2−y, 1/2+z] 3.567 Å, S(11)–C(21) [x, 1/2−y, −1/2+z] 3.583 Å, and S(20)–S(20) [−x, 1−y, 1−z] 3.617 Å.

All the computations were carried out on an ACOS 800 computer at the Computation Center, Osaka University, and on an ACOS 700S computer at the Crystallographic Research Center, Institute for Protein Research, Osaka University.

The authors wish to express their deep thanks to Professor Masao Nakazaki and his co-workers of Osaka University for their kindness in supplying samples and their valuable discussions. We would also like to thank Professor Richard H. Boyd and Dr. Marc Mansfield for supplying their excellent computer programs. The present work was partially supported by a Grant-in-Aid for Co-operative Research (No. 434026) from the Ministry of Education, Science and Culture.

(Received March 11, 1983)

The detailed molecular geometry of albocycline ($C_{18}H_{28}O_4$) has been examined by X-ray crystal analysis. The crystals are monoclinic, with four molecules in a unit cell with dimensions of $a=16.177(2)$, $b=9.562(1)$, $c=11.742(2)$ Å, and $\beta=90.43(1)°$; the space group is $P2_1$. 3062 unique intensity data were collected on a four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation. The structure was elucidated by the Monte Carlo direct method, using the 30 reflections with the greatest $|E|$ values as the starting set; the 174th random phase set led to the correct solution. The R value reached 0.057 by block-diagonal least-squares refinements. The two crystallographically-independent molecules are connected by two O–H···O hydrogen bonds, forming a hydrogen-bonded dimer. The conformations of the fourteen-membered macrolide rings in these two molecules are considerably different from each other; *e.g.*, great differences of 165, 153, and 108° are found for the torsion angles around the C(4)–C(5), C(6)–C(7), and C(7)–C(8) single bonds respectively.

Albocycline is a macrolide antibiotic isolated from such strains of *Streptomyces* as *S. brunneogriseus*[1] and *S. maizeus*,[2] and is active mainly against staphylococci. On the basis of degradative and spectroscopic experiments,[3-5] the **1** structure was proposed for this antibiotic. A nuclear-Overhauser-effect study later suggested that the C(8)=C(9) double bond might be not *cis* but *trans*.[6] Therefore, in order to establish the molecular structure, we undertook an X-ray crystal structure analysis of albocycline itself. However, soon after this analysis has completed, the results of the X-ray study of (*p*-bromobenzoyl)albocycline (**2**) were published.[7] According to that report, albocycline has the **3** structure, which agrees with our conclusion. The present paper gives a detailed description of the two different molecular conformations found in the albocycline crystal.

2 : R = p-BrC$_6$H$_4$CO
3 : R = H

Experimental

Colorless single crystals of albocycline were grown from a hexane–diethyl ether solution. The sample used for the X-ray experiment had dimensions of about $0.3\times0.4\times0.5$ mm^3. The crystal data are summarized in Table 1. The unit-cell dimensions and diffraction intensities were measured on a Rigaku four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation ($\lambda=0.71069$ Å). The ω-2θ scan technique was applied at a 2θ scan rate of 4° min^{-1}; the scan width in ω was $(0.9+0.34\tan\theta)°$. The background was measured for 10 s at each end of the scan range. The intensities were corrected for the Lorentz and polarization factors, but not for the absorption or the extinction effect. In the range of 2θ value s up to 55°, 3062 independent structure factors above the $\sigma(F)$ level were selected for the structure determination.

TABLE 1. THE CRYSTAL DATA

$C_{18}H_{28}O_4$	Mol wt 308 42
Crystal system	Monoclinic
Space group	$P2_1$

	b = 9.562(1) Å
	c = 11.742(2) Å
	β = 90.43(1)°
V	1816.2 Å^3
Z	4
D_c	1.128 g cm^{-3}
μ(Mo $K\alpha$)	0.730 cm^{-1}

Structure Determination

In the early stage of the structure determination, various attempts were made to solve the structure with the MULTAN-78 program,[8] but all such attempts were unsuccessful. The structure was finally elucidated by the Monte Carlo direct method,[9] using the reflections with 2θ values less than 50°. The starting set was composed of the 30 reflections having the greatest $|E|$ values. In order to extend each of the tentative-phase sets derived from random numbers, 12 cycles of the tangent procedure were carried out by the use of 711 $|E|$ values above 1.30. Since the 174th random phase set showed a low R_K value of 0.316 ($R_K=\Sigma||E_o|-k|E_c||/\Sigma|E_o|$), 6 additional cycles of the tangent procedure were performed using 861 $|E|$ values above 1.20; consequently, the R_K value was reduced to 0.266. An E-map based on 828 phases revealed the locations of all the 44 non-hydrogen atoms.

The structure thus obtained was refined by the block-diagonal least-squares method with anisotropic temperature factors, using all the 3062 reflections. After all the 56 hydrogen atoms had been located in a difference Fourier map, further least-squares refine-

a) $B_{eq} = 8\pi^2(u_1^2+u_2^2+u_3^2)/3$, where u_i is the root-mean-square deviation in the i-th principal axis of the thermal ellipsoid.

ments were carried out including the hydrogen atoms with isotropic temperature factors. For these refinements, the following weighting scheme was used:

$$w=1/\{\sigma(F)^2 \exp(c_1X^2+c_2Y^2+c_3XY+c_4X+c_5Y)\},$$

where $X=|F_o|$ and $Y=\sin\theta/\lambda$. The c_1, c_2, c_3, c_4, and c_5 coefficients were evaluated from the $(\Delta F)^2$ distribution: $c_1=-0.377\times10^{-4}$, $c_2=24.1$, $c_3=0.0518$, $c_4=-0.265\times10^{-2}$, and $c_5=-27.3$. In this manner, the R value reached 0.057. The final atomic parameters are listed in Table 2.[10)]

The calculations were done on a HITAC M-200H computer at the Hokkaido University Computing Center, using our own programs. The atomic scattering factors were taken from the International Tables.[11)]

Results and Discussion

Molecular Structure. The frameworks of the two crystallographically-independent molecules, A and B, are illustrated in Fig. 1, while the bond distances and angles and the torsion angles are given in Tables 3 and 4 respectively. These results demonstrate that albocycline has the **3** structure in which the fourteen-membered macrolide ring contains a *trans,trans,trans*-triene system.

Notwithstanding the incorporation in the macrolide ring, the ester moiety in each of the A and B molecules keeps the geometry characteristic of secondary alcohol esters, *i.e.*, the synperiplanar configuration of the

a) The e.s.d.'s are 0.4—0.9°.

C(13)–O(1)–C(1)=O(2) segment and the eclipsed conformation of the H(13)–C(13)–O(1)–C(1) segment. This geometry brings the O(2) and H(13) atoms close to each other; their distances are 2.49(4) and 2.30(5) Å for the A and B molecules respectively. The C(2)=C(3) and C(1)=O(2) conjugated double bonds are transoid and nearly coplanar for both molecules. Consequently, the C(13)–O(1)–C(1)(O(2))–C(2)=C(3)–C(4) segment as a whole has a rigid and nearly-planar configuration. This coplanarity of the five consecutive bonds makes it

impossible for the ring to take a rectangular form.

As will be seen from Fig. 1, the ring conformations of the A and B molecules differ considerably from each other. The C(5) and C(6) atoms in the former molecule are situated above and below the mean plane of the ring respectively, while those in the latter are placed in the opposite way. This remarkable variation in the orientation of the C(5)=C(6) double bond is caused mainly by great changes (165, 153, and 108° respectively) of the C(3)–C(4)–C(5)=C(6), C(5)=C(6)–C(7)–C(8), and C(6)–C(7)–C(8)=C(9) torsion angles. These torsional changes further alter the orientations of the atomic groups at the C(4) and C(7) atoms in a regular manner; *i.e.*, the O(3)H, C(14)H_3, and O(4)–C(15)H_3 groups in the A molecule are pseudo-equatorial, pseudo-axial, and pseudo-axial respectively, whereas those in the B molecule are pseudo-axial, pseudo-equatorial, and pseudo-equatorial respectively. On the other hand, the C(17)H_3 and C(18)H_3 groups remote from the C(4)–C(5)=C(6)–C(7) segment are pseudo-equatorial for both molecules.

When the macrolide ring in the B molecule is viewed along the normal of its mean plane, it looks like a somewhat-deformed trapezoid having the nearly-planar C(13)–O(1)–C(1)(O(2))–C(2)=C(3)–C(4), C(4)–C(5)=C(6)–C(7), C(7)–C(8)(C(16))=C(9)–C(10), and C(10)–C(11)=C(12)–C(13) segments as the four sides (see Fig. 1). The mean planes for these segments make angles of 33, 12, 5, and 16° with the normal of the ring plane respectively. On the other hand, the macrolide ring in the A molecule is too greatly deformed to be regarded as having such a trapezoid form. That is to say, the mean planes for the C(13)–O(1)–C(1)(O(2))–C(2)=C(3)–C(4) and C(7)–C(8)(C(16))=C(9)–C(10) segments incline at large angles of 46 and 70° with the normal of the ring plane respectively, although those for the C(4)–C(5)=C(6)–C(7) and C(10)–C(11)–C(12)–C(13) segments are at small angles of 17 and 9° with this normal respectively. The marked inclination of the C(7)–C(8)(C(16))=C(9)–C(10) segment results mainly from the eclipsed conformation of the C(6)–C(7)–C(8)=C(9) segment. The (*p*-bromobenzoyl)albocycline molecule[7] has almost the same ring conformation as the A molecule of albocycline. A ring conformation such as the B molecule takes may be unfavorable for the derivative molecule because of the pseudo-axial orientation of the large *p*-bromobenzoyloxyl group.

The ring formation results in considerable deformation of the vinylene groups. The deviations of the C(1)–C(2)=C(3)–C(4), C(4)–C(5)=C(6)–C(7), and C(7)–C(8)=C(9)–C(10) torsion angles from the value (180°) for the ideal planar *trans* configuration are 12.0, 10.4, and 2.5° for the A molecule respectively, and are 14.7, 20.8, and 7.7° for the B molecule respectively. It is of interest to note that each vinylene group in the B molecule is more greatly deformed than the corresponding group in the A molecule. Apart from the O(1)–C(1)–C(2)=C(3) segment which has the synperiplanar conformation because of the strong conjugation between the C(2)=C(3) and C(1)=O(2) double bonds, there are three and four synperiplanar segments of the C=C–C–X type in the A and B molecules respectively (see Table 5). Of these seven segments, two are the C(2)=C(3)–C(4)–O(3) segments in the two molecules. It is known that, in the preferred conformations of *unsym*-butene (CH_2=CH–CH_2–CH_3) and allyl alcohol (CH_2=CH–CH_2–OH), the C=C double bond eclipses one of the hydrogen atoms at the allylic position.[12] The C(5)=C(6)–C(7)–H(7) and H(7)–C(7)–C(8)=C(9) segments in the B molecule have such eclipsed conformations. On the other hand, the eclipsed conformations of the C(5)=C(6)–C(7)–O(4) and C(6)–C(7)–C(8)=C(9) segments in the A molecule result in significant enlargement of the C(5)=C(6)–C(7), C(6)–C(7)–O(4), C(6)–C(7)–C(8), and C(7)–C(8)=C(9) bond angles, the observed values of which are greater than the corresponding values in the B molecule by 1.7, 3.6, 5.5, and 2.6° respectively. The O(3)–C(4)–C(5) bond angle in the B molecule is greater than that in the A molecule by 5.0°. This is also explained by the fact that, while the C(5)=C(6) double bond in the former molecule eclipses the C(4)–O(3) bond, that in the latter is gauche to the C(3)–C(4) and C(4)–C(14) bonds.

Crystal Structure. The molecular arrangement viewed along the b axis is shown in Fig. 2. There are two kinds of hydrogen bonds, O(A3)–H···O(B4) and

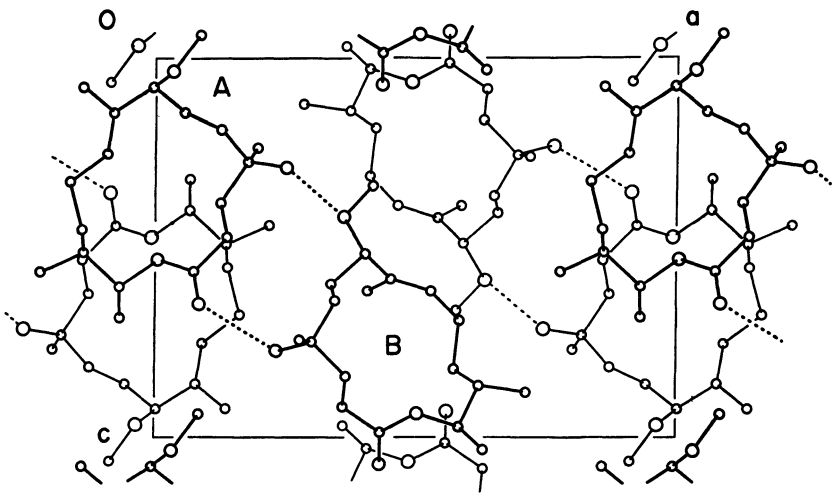

Fig. 2. The molecular arrangement viewed along the b axis.

Table 5. The synperiplanar segments of the C=C–C–X type and their torsion angles(ϕ/°)

(1) Molecule A	
C(2)=C(3)–C(4)–O(3)	8.3(7)
C(5)=C(6)–C(7)–O(4)	18.6(6)
C(6)–C(7)–C(8)=C(9)	1.4(7)
(2) Molecule B	
C(2)=C(3)–C(4)–O(3)	2.4(7)
O(3)–C(4)–C(5)=C(6)	−18.3(7)
C(5)=C(6)–C(7)–H(7)	−15(3)
H(7)–C(7)–C(8)=C(9)	9(3)

O(B3)–H···O(A2); their O···O distances are 2.957(5) and 2.867(5) Å respectively. Through these hydrogen bonds, the O(2)–C(1)–C(2)=C(3)–C(4)–O(3)–H(O3) segment in the A molecule and the H(O3)–O(3)–C(4)–C(5)=C(6)–C(7)–O(4) segment in the B molecule are connected to form a fourteen-membered ring; consequently, the two molecules form a hydrogen-bonded dimer oriented nearly in the [101] direction. The macrolide-ring planes of the A and B molecules in the same dimer make an angle of 30° with each other, and incline at angles of 15 and 37° to the (010) plane respectively. The hydrogen-bonded dimers are further held together mainly by the van der Waals interactions.

Kinetic Parameters of the Electrode Reaction of Carbonatocobalt(III) Complexes at Mercury Electrodes

Akifumi YAMADA,* Yutaka KADO, and Yu YOKOYAMA

Department of Materials Science and Technology, Technological University of Nagaoka, Kamitomioka, Nagaoka 949-54

(Received January 27, 1983)

The electroreduction of $[Co(CO_3)(NH_3)_5]^+$, $[Co(CO_3)(NH_3)_4]^+$, $[Co(CO_3)(tn)_2]^+$, $[Co(CO_3)(pn)_2]^+$, $[Co(CO_3)(en)_2]^+$, and $[Co(CO_3)_2(en)]^-$ (tn=trimethylenediamine, pn=propylenediamine, en=ethylenediamine) have been studied at mercury electrodes in weak acid solutions. All complexes exhibit two irreversible reduction waves; the first corresponds to $Co^{III} \longrightarrow Co^{II}$, and the second, to $Co^{II} \longrightarrow Co^0$. The kinetic parameters of the electrode reactions of the first step were determined by means of Tast and pulse polarography in solutions containing 0.005 M sodium acetate–acetic acid buffer (pH=6) and 0.995 M sodium nitrate at 25 °C. The differential pulse polarograph hic characteristics of these complexes are also given.

The polarography of carbonatocobalt(III) complexes has been briefly reported in the course of the survey of the half-wave potential for mixed ammine cobalt[1,2] and ethylenediamine cobalt[3] complexes. However, a systematic study of a series of carbonatocobalt(III) complexes under the same conditions has not yet been made. Data for electrochemical kinetic parameters are of importance in the discussion not only of the properties of electrode reactions but also the effect of the solvent, the supporting electrolytes and the electrical double layer on the reactions.

In this paper, the kinetic parameters of the electrode reactions of several carbonatocobalt(III) complexes were examined by means of Tast and pulse polarography.

Experimental

Materials. The complexes, $[Co(CO_3)(en)_2]ClO_4$,[4] $[Co(CO_3)(pn)_2]NO_3$,[5] $[Co(CO_3)(tn)_2]ClO_4$,[6] $[Co(CO_3)(NH_3)_4]NO_3 \cdot 0.5H_2O$,[7] $[Co(CO_3)(NH_3)_5]NO_3 \cdot 0.5H_2O$,[8] $K[Co(CO_3)_2(en)]$,[9] $[Co(NH_3)_6](NO_3)_3$,[10] and $Na[Co(edta)]$[11] were prepared by the literature methods. The concentration of 0.001% polyacrylamide (PAA) was used as the maximum suppressor. All the other chemicals used were of a guaranteed reagent-grade.

Electrochemical Measurements. A three-electrode cell[12] equipped with a saturated calomel electrode (Yanagimoto MR-P2-05-1) and a platinum wire electrode was employed. The dropping mercury electrode (flow rate, 1.25 mg s^{-1} and drop time, 2.99 s in 1 M (1 M=1 mol dm^{-3}) sodium nitrate solutions) served as a working electrode. The kinetic parameters of the electrode reactions were determined by means of Tast and pulse polarography. The polarograms were recorded on Yanagimoto Model P-1000 polarograph with a Riken Denshi Model F3EP x-y recorder. A Takeda Riken digital multimeter, Model TR-6355, was used; the current and the potential were thus measured precisely. Electrolytic solutions were deaerated by bubbling purified nitrogen gas through the solution. All measurements were made at 25±0.1 °C.

In a series of determination of the electrochemical kinetic parameters of various cobalt(III) complexes, the electrochemical procedure was as follows. After measurements of residual current of 10 ml of supporting electrolyte solution, a solid sample of the cobalt complex under test was added to the solution. The electrode potential which is premeditatedly selected was applied. The current was then measured. Measurements were made within ten minutes to avoid the decomposition of complexes in the solution.

Results and Discussion

Many mixed cobalt(III) complexes with various ligands have been prepared, but the kinetic parameters of the electrode reactions have been studied only for a few.[13] For the carbonatocobalt(III) complexes, the polarographic half-wave potentials in neutral solutions have been reported only for carbonatopentaamminecobalt(III),[1] carbonatotetraamminecobalt(III),[2] and carbonatobis(ethylenediamine)cobalt(III)[3] complexes. These cobalt(III) complexes are reduced in two steps: the first corresponds to $Co^{III} \rightarrow Co^{II}$ and the second, to $Co^{II} \rightarrow Co^0$. This work reports extensive kinetic studies of carbonatocobalt(III) complex ions, such as $[Co(CO_3)(en)_2]^+$, $[Co(CO_3)(pn)_2]^+$, $[Co(CO_3)(tn)_2]^+$, $[Co(CO_3)(NH_3)_4]^+$, $[Co(CO_3)(NH_3)_5]^+$, and $[Co(CO_3)_2(en)]^-$. They are made in acid solutions at mercury electrodes.

The carbonatocobalt(III) complexes gave two polarographic waves. The limiting currents of both the first and the second wave were diffusion-controlled and were proportional to the concentration of the complex. The limiting current of the second wave was twice that of the first one, which suggests that a one-electron reduction is followed by a two-electron reduction. From a polarographic log-plot analysis[14] and other polarographic experiments, both steps are considered to be totally irreversible. The present investigation is concerned only with the reduction of cobalt(III) to cobalt(II).

Figure 1 shows the Tast polarogram of the first wave of several carbonatocobalt(III) complexes obtained in solutions containing 0.005 M sodium acetate-acetic acid buffer (pH=6) and 0.995 M sodium nitrate. In the carbonatocobalt(III) complexes studied, the CO_3^{2-} acts as a bidentate ligand, except for $[Co(CO_3)(NH_3)_5]^+$, in which the carbonate ions are unidentate ligands. An examination of Fig. 1 shows the half-wave potentials for the first wave of the complex depend on the types of coordination. The order of the half-wave potential in the series of complexes is:

$$[Co(CO_3)(NH_3)_5]^+ > [Co(CO_3)(NH_3)_4]^+ > [Co(CO_3)_2(en)]^-$$

and

$$[Co(CO_3)(tn)_2]^+ > [Co(CO_3)(pn)_2]^+ > [Co(CO_3)(en)_2]^+.$$

In the first series, carbonatopentaamminecobalt(III)

	(−0.57)[a]	(−0.38)[a]	—
$[Co(NH_3)_6]^{3+}$	−0.363	−1.3	113
$[Co(edta)]^-$	+0.145	−3.2	102

a) Corresponds to the second peak.

may be less stable than carbonatotetraamminecobalt(III) since the ligand CO_3^{2-} acts as unidentate in $[Co(CO_3)(NH_3)_5]^+$. Dicarbonatoethylenediaminecobaltate(III) may be more stable than carbonatotetraamminecobalt(III) because the CO_3^{2-} ligand occupies four coordination positions in the former, but only two in the latter. In the second series, the order of the half-wave potential is in accordance with that of the tris-type complexes ($[Co(tn)_3]^{3+}$>$[Co(pn)_3]^{3+}$>$[Co(en)_3]^{3+}$).[15] The trimethylenediamine chelate ring is more bulky than the ethylenediamine chelate ring, and carbonatobis(trimethylenediamine)cobalt(III) may be less stable than carbonatobis(ethylenediamine)cobalt(III).

Figure 2 shows the differential pulse polarograms of the first wave of several carbonatocobalt(III) complexes. The wave height of $[Co(CO_3)_2(en)]^-$ was about one-third of $[Co(CO_3)(en)_2]^+$. The differential pulse polarogram of $[Co(CO_3)(NH_3)_5]^+$ showed two peaks while the Tast polarogram gave a single wave as is seen in Fig. 1. Tast and pulse polarograms of this complex were observed over a wide potential range.

Various parameters which characterize a differential pulse polarogram were obtained; they are shown in Table 1 together with those of hexaamminecobalt(III) and ethylenediaminetetraacetatocobaltate(III) ions. The electrode reaction of $[Co(NH_3)_6]^{3+}$ at a mercury electrode is recognized as a typical key reaction for an irreversible electron-transfer process.[13] On the contrary, the electrode reaction of $[Co(edta)]^-$ is known to proceed reversibly at a mercury electrode.[16] For all the complexes studied, the peak currents of the first wave were found to be much smaller than that expected for a reversible electron-transfer process indicating that the electrode reaction is irreversible.

The reduction of carbonatocobalt(III) to cobalt(II) species in an acid solution was considered to be irrever-

sible from the facts described above. For a totally irreversible electrode reaction, the following relations of the Tast polarography are derived:[17,18]

$$(\boldsymbol{R}T/an\boldsymbol{F})\ln[2x(3-x)/5(1-x)] = E_{1/2} - E, \quad (1)$$

with:

$$x = I/I_d, \quad (2)$$

and:

$$E_{1/2} = (\boldsymbol{R}T/an\boldsymbol{F})\ln[1.35\, k_c^\circ (t_d/D)^{1/2}], \quad (3)$$

where I is the current at the potential E; I_d the diffusion-controlled current; D, the diffusion coefficient; t_d, the drop time; α, the transfer coefficient; k_c°, the cathodic rate constant at $E=0$; n, the number of electrons; $\boldsymbol{R}$, $\boldsymbol{F}$, and T have usual meanings. According to Eq. 1, a plot of $\ln[2x(3-x)/5(1-x)]$ *vs.* E should be a straight line. The transfer coefficient, α, can be obtained from $E_1/_2$ by applying Eq. 3. These relations are derived under the assumptions that a transfer coefficient is independent on electrode potentials and extrapolation to $E=0$ is possible for the rate constants. The analysis of electrode kinetics by these relations, therefore, may be limited to a first approximation. However, such kinetic parameters of electrode reactions play an important role in the interpretation of electrode kinetics, because the available data have been reported only few.[13]

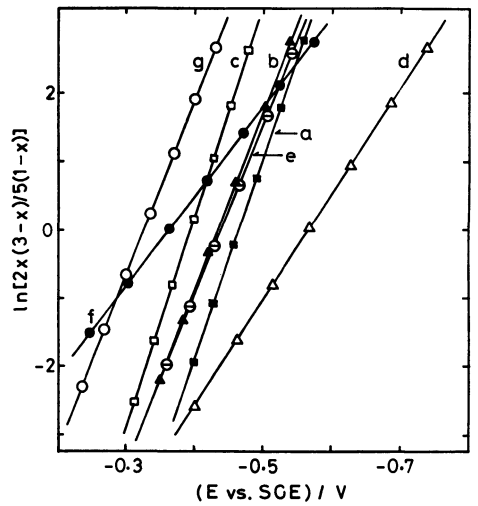

Fig. 3. Tast polarographic log plots for the first wave of several carbonatocobalt(III) complex ions obtained in 0.005 M acetate buffer (pH=6), 0.995 M sodium nitrate and 0.001% PAA at 25 °C.
(a) $[Co(CO_3)(en)_2]^+$, (b) $[Co(CO_3)(pn)_2]^+$, (c) $[Co(CO_3)(tn)_2]^+$, (d) $[Co(CO_3)_2(en)]^-$, (e) $[Co(CO_3)(NH_3)_4]^+$, (f) $[Co(CO_3)(NH_3)_5]^+$, (g) $[Co(NH_3)_6]^{3+}$.

An example of the plots for Eq. 1 is given in Fig. 3. Table 2 summarizes the kinetic parameters of the electrode reactions corresponding to the first wave for various carbonatocobalt(III) complexes. The diffusion coefficients required for the calculation of kinetic parameters were taken from the earlier work.[19] These kinetic parameters obtained were checked by calculating the current according to the relation:

$$2x(3-x)/5(1-x) = 1.35\, k_c^\circ (t_d/D)^{1/2} \exp(-an\boldsymbol{F}E/\boldsymbol{R}T). \quad (4)$$

The calculated currents were in agreement with the observed ones except for the case of $[Co(CO_3)(NH_3)_5]^+$. The order of a specific rate constant (k_c°) was found to be 10^{-6}—10^{-9} cm s^{-1}. The transfer coefficients were found to be above 0.5 except for the cases of $[Co(CO_3)(NH_3)_5]^+$ and $[Co(CO_3)_2(en)]^-$.

The kinetic parameters of electrode reactions for these carbonatocobalt(III) complexes are also determined by means of pulse polarography. To a pulse response of totally irreversible system, the following equations are applied:[17,18]

$$(\boldsymbol{R}T/2an\boldsymbol{F})\ln[x^2(1.75+x)/(1-x)] = E_{1/2} - E, \quad (5)$$

with:

$$E_{1/2} = (\boldsymbol{R}T/an\boldsymbol{F})\ln[2.31\, k_c^\circ (t_d/D)^{1/2}]. \quad (6)$$

where x is defined by Eq. 2. In this case a plot of $\ln[x^2(1.75+x)/(1-x)]$ *vs.* E should give a straight line. The transfer coefficient (α) and the specific rate constant (k_c°) can be claculated if a linear plot is obtained.

Examples of the plot of Eq. 5 obtained at various electrode potentials are given in Fig. 4. A linear plot was obtained except for $[Co(CO_3)(NH_3)_5]^+$. The log plot for $[Co(CO_3)(NH_3)_5]^+$ is somewhat sigmoid in shape. The kinetic parameters obtained from these plots are given in Table 3. The half-wave potentials obtained by means of pulse polarography were found to shift to more negative potentials. This is expected from the magnitude of the sampling time as is given by Eqs. 3 and 6. The measurements were made at sampling times of 2.99 and 0.04 s for the Tast and the pulse polarography, respectively.

The transfer coefficients obtained by means of those

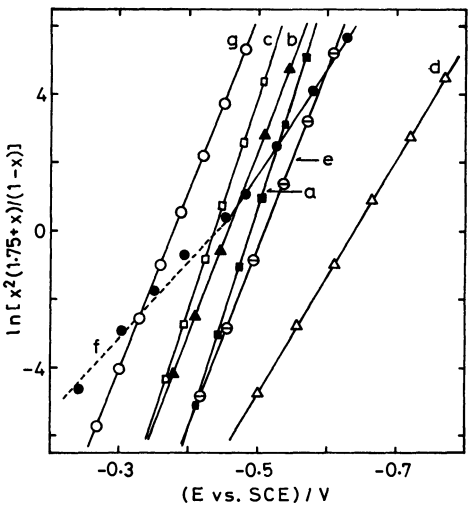

Fig. 4. Pulse polarographic log plots for the first wave of several carbonatocobalt(III) complex ions obtained in 0.005 M acetate buffer (pH=6), 0.995 M sodium nitrate and 0.001% PAA at 25 °C.
(a) $[Co(CO_3)(en)_2]^+$, (b) $[Co(CO_3)(pn)_2]^+$, (c) $[Co(CO_3)(tn)_2]^+$, (d) $[Co(CO_3)_2(en)]^-$, (e) $[Co(CO_3)(NH_3)_4]^+$, (f) $[Co(CO_3)(NH_3)_5]^+$, (g) $[Co(NH_3)_6]^{3+}$.

Tast polarography, however, were found to be smaller than those of the pulse polarography. In the Tast polarography, the electrolysis proceeds simultaneously during the drop life, while in the pulse polarography the faradaic current is negligibly small before the pulse is applied. Therefore, the differencies of the kinetic parameters obtained by the two electrochemical methods may be mainly attributed to the depletion effect as was pointed out by Hans *et al.*[20] Furthermore, the electrode reactions of the cobalt complex studied here are followed by chemical reactions as described below. This may enhance the depletion effect. The evaluated specific rate constant (k_c°) may be smaller when the transfer coefficient increases as is seen from Eqs. 3 and 6.

As for $[Co(CO_3)(NH_3)_5]^+$, the current-potential curves between −0.25 and −0.45 V *vs.* SCE were used in this calculation. The alternative value of $\alpha=0.44$, and $k_c^\circ/\sqrt{D}=7.8\times10^{-4}$ $s^{-1/2}$ were obtained for the use of the current between −0.45 and −0.60 V *vs.* SCE. If the whole data are used the following values can be determined: $\alpha=0.32$, and $k_c^\circ/\sqrt{D}=1.1\times10^{-2}$ $s^{-1/2}$. N. Maki *et al.*[1] have reported the half-wave potential of carbonato- and dicarbonatoethylenediaminecobalt(III) complex in solution of 0.5 M K_2SO_4: $E_{1/2}=-0.50_0$ V *vs.* SCE for $[Co(CO_3)(NH_3)_5]^+$ and $E_{1/2}=-0.50_2$ V *vs.* SCE for $[Co(HCO_3)(NH_3)_5]^{2+}$. The hydrogencarbonate complex may exist partly in the solution, but no further experiments were done.

Among the cobalt complexes used here, cobalt(III) is substitution-inert towards solvolysis, while cobalt(II) is substitution-labile. In general, dissociation of the inert cobalt(III) complexes can be neglected from the standpoint of polarography, whereas that of the labile cobalt(II) complexes occurs rapidly compared with the scanning rate of the applied potential. Therefore, the cobalt(II) complex results in the formation of an aquacobalt(II) mixture in an equilibrium state with water molecules in aqueous solutions.

The overall electrode reaction for the first wave was evaluated by a comparison of its electrode reaction with that of other cobalt(III) complexes.[13] Thus,

$$[Co(CO_3)(NH_3)_5]^+ + e \longrightarrow [Co(CO_3)(NH_3)_5], \quad (7a)$$

$$[Co(CO_3)(NH_3)_5] + pH_2O \longrightarrow [Co(H_2O)_p(NH_3)_{6-p}]^{2+} + CO_3^{2-} + (p-1)NH_3, \quad (7b)$$

for the pentaammine complex, and

$$[Co(CO_3)(NH_3)_4]^+ + e \longrightarrow [Co(CO_3)(NH_3)_4], \quad (8a)$$

$$[Co(CO_3)(NH_3)_4] + (p+2)H_2O \longrightarrow [Co(H_2O)_{p+2}(NH_3)_{4-p}]^{2+} + CO_3^{2-} + pNH_3, \quad (8b)$$

for the tetraammine complex. With the bis(diamine) complex:

$$[Co(CO_3)(N)_2]^+ + e \longrightarrow [Co(CO_3)(N)_2], \quad (9a)$$

$$[Co(CO_3)(N_2)] + (2p+2)H_2O \longrightarrow [Co(H_2O)_{2+2p}(N)_{2-p}]^{2+} + CO_3^{2-} + p(N). \quad (9b)$$

((N)=en, pn, tn)

The electrode reaction of dicarbonatoethylenediaminecobaltate(III) complex may be:

$$[Co(CO_3)_2(en)]^- + e \longrightarrow [Co(CO_3)_2(en)]^{2-}, \quad (10a)$$

$$[Co(CO_3)_2(en)]^{2-} + (2p+q)H_2O \longrightarrow [Co(H_2O)_{2p+2q}(en)_{1-p}]^{2-} + pCO_3^{2-} + q\text{en}. \quad (10b)$$

The kinetic parameters given in Table 2 and 3 correspond to the electrode reactions $Co^{III}\rightarrow Co^{II}$ (Eqs. 7a, 8a, 9a, and 10a). Furthermore, the experimental data obtained for complexes $[Co(CO_3)(en)_2]^+$, $[Co(CO_3)(pn)_2]^+$, $[Co(CO_3)(tn)_2]^+$, $[Co(CO_3)(NH_3)_4]^+$, and [Co-

$(NH_3)_6]^{3+}$ show transfer coefficients above 0.5, indicating that the electrode process follows outer-sphere pathways.[21]

The authors wish to thank the Ministry of Education, Science and Culture for the financial support granted for this research.

Ion-chromatographic Behavior of Silica Gels Modified by Poly- and Bis(crown ether)s of Benzo-18-crown-6

Masaki NAKAJIMA, Keiichi KIMURA,* and Toshiyuki SHONO*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received February 25, 1983)

Chromatographic behavior of crown ether modified silicas, in which poly- and bis(benzo-18-crown-6)s were attached covalently to silica gel, was investigated on separation of alkali and alkaline earth metal salts, using water or water/methanol as the mobile phase. Poly- and bis(benzo-18-crown-6)-modified silicas have a large affinity for Cs^+, the retention time of alkali metal cations being in the order $Li^+ < Na^+ < Rb^+ < K^+ < Cs^+$. Various anions having a common cation are separable as well as the metal cations on the modified silicas. Also, alkaline earth metal cations were separated on the stationary phases. The temperature effect of retention of alkali metal chlorides was also examined on bis(benzo-18-crown-6)-modified silica.

In the previous papers,[1,2] we have already reported the syntheses of silica gels modified by poly- and bis-(benzo-15-crown-5) derivatives as stationary phases of liquid chromatography, and the chromatographic separation of alkali and alkaline earth metal salts on the modified silicas using water or water/methanol as the mobile phase. The following conclusions were attained on the crown ether modified silicas: 1) The stationary phases have a great affinity for K^+ among alkali metal cations, and the retention time increases in the order $Li^+ < Na^+ < Cs^+ < Rb^+ < K^+$; 2) pure solvents such as water or water/methanol can be utilized as the mobile phase without addition of acids, alkalies, and salts unlike the case of conventional ion chromatography; 3) the separation can be controlled by changing the fraction of methanol in the water mobile phase. Thus, poly- and bis(benzo-15-crown-5)-modified silicas have obviously many attractive properties as compared with conventional ion-exchange resins.

On the other hand, poly- and bis(crown ether)s containing benzo-18-crown-6 moiety have exhibited great cation-binding ability for Cs^+ among alkali and alkaline earth metal cations,[3] which has also been verified by the studies of solvent extraction[4] and ion-selective electrodes[5] using them. This specific cation-binding ability of poly- and bis(benzo-18-crown-6) derivatives is expected to be applied to the stationary phase of liquid chromatography.

This paper describes the liquid chromatography of alkali and alkaline earth metal salts on silica gels modified by poly- and bis(benzo-18-crown-6) derivatives. The temperature effect on the chromatographic behavior of the crown ether modified silicas is also discussed.

Experimental

Syntheses of Stationary Phases. Poly(benzo-18-crown-6)-modified silica (I) and bis(benzo-18-crown-6)-modified silica (II) were synthesized in similar ways to the poly- and bis(benzo-15-crown-5)-modified silicas, respectively, as reported in our previous work.[2] The silica gel employed was an irregular type and the average particle diameter was 10 μm. The crown ether contents of poly(benzo-18-crown-6)-modified silica, which were calculated from the weight increase and the carbon elemental analysis, are 0.28 mmol and 0.27 mmol per 1 g of dry modified silica, respectively. The bis(crown ether) contents of bis(benzo-18-crown-6)-modified silica are 0.31 mmol and 0.33 mmol per 1 g of dry modified silica, respectively. The expected structures of them are shown in Fig. 1.

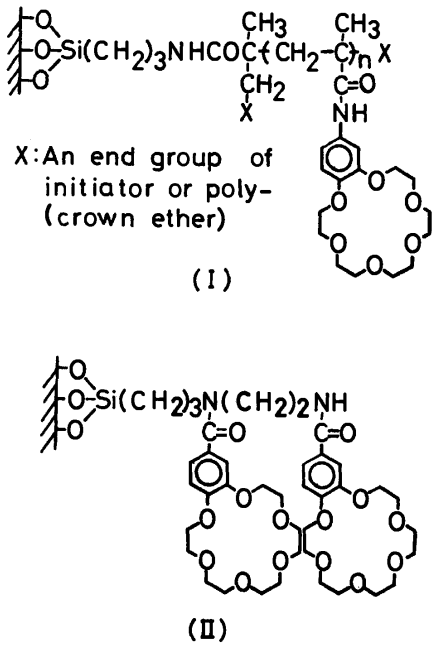

Fig. 1. Expected structures of poly(benzo-18-crown-6)-modified silica and bis(benzo-18-crown-6)-modified silica.

Materials. Alkali and alkaline earth metal salts employed here were of analytical grade. Water and methanol used as the LC mobile phase were purified by fractional distillation, followed by ultrafiltration, and then were degassed with an ultrasonic cleaner.

Instrumentation. Chromatographic experiments were performed with two chromatograph systems. One was the system assembled with commercially available modules, consisting of a pump (Milton Roy 0369-57), a sample injector (Kyowaseimitsu KHP-UI-130), and a refractometer detector (Waters Associates R-401). The other was also assembled with commercially available modules, consisting of a pump (Waters Associates 6000A), a sample injector (Waters Associates U6K), and a conductivity detector (LDC C-203). In this study, the former and the latter systems were referred to as chromatograph systems 1 and 2, respectively.

A stainless steel column (4 mm i.d., 300 mm length) was

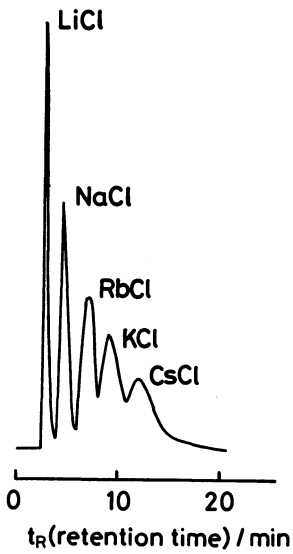

Fig. 2. Separation of alkali metal chlorides on poly-(benzo-18-crown-6)-modified silica.
LiCl, 0.08 mg; NaCl, 0.21 mg; KCl, 0.15 mg; RbCl, 0.24 mg; CsCl, 0.34 mg; mobile phase, water/methanol (90/10 vol/vol).

packed with the modified silica (I), by a balanced-density slurry technique, and incorporated to chromatograph system 1. The other stainless steel column (4 mm i.d., 150 mm length) was packed with the modified silica (II), and incorporated to chromatograph system 2.

After the columns were conditioned by elution with a large quantity of water or water/methanol, sample (50 μl (1 l= 1 dm^3)) containing 0.02—0.04 mol l^{-1} salts was injected into systems 1 and 2. Chromatography was performed at a flow rate of 1.0 ml min^{-1} and at room temperature unless otherwise stated. The pressure drops ranged from 40 to 90 kg cm^{-2} on the chromatograph systems. In spite of the longer column length, the pressure drop on system 1 was not so high as that on system 2, of which the double damper system induced extra pressure drop. In some cases, the column temperature on chromatograph system 2 was controlled using a glass column jacket connected to a circulating water bath.

Results and Discussion

Separation of Alkali Metal Salts. A typical chromatogram of alkali metal chlorides on poly(benzo-18-crown-6)-modified silica is depicted in Fig. 2. A mixture of alkali metal (Li^+, Na^+, K^+, Rb^+, and Cs^+) chlorides was separated successfully on the crown ether modified silica, their retention time increasing in the sequence $Li^+ < Na^+ < Rb^+ < K^+ < Cs^+$. The crown ether modified silica showed a large affinity for Cs^+, which is presumably attributed to the cation-binding ability of the crown ether. Since poly- and bis(crown ether)s possessing neighboring crown ether moieties are favorable for forming sandwich-type 2 : 1 crown ether ring to cation complexes with particular metal cations which are slightly larger than the crown ether cavity, they often exhibit excellent selectivities and great cation-binding abilities for Cs^+ compared to the corresponding monocyclic crown ethers.[3-5] This cooperative effect of poly(benzo-18-crown-6) on binding metal cations is reflected on the chromatographic behavior of the modified silica. As a result, Cs^+ was retained longer than other alkali metal cations. K^+, which can fit into the cavity of benzo-18-crown-6, forms stable 1 : 1 crown ether ring to cation complexes. Rb^+, which is between Cs^+ and K^+ in cation size, is thought to form both 1 : 1 and 2 : 1 crown ether ring to cation complexes, but they may not be very stable. Na^+, which has a smaller cation size than K^+, is not bound very strongly by the crown ether. Conceivably, there is no appreciable interaction between the crown ether and Li^+, which has the smallest size among alkali metal cations. Obviously, the complexing ability of poly-(benzo-18-crown-6) derivatives is reflected on the elution sequence of alkali metal salts.

Table 1. Retention time of alkali metal chlorides on poly(benzo-18-crown-6)-modified silica

	Retention time/min		
		H_2O/MeOH	
	H_2O	90/10	75/25
Li^+	2.8	2.7	2.9
Na^+	4.3	4.5	5.8
K^+	7.7	9.0	12.5
Rb^+	6.2	7.0	9.5
Cs^+	8.7	12.0	20.7

Table 2. Separation factor of alkali metal chlorides on poly(benzo-18-crown-6)-modified silica

	Separation factor[a]		
		H_2O/MeOH	
	H_2O	90/10	75/25
Na^+	3.8	5.2	5.8
K^+	1.2	1.5	1.8
Rb^+	1.7	2.2	2.6

a) Separation factor of Na^+, K^+, and Rb^+ over Cs^+.

The retention time of alkali metal chlorides and the separation factors of NaCl, KCl, and RbCl over CsCl on poly(benzo-18-crown-6)-modified silica with water and water/methanol elution systems are given in Tables 1 and 2, respectively. Although the difference of retention time between K^+ and Cs^+ was observed by elution of pure water, the Cs^+ peak was too broad to be separated completely from the neighboring K^+ one. When a mixture of metal chlorides was eluted by water, the chromatogram gave four apparent peaks, which can be assigned to Li^+, Na^+, Rb^+, and K^+/Cs^+. If a water/methanol mixture is utilized instead of pure water as the mobile phase, the retention time of alkali metal cations increases with the rise of methanol fraction in the mobile phase except for Li^+ which is scarcely complexed by the crown ether. Consequently, the differences of retention time among their cations also increased. This is mainly due to the increased complexing abilities of the crown ether in water/methanol compared with that in water. The separation factor

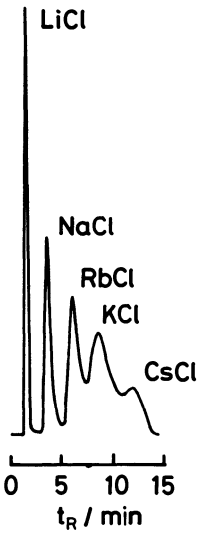

Fig. 3. Separation of alkali metal chlorides on bis-(benzo-18-crown-6)-modified silica.
LiCl, 0.08 mg; NaCl, 0.12 mg; KCl, 0.15 mg; RbCl, 0.25 mg; CsCl, 0.34 mg; mobile phase, water/methanol (75/25 vol/vol).

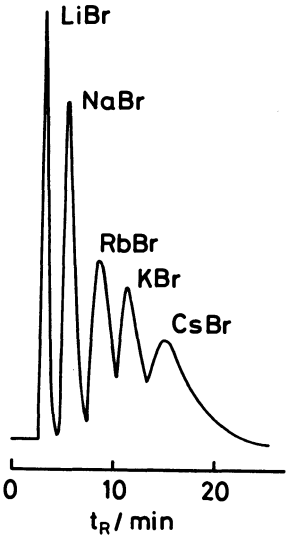

Fig. 4. Separation of alkali metal bromides on poly-(benzo-18-crown-6)-modified silica.
LiBr, 0.17 mg; NaBr, 0.24 mg; KBr, 0.24 mg; RbBr, 0.34 mg; CsBr, 0.53 mg; mobile phase, water/methanol (90/10 vol/vol).

of K^+ over Cs^+ changed from 1.2 with water to 1.8 with water/methanol (75/25 vol/vol). In practice, the elution with water/methanol led to the base-line separation of K^+ and Cs^+, while their peaks overlapped each other on elution with water. However, the chromatography of alkali metal halides by elution with water/methanol (75/25 vol/vol) is rather time-consuming, and the separation of Rb^+ and K^+ is slightly inferior to that with water/methanol (90/10 vol/vol). Thus, the best chromatographic separation of alkali metal chlorides on poly(benzo-18-crown-6)-modified silica was attained using water/methanol (90/10 vol/vol) as the mobile phase, as can be seen in Fig. 2. Chromatographic retention of alkali metal chlorides on bis(crown ether)-modified silica containing benzo-18-crown-6 moiety is similar to that on the poly(crown ether)-modified silica. The alkali metal cation affinity to the modified silica increased again in the sequence $Li^+ < Na^+ < Rb^+ < K^+ < Cs^+$, and thus the modified silica retained Cs^+ longer. In this case, some cooperative effect of bis(crown ether)s on binding alkali metal cations also seems to contribute to the Cs^+ selectivity. On this stationary phase, K^+ and Cs^+ were not separated at all when pure water was used as the mobile phase, but addition of methanol to the mobile phase allowed them to separate each other. A typical chromatogram of alkali metal chlorides on bis(benzo-18-crown-6)-modified silica is demonstrated in Fig. 3. Each peak of Rb^+, K^+, and Cs^+ was so broad that their separations were not base-line ones. The retention time of alkali metal chlorides is summarized in Table 3. Naturally, they were eluted faster on bis(benzo-18-crown-6)-modified silica because of the difference in the column length.

With the stationary phase consisting of poly(benzo-18-crown-6)-modified silica, alkali metal bromides and iodides were also separated (Fig. 4). The elution orders

Table 3. Retention time of alkali metal chlorides on bis(benzo-18-crown-6)-modified silica

	Retention time/min			
	H_2O	H_2O/MeOH		
		90/10	75/25	50/50
Li^+	1.4	1.4	1.4	1.5
Na^+	2.1	2.6	2.8	5.9
K^+	4.2	5.6	7.5	18.0
Rb^+	3.1	3.9	5.3	13.4
Cs^+	4.8	6.5	11.6	25.4

of alkali metal bromides and iodides were the same as that of alkali metal chlorides. Generally, the complexing abilities of crown ethers for metal cations are also governed by the kind of counter anions, and cations possessing a large anion tend to be complexed easily by crown ether. Capacity factors of alkali metal chlorides, bromides, and iodides in chromatographic separation on the modified silica by elution with water/methanol (90/10 vol/vol) are shown in Fig. 5. The capacity factor of anions having a common cation increased in the sequence $Cl^- < Br^- < I^-$. Salts containing a much larger anion such as thiocyanate had greater capacity factors than the metal halides. Chromatographic retention of alkali metal bromides and iodides also depended on the fraction of water and methanol. Similar anion-dependence was observed for bis(benzo-18-crown-6)-modified silica as well. There is a remarkable difference in capacity factors among alkali metal chlorides, bromides, and iodides, as shown in Fig. 5. This means that separation of anions possessing a common cation can be attained, as demonstrated in Fig. 6.

Separation of Alkaline Earth Metal Salts. Crown ethers have an ability to form complexes with alkaline

NaCl, 0.12 mg; NaBr, 0.24 mg; NaI, 0.30 mg; NaSCN, 0.16 mg; mobile phase, water/methanol (75/25 vol/vol).

Table 4. Retention time of alkaline earth metal chlorides on poly(benzo-18-crown-6) modified silica

	Retention time/min		
	H_2O	H_2O/MeOH	
		90/10	75/25
Mg^{2+}	2.9	2.8	3.0
Ca^{2+}	3.1	3.3	3.8
Sr^{2+}	5.1	6.3	7.9
Ba^{2+}	8.4	9.0	12.6

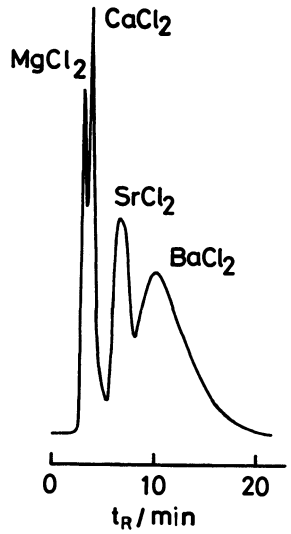

Fig. 7. Separation of alkaline earth metal chlorides on poly(benzo-18-crown-6)-modified silica.
$MgCl_2$, 0.10 mg; $CaCl_2$, 0.15 mg; $SrCl_2$, 0.27 mg; $BaCl_2$, 0.63 mg; mobile phase, water/methanol (90/10 vol/vol).

earth metal cations as well. However, not only the relative size of alkaline earth metal cation and crown ether ring, but also their strong hydration affects the complexing ability of the crown ethers. When alkaline earth metal chlorides were chromatographed on poly-(benzo-18-crown-6)-modified silica, the retention time increased in the sequence $Mg^{2+}<Ca^{2+}<Sr^{2+}<Ba^{2+}$. That is to say, this modified silica has a large affinity for Ba^{2+} among alkaline earth metal cations. Mg^{2+} and Ca^{2+} were slightly separated using pure water as the mobile phase, but their separation was improved with addition of methanol, successful separation being observed with water/methanol (75/25 vol/vol). However, since the peak of Ba^{2+} is broadened on this elution condition, the peaks of Sr^{2+} and Ba^{2+} overlapped with each other. A typical chromatogram of alkaline earth metal salts on poly(benzo-18-crown-6)-modified silica is given in Fig. 7, the retention time being listed in Table 4. Bis(benzo-18-crown-6)-modified silica exhibited chromatographic behavior analogous to poly(benzo-18-crown-6)-modified silica. Also, in the chromatographic separation of alkaline earth metal salts on the crown ether modified silica, the anion dependence was the same as that for alkali metal salts.

Temperature Effect of Retention of Alkali Metal Chlorides on Bis(benzo-18-crown-6)-modified Silica. Generally, the column temperature plays an important role in the sample solubility, the retention time, the viscosity of the mobile phase, and the column efficiency. Therefore, the temperature dependence of the retention time for alkali metal chlorides was examined using bis(benzo-18-crown-6)-modified silica. The retention time decreased with increasing column temperature except that of Li^+ which scarcely changed at any temperature. Plots of ln k (capacity factor) *vs.* $1/T$ for the alkali metal cations gave straight lines with positive slopes (Fig. 8). It is known that the complexation of crown ethers with cation is an exothermic reaction, which is reflected in

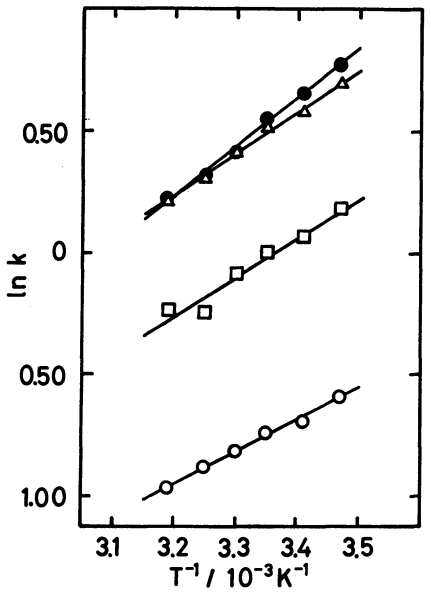

Fig. 8. Plots of ln k *vs.* $1/T$ on bis(benzo-18-crown-6)-modified silica.
(○), NaCl; (△), KCl; (□), RbCl; (●), CsCl.

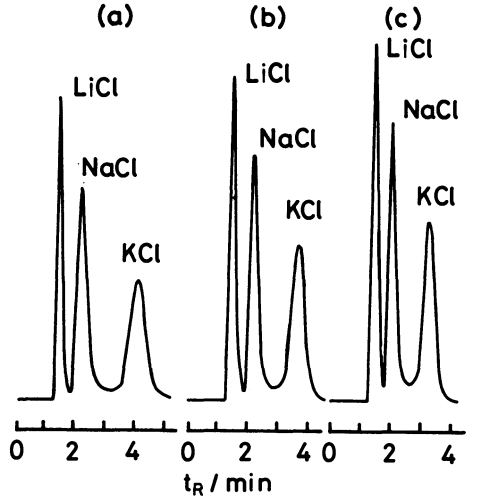

Fig. 9. Temperature dependence of chromatographic behavior of alkali metal chlorides on bis(benzo-18-crown-6)-modified silica.
LiCl, 0.09 mg; NaCl, 0.12 mg; KCl, 0.15 mg; mobile phase, water; (a), 20 °C; (b), 30 °C; (c), 40 °C.

the negative enthalpy changes (the positive slopes of the straight lines). Although the retention time approached to each other with the rise of temperature, separation of a mixture of Li^+, Na^+, and K^+ was rather excellent at elevated temperatures (Fig. 9). This is mainly due to the high column efficiency derived from a large diffusion coefficient of the mobile phase. Furthermore, the separation time was shorter at 40 °C (within 4 min) than at 15 °C (within 5.5 min). Thus the separation time can be easily adjusted to the best one by varying the column temperature.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 57750671 from the Ministry of Education, Science and Culture.

Ion-pair Extraction of Pyrocatechol Violet into Chloroform with Quaternary Ammoniun Salts

Yoshio HIRANO,† Masahito ANDO,†† Kunishige NAITO,* and Shinsuke TAKEI

Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Nakanarusawa-cho, Hitachi 316

(Received March 19, 1983)

An extraction method was first examined for establishing possible distributions of surface-active dodecyltrimethylammonium chloride (DTMAC) and non-surface active tetrabutylammonium chloride (TBAC) between aqueous and organic phases. Both quaternary ammonium salts seem to be present in the form of a free ion in the aqueous phase and in the forms of an ion pair(monomer) and a dimer in the organic phase. A possible distribution of DTMAC in the organic phase was confirmed spectrometrically by following the formation of a 1 : 1 DTMAC–iodine adduct in chloroform solution. On the basis of the possible distribution of quaternary ammonium salts, an ion pair forming extraction of Pyrocatechol Violet (PV) can be successfully interpreted in terms of the anion-exchange mechanism.

Spectrophotometric determinations of metal ions with various ligands in the presence of some cationic surfactants have provided some interesting advantages, such as improved sensitivity and/or selectivity, and a considerable reduction in analytical operation. Such analytical methods have been much advanced in practical applications but fundamental studies have been rare. We intended first to confirm possible distribution of water-soluble cationic surfactant species in aqueous and nonaqueous solutions for clarifying some questions, such as what the true roles of the surfactant species are in the formation of ternary metal–ligand–surfactant complexes.

A surfactant solution is a complicated system involving different chemical species equilibrated with each other through ion associations and molecular aggregations. To examine such a complex system, an extraction method has often been used under well-defined conditions because of its flexibilities. H. K. Biswas and B. M. Mandal[1] successfully analyzed their experimental data of extraction of hexadecyltrimethylammonium bromide with a dyestuff, on the condition that the quaternary ammonium salt was present in the form of free ion in an aqueous phase and an ion pair(monomer) in an organic phase at the low concentration (10^{-5} mol dm^{-3}). In the present study, extractions of two different types of quaternary ammonium salts from aqueous chloride solutions into chloroform were studied in order to establish possible distributions of their chemical species in both solutions. Surface-active dodecyltrimethylammonium chloride (DTMAC) was selected to provide a more complicated system than that of H. K. Biswas and B. M. Mandal because of its relatively higher cmc. A part of the extraction results was confirmed by following the reaction of DTMAC with free iodine in chloroform. And finally, the extraction of Pyrocatechol Violet (PV) with both quaternary ammonium salts was studied on the basis of the possible distributions of quaternary ammonium species.

Experimental

Reagent. A DTMAC solution was prepared by dissolving a weighed amount of DTMAC in distilled water or purified chloroform. The solution was diluted precisely to 100 cm^3 and was used without further dilution. A TBAC solution was prepared by dissolving about 7 g of TBAC in 250 cm^3 of distilled water and standardized by Mohr's argentimetric titration before use. Stock solution of PV (2.50×10^{-3} mol dm^{-3}) and Thymol Blue (TB) (5.00×10^{-4} mol dm^{-3}) were prepared with Dotite PV and TB for a pH indicator, respectively. They were dried to a constant weight under vacuum. An iodine solution (1.00 g dm^{-3}) in chloroform was prepared for each experimental run and was used without dilution. Chrlorform, of chemically pure reagent grade, was purified by the ordinary method and kept in an amber glass bottle; 0.5% (v/v) of ethanol was added as a stabilizer. The other chemicals, of guaranteed reagent grade or chemically pure reagent grade, were used without further purification.

Procedure. Determination of Distribution of DTMAC and TBAC: Ten cubic centimetres of an aqueous phase, containing a fixed amount of DTMAC or TBAC, sodium chloride and hydrochloric acid, was equilibrated with 10 cm^3 of purified chloroform in a 50 cm^3 glass-stoppered test tube by shaking for about 20 min (the first extraction). The quaternary ammonium salt extracted was spectrophotometrically determined as its 1 : 1 ion pair with TB extracted at pH 6.5 into chloroform. From this determination and the original amount of quaternary ammonium salt, distribution ratios of DTMAC and TBAC in the first extraction were calculated.

Reaction of DTMAC with Iodine in Chloroform: A desired amount of DTMAC solution and iodine solution in chloroform were mixed to be diluted precisely to 10 cm^3 with purified chloroform. Absorbance of the solution was measured in a quartz cell with 1 cm path length at 364 nm.

Extraction of PV with DTMAC and with TBAC: Fifteen cubic centimetres of an aqueous phase, containing PV (5.00×10^{-4} mol dm^{-3} except for the varying concentration), DTMAC or TBAC, sodium chloride and hydrochloric acid, was equilibrated with 15 cm^3 of purified chloroform in a 50 cm^3 glass-stoppered test tube by shaking for 10 min. Absorbances of the aqueous and chloroform layers were measured at 445 and 440 nm, respectively, after separating the clear liquid phases.

Results and Discussion

Partition of DTMAC and TBAC between Aqueous and Chloroform Phases. We first examined an extraction of surface-active DTMAC from an aqueous chloride solution into chloroform at a constant pH and at a fixed total concentration of chloride ion, but at various total concentrations of DTMAC. Figure 1 shows that

pH 1.5 (DTMAC), pH 1.0 (TBAC).

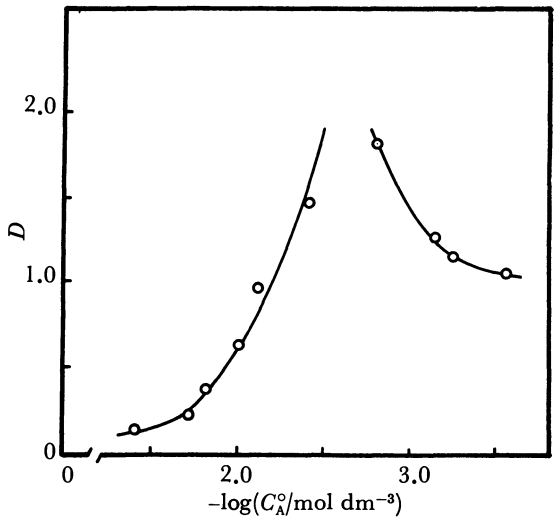

Fig. 1. Distribution ratio of DTMAC between aqueous and chloroform phases.
pH 1.8 and $C^\circ_{Cl}=0.20$ mol dm^{-3}.

the distribution ratio of DTMAC is influenced through the formation of higher aggregates in the organic phase than in the aqueous phase at a concentration lower than 2.5×10^{-3} mol dm^{-3}. These dependences reverse at higher concentrations. Because of a violent emulsification which occurred at concentrations above 2.5×10^{-3} mol dm^{-3}, our extraction method was exclusively applied to examinations at a lower concentration than this one.

The distribution ratios of DTMAC and TBAC were determined as a function of the total concentration of quaternary ammonium salt and chloride ion at a constant pH of an aqueous phase. The distribution ratio of both quaternary ammonium salts was increased with an increase of the total concentration of them and of chloride ions. This concentration dependence suggests that the extraction was enhanced with quaternary ammonium salt itself and with chloride ion. A higher aggregate of quaternary ammonium salt may be formed in a chloroform layer than in an aqueous phase. The present extraction system can be thus interpreted in terms of the following equilibria: formation of an ion pair of quaternary ammonium salt in the aqueous phase, partition of it into the chloroform layer, and formations of its aggregates such as a dimer and a trimer in chloroform. The distribution ratio of quaternary ammonium salt, D, can be written as,

$$D=\frac{[\mathrm{ACl}]_o+2[(\mathrm{ACl})_2]_o+3[(\mathrm{ACl})_3]_o+\cdots}{[\mathrm{A}^+]_w+[\mathrm{ACl}]_w}, \quad (1)$$

where A^+, ACl, $(ACl)_2$, and $(ACl)_3$ are a free quaternary ammonium ion, an ion pair of it with chloride ion (monomer) and its molecular aggregates, a dimer and trimer, respectively. Two subscripts, w and o, denote the aqueous phase and the organic layer. From the material balance of quaternary ammonium salt and the experimental conditions, Eq. 1 can be rewritten

$$D=\left(\frac{KPC^\circ_{Cl}}{1+KC^\circ_{Cl}}\right)+2K_2\left(\frac{KPC^\circ_{Cl}}{1+KC^\circ_{Cl}}\right)^2C_w + 3K_3\left(\frac{KPC^\circ_{Cl}}{1+KC^\circ_{Cl}}\right)^3C_w^2+\cdots, \quad (2)$$

where K, P, K_2, and K_3 are the formation constant of the ion pair in the aqueous phase, its partition coefficient, and the formation constants of the dimer and the trimer in the chloroform layer, respectively. C°_{Cl} represents the total concentration of chloride ion in the extraction system and C_w that of quaternary ammonium salt in the aqueous phase. This equation predicts a linear or a curved graph on D *vs.* C_w diagram at every constant C°_{Cl} value.

A practical plotting of D against C_w gave a series of straight lines with varying slopes and intercepts as a function of C°_{Cl} for both quaternary ammonium salts. Their results suggests that quaternary ammonium salt can be present in the monomeric and dimeric forms in chloroform under the conditions studied. K. Inoue *et al.*[2] and K. Inoue and Y. Baba[3] have reported a similar result in their paper of extraction equilibria of hydrochloric and acetic acids with a long-chain alkylamine. From Table 1, intercepts of these lines were directly proportional to C°_{Cl}, so that the first term of Eq. 2 can be regarded as KPC°_{Cl}, that is, $KC^\circ_{Cl}\ll1$. This is supported by the fact that a linear graph with a small intercept is obtained by plotting slopes of the serial straight lines against $C^{\circ 2}_{Cl}$. These suggest that a free quaternary ammonium ion is a predominant species in the aqueous phase. Under these conditions, the distribution ratio of quaternary ammonium salt can be expressed by

$$D=KPC^\circ_{Cl}+2K_2(KPC^\circ_{Cl})^2C_w. \quad (3)$$

From these linear relations, the extraction constant of

the ion pair of quaternary ammonium salt, *KP*, and its dimerization constant, K_2, can be estimated as 4.45 and 440 $dm^3\ mol^{-1}$ for DTMAC and as 0.35 and 140 $dm^3\ mol^{-1}$ for TBAC, respectively.

Reaction of DTMAC with Free Iodine in Chloroform. To confirm the above conclusion, the reaction of DTMAC with isolated iodine was followed spectrophotometrically in a chloroform solution. An iodine solution in chloroform showed an absorption maximum near 514 nm and one near 364 nm on the absorption spectra in the absence and presence of DTMAC, respectively. Since only one isosbestic point is found on the spectra, only one DTMAC–iodine adduct may be formed on adding DTMAC into an iodine solution. This adduct composition was found to be the 1 : 1 molar ratio by the continuous variation method.

In the presence of an excess of free iodine, absorbance of the solution at 364 nm increased linearly with the total concentration of DTMAC, C_A°. A slope of this linear graph increased with an increase of the total concentration of free iodine, $C_{I_2}^\circ$. In the presence of an excess of DTMAC, a similar linear graph was obtained on an absorbance-$C_{I_2}^\circ$ diagram. We considered for simplicity that quaternary ammonium salt was present in three different forms: a monomer, a dimer and a 1 : 1 adduct of monomeric DTMAC with free iodine, and that iodine was present as two species: free iodine and the 1 : 1 DTMAC–iodine adduct in the chloroform solution. Since $C_{I_2}^\circ = [I_2]_o$ in the presence of an excess of free iodine, the absorbance of the solution can be approximated as

$$A_s = \varepsilon_{I_2} \cdot C_{I_2}^\circ + \varepsilon \cdot [ACl \cdot I_2]_o, \quad (4)$$

where $[I_2]_o$ is the actual concentration of free iodine in the solution and ε_{I_2} and ε are molar absorptivities of free iodine and the 1 : 1 DTMAC–iodine adduct at 364 nm, respectively. On the other hand, in the presence of an excess of DTMAC, the absorbance of free iodine, $\varepsilon_{I_2} \cdot [I_2]_o$, was negligible as compared with that of the adduct because of small values of ε_{I_2} and $[I_2]_o$. Thus, absorbance of the solution can be approximated as $A_s = \varepsilon \cdot [ACl \cdot I_2]_o$. Taking account of the dimerization of DTMAC and the formation of the 1 : 1 DTMAC–iodine adduct, the following equations can be derived in the presence of an excess of free iodine and of DTMAC, respectively:

$$\frac{C_A^\circ}{A_s - \varepsilon_{I_2} \cdot C_{I_2}^\circ} = \frac{1 + K_f \cdot C_{I_2}^\circ}{\varepsilon \cdot K_f \cdot C_{I_2}^\circ} + \frac{2K_2}{\varepsilon^2 \cdot K_f^2 \cdot C_{I_2}^{\circ 2}} (A_s - \varepsilon_{I_2} \cdot C_{I_2}^\circ) \quad (5)$$

and

$$\frac{(C_A^\circ - A_s/\varepsilon) \cdot (C_{I_2}^\circ - A_s/\varepsilon)}{A_s/\varepsilon} = \frac{1}{K_f} + \frac{2K_2}{\varepsilon^2 \cdot K_f^2 \cdot C_{I_2}^{\circ 2}} \cdot \frac{A_s/\varepsilon}{C_{I_2}^\circ - A_s/\varepsilon}, \quad (6)$$

where K_f and K_2 are formation constants of the adduct and the dimeric DTMAC, respectively. A series of straight lines on the $C_A^\circ/(A_s - \varepsilon_{I_2} \cdot C_{I_2}^\circ)$ *vs.* $(A_s - \varepsilon_{I_2} \cdot C_{I_2}^\circ)$ diagram indicate the validity of Eq. 5. Table 2 summarizes the intercept and slope of these straight lines determined by the least-square regression method. A linear graph was then drawn by plotting the intercept against $1/C_{I_2}^\circ$. From the intercept and the slope of this graph, the molar absorptivity and the formation constant of the 1 : 1 DTMAC–iodine adduct were estimated as $\varepsilon = 7622\ dm^3\ mol^{-1}\ cm^{-1}$ and $K_f = 711\ dm^3\ mol^{-1}$, respectively. Logarithmic plot of the slope *vs.* $C_{I_2}^\circ$ also gave a straight line with a slope of -1.97. From the intercept of this graph, the formation constant of the dimeric DTMAC was found as $K_2 = 683\ dm^3\ mol^{-1}$, closed fairly to that of $K_2 = 440\ dm^3\ mol^{-1}$ estimated through the extraction experiment. On the other hand, a reversed L-shaped curve appeared on the $(C_A^\circ - A_s/\varepsilon) \cdot (C_{I_2}^\circ - A_s/\varepsilon)/(A_s/\varepsilon)$ *vs.* $(A_s/\varepsilon)/(C_{I_2}^\circ - A_s/\varepsilon)$ diagram (Fig. 2). This suggests that a monomeric DTMAC is the dominant species at DTMAC concentrations below about $9.0 \times 10^{-4}\ mol\ dm^{-3}$ and the dimeric one is dominant above this concentration. From the constant value of the graph, the formation constant of the adduct was also estimated as $K_f = 797\ dm^3\ mol^{-1}$, closed to that of $K_f = 711\ dm^3\ mol^{-1}$. And from the slope of the linearly increasing part of the curve, the formation constant of the dimeric DTMAC was found to be $K_2 = 626\ dm^3\ mol^{-1}$, comparable to that of $K_2 = 638\ dm^3\ mol^{-1}$. These results lead to the same conclusion as that of the extraction experiment of DTMAC.

Extraction of PV with DTMAC and with TBAC from Aqueous Phase into Chloroform. PV was extracted into chloroform with DTMAC or with TBAC but only

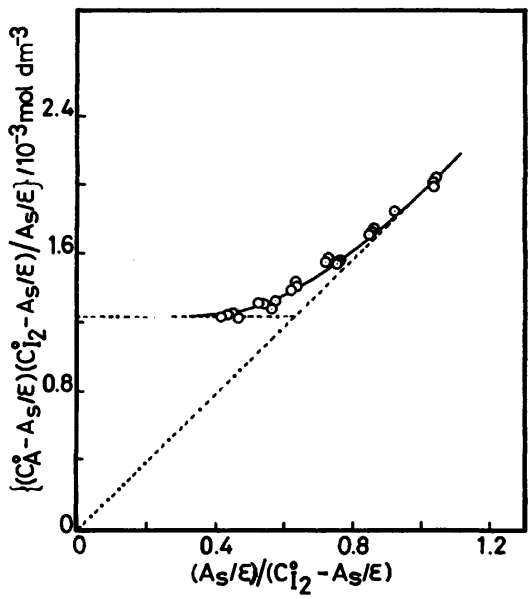

Fig. 2. $(C_A^\circ - A_s/\varepsilon) \cdot (C_{I_2}^\circ - A_s/\varepsilon)/(A_s/\varepsilon)$ *vs.* $(A_s/\varepsilon)/(C_{I_2}^\circ - A_s/\varepsilon)$ plot.

with difficulty without such quaternary ammonium salts. Depending upon the pH value of the aqueous phase, two different PV species could be extracted into chloroform. They were extractable at a pH lower than 6 and between pH 7 and 11, and showed absorption bands near 450 and 610 nm on the spectra. For the PV species extracted at a pH above 7, time-dependent absorptions spectra were observed, so that the extraction of PV with DTMAC and TBAC was examined more in detail at a low pH. The literature[4-6] reports a stable PV species in the low pH range to be a protonated form with three dissociative hydroxyl groups (H_3L^-). In the range lower than pH 2, another PV species with an absorption band near 560 nm newly appeared in the aqueous phase. This was regarded as a more protonated form of the H_3L^- species, such as H_4L or H_5L^+. Comparing the absorption spectra of chloroform and aqueous solutions containing PV, we considered that the H_3L^- species was the extractable species of PV with quaternary ammonium salt in this pH range. Since very similar absorption spectra were observed in the absence and presence of the quaternary ammonium salt, we conclude that no PV species interacting with it was present in the aqueous phase equilibrated once with chloroform. No aggregated form of the PV species may be present in either phase because the ratio of absorbances of the two related phases stayed constant at any concentration of PV(C_L°). Even in the presence of a large excess of quaternary ammonium salt, quantitative extraction of PV could occur only with difficulty in the present study. Thus, an absorbance ratio of both phases, $Y = A_{s_o}/A_{s_w}$, was used for analyzing experimental data, instead of a distribution ratio. Figure 3 shows a parabolic curve on the Y *vs.* C_A° diagram for the DTMAC–PV system. This suggests the formation of an aggregated DTMAC species involving only one PV molecule in a chloroform layer. A similar curve was observed for the TBAC–PV system. We considered that PV species were present in the form of H_3L^-, H_4L, and H_5L^+ in the aqueous phase and H_3LA and $H_3LA \cdot ACl$, regarded as anion-exchanged forms of ACl and $(ACl)_2$, in the chloroform layer. According to Beer's law and linear additivity of absorbances, the absorbance ratio, Y, can be expressed as

$$Y = \frac{\varepsilon_o \cdot [H_3LA]_o + \varepsilon_o' \cdot [H_3LA \cdot ACl]_o}{\varepsilon_{w(3)} \cdot [H_3L^-]_w + \varepsilon_{w(4)} \cdot [H_4L]_w + \varepsilon_{w(5)} \cdot [H_5L^+]_w}, \quad (7)$$

where ε_o, ε_o', $\varepsilon_{w(3)}$, $\varepsilon_{w(4)}$, and $\varepsilon_{w(5)}$ are molar absorptivities of the species, H_3LA, $H_3LA \cdot ACl$, H_3L^-, H_4L, and H_5L^+, respectively. Using equilibrium constants of extraction reaction and dimerization of ACl, extraction reactions of PV with ACl and with $(ACl)_2$ by anion exchange, and protonation of the H_3L^- species in an aqueous phase, the following equation was derived:

$$Y = \frac{\varepsilon_o K_{ex(1)} KP[A^+]_w + \varepsilon_o' K_2 K_{ex(2)} K^2 P^2 C_{Cl}^\circ [A^+]_w^2}{\varepsilon_{w(3)} + \varepsilon_{w(4)} K_{H(4)} [H^+]_w + \varepsilon_{w(5)} K_{H(4)} K_{H(5)} [H^+]_w^2}, \quad (8)$$

where $K_{ex(2)}$ and $K_{ex(2)}$ are extraction constants of PV with ACl and with $(ACl)_2$, and $K_{H(4)}$, and $K_{H(5)}$ are successive protonation constants of the H_3L^- species. Under the experimental conditions, $C_A^\circ \gg C_L^\circ$, so that the following relation is approximately valid:

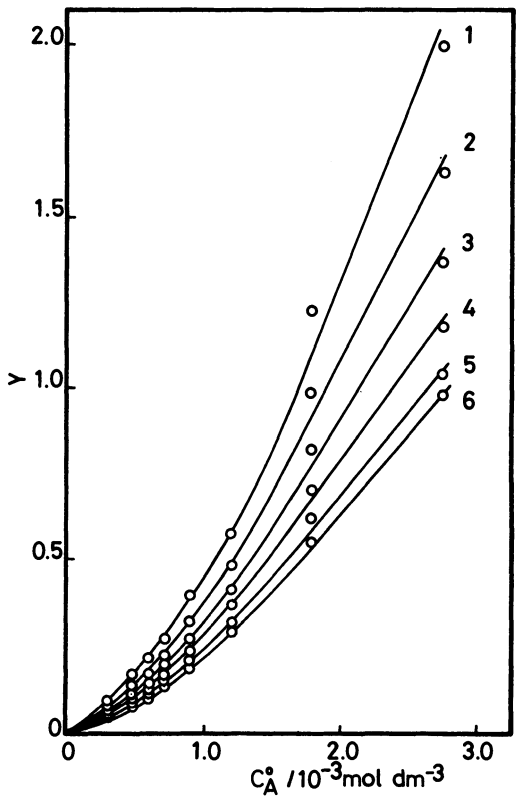

Fig. 3. Y *vs.* C_A° plot for DTMAC.
pH 2.3, $C_L^\circ = 4.03 \times 10^{-5}$ mol dm^{-3} and C_{Cl}°: 1; 0.10, 2; 0.20, 3; 0.30, 4; 0.40, 5; 0.50, 6; 0.60 mol dm^{-3}.

$$C_A^\circ = [A^+]_w + [ACl]_o + 2[(ACl)_2]_o,$$

that is,

$$C_A^\circ = (1 + KPC_{Cl}^\circ)[A^+]_w + 2K_2(KPC_{Cl}^\circ)^2[A^+]_w^2. \quad (9)$$

Since KP and K_2 are known, $[A^+]_w$ could be calculated at any C_{Cl}° from this equation. Equation 8 predicts that a series of straight lines with the same intercept but with the C_{Cl}°-dependent slopes may be obtained by plotting $Y/[A^+]_w$ *vs.* $[A^+]_w$ at a constant pH of the aqueous phase. This prediction was experimentally confirmed for the DTMAC–PV system. The intercept and slope of the regression line are listed in Table 3. The values of $(\varepsilon_o/\varepsilon_w)K_{ex(1)}$ and $(\varepsilon_o'/\varepsilon_w)K_{ex(2)}$ were estimated as 46 and 855 from these values. However, extraction constants, $K_{ex(1)}$ and $K_{ex(2)}$, were difficult to be determined because of our failure to find the molar absorptivities. For the TBAC–PV system, a

Table 3. Intercept and slope of linear graph of $Y/[A^+]_w$ against $[A^+]_w$ for DTMAC

C_{Cl}° / mol dm^{-3}	Intercept / dm^3 mol^{-1}	Slope / dm^6 mol^{-2}
0.1	209	0.724×10^6
0.2	218	1.38×10^6
0.3	193	2.13×10^6
0.4	199	2.95×10^6
0.5	208	3.66×10^6
0.6	191	4.76×10^6

$C_L^\circ = 4.03 \times 10^{-5}$ mol dm^{-3} and pH 2.3.

series of linear graphs was drawn at a fixed C°_{Cl} on the $Y/[A^+]_w$ *vs.* $[A^+]_w$ diagram. Their different intercepts and slopes, calculated by the least-square regression method, are shown in Table 4. The reciprocals of the intercept and the slope was well correlated linearly to the square of hydrogen ion concentration. This suggests a simultaneous protonation of the H_3L^- species with two hydrogen ions. I. S. Mustafin *et al.*[6] have reported the simultaneous uptake of two hydrogen ions due to a quinone and a sulfonate groups of the PV molecule. From the intercept and the slope of the linear reciprocal plots, $(\varepsilon_o/\varepsilon_{w(3)})K_{ex(1)}$, $(\varepsilon'_o/\varepsilon_{w(3)})K_{ex(2)}$, $(\varepsilon_o/\varepsilon_{w(5)})K_{ex(1)}/K_{H(4)}K_{H(5)}$, and $(\varepsilon'_o/\varepsilon_{w(5)})K_{ex(2)}/K_{H(4)}K_{H(5)}$ were determined to be 69, 550, 20 $dm^3\ mol^{-1}$ and 127 $dm^3\ mol^{-1}$, respectively, for the TBAC–PV system. In this case, the absorbance ratio can be written simply

$$Y = \frac{\varepsilon_o K_{ex(1)} KP[A^+]_w + \varepsilon_o' K_2 K_{ex(2)} K^2 P^2 C^\circ_{Cl}[A^+]^2_w}{\varepsilon_{w(3)} + \varepsilon_{w(5)} K_{H(4)} K_{H(5)} [H^+]^2_w}. \quad (10)$$

From these results and discussion, we concluded that both surface-active DTMAC and non-surface active TBAC were present in the form of free ions in an aqueous phase and in the monomeric and dimeric forms in a chloroform layer. The extraction of PV with quaternary ammonium salt could be successfully interpreted by an anion-exchange mechanism on the basis of the distributions of quaternary ammonium salt established. It should be noted that the same distributions could be established for quaternary ammonium salts with and without surface activity. We continue our interest in studying possible distributions of chemical species in the surfactant solution.

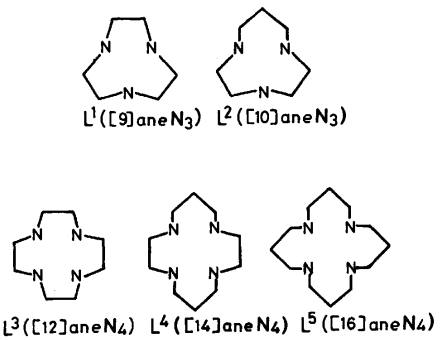
Response of a Copper(II) Ion-selective Electrode in Cupric Buffers Based on Macrocyclic Polyamines

Akinori Jyo,* Akiyoshi Nagamoto, Takashi Khono, and Akira Ohyoshi
Department of Industrial Chemistry, Faculty of Engineering, Kumamoto University, Kurokami, Kumamoto 860
(Received April 11, 1983)

The behavior of a copper(II) ion-selective electrode at extremely low activity levels of free copper(II) was examined in copper(II) buffers based on macrocyclic triamines ([9]aneN$_3$ and [10]aneN$_3$) and macrocyclic tetramines ([12]aneN$_4$, [14]aneN$_4$, and [16]aneN$_4$). Although the electrode showed the ideal behavior in the buffers based on [12]aneN$_4$ and [16]aneN$_4$, non-ideal behavior was observed for the macrocyclic triamines and [14]aneN$_4$. Thus, the macrocyclic polyamines did not always give the ideal copper(II) buffers for the electrode, in contrast to the case of acyclic polyamines. Stability constants, which were in good agreement with the reported values, could be determined only for [12]aneN$_4$ and [16]aneN$_4$. An application of the cyclic tetramines to complexiometry is also presented.

Recently, much attention is being paid to metal complexes of macrocyclic polyamines. Particular attention has been paid for copper(II) complexes of the amines, since some of them can be regarded as simplified models for naturally occurring structures in proteins.[1] The solution chemistry of the copper(II) complexes has produced a number of stability constants. Although several techniques have been used in determination of stability constants of copper(II)–macrocyclic polyamine complexes,[2,3] no use of a copper(II) ion-selective electrode in determination of their stability constants has been reported.

An ion-selective electrode provides a simple method for determination of a stability constant if the electrode behaves ideally in buffered solutions of the objective ion of the electrode. However, the copper(II) ion-selective electrode does not always respond to its objective ion at extremely low activity levels. In this connection, Nakagawa *et al.* and Heijne *et al.* have found the ideal behavior of the electrode down to 10^{-22}—10^{-23} M (M=mol dm^{-3}) of free copper(II) activity in copper(II) buffers based on acyclic polyamines.[4-6] This led us to investigate the behavior of the electrode in copper(II) buffers based on the macrocyclic polyamines, since the complexing behavior of copper(II) with the macrocyclic polyamines is considerably different from that with the acyclic polyamines.[2,3] This paper describes the behavior of the electrode in the copper(II) buffers based on the following macrocyclic polyamines (L^1—L^5).



Scheme 1.

Experimental

Materials. The macrocyclic triamines, L^1 and L^2 (as 3HBr salts), were prepared by the method of Koyama *et al.*[7] The macrocyclic tetramines, L^3—L^5 (L^3 and L^5 as 4HCl salts, L^4 as $2H_2SO_4$ salt) were prepared by the method of Richman *et al.*[8] Their purities were checked by CHN analysis, ^{1}H NMR, melting point or potentiometric titration. A copper(II) standard was prepared from a reagent grade copper(II) sulfate and standardized against an EDTA solution by the use of a copper(II) ion-selective electrode as an indicator. Other reagents were of reagent grade and were used as received.

Apparatus. A Denki Kagaku Keiki (DKK) digital mV meter IOC 10 was used in potential and pH measurements. The following cell was arranged by using an Orion 94-29A copper(II) ion-selective electrode and a DKK reference electrode (silver/silver chloride electrode of a double junction type): Ag/AgCl/stand. KCl//10% KNO_3//test solution/copper(II) ion-selective electrode.

The ionic strength of the test solution was adjusted with potassium nitrate. During potential measurements, the test solution was stirred. At first, preliminary measurements were made under ambient conditions, and then almost the same measurements were repeated at 25±0.1 °C.

Testing of Electrode Response in the Copper(II) Buffers. The behavior of the electrode was examined in the presence of a given macrocyclic polyamine in excess. Here, the total concentration of copper(II) was varied, while that of the amine, pH, and ionic strength were maintained at appropriate values. In the case of the triamines, the electrode response was examined in the pH range 5.5—6.8, because of the relatively small stability constants of the copper(II)–triamine complexes.[2,3] For the tetramines, the electrode response was tested in the pH range of 10.4—11.1 since the tetramines form extremely stable copper(II) complexes.[2,3]

Determination of Stability Constants. Two kinds of solutions containing copper(II) and a given polyamine were prepared. Both had the same compositions except for pH. In each solution, the total concentration of the amine is greater than that of copper(II) by about ten times. One solution had a high pH and the other a low pH; the pH of each was adjusted with sodium hydroxide or nitric acid. The solution with a high pH was titrated with the solution with a low pH. Potentials of the electrode and pH were measured during the titration.

Results and Discussion

Electrode Response in the Copper(II) Buffers. In the case of the triamines, ideal behavior of the electrode was

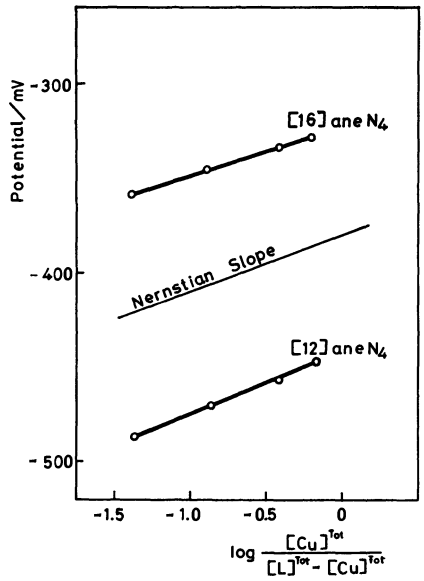


Fig. 1. Electrode response in cupric buffers at 25 °C. $[L]^{Tot}$: $8.9_2\times10^{-3}$ M, $[Cu^{2+}]^{Tot}$: $3.5_8\times10^{-4}$—$3.5_8\times10^{-3}$ M, pH: 10.85±0.05 for [12]aneN$_4$ and 10.55±0.15 for [16]aneN$_4$, ionic strength: 0.14.

not observed. Potentials were not so stable and prolonged response time longer than 10 min was frequently observed. In addition, electrode potentials themselves were not highly reproducible. In the case of the tetramines, on the other hand, the response was rapid and the potentials were stable. However, [14]aneN$_4$ gave rather strange results; the response was rapid and potentials were stable, but the potential values changed from run to run. Accordingly, only [12]aneN$_4$ and [16]aneN$_4$ gave satisfactory results.

As described later, [12]aneN$_4$ and [16]aneN$_4$ form the 1 : 1 complexes with copper(II) and their stability constants are extremely large. Thus, one can get the relation at a given pH:

$$[Cu^{2+}] \propto [Cu^{2+}]^{Tot}/([L]^{Tot}-[Cu^{2+}]^{Tot}), \quad (1)$$

where $[Cu^{2+}]^{Tot}$ and $[L]^{Tot}$ are respective total concentrations of copper(II) and the ligand, and $[Cu^{2+}]$ represents the concentration of free copper(II). Then, if the electrode shows a Nernstian response even in the copper(II) buffers, one can expect that the plot of the electrode potential against log $([Cu^{2+}]^{Tot}/([L]^{Tot}-[Cu^{2+}]^{Tot}))$ will give a straight line having a slope of $2.303RT/2F$. This expectation is satisfied for the copper(II) buffers based on [12]aneN$_4$ and [16]aneN$_4$, as is shown in Fig. 1.

Determination of Stability Constants. As mentioned in the previous section, one can expect that the stability constants of the copper(II) complexes with [12]aneN$_4$ and [16]aneN$_4$ can be determined by the copper(II) ion-selective electrode. The results for potentiometric titrations are shown in Fig. 2. From the definition, and from the mass balance, one can get the relations:

$$pCu = \log\beta_n - npL - \log[CuL_n], \quad (2)$$

$$[CuL_n] = [Cu^{2+}]^{Tot} - [Cu^{2+}], \quad (3)$$

$$[L] = ([L]^{Tot} - n[CuL_n])/\alpha_{L(H)}. \quad (4)$$

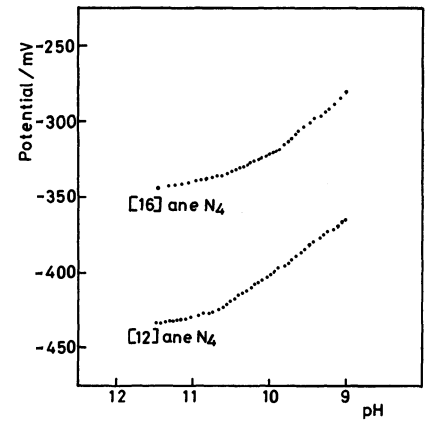

Fig. 2. Response potentials *vs.* pH at 25 °C. [12]aneN$_4$: $[L]^{Tot}=5.0_0\times10^{-3}$ M, $[Cu^{2+}]^{Tot}=5.0_0\times10^{-4}$ M, ionic strength=0.10. [16]aneN$_4$: $[L]^{Tot}=1.0_0\times10^{-2}$ M, $[Cu^{2+}]^{Tot}=1.0_0\times10^{-3}$ M, ionic strength =0.10.

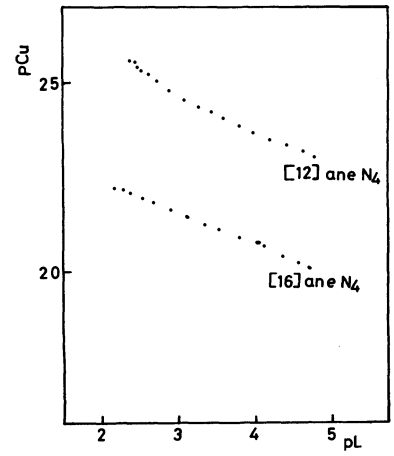

Fig. 3. Plots of pCu *vs.* pL. Conditions are given in Fig. 2.

Here, $\alpha_{L(H)}$ is a side reaction coefficient of the ligand and other symbols have their usual meanings. As pCu can be estimated from the electrode potential, β_n can be calculated from Eqs. 2, 3, and 4. The relations between pCu and pL are shown in Fig. 3. Figure 3 shows that the coordination number, n, is unity for both ligands. The stability constants determined are given in Table 1. Although our experimental conditions are somewhat different from the reported ones, the determined stability constants are in fair agreement with the reported values.

In conclusion, the macrocyclic polyamines do not always give the copper(II) buffers in which the electrode responds to free copper(II) ideally. This is in contrast to the case of acyclic polyamines; most of them give the ideal copper(II) buffers for the electrode.[4-6,9] In this work, we could show that the electrode responds to free copper(II) down to 10^{-25}—10^{-26} M in the copper(II) buffer based on [12]aneN$_4$.

Application of the Macrocyclic Tetramines to Complexiometry. Although fundamental works on macro-

cyclic polyamines have been reported, practical studies are rare. In this work, the solutions of the tetramines were standardized against a copper(II) sulfate solution by the use of the electrode as an indicator. Some examples of titration curves are shown in Fig. 4. The ligands, [12]aneN$_4$ and [16]aneN$_4$, give greater breaks than EDTA. This means that both amines are preferable to EDTA as the reagent for complexation titration of copper(II) as long as the end point is detected with the electrode. Although the stability constants predict that [14]aneN$_4$ will give a greater break than [12]aneN$_4$ does, the reversed results are observed. This may be ascribable to the anomalous response of the electrode in the presence of [14]aneN$_4$.

Double Potential Step Chronoamperometry for Reversible Follow-up Chemical Reactions. Application to the Aquation Kinetics of Bis(ethylenediaminemonoacetato)cobalt(II)

Takeo OHSAKA, Tadashi SOTOMURA,†,†† Hiroaki MATSUDA,† and Noboru OYAMA*

(Received April 30, 1983)

A theory of double potential step chronoamperometry (DPSCA) is developed for the reversible follow-up reactions represented as $Ox+ne \rightleftarrows Red$, $Red \underset{kK}{\overset{k}{\rightleftarrows}} Z$, where k and K are the rate and the equilibrium constants of the follow-up chemical reaction, respectively. DPSCA is applied to investigate the kinetics of aquation reaction of $[Co(edma)_2]^0$ (edma: ethylenediamine-*N*-acetate), which is produced by electrolytic reduction of $[Co(edma)_2]^+$ in the range of pH 1.5 to 10.5. At pH$<$4.5, the aquation reaction of $[Co(edma)_2]^0$ is irreversible. The rate of aquation reaction is accelerated by hydrogen ions and approaches an upper limiting value (2.1×10^3 s^{-1}). At pH$>$4.5, on the other hand, the hydrogen ions do not substantially contribute to the aquation and thus the rate approaches a lower limiting value (4.7×10^2 s^{-1}), which is in good agreement with that obtained in neutral region (4.5$<$pH$<$7), where the reverse (complex formation) reaction must be taken into consideration. Above pH 7, the $[Co(edma)_2]^0$ species exists as main species in the solution and thus the kinetic behavior of the aquation is not observed. It is demonstrated that DPSCA is a useful method for kinetic studies of the dissociation-association reactions of labile complexes.

The double potential step (DPS) chronoamperometry (CA) and the DPS chronocoulometry (CC) are well-developed techniques for studying the kinetics of homogeneous chemical reactions of the species, which may be produced by charge transfer reactions. Schwarz and Shain[1] first presented the DPSCA to determine the rate constant of the benzidine rearrangement reaction and showed that this technique has a high potentiality for the determination of rate constants of follow-up chemical reactions. Christie[2] modified the technique originally devised by Schwarz and Shain by recording the charge *vs.* time variations instead of the current *vs.* time curves, and this modified technique is usually referred to as DPSCC. Since then, various authors have reported several modifications of these techniques[3-9] as well as their application to practical problems.[10-20] However, almost all treatments reported up to date are restricted to completely irreversible follow-up reactions. The recent paper of Hanafey *et al.*[9] is only one exceptional one, in which they reported the explicit finite difference simulation of DPS current, charge and absorbance responces for 22 two-parameter electrochemical mechanisms, including the second-order kinetics.

Recently, we have attempted an application of DPSCA to the kinetics of aquation reactions of labile complexes which may be produced by charge transfer reactions of the corresponding inert complexes. In this case, if it is desired to perform measurements in a wide range of free ligand concentrations or of pH, the effects of the reverse (complex formation) reactions should be taken into consideration. Then, the follow-up reactions must be regarded as reversible. In the present paper, we shall develope a theory of DPSCA for reversible follow-up reactions in an analytical way and apply it to determining the rate constant of aquation reaction of bis(ethylenediaminemonoacetato)cobalt(II), which is produced by electrolytic reduction of bis(ethylenediaminemonoacetato)cobalt(III) (corresponding inert complex species).

Theoretical

Consider the electrode reaction followed by a first-order chemical reaction, which is symbolically represented by

$$Ox + ne \rightleftarrows Red, \quad Red \underset{kK}{\overset{k}{\rightleftarrows}} Z,$$

where k and K are the rate and the equilibrium constants of the follow-up chemical reaction, respectively. The plane boundary value problem for the diffusion processes corresponding to the above mechanism can be solved by utilizing the method of Laplace transformation under the assumption that the diffusion coefficients of Red and Z have the common value.[21] Thus, the concentration of Ox and Red at the electrode surface, C_O^s and C_R^s, can be expressed as

$$C_O^s = C_O^\circ - \frac{1}{\sqrt{D_O\pi}}\int_0^t \frac{[i(u)/nFA]}{\sqrt{t-u}}du, \tag{1}$$

$$C_R^s = \frac{1}{(1+K)\sqrt{D\pi}}\int_0^t \frac{K+\exp[-\rho(t-u)]}{\sqrt{t-u}}[i(u)/nFA]du, \tag{2}$$

with

$$\rho = k(1+K), \tag{3}$$

where C_O° denotes the bulk concentration of Ox; the bulk concentrations of Red and Z are assumed to be equal to zero; D_O is the diffusion coefficient of Ox; D is the common diffusion coefficient of Red and Z; $i(t)$ denotes the current intensity; A is the surface area of the electrode; t is the lapse of the time after the beginning of the electrolysis.

The electrolysis condition of DPSCA is as follows:

†† Present address: Matsushita Electric Industrial Co., Ltd., 1006, Kadoma, Kadoma, Osaka 571.

the potential is stepped from some initial value, where no current flows, to a value which causes the electrode reaction product, Red, to be generated at a diffusion-controlled rate. After a given generation time, τ, the potential is returned to the initial value, where the electrode reaction is reversed, consuming Red at a diffusion-controlled rate. Thus, the electrolysis condition can be expressed by

$$0 < t < \tau : C_O^S = 0, \tag{4}$$

$$\tau < t : C_R^S = 0, \tag{5}$$

For $0<t<\tau$, inserting Eq. 1 into Eq. 4 and solving the resultant Abel integral equation yields immediately the cathodic limiting diffusion current, i_c:

$$i_c = nFA\, C_O^\circ \sqrt{D_O}/\sqrt{\pi t}. \tag{6}$$

For $t>\tau$, on the other hand, substituting Eq. 2 into Eq. 5 and noting that the current intensity during the first potential pulse ($0<t<\tau$) is given by Eq. 6, we obtain after some rearrangements

$$\int_\tau^t \frac{K+\exp[-\rho(t-u)]}{\sqrt{t-u}} \left\{ \frac{-i_a(u)}{nFA} + \frac{C_O^\circ \sqrt{D_O}}{\sqrt{\pi u}} \right\} du = \frac{C_O^\circ \sqrt{D_O}}{\sqrt{\pi}} \int_0^t \frac{K+\exp[-\rho(t-u)]}{\sqrt{u(t-u)}} du, \tag{7}$$

where i_a denotes the anodic current to be measured for $t>\tau$. Here, it is convenient to introduce the dimensionless variable:

$$\xi = (t-\tau)/\tau, \tag{8}$$

which denotes the portion of the lapse of time after the beginning of the second potential pulse to the switching time τ. Further, we introduce new integral variables: $u=\tau(1+v)$ and $u=\tau(1+\xi)(1-v)$ into the left- and right-hand sides of Eq. 7, respectively. Then we obtain after evaluating the definite integral on the right-hand side of the resulting equation[22]

$$\int_0^\xi \frac{K+\exp[-\rho\tau(\xi-v)]}{\sqrt{v(\xi-v)}} \Psi(v) dv = \pi \left\{ K+\exp[-(\rho\tau/2)(1+\xi)] I_0\left(\frac{\rho\tau}{2}[1+\xi]\right) \right\}, \tag{9}$$

with

$$\Psi(v) = (-i_a/i_c) + \sqrt{\xi/(1+\xi)}, \tag{10}$$

where I_0 is the zero-order modified Bessel function of the first kind. $(-i_a/i_c)$ denotes the ratio of the anodic current measured at a given time t during the second pulse to the cathodic current measured at $(t-\tau)$ during the first pulse, and will be used for constructing the working curves, following the suggestion of Schwarz and Shain.[1] Since Eq. 9 is the Volterra integral equation of the first kind with respect to $\Psi(\xi)$, its analytical solution may be obtained in a closed form by utilizing the method of Laplace transformation. However, when practically constructing the working curves by using the analytical solution, it is necessary to evaluate numerically the definite integral. Such a numerical method is described in Appendix. Numerical calculations were performed for various combinations of the values of K and $k\tau$ by means of a digital computer FACOM M-160, and the values of $\Psi(\xi)$ were obtained as functions of ξ. Then, for a given constant value of ξ, say $\xi=1$, the working curves, *i.e.*, $(-i_a/i_c)$ *vs.* $k\tau$ plots, were drawn for a series of values of K. As examples, such working curves constructed for $\xi=1$ are shown for a series of values of K in Fig. 1. Of course, the curve for $K=0$ is in agreement with that of Schwarz and Shain.[1] As can be seen from Fig. 1, when the parameter $k\tau$ is increased, the working curves are at first decreased and then, after passing through the corresponding minima, they are increased. This behavior is understandable in view of the fact that Red may be reproduced from Z by the reverse reaction during the second pulse. Thus, there arises a problem that one measured value of $(-i_a/i_c)$ corresponds to the two values of $k\tau$. This problem may simply be solved by examining whether $(-i_a/i_c)$ is decreased or increased when the switching time τ is slightly increased.

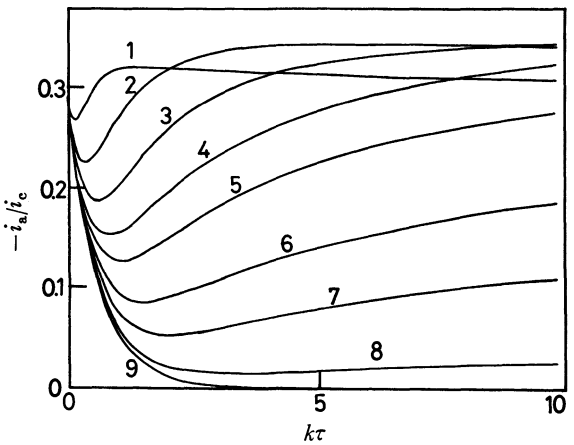

Fig. 1. Typical working curves for a series of values of K at $\xi=1$.

Experimental

Reagents. *Trans*-bis(ethylenediaminemonoacetato)cobalt(III) chloride dihydrate, *trans*-[Co(edma)$_2$]Cl·2H$_2$O, and ethylenediaminemonoacetic acid dihydrochloride dihydrate, Hedma·2HCl·2H$_2$O, were prepared and purified by the method of Fujii *et al.*,[23] where edma$^-$ is an abbreviation of $H_2NCH_2CH_2NHCH_2COO^-$. Sodium acetate and disodium hydrogen phosphate were purified by recrystallizing twice from water. All other chemicals used were prepared and purified by the methods described previously.[24]

Cell and Electrodes. The electrolytic cell used was all-glass six neck vessel of the same type as described previously,[25] which was equipped with various electrodes, argon gas inlet and outlet, and two burets. The electrode assembly consisted of a dropping mercury working electrode (DME), a saturated calomel reference electrode (SCE) and a mercury pool auxiliary electrode (AE), the latter being placed at the bottom of the cell. The characteristics of DME used were: drop time = 7.9 s and flow rate of mercury = 1.45 mg s^{-1} in 1.0 M (1 M = 1 mol dm^{-3}) $NaClO_4$ solution at 45 cm of the height of mercury head with no applied potential. The SCE was connected to the cell throught a junction salt bridge containing sodium chloride solution. A glass electrode (Beckman No. 40495) and a Ag–AgCl reference electrode were used for pH measurements of the test solutions.

Instrumentation. The pulse experiments were performed

on the solid state instrument constructed from readily available components, which consisted of a drop fall detector, timing control logic circuitry, a pulse generator and a potentiostat. A spike-like pulse, generated at the moment of drop detachment from the capillary tip, was employed as a trigger signal for the timing controlling pulse train.[26] When the spike was detected, the AE was disconnected from the potentiostat by means of a FET switch. The measuring device was a Nicolet 1090A Explorer digital oscilloscope. The current responces were monitored and stored on it and then the enlarged current-time curves were displayed on an X-Y recorder (Riken-Denshi Model F-42CP). No IR compensation was employed.

The polarograph used for preliminary experiments was the same as described previously.[24] The pH measurements were performed on an Orion Research Model 801 digital pH/mV meter.

Procedures. All measurements were performed in a paraffin oil thermostat at 25.0±0.1 °C. Two kinds of the solution composition were used: 1.0 mM *trans*-$[Co(edma)_2]^+$, 20 and 50 mM Hedma, and 1.0 M $NaClO_4$. No buffer was added in the pH ranges 1.0—3.5 and 6.5—10.0, because the ligand present in a large excess was expected to have a sufficiently large buffer capacity in these pH ranges. In the pH range 3.5—6.5, the acetate (for pH 3.5—5.5) and phosphate (for pH 5.5—6.5) buffers were used at the concentration of 50 mM. The pH values of the test solutions were changed and measured following the procedure described previously.[27] Deaeration of the solution was accomplished with pure argon gas by bubbling through the solution for 1 h before each run and with a steady flow maintained over the solution during measurements.

The potential applied to the working electrode was a single square pulse with an amplitude of 0.55 V and this pulse was applied at the moment when the mercury drop sufficiently grew, *i.e.*, 4—5 s after the beginning of the drop growth. The initial d.c. level E_1 was selected from the behavior of d.c. polarographic reduction waves of *trans*-$[Co(edma)_2]^+$ as follows: $E_1=-0.05$ *V vs.* SCE for pH 1—6, $E_1=-0.10$ *V vs.* SCE for pH 6—8 and $E_1=-0.20$ *V* vs. SCE for pH 8—10. In acidic solutions the applied potentials always fell in the diffusion-controlled limiting current region for each depolarizer species. However, in the alkaline region, the foot of the mercury desolution wave slightly overlapped with the reduction wave of $[Co(edma)_2]^+$ species. Thus, data obtained in alkaline solutions may be less reliable, although several trials for selection of E_1 were performed and a blank correction was made using current-time curves measured in solutions containing no $[Co(edma)_2]^+$ species.

Results and Discussion

The electrode reaction of Co(III)/Co(II)–edma system may be formally expressed by Scheme 1, where, $(k_1)_{app}$ and $(k_2)_{app}$ denote the apparent rate constants of the step-wise aquation processes, respectively.

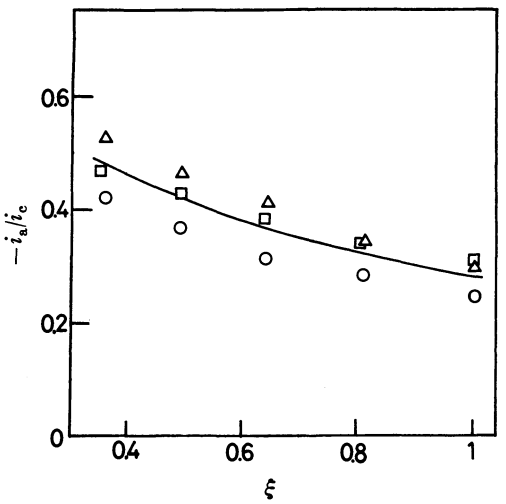

Fig. 2. Typical plots of the current ratio $(-i_a/i_c)$ *vs.* ξ under the diffusion-controlled conditions.
Concentration of *trans*-$[Co(edma)_2]^+=1.0$ mM. Total concentration of Hedma=20 mM. (□): pH 7.38, (○): pH 8.75, (△): pH 10.66. Solid line represents the theoretical curve calculated by Eq. 11.

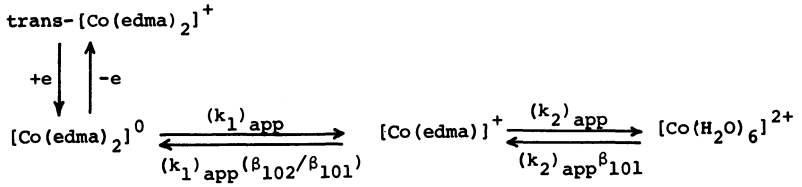
β_{101} and β_{102} are the overall formation constants of $[Co(edma)]^+$ and $[Co(edma)_2]^0$ species, respectively, the values of which were determined previously[27] as follows: $\log \beta_{101}=7.51$ and $\log \beta_{102}=14.05$.

First, consider the reaction in the alkaline region higher than pH 7. In this pH region, $[Co(edma)_2]^0$ species is stable for the ligand concentrations of 20—50 mM and thus the aquation reaction does not occur. Therefore, the anodic-cathodic current ratio, $(-i_a/i_c)$, must satisfy the following equation for the diffusion-controlled conditions:[1]

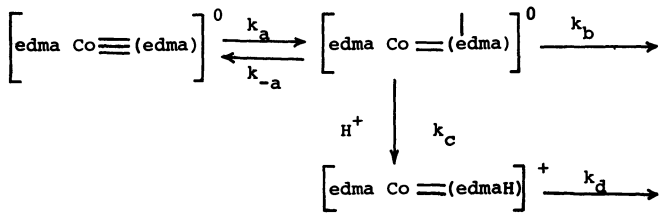
$$(-i_a/i_c) = 1 - [\xi/(1+\xi)]^{1/2}, \qquad (11)$$

where ξ is defined by Eq. 8. Some typical results of $(-i_a/i_c)$ *vs.* ξ plot for several pH values are shown in Fig. 2, where the points are the experimental values, and the solid line represents the theoretical behavior calculated by Eq. 11. The results show that the anodic currents are essentially controlled by diffusion of $[Co(edma)_2]^0$ to the electrode surface. Slight deviations of $(-i_a/i_c)$ from theory could be attributed to the overlapping of the mercury desolution current with the anodic current of $[Co(edma)_2]^0$.

Next, the reaction in the acidic region lower than pH 4.5 will be examined. In this acidic region, the first step aquation process becomes irreversible, because the rate of the corresponding reverse process may be neglected, as can be proved from the concentrations of $[Co(edma)]^+$ and $edma^-$ calculated by the use of the



Scheme 1.



Scheme 2.

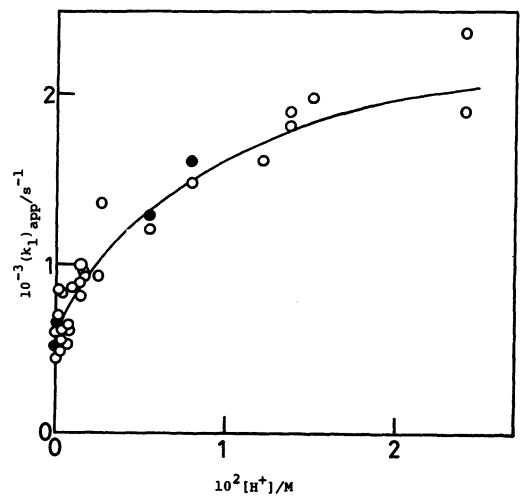


Fig. 3. Dependence of the apparent rate constant of the aquation reaction of $[Co(edma)_2]^0$ upon the concentration of hydrogen ion.
$[Co(edma)_2]^0$ was produced by the electrolytic reduction of 1.0 mM *trans*-$[Co(edma)_2]^+$ in 1.0 M $NaClO_4$ solutions containing 20 mM Hedma (open circle) or 50 mM Hedma (solid circle). The solid curve indicates the values of $(k_1)_{app}$ calculated by the use of Eq. 12 with the values of k_a, k_b/k_{-a}, and k_c/k_{-a} obtained.

formation constants of complex species and the protonation constants of edma$^-$, $\log \beta_{011}=9.97$, $\log \beta_{021}=16.71$, and $\log \beta_{031}=18.76$.[27] Therefore, analysis of the current-time curves was made by using the working curves with $K=0$ (*e.g.*, see curve 9 in Fig. 1.). The values of $(k_1)_{app}$ thus obtained for various pH values are shown in dependence of the hydrogen ion concentration, $[H^+]$, in Fig. 3. We see that the apparent rate constant greatly increases with an increase in $[H^+]$, indicating that the first aquation step is accelerated by the presence of hydrogen ion. A possible mechanism for such an acid-catalyzed dissociation of multidentate ligands may be expressed by Scheme 2, where it is assumed that the protonation of the intermediate containing bidentated edma$^-$ is irreversible, because of the fact that no evidence for the presence of protonated species was observed in potentiometric titrations.[27] Similar schemes were previously proposed for the dissociation of nickel(II),[28] iron(II),[29,30] and cobalt(II)[31-35] complexes with polyamines such as ethylenediamine (en), diethylenetriamine (dien), triethylenetetraamine (trien), 2,2′-bipyridine (bpy), 2,2′ : 6′,2″-terpyridine (terp) and 1,10-phenanthroline (phen), and the 2,4-pentanedionate complexes[36] of chromium(II), cobalt(II), and ruthenium(II). According to Sheme 2 and considering stationary-state kinetics for

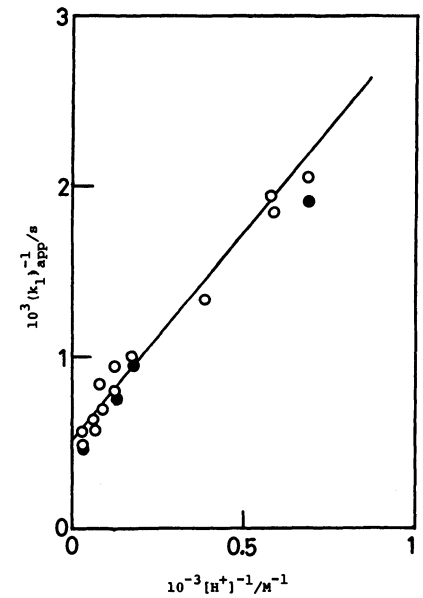

Fig. 4. Plot of $1/(k_1)_{app}$ *vs.* $1/[H^+]$.
The experimental conditions and the symbols used are the same as those in Fig. 3.

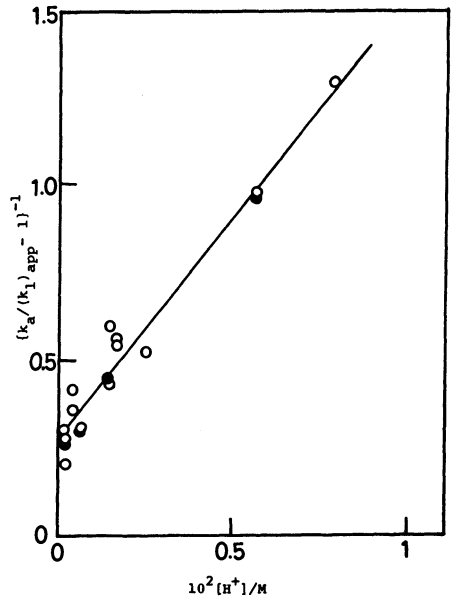

Fig. 5. Plot of $1/\{(k_a/(k_1)_{app})-1\}$ *vs.* $[H^+]$.
The experimental conditions and the symbols used are the same as those in Fig. 3.

unprotonated bidentated species, $(k_1)_{app}$ will be given by

$$(k_1)_{app}=\frac{k_a(k_b+k_c[H^+])}{k_{-a}+k_b+k_c[H^+]}. \quad (12)$$

Equation 12 can be rearranged to

$$\frac{1}{(k_1)_{app}}=\frac{1}{k_a}+\frac{k_{-a}}{k_a(k_b+k_c[H^+])}. \quad (13)$$

At sufficiently low pH where $k_b \ll k_c[H^+]$, a plot of $1/(k_1)_{app}$ *vs.* $1/[H^+]$ is linear, and k_a is derived by extrapolation to $1/[H^+]\rightarrow 0$. The graph for the first step dissociation of $[Co(edma)_2]^0$ is shown in Fig. 4. The corresponding values of the rate constants derived from the intercept and the slope are

$$k_a = 2.1 \times 10^3\ s^{-1}$$
$$(k_c/k_{-a}) = 1.9 \times 10^2.$$

Further rearrangement of Eq. 12 yields

$$1/[\{k_a/(k_1)_{app}\} - 1] = (k_b/k_{-a}) + (k_c/k_{-a})[H^+]. \quad (14)$$

Figure 5 shows the plots of $1/[\{k_a/(k_1)_{app}\} - 1]$ *vs.* $[H^+]$, which is linear as expected from Eq. 14. The intercept and the slope give the following values for the corresponding rate constants:

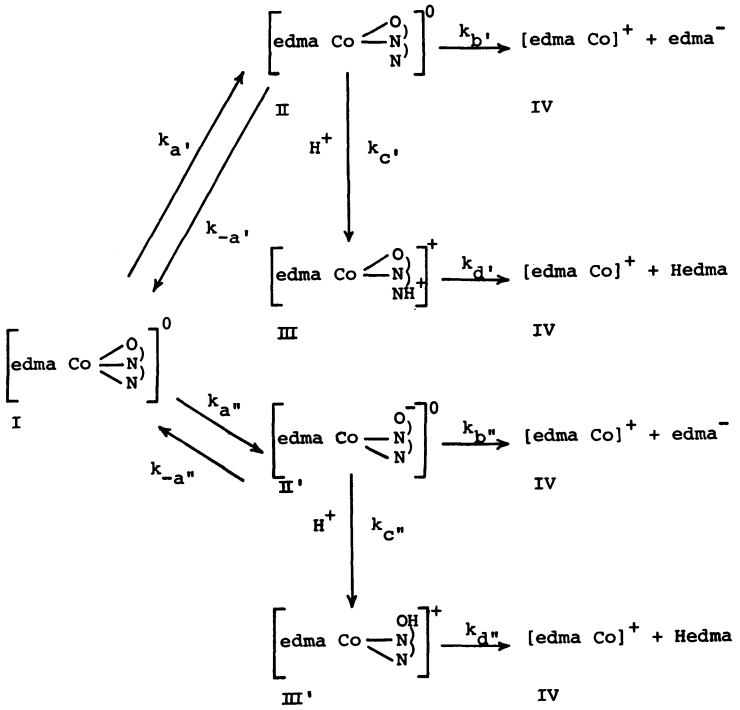
$$(k_b/k_{-a}) = 2.9 \times 10^{-1}$$
$$(k_c/k_{-a}) = 1.4 \times 10^2.$$

Two values of (k_c/k_{-a}) obtained from the two different plots are in good agreement with each other. To summarize briefly, the rate constant of the first step dissociation of $[Co(edma)_2]^0$ approaches to a limiting value ($2.1 \times 10^3\ s^{-1}$) for pH$<$1.3, in which the first bond rupture is the rate determining step for the dissociation and the hydrogen ion acts as an effective scavenger for the detached bond of bidentated edma. On the other hand, the rate constant is reduced to another limiting value ($4.7 \times 10^2\ s^{-1}$) for pH$<$4.3, in which the hydrogen ion does not participate directly in the dissociation process. We can calculate $(k_1)_{app}$ at various concentrations of hydrogen ion by the use of Eq. 12 with the values of k_a, k_b/k_{-a}, and k_c/k_{-a} obtained. The calculated values (solid curve in Fig. 3) are in agreement with the measured ones.

Two mechanisms are possible, depending on whether the first bond rupture occurs on the Co–N bond of a primary amino group or on the Co–O bond of carboxyl group, where the rupture of Co–N bond of secondary amino group is ruled out taking into account the steric factors. If the first bond rupture occurs on the Co–N bond of a primary amino group, the dissociation reaction proceeds through "glycinate intermediate".[37,38] On the other hand, if the Co–O bond of carboxyl group ruptures first, the subsequent dissociation reaction proceeds *via* "ethylenediamine intermediate."[37,38] The both possible reaction paths for the first step of the dissociation of $[Co(edma)_2]^0$ complex produced by the electrochemical reduction of the corresponding cobalt(III) complex can be expressed by Scheme 3, where edma$^-$ and N–N–O$^-$ stand for NH_2–CH_2–CH_2–NH–COO^- and Hedma denotes the protonated edma$^-$.

As being obtained above, the rate constant of the first bond rupture corresponding to $k_{a'}$ or $k_{a''}$ is $2.1 \times 10^3\ s^{-1}$. This value is almost equal to those of the corresponding first bond rupture of $[Co(en)_2]^{2+}$ and $[Co(trien)]^{2+}$ (1.4×10^3 and 2.1×10^3, respectively).[31] Each of these three cobalt(II) complexes has four nitrogen atoms as a donating atom. Further, the rate constants of the first bond rupture of cobalt(II) complexes with edma$^-$ or such aliphatic polyamines as en, dien and trien increase in the order:[31] $[Co(en)]^{2+} < [Co(dien)]^{2+} < [Co(en)_2]^{2+} \approx [Co(trien)]^{2+} \approx [Co(edma)_2]^0 < [Co(en)_3]^{2+} \approx [Co(dien)_2]^{2+}$. It is likely that in the dissociation of cobalt(II) complexes with aliphatic polyamines and polyamine-*N*-carboxylates the rate constant of the first bond rupture increases with an increase in the number of nitrogen donor atoms. From the fact that the rate constant of the first bond rupture for $[Co(edma)_2]^0$ is almost equal to those for $[Co(trien)]^{2+}$ and $[Co(en)_2]^{2+}$, it seems reasonable that the first bond rupture occurs on the Co–N bond of a primary amino group.

The ratio k_c/k_{-a} ($(1.7 \pm 0.3) \times 10^2$) for $[Co(edma)_2]^0$ is almost equal to those for $[Co(trien)]^{2+}$ and $[Co(en)_2]^{2+}$ (3.6×10^2 and 1.6×10^2, respectively).[31] This means that for these cobalt(II) complexes the hydrolysis involving protonation is much faster than the re-



Scheme 3.

formation of the chelate ring and further for the $[Co(edma)_2]^0$ complex the protonation of an uncoordinated ligand can occur with the same easiness as those in the $[Co(en)_2]^{2+}$ and $[Co(trien)]^{2+}$ complexes.

The ratio k_b/k_{-a} is a measure of the probability for complete dissociation of a ligand once the first bond rupture occurred. The value (2.9×10^{-1}) of k_b/k_{-a} for $[Co(edma)_2]^0$ is about forty times larger than those (7.9×10^{-3})[31] for $[Co(en)_2]^{2+}$ and $[Co(trien)]^{2+}$. This may be due to the difference between the type of the bond of the still-bound ligand after the first bond rupture in the $[Co(edma)_2]^0$ dissociation and that for $[Co(en)_2]^{2+}$ and $[Co(trien)]^{2+}$. In the former the still-bound ligand has a possibility to make "glycinate intermediate" (II) and/or "ethylenediamine intermediate" (II'), while in the latter the formation of "ethylenediamine intermediate"[31] can be only expected. The processes II→IV and II'→IV shown in Scheme 3 may be considered to be similar to the first detachment processes of glycine (gly) and ethylenediamine (en) from the cobalt(II) complexes with gly and en, respectively. The rate constant of the first step of the dissociation of the $[Co(gly)_3]^-$ is by *ca.* 10 times larger than that of the $[Co(en)_3]^{2+}$.[36,39-41] Similarly, the dissociation of the nickel(II)–glycine complexes is faster than that of the corresponding ethylenediamine complexes.[42] Thus, the large difference between the value of k_b/k_{-a} for $[Co(edma)_2]^0$ and those for $[Co(en)_2]^{2+}$ and $[Co(trien)]^{2+}$ seems to eliminate the possibility of an ethylenediamine reaction mechanism in the $[Co(edma)_2]^0$ dissociation. This finding is contrary to the observation of Kodama *et al.*[37,38] obtained in their kinetic study of the substitution reactions of nickel(II)–edma$^-$ complex with diethylenetriamine-*N*,*N*,*N'*,*N''*,*N''*-pentaacetic acid (DTPA). The substitution reaction of nickel(II)–edma$^-$ complex with DTPA proceeds through "ethylenediamine intermediates."

Lastly, consider the reaction in the near neutral region of pH values from 4.5 to 7. In this pH region, the $[Co(edma)_2]^0$, $[Co(edma)]^+$, and $[Co(H_2O)_6]^{2+}$ species coexist in the solution, as can be seen from the concentration distributions calculated by the use of the formation constants of the $[Co(edma)_2]^0$ and $[Co(edma)]^+$ species and the protonation constants of edma$^-$.[27] Then the effects of the reverse (complex formation) reactions should be taken into consideration. It has been well known[41-46] that the rate constant of the first detachment step of the ligand (*i.e.*, dissociation reaction) of the labile complexes is larger than those of the subsequent steps. Thus, we assumed that the second step process $[Co(edma)]^+ \rightleftarrows [Co(H_2O)_6]^{2+}$ dose not proceed substantially compared with the first step process $[Co(edma)_2]^0 \rightleftarrows [Co(edma)]^+$ within the time scale of DPSCA. Further, the experiments were mainly conducted under the experimental conditions where $[Co(H_2O)_6]^{2+}$ ion is scarcely present in the solution. The second step process was thus ignored in examining the mechanism of overall aquation reaction of $[Co(edma)_2]^0$. Furthermore, the reaction path through the protonation of the amino group, which is the main path of the dissociation in an acidic solution, can be neglected, since the ratio of $k_c[H^+]$ to k_b which

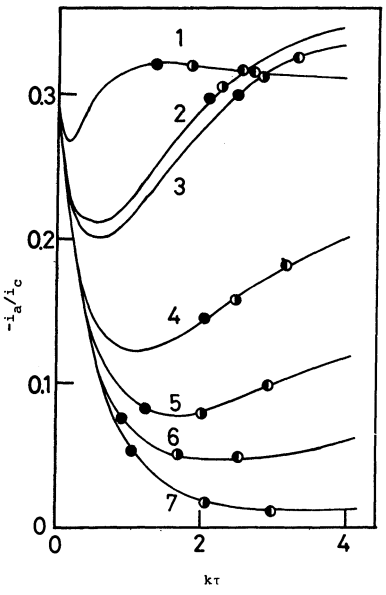


Fig. 6. Dependence of the measured values of the current ratio $(-i_a/i_c)$ on $k\tau$ for various values of K at $\xi=1$.
(●): $\tau=3.0$ ms, (◑): $\tau=4.7$ ms, (◐): $\tau=6.5$ ms.
(1): $K=3.00$, [Hedma]=20.0 mM, pH 6.22; (2): $K=0.592$, [Hedma]=20.0 mM, pH 5.84; (3): $K=0.541$, [Hedma]=15.7 mM, pH 5.90; (4): $K=0.173$, [Hedma]=60.9 mM, pH 5.32; (5): $K=0.110$, [Hedma]=40.5 mM, pH 5.30; (6): $K=0.048$, [Hedma]=20.0 mM, pH 5.20; (7): $K=0.05$, [Hedma]=14.0 mM, pH 5.00. In all cases, the concentration of *trans*-$[Co(edma)_2]^+$ is 1.0 mM. Solid lines represent the theoretical curves for various values of K which correspond to the solution compositions ((1)—(7)).

can be estimated by using the values of k_b/k_{-a} and k_c/k_{-a} obtained above is sufficiently small at pH>*ca.* 5. According to the reaction scheme (Scheme 1), the apparent rate constant, $(k)_{app}$, and the equilibrium constant, K, can be expressed by $(k_1)_{app}$ and $l(\beta_{102}/\beta_{101})$, respectively, in which l is the concentration of free edma$^-$. In Fig. 6 the experimental values of the ratio $(-i_a/i_c)$ are shown as a function of the product of the rate of the follow-up chemical reaction (k) and the switching time (τ) at various analytical concentrations of Hedma and pH's. The value of $(k_1)_{app}$ was independent of the analytical concentrations of Hedma and pH's within the experimental error, as can be expected from the above mentions. The value of $(k_1)_{app}$ was estimated to be $(4.1\pm0.6)\times10^2\,s^{-1}$, which is almost equal to the value $(4.7\times10^2\,s^{-1})$ obtained in the acidic region (pH<4.5).

The results may be summarized as follows: The mechanism of the aquation of the $[Co(edma)_2]^0$ can be described by Scheme 1 in the range of pH 1.5 to 10.6. At pH<4.5, the process of the detachment of the first edma$^-$ from the $[Co(edma)_2]^0$ is irreversible and the rate of this process is accelerated by hydrogen ions (Scheme 2). The first step of the dissociation of the $[Co(edma)_2]^0$ is the bond rupture of the Co–N bond of a primary amino group and the dissociation reaction proceeds through "glycinate intermediate" (see Scheme 3). In the region of further lower pH (pH<1), the

rate of the dissociation approaches an upper limiting value ($2.1\times10^3\ s^{-1}$). At pH>4.5, on the other hand, the hydrogen ions do not substantially contribute to the aquation and thus the rate approaches a lower limiting value ($4.7\times10^2\ s^{-1}$), which is in good agreement with that obtained in neutral region (4.5<pH<7), where the reverse (complex formation) reaction must be also taken into consideration. Above pH 7, the $[Co(edma)_2]^0$ species exists as main species in the solution and thus the kinetic behavior of the aquation is not observed.

Appendix

If we make the following substitution:

$$\eta = \sqrt{v}, \tag{A-1}$$

$$\sigma = \sqrt{\xi}. \tag{A-2}$$

Eq. 10 can be converted into the following equation;

$$2\int_0^{\sigma} \frac{K+\exp[-\rho\tau(\sigma^2-\eta^2)]}{\sqrt{\sigma^2-\eta^2}}\Psi(\eta)d\eta = C(\sigma^2,K,\rho\tau), \tag{A-3}$$

with

$$C(\sigma^2,K,\rho\tau) = \pi\left[K+\exp\left\{-\frac{\rho\tau(1+\sigma^2)}{2}\right\}\cdot I_0\left(\frac{\rho\tau[1+\sigma^2]}{2}\right)\right]. \tag{A-4}$$

Equation A-4 can be solved numerically in the following way:[22] First, divide the σ -axis into N equal intervals of $\Delta\sigma$, and transform Eq. A-3 into

$$2\sum_{p=1}^{N}\int_{(p-1)\Delta\sigma}^{p\Delta\sigma}\Psi(\eta)\frac{K+\exp[-\rho\tau\{(N\Delta\sigma)^2-\eta^2\}]}{\sqrt{(N\Delta\sigma)^2-\eta^2}}d\eta = C((N\Delta\sigma)^2,K,\rho\tau), \tag{A-5}$$

with

$$C((N\Delta\sigma)^2,K,\rho\tau) = \left[K+\exp\left\{-\frac{\rho\tau(1+(N\Delta\sigma)^2)}{2}\right\}\cdot I_0\left(\frac{\rho\tau(1+(N\Delta\sigma)^2)}{2}\right)\right]. \tag{A-6}$$

Next, approximate the function $\Psi(\eta)[K+\exp\{-\rho\tau((N\Delta\sigma)^2-\eta^2\}]$ in the interval $(p-1)\Delta\sigma\leqq\eta\leqq p\Delta\sigma$ by its arithmetic mean

$$\frac{1}{2}\{\Psi(p\Delta\sigma)[K+\exp\{-\rho\tau(N^2-p^2)(\Delta\sigma)^2] + \Psi([p-1]\Delta\sigma)[K+\exp\{-\rho\tau(N^2-[p-1]^2)(\Delta\sigma)^2]\}, \tag{A-7}$$

and perform the integration of the remaining part. Then, we obtain, after some rearrangements,

$$\Psi(\Delta\sigma) = \frac{C((N\Delta\sigma)^2,K,\rho\tau)-\Psi(0)[K+\exp\{-\rho\tau(\Delta\sigma)^2\}]H(1,1)}{(K+1)H(1,1)}, \tag{A-8}$$

$$\Psi(N\Delta\sigma) = \frac{1}{(K+1)H(N,N)}\Big[C((N\Delta\sigma)^2,K,\rho\tau)-\Psi(0)H(N,N)[K+\exp\{-\rho\tau(\Delta\sigma)^2N^2\}]-\sum_{p=1}^{N}\Psi(p\Delta\sigma)[K+\exp\{-\rho\tau(\Delta\sigma)^2(N^2-p^2)\}][H(N,p)+H(N,p-1)\Big], \tag{A-9}$$

with

$$H(N,p) = \sin^{-1}\left(\frac{p}{N}\right)-\sin^{-1}\left(\frac{p-1}{N}\right), \tag{A-10}$$

where

$$\Psi(0) = \frac{1}{K+1}\left[K+\exp\left(-\frac{\rho\tau}{2}\right)\cdot I_0\left(\frac{\rho\tau}{2}\right)\right]. \tag{A-11}$$

The condition A-11 is given by solving the Eq. 9 at $\xi\to0$. Thus, the numerical values of $\Psi(\sigma)$ can be obtained stepwise with $N=1,2,3,\cdots$ for the various choices of the parameters K and $\rho\tau$. Numerical calculations were carried out on a digital computer FACOM M-160 for a series of values of K and $\rho\tau$ ranging from 0 to 100 and 0 to 10, respectively, by setting $\Delta\sigma=0.001$.

Synthesis of *N*-Unsubstituted Di- and Triaza Crown Ethers

Hirokazu MAEDA, Shigeo FURUYOSHI, Yohji NAKATSUJI, and Mitsuo OKAHARA*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-oka 2-1, Suita, Osaka 565

(Received March 1, 1983)

Facile syntheses of di- and triaza crown ethers by intramolecular cyclization of oligoethylene glycols containing two or three imino groups or by their intermolecular cyclization with oligoethylene glycol bis(*p*-toluenesulfonate)s are described.

N-Unsubstituted oligoaza crown ethers are important as intermediate in the synthesis of cryptands[1] or macrotricyclic compounds.[2-8] They can also be transformed into polymers having crown rings in the backbone.[9-13] Diaza crown ethers as *N*-unsubstituted oligoaza crown ethers have been synthesized by the reaction between diamine and bis(acyl chloride),[1,14] bis(tosylamide) or sodium tosylamine and ditosylate or dichloride,[15-17] and bis(trifluoroacetamide) and ditosylate.[18] However, in all these methods, the elimination of protecting groups is needed in the final step. The reaction of triethylene glycol dichloride with excess ammonia gives diaza-18-crown-6 in low yield with many by-products.[18] Although the preparation by *N*-alkylation of diamine with dichloride[19] or diiodide[20] has been reported, the synthesis of *N*-unsubstituted diaza crown ethers by *O*-alkylation has not been published except some preparations of special diaza crown ethers.[21,22]

We have previously reported that *N*-unsubstituted monoaza crown ethers can be obtained by the reaction of readily available dialkanolamines with oligoethylene glycol bis(*p*-toluenesulfonate)s without protection of the amino group, based on the higher reactivity of alkoxide anion.[23-25] We have also reported one-pot synthesis of substituted and unsubstituted crown ethers by treating various oligoethylene glycol derivatives with arenesulfonyl chlorides.[26] In this paper, the results of the syntheses of *N*-unsubstituted di- and triaza crown ethers by intramolecular cyclization of oligoethylene glycols including two or three imino groups or by intermolecular cyclization of them with oligoethylene glycol bis(*p*-toluenesulfonate)s are described.

Results and Discussion

The starting materials, oligoethylene glycols (**3**) containing two imino groups, were obtained from 2-amino-1-hydroxy compounds (**1**) and oligoethylene glycol dichlorides (**2**) (Scheme 1). When **2** ($m=1$) was used in this reaction, a morpholine derivative was obtained from the intramolecular substitution by the attack of the amino group of the intermediate compound.[18] On the other hand, as the use of 1,2-dichloroethane (**2**, $m=0$) may result in the formation of aziridine derivatives, it is necessary to use **2** having more than two oxyethylene units ($m\geq 2$) in order to get **3** in satisfactory yield. 2-[2-(2-Hydroxyethylamino)ethylamino]ethanol (**4**) and N^{α},N^{ω}-bis(2-hydroxycyclohexyl)-oligoazaalkane-α,ω-diamines (**6**) were obtained from the reaction of excess 2-(2-aminoethylamino)ethanol with 2-chloroethanol and the reaction of oligoazaalkane-α,ω-diamine (**5**) with cyclohexene oxide, respectively.

The preparation of diaza crown ethers by the intramolecular cyclization of **3** was achieved (Scheme 2). After **3** was treated with an equimolar amount of *p*-toluenesulfonyl chloride in dioxane suspension of powdered alkali metal hydroxide at 60 °C, the product

a) Total amine number(calcd): 505.6(514.0), tertiary amine number: 18.1. b) Purified by distillation. c) Purified by column chromatography.

was obtained by distillations in a Kugelrohr apparatus.

In this reaction, *p*-toluenesulfonyl chloride is first attacked by alkoxide anion to give mono(*p*-toluenesulfonate)s (**7**), and then an intramolecular attack by an alternative alkoxide anion can generate the diaza crown ethers (**8**). If *p*-toluenesulfonyl chloride reacts with imino groups, sulfonamide derivatives may be formed. But, the resonance of *p*-toluenesulfonamides is hardly observed in the ^{1}H NMR spectrum of the crude products of **8a**—**e** before distillation. While, intramolecular reactions of **7** with imino groups may result in *N*-substituted derivatives (**9** and **10**). In the ^{1}H NMR spectrum of the crude product, in fact, resonances are observed at δ 1.16, 1.72, and 2.41, which are ascribed to the protons of aziridine derivatives. However, it is found that the products (**8a**—**c**) obtained by distillations are almost pure *N*-unsubstituted diaza crown ethers (**8**), probably because of the thermal instability of aziridine derivatives. As the distillation product for **8d**, **e** is a mixture of aziridine compound, **8d**, **e** is further purified by alumina column chromatography. Although the product obtained is a mixture of stereoisomers, further purification was not performed. These results are shown in Table 1.

3a and potassium metal were dissolved in *t*-butyl alcohol, then diethylene glycol bis(*p*-toluenesulfonate) (**11a**) in dioxane was added dropwise to the solution at 40 °C. The crude product was distilled in a Kugelrohr apparatus to give diaza 21-crown-7 (**8f**) in 38% yield (Scheme 3).

This synthetic method is similar to that previously reported for the synthesis of monoaza crown ethers,[22,23] and **8f** generated from selective *O*-alkylation under these conditions. Although it is confirmed by the measure-

ment of tertiary amine content of product **8f** that the isomeric hydroxy compounds (**13** and **14**) to be formed by *N*-alkylation of **12** are scarcely generated, diethylene glycol di-*t*-butyl ether is formed by the attack of *t*-butoxide anion on **11a** as a by-product.[27]

In a similar manner to **8f**, di- and triaza crown ethers (**15** and **16**) have also been obtained (Table 2). The better yields of crown compounds (**16a**, **b**) with a cyclohexane ring than compounds (**15a**, **b**) without the ring may be explained by the higher solubility of their intermediate alkoxides in the solvent. In the case of crown ethers (**16c**, **d**) having three imino groups, the yields are lower and about half of the starting (**6b**) is recovered unreacted. This is due to the decrease of the template effect, because a softer *N*-doner than *O*-doner is not apt to complex with a hard alkali metal cation.[28]

Experimental

IR and ^{1}H NMR spectra were recorded on a Hitachi 260 spectrometer and a JEOL JNM-PS-100 spectrometer respectively. Mass spectral data were measured with a Hitachi RMU-6E mass spectrometer at an ionization potential of 70 eV. GLC analyses were performed on a Shimadzu gas chromatograph GC-3BF using two 1 m×3 mm columns packed with 10% Silicone SE-30 on Celite 545 and OV-1 on Uniport KS or on a Shimadzu gas chromatograph GC-3BT employing 0.7 m×3 mm column packed with 10% Carbowax on Celite 545. Amine contents were determined by titration.[29,30]

Most starting materials were obtained from commercial sources. Their purity was checked by GLC and when necessary they were purified by distillation. α-(2-Chloroethyl)-ω-chlorooligo(oxyethylenes)(**2b**, **c**) were prepared from the corresponding glycols and thionyl chloride. 6,9-Dioxa-3,12-diazateradecane-1,14-diol (**3a**)[18] and oligoethylene glycol bis(*p*-toluenesulfonate)s (**11a**, **b**)[31] were synthesized as described previously.

7,10-Dioxa-4,13-diazahexadecane-2,15-diol (3e). 1,8-Dichloro-3,6-dioxaoctane (18.7 g, 0.1 mol) was added to a suspension of 1-amino-2-propanol (75.1 g, 1.0 mol) and powdered sodium carbonate (15.9 g, 0.15 mol), and the mixture was heated at 120 °C with stirring. After 30 h, methanol (100 ml) was added. The mixture was filtered, and the excess amine and methanol were removed from the filtrate. The residue was distilled in a Kugelrohr apparatus at 175—180 °C (0.03 Torr) to give a crude product (15.5 g). It was purified by recrystallization from hexane–THF (50 : 50) to afford 11.9 g (45%) of **3e** as a white solid: mp 65—67.5 °C; ^{1}H NMR ($CDCl_3$) δ=1.16 (d, 6H), 2.30—2.92 (m, 8H), 3.29 (s, 4H), 3.47—3.68 (m, 8H), 3.69—3.99 (m, 2H); MS, *m/e* (relative intensity) 249(3), 219(100), 164(59), 132(25), 102(76) 88(68), 44(49); IR (KBr) 3300, 2920, 2880, 1460, 1355, 1120 cm^{-1}. Found: C, 54.25; H, 10.60; N, 10.33. Calcd for $C_{12}H_{28}N_2O_4$: C, 54.52; H, 10.68; N, 10.60. Using a similar procedure, **3b**, **3c**, and **3d** were also obtained.

6,9,12-Trioxa-3,15-diazaheptadecane-1,17-diol (3b). Bp 180—185 °C (0.01 Torr,** Kugelrohr distillation); yellowish viscous liquid; 20% yield; ^{1}H NMR ($CDCl_3$) δ=2.56—2.93 (m, 8H), 3.39—3.95 (m, 16H), 3.64 (s, 4H); *m/e* (relative intensity) 249(11), 194(20), 176(28), 165(15), 88(42), 74(100), 44(30); IR (neat) 3300, 2930, 2880, 1460, 1360, 1110 cm^{-1}. Found: C, 51.12; H, 9.89; N, 10.19. Calcd for $C_{12}H_{28}N_2O_5$: C, 51.41; H, 10.07; N, 9.99.

6,9,12,15-Tetraoxa-3,18-diazaeicosane-1,20-diol (3c). Bp 190—195 °C (0.005 Torr, Kugelrohr distillation); yellowish viscous liquid; 22% yield; ^{1}H NMR ($CDCl_3$) δ=2.56—2.96 (m, 8H), 3.28 (s, 4H), 3.44—3.85 (m, 20H); MS, *m/e* (relative intensity) 293(18), 238(43), 220(37), 132(24), 100(24), 88(41), 74(100); IR(neat) 3290, 2930, 1460, 1355, 1100 cm^{-1}. Found: C, 51.56; H, 10.02; N, 8.71. Calcd for $C_{14}H_{32}N_2O_6$: C, 51.83; H, 9.94; N, 8.64.

2,13-Diethyl-6,9-dioxa-3,12-diazatetradecane-1,14-diol (3d). Bp 170—175 °C (0.01 Torr, Kugelrohr distillation); white waxy solid at 30 °C; 49% yield; ^{1}H NMR ($CDCl_3$) δ=0.92 (t, 6H), 1.24—1.64 (m, 4H) 2.37—2.96 (m, 6H), 3.02 (s, 4H), 3.24—3.76 (m, 12H); MS, *m/e* (relative intensity) 292 (M^+, 1), 261(100), 243(6), 178(27), 116(61), 102(53), 44(71); IR (KBr) 3300, 2910, 2880, 1460, 1360, 1120 cm^{-1}. Found: C, 57.88; H, 10.76; N, 9.71. Calcd for $C_{14}H_{32}N_2O_4$: C, 57.50; H, 11.03; N, 9.58.

2-[2-(2-Hydroxyethylamino)ethylamino]ethanol (4). 2-Chloroethanol (8.5 g, 0.1 mol) was added to a suspension of 2-(2-aminoethylamino)ethanol (104 g, 1 mol) and powdered sodium carbonate (8.0 g, 0.08 mol); the reaction was continued with stirring at 120 °C for 29 h. After the reaction mixture cooled to room temperature, methanol (150 ml) was added, and the mixture was filtered. Evaporation of the filtrate gave a crude

** 1 Torr≈133.322 Pa.

product (15.5 g), which was recrystallized twice from THF to give 7.6 g (51%) of **4** as a white solid: mp 98—100 °C; ^{1}H NMR (CD_3OD) δ=2.40—2.92 (m, 8H), 3.63 (t, 4H); MS, *m/e* (relative intensity) 118(10), 74(100), 56(59), 44(62); IR (KBr) 3330, 2950, 2875, 1450, 1360, 1070 cm^{-1}. Found: C, 48.34; H, 10.63; N, 19.14. Calcd for $C_6H_{16}N_2O_2$: C, 48.63; H, 10.88; N, 18.90.

*N,N'-Bis(2-hydroxycyclohexyl)ethylenediamine (**6a**).* Cyclohexene oxide (19.6 g, 0.2 mol) was added dropwise to ethylenediamine (6.02 g, 0.1 mol) at 85 °C. After the addition, the mixture was heated at 110 °C for 3 h and gradually became a solid. The crude product was recrystallized from methanol–water (99 : 1) to give 8.32 g (32%) of **6a** as a white solid: mp 190—193 °C; ^{1}H NMR (CD_3COOD) δ=1.02—2.49 (m, 16H), 2.76—3.36 (m, 2H), 3.37—4.05 (m, 6H); MS, *m/e* (relative intensity) 220(8), 128(100), 100(27), 81(19), 44(17); IR (KBr) 3290, 2950, 2880, 1475, 1090 cm^{-1}. Found: C, 65.55; H, 11.01; N, 10.90. Calcd for $C_{14}H_{28}N_2O_2$: C, 65.59; H, 11.01; N, 10.93.

*Bis[2-(2-hydroxycyclohexylamino)ethyl]amine (**6b**).* The above procedure was followed, using cyclohexene oxide (19.6 g, 0.2 mol) and bis(2-aminoethyl)amine (10.3 g, 0.1 mol). The crude product was recrystallized from THF to give 7.6 g (25%) of **6b** as a white solid: mp 132—135 °C; ^{1}H NMR ($CDCl_3$) δ=0.69—2.13 (m, 16H), 2.14—3.03 (m, 10H), 2.86 (s, 5H), 3.04—3.47 (m, 2H); MS, *m/e* (relative intensity)

TABLE 3. CHARACTERIZATION OF DI- AND TRIAZA CROWN ETHERS

Crown ether	IR(neat) $\tilde{\nu}$/cm^{-1}	^{1}H NMR($CDCl_3$) δ	MS(70 eV), *m/e* (relative intensity)

16c	$C_{20}H_{39}N_3O_3$	10.98(10.64)	64.65(65.00)	11.48(11.37)
16d	$C_{22}H_{43}N_3O_4$	10.78(10.48)	63.79(63.89)	9.88(10.16)

171(100), 159(31), 128(83), 98(21); IR (KBr) 3270, 2950, 2870, 1460, 1140 cm^{-1}. Found: C, 64.08; H, 11.08; N, 13.92. Calcd for $C_{16}H_{33}N_3O_2$: C, 64.18; H, 11.11; N, 14.03.

*1,4,10-Trioxa-7,13-diazacyclopentadecane (**8a**)* via *Intramolecular Cyclization.* *p*-Toluenesulfonyl chloride (3.81 g, 0.02 mol) dissolved in 20 ml of dioxane, was slowly added dropwise to a suspension of powdered sodium hydroxide (6.3 g, 0.15 mol) and 6,9-dioxa-3,12-diazatetradecane-1,14-diol (**3a**, 4.73 g, 0.02 mol) in 60 ml of dioxane over a period of 2 h at 60 °C. After the addition, the reaction was continued for 3 h and the reaction mixture filtered. The precipitate was washed with dichloromethane, and the solvent removed from the combined solution of filtrate and washings. Water (10 ml) was added to the residue and the solution extracted five time with dichloromethane. The solvent was removed from the dichloromethane extracts to give the crude product (3.51 g). In the ^1H NMR ($CDCl_3$) spectrum of it, resonances were observed at δ 1.16 and 1.72, which were ascribed to the aziridine ring protons. No resonances for *p*-toluenesulfonamides were observed. After the crude product was neutralized by hydrochloric acid, it was distilled in the presence of sodium carbonate (2.12 g, 0.02 mol) by Kugelrohr distillation at 75—90 °C (0.03 Torr) to give a white waxy solid (1.61 g, 37%). It was again distilled in a Kugelrohr apparatus at 80—85 °C (0.015 Torr) to afford 1.14 g (26%) of GLC-pure **8a** as a white solid: mp 91—93 °C (lit,[1] 89—90 °C). In the ^1H NMR of the product, resonances of aziridine ring protons were no longer observed, because aziridine derivatives were lost by further reaction during distillation. This procedure was typical for the preparation of diaza crown ethers (**8b—e**) by intramolecular cyclization, and **8d**, **e** were separated from the first distillation product by alumina column chromatography (acetone–hexane 50 : 50), and further purified by distillation. Characterization of **8** was accomplished by a standard method (Tables 1 and 3) and elemental analysis of **8** is shown in Table 4.

*1,4,7,13,16-Pentaoxa-10,19-diazacycloheneicosane (**8f**)* via *Intermolecular Cyclization.* 6,9-Dioxa-3,12-diazatetradecane-1,-14-diol (**3a**, 4.73 g, 0.02 mol) and potassium metal (1.72 g, 0.044 mol) were dissolved in *t*-butyl alcohol (160 ml), and diethylene glycol bis(*p*-toluenesulfonate) (**11a**, 8.29 g, 0.02 mol) in dioxane (60 ml) was added dropwise to the solution at 40 °C during 2 h. After the addition, the reaction was continued for 2 h, when the reaction mixture was filtered. The precipitate was washed with dichloromethane, and the solvent removed from the combined solution of filtrate and washings. Water (10 ml) was added to the residue and the solution was extracted twice with hexane to remove by-products. It was then extracted several times with dichloromethane. The hexane was removed from the extracts, and the main by-product was isolated from the residue by preparative GLC and identified as diethylene glycol di-*t*-butyl ether: ^1H NMR ($CDCl_3$) δ=1.19 (s, 18H), 3.47—3.71 (m, 8H). The dichloromethane extracts were combined, the solvent evaporated. The crude product (5.48 g) was purified two distillations in a Kugelrohr apparatus at 120—124 °C (0.005 Torr) to give GLC-pure **8f** (2.33 g, 38%) as a clear liquid. The tertiary amine number of the product was found to be almost negligible (11.5), but the total amine number (363.6) agreed well with the calculated number (366.2). Using a similar procedure, oligoaza crown ethers (**15** and **16**) were also obtained (Tables 2 and 3).

(Received March 23, 1983)

Two new methods for selective hydration of 1,1,4-trisubstituted 2-butyne-1,4-diols (**1**) to give 4,5-dihydro-3(2*H*)-furanone derivatives are reported. The first involves selective monoacetylation of the less hindered hydroxyl group of **1** followed by Ag(I)-catalyzed rearrangement and cyclization to give 3-acetoxy-2,2,5-trisubstituted 2,5-dihydrofurans (**2**). Final hydrolysis yielded 2,2,5-trisubstituted 4,5-dihydro-3(2*H*)-furanones. Oxidation of the enol acetates **2** with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone gave 3(2*H*)-furanones. The new method was applied to the synthesis of naturally occurring 3(2*H*)-furanones such as bullatenone and geiparvarin from the corresponding 2-butyne-1,4-diol derivatives. The second approach is concerned with the synthesis of the opposite regioisomer, 2,5,5-trisubstituted 4,5-dihydro-3(2*H*)-furanones, from diols **1** with a polymer reagent Hg/Nafion-H.

In extension of our efforts in regio- and stereoselective cyclopentannulation starting with 2-butyne-1,4-diol derivatives,[1] we have found that the acetylenic diols provide excellent means of regiocontrolled construction of 3(2*H*)-furanone skeleton.[2] Compounds of this type are important in view of their distribution in nature,[3] cytotoxic and antitumor actions,[4] and versatility as synthetic intermediates[5,6] in the synthesis of muscarine alkaloids,[7] for example. The furanones are valued by perfumers,[8] pharmacologists,[7] and the food and beverage industries.[9] The 3-hydroxyfurans have been investigated with theoretical interest[10] in keto-enol tautomerism. Among the methods for the construction of the 3(2*H*)-furanone ring, the transformation of 2-butyne-1,4-diol derivatives into 4,5-dihydro-3(2*H*)-furanones is most promising in a practical sense because of the simple synthetic pathway.[11] Though well-established for symmetrical 2-butyne-1,4-diols, this process has not been used for the synthesis of furanone derivatives in general, due mainly to the lack of the regiocontrol in the hydration of the carbon-carbon triple bond.[12,13] Many naturally occurring 3-furanones possess the 2,2,5-trisubstituted 3(2*H*)-furanone ring-system,[3] which is not readily accessible by previous methods.[11,12] Selective hydration at the position *a* (or *b*) in the formula **1** is, therefore, important in respect of regiocontrolled construction of the 3(2*H*)-furanone skeleton.

We have found that introduction of an oxygen function at the position *a* of the triple bond of **1** to give **3** is achieved by method A (Scheme 1) with complete regioselectivity. This involves selective monoacetylation of unsymmetrical 2-butyne-1,4-diols **1** followed by Ag(I)-catalyzed cyclization with acetoxyl migration to give enol acetates **2**, whose hydrolysis yields 2,2,5-trisubstituted 4,5-dihydro-3(2*H*)-furanones (**3**). In contrast, the opposite regioisomer **4** of the dihydrofuranones was prepared directly from the diol **1** by treatment with a polymer reagent Hg/Nafion-H[14] (method B). Details are reported herein.[15]

*Transformation of Diols **1** into 4,5-Dihydro-3(2H)-furanones of Type **3** (Method A).* Unsymmetrically substituted 2-butyne-1,4-diols (**1**) were prepared from corresponding carbonyl compounds and propargyl alcohol derivatives. Treatment of **1** with acetic anhydride and pyridine at 25 °C resulted in acetylation of the less hindered hydroxyl group. The intermediates **1** were not necessarily isolated and were subjected directly to the monoacetylation; especially effective for **6f** and **6g**.

The monoacetates **6** were then treated with 5 mol% of silver perchlorate (or silver tetrafluoroborate) in refluxing benzene in the dark to give the enol acetates **2**[16] in good yields. Results are summarized in Table 1. The transformation can be explained by assuming Ag(I)-catalyzed isomerization[17] of the monoacetates **6** to allenyl acetates **7** followed by Ag(I)-assisted cyclization[18] (Scheme 2). The selective introduction of an

† Present address: Sagami Chemical Research Center, 4-4-1, Nishiohnuma, Sagamihara, Kanagawa 229.

Table 1. Ag(I)-Catalyzed synthesis of dihydro-3(2*H*)-furanone enol acetates 2[a)]

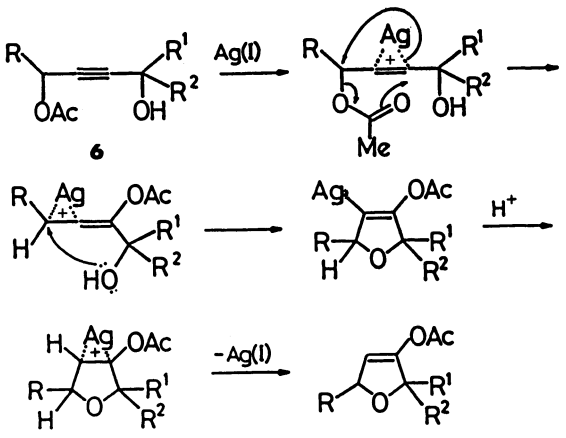
2-Butyne-1,4-diol derivative **1**	Yield[b)]/% of monoacetate **6**	Yield[b)]/% of dihydro-3(2*H*)-furanone enol acetate **2**
 **1a**	99	 **2a** 83
 **1b**	>99	 **2b** 99
 **1c**	>99	 **2c** 63[c)]
 **1d**	>99	 **2d** 80
 **1e**	90	 **2e** 74
 **1f**	81[d)]	 **2f** 63
 **1g**	86[d)]	 **2g** 61[d)]

a) The monoacetates **6** were treated with 5 mol% of silver perchlorate. b) Isolated yields. c) Silver tetrafluoroborate (10 mol%) was used. d) Overall yields from the corresponding aldehyde and 2-methyl-3-butyn-2-ol. e) Silver perchlorate (15 mol%) was employed.

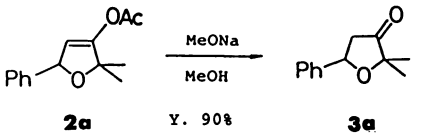
oxygen function at the position *a* is now achieved by this Ag(I)-mediated intramolecular rearrangement. Although this reaction was monitored very carefully, the allenyl acetates **7** were never isolated. It is worthy to note that the carbon-carbon double bond in the substrate **1** was not affected (Table 1, compounds **2e**, **2f**, and **2g**) and the olefinic configuration was completely retained through the reaction.

Finally, the enol acetate **2** was converted into the 4,5-dihydro-3(2*H*)-furanone **3** by treatment with sodium methoxide in methanol at r.t. (Scheme 3).

Oxidation of the Enol Acetates 2 to 3(2H)-Furanones 5. Application to a Practical Synthesis of Bullatenone (5a) and Geiparvarin (5g). The attempted transformation of **2** into the corresponding 3(2*H*)-furanones **5** involves the bromination dehydrobromination process (Scheme 3). Molecular bromine was allowed to react with the enol acetates **2** and the resulting bromodihydrofuranones **8** were treated with Li_2CO_3 (and LiCl) in *N*,*N*-dimethylformamide (DMF) or hexamethylphosphoric triamide (HMPA) to give **5**. Although this transformation was effective for **5a** and **5e**, the yield of **5f** was disappointedly low.



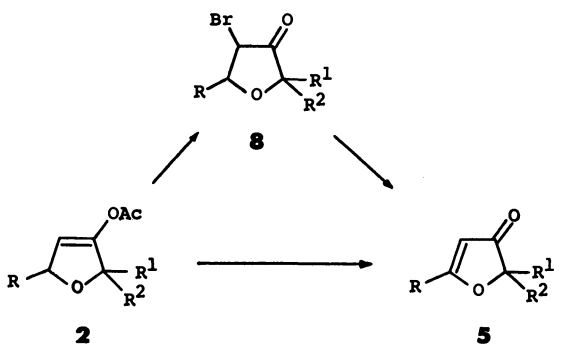
Scheme 2.



Scheme 3.

The use of 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) very much improved the oxidation step. Treatment of **2** with DDQ in benzene at 25 °C for several hours afforded **5** quantitatively (Table 2). The present transformation of the diols **1** into 3-furanones of type **3** and **5** should hold considerable promise as a general synthetic method.

Thus, the combined process allowed us to synthesize bullatenone (**5a**),[19)] a naturally occurring 3(2*H*)-



Scheme 4.

Table 2. Isolated yields (%) of 3(2*H*)-furanones **5**

Enol acetate **2**	3(2*H*)-Furanone **5**	Oxidation with DDQ[a]	Bromination and dehydromination[b]
 **2a**	 bullatenone **5a**	99	85
 **2e**	**5e**	>99	66
 **2f**	 **5f**	>99	46
 **2g**	 geiparvarin **5g**	>99	

a) The enol acetates were treated with DDQ (1.2—1.9 equiv). b) See the experimental part for each transformation.

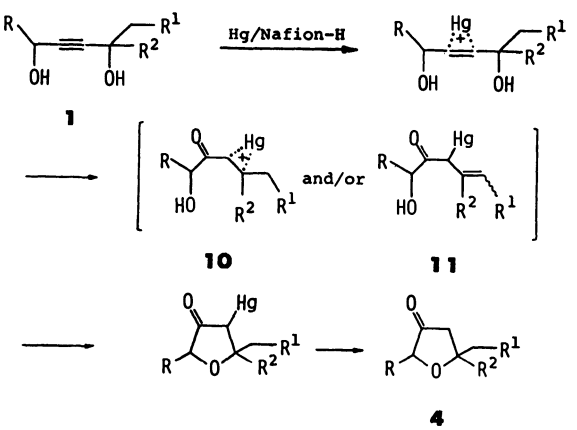
furanone isolated from blistered leaf myrtle (*Myrtus bllata*),[3b] a shrub endemic to New Zealand, in 81% overall yield from benzaldehyde. The dilithium salt of 2-methyl-3-butyn-2-ol was allowed to react with benzaldehyde in THF to give 4-methyl-1-phenyl-2-pentyne-1,4-diol (**1a**) (98% yield). The adduct **1a** was converted into the monoacetate **6a** (99% yield) which was then subjected to Ag(I)-catalyzed rearrangement and cyclization to yield the enol acetate **2a** (84% yield); finally oxidation of **2a** with DDQ afforded bullatenone **5a** in a quantitative yield.

Similarly, an antitumor 3(2*H*)-furanone, geiparvarin (**5g**)[3e-h] isolated from *Geijera parviflora*, was stereospecifically synthesized from (*E*)-4-(2-oxo-2*H*-chromen-7-yloxy)-2-methyl-2-butenal (**9**)[20] in 52% overall yield. Treatment of **9** with 2-methyl-3-butyn-2-ol dianion followed by acetylation gave the corresponding monoacetate **6g** (86% overall yield). The monoacetate **6g** was then treated with 15 mol% of silver perchlorate in refluxing benzene, giving rise to **2g** (61% yield), whose oxidation with DDQ yielded geiparvarin (**5g**) quantitatively. The spectral data (IR, ^{1}H-NMR) and mp were identical with those of the natural product.[3d-f] The absence of the (*Z*) isomer[9a,b] in the reaction product was ascertained by the ^{1}H-NMR spectra.

Hg/Nafion-H Catalyzed Transformation of Acetylenic Diols ***1*** *into 4,5-Dihydro-3(2*H*)-furanones of Type* ***4*** *(Method B).* In order to introduce an oxygen function at the position *b* in the formula **1** to obtain **4**, diols **1** were treated with the polymer reagent Hg/Nafion-H in the presence of 5 equiv of water in ethanol at 25 °C for several hours; results are summarized in Table 3. Apparently, introduction of the oxygen function into **1** takes place at the acetylenic carbon of less steric hindrance.[21] Although the selectivity in **1a**, **1b**, and **1d** (secondary *vs.* tertiary hydroxyl) was moderate (4 : 1 to 1 : 1), the preference of the primary hydroxyl group over the tertiary one was excellent. This is exemplified in the reaction of **1c** and **1i—n**.

In order to gain an insight into the reaction mechanism, the propargyl alcohol adducts of 2-methylcyclohexanone were prepared. Cyclization of the 3 : 2 mixture of the diastereomers[1] **1j** and **1j'** gave the dihydro-3(2*H*)-furanones **4j** and **4j'** as a 40 : 60 diastereomeric mixture. The separately isolated **1j** or **1j'** also produced a 48 : 52 or 45 : 55 mixture of **4j** and **4j'**; the ratio being very similar irrespective of the stereochemistry of the diol (**1j** or **1j'**). The hypothetical mechanism of Scheme 5 explains the results. The Hg(II)-catalyzed hydration and elimination of the hydroxyl group lead to **10** and/or **11** and final cyclization produces the desired dihydro-3(2*H*)-furanones **4**.

Although the Hg/Nafion-H catalyzed formation of **4** is extremely efficient, a side reaction sometimes competes with the transformation of **1m**[22] into **4m** particularly.



Scheme 5.

a) Isolated yields refer to fully characterized compounds produced from the diols **1** on treatment with Hg/Nafion-H. b) (*E*)-4-Hydroxy-4-methyl-1-phenyl-1-penten-3-one (**12a**) was produced (11% yield) as a by-product. c) The diastereomeric ratio of **4j** to **4j'**. d) The transformation was carried out at 60 °C in a 1 : 1 mixture of hexane–ethanol. 3-Cycloheptylidene-1-hydroxy-2-propanone (**12k**) was produced (13% yield) along with **4k**. e) A by-product, 3-cyclooctylidene-1-hydroxy-2-propanone (**12l**) was formed in 23% yield. f) 3-Cyclododecylidene 1-hydroxy-2-propanone (**12m**) was produced (10% yield) along with **4m**. g) The reaction was carried out at 50 °C, **12m** being produced in 3% yield. h) The transformation was carried out at 0—10 °C. The yield of **12m** was 22% i) 4-Ethyl-1-hydroxy-3-nonen-2-one (**12n**) was formed(30% yield) as a by-product. *j*) 1-Ethoxy-4-hydroxy-3-decanone (**12o**) was produced (15% yield) along with **4o**. k) Using the recoverd polymer regent, **1p** was converted into **4p** in 82% yield.

A by-product, 3-cyclododecylidene-1-hydroxy-2-propanone (**12m**), was produced in 10% yield which was slowly converted into **4m** under the reaction conditions. Formation of **12m** was temperature-dependent; at 50 °C only 3%; at 0—10 °C as much as 22% yield, whereas the yield of **4m** remained almost constant. In any event, the procedure is applicable to the synthesis of dihydrofuranones of type **4**.

As is usual with polymer reagent, the experimental procedure for Hg/Nafion-H mediated transformation is very simple. Workup involves only removal of the catalyst by filtration and concentration of the filtrates. The polymer reagent could be recovered easily by washing with dichloromethane and drying, and reused: For example, the diol **1p** was converted into **4p** repeatedly (first run, 90% yield, and second run with the recovered reagent, 82% yield). The present Hg/Nafion-H catalyzed transformation proceeded under milder conditions (25 °C) with higher selectivity than the previous methods.[11,12] Whereas the diol **1b** gives a 1 : 1 mixture of 3-furanones **3b** and **4b** with a conventional catalyst, HgO,[12d] in ether-aqueous sulfuric acid, the transformation with Hg/Nafion-H preferred **4b** formation (**3b** : **4b** 1 : 2).

Experimental

Distillation was carried out by use of Kugelrohr (Büchi) and boiling points were determined by measuring the bath temperature. All mp and bp are not corrected. ^{1}H-NMR spectra (tetramethylsilane as an internal standard) were obtained on a Varian EM 390 spectrometer, chemical shifts being given in ppm units, IR spectra of neat liquid film samples (unless otherwise noted) on a Shimadzu IR-27G spectrometer, MS on a Hitachi RMU-6L spectrometer, and exact mass on a Hitachi M 80 spectrometer. Gas-liquid phase chromatography (GLC) analyses were performed with a Yanagimoto

GCG-550F chromatograph, and preparative GLC with a JEOL-JGC-20K chromatograph. Preparative TLC plates (20 cm×20 cm) were prepared with Merck Kiesel-gel PF_{254}. Column chromatography was carried out with silica gel (Wakogel C-100) at atmospheric pressure. Propargyl alcohol and 2-methyl-3-butyn-2-ol were distilled before use. 3-Butyn-2-ol (Tokyo Kasei-Kogyo Co. or Nakarai Chemicals Ltd., 55% aqueous solution) was used.

*Preparation of 4-Methyl-1-phenyl-2-pentyne-1,4-diol (**1a**) (A Typical Procedure).* A hexane solution of butyllithium (1.53 M,† 19.6 ml, 30.0 mmol) was added at −78 °C under an argon atmosphere to a THF (150 ml) solution of 2-methyl-3-butyn-2-ol (1.26 g, 15.0 mmol). The reaction mixture was stirred for 2 h at −78 °C. To this solution a THF (4 ml) solution of benzaldehyde (1.06 g, 10.0 mmol) was added at −65 °C. The whole was stirred for 6 h and allowed to warm to 25 °C. The resulting solution was then poured into water (50 ml) and extracted with ethyl acetate. The extracts were dried with anhydrous sodium sulfate and concentrated to yield a crude product. Purification of the residue by column chromatography (hexane–ethyl acetate 1 : 1) gave the diol **1a**[19a] (1.87 g, 98% yield) having ^{1}H-NMR (CCl_4): δ=1.43 (s, 6H), 4.13 (br s, 1H), 5.34 (s, 1H), 7.1—7.6 (m, 5H); IR (CCl_4): 3330, 1162, 942 cm^{-1}; MS: *m/e* 190 (M^+).

In general, experiments of no less than 10 mmol scale are preferable in order to secure high yields of the adducts **1**. This procedure applies to the synthesis of **1b**, **1c**, **1e**, **1h**, **1i**, **1k**, **1l**, **1n**, and **1o**. The yields and spectral properties are summarized below.

*2-Methyl-3-hexyne-2,5-diol (**1b**).*[23] Yield 95%. Bp 132—140 °C (bath temp)/3.0 Torr;** ^{1}H-NMR (CCl_4): δ=1.41 (d, J=6.8 Hz, 3H), 1.49 (s, 6H), 4.4—4.7 (m, 3H); IR: 3320, 1165 cm^{-1}; MS: *m/e* 113 (M^+-CH_3).

*1-(3-Hydroxy-1-propynyl)cyclohexanol (**1c**).*[24] Yield 88%. ^{1}H-NMR (CCl_4): δ=1.0—2.2 (m, 10H), 4.33 (s, 2H), 4.56 (br s, 2H); IR: 3330, 1073 cm^{-1}; MS: *m/e* 154 (M^+).

*2-Methyl-6-octen-3-yne-2,5-diol (**1e**).*[25] Yield 90%. ^{1}H-NMR (CCl_4): δ=1.49 (s, 6H), 1.74 (d, J=6.0 Hz, 3H), 4.28 br s, 2H), 4.79 (d, J=5.3 Hz, 1H), 5.57 (dd, J=15.2, 5.3 Hz, 1H), 5.78 (dq, J=15.2, 6.0 Hz, 1H); IR: 3340, 1164, 963, 944 cm^{-1}; MS: *m/e* 139 (M^+-CH_3).

*1-(3-Hydroxy-3-methyl-1-butynyl)cyclohexanol (**1h**).*[5a,26] Yield 84%. Mp 95.0—96.0 °C (methanol); ^{1}H-NMR (CCl_4): δ=1.0—2.1 (m+s (δ=1.53), 16H), 4.10 (br s, 2H); IR (Nujol): 3250, 1460, 1080, 950 cm^{-1}; MS: *m/e* 182 (M^+).

*Bis(1-hydroxycyclohexyl)acetylene (**1i**).*[27] This product was prepared from cyclohexanone and 1-ethynylcyclohexanol (51% yield, 99% yield based on consumed 1-ethynylcyclohexanol). ^{1}H-NMR ($CDCl_3$): δ=0.9—2.2 (m, 20H), 2.27 (br s, 2H); IR (Nujol): 3350, 1070 cm^{-1}; MS: *m/e* 222 (M^+).

*1-(3-Hydroxy-1-propynyl)cycloheptanol (**1k**).* Yield 79%. Bp 131—132 °C (bath temp)/0.15 Torr; ^{1}H-NMR (CCl_4): δ=1.2—2.2 (m, 12H), 4.27 (br s, 2H), 4.37 (s, 2H); IR: 3340, 1461, 1445, 1026 cm^{-1}; MS: *m/e* (rel intensity) 168 (M^+, 4), 150(11), 111(71), 65(75), 55(100), 40(93). Found: C, 71.15; H, 9.80%. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%.

*1-(3-Hydroxy-1-propynyl)cyclooctanol (**1l**).* Yield 54%. Bp 153—154 °C (bath temp)/0.10 Torr; ^{1}H-NMR ($CDCl_4$): δ=1.1—2.1 (m, 14H), 4.26 (s, 2H), 4.46 (br s, 2H); IR: 3340, 1447, 1040, 1014 cm^{-1}; MS: *m/e* (rel intensity) 182 (M^+, trace), 164(7), 111(46), 93(48), 79(50), 65(57), 55(100), 41(99). Found: *m/e* 164.1226. Calcd for $C_{11}H_{16}O$: M^+-H_2O, 164.1201

*4-Ethyl-2-nonyne-1,4-diol (**1n**).* Yield 81%. Bp 109—110 °C (bath temp)/0.13 Torr; ^{1}H-NMR (CCl_4): δ=0.9—2.0 (m+t (δ=0.97, J=6.6 Hz)+t (δ=1.01, J=7.5 Hz), 16H), 3.30 (br s, 1H), 3.55 (br s, 1H), 4.26 (s, 2H); IR: 3350, 1465, 1011 cm^{-1}; MS: *m/e* (rel intensity) 155 ($M^+-C_2H_5$, 37), 113 (100), 67 (89), 43 (82). Found: C, 71.67; H, 11.13%. Calcd for $C_{11}H_{20}O_2$: C, 71.70; H, 10.94%.

*2-Decyne-1,4-diol (**1o**).*[28] Yield 77%. ^{1}H-NMR (CCl_4): δ=0.7—1.9 (m, 13H), 4.1—4.8 (m, 5H); IR: 3310, 1017 cm^{-1}; MS: *m/e* 170 (M^+).

*1-(3-Hydroxy-1-butynyl)cyclohexanol (**1d**).* Potassium hydroxide (3.36 g, 60.0 mmol) was dissolved in a 55% aqueous solution of 3-butyn-2-ol (2.86 g, 22.5 mmol) and the resulting mixture was stirred at 40 °C for 10 min. To this solution cyclohexanone (1.47 g, 15.0 mmol) dissolved in THF (3 ml) was added drop by drop during 2 h at 25 °C. The whole was stirred for 26 h at 40 °C, then diluted with ether (20 ml) and cold water (10 ml). Extractive workup with ether gave an oil (3.05 g). Purification of the crude adduct by column chromatography (hexane-ethyl acetate 2 : 1 to 1 : 1) afforded the diol **1d**[23] (2.27 g, 90% yield). ^{1}H-NMR (CCl_4): δ=1.0—2.1 (m+d (δ=1.43, J=6.9 Hz), 13H), 4.01 (br s, 2H), 4.53 (q, J=6.9 Hz, 1H); IR: 3330, 1072 cm^{-1}; MS: *m/e* 168 (M^+).

*Transformation of the Diols **1** into the Enol Acetates **2**.*

*Preparation of 3-Acetoxy-2,2-dimethyl-5-phenyl-2,5-dihydrofuran (**2a**) (A Typical Procedure):* A dichloromethane (0.25 ml) solution of **1a** (0.21 g, 1.1 mmol) was treated with acetic anhydride (0.5 ml) and pyridine (0.05 ml) at 25 °C. As soon as the starting diol was consumed (1.5 h), all the volatile materials were evaporated. Purification of the residue by column chromatography (hexane–ethyl acetate 10 : 1 to 2 : 1) gave 5-acetoxy-2-methyl-5-phenyl-3-pentyn-2-ol (**6a**) (0.25 g, 99% yield) having ^{1}H-NMR (CCl_4): δ=1.51 (s, 6H), 2.03 (s, 3H), 2.96 (br s, 1H), 6.41 (s, 1H), 7.2—7.6 (m, 5H); IR: 3400, 1740, 1220 cm^{-1}; MS: *m/e* (rel intensity) 232 (M^+, trace), 190 (4), 189(4), 172(33), 129(31), 43(100).

A benzene (1 ml) solution of **6a** (77 mg, 0.33 mmol) was heated at 80 °C in the presence of silver perchlorate (4 mg, *ca.* 5 mol%) for 10 h in the dark under an argon atmosphere. The reaction mixture was then diluted with dichloromethane (10 ml) at 25 °C and washed with 10% aqueous ammonia (3 ml) and sat. aqueous sodium chloride solution (3 ml). Concentration of the organic phase gave the crude product which was purified by column chromatography (hexane–ethyl acetate 10 : 1) to afford **2a** (65 mg, 84% yield). Bp 122—124 °C (bath temp)/ 0.04 Torr; ^{1}H-NMR (CCl_4): δ=1.36 (s, 3H), 1.38 (s, 3H), 2.17 (s, 3H), 5.70 (d, J=1.5 Hz, 1H), 5.81 (d, J=1.5 Hz, 1H), 7.26 (br s, 5H); IR: 1781, 1698, 1658, 1207, 1193, 1050 cm^{-1}; MS: *m/e* (rel intensity) 232 (M^+, 2), 217(2), 190(34), 189(19), 105(41), 102(27), 77(32), 43(100). Found: C, 72.48; H, 6.84%. Calcd for $C_{14}H_{16}O_3$: C, 72.39; H, 6.94%.

This procedure applies to the synthesis of **6b—e**, **2b**, and **2d—g**, whose physical properties are summarized below.

*5-Acetoxy-2-methyl-3-hexyn-2-ol (**6b**) and 3-Acetoxy-2,2,5-trimethyl-2,5-dihydrofuran (**2b**):* The monoacetate **6b** showed ^{1}H-NMR (CCl_4): δ=1.43 (d, J=6.8 Hz, 3H), 1.44 (s, 6H), 2.01 (s, 3H), 2.66 (br s, 1H), 5.33 (q, J=6.8 Hz, 1H); IR: 3425, 1740, 1230 cm^{-1}; MS: *m/e* (rel intensity) 196 (M^+, trace), 144(3), 118(7), 99(20), 84(39), 56 (28), 43(100). The Bp of **2b**: 101—102 °C (bath temp)/18 Torr; ^{1}H-NMR (CCl_4): δ=1.22 (s, 3H), 1.23 (d, J=6.0 Hz, 3H), 1.27 (s, 3H), 2.14 (s, 3H), 4.83 (dq, J=1.7, 6.0 Hz, 1H), 5.66 (d, J=1.7 Hz, 1H); IR: 1782, 1760, 1660, 1204, 1033 cm^{-1}; MS: *m/e* (rel intensity) 170 (M^+, trace), 155(6), 128(9), 126(13), 113(30), 68(23), 43(1000). Found: C, 63.62; H, 8.46%. Calcd for $C_9H_{14}O_3$: C, 63.51; H, 8.29%.

*1-(3-Acetoxy-1-propynyl)cyclohexanol (**6c**) and 4-Acetoxy-1-oxaspiro[4.5]dec-3-ene (**2c**):* ^{1}H-NMR (CCl_4) of **6c**: δ=1.0—2.0 (m, 10H), 2.06 (s, 3H), 2.30 (br s, 1H), 4.64 (s, 2H); IR:

† 1 M=1 mol dm^{-3}.

** 1 Torr=133.322 Pa.

3420, 1747, 1229 cm^{-1}; MS: *m/e* (rel intensity) 196 (M^+, 1), 154(19), 153(22), 139(48), 111(52), 43(100). Silver tetrafluoroborate (10 mol%) was used instead of silver perchlorate for the transformation of **6c** into **2c** having bp 122—125 °C (bath temp)/0.04 Torr; ^{1}H-NMR (CCl_4): δ=1.4—1.9 (m, 10H), 2.13 (s, 3H), 4.54 (d, J=1.7 Hz, 5.73 (t, J=1.7 Hz, 1H); IR: 1780, 1757 (sh), 1658, 1194 cm^{-1}; MS: *m/e* (rel intensity) 196 (M^+, 3), 168(8), 153(12), 111(28). 97(17), 81(12), 69(13), 55(27), 43(100). Found: C, 67.60; H, 8.33%. Calcd for $C_{11}H_{16}O_3$: C, 67.32; H, 8.22%.

*1-(3-Acetoxy-1-butynyl)cyclohexanol (**6d**) and 4-Acetoxy-2-methyl-1-oxaspiro[4.5]dec-3-ene (**2d**)*: The monoacetate **6d** showed ^{1}H-NMR (CCl_4): δ=1.1—2.0 (m+d (δ=1.45, J=6.9 Hz), 14H), 2.03 (s, 3H), 5.41 (q, J=6.9 Hz, 1H); IR: 3425, 1740, 1235 cm^{-1}; MS: *m/e* (rel intensity) 168 ($M^+-C_2H_2O$, 15), 107(30), 80(58), 43(100). The bp of **2d**: 92 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ=1.22 (d, J=6.3 Hz, 3H), 1.2—1.9 (m, 10H), 2.10 (s, 3H), 4.73 (dq, J=1.5, 6.3 Hz, 1H), 5.60 (d, J=1.5 Hz, 1H); IR: 1784, 1758, 1659, 1198 cm^{-1}; MS: *m/e* (rel intensity) 210 (M^+, 4), 168(16), 153(24), 125(42), 111(51), 69(22), 55(25), 43(100). *5-Acetoxy-2-methyl-6-octen-3-yn-2-ol (**6e**) and 3-Acetoxy-2,2-dimethyl-5-[(E)-1-propenyl]-2,5-dihydrofuran (**2e**)*: ^{1}H-NMR (CCl_4) of **6e**: δ=1.48 (s, 6H), 1.77 (d, J=6.8 Hz, 3H), 2.04 (s, 3H), 2.17 (br s, 1H), 5.66 (dd, J=15.3, 6.5 Hz, 1H), 5.84 (d, J=6.5 Hz, 1H), 6.03 (dq, J=15.3, 6.8 Hz, 1H); IR: 3430, 1738, 1224 cm^{-1}; MS: *m/e* (rel intensity) 196 (M^+, trace), 136(39), 121(47), 77(45), 43(100). The enol acetate **2e** showed bp 117—118 °C (bath temp)/0.04 Torr; ^{1}H-NMR (CCl_4): δ=1.25 (s, 3H), 1.28 (s, 3H), 1.69 (d, J=5.3 Hz, 3H), 2.14 (s, 3H), 5.02 (dd, J=1.5, 5.9 Hz, 1H), 5.52 (dd, J=5.9, 15.0 Hz, 1H), 5.61 (d, J=1.5 Hz, 1H), 5.62 (dq, J=15.0, 5.3 Hz, 1H); IR: 1781, 1761 (sh), 1656, 1200, 1041, 963 cm^{-1}; MS: *m/e* (rel intensity) 154 (M^+, 30), 139(42), 113(12), 111(18) 69(26), 43(100). Found: C, 67.40; H, 8.42%. Calcd for $C_{11}H_{16}O_3$: C, 67.32; H, 8.22%.

*Preparation of (E)-5-Acetoxy-2,6-dimethyl-8-(4-methoxyphenoxy)-6-octen-3-yn-2-ol (**6f**)*: Under an argon atmosphere a THF (8 ml) solution of 4-methoxyphenol (**13**) (1.30 g, 10.5 mmol) was added to sodium hydride (50% in oil, 0.50 g, 10.5 mmol) in THF (15 ml) at 25 °C in 10 min. After stirring for 30 min ethyl 4-bromotiglate (2.07 g, 10.0 mmol) dissolved in THF (3 ml) was added to the reaction mixture . The whole was stirred for 4.5 h at reflux temperature. Workup followed by column chromatography (hexane–ethyl acetate 5 : 1 to 2 : 1) gave ethyl (*E*)-4-(4-methoxyphenoxy)-2-methyl-2-butenoate (**14**) (1.61 g, 51% yield; 97% yield based on the consumed phenol **13**). ^{1}H-NMR (CCl_4): δ=1.30 (t, J=7.2 Hz, 3H), 1.88 (s, 3H), 3.74 (s, 3H), 4.20 (q, J=7.2 Hz, 2H), 4.62 (d, J=6.2 Hz, 2H), 6.7—7.0 (m, 5H); IR: 1712, 1658, 1593, 1510, 1233, 1134, 1039, 826 cm^{-1}; MS: *m/e* (rel intensity) 250 (M^+, 18), 177(9), 133(9), 124(100), 123(71), 109(26), 99(18), 95(13), 43(24). Found: *m/e* 250.1219. Calcd for $C_{14}H_{18}O_4$: M^+, 250.1205.

An ether (10 ml) solution of **14** (1.28 g, 5.1 mmol) was added at 0 °C to an ether (20 ml) suspension of lithium aluminum hydride (0.18 g, 4.6 mmol). After stirring for 5 min at 0 °C, extractive workup gave (*E*)-4-(4-methoxyphenoxy)-2-methyl-2-buten-1-ol (**15**) (0.90 g, 85% yield) having ^{1}H-NMR ($CDCl_3$): δ=1.73 (s, 3H), 3.67 (br s, 1H), 3.75 (s, 3H), 4.05 (s, 2H), 4.50 (d, J=7.2 Hz, 2H), 5.75 (t, J=7.2 Hz, 1H), 6.80 (s, 4H).

A dichloromethane (10 ml) solution of the crude alcohol **15** (0.86 g, 4.1 mmol) was added to pyridinium chlorochoromate (1.34 g, 6.2 mmol) and sodium acetate (0.10 g, 1.2 mmol) in dichloromethane (10 ml) at 0 °C. The reaction mixture was stirred for 2 h at 0—25 °C, and then diluted with ether (50 ml). The resulting solution was filtered through silica gel and celite. Concentration of the filtrate gave (*E*)-4-(4-methoxyphenoxy)-2-methyl-2-butenal (**16**) (0.58 g, 70% yield), ^{1}H-NMR (CCl_4): δ=1.82 (s, 3H), 3.77 (s, 3H), 4.81 (d, J=3.6 Hz, 2H), 6.65 (t, J=3.6 Hz, 1H), 6.82 (s, 4H), 9.54 (s, 1H). The crude aldehyde **16** was subjected to the next transformation without further purification.

A hexane solution of butyllithium (1.57 M, 5.3 ml, 8.3 mmol) was added at −78 °C to 2-methyl-3-butyn-2-ol (0.35 g, 4.2 mmol) in THF (55 ml). The mixture was stirred for 2 h. To this solution was added a THF (5 ml) solution of **16** (0.57 g, 2.8 mmol) at −50 °C. The resulting solution was stirred for 4 h and allowed to warm to 25 °C. Water (30 ml) and ethyl acetate (30 ml) were then added. Extraction with ethyl acetate and concentration of the extracts gave (*E*)-2,6-dimethyl-8-(4-methoxyphenoxy)-6-octen-3-yne-2,5-diol (**1f**) (0.82 g) having ^{1}H-NMR (CCl_4): δ=1.50 (s, 6H), 1.78 (s, 3H), 3.50 (br s, 2H), 3.70 (s, 3H), 4.46 (d, J=6.0 Hz, 2H), 4.70 (s, 1H), 5.84 (t, J=6.0 Hz, 1H), 6.71 (s, 4H).

The crude adduct **1f** (0.81 g, 2.8 mmol) in dichloromethane (0.5 ml) was treated with acetic anhydride (1.5 ml) and pyridine (0.15 ml) for 1.6 h at 25 °C. Purification of the concentrated residue (0.89 g) by column chromatography (hexane–ethyl acetate 5 : 1 to 2 : 1) gave **6f** (0.74 g, 81% yield from **16**). Bp 168—170 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ=1.48 (s, 6H), 1.79 (s, 3H), 2.06 (s, 3H), 2.66 (br s, 1H), 3.73 (s, 3H), 4.50 (d, J=6.0 Hz, 2H), 5.78 (s, 1H), 5.93 (t, J=6.0 Hz, 1H), 6.75 (s, 4H); IR: 3450, 1739, 1510, 1224, 1037, 1015 cm^{-1}; MS: *m/e* (rel intensity) 332 (M^+, 1), 314(1), 272(1), 191(6), 149(19), 124(57), 109(26), 43(100). Found: C, 68.93; H, 7.21%. Calcd for $C_{19}H_{24}O_5$: C, 68.65; H, 7.28%.

*3-Acetoxy-2,2-dimethyl-5-[(E)-3-(4-methoxyphenoxy)-1-methyl-1-propenyl]-2,5-dihydrofuran (**2f**)*: Bp 160—162 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ=1.27 (s, 3H), 1.30 (s, 3H), 1.67 (s, 3H), 2.15 (s, 3H), 3.71 (s, 3H), 4.49 (d, J=6.0 Hz, 2H), 5.11 (br s, 1H), 5.63 (d, J=1.5 Hz, 1H), 5.70 (t, J=6.0 Hz), 6.73 (s, 4H); IR: 1778, 1657, 1592, 1509, 1230, 1205, 1040, 1013 cm^{-1}; MS: *m/e* (rel intensity) 332 (M^+, 1), 209(6), 167(91), 124(100), 113(45), 78(97), 52(25), 43(72). Found: C, 68.80; H, 7.25%. Calcd for $C_{19}H_{24}O_5$: C, 68.65; H, 7.28%. The double bond in the appendage was supposed to have the (*E*) configuration on analogy of the results of **2e**, **2g**, and **5g**.

*(E)-5-Acetoxy-2,6-dimethyl-8-(2-oxo-2H-chromen-7-yloxy)-6-octen-3-yn-2-ol (**6g**)*: A hexane solution of butyllithium (1.67 M, 18.0 ml, 30.0 mmol) was added at −78 °C to 2-methyl-3-butyn-2-ol (1.3 g, 15.0 mmol) in THF (120 ml). After stirring for 3 h (*E*)-4-(2-oxo-2*H*-chromen-7-yloxy)-2-methyl-2-butenal (**9**)[20] (2.4 g, 10.0 mmol) dissolved in THF (5 ml) was added at −78 °C. The reaction mixture was stirred for 3 h, being warmed to −20 °C and treated with methanol (30 ml) and water (20 ml). Extractive workup gave the crude adduct **1g** (3.06 g), whose dichloromethane (3 ml) solution was stirred with acetic anhydride (1.9 ml) and pyridine (4.0 ml) for 3 h at 20 °C and then concentrated. Purification of the residue by column chromatography (hexane–ethyl acetate 1 : 1) gave **6g** (3.2 g, 86% yield from **9**). Bp 205—210 °C (bath temp)/0.02 Torr; ^{1}H-NMR ($CDCl_3$): δ=1.50 (s, 6H), 1.84 (s, 3H), 2.09 (s, 3H), 4.63 (d, J=6.0 Hz, 2H), 5.84 (s, 1H), 5.93 (t, J=6.0 Hz, 1H), 6.25 (d, J=9.3 Hz, 1H), 6.7—6.9 (m, 2H), 7.34 (d, J=5.8 Hz, 1H), 7.61 (d, J=9.3 Hz, 1H); IR: 3435, 1734, 1613, 1225, 1123 cm^{-1}. Found: C, 68.13; H, 6.03%. Calcd for $C_{21}H_{22}O_6$: C, 68.09; H, 5.99%.

*3-Acetoxy-5-[(E)-3-(2-oxo-2H-chromen-7-yloxy)-1-methyl-1-propenyl]-2,2-dimethyl-2,5-dihydrofuran (**2g**)*: Bp 180—183 °C

(bath temp)/0.05 Torr; ^{1}H-NMR ($CDCl_3$): δ=1.35 (s, 3H), 1.38 (s, 3H), 1.74 (s, 3H), 2.21 (s, 3H), 4.66 (d, J=6.0 Hz, 2H) 5.23 (br s, 1H), 5.69 (d, J=1.5 Hz, 1H), 5.83 (t, J=6.0 Hz, 1H), 6.25 (d, J=9.6 Hz, 1H), 6.8—7.0 (m, 2H), 7.3—7.5 (m, 1H), 7.68 (d, J=9.6 Hz, 1H); IR (CCl_4): 1780, 1745, 1615, 1196, 1121 cm^{-1}; MS: *m/e* (rel intensity) 370 (M^+, trace), 343 (1), 326(1), 167(15), 162(8), 59(23), 55(18), 43(100). Found: C, 68.29; H, 5.75%. Calcd for $C_{21}H_{22}O_6$: C, 68.09; H, 5.99%.

Transformation of **2a** *into 2,2-Dimethyl-5-phenyl-4,5-dihydro-3(2H)-furanone (***3a***).* The enol acetate **2a** (33 mg, 0.14 mmol) was treated with a methanol solution of sodium methoxide (0.01 M, 1 ml, 0.01 mmol) at 25 °C for 40 min. Workup followed by column chromatography (hexane–ethyl acetate 10 : 1) gave **3a**[13q,29] (25 mg, 90% yield). ^{1}H-NMR (CCl_4): δ=1.27 (s, 3H), 1.34 (s, 3H), 2.39 (dd, J=10.4, 18.0 Hz, 1H), 2.79 (dd, J=6.3, 18.0 Hz, 1H), 5.15 (dd, J=6.3, 10.4 Hz, 1H), 7.2—7.5 (m, 5H); IR: 1752, 1171, 1010, 693 cm^{-1}; MS: *m/e* 190 (M^+).

Oxidation of the Enol Acetates **2** *to 3(2H)-Furanones* **5**.

(1) Bromination-dehydrobromination of **2a** *(A Typical Procedure)*: A chloroform solution of bromine (0.5 M, 1.4 ml, 0.69 mmol) was added at −20 °C in 10 min to **2a** (0.16 g, 0.69 mmol) dissolved in chloroform (0.5 ml). The reaction mixture was stirred for 30 min and allowed to warm up to 25 °C. Concentration of the resulting solution afforded crude 4-bromo-2,2-dimethyl-5-phenyl-4,5-dihydro-3(2*H*)-furanone (**8a**) (*ca.* 0.19 g) having ^{1}H-NMR (CCl_4): δ=1.35 (s, 3H), 1.64 (s, 3H), 4.38 (d, J=3.6 Hz, 1H), 5.25 (d, J=3.6 Hz, 1H), 7.43 (s, 5H); IR: 1725, 1172, 1110 cm^{-1}.

The bromide **8a** (*ca.* 0.19 g) dissolved in DMF (1 ml) was treated with lithium carbonate (0.23 g, 3.5 mmol) at 120 °C for 40 min. Workup followed by column chromatography (hexane–ethyl acetate 10 : 1) gave bullatenone (**5a**) (0.11 g, 85% yield from **2a**). Mp 67.5—68.0 °C (hexane); ^{1}H-NMR (CCl_4): δ=1.43 (s, 6H), 5.89 (s, 1H), 7.3—7.6 (m, 3H), 7.7—7.9 (m, 2H); IR (CCl_4): 1702, 1608, 1594, 1568, 1162 cm^{-1}; MS: *m/e* (rel intensity) 188 (M^+, 22), 102 (100). The spectral data (IR, ^{1}H-NMR) and mp were identical with the recorded ones.[10f,10g,19]

*2,2-Dimethyl-5-[(E)-1-propenyl]-3(2H)-furanone (***5e***).* According to the method described above **2e** (0.31 g, 1.6 mmol) was transformed into the corresponding bromide which was treated with lithium chloride (0.20 g, 4.8 mmol) and lithium carbonate (0.35 g, 4.8 mmol) in HMPA (2 ml) at 80 °C for 11 h. Workup and purification by column chromatography (hexane–ethyl acetate 5 : 1) gave **5e** (0.16 g, 66% overall yield). Bp 120—122 °C (bath temp)/0.04 Torr; ^{1}H-NMR (CCl_4): δ=1.33 (s, 6H), 1.96 (d, J=6.8 Hz, 3H), 5.29 (s, 1H), 6.23 (d, J=15.8 Hz, 1H), 6.74 (dq, J=15.8, 6.8 Hz, 1H); IR: 1700, 1651, 1565, 1382, 1177, 984, 964 cm^{-1}; MS: *m/e* (rel intensity) 152 (M^+, 23), 137(8), 94(11), 66(100). Found: C, 71.32; H, 8.09%. Calcd for $C_9H_{12}O_2$: C, 71.02; H, 7.95%.

*2,2-Dimethyl-5-[(E)-3-(4-methoxyphenoxy)-1-methyl-1-propenyl]-3(2H)-furanone (***5f***).* According to the method for the transformation of **2e** into **5e**, the enol acetate **2f** was converted into **5f** (46% overall yield) having mp 77.5—78.0 °C (methanol); bp 165—168 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ 1.35 (s, 6H), 1.96 (s, 3H), 3.70 (s, 3H), 4.62 (d, J=6.0 Hz, 2H), 5.43 (s, 1H), 6.66 (t, J=6.0 Hz, 1H), 6.70 (s, 4H); IR (CCl_4): 1702, 1564, 1509, 1226, 1181, 1041 cm^{-1}; MS: *m/e* (rel intensity) 288 (M^+, 5), 200(9), 151(11), 124(18), 109(18), 79(45), 40(100). Found: C, 70.70; H, 7.09%. Calcd for $C_{17}H_{20}O_4$: C, 70.81; H, 6.99%. The double bond in the appendage was supposed to have the (*E*) configuration by comparison with the results of **5e** and **5g**.

(2) Oxidation of the Enol Acetate **2a** *with DDQ (A Typical Procedure)*: The enol acetate **2a** (0.11 g, 0.49 mmol) was treated with DDQ (0.16 g, 0.71 mmol) in benzene (1 ml) at 25 °C for 1.8 h. The reaction mixture was washed with sat. aqueous sodium sulfite solution. The aqueous layer was extracted with dichloromethane. Concentration of the combined organic layer followed by column chromatography of the residue (dichloromethane–ethyl acetate 20 : 1) gave **5a** (92 mg, 99% yield). This procedure applies to the synthesis of **2e—g**.

*5-[(E)-3-(2-oxo-2H-chromen-7-yloxy)-1-methyl-1-propenyl]-2,2-dimethyl-3(2H)-furanone, Geiparvarin (***5g***).* Mp 159.5—160.5 °C (colorless prisms from methanol); ^{1}H-NMR ($CDCl_3$): δ=1.39 (s, 6H), 2.01 (s, 3H), 4.82 (d, J=6.0 Hz, 2H), 5.57 (s, 1H), 6.22 (d, J=9.3 Hz, 1H), 6.6—7.0 (m+t (δ 6.73, J=6.0 Hz), 3H), 7.37 (d, J=8.7 Hz, 1H), 7.61 (d, J=9.3 Hz, 1H); IR ($CHCl_3$): 1727, 1696, 1615, 1561, 1278, 1171, 1158, 1123, 1017, 838 cm^{-1}; MS: *m/e* (rel intensity) 326 (M^+, trace), 249(11), 247(11), 149(19), 99(48), 83(63), 55(85), 43(100). The synthetic material showed more than 97% purity of the (*E*) isomer as evidenced by the ^{1}H-NMR spectrum consistent with the literature values.[3e-g,9b]

Hg/Nafion-H Catalyzed Transformation of Acetylenic Diols **1** *into 4,5-Dihydro-3(2H)-furanones of Type* **4** *(Method B, a Typical Procedure).* The polymer reagent Hg/Nafion-H[14] was prepared as follows. Nafion® 511 (20.4 g) was treated with 12% hydrochloric acid (25 ml) for 6 h and the resin was filtered and superficially washed with water. This procedure was repeated 5 times. Finally the resin was washed more thoroughly with water and dried at 85 °C for 10 h under *ca.* 1 Torr to give Nafion®-H, perfluorinated resin-sulfonic acid, which contained 0.94 mmol of $-SO_3H$ group per 1 g. The resin-sulfonic acid (20.4 g) was stirred in sat. aqueous mercury(II) acetate solution (25 ml) at 25 °C for 7 h. The resin was collected by filtration, washed with water, and dried at 25°C under 1 Torr for 1 d. Hg/Nafion-H thus prepared contained 0.38 mmol of Hg(II) per 1 g.

The diols **1** (1 mmol) in ethanol (1 ml) were treated with Hg/Nafion-H (*ca.* 0.5 g) in the presence of water (5 mmol) at 25 °C for several hours. The reaction mixture was filtered, and the catalyst was washed with dichloromethane. Concentration of the combined filtrates followed by purification gave the desired products.

*5,5-Dimethyl-2-phenyl-4,5-dihydro-3(2H)-furanone (***4a***).* The reaction of **1a** with Hg/Nafion-H afforded a 1 : 4 mixture of **3a** and **4a** (14% and 56% isolated yield respectively) along with a by-product, (*E*)-4-hydroxy-4-methyl-1-phenyl-1-penten-3-one (**12a**) (11% yield). Physical properties of **4a** are given. Bp 108—109 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ=1.40 (s, 3H), 1.55 (s, 3H), 2.35 (s, 2H), 4.82 (s, 1H), 7.2—7.5 (m, 5H); IR: 1758, 1182, 1056, 699 cm^{-1}; MS: *m/e* (rel intensity) 190 (M^+, 4), 162(11), 107(100), 105(35), 56(98). Found: C, 75.90; H, 7.59%. Calcd for $C_{12}H_{14}O_2$: C, 75.76; H, 7.42%. The enone **12a** showed bp 131—132 °C (bath temp)/0.14 Torr; ^{1}H-NMR (CCl_4): δ=1.40 (s, 6H), 3.64 (br s, 1H), 7.04 (d, J=15.6 Hz, 1H), 7.3—7.7 (m, 5H), 7.81 (d, J=15.6 Hz, 1H); IR: 3450, 1681, 1610, 1600, 1071, 973, 764 cm^{-1}; MS: *m/e* (rel intensity) 172 (M^+-H_2O, 2), 147(25), 132(32), 131(47), 104(34), 59(100). Found: C, 75.50; H, 7.51%. Calcd for $C_{12}H_{14}O_2$: C, 75.76; H, 7.42%.

*2,2,5-Trimethyl-4,5-dihydro-3(2H)-furanone (***3b***) and 2,5,5-Trimethyl-4,5-dihydro-3(2H)-furanone (***4b***).* A mixture of **3b**[12b] and **4b**[12b] (**3b** : **4b** being 1 : 2 based on ^{1}H-NMR) were produced in 80% yield. The mixture showed bp 135—140 °C (bath temp)/20 Torr; IR: 1759, 1371, 1195, 1098 cm^{-1}; MS: *m/e* 128 (M^+); ^{1}H-NMR (CCl_4) of **3b**: δ 1.13 (s, $C\underline{H}_3$–C–CH_3), 1.18 (s, CH_3–C–$C\underline{H}_3$), 1.29 (d, J=5.2 Hz, CH–$C\underline{H}_3$), 2.03 (dd, J=9.9, 17.4 Hz, $\underline{H}$–C–H), 2.49 (dd, J=6.0, 17.4 Hz,

H-C-H), 4.0—4.4 (m, CH-CH_3, 0.33H); ^{1}H-NMR (CCl_4) of **4b**: δ=1.25 (d, J=6.9 Hz, CH-CH_3), 1.31 (s, CH_3-C-CH_3), 1.40 (s, CH_3-C-CH_3), 2.25 (s, H-C-H), 3.91 (q, J=6.9 Hz, CH-CH_3, 0.67H).

*1-Oxaspiro[4.5]decan-3-one (**4c**).*[12a] ^{1}H-NMR (CCl_4): δ=1.1—2.0 (m, 10H), 2.24 (s, 2H), 3.94 (s, 2H), IR: 1760, 1184, 1064 cm^{-1}; MS: *m/e* 154 (M^+).

*2-Methyl-1-oxaspiro[4.5]decan-4-one (**3d**) and 2-Methyl-1-oxaspiro[4.5]decan-3-one (**4d**).* The ratio of **3d**[12g] to **4d**[12d] (1 : 1 to 1 : 2) was estimated by the examination of the ^{1}H-NMR spectrum of the mixture having IR: 1755, 1450, 1190, 1105, 1065 cm^{-1}; MS: *m/e* 168 (M^+); ^{1}H-NMR (CCl_4, *refers to **4d**): δ=1.0—2.0 (m+d (δ=1.22*, J=6.8 Hz)+d (δ=1.38, J=6.3 Hz), 13H), 2.05 (dd, J=10.2, 17.9 Hz), 2.20* (d, J=17.6 Hz), 2.32* (d, J=17.6 Hz), 2.50 (dd, J=6.0, 17.9 Hz), 3.88* (q, J=6.8 Hz, CH-CH_3, 0.69—0.50H), 4.23 (ddq, J=6.0, 10.2, 6.8 Hz, CH-CH_3, 0.31—0.50H).

*2,2-Dimethyl-1-oxaspiro[4.5]decan-4-one (**3h**) and 2,2-Dimethyl-1-oxaspiro[4.5]decan-3-one (**4h**).* The ratio of **3h**[5e] to **4h**[5e] was estimated by GLC (PEG 20 M, 10% on Celit 545, 2 m, 123 °C, N_2 carrier gas 0.5 kg/cm^2, FID detector) to be *ca.* 1 : 2, R_t being 5.7 min and 6.4 min respectively; each isomer could be isolated by preparative GLC (PEG 20 M, 30% on Celite 545, 3 m, 150 °C, He carrier gas 0.8 kg/cm^2, TCD detector; **3h** R_t 7.0 min; **4h**, R_t 8.5 min). The structure of regioisomers was established by the examination of the ^{1}H-NMR spectra in the presence of Eu(fod)$_3$. ^{1}H-NMR (CCl_4) of **3h**: δ=1.1—1.8 (m+s (δ=1.36), 16H), 2.39 (s, 2H); **4h**: δ=1.22 (s, 6H), 1.2—1.9 (m, 10H), 2.36 (s, 2H). The mixture showed IR: 1754, 1159, 990 cm^{-1}; MS: *m/e* 182 (M^+).

*7-Oxadispiro[5.1.5.2]pentadecan-14-one (**4i**).*[30] Bp 150—151 °C (bath temp)/8 Torr; ^{1}H-NMR (CCl_4): δ=1.0—2.2 (m, 20H), 2.38 (s, 2H); IR: 1750, 1451, 1064, 990 cm^{-1}; MS: *m/e* 222 (M^+).

*6-Methyl-1-oxaspiro[4.5]decan-3-one (**4j**) and (**4j'**).* A 3 : 2 diastereomeric mixture of **1j** and **1j'** (TLC, hexane–ethyl acetate 1 : 2, R_f 0.14 and 0.22 respectively)[1] was transformed into **4j** and **4j'**, which were separated by preparative TLC (hexane–ethyl acetate 5 : 1, double development) to give **4j** (R_f 0.35—0.45) and **4j'** (R_f 0.45—0.55). Physical properties of **4j** are given. Bp 111—112 °C (bath temp)/0.12 Torr; ^{1}H-NMR (CCl_4): δ=0.94 (d, J=6.9 Hz, 3H), 1.0—2.0 (m, 9H), 2.06 d, J=18.3 Hz, 1H), 2.35 (d, J=18.3 Hz, 1H), 3.92 (s, 2H); IR: 1761, 1184, 1067 cm^{-1}; MS: *m/e* (rel intensity) 168 (M^+, 41), 125(43), 111(100), 98(45), 67(42). Found: C, 71.41; H, 9.84%. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%. The isomer **4j'** showed bp 92—93 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ=0.97 (d, J=5.9 Hz, 3H), 1.0—2.0 (m, 9H), 2.06 (d, J=18.0 Hz, 1H), 2.51 (d, J=18.0 Hz, 1H), 3.90 (s, 2H); IR: 1760, 1188, 1066 cm^{-1}; MS: *m/e* (rel intensity) 168 (M^+, 38), 125(48), 111(100), 98(46), 67(46). Found: C, 71.25; H, 9.86%. Calcd for $C_{10}H_{16}O_2$: C, 71.39, H, 9.59%.

*1-Oxaspiro[4.6]undecan-3-one (**4k**).* Isolated by preparative TLC (hexane–ethyl acetate 2 : 1, R_f 0.60—0.75) along with 3-cycloheptylidene-1-hydroxy-2-propanone (**12k**) (R_f 0.40—0.50). The furanone **4k** showed bp 109 °C (bath temp)/0.15 Torr; ^{1}H-NMR (CCl_4): δ=1.2—2.1 (m, 12H), 2.24 (s, 2H), 3.88 (s, 2H); IR: 1760, 1462, 1447, 1066 cm^{-1}; MS: *m/e* (rel intensity) 168 (M^+, 16), 111(100), 98(44), 83(44), 67(47). Found: C, 71.26; H, 9.76%. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%. Bp of **12k**: 120—125 °C (bath temp)/0.20 Torr; ^{1}H-NMR (CCl_4): δ=1.3—2.0 (m, 8H), 2.42 (t, J=5.0 Hz, 2H), 2.95 (t, J=5.0 Hz, 2H), 3.05 (br s, 1H), 4.13 (s, 2H), 5.99 (s, 1H); IR: 3455, 1704, 1678, 1605, 1444, 1066 cm^{-1}; MS: *m/e* (rel intensity) 168 (M^+, 4), 137(76), 113(100), 95(67), 67(65), 55(80). Found *m/e* 168.1145. Calcd for $C_{10}H_{16}O_2$: M^+, 168.1149.

*1-Oxaspiro[4.7]dodecan-3-one (**4l**).* Isolated by preparative TLC (hexane–ethyl acetate 3 : 1, R_f 0.61—0.72) together with 3-cyclooctylidene-1-hydroxy-2-propanone (**12l**) (R_f 0.50—0.60). Physical properties of **4l** are given. Bp 110—112 °C (bath temp)/0.15 Torr; ^{1}H-NMR (CCl_4): δ=1.0—2.4 (m+s (δ=2.22), 16H), 3.89 s, 2H); IR: 1760, 1180, 1064 cm^{-1}; MS: *m/e* (rel intensity) 182 (M^+, 12), 111 (100), 98(63), 83(35), 55(40). Found: C, 72.42; H, 10.20%. Calcd for $C_{11}H_{18}O_2$: C, 72.49; H, 9.95%. The enone **12l** showed bp 102—103 °C (bath temp)/0.18 Torr; ^{1}H-NMR (CCl_4): δ=1.1—2.1 (m, 10H), 2.34 (t, J=6.0 Hz, 2H), 2.79 (t, J=6.0 Hz, 2H), 2.99 (br s, 1H), 4.10 (s, 2H), 6.02 (s, 1H); IR: 3450, 1682, 1607, 1449, 1050 cm^{-1}; MS: *m/e* (rel intensity) 182 (M^+, 4), 151(69), 81(100), 67(71), 55(83). Found: C, 72.26; H, 10.20%. Calcd for $C_{11}H_{18}O_2$: C, 72.49; H, 9.95%.

*1-Oxaspiro[4.11]hexadecan-3-one (**4m**).* Mp 81.5—82.0 °C (colorless needles from hexane); ^{1}H-NMR (CCl_4): δ=1.2—2.0 (m, 22H), 2.19 (s, 2H), 3.87 (s, 2H), IR ($CHCl_3$): 1763, 1471, 1448, 1180, 1062 cm^{-1}; MS: *m/e* (rel intensity) 238 (M^+, 8), 111 (100), 98(56), 55(48). Found: C, 75.64; H, 10.98%. Calcd for $C_{15}H_{26}O_2$: C, 75.58; H, 11.00%. The by-product was proved to be 3-cyclododecylidene-1-hydroxy-2-propanone (**12m**) having mp 43.0—44.0 °C (hexane); bp 136—138 °C (bath temp)/0.04 Torr; ^{1}H-NMR (CCl_4): δ=1.1—1.9 (m, 18H), 2.27 (t, J=6.8 Hz, 2H), 2.80 (t, J=6.8 Hz, 2H), 3.09 (br s, 1H), 4.61 (s, 2H), 6.07 (s, 1H); IR (CCl_4): 3455, 1687, 1614, 1063 cm^{-1}; MS: *m/e* (rel intensity) 238 (M^+, 3), 207(33), 83(56), 55(100). Found: C, 75.41; 11.13%. Calcd for $C_{15}H_{26}O_2$: C, 75.58; H, 11.00%.

*5-Ethyl-5-pentyl-4,5-dihydro-3(2H)-furanone (**4n**).* Bp 89 °C (bath temp)/0.13 Torr; ^{1}H-NMR (CCl_4): δ=0.6—1.9 (m, 16H), 2.24 (s, 2H), 3.89 (s, 2H); IR: 1761, 1465, 1185, 1067 cm^{-1}; MS: *m/e* (rel intensity) 155 ($M^+-C_2H_5$, 38), 113(100), 85(55), 57(72), 55(84). Found: *m/e* 155.1057. Calcd for $C_9H_{15}O_2$: $M^+-C_2H_5$, 155.1071. The by-product, (*E*)- and (*Z*)-4-ethyl-1-hydroxy-3-nonen-2-one (**12n**) showed bp 110 °C (bath temp)/0.08 Torr; ^{1}H-NMR (CCl_4): δ=0.7—2.0 (m, 12H), 2.22 (m, 2H), 2.63 (m, 2H), 3.07 (br s, 1H), 4.12 (s, 2H), 5.87 (s, 0.5H), 5.97 (s, 0.5H); IR: 3450, 1688, 1618, 1462, 1071, 1053 cm^{-1}; MS: *m/e* (rel intensity) 184 (M^+, trace), 153(73), 83(59), 69(59), 57(64), 55(50), 41(100). Found: C, 71.45; H, 11.19%. Calcd for $C_{11}H_{20}O_2$: C, 71.70; H, 10.94%.

*5-Hexyl-4,5-dihydro-3(2H)-furanone (**4o**).* Bp 120 °C (bath temp)/0.15 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.9 (m, 13H), 2.04 (dd, J=9.5, 17.7 Hz, 1H), 2.46 (dd, J=6.3, 17.7 Hz, 1H), 3.70 (d, J=17.3 Hz, 1H), 3.99 (d, J=17.3 Hz, 1H), 4.18 (m, 1H); IR: 1765, 1170, 1064 cm^{-1}; MS: *m/e* (rel intensity) 170 (M^+, 6), 140(34), 85(97), 57(100), 55(83), 43(77) Found: C, 70.30; H, 10.75%. Calcd for $C_{10}H_{18}O_2$: C, 70.55; H, 10.66%. The by-product was proved to be 1-ethoxy-4-hydroxy-3-decanone (**12o**) having bp 113—114 °C (bath temp)/0.09 Torr; ^{1}H-NMR (CCl_4): δ=0.7—2.0 (m+t (δ=1.15, J=7.1 Hz), 16H), 2.63 (t, J=6.3 Hz, 2H), 3.30 (br s, 1H), 3.45 (q, J=7.1 Hz, 2H), 3.65 (t, J=6.3 Hz, 2H), 4.04 (m, 1H); IR: 3480, 1712, 1115 cm^{-1}. Found: C, 66.88; H, 11.42%. Calcd for $C_{12}H_{24}O_3$: C, 66.63; H, 11.18%.

*2,2,5,5-Tetramethyl-4,5-dihydro-3(2H)-furanone (**4p**).* Using the recovered polymer reagent Hg/Nafion-H (200 mg), **1p** (91 mg, 0.64 mmol) was converted into **4p**[11] (74 mg, 82% yield) having ^{1}H-NMR (CCl_4): δ=1.20 (s, 6H), 1.33 (s, 6H), 2.37 (s, 2H); IR: 1757, 1369, 1153, 990 cm^{-1}; MS: *m/e* 142 (M^+).

New Methods for the Synthesis of 3(2*H*)-Furanones and 2(5*H*)-Furanones

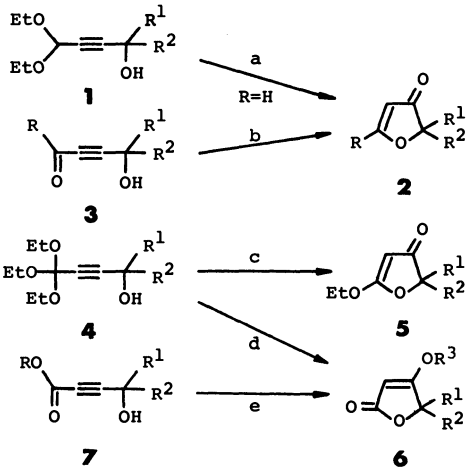
Hiroyuki Saimoto, Masaki Shinoda, Seijiro Matsubara, Koichiro Oshima, Tamejiro Hiyama,*,† and Hitosi Nozaki

Department of Industrial Chemistry, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606

(Received March 23, 1983)

New procedures for the synthesis of 3(2*H*)-furanones and 4-alkoxy-2(5*H*)-furanones are reported. Reaction of ketones with the lithium salt of propynal diethyl acetal, followed by treatment of the resulting 4-hydroxy-2-alkynal diethyl acetals with sulfuric acid–methanol, gave 2,2-disubstituted 3(2*H*)-furanones. The action of a polymer reagent Hg/Nafion-H upon 4-hydroxy-2-alkynones produced 2,2,5-trisubstituted 3(2*H*)-furanones. Reaction of 1,1,1-triethoxy-2-alkyn-4-ols (**4**) with trifluoroacetic acid and mercury(II) acetate provided 5-ethoxy-2,2-disubstituted 3(2*H*)-furanones. In contrast, the adducts **4** were converted into 4-alkoxy-5,5-disubstituted 2(5*H*)-furanones upon reaction with Hg/Nafion-H.

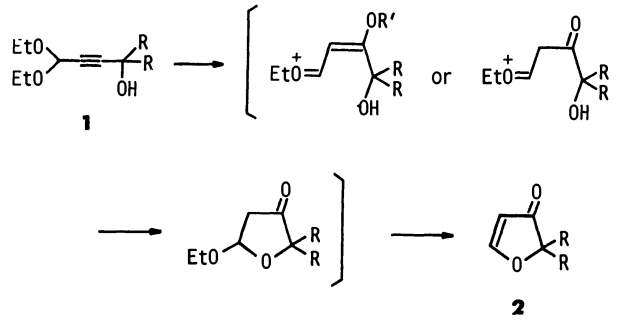
In the preceding paper we have reported new methods for regiocontrolled synthesis of 4,5-dihydro-3(2*H*)-furanones from 2-butyne-1,4-diol derivatives.[1] As the final step of the procedure was the oxidation to 3(2*H*)-furanones, it was anticipated that employing the derivatives of 2-butyne-1,4-diols with higher oxidation stage as the starting materials would lead to 3(2*H*)-furanones[2] directly. This was indeed the case as demonstrated by the reactions summarized in Scheme 1.



a) H_2SO_4–MeOH; b,d,e) Hg/Nafion-H; c) CF_3COOH, $Hg(OAc)_2$.

Scheme 1.

Transformation of 4-Hydroxy-2-alkynal Diethyl Acetals **1** *into 3(2H)-Furanones* **2**. The carbonyl addition of the lithiated propynal diethyl acetals to ketones produced the acetylenic alcohols **1**.[3] Treatment of the adducts **1** with a 1 : 1 mixture of sulfuric acid and methanol at 0 °C gave 3(2*H*)-furanones **2**.[4] Results are summarized in Table 1. The new transformation is understood in terms of the sequence in Scheme 2. Initial elimination of an ethoxyl group and hydration of the triple bond are followed by intramolecular nucleophilic attack of the tertiary hydroxyl group. The Baldwin's rule[5] says that the 5-*exo-trig.* reaction is allowed. It is worthy to note



Scheme 2.

that the propargylic tertiary hydroxyl group in **1** remains intact under the acidic conditions.[6]

Synthesis of 3(2H)-Furanones **2** *from 4-Hydroxy-2-alkynones* **3**. The hydroxy ketones **3** were previously prepared by MnO_2 oxidation of the corresponding 2-butyne-1,4-diols in poor yields.[7,8] We found that treatment of the 2-butyne-1,4-diol derivatives with *t*-butyl hydroperoxide and Nafion-H[9] at 25 °C provided ketones **3** effectively. They were converted by step b in Scheme 1 into 3(2*H*)-furanones **2** in excellent yields with Hg/Nafion-H reagent[1] in the presence of 5 equivalents of water in ethanol at 40 °C[10] (Table 2). The conjugate addition of water to the triple bond took place efficiently with complete regioselectivity.

The combined process was applied to the synthesis of a naturally occurring 3(2*H*)-furanone, bullatenone (**2f**)[11] of Table 2. Oxidation of 4-methyl-1-phenyl-2-pentyne-1,4-diol with *t*-butyl hydroperoxide and Nafion-H followed by treatment with Hg/Nafion-H gave the furanone **2f** in a quantitative yield.

Transformation of 1,1,1-Triethoxy-2-alkyn-4-ols **4** *into 5-Ethoxy-3(2H)-furanones* **5** *and 4-Alkoxy-2(5H)-furanones* **6**. The starting alkynols **4** were prepared by the reaction of ketones with the lithium salt of 3,3,3-triethoxypropyne in THF. Treatment of the adduct **4** with trifluoroacetic acid and mercury(II) acetate at reflux temperature (step c in Scheme 1) afforded the 3-furanones **5** in moderate yields (Table 3).

On the other hand, the reaction of the ortho ester **4a** with the Hg/Nafion-H reagent and 5 equivalents of water in ethanol gave 2(5*H*)-furanone[12] **6a** in 81% yield (step d in Scheme 1). This transformation could

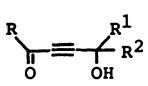
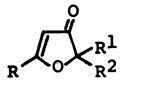
Table 1. 3(2*H*)-Furanones **2** from 4-hydroxy-2-alkynal diethyl acetals **1**

Ketone	Yield/% of the adduct[a,b]		Yield/% of 3(2*H*)-furanone[a,c]	
Acetone	 **1a**	64	 **2a**	98
Cyclohexanone	 **1b**	99	 **2b**	67
Cyclododecanone	 **1c**	79	 **2c**	70

a) Isolated yields. b) Ketones were allowed to react with the lithium salt of propynal diethyl acetal. c) The adducts **1** were treated with H_2SO_4–MeOH.

Table 2. Transformation of 4-hydroxy-2-alkynones **3** into 3(2*H*)-furanones **2**





Yield/%[a,b]

	R	R^1	R^2		
3a	Me	Me	Me	**2d**	92
3b	Me		$-(CH_2)_5-$	**2e**	87
3c	Ph	Me	Me	**2f**	100
3d		$-(CH_2)_8-$	H	**2g**	90[c]

a) Isolated yields. b) Alkynols **3** were treated with Hg/Nafion-H. c) 4-Acetoxy-2-cyclododecyn-1-one was employed as a starting material.

Table 3. Synthesis of 5-ethoxy-3(2*H*)-furanones **5** from 1,1,1-triethoxy-2-alkyn-4-ols **4**

Ketone	Yield/% of the adduct[a,b]		Yield/% of 3(2*H*)-furanone[b,c]	
Acetone	 **4a**	67	 **5a**	63
Cyclohexanone	 **4b**	66	 **5b**	49

a) Ketones were allowed to react with lithium salt of triethyl orthopropiolate. b) Isolated yields. c) The adducts **4** were treated with CF_3CO_2H–$Hg(OAc)_2$.

be effected by a mixture of sulfuric acid–methanol less efficiently[13] (Table 4). Monitoring experiments revealed the intermediacy of ethyl 4-hydroxy-2-alkynoates. Thus the methyl ester **7b** generated independently gave the 2(5*H*)-furanone **6c** on treatment with Hg/Nafion-H (step e in Scheme 1).

Table 4. Synthesis of 4-alkoxy-2(5*H*)-furanones **6**

Starting alkynol	Yield/% of **6**[a]	
 **4a**	 **6a**	81[b]
 **4b**	 **6b**	30[c]
 **7b**	 **6c**	85[b]

a) Isolated yields. b) Hg/Nafion-H was used for the cyclization. c) The alkynol **4b** was treated with H_2SO_4–MeOH.

Experimental

Distillation was carried out by use of Kugelrohr (Büchi) and boiling points were determined by measuring the bath temperature. All mp and bp are not corrected. ^{1}H-NMR spectra (tetramethylsilane as an internal standard) were obtained on a Varian EM 390 spectrometer, chemical shifts being given in ppm units, IR spectra of neat liquid film samples (unless otherwise noted) on a Shimadzu IR-27G spectrometer, MS on a Hitachi RMU-6L spectrometer, and exact mass on a Hitachi M 80 spectrometer. Gas-liquid phase chromatography (GLC) analyses were performed with a Yanagimoto GCG-550F chromatograph, and preparative GLC with a JEOL JGC-20K chromatograph. Preparative TLC plates were prepared with Merck Kiesel-gel PF_{254}. Column chromatography was carried out with silica gel (Wakogel C-100) at atmospheric pressure. Commercial sulfuric acid (97%) and *t*-butyl hydroperoxide (Nakarai Chemicals Ltd., 70% aqueous solution) were used.

Synthesis of 1-Oxaspiro[4.11]hexadec-2-en-4-one (2c) from Cyclo-

dodecanone (A Typical Procedure). To a THF (10 ml) solution of propynal diethyl acetal[14] (0.96 g, 7.5 mmol) was added a hexane solution of butyllithium (1.85 M,** 4.1 ml, 7.5 mmol) at −78 °C. After 10 min cyclododecanone (0.91 g, 5.0 mmol) dissolved in THF (7 ml) was added in 15 min. The reaction mixture was stirred at −78 °C for 1 h and at 25 °C for 30 min. Workup followed by column chromatography (hexane–ether 5 : 1) gave 1-(3,3-diethoxypropynyl)cyclododecanol **1c** (1.22 g, 79% yield). Mp 45.0—45.5 °C (hexane); bp 192—193 °C (bath temp)/0.15 Torr;†† ^{1}H-NMR (CCl_4): δ=1.19 (t, J=7.5 Hz, 6H), 1.2—2.2 (m, 23H), 3.3—3.8 (m, 4H), 5.11 (s, 1H); IR: 3430, 2270, 1121, 1055, 1008 cm^{-1}; MS: *m/e* (rel intensity) 310 (M^+, 5), 265(20), 149(8), 119(98), 117(100), 103(60). Found: C, 73.25; H, 11.02%. Calcd for $C_{19}H_{34}O_3$: C, 73.50; H, 11.04%.

The adduct **1c** (0.22 g, 0.71 mmol) was dissolved in methanol (1.0 ml) and cooled at 0 °C. To this solution was added sulfuric acid (1.0 ml) dropwise over 10 min. After stirring for 30 min, the reaction mixture was diluted with ether and neutralized with aqueous sodium hydrogencarbonate solution. Extractive workup followed by preparative TLC purification (hexane–ether 1 : 1, R_f 0.33—0.47) gave **2c** (0.12 g, 70% yield). Mp 81.0—81.5 °C (hexane); IR (Nujol): 1709, 1684, 1569 cm^{-1}; ^{1}H-NMR (CCl_4): δ=1.2—1.8 (m, 22H), 5.43 (d, J=2.7 Hz, 1H), 8.04 (d, J=2.7 Hz, 1H); MS: *m/e* (rel intensity) 236 (M^+, 32), 123(32), 110(31), 97(100). Found: C, 75.92; H, 10.23%. Calcd for $C_{15}H_{24}O_2$: C, 76.22; H, 10.24%.

This procedure applies to the synthesis of **1a**, **1b**, **2a**, and **2b**, whose physical properties are summarized below.

*5,5-Diethoxy-2-methyl-3-pentyn-2-ol (**1a**).*[38] ^{1}H-NMR (CCl_4): δ=1.19 (t, J=7.5 Hz, 6H), 1.48 (s, 6H), 2.96 (br s, 1H), 3.3—3.8 (m, 4H), 5.12 (s, 1H); IR: 3400, 2270, 1104, 1045, 1009 cm^{-1}; (Found: *m/e* 185.1198, M^+-1).

*5,5-Dimethyl-3(2H)-furanone (**2a**).*[15] ^{1}H-NMR (CCl_4): δ=1.33 (s, 6H), 5.48 (d, J=2.7 Hz), 8.06 (d, J=2.7 Hz, 1H); IR: 1702, 1555, 794 cm^{-1}; MS: *m/e* 112 (M^+).

*1-(3,3-Diethoxypropynyl)cyclohexanol (**1b**).* Bp 103—110 °C (bath temp)/0.05 Torr; ^{1}H-NMR (CCl_4): δ=1.20 (t, J=7.5 Hz, 6H), 1.2—2.0 (m, 10H), 2.6—3.0 (m, 1H), 3.3—3.9 (m, 4H), 5.15 (s, 1H); IR: 3405, 2260, 1112, 1048, 1005 cm^{-1}; MS: *m/e* (rel intensity) 226 (M^+, 5), 197(3), 181(100), 153(29), 107(25), 79(35), 55(57). Found: C, 68.81; H, 9.74%. Calcd for $C_{13}H_{22}O_3$: C, 68.99; H, 9.80%.

*1-Oxaspiro[4.5]dec-2-en-4-one (**2b**).*[16] ^{1}H-NMR (CCl_4): δ=1.1—2.0 (m, 10H), 5.48 (d, J=2.6 Hz, 1H), 8.09 (d, J=2.6 Hz, 1H); IR: 1700, 1562, 1173 cm^{-1}; MS: *m/e* 152 (M^+).

*Transformation of 4-Hydroxy-4-methyl-1-phenyl-2-pentyn-1-one (**3c**) into Bullatenone (**2f**) (A Typical Procedure).* 4-Methyl-1-phenyl-2-pentyne-1,4-diol[1] (28 mg, 0.15 mmol) was treated with Nafion®-H[1,9] (24 mg) in 70% aqueous *t*-butyl hydroperoxide (1 ml) at 25 °C for 42 h. The reaction mixture was filtered, and the catalyst was washed with dichloromethane. Concentration of the combined filtrates *in vacuo* afforded **3c**[10a] (28 mg) quantitatively. An ethanol (1 ml) solution of **3c** (37 mg, 0.20 mmol) was stirred with Hg/Nafion-H[1] (52 mg) in the presence of water (18 mg, 1.0 mmol) at 40 °C for 14 h. Removal of the polymer reagent by filtration and concentration of the filtrate gave bullatenone (**2f**)[11] (37 mg, 100%) whose spectral data were identical with the recorded ones.

Spectral properties of **2d** and **3e** are listed below.

*2,2,5-Trimethyl-3(2H)-furanone (**2d**)*[17] *from **3a**.*[18] ^{1}H-NMR (CCl_4): δ=1.29 (s, 6H), 2.17 (s, 3H), 5.20 (s, 1H); IR: 1700, 1601, 1390, 1179 cm^{-1}; MS: *m/e* 126 (M^+).

*2-Methyl-1-oxaspiro[4.5]dec-2-en-4-one (**2e**)*[19] *from **3b**.*[20] ^{1}H-NMR (CCl_4): δ=1.0—2.1 (m, 10H), 2.21 (s, 3H), 5.26 (s, 1H); IR: 1697, 1601, 1386, 1348, 1062 cm^{-1}; MS: *m/e* 166 (M^+).

*13-Oxabicyclo[8.2.1]tridec-1(12)-en-11-one-1(**2g**).* 2-Cyclododecyne-1,4-diol[21] (284 mg, 1.5 mmol) was treated with acetic anhydride (148 mg, 1.5 mmol) and pyridine (1 ml) at 25 °C for 5 h, and the reaction mixture was concentrated. Purification of the residue by column chromatography (hexane–ethyl acetate 5 : 1) gave 4-acetoxy-2-cyclodecynol (159 mg, 46% yield) together with the diol (76 mg) and the diacetate (92 mg). ^{1}H-NMR (CCl_4) of the monoacetate: δ= δ=1.1—2.1 (m+s (δ=2.00), 20H), 4.2—4.4 (m, 1H), 5.1—5.4 (m, 1H); IR: 3430, 1741, 1229, 1020 cm^{-1}; MS: *m/e* 238 (M^+).

A dichloromethane (3 ml) solution of the monoacetate (64 mg, 0.27 mmol) was added to pyridinium chlorochromate (87 mg, 0.40 mmol) and sodium acetate (7 mg, 0.08 mmol) in dichloromethane (0.5 ml) at 0 °C. After stirring for 6 h at 25 °C, workup followed by column chromatography (ether) gave 4-acetoxy-2-cyclododecyn-1-one (55 mg, 90%yield). Bp 140—142 °C (bath temp)/0.09 Torr; ^{1}H-NMR (CCl_4): δ= 1.1—2.1 (m+s (δ=2.04), 17H), 2.3—2.6 (m, 2H), 5.46 (t, J=6.0 Hz, 1H); IR: 2250, 1742, 1672, 1218, 1020 cm^{-1}; MS: *m/e* (rel intensity) 236 (M^+, trace), 194(3), 123(11), 97(17), 79(17), 55(21), 43(100). Found: C, 70.91; H, 8.51%. Calcd for $C_{14}H_{20}O_3$: C, 71.16; H, 8.53%.

An ethanol (0.5 ml) solution of the acetylenic ketone (30 mg 0.13 mmol) was stirred with Hg/Nafion-H (31 mg) in the presence of water (11 mg, 0.64 mmol) at 40 °C for 7 h. Filtration of the reaction mixture and concentration of the filtrate gave **2g** (22 mg, 90% yield). Mp 60.5—61.5 °C (hexane); ^{1}H-NMR (CCl_4): δ=0.8—2.9 (m, 16H), 4.34 (t, J=7.8 Hz, 1H), 5.34 (s, 1H), IR (CCl_4): 1700, 1590, 1376, 1158 cm^{-1}; MS: *m/e* (rel intensity) 194 (M^+, 5), 148(41), 122(44), 81(55), 69(68), 67(62), 55(74), 40(100). Found: *m/e* 195.1295. Calcd for $C_{12}H_{19}O_2$: M^++1, 195.1383.

*Synthesis of 2-Ethoxy-1-oxaspiro[4.5]dec-2-en-4-one (**5b**) (A Typical Procedure).* A hexane solution of butyllithium (1.60 M, 4.4 ml, 7.0 mmol) was added at −78 °C to 3,3,3-triethoxypropyne[22] (1.20 g, 7.0 mmol) in THF (10 ml). After stirring for 40 min, cyclohexanone (0.97 g, 9.9 mmol) dissolved in THF (6 ml) was added in 20 min. Stirring at −78 °C for 50 min, at 25 °C for 20 min, followed by workup and column chromatography (hexane–ethyl acetate 5 : 1) gave the adduct **4b** (1.24 g, 66% yield). Bp 148—150 °C (bath temp)/0.12 Torr; ^{1}H-NMR (CCl_4): δ=1.0—2.4 (m+t (δ=1.20, J=6.6 Hz), 20H), 3.57 (q, J=6.6 Hz, 6H); IR: 3400, 2230, 1240, 1084, 1041 cm^{-1}; MS: *m/e* (rel intensity) 225 (M^+ $-C_2H_5O$, 100), 179(40), 141(26), 105(35), 95(30), 81(30). Found: *m/e* 255.1557. Calcd for $C_{14}H_{23}O_4$: M^+-CH_3, 255.1594.

Trifluoroacetic acid (3 ml) was added at 25 °C to the adduct **4b** (122 mg, 0.45 mmol) and mercury(II) acetate (144 mg, 0.45 mmol). After stirring for 15 min at reflux temperature, workup and preparative TLC purification (hexane–ethyl acetate 2 : 1, double development) gave **5b** (R_f 0.30—0.40, 43 mg, 49% yield). Mp 54.1 °C (hexane); ^{1}H-NMR (CCl_4): δ=1.0—2.0 (m+t (δ=1.48, J=7.5 Hz), 13H), 4.21 (q, J= 7.5 Hz, 2H), 4.57 (s, 1H); IR: 1696, 1573, 1427, 1360, 881 cm^{-1}; MS: *m/e* (rel intensity) 197 (M^++1, 4), 196 (M^+, 24), 141(21), 115(21), 83(36), 81(36), 69(77), 40(100). Found: C, 67.44; H, 8.36%. Calcd for $C_{11}H_{16}O_3$: C, 67.32; H, 8.22%.

This procedure was applied to the synthesis of **4a** and **5a**.

*4,4,4-Triethoxy-2-methyl-3-pentyn-2-ol (**4a**) and 2,2-Dimethyl-5-ethoxy-3(2H)-furanone (**5a**).* The ortho ester **4a** showed bp 135—136 °C (bath temp)/0.12 Torr; ^{1}H-NMR (CCl_4):

** 1 M=1 mol dm^{-3}; †† 1 Torr=133.322 Pa.

δ=0.80 (t, J=7.2 Hz, 9H), 1.12 (s, 6H), 1.4—1.8 (m, 1H), 3.17 (q, J=7.2 Hz, 6H); IR: 3450, 2250, 1240, 1170, 1085, 1034 cm^{-1}; MS: *m/e* (rel intensity) 185 ($M^+-C_2H_5O$, 84), 111(44), 95(100), 71(36), 67(37), 59(42), 43(80). Found: *m/e* 231.1578. Calcd for $C_{12}H_{23}O_4$: M^++1, 231.1594.

Physical properties of the 3-furanone **5a** are given. Bp 98—100 °C (bath temp)/0.13 Torr; ^{1}H-NMR (CCl_4): δ=1.39 (s, 6H), 1.47 (t, J=7.2 Hz, 3H), 4.28 (q, J=7.2 Hz, 2H), 4.55 (s, 1H); IR: 1675, 1567, 1175, 1057 cm^{-1}; MS: *m/e* (rel intensity) 157 (M^++1, 4), 156 (M^+, 23), 111(2), 97(12), 87(12), 69(100), 59(55), 43(30). Found: *m/e* 156.0885. Calcd for $C_8H_{12}O_3$: M^+, 156.0786.

*5,5-Dimethyl-4-ethoxy-2(5H)-furanone (**6a**).* An ethanol (1 ml) solution of **4a** (40 mg, 0.17 mmol) was stirred with Hg/Nafion-H (46 mg) in the presence of water (13 mg, 0.74 mmol) at 40 °C for 40 h. Filtration of the reaction mixture followed by concentration of the filtrate gave **6a**[13a] (22 mg, 81% yield). Bp 114—115 °C (bath temp)/0.12 Torr; ^{1}H-NMR (CCl_4): δ=1.41 (t, J=6.9 Hz, 3H), 1.42 (s, 6H), 4.05 (q, J=6.9 Hz, 2H), 4.81 (s, 1H); IR: 1754, 1634, 1342, 1266, 1260 cm^{-1}; MS: *m/e* 156 (M^+).

When the reaction was carried out at 25 °C for 1.5 h, ethyl 4-hydroxy-4-methyl-2-pentynoate (**7a**)[23] was produced in a quantitative yield. Bp 100—101 °C (bath temp)/0.5 Torr; ^{1}H-NMR (CCl_4): δ=1.29 (t, J=7.2 Hz, 3H), 1.52 (s, 6H), 3.26 (s, 1H), 4.14 (q, J=7.2 Hz, 2H); IR: 3410, 2230, 1712, 1253, 1030 cm^{-1}; MS: *m/e* 141 (M^+).

*4-Methoxy-1-oxaspiro[4.5]dec-3-en-one (**6b**).* A mixture of sulfuric acid (0.15 ml) and methanol (0.15 ml) was added to **4b** (62 mg, 0.23 mmol) dissolved in methanol (0.15 ml) at 25 °C in 10 min. After stirring for 2 h, workup followed by preparative TLC separation (hexane–ether 1 : 1) gave **6b**[13a] (R_f 0.08—0.12, 13 mg, 30% yield) having ^{1}H-NMR (CCl_4): δ=1.0—2.5 (m, 10H), 3.77 (s, 3H), 5.03 (s, 1H); IR: 1711, 1614, 1228, 1030 cm^{-1}; MS: *m/e* 182 (M^+).

*4-Ethoxy-1-oxaspiro[4.5]dec-3-en-2-one (**6c**).* Methyl 4-(1-hydroxycyclohexyl)-2-butynoate (**7b**)[13a] (50 mg, 0.28 mmol) dissolved in ethanol (1 ml) was treated with Hg/Nafion-H (103 mg) in the presence of water (25 mg, 1.4 mmol) at 40 °C for 50 h. Removal of the polymer reagent by filtration and concentration of the filtrate gave **6c** (46 mg, 85% yield). Mp 70—71 °C (hexane); bp 95—97 °C (bath temp)/0.07 Torr; ^{1}H-NMR (CCl_4): δ=0.9—2.1 (m+t(δ=1.40, J=6.8 Hz), 13H), 4.00 (q, J=6.8 Hz, 2H), 4.74 (s, 1H); IR: 1751, 1627, 1336, 1195, 976 cm^{-1}; MS: *m/e* (rel intensity) 196 (M^+, 25), 168(22), 153(28), 140(56), 125(34), 112(41), 69(100), 55(56), 43(31). Found: C, 67.37; H, 8.48%. Calcd for $C_{11}H_{16}O_3$: C, 67.32; H, 8.22%.

Financial support by the Nissan Kagaku Kogyo Ltd. and the Ministry of Education, Science and Culture (Grant-in-Aid for Special Project Research No. 57118006) is acknowledged.

A Novel Synthesis of α-Methylene-γ-butyrolactones

Hiroyuki Saimoto, Koji Nishio, Hajime Yamamoto, Masaki Shinoda, Tamejiro Hiyama,*,† and Hitosi Nozaki

Department of Industrial Chemistry, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606

(Received March 23, 1983)

A new method is reported for constructing α-methylene-γ-butyrolactone moiety under neutral, anhydrous conditions. Olefin–dibromocarbene adducts were transformed into methyl 1-(dimethylaminomethyl)cyclopropanecarboxylates (**3**). Treatment of **3** with trimethylsilyl iodide followed by thermolytic distillation of the crude products gave α-methylene-γ-butyrolactones with high regio- and stereoselectivity.

Many compounds of natural or synthetic origin having α-methylene-γ-butyrolactone moiety possess a variety of biological activity.[1] Efforts for synthesizing the structural unit have been made extensively,[2,3] but a highly selective method seems still awaited. We found a novel method for constructing the structure under neutral, anhydrous conditions. The process involves ring reorganization of methyl 1-(dimethylaminomethyl)cyclopropanecarboxylates (**3**) with concomitant elimination of the amino group,[4] and is characterized by its high stereo- and regioselectivity. The transformation is accomplished by treatment of **3** with trimethylsilyl iodide[5] followed by thermolytic distillation.[6]

Scheme 1.

The amino esters **3** were prepared as shown in Scheme 1. *gem*-Dibromocyclopropanes **1** underwent bromine–lithium exchange reaction on treatment with butyllithium at −95 °C.[7] The resulting carbenoids then reacted with *N,N*-dimethylmethaniminium iodide[8] to give amino bromides **2**. The configuration of the dimethylaminomethyl group was inferred to be *cis* or *endo* relative to the substituents R and R^1 of **2a—d** on the analogy of our previous observation.[9] Successively, **2** were converted into cyclopropyllithium by the action of butyllithium (for **2a**) or *t*-butyllithium (for **2b—e**) at −78 °C. The bromine–lithium exchange was particularly facilitated by the dimethylamino group which coordinates lithium cation.[10] The cyclopropyllithium reacted with dimethyl carbonate to give **3**.

The amino esters **3** were treated with 3 mol of trimethylsilyl iodide in benzene (for **3a**, **3b**) or 1,2-dichloroethane (for **3c—e**) at 50—95 °C for several hours. After the starting esters were consumed (TLC), all the volatile materials were evaporated *in vacuo*. At first, we dissolved the residue in high boiling solvents and heated as high as 200 °C, but no trace of the desired product was formed.[11] The transformation into the lactones **4** was effectively executed by the thermolytic distillation of the residue under reduced pressure with bath temperature of 170 °C or above by use of Kugelrohl, thermally unstable product being immediately removed from the hot reaction pot. The results are summarized in Table 1.

The transformation of **3a** afforded a plant growth inhibitory α-methylene-γ-lactone (**4a**)[11] as the sole product. Thus, the bond between the substituted carbons of cyclopropane ring is preferentially cleaved. The same preference was observed in the reaction of **3b** which gave **4b** as the major product (71%) accompanied by the regioisomer (29%).[12] The carbon-carbon bond cleavage and carbon-oxygen bond formation proceeded with retention of configuration as observed in the reaction of **3c—e**. Only the *cis* product **4c** was produced from **3c**, and **4d** (*cis-trans* 94 : 6) from **3d** which was derived from **1d** (*cis-trans* 84 : 16). The reaction of *trans* isomer **3e** gave only the *trans* lactone **4e**.

Of special interest in the transformation is the intermediary species leading to **4**. Treatment of **3c** with trimethylsilyl iodide followed by evaporation as above gave an oil which exhibited a singlet peak at δ 3.69 (^{1}H-NMR in $CDCl_3$) without reasonably intense

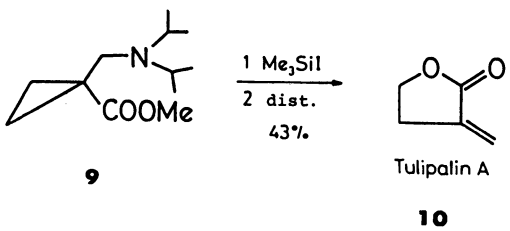

Scheme 4.

peaks due to trimethylsilyl groups. The IR spectrum (neat) revealed the presence of carboxylate (1620, 1400 cm^{-1}) and/or carboxylic acid (3650—2200, 1710 cm^{-1}) functional group(s). Thus, the most likely intermediate seems to be **5** which is derived from trimethylsilyl iodide mediated ester hydrolysis and quaternization. The initial phase of the reaction would be *N*-trimethylsilyl ammonium formation followed by trimethylsilyl-methyl exchange.[13] Indeed, when **5** was produced alternatively by quaternization with methyl iodide and hydrolysis with a base, subsequent thermolysis gave **4c** albeit in somewhat lower yields (Table 2, method A—C). Another possible intermediate **6** could clearly be eliminated as following two procedures failed to give **4c** (Scheme 2): D, (1) hydrolysis of **3c** with aq KOH, (2) neutralization with HCl, (3) distillation; E, (1) hydrogenolysis of benzyl ester **7**, (2) distillation. Of course, the benzyl ester **7** was transformed into **4c** by the standard procedure or by hydrogenolysis followed by quaternization and distillation (Table 2, method F, G). According to recent studies on the trimethylsilyl iodide mediated ring opening of cyclopropanecarboxylates,[14] the stereoselectivity can be explained by the intermediacy of **8** (Scheme 3).

Thus the α-methylene-γ-butyrolactone synthesis described herein has a remarkable feature involving anhydrous, neutral conditions in sharp contrast to the related system which employs aqueous strong acidic conditions.[15] Furthermore, the method has wide applicability as the starting *gem*-dibromocyclopropanes are readily available from olefins and dibromocarbene.

Finally, the sequence was successfully applied to the synthesis of tulipalin A (**10**), a cytotoxic lactone isolated from tulip bulbs[16] and also from Adder's Tongue (*Erythronium americanum*),[17] starting from amino ester **9** (Scheme 4). In this reaction diisopropylamino group is especially pertinent as the dimethylamino derivatives gave only trace amount of **10**. The bulky amino leaving group seems essential for the isolation of the remarkably unstable product.[17]

Experimental

Bulb-to-bulb distillation was carried out by use of Kugelrohr (Büchi) and boiling points were determined by measuring the bath temperature. All mp and bp are not corrected. ^1H-NMR spectra (tetramethylsilane as an internal standard) were obtained on a Varian EM-390 spectrometer, chemical shift being given in ppm units, IR spectra of neat liquid film samples (unless otherwise noted) on a Shimadzu IR-27G spectrometer, MS on a Hitachi RMU-6L spectrometer, and exact mass on a Hitachi M 80 spectrometer. Preparative TLC plates were prepared with Merck Kiesel-gel PF_{254}. Column chromatography was carried out with silica gel

(Wakogel C-100) at atmospheric pressure.

*Transformation of 7,7-Dibromonorcarane (**1c**) into the Lactone **4c** (A Typical Procedure).* *7-exo-Bromo-7-endo-(dimethylaminomethyl)norcarane (**2c**)*: At −95 °C a hexane solution of butyllithium (1.7 M†, 3.4 ml, 5.8 mmol) was added under an argon atmosphere to **1c**[18] (1.32 g, 5.2 mmol) dissolved in THF (30 ml). After 10 min stirring *N,N*-dimethylmethaniminium iodide (1.40 g, 7.5 mmol) was added portionwise at −95 °C. The heterogeneous reaction mixture was stirred for 15 h and warmed gradually to r.t. Workup followed by column chromatography (hexane–ether 10 : 1 to 1 : 100) gave **2c** (0.73 g, 61% yield). Bp 70—80 °C (bath temp)/0.3 Torr;†† ^{1}H-NMR (CCl_4): δ=0.9—2.0 (m, 10H), 2.27 (s, 6H), 2.63 (s, 2H); IR: 2950, 2870, 2835, 2780, 1450, 1025 cm^{-1}; MS: *m/e* (rel intensity) 233 (M^++2, 1), 232 (M^++1, 0.7), 231 (M^+, 1), 152(21), 91(19), 79(31), 68(21), 59(81), 58(43), 46(100), 44(86). Found: *m/e* 231.0641. Calcd for $C_{10}H_{18}BrN$: M^+, 231.0622.

*7-exo-Methoxycarbonyl-7-endo-(dimethylaminomethyl)norcarane (**3c**)*: A pentane solution of *t*-butyllithium (2.3 M, 1.5 ml, 3.4 mmol) was added to a THF (25 ml) solution of **2c** (0.71 g, 3.1 mmol) at −78 °C under an argon atmosphere. After stirring for 1 h, dimethyl carbonate (0.54 g, 6.0 mmol) was added at −78 °C. The whole was stirred for 15 h and warmed to r.t. Workup and column chromatography (hexane–ether 5 : 1 to 1 : 100) gave **3c** (0.39 g, 61% yield). Bp 85—100 °C (bath temp)/0.5 Torr; ^{1}H-NMR (CCl_4): δ=1.1—2.0 (m, 10H) 2.17 (s, 6H), 2.67 (s, 2H), 3.57 (s, 3H); IR: 2950, 2870, 2830, 2780, 1720, 1238, 1186, 1164, 1145 cm^{-1}; MS: *m/e* (rel intensity) 211 (M^+, 1), 168(3), 107(5), 99(4), 90(4), 79(9), 67(4), 59(87), 45(100). Found: C, 68.13; H, 10.25; N, 6.39%. Calcd for $C_{12}H_{21}NO_2$: C, 68.21; H, 10.02; N, 6.63%.

*cis-Hexahydro-3-methylene-2(3H)-benzofuranone (**4c**)*: Trimethylsilyl iodide (0.52 g, 2.6 mmol) was added to **3c** (170 mg, 0.81 mmol) in 1,2-dichloroethane (7 ml) under an argon atmosphere, and the reaction mixture was stirred at reflux temperature for 14 h. Concentration and distillation of the residue (Kugelrohr) gave the crude product collected at 160—210 °C (bath temp) at 0.05 Torr. Purification by preparative TLC (hexane–ether 1 : 1) gave **4c** (R_f 0.4, 78 mg, 64% yield) identical in all respects with the reported data.[19] Bp 105—110 °C (bath temp)/0.5 Torr; ^{1}H-NMR (CCl_4): δ=1.1—2.2 (m, 8H), 2.8—3.2 (m, 1H), 4.46 (dq, *J*=5.1, 6.2 Hz, 1H), 5.43 (d, *J*=2.6 Hz, 1H), 6.08 (d, *J*=2.6 Hz, 1H); IR: 2950, 2860, 1765, 1665, 1255, 1123, 1100, 1010, 889 cm^{-1}; MS: *m/e* 152 (M^+).

This procedure applies to the transformation of **1a**, **1b**, **1d**, and **1e** into **4a**, **4b**, **4d**, and **4e** respectively. Physical properties are summarized below.

*r-1-Bromo-1-(dimethylaminomethyl)-t-2-phenylcyclopropane (**2a**) from **1a**:*[18] Bp 105—115 °C (bath temp)/0.2 Torr; ^{1}H-NMR (CCl_4): δ=1.4—1.7 (m, 2H), 1.88 (d, *J*=13.8 Hz, 1H), 2.12 (s, 6H), 2.56 (d, *J*=13.8 Hz, 1H), 2.75 (t, *J*=8.5 Hz, 1H), 7.20 (s, 5H); IR: 2950, 2830, 2780, 1602, 1500, 1452, 1036, 774, 701 cm^{-1}; MS: *m/e* (rel intensity) 255 (M^++2, 3), 254 (M^++1, 1), 253 (M^+, 3), 175(10), 135(12), 134(100), 129(27), 128(18), 115(15), 91(13), 77(10), 70(15), 59(13), 58(100). Found: *m/e* 253.0472. Calcd for $C_{12}H_{16}BrN$: M^+, 253.0466.

*1-(Dimethylaminomethyl)-r-1-methoxycarbonyl-t-2-phenylcyclopropane (**3a**)*: Bp 105—115 °C (bath temp)/2 Torr; ^{1}H-NMR (CCl_4): δ=1.42 (dd, *J*=3.0, 4.7 Hz, 1H), 1.44 (d, *J*=8.4 Hz, 1H), 1.86 (dd, *J*=3.0, 5.8 Hz, 1H), 1.92 (s, 6H), 2.46 (dd, *J*=4.7, 5.8 Hz, 1H), 2.66 (d, *J*=8.4 Hz, 1H), 3.44 (s, 3H), 6.6—6.9 (m, 5H); IR: 2970, 2840, 2780, 1718, 1605, 1502, 1460, 1437, 1243, 1176, 765, 700 cm^{-1}; MS: *m/e* (rel intensity) 234 (M^++1, 2), 233 (M^+, 4), 219(2), 142(72), 134(19), 129(26), 115(8), 91(9), 58(100). Found: C, 71.84; H, 8.25; N, 6.06%. Calcd for $C_{14}H_{19}NO_2$: C, 72.07; H, 8.21; N, 6.00%.

*5-Phenyl-4,5-dihydro-3-methylene-2(3H)-furanone (**4a**)*:[2x,20] Mp 48—49.5 °C; ^{1}H-NMR (CCl_4): δ=2.88 (ddt, *J*=6.6, 17.0, 2.9 Hz, 1H), 3.40 (ddt, *J*=8.0, 17.0, 2.5 Hz, 1H), 5.50 (dd, *J*=6.6, 8.0 Hz, 1H), 5.66 (dd, *J*=2.5, 2.9 Hz, 1H), 6.28 (dd, *J*=2.5, 2.9 Hz, 1H), 7.34 (s, 5H); IR: 1760, 1665, 1500, 1265, 1120, 1015 cm^{-1}; MS: *m/e* 174 (M^+).

*r-1-Bromo-1-(dimethylaminomethyl)-t-2-hexylcyclopropane (**2b**)*: The dibromocyclopropane **1b**[18] was converted into a stereoisomeric mixture of **2b** and **2b′**, *r*-1-bromo-1-(dimethylaminomethyl)-*c*-2-hexylcyclopropane. The ratio of **2b** to **2b′** (88 : 12) was estimated by the examination of the ^{1}H-NMR spectrum of a mixture of **3b** and **3b′**. The mixture of **2b** and **2b′** showed bp 72—80 °C (bath temp)/0.5 Torr; ^{1}H-NMR (CCl_4): δ=0.5—1.6 (m, 15H), 2.04 (m, 1H), 2.26 (s, 6H), 2.32 (d, *J*=13.5 Hz, 1H), 2.79 (d, *J*=13.5 Hz, 1H); IR: 2950, 2870, 2825, 2780, 1460, 1250, 1190, 1128, 1038 cm^{-1}; MS: *m/e* (rel intensity) 263 (M^++2, 2), 262 (M^++1, 1), 261 (M^+, 2), 182(18), 142(5), 96(6), 85(9), 70(8), 67(11), 58(100), 55(20), 46(55), 45(46), 44(46), 43(44). Found: *m/e* 261.1068. Calcd for $C_{12}H_{24}BrN$: M^+, 261.1092.

*1-(Dimethylaminomethyl)-r-1-methoxycarbonyl-t-2-hexylcyclopropane (**3b**)*: The mixture of **2b** and **2b′** was transformed into an 88 : 12 mixture of **3b** and the stereoisomer **3b′**, 1-(dimethylaminomethyl)-*r*-1-methoxycarbonyl-*c*-2-hexylcyclopropane, having ^{1}H-NMR (CCl_4): δ=0.5—1.6 (m, 16H), 2.08 (d, *J*=13.1 Hz, 1H), 2.13 (s, 6H), 2.98 (d, *J*=13.1 Hz, 1H), 3.57 (s, CO_2Me, 2.64H), 3.61 (s, CO_2Me, 0.36H); IR: 2935, 2860, 2820, 2770, 1725, 1245, 1185, 1152, 1133, 1025 cm^{-1}; MS: *m/e* (rel intensity) 241 (M^+, 3), 198(2), 170(2), 157(2), 142(13), 98(4), 58(100), 46(34), 45(78), 44(21). Found: C, 69.45; H, 11.52; N, 5.55%. Calcd for $C_{14}H_{27}NO_2$: C, 69.66; H, 11.28; N, 5.80%. Bp 72—80 °C (bath temp)/0.5 Torr.

*5-Hexyl-4,5-dihydro-3-methylene-2(3H)-furanone (**4b**)*:[2g,20] The 88 : 12 mixture of **3b** and **3b′** gave the lactones **4b** and **4b′**, 4-hexyl-4,5-dihydro-3-methylene-2(3*H*)-furanone, as a 71 : 29 regioisomeric mixture,[12] ^{1}H-NMR (CCl_4): δ=0.7—1.9 (m, 13H), 1.1—1.8 (m, 10H), 2.41 (ddt, *J*=6.0, 17.0, 3.0 Hz, HCH of **4b**, 0.71H), 2.9—3.1 (m+ddt (δ=3.00, *J*=7.5, 17.0, 2.6 Hz, HCH of **4b**), 1H), 3.93 (dd, *J*=5.7, 9.0 Hz, HCH of **4b′**, 0.29H), 4.35—4.55 (m+dd(δ=4.42, *J*=8.3, 9.0 Hz, HCH of **4b′**), 1H), 5.55 (d, *J*=2.8 Hz, 0.29H), 5.58 (dd, *J*=2.6, 3.0 Hz, 0.71H), 6.18 (dd, *J*=2.6, 3.0 Hz, 0.71H), 6.23 (d, *J*=2.8 Hz, 0.29H); IR: 1760, 1662 cm^{-1}; MS: *m/e* (rel intensity) 182 (M^+, 1), 140(10), 97(100), 41(42); bp 102—108 °C (bath temp)/0.5 Torr. Found: *m/e* 181.1274. Calcd for $C_{11}H_{17}O_2$: M^+−1, 181.1226.

When stereochemically pure **3b** was subjected to the reaction conditions, the product ratio was improved a little (**4b**: **4b′** 82 : 18).

*r-1-Bromo-c-2,c-3-dihexyl-1-(dimethylaminomethyl)cyclopropane (**2d**)*: The reported procedure[21] was applied to the transformation of 7-tetradecene (*cis* : *trans* 84 : 16)[22] into the dibromocyclopropane **1d** together with the *trans* isomer **1e** (85% tield), bp 120—125 °C/0.11 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.6 (m, 28H); IR: 1464, 1455, 715 cm^{-1}. Found: *m/e* 366.0516. Calcd for $C_{15}H_{28}Br_2$: M^+, 366.0558.

The stereoisomer **2d** showed ^{1}H-NMR (CCl_4): δ=0.7—1.7 (m, 28H), 2.26 (s, 6H), 2.48 (s, 2H); IR: 1466, 1034 cm^{-1}; MS: *m/e* (rel intensity) 347 (M^++2, trace), 345 (M^+, trace), 267(8), 266(10), 69(16), 58(100), 55(26), 46(22), 45(66), 43(29), 41(29); bp 165—167 °C (bath temp)/0.12 Torr. Found: C, 62.68; H, 10.70; N, 3.96%. Calcd for $C_{18}H_{36}BrN$: C, 62.41; H, 10.48; N, 4.04%.

† 1 M=1 mol dm^{-3}; †† 1 Torr=133.322 Pa.

t-*2*,t-*3-Dihexyl-1-(dimethylaminomethyl)*-r-*1-(methoxycarbonyl)-cyclopropane (3d)*: Bp 142 °C (bath temp)/0.07 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.7 (m, 28H), 2.23 (s, 6H), 2.64 (s, 2H), 3.58 (s, 3H); IR: 1721, 1476, 1259, 1197 cm^{-1}; MS: *m/e* (rel intensity) 325 (M^+, trace), 310 (trace), 240(14), 58(93), 46(76), 45(100), 44(23), 43(17), 41(19). Found: C, 73.58; H, 12.23; N, 4.07%. Calcd for $C_{20}H_{39}NO_2$: C, 73.79; H, 12.08; N, 4.03%.

cis-*4,5-Dihexyl-4,5-dihydro-3-methylene-2(3H)-furanone (4d)*: A 94 : 6 stereoisomeric mixture of **4d** and its *trans* isomer **4e** was synthesized from the amino esters (**3d** and **3e**) which were derived from 7-tetradecene (*cis* : *trans* 84 : 16). The mixture of **4d** and **4e** showed bp 141—142 °C (bath temp)/0.18 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.6 (m, 26H), 2.80 (m, 1H), 4.30 (dt, J=5.1, 6.3 Hz, 1H), 5.30 (d, J=2.3 Hz, 1H), IR: 1764, 1660, 1464, 1264, 1111 cm^{-1}; MS: *m/e* (rel intensity) 266 (M^+, 2), 152(56), 96(72), 95(72), 82(100), 55(64), 54(92). Found: C, 76.46; H, 11.49%. Calcd for $C_{17}H_{30}O_2$: C, 76.64; H, 11.35%.

r-*1-Bromo*-c-*2*,t-*3-dihexyl-1-(dimethylaminomethyl)cyclopropane (2e)*: *trans*-1,1-Dibromo-2,3-dihexylcyclopropane (**1e**) was prepared from *trans*-7-tetradecene[22] according to the reported procedure[21] (75% yield, 97% yield based on the consumed olefin). ^{1}H-NMR (CCl_4) of **1e**: δ=0.7—1.7 (m, 28H); IR: 1466, 733, 722 cm^{-1}; bp 105—115 °C/0.08 Torr. Found: C, 49.02; H, 7.70%. Calcd for $C_{15}H_{28}Br_2$: C, 48.93; H, 7.67%.

The amino bromide **2e** showed bp 162—163 °C (bath temp)/0.11 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.8 (m, 28H), 2.23 (s, 6H), 2.28 (d, J=12.8 Hz, 1H), 2.85 (d, J=12.8 Hz, 1H); IR: 1464, 1454, 1033 cm^{-1}; MS: *m/e* (rel intensity) 266 (M^+—Br, 5), 81(5), 79(4), 69(5), 67(5), 58(100), 46(13), 45(43). Found: *m/e* 266.2854. Calcd for $C_{18}H_{36}N$: M^+—Br, 266.2846.

c-*2*,t-*3-Dihexyl-1-(dimethylaminomethyl)*-r-*1-(methoxycarboxyl)-cyclopropane (3e)*: Bp 165 °C (bath temp)/0.11 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.7 (m, 28H), 2.16 (s, 6H), 2.30 (d, J=13.2 Hz, 1H), 2.75 (d, J=13.2 Hz, 1H), 3.65 (s, 3H); IR: 1724, 1461, 1190, 1158 cm^{-1}; MS: *m/e* (rel intensity) 325 (M^+, trace), 310(1), 382(1), 240(12), 226(4), 58(100), 46(45), 45(55). Found: C, 73.56; H, 12.28; N, 4.17%. Calcd for $C_{20}H_{39}NO_2$: C, 73.79; H, 12.08; N, 4.30%.

trans-*4,5-Dihexyl-4,5-dihydro-3-methylene-2(3H)-furanone (4e)*: Bp 140—142 °C (bath temp)/0.18 Torr; ^{1}H-NMR (CCl_4): δ=0.7—1.8 (m, 26H), 2.53 (m, 1H), 4.04 (dt, J=3.6, 5.3 Hz, 1H), 5.45 (d, J=2.6 Hz, 1H), 6.13 (d, J=2.6 Hz, 1H); IR: 1763, 1658, 1465, 1265, 1116 cm^{-1}; MS: *m/e* (rel intensity) 266 (M^+, 1), 181(16), 152(39), 95(45), 82(52), 67(41), 55(57), 43(91), 41(100). Found: C, 76.83; H, 11.23%. Calcd for $C_{17}H_{30}O_2$: C, 76.64; H, 11.35%.

Preparation of the Lactone 4c from the Amino Ester 3c or 7.

Method A: Treatment of **3c** (98 mg, 0.47 mmol) with methyl iodide (1 ml) at reflux temperature for 14 h was followed by concentration. The resulting residue was allowed to react with trimethylsilyl iodide (186 mg, 0.93 mmol) in 1,2-dichloroethane at 50 °C for 15 h. Evaporation of all the volatile materials and the subsequent thermolysis gave **4c** (35 mg, 45% yield).

Method B: The ester **3c** (105 mg, 0.50 mmol) in methyl iodide (2 ml) was stirred for 2 h at reflux temperature, and the excess reagent was then removed. The residue was treated with a methanol–water (1 : 1) solution of potassium hydroxide (0.24 M, 0.59 mmol) at 80 °C (bath temp) for 15 h. Concentration of the reaction mixture *in vacuo* followed by distillation gave **4c** (33 mg, 43% yield).

Method C: Treatment of **3c** (90 mg, 0.43 mmol) with a methanol–water (1 : 1) solution of potassium hydroxide (0.23 M, 0.51 mmol) followed by concentration gave a solid. Methyl iodide (2 ml) was added to the residue and the whole was stirred at reflux temperature for 2.5 h. Removal of excess methyl iodide and the thermolytic distillation gave **4c** (22 mg, 34% yield).

Method D: Hydrolysis of **3c** (90 mg, 0.43 mmol) with a methanol–water (1 : 1) solution of potassium hydroxide (0.24 M, 0.51 mmol) was followed by neutralization with hydrochloric acid (1.0 M, 0.51 mmol). Concentration of the reaction mixture *in vacuo* and the subsequent distillation failed to give the desired lactone **4c**.

Method E: Benzyl alcohol (0.23 g, 2.1 mmol) was treated with sodium hydride (1.8 mmol) in benzene (4 ml) at 80 °C for 30 min, and **3c** (192 mg, 0.91 mmol) in benzene (1 ml) was then added at r.t. After stirring for 3 h at 80 °C, workup and distillation gave 7-*exo*-benzyloxycarbonyl-7-*endo*-(dimethylaminomethyl)norcarane (**7**) (108 mg, 42% yield); bp 162—163 °C (bath temp)/0.11 Torr; ^{1}H-NMR (CCl_4): δ=1.0—2.1 (m, 10H), 2.16 (s, 6H), 2.71 (s, 2H), 4.98 (s, 2H), 7.26 (br s, 5H); IR: 1710, 1244, 1172, 695 cm^{-1}; MS: *m/e* (rel intensity) 287 (M^+, trace), 196(15), 91(95), 65(29), 58(100), 46(74), 45(94), 44(42). Found: C, 74.97; H, 8.80; N, 4.78%. Calcd for $C_{18}H_{25}NO_2$: C, 75.22; H, 8.77; N, 4.87%.

An ethanol (1 ml) solution of **7** (115 mg, 0.42 mmol) was treated with Pd on carbon (5%, 12 mg) under a hydrogen atmosphere for 20 h. Filtration followed by concentration and the thermolysis failed to give **4c**.

Method F: Treatment of **7** (72 mg, 0.25 mmol) with trimethylsilyl iodide (51 mg, 0.51 mmol) in refluxing 1,2-dichloroethane (2 ml) for 15 h was followed by concentration. Thermolysis of the residue gave **4c** (23 mg, 60% yield).

Method G: An ethanol (1 ml) solution of **7** (94 mg, 0.33 mmol) was stirred with Pd on carbon (5%, 10 mg) under a hydrogen atmosphere for 15 h. Filtration and concentration gave a solid, which was treated with methyl iodide (3 ml) at reflux temperature for 1.5 h. Removal of the excess reagent followed by the thermolysis gave **4c** (25 mg, 51% yield).

Synthesis of Tulipalin A (10). Methyl 2-(bromomethyl)acrylate was prepared from dimethyl bis(hydroxymethyl)-malonate according to reported methods[23] (32% overall yield). ^{1}H-NMR (CCl_4): δ=3.78 (s, 3H), 4.12 (s, 2H), 5.91 (s, 1H), 6.27 (s, 1H); IR: 1716, 1628, 1440, 1321, 1300, 1210, 1187, 1162, 1110 cm^{-1}; MS: *m/e* (rel intensity) 180 (M^++2, 17), 178 (M^+, 18), 149(21), 147(21), 121(21), 119(21), 99(100), 69(21), 59(50), 45(16), 41(24). Found: C, 33.65; H, 4.07%. Calcd for $C_5H_7BrO_2$: C, 33.56; H, 3.91%. Bp 85—90 °C/32 Torr.

A reported procedure[23b] was applied to the transformation of methyl 2-(bromomethyl)acrylate into methyl 2-(diisopropylaminomethyl)acrylate (91% yield). Bp 70—78 °C/1 Torr; ^{1}H-NMR (CCl_4): δ=0.98 (d, J=6.6 Hz, 12H), 2.99 (septet, J=6.6 Hz, 2H), 3.21 (t, J=1.8 Hz, 2H), 5.8—5.9 (m, 1H), 6.0—6.1 (m, 1H); IR: 2980, 1717, 1630, 1436, 1366, 1287, 1250, 1172, 1125 cm^{-1}; MS: *m/e* (rel intensity) 199 (M^+, 11), 185(100), 142(43), 110(100), 69(54), 41(47). Found: C, 66.37; H, 10.90; N, 6.95%. Calcd for $C_{11}H_{21}NO_2$: C, 66.29; H, 10.62; N, 7.03%.

Thus prepared amino ester (1.1 g, 5.58 mmol) was treated with an ether (10 ml) solution of diazomethane (large excess) for 15 h at 25 °C and the reaction mixture was concentrated. A benzene (50 ml) solution of the residue was placed in a Pyrex tube and irradiated with a 200 W high-pressure mercury lamp externally for 7 h at 25 °C under a nitrogen atmosphere. Purification of the concentrated residue by column chromatography (hexane–ether 5 : 1) gave methyl 1-(diisopropylaminomethyl)cyclopropanecarboxylate (**9**) (0.42 g, 35% yield). Bp 118 °C (bath temp)/1 Torr; ^{1}H-NMR (CCl_4): δ=0.5—0.8 (m, 2H), 0.8—1.1 (m+d (δ=0.95, J=6.3 Hz), 14H), 2.78 (s, 2H), 2.96 (septet, J=6.3 Hz, 2H), 3.57 (s, 3H); IR: 2990, 1720,

1436, 1348, 1241, 1180, 1134 cm^{-1}; MS: *m/e* (rel intensity) 213 (M^+, 9), 198(100), 124(46), 114(42), 113(26), 86(20), 83(27), 81(35), 44(36), 43(25), 41(27). Found: C, 67.78; H, 10.79; N, 6.61%. Calcd for $C_{12}H_{23}NO_2$: C, 67.56; H, 10.87; N, 6.57%.

A 1,2-dichloroethane (6 ml) solution of **9** (107 mg, 0.51 mmol) was treated with trimethylsilyl iodide (402 mg, 2.01 mmol) at reflux temperature for 15 h under an argon atmosphere. Thermolysis of the concentrated residue yielded the crude product. Purification by preparative TLC (hexane–ether 1 : 1) gave **10** (21 mg, 43% yield, R_f 0.3) identical in all respects with the reported data.[24] Bp 92—95 °C (bath temp)/11 Torr; ^{1}H-NMR (CCl_4): δ=2.97 (tt, J=2.9, 7.4 Hz, 2H), 4.63 (t, J=7.4 Hz, 2H), 5.64 (t, J=2.9 Hz, 1H), 6.24 (t, J=2.9 Hz, 1H); IR ($CHCl_3$): 1759, 1667, 1107, 1021, 940 cm^{-1}; MS: *m/e* 98 (M^+).

This work was financially supported by the Ministry of Education, Science and Culture (Grant-in-Aid Nos. 303023 and 56430027).

(Received March 28, 1983)

The condensation of 4-acetyltropolone with various arenecarbaldehydes gave a wide variety of 4-cinnamoyltropolone derivatives in good yield. The same reaction with 2-furaldehyde and cinnamaldehyde also afforded the corresponding 4-substituted tropolones. These products were converted to their oximes (with hydroxylamine hydrochloride), which in turn were hydrogenated over 5% Pd/C in acetic acid and then acetylated with acetic anhydride, to yield 4-(1-acetamido-3-aryl-2-propenyl)tropolones. The catalytic hydrogenation of these olefinic products over 10—30% Pd/C in aqueous KOH gave various 4-(1-acetamido-3-arylpropyl)tropolones, which possess a B-ring-open structure of colchiceine. The structures of these products are discussed on the basis of UV, IR, and ^{1}H-NMR spectra.

Colchicine (**1**), one of the major alkaloid constituents of the autumn crocus (*Colchicum automnale L.*), is well known to block cell division during mitosis, and has been valued for its use in the treatment of gout.[3] This compound has also drawn the attention of synthetic organic chemists for almost three decades, and the total synthesis has been accomplished by several groups.[4] These synthetic routes, however, are apparently unsuitable not only for the practical synthesis of colchicine but also for the preparation of various kinds of colchicine analogues having potential utility of their biological activity.

A considerable interest in the physiological activity of colchicine, particularly concerning the binding sites of the microtubrins in the muscle and nerve cells,[3] led us to complete our longstanding, convenient synthetic scheme involving variously substituted 4-cinnamoyltropolones as intermediates.[1,2] As the intial part of our reinvestigation, we have recently reported[5] a convenient synthesis of 4-acetyltropolone (**5**) from hinokitiol (**3**), because of the limited supply of naturally occurring β-dolabrin[6] (**4**) which had previously been used[1,2] as the starting material for the preparation of **5**. We now wish to describe a convenient synthesis of analogues of colchiceine (**2**) starting from 4-acetyltropolone (**5**).

The condensation of compound **5** with various

a) Characteristic absorptions due to NH, OH, and C=O groups. b) Inflections in underlines. c) Species: Monocation (+) in 0.1 M (1 M=1 mol dm^{-3}) HCl/MeOH; neutral species (0) and Zwitterion (±) in MeOH; monoanion (−) and dianion (− −) in 0.1 M NaOH/MeOH. d) For oximes of the lower melting point. e) For oximes of the higher melting point. f) No satisfactory analytical figures available even by repeating the analysis.

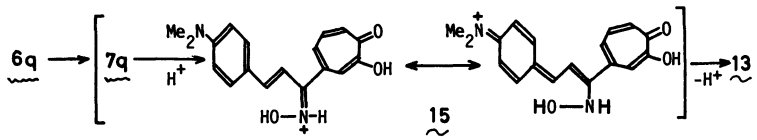
substituted benzaldehydes in methanolic potassium hydroxide at 0 °C readily afforded 17 4-cinnamoyltropolones (**6a**—**q**) in most cases in excellent yields. Similarly, the reaction of **5** with 2-furaldehyde and cinnamaldehyde gave 4-[3-(2-furyl)propenoyl]- (**10**) and 4-(5-phenyl-2,4-pentadienoyl)tropolone (**11**), respectively. However, the condensation with isovanilline and salicylaldehyde afforded the products (**6o** and **6p**, respectively) in moderate or poor yields, whereas that with vanilline failed to give any condensation products. These results, together with the elemental analysis and spectral data, are summarized in Table 1.

The presence of a conjugated carbonyl group was supported by the IR (≃1660 cm^{-1}) and ^{1}H-NMR spectra: The *E*-configuration of the olefinic group of these products was established from the large magnitude (14—16 Hz) of the coupling constants of the olefinic proton signals in the NMR spectra. The neutral species of these compounds exhibited the longest wavelength absorption maxima at 340—390 nm in the UV spectra, whereas the anionic species (troponate anions) showed a significant bathochromic shift (50—100 nm) in these absorption maxima; the acidic pK_a values of these compounds are considered to be *ca.* 6, as exemplified by the value (6.08)[5] of **6a**. The red-colored *p*-dimethylamino derivative (**6q**) apparently exists mostly as the Zwitterion form (**12**) on the evidence of the UV spectrum in methanol; the spectra of the neutral and anionic species of **6q** closely resembled those of anionic species of other cinnamoyltropolones, whereas the spectrum of the monocation of **6q** corresponded to those of the neutral species of the other derivatives (**6**) (see Table 1).

The treatment of compounds **6** with hydroxylamine hydrochloride in refluxing ethanol gave the corresponding oximes (**7a**—**m**); in some cases two isomers (*syn* and *anti*) were separated by fractional recrystallization. The structures of these oximes were supported by the elemental analysis and the IR spectra (namely, the disappearance of the strong absorptions at ≃1660 cm^{-1} due to the conjugated carbonyl group; see Table 1).

The isoxazoline structure (**13**) was assigned for the product derived from the *p*-dimethylamino compound (**6q**) on the basis of the ^{1}H-NMR spectrum, which showed three aliphatic proton signals of an ABX type at δ 3.32, 3.67, and 5.71 in addition to the signals due to the dimethylamino group (δ 2.94) and the aromatic ring-protons [δ 6.68 (2H), 7.1—7.4 (5H), and 7.77 (1H)]. Moreover, the UV spectrum of **13** closely resembled that of the 4-acetyltropolone oxide,[6] supporting the isoxazoline structure for this product. The exclusive formation of **13** (instead of an oxime derivative **7q**) from **6q** could be explained by the presence of the strongly electron-donating *p*-dimethylamino group, which should facilitate protonation at the intermediately formed oxime nitrogen even under the weakly acidic conditions compared to other oximes **7a**—**m**; the resonance-stabilized monocation (**15**) thus formed would in turn easily result in the isoxazoline ring closure to give **13** (Scheme 1).

The catalytic hydrogenation of the oximes (**7**) in the presence of 5% Pd/C in acetic acid containing a small amount of hydrochloric acid smoothly afforded the corresponding 4-(1-amino-3-aryl-2-propenyl)tropolones (**8a**—**j**) in good yields (see Table 1 for the summarized results). These yellow-colored amino compounds were considered to exist mostly as the Zwitterion form (**14**)



Scheme 1. A reaction pathway for the formation of **13** from **6q**.

on the evidence of the UV spectra; in this case, the longest wavelength absorptions of the neutral species of **8** resembled those of the troponate anions and, on acidification, an appreciable hypsochromic shift (≃40 nm) was observed in these absorptions (see Table 1). This ionic form **14** would be in conformity with the generally observed pK_a values of usual primary amines (9—10)[7] and tropolones (6.7—7.1).[5,8]

These amino compounds were acetylated with acetic anhydride to afford the stable acetamido derivatives (**9a**—**j**) (see Table 1). The presence of an acetamido group and two olefinic protons of *E*-configuration in **9** were confirmed by the IR and ^{1}H-NMR spectra. Because of the disappearance of the basic amino group, compounds **9** exist in the normal tropolone form, as shown by the UV spectra of their neutral species, which became similar to those of the cationic species of the amino compounds **8**.

After intensive studies, we found that the reduction of the olefinic group in compounds **9** was best accomplished by catalytic hydrogenation over 10—30% Pd/C in aqueous potassium hydroxide at room temperature (*ca.* 50 h). The 4-(1-acetamido-3-arylpropyl)tropolones (**15a**—**e**) were thus obtained in good yields. The structures of these reduced products were readily established by elemental analysis and spectroscopy (NMR, IR, and UV, see Table 1 and Experimental part).[9]

Among these products, compound **15a**, which was readily available from **5** in four steps in an overall yield of *ca.* 40—45% as shown above, possesses a structure analogous to that of colchiceine (**2**), in which the C_{1a}–C_{12a} bond is disconnected, having the B-ring-open form.

These findings so far described are believed to be of considerable value not only for the exploration of a convenient and efficient route to prepare various kinds of colchicine analogues but also for the development of the fundamental chemistry of troponoid compounds,[10] which are currently under investigation.

Experimental

All melting points are uncorrected. The microanalyses were carried out at Tohoku University and the results are summarized in Table 1. The ^{1}H-NMR spectra were recorded in $CDCl_3$ with a Hitachi R-22 (90 MHz). Chemical shifts are reported as δ values in parts per million relative to tetramethylsilane (δ 0.0) as an internal standard. Spin decoupling was performed for each proton signal to confirm the coupling constants. IR and UV spectra were obtained on Hitachi 215 and 340 spectrometers, respectively, and the characteristic absorption maxima are recorded in Table 1. All reactions were monitored by paper chromatography (on phosphoric acid-treated Toyo paper developed in benzene) or TLC [conducted on plates precoated with silica gel (0.25 mm, Merck)]. The yields referred to in this section are in most cases those of crude, but chromatographically pure, products; specimens for analysis can be purified by recrystallization from the appropriate solvents.

General Procedure for the Reaction of 4-Acetyltropolone (5) with Arenecarbaldehydes. A 50% aqueous potassium hydroxide solution (5 ml) was added dropwise, at 0 °C, to a stirred suspension of **5** (4.0 g) and 1.2 mol equiv of an arenecarbaldehyde in methanol (60 ml) over a period of 20 min. The mixture was stirred for 4—10 h, allowed to stand overnight at 0 °C, and then diluted with cold water (100 ml). On acidification with 6 M HCl, the corresponding 4-cinnamoyltropolone (**6**) [or compounds **10** and **11**] precipitated. The product was filtered off and recrystallized.

4-(3,4,5-Trimethoxycinnamoyl)tropolone (6a): Yellow needles (≃100% yield), mp 185—186 °C (from MeOH–$CHCl_3$); ^{1}H-NMR 3.92 (9H, s, 3MeO), 6.87 (2H, s, H-2′,6′), 7,21 (1H, d, J=14 Hz, H-9), 7.5 (3H, m, H-5,6,7), 7.6 (1H, m, HO-2, exchangeable with D_2O), 7.67 (1H, d, J=14 Hz, H-10), and 7.80 (1H, s, H-3).

4-(3,4-Dimethoxycinnamoyl)tropolone (6b): Yellow crystals (≃100% yield), mp 154—155 °C (from MeOH–$CHCl_3$).

4-(3,4-Methylenedioxycinnamoyl)tropolone (6c): Orange-yellow scales (≃100% yield), 162—163 °C (from AcOH).

4-Cinnamoyltropolone (6d): Yellow crystals (≃100% yield), mp 132—133 °C (from AcOH).

4-(4-Methylcinnamoyl)tropolone (6e): Yellow plates (≃100% yield), mp 175—176 °C (from EtOAc).

4-(4-Benzyloxy-3-methoxycinnamoyl)tropolone (6f): Yellow plates (≃100% yield), mp 146—147 °C (from MeOH).

4-(3-Benzyloxy-4-methoxycinnamoyl)tropolone (6g): Yellow crystals (95% yield), mp 143—144 °C (from EtOH).

4-(4-Chlorocinnamoyl)tropolone (6h): Yellow prisms (≃100%) mp 208—209 °C (from $CHCl_3$).

4-(2,4-Dichlorocinnamoyl)tropolone (6i): Yellow scales (≃100 % yield), mp 162—163 °C (from EtOAc).

4-(4-Methoxycinnamoyl)tropolone (6j): Yellow needles (≃100 % yield), mp 163—164 °C (from $CHCl_3$).

4-(4-Bromocinnamoyl)tropolone (6k): Yellow crystals (94% yield), mp 213—214 °C (from $CHCl_3$).

4-(4-Methoxy-3-nitrocinnamoyl)tropolone (6l): Yellow crystals (≃100% yield), mp 272—273 °C (from dioxane).

4-(3-Nitrocinnamoyl)tropolone (6m): Yellow crystals (≃100% yield), mp 185—186 °C (from EtOH–dioxane).

4-(4-Nitrocinnamoyl)tropolone (6n): Orange needles (77% yield), mp 216—217 °C (from AcOH).

4-(3-Hydroxy-4-methoxycinnamoyl)tropolone (6o): Yellow crystals (49% yield), mp 174—175 °C (from AcOH).

4-(2-Hydroxycinnamoyl)tropolone (6p): Pale yellow crystals (22% yield), mp 172—173 °C (from EtOAc).

4-[4-Dimethylamino)cinnamoyl]tropolone (6q): Red needles (79% yield), mp 160—161 °C (from AcOH).

4-[3-(2-Furyl)propenoyl]tropolone (10): Yellow needles (91% yield), mp 160—161 °C (from EtOAc).

4-(5-Phenyl-2,4-pentadienoyl)tropolone (11): Yellow crystals (83% yield), mp 134—135 °C (from AcOH).

General Procedure for the Preparation of Oximes (7a—m) and Isoxazoline (13). A solution of 4-cinnamoyltropolone **6** (1 g) and 6.6 mol equiv of hydroxylamine hydrochloride in ethanol (10 ml) was refluxed for 4—13 h, and then, after cooling, diluted with water (30 ml), affording **7** (or **13**) as precipitates.

4-(3,4,5-Trimethoxycinnamoyl)tropolone Oxime (7a): Pale yellow crystals (75% yield), mp 230 °C (decomp) (from AcOH).

4-(3,4-Dimethoxycinnamoyl)tropolone Oximes (7b): Two isomers both as pale yellow crystals (75% combined yield), mp 216—217 and 219—220 °C after fractional recrystallization from dioxane.

4-(3,4-Methylenedioxycinnamoyl)tropolone Oximes (7c): Two isomers both as pale yellow crystals (76% combined yield), mp 176—178 and 208—209 °C (decomp) after fractional recrystallization from dioxane.

4-Cinnamoyltropolone Oximes (7d): Two isomers of colorless needles, mp 171—172 °C, and colorless prisms, mp 190—191 °C (43% combined yield) after fractional recrystallization

from EtOH.

4-(4-Methylcinnamoyl)tropolone Oxime (7e): Pale amber crystals (85% yield), mp 177—178 °C (from benzene).

4-(4-Benzyloxy-3-methoxycinnamoyl)tropolone Oxime (7f): Pale yellow crystals (92% yield), mp 180—181 °C (from benzene).

4-(3-Benzyloxy-4-methoxycinnamoyl)tropolone Oxime (7g): Pale yellow crystals (59% yield), mp 174—175 °C (from benzene).

4-(4-Chlorocinnamoyl)tropolone Oxime (7h): Pale yellow crystals (90% yield), mp 153—154 °C (from benzene).

4-(2,4-Dichlorocinnamoyl)tropolone Oxime (7i): Colorless crystals (59% yield), mp 219—220 °C (from EtOAc–dioxane).

4-(4-Methoxycinnamoyl)tropolone Oxime (7j): Pale amber crystals (45% yield), mp 178—179 °C (from dioxane).

4-(4-Bromocinnamoyl)tropolone Oxime (7k): Colorless crystals (81% yield), mp 163—164 °C (from benzene).

4-(4-Methoxy-3-nitrocinnamoyl)tropolone Oxime (7l): Yellow crystals (73% yield), mp 167—168 °C (decomp) (from benzene–EtOAc).

4-(3-Nitrocinnamoyl)tropolone Oxime (7m): Pale amber crystals (86% yield), mp 196—197 °C (from acetone).

4-[5-[4-(Dimethylamino)phenyl]-4, 5-dihydro-3-isoxazolyl]tropolone (13): Yellow crystals (91% yield), mp 172—173 °C (from benzene–$CHCl_3$); ^{1}H-NMR 2.94 (6H, s, Me_2N), 3.32, 3.67 (1H each, dd, J=16, 10 Hz, 2H-9), 5.71 (1H, t, J=10 Hz, H-10), 6.68 (2H, d, J=8.8 Hz, H′-3,5), 7.1—7.4 (5H, m, H-4,5,6 and H′-2,6), and 7.77 (1H, s, H-3).

General Procedure for the Hydrogenation of Oximes (7). A solution of the oxime (3.8 g) in acetic acid (47 ml) containing conc hydrochloric acid (5 ml) was hydrogenated in the presence 5% Pd/C at room temperature, until 2 mol equiv of hydrogen was absorbed. The catalyst was removed by filtration, the filtrate diluted with water (150 ml) and then washed with chloroform. The aq layer was neutralized with 59% aq KOH, depositing the corresponding amino compounds (**8**).

4-[1-Amino-3-(3,4,5-trimethoxyphenyl)-2-propenyl]tropolone (8a): Yellow crystals (82% yield), mp 153—154 °C (decomp) (from aq MeOH).

4-[1-Amino-3-(3,4-dimethoxyphenyl)-2-propenyl]tropolone (8b): Yellow crystals (85% yield), mp 154—155 °C (decomp) (from EtOH).

4-[1-Amino-3-(3, 4-methylenedioxyphenyl)-2-propenyl]tropolone (8c): Yellow crystals (77% yield), mp 187—188 °C (decomp) (from EtOH).

4-(1-Amino-3-phenyl-2-propenyl)tropolone (8d): Yellow crystals (98% yield), mp 191—192 °C (decomp) (from dioxane).

*4-(1-Amino-3-*p*-tolyl-2-propenyl)tropolone (8e)*: Yellow crystals (97% yield), mp 185—186 °C (decomp) (from dioxane).

4-[1-Amino-3-(4-benzyloxy-3-methoxyphenyl)-2-propenyl]tropolone (8f): Yellow crystals (80% yield), mp 146—147 °C (decomp) (from EtOH).

4-[1-Amino-3-(3-benzyloxy-4-methoxyphenyl)-2-propenyl]tropolone (8g): Yellow crystals (88% yield), mp 155—156 °C (decomp) (from EtOH).

4-[1-Amino-3-(4-chlorophenyl)-2-propenyl]tropolone (8h): Yellow crystals (93% yield), mp 198—199 °C (decomp) (from MeOH).

4-[1-Amino-3-(2,4-dichlorophenyl)-2-propenyl]tropolone (8i): Yellow crystals (93% yield), mp 185—186 °C (decomp) (from MeOH).

4-[1-Amino-3-(4-methoxyphenyl)-2-propenyl]tropolone (8j): Yellow crystals (90% yield), mp 182—183 °C (decomp) (from EtOH).

General Procedure for the Acetylation of the Amino Compounds (8). A mixture of **8** (2 g) and acetic anhydride (8 ml) was heated until it became a solution and then, after cooling, diluted with water (50 ml), depositing the acetamido compounds (**9**).

4-[1-Acetamido-3-(3,4,5-trimethoxyphenyl)-2-propenyl]tropolone (9a): Colorless leaflets (85% yield), mp 192—193 °C (from EtOH); ^{1}H-NMR 2.06 (3H, s, AcN), 3.84 (9H, s, 3MeO),5.2 (2H, m, OH. NH, exchangeable with D_2O), 5.60 (1H, m, H-8), 6.48 (1H, dd, J=14, 5 Hz, H-9) 6.55 (2H, s, H-2′,6′), 7.05—7.35 (4H, m, H-5,6,7,10), 7.25 (1H, d, J=14 Hz, H-10), and 7.40 (1H, s, H-3).

4-[1-Acetamido-3-(3, 4-dimethoxyphenyl)-2-propenyl]tropolone (9b): Colorless needles (93% yield), mp 183—184 °C (from MeOH).

4-[1-Acetamido-3-(3,4-methylenedioxyphenyl)-2-propenyl]tropolone (9c): Colorless needles (86% yield), mp 177—178 °C (from MeOH).

4-(1-Acetamido-3-phenyl-2-propenyl)tropolone (9d): Colorless needles (79% yield), mp 162—163 °C (from MeOH).

*4-(1-Acetamido-3-*p*-tolyl-2-propenyl)tropolone (9e)*: Colorless needles (92% yield), mp 182—183 °C (from EtOAc).

4-[1-Acetamido-3-(4-benzyloxy-3-methoxyphenyl)-2-propenyl]tropolone (9f): Colorless crystals (62% yield), mp 148—149 °C (from EtOAc).

4-[1-Acetamido-3-(3-benzyloxy-4-methoxyphenyl)-2-propenyl]tropolone (9g): Colorless crystals (89% yield), mp 154—155 °C (from EtOAc).

4-[1-Acetamido-3-(4-chlorophenyl)-2-propenyl]tropolone (9h): Colorless crystals (95% yield), mp 154—155 °C (from EtOAc).

4-[1-Acetamido-3-(2,4-dichlorophenyl)-2-propenyl]tropolone (9i): Colorless needles (54% yield), mp 121—122 °C (from EtOAc).

4-[1-Acetamido-3-(4-methoxyphenyl)-2-propenyl]tropolone (9j): Colorless crystals (90% yield), mp 122—123 °C (from EtOH).

General Procedure for the Preparation of Compounds **15**. A solution of the olefin **9** (3 g) in 0.25—1.0 M aq KOH (30 ml) was reduced with hydrogen in the presence of 10—30% Pd/C at room temperature until the starting material disappeared (*ca.* 50 h). After filtration of the catalyst, the filtrate was acidified with 6 M HCl, depositing the product **15**; when necessary, the product was extracted with chloroform.

4-[1-Acetamido-3-(3,4,5-trimethoxyphenyl)propyl]tropolone (15a): Colorless needles (98% yield), mp 129—130 °C (from EtOAc); ^{1}H-NMR 1.97 (3H, s, AcN), 2.0 (2H, m, 2H-9), 2.55 (2H, m, 2H-10), 3.92 (9H, s, 3MeO), 4.3 (1H, m, NH), 4.90 (1H, q, J=7 Hz), 6.36 (2H, s, H-2′,6′), and 7.1—7.4 (4H, m, H-3,4,6,-7).

4-[1-Acetamido-3-(3,4-dimethoxyphenyl)propyl]tropolone (15b): Colorless crystals (93% yield), mp 143—144 °C (from EtOAc–MeOH).

4-[1-Acetamido-3-(3, 4-methylenedioxyphenyl)propyl]tropolone (15c): Colorless crystals (67% yield), mp 168—169 °C (from EtOAc).

4-(1-Acetamido-3-phenylpropyl)tropolone (15d): Colorless needles (88% yield), mp 148—149 °C (EtOH).

*4-(1-Acetamido-3-*p*-tolypropyl)tropolone (15e)*: Colorless needles (90% yield), mp 149—150 °C ($CHCl_3$).

We are grateful to Mr. H. Akiyama for carrying out a part of the experiments. The present work was partially supported by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture and also a Research Grant from Sankyo Co. Ltd., Tokyo, to which we wish to express our thanks.

Synthesis and the Spectral Analysis of 4- and 6-[1-Acetamido-3-(3,4,5-trimethoxyphenyl)propyl]-2-methoxytropones (B-Ring-open Analogues of Colchicine)[1]

Hiroshi YAMAMOTO,* Atsushi HARA, Saburo INOKAWA, and Tetsuo NOZOE†
Department of Chemistry, Faculty of Science, Okayama University, Tsushima, Okayama 700
(Received April 16, 1983)

The treatment of 4-[1-acetamido-3-(3,4,5-trimethoxyphenyl)propyl]tropolone with ethereal diazomethane gave the 6- and 4-substituted title compounds in 51 and 38% yields, respectively. The 270-MHz ^{1}H-NMR spectral analysis performed on these compounds, colchicine, and two methyl ethers of hinokitiol permits unequivocal assignment of the position of the *C*-substituent on these 2-methoxytropone rings. Attempts were made to effect the direct B-ring closure of these intermediates and 4-[1-acetamido-3-(3,4,5-trimethoxyphenyl)propyl]-5-aminotropolone using various oxidizing reagents.

In our effort to explore a convenient and efficient route for the preparation of colchicine (**1**) and its analogues, and also as a part of our study of troponoid chemistry, we have previously reported[2,3] a facile synthesis of 4-(1-acetamido-3-arypropyl)tropolones (*e.g.* **4**) from 4-acetyltropolone (**3**). We wish to describe herein the preparation of B-ring-open colchicine analogues and an effective use of ^{1}H-NMR spectroscopy in the structural assignment of the related 2-methoxytropone derivatives.

As a representative example of the derivatization to colchicine analogues, 4-[1-acetamido-3-(3,4,5-trimethoxyphenyl)propyl]tropolone (**4**) prepared[3] from **3** in five steps with an overall yield of *ca.* 35—40% was treated with ethereal diazomethane at 0 °C to furnish colorless needles of **5** (mp 119—121 °C) and **6** (180—182 °C) after chromatographic separation. The high-resolution EI mass spectra of both compounds clearly gave the molecular ions at *m/e* 401 ($C_{22}H_{27}O_6N$) corresponding to the methyl ethers of **4**. The structural assignments of these two isomers were effectively made by the analysis of the 270 MHz ^{1}H-NMR spectral signals at δ 6.7—7.3 due to their tropolone ring moiety (see Fig. 1). Namely, the doublet at δ 6.70 in the spectrum of **5** was readily assigned to H-3 on the evidence of a long-range spin coupling (J=0.3 Hz) with the methoxyl group on C-2, as had been observed for methyl ether derivatives of salicylaldehyde[4] and 5-aminotropolones.[5] The other ring-proton signals were then automatically assignable by decoupling experiments, leading to structure **5**, 6-[1-acetamido-3-(3,4,5-trimethoxyphenyl)propyl]-2-methoxytropone (the colchicine molecule being cleaved at the C_{1a}–C_{12a} bond), for the product available from the faster-eluting fraction; see Table 1 for parameters of the NMR spectrum of **5**.

Similarly, the spectrum of the other product can be rationalized in terms of the isomeric structure, 4-substituted 2-methoxytropone (**6**) (an analogue of isocolchicine); the parameters of the spectrum and the assignments of the signals are also summarized in Table 1.

The remarkable difference in the splitting patterns of the H-3 signals between these two isomers **5** (doublet) and **6** (slightly broadened singlet) readily permits the assignment of the position of the *C*-substituent on the 2-methoxytropone nucleus. This evidence is of value for distinguishing between the 4- and 6-positional isomers of the methyl ethers derived from many kinds of naturally occurring 4-substituted troponoids,[6,7] such as colchiceine (**2**), hinokitiol (**7**), and β-dolabrin (**8**). The two methyl ethers **9** and **10**, which had been reported as an inseparable mixture upon treatment of **7** with diazomethane,[8,9] have now been separated into pure components by silica-gel column chromatography. Their structures can easily be established by their ^{1}H-NMR spectral analysis even at 60 MHz; see the assignments for each compound recorded in Table 1.[10] The distinction between these two isomers **9** and **10** had

previously been made either by chemical conversion to the known tropolone derivatives[11] or by examining the out-of-plane bending bands in their IR spectra.[12] Although the latter method is useful for relatively simple tropolone derivatives, the distinction by the NMR spectroscopy is obviously more reliable and has a wider applicability.

The ^{1}H-NMR spectrum of colchicine (**1**) taken at 270 MHz is in accord with the characteristic features discussed above. The assignment of all signals, which can reasonably be made by considering (with the aid of the CPK and Dreiding models) the dihedral angles between the A and C rings, are recorded in Table 1. It is noted that, when **1** is hydrolyzed to colchiceine (**2**) either with hot, dilute hydrochloric acid[13] or with cold alkali, an appreciable downfield shift (0.3—0.4 ppm) of the H-3 and H-4 signals occurs. A similar shift can be seen, when the H-3 and -4 signals of the analogue **5** are compared with those of **4** (see Table 1).[14]

Various attempts were made to effect the B-ring-closure of compounds **4** and **5** to provide **2** and **1**, respectively, using the following oxidizing reagents which have been effective for the oxidative coupling of phenols:[15] i) diphenyl selenoxide,[16] ii) thallium(III) tris(trifluoroacetate),[17] and iii) manganese(III) acetylacetonate.[18] However, these procedures were found to be unsuccessful and the starting materials remained unchanged in most cases. Alternatively, in order to utilize the Pschorr reaction for the ring-closure,[19] the amino compound **12**, obtained from **4** *via* 5-*p*-tolylazo compound (**11**),[20] was first diazotized to the 5-diazonium salt (**13**) and subjected to various conditions of the Pschorr reaction,[21] but no appreciable amount of anticipated colchiceine (**2**) was detected among the reaction products. Attempts at partial or total demethylation of the methoxyl groups on the phenyl ring in **4** (to lead to *e.g.* compound **14**) using trimethylsilyl iodide[22] or conc hydrobromic acid resulted in extensive decomposition.

These findings are believed to be of value, not only from the viewpoint of modifications of the ring-closure for an efficient synthesis of various kinds of colchicine analogues having a potential biological activity, but also from that of the development of the fundamental chemistry of troponoids.[23]

Experimental

Melting points were measured with a Yanagimoto MP-3 instrument and are uncorrected. The ^{1}H-NMR spectra were recorded in $CDCl_3$ with a Hitachi R-20A (60 MHz) [or Brucker WH-270 cryospectrometer (270 MHz) for compounds **1**, **5**, and **6**]. Chemical shifts are reported as δ values in parts per million relative to tetramethylsilane (δ 0.0) as an internal standard. Spin decoupling was performed for all proton signals to confirm the coupling constants. Mass spectra were measured with a Hitachi M-80 high-resolution instrument and are given in terms of *m/e* (relative intensity) compared with the base peak and possible assignments. IR And UV spectra were obtained on Hitachi 215 and 340 spectrometers, respectively. All reactions were monitored by TLC [conducted on plates precoated with silica gel (0.25 mm, Merck)]. Column chromatography was performed using Merck Lobar silica gel.

6-[1-Acetamido-3-(3,4,5-trimethoxyphenyl)propyl]-2-methoxytropone (5) and Its 4-Propyl Isomer (6). A solution of 257 mg of the tropolone[3] **4** in 20 ml of dry dichloromethane was treated with an excess amount of *ca.* 0.5 M (1 M=1 mol dm^{-3}) ethereal diazomethane at 0 °C for 1 h. The solvent was evaporated *in vacuo*, and the residue chromatographed on a column of silica gel with CCl_4 (which was gradually changed to $CHCl_3$) as eluent, giving **5** (136 mg, 51%) and **6** (100 mg, 38%).

5: Colorless needles, mp 119—121 °C (from CH_2Cl_2–EtOAc); R_f 0.60 (10% MeOH/$CHCl_3$, v/v); ^{1}H-NMR, see Table 1; IR (KBr) 3280, 2910, 1660, 1590, 1450, 1220, 1120, 1000, 790, and 780 cm^{-1}; EI MS *m/e* (rel intensity) 401 (29; M$^+$), 342 (35; M−$AcNH_2$), 220 (28; M−Ar*CH_2), 207 (100; M−Ar*CH=CH_2), 195 (48; Ar*CH=CH_2), 182 (43; Ar*CH_2), 181 (25), and 164 (44; M−Ar*CH=CH_2−Ac); exact mass, calcd for $C_{22}H_{27}O_6N$ 401.1837, found 401.1855.

6: Colorless needles, mp 180—182 °C (from EtOAc–hexane); R_f 0.55 (10% MeOH/$CHCl_3$); ^{1}H-NMR, see Table 1; IR (KBr) 3250, 2900, 1655, 1590—1500, 1440, 1270, 1250, 1225, 1200, 1120, 1020, 960, 820, 790, and 770 cm^{-1}; EI MS *m/e* (rel intensity) 401 (76; M$^+$), 342(18), 220(85), 207(58), 195(89), 182(51), 181(100), and 164(45); exact mass, Calcd for $C_{22}H_{27}O_6N$ 401.1837, Found 401.1841.

6- and 4-Isopropyl-2-methoxytropone (9 and 10). Hinokitiol (**7**; 200 mg) was similarly treated with cold ethereal diazomethane, and the crude products chromatographed on a column of silica gel, using benzene–ethyl acetate as eluent, thus giving **9** (47% yield) and **10** (31% yield).

Ar*: 3,4,5-Trimethoxyphenyl.

9 and **10**: Both colorless oil (*cf.* Ref. 11, oil): R_f 0.45 and 0.50, respectively, (3% EtOH–EtOAc, v/v); ^{1}H-NMR, see Table 1.

Colchiceine (2). A mixture of 49 mg of **1**, 0.5 ml of ethanol, and 0.5 ml of 1 M KOH was stirred at 20 °C for 17 h. The ethanol was removed *in vacuo*, and the residue brought to pH 4, extracted with CH_2Cl_2, dried (Na_2SO_4), and evaporated, thus giving, after recrystallization from ethyl acetate, 37 mg (78%) of **2**, mp 177—178 °C (Ref. 13, 178—179 °C).

4-[1-Acetamido-3-(3,4,5-trimethoxyphenyl)propyl]-5-(p-tolylazo)-tropolone (11). A cold solution of *p*-toluenediazonium chloride prepared from 12 mg of *p*-toluidine and 8 mg of sodium nitrite by the usual method was added to a solution of 40 mg of **4** in 0.15 ml of dry pyridine at 0 °C. After having been stirred for 3 h, the mixture was diluted with cold water (1 ml), and the precipitates were filtered off and washed with benzene, thus affording 40 mg (88% yield) of **11** as reddish orange crystals: mp 127—128 °C; ^{1}H-NMR, see Table 1; λ_{max} (MeOH) 230, 285, 430 nm (log ε 4.48, 4.06, 4.43); Found: C, 63.85; H, 6.36; N, 7.80%. Calcd for $C_{28}H_{31}O_6N_3 \cdot H_2O$: C, 64.23; H, 6.35; N, 8.03%.

4-[1-Acetamido-3-(3, 4, 5-trimethoxyphenyl)propyl]-5-aminotropolone (12). A suspension of 37 mg of **11** in 1 ml of methanol was hydrogenated over 1 mg of 10% Pd/C at 27 °C under atmospheric pressure until two equivalents of hydrogen was absorbed (20 min). The catalyst was filtered off and the filtrate was concentrated *in vacuo* to give 28 mg (95% yield) of **12** as yellow needles: mp 122—123 °C (from EtOAc); ^{1}H-NMR, see Table 1; λ_{max} (MeOH) 232, 360, 400 nm (log ε 4.42, 4.06, 3.96); Found: C, 62.67; H, 6.76; N, 7.21%. Calcd for $C_{21}H_{26}O_6N_2$: C, 62.67; H, 6.51; N, 6.96%.

We wish to thank Mr. K. Suzuki for carrying out a part of experiments and Dr. T. Takita of Institute of Bioorganic Chemistry, Kawasaki, for the kind measurements of the 270 MHz ^{1}H-NMR and the high-resolution mass spectra. The present work was partially supported by a Research Grant (to H.Y.) from the Suntory Institute of Bioorganic Research, Osaka, to which we wish to express our thanks.

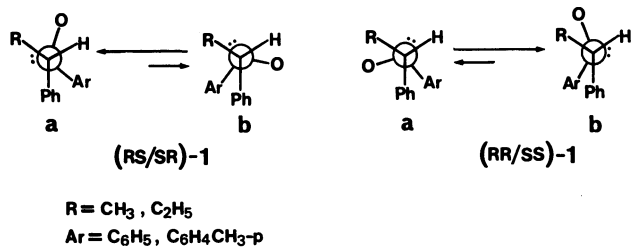
(Received April 18, 1983)

The conformations of the diastereomers of 1-*p*-tolyl-2-phenyl-1-propanols[(*RS*/*SR*)-**3** and (*RR*/*SS*)-**3**], 1-*p*-tolyl-2-phenylethanol (**4**), and 1-*p*-tolyl-2-phenyl-1-propanone (**5**) were studied by means of NMR spectroscopy, mostly with the aid of the computer-simulation of the lanthanoid-induced shifts. It has been suggested that the rotamers in which the tolyl group lies close to the phenyl group are preferred in the conformational equilibria of (*RS*/*SR*)-**3**, **4**, and **5**. For (*RR*/*SS*)-**3**, the most stable rotamer (in $CDCl_3$) has been suggested to have the tolyl group *anti* to the phenyl group and *gauche* to the methyl group. The results have been discussed in view of the general occurrence of the folded conformation.

Our recent nuclear magnetic resonance studies of several diastereomeric 1-phenylalkyl aryl sulfoxides, (*RS*/*SR*)- or (*RR*/*SS*)-$C_6H_5CH(R)$–SO–Ar (**1**),[1] have demonstrated that the conformational equilibria of these compounds are like those illustrated in Scheme 1. That is to say, it has been found that the rotamers in which the aromatic group(Ar) is positioned *gauche* to the phenyl group (Ph) (**a** and **b** rotamers) are most populated in the conformational equilibria of these compounds.



Scheme 1.

This phenomenon (favored *gauche* interactions) is interesting in relation to a similar one hitherto observed for the compounds of the following type: $C_6H_5CH(CH_3)$–X–R (**2**) [X=S,[14] SO,[1,10] CH_2,[13] CHOH,[4,7] CO;[9] R=CH_3, C_2H_5, *i*-C_3H_7, *t*-C_4H_9]. These findings have now prompted us to investigate the conformational analysis of a few alcohols, the diastereomeric pairs of 1-*p*-tolyl-2-phenyl-1-propanol [(*RS*/*SR*)-**3** and (*RR*/*SS*)-**3**], 1-*p*-tolyl-2-phenylethanol (**4**), and a ketone, 1-*p*-tolyl-2-phenyl-1-propanone (**5**), which have the structural resemblance to **1**. It is quite important to explore the generality of the phenomenon (favored *gauche* interactions) in order to know the nature of the interactions, which provide the molecular shapes of these compounds. In this paper we wish to report the results for the conformational assignments of the compounds (**3**—**5**) accomplished with the aid of NMR spectroscopy and comments concerning the interactions involved in the conformational equilibria.

Experimental

(RS/SR)- *and* (RR/SS)-*1*-p-*Tolyl-2-phenyl-1-propanols (3).* 2-Phenylpropionaldehyde (50 g, 0.37 mol) was treated with a Grignard reagent derived from 70 g (0.41 mol) of *p*-bromotoluene and 10 g (0.41 mol) of magnesium in dry ether. After the usual work-up, the crude product was purified by fractional distillation to yield a diastereoisomeric mixture of **3** (73 g, 87% yield); bp 138—139 °C/1—2 Torr (1 Torr≈133.322 Pa). The diastereomeric ratio, (*RS*/*SR*)-**3** : (*RR*/*SS*)-**3**, of the products evaluated by NMR was about 6 : 1. The separation of the diastereoisomers was carried out using a procedure similar to that described for 1,2-diphenylpropanols by Cram and Erhafez.[2] Thus the above mixture (15.2 g, 67 mmol) was treated with *p*-nitrobenzoyl chloride (12.5 g, 67 mmol) in 25 cm^3 of dry pyridine at 90—95 °C for 2 h. Five recrystallizations of the resulting mixture of esters from ethyl acetate yielded the *p*-nitrobenzoyl ester of (*RS*/*SR*)-**3** (9.3 g, 37%); mp 98 °C. The hydrolysis of the above ester (5.3 g, 14 mmol) was carried out in a mixture of 10 cm^3 of water and 10 cm^3 of methanol, with 0.8 g of potassium hydroxide and 0.6 g of sodium hydroxide, to yield 2.9 g of (*RS*/*SR*)-**3**. This was purified by column chromatography on silica gel using ether–hexane (1 : 3) as the eluent. Yield 2.4 g (76%); bp 138 °C/1—2 Torr. Found: C, 84.55; H, 7.98%. Calcd for $C_{16}H_{18}O$: C, 84.92; H, 8.02%.

1-*p*-Tolyl-2-phenyl-1-propanone (**5**) (9.9 g, 44 mmol) was treated with 1.5 g of lithium alminium hydride to yield a mixture of the diastereoisomeric alcohols (9.1 g, 91%); bp 135 °C/1 Torr. The diastereomeric ratio, (*RS*/*SR*)-**3** : (*RR*/*SS*)-**3**, was evaluated to be *ca.* 1 : 4 by NMR. The above mixture (2.5 g, 11 mmol) was treated with 1.7 g (11 mmol) of phthalic anhydride in 2 cm^3 of dry pyridine at 100 °C for 2 h to produce the phthalic acid monoesters of **3**. Four recrystallizations of the ester from ethyl acetate–hexane yielded the ester of (*RR*/*SS*)-**3** (1.9 g, 46%); mp 131—132 °C. The free alcohol (1.0 g) was obtained by hydrolyzing the ester (1.75 g, 4.7 mmol) in 6 cm^3 of methanol–water (1 : 1) using a mixture of potassium hydroxide (0.5 g) and sodium hydroxide (0.5 g). The subsequent column chromatography on silica gel, eluting with ether–hexane (1 : 3), afforded analytically pure (*RR*/*SS*)-**3** (0.95 g, 90%). Found: C, 84.91; H, 8.05%. Calcd for $C_{16}H_{18}O$: C, 84.92; H, 8.02%.

1-p-*Tolyl-2-phenylethanol (4).* This compound was

prepared by the reaction of phenylacetaldehyde (18 g) with *p*-tolylmagnesium bromide (derived from 27 g of *p*-bromotoluene and 3.9 g of magnesium) in dry ether. After the usual work-up, column chromatography of the crude product on silica gel (ether : hexane=1 : 3), followed by the recrystallization from hexane, yielded analytically pure **4** (23.5 g, 74%); mp 68—69 °C (lit,[3] 68—69 °C).

1-p-Tolyl-2-phenyl-1-propanone (5). The diastereomeric mixture of 1-*p*-tolyl-2-phenyl-1-propanols(**3**) (10.4 g, 46 mmol) was oxidized with 50 mmol of Jones reagent in 200 cm^3 of acetone. The usual work-up, followed by the fractional distillation of the crude product gave analytically pure **5** (7.6 g, 74%); bp 125 °C/1 Torr. Found C, 85.13; H, 7.14%. Calcd for $C_{16}H_{16}O$: C, 85.68; H, 7.19%.

NMR Measurements. The ^1H and ^{13}C NMR spectra were measured for solutions in $CDCl_3$ and/or C_6D_6 (*ca.* 0.3 mol/dm^3) on a JEOL FX-90Q spectrometer. The chemical shifts are given in ppm downfield from internal tetramethylsilane (TMS). The assignments for the carbon resonances were aided by the comparisons of the lanthanoid-induced shifts (LIS).

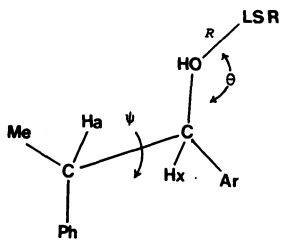
Lanthanoid-induced Shifts (LIS) Measurements. The LIS were determined, for $CDCl_3$ and C_6D_6 solutions, as described in the preceding paper[1] using $Yb(fod)_3$ or $Eu(fod)_3$ as the lanthanoid shift-reagents (LSR). Table 1 lists the relative LIS's for protons and carbons in (*RS/SR*)-**3**, (*RR/SS*)-**3**, **4**, and **5**. The vicinal coupling constants, $^3J_{H_aH_x}$, have been found to be insensitive to the addition of the LSR. Perturbation to the conformational equilibria by coordination is therefore unimportant for **3** and **4**.

Computer-simulation of LIS. The computer simulation of the LIS was carried out according to the procedure described in the previous papers.[4,10] Thus, the distribution of the LSR and the conformation of the molecule (with regard to the central C–C bond) were varied, step by step, in the search for an acceptable fit of the computed LIS's [assuming the McConnell–Robertson's relationship: $LIS_i^{calcd}=K(3\cos^2\chi_i-1)r_i^{-3}$] with the observed values. For the methyl and aromatic protons, and for C(2) and C(3), the contribution of the individual nuclei was calculated and then averaged. The Hamilton reliability factor, $AF=[\sum_i(LIS_i^{obsd}-LIS_i^{calcd})^2/\sum_i(LIS_i^{obsd})^2]^{1/2}$, was used in order to assess the agreement between the computed LIS's and the experimental ones. The calculated shifts were normalized to the average experimental LIS in the computational process.

Results

Figure 1 plots the agreement factor (*AF*) against the O–C(8)–C(7)–C_6H_5 dihedral angle (ϕ) for (*RS/SR*)-**3**. The values of *R* (LSR–O distance), θ (LSR–O–C angle), and *A* (index for the LSR-distribution)[4] are fixed at 0.32 nm, 130°, and 0.8, respectively (see Scheme 2).

An interesting feature of these profiles is the appearance



Scheme 2. A typical model for the (*RS/SR*)-3-LSR complex (Ph: C_6H_5, Ar: $C_6H_4CH_3$-*p*, Me: CH_3).

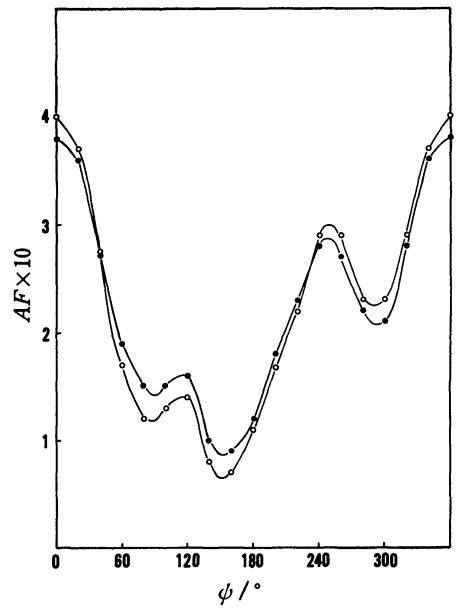


Fig. 1. Plots of *AF vs.* the OH/Ph dihedral angle (ϕ) for (*RS/SR*)-**3**. ●—●: H_a, Me_1, H_x, H_{o1}, H_{o2}, C_1, and C_{16} were used as the monitor nuclei. ○—○: Computed with five proton LIS's.

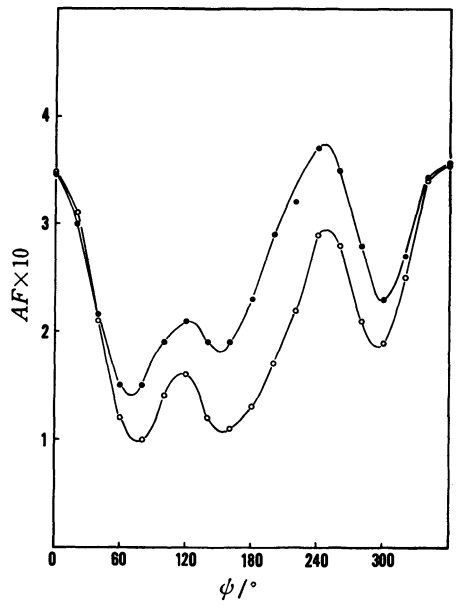

Fig. 2. Plots of *AF vs.* the OH/Ph dihedral angle (ϕ) for (*RR/SS*)-**3**. ●—●: H_a, Me_1, H_x, H_{o1}, H_{o2}, C_1, C_{12}, and C_{16} were used as the monitor nuclei. ○—○: Computed with five proton LIS's.

of three minima at around the staggered geometries (ϕ 80—100°, 140—160°, and 280—300°) of the molecule. Meantime, these results do not differ significantly from those obtained for the sulfoxide analogue, (*RS/SR*)-**1**.[1] For reasons described in previous papers,[1,4,10] we believe that the values of ϕ and *AF* at the minima reflect, although in an indirect manner, the approximate geometries and the contribution of the possible rotamers.[5] Thus, it is suggested that a rotamer in which the tolyl group (Ar) lies about *anti* to the methyl group (Me) and *gauche* to the phenyl group (Ph) (**a** rotamer;

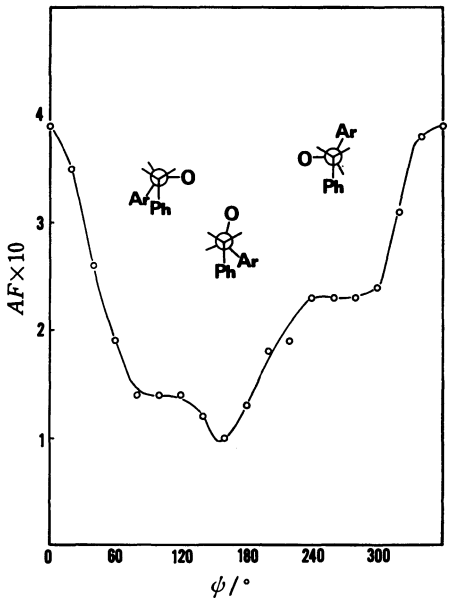

Fig. 3. A plot of *AF vs.* the OH/Ph dihedral angle (ψ) for **4**. The monitor nuclei are H_a, H_x, H_{o1}, H_{o2}, C_1, C_4, C_9, and C_{12}.

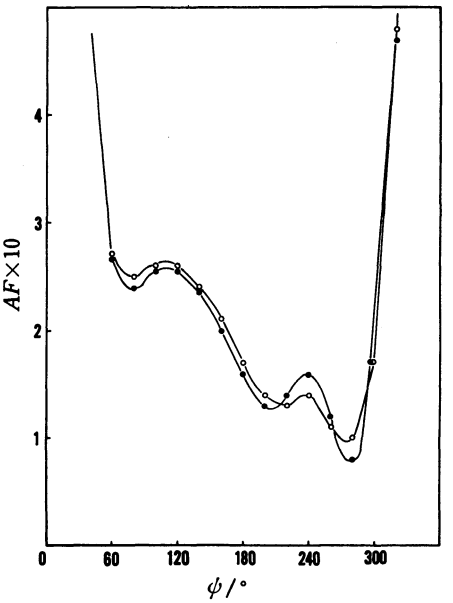

Fig. 4. Plots of *AF vs.* the C=O/Ph dihedral angle(ψ) for **5**. The monitor nuclei are H_a, Me_1, H_{o1}, H_{o2}, C_1, C_4, C_9, C_{12}, and C_{16}. ●—●: R=0.34 nm; ○—○: R= 0.32 nm.

see Fig. 5) is most preferred in the conformational equilibrium of this compound. The second most stable one is suggested to be the **b** rotamer in which Ar is flanked by Me and Ph.

Figure 2 represents the AF/ψ profiles[6] for (*RR*/*SS*)-**3**. The smallest *AF* is recorded at ψ 60—80° and the second minimum is found at 140—160°; here the most stable rotamer seems to have Ar *anti* to Ph but close to Me (**c** rotamer; see Fig. 5).

In Fig. 3 is given an AF/ψ profile[6] recorded for the benzylic alcohol (**4**). The result is rather similar to those obtained previously for its analogues, in which

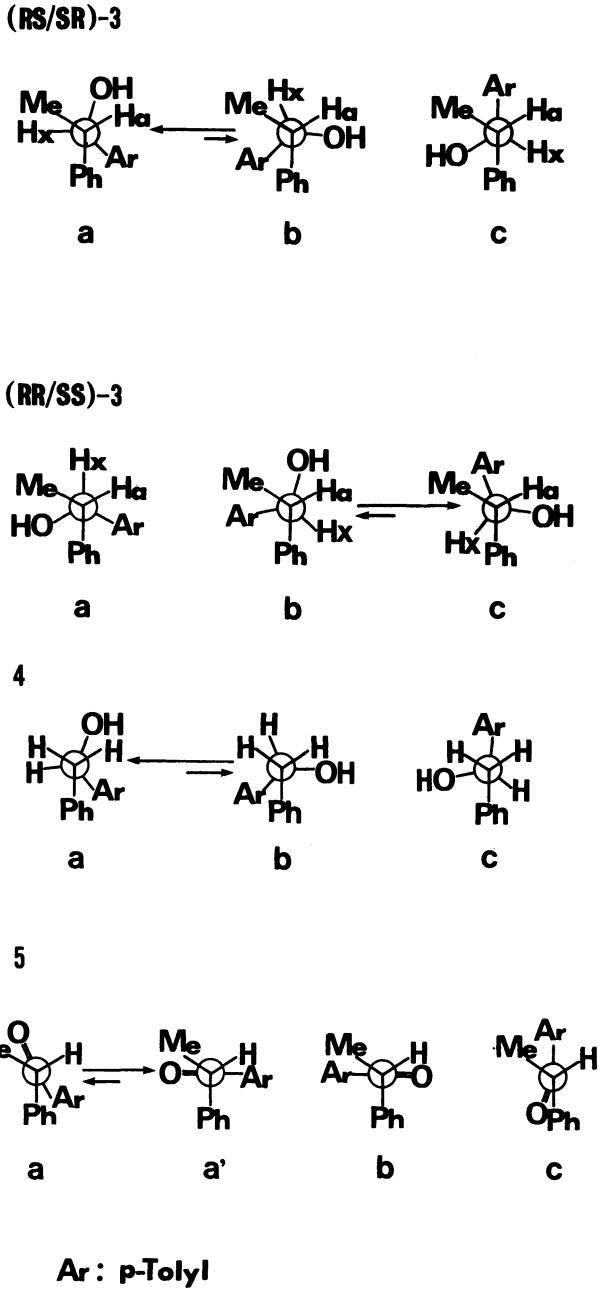

Fig. 5. Plausible conformations and the rotameric equilibria suggested by the LIS-simulation for (*RS*/*SR*)-**3**, (*RR*/*SS*)-**3**, **4**, and **5**.

the tolyl group of **4** is replaced by an alkyl group.[7] Thus, the rotamer having the OH group *anti* to Ph (ψ *ca.* 160°) is suggested to be most preferred.

The profiles obtained for the 1-*p*-tolyl-2-phenyl-1-propanone (**5**) are shown in Fig. 4[8] (R=0.34 nm, θ= 140°, p=0.4). The smallest *AF* values are recorded at ψ [O(=C)/Ph dihedral angle] *ca.* 280° and then 200—220°; the results are analogues to its alkyl derivative, in which the tolyl group in **5** is replaced by an isopropyl group.[9]

Discussion

Figure 5 summarizes the results obtained by the LIS

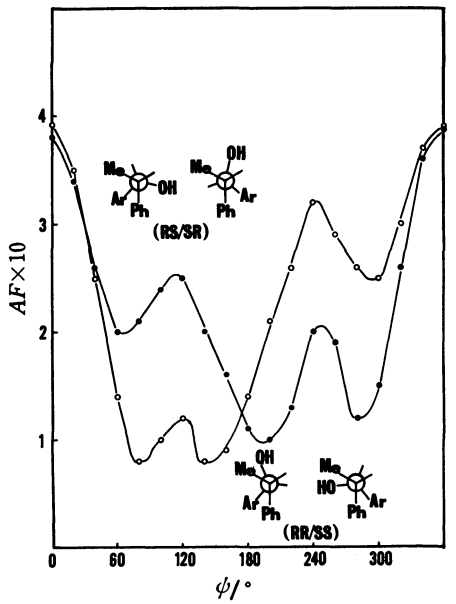

Fig. 6. Plots of *AF vs.* the OH/Ph dihedral angle (ϕ) for (*RS/SR*)-**3** (○—○) and (*RR/SS*)-**3** (●—●). The LIS's were obtained with the use of Eu(fod)$_3$ in C_6D_6 for five protons (H_a, Me_1, H_x, H_{o1}, and H_{o2}).

method for the four compounds, (*RS/SR*)-**3**, (*RR/SS*)-**3**, **4**, and **5**.

We do not wish to mean that the molecular geometries illustrated in Fig. 5 correspond exactly to the shapes of the stable rotameres, since the model (on which the computation is based) is rather primitive and a number of approximations were introduced in the simulation process. The values of *AF*, either, do not necessarily reflect the correct order of the stability (above all, if the difference is small) of the possible rotamers. We may conclude from above results, however, that the folded rotamers are generally preponderant in the conformational equilibria of these compounds. Thus, in the cases of (*RS/SR*)-**3**, the benzylic alcohol (**4**), and the ketone (**5**), the most populated rotamers are suggested to have their tolyl group *gauche* to Ph [rotamers **a** and **b** for (*RS/SR*)-**3** and **4**; rotamers **a** and **a'** for **5**]. The results are consistent with those obtained for the sulfoxide analogues,[1,10] (*RS/SR*)-**1**[11] and the alkyl analogues (**2**).[4,7,9] Meanwhile, in the conformational equilibrium of **5**, the conformer in which the tolyl group is *anti* to Ph (rotamer **c**; C=O is eclipsed to Ph) is least favorable (Fig. 4). The absence of this rotamer has been reported also for other carbonyl compounds.[9] In this respect, it is noteworthy that, in all of the conformations suggested to be preferred (see Figs. 1—4, Figs. 8 and 9 in Ref. 4, Fig. 4 in Ref. 9, and Fig. 3 in Ref. 7), the C=O and OH groups have never been found to lie eclipsed with the phenyl group; *AF*'s are always largest at ϕ *ca.* 0°.

The compound (*RR/SS*)-**3** represents a somewhat different case; here the most stable rotamer seems to have the tolyl group *anti* to the phenyl group but close to the methyl group (**c** rotamer). The second most populated one seems to be the **b** rotamer whereby the tolyl group is flanked by the methyl group and the phenyl group. The result differs from those obtained for the sulfoxide analogue,[1] (*RR/SS*)-**1**.[11] In order to confirm the above suggestions the NMR parameters listed in Tables 2 and 3 were examined in detail.

Chemical Shifts. In harmony with the suggested predominance of the *gauche* Tolyl/Ph conformations, appreciable upfield shifts are observed for the aromatic protons of (*RS/SR*)-**3**. The *ortho* protons (H_{o1} and H_{o2}) give rise to peaks at considerably higher magnetic field (δ 7.07—7.09) as compared to those in reference compounds (δ 7.18—7.23 for alkyl homologues: **2**, X= CHOH).[4] The high-field shifts are not significant in

Table 1. The lanthanoid-induced shifts[a] of 1-*p*-tolyl-2-phenyl-1-propanols(**3**), 1-*p*-tolyl-2-phenylethanol(**4**), and 1-*p*-tolyl-2-phenyl-1-propanone(**5**)

a) Reported in ppm downfield from internal TMS in $CDCl_3$.

the case of (*RR/SS*)-alcohol. This is not unexpected since the aromatic groups are remote from each other in the most preferred rotamer of this compound. Noteworthy in this regard, is the chemical shift of the methyl protons. The signal attributed to Me (δ 1.05) is remarkably shifted upward in the (*RR/SS*)-isomer as compared with that in (*RS/SR*)-**3** (δ 1.29). This is consistent with the suggestion that in (*RR/SS*)-**3** Me is close to the tolyl group in both of the preferred rotamers (**c** and **b**).

Vicinal Coupling Constants. The spin-coupling constant regarding the vicinal protons ($^3J_{H_aH_x}$) is smaller in (*RS/SR*)-**3** than in (*RR/SS*)-**3**. This may be an indication that the H_a/H_x torsional angle (see Fig. 5) in the most important contributor [rotamer **a** for (*RS/SR*), rotamer **c** for (*RR/SS*)] is closer to 180° in (*RR/SS*)-alcohol than in (*RS/SR*)-isomer, or the proportion of the most stable rotamer is larger in (*RR/SS*)-alcohol than in (*RS/SR*)-alcohol.

Conformational Change in C_6D_6. It is noted that $^3J_{H_aH_x}$ of (*RS/SR*)-**3** does not differ significantly in $CDCl_3$ and in C_6D_6 (Table 2), however, for (*RR/SS*)-**3** it becomes appreciably smaller by replacing the solvent from $CDCl_3$ (8.8 Hz) to C_6D_6 (7.8 Hz). We therefore determined the LIS in C_6D_6 for the diastereoisomeric alcohols and carried out the simulation with the use of these data (Table 1). For (*RS/SR*)-isomer, the profiles are similar to each other in these two solvents. A remarkable difference is found, on the other hand, in the case of (*RR/SS*)-alcohol (Figs. 2 and 6). In C_6D_6 solution, the **b** and **a** rotamers seem to become the most important contributors. The results are compatible with the coupling data. We, however, reserve further discussion on this matter, until more exact knowledge about the conformational equilibria becomes available.

Aromatic Solvent-induced Shifts (ASIS).[46] The ASIS data are listed in Table 2. The results are consistent with the suggested equilibria of these alcohols, but here we only cite an interesting observation that ASIS's for the methyl and aromatic protons are negative in (*RS/SR*)-**3**; at present we have no clear explanation for this phenomenon.

^{13}C NMR Data. The peak attributed to the methyl carbon [C(16)] appears at considerably higher magnetic field (δ 15.1) in (*RS/SR*)-**3** than in the (*RR/SS*)-alcohol (δ 18.4) (Table 3). This is well understood in terms of the *γ-gauche* effect.[1,12] In the most stable rotamer of (*RS/SR*)-**3** (**a** rotamer) OH is *gauche* to Me, but in (*RR/SS*)-**3** this is remote from Me in the most preferred rotamer (**c** rotamer).

In summary, inspection of these conformational analyses reveals that the molecules, (*RS/SR*)-**3**, **4**, and **5**, tend to adopt the folded conformations in solution. In addition, we felt it probable that the phenomenon is general to other kind of molecules, in view of the common preference of the *gauche* rotamers, at least in these simplest systems studied thus far [$C_6H_5CH(R^1)$-X-R^2 : R^1=H, CH_3, or C_2H_5; R^2=alkyl or aryl group; X=CH_2,[13] CHOH,[4,7] CO,[9] S,[14] SO,[1,10] or SO_2,[14]]. The generality of the favored *gauche* alkyl/phenyl conformation (CH/π interaction)[15] was argued previously.[9,16] The scope was therefore examined for the phenomenon in systems, where aromatic groups are incorporated in each end of the molecules.

Table 4 is a summary of a literature survey on compounds relevant to this problem. X-ray studies of 1,2-

TABLE 4. TYPICAL COMPOUNDS WHICH EXHIBIT THE PREFERENTIAL FOLDED CONFORMATION

Compound	Method	Favored conformation	Ref.

Methods: NMR-1 = vicinal coupling constant: NMR-2 = ^1H chemical shift; NMR-3 = T_1 measurement (^{13}C); NMR-4 = *γ-gauche* effect; NMR-5 = LIS-simulation; UV = observation of charge-transfer band; CD = circular dichroism; FL = fluorometry; EFF = empirical force-field calculation; EFF/EHMO = EFF/extended Hückel MO hybrid method.

diphenylethane (**6**),[17] *p*-methoxybenzyl *p*-chlorophenyl sulfone (**7**),[18] and (*RS*/*SR*)-**1**[19] demonstrated that these molecules adopt the extended conformations (*anti* aromatic groups) in the crystal fields. In solution, however, **7**,[18] **1**,[1,20] and their analogues[14,20,21] have been shown to be present in folded (*gauche* aromatic groups) conformations. For solution (or gas phase) conformation of **6** and its homologue, 1,2-diphenylpropane(**8**), the results obtained earlier are rather contradictory. Thus, force-field and semi-empirical MO calculations showed that **6**[22] and **8**[23] are more stable in *gauche* Ph/Ph conformations. On the other hand, NMR spin-coupling data of **8**[23,24] (as well as the EFF/EHMO results on **6** and **8**[25] were reported to be incompatible with this conclution. We do not know the reason for the above disagreement, but it may be pointed out that an argument based only on coupling constants often leads to an ambiguous conclusion. Huang *et al.* studied the conformations of substituted 1,2-diphenylethanes(**6'**)[26] and 2,3-diphenylbutane derivatives (**9**),[27] and reported that these molecules prefer the *anti* Ar/Ar conformations (an appreciable proton resides in the *gauche* conformation, however). The conformations of 2-arylethyl *p*-toluenesulfonate (**10**),[28] (*N*-substituted benzyl)anilines (**11**),[29] arylalkyl 2,4,6-trinitrobenzoates (**12**),[30] *N*,*N'*-bis(α-tosylbenzyl)-urea(**13**),[31] *p*-dimethylaminophenyl *N*-methyl-*N*-(*p*-nitrophenylsulfonylmethyl)carbamate(**14**),[32] certain flavinyl peptides (**15**),[33] nicotinamide-adenine dinucleotides (**16**),[34–36] and its analogues (**17**),[37–39] 9-[3-(adenin-9-yl) propyl]-6-(3-methyl-2-butenylamino)-purine (**18**),[40] several mixed-ligand metal complexes (**19**),[41] and somatostatin (**20**)[42] (a cyclic tetradecapeptide) were also studied and they have been shown to exist preferentially in folded forms, whereby two aromatic groups in the molecules are approached to each other.

The reason of the discrepancy cited as above for the conformations of **6** (or **6'**) and **8** remains to be clarified. We believe, however, that the folding tendency of groups (Ar/Ar, Alkyl/Ar,[9,16] and Alkyl/Alkyl[43]) is general to a wide variety of compounds. It may be a rule rather than an exception. In other words, one must seek an explanation if one finds an extended conformation.

As to the origin of the folded conformations, it may be the dispersion force,[13,28,43b,43d] CH/π interaction,[15,44] CH/n interaction,[9,44] and/or other interactions which are not yet disclosed. A folded conformation may, of course, be brought about by other type (such as the hydrogen bonding,[45] dipole/quadrupole,[46] quadrupole/quadrupole, *gauche*-vicinal H/H[47]) of interactions. In any event, the geometry of a molecule is determined as a result of a compromise of various (attractive as well as repulsive) effects. In view of this, it is surprising that the important contribution of weak, attractive interactions has hitherto been underestimated in organic chemistry.[48]

We wish to thank Prof. Masayoshi Kinoshita of Osaka City University for his encouragement.

Photoinduced Intramolecular Cyclization of 9-(ω-Anilinoalkyl)phenanthrenes

Akira Sugimoto,* Katsumi Sumi, Keiji Urakawa, Mamoru Ikemura, Satoshi Sakamoto, Shigeo Yoneda, and Yoshio Otsuji*

Department of Applied Chemistry, University of Osaka Prefecture, Mozu-Umemachi, Sakai, Osaka 591

(Received April 23, 1983)

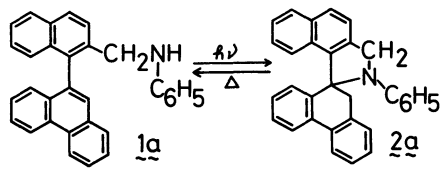
Photoreactions of a series of compounds of the type 9-phenanthryl–A–$CH_2NHC_6H_5$ [–A–=*o*-phenylene (**1b**), $-(CH_2)_2-$ (**1c**), $-(CH_2)_3-$ (**1d**), $-(CH_2)_4-$ (**1e**), $-CH_2-$ (**1f**)] in benzene were studied. From **1b—d**, the spiro compounds are obtained by an intramolecular *cis*-addition of the N–H function to the C_9, C_{10}-double bond of the phenanthrene ring. These photoproducts can be converted to the starting materials by treating with trifluoroacetic acid or heating above their melting temperatures. The mechanistic features of these reactions are described.

Photoreactions between excited aromatic hydrocarbons and amines in their ground states have been extensively studied in recent years.[1] For example, primary and secondary amines undergo the photoaddition to aromatic hydrocarbons such as benzene,[2] naphthalene,[3] and anthracene[4] *via* an exciplex or an electron-transfer from the amines to the excited aromatics.[5]

In a previous paper, we reported that irradiation of 9-(2-anilinomethyl-1-naphthyl)phenanthrene (**1a**) in benzene affords pyrroline derivative **2a** in high yield by an intramolecular addition of the anilino function to the phenanthrene ring (Scheme 1).[6] The high efficiency of this photoreaction was attributed to a structural feature that the anilino function lies close to the phenanthrene ring in **1a** by a steric reason. We now report the photoinduced intramolecular cyclization of 9-(ω-anilinoalkyl)phenanthrenes **1b—f** which have a much greater flexibility in conformation compared with **1a**.

Results and Discussion

The phenanthrene derivatives, **1b—f**, were prepared by the routes shown in Scheme 2 and characterized from their ^1H NMR and IR spectral data and elemental analyses.

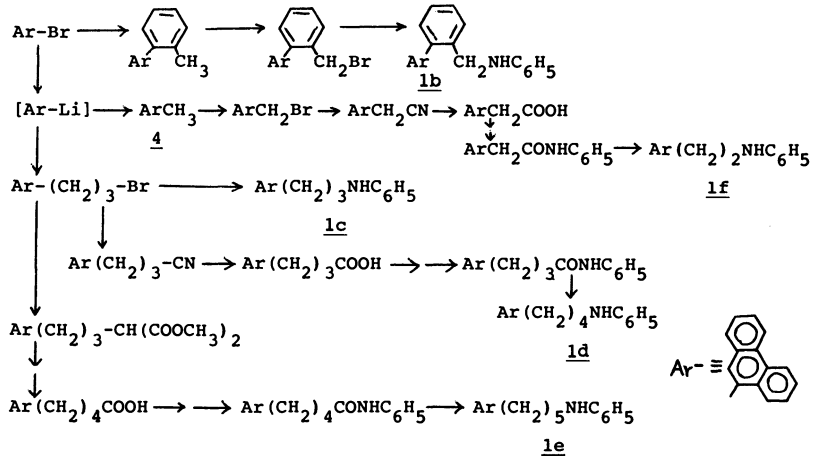


Scheme 1.

Photoproducts. Irradiation of a degassed benzene solution of **1b** (1.6×10^{-2} mol/dm^3) through a Pyrex filter with a 300 W Hg lamp for 90 min gave spiro compound **2b** in 73% yield. The irradiation for 3 h gave **2b** in quantitative yield. Similar irradiation of **1c** and **1d** afforded the corresponding spiro compounds **2c** and **2d**, respectively. The yields are shown in Table 1, together with the UV and fluorescence spectral data of the starting materials.

The spiro compounds produced by the photoreaction could be converted to the starting materials in quantitative yields by treating with trifluoroacetic acid or by heating above their melting temperatures. Structures of the photoproducts were established from their spectral data and chemical behaviors. The pertinent ^1H NMR and IR spectral data are listed in Table 2, together with those of the starting materials.

The IR spectrum of **2b** showed no NH stretching band. The ^1H NMR spectrum of **1b** changed markedly upon UV irradiation. A characteristic multiplet around δ 8.5 (2H, the H-4 and H-5 protons on the phenanthrene ring) shifted to up-field and became overlapped with signals due to other aromatic protons. A broad singlet at δ 3.54 (1H, NH) disappeared. A singlet at δ 3.91 (2H, $-CH_2-N=$) shifted to δ 4.81. A new AB quartet (J=16 Hz) centered at δ 2.60 (1H) and δ 4.30 (1H) appeared, and these signals were assigned to the H_A



Scheme 2.

Table 1. Photoreaction and spectral data of phenanthrene derivatives[a)]

Compd	UV absorption maximum λ/nm (log ε)	Relative intensity of fluorescence at 366 nm[b)]	Product	Yield (Recovery)[c)]/% In C_6H_6		In CH_3CN	
1b	299 (4.11)	1	**2b**	73[d)]	(27)[d)]	69[d)]	(31)[d)]
1c	298 (4.11)	11	**2c**	76	(12)	68	(16)
1d	298 (4.11)	20	**2d**	31	(61)	40	(52)
1e	298 (4.11)	61	—		(83)		(82)
1f	298 (4.00)	69	**3**	56	(26)	38	(41)
4	297 (4.06)	780	—		(100)		—

a) All the photoreactions were carried out by irradiating 1.6×10^{-2} mol/dm³ solutions with a 300 W Hg lamp for 90 min under the same conditions. b) Excited by a 300 nm light in hexane. c) Isolated yields. d) Estimated from the intensity of ^{1}H NMR signals.

and H_B protons on the pyrroline ring of **2b** (Scheme 3), respectively. A down-field shift of the H_B proton compared with the H_A proton may be due to a deshielding effect of lone-pair electrons on the nitrogen atom of the pyrroline ring. A similar spectral pattern was also observed in **2a**.[6)] A further support for the structure of **2b** was obtained from the following observations.

Irradiation of **1b** in a D_2O-saturated benzene gave a monodeuterated compound of **2b** (**2b**-$\mathbf{D_B}$) which showed a singlet at δ 2.60 (1H) but no signal at δ 4.30 in its ^{1}H NMR spectrum. Other ^{1}H NMR pattern of this compound was identical to that of **2b**. Treatment of **2b**-$\mathbf{D_B}$ with trifluoroacetic acid, followed by irradiation in benzene, afforded as a major product the other monodeuterated compound of **2b** (**2b**-$\mathbf{D_A}$), whose ^{1}H NMR spectrum showed a singlet at δ 4.30 but no signal at δ 2.60, along with a small amount of **1b**. These results can be explained in terms of the reaction pathway shown in Scheme 4 and support the assigned structure for **2b**. A remarkable feature of the photocyclization of **1b** to the spiro compound **2b** is that the N–H function adds stereospecifically to the C_9, C_{10} double bond of the phenanthrene ring in a *cis*-mode. The acid-catalyzed conversion of **2b** to **1b** occurs preferentially *via* the *trans*-elimination of the N–H function.

Compounds **1c** and **1d** behaved similarly when the compounds were irradiated in a D_2O-saturated benzene, supporting the assigned structures for **2c** and **2d**. In the case of **1e**, no photoreaction occurred. However, irradiation of **1f** in benzene gave 9-methylene-9,10-dihydrophenanthrene (**3**) (Scheme 5) which was characterized by ^{1}H NMR and IR spectra (see Experimental) and chemical evidence.[7)]

Mechanistic Features. UV spectra of **1b**—**f** in hexane were similar to each other in shape and resemble that of 9-methylphenanthrene (**4**) (Table 1). All these compounds also displayed fluorescence spectra similar to the fluorescence spectrum of **4** in the region of 340—450 nm in hexane (Fig. 1). Their intensities of the emission at 370 nm decreased in the order; **4**>**1f**>**1e**>**1d**>**1c**>**1b** (Table 1). The fluorescence of **4** was quenched by *N*-methylaniline. The low intensities of

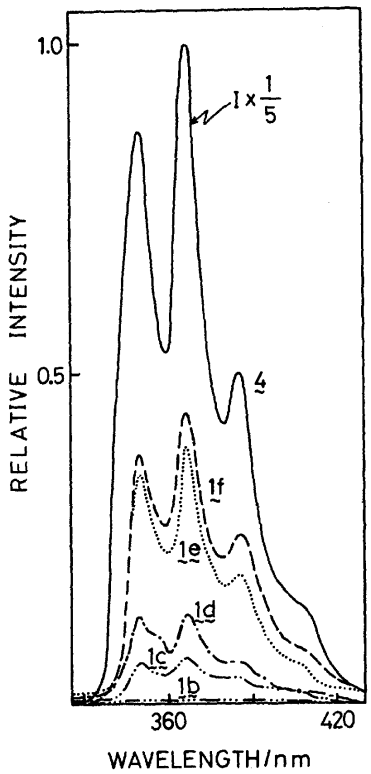

Fig. 1. Fluorescence spectra of the phenanthrene derivatives in hexane: concentration 1.00×10^{-4} mol/dm^3, excited at 300 nm.

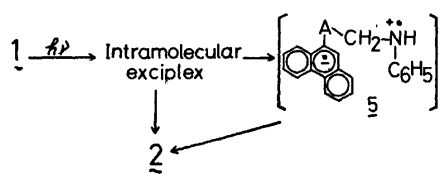
1b—**f** compared with **4** suggest that an intramolecular quenching of fluorescence by the anilino group occurs in these compounds. The quenching of fluorescence of an aromatic hydrocarbon by a primary or secondary amine has been attributed to the formation of an exciplex between the excited aromatic hydrocarbon and the amine.[5] Accordingly, the above results strongly suggest that intramolecular exciplexes are formed between the excited phenanthrene moiety and the anilino group in **1b**—**d**, and that the Hirayama rule[8] in intramolecular exciplex formation can also be applicable to these systems.

In the photoreactions of **1b**—**e**, the less emissive compounds afford the photoproducts in the higher yields as shown in Table 1. No appreciable solvent effect on the yields of the photoproducts was observed in these photoreactions (Table 1).

On the basis of all the results presented above, we propose the mechanistic pathways of the photoreactions as shown in Scheme 6. In benzene, the photoreactions probably occur from exciplexes formed by interaction between the excited phenanthrene moiety and the anilino group. In acetonitrile, the exciplexes may dissociate to ion-radical pairs **5**. However, no appreciable solvent effect on these photoreactions suggests that the photoreactions occur in a solvent cage even if the ion-radical pairs are formed. This assumption was supported by the fact that no quenching was observed when the photoreactions were carried out in triethylamine: irradiations of **1b** and **1c** in triethylamine for 90 min gave **2b** in 80% yield and **2c** in 82% yield (compare these yields with those cited in Table 1). The mechanism of the formation of **3** from **1f** remains equivocal.



Scheme 6.

Experimental

All melting points are uncorrected. IR spectra were obtained on a Hitachi 215 infrared spectrophotometer. ^{1}H NMR spectra were recorded on a Hitachi R-24A spectrometer (60 MHz) with tetramethylsilane as an internal standard. UV and visible absorption spectra were obtained on a Hitachi EPS-3T spectrometer. Fluorescence spectra were obtained for degassed samples with a Nippon Bunko FP-500S Fluorophotometer by exciting with 300 nm light.

Materials. *9-(o-Anilinomethylphenyl)phenanthrene (**1b**)*: A Grignard reagent, prepared from *o*-bromotoluene (17.5 g, 0.102 mol) and magnesium (2.5 g, 0.103 mol) in ether (40 cm^3) was added to a solution of 9-bromophenanthrene (15.5 g, 0.06 mol) and dichlorobis(triphenylphosphine)nickel(II) (0.20 g) in benzene–ether (1 : 1, v/v) (100 cm^3) over 1.5 h under gentle refluxing.[9] The mixture was refluxed further for 30 min and acidified with dil hydrochloric acid. The organic layer was separated, dried (Na_2SO_4), and evaporated. The residue solidified upon trituration with petroleum ether to give 11.7 g (69% based on 9-bromophenanthrene) of 9-(*o*-tolyl)phenanthrene. Recrystallization from hexane gave an analytical sample; mp 132—133 °C: ^{1}H NMR (CCl_4) δ 7.0—8.7 (13H, m, aromatic), 2.00 (3H, s, CH_3). Found: C, 93.98; H, 5.83%. Calcd for $C_{21}H_{16}$: C, 93.99; H, 6.01%.

A mixture of 9-(*o*-tolyl)phenanthrene (2.7 g, 7.8 mmol), *N*-bromosuccinimide (1.9 g, 10.7 mmol) and a small amount of benzoyl peroxide in CCl_4 (50 cm^3) was refluxed for 16 h. After cooling, the mixture was filtered and the filtrate was concentrated to give 9-(*o*-bromomethylphenyl)phenanthrene as a viscous oil which was purified by chromatography on silica gel with hexane.

A mixture of 9-(*o*-bromomethylphenyl)phenanthrene (2.9 g, 8 mmol) and aniline (3 g, 32 mmol) in 1,2-dimethoxyethane (10 cm^3) was stirred for 20 h at room temperature and filtered. The filtrate was concentrated under reduced pressure. The viscous oily residue was washed with dil hydrochloric acid to give a solid which was suspended in benzene and washed with dil aqueous sodium hydroxide. The benzene layer was dried and evaporated. The residue was recrystallized from hexane to give **1b** as a colorless needles in 57% yield; mp 141—141.5 °C: ^{1}H NMR (CCl_4) δ 6.0—8.7 (18H, m, aromatic), 3.91 (2H, s, CH_2), 3.55 (1H, s, NH); IR (KBr) 3430 cm^{-1} (NH). Found: C, 90.50; H, 5.61; N, 3.86%. Calcd for $C_{27}H_{21}N$: C, 90.21; H, 5.89; N, 3.90%.

*9-(3-Anilinopropyl)phenanthrene (**1c**).* To a stirred solution of 7.8 g (30 mmol) of 9-bromophenanthrene in 40 cm^3 of anhydrous ether was added butyllithium (60 mmol) in hexane and then 13 g (64 mmol) of 1,3-dibromopropane. After refluxing for 4 h, the mixture was poured into water and extracted with ether. The extract was dried (Na_2SO_4) and evaporated. The oily residue was chromatographed on silica gel with hexane to give 1.96 g (22%) of 1-bromo-3-(9-phenanthryl)propane as colorless solid; mp 55—57 °C: ^{1}H NMR

($CDCl_3$) δ 7.3—8.7 (9H, m, aromatic), 3.0—3.5 (4H, m, $-CH_2-C-CH_2$), and 2.1—2.5 (2H, m, $C-CH_2-C$).

A mixture of 1-bromo-3-(9-phenanthryl)propane (670 mg, 2.2 mmol), aniline (5 cm³, 54 mmol), and Na_2CO_3 (5 g) in DMF (30 cm³) was stirred for 42 h at room temperature. The deposited solid was filtered off and washed with a small amount of benzene. The filtrate and the benzene washing were combined and evaporated. The residue was washed with 100 cm³ of hydrochloric acid to give a solid which was dissolved in benzene and washed with an aqueous Na_2CO_3 solution. The benzene layer was dried (Na_2SO_4) and evaporated. TLC of the residue gave 450 mg (65%) of **1c**; mp 77—79 °C: ^1H NMR ($CDCl_3$) δ 6.3—8.7 (14H, m, aromatic), 3.4 (1H, br s, NH), 2.8—3.2 (4H, m, CH_2-C-CH_2), and 1.6—2.2 (2H, m, $C-CH_2-C$). IR (KBr) 3420 cm^{-1} (NH). Found: C, 88.98; H, 6.69; N, 4.57%. Calcd for $C_{23}H_{21}N$: C, 88.71; H, 6.80; N, 4.50%.

*9-(4-Anilinobutyl)phenanthrene (**1d**).* A mixture of 1-bromo-3-(9-phenanthryl)propane (1.49 g, 5 mmol) and KCN (0.4 g, 6.1 mmol) in ethanol (40 cm³) was refluxed for 42 h. The solvent was evaporated under reduced pressure and the residue was washed with water and extracted with ether. The extract was dried (Na_2SO_4) and evaporated to give 1.17 g (96%) of 4-(9-phenanthryl)butanenitrile as colorless needles which was recrystallized from hexane–benzene (9 : 1); mp 90—91 °C: IR (KBr) 2250 cm^{-1} (CN); ^1H NMR ($CDCl_3$) δ 7.4—8.8 (9H, m, aromatic), 3.22 (2H, t, $J=7$ Hz, $Ar-CH_2-$), 1.9—2.5 (4H, m, $-CH_2CH_2CN$). Found: C, 87.99; H, 5.78; N, 5.48%. Calcd for $C_{18}H_{15}N$: C, 88.13; H, 6.16; N, 5.71%.

The hydrolysis of 4-(9-phenanthryl)butanenitrile with KOH in ethanol by refluxing for 20 h gave 4-(9-phenanthryl)-butanoic acid in 90% yield; mp 169—170 °C (lit,[10] 172.8—174 °C); IR (KBr) 1710 cm^{-1} (CO).

4-(9-Phenanthryl)butanoic acid (1.1 g, 4.1 mmol) was added in small portions to thionyl chloride (13 cm³) and the mixture was refluxed for 10 min. Excess thionyl chloride was removed by evaporation under reduced pressure. The residue was dissolved in ether (140 cm³) and added to a solution of aniline (3 cm³, 32 mmol) in ether (15 cm³). The mixture was stirred for 4.5 h at room temperature, washed with 3 M hydrochloric acid, and the ether layer was separated. The aqueous layer was extracted with dichloromethane. Both the organic solutions were combined and evaporated to give 1.35 g (98%) of *N*-phenyl-4-(9-phenanthryl)butanamide; mp 152.5—155.5 °C: IR (KBr) 3300 (NH) and 1660 cm^{-1} (CO).

To a stirred solution of *N*-phenyl-4-(9-phenanthryl)butanamide (1.27 g, 3.7 mmol) in THF–ether (40 cm³) was added $LiAlH_4$ (1.0 g) in small portions over 10 min. After refluxing for 3.5 h, the mixture was washed with a saturated aqueous solution of ammonium chloride and extracted with ether. Evaporation of the solvent from the ether extract under reduced pressure gave the amine **1d** (1.1 g, 90%) which was chromatographed on silica gel with benzene and then recrystallized from hexane; mp 101—102 °C: IR (KBr) 3380 cm^{-1} (NH); ^1H NMR ($CDCl_3$) δ 9.0—6.5 (14H, m, aromatic), 2.8—3.7 (5H, m, NH and CH_2), and 1.5—2.2 (4H, m, CH_2). Found: C, 88.53; H, 7.08; N, 4.25%. Calcd for $C_{24}H_{23}N$: C, 88.57; H, 7.12; N, 4.30%.

*9-(5-Anilinopentyl)phenanthrene (**1e**).* A solution of 1-bromo-3-(9-phenanthryl)propane (0.86 g, 2.85 mmol) in benzene (10 cm³) was added at 50 °C to a stirred mixture of sodium methoxide (prepared from 0.1 g of sodium) and dimethyl malonate (0.7 cm³, 6.1 mmol) in methanol (10 cm³). The mixture was refluxed for 3 d and diluted with a large amount of water, and then extracted with ether. The extract was dried (Na_2SO_4) and the solvent was evaporated completely. The residue was added to a solution of KOH (3 g) in methanol (20 cm³) and water (3 cm³), and the mixture was refluxed for 40 h. After removal of the solvent, the residue was shaken with a mixture of water and ether. The aqueous layer was separated, acidified with hydrochloric acid and extracted with ether. The extract was dried (Na_2SO_4) and evaporated. The colorless solid obtained (0.69 g) was heated up to its melting temperature under argon atmosphere to give 5-(9-phenanthryl)pentanoic acid (0.45 g); mp 145—150 °C: IR (KBr) 1710 cm^{-1} (CO).

5-(9-Phenanthryl)pentanoic acid was converted to the amine **1e** in 60% yield by the method similar to that used for the preparation of **1d**. Colorless solid; mp 101.5—103 °C: IR (KBr) 3400 cm^{-1} (NH); ^1H NMR ($CDCl_3$) δ 6.3—8.7 (14H, m, aromatic), 3.4 (1H, br s, NH), 2.8—3.2 (4H, m, CH_2), and 1.3—2.1 (6H, m, CH_2). Found: C, 88.38; H, 7.53; N, 4.11%. Calcd for $C_{25}H_{25}N$: C, 88.45; H, 7.42; N, 4.13%.

*9-(2-Anilinoethyl)phenanthrene (**1f**).* 9-Phenanthreneacetic acid[11] (2.4 g, 10.2 mmol) was converted to the corresponding anilide by a standard method *via* the acid chloride, mp 225—226 °C; IR (KBr) 3300 (NH), 1670 cm^{-1} (CO). Found: C, 84.85; H, 5.33; N, 4.63%. Calcd for $C_{22}H_{17}NO$: C, 84.86; H, 5.50; N, 4.50%. To a solution of this anilide (1.56 g) in THF–ether (2 : 1, v/v, 140 cm³) was added $LiAlH_4$ (1.0 g) in small portions at room temperature. The mixture was refluxed for 5 h and washed with an aqueous ammonium chloride solution, and then extracted with ether. The extract was dried (Na_2SO_4) and evaporated. The residue was recrystallized from hexane to give **1f** as colorless needles (840 mg, 56%); mp 108—108.5 °C: IR (KBr) 3400 cm^{-1} (NH); ^1H NMR ($CDCl_3$) δ 6.3—8.7 (14H, m, aromatic), 3.1—3.8 (5H, m, CH_2 and NH). Found: C, 89.01; H, 6.50; N, 4.34%. Calcd for $C_{22}H_{19}N$: C, 88.85; H, 6.44; N, 4.71%.

Photoreactions. A general procedure is shown with the photoreaction of **1b**. A solution of **1b** in benzene (1.6×10^{-2} mol/dm³) in a Pyrex tube was degassed by three freeze-pump-thaw cycles under argon, and the tube was sealded under reduced pressure. The solution was irradiated externally with a 300 W high-pressure mercury lamp using a merry-go-round apparatus (Eikosha PIH-300): The distance between the light source and the sample solutions was 5 cm. After irradiation for 90 min, the solvent was removed under reduced pressure and the residue was chromatographed on silica gel. Elution with benzene–hexane (1 : 1) gave **2b**, mp 96—135 °C: ^1H NMR ($CDCl_3$) δ 6.3—8.0 (17H, m, aromatic), 4.81 (2H, s, CH_2), and AB quartet signals centered at 4.30 and 2.60 (2H, $J=16$ Hz, CH_2). Found: C, 90.25; H, 5.74; N, 3.62%. Calcd for $C_{27}H_{21}N$: C, 90.22; H, 5.89; N, 3.90%. **2c**: mp 100—102 °C; ^1H NMR ($CDCl_3$) δ 6.3—7.8 (13H, m, aromatic), AB quartet signals centered at 4.03 and 2.30 (2H, $J=$ 16 Hz, CH_2), 3.5—3.75 (2H, m, $=N-CH_2$), and 1.7—2.2 (4H, m, $-CH_2CH_2-$). Found: C, 88.56; H, 6.57; N, 4.67%. Calcd for $C_{23}H_{21}N$: C, 88.70; H, 6.80; N, 4.50%. **2d**: mp 117—120 °C; ^1H NMR ($CDCl_3$) δ 6.5—8.0 (13H, m, aromatic), AB quartet signals centered at 3.84 and 2.94 (2H, $J=$ 16 Hz, CH_2), 3.5—4.0 (2H, m, $N-CH_2-C$), 2.2—1.3 (6H, m, $CH_2CH_2CH_2$). Found: C, 88.64; H, 7.05; N, 4.46%. Calcd for $C_{24}H_{23}N$: C, 88.57; H, 7.12; N, 4.30%. **3**[7]: IR (liquid film) 3060, 3030, 2945, 1635, 1605, 1490, 1455, 895, 770, and 745 cm^{-1}; ^1H NMR ($CDCl_3$) δ 7.0—7.8 (8H, m, aromatic), 5.26 (1H, d, $J=1.5$ Hz, $=CH_2$), 5.06 (1H, d, $J=1.5$ Hz, $=CH_2$), and 3.65 (2H, s, CH_2). Found: C, 93.71; H, 6.02%. Calcd for $C_{15}H_{12}$: C, 93.71; H, 6.29%.

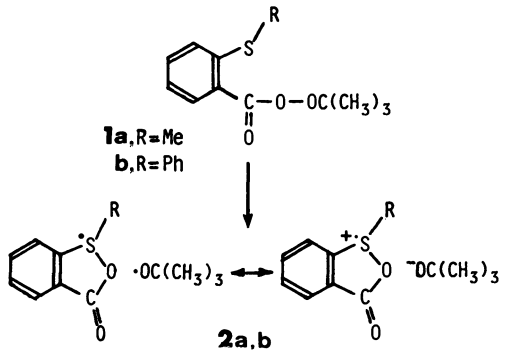
The Sulfuranyl Radical Structure and Reactions of *o*-(Thio)benzoyloxyl Radicals Formed by the Decomposition of *t*-Butyl *o*-(Thio)-perbenzoates Studied by ^{1}H and ^{13}C CIDNP and ^{17}O NMR

Warō Nakanishi,* Yoshiaki Kusuyama, Yoshitsugu Ikeda, and Hiizu Iwamura*,†
Department of Chemistry, Faculty of Education, Wakayama University, Masagocho, Wakayama 640
†*Division of Applied Molecular Science, Institute for Molecular Science, Myodaiji, Okazaki 444*
(Received May 4, 1983)

^{1}H and ^{13}C CIDNP signals were observed in the methyl group of *o*-(methylthio)benzoic acid and the methylene group of 3,1-benzoxathian-4-one (**6**) during the thermal decomposition of *t*-butyl *o*-(methylthio)perbenzoate. The results show that the free "*o*-(methylthio)benzoyloxyl radical" itself is better represented as the bridged sulfuranyl radical in which most of the spin density is localized at the sulfur atom rather than in the carboxyl. Thermolysis of *t*-butyl *o*-(methylthio)- and *o*-(phenylthio)perbenzoates-*carbonyl*-^{17}O was carried out and the oxygen labels were detected by ^{17}O NMR spectroscopy preferentially at the carbonyl oxygen of **6** and diphenyl 2,2′-dithiodibenzoate ruling out the zwitterionic radical structure. The migration of phenyl group and the peroxomonosulfate oxidation of *o*-(phenylthio)benzoic acid are also discussed.

The rate of thermolysis of *t*-butyl perbenzoate is enhanced by the substitution at the *ortho* positions with iodo,[1] vinyl,[2] and thio[1,3] groups. In the case of *t*-butyl *o*-(methylthio)- and *o*-(phenylthio)perbenzoates (**1a** and **1b**, respectively), for example, the rate acceleration reaches upwards of 10^4 times relative to the unsubstituted system (**1e**) at 60 °C in chlorobenzene. The decomposition proceeds with the significant lower $\Delta H^{\ddagger}$ and negative $\Delta S^{\ddagger}$ values.[1] The transition state is also considered to accompany a considerable polar character[4] as shown in the susceptibility of the rate of the thermal decomposition of **1b** to the substituents, solvent ionizing powers, and added salts. Martin *et al.*



2a,b

proposed a mechanism of the homolytic O–O bond cleavage anchimerically assisted by the neighboring sulfur atom with structure **2** contributing to the transition state.[1] The heavy atom effect as seen in *o*-iodo derivative[5] was excluded here and the steric acceleration was not important because *o*-(*t*-butyl) derivative showed little rate enhancement.[1]

The question we want to raise is if the sulfuranyl radical structure (**3** and/or **4**) should only be the contributing structure in the transition state for the thermolysis reaction or could also be an important representation of the resulting "*o*-(thio)benzoyloxyl radicals." Our strategy was two-fold: The CIDNP method and ^{17}O labeling technique. The CIDNP method has been employed to the elucidation of a number of free radical reaction mechanisms.[6] When applied to the structural study of 2-chloroethyl,[7] 2-bromoethyl,[8] phenethyl,[7] and neophyl[9] radicals, only the classical structures were concluded. In the present case, the cyclic sulfuranyl radical *vs.* "*o*-(thio)benzoyloxyl radical" will be answered by the CIDNP effect in the S-methyl protons and carbon.[10] Secondly, in contrast to the ^{18}O tracer technique[11] widely used to elucidating structures and reaction mechanisms in organic chemistry, the ^{17}O labeling coupled with ^{17}O NMR determination[12] has not been very much publicized and yet has the strong advantage as a nondestructive method; by employing chemical shifts and integration of the signal intensities, the site and distribution of the isotopes in the product molecules can be determined directly.

^{17}O NMR spectroscopy has now been applied to thermal decomposition of ^{17}O labeled *t*-butyl *o*-(methylthio)- and *o*-(phenylthio)perbenzoates (**1a*** and **1b***, respectively).[12]

Quite independently from ours, Martin *et al.* treated the problem by using ESR spectroscopy.[13]

Results and Discussion

The CIDNP Results. Thermolysis of *t*-butyl *o*-(methylthio)perbenzoate (**1a**) produces *o*-(methylthio)-benzoic acid (**5a**: 30%), 3,1-benzoxathian-4-one (**6**: 12%), *t*-butyl alcohol (62%), and acetone (21%) in chlorobenzene at 70 °C.[1]

When a solution of 5 mg of **1a** in 0.5 ml of *o*-dichlorobenzene was heated at 80 °C in a ^{1}H NMR probe, strong emission (E) and enhanced absorption (A) signals were observed at δ 2.38 and 5.21, respectively (Fig. 1).[14] By adding a small amount of the authentic samples to the completed reaction mixture and observing increase in the corresponding signal intensities, it was found that the methyl protons of **5a** were in E and methylene protons[15] of **6** were in A. The signals due to acetone and *t*-butyl alcohol were not spin-polarized. CIDNP was not clear in the aromatic protons for the reaction run in tetrachloroethylene or decalin. The ^{13}C experiments of **1a** were carried out on a solution of 150 mg of **1a** in 1 ml of *o*-dichlorobenzene at 75 °C.

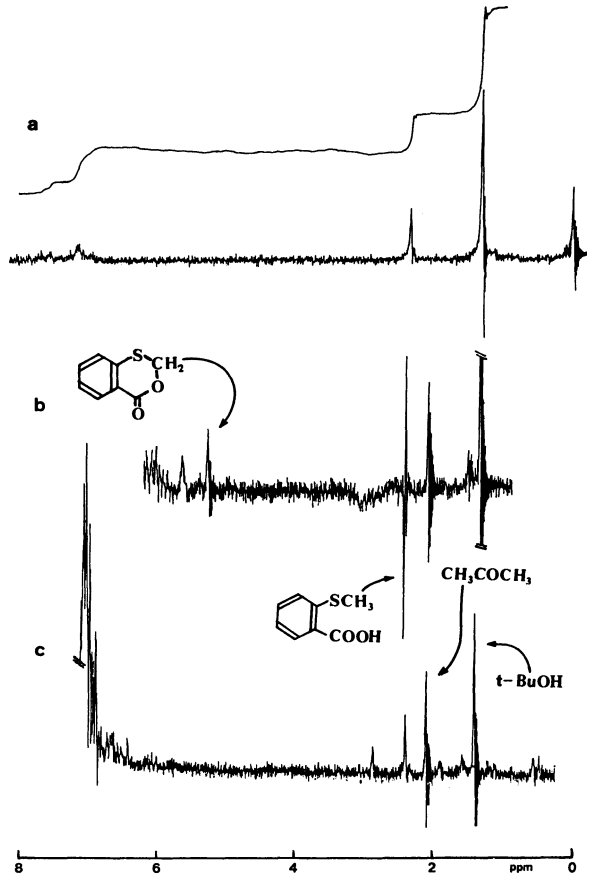


Fig. 1. ^{1}H NMR spectra of **1a**. a: In carbon tetrachloride at 27 °C, b: during the decomposition in *o*-dichlorobenzene at 80 °C, c: after the reaction at 80 °C.

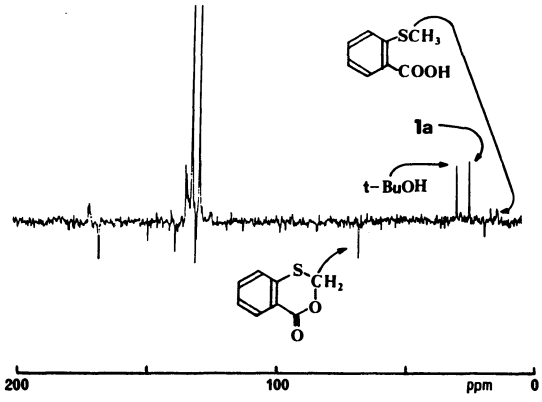

Fig. 2. ^{13}C CIDNP spectrum obtained during the decomposition of **1a** in *o*-dichlorobenzene at 75 °C. See also Ref. 16.

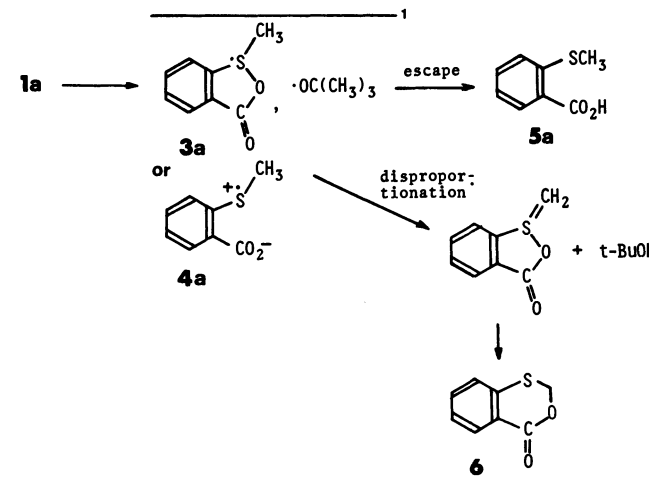
As shown in Fig. 2, the methylene carbon of **6** was in strong E at δ 68.7. The *S*-methyl carbon of **5a** at 15.5 was in A. There were some polarization signals yet to be assigned in the aromatic carbons. There were no polarization signals in the C=O carbon region of **5a** and **6**.[16]

All the results, especially strong polarization in the *S*-methyl group and no polarization in the carbonyl carbons in **5a** and **6** indicate that hyperfine interactions of the methyl protons and carbons are quite large and that the considerable spin density must be localized at the sulfur atom and not in the carboxyl group in the "*o*-(methylthio)benzoyloxyl radical" (**3a**). This is in accordance with the ESR measurement of **3a** and a close analog of **3a** performed by Martin *et al.*[13] The *g*-value of **3a** is 2.0080 and the proton hyperfine splitting of *S*-methyl group is 9.0 G and that of aromatic proton *ortho* to carbonyl group is 1.5 G. The ESR results are best interpreted in terms of a bridged radical with an S–O bond, in which the odd electron is in a σ-type orbital with a large spin density on sulfur. The sign for hyperfine coupling are expected to be plus for the β-H and minus for the α-C in the methyl group of *S*-centered radical **3a**.

The CIDNP spectra are reasonably explained only when the radical has structure of **3a** (or **4a**). In reference to the Kaptein rule,[6b] Scheme 1 is proposed for the observed CIDNP.

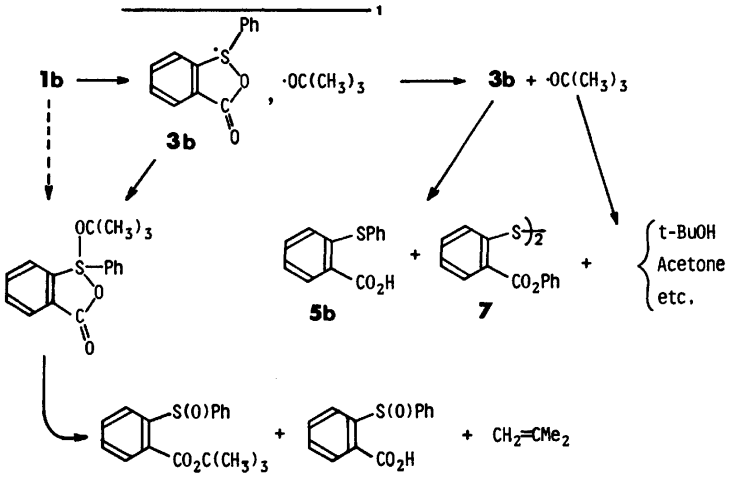


Scheme 1.

$$\Gamma_{ne}(i) = \mu\varepsilon\Delta g A_i,$$

where the sign of polarization of nucleous i due to the net effect (Γ_{ne}(i)) is given by the product of signs of the spin multiplicity of the precursor, the mode of the reaction, the difference in the *g* factors in the radical pair, and the hyperfine coupling constant of nucleus i. The Δg term is negative for **3a** because *g*-value of **3a** is 2.0080 while that of *t*-butoxyl radical is 2.009.[14] The opposite signs of polarization found in the *S*-methyl group of **5a** and the methylene group of **6** are reasonably ascribed to the different mode of formation of these products:[6] **5a** is an escape product ($\varepsilon<0$) while ε for **6** is positive which may be formed by cage-disproportionation followed by rearrangement.

Similar CIDNP experiments on *t*-butyl *p*-(methylthio)perbenzoate and the *o*-methoxyl derivative (**1c**) gave negative results. The ^{1}H signals due to acetone, *t*-butyl alcohol, and methyl protons of *p*-(methylthio)-benzoic acid of the products increased monotonically during the decomposition of *t*-butyl *p*-(methylthio)-perbenzoate in hexachlorobutadiene at 155 °C. No CIDNP was observed in the methoxyl groups of anisole and *o*-methoxybenzoic acid in thermolysis of **1c** in *o*-dichlorobenzene at 147 °C.



Scheme 2.

CIDNP experiments were also carried out on the thermolysis of *t*-butyl *o*-(phenylthio)perbenzoate (**1b**). Some polarized signals were observed in the phenyl carbon region, but none of them could be assigned to *o*-(phenylthio)benzoic acid (**5b**), diphenyl 2,2′-dithiodibenzoate (**7**), or *o*-(phenylsulfinyl)benzoic acid. Strong polarization was ascribed only to the solvent reacted products. The decomposition mechanism of **1b** proposed by Martin *et al.* is shown in Scheme 2.[3c]

Thus the CIDNP experiments clearly exhibit that most of the spin density should be localized at the sulfur atom. This is possible only when the radical has either the cyclic sulfuranyl radical (**3a**) or a zwitterion radical (**4a**) structure. The "*o*-(thio)benzoyloxyl radical" structure is very unlikely.

Decomposition of ^{17}O-labeled Peroxy Esters. As an operational test to differentiate between the two possibilities, we had recourse to the ^{17}O labeling technique in which the carbonyl oxygen of the starting peroxy esters was specifically enriched with ^{17}O and distribution of the isotope in the cyclic product was examined. Unfortunately scrambling of the two oxygen sites in the carboxyl group did not allow us to study the ^{17}O distribution in the major product **5a**.

Thermal decomposition of *t*-butyl *o*-(methylthio)-perbenzoate enriched with ^{17}O selectively at the carbonyl group (**1a***) was carried out in chlorobenzene at 76 °C. Carbonyl oxygen in **1a*** is estimated to be enriched by *ca.* 4.6 atom%. The contribution from the natural abundance isotope to ^{17}O NMR spectra is less than 1%, since natural abundance of ^{17}O is only 0.037 atom%.

^{17}O-labeled 3,1-benzoxathian-4-one (**6***) was isolated as a decomposition product. As shown in Fig. 3, the ^{17}O NMR spectrum of the lactone contains two signals: The downfield signal (365 ppm from external D_2O) due to the carbonyl oxygen and the higher one (159 ppm) due to the ether oxygen.[17] They were found to be in the integration ratio of 66 : 34. The ratio was 50 : 50 when the ^{17}O NMR spectrum of **6** in natural abundance was measured. Thus the oxathianone-*carbonyl*-^{17}O (**6***[**C=O***]) and the oxathianone-3-^{17}O (**6***[**–O***–]) were found in the ratio of 66 : 34 when **1a*** was decomposed under the conditions described above.[18] As shown in Table 1, the formation of **6***[**C=O***] in preference to **6***[**–O***–] was more favored as the temperature of decomposition was lowered.

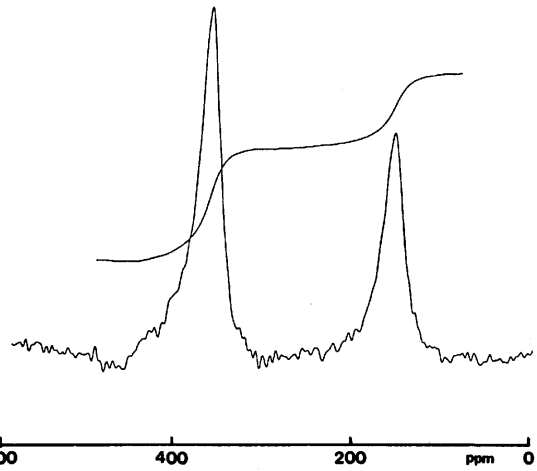


Fig. 3. ^{17}O NMR spectrum of **6*** derived from the thermal decomposition of **1a*** at 76 °C.

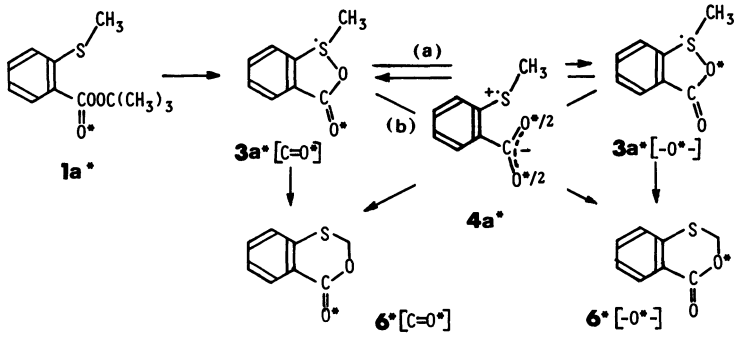
Table 1. Population of the ^{17}O label in **6** and the temperature of decomposition of **1a***

Temperature/°C	**6***[**C-O***]	**6***[**–O***–]
76	66	34
62	69	31
40	74	26

A similar study has been carried out on the decomposition of *t*-butyl *o*-(phenylthio)perbenzoate-*carbonyl*-^{17}O (**1b***). Thermolysis of **1b** gives diphenyl 2,2′-dithiodibenzoate (**7**) among many other products as shown in Scheme 2.[1,3c] ^{17}O-labeled **7** (**7***) was isolated as a decomposition product of **1b*** in chlorobenzene at 52 °C. Here we encountered a typical example showing the limitation of the ^{17}O NMR method. Since the line width of ^{17}O NMR signals is governed by quadrupolar relaxation, line broadening of the signal becomes serious as the size (represented by a^3 of a spherical molecule of the radius *a*) of molecules increases.

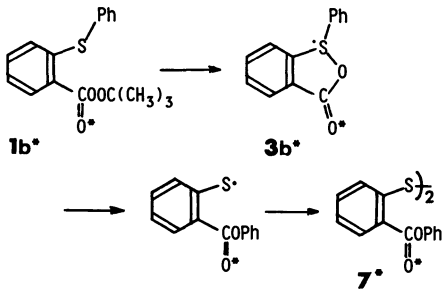


Scheme 3.

Whereas the signal due to the ^{17}O enriched carbonyl oxygen was easily determined, it was difficult to get a reasonable S/N for ^{17}O poor ether oxygen of **7***. Therefore a strategy of carrying out the measurement on a smaller molecule was adopted. Population of the ^{17}O label was thus determined on phenyl *o*-mercaptobenzoate obtained by cleavage of the S–S bond of **7*** into two halves by the method of Overman *et al.*[19] Integration of the peaks at δ 363 and 191 for the carbonyl and ether oxygens, respectively, gave a ratio of 71 : 29.

Martin and Koenig[2b] investigated the distribution of ^{18}O in 3-benzhydrylphthalide obtained from the decomposition of *t*-butyl *o*-(2,2-diphenylvinyl)perbenzoate labeled with ^{18}O in the carbonyl position. By comparing the content of the ^{18}O isotope before and after the saponification/relactonization procedure, it was found that the identity of the carbonyl oxygen of the phthalide was in 88% retention.

As shown in Scheme 1, thermal decomposition of **1a** produces **5a** and **6** as escape and disproportionation products, respectively, of the primary radical pair formed by the O–O bond cleavage of **1a**.[1] If the anchimerically assisted O–O bond cleavage takes place by intramolecular electron transfer from the sulfur to the antibonding O–O orbital and the structure of "*o*-(methylthio)benzoyloxyl radical" formed is **3a**, **6*[C=O*]** should be exclusively formed from **1a***. Structure **4a** should operationally lead to scrambling of the label between the two oxygen atoms, although there may be some lifetime before the requisite rotation of the Ar–CO_2^- bond takes place. The results in Table 1 indicate that the identity of the carbonyl oxygen can be kept through the reaction path to lactone **6*** and that there is a competitive channel available for the scrambling of the oxygen label which has the higher activation energy of the reaction than that retentive path by 2.3 kcal/mol. The scrambling of the label between the carbonyl and endocyclic oxygens may take place either before or during the course of the Pummerer type rearrangement (a or b in Scheme 3). Zwitterionic radical is supposedly an intermediate or a transient species in these scrambling processes. Therefore it is concluded that the "*o*-(methylthio)benzoyloxyl radical" should be described as cyclic structure **3a**. However the contribution of the induced decomposition[1] which could be another mechanism for the retention of oxygen label may take place in the decomposition of **1a**.* In



Scheme 4.

the case of **1b***, the contribution of the induced decomposition such as **1a*** is negligible.[1] The 71% of ^{17}O retention in the carbonyl oxygen of **7*** well establishes the sulfuranyl radical structure **3b** for the "*o*-(phenylthio)benzoyloxyl radical" (Scheme 4).

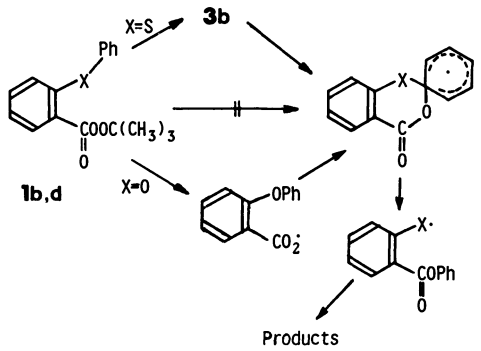
Thus the sulfuranyl radical structure has been well established by a combination of CIDNP and ^{17}O NMR spectroscopy.

Phenyl Migration in o-*Phenoxy- and* o-*(Phenylthio)-benzoyloxyl Radicals.* DeTar and Hlynsky[20] reported predominant phenyl migration in *o*-phenoxybenzoyloxyl radical produced by the decomposition of bis(2-phenoxybenzoyl) peroxide. In this study, the decomposition of *t*-butyl *o*-phenoxyperbenzoate (**1d**) was examined. As shown in Table 2, the decomposition rate constant for **1d** in chlorobenzene at 132 °C is 4.13×10^{-4} s^{-1} which is almost as fast as that calculated from the kinetic parameters (ΔH^*=33.5 kcal/mol and ΔS^*= 7.8 e.u.)[21] of *t*-butyl perbenzoate (**1e**) at the temperature. Phenyl salicylate was produced in 7—10% in this reaction.[22] The rate constant for the decomposition of *t*-butyl *o*-methoxyperbenzoate (**1c**) was also determined as 5.23×10^{-4} s^{-1} in chlorobenzene at 118 °C. The rate constant is 6.7 times larger than that estimated for nonsubstituted one. *o*-Methoxybenzoic acid was produced in *ca.* 40% yield at 118 °C. However it was

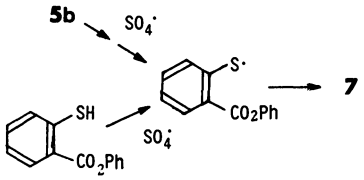
Table 2. Rate constant for decomposition of *t*-butyl *o*-(oxy)perbenzoates

Compound	k/s^{-1}	(Temp/°C)	k_{rel}
1c	5.23×10^{-4}	(118)	6.7
1d	4.13×10^{-4}	(132)	1.1
1e[a]			1.0

a) Ref. 21.



Scheme 5.



Scheme 6.

ca. 10% at 132 °C in chlorobenzene with the formation of anisole in *ca.* 10%.

As also suggested by Martin,[1] the oxygen atom *ortho* to the peroxy ester moiety does not play an important role in the O–O bond homolysis, that is, anchimeric assistance is absent in *o*-(oxy)perbenzoates. By comparing the rate constant for **1d** with those of **1c** and nonsubstituted one, participation of phenyl ring can be excluded (Scheme 5). Therefore, the phenyl migration in **1b** and **1d** is explained by a two step mechanism. The phenyl migration in **3b** occurs *via* 1,2-shift of the phenyl group in sulfuranyl radical.[1] In the case of **3d**, the ipso attack by the carboxyl radical to the phenoxyl group may occur. The direct attack of the phenyl group to O–O bond is negligible.

The rearranged thiyl radical was directly formed by potassium peroxomonosulfate oxidation[23] of phenyl *o*-mercaptobenzoate. Treatment of phenyl *o*-mercaptobenzoate with equimolar peroxomonosulfate in boiling water gave **7** in 90—95% yield. Oxidation of *o*-(phenylthio)benzoic acid (**5b**) with peroxomonosulfate resulted in the formation of 30% of **7** and *ca.* 10% of by-products with *ca.* 60% of recovery of the starting material. In the presence of catalytic amount of silver ion and 3 molar excess peroxomonosulfate, the yield of **7** was very much improved. The formation of **7** from H-abstraction of **5b** shows that the phenyl migration also occurs in this case (Scheme 6).

Experimental

^{1}H spectra were obtained on a JEOL C 60HL spectrometer operating at 60 MHz. ^{13}C spectra were obtained on a Varian PFT 80 CFT 20 Pulse Fourier Transform spectrometer operating at 20.1 MHz or on a JEOL FX-60Q spectrometer operating at 15 MHz.

CIDNP Measurement. For a typical run, a solution of 5 mg of **1a** in 0.5 ml of chlorobenzene was sealed in a 5 mm ϕ NMR sample tube. ^{1}H NMR spectra were measured at room temperature. Then the sample was put into an NMR probe preheated at 80 °C. The CW ^{1}H NMR spectra were obtained at 20 s, 60 s, and so on after the sample tube was brought into the probe. Time-dependent spectra containing polarized signals were obtained. After the reactions were over, a small amount of authentically prepared compounds was added to assign the CIDNP signals. The chemical shifts were determined from acetone, one of the products, as δ 2.18.

^{13}C CIDNP spectra were obtained in a similar manner on a solution of 150 mg of **1a** in 1 ml of *o*-dichlorobenzene at 75 °C using a Varian CFT-20 spectrometer. A 8 μs pulse was applied with an acquisition time of 0.909 s over the spectral width of 4.5 kHz. The number of data points was 8 K and the number of transients accumulated was *ca.* 300.

As solvents, chlorobenzene, *o*-dichlorobenzene, tetrachloroethylene, 1,1,2,2-tetrachloroethane, hexachlorobutadiene, and decalin were employed after distillation and checked by ^{1}H NMR.

^{17}O NMR Measurement. ^{17}O NMR spectra were measured on a Varian FT-80A spectrometer at 10.782 MHz, using a 90° pulse of 0.02 s. A spectral width was 8000 Hz with 323 data points, the Fourier number being kept at 16384. The labeled sample (*ca.* 300 mg) was dissolved in chloroform-*d* and the temperature of the probe was set at 60 °C in order to obtain a better S/N of the signals due to narrower half-band widths. A reasonable S/N of *ca.* 8 of the spectra was obtained by 1 h's accumulation (the number of transients accumulated was 10^{5}) for enriched samples of this size of molecules. Three to four such data were averaged; the reporoducibility of the relative peak areas was ±2%.

Materials. *t*-Butyl *o*-(methylthio)- and *o*-(phenylthio)-perbenzoates (**1a** and **1b**, respectively) and 3,1-benzoxathian-4-one (**6**) were prepared in analogy with Martin's method.[1] Physical properties agreed well with those in the literature.

t-Butyl o-Methoxyperbenzoate (1c) and t-Butyl o-Phenoxyperbenzoate (1d). These compounds were prepared in a similar manner to that for **1a** and **1b**.

1c: Recrystallization from pentane-ether after low temperature chromatography on basic alumina. Mp 52.0—52.5 °C. Found: C, 64.43; H, 7.31%. Calcd for $C_{12}H_{16}O_4$: C, 64.27; H, 7.19%.

1d: Purified by chromatography on basic alumina with ether as an eluent at low temperature. Colorless oil. Found: C, 71.19; H, 6.28%. Calcd for $C_{17}H_{18}O_4$: C, 71.31; H, 6.34%.

^{17}O Enriched o-(Methylthio)benzoic Acid (5a).* Sodium hydroxide 2.2 g (55.6 mmol) and 1 g of water enriched with ^{17}O in 20 atom% (Prochem, 55.6 mmol) were dissolved in 80 ml of dioxane in the presence of a small amount of 18-crown-6. Then 10.36 g (55.6 mmol) of *o*-(methylthio)benzoyl chloride in 20 ml of dioxane was added at 70 °C, and refluxed for 10 h. After evaporation of the solvent, the mixture was acidified with cold diluted hydrochloric acid (*ca.* 0.005 mol dm^{-3}). The precipitate was washed with cold water and recrystallized from hot water yielded 7.77 g (83%). Mp 169—170 °C (lit,[24] 169 °C). From Mass spectra, the *o*-(methylthio)benzoic acid prepared above was enriched with ^{17}O by 9.1%. So each oxygen in **5a*** is enriched with ^{17}O by 4.6%.

t-Butyl o-(Methylthio)perbenzoate-carbonyl-^{17}O (1a).* To a solution of 5.0 g (31 mmol) of 1,1′-carbonyldiimidazole in 100 ml of THF was added a solution of 5.0 g (30 mmol) of **5a*** in 50 ml of THF, then stirred at 40 °C for 2 h.[25] After evolution of carbon dioxide, 5.4 g (60 mmol) of *t*-butyl hydroperoxide in THF (50 ml) was dropped at −10 °C, and stirred for 2 h. After one night at −20 °C, the solvent was evaporated *in vacuo* below 0 °C. Then cold ether was added and washed with cold water as soon as possible. After drying

over calcium chloride at low temperature, the solvent was evaporated below 0 °C. The residue was purified by chromatography on basic alumina with ether as an eluent at −15 °C. Five and three tenth grams (74%) of **1a*** was obtained. Physical properties and ^{1}H and ^{13}C NMR spectra of **1a*** were the same as those of **1a**.

t-Butyl o-(Phenylthio)perbenzoate-carbonyl-^{17}O (1b).* This compound was prepared in the same manner as that for **1a***.

*Decomposition of 1a**. A solution of 5.3 g of **1a*** in 69 ml of chlorobenzene was stirred at 76 °C for 30 min under nitrogen atmosphere. The solvent was removed *in vacuo*. The residue was chromatographed on silica gel with chloroform as an eluent. Pure **6*** (327 mg) was obtained with 300 mg of a mixture of **6*** and **5a***.

*S–S Bond Cleavage of 7**. Decomposition of **1b*** was carried out similarly at 52 °C and **7*** was isolated. Then **7*** (95 mg) and 52 mg of triphenylphosphine were dissolved in 2 ml of dioxane. The solution was acidified with 0.5 ml of 0.02 mol dm^{-3} hydrochloric acid and kept under nitrogen at 40 °C for 1 h. After removing most of the solvent under reduced pressure, the risidue was extracted with ether, dried over anhydrous magnesium sulfate and chromatographed on silica gel to give 73 mg of phenyl *o*-mercaptobenzoate[19] enriched with ^{17}O.

Oxidation of 5b with Potassium Peroxomonosulfate. To a suspention of 1.0 g of **5b** in boiling water (30 ml) was added a solution of 1.17 g of potassium peroxomonosulfate in 20 ml of water and refluxed for 3 h.[23] After cooling and acidified with diluted hydrochloric acid, crude products were obtained. The crude products contained **7** (30%), **5b** (*ca.* 60%), and by-products. When the mixture was chromatographed on basic alumina, **7** and one of by-products were isolated. In the presence of silver ion and 3 molar excess peroxomonosulfate, the yield of **7** was very much increased but that of the by-product was not improved and occasionally it was not found in the mixture.

Oxidation of phenyl *o*-mercaptobenzoate with peroxomonosulfate yielded 90—95% of **7** without silver ion.

14) There is an argument that the *t*-butoxyl radical has probably a very short electron relaxation time due to large *g*-tensor anisotropy and therefore ESR observation of this radical in solution is difficult. The radical may not be able to be a component of a radical pair responsible for CIDNP effect (J. den Hollander, Ph. D. Thesis, University of Leiden, Leiden, The Netherlands, 1976.). However, there are some reports in which the pair containing the *t*-butoxyl radical does produce CIDNP (P. D. Bartlett and N. Shimizu, *J. Am. Chem. Soc.*, **97**, 6253 (1975).).

15) As shown in Ref. 1, the chemical shift of the methylene protons of **6** shows rather large solvent dependence.

16) A strong emission was observed at δ 165.4 and enhanced absorptions at 168.8 and 169.2. However they are not assigned to carbonyl carbons of **5a** and/or **6**, because the chemical shifts of the carbons of **5a** and **6** are 171.2 and 163.2, respectively, under the same conditions.

The Formation and Thermal Decomposition of Hydrous Lead(II) Oxide Prepared by the Alkoxide Method

Eiichi NARITA,* Makito KOBAYASHI, Hirobumi SHINJO, Hisashi TSUCHIDA,** and Hiroyuki NAITO**

Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Aramaki, Sendai 980

***Mizusawa Factory, Mizusawa Industrial Chemicals, Ltd., Nishime, Tsuruoka 999-75*

(Received December 7, 1982)

Lead(II) isopropoxide was hydrolyzed by addition to water in order to investigate the effects of temperature, rate of hydrolysis, seeds and anions added in aqueous phase on the formation of hydrous lead(II) oxide. Thermal decomposition of the resulting hydrous lead(II) oxide was also investigated using TG and DTA techniques. It was found that the metastable phase of lead(II) oxide, $3PbO \cdot H_2O$ (tetragonal), was formed only under certain strict conditions, *i.e.*, at higher rate of hydrolysis and at temperatures below 40 °C, whereas the anhydrous lead(II) oxides such as massicot (orthorhombic), litharge (tetragonal), or a mixture of the two were formed under conditions other than those described above. In the presence of massicot seed in aqueous phase, massicot was predominantly formed under the formation conditions of $3PbO \cdot H_2O$. It was also found that the presence of anions such as citrate and EDTA ions, which have higher complexing ability with Pb^{II} ion, facilitated the formation of $3PbO \cdot H_2O$ even under the formation conditions of massicot. In the heating process, $3PbO \cdot H_2O$ was changed to litharge at 168 °C with the release of its water of crystallization and then transformed to massicot at 650 °C. The reaction order and activation energy for the dehydration were 0.9 and 112.6 kJ mol^{-1}, respectively.

Although many hydrous lead(II) oxides such as $5PbO \cdot 2H_2O$,[1,2] $8PbO \cdot 3H_2O$,[2] $3PbO \cdot H_2O$,[3-5] and $2PbO \cdot H_2O$[3,4] have been prepared by the hydrolysis of $Pb(NO_3)_2$ and $Pb(CH_3COO)_2$ solutions, these contents of the water of crystallization have been thought to be ambiguous. This is because of this small amounts compared with the total weights of these hydrous lead(II) oxides and of the strong affinities for carbon dioxide in air.[5] Therefore, an investigation to clarify the relationship between the formation conditions and the chemical composition and other properties of the hydrous lead(II) oxides is desirable.

The authors have previously proposed a new industrial method for the production of lead(II) oxide ("Oxygen Pressurized Wet Milling Method"[6,7]), in which many spherical granules of metallic lead (3—5 mm in diameter) are oxidized with pressurized oxygen in the presence of water at temperatures below about 60 °C in a rotating mill. In the course of this developments further information about the formation of the hydrous lead(II) oxides was also necessary, since the hydrous lead(II) oxide ($3PbO \cdot H_2O$) was formed together with massicot and litharge according to the conditions. $3PbO \cdot H_2O$ is characterized by its very small particle size and higher activity for chemical reactions; which properties seem to be advantageous for a variety of industrial uses.

On the other hand, it is well known that the products obtained by the hydrolysis of lead(II) salts tend to be affected by the presence of anions such as CH_3COO^-, NO_3^-, and Cl^-, and anhydrous lead(II) oxides or basic lead(II) compounds are often formed instead of the hydrous lead(II) oxides.[8,9] As a starting material for the hydrolysis of $lead^{II}$ ion without the effect of anions, lead(II) isopropoxide can be used conveniently.[10]

This study will deal with the formation of hydrous lead(II) oxide by the hydrolysis of lead(II) isopropoxide, especially with the effects of changes in temperature, rate of hydrolysis, and additions of seeds and anions. The thermal decomposition of the resulting hydrous lead(II) oxide was also studied by TG and DTA techniques.

Experimental

Reagents. All the reagents used were of extra pure grade. The isopropyl alcohol was purified by fractional distillation. Anhydrous lead(II) acetate was used after drying overnight at 110 °C. The water used was obtained by double distillation of dilute potassium manganate(VII) aqueous solution.

Procedure. An alcoholic solution containing 3.0 wt% lead(II) isopropoxide was prepared according to the method reported by Yamaguchi *et al.*[10] Sodium isopropoxide was first prepared by the reaction of 0.68 g metallic sodium with a 200 cm^3 of isopropyl alcohol (Eq. 1). Then, 4.8 g of anhydrous lead(II) acetate was

$$Na + C_3H_7OH \longrightarrow Na(OC_3H_7) + 1/2H_2, \quad (1)$$

added to the alcoholic solution and the mixture refluxed for 6 h (Eq. 2). After centrifuging to remove sodium acetate, 3.0 wt% lead(II) isopropoxide solution was obtained.

$$Pb(CH_3COO)_2 + 2NaOC_3H_7 \xrightarrow[C_3H_7OH]{83\,^\circ C,\ 6\ h} Pb(OC_3H_7)_2 + 2CH_3COONa\downarrow \quad (2)$$

The hydrolysis of the alkoxide was carried out as follows: A 400 cm^3 of the distilled water was transferred to a 1 dm^3 three-necked glass flask equipped with a reflux condenser, a dropping funnel, a thermometer, and a magnetic stirrer, and heated to the desired temperature under nitrogen atmosphere. Subsequently, a 200 cm^3 portion of alcoholic solution of the alkoxide in the dropping funnel was added to the distilled water with vigorous stirring (Eq. 3). The resulting suspension was stirred for further 30 min.

$$Pb(OC_3H_7)_2 + H_2O \longrightarrow PbO\downarrow + 2C_3H_7OH \quad (3)$$

After measuring the pH of the suspension, the product was filtered off, washed with acetone and diethyl ether, and dried over P_2O_5 under reduced pressure.

Analysis. The X-ray diffraction patterns were obtained using a Rigaku Denki Geigerflex D-2F with Ni filtered Cu *Ka* radiation, with 30 kV and 15 mA. The observation of the product was carried out with a Hitachi-Akashi Scanning

Electron Microscope MSM 4C-102. The IR absorption spectra were obtained on a Nippon Bunko IR-E spectrometer with the KBr pellet technique. DTA and TG were performed using a Rigaku Denki Thermoflex over the range from room temperature to 700 °C. α-Al_2O_3 was used as a standard substance and the rate of temperature rise was 10 °C/min.

Results and Discussion

Effects of Temperature and Hydrolysis Rate. The effects of temperature and hydrolysis rate on the crystal form of the product are given in Table 1. In these experiments, the hydrolysis rate was changed by controlling the rate of addition of the alkoxide solution to the aqueous phase. Figure 1 also shows the X-ray diffraction patterns of these typical products shown in Table 1. According to the conditions, three kinds of lead(II) oxides, *i.e.*, $3PbO \cdot H_2O$,[11] massicot,[12] and litharge[13] were formed as single phases or as binary mixtures. A product consisting of only $3PbO \cdot H_2O$ was obtained under the conditions of low temperatures (<40 °C) and high hydrolysis rate. With decreasing hydrolysis rate, the amount of massicot in addition $3PbO \cdot H_2O$ was gradually increased. One other noticeable result was that the formation of $3PbO \cdot H_2O$ was independent of the pH of the resulting suspension in the range of 9—12. On the other hand, a product consisting of only litharge was obtained under the conditions of high temperatures and hydrolysis rate. Similarly the amount of massicot in addition to litharge increased with decreasing hydrolysis rate, and a product consisting of only massicot was obtained at low hydrolysis rate. Thus formation of massicot and litharge is identical

Table 2. Free energies of formation of lead(II) oxide

Lead(II) oxide	ΔG_f° / kJ mol^{-1}	
	Latimer[14]	Spencer *et al.*[15]
$3PbO \cdot H_2O$	—	−187.7
Massicot	−188.5	−188.1
Litharge	−189.4	−188.7

with that reported by Yamaguchi *et al.*[10] As shown in Fig. 2, the precipitated $3PbO \cdot H_2O$ was a petal shaped crystal of 2—5 μm in size, which were smaller than those of massicot and litharge. Figure 3 demonstrates the formation regions of these three lead(II) oxides. It was found that the formation of pure $3PbO \cdot H_2O$ was limited to a sharply defined region of low temperature and high hydrolysis rate.

In general, a crystal nuclei generated from a homogeneous phase during a reaction (Eq. 3) does not always correspond with that of the thermodynamically stable phase. A crystal nuclei of a metastable phase is often formed under nonequilibrium states of supersaturation. The standard free energies of formation of these three lead(II) oxides are given in Table 2.[14,15] The thermodynamical stability is found to be litharge>massicot> $3PbO \cdot H_2O$ in that order. Thus, $3PbO \cdot H_2O$ is a metastable phase.

Effect of Seed. A series of experiments was carried out in which three kinds of lead(II) oxides prepared by the alkoxide method were previously added in an aqueous phase and the results of the effect of various seeds on the crystal form of the product are given in Table 3. When 0.2 g (corresponding 20 wt% amount for the product yield) of massicot seed was added, the product, consisting only of massicot, was obtained even under the formation conditions of $3PbO \cdot H_2O$, whereas the addition of 0.1 g of massicot seed had no affect because its amount was not enough against the supersaturation. The same results in the presence of massicot seed was also observed under the formation conditions of litharge. This result means that massicot is apparently more stable than litharge in this experiment, contrary to the thermodynamical stability order. It is generally known that the crystal form of lead(II) oxide is affected by a small amount of impurities (especially Si^{IV} ion) and massicot is predominantly formed.[16] Following the addition of $3PbO \cdot H_2O$ and litharge seeds under the formation conditions of massicot, the crystal form of the product was always massicot, as expected from the apparent stability order.

Heating rate of furnace: 10 deg/min, amount of sample: 37.4 mg.

Effect of Anions. A series of experiments was carried out under the formation conditions of massicot in which several anions were previously dissolved in aqueous phase in a concentration range of 1×10^{-4}—1×10^{-3} mol dm^{-3}. The results of the effect of these anions on the formation of $3PbO \cdot H_2O$ are given in Table 4. A product consisting only of $3PbO \cdot H_2O$ was obtained instead of massicot following the addition of citrate ion or EDTA ion. A minor amount of $3PbO \cdot H_2O$ was also obtained, together with massicot, following the addition of sulfate ion. However, the coexisting acetate and chloride ions did not affected the crystal form of the product. The complexing ability of these anions with lead^{II} ion is decreased in the order: EDTA>citrate> sulfate>acetate>chloride.[17] Therefore, it was concluded that the presence of the anions having higher formation ability of the lead^{II} complex facilitated the selective formation of $3PbO \cdot H_2O$.

Lead^{II} ion forms an octahedron configuration coordinating H_2O molecule or OH^- ion in aqueous solution. If certain anions having high complexing ability with lead^{II} ion are presented in the solution, H_2O molecule or OH^- ion is rapidly substituted for these anions according to these complexing abilities and concentrations. It is generally known that the crystal form of the nuclei is affected by the coordinating anions when metal ions such as iron and titanium are precipitated by the hydrolysis.[18,19] In these studies, the polymorphism has been interpreted by a mechanism in which the order of the formation energy of the critical nuclei is

7	EDTA	1×10^{-4}	M
8	EDTA	1×10^{-3}	H

a) All experiments were conducted under the conditions as follows: temperature, 25 °C; adding speed of alkoxide, 50 min/200 cm; pH of suspension, 9.5—9.8. b) H: $3PbO \cdot H_2O$, L: litharge, M: massicot, BS: basic salt.

reversed by the adsorption of the coordinating anions. The results obtained here are also consistant with the mechanism reported by earlier investigators.

Thermal Decomposition of $3PbO \cdot H_2O$. TG and DTA curves, in air, for $3PbO \cdot H_2O$ obtained by the alkoxide method are shown in Fig. 4. The weight loss on heating was indicated on the TG curve at 160—170 °C. This was due to the release of the water of crystallization, corresponded with the sharp endothermic peak of the DTA curve at 168 °C. A second weight loss was also indicated on the TG curve in the temperature range of 180—350 °C. The X-ray diffraction patterns of three samples obtained at A (before heating), B (180 C°), and C (720 °C) in Fig. 4 indicated that they were $3PbO \cdot H_2O$, litharge and massicot, respectively. That is, $3PbO \cdot H_2O$ was first changed to litharge with the release of the water of crystallization and then transferred to massicot in the heating process. Although

$$3PbO \cdot H_2O \xrightarrow{160\,^\circ C} PbO(\text{litharge}) \xrightarrow{650\,^\circ C} PbO(\text{massicot})$$

the weight loss calculated from the formula of $3PbO \cdot H_2O$ should be 2.5 wt%, the total weight loss obtained from the TG curve in Fig. 4 was 3.2 wt%. Therefore, it would seem that only the first weight loss (2.5 wt%) is due to the release of the water of crystallization and the second to the release of other impurities. Figure 5 shows the IR spectra for the three samples A, B, and C. The spectrum of sample A ($3PbO \cdot H_2O$) displays four distinct bands at 860, 1420, 1630, and 3200 cm^{-1}. The bands at 1630 and 3200 cm^{-1} are the OH stretching band and the OH bending band, respectively. The bands of 860 and 1420 cm^{-1} can be assigned to CO_3^{2-}. As described previously, $3PbO \cdot H_2O$ has strong affinity for CO_2 gas in air, which being responsible for the ambiguous amount of the water of crystallization of hydrous lead(II) oxides. Doi *et al.*[20] proposed the following thermal decomposition scheme for lead(II) carbonate:

$$3PbCO_3 \longrightarrow 2PbCO_3 \cdot PbO + CO_2\uparrow(316\,^\circ C), \quad (4)$$

$$2(2PbCO_3 \cdot PbO) \longrightarrow 3(PbCO_3 \cdot PbO) + CO_2\uparrow(339\,^\circ C), \quad (5)$$

$$3(PbCO_3 \cdot PbO) \longrightarrow 2(PbCO_3 \cdot 2PbO) + CO_2\uparrow(373\,^\circ C), \quad (6)$$

$$PbCO_3 \cdot 2PbO \longrightarrow 3PbO + CO_2\uparrow(\text{about } 435^\circ C). \quad (7)$$

From this result, it was concluded that the second weight loss at 180—350 °C in Fig. 4 was due to this decomposition of $PbCO_3$ in the precipitate.

The methods of Freeman-Carroll[21] and Coats-Redfern[22] were used to study the kinetics of the dehydration. These methods can only be used for a single elementary reaction. The formura of the Freeman-Carroll method is written as

$$\Delta \log(dW/dt)/\Delta \log W_r = n - \Delta(1/T)/2.303\,RT(\Delta \log W_r), \quad (8)$$

where dW/dt is the weight change in mg per minute, n the order of the reaction, T the absolute temperature, and $W_r = W - W_c$, where W is the weight (mg) at time t, and W_c the weight (mg) of the sample at the end of the reaction. E is the energy of activation. If the plot of the ratio $\Delta\log(dW/dt)/\Delta\log W_r$ values *vs.* $\Delta(1/T)/\Delta\log W_r$ is linear, the activation energy and the reaction order will be given by its slope and intercept, respectively. This is illustrated in Fig. 6, where the linear relationship is observed. The results are given in Table 5.

When the reaction order is other than unity, the formula of the Coats-Redfern method is written as

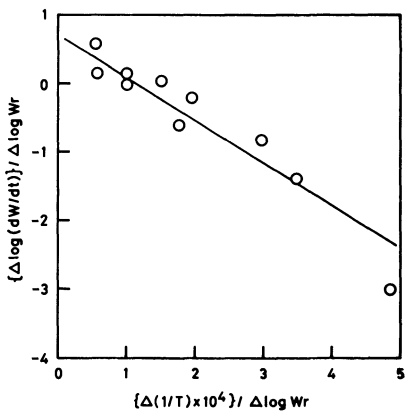

Fig. 6. Freeman-Carroll straight line for the dehydration step of the hydrous lead(II) oxide ($3PbO \cdot H_2O$).

Table 5. Reaction order and activation energy of the thermal dehydration of the hydrous lead(II) oxide

Method	Activation energy / kJ mol^{-1}	Reaction order
Freeman-Carroll	112.8	0.7
Coats-Redfern	112.4	1.0
Average	112.6	0.9

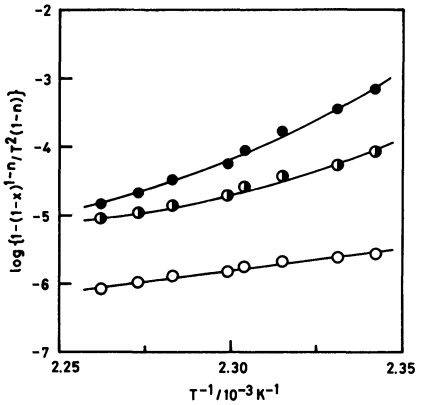

Fig. 7. Coats–Redfern straight line for the dehydration step of the hydrous lead(III) oxide ($3PbO \cdot H_2O$). order n —●: 1.0, ◑: 2.0, ○: 3.0.

$$\log\{1-(1-x)^{1-n}/(1-n)T^2\} = \log(AR/\phi E)(1-2RT/E) - E/2.303RT, \quad (9)$$

where x is the fraction of reaction, ϕ the heating rate of furnace and A the frequency factor. Graphic representation of the $\log\{1-(1-x)^{1-n}/(1-n)T^2\}$ values as a function of $1/T$ gives a straight line of slope $-E/2.303R$ for the correct value of n. This is illustrated in Fig. 7 and the results are given in Table 5. No difference between the results obtained by either method was observed and the average apparent activation energy and reaction order were 112.6 kJ mol^{-1} and 0.9, respectively.

The authors wish to thank Prof. Taijiro Okabe of the Department of Applied Chemistry, Tohoku University for his helpful discussion.

Semiexperimental Magnetic Study of Some Methyl Derivatives of Benzoic Acid

Mohamed Mahmoud Abdel-Kader
Physics Department, Faculty of Science, University of Cairo, Giza, Egypt
(Received October 6, 1982)

The mean molar susceptibilities of some methyl derivatives of benzoic acid have been measured. From these measurements and the calculated value of the in-plane susceptibilities (K_1, K_2) of each molecule, the semiexperimental magnetic anisotropy of the acid molecule has been determined. The obtained magnetic data are explained on the basis of the hydrogen bonding systems of these molecules.

The peculiar magnetic properties of aromatic compounds (besides exaltation, there are large magnetic anisotropies and anomalous nmr chemical shifts) are widely held to be results of the relatively large magnetic moment induced in the fully delocalized π-electrons characteristic of these molecules.[1-3] This has come to be called the "ring current." The contribution of the ring current to the magnetic susceptibility is amenable to theoretical calculation. The literature in this field is extensive.[4-9]

Although the contribution of the ring current to the magnetic susceptibility is comparatively large and is the main cause of the anisotropy of the diamagnetic susceptibility of a molecule,[6] yet other contribution of σ-electrons and localized π-electrons are also important.[10] Hoarau[11] suggested that the ring current probably accounts for not more than half of the observed anisotropy of benzene. He discussed the anisotropy of benzene and other aromatic hydrocarbons according to the scheme:

$$\Delta K_{\text{obsd}} = \Delta K_{\text{London}} + \Delta K_{\sigma} + n\Sigma\Delta K_{\pi}. \quad (1)$$

The first term is the anisotropy according to London theory, *i.e.* the component due to the ring currents in the delocalized π-electrons; the second term represents the anisotropy due to σ-electrons, and the third term is the sum of anisotropies due to localized π-electrons. The effect of the last term is to increase the anisotropy, not through the usual enhancement of the out-of-plane susceptibility (K_3), but by a decrease in the in-plane susceptibilities K_1 and K_2. Davies[10] calculated the π-electron susceptibility ΔK^{π} of benzene and other system and gave the empirical equation:[12]

$$\Delta K^{\pi} = K_3 - \Sigma\chi_{\text{atomic}}, \quad (2)$$

where K_3 is the experimental out-of-plane susceptibility. A more recent calculation of ΔK^{π} was given by Edwards and McWeeny.[6] A complete discussion of the use of ring current concept in the magnetic susceptibility, magnetic anisotropy and nmr chemical shift was given recently by Gomes.[13]

In general, the principal susceptibilities (K_1, K_2, and K_3) and therefore the anisotropy of the diamagnetic susceptibility for a molecule can be found from the measured values of the crystal susceptibilities (χ_1, χ_2, and χ_3) along the principal axes of the crystals, combined with the orientation of the molecule in it. The set of equations that commonly used is:

$$\left.\begin{aligned}\chi_1 &= K_1\cos^2\alpha_1 + K_2\cos^2\alpha_2 + K_3\cos^2\alpha_3,\\ \chi_2 &= K_1\cos^2\beta_1 + K_2\cos^2\beta_2 + K_3\cos^2\beta_3,\\ \chi_3 &= K_1\cos^2\gamma_1 + K_2\cos^2\gamma_2 + K_3\cos^2\gamma_3,\end{aligned}\right\} \quad (3)$$

where ($\cos\alpha_1$, $\cos\beta_1$, and $\cos\gamma_1$) are the direction consines of K_1 relative to the axes of the triaxial ellipsoide. These direction consines are determined from the atomic coordinates as given by X-ray structure analysis, but after performing the transformation needed for systems other than the orthogonal one. Several investigators have been made in this way.[14-21] According to Akamatu,[3] such a method is the orthodox one. Recently both the magnetic susceptibility and the anisotropy are calculated semiemperically or theoretically.[6-8,22-24]

In this paper, the method suggested by Hoarau[11] is used. Accordingly, the value of $(1/2)(K_1+K_2)_{\text{calcd}}$ is given by:

$$(1/2)(K_1+K_2)_{\text{calcd}} = \Sigma\chi_{\text{atomic}} + n\alpha, \quad (4)$$

where n is the number of trigonally hybridized carbon atoms and α is a constitutive correction ($\simeq +3.8\times 10^{-6}$ emu mol^{-1}) expressing quantitatively the effect of ΔK_{π} of Eq. 2 on the in-plane susceptibilities.

Since the magnetic anisotropy of a molecule is given by

$$\Delta K = K_3 - (1/2)(K_1+K_2),$$

and

$$\chi_{\text{M}}^{\text{obsd}} = (1/3)(K_1+K_2+K_3),$$

therefore

$$\Delta K_{\text{semi}} = 3[\chi_{\text{M}}^{\text{obsd}} - (1/2)(K_1+K_2)].$$

Experimental

The compounds studied in this paper are:
a) *o*-Methylbenzoic acid (*o*-Toluic acid).[25]
b) *m*-Methylbenzoic acid (*m*-Toluic acid).[26]
c) *p*-Methylbenzoic acid (*p*-Toluic acid).[27]

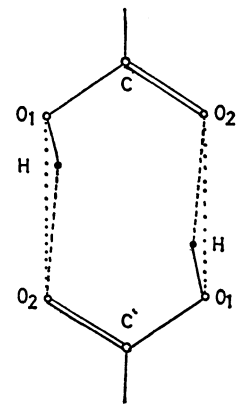

Fig. 1. The 8-membered ring.

d) 2,6-Dimethylbenzoic acid.[28]
e) 3,5-Dimethylbenzoic acid.[29]
f) 2,3,4-Trimethylbenzoic acid.[26]
g) 2,4,6-Trimethylbenzoic acid.[30]
h) 3,4,5-Trimethylbenzoic acid.[31]

The unit cell parameters of these compounds were previously obtained by different authors.[25-31] The purity of these compounds was tested by measuring their melting points. Purification by vacuum distillation and/or recrystallization from suitable solvents were carried out when the melting point of the compound is slightly different from those given in the literatures.

The Gouy method was employed for the measurements of the mean magnetic susceptibility of each compound. The apparatus consists essentially of an electromagnet and a sensitive Mettler balance. The magnetizing current is taken from a stabilized unit supplied with the electromagnet. The degree of stability of current amounts to 10^{-4}. The electromagnet is kept in a glass cabinet on top of which a sensitive Mettler balance is placed.

The purified material was finely powdered and was uniformally packed in the specimen tube. The later was made of Monax glass fitted with a glass stopper. The specimen in its container was suspended from one arm of the Mettler balance whose accuracy is 10^{-5} g. Suspension was done such that the tube is symmetrical with the pole pieces; its bottom being in the strong part of the field and the top well outside the field gap. The effect of the container and the correction of porosity of the packed powder were taken into account. Among a series of measurements, the calibration was checked with naphthalene and with benzoic acid.

In the Gouy method random orientation might be assumed since good powdering and packing were followed. The results obtained from adopting such a procedure gave consistent diamagnetic susceptibilities values with accuracy better than 1%.

Results and Discussion

The specific susceptibility χ_s, the observed molar susceptibility χ_M^{obsd} and the calculated molar susceptibility χ_M^{calcd} according to Pascal-Pacult method are given in Table 1. The atomic susceptibilities and the constitutive corrections (in 10^{-6} emu mol^{-1}) used in these calculations are:

$$\chi_C = -7.4,\ \chi_H = -2.0,\ \chi_{C\begin{smallmatrix}/O\\ \backslash O\end{smallmatrix}} = -15.15,$$

$$\chi_O = -5.30,\ \lambda_{benzene} = -1.40,\ \lambda_{CH_3} = -0.85$$

These values were given by Hoarau. For the CH_3 group, its magnetic susceptibility is taken as -13.24×10^{-6} emu mol^{-1}.[32]

It can be seen from Table 1 that the observed values of the molar susceptibilities of the *o*-, *m*-, and *p*-methylbenzoic acid are not equal. The slight difference (about one unit) in the χ_M^{obsd} of the *o*- and *m*-compound can be explained in terms of positional isomerism. According to Sriraman,[33] the CH_3 group is *o-p* directing and when substituted in the benzene ring gives higher value for ortho than for meta or isomers. The order of susceptibility should therefore be *o*->*p*->*m*-. French[34] pointed out that such an order should normally be expected. Since the CH_3 group is not strong *o-p* directing and no evidence exists for resonance in these compounds,[24,27] therefore the difference in χ_M^{obsd} is expected to be small. The results shown in Table 1 support these rules.

In Table 2, the values of $(1/2)(K_1+K_2)$, the out-of-plane susceptibility (K_3) and the semiexperimental magnetic anisotropy (ΔK_{semi}) of each compound are listed. For the benzoic acid, $\chi_M^{obsd} = -71.00\times 10^{-6}$ emu mol^{-1}, $(1/2)(K_1+K_2)_{calcd} = -47.80\times 10^{-6}$ emu mol^{-1}

Table 1. Observed and calculated magnetic susceptibilities[a]

Compound	Mol wt	χ_s	χ_M^{obsd}	χ_M^{calcd}	$\Delta\chi_M$
o-Methylbenzoic acid	136	−0.6117±0.001	−83.20	−85.04	−1.84

2,3,4-Trimethylbenzoic acid	−43.30	−38.20	−5.10	−69.90	−65.00	−4.90
2,4,6-Trimethylbenzoic acid	−44.80	−38.20	−6.6	−71.40	−65.00	−6.40
3,4,5-Trimethylbenzoic acid	−42.60	−38.20	−4.4	−69.00	−65.00	−4.00

$\Delta = \Delta K'_{mol} - \Delta K'_{benzene}$ and $\Delta = \Delta K_{semi} - \Delta K_{calcd}$.

and $\Delta K_{semi} = -69.60 \times 10^{-6}$ emu mol^{-1}. The observed magnetic data of this compound (in 10^{-6} emu mol^{-1}) as previously obtained by the author[16-18] are:

$K_1 = -48.09$, $K_2 = -46.09$, $K_3 = -117.32$,

$(1/2)(K_1+K_2)_{obsd} = -47.53$ and $\Delta K = -69.79$

It is clear that the values of $(1/2)(K_1+K_2)_{obsd}$ and that calculated according to Eq. 2 are identical. This can be regarded as a check on the accuracy of this method. It is of interest to correlate the magnetic data of these molecules with their hydrogen-bonding systems.

In the crystalline state, these compounds are strongly hydrogen-bonded. The main feature of the crystal structure of the acid molecules is that, each two molecules are associated by intermolecular hydrogen bonding to form dimer. The carboxyl groups of the two molecules and the hydrogen bonds form an 8-membered ring. In recent years much attention has been paid to study the effect of hydrogen bonding on the magnetic properties of aromatic compounds.

Preliminary results on a general investigation of diamagnetism and hydrogen bonding were discussed by Rumpf and Seguin.[35] They used Pascal-Pacault method for the calculation of the mean susceptibility χ_M^{calcd} of some aromatic molecules associated with hydrogen bonds. Upon comparing the calculated value of χ_M^{calcd} of a given molecule with its observed one, a lowering was observed. They attributed this small difference between the calculated and the observed values of χ_M to the effect of the hydrogen bonding. The application of this method on the compounds under investigation is shown in Table 1. The small difference $\Delta\chi_M$ between χ_M^{calcd} and χ_M^{obsd} may be due to the contribution of the intermolecular hydrogen bonding of these molecules. This conclusion was confirmed recently by Haberditzl[36] on a similar work, who observed that a change in diamagnetism of 1—5% is obtained on the formation of the hydrogen bonds.

According to Lonsdale,[37] any satisfactory study of the effect of the hydrogen bonds on diamagnetism must take into account the three principal susceptibilities (K_1, K_2, and K_3) of the molecule. Furthermore, Mason[38] showed that the hydrogen bond can give rise to electron delocalization resulting in magnetic anisotropy. The effective delocalization term $\Delta K'$ as given by Mason, Davies,[12] and by Craig[39] is

$$\Delta K' = K_3 - \Sigma\chi_{atomic}.$$

Constitutive corrections are not used.[10] For benzene ring, $K_3 = -94.60 \times 10^{-6}$ emu mol^{-1} [40] and $\Sigma\chi_{atomic} = -56.40 \times 10^{-6}$ emu mol^{-1}, thus the value of $\Delta K'$ is -38.20×10^{-6} emu mol^{-1}. This value of $\Delta K'$ for benzene ring is in agreement with a value of -37.80×10^{-6} emu mol^{-1} as calculated recently by Edwards and McWeeny.[9] The values of the effective delocalization term of each compound are shown in Table 3. As can be seen from Table 3, the value of $\Delta K'$ of each molecule of the eight compounds is numerically higher than that of the benzene ring. This may be due to the additional delocalization resulting from the intermolecular hydrogen bonding of these molecules as suggested by Mason.

The contribution of the hydrogen bonding on the magnetic anisotropy of the molecule may also be investigated by comparing the semiexperimental magnetic anisotropy with the calculated one. The most recent calculated values of the magnetic anisotropy (in 10^{-6} emu mol^{-1}) of the benzene ring are: −60.90,[6] −58.61,[8] −60.24,[22] and 60.00.[23] Its observed that magnetic anisotropy is −59.70.[40] The magnetic anisotropy of the benzene ring is taken as −60.00 through this paper. The magnetic anisotropy of the COOH group is -5×10^{-6} emu mol^{-1}.[20] The CH_3 group or (groups) is or (are) assumed to be magnetically isotropic. Thus the magnetic anisotropy of any acid molecule is -65×10^{-6} emu mol^{-1}. The difference between the semiexperimental anisotropy and the calculated one is taken as the effect of the hydrogen bonding.

From Table 3, it is clear that the numerical increase in the semiexperimental magnetic anisotropy over the calculated one for one molecule is about -5×10^{-6} emu mol^{-1}. Thus for one dimer (two molecules), this contribution is about -10×10^{-6} emu mol^{-1}. Referring to the crystal structures, this value is ascribed to the magnetic anisotropy of an 8-membered ring formed by the two hydrogen bonds linking the two molecules of the dimer.

Polarographic Studies on Mixed Ligand Complexes of Cadmium with DL-3-(3,4-Dihydroxyphenyl)alanine and Some Dicarboxylic Acids

Nishi GUPTA, Chandra Pal Singh CHANDEL, Prakash Chandra GUPTA, and Chand Mal GUPTA*

Chemical Laboratories, Rajasthan University, Jaipur 302004, India

(Received November 18, 1982)

The reductiou of Cd(II) has been carried out polarographically in the aqueous solution of DL-3-(3,4-dihydroxyphenyl)alanine(DOPA). The stability constants were determined for the simple Cd-DOPA system first, and then mixed-ligand complexes of cadmium with DOPA and dicarboxylic acids (oxalic and malic) have been studied. The stability constants of mixed-ligand complexes have been evaluated by the method of Schaap and McMasters. With these data the statistical and electrostatic effects have also been considered.

The importance of amines and their derivatives has been widely recognised in the biochemical, analytical, and pharmaceutical fields. These compounds are therefore attracting wide attention in different areas of research. Potentiometric investigations of the complexation behaviour of some metal ions with DOPA has been carried out by Rajan and coworkers.[1-4] However, there is not a single reference about the polarographic studies of cadmium with DOPA. Hence the present work has been undertaken. This communication deals with the study of simple and mixed ligand complexes of cadmium with DOPA and some dicarboxylic acids.

Theory

Since Cd forms hexacoordinated complexes with DOPA–oxalate and malate ions, there can be, at maximum a possibility of the existence of three mixed complex species of the type Cd(XY), $Cd(XY_2)$, and $Cd(X_2Y)$, the total number of ligands being limited to three due to the bidentate nature of the ligands under investigation.

Hence for a complexation reaction,

$$M + iX + jY \rightleftharpoons MX_iY_j. \quad (1)$$

Where i, j are stoichiometry numbers, X and Y are two different ligands and charges have been ignored for simplicity.

The overall stability constant β_{ij} for the above reaction is given by

$$\beta_{ij} = \frac{MX_iY_j}{M[X]^i[Y]^j}.$$

The DeFord and Hume function $F_o(X)$ may be extended to a new function $F_{oo}(X,Y)$ given by,

$$F_{oo}(X,Y) = \sum MX_iY_j[X]^i[Y]^j = \text{antilog}\frac{0.4343\,nF}{RT}\Delta E_{1/2} + \log\frac{I_m}{I_c}. \quad (2)$$

Where activity coefficients have been ignored and n is the number of electrons involved in the reversible reduction, F the Faraday number, R the gas constant, T the absolute temperature and I_m and I_c are the diffusion current constants for the metal and mixed complex respectively.

The factorization of $F_o(X,Y)$ using Leden's approach[14] leads to,

$$F_{oo}(X,Y) = \{\beta_{oo} + \beta_{01}[Y] + \beta_{02}[Y]^2 + \beta_{03}[Y]^3\}[X]^\circ + \{\beta_{10}+\beta_{11}[Y]+\beta_{12}[Y]^2\}[X] + \{\beta_{20}+\beta_{21}[Y]\}[X]^2 + \{\beta_{30}\}[X]^3 \quad (3)$$

or

$$F_{oo}(X,Y) = A + B[X] + C[X]^2 + D[X]^3 \quad (4)$$

Where A, B, C, and D have values as defined by Eq. 3.

The graphical method may be extended to the $F_{oo}(X,Y)$ data if the activity of one of the ligands is kept constant while that of the other, (Y) is varied. The intercept on the F_{oo} axis in the plot of F_{oo} *versus* [X] gives A. Therefore,

$$F_{10}(X,Y) = \frac{F_{oo}(X,Y)-A}{[X]} = B + C[X] + D[X]^2 \quad (5)$$

By a similar plotting of $F_{10}(X,Y)$ *versus* [X] and taking the intercept on $F_{10}(X,Y)$ axis as B, we have,

$$F_{20}(X,Y) = \frac{F_{10}(X,Y)-B}{[X]} = C + D[X] \quad (6)$$

and so on.

From the knowledge of C, the mixed stability constant β_{21} may be calculated. The values of β_{11} and β_{12} may be computed by the values of B at two [Y] concentrations.

Experimental

DOPA, oxalic acid, and malic acid used were of AnalaR grade and were used as complexing agents. Potassium nitrate as supporting electrolyte was used to maintain ionic strength at 1.0 M and 0.004% gelatin in the final solution sufficed to suppress the maxima observed. The temperature was maintained constant at 303±1 K.

The experimental technique was the same as described earlier.[5]

Results

Simple Systems. Before the study of the mixed ligand complexes, the formation constants of the complexes of Cd^{2+} with DOPA, oxalic acid, and malic acid were determined by the method of DeFord and Hume.[6] The results which are in good agreement with the previous studies[7-10] are tabulated in Table 1.

The Mixed Systems. The cadmium–DOPA–oxalate and cadmium–DOPA–malate systems were studied by keeping the concentration of the weaker ligand (oxalic and malic acid) constant at two values, while varying the concentration of the second ligand.

At each fixed concentration of oxalate and malate ions with varying concentration of DOPA, the slope

of the straight line for the plot of $E_{d.e.}$ *versus* $\log \frac{i}{id-i}$ was 31±1 mV. The direct proportionality of the diffusion current to the square root of effective height of mercury column indicated that the reduction is entirely diffusion controlled.

A shift in half-wave potential to more negative side with increase in DOPA concentration was observed. This shift in half-wave potential is greater in presence of the weaker ligands (oxalic and malic acid) than in their absence. This indicates mixed ligand complex formation by the DOPA and oxalate and malate ions.

The Schaap and McMasters[11] treatment was applied for calculating the $F_{1o}(X,Y)$ functions and Leden's graphical extrapolation method to calculate *A*, *B*, *C*, and *D* at two concentrations of [Ox] and [Mal]. The details of the calculations are presented in Tables 2 and 3.

The formation constant β_{11} and β_{12} were evaluated

Cd-DOPA-oxalate	6.80	7.88	10.03
Cd-DOPA-malate	6.10	7.04	9.47

from the two values of B, the two values of C gave two values of β_{21} in good agreement with each other and have been presented in Table 4.

The experimental values of D should also coincide with β_{30} as at the final concentration of DOPA, all the dicarboxylate ions have been replaced and only $Cd(DOPA)_3$ complex exists in solution. This indeed is found to be so.

$$\log \beta_{30} = 11.790$$

$$\log D = \begin{cases} 11.797,\ 11.789 \text{ (for oxalate)} \\ 11.789,\ 11.851 \text{ (for malate)} \end{cases}$$

The results are summarised in the form of Schemes 1 and 2 where the numerical values indicate the logarithms of the equilibrium constant.

Discussion

The mixed ligand complex formation may also be explained by considering Schemes 1 and 2. The tendency to add X (X=DOPA) to CdX and CdY (Y= oxalate and malate) can be compared. The logarithm of stability constants of the above complexes are (2.91 and 3.98) and (2.91 and 4.20) for cadmium-DOPA-oxalate and cadmium-DOPA-malate respectively. The largest part of the difference in $\log K$ must be attributed to entropy and electrostatic effects which would favour the formation of a charged complex. The logarithm of stability constants of addition of oxalate to Cd(Ox) and Cd(DOPA) and malate to Cd(mal) and Cd(DOPA) are 1.40 and 1.41 and 0.90 and 0.71 respectively, indicating that the mixed ligand complexation is favoured.

The $\log K$ values for addition of X to $Cd(X)_2$, Cd(XY), and $Cd(Y)_2$ are (3.49, 3.23, and 3.66) and (3.49, 3.37, and 4.24) for Cd-DOPA-oxalate and Cd-DOPA-malate respectively and show that the addition of amino acids is preferred to a weaker ligand.

The $\log K$ values for the addition of Y to $Cd(Y)_2$, Cd(XY), and $Cd(X)_2$ are (0.94, 1.08, and 1.73) and (0.60, 1.03, and 1.17) for oxalate and malate systems respectively, indicating that the addition of dicarboxylate ion is preferred to [Cd(dicarboxylate)(DOPA)] as compared to Cd(dicarboxylate)$_2$ and $Cd(DOPA)_2$.

The case of mixed ligand complex formation by the addition of dicarboxylate ions to $Cd(DOPA)_2$ and [Cd(DOPA)(dicarboxylate)] may easily be confirmed on the basis of statistical considerations[12] using Eqs. 7—9 as proposed by Watter's and Dewitt.[13]

$$\beta_{11} = 2 \times 3 \times \beta_{20}^{1/3} \times \beta_{03}^{1/3} \quad (7)$$

$$\beta_{12} = 3 \times \beta_{30}^{1/3} \times \beta_{03}^{2/3} \quad (8)$$

$$\beta_{21} = 3 \times \beta_{30}^{2/3} \times \beta_{03}^{1/3} \quad (9)$$

The values of stability constants so obtained from

Table 5. Values of stability constants of mixed-ligand complexes of Cd(II) with DOPA and oxalate and malate as calculated by Watters and Dewitteqs

System	$\log \beta_{11}$	$\log \beta_{12}$	$\log \beta_{21}$
Cd-DOPA-oxalate	6.42	7.84	10.05
Cd-DOPA-malate	5.84	6.67	9.46

above equations are given in Table 5 and when compared with the observed values, it indicates that MXY, MXY_2, and MX_2Y complexes have been formed purely on the statistical factors.

The tendency of formation of simple and mixed complexes can be easily expressed by calculating the disproportionation constant K^D for the equilibria

$$2Cd(XY) \rightleftharpoons Cd(X)_2 + Cd(Y)_2$$

The value of $\log K^D$ is -0.6 statistically but the observed values are found to be -1.08 and -1.10 for the Cd(DOPA)(Ox) and Cd(DOPA)(Mal) systems respectively. More negative values of $\log K^D$ for each equilibria account for the stability of the mixed ligand complexes.

One of the authors (Nishi Gupta) is thankful to U.G.C. for providing junior research fellowship and C.P.S. Chandel is thankful to C.S.I.R., New Delhi for financial support. They are also thankful to the Head, Chemistry Department for providing the laboratory facilities.

Capillary Ripple Response of Cholesterol and Lecithin Monolayers

Jamil Ahmad
Chemistry Department, University College, Bahrain
(Received November 27, 1982)

Capillary ripple characteristics of monolayers of cholesterol and dipalmitoyllecithin and a 1:1 mixture of the two over air-water interface were studied. The ripple damping coefficient and the wavelength were determined as a function of the surface concentration. A stronger chain-chain interaction exists between the molcules in the pure cholesterol monolayer compared to pure lecithin as indicated by the sharp maximum in the damping coefficient curve for the former case. In the monolayer of the mixture, there is evidence of an interaction between the chains of the two substances.

The focus of this paper is the exploration of the capillary ripple response of the monolayers from lecithin, cholesterol and a 1:1 cholesterol–lecithin mixture on air-water interface. In particular, the dependence of the ripple damping coefficient and the wavelength on the surface concentration was studied. It is expected that this work would generalize into a new technique for the study of biomembrane surface properties.

The capillary ripple method allows study of the dynamic response of monolayers over the frequency range of 10 Hz to 2 kHz. In this method, ripples are generated on the air-water interface on which the appropriate monolayer is spread and the damping coefficient and the wave number are measured. The value of these parameters reflect the elastic and viscous response of the monolayer. The review article by Hansen and Ahmad[1] summarizes several studies using the method.[2–5] The dependence of the values of the ripple parameters on the surface tension and the surface tension gradient was shown by van den Tempel and coworkers.[6] Hansen and Mann[7] included additional elastic and viscosity terms in their treatment.

Experimental

The experimental set up was similar to the one used by other workers.[1] It involved generation of ripples at the air/water interface on which a monomolecular film of interest was spread. The ripples were generated by a probe made from a stainless steel razor blade. A steel wire was soldered to the end of the blade and connected to the coil of an electromechanical transducer, essentially a modified speaker. The speaker was excited by the output from the reference channel of a precision lock-in amplifier. The frequency and the level of the input signal were monitored. For the results reported here, the input signal of 200 Hz was used. The ripple sensing probe was similar in design to the generating probe. The waves generated are reflected by the sensing probe and a stationary wave pattern is set up with the probes acting as boundaries. The sensing probe is fitted to a phonographic cartridge in the place of the usual needle. The motion of the receiving probe was converted into an electrical signal which was fed into the lock-in amplifier, where only that part of the signal was amplified which had the same frequency as the reference signal used to drive the generating probe.

The precise determination of the ripple parameters by the method described by Mann and Ahmad[8] is a tedius procedure and is impractical when several measurements have to be made. Instead, a variation of the method was followed in the present set of experiments. The probe output voltage, a quantity assumed proportional to the wave amplitude, is given by Eq. 2 of Mann and Ahmad.[8] This quantity is an oscillatory function of the distance between the probes. The maxima in the voltage-distance curve $\overline{V}(L)$, are given by

$$\overline{V}(L) = \frac{V_o\{1-\exp(\beta)\}}{1-\exp\{-(2\alpha L+\beta)\}}\exp(-\alpha L), \quad (1)$$

where V_0 is the output voltage, when the probe separation, L, is zero. α is the ripple damping coefficient and β is the reflection coefficient at the boundaries. If α is of the order of 0.4 cm^{-1}, L is kept around 4 cm or more and the reflection coefficient, β, is of the order of 1, then

$$1 - \exp\{-(2\alpha L+\beta)\} \approx 1.$$

The upper limit to the error introduced by this approximation is 2%. Thus Eq. 1 can be rewritten as

$$\overline{V}(L) = C\exp(-\alpha L). \quad (2)$$

If for pure water, the distance between the probes is fixed such that they are perfectly in phase at a desired frequency, the output voltage is given by Eq. 2. If the monolayer is now spread on the surface, the wave number will be different from the case of the pure water and the two probes may not be in phase. If the probe separation is adjusted slightly to bring back the probes in phase, Eq. 2 can be applied. The maximum adjustment needed will not be more than one half of a wavelength. The maximum error introduced by this change of the probe separation is about 2%. If for the monolayer covered surface, output voltage is $\overline{V}'(L)$, then

$$\overline{V}'(L) = C\exp(-\alpha' L). \quad (3)$$

From Eq. 2 and 3 $\ln\frac{V'(L)}{\overline{V}(L)} = L(\alpha - \alpha')$.

Thus knowing L and the damping coefficient for pure water, α', the damping coefficient for the monolayer can be calculated. The procedure is repeated at various film pressures. The other important parameter of the capillary ripple experiment, the wavelength, can be measured in a separate experiment by observing the voltage change as the probe separation is increased in small steps, and measuring the distance between the probe positions corresponding to successive maxima and minima. The wave number, k, can then be calculated by the relation

$$k = \frac{2\pi}{\lambda};\ \lambda \text{ being the wavelength.}$$

Along with the ripple measurements, simultaneous measurements of the film pressure were made with a balance similar to the one described by Mann and Hansen.[9] The film balance system involved a Teflon trough milled out of a single Teflon slab, and a movable surface piston or "barrier". Near one and of the trough was a torsion balance.

A Teflon float was coupled to the torsion wire by the help of a vertical bar. A horizontal bar was fixed to the torsion wire, and was coupled to the core of a 0.084 cm travel linear variable differential transformer (LVDT). The LVDT output as monitored on a strip chart recorder was calibrated in terms of the force acting on one cm of the float.

The reproducibility of the values of the damping coefficient and the wave number is 4% or better. The film balance could detect a change in surface pressure of 5×10^{-5} N m^{-1}.

Solutions of known concentration of synthetic β,γ-dipalmitoyl-DL-α-lecithin, cholesterol and an equimolar mixture of the two were made in chloroform. The lecithin used was supplied by Nutritional Biochemical Corporation, Cleveland, Ohio, U.S.A. and cholesterol by General Biochem. Lab., Chagrin Falls, Ohio, U.S.A. The concentration of the solute was such that approximately 200 microliters of the solution spread on the trough gave a sub-monomolecular layer suitable for compression to full coverage. Line distilled water distilled from the alkaline $KMnO_4$ solution and redistilled from a quartz still was used as the substrate. The monolayer was spread from a microsyringe drop by drop. The surface piston was then moved in steps to decrease the area available to the monolayer. After each change of the barrier position, the surface was allowed to come to equilibrium, indicated by a constant film pressure. The ripple measurements were then made. A series of measurements was made until the monolayer collapsed as indicated by leveling off of the surface pressure.

From the measured values of α and k, dimensionless parameters $Y_1\left(=\frac{\rho\omega^2}{\gamma k^3}\right)$ and $Y_2\left(=\frac{\alpha}{k}\right)$ were obtained. Here ρ is the density of water, γ the surface tension calculated from the film pressure, and ω is the angular frequency given by $\omega=2\pi\nu$; ν being the frequency of the probe vibration.

Results and Discussion

Figure 1 shows the damping coefficient curves. The curve for the mixture is intermediate in character between the curves for the pure compounds. All the damping coefficient curves show a maximum which is sharp in the case of cholesterol and a plateau rather than a distinct maximum for lecithin.

The mixed film also shows a relatively sharp maximum.

The damping coefficient and the sharpness of its maximum can be related to the chain-chain interaction in the molecules forming the monolayer. The effect of the surface diffusion on the wave damping has been calculated from the hydrodynamic theory.[1] This theory predicts a maximum in the damping coefficient as the surface elastic modulus increases. This has been verified experimentally for various soluble and insoluble film-forming substances.

Physically we can interpret the results as follows. As the wave passes, the surface is alternately compressed and expanded. Because of the surface elasticity in the presence of the surfactant molecules, the waves are damped. The damping is caused by the surface tension gradients set up by the stretching and contraction of the surface as the wave passes. If there is appreciable surface to bulk or surface to surface diffusion of the surfactant molecules in one wave period, these surface tension gradients are reduced and the damping is reduced. For insoluble monolayer like cholesterol and lecithin, the bulk to surface diffusion is irrelevant, only the surface to surface diffusion is important. If the chain-chain interaction in the monolayer is strong, this diffusion is low, resulting in a high damping coefficient.

From the results it is obvious that the chain-chain interaction in cholesterol monolayer is stronger than in the lecithin film. The relatively sharp maximum in the curve for the mixture indicates that there is appreciable interaction between the molecules of the mixture. This evidence favors the suggestion by Demel and Joos[10] that at low surface pressures, there is an interaction between the chains of the two substances in a monolayer.

The capillary ripple theory[1] makes it obvious that the ripple damping coefficient is sensitive to the elastic modulus only at intermediate values of the elastic modulus *i.e.* near the damping coefficient maximum. At low or high surface elasticity values the damping coefficient is virtually independent of the surface elastic modulus. This method is therefore sensitive to the value of the surface elastic modulus and hence to any property affecting this modulus only at such intermediate values. Thus, though this study suggests that there is an appreciable molecular interaction at intermediate surface elasticity which corresponds to quite dense films for these systems, it does not rule out such interaction at lower surface pressures.

A consideration of the dimensionless group Y_1 and

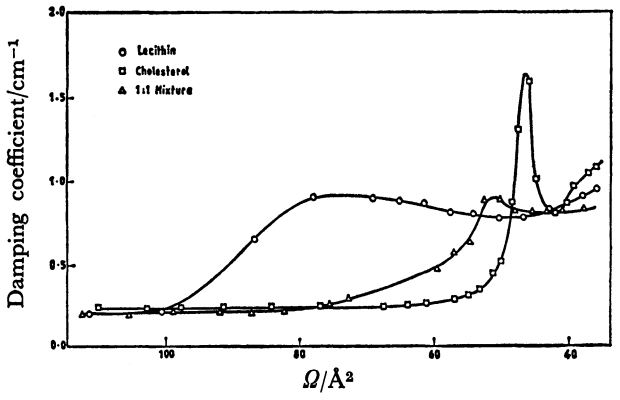

Fig. 1. Capillary ripple damping coefficient for the monolayers at various surface concentrations, frequency=200 Hz, temperature=25 °C.

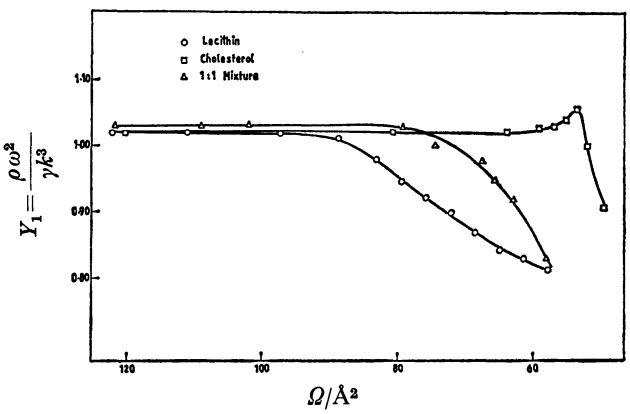

Fig. 2. Dimensionless parameter Y_1 for the monolayers.

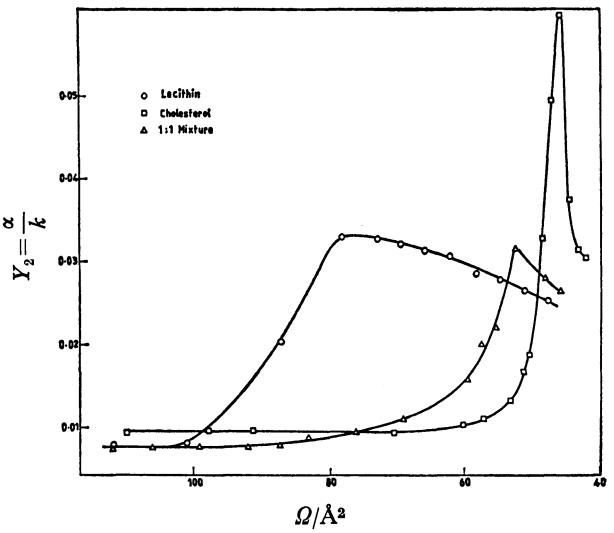

Fig. 3. Parameter Y_2 as a function of area per molecule, Ω, for the various monolayers.

Y_2 is useful when comparing monolayers formed by different substances. $Y_1=1$ is the Kelvin equation and is followed by pure water and by the monolayers in the limits of zero surface elasticity and surface viscosity. The curves in Fig. 2 follow this pattern. At high film densities the deviation from ideality sets in, this being due to compressional elastic modulus as well as surface viscosity. The different surface elastic moduli in the pure and the mixed film cause the curves to separate out at higher densities.

The amplitude of the waves in this study was small enough that the monolayer did not collapse by the passage of the waves, even for the near rigid films. This was confirmed by the stability of the values of the film pressures during the course of the ripple experiment.

Thermal Investigation of Nickel(II) Diamine Complexes in Solid State

Goutam De, Prasanta Kumar Biswas, and Nirmalendu Ray Chaudhuri*

Department of Inorganic Chemistry, Indian Association for the Cultivation of Science, Calcutta 700032, India

(Received August 24, 1982)

Three tris(ethylenediamine)nickel(II) chloride dihydrate having identical composition, apparently similar in color, magnetic moment and spectral properties showed differences in thermal profile. Thermal investigations of $[Ni(en)_3]Br_2\cdot 2H_2O$, $[Ni(tn)_3]Cl_2\cdot 2H_2O$, and $[Ni(tn)_3]Br_2\cdot H_2O$ where en=ethylenediamine and tn=1,3-propanediamine were carried out. Several bis and mono(diamine) complexes were synthesized in solid state from the corresponding tris complexes. All the bis and mono(diamine) complexes were found to be O_h and T_d symmetry respectively. All tris(diamine) complexes generate *cis* bis(diamine) species upon heating. But only one tris(ethylenediamine)nickel(II) chloride dihydrate generates *cis* bis species by the isomerization from the *trans* species temporarily formed. Monodiamine complexes decomposed through $[Ni_2(diamine)Cl_4]$ species which showed unusually high magnetic moment. The probable mechanistic path for each step of decomposition was also reported.

Thermal investigations of transition metal diamine complexes have been carried out by several workers.[1-4] Solid state kinetics of Cr^{III} complexes of ethylenediamine are well known in literature.[5] Thermal investigations of metal complexes of 1,2-propanediamine are known.[1] But the studies on the complexes of 1,3-propanediamine (tn) are scanty.[4] It is reasonable to expect that the thermal decomposition of $[Ni^{II}(tn)_3]X_2$ (X=Cl or Br) would be a matter of great interest as the complexes may lead to the formation of some new stoichiometric 1,3-propanediamine complexes of nickel(II) in solid state which could not be synthesized even in solution. Previously some work[2] on the thermal decomposition of $[Ni^{II}(en)_3]X_2$ (X=Cl or Br) has been done. Since thermal decomposition pattern is sometimes governed by the instrumental techniques used as also on the experimental conditions, studies on $[Ni^{II}(en)_3]X_2$ are also relevant. The present paper reports the thermal studies of $[Ni^{II}L_3]X_2$, where L=en or tn and X=Cl or Br. It deals with the synthesis and characterization of some new compounds derived in solid state. It also reports the probable mechanistic path for each step of decomposition.

Experimental

Preparation. *$[Ni(en)_3]Cl_2\cdot 2H_2O$ (**1**), $[NiCl_2(en)_2]$ (**4**)*: These were prepared following the method described in literature.[6]

*$[Ni(en)_3]Cl_2\cdot 2H_2O$ (**2**)*: Methylhydrazine or *N,N*-dimethylhydrazine or *N,N*-diethylethylenediamine (3 mmol) was added slowly to $[NiCl_2(en)_2]$ (**4**) (1 mmol) dissolved in water–ethanol (1:9) mixture. Shining pinkish crystals separated out. These crystals were collected and purified by washing with ethanol.

*$[Ni(en)_3]Cl_2\cdot 2H_2O$ (**3**)*: Addition of pyridine (3 mmol) to $[NiCl_2(en)_2]$ (**4**) (1 mmol) dissolved in water–ethanol (1:9) mixture, yielded shining pinkish crystals. These crystals were collected and purified by washing with ethanol.

*$[NiCl_2en]$ (**5**)*: This was synthesized by pyrolysis of the complexes **2** or **3** or **4** at 325 °C for 5 min in nitrogen atmosphere.

*$[Ni(en)_3]Br_2\cdot 2H_2O$ (**6**), $[Ni(tn)_3]Cl_2\cdot 2H_2O$ (**3**), and $[Ni(tn)_3]Br_2\cdot H_2O$ (**12**)*: These were prepared by mixing ethanolic solution of diamine (3 mmol) drop by drop to the ethanolic solution of nickel salt (1 mmol). While stirring the mixture, shining crystals separated out slowly. These crystals were collected and purified by washing with ethanol.

*$[NiBr_2(en)_2]$ (**7**)*: This was synthesized by pyrolysis of $[Ni(en)_3]Br_2\cdot 2H_2O$ (**6**) at 275 °C in nitrogen atmosphere.

*$[NiCl_2(tn)_2]$ (**9**)*: This was prepared by pyrolysis of $[Ni(tn)_3]Cl_2\cdot 2H_2O$ at 180 °C for 5 min in nitrogen atmosphere.

*$[NiCl_2tn]$ (**10**)*: This was prepared by pyrolysis of $[Ni(tn)_3]Cl_2\cdot 2H_2O$ (**8**) or $[NiCl_2(tn)_2]\cdot 1.5H_2O$ (**11**) at ≈278 °C in nitrogen atmosphere.

*$[NiCl_2(tn)_2]\cdot 1.5H_2O$ (**11**)*: This was synthesized by the same method adopted for the preparation of $[NiCl_2(en)_2]$ (**4**). This was also synthesized by keeping $[NiCl_2(tn)_2]$ (**9**) in an open air.

*$[NiBr_2(tn)_2]$ (**13**)*: This was synthesized by pyrolysis of $[Ni(tn)_3]Br_2\cdot H_2O$ (**12**) at 230 °C in nitrogen atmosphere.

Thermal Measurements. The thermal analysis was carried out using a Shimadzu DT-30 thermal analyzer. A constant flow of nitrogen (30 $cm^3\ min^{-1}$) was maintained. Platinum crucibles were used. Heating rate (10 °C min^{-1}) was maintained. The particle size of the samples was within 150—200 mesh. Aluminum oxide was used as reference. Zinc metal was used as calibrant for evaluation of enthalpy change.

Other Measurements. Infrared spectra in KBr (4000—250 cm^{-1}) and electronic spectra in mull (28570—11111 cm^{-1}) were recorded using a Beckman IR-20A and Pye Unicam SP8-150 spectrophotometers respectively. Cary 17D was also used for mull spectra in some cases. Magnetic moments of the compounds were evaluated at room temperature from the magnetic susceptibilities of the samples, corrected by applying Pascal's constants of the elements involved, using the Gouy technique where $Hg[Co(SCN)_4]$ was taken as standard. EG and G PAR 155 vibrating sample magnetometer was also used for measuring magnetic moment in some cases.

Results

$[Ni(en)_3]Cl_2\cdot 2H_2O$ (**1**) becomes anhydrous at 140 °C (Fig. 1, Table 1). The anhydrous species is thermally stable upto 190 °C. On further heating, it starts to lose en and transforms to metal chloride through bis, mono and hemi(diamine) species. None of the intermediate species and even the metal chloride are isolable. TG curve (Fig. 1) hints the elimination of water taking place in two steps. But the corresponding DTA curve predicts the water elimination occurring

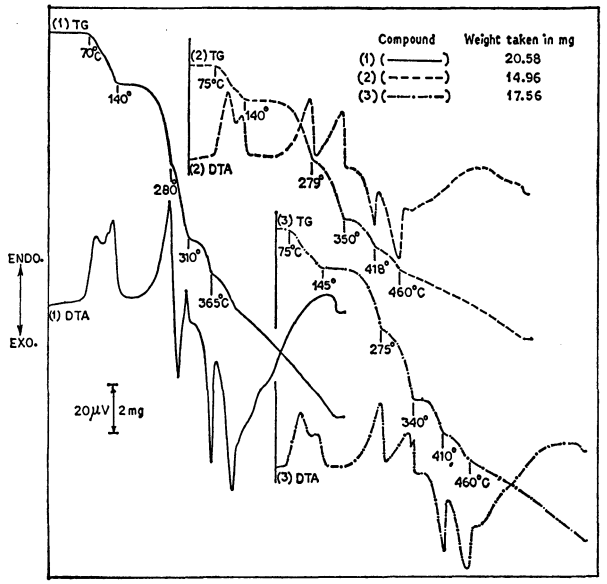

Fig. 1. Thermal curves of $[Ni(en)_3]Cl_2 \cdot 2H_2O$ (**1**) (——), $[Ni(en)_3]Cl_2 \cdot 2H_2O$ (**2**) (— — — —), and $[Ni(en)_3]Cl_2 \cdot 2H_2O$ (**3**) (—·—·—·—).

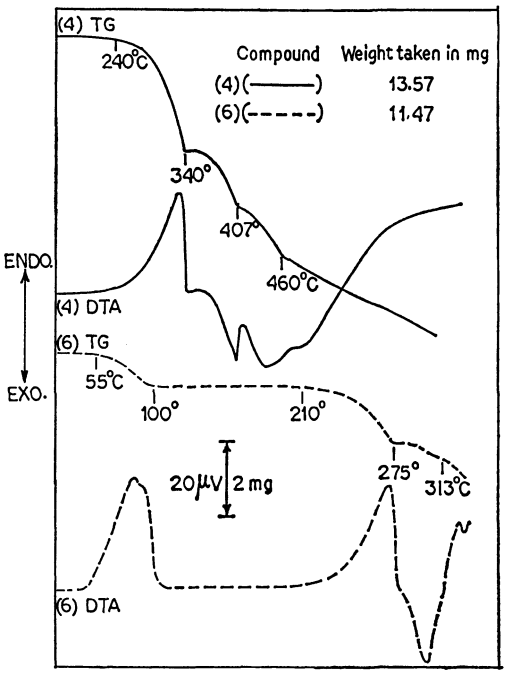

Fig. 2. Thermal curves of $[NiCl_2(en)_2]$ (**4**) (——) and $(Ni(en)_3]Br_2 \cdot 2H_2O$ (**6**) (— — — —).

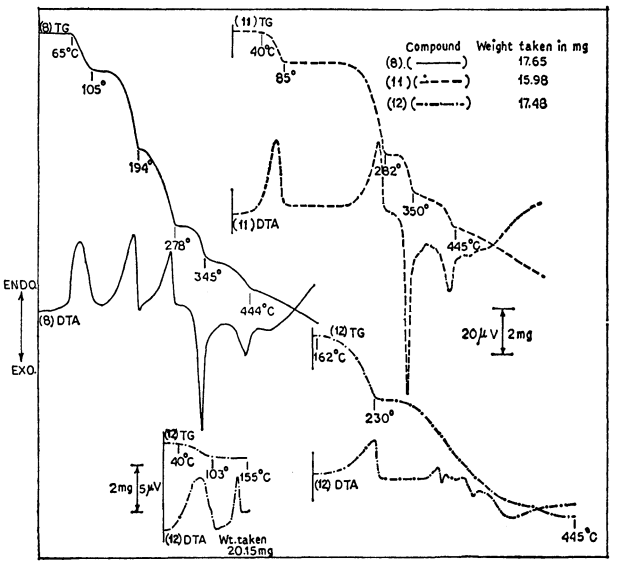

Fig. 3. Thermal curves of $[Ni(tn)_3]Cl_2 \cdot 2H_2O$ (**8**) (——), $[NiCl_2(tn)_2] \cdot 1.5H_2O$ (**11**) (— — — —), and $[Ni(tn)_3]Br_2 \cdot H_2O$ (**12**) (—·—·—·—).

actually in three steps. DTA profile for the elimination of two molecules of en shows first an endotherm followed by an exotherm followed by an another endotherm. It shows two prominent exotherms for the elimination of last molecule of en. On the other hand, $[Ni(en)_3]Cl_2 \cdot 2H_2O$ (**2**) loses two molecules of water in two steps as evident from its TG as well as DTA curves (Fig. 1). TG curve of the anhydrous species is almost similar to that of the complex **1**. But the DTA curve shows two prominent endotherms for the elimination of first two molecules of en and two exotherms for the elimination of last molecule of en. Thermal profile (Fig. 1) of complex **3** is almost similar to that of complex **2**. The only difference observed in the DTA curve is that endotherm responsible for the elimination of second molecule of en splits here. Thermal behavior of $[NiCl_2(en)_2]$ (**4**) is practically similar to that of the complex **2** in the decomposition from the stage of $[NiCl_2(en)_2]$. The isolation of mono(diamine) species is feasible by temperature arrest technique in nitrogen atmosphere from the complexes **2**, **3**, and **4**.

$[Ni(en)_3]Br_2 \cdot 2H_2O$ (**6**) becomes anhydrous at 100 °C in single step as observed from TG curve (Fig. 2, Table 1). But DTA curve shows elimination of water taking place in two steps. The anhydrous species starts to decompose at 210 °C and generates $[NiBr_2(en)_2]$ (**7**) at 275 °C showing a prominent endotherm in the DTA curve. An exotherm is displayed at the quite early stage of decomposition of the bis species which melts on further heating.

$[Ni(tn)_3]Cl_2 \cdot 2H_2O$ (**8**) becomes anhydrous at 105 °C (Fig. 3, Table 1). The anhydrous species starts to lose tn at 135 °C and transforms to metal chloride through bis (**9**), mono (**10**) and hemi(diamine) species. Bis and mono complexes are isolated in solid state by temperature arrest technique in nitrogen atmosphere. But we could not isolate the hemi species in pure form. The DTA curve shows two distinctly separated endotherms for the elimination of first two molecules of tn and two exotherms for the elimination of rest tn molecule.

$[Ni(tn)_3]Br_2 \cdot H_2O$ (**12**) starts to lose its water molecule at 40 °C and becomes anhydrous at 103 °C (Fig. 3, Table 1). This anhydrous species shows an endothermic peak in the temperature range 135—155 °C without showing any mass loss. After this change it starts to lose one molecule of tn at 162 °C and becomes $[NiBr_2(tn)_2]$ (**13**) at 230 °C which is isolable in the solid state. On further heating it transforms to metal bromide at 415 °C. But this transformation is found to be very complicated as evident from its TG and

Table 1. Thermal parameters of nickel(II) diamine complexes

Decomposition reactions	Temperature range/°C	DTA peak temperature/°C		ΔH/kJ mol^{-1}
		Endo	Exo	
$[Ni(en)_3]Cl_2\cdot 2H_2O$ (**1**) → $[Ni(en)_3]Cl_2$	70—140	98, 115, 135		153
$[Ni(en)_3]Cl_2$ → $[NiCl_2(en)_2]$	190—280	277		b)
$[NiCl_2(en)_2]$ → $[NiCl_2en]$	280—310	308	290	b)
$[NiCl_2en]$ → $[Ni_2Cl_4en]$	310—365		360	b)
$[Ni_2Cl_4en]$ → $NiCl_2$	365—416		398	b)

Discussion

Ethylenediamine Complexes of Nickel(II) Chloride. It is interesting to note that complexes **1**, **2**, and **3** seem apparently identical (Table 2) but they are basically different in structures as evident from their DTA profiles. These structural differences may be due to the changes in conformation of the individual chelate ring as may be expected for these complexes. But the possession of similar IR bands by these three tris complexes rules out the possibility of conformational changes. Structural changes observed against these three complexes are not due to the changes in microsymmetry (D_3) as evident from their identical electronic spectra (Table 3). It is expected that the differences as observed during the decomposition appear to be due to the existence of different crystal symmetries belonged to them or due to some other factors (*vide supra*). It is difficult to understand what mechanism plays while synthesizing complexes **2** and **3** by adding pyridine, methylhydrazine *etc.* to the bis complex **4**. However, it is expected that non-bridging of halide ion in $[NiCl_2(en)_2]$ resulting in bond stretching phenomenon as reported by Benson and Haim[7] is responsible for the transformation of $[NiCl_2(en)_2]$ to $[Ni(en)_3]Cl_2$. It is observed that dehydration pattern of complex **1** is different (Fig. 1) from the complexes **2** and **3**. One interesting observation is that these three anhydrous tris complexes take two molecules of water while keeping them in air. The difference exhibited in the dehydration process does not exist in the dehydration of the rehydrated complexes in solid state. This is probably due to different attachment of H_2O molecules between **1** and the rehydrated compounds of anhydrous **1**. DTA profile for the transformation of bis→mono species in complex **1** is an exotherm followed by an endotherm (Fig. 1) which suggests that the decomposition takes place after geometrical isomerization. In complex **1** three chelated en are arranged in such a manner that during tris→bis transformation, a square pyramidal intermediate[8] is expected to be formed by chelate opening followed by the instantaneous axial coordination by chloride ion to the unstable intermediate (Scheme 1). The further heating develops unstable *trans*-$[NiCl_2(en)_2]$ which transforms to *cis* variety as Cl^- acts as reasonably good *cis* directing product.[5] As a consequence, the exotherm at the beginning of the decomposition of bis species is responsible for the *trans*→*cis* isomerization as evident from literature[9] that such isomerization would generally cause exotherm in the system. Moreover, a weakly resolved plateau in TG curve for tris→bis formation in **1**, unlike the cases of **2** and **3** (Fig. 1) is probably due to the formation of unstable *trans* intermediate (Scheme 1). On the other hand, during the isomerization process complexes **2** and **3** exhibit simply endotherms for bis→mono transformation. Occurrence of splitting in endotherm in complex **3** suggests that complexes **2** and **3** are possibly structurally different, which would indicate that bis→mono transformation occurs in two steps though the corresponding TG curve shows no inflexion due to the extreme instability of the intermediate complex species. The above observation indicates that the complex **2** possesses more simple structure in comparison to that of complex **3**. $[NiCl_2(en)_2]$ (**4**) is undoubtedly *cis* as evident from IR assignments[10–13] and X-ray crystallographic studies.[14] TG curves (Fig. 1) of the decomposition of **1**, **2**, and **3** do not permit the isolation of bis$[NiCl_2(en)_2]$ in very pure state. However, we have isolated the bis species from complexes **2** and **3**. The IR spectral data of these two bis species support the configuration as that (Table 4) of complex *cis*-$[NiCl_2(en)_2]$ (**4**). This shows that basic *cis* form of complex **4** is not disturbed at all while synthesizing the complexes **2** and **3**.

It is a matter of great interest that mono species, $[NiCl_2en]$ (**5**), green in color, has been isolated in pure form in solid state, whilst attempt for the preparation of this compound in solution has been unsuccessful. The IR spectrum (Table 4) of this compound suggests that en is chelated. Moreover, the medium broad band at $\approx 330\ cm^{-1}$ in IR spectrum is well

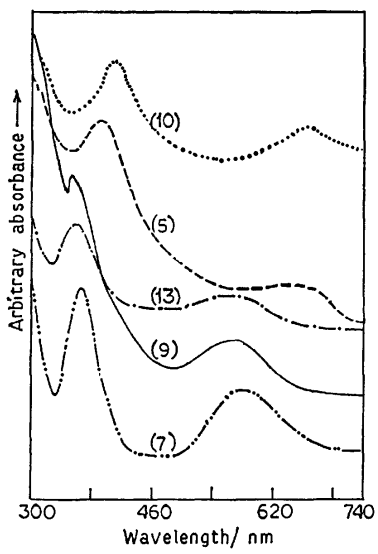

Fig. 4. Electronic spectra of $[NiBr_2(en)_2]$ (**7**) (—··—··—··—), $[NiCl_2(tn)_2]$ (**9**) (——), $[NiBr_2(tn)_2]$ (**13**) (—·—·—·—), $[NiCl_2en]$ (**5**) (— — — —), and $[NiCl_2tn]$ (**10**) (·····) in mull).

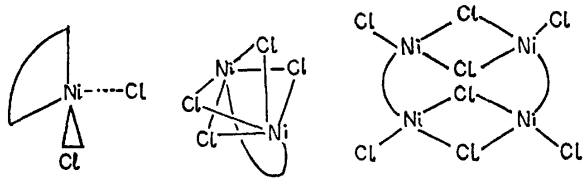

significant for Ni–Cl terminal coordination in T_d symmetry.[15] Magnetic moment (Table 2) is higher than those of the complexes **2**, **3**, and **4** which suggests that the symmetry is lowered in $[NiCl_2en]$ causing greater orbital contribution. The electronic spectra in mull (Fig. 4) display the characteristic band of the T_d Ni^{II} system (Structure 1) at ≈650 nm which is tentatively assignable to the $^3T_1 \rightarrow {}^3T_1(P)$ transition (ν_3).[16,17]

We could not isolate $[Ni_2Cl_4en]$ in pure form as TG curve (Fig. 1) does not indicate stable step. But we have measured magnetic moment of this species isolated by temperature arrest technique at the temperature (410 °C) where the desired composition corresponds to the TG curve. The compound possesses unusually high magnetic moment (μ_{eff}=10.0 BM using the formula, $[Ni_2Cl_4en]$). This may be due to the ferromagnetic behavior which is possibly developed from the Cl^- bridging[18–20] and metal-metal interaction.[21] These phenomena and the stoichiometry of the compound would require either pentacoordinated species (Structure 2) developed from monomeric $[Ni_2Cl_4en]$ or tetracoordinated tetrahedral species (Structure 3) formed from dimeric $[Ni_2Cl_4en]$ *i.e.*, $[Ni_4Cl_8(en)_2]$. In this type of geometry two Ni^{II} ions probably come closer with each other to satisfy the proposed interaction. Since the compound is hygroscopic (in nature) its IR spectrum is not well resolved. However, comparing the complicated IR spectrum of $[NiCl_2en]$ (**5**) with the simpler IR of $[Ni_2Cl_4en]$ it is expected that en is possibly bridged and *trans*. Electronic spectrum in mull of $[Ni_2Cl_4en]$ is not also well resolved. As a result it would not be prudent to support the structures from electronic spectrum.

Ethylenediamine Complexes of Nickel(II) Bromide. Dehydration of $[Ni(en)_3]Br_2\cdot 2H_2O$ (**6**) occurs in two steps like complexes **2** and **3**. Isolation of $[NiBr_2(en)_2]$ (**7**) in pure state from complex **6** is possible unlike the corresponding chloro complexes. This bis complex (**7**) is expected to possess *cis* configuration as the IR spectrum of it closely resembles that of *cis* variety of $[NiCl_2(en)_2]$ (**4**). Though the method or preparation of complexes **4** and **7** are different the complexes are having *cis* configuration. As the intermediate bis species obtained from the complexes **2** and **3** are exhibiting almost similar IR spectra with those of **4** and **7** the possession of similar *cis* configuration like that of complexes **4** and **7** is also supported here for the bis species isolated from **2** and **3**. It is interesting to note that an exotherm appears in DTA profile (Fig. 2) at the threshold of decomposition of *cis*-$[NiBr_2(en)_2]$. This exotherm is probably due to the isomerization process. However, it is difficult to say which configuration is being formed here. On the contrary, it is expected that melting process generally happens to more symmetric species. As *trans* species is more symmetric than *cis*, *trans* configuration is possibly formed before melting. As a consequence, it seems that the initial configurations of the bis products obtained from the decomposition of **1** and **6** are not similar. Such differences are possibly due to the different polarizability of halide ions. It is reasonable to expect that, Br^- has stronger bridging character owing to its higher polarizability and larger size than Cl^- which prefers *cis* configuration as evident from the isolable *cis* complex **7**. On the other hand, the less polarizability and smaller size of Cl^- possibly hinders bridging character, and so the *cis* form (Scheme 1) generated is less stable (Fig. 1, Table 1).

Attempt to prepare $[Ni(en)_3]Br_2$ by the treatment of complex $[NiBr_2(en)_2]$ with pyridine, methylhydrazine *etc.* has been unsuccessful unlike the cases of complexes **2** and **3**. It is not unlikely to expect that bond stretching phenomenon of Ni–Br in $[NiBr_2(en)_2]$ is not pronounced here since the Br^- has greater tendency to form bridge.

1,3-Propanediamine Complexes of Nickel(II) Chloride. $[Ni(tn)_3]Cl_2\cdot 2H_2O$ (**8**) shows almost similar thermal behavior as observed by the complex **2**. We have synthesized $[NiCl_2(tn)_2]\cdot 1.5H_2O$ in two ways. We thought initially that two types of $[NiCl_2(tn)_2]\cdot 1.5H_2O$ would be generated due to the difference in synthetic procedure. But we find no difference in structure between the two bis species owing to their similar spectral and thermal behavior. This bis species is also suggested to possess *cis* configuration like $[NiCl_2(en)_2]$ (**4**) as evident from a number of bands in the region 1550—1650 cm^{-1} (Table 4) which are mainly contributed due to $\delta_{(NH_2)}$ vibration. Here also, this bis species did not yield tris species at all by the reaction with pyridine, methylhydrazine *etc.* unlike the complex **4**. The reason is probably due to the longer chain of chelate ring in the complex than en, whose effect is

pronounced for Br^- rather than Cl^- ion. Another intermediate complex, $[NiCl_2tn]$ (**10**) synthesized in solid state from complex **8** is much hygroscopic in nature, and green in color like **5**. IR, electronic spectra (in mull) as well as magnetic moment of $[NiCl_2tn]$ suggests its T_d symmetry similar to the corresponding en complex. Here also, we could not isolate $[Ni_2Cl_4tn]$ in pure form. It is interesting to note that $[Ni_2Cl_4tn]$ is also ferromagnetic like $[Ni_2Cl_4en]$.

1,3-Propanediamine Complexes of Nickel(II) Bromide. $[Ni(tn)_3]Br_2 \cdot H_2O$ (**11**) after dehydration, exhibits an endotherm with no weight loss. The detail studies of the observed phase change is to be reported separately[22] along with the other phase transition phenomena occurring in diamine complexes. Decomposition of this dehydrated complex species (**12**) to bis complex follows the path similar to that of complex **2** (Fig. 3). The $[NiBr_2(tn)_2]$ (**13**) is O_h suggested by its magnetic moment (Table 2) and electronic spectra in mull (Table 3). IR spectrum of $[NiBr_2(tn)_2]$ also shows more bands than *trans* chelated $[Ni(NCS)_2(tn)_2]$[23] which indicate that two tn molecules are chelated (Table 4). The decomposition of $[NiBr_2(tn)_2]$ to $NiBr_2$ follows in multiple steps, unlike $[NiCl_2(tn)_2]$.

It is clear from the decomposition patterns of the complexes that change of halide ion in the system causes remarkably different decomposition, whilst the increase in chain length in the diamines does not affect it much.

Water elimination in tris(diamine) complexes of nickel(II) bromide takes place at lower temperature (Table 1) in comparison to those of the corresponding chloride. This is probably due to anion variation in the complexes. The value of enthalpy change for water elimination appears very low in $[Ni(tn)_3]Br_2 \cdot H_2O$ (**12**) which indicates that attraction of water molecule towards nickel(II) is less here in comparison of enthalpy changes among **1**, **2**, **3**, **6**, and **8** complexes (Table 1). It is reasonable to expect that the water molecule in **12** is attached by van der Waals force only. On the other hand, water molecules in the **1**, **2**, **3**, **6**, and **8** complexes are probably attached by hydrogen bonding as well as van der Waals force causing more attraction of the water molecules in the species.

It is interesting to note that the ΔH value for the decomposition of $[NiCl_2tn]$ to $[Ni_2Cl_4tn]$ is considerably high (Table 1) in comparison to that for $[NiCl_2en]$ to $[Ni_2Cl_4en]$ transformation. Here the ΔH values involve the metal ligand bond energies, polarization energies of the ligands and other contributions. However, it is rather difficult to say which factor is predominant to cause such difference in the ΔH values of the two transformations.

Graphical Enumeration of the Sextet Polynomials. Novel Identities of Resonant Sextet Numbers of Cata-condensed Benzenoid Hydrocarbons†

Sherif EL-BASIL
Faculty of Pharmacy, Kasr El-Aini Street, Cairo, Egypt
(Received November 20, 1982)

Novel graph-theoretical identities of resonant sextet numbers of certain nonbranched and branched cata-condensed benzenoid hydrocarbons are given, which are based on transforming Kekulé valence-bond structures into the subspace of their double bonds. Analytic expressions are given which allow construction of sextet polynomials of certain types of benzenoid hydrocarbons of very large sizes in a few seconds without drawing any graphs.

A little more than a decade ago Hosoya introduced his concept of nonadjacent numbers[1] as the sum of a set of numbers $p(G,k)$'s defined as the number of ways in which k bonds in graph G are so chosen that no two of them are connected. Thus $p(G,2)$ *e.g.* would be the number of disconnected K_2 graphs in G. Hosoya correlated such numbers with boiling points of alkanes.[1] The concept is related to the so called bond eigenfunctions of many-electron molecules adopted in old resonance theory.[2] The reference polynomial[3] of benzenoid hydrocarbons, BH's is expressed as simple functions of such disconnected K_2 graphs.[4]

Some years later Hosoya and Yamaguchi[5] extended the "nonadjacent" concept to Clar's sextet theory[6] by defining a resonant sextet number, $r(G,k)$ for a BH graph G as the number of ways in which k disconnected but mutually resonant sextets are chosen from G. Such resonant sextet numbers are used to construct sextet polynomials, $B_G(X)$'s, as given by

$$B_G(X) = \sum_{k=0}^{m} r(G,k)X^k,$$

where $r(G,0)$ is defined as unity and m is the maximal number of disconnected sextets in G. Two years later, Gutman[7] correlated sextet polynomials with characteristic polynomials of certain trees, $P_T(X)$, corresponding to nonbranched cata-condensed BH's, where

$$P_T(X) = \sum_{k=0}^{(N/2)} (-1)^k p(T,k)X^{N-2k},$$

N is the number of vertices in the tree, and $p(T,k)$ is the number of ways in which k nonincident edges are selected from T. Gutman demonstrated and proved the equality of the two variables, *viz.*,

$$r(G,k) = p(T,k).$$

In quite a recent development, Gutman[8] constructed his so called C graphs associated with a BH composed of y hexagons, $h_1, h_2, \ldots, h_y$. The vertices of the C graph $v_1, v_2, \ldots, v_y$ correspond to the h's such that v_r and v_s are adjacent if and only if h_r and h_s in BH are mutually nonresonant. Gutman[8] discovered the interesting relation that such C graphs are actually the line graphs[9] corresponding to tree graphs associated with nonbranched cata-condensed BH's so that we may write:

$$L^{-1}(C) = T.$$

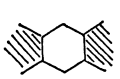
In a related development Aihara[10] defined a new polynomial based on the $r(G,k)$ numbers from which an expression was deduced for resonance energies of BH's. The above history of the sextet polynomial stimulated many people of deriving algorithms for its construction[11] due to its importance to both theorists and organic chemists.

In this work we analyze the sextet polynomial from a novel vent, namely from the permutation[12] of double bonds in Kekulé structures of BH's. First we cite some terms and their meanings.

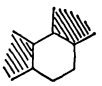
Definitions

Types of Benzenoid Hydrocarbons. We shall adopt the following terminology in this paper: A molecular network which is entirely composed of hexagons is called benzenoid. If all benzene rings in one of the Kekulé structures have an aromatic sextet the hydrocarbon is called all-benzenoid (in the opposite sense, a nonall benzenoid). If no three hexagons have a common atom, the system is called cata-condensed. If every hexagon of a cata-condensed system has at most two neighbouring hexagons, it is said to be nonbranched. If there is at least one hexagon in a cata-condensed hydrocarbon that is surrounded by three other hexagons, it is said to be branched.

Modes of Ring Annellation, the L,A-Sequence.[7] The nonterminal hexagons in a nonbranched cata-condensed system can be annellated in just two ways,[7] *viz.*,

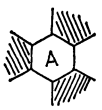


L-mode



A-mode

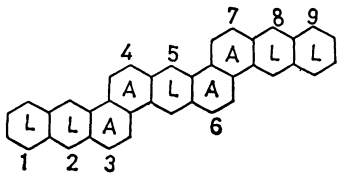
Furthermore we shall adopt an additional convention that a hexagon which is fused simultaneously to three other hexagons (*i.e.* a branched hexagon) will be assigned the symbol A, *viz.*,



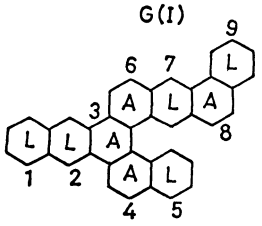
Therefore an ordered R-tuple of symbols L,A, the so called L,A-sequence,[7] might be associated with a cata-condensed BH containing R hexagons, thus: $S_1, S_2, \ldots, S_R$ where, by definition[7] $S_1 = S_R = L$ while S_n, $1 < n < R$, is assigned the symbol L or A depending on its mode of annellation. As an illustration we consider G(I)

† This paper is dedicated to Professor Nenad Trinajstić.

and G(II) representing molecular graphs of a non-branched and a branched cata-condensed BH and their L,A sequences



G(I)



G(II)

We distinguish three types of induced subgraphs[9] which might be partitioned out of the molecular graph of the BH, *viz*,

$$\langle g_1 \rangle = \mathrm{L}^{s_1}\mathrm{A}, \tag{1}$$

$$\langle g_2 \rangle = \mathrm{AL}^{s_2}\mathrm{A}, \tag{2}$$

$$\langle g_3 \rangle = \mathrm{AL}^{s_3}. \tag{3}$$

where L^s means L repeated s times (thus L^3 means L L L and so on). The values of s_1 and $s_3 \neq 0$ while s_2 may or may not be zero depending on the structure of G. As an illustration we consider all the induced subgraphs in G(I) and G(II). For G(I) we have:

$$\langle g_1 \rangle \supset \langle S_1, S_2, S_3 \rangle$$

$$\langle g_2 \rangle \supset \langle S_3, S_4 \rangle \; ; \; \langle S_4, S_5, S_6 \rangle \; ; \; \langle S_6, S_7 \rangle$$

$$\langle g_3 \rangle \supset \langle S_7, S_8, S_9 \rangle.$$

While G(II) is partitioned into:

$$\langle g_1 \rangle \supset \langle S_1, S_2, S_3 \rangle$$

$$\langle g_2 \rangle \supset \langle S_3, S_6 \rangle \; ; \; \langle S_3, S_4 \rangle \; ; \; \langle S_6, S_7, S_8 \rangle$$

$$\langle g_3 \rangle \supset \langle S_8, S_9 \rangle \; ; \; \langle S_4, S_5 \rangle.$$

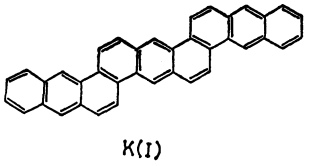
The number of induced subgraphs will be denoted as L. Thus $L(\mathrm{G(I)})=5$; $L(\mathrm{G(II)})=6$; L(linear acene)$=1$.

Clar Representation of Kekulé Structures, Dualist and Factor Graphs. In a recent graph-theoretical analysis of Clar sextet theory,[6] Hosoya *et al.*[13] distinguished two types of sextets proper and improper, *viz.*,

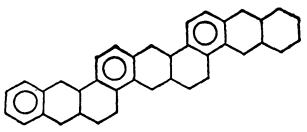
proper sextet

improper sextet

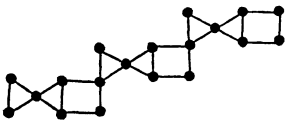
If, in a Kekulé structure circles are placed into hexagons containing proper sextets and then double bonds are replaced by single bonds a Clar formula, $\mathcal{C}$, results. When a Kekulé structure is transformed into the subspace of its double bonds, a factor graph,[14] $F(K)$ results. If the benzene rings of the benzenoid hydrocarbon are replaced by vertices and then connecting adjacent ones, a dualist,[15] D, results. As an illustration we consider a Kekulé structure for G(I), its Clar formula, factor graph and dualist:



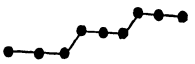
K(I)



$\mathcal{C}$(I)



F(K,I)



D(I)

Partition Sequence, $S(P)$ of the Factor Graphs

The factor graphs corresponding to the Kekulé structures of a BH might be partitioned according to the degrees of vertices composing them. Our treatment is restricted to BH's and the vertices of their factor graphs might have only degrees of 2, 3, and/or 4.[16] Figure 1 shows all $F(K)$'s of picene where the numbers in braces are populations of bivalent, tervalent and quadrivalent vertices respectively. We might, therefore, construct the following partition sequence for picene

$$S(P) = \{7,0,4\} + 5\{6,2,3\} + 6\{5,4,2\} + \{4,6,1\}.$$

One observes that the sextet polynomial of picene is given by $B_{\mathrm{G}}(X)=1+5X+6X^2+X^3$. The identity between the coefficients of our sequence and those of the polynomial is obvious.[17] In general one might define as ith partition, P_i as:

$$P_i = \{v_{2,i} \; ; \; v_{3,i} \; ; \; v_{4,i}\},$$

where $v_{2,i}$ is the number of bivalent vertices in ith partition and similarly for $v_{3,i}$ and $v_{4,i}$. Since, however, v_2, v_3, and v_4 for a BH are linearly related,[16] we might record only one variable, say v_2's. Thus our partition sequence takes the following general form for a set of $F(K)$'s with n partitions:

$$S(P) = a_{\bar{m}}[\bar{m}] + a_{\bar{m}-1}[\bar{m}-1] + \cdots + a_{\bar{m}-n+1}[\bar{m}-n+1], \tag{4}$$

where $[\bar{m}]$ is a partition for which v_2 is maximum and $a_{\bar{m}}$ is its population. The value $\bar{m}-n+1$ is minimum $v_2=\underline{m}$, and n is the number of partitions. Equation 4 might be written as:

$$S(P) = \sum_{j=0}^{n-1} a_{\bar{m}-j}[\bar{m}-j]$$

where

$$\sum_{j=0}^{n-1} a_{\bar{m}-j} = K,$$

being the Kekulé count. For picene we have

$$n = 4 \; ; \; a_{\bar{m}} = 1 \; ; \; a_{\bar{m}-1} = 5 \; ; \; a_{\bar{m}-2} = 6 \; ; \; a_{\bar{m}-3} = 1$$

whence K(picene)$=1+5+6+1=13$. One observes that the corresponding $r(\mathrm{G},k)$'s are:

$$r(G,0) = 1 \; ; \; r(\mathrm{G},1) = 5 \; ; \; r(\mathrm{G},2) = 6 \; ; \; r(\mathrm{G},3) = 1.$$

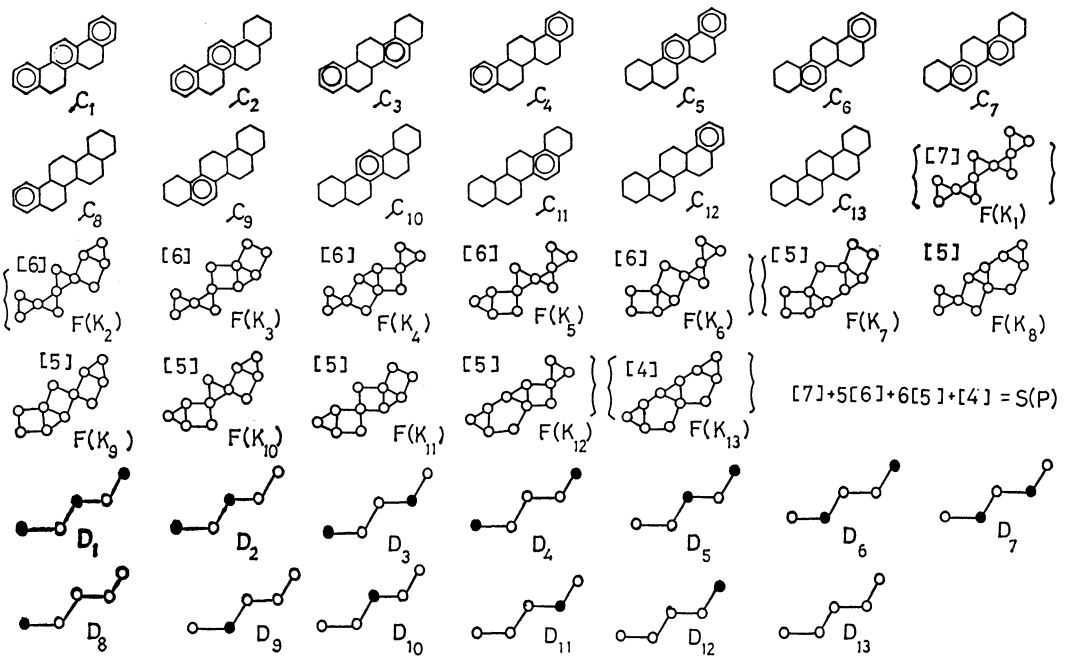


Fig. 1. Graphical illustration of Sextet Polynomial of pentaphene (a NBCCABH). The ⟋C's are Clar formulas, $F(K)$'s are the corresponding factor graphs while the D's being the corresponding dualists colored such that solid vertices correspond to hexagons containing circles. Thus dualists containing one solid vertex correspond to $r(G,1)$ or $N(1)$, those containing two solid vertices correspond to $r(G,2)$ or $N(2)$ and so on. Numbers in square brackets are v_2's in each $F(K)$.

Results

The Linear Acenes. $S(P)$'s and $B_G(X)$'s of the lower numbers of the linear acenes are listed below

Benzene	:	$0[4] + 2[3]\ ;\ 1 + X$,
Naphthalene	:	$[4] + 2[3]\ ;\ 1 + 2X$,
Anthracene	:	$2[4] + 2[3]\ ;\ 1 + 3X$,
Naphthacene:	:	$3[4] + 2[3]\ ;\ 1 + 4X$,
Pentacene	:	$4[4] + 2[3]\ ;\ 1 + 5X$.

The following relations hold for a linear acene

$$a_4 = a_{\bar{m}} = R - 1 = r(G,1) - 1, \tag{5}$$

$$a_{\underline{m}} = a_3 = 2, \tag{6}$$

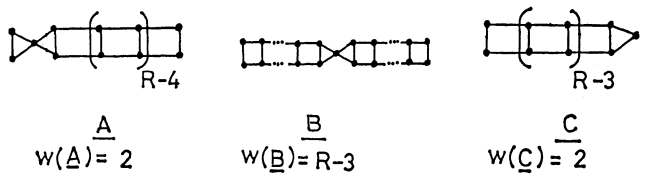
$$n = 2. \tag{7}$$

Theorem: The vertices of a set of $F(K)$'s of a linear acene partition themselves in only two distinct ways; such that two of these $F(K)$'s have only three bivalent vertices while the remaining factor graphs contain four bivalent vertices each. *i.e.*

$$S(P)_{\text{Linear acene}} = (R-1)[4] + 2[3]. \tag{8}$$

R being the number of benzene rings.

Proof: We consider the most general case first, of a linear acene containing R rings, $R \geqslant 4$. One can easily show that there are three types of factor graphs belonging to such a linear acene, A, B, and C, *viz.*,



Where w is the multiplicity of factor graph type. *E.g.* there are two forms of A *i.e.* A and its mirror image and similarly for C, while the B type generates $(R-3)$ $F(K)$'s. The number of cycles in B is, of course, R. We observe that the sum of w's is $2+R-3+2=R+1=K$. Furthermore types A and B lead to partition with maximum number of bivalent vertices, thus $a_{\bar{m}}=w(A)+w(B)=2+R-3=R-1$. Type C leads to $[\underline{m}]$, and since $w(C)=2$, $\bar{m}=4$ and $\underline{m}=3$ Eq. 8 is proved for $R \geq 4$.

The proof can easily be demonstrated for $R<4$. *E.g.* when $R=2$, A=B= and w () $=1$;

C= $w(C)=2$. When $R=3$, $w(B)=0$ while

A=  $w(A)=2$, and C=  $w(C)=2$.

Again A and C lead to $[\bar{m}]$ and $[\underline{m}]$ respectively, where $\bar{m}=4$, $\underline{m}=3$. When the values of w's are used, Eq. 8 results.

Nonbranched Cata-condensed All-benzenoid Hydrocarbons NBCCABH's. An all-benzenoid cata-condensed hydrocarbon is defined above. In terms of Eqs. 1—3, only three types of induced subgraphs[9] might be factored out of the molecular graph of a NBCCABH, *viz.*,

$$\langle g_1 \rangle = \text{LA},$$

$$\langle g_2 \rangle = \text{A}^2,$$

$$\langle g_3 \rangle = \text{AL}.$$

Thus for a NBCCABH containing R rings the L,A sequence would be LA^{R-2}L. Consequently for this

TABLE 1. PARTITION SEQUENCES $S(P)$'s, (ABOVE), AND SEXTET POLYNOMIALS, $B_G(X)$'s, (BELOW), OF SOME NONBRANCHED ALLBENZENOID SYSTEMS

R	Example	$S(P)$; $B_G(X)$
3		$[5]+3[4]+[3]$ $1+3X+X^2$
4		$[6]+4[5]+3[4]$ $1+4X+3X^2$
5		$[7]+5[6]+6[5]+[4]$ $1+5X+6X^2+X^3$
6		$[8]+6[7]+10[6]+4[5]$ $1+6X+10X^2+4X^3$
7		$[9]+7[8]+15[7]+10[6]+[5]$ $1+7X+15X^2+10X^3+X^4$
10		$[12]+10[11]+36[10]+56[9]+35[8]+6[7]$ $1+10X+36X^2+56X^3+35X^4+6X^5$

class of BH's we may write:

$$R = L + 1. \tag{9}$$

Table 1 outlines $S(P)$'s and $B_G(X)$'s for some representative members of this topology. The following identity holds for NBCCABH's:

$$a_{\bar{m}-j} = r(G,j). \tag{10}$$

Equation 10 might easily be induced from observation of the results. The following relations hold for population coefficients:

$$a_{\bar{m}} = 1 = a_{R+2}\ ;\ (\bar{m}=R+2), \tag{11}$$
$$a_{\bar{m}-1} = R, \tag{12}$$
$$a_{\bar{m}-2} = 2^{-1}(R-2)(R-1), \tag{13}$$
$$a_{\bar{m}-3} = 6^{-1}(R-4)(R-3)(R-2), \tag{14}$$
$$a_{\bar{m}-4} = 24^{-1}(R-6)(R-5)(R-4)(R-3), \tag{15}$$
$$a_{\bar{m}-5} = 120^{-1}(R-8)(R-7)(R-6)(R-5)(R-4), \tag{16}$$
$$a_{\bar{m}-6} = 720^{-1}(R-10)(R-9)(R-8)(R-7)(R-6)(R-5). \tag{17}$$

Thus, a general expression is given by:

$$a_{m-j} = r(G,j) = (j!)^{-1}(R+1-j)\prod_{m=0}^{j-2}(R-j-m) \tag{18}$$
$$= \binom{R+1-j}{j}.$$

The algebraic properties of the above factorials make the derivation of higher populations possible. Naturally the sum of these coefficients will lead to K. The number of different partitions, n, is related to R in the following way:

R	n
3, 4	3
5, 6	4
7, 8	5
9, 10	6 ··· *etc.*

Thus

$$n = \frac{(R+1)}{2} + 1 \qquad (R \text{ odd})$$
$$= \frac{R}{2} + 1 \qquad (R \text{ even})$$

or by using the Gaussian brackets

$$n = \left[\frac{(R+1)}{2}\right] + 1.$$

The value of $a_{\underline{m}} = a_{\bar{m}-n+1}$ is given by:

$$a_{\underline{m}} = 1 \qquad (R \text{ odd}) \tag{19}$$
$$a_{\underline{m}} = \frac{R}{2} + 1 \qquad (R \text{ even}) \tag{20}$$

Non-branched Cata-condensed Nonall-benzenoid Hydrocarbons for Which $L=2$, (NBCCNABH's)$_{L=2}$. Dualists of this class of BH's are characterised by having just one bend (kink),[18] *i.e.* $L=2$ (See Table 2 for some representative members). It is convenient to express their partition sequence as:

TABLE 2. PARTITION SEQUENCES, $S(P)$, (ABOVE), AND SEXTET POLYNOMIALS, $B_G(X)$, (BELOW), OF NONBRANCHED NONALL-BENZENOIDS CONTAINING TWO LINEAR SUBGRAPHS

R	Dualist	$S(P)$; $S_G(X)$
4		$[3]+4[4]+2[5]$; $1+4X+2X^2$
5		$[3]+5[4]+4[5]$; $1+5X+4X^2$
5		$[3]+5[4]+3[5]$ $1+5X+3X^2$
6		$[3]+6[4]+4[5]$ $1+6X+4X^2$
6		$[3]+6[4]+6[5]$; $1+6X+6X^2$
7		$[3]+7[4]+5[5]$; $1+7X+5X^2$
7		$[3]+7[4]+9[5]$; $1+7X+9X^2$
7		$[3]+7[4]+8[5]$; $1+7X+8X^2$

$$S(P)_{(\text{NBCCNABH})_{L=2}} = a_3[3] + a_4[4] + a_5[5], \quad (21)$$

i.e. $\underline{m}=3$; $\bar{m}=5$; $n=3$ for this class of BH's. Furthermore, their resonant numbers are identified with their population coefficients as given by:

$$a_{\underline{m}+i} = r(\mathrm{G},i). \quad (22)$$

Equation 22 can easily be induced from observation of the results (Table 2). Equation 22 leads to three explicit expressions of the individual resonant numbers, .,*viz*

$$a_3 = r(\mathrm{G},0) = 1, \quad (23)$$

$$a_4 = r(G,1) = R, \quad (24)$$

$$a_5 = r(\mathrm{G},2) = e\langle g_1\rangle\, e\langle g_3\rangle, \quad (25)$$

where $e\langle g_1\rangle$ is size of $\langle g_1\rangle$ *i.e.* number of its edges and similarly for $e\langle g_3\rangle$. (*c.f.* Eqs. 1, 3). Thus for pentaphene, *e.g.* $e\langle g_1\rangle = e\langle g_3\rangle = 2$; whence $a_5=4$. An expression for K for this class of BH's is:

$$K_{(\text{NBCCNABH})_{L=2}} = \sum_{i=0}^{2} a_{\underline{m}+i} = 1 + R + e\langle g_1\rangle \cdot e\langle g_3\rangle. \quad (26)$$

Conjecture: The set of $F(K)$'s of a NBCCNABH for which $L=2$ (*i.e.* whose graph has only one hexagon with an A annellation mode) may partition themselves into three subsets only, in which the number of bivalent vertices may take on values of three, four, or five.

Non-branched Cata-condensed Nonall-benzenoid Hydrocarbons for which $L=3$; $(NBCCNABH's)_{L=3}$. We report results for only two types of this class as illustrations, *viz.*,

Class i for which the size of the middle subgraph is unity, *i.e.* $e\langle g_2\rangle = 1$ (Table 3).

Class ii for which $e\langle g_2\rangle = 2$ (Table 4).

We conjecture that for both types, the partition sequence is described by Eq. 27, *viz.*

$$S(P)_{(\text{NBCCNABH})_{L=3}} = a_4[4] + a_5[5] + a_6[6]. \quad (27)$$

Table 3. Partition sequences, $S(P)$, (above), and sextet polynomials, $B_G(X)$, (below), of nonbranched nonall-benzenoids containing three G_L's such that the middle G_L has only one edge *i.e.*, $e(G_{L_2})=1$

$a_5(R+1)-a_5(R)$[a]	2	3
$r(\mathrm{G},2)$	$a_6+(R-2)$	$\frac{1}{2}a_6+2(R-3)$
$r(\mathrm{G},3)$	0.00	$e\langle g_1\rangle \cdot e\langle g_3\rangle$
K	$2R+e\langle g_1\rangle \cdot e\langle g_3\rangle - 1$	$3R+2e\langle g_1\rangle \cdot e\langle g_3\rangle - 5$

a) $a_5(R)$ is population coefficient of partition whose $v_2=5$ of a BH containing R rings and similary for $a_5(R+1)$.

We outline the following useful topological properties for these two classes of graphs:

Branched Cata-condensed Benzenoid Hydrocarbons. The structure of the sextet polynomials of branched cata-condensed systems depends on the mode of growth of the hexagons on the triphenylene unit. We consider the two modes of ring annellation *viz.* linear and angular ways as illustrated below on dualists of some triphenylene derivatives:

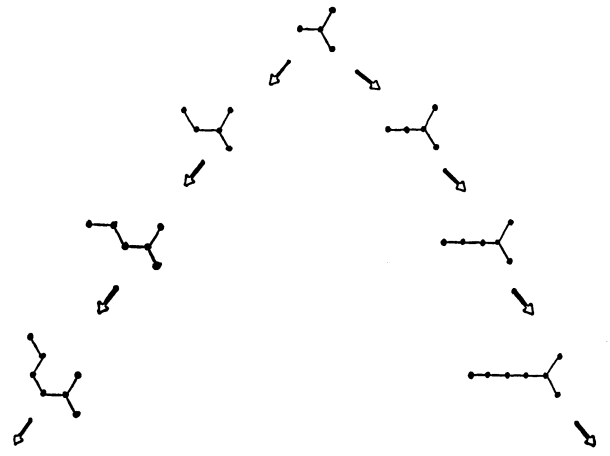

TABLE 6. PARTITION SEQUENCES, $S(P)$'s (ABOVE), AND SEXTET POLYNOMIALS, $B_G(X)$'s, (BELOW), OF SOME BRANCHED CATACONDENSED BENZENOID HYDROCARBONS

R	Dualist	$S(P)$; $B_G(X)$
4		$2[6]+3[5]+3[4]+[3]$ $1+4X+3X^2+X^3$
5		$3[6]+5[5]+4[4]+[3]$ $1+5X+5X^2+2X^3$
6		$4[6]+7[5]+5[4]+[3]$ $1+6X+7X^2+3X^3$
5		$2[7]+5[6]+5[5]+2[4]$ $1+5X+6X^2+2X^3$
6		$2[8]+7[7]+8[6]+5[5]+[4]$ $1+6X+10X^2+5X^3+X^4$
7		$2[9]+9[8]+13[7]+10[6]+3[5]$ $1+7X+15X^2+11X^3+3X^4$

The group of dualists to the right are derived from triphenylene by linear annellation of hexagons while those to the left by angular annellation. Table 6 lists $S(P)$'s and $B_G(X)$'s of these dualists. We now list some of the mathematical properties of these branched systems.

i) Systems Derived by Linear Ring Annellation: Throughout the following equations, by definition of a branched cata-condensed system, $R \geqslant 4$:

$$a_{\bar{m}} = R-2 = a_6, \tag{28}$$

$$a_{\bar{m}-1} = 2R-5 = a_5 = r(\mathrm{G},2), \tag{29}$$

$$a_{\bar{m}-2} = R-1 = a_4, \tag{30}$$

$$a_{\bar{m}-3} = a_{\underline{m}-3} = a_3 = 1, \tag{31}$$

$$r(\mathrm{G},3) = R-3. \tag{32}$$

One can easily deduce an expression for the Kekulé count of branched cata-condensed benzenoid hydrocarbons whose dualists have the general formula:

, $m=0, 1, 2, \cdots$

as:

$$K = a_6 + a_5 + a_4 + a_3 = 4R-7. \tag{33}$$

ii) Systems Derived by Angular Ring Annellation:

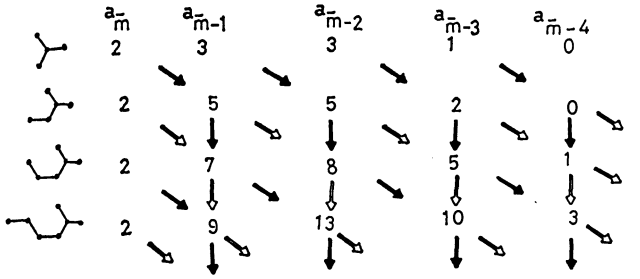
$$a_{\bar{m}} = 2 = a_{R+2}, \tag{34}$$

$$a_{\bar{m}-1} = 2R-5, \tag{35}$$

$$a_{\bar{m}-2}(\mathrm{R}) + a_{\bar{m}-2}(R+1) = a_{\bar{m}-2}(R+2), \tag{36}$$

where $a_{\bar{m}-2}(R)$ is population of the partition $[\bar{m}-2]$ for an allbenzenoid benzenoid hydrocarbon containing R rings and one branched ring (*i.e.* a ring which is fused simultaneously to three other rings) and similarly for $a_{\bar{m}-2}(R+1)$ and $a_{\bar{m}-2}(R+2)$. *I.e.* the coefficients of $[\bar{m}-2]$ in a homologous series of this class of branched systems define a Fibonacci sequence.[19]

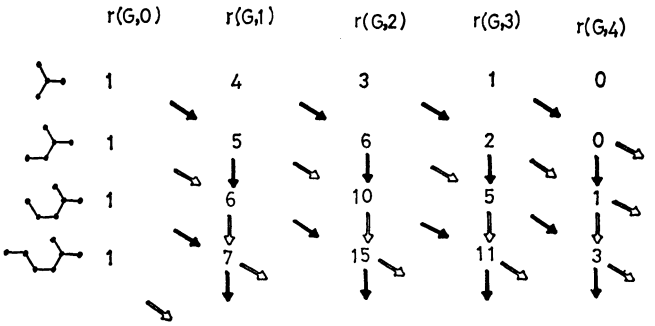
The relation among the coefficients of the partition sequences of this class of hydrocarbons is best shown in the following diagram (see Table 6) where the first row corresponds to triphenylene:



The above relation might be expressed as:

$$a_{\bar{m}}(R) + a_{\bar{m}-1}(R+1) = a_{\bar{m}-1}(R+2). \tag{37}$$

A similar relation holds for the resonant numbers as diagramed below: (the first row correspond to triphenylene).



So that we may write

$$r(\mathrm{G},j)_R + r(\mathrm{G},j+1)_{R+1} = r(\mathrm{G},j+1)_{R+2}, \tag{38}$$

where $r(\mathrm{G},j)_R$ is $r(\mathrm{G},j)$ for a member of this set of branched hydrocarbons containing R rings and similarly for other notations. Diagrams like the ones shown above allow the systematic synthesis of sextet polynomials of very large graphs. Furthermore we have:

$$r(\mathrm{G},2) = \sum_{j=2}^{R-1} (R-j)\ ;\ R \geqslant 4. \tag{39}$$

Restricted Disjoint Interactions, RDI's

A pair of RDI is defined between two dualist vertices v_r and v_s such that:

i) v_r and v_s are not part of the same induced subgraph defined by Eqs. 1—3.

ii) v_r and v_s are never adjacent.

i) and ii) are equivalent to saying that v_r and v_s form a pair of RDI if and only if the corresponding hexagons, h_r and h_s, in BH are resonant. We now recall that the so called C(Clar) graph recently introduced by Gutman[8] has its v_r and v_s adjacent only if the corresponding h_r and h_s are nonresonant. We might, there-

fore, call the elements of our RDI's "non-Clar graphs". Examples of such pairs of RDI's are shown as solid circles in dualists of pentaphene (Fig. 1). The number of such pairs of RDI's will be denoted as $N(2)$.

Analogously we define $N(3)$ as triplet of RDI's *e.g.* $N(3)$ for pentaphene=1 (Fig. 1).

Quartets, Quintets *etc.* might similarly be defined. It can be shown that for any type of cata-condensed BH. The following identity holds:

$$N(j) = r(G,j). \tag{40}$$

The validity of the above identity is a result of the definition of RDI's and the fact that in a cata-condensed BH every induced subgraph (Eqs. 1—3) might have only one resonant sextet. This topology makes $N(j)$ identical with the number of ways in which j mutually resonant but disconnected sextets are selected from BH graph. For NBCCABH's the sextet numbers are related to population coefficients by:

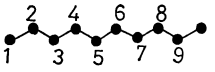
$$r(G,j) = a_{\bar{m}-j}. \tag{41}$$

Whence

$$a_{\bar{m}-j} = r(G,j) = N(j). \tag{42}$$

Therefore finding expressions for $N(j)$'s allows construction of sextet polynomials and generation of partition sequences of nonbranched allbenzenoid hydrocarbons without actually writing any Kekulé structures.

For the purpose of illustration we consider a NBCCABH containing ten rings. One such dualist is shown below:



We would like to compute, *e.g.* $r(G,5)$ *i.e.* coefficient of X^5 in sextet polynomial or $a_{\bar{m}-5}$ and since $\bar{m}=R+2$ (for NBCCABH) we are looking for $a_{12-5}=a_7$ *i.e.* population of [7] (that is the number of factor graphs for which $v_2=7$). We simply list the following quintets of RDI's (1,3,5,7,9); (1,3,5,8,10); (1,3,5,7,10); (1,3,6,8,10); (1,4,6,8,10); and (2,4,6,8,10). Therefore there are six Kekulé structures containing each, five disconnected but mutually resonant sextets. Alternatively, we say, there are six $F(K)$'s containing, each, seven bivalent vertices. Actually we do not have to "synthesize" these RDI's we may use Eq. 16, *viz.*,

$$a_{m-5} = 120^{-1}(R-8)(R-7)(R-6)(R-5)(R-4)$$
$$= 120^{-1}(2)(3)(4)(5)(6) = 6.$$

Obviously to use the approach originally suggested by Hosoya and Yamaguchi[5] would be rather a formidable task, especially for higher tuplets. Also, Gutman's method[7,8] requires the construction of the C graph and its $L^{-1}C$ as well as knowledge on characteristic polynomials of trees. To our knowledge our method is simple enough to be carried out by an "average" chemistry student !.

I wish to thank Professor Nenad Trinajstić for correcting some of my mathematical terms, namely dualist instead of dual graph and K_2 subgraphs for non-adjacent numbers. I am also indebted to Professor Ivan Gutman for sending me his recent work on the subject (Ref. 8).

Pandurang V. Nikrad, and Vasant K. Sharma
National Chemical Laboratory, Poona 411008, India

(Received December 7, 1982)

Dinitroarenes containing substituents such as hydroxyl and amine groups could be conveniently reduced with 3 molar equivalents of hydrazine hydrate in presence of Raney nickel catalyst in ethanol/1,2-dichloroethane solvent mixture to give a product wherein one of the two nitro groups was reduced to the amino group. The yields of the partial reduction products are good. Under similar conditions alkoxyl substituents in the *o,p*-position to the nitro groups were displaced by the hydrazino group to give 2,4-dinitrophenylhydrazine as the main product. The details of the reduction reaction are described.

We reported the high reduction ability of hydrazine hydrate in presence of Raney nickel in ethanol/1,2-dichloroethane solvent mixture to reduce nitroarenes under mild conditions.[1] The reaction conditions and solvent system are ideal for the reduction of nitro compounds having limited solvent solubility. The scope of the method has been extended for the reduction of one of the two nitro groups of dinitroarenes. The results of the partial reductions are discussed here.

Usually partial reduction is carried out in aqueous medium by using sodium sulfide under alkaline conditions (Zinin reduction) or tin(II) chloride under acidic conditions. The latter has a tendency to reduce the less hindered nitro group. The dinitro compounds such as 2,4-dinitrophenol, its ethers and 2,4-dinitroaniline derivatives undergo reduction with sulfide reagents at the nitro group ortho to the phenolic or ether oxygen or amino substituent.[2] Ruthenium-on-carbon catalyst, which can be used for the partial reduction of 2,4-dinitroaniline to 4-nitro-*o*-phenylenediamine with hydrazine, was shown to be useful for the synthesis of 1-*N*-substituted 4-nitro-*o*-phenylenediamines.[3] Use of Raney nickel catalyst under identical conditions yielded a complex mixture. Catalytic hydrogenation of 2,4-dinitroaniline at 2.72 atm in presence of 5% rhodium on alumina catalyst and ammonia in DMF yielded 4-nitro-*o*-phenylenediamine in 87% yield.[4] 4-Nitro-*o*-phenylenediamine has commercial utility as an analytical reagent, as an ingredient of hair dyes and as a drug and dye intermediate.

Results and Discussion

We found that 1,3-dinitrobenzene (**1a**) could be conveniently reduced to *m*-nitroaniline (**2a**) by using 3 mol of hydrazine hydrate per mol of **1a** in presence of Raney nickel catalyst in ethanol/1,2-dichloroethane solvent mixture at 50—60 °C.[1] The yield of **2a** exceeded 90%. The procedure is advantageously used for the partial reduction of dinitroarene derivatives containing various substituents. Ethanol/1,2-dichloroethane (1:1) mixture was used as the solvent. In general, the ortho nitro group in 2,4-dinitroarylamine derivatives was preferentially reduced, giving 2-amino-4-nitroarylamine derivatives as the main products. The less hindered para-nitro groups was reduced to a small extent. The results are summarised in Table 1. It can be seen that the yield of the partial reduction products by our method are excellent.

Reduction of 2,4-dinitrophenol (**1b**) with 3 molar equivalent of hydrazine hydrate in presence of Raney nickel in ethanol/1,2-dichloroethane (1:1) at 50—60 °C for 4 h gave 2-amino-4-nitrophenol (**2b**) and 4-amino-2-nitrophenol (**2c**) in 92% and 7% isolable yields respectively. Similarly, 2,4-dinitroaniline (**1c**), under identical conditions for 6 h gave 4-nitro-*o*-phenylenediamine (**2d**) and 2-nitro-*p*-phenylenediamine (**2e**) in 95% and 3% isolable yields. Quantitative yield of 2-amino-*N*-ethyl-4-nitro-aniline (**2f**) was obtained from *N*-ethyl-2,4-dinitroaniline (**1d**). With *N*-isopropyl-2,4-dinitroaniline (**1e**), however, the reduction was effected only upto the hydroxylamine stage. The hitherto unknown 2-hydroxy-*N*-isopropyl-4-nitroaniline (**2g**) was isolated in quantitative yield. With *N*-phenyl-substituted amino compounds such as 2,4-dinitrodiphenylamine (**1f**), the yield of the ortho-amino product, 2-amino-4-nitrodiphenylamine (**2h**) fell down to 70% and that of the isomeric para-amino product, 4-amino-2-nitrodiphenylamine (**2i**) increased to 29%. Thus, in the cases described so far, nitro group in the ortho position to amino or hydroxyl substituent was preferentially reduced giving ortho-amino derivatives as major or sole products. Apparently the hydrogen bonding between the amino or the hydroxyl substituent and the ortho-nitro group plays a decisive role in these cases. If such a hydrogen bonding is not possible, as in the case of 2,4-dinitrotoluene (**1j**), the reduction of the para-nitro group was predominant resulting in 88% of 2-nitro-*p*-toluidine (**2n**) and only 10% of 4-nitro-*o*-toluidine (**2o**). Sodium sulfide also selectively reduces the para-nitro group of 2,4-dinitrotoluene.[5,6] The reduction of 2,6-dinitro-*p*-creasol (**1g**) yielded 2-amino-6-nitro-*p*-cresol (**2j**) in 98% yield. During the partial reduction of 3,5-dinitrobenzoic acid, hydrazine salt of 3,5-dinitrobenzoic acid (mp 170 °C, lit,[7] 168 °C) was found to be an intermediate product, which could be isolated and characterized. Ultimately, 3-amino-5-nitrobenzoic acid (**2k**) was isolated in 85% yield. As a representative example of naphthalene series, the partial reduction of 1,5-dinitronaphthalene (**1i**), using 3 molar equivalents of hydrazine hydrate was studied. The reduction product consisted of 20.33% 5-nitro-1-naphthylamine (**2l**), 47.26% 1,5-naphthalenediamine (**2m**) and 32.41% of the starting 1,5-dinitronaphthalene (**1i**). The product analysis was carried out by using IATROSCAN TH

a) Dinitrophenol ether **3**: hydrazine hydrate ratio 1:3; 0.3 g of catalyst; 10 ml of solvent $C_2H_5OH/ClCH_2CH_2Cl$ (1:1 v/v) per g of **3**. Temperature 50—60 °C. b) The rest of the product amounting 91—99% is 2,4-dinitrophenylhydrazine (**5**) isolated in every case; mp 200 °C (Ref. 31, 200 °C). c) Yield isolated product. d) Characterized by spectral and elemental analysis.

10 TLC/FID analyzer (Iatron Laboratories, Inc., Japan). Apparently, the initially formed partially reduced product undergoes parallel reduction reaction to give **2m** in organic solvent medium.

Using the same conditions as mentioned above, alkyl and aryl ethers of 2,4-dinitrophenol were allowed to react with 3 molar equivalents of hydrazine hydrate in presence of Raney nickel catalyst. The reactions resulted in rapid replacement of the alkoxyl or the aryloxyl groups with the formation of 2,4-dinitrophenylhydrazine (**5**) as the predominant product. The results are summerised in Table 2. Partial reduction products having amino groups in ortho positions to the alkoxyl or the aryloxyl substituents were isolated in yields ranging from 0.5 to 8%. In general, the bulkier groups (such as 2-hydroxyethoxy, 2-methoxyethoxy, propoxy, isopropoxy 2,4-dichlorophenoxy, phenoxy, 2,3-dihydroxypropoxy, and benzyloxy groups of **3c**—**3j** are replaced with ease with the formation of 2,4-dinitrophenylhydrazine (**5**). The yields of the corresponding partial reduction products **4c**—**4i** and **4l** ranged from 0.5 to 1%. The compound **4f**, known as P4000, is the sweetest material known and is 4000 times sweeter than sucrose.[8] In the case of **3a** and **3b** with less bulkier methoxyl and ethoxyl substituents, the yields of 4-nitro-*o*-anisidine (**4a**) and 4-nitro-*o*-phenetidine (**4b**) were 8% and 6% respectively. The formation of **5** involves nucleophilic substitution reaction similar to the reaction of amines with 2,4-dinitrophenyl ethers, resulting in the formation of 2,4-dinitroanilines.[8–10] The 2,4-dinitrophenylhydrazine (**5**), which is formed in high yields within 4 h, has a tend-

ency to undergo subsequent reaction, if prolonged further, resulting in the formation of side products as indicated by TLC. Under basic reaction conditions, triazoles and other products arising from partial and complete reduction of **5** are produced.[11] Apparently, the catalyst played no role, when 2,4-dinitrophenyl ethers were allowed to react with hydrazine under our conditions. When 2,4-dinitrophenyl ethers **3a**, **3b**, **3c**, **3e**, and **3g** were allowed to react with 3 molar equivalents of hydrazine hydrate in the absence of catalyst in ethanol/1,2-dichloroethane solvent at 60 °C for 4 to 6 h the expected 2,4-dinitriphenylhydrazine (**5**) was obtained as the sole product. There was no trace of any side product.

In order to study the role of solvent, 1,3-dinitrobenzene (**1a**) was allowed to react with 3 molar equivalents of 20, 40, 60, and 80% hydrazine hydrate in aqueous medium at 90 °C for 16—18 h. The yields (based on TLC/FID analysis using IATROSCAN TH 10) of *m*-nitroaniline (**2a**) were 74, 86, 100, and 100% respectively. Since 60% hydrazine hydrate gave quantitative yield of **2a**, it was used for the noncatalytic reduction of other dinitroarenes. The results are summerised in Table 3. The partially reduced products, 2-amino-4-nitrophenol (**2b**) and 2-nitro-*p*-toluidine (**2n**) were obtained in 98% and 92% yields from 2,4-dinitrophenol (**1b**) and 2,4-dinitrotoluene (**1j**) respectively. The reductions were, however, slow and took 16 to 18 h for completion. In the case of *N*-ethyl-2,4-dinitroaniline (**1d**), the yield of **2f** was 70%. The success of this method is noteworthy in the case of 1,5-dinitronaphthalene (**1i**). The yield of the partially reduced product, 5-nitro-1-naphthylamine (**2l**) was 80%. The rest of the product consisted of the starting material **1i**. Apparently in this case, the partially reduced product **2l** falls out of the reaction medium and is inaccesible for further reduction to **2m**. Such a partial reduction of 1,5-dinitronaphthalene by noncatalytic hydrazine hydrate in the absence of solvents has been reported in a patent.[12] Mononitro compounds such as *p*-nitrotoluene (**6**) or difficultly soluble dinitro compounds such as bis(3-nitrodiphenyl) sulfone (**7**) were not reduced under similar conditions even after 36 h. Their complete insolubility in aqueous 60% hydrazine hydrate is responsible for the nonreducibility. The dinitrophenol ethers **3a**, **3b**, **3e**, **3f**, **3g**, and **3i**, as expected yielded 2,4-dinitrophenylhydrazine (**5**) quantitatively within 0.5 h even at 65 °C. Lower concentrations of hydrazine hydrate (*e.g.* 20%) also yielded **5** quantitatively at 90 °C for 2 h. Alkaline sulfide reductions of 2,4-dinitriphenol ethers are known to give the corresponding partial reduction products.[13]

Recently it was shown that if nitro compounds containing *N*- or *O*-benzyl groups were added to a refluxing mixture of excess of hydrazine hydrate, Raney nickel and methanol, nitro groups got reduced to the amino groups; but the benzylamino or the benzyloxy groups were unaffected. Thus 2,4-dinitrophenyl benzyl ether (**3j**) gave 2,4-diaminophenyl benzyl ether with 10 molar equivalents of hydrazine hydrate.[14] We carried out the same reaction under identical conditions by using 3 molar equivalents of hydrazine hydrate and obtained 2,4-diaminophenyl benzyl ether in 43% yield (isolated as dihydrochloride, mp 134 °C), the rest of the product consisted of unreacted starting material. Apparently the mode of addition of the nitro compounds and other reaction conditions play an important role in the selective reduction of dinitroarenes. Thus, when 2,4-dinitroanisole, **3a** (**3a**: hydrazine hydrate ratio 1:3, 0.3 g Raney nickel, 0.01 mol **3a** and methanol 40 ml per g of **3a**, 4 h reaction time) was added to hydrazine hydrate, methanol and Raney nickel mixture at 0 °C, about 95% of unreacted **3a** and 5% 2-amino-4-nitroanisole (**4a**) were isolated. At 28—30 °C, there was 94% formation of **5** and the rest a complex mixture giving a series of spots on silica gel TLC plate. At 40—50 °C, the formation of **5** was 86% and that of **4a** was 8.8% (isolated yield). There was also evidence for the formation of other complex reduction products as noticed by TLC analysis. When **3a** was added to a refluxing mixture of methanol, hydrazine hydrate and Raney nickel, formation of **5** was not noticed. Only 2,4-diaminoanisole was isolated as dihydrochloride, mp 248 °C (mixed mp with an authentic sample was not depressed) in 46% yield. Under identical conditions, **3j** was reduced with 3 molar equivalents of hydrazine hydrate to give a product consisting of 44% of unreacted **3j**, and 43% of 2,4-diaminophenyl benzyl ether isolated as dihydrochloride. Finally, a mixture of methanol, hydrazine hydrate and Raney nickel was refluxed for 10—12

Table 3. Reduction[a] of nitroarene (**6**), dinitroarenes (**7** and **1**) and dinitrophenol ethers (**3**) with 60% aq. hydrazine hydrate alone

a) Substrate: hydrazine hydrate ratio, 1:3. b) Yield of isolated product. c) 30% unreacted **1d** is isolated. d) 20% unreacted **1i** is isolated. e) 20% aq. hydrazine hydrate is used.

min, dinitroarenes **3a**, **3d**, **3f**, **3g**, and **3j** (1 mol per 3 mol of hydrazine) were added to the cooled mixture at 5 °C, and stirred for 45 min at that temperature. Hydrazine hydrate in this case probably has decomposed to hydrogen and nitrogen (along with ammonia) in the beginning, leaving most of the alkoxyl of aryloxyl group unaffected. Here, thus, we could isolate partially reduced products without the replacement of *O*-

Table 4. Partial reduction[a] of dinitrophenol ethers (**3**) with hydrazine hydrate/Raney nickel

Substrate No.	Product		Yield[b] %	Mp θ_m/°C Found	Ref.

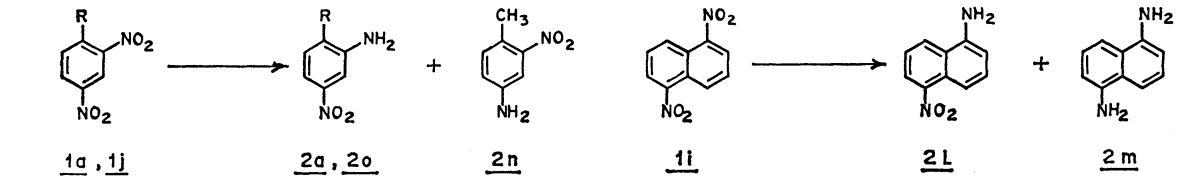
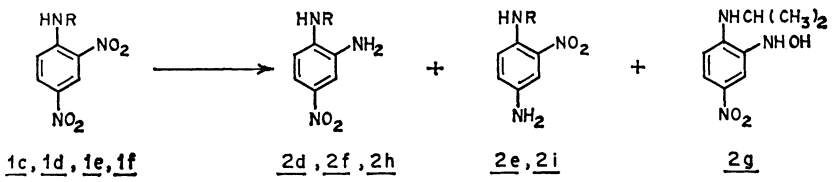
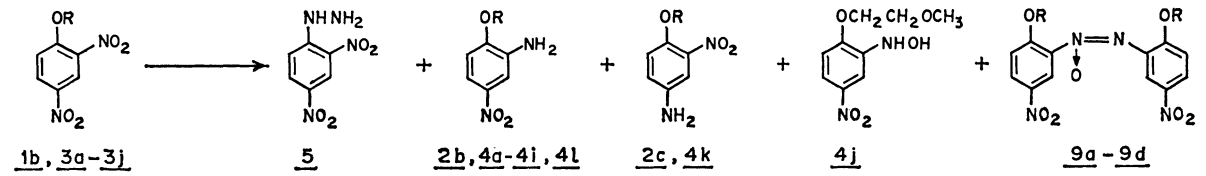
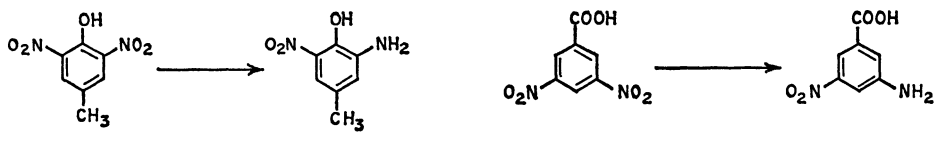
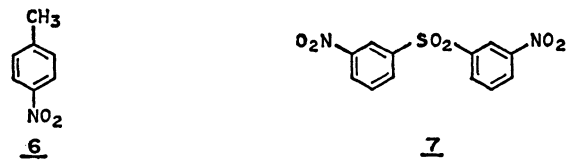
a) Substrate: Hydrazine hydrate ratio 1:3; 0.3 g of catalyst; 40 ml of methanol per g of **3**. Temperature 4—5 °C, time 45 min. b) Yield of isolated products. c) Compounds characterized by spectral and elemental analysis.











alkyl or *O*-aryl groups (Table 4). The reduction of **3a** gave 2-amino-4-nitroanisole (**4a**) in 33% yield. Under similar conditions, the yields of 2-amino-4-nitro-1-propoxybenzene (**4f**), 2-amino-4-nitro-2′,4′-dichlorodiphenyl ether (**4g**) and 2-amino-4-nitrophenyl benzyl ether (**4l**) were 10, 22.5, and 6% respectively. The 2,4-dinitrophenyl 2-methoxyethyl ether (**3d**), however, gave only 2-hydroxyamino-4-nitrophenyl 2-methoxyethyl ether (**4j**) in 30% yield. In the case of **3a**, **3d**, **3f**, and **3j**, we could additionally isolate the hitherto unknown pale yellow azoxy compounds, 2,2′-disubstituted 5,5′-dinitroazoxybenzenes, **9a**—**9d** as major products in 22.9, 36, 24, and 31% yields respectively. Such azoxy compounds were not isolated during the reduction of dinitroarenes **1**. The compound **3g** yielded the para-nitro reduction product, 4-amino-2-nitro-2′,4′-dichlorodiphenyl ether (**4k**) in 20% yield. About 49% of **3g** and 53% of **3j** were recovered unreacted. All the unknown compounds were characterized by their spectral and analytical data.

Features of the present method are: (1) the preferential formation of 2-amino-4-nitroanilines from the corresponding dinitroanilines, (2) the formation of 2,4-dinitrophenylhydrazine (**5**) by the replacement of *O*-alkyl or *O*-aryl groups in 2,4-dinitrophenyl ethers by hydrazino group; and (3) the simplicity of the work-up procedures.

Experimental

Melting points were uncorrected. IR spectra were recorded on a Perkin-Elmer infrared spectrometer-model 137B, ^{1}H NMR spectra on a Varian T-60 spectrometer using TMS as internal standard. Mass spectra were determined on CEC-2L-11OB spectrometer.

*Reduction of Dinitroarenes **1** and **3**. General Procedure*: A mixture of dinitroarene (0.1 mol), 1:1 (v/v) ethanol/1,2-dichloroethane (10 ml per g of **1** and **3**), and hydrazine hydrate (0.3 mol) is stirred for 10 min at 28—30 °C. Raney nickel (0.3 g) is added with stirring in three portions over a period of 40 min. The reaction is vigorous and the temperature increases to 50—60 °C. (Temperature is not allowed to rise above 60 °C). After 30 min, when the reaction has subsided, stirring is continued for 3 to 8 h at 50—60 °C (Tables 1 and 2). Complete conversion of the dinitroarene can be confirmed by TLC analysis on silica gel using benzene/ethanol (19:1) as eluent and colour development with iodine vapours. The catalyst is removed by filtration. The solvent is evaporated and the residue is crystallized from ethanol (**1a**—**1e**; **1g**—**1i**) and from pet.ether/benzene (**1f**). The filtrates were chromatographed to give minor aminonitroarenes, **2c**, **2e**, and **2i**. In case of **1i**, the product mixture is analyzed by IATROSCAN TH 10 TLC/FID analyzer using benzene:ethanol (99:1, v/v) as solvent to give 1,5-dinitronaphthalene (**1i**) 32.41%, 5-nitro-1-naphthylamine (**2l**), 20.33%, and 1,5-naphthalenediamine (**2m**), 47.26%. The reduction product from **1j** is chromatographed on silica gel (eluent, benzene) to give **2n** and **2o** respectively. The aminonitroarenes **2a**—**2f** and **2h**—**2o** are characterized by mp, mixed mp and elemental micro analysis. The orange product, 2-hydroxyamino-*N*-isopropyl-4-nitroaniline (**2g**) is isolated from the reduction of *N*-isopropyl-2,4-dinitroaniline (**1e**); mp 165 °C. IR (nujol) 3345, 3200, 1585, 1535, 1445, 1370, 1300, 1280 1240, 1220, 1155, 1120, 1100 cm^{-1}; ^{1}H NMR (pyridine) δ 1.26 (s, 3H), 1.40 (s, 3H), 4.1 (q, 1H); (DMSO), 4.63 (d, 1H, exchangeable with D_2O), 4.93 (s, 1H exchangeable with D_2O), 5.6 (s, 1H, exchangeable with D_2O), 6.33 (d, 1H), 7.10—7.4 (m, 2H); MS *m/e* 211. Found: C, 50.62; H, 6.52; N, 19.82%. Calcd for $C_9H_{13}N_3O_3$: C, 51.17; H, 6.20; N, 19.89%.

Dinitrophenylhydrazine (**5**), a major product from dinitrophenol ethers (**3a**—**j**) (Table 2) is isolated by crystallisation from ethanol, mp 200 °C (Lit,[34] mp 200 °C). The filtrate is evaporated and the residue is chromatographed on silica gel (eluent, benzene) to obtain minor partial reduction products (**4**). They are characterized (**4a**—**4f**; **4h**, **4i**, **4l**) by mp (mixed mp with authentic sample is not depressed). The unknown 2-amino-4-nitro-2′,4′-dichlorodiphenylether (**4g**) is characterized by spectral and microanalytical data. IR (Nujol) 3425, 3300, 3200, 1625, 1570, 1510, 1460, 1380, 1340, 1270, 1250, 1230, 1140, 1100, 1050, 865 cm^{-1}. ^{1}H NMR (CH_3CN) δ 4.57 (br s, 2H), 6.66—7.53 (m, 6H); MS *m/e* 299. Found: C, 47.81; H, 2.96; N, 9.33%. Calcd for $C_{12}H_8Cl_2N_2O_3$: C, 48.18; H, 2.69; N, 9.36%.

*Reduction of Nitroarene (**6**), Dinitroarenes (**1b**, **1d**, **1i**, **1j**, and **7**) and Dinitrophenol Ethers (**3a**, **3b**, **3e**, **3f**, **3g**, **3i**) with 60% Hydrazine Hydrate Alone.* A mixture of 2,4-dinitrophenol (**1b**) (0.05 mol), and 60% hydrazine hydrate (0.15 mol) is stirred for 10 min at 28—30 °C. Temperature is then raised to 90 °C in 45 min and stirring is continued for 18 h at 90 °C on water bath. Complete conversion of the nitroarene (**1b**) can be confirmed by TLC analysis on silica gel using benzene/ethanol (19:1) as eluent and colour development with iodine vapours. The dark red coloured reaction mixture is neutralized with dilute hydrochloric acid, when 2-amino-4-nitrophenol (**2b**) gets precipitated out. The solid filtered and crystallized from ethanol. Yield 7.53 g (98%), mp 141 °C (Lit,[16] mp 142—143 °C); mixed mp not depressed. Similar reactions of **1d**, **1i**, and **1j** give **2f**, **2l**, and **2n** in 70, 80, and 92% yields respectively (Table 3). In the case of **6** and **7**, there is no reduction and starting material can be recovered even after 36 h heating at 90 °C. The dinitrophenol ethers under similar treatment give 2,4-dinitrophenylhydrazine exclusively at 65 °C in 0.5 h.

*Reduction of Dinitrophenol Ethers (**3a**, **3d**, **3f**, **3g**, **3j**) in Methanol at 5 °C.* A mixture of methanol (40 ml), 80% hydrazine hydrate (1.9 ml) and Raney nickel (0.3 g) is refluxed for 10—12 min and cooled to 5 °C. To this cold solution is added 2,4-dinitroanisole (**3a**) (1.98 g, 10 mmol) in methanol (40 ml) under stirring. The reaction is continued for additional 45 min. Complete conversion of **3a** can be confirmed by TLC analysis on silica gel using benzene/ethanol (19:1) as eluent and colour development with iodine vapours. The catalyst is removed by filtration. The solvent is evaporated and the residue is chromatographed on silica gel (eluent, benzene). The aminonitrophenolic ethers (**4a**, **4f**, **4g**, **4l**) are characterized by mp, mixed mp and microanalysis. The unknown partial reduction product, 2-hydroxyamino-4-nitrophenyl 2-methoxyethyl ether (**4j**) mp 116 °C, from **3d** is characterized by spectral and microanalytical data. IR (Nujol) 3280, 3180, 1510, 1460, 1333, 1290, 1270, 1200, 1140, 1120, 1080, 1030, 973 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ 3.44 (s, 3H), 3.8 (t, 2H), 4.16—4.54 (m, 3H, 1H exchangeable with D_2O), 4.72 (br s, 1H, exchangeable with D_2O), 7.08—7.40 (m, 1H), 7.92—8.72 (m, 2H). MS *m/e* 228. Found: C, 47.68; H, 5.58; N, 12.01%. Calcd for $C_9H_{12}N_2O_5$: C, 47.37; H, 5.20; N, 12.27%. The hitherto unknown compound 4-amino-2-nitro-2′,4′-dichlorodiphenyl ether (**4k**), mp 86 °C, isolated from **3g** is characterized by spectral and microanalytical data. IR (Nujol) 3480, 3365, 3300, 1625, 1580, 1510, 1460, 1380, 1340, 1270, 1250, 1230,

1140, 1100, 1050, 865 cm^{-1}; ^1H NMR (CH_3CN) δ 3.77 (brs, 2H), 6.43—7.23 (m, 6H); MS *m/e* 299. Found: C, 48.20; H, 3.07; N, 9.73%. Calcd for: $C_{12}H_8N_2Cl_2O_3$: C, 48.18; H, 2.69; N, 9.36%.

The major products, 2',2'-disubstituted 5,5'-dinitroazoxybenzenes (**9a**, **9b**, **9c**, **9d**) were isolated from **3a**, **3d**, **3f**, and **3j** respectively by column chromatography on silica gel column using benzene as eluent. They were characterized as follows:

2,2'-Dimethoxy-5,5'-dinitroazoxybenzene (**9a**), mp, 210 °C. IR (Nujol) 3090, 1600, 1525, 1450, 1340, 1290, 1145, 1090, 1020, 895, 815 cm^{-1}; ^1H NMR ($CDCl_3$) δ 4.26 (d, 6H), 7.16—7.56 (m, 3H), 8.36—9.23 (m, 3H). MS *m/e* 348. Found: C, 48.08; H, 4.00; N, 16.16%. Calcd for $C_{14}H_{12}N_4O_7$: C, 48.28; H, 3.47; N, 16.08%.

2,2'-Bis(2-methoxyethoxy)-5,5'-dinitroazoxybenzene (**9b**), mp 178 °C. IR (Nujol) 3100, 2850, 1600, 1590, 1450, 1340, 1290, 1280, 1200, 1140, 1125, 1080, 1040, 940, 860, 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ 3.66 (s, 6H), 4.0 (m, 4H), 4.56 (m, 4H), 7.20—7.66 (m, 3H), 8.33—8.93 (m, 3H); MS *m/e* 436. Found: C, 50.10; H, 4.89; N, 12.31%. Calcd for $C_{18}H_{20}N_4O_9$: C, 49.54; H, 4.62; N, 12.84%.

2,2'-Dipropoxy-5,5'-dinitroazoxybenzene (**9c**), mp 106 °C. IR (Nujol) 3080, 1605, 1515, 1455, 1375, 1350, 1280, 1150, 1070, 1000, 900, 820, 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.20 (t, 6H) 1.72—2.30 (m, 4H), 4.40 (t, 4H), 7.2—7.66 (m, 3H), 8.56—9.33 (m, 3H); MS *m/e* 404. Found: C, 52.95; H, 5.25; N, 13.24%. Calcd for $C_{18}H_{20}N_4O_7$: C, 53.46; H, 4.29; N, 13.85%.

2,2'-Bis(benzyloxy)-5,5'-dinitroazoxybenzene (**9d**), mp 205 °C. IR (Nujol) 3080, 1600, 1530, 1415, 1345, 1275, 1142, 1085, 905, 815 cm^{-1}; ^1H NMR ($CDCl_3$) δ 5.43 (d, 4H), 7.16—7.76 (m, 13H), 8.26—8.80 (m, 3H); MS *m/e* 500. Found: C, 62.25; H, 4.57; N, 11.41%. Calcd for $C_{26}H_{20}N_4O_7$: C, 62.40; H, 4.00; N, 11.20%.

The Resonance Raman Spectra of (*meso*-Tetraphenylporphinato)-cobalt(II)-d_0 [Co (TPP)-d_0], -d_8, and -d_{20}

Muneteru KOZUKA* and Masamoto IWAIZUMI
Chemical Research Institute of Non-Aqueous Solutions, Tohoku University, Katahira, Sendai 980
(Received January 6, 1983)

Synopsis. The resonance Raman spectra of the title complexes were measured, and a normal coordinate analysis was carried out. The 1604 and 1243 cm^{-1} polarized bands of Co(TPP)-d_0 were assigned to resonance-enhanced phenyl modes. This suggests the presence of appreciable porphine-phenyl resonance interaction in this complex.

Many vibrational studies have been devoted to the TPP ligand. Since there is no physiological porphine with aromatic groups at its *meso* positions, it is important to check the TPP's characteritic features which are caused by the peripheral phenyl group. Recently, Burke *et al.* tentatively assigned the 1240 cm^{-1} band of Fe(TPP) and the corresponding bands of the analogues to a mode mainly associated with the C_m–Ph (mesocarbon-phenyl) stretching vibration and stated that the porphine-phenyl resonance interaction in the ground state was no required to interpret any of the RR data.[1,2] On the other hand, Fuchsman *et al.* assigned the halogen-sensitive resonance Raman (RR) bands (1100 — 1050 cm^{-1}) of tetra(*p*-halophenyl)porphine derivatives[3] and the 1234 cm^{-1} band of Cu(TPP)[4] to phenyl modes and pointed out that this was direct evidence of the resonance interaction. Adequate vibrational data to shed light on this controversial point were not found in the literature. Fortunately, however, our understanding of the fundamental vibration of the porphine core has been extensively advanced by Kitagawa *et al.*'s detailed experimental[5] and theoretical[6] studies of (octaethylporphinato)nickel(II) [Ni(OEP)]. Although the pattern of peripheral substitution in TPP is quite different from that in OEP, X-ray crystallographic studies suggest that the bonding within the porphine core is essentially the same in both porphines.[7,8] Hence, we tried to explain our RR data with reference to the results of normal coordinate analyses.

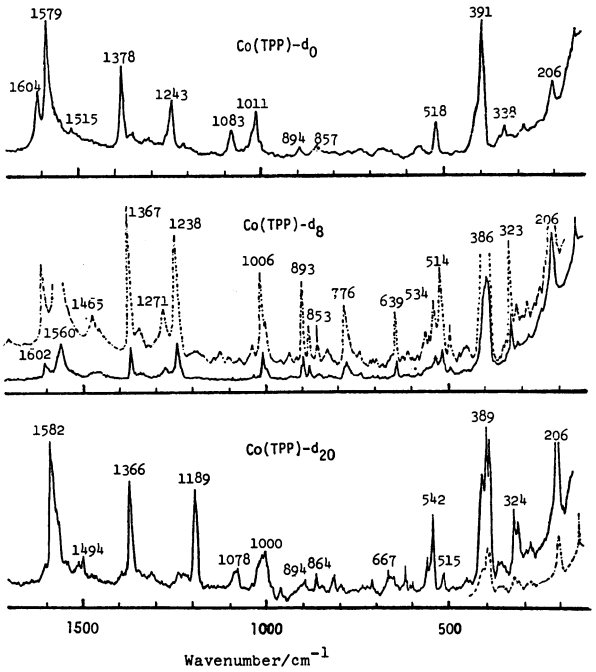

Fig. 1. RR spectra of Co(TPP)-d_0, -d_8, and -d_{20}. The samples were deposited on a cold tip at 10 K as films and excited by the 457.9 nm line of an Ar-ion laser.

Figure 1 shows the RR spectra of the well-purified samples, which were vaporized from a "miniature oven" and deposited onto a cold Cu tip to make films. The films at 10 K were excited by the 457.9 nm line of an Ar-ion laser. The details and the spectrometer have been described previously.[9] The spectra closely resemble those in Ar matrices.[9] All the strong bands were found to be polarized, as was expected from the fact that the RR spectra of metalloporphines were dominated by the totally symmetric modes (A_{1g} species

a) The data were cited from Ref. 6. b) This band was distinctly detected in Ar matrices, but was smeared out in films (Ref. 9).

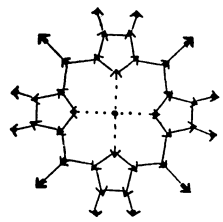

Fig. 2. The eigenvector of the Co(TPP)-d_0's ν_9 mode (A_{1g}, 206 cm^{-1}).

under D_{4h} symmetry) when the exciting frequency approaches that of the Soret band.[10] An experimental assignment is shown in Table 1, along with the calculated frequencies.

To carry out the normal coordinate calculation, the following assumptions were adopted: the symmetry of the porphine core is D_{4h}, and the phenyl group is regarded as a single dynamic unit with a mass of 77 ($-d_0$ and $-d_8$) and 82 ($-d_{20}$). The structural parameters were taken from the result of X-ray crystallographic analysis of Co(TPP),[8] but slightly modified to keep the D_{4h} symmetry. The potential energy was expressed with the same type of modified Urey-Bradley force field as that used for (NiOEP) by Abe *et al.*[6] The calculations were carried out by means of a NEAC-ACOS 1000 computer system at Tohoku University with AXSMZ and LSMX programs.[11]

The A_{1g}-calculated frequencies are in good agreement with the observed frequencies. The determined stretching and repulsive force constants were slightly different from those of Ni(OEP) in a manner roughly corresponding to their structural change. The experimental Teller-Redlich A_{1g} product ratios of Co(TPP)-d_8 and $-d_{20}$ to $-d_0$ were 0.499 and 0.970, which were close to the theoretical values of 0.500 and 0.969 respectively.[12] The 1604 and 1243 cm^{-1} bands ($-d_0$) were not included in the A_{1g} mode. Some other weakly observed bands were explained with B_{1g}, A_{2g}, and B_{2g} frequencies calculated at the same time.

Although Fuchsman *et al.* supposed that some porphine-core modes of Cu(TPP) shifted to a frequency range lower by about 35 cm^{-1} upon the phenyl deuteration,[4] the calculated frequencies of Co(TPP)-d_0 and $-d_{20}$ show that the maximum frequency shift is only 5 cm^{-1} in the ν_9 mode (Fig. 2). In this mode, the phenyl groups vibrate in-phase with each other and with the largest amplitude, while those in the other core modes are negligibly small. The mesocarbons vibrate in the same phase as do the phenyl groups, but with a slightly smaller amplitude. From the calculation, it is now evident that the 1243 cm^{-1} band ($-d_0$) shifted to 1189 cm^{-1} ($-d_{20}$). This large frequency shift and the disappearance of the 1604 cm^{-1} band upon the phenyl deuteration suggest that they are phenyl modes.

To confirm this assignment, a normal coordinate treatment for [*a,a,a,a-meso*-(*o*-pivaloylamidophenyl)porphinato]cobalt(II), [Co(T_{piv}PP)], was also carried out, where the same structural parameters and force constants as those used for Co(TPP) were employed. The calculated frequencies well explained the observed frequencies of Fe(T_{piv}PP)[2] in Table 1. A comparison between the calculated frequencies of Co(TPP)-d_0 and Co(T_{piv}PP) shows that the drastic changes in the mass (from 77×4 to 176×4 amu) and structure in the periphery do not substantially affect the A_{1g} normal frequencies, except for the ν_9 mode. This means that the second assumption, or the separation of the phenyl modes from the porphine-core modes, is appropriate. If the 1240 cm^{-1} band of Fe(TPP) is one of the core modes, as assigned by Burke *et al.*,[2] its counterpart in Fe(T_{piv}PP) should be found in a slightly lower frequency region. However, this is not the case.

The present work thus supports Fuchsman *et al.*'s results.

The authors wish to thank Professor Ichiro Nakagawa and Dr. Yoshiyuki Morioka of Tohoku University for their critical reading of the manuscript and their helpful discussions. We are also indebted to Professor Kazuo Nakamoto of Marquette University for his kindness in allowing us to use the RR data recorded at his laboratory, and to Dr. James Kincaid of Kentucky University for the gift of the deuterated samples.

Carbon-13 Relaxation Times of Poly(vinylnaphthalene)s in Solution

Kazuhiko SEKI* and Yoshio IMAMURA

Department of Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received January 31, 1983)

Synopsis. Carbon-13 spin-lattice relaxation times and nuclear Overhauser enhancement factors were measured at 25.03 MHz and 40 °C for a solution of poly(1-vinylnaphthalene)(P1VN) and poly(2-vinylnaphthalene)(P2VN). The backbone motions in P1VN and P2VN were characterized by a distribution of correlation times. The relative mobilities of P1VN, P2VN, and polystyrene were as follows: $\bar{\tau}_{\text{polystyrene}} < \bar{\tau}_{\text{P2VN}} < \bar{\tau}_{\text{P1VN}}$ for the average correlation times. These results were explained on the basis of the energy contour maps for polystyrene, P2VN, and P1VN.

In our previous papers,[1-3] we explained the conformational characteristics of poly(1-vinylnaphthalene) (P1VN) and poly(2-vinylnaphthalene) (P2VN), by estimating the steric compression energies of the rotational isomeric states (RIS) of the naphthyl side groups and the conformational energies of the skeletal bonds.

The revealed differences of the characteristics between P1VN and P2VN corresponded well with the difference of the solution properties of P1VN and P2VN, such as in transition[1] phenomenon, NMR spectra patterns[2] and in fluorescence spectra of the solution.[3]

Futhermore, some information about the molecular dynamics of P1VN and P2VN can be also drawn from the previous calculations. The segmental motion of P1VN chain may undergo the steric restriction of the neighboring 1-naphthyl groups. Since the P2VN chain is not so spatially crowded by neighboring 2-naphthyl groups as the chain in P1VN is, the motion of the main chain in the former would not be so influenced by the restriction of neighboring groups. Consequently, the relative mobilities of P1VN, P2VN, and polystyrene chains can be predicted as follows: $\tau_{\text{polystyrene}} < \tau_{\text{P2VN}} < \tau_{\text{P1VN}}$ for the correlation time τ. These correlation times can be estimated by the measurement o carbon-13 spin relaxation time and nuclear Overhauser enhancement. The purpose of this paper is to discuss the segmental motion in P1VN and P2VN chain as characterized by a distribution of the correlation times.

Experimental

Samples of P1VN and P2VN were prepared by radical polymerization, using α,α'-azobisisobutyronitrile as an initiator. The number-average molecular weights of these polymers were determined using a "KUNAUAR's Membrance Osmometer" in chloroform solution at 37 °C. The average molecular weights of P1VN and P2VN were 4.0×10^4 and 7.5×10^4, respectively. In the vinyl aromatic polymers with this range of the degree of polymerization, the T_1 values are almost independent of the chain lengths.[4,5]

Natural abundance ^{13}C NMR spectra were obtained at 25.03 MHz by Fourier transform techniques using a JEOL JNM PS-100 spectrometer; details described before.[2] Spin-lattice relaxation times T_1 were measured from PRFT spectra obtained from 180°-t-90° sequences. The spectra of the polymer solutions of *ca.* 30% concentrations in dioxane-d_8 were observed at 40 °C. Nuclear Overhauser enhancements (NOE) were measured by comparison of coupled and decoupled spectra. The maximum errors in T_1 and NOE were within ±10%.

Calculation

Assuming only the dipolar interactions between a methine carbon and the proton bonded to it, the ^{13}C T_1 and NOEF (NOE-1) are given by[6,7]

$$1/T_1 = 2.190\times10^9(f(\omega_1)+3f(\omega_2)+6f(\omega_3))\ \text{s}^{-1}, \quad (1)$$

$$\text{NOEF} = \frac{(-f(\omega_1)+6f(\omega_2))}{(f(\omega_1)+3f(\omega_2)+6f(\omega_3))}\times 3.976, \quad (2)$$

$$\omega_1 = \omega_H - \omega_C, \quad (3)$$

$$\omega_2 = \omega_C, \quad (4)$$

and

$$\omega_3 = \omega_H + \omega_C, \quad (5)$$

where ω_C and ω_H are the Larmor frequencies for ^{13}C and ^{1}H, respectively and for ^{13}C measurement at 25.03 MHz, $\omega_1=4.682\times10^8$ rad s^{-1}, $\omega_2=1.573\times10^8$ rad s^{-1}, $\omega_3=7.828\times10^8$ rad s^{-1}. As the backbone motion in a polymer is characterized by a distribution of correlation times, the spectral density function $f(\omega_i)$ is written by considering a log $-\chi^2$ distribution,[8,9] as follows:

$$f(\omega_i) = \frac{\bar{\tau}\Gamma^{(p)}(s)(b^s-1)\mathrm{d}s}{(b-1)(1+\omega_i^2\bar{\tau}^2((b^s-1)/(b-1))^2)} \quad (6)$$

$$\Gamma^{(p)}(s) = \frac{1}{\Gamma(p)}(ps)^{p-1}\exp(-ps)p\mathrm{d}s, \quad (7)$$

and

$$s = \log_b(1+(b-1)\tau/\bar{\tau}) \quad (8)$$

where Γ function, $\Gamma(p)$, normalizes $\Gamma^{(p)}(s)$ to unity, and the width of the distribution is characterized by p. The value of log base $b=1000$ is used. The $\bar{\tau}$ represents an average correlation time. Using Eqs. 1—8, T_1 and NOEF were computed by varying the width parameter p from 1 to 100 in 1-unit steps, and by varying the average correlation time $\bar{\tau}$ from 1.0×10^{-7} to 1.0×10^{-12} s^{-1}.

Results and Discussion

The proton-decoupled ^{13}C NMR spectra of P1VN and P2VN at 40 °C are shown in Figs. 1a and b, respectively. The signal peaks of naphthyl carbons are denoted by the symbols A, B, C, D, E, and F from the order of the low magnetic field. Table 1 shows the ^{13}C T_1 values for the aromatic peaks in P1VN and P2VN, together with those for polystyrene reported in the literature.[5,10,11] The T_1 for the aromatic carbons suggests that A–C peaks correspond to the nonprotonated carbons, and that D–F for P1VN and D, E for P2VN correspond to the protonated carbons. The line widths of A peaks in P1VN and P2VN are somewhat broader than that of B or C peak. Since this feature is attributed

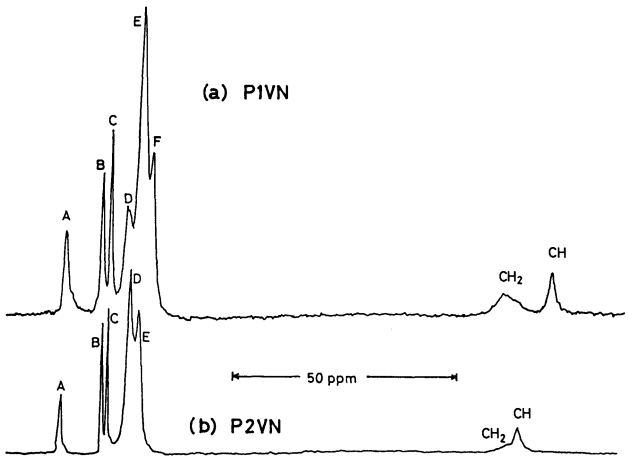

Fig. 1. Proton-decoupled, natural abundance ^{13}C FT NMR spectra of (a) P1VN and (b) P2VN in dioxane-d_8 at 25.03 MHz and 40 °C.

to the tacticity number in the polymer samples used, the A peak can be assigned to the naphthyl carbons, which bond to α-carbon. A similar phenomenon was observed in polystyrene. The other peaks of the aromatic carbons can not be assigned to each carbon in the naphthyl group at the present stage. T_1 values of the protonated carbon in P1VN and P2VN are smaller than that of polystyrene. This observation suggests that the naphthyl ring rotation is perturbed by the neighboring naphthyl rings, CH and CH_2 groups.

The average correlation times $\bar{\tau}$ and width parameter p satisfying the observed values (T_1 and NOE) are given in Table 2. T_1 value of methine carbon in P1VN was approximately equal to that of P2VN or polystyrene. It is apparent that the correlation time can not be adequately approximated by the T_1 value, and the $\bar{\tau}$ values for the segmental motion of these polymer are mainly influenced by the NOEF.

The segmental motion of P1VN was estimated to be slower than that for P2VN and polystyrene, as was expected. The order of the relative mobilities of the polymer chains agreed with that described above. These experimental results are explained as follows. The mobility of the main chain would be correlated to the values of the contour lines of the energy maps, which surround all the minima (tt, gt, tg, and gg) positions, since the energy value of each contour has a influence upon the magnitude of the change in RIS (t and g) of the molecular chain. In a previous paper,[3] all minima in the conformational energy maps of P1VN chain were shown to be surrounded by the contour lines of 9 kcal mol^{-1},† in the P2VN chain, the lines were 7—8 kcal mol^{-1}, while in polystyrene, it was sufficient to surround the all minima by contours of 5—6 kcal mol^{-1}. The order of the energy of these contours was found to be that of the chain mobilities described above.

Wetting of Coal by Nonionic Surfactant and Mixtures of Nonionic and Anionic Surfactants

Kunio Esumi,* Kenjiro Meguro, and Hidemasa Honda
Department of Applied Chemistry and Institute of Colloid and Interface Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received May 16, 1983)

Synopsis. The rates of wetting of coals with various carbon contents by aqueous nonionic surfactants and mixtures of nonionic and anionic surfactants were examined. It was found that the wetting rate of each coal decreased with an increase of the length of oxyethylene chain in the nonionic surfactant. Further, the wetting rate of coal by anionic surfactant was enhanced by the addition of nonionic surfactant. This enhancement was most effective for coals with relatively low carbon content.

Wettability of coal allows us to understand mechanisms of coal flotation, coal dust suppression, and coal–water mixing. A number of techniques[1-3] have been used to measure the wettability of coal. Glanville and Wightman[4] have employed a wetting time method. They have reported that rates of wetting of coal by aqueous surfactant solution are accelerated by addition of dipositive metal ions. Esumi *et al.*[5] have studied the effect of dipositive metal ions on wetting of coals with various carbon contents by anionic surfactant solutions. They have demonstrated that the rates of wetting of coals are enhanced more effectively by anionic surfactants with long-chain hydrophobic groups than those with short-chain ones, in the presence of dipositive metal ions.

In this work, effects of nonionic surfactants and mixtures of nonionic and anionic surfactant solutions on the wetting of coals were investigated by measuring the wetting rates and the zeta potential of wetted coal particles.

Experimental

Materials. The coals used in this work were Yallourn, Taiheiyo, Miike, and Hon-gay coals, whose carbon contents were 61.6, 74.8, 85.2, and 93.0 wt%, respectively. They were sieved between 60 and 100 mesh. The other physical properties for them have been described elsewhere.[6]

Sodium 1,2-bis(2-ethylhexyloxycarbonyl)ethanesulfonate (Aerosol OT), sodium 1,2-bis(2-methylpentyloxycarbonyl)-ethanesulfonate(Aerosol MA), and sodium 1,2-bis[diamyl-(mixture of 2-methylbutyl and 3-methylbutyl)oxycarbonyl]-ethanesulfonate (Aerosol AY) were obtained from the American Cyanamid Co. Poly(oxyethylene)nonylphenyl ethers (NP-*n*, where *n* indicates the average mole number of oxyethylene units) were supplied by Nikko Chemicals Co., Ltd. These surfactants were used without further purification.

The water used was purified by passing through Milli-Q Reagent-Grade Water Systems until its specific conductivity fell below $10^{-7}\ \Omega^{-1}\ cm^{-1}$.

Measurements. To estimate rates of wetting of coal, sink times were measured for 0.30 g of coal gently deposited on the surface of the aqueous surfactant solution in a 100 ml beaker at 25 °C. The time taken for the last trace of unwetted coal particles to break through the surface of the aqueous surfactant solution was measured with a stopwatch. The average value of four or five run was taken as the final sink time. Here, the rate of wetting of coal was expressed as the surface area of coal wetted per second to compare the wettability of coals with different surface area.

The zeta potential of coal particles after exposure to the aqueous surfactant solution was measured using a Pen Kem Laser Zee^{tm} Model 500. The surface tension of the aqueous surfactant solution was measured using a Wilhelmy-type tensiometer at 25 °C.

Results and Discussion

Figure 1 shows the wetting rates of coals with various carbon contents as a function of the concentration of nonionic surfactants. It can be seen that the wetting rate of each coal is enhanced with an increase of the concentration of nonionic surfactant. Further, the wetting rates of coals are influenced by the length of the oxyethylene chain in the nonionic surfactant; the wetting rate of each coal decreases with an increase of the length of oxyethylene chain from 7.5 to 50. In this study, the optimum oxyethylene chain at which a maximum wetting rate of all the coals except Hon-gay coal is attained is located at 7.5—15 mol. Glanville and Haley[7] have also studied the wetting rates of coal obtained from the Pocahontas No. 3 Seam of McDowell County, West Virginia by using a series of polyethoxylated alkylphenol and have reported that there is an optimum degree of ethoxylation for a maximum wetting rate of coal dust. Thus, the above results can be interpreted by considering the surface tension of the nonionic surfactant and the diffusion rate to the coal surfaces: as the surface tension of nonionic surfactant

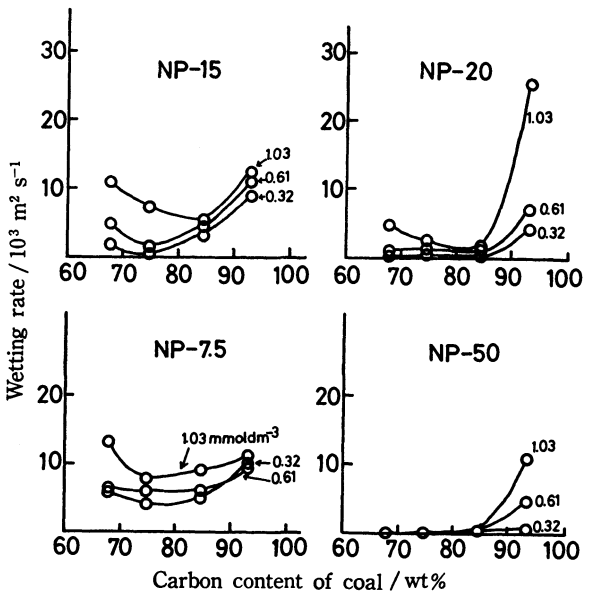

Fig. 1. The rates of wetting of coals with various carbon content by nonionic surfactant solutions.

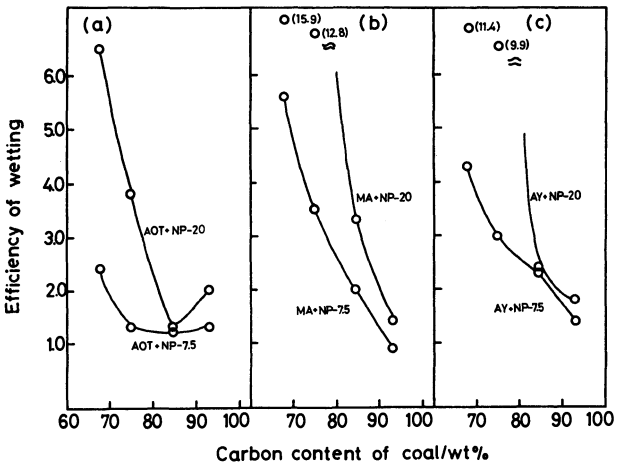

Fig. 2. The efficiency of wetting of coals with various carbon content by addition of nonionic surfactant in the presence of anionic surfactant.
(a): Aerosol OT, 1.38 mmol dm^{-3}, NP-*n*, 0.61 mmol dm^{-3}, (b): Aerosol MA, 7.5 mmol dm^{-3}, NP-*n*, 0.61 mmol dm^{-3}, (c): Aerosol AY, 14 mmol dm^{-3}, NP-*n*, 0.61 mmol dm^{-3}.

at a same concentration increases from NP-7.5 to NP-50, the wetting rate of coal by the nonionic surfactant is accelerated from NP-50 to NP-7.5 and the nonionic surfactants with longer oxyethylene chains are believed to diffuse more slowly than those with shorter ones. Compared with anionic surfactants[5] such as Aerosol OT, MA, and AY, the addition of the nonionic surfactants is less effective on the wetting rate of coal.

As the addition of nonionic surfactant has been shown to increase the wetting power for textile[8] by some anionic surfactants, a similar effect will be expected for the wettability of coal. So, the effect of nonionic surfactants on the wetting rate of coal by anionic surfactant solution was examined. Here, the efficiency of wetting rate of coal by the addition of nonionic surfactant can be evaluated by the ratio of the wetting rate of coal by the addition of nonionic surfactant in the presence of anionic surfactant to the sum of wetting rates of coal in each surfactant. The results are given in Fig. 2. In Aerosol OT–NP-*n* system, the efficiency of wetting decreases with an increase of carbon content and shows a minimum at 85.2 wt%, then increases for both NP-7.5 and NP-20. On the other hand, the efficiency of wetting decreases gradually with an increase of carbon content until 74.8 wt%, then rapidly for Aerosol MA–NP-*n* and Aerosol AY–NP-*n* systems. Particularly, the wetting rates of Yallourn and Taiheiyo

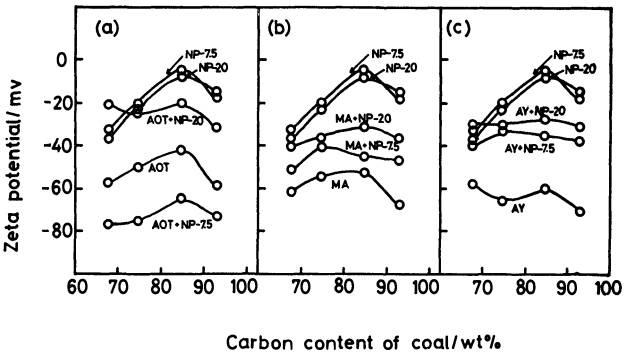

Fig. 3. The zeta potentials of coals shown in Fig. 2.

coals are enhanced most effectively by the addition of NP-20 in the presence of Aerosol MA and AY, respectively. Since the surface tensions of these systems are not so different, this enhancement might be attributed to an increase caused by the nonionic surfactant in the mobility of the anionic surfactant, resulting in more rapid diffusion to the surface of coal particles.

To elucidate the interaction of coal surfaces and the anionic surfactant by the addition of the nonionic surfactant, the zeta potentials of coal particles after their exposure to the aqueous surfactant solution were measured. The results are depicted in Fig. 3. The magnitudes of zeta potentials of coal particles after the exposure to the anionic surfactant–NP-*n* systems are located between that of anionic and of nonionic surfactants alone, except for the Aerosol OT–NP-7.5 system. The above results imply that co-adsorption of anionic and nonionic surfactants occurs on the coal surface and weakens the repulsion forces between anionic surfactant molecules, resulting in the promotion of the wetting rates of coal.

Enthalpies of Combustion of Organic Compouds. V. 3- and 4-Nitroanilines†

Keiichi NISHIYAMA, Minoru SAKIYAMA,* and Syûzô SEKI††
Chemical Thermodynamics Laboratory and Department of Chemistry, Faculty of Science, Osaka University, Toyonaka 560
(Received June 13, 1983)

Synopsis. Precision oxygen bomb combustion calorimetry was carried out for the title compounds in the crystalline states. Standard enthalpies of formation at 298.15 K for the crystalline and gaseous states were derived.

Although standard enthalpies of combustion has been reported for 3- and 4-nitroanilines by several authors,[1-4] the agreement between these values is poor. In order to obtain more reliable values, oxygen bomb combustion calorimetry accompanying carbon dioxide analysis has been conducted for these compounds.

Experimental

Materials. Microanalytical standard 4-nitroaniline (Kishida, SMA-SP-18) was used after applying the pellet drying procedure.[5] Commercial 3-nitroaniline (Wako, special Grade) was purified by recrystallization from aqueous solution and then from ethanol solutions (three times). After preliminary drying, the purified material was subjected to the pellet drying.

Combustion Calorimetry. An isoperibol rotating bomb calorimeter, described elsewhere,[6,7] was used without rotating the bomb. The calorimeter was calibrated by burning thermochemical standard benzoic acid (N. B. S. SRM 39i) under certificate conditions. Mean and standard deviation of the mean for the energy equivalent of the empty calorimeter, ε° (calor), was obtained to be (15 163.52±0.51) J K^{-1} from eight calibration experiments. The substances were found to produce a small amount of soot, when a pellet weighing about 1.2 g was ignited alone in an ordinary open crucible at 3 MPa of oxygen pressure. The use of a deep crucible with a small lid[8] or the use of a higher pressure (4 MPa) was not efficient in preventing the soot formation. Consequently, a pellet of the thermochemical standard benzoic acid, weighing 0.3 g, was placed on a pellet of either substance in the ordinary crucible, and they were ignited at 3 MPa of oxygen pressure. In this way, the soot formation was effectively suppressed. In order to examine the completeness of combustion and/or the purity of tha sample, carbon dioxide recovery was determined by the method described previously.[7] Carbon monoxide was barely detected. Nitric acid was determined by titration with aqueous sodium hydroxide solution.

Table 1. Auxiliary data for the calculation of standard energy of combustion

Material	Formula	ρ / g cm^{-3}	c_p / J K^{-1} g^{-1}	$-(\partial U/\partial p)_T$ / J MPa^{-1} g^{-1}
3-Nitroaniline	$C_6H_6O_2N_2$	1.430	1.15	(0.048)
4-Nitroaniline	$C_6H_6O_2N_2$	1.424	1.116	(0.048)
Benzoic acid	$C_7H_6O_2$	1.320	1.21	0.0527
Cotton fuse	$CH_{1.86}O_{0.93}$	1.5	1.7	0.0290

Auxiliary Quantities. Relative atomic masses were taken from the recommendation of IUPAC Commission on Atomic Weights (1977). Densities, specific heat capacities, and $(\partial U/\partial p)_T$ values are collected in Table 1. Other auxiliary quantities are as follows: T_h=298.15 K, V(bomb)=0.3469 cm^3, ΔU_c°(fuse)=−16507 J g^{-1}, and $\Delta U_c^\circ/M$(benzoic acid)=−(26414±1) J g^{-1}, where uncertainty is the estimated standard deviation of the mean.

Results

Molar srandard energies and enthalpies of combustion, given in this paper, refer to the following idealized combustion reaction at 298.15 K: $C_6H_6O_2N_2(c)+(13/2)O_2(g)=6CO_2(g)+N_2(g)+3H_2O(l)$. Details of the combustion calorimetry are presented in Table 2. Most of the symbols in the table are essentially similar to those used by Hubbard *et al.*[9] Mean and standard deviation of the mean for molar standard energy of combustion, $\Delta U_c^\circ(c)$, and those for relative total carbon dioxide recovery, $[m(CO_2,\text{obsd})/m(CO_2,\text{calcd})]$, are

$-(3185.56\pm0.41)$ kJ mol^{-1} and (1.0002 ± 0.0001), respectively, for 3-nitroaniline, and $-(3174.22\pm0.41)$ kJ mol^{-1} and (1.0002 ± 0.0001), respectively, for 4-nitroaniline.

Derived standard thermodynamic quantities are presented in Table 3. CODATA key values of thermodynamics[10] and the calorimetric values of standard enthalpy of sublimation, reported by Malaspina *et al.*,[11] were used to calculate ΔH_f°(c) and ΔH_f°(g), respectively. Uncertainties for ΔU_c°(c) and ΔH_c°(c) are the uncertainty intervals defined by Rossini.[12] Those for ΔH_f°(c) and ΔH_f°(g) were calculated by combining the relevant uncertainties by use of the equation of error propagation.

Discussion

The present values are compared with literature values in Tabel 4. The present value for 3-nitroaniline is intermediate between the literature values. The one for 4-nitroaniline is less negative than the rest. Although the present value is closer to that of Levedeva *et al.*,[3] they do not agree with each other within the sum of the uncertainties. The present results for both substances, seem to be more reliable, since the chemical aspect of the combustion calorimetry is evidenced to be quite normal by the results of carbon dioxide analysis.

(Received February 17, 1983)

Synopsis. The crystal of 0.96 $MgTiO_3$–0.04 $CaTiO_3$ was grown by a TSFZ method. The distribution of $CaTiO_3$ in the crystal was analyzed by SEM and EPMA. The results obtained suggest that the change of dielectric properties of $MgTiO_3$ by adding $CaTiO_3$ results from the independent distribution of $CaTiO_3$ in $MgTiO_3$.

Some dielectric materials have been studied up to date to develope high-quality filters of microwave resonator. From the characteristics of practical filters, the following three dielectric properties are required for materials: (i) high dielectric constant, (ii) high dielectric Q value, and (iii) low temperature coefficient ($=\eta_f$) of resonant frequency.[1] There exsist, for example, systems of BaO–TiO_2, $MgTiO_3$–$CaTiO_3$, $Ba(Zn_{1/3}Nb_{2/3})O_3$–$Ba(Zn_{1/3}Ta_{2/3})O_3$ *etc.*[2-4] which satisfy such requirements.

In the system of $MgTiO_3$–$CaTiO_3$, to add a slight amount of $CaTiO_3$ into $MgTiO_3$ betters the temperature coefficient η_f of $MgTiO_3$.[2] The purposes of the present report are to study the crystal growth of $(Mg_{0.96}Ca_{0.04})TiO_3$ by a travelling solvent floating zone method and to study the detailed phase diagram of the system of $MgTiO_3$–$CaTiO_3$ just near both end-members in order to make clear an effect of adding $CaTiO_3$ on the dielectric properties, especially on the coefficient η_f, of $MgTiO_3$–$CaTiO_3$ system.

Starting materials were MgO, $CaCO_3$ (99% purity), and TiO_2 (99.5% purity). They were weighed at the molar ratio of Mg : Ca : Ti=0.96 : 0.04 : 1, sufficiently mixed in acetone for 2 h, and fired at 1200 °C for 12 h. After the compound obtained was remixed in acetone for 2 h, it was pressed into a cylindrical rod of 10 mm in diameter and 100 mm in length under the hydrostatic pressure of 1 t/cm². The rod was sintered at 1400 °C in oxygen gas for 2 h; this rod was used as a feed of the crystal growth. An apparatus used for the crystal growth was the ellipsoidal image furnace (Nippon Electric Co.) whose heater source was a halogen lamp of 1.5 kW located at one focus position. The sintered rod was set up at the other focus position of the furnace where the light emitted from the halogen lamp focuses. The crystal was grown under the following conditions: the seed and feed were counter-rotated at the rate of 35 cm^{-1}, the growth rate was 2 mm/h, and the flow rate of air was 5 l/min. The dimension of the crystal obtained was 10 mm in diameter and 50 mm in length. The chemical analysis of the middle part of the crystal indicates Mg=19.1, Ca=1.20, and Ti=39.7 in wt%, which agrees with the composition of the starting material, that is, Mg=19.3, Ca=1.33, and Ti=39.6 in wt%.

The microscopic analysis in the middle part of the crystal was performed by the scanning electron microscope (SEM) and by the electron probe microanalyzer (EPMA). Figure 1 shows the result of qualitative analysis by SEM, together with the variation of intensities of the characteristic X-rays of both Mg and Ca ions along a straight line a. As seen from the figure, there exsist two domains; one is a light enclosed domain and the other is a dark dominant domain. The content of Mg is large outside of the light domain, while inside of the light domain, its content is very small. The behaviors of Ca is quite opposite to that of Mg: the content is extremely small outside of the light domain but large inside. On contrary to Mg and Ca, the content of Ti changes little over both the domains.

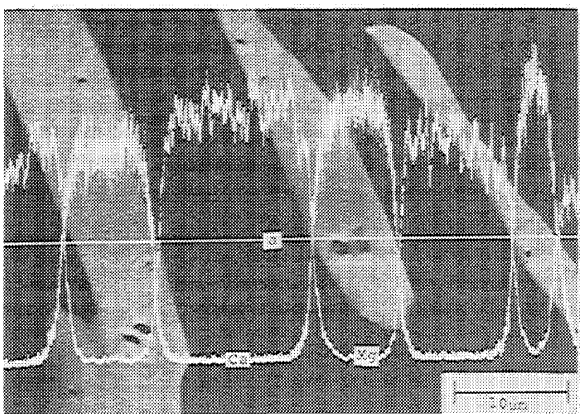

Fig. 1. Composition image of SEM for the middle part of the crystal $(Mg_{0.96}Ca_{0.04})TiO_3$. Lines denoted by Mg and Ca respectively show the results of the line analysis of Mg and Ca contents along a line a.

TABLE 1. EPMA ANALYSIS OF THE CRYSTAL

	Mg(wt %)	Ca(wt %)	Ti(wt %)	O(wt %)
Dark domain	20.15	0.06	40.85	40.53
Light domain	0.29	29.77	34.81	32.81

In order to determine the compositions of both the domains, the distribution of Mg, Ca, Ti, and O was quantitatively analyzed by EPMA; the results are summarized in Table 1. Two kinds of product could be observed as predicted from the phase diagram reported by Rouf *et al.*,[5] the products being roughly expressed by $MgTiO_3$ and $CaTiO_3$, respectively. $MgTiO_3$ occupies dominant part of the crystal corresponding to the dark domain in Fig. 1, while $CaTiO_3$ is a little interpersed as inclusions along the growth direction, corresponding to the light domain in Fig. 1. Table 1 shows that $CaTiO_3$ is solved into $MgTiO_3$ by 0.2 wt% ($=C_1$), while $MgTiO_3$ also into $CaTiO_3$ by 1.4 wt% ($=C_2$). This suggests that there exsist solid solutions just near both the end-members of the system $MgTiO_3$–$CaTiO_3$, which are not shown in the diagram reported by Rouf *et al.*[5] The result that $C_2 \gg C_1$ is reasonable since Mg ions more easily substitute Ca ions than Ca ions do Mg ions because of $r_{Ca} > r_{Mg}$, where r

indicates a radius. The result of powdered X-ray diffraction shows that both solid solutions have same crystal structures and lattice constants as $MgTiO_3$ (ilmenite type) and $CaTiO_3$ (perovskite type), respectively. The physical properties of the solid solution are, therefore, almost same as the original materials, $MgTiO_3$ and $CaTiO_3$.

As mentioned above, the temperature coefficient η_f changes by adding $CaTiO_3$ by about 4—6 mol% into $MgTiO_3$. In practice, the η_f of the crystal is −38 ppm/deg although it contains oxygen defects, the absolute value of the η_f being smaller than that (η_f= −60 ppm/deg) of $MgTiO_3$ reported by Courtney.[3] Thus, the experimental results lead us the conclusion that the change of the coefficient η_f does not result from forming solid solution such as $(Mg,Ca)TiO_3$ whose temperature coefficient η_f is nearly equal to zero, but from the independent distribution of $CaTiO_3$ and $MgTiO_3$ whose coefficients η_f have mutually opposite sign.[2]

The authors thank Prof. Shioichiro Nomura, Dr. Isamu Shindo and Dr. Masayuki Tsukioka for their valuable suggestions concerning the crystal growth and the dielectric properties of $MgTiO_3$. The authors also thank Mr. Satoshi Takenouchi and Mrs. Michiko Kobayashi to perform the chemical analysis.

(Received February 22, 1983)

Synopsis. Pale-yellowish white needles were isolated from a rotten mixture of swine urine and feces by vacuum distillation and identified to be *cyclo*-octasulfur by means of mass spectrometry and other methods. This is the first time that this compound has been detected in swine manure.

cyclo-Octasulfur is the most stable form having a crown structure[1] and a main component in monoclinic and rhombic sulfurs.[2] Khare and Sagan[3] detected large amounts of *cyclo*-octasulfur in photoreaction products of hydrogen sulfide and other gaseous compounds. This compound was also isolated from a culture filtrate when a marine fungus was cultivated in a sulfite-pulp waste-liquor medium and was characterized by mass spectrometry.[4] White and Lee[5] found *cyclo*-octasulfur in a coal extract by gas chromatography-mass spectrometry using a capillary column and flame photometric detection. *cyclo*-Octasulfur has hardly been detected in other environmental samples. This article describes an identification of *cyclo*-octasulfur in swine manure.

Experimental

Isolation of cyclo-*Octasulfur.* A rotten mixture of swine urine (700 mL) and feces (400 g) was frozen at *ca.* −80 °C and vacuum-distilled in a frozen state at a pressure of *ca.* 10^{-4} Torr (1 Torr=133.322 Pa): The trap for volatile substances was cooled at −80 to −100 °C. The sample flask was kept at room temperature for 1 d, heated at 40 °C for 2 d, and finally heated at 100 °C for 4 d. The distillation residue (35 g) was mixed with diethyl ether (1 L) for 1 d. The filtrate was concentrated to *ca.* 50 mL and then vacuum-distilled in order to separate volatile from nonvolatile matters. The volatile matters were combined with the volatile in the trap as described below.

The ice (960 mL) containing the volatile compounds in the trap was melted and the volatile substances were extracted with diethyl ether (200 mL) by a liquid-liquid continuous extractor for 2 d. The extracted solution was combined with the volatile matters from the residue and then concentrated at atmospheric pressure with a Kuderna–Danish concentrator. When most of the diethyl ether was removed, white needle crystals were precipitated from the solution. The isolated crystals (3.35 mg), mp 112—119 °C, were characterized by mass spectrometry and other methods.

Gas Chromatography–Mass Spectrometry. The gas chromatographic conditions used were as follows: apparatus, HEWLETT PACKARD HP5710A gas chromatograph; column, glass column (3 m×3 mm i.d.) packed with 5% Thermon-3000 on 80—100 mesh Chromosorb W (AM-DMCS); column temperature, 50 °C initially for 2 min, increased to 250 °C at a rate of 4 °C/min; injection temperature, 250 °C; helium flow rate, 20 mL/min. The mass spectrometric conditions used were as follows: apparatus, JEOL JMS-DX 300 mass spectrometer and JEOL JMA 3500 mass data analysis system; ionizing current, 300 μA; electron energy, 70 eV; accelerating voltage, 3 kV; scan range, *m/e* 10—400; scan speed, 1.6 s/scan; repetition time, 2.5 s; ionization chamber pressure, 1—2×10^{-6} Torr; ionization chamber temperature, 180—210 °C.

† Present address: Hokkaido Research Institute for Environmental Pollution, West 12, North 19, Kita-ku, Sapporo Hokkaido 060.

Results and Discussion

The needle crystals isolated from rotten swine manure were pale-yellowish white and smelled of sulfur, which we usually experience near volcanos. They were easily soluble in benzene and chloroform, slightly soluble in diethyl ether and tetrahydrofuran, and insoluble in acetone. Their mass spectra were measured both by the direct inlet method and by the GC/MS method. The mass spectra, shown in Fig. 1, were identical with each other and only one peak was observed in a total ion monitoring by GC/MS, as shown in Fig. 2. Therefore, these crystals are not a mixture but a single compound. The mass spectrum measured in this study is the same as that of *cyclo*-octasulfur, though the relative intensities of the peaks at *m/e* 128, 160, 192, and 256 are somewhat different from those already reported.[4,6,7] With the direct inlet method, all mass spectra are essentially identical irrespective of sample temperature. No signals were observed in a measurement of ^{1}H NMR spectra, indicating that there is no hydrogen atom in the molecule. The electronic spectrum of this compound in

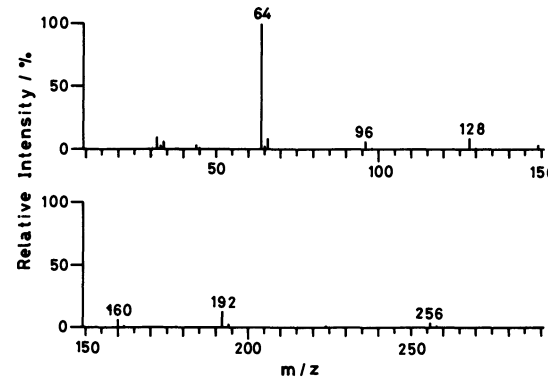

Fig. 1. Mass spectrum of *cyclo*-octasulfur.

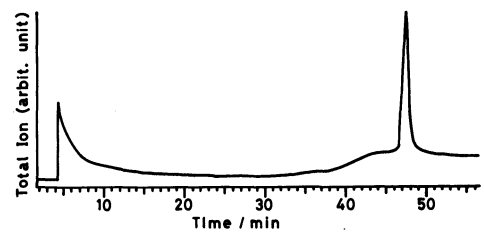

Fig. 2. Total ion monitoring of *cyclo*-octasulfur in GC/MS.

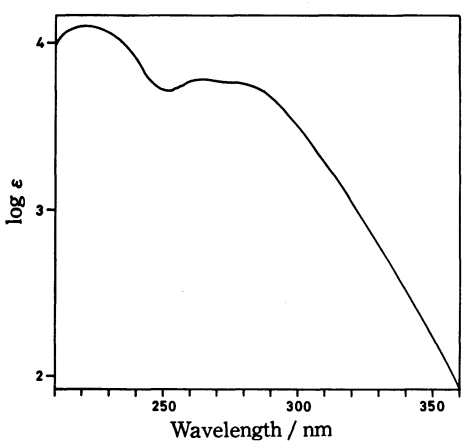

Fig. 3. Electronic spectrum of *cyclo*-octasulfur. Solvent, THF.

tetrahydrofuran solution, shown in Fig. 3, is slightly different from the one in the literature.[8] The IR spectrum of *cyclo*-octasulfur has already been reported by a few investigators,[3,9] although it is not clear-cut because of too small a sample amount. From these results, this compound has been decided to be *cyclo*-octasulfur.

cyclo-Octasulfur was detected only in rotten mixtures of swine urine and feces (two samples) and not in rotten swine urine (two samples). A semiquantitative result gave an amount of 3.35 mg of *cyclo*-octasulfur with a rotten mixture of 700 mL urine and 400 g feces. This compound has not always been detected in swine manure, since the formation of *cyclo*-octasulfur as a single substance of elemental sulfur might require some specific conditions which can seldom been realized in natural environment. According to Yurovskii's theory,[10] *cyclo*-octasulfur might be produced *via*

$$2FeSO_4+5H_2S \longrightarrow 2FeS_2+2S+H_2SO_4+4H_2O,$$

where the hydrogen sulfide is anaerobically formed from sulfate by bacteria. It has been known that a large amount of hydrogen sulfide is produced from liquid swine manure by anaerobic digestion.[11] Furthermore, dimethyl disulfide is found in swine manure.[12] It is reasonable to consider that *cyclo*-octasulfur results from the hydrogen sulfide evolved in swine manure. Since the offensive hydrogen sulfide raises environmental odor problems, the conversion of hydrogen sulfide to *cyclo*-octasulfur is very desirable. Also, it is interesting to examine whether or not *cyclo*-octasulfur is to be detected in other environments where hydrogen sulfide is evolved.

cyclo-Octasulfur can be detected by means of GC/MS or GC with a flame photometric detector, since GC with a flame ionization detector cannot have any responses. The ionization efficiency of *cyclo*-octasulfur in mass spectrometry was roughly investigated. Dimethylsulfone was used as a reference material, because it is often contained in swine manure and it gives a weak peak at mass number 64 (SO_2^+) in its mass spectrum. In the mass spectrum of *cyclo*-octasulfur, a base peak (S_2^+) locates at mass number 64. The molar ratio in peak intensity of *cyclo*-octasulfur to dimethylsulfone at *m/e* 64 is 0.200. As the relative intensity of the peak at *m/e* 64 to the base peak at *m/e* 79 ($CH_3SO_2^+$) in dimethylsulfone is 0.021, the molar ratio in base peak intensity of *cyclo*-octasulfur to dimethylsulfone is 0.0041. Namely, the ionization efficiency of *cyclo*-octasulfur is very low compared with dimethylsulfone which is detectable at usual sensitivities. The detection limit is around 100 ng. Therefore, the determination of a trace amount of *cyclo*-octasulfur by mass spectrometry is very difficult.

A Reinforced Oleophilic Anion-exchange Resin Membrane as a Sensitive Membrane of Anion-selective Electrodes

Akinori Jyo,*,† Toshihiko Imato, Hirofumi Kohno, and Nobuhiko Ishibashi
Department of Applied Analytical Chemistry, Faculty of Engineering, 36, Kyushu University, Fukuoka 812
(Received April 8, 1983)

Synopsis. Based on an impregnation technique for the preparation of ion-exchange resin membranes, a simple way was proposed for the preparation of a reinforced oleophilic anion-exchange resin membrane as an anion-selective electrode membrane with a chemically fixed site. The resulting exchange resin membrane is thin (*ca.* 25 μm) and flexible. It gives anion-selective electrodes with high performances.

We have developed anion-selective electrodes based on an oleophilic anion-exchange resin membrane, which is a homogeneous crosslinked polystyrene membrane with a chemically fixed benzyltrioctylammonium ion as the anion-exchange site.[1] The resin membrane performs almost the same as the sensitive membrane of a liquid membrane anion-selective electrode when it is impregnated with a water-immiscible organic solvent.[1] Since the membrane is based on a homogeneous crosslinked polystyrene matrix, it is hard and weak to bending. In addition, much experience and skill are generally required for the preparation of homogeneous ion-exchange resin membranes.[2,3] Thus from a practical point of view, it is desirable to develope a simple method of preparing a flexible membrane.

Based on an impregnation technique widely used in the preparation of usual hydrophilic ion-exchange resin membranes,[2] we have developed a simpler way to prepare an oleophilic anion-exchange resin membrane. The newly developed membrane is thinner and more flexible than the previously reported membrane. This note will describe the preparation of the membrane. The performances of anion-selective electrodes based on the membrane will also be presented.

Experimental

Preparation of the Oleophilic Anion-exchange Resin Membrane. A sheet of Duragard (macroporous film of polypropylene, thickness, 25 μm; Polyplastic Co.) was cut into appropriate squares (3 cm × 3 cm or 4 cm × 4 cm). They were immersed in a styrene–divinylbenzene mixture (20 ml : 0.5 ml) containing benzoyl peroxide (0.2 g) for 24 h. The sheets impregnated with the monomers were then inserted between piled glass plates. After the glass plates had been fastened, they were immersed in a hot solution of saturated sodium sulfate (70 °C) for 8—10 h in order to polymerize the monomers.[3] Although the original Duragard itself was opaque, a translucent membrane was thus obtained. After the membrane had been soaked in hot water for 1 h, it was washed with ethanol for 2 h and then with acetone for 30 min in a Soxhlet extractor. After drying in a vacuum desiccator, it was weighed. The increase in weight was 48% of the initial weight of the sheet. The membrane was then chloromethylated by the conventional method.[4] After the chloromethylated membrane had been soaked in a mixture of hydrochloric acid and ethanol (1 : 10) overnight, it was washed with acetone in a Soxhlet extractor for 20 h and then dried. After it had swollen in a trioctylamine–ethanol mixture (2 : 1) overnight at room temperature, the mixture was maintained at 80 °C for 30 h in order to effect the quaternization of the membrane with the amine. In this stage, the membrane expanded in every direction by 1.2 times, while no marked change in the size was observed before the quaternization process. The resulting anion-exchange resin membrane was washed with ethanol in a Soxhlet extractor for 30 h. The conditioning of the membrane and determination of the exchange capacity were performed by the previously reported procedures.[1]

Ion-selective Electrode Assemblies. The membrane was converted into the nitrate or perchlorate form according to the previously reported procedures.[1] As a solvent to be impregnated in the membrane, nitrobenzene was used. The fabrication of the electrode and the evaluation of the electrode performances have been reported in detail elsewhere.[1]

Results and Discussion

The exchange capacity of the membrane is 0.68 mequiv./g of resin, which is smaller than those of the previously reported homogeneous membranes (1.0—1.1 mequiv./g of resin).[1] This may be due to the fact that the present membrane contains polypropylene as a reinforcing material. The membrane is thin (*ca.* 25 μm) and flexible. It is strong for bending. In the case of the homogeneous membrane, it took more than a week to change its ionic form by means of ion exchange since it is relatively thick (0.2—0.5 mm). The thickness of the present membrane is reduced to about one-tenth of the previous one. Accordingly, the ion exchange could be easily finished within a week. The present membrane also showed the oleophilic property; it is easily wetted with organic solvents, but is hardly to wet with water.[5]

Nitrate and perchlorate ion-selective electrodes were fabricated by using the membranes in nitrate and perchlorate forms respectively. The results for electrode

Table 1. Performances of anion-selective electrodes based on oleophilic anion-exchange resin membranes

Membrane	Sensing ion of electrode	Slope[a] (mV/log *a*)	Lower limit of linear response/M
Present membrane	NO_3^-	−57	$10^{-4.3}$
(Reinforced membrane)	ClO_4^-	−59	$10^{-4.3}$
Previous membrane	NO_3^-	−57	$10^{-4.3}$
(Homogeneous membrane)	ClO_4^-	−58	$10^{-4.3}$

a) The solvent impregnated in the membrane is nitrobenzene. The electrodes were calibrated at an ionic strength of 0.3 (0.10 M Na_2SO_4).

Table 2. Selectivity coefficients of nitrate ion-selective electrodes based on oleophilic anion-exchange resin membrane

Membrane	Selectivity coefficient ($\log K^{pot}_{NO_3,j}$)[a]			
(j)	Cl^-	NO_2^-	CH_3COO^-	
Concn of j-ion/M	0.0050	0.0010	0.10	
Present membrane	−2.1	−1.1	−3.6	
Previous membrane	−2.0	−1.4	−3.4	

a) The solvent impregnated in the membrane is nitrobenzene.

calibrations are summarized in Table 1. The performances are almost the same as those of the previously reported electrodes based on the homogeneous membranes.[1] Although the response of the present electrodes was also rapid within the concentration range of the linear response, a small oscillation of potentials was sometimes observed. This presents no serious problem, however, since the oscillation is less than ± 0.3 mV.

Table 2 gives the selectivity coefficients of the nitrate ion-selective electrode. They were determined by the mixed-solution method under fixed activity of an interferent ion.[6] No marked difference in selectivity is seen between the present and previous electrodes when a common solvent, nitrobenzene, is impregnated in the membranes. That is, no marked influence of polymer matrices on the electrode selectivity can be seen. This observation is in accordance with the view that the selectivity of anion-selective electrodes of the liquid membrane type is essentially governed by the solvent of the membrane.[7]

Extractive Spectrophotometric Determinaton of Molybdenum(VI) with 8-Hydroxy-5-quinolinesulfonic Acid and Methyltrioctylammonium Chloride

Masao SUGAWARA,* Masayuki UTO, and Tomihito KAMBARA
Department of Chemistry, Faculty of Science, Hokkaido University, Kita-ku, Sapporo 060

(Received April 19, 1983)

Synopsis. Molybdenum(VI) complex with 8-hydroxy-5-quinolinesulfonic acid (H_2qs) is reduced to the quinquevalent state by hydrazinium sulfate and extracted into chloroform as the ion-association complex with methyltrioctylammonium chloride(Q^+Cl^-). Molybdenum(VI) in the ppm range is determined spectrophotometrically. The composition of the extracted species was estimated to be $[(MoO_2qs)_2(Hqs)_3(Q)_5]$.

When molybdenum(VI) in a weakly acidic solution in the presence of 8-hydroxy-5-quinolinesulfonic acid (H_2qs) is reduced by hydrazine, a yellow molybdenum(V)–H_2qs complex is formed, which changes to a red-purple complex on heating.[1,2] The formation of the red-purple complex is the basis of spectrophotometric determination of molybdenum in water.[3] The composition of yellow complex has been ascribed[4] to two monomers, *i.e.*, $[MoO_2qs(OH)]^{2-}$ and $[MoO_2qs]^-$, and the red-purple complex to the dimer $[(MoO_2qs)_2(Hqs)_3]^{5-}$.

In the present work, spectrophotometric determination of molybdenum after extraction of the red-purple complex as an ion-association complex with a quaternary ammonium salt is described. Determination of molybdenum in the organic phase is more sensitive than in water, owing to the concentration effect, and selectivity of the method has also been improved.

Experimental

Apparatus. Spectrophotometric measurements were carried out with a Shimadzu spectrophotometer UV-240 and a 10-mm cell. A Hitachi-Horiba glass electrode pH meter F-7LC was used for pH measurements. A Yamato Shaker FA-31 was used.

Reagents. A 0.01 M (1 M=1 mol dm^{-3}) of stock solution of molybdenum(VI) was prepared from hexaammonium heptamolybdate tetrahydrate $(NH_4)_6Mo_7O_{24}\cdot 4H_2O$ and standardized chelatometrically. Commercially available 8-hydroxy-5-quinolinesulfonic acid (H_2qs) was recrystallized from water. A 0.1 M stock solution of NaHqs was prepared by dissolving the weighed amount of H_2qs into the equivalent amount of sodium hydroxide solution and diluting to the volume with water. A 1.9 M hydrazine solution was prepared by dissolving 123.9 g of hydrazinium sulfate into water, neutralizing to about pH 7 with sodium hydroxide solution and diluting to 500 cm^3 with water. A 0.01 M methyltrioctylammonium chloride (Q^+Cl^-) solution was prepared by diluting 25 g of Capriquat (Dojindo Laboratories) to 500 cm^3 with chloroform. Acetate buffer solutions were prepared in the usual way. Deionized water was used. Other reagents used were of G. R. grade.

Procedure. To a sample up to 5 cm^3 containing 38—288 μg molybdenum(VI) in a 100-cm^3 Erlenmeyer flask are added 5 cm^3 of 0.1 M NaHqs solution, 5 cm^3 of 1 M acetate buffer solution (pH 4.6) and 5 cm^3 of 1.9 M hydrazine solution. The mixture is diluted to 20 cm^3 with water and heated for 20 min over a boiling water-bath. The solution at room temperature is transferred into a 100-cm^3 separatory funnel and diluted to 50 cm^3 with water. After addition of 10 cm^3 of 0.01 M QCl–chloroform solution, two phases are shaken for 5 min and allowed to stand for 5 min. The organic phase, dehydrated with anhydrous sodium sulfate, is subjected to optical measurements at 570 nm against the reagent blank obtained in the same manner.

Results and Discussion

Reduction of Mo^{VI}–H_2qs Complex. To a solution containing 96 μg molybdenum(VI) are added 5 cm^3 of 0.1 M NaHqs solution, 5 cm^3 of 1 M acetate buffer solution (pH 4.6) and different amount of 1.9 M hydrazine solution. After diluting the mixture to 20 cm^3 with water, the solution was heated for 40 min over a boiling water-bath. The solution at room temperature was transferred into a 50-cm^3 volumetric flask and diluted to the volume with water. Absorbance of the solution at 538 nm was measured against the reagent blank. It was found that the addition of more than 5 cm^3 of 1.9 M hydrazine solution is required for quantitative color development of the red molybdenum(V) complex. With 5 cm^3 of 1.9 M hydrazine solution, a maximum and constant absorbance of the molybdenum(V) complex was obtained for the heating time above 25 min. Effect of pH on the absorbance of the molyb-

Table 1. Effect of diverse ions

Foreign ion	Added as	Added (μg)	Mo found (μg)	Error %
Ca^{II}	Sulfate	10000	94.9	−1.1
Mg^{II}	Sulfate	9700	96.4	+0.4
Zn^{II}	Chloride	1000	99.6	+3.7
Al^{III}	Chloride	200	98.9	+3.0
W^{VI}	Sodium salt	200	98.9	+3.0
V^{IV}	Sulfate	50	99.6	+3.7
Ni^{II}	Sulfate	20	99.5	+3.6
Cr^{III}	Chloride	20	96.7	+0.7
Cu^{II}	Sulfate	20	90.7	−5.5
Mn^{II}	Sulfate	20	94.1	−2.0
Co^{II}	Chloride	12	97.8	+1.9
Fe^{III}	Mohr's salt	10	159.1	+65.7
Fe^{III}	Mohr's salt	10[a)]	102.4	+6.4

Mo^{VI} taken: 96.0 μg. a) Backwashed with 0.2 M sodium oxalate solution (pH 4).

denum(V) complex is shown in Fig. 1. The absorbance of the complex is constant in the pH range from 4.5 to 4.8.

Extraction of Mo^{V}–H_2qs Complex. The molybdenum(V) complex extracted according to the above procedure shows absorption maxima at 372 and 570 nm. The complex is quantitatively extracted in the pH range from 4.0 to 4.7, as shown in Fig. 1. A maximum and stable absorbance of the extracts at 570 nm was obtained for the addition of more than 4 cm^3 of 0.1 M NaHqs solution and for QCl concentration above 40 mM. The molybdenum(V) complex is quantitatively extracted for shaking time of 1—10 min at an aqueous-to-organic volume ratio of 5 : 1. Absorbance of the extracts remains constant at least for 30 min.

Calibration Curve. The calibration curve does not pass through the origin, but it is linear in the concentration range of molybdenum(V) from 38 to 288 μg in 10-cm^3 extracts. The results of regression analysis for the linear calibration range gave $Y=-(61\pm6.7)\times10^{-3}+(51\pm0.47)\times10^{-3}\ X$ at a significance level of $\alpha=0.05$, where Y is absorbance of the extracts at 570 nm and X is the concentration of molybdenum(V) in μg/cm^3-extracts.

Effect of Diverse Ions. Effect of foreign metal ions on the determination of molybdenum is given in Table 1. Interference by vanadium(IV) and iron(III) was significantly diminished as compared with the method of Busev and Fan.[3)]

Composition of the Extracted Species. When the molybdenum(V)–H_2qs complex having the absorption maximum at 570 nm is predominantly extracted, the equilibrium is given by

$$M^{m-} + m\,QCl_o \rightleftharpoons MQ_{m,o} + m\,Cl^- \quad (1)$$

where M^{m-} indicates the anionic Mo^{V}–H_2qs complex and subscript o the organic phase. The distribution ratio D of molybdenum(V) complex is given by

$$D = \frac{A}{A_{max}-A} \quad (2)$$

where A is the absorbance of the extracts at 570 nm and A_{max} that of the extracts where molybdenum(V) is quantitatively extracted. Thus, a plot of log D *vs.* log $[QCl]_o$ should give a straight line with a slope of m. As shown in Fig. 2, the plot has a slope of $m=4.7$, suggesting the composition of $[(MoO_2qs)_2(Hqs)_3(Q)_5]_o$.

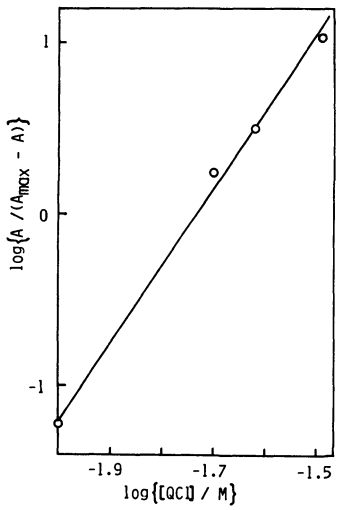

Fig. 2. A plot of log D *vs.* log[QCl] at pH 4.6.
Aqueous layer: [Mo]=96 μg, [NaHqs]=0.01 M, [Hydrazine]=0.19 M, [NaCl]=0.1 M.
The plot has a slope of 4.7 as evaluated by the method of least squares.

Fluorescence as a Means for Kinetic Studies. III. Bimolecular Reaction of Fluorescent Reagent as Quenching Probes

Hideharu Ushiki,* Akio Okamoto,† Kazuyuki Horie,† and Itaru Mita,†
Laboratory of Chemistry, Faculty of General Education, Tokyo University of Agriculture and Technology, 3-5-8, Saiwai-cho, Fuchu, Tokyo 183
†*Institute of Interdisciplinary Research, Faculty of Enginnering, The University of Tokyo, 4-6-1, Komaba, Meguro-ku, Tokyo 153*
(Received April 28, 1983)

Synopsis. In order to study the rate of bimolecula reaction between 9-(3-aminopropyl)carbazole and dansyl chloride, the change of fluorescent intensity of dansyl group has been measured. It has been found that the rate of increase in fluorescent intensity of the dansyl group is equal to the rate of decrease in fluorescent intensity of the carbazolyl group during progress of this bimolecular reaction. Another *quenching probe* was also examined briefly.

Fluorescent probes are defined as fluorescent molecules whose spectral response (quantum yield, excitation, and emission) varies as a function of the physical and chemical environment with which the probe is associated.[1] In recent years the studies of bimolecular reaction rates in nonaqueous solution by using the fluorescent probe have been reported by many authors.[2-7] Especially, the fluorescent probe method is effective for the study on reaction rate of macromolecules because the rates of bimolecular reaction between polymers must be measured in a very dilute solution.[8]

Instrumental sensitivity for the detection of fluorescence emission is usually several orders of magnitude greater than that for absorption measurements. Thus the fluorescent probe method is the most effective for the study on rates of organic reaction in dilute solution. But there is a difficult problem on fluorescent probe method because the probes are restricted to special organic compounds. The most remarkable characteristics of fluorescent probe is the fact that these probes must have a fluorescence emission only after this reaction.

The reaction product between the one having energy donor group and the other having energy acceptor group shows the intramolecular energy transfer such as 9-[3-(5-dimethylamino-1-naphthylsulfonylamino)propyl]carbazole (DNSPC) shows the intramolecular singlet-singlet energy transfer between carbazolyl group (energy donor) and dansyl group (energy acceptor). So, it is contemplated that the decrease in fluorescent intensity based upon singlet-singlet energy transfer will be observed during progress of the bimolecular reaction between the compound having energy donor group and the other having energy acceptor group.

In this paper, the rates of bimolecular reaction between amino group and chlorosulfonyl or carbonyl chloride groups in nonaqueous solution have been measured by *quenching probe method.*

Experimental

Materials. 9-(2-Cyanoethyl)carbazole (CEC) was prepared in a similar way to that reported by other authors.[9]

9-(3-Aminopropyl)carbazole (APC) was prepared by the reduction of CEC by using lithium aluminium hydride r($LiAlH_4$).[10]

Anthraquinone-2-sulfonyl chloride (ASCl) was prepared in a similar way to that reported by other author.[11] The each product was identified by infrared and NMR spectra.

Measurements. Sample solution in a rectangular quartz cell with cap was set in a thermostat (60 °C), and the fluorescence spectra were measured by using JASCO FP-550 spectrofluorometer. Dotite-Luminasol-grade ethyl acetate was used as a solvent for fluorescent measurements.

Results and Discussion

The fluorescence spectra in the bimolecular reaction between 9-(3-aminopropyl)carbazole (APC) and 5-dimethylamino-1-naphthalenesulfonyl chloride (dansyl chloride, DNSCl) in ethyl acetate at 60 °C are shown in Fig. 1. The kinetic scheme of this bimolecular reaction is shown below.

$$\mathrm{CazCH_2CH_2CH_2NH_2} + \mathrm{DNSCl} \longrightarrow \mathrm{CazCH_2CH_2CH_2NHSO_2DN} + \mathrm{HCl} \quad (1)$$

In organic solvents, hydrogen chloride formed reacts immediately with amine.[12]

$$\mathrm{CazCH_2CH_2CH_2NH_2} + \mathrm{HCl} \longrightarrow \mathrm{CazCH_2CH_2CH_2NH_3^+Cl^-} \quad (2)$$

The rate of this bimolecular reaction can be measured by the increase in fluorescent intensity of the dansyl group (499 nm) because the dansyl group shows a fluorescence emission only after this reaction. The rate constants for pseudo-first-order reaction under the concentrations of $[APC]=3.9\times10^{-5}$ M, 1.0×10^{-3} M, and 2.0×10^{-3} M, $[DNACl]=3.9\times10^{-5}$ M were measured in ethyl acetate at 60 °C by the increase in fluorescent intensity of the dansyl group. The plots of pseudo-first-order reaction show a straight line. The values of k_2 for second-order reaction are 0.059 s^{-1} M^{-1} ($[APC]=3.9\times10^{-5}$ M), 0.038 s^{-1} M^{-1} ($[APC]=1.0\times10^{-3}$ M), and 0.032 s^{-1} M^{-1} ($[APC]=2.0\times10^{-3}$ M). On the other hand, it has been supposed that the rate of increase in fluorescent intensity for the dansyl group is equal to the rate of increase in fluorescent intensity for the carbazolyl group during progress of bimolecular reaction in Fig. 1. DNSPC must show the intramolecular singlet-singlet energy transfer between carbazolyl group (energy donor : 81 kcal) and dansyl group (energy acceptor : 57 kcal). Consequently, the rate for this bimolecular reaction can be determined by the decrease in fluorescent intensity of the carbazolyl group, and the values of k_2 obtained by *quenching probe method* agree well with that by fluorescent probe method.

The value of k_2 for the bimolecular reaction between buthylamine and dansyl chloride was measured in ethyl acetate at 60 °C by the fluorescent probe method, and

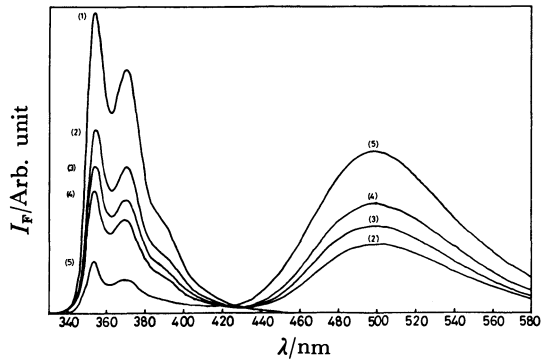

Fig. 1. Fluorescence spectra in the bimolecular reaction between 9-(3-aminopropyl)carbazole (APC) and dansyl chloride (DNSCl) in ethyl acetate. [APC]=[DNSCl]=3.9×10^{-5} M. Excitation wavelength: 350 nm. (1); 0 h (in the absence of DNSCl), (2); 51 h, (3); 94 h, (4); 143 h, (5); 598 h (at end point).

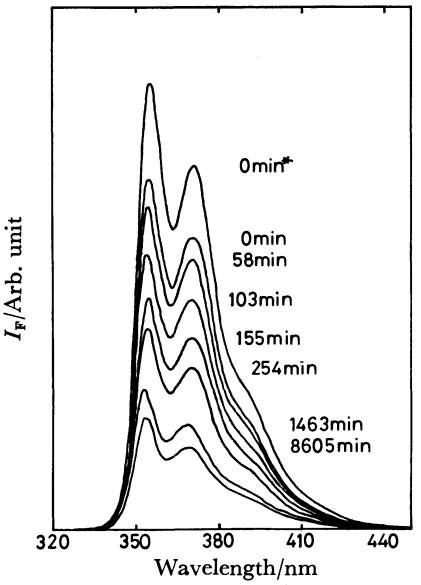

Fig. 2. Fluorescence spectra in the bimolecular reaction between 9-(3-aminopropyl)carbazole (APC) and antraquinone-2-sulfonyl chloride (ASCl) in ethyl acetate. [APC]=[ASCl]=3.9×10^{-5} M. Excitation wavelength: 350 nm. 0 min* is the condition in the absence of ASCl.

was 0.20 s^{-1} M^{-1}.[6] But the value of k_2 for the bimolecular reaction between APC and dansyl chloride under the above conditions was about 0.2—0.3 times as large as that for bimolecular reaction between butylamine and dansyl chloride. The bimolecular reaction between amino group and chlorosulfonyl group is well-known as the bimolecular nucleophilic substitution reaction (S_N2). The S_N2 displacement is less affected by electrometric effect (resonance, inductive, *etc.*) since there is relatively little charge on sulfur in the transition state.[13] Consequently, it seems reasonable to assume that the bimolecular reaction between APC and dansyl chloride is reduced by nonpolar effect of its own carbazolyl group.

The rates of bimolecular reactions between APC and ASCl or anthraquinone-2-carbonyl chloride (ACCl) in ethyl acetate at 60 °C can be measured by *quenching probe method* but not by fluorescent probe method. The kinetic schemes of those bimolecular reactions are below.

$$CazCH_2CH_2CH_2NH_2 + AQSO_2Cl \longrightarrow CazCH_2CH_2CH_2NHSO_2AQ \quad (3)$$

$$CazCH_2CH_2CH_2NH_2 + AQCOCl \longrightarrow CazCH_2CH_2CH_2NHCOAQ \quad (4)$$

The products formed by this bimolecular reaction shows the intramolecular singlet-singlet energy transfer between carbazolyl group (energy donor : 81 kcal) and anthraquinon-2-yl group (energy acceptor : 67 kcal). Moreover, anthraquinon-2-yl group does not fluoresce. The fluorescence spectra in the bimolecular reaction between APC and ASCl under the conditions of [APC]=[ASCl]=3.9×10^{-5} M in ethyl acetate at 60 °C are shown in Fig. 2. These values of k_2 obtained by plots for second-order reaction are 3.2 s^{-1} M^{-1}(between APC and ASCl) and 7.6 s^{-1} M^{-1} (between APC and ACCl). The values of k_2 for bimolecular reactions between APC and ASCl or ACCl in ethyl acetate at 60 °C are about 54 or 129 times as large as that for the bimolecular reaction between APC and dansyl chloride. The accelerating effect in the reaction with ASCl should be predictable from the distinction of electromeric effect on the sulfur atom in sulfonyl group between anthraquinon-2-yl group and dansyl group. These results are compatible with ones in other reaction between amino group and chlorosulfonyl or carbonyl chloried groups.

In conclusion, DNSPC formed by bimolecular reaction between APC and dansyl chloride shows the intramolecular singlet-singlet energy transfer between carbazolyl group and dansyl group. So, the decrease in fluorescent intensity based upon singlet-singlet energy transfer was observed during progress of the bimolecular reaction between the compound having energy donor group and the other having energy acceptor group. The rates of bimolecular reaction between APC and ASCl or ACCl could be measured by *quenching probe method.*

Single-step Lithium-ion Exchange on α-Hafnium Phosphate

Isao TOMITA,* Kazuo MAGAMI,† Hiroshi WATANABE,†
Koji SUZUKI,† and Toshihiro NAKAMURA†
Tokyo University of Fisheries, Konan, Minato-ku, Tokyo 108
Department of Industrial Chemistry, Faculty of Engineering, Meiji University, Higashi-Mita, Tama-ku, Kawasaki 214
(Received May 7, 1983)

Synopsis. Forward and backward pH titration curves were measured for lithium-ion exchange on crystalline α-hafnium phosphate. The forward reaction proceeded in a single step, in contrast to the corresponding process in α-zirconium phosphate. In the backward process, no intermediate crystalline phases were observed during the exchange, and the exchanger was gradually converted into gel.

The ion-exchange properties of crystalline α-hafnium bis(hydrogenphosphate) monohydrate, $Hf(HPO_4)_2 \cdot H_2O$ (referred to as α-HP), had been expected to be similar to those of α-zirconium phosphate, $Zr(HPO_4)_2 \cdot H_2O$ (α-ZP), but had scarcely been investigated[1] because of its difficulty in practical use and because of the rather easy inference of the properties due to the nearly identical chemistries of zirconium and hafnium. The authors have found that many properties are similar to those of α-ZP, as was expected. Attention has, however, been attracted to Li^+ ion exchange because the behavior of this ion is quite different between α-titanium phosphate (α-TP)[2,3] and α-ZP,[4] which have almost the same structure and interlayer distance. Information on Li^+ ion exchange behavior on α-HP is thus worth mentioning in the interpretation of ion exchange on this type of exchanger.

Experimental

Crystalline α-HP was prepared by refluxing newly formed amorphous hafnium phosphate in from 11 to 12 $mol \cdot dm^{-3}$ of H_3PO_4 at the boiling point for more than 210 h. The resulting crystallite was identified by means of X-ray diffractometry and thermal analysis (TG–DTA). The fully exchanged Li^+ form of the exchanger, $Hf(LiPO_4)_2 \cdot 4H_2O$ (Li–HP) was prepared from α-HP in two ways. One was prepared by the gradual addition of 0.1 $mol \cdot dm^{-3}$ LiOH to a suspension of α-HP in distilled water, keeping the pH of the mixed solution as high as about 9. Another Li–HP was produced by the batch technique in the same way as in the forward exchange.

The ion exchange experiment was carried out by the batch method. Forward and backward pH titration curves were measured at 25 °C. In the forward process, where H^+ ions of α-HP were replaced by Li^+ ions, mixed solutions of 0.1 $mol \cdot dm^{-3}$ LiCl and 0.1 $mol \cdot dm^{-3}$ LiOH were prepared at variable mixing ratios to give solutions of differing LiOH concentrations, keeping the lithium concentration constant. Then, α-HP (200 mg) was placed in contact with a 20-cm^3 portion of each of the above-mentioned mixed solutions, and the mixture was shaken for 4 d. The solution was centrifuged, and the supernatant liquid was subjected to pH measurement, as well as to the determination of lithium and phosphate by means of flame photometry and absorptiometry respectively. The analytical data for lithium were used for the calculation of the lithium ionic fractions ($\overline{XLi}$) of the exchanger, while those for phosphate were used for examining the degradation of the exchanger. The solid phase was analyzed by means of X-ray powder diffractometry and thermogravimetry. In the backward titration, the solutions to be placed in contact with Li–HP consisted of 0.1 $mol \cdot dm^{-3}$ LiCl and 0.1 $mol \cdot dm^{-3}$ HCl at variable mixing ratios. Twenty-cm^3 portions of each of the solutions were used, and the amount of Li–HP taken was such that it was equivalent to 200 mg of α-HP. Thus, the solution-to-solid ratio was kept constant (100 cm^3/g) in both the forward and backward titrations.

Results and Discussion

The forward titration curve is shown in Fig. 1. It gives a single plateau at a pH value around 5.3. An initial slope up to about 20% of conversion corresponds to the solid-solution formation of Li^+ ions in the α-HP lattice. There is no indication of a pH jump at a half-exchange. The lowest-angle region of the X-ray powder diffraction patterns of the exchanger are presented in Fig. 2. Up to $\overline{XLi}$ of 0.3, only the reflection peak due to the interlayer distance (d_{002}) of α-HP was found; *i.e.*, the Li^+ ions are incorporated with α-HP without any essential change in the crystal structure. This region corresponds to the initial slope of the titration curve. In the subsequent plateau region, a new phase with the interlayer distance of 10 Å appeared. As the exchange proceeded, the intensity of the reflection of this phase increased with a decrease in that of α-HP. Beyond a half-exchange, however, the α-HP was not completely converted into the new phase, but coexisted with that phase. Another phase with the interlayer distance of 7.9 Å appeared at a relatively higher conversion, and sometimes three reflection lines (at 7.6, 7.9, and 10.1 Å) coexisted. If the sample for the X-ray measurement was dried under an infrared lamp for 10, 40, and 70 m, the peak at 10.1 Å gradually diminished and peak at 7.9 Å increased in intensity.

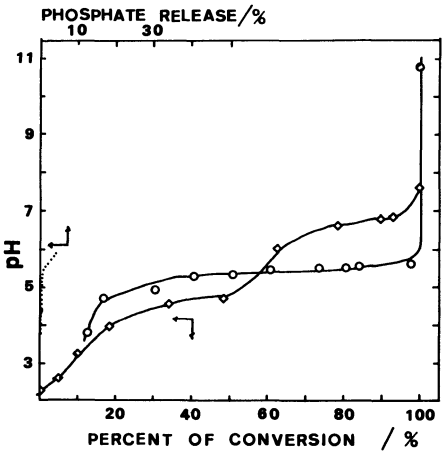

Fig. 1. The forward and backward pH titration curves for Li^+ ion exchange and the phosphate release curve in the forward titration.
○: Forward, ◇: Backward. The point at 13% conversion in the forward run was obtained when contacting the exchanger with 0.1 $mol \cdot dm^{-3}$ LiCl only.

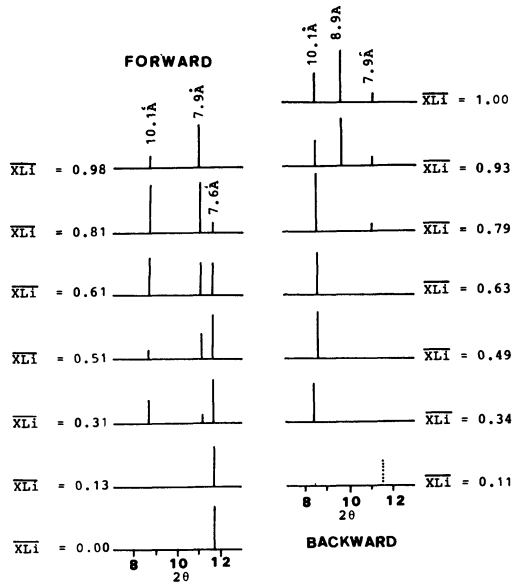

Fig. 2. The lowest angle regions of the X-ray powder diffraction patterns of the exchanger at several stages of exchange. $\overline{XLi}$ denotes the lithium ionic fraction.

From these results as well as the data for α-ZP, the 7.9- and 10.1 Å peaks were ascribed to Li–HP monohydrate and tetrahydrate respectively. Whether or not the exchanged phases with different hydration numbers exist *in situ* during exchange is difficult to confirm, though at equilibrium the phase-rule requirement rules out the coexistence of three solid phases including α-HP. From the shape of the curve and the X-ray evidence the Li^+ ion exchange on α-HP is considered to proceed essentially in a single step, without the formation of any intermediate Li^+ ion-exchanged phases.

The backward titration curve is given in Fig. 1. The curve has some slopes, and an inflection point is seen around a half-exchange. No evidence, however, of a two-step exchange has been obtained from the X-ray data shown in Fig. 2. Further, as the backward exchange progressed, the conversion of the crystalline exchanger into gel became extensive. This phenomenon is what has been observed in the backward titration of Li^+ form of α-ZP.[5] If the resulting gels were stored for a few months, a partial recrystallization into α-HP was found, the phenomenon being shown as dotted reflection lines at $\overline{XLi}$=0.11 in Fig. 2.

It should be noted that the X-ray powder patterns of the Li–HP forms prepared by the different methods are not the same. The exchanged form prepared by the gradual addition of LiOH had an additional reflection peak at 8.9 Å besides the 10- and 7.9 Å peaks. The intensity of the 8.9 Å reflection depended on the drying conditions of the sample for the X-ray measurement. Thus, the peak is to be ascribed to the di- or trihydrate of Li–HP. The results of thermogravimetry also depended upon the drying condition of the sample, but a typical air-dried product had 3.7 mol of water per formula weight. This is a mixture of Li–HP forms with varing numbers of hydration, the majority of them being tetrahydrate. The curve given in Fig. 1 is the one obtained for Li–HP prepared by the slow addition of LiOH, but the curve for Li–HP prepared by the batch method has almost the same shape. It is of interest that even the latter product gave the 8.9 Å peak at the initial stage of the backward titration.

The phosphate release into the solution was measured at every stage of exchange. The result of the forward titration are given in Fig. 1; they were usually less than 0.1 mmol P/g α-HP. In the backward titration, the release was between 0.1 and 0.15 mmol P/g α-HP. Since the theoretical capacity of α-HP is 5.15 mequiv./g, the phosphate release affects the capacity by only 3% or less as long as the exchanger is used in acidic media.

The interlayer distances of α-ZP and α-TP are almost the same, 7.6 Å.[6] It is, therefore, quite likely that the ion-exchange behavior of these exchangers also has a strong resemblance in many respects—for example, the ion-sieve effect, the selectivity sequence, and the exchange mechanism. The Li^+ ion-exchange behavior on α-TP does differ from that of α-ZP in that the former exhibits a single-step exchange, in contrast to three-step exchange in the latter. This process in α-ZP may be expressed as follows:[6]

$$\underset{(7.6\text{ Å})}{\overline{HH}\cdot H_2O} \longrightarrow \underset{(10.1\text{ Å})}{\overline{HLi}\cdot 4H_2O} \longrightarrow \underset{(10.1\text{ Å})}{\overline{H_{0.5}Li_{1.5}}\cdot 4H_2O} \longrightarrow \underset{(10.0\text{ Å})}{\overline{LiLi}\cdot 4H_2O} \quad (\alpha\text{-ZP})$$

Here, $\overline{HH}$, $\overline{HLi}$, $\overline{H_{0.5}Li_{1.5}}$, and $\overline{LiLi}$ denote α-ZP, monolithium form, the 1.5 Li^+-exchanged form, and the dilithium form respectively. The hydration numbers are given as H_2O and $4H_2O$. The interlayer distances are given in the parentheses. The lithium-ion exchange on α-TP may be shown in the same fashion:

$$\underset{(7.6\text{ Å})}{\overline{HH}\cdot H_2O} \longrightarrow \underset{(7.6\text{ Å})}{\overline{LiLi}\cdot H_2O} \quad (\alpha\text{-TP})$$

In α-HP, the Li^+ ion exchange in the forward directions is between those of α-TP and α-ZP:

$$\underset{(7.6\text{ Å})}{\overline{HH}\cdot H_2O} \longrightarrow \underset{(10.1\text{ Å})}{\overline{LiLi}\cdot 4H_2O} \quad (\alpha\text{-HP})$$

This is also nearly the case for zirconium titanium phosphate mixed crystals (ZTP):[7]

$$\underset{(7.6\text{ Å})}{\overline{HH}\cdot H_2O} \longrightarrow \underset{(9.9\text{—}10.1\text{ Å})}{\overline{LiLi}\cdot 4H_2O} \quad (\text{ZTP})$$

As the presence of any intermediate exchanged phase corresponds to a step-by-step ion exchange, α-HP does not seem to form as many exchanged phases as α-ZP.

(Received January 24, 1983)

Synopsis. 2,5,8,20,23,26-Hexaoxa[7.7]- and 2,5,8,11,23,26,29,32-Octaoxa[10.10](1,8)anthraquinonophanes (**2** and **3**) were synthesized, examined for complexation behavior with alkali and alkaline earth metal cations, and observed to show significant selectivity among the cations studied. The electroreduction of **2** by cyclic voltammetry was studied with the related compounds.

Crown compounds including a quinone-hydroquinone redox system in the molecule demonstrate complexation behavior. Recently, Vögtle *et al.* synthesized 4,7,10-trioxa-1,13-dithia[13](9,10)anthraquinonophane[2a)] and 1,4,7,10,13-pentaoxa[13]- and 1,4,7,10,13,16-hexaoxa-[16](1,2)anthraquinonophanes.[2b)] Misumi *et al.* have reported the synthesis of "crowned" quinone-hydroquinone redox systems, for which the 2,4-dinitrophenylhydrazone derivatives exist only as tautometric "crowned" dinitrophenylazophenols. They showed cation selectivity for Li(I).[3a,b)] These compounds were applied to the spectrophotometric determination of Li(I).[3c)]

Here, we report the synthesis of a new series of "crowned" anthraquinone (**1**, **2**, **3**, and **6**) according to Chart 1.

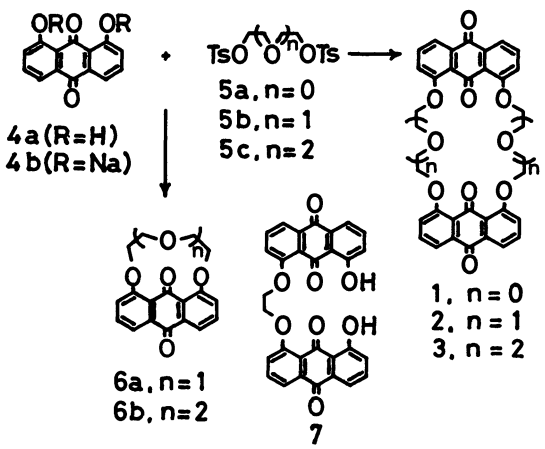

Chart 1.

TABLE 1. RESULTS OF SOLVENT EXTRACTION AT 20 °C

Ion	**2**(%)	**3**(%)	**7**(%)	Ionic radius/Å
Li^+	5.8	12.8	0.7	0.60
Na^+	9.9	22.6	2.1	0.95
K^+	12.8	56.6	2.8	1.33
Rb^+	28.6	49.9	3.1	1.48
Cs^+	25.5	35.7	2.7	1.69
Mg^{2+}	2.4	3.2	1.4	0.65
Ca^{2+}	3.8	7.1	2.6	0.99
Sr^{2+}	3.4	4.0	2.4	1.13
Ba^{2+}	5.4	30.4	2.3	1.35

Treatment of the sodium salt (**4b**) of 1,8-dihydroxyanthraquinone with ethylene glycol ditosylate (**5a**) in the presence of NaOH in xylene under reflux for 10—15 h did not gave the cyclic ether **1** but the acyclic ether **7** in 2.5% yield. On the other hand the reactions of **4b** with **5b** and **5c** afforded **2** (8.9%) and **3** (0.6%). Neither the expected **6a** and **6b** were obtained. An attempt to synthesize **6** ($n=1$ or 2) by the reaction of **4b** with the corresponding **5b** or **5c** was unsuccessful. The structures of **2**, **3**, and **7** obtained here, were identified by elemental analyses, IR, mass spectra, and ^1H NMR. The complex formation between a macrocyclic polyether (**2** or **3**) and a variety of alkali and alkaline earth metal salts could be readily established by Pedersen's solvent extraction method.[4)] Results obtained by the solvent extraction of the complexed crowns from a mixture of picric acid, alkali, or alkaline earth metal salt (Li^+, Na^+, K^+, Rb^+, Cs^+, Mg^{2+}, Ca^{2+}, Sr^{2+}, or Ba^{2+}) and the crown (**2** or **3**) in CH_2Cl_2–H_2O are shown in Table 1.

Appreciable selectivity was shown by **2** for Rb^+ and Cs^+, and by **3** for K^+, Rb^+, and Cs^+ among alkali cations and also by **3** for Ba^{2+} among alkaline earth metal cations. It was also clear that the acyclic diol **7** did not participate significantly in the extraction. These facts seem to be related to the relative size of the cations and the cavity of **2** or **3**.[5)]

Electrochemical properties of **2** were studied by cyclic voltammetry together with related quinones.[6)] The reduction potentials of these quinones are summarized in Table 2. The acyclic compound **7** has two redox couples (−0.66 and −1.35 V), whose difference ($E_{p1}-E_{p2}$) corresponds well to that of 9,10-anthraquinone. In contrast the cyclic voltammogram of **2** gave a well-defined three wave pattern contrary to that expected for two or four redox couples. The differences between the redox potentials ($E_{p1}-E_{p2}$ and $E_{p2}-E_{p3}$) of **2** were characteristically very small, *i.e.*, 0.22 and 0.33 V, respectively. This behavior of **2** is not completely explained but seems to be related to the easy delocalization of the electron(s) in the corresponding dianion species (dianion or dianion diradical) arising from the reduction of **2**. Thus, the dianion species appear to be more stabilized by delocalization than the corresponding mono-, tri-, or tetraanion species

TABLE 2. ELECTROCHEMICAL REDUCTION POTENTIALS (V *vs.* SCE)

9,10-Anthraquinone	−0.96	−1.67	—	0.71	—
7	−0.66	−1.35	—	0.69	—
2	−0.85	−1.07	−1.40	0.22	0.33

derived from **2**.

Experimental

Ultraviolet absorption (UV) spectra and IR spectra were measured on Shimadzu UV-300 and JASCO IRA-2 spectrometers, respectively. ^{1}H NMR spectra were obtained on a JEOL FX 90Q spectrometer. The chemical shifts are in ppm using TMS as an internal standard. Mass spectra were obtained with a JEOL JMS-01SG mass spectrometer.

General Procedure. *Polyethylene glycol ditosylate* (**5a**, **5b**, or **5c**, 80 mmol) was added to a solution of disodium 9,10-dioxo-1,8-anthracenediolate prepared by azeotropic distillation of a mixture of aqueous NaOH solution (160 mmol), 1,8-dihydroxyanthraquinone (19.20 g, 80 mmol), and xylene (500 ml). The above mixture was refluxed for 10—15 h. The reaction mixture was filtered and the residue washed thoroughly with xylene (100 ml). The combined xylene solution was evaporated *in vacuo* and the solid residues were washed with acetone to give **2**, **3**, and **7**, respectively. The unreacted tosylate was recovered from the filtrate. The compounds (**2**, **3**, and **7**) were recrystallized from toluene.

2,5,8,20,23,26-Hexaoxa[7.7](1,8)anthraquinonophane (2): Yellow crystals; mp 190 °C; IR (KBr): 1670, 1630, and 1585 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=4.04—4.36 (m, 16H, $-CH_2-$) and 7.15—7.98 (m, 12H, aromatic H); UV (CH_2Cl_2): 396 nm (ε 9750); Found: C, 69.70; H, 5.00%; M$^+$, 620. Calcd for $C_{36}H_{28}O_{10}$: C, 69.67; H, 4.55%; M, 620.

2,5,8,11,23,26,29,32-Octaoxa[10.10](1,8)anthraquinonophane (3): Pale yellow crystals; mp 278—280 °C; IR (KBr): 1670, 1625, and 1590 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=3.60—4.22 (m, 24H, $-CH_2-$) and 7.12—7.83 (m, 12H, aromatic H); UV (CH_2Cl_2): 380 nm (ε 8490); Found: C, 66.10; H, 4.99%: M$^+$, 708. Calcd for $C_{40}H_{36}O_{12}\cdot H_2O$: C, 66.11; H, 5.27%; M, 708.

1,1'-Bis(8-hydroxy-9,10-dioxo-1-anthryloxy)ethylene (7): Yellow crystals; mp 280 °C decomp; IR (KBr): 3400, 1675, 1635, and 1585 cm^{-1}; ^{1}H NMR ($CDCl_3$): δ=4.74 (s, 4H, $-CH_2-$), 12.72 (s, 2H, OH), and 7.25—7.96 (m, 12H, aromatic H); UV (CH_2Cl_2): 411 nm (ε 11000); Found: C, 73.48; H, 4.54%; M$^+$, 506. Calcd for $C_{30}H_{18}O_8\cdot 1/2C_7H_8$: C, 73.69; H, 4.18%; M 506.

Solvent Extraction Experiments of Metal Ions by 2, 3, and 7:[4] After a mixture of picric acid (7×10^{-5} M, 5 ml of aqueous solution; 1 M=1 mol dm^{-3}), metal chloride (0.1 equiv., 5 ml of aqueous solution) was shaked vigorously with **2**, **3**, or **7** (7×10^{-4} M, 5 ml of CH_2Cl_2 solution), the absorbance of the aqueous layer was measured. The extraction ratios obtained by the reduced absorbance to that of the original aqueous layer are shown in Table 1.

Electrochemical Measurements of the Quinones: According to Ref. 6 all measurements were carried out in *N,N*-dimethylformamide containing 0.1 M tetrabutylammonium perchlorate at 20±0.2 °C using a three electrode cell.

The authors wish to express their thanks to Professor Soichi Misumi and Dr. Takahiro Kaneda of Osaka University for valuable discussions.

Studies of Tritylated Pentoses and 6-Deoxyhexoses. III. The *O*-Tritylation of Methyl α- and β-D-Xylopyranoside[1)]

Toshiki OTAKE* and Toru SONOBE†

Department of Food and Nutrition, Yamanashi Gakuin Junior College, 502, Sakaori-machi, Kofu 400

(Received March 14, 1983)

Synopsis. The tritylation of methyl α- and β-D-xylopyranoside afforded three isomeric trityl ethers in both cases. All the ethers were separated by column chromatography in almost pure forms on TLC. Among them, methyl 2-*O*-trityl-α- and methyl 3-*O*-trityl-β-D-xylopyranoside were crystallized from aqueous ethanol. The position of the trityl group in each ether was mainly established by the use of ^{1}H NMR with its diacetyl derivative.

In previous papers of this series, it was shown that methyl α-D-fucopyranoside[2)] and methyl α- and β-L-rhamnopyranoside[3)] readily formed trityl ethers, although they had no primary hydroxyl group in their molecules. In these glycosides, the equatorial hydroxyl groups, each of which is in a *cis*-form with an axial hydroxyl group, seem reactive toward tritylation.

Jackson, Hockett, and Hudson[4-5)] have reported that methyl β-D-xylopyranoside (**2**) reacted with trityl chloride in dry pyridine to give ethers. This glycoside also has no primary hydroxyl group in its molecule. They isolated two crystalline ditrityl ethers and two monotrityl ethers as crystalline di-*O*-acetates. However, they did not describe their structures. Robertson and Speedie[6)] prepared methyl 2,4-di-*O*-methyl-3-*O*-tosyl-β-D-xylopyranoside from a syrupy tritylation product of **2** through crystalline methyl di-*O*-acetyl-β-D-xylopyranoside mononitrate. From the position of the tosyl group in the resulting compound, they assumed that the starting tritylation product consisted mainly of methyl 3-*O*-trityl-β-D-xylopyranoside. They did not describe any physical data of the trityl ether or the presence of other tritylation products of **2**. Also, there has been no report about the tritylation of methyl α-D-xylopyranoside (**1**). This paper will deal with the chromatographic isolation of the three possible trityl ethers from each tritylation product of **1** and **2** and with their structures.

Results and Discussion

The reaction of **1** with 1.5 molar equivalents of trityl chloride in pyridine afforded three monotrityl ethers: the 2-*O*- (**3a**), 3-*O*- (**4a**), and 4-*O*-trityl derivatives (**5a**), in a ratio of 45 : 34 : 21 and in a combined yield of 58%. Among them, **3a** was crystallized from aqueous ethanol. A dark green spot, the R_f value of which was higher than that of triphenylmethanol, was observed on a TLC of the reaction mixture; it was assumed to correspond to the ditrityl ether of **1**. The analogous tritylation of **2** gave a 39 : 34 : 27 mixture of three monotrityl ethers: the 2-*O*- (**6a**), 3-*O*- (**7a**), and 4-*O*-trityl derivatives (**8a**), in a combined yield of 67%. Among them, **7a** was crystallized from aqueous ethanol. Two dark green spots with high R_f values on a TLC of the reaction mixture were assumed to be the di-*O*-trityl derivatives of **2**. All the mono-*O*-trityl-di-*O*-acetyl derivatives (**3b**, **4b**, **5b**, **6b**, **7b**, and **8b**) derived from each monotrityl ether were crystallized from aqueous ethanol. Two acetates, **6b** and **8b**, have almost the same mp's as the compounds reported by Jackson *et al.*;[5)] however the $[\alpha]_D$'s of **6b** and **8b** do not agree with those of the compounds in their report. The ^{1}H NMR spectra of the trityl acetyl derivatives were analyzed with a favorable Cl conformation, aided by the nuclear magnetic double resonance (NMDR) technique, thus confirming the structures. *O*-Trityl-methine proton signals are distinguished by their high-field shifts from signals of acetylmethine protons. The ^{1}H NMR data in the first-order analysis of the trityl acetyl derivatives are summarized in Table 1.

In the reactions of both **1** and **2**, the sequence of the reactivity of the hydroxyl groups toward tritylation was OH-2, OH-3, and OH-4. No considerable difference was recognized in the ratios of the three monotrityl ethers between the tritylation products of **1** and **2**.

Experimental

General Methods. The solutions were evaporated under reduced pressure below 40 °C. The optical rotations were measured with a Japan Spectroscopic DIP-SL polarimeter. The TLC was performed using a DC-Alufolien Kieselgel 60 F_{254} plate, 0.2 mm in thickness (Merck), developed two times with a solvent system of methanol–acetone–pyridine–water–chloroform (1.5 : 1.5 : 0.5 : 0.5 : 96). Preparative column chromatography was achieved using Wakogel C-200 (Wako Junyaku Co., Ltd.), eluted with the same solvent system as that used in the TLC described above. The ^{1}H NMR spectra were recorded with a Varian EM 390 (90 MHz), a Varian XL-100 (100 MHz) or a JEOL XF-200 (200 MHz) spectrometer, chloroform-*d* being used as the solvent and tetramethylsilane as the internal standard.

Tritylation of Methyl α- (1) and β-D-Xylopyranoside (2). Xyloside **1** and **2** were prepared from commercial D-xylose. A mixture of **1** or **2** and trityl chloride in a molar ratio of 1 : 1.5, dissolved in dry pyridine (×5), was allowed to stand for five days at room temperature. Thus, a small amount of water was added to the solution. After concentration, the residue was dissolved in toluene (×5). Triphenylmethanol (TPM) was then filtered from the toluene solution, and the TPM-free concentrate was subjected to recycling column chromatography eight times on silica gel (30 g). In the reaction of **1** (3.28 g), the evaporation of the eluting solvent in the fraction with R_f values of 0.29, 0.57, and 0.39 gave 2.128 g of **3a**, 1.599 g of **4a**, and 1.022 g of **5a** respectively. Compound **3a** was crystallized from 80% ethanol as white prisms: mp 135—136 °C. $[\alpha]_D^{20}$ (*c* 2.0 chloroform): **3a**, +41.3°; **4a**, +5.9°; **5a**, +53.3°. Found: **3a**, C, 73.67; H, 6.49%; **4a**, C, 74.02; H, 6.60%; **5a**, C, 73.86; H, 6.56%. Calcd for $C_{25}H_{26}O_5$: C, 73.86; H, 6.45%.

The TPM-free concentrate of the tritylation product of **2** (3.28 g) was chromatographed on silica gel (30 g) in a recycling manner eight times. The concentration of the fractions with R_f values of 0.71, 0.60, and 0.52 on a TLC gave 2.101 g of **6a**, 1.875 g of **7a**, and 1.500 g of **8a** respectively. Compound **7a** was crystallized from 80% ethanol as white needles: mp 80—81 °C. $[\alpha]_D^{20}$ (*c* 2.0 chloroform): **6a**, +10.4°; **7a**, −48.0°; **8a**, −73.5°. Found: **6a**, C, 73.57; H, 6.48%; **7a**, C, 73.63; H, 6.45%; **8a**, C, 73.58; H, 6.57%. Calcd for $C_{25}H_{25}O_5$: C, 73.86; H, 6.45%.

Acetylation of Methyl O-Tritylxylopyranosides. Each sample was acetylated under standard conditions for 2 d. After chromatographic purification, all the acetates were recrystallized from 80% ethanol in yields of 70—80%. Mp: **3b**:176—177 °C; **4b**, 154 °C; **5b**, 107—108 °C; **6b**, 169—171 °C; **7b**, 162—163 °C; **8b**, 125—126 °C. $[\alpha]_D^{20}$ (*c* 2.0 chloroform): **3b**, +61.8°; **4b**, +65.5°; **5b**, +55.6°; **6b**, −6.4°; **7b**, −27.6°; **8b**, −54.2°. Chemical shifts of methyl protons in ^{1}H NMR δ=**3b**, 1.84, 1.98, 3.24; **4b**, 1.52, 1.59, 3.17; **5b**, 1.87, 2.03, 3.31; **6b**, 1.79, 2.11, 2.99; **7b**, 1.57, 1.73, 3.39; **8b**, 1.70, 2.05, 3.39. Found: **3b**, C, 71.14; H, 6.29%; **4b**, C, 70.83; H, 6.30%; **5b**, C, 70.89; H, 6.30%; **6b**, C, 71.11; H, 6.28%; **7b**, C, 70.86; H, 6.35%; **8b**, C, 70.76; H, 6.37%. Calcd for $C_{29}H_{30}O_7$: C, 71.00; H, 6.16%.

Synthesis of Cyclic Guanidines Fused with Aromatic Ring through Metal Ion Promoted Cyclization

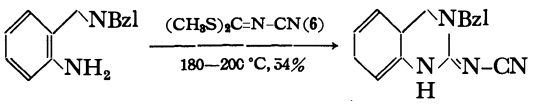
Hiroyuki OBASE,* Nobuhiro NAKAMIZO, Haruki TAKAI, and Masayuki TERANISHI
Tokyo Research Laboratory, Kyowa Hakko Co., Ltd., Asahimachi 3-6-6, Machida, Tokyo 194

(Received March 29, 1983)

Synopsis. A convenient synthetic method of five- and six- membered cyclic guanidines fused with aromatic ring was presented. 2-Aminoaniline or 2-(aminomethyl)aniline was treated with dimethyl carbonimidodithioates to give isothiourea which was cyclized to cyclic guanidine by using soft metal cations (Ag^+, Hg^{2+}).

As part of a program directed towards the preparation of potential antiphypertensive agents, it was necessary to synthesize cyclic guanidines fused with aromatic ring under mild conditions. We describe herein a new and mild synthesis of cyclic guanidines with formula **5** which is the key intermediate for the preparation of hypotensive agents, utilizing metal ion promoted reaction.

There are methods available for the synthesis of cyclic guanidines from 2-amino- or 2-(aminomethyl)aniline derivatives.[1-3] However, their syntheses need drastic conditions because of the poor reactivity of an anilino nitrogen. 2-(Cyanoimino)tetrahydroquinazoline **2** has been prepared in 54% yield by heating 2-(benzylaminomethyl)aniline (**1**) with dimethyl cyanocarbonimidodithioate (**6**) at 180—200 °C.[1] Rodricks *et al.* reported



1 **2**

that 2-(tosylamino)benzimidazole could be obtained from the reaction of dimethyl tosylcarbonimidodithioate with *o*-phenylenediamine in DMF at 150—160 °C for 12—16 h.[2] The reactivity of anilino nitrogen in **3** is reduced considerably due to the hindered nature of these molecules. Therefore, the reaction conditions to obtain cyclic guanidine **5** would be more drastic than that reported earlier. Our two-step method is depicted below.

b	CH_2Ph	1	COOMe
c	CH_2Ph	1	COMe
d	COOEt	0	CN

The synthesis of cyclization precursor **4** was attained as follows. Wittenbrook and coworker reported the preparation of 2-(cyanoimino)-1*H*-benzimidazole *via* base catalyzed reaction of *o*-phenylenediamine with **6**.[3] However, when 1-ethoxycarbonyl-4-(2-aminoanilino)-piperidine (**3b**) was reacted with **6** under the reaction conditions described by them (using triethylamine as a base, in refluxing ethanol), neither **4d** or **5d** could be detected and unchanged starting materials were recovered. The reaction carried out in dioxane in the presence of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) at 80 °C gave an isothiourea **4d** in a moderate yield. In this case, side product such as 2-(methylthio)benzimidazole derivative reported by D' Amico[4] was not detected. The other cyclization precursors **4a**—**c** required for the synthesis of 1,2,3,4-tetrahydroquinazoline **5a**—**c** were obtained in high yields under milder conditions (at room temperature, in ethanol). The yield and physical properties of **4** are summarized in Table 1.

The cyclization of **4** to cyclic guanidine **5** was achieved by using soft metal cations. The result are shown in Table 2.

The kinds of soft metal ion available in this reaction were Hg^{2+} [$HgCl_2$, $Hg(OAc)_2$] and Ag^+ (CH_3COOAg, CF_3COOAg, CH_3SO_3Ag, and CF_3SO_3Ag). The table clearly indicates that the reaction becomes faster as increase with the softness of the metal cations. Cu(I) and Cu(II) did not promote this reaction because of preferential δ or π complexation of amino group to copper.[5-6]

a) Starting material (0.25 mmol) in 2 ml of methanol.
b) Isolated yield.

A thiol ester is known to react with an alcohol in the presence of soft metal cations to afford the corresponding ester or lactone,[7] and also a selenol ester was demonstrated to serve as active acyl-transfer agent in the presence of copper(I) or mercury(II).[5-6] However, no example of intramolecular C–N bound formation with soft metal cations has been reported. Thus, it is noteworthy that this novel metal ion promoted reaction can afford cyclic guanidines in good yield under very simple and mild conditions and will be useful for constructing a variety of nitrogen heterocycles.

Experimental

The melting points for the samples were determined with a Mitamura hot-stage apparatus and are uncorrected. IR spectra were recorded on a Shimadzu, IR-27G grating IR spectrometer. ^{1}H NMR spectra were determined on a JNM-FX-100 spectrometer. Chemical shifts are reported in δ values relative to Me_4Si as a standard. The physical properties for samples in the experimental section are presented in Table 1.

N-[3-(1-Benzyl-4-piperidinylamino) phenylmethyl]-N′-cyano-S-methylisothiourea (4a). A solution of 1-benzyl-4-[2-(aminomethyl)anilino]piperidine[8] (**3a**, 1.0 g, 3.4 mmol), dimethyl dithiocarboimidate[9] (**6**, 0.59 g, 4 mmol), and triethylamine (0.5 g, 4.9 mmol) in 15 ml of EtOH was stirred for 2 h and concentrated under reduced pressure. The residue was triturated with 2-propanol. The crystals were collected by filtration and recrystallized from EtOH to give 1.4 g (92%) of **4a**. Found: C, 67.37; H, 6.98; N, 17.92%. Calcd for $C_{22}H_{27}N_5S$: C, 67.14; H, 6.91; N, 17.92%.

N-[2-(1-Benzyl-4-piperidinylamino) phenylmethyl]-N′-methoxycarbonyl-S-methylisothiourea (4b). Similarly **3a** (1.0 g, 3.4 mmol) was reacted with **7**[10] (0.68 g, 3.8 mmol) in the presence of triethylamine (0.5 g, 4.9 mmol) in 10 ml of EtOH. The reaction mixture was concentrated under reduced pressure and the residue was purified by chromatography on silica gel with $CHCl_3$–MeOH, 30 : 1. Pure **4b** was obtained in 85% yield as an oil. Found: C, 64.72; H, 7.12; N, 12.94%. Calcd for $C_{23}H_{30}N_4O_2S$: C, 64.76; H, 7.09; N, 13.13%.

N-[2-(1-Ethoxycarbonyl-4-piperidinylamino)phenyl]-N′-cyano-S-methylisothiourea (4d). A solution of 1-ethoxycarbonyl-4-(2-aminoanilino)piperidine[11] (**3b**, 1.5 g, 5.7 mmol), **6** (1.5 g, 5.8 mmol), and DBU (1.5 g, 12.1 mmol) in 20 ml of dioxane was heated at 80 °C for 12 h and concentrated. The residue was extracted with ethyl actate and the extract was washed successively with 0.3 mol dm^{-3} acetic acid, 0.57 mol dm^{-3} hydrochloric acid and water. After being dried over Na_2SO_4, the solvent was removed under reduced pressure and the residue was purified by silica-gel chromatography using $CHCl_3$–MeOH, 50 : 1 as eluent to afford 0.93 g (45%) of **4d**. An analytical sample was recrystallized from 2-propanol. Found: C, 56.36; H, 6.44; N, 19.19%. Calcd for $C_{17}H_{23}N_5O_2S$: C, 56.49; H, 6.41; N, 19.38%.

1-(1-Benzyl-4-piperidinyl)-2-cyanoimino-1,2,3,4-tetrahydroquinazoline (5a). A mixture of **4a** (973 mg, 2.5 mmol) and silver acetate (450 mg, 2.7 mmol) in 10 ml of MeOH was heated at 50 °C for 5 h and filtered through Celite. The filtrate was concentrated. The residue was dissolved in water, basified with 1 mol dm^{-3} NaOH, and extracted with $CHCl_3$. The extract was washed with aqueous NaCl and water, and dried over Na_2SO_4. Removal of the solvent gave essentially pure **5a** (777 mg, 90%). An analytical sample was recrystallized from 2-propanol. Found: C, 73.09; H, 6.77; N, 20.24%. Calcd for $C_{21}H_{23}N_5$: C, 73.01; H, 6.71; N, 20.28%.

1-(1-Benzyl-4-piperidinyl)-2-methoxycarbonylimino-1,2,3,4-tetrahydroquinazoline (5b). Similar reaction as described for **5a** was repeated by using **4b** (1.29 g, 3 mmol) and silver acetate (0.6 g, 3.6 mmol) in 20 ml of MeOH afforded 990 mg (87%) of **5b**. An analytical sample was recrystallized from AcOEt–hexane. Found: C, 69.76; H, 6.92; N, 14.77%. Calcd for $C_{22}H_{26}N_4O_2$: C, 69.81; H, 6.92; N, 14.81%.

2-Cyanoimino-3-(1-ethoxycarbonyl-4-piperidinyl)-2,3-dihydro-1H-benzimidazole (5d). A solution of **4d** (600 mg, 1.66 mmol) and mercury(II) acetate (535 mg, 1.68 mmol) in 10 ml of MeOH was stirred at room temperature for 1 h and concentrated. The residue was dissolved in $CHCl_3$ and the solution was washed with aqueous NaCl and water. The organic layer was separated and filtered through Celite. The filtrate was dried over Na_2SO_4 and concentrated. The residue almost pure **5d** (485 mg, 93%). An analytical sample was recrystallized from 2-propanol. Found: C, 61.54; H, 6.11; N, 22.18%. Calcd for $C_{16}H_{19}N_5O_2$: C, 61.32; H, 6.11; N, 22.35%.

A Kinetic Study on Denitration of 9,9′-Dinitro-9,9′-bifluorenyl by Tin(II) Chloride in *N,N*-Dimethylformamide

Kimitoshi FUKUNAGA* and Makoto KIMURA
Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube, Yamaguchi 755
(Received April 25, 1983)

Synopsis. The kinetics of the reductive elimination of nitro groups from 9,9′-dinitro-9,9′-bifluorenyl by tin(II) chloride in *N,N*-dimethylformamide (DMF) at 20 °C was investigated. It was found that the present elimination is a second-order reaction.

The potential usefulness of a radical anion-radical chain elimination reaction ($E_{RC}l$) has been widely recognized.[1] Although numerous works have been published on the $E_{RC}l$ of vicinal dinitro compounds,[2,3] α-cyano-β-nitro esters,[4] α-acetyl-β-nitro ketones,[5] and β-nitro sulfones,[6] little was known of their kinetics. The kinetic approach to the $E_{RC}l$, in general, suffers from the drawbacks that the reaction system is heterogeneous, and that the reaction is carried out under the photoirradiation or at elevated temperatures. However, in the previous work[3] it was found that the denitration of α,β-diaryl vicinal dinitro compounds with tin(II) chloride in DMF proceeded readily at room temperature. Moreover, the $E_{RC}l$ product from 9,9′-dinitro-9,9′-bifluorenyl (**1**) is 9,9′-bifluorenylidene (**2**), which has absorptions in the visible region probably attributable to a π-π^* electronic transition. The large molar absorptivity of product **2** permits low concentrations of the reactants to be used, thus eliminating problems arising from the limted solubility of tin(II) chloride. Based on these preliminary findings, a kinetic study on $E_{RC}l$ of **1** with tin(II) chloride in DMF has been made.

Experimental

Chemicals. Commercial anhydrous tin(II) chloride and DMF of the purest grade were used without further purification. Compound 1 was prepared according to the literature method.[3]

Procedure and Apparatus. The reaction of **1** with tin(II) chloride in DMF was initiated by the addition of the latter solution into a stirred solution of **1**, which was placed in the spectrophotometric cell (width 1 cm, quartz) immersed in a water bath thermostated at 20±0.1 °C. Red compound **2** has an extremely large absorptivity in DMF, $\varepsilon = 2.30 \times 10^4$ $dm^3\ mol^{-1}\ cm^{-1}$ at 458 nm, while the other species in the reaction solution are transparent under the given concentrations. Consequently the absorbance of **2** formed was measured at an appropriate reaction time using a Hitachi Model 330 spectrophotometer.

Results and Discussion

A typical spectral change of the reaction mixture is shown in Fig. 1. Figure 2 shows a typical reaction profile. The concentrations used were 4.54×10^{-4}—9.5×10^{-3} mol dm^{-3} for **1** and 1.96×10^{-3}—2.78×10^{-2} mol dm^{-3} for tin(II) chloride. The runs were carried out to about 0.07—0.7% completion. For the reaction under consideration, we may write as follows:

$$r = d[\mathbf{2}]/dt = k[\mathbf{1}]^a[SnCl_2]^b, \quad (1)$$

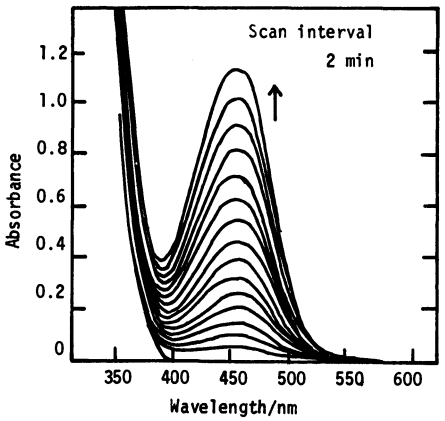

Fig. 1. Absorption spectral change due to the increase of 9,9′-bifluorenylidene (**2**) in the reaction of 9,9′-dinitro-9,9′-bifluorenyl (**1**) (2.73×10^{-3} mol dm^{-3}) with tin(II) chloride (1.86×10^{-2} mol dm^{-3}) in DMF at 20 °C.

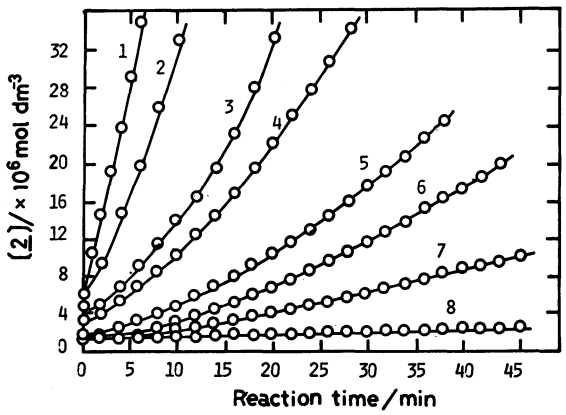

Fig. 2. Formation of **2** from **1** in a DMF solution at 20 °C.
The concentrations were as follows: 1, $[\mathbf{1}] = 9.50 \times 10^{-3}$ M and $[SnCl_2] = 2.78 \times 10^{-2}$ M; 2, $[\mathbf{1}] = 5.68 \times 10^{-3}$ M and $[SnCl_2] = 2.78 \times 10^{-2}$ M; 3, $[\mathbf{1}] = 2.73 \times 10^{-4}$ M and $[SnCl_2] = 2.78 \times 10^{-2}$ M; 4, $[\mathbf{1}] = 2.73 \times 10^{-4}$ M and $[SnCl_2] = 1.86 \times 10^{-2}$ M; 5, $[\mathbf{1}] = 2.73 \times 10^{-4}$ M and $[SnCl_2] = 1.43 \times 10^{-2}$ M; 6, $[\mathbf{1}] = 2.73 \times 10^{-4}$ M and $[SnCl_2] = 1.07 \times 10^{-2}$ M; 7, $[\mathbf{1}] = 2.73 \times 10^{-4}$ M and $[SnCl_2] = 5.27 \times 10^{-3}$ M; 8, $[\mathbf{1}] = 2.73 \times 10^{-4}$ M and $[SnCl_2] = 1.96 \times 10^{-3}$ M.

where r, [ ], t, k, a, and b denote the reaction rate, the concentration, the time, the rate constant, kinetic order with respect to **1**, and that with respect to tin(II) chloride, respectively. From Eq. 1, we get

$$\log r = \log(d[\mathbf{2}]/dt) = \log k + a \log[\mathbf{1}] + b \log[SnCl_2]. \quad (2)$$

Thus from measurements of the initial rate of the reaction in separate experiments, in which either of the reactants

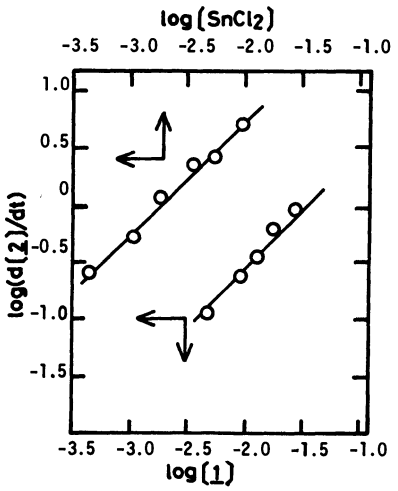

Fig. 3. log-log plots of the initial rate of the reaction of **1** with tin(II) chloride in DMF at 20 °C against the concentrations of **1** and tin(II) chloride.

is kept constant, we may find orders a and b. Plots of both log [**1**] and log [$SnCl_2$] *vs.* og $r_{t\to 0}$ will give a straight line with each slope of a and b. Each linear plot with a slope of $a=1.00$ and $b=1.04$ in Fig. 3 suggests that the reaction rate is expressed by an equation

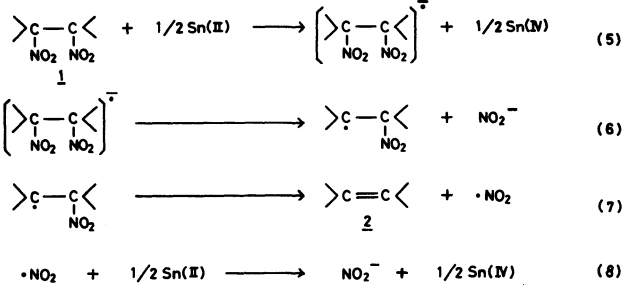
$$r = d[\mathbf{2}]/dt = k[\mathbf{1}]^{1.00}[SnCl_2]^{1.04} \quad (3)$$

with a second-order constant $k=1.49\times10^4$ M^{-1} min^{-1} (1 M=1 mol dm^{-3}) at 20 °C. The net reaction is thus given by the following equation:

$$\mathbf{1} + Sn(II) \longrightarrow \mathbf{2} + Sn(IV) + 2\,NO_2^- . \quad (4)$$

The mechanism of the present elimination appears to be one of the $E_{RC}1$[1] whose mechanism has been confirmed in the reaction of vicinal dinitro compounds or β-nitro sulfones with tributyltin hydride,[6] and the elimination seems to proceed according to the following reactions. By combining Eqs. 5—8 we obtain Eq. 4.

The k value is *ca.* 7×10^5 times greater than the second-order rate constant for a similar reductive elimination of *meso*-stilbene dibromide with tin(II) chloride in DMF at 59.4 °C reported by Kwok and



Miller.[7] It is also important to note that the k value is comparable to those for second-order electron transfer reactions among metal ions in liquid phase such as $Fe^{2+}+Co^{3+}\to Fe^{3+}+Co^{2+}$ at 0—25 °C.[8] The observed rate constant appears to be accounted for by the fact that the nitro group accepts most readily one electron among all the common functional groups.[6]

Condensations of 3,4-Bis(diphenylmethylene)-1,2-cyclobutanedione with *o*-Phenylenediamine under Ionic and Radical Reaction Conditions

Zaiko Ro,† Koichi Tanaka, and Fumio Toda*
Department of Industrial Chemistry, Faculty of Engineering, Ehime University, Matsuyama 790
(Received May 9, 1983)

Synopsis The title condensations under ionic and radical reaction conditions gave 1,2-bis(diphenylmethylene)-1,2-dihydrocyclobuta[*b*]quinoxaline and 7,8-bis(diphenylmethylene)-7,8-dihydrobenzo[*b*][1,4]diazocine-6,9(5*H*,10*H*)-dione respectively.

Recently, McOmie and his co-workers have found that the kind of the condensation product of substituted benzocyclobutene-1,2-dione (**1**) with *o*-phenylenediamine (**2**) is very sensitively affected by the substituents of the former. For example, the condensation of **1a**—**c** with **2** in MeOH containing AcOH gave the corresponding 5,10-diazabenzo[*b*]biphenylenes (**3a**—**c**), whereas the similar condensation of **1d**—**f** gave the corresponding dibenzo[*b*,*f*][1,4]diazocine-6,11(5*H*,12*H*)-diones (**4d**—**f**).[1] However, the reason for the difference has not been clear.

We have now found that the condensations of 3,4-bis(diphenylmethylene)-1,2-cyclobutanedione (**5**) with **2** under ionic and radical reaction conditions gave 1,2-bis(diphenylmethylene)-1,2-dihydrocyclobuta[*b*]quinoxaline (**7**) and 7,8-bis(diphenylmethylene)-7,8-dihydrobenzo[*b*][1,4]diazocine-6,9(5*H*,10*H*)-dione (**8**) respectively. When a solution of **5**[2] and an equimolar amount of **2** in CCl_4 was kept at room temperature for 120 min, **7** and **8** were obtained in 46 and 53% yields respectively (Table 1). When the reaction was carried out in the dark, the yield of **7** increased slightly. The condensation reaction was accelerated by the addition of AcOH. The reaction in CCl_4 containing 3% AcOH ceased within 15 min and gave **7** and **8** in 56 and 43% yields respectively. When the concentration of AcOH was increased to 20 or 50%, the reaction was much more accelerated and gave only **7** in a 98% yield in both cases. The termination of the reaction can easily be followed by observing the disappearance of the deep green color of **5**. The above results clearly show that the acide catalyzed condensation of **5** and **2** gives **7**.

On the contrary, the reaction in the presence of the radical initiator $CBrCl_3$ gave **8** in an 85% yield in addition to a small amount of **7**. When the same reaction was carried out in the dark, however, the yield of **8** decreased to 50% and the yield of **7** increased to 44%. The homolysis of $CBrCl_3$ to trihalomethyl and halogeno radicals is accelerated by light.[3] The formation of **8** by the reaction in CCl_4 in the dark may be due to radical species produced by a dark reaction of **2** and CCl_4, for no reaction occurred in MeOH in the dark.

The plausible reaction pathways are shown in Scheme 1. The reaction of **5** and **2** gives the diol intermediate (**6**), which, upon acid-catalyzed dehydration and radical-induced dehydrogenation, affords **7** and **8** respectively. When the halogeno radical abstracts hydrogen from **6**, **8**, and hydrogen halide are formed. The hydrogen halide thus formed catalyzes the dehydration of **6**. This would be the reason that the formation of **8** always accompanies that of **7**.

Nonetheless, it is not clear whether McOmie's case is similar to ours or not.[4]

Experimental

*Condensation Reaction of **5** with **2** in the Absence of AcOH.* When a solution of **5**[2] (0.24 g, 0.58 mmol) and **2** (0.063 g, 0.58 mmol) in CCl_4 (20 ml) was kept at room temperature for 120 min, the deep green color of **5** disappeared completely, resulting in an orange-colored CCl_4 solution. This solution was poured into a column filled with silica gel; it was subsequently eluted by $CHCl_3$ and THF to give **7** as yellow prisms (0.128 g; 46%; mp 240—241 °C (lit,[2] mp 240—241 °C)) and **8** as colorless prisms (0.16 g; 53% mp 287—288 °C) respectively. IR (Nujol) 3170 (NH) and 1660 cm^{-1} (CO). UV ($CHCl_3$) 298 (ε 8300) and 356 nm (3400). MS (75 eV) *m/e* (rel intensity) 518 (M^+; 100), 340(90), and 322(20), ^1H NMR ($CDCl_3$) δ=4.38 (s, NH, 2H) and 6.5—7.6 (m, Ar, 24H).

Found: C, 83.11; H, 5.07; N, 5.29%. Calcd for $C_{36}H_{26}O_2N_2$: C, 83.37; H, 5.05; N, 5.40%.

The reaction mixture obtained by carrying out the reaction in the dark and in the presence of $CBrCl_3$ was treated by the same method as above (Table 1).

*Condensation Reaction of **5** with **2** in the Presence of AcOH.* The reaction was carried out by a method similar to that used for the reaction in the absence of AcOH. The reaction mixture was washed with aq $NaHCO_3$ and water, and dried over Na_2SO_4. The dried CCl_4 solution was then column-chromatographed on silica gel in the same manner as that described above (Table 1).

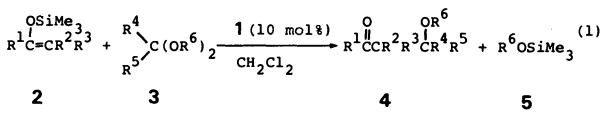
Stereoselective Cross-Aldol Reactions of Silyl Enol Ethers with Acetals Catalyzed by Iodotrimethylsilane[1)]

Hideki SAKURAI,* Koshi SASAKI, and Akira HOSOMI
Department of Chemistry, Tohoku University, Sendai 980

(Received May 20, 1983)

Synopsis. Iodotrimethylsilane catalyzes effectively erythroselective aldol type condensation of silyl enol ethers with acetals.

Recently, much attention has been focused on the stereoselective aldol condensations[2)] in relation to syntheses of acyclic β-hydroxy ketones as a structural unit of natural macrolide antibiotics.[3)] We have found previously that iodotrimethylsilane is an efficient catalyst for the regiospecific allylation of acetals with allylsilanes.[4)] As an extension of the work, we report here that highly nucleophilic silyl enol ethers (**2**), like allylsilanes, undergo the reaction with acetals (**3**) in the presence of a catalytic amount of iodotrimethylsilane (**1**), prepared from hexamethyldisilane and iodine at ambient temperature,[5)] to afford erythro-selective β-alkoxy ketones (**4**) in excellent yield. (Eq. 1).



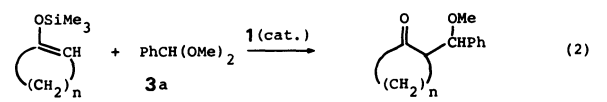
(1)

2 **3** **4** **5**

Results and Discussion

The essential feature of the reaction is rather similar to the trimethylsilyl triflate-catalyzed reaction,[6)] and the results are listed in Table 1.

In all cases, the reaction of **2** with a variety of **3** proceeds very smoothly and completes within 30 min at −78 °C.[7)] It is important to note that the reaction mixture should be hydrolyzed by a saturated hydrogen sodium carbonate solution at −78 °C. One of the important features of the present reaction is the erythro selective aldol condensation. For example, reactions of benzaldehyde dimethyl acetal (**3a**) with silyl enol ethers, **2a** and **2b**, derived from cyclopentanone and cyclohexanone, gave mixtures of erythro and threo derivatives in a ratio of 99 : 1 and 95 : 5, respectively. (Eq. 2).

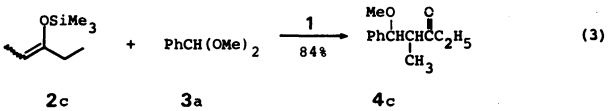


(2)

2a, n = 3 — **4a**, 87%; Erythro:Threo = 99:1

b, n = 4 — b, 89%; Erythro:Threo = 95:5

On the other hand, 3-trimethylsiloxy-2-pentene (**2c**, *E* : *Z*=21 : 79), prepared by Et_3N/Me_3SiCl in DMF,[8)] gave a 57 : 43 mixture of erythro and threo derivatives. (Eq. 3).



(3)

2c **3a** **4c**

E:Z = 21:79 — Erythro:Threo = 57:43

Table 1. Reactions of silyl enol ethers (**2**) with acetals (**3**) and orthoformates (**6**) catalyzed by iodotrimethylsilane (**1**) in dichloromethane at −78 °C

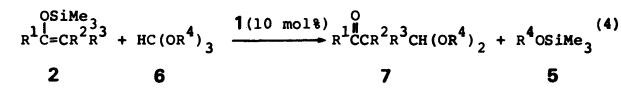
2a	$PhCH{=}CHCH(OMe)_2$ (**3d**)	50		82 (80/20)
2a	$CH_3CH_2CH(OCH_2Ph)_2$	90		65
2a	$(CH_3)_2C(OMe)_2$ (**3e**)	50		90
2a	$CH(OMe)_3$ (**6a**)	60		81
$OSiMe_3$ (**2b**)	**3a**	60	 (**4b**)	89 (95/ 5)
2b	$(CH_3)_2CHCH_2(OMe)_2$	25		70 (79/21)
2b	**3b**	30		87 (86/14)
2b	**3d**	60		92 (89/11)
2b	**3e**	60		82
2b	**6a**	60		80
$OSiMe_3$ (**2c**)	**3a**	55		84 (57/43)
2c	**3e**	60		86
$OSiMe_3$ Ph (**2d**)	**3a**	40		90
2d	**3c**	50		90
2d	**3e**	50		84
2d	**6a**	60		88
2d	$CH(OEt)_3$	60		87

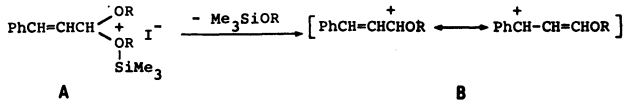
a) Yields after isolation by TLC. b) Determined by NMR. Erythro and threo derivatives (**4**) were characterized by comparing the vicinal coupling constants (J_{ab}). Observations that J_{threo} of *e.g.* **4b** (13 Hz) is greater than $J_{erythro}$ (4 Hz) is in accordance with other erythro–threo systems.[6,10)] c) At −35 °C.

It is notable that orthoformate (**6**) reacts with **2** by catalysis of **1** to give β-keto acetal (**7**). No further reaction with the resulting β-keto acetal occurred. Apparently, the reaction of **7** with **2** is slower than the reaction of **6**.



2 **6** **7** **5**

From the mechanistic point of view, it is interesting that reactions with α,β-unsaturated acetals catalyzed by **1** proceed very selectively on the acetal carbon (see Table 1). This fact suggests strongly that a silyloxonium ion A, not a carbenium ion like B, is the most important intermediate in the reaction.



A **B**

Experimental

Reactions Summarized in Table 1. The following procedure is typical. To a mixture of **2** (1.2 mmol) and **3** (or **6**) (1.0 mmol) in dry dichloromethane (2 ml) was added iodotrimethylsilane (0.02 g, 0.1 mmol) by a syringe under nitrogen at −78 °C. The reaction mixture was stirred for given conditions in Table 1 and hydrolyzed with a saturated solution of hydrogen sodium carbonate at −78 ° C.After usual work-up, the crude product was purified by preparative thin-layer chromatography on silica gel.[9]

Reactivity of Aromatic *o*-Hydroxy Oximes. II. The Use of Esters of Aromatic *o*-Hydroxy Oximes in Peptide Synthesis

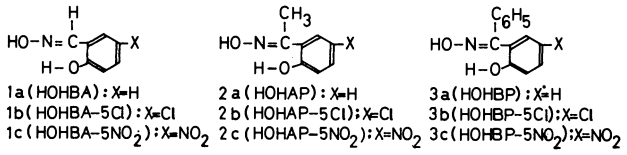
Ikuo HAYASHI* and Kiyoshi SHIMIZU

Research and Development Laboratory of Nitto Boseki Co., Ltd., Fukuyama-cho, Koriyama 963

(Received March 1, 1983)

Synopsis. Esters of *N*-protected amino acids with *o*-hydroxybenzaldehyde oxime, *o*-hydroxyacetophenone oxime, *o*-hydroxybenzophenone oxime, and their 5-Cl and 5-NO_2 derivatives were prepared by several methods. Various dipeptide derivatives with high purity were obtained in good yield by use of these active ester reagents.

There are numerous reports on the use of oxime compounds and their derivatives for peptide synthesis.[1,2] The reactivity of oxime esters with an amine component is generally low.[2] Therefore, weak acid catalysts are often used to enhance the reactivity of oxime esters. We reported in the previous paper[3] that esters with *N*-(benzyloxycarbonyl)glycine (Z–Gly) of aromatic *o*-hydroxy oximes, *e.g.*, *o*-hydroxybenzaldehyde oxime (HOHBA), *o*-hydroxyacetophenone oxime (HOHAP), *o*-hydroxybenzophenone oxime (HOHBP), and their 5-Cl and 5-NO_2 derivatives of (*E*)-configuration, react rapidly with benzylamine without use of any acids in THF at 30 °C. In the present study, we report that some new esters of the above-mentioned oximes with various acylamino acids have been prepared and that these oxime esters are very effective for peptide synthesis.



Results and Discussion

The active esters of *N*-protected amino acids were prepared from the amino acids and the oxime **1**, **2**, or **3** (A) by a direct condensation using dicyclohexylcarbodiimide (DCC), (B) with carbonic carboxylic anhydride, or (C) with acid chloride. Method (A) appears to be more useful than the others because of its mild reaction conditions.

Table 1. Oxime esters of amino acids

Ester[a]	Method	Yield %	Mp θ_m/°C	$[\alpha]_D^{24}$/° (*c* 1, DMF)

Boc–Lys(Z)–OHAP	(A)	72.8	105—107	−32.9
Nps–Pro–OHAP	(A)	85.5	152.5—154	−193.5

a) Abbreviations were used in the same mode as in the previous paper[3] and all oxime esters were characterized by elemental analysis. b) In $CHCl_3$.

The active esters of the oximes are shown in Table 1 except those[3] of Z–Gly previously reported. Although the oximes themselves have a bifunctional nature, only the hydroxyimino group in the molecule is esterified with *N*-protected amino acids.[3] Therefore, it is not necessary to protect the phenolic hydroxyl group for the preparation of these esters. When **4** is prepared by these methods, alkaline washing of the reaction mixture cannot be applied in the case of the reaction with **1c**, **2c**, or **3c** because of the existence of *o*-hydroxyl group which is considerably acidic, and therefore the procedure for the isolation of **4** requires some considerations.

The results are summarized in Table 2. The yield of reaction products was always good and their purity was also quite satisfactory. The most significant advantage of our oxime ester method is that no addition of acid

4

catalyst is required for enhancing the reactivity of **4**, since the aminolysis accelerates by the favorable mechanism of intramolecular acid-catalysis.[3]

With this new coupling method, the reaction of **4** with the amine component can progress successfully without any addition of weak acid catalyst. To check the reactivity of **4**, the reaction of Z–Gly–OHAP (**4**; $R=CH_3$, $X=H$)[3] and Z–Gly–OAP (**5**; $R=CH_3$, $X=H$)[2] with ethyl glycinate (Gly–OEt) in THF at room temperature was carried out with a reaction time of 60 min. The yields of Z–Gly–Gly–OEt obtained were 75 and 35%, respectively. From the above instances, a period of one night may be regarded as a sufficient reaction time for the completion of the condensation. The dipeptide derivative from a reaction mixture is easily isolated by alkaline washing in the usual fashion, since the free oxime has an acidic *o*-hydroxyl group, especially with the 5-NO_2 derivatives. Because of high reactivity of **4** and easy availability of the peptide derivatives, these esters appear to be quite useful for peptide synthesis.

Experimental

The purity of products was tested by TLC.[3] The IR spectra of all compounds were determined by a JASCO A-102 spectrophotometer. The specific rotations were measured with a JASCO automatic polarimeter DIP-140. All the amino acids except Gly were of L-configuration. All the oximes and active esters **4** were prepared as described in the previous paper.[3] *N*-Benzyloxycarbonyl amino acids and *N*-(*t*-butoxycarbonyl) (Boc) amino acids were prepared in the usual way. *N*-(*o*-Nitrophenylsulphenyl) (Nps) amino acids were prepared as described by Zervas *et al.*[4]

Preparation of Dipeptides. Twenty mmol of *N*-protected amino acid oxime ester **4**, 20 mmol of hydrohalide of amino acid alkyl ester, and 20 mmol of triethylamine were dissolved in THF or DMF (about 150 ml). The mixture was stirred overnight at room temperature and then the solvent was removed. The crude products was dissolved in ethyl acetate. The solution was washed successively with 5% citric acid, 1 mol dm^{-3} $NaHCO_3$, and water, and dried over magnesium sulfate. The ethyl acetate was removed *in vacuo*. The resulting residue was triturated with petroleum ether to give a solid. The purified product was recrystallized from an appropriate solvent.

Comparison of Reactivity between Z–Gly–OHAP and Z–Gly–OAP. Triethylamine (1.4 ml, 10 mmol) was added to a suspension of Gly–OEt·HCl (1.40 g, 10 mmol) in THF (50 ml) with stirring. After 15 min, Z–Gly–OHAP (3.42 g, 10 mmol) was added to the solution at room temperature. After 60 min, a cold 2 mol dm^{-3} HCl was added to the mixture in order to terminate the coupling, and the mixture was worked up similarly to the above procedure. A recrystallization of crude product from ethyl acetate-petroleum ether gave Z–Gly–Gly–OEt: 2.21 g; mp 79.5—80.5 °C. The reaction of Z–Gly–OAP with Gly–OEt was carried out simultaneously under the same conditions with the result: 1.04 g, mp 76—78.5 °C.

Synthesis of Cyclic Imines Having Conjugated Exocyclic Double Bond

Yujiro NOMURA,* Takashi BANDO, Yoshito TAKEUCHI, and Shuji TOMODA
Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 113

(Received April 15, 1983)

Synopsis. Cyclic imines with conjugated exocyclic double bond have been synthesized by the reaction of 1-pyrroline trimer or 2,3,4,5-tetrahydropyridine trimer with various aldehydes in methanol in moderate to decent yields.

Cyclic amines possessing the general structure **1** and their quaternary ammonium salts have attracted attention because of their intriguing pharmacological activities. In particular, the five-membered analogs **1a**, in which both R^1 and R^2 are phenyl, have been known to exhibit potent antihistamine and anticholine activities and indeed some of them have been subjected to clinical applications.[1)]

The synthesis of these compounds (**1**) heavily depends on the availability of the unsaturated imines (**2**) for which a number of synthetic methods have been reported to date.[2)] Herein we wish to describe a novel method for the synthesis of **2**.

The new method rests on ready availability of 1-pyrroline trimer (**3a**), the synthesis of which we reported some time ago,[3)] and 2,3,4,5-tetrahydropyridine trimer (**3b**).[4)] We have now found that these imines react with a variety of aldehydes to give **2** in the yields shown in Table 1.

a) In $CDCl_3$ relative to TMS.

The yields of the reactions involving benzaldehyde (entries 2—5) were about 40% at reflux or room temperature, but the presence of molecular sieves did improve the yield of room temperature reaction (entry 5). It is clear that among para-substituted benzaldehydes (entries 6—11), the yield was significantly increased with electron-withdrawing substituents. As seen in entry 12, the reaction is equally effective for aliphatic aldehydes. The best yield was obtained with 2-furaldehyde (entry 13).

The structures of these conjugated imines (**2**) were elucidated by spectral data (MS, IR, ^{1}H- and ^{13}C-NMR) as well as by combustion analysis. The presence of conjugated imine moiety was inferred from the following spectral evidence; a strong to medium IR band between 1592 and 1640 cm^{-1}, a low-field doublet near δ 165 in ^{13}C NMR[5] and a characteristic triplet ($\delta\approx8$, $J=$ 2.5—2.7 Hz) in ^{1}H NMR spectra. A small coupling between allylic methylene protons ($\delta\approx2.7$, m, 2H) and the exocyclic olefin proton ($\delta\approx6.5$, t, $^4J=2.5$—2.7 Hz) suggested the trans-relationship of these protons.[6] The spectroscopic data together with analytical results are summerized in Table 2.

Experimental

Methanol was purified by distillation over sodium under dry nitrogen atmosphere. All reactions were performed under dry nitrogen. Spectral data were obtained by the following spectrometers; Hitachi-Perkin Elmer RMU-6D mass spectrometer, JASCO DS-403G IR spectrometer, JEOL FX-90Q spectrometer, JEOL MH-100 spectrometer. All chemical shifts are reported in δ relative to internal TMS in $CDCl_3$.

General Procedure for the Preparation of **2**. A mixture of **3a** or **3b** (2 mmol) and an aldehyde (6 mmol) in methanol (20 ml) was stirred magnetically in the presence or absence of 3A molecular sieves under the conditions indicated in Table 1. After having been stirred for appropriate period (see Table 1), it was concentrated *in vacuo* and the residue purified by silica gel column chromatography. The product was further purified by distillation, sublimation or recrystallization if necessary.

Studies on Bile Salt Solutions. Part 2. Acid Catalyzed Hydrolysis of Trimethyl Orthobenzoate in Solutions of Glycine and Taurine Conjugated Bile Salts

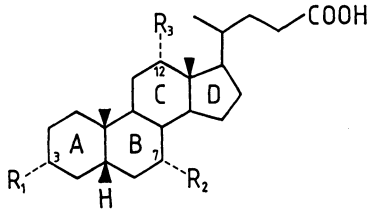
Charmian J. O'Connor* and Beng Tatt Ch'ng
Chemistry Department, University of Auckland, Private Bag, Auckland, New Zealand

(Received November 1, 1982)

Synopsis. The reactivity of trimethyl orthobenzoate has been studied, at 310.5 K, in solutions of the glycine and taurine conjugates of the cholanic acids. The rate-concentration profiles are characterized by peaks and troughs which coincide with discontinuities in the slopes of the surface tension-concentration profiles.

Trimethyl orthobenzoate **1** is one of the few substrates whose acid catalyzed hydrolysis is subject to catalysis by anionic surfactants.[1-6] The kinetic effects are accentuated when the hydrophobic interactions between **1** and surfactants are accentuated. Increasing the hydrocarbon chain length of sodium alkyl sulfates causes a more dramatic increase in rate.[1]

Bile salts **2** are important surfactants in the biological system and they offer an attractive opportunity for



correlating chemical composition with micellar properties in a series of molecules differing only slightly in their chemical structure. It is therefore surprising that only five publications can be identified[7-11] which report kinetic investigations by these amphiphiles in aqueous solution in the absence of enzymes.

We now report on the reactivity of **1** in solutions of the taurine and glycine conjugates of trihydroxy- and dihydroxy cholates; taurocholate, TC, and glycocholate, GC, ($R_1=R_2=R_3=OH$); taurochenodeoxycholate, TCDC, and glycochenodeoxycholate, GCDC, ($R_1=R_2=OH$, $R_3=H$); and taurodeoxycholate, TDC, and glycodeoxycholate, GDC, ($R_1=R_3=OH$, $R_2=H$). In contrast to the literature studies[7-11] on reactivity in bile salt solutions which have concentrated, for the most part, on concentrations greater than CMC and in solutions of alkaline pH where all the bile salts are converted to the anionic form, we have used solutions of pH<7. Inevitably this has placed a relatively low limit on the maximum concentration able to be solubilized so that many of our data refer to concentrations well below CMC.

Experimental

Materials. The bile salts and bile acids were Sigma products. Their purity was monitored by TLC analysis using the solvent system of acetone: dibutyl ether in the ratio 3:7 and development in an iodine chamber. Acetic acid used for preparation of buffer solutions was freshly distilled. All water was triply distilled and the pH of each solution was measured, using as a standard BDH buffer for blood pH determination with pH 6.840 at 311 K, with a Radiometer PHM 4d pH meter and a dual walled sample holder held at 310.5 K by means of a Grant thermocirculator. Trimethyl orthobenzoate was prepared according to the method of McElvain and Venerable[14] (Bp 387—388 K at 25 mmHg).

Measurement of Rate Constants of Hydrolysis. The hydrolysis of **1** was followed by measuring the appearance of methyl benzoate at 228 nm. (Under acidic conditions methyl benzoate is converted slowly to benzoic acid but the extinction coefficients of the intermediate and final products of hydrolysis are identical at 228 nm.) The reaction was initiated by injecting 8—20 μl of a 5.8×10^{-4} mol dm^{-3} solution of **1** in absolute ethanol into the contents of the reaction cell which had previously been brought to equilibrium temperature (310.5 K) in the cell compartment of a Cary 219 recording Spectrophotometer. Pseudo first order rate constants were calculated from the absorbance data on a Burroughs B6700 or Commodore 3032 minicomputer. Rate data were duplicated and showed a reproducibility of $<+2\%$.

Results and Discussion

The pseudo first order rate constant, k_ψ, for hydrolysis of **1** in acid solution is linearly dependent on the hydronium ion concentration. At 310.5 K in 0.03 mol dm^{-3} sodium acetate buffer the values of k_ψ are 2.07×10^{-2} and 0.070×10^{-2} s^{-1} at pH values of 4.07 and 5.47 respectively. All rate measurements described in this investigation were made within this pH range and using this buffer medium and temperature.

Figures 1—3 show the values of k_ψ for hydrolysis of **1** in the bile salt solutions. Superimposed on all the rate concentration profiles are plots of the surface tension values of these same bile salt solutions measured under identical conditions of pH and temperature. Determination of these surface tension values has been reported separately.[12]

In contrast to the relatively simple multiphasic rate-concentration profile reported for hydrolysis of **1** in sodium alkyl sulfate solutions[1] the profiles presented here are quite complicated, being characterized by plateaux, peaks and troughs. Each change in slope in the rate-profile is matched by a discontinuity in the slope of the corresponding surface tension-profile.

We were able to explain the surface tension data by use of a multi-equilibrium model involving the step-wise aggregation of monomers or small oligomers. We believe that micelle formation of bile salts passes through several successive distinct stages, each one being characterized by constant properties of the solute. Our rate data support this postulate, for it seems that, at the pH values we have used, the association process in bile salts is one of multiple association rather than a monomer$\rightleftharpoons$*n-mer* equilibrium and that each of the small aggregates has its own characteristic binding constant leading to an individual kinetic identity, as well as an unique ability to modify the surface tension properties of the solvent.

However, the changes we have observed are small. The maximum percentage change observed was

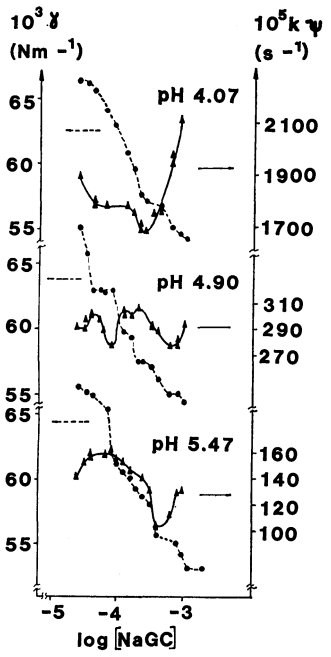


Fig. 1.

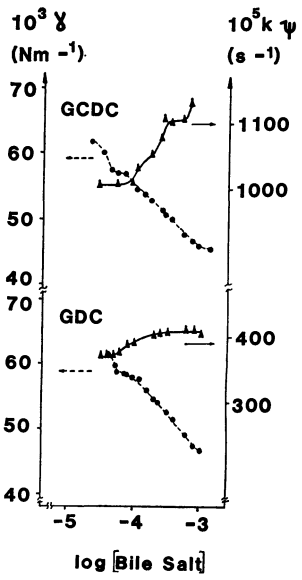

Fig. 2.

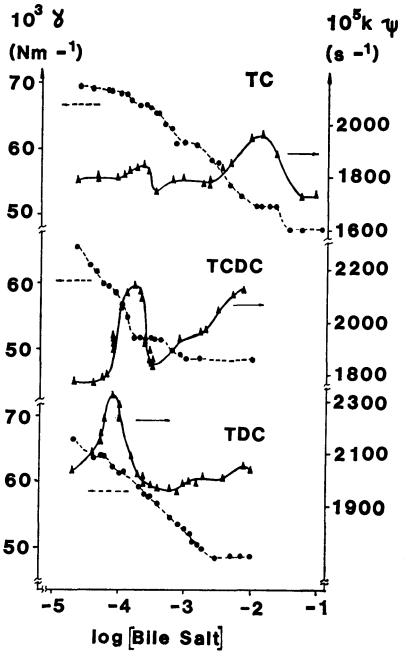

Fig. 3.

Fig. 1—3. The pseudo first order rate constant of hydrolysis, k_ψ, of trimethyl orthobenzoate (▲ and solid line) and the equilibrium surface tension values, γ, (● and broken line) in solutions of bile salts in 0.03 mol dm^{-3} acetate buffer at 310.5 K. Fig. 1, sodium glycochoate at pH values of 4.07, 4.90, and 5.47 (43%, 10%, and 3% protonation respectively); Fig. 2, sodium glycochenodeoxycholate at pH 4.34 and sodium glycodeoxycholate at pH 4.77 (both 43% protonated); Fig. 3, sodium taurocholate, sodium taurochenodeoxycholate and sodium taurodeoxycholate at pH 4.09.

+100% for GC at pH 5.47 and TDC was the only other salt to show a significant increase in rate (+22%) at its maximum value. At the minimum values of k_ψ all the salts except TDC were slightly inhibitory (the maximum inhibition of −16% was observed for GC at pH 4.07).

The pK_a values for GC, GDC and GCDC range from 3.8—4.1, 4.7—4.8, and 4.2—4.3 respectively[13] while those for the taurine conjugates have pK_a values less than 2. This means that a substantial portion of the glycine conjugates is present in the undissociated form at the pH values we have used (43%, 10%, and 3% protonation at pH values of 4.07, 4.90, and 5.47 respectively) while the taurine conjugates will be 100% deprotonated. Increasing the pH from 4.07 to 4.47 increases the value of k_2 (min) for GC (where $k_2=k_\psi/[H_3O^+]$ is the second order rate constant) from 198 to 301 dm^3 mol^{-1} s^{-1} and the value of k_2 (max) from 248 to 472 dm^3 mol^{-1} s^{-1}. Thus the presence of the acid form of the bile salt inhibits the rate of hydrolysis. The bile acids are sparingly soluble in water and cannot themselves form micelles, but they are solubilized as "mixed" micelles of anion and acid. Solubilization of free acid in the mixed micelles will lessen the hydrophobic environment and thereby inhibit the catalytic efficiency for hydrolysis of **1**.

The hydrophobicity of the bile salts increases in order TC<TCDC<TDC and this is also the order of increasing values of k_2 (max), *i.e.* the more hydrophobic the surfactant, the more of **1** is in the micellar phase and the greater is the catalysis. However in these micellar systems the aggregation number, the pK_a value and the binding constant of substrate to micelle will depend very delicately upon the reaction conditions and these will also affect the rate of hydrolysis. In the light of these factors further discussion of the small rate enhancements does not seem warranted.

Equipment grants from the New Zealand Universities' Grants Committee and the University of Auckland are gratefully acknowledged.

Light-induced Redox Characteristics of [Tetrakis(4-methylpyridyl)-porphyrinato]manganese(III)

Koushin TAKAHASHI,* Teruhisa KOMURA, and Hiroto IMANAGA
Faculty of Technology, Kanazawa University, Kanazawa 920

(Received March 10, 1983)

[Tetrakis(4-methylpyridyl)porphyrinato]manganese(III) (Mn^{III}(tmpp)) undergoes reversible one-electron transfer reactions in aqueous solutions. The half-wave potential of $Mn^{III/II}$(tmpp) redox couple is −0.21 V (*vs.* 3.33 M KCl, AgCl/Ag) between pH 4 and 12. On the other hand, the half-wave potential of $Mn^{IV/III}$-(tmpp) redox couple becomes less positive with increasing pH in alkaline solution. A small amount of methylviologen cation radical ($MV^{+\cdot}$) is built up by irradiating with visible light an alkaline solution containing Mn^{III}(tmpp), methylviologen (MV^{2+}), and sacrificial electron donors. The formation of $MV^{+\cdot}$ is attributed to either the reduction of photoexcited Mn^{III}(tmpp) ($^*Mn^{III}$(tmpp)) with an electron donor or the oxidation of $^*Mn^{III}$(tmpp) with MV^{2+}.

Much attention has been drawn to light-induced electron transfer reactions sensitized by tris(2,2′-bipyridyl)ruthenium(II) complex and metalloporphyrins from the standpoint of conversion of solar to chemical energy.[1–5] For example, MV^{2+} is reduced to $MV^{+\cdot}$ under irradiation with light in the presence of tris(2,2′-bipyridyl)ruthenium(II) complex and ethylenediaminetetraacetic acid (EDTA),[1] and colloidal platinum catalyzes the hydrogen generation from water in this system.[6,7] Ruthenium dioxide catalyzes the oxygen generation when it substitutes for EDTA. On the other hand, a Mn-protein possibly catalyzes the oxygen generation in the photosynthesis, but the mechanism has hardly been known. Calvin[8] has proposed a general scheme for the photochemical generation of oxygen sensitized by manganese porphyrin. Harriman *et al.*[9–11] reported on the photoredox characteristics of water-soluble Mn(III) porphyrin. The electron transfer reactions sensitized by these compounds are probably very complex since Mn can take several oxidation number.

We previously reported on the redox and photoreductive properties of Mn^{III}(tmpp).[13] This paper presents the light-induced redox characteristics of Mn^{III}(tmpp) in the presence of MV^{2+} and electron donors.

Experimental

The preparation of Mn^{III}(tmpp) was described in the previous paper.[13] [Tetrakis(4-methylpyridyl)porphyrinato]-zinc(II) (Zn(tmpp))[14] and tris(2,2′-bipyridyl)ruthenium(II) chloride ($[Ru(bpy)_3]Cl_2$)[15] were prepared according to literature methods. Sodium acetate, sodium borate, and potassium phosphate (special grade) were recrystallized from water, and sodium sulfate (special grade) was recrystallized three times from water. Methylviologen dichloride (special grade) was recrystallized from ethanol and dried for 7 h at 60 °C *in vacuo*. Other chemicals (reagent grade) were used without further purification. All solutions were prepared with doubly distilled water.

Cyclic voltammetric experiments were performed in a purified nitrogen atmosphere by using a potentiostat (Nikko Keisoku NPGS-301), a potential sweeper (Nikko Keisoku NPG-2), and a three-electrode configuration. A Pt-wire was used as the warking electrode, a Pt-coil as the counter-electrode, and a commercially available 3.33 M KCl, AgCl/Ag electrode as the reference electrode (1 M = 1 mol dm^{-3}). An X-Y plotter (Riken Denshi Co., Ltd. Model F-3B) was used to record current-voltage curves. Half-wave potentials were measured as the average of cathodic and anodic peak potentials.

The pH of solutions was adjusted to a desired pH with 0.01 M acetate, phosphate, or borate buffer solution. The N_2-purged sample solution was transferred to an optical glass cell with a 1 cm-photopath length and a stopper in a nitrogen atmosphere. A 500 W Xenon arc lamp (Ushio Electric, Co., Ltd. UXL-500D-O) was used for steady-state irradiation experiments. The light was passed through a cut-off filter (Toshiba L-39) and water (1 cm), and focused onto a sample cell thermostated at 25 °C. The sample solution was continuously stirred with a magnetic stirrer throughout the irradiation period. Absorption spectra were measured with a Hitachi Model 124 spectrophotometer.

Results and Discussion

Cyclic Voltammetry of Mn^{III}(tmpp). [Tetrakis(4-methylpyridyl)porphyrinato]manganese(III) was reduced to Mn^{II}(tmpp) with sodium dithionite in a deoxygenated aqueous solution between pH 4 and 12, and was oxidized to Mn^{IV}(tmpp) with potassium peroxodisulfate, sodium hypochlorite, or pentaamminechlorocobalt(III) chloride between pH 9 and 12.[9,13] Table 1 shows the molar extinction coefficients for the absorption peaks of Mn^{II}(tmpp), Mn^{III}(tmpp), and Mn^{IV}(tmpp) in aqueous solution.[13]

Figure 1 shows a typical cyclic voltammogram of Mn^{III}(tmpp) in 0.2 M Na_2SO_4 aqueous solution at pH 12.0. The current-voltage curve shows two reversible waves. The following electrode reactions probably occur:

$$Mn^{III}(tmpp) + e^- \rightleftharpoons Mn^{II}(tmpp), \quad (1)$$

$$Mn^{IV}(tmpp) + e^- \rightleftharpoons Mn^{III}(tmpp). \quad (2)$$

TABLE 1. THE MOLAR EXTINCTION COEFFICIENTS AT ABSORPTION PEAK (λ_{max}/nm) OF Mn(tmpp) IN AQUEOUS SOLUTION[a]

	pH	λ_{max}/nm	ε/M^{-1} cm^{-1}
Mn^{II}(tmpp)	6.0	449	1.92×10^{5} [b]
Mn^{III}(tmpp)	6.0	463	1.59×10^{5}
Mn^{IV}(tmpp)	10.0	429	9.80×10^{4} [c]

a) From Ref. 13. b) Mn^{II}(tmpp) was formed by the reduction of Mn^{III}(tmpp) with $Na_2S_2O_4$. c) Mn^{IV}-(tmpp) was formed by the oxidation of Mn^{III}(tmpp) with $[CoCl(NH_3)_5]Cl_2$.

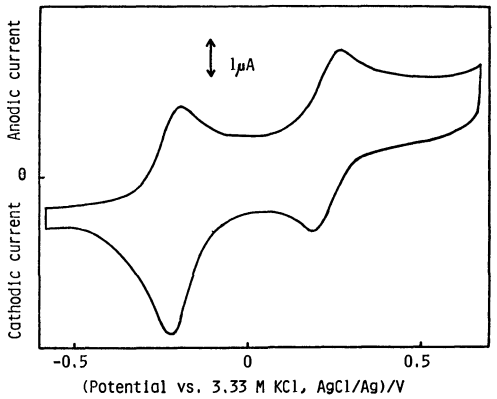

Fig. 1. A typical cyclic voltammogram of 1.0×10^{-3} M Mn^{III}(tmpp) in 0.2 M Na_2SO_4 aqueous solution at pH 12.0 (scan rate 20 mV/s).

TABLE 2. HALF-WAVE POTENTIALS/V (*vs.* 3.33 M KCl AgCl/Ag) OF $Mn^{III/II}$(tmpp) AND $Mn^{IV/III}$(tmpp) REDOX COUPLES IN 0.2 M Na_2SO_4 AQUEOUS SOLUTION AT ROOM TEMPERATURE

pH	$E_{1/2}$(III/III)	$E_{1/2}$(IV/III)
4.1	−0.20	—
5.6	−0.22	—
10.2	−0.21	0.45
10.7	−0.20	0.38
12.0	−0.22	0.23

The half-wave potentials of the two redox couples are given in Table 2. The half-wave potential of Reaction 1, $E_{1/2}$(III/II), is −0.21 V (*vs.* AgCl/Ag) between pH 4 and 12, but that of Reaction 2, $E_{1/2}$(IV/III), becomes less positive with increasing pH in alkaline solution. No anodic peak of Mn^{III}(tmpp) was observed below pH 8 because of the oxidation of water.

Photoreduction of Mn^{III}(tmpp). When a solution of Mn^{III}(tmpp) was irradiated with visible light in the presence of an electron donor (D) such as EDTA, triethanolamine (TEOA), triethylamine (TEA), or nicotine (NT), Mn^{III}(tmpp) was reduced to Mn^{II}(tmpp). Figure 2 shows the pH dependence of the concentration of Mn^{II}(tmpp) produced by irradiating an aqueous solution containing Mn^{III}(tmpp) (9.0×10^{-6} M) and EDTA (1×10^{-4} M) or TEOA (0.01 M).[13] The concentration of Mn^{II}(tmpp) ($C_{Mn^{II}}$) was estimated from the following equation:

$$C_{Mn^{II}} = (A_{449}-A_{449}^{\circ})/(\varepsilon_{449}^{II}-\varepsilon_{449}^{III}), \quad (3)$$

where A_{449}° and A_{449} are the absorbances at 449 nm before and after irradiation, and ε_{449}^{II} and ε_{449}^{III} are the molar extinction coefficients at 449 nm of Mn^{II}-(tmpp) and Mn^{III}(tmpp), respectively. As shown in Fig. 2, Mn^{III}(tmpp) was almost completely reduced to Mn^{II}(tmpp) with EDTA between pH 6 and 10, but only at pH 10 with TEOA. Figure 3 shows the concentration of Mn^{II}(tmpp) produced by irradiation for 30 min at different concentrations of electron donor at pH 10.0. In a high concentration (0.01 M) of EDTA, the chromophore was partly bleached. The reducing power of electron donors can be regarded as being in the order EDTA>TEOA>TEA>NT.

Total concentration of Mn(tmpp): 9.0×10^{-6} M.
○, 1×10^{-4} M EDTA; △, 0.01 M TEOA.

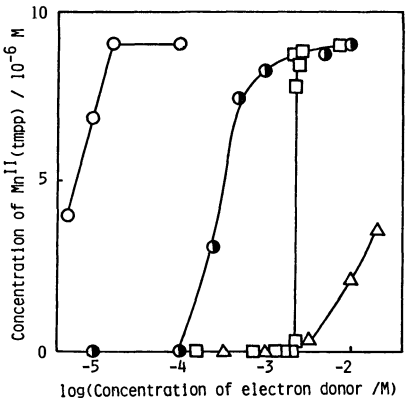

Fig. 3. The concentration of Mn^{II}(tmpp) produced by irradiation for 30 min at different concentrations of electron donors at pH 10.0.
Total concentration of Mn(tmpp): 9.0×10^{-6} M.
○, EDTA; ◑, TEOA; △, NT; □, TEA.

The following reactions can be proposed as the mechanism of the photoreduction of Mn^{III}(tmpp):

$$Mn^{III}(tmpp) \xrightarrow{h\nu} {}^{*}Mn^{III}(tmpp), \quad (4)$$

$$^{*}Mn^{II}(tmpp) + D \longrightarrow Mn^{II}(tmpp) + D_{ox}, \quad (5)$$

or

$$^{*}Mn^{III}(tmpp) + Mn^{III}(tmpp) \longrightarrow Mn^{II}(tmpp) + Mn^{IV}(tmpp), \quad (6)$$

$$Mn^{IV}(tmpp) + D \longrightarrow Mn^{III}(tmpp) + D_{ox}, \quad (7)$$

where D_{ox} is an oxidative decomposition product of D. Reaction 5 means that an excited Mn^{III}(tmpp) ($^{*}Mn^{III}$(tmpp)) is reduced to Mn^{II}(tmpp) with D. Reaction 6 means that $^{*}Mn^{III}$(tmpp) is reduced or oxidized with a ground-state Mn^{III}(tmpp), and Reaction 7 means that Mn^{IV}(tmpp) is scavenged with D.

Porphyrinatomanganese(III)-sensitized Reduction of MV^{2+} with Strong Electron Donors. In an aqueous solution containing Mn^{III}(tmpp) (2.0×10^{-5} M), MV^{2+} (2.0×10^{-3} M), and EDTA (0.01 M) between pH 5 and 11, the color of the solution did not change in the dark, but under irradiation it rapidly changed from orange to yellow green and finally into green. Figure 4 shows

the change in the absorption spectra of the solution as a function of irradiation time at pH 10.9. The absorption peaks at 463 and 570 nm of Mn^{III}(tmpp) rapidly disappeared under irradiation, and the new peaks at 395, 451, 579, and 606 nm appeared. The peaks at 395 and 606 nm originate from MV^{+},[16] and those at 451 and 579 nm from Mn^{II}(tmpp).[13] As shown in Fig. 4, Mn^{III}(tmpp) was almost completely reduced to Mn^{II}(tmpp) under irradiation. Because MV^{2+} was not photoreduced to MV^{+} in the absence of Mn^{III}(tmpp) or EDTA, Mn^{III}(tmpp) acts as a sensitizer and EDTA as an electron donor. Figure 5 shows the concentration of MV^{+} produced by irradiation for 30 min an aqueous solution containing Mn^{III}(tmpp) (2.0×10^{-5} M), MV^{2+} (2.0×10^{-3} M), and EDTA or TEOA (0.01 M). The concentration of MV^{+} ($C_{MV^{+}}$) was estimated on the following equation from the measurements of absorbance at 606 nm (A_{606}):

$$C_{MV^{+}} = (A_{606} - C_t\varepsilon_{606}^{II})/\varepsilon_{606}, \quad (8)$$

where C_t is the total concentration of Mn(tmpp), ε_{606}^{II} (7.9×10^{3} M^{-1} cm^{-1}) and ε_{606} (1.37×10^{4} M^{-1} cm^{-1})[18] are the molar extinction coefficients at 606 nm of Mn^{II}(tmpp) and MV^{+}, respectively. As shown in Fig. 5, a small amount of MV^{+} was built up between pH 5 and 8 in the presence of EDTA, but not in the presence of TEOA. On the other hand, above pH 9 MV^{+} was formed in considerable quantity in the presence of both the electron donors. This can be attributed to the pH dependence of the reducing powers of EDTA and TEOA. Their reducing powers increase with an increase in pH because the oxidative decompositions of EDTA and TEOA are attended by the formation of proton.[17,18] It is inferred from a comparison of Fig. 5 with Fig. 2 that a certain amount of MV^{+} is built up only when Mn^{III}(tmpp) is photoreduced to Mn^{II}(tmpp) with an electron donor. Figure 6 shows the concentration of MV^{+} produced by irradiation for 30 min and the turnover number of Mn^{III}(tmpp) at different concentrations of Mn^{III}(tmpp) at pH 10.1. The turnover number (N) was calculated by the following equation:

$$N = C_{MV^{+}}/C_t. \quad (9)$$

The concentration of MV^{+} rapidly increased with an increase in the concentration of Mn^{III}(tmpp) below 2×10^{-6} M, and the maximum turnover number of Mn^{III}(tmpp) was 37 at 5×10^{-7} M Mn^{III}(tmpp). Above 1×10^{-6} M Mn^{III}(tmpp), a photoexcited Mn(tmpp) is possibly self-quenched at high concentrations of Mn(tmpp).

The reaction scheme in Fig. 7 can be proposed as the mechanism for the Mn^{III}(tmpp)-sensitized reduction of MV^{2+} with strong electron donors. An excited Mn^{III}(tmpp) can first be reduced to Mn^{II}(tmpp) with an electron donor (Reaction 5). Furthermore, an excited Mn^{II}(tmpp) ($*Mn^{II}$(tmpp)) can be oxidized to

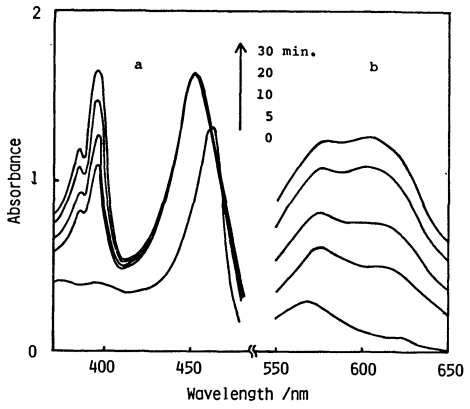

Fig. 4. Absorption spectral profiles showing the appearance of MV^{+} and Mn^{II}(tmpp) as a function of irradiation time at pH 10.9.
a, The concentrations of Mn^{III}(tmpp), MV^{2+}, and EDTA are 9.0×10^{-6}, 5.3×10^{-4}, and 0.01 M, respectively. b, The concentrations of Mn^{III}(tmpp), MV^{2+}, and EDTA are 2.0×10^{-5}, 2.1×10^{-3}, and 0.01 M, respectively.

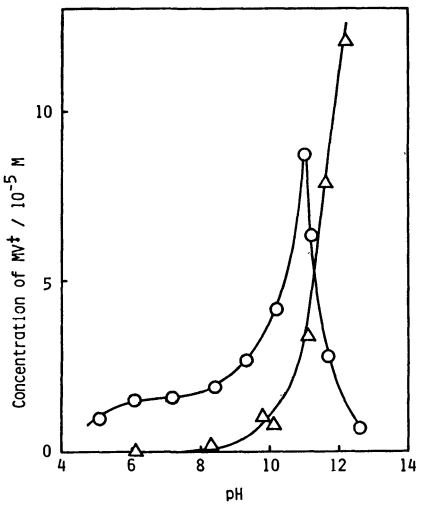

Fig. 5. The pH dependence of the concentration of MV^{+} produced by irradiation for 30 min.
Concentration of Mn^{III}(tmpp): 2.0×10^{-5} M. Concentration of MV^{2+}: 2.0×10^{-3} M. ○, 0.01 M EDTA; △, 0.01 M TEOA.

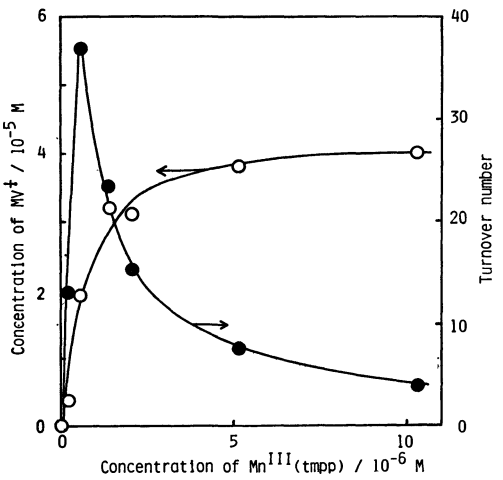

Fig. 6. The concentration of MV^{+} produced and the turnover number of Mn^{III}(tmpp) at different concentrations Mn^{III}(tmpp) at pH 10.1.
Concentration of MV^{2+}: 1.8×10^{-3} M. Concentration of EDTA: 0.01 M. Irradiation time: 30 min.

$Mn^{III}(tmpp)$ with MV^{2+}, and MV^{+} can be produced:

$$Mn^{II}(tmpp) \xrightarrow{h\nu} {}^{*}Mn^{II}(tmpp), \quad (10)$$

$$^{*}Mn^{II}(tmpp) + MV^{2+} \longrightarrow Mn^{III}(tmpp) + MV^{+}. \quad (11)$$

MV^{2+} is not reduced with the ground-state $Mn^{II}(tmpp)$ because the values of $E°(MV^{2+}/MV^{+})$ and $E_{1/2}(III/II)$ are -0.67 and -0.21 V (*vs.* AgCl/Ag), respectively. The energy level of $^{*}Mn^{II}(tmpp)$ is probably over 0.46 eV higher than that of $Mn^{II}(tmpp)$. $Mn^{III}(tmpp)$ is also reduced to $Mn^{II}(tmpp)$ with MV^{+} because of the back electron transfer:

$$Mn^{III}(tmpp) + MV^{+} \longrightarrow Mn^{II}(tmpp) + MV^{2+}. \quad (12)$$

The rate of Reaction 11 is probably higher than that of Reaction 12 because an appreciable amount of MV^{+} is built up.

Porphyrinatomanganese(III)-sensitized Reduction of MV^{2+} with Weak Electron Donors. Figure 8 shows the concentration of MV^{+} produced by irradiation for 30 min at different concentrations of electron donors in an aqueous solution containing $Mn^{III}(tmpp)$ (2.1×10^{-5} M) and MV^{2+} (2.0×10^{-3} M) at pH 10.1. The concentration of MV^{+} monotonously increased with an increase in the concentration of EDTA or TEA,

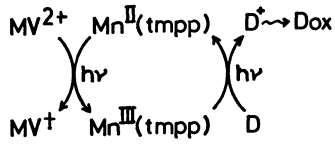

Fig. 7. A schematic representation of photosensitized reaction in the presence of EDTA.

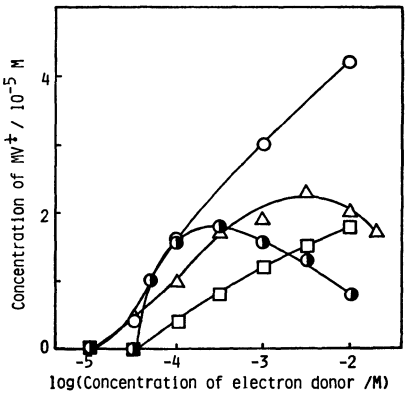

Fig. 8. The concentration of MV^{+} produced by irradiation for 30 min at different concentrations of electron donors at pH 10.1.
Concentration of $Mn^{III}(tmpp)$: 2.1×10^{-5} M. Concentration of MV^{2+}: 2.0×10^{-3} M. ○, EDTA; ◑, TEOA; △, NT; □, TEA.

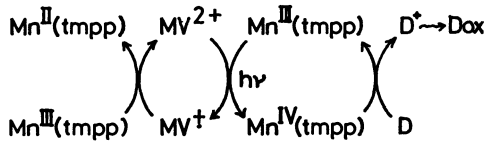

Fig. 9. A schematic representation of photosensitized reaction in the presence of weak electron donors (TEA, NT) below 2×10^{-3} M.

but exhibited a maximum in the case of TEOA or NT. A comparison of Fig. 8 with Fig. 3 shows that a certain amount of MV^{+} was built up even at the low concentration of NT, TEA, or TEOA, at which $Mn^{III}(tmpp)$ was not photoreduced in the absence of MV^{2+}. The formation of $Mn^{II}(tmpp)$ was also observed at such a low concentration (1×10^{-4} M) of NT, TEA, or TEOA.

The reaction scheme in Fig. 9 can be proposed as the mechanism for the $Mn^{III}(tmpp)$-sensitized reduction of MV^{2+} with weak electron donors at low concentrations. An excited $Mn^{III}(tmpp)$ can first be oxidized to $Mn^{IV}(tmpp)$ with MV^{2+}, and MV^{+} can be produced:

$$^{*}Mn^{III}(tmpp) + MV^{2+} \longrightarrow Mn^{IV}(tmpp) + MV^{+}. \quad (13)$$

The energy level of $^{*}Mn^{III}(tmpp)$ is probably over 1.12 eV higher than that of $Mn^{III}(tmpp)$ at pH 10 because the values of $E°(MV^{2+}/MV^{+})$ and $E_{1/2}(IV/III)$ are -0.67 and 0.45 V (*vs.* AgCl/Ag), respectively. The back electron transfer reaction (14) can be suppressed if $Mn^{IV}(tmpp)$ can rapidly be scavenged with an electron donor (Reaction 7):

$$Mn^{IV}(tmpp) + MV^{+} \longrightarrow Mn^{III}(tmpp) + MV^{2+}. \quad (14)$$

Furthermore, Reactions 12 and 11 can occur although Reaction 5 does not proceed with weak electron donors.

Figure 10 shows the dependence of the concentration of $Mn^{II}(tmpp)$ photoproduced at pH 6.0 on the concentration of MV^{2+} in an aqueous solution containing $Mn^{III}(tmpp)$ (5.3×10^{-6} M) and TEOA (0.01 M). Porphyrinatomanganese(III) was reduced to Mn^{II}-(tmpp) above 5×10^{-3} M MV^{2+}, but the formation of MV^{+} was not observed. At pH 6 the rate of Reaction 13 is slow since $E_{1/2}(IV/III)$ becomes more positive with decreasing pH. When $Ru(bpy)_3^{2+}$ or Zn(tmpp) was used as a sensitizer, 6.1×10^{-5} or 1.6×10^{-4} M MV^{+}, respectively, was built up by irradiating for 10 min a solution (pH 6.0) containing the sensitizer (2.0×10^{-5} M), MV^{2+} (2.0×10^{-3} M), and TEOA (0.01 M). [Tetrakis(4-methylpyridyl)porphyrinato]manga-

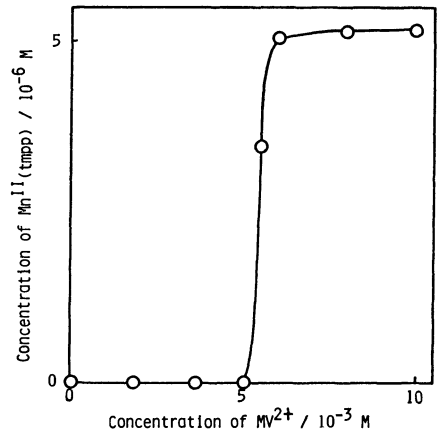

Fig. 10. The concentration of $Mn^{II}(tmpp)$ photoproduced at pH 6.0 at different concentrations of MV^{2+}.
Total concentration of Mn(tmpp): 5.3×10^{-6} M. Concentration of TEOA: 0.01 M. Irradiation time: 30 min.

nese(III) emitted a very weak luminescence around 540 nm in aqueous solutions. The excited triplet state lifetime of [tetrakis(4-pyridyl)porphyrinato]manganese(III) in ethanol glass at 77 K is below 0.1 ms,[10] but that of [tetrakisphenylporphyrinato]zinc(II) in methylcyclohexane at 77 K is 26 ms.[19] The oxidative electron transfer quenching of the excited Mn(III) porphyrin with MV^{2+} is less effective than that of the excited Zn(II) porphyrin.

Decomposition of 2-Butanol Catalyzed by Iron Oxide and Mixed Oxides Containing Iron

Tuo JIN, Hideshi HATTORI, and Kozo TANABE*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received March 29, 1983)

Three types of binary oxides, Fe_2O-TiO_2, Fe_2O_3-ZrO_2, and Fe_2O_3-ZnO, were prepared by a coprecipitation method, and their catalytic behaviors in the decomposition of 2-butanol were examined. The activities and selectivities of the catalysts varied with the type of the oxide with which Fe_2O_3 was combined, with the content of Fe_2O_3 in the binary oxides, and with the reduction temperature of the catalysts. Over the Fe_2O_3-TiO_2 catalysts, 2-butanol underwent primarily dehydration and the activity decreased with an increase in Fe_2O_3 content. Over the Fe_2O_3-ZnO catalysts, dehydrogenation preferentially occurred, the maximum activity being observed for the catalyst containing 67% Fe_2O_3. The Fe_2O_3-ZrO_2 catalysts exhibited an intermediate nature between the Fe_2O_3-TiO_2 catalysts and Fe_2O_3-ZnO catalysts. Reduction of catalysts tended to increase the dehydrogenation selectivity. Reduction also brought about the formation of butane. The maximum formation of butane was observed when the catalysts were reduced with hydrogen at about 350—400 °C. The reaction mechanisms of the formation of butane were elucidated by tracer experiments, and it was concluded that butane was formed by the mechanism involving the first order nucleophilic substitution (S_N1) of OH^- by H^- which was liberated in the dehydrogenation of butanols.

The catalysts containing iron have been used in various reactions such as ammonia synthesis, Fischer-Tropsch synthesis, water gas shift reaction, dehydrogenation of hydrocarbons, and oxidation reactions.[1] Meanwhile, combination of two types of oxides has been known to result in generation of acidic properties in many cases.[2] The acid-base properties of the catalysts containing iron, however, have not extensively been studied. Decomposition of 2-butanol generally yields butenes by dehydration over acidic catalyst and yields ethyl methyl ketone by dehydrogenation over basic catalyst.[3] Therefore, decomposition of 2-butanol seems to be an appropriate diagnostic reaction to see the acidic and basic properties of the catalysts. In the present work, variations in the catalytic activities and selectivities of the catalysts containing iron were examined as functions of catalyst composition, of reduction temperature and of types of oxides with which Fe_2O_3 was combined.

As previously reported, the formation of butane was observed during decomposition of 2-butanol over Fe_2O_3 catalyst.[4] In order to elucidate the reaction mechanism of the formation of butane, tracer experiments were also undertaken.

Table 1. Compositions and surface areas of catalysts

Nomenclature	Composition Fe/(Fe+X)/%[a]	Surface area $m^2\ g^{-1}$
TiO_2	0	42
Fe_2O_3-TiO_2(1/9)	10	62
Fe_2O_3-TiO_2(1/3)	25	42
Fe_2O_3-TiO_2(1/1)	50	38
Fe_2O_3-TiO_2(7/3)	70	40
Fe_2O_3-TiO_2(9/1)	90	21
ZrO_2	0	64
Fe_2O_3-ZrO_2(1/9)	10	77

a) X represents Ti, Zr, or Zn.

Experimental

Catalyst Preparation. The Fe_2O_3-TiO_2 catalysts with different compositions were prepared by hydrolysis of mixed solutions of ferric nitrate and titanium tetrachloride in different molar ratios with aqueous ammonia, the final pH being 8—9. The Fe_2O_3-ZrO_2 catalysts and the Fe_2O_3-ZnO catalysts with different compositions were similarly prepared from mixed solutions of iron(III) nitrate and zirconium nitrate or zinc nitrate. The precipitates obtained by the hydrolysis were washed with deionized water, dried at 100 °C for 20—30 h, and finally calcined at 500 °C in air for 2—3 h. The compositions, surface areas and nomenclatures of the resulting catalysts are given in Table 1.

X-Ray Diffraction. X-Ray diffraction patterns were measured with powdered samples on a Toshiba GD-3 diffractometer, the radiation source being Ni-filtered Cu $K\alpha$. For the samples reduced with hydrogen, the sample was cooled to room temperature under a helium stream, and slowly exposed to air to prevent the sample from rapid oxidation.[5,6]

Hydrogen Consumption during Reduction. The amounts of hydrogen consumed during reduction at different temperatures were measured for the Fe_2O_3 catalyst, the Fe_2O_3-ZrO_2 (7:3) catalyst, the Fe_2O_3-ZnO (2:1) catalyst, and the Fe_2O_3-TiO_2 (7:3) catalyst by use of a recirculation system of a small volume, 40 ml. The sample (0.1 g) was placed in a U tube and outgassed at 500 °C for 2 h. After cooling the sample to room temperature, hydrogen (200 Torr, 1 Torr = 133.3 Pa) was introduced in the system and circulated in the loop which was attached by a liquid nitrogen trap. The temperature of the sample was raised to 250 °C and kept at the temperature for 30 min. The amount of hydrogen consumed for reduction of the sample was measured by decrease in the pressure. Then the sample was heated stepwise by 50 °C increment to 500 °C. At each increment, the temperature was kept for 30 min.

Reaction Procedures. For the kinenic measurement of

decomposition of 2-butanol, a microcatalytic pulse reactor was employed. A catalyst (0.1 g) was placed in a U-tube reactor and pretreated in a helium stream at 500 °C for 2 h. The catalyst was then cooled to the reaction temperature of 250 °C in a helium stream. In experiments with reduced catalysts, the catalysts were pretreated in a hydrogen stream for 30 min before cooling to the reaction temperature. The flow rate of helium was adjusted to 75 ml/min. 2-Butanol (10 μl) was injected by a syringe into a helium stream ahead of the catalyst. The reaction products were once trapped in a liquid nitrogen and flash-evaporated into gas chromatographic columns. The columns, PEG-20 M and VZ-7, were arranged in series for total analysis. By the former column operated at 80 °C, butenes plus butane, ethyl methyl ketone, and 2-butanol were separated. By the latter column operated at 0 °C, each isomer of butenes and butane were separated. The data of Figs. 2—5 and Table 4 were taken from No. 5 pulses which gave steady rates.

For carrying out some reactions, a closed recirculation reactor having a volume of 1280 ml was also employed. A catalyst (0.2 g) was outgassed at 500 °C for 2 h and reduced at 350 °C for 30 min by circulating hydrogen (150 Torr) in a loop of the reactor which was equipped with a trap of liquid nitrogen temperature. The catalyst was then outgassed at 240 °C for 30 min. A mixture of 1-butene (16 Torr) and hydrogen (18 Torr) or a mixture of 1-butene (3 Torr) and 2-propanol (27 Torr) was allowed to react at 242 °C over the Fe_2O_3 catalyst.

Two tracer experiments were also carried out in a closed recirculation reactor. One tracer experiment was the reaction of a mixture of 2-butanol (16 Torr) and deuterium (40 Torr). The other was the reaction of a mixture of monodeuterio 2-butanol ($CH_3CH_2CH(OD)CH_3$, 16 Torr) and heavy water (D_2O, 14 Torr). The isotopic distribution of butane was determined by mass spectrometry.

Results

X-Ray Diffraction. Crystalline structures detected by X-ray diffraction for the samples calcined at 500 °C in air are summarized in Table 2. For binary oxides of Fe_2O_3–ZrO_2 and Fe_2O_3–TiO_2, the crystalline structures detected were those of the mixture or one of the component oxides. New crystalline structures were not detected. For the Fe_2O_3–ZnO (2/9) and the Fe_2O_3–ZnO (2/1), a spinel structure of $ZnFe_2O_4$ was detected. All peaks detected for binary oxides calcined at 500 °C were weak in intensity and broad as compared with those for single component oxides.

Crystalline structures detected for the samples, Fe_2O_3, Fe_2O_3–ZrO_2 (7/3), Fe_2O_3–ZnO (2/1), and Fe_2O_3–TiO_2 (7/3), reduced with hydrogen at different temperatures

Table 2. Crystalline structure of the catalysis detected by XRD

Table 3. Crystalline structure of pretreated catalysts detected by XRD

Catalyst	Temp of H_2 treatment	Observed spectra
Fe_2O_3	Untreated	Fe_2O_3(sharp)
Fe_2O_3	250 °C	Fe_3O_4, Fe(trace)
Fe_2O_3	350 °C	Fe(trace), Fe_3O_4(trace)
Fe_2O_3	500 °C	Fe(sharp)
Fe_2O_3-ZnO(2/1)	Untreated	$ZnFe_2O_4$(broad)
Fe_2O_3-ZnO(2/1)	250 °C	ZnO(broad), Fe_3O_4(trace), Fe(trace)
Fe_2O_3-ZnO(2/1)	350 °C	ZnO, Fe(trace), FeO(trace)
Fe_2O_3-ZnO(2/1)	500 °C	Fe(sharp), ZnO(sharp)
Fe_2O_3-ZrO_2(7/3)	Untreated	Fe_2O_3(broad), ZrO_2(broad)
Fe_2O_3-ZrO_2(7/3)	250 °C	ZrO_2(broad), Fe_3O_4(tract)
Fe_2O_3-ZrO_2(7/3)	350 °C	ZrO_2(broad), Fe_3O_4(trace), FeO(trace)
Fe_2O_3-ZrO_2(7/3)	500 °C	Fe(sharp), ZrO_2(sharp)
Fe_2O_3-TiO_2(7/3)	Untreated	Fe_2O_3(broad)
Fe_2O_3-TiO_2(7/3)	250 °C	Fe_3O_4(trace)
Fe_2O_3-TiO_2(7/3)	350 °C	Almost nothing
Fe_2O_3-TiO_2(7/3)	500 °C	Fe(sharp)

are summarized in Table 3. By reduction at 250 °C, the pattern of Fe_2O_3 disappeared and the pattern of Fe_3O_4 appeared for all samples, though all peaks for the binary oxides were broad and weak. By raising the reduction temperature to 500 °C, the patterns of oxide forms of Fe such as Fe_2O_3, Fe_3O_4, and FeO diminished and the sharp patterns of metallic Fe appeared. The spinel structure, $ZnFe_2O_4$, in the Fe_2O_3–ZnO (2/1) sample disappeared on reduction at 250 °C.

Hydrogen Consumption during Reduction. The amounts of hydrogen consumed in reduction of the Fe_2O_3, Fe_2O_3–ZrO_2 (7/3), Fe_2O_3–ZnO (2/1), and Fe_2O_3–TiO_2 (7/3) are plotted against the reduction temperature in Fig. 1. The easiness of reduction of these samples is in the following order:

$Fe_2O_3 > Fe_2O_3$–ZrO_2 (7/3) $> Fe_2O_3$–ZnO (2/1) $> Fe_2O_3$–TiO_2 (7/3).

Assuming that a part of Fe^{3+} ions were reduced only to Fe^{2+} ions at 350 °C for all samples, the percentages of Fe^{3+} ions reduced to Fe^{2+} ions were calculated to be 50, 43, 32, and 22% for the Fe_2O_3, Fe_2O_3–ZrO_2 (7/3), Fe_2O_3–ZnO (2/1), and Fe_2O_3–TiO_2 (7/3), respectively. Since reduction of Ti^{4+} ions might occur to some extent for the Fe_2O_3–TiO_2 (7/3), the value, 22% is the maximum percentage of Fe^{3+} ions converted to Fe^{2+} ions.

Effects of Reduction of Catalysts on Activity and Selectivity for Reaction of 2-Butanol. Reaction of 2-butanol gave ethyl methyl ketone, butenes, and butane. The rate of conversion of 2-butanol and the product distribution varied with type of binary oxide and with pretreatment condition of catalysts. The percentage conversions of 2-butanol and the molar percentages of each product are plotted against the reduction temperature of catalysts in Figs. 2—5 for the Fe_2O_3 catalyst, the Fe_2O_3–ZrO_2 (7/3) catalyst, the Fe_2O_3–ZnO (2/1) catalyst, and the Fe_2O_3–TiO_2 (7/3) catalyst, respectively.

With the Fe_2O_3 catalyst, the main product was ethyl methyl ketone over the whole range of the reduction temperature. The conversion of 2-butanol exhibited a maximum at the reduction temperature of 300 °C, and the ketone yield exhibited a maximum at the reduction temperature of 250 °C. It should be noted that considerable amounts of butane were produced when the catalyst was reduced in the temperature range of 300—400 °C. The formation of butane became maximum at the reduction temperature

of 350 °C.

With the Fe_2O_3–ZrO_2 catalyst, the main product was ethyl methyl ketone. The conversion of 2-butanol showed a maximum at the reduction temperature of 400 °C. The formation of butane was also observed over the wide range of the reduction temperature, 250—500 °C. The maximum formation was observed when the catalyst was reduced at 350 °C.

With the Fe_2O_3–ZnO (2/1) catalyst, the main product was also ethyl methyl ketone. The conversion of 2-butanol decreased steadily with an increase in the reduction temperature. The formation of butane reached maximum when the catalyst was reduced between 300—500 °C.

With the Fe_2O_3–TiO_2 (7/3) catalyst, the conversion of 2-butanol was almost independent of the reduction temperature. However, the ratios of ethyl methyl ketone/butenes changed much with the reduction temperature. When the reduction temperature was below 300 °C, butenes were produced much more than ethyl methyl ketone. On the contrary, ethyl methyl ketone was produced much more than butenes as the reduction temperature exceeded 350 °C. The amount of butane formed was less than 5% of total products, which was small as compared with the other catalysts. The maximum formation of butane was observed at the reduction temperature of 400 °C.

Activity and Selectivity of Catalysts with Different Compositions for Reaction of 2-Butanol. Product distributions in the reaction of 2-butanol over the binary oxides with different compositions and the component oxides are given in Table 4, in which the results both for the catalysts unreduced and for one reduced at 350 °C are included.

With unreduced Fe_2O_3–ZrO_2 catalysts, the dehydrogenation activities markedly increased as Fe_2O_3 was added to ZrO_2. The dehydration activities decreased with an increase in Fe_2O_3 content. The formation of butane was not observed. With the Fe_2O_3–ZrO_2 catalysts reduced at 350 °C, the maximum conversion of 2-butanol and activity for dehydrogenation were observed for the Fe_2O_3–ZrO_2 (1/1) catalyst. The formation of butane became maximum for the Fe_2O_3–ZrO_2 (7/3) catalyst.

With the unreduced Fe_2O_3–ZnO catalysts, the conversion of 2-butanol and the dehydrogenation activity became maximum for the Fe_2O_3–ZnO (2/1) catalyst. The dehydration activities were low, and the formation of butane was not appreciable for any compositions of the catalysts. With the reduced Fe_2O_3–ZnO catalysts, the conversion of 2-butanol and the dehydrogenation activity became maxima for the Fe_2O_3–ZnO (2/1) catalyst. The dehydration activity decreased as the content of Fe_2O_3 increased. The formation of butane was considerable and increased with an increase in the Fe_2O_3 content.

With the unreduced Fe_2O_3–TiO_2 catalysts, the dehydration activity decreased with an increase in the Fe_2O_3 content. The dehydrogenation activity became maximum for the Fe_2O_3–TiO_2 (1/1) catalyst. The formation of butane was not observed. With the reduced Fe_2O_3–TiO_2 catalysts, the dehydration activities decreased with an increase in Fe_2O_3 content. The dehydrogenation activity showed a maximum for the Fe_2O_3–TiO_2 (1/1) catalyst. The activities of the reduced Fe_2O_3–TiO_2 catalysts for the formation of butane were generally low as compared with those of the reduced Fe_2O_3–ZrO_2 catalysts and of Fe_2O_3–ZnO_2 catalysts.

Reaction of 1-Butene with Hydrogen. The compositions of the products in the reaction of 1-butene with H_2 over the Fe_2O_3 catalyst reduced at 350 °C are given in Table 5. The hydrogenation of butenes to butane was slow, the rate being 2.9×10^{-6} mol min^{-1} g^{-1}.

Reaction of 1-Butene in the Presence of 2-Propanol. The result for the reaction of a mixture of 1-butene and 2-propanol over the Fe_2O_3 catalyst reduced at

TABLE 5. REACTION OF 1-BUTENE(6 Torr) IN H_2(18 Torr) OVER Fe_2O_3

Reaction temp	Reaction time	Conversion	Product yield/%		
°C	min	%	Butane	*t*-2-Butene	*c*-2-Butene
242	20	84.3	2.8	50.5	31.0

350 °C is shown in Table 6. The products consisted of propane, propene, and acetone. Butane was not formed, though propane was produced.

Reaction of 2-Butanol in the Presence of Deuterium. In the reaction of a mixture of 2-butanol and deuterium at 240 °C over the Fe_2O_3 catalyst reduced at 350 °C, monodeuteriobutane (butane-d_1) and dideuteriobutane (butane-d_2) were formed in addition to nondeuteriated butane. The percentages of butane-d_1 and butane-d_2 in total isotopic butanes are plotted against the conversion to butane in Fig. 6. Extrapolation to zero conversion gives nearly zero percentage for both the butane-d_1 and butane-d_2. The rate of the formation of butane was 4.0×10^{-6} mol min^{-1} g^{-1}, which was higher than the hydrogenation of 1-butene, 2.9×10^{-6} mol min^{-1} g^{-1}.

*Reaction of Deuterio 2-Butanol-*d *in the Presence of Heavy Water.* When a mixture of $CH_3CH_2CH(OD)CH_3$ and D_2O was allowed to react at 240 °C over the Fe_2O_3 catalyst reduced at 350 °C, formation of butane-d_1 was observed in addition to that of nondeuteriated butane. In Fig. 7, the percentage of butane-d_1 in total butane products is plotted against conversion of

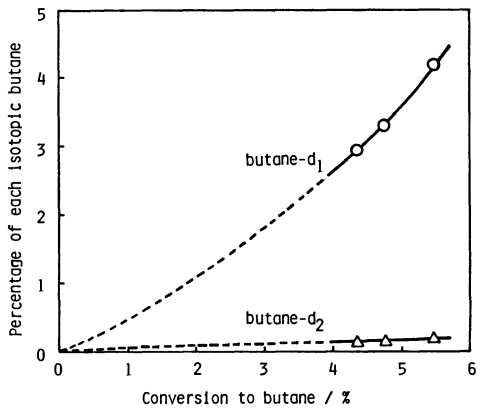

Fig. 6. Distribution of deuterated butane formed by reaction of 2-butanol with D_2. ○: butane-d_1, △: butane-d_2.

2-butanol. Extrapolation to the zero conversion gives less than 50% for butane-d_1 and approached to nearly zero percentage at the zero conversion.

Discussion

X-Ray diffraction patterns of the binary oxides were generally weak and broad. The binary oxides consisted mostly of amorphous parts. By treatment with hydrogen, one component oxide, Fe_2O_3, was reduced and converted mainly to amorphous species. Metallic iron was considerably yielded by raising the temperature to 500 °C. The reduction became difficult when Fe_2O_3 was mixed with the other oxides; ZrO_2,

Table 6. Reaction of mixture 1-butene and 2-propanol over Fe_2O_3[a)]

Reaction time	Composition of products/%					
min	1-Butene	2-Propanol	Propane	Propene	Acetone	Butane
0	10.00	90.00	0	0	0	0
40	10.06	64.87	1.53	0.56	22.98	0
70	10.07	50.18	2.17	0.99	36.59	0

a) The initial pressures of 1-butene and 2-propanol are 3 and 27 Torr, respectively.

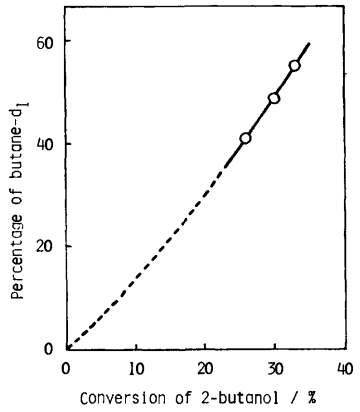

Fig. 7. Distribution of deuterated butane formed by reaction of 2-butanol with D_2O.

ZnO, and TiO_2. The difficulty of reduction of Fe_2O_3 in the binary oxides depended on the kinds of the other component oxides. There should be some chemical interactions between Fe_2O_3 and the other component oxides.

As for the activity and selectivity of the unreduced binary oxides, the catalytic properties of each component oxide seem to reflect on the activity and selectivity of the corresponding binary oxide catalysts. The catalytic properties of TiO_2 and ZrO_2 favored the dehydration, while those of ZnO and Fe_2O_3 favored the dehydrogenation. The binary oxides, Fe_2O_3–TiO_2 of any compositions and Fe_2O_3–ZrO_2 (1/9) mainly formed butenes, while Fe_2O_3–ZnO of any compositions and Fe_2O_3–ZrO_2 (3/7—9/1) gave ketone preferentially. It should be noted that a marked increase in the ketone yield was observed for the Fe_2O_3–ZnO (2/1) catalyst as compared with each component oxide.

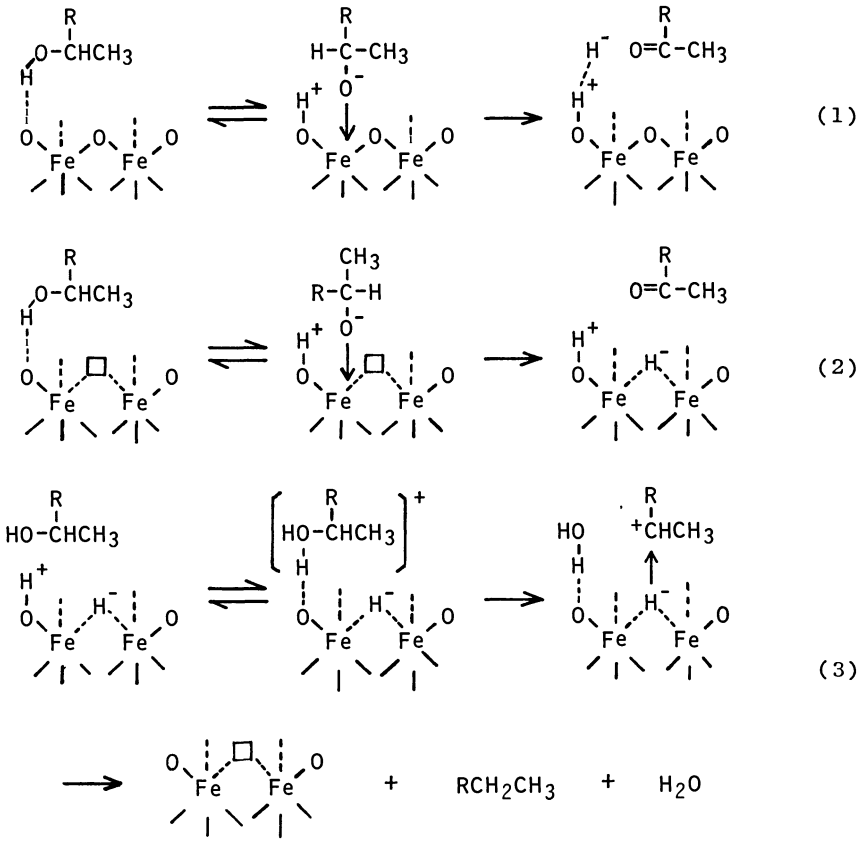
Reduction of the catalysts brought about obvious changes in both the selectivity and activity. Direction of the changes depended upon types of the binary oxides. One of the factors to control the selectivity in decomposition of alcohols is an acid-base properties of catalyst.[3)] With acidic catalysts, the dehydration predominantly takes place, while, with basic catalysts, the dehydrogenation proceeds. Changes in the dehydration and dehydrogenation selectivity of the binary oxides suggest that the acidic and basic properties of the catalysts change with the reduction state of Fe_2O_3 in the binary oxides. The change was especially marked for the Fe_2O_3–TiO_2 (7/3) catalyst. It appears that the basic property of the Fe_2O_3–TiO_2 (7/3) catalyst was strengthened by reduction above 350 °C.

The most prominent change in the selectivity occurred on reduction was the appearance of the formation of butane. For the catalysts, Fe_2O_3, Fe_2O_3–ZnO (2/1), Fe_2O_3–ZrO_2 (7/3), and Fe_2O_3–TiO_2 (7/3), the reduction temperatures which gave maximum formation of butane were 350, 350, 350, and 400 °C, respectively. These temperatures are close to the temperatures which were required to reduce Fe_2O_3 in those catalysts to Fe_2O_{3-x} (x=0.5) as seen in Fig. 1. Besides, these temperatures are also the temperature at which most of Fe_2O_3 in the catalysts converted to an amorphous species. Although the amounts of butane formed on unit amount of Fe_2O_3 in the binary oxides were not the same for different binary oxides, the amorphous iron oxide formed by the reduction seems to be the active species for the formation of butane.

The formation of butane from 2-butanols was observed over TiO_2 for the first time by Vinek *et al.*[7)] However, the activity of the reduced Fe_2O_3 for the formation of butane is much higher than that of TiO_2 as shown in Table 4.

Several possibilities are considered as to the reaction mechanism of the formation of butane. Hydrogenation of butenes which were produced by dehydration of 2-butanol with hydrogen which resulted from dehydration would be one of them. However, the rate of hydrogenation of 1-butene was lower than that of the formation of butane from 2-butanol. In addition, the presence of hydrogen had no marked effect on the rate of butane formation from 2-butanol.[4)] Therefore, hydrogenation of butene should be ruled out. Another possibility that butenes are hydrogenated by use of adsorbed hydrogen atoms or ions which are formed by the dehydrogenation of 2-butanol might be taken into account. If the formation of butane from 2-butanol occurred *via* butene, the formation of propane from 2-propanol would also occur *via* propene. If this is the case, the reaction of a mixture of 1-butene and 2-propanol would yield both butane and propane, since propene undergoes hydrogenation only 1.5 times faster than 1-butene does.[8)] The observed results showed that propane was produced, while butane was not produced (Table 5). This rules out the possibility that butane was formed through butenes by use of adsorbed hydrogen.

Vinek *et al.*[7)] proposed on the basis of higher reactivity of 1-butanol as compared with 2-butanol that butane was formed *via* the second order nucleophilic substitution (S_N2) of OH^- by H^-. They concluded that the source of the H^- nucleophile is water which results from the dehydration of butanols, as they did not take into account the adsorbed H^- which results



Scheme. Reaction scheme over Fe_2O_3 and reduced Fe_2O_3.

from the dehydrogenation.

In the present work, we propose that butane is formed *via* the first order nucleophilic substitution (S_N1) and that the H^- nucleophile is provided by the dehydrogenation of butanols. If the nucleophilic substitution proceeded by the S_N2 mechanism, 1-butanol would be easier to form butane than 2-butanol. If the substitution proceeded by the S_N1 mechanism, 2-butanol would undergo reaction much faster than 1-butanol. Our previous data[4] have shown that 2-butanol was easier to form butane than 1-butanol over the Fe_2O_3–ZrO_2 (7/3) catalyst. This suggests that the operating mechanism over the catalyst containing Fe_2O_3 is the first order nucleophilic substitution (S_N1) mechanism rather than the S_N2 mechanism.

The source of hydrogen would be either water[7] which results from dehydration or hydrogen which results from dehydrogenation. The amount of ethyl methyl ketone exceeded those of butane for all catalysts, whereas the amounts of butenes were lower than those of butane in the cases of some catalysts, Fe_2O_3, Fe_2O_3–ZnO (2/1—18/1), and Fe_2O_3–ZrO_2 (7/3—9/1) as seen in Table 4. It is, therefore, likely that the H^- nucleophile is supplied by the dehydrogenation of 2-butanol, but not from water. This is also supported by the percentage less than 50 of deuteriobutanes in total butane produced by the reaction of a mixture of the 2-butanol-*d* ($CH_3CH_2CH(OD)CH_3$) and heavy water, because if the hydride ion came from water formed from $CH_3CH_2CH(OD)CH_3$, the extrapolation to zero conversion should give 50% butane-d_1.

No incorporation of deuterium atoms into the butane molecules in the initial stage of the reaction of a mixture of 2-butanol and deuterium (Fig. 6) suggests that the hydrogen acting as the hydrogen source does not originate from molecular hydrogen, but from the adsorbed hydrogen which results from dehydrogenation of 2-butanol.

The reaction mechanism of the formation of butane could be drawn as follows. When dehydrogenation of alcohol occurs over the iron oxide catalyst, the alcohol dissociates into proton and alkoxide ion to adsorb on the catalyst surface at first, followed by losing of α hydrogen as hydride ion to form ketone (Scheme 1 or 2). The α hydrogen can be abstracted either by a proton or by an oxygen vacancy on the surface.[9] With the unreduced catalyst, the α hydrogen can be abstracted by H^+ (Scheme 1), since the metal ions are covered by oxygen atoms. In the case of the reduced catalyst, however, the α hydrogen tends to be abstracted as a hydride ion by an oxygen vacancy formed by reduction (Scheme 2). An alcohol molecule comes to the surface on which H^+ and H^- coexist and an alkoxonium ion is formed by the addition of H^+ to the alcohol. Since the present reaction was ascertained to proceed by the S_N1 mechanism, the alkoxonium ion must dissociate to form an alkyl cation. An alkane is produced by the nucleophilic attack of H^- to the alkyl cation (Scheme 3).

A Further ESR Study of Irradiated D_2O Ice. On the Nature of the Species Appeared at $g=2.08$

Hirotomo HASE* and Takenobu HIGASHIMURA

Research Reactor Institute, Kyoto University, Kumatori-cho, Sennan-gun, Osaka 590-04

(Received April 6, 1983)

For D_2O ice warmed at *ca.* 120 K after the irradiation at 77 K, "$g=2.08$ line" was isolatedly detected at 4 K. The intensity of the line increased for the sample containing an electron scavenger. Photobleaching of solvated electrons caused no change in the intensity of the line. In D_2O single crystal, angular dependency of the line was not observed. The overall results were not accomodated to the hypothesis that "$g=2.08$ line" was due to O^- radical, but rather indicated the possibility that the species is a sort of positive ion or trapped hole.

Among numerous electron spin resonance (ESR) studies on irradiated ices, a few reports[1,2] described an asymmetric singlet line at $g=2.08$. However, the line was neither studied in detail nor identified until its thermal reversibility was firstly reported by Johnson and Moulton in 1978.[3] They found that in polycrystalline H_2O or D_2O ice irradiated at 4 or 77 K, "$g=2.08$ line" was observed only when ESR measurements were made at temperatures lower than 24 K. They proposed that "$g=2.08$ line" was probably due to H_2O^+ radical in irradiated H_2O ice, and D_2O^+ radical in irradiated D_2O ice.

Recently, however, Symons[4,5] has claimed that O^- radical is possibly responsible for "$g=2.08$ line". The experimental evidences on which the O^- hypothesis stands were: (i) the interconversion between OH radical and the species amounted to 50% for H_2O and 80% for D_2O ice[4] and (ii) when $D_2{}^{17}O$ ice was irradiated, a new line was observed in the $g=2.16$ region which was tentatively assigned to one of $g_{//}$ components of $^{17}O^-$ radical, although 6 $g_\perp$ components of $^{17}O^-$ radical could not be visible.[5] By analogy with NH_2^+ radical, Symons speculated that the H_2O^+ hypothesis must be rejected on the following reasons: (i) proton coupling of an order of 25 G† should be expected for H_2O^+; (ii) g-value should be close to 2.00 for H_2O^+. It was also stressed by Symons that ESR spectrum of the species was similar in profile to that for O^- in alkaline ice.

The argument by Symons for identification of the species is not completely convincing for us, since (i) the argument partly stands on the analogy with other radicals; (ii) there are scarecely any positive evidences which support the O^- hypothesis; (iii) direct observation of 6 hyperfine lines due to $^{17}O^-$ radical failed except for a new line at $g=2.16$ which might be attributed to $g_{//}$ component of $^{17}O^-$ radical.

Under these circumstances, it is worthwhile to study the nature of the species corresponding to "$g=2.08$ line" in order to further shed light on its identification.

In the present work, we have studied the effects of thermal annealing, addition of solute which is known as electron scavenger and photobleaching of solvated electrons(e^-_{sol}) on the "$g=2.08$ line" in polycrystalline D_2O ice containing NaOD. We have also studied the angular dependency of "$g=2.08$ line" in D_2O single crystal. Based on the results, we will discuss on the entity of "$g=2.08$ line".

† $1\,G=10^{-4}\,T$.

Experimental

D_2O(99.75%) and NaOD(40% in D_2O) were obtained from MSD (Japan) and used without further purification. Reagent grade $AgNO_3$ were used. Polycrystalline samples were made in suprasil quartz ESR tubes by immersing the liquid samples into liquid nitrogen. Single crystals of D_2O were made as described previously.[6] Samples were irradiated by ^{60}Co gamma rays at 77 and 4 K at a dose of 2.2 Mrad/h. ESR measurements were carried out with a Varian E-9 spectrometer at 77 and 4 K.

Results and Discussion

Figure 1 shows ESR spectra of polycrystalline D_2O ice irradiated at 77 K. Figure 1(A) presents the spectrum recorded at 4 K and shows an asymmetric singlet line at $g=2.08$ in addition to the lines due to OD radical in the $g=2.00$ region. Yields of species corresponding to "$g=2.08$ line" and OD radical increased linearly with gamma dose upto at least 20 Mrads. When ESR spectrum was recorded at 77 K, "$g=2.08$ line" was no longer visible. This spectral change is the same as reported firstly by Johnson and Moulton.[3] After the sample was warmed at *ca.* 120 K, ESR spectrum was recorded at 4 K. The spectrum is shown in Fig. 1(B). It is noted in Fig. 1(B) that "$g=2.08$ line" is still visible, although its intensity is reduced. The weak signal remaining in the $g=2.00$ region is

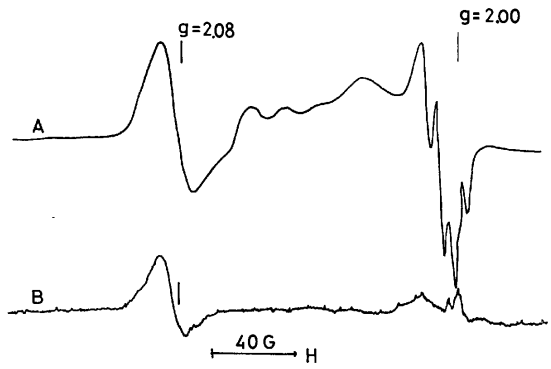

Fig. 1. ESR spectra of polycrystalline D_2O ice irradiated at 77 K. ESR spectrum at 4 K, (B) ESR spectrum at 4 K after warming to *ca.* 120 K. The ESR sensitivity for spectrum (B) was 5 times as large as that for spectrum (A).

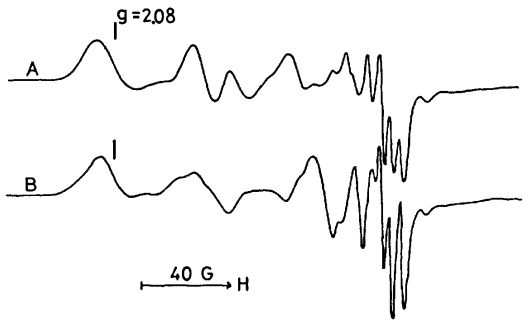

Fig. 2. ESR spectra of D_2O single crystal irradiated at 77 K. (A) ESR spectrum at 4 K, (B) ESR spectrum at 4 K after the cylindrical sample was rotated about 50°. The intensity of "g=2.08 line" remained nearly unchanged with any rotation angles.

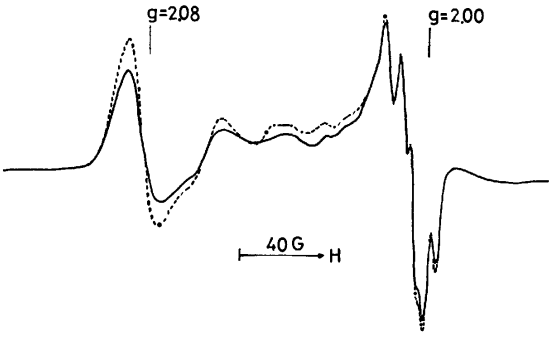

Fig. 3. ESR spectra of polycrystalline D_2O ice containing 0.1 M (solid line) and 0.5 M (dotted line) $AgNO_3$ which was irradiated at 77 K. ESR spectra were recorded at 4 K.

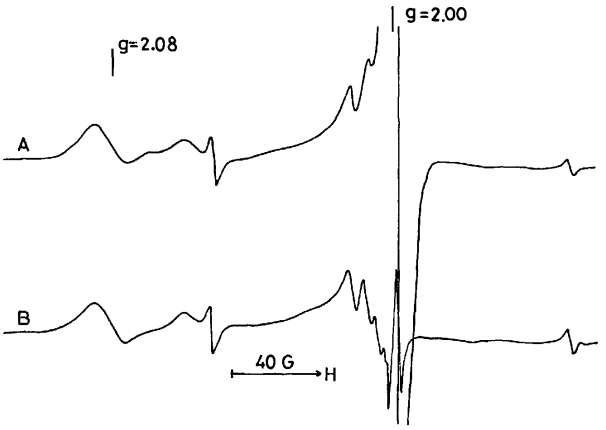

Fig. 4. ESR spectra of polycrystalline D_2O ice containing 1 M NaOD which was irradiated at 4 K. (A) ESR spectrum at 4 K, (B) ESR spectrum at 4 K after photobleaching the sample with the visible light at 4 K.

different from the signal due to either OD radical or $g_{//}$ component of O^- radical.

O^- radical is often reported for irradiated alkaline ices.[7,8] It is known that the $g_{//}$ component of O^- radical in the g=2.00 region provides a featureless broad line with ESR intensity comparable to that of the $g_\perp$ component in the g=2.07 region. Thus the signal remaining in the g=2.00 region in Fig. 1(B) is unlikely O^- radical.

The "g=2.08 line" was also observed in D_2O single crystal irradiated at 77 K. The relative intensities of the ESR lines due to OD radical changed remarkably with rotation of the cylindrical samples, while the intensity of "g=2.08 line" remained almost unchanged. This is illustrated in Fig. 2. The luck of the angular dependency for the "g=2.08 line" suggests that the line may be broadened partly by an unresolved hyperfine interactions with surrounding nuclei similar to those for trapped electrons in alkaline ices. This may also contrast to the result that ESR spectrum of bromine atom having an unpaired electron orbital like O^- radical showed a prominent angular dependency due to a large proton superhyperfine coupling in *N*-bromosuccinimide single crystal.[9]

When polycrystalline D_2O ice was irradiated at 4 K and ESR measurements were made at 4 K, the spectrum obtained was the same as that reported by Johnson and Moulton and showed "g=2.08 line" together with lines due to OD radical, trapped D atom and H atom.

Polycrystalline D_2O ices containing 0.1 or 0.5 M†† $AgNO_3$ were irradiated at 77 K. The "g=2.08 line" was observed in the ESR spectra recorded at 4 K. The intensity of "g=2.08 line" increased with concentration of $AgNO_3$, being 1.4 and 2.1 times for 0.1 and 0.5 M $AgNO_3$ solutions, respectively, as large as that for the solute-free D_2O ice. This is illustrated in Fig. 3. Since $AgNO_3$ is an electron scavenger, the observed effect of $AgNO_3$ in D_2O ice is consistent with the hypothesis that "g=2.08 line" is ascribed to a positive ion or hole, *e.g.* D_2O^+. O^- radical is also a cation-like species, but may not be a candidate for "g=2.08 line" in consideration of the previous result[7] that O^- yield was not affected by electron scavengers in alkaline ices at 77 K.

In polycrystalline D_2O ice containing 0.1 or 1.0 M NaOD, "g=2.08 line" was observed at 4 K. The intensity of the line was not affected by concentration of NaOD and remained nearly the same in both matrices. This result is in a remarkable contrast to the previous report[7] that O^- yield increased with concentration of NaOH. An intense singlet line due to e^-_{sol} was observed in the g=2.00 region in 1.0 M NaOD solution. Photobleaching of e^-_{sol} at 4 K caused little changes in the intensity of "g=2.08 line". That this is the case is shown in Fig. 4. It is previously reported[7] that complete photobleaching of e^-_{sol} in alkaline ices resulted in a decrease of about 70% of concentration of O^- radicals and that the decrease was attributed to the reaction of photodetached electrons with O^- radicals. Thus if "g=2.08 line" was attributed to O^- radicals, complete photobleaching of e^-_{sol} would reduce the intensity of "g=2.08 line". We infer that O^- radical must be produced in 1.0 M NaOD solution and that a broad ESR signal due to O^- radicals is probably masked in the apparent ESR spectrum. We also suppose that photodetached electrons in 1.0 M NaOD solution undergo a reaction

†† 1 M=1 mol dm^{-3}.

with O^- radicals more dominantly than another reaction with positive ion or hole. Thus the observed effects of NaOD in D_2O ice would be another evidence that "$g=2.08$ line" is not attributed to O^- radical.

In conclusion, we could not obtain any positive evidences for the hypothesis that "$g=2.08$ line" is ascribed to O^- radical.

This work was partially supported by a Grant-in-Aid for Scientific Research from Ministry of Education, Science and Culture. The authors are deeply indebted to Dr. Keisuke Kawabata at Radiation Center of Osaka Prefecture for his kind preparation of single crystal D_2O ice and fruitfull discussion throughout this study.

Adsorption of Dodecyltrimethylammonium Chloride–Decylammonium Chloride Mixtures at Water/Air Interface

Shozo URYU,† Makoto ARATONO, Michio YAMANAKA, Kinsi MOTOMURA,* and Ryohei MATUURA

Department of Chemistry, Faculty of Science, Kyushu University 33, Higashi-ku, Fukuoka 812

† *Chikushigaoka Highschool, 2-13-1 Noma, Minami-ku, Fukuoka 815*

(Received April 11, 1983)

The surface tension of the aqueous solution of dodecyltrimethylammonium chloride and decylammonium chloride mixture has been measured as a function of the total concentration and composition of the surfactants at 298.15 K under atmospheric pressure. It has been observed that the surface tension decreases with an increase in the composition of dodecyltrimethylammonium chloride at a fixed total concentration. A break point has been observed on the surface tension *vs.* total concentration curve. By applying the thermodynamic relations, the surface densities of surfactants have been evaluated numerically. It has been proved that the phase transition of the mixed adsorbed film takes place from a gaseous to an expanded state at the break point. By comparing the composition in the adsorbed film with that in the bulk phase, the difference between the compositions has been found to diminish as the surface tension decreases. It has been shown that the mutual relation between the compositions of the gaseous and expanded films at the transition point is described by the two-dimensional phase diagram.

The surface tension of the aqueous solution of surfactant mixture has been measured extensively and analyzed by applying the Gibbs adsorption equation.[1–14] However, most studies have been conducted in connection with the formation of mixed micelle at relatively high concentrations. In a recent paper,[15] we have investigated the adsorption of dodecylammonium chloride (DAC)–decylammonium chloride (DeAC) mixture at water/air interface in a relatively dilute concentration region; it has been shown that the phase transition of the mixed adsorbed film takes place from a gaseous state to an expanded one and its behavior can be treated thermodynamically by extending our method.[16] Further it has been shown that the two-dimensional phase diagram is useful to clarify the relation between the two coexisting phases.

In order to make sure that the occurence of the phase transition in mixed adsorbed films is a general phenomenon and our thermodynamic treatment is useful, we will investigate the mixed system of dodecyltrimethylammonium chloride (DTAC), of which the adsorbed film is accompanied by the phase transition,[17] with DeAC. The surface tension of the aqueous solution will be measured as a function of the total concentration and composition of the surfactants at constant temperature and pressure and analyzed by the thermodynamic equations advanced.

Experimental

Decylammonium chloride and dodecyltrimethylammonium chloride were synthesized and purified by the methods described previously.[15,17] Their purities were checked by the elementary analysis and guaranteed by the absence of minimum near the critical micelle concentration on the surface tension *vs.* concentration curves at 298.15 K. Water was distilled triply from alkaline permanganate.

The surface tension of solutions was measured by the drop volume technique described previously.[16] The temperature was kept constant at 298.15±0.01 K by immersing the measuring cell in a thermostat. The error estimated for the surface tension value was less than 0.05 mN m^{-1}.

Results and Discussion

The system under consideration is composed of two bulk phases and four components. Let us choose the total molality of surfactants m_t^w in the aqueous solution defined by

$$m_t^w = m_1^w + m_2^w, \tag{1}$$

and the composition of the second surfactant X_2^w defined by

$$X_2^w = m_2^w/(m_1^w + m_2^w), \tag{2}$$

as the thermodynamic independent variables at constant temperature T and pressure p. The subscripts 1 and 2 refer to DTAC and DeAC, respectively. The surface tension γ of the aqueous solution of surfactant mixture was measured as a function of m_t^w at fixed X_2^w and at 298.15 K under atmospheric pressure.

The values of γ are plotted against m_t^w at various X_2^w values in Fig. 1(a). It is seen that the curve has a break point and the m_t^w value of the break point increases, while the γ value decreases, as X_2^w increases. This can be seen more clearly from Fig. 1(b) which is the magnification of the γ *vs.* m_t^w curve in the neighborhood of the break point in Fig. 1(a). We confirmed the presence of the break by the fact that any extrapolation of the γ *vs.* m_t^w curve from concentrations above the break to zero concentration never gives, even if the experimental error is taken into account, the value for the pure water/air interface.[15] It has been proved thermodynamically that the presence of a break point on the surface tension *vs.* concentration curve means the phase transformation between two states in the adsorbed film.[15–17] Here also we may say that the phase transition takes place in the mixed adsorbed film of DTAC and DeAC.

In Fig. 2, the γ *vs.* X_2^w curves at fixed m_t^w values are illustrated, which are obtained from Fig. 1. It is found that γ increases with X_2^w and some curves have break points which are linked by the dotted line. It will be proved later that the region above and below the dotted line correspond to the gaseous and expanded states, respectively.

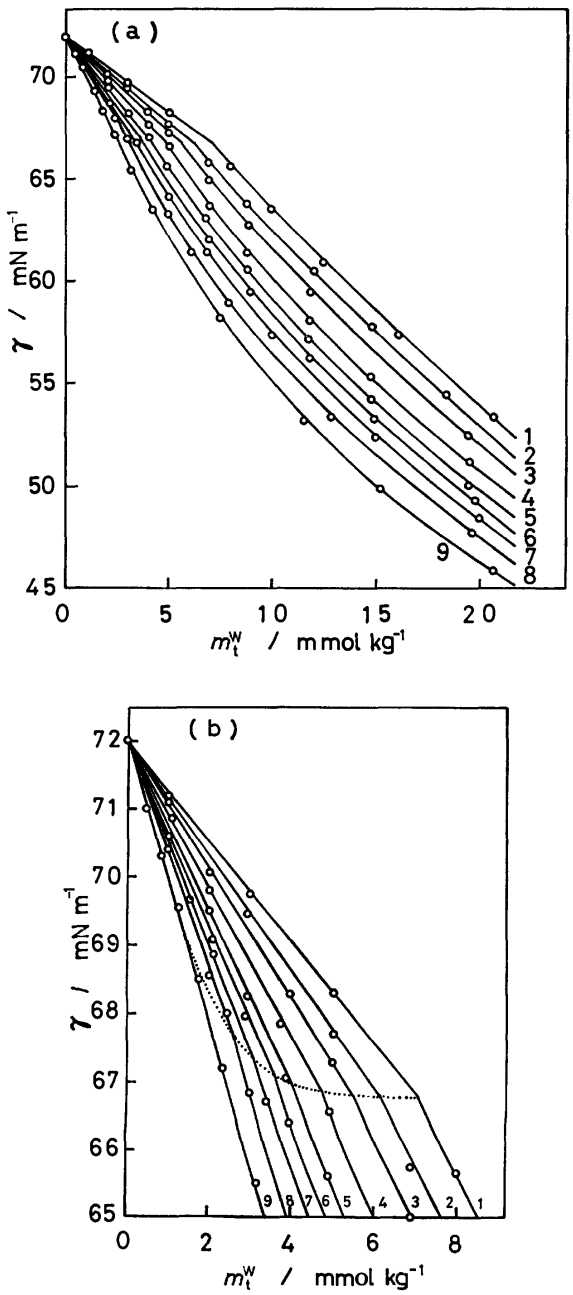

Fig. 1. Surface tension *vs.* total molality curves at constant bulk composition. (1) $X_2^w=1$, (2) 0.950, (3) 0.894, (4) 0.800, (5) 0.697, (6) 0.601, (7) 0.498, (8) 0.300, (9) 0.

Now let us consider the evaluation of the surface excess number of moles per unit area, Γ_i^H, of surfactant i defined with respect to the two dividing planes which are positioned so as to make the surface excess numbers of moles of water and air be zero.[18] Both surfactants in the present study are uni-uni valent strong electrolytes, which have the common anion and dissociate completely into ions. Then the surface tension can be expressed as a function of the total molality m_t^w and the composition X_2^w at constant temperature and pressure as[15]

$$d\gamma = -2RT[(\Gamma_1^H+\Gamma_2^H)/m_t^w]dm_t^w - RT[(X_1^w\Gamma_2^H-X_2^w\Gamma_1^H)/X_1^wX_2^w]dX_2^w. \quad (3)$$

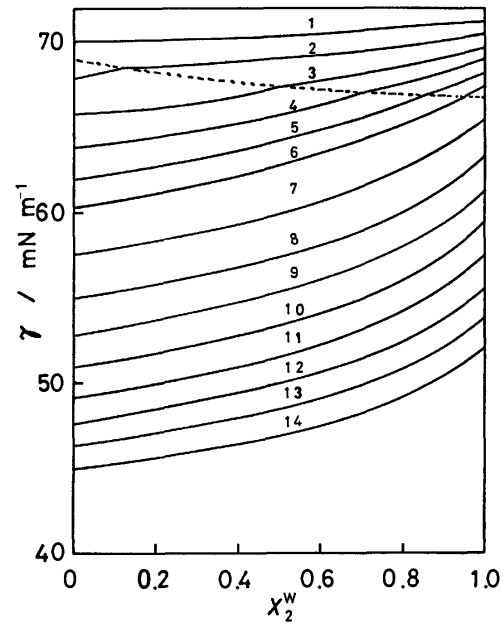

Fig. 2. Surface tension *vs.* bulk composition curves at constant total molality. (1) $m_t^w=1$ mmol kg^{-1}, (2) 2, (3) 3, (4) 4, (5) 5, (6) 6, (7) 8, (8) 10, (9) 12, (10) 14, (11) 16, (12) 18, (13) 20, (14) 22.

Introducing the total surface density Γ_t^H defined by

$$\Gamma_t^H = \Gamma_1^H + \Gamma_2^H, \quad (4)$$

Γ_t^H is found to be related to the change in γ with m_t^w at fixed X_2^w by the expression

$$\Gamma_t^H = -(m_t^w/2RT)(\partial\gamma/\partial m_t^w)_{T,p,X_2^w}, \quad (5)$$

which is derived from Eq. 3. On the other hand, the derivative of γ with respect to X_2^w at constant m_t^w is related to X_2^H in the form

$$X_2^H = X_2^w - (X_1^wX_2^w/RT\Gamma_t^H)(\partial\gamma/\partial X_2^w)_{T,p,m_t^w}, \quad (6)$$

where X_2^H is the composition of DeAC in the adsorbed film defined by

$$X_2^H = \Gamma_2^H/\Gamma_t^H. \quad (7)$$

Combination of Eqs. 5 and 6 gives the values of Γ_1^H and Γ_2^H. Further, Eq. 6 provides information regarding the difference between the compositions of surfactants in the adsorbed film and aqueous solution under the condition that T, p, and m_t^w are kept constant. It is noteworthy that the relation between X_2^H and X_2^w, when T, p, and γ are specified, is given by

$$X_2^H = X_2^w - (2X_1^wX_2^w/m_t^w)(\partial m_t^w/\partial X_2^w)_{T,p,\gamma}. \quad (8)$$

By applying Eq. 5 to the experimental data shown in Fig. 1, the value of Γ_t^H can be evaluated numerically. The Γ_t^H *vs.* m_t^w curves at various X_2^w values are drawn in Fig. 3. It should be noted that the values of Γ_t^H increase monotonously with increase in X_2^w although they change discontinuously at the m_t^w value of the break point in Fig. 1. Taking into account that the values of Γ_t^H at the discontinuous point are similar in magnitude to those of the DAC–DeAC system,[15] we can conclude that the phase transition occurs between a gaseous and an expanded state. It deserves further attention that the difference in the Γ_t^H value

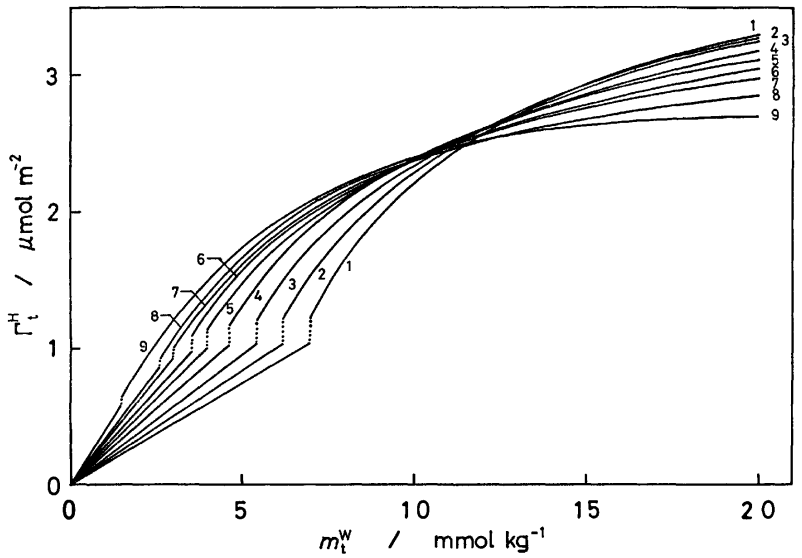

Fig. 3. Total surface density *vs.* total molality curves at constant bulk composition. (1) $X_2^W=1$, (2) 0.950, (3) 0.894, (4) 0.800, (5) 0.697, (6) 0.601, (7) 0.498, (8) 0.300, (9) 0.

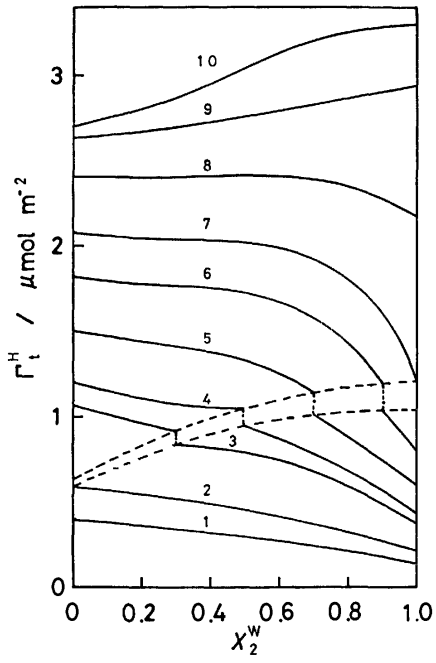

Fig. 4. Total surface density *vs.* bulk composition curves at constant total molality. (1) $m_t^W=1$ mmol kg^{-1}, (2) 1.5, (3) 2.6, (4) 3, (5) 4, (6) 5.45, (7) 7, (8) 10, (9) 15, (10) 20.

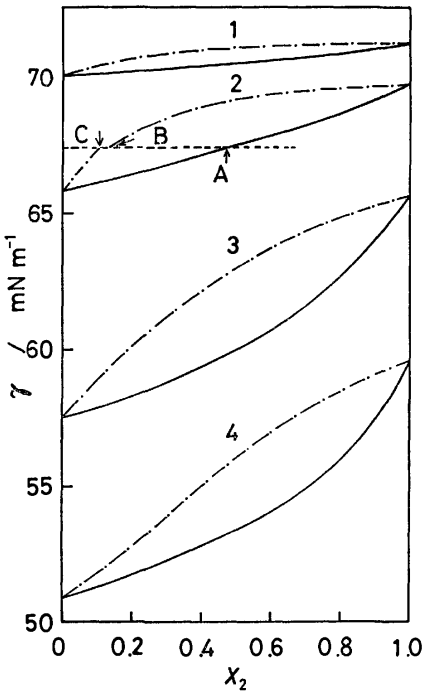

Fig. 5. Surface tension *vs.* composition curves at constant total molality. (1) $m_t^W=1$ mmol kg^{-1}, (2) 3, (3) 8, (4) 14, (——) γ *vs.* X_2^W, (----) γ *vs.* X_2^H.

between the two states becomes large as X_2^W increases.

In Fig. 4, the variation of Γ_t^H with X_2^W is drawn at constant m_t^W. It is seen that the value of Γ_t^H decreases with increasing X_2^W at a smaller value of m_t^W. However, the dependence of Γ_t^H on X_2^W reverses at about 11 mmol kg^{-1} in the expanded film. This observation seems to indicate that the hydrocarbon chain length of the surfactant has a great influence on the adsorption at water/air interface when the value of Γ_t^H is relatively small, but the effect of the size of ionic head group of DTAC becomes predominant as the value of Γ_t^H increases.

Next let us evaluate the composition of surfactants in the adsorbed film at given T, p, and m_t^W. Applying Eq. 6 to the γ *vs.* X_2^W curve shown in Fig. 2, the value of X_2^H can be calculated as a function of X_2^W. In Fig. 5, the results are illustrated in the form of the γ *vs.* X_2^H as well as the corresponding γ *vs.* X_2^W curve at various m_t^W values. We can read the relation between X_2^H and X_2^W at a given value of γ from the diagram indicated by 1 in the gaseous film and from the diagrams 3 and 4 in the expanded film. They are similar

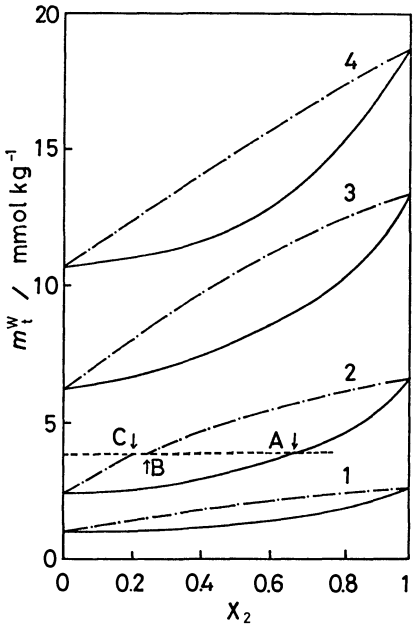

Fig. 6. Total molality *vs.* composition curves at constant surface tension. (1) $\gamma=70$ mN m^{-1}, (2) 67, (3) 60, (4) 55, (——) m_t^W *vs.* X_2^W, (– – –) m_t^W *vs.* X_2^H.

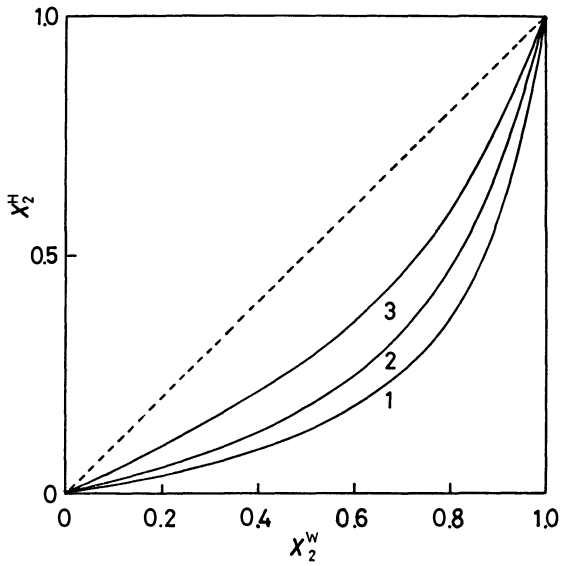

Fig. 7. Surface composition *vs.* bulk composition curves at constant surface tension. (1) $\gamma=70$ mN m^{-1}, (2) 60, (3) 50.

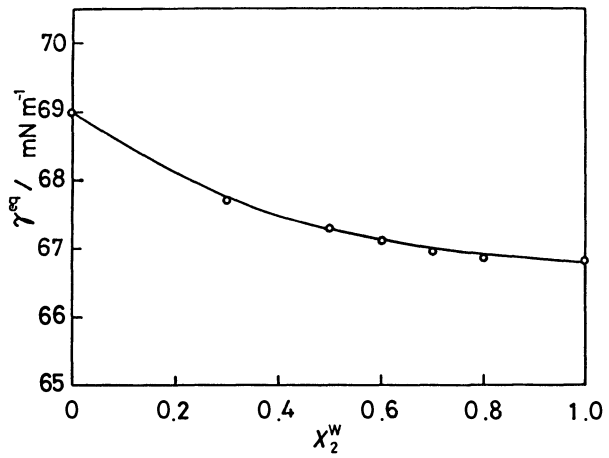

Fig. 8. Equilibrium surface tension *vs.* bulk composition curve.

in form to each other although the former takes the shape of a deflated cigar and the latters of a swollen cigar. However the diagram is slightly complex when the phase transition takes place in the adsorbed film. At $m_t^W=3$ mmol kg^{-1} (the diagram 2), the γ *vs.* X_2^W curve breaks at the point A and the γ *vs.* X_2^H curve changes discontinuously from the point B of the gaseous film to the point C of the expanded film. It should be noted that the alteration in the slope at A is related closely to the difference between the X_2^H values of B and C.

Further the value of X_2^H at constant T, p, and γ can be calculated by use of Eq. 8. The m_t^W *vs.* X_2^H and m_t^W *vs.* X_2^W are shown in Fig. 6. It is seen that the essential form of the diagram is quite similar to that in Fig. 5. It is important to note that the diagram 2, like the diagram 2 in Fig. 5, has a break point on the m_t^W *vs.* X_2^W curve and a discontinuous change on the m_t^W *vs.* X_2^H curve.

An interesting feature is manifested by plotting the value of X_2^H against X_2^W. The results at constant γ is illustrated in Fig. 7. We can see that the curve recedes from the diagonal line as the surface tension increases, *i.e.*, the difference between the compositions in the bulk phase and in the adsorbed film becomes large as the surface tension increases. This observation coincides with our previous result of the mixed system of DAC and DeAC.[15] Taking into account that DTAC and DAC are more surface active than DeAC, these facts indicate that the fraction of the more surface active molecule in the adsorbed film is enhanced remarkably at a larger value of γ.

Next, we shall elucidate the mutual relation between the compositions of the gaseous and expanded films at the phase transition point in connection with the two-dimensional phase diagram. When the two phases coexist in equilibrium, $X_2^{H,g}$ and $X_2^{H,e}$ are related to the equilibrium surface tension γ^{eq} by the expression

$$X_2^{H,g}-X_2^{H,e}=[X_1^W X_2^W(1/\Gamma_t^{H,e}-1/\Gamma_t^{H,g})/RT] \times(\partial\gamma^{eq}/\partial X_2^W)_{T,p}. \quad (9)$$

It is important to recognize that the variation in γ^{eq} with X_2^W, which is illustrated in Fig. 8, is determined by the difference $X_2^{H,g}-X_2^{H,e}$. By virtue of the diagram 2 in Fig. 5 and analogues, attended by the phase transition, we can obtain the γ^{eq} *vs.* $X_2^{H,g}$ and γ^{eq} *vs.* $X_2^{H,e}$ curves which are drawn in Fig. 9. It was found that the numerical value of $X_2^{H,g}-X_2^{H,e}$ calculated by applying Eq. 9 to the curve in Fig. 8 is approximately equal to the corresponding one in Fig. 9. This fact thermodynamically proves that the phase transition does take place at the break point on the γ *vs.* m_t^W curves.

It is seen in Fig. 9 that the value of $X_2^{H,e}$ is smaller than that of $X_2^{H,g}$. This means that the fraction of the more surface active component in the expanded film is larger than that in the gaseous film. A similar

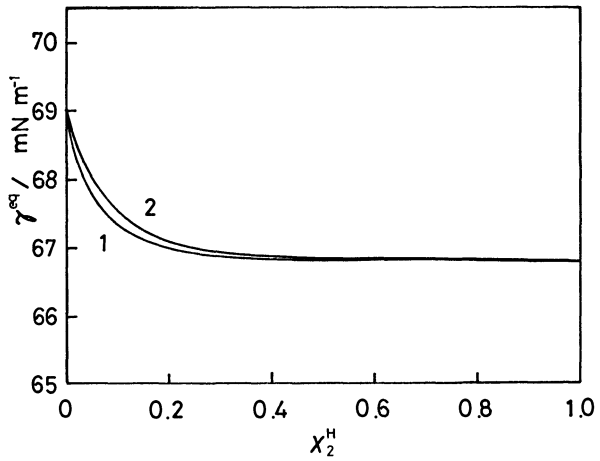

Fig. 9. Equilibrium surface tension *vs.* surface composition curves. (1) γ^{eq} *vs.* $X_2^{H,e}$, (2) γ^{eq} *vs.* $X_2^{H,g}$.

result has been obtained for the mixed adsorbed film of DAC and DeAC.[15] It is important to note that such a behavior has been observed in the case of mixed insoluble films on water if their equilibrium surface pressure *vs.* composition curves have no extremum.[19] Therefore, Fig. 9 is the two-dimensional phase diagram of the transition between the gaseous and expanded states of DTAC–DeAC mixed adsorbed film at 298.15 K under atmospheric pressure. It may be concluded that the phase transition in the mixed adsorbed film is described by the phase diagram like that in the mixed insoluble monolayer.

Conformational Analysis of Terphenyls by Photoelectron Spectroscopy

Tsunetoshi KOBAYASHI

The Institute of Physical and Chemical Research, Wako, Saitama 351

The Institute for Solid State Physics, The University of Tokyo, Roppongi, Minato-ku, Tokyo 106

(Received April 21, 1983)

Vapor phase HeI photoelectron spectra of *o*- and *m*-terphenyl were measured, and conformational analysis of biphenyl, *o*-, *m*-, and *p*-terphenyl was made by comparing the observed photoelectron spectral patterns with the calculated ones by the CNDO/S method, the inter-ring twist angles in these compounds being estimated to be around 40°, 60°, 40°, and 40°, respectively. The result that the inter-ring twist angles in *o*-terphenyl are far smaller than 90° is completely in contrast to the long believed perpendicular model of *o*-terphenyl suggested by the gas electron diffraction study.

Concerning experimental studies of molecular conformations of terphenyls in the vapor phases, there has been only one research about *o*-terphenyl by Karle and Brockway[1] so far as we know. They studied the molecular structure of *o*-terphenyl by the gas electron diffraction (ED) method, concluding that the inter-ring twist angles θ about the apparently single CC bonds are 90°, and this result has long been believed. However, if their result be correct, it will be unusually interesting because in the case of (*Z*)-stilbene, which is structurally close to *o*-terphenyl, the two phenyl rings are twisted by only 43.2° from the central olefinic group plane according to the recent gas ED study.[2]

In this paper we study the conformation of *o*-terphenyl in the vapor phase from the standpoint of photoelectron (PE) spectroscopy to see if Karle and Brockway's result is reasonable. At the same time *m*- and *p*-terphenyl, the conformations of which have not been studied in the vapor phase as yet, are also treated here. This study forms a part of our program to investigate molecular conformations by PE spectroscopy,[3] and may present a typical example of the conformational analysis of rather large free molecules by PE spectroscopy.

Concerning the PE spectra of terphenyls, Dewar and Goodman[4] reported formerly the ionization energy (IE) values of *o*-, *m*-, and *p*-terphenyl with a low resolution instrument, and Hino *et al.*,[5] the PE spectrum of *p*-terphenyl by a high resolutior. instrument.

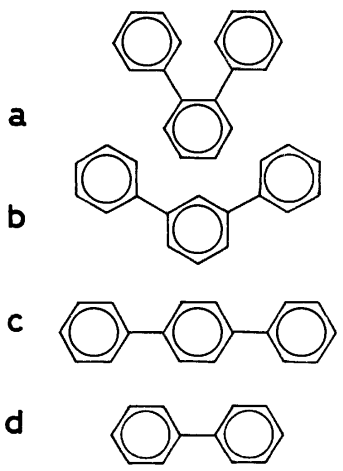

Fig. 1. Structural formulae of (a) *o*-, (b) *m*-, (c) *p*-terphenyl, and (d) biphenyl.

Experimental

Materials. Commercially available *o*- and *m*-terphenyl were recrystallized from methanol and ethanol, respectively, just before use.

Spectroscopic Measurements. Vapor phase HeI PE spectra of *o*- and *m*-terphenyl were measured with the PE spectrometer described formerly.[6] The sample inlet and target chamber systems were heated and kept at 104° for *o*-terphenyl and 105° for *m*-terphenyl by circulating hot silicone oil. Xe gas was used as the internal reference for the calibrations of the energy scale.

Computational

CNDO/S[7] calculations of biphenyl, *o*-, *m*-, and *p*-terphenyl were carried out on a FACOM 230-75 computer at the Institute of Physical and Chemical Research. All the atomic integral and parameter values necessary for the CNDO/S calculations were taken from or estimated according to Ref. 7.

In the calculations, all the benzene rings of the compounds treated here were assumed to be regular hexagons. In the case of biphenyl, the inter-ring CC single bond length was taken to be 1.489 Å and the CC bond lengths of the benzene rings, 1.396 Å according to the gas ED study.[8] All the CH bond lengths of biphenyl were assumed to be 1.0845 Å based on the gas ED data of benzene.[9]

Concerning *o*-terphenyl, Aikawa *et al.*[10] reported the molecular structural data in the crystalline state by X-ray diffraction (XD) and Brown and Levy,[11] by neutron diffraction (ND). In the present calculations, we used the averaged CC and CH bond lengths based on the data by ND, that is, the inter-ring CC bond lengths were assumed to be 1.487 Å, the benzene ring CC bond lengths, 1.390 Å, and the CH bond lengths, 1.090 Å.

In the calculations of *m*- and *p*-terphenyl, the CC and CH bond length values were assumed to be the same as those used in the calculations of biphenyl.

The CNDO/S calculations were carried out for various conformations of biphenyl and the terphenyls, the θ values being changed at intervals of 15° mostly. In the calculations the two phenyl rings in each terphenyl were twisted by the same angle.

Results and Discussion

Photoelectron Spectra. The PE spectra of *o*- and *m*-terphenyl are shown in Fig. 2 and the vertical IEs of these compounds obtained from these spectra are summarized in Table 1 with those of the related compounds.[5,12–15] The high resolution PE spectrum of

p-terphenyl was formerly reported by Hino and coworkers.[5] In contrast to the simple pattern of the lower IE part of the PE spectrum of *p*-terphenyl, the lower energy part of the PE spectrum of *o*-terphenyl is highly complicated and the spectrum of *m*-terphenyl is regarded to be the intermediate case. Now we use these PE spectral patterns for the conformational analysis of the terphenyls by comparing the spectral patterns calculated by the CNDO/S method.

Conformational Analysis. Biphenyl: At first we examine the validity of the PE spectroscopic method for conformational analysis, which we are now going to use, in the case of biphenyl, as this compound is structurally very close to the terphenyls. The θ value of biphenyl in the vapor phase is $(41.6\pm2)°$ according to the gas ED study,[8] while this compound is essentially planar in the solid state.[16]

The PE spectrum of biphenyl shows four bands in the IE region from 7.5 eV to 10.5 eV, the second and third bands overlapping highly with each other, and these four bands correspond to the ionizations from the four HO-π-MOs formed by the interactions between the totally four e_{1g}-like π orbitals of the two benzene rings mainly.[12]

In Fig. 3 is shown the orbital energy diagram calculated by the CNDO/S method with the observed vertical IEs of biphenyl. If we compare the vertical IE difference between the first and fourth PE spectral bands with the calculated energy difference between the first and fourth HO-π-MOs, we get 39.3° as the estimated θ value for biphenyl in the vapor. This estimated θ value coincides almost perfectly with the observed one in the vapor by the ED method,[8] that is, in the case of biphenyl the calculated energy difference between the first and fourth HO-π-MOs can directly be compared with the observed splitting between the corresponding PE bands without any corrections in order to estimate the θ value. The similar situation was experienced also in the case of stilbenes[3d] closely related to terphenyls.

Concerning the absolute values of the first four IEs of biphenyl, the CNDO/S calculation for $\theta=39.3°$

predicts the IE values slightly higher (by *ca.* 0.8 eV) than the observed ones commonly, if we assume the validity of the Koopmans theorem,[17] though the intervals between the four bands are well predicted by the calculation.

The vertical IEs of the perpendicular type conformer of biphenyl with $\theta=90°$ are estimated to be 9.534 eV for the first e band, 9.906 eV for the second a_2 band, and 10.082 eV for the third b_1 band by using the CNDO/S orbital energies on the basis of the Koopmans theorem. The predicted splitting of the second and third bands of this conformer is due to a spiroconjugation.[18] By using the first two vertical IEs of toluene,[13] the e band IE of the perpendicular conformer is estimated to be 8.85 eV and the a_2 and b_1 band IEs, 9.34 eV, the spiroconjugation being neglected. That is, in the case of the perpendicular conformer also, the calculation seems to predict slightly higher (by 0.7 eV) IEs, but the difference between the first IE and the averaged IE of the second and third bands predicted by the CNDO/S calculation is 0.46 eV and this value is very close to the estimated one by using the experimental IEs of toluene, 0.49 eV. So far as the IE difference or orbital energy differences are concerned, the calculated orbital energy diagram seems to be realistic over a wide range of θ in the case of biphenyl.

As terphenyls are structurally close to biphenyl and stilbenes, now we may safely apply the same method as used for biphenyl to evaluate the θ values in the terphenyls.

p-*Terphenyl*: At first let us treat the simplest case, *p*-terphenyl. The PE spectrum of *p*-terphenyl shows three bands in the IE region from 7.5 eV to 10.5 eV with the intensity ratio 1:4:1.[5] Similarly to the case of biphenyl, in this energy region totally six bands are expected to appear, corresponding to the six HO-π-MOs formed by the interactions between the six e_{1g}-like π orbitals of the three benzene rings mainly. Therefore, the first and third bands are regarded to correspond to the ionizations from the first and sixth HO-π-MOs, respectively, judging from the above intensity ratio.[5]

In Fig. 4 is shown the orbital energy diagram for the D_{2h} and C_{2h} conformers calculated by the CNDO/S method with the observed vertical IEs[5] for *p*-terphenyl. The energy diagram for the D_{2h} and D_2 conformers is also similar to Fig. 4. By comparing the observed splitting between the first and apparently third PE spectral bands with the energy difference between the first and sixth HO-π-MOs just as in the case of biphenyl, we get 43° as the θ values of *p*-terphenyl if we assume the C_{2h} conformer and 42°, the D_2 conformer. That is, *p*-terphenyl is twisted in the vapor as biphenyl in the vapor, though the θ values of *p*-terphenyl were observed to be 0.4° in the room-temperature stable monoclinic crystal (space group, $P2_1/a$) by the XD and ND methods,[19a] and 15.2°, 18.2°, 23.4°, and 26.8° in the low-temperature stable crystal (space group, $P\bar{1}$) by XD.[19b]

Suzuki[20] estimated the θ values of *p*-terphenyl in solution by the HMO level consideration using the

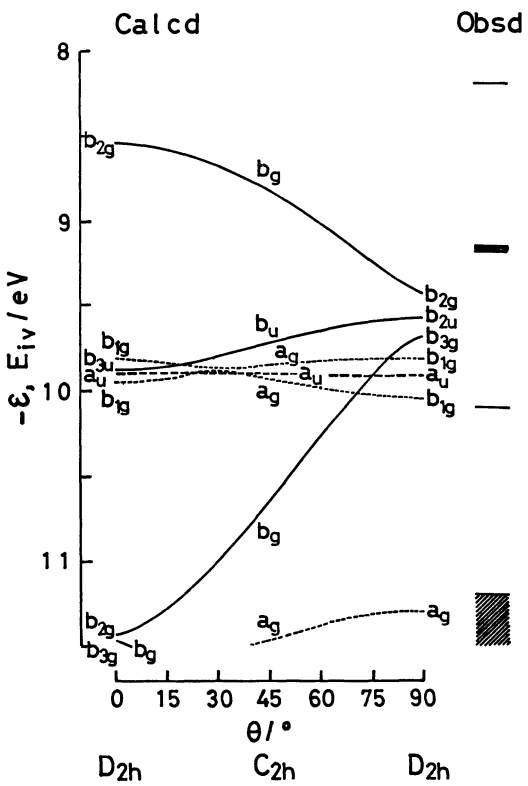

Fig. 4. Calculated orbital energy (ε) diagram with observed vertical ionization energies (E_{iv}) of *p*-terphenyl. The calculated results shown are for the D_{2h} and C_{2h} conformers. The *z*-axis was taken along the long molecular axis.

electronic absorption spectra and got 9.5—12.5°. These values do not seem to contradict ours, if we note the point that in the case of biphenyl the θ value was estimated to be 40—43° for the vapor phase and 19—26° for the solution phase by his method.[21] If we estimate the θ value ranges of biphenyl and *p*-terphenyl by using the van der Waals radii,[22] we get the result, $\theta\geq43°$. The value 43° is very close to the observed θ value of biphenyl in the vapor and those of *p*-terphenyl estimated just now. The reasonable result obtained here for *p*-terphenyl strongly supports the validity of the extended application of the method of conformational analysis tested in the case of biphenyl to the case of terphenyls.

The first and third PE spectral bands of *p*-terphenyl with the twist angles around 43° are ascribed to the ionizations from the two π orbitals delocalized completely over the entire carbon framework. In the case of *p*-terphenyl also the CNDO/S calculations predict the first six IE values slightly higher (by 0.6—0.8 eV) than the observed ones, though the intervals between the calculated ones are reasonable.

m-*Terphenyl*: Now we move to the slightly more complicated case, *m*-terphenyl. In this case, the PE spectrum shows apparently five bands in the energy region from 7.5 eV to 10.5 eV, the third band being stronger than the others. As in this energy region totally six PE spectral bands are expected to appear in the case of *m*-terphenyl also as in the case of *p*-terphenyl, the third band is regarded to be composed

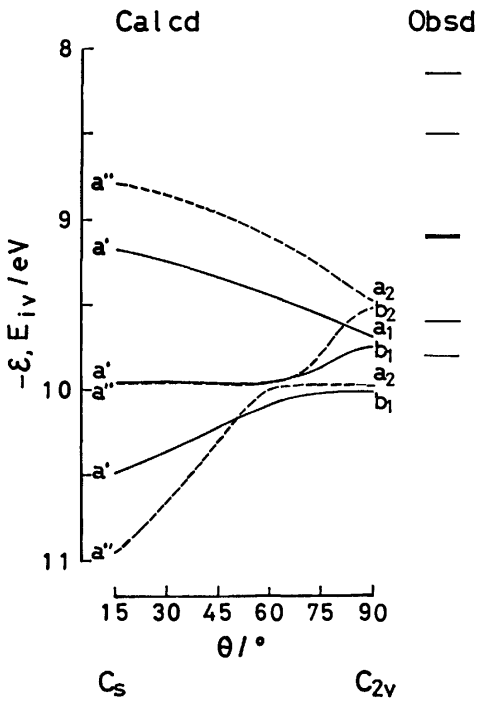

Fig. 5. Calculated orbital energy (ε) diagram with observed vertical ionization energies (E_{iv}) of *m*-terphenyl. The calculated results shown are for the C_{2v} and C_s conformers.

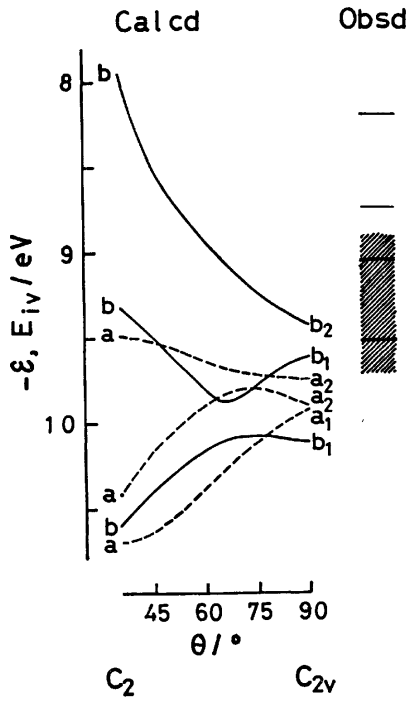

Fig. 6. Calculated orbital energy (ε) diagram with observed vertical ionization energies (E_{iv}) of *o*-terphenyl. The calculated results shown are for the C_{2v} and C_2 conformers.

of two bands overlapping highly with one another.

In Fig. 5 is shown the orbital energy diagram for the C_{2v} and C_s conformers calculated by the CNDO/S method with the observed vertical IEs for *m*-terphenyl. Just as in the case of *p*-terphenyl, by comparing the observed energy splitting between the first and apparently fifth PE spectral bands with the energy difference between the first and sixth HO-π-MOs calculated by the CNDO/S method, we get 35° as the θ values of *m*-terphenyl on the assumption of the C_s conformer and 38°, the C_2 conformer.

The θ value ranges for *m*-terphenyl are estimated to be $\theta \geq 43°$ by using the van der Waals radii,[22] and this value 43° is rather close to those estimated from the PE spectrum here. There have been no gas phase structural data about *m*-terphenyl, but the θ values of 1,3,5-triphenylbenzene closely related to *m*-terphenyl are (46±5)° according to the gas ED study by Bastiansen.[23] According to the XD study by Farag[24] the θ values of 1,3,5-triphenylbenzene are (34±2)°, (−27±2)°, and (24±2)° in the solid state. Recently Busing[25] estimated the θ values in an isolated 1,3,5-triphenylbenzene molecule to be 43.6° using the intramolecular potential function empirically determined from the crystalline data. These literature values for 1,3,5-triphenylbenzene are all consistent with our result for *m*-terphenyl by the PE spectroscopic method.

The calculated orbital sequence of the six HO-π-MOs of *m*-terphenyl is the same as that predicted by the simple HMO model around the twist angles estimated here. The first, second, fifth, and sixth HO-π-MOs are delocalized over the three benzene rings, the third and fourth ones being localized on the two *m*-phenyl groups. The CNDO/S calculations predict IEs slightly higher (by 0.7—0.9 eV) than the observed vertical ones for the first six IEs in the case of *m*-terphenyl also, but the calculated intervals between these six IEs are reasonable. Now the first apparently five bands of *m*-terphenyl are assigned to the a″ (a), a′ (b), overlapping a′ (b) and a″ (a), a′ (b), and a″ (a) bands from the top, respectively, for the C_s (C_2) conformer, the apparently third band being ascribed to the two highly overlapping bands.

o-Terphenyl: Now we may safely be able to treat our primary object, *o*-terphenyl, the most complicated one of the three terphenyls. The PE spectrum of *o*-terphenyl shows apparently four band maxima in the energy region from 7.5 eV to 10.5 eV. The first band is isolated from the following band group, their intensity ratio being approximately 1:5. As in this energy region totally six π bands are expected to appear in the case of *o*-terphenyl also just as in the case of *m*- and *p*-terphenyl, the first band is reasonably ascribed to the ionization from only the first HO-π-MO. As the 8.7 eV peak is also weak relative to the 9.1 and 9.5 eV apparent band maxima, the 8.7 eV peak may correspond to one ionization band, and each of the following two apparent strong band maxima may correspond to two overlapping bands. Keeping these points in mind let us carry out the conformational analysis of *o*-terphenyl.

In Fig. 6 is shown the orbital energy diagram calculated by the CNDO/S method for the C_{2v} and C_2 conformers of *o*-terphenyl with the observed vertical IEs. By comparing the observed energy difference between the first and the apparently fourth PE spectral bands with the calculated energy difference between

the first and sixth HO-π-MOs, we get 63° as the θ values of *o*-terphenyl on the assumption of the C_2 conformer and 66°, the C_s conformer. The θ value ranges estimated from the van der Waals radii are $\theta \geq 63°$ for the C_2 conformer and $\theta \geq 80°$ for the C_s conformer of *o*-terphenyl, and, therefore, we regard 63° for the C_2 conformer as the most probable θ values of *o*-terphenyl. These values are far from 90° determined by the gas ED method formerly,[1] and rather very close to those observed by the XD[10] and ND[11] methods for the solid states.

Suzuki estimated the θ values of *o*-terphenyl in solution as 42.5—43° by the electronic absorption spectroscopic method,[20] and these values do not contradict ours, if we remember the results for biphenyl mentioned just before in the discussion of *p*-terphenyl. Busing estimated the θ values in an isolated *o*-terphenyl molecule as 54.3° by the intramolecular potential function method.[25] These values are close to ours.

From the discussion given above, the θ values in *o*-terphenyl are around 60° in the vapor phase and at least far from 90°.

The calculated spectral pattern of *o*-terphenyl for the C_2 conformer around $\theta=63°$ based on the Koopmans theorem[17] reproduces well the overall feature of the observed one though the former is slightly shifted (by 0.6—0.9 eV) to the higher IE side relative to the latter. The orbital sequence of the fifth and sixth HOMOs predicted by the CNDO/S method is reversed to that predicted by the simple HMO model. In the case of *o*-terphenyl as in the case of (*Z*)-stilbene[26] the overlap integrals between the two twisted *o*-phenyl ring group π orbitals are not negligible and through-space orbital interactions between these orbitals, which are taken into account in the CNDO calculations automatically, may influence the orbital orderings. However, further detailed discussions about the orbital orderings of *o*-terphenyl are hindered by the highly overlapping nature of the PE spectral bands. Now the first apparently three bands of *o*-terphenyl are ascribed from the top, respectively, to the b, a, and overlapping b and a bands followed by the overlapping b and a bands corresponding to the fourth apparent band maximum for the C_2 conformer.

Summary of θ Values by Various Methods. Finally the θ values in the terphenyls and related compounds given by various methods for various phases are summarized in Table 2 for the sake of comparison. Le Fèvre *et al.*[27] estimated the θ values of the terphenyls and 1,3,5-triphenylbenzene in solution phases based on the molecular polarizability data or molar Kerr constants as given in Table 2. Their results are qualitatively consistent with ours. Recently Wakayama[28] estimated the θ values of *p*-terphenyl in solution at 77 K to be larger than 16° from its $S_1 \leftarrow S_0$ absorption in solution compared with that of crystalline state at 77 K on the basis of the XD data by Baudour *et al.*[19b] Theoretically Gamba *et al.*[29,30] calculated the θ values of biphenyl and the terphenyls by the molecules-in-molecule method by taking into account the non-bonded interactions, and their theoretical values are consistent with our present results.

Conclusion

Summing up the discussion given above it is concluded that *o*-terphenyl is more twisted than biphenyl, *m*- and *p*-terphenyl, but the inter-ring twist angles in *o*-terphenyl are around 60° and far from 90° in the vapor phase in contrast to the former gas ED result. It has been demonstrated that PE spectroscopy is very useful for the conformational analysis of rather large molecules in the vapor phase to which the other methods such as the gas ED method and the microwave spectroscopic method are not so easy to be applied.

The author thanks Professor Y. Maruyama of Ochanomizu University for his interest in this work.

Liquid Crystal Formation in Binary Systems. VIII.[1] Induction of Smectic Phases by the Addition of 4-Alkoxynitrobenzene or 4-Alkoxybenzonitrile to *N*-(4-Propoxybenzylidene)-4-hexylaniline

Eiji CHINO and Yoshio MATSUNAGA*

Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060

(Received April 25, 1983)

When 4-alkoxynitrobenzenes are mixed with *N*-(4-propoxybenzylidene)-4-hexylaniline, smectic A phases which are not found with the component compounds, are produced. The liquid crystals are stable if the number of carbon atoms in the alkoxyl group is eight or more, the maximum temperature being 49 °C with dodecyloxyl group, but they are entirely metastable if the number of carbon atoms is six or less. The extrapolation of the partly-observed smectic A-isotropic transition point curve indicates that 4-(dodecyloxy)-nitrobenzene has a latent transition point at about −25 °C and that all the examined *p*-disubstituted benzenes are potentially smectogenic. Smectic A phases are also induced by the addition of 4-alkoxybenzonitriles to the above Schiff base. The transition to the induced mesophase is enantiotropic when the alkoxyl group is decyloxyl or dodecyloxyl. The replacement of the propoxyl group in the Schiff base with an ethoxyl group makes the induced smectic A phases thermally less stable. The change is drastic when the alkoxyl group in the *p*-disubstituted benzene is hexyloxyl or shorter.

We reported in earlier papers,[2-5] that nematic and smectic liquid crystals can be induced by mixing a nonmesogenic electron donor and a nonmesogenic electron acceptor of the type 4-*X*-C_6H_4-*Z*-C_6H_4-*Y*-4. The appearance of mesophases in these binary systems was attributed to the thermal stabilization of the potential mesophases of the component compounds by the charge-transfer interaction introduced by mixing. It is generally believed that monomeric *p*-disubstituted benzenes are not mesogenic. However, the possibility that they are potentially mesogenic cannot be excluded. The observation of a smectic phase in the 4,4′-bis-(hexyloxy)azoxybenzene–4-(hexyloxy)nitrobenzene system covering the range as wide as 70 mol% reported by Schroeder and Schroeder[6] may be indicative of the potentially smectogenic behavior of 4-alkoxynitrobenzenes. We report here that the potential liquid crystal behavior of 4-alkoxynitrobenzenes and 4-alkoxybenzonitriles are readily demonstrable by the induction of new mesophases in the binary systems. For this purpose, we employed *N*-(4-propoxybenzylidene)-4-hexylaniline, which gives a nematic phase stable between 42 and 63 °C and a metastable smectic B phase below 21 °C, and its related compounds as the other components.[7]

Experimental

Materials. *N*-(4-Propoxybenzylidene)-4-hexylaniline, hereafter abbreviated as (3O, 6) designating the alkoxyl and alkyl carbon numbers for the substituents, was prepared by a condensation reaction between 4-propoxybenzaldehyde and 4-hexylaniline. The Schiff bases (2O, 6), (3O, 4), and (9O, 3) were similarly prepared. A homologous series of 4-alkoxynitrobenzenes was obtained by the alkylation of 4-nitrophenol following the procedure reported by Gray and Jones.[8] The compounds will be referred to as *n*O, NO_2 on the basis of the substituents where *n* is the number of carbon atoms in the alkoxyl group. By replacing 4-nitrophenol with 4-hydroxybenzonitrile, the 4-alkoxybenzonitriles, *n*O, CN, could be obtained.

Measurements. The calorimetric curves were recorded on a Rigaku Thermoflex differential scanning calorimeter equipped with a low-temperature unit. The heating and cooling rates in this work were 3 °C min^{-1}. The mesophases were identified by examining the texture with the aid of a polarizing microscope and by studying the continuous miscibility with the reference mesophases given by (9O, 3).

Results and Discussion

4-Alkoxynitrobenzenes, nO, NO_2. The even carbon number homologs up to $n=12$ were examined. Induced smectic A phases were observed in all the mixtures with (3O, 6). The phase diagrams of the binary systems containing each of 2O, NO_2, 6O, NO_2, and 10O, NO_2 are shown in Fig. 1. The open and shaded circles indicate the transitions recorded during the processes of heating and cooling respectively.

In Fig. 1a, the smectic phase found in the composition range from 61 to 87 mol% of (3O, 6) shows a texture different from the smectic B phase of (3O, 6); therefore, the induction of a smectic A phase by mixing is highly probable. This conclusion is confirmed by a study of the phase diagram of the pseudo-binary system consisting of the 81 mol% mixture (shown by an arrow in Fig. 1a) and (9O, 3). The latter compound gives a smectic A phase stable between 71.5 and 84 °C and also a smectic B phase stable between 48 and 71.5 °C.[9] The results presented in Fig. 1b firmly establish that the monotropic transition observed at 24 °C in the 81 mol% mixture is from a supercooled nematic phase to a smectic A phase. The smectic B phase exhibited by (3O, 6) appears to be drastically destabilized by the addition of 2O, NO_2.

The smectic A phase induced in the 4O, NO_2-(3O, 6) system covers the composition range from 50 to 82 mol% of (3O, 6), the maximum being located at 29 °C and near 80 mol%. This temperature is higher by 12 °C than that of the eutectic point. The transition temperature of (3O, 6) from the nematic phase to the smectic B phase is not much lowered by the addition of 4O, NO_2. At 89 mol% of (3O, 6) the supercooled nematic phase is transformed into the smectic B phase at 16 °C.

The compound 6O, NO_2 melts at 26 °C, the lowest among the melting points of *n*O, NO_2 examined. The

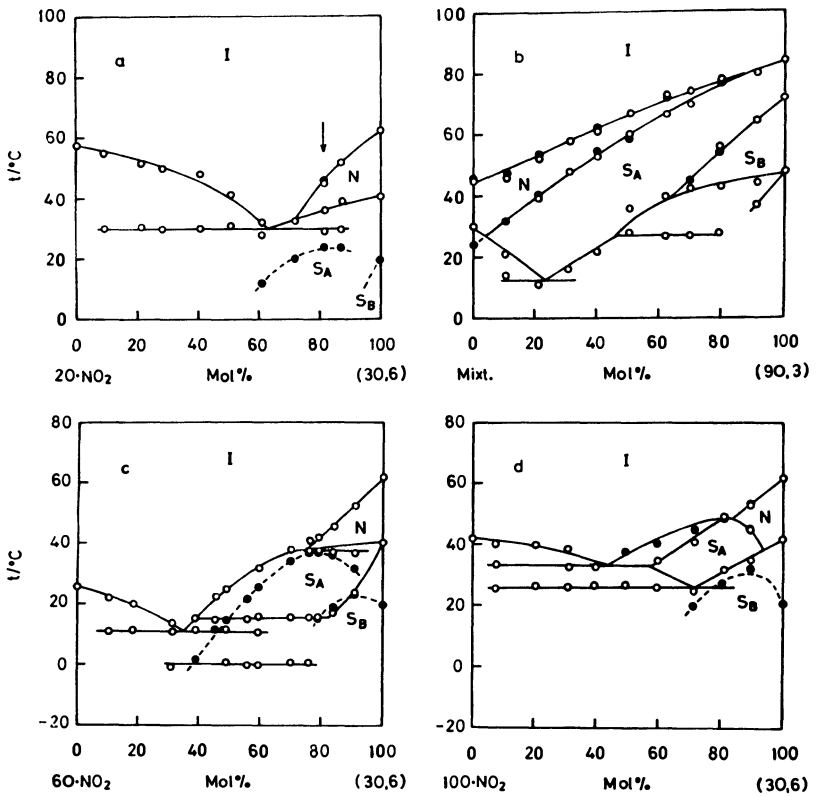

Fig. Phase diagrams of (a) 2O, NO_2-(3O, 6), (b) its 81 mol% mixture-(9O, 3), (c) 6O, NO_2-(3O, 6), and (d) 10O, NO_2-(3O, 6) systems. The open and shaded circles are transitions observed in the processes of heating and cooling respectively.

system with (3O, 6) exhibits a smectic A phase in the range from 39 to 91 mol% of (3O, 6). Around 78 mol%, the transition point curve reaches its maximum of 38 °C. The stabilization of the smectic B phase by 6O, NO_2 is also noted in this binary system. The monotropic transition at 91 mol% is found at 24 °C (see Fig. 1c).

The smectic A liquid crystals in the systems with each of 8O, NO_2, 10O, NO_2, and 12O, NO_2 can exist as stable phases. As the three phase diagrams are of the same type, they are exemplified by that of the 10O, NO_2-(3O, 6) system (see Fig. 1d). The transition between the isotropic liquid and the smectic A phase does not occur at a fixed temperature, that is, there is a range over which the isotropic liquid and the smectic A phase coexist. The smectic A-smectic B transition point curve is markedly convex upwards. As summarized in Fig. 2, the maximum smectic A-isotropic transition temperature against chain-length plot (see Curve a) shows a continued rise up to $n=10$ and then levels out. This change is of a common type for relationships known for homologous series of mesogenic compounds.[10]

The nematic-isotropic transition point curve is convex upwards in Fig. 1a, while the corresponding ones in the other systems are essentially straight (see Figs. 1c and 1d). Nevertheless, the latent transition point estimated for nO, NO_2 by the extrapolation to 0 mol% of (3O, 6) cannot be accurate since the observed fragment is not long enough. To a rough approximation, it is about −50 °C when $n=4$ and about −20 °C when

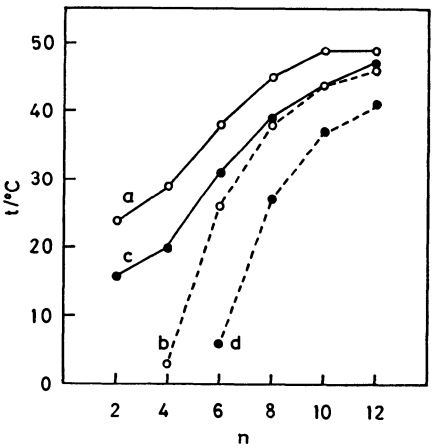

Fig. 2. Plots of the maximum temperatures of the induced smectic A phases against the length of the alkyl chain, n, for (a) nO, NO_2-(3O, 6) (b) nO, NO_2-(2O, 6), (c) nO, CN-(3O, 6), and (d) nO, CN-(2O, 6) systems.

$n=12$. If one similarly extrapolates plot of the smectic A-isotropic transition points against the composition, the latent smectic A-isotropic or -nematic transition point of nO, NO_2 may be estimated. Unfortunately, the plot is far from linear and the available points are limited to a high mol% range. By guess, one might infer about −60 °C for 6O, NO_2 and between −30 to −20 °C for 10O, NO_2 and 12O, NO_2: therefore, these temperatures are for transitions from smectic A phase to nematic phase.

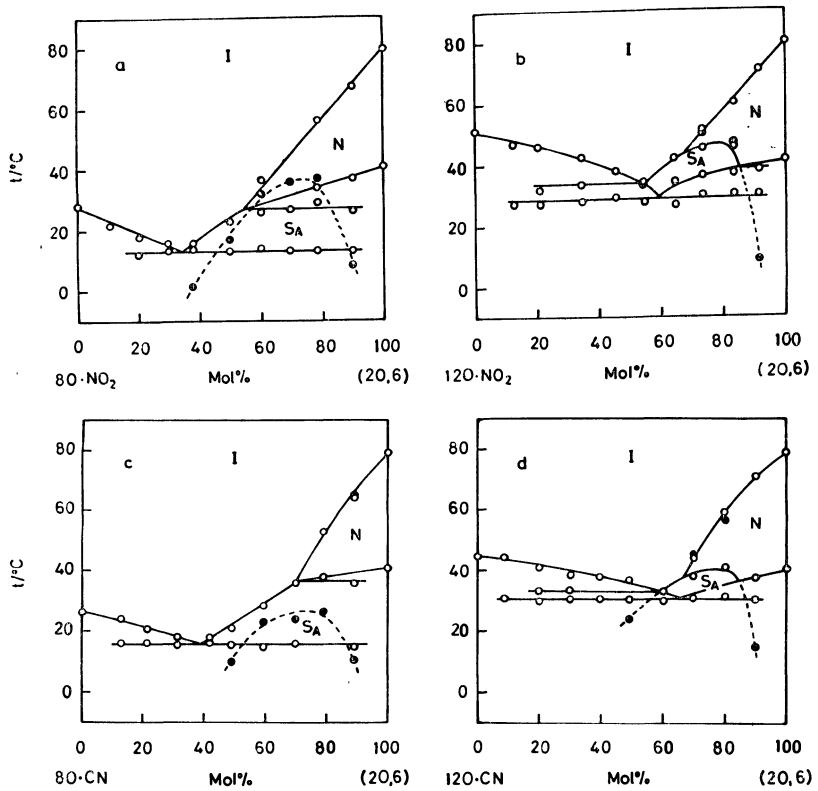

Fig. 3. Phase diagrams of (a) 8O, NO_2-(2O, 6), (b) 12O, NO_2-(2O, 6), (c) 8O, CN-(2O, 6), and (d) 12O, CN-(2O, 6) systems. As to the open and shaded circles, see the caption of Fig. 1.

The potential liquid crystal behavior of nO, NO_2 is supported also by the work on the systems with (2O, 6). The compound (2O, 6) is known to be nematogenic.[7] The mesophase is stable between 40.5 and 79.5 °C. Except for 2O, NO_2, smectic A phases are induced in all the combinations. The maximum smectic A-isotropic transition temperatures are given in Fig. 2 (see Curve b). Because of the steep rise between $n=4$ and 6 and that between $n=6$ and 8, Curve b lies far below Curve a at $n=2$ but the two approach to each other at $n=12$. Only when $n=10$ and 12, does the induced mesophase have a region of stable existence. The phase diagrams of the systems with each of 8O, NO_2 and 12O, NO_2 are presented in Fig. 3. The latent smectic A-nematic transition point of 8O, NO_2 may be estimated to be about −50 °C. As the smectic A phase induced in the 4O, NO_2-(2O, 6) system covers only the range from 70 to 80 mol% of (2O, 6), we studied further the system with (3O, 4). This mesogen exhibits a nematic phase stable between 41 and 58 °C and also a smectic B phase appearing from the supercooled nematic phase at 23.5 °C.[7] In the mixture with 4O, NO_2, the smectic A phase can be seen in the range from 50 to 90 mol% of (3O, 4), the maximum lying at 20 °C and about 75 mol%. Although the maximum temperature is lowered by 9 °C compared with that found in the corresponding system with (3O,6), there is no significant difference between the extent of the observable composition range. The latent smectic A phase of 4O, NO_2 may be located at a temperature as low as −70 °C. When 2O, NO_2 is mixed with (3O, 4), a smectic A phase is induced in the range from 70 to 88 mol%. In general, the stabilization of the smectic A phase by mixing with *N*-(4-alkoxybenzylidene)-4-alkylaniline appears to decrease in this order: (3O, 6)>(3O, 4)>(2O, 6).

4-Alkoxybenzonitriles, nO, CN. As exemplified by the binary systems consisting of (3O, 6) and each of 2O, CN, 6O, CN, and 10O, CN, these *p*-disubstituted benzenes are also potentially smectogenic. In Fig. 4a, the appearance of a new mesophase is indicated by the two monotropic transitions at 91 mol% of (3O, 6). The phase diagram of the pseudo-binary system, the 81 mol% mixture-(9O, 3), establishes that the newly-appeared phase is of the smectic A type (see Fig. 4b). The temperature range where this mesophase is observable is lower by 8 to 10 °C than that found in the 2O, NO_2-(3O, 6) system.

By mixing with (3O, 6), the compound 4O, CN produces a metastable smectic A phase covering the range from 40 to 90 mol%. The maximum temperature lies at 20 °C near 80 mol%. The transition to the smectic B phase located at 11 °C and 77 mol% may imply that the latent smectic B phase is thermally more stable than the smectic A phase when extrapolated to pure 4O, CN. It may be added that 4O, CN has the lowest melting point, 18.5 °C, among the 4-alkoxybenzonitriles employed in this work.

The phase diagram for the 6O, CN-(3O, 6) system is shown in Fig. 4c. In this system, the smectic A-smectic B transition point curve exhibits a maximum at about 90 mol% and 27 °C but the observation of the smectic B phase is limited to the range above 80 mol%.

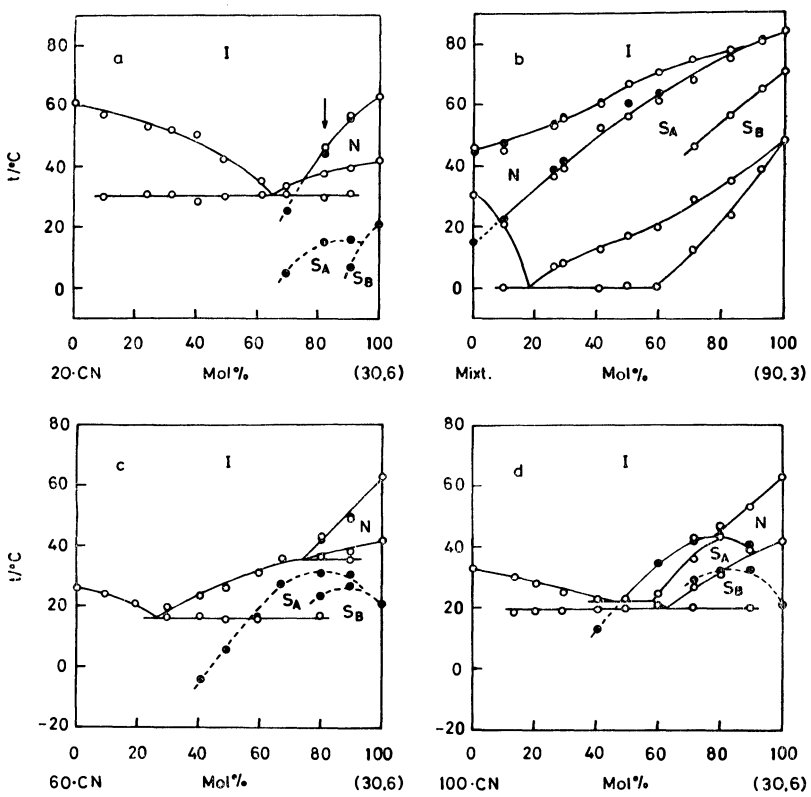

Fig. 4. Phase diagrams of (a) 2O, CN-(3O, 6), (b) its 81 mol% mixture-(9O, 3), (c) 6O, CN-(3O, 6), and (d) 10O, CN-(3O, 6) systems. As to the open and shaded circles, see the caption of Fig. 1.

With 8O, CN the stabilization of the smectic phases is appreciable. The maximum of the monotropic isotropic-smectic A transition point curve is at 39 °C and almost coincides with the horizontal line extending from the intersection between the isotropic-nematic transition point curve and the freezing point curve of (3O, 6). The smectic B phase is observable above 70 mol% with the maximum at 29 °C and about 85 mol%.

As is shown in Fig. 4d, a stable smectic A phase is found in the 10O, CN-(3O, 6) system. The compound 12O, CN also produces a diagram of the same type when it is mixed with (3O, 6). Although the diagram given in Fig. 4d bears a close similarity to that in Fig. 1d, it must be noted that the stabilization of smectic B phase with benzonitrile is more pronounced than that with nitrobenzene.

In Fig. 2, Curve c gives the plot of the maximum temperature of the smectic A-isotropic transition point curve against n. The temperature is 16 °C at $n=2$ and steadily increases to 47 °C at $n=12$.

Smectic A phases could be observed by mixing (2O, 6) with 6O, CN, 8O, CN, 10O, CN, and 12O, CN; however, only with the last benzonitrile the liquid crystal can be stable in a small region (see Figs. 3c and 3d). The maximum transition temperature in the nO, CN-(2O, 6) system is shown by Curve d in Fig. 2. The value is 6 °C at $n=6$ and 41 °C at $n=12$. Contrary to the 2O, NO_2-(3O, 4) system, the compound 2O, CN gives no smectic A phase when mixed with (3O, 4); however, the thermal stabilization of the smectic B phase is extensive and is observed to 78 mol% of (3O, 4), the temperature at this composition being 0 °C. When 4O, CN is employed with (3O, 4), a metastable smectic A phase appears in the range from 55 to 80 mol% of (3O, 4). The transition occurs at 16 °C at the upper limit and no maximum is located for this composition.

In conclusion, 4-alkoxynitrobenzenes and 4-alkoxybenzonitriles are potentially smectogenic. This potential liquid crystal behavior is possibly common to a wide range of *p*-disubstituted benzenes. The induction observed in the present systems may be partly attributed to the electron-donor-acceptor interaction as indicated by the pale yellow color developed on mixing and also may be partly due to a dipole-dipole interaction. As described above, the smectic A phases induced are observable mostly above 50 mol% of the Schiff base. This limitation may be ascribed to the relatively low latent transition temperatures of the *p*-disubstituted benzenes. In order to estimate the latent transition temperatures, it seems highly desirable to obtain essentially straight transition point curves in the binary systems with reference mesogens. With such systems, the effects of terminal substituents on liquid crystal behavior may be firmly established because of the simplicity of molecular structure. Attempts along this line are now in progress.

The present work was partly supported by a Grant-in-Aid for Scientific Research No. 543001 from the Ministry of Education, Science and Culture.

Excimer Formation and Phase Separation of Hydrocarbon and Fluorocarbon Bilayer Membranes[1)]

Toyoki KUNITAKE,* Shin-ichiro TAWAKI, and Naotoshi NAKASHIMA
Department of Organic Synthesis, Faculty of Engineering, Kyushu University, Higashi-ku, Fukuoka, 812
(Received June 3, 1983)

The benzene chromophore contained in double-chain(hydrocarbon) ammonium amphiphiles gives both of monomer and excimer fluorescence in the fluid(liquid crystalline) bilayer organization. The excimer emission disappears by phase transition to the rigid(crystalline) bilayer. In contrast, the corresponding fluorocarbon bilayer, in the absence of phase transition phenomena, shows excimer emission at all temperatures(15—50 °C). The excimer emission decreases when these probe amphiphiles are diluted in matrix bilayers. These results are applied to study the phase separation behavior of hydrocarbon and fluorocarbon bilayer membranes. The fluorocarbon bilayer is not extensively miscible with the hydrocarbon bilayer, and *vice versa*. The miscibility is influenced additionally by the chemical structure of amphiphiles. The rate of mixing is determined by the component miscibility as well as by the aggregate morphology. The DSC study supports these conclusions and further indicates that an unsymmetrical, double-chain(one hydrocarbon and one fluorocarbon chains) amphiphile can promote mixing of typical hydrocarbon and fluorocarbon bilayers.

It was recently reported from these laboratories that bilayer membranes are spontaneously formed from single-chain and double-chain ammonium amphiphiles with perfluoroalkyl groups.[2)] These fluorocarbon membranes combine organized assemblage similar to that of the hydrocarbon bilayer membrane and peculiar physicochemical properties of fluorocarbon compounds. For example, the fluorocarbon bilayer vesicle was more stable and less permeable to some organic probes than the hydrocarbon counterpart.

One of the interesting characteristics of fluorocarbon micelles is their limited miscibility with the hydrocarbon micelle.[3-7)] It is therefore expected that phase separation is readily induced in mixed membranes of hydrocarbon and fluorocarbon amphiphiles. Phase separation plays important roles in regulation of the biomembrane function. In the case of the synthetic bilayer membrane, phase separation was used to detect the interaction of the surface receptor with added ions,[8)] and the rates of hydroxide- and imidazole-catalyzed cleavage of phenyl esters were affected by phase separation of reacting species in the bilayer matrix.[9,10)]

The excimer formation has been used to probe the distribution and orientation of component amphiphiles in bilayers. For example, phosphatidylcholine lipids which contain covalently-bound pyrene chromophore were prepared by Sunamoto and coworkers and the excimer formation in the liposomal matrix was discussed in terms of membrane organization.[11,12)] Nagamura *et al.* reported that dialkylammonium salts which contain the phenoxy moiety in the alkyl chain portion gave weak excimer emission in the bilayer state.[13)] We reported recently that anthracene-containing, single-chain amphiphiles form bilayer membranes and that strong excimer emission is observed when the amphiphile is buried in the dialkylammonium bilayer matrix.[14)]

In the present paper, we describe our recent finding that double-chain ammonium amphiphiles which contain the benzene chromophore in the spacer portion

give strong excimer emission in the bilayer organization. Since the double-chain can be either hydrocarbon or fluorocarbon and since the excimer emission is highly dependent on the membrane physical state, these amphiphiles become very convenient probes for studying phase separation of hydrocarbon and fluorocarbon bilayers. The amphiphiles used are shown above together with their abbreviations.

Experimental

Fluorocarbon Amphiphile. 2*H*,2*H*,3*H*,3*H*-Perfluorundecanoic acid(24.6 g, 0.05 mol, Ugine Kuhlmann) was suspended in 18 g(0.15 mol) of thionyl chloride and the mixture was refluxed for 2 h and distilled *in vacuo*: colorless oil, yield 22.4 g(88%), bp 102—104 °C/13—14 mmHg(1 mmHg ≈133.3 Pa). The acid chloride(12 g, 0.024 mol) in 50 cm³ of $CHCl_3$ was added dropwise with stirring to an ice-cooled mixture of 1 g(8.4×10^{-3} mol) of commercial bis(2-hydroxyethyl)methylamine and 2 g(0.02 mol) of triethylamine in 100 cm³ of $CHCl_3$. The mixture was stirred further at room temperature for 1 h and at 40—50 °C for 24 h, and washed with water and aqueous Na_2CO_3 and dried over Na_2SO_4. The solvent was removed and the residue was distilled: colorless wax, yield 6.4 g(71%), bp 140—190 °C/0.03 mmHg. The formation of the diester was confirmed by IR and NMR spectroscopies. A large excess of CH_3Br was introduced to the diester(1 g, 9.4×10^{-4} mol) in 100 cm³ of tetrahydrofuran (THF). The mixture was stirred for 120 h at room temperature, and the precipitates formed were recrystallized from methanol and benzene: colorless flakes, yield 0.7 g(64%), mp 165—169.5 °C. The spectroscopic data(NMR and IR) were consistent with **2**. Found: C, 28.88; H, 1.87; N, 1.25%. Calcd for $C_{28}H_{22}NO_4F_{34}$: C, 28.93; H, 1.91; N, 1.20%.

A mixture of 4.5 g(0.042 mol) of commercial bis(2-hydroxyethyl)methylamine and 1.0 g(0.01 mol) of triethylamine in 100 cm³ of $CHCl_3$ was added dropwise to 5.0 g(0.01 mol) of the acid chloride in 50 cm³ of $CHCl_3$ with ice cooling. The mixture was then stirred at room temperature for 72 h, washed with water and aqueous Na_2CO_3, and dried. The solvent was removed, and toluene was added to the residual yellow oil, which was then kept in a refregerator. The colorless precipitates were recovered by quick separation, but they turned to colorless oil at room temperature: yield 3.0 g(51%). IR and NMR spectra showed the product to be the monoester. Undecanoyl chloride(1.3 g, 6.1×10^{-3} mol) in 40 cm³ of $CHCl_3$ was added dropwise to a solution of 3.0 g(5.1×10^{-3} mol) of the monoester and 0.6 g(6×10^{-3} mol) of triethylamine in 60 cm³ of $CHCl_3$ with ice cooling. The mixture was further stirred at 40 °C for 12 h, washed with water and aqueous $NaHCO_3$, and dried. The solvent was removed and colorless oil(TLC-FID, single peak) was recovered. A large excess of CH_3Br was introduced to 3.6 g(4.6×10^{-3} mol) of the product dissolved in 100 cm³ of dry THF, and the mixture stirred at room temperature for 24 h. The colorless precipitates were recrystallized from benzene, separated from the $CHCl_3$-insoluble by-product, and recrystallized again from benzene: colorless wax, yield 0.9 g (22%), mp 100→193 °C(the arrow indicates the liquid crystalline range). The structure (**4**) was confirmed by NMR spectroscopy. Found: C, 39.58; H, 4.74; N, 1.65%. Calcd for $C_{29}H_{41}F_{17}O_4NBr\cdot0.5H_2O$: C, 39.60; H, 4.81; N, 1.59%.

Amphiphiles **1**, **3**, and **9** were provided by S. Yasunami[2,15]

Hydrocarbon Amphiphile. *N*,*N*-bis[2-dodecanoyloxy)-ethyl]methylamine hydrochloride[15] (colorless powder, mp 105→120 °C)(2.5 g, 4.4×10^{-3} mol) in benzene was treated with aqueous Na_2CO_3 and dried. A large excess of CH_3Br gas was introduced to the solution and the mixture stirred at room temperature for 70 h. The colorless precipitates formed were recrystallized from ethyl acetate to give colorless powder of **7**: yield 1.4 g(55%), mp 173—175 °C. Found: C, 62.06; H, 10.38; N, 2.24%. Calcd for $C_{30}H_{60}O_4NBr$: C, 62.26; H, 10.45; N, 2.42%. Amphiphile **5** was provided by H. Fukushima.[16] Amphiphile **8** was described elsewhere.[19] The preparations of a series of dialkylammonium salts **6** were described briefly.[17,18] CTAB and CTAC are recrystallized from ethanol.

Miscellaneous. Electron micrographs were obtained with a Hitachi H-600 instrument, and fluorescence spectra were measured with a Hitachi 650-10S spectrofluorimeter. The degree of fluorescence polarization, P was obtained by Eq. 1.

$$P = \frac{I_{//\,//} - I_{//\perp}(I_{\perp//}/I_{\perp\perp})}{I_{//\,//} + I_{//\perp}(I_{\perp//}/I_{\perp\perp})}, \quad (1)$$

where $I_{//\,//}$ and $I_{\perp\perp}$ are emission measured with parallel polarizers(vertical and horizontal) and $I_{//\perp}$ and $I_{\perp//}$ are those measured with crossed polarizers.[20] UV-visible spectra were obtained with Hitachi spectrophotometers 200 and 220 A. Differential scanning calorimetry (DSC) was conducted for 20-mM samples with a Daini-Seikosha SSC/560 instrument. The temperature was raised from 0 °C at a rate of 2 °C/min.[21]

Results and Discussion

Aggregation Behavior. Figure 1 shows electron micrographs of $2C_{11}^F$-de-N^+, C_{11}^F,C_{12}-de-N^+, and $2C_{12}$-de-N^+. The sample preparation has been described before.[22] However, satisfactory staining was not attained by the previous method in the case of fluorocarbon membranes. In an improved procedure, crystalline membrane compounds and uranyl acetate were suspended in water and sonicated together. The bilayer structure(vesicle and lamella) is clearly observed for $2C_{11}^F$-de-N^+. C_{11}^F,C_{12}-de-N^+ gives very

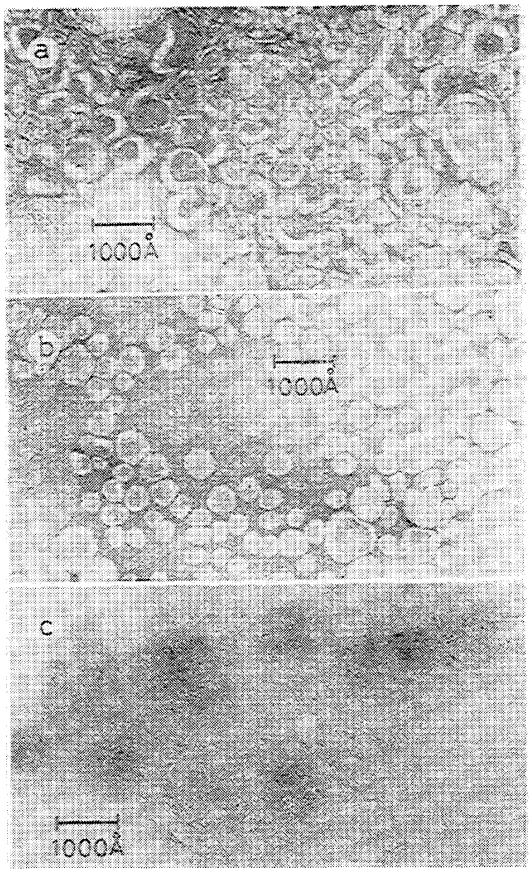

Fig. 1. Electron micrographs.
Sample 10 mM; initial magnification, ×30,000; stained by uranyl acetate, (a) $2C_{11}^{F}$-de-N^+ (b) C_{11}^{F}, C_{12}-de-N^+, (c) $2C_{12}$-de-N^+.

well dispersed, single-walled vesicles. The hydrocarbon counterpart, $2C_{12}$-de-N^+ gives multi-walled vesicles. These three compounds differ only in the long-chain portion(hydrocarbon or fluorocarbon). The bilayer organization is maintained when the hydrocarbon tail is replaced by the fluorocarbon tail of similar length, as mentioned previously.[2] However, it is interesting that the combination of hydrocarbon and fluorocarbon tails in an amphiphile gives single-walled vesicles that are much better dispersed than those of the bilayer aggregate of amphiphiles with two hydrocarbon(or fluorocarbon) tails.

All the other double-chain amphiphiles have been shown to form stable bilayer membranes.[2,15,16]

Excimer Emission of Hydrocarbon and Fluorocarbon Bilayers. Figure 2 describes fluorescence spectra of the aqueous bilayer of $2C_{12}$-L-Glu-ph-C_2N^+.[21] The excitation wavelength is set at 260 nm where the benzene ring absorbs. At 20 °C, the emission maximum appears at 320 nm, which is located close to that observed in methanol (312 nm). This peak is, therefore, attributed to the monomer emission. With rising temperature, this peak is lessened and a new, broader peak appears at 360 nm. The separation of the two peaks corresponds to *ca.* 4000 cm^{-1}, and this extent of energy difference is typical of the excimer formation.[24] The 360-nm peak shifts completely to 320 nm by addition of the CTAB micelle (2 mM), in consistence with excimer emission.

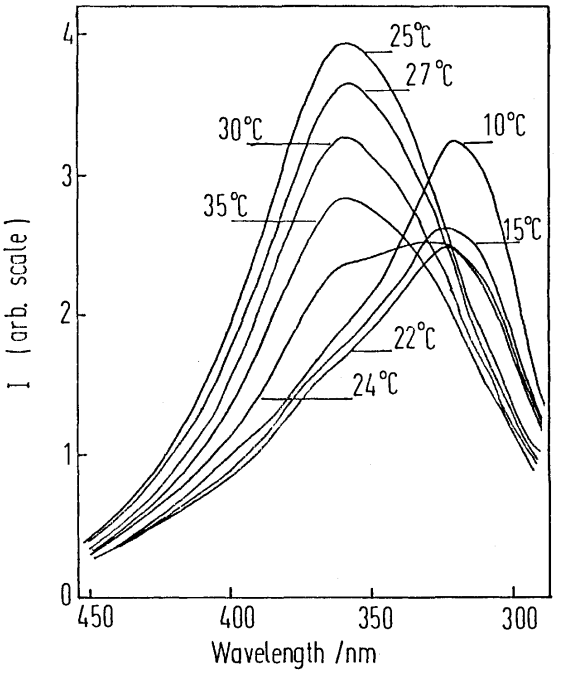

Fig. 2. Temperature dependence of fluorescence spectra of the aqueous $2C_{12}$-L-Glu-ph-C_2N^+ bilayer.
$2C_{12}$-L-Glu-ph-C_2N^+, 1.0×10^{-4} M, excitation at 260 nm.

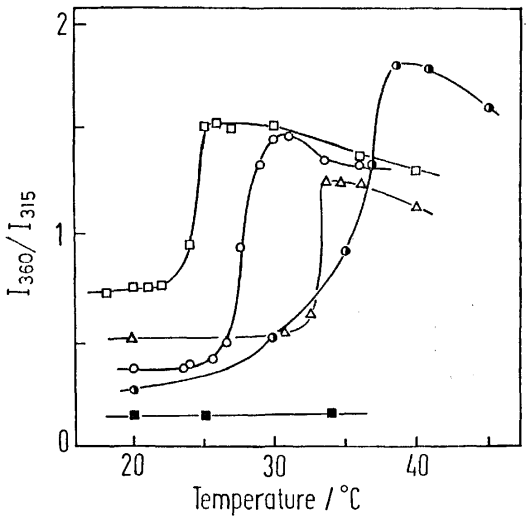

Fig. 3. Temperature dependence of I_{360}/I_{315} of hydrocarbon probes in water and in methanol.
[Amphiphiles] = 1.0×10^{-4} M.
—□—: $2C_{12}$-L-Glu-phC_2N^+ bilayer in water, —○—: $2C_{12}$-L-Glu-ph-C_4N^+ bilayer, in water, —◑—: $2C_{12}$-L-Glu-ph-C_6N^+ bilayer in water, —△—: $2C_{12}$-L-Asp-ph-C_4N^+ bilayer in water, —■—: $2C_{12}$-L-Glu-phC_2N^+ in methanol.

Figure 3 illustrates the temperature dependence of the ratio of fluorescence intensity at 360 and 315 nm. In the case of $2C_{12}$-L-Glu-ph-C_2N^+, this value increases rather abruptly in a narrow temperature range of 23 to 25 °C, and then gradually decreases with temperature. The maximum is located in the phase transition region: T_c (peak top temperature in the DSC thermogram)=27 °C. The I_{360}/I_{315} value in

methanol is smaller(0.15) and temperature-independent, as expected. Similar situations(excimer formation and temperature dependence) are found for other probe membranes in which the spacer length is different or the glutamate connector is replaced by the aspartate connector. The maxima exist more clearly in the case of the latter probes. It is interesting that the excimer emission is most enhanced with partially fluid membranes. Apparently the spatial arrangement of the neighboring benzene ring in the rigid bilayer is not suited for excimer formation.

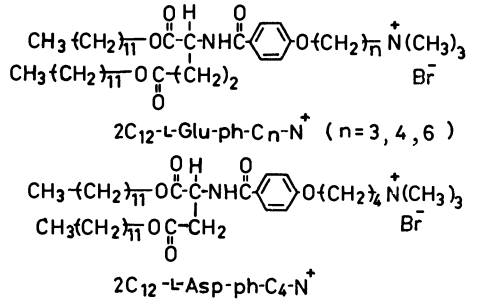

Figure 4 shows examples of the variation of fluorescence polarization(P) with temperature. In the case of a methanol solution in which $2C_{12}$–L-Glu–ph-C_4–N^+ is molecularly dispersed, P is 0.31 and temperature-independent. In the corresponding bilayer system, the emission at 310 nm gives a constant P value(0.43) in all temperature range, whereas P of the 360-nm emission changes in the phase transition region from 0.42 (low temperature) to 0.20(high temperature). The two P values (0.42 and 0.20) are mainly associated with the monomer and excimer emissions, respectively. The high P value observed for the monomer emission implies that this emission is derived from the benzene chromophore of fixed orientation. The lowered P value of the excimer emission is indicative of lessened orientation characteristic of the excimer. Similar results are found for $2C_{12}$–L-Glu–ph-C_2–N^+.

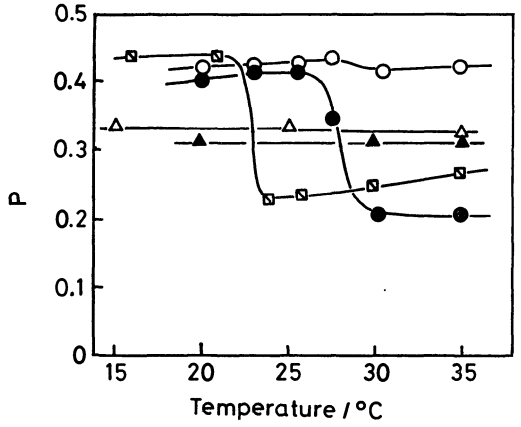

Fig. 4. Temperature dependence of the fluorescence polarization (P).
Sample, 1.0×10^{-4} M.
—▨—: $2C_{12}$-L-Glu-ph-C_2-N bilayer (Ex 265 nm, Em 360 nm), —○—: $2C_{12}$-L-Glu-ph-C_4N^+ bilayer (Ex 265 nm, Em 310 nm) —●—: $2C_{12}$-L-Glu-ph-C_4N^+ bilayer (Ex 265 nm, Em 360 nm), —△—: $2C_{12}$-L-Glu-ph-C_2N^+ in methanol (Ex 265 nm, Em 310 nm), —▲—: $2C_{12}$-L-Glu-phC_4N^+ in methanol (Ex 265 nm, Em 310 nm).

The fluorescence behavior of the corresponding fluorocarbon bilayer is not the same. The spectrum of the $2C^F_{10}$–L-Glu–ph-C_4–N^+ bilayer possesses a maximum at 365 nm with a shoulder at *ca.* 320 nm. This spectrum does not change in the temperature range examined (15—50 °C), in consistence with the lack of major changes in the physical state(no DSC peak observed). The I_{365}/I_{320} value decreases linearly with temperature: 1.8 at 15 °C and 1.3 at 45 °C. Apparently the excimer emission is predominant at all temperatures. The excimer emission is suppressed when the fluorocarbon probe is diluted by a large excess of a fluorocarbon membrane matrix. The pure monomer peak (320 nm) is observed when $2C^F_{10}$–L-Glu–ph-C_4N^+ is imbedded in 50 times excess of $2C^F_{11}$–de-N^+. The degree of polarization of the excimer peak (365 nm) was 0.11—0.13 at 14 to 47 °C, and that of the monomer peak (320 nm) was 0.3 in the same range.

Comparison of Excimer Formation of Hydrocarbon and Fluorocarbon Bilayers. A comparison of the fluorescence behavior(excimer formation) between the hydrocarbon and fluorocarbon probes is interesting. The excimer formation is determined by the distance and orientation of the two chromophore. The X-ray diffraction data indicate that the interplanar distance is 3.2 Å for typical excimer-forming pairs of the chromophore.[24] The bilayer membrane of the hydrocarbon probe gives strong circular dichroism (CD) enhancement due to the exciton coupling, if in the crystalline state.[25] This implies that there exist a long-range interaction among the aromatic chromophores due to their fixed orientation. However, the excimer formation is not observed for these rigid membranes. Apparently, the spatial arrangement of the fixed chromophore is not suitable in this case for excimer formation. Instead, the excimer is formed much more readily for partially or fully liquid-crystalline bilayers. The CD enhancement is not observed in the same temperature ranges.

The excimer-formation behavior of the fluorocarbon probe resembles that of the partially fluid hydrocarbon probe at all temperatures. This result, together with the lack of phase transition, suggests that the fluorocarbon probe maintains fluidity required for excimer formation in the whole temperature range. This is consistent with the absence of the CD enhancement for this probe.[26] The excimer naturally disappears upon dilution with a nonfluorescent fluorocarbon bilayer. It is well known that the intermolecular interaction of fluorocarbons is much smaller than that of the corresponding hydrocarbon. This difference can explain the fluorescence behavior of the two kinds of the membrane.

Phase Separation as Estimated by Fluorescent Probe. It is clear from the above results that the excimer emission is related to the formation of the probe cluster. Phase separation of hydrocarbon and fluorocarbon membranes was subsequently examined by using fluo-

Table 1. Phase separation of fluorocarbon probe

	Hydrocarbon matrix			Fluorocarbon matrix		
	$2C_{16}N^+$	$2C_{12}$-L-Glu-N^+	$2C_{12}$-de-N^+	$2C^F_{11}$-de-N^+	C^F_{11},C_{12}-de-N^+	$2C^F_{11}$-de-C_{11}-N^+
I_{365}/I_{320}	1.09	0.98	0.90	0.46	0.64	0.71

$(I_{365}/I_{320})_{monomer}$=0.40. $(I_{365}/I_{320})_{cluster}$=1.20, [matrix]=1.0 mM, [probe]=0.1 mM, 33 °C.

Table 2. Phase separation of hydrocarbon probe

	Hydrocarbon matrix	Fluorocarbon matrix				
	$2C_{12}$-de-N^+ 1 mM	$2C^F_{11}$-de-N^+ 1 mM	C^F_{11},C_{12}-de-N^+			
			0.1 mM	1 mM	5 mM	10 mM
I_{355}/I_{320}	0.52	0.84	1.20	0.71	0.66	0.61
Cluster(%)	2	36	74	22	17	12

[Probe]=0.1 mM, 33 °C. $(I_{355}/I_{320})_{monomer}$=0.50, $(I_{355}/I_{320})_{cluster}$=1.45.

rocarbon probe $2C^F_{10}$-L-Glu-ph-C_4-N^+. Matrix (1 mM) and probe (0.1 mM) were cosonicated for 1 min to give clear solutions. The I_{365}/I_{320} values of the mixed membrane thus obtained did not virtually change with time.

The amount of the probe cluster(*i.e.*, extent of phase separation) is estimated by

$$\text{cluster}(\%) = \frac{(I_{365}/I_{320})_{obsd} - (I_{365}/I_{320})_{monomer}}{(I_{365}/I_{320})_{cluster} - (I_{365}/I_{320})_{monomer}} \times 100, \quad (2)$$

where I_{365}/I_{320} for cluster and monomer are obtainable from Fig. 5.

Table 1 summarizes the phase separation data of the fluorocarbon probe. In the case of the hydrocarbon matrices, most of the probe molecule are in the cluster, $2C_{16}N^+$ being least miscible. The fluorocarbon matrix is more miscible with the fluorocarbon probe, as expected. $2C^F_{11}$-de-N^+ is best miscible, as also shown in Fig. 5. The I_{365}/I_{320} value decreases linearly with decreasing molar ratios of the probe and matrix, and reaches a constant value (cluster disappears) when more than 10 times matrix molecules are present. Unsymmetrical double-chain matrix C^F_{11},C_{12}-de-N^+ solubilizes the probe less efficiently. It is interesting that a considerable amount of the probe cluster remains in the double fluoroalkyl matrix of $2C^F_{11}$-de-C_{11}-N^+. Apparently, the presence of the hydrocarbon spacer, $(CH_2)_{10}$, is responsible for this result.

The influence of the micellar matrix is similar to that of the membrane matrix. Thus, the probe (0.1 mM) exists predominantly as monomer (90%) in the fluorocarbon micelle of C^F_{11}-C_3-N^+ (10 mM). The amount of the cluster increases in CTAB (56%).

Subsequently, phase separation was examined by using hydrocarbon probe, $2C_{12}$-L-Glu-ph-C_2-N^+. This probe was selected because of its low T_c. The experimental procedures were the same as in the case of the fluorocarbon probe. The temperature used (33 °C) is higher than T_c of the probe membrane, so

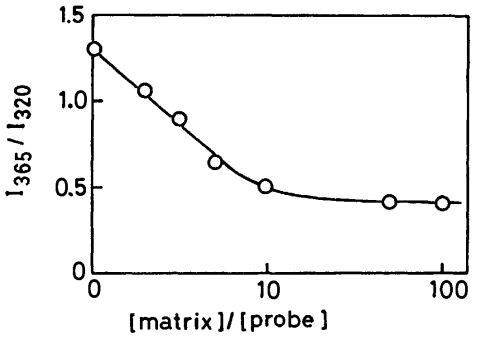

Fig. 5. Influence of the molar ratio ([matrix]/[probe]) on the relative excimer emission, I_{365}/I_{320}. 33 °C; $2C^F_{10}$-L-Glu-ph-C_4N^+ probe, 1.0×10^{-4} M; $2C^F_{11}$-de-N^+ matrix, 1×10^{-4}—1×10^{-2} M.

that the excimer formation is assured if the cluster is formed. The fluorescence intensities at 355 and 320 nm were compared, and the results are given in Table 2. The probe molecule exists almost completely as monomer in the hydrocarbon matrix (10 times excess) of $2C_{12}$-de-N^+. The cluster is formed more readily in the fluorocarbon matrix of $2C^F_{11}$-de-N^+ than in C^F_{11},C_{12}-de-N^+, and in the latter matrix, the cluster decreases with increasing matrix concentrations.

Membrane Mixing as Examined by Fluorescent Probe. Fusion and/or mixing processes of the bilayer aggregate can be followed by using the excimer emission. Sonicated solutions (0.9 cm^3) of the matrix membrane were aged in quartz cells for 30 min at 33 °C, and then sonicated solutions (0.1 cm^3) of the probe membrane were added. Figure 6 illustrates the decrease of I_{365}/I_{320} of the fluorocarbon probe with time in the fluorocarbon matrix. Mixing of the probe membrane with the C^F_{11},C_{12}-de-N^+ membrane proceeds more smoothly than with $2C^F_{11}$-de-N^+. This result is strange at first glance, since the extent of phase separation of the probe after sonication is larger with C^F_{11},C_{12}-de-N^+ than with $2C^F_{11}$-de-N^+ (Table 1). The mixing rate

is determined by the kinetic and thermodynamic factors. Since the thermodynamic factor can be inferred from the extent of phase separation after sonication, the discrepancy may be associated with the kinetic factor. Electron microscopy indicates that the aqueous aggregate of C_{11}^{F},C_{12}-de-N^{+} is much better dispersed (single-walled vesicle) than that of $2C_{11}^{F}$-de-N^{+} (lamella and vesicle). Therefore, the initial mixing with the probe membrane would be more efficient in the case of C_{11}^{F},C_{12}-de-N^{+}.

Mixing of the fluorocarbon probe with $2C_{11}^{F}$-de-C_{11}-N^{+} is very slow in s ite of the fact that the two compounds possess the same fluoroalkyl chain in common. This result reflects the fact that $2C_{11}^{F}$-de-C_{11}-N^{+} does not mix well with the fluorocarbon probe probably because of the hydrocarbon spacer (Table 1). The morphological characteristics of $2C_{11}^{F}$-de-C_{11}-N^{+} (lamella)[15] may make the mixing even more sluggish.

Figure 7 displays the mixing process of the fluorocarbon probe and hydrocarbon matrices. The mixing with the dialkylammonium membranes is very slow, as anticipated from their extensive phase separation (Table 1). The mixing with the hydrocarbon membranes of $2C_{12}$-L-Glu-N^{+} and $2C_{12}$-de-N^{+} is unexpectedly facile, and comes close to the equilibrated phase separation of Table 1 within 1—2 h. The contact of probe and matrix must be efficient because of the morphologies of the latters.

Similar mixing experiments were carried out for the hydrocarbon probe (Fig. 8). As expected, this probe is readily mixed with the hydrocarbon matrix of $2C_{12}$-de-N^{+}. The miscibility is lessened with increasing fluoroalkyl contents. The I_{355}/I_{320} values become virtually constant in 15 min. The final values in the fluorocarbon matrix are larger than those obtained upon sonication. Therefore, complete mixing of the hydrocarbon probe and the fluorocarbon matrices cannot be attained without sonication.

DSC Study of Membrane Mixing. Synthetic bilayer membranes of dialkyl amphiphiles usually give DSC peaks due to the crystal-to-liquid crystal phase transition.[18] Therefore, the DSC technique can be conveniently applied to the study of the phase separation behavior of multi-component membranes when the spectroscopic probe is absent.

Three double-chain amphiphiles of closely related structures were selected for this purpose. Multi-component samples were prepared by sonication or simple mixing. Clear aqueous solutions were obtained by sonication of multi-component suspensions (20 mM each) in the sonication procedure, and the separately-prepared(by sonication) solutions were mixed without sonication in the simple-mixing procedure. The former procedure gives information on the final state of mixing, and the latter data are related to the mixing process.

Figure 9 illustrates the variation of the DSC peak of $2C_{12}$-de-N^{+}. The single-component sample gives a

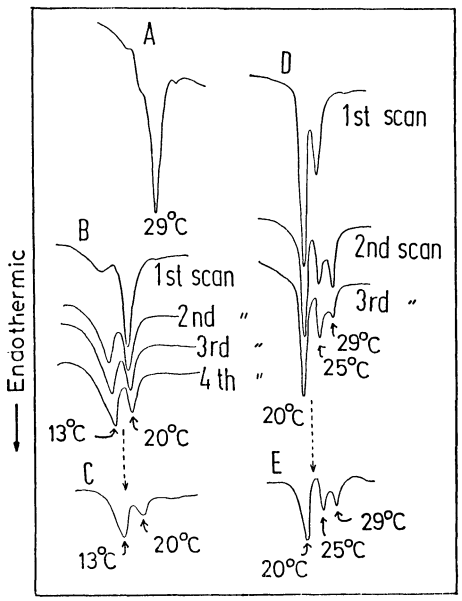

Fig. 9. DSC thermograms of the $2C_{12}$-de-N^+ bilayer alone and in combinations with related bilayers.
A, $2C_{12}$-de-N^+ alone (20 mM). B, an equimolar mixture with C_{11}^F,C_{12}-de-N^+. The sample was prepared by mixing of the two solutions without sonication. C, the same sample as B after sonication. D, an equimolar mixture with $2C_{11}^F$-de-N^+. The sample was prepared by mixing of the two solution without sonication. E, the same sample as D after sonication.

sharp peak at 29 °C with ΔH=38.5 kJ/mol, but those of $2C_{11}^F$-de-N^+ and C_{11}^F,C_{12}-de-N^+ do not give any DSC peak at 0 to 70 °C. An equimolar mixture of solutions of $2C_{12}$-de-N^+ and $2C_{11}^F$-de-N^+ (prepared without sonication) gives endothermic peaks at 20 °C (major peak) and 25 °C, in the first scan. In the second and third scans, three peaks appear at 20 (major peak), 25 and 29 °C. The DSC behavior observed upon repeated scans agrees with that of the sonicated sample. The ΔH value of the triplet peak is 15.9 kJ/mol, which is much smaller than 38.5 kJ/mol of $2C_{12}$-de-N^+ alone. An equimolar mixture (without sonication) of $2C_{12}$-de-N^+ with C_{11}^F,C_{12}-de-N^+ give peaks at 13 and 20 °C, and the latter peak becomes smaller upon repeated scans. In fact, a sonicated sample of the mixture gives peaks at 13(major) and 20 °C with reduced intensity(ΔH=10.0 kJ/mol).

It is suggested from these data that the fluorocarbon bilayer of $2C_{11}^F$-de-N^+ and the hydrocarbon bilayer of $2C_{12}$-de-N^+ are partially miscible. The decreased ΔH value implies the presence of rather small domains of $2C_{12}$-de-N^+. The miscibility is apparently improved in the mixture of $2C_{12}$-de-N^+ and $2C_{11}^F$-de-N^+, because the peaks appear at lower temperatures with smaller intensity.

Sturtevant and co-workers[27] prepared phospholipids labeled by fluorine at several positions of the acyl chain, and examined their mixing behavior with unlabeled phospholipids. The DSC data showed that the fluorine-labeled phosphocholines are not ideally distributed. These results are consistent with our data on a mixed membrane of $2C_{12}$-de-N^+ and $2C_{11}^F$-de-N^+ in that T_c shifts to lower temperatures and that ΔH decreases considerably.

The miscibility of the two-component membranes is improved in an equimolar, three-component mixture of $2C_{12}$-de-N^+, $2C_{11}^F$-de-N^+, and C_{11}^F,C_{12}-de-N^+. Very small DSC peaks appear at 16.5 and 22.5 °C in the first scan of this mixture(without sonication), but they disappear completely in the second scan. The peaks are totally absent in a sonicated mixture. This indicates that, although $2C_{12}$-de-N^+ is only partially miscible with either of $2C_{11}^F$-de-N^+ and C_{11}^F,C_{12}-de-N^+ it is completely miscible in a mixed membrane of $2C_{11}^F$-de-N^+ and C_{11}^F,C_{12}-de-N^+.

Conclusion

It is established that the excimer formation of the benzene unit is unusually facilitated due to the bilayer assemblage. This novel phenomenon is very useful for examining the phase separation behavior of hydrocarbon and fluorocarbon bilayers. We showed elsewhere that the anthracene chromophore included in the bilayer assemblage give strong excimer emission when it is partially buried in a bilayer matrix.[14] The intensity of the excimer emission depended on the mole ratio of the anthracene amphiphile and the dialkylammonium matrix. Thus, the excimer formation may be used widely as a means for elucidation of the phase separation.

The limited miscibility of hydrocarbon and fluorocarbon bilayers may also be used for developing novel catalytic functions. We already showed in the micellar system that high catalytic efficiency and selectivity are attainable by combinations of hydrocarbon and fluorocarbon reagents.[28]

23) The fluorescence spectrum of $2C_{12}$-L-Glu-ph-C_2-N^+ is affected by the extent of sonication. The temperature-dependent spectrum of Fig. 2 is obtained when the sonication time is less than 2 min(Branson cell disruptor 185, sonic power 60 W. When the aqueous sample was sonicated for more than 3 min, the spectrum consisted of a single peak at 363 nm at all temperatures. It seems that the delicate molecular arrangement is destroyed by extensive sonication and that an alternate (probably less ordered) bilayer structure is formed. This strange effect is not observed for the other membranes of $2C_{12}$-L-Glu-ph-C_n-N^+ ($n=3$, 4, 6, and 10).

Salt Effect on the Solubility of Copper and Beryllium Chelates of 4,4,4-Trifluoro-1-phenyl-1,3-butanedione

Yasuki YOSHIMURA,* Nobuyoshi SATO, and Makoto KIKUCHI

Laboratory of Chemistry, College of Humanities and Social Sciences, Iwate University, Ueda, Morioka 020

(Received February 18, 1983)

In order to examine whether the substitution of a trifluoromethyl group for a methyl group in metal chelates of 1-phenyl-1,3-butanedione (BA) affects the salt effect on the solubility of these chelates, the solubility of copper and beryllium chelates of 4,4,4-trifluoro-1-phenyl-1,3-butanedione (BFA) in water and in some aqueous salt solutions was measured at 25 °C. The solubility in water (S_0) was $9.07\pm0.22\times10^{-7}$ mol dm^{-3} for the copper chelate and $4.85\pm0.08\times10^{-6}$ mol dm^{-3} for the beryllium chelate. These solubility values are compared with those of the corresponding BA chelates and an influence of fluorination on the solubility of these BA chelates is discussed. It was found that the solubility of the above BFA chelates in the aqueous salt solutions (S) could be expressed satisfactorily by the equation, $\log(S_0/S)=a\sqrt{C_s}+bC_s$, where C_s is the concentration of salt. This result suggests that introduction of CF_3 group brings about a specific interaction between the fluorinated chelates and their surroundings.

In a series of our investigations, the salt effect on the solubility of bis(1-phenyl-1,3-butanedionato)copper-(II) ($Cu(bzac)_2$) and bis(1-phenyl-1,3-butanedionato)-beryllium(II) ($Be(bzac)_2$) has been studied and a generalized interpretation for the salt effect in the solvent extraction of metal chelates was presented[1,2]. The substitution of a trifluoromethyl group for a methyl group in the metal chelates of β-diketones affects their properties such as volatility.[3] The polarity of the metal chelates of the above fluorinated β-diketones is expected to be higher than that of parent chelates because of the high electronegativity of fluorine atoms.

On the other hand, in our studies on the salt effect on the solubility of BA and BFA, it was suggested that species of the latter was less polar than that of the former in aqueous solutions.[4,5] It is very interesting to see whether fluorination of β-diketone chelates affects the salt effect or not. Thus, in the present study, the solubility of bis(4,4,4-trifluoro-1-phenyl-1,3-butanedionato)copper(II) ($Cu(bfac)_2$) and bis(4,4,4-trifluoro-1-phenyl-1,3-butanedionato)beryllium(II) ($Be(bfac)_2$) in water and in aqueous salt solutions is measured and the salt effect on the solubility of these chelates is compared with that for $Cu(bzac)_2$ and $Be(bzac)_2$.

Experimental

Materials. The copper and beryllium chelates of BFA were prepared and purified by the same procedures as used for $Cu(bzac)_2$ and $Be(bzac)_2$.[1,2] The melting points of these chelates were 239 °C (Ref. 6, 241 °C) and 143 °C (Ref. 6, 143 °C), respectively. Aqueous solutions of LiCl, $NaClO_4$, NaCl, $NaNO_3$, and Na_2SO_4 were also prepared as previously reported.[1,2] Redistilled water was used and heptane was purified by an ordinary method.

Solubility Measurement. The apparatus and procedure used for the solubility measurement were similar to those previously reported,[1] except for the procedure modified to extract completely BFA into heptane. Filtered aliquots of the solution saturated with $Cu(bfac)_2$ or $Be(bfac)_2$ were acidified with one drop of 5 M (1 M = 1 mol dm^{-3}) HCl solution and then exact volume of these acidified solutions (30 cm^3 for $Cu(bfac)_2$ and 10—20 cm^3 for $Be(bfac)_2$) was transferred to 50 cm^3 centrifuge tubes in which Na_2SO_4 was previously placed. As the partition coefficient of BFA between water and heptane is lower than that of BA,[7] Na_2SO_4 was added to the above acidified solutions as a salting-out reagent to extract completely BFA. BFA was completely extracted at the concentrations of Na_2SO_4 over 1.5 M, and so in most cases Na_2SO_4 was added to give the concentration of 2 M. In the cases in which the addition of 2 M Na_2SO_4 results in the precipitation of salts while being extracted, for example, in the solubility measurement for $Be(bfac)_2$ in 3 M salt solutions, Na_2SO_4 concentration was reduced to 1 M. Even in these cases, the complete extraction of BFA was confirmed by stirring again aliquots of the aqueous phases, from which BFA was once extracted, with freshly added heptane. The mixtures of the aqueous solutions prepared as described above and 5 cm^3 of heptane were warmed at 30 °C to dissolve completely added Na_2SO_4 and stirred for 2 h with a magnetic stirrer.

The calibration curve to determine the concentration of BFA extracted into heptane phase was obtained as follows. Three independent series of standard solutions of BFA in heptane were prepared over the concentration range of 6.47×10^{-6}—3.24×10^{-5} M, and 5 cm^3 portions of these standard solutions were stirred for 2 h with 10—30 cm^3 of 2 M Na_2SO_4 acidified with one drop of 5 M HCl. After the heptane phases were separated by centrifugation, the absorbance at 323 nm in the heptane phases was measured, and the least-squares method was applied to these data. The calibration curve is expressed as

$$C=(A+0.0077)/(1.48\times10^4), \quad (1)$$

where C and A are the concentration(M) of BFA, and the absorbance at 323 nm in heptane phases, respectively.

The pH of sample solutions (250 cm^3) to be saturated with $Cu(bfac)_2$ or $Be(bfac)_2$ was adjusted within the ranges described in the following section by adding 0.1—0.4 cm^3 of 0.08 M sodium tetraborate-5 M HCl mixed solution of pH 7.4.

Results and Discussion

Solubility of $Cu(bfac)_2$ and $Be(bfac)_2$ in Water. The results of solubility measurement of $Cu(bfac)_2$ and $Be(bfac)_2$ in water are presented in Tables 1 and 2, respectively, in order to demonstrate influences of pH and equilibration time. The solubility values calculated from the concentration of BFA in heptane phases were practically constant over the pH ranges of 6.9—7.2 for $Cu(bfac)_2$ and 6.2—6.5 for $Be(bfac)_2$. For $Be(bfac)_2$, fairly long equilibration time was required to attain complete saturation.

Table 3. Melting points and solubilities in water (S_0) at 25 °C for Cu and Be chelates with BA and BFA

Chelate	Mp θ_m/°C	S_0/mol dm^{-3}
$Cu(bzac)_2$[a]	195	1.38×10^{-6}
$Cu(bfac)_2$	239	9.07×10^{-7}
$Be(bzac)_2$[b]	211	9.98×10^{-7}
$Be(bfac)_2$	143	4.85×10^{-6}

a) Ref. 1. b) Ref. 2.

A comparison of the solubility of $Cu(bfac)_2$ and $Be(bfac)_2$ in water with that of $Cu(bzac)_2$ and $Be(bzac)_2$ is very interesting. As shown in Table 3, the higher the melting points of these chelates are, the smaller their solubilities are. This is a general phenomenon for the solubility of similar solids in their natures.[8] The extremely low melting point of $Be(bfac)_2$ may be ascribed to a mutual repulsion between molecules in its solid state caused by the introduction of CF_3 group.[6]

Salt Effect on the Solubility of $Cu(bfac)_2$ and $Be(bfac)_2$. For the solubility measurement in aqueous LiCl, $NaNO_3$, $NaClO_4$, NaCl, and Na_2SO_4 solutions, the pH ranges which gave constant values for BFA concentration in heptane phases were 6.4—6.9 for $Cu(bfac)_2$ and 6.0—6.5 for $Be(bfac)_2$. For each sample solution, the solubility measurement was made independently 4 times for $Cu(bfac)_2$ and 4—7 times for $Be(bfac)_2$ at adequate time intervals (*cf.* Tables 1 and 2). The number of solubility measurement for $Be(bfac)_2$ depends on the volume taken out of the saturated solutions. The standard deviations of these measurements were within 3% in all cases.

In the previous studies, it was confirmed that the solubility of $Cu(bzac)_2$ and $Be(bzac)_2$ in aqueous salt solutions (S) could be expressed by

$$\log S = \log S_0 - k_s C_s, \quad (2)$$

where S_0, k_s, and C_s were the solubility of these chelates in water, salting coefficient, and the concentration of salts, respectively.[1,2] For $Cu(bfac)_2$ and $Be(bfac)_2$, as the plot of log (S) *vs.* C_s did not give straight lines, Eq. 2 was not valid.

As shown in Figs. 1 and 2, where log (S_0/S) is plotted against $\sqrt{C_s}$ for $Cu(bfac)_2$ and $Be(bfac)_2$, it was found that the solubility data for these chelates might be expressed by

$$\log (S_0/S) = a\sqrt{C_s} + bC_s \quad (3)$$

The values for a and b in Eq. 3 obtained by applying the least-squares method to the solubility data are listed in Table 4, where the square root of the dispersions of residues of log (S_0/S), *i.e.*,

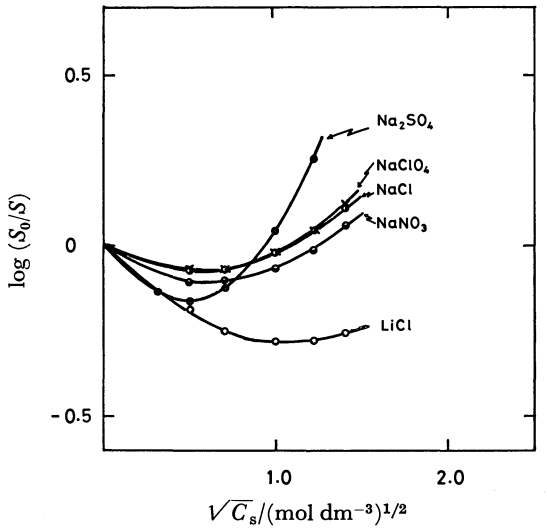

Fig. Plot of log (S_0/S) *vs.* $\sqrt{C_s}$ for $Cu(bfac)_2$. Solid lines are values calculated from log (S_0/S) = $a\sqrt{C_s}+bC_s$ by using the least-squares method.

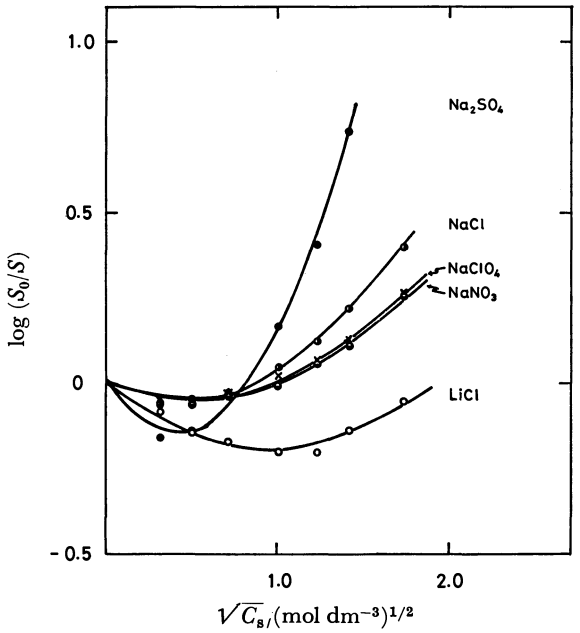

Fig. 2. Plot of log (S_0/S) *vs.* $\sqrt{C_s}$ for $Be(bfac)_2$. Solid lines are values calculated from log (S_0/S) = $a\sqrt{C_s}+bC_s$ by using the least-squares method.

$$\sigma = [\sum_{i=1}^{n} \{\log (S_0/S_i) - (a\sqrt{C_{si}} + bC_{si})\}^2/(n-1)]^{1/2}$$

is also tabulated. The S_0/S term in Eq. 3 represents the ratio of the activity coefficient of chelates in aqueous salt solutions to that of chelates in water.[9]

For all the salts studied in this work, the values for *a*-coefficient were negative and those for *b*-coefficient were positive (see Table 4). In a low region of C_s, the $a\sqrt{C_s}$ term is larger than the bC_s term and the solubility of $Cu(bfac)_2$ and $Be(bfac)_2$ in aqueous salt solutions is higher than the solubility in water. On the other hand, in a high region of C_s, the bC_s term is predominant and the solubility of these chelates decreases with increasing C_s. From a comparison of the salt effect on the solubility of $Cu(bfac)_2$ with that for $Be(bfac)_2$, it seems that the influence of the introduction of CF_3 group on the salt effect scarcely varies with the configuration of the chelates.

When the value for *a*-coefficient in Eq. 3 is negligible, Eq. 3 agrees with Eq. 2. Thus, a difference between the salt effect on the solubility of $Cu(bfac)_2$ or $Be(bfac)_2$ and that for $Cu(bzac)_2$ or $Be(bzac)_2$ is attributed to the $a\sqrt{C_s}$ term. Although the $a\sqrt{C_s}$ term must reflect a specific interaction between fluorinated chelates and water molecules or ions, more detailed study is required for clarifying the interaction.

Table 4. *a*- and *b*-coefficients in $\log(S_0/S)=a\sqrt{C_s}+bC_s$ for $Cu(bfac)_2$ and $Be(bfac)_2$

Bis(2-aminoethanol)cadmium(II) Tetracyanonickelate(II)–Pyrrole (1/1) and 2-Aminoethanolcadmium(II) Tetracyanonickelate(II)–Benzene (1/2). Variation of Metal Complex Host Structure with the Size of Aromatic Guest Molecule

Shin-ichi Nishikiori and Toschitake Iwamoto*

Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153

(Received April 22, 1983)

Two modifications of the host structures analogous to that of Hofmann-type $Cd(NH_3)_2Ni(CN)_4$ have been found in the crystal structures of $Cd(mea)_2Ni(CN)_4\cdot C_4H_5N$ and $Cd(mea)Ni(CN)_4\cdot 2C_6H_6$ which were prepared using mea (2-aminoethanol=monoethanolamine) in place of the NH_3 as the ligands in the host metal complexes. In the former pyrrole clathrate, Hofmann-mea-type(1), the mea behaves as a unidentate ligand like the NH_3 in Hofmann-type, but in the latter benzene one, Hofmann-mea-type(2), it behaves ambidently like the en in Hofmann-en-type host $Cd(en)Ni(CN)_4$. In Hofmann-mea-type(1) host, the layered metal cyanide network is puckered, whereas that in Hofmann-ema-type(2) host is coplanar. The size of the guest molecule appears to control the behavior of mea and the structure of the metal cyanide network.

In the course of our studies involving the design and synthesis of clathrate compounds analogous to Hofmann-type $M(NH_3)_2M'(CN)_4\cdot 2G$, novel three-dimensional host structures have been developed using such ambident ligands as ethylenediamine (en), trimethylenediamine, propylenediamine (pn), in place of the NH_3 ligands in Hofmann-type host. Another strategy we have applied is to use tetrahedral tetracyanometallate(II) moieties such as $Cd(CN)_4$, $Hg(CN)_4$, in place of the square-planar $M'(CN)_4$ (M'=Ni, Pd, or Pt) in order to develop three-dimensional host structures.[1-5] The ambident ligands used are symmetric with respect to their coordination sites, although the skeletal structure of pn is asymmetric.[6]

In the present investigation, mea (monoethanolamine=2-aminoethanol: $NH_2CH_2CH_2OH$) was chosen as the ligand replacing the NH_3 in Hofmann-type to develop novel host structures; mea was expected to behave either as a unidentate ligand like the NH_3 in Hofmann-type or as an ambident one like the en in Hofmann-en-type $Cd(en)Ni(CN)_4\cdot 2G$.[7-11] In the former case, mea with a bulky $-CH_2CH_2OH$ group does not have any proper rotational axes like the threefold one of NH_3; in the latter case, it is also asymmetric with respect to the coordination sites $-NH_2$ and $-OH$. Both cases have been demonstrated in the host structures of novel clathrates, $Cd(mea)_2Ni(CN)_4\cdot C_4H_5N$ (**1**), and $Cd(mea)Ni(CN)_4\cdot 2C_6H_6$ (**2**), as has been reported briefly in the previous communication.[12] This paper describes their crystal structures in detail and discusses their structural features from the viewpoint of molecular inclusion phenomena occurring in the series of Hofmann-type and the analogous metal complex hosts.

Experimental

Preparation. Into 100 ml of 0.1 M $CdCl_2$ (M=mol dm^{-3}), 11.6 ml of 2-aminoethanol and 100 ml of 0.1 M $K_2[Ni(CN)_4]$ were added successively. The pH of the mixed solution was adjusted to *ca.* 9.5 by adding a few drops of 6 M HCl. The aqueous phase in a conical flask was covered with the organic phase of pyrrole-toluene (1:15) mixture, thiophene-*o*-xylene (1:1) mixture, or neat benzene to prepare the pyrrole, thiophene, or benzene clathrate, respectively. By leaving the flasks in a refrigerator at 5 °C for a few days, yellow crystals of the clathrates grew up at the interface between the aqueous and the organic phases. The freshly prepared crystals were subjected to the analyses of metal contents by chelatometry in this laboratory. The C, H, and N microanalyses were carried out for the specimens sealed in glass vials at the laboratory of elemental analysis in Department of Chemistry, Facultry of Science of this University a few days after the preparation. The pyrrole clathrate was stable enough to give the satisfiable analytical results, but the thiophene and the benzene ones were unstable even when reserved in sealed

Table 1. The analytical results and the compositions determined

Composition†	Found/Calcd(%)				
	C	H	N	Cd	Ni
$Cd(NH_2CH_2CH_2OH)_2Ni(CN)_4\cdot C_4H_5N$	31.2 / 31.03	4.17 / 4.12	21.2 / 21.11	23.8 / 24.20	12.7 / 12.63
$Cd(NH_2CH_2CH_2OH)_2Ni(CN)_4\cdot C_4H_4S$	29.1 / 29.93	3.28 / 3.77	17.6 / 17.45	23.2 / 23.34	12.4 / 12.19
$Cd(NH_2CH_2CH_2OH)Ni(CN)_4\cdot 2C_6H_6$	38.4 / 43.89	3.24 / 3.89	15.7 / 14.22	23.1 / 23.82	12.7 / 11.91

vials. The benzene clathrate was extremely unstable: it decomposed immediately at room temperature, even in contact with neat benzene. The analytical results listed in Table 1 appear to reflect the instability of the thiophene and the benzene clathrates, especially with respect to the values of C, H, and N.

Structure Determination

Data Collection. In order to avoid the spontaneous decomposition of the specimens under ambient conditions, each crystal was coated with epoxy resin before the X-ray experiments. Preliminary Weissenberg photographs were taken to check the crystal symmetries and lattice parameters for the pyrrole, the thiophene, and the benzene clathrates, respectively. The refinement of lattice parameters and the collection of Lp-corrected intensity data were carried out for the pyrrole clathrate (**1**), on a Rigaku automated four-circle diffractometer,[13] and for the benzene clathrate (**2**), on a Phillips one[14] using Mo $K\alpha$ radiation at ambient temperature. The lattice parameters were refined for **1** using 30 reflections with $45°<2\theta<50°$, and for **2** using 24 reflections with $20°<2\theta<64°$. The intensities of three standard reflections, recorded every fifty measurements, showed no significant variations. The experimental conditions and the crystallographic data are listed in Table 2.

Solution and Refinement of the Structures. The structures of **1** and **2** were solved by the heavy-atom method. The refinements were carried out by the successive Fourier and difference Fourier syntheses and by the block-diagonal least-squares method; for **2**, the full-matrix least-squares method was applied at the later stages. All the calculations were carried out on a HITAC M-200H computer at the Computer Center of this University using the programs in UNICS[15] and their local versions. The atomic scattering factors used were those in the *International Tables*.[16]

The Pyrrole Clathrate (1): The absorption correction for a cube was applied for the intensities of all the reflections used. From the observed systematic absences of reflections in the orthorhombic system, the space group was limited to either non-centrosymmetric $Pna2_1$ or centrosymmetric Pnam. On the Patterson map, the positions of Cd and Ni atoms were first found. Then those of C, N, and O atoms were revealed on the successive Fourier and difference Fourier maps.

At the stage of refinement with the anisotropic thermal parameters for the atoms of the host moieties except H's, and the isotropic ones fixed at 5.0 Å^2 for the skeletal atoms of pyrrole molecule, the possible space groups $Pna2_1$ and Pnam were compared. The $Pna2_1$ was chosen for the following reasons: (i) the R value of 0.043 was lower than 0.048, (ii) the preference in the Hamilton test with the significance level of 0.005, (iii) the acceptable bond lengths and angles, and (iv) the Patterson syntheses was fully supported by this space group.

In the final stage of refinement applying the $Pna2_1$ space group, the H atoms belonging to the host moieties, *i.e.*, those of the mea ligands, were located on the positions found on the difference Fourier map, except for those H's bonded to the O atoms. All the skeletal atoms of the pyrrole molecule were regarded as C because no significant discrimination of N was possible in the revealed structure. In the final block-diagonal least-squares calculations, the atomic coordinates of the host H atoms were fixed at the positions found on the difference Fourier map, and the thermal parameters of the host H atoms and the guest skeletal C atoms were fixed at 4.0 Å^2 and 5.0 Å^2, respectively, but these parameters were included in the evaluation of R values. After a few cycles of the calculations, the parameters to be determined converged into the range less than 0.5 times their

a) The U_{ij}'s are defined by $\exp[-2\pi^2(U_{11}h^2a^{*2}+U_{22}k^2b^{*2}+U_{33}l^2c^{*2}+2U_{12}hla^*b^*+2U_{13}hla^*c^*+2U_{23}klb^*c^*)]$. The positional and thermal parameters are multiplied by 10^4 and 10^3, respectively, for the atoms from Cd to O(2); those positional parameters for the atoms from H(15) to C(32) are multiplied by 10^3. The parameters lacking the estimated standard deviations were not refined, but were included in the evaluation of the R values (see text).

estimated standard deviations, except those for O(1) and O(2) atoms, and the R and R_w went down to 0.041 and 0.053, respectively.[17]

The Benzene Clathrate (2): On the Patterson map, the atomic coordinates of Cd and Ni atoms were fixed uniquely. Since the possible space groups predicted from the photographs and the collected intensity data are P4/mmm, P4mm, P422, P$\bar{4}$2m, and P$\bar{4}$m2, there should be statistical distributions at least in the orientation of mea molecule in the crystal structure. In the successive Fourier and difference Fourier syntheses and the block-diagonal least-squares calculations, the positions of the C and N atoms of cyanide group and the C atoms of benzene molecule were found out. By applying the anisotropic thermal parameters for the Ni and Cd, and the isotropic ones for the C and N atoms, the full-matrix least-squares calculations were done for the check of the most proper space group.

Dihedral angle between the statistically distributed pyrrole molecular planes: 71.8°

Since the space groups P$\bar{4}$2m and P$\bar{4}$m2 require the mea and the benzene molecules to take extremely unusual arrangements and orientations, these two were discarded. Although no significant differences were observed in R values among the three possible space groups, those other than P4/mmm required the mea and the benzene molecules to be arranged with higher disorder. Because there are no positive reasons to take such unusual disorder, the space group P4/mmm was adopted. In this space group, however, the mea molecule should be distributed statistically about the fourfold axis and three sets of mirror planes of crystal. Therefore, the N and O atoms of mea were not distinguishable but the O atom was regarded as N, and each of the C and N(=O) of mea was distributed with the occupancy factor of 0.25 about the fourfold axis and the mirror planes in the refinement. By applying the anisotropic thermal parameters to the Cd, Ni, C, and N atoms of cyanide, and C atoms of benzene, and the isotropic ones to the C and N(=O) atoms of mea, the final full-matrix calculations converged to the R and R_w values of 0.047 and 0.063, respectively.[17]

Description of Structures and Discussion

As is shown in Table 1, the pyrrole and the thiophene clathrates have the composition $Cd(mea)_2Ni(CN)_4 \cdot G$ ($G = C_4H_5N$ or C_4H_4S) different from that of the benzene clathrate $Cd(mea)Ni(CN)_4 \cdot 2C_6H_6$ in the numbers of the mea ligands and of the guest molecules in the formula unit. The thiophene clathrate can be thought of as having a structure similar to the pyrrole one, as the crystallographic data in Table 2 show.

The atomic parameters determined for **1** and **2** are listed in Tables 3 and 4, and the illustrations of the structures are shown in Figs. 1 and 2 with the atomic notations; the selected bond lengths and angles are summarized in Tables 5 and 6.

The Structure of Pyrrole Clathrate (1). The pyrrole clathrate has the structure which is considerably distorted from those of the Hofmann-type and those of the analogous clathrates with the hosts containing square-planar $Ni(CN)_4$ moiety so far known, although some similarity to Hofmann-type host $Cd(NH_3)_2Ni(CN)_4$ is seen with regard to the layered two-dimensional network of metal cyanide and the projections of mea ligands from the six-coordinate Cd atoms in the network. The $Ni(CN)_4$ moiety, being almost coplanar by itself, is distorted from the D_{4h} symmetry with the bond angles slightly deviated from 90° about the central Ni atom and with the alignment of Ni–C–N linkages slightly bent from 180°. Furthermore, the joint between the $Ni(CN)_4$ moiety and the Cd atom is bent by 23.8° at the N(1) and by 12.6° at the N(4)

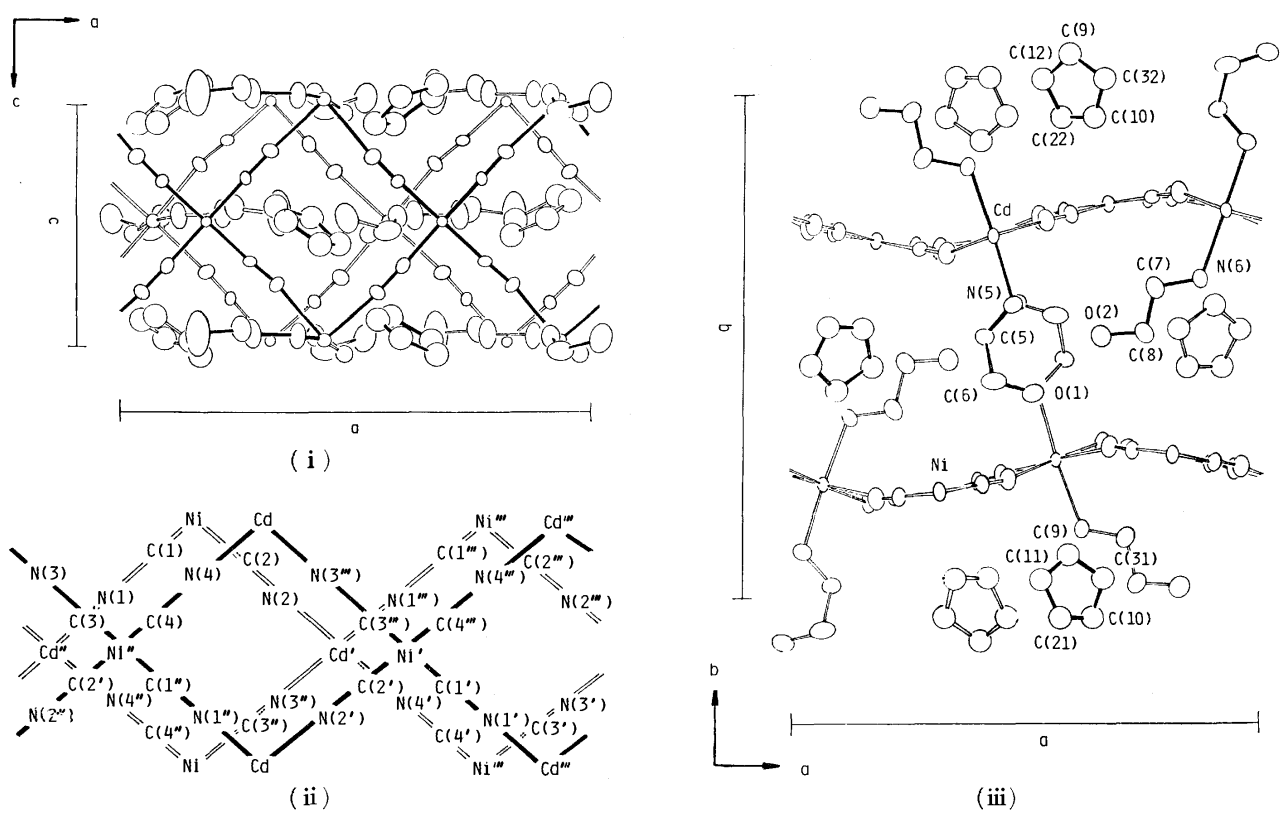

Fig. 1. The structure of $Cd(mea)_2Ni(CN)_4 \cdot C_4H_5N$. (i) Projection along the b axis: the bonds of the moieties belonging to the upper layer are shown with solid lines. (ii) Numbering of the atoms in the metal cyanide networks. Key: normal, x, y, z; with ′, $\bar{x}$, $\bar{y}$, $\frac{1}{2}+z$; with ″, $\frac{1}{2}-x$, $\frac{1}{2}+y$, $\frac{1}{2}+z$; and with ‴, $\frac{1}{2}+x$, $\frac{1}{2}-y$, z. (iii) Projection along the c axis with numbering of the atoms: the bonds of the moieties viewed on this side are shown with solid lines. In (i) and (ii), the hydrogen atoms of the pyrrole molecule and those of the mea, H(n5) at N(5), H(n6) at N(6) (n=1 or 2), H(mn) at C(m) (m=5—8, n=1 or 2), and those at O(1) and O(2), are not shown.

TABLE 6. SELECTED BOND LENGTHS AND ANGLES FOR $Cd(mea)Ni(CN)_4 \cdot 2C_6H_6$ AND THEIR ESTIMATED STANDARD DEVIATIONS (IN PARENTHESES)

Bond length	l/Å	Bond length	l/Å	Bond length	l/Å

C(3)-C(2)-C(3′)	117.6(9)				

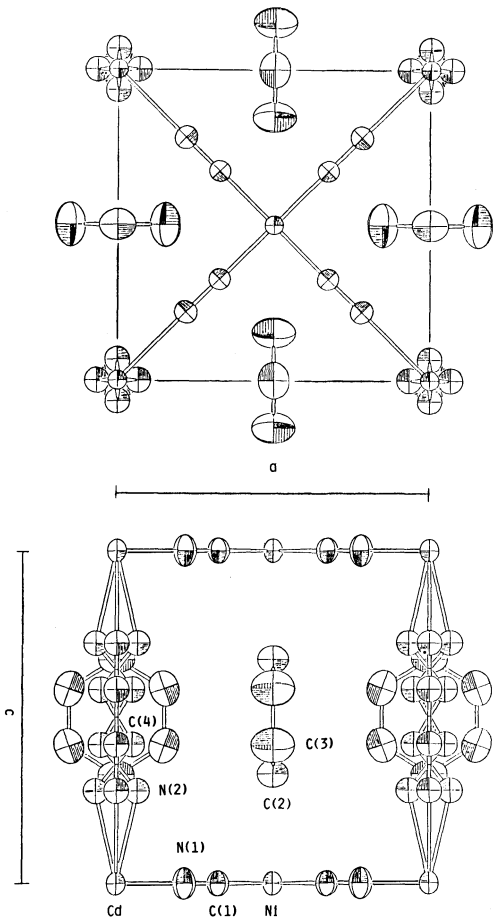

Fig. 2. The structure of $Cd(mea)Ni(CN)_4 \cdot 2C_6H_6$. Top: projection along the c axis, bottom: projection along the b axis.

atom, the distortion leading the layered network to a puckered structure along the crystal a-axis. However, the related bond distances are not unusual. The puckered metal cyanide networks are stacked along the crystal b-axis with an alternate shift approximately by $a/4$ and $c/2$, so that the six-coordinate Cd atom is approximately placed over or beneath the square-planar Ni atom along the crystal b-axis; in Hofmann-type host, the metal cyanide layers are arranged completely parallel to each other. There can be seen two kinds of cavities: one is a real cavity occupied by a guest pyrrole molecule; the other appears to be a pseudo-cavity occupied by the tail parts of two crystallographically-independent mea ligands. One mea plays a role of the column dividing the two kinds of cavities but its OH-end intrudes into the pseudo-cavity occupied mainly by another mea. The latter mea behaves as a pseudo-guest to insert its $-CH_2CH_2OH$ skeleton into the pseudo-cavity. The column mea has approximately a cis form of the N–C–C–O skeleton, and the pseudo-guest mea has a trans form. The O(2) of the latter appears to form hydrogen bonds with the O(1) and the N(5) of the former; the distances are 2.80(1) Å for O(2)–O(1), 3.30(1) Å for O(2)–N(5), and *ca.* 2.2 Å for O(2)–H(51). On the Fourier and difference Fourier maps, it was difficult to find out the positions of protons assigned to the OH groups of O(1) and O(2). As relatively large thermal parameters and their estimated standard deviations have been observed for the O(1) and O(2) atoms, the supposed hydrogen bonds are thought to be not so strong.

Although there should be only one crystallographically-independent pyrrole molecule in an asymmetric unit, three skeletal atoms (not C(9) and C(10)) are statistically distributed about a pseudo-mirror plane (001). If the space group Pnam had been applied, the symmetry operations would have required the statistical distributions not only for the pyrrole molecule but also for the mea ligands. The fact that the estimated standard deviations of the positional parameters are relatively large for the skeletal atoms of the mea ligands suggests the possibility of the Pnam space group. However, this space group was exclude from the consideration of structure because of the unacceptable molecular forms of the mea, as has been described in the Structure Determination section. Both the possible orientations of pyrrole molecule in a cavity appear to be almost equivalent to each other with respect to the host-guest contacts. Therefore, the respective atomic coordinates have been listed in Table 3, and both the orientations have been illustrated in Fig. 1.

The Structure of the Benzene Clathrate (2). The structure of $Cd(mea)Ni(CN)_4 \cdot 2C_6H_6$ is similar to that of Hofmann-en-type $Cd(en)Ni(CN)_4 \cdot 2C_6H_6$ (**2′**),[9] as expected from the similarity in the formula. The metal cyanide network keeps a D_{4h} symmetry and the unit cell contains a formula unit. Trivial differences between **2** and **2′** are found in that the aromatic plane of the guest benzene molecule is vertical to the (100) or (010) plane of the crystal in **2** (space group P4/mmm), whereas the inclination angle is 85° in **2′** (space group P4/m). Additionally, the N- and O-

ends of the mea ligand are indistinguishable from each other in the P4/mmm space group of **2**. The axial disorder of mea which bridges adjacent metal cyanide networks in **2** is also similar to that observed for en in **2'**. Although a rotating model about the fourfold axis of crystal has been applied for en in **2'**, the N(=O) and C atoms of mea in **2** are located on the (100) and (010) planes with an equal probability of 0.25. The deviation from the fourfold axis, *i.e.*, the radius in a rotating model, is 0.507 Å for the N(=O) and 0.382 Å for the C, whereas that of the N in **2'** is 0.63 Å.

Discussion. Each series of Hofmann-type and the analogous clathrates so far known, *e.g.*, Hofmann-type $M(NH_3)_2M'(CN)_4\cdot 2G$, en-Td-type $Cd(en)M'(CN)_4\cdot 2G$ (M'=Cd or Hg), Hofmann-pn-type $Cd(pn)Ni(CN)_4\cdot 1.5G$, *etc.*, has a general composition common to each member of the series for the various guests G, and the hosts are almost isostructural to each other. However, in the case of mea-containing hosts, two kinds of structures have been obtained under similar preparation conditions. In Hofmann-mea-type(1) $Cd(mea)_2Ni(CN)_4\cdot G$ ($G=C_4H_5N$ or C_4H_4S), the mea ligand behaves as a unidentate ligand, whereas in Hofmann-mea-type(2) $Cd(mea)Ni(CN)_4\cdot 2C_6H_6$, it behaves ambidently. The behavior of mea either as a unidentate in type(1) or as an ambident in type(2) probably depends on the size of the guest molecule, the diameter of which, approximated to a ring, is smaller by 0.75 Å for the pyrrole and thiophene than for the benzene in the gaseous state.

As the instability of the benzene clathrate shows, the mea-bridged structure appears to be essentially unfavorable owing to the lower affinity of the O atom of mea as the ligating site to the Cd(II) atom in the metal cyanide network. Except for the present type-(2) structure, few cases have been known where mea behaves as an ambident ligand between different metal atoms. Therefore the unidentate behavior in type(1) appears preferable to the ambident one in type(2) from the viewpoint of the coordination chemistry about the central Cd atom and the ligating atoms. However, the distortion of the metal complex network demonstrated in type(1) structure is unfavorable in terms of the conjugation of π-electrons of cyanide groups throughout the network. This unfavorable outcome may be recovered in a some extent by the interactions between the host mea ligands and the guest pyrrole molecule occupying the larger cavity, and by the interactions of the mea ligands through hydrogen bonds in the smaller pseudo-cavity. A benzene molecule may be too large as a guest to be enclathrated in type(1) host, because the distortion of the metal cyanide network should become too much to cancel the imbalance of the volumes between the benzene molecule in the larger cavity and the mea ligands in the smaller pseudo-cavity.

These observations suggested that we develop another way of design and synthesis of the clathrate compounds analogous to Hofmann-type, using the amine ligands with bulky substituents which bring about distortion of the cyanide network but provide cavities with the guest molecules in various size and shape. The first attempt has been reported briefly.[18,19]

Bis(crown ether) Dyes Incorporating Azophenol Structure

Sadaya KITAZAWA, Keiichi KIMURA,* and Toshiyuki SHONO*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamada-oka, Suita 565

(Received April 25, 1983)

Three types of bis(crown ether) dyes bearing one or two azophenol units were synthesized, which may be expected to show different cation-complexing properties from the corresponding monocyclic crown ether dyes. The extraction of alkali and alkaline-earth metal salts with the crown ether dyes suggested that some cooperative action of the two adjacent crown ether moieties of the bis(crown ether)s occurs on complexing metal cations, although the bis(crown ether) effect is not very remarkable.

Considerable attention has been focussed on crown ether dyes(or chromogenic crown ethers), where a chromophore such as picrylamine,[1,2] azo dye,[3-5] and other dye stuff,[6,7] is incorporated into a crown ether moiety. Some of the crown ether dyes possess a potential anionic site attached to their chromophore either inside or outside the crown ether cavity, which results in formation of intramolecular ion-pair complexes with alkali and alkaline-earth metal cations under basic conditions. The complex formation leads to marked color changes of dye solutions. In the other crown ether dyes which do not contain any dissociable group in the vicinity of the chromophore, crown ether amines are incorporated into dye molecules in such a manner that the chromophore directly affects the complexation with metal cations, thus showing characteristic coloration in the presence of various metal cations. The coloration of both types of crown ether dyes is influenced considerably by the relative size of crown ether cavity and complexed metal cations, and the charge density of cations, so they are often called ion-selective dyes. Thus, the crown ether derivatives bearing chromophore are promising analytical reagents for colorimetry and metal-ion indicators.

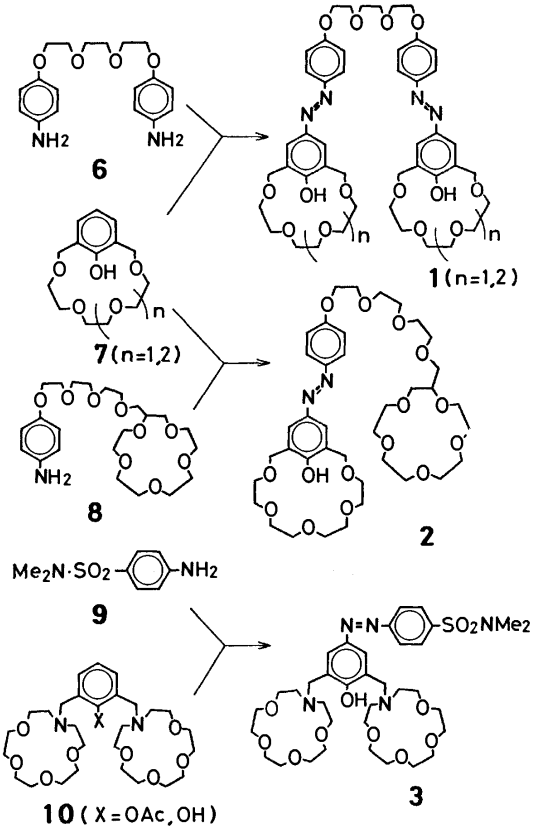
Bis(crown ether) derivatives, macrobicyclic polyethers containing two crown ether moieties at the end of a short aliphatic chain, are known to have attractive cation-complexing properties different from the corresponding monocyclic crown ethers.[8-10] They can form intramolecular sandwich-type metal complexes easily by cooperative action of two adjacent crown ether rings. The complexing behavior of the bis(crown ether)s is typical of certain alkali metal cations which are slightly larger in size than the cavity of the crown ether ring. It seems likely that this type of complex formation provides the bis(crown ether) derivatives with excellent cation-complexing abilities and/or selectivities.

These observations induced us to incorporate chromophore into bis(crown ether)s and to see what the difference in the ion-selectivity is between the bis(crown ether) dyes and the corresponding monocyclic ones. This paper concerns with the syntheses of various bis(crown ether) dyes containing azophenol skeleton and their coloration behavior on extraction of alkali and alkaline-earth metal salts.

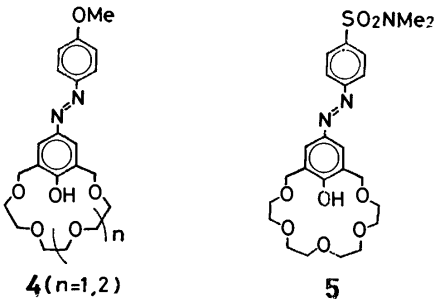
Results and Discussion

Syntheses of Bis(crown ether) Dyes. Azophenol structure was selected as a chromophore of bis(crown ether) dyes. Three types of bis(crown ether) dyes **1** through **3** were synthesized as shown in scheme 1. The general procedure consists of a conventional diazotization-coupling reaction of aromatic amines with phenols containing crown ether moieties.

The first type of bis(crown ether) dyes **1** (n=1,2) are made up of two monocyclic crown ether bearing an intra-annular phenolic group in the azophenol structure. Diazotization of triethylene glycol bis(p-amino-



Scheme 1.



phenyl) ether (**6**), followed by coupling reaction with crown ether phenol **7** (n=1,2)[11] affords yellow-powdery bis(crown ether) dyes **1** (n=1,2).

In the second type of bis(crown ether) dye **2**, monocyclic crown ether dye **4** (n=2) is connected to 15-crown-5 using an oligo(oxyethylene) chain. The yellow oil of the unsymmetrical bis(crown ether) dye was obtained by the diazotization-coupling reaction of crown ether phenol **7** (n=2) with 15-crown-5 derivative carrying aminophenyl group, which can be prepared by the condensation of hydroxymethyl-15-crown-5 and triethylene glycol mono(p-nitrophenyl) ether, followed by hydrogenation over palladium-carbon.

In the third type of bis(crown ether) dye **3**, an azophenol dye is set up on the bridge containing two azacrown ether rings, the phenolic group being outside the crown ether cavity unlike the preceding ones. Bis(crown ether) **10** (X=$OCOCH_3$) was synthesized at first by condensation reaction of 2,6-bis(bromomethyl)phenyl acetate with two equivalents of monoaza-15-crown-5, and then hydrolyzed to bis(crown ether) phenol **10** (X=OH). The diazotization-coupling reaction of *N*,*N*-dimethyl-*p*-aminobenzenesulfonamide with the bis(crown ether) phenol gave orange oil of bis(crown ether) dye **3**.

Monocyclic crown ether dyes **4** (n=1,2) and **5** were also synthesized by the conventional diazotization-coupling reaction for comparison.

Complexation with Alkali and Alkaline-earth Metal Salts. For rapid screening of the complexing abilities of the bis(crown ether) dyes, **1** through **3**, extractions were carried out from aqueous solutions of alkali and alkaline-earth metal(Li^+, Na^+, K^+, Sr^{2+}, and Ba^{2+}) hydroxide with crown ether dye chloroform solutions. The corresponding monocyclic crown ether dyes, **4** and **5**, were also employed for comparison. Figures 1 and 2 depict the absorption spectra of the chloroform layer containing bis(crown ether) dyes **1** (n=1,2), which were obtained immediately after the extraction. The color of the chloroform layer changed from yellow to orange after the extraction of metal hydroxides, that

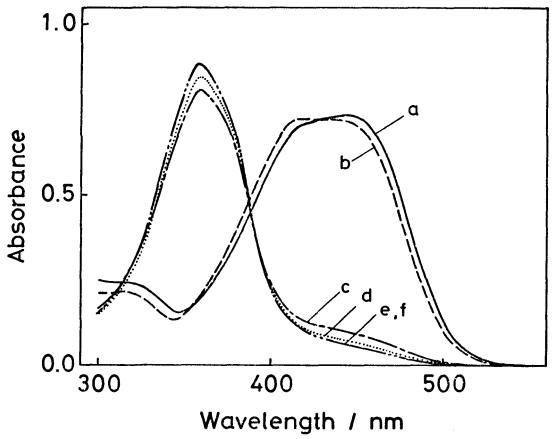


Fig. 1. Absorption spectra of 2×10^{-5} M **1**(n=1) in chloroform equilibrated with 0.04 M aqueous metal hydroxide solution. (1 M=1 mol dm^{-3})
a, $Ba(OH)_2$; b, $Sr(OH)_2$; c, LiOH; d, NaOH; e, KOH; f, without salt.

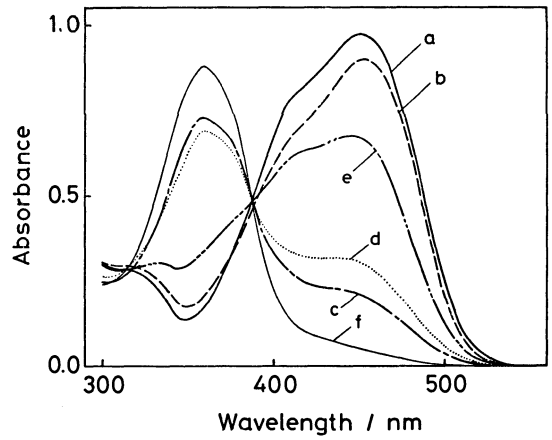

Fig. 2. Absorption spectra of 2×10^{-5} M **1**(n=2) in chloroform equilibrated with 0.04 M aqueous metal hydroxide solution.
The symbols are the same as those in Fig. 1.

is, a new peak appears at the higher wavelength, as the peak based on the uncomplexed crown ether dye diminishes at the lower wavelength. This indicates that when the crown ether dye complexes metal cations, the phenolic group interacts with the complexed cation appreciably. Since the molar absorptivity for the metal complexes does not change very much from one metal cation to the other, the complexing abilities of the crown ether dyes for metal cations can be discussed qualitatively from the absorbance of the new peaks. The complexing ability of bis(crown ether) dye **1**(n=1) decreases in the order $Ba^{2+}>Sr^{2+}\gg Li^+>Na^+>K^+$, while that of bis(crown ether) dye **1**(n=2) follows the order $Ba^{2+}>Sr^{2+}>K^+>Na^+>Li^+$. The corresponding monocyclic crown ether dyes **4** and **5** were essentially the same in the complexing tendency. However, it is worth noting that there is some difference in the absorption spectra between bis(crown ether) dye **1**(n=1) and monocyclic one **4**(n=1), as illustrated in Fig. 3. The complexing abilities of **4**(n=1) for Ba^{2+}, Sr^{2+}, Na^+, and K^+ were improved by the introduction of bis(crown ether) structure.

In the unsymmetrical bis(crown ether) dye **2**, the aliphatic crown ether moiety is expected to take an extra part in the complexation of the crown ether phenol moiety with metal cations. Unfortunately, the absorption spectra obtained in the **2**–metal hydroxide extraction system(Fig. 4) do not offer any distinct evidence about the cooperative complexation of two different crown ether moieties. Another possibility is that the aliphatic crown ether moiety complexes a metal cation by itself, then the crown ether phenol approaches the complex intramolecularly as the counter anion, but no further investigation was performed about this point.

In the third type of bis(crown ether) dye **3**, an azophenol unit exists on the bridge connecting two azacrown ethers, the phenolic group being outside the crown ether moieties unlike the preceding types of bis(crown ether) dyes, **1** and **2**. The absorption spectra obtained in the metal hydroxide extraction systems (Fig. 5) show that the complexing ability of bis(crown

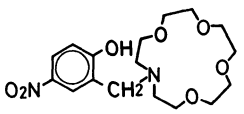
The symbols are the same as those in Fig. 1.
Crown ether unit concentration: 4×10^{-5} M, alkali metal concentration: 0.4 M, alkaline-earth metal concentration: 0.004 M.

ether) dye **3** for alkaline-earth metal cations is rather low compared to that of **1** and **2**. Crown ether dye **11**, the complexing ability of which has been studied by Nakamura *et al.*,[12] can be chosen as the corresponding monocyclic one of **3**, although the dye component is not azophenol but *p*-nitrophenol unit. Therefore,



11

in order to compare the complexing ability of **3** with that of **11**, extractions were also made under the identical conditions in the **11** system, that is, from a metal chloride aqueous solution with a crown ether dye chloroform solution containing triethylamine. The extraction equilibrium constant(K_e) and the acid-dissociation constant(K_a) are listed in Table 1, together with the values for **11**. In the monocyclic crown ether dye **11**, the extractability(the complexing ability) decreases in the order $Li^+>Na^+>K^+$. This moderate lithium selectivity of **11** was explained in terms of the coordination interaction of the phenolate anion with the crown-complexed cation.[12] On the other hand, the extractability of bis(crown ether) dye **3** follows the order $Na^+>Li^+>K^+$, where the extractability for Na^+ is

slightly higher than that for Li^+. It has been discussed in detail by Nakamura *et al.*,[5] how the basicity(or acidity) of an anionic site can contribute to ion-selectivity of various crown ethers carrying a phenolic group in the periphery. It is likely that the anionic site possessing a localized charge(high basicity) coordinates to the crown-complexed metal cation, thus resulting in the preference for the smaller alkali metal cations. In contrast with the above site, the anionic site with a delocalized charge(low basicity) favors an

ion-pair interaction with the complexed metal cations. As the acid-dissociation constant of bis(crown ether) dye **3** is larger than monocyclic one **11** by about two orders of magnitude, the azophenol unit itself tends to enhance the Li^+-extractability of the crown ether dye compared with the *p*-nitrophenol unit. Nevertheless, bis(crown ether) dye **3** prefers Na^+ to Li^+ in the extraction of alkali metal salts. This finding indicates the possibility of such specific complex formation of the bis(crown ether) dye as often observed in the conventional bis(crown ether) derivatives.

Experimental

Syntheses of Crown Ether Dyes. General Procedure of Diazotization-coupling Reaction: An aniline derivative (10 mmol) in 1 M† HCl (30 cm^3) was diazotized by treating with $NaNO_2$ (12 mmol) at 0°C. The resulting diazonium salt solution was added dropwise to a phenol derivative dissolved in 0.25 M NaOH (50 cm^3) with vigorous stirring at room temperature. In the meantime the color of the solution changed to orange and then to yellow. To this mixture was added 1 M NaOH until the color turned again to orange, and then the mixture was allowed to stand overnight. Acidification of this solution by 1 M HCl gave yellow or orange precipitates, which were recovered by filtration and washed with water. The purification steps depended on the nature of the product, and most of the solid product were purified by recrystallization from ethanol–water(2:1).

Bis(crown ether) Dyes ***1****(n=1,2)*: The aniline component, 1,8-bis(*p*-aminophenoxy)-3,6-dioxaoctane, was obtained by the reaction of *p*-nitrophenol with 1,8-dibromo-3,6-dioxaoctane in acetone in the presence of K_2CO_3, followed by hydrogenation on palladium-carbon in dioxane. **1**(*n*=1): yellow crystals; mp 150 °C(decomp); UV($CHCl_3$) 358 nm (ε 5.3×10^4); IR(KBr) 3300(O–H), 1600(aromatic nuclei), 1590(N=N), and 1120 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ= 3.55—3.98(36H, m, OCH_2CH_2O), 4.10(4H, t, CH_2OPh), 4.71(8H, s, CH_2Ph), 6.98(4H, d, aromatic H), 7.68—7.96 (8H, m, aromatic H), and 8.12(2H, s, OH); Found: C, 61.72; H, 6.64; N, 6.17%. Calcd for $C_{46}H_{58}N_4O_{14}$: C, 62.01; H, 6.56; N, 6.29%. **1**(*n*=2): yellow crystals; mp 123 °C(decomp); UV($CHCl_3$) 358 nm(ε 5.4×10^4); IR(KBr) 3250(O–H), 1590(aromatic nuclei), 1575(N=N), and 1100 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ=3.60—3.98(44H, m, OCH_2CH_2O), 4.11(4H, t, CH_2OPh), 4.76(8H, s, CH_2PH), 7.02(4H, d, aromatic H), 7.75—7.99(8H, m, aromatic H), and 8.57(2H, s, OH). Found: C, 60.88; H, 6.75; N, 5.68%. Calcd for $C_{50}H_{66}N_4O_{16}$; C, 61.34; H, 6.79; N, 5.72%.

Bis(crown ether) Dye ***2***: The aniline component, [10-(*p*-nitrophenoxy)-2,5,8-trioxadecyl]-15-crown-5 (**8**) was prepared by the reaction of hydroxymethyl-15-crown-5 with 8-(*p*-nitrophenoxy)-3,6-dioxaoctyl tosylate in THF in the presence of NaH, followed by hydrogenation on palladium-carbon. After the coupling reaction and the acidification the product was extracted with chloroform(30 $cm^3\times5$). The combined extract was washed successively with 5% NaOH, water, 1 M HCl, and water and then dried. Bis(crown ether) dye **2** was purified by silica-gel column chromatography using chloroform–ethanol(5:2). **2**: orange oil: UV ($CHCl_3$) 358 nm(ε 2.2×10^4); IR(KBr) 3340(O–H), 1600 (aromatic nuclei), and 1110 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ=3.50—3.90(47H, m, OCH_2CH_2O), 4.15(2H, m, CH_2OPh), 4.73(4H, s, CH_2Ph), 7.02(2H, d, aromatic H), 7.68—7.86 (4H, m, aromatic H), and 8.48(1H, s, OH).

Bis(crown ether) Dye ***3***: The precursor of the phenol component containing a bis(crown ether) moiety, **10**(X=$OCOCH_3$), was made up as follows. To an acetonitrile solution(50 cm^3) of monoaza-15-crown-5[13] (20 mmol) was added 2,6-bis(bromomethyl)phenyl acetate[14] (10 mmol) dissolved in acetonitrile(50 cm^3) under a nitrogen atmosphere at the refluxing temperature. After refluxing for 6 h, K_2CO_3 (20 mmol) was added to the reaction mixture, which was then continued to reflux with vigorous stirring for three more hours. The insoluble materials were filtered off and then washed with acetonitrile. Solvent evaporation of the filtrate gave a pale yellow oil of **10**(X=$OCOCH_3$); IR (neat) 1705(ester C=O), 1600(aromatic nucleus), and 1125 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ=2.11(3H, s, CH_3CO), 2.70—3.00(8H, m, NCH_2), 3.50—3.90(32H, m, OCH_2), 3.83(4H, s, CH_2Ph), and 6.64—7.16(3H, m, aromatic H); MS(70 eV) *m/e*(rel intensity) 598(M^+, 4), 555(7), 379(32), 337(47), and 43(100). Bis(crown ether) phenol **10**(X=OH), which is accessible from **10**(X=$OCOCH_3$) by treating with 1 M NaOH, is labile to air oxidation, and subjected coupling reaction immediately after the hydrolysis. On the coupling reaction a small quantity of ethanol(10%) was required for solubilizing the aniline component **9**. After the reaction the crude product was extracted by chloroform (20 $cm^3\times5$) without the acidification process, and then back-extracted to 1 M HCl. The solution was adjusted to pH *ca.* 9 with concentrated aqueous ammonia and thereafter the product was again extracted with chloroform(20 $cm^3\times5$). The extract was washed with water, dried over Na_2SO_4, and concentrated to yield brown oil. Column chromatography[neutral alumina, ethanol–benzene(1:10)] affords pure bis(crown ether) dye **3**: reddish orange oil; UV($CHCl_3$) 378 nm(ε 2.6×10^4); IR(neat) 1600(aromatic nuclei), 1350 and 1165(SO_2), and 1125 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ=2.74(6H, s, NCH_3), 2.86(8H, t, CH_2N), 3.50—3.90(32H, m, CH_2O), 3.86(4H, s, CH_2Ph), and 7.75—8.00(6H, m, aromatic H).

Monocyclic Crown Ether Dyes ***4*** *and* ***5***: They can be synthesized according to the general procedure. **4**(*n*=1): yellow crystals; mp 136—137 °C; UV($CHCl_3$) 358 nm(ε 2.2×10^4); IR(KBr) 3260(O–H), 1600(aromatic nuclei), 1580(N=N), and 1130 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ=3.60—3.80 (12H, m, OCH_2CH_2O), 3.87(3H, s, OCH_3), 4.71(4H, s, CH_2Ph), 6.98(2H, d, aromatic H), 7.69—7.89(4H, m, aromatic H), and 8.12(1H, s, OH). **4**(*n*=2): yellow crystals; mp 95.5—96.5 °C; UV($CHCl_3$) 358 nm(ε 2.2×10^4); IR (KBr) 3260(O–H), 1590(aromatic nuclei), and 1100 cm^{-1} (C–O–C); ^{1}H-NMR($CDCl_3$) δ=3.60—3.80(16H, m, OCH_2-CH_2O), 3.87(3H, s, OCH_3), 4.75(4H, s, CH_2Ph), 6.98(2H, d, aromatic H), 7.73—7.79(4H, m, aromatic H), and 8.50 (1H, s, OH).

On the synthesis of **5**, the addition of ethanol was necessary because of the poor water-solubility, in a similar way to bis(crown ether) dye **3**. **5**: orange crystalline plates; mp 143.5—144.5 °C; UV($CHCl_3$) 364 nm(ε 2.9×10^4); IR (KBr) 3270(O–H), 1600(aromatic nuclei), 1350 and 1175 (SO_2), and 1120 cm^{-1}(C–O–C); ^{1}H-NMR($CDCl_3$) δ=2.74 (6H, s, NCH_3), 3.60—3.90(16H, m, OCH_2CH_2O), 4.77(4H, s, CH_2Ph), 7.79—8.04(6H, m, aromatic H), and 8.77(1H, s, OH).

Solvent Extraction. Extraction of Metal Hydroxide: In a stoppered 1-cm cell with about 10 cm^3 of volume was placed 4 cm^3 of a 0.04 M alkali or alkaline-earth metal hydroxide aqueous solution and 4 cm^3 of 4×10^{-5} M(for azophenol unit) crown ether dye chloroform solution, and

† 1 M=1 mol dm^{-3}.

then shaken vigorously at ambient temperature. After the complete phase separation the absorption spectrum of the chloroform layer was taken using a Hitachi 340 recording spectrometer.

Extraction of Metal Chloride in the Presence of Triethylamine: The experiments were done in a similar way to that in the literature.[2] Equal volumes(10 cm^3) of 0.5 or 0.1 M alkali metal chloride solution and$(0.5—2.5)\times10^{-5}$ M crown ether dye chloroform solution containing 0.2 M triethylamine were introduced into a stoppered flask and then shaken at 25.0 $\pm$0.1 °C for 30 min. Then, the absorbance of the chloroform layer was measured at 378 nm(uncomplexed, ε 2.61×10^4), and at 487 nm(Li^+ complex, ε 3.29×10^4), 493 nm(Na^+ complex, ε 3.49×10^4), or 500 nm(K^+ complex, ε 3.50×10^4) using 1-cm standard cell. Thus, each of the species in the chloroform layer can be calculated using the ε values, which were determined in separate experiments. The values of K_e and K_a were determined according to the published method.[2]

Copper(II)–Sulfur Interactions in Pyridine- and Imidazole-containing Disulfide Complexes. Syntheses, Spectra, and Solution Equilibria

Osamu YAMAUCHI,* Hiroko SEKI, and Toshiya SHODA

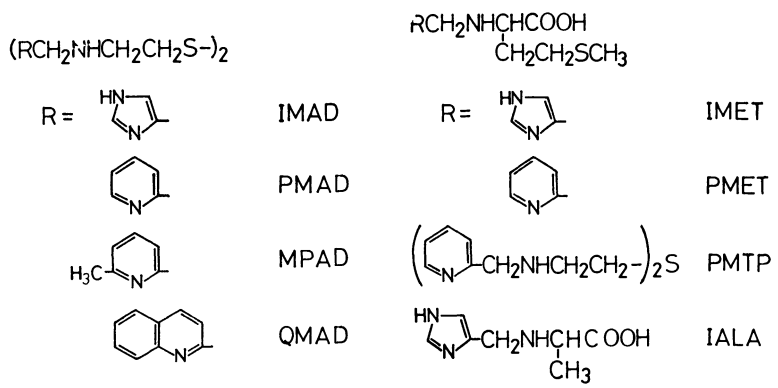
Faculty of Pharmaceutical Sciences, Kanazawa University, Takaramachi, Kanazawa 920

(Received April 25, 1983)

Synthetic, spectroscopic, and potentiometric studies on the copper(II) complexes of pyridine-, quinoline-, and imidazole-ring-containing disulfides and related compounds have been made with emphasis on copper(II)–sulfur interactions. In the presence of copper(II), disulfide ligands, $(RCH_2NHCH_2CH_2S-)_2$, where R=4-imidazolyl (IMAD), 2-pyridyl (PMAD), 6-methyl-2-pyridyl (MPAD), and 2-quinolyl (QMAD), are more stable in acid solution than in neutral–alkaline solution. A stable 1:1 copper(II) complex, $Cu(IMAD)(ClO_4)_2 \cdot H_2O$, was isolated as crystals from aqueous solution, whereas a binuclear complex, $Cu_2(PMAD)Cl_4$, was obtained as crystals in ethanol. The Cu(II)–IMAD systems exhibit a single d-d peak at 585 nm indicative of a CuN_4 chromophore but no charge transfer (CT) band in the region 300—900 nm. The other Cu(II)–disulfide systems exhibit d-d bands at 650 and $\approx$850 nm. A shoulder at 310—330 nm observed for the Cu(II)–PMAD and –MPAD systems at pH $\approx$4 and $>$6, respectively, is assigned to the S$\rightarrow$Cu(II) CT transition. Thioether ligands, *N*-(2-pyridylmethyl)-L-methionine and *N*-(4-imidazolylmethyl)-DL-methionine, show the S$\rightarrow$Cu(II) CT peak at $\approx$310 nm at pH 9 in the 1:1 Cu(II)–ligand systems. Equilibrium constants of the proton-ligand and Cu(II)–ligand systems were determined by pH titrations at 25 °C and I=0.1(KNO_3). The Cu(II)–disulfide systems were analyzed by considering monomeric species CuL, CuLH, and $CuLH_2$ (L=ligand; H=proton) and a binuclear species Cu_2L; the $\log \beta_{110}$ values for CuL are 13.38, 13.32, and 9.46 for L=IMAD, PMAD, and MPAD, respectively. Conductivity measurements showed that the Cu(II)–IMAD complex isolated as crystals is monomeric in aqueous solution. Comparison of the electronic absorption and electron spin resonance spectral data and stability constants for various systems suggests that Cu(II)–PMAD has a square-pyramidal CuN_4S chromophore with a sulfur atom in an equatorial position, whereas Cu(II)–IMAD has a planar CuN_4 chromophore. The stability of disulfide bonds in copper(II) complexes in aqueous solution is briefly discussed on the basis of the modes of coordination.

Sulfur as a soft Lewis base is an important ligand atom in various metal complexes and is now established as a constituent of the biological copper site in plastocyanin[1] and azurin,[2] where copper is bound to a thiolate and a thioether sulfur and two imidazole nitrogens. For the copper(I)/copper(II) redox systems, the binding site should have a proper affinity for both oxidation states, and combination of sulfurs and aromatic nitrogens around copper in the proteins may be a necessary consequence.

Disulfide sulfurs, on the other hand, have been postulated to be involved in the copper binding in stellacyanin.[3–5] Because of the coordinating ability of sulfur and the redox activities of copper and disulfide groups,[6–8] copper–disulfide systems may play a unique role in biological systems. Disulfide and thioether groups usually exhibit weak ligation toward copper (II)[9] unless effective neighboring donor groups force them to be in the vicinity of copper(II). The interactions of copper(I) and copper(II) with multidentate disulfide ligands are particularly intriguing because (i) the disulfide group involved in a multidentate ligand with aromatic nitrogens and other donor groups may coordinate to copper to form a binuclear or a dimeric complex of potential biological significance and (ii) it may participate in redox reactions with copper(I) and/or copper(II) upon complex formation. Lewis acids such as silver(I) and mercury(I) are known to cleave disulfide bonds.[10] Seff and his collaborators found that the reaction of copper(II) with di-2-pyridyl disulfide gives the corresponding copper(I)–disulfide complex as the main product and a small amount of the copper(II) complex of 2-pyridinesulfinate.[11] We have recently observed that a pyridine-containing disulfide, bis[2-(2-pyridylmethylamino)-ethyl] disulfide (PMAD), reacts with copper(II) under aerobic conditions to give the copper(II) complex of 2-(2-pyridylmethylamino)ethanesulfinate[12] and that the oxygen atoms from molecular oxygen are partly incorporated into the sulfinate moiety.[13] Since



such reactions of disulfide ligands depend much on their structures, the modes of copper(II)–disulfide interactions would have a crucial effect on the stability of the disulfide bond in aqueous solution.

In view of the potential importance of the structural and functional properties expected for copper–disulfide systems and the paucity of relevant information, we now investigated the properties of the copper(II) complexes of disulfide and related ligands involving pyridine, quinoline, and imidazole rings in order to acquire basic information of the modes of copper(II)–sulfur interactions and their effects on the complex and disulfide bond stabilities in solution. We initiated this study on the presumption that only the complexes with weak or no disulfide sulfur–copper(II) interactions are stable in aqueous solution, whereas those with strong interactions suffer disulfide bond cleavage.

Experimental

Materials. 2-Pyridinecarbaldehyde was obtained from Tokyo Kasei Kogyo, and cystamine (bis(2-aminoethyl) disulfide) dihydrochloride and methyl L-alaninate hydrochloride from Nakarai Chemicals. Methyl L-methioninate was purchased from Sigma. 4-Imidazolecarbaldehyde was prepared from 4-(hydroxymethyl)imidazole hydrochloride by oxidation with nitric acid.[14] 1.9-Di-2-pyridyl-2,5,8-triazanonane (PDIEN) trihydrochloride[15] was prepared by reducing the Schiff base obtained from 2-pyridinecarbaldehyde and diethylenetriamine. All the materials used were of reagent grade, and distilled and deionized water was used throughout.

Syntheses.[16] *Bis[2-(4-imidazolylmethylamino)ethyl] Disulfide (IMAD)*: To a solution of cystamine dihydrochloride (11.26 g, 0.050 mol) in ethanol was added potassium hydroxide (5.61 g, 0.10 mol) dissolved in methanol, and the resulting inorganic salt (KCl) was removed by filtration. 4-Imidazolecarbaldehyde (9.60 g, 0.10 mol) in methanol was added to the filtrate, which was stirred for 30 min at 40—50 °C. A solution of $NaBH_4$ (3.8 g, 0.1 mol) in methanol was then added dropwise to the solution under cooling. The reaction mixture was neutralized with 1 M HCl (M= mol dm^{-3}), concentrated *in vacuo*, and extracted with methanol. Dry HCl gas was bubbled through the extract in methanol, when colorless crystals separated. These were filtered, washed with ethanol, and recrystallized from methanol to give IMAD·3HCl·H_2O in 80% yield. Found: C, 32.89; H, 5.73; N, 19.11; Cl, 24.18; S, 14.58%. Calcd for $C_{12}H_{23}N_6Cl_3S_2 \cdot H_2O$: C, 32.89; H, 5.76; N, 18.94; Cl, 24.15; S, 14.56%.

Bis[2-(2-pyridylmethylamino)ethyl] Disulfide (PMAD):[17] This disulfide was obtained as tetrahydrochloride in the same manner from cystamine dihydrochloride (11.26 g, 0.050 mol) and 2-pyridinecarbaldehyde (10.8 g, 0.10 mol) in 70% yield. Mp 167 °C (decomp). Found: C, 38.28; H, 5.40; N, 11.39; Cl, 28.49; S, 12.84%. Calcd for $C_{16}H_{26}N_4Cl_4S_2 \cdot H_2O$: C, 38.56; H, 5.66; N, 11.24; Cl, 28.46; S, 12.87%.

Bis[2-(6-methyl-2-pyridylmethylamino)ethyl] Disulfide (MPAD): This was prepared in methanol in the manner described for IMAD from cystamine dihydrochloride (4.68 g, 0.021 mol) and 6-methyl-2-pyridinecarbaldehyde (5.05 g, 0.042 mol) and recrystallized from methanol–ethanol. Yield, 25%; mp 191—193 °C. Found: C, 40.03; H, 6.30; N, 10.06%. Calcd for $C_{18}H_{30}N_4Cl_4S_2 \cdot 2H_2O$: C, 39.71; H, 6.29; N, 10.29%.

Bis[2-(2-quinolylmethylamino)ethyl] Disulfide (QMAD): This was prepared in tetrahydrofuran–methanol in an analogous manner from cystamine dihydrochloride (5.54 g, 0.024 mol) and 2-quinolinecarbaldehyde (7.60 g, 0.048 mol) and recrystallized from ethanol. Yield, 10%; mp 199—200 °C. Found: C, 56.53; H, 5.56; N, 10.79%. Calcd for $C_{24}H_{23}N_4Cl_2S_2$: C, 56.79; H, 5.56; N, 11.04%.

Bis[2-(2-pyridylmethylamino)ethyl] Sulfide (PMTP):[18,19] To a solution of bis(2-aminoethyl) sulfide dihydrochloride (9.65 g, 0.050 mol) in anhydrous ethanol was added potassium hydroxide (5.6 g, 0.1 mol) in ethanol under N_2. After the inorganic salt was quickly removed by filtration, 2-pyridinecarbaldehyde (10.8 g, 0.1 mol) was added to the filtrate and the mixture was stirred for 10 min at room temperature. Reduction with $NaBH_4$ (3.8 g, 0.1 mol) and isolation as a hydrochloride were performed in the manner described for IMAD. Repeated recrystallization from ethanol gave PMTP·2HCl·H_2O as a pale yellow powder, mp 148 °C, in 60% yield. Found: C, 48.89; H, 6.20; N, 14.14; Cl, 18.95; S, 7.91%. Calcd for $C_{16}H_{24}N_4Cl_2S \cdot H_2O$: C, 48.85; H, 6.66; N, 14.24; Cl, 18.10; S, 8.15%.

N-(4-Imidazolylmethyl)-DL-methionine (IMET): A solution of methyl L-methioninate in methanol, prepared from the hydrochloride (11.75 g, 0.050 mol) and potassium hydroxide (2.81 g, 0.050 mol) in methanol, was added dropwise to a solution of 4-imidazolecarbaldehyde (4.80 g, 0.050 mol) in methanol. The mixture was stirred for 1—2 h at 30—40 °C, cooled, and treated with $NaBH_4$ (1.90 g, 0.050 mol) in methanol and then with 1 M HCl as described for IMAD. Sodium hydroxide (2.0 g, 0.05 mol) dissolved in water was added to the mixture, which was stirred for 30 min at room temperature, acidified with hydrochloric acid, and concentrated *in vacuo*. The residue was extracted several times with methanol and concentrated *in vacuo*. Recrystallization from methanol containing hydrochloric acid gave IMET·HCl as a colorless powder, mp 240—242 °C (decomp), in 80% yield. Found: C, 40.71; H, 6.12; N, 16.21; Cl, 12.61; S, 11.62%. Calcd for $C_9H_{16}N_3O_2ClS$: C, 40.68; H, 6.07; N, 15.81; Cl, 13.34; S, 12.06%. The Cu(II)–IMET systems did not give the expected circular dichroism (CD) spectral peaks in the d-d region, and accordingly IMET·HCl is described as a racemic mixture.

N-(2-Pyridylmethyl)-L-methionine (PMET): This was prepared in 80% yield in the manner described for IMET from methyl L-methioninate hydrochloride (11.75 g, 0.050 mol) and 2-pyridinecarbaldehyde (5.36 g, 0.050 mol). Recrystallization from ethanol gave PMET as a colorless powder, mp 219—220 °C (decomp). Found: C, 54.98; H, 6.72; N, 11.33; S, 13.34%. Calcd for $C_{11}H_{16}N_2O_2S$: C, 54.98; H, 6.71; N, 11.66; S, 13.83%.

N-(4-Imidazolylmethyl)-L-alanine (IALA): This was prepared similarly from methyl L-alaninate hydrochloride (4.00 g, 0.025 mol) and 4-imidazolecarbaldehyde (2.4 g, 0.025 mol) in 50% yield. Recrystallization from methanol gave IALA·HCl·H_2O as a colorless powder, mp 215 °C (decomp). Found: C, 37.59; H, 6.31; N, 18.79%. Calcd for $C_7H_{12}N_3O_2Cl \cdot H_2O$: C, 37.05; H, 6.06; N, 18.32%.

[Cu(IMAD)](ClO$_4$)$_2$·H$_2$O: A concd solution of Cu-$(ClO_4)_2 \cdot 6H_2O$ (3.7 g, 0.01 mol) in water was added to a solution of IMAD·3HCl·H_2O (4.4 g, 0.01 mol) in water, and the pH of the resulting solution was adjusted at $\approx$6.0 with 2 M NaOH. The deep blue solution was passed through a column packed with Amberlite IRA-410 ion exchange resin in the ClO_4^- form and stored at 10—15 °C, when dark violet crystals separated. Recrystallization from water gave pure crystals of [Cu(IMAD)]$(ClO_4)_2 \cdot H_2O$. Found: C, 24.41; H, 3.89; N, 14.26%. Calcd for $C_{12}H_{20}N_6O_8Cl_2CuS_2 \cdot H_2O$: C, 24.31; H, 3.74; N, 14.18%.

Attempts to isolate pure complexes from solutions containing Cu(II) and IMAD in the molar ratio of 2:1 were unsuccessful.

[Cu_2(PMAD)]Cl_4: To a solution of PMAD·4HCl·H_2O (5.0 g, 0.01 mol) in ethanol (50 ml) was added with stirring a solution of $CuCl_2 \cdot 2H_2O$ (3.4 g, 0.02 mol) in ethanol (20 ml). The pale blue precipitate which separated from the solution was filtered and washed with ethanol. Found: C, 31.56; H, 3.69; N, 9.31; Cl, 23.43; S, 10.57%. Calcd for $C_{16}H_{22}N_4Cl_4Cu_2S_2$: C, 31.85; H, 3.67; N, 9.29; Cl, 23.50; S, 10.67%.

[Cu(PMET)]$ClO_4 \cdot H_2O$: To a solution of PMET (2.4 g, 0.01 mol) in aqueous methanol was added a solution of $Cu(ClO_4)_2 \cdot 6H_2O$ (3.7 g, 0.01 mol) in methanol. The resulting solution was neutralized with 1 M NaOH and kept in a refrigerator, when greenish blue crystals separated. These were recrystallized from methanol. Found: C, 31.25; H, 4.19; N, 6.32%. Calcd for $C_{11}H_{15}N_2O_6ClCuS \cdot H_2O$: C, 31.43; H, 4.08; N, 6.66%.

[Cu(PDIEN)]$(ClO_4)_2$: PDIEN·3HCl (3.9 g, 0.01 mol) and $Cu(ClO_4)_2 \cdot 6H_2O$ (3.7 g, 0.01 mol) were dissolved in water, and the pH of the resulting solution was adjusted at $\approx$7.0. The blue violet solution was passed through a column packed with Amberlite IRA-410 ion exchange resin in the ClO_4^- form and kept at room temperature, when blue violet needles separated. Found: C, 34.93; H, 4.10; N, 12.72%. Calcd for $C_{16}H_{23}N_5O_8Cl_2Cu$: C, 35.07; H, 4.24; N, 12.79%.

Spectroscopic Measurements. Absorption spectra were measured in water with a Hitachi 323 and a Union Giken SM-401 high-sensitivity recording spectrophotometer and CD spectra with a JASCO MOE-1 spectropolarimeter, the concentrations of samples being 1—4 mM for visible and 0.1—0.8 mM for ultraviolet spectral measurements. Electron spin resonance (ESR) spectra were measured for 4—5 mM solutions with JEOL FE-3X and FE-1X ESR spectrometers.

Conductivity Measurements. Conductivities of various copper(II) complexes were measured in water at 25 °C under N_2 with a Kyoto Denshi CM-07 conductivity meter calibrated with 0.01 M potassium chloride.

pH Titrations. *Reagents*: Carbonate-free 0.1 M KOH was prepared according to the method of Armstrong[20] and standardized against standard potassium hydrogen phthalate (Merck DIN 19226). Copper(II) nitrate (0.01 M) was prepared from $Cu(NO_3)_2 \cdot 3H_2O$ and standardized by chelatometry using metallic zinc (JIS primary standard) as standard.

Apparatus and Procedure: Measurements of pH were made with an Orion Research 901 ion meter equipped with an Orion 90-01-00 glass electrode and a 91-02-00 double junction reference electrode. The meter was calibrated with NBS standard buffer solutions (4.008, 7.413, and 9.180 at 25 °C). Conversion of pH meter reading (pH_M) to $-\log$ [H], where [H] refers to hydrogen ion concentration, was made by correcting the difference (0.060) between pH_M and $-\log$ [H] obtained by titrating 0.01 M HNO_3 with 0.1 M KOH at the ionic strength (I) of 0.1 M (KNO_3). The hydroxide ion concentration [OH] was calculated from the apparent ion product of water $pK_w' = 13.91$ ($= pH_M - \log$ [OH]) determined by titrating 0.1 M KNO_3 with 0.1 M KOH. Titrations were performed at 25±0.05 °C under N_2 for solutions containing a ligand only and those containing a ligand and Cu(II) in the molar ratio of 1:1, 1:2, and 2:1. Reproducibility was checked by multiplicate titrations.

Calculation of Equilibrium Constants. The equilibria in the present systems and the relevant equilibrium constants, β_{pqr}, are defined by Eqs. 1 and 2, respectively (charges are omitted for simplicity):

$$p\mathrm{Cu} + q\mathrm{L} + r\mathrm{H} \overset{\beta_{pqr}}{\rightleftharpoons} \mathrm{Cu}_p\mathrm{L}_q\mathrm{H}_r, \quad (1)$$

$$\beta_{pqr} = \frac{[\mathrm{Cu}_p\mathrm{L}_q\mathrm{H}_r]}{[\mathrm{Cu}]^p[\mathrm{L}]^q[\mathrm{H}]^r}, \quad (2)$$

where p, q, and r are the numbers of moles of Cu(II), ligand (L), and proton (H) in the complex $Cu_pL_qH_r$, respectively, and a negative value of r denotes the deprotonation from the complex. Calculation of β_{pqr} was made by the method of nonlinear least-squares with the use of the computer program MINIQUAD[21] where the function minimized is the sums of squares of the residuals in the mass balance equations for total hydrogen ion, total metal, and total ligand. A graphical method[22] was used for calculation of the stability constants for Cu(II)–PMET and –PMTP for which the least-squares treatment was not effective because of the small pH changes with the addition of alkali.

The β_{110} value for Cu(II)–PMTP was calculated by Eq. 3 derived from the material balance equations and the electroneutrality of solution:

$$\beta_{110} = \frac{(A\alpha - C_L\beta)(3\alpha - \beta)}{[(3C_M - A)\alpha + (C_L - C_M)\beta](3C_L - A)}, \quad (3)$$

where

$$A = 3[\mathrm{CuL}] + 3[\mathrm{L}] + 2[\mathrm{HL}] + [\mathrm{H_2L}],$$

$$\alpha = 1 + [\mathrm{H}]/K_{a_3} + [\mathrm{H}]^2/K_{a_3} \cdot K_{a_2} + [\mathrm{H}]^3/K_{a_3} \cdot K_{a_2} \cdot K_{a_1},$$

and

$$\beta = 2[\mathrm{H}]/K_{a_3} + [\mathrm{H}]^2/K_{a_3} \cdot K_{a_2}.$$

The K_a values are acid dissociation constants. The equation for Cu(II)–PMET (Eq. 4) was derived in a similar way:

$$\beta_{110} = \frac{(2\alpha - \beta)(A\alpha - C_L\beta)[\mathrm{H}]^2}{[(2C_M - A)\alpha + (C_L - C_M)\beta](2C_L - A)}, \quad (4)$$

where

$$A = 2[\mathrm{CuL}] + 2[\mathrm{L}] + [\mathrm{HL}],$$

$$\alpha = 1 + [\mathrm{H}]/K_{a_2} + [\mathrm{H}]^2/K_{a_2} \cdot K_{a_1},$$

and

$$\beta = 2 + [\mathrm{H}]/K_{a_2}.$$

Results

Synthesis of Complexes. At pH>6 PMAD is decomposed by Cu(II) in the presence of dioxygen to give the Cu(II) complex of the sulfinate derived from PMAD.[12,13] Probably because of the cleavage and subsequent redox reactions, preparation of the Cu(II)–PMAD complex was not feasible in aqueous solution (pH$\approx$7); in ethanol, however, PMAD·4HCl gave a binuclear complex of the composition, Cu_2(PMAD)Cl_4, as crystals. The imidazole-containing disulfide IMAD was less susceptible to the cleavage at pH 6—7, giving a 1:1 complex Cu(IMAD)$(ClO_4)_2 \cdot H_2O$ which is stable in water. At higher pH it also affords the Cu(II)–sulfinate complex.[23] The methionine derivative PMET and the pyridine-containing diethylenetriamine derivative PDIEN gave the corresponding 1:1 complexes with Cu(II), but attempted isolation of the Cu(II)–PMTP and –IALA complexes was not successful under the conditions used.

Spectra. The Cu(II)–disulfide systems are relatively stable in acid solution. Figure 1 illustrates the absorption spectra of some 1:1 Cu(II)–ligand systems, and Tables 1 and 2 show the spectral data for various binary and ternary systems, respectively, in acid–neutral solution. The 1:1 and 2:1 Cu(II)–PMAD systems have an absorption peak at 650 nm and a shoulder at ≈330 nm at pH≈4, whereas the 1:1 and 1:2 Cu(II)–2-(aminomethyl)pyridine (ampy) systems have a peak at 650 and 585 nm, respectively. An additional band is observed at 850 nm as a shoulder for the 1:1 Cu(II)–PMAD system and the 2:1 system at pH<4.0. Interestingly, the peak at 650 nm of Cu(II)–PMAD remained unchanged on going from the 1:1 binary system to the 1:1:1 Cu(II)–PMAD–ampy ternary system. The isolated complex $Cu_2(PMAD)Cl_4$ exhibited a peak at 760 nm in dimethyl sulfoxide and at 660 nm in water (pH 4.2). The Cu(II)–MPAD and –QMAD systems show spectral behavior partly similar to those of Cu(II)–PMAD; the d-d peaks are observed at ≈650 nm, but the band in the region 300—350 nm appears only at pH>6 for the Cu(II)–MPAD system, while it is undetectable for the Cu(II)–QMAD

a) sh=Shoulder; br=broad.

system because of the strong quinoline peaks.

In the region 300—900 nm the 1:1 Cu(II)–IMAD system at pH 5 has a single peak at 585 nm with a normal intensity. The wavelength and molar absorption coefficient of the peak are not affected by concentrations of the solution covering the range 10^{-4}—10^{-2} M, suggesting that the 1:1 Cu(II)–IMAD complex has a monomeric structure with an N_4 donor set analogous to that of 1:2 Cu(II)–ampy and of 1:2 Cu(II)–4-(aminomethyl)imidazole (amim). The ESR spectrum shows at least seven resolved superhyperfine structures due to nitrogen donors, the g values, $g_{//}$= 2.23 and $g_{\perp}$=2.06, being typical of a tetragonal structure with axial symmetry (Table 3).

The 1:1 Cu(II)–PMTP system, where a thioether sulfur replaces the disulfide sulfurs of PMAD, exhibits a strong peak at 320 nm (ε=3500) and well-resolved d-d bands at 600 and 850 nm. The 320-nm peak has been assigned to the S→Cu(II) charge transfer (CT) transition,[18)] which is compatible with the equatorial S–Cu(II) bonding. Because no CT band is observed for the five-coordinate complex of PDIEN which is the nitrogen analog of PMTP, the chromophore of Cu(II)–PMTP is described as CuN_4S with an axial nitrogen coordination. Complexes of analogous pyridine-containing thioethers with CuN_2S_2 chromophores have been reported to show the S→Cu(II) CT band at 340—380 nm.[24)] The 1:1 systems with PMET and IMET give a d-d band at 670—680 nm corresponding with a CuN_2O_2 chromophore, but an additional band appears at ≈310 nm with pH increase. The negative CD peak at 325 nm and its absence in 1:1 Cu(II)–IALA reveal that the 310-nm peak is due to the S→Cu(II) CT transition. The Cu(II)–methionine system in ethanol has been reported to give two S→Cu(II) CT peaks at 380 and 450 nm.[25)]

Solution Equilibria. Figure 2 shows the titration curves for some ligands in the absence and the presence of Cu(II). The overall proton-ligand stability constants, log β_{01r}, calculated from these data are listed in Table 4 and the stepwise dissociation constants (pK_a) in Table 5. The two lower acid dissociation steps of IMAD are assigned to the imidazole nitrogens, because the imidazole moiety of amim has the pK_a value of 4.73.[26)] As observed for PDIEN,[15)] the protonation of the least basic pyridine rings of PMAD and PMTP occurs only at pH<2.5.

Since the disulfide bonds are susceptible to cleavage in the presence of Cu(II) at neutral and alkaline pH, the stability constants were calculated from the data covering the pH ranges 2—3.5 for PMAD, 2.6—5.0 for MPAD, and 2.8—5.9 for IMAD. Considering

that the absorption spectra of 1:1 and 2:1 Cu(II)–PMAD and –MPAD systems have a peak at 650 nm indicative of a monomeric species and that a complex with the composition Cu_2L (L=PMAD) was isolated, we attained convergence in the computer simulations by including the species $CuLH_2$ (for L=IMAD and MPAD), CuLH, CuL, and a binuclear species Cu_2L. The analysis of the 1:1 Cu(II)–IMAD system was possible either by the set of species $CuLH_2$, CuLH, and CuL, or by the set $CuLH_2$, CuLH, and Cu_2L_2, the sums of the squares of residuals being approximately the same. However, Cu_2L_2 was rejected in the simulation including both CuL and Cu_2L_2. From this fact and the absorption spectral behavior of the Cu(II)–IMAD systems, we preferred the set with monomeric species. This conclusion is further supported by the conductivity measurements of Cu(II) complexes (Fig. 3); $Cu(IMAD)(ClO_4)_2$ has the same molar conductivity as shown by $Cu(PDIEN)(ClO_4)_2$ and other

a) Values in parentheses are estimated standard deviations. b) Calculated for 1:1 Cu(II)-ligand systems. c) Calculated for 2:1 Cu(II)-ligand systems. d) Obtained by graphical methods. e) Ref. 19. f) Ref. 15. g) ampy=2-(Aminomethyl)pyridine. h) Ref. 27. i) amim=4-(Aminomethyl)imidazole. j) Ref. 26.

bility decrease in Cu(II)–MPAD due to the 6-methyl group, the log β_{110} value of 9.46 being as low as that of Cu(II)–ampy. The results imply that PMAD and IMAD behave as multidentate ligands coordinating through most of the available donor atoms, whereas MPAD coordinates to Cu(II) in the same way as ampy. We may compare the log β_{110} values for PMAD and IMAD with the log β_{120} values for ampy and amim: the log β_{110} values for the disulfides are smaller than these log β_{120} values, which could result from the difference in the ligand basicity and/or in the donor sets in the coordination plane.

The stability constants for Cu(II)–PMTP and Cu(II)–PMET were calculated by a graphical method. Both systems were analyzed by considering CuL only, and protonated species $CuLH_2$ and CuLH were negligible. The pyridine-containing thioether PMTP forms a 1:1 complex with log β_{110}=16,3,[28] whereas PDIEN forms a complex with log β_{110}=20.85.[15] The stability difference of 4.5 log unit is attributed to the difference in the coordinating ability of an amine nitrogen and a thioether sulfur, and further supports the conclusion derived from the spectra that Cu(II)–PMTP has an N_3S donor set in the coordination plane.

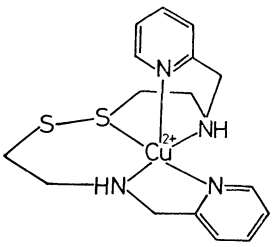
The amino acid derivative PMET forms a 1:1 complex with log β_{110}=9.30, which is smaller than the value of 11.8 reported for *N*-(2-pyridylmethyl)glycine with higher pK_a values.[29] At pH>7 the complex liberates an additional proton probably from the coordinated water molecule, whose dissociation constant was calculated by assuming the following step:

$$CuL \rightleftharpoons CuL(OH) + H. \quad (5)$$

Discussion

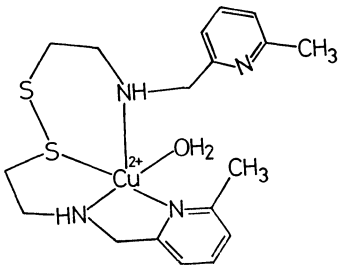
Structures of Complexes in Solution. The intensity and location of the S→Cu(II) CT band are affected by the mode of S–Cu(II) interactions.[30–32] The CT band due to equatorial thioether–Cu(II) bonding is strong, while the band due to apical bonding is sometimes too weak to be detected: the Cu(II) complex of an imidazole-containing thioether ligand, bis(4-phenyl-2-imidazolylmethyl) sulfide, has an apical S–Cu(II) bonding (2.824 Å) but shows no CT band.[32] The spectral properties of disulfide–Cu(II) bonding may be considered analogously, and the CT band arising from the apical disulfide–Cu(II) interaction may not be detected because of the poor overlap of the Cu(II) $d_{x^2-y^2}$ and S orbitals and the long axial S–Cu(II) bond as seen in the Cu(II) complexes of oxidized D-penicillamine (3.057 and 3.138 Å)[33] and glutathione (3.16 and 3.28 Å),[34] both of which apparently lack obvious S→Cu(II) CT bands. The Cu(II)···S separations in these complexes are much longer than the Cu(I)–S bonds (2.3—2.4 Å) in some Cu(I)–disulfide complexes.[35–38] Therefore, the 330-nm shoulder shown by Cu(II)–PMAD is assigned to the equatorial S→Cu(II) CT transition by analogy with the spectrum of the related system Cu(II)–PMTP.[18] The observed intensity (ε=1100) indicates that the S–Cu(II) interaction is weaker than that in Cu(II)–PMTP. For the system Cu(II)–tetramethylcystamine (=bis[2-(dimethylamino)ethyl] disulfide) Downes *et al.* observed three bands and suggested that both of the disulfide sulfur atoms are involved in the interactions with Cu(II).[39] Although a somewhat reduced $|A_{//}|$ value observed for Cu(II)–PMAD suggests sulfur coordination,[40] the ESR parameters do not explicitly point to the Cu(II)–S bonding. The splitting of the d-d band is ascribed to a square-pyramidal structure[41] with a donor group of PMAD occupying an apical position; in the 2:1 system the 850-nm band disappears at pH>4.1, indicating that the apical donor is used for forming a binuclear complex Cu_2L. The d-d band at 650 nm is remote from the band exhibited by 1:2 Cu(II)–ampy (585 nm) with a CuN_4 chromophore. Sterically PMAD may be coordinated to Cu(II) in the same way as ampy in 1:2 Cu(II)–ampy, but actually the maximum wavelength of 1:1 Cu(II)–PMAD is the same as that of 1:1 Cu(II)–ampy. Addition of ampy has no apparent effect on the spectrum of 1:1 Cu(II)–PMAD (Table 2), which may indicate either that the bonding by added ampy is similar to that by one of the two 2-pyridylmethylamino moieties of PMAD or that ampy does not coordinate to Cu(II) at all. With 2,2′-bipyridine (bpy), which probably

occupies two equatorial positions, the maximum at 650 nm shifts to 680 nm with concomitant loss of the 330-nm CT peak. An additional band is observed in both ternary systems at 850 nm as a shoulder. The 680-nm peak is close to the peak at 690 nm exhibited by 1:1:1 Cu(II)–ampy–bpy. This indicates that Cu(II)–PMAD–bpy and Cu(II)–ampy–bpy have a similar chromophore. Incidentally 1:2 Cu(II)–bpy complexes with various geometries often exhibit an electronic reflectance spectral peak at $\approx$650 nm.[42,43] From these considerations, the chromophore of 1:1 Cu(II)–PMAD in acid solution is best described as CuN_4S with apical coordination by a nitrogen donor, and we propose structure **1**, which is reminiscent of the probable structure of Cu(II)–PMTP.[18] Octahedral Ni(II)–PMAD complexes in the solid state have been reported to involve PMAD as a pentadentate ligand.[7,44]



1

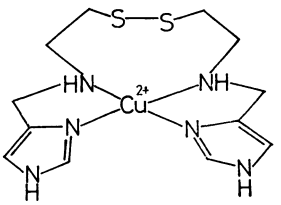
Another line of evidence is provided by the stability and the spectrum of the Cu(II)–MPAD system. In sharp contrast with the Cu(II)–PMAD system, it has the same stability constant as that of Cu(II)–ampy, which confirms an analogous mode of coordination in the square plane. The stability difference of 3.9 between Cu(II)–PMAD and Cu(II)–MPAD (Table 6) corresponds to the difference of one nitrogen donor in the plane, again indicating that at least three nitrogens are involved in the equatorial bonding in Cu(II)–PMAD. Space-filling molecular models show that, when MPAD is coordinated through the pyridine and amine nitrogens and the disulfide sulfur (structure **2**),



2

the methyl group severely interferes with the equatorial bonding by the rest of the donors. This is in accord with the lower stability and the lack of the S→Cu(II) CT band at pH<6.

On the other hand, the optical and ESR spectra (Tables 1 and 3) indicate that 1:1 Cu(II)–IMAD has a planar CuN_4 coordination structure with no strong Cu(II)–S bonding. Molecular models suggest that



3

both *cis* and *trans* structures are possible with respect to the imidazole nitrogens and that the dithio group apically approaches Cu(II) in the *trans* structure. Although the apical S–Cu(II) interaction is not incompatible with lack of S→Cu(II) CT bands, we prefer the *cis* structure (**3**) with negligible S–Cu(II) interactions on the basis of the stability of the 1:1 complex toward the disulfide bond cleavage as has been observed for PMAD.[12,13] It should be noted in addition that the 1:1 Cu(II) complex of *N,N'*-bis(4-imidazolylmethyl)ethylenediamine with an N_4 donor set shows the same absorption and ESR spectral parameters as those of the 1:1 Cu(II)–IMAD system (Tables 1 and 3). The ternary Cu(II)–IMAD–bpy systems show a broad peak at 700 nm and a shoulder at 870 nm, indicating a change from the square-planar to the square-pyramidal structure. Structures **1** and **3** are related to each other and may be determined by steric requirements for pyridine and imidazole rings in the *cis* coordination positions.

Effects of Sulfur Coordination on Stability Constants of Copper(II) Complexes. The difference of $\approx$4.5 between the $\log \beta_{110}$ values for PMTP and PDIEN is attributed to the difference in the complexing ability of a thioether sulfur and an amine nitrogen. An analogous stability difference exists between the Cu(II) complexes of diethylenetriamine ($\log \beta_{110}=15.9$) and bis(2-aminoethyl) sulfide ($\log \beta_{110}=9.07$).[27] The complex of PMAD is less stable than that of PMTP in spite of similar coordination structures of CuN_4S as inferred from absorption spectra. An explanation for this is the orbital overlap in the S–Cu(II) interaction, which is considered from the CT band intensities to be small in Cu(II)–PMAD and large in Cu(II)–PMTP. Steric effects due to the presence of two sulfur atoms in one of the chelate rings should also affect the stability. The $\log \beta_{110}$ value for PMAD is expectedly smaller than $\log \beta_{120}$ for 1:2 Cu(II)–ampy with an N_4 donor set by 3.9 log units. The low stability of Cu(II)–MPAD is ascribed to the bidentate nature of MPAD due to the steric hindrance arising from the 6-methyl group.

Although 1:1 Cu(II)–IMAD and 1:2 Cu(II)–amim probably have the same donor groups in the coordination plane, the difference between $\log \beta_{110}$ of Cu(II)–IMAD and $\log \beta_{120}$ of Cu(II)–amim is rather large ($\approx$3.8) and may be caused by lower basicity of IMAD and steric strains due to the disulfide bond.

The terdentate thioether ligand PMET forms a 1:1 complex ($\log \beta_{110}=9.3$), which is more stable than the Cu(II)–L-methioninate complex ($\log \beta_{110}=7.849$).[45] The stability enhancement is due primarily to the pyridine nitrogen, and contribution by the

thioether moiety may be negligible, because Cu(II)–ampy has approximately the same stability. In this connection, L-methionylglycine and *S*-methyl-L-cysteinylglycine form Cu(II) complexes CuL with significantly higher stability than expected from the basicity of the terminal amino group of various dipeptides; the thioether sulfur of glycyl-L-methionine has no effect on the stability of CuL owing to the inaccessibility of the side chain to Cu(II).[46]

Dependence of the Disulfide Bond Stability on the Coordination Structure. Disulfides are susceptible to heterolytic cleavage by Ag(I), Hg(I), and other soft Lewis acids, forming sulfinic acids and thiols by the reaction with water and subsequent disproportionation.[10] Formation of 2-pyridylsulfinate from di-2-pyridyl disulfide in the presence of Cu(II) has been interpreted as due to the same heterolytic cleavage reaction.[11] PMAD is readily converted to 2-(2-pyridylmethylamino)ethanesulfinate in the presence of Cu(II) and dioxygen at pH $\approx$7.[12,13] Although this reaction has been found to require dioxygen,[13] it must involve the heterolytic cleavage and the reaction with water, because the oxygens incorporated from dioxygen account for only 25—30% of the total sulfinate oxygens. The 2:1 Cu(II)–PMAD system at pH$\approx$7 exhibits a transient but resolved peak at 330 nm,[13] indicating that the Cu(II)–S interaction is stronger than in acid solution where the 330-nm peak appears as a shoulder. The Cu(II)–tetramethylcystamine system in acetonitrile, whose disulfide bond is more stable than that in the Cu(II)–cystamine system, gives strong S$\rightarrow$Cu(II) CT peaks and is rapidly decomposed by addition of a second equivalent of sodium methoxide.[39] On the other hand, the Cu(II)–penicillamine disulfide[33] and –glutathione disulfide[34] complexes, which were isolated from aqueous solution, have long Cu(II)$\cdots$S distances (3.0—3.3 Å) and show no CT bands. Also, the Cu(II)–IMAD system is more stable in aqueous solution and gives a 1:1 complex as crystals; in line with this, the system shows no band ascribable to the S$\rightarrow$Cu(II) CT transition. Since the stability constants of Cu(II)–disulfide and –thioether complexes are usually low,[47–50] neighboring effective Cu(II)-binding sites which bring the disulfide group close to Cu(II) would promote the cleavage reaction. These observations probably indicate that only those complexes which involve weak Cu(II)–S bonds are stable in aqueous solution.

The disulfide bond has been proposed as a copper binding site in stellacyanin[3–5] which lacks the methionyl residue established as a binding site in plastocyanin and azurin. While the proposal is attractive in view of the coordinating ability of the disulfide sulfurs, it becomes necessary to cope with the dichotomy between coordination and disulfide bond cleavage. We may infer from the present observations that the copper site should meet one of the following requirements for the stability of the bond in the vicinity of Cu(II): (i) the S$\cdots$Cu(II) separation is as large as 3.0 Å; (ii) water and other nucleophiles are excluded from the copper binding site. Just as the Cu(II)$\cdots$S(methionine) distance found in plastocyanin is unusually long (2.90 Å),[1] a disulfide group would be able to contribute to the copper binding in stellacyanin through weak interaction with a large Cu(II)$\cdots$S separation.

We thank Mr. Kiyoshi Takami for assistance with the experiments. Thanks are also due to Dr. Yukio Sugiura of Kyoto University and Drs. Shinnichiro Suzuki and Takeshi Sakurai of Osaka University for ESR spectral measurements. We are indebted to Dr. P. Gans of the University of Leeds for suggestions on the use of the computer program MINIQUAD. This work was supported by a Grant-in-Aid for Special Project Research (No. 57102001) from the Ministry of Education, Science and Culture.

Synthesis and Characterization of a New Quinquedentate Ligand Consisting of Salen Skeleton and Phenolic Tail Capable of Axial Coordination and Its Metal Complexes

Wakako KANDA, Hisashi ŌKAWA,* and Sigeo KIDA

Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812

(Received May 2, 1983)

A New quinquedentate ligand *N,N'*-disalicylidene-2-methyl-4-(2-hydroxy-5-methylphenyl)-1,2-butanediamine (H_2(sal-Hpen)) has been prepared, which is a salen derivative containing a phenolic tail capable of axial coordination. It formed the complexes of a general formula [M(sal-Hpen)] with copper(II), nickel(II), and cobalt(II) ions. Based on infrared, electronic and ESR spectra, the complexes were revealed to assume a planar coordination, free from axial coordination of the phenolic tail. On the other hand, distorted octahedral cobalt(III) and tetragonal pyramidal iron(III) complexes, [Co(sal-pen)py] and [Fe(sal-pen)], were obtained, where sal-pen^{3-} acts as a quinquedentate ligand.

Metal complexes of *N,N'*-disalicylideneethylenediamine (H_2salen) and its derivatives are known to assume planar coordination and show some characteristics relevant to biological systems, such as reversible oxygen adducts[1-11] and alkyl-cobalt(III) complexes[12,13] formations and catalytic function in substrate oxidation.[14-17] In these complexes, the fifth and sixth coordination at the axial positions plays a key role in the biomimetic functions. Therefore, it is interesting to synthesize salen derivatives possessing a tail group capable of axial coordination. However, synthesis of quinquedentate salen derivatives are limited to those with a thioether[18] or a pyridyl group[19] as an axial coordinating group.

In this study, a quinquedentate salen derivative, *N,N'*-disalicylidene-2-methyl-4-(2-hydroxy-5-methylphenyl)-1,2-butanediamine (abbreviated as H_2(sal-Hpen)), has been prepared. The complexes of this ligand may serve for elucidating the effects of the axial coordination of a phenolic oxygen on the electronic property and the reactivity of complexes and as a model for an intermediate in oxygenase reaction.[20]

In order to examine the net effect of axial phenolato donation, *N,N'*-disalicylidene-2-methyl-4-(2-methoxy-5-methylphenyl)-1,2-butanediamine (H_2(sal-mpen)) and its metal complexes were also prepared, where methyl group was substituted for phenolic hydrogen of H_2(sal-Hpen) so that practically no axial coordination is feasible. The synthetic methods for H_2(sal-Hpen) and H_2(sal-mpen) are schematically shown in Fig. 1.

Experimental

Syntheses. Methyl 2-(2-Methoxy-5-methylphenyl)ethyl Ketone: Ethyl acetoacetate (52 g) was added with stirring to a sodium ethoxide solution prepared by dissolving sodium (9.2 g) in absolute ethanol (350 cm^3). To this solution was added 2-methoxy-5-methylbenzyl chloride (68 g) with gentle boiling, and the mixture was refluxed for 3 h. When the reaction was completed, the mixture was cooled and sodium chloride separated was removed by filtration. The salt was washed with a small amount of ether and washings were combined with the main solution. The solution was evaporated to dryness to give a pale yellow substance. It

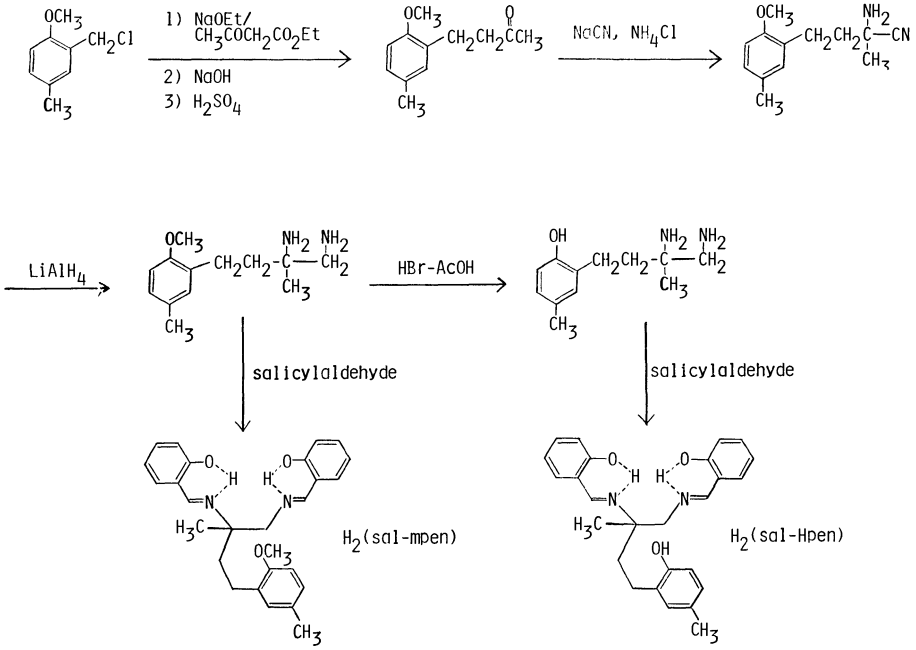

Fig. 1. Synthetic method for H_2(sal-Hpen) and H_2(sal-mpen).

was suspended in a 5% aqueous sodium hydroxide solution (640 cm^3) and the solution was stirred at room temperature overnight. The insoluble oily substance was removed and the aqueous solution was acidified by adding 50% sulfuric acid (160 cm^3). The mixture was refluxed for 2 h and the resulting yellow oily substance was separated with a separatory funnel. The aqueous layer was shaken with benzene and the extracts were combined and dried over anhydrous sodium sulfate. After the solvent was evaporated, the residue was distilled at 149—151 °C/13 mmHg (1 mmHg ≈133.322 Pa) to give a colorless liquid (30 g).

Found: C, 76.64; H, 8.42%. Calcd for $C_{12}H_{16}O_2$: C, 74.79; H, 8.39%.

2-Amino-2-methyl-4-(2-methoxy-5-methylphenyl)butanenitrile: A solution of ammonium chloride (5 g) in water (20 cm^3), sodium cyanide (4 g), and aqueous ammonia (28%, 11 cm^3) were mixed in a 500 cm^3 round-bottomed flask. To this was added methyl 2-(2-methoxy-5-methylphenyl)ethyl ketone (15 g), and the flask was sealed with a glass stopper and heated at 60 °C on a water bath for 5 h. The reaction mixture was shaken with five 60 cm^3 portions of ether, and the etherial extracts were combined and dried over sodium sulfate. On evaporating the solvent, the amino nitrile was obtained as an orange paste. It was used for the following reaction without purification.

2-Methyl-4-(2-methoxy-5-methylphenyl)-1,2-butanediamine Dihydrochloride (mpen·2HCl): To a stirred suspension of $LiAlH_4$ (25 g) in absolute ether (400 cm^3) was added a solution of the aminonitrile (10 g) in ether (50 cm^3). The reaction mixture was refluxed for 13 h and decomposed by adding water under ice cooling. The ethereal layer was separated and the residue was extracted with three 100 cm^3 portions of ether. The ethereal solutions were combined and dried over sodium sulfate. When dry hydrogen chloride was bubbled into the solution, crude mpen·2HCl was separated as a milky white precipitate. It was used for the following reaction without further purification because of its high hygroscopicity.

2-Methyl-4-(2-hydroxy-5-methylphenyl)-1,2-butanediamine Dihydrobromide (Hpen·2HBr): A mixture of crude mpen·2HCl (3.2 g), acetic acid (35 cm^3), hydrobromic acid (40%, 35 cm^3), and hydroiodic acid (55%, 3.5 cm^3) was refluxed for 20 h. The reaction mixture was evaporated to dryness to give dark brown mass. It was dissolved in methanol and decolorated with activated charcoal. When the solvent was evaporated, Hpen·2HBr was obtained as yellow mass. Since it was very hygroscopic, it was used for the preparation of H_2(sal-Hpen) without purification.

N,N′-Disalicylidene-2-methyl-4-(2-hydroxy-5-methylphenyl)-1,2-butanediamine (H_2(sal-Hpen)): This was obtained as yellow needles by the reaction Hpen·2HBr (0.3 g) and salicylaldehyde (0.2 g) in methanol (20 cm^3) in the presence of triethylamine (0.17 g).

Found: C, 74.74; H, 6.83; N, 6.74%. Calcd for $C_{26}H_{28}N_2O_3$: C, 74.79; H, 7.00; N, 6.89%.

N,N′-Disalicylidene-2-methyl-4-(2-methoxy-5-methylphenyl)-1,2-butanediamine (H_2(sal-mpen)): This was obtained as yellow needles in nearly the same way as that of H_2(sal-Hpen) except for using mpen·2HCl (0.2 g) instead of Hpen·2HBr.

Found: C, 75.15; H, 7.11; N, 6.52%. Calcd for $C_{27}H_{30}N_2O_3$: C, 75.32; H, 7.02; N, 6.51%.

[Cu(sal-Hpen)]: To a methanolic solution (30 cm^3) of H_2(sal-Hpen) (0.2 g) was added a methanolic solution of copper(II) acetate monohydrate (0.1 g). The mixture was heated at 60 °C for 5 h and allowed to stand overnight. Pu ple crystals separated were filtered and recrystallized from methanol.

Found: C, 64.58; H, 5.72; N, 5.79%. Calcd for $C_{26}H_{26}N_2O_3Cu\cdot\frac{1}{2}H_2O$: C, 64.12; H, 5.59; N, 5.75%.

[Ni(sal-Hpen)]: This complex was obtained as red crystals by the reaction of H_2(sal-Hpen) (0.2 g) and nickel (II) acetate tetrahydrate (0.12 g) in methanol. It was recrystallized from methanol.

Found: C, 65.69; H, 5.62; N, 6.00%. Calcd for $C_{26}H_{26}N_2O_3Ni$: C, 65.99; H, 5.53; N, 5.92%.

[Co(sal-Hpen)]: This complex was obtained as orange powder by the reaction of H_2(sal-Hpen) (0.2 g) and cobalt (II) acetate tetrahydrate (0.12 g) in absolute ethanol in an atmosphere of nitrogen.

Found: C, 65.60; H, 5.61; N, 5.94%. Calcd for $C_{26}H_{26}N_2O_3Co$: C, 65.96; H, 5.54; N, 5.92%.

[Fe(sal-pen)]: This complex was obtained as brownish purple crystalline powder by the reaction of H_2(sal-Hpen) (0.2 g) and iron(III) acetate (0.08 g) in absolute ethanol.

Found: C, 65.58; H, 5.44; N, 5.78%. Calcd for $C_{26}H_{25}N_2O_3Fe\cdot\frac{1}{2}H_2O$: C, 65.28; H, 5.47; N, 5.86%.

[Co(sal-pen)py]: [Co(sal-Hpen)] (0.1 g) was dissolved in dichloromethane (30 cm^3) containing pyridine (0.02 g), and to this was bubbled air for 3 h. On concentrating the solution, reddish brown crystalline powder was separated.

Found: C, 65.16; H, 5.39; N, 7.35%. Calcd for $C_{31}H_{30}N_3O_3Co\cdot H_2O$: C, 65.38; H, 5.66; N, 7.37%.

[Cu(sal-mpen)]: This complex was obtained as purple needles in the same way as that of [Cu(sal-Hpen)] except for using H_2(sal-mpen) (0.2 g) instead of H_2(sal-Hpen).

Found: C, 65.65; H, 5.74; N, 5.68%. Calcd for $C_{27}H_{28}N_2O_3Cu$: C, 65.77; H, 5.92; N, 5.68%.

[Ni(sal-mpen)]: This complex was obtained as red needles in the same way as that of [Ni(sal-Hpen)] except for using H_2(sal-mpen) (0.2 g) instead of H_2(sal-Hpen).

Found: C, 65.97; H, 5.86; N, 5.73%. Calcd for $C_{27}H_{28}N_2O_3Ni$: C, 66.42; H, 5.98; N, 5.73%.

[Co(sal-mpen)]: This complex was obtained as orange microcrystalline powder in the same way as that of [Co(sal-Hpen)] except for using H_2(sal-mpen) (0.2 g) instead of H_2(sal-Hpen).

Found: C, 66.34; H, 5.75; N, 5.79%. Calcd for $C_{27}H_{28}N_2O_3Co$: C, 66.39; H, 5.98; N, 5.73%.

Measurements. Infrared spectra were recorded on a Hitachi Infrared Spectrometer Model 215 on KBr disks or hexachlorobutadiene mulls. Electronic spectra were recorded on a Shimadzu Multipurpose Spectrophotometer Model MPS-5000 and a Shimadzu UV-VISIBLE Recording Spectrometer Model UV-240 in dichloromethane. Magnetic susceptibilities were measured by the Faraday method. The apparatus was calibrated by the use of $[Ni(en)_3]S_2O_3$.[21] Diamagnetic corrections were carried out using Pascal's constants and effective magnetic moments were calculated by the equation $\mu_{eff}=2.828(\chi_A\times T)^{1/2}$.

Results and Discussion

Infrared spectra of [M(sal-Hpen)](M=Cu^{II}, Ni^{II}, and Co^{II}) are quite similar to those of [M(sal-mpen)], except for a band at 3300—3200 cm^{-1} which is absent in the spectra of [M(sal-mpen)]. This band should be due to the stretching vibration of the phenolic hydroxy group in the tail.

Electronic spectra of [M(sal-Hpen)] and [M(sal-mpen)] were measured in dichloromethane and are shown in Fig. 2. The spectra of [Cu(sal-Hpen)] and [Cu(sal-mpen)] resemble each other in the region (15—35)$\times 10^3$ cm^{-1}, exhibiting a d-d band centered around

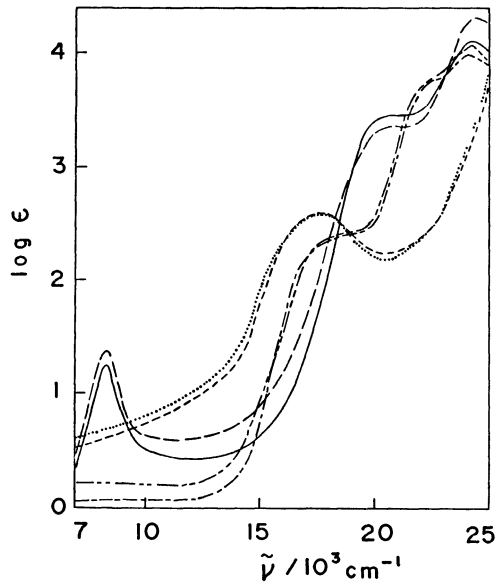

Fig. 2. Electronic spectra of (— — —)[Cu(sal-Hpen)], (·····) [Cu(sal-mpen)], (—·—·—) [Ni(sal-Hpen)], (—··—) [Ni(sal-mpen)], (——)[Co(sal-Hpen)], and (— — —) [Co(sal-mpen)].

18×10^3 cm^{-1}. Furthermore, these spectra are nearly the same as that of [Cu(salen)].[22-24] These facts clearly indicate that the geometry around the metal in the present complexes is essentialy planar without coordination of the hydroxyl or methoxyl group of the tail. Planar configuration for [Cu(sal-Hpen)] and [Cu(sal-mpen)] was also supported by their ESR spectra showing a tetragonal pattern, whose ESR parameters ([Cu(sal-Hpen)]: $g_{\parallel}=2.18$ and $A_{\parallel}=203$ G(1 G$=10^{-4}$T); [Cu(sal-mpen)]: $g_{\parallel}=2.18$ and $A_{\parallel}=201$ G) are practically the same as those of [Cu(salen)] ($g_{\parallel}=2.20$ and $A_{\parallel}$195 G).[25]

Electronic spectra of [Ni(sal-Hpen)] and [Ni(sal-mpen)] resemble each other in the region $(15—35) \times 10^3$ cm^{-1}. Both showed a d-d band at 18.5×10^3 cm^{-1}, which is nearly the same in frequency as that of [Ni(salen)].[24,26,27] Planar configuration around the metal in [Ni(sal-Hpen)] and [Ni(sal-mpen)] appeared to be reasonable, considered from the facts that [Ni(salen)] and its congeners are known to retain the planar configuration even in polar solvents such as pyridine.[26]

Effective magnetic moments of [Co(sal-Hpen)] and [Co(sal-mpen)] are *ca.* 2.4 BM at room temperature. Electronic spectra of these complexes show a weak band at 8.3×10^3 cm^{-1}, which is characteristic of low-spin, planar cobalt(II) complexes with salen-like Schiff bases.[28-30] Powder ESR spectra of [Co(sal-Hpen)] and [Co(sal-mpen)] both showed a typical ESR pattern of a low-spin, planar cobalt(II) with the $(d_{yz})^1$ ground state[31,32] (Fig. 3). The ESR parameters of the signal at the lower magnetic field are as follows: $g_{\parallel}=3.50$ and $A_{\parallel}=127$ G for [Co(sal-Hpen)]; $g_{\parallel}=3.50$ and $A_{\parallel}=121$ G for [Co(sal-mpen)]. From these facts we may conclude that the present cobalt(II) complexes are of square planar coordination.

Despite marked resemblance in electronic and ESR spectra, [Co(sal-Hpen)] distinctly differ from [Co(sal-mpen)] in reactivity to atmospheric oxygen; the former is very sensitive to molecular oxygen while the latter is practically insensitive in dichloromethane. This suggests that the hydroxy group in the tail exerts some effect on the oxygenation or oxidation at the metal though this group is free from coordination in the cobalt(II) complex.

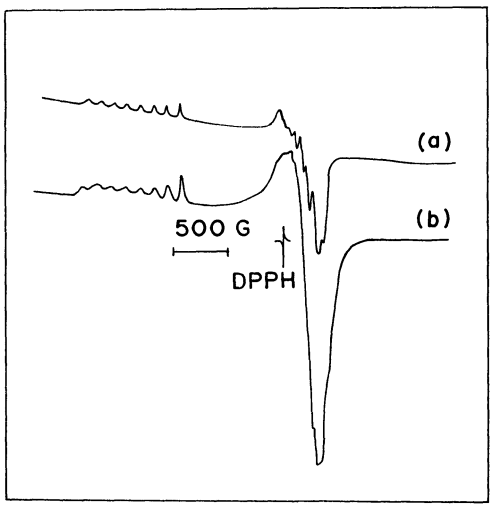

Fig. 3. ESR spectra of (a) [Co(sal-mpen)] and (b) [Co(sal-Hpen)].

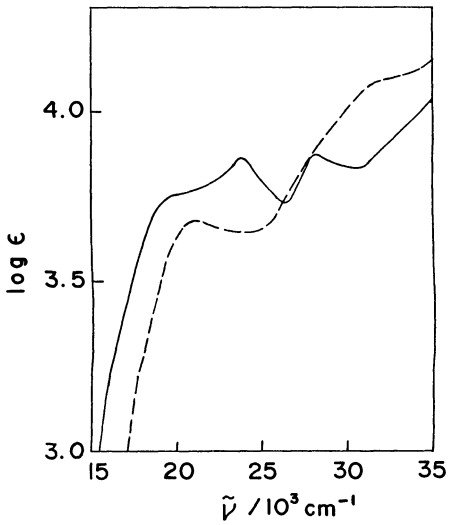

Fig. 4. Electronic spectra of (——) [Co(sal-pen)py] and (— — —) [Fe(sal-pen)].

Reddish brown [Co(sal-pen)py] prepared by air-oxidation of [Co(sal-Hpen)] in dichloromethane-pyridine is diamagnetic. Electronic spectrum of this complex shows an absorption at 20×10^3 cm^{-1} with a shoulder near 16.5×10^3 cm^{-1} (Fig. 4). Coordination of pyridine to the cobalt(III) ion was deduced by an IR band at 690 cm^{-1}. The absence of band due to O-H stretching mode in the region 3300—3200 cm^{-1} implies deprotonation of the phenolic OH group in the tail. All these facts suggest that H_2(sal-Hpen) acts as a quinquedentate ligand to form a six-coordinate cobalt(III) complex with the phenolic oxygen of the tail at the fifth donating site and a pyridine molecule

at the sixth site.

Magnetic susceptibility of [Fe(sal-pen)] is 5.8 BM at room temperature, which falls in the range for high-spin iron(III) complex. This complex exhibits no IR band in the region 3300—3200 cm^{-1}, implying the formation of a five-coordinate iron(III) complex with the deprotonated phenolic oxygen in the tail at the apex. It exhibits a visible spectrum with an absorption at 21×10^3 cm^{-1} ($\varepsilon \approx 4800$ M^{-1} cm^{-1}), which can be attributed to the charge transfer from the phenolic oxygen in the tail to the iron(III) ion (Fig. 4). Notably, this spectrum differs from those of [Fe(salen)-X] with phenolate or unidentate catecholate group as X; the latter complexes show the CT band in the region $(24.0—24.5) \times 10^3$ cm^{-1} ($\varepsilon \approx 7000$ M^{-1} cm^{-1}).[20] The reason for the absorption spectral difference between [Fe(sal-pen)] and [Fe(salen)X] is unclear at present. It is likely that the phenolic tail incorporated into the salen moiety affects the electronic property of iron(III) ion in a manner different from a monodentate phenolic donor. It is notable that the spectrum of [Fe(sal-pen)] resembles those of catechol 1,2-dioxygenase[33] and protocatechuate 3,5-dioxygenase,[34] which show the CT band from tyrosinate to iron at $(22.0—21.7) \times 10^3$ cm^{-1} ($\varepsilon \approx 3000—4000$ M^{-1} cm^{-1}).

Synthesis and Optical Resolution of $[Rh^{III}(S)_3(N)_3]$ Type Complexes Containing a Thiolato, Sulfenato, or Sulfinato Donor Group

Masakazu KITA,* Kazuaki YAMANARI, and Yoichi SHIMURA

Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560

(Received May 4, 1983)

Rhodium(III) complexes, $[Rh(SCH_2CH_2NH_2)_3]$ and $[Rh\{S(O)CH_2CH_2NH_2\}_n\{S(O)_2CH_2CH_2NH_2\}_{3-n}]$ ($n=3$, 2, 1, and 0), were prepared and optically resolved by means of column chromatography or preferential crystallization of diastereomeric molecular compound with (*R,R*)-tartaric acid, d-$C_4H_6O_6\cdot(-)_{300}^{CD}$-$[Rh\{S(O)CH_2CH_2NH_2\}_3]\cdot H_2O$ or d-$C_4H_6O_6\cdot(+)_{300}^{CD}$-$[Rh\{S(O)CH_2CH_2NH_2\}_2\{S(O)_2CH_2CH_2NH_2\}]$. All the present complexes have only the *fac*(*S*) geometry. The (*R*) configuration of sulfenato group is more stable than the (*S*) one in the *Λ*-isomer.

In a previous paper[1] we have reported the synthesis, optical resolution, and stereoselectivity of neutral cobalt(III) complexes, $[Co(aet)_3]$ and $[Co(aese)_n(aesi)_{3-n}]$ ($n=3$, 2, 1, and 0).[2] These S-bonded sulfenato and sulfinato cobalt(III) complexes showed several unique chemical and spectrochemical behaviors. In particular, one of the isomers of $[Co(aese)_3]$ was resolved *via* diastereomeric molecular compound with (*R,R*)-tartaric acid. It is interesting to compare the properties of cobalt(III) complexes with those of the corresponding rhodium(III) complexes, because there is a general tendency for the metals of the second transition series to exhibit a greater affinity toward sulfur donors than do the metals of the first transition series.[3] No optically active sulfenato or sulfinato complexes has so far been reported for rhodium(III). This paper is concerned with the preparation, optical resolution, and stereochemistry of $[Rh(aet)_3]$ and $[Rh(aese)_n(aesi)_{3-n}]$ ($n=3$, 2, 1, and 0).

Experimental

Preparation, Separation, and Optical Resolution of Complexes. *(1)* $[Rh(aet)_3]$: To a solution of 3.0 g (39 mmol) of 2-aminoethanethiol and 1.5 g (38 mmol) of sodium hydroxide in 20 cm^3 of water was added 2.0 g (9.6 mmol) of $RhCl_3$ and the mixture was stirred at 95 °C for 4 h. The white curdy precipitate with a yellow tint (1.5 g, 47%) was filtered and washed with water. Found: C, 21.52; H, 5.41; N, 12.59%. Calcd for $[Rh(aet)_3]=C_6H_{18}N_3S_3Rh$: C, 21.75; H, 5.48; N, 12.68%.

(2) $[Rh(aese)_n(aesi)_{3-n}]$ *(n=3, 2, 1, and 0)*: These complexes were prepared *via* H_2O_2 oxidation of $[Rh(aet)_3]$ and isolated by the column chromatographic technique used for $[Co(aese)_n(aesi)_{3-n}]$ ($n=3$, 2, 1, and 0).[1]

To a suspension of 1.0 g (3.0 mmol) of $[Rh(aet)_3]$ in 20 cm^3 of water was added 20 cm^3 (9.0 mmol) of 1.5% aqueous H_2O_2 with stirring below 5 °C, leading to a faint yellow solution. On addition of acetone (100 cm^3) and diethyl ether (200 cm^3), a faint yellow precipitate (1.2 g) appeared. This was dissolved in a small amount of water, adsorbed on a column of anion-exchange resin {QAE Sephadex A-25, (*R,R*)-tartrate form} and eluted with water. The eluates were collected with five cm^3 portions. Four complexes, I, II, III, and IV, were eluted in this order. At this stage all complexes were partially resolved: The earlier eluted fractions of each complex showed positive CD at the longest wavelength regon of the first d-d absorption band.

Combined eluate of each the complex was concentrated in a vacuum rotary evaporator at *ca.* 8 °C to give the precipitate. The precipitate was collected by filtration and washed with ethanol–ether (1:1). The complex I partially isomerized into the complex II during the crystallization. The isomerization was confirmed by column chromatography and the ^{13}C NMR spectra. The sparingly soluble white complex V was obtained *via* oxidation of $[Rh(aet)_3]$ by an excess of 30% H_2O_2. Further oxidation of each complex I, II, III, or IV by dilute H_2O_2 showed that the oxidation process is stepwise in a series of I (or II)→III→IV→V and the complex V was the final oxidation product. On the basis of the absorption measurements and elemental analyses, the complexes I (and II), III, IV, and V were assigned to $n=3$, 2, 1, and 0 in $[Rh(aese)_n(aesi)_{3-n}]$ series, respectively. Found for I: C, 15.76; H, 5.60; N, 9.20%. Calcd for $[Rh(aese)_3]\cdot 4H_2O=C_6H_{26}N_3O_7S_3Rh$: C, 15.97; H, 5.80; N, 9.31%. Found for II: C, 16.75; H, 5.45; N, 9.76%. Calcd for $[Rh(aese)_3]\cdot 3H_2O=C_6H_{24}N_3O_6S_3Rh$: C, 16.63; H, 5.58; N, 9.70%. Found for III: C, 16.77; H, 5.14; N, 9.85%. Calcd for $[Rh(aese)_2(aesi)]\cdot 2H_2O=C_6H_{22}N_3O_6S_3Rh$: C, 16.71; H, 5.14; N, 9.74%. Found for IV: C, 16.52; H, 4.66; N, 9.52%. Calcd for $[Rh(aese)(aesi)_2]\cdot 1.5H_2O=C_6H_{21}N_3O_{6.5}S_3Rh$: C, 16.44; H, 4.83; N, 9.59%. Found for V: C, 16.77; H, 4.32; N, 9.58%. Calcd for $[Rh(aesi)_3]\cdot 0.5H_2O=C_6H_{19}N_3O_{6.5}S_3Rh$: C, 16.51; H, 4.39; N, 9.63%.

(3) Optical Resolution: The racemate II, $[Rh(aese)_3]\cdot 3H_2O$ (1.0 g, 2.3 mmol), or the racemate III, $[Rh(aese)_2(aesi)]\cdot 2H_2O$ (1.0 g, 2.3 mmol), was dissolved in an ethanol–water (2:1) mixture and then (*R,R*)-tartaric acid (0.35 g, 2.3 mmol) was added to the solution, and after a few minutes, a slightly yellow diastereomeric molecular compound, d-$C_4H_6O_6\cdot(-)_{300}^{CD}$-$[Rh(aese)_3]\cdot H_2O$ (II*) or a white diastereomeric molecular compound, d-$C_4H_6O_6\cdot(+)_{300}^{CD}$-$[Rh(aese)_2(aesi)]$ (III*) began to deposit, respectively. The crystals were filtered and washed with ethanol. Found for II*: C, 21.64; H, 4.71; N, 7.55%. Calcd for d-$C_4H_6O_6\cdot(-)_{300}^{CD}$-$[Rh(aese)_3]\cdot H_2O=C_{10}H_{26}N_3O_{10}S_3Rh$: C, 21.95; H, 4.79; N, 7.67%. Found for III*: C, 21.79; H, 4.44; N, 7.72%. Calcd for d-$C_4H_6O_6\cdot(+)_{300}^{CD}$-$[Rh(aese)_2(aesi)]=C_{10}H_{24}N_3O_{10}S_3Rh$: C, 22.02; H, 4.44; N, 7.70%.

The diastereomeric molecular compound, II* or III*, was converted into $(-)_{300}^{CD}$-II or $(+)_{300}^{CD}$-III by treating with an equimolar amount of $Ca(OH)_2$. The CD spectrum was measured for the filtrate whose concentration was calculated from the measured absorbance using the extinction coefficient of the corresponding racemate.

Optically pure complexes IV and V could be prepared by the oxidation of the optically active complex II or III, $(-)_{300}^{CD}$-$[Rh(aese)_3]$ or $(+)_{300}^{CD}$-$[Rh(aese)_2(aesi)]$. The oxidation product of $(-)_{300}^{CD}$-I, which was obtained by the column chromatography described above, was the same as that of $(-)_{300}^{CD}$-II.

(4) $[Co(aese)_3]$: The *rac*{*Λ*-(*S,S,S*)/*Λ*-(*R,R,R*)}-$[Co(aese)_3]$ was obtained by the previously reported procedure.[1]

Measurements. The visible and ultraviolet absorption spectra were measured on a Hitachi 330 spectrophotometer. The CD spectra were recorded on a JASCO MOE-1 spectropolarimeter and the MCD spectra were measured on the same instrument in 1.5 T magnetic field. The absorption, CD and MCD measurements of the complexes were made in aqueous solutions at room temperature. The ^{13}C NMR spectra were obtained with a Varian XL-100-15 NMR spectrometer in D_2O containing dioxane as an internal standard.

Results and Discussion

Geometry of [Rh(aet)$_3$]. The absorption spectra and data of [Rh(aet)$_3$] are shown in Fig. 1 and Table 1, respectively. The corresponding cobalt(III) complex [Co(aet)$_3$] takes the *fac(S)* geometry and its absorption peaks appear at 17200, 22700, and 36400 cm^{-1}, which were assigned to the first and second spin-allowed d-d transitions[1,4] ($^1T_1 \leftarrow {}^1A_1$), ($^1T_2 \leftarrow {}^1A_1$), and Co(σ^*)←S(σ) LMCT transition, respectively.[1,5] Analogously the absorption bands of [Rh(aet)$_3$] at 25000, 29500, and 44200 cm^{-1} are assigned to $^1T_1 \leftarrow {}^1A_1$, $^1T_2 \leftarrow {}^1A_1$, and Rh(σ^*)←S(σ) LMCT transitions, respectively.[4,5] The complex II, which was the oxidation product of [Rh(aet)$_3$], showed two ^{13}C NMR resonances, and therefore has C_3 symmetry (Table 2).

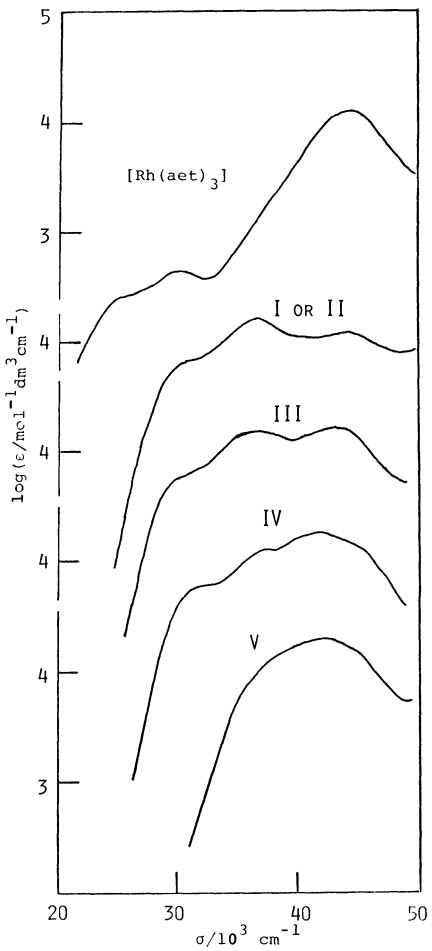

Fig. 1. Absorption spectra of [Rh(aet)$_3$] and [Rh(aese)$_n$(aesi)$_{3-n}$]: I or II (n=3), III (n=2), IV (n=1), and V (n=0).

As will be shown later both the complexes I and II have the *fac(S)* geometry. Therefore, it is concluded that the starting thiolato complex [Rh(aet)$_3$] exists in the *fac(S)* form.

Characterization of [Rh(aese)$_n$(aesi)$_{3-n}$] (n=3, 2, 1, and 0). The absorption spectra of the complexes for the series are shown in Fig. 1. All complexes showed an intense band in 42000—44000 cm^{-1} region, which is assigned to the Rh(σ^*)←S(σ) LMCT transition. The complexes I—IV show another intense band at *ca.* 36000 cm^{-1} whose molar absorption coefficient decreases successively with the decrease of the number of sulfenato groups. Therefore, the bands at *ca.* 36000 cm^{-1} can be assigned to LMCT Rh(σ^*)←sulfenato group. The d-d absorption bands of these oxidation products are somewhat obscured by the intense LMCT

Table 1. Absorption and CD spectral data

bands. The MCD pattern of the racemic complex II is similar to that of *rac*{*Δ*-(*S,S,S*)/*Λ*-(*R,R,R*)}-[Co(aese)$_3$] in the spin-allowed d-d and LMCT region (Table 3 and Fig. 2). The *Λ*-(*R,R,R*)-[Co(aese)$_3$] showed the CD extrema at 20000 cm^{-1} ($\Delta\varepsilon$=+6.96) and 22400 cm^{-1} ($\Delta\varepsilon$=−4.12) in the ligand field transition region[1] and the corresponding MCD extremum at 21100 cm^{-1} ($\Delta\varepsilon_M$=+0.12). The MCD extremum of the rhodium(III) complex *rac*-II at 29900 cm^{-1} ($\Delta\varepsilon_M$=+0.18) is assigned to the ligand field transition on the analogy of the MCD pattern. The shoulder at *ca.* 30000 cm^{-1} of the complex III or IV in Fig. 3 is assigned to the ligand field transition band. A similar band of [Rh(aesi)$_3$] (V) was quite obscured in the absorption spectrum but the CD shoulder exists at 35700 cm^{-1}.

The complexes containing the sulfenato groups should have two CD contributions, one from the configurational chirality based on the skew pair of chelate rings (*Δ* or *Λ*) and the other from the chirality based on the asymmetric sulfur donor atom of sulfenato group (*S* or *R*). Since the complex $(-)^{CD}_{300}$-II has C_3 symmetry as determined from the ^{13}C NMR spectrum, the structure is one of the following four with *fac*(*S*) geometry, *Δ*-(*R,R,R*), *Δ*-(*S,S,S*), *Λ*-(*R,R.R*), or *Λ*-(*S,*-

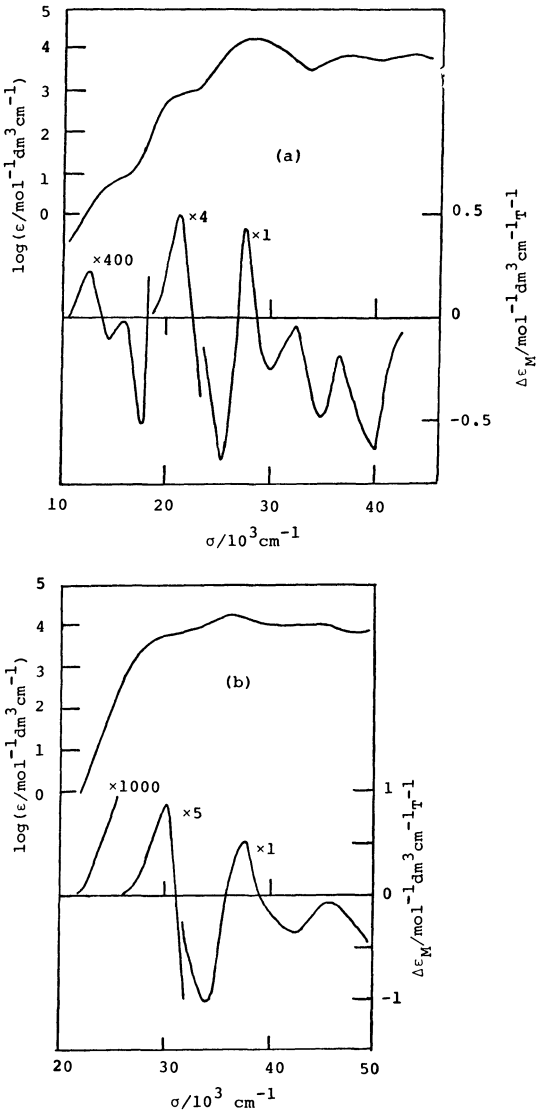

Fig. 2. Absorption and MCD spectra of (a): *rac*{*Δ*-(*S,S,S*)/*Λ*-(*R,R,R*)}-[Co(aese)$_3$] and (b): the complex II.

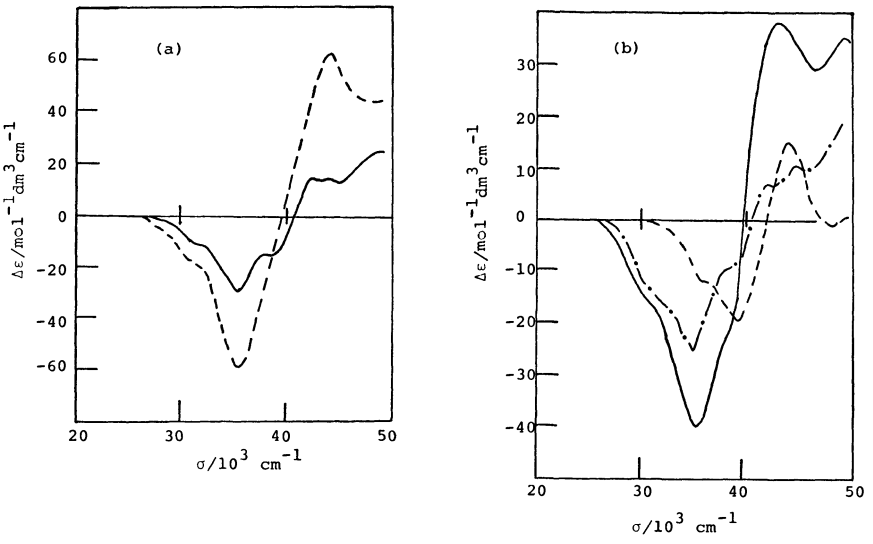

Fig. 3. CD spectra of the complexes (a): $(-)^{CD}_{300}$-I (——), and $(-)^{CD}_{300}$-II (—·—), and (b): $(-)^{CD}_{300}$-III (——), $(-)^{CD}_{300}$-IV (—·—), and $(-)^{CD}_{300}$-V (—·—).

S,S). The absolute configurations of sulfenato groups can be deduced from the cobalt(III) complexes by the CD sign and intensity ($\Delta\varepsilon$) in the sulfenato LMCT region.[1,6] For example, a positive CD band ($\Delta\varepsilon$= +11.71) was observed in the sulfenato LMCT reigon (*ca.* 27000 cm^{-1}) for *Λ-(S)*-[Co(aese)$(en)_2]^{2+}$, and a negative one for the *Λ-(R)* complex.[1] Assuming the same criterion for the sulfenato rhodium(III) complexes, it can be concluded that all the complexes $(-)^{CD}_{300}$-I, $(-)^{CD}_{300}$-II, $(-)^{CD}_{300}$-III, and $(-)^{CD}_{300}$-IV have mainly (*R*) sulfenato groups, because the $\Delta\varepsilon_{ext}$ values were −30.6, −57.6, −40.0, and −21.2 for $(-)^{CD}_{300}$-I, $(-)^{CD}_{300}$-II, $(-)^{CD}_{300}$-III, and $(-)^{CD}_{300}$-IV, respectively. The oxidation of the complexes $(-)^{CD}_{300}$-I and $(-)^{CD}_{300}$-II gave the same product $(-)^{CD}_{300}$-III, which in succession gave the $(-)^{CD}_{300}$-IV. These observations lead to the assignments *(R,R,S)*, *(R,R,R)*, *(R,R)*, and *(R)* for $(-)^{CD}_{300}$-I, $(-)^{CD}_{300}$-II, $(-)^{CD}_{300}$-III, and $(-)^{CD}_{300}$-IV, respectively. As in the case of *fac(S)*-[Co$(aese)_3$],[1] three sulfenato oxygen atoms of the *Λ-(R,R,R)* isomer should take the crowded axial positions on the *fac(S)* plane, whereas the oxygen atoms of the *Λ-(R,R,R)* isomer occupy the less-crowded equatorial ones. Therefore, the *Λ-(R,R,R)* configuration is desirable as the structure of the complex $(-)^{CD}_{300}$-II rather than the *Δ-(R,R,R)* one. The latter isomer was apparently undetectable in the preparation of *fac-(S)*-[Rh$(aese)_3$]. In conclusion the complex $(-)^{CD}_{300}$-I, $(-)^{CD}_{300}$-II, $(-)^{CD}_{300}$-III, $(-)^{CD}_{300}$-IV, or $(-)^{CD}_{300}$-V has *Λ-(R,R,S)*, *Λ-(R,R,R)*, *Λ-(R,R)*, *Λ-(R)*, or *Λ* configuration, respectively. These assignments rationalize the isomerization of $(-)^{CD}_{300}$-I into $(-)^{CD}_{300}$-II in the aqueous solutions, because the latter having less-crowded configuration than the former. The configurational chirality of [Co$(aese)_n(aesi)_{3-n}$] (n=3, 2, 1, or 0) was assigned on the basis of the sign of the longest wavelength CD band: the *Λ*-configuration show a positive CD.[1] It is noteworthy that this relation is reversed in the present complexes [Rh$(aese)_n(aesi)_{3-n}$] (n=3, 2, 1, and 0). This is probably due to the close overlapping of the d-d and LMCT bands (both in absorption and CD spectra) in the rhodium(III) complexes.

The column chromatographic behaviors also support the above chirality assignment. It the separation using QAE-Sephadex A-25 {(*R,R*)-tratrate form} with water as eluent, the *Λ* isomers were eluted more rapidly than the corresponding *Δ* ones in both the cobalt(III) and rhodium(III) complexes.

The optical resolution *via* diastereomeric molecular compound with *d*-tartaric acid was successful for the two kinds of rhodium(III) complexes, *fac(S)*-[Rh$(aese)_3$] and *fac(S)*-[Rh$(aese)_2(aesi)$]. The less soluble diastereomeric molecular compound *d*-$C_4H_6O_6\cdot(-)^{CD}_{300}$-[Rh$(aese)_3]\cdot H_2O$ has the same composition as the corresponding cobalt(III) compound *d*-$C_4H_6O_6\cdot(+)^{CD}_{500}$-[Co$(aese)_3]\cdot H_2O$. Since the X-ray diffraction study of the latter compound showed that the contains the *fac(S)-Λ-(R,R,R)* isomer,[7] it seems that the configuration of $(-)^{CD}_{300}$-[Rh$(aese)_3$] (III) is *fac(S)-Λ-(R,R,R)*. This is in accord with the above assignment from CD. The another molecular compound containing *fac(S)*-[M$(aese)_2(aesi)$] was found only in the rhodium(III) series and not in the cobalt(III) series. It remains puzzling that the isomer which forms the less soluble diastereomeric molecular compound with *d*-tartaric acid has the *Δ-(S,S)* configuration for the [Rh$(aese)_2(aesi)$] complex in contrast to the case of [Rh$(aese)_3$], for which the less soluble molecular compound contains the *Λ-(R,R,R)* isomer.

An X-Ray Diffraction Study on the Structures of Bis- and Tris(ethylenediamine)copper(II) Complexes in Solution

Tadao FUJITA and Hitoshi OHTAKI*

Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta, Nagatsuta-cho, Midori-ku, Yokohama 227

(Received May 19, 1983)

The structure of copper(II) complexes with ethylenediamine (en) in solution has been determined by means of X-ray diffraction. The measurements were performed at 25 °C for aqueous ethylenediamine solutions of copper(II) nitrate, the mole ratio (en/Cu) in the solutions being 2.09 and 5.14. In the former solution the bis(ethylenediamine)copper(II) complex was contained as the main species, while the tris(ethylenediamine)copper(II) complex was predominantly formed in the latter solution. The analysis of the X-ray scattering data of the solutions showed that in the bis-complex four nitrogen atoms of the two ethylenediamine molecules coordinated to the central metal ion at the distance of 1.93 Å in a planar form and oxygen atoms of two water molecules were located at 2.92 Å above and below the plane. Since the axial Cu–OH_2 bond distance is very long, the structure of the bis-complex can be regarded as square-planar. In the tris-complex the equatorial Cu–N bond length was 1.92 Å, which was practically the same as that within the bis-complex. The axial Cu–N distance was 2.22 Å.

There exist nine electrons in the d-orbital of a copper(II) ion, and thus, a hexacoordinated copper(II) complex tends to have a distorted octahedral structure. Structures of copper(II) complexes have been extensively studied by the spectroscopic analysis of solutions, as well as by the crystallographic method. The distortion of the structure of the $[Cu(OH_2)_6]^{2+}$ complex was first investigated by the X-ray crystal analysis, and it was found that the equatorial Cu–O bond distance within the complex comparatively shortened to be 2.16 Å, while the axial Cu–O bond length was 2.2—2.5 Å.[1-5] The distorted octahedral structure of the $[Cu(OH_2)_6]^{2+}$ complex was also found in solution by the X-ray diffraction method.[6-8] Ohtaki and his coworkers[7,8] reported that the equatorial and axial Cu–O bond lengths within the $[Cu(OH_2)_6]^{2+}$ complex were 1.94 and 2.43 Å, respectively, in a copper(II) perchlorate solution.

Yamaguchi and Ohtaki[9] reported the structures of the $[Cu(NH_3)_4(OH_2)_2]^{2+}$ and $[Cu(NH_3)_5X]^{2+}$ (X= NH_3 or H_2O) complexes by means of X-ray diffraction in solution. The Cu–N_{eq} and Cu–O_{ax} distance within the former were 2.03 and 2.33 Å, respectively, whereas the Cu–N_{eq}, Cu–N_{ax}, and Cu–X_{ax} were 1.93, 2.30, and 2.30 Å, respectively, in the latter.

The structures of the copper(II)–ethylenediamine complexes have been investigated by the ESR spectroscopy[10] and the X-ray diffraction method in crystal. In the tris(ethylenediamine)copper(II) sulfate, the CuN_6 moiety of the complex has an octahedral structure in which all the Cu–N bond distances are 2.15 Å.[11] The indifferent bond length within the complex was explained in terms of the dynamic Jahn-Teller effect. Since the angle of the N–Cu–N bond within the complex was not 90 °, the symmetry of the complex was not O_h but D_3.[11]

A regular octahedral structure was also found for $K_2Pb[Cu(NO_2)_6]$ in which all the Cu–N distances were 2.11 Å.[12] However, most of the hexacoordinated copper(II) complexes have distorted octahedral structures with two elongated bonds along the axis of the octahedron. The tris-complexes of copper(II) ion containing 2,2′-bipyridine and 1,10-phenanthroline were distorted octahedral.[13,14] In the tris(2,2′-bipyridine)copper(II) complex, the equatorial Cu(II)–N bond distance was 2.031 Å, but the axial Cu–N bond lengths were 2.450 and 2.226 Å.[13] On the other hand, in the tris(1,10-phenanthroline)copper(II) complex the two axial Cu–N bond lengths were the same to be 2.33 Å, the equatorial Cu–N distance being 2.05 Å.[14]

Bertini *et al.*[15] investigated the effect of counter anions on the distortion of the octahedral structure of the tris(ethylenediamine)copper(II) complex in crystal containing various counter anions by using the ESR spectroscopy. They showed that the degree of the distortion varied with the counter anions.[15] The shape of the ESR spectra of the sulfate and nitrate salts was different and they suggested that the structure of the $[Cu(en)_3]^{2+}$ ion of the nitrate may be octahedrally distorted. On the contrary, the distortion of the structure of the $[Cu(en)_3]^{2+}$ ion in the sulfate was suggested to be small, which had also been studied crystallographically by Cullen and Lingafelter.[11]

The structure of the bis(ethylenediamine)copper(II) complex has been extensively investigated by the spectroscopic and crystallographic methods and it has been found that the complex ion has a distorted octahedral structure with counter anions or water molecules at the axial positions. The equatorial bond length within the bis-complex was about 2.05 Å, which was almost the same as that within the tris-complex.[14,16] When water molecules bound to the central copper(II) ion at the axial position, the Cu–OH_2 bond length remarkably changed from 2.22 Å to 2.89 Å depending on counter anions. The bond distance between the central copper ion and a thiocyante ion within the $[Cu(ClO_4)(NCS)(en)_2]$ complex was determined to be 2.73 Å by means of X-ray diffraction in the crystal.[17] Thus, the structure can be practically regarded as square-planar.

Although the structure of the $[Cu(en)_3](NO_3)_2$ compound has been assumed to be a distorted octahedron by a spectroscopic measurement,[15] the structure has not been determined by the X-ray diffraction method in crystal or in solution. In the present study, we have attempted to determine the structures of the bis-

and tris(ethylenediamine)copper(II) complexes in aqueous solutions and to compare them with the structures of copper-ammine complexes,[9] as well as those of ethylenediamine complexes of zinc(II),[18] cadmium-(II),[19] and nickel(II)[20] in solution.

Experimental

Preparation and Analysis of Sample Solutions. Ethylenediamine was purified by the method previously reported.[18] Copper(II) nitrate of reagent grade was purchased from Wako Pure Chemicals Co., Osaka, and recrystallized twice from water. The sample solutions were prepared by dissolving copper(II) nitrate into aqueous ethylenediamine solutions by the similar way to that described in previous papers.[18-20]

Concentrations of copper(II) ions in the test solutions were determined by electrogravimetry. The concentration of nitrate ions was calculated from the stoichiometry of copper-(II) nitrate. The density of the test solutions was measured pycnometrically. The composition of the test solutions is given in Table 1.

Method of Measurements and Treatment of X-Ray Scattering Data. The method of measurements and the apparatus used were essentially the same as those employed in the previous works.[7,8,18-20] Mo $K\alpha$ radiation ($\lambda=0.7107$ Å) was used for the measuremets over the range $1°<\theta<70°$ (2θ is the scattering angle). The data were recorded twice over the whole angle range. Corrections and analysis of the scattering data were performed in the same ways as those previously reported. Coherent and reduced intensities of the solutions are given in Figs. 1 and 2, respectively. The

radial distribution function $D(r)$ was calculated by the following equation:

$$D(r) = 4\pi r^2\rho_0 + \frac{2r}{\pi}\int_0^{s_{max}} s\cdot i(s)\cdot M(s)\cdot\sin(rs)ds, \quad (1)$$

where ρ_0 is the average scattering density in the stiochiometric volume V of the solution per Cu atom and s_{max} denotes the maximum s-value attained in the measurements ($s_{max}=16.7$ Å^{-1}). $M(s)$ represents the modification function[21] and the reduced intensities $i(s)$ are given by

$$i(s) = I^{coh}(s) - \Sigma n_i\{(f_i(s)+\Delta f_i')^2+(\Delta f_i'')^2\}, \quad (2)$$

where n_i is the number of atom i and $f_i(s)$ denotes the scattering factor of atom i at s. $\Delta f_i'$ and $\Delta f_i''$ represent the real and imaginary parts of the anomalous dispersion, respectively.

The theoretical scattering intensities due to atom-pairs of all possible combinations were obtained as follows:

$$i_{calcd}(s) = \sum_{i}\sum_{\substack{j \\ i\neq j}} n_{ij}\{(f_i(s)+\Delta f_i')(f_j(s)+\Delta f_j') + (\Delta f_i'')(\Delta f_j'')\}\frac{\sin(r_{ij}s)}{(r_{ij}s)}\cdot\exp(-b_{ij}s^2), \quad (3)$$

where r_{ij}, b_{ij}, and n_{ij} denote the distance, the temperature factor and the frequency factor of the atom-pair i-j, respectively.

Calculations were mainly carried out with the computer M 160 and M 180 using NLPLSQ[21] and KURVLR[22] programs at the Tokyo Institute of Technology and partly with the computer M 200H at the Instituse for Molecular Science in Okazaki.

Results

According to the stability constants so far reported,[23] the bis(ethylenediamine)copper(II) complex is contained as the main species in solution A.

The stability constant of the tris(ethylenediamine)-copper(II) complex is comparatively small ($\log K_3 \simeq 1$[23]), and thus, the tris-complex can only exist in a solution containing a large excess of ethylenediamine. In solution B in which the mole ratio of ethylenediamine to copper(II) ion is 5.14, the tris(ethylenediamine)-copper(II) complex is expected to be formed as the predominant species. The coexistence of the bis-complex with the tris-complex in solution B must also be taken into account in the course of the analysis of the scattering data.

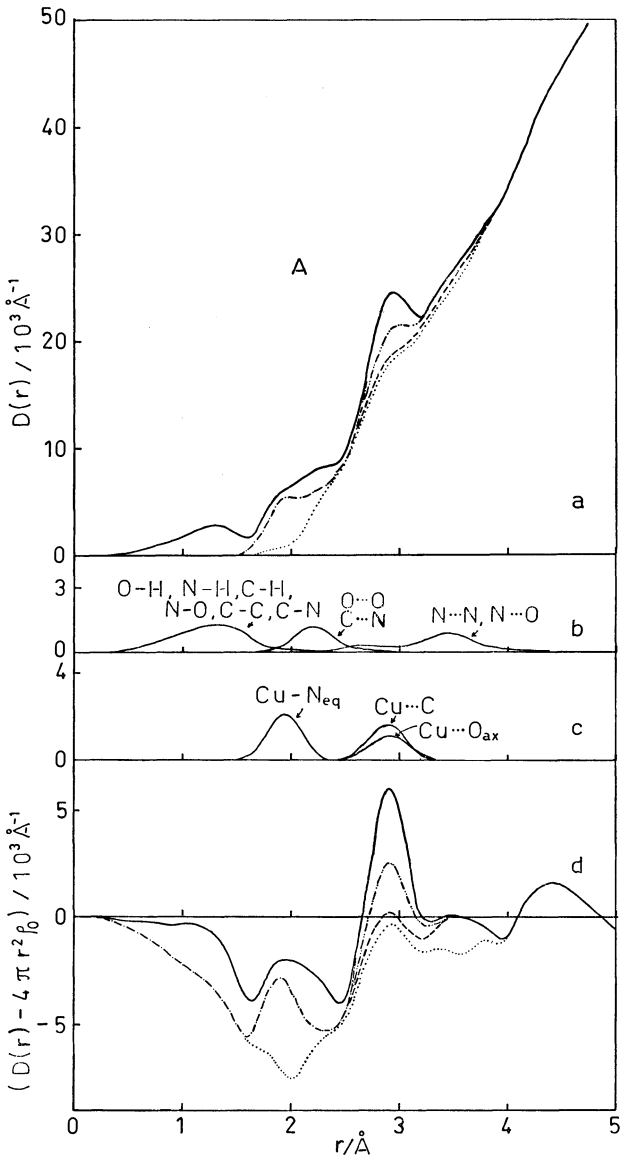

Fig. 3. (a); The $D(r)$ curve for solution A. The chain line (·—·—) shows the residual curve after subtraction of the theoretical peaks shown in b except for N···N and N···O interactions. The chain line (—··—··) shows the residual curve after subtraction of the theoretical peak shape due to the Cu···C interaction. Furthermore, after subtraction of the theoretical curve of the Cu–O_{ax} interaction, the dashed line is obtained. After subtraction of the theoretical peaks due to the Cu–N_{eq}, N···N, and N···O interactions the dotted line is obtained. (b) and (c); The theoretical peak shapes of each atom pair. (d); The corresponding $D(r)-4\pi r^2\rho_0$ curve to (a).

Solution A. From the corrected diffraction intensities (Fig. 1A) the $s \cdot i(s)$ curve was obtained (Fig. 2A), and thus, the radial distribution and differential radial distribution curves (Fig. 3, a and d, respectively) were calculated. In the radial distribution curve of solution A, five peaks were observed in the region 1—5 Å (see Fig. 3, a and d).

A broad and small peak at about 1.2 Å is composed of peaks due to the O–H bond within water molecules, the N–H, C–H, C–C, and C–N bonds within ethylenediamine molecules and the N–O bond within nitrate ions in the solution (see Fig. 3, b). The second peak appearing at about 2.0 Å may be attributed to the Cu–N bond within the metal complex, the O···O pair within nitrate ions and the C···N interaction within ethylenediamine molecules. The third peak around 2.9 Å may be ascribed to the nonbonding Cu···C interactions within the complex and the O···O interactions in the bulk water. The O···O pairs within nitrate ions may also contribute to this peak. The Cu–OH_2 bond, if it exists, can be expected to be included in this peak. A broad peak around 4 Å must include some longer intramolecular interactions, as well as intermolecular interactions between ions in the solution. The fifth peak at about 5 Å might consist of much longer intermolecular interactions, which will not be taken into consideration in the present analysis.

At the first step of analysis of the radial distribution curve, the theoretical peaks of the intramolecular interactions within ethylenediamine molecules and nitrate ions were subtracted from the original $D(r)$ curve, and then the curve expressed by the chain line (·—·—·) was obtained. The analysis of the residual curve revealed that the Cu–N_{eq} bond distance and its temperature factor were 1.93 Å and 0.002 Å^2, respectively. The frequency factor (n) of the Cu–N_{eq} bond was evaluated to be four from the area under the peak at 1.93 Å. The nonbonding Cu···C distance was estimated to be about 2.85 Å by using a suitable structure model of ethylendiamine and the Cu–N_{eq} distance estimated. After subtraction of the theoretical peak due to the Cu···C interactions, a double-dotted chain line (··—··—··) was obtained. A peak still remaining at about 2.9 Å was larger and sharper than that expected from the contribution of the only bulk water. Therefore, we assumed that the interaction between the central copper(II) ion and water molecules at the axial position may be included in the peak besides the H_2O···H_2O and NO_3···H_2O interactions. After subtraction of the Cu–O_{ax} interactions, the distance of which was assumed to be 2.95 Å, the dotted line (·····) with no appreciable peak was obtained in the region of 1.5—2.5 Å (Fig. 3, a and d). The N···N and N···O distances were estimated from the Cu–N_{eq} and Cu–O_{ax} lengths within the bis-complex on the basis of the structural model employed in the calculation mentioned above. Subtraction of the theoretical curve for the Cu–O_{ax} interaction, as well as the N···N and N···O interactions led to a smooth back-ground curve shown by the dotted line. A broad peak still left at about 2.9 Å could be ascribed to the adjacent O···O interac-

tions in the bulk water and hydrated nitrate ion, which were not taken into account in the calculation examined here. The parameter values were finally refined by the least-squares method by using the $s \cdot i(s)$ data of the high-angle region.

Solution B. An analytical procedure similar to that employed in the previous section was performed on the scattering data obtained from solution B. Subtraction of the theoretical peaks due to the O–H bond within H_2O, the N–H, C–H, C–C, C–N and C···N interactions within ethylenediamine molecules, and the N–O and O···O interactions within NO_3^- from the radial distribution curve of solution B led to a residual curve shown by a chain line (·—·—·) (Fig. 4, a and d). Two peaks observed at 1.9 and 2.2 Å in the residual curve may be identified to be due to the Cu–N_{eq} and Cu–N_{ax} bonds within the tris-complex. The area under the former and latter peaks corresponded to four and two Cu–N interactions, respectively. The former peak at 1.9 Å was, therefore, ascribed to the equatorial Cu–N bond. The temperature factors were estimated to be 0.002—0.0025 Å^2 to the former interaction and 0.003—0.0035 Å^2 to the latter. The peak obtained at 2.85 Å may partly be attributed to the nonbonding Cu···C interaction, and therefore, the double-dotted chain line (··—··—··) was obtained by subtracting the peak due to the nonbonding Cu···C interaction. A further subtraction of the peak due to the intramolecular N···N pairs within the tris-complex gave a dotted-line (·····) (Fig. 4, a and d). The parameter values were refined by using the least-squares procedure.

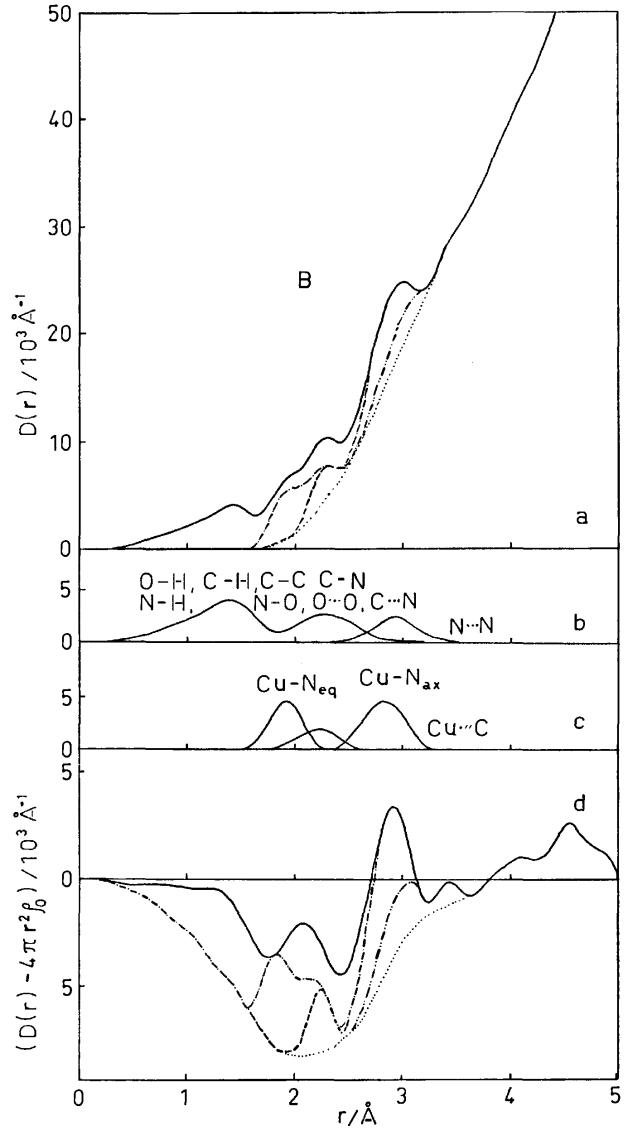

Fig. 4. (a); The $D(r)$ curve for solution B. The chain line (·—·—) shows the residual curve after subtraction of the theoretical peak shapes in (b) except for the N···N interaction from the original curve (solid line). After subtraction of the theoretical peak shape due to the Cu–N_{eq} bond from the chain line (·—·—·), the dashed line is obtained. The chain line (··—··—) shows the residual curve of the theoretical peak shape of the Cu···C interaction. After subtraction of the theoretical peak shapes of the Cu–N_{ax} and N···N interactions, the dotted line is obtained as the residual curve. (b) and (c); The theoretical peak shapes of atom-pairs indicated in the figure. (d); The corresponding $D(r)-4\pi r^2\rho_0$ curve to (a).

Least-squares Refinements. The $s \cdot i(s)$ data obtained in a high-angle region where $s>5$ Å^{-1} for solutions A and B were used for the least-squares refinement of the structure parameters of the bis- and tris-complexes in the solutions. In order to avoid introduction of errors by neglecting long-range intermolecular interactions in the solutions in the course of the refinements, the lower limit of the s-value was changed from 4.5 Å^{-1} to 7 Å^{-1}. In the least-squares calculations for solution A, in which the bis(ethylenediamine)copper(II) complex was predominantly formed, two types of calculations, I and II, were carried out. In type I, frequency factors n of all atom-pairs within the bis-complex were floated as well as the bond distances r and temperature factors b. In type II, on the other hand, the frequency factors were fixed and the only distances and temperature factors were refined. Throughout these refinements, the structure of the bis(ethylenediamine)copper(II) complex was assumed to be octahedral (Table 2).

The contribution from the O–H bond within water molecules was taken into account by using the structural parameters reported in the literature.[7,8,16,24] Structural parameters of the atom-pairs within ethylenediamine molecules were quoted from the work by Yokozeki and Kuchitsu[25] determined in the gas phase, as have been done in the previous studies.[18–20] The parameter values of the N–O pairs within NO_3^- were taken from the work by Caminiti *et al.*[26] and Maeda *et al.*[27] Contributions of all the atom-pairs were comparatively small in the s-region where we refined the structural parameters of the intramolecular interactions within the bis(ethylenediamine)copper(II) complex in the solution.

The parameter values for the O···O (NO_3^-), C···N (en), Cu···O_{ax}, Cu···C, and N···N ($Cu(en)_2(H_2O)_2$) atom-pairs were refined as independent variables. The change in the s-region in the course of the refinements did not practically affect the parameter values. The refined parameter values obtained by both I and II

Table 2. Least-squares refinements for solution A obtained over various s ranges
The parameter values, r=distance (Å), b=temperature factor (Å^2), and n=frequency factor, were refined. The values in parentheses are their standard deviations.

a) Fixed. b) The temperature factor of the interaction was fixed at 0.006 Å^2. c) The temperature factor of the interaction was fixed at 0.006 Å^2. d) The bond length, temperature factor, and frequency factor were fixed. *The calculated $s\cdot i(s)$ curve in Fig. 2 was obtained by using the parameter values given here.

types of calculations were almost consistent. The frequency factors of the Cu-N_{eq} and Cu-O_{ax} interactions obtained by the I-type calculation were close to four and two, respectively, and the frequency factor of the nonbonding Cu···C interaction was approximately four. Therefore, the distorted octahedral structure of the bis(ethylenediamine)copper(II) complex was thus confirmed from the least-squares calculations.

The Cu-N_{eq}, Cu-O_{ax}, and Cu···C distances were 1.93, 2.92, and 2.89 Å, respectively. Since the temperature factors of intramolecular interactions within the bis-complex except for the temperature factor of the Cu-N_{eq} bond were estimated to be about 0.006 Å^2 from the analysis of the radial distribution curve, they were assumed to be constant at 0.006 Å^2 in the course of the least-squares calculations.

The least-squares refinements of the parameter values of the tris(ethylenediamine)copper(II) complex were carried out by the similar way to that employed in the case of the bis-complex (Table 3). In the I-type calculation frequency factors n of all atom-pairs within the tris-complex were allowed to vary. In the II-type calculation frequancy factors of the atom-paris within the tris-complex were fixed by assuming the structure of the tris-complex to be distorted octahedral. In the III-type calculation the intramolecular N..N distance was also fixed. Throughout these calculations the temperature factors were kept constant at 0.003, 0.006, and 0.007 Å^2 for Cu-N_{ax}, Cu···C, and N···N interactions, respectively.

The frequency factors of the Cu-N_{eq}, Cu-N_{ax}, and Cu···C interactions found were practically four, two and six, respectively, in the I-type calculation. The Cu-N_{eq} distance within the tris-complex was almost the same as that of the bis-complex. In the analysis of the $s\cdot i(s)$ curve of solution B, the coexistence of the bis-complex together with the predominant tris-complex was taken into account. However, the experimental $s\cdot i(s)$ values were well reproduced by the structure model of the only tris-complex, and the contribution of the minor species of the bis-complex did not practically improve the result. Therefore, the values shown in Table 4 obtained by the least-squares method were those calculated on the assumption of the existence of the only bis-complex in solution A and the only tris-complex in solution B.

The final values for the distances of the Cu-N_{eq}, Cu-N_{ax}, Cu-O_{ax}, and Cu···C pairs of the bis- and tris-complexes are summarized in Table 4.

Discussion

In crystals the length of the axial Cu-OH_2 bond is affected by ligand molecules coordinated at the equatorial positions, counter ions and crystal structures (see Table 5). In copper(II) complexes in which nitrogen atoms are coordinated to the central copper(II) ion in the equatorial plane while two water molecules are located at the axial position, the shorter the equatorial Cu-N bond distance becomes, the longer the axial Cu-OH_2 bond length is[14] (Fig. 5, see also Tables 5 and 6). The Cu-N_{eq} distance (1.92 Å) within the tris(ethylenediamine)copper(II) complex in solution is shorter than that in other tris-complexes observed in

the $Cu-N(NH_3)$ one. On the other hand, the $Cu-O_{ax}$ distance within the former complex becomes longer than that within the latter. Therefore, the bis(ethylenediamine)copper(II) complex is more distorted than the tetraamminecopper(II) complex owing, probably, to a higher electron density at the copper(II) atom of the bis(ethylenediamine)copper(II) complex by a stronger electron donation from the coordinated ethylenediamine molecules, and thus, a more weakened $Cu-OH_2$ interaction along the axis results.

In the bis(ethylenediamine)copper(II) complex, the axial $Cu-OH_2$ distance is so long (2.92 Å) that the complex can be regarded as square-planar.

In the CuN_4O_2-type complexes in solution the ratio of the axial bond length to the equatorial one is smaller than that in crystal (see Fig. 5). The enhanced lengthening in the $Cu-O_{ax}$ bond in crystal may be caused by interactions of the coordinated oxygen atom with another copper(II) ion (*e.g.*, in the case of $[Cu(NH_3)_4]SO_4\cdot H_2O$) or anions.

Only a few crystal structures of the CuN_6-type complexes have been reported so far (Table 7). In the X-ray analysis of the $[Cu(en)_3]SO_4$ in crystal, the structure was regularly octahedral. On the contrary, the tris(ethylenediamine)copper(II) ion in solution was concluded to have a distorted octahedral structure. The symmetrical structure of the $[Cu(en)_3]^{2+}$ ion in the $[Cu(en)_3]SO_4 \cdot H_2O$ crystal has been explained in terms of the dynamic Jahn-Teller effect.[11] In the solution, on the other hand, the distorted octahedral structure of the $[Cu(en)_3]^{2+}$ ion is clearly seen by the X-ray diffraction method, because such a dynamic distortion in the structure of a species is not observable but it is recognized as a random distribution of a distorted species in the analysis of scattering data in solution.

The $[Zn(en)_2]^{2+}$ ion has a regular tetrahedral structure with the Zn–N bond length of 2.131 Å.[18] A similar tetrahedral structure is kept in the $[Cd(en)_2]^{2+}$ complex, in which the Cd–N distance is found to be 2.339 Å.[19] The structure of the $[Ni(en)_2]^{2+}$ ion has an almost regular octahedral structure by combining with additional two water molecules in the coordination sphere.[20] The Ni–N distance, as well as the Ni–O distance, within the complex is 2.10 Å.[20] The bis(ethylenediamine)copper(II) complex is square-planar.

The $[Zn(en)_3]^{2+}$ complex is regular octahedral, and the Zn–N bond length is 2.276 Å,[18] which is larger than the Ni–N distance within the $[Ni(en)_3]^{2+}$ complex (2.202 Å[20]). In the $[Cu(en)_3]^{2+}$ complex the $Cu-N_{eq}$ bond is much smaller than the Zn–N and Ni–N distances of the relevant tris-complexes. The $Cu-N_{ax}$ bond, on the contrary, is longer than the Ni–N bond within the $[Ni(en)_3]^{2+}$ ion, although the Cu–N distance is slightly shorter than the Zn–N bond length within the $[Zn(en)_3]^{2+}$ complex. Obviously the Cu–N bond length within the $[Cu(en)_3]^{2+}$ complex is shorter than the Cd–N distance within the $[Cd(en)_3]^{2+}$ ion, because Cd^{2+} ion has a much larger ionic size than Cu^{2+} ion.

The work has been financially supported, in part, by the Grant-in-Aid for Scientific Research No. 57470054 from the Ministry of Education, Science and Culture. A part of the computer calculations carried out in the present work has been performed at the Institute for Molecular Science in Okazaki.

A Calorimetric Study on the Relative Thermal Stabilities of Some Cobalt(III)-Ammine Complexes in Solid Phase

Ryokichi TSUCHIYA,* Akira UEHARA, and Takashi NAKAYAMA
Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa 920
(Received May 20, 1983)

The enthalpy changes (ΔH) in the reaction of $[CoX_n(NH_3)_{6-n}]X_{3-n}$ type complexes with an alkaline sodium sulfide solution were calorimetrically measured at 25 °C, where X is Cl^-, Br^-, I^-, NO_3^-, or ClO_4^-. The thermal stabilities were found to decrease in the following orders: in the hexaammine series, chloride > bromide > nitrate > iodide > perchlorate; in the pentaammine series, chloride > bromide > nitrate; and in the *trans*-tetraammine series, chloride > bromide and chloro > bromo complexes. In addition, in the tetraammine series, the possibility of trans-to-cis isomerization, which has actually been observed, was reasonably explained on the basis of the difference in lattice energies between *trans*- and *cis*-$[CoCl_2(NH_3)_4]Cl$.

In the previous paper, we measured calorimetrically the enthalpy changes in the reaction of solid $Ni(AA)_2X_2 \cdot nH_2O$ (AA: *N,N*- or *N,N'*-diethylethylenediamine; X: Cl^-, Br^-, I^-, or NO_3^-; *n*: 0 or 2) with an aqueous potassium cyanide, and found that the thermal stabilities of the complexes decrease in the order, chloride > bromide > nitrate > iodide.[1] In addition, the enthalpy changes in the reaction of solid $[CoX_2(AA)_2]X$ type complexes (AA: diamine such as 1,2-ethanediamine; X: Cl^-, Br^-, or ClO_4^-) with an alkaline sodium sulfide solution were measured, and the differences in lattice energy among the above complexes were evaluated therefrom. Comparison of their lattice energies revealed that the thermal stabilities decrease in the order, chloride > bromide > perchlorate.[2] As a continuation of these calorimetric studies, the present study was undertaken to decide the order of the thermal stabilities among chloride, bromide, iodide, nitrate, and perchlorate in each series of the hexaammine-, pentaammine-, and tetraamminecobalt(III) complexes, and among the complexes of these three series when the anions involved are chloride, bromide and nitrate ions, respectively.

In $[CoX_2(en)_2]X$ type complexes (X=Cl^- or Br^-), the cis-to-trans isomerization was predicted to occur on the basis of the enthalpy measurement for trans- and cis-complexes, and the prediction was actually verified.[3] As for the corresponding ammine complexes, $[CoX_2(NH_3)_4]X$ (X:Cl^- or Br^-), however, no such calorimetric prediction has been made on the direction of isomerization (trans-to-cis or cis-to-trans). To solve this problem by the enthalpy measurement is the second purpose of this study.

Experimental

Preparation of Complexes. The following complexes were prepared by the literature methods: $[Co(NH_3)_6]Cl_3$, $[Co(NH_3)_6]Br_3$, $[Co(NH_3)_6](NO_3)_3$, $[Co(NH_3)_6]I_3$, $[Co(NH_3)_6](ClO_4)_3$,[4] $[CoCl(NH_3)_5]Cl_2$, $[CoCl(NH_3)_5]Br_2$,[5] $[CoBr(NH_3)_5]Br_2$, $[CoBr(NH_3)_5]Cl_2$,[6] $[Co(NO_3)(NH_3)_5](NO_3)_2$,[7] $[CoI(NH_3)_5]Cl_2$,[8] *trans*-$[CoCl_2(NH_3)_4]Cl$,[9] *cis*-$[CoCl_2(NH_3)_4]Cl$,[10] and *trans*-$[CoBr_2(NH_3)_4]Br$.[11]

Calorimetric Measurements. The enthalpy changes in the reaction of the complexes in the powder state with an alkaline sodium sulfide solution were measured with a Tokyo-Riko twin isoperibol calorimeter TIC-2S at 25 °C. In each run, the complex was accurately weighed and let react with 100 cm^3 of a mixture containing 2×10^{-2} mol dm^{-3} Na_2S and 1 mol dm^{-3} NaOH.

Results and Discussion

Thermal Stability of $[Co(NH_3)_6]X_3$ Complexes. The enthalpy changes (ΔH_{exp}) measured for the reaction of hexaammine cobalt(III) complexes with an alkaline sodium sulfide solution, *i.e.*, $[Co(NH_3)_6]X_3(s) + 3/2\ S^{2-}(aq) = 1/2\ Co_2S_3(s) + 6NH_3(aq) + 3X^-(aq)$ are summarized in Table 1. Combining these data with the values in the following changes,[12]

$$\left.\begin{array}{ll} Cl^-(aq) = Cl^-(g) & \Delta H = -76.5\ kJ\ mol^{-1} \\ Br^-(aq) = Br^-(g) & \Delta H = -110.5\ kJ\ mol^{-1} \\ NO_3^-(aq) = NO_3^-(g) & \Delta H = -128.9\ kJ\ mol^{-1} \\ I^-(aq) = I^-(g) & \Delta H = -154.0\ kJ\ mol^{-1} \\ ClO_4^-(aq) = ClO_4^-(g) & \Delta H = -217.6\ kJ\ mol^{-1} \end{array}\right\}, \quad (1)$$

the enthalpy changes (ΔH_{rel}) for the following reactions, $[Co(NH_3)_6]Cl_3(s) + 3X^-(g) = [Co(NH_3)_6]X_3(s) + 3Cl^-(g)$, were calculated as below:

for $X^- = Br^-$ $\Delta H_{rel} = 82.6\ kJ\ mol^{-1}$,
for $X^- = NO_3^-$ $\Delta H_{rel} = 125.2\ kJ\ mol^{-1}$,
for $X^- = I^-$ $\Delta H_{rel} = 210.0\ kJ\ mol^{-1}$,
for $X^- = ClO_4^-$ $\Delta H_{rel} = 377.5\ kJ\ mol^{-1}$.

These values correspond to the decreases of lattice energies of the solid complexes which give the magnitudes of instabilities of the bromide, nitrate, iodide, and perchlorate relative to that of the chloride as a standard. The enthalpy levels for the hexaammine complexes are diagrammatically shown in Fig. 1. The numeral attached to each level is the value obtained above. Inspection of the figure reveals that, in this series of complexes, the thermal stability decreases in

Table 1. Enthalpy changes, ΔH_{exp}, for the reaction of cobalt(III)-ammine complexes $[CoX_n(NH_3)_{6-n}]X_{3-n}$ with sodium sulfide solution (kJ mol^{-1})

X	$[Co(NH_3)_6]X_3$	$[CoX(NH_3)_5]X_2$	$[CoX_2(NH_3)_4]X$	
			trans	*cis*
Cl^-	29.5	12.2	−70.8	−56.2
Br^-	48.9	23.7	−215	
NO_3^-	61.5	29.6		
I^-	52.0			
ClO_4^-	75.3			

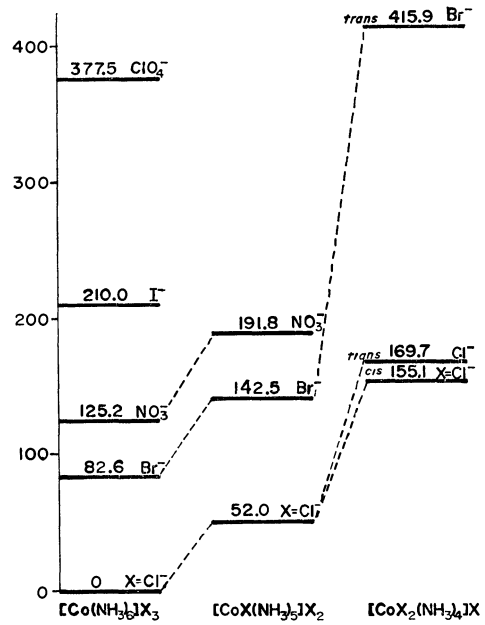

Fig. 1. Enthalpy level diagram for $[Co(NH_3)_6]X_3$, $[CoX(NH_3)_5]X_2$, and $[CoX_2(NH_3)_4]X$, where X is Cl^-, Br^-, NO_3^-, I^-, or ClO_4^-. The numerals are in kJ mol^{-1}.

the order, chloride>bromide>nitrate>iodide>perchlorate.

Thermal Stability of $[CoX(NH_3)_5]X_2$ *Complexes.* Combining the values of the enthalpy changes measured for the reaction of the pentaammine series of complexes (Table 1) with the values (1) concerned, the enthalpy changes (ΔH_{rel}) for substituting bromide and nitrate ions for chloride ions in chloropentaamminecobalt(III) chloride were calculated as below:

$$[CoCl(NH_3)_5]Cl_2(s) + 3X^-(g) = [CoX(NH_3)_5]X_2(s) + 3Cl^-(g),$$

for $X^- = Br^-$ $\quad \Delta H_{rel} = 90.5$ kJ mol^{-1},

for $X^- = NO_3^-$ $\quad \Delta H_{rel} = 139.8$ kJ mol^{-1}.

In the series of pentaammine complexes in which both the ion coordinated and the counter anions are the same, it is evident that the thermal stability decreases in the order, chloride>bromide>nitrate. The situation is parallel to the case of the hexaammine series (Fig. 1).

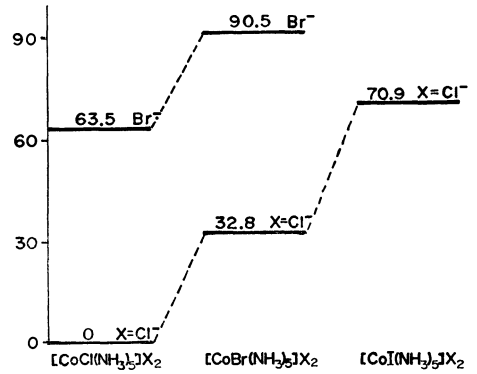

Fig. 2. Enthalpy level diagram for $[CoCl(NH_3)_5]X_2$, $[CoBr(NH_3)_5]X_2$ (X=Cl^- or Br^-) and $[CoI(NH_3)_5]Cl_2$. The numerals are in kJ mol^{-1}.

On the other hand, in the complexes where the counter halide ion is varied from Cl^- to Br^- without changing the coordinated ion, and where the coordinated ion is varied from Cl^- to Br^- and then to I^- without changing the counter ion, the enthalpy changes (ΔH_{exp}) measured and those (ΔH_{rel}) evaluated from them for successive substitution of halide anions inside and outside the coordination sphere are summarized in Table 2. The enthalpy levels of these pentaammine complexes are illustrated in Fig. 2. As seen in Table 2 and Fig. 2, if the counter ion is varied, the thermal stability of the bromides is less stable than that of the corresponding chlorides in both chloro- and bromo-complexes. The enthalpy changes (ΔH_{rel}) for substituting Br^- and I^- for Cl^- coordinated in the series of complex chlorides suggest that the thermal stabilities decrease in the order, chloro->bromo->iodo-complexes. And the enthalpy change for substituting Br^- for Cl^- coordinated in the bromide indicates the stability of the bromo complex to be lower than that of the chloro complex. This order coincides with that of the decrease of ligand field strength of halide ions.

It should be, in addition, noted from Fig. 2 that the enthalpy change for substituting Br^- for Cl^- per one mole of halide ion is about 30 kJ regardless of whether the halide ion is inside or outside the coor-

Table 2. Enthalpy changes, ΔH_{exp}, for the reaction with sodium sulfide solution and enthalpy changes, ΔH_{rel}, for substitution reaction of halide ion inside or outside the coordination sphere in series of pentaamminecobalt(III) complexes (kJ mol^{-1})

dination sphere.

Comparison of Thermal Stability among Hexaammine, Pentaammine, and Tetraammine Complexes. By combining the enthalpy changes in Table 1 with the following value,[12]

$$NH_3(aq) = NH_3(g) \qquad \Delta H = 34.7\ kJ\ mol^{-1},$$

the enthalpy changes (ΔH_{rel}) for substituting chloride ion for ammonia in hexaamminecobalt(III) chloride to form chloropentaammine and dichlorotetraammine chlorides were obtained as follows:

$$[Co(NH_3)_6]Cl_3(s) = [CoCl(NH_3)_5]Cl_2(s) + NH_3(g)$$
$$\Delta H_{rel} = 52.0\ kJ\ mol^{-1},$$
$$[Co(NH_3)_6]Cl_3(s) = trans\text{-}[CoCl_2(NH_3)_4]Cl(s) + 2NH_3(g)$$
$$\Delta H_{rel} = 169.7\ kJ\ mol^{-1},$$
$$[Co(NH_3)_6]Cl_3(s) = cis\text{-}[CoCl_2(NH_3)_4]Cl(s) + 2NH_3(g)$$
$$\Delta H_{rel} = 155.1\ kJ\ mol^{-1}.$$

The enthalpy changes (ΔH_{rel}) for substituting bromide ion for ammonia in hexaamminecobalt(III) bromide and those for substituting nitrate ion in the corresponding nitrate were also obtained similarly as below,

$$[Co(NH_3)_6]Br_3(s) = [CoBr(NH_3)_5]Br_2(s) + NH_3(g)$$
$$\Delta H_{rel} = 59.9\ kJ\ mol^{-1},$$
$$[Co(NH_3)_6](NO_3)_3(s) = [Co(NO_3)(NH_3)_5](NO_3)_2(s) + NH_3(g)$$
$$\Delta H_{rel} = 66.6\ kJ\ mol^{-1}.$$

In order to illustrate the thermal stabilities of all the cobalt(III) ammine complexes, the enthalpy levels for pentaammine and tetraammine complexes are also shown in Fig. 1. The numeral designated at each enthalpy level reflects the difference of their lattice energies. Thus, the figure shows that the thermal stabilities decrease in the order,

$$[Co(NH_3)_6]X_3 > [CoX(NH_3)_5]X_2 > trans\text{- or } cis\text{-}[CoX_2(NH_3)_4]X,$$

where $X = Cl^-$ or Br^-.

Difference of Thermal Stability between trans- *and* cis-*$[CoCl_2(NH_3)_4]Cl$ complexes and Thermodynamic Possibility of Isomerization.* The occurrence of the partial trans-to-cis isomerization of $[CoCl_2(NH_3)_4]Cl$ has already been reported.[13] However, there have been no thermodynamical data to support this observation. Therefore, the enthalpy change of the trans-to-cis isomerization was estimated as below as shown in Table 1 and Fig. 1.

$$trans\text{-}[CoCl_2(NH_3)_4]Cl(s) = cis\text{-}[CoCl_2(NH_3)_4]Cl(s)$$
$$\Delta H = -14.6\ kJ\ mol^{-1}$$

Statistically, the entropy change of the isomerization is evaluated as[3]

$$\Delta S = 11.5\ J\ mol^{-1}\ K^{-1}.$$

The free energy change is, therefore, calculated as

$$\Delta G^\circ = -28.0\ kJ\ mol^{-1}$$

These data are consistent with the fact that the trans-to-cis isomerization takes place in $[CoCl_2(NH_3)_4]Cl$.

Extended X-Ray Absorption Fine Structure Studies in Some Aqueous Copper(II) Solutions

Mitsuru SANO,* Tetsuya MARUO,† and Hideo YAMATERA†

Laboratory of Inorganic Chemistry, College of General Education, Nagoya University, Chikusa-ku, Nagoya 464

† *Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464*

(Received May 23, 1983)

With a laboratory EXAFS apparatus consisting of a usual X-ray generater, an LiF crystal, and a position sensitive X-ray detector with a self-scanning photodiode array, EXAFS spectra were obtained for aqueous $[Cu(NH_3)_4]SO_4$, $[Cu(en)_2]Cl_2$ (en = ethylenediamine), and $CuSO_4$ solutions. By reference to similar spectra of the corresponding crystals, the solution spectra were analyzed by the curve-fitting method. The values obtained for the distances between the metal and its first-shell atoms in the ammine and sulfate solutions are 2.03 (±0.02) and 1.98 (±0.03) Å, in accordance with those derived from the X-ray diffraction experiments. The Cu–N distance of $[Cu(en)_2]^{2+}$ in solution is 2.02 or 2.04 (±0.02) Å. These values obtained for the solutions are very close to those of corresponding solid complexes.

The chemistry of electrolyte solutions has made a great progress with the development of new methods such as nmr and laser-Raman spectroscopies and X-ray and neutron diffractions. Extended X-ray absorption fine structure (EXAFS) has also given significant information about the species dissolved in solution and become one of the most powerful techniques to study the local environment of the concerned atom.[1-3] However, there are some experimental difficulties in an EXAFS measurement, in which the total absorption coefficient, $\mu(E)$, must be measured with high accuracy. We have developed a laboratory apparatus utilizing a position sensitive detector to measure all the absorption coefficient at one time to improve the data collection efficiency.[4-5] In our previous EXAFS study[4] of the hydrated Cu^{2+} ion using a laboratory system equipped with a position sensitive photodiode array, the spectra was of low signal-to-noise ratio and their Fourier functions were not sufficiently reliable.[6] Thus we improved the apparatus by changing the electronic circuit of the preamplifier, adjusting the timing of the AD converter, cooling the SSPA, and so on, and used it in an EXAFS study of the aqueous cyanocuprate(I) solutions.[7] This paper is concerned with the EXAFS study of some aqueous copper(II) solutions on the laboratory EXAFS apparatus with position sensitive photodiode array. The purpose of the present study is to check the accuracy of obtained structual parameters as well as to compare the bond lengths of the species in solution with the solid complexes.

X-ray diffraction studies of aqueous solutions containing a copper(II) compound have been made by Ohtaki *et al.* (perchlolate,[8] the ammine complex,[9] and the ethylenediamine complex[10]), Wertz[11] (some chloride solutions), and Magini[12] (perchlolate, sulfate, and chloride). The EXAFS study for aqueous copper(II) perchlorate solution reported by Sham *et al.*[3] gave results in agreement with those from the X-ray diffraction studies. Lagarde *et al.*[1] studied $CuBr_2$ solutions of various concentrations reported that the local order of Cu^{2+} and Br^- ions at high concentration and is close to that found in the solid.

Experimental

The laboratory EXAFS system consists of three parts: a usual X-ray generater, an LiF crystal, and a position sensitive detector with a self-scanning photodiode array (SSPA). This is schematically shown in Fig. 1. We used a tungsten sealed X-ray tube (Philips fine focus tube, 1.5 kW) as the X-ray source, which was operated with a conventional X-ray power supply (Rigaku Co. Ltd., 1.5 kW) mostly with 25 mA at 17 kV. The generated continuous X-ray beam (uncollimated) is dispersed according to the Bragg condition by the LiF(200) crystal mounted on a goniometer. The SSPA (512 K MEL Matsushita Co. Ltd.) for one-dimensional X-ray detection consists of 512 photodiodes and MOS switches without pyrex window and has the total effective length of 14.4 mm (28 μm/channel); X-rays of different wavelengths can be detected by different channels of SSPA. The analog signal from SSPA is amplified, digitalized by an AD converter (Osaka Dempa Co. Ltd.), and transferred to the memory of a micro-computer (Sord M-100 ACE IV). The same type of the laboratory EXAFS system was used in our previous study.[7] A performance test has been carried out with Cu foil; Figure 2 shows the Cu *K* absorption spectrum for one-hour measurement at the condition of 17 kV and 25 mA. Except that

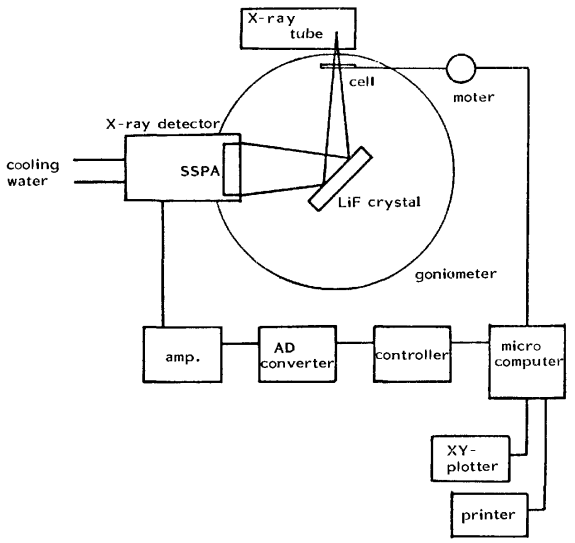

Fig. 1. The block diagram of the laboratory EXAFS system with a position sensitive photodiode array.

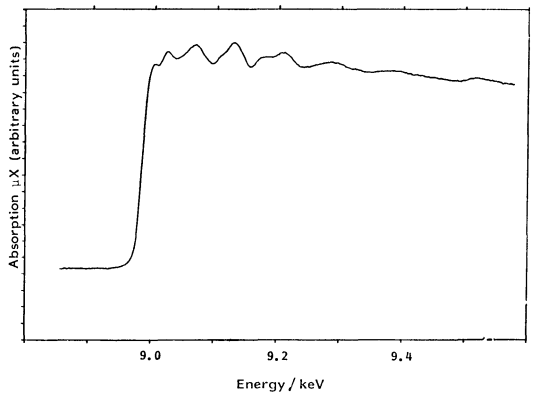

Fig. 2. X-Ray absorption spectrum of Cu-foil.

the spectrum shows a "glitch" at 9.52 keV from characteristic X-rays of W $L\beta_4$, it is comparable to that from other experiments.

The spectrum ($\mu X = \ln[(I_0 - I_d)/(I_s - I_d)]$) of each solution was obtained by measuring, in sequence and repeatedly, the beams transmitted by the sample (I_s) and by water (I_0) and the dark current without X-ray (I_d). Each step of the measurement was controlled by a micro-computer, which drives the cells at appropriate time intervals. A plastic cell contained a small volume of the sample solution between mylar windows spaced 0.6—1.0 mm apart. The solid sample was well grounded and deposited to scotch-tape.

Copper(II) sulfate and bis(ethylenediamine)copper(II) solutions were prepared by dissolving the corresponding copper salts in distilled water. The ammine solution was prepared by dissolving $[Cu(NH_3)_4]SO_4 \cdot H_2O$ in aqueous ammonia (0.14 M).† The known stability constants show that the main species contained in these solutions are $[Cu(H_2O)_6]^{2+}$ for the sulfate, $[Cu(en)_2]^{2+}$ for the ethylenediamine, and $[Cu(NH_3)_4]^{2+}$ for the ammonia solutions. The concentrations of copper ion were determined by titration with EDTA; 0.297 and 1.181 M for the sulfate, 0.321 M for the ammine, and 0.380 M for the ethylenediamine solutions.

Results and Discussion

The EXAFS spectrum $k^2\chi(k)$, in the k space, of crystalline bis(ethylenediamine)copper(II) salt ($[Cu(en)_2]Cl_2 \cdot 2H_2O$) is shown in Fig. 3 which was derived from the absorption spectrum. Fig. 4 shows the results of Fourier transformation from the k space to the r space; the transformation is applied to the $k^2\chi(k)$ values in the k range of 3.4—9.0 ($Å^{-1}$). The radial distribution curve shows two peaks, of which the larger one should corresponds to the N atoms of the coordinated ethylenediamine ligands and the smaller one may be due to the C atoms of the ligands.

The curve-fitting analysis was performed according to the method of Cramer *et al.*[13] using the following the formula for $k^2\chi(k)$:

$$k^2\chi(k) = c_0 N r^{-2} \exp(-c_1 k^2) k^{c_2} \sin[a_0 + (a_1 + 2r)k + a_2 k^2], \quad (1)$$

where N and r represent the coordination number and the interatomic distance, respectively, and c_0, c_1, and c_2 are the parameters for amplitude functions and

† 1 M = 1 mol dm^{-3}.

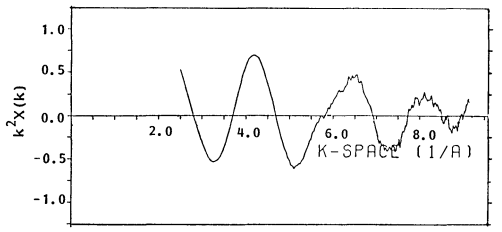

Fig. 3. EXAFS spectrum of $[Cu(en)_2]Cl_2 \cdot 2H_2O$.

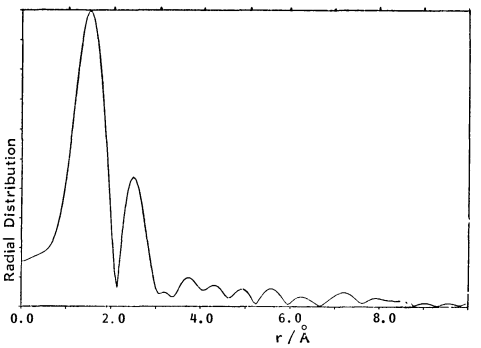

Fig. 4. Fourier transformation of the EXAFS spectrum (Fig. 3).

TABLE 1. CROSS-CHECK OF THE RESULTS OF LEAST-SQUARES FIT TO EXAFS DATA FOR CRYSTALLINE $[Cu(NH_3)_4]SO_4 \cdot H_2O$ AND $[Cu(en)_2]Cl_2 \cdot 2H_2O$

	Coordination number	Cu-N distance / Å
$[Cu(NH_3)_4]SO_4 \cdot H_2O$	4.01±0.73 (4.0)	2.03±0.02 (2.05) a)
$[Cu(en)_2]Cl_2 \cdot 2H_2O$	3.91±0.70 (4.0)	2.04±0.02 (2.03) b)

a) Obtained with parameters derived from EXAFS of the en complex. (The values in parentheses are the results of an X-ray diffraction study.[15]) b) Obtained with parameters derived from EXAFS of the ammine complex. (The values in parentheses are the results of an X-ray diffraction study.[14])

a_0, a_1, and a_2, the phase shift parameters. To determine the parameter values, we first examined the spectra of crystalline $[Cu(NH_3)_4]SO_4 \cdot H_2O$ and $[Cu(en)_2]Cl_2 \cdot 2H_2O$ of which the structures are known ($r_{Cu-N} = 2.05$ Å[14] for ammine-N and $r_{Cu-N} = 2.03$ Å[15] for ethylenediamine-N and $N = 4$ for both complexes). With fixed N and r, we obtained two sets of six parameters by curve-fitting the Fourier-filtered spectra for the isolated Cu–N interaction. For checking the accuracy of the analysis, the least-squares fit to the EXAFS spectrum of $[Cu(en)_2]Cl_2 \cdot 2H_2O$ was carried out in the range of $k = 3.8$—8.6 ($Å^{-1}$) with the set of parameters obtained above from the EXAFS spectrum of $[Cu(NH_3)_4]SO_4 \cdot H_2O$; the determined coordination number (N) and atomic distances (r_{Cu-N}) are shown in Table 1. On the other hand, the N and r_{Cu-N} values of the latter complex were obtained from the analysis of its EXAFS spectrum with the set of parameter values derived from the spectrum of the former (Table 1). The obtained values are within

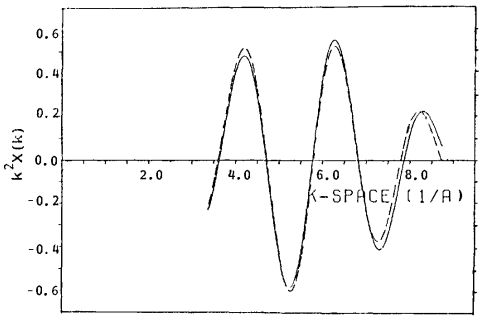

Fig. 5. First-shell fit for structure determination of an aqueous $[Cu(en)_2]^{2+}$ solution by use of a set of parameters obtained from the spectrum of solid $[Cu(NH_3)_4]SO_4 \cdot H_2O$. The solid line is the filtered EXAFS spectrum and dashed line is the least-squares fit.

Table 2. Results of curve-fitting analyses of aqueous $[Cu(NH_3)_4]^{2+}$ (0.32 M) and $[Cu(en)_2]^{2+}$ (0.38 M) solutions

	Set of parameters	Coordination number	Cu-N distance Å
$[Cu(NH_3)_4]^{2+}$	A	4.19±0.70	2.03±0.02
	B	4.24±0.71	2.02±0.02
$[Cu(en)_2]^{2+}$	A	4.59±0.72	2.04±0.02
	B	4.73±0.73	2.02±0.02

the experimental error of those of X-ray diffraction analyses. This demonstrates that the analysis adopted here gives a reliable structural information.

Then we determined the structure parameters of the ammine and ethylenediamine complexes of copper(II) in aqueous solutions with both sets of parameters. The Fourier-filtered and least-squares fit curves are shown in Fig. 5 for a solution of ethylenediamine copper(II) chloride; a set of parameters obtained from the spectrum of solid $[Cu(NH_3)_4]SO_4 \cdot H_2O$ was used in the analysis. The numerical results are summarized in Table 2. Analyses with two different sets of parameters gave results in good agreement with each other. Obtained coordination numbers are about four and Cu–N distances are about 2.03 Å for both solutions;[16] these values are close to those for solid complexes. The values of ammine solution are also in good agreement with the results of Ohtaki *et al.*[9] for the concentrated aqueous solutions of ammine copper(II) salt by X-ray diffraction technique (coordination numbers of 4 and the Cu–N distances of 2.03 Å for the $[Cu(NH_3)_4]^{2+}$ solution). However, our r_{Cu-N} value (2.03 Å) for $[Cu(en)_2]^{2+}$ solutions is significantly larger than Ohtaki's (1.93 Å).[10] This inconsistency need to be further investigated by measurements of higher accuracy and precision. Generally speaking, however, the EXAFS method as applied to solutions has the advantage that it detects only the interatomic interactions in which the copper atom (or any other atom concerned) is involved, whereas the X-ray diffraction method gives a diffraction pattern which is the superposion of various diffractions by different pairs of atoms at different distances. One of the disadvantage of the EXAFS method is that the determination of interatomic distances include the estimation of the phase-shift parameter which cannot be predicted by the theory with satisfactory precision and was obtained here by an empirical method.

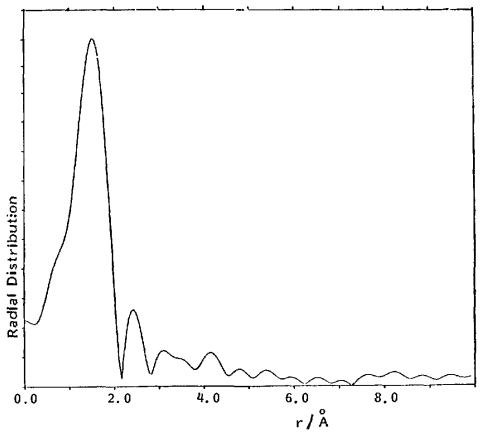

Fig. 6. Fourier transformation of the EXAFS spectrum of solid $CuSO_4 \cdot 5H_2O$.

Table 3. Results of curve-fitting analysis of aqueous $CuSO_4$ solutions

	Coordination number	Cu-O distance Å
0.30 M $CuSO_4$	4.25±0.57	1.98±0.03
1.18 M $CuSO_4$	4.13±0.57	1.98±0.03

Figure 6 shows the radial distribution from Fourier transformation of EXAFS for solid $CuSO_4 \cdot 5H_2O$, giving only one peak which corresponds to the Cu–O_{eq} interaction. Satelite at a distant position (2.3 Å) is doubtful to be a peak corresponding to Cu–O_{ax} because Fourier transformation may ripple beside the peak. Absence of the evidence for the second-nearest neighbour (O_{eq} at 2.4 Å) in the EXAFS spectrum has also been reported by Joyner.[17] To determine the Cu–O distances in solution, curve-fitting analysis was carried out using a set of parameters from solid $CuSO_4 \cdot 5H_2O$ (Cu–O=1.97 Å).[18] Table 3 shows the results for the structure parameters of two aqueous $CuSO_4$ solutions. The distance obtained is about 1.98 Å for both solutions, which generally agrees with the value from X-ray diffraction studies[8,12] within experimental error.

Concluding Remarks

An EXAFS study was carried out for aqueous solutions of some copper compounds with a position sensitive photodiode array, with which good spectra were easily obtained. The bond distance and coordination number obtained by curve-fitting method are 2.03 Å

and 4—5 for aqueous $[Cu(NH_3)_4]^{2+}$ and $[Cu(en)_2]^{2+}$ solutions. For $CuSO_4$ solutions, $Cu-O_{eq}$ is 1.98 Å and the first coordination sphere contains 4 O atoms. These results are very close to those of corresponding solid complexes.

This work was supported in part by a Grant-in-Aid from the Mitsubishi Fundation.

Mössbauer Studies of Mercury(II) Salt Adducts of [2]Ferrocenophane Derivatives

Masanobu WATANABE, Hajime ICHIKAWA, Izumi MOTOYAMA, and Hirotoshi SANO*

Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya-ku, Tokyo 158

(Received May 23, 1983)

Various adducts of mercuric salts with [2]ferrocenophane and 1,1,2,2-tetramethyl[2]ferrocenophane, were prepared by treating HgX_2 ($X=Cl^-$, I^-, CN^-) with the [2]ferrocenophane derivatives in ether. The adducts were studied by Mössbauer spectroscopy and other physicochemical measurements. Anomalously large quadrupole splitting values of the adducts (about 3.10—3.30 mm s^{-1} at 78 K) suggest the presence of a strong direct interaction between the Fe and Hg atoms.

Since the discovery of ferrocene, the bonding states of this compound and its oxidized compounds, ferrocenium salts, have been investigated by various physicochemical measurements. Mössbauer spectroscopy has been applied to the investigation as one of the most useful tools to study the chemical state of iron atoms and it was found that Mössbauer parameters of ferrocene and ferrocenium salts are 2.41 mm s^{-1} and $\leq$0.5 mm s^{-1} in quadrupole splitting (Q.S.) value and 0.52 mm s^{-1} in isomer shift (I.S.) value both at 78 K. For most of the ferrocene and ferrocenium derivatives, the variation in isomer shift is slight, while the quadrupole splitting ranges from about 2.5 to 2.0 mm s^{-1} and 0 to 0.5 mm s^{-1}, respectively, depending upon the chemical state, such as the kind of substituent attached to the cyclopentadienyl rings.

Roger M. G. Roberts *et al.* recently reported Mössbauer spectroscopic studies of the $HgCl_2$ adduct of ferrocene synthesized from $HgCl_2$ and ferrocene in ether.[1] The Q.S. values of the adduct (3.09 mm s^{-1} at 78 K and 2.94 mm s^{-1} at 298 K) are one of the largest among values reported for most ferrocene derivatives suggesting an iron–mercury bonding interaction, although the adduct is not stable; *i.e.*, the orange-red color of the adduct changes into blue on standing at room temperature. Magnetic susceptibility measurements at room temperature have shown that the orange-red $Fe(Cp)_2\cdot 7HgCl_2$ compound is diamagnetic and the blue $Fe(Cp)_2\cdot 7HgCl_2$ compound paramagnetic with a magnetic moment of 2.36 BM, (1 BM$=9.274078\times10^{-24}$ J T^{-1}). This corresponds to that of a ferrocenium salt.[2]

Based on these results, it was concluded that there should be some kind of bonding interaction between Fe and Hg atoms in the orange compound, while on standing at room temperature the compound would suffer from a slow oxidation accompanying the Fe–Hg bond rupture.

Another interesting observation on the large quadrupole splitting value (2.72 mm s^{-1} at 80 K) was reported by R. M. G. Roberts *et al.* for the $Fe(Cp)_2$–$HAlCl_4$ adduct, suggesting an interaction between iron and hydrogen atoms.[3]

On the other hand, [2]ferrocenophane, one of the bridged ferrocenophane derivatives, was synthesized by H. L. Lentzner and W. E. Watts in 1971.[4] The structure was investigated by X-ray structural analysis and it was found that the cyclopentadienyl rings are inclined at *ca.* 23° to each other.[5] Various other studies of NMR,[4] electronic spectroscopy[4] and electric dipole moment measurements[6] on the [2]ferrocenophane are consistent with the "naked" structure of the iron atom in this compound. The present work was planned to study the possibility of producing an adduct of [2]ferrocenophane–HgX_2 ($X^-=Cl^-$, ClO_4^-, BF_4^-), which can be expected to be more stable than the ferrocene–$HgCl_2$ adduct because of the "naked" structure of iron atoms in the tilted-ring molecular structure.

Experimental

Materials. [2]Ferrocenophane·$3HgCl_2$ was prepared by mixing [2]ferrocenophane (1.0 g) dissolved in 50 ml diethyl ether with a large excess of $HgCl_2$ dissolved in diethyl ether. The red-orange precipitates were filtered, washed with ether and dried under vacuum. Calcd for $C_{12}H_{12}Fe\cdot 3HgCl_2$: C, 14.03, H, 1.16. Found: C, 13.18; H, 1.21.

1,1,2,2-Tetramethyl[2]ferrocenophane·$3HgCl_2$ was synthesized by the same method as that used for [2]ferrocenophane·$3HgCl_2$. Calcd for $C_{16}H_{20}Fe\cdot 3HgCl_2$: C, 17.97; H, 2.18%. Found: C, 18.00; H, 2.00%.

[2]Ferrocenophane·$0.5Hg(ClO_4)_2$ was prepared by mixing [2]ferrocenophane (0.21 g) dissolved in 150 ml absolute ethanol with about 10 drops of perchloric acid. Yellow-orange crystals started to precipitate. The precipitates were filtered, washed with absolute ethanol and dried under vacuum. Calcd for $C_{12}H_{12}Fe\cdot 0.5Hg(ClO_4)_2$: C, 34.97; H, 2.91%. Found: C, 32.88; H, 2.90%.

[2]Ferrocenophane·$0.5Hg(BF_4)_2$ was prepared by mixing [2]ferrocenophane (113 mg) with $Hg(CN)_2$ (0.32 mmol) each in 100 ml of absolute ethanol. To the solution, approximately 8 drops of 50% aqueous tetrafluoroboric acid was added. Yellow-orange crystals started to precipitate and the precipitates were filtered, washed with absolute ethanol and dried under vacuum. Calcd for $C_{12}H_{12}Fe\cdot 0.5Hg(BF_4)_2$: C, 36.08; H, 3.00%. Found: C, 35.92; H, 2.91%.

Measurements. ^{57}Fe-Mössbauer measurements were carried out using a ^{57}Co(Pt) source moving in a constant acceleration mode. The isomer shifts were determined relative to metallic iron foil. The experimental errors of the isomer shift and quadrupole splitting values are 0.02 mm s^{-1}. Electronic absorption spectra were measured in an acetonitrile solution with a Hitachi spectrophotometer model-220.

Results and Discussion

It has been reported that ferrocene reacts with $HgCl_2$ in ethanol or ether giving red-orange precipi-

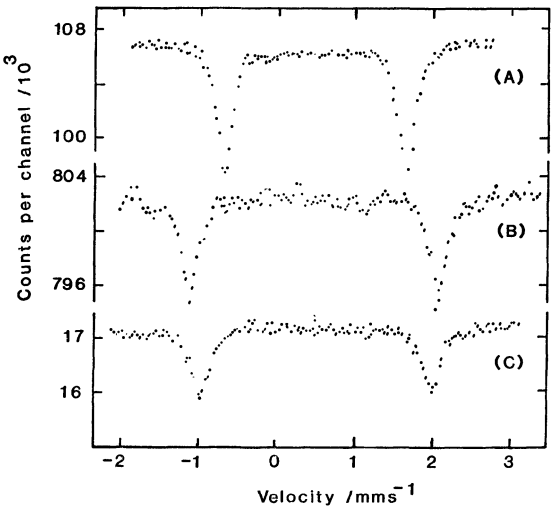

Fig. 1. Mössbauer spectra of (A) [2]ferrocenophane, (B) [2]ferrocenophane-$3HgCl_2$ adduct, and (C) [2]-ferrocenophane-$0.5Hg(BF_4)_2$ adduct all at 78 K.

tates. On standing at room temperature, this complex is also known to change color to blue. On the other hand, the present studies revealed that [2]ferrocenophane reacts with $HgCl_2$ in ether or ethanol giving red-orange precipitates, which are stable on standing, without change of color. Mössbauer spectra of [2]ferrocenophane and its mercury(II) chloride adduct are shown in Fig. 1. The quadrupole splitting of [2]ferrocenophane is found to be 2.41 mm s^{-1}, and that of 1,1,2,2-tetramethyl[2]ferrocenophane, 2.36 mm s^{-1}, both at 78 K. These values are almost the same as that of ferrocene (2.41 mm s^{-1}), indicating that the electric field gradient at the Fe nucleus in [2]ferrocenophane remains almost the same as that of ferrocene, although the cyclopentadienyl rings are largely inclined by *ca.* 23° each other.

A similar observation was reported by R. A. Abramovitch *et al.* in 1975 for 1-thia-2-aza[2]ferrocenophane 1,1-dioxide, in which cyclopentadienyl rings were bridged by sulfur and nitrogen atoms instead of carbon atoms.[7] The quadrupole splitting value of this compound is almost the same as that of ferrocene, as in the case of [2]ferrocenophane.

On the contrary, a remarkable difference was observed in the Mössbauer spectra of mercury(II) halide adducts of [2]ferrocenophane derivatives from that of ferrocene. The quadrupole splitting value of [2]ferrocenophane·$3HgCl_2$ is 3.29 mm s^{-1} at 78 K, which is the largest of all the reported ferrocene derivatives, while the Q.S. value of ferrocene·$7HgCl_2$ has been reported to be 3.09 mm s^{-1} at 78 K.

The large Q.S. value of [2]ferrocenophane·$3HgCl_2$ compound compared with that of ferrocene·$7HgCl_2$ suggests a stronger bonding formed between iron and mercury atoms in the adduct. The suggestion may also be supported by the fact that the [2]ferrocenophane·$3HgCl_2$ adduct remains more stable on standing, even after 180 d, than the ferrocene·$7HgCl_2$ adduct which changes to the ferrocenium salt. The results imply that the bonding formed by the "naked" electrons of Fe atom coordinating with an orbital of a Hg atom is so stable that the red-orange color of the mercury(II) chloride adduct of [2]ferrocenophane does not change on standing. The quadrupole splitting value of the mercury(II) iodide adduct, 1,1,2,2-tetramethyl[2]ferrocenophane·$2HgI_2$, is a little smaller than that of the mercury(II) chloride adduct of [2]-ferrocenophane.

D. N. Hendrickson *et al.* reported the structure and bonding state of ruthenocene compounds such as $[(Cp)_2Ru]_2HgX_2$ ($X=PF_6^-$, BF_4^-, ClO_4^-) by means of various physicochemical techniques.[8] It was found that a strong line component remained unchanged in the Raman spectra of $[(Cp)_2Ru]_2HgX_2$ except for the absorptions attributable to the different kinds of anion and that the strong Raman band observed at 110 cm^{-1} both in solid and in a solution containing the cation was assigned to a symmetrical Ru–Hg–Ru stretching mode. In their study of the electronic absorption spectrum of $[(Cp)_2Ru]_2Hg(PF_6)_2$ at room temperature, a strong new absorption band was observed at 320 nm and assigned to a transition associated with the Ru–Hg–Ru unit, based on studies of $M_2(CO)_{10}$ ($M=Mn$, Re) complexes.[9] From their results, they proposed that the structure of $[Ru(Cp)_2]_2HgX_2$ should be expressed as $[(Cp)_2Ru(II)–Hg(II)–Ru(II)(Cp)_2]X_2$.

Although ferrocene does not react with mercury(II) cyanide and does not form $[(Cp)_2Fe–Hg–Fe(Cp)_2]^{2+}$ but produces the ferrocenium salt, [2]ferrocenophane derivatives react with mercury(II) cyanide and produce mercury(II) salt adducts, $[(C_5H_4CH_2)_2Fe]_2HgX_2$, ($X^-=ClO_4^-$, BF_4^-), under similar conditions. Mössbauer parameters of the compounds are listed in Table 1 and typical Mössbauer spectra of the mercury(II) salt adducts are also shown in Fig. 1. The quadrupole splitting values of [2]ferrocenophane·$0.5Hg(BF_4)_2$ are 3.11 mm s^{-1} at 78 K and 3.10 mm s^{-1} at 300 K, and those of 1,1,2,2-tetramethylferrocenophane·$0.5Hg(BF_4)_2$ are 3.12 mm s^{-1} at 78 K and 3.08 mm s^{-1} at 300 K. Both values are larger than those of [2]ferrocenophane and 1,1,2,2-tetramethyl[2]ferrocenophane and are similar to that of mercury(II) chloride adducts, [2]ferrocenophane·$3HgCl_2$. This fact shows

Table 1. Mössbauer parameters of [2]ferrocenophane, $(C_5H_4CH_2)_2Fe$, and tetramethyl[2]ferrocenophane, $(C_5H_4C(CH_3)_2)_2Fe$, and their adducts with mercury(II) salts

Compound	Temp K	Q.S. mm s^{-1}	I.S. mm s^{-1}
$(C_5H_4CH_2)_2Fe$	78	2.41	0.49
$[(C_5H_4CH_2)_2Fe]·(HgCl_2)_3$	78	3.29	0.49
$[(C_5H_4CH_2)_2Fe]·$ 1/2 $Hg(ClO_4)_2$	78	3.14	0.53
$[(C_5H_4CH_2)_2Fe]·$ 1/2 $Hg(BF_4)_2$	78	3.11	0.53
	300	3.10	0.46
$(C_5H_4C(CH_3)_2)_2Fe$	78	2.36	0.53
$[(C_5H_4C(CH_3)_2)_2Fe]·$ 1/2 $Hg(BF_4)_2$	78	3.12	0.53
	300	3.08	0.44
$[(C_5H_4C(CH_3)_2)_2Fe]·$ $(HgI_2)_2$	78	3.09	0.51

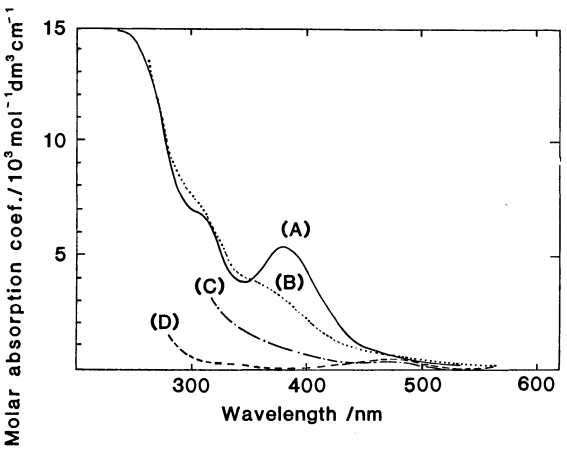

Fig. 2. Absorption spectra of an acetonitrile solution of bis([2]ferrocenophane)mercury(II) perchlorate, $[(C_5H_4CH_2)_2Fe]_2$-$Hg(ClO_4)_2$ (A) 4 min, (B) 20 min, (C) 50 min after preparation, and (D) an acetonitrile solution of [2]ferrocenophane, $(C_5H_4CH_2)_2Fe$.

that there is also a strong interaction between Fe–Hg atoms in these adducts described as $[(C_5H_4CH_2)_2Fe$–Hg–$Fe(C_5H_4CH_2)_2]^{2+}X^-_2$ in a similar way to the structure of $[Ru(Cp)_2]_2HgX_2$.

Figure 2 shows the electronic absorption spectra of $[(C_5H_4CH_2)_2Fe]_2Hg(ClO_4)_2$ dissolved in acetonitrile. A new absorption band, which is similar to that of the $[(Cp)_2Ru]_2HgX_2$ solution in spectral shape, appears at 380 nm, although the intensity of the band decreases gradually as the solution is allowed to stand, probably because of dissociation of the adduct in solution, as found in the solutions of $[(Cp)_2Ru]_2HgX_2$. The results suggest that the absorption band is assigned to an electronic transition associated with the Fe–Hg–Fe unit corresponding to that of the Ru–Hg–Ru unit.

All the results obtained in the present studies lead us to the conclusion that [2]ferrocenophane and 1,1,2,2-tetramethyl[2]ferrocenophane give stable adducts in which a direct bond is formed between iron and mercury atoms and that the bonding is stabilized by coordinating the "naked" electrons of iron atoms to one of the vacant orbitals of mercury atoms in the tilting structure of cyclopentadienyl rings in [2]ferrocenophanes, as in the case of [2]ferrocenophane–tin(IV) chloride adduct.[10]

Kinetics of the Thermal Decomposition of Nickel Sulfate

Kaoru Onuki,* Saburo Shimizu, Hayato Nakajima, Yasumasa Ikezoe, and Shoichi Sato

Japan Atomic Energy Research Institute, Tokai-mura, Ibaraki, 319-11

(Received May 26, 1983)

The rate of thermal decomposition of nickel sulfate was measured in the temperature range from 1003 K to 1078 K. When a powder sample was used, this reaction was characterized as a contracting volume reaction, with apparent activation energy of 296 kJ mol^{-1}. The gaseous products were sulfur trioxide, sulfur dioxide, and oxygen. The composition of the gaseous products was near equilibrium in regard to the reaction, $SO_3 = SO_2 + 1/2\,O_2$, because the nickel oxide formed had high catalytic activity for this reaction.

We have proposed a thermochemical hydrogen production cycle composed of the following chemical reactions (NIS process).[1)]

$$SO_2 + I_2 + 2H_2O = 2HI + H_2SO_4 \quad (1\text{-}1)$$

$$2HI + H_2SO_4 + 2Ni = NiI_2 + NiSO_4 + 2H_2 \quad (1\text{-}2)$$

$$NiI_2 = Ni + I_2 \quad (2)$$

$$NiSO_4 = NiO + SO_3 \quad (3\text{-}1)$$

$$SO_3 = SO_2 + 1/2\,O_2 \quad (3\text{-}2)$$

$$NiO + H_2 = Ni + H_2O \quad (4)$$

Studies on the nickel salt separation[2)] and dehydration equilibrium of nickel iodide[3)] have been made about the process. In this paper, we report the study of reaction (3-1), the thermal decomposition of nickel sulfate.

The kinetics of the decomposition of nickel sulfate have been studied by a few investigators. Ingraham and Marier[4)] measured the rates of formation and decomposition of nickel sulfate by thermogravimetry. They reported that nickel oxide was formed at a well-defined interface between sulfate and oxide, and the interface migrated into the sulfate phase at a constant rate. Also, they found that a small amount of sulfur trioxide in the decomposition atmosphere caused a substantial decrease in the rate of decomposition. The same equation was reported by other investigators,[5–7)] but the apparent activation energies reported were widely different from each other as shown in Table 1. Dollimore and Pearce[8)] have measured the density and the surface area of a half- hour ignition sample at various temperatures, and observed the occurrence of cracking and adhesion of particles during decomposition.

In the present work, we studied the decomposition rate, the composition of the gaseous products and the characteristics of the solid product.

Experimental

Nickel sulfate hexahydrate ($NiSO_4 \cdot 6H_2O$) of analytical grade was dehydrated for 5 h at 723 K to the anhydrous form and then ground into powder.

Decomposition experiments were made with the apparatus shown in Fig. 1. The flow system was composed of a carrier gas flow controller, a vertical reactor, a sulfuric acid demister, a sulfur oxides (SO_x) trap, and oxygen meter. The reactor was made of a cylindrical quartz tube (o.d.=15 mm) and a sintered quartz disc. The powder sample was placed on the disc and covered with quartz wool. Temperature of the reaction zone was kept constant throughout the decomposition experiment, and was measured by two alumel–chromel thermocouples. One thermocouple was put in a quartz tube inside the reactor, and the other was set at the outer wall of the reactor. Gaseous decomposition products were carried away from the reactor by argon carrier gas and the sulfur oxides were absorbed in 0.1 mol dm^{-3} iodine solution added with potassium iodide. The acid mist in the product gas stream was caught efficiently by two sintered glass filters which was moistened with the iodine solution as shown in Fig. 1.

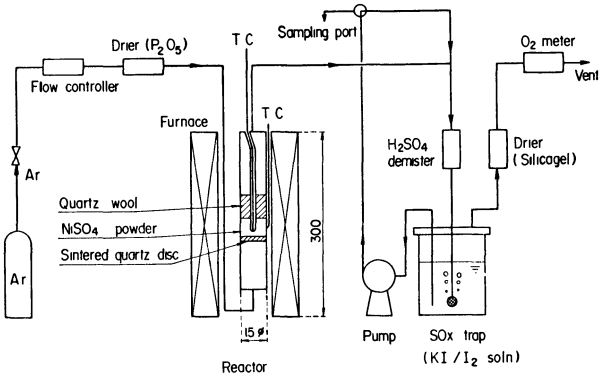

Fig. 1. Experimental apparatus (schematic).

The amounts of sulfur oxides produced were measured by acidimetry and iodometry. The oxygen concentration in the tail gas was continuously measured by an oxygen meter with zirconia solid electrolyte (Toray, Model LC 700-H).

Decomposition experiments were made with 1 g of the sample (in anhydrous form), in the temperature range from 1003 to 1078 K at 1.06×10^5 Pa pressure and 0.1 to 0.6 dm^3-NTP min^{-1} argon flow rate.

The scanning electron microscope (SEM) observation, the flowing BET surface area measurement,[9)] and X-ray diffraction measurement of the sample powder were done before and after decomposition.

Results and Discussion

First, all gaseous products from decomposition were measured at all stages of the reaction. The composition of the gaseous products was found to be almost constant throughout the decomposition. Then, the fraction decomposed, α was followed by measuring the oxygen concentration. The time dependent curves of α are shown in Fig. 2 at three temperatures and an argon flow rate of 0.5 dm^3 min^{-1}. The decomposition rates decrease continuously with time. The effect of argon flow rate on the reaction rate at a constant α of 0.3, $V_{0.3}$ is shown in Fig. 3. The decomposition

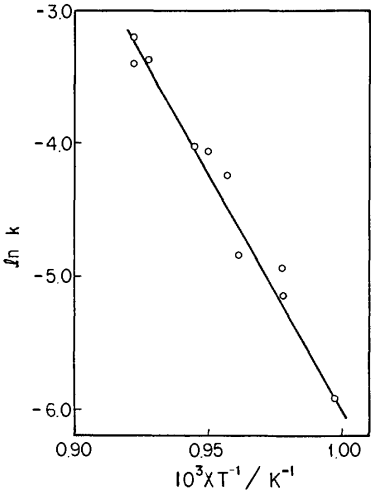

Fig. 5. Arrhenius' relationship for the decomposition of $NiSO_4$.

rates increase with increasing the flow rates to *ca.* 0.5 $dm^3\ min^{-1}$ and are constant above that flow rate. So, the data at a flow rate of 0.5 $dm^3\ min^{-1}$ are considered hereafter.

The rate equation of the reaction was obtained by Sharp-Brindley-Achar method.[10] By replotting α against the time normalized at $\alpha=0.5$, $t/t_{0.5}$, all data were expressed by a single curve. Then, the rate equation for the nickel sulfate decomposition could be expressed as follows:

$$1-(1-\alpha)^{1/3}=kt. \tag{5}$$

Here, k is the reaction rate constant and t is the reaction time. The plot of the experimental data according to Eq. 5 is shown in Fig. 4. A good linearity is found in the range of α to *ca.* 0.8. Equation 5 is considered for the contracting volume reaction.[11] The rate equation obtained is consistent with that previously reported.[4-7]

The Arrhenius' plot of the rate constants, k is shown in Fig. 5. From the plot, we can obtain the apparent rate parameters as follows:

$$k=1.18\times10^{11}\exp\left\{-\frac{296(\text{kJ mol}^{-1})}{RT}\right\}(\text{s}^{-1}). \tag{6}$$

Here, R is the gas constant. The apparent activation energies reported for the thermal decomposition of nickel sulfate are listed in Table 1 together with that obtained in the present study. Our result is close to those of Ingraham *et al.*[4] and Karwan *et al.*[6]

Table 1. Apparent activation energy for thermal decomposition of nickel sulfate

Decomposition atmosphere	Temperature range / K	Activation energy / kJ mol^{-1}	Reference
N_2	1031—1124	255±12	4)
Air	975—1064	115	5)
Air	1075—1250	305±32	6)
N_2 or Ar	1075—1220	162	7)
Ar	1003—1078	296	This work

The X-ray diffraction pattern showed the solid product was nickel oxide, NiO. The SEM picture of the sample powder before and after decomposition are shown in Figs. 6-a and 6-b, respectively. The granular product is very porous and fluffy, and the size of product particle is much larger than that of reactant. The specific surface areas of the sample powder before and after decomposition are 8.4 $m^2\ g^{-1}$ and 15.5 $m^2\ g^{-1}$, respectively. These observations are qualitatively explained assuming the following decomposition sequence.[8] As the decomposition proceeds, the particle is broken up into smaller particles due to the strain

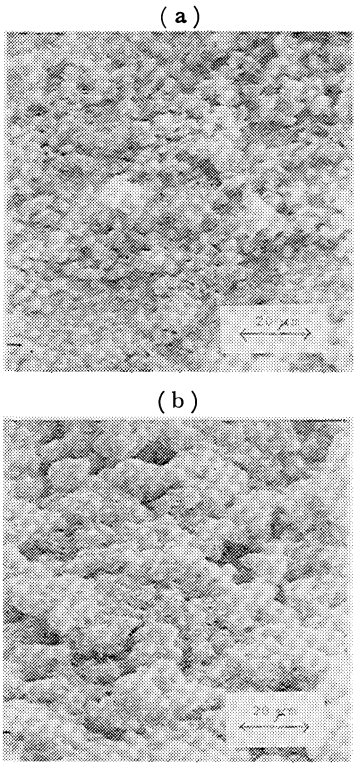

Fig. 6. (a) Scanning electron microscope picture of nickel sulfate powder used in the experiment. (b) Scanning electron microscope picture of the nickel oxide powder produced by the decomposition of sulfate at 1043 K.

imposed by the decomposition. Simultaneously, the adhesion of particles takes place and the porous and fluffy layer is formed.

The molar ratios of sulfur dioxide produced to the reactant, $NiSO_4$ at various decomposition temperatures and carrier gas flow rates are shown in Fig. 7. As seen in the figure, the ratio is almost independent of the reaction temperature and the carrier gas flow rate, and is very close to the equilibrium value which ranges from 0.88 to 0.96. The equilibrium value was calculated from the thermodynamic data[12] for the reaction:

$$SO_3 = SO_2 + 1/2\,O_2. \quad (3\text{-}2)$$

The sulfur trioxide concentration was estimated from the amount of the reactant, $NiSO_4$ and the time difference between the time of $\alpha=0.1$ and the time of $\alpha=0.9$.

The effect of oxygen on the product gas composition was also examined using air as the carrier gas as shown in Fig. 7. At 1043 K and 0.5 $dm^3\,min^{-1}$, the ratio is 0.66. This value is equal to the equilibrium one calculated for the oxygen fraction in the carrier gas, 0.21.

These results suggest that the decomposition product, NiO acts as an active catalyst for reaction (3-2) under the experimental conditions. The catalytic activity of the nickel oxide produced was tested as follows. After the nickel sulfate was completely decomposed by heating at 1073 K for 2.5 h in an argon stream, a gas mixture of argon and 3.8 vol% sulfur trioxide was introduced to the reactor and the oxygen

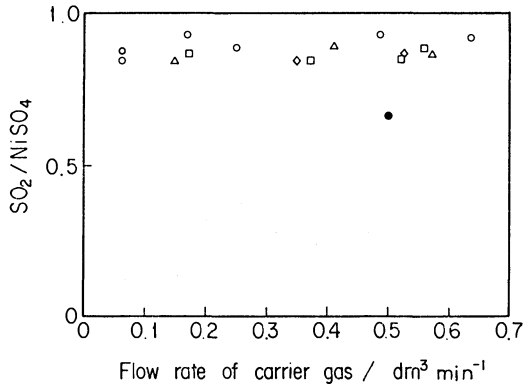

Fig. 7. Effect of the decomposition conditions on the molar ratio of SO_2 produced to $NiSO_4$.
Argon atmosphere: (◇); 1023 K, (□); 1043 K, (△); 1063 K, (○); 1078 K, air atmosphere: (●); 1043 K.

concentration of the tail gas was measured at 1073 K. At a contact time of 0.48 s, the fraction of sulfur trioxide decomposed was 0.77 ± 0.07. This concentration of SO_3 and the contact time were chosen so as to simulate the thermal decomposition condition in the present study. The equilibrium fraction of sulfur trioxide decomposed under the condition is calculated to be 0.90. Thus, it was proved that nickel oxide had an enough catalytic activity for reaction (3-2) under the experimental conditions. It should be noted that the reactor wall and the sintered quartz disc had no catalytic activity for reaction (3-2). These results suggest simplification of the NIS process, because reaction (3-1) and (3-2) may be operated in one step.

The authors are indebted to Dr. Norio Masaki for the X-ray diffractometry, to Mr. Hitoshi Otsu for the scanning electron microscope observation.

(Received May 30, 1983)

The title complex crystallizes in the monoclinic space group C2/c with $a=24.900(6)$ Å, $b=8.272(2)$ Å, $c=30.437(9)$ Å, and $\beta=97.23(2)°$. The structure analysis, which converged at $R=0.061$ and $R_w=0.083$ with 3017 reflections for which $F_o^2>3\sigma(F_o^2)$, showed that the palladium has a complete square-planar coordination geometry. While one of the tfac ligands is chelating, the other is bound to the metal only through the carbonyl oxygen adjacent to CH_3. The *O*-unidentate tfac ligand lies trans to the CF_3CO moiety of chelating tfac and has a planar structure in which the dangling CF_3CO group is situated trans to the bonding oxygen atom with respect to the C=C bond. The *ab initio* MO calculation for the *Z,Z*-form of the tfac anion indicated that the coordination ability of the acetyl oxygen is higher than that of the trifluoroacetyl oxygen in consistence with the observed structure.

In recent years the reactions of binary and mixed-ligand bis(β-diketonato)palladium(II) and -platinum(II) chelates[1] with various nitrogen bases[2-4] and tertiary phosphines[5] have been studied very extensively. Many types of products were obtained depending on the natures of the central metals, β-diketonate ligands, attacking Lewis bases, and solvents employed. For example, the [Pd(acac)(acac-C^3)L] complexes containing both the *O,O'*-chelated and the central-carbon-bonded 2,4-pentanedionate ligands (acac and acac-C^3, respectively) were afforded by the reactions of [Pd(acac)$_2$] with Lewis bases (L) such as diethylamine, pyridine, and triphenylphosphine as neat liquids and in benzene, respectively.[6]

The kinetic and equilibrium studies on the reaction of [Pd(acac)$_2$] with various alkylamines in solutions revealed that the carbon-bonded acac complexes are not derived directly from the starting bis-chelate, but resulted *via* the salt-like complexes [Pd(acac)L$_2$](acac).[7]

$$[Pd(acac)_2] + 2L \rightleftharpoons [Pd(acac)L_2](acac) \quad (1)$$

$$[Pd(acac)L_2](acac) \rightleftharpoons [Pd(acac)(acac\text{-}C^3)L] + L \quad (2)$$

In the first stage (Eq. 1) of the overall reaction, one of the chelating acac ligands seems to be displaced *via* the *O*-unidentate state although the intermediate complex [Pd(acac)(acac-*O*)L] was not detected spectrophotometrically in these particular reactions.[7]

In fact several [M(β-dik)(tfac-*O*)(PR$_3$)]-type complexes (M=Pd^{II} and Pt^{II}; β-dik=acac and tfac; R=ethyl, phenyl, *o*-tolyl, and cyclohexyl) containing the *O*-unidentate 1,1,1-trifluoro-2,4-pentanedionate anion (tfac-*O*) were prepared by the reactions of [M(β-dik)(tfac)] with tertiary phosphines.[5] According to the kinetic and equilibrium studies,[8] the reaction of [Pd(tfac)$_2$] with tri-*o*-tolylphosphine proceeds reversibly to afford the *O*-unidentate tfac complex exclusively, the equilibrium constant being 1.38×10^3, 4.35×10^3, and more than 10^9 dm^3 mol^{-1} in benzene, dichloromethane, and methanol, respectively, at 25 °C. The steric requirement of P(*o*-tolyl)$_3$ may prevent the formation of [Pd(tfac){P(*o*-tolyl)$_3$}$_2$](tfac) and [Pd(tfac)(tfac-C^3)-{P(*o*-tolyl)$_3$}].

The *O*-unidentate bonding of the β-diketonate anion was observed first for Me$_2$Si(acac-*O*)$_2$ and Me$_3$Si(acac-*O*)[9] followed by [Hg(β-dik-*O*)$_2$] (β-dik=acac, 2,6-dimethyl-3,5-heptanedionate, and 2,2,6,6-tetramethyl-3,5-heptanedionate anions),[10] [Pt(acac-*O*)$_2$L$_2$](L=PEt$_3$[11] and piperidine[12]), [Cu(acac)(hfac-*O*)(phen)] (hfac=1,1,1,5,5,5-hexafluoro-2,4-pentanedionate anion),[13] and [M(CO)$_3${PPh(acac-*O*)$_2$}] (M=Cr and W)[14] as well as the above-mentioned [M(β-dik)(tfac-*O*)(PR$_3$)] complexes.[5] This paper reports the crystal and molecular structure of [Pd(tfac)(tfac-*O*){P(*o*-tolyl)$_3$}] which was determined by the X-ray diffraction method in order to disclose for the first time the *O*-unidentate structure of tfac in a crystal.[15]

Experimental

The compound was prepared by the reaction of [Pd(tfac)$_2$] with P(*o*-tolyl)$_3$ in hot benzene and an orange plate ($0.09\times0.25\times0.25$ mm^3) for X-ray analysis was obtained on addition of hexane to the solution and spontaneous cooling to room temperature.[5] Crystal Data: Monoclinic, $a=24.900(6)$ Å, $b=8.272(2)$ Å, $c=30.437(9)$ Å, $\beta=97.23(2)°$, Space group C2/c, $D_m=1.52$ g cm^{-3}, $D_c=1.532$ g cm^{-3}, $Z=8$, μ(Mo $K\alpha$)$=7.14$ cm^{-1}. The Laue symmetry and the space group were determined from Weissenberg and precession photographs. The unit cell dimension was obtained from the least-squares treatment of 14 θ values of higher angle reflections ($\theta=7-15°$) measured on an automated diffractometer by use of Mo $K\alpha$ radiation.

The intensities were measured on the diffractometer by using the graphite-monochromated Mo $K\alpha$ radiation. The background was counted at each side of the scan range ($\omega=1.0+0.4\tan\theta$), the speed of ω scan being 0.033° s^{-1}. The intensities of three standard reflections monitored every 4 h showed no appreciable variation during the data collection.

Of 3839 independent reflections collected in the $2\theta\leq44°$ range, 3017 with $F_o^2>3\sigma(F_o^2)$ were used for the structure determination. The crystal structure was solved by the heavy atom technique. The positional and thermal parameters were refined by block-diagonal-matrix least-squares to R 0.061, R' ($=[\sum w\Delta^2/\sum wF_o^2]^{1/2}$) being 0.083. The minimized function was $\sum w(F_o-|F_c|)^2$, where $w=1/\sigma^2(F_o)$. No attempt was made to locate hydrogen atoms. In the course

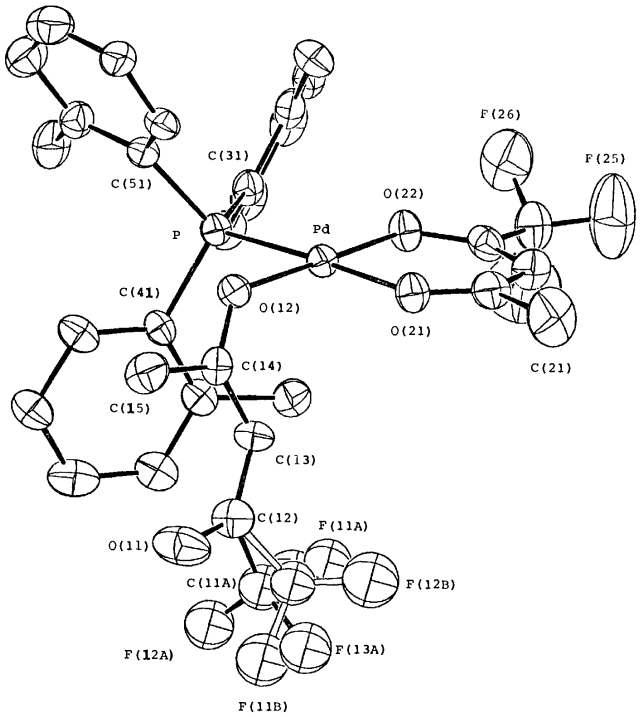

Fig. 1. ORTEP drawing of [Pd(tfac)(tfac-*O*){P(*o*-tolyl)$_3$}]. Thermal ellipsoids are drawn at 30% probability level. The CF_3 group composed of C 11), F(11), F(12), and F(13) is twofold disordered

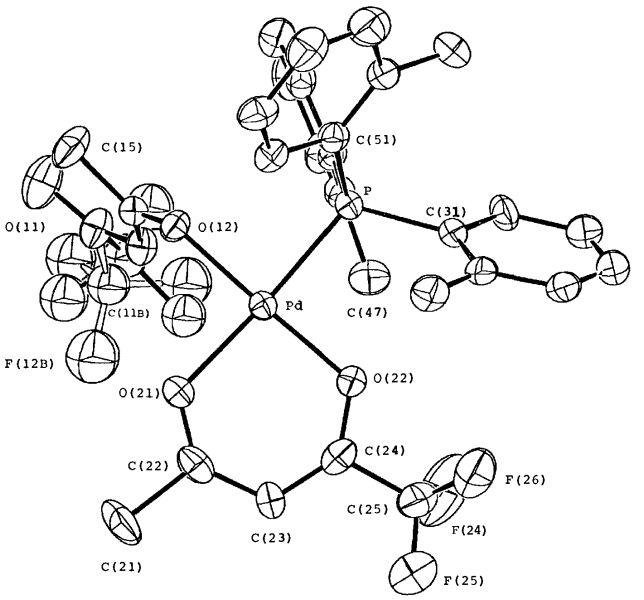

Fig. 2. Projection of the complex along the normal of coordination plane. Thermal ellipsoids are drawn at 30% probability level.

of the structure analysis, one of the CF_3 groups was found to be in disorder. The electron density distribution for this group was best interpreted by the model (twofold disorder) shown in Figs. 1 and 2. Occupancies for the disordered CF_3 groups were assumed to be equal. All parameter shifts in the final cycle of the refinement were less than 0.5σ except for the atomic parameters of the disordered CF_3 group, for which the shifts were in the $0.15\sigma-1.5\sigma$ range.

The atomic scattering factors with correction for anomalous dispersion of the metal atom were taken from Ref. 16. The

atomic coordinates are given in Table 1. The F_o—F_c table and the anisotropic thermal parameters are preserved at the Chemical Society of Japan (Document No. 8347). The computation was performed by a FACOM 230-60 computer at Osaka City University and an ACOS-700 computer at the Crystallographic Research Center of Osaka University by use of the programs in the UNICS[17] and ORTEP.[18]

Results and Discussion

Figures 1 and 2 show the perspective view of the molecule and its projection along the normal of the coordination plane, respectively. Figure 3 gives the view of the P(*o*-tolyl)$_3$ ligand along the M–P vector. Bond lengths and angles are summarized in Table 2. Average values are given for the parameters of CF_3 groups, since these groups have large thermal parameters indicative of a disorder (Table 1) and hence individual structural parameter is of less importance.

The Pd atom lies on a complete plane comprised of 3O and P atoms (Table 3). While one of the two tfac ligands is *O,O'*-chelated in the usual fashion, the other is linked to the metal atom only through the acetyl oxygen atom. Of the two Pd–O bonds constructing the chelate ring, the Pd–O(21) bond is more

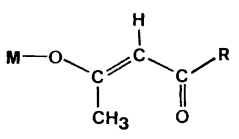
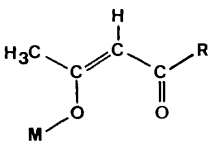
than 0.06 Å longer than the other Pd–O(22) bond probably owing to the trans influence of the tertiary phosphine ligand. The unidentate tfac enolate ligand has a planar structure in which the dangling CF_3CO group lies trans to the bonding oxygen around the C=C bond, the torsion angle between the C(14)–C(15) and C(12)–O(11) bonds being 1.1°. The electron density due to the disordered CF_3 group is best interpreted by the model shown in Fig. 1. The C(12)–C(11A) and C(12)–C(11B) bonds make angles 13.1° and 9.4°, respectively, with the [O(11), C(12), C(13)] plane.

Since the chelating tfac ligand is unsymmetric, two geometrical arrangements around the metal atom are conceivable for this complex even if the unidentate tfac ligand is bound to the metal exclusively through the acetyl oxygen. In fact the two isomers exist in equilibrium in $CDCl_3$ and the present isomer (*trans*-[P,O(21)]) is overwhelmingly abundant (>80%) at ambient temperature.[5] As may be imagined from Fig. 2, there exists no severe atom overcrowding in the *cis*-[P,O(21)] isomer either and hence the higher stability of the *trans*-[P,O(21)] isomer seems to stem from some electronic origin. The σ-donating ability of the CH_3CO moiety of the chelating tfac is higher than that of the CF_3CO moiety (*vide infra*) and may strengthen the Pd-phosphine π-bonding.[5]

The planar *O*-unidentate β-diketonate ligand may have either the trans or cis configuration with respect to the C=C bond. By the ^{1}H NMR studies Pinnavaia and his collaborators found that the R_3Si(acac-*O*) complexes are composed of cis and trans isomers in



trans

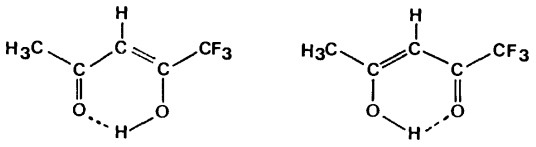


cis

equilibrium and the former is fluxional undergoing the head-to-tail coordinating atom exchange in solution.[19] On the other hand, the acac anions involved in $[Pt(acac\text{-}O)_2(PEt_3)_2]$[11] and $[Pt(acac\text{-}O)_2(piperidine)_2]$[4] have the cis configuration exclusively, exhibiting no fluxional motion. The cis configurations of acac in $[Cr(CO)_5\{PPh(acac\text{-}O)_2\}]$[14] and of hfac in [Cu(acac)(hfac-*O*)(phen)][13] were confirmed by X-ray analysis. The ^1H NMR spectrum of the present complex in $CDCl_3$ also indicated that the *O*-unidentate tfac ligand has the cis configuration[5] in contradiction with the present X-ray structure. The discrepancy between the structures in solution and a crystal can not be reasonably rationalized.

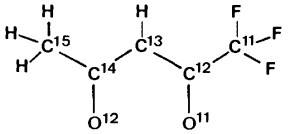
The *O*-unidentate tfac ligand should have a greater contribution from the structure $^-O\text{–}C(CH_3)\text{=}CH\text{–}C(CF_3)\text{=}O$, but no evidence for the π electron localization can be detected. Thus, although the C(12)–O(11) distance is shorter than the C(14)–O(12) distance (Table 2), it can not be the conclusive evidence for the π electron localization since (i) the thermal parameter is larger for O(11) than for O(12) and (ii) no significant difference exists between the C(12)–C(13) and C(13)–C(14) distances. On the contrary, the coplanar disposition of the O(12), C(14), C(15), C(13), C(12), and O(11) atoms is suggestive of some extent of π electron delocalization (Table 3). The nonbonded O(11)···C(15) distance (2.87(2) Å) is noteworthy, since it is considerably shorter than the value expected from the van der Waals radii of the components. Although the unidentate and bidentate tfac ligands differ in configuration, there is no remarkable difference between the corresponding structural parameters.

The enol tautomers of acacH[20] and hfacH[21] in gas phase were found by the electron diffraction method to have the planar symmetric hydrogen-chelate structure.[22] On the other hand, neutron diffraction data confirmed that the enol molecule of 1,3-diphenyl-1,3-propanedione has an asymmetric intramolecular hydrogen bond, the difference in the two O–H bond lengths being 0.199(17) Å.[25] The enol molecule of tfacH should certainly have an asymmetric hydrogen-chelate structure (A) or (B).



(A) (B)

Takeuchi and his collaborators compared the ^{13}C chemical shifts of the carbonyl carbons in tfacH in several solvents.[26] The intramolecular hydrogen bond retained in nonpolar solvents was supposed to be cleaved in dimethyl sulfoxide (DMSO-d_6) to form an intermolecular hydrogen bond. The signal from the carbonyl carbon adjacent to CH_3 showed a marked upfield shift (5.2 ppm) in DMSO-d_6 as compared with that in $CDCl_3$, while the chemical shift of the carbonyl carbon adjacent to CF_3 showed a minor difference (1.0 ppm) in these solvents. Based on this observation, Takeuchi *et al.* concluded that tfacH has structure (A) rather than (B) in nonpolar solvents.[26] If this structure assignment is correct, the proton affinity of the trifluoroacetyl oxygen (O(11)) must be higher than that of the acetyl oxygen (O(12)), and the tfac anion may be expected to be bound to a metal atom through O(11) when it serves as a unidentate ligand. The coordination mode found for the present complex is contrary to this expectation, the tfac anion being bound to palladium through O(12).



Coordination ability of the oxygen atom in a substituted 2,4-pentanedionate anion is enhanced with increase of the negative net charge on the donor atom, and also with increase of the square of AO coefficient at the oxygen in the σ-type HOMO. These values were calculated by the *ab initio* MO method with the STO-3G minimal base set and the results obtained are shown in Table 4. The negative net charge on either of oxygen atoms in the tfac anion is smaller than that in acac in accordance with higher acidity of tfacH than acacH.[28] In the tfac anion, both the negative charge and AO coefficient in the σ-type HOMO are larger on O(12) than on O(11), indicating that the coordination ability of the acetyl oxygen is higher than that of the trifluoroacetyl oxygen. These results are consistent with the unidentate structure of tfac in Pd^{II} and Pt^{II} complexes observed in crystals and solution.

Table 4. The net charge and AO coefficient in the σ-type HOMO at the oxygen atoms in the 2,4-pentanedionate and 1,1,1-trifluoro-2,4-pentanedionate anions of the *Z,Z*-form[a]

	Net charge on		AO coefficient in the σ-type HOMO at	
	O(11)	O(12)	O(11)	O(12)
acac	−0.374	−0.374	0.6577	0.6577
tfac	−0.346	−0.357	0.6179	0.6847

a) The following geometrical parameters[27] were used in the *ab initio* calculation for the tfac anion; bond lengths (Å): r(C(11)-C(12))=r(C(14)-C(15))=1.51, r(C(12)-C(13))=r(C(13)-C(14))=1.40, r(C(12)-O(11))=r(C(14)-O(12))=1.28, r(C(13)-H)=1.08, r(C(15)-H)=1.09, r(C(11)-F)=1.38; bond angles: CCC=CCO=HC(13)C=120°, HCH=FCF=109.47°

Solvent Effects on Dimerization of Copper(II) Decanoate in Alcohol Solvents

Hiromichi YAMADA,* Ryoji KITAZAKI, and Ikuo KAKIMI
Faculty of Engineering, Gifu University, 1-1, Yanagido, Gifu 501-11
(Received June 6, 1983)

The extraction of copper(II) with decanoic acid in some alcohol solvents was carried out at 25 °C and at 0.1 mol/dm³ ($NaClO_4$) aqueous ionic strength. Alcohols used are cyclohexanol, 1-pentanol, 1-hexanol, and 1-heptanol. In these solvents, monomeric and dimeric copper(II) decanoates are responsible for the extraction. Species involved in each organic phase are CuA_2, Cu_2A_4, and $Cu_2A_4(HA)_2$ (HA: decanoic acid). The dimerization and adduct formation of copper(II) decanoates in each organic phase are written as:

$$2CuA_2 \overset{K_{dim-1}}{\rightleftharpoons} Cu_2A_4$$

$$Cu_2A_4 + 2HA \overset{\beta_{ad,dim}}{\rightleftharpoons} Cu_2A_4(HA)_2$$

The following dimerization and adduct formation constants were obtained: $\log K_{dim-1} = 2.23$ and $\log \beta_{ad,dim} = 0.26$ for cyclohexanol, 2.26 and −0.03 for 1-pentanol, 2.77 and −0.04 for 1-hexanol, and 3.04 and −0.24 for 1-heptanol, respectively.

It is well-known that the dimeric copper(II) carboxylate involving free carboxylic acids, $Cu_2A_4(HA)_2$ is responsible for the extraction of copper(II) with aliphatic carboxylic acids in various inert solvents.[1-6] In the previous paper,[7] it has been shown that copper(II) is extracted with decanoic acid in several inert solvents as dimeric copper(II) decanoate, $Cu_2A_4(HA)_2$, and that the solvent effect on the extraction constants is interpreted in terms of the regular solution theory. In the subsequent paper,[8] the extracted species of copper(II) with decanoic acid in 1-octanol have been established to be not only the dimeric copper(II) decanoates(Cu_2A_4 and $Cu_2A_4(HA)_2$) but also the monomeric ones(CuA_2 and CuA_2HA). Also, the adduct formation and dimerization of copper(II) decanoates in 1-octanol have been mentioned.

The following solvent series, in which the formation of dimeric copper(II) carboxylates becomes more prominent, is reported: water, pyridine<methanol<ethanol, acetone, chloroform, benzene<carbon tetrachloride, dioxane<diethyl ether, and it is remarked that this solvent series can be discussed in terms of the dielectric constant of the solvents and the coordination power of the solvents to the metal or complex ion.[9]

The present paper describes the results of the extraction of copper(II) decanoates in several alcohol solvents. The solvent effect on the dimerization constant of copper(II) decanoate is interpreted in terms of the regular solution theory.

Experimental

Reagents. *Solvents*: 1-Pentanol, 1-hexanol, and 1-heptanol of reagent grade were washed successively first with dilute sodium hydroxide solution, secondly with dilute perchloric acid solution and thirdly with distilled water. Furthermore, they were purified by distillation and saturated with distilled water at 25 °C. Cyclohexanol of reagent grade was purified by distillation and saturated with distilled water at 25 °C.

Copper(II) perchlorate, sodium perchlorate, and decanoic acid were the same as presented previously.[8]

All other reagents were reagent grade and used without further purification.

Procedure. Experiments were carried out in the same manner as was stated in the previous report.[8]

Apparatus. The apparatus were similar to those previously used,[8] except for the use of Orion research microprocessor Ionalyzer 901(Orion Research Inc., U.S.A.) for the determination of hydrogen ion concentration in the aqueous phase.

Results and Discussion

Extraction Equilibrium. As previously described, if a j-merized copper(II) decanoate, $Cu_jA_{2j}(HA)_a$ is extracted into the organic phase, the extraction equilibrium can be expressed as follows:

$$jCu^{2+} + (2j+a)(HA)_o \rightleftharpoons (Cu_jA_{2j}(HA)_a)_o + 2jH^+$$

with the extraction constant:

$$K_{ex(ja)} = \frac{[Cu_jA_{2j}(HA)_a]_o[H^+]^{2j}}{[Cu^{2+}]^j[HA]_o^{(2j+a)}}, \quad (1)$$

where the subscript o refers to the organic phase.

Total concentration of copper in the organic phase, $C_{Cu,o}$ is represented as:

$$C_{Cu,o} = \sum_j \sum_a j[Cu_jA_{2j}(HA)_a]_o$$
$$= \sum_j \sum_a jK_{ex(ja)}[Cu^{2+}]^j[HA]_o^{(2j+a)}[H^+]^{-2j}. \quad (2)$$

It is expected from the results of the extraction of copper(II) with decanoic acid in 1-octanol that the monomer $CuA_2(HA)_a$ and the dimer $Cu_2A_4(HA)_p$ are both responsible for the present extraction systems. Then, the following equation can be derived from Eq. 2:

$$\log C_{Cu,o} - (\log C_{Cu,w} - 2\log[H^+]) = \log K_{ex(1a)} + (2+a)\log[HA]_o + \log\left(1 + \frac{2K_{ex(2p)}}{K_{ex(1a)}}[HA]_o^{(2+p-a)}C_{Cu,w}[H^+]^{-2}\right), \quad (3)$$

where the subscript w refers to the aqueous phase, and $K_{ex(1a)}$ and $K_{ex(2p)}$ represent the extraction constants of the monomer $CuA_2(HA)_a$ and the dimer $Cu_2A_4(HA)_p$, respectively. Then, by comparing the plot of the values of the left-hand side of Eq. 3 against ($\log C_{Cu,w}$—$2\log[H^+]$) at constant $[HA]_o$ with the

normalized curve, $\log(1+X)$ *vs.* $\log X$, we can check the degree of polymerization of the extracted species. The result obtained for 1-hexanol is shown in Fig. 1. As expected, it was proved that the monomeric and dimeric copper(II) decanoates were responsible for the extraction in which 1-hexanol was used as a diluent. For the other alcohols used the same results were obtained.

In the region where the monomer prevails, Eq. 2 is simplified to:

$$\log C_{Cu,o} - (\log C_{Cu,w} - 2\log[H^+]) = \log \sum_a (K_{ex(1a)}[HA]_o^{(2+a)}). \quad (4)$$

According to Eq. 4, we can find the number of decanoic acid molecules involved in the monomer from the slope of the plots of $\{\log C_{Cu,o} - (\log C_{Cu,w} - 2\log[H^+])\}$ against $\log[HA]_o$. The result for 1-hexanol is illustrated in Fig. 2. As evident from Fig. 2, the plot fits well a straight line with a slope of two, that is, $2+a=2$ or $a=0$. The same results were obtained for the other solvents. Consequently, the composition of the monomeric copper(II) decanoate is CuA_2 irrespective of the solvent. The monomeric species CuA_2HA for 1-octanol[8] is not extracted to any appreciable extent in these extraction systems. The extraction constant $K_{ex(10)}$ of the monomer can be determined from Eq. 4($a=0$). The values obtained for the respective solvent are summarized in Table 1 together with the other constants. The previous results for 1-octanol are also included in Table 1 for comparison.

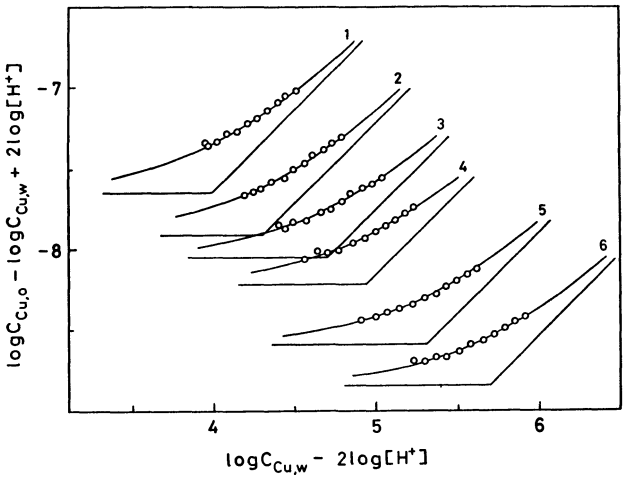

Fig. 1. The identification of the degree of polymerization of Cu(II) decanoates.
Solid curves are the normalized curves, $\log(1+X)$ *vs.* $\log X$. Solid lines are the asymptotes of the normalized curves. C_{HA}; No. 1: 2.0, No. 2: 1.5, No. 3: 1.25, No. 4: 1.0, No. 5: 0.7, No. 6: 0.5 mol/dm^3. Solvent: 1-hexanol.

On the other hand, in the region where the predominant extracted species are the dimer, that is, the plots shown in Fig. 1 fit with the straight line asymptotes with a slope of unity, the following expression is derived from Eq. 2:

$$\log C_{Cu,o} - 2(\log C_{Cu,w} - 2\log[H^+]) = \log 2\sum_p (K_{ex(2p)}[HA]_o^{(4+p)}). \quad (5)$$

According to Eq. 5, the slope of the plot of the left-hand side of Eq. 5 against $\log[HA]_o$ gives the number of decanoic acid molecules involved in the dimeric species. The results for 1-hexanol are shown in Fig. 3. As evident from Fig. 3, at least two dimeric copper(II) decanoates with the different number of decanoic acid molecules are responsible for the extraction. At lower concentration of decanoic acid in the organic phase, the plot is close to a straight line with a slope of 4.0. Therefore, one of the dimers is certainly Cu_2A_4 ($p=0$ in Eq. 5). In addition, the slope of the plot described above gets steeper with the concentration of decanoic acid in the organic phase. It is suggested that another dimer $Cu_2A_4(HA)_p$ ($p \geqq 1$) is responsible for the extraction at higher $[HA]_o$. Then, in the region where the dimer predominates, the fol-

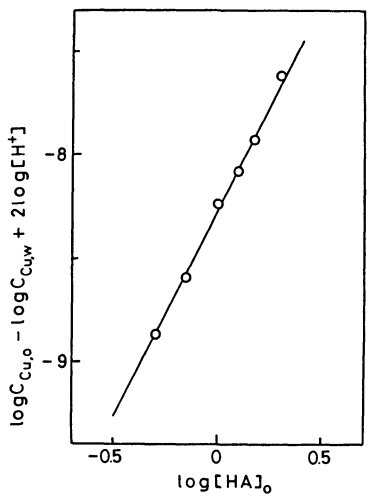

Fig. 2. Determination of the number of decanoic acid molecules involved in the monomeric Cu(II) decanoate.
Solid line is the straight line with a slope of 2.0. Solid line is the straight line with a slope of 2.0. Solvent: 1-hexanol.

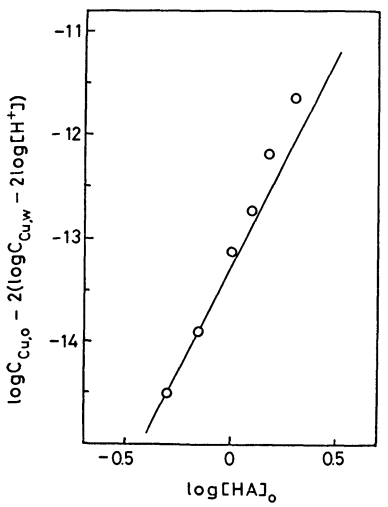

Fig. 3. Determination of the number of decanoic acid molecules involved in the dimeric Cu(II) decanoates.
Solid line is the straight line with a slope of 4.0. Solvent: 1-hexanol.

lowing expression can be written from Eq. 2:

$$C_{Cu,o} = 2([Cu_2A_4]_o + [Cu_2A_4(HA)_p]_o)$$
$$= 2K_{ex(20)}[Cu^{2+}]^2[HA]_o^4[H^+]^{-4} \times\left(1+\frac{K_{ex(2p)}}{K_{ex(20)}}[HA]_o^p\right), \quad (6)$$

which is rewritten as a logarithmic form:

$$\log C_{Cu,o} - 2(\log C_{Cu,w} - 2\log[H^+]) - 4\log[HA]_o$$
$$= \log\left(1+\frac{K_{ex(2p)}}{K_{ex(20)}}[HA]_o^p\right) + \log K_{ex(20)} + \log 2, \quad (7)$$

where $K_{ex(20)}$ and $K_{ex(2p)}$ represent the extraction constants of Cu_2A_4 and $Cu_2A_4(HA)_p$, respectively. Compared the plot of $\{\log C_{Cu,o} - 2(\log C_{Cu,w} - 2\log[H^+]) - 4\log[HA]_o\}$ *vs.* $\log[HA]_o$ with the normalized curves, $\log(1+X^n)$ *vs.* $\log X$, we find the composition of another dimeric copper(II) decanoate. The result for 1-hexanol is shown in Fig. 4. Figure 4 shows that the plot fits well the normalized curve, $\log(1+X^2)$ *vs.* $\log X$, that is, $p=n=2$. Thus, we have $Cu_2A_4(HA)_2$ together with Cu_2A_4 in the organic phase. From Fig. 4 we can also obtain the respective extraction constants, $K_{ex(20)}$ and $K_{ex(22)}$ by fitting the normalized curve to the observed values. In a similar manner as above, it was found that the same dimeric copper(II) decanoates as just described were responsible for the other extraction systems in which 1-heptanol, 1-pentanol, and cyclohexanol were used as solvents.

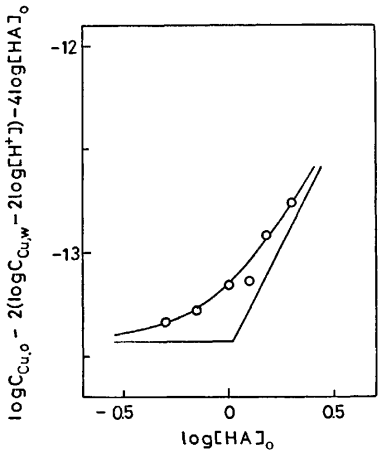

Fig. 4. Determination of the number of decanoic acid molecules involved in the dimeric Cu(II) decanoates by the curve fitting method.
Solid curve is the normalized curve, $\log(1+X^2)$ *vs.* $\log X$. Solid lines are the asymptotes of the normalized curve. Solvent: 1-hexanol.

Consequently, we conclude that the extraction equilibria for the present extraction systems are described as follows:

$$Cu^{2+} + 2(HA)_o \overset{K_{ex(10)}}{\rightleftharpoons} (CuA_2)_o + 2H^+,$$
$$2Cu^{2+} + 4(HA)_o \overset{K_{ex(20)}}{\rightleftharpoons} (Cu_2A_4)_o + 4H^+,$$
$$2Cu^{2+} + 6(HA)_o \overset{K_{ex(22)}}{\rightleftharpoons} (Cu_2A_4(HA)_2)_o + 4H^+.$$

The corresponding extraction constants are summarized in Table 1.

Then, the adduct formation and dimerization of copper(II) decanoates in these alcohol solutions can be described as follows:

$$Cu_2A_4 + 2HA \overset{\beta_{ad,dim}}{\rightleftharpoons} Cu_2A_4(HA)_2,$$
$$2CuA_2 \overset{K_{dim-1}}{\rightleftharpoons} Cu_2A_4.$$

The corresponding adduct formation and dimerization constants can be calculated from the respective extraction constants for each solvent. The results obtained are summarized in Table 1 together with the extraction constants.

Solvent Effects on the Dimerization of Copper(II) Decanoate in the Alcohol Solutions. According to the regular solution theory,[10] the activity of a solute A in a solvent S can be approximated in a dilute solution by the following equation:

$$\ln a_A = \ln \phi_A + \ln(V_s/V_A) + V_A(\delta_s-\delta_A)^2/RT, \quad (8)$$

where ϕ, V, and δ refer to the volume fraction, the molar volume and the solubility parameter, respectively. The molar concentration of a solute A is written as:

$$[A] = 1000\phi_A/V_A. \quad (9)$$

From Eqs. 8 and 9, the following expression can be derived:

$$\log a_A = \log[A] + \log V_s + 0.43V_A(\delta_s-\delta_A)^2/RT - 3. \quad (10)$$

The dimerization constant of copper(II) decanoate,

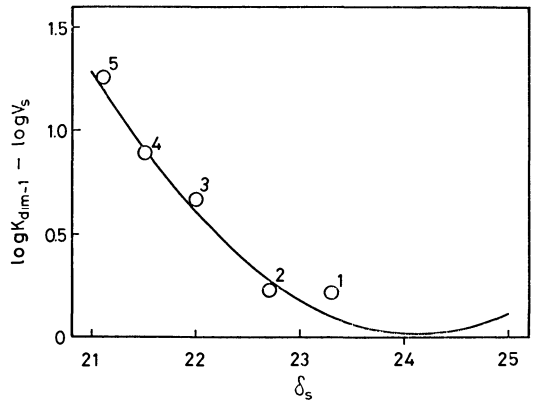

Fig. 5. Estimation of the solubility parameter of Cu(II) decanoate.
Solid line is the calculated curve of the second order with respect to δ_s on the basis of Eq. 12. No. 1: Cyclohexanol, No. 2: 1-pentanol, No. 3: 1-hexanol, No. 4: 1-heptanol, No. 5: 1-octanol.

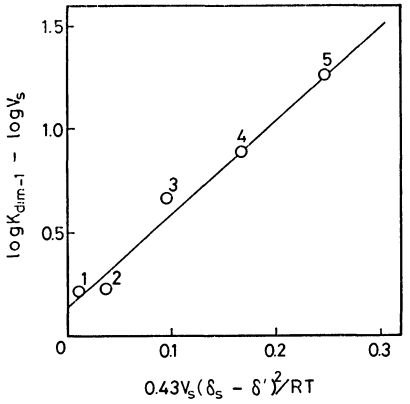

Fig. 6. Correlation of the dimerization constant of Cu(II) decanoate with the solubility parameter of solvents.
Solid line is the straight line with a slope of 4.5. $\delta'=24.1$ ($J^{1/2}/cm^{3/2}$). Numbers are the same as in Fig. 5.

K_{dim-1} is given as follows:

$$\log K_{dim-1} = \log K_{dim-1}^{\circ} + \log \frac{(f_{CuA_2})^2}{f_{Cu_2A_4}}, \qquad (11)$$

where K_{dim-1}° denotes the dimerization constant of copper(II) decanoate in an ideal solution and f's are the activity coefficients of the monomeric and dimeric copper(II) decanoates. If the monomeric and dimeric copper(II) decanoates have the same solubility parameter, we can obtain the following expression from Eq. 10:

$$\log K_{dim-1} - \log V_s = 0.43nV_s(\delta_s-\delta')^2/RT + \log K_{dim-1}^{\circ} - 3, \qquad (12)$$

where n denotes the number of solvent molecules set free in the dimerization of copper(II) decanoate, that is, $nV_s=2V_{CuA_2}-V_{Cu_2A_4}$, and $\delta'=\delta_{CuA_2}=\delta_{Cu_2A_4}$. Although the value of V_s in Eq. 12 varies from solvent to solvent, that of ($\log K_{dim-1}-\log V_s$) can be approximately related to the second order with respect to δ_s. Then it is expected that the value of ($\log K_{dim-1}-\log V_s$) is minimized at $\delta_s=\delta'$. This relationship between ($\log K_{dim-1}-\log V_s$) and δ_s is illustrated in Fig. 5. In Fig. 5, the plot was extrapolated as smooth as possible to find the value of δ', and resulted in $\delta'=24.1$ ($J^{1/2}/cm^{3/2}$). Further, according to Eq. 12, the plot of ($\log K_{dim-1}-\log V_s$) *vs.* $0.43V_s(\delta_s-\delta')^2/RT$ should yield a straight line with a slope of n. As expected, the validity of Eq. 12 is demonstrated in Fig. 6. The values of n and $\log K_{dim-1}^{\circ}$ were calculated to be 4.5 and 3.14, respectively, by the least squares method. Therefore, it is suggested that 4 to 5 molecules of solvent are liberated in the dimerization of copper(II) decanoate.

The authors wish to thank Professor Motoharu Tanaka of Nagoya University for his valuable discussion, and Professor Masateru Mizuta and Dr. Yukio Fujii of Gifu University for their interests in this work.

Selective α-Monoalkylation of Phenylacetonitrile Using Alkali Metal Hydroxide Impregnated on Alumina

Kazuaki SUKATA

Nihon Tokushu Kagaku Kogyo Co., Ltd., 3-36, Tohda-cho, Moriguchi, Osaka 570

(Received January 26, 1983)

In the alkylation of phenylacetonitrile with alkyl halides, alkali metal hydroxides impregnated on alumina act as efficient bases for selective α-monoalkylation in benzene. It is proposed that the reaction may take place exclusively in the pore. The selectivity for α-monoalkylation is explained in terms of steric hindrance.

In recent years, processes using inorganic solids have been rapidly developed for organic syntheses.[1] The unique effectiveness of inorganic solids may be due to their large effective surface area, the presence of pores, and the adsorption of reactants.

This paper describes results of the following selective α-monoalkylation of phenylacetonitrile (PAN) with alkyl halides on a chromatographic-grade alumina impregnated with sodium or potassium hydroxide (NaOH/Al_2O_3 or KOH/Al_2O_3):

$$PhCH_2CN + RX \xrightarrow{\text{base}} PhCHRCN + PhCR_2CN. \quad (1)$$

Results and Discussion

In order to elucidate the effect of supports, the alkylation of PAN with ethyl bromide in the presence of different supports impregnated with KOH was carried out in benzene. Table 1 shows the results. The reactivity of KOH/Al_2O_3 was extremely high in comparison with the other solid suppotrs examined and its selectivity for α-monoalkylation was also high. The pore size of Al_2O_3[2] is much larger than those of Mc-lecular Sieves.[3] The surface area of Celite is very small in comparison with those of the other supports. These facts and the present findings suggest that the reaction of $[PhC\bar{H}CN]^-$ or $[PhC\bar{R}CN]^-$ with alkyl halide may take place predominantly in the pore, so that the reactivity of the impregnated KOH may be ascribed to the pore size of the support. The present findings can be interpreted as follows: The pore size of Al_2O_3 is suitable for the reaction,[4] whereas those of Molecular Sieves are too small. In the case of Celite, the reaction is very slow probably because of its small surface area.[5]

Table 1. Alkylation of PAN with ethyl bromide using KOH impregnated on several supports[a]

Support		Yield[b]/% Mono	Di
Molecular Sieve 5A	(60—80 mesh)	<1	—
	(powder)	<1	—
13X	(60—80 mesh)	<1	—
	(powder)	<1	—
Celite[c]	(powder)	3.5	—
Al_2O_3	(70—230 mesh)	91	4

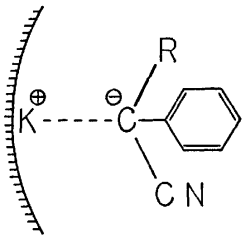
a) Unless otherwise noted, reactions were carried out with KOH (75 mmol)/support (20 g), PAN (10 mmol), ethyl bromide (12 mmol), and benzene (30 mmol) as a solvent at 40 °C for 4 h. b) Determined by GLC with dodecane as an internal standard. c) Fifteen grams of Celite and 40 ml of benzene were used.

Table 2. Alkylation of PAN with ethyl bromide using KOH/Al_2O_3 in several solvents[a]

Solvent	Reaction time/h	Yield[b]/% Mono	Di
Acetonitrile	0.5	69	23
THF	2.0	81	12
Dioxane	2.0	83	4
	4.0	84	6
Benzene	4.0	91	4

a) All reactions were carried out with KOH (75 mmol)/Al_2O_3 (15 g), PAN (10 mmol), ethyl bromide (12 mmol), and a solvent (15 ml) at 40 °C. b) Determined by GLC with dodecane as an internal standard.

In order to reveal the effect of solvents, the alkylation of PAN with ethyl bromide was carried out using KOH/Al_2O_3 in several solvents. Table 2 shows the results. The order of rates of the reaction was acetonitrile > tetrahydrofuran > dioxane ≈ benzene. On the contrary, the order of the selectivities for α-monoalkylation was benzene>dioxane>tetrahydrofuran> acetonitrile. In a nonpolar solvent such as benzene, $[PhC\bar{R}CN]^-$ formed would be strongly adsorbed onto the wall of the pore as the carbanion is directed toward K^+:



Consequently, the reaction of $[PhC\bar{R}CN]^-$ with the second alkyl halide will be strongly sterically hindered On the other hand, polar solvents would weaken the degree of the interaction, decreasing the degree of the steric hindrance. Also, the reaction in the bulk organic phase should not be ignored when polar solvents are employed.

The influence of the molecular size of alkylating agent was examined by use of the alkylation of PAN with various alkyl halides using KOH/Al_2O_3 or NaOH/Al_2O_3 in benzene. Table 3 summarizes the results. In a phase-transfer alkylation[6] using aqueous alkali

	s-C_4H_9Br	7	40	69	≈0
$NaOH/Al_2O_3$	C_2H_5Br	4	40	90	1
	C_2H_5Br[c]	4	40	55	≈0
	C_2H_5I	4	40	64	≈0
	n-C_3H_7Br	6	40	82	≈0
	n-C_3H_7Br[c]	6	40	47	≈0
	n-C_3H_7I	6	40	68	≈0
	n-C_4H_9Br	6	40	79	≈0
	n-C_4H_9Br[c]	6	40	48	≈0
	n-C_4H_9I	6	40	55	≈0

a) All reactions were carried out with KOH or NaOH (75 mmol) / Al_2O_3 (15 g), PAN (10 mmol), alkyl halide (12 mmol), and benzene (15 ml) as a solvent. b) Determined by GLC with dodecane as an internal standard. c) Water was added to NaOH in 15% by weight.

metal hydroxide as a base, formation of *ca.* 10% of α,α-dialkylated products has been unavoidable under a similar molar ratio of alkyl halide to PAN. The alkylation using KOH/Al_2O_3 or $NaOH/Al_2O_3$ gave rapidly and exclusively α-monoalkylated products. In the case of $NaOH/Al_2O_3$, the addition of *ca.* 15% by weight of water to NaOH resulted only in slowing down the reaction. In regard to the selectivity for α-monoalkylation, however, $NaOH/Al_2O_3$ was better than KOH/Al_2O_3. When KOH/Al_2O_3 was employed, the reaction with alkyl iodides was faster than that with alkyl bromides. In contrast to KOH/Al_2O_3, the reaction with alkyl iodides was slower than that with alkyl bromides when $NaOH/Al_2O_3$ was employed. Since the ionic radius of Na^+ is smaller than that of K^+, Na^+ may attract the carbanion formed more closely to the wall of the pore than K^+, increasing to a greater extent the degree of the steric hindrance against the reaction of the carbanion with alkyl halide. It can also be explained in terms of the steric hindrance that the increase in the bulkiness of alkyl groups raises the selectivity for α-monoalkylation. In general, alkyl iodide is slightly better than alkyl bromide with respect to the selectivity for α-monoalkylation. Since alkyl iodide is bulkier than the corresponding alkyl bromide, alkyl iodide would be more sterically hindered than alkyl bromide for the reaction with $[PhC\bar{R}CN]^-$, giving a small amount of α,α-dialkylated product.

Experimental

Materials. Unless otherwise stated, all reagents were obtained commercially and dried with Molecular Sieve 4A. Alumina (Merck Ltd. Type 90 for column chromatography, activity I, 70—230 mesh), Molecular Sieves (for gas chromatography), Celite (for column chromatography), 85% KOH, and NaOH were also obtained commercially and used as obtained.

Impregnation of Alkali Metal Hydroxide on Inorganic Supports. An inorganic support was added to an aqueous alkali metal hydroxide, and the water was removed under reduced pressure at 50 °C. The impregnated reagent was further dried under vacuum (0.1 mmHg)(1 mmHg=133.322 Pa) at 90 °C for 1 h. By this procedure, the NaOH impregnated became nearly anhydrous. However, the KOH impregnated contained *ca.* 15% by weight of water. After the drying of the impregnated reagent for further 7 h, almost no decrease in its weight could be observed.

Typical Procedure for Alkylation of PAN. All the products were known compounds and identified by comparing GLC retention times with those of authentic samples prepared by the literature procedures.[6] A typical procedure is as follows: A mixture of KOH/Al_2O_3 (20.0 g) obtained from 85% KOH (5.0 g, 75 mmol) and Al_2O_3 (15.0 g), PAN (10 mmol), ethyl bromide (12 mmol), and benzene (15 ml) as a solvent was heated at 40 °C for 4 h with vigorous stirring. The yields of α-mono- and α,α-dialkylated products were determined by GLC with dodecane as an internal standard.

The author thanks Nihon Tokushu Kagaku Kogyo Co., Ltd. for permission to publish this article, and also Dr. Nobuaki Wada for useful suggestions during this work.

Lett.*, **1982**, 651; S. Tamagaki, K. Suzuki, and W. Tagaki, *ibid.*, **1982**, 1237.

2) According to Regen *et al.*, the average pore diameter of neutral alumina is 40 Å (80% being<120 Å): S. L. Regen, S. Quici, and M. D. Ryan, *J. Am. Chem. Soc.*, **101**, 7629 (1979).

3) The pore diameters of Molecular Sieves 5A and 13X are 5 and 10 Å, respectively.

4) The impregnated reagent was washed with water until almost all the alkali was recovered and then the amount of the eluted aluminium ion was determined to be *ca.* 4 mol% to the alkali used by the chelatometry using EDTA. This result indicates that the destruction of the pore structure of Al_2O_3 by concentrated aqueous alkali and the action of alkali metal aluminate as the base can be practically ignored under the present experimental conditions.

5) An alternative explanation is as follows. The KOH impregnated on Celite which is an acidic solid support might be neutralized and consequently the reactivity of KOH/Celite might be weakened.

Pressure Dependence of Carboxypeptidase A Action

Mitsuhiro FUKUDA, Shigeru KUNUGI,* and Norio ISE

Department of Polymer Chemistry, Kyoto University, Sakyo-ku, Kyoto 606

(Received February 21, 1983)

The effect of pressure on the peptide hydrolysis by carboxypeptidase A and its inhibition by several substrate-analogs were investigated. The activation volumes for k_{cat} were -4 and -8 ml mol^{-1} for the hydrolysis of 3-(2-furyl)acryloyl–Gly–L-Phe and 3-(2-furyl)acryloyl–L-Phe–L-Phe, respectively. The reaction volumes for the binding process (ΔV_{ass}) for these dipeptide substrates and for the competitive inhibitors of the peptide hydrolysis (peptide-like inhibitors), such as Gly–L-Tyr and L-Phe, were about 30 ml mol^{-1}. In contrast, ΔV_{ass} values for 3-phenyllactate and L-mandelate, both of which are classified as the noncompetitive inhibitors for the peptide hydrolysis (ester-like inhibitors), were comparably small, 5 and 6 ml mol^{-1}, respectively. Furthermore the pressure dependence of the inhibition by D-Phe or D-mandelate was largely different from that of the corresponding L-form; namely ΔV_{ass} for D-Phe was 4 ml mol^{-1} and that for D-mandelate was 21 ml mol^{-1}. The pH dependence of the inhibition constant was classified into two groups; Gly–L-Tyr and L-Phe inhibited more strongly at higher pH while 3-phenyllactate and others did more effectively at lower pH. Taking into account the previously published result of the X-ray crystallographic studies (*e. g.*, J. A. Hartsuck and W. N. Lipscomb, "The Enzymes," 3rd ed, ed by P. D. Boyer, Academic Press, New York (1971), Vol. 3, p. 1), the present results were accounted for in terms of two different (electrostatic) interactions between the substrate or inhibitor and the active site of the enzyme.

The activation volumes or reaction volumes evaluated from the pressure dependence of chemical reactions often reflect the differences in the reaction mechanisms.[1] These parameters also provide important information on enzyme reaction,[2] as shown by the recent examinations of trypsin[3] or α-chymotrypsin catalysis.[4] By measuring the pressure dependence of enzyme reaction under appropriate experimental conditions, we can obtain the information on volumetric changes occurring in the reaction process, such as those due to changes in charge and bond states at the active site, higher-order structure of protein molecule and the hydration of the enzyme and the substrate. In the present study, we examined pressure dependence of peptide hydrolysis and the binding of several kinds of substrate analogs in bovine carboxypeptidase A (CPA). CPA is a representative zinc-containing metallo-protease, and various kinds of studies, such as primary and three dimensional structures,[5,6] metal substitution,[7,8] chemical modification,[9,10] and cryoenzymolozy,[11] have been carried out to reveal the role of the zinc together with that of other functional amino acid residues in the active site. However, due to the apparent complexities in its catalytic behavior toward peptides and esters or their analogs,[12] the detailed functional roles of these groups and the mode of catalytic functions are still ambiguous. Above all, the multiple binding of the substrate or inhibitor and a difference in the peptidase and esterase actions have prevented the straightforward interpretation of the kinetic data of this enzyme. In order to know much more details of the mechanism, especially to differentiate the mechanisms of the two kinds of enzyme activities, we measured the pressure dependence of kinetic parameters and inhibitory actions for several substrates and inhibitors.

Experimental

Materials. Bovine carboxypeptidase A (Cox) was purchased as an aqueous suspension with toluene preservative from Sigma Chemical Co., (St. Louis, Missouri, USA) (lot 119c8030). It was washed three times with cold deionized water followed by centrifugation and finally dissolved in 0.05 M Hepes buffer containing 1 M NaCl (1 M=1mol dm^{-3}). The enzyme concentration was determined spectrophotometrically at 25 °C, using ε=64200 at 280 nm.[13] 3-(2-Furyl)acryloylglycyl-L-phenylalanine (FuaGlyPhe), FuaGlyLeu and FuaPhePhe were synthesized according to the method in the literature.[14] FuaGlyPhe; mp 184—185 °C, Found; C, 62.93; H, 5.30; N, 8.12%. Calcd for $C_{18}H_{18}N_2O_5$: C, 63.15; H, 5.26; N, 8.18%. FuaGlyLeu; mp 202—204 °C, Found; C, 58.58; H, 6.56; N, 9.04%. Calcd for $C_{15}H_{20}N_2O_5$: C, 58.44; H, 6.49; N, 9.09%. FuaPhePhe; mp 203—205 °C, Found; C, 66.88; H, 5.87; N, 6.22%. Calcd for $C_{25}H_{24}O_5N_2\cdot H_2O$: C, 66.65; H, 5.82; N, 6.22%. Thinlayer chromatography on Kieselgel 60E (E. Merck, Darmstadt, West Germany) using chloroform–methanol–acetic acid (20:1:1) and/or 1-butanol–acetic acid–water–pyridine (15:10:12:3) showed a single UV quenching spot for each substrate. Inhibitors used were as follows ; Gly-L-Tyr, L-Phe, ZPhe (Protein Research Foundation, Osaka), L-2-hydroxy-3-phenylpropionic acid (3-phenyllactate), L-mandelate, D-mandelate (Aldrich, Milwaukee, Wisconsin, USA), 3-phenylpropionate, D-Phe (Wako Pure Chemicals, Osaka), L-Phe–L-Phe (Vega, Tucson, Arizona, USA). Good's buffers ; Mes, Hepes, and Taps were from Dojin Chem. Lab. (Kumamoto).

Methods. The rate of substrate hydrolysis was measured by following the absorbance change at around 340 nm due to the scission of the *C*-terminal peptide bond of Fua substituted amino acid, analogous to the case of thermolysin.[15,16] The difference extinction coefficient at 340 nm was determined as 870 (M^{-1} cm^{-1}) for FuaPhePhe and 830 (M^{-1} cm^{-1}) for FuaGlyPhe. An ultraviolet-visible spectrophotometer with a Drickamer type high pressure optical cell was used as previously described.[3] When the kinetics seem to follow a simple Michaelis-Menten scheme including only a competitive product inhibition, the steady-state rate expression is given by

$$v = -\mathrm{d}[S]/\mathrm{d}t = k_{cat}[E][S]/(K_m(1+([S]_0-[S])/K_p)+[S]), \quad (1)$$

where t is time, $[S]_0$ is the initial substrate concentration, [S] is the substrate concentration at time t, K_p is the product inhibitory constant and k_{cat} and K_m have their usual meanings.

In order to measure the second order rate constant (k_{cat}/

K_m), the substrate concentration is set sufficiently low with respect to both K_m and K_p, and Eq.1 is reduced to

$$v = -d[S]/dt = k_{cat}[E][S]/K_m. \quad (2)$$

In our experimental conditions, 0.03—0.05 mM FuaGlyPhe, Eq.2 is always satisfied (see results). The observed k_{cat}/K_m from the pseudo-first-order conditions (Eq. 2) is about 98% (pH 5—8), 95% (pH8—9), and 93% (pH above 9) confidence level. K_i values were measured under the condition of $[S]_0 \ll K_m$, K_p, where we cannot distinguish competitive and noncompetitive modes and therefore the inhibition constant was obtained from Eq. 3.

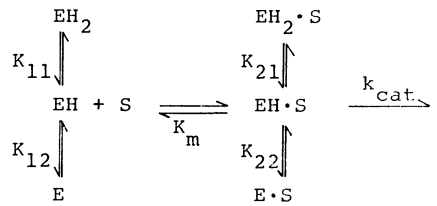
$$1 + [I]/K_I = (k_{cat}/K_m)_{[I]=0}/(k_{cat}/K_m)_{app}. \quad (3)$$

In the study of pH dependence, 0.05 M Hepes, 0.05 M Taps or 0.02 M Mes containing 0.33 M NaCl was used. At such a concentration the buffer dependence of the reaction was not significant.

The pressure dependence of pH of these buffers was examined according to the method of Neuman *et al.*[17] Hepes, Taps and Mes were rather pressure independent as was the case with Tris–HCl. The pH value given in this paper is the corrected one for the pressure dependence. Pressure dependence of K_i was measured in Hepes buffer at 270, 500, 750, and 1000 atm against the hydrolysis of FuaGlyPhe. In the case of L-Phe, FuaGlyLeu was also used as the substrate to avoid the influence of the product inhibition by L-Phe produced from FuaGlyPhe, since the K_p of L-Phe becomes markedly low at pH above 8, as shown in the results section. The change in the concentration of the solute in the solution under high pressure was corrected as previously reported.[3] The nonlinear regressions were carried out following the principle given in the literature.[18]

Results

Kinetic Parameters. First we examined the effect of pressure on the acid-base equilibria of the enzyme active site (Fig. 1) by using pseudo-first-order rate measurement with a substrate of poor K_m values (FuaGlyPhe). The pH dependence of k_{cat}/K_m at 25 °C, 1 atm showed a bell-shaped profile, as was previously reported for the hydrolysis of tripeptide substrate.[19] Under 1000 atm, though the activity was lower by a factor of three than that at 1 atm, a similar simple bell-shaped pH profile was obtained. By increasing pressure, the pK_{a1} shifted toward lower pH (from 6.04 to 5.72) and pK_{a2} changed in the same direction to a less extent (from 9.10 to 8.98). Though, in general, there can be a number of factors which may complicate the pH dependence of the enzyme and several mechanisms which can fit the result obtained, the simplest mechanism to explain these pH dependences is as follows:



Scheme 1. K_{ij} means the proton dissociation constant for each species.

Then the observed two pK_a's are corresponding to the acid-base equilibria of the free enzyme (K_{11}, K_{12}), which shifted to the deprotonated state with an increase in pressure. We can estimate ΔV values for these deprotonation processes from the pK_a shifts; 18±5 ml mol^{-1} for pK_{a1} and 6±3 ml mol^{-1} for pK_{a2}. The following measurement under high pressure, therefore, was carried out at pH around 7 to minimize the influence from these pK_a shifts. FuaGlyPhe showed a substrate activation at high substrate concentration as shown in Fig. 2-a, similar to some other dipeptide

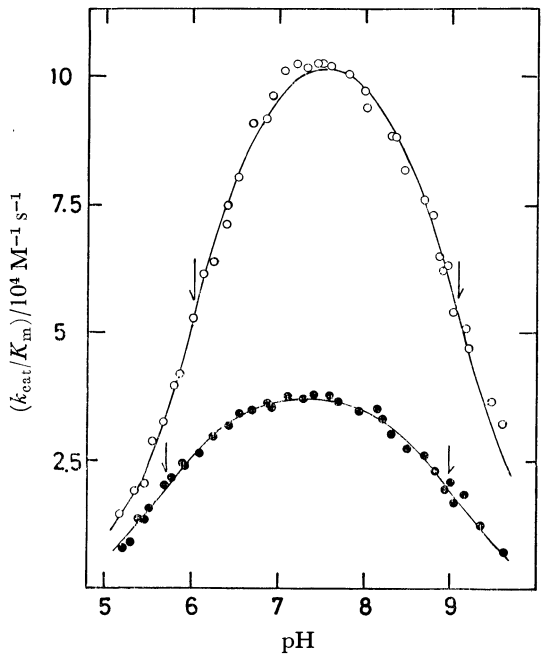


Fig. 1. The pH dependence of k_{cat}/K_m for FuaGlyPhe hydrolysis, (○) 1 atm, (●) 1000 atm. [FuaGlyPhe]=0.03—0.05 mM, [E]=(1—3)×10^{-7} M, 25 °C. 0.02 M Mes (pH 5.2—7.2), 0.05 M Hepes (pH 6.5—8.2), 0.05 M Taps (pH 7.5—9.5), NaCl 0.5 M. Arrows indicate the position of pK_a.

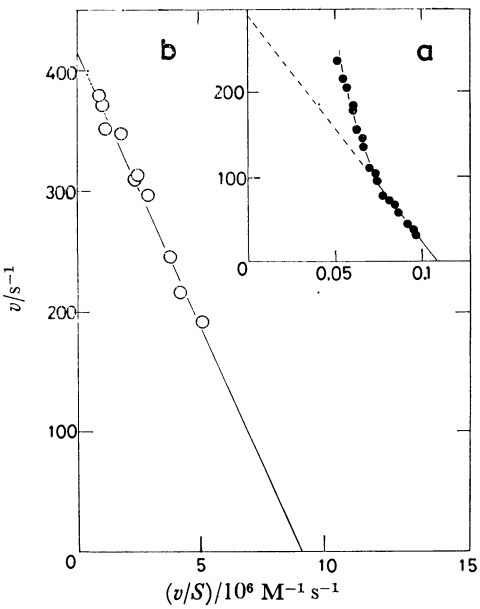

Fig. 2. Eadie plots for hydrolysis of FuaGlyPhe (a), and FuaPhePhe (b). 0.05 M Hepes, 0.33 M NaCl, pH 7.35, 25 °C.

substrates reported in the literature.[20] On the contrary, FuaPhePhe did exhibit neither substrate activation nor substrate inhibition within the concentration range studied here and its reactivity was considerably high (Fig. 2-b).

The hydrolytic rate of Fua–Phe was found to be very slow and its contribution was safely neglected in the interpretation of the observed rate process for FuaPhePhe. Table 1 shows k_{cat}, K_m, and k_{cat}/K_m at different pressures. The logarithms of these parameters were in linear relations with pressure and the activation and reaction volumes given in this paper were calculated at 1 atm.

The temperature dependence of k_{cat} and K_m was also studied for FuaPhePhe between 10 to 35 °C (in 0.05 M Hepes, 0.33 M NaCl pH 7.3). The thermodynamic parameters calculated are; $\Delta H^* = 8.0$ kcal mol^{-1} (1 cal=4.184 J) and $\Delta S^* = -20$ cal deg^{-1} mol^{-1} for k_{cat} and $\Delta H = 1.7$ kcal mol^{-1} and $\Delta S = 25$ cal deg^{-1} mol^{-1} for K_m^{-1}. The ΔH_{a1} value for pK_{a1} obtained from the temperature dependence of the pH profile of k_{cat}/K_m was about 4 kcal mol^{-1} for FuaGlyPhe hydrolysis.

Inhibition Constants. Figure 3 shows the pH dependence of the inhibition constants for various inhibitors. In order to prevent the complex multiple binding of these inhibitors on CPA,[21] the concentration of inhibitors were set below 1.5 fold of K_i over the whole range of pH examined. Under this condition, the [I] *vs.* [I]/K_i plot gave straight lines. As shown in Figs. 3-a and 3-b, K_i of GlyTyr, L-Phe and D-Phe increased as the pH became lower, and for GlyTyr, K_i showed a minimum at pH 8.5. On the contrary, the K_i values of 3-phenyllactate, L-madelate (Fig. 3-c), D-mandelate, 3-phenylpropionate and ZPhe (3-d) increased with pH increase. The profile of the last three were quite similar but the first two showed

some characteristic features.

We note that the inhibitors of zwitter-ion type showed K_i decreasing with increasing pH while those having only carboxylate as the ionic residue showed K_i increasing with increasing pH. This classification is similar to that observed in the inhibitor interaction with thermolysin.[16] The fundamental feature of the pH dependence of the K_i of these zinc proteases, therefore, seems to be determined by the relation of the net charges of the inhibitor and the active site of the enzyme in both instances.

The pressure dependence of K_i was measured at pH around 7 (Table 2). Though, for some inhibitors which do not show maxima or minima around this pH, the measured pressure dependences involve influences

Table 2. Reaction volumes and inhibition constants of several substrate analogs[a]

Inhibitor	ΔV_{ass}/ml mol^{-1} [b]	$K_i/10^{-4}$ M

from the pK_a shifts of the residues which control the binding process of these inhibitors, the logarithm of the observed K_i values were in good linear relations to pressure as shown in Fig. 4. Inhibitors of CPA have been grouped into two; one such as GlyTyr acts competitive towards peptidase activity[20] and the other such as 3-phenylpropionate acts noncompetitive towards peptidase but competitive towards esterase.[7,20] By considering the structure of the inhibitors presently used and the inhibition studies on the related substances,[21,22] we understand that PhePhe, ZPhe and L-Phe fall in the former category (peptide-like inhibitors) while 3-phenyllactate and L-mandelate do in the latter (ester-like inhibitors). For the apparent reaction volumes of the formation process of the complex (ΔV_{ass}) we notice that the former group gave considerably large values, similar to that for the binding of the peptide substrates, FuaGlyPhe and FuaPhePhe, while the latter gave smaller values. We also notice that D-isomers of Phe and mandelate gave ΔV_{ass} values quite in contrast to the corresponding L-isomers.

Discussion

Assignment of Catalytic Group. From the pH dependences of the kinetic parameters of CPA, there have been arguments on the ionic state of the active site amino acid residues.[22-25] Based on the X-ray crystallographic studies of this enzyme which binds GlyTyr, three interpretations were given so far for the origin of the pK_{a1}: The ionization of the water molecules coordinated on Zn; the dissociation of a Zn–His bond followed by pH effects associated with His 69 or His 196; the interactions of the charged residue(s) (probably Glu 270) in the active site.[6] The measured ΔH_{a1} for the pK_{a1} process (4 kcal mol^{-1}) is comparable to the corresponding values (≈3 kcal mol^{-1}) reported for the hydrolysis of ZGlyGlyVal and ZGlyGlyLeu.[25] These values are intermediate between those reported for a free carboxyl (±1 kcal mol^{-1}) and a free imidazole or a water coordinated on zinc (6—7 kcal mol^{-1})[26-28] The presently obtained ΔV_{a1} value is apparently comparable to the ΔV value reported for a free carboxyl group (≈15 ml mol^{-1}).[27] Thus the ΔH_{a1} and ΔV_{a1} might give different interpretations. In general, ΔV has strong correlation with ΔS for various reactions in solution[2] and hence the problem is equivalent to telling which of the enthalpic and entropic factors plays a dominant part to determine the unusual (perturbed) pK_a values in the active site of the enzyme. The accumulated data on the thermodynamic measurement of the pK_a's of various acids in mixed solvents[28] tell us that, by changing the solvent composition, the entropic term varies significantly and the enthalpic one does partly compensate this change. This allows us to say that, at least in the case of pK_a, the enthalpic parameter is less influenced by the perturbation of the environments and it is better to assume the nature of the dissociative residues on the basis of this term. Then the value of ΔH_{a1} (3—4 kcal mol^{-1}) is considered to reflect the contributions from both carboxyl group and the H_2O on the zinc. In the hydrolysis by ther-

molysin, which is a microbial zinc protease similar to CPA with respect to the amino acid components of the active site and showed ΔH_{a1} of $\simeq$8 kcal,[16] there were two possible functional groups which dominated the pK_{a1}; the imidazol of His231 and the proton-sharing combination of the carboxylate of Glu and the zinc-coordinated water. Taking the absence of histidine residue in the active site of CPA into consideration, we can consider the latter is the case for the group controlling the pK_{a1} in the present enzyme.

Two Binding Modes of Inhibitors and Substrates. The X-ray crystallographic studies suggested that Arg-145, Glu270, Tyr248, and zinc ion at the active site are important in the CPA catalysis.[12] There have been many studies concerning the roles of these residues in the peptidase and esterase activities. A mechanistic difference between these two types of catalyses was inferred in most of the studies; *e.g.* different influence of metal substitution or metal extraction on the binding and/or catalytic processes of two types of the substrates[30] and a different influence of the chemical modification of the Arg residue.[9] One interpretation of these results was that the carboxyl group of the ester substrates interacts with zinc ion in the binding process while the carbonyl group of the peptide substrate does so during the hydrolytic process.[8] That is, in the binding process of peptide substrate, the Arg145 residue is considered to interact electrostatically with the terminal carboxylate. Such a purely electrostatic interaction is similar to the one observed in the substrate binding process of trypsin and its homologous proteases. Judging from the result on the pressure dependence of trypsin catalysis[3] and of other low molecular weight ionic associations[29] a fairly large and positive volume change is expected for such an association. In fact the pressure dependence of K_m^{-1} gave a large and positive ΔV_{ass} ($+30$ ml mol^{-1}) and the ΔV_{ass}'s for the peptide-like inhibitors such as GlyTyr, PhePhe, L-Phe, and ZPhe were also positive and large. In contrast, fairly small ΔV_{ass} values were observed for the binding of ester-like inhibitors such as 3-phenyllactate and L-mandelate. These smaller ΔV_{ass} values, then, would be related to the interaction of terminal carboxylate directly with the zinc ion instead of the guanidinium cation of Arg145. (Though these ester-like inhibitors behave noncompetitive to the peptidase activity, their competitive actions on ester one[22,23] and other physicochemical studies[6,30,31] comfirmed direct interaction of these inhibitors with the active site of enzyme.) The interaction of divalent metal ion with various carboxylic acids in aqueous solution has shown relatively small ΔV values (<10 ml mol^{-1}) as known in the literature.[29] Thus the present result gives strong support for the interpretation of Auld and Holmquist.[7] However it cannot exclude the possibility that such a direct coordination of terminal carboxylate to the zinc ion is limited to the case of ester-like *inhibitor* interacting with the active site where the peptide *substrate* is already located on the Arg residue and that the ester *substrate* might be bound in a similar manner to the peptide substrate.[32,33]

D-Phe showed a considerably different ΔV_{ass} value from L-form and this can be interpreted by the scheme

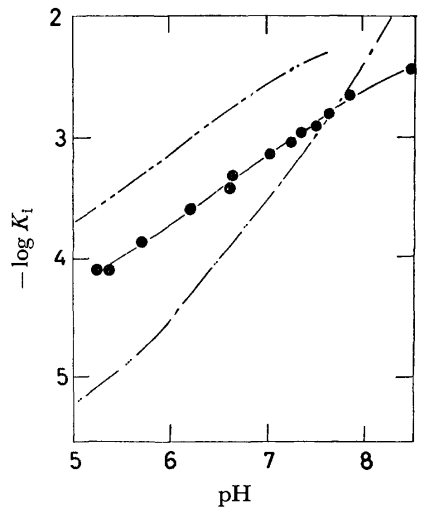

Fig. 5. Comparison of pH dependences of inhibitions by ZPhe for thermolysin and CPA.
●: Inhibition of CPA by ZPhe (taken from Fig. 3-d), ——: inhibition of thermolysin by ZPhe (taken from Ref. 16), – – – –: inhibition of thermolysin by ZLeuGly (taken from Ref. 16).

given by Lipscomb[34] that the terminal carboxylate of D-Phe does not interact with Arg but directly to zinc ion, just like the ester-type inhibitor. In fact D-Phe gave a ΔV_{ass} value which can be classfied into the latter. On the contrary D-form of mandelate showed a larger ΔV_{ass} value than L-form and in this case the D-isomer would interact with Arg residue just like peptide-like inhibitors.

pH-Dependent Alternation of Binding Modes. In the inhibition of thermolysin, ZPhe showed a very strong pH dependence and it was related to the direct interaction of terminal carboxylate of this inhibitor with zinc ion at a relatively low pH.[16,35] The inhibition of CPA by this inhibitor is less pH dependent as compared in Fig. 5 but it resembles the binding of the dipeptidyl inhibitor (ZLeuGly)[16] or tripeptidyl substrate (Fua-GlyLeuAla) (Fukuda *et al.*, unpublished result) on thermolysin. In the latter instances the pH profile can be interpreted as that the inhibitor or substrate interacts with the active site in a productive (normal) manner at neutral pH, while at lower pH it interacts in a nonproductive (reversed) manner just like ZPhe interaction with carboxylate coordinating on zinc. The situation seems analogous in the case of ZPhe interaction with CPA. At pH 7, where the pressure dependence was measured, the interaction of this inhibitor is normal and similar to the peptide substrate but at lower pH it would undergo a direct interaction with zinc ion and would have a character of ester-like inhibitor. D-Mandelate and 3-phenylpropionate showed fundamentally similar pH dependences to ZPhe and therefore a similar explanation can be valid for these inhibitors. Especially in the case of 3-phenylpropionate, we notice a ΔV_{ass} value of an intermediate between two extremes. Though this inhibitor behaved as a noncompetitive one for the peptidase,[7] a stopped-flow study revealed that an analogous inhibitor, phenylacetate, interacted with CPA in a mixed manner.[36]

Thus we can expect that the present intermediate ΔV_{ass} value of 3-phenylpropionate comes from two types of interactions. When the alternation of two binding modes occurs at relatively higher pH, as in these two instances, intermediate values of the parameters are observed even in ordinary measuring conditions. To substantiate this explanation further, we are measuring the pH dependence of ΔV_{ass} for these inhibitors.

(Received March 10, 1983)

Heating of 3,3,4,4-tetrabromo-1,2-bis(diphenylmethylene)cyclobutane in dichloroacetic acid afforded bridge-head olefin, 7-bromo-1,4,8-triphenyl-2,3-benzobicyclo[3.3.0]octa-2,4,7-trien-6-one, and spiroketone, 2-bromo-2′,3-diphenylspiro[1*H*-indene-1,1′(4′*H*)-naphthalen]-4′-one (**13**). Mechanism of the reaction was discussed. X-Ray structural study of the spiroketone **13** was also reported.

Formation of the bisallyl diradical intermediate (**2a**) in dimerization of chlorotriphenylallene (**1a**) or in thermal ring-cleavage of 3,4-dichloro-3,4-diphenyl-1,2-bis(diphenylmethylene)cyclobutane (**3a**) is the key-step of the *rubrene reaction* which finally gives so-called *rubrene*, 5,6,11,12-tetraphenylnaphthacene (**4a**).[1] We studied thermal reaction of 3,3,4,4-tetrabromo-1,2-bis-(diphenylmethylene)cyclobutane (**3b**)[2] in expectation of the formation of 5,11-dibromo-6,12-diphenylnaphthacene (**4b**) via the bisallyl diradical intermediate (**2b**), and we found that **3b** is thermally stable but heating of **3b** in dichloroacetic acid affords bridge-head olefin, 7-bromo-1,4,8-triphenyl-2,3-benzobicyclo-[3.3.0]octa-2,4,7-trien-6-one (**8a**) and spiroketone, 2-bromo-2′,3-diphenylspiro[1*H*-indene-1,1′(4′*H*)-naphthalen]-4′-one (**13**).

Heating of **3b** in dichloroacetic acid at 120 °C for 1 h gave **8a** and **13** in 30 and 36% yields, respectively. Plausible reaction pathways are shown in Scheme 1. Intermediacy of **5** and **6** was proven by preparing these by separate method. Heating of **3b** in benzene containing a small amount of conc H_2SO_4 under reflux for 7 h gave 7,8,8-tribromo-2,5,5-triphenyl-3,4-benzobicyclo[4.2.0]octa-1,3,6-triene (**5**) in 44% yield. Treatment of **5** with $AgClO_4$ in THF–MeOH gave 7,8-dibromo-5-methoxy-2,5,6-triphenyl-3,4-benzobicyclo[4.2.0]octa-1,3,7-triene (**6b**) in 81% yield. Heating of **5** in dichloroacetic acid for 30 min at 120 °C gave **8a** and **13** in 32 and 35% yields, respectively. Similar heating of **6b** gave **8a** in 88% yield. In the reaction of **5**, rearrangement of phenyl group which leads to **6** is probably competing with that of bromine atom which does to **9**. This was clarified by the reaction of the chloro-analog of **3a** (**3c**) in dichloroacetic acid which gives only the chloro-analog of **8a** (**8b**) in 90% yield. Much easier rearrangement of Br than Cl on four-membered ring has been reported.[3] Formation of cyclopropenyl-substituted indene intermediate such as **11** seems to be necessary for the conversion of **3** into **13**.

Due to distorted bridge-head olefinic linkage, **8** is reactive and shows interesting reactions. $KMnO_4$ oxidation of **8a** occurred vigorously at room temperature and 2-bromo-1,3,4-triphenylnaphthalene (**17**)[4] was obtained in 60% yield. A plausible reaction pathway is shown in Scheme 2. Ring-reconstruction of the carbonium ion intermediate (**14**) which was initially formed by an attack of hydroxyl cation on the distorted double bond of **8a** gives cyclic diketone (**16**) *via* **15**, which on decarbonylation finally affords **17**. Michael-type additions of MeOH by a base-catalyzed reaction and of benzene by an $AlCl_3$-catalyzed one to **8a** easily gave 7-bromo-4-methoxy-1,4,8-triphenyl-2,3-benzobicyclo[3.3.0]octa-2,7-dien-6-one (**18a**) and 7-bromo-1,4,4,8-tetraphenyl-2,3-benzobicyclo[3.3.0]octa-2,7-dien-6-one (**18b**), respectively.

From the viewpoint of structural resemblance of **13** to one bioactive component of *Cannabis sativa L*, cannabispirenone-B (**19**),[5] studies of crystal structure of **13** are interesting subjects. X-Ray crystallographic

data are shown in Tables 1—5, and perspective view of **13** is shown in Fig. 1. Angles between the following two ring planes are shown in parentheses, A–C (55.3), B–C (3.6), C–E (89.6), D–F (50.4), and E–F (6.0°). These data show that two spiro rings are almost perpendicular each other. Distances between Br and the following atoms are shown in parentheses, C6 (3.42), C10 (3.37), C15 (3.79), and C25 (3.62 Å). However, absolute configuration of **13** was not determined.

Experimental

All the melting points are uncorrected. The IR, UV, and NMR spectra were measured in Nujol mull, $CHCl_3$, and $CDCl_3$, respectively. The mass spectra were obtained with an ionization energy of 75 eV.

*Thermal Reaction of 3,3,4,4-Tetrabromo- (**3b**) and 3,3,4,4-Tetrachloro-1,2-bis(diphenylmethylene)cyclobutane (**3c**) in Dichloroacetic Acid.* A solution of **3b** (5.6 g) in dichloroacetic acid (100 ml) was heated at 120 °C for 1 h. The crude solid obtained by addition of water to the reaction mixture was filtered and dried. Recrystallization of the solid from ethyl acetate gave yellow and colorless crystals, which were separated mechanically. Recrystallization of the former from ethyl acetate gave **8a** (1.14 g, 30%) as yellow prisms, mp 185—186 °C; IR 1690 cm^{-1} (C=O); UV 244 (23,400), 289 (14,100), and 364 nm (ε, 8900); ^{13}C NMR δ 70.5 (CPh); MS (*m/e*) 476 and 474 (M^+). Found: C, 75.73; H, 3.85%. Calcd for $C_{30}H_{19}OBr$: C, 75.80; H, 4.03%. Recrystallization of the latter from ethyl acetate gave **13** (1.37 g, 36%) as colorless needles, mp 197—198 °C; IR 1645 cm^{-1} (C=O); UV 243 (23,400), 270sh (15,600), and 283 nm (ε, 16,200); ^{13}C NMR δ 65.0 (spiro C); S (*m/e*) 476 and 474 (M^+). Found: C, 75.59; H, 4.11%. Calcd for $C_{30}H_{19}OBr$: C,

Synthesis of 7,8,8-Tribromo-2,5,5-triphenyl-3,4-benzobicyclo[4.2.0]octa-1,3,6-triene (5). A solution of **3b** (1.36 g) in benzene (35 ml) containing a small amount of conc H_2SO_4 was heated under reflux for 7 h. The crude product remained after evaporation of the solvent was recrystallized from acetone to give **5** (0.53 g, 44%) as colorless prisms, mp 159—160 °C; UV 326 (12,600) and 252 nm (ε, 21,400); MS (*m/e*) 622, 620, 618, and 616 (M^+). Found: C, 58.47; H, 2.86%. Calcd for $C_{30}H_{19}Br_3$: C, 58.19; H, 3.07%.

Synthesis of 7,8-Dibromo-5-methoxy-2,5,6-triphenyl-3,4-benzobicyclo[4.2.0]octa-1,3,7-triene (6b). A solution of **5** (0.4 g) in THF–MeOH (3:1, 20 ml) was treated with $AgClO_4$ (0.4 g) at room temperature. Excess $AgClO_4$ was decomposed with NaCl and filtered. The crude product remained after evaporation of the solvent of the organic layer was extracted with ether. The ether solution was washed with water and dried over Na_2SO_4. Crystals obtained from the ether solution were recrystallized from acetone–$CHCl_3$ (1:1) to give **6b** (0.3 g, 81%) as colorless prisms, mp 215—216.5 °C; IR 1075 cm^{-1} (ether); ^1H NMR δ 2.79 (s, MeO) and 6.3—7.8 (m, Ph). Found: C, 65.21; H, 3.81%. Calcd for $C_{31}H_{22}OBr$: C, 65.26; H, 3.86%.

Thermal Reaction of 5 and 6b in Dichloroacetic Acid. A solution of **5** (3.1 g) in dichloroacetic acid (50 ml) was heated at 120 °C for 1 h. The reaction mixture was worked up as done for the thermal reaction mixture of **3b** in dichloroacetic acid, and **8a** (0.76 g, 32%) and **13** (0.83 g, 35%) were obtained. When **6b** (0.1 g) was heated in dichloroacetic acid (10 ml) at 120 °C for 30 min and then worked up as above, **8a** (0.075 g, 88%) was obtained.

Potassium Permanganate Oxidation of 8a. When $KMnO_4$ (0.5 g) was added to a solution of **8a** (0.1 g) in acetone (10 ml), exothermic reaction occurred. After 3 h, excess $KMnO_4$ was decomposed with MeOH, and MnO_2 was filtered. Crude product remained after the evaporation of the solvent of acetone solution was recrystallized from acetone to give **17** (0.55 g, 60%) as colorless prisms, mp 244—245 °C (lit,[4] 245 °C). IR spectrum was identical to that of the authentic sample.[4]

Base-catalyzed Addition of MeOH to 8a. A solution of **2** (1.0 g) in THF (10 ml) was added to 5% KOH–MeOH (30 ml) and then heated under reflux for 1 h. Crude product remained after the evaporation of the solvent was washed with water, dried, and recrystallized from ethyl acetate to afford **18a** (0.95 g, 84%) as pale yellow prisms, mp 215—217 °C; IR 1710 cm^{-1} (C=O); UV 288 (18,600) and 358 nm (ε, 900); ^1H NMR δ 2.98 (s, MeO), 3.57 (s, CH), and 6.5—7.5 (m, Ph); MS (*m/e*) 508 and 506 (M^+). Found: C, 73.10; H, 4.35%. Calcd for $C_{31}H_{23}O_2Br$: C, 73.38; H, 4.54%.

$AlCl_3$-catalyzed Addition of Benzene to 8a. A mixture of **8a** (1.0 g), benzene (20 ml), and $AlCl_3$ (1.0 g) was stirred at room temperature for 3 h. The reaction mixture was decomposed with water and extracted with benzene. The benzene solution was washed with dil HCl and water, and dried over Na_2SO_4. Crude crystals obtained by the evaporation of the solvent were recrystallized from ethyl acetate to give **18b** (1.05 g, 90%) as colorless prisms, mp 255 °C; IR 1710 cm^{-1} (C=O); UV 215 (43,300) and 285 nm (ε,

8500); ^{1}H NMR δ 4.2 (s, CH) and 6.6—7.6 (m Ph); MS (*m/e*) 554 and 552 (M^+). Found: C, 77.82; H, 4.39%. Calcd for $C_{36}H_{25}OBr$: C, 77.93; H, 4.52%.

X-Ray Analysis of ***13***. A crystal used for the intensity measurement was $0.3\times0.2\times0.2$ mm^3. Intensity data were obtained on a Rigaku four-circle automatic diffractometer, equipped with graphite-monochromated Cu $K\alpha$ radiation, and using the $2\theta/\omega$ scan technique ($2\theta\leqq130°$). Two thousands sixty one independent reflections of $F_o\geqq3\sigma(F_o)$ were corrected for Lorentz and polarization factors but not for absorption.

Crystal data: $C_{30}H_{19}OBr$, monoclinic, $P2_1$, $Z=2$, $a=9.139(2)$, $b=16.020(3)$, $c=7.838(4)$ Å, $\beta=106.2(1)°$, $D_c=1.433$ g cm^{-3}, $\mu=3.2$ mm^{-1} (for Cu $K\alpha$)

The structure was solved by the heavy atom method. The positions of hydrogen atoms were located from the difference Fourier map. The positional and thermal parameters were refined by the block-diagonal least-squares method. The R factor was converged to 0.034 with an equal weight for each reflection.

We thank Professor H. H. R. Hoffmann of Technischen Universität at Hannover for sending IR spectrum of **17** (Ref. 4) which had been recorded by Professor G. Köbrich at the same University.

The Reaction of Cyanoguanidine with Formaldehyde. I. Hydroxymethylation and Methoxymethylation of Cyanoguanidine

Michiaki Takimoto,* Toichi Ebisuno, and Ryuichi Shiba†

Department of Chemistry, Faculty of Science, Toho University, Miyama 2-2-1, Funabashi, Chiba 274

† *Department of Applied Science, Faculty of Technology, Tokyo Denki University, Kanda, Chiyoda-ku, Tokyo 101*

(Received April 7, 1983)

In order to examine the reactivity of cyanoguanidine (CG) with formaldehyde, CG was first hydroxymethylated, then methoxylated, and finally exhaustively hydroxymethylated with a large excess of formaldehyde. 4-Cyanoimino-3-methoxymethylperhydro-1,3,5-oxadiazine was isolated as a major reaction product of 1,3-bis(methoxymethyl)-2-cyanoguanidine with formaldehyde. This product is an adduct of 3 mol of formaldehyde per mole of CG and a six-membered cyclic ether. Minor products were further methoxylated and 3,5-bis(methoxymethyl)-4-methoxymethyl(carbamoylimino)perhydro-1,3,5-oxadiazine was isolated. This is an adduct of 2 mol of formaldehyde to the amidinated product derived from the major product by the hydration of the cyano group. The ring structure of perhydro-1,3,5-oxadiazine was so stable that it could not be decomposed under acidic conditions if the methoxymethyl groups were fully acid-hydrolyzed.

The resinous products of cyanoguanidine (CG) with formaldehyde are useful as sticking agents for dyes,[1] modifiers for urea- and melamine–formaldehyde resins[2] and commercial flocculants.[3] CG is first hydroxymethylated with formaldehyde; this procedure is followed by the condensation and polymerization into CG–formaldehyde resin. The reaction mechanism and properties of CG have seldom been reported, in contrast to the abundant reports on urea- and melamine–formaldehyde resins.[4–7]

Hamada,[8] Yamada,[9] and Miyaoka and Matsui[10] observed that the pH value of the reaction solution of CG with formaldehyde approached 8.5—9.0 from the initial value under acidic or alkaline conditions as the reaction proceeded. Under acidic conditions, a partial conversion of CG to amidinourea (AU), a basic compound, was confirmed by IR spectrometry. Under alkaline conditions, possible conversions of CG to cyanourea or urea and of formaldehyde to MeOH and formic acid have been speculated about, but the details of the reaction remained to be elucidated. Only two hydroxymethylated products, mono- and 1,3-bis-(hydroxymethyl)-2-cyanoguanidine (CG-1F and CG-2F), were isolated[8] and other hydroxymethylated products were not obtained in the reaction of CG with formaldehyde. Therefore, the reactivity of CG with formaldehyde (the maximal number of the introduced hydroxymethyl groups to CG) has been estimated to be 2 or 3 at the most. However, it can be anticipated to be 4 by analogy with urea which has the analogous structure to CG and reacts with formaldehyde into tetrakis(hydroxymethyl)urea derivatives.

Furthermore, the maximal wavelength of the strong absorption band in the UV region (λ_{max}) of hydroxymethylated products depends on the number of the introduced hydroxymethyl groups; their band positions shift to the longer wavelength side against the number of the hydroxymethyl groups in the reaction of melamine, melam, melem, ammelide or ammeline with formaldehyde.[11–12] If a similar relationship occurs for hydroxymethylated CG, our observation on λ_{max} of CG, CG-1F, CF-2F, and products of CG with a large excess of formaldehyde suggests that the reactivity of CG is about 4. In order to examine this suggestion, CG was exhaustively hydroxymethylated.

Results and Discussion

1,3-Bis(methoxymethyl)-2-cyanoguanidine (CG-2M) was used as a starting material for the exhaustive hydroxymethylation of CG with formaldehyde, because the usual hydroxymethylation is always attended by the reverse reactions and fails to prepare tris- and tetrakis(hydroxymethyl)-2-cyanoguanidine and because hydroxymethylated CG polymerizes and CG converts to AU together with other unknown compounds under severe reaction conditions. CG-2M could be prepared from CG-2F and MeOH in good yield by the addition of a large excess of an acid catalyst at low temperatures while, at the boiling point of MeOH in the presence of a small amount of an acid, intermolecular condensates were largely produced and CG-2M was poorly prepared. CG-2M was assigned by the elemental analysis and the appearance of ^{1}H-NMR signal of the methyl proton (δ=3.20) and the disappearance of the signal of the hydroxyl proton (δ=5.72 in CG-2F).

1-Methoxymethyl-2-cyanoguanidine (CG-1M) was obtained from CG-1F and MeOH and assigned in a similar way.

CG-2M was further hydroxymethylated in the presence of excess formaldehyde. The major product was assigned as 4-cyanoimino-3-methoxymethylperhydro-1,3,5-oxadiazine (CG-1Mcyc2F), a six-membered cyclic ether, by the elemental analysis, FD-MS and ^{1}H-NMR spectrometry. The X-ray diffraction data which will be reported elsewhere also confirmed this assignment. The λ_{max} of this product was plotted on the extrapolation of the linear λ_{max} *versus* the number of hydroxymethyl and/or methoxymethyl groups of CG, CG-1F, CG-1M, CG-2F, and CG-2M. Figure 1 shows that this contains three hydroxymethyl and/or methoxymethyl groups. This was probably derived by the intramolecular elimination of MeOH between the hydroxymethyl group which was introduced to one of two imino groups in CG-2M and the methoxymethyl group in the other imino group because the newly introduced hydroxymethyl group was labile and stabilized by the cyclization. This was an adduct of 3 mol of formaldehyde per mole of CG and showed that the reactivity of CG is 3 at least.

Then, in order to prepare 1,3-bis(hydroxymethyl)-1,3-bis(methoxymethyl)-2-cyanoguanidine (CG-2F2M) or 4-cyanoimino-3,5-bis(methoxymethyl)perhydro-1,3,5-oxadiazine (CG-2Mcyc2F), CG-2M was treated with formaldehyde under various conditions. Under mild conditions, no hydroxymethyl group was introduced into CG-2M. Under severe conditions, condensated polymers were mainly produced. The value of λ_{max} (232 nm) of the solution containing these products as shown in Fig. 1 suggested the possible production of CG-2F2M and/or CG-2Mcyc2F but none of them could be isolated.

CG-1Mcyc2F was also prepared from CG-1M and formaldehyde in a comparable yield with that from CG-2M and formaldehyde (scheme 1). In this preparation, two molecules of formaldehyde were added, one by one, to the free amino group and then to the imino group which had a methoxymethyl group. The dehydration from two of the hydroxymethyl groups selectively occurred and the MeOH elimination from one hydroxymethyl and one methoxymethyl group did not, because 4-cyanoimino-3-hydroxymethylperhydro-1,3,5-oxadiazine (CG-1Fcyc2F) could not be obtained.

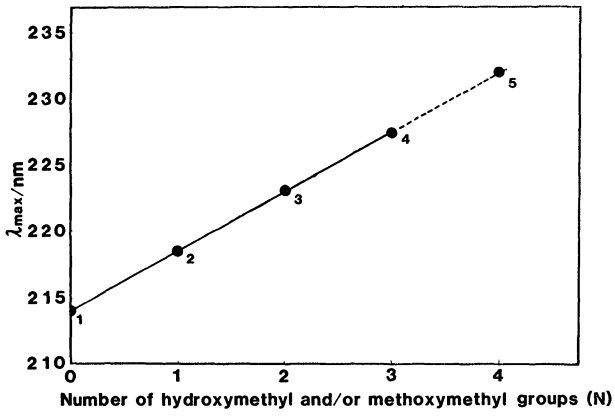

Fig. 1. Relationship of the maximal wavelength of absorption bands in UV region (λ_{max}) of CG, hydroxymethylated CG and methoxymethylated CG with the number (N) of hydroxymethyl and/or methoxymethyl groups.
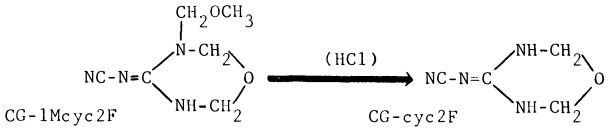
1; CG, 2; CG-1F or CG-1M, 3; CG-2F or CG-2M, 4; CG-1Mcyc2F, 5; pasty products of CG-2M with a large excess of formaldehyde at 85—90 °C for 20 min.

4-Cyanoimino-3-ethoxymethylperhydro-1,3,5-oxadiazine (CG-1Ecyc2F) was prepared from 1-ethoxymethyl-2-cyanoguanidine (CG-1E) and formaldehyde in a 76% yield and condensated polymers and by-products were minimized. In the reaction of 1-alkoxymethyl-2-cyanoguanidine (CG-1M or CG-1E) with formaldehyde, the ring formation by the dehydration was a major reaction and preceded the intermolecular condensation, while in the reaction of hydroxymethylated CG which was not alkoxylated, this condensation preceded the ring formation.



As 4-(cyanoimino)perhydro-1,3,5-oxadiazine (CG-cyc2F) could be obtained from CG-1Mcyc2F by acid-hydrolysis, the six-membered cyclic structure was so stable that it remained undecomposed but the methoxymethyl group was fully acid-hydrolyzed into formaldehyde, whose quantity was determined colorimetrically to be in agreement with the calculated amount.

After removal of the major reaction product of CG-2M with formaldehyde, the minor products were further treated with MeOH under acidic conditions. The isolated product lost the absorption band at 2140—2180 cm^{-1} in IR spectrum which is characteristic of

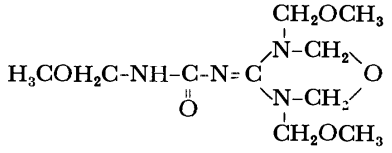
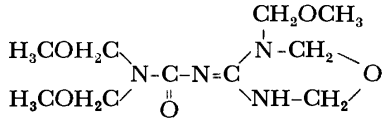
Hydrated product	—	155.3	163.6

the stretching vibration of -CN. The results in the ^{13}C-NMR spectrum shown in Table 1 suggest that this product has the structure of =N-CO-N= derived by the hydration of the cyano group of CG-1Mcyc2F and that the hydrated CG-1Mcyc2F is one of the minor products of CG-2M with formaldehyde. The λ_{max} of this product was 238 nm, which deviated to the wavelengths longer than the extrapolated value in Fig. 1 probably because of the structural conversion of CG itself to AU. This product had three easily acid-hydrolyzed methoxymethyl groups, whose presence was ascertained by the colorimetric determination of formaldehyde released. The following two structures were considered for this hydrated product. The structure of **1**, 3,5-bis(methoxymethyl)-4-methoxymethyl(carbamoylimino)perhydro-1,3,5-oxadiazine (AU-3Mcyc2F) is thought more feasible than **2** from the ^{13}C-NMR and ^{1}H-NMR spectra using a shift reagent.



1



2

Two molecules of formaldehyde were added to the newly formed amino group and to the imino group in the ring, one by one, to form AU-3Mcyc2F. However, it remained obscure how the hydrogen of the imino group in the ring could be substituted for by the hydroxymethyl group in the presence of the cyano group which had not been hydrated.

The reaction mechanisms and characteristics of CG-1Mcyc2F and AU-3Mcyc2F are under investigation and will be reported elsewhere.

Experimental

NMR spectra of reaction products in DMSO-d_6 were obtained at 90 MHz on a JOEL FX-90Q instrument using TMS as an internal standard.

1,3-Bis(methoxymethyl)-2-cyanoguanidine (CG-2M). Keeping the temperature of the solution at 14—15 °C by using an ice bath, 5 ml of concentrated HCl was added dropwise with stirring to 2 g of CG-2F which was prepared according to the procedure of Hamada[8] in 50 ml of MeOH. After 15 min, the reaction solution was neutralized with 20% NaOH solution to the endpoint of phenolphthalein and evaporated to dryness under reduced pressure at low temperatures. A product, CG-2M, was recrystallized from EtOH as columnar crystals. (yield in crude; *ca.* 70%): mp 121.5—122.2 °C: Found: C, 41.75; H, 7.05; N, 32.15%: Calcd for $C_6H_{12}N_4O_2$, C, 41.86; H, 6.98; N, 32.56%: ^{1}H-NMR(DMSO-d_6): δ=3.20 (6H, s, -CH$_3$), 4.53 (4H, d, J=6 Hz, -CH$_2$OCH$_3$), 8.04 (2H, t, J=6 Hz, -NH-).

CG-1M was prepared from CG-1F and MeOH in a similar way as CG-2M (yield in crude; *ca.* 70%): mp 121.5—122.2 °C: Found: C, 37.38; H, 6.41; N, 43.54%: Calcd for $C_4H_8N_4O$, C, 37.49; H, 6.29; N, 43.73%: ^{1}H-NMR (DMSO-d_6): δ=3.09 (3H, s, -CH$_3$), 4.47 (2H, d, J=6 Hz, -CH$_2$OCH$_3$), 6.99 (2H, s, -NH$_2$), 7.62 (1H, t, J=7 Hz, -NH-).

4-Cyanoimino-3-methoxymethylperhydro-1,3,5-oxadiazine (CG-1Mcyc2F). Twenty-five ml of 37% formalin solution was added to 5 g of CG-2M (mole ratio of formaldehyde/CG-2M=10) and the pH of the solution was adjusted with 0.1 M NaOH solution to 8.8. After stirring for 10 min at 80 °C, the reaction mixture was cooled in an ice bath to stop the reaction and evaporated to dryness under reduced pressure at low temperatures. A large excess of acetone was added to the desiccated products. After the acetone-insoluble products were filtrated off, the acetone solution was concentrated to a viscous solution under reduced pressure; then a small amount of EtOH was added. On cooling, white powder was deposited (yield in crude; 51%). This was separated by filtration and recrystallized from 2-propanol to give plate crystals. Mp 113.8—114.0 °C: Found: C, 42.35; H, 5.88; N, 32.71%: Calcd for $C_6H_{10}N_4O_2$, C, 42.35; H, 5.88; N, 32.94%: ^{1}H-NMR(DMSO-d_6): δ=3.23 (3H, s, -CH$_3$), 4.73, 4.81 (4H, s, -CH$_2$OCH$_2$-), 4.90 (2H, s, -CH$_2$OCH$_3$), 8.47 (1H, t, J=4 Hz, -NH-): MS(FD): *m/e* 170 (M^+).

After removal of the major product, CG-1Mcyc2F, by filtration, the filtrate was concentrated to a viscous solution. A thin layer chromatogram of this viscous solution on silica gel (Merck F254) developed in 2-propanol showed three major spots under UV light. The isolation of these products by various solvents was, however, unsuccessful.

CG-1Mcyc2F was also prepared (yield in crude; 40%) from 5 g of CG-1M and 33 ml of 37% formalin solution (mole ratio of formaldehyde/CG-1M=10) in a way similar to the above.

The preparation conditions of 4-cyanoimino-3-ethoxymethylperhydro-1,3,5-oxadiazine (CG-1Ecyc2F) was virtually identical to that of CG-1Mcyc2F, but CG-1M was replaced with CG-1E. The yield of CG-1Ecyc2F was 76% in crude.

4-(Cyanoimino)perhydro-1,3,5-oxadiazine (CG-cyc2F). One g of CG-1Mcyc2F was dissolved in 50 ml of 0.1 M HCl and hydrolyzed at 80 °C for 20 min. The reaction mixture was neutralized and concentrated under reduced pressure. The resulting viscous solution was treated with EtOH and the deposited white crystals were recrystallized from dioxane. (yield in crude; 72%) mp 137.0—137.3 °C: Found: C, 38.12; H, 4.79; N, 44.31%: Calcd for $C_4H_6N_4O$, C, 38.09; H, 4.80; N, 44.42%: ^{1}H-NMR (DMSO-d_6): δ=4.73 (4H, s, -CH$_2$OCH$_2$-), 8.21 (2H, t, J=4 Hz, -NH-): MS (70 eV): *m/e*(rel intensity) 126 (M^+, 67), 96 (100), 68 (88).

3,5-Bis(methoxymethyl)-4-methoxymethyl(carbamoylimino)perhydro-1,3,5-oxadiazine (AU-3Mcyc2F). To 5 g of the viscous solution described in the preparation of CG-1Mcyc2F, 100 ml of MeOH was added. The solution was chilled to

below −10 °C by the use of Dry Ice and MeOH, then 5 ml of concentrated HCl was added and gradually allowed to warm to 10—12 °C. The reaction was carried out at 10—12 °C for 15 min. Keeping the temperature of the solution below −10 °C, the solution was neutralized with 20% NaOH solution. The solution was concentrated under reduced pressure at low temperatures. The resulting viscous solution was extracted with dioxane. Then, the dioxane soluble fraction was extracted with hexane three times. White crystals were obtained from hexane extracts (yield in crude; 12%). mp 58.0—58.6 °C: Found: C, 43.40; H, 7.27; N, 20.21%: Calcd for $C_{10}H_{20}N_4O_5$, C, 43.48; H, 7.25; N, 20.29%: ^{1}H-NMR(DMSO-d_6): δ=3.18 (6H, s, $-CH_3$), 3.24 (3H, s, $-CH_3$), 4.87 (4H, s, $-CH_2OCH_2-$), 4.93 (2H, s, $-CH_2OCH_3$), 9.86 (1H, t, J=4 Hz, $-NH-$): MS(FD): m/e 277 (MH^+).

Studies on the β-Turn of Peptides. VI.[1] Nuclear Magnetic Resonance Study on the Conformations of *N*-(2,4-Dinitrophenyl)tetrapeptide *p*-Nitroanilides Related to the β-Turn Part of Gramicidin S

Tsutomu HIGASHIJIMA,† Kazuki SATO,* and Ukon NAGAI

Mitsubishi-Kasei Institute of Life Sciences, 11 Minamiooya, Machida, Tokyo 194

† *Department of Biophysics and Biochemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113*

(Received April 21, 1983)

The conformations of *N*-(2,4-dinitrophenyl)-L-Leu-X-L-Pro-L-Val *p*-nitroanilides (**I**, X=D-Ala; **II**, X=Gly; **III**, X=L-Ala) were studied by nuclear magnetic resonance and circular dichroism spectroscopies. The L-Val-NH group of compound **I** takes part in an intramolecular hydrogen bonding, and the folded conformation is considered to be type II′ β-turn structure as in the case of [D-Ala$^{4,4'}$]-gramicidin S. The populations of β-turn conformer were considered to be in the order of **I**>**II**>**III**≈0 in methanol and *N*,*N*-dimethylformamide solutions, and decreased in dimethyl sulfoxide solution. Compound **II** in dimethyl sulfoxide and **III** in all the three solvents do not take a β-turn conformation. The data obtained from NMR and CD experiments showed a good correlation between the magnitudes of the Cotton effects (250—400 nm) and the populations of the β-turn conformation of these peptides. The proximity of the two chromophores was ascertained directly for compound **I** in *N*,*N*-dimethylformamide solution by nuclear Overhauser effects experiment. In addition, the β-turn preference of these peptides were in good accordance with the antibiotic activities of the gramicidin S analogs having the same tetrapeptide sequences at their β-turn parts.

Gramicidin S (GS) is a cyclic decapeptide antibiotic with the primary structure *cyclo*(-L-Val^1-L-Orn^2-L-Leu^3-D-Phe^4-L-Pro^5-L-Val$^{1'}$-L-Orn$^{2'}$-L-Leu$^{3'}$-D-Phe$^{4'}$-L-Pro$^{5'}$-).[2] Conformation of GS consists of the intramolecular antiparallel β-sheet with four hydrogen bonds between L-Val and L-Leu residues and two β-turns (type II′) around the D-Phe-L-Pro sequences (Fig. 1).[3] The characteristic feature of the conformation is the orientation of side chains in which the charged L-Orn side chains are on one side and the hydrophobic L-Val and L-Leu side chains on the other side of the molecule. The conformation of GS is considered to be stabilized not only by the four intramolecular hydrogen bonds but also by the stable β-turns formed by two D-Phe-L-Pro sequences. Izumiya *et al.* summarized the antibacterial activities of many GS analogs.[4] The activities of GS analogs were correlated to their conformations.[5] For example, the activities and the populations of GS-type β-sheet conformer were in the order of GS≈[D-Ala$^{4,4'}$]-GS>[Gly$^{4,4'}$]-GS≫[L-Ala$^{4,4'}$]-GS≈0.[6] It is of interest to study the β-turn preference of the amino acid sequences at the corner positions of GS analogs.

In the previous paper, we gave an outline of a new method to study the β-turn conformation of linear tetrapeptides.[7] *N*-(2,4-Dinitrophenyl)tetrapeptide *p*-nitroanilides (Dnp-tetrapeptide-pNA's) exhibited characteristic CD spectra above 250 nm, and the Cotton effects were considered to be due to the exciton coupling of the transition moments in the two terminal chromophores. The magnitudes of the Cotton effects near 310 and 350 nm were expected to reflect well the β-turn preference of the peptides.

This paper describes ^{1}H and ^{13}C nuclear magnetic resonance (NMR) studies on the conformations of tetrapeptide derivatives related to the β-turn part of GS, Dnp-L-Leu-X-L-Pro-L-Val-pNA (**I**, X=D-Ala; **II**, X=Gly; **III**, X=L-Ala), to study a correlation between the Cotton effects and the conformations of these peptides (Fig. 2). ^{1}H NMR measurements were systematically carried out including (a) temperature dependence of NH proton chemical shifts in various solutions, (b) nuclear Overhauser effects on amide, CH, and aromatic proton resonances, and (c) solvent dependences of NH and CH proton chemical shifts and spin-coupling constants ($^3J_{NH-C^{\alpha}H}$).

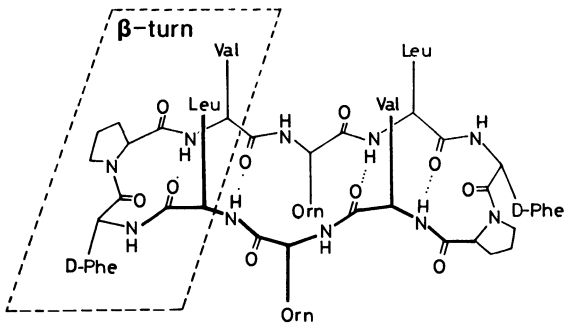

Fig. 1. β-Sheet conformation of gramicidin S.

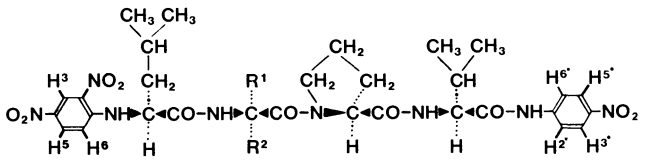
Experimental

Syntheses of **I**—**III** were reported previously.[8] The solvent DMSO-d_6 (99.8%) was obtained from Commissariat a l'Energy Atomique and CD_3OH (99.5%) and DMF-d_7 (99.5%) from E. Merck.

^{1}H NMR spectra were recorded on a Bruker WH-270 spectrometer (270 MHz for ^{1}H), equipped with a Bruker B-ST-100/700 temperature control unit. ^{13}C NMR spectra were recorded on a JEOL FX-90Q (22.5 MHz for ^{13}C),



I (X = D-Ala) : R^1 = H, R^2 = CH_3
II (X = Gly) : R^1 = H, R^2 = H
III (X = L-Ala) : R^1 = CH_3, R^2 = H

Fig. 2. Primary structures of Dnp-tetrapeptide-pNA's (**I**—**III**).

with a variable-temperature unit. Internal references for chemical shift were DSS for ^1H and TMS for ^{13}C. Nuclear Overhauser effect (NOE) data were also recorded on a Bruker WH-270 instrument at the concentration of 5 mM (1 M=1 mol dm^{-3}) at 23 °C. The FID's were collected after applying a 5-s low power saturation pulse in alternating blocks of 16 on-resonance and 16 off-resonance spectra using a SW of 3000 Hz with 16K data points for 512 spectral acquisitions each, Fourier transformed and subtracted to obtain the difference spectra.

CD spectra were measured on a JASCO J-40A spectropolarimeter at the concentration of 0.1 mM at room temperature (23±2 °C).

Results

CD Measurements. CD spectra of **I**—**III** were measured in DMF and DMSO solutions, and the results are summarized in Fig. 3 together with those measured in MeOH solutions.[7] Compound **I** having D-Ala at the second position showed the largest Cotton effects in DMF and DMSO solutions as well as in MeOH solution of the three compounds. In DMSO solution, however, the Cotton effects decreased to about 40% of those in DMF and MeOH solutions. Compound **III** showed no significant CD band near 310 nm and 350 nm in any solutions, and **II** showed intermediate CD spectra between **I** and **III**. The strong CD bands of **I** are not due to intermolecular interaction, since CD spectra of **I** showed no concentration dependences at the range from 5 mM to 0.1 mM. Accordingly, the strong CD bands are attributed to the intramolecular interaction between the two terminal chromophores in **I**.

Assignments of ^1H Resonances. The ^1H NMR spectra of **I**—**III** were assigned with the aid of spin-decoupling, H–D exchange of NH protons, and saturation transfer (between the two conformers) in CD_3OH, DMSO-d_6, and DMF-d_7 solutions as shown in Table 1. All the spectra showed two sets of resonances for most of the protons due to *cis-trans* isomerism for the X–L-Pro bonds. Chemical shifts of aromatic protons are shown in Fig. 4, and those of the other protons are listed in Table 1 together with spin-coupling constants ($^3J_{NH-C^\alpha H}$). In all the solutions, aromatic protons of major conformer were shifted to higher field in the order of **I**>**II**>**III**, while those of minor conformers did not show such significant sequence dependences (Fig. 4). In DMSO-d_6 solution, the L-Pro–C$^\alpha$H proton of the major conformer of **I** showed higher field shift (4.41 ppm) than that of the minor conformer (4.87 ppm) suggesting that major conformer had *trans* D-Ala–L-Pro bond. This assignment was ascertained by ^{13}C NMR study as described in the next section. In the other solutions and also in the other compounds (**II** and **III**), the L-Pro–C$^\alpha$H protons of the major conformers showed the similar chemical shifts to that of the major conformer of **I** in DMSO-d_6 solution. The D-Ala residue in major conformer of **I** showed small spin-coupling constants ($^3J_{NH-C^\alpha H}$) of 3.9 and 4.0 Hz in CD_3OH and in DMF-d_7 solutions, respectively, suggesting that the ϕ angle of D-Ala residue is certainly fixed in these solutions, whereas the L-Ala residue of **III** showed spin-coupling constants

typical to free rotation.

Assignments of ^{13}C Resonances. ^{13}C NMR is useful for the study of *cis-trans* isomerism of the X–L-Pro peptide bond.[9] Chemical shifts of the L-Pro–C^β and C^γ carbons of **I**—**III** in DMSO-d_6 solutions were determined in order to assign the two sets of resonances to the conformers with *trans* or *cis* X–L-Pro bond. Though the resonances of the L-Pro–C^γ carbons were overlapped with those of L-Leu–C^γ and C^δ carbons, those of the L-Pro–C^β carbons were clearly observed; the major and the minor resonances were 28.99 and 31.85 ppm for **I**, 29.10 and 31.97 ppm for **II**, and 28.75 and 31.56 ppm for **III**, respectively. The results indicate that major resonances can be attributed to the conformers with *trans* X–L-Pro bond.

Temperature Dependences of Proton Chemical Shifts. The temperature dependences of chemical shifts of amide proton resonances are useful for distinguishing between "exposed" and "intramolecularly hydrogen-bonded" amide proton;[10] exposed protons exhibit larger temperature coefficients than hydrogen-bonded amide protons. The temperature dependences of amide proton chemical shifts are shown in Fig. 5 for major conformers of **I**—**III**. The L-Val–NH proton of **I** showed much smaller temperature dependences (-2.72×10^{-3} and -2.13×10^{-3} ppm °C^{-1}) than the D-Ala–NH proton (-7.06×10^{-3} and -5.93×10^{-3} ppm °C^{-1}) in CD_3OH and in DMF-d_7 solutions, respectively, indicating that the L-Val–NH proton of **I** was involved in stable hydrogen bonding. In DMSO-d_6 solution, the L-Val–NH proton of **I** also showed smaller temperature dependence (-3.44×10^{-3} ppm °C^{-1}) than the D-Ala–NH proton (-4.59×10^{-3} ppm °C^{-1}), though the difference between the two NH protons was not so clear as that in CD_3OH or DMF-d_7 solution. The L-Val–NH proton of **II** showed a little smaller temperature dependence than the Gly–NH proton in CD_3OH and in DMF-d_7 solutions, though the values (-6.85×10^{-3} and -5.00×10^{-3} ppm °C^{-1}, respectively) were too large for strongly hydrogen-bonded species. The values for the L-Val–NH and Gly–NH protons of **II** were reversed in DMSO-d_6 solution. The L-Val–NH proton of **III** always showed larger temperature dependences than the L-Ala–NH proton. The temperature dependences of L-Val–NH protons were in the order of **I**<**II**<**III** in any solvents. Most of the protons other than amide ones showed little temperature dependences, suggesting that the conformations of **I**—**III** did not change significantly in the temperature range of these experiments.

Nuclear Overhauser Effects. Nuclear Overhauser effects (NOE's) are useful for the conformational analysis of peptides, since the effects are inversely proportional to the sixth power of the distance between the irradiated and observed protons. NOE's were observed for **I**—**III** in DMF-d_7 solutions at 23 °C as shown in Table 2. It is noteworthy that NOE's were observed for Dnp–H^3 resonance and D-Ala–$C^\alpha H$ proton resonance by the irradiation of pNA aromatic protons (Fig. 6A) and L-Pro–$C^\alpha H$ proton (Fig. 6B) resonances, respectively. On the other hand, the NOE enhancement was not observed for **III** between Dnp and pNA aromatic protons.

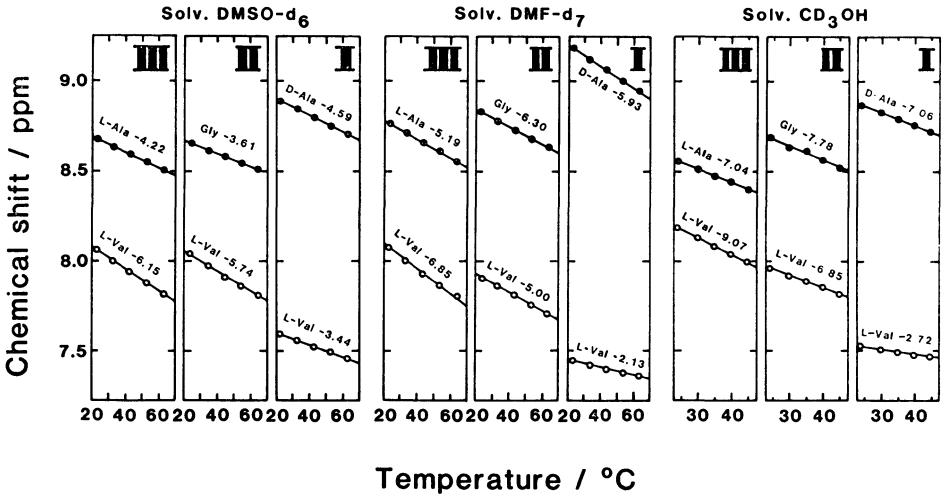

Fig. 5 Temperature dependences of amide proton chemical shifts of major resonances of **I**—**III**. Numbers on the lines refer to $10^3 \times$temperature coefficient in ppm $°C^{-1}$. ○: L-Val[4]-NH, ●: X^2-NH.

TABLE 2. NOE OBSERVATIONS FOR Dnp-L-Leu-X-L-Pro-L-Val-pNA (**I**—**III**) IN DMF-d_7 AT 23 °C[a)]

a) Signals of minor conformer with *cis* X-L-Pro bond are omitted. b) C^δH and C^δH′ are a lower and a higher field signals, respectively.

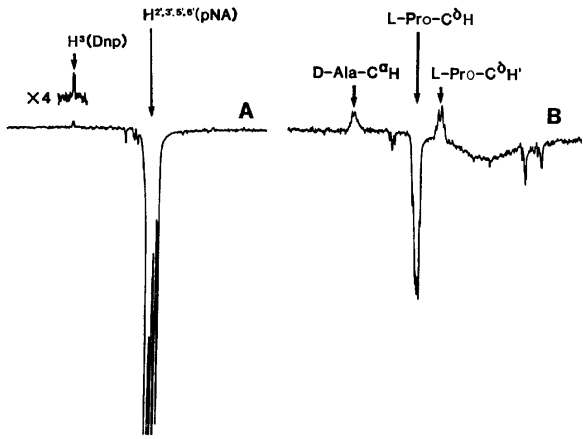

Fig. 6. NOE observations of **I** in DMF-d_7 solution. Signals irradiated were (A) pNA-$H^{2',3',5',6'}$ protons and (B) L-Pro-$C^{\beta}H$ proton.

Discussion

Cis-trans *Isomerism for X-L-Pro Bonds.* Major resonances of **I**—**III** in DMSO-d_6 solutions were attributed to the conformers with *trans* X–L-Pro bonds by ^{13}C NMR resonances. In CD_3OH and DMF-d_7 solutions, also, major resonances of **I**—**III** are considered to be due to the *trans* isomer, since all the major L-Pro–$C^{\alpha}H$ proton resonances showed similar chemical shifts to those in DMSO-d_6 solution. Populations of *trans* conformers of **I** and **II** increased in the order of in DMSO-d_6<DMF-d_7<CD_3OH solutions (Table 1). On the other hand, those of **III** did not show such large solvent dependences. It seems that the *cis* conformers of **I**—**III** are not in the fixed conformations in all solvents examined, since they showed similar chemical shifts of aromatic and some other protons for the three compounds (Fig. 4 and Table 1). These are ascertained by the large temperature dependences of the L-Val and X (X=D-Ala, Gly, or L-Ala) NH proton chemical shifts for the *cis* conformers. In contrast, the *trans* conformers of **I**—**III** showed large sequence and solvent dependences of chemical shifts for most of the NH and $C^{\alpha}H$ protons, indicating that their *trans* conformations depend on sequence and solvent. Detailed discussions are described hereafter for the conformations of *trans* (major) isomer of **I**—**III**.

Intramolecular Hydrogen Bonding. The L-Val–NH proton of **I** is concerned in a strong hydrogen bonding in CD_3OH or DMF-d_7 solution as shown in Fig. 5. In DMSO-d_6 solution, also, the L-Val–NH group is hydrogen-bonded. The hydrogen bonding is intramolecular, since **I** showed no concentration dependence of CD spectra. On the other hand, the L-Val–NH proton chemical shifts of **III** showed such large temperature dependences as that of *N*-methylacetamide in all the three solvents, indicating that the L-Val–NH group is not involved in an intramolecular hydrogen bonding. The temperature coefficients of L-Val–NH chemical shifts of **II** are intermediate of **I** and **III** for the three solutions. Accordingly, it seems that the magnitudes of the hydrogen bonding of the L-Val–NH protons of **I**—**III** are in the order of **I**>**II**>**III**≈0 in CD_3OH and DMF-d_7 solutions and **I**>**II**≥**III**≈0 in DMSO-d_6 solution.

The two CO groups of L-Leu (β-turn) and D-Ala (γ-turn) are the candidate for the acceptor of the intramolecular hydrogen bonding of L-Val–NH proton for compound **I**. It is noteworthy that the coupling constant ($^3J_{NH-C^{\alpha}H}$) of D-Ala residue for compound **I** is as small as 3.9 Hz and 4.0 Hz in CD_3OH and DMF-d_7 solution, respectively. The coupling constant ($^3J_{NH-C^{\alpha}H}$) of L-Ala residue is 8.5 Hz for Ac–L-Ala–$NHCH_3$, and 7.1 Hz for Ac–L-Ala–(*trans*)-L-Pro–OH,[11] which do not have specific conformations. These indicate that the ϕ angle of D-Ala residue of compound **I** is fairly fixed. This holds for the β-turn conformation (L-Leu^1–CO···HN–L-Val^4) of compound **I**: The ϕ angle of the second [$(i+1)$th] residue of β-turn conformation is known to be −60° for L-amino acid or +60° for D-amino acid, which indicates that the coupling constant ($^3J_{NH-C^{\alpha}H}$) for the residue is *ca.* 3.5 Hz.

In this series of compounds, the weaker is the hydrogen bonding of L-Val residue, the larger is the coupling constant ($^3J_{NH-C^{\alpha}H}$) of X-residue (X=L-Ala or D-Ala). On the other hand, the ϕ angle will not be fixed in the case of γ-turn conformation (D-Ala^2–CO···HN–L-Val^4).

*Type of the β-Turn of **I** and **II**.* [D-$Ala^{4,4'}$]-GS, which has similar conformation to that of GS,[6] is a good measure to estimate the type of the β-turn of **I**, though it is difficult usually to discriminate exactly the type of the β-turn of such a linear peptide as **I**. The NH protons of **I** in CD_3OH and DMF-d_7 solutions showed similar chemical shifts, coupling constants and temperature dependences to those of [D-$Ala^{4,4'}$]-GS in DMSO-d_6 solution (chemical shifts: D-Ala, 8.92 ppm; L-Val, 7.40 ppm; $^3J_{NH-C^{\alpha}H}$: D-Ala 3.7 Hz; L-Val, 8.8 Hz; temperature dependences: D-Ala, -7.50×10^{-3} ppm $°C^{-1}$; L-Val, -2.52×10^{-3} ppm $°C^{-1}$). Furthermore, NOE observation between D-Ala–$C^{\alpha}H$ and L-Pro–$C^{\beta}H$ protons of **I** indicates the proximity of these two protons (Fig. 6B). These results suggest that **I** takes the same type II′ β-turn as that of [D-$Ala^{4,4'}$]-GS. Since the corresponding residue of **II** to the D-Ala of **I** for the β-turn conformation is Gly, the type of the β-turn of **II** is expected to be similar to that of **I** (type II′).

Interaction between Dnp and pNA Chromophores. As the results of β-turn formation of peptide backbone, N- and C-terminal chromophores approach to each other. Certainly, higher-field shifts of aromatic proton chemical shifts of Dnp and pNA groups in *trans* isomer of **I** are due to ring-current effects, indicating the proximity of the two terminal chromophores (Fig. 4). On the other hand, aromatic protons of both isomers of **III** did not show large higher-field shifts but show the similar chemical shifts as those in *cis* isomer of **I**. Aromatic protons in the *trans* isomer of **II** showed intermediate higher-field shifts between those of the *trans* isomer of **I** and **III**. NOE observation between the aromatic protons of Dnp and pNA chromophores in the *trans* isomer of **I** is a direct evidence of the approach of these two chromophores (Fig. 6A).

Correlation between CD Spectra and β-Turn Conformations. The characteristic CD spectra of Dnp–tetrapeptide–pNA's are considered to be due to the exciton coupling of the transition moments in the two terminal chromophores. The order of Cotton effects of **I**—**III** shown in Fig. 3 is in a good accordance with the order of populations of β-turn conformers in **I**—**III** estimated from NMR measurements: In CD_3OH and in DMF-d_7 solutions, **I** has higher population of β-turn conformers than **II**, and **III** does not take a β-turn conformation. In DMSO-d_6 solution, **I** has some populations of β-turn conformer, though at a lower level than those in CD_3OH and in DMF-d_7 solutions, while **II** has little population of β-turn conformer as well as **III**. These good agreements suggest that the CD spectra of Dnp–pNA derivatives of tetrapeptides are good reflections of β-turn preference of the peptides.

Structure-activity Relationship of Gramicidin S Analogs. The β-turn preferences of **I**—**III** showed good correlation with the activities of the GS analogs having the same tetrapeptide sequences as **I**—**III** at their β-turn parts. This means that conformational preference of partial sequences of GS analogs seem to play a significant role for determining their biological activities as the results of stabilization of their active conformations.

We thank Professor Tatsuo Miyazawa of The University of Tokyo for helpful discussion.

Studies on the β-Turn of Peptides. VII.[1] Syntheses and Antibiotic Activities of Gramicidin S Analogs with L-Pro-L-Asn or L-Pro-D-Ala Sequence at the β-Turn Part

Kazuki SATO* and Ukon NAGAI

Mitsubishi-Kasei Institute of Life Sciences, 11 Minamiooya, Machida, Tokyo 194

(Received April 30, 1983)

Two analogs of gramicidin S (GS), [L-Pro$^{4,4'}$, L-Asn$^{5,5'}$]-GS (**10a**) and [L-Pro$^{4,4'}$, D-Ala$^{5,5'}$]-GS were synthesized to investigate the possibility of replacing the β-turn part of GS by a different type of β-turn keeping the biological activity. For the synthesis of **10a**, three procedures were examined and satisfactory results were obtained by the active ester method applied to cyclization of linear decapeptide with L-Pro at the C-terminus. Neither analog showed antibiotic activity indicating that the β-turn part of GS could not be replaced with L-Pro-L-Asn or L-Pro-D-Ala sequences without affecting on its activity. The CD and ORD spectra of the analogs and their 2,4-dinitrophenyl derivatives showed weaker Cotton effects than those of GS and its derivative, respectively. So, the analogs were considered not to take GS-like β-sheet conformation. The reason why the analogs did not take such conformations was investigated by the model tetrapeptides with chromophoric substituents.

Gramicidin S (GS) is a cyclic decapeptide antibiotic with the primary structure shown in Fig. 1.[2] Several models have been proposed for the conformation of GS in solid state and solution.[3] The most favorable model is the intramolecular antiparallel β-sheet with four hydrogen bonds between Val and Leu residues, and two β-turns (type II') around the D-Phe–Pro sequences (Fig. 2).[4] The characteristic feature of this conformation is the orientation of side chains in which the charged Orn side chains are on one side and the hydrophobic Val and Leu side chains on the other side of the molecule.[5] Kato and Izumiya introduced the word "sidedness hypothesis" which means that the sidedness is important for the antibiotic activity of GS.[6,7] The hypothesis is supported by the results of many investigations of synthetic amino acid-substituted analogs.[8] The characteristic conformation of GS is considered to be stabilized not only by the four intramolecular hydrogen bonds but also by the stable β-turns formed by the two D-Phe–Pro sequences. The antibacterial activities of the GS analogs substituted both or either of 4,4' and 5,5' positions are summarized as follows:[8] The analogs in which D-Phe residues at the 4,4' positions are replaced with other D-amino acids show antibacterial activity, while replacement with L-amino acids leads to loss of activity, and the analog replaced with Gly shows weaker activity than the D-amino acid analogs. The Pro residues at the 5,5' positions can be replaced by a variety of amino acids (Gly, Sar, Leu, *etc.*) without loss of activity. One of the exceptions is [Aib$^{5,5'}$]-GS which shows no antibacterial activity. The activity of these analogs closely correlate to their conformations.[9] For example, the population of GS-type β-sheet conformer was in the order of GS≈[D-Ala$^{4,4'}$]-GS>[Gly$^{4,4'}$]-GS≫[L-Ala$^{4,4'}$]-GS≈0.[10]

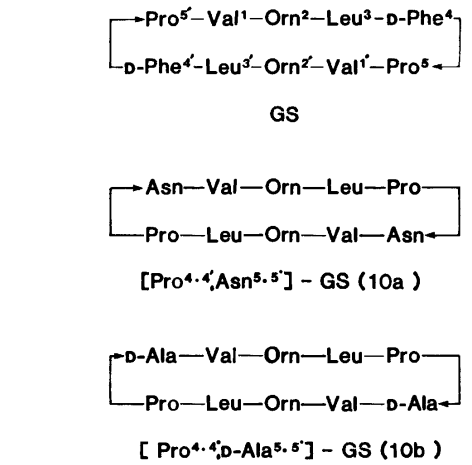

Fig. 1. Primary structures of GS and its analogs (**10a** and **10b**).

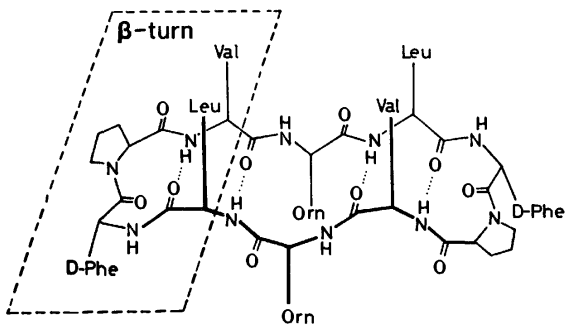

Fig. 2. β-Sheet conformation of GS.

In the course of studies on the β-turn of peptides, we proposed a new method to study the β-turn conformation of linear tetrapeptides.[1,11–15] *N*-(2,4-Dinitrophenyl)tetrapeptide *p*-nitroanilides (Dnp–tetrapeptide–pNA's) exhibit characteristic CD spectra above 250 nm when they take β-turn conformations. The Cotton effects are considered to be due to the exciton coupling of the transition moments in the two terminal chromophores. The magnitude of the Cotton effects near 350 and 310 nm were shown to reflect well the β-turn preference of the tetrapeptides.[11] In the case of model peptides related to the β-turn part of GS, β-turn preferences of the tetrapeptide derivatives had strong correlation with antibiotic activities of the GS analogs containing similar tetrapeptide sequences at their β-turn part.[12] Another series of compounds with a general structure Dnp–Gly–Pro–Y–Gly–pNA (Y=Asn, Gly, Ala, Gln, D-Ala) showed strong CD bands with opposite sign to those of GS-model peptides.[13] The

results indicated that the type of β-turn of the latter compounds were different from that of GS-model peptides (type II'). When Y was D-Ala, the strongest CD bands were observed and next ones were observed when Y was Asn (*cf.* Fig. 9).

It is of interest whether the β-turn part of GS can be replaced by a different type of β-turn keeping the biological activity. This paper describes the syntheses, antibiotic activities, and CD and ORD measurements of [Pro$^{4,4'}$, Asn$^{5,5'}$]-GS (**10a**) and [Pro$^{4,4'}$, D-Ala$^{5,5'}$]-GS (**10b**), in which the D-Phe–Pro sequences in GS were replaced by Pro–Asn and Pro–D-Ala sequences, respectively (Fig. 1). If Pro–Asn or Pro–D-Ala sequence could take stable β-turn conformation when incorporated in a cyclic decapeptide structure, the analogs would take GS-like β-sheet conformation, which would fulfil the "sidedness hypothesis," and would exhibit antibiotic activity.

Results and Discussion

Syntheses of Peptides. First, we chose the route A shown in Fig. 3 for the synthesis of **10a**, because GS and its analogs had been synthesized in satisfactory results by cyclization of linear decapeptides with Leu at the C-terminus.[16,17] Stepwise chain elongation from C-terminal tripeptide H–Val–Orn(Z)–Leu–OEt[17] gave Boc–pentapeptide ester (**3**), which was converted into pentapeptide ester (**4**) and Boc–pentapeptide hydrazide (**5**) with the aid of hydrogen chloride in formic acid and hydrazine hydrate, respectively. Fragment condensation of **4** and **5** by azide method afforded Boc–decapeptide ester (**6**), which was converted into the hydrazide derivative (**7**) by treatment with hydrazine hydrate. Deblocking of Boc-group of **7** gave N-terminal-free decapeptide hydrazide (**8**). Cyclization of **8** by azide method was examined, but the results were not satisfactory because of low yields ($\leq$11%) of the crude cyclized peptide and many by-products contaminated. These results forced us to change the synthetic strategy.

Next, we examined two different routes (routes B and C) concurrently, in which the Pro residue was placed at the C-terminus and azide method and active ester method were employed for cyclization as shown in Figs. 4 and 5, respectively. In route B, Boc–pentapeptide ester (**17**) was prepared by stepwise elongation from C-terminal H–Pro–OBzl. Pentapeptide ester (**18**) and Boc–pentapeptide hydrazide (**19**) both derived from **17** were coupled by azide method to afford Boc–decapeptide ester (**20**), which was converted into the

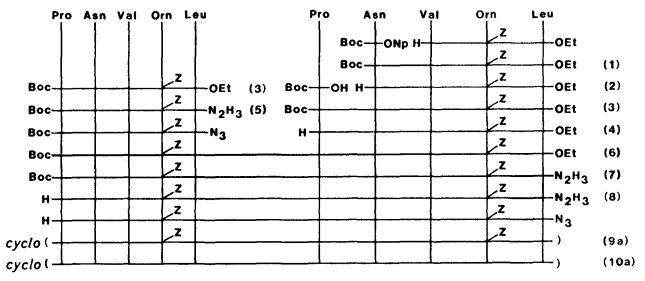

Fig. 3. Route A for the synthesis of **10a**.

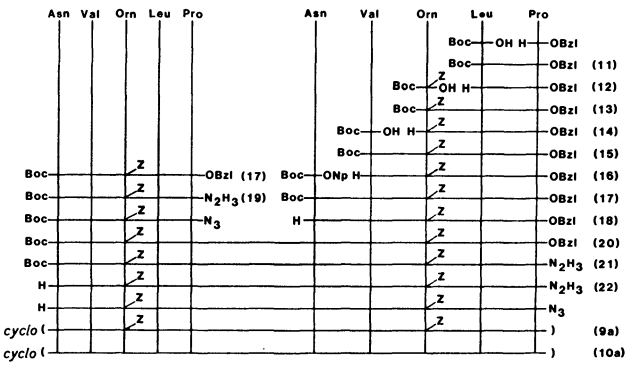

Fig. 4. Route B for the synthesis of **10a**.

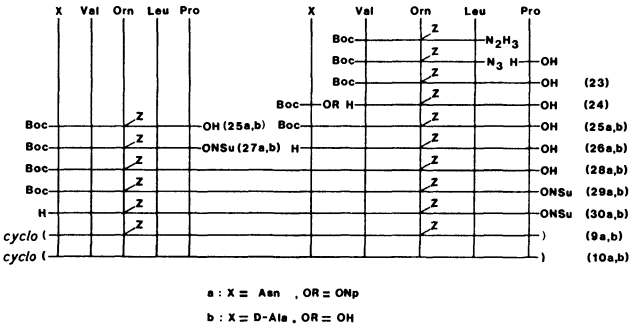

Fig. 5. Route C for the synthesis of **10a** and **10b**.

hydrazide derivative (**21**). Cyclization of **22** derived from **21** gave higher yield (38%) of crude cyclized peptide than that in route A. The crude product was purified by Sephadex LH-20 column chromatography and repeated recrystallization, however, small amount of by-product could not be removed. In route C, Boc-tetrapeptide with free carboxy terminus (**23**) was prepared by azide coupling of Boc–Val–Orn(Z)–Leu–N_2H_3[10] with H–Pro–OH. Compound **23** was treated with hydrogen chloride in formic acid, and subsequent active ester coupling of **24** with Boc–Asn–ONp afforded Boc–pentapeptide (**25a**). Pentapeptide (**26a**) and Boc–pentapeptide–ONSu (**27a**) both derived from **25a** were coupled to afford Boc–decapeptide (**28a**), which was converted into Boc–decapeptide–ONSu (**29a**). Boc-group of **29a** was removed with TFA to afford decapeptide–ONSu (**30a**). Cyclization of **30a** by active ester method gave satisfactory results: Yield of the crude cyclized peptide was 84%, and analytically pure **9a** was obtained after gel filtration with Sephadex LH-20 in 81% yield from **30a**. Compound **9a** prepared by route C was hydrogenated to afford [Pro$^{4,4'}$, Asn$^{5,5'}$]-GS (**10a**).

Another analog, [Pro$^{4,4'}$, D-Ala$^{5,5'}$]-GS (**10b**), was synthesized by the similar manner to that described for **10a** according to route C as shown in Fig. 5. The homogeneity of **10a** and **10b** was confirmed by thin-layer chromatography, paper electrophoresis, elemental analysis, and amino acid analysis.

It is interesting that the results of the cyclization largely depend on the sequence of the linear decapeptide precursor and on the activation method. Minematsu *et al.* reported high sequence dependence in the cyclization of linear pentapeptide precursor of GS.[18] They considered that steric character of terminal amino acids

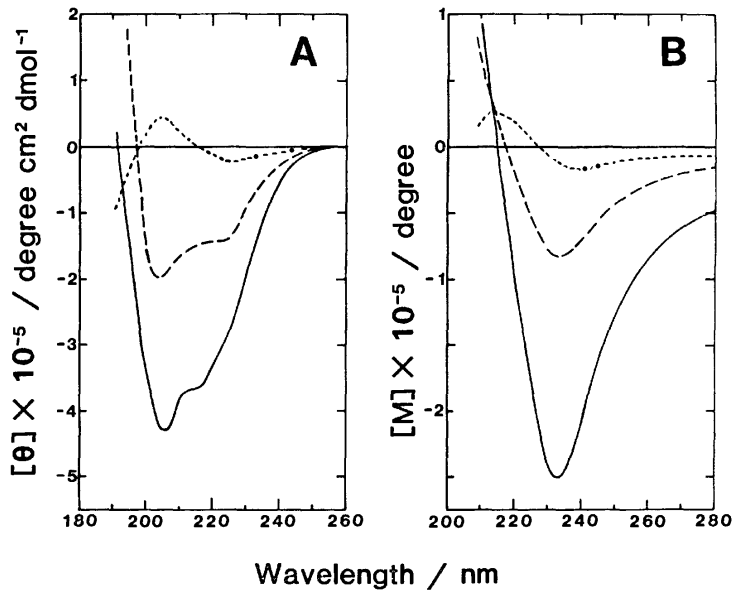

Fig. 6. CD (A) and ORD (B) spectra of GS and its analogs (**10a** and **10b**) in MeOH. ——: GS, – – –: **10a**, ·····: **10b**.

and conformation of peptide in the precursor might be important factors governing the marked differences in the mode of cyclization. Lee and Izumiya explained the sequence dependence in the cyclization of linear hexapeptide precursor of protodestruxin through the assumed conformation of the linear hexapeptide.[19] However, as far as we are aware, such a high sequence dependence as that shown in this work has not been reported in the case of cyclization of linear decapeptide precursor of GS and its analogs. Although the reason why such a high sequence dependence was observed is not clear, steric character of terminal amino acids is considered to play an important role for determining the mode of cyclization. Nucleophilic attack of amino group of Asn residue to carbonyl group of Pro residue (routes B and C) may be less hindered than that of imino group of Pro residue to carbonyl group of Leu residue (route A). As to activation method, active ester method seems to be more useful than azide method because of higher yield and experimental simplicity, when racemization-free amino acid such as Pro or Gly is used at the C-terminus of the linear precursor peptide.

CD and ORD Studies. Figure 6 shows the CD and ORD spectra of GS and its analogs (**10a** and **10b**). The analog **10a** shows similar curves to those of GS in shape, but the Cotton effects were much weaker than those of GS. In the case of **10b**, the shapes of the curves were also much different from those of GS. Usually, active analogs of GS having GS-like β-sheet conformation are considered to show similar ORD curves to that of GS.[9] It is possible for the analogs, **10a** and **10b**, to show the different CD and ORD spectra from those of GS even when they have β-sheet conformations, because the type of the β-turn of these analogs is considered to differ from that of GS. However, weak Cotton effects shown by the analogs suggest that they have some unordered conformations. The CD spectrum of the bis(Dnp) derivative of GS, [Orn(Dnp)[2,2']]-GS (**31c**), shows strong Cotton effects

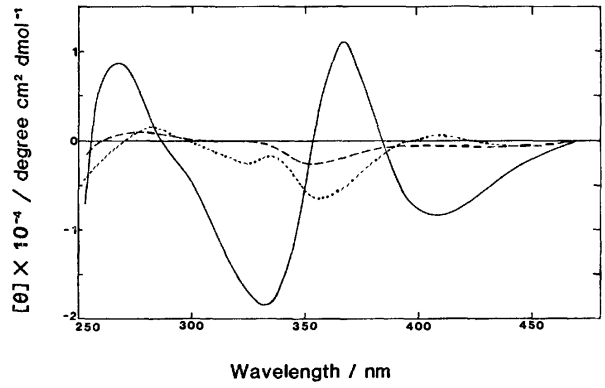

Fig. 7. CD spectra of bis(Dnp) derivatives of GS (**31c**), **10a** (**31a**), and **10b** (**31b**) in MeOH. ——: **31c**, – – –: **31a**, ·····: **31b**.

above 250 nm due to the interaction of the two Dnp chromophores, because the side chains of the two Orn residues in GS are close to each other owing to the β-sheet conformation of GS (Fig. 2).[10] Both of the bis(Dnp) derivatives of **10a** and **10b** (**31a** and **31b**, respectively) showed much weaker Cotton effects than that of GS, suggesting that neither **10a** nor **10b** took GS-like β-sheet conformation (Fig. 7).

Biological Activities. Neither **10a** nor **10b** showed antibiotic activities even at the concentration of 100 μg/ml. At such higher concentrations as 400 μg/ml and 200 μg/ml, respectively, **10a** and **10b** showed antibiotic activities on some Gram-positive bacteria, but practically they were inactive. The results indicate that the β-turn part of GS cannot be replaced with Pro–Asn or Pro–D-Ala sequences without affecting on its activity. Certainly, both analogs were hard to be absorbed on the cells of GS-sensitive strains (*B. subtilis* and *S. aureus*).[20]

Conformations and β-Turn Preferences. The inactivities of the analogs (**10a** and **10b**) seemed to result

from the fact that they did not take GS-like β-sheet conformation on the basis of the CD and ORD studies. So, the reason why they did not take such conformations was investigated. Heretofore, the high β-turn preferences of Pro–Asn and Pro–D-Ala sequences have been discussed by the model peptides with Gly residues at the first and the fourth positions of tetrapeptides,[13] however in the GS analogs these positions are occupied by Leu and Val residues, respectively. So, we synthesized Dnp–Leu–Pro–Asn–Val–pNA (**37a**) and Dnp–Leu–Pro–D-Ala–Val–pNA (**37b**), in which the terminal positions of Dnp–Gly–Pro–Y–Gly–pNA (Y=Asn or D-Ala) were replaced with Leu and Val residues, respectively (Fig. 8). Both of **37a** and **37b** showed weak Cotton effects similar to those of Dnp–Leu–Ala–Pro–Val–pNA which is considered to take random conformation (Figs. 9A and 9B).[11] The results indicated the importance of the terminal amino acid residues for the tetrapeptide sequences to take β-turn conformation. So, reluctance of the tetrapeptide sequences to take β-turn is considered to be the reason why **10a** and **10b** do not take GS-like β-sheet conformation. It is interesting to note that in the case of GS-model peptides, similar replacement of the terminal residues do not affect the β-turn preference (Fig. 9C).[12]

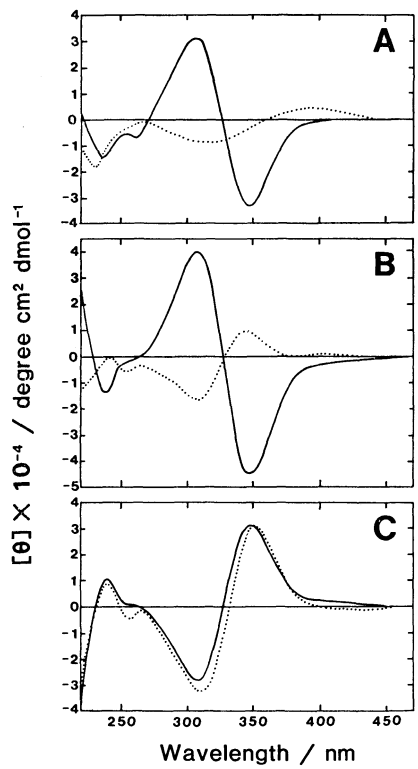

Fig. 9. CD spectra of Dnp-X′-Pro-Asn-Y′-pNA (A), Dnp-X′-Pro-D-Ala-Y′-pNA (B), and Dnp-X′-D-Ala-Pro-Y′-pNA (C)[12] in MeOH. ——: X′=Y′=Gly, ·····: X′=Leu, Y′=Val.

Experimental

Syntheses of Peptides. All the melting points were measured on a Yanagimoto micro melting point apparatus and were uncorrected. TLC's were carried out on Merck silica gel 60 F_{254} plates with the following solvent systems: R_f^1, $CHCl_3$–MeOH (5:1, v/v); R_f^2, $CHCl_3$–MeOH–AcOH (95:5:1, v/v); R_f^3, *n*-BuOH–AcOH–pyridine–H_2O (4:1:1:2, v/v). Optical rotations were measured on an Union automatic polarimeter PM-201. Amino acid analyses of peptides were performed by Durrum D-500 Amino Acid Analyzer after hydrolyses in 6 M (1 M=1 mol dm^{-3}) HCl at 105 °C for 20 h.

*Boc–Asn–Val–Orn(Z)–Leu–OEt (**1**).* To a solution of H–Val–Orn(Z)–Leu–OEt·HCl[17] (2.72 g, 5 mmol) and TEA (0.7 ml, 5 mmol) in DMF (20 ml) was added Boc–Asn–ONp (1.77 g, 5 mmol). The reaction mixture was stirred at room temperature overnight and evaporated to leave a solid which was collected by filtration with the aid of water and washed successively with 10% citric acid, 4% $NaHCO_3$, and water, and dried *in vacuo* over P_2O_5. The crude product was recrystallized from MeOH; yield, 2.67 g (74%); mp 214 °C; $[\alpha]_D^{22}$ −57.2° (*c* 1, MeOH); R_f^1 0.69, R_f^2 0.24, R_f^3 0.97.

Found: C, 58.58; H, 7.48; N, 11.47%. Calcd for $C_{35}H_{56}O_{10}N_6$: C, 58.32; H, 7.83; N, 11.66%.

*H–Asn–Val–Orn(Z)–Leu–OEt·HCl (**2**·HCl).* Compound **1** (2.16 g, 3 mmol) was dissolved in 0.1 M hydrogen chloride in formic acid (36 ml). The solution was allowed to stand at room temperature for 30 min and evaporated. The residue was solidified by the addition of ether; yield, 1.97 g (100%); mp 210—212 °C; $[\alpha]_D^{22}$ −33.0° (*c* 1, MeOH); R_f^1 0.25, R_f^3 0.71.

Found: C, 54.62; H, 7.51; N, 12.77%. Calcd for $C_{30}H_{49}O_8N_6Cl$: C, 54.83; H, 7.52; N, 12.79%.

*Boc–Pro–Asn–Val–Orn(Z)–Leu–OEt (**3**).* To a chilled solution of Boc–Pro–OH (344 mg, 1.6 mmol) and TEA (0.22 ml, 1.6 mmol) in THF (5 ml) was added isobutyl chloroformate (0.21 ml, 1.6 mmol) at −15 °C. After 10 min, a chilled solution of **2**·HCl (1.05 g, 1.6 mmol) and TEA (0.22 ml, 1.6 mmol) in DMF (5 ml) was added. The mixture was stirred at 0 °C for 1 h and at room temperature overnight and evaporated *in vacuo*. After the addition of water, the solid formed was collected by filtration and washed as described for **1**. The crude product was recrystallized from EtOH; yield, 1.11 g (85%); mp 193 °C; $[\alpha]_D^{22}$ −75.8° (*c* 1, MeOH); R_f^1 0.67, R_f^2 0.13, R_f^3 0.93.

Found: C, 58.54; H, 7.66; N, 11.71%. Calcd for $C_{40}H_{63}O_{11}N_7$: C, 58.73; H, 7.76; N, 11.99%.

*H–Pro–Asn–Val–Orn(Z)–Leu–OEt·HCl(**4**·HCl).* Compound **3** (409 mg, 0.5 mmol) was treated with 0.1 M hydrogen chloride in formic acid (6 ml) as described for **2**·HCl; yield, 362 mg (96%); mp 220—222 °C; $[\alpha]_D^{22}$ −62.8° (*c* 0.5, MeOH); R_f^1 0.12, R_f^3 0.69.

Found: C, 55.58; H, 7.17; N, 13.00%. Calcd for $C_{35}H_{56}O_9N_7Cl$: C, 55.73; H, 7.48; N, 13.00%.

*Boc–Pro–Asn–Val–Orn(Z)–Leu–N_2H_3 (**5**).* A solution of **3** (491 mg, 0.6 mmol) and hydrazine hydrate (0.58 ml,

12 mmol) in DMF (3 ml) was allowed to stand at room temperature for 2 d. The solution was poured dropwise into chilled water (100 ml), and the precipitate formed was collected by filtration, washed with water, and dried. The crude product was recrystallized from EtOAc; yield, 357 mg (74%); mp 235—236 °C; $[\alpha]_D^{22}$ −63.0° (*c* 0.2, MeOH); R_f^1 0.47, R_f^3 0.83.

Found: C, 56.33; H, 7.59; N, 15.65%. Calcd for $C_{38}H_{61}O_{10}N_9 \cdot 1/2\ H_2O$: C, 56.13; H, 7.69; N, 15.51%.

Boc–(Pro–Asn–Val–Orn(Z)–Leu)$_2$–OEt (**6**). To a solution of **5** (322 mg, 0.4 mmol) in DMF (2 ml) were added 2 M hydrogen chloride in EtOAc (0.8 ml) and isopentyl nitrite (0.056 ml, 0.4 mmol) at −60 °C. After being stirred at −20 °C for 10 min, the solution was cooled again to −60 °C and neutralized with TEA (0.22 ml, 1.6 mmol). To the solution was added a chilled solution of **4**·HCl (302 mg, 0.4 mmol) and TEA (0.056 ml, 0.4 mmol) in DMF (1 ml). The reaction mixture was stirred at 0 °C for 2 d and then evaporated. Addition of water to the residue gave a white precipitate, which was filtered, washed successively with 10 % citric acid, 4% $NaHCO_3$, and water, and dried over P_2O_5. The crude product dissolved in MeOH (5 ml) was applied to a column (3×170 cm) of Sephadex LH-20 and eluted with MeOH. The fractions with the desired product detected by UV absorption and TLC were collected and evaporated to leave a solid which was recrystallized from EtOH; yield, 439 mg (74%); mp 227—228 °C; $[\alpha]_D^{22}$ −96.0° (*c* 0.2, MeOH); R_f^1 0.64, R_f^3 0.86.

Found: C, 58.05; H, 7.33; N, 12.96%. Calcd for $C_{73}H_{112}O_{19}N_{14} \cdot H_2O$: C, 58.15; H, 7.62; N, 13.01%.

Boc–(Pro–Asn–Val–Orn(Z)–Leu)$_2$–N_2H_3 (**7**). A solution of **6** (402 mg, 0.27 mmol) and hydrazine hydrate (0.65 ml, 13.5 mmol) in DMF (5 ml) was treated as described for **5**. The crude product was recyrstallized from DMF–ether; yield, 325 mg (82%); mp 238—240 °C; $[\alpha]_D^{22}$ −76.0° (*c* 0.2, MeOH); R_f^1 0.31, R_f^3 0.83.

Found: C, 57.14; H, 7.41; N, 15.11%. Calcd for $C_{71}H_{110}O_{18}N_{16} \cdot H_2O$: C, 57.08; H, 7.56; N, 15.01%.

H–(Pro–Asn–Val–Orn(Z)–Leu)$_2$–N_2H_3·2HCl (**8**·2HCl). Compound **7** (295 mg, 0.2 mmol) was treated with 0.1 M hydrogen chloride in formic acid (5 ml) as described for **2**·HCl; yield, 284 mg (98%); mp 215—217 °C; $[\alpha]_D^{22}$ −89.0° (*c* 0.2, MeOH); R_f^1 0.02, R_f^3 0.66.

Found: C, 54.41; H, 7.11; N, 15.21%. Calcd for $C_{66}H_{104}O_{16}N_{16}Cl_2$: C, 54.72; H, 7.24; N, 15.47%.

cyclo(–(*Pro–Asn–Val–Orn(Z)–Leu)$_2$*–) (**9a**). To a solution of **8**·2HCl (174 mg, 0.12 mmol) in DMF (2 ml) were added 2 M hydrogen chloride in EtOAc (0.24 ml) and isopentyl nitrite (0.017 ml, 0.12 mmol) at −60 °C. After 20 min, the reaction mixture was added to pyridine (60 ml) at 0 °C. After being stirred at 0 °C for 3 d, the solution was evaporated and the residue was dissolved in a mixture (120 ml) of MeOH–H_2O (5:1, v/v). The solution was applied to columns (1.6×10 cm each) of Dowex 50 (H^+ form) and Dowex 1 (OH^- form). The columns were washed with the same solvent (200 ml) and the effluent was evaporated to leave a white solid, which was collected by filtration with the aid of water. Because of the low yield, 17 mg (11%), and the contaminated by-products (R_f^1, 0.40 and 0.35) estimated to 50% of the crude product, further treatment of the crude product was not carried out. Cyclizations examined further two times gave similar results.

Boc–Leu–Pro–OBzl (**11**). Boc–Leu–OH (4.63 g, 20 mmol) and H–Pro–OBzl·HCl (4.83 g, 20 mmol) were coupled by mixed anhydride method as described for **3**. The reaction mixture was evaporated and the residue was dissolved in EtOAc. The solution was washed successively with 10% citric acid, 4% $NaHCO_3$, and water, dried over Na_2SO_4, and evaporated to leave an oil; yield, 7.61 g (91%); R_f^1 0.89, R_f^2 0.76.

H–Leu–Pro–OBzl·HCl (**12**·HCl). Compound **11** (7.61 g, 18 mmol) was treated with 0.1 M hydrogen chloride in formic acid as described for **2**·HCl; yield, 6.36 g (90%); mp 150—151 °C; $[\alpha]_D^{22}$ −67.8° (*c* 1, MeOH); R_f^1 0.48, R_f^2 0.04, R_f^3 0.70.

Found: C, 60.52; H, 7.05; N, 8.01%. Calcd for $C_{18}H_{27}O_3N_2Cl$: C, 60.92; H, 7.67; N, 7.89%.

Boc–Orn(Z)–Leu–Pro–OBzl (**13**). This compound was prepared from Boc–Orn(Z)–OH (1.72 g, 4.7 mmol) and **12**·HCl (1.67 g, 4.7 mmol) as described for **11**; yield of an oil, 2.44 g (78%); R_f^1 0.88, R_f^2 0.58, R_f^3 0.92.

H–Orn(Z)–Leu–Pro–OBzl·HCl (**14**·HCl). A solution of **13** (2.44 g, 3.7 mmol) in 0.1 M hydrogen chloride in formic acid was allowed to stand at room temperature for 30 min and evaporated to leave an oil, which was kept over KOH pellets under reduced pressure overnight and used for the next reaction without further treatment; yield, 2.21 g (100%); R_f^1 0.71, R_f^2 0.09, R_f^3 0.75.

Boc–Val–Orn(Z)–Leu–Pro–OBzl (**15**). This compound was prepared from Boc–Val–OH (0.08 g, 3.7 mmol) and **14**·HCl (2.21 g, 3.7 mmol) as described for **11**; yield of an oil, 2.35 g (84%); R_f^1 0.89, R_f^2 0.54, R_f^3, 0.98.

H–Val–Orn(Z)–Leu–Pro–OBzl·HCl (**16**·HCl). Compound **15** (2.35 g, 3.1 mmol) was dissolved in 0.1 M hydrogen chloride in formic acid, and the solution was allowed to stand at room temperature for 30 min and evaporated. The residue dissolved in a mixture (5 ml) of $CHCl_3$–MeOH–AcOH (95:5:1, v/v) was applied to a column (3.3×35 cm) of silica gel 60 (Merck) and the column was washed with the same solvent. The desired product was eluted with a mixture of $CHCl_3$–MeOH (9:1, v/v); yield of an oil, 1.98 g (92%); R_f^1 0.36, R_f^2 0.07.

Boc–Asn–Val–Orn(Z)–Leu–Pro–OBzl (**17**). Boc–Asn–ONp (0.99 g, 2.8 mmol) and **16**·HCl (1.98 g, 2.8 mmol) were treated as described for **1**. The crude product dissolved in MeOH (5 ml) was applied to a column (3×170 cm) of Sephadex LH-20 and eluted with MeOH. The fractions with the desired product were collected and evaporated. Addition of ether to the residue gave a solid which was recrystallized from MeOH–ether; yield, 1.91 g (77%); mp 186—188 °C; $[\alpha]_D^{22}$ −90.0° (*c* 1, MeOH); R_f^1 0.75, R_f^2 0.25, R_f^3 0.95.

Found: C, 61.29; H, 7.52; N, 11.08%. Calcd for $C_{45}H_{65}O_{11}N_7$: C, 61.41; H, 7.45; N, 11.14%.

H–Asn–Val–Orn(Z)–Leu–Pro–OBzl·HCl (**18**·HCl). Compound **17** (409 mg, 0.46 mmol) was treated with 0.1 M hydrogen chloride in formic acid (5.5 ml) as described for **2**·HCl; yield, 376 mg (100%); mp 185—188 °C; $[\alpha]_D^{22}$ −72.2° (*c* 1, MeOH); R_f^1 0.31, R_f^3 0.72.

Found: C, 56.68; H, 7.02; N, 11.73%. Calcd for $C_{40}H_{58}O_9N_7Cl \cdot 3/2\ H_2O$: C, 56.96; H, 7.29; N, 11.62%.

Boc–Asn–Val–Orn(Z)–Leu–Pro–N_2H_3 (**19**). Compound **17** (491 mg, 0.6 mmol) was treated with hydrazine hydrate (1.16 ml, 24 mmol) as described for **5**; yield, 302 mg (68%); mp 176—178 °C; $[\alpha]_D^{22}$ −96.8° (*c* 0.5, MeOH); R_f^1 0.43, R_f^2 0.02, R_f^3 0.85.

Found: C, 56.58; H, 7.74; N, 15.35%. Calcd for $C_{38}H_{61}O_{10}N_9$: C, 56.77; H, 7.65; N, 15.68%.

Boc–(Asn–Val–Orn(Z)–Leu–Pro)$_2$–OBzl (**20**). This compound was prepared from **19** (260 mg, 0.35 mmol) and **18**·HCl (264 mg, 0.35 mmol) as described for **6**; yield, 410 mg (76%); mp 218—220 °C; $[\alpha]_D^{22}$ −90.4° (*c* 0.5, MeOH); R_f^1 0.58, R_f^3 0.89.

Found: C, 60.12; H, 7.37; N, 12.58%. Calcd for

$C_{78}H_{114}O_{19}N_{14}$: C, 60.37; H, 7.41; N, 12.64%.

*Boc-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-N_2H_3 (**21**).* Compound **20** (372 mg, 0.24 mmol) was treated with hydrazine hydrate (0.58 ml, 12 mmol) as described for **4**. The crude product was recrystallized from EtOH; yield, 307 mg (87%); mp 201—203 °C; $[\alpha]_D^{22}$ −104° (*c* 0.2, MeOH); R_f^1 0.21, R_f^3 0.82.

Found: C, 57.07; H, 7.51; N, 15.06%. Calcd for $C_{71}H_{110}O_{18}N_{16}\cdot H_2O$: C, 57.09; H, 7.56; N, 15.00%.

*H-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-N_2H_3·2HCl (**22**·2HCl).* Compound **21** (138 mg, 0.094 mmol) was treated with 0.1 M hydrogen chloride in formic acid (2.3 ml) as described for **2**·HCl; yield, 133 mg (98%); mp 168—169 °C; $[\alpha]_D^{22}$ −68.0° (*c* 0.2, MeOH); R_f^1 0.03, R_f^3 0.69.

Found: C, 52.67; H, 6.91; N, 14.73%. Calcd for $C_{66}H_{104}O_{16}N_{16}Cl_2\cdot 3H_2O$: C, 52.76; H, 7.37; N, 14.91%.

cyclo(-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-) (**9a**). Cyclization of **22**·2HCl (123 mg, 0.085 mmol) was examined by the similar manner to that of **8**·2HCl. The crude product (43 mg, 38%) eluted from columns of Dowex 50 and Dowex 1 showed one major spot (R_f^1 0.66) and two minor spots (R_f^1 0.40 and 0.55) on TLC. All the crude product was dissolved in MeOH (5 ml) and applied to a column (3×170 cm) of Sephadex LH-20, and eluted with MeOH. The fractions containing the desired product were collected and evaporated to leave a white solid, which was collected by filtration with the aid of MeOH–ether; yield of semi-purified product, 34 mg (30%). By-product with R_f^1 0.40 was removed by this treatment but that with R_f^1 0.55 was not. Repeated recrystallization did not give satisfactory results.

*Boc-Val-Orn(Z)-Leu-Pro-OH (**23**).* To a solution of Boc-Val-Orn(Z)-Leu-N_2H_3[10] (2.37 g, 4 mmol) in DMF (10 ml) were added 2 M hydrogen chloride in EtOAc (6 ml) and isopentyl nitrite (0.56 ml, 4 mmol) at −60 °C. After being stirred at −20 °C for 10 min, the solution was cooled again to −60 °C and neutralized with TEA (1.68 ml, 12 mmol). To the solution was added a chilled solution of H-Pro-OH (0.59 g, 6 mmol) and TEA (0.84 ml, 6 mmol) in H_2O (4 ml). The reaction mixture was stirred at 0 °C for 3 days and evaporated. To the residue were added 3% NH_4OH and EtOAc. The aqueous layer was washed with EtOAc and acidified with 10% citric acid, and the oily product separated was extracted with EtOAc. The organic layer was washed with water, dried (Na_2SO_4), and evaporated. The residue was solidified by successive addition of ether and petroleum ether, and the crude product was dissolved in a mixture of $CHCl_3$–MeOH (5:1, v/v), applied to a column (3.3×35 cm) of silica gel 60 (Merck), and eluted with the same solvent. The fractions containing the desired product were collected and evaporated. Addition of a small amount of EtOAc to the residue gave colorless crystals; yield, 2.03 g (73%); mp 158—160 °C; $[\alpha]_D^{22}$ −62.2° (*c* 1, MeOH); R_f^1 0.44, R_f^2 0.24, R_f^3 0.83.

Found: C, 58.27; H, 7.51; N, 10.00%. Calcd for $C_{34}H_{53}O_9N_5\cdot 3/2\ H_2O$: C, 58.10; H, 8.03; N, 9.96%.

*H-Val-Orn(Z)-Leu-Pro-OH·HCl (**24**·HCl).* Compound **23** (946 mg, 1.4 mmol) was treated with 0.1 M hydrogen chloride in formic acid (15.4 ml) as described for **2**·HCl. The product was used for the next reaction without further treatment; yield, 857 mg (100%); R_f^3 0.71.

*Boc-Asn-Val-Orn(Z)-Leu-Pro-OH (**25a**).* To a chilled solution of **24**·HCl (857 mg, 1.4 mmol) and TEA (0.39 ml, 2.8 mmol) in DMF (10 ml) was added Boc-Asn-ONp (742 mg, 2.1 mmol). The mixture was stirred at 0 °C for 1 h and at room temperature overnight and evaporated. To the residue were added 10% citric acid and EtOAc. When the organic layer was being washed with water, crystallization of the product occurred. So, the crystals were filtered and dried *in vacuo* over P_2O_5. The crude product dissolved in MeOH (5 ml) was applied to a column (3×170 cm) of Sephadex LH-20 and eluted with MeOH. The fractions containing the desired product were collected and evaporated. The residue was crystallized by successive addition of MeOH and ether; yield, 867 mg (78%); mp 172—173 °C; $[\alpha]_D^{22}$ −78.0° (*c* 1, MeOH); R_f^1 0.61, R_f^2 0.03, R_f^3 0.80.

Found: C, 56.65; H, 7.47; N, 12.16%. Calcd for $C_{38}H_{59}O_{11}N_7\cdot H_2O$: C, 56.49; H, 7.61; N, 12.14%.

*H-Asn-Val-Orn(Z)-Leu-Pro-OH·HCl (**26a**·HCl).* Compound **25a** (158 mg, 0.2 mmol) was treated with 0.1 M hydrogen chloride in formic acid (3 ml) as described for **2**·HCl. The product was used for the next reaction without further treatment; yield, 145 mg (100%); R_f^3 0.61.

*Boc-Asn-Val-Orn(Z)-Leu-Pro-ONSu (**27a**).* To a chilled solution of **25a** (237 mg, 0.3 mmol) and HONSu (59 mg, 0.6 mmol) in a mixture of DMF (2 ml) and CH_2Cl_2 (2 ml) was added EDC·HCl (115 mg, 0.6 mmol), and the reaction mixture was stirred at 0 °C overnight and evaporated. The residue was triturated with the aid of chilled water, filtered, and dried *in vacuo* over P_2O_5. The product was used for the next reaction without further treatment; yield, 263 mg (99%); R_f^1 0.58, R_f^2 0.11, R_f^3 0.81.

*Boc-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-OH (**28a**).* To a chilled solution of **26a**·HCl (145 mg, 0.2 mmol) and TEA (0.056 ml, 0.4 mmol) in DMF (2 ml) was added **27a** (222 mg, 0.25 mmol), and the mixture was stirred at 0 °C for 2 days and evaporated. The residue was solidified by addition of 10% citric acid, filtered, washed with water, and dried. The crude product was purified by column chromatography with Sephadex LH-20 as described for **6**; yield, 276 mg (94%); mp 210—211 °C; $[\alpha]_D^{22}$ −94.0° (*c* 0.5, MeOH); R_f^1 0.14, R_f^3 0.83.

Found: C, 57.25; H, 7.46; N, 13.15%. Calcd for $C_{71}H_{108}O_{19}N_{14}\cdot 3/2\ H_2O$: C, 57.28; H, 7.51; N, 13.17%.

*Boc-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-ONSu (**29a**).* Compound **28a** (248 mg, 0.17 mmol) and HONSu (39 mg, 0.34 mmol) was treated as described for **27a**; yield, 265 mg (100 %); R_f^1 0.45, R_f^3 0.80.

*H-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-ONSu·TFA (**30a**·TFA).* Compound **29a** (265 mg, 0.34 mmol) was dissolved in TFA (5 ml), and the solution was allowed to stand at 0 °C for 1 h and evaporated. The residue was solidified by addition of ether, filtered, dried *in vacuo* over KOH. The product was used for the next reaction without further treatment; yield, 243 mg (91%); R_f^1 0.35, R_f^3 0.74.

cyclo(-(Asn-Val-Orn(Z)-Leu-Pro)$_2$-) (**9a**). A solution of **30a**·TFA (243 mg, 0.16 mmol) in DMF (8 ml) was added dropwise to pyridine (80 ml) at room temperature, and the mixture was stirred overnight and evaporated. The residue was dissolved in a mixture (60 ml) of MeOH–H_2O (5:1, v/v), and the solution was applied to columns (1.6×10 cm each) of Dowex 50 (H^+ form) and Dowex 1 (OH^- form). The columns was washed with the same solvent (150 ml.) and the combined effluent was evaporated to leave a white solid, which was collected with the aid of water. The crude product was purified by column chromatography with Sephadex LH-20 as described for **6**. The product was recrystallized from MeOH–ether; yield, 168 mg (81%); mp 241—243 °C; $[\alpha]_D^{22}$ −102° (*c* 0.5, MeOH); R_f^1 0.66, R_f^2 0.08, R_f^3 0.83. Amino acid ratios in acid hydrolyzate: Asp (1.00), Val (0.95), Orn (1.00), Leu (1.00), Pro (1.06).

Found: C, 58.27; H, 7.44; N, 14.28%. Calcd for $C_{66}H_{98}O_{16}N_{14}\cdot H_2O$: C, 58.22; H, 7.40; N, 14.40%.

cyclo(-(Asn-Val-Orn-Leu-Pro)$_2$-)·2HCl (**10a**·2HCl). Compound **9a** (67 mg, 0.05 mmol) dissolved in 0.05 M hy-

drogen chloride in MeOH (4 ml) was hydrogenated with paradium black as a catalyst. After removal of the catalyst by filtration, the filtrate was evaporated to leave a solid, which was recrystallized from MeOH–ether; yield, 49 mg (86%); mp 228—230 °C; $[\alpha]_D^{22}$ −98° (*c* 0.5, MeOH); R_f^3 0.38. Amino acid ratios in acid hydrolyzate: Asp (0.98), Val (0.94), Orn (1.00), Leu (1.00), Pro (1.05).

Found: C, 49.48; H, 7.56; N, 15.84%. Calcd for $C_{50}H_{88}O_{12}N_{14}Cl_2 \cdot 4H_2O$: C, 49.21; H, 7.93; N, 16.07%.

*Boc-D-Ala-Val-Orn(Z)-Leu-Pro-OH (**25b**).* This compound was prepared from Boc-D-Ala-ONSu (401 mg, 1.4 mmol) and **24**·HCl (857 mg, 1.4 mmol) as described for **25a**; yield, 544 mg (52%); mp 174—175 °C; $[\alpha]_D^{22}$ −52.0° (*c* 0.5, MeOH); R_f^1 0.31, R_f^2 0.09, R_f^3 0.83.

Found: C, 58.84; H, 7.73; N, 11.09%. Calcd for $C_{37}H_{58}O_{10}N_6 \cdot 1/2\ H_2O$: C, 58.78; H, 7.87; N, 11.12%.

*H-D-Ala-Val-Orn(Z)-Leu-Pro-OH·HCl (**26b**·HCl).* Compound **25b** (0.185 mg, 0.25 mmol) was treated with 0.1 M hydrogen chloride in formic acid (4 ml) as described for **2**·HCl. The product was used for the next reaction without further treatment; yield, 177 mg (100%); R_f^3 0.68.

*Boc-D-Ala-Val-Orn(Z)-Leu-Pro-ONSu (**27b**).* This was prepared from **25b** (299 mg, 0.4 mmol) and HONSu (69 mg, 0.6 mmol) as described for **27a**. The product was used for the next reaction without further treatment; yield, 214 mg (63%); R_f^1 0.78, R_f^2 0.30.

*Boc-(D-Ala-Val-Orn(Z)-Leu-Pro)$_2$-OH (**28b**).* This was prepared from **26b**·HCl (150 mg, 0.22 mmol) and **27b** (186 mg, 0.22 mmol) as described for **28a**; yield, 162 mg (54%); mp 143—145 °C; $[\alpha]_D^{22}$ −52.0° (*c* 1, MeOH); R_f^1 0.48, R_f^2 0.07, R_f^3 0.83.

Found: C, 59.77; H, 7.74; N, 12.31%. Calcd for $C_{69}H_{106}O_{17}N_{12} \cdot 1/2\ H_2O$: C, 59.85; H, 7.79; N, 12.14%.

*Boc-(D-Ala-Val-Orn(Z)-Leu-Pro)$_2$-ONSu (**29b**).* This was prepared from **28b** (138 mg, 0.1 mmol) and HONSu (23 mg, 0.2 mmol) as described for **27a**. The product was used for the next reaction without further treatment; yield, 134 mg (91%); R_f^1 0.76, R_f^2 0.29.

*H-(D-Ala-Val-Orn(Z)-Leu-Pro)$_2$-ONSu·TFA (**30b**·TFA).* Compound **29b** (134 mg, 0.091 mmol) was treated with TFA (3 ml) as described for **30a**. The product was used for the next reaction without further treatment; yield, 136 mg (100%); R_f^1 0.54, R_f^2 0.13.

cyclo(-(D-Ala-Val-Orn(Z)-Leu-Pro)$_2$-) (**9b**). This was prepared from **30b**·TFA (136 mg, 0.091 mmol) as described for **9a**; yield; 74 mg (65%); mp >300 °C; $[\alpha]_D^{22}$ −44.9° (*c* 0.5, MeOH); R_f^1 0.66, R_f^2 0.13, R_f^3 0.85. Amino acid ratios in acid hydrolyzate: Ala (1.07), Val (1.04), Orn (1.06), Leu (1.00), Pro (1.11).

Found: C, 60.55; H, 7.68; N, 13.13%. Calcd for $C_{64}H_{96}O_{14}N_{12} \cdot H_2O$: C, 60.26; H, 7.74; N, 13.18%.

cyclo(-(D-Ala-Val-Orn-Leu-Pro)$_2$-)·2HCl (**10b**·2HCl). Compound **9b** (50 mg, 0.04 mmol) was hydrogenated as described for **10a**·2HCl; yield, 33 mg (78%); mp 261—263 °C; $[\alpha]_D^{22}$ −36.1° (*c* 0.5, MeOH); R_f^3 0.44. Amino acid ratios in acid hydrolyzate: Ala (1.00), Val (0.95), Orn (1.00), Leu (1.00), Pro (1.05).

Found: C, 52.11; H, 8.04; N, 15.04%. Calcd for $C_{48}H_{86}O_{10}N_{12}Cl_2 \cdot 2H_2O$: C, 52.49; H, 8.26; N, 15.30%.

*Bis(Dnp) Derivatives of **10a** and **10b** (**31a** and **31b**).* A small amount of **10a** and **10b** were treated with N_2ph–F as usual way[10] and purified by silica-gel (Merck) column chromatography; **31a**: R_f^1 0.63, R_f^2 0.08, R_f^3 0.78; **31b**: R_f^1 0.68, R_f^2 0.22, R_f^3 0.82.

*Boc-Asn-Val-pNA (**32a**).* Boc-Asn-ONp (706 mg, 2 mmol) and H-Val-pNA (476 mg, 2 mmol) were treated as described for **1**. The crude product was recrystallized from EtOH; yield, 666 mg (74%); mp 225—227 °C; $[\alpha]_D^{22}$ −121.0° (*c* 0.2, MeOH); R_f^1 0.63, R_f^2 0.16, R_f^3 0.92.

Found: C, 52.89; H, 6.36; N, 15.32%. Calcd for $C_{20}H_{29}O_7N_5$: C, 53.20; H, 6.47; N, 15.51%.

*H-Asn-Val-pNA·HCl (**33a**·HCl).* Compound **32a** (451 mg, 1 mmol) was treated with 0.1 M hydrogen chloride in formic acid (12 ml) as described for **2**·HCl; yield, 413 mg (100%); mp 160—162 °C; $[\alpha]_D^{22}$ −18.4° (*c* 1, MeOH); R_f^1 0.16, R_f^3 0.73.

Found: C, 45.26; H, 5.58; N, 17.56%. Calcd for $C_{15}H_{22}O_5N_5Cl \cdot 1/2\ H_2O$: C, 45.39; H, 5.84; N, 17.65%.

*Boc-Leu-Pro-OH (**34**).* Compound **11** (1.38 g, 3.3 mmol) dissolved in MeOH (10 ml) was hydrogenated with paradium black as a catalyst. After removal of the catalyst by filtration, the filtrate was evaporated to a foam, which was used for the next reaction without further treatment; yield, 1.08 g (100%); R_f^1 0.69, R_f^2 0.47, R_f^3 0.67.

*Boc-Leu-Pro-Asn-Val-pNA (**35a**).* To a chilled solution of **33a**·HCl (116 mg, 0.3 mmol) in $CHCl_3$ (3 ml) were added TEA (0.042 ml, 0.3 mmol), **34** (99 mg, 0.3 mmol), and EDC·HCl (58 mg, 0.3 mmol). The reaction mixture was treated as described for **11**, and the crude product obtained as a solid was purified by LH-20 column chromatography as described for **17**; yield, 75 mg (38%); mp 128—130 °C; $[\alpha]_D^{22}$ −130.0° (*c* 0.5, MeOH); R_f^1 0.67, R_f^2 0.15, R_f^3 0.81.

Found: C, 55.70; H, 7.13; N, 14.77%. Calcd for $C_{31}H_{47}O_9N_7 \cdot 1/2\ H_2O$: C, 55.51; H, 7.21; N, 14.62%.

*H-Leu-Pro-Asn-Val-pNA·HCl (**36a**·HCl).* Compound **35a** (47 mg, 0.07 mmol) was treated with 0.1 M hydrogen chloride in formic acid (0.8 ml) as described for **2**·HCl, and the residue was used for the next reaction without further treatment; yield was quantitative; R_f^1 0.18, R_f^3 0.74.

*Dnp-Leu-Pro-Asn-Val-pNA (**37a**).* To a solution of **36a**·HCl (42 mg, 0.07 mmol) and TEA (0.029 ml, 0.21 mmol) in DMF (2 ml) was added N_2ph–F (26 mg, 0.14 mmol), and the reaction mixture was stirred at room temperature for 3 h and evaporated. The residue dissolved in $CHCl_3$ (5 ml) was applied to a column (1.8×20 cm) of silica gel 60 (Merck), and the column was washed with $CHCl_3$. The fractions containing the desired product eluted with a mixture of $CHCl_3$–MeOH (19:1, v/v) were evaporated to leave a solid, which was recrystallized from EtOAc–ether; yield, 42 mg (83%); mp 145—148 °C; $[\alpha]_D^{22}$ −90.2° (*c* 1, MeOH); R_f^1 0.67, R_f^2 0.13, R_f^3 0.79.

Found: C, 52.44; H, 5.72; N, 17.11%. Calcd for $C_{32}H_{41}O_{11}N_9$: C, 52.82; H, 5.68; N, 17.32%.

*Boc-D-Ala-Val-pNA (**32b**).* This compound was prepared from Boc-D-Ala-OH (189 mg, 1 mmol) and H-Val-pNA (238 mg, 1 mmol) as described for **35a**. The crude product was recrystallized from EtOH–ether; yield, 306 mg (76%); mp 160 °C; $[\alpha]_D^{22}$ −47.0° (*c* 1, MeOH); R_f^1 0.82, R_f^2 0.45, R_f^3 0.91.

Found: C, 55.77; H, 6.98; N, 13.68%. Calcd for $C_{19}H_{28}O_6N_4$: C, 55.87; H, 6.91; N, 13.72%.

*H-D-Ala-Val-pNA·HCl (**33b**·HCl).* Compound **32b** (245 mg, 0.6 mmol) was treated with 0.1 M hydrogen chloride in formic acid (7 ml) as described for **2**·HCl; yield, 209 mg (100%); mp 170—173 °C; $[\alpha]_D^{22}$ −42.2° (*c* 1, MeOH); R_f^1 0.33, R_f^2 0.02, R_f^3 0.75.

Found: C, 48.01; H, 6.03; N, 16.19%. Calcd for $C_{14}H_{21}O_4N_4Cl \cdot 1/4\ H_2O$: C, 48.14; H, 6.20; N, 16.04%.

*Boc-Leu-Pro-D-Ala-Val-pNA (**35b**).* This compound was prepared from **33b**·HCl (209 mg, 0.6 mmol) and **34** (197 mg, 0.6 mmol) as described for **35a**; yield, 209 mg (56%); mp 140—142 °C; $[\alpha]_D^{22}$ −20.6° (*c* 1, MeOH); R_f^1 0.79, R_f^2 0.38, R_f^3 0.86.

Found: C, 57.36; H, 7.37; N, 13.09%. Calcd for $C_{30}H_{48}O_8N_6 \cdot 1/2\ H_2O$: C, 57.40; H, 7.55; N, 13.39%.

*H–Leu–Pro–D-Ala–Val–pNA·HCl (**36b**·HCl).* Compound **35b** (62 mg, 0.1 mmol) was treated with 0.1 M hydrogen chloride in formic acid (1.5 ml) as described for **2**·HCl, and the residue was used for the next reaction without further treatment; yield was quantitative; R_f^1 0.27, R_f^3 0.69.

*Dnp–Leu–Pro–D-Ala–Val–pNA (**37b**).* This compound was prepared from **36b**·HCl (56 mg. 0.1 mmol) as described for **37a**; yield, 59 mg (86%); mp 231 °C; $[\alpha]_D^{23}$ −38.4° (*c* 1, MeOH); R_f^1 0.77, R_f^2 0.36, R_f^3 0.82.

Found: C, 54.26; H, 5.78; N, 16.18%. Calcd for $C_{31}H_{40}O_{10}N_8$: C, 54.37; H, 5.89; N, 16.39%.

Paper Electrophoresis. Electrophoresis was carried out with Whatman No. 1 paper and a solvent system of HCOOH–AcOH–MeOH–H_2O (1:3:6:10, v/v, pH 1.8) for 2 h at 500 V/30 cm. Each of the analogs (**10a** and **10b**) showed single spot and their mobilities were as follows: **10a**, 7.3 cm; **10b**, 7.5 cm; GS, 7.1 cm.

CD and ORD Measurements. These spectra were recorded on a JASCO J-20 spectropolarimeter in MeOH solution at room temperature (23±2 °C).

Microbiological Assays. The minimum concentration of the compounds necessary for the complete inhibition of growth of several microorganisms was determined by a dilution method using a nutrient agar. Natural GS used as a reference showed complete inhibition at 3.13 and 6.25 μg/ml on *B. Subtilis* and *S. Aureus*, respectively, and was inactive on *E. Coli* at 100 μg/ml.

We thank Professor Tatsuo Miyazawa and Dr. Tsutomu Higashijima of The University of Tokyo for helpful discussions. We are indebted to Dr. Haruyasu Kinashi and Miss Kinumi Someno of this institute for the microbiological assays. We are also grateful to the members of Analytical Department of System Engineering Laboratory, Mitsubishi-Kasei Industries Ltd. for elemental analyses.

The Substituent Effects in Thiophene Compounds. II.[1] ^{1}H NMR and IR Studies in Methyl (Substituted 3-Thiophenecarboxylate)s

Hajime SATONAKA

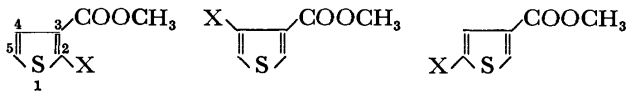
Industrial Research Institute of Kanagawa Prefecture, 3173, Showa-machi, Kanazawa-ku, Yokohama 236

(Received April 22, 1983)

The ^{1}H NMR spectra and the IR carbonyl stretching frequencies of methyl (2-, 4-, and 5-substituted 3-thiophenecarboxylate)s are reported. Good linear correlation between the chemical shifts of the ring protons in methyl (5-substituted 3-thiophenecarboxylate)s and those of the corresponding protons in substituted thiophenes was observed. It was found that in methyl (2- and 4-substituted 3-thiophenecarboxylate)s, which have the carbonyl or nitro group in an *ortho* position, the chemical shifts for the ring protons were considerable affected by the conformation of carbonyl group, the steric hindrance, and the intramolecular hydrogen bonding. Some of methyl (*ortho*-substituted 3-thiophenecarboxylate)s showed the two C=O stretching bands. They were assigned to *anti-s-trans* and *syn-s-trans* forms. The substitutent effects in the C=O frequencies are also discussed. The coupling constants between ring protons of methyl (substituted 3-thiophenecarboxylate)s were correlated very closely with the corresponding ones in substituted thiophenes. The coupling constants in methyl 3-thiophenecarboxylate series were found to vary linearly with the sum of the electronegativities of the substituent on the ring.

In an earlier paper,[1] the ^{1}H NMR spectra have been reported for 2-substituted thiophenes (**1**), 3-substituted thiophenes (**2**), methyl (3-substituted 2-thiophenecarboxylate)s (**3**), methyl (4-substituted 2-thiophenecarboxylate)s (**4**), and methyl (5-substituted 2-thiophenecarboxylate)s (**5**). The effects of the substituents were discussed.

The present study was undertaken to examine the substituent effects in methyl (2-, 4-, and 5-substituted 3-thiophenecarboxylate)s (**6**—**8**). The correlations of



6 **7** **8**

the chemical shifts and of the coupling constants between methyl (substituted 3-thiophenecarboxylate)s and substituted thiophenes have been discussed in this paper. Attempts have also been made to compare the IR C=O stretching frequencies in methyl (substituted 3-thiophenecarboxylate)s with the chemical shifts in substituted thiophenes, and the coupling constants in methyl (substituted 3-thiophenecarboxylate)s with the electronegativities of the substituents. The influences of the conformation, steric hindrance, and intramolecular hydrogen bonding upon the chemical shifts of ring protons and C=O stretching frequencies in methyl (2- and 4-substituted 3-thiophenecarboxylate)s have been discussed.

Results and Discussion

The ^{1}H NMR spectra of methyl (2-, 4-, and 5-substituted 3-thiophenecarboxylate)s (**6**—**8**) were measured in deuteriochloroform at 25 °C. The assignments of the spectra were made on the basis of the chemical shifts and the characteristic ring coupling constants. The refined chemical shifts and coupling constants were obtained iteratively using LAOCN 3.[2] The results are given in Tables 1—3. For convenience, the notation H_r(**N**) for the rth(position)-proton on thiophene ring of the series of compounds **N**, δ_r(**N**) for its chemical shift, and *cc*, *p*, *i*, and *s* for the correlation coefficient, slope, intercept, and standard deviation in the least-squares analysis. For comparison of the effect of substituents on methyl (substituted 3-thiophenecarboxylate)s and substituted thiophenes, the chemical shifts of corresponding protons from the two series of compounds were plotted against each other. The plots of δ_4 (**8**) against δ_3(**1**)[1] (A, *cc* 0.999, *p* 0.958, *i* 0.069, *s* 0.019) and δ_2(**8**) against δ_5(**1**)(B, *cc* 0.999, *p* 0.847, *i* 1.857, *s* 0.011) gave excellent correlations as shown in Fig. 1. Line A runs almost parallel with B. The

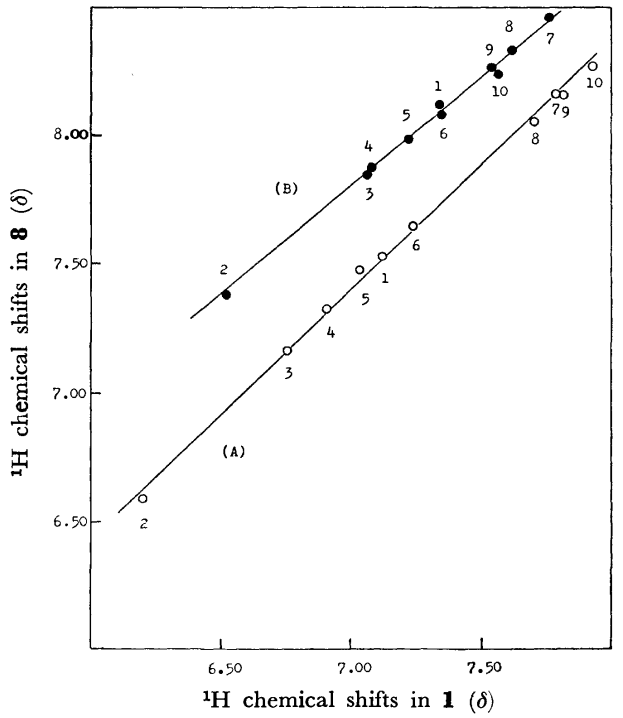

Fig. 1. Correlation between ^{1}H chemical shift in **8** and **1**; numbering as in Table 3. A, δ_4(**8**) *vs.* δ_3(**1**). B, δ_2(**8**) *vs.* δ_5(**1**).

correlation between δ_4(**8**) and δ_2(**8**) is in good accord with that between δ_3(**1**) and δ_5(**1**). These data seem to show that the introduction of methoxycarbonyl group into position 4 of 2-substituted thiophene is confined to the parallel transfer of the substituent effects on H_3 and H_5. The author further compared the chemical shifts of the ring protons in **8** with those in methyl (4-substituted 2-thiophenecarboxylate)s (**4**). The correlation between δ_4(**8**) and δ_3(**4**) was in agreement with that between δ_3(**1**) and δ_4(**2**). The correlation between δ_2(**8**) and δ_5(**4**) was also in agreement with that between δ_5(**1**) and δ_2(**2**). These correlations also demonstrate that the substituent effects in the series of compounds **8** and **4** follow the same trend.

Figure 2 shows the rough linearities between the effects of the substituents on δ_5(**6**) and those on δ_5(**1**) (A, *cc* 0.934, *p* 0.821, *i* 1.20, *s* 0.108) and between those on δ_4(**6**) and those on δ_4(**1**)(B, *cc* 0.868, *p* 0.590, *i* 3.28, *s* 0.055). The correlation between δ_5(**6**) and δ_4(**6**) is worse than that between δ_5(**1**) and δ_4(**1**). The author has compared the chemical shifts of the ring protons in **6** with those in methyl (3-substituted 2-thiophenecarboxylate)s (**3**), both of which belong to *ortho*-disubstituted thiophenes. The correlation between δ_4(**6**) and δ_4(**3**) was considerably worse than that between δ_4(**1**) and δ_4(**2**). Furthermore, the correlation between δ_5(**6**) and δ_5(**3**) was remarkably worse than that between δ_5(**1**) and δ_5(**2**). These results show that the additivity rule on the substituent effect in substituted thiophenes is not applicable to compounds **6**.

Figure 3 shows the good linearity between the effects of the substituents on δ_5(**7**) and those on δ_2(**2**)(A, *cc* 0.970, *p* 0.853, *i* 1.06, *s* 0.128), and no correlation between those on δ_2(**7**) and those on δ_5(**2**)(B, *cc* 0.085,

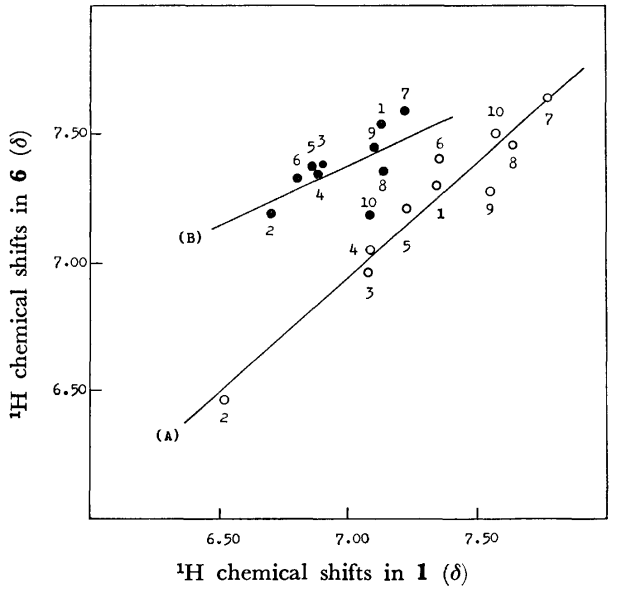

Fig. 2. Correlation between ^{1}H chemical shifts in **6** and **1**; numbering as in Table 1. A, δ_5(**6**) *vs.* δ_5(**1**). B, δ_4(**6**) *vs.* δ_4(**1**).

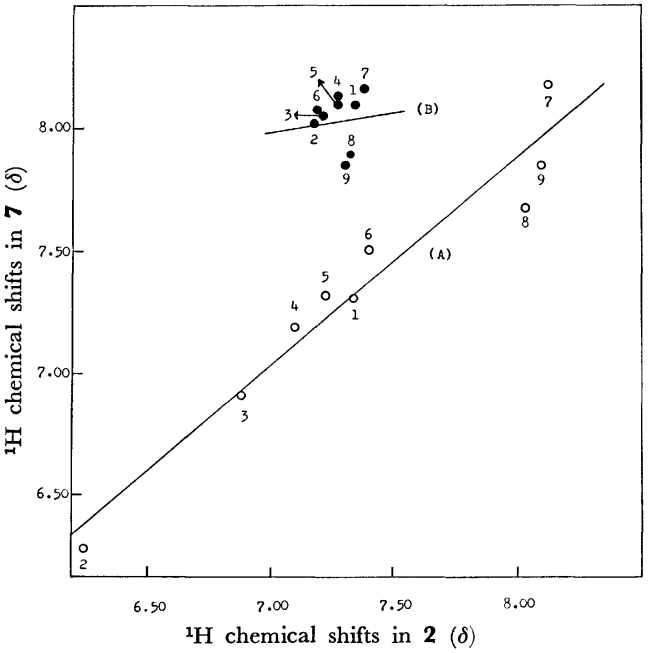

Fig. 3. Correlation between ^{1}H chemical shifts in **7** and **2**; numbering as in Table 2. A, δ_5(**7**) *vs.* δ_2(**2**). B, δ_2(**7**) *vs.* δ_5(**2**).

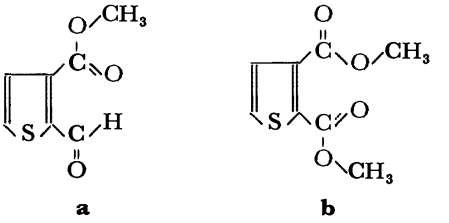
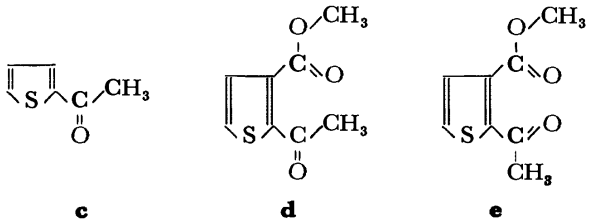
p 0.126, *i* 7.09, *s* 0.104). As given in Table 2, the chemical shifts of H_2 in the series of compounds **7** appear at significantly lower fields than those in the series of compounds **8**. It is noticeable that the H_2 signals of acetyl and methoxycarbonyl derivatives appear at higher fields than those in methoxy and methyl derivatives. These facts seem to account for the very poor correlation between δ_2(**7**) and δ_5(**2**).

Methyl proton chemical shifts of methyl (substituted 3-thiophenecarboxylate)s, which show the narrow range of variation, were found to be correlated with the chemical shifts of the corresponding protons of similarly substituted thiophenes. The result implies that the substituent effect is transmitted to the methyl group in a "through-bond" manner through the –CO–O–π system. The effect is attenuated by a factor of about 10.

The chemical shifts of the ring protons in methyl (2-, 4-, and 5-substituted 3-thiophenecarboxylate)s were calculated by making use of those of 2- and 3-substituted thiophenes. The observed chemical shifts are in good agreement with the calculated ones, within δ 0.1 in the series of compounds **8**. For example, the calculated ring proton chemical shifts were δ 7.83 and 7.16 for methyl 5-methyl-3-thiophenecarboxylate and δ 8.11 and 7.65 for methyl 5-iodo-3-thiophenecarboxylate. These calculated values were in good accord with the observed ones. This agreement suggests that the additivity rule, which is based on substituted thiophenes, is applicable to the chemical shifts of the ring protons in **8**, as well as in **4**.[1] In the series of compounds **6**, large deviations of the observed values from the calculated are seen in the carbonyl derivatives. As mentioned in the preceding paper,[1] methyl 2-formyl-3-thiophenecarboxylate and dimethyl 2,3-thiophenedicarboxylate are considered to take preferably the conformations **a** and **b**, respectively. The calculated chemical shifts of H_4 and H_5

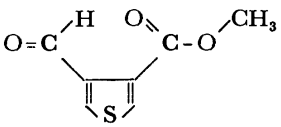


in methyl 2-acetyl-3-thiophenecarboxylate are δ 7.54 and 7.59 respectively, but the doublets occur at δ 7.35 and 7.46 and produce significant shifts to higher fields than the calculated values. The acetyl ester has a single ester carbonyl stretching band assignable to *anti-s-trans* form at 1731 cm^{-1}, quite analogous to methyl 2-formyl-3-thiophenecarboxylate (1729 cm^{-1}). It is confirmed that 2-acetylthiophene exists in *syn-s-trans* form **c**.[3] However, the C=O stretching band of acetyl group of this acetyl ester appears at 1671 cm^{-1} with a shoulder at 1686 cm^{-1}. Consequently, it is considered that another conformation **e** will exist in addition to the predominant conformation **d** in this compound. It is expected that the difference between the chemical shifts of H_4 and H_5 is enlarged by the presence of the conformation **e**. The signals at δ 7.35 and 7.46 may thus be assignable to those of H_4 and H_5, respectively. The discrepancy between the

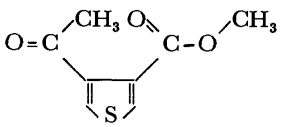


observed chemical shifts of H_4 and H_5 and those estimated seems to suggest that the coplanarity of carbonyl functions to the thiophene ring is lost by the steric hindrance. The H_4-chemical shift of methyl 2-nitro-3-thiophenecarboxylate is δ 7.18. This is a considerably higher field than the calculated value. The UV spectrum of nitro ester [λ_{max}: 284 nm(ε 6620)] is more similar to one of 2-nitrothiophene[λ_{max}: 300 nm(ε 6730), 282 nm(ε 5970)] than one of methyl 3-thiophenecarboxylate[λ_{max}: 239 nm(ε 7550)]. Consequently, it is considered that the methoxycarbonyl group at position 3 will exist with the considerable loss of the coplanarity to thiophene ring by the steric hindrance.

The discrepancy is largest in the series of compounds **7**, which is the *ortho*(3,4)-disubstituted derivative. It is considered that the contribution of the rotational isomer **f** involving a weak intramolecular hydrogen bond affects the chemical shifts of the ring and formyl protons in methyl 4-formyl-3-thiophenecarboxylate, as in methyl 3-formyl-2-thiophenecarboxylate[1] and methyl 2-formyl-3-thiophenecarboxylate. The H_2- and H_5-signals of this compound shift to significantly lower fields than the corresponding signals of acetyl derivative and dimethyl 3,4-thiophenedicarboxylate. The formyl proton chemical shift of methyl 4-formyl-3-thiophenecarboxylate is δ 10.50, and absorbs at δ *ca.* 0.6 lower field than that of methyl 4-formyl-2-thiophenecarboxylate(δ 9.91). The strong carbonyl band in IR spectrum appears at 1729 cm^{-1}, and is assignable to *syn-s-trans* form. Methyl 4-acetyl-3-thiophenecarboxylate has a single ester carbonyl band at 1730 cm^{-1} and a single acetyl carbonyl band at 1695 cm^{-1}. The observed chemical shifts of the ring protons in this ester are to significantly higher fields than the calculated values. This discrepancy suggests the loss of the coplanarity of carbonyl functions to thiophene ring by the steric hindrance, although this compound seems to exist in the preferred conformation **g**. The chemical shifts of H_2 and H_5 in dimethyl



f



g

3,4-thiophenedicarboxylate are equivalent and δ 8.07 in the calculations, but appear at δ 7.85 in the experiment. This discrepancy suggests the participation of the repulsion by the lone pair electrons and the steric hindrance. The IR carbonyl band, which appears as a broad peak centered at 1735 cm^{-1}, also suggests coexistence of several conformations. The additional feature in this series is the discrepancy between the observed and the calculated values in halogen derivatives. Two carbonyl stretching vibrations, which are assignable to *syn-s-trans* and *anti-s-trans* forms, are observed in these compounds. The chemical shifts, which are calculated on the basis of the *syn-s-trans* form in methyl 3-thiophenecarboxylate, are considered to change largely due to the presence of the *anti-s-trans* form.

In summary, the discrepancy between the observed and estimated values in methyl (2-substituted 3-thiophenecarboxylate)s (**6**) and methyl (4-substituted 3-thiophenecarboxylate)s (**7**), which belong to *ortho*-substituted thiophenes, may be caused by (i) the change of the conformation in methoxycarbonyl, formyl, and acetyl groups, (ii) the loss of coplanarity of carbonyl functions to the thiophene ring by the steric hindrance and the repulsion of the lone pair electrons, and (iii) the electric field effect and the conformational effect by the weak intramolecular hydrogen bond.

The ester carbonyl stretching frequencies of methyl (substituted 3-thiophenecarboxylate)s, which were measured in CCl_4, are listed in Table 4. The correlations between the wavenumber of the C=O band (*syn-s-trans* form) and the proton chemical shift of the corresponding substituted thiophene were examined. A good correlation is obtained between $\nu_{C=O}$(**8**)[4] and δ_4(**1**). However, the C=O frequency data in other two series gave no correlation with ^1H chemical shifts of the corresponding substituted thiophenes. The correlation between the C=O frequencies of methyl (substituted 3-thiophenecarboxylate)s and methyl (substituted 2-thiophenecarboxylate)s was also examined. Reasonably good correlations were obtained between $\nu_{C=O}$(**6**) and $\nu_{C=O}$(**3**), and between $\nu_{C=O}$(**8**) and $\nu_{C=O}$(**4**), as well as $\nu_{C=O}$(**8**) and $\nu_{C=O}$(**5**). The correlation between $\nu_{C=O}$(**7**) and $\nu_{C=O}$(**3**) was excellent, and better than that between $\nu_{C=O}$(**6**) and $\nu_{C=O}$(**3**). It is interesting that these correlations are in good agreement with those between the chemical shifts of the ring protons in the three series of compounds **7**, **6**, and **3**, as mentioned above.

The plots of the proton-proton coupling constants in methyl (substituted 3-thiophenecarboxylate)s against those of the corresponding thiophenes gave good correlations, as shown in Fig. 4. The correlation of J_{45}(**3**)[5] against J_{45}(**1**) was found to be excellent, in contrast to that of the chemical shifts between both series. Furthermore, the correlations between the coupling constants of methyl (substituted 3-thiophenecarboxylate)s and those of methyl (substituted 2-thiophenecarboxylate)s were examined. Fair correlations were obtained between J_{45}(**6**) and J_{45}(**3**), and be-

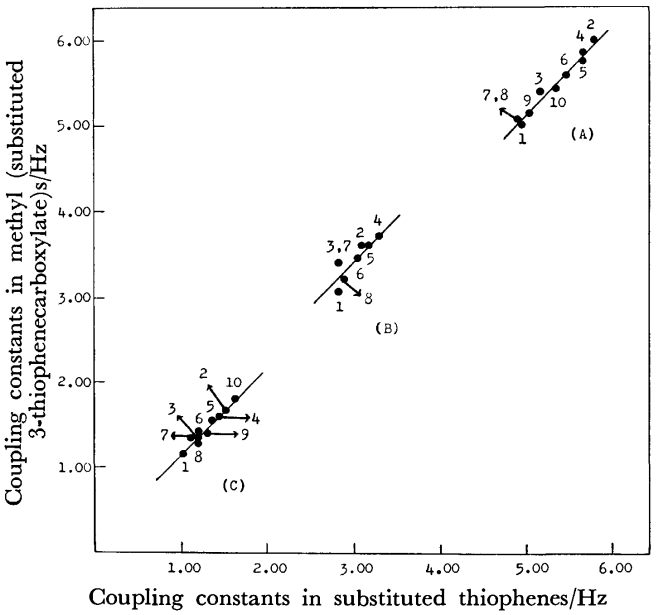

Fig. 4. Correlation between coupling constants in methyl (substituted 3-thiophenecarboxylate)s and substituted thiophenes, numbering as in Table 1. A, J_{45}(**6**) *vs.* J_{45}(**1**). B, J_{25}(**7**) *vs.* J_{25}(**2**). C, J_{24}(**8**) *vs.* J_{35}(**1**).

tween J_{24}(**8**) and J_{35}(**4**). For methyl (substituted 3-thiophenecarboxylate)s as well as for methyl (substituted 2-thiophenecarboxylate)s, the relationship of the coupling constants against the sum of the electronegativities of substituents including methoxycarbonyl group were examined. The individual coupling constants in the series of compounds **6**, **7**, and **8** gave good correlations with the electronegativities. The slope of the correlation for the series of compounds **6** is twice as large as those in the series of compounds **3**, **4**, **5**, **7**, and **8**. This fact shows that the electronegativity effect of the substituent on position 2 is more sensitive to J_{45} than those in all other cases, and is transmitted by a factor of about 2.

Experimental

The ^{1}H NMR spectra of the compounds were obtained at 100 MHz on a JEOL PS-100 spectrometer. The chemical shifts were determined with an accuracy of δ $\pm$0.005 relative to TMS as an internal standard and the coupling constants were determined with an accuracy of $\pm$0.02 Hz. The concentrations of solutions were adjusted approximately at 0.3 mol dm^{-3} with respect to substrates. The IR spectra were recorded on a Perkin-Elmer 257 spectrometer. The UV spectra were recorded on a Shimadzu MPS 5000 spectrometer in hexane.

Methyl 3-thiophenecarboxylate, methyl 2-bromo-3-thiophenecarboxylate, methyl 2-formyl-3-thiophenecarboxylate, methyl 4-methoxy-3-thiophenecarboxylate, methyl 4-bromo-3-thiophenecarboxylate, methyl 4-formyl-3-thiophenecarboxylate, dimethyl 3,4-thiophenedicarboxylate, methyl 5-chloro-3-thiophenecarboxylate, methyl 5-formyl-3-thiophenecarboxylate, and methyl 5-nitro-3-thiophenecarboxylate were prepared according to the reported procedures.[6-12]

Methyl 5-Methoxy-3-thiophenecarboxylate. This material was prepared by the oxidation of 5-methoxy-3-thiophenecarbaldehyde[13] followed by the esterification, bp 101.5—103 °C/4 mmHg (1 mmHg$\approx$133.322 Pa). Found: C, 48.68; H, 4.37; S, 18.88%. Calcd for $C_7H_8O_3S$: C, 48.82; H, 4.68; S, 18.62%. IR (neat, cm^{-1}): 3120(=C–H), 1720(C=O), 1552, 1438, 727(thiophene ring).

The following esters were prepared by the esterification of the corresponding carboxylic acids.[14-23]

Methyl 2-Methoxy-3-thiophenecarboxylate. Bp 146—147 °C/21 mmHg. Found: C, 48.96; H, 4.60; S, 18.53%. Calcd for $C_7H_8O_3S$: C, 48.82; H, 4.68; S, 18.62%. IR (neat, cm^{-1}): 3120(=C–H); 1716(C=O); 1542, 1438, 754 (thiophene ring).

Methyl 2-Methyl-3-thiophenecarboxylate. Bp 99—101 °C/16 mmHg. Found: C, 53.92; H, 5.04; S, 20.75%. Calcd for $C_7H_8O_2S$: C, 53.83; H, 5.16; S, 20.53%. IR (neat, cm^{-1}): 3110, 3090 (=C–H); 1712 (C=O); 1537, 1438, 708 (thiophene ring).

Methyl 2-Chloro-3-thiophenecarboxylate. Bp 124—125 °C/30 mmHg. Found: C, 40.68; H, 2.82; Cl, 20.33; S, 17.98%. Calcd for $C_6H_5ClO_2S$: C, 40.80; H, 2.85; Cl, 20.07; S, 18.15%. IR(neat, cm^{-1}); 3120, 3090(=C–H); 1712(C=O); 1529, 1440, 702(thiophene ring).

Methyl 2-Iodo-3-thiophenecarboxylate. Bp 127.5—128 °C/5 mmHg. Found: C, 26.90; H, 1.70; I, 47.50; S, 12.02%. Calcd for $C_6H_5IO_2S$: C, 26.88; I, 1.88; I, 47.34; S, 12.06%. IR(neat, cm^{-1}): 3100, 3090(=C–H); 1710(C=O); 1515, 1436, 707(thiophene ring).

Methyl 2-Acetyl-3-thiophenecarboxylate. Bp 118—119 °C/4.5 mmHg. Found: C, 52.08; H, 4.52; S, 17.35%. Calcd for $C_8H_8O_3S$: C, 52.16; H, 4.38; S, 17.41%. IR(neat, cm^{-1}): 3100(=C–H); 1728, 1672(C=O); 1527, 1438, 737 (thiophene ring).

Methyl 2-Nitro-3-thiophenecarboxylate. Bp 132—133.5 °C/3 mmHg. Found: C, 38.37; H, 2.58; N, 7.30; S, 17.25%. Calcd for $C_6H_5NO_4S$: C, 38.50; H, 2.69; N, 7.48; S, 17.13%. IR(neat, cm^{-1}): 3100(=C–H); 1737(C=O); 1515, 1345(NO_2); 1548, 1437, 742(thiophene ring).

Methyl 4-Methyl-3-thiophenecarboxylate. Bp 110—111 °C/21 mmHg. Found: C, 53.97; H, 5.29; S, 20.38%. Calcd for $C_7H_8O_2S$: C, 53.92; H, 5.16; S, 20.53%. IR (neat, cm^{-1}): 3120(=C–H); 1718(C=O); 1538, 1450, 777 (thiophene ring).

Methyl 4-Chloro-3-thiophenecarboxylate. Mp 51.5 °C. Found: C, 40.98; H, 2.92; Cl, 20.00; S, 18.01%. Calcd for $C_6H_5ClO_2S$: C, 40.80; H, 2.85; Cl, 20.07; S, 18.15%. IR(KBr, cm^{-1}): 3120(=C–H); 1715(C=O); 1507, 1440, 781 (thiophene ring).

Methyl 4-Iodo-3-thiophenecarboxylate. Mp 32 °C. Found: C, 26.92; H, 1.70; I, 47.15; S, 11.82%. Calcd for $C_6H_5IO_2S$: C, 26.88; H, 1.88; I, 47.34; S, 11.96%. IR (KBr, cm^{-1}): 3110(–C–H); 1710(C–O); 1488, 1438, 777 (thiophene ring).

Methyl 4-Acetyl-3-thiophenecarboxylate. Bp 108.5—110 °C/2.5 mmHg. Found: C, 52.08; H, 4.52; S, 17.30%. Calcd for $C_8H_8O_3S$: C, 52.16; H, 4.38; S, 17.41%. IR (neat, cm^{-1}): 3110(=C–H); 1712, 1683(C=O); 1512, 1453, 798(thiophene ring).

Methyl 5-Methyl-3-thiophenecarboxylate. Bp 118—120 °C/26 mmHg. Found: C, 53.97; H, 5.31; S, 20.38%. Calcd for $C_7H_8O_2S$: C, 53.83; H, 5.16; S, 20.53%. IR (neat, cm^{-1}): 3110(=C–H); 1718(C=O); 1550, 1468, 738 (thiophene ring).

Methyl 5-Bromo-3-thiophenecarboxylate. Mp 43 °C. Found: C, 32.47; H, 2.09; Br, 36.03; S, 14.63%. Calcd for $C_6H_5BrO_2S$: C, 32.60; H, 2.28; Br, 36.14; S, 14.50%. IR(KBr, cm^{-1}): 3100(=C–H); 1718(C=O); 1527, 1442, 738 (thiophene ring).

Methyl 5-Iodo-3-thiophenecarboxylate. Mp 72 °C. Found:

C, 26.98; H, 1.70; I, 47.23; S, 11.82%. Calcd for $C_6H_5IO_2S$: C, 26.88; H, 1.88; I, 47.34; S, 11.96%. IR (KBr, cm^{-1}): 3090(=C–H); 1700(C=O); 1520, 1439, 736 (thiophene ring).

Methyl 5-Acetyl-3-thiophenecarboxylate. Mp 114 °C. Found: C, 52.31; H, 4.53; S, 14.28%. Calcd for $C_8H_8O_3S$: C, 52.16; H, 4.38; S, 17.41%. IR(KBr, cm^{-1}): 3120, 3100 (=C–H); 1712, 1663 (C=O); 1534, 1428, 759 (thiophene ring).

The author wishes to thank to Professor Minoru Hirota of Yokohama National University for his kind suggestions and encouragement, to Dr. Hiroshi Ozawa of the University of Tokyo for his permission to use the Computation Program LAOCN 3, and to Mr. Takayoshi Ozawa for the elemental analyses.

The Platinum Complex Catalyzed Reductive *N*-Carbonylation of Nitroarenes to the Carbamates

Yoshihisa WATANABE,* Yasushi TSUJI, Ryo TAKEUCHI, and Naoki SUZUKI

Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606

(Received April 25, 1983)

The platium catalyst combined with triphenylphosphine, tin(IV) chloride, and triethylamine showed high activity for the reductive *N*-carbonylation of nitroarene in ethanol at 180 °C under carbon monoxide of 60 kg cm^{-2}. From nitrobenzene, ethyl phenylcarbamate was obtained in 83% yield. Iron(III) chloride, aluminum chloride and titanium(IV) chloride could be used as Lewis acids in place of tin(IV) chloride. Various nitroarenes were transformed into corresponding carbamate in moderate to excellent yields with the platinum catalyst.

Organic syntheses with carbon monoxide and synthesis gas are of current interest.[1,2] Many fundamental chemical feedstocks are derived by reaction with the gases. Among those chemicals, isocyanates are often employed for the production of urethane rubber, fiber, and synthetic leather. The conventional commercial methods for production of isocyanates consist of the catalytic hydrogenation of nitroarenes to aminoarenes and phosgenation of amines (Eq. 1).[3] However, this

$$ArNO_2 + 3H_2 \xrightarrow[-2H_2O]{} ArNH_2 \xrightarrow[-2HCl]{COCl_2} ArNCO \quad (1)$$

conventional process has several disadvantages: use of poisonous phosgen, formation of a lot of hydrogen chloride as a by-product, and consumption of a lot of electricity for production of phosgen. In place of this method, increasing attention has been paid to the reductive *N*-carbonylation of nitroarenes(Eq. 2). Intensive stud-

$$ArNO_2 + 3CO \longrightarrow ArNCO + 2CO_2 \quad (2)$$

ies have been focused on the catalyst for this reaction: several catalysts including palladium,[4] rhodium,[5] and selenium[6] compounds show high activities. When the reaction carried out in an alcohol medium, the carbonylation proceeds under milder conditions(Eq. 3).

$$ArNO_2 + 3CO + ROH \longrightarrow ArNHCOOEt + 2CO_2 \quad (3)$$

The products are arylcarbamates, which can be easily converted to the corresponding isocyanates by pyrolysis.[7]

Only a few studies have been reported on platinum complex catalyzed carbonylation with carbon monoxide. Ogata *et al.*[8] and Knifton[9] have reported that a platinum–tin(II) chloride catalyst system is effective for hydroformylation and hydroesterification of 1-alkene.

We recently reported the preliminary results of platinum complex catalyzed reductive *N*-carbonylation of nitrobenzene to ethyl phenylcarbamate.[10] To our knowledge, this is the first example of a platinum catalyst having a high activity for the reductive *N*-carbonylation nitrobenzene to the carbamate. In this paper, we describe the full details of our results(Eq. 4)

$$ArNO_2 + 3CO + EtOH \xrightarrow[Et_3N]{PtCl_2(PPh_3)_2\text{-}SnCl_4} ArNHCOOEt + 2CO_2 \quad (4)$$

Results and Discussion

The catalytic activity of dichlorobis(benzonitrile)-platinum ($Pt(PhCN)_2Cl_2$)–tin(II or IV) chloride system for reductive *N*-carbonylation of nitrobenzene was examined in the presence of different phosphorus(III) ligands. The results are listed in Table 1. Ethyl phenylcarbamate and aniline were obtained as the reaction products. In all cases, yields of the carbamate

a) Nitrobenzene(40 mmol), platinum complex(0.2 mmol), $SnCl_4$(2.0 mmol), triethylamine(1.0 ml), EtOH(20 ml) at 180 °C for 4 h under the initial pressure of 60 kg cm^{-2} carbon monoxide. b) Determined by GLC based on the amount of nitrobenzene charged. c) Ethyl phenylcarbamate. d) 0.4 mmol.

were low. Among the phosphorus (III) ligands, triphenylphosphine, which is an effective ligand for the platinum catalyzed hydroformylation,[9a] gave the best yield(22%) of the carbamate, when combined with tin(IV) chloride(Run 1). However, tributylphosphine, a more basic ligand, gave no *N*-carbonylated product. Ogata and co-workers reported that diphosphorus(III) ligands ($Ph_2P(CH_2)_nPPh_2$), especially $n=4$, are highly effective for platinum catalyzed hydroformylation.[8] The diphosphorus(III) ligands such as 1,2-ethanediylbisdiphenylphosphine, 1,3-propanediylbisdiphenylphosphine, 1,4-butanediylbisdiphenylphosphine in this *N*-carbonylation, gave only low yields of the carbamate. But aniline was formed in large amounts with an increase in the methylene length of the ligands indicating that these ligands were not effective for *N*-carbonylation (Runs 5—7). These bidentate ligands were effective for transformation of nitrobenzene to aniline.

The catalytic activity of platinum–tin(IV) chloride for *N*-carbonylation was dramatically improved by the addition of a tertiary amine, such as triethylamine. The results are listed in Table 2. Some references indicated that in the transformation of nitroarenes to the corresponding isocyanates, activities of the palladium and rhodium catalysts are highly enhanced by adding a Lewis acid and an amine.[4-6] The platinum–tin(IV) chloride combined with triethylamine drastically enhanced the yield and selectivity of the carbamate(Runs 11 and 12). The triphenylphosphine-$PtCl_2(PhCN)_2$ pair showed a comparable catalytic activity with dichlorobis(triphenylphosphine)platinum ($PtCl_2(PPh_3)_2$).

The platinum catalyst showed the highest activity only when combined with triphenylphosphine, tin(IV) chloride, and triethylamine. If one of these components was removed from the reaction system, yield of the carbamate was reduced drastically(Runs 13—16). The carbamate was not obtained in the absence of the platinum complex or tin halide(Runs 13—15). It is well known that tin(II) chloride is effective as co-catalyst for platinum catalyzed hydroformylation[8,9a] and hydroesterification.[9b] When tin(II) chloride was used in place of tin(IV) chloride for this reaction, the yield of the carbamate was only 5%(Run 17), indicating that tin(IV) chloride is much more favorable for this reaction. Thus, the present platinum catalyst system was distinct from the previously reported platinum catalyst system.

TABLE 3. THE EFFECT OF AMINE ADDITIVES ON THE REDUCTIVE *N*-CARBONYLATION OF NITROBENZENE[a]

Run	Amine	Conversion %	Yield of products/%[b] Carbamate[c]	Aniline

22	Butylamine	90	13	31
23	Aniline	71	1	5

a) Nitrobenzene(40 mmol), $PtCl_2(PPh_3)_2$(0.2 mmol), $SnCl_4$(2.0 mmol), amine(1.0 ml), EtOH(20 ml) at 180 °C for 4 h under the initial pressure of 60 kg cm^{-2} carbon monoxide. b) Determined by GLC based on the amount of nitrobenzene charged. c) Ethyl phenylcarbamate. d) 1,8-Diazabicyclo[5.4.0.]undec-7-ene.

The carbamate was also produced in the presence of other tertiary amines(Table 3). There was no linear relationship between the pk_a value of the conjugated acid of amine and the yield of the carbamate. However, generally tertiary amines with high basicity were effective for the *N*-carbonylation. Secondary and primary amines were less favorable.

In Table 4, effects of different Lewis acids on the reaction were examined fixing a molar ratio of Lewis acid to Pt was 20. Tin(IV) chloride was the most effective among the Lewis acid examined. With tin(IV) halide, the yield of the carbamate was reduced in the following order; $SnCl_4 > SnBr_4 \gg SnI_4$. This is the order in which Lewis acidity decreased. In the precedent platinum catalyzed reactions(hydroformylation and hydroesterification),[8,9] only the combination of platinum complex with tin(II) chloride exhibits the high catalytic activity. It is noticeable that iron(III) chloride, aluminum chloride, and titanium(IV) chloride had comparable effectiveness to tin(IV) chloride as co-catalysts(Runs 28—30).

The reaction was remarkably affected by the nature of the diphosphorus(III) ligands. The results are listed

in Table 5. Triphenylphosphine was most effective. Chelating diphosphorus(III) ligands reduced the catalytic activity. Those bidentate ligands would form thermodynamically stable complexes and these rigid complexes would be unfavorable as catalysts. Tributylphosphine and triphenyl phosphite were less effective as ligands.

The optimum reaction temperature was 180 °C under the initial pressure of 60 kg cm^{-1} carbon monoxide. The results are listed in Table 6. Under the initial pressure of 40 kg cm^{-2} carbon monoxide, the yield of the carbamate decreased(Run 38, *cf.* Run 11). The carbamate was not obtained under lower pressure of carbon monoxide. The reaction at 200 °C reduced the selectivity of the carbamate and the reaction at 160 °C reduced both the conversion of nitrobenzene and the selectivity.

Various nitroarenes were also *N*-carbonylated by this procedure(Table 7). From nitroarenes with a methyl substituents, the corresponding carbamates were obtained in good to excellent isolated yields(Runs 42, 45, and 46). On the other hand, nitroarenes with a methoxyl substituent gave the corresponding

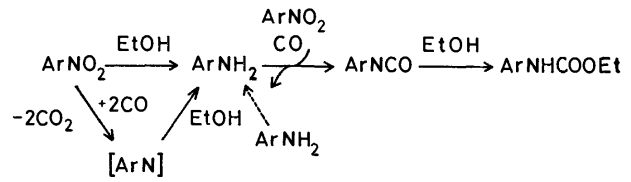
a) Nitroarene(40 mmol), $PtCl_2(PPh_3)_2$(0.2 mmol), $SnCl_4$(4.0 mmol), triethylamine(1.0 ml), EtOH(20 ml) at 180 °C for 4 h under the initial pressure of 60 kg cm^{-2} carbon monoxide. b) Isolated yields.

carbamate in only moderate isolated yields and the reaction was accompanied by a considerable amount of tarry material (Runs 43 and 47). Under the same reaction conditions, *p*- or *o*- chloronitrobenzene gave moderate yields of the corresponding carbamates(Runs 44 and 48). 1-Nitronaphthalene gave only 1-naphthylamine as the product in 26% yield. From *p*-nitroaniline and *N*,*N*-dimethyl-3-nitroaniline, the corresponding *N*-carbonylated products were not obtained.

Two routes are possible for the reaction. One is the path in which aminoarene is carbonylated with carbon monoxide (Path A). Small amounts of aminoarenes were always detected as by-products. These would be formed by hydrogen transfer from ethanol to nitroarene or hydrogen abstraction by nitrene intermediate from ethanol. It is well known that the carbamates are obtained by transition metal catalyzed *N*-carbonylation of aminoarenes in the presence of an oxidant, such as nitroarenes or molecular oxygen.[11]



Path A.

In the present reaction, nitroarene may function as the oxidant for the carbonylation of aminoarene to the carbamate(Path A). However, an equimolar mixture of nitrobenzene and aniline under the same conditions as Run 11 gave low conversion of aniline, the yield of the carbamate was reduced to 38%, based on the total amount of nitrobenzene and aniline. This result indicated that Path A is unfavorable.

The other path is the route involving the carbonylation of a nitrene intermediate(Path B). Bennett *et al.* have reported formation of phenyl isocyanates from phenyl azide under carbon monoxide pressure.[12]

$$ArNO_2 \xrightarrow[-CO_2]{2CO} (ArN)[Pt] \xrightarrow{CO} (ArNCO)[Pt] \xrightarrow{EtOH} ArNHCOOEt + [Pt]$$

Path B.

They have proposed that phenylnitrene is the reaction intermediate. Collman *et al.* have also reported similar phenyl isocyanate formation from phenyl azide in the presence of a transition metal.[13] In our reaction, a nitrene intermediate would be generated by deoxygenation of nitroarene with carbon monoxide and the carbonylation of the nitrene intermediate would be followed, as shown in Path B. Iqbal also proposed the nitrene intermediate in the reaction of nitrobenzene with carbon monoxide.[14]

In this reaction, characterization of the active species could not be done. Several studies have indicated that a Lewis acid promotes migratory insertion of coordinated carbon monoxide to a carbon-metal bond.[15] In our reaction, a Lewis acid would be operative in promoted the insertion of carbon monoxide into a nitrogen-metal bond, which consequently generates an aryl isocyanate complex(Path B). Several transition metal nitrene complex[16] and isocyanate organometallic complex were isolated.[17] Schwetlick *et al.* isolated an isocyanate complex in the course of rhodium-catalyzed reductive *N*-carbonylation of nitromesitylene.[18] In the absence of amine, the yield of the carbamate was quite low and a considerable amount of tarry material was obtained. In the presence of amine, the reaction proceeded smoothly. The amine may function to weaken the Lewis acidity and to suppress side reaction promoted by Lewis acid.

Experimental

Material. The reagents employed in this study were purified before use. Carbon monoxide (>99.9%) was used without further purification. Ethanol(99.5%) was dried by reflux over freshly ignited and crushed CaO for 9 h and distilled carefully under Ar atmosphere. Platinum complexes were prepared by the literature methods.[19]

General Procedure. A 100 ml stainless steel autoclave (Nitto Koatsu) equipped with a magnetically driven stirrer was used. A glass liner was set in the autoclave and the inside of it was heated by a heat gun (400 W) for 2 min. After cooling in Ar steam, the reagents were charged in the following order: ethanol(20 ml), nitroarene(40 mmol), triethylamine(1.0 ml, 7.2 mmol), $PtCl_2(PPh_3)_2$ (158 mg, 0.2 mmol; 0.5 mol% based on nitroarene), and $SnCl_4$(0.47 ml, 4.0 mmol). After sealing and flushing with carbon monoxide, the reactor was pressured with carbon monoxide to 60 kg cm^{-2}. The autoclave was heated to 180 °C(20 min required) and then held at this temperature for 4 h. The reaction was terminated by rapid cooling and the autoclave was discharged. The resulting brown solution was analyzed with GLC. The products were isolated by vacuum distillation. The identification of the products was confirmed by elemental analysis, IR, ^{1}H-NMR, ^{13}C-NMR, and mass spectra. The boiling points and melting points are uncorrected. The GLC analysis was made with a column (3 mm $\phi \times 3$ m) packed with Silicone OV-17(2%) on Uniport HP 60—80 mesh. The oven temperature was programmed from 100 °C to 200 °C at a rate of 5 °C min^{-1}. The IR spectra were measured on a Hitachi model 215 grating spectrophotometer. The ^{13}C-NMR and ^{1}H-NMR spectra were recorded at 25.05 and 100 MHz respectively with a JEOL JNM FX 100 spectrometer. Samples were dissolved in $CDCl_3$, and the chemical shift values were expressed in relative to Me_4Si as an internal standard. Elemental analyses were performed at Microanalytical Center of Kyoto University. The mass spectra were recorded on a JMS OISG mass spectrometer.

The analytical data of the products are described below. The phenyl carbon resonances in the ^{13}C-NMR spectra were tentatively assigned by calculating their chemical shifts with additive parameters.[20]

Ethyl Phenylcarbamate. Yellow oil 117—119 °C/4 mmHg (1 mmHg≈133.322 Pa). All the spectral data (^{1}H-NMR, ^{13}C-NMR, and IR spectra) were consistent with those of an authentic sample.

Ethyl 4-Methylphenylcarbamate. Yellow oil, Kugelrohr distillation(65 °C/0.12 mmHg) ^{1}H-NMR (100 MHz)($CDCl_3$); δ 1.20 (t, 3H, $-OCH_2\underline{CH_3}$), 2.21 (s, 3H, $-\underline{CH_3}$), 4.41 (q, 2H, $-OC\underline{H_2}CH_3$), 6.98 (d, 2H, phenyl) 7.34 (d, 2H, phenyl). ^{13}C-NMR (25.05 MHz)($CDCl_3$); 14.6(q, $-OCH_2\underline{CH_3}$), 20.7 (q, $-\underline{CH_3}$), 60.9(t, $-O\underline{CH_2}CH_3$), 119.1 (d, phenyl 2, 6), 129.3 (d, phenyl 3, 5), 132.5(s, phenyl 4), 135.7(s, phenyl 1), 154.2

(s, C=O). IR(KBr): 3300 cm^{-1} (ν_{N-H}), 1710 cm^{-1} ($\nu_{C=O}$). MS(*m/e*): 179(M^+), 106(M^+—COOEt). Calcd for $C_{10}H_{13}NO_2$: C, 67.02; H, 7.31; N, 7.82%. Found: C, 67.06; H, 7.42; N, 7.91%.

Ethyl 4-Chlorophenylcarbamate. Yellow crystals, bp 114—120 °C/0.18 mmHg. ^{1}H-NMR (100 MHz)($CDCl_3$); δ 1.28(t, 3H, $-OCH_2C\underline{H}_3$), 4.21(q, 2H, $-OC\underline{H}_2CH_3$), 7.20 (d, 2H, phenyl), 7.35(d, 2H, phenyl). ^{13}C-NMR (25.05 MHz)($CDCl_3$); 14.5(q, $-OCH_2\underline{C}H_3$), 61.4(t, $-O\underline{C}H_2CH_3$), 120.0(d, phenyl 2, 6), 128.2(s, phenyl 4), 128.9(d, phenyl 3, 5), 136.7(s, phenyl 1), 153.7(s, C=O). IR(KBr): 3300 cm^{-1} (ν_{N-H}), 1690 cm^{-1} ($\nu_{C=O}$). MS(*m/e*): 199(M^+), 126 (M^+—COOEt). Calcd for $C_9H_{10}NO_2Cl$: C, 54.15; H, 5.05; N, 7.02; Cl, 17.76%. Found: C, 54.17; H, 5.09; N, 7.02; Cl, 17.91%.

Ethyl 3-Methylphenylcarbamate. Yellow oil, bp 93 °C/0.08 mmHg. ^{1}H-NMR (100 MHz)($CDCl_3$); δ 1.25(t, 3H, $-OCH_2C\underline{H}_3$), 2.25(s, 3H, $-C\underline{H}_3$), 4.18(q, 2H, $-OC\underline{H}_2CH_3$), 6.79—7.17(m, 5H, phenyl and NH). ^{13}C-NMR(25.05 MHz) ($CDCl_3$); 14.5 (q, $-OCH_2\underline{C}H_3$), 21.4 (s, $-\underline{C}H_3$), 61.0 (t, $-O\underline{C}H_2CH_3$), 115.9(d, phenyl 6), 119.4(d, phenyl 2), 124.0 (d, phenyl 4), 128.7(d, phenyl 5), 138.1(s, phenyl 3), 138.7 (s, phenyl 1), 153.9(s, C=O). IR(neat): 3320 cm^{-1} (ν_{N-H}), 1705 cm^{-1} ($\nu_{C=O}$). MS(*m/e*): 179(M^+), 106(M^+—COOEt). Calcd for $C_{10}H_{13}NO_2$: C, 67.02; H, 7.31; N, 7.82%. Found: C, 67.20; H, 7.22; N, 7.81%.

Ethyl 4-Methoxyphenylcarbamate. Yellow crystals, bp 126 °C/0.08 mmHg. ^{1}H-NMR (100 MHz) ($CDCl_3$); δ 1.27 (t, 3H, $-OCH_2C\underline{H}_3$), 3.74 (s, 3H, $-OC\underline{H}_3$), 4.19(q, 2H, $-OC\underline{H}_2CH_3$), 6.81(d, 2H, phenyl), 6.94(br, 1H, N$\underline{H}$), 7.29 (d, 2H, phenyl). ^{13}C-NMR (25.05 MHz)($CDCl_3$); 14.6(q, $-OCH_2\underline{C}H_3$), 55.5(q, $-O\underline{C}H_3$), 61.6(t, $-O\underline{C}H_2CH_3$), 114.1 (d, phenyl 3,5), 120.9(d, phenyl 2,6), 131.1(s, phenyl 1), 154.2(s, phenyl 4), 155.8(s, C=O). IR(KBr): 3310 cm^{-1} (ν_{N-H}), 1690 cm^{-1} ($\nu_{C=O}$). MS(*m/e*): 195(M^+), 122(M^+—COOEt). Calcd for $C_{10}H_{13}NO_3$: C, 61.53; H, 6.71; N, 7.18%. Found: C, 61.62; H, 6.63; N, 7.02%.

1-Naphthylamine. Red oil, bp 126 °C/0.12 mmHg. Spectra data of the isolated product were consistent with those of the authentic sample.

Ethyl 2-Methylphenylcarbamate. Colorless oil, bp 78—80 °C/0.06 mmHg. ^{1}H-NMR (100 MHz) ($CDCl_3$); δ 1.25 (t, 3H, $-OCH_2C\underline{H}_3$), 2.16 (s, 3H, $-C\underline{H}_3$), 4.16 (q, 2H, $-OC\underline{H}_2CH_3$), 6.65(br, 1H, N$\underline{H}$), 6.95—7.71(m, 4H, phenyl). ^{13}C-NMR(25.05 MHz)($CDCl_3$): 14.6(t, $-OCH_2\underline{C}H_3$), 17.6 (t, $-CH_3$), 61.6(t, $-O\underline{C}H_2CH_3$), 121.5(d, phenyl 6), 124.1 (d, phenyl 4), 126.6(d, phenyl 5), 128.0(s, phenyl 2), 130.3 (d, phenyl 3), 135.9(s, phenyl 1), 154.0(s, C=O). IR(neat): 3300 cm^{-1} (ν_{N-H}), 1730 cm^{-1} ($\nu_{C=O}$). MS(*m/e*): 179(M^+), 106(M^+—COOEt). Calcd for $C_{10}H_{13}NO_2$: C, 67.02; H, 7.31; N, 7.82%. Found: C, 67.45; H, 7.27; N, 7.84%.

Ethyl 2-Methoxyphenylcarbamate. Colorless oil, bp 95—97 °C/0.13 mmHg. ^{1}H-NMR (100 MHz) ($CDCl_3$): δ 1.28 (t, 3H, $-OCH_2C\underline{H}_3$), 3.78 (s, 3H, $-OC\underline{H}_3$), 4.20 (q, 2H, $-OC\underline{H}_2CH_3$), 7.23(br, 1H, N$\underline{H}$), 6.70—7.23(m, 3H, phenyl), 7.97—8.12(m, 1H, phenyl). ^{13}C-NMR(25.05 MHz)($CDCl_3$): 14.6(q, $-OCH_2\underline{C}H_3$), 55.8(q, $-O\underline{C}H_3$), 61.6(t, $-O\underline{C}H_2CH_3$), 110.0(d, phenyl 3), 118.2(d, phenyl 6), 121.0 (d, phenyl 5), 122.7(d, phenyl 4), 127.7(s, phenyl 1), 147.6 (s, phenyl 2), 153.5(s, C=O). IR (neat): 3420 cm^{-1} (ν_{N-H}), 1730 cm^{-1} ($\nu_{C=O}$). MS (*m/e*): 195 (M^+). Calcd for $C_{10}H_{13}NO_3$: C, 61.53; H, 6.71; N, 7.18. Found: C, 60.42; H, 6.51; N, 6.94.

Ethyl 2,5-Dimethylphenylcarbamate. Ethanol was removed from the reaction mixture *in vacuo* at 50 °C. Then, petroleum ether was added to the residue. A soluble part was separated by filtration, and then the solvent was removed *in vacuo*. The product was afforded as crystals: brown crystals, mp 94—95 °C. ^{1}H-NMR (100 MHz) ($CDCl_3$): δ 1.31(t, 3H, $-OCH_2C\underline{H}_3$), 2.19(s, 3H, $-C\underline{H}_3$), 2.31(s, 3H, $-C\underline{H}_3$), 4.22(q, 2H, $-OC\underline{H}_2CH_3$), 6.36(br, 1H, $-N\underline{H}$), 6.83 (d, 1H, phenyl), 7.02(d, 1H, phenyl), 7.61(s, 1H, phenyl). ^{13}C-NMR(25.05 MHz)($CDCl_3$): δ 14.6(q, $-OCH_2\underline{C}H_3$), 17.2 (q, $-\underline{C}H_3$), 21.1(q, $-\underline{C}H_3$), 61.2(t, $-O\underline{C}H_2CH_3$), 121.8(d, phenyl 6), 124.5(s, phenyl 2), 124.8(d, phenyl 4), 130.1(d, phenyl 3), 135.6(s, phenyl 5), 136.5(s, phenyl 1), 153.9(s, C=O). IR(KBr): 3290 cm^{-1} (ν_{N-H}), 1685 cm^{-1} ($\nu_{C=O}$). MS (*m/e*): 193(M^+), 120(M^+—COOEt). Calcd for $C_{11}H_{15}NO_2$: C, 68.37; H, 7.82; N, 7.25%. Found: C, 68.53; H, 7.92; N, 7.18%.

Ethyl 2-Chlorophenylcarbamate. Colorless oil, bp 70—72 °C/0.07 mmHg. ^{1}H-NMR(100 MHz)($CDCl_3$): δ 1.30(t, 3H, $-OCH_2C\underline{H}_3$), 4.22(q, 2H, $-OC\underline{H}_2CH_3$), 6.93(t of d, 1H, phenyl), 7.22 (t of d, 1H, phenyl), 7.29 (d of d, 1H, phenyl), 8.15(d of d, 1H, phenyl). ^{13}C-NMR(25.05 MHz) ($CDCl_3$): δ 14.5(t, $-OCH_2\underline{C}H_3$), 61.5(t, $-O\underline{C}H_2CH_3$), 119.9 (d, phenyl 6), 122.0 (s, phenyl 2), 123.6 (d, phenyl 4), 127.7 (d, phenyl 5), 129.0(d, phenyl 3), 134.8(s, phenyl 1), 153.2 (s, C=O). IR(neat): 3410 cm^{-1} (ν_{N-H}), 1730 cm^{-1} ($\nu_{C=O}$). MS(*m/e*): 199(M^+), 126(M^+—COOEt). Calcd for $C_9H_{10}NO_2Cl$: C, 54.15; H, 5.05; N, 7.02; Cl, 17.76%. Found: C, 54.97; H, 5.07; N, 7.36; Cl, 17.89%.

(Received May 14, 1983)

Photolysis of 6-methylcholest-5-en-3β-ol nitrite and 4,4,6-trimethylcholest-5-en-3β-ol nitrite in benzene with monochromatic light respectively gave a seven-membered cyclic hydroxamic acid arising from rearrangement albeit in low yields. Photolysis of 3α-methylcholest-5-en-3β-ol nitrite and 3α,4,4-trimethylcholest-5-en-3β-ol nitrite respectively gave a nitroso dimer arising from β-scission.

In a series of previous papers,[2)] we have reported the results of the photorearrangements of several steroidal and nonsteroidal cyclic homoallyl alcohol nitrites.[2)]

These studies have shown that the products in the photorearrangement of cyclic homoallyl alcohol nitrites are always those arising from the combination of nitrogen monooxide and the less substituted carbon terminus of the allyl radical intermediates. These are generated by the β-scission of the corresponding oxyl radicals, with the formation of more highly substituted olefins.

We have found, however, an exception to this rule in the photorearrangement of 4,4-dimethylcholesteryl nitrite[2)] in which the nitrogen monooxide shifts regioselectively to the more substituted terminus of the intermediary allyl radical. This reverse regioselectivity observed in the radical combination between the allyl radical and nitrogen monooxide was explained as due to the shielding of the C-6 by the 10β-methyl group and the *quasi*-axial 7α-H.[3)]

In order to gain more insight into the effects of alkyl substitution around the reacting radical center, we investigated the photoreactions of two 6-methylcholest-5-en-3β-ol nitrites (**2**) and (**4**) and two 3α-methylcholest-5-en-3β-ol nitrites (**6**) and (**8**) with monochromatic light as well as with Pyrex-filtered light. The photolysis of these nitrites with monochromatic light was especially desirable in order to avoid the secondary photo-decomposition of the photo-products.

6-Methylcholest-5-en-3β-ol nitrite (**2**), 4,4,6-trimethylcholest-5-en-3β-ol nitrite (**4**) and 3α-methylcholest-5-en-3β-ol nitrite (**6**) were prepared from the corresponding 3β-ols (**1**),[4,5)] (**3**),[5)] and (**5**),[6)] by the standard method. Nitrosation of 3α,4,4-trimethylcholest-5-en-3β-ol (**7**)[7)] with nitrosyl chloride–pyridine by the standard method, was found to be difficult and to give a 1:2.4 mixture of the starting alcohol and nitrite **8** as determined by the signal ratio of 6-H in the ^1H NMR spectrum.

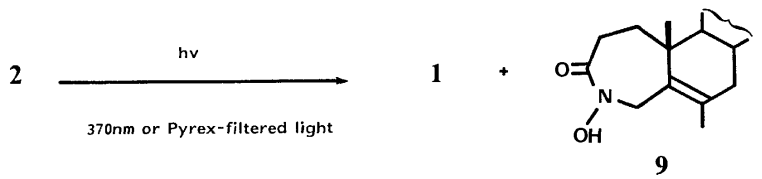
Irradiation of nitrite **2** in dry benzene with 370 nm monochromatic light gave mainly the parent alcohol (**1**) (57%) arising from a hydrogen abstraction of the corresponding oxy radical together with a 7% yield of a crystalline product (**9**). This was proved to be 4-hydroxy-6-methyl-4-aza-*A*-homocholest-5-en-3-one, a hydroxamic acid, from its spectroscopic data (Scheme 1).

Photolysis of nitrite **2** with a Pyrex-filtered light gave **9** in a much higher yield (37%) and the parent alcohol **1** (26%).

Photolysis of nitrite **4** with a 373 nm light also gave a mixture of products from which the parent alcohol **3** (18%), 4,6-dimethyl-4-methylene-3,4-secocholest-5-en-3-al (**10**) (25%) and 4-hydroxy-4a,4a,6-trimethyl-4-aza-*A*-homocholest-5-en-3-one (**11**) (13%) were obtained by preparative TLC (Scheme 2).

Photolysis of **4** with a Pyrex-filtered light was also found to give the parent alcohol **3** (18%) and a secoaldehyde **10** (6%) together with 4,4,6-trimethylcholest-5-en-3-one (**12**)[8)] (4%). No hydroxamic acid **11**, however, was found in the product mixture.

Although the observed differences between the results of the photolysis with monochromatic light and those with a Pyrex-filtered light are not clear at present, it has thus again been shown that seven-membered cyclic hydroxamic acid can be prepared from the photoreaction of 3-hydroxy-Δ^5-steroid nitrites.[2)] It should be noted that the product of the photorearrangement of (**2**) is a hydroxamic acid **9** and not the corresponding seven-membered cyclic nitrone.[9)] This



9

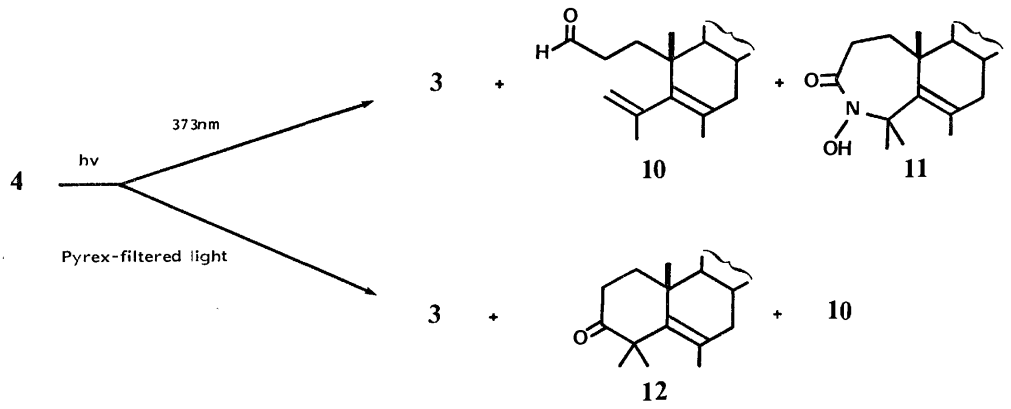
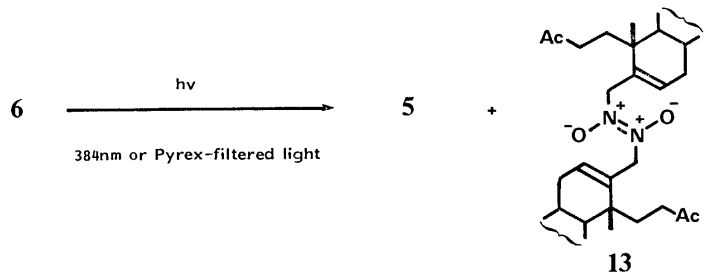
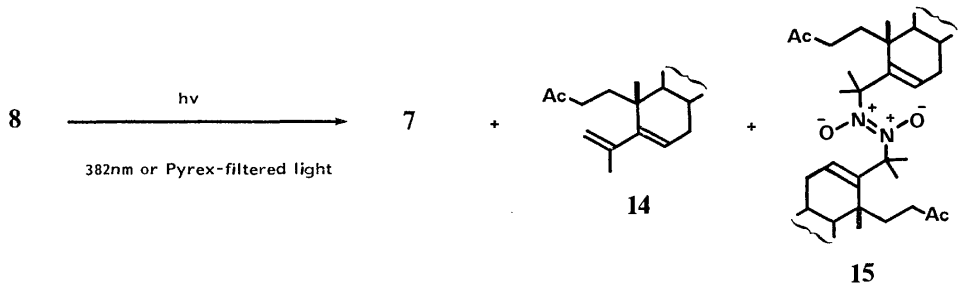


Scheme 2.



Scheme 3.



Scheme 4.

result is entirely parallel with that obtained in the photorearrangement of cholesterol nitrite.[2] The reason why the nitrone is not formed in this photorearrangement of cyclic homoallyl alcohol nitrite has already been discussed in the previous paper.[2]

We then studied the photolysis of two 3α-methylcholest-5-en-3β-ol nitrites (**6**) and (**8**) from which hydroxamic acids can not be formed even after β-scission.

The photolysis of 3α-methylcholest-5-en-3β-ol nitrite (**6**) with a 384 nm light resulted in the formation of a mixture of the products. Preparative TLC of the product gave the parent alcohol **5** (14%) and a crystalline nitroso dimer (**13**) (12%) together with several ill-defined products. The structure of the nitroso dimer **13** as (*E*)-4,4'-azobis(3,4-seco-3-methylcholest-5-en-3-one) *N*,*N*'-dioxide was confirmed by means of spectroscopy (see Experimental section). The photolysis of **6** with a Pyrex-filtered light gave a similar result with a better yield of the nitroso dimer (21%) (Scheme 3).

On the other hand, irradiation of a mixture of the alcohol **7** and the nitrite **8** with 382 nm monochromatic light gave three products; an amorphous seco-ketone (**14**)(13%), the parent alcohol **7** (23%) and an unstable amorphous nitroso dimer(**15**) (11%). The structures of **14** and **15** were shown to be 3,4-dimethyl-4-methylene-3,4-secocholest-5-en-3-one and (*E*)-4,4'-azobis (3,4-seco-3,4,4-trimethylcholest-5-en-3-one) *N*,*N*'-dioxide on the basis of their ^{1}H NMR, UV, IR, and Mass spectra (Scheme 4).

The photolysis of **8** with a Pyrex-filtered light also gave the seco-ketone **14** and the nitroso dimer **15** in better yields together with a lower yield of the parent 3β-ol **7**.

It has thus again been shown that the nitrogen monooxide migrates to the more substituted carbon terminus of the intermediary allyl radical in the photolysis of 4,4-dimethyl-3β-hydroxy-Δ^5-steroid nitrite. As has been discussed in the previous paper,[2] this anomaly in the site of the combination of radicals may be steric in its origin and may be due to the fact that the C-6 terminus of the intermediary allyl radical is more shielded for the approach of nitrogen monooxide.

Experimental

Mp's were determined with a Yanagimoto micro mp apparatus. IR spectra were determined for Nujol mulls, unless stated otherwise, with a JASCO IR-E spectrophotometer. UV spectra were determined with a Hitachi 124 double-beam spectrophotometer, unless stated otherwise. ^{1}H NMR spectra were determined with a JEOL PS 100 high-resolution spectrometer (100 MHz) (solvent $CDCl_3$, $SiMe_4$ as internal reference). ^{1}H NMR spectra of **8**, **11** and **15** were determined with a JEOL PS 200 high-resolution FT NMR spectrometer (200 MHz). ^{13}C NMR spectra were determined with a JNM-FX-100 (25 MHz) high-resolution spectrometer ($CDCl_3$, $SiMe_4$ as an internal reference). TLC was carried out on Wako silica gel B-5. Low resolution mass spectra of **9**, **10**, **13**, and **14** were recorded with JEOL JMS-D-300 spectrometer (70 eV) (The Faculty of Agriculture of this University.) Low resolution mass spectra of **11** and **15** were recorded with a JEOL JMS-D-300 spectrometer (70 eV) (The Faculty of Pharmaceutical Sciences of this University). The high resolution mass spectrum of **9** was determined with a JEOL JMS-D-300 spectrometer (70 eV). High resolution mass spectra of **13** and **14** were determined with a JEOL JMS-D 300 spectrometer (70 eV) (The Faculty of Agriculture) and that of **11** was determined with JEOL JMS-D-300 spectrometer (the Faculty of Pharmaceutical Sciences).

The Procedure of the Photolysis. (a) With a Pyrex-filtered Light: A benzene solution of each nitrite in a Pyrex tube was flushed with oxygen-free nitrogen and irradiated with a 100-W high pressure Hg arc (EIKOSHA PIH-100) until all the nitrite was decomposed. The progress of the photolysis was monitored by TLC at appropriate time intervals.

(b) With Monochromatic Light: A solution of each nitrite (2—300 mg) in dry benzene (2—3 cm^3) in a quartz cell (10×10×45 mm^3) was placed in a chamber of a JASCO CRM-FA grating spectro-irradiator equipped with 2KW Xe arc lamp and irradiated with appropriate monochromatic light until all the nitrite was decomposed. The progress of the photolysis was monitored by TLC.

Preparation of 6-Methylcholest-5-en-3β-ol Nitrite (2). To 6-methylcholesterol (800 mg) in pyridine (15 cm^3) cooled with Dry Ice–ethanol was added nitrosyl chloride in pyridine dropwise. The solution was stirred for 1 h and poured into water. The crystals (684 mg) of **2** were collected, washed with water and dried. Mp 88.5—90 °C; $[\alpha]_D^{25}$ −26.5° (*c* 1.0, $CHCl_3$); IR, 1645 and 1598 (*trans* and *cis* N–O), 782 (O–N), and 680 cm^{-1} (O–N=O); ^{1}H NMR, δ=0.69 (3H, s, 18-H), 1.03 (3H, s, 19-H), 1.64 (3H, s, 6-methyl), and 5.19 (1H, broad s, 3α-H); UV (benzene) 398 (ε 45), 374 (94), 362 (75), 348 (60), and 337 (45).

Photolysis of 2 with Pyrex-filtered Light. The nitrite (**2**) (620 mg) in benzene (40 cm^3) was irradiated for 3 h 20 min. The solvent was evaporated and the product (669 mg) was subjected to preparative TLC with hexane–ethyl acetate (5:1) to give eight fractions (A—H) in the order of decreasing mobilities. The fractions A (25 mg), B (33 mg), C (63 mg), E (30 mg), F (29 mg), and H (45 mg) could not be identified. The fraction D (150 mg, 26%) was the parent 3β-ol. The fraction G (231 mg, 37%) was 4-hydroxy-6-methyl-4-aza-*A*-homo-5-cholesten-3-one (**9**). This hydroxamic acid was recrystallized once from methanol and then from acetone to yield a specimen (179 mg) for analysis. Mp 180—184 °C; $[\alpha]_D^{20}$ −8.2° (*c* 1.6 $CHCl_3$); (Found: *m/z* 429.3632. Calcd for $C_{28}H_{47}NO_2$; M 429.3604. Found: C, 78.08; H, 11.06; N, 3.47%. Calcd for $C_{28}H_{47}NO_2$: C, 78.27; H, 11.03; N, 3.26%) IR, 3100 (OH), 1621 (amide C=O), 1230, and 768 cm^{-1}; ^{1}H NMR ($CDCl_3$), δ=0.69 (3H, s, 18-H), 0.98 (3H, s, 19-H), 1.74 (3H, s, 6-methyl), and 4.27 and 4.32 (2H, AB q, J=15 Hz, 4a-H_2); ^{13}C NMR, ($CDCl_3$), δ=167.9 (NCO), 136.1 (C-5) and 129.9 (C-6); MS *m/e* (rel intensity) 429 (M^+, 100), 413 (M^+—O, 16.8), 412 (M^+—OH, 52,3), 384 (57.7), 137 (67.4), 133 (45.7), 95 (28.0), 57 (32.0), 55 (36.9), and 43 (45.5).

Photolysis of 2 with 370 nm Monochromatic Light. A solution of 6-methylcholest-5-en-3β-ol nitrite (**2**) (260 mg) in dry benzene (2.5 cm^3) in a quartz cell was placed in a chamber of a JASCO CRM FA grating spectro-irradiator and was irradiated with 370 nm light for 9 h; complete decomposition of the nitrite had occurred after this period. The solvent was removed by distillation under vacuum and the photolysate was subjected to preparative TLC with hexane–ethyl acetate (5:1) as developer to give three fraction A—C in the order of increasing mobility. The least mobile fraction A (18 mg, 7%) was the hydroxamic acid **9**. Fraction B (138 mg, 57%) was the parent alcohol **1**. The most mobile fraction C (6 mg) was an intractable mixture.

Preparation of 4,4,6-Trimethylcholest-5-en-3β-ol Nitrite (4). To the 3β-ol **3** (428 mg) in pyridine (15 ml) cooled by Dry Ice–ethanol, was added nitrosyl chloride (1 cm^3). The solution was stirred for 30 min and poured into water and ice. The nitrite was collected by filtration and washed with water. The amount of the nitrite obtained was 440 mg (96%). It melted at 117.0—119.5 °C. This nitrite was recrystallized from acetone to yield an analytical specimen, mp 118.5—120 °C; $[\alpha]_D^{19}$ −26.8° (*c* 0.5, $CHCl_3$); IR, 1648 and 1613 (ONO), 801 and 776 cm^{-1} (ONO); ^{1}H NMR, δ=0.67 (3H, s, 18-H), 1.05 (3H, s, 19-H), 1.14 and 1.27 (each 3H, each s, 4,4-dimethyl), 1.76 (3H, s, 6-methyl), and 5.12 (1H, dd, J=5 and 11 Hz, 3α-H); UV (benzene) 386 (ε50), 373 (90), 357 (89), 345 (65), and 334 (48).

Photolysis of 4,4,6-Trimethylcholest-5-en-3β-ol Nitrite (4) with 373 nm Monochromatic Light. A solution of the nitrite (260 mg) in dry benzene (3 cm^3) in a quartz cell was placed in a chamber of a JASCO CRM-FA grating spectroirradiator and irradiated with 373 nm light for 12 h; complete decomposition of the nitrite had occurred after this period. The solvent was removed under vacuum and the photolysate (271 mg) was subjected to preparative TLC with benzene as developer to give six fractions, A—F in the order of increasing mobility. The least mobile fraction A (24 mg, 13%) was the hydroxamic acid **11**. It crystallized from acetone. Mp 178—181 °C. (Found: *m/z* 457.3907. Calcd for $C_{30}H_{51}NO_2$, M, 457.3919) MS, *m/z* (rel intensity) 457 (M^+, 21.9), 442 (M^+—CH_3, 18.3), 441 (M^+—0.69), 440 (M^+—OH, 9.5), 427 (M^+—$2CH_3$, 11.1), 426 (M^+—CH_3—O, 339), 369 (100), and 327 (52.6); IR 3400 (br, OH), and 1626 cm^{-1} (amide CO); ^{1}H NMR δ=0.68 (3H, s, 18-H), 1.22 (3H, s, 19-H), 1.67 and 1.73 (each 3H, each s, 4a-*gem* dimethyl), and 1.85 (3H, s, 6-methyl).

Fraction B (44 mg, 18%) was identical with the parent 3β-ol **3**. The fractions C (21 mg), D (15 mg), and E (8 mg) were intractable mixtures. Fraction F (60 mg, 25%) was the seco-aldehyde **10**. It could not be induced to crystallize but its spectroscopic data were identical with those of 4,6-dimethyl-4-methylene-3,4-secocholest-5-en-3-al obtained from the irradiation of 3β-ol **3** in benzene containing mercury (II) oxide and iodine.[5] [In the mass spectrometric data on compound **10** in the reference 5, 411 (M^+—CH_2CH_2CHO, 100) should read 411 (M^+—CH_3, 8.5), 369 (M^+—CH_2-CH_2CHO, 100)].

Photolysis of 4,4,6-Trimethycholest-5-en-3β-ol Nitrite with a Pyrex-filtered Light. The nitrite **4** (280 mg) in dry benzene (38 cm³) in a Pyrex vessel was irradiated for 10 h in a nitrogen atmosphere. The solvent was removed by rotary evaporation and the product was subjected to preparative TLC with benzene to yield 3β-ol (47 mg, 18%), 4,4,6-trimethylcholest-5-en-3-one (10 mg, 4%) and seco-aldehyde **10** (16 mg, 6%). No hydroxamic acid **11** was found in the product.

Preparation of 3α-Methylcholest-5-en-3β-ol Nitrite (6). The 3β-ol **5** (200 mg) in pyridine (6 cm³) was treated with nitrosyl chloride in pyridine in a usual manner to afford a crystalline nitrite, mp 115—117 °C (185 mg, 86%); $[\alpha]_D^{18}$ +6.9° (*c* 0.9, $CHCl_3$); IR 1628 (ONO), 810 (ONO), and 768 cm^{-1} (ONO); ^1H NMR, δ=0.68 (3H, s, 18-H), 1.07 (3H, s, 19-H), 1.54 (3H, s, 3α-methyl) and 5.45 (1H, br s, 6-H); UV (THF) 400 (ε49), 384 (75), 367 (67), 355 (46), and 342 (27).

Photolysis of 3α-Methylcholest-5-en-3β-ol Nitrite (6) with 384 nm Monochromatic Light. The nitrite (180 mg) in dry benzene (3 cm³) in a quartz vessel was placed in a chamber of JASCO CRM-FA grating spectroirradiator and was irradiated with 384 nm light for 10.5 h. The solvent was removed under vacuum and the brownish photolysate (155 mg) was subjected to preparative TLC with benzene–diethyl ether (10:1) to give four fractions A—D in the order of increasing mobility. The least mobile fraction A (21 mg, 12%) was the nitroso dimer **13**. This was recrystallized from methanol. Mp 111—113 °C; (Found: M^+ 429.3601. Calcd for $C_{28}H_{47}NO_2$: 429.3606); IR 1718 (acetyl) and 1196 cm^{-1}; ^1H NMR, δ=0.66 (3H, s, 18-H), 1.06 (3H, s, 19-H), 2.15 (3H, s, acetyl), 4.65 and 4.86 (each 1H, each d, *J*=13.5 Hz, 4-methylene), and 5.58 (1H, br, s, 6-H) MS, *m/z* (rel intensity), 429 (1.0), 341 (100, $M^+-CH_3COCH_2-CH_2$), 71 (91.2), 57 (89.2), and 43 (86.2). UV (dioxan) 294 (ε8300). Fraction B (20 mg) was an unidentified gum.

Fraction C (23 mg, 14%) was the parent 3β-ol. The most mobile fraction D (13 mg) was an unidentified gum.

Photolysis of 3α-Methylcholest-5-en-3β-ol Nitrite (6) with Pyrex-filtered Light. The nitrite (160 mg) in dry benzene (15 cm³) in a Pyrex-vessel was irradiated for 1.5 h. The crude product (173 mg) was subjected to preparative TLC with hexane–diethyl ether (5:1). The TLC plates were developed with the solvent twice to give five fractions A—E in the order of increasing mobility. The least mobile fraction A (110 mg) was again subjected to preparative TLC to afford three fractions E_1—E_3. Fractions E_1 (29 mg) and E_3 (112 mg) were not identified. Fraction E_2 (34 mg, 21%) was the nitrosodimer **13** which, after recrystallization, was identical with the specimen obtained by monochromatic light photolysis. The fractions B (7 mg), D (6 mg), and E (7 mg) were unidentified gums. Fraction C (27 mg, 18%) was the parent 3β-ol.

Preparation of 3α,4,4-Trimethylcholest-5-en-3β-ol Nitrite (8). The 3β-ol (330 mg) in pyridine (3 cm³) was treated with nitrosyl chloride–pyridine in a usual manner while the flask was cooled by ice. The solution was poured into water and the solid obtained was collected by filtration to give a gummy nitrite. This was dissolved in diethyl ether and the ethereal solution was dried over anhydrous sodium sulfate. The removal of the solvent gave a crystalline mixture of 3β-ol **7** and the nitrite 8, IR 1622 (ONO), 795 and 760 cm^{-1} (ONO); ^1H NMR δ=0.68 (s, 18-H of **7** and **8**), 1.05 (s, 19-H of **8**), 1.14 and 1.15 (each s, *gem*-dimethyl group at the C-4 of **8**), 1.52 (s, 3α-methyl of **8**), 5.49 (br s, 6-H of **7**), and 5.56 (br s, 6-H of **8**). The ratio of **7** to **8** estimated by the signal areas of 6-H of **7** and that of **8** was 1:2.4. UV (THF) 398, 382, 366, 353, and 340.

Photolysis of 3α,4,4-Trimethylcholest-5-en-3β-ol Nitrite (8) with 382 nm Monochromatic Light. The above nitrite (285 mg) in benzene (3 cm³) in a quartz cell was placed in a chamber of CRM-FA grating spectroirradiator and photolyzed with 382 nm light for 5.5 h. The solvent was evaporated and the product was subjected to preparative TLC to give six fractions (A—F) in the order of their mobility on the TLC plate. The most mobile fraction A (24 mg, 13%) was an oily methyl ketone **14** and this was again purified by TLC. (Found: *m/z* 426.3851. Calcd for $C_{30}H_{50}O$; M, 426.3858); MS, *m/z* (rel intensity) 426 (M^+, 34.6), 383 (18.1), 355 ($M^+-CH_3COCH_2CH_2$, 100), 313 (16.8), 147 (63.4), 133 (31.1) 121 (34.6), 105 (43.6), 95 (48.5), 84 (36.4), 69 (35.8), 57 (44.4), 55 (42.6), and 43 (71.3); IR (neat), 1724 (CH_3CO), 1164, and 898 cm^{-1}; ^1H NMR, δ=0.68 (3H, s, CH_3CO), 4.47 and 4.84 (each 1H, each br s, 4-methylene), and 5.61 (1H, br d, *J*=4.5 Hz, 6-H) UV (EtOH) 274 (ε 4000), and 203 (57600).

Fractions B (25 mg), D (8 mg), and F (11 mg) were intractable mixtures. Fraction C (126 mg, 23%) was identical with the parent alcohol **7**. Fraction E (23 mg, 11%) was, after purification by TLC, identified as an amorphous nitroso dimer **15**. MS, *m/z* (rel intensity) 427 (8.3) 426 (14.4), 355 (*m/z* 426 $-CH_3COCH_2CH_2$, 41.2) and 43 (100); IR (neat), 1717 (CH_3CO), 1541, and 1165 cm^{-1}; ^1H NMR, δ=0.67 (6H, s, 18- and 18′-H), 1.21 (6H, s, 19- and 19′-H), 1.40 (12H, s, *gem*-dimethyl groups at C-4 and C-4′), 2.15 (6H, s, 3- and 3′-methyl), and 5.67 (2H, 6H and 6′-H).

Photolysis of 3α,4,4-Trimethylcholest-5-en-3β-ol Nitrite with a Pyrex-filtered Light. The 3β-ol nitrite (485 mg) in benzene (32 cm³) was irradiated for 2.5 h under a nitrogen atmosphere. The product (482 mg) was subjected to preparative TLC with benzene to give 6 fractions A to F in the order of decreasing mobilities. The fraction A (112 mg, 35%) was an oily methyl ketone **14**.

Fraction D (161 mg, 6%) was, after further purification, identical with the parent 3β-ol **7**. Fraction F (54 mg, 16%) was the nitroso dimer **15**.

An X-Ray Crystallographic Study on the Absolute Configuration of Dihydroyashabushiketol and the Solvent-dependence of Its Optical Rotation

Takayuki SUGA,* Shinji OHTA, Tadashi AOKI, and Toshifumi HIRATA

Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Naka-ku, Hiroshima 730

(Received May 16, 1983)

The absolute configuration of dihydroyashabushiketol was established to be *S* on the basis of the X-ray crystallographic analysis of the 4′,4″-dibromo derivative. In addition, it was found that the sense of the optical rotations of dihydroyashabushiketol and its dibromo derivative is determined by the interaction of their C-5 hydroxyl group with the solvent used for the measurements.

The absolute configurations of both dihydroyashabushiketol (**1**) and yashabushiketol (**2**) isolated from the male flowers of *Alnus sieboldiana* are reported to be *S*[1] on the basis of the benzoate rule[2] and Horeau's asymmetric synthesis.[3] However, the benzoate rule is not adapted to such a type of compounds in which the carbinyl carbon is flanked by two methylenes.[4] In the case of **1**, in addition, the optical yield of α-phenylbutyric acid was too low (only 1.5 %[1]) to determine the absolute configuration. These suspicious points necessitated the establishment of the absolute configuration of **1**† by use of an unambiguous method. Then, the absolute configuration was reexamined by the X-ray crystallographic analysis of the 4′,4″-dibromo derivative (**3**) prepared from **1**, and the absolute configuration proposed previously for **1** was validated. During the course of this reexamination, it was found that the sense of the optical rotation of **1** and **3** is determined by the interaction of their C-5 hydroxyl group with the solvent used for measurements of the optical rotation. We now wish to report these results.

Experimental

General. The ^1H NMR spectra were taken on a Hitachi R-22 spectrometer using TMS as an internal standard. The ^{13}C NMR spectra were obtained on a Hitachi R-42 FT NMR (22.6 MHz) spectrometer ($\delta_{TMS}=0$). The Mass spectra were recorded by direct inlet at 70 eV ionization. The optical rotation was measured on a Yanaco Automatic Digital Polarimeter OR-50D spectrometer. The ORD curves were taken on a JASCO ORD/UV-5 spectropolarimeter at 25 °C by use of a 10 mm cell in path-length. The UV spectra were obtained on a Shimadzu UV-240 spectrometer. Analytical TLC and preparative TLC were carried out on 0.25 and 0.75 mm thick silica gel plates (Merck 60, GF_{254}), respectively.

The physical and spectral data of compounds **1** and **3**—**5** are summarized in Tables 1—4.

Isolation and Identification of Dihydroyashabushiketol (1). The benzene extract of the male flowers (13 kg) of *Alnus sieboldiana* MATSUM., which were collected on the mountain in the suburbs of Hiroshima City in February, was worked up in a similar manner as described in the literature[1] to give compound (**1**) (1.35 g). This compound (**1**) was

TABLE 1. PHYSICAL DATA OF **1**, **3**, **4**, AND **5**

confirmed to be identical with dihydroyashabushiketol[1] by direct comparison of the ^{1}H NMR spectra taken in $CDCl_3$ and the Mass spectra,[5] and then characterized as 1,7-diphenyl-5-hydroxy-3-heptanone on the basis of the elemental analysis and the UV, IR, ^{1}H and ^{13}C NMR, and Mass spectral data. Acetylation of **1** (96 mg) with a mixture of acetic anhydride (2 cm^3) and dry pyridine (2 cm^3) gave its acetate (**4**) (108 mg).

Bromination of 1. Following the method for the iodination of veratrole described in the literature,[6] the bromination of **1** (129 mg) was carried out by use of bromine (183 mg) in place of iodine under the conditions similar to those described. The resulting mixture was subjected to preparative TLC with EtOAc–hexane (3:7 v/v) to give a dibromo derivative (**3**) (48 mg), which was characterized as 1,7-bis(4-bromophenyl)-5-hydroxy-3-heptanone on the basis of the elemental analysis and the spectral data. Acetylation of **3** (48 mg) in the same way as in the case of **1** gave its acetate (**5**) (50 mg).

X-Ray Crystallographic Analysis. The single-crystals of **3** for the X-ray analysis were obtained by crystallization from MeOH–H_2O. The single-crystal used was about 0.2 mm×0.5 mm×0.7 mm in size. Cell dimensions were determined by least-squares calculations from 2θ values of 16 reflections measured on a Syntex R-3 automated four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation. Crystal data: orthorhombic, space group $P2_12_12_1$, four molecules per unit cell with dimensions a=5.012(3), b=

a) $\Delta|F_o| = |F_o(hkl)| - |F_o(\bar{h}\bar{k}\bar{l})|$. b) $\Delta|F_c| = |F_c(hkl)| - |F_c(\bar{h}\bar{k}\bar{l})|$. c) $|S| = ||F_c(hkl)| - |F_c(\bar{h}\bar{k}\bar{l})||/\sigma(F_o)$.

12.315(6), c=30.480(15) Å; U=1881(2) Å; D_c=1.55 g cm^{-3}; D_m=1.54 g cm^{-3}; μ(Mo $K\alpha$)=45.7 cm^{-1}. A total of 2130 reflections with the Friedel pair of (h,k,l) and $(\bar{h},\bar{k},\bar{l})$ were collected by use of the ω-scan technique in the range $2\theta \leq 50.0°$. 1286 reflections having $F_o > 2\sigma(F_o)$ were used for the structure determination. The structure was solved by the conventional heavy-atom method. The bromine atom positions were obtained from a Patterson function, and then the positions of oxygen and carbon atoms were determined by difference-Fourier syntheses. A least-squares refinement was carried out by use of anisotropic temperature factors for bromine, carbon, and oxygen atoms and isotropic temperature factors for hydrogen atoms. In the least-squares calculation, the quantity minimized was $\sum w(|F_o| - |F_c|)^2$ with w=1.0 for all the reflections. Final refinements were done by use of the anomalous dispersion effect[7] of bromine and oxygen atoms and the index $R = [\sum(|F_o| - |F_c|)^2 / \sum|F_o|^2]^{1/2}$ was 0.094 for the S configuration and 0.105 for the R configuration, respectively. Bijvoet pairs[8] of 1286 reflections were considered for the S configuration and 20 pairs having the largest $||F_c(hkl)| - |F_c(\bar{h}\bar{k}\bar{l})||/\sigma(F_o)$ values are given in Table 5.

The complete $F_o - F_c$ data and the tables of anisotropic thermal parameters for **3** are deposited as Document No. 8346, at the Chemical Society of Japan.

Results and Discussion

The absolute configuration of dihydroyashabushiketol (**1**) was examined by the X-ray crystallographic analysis of the dibromo derivative (**3**). The absolute configuration of **3** was established by the X-ray anomalous-scattering technique.[7] Comparison of the R factors[9] for two enantiomeric configurations indicated that the absolute configuration of **3** is S. Final atomic

coordinates, bond lengths, and bond angles are given in Tables 6—8. The observed and calculated Bijvoet inequalities[8] for the *S* configuration were in good agreement with each other, as shown in Table 5. Thus, the absolute configuration of **3** was determined to be *S*, as shown in the ORTEP drawing of Fig. 1, and that of dihydroyashabushiketol (**1**) was necessarily

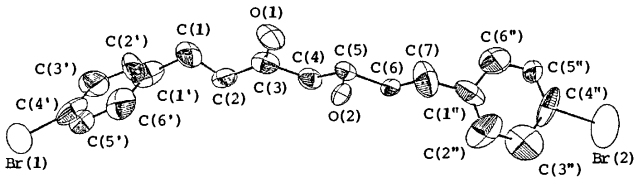

Fig. 1. ORTEP drawing[10] of the molecular structure of the 4′,4″-dibromo derivative (**3**).

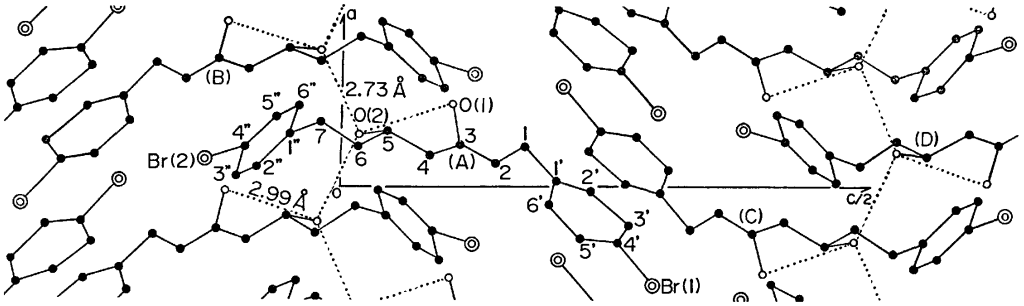

Fig. 2. Projection of the 4′,4″-dibromo derivative (**3**) along the b axis. The atoms indicated with ●, O, and ◎ denote carbon, oxygen, and bromine atoms respectively. The hydrogen bondings are shown by a broken line. The transformations of the atomic coordinates are (A) x, y, z; (B) $1/2+x$, $1/2-y$, $-z$; (C) $-x$, $1/2+y$, $1/2-z$; (D) $1/2-x$, $-y$, $1/2+z$.

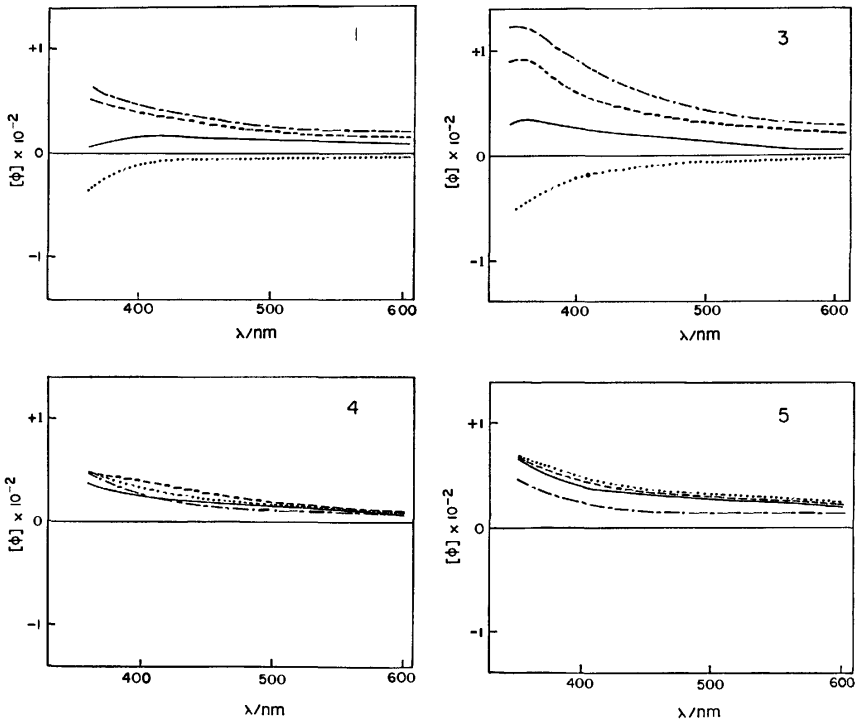

Fig. 3. ORD curves of **1**, **3**, **4**, and **5** in selected solvents at 25 °C; — — — in CCl_4; ---- in $CHCl_3$; —— in dioxane; ····· in MeOH. The measurements were carried out under the following concentrations in each solvent: **1**, *c* 0.85; **3**, *c* 2.20; **4**, *c* 0.97; **5**, *c* 2.60.

concluded to be *S*.

As shown in Table 2, the IR spectrum of **3** taken in a Nujol mull exhibited the bands at 3355 and 3275 cm^{-1} due to the inter- and intramolecular hydrogen bondings, respectively.[11] The presence of these bondings was confirmed by the diagnosis of the crystal structure as described below. The molecular arrangement and the hydrogen bond networks of **3** are given in Fig. 2. As shown in Table 9, the heptane chain was almost on the same plane, with the exception of the torsion angle of −157.7° at C2–C3–C4–C5. This torsion angle may result from the intramolecular hydrogen bonding between the carbonyl group at the 3-position and the hydroxyl group at C-5. This hydroxyl group is furthermore linked with the hydroxyl groups at C-5 of the adjacent molecules by intermolecular hydrogen bonds, and the molecules build up an infinite chain along the a axis by intermolecular hydrogen bondings. The chain is coupled with the next chain by the van der Waals force among the hydrophobic groups.

During the course of the study on the absolute configuration, it was observed that when the solvent used for measuring the optical rotation was changed from $CHCl_3$ to MeOH, the optical rotations of **1** and **3** changed from the dextrorotatory sense to the levorotatory one, but this was not the case for the corresponding acetates (**4** and **5**); these acetates were dextrorotatory in both of the solvents. These phenomena were also observed for ORD curves in the wavelength range of 350 to 600 nm, as shown in Fig. 3. The compounds **1** and **3** showed positive ORD curves in CCl_4, $CHCl_3$, and dioxane, while negative ORD curves in MeOH. On the other hand, their corresponding acetates (**4** and **5**) showed positive plain curves in all the solvents used. This indicates that the intermolecular hydrogen bonding between the hydroxyl group at C-5 of **1** and **3** and the functional or polar group of the solvent molecule participates in the inversion in the sense of their optical rotation. A similar solvent-dependence of the optical rotation is also observed for *cis*-verbenol,[12] (*S*)-marmesin,[13] and (*R*)-1-methylindan.[14] However, any causes for the inversion in the sense of the optical rotation have not been solved yet. Detailed investigations on causes involved for the inversion in the sense of the optical rotation of the diarylheptanoids are now in progress, and the results will be reported elsewhere.

The elemental analysis for bromine atom was performed in the Elemental Analytical Center of Kyoto University.

Reactions of 3-Acetyltropolone and Its Methyl Ethers with 1,2-Ethanediamines

Yasunori SUDOH,† Katsunobu ONITSUKA,†† Kimiaki IMAFUKU,* and Hisashi MATSUMURA†††

Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami, Kumamoto 860

(Received June 6, 1983)

3-Acetyltropolone reacted with 1,2-ethanediamine to give *N,N'*-bis(3-acetyl-2-oxo-3,5,7-cycloheptatrienyl)-1,2-ethanediamine (**3**) and 5-acetyl-3,4-dihydro-2*H*-cyclohepta[*b*]pyrazine (**4**), along with a small amount of by-products, which were 8-acetyl-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehyde (**5**), 5-acetyl-1,2,3,4-tetrahydroquinoxaline (**6**), and 2-methyl-5,6-dihydro-4*H*-pyrrolo[1,2,3-*de*]quinoxaline (**7**). The minor products (**5**—**7**) resulted from the contraction of the seven-membered ring of the compound **4**. 2-Acetyl-7-methoxytropone (**2a**) also reacted with 1,2-ethanediamine to give the same products (**3**—**7**) in higher yields. On the other hand, the same reaction of 3-acetyl-2-methoxytropone (**2b**) readily gave **4**—**7**. The reaction of **2a** with *N*-methyl-1,2-ethanediamine gave *N*-(3-acetyl-2-oxo-3,5,7-cycloheptatrienyl)-*N'*-methyl-1,2-ethanediamine (**14**), 5-acetyl-1-methyl-2,3-dihydro-1*H*-cyclohepta[*b*]pyrazine (**15**), 8-acetyl-4-methyl-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehyde (**16**), 5-acetyl-1-methyl-1,2,3,4-tetrahydroquinoxaline (**17**), and 2,6-dimethyl-5,6-dihydro-4*H*-pyrrolo[1,2,3-*de*]quinoxaline (**18**). The same reaction of **2b** also gave the products (**15**—**18**). The several reactions of these products are also described.

Recently, we found that 3-acetyltropolone and its methyl ethers reacted with a variety of nucleophilic reagents having two functional groups, such as amino and hydroxyl groups, to give heterocycle-fused troponoid compounds.[1] Amines[2] and *o*-aminophenol[3] reacted at the tropone carbonyl carbon atom and the adjacent carbon atom having the methoxyl group, while hydrazines[4-6] and hydroxylamine[7] reacted at the acetyl group and the adjacent carbonyl carbon atom or carbon atom having the methoxyl group. Furthermore, guanidine,[8] amidines,[8] and *o*-phenylenediamine[9] reacted in the former and in the latter forms to give two types of heterocycle-fused compounds. On the other hand, it was reported that the reactions of 5-nitroso- and 5-phenylazotropolones with 1,2-ethanediamine gave respectively oxime and phenylhydrazone of 7*H*-cyclohepta[*b*]pyrazin-7-one by dehydrogenation in the dihydropyrazine ring.[10] It was also found that 4,5-benzotropolone reacted with 1,2-ethanediamine to give benzo[4,5]cyclohepta[1,2-*b*]pyrazine.[11]

We now describe the reactions of 3-acetyltropolone (**1**) and its two isomeric methyl ethers——2-acetyl-7-methoxytropone (**2a**) and 3-acetyl-2-methoxytropone (**2b**)——with 1,2-ethanediamine and *N*-methyl-1,2-ethanediamine.

Results and Discussion

Reactions with 1,2-Ethanediamine. When 3-acetyltropolone (**1**) and 1,2-ethanediamine were refluxed for 2 h in methanol, *N,N'*-bis(3-acetyl-2-oxo-3,5,7-cycloheptatrienyl)-1,2-ethanediamine (**3**) and 5-acetyl-3,4-dihydro-2*H*-cyclohepta[*b*]pyrazine (**4**) were isolated in 1 and 3% yields, respectively. Their structures were determined by the elemental analyses and spectral data. The IR, UV, and ^{1}H NMR spectra of the compound **3** are very similar to those of 2-acetyl-7-ethylaminotropone.[2] The ^{13}C NMR spectrum of the compound **4** shows a signal at $\delta=202.13$, which is assigned to the acetyl carbonyl carbon atom. On the other hand, the acetyl carbonyl absorption in the IR spectrum is remarkably shifted to lower frequency region (1600 cm^{-1}) because of hydrogen-bonding with the 4-NH proton. The dehydrogenation reaction of **4** with 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ) failed.

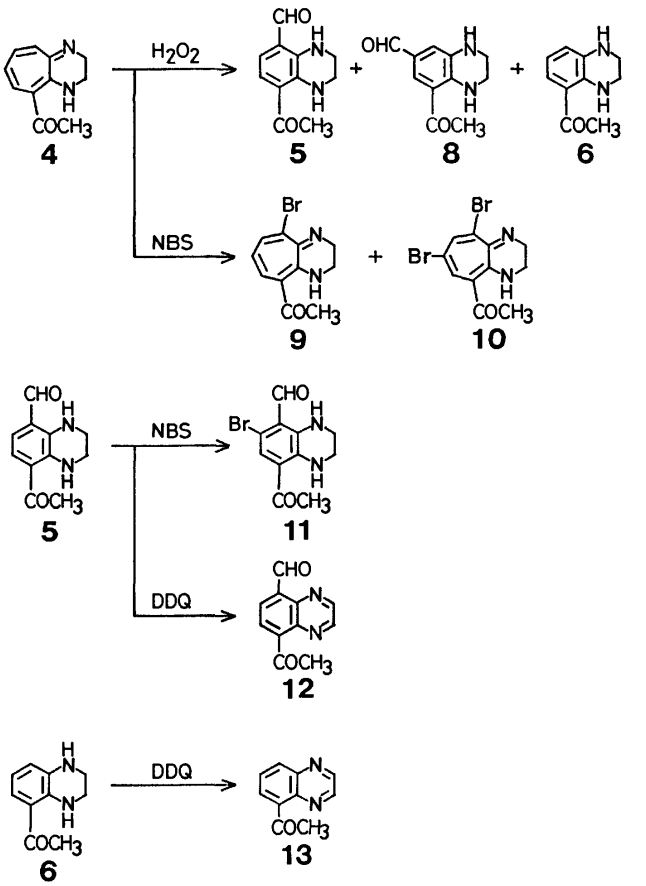
†† Present address: Kumamoto Municipal Institute of Public Health, Tamukae-machi, Kumamoto 862.

††† Present address: Kumamoto Institute of Technology, Ikeda, Kumamoto 860.

Prolonged reaction (24 h) of **1** with 1,2-ethanediamine afforded **3** and **4** in 4 and 6% yields, respectively, together with traces of 8-acetyl-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehyde (**5**) (1%), 5-acetyl-1,2,3,4-tetrahydroquinoxaline (**6**) (trace), and 2-methyl-5,6-dihydro-4*H*-pyrrolo[1,2,3-*de*]quinoxaline (**7**) (1%). The products (**5**—**7**) were assigned on the basis of their elemental analyses and spectral data. Bromination of **4** with *N*-bromosuccinimide (NBS) gave 5-acetyl-9-bromo- (**9**) and 5-acetyl-7,9-dibromo-3,4-dihydro-2*H*-cyclohepta[*b*]pyrazine (**10**). The IR spectrum of the compound **5** shows the characteristic absorptions at 2840 and 2740 cm^{-1} for the formyl group and a broad absorption at 1670—1640 cm^{-1} for the acetyl and formyl groups which exhibited hydrogen-bonding with the NH protons at 1- and 4-positions, respectively. The ^1H NMR spectrum shows two doublets at δ=6.70 and 6.96 (J=9 Hz) for the two protons in the benzene ring. The ^{13}C NMR spectrum shows two peaks at δ=193.86 and 201.03, which are assigned to the formyl and acetyl carbonyl carbon atoms, respectively. The compound **5** reacted with NBS to afford 8-acetyl-6-bromo-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehyde (**11**) and was dehydrogenated with DDQ to afford 8-acetyl-5-quinoxalinecarbaldehyde (**12**). For the compound **6**, the IR spectrum shows an absorption at 1635 cm^{-1} for the hydrogen-bonded acetyl group. In the ^1H NMR spectrum, the ABX pattern is observed at δ=6.35, 6.51, and 7.08 (J= 7, 7, and 3 Hz) for the three protons in the benzene ring. This compound **6** was also dehydrogenated with DDQ to afford 5-acetylquinoxaline (**13**). The compound **7** was very unstable on exposure to air. Difference in the UV spectra in methanol and in 6 M sulfuric acid (1 M=1 mol dm^{-3}) is very similar to behavior in spectra of indoles.[12] The ^1H NMR spectrum shows an ABX pattern for the three protons in the benzene ring at δ=6.23, 6.77, and 6.90 (J= 8, 6.5, and 2 Hz) and 1-H proton at δ=6.08 which exhibited a long-range coupling with the methyl protons (J=1 Hz). These compounds (**5**—**7**) were revealed to be secondary products from **4** by time dependence of the yields and conversion of **4** with base—1,2-ethanediamine. In addition, the compound **4** was treated with hydrogen peroxide to afford **5** and **6**, together with 8-acetyl-1,2,3,4-tetrahydro-6-quinoxalinecarbaldehyde (**8**). Although the compound **8** was very unstable, the assignment of the structure is based on the spectral evidences.



Scheme 2.

The reaction of 2-acetyl-7-methoxytropone (**2a**) with 1,2-ethanediamine also gave the five same products (**3**—**7**), as shown in Table 1. On the other hand, 3-acetyl-2-methoxytropone (**2b**) reacted with 1,2-ethanediamine to give the four products (**4**—**7**). The yield of the product (**4**) decreased, while the yields of the products (**5**—**7**) increased with reaction time.

Reactions with N-*Methyl-1,2-ethanediamine.* As shown in Table 2, 2-acetyl-7-methoxytropone (**2a**) reacted with *N*-methyl-1,2-ethanediamine to afford *N*-(3-acetyl-2-oxo-3,5,7-cycloheptatrienyl)-*N'*-methyl-1,2-ethanediamine (**14**), 5-acetyl-1-methyl-2,3-dihydro-1*H*-cyclohepta[*b*]pyrazine (**15**), 8-acetyl-4-methyl-1,2,3,4-

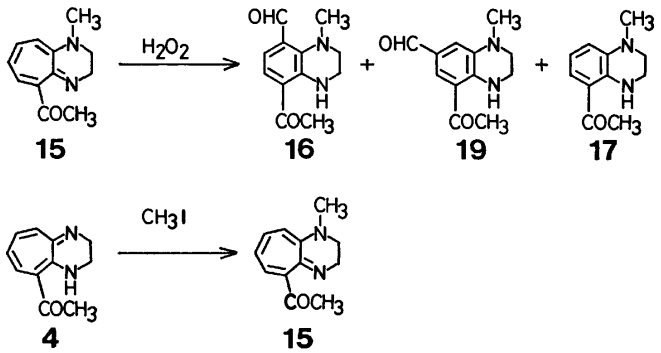

Scheme 4.

tetrahydro-5-quinoxalinecarbaldehyde (**16**), 5-acetyl-1-methyl-1,2,3,4-tetrahydroquinoxaline (**17**), and 2,6-dimethyl-5,6-dihydro-4*H*-pyrrolo[1,2,3-*de*]quinoxaline (**18**).

Their structures were assigned in comparison of the spectral data with those of the corresponding products from the reactions with 1,2-ethanediamine. The compound **15** was also obtained by methylation of **4** with methyl iodide and converted to the compounds (**16**—**18**) by heating in the presence of *N*-methyl-1,2-ethanediamine. Furthermore, the oxidation with hydrogen peroxide gave 8-acetyl-4-methyl-1,2,3,4-tetrahydro-6-quinoxalinecarbaldehyde (**19**), together with **16** and **17**. On the other hand, the reaction of 3-acetyl-2-methoxytropone (**2b**) with *N*-methyl-1,2-ethanediamine similarly gave the products (**15**—**18**).

Experimental

Measurements. The melting points were determined with a Yanagimoto MP-S2 apparatus and are uncorrected. The IR spectra were taken on a JASCO IRA-1 spectrophotometer, and the UV spectra on a Hitachi EPS-3T spectrophotometer. The ^1H and ^{13}C NMR spectra were recorded with a Hitachi R-24 (60 MHz) and a JEOL JNM-FX-100 spectrometer (100 MHz), respectively. The mass spectra were obtained with a JEOL JMS-01SG-2 and JMS-DX-300 spectrometers.

*Reactions of 3-Acetyltropolone (**1**) with 1,2-Ethanediamine. (a)*: A mixture of 3-acetyltropolone (**1**) (164 mg, 1.0 mmol) and 1,2-ethanediamine (0.1 ml, 1.5 mmol) in methanol (10 ml) was refluxed for 2 h on a water bath. After removal of the solvent, the residue was twice chromatographed on a Wakogel B-10 plate (30×30 cm^2) with ethyl acetate. The upper fraction was recrystallized from ethanol to give 4 mg (1%) of *N,N'*-bis(3-acetyl-2-oxo-3,5,7-cycloheptatrienyl)-1,2-ethanediamine (**3**) as yellowish brown needles; mp 214—215 °C (decomp); IR ($CHCl_3$) 3240 (NH), 1700 ($COCH_3$), and 1600 cm^{-1} (C=O); UV (CH_3OH) 248 (log ε 4.44), 354 (4.03), and 430 nm (4.22); ^1H NMR [$(CD_3)_2SO$] δ=2.41 (s, 6H, $CH_3\times2$), 3.6—3.9 (m, 4H, $CH_2\times2$), 6.4—6.9 (m, 4H, arom-H), 7.1—7.6 (m, 4H, arom-H), and 8.5 (br, 2H, NH×2). Found: C, 67.93; H, 5.59; N, 7.97%. Calcd for $C_{20}H_{20}N_2O_4$: C, 68.17; H, 5.72; N, 7.95%. The lower fraction was recrystallized from diethyl ether to give 6 mg (3%) of 5-acetyl-3,4-dihydro-2*H*-cyclohepta[*b*]pyrazine (**4**) as light brown prisms; mp 73—74 °C; IR ($CHCl_3$) 3180 (NH) and 1600 cm^{-1} ($COCH_3$); UV (CH_3OH) 254 (log ε 4.25), 303 (3.61), 386 (3.77), and 458 nm (3.97); ^1H NMR ($CDCl_3$) δ=2.48 (s, 3H, CH_3), 3.2—3.5 (m, 2H, CH_2), 3.7—3.9 (m, 2H, CH_2), 5.91 (ddd, 1H, J=12, 7, and 2 Hz, H-7), 6.41 (dd, 1H, J=12 and 2 Hz, H-6), 12.2 (br, 1H, NH); ^{13}C NMR ($CDCl_3$) δ=29.88 (CH_3), 38.69 (C-3), 49.90 (C-2), 108.26 (C-5), 116.77, 128.63, 131.16, 132.62, 149.71 (C-4a), 159.69 (C-9a), and 202.13 (C=O). Picrate: mp 216—218 °C. Found: C, 48.85; H, 3.67; N, 16.50%. Calcd for $C_{17}H_{15}N_5O_8$: C, 48.92; H, 3.62; N, 16.78%.

(b): A mixture of **1** (164 mg, 1.0 mmol) and 1,2-ethanediamine (0.1 ml, 1.5 mmol) in methanol (10 ml) was refluxed

for 8 h. After removal of the solvent, the residue was thrice chromatographed on a Wakogel B-10 plate (30×30 cm²) with chloroform. The first fraction was recrystallized from methanol–water to give 0.5 mg of 8-acetyl-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehyde (**5**) as red needles; mp 132—133 °C; IR ($CHCl_3$) 3300 (NH), 2840 (CHO), 2740 (CHO), and 1670—1640 cm^{-1} (br, CHO and $COCH_3$); UV (CH_3OH) 214 (log ε 4.21), 240 (4.26), 277 (4.00), 328 (4.07), and 490 nm (3.74); ^1H NMR ($CDCl_3$) δ= 2.54 (s, 3H, CH_3), 3.50 (m, 4H, $CH_2\times2$), 6.70 (d, 1H, J=9 Hz, H-6), 6.96 (d, 1H, J=9 Hz, H-7), 8.57 (br, 1H, 4-NH), 9.05 (br, 1H, 1-NH), and 9.75 (s, 1H, CHO); ^{13}C NMR ($CDCl_3$) δ=28.47 (CH_3), 38.28 (C-2 or -3), 38.57 (C-2 or -3), 116.36 (C-4a or -8a), 116.48 (C-4a or -8a), 116.83 (C-6), 118.95 (C-7), 139.03 (C-5 or -8), 139.55 (C-5 or -8), 193.86 (CHO), and 201.03 (acetyl C=O). Found: C, 64.42; H, 6.07; N, 13.72 %. Calcd for $C_{11}H_{12}N_2O_2$: C, 64.69; H, 5.92; N, 13.72%. The second fraction was recrystallized from hexane to give 1 mg of 2-methyl-5,6-dihydro-4*H*-pyrrolo[1,2,3-*de*]quinoxaline (**7**) as colorless needles; mp 64—65 °C; IR ($CHCl_3$) 3380 cm^{-1} (NH); UV (CH_3OH) 226 (log ε 4.44) and 282 nm (3.89); ^1H NMR ($CDCl_3$) δ=2.29 (d, 3H, J=1 Hz, CH_3), 3.3—3.5 (m, 2H, CH_2), 3.58 (br, 1H, NH), 3.9—4.1 (m, 2H, CH_2), 6.08 (q, 1H, J=1 Hz, H-1), 6.23 (dd, 1H, J= 6.5 and 2 Hz, H-7), 6.81 (dd, 1H, J=8 and 6.5 Hz, H-8), and 6.90 (dd, 1H, J=8 and 2 Hz, H-9); ^{13}C NMR ($CDCl_3$) δ=11.57 (CH_3), 41.45 (C-4 or 5-), 41.98 (C-4 or -5), 99.16 (C-1), 102.27 (C-7), 110.02 (C-9), 119.94 (C-8), 125.87 (C-6a or -9a), 126.40 (C-6a or -9a), 132.16 (C-2 or -9b), and 134.33 (C-2 or -9b); MS *m/e* 172 (M^+). Found: C, 76.68; H, 7.11; N, 16.31%. Calcd for $C_{11}H_{12}N_2$: C, 76.71; H, 7.02; N, 16.27%. The third fraction was recrystallized from hexane to give 0.5 mg of 5-acetyl-1,2,3,4-tetrahydroquinoxaline (**6**) as yellow needles; mp 78—79 °C; IR ($CHCl_3$) 3310 (NH) and 1635 cm^{-1} ($COCH_3$); UV (CH_3OH) 215 (log ε 4.34), 262 (4.06), and 419 nm (3.72); ^1H NMR ($CDCl_3$) δ=2.49 (s, 3H, CH_3), 3.2—3.7 (m, 4H, $CH_2\times2$), 3.7 (br, 1H, 1-NH), 6.33 (dd, 1H, J=7 and 7 Hz, H-7), 6.49 (dd, 1H, J=7 and 3 Hz, H-8), 7.08 (dd, 1H, J=7 and 3 Hz, H-6), and 8.7 (br, 1H, 4-NH); MS *m/e* 176 (M^+). Found: C, 68.19; H, 6.93; N, 15.96%. Calcd for $C_{10}H_{12}N_2O$: C, 68.16; H, 6.86; N, 15.96%. The fourth fraction was rechromatographed on a Wakogel B-10 plate (30×30 cm²) with ethyl acetate to afford **3** (3 mg, 1%) and **4** (10 mg, 5%).

(c): A mixture of **1** (164 mg, 1.0 mmol) and 1,2-ethanediamine (0.1 ml, 1.5 mmol) in methanol (10 ml) was refluxed for 24 h and worked up, as mentioned above, to give **3** (17 mg, 5%), **4** (12 mg, 6%), **5** (2 mg, 1%), **6** (0.2 mg, trace), and **7** (2 mg, 1%).

*Reaction of 2-Acetyl-7-methoxytropone (**2a**) with 1,2-Ethanediamine.* A mixture of 2-acetyl-7-methoxytropone (**2a**) (178 mg, 1.0 mmol) and 1,2-ethanediamine (0.1 ml, 1.5 mmol) in methanol (10 ml) was refluxed and worked up, as mentioned above, to give the following results: (i) Reaction time, 2 h: **3** (8 mg, 2%), **4** (67 mg, 37%), **5** (0.2 mg), **6** (0.6 mg), and **7** (0.6 mg); (ii) Reaction time, 8 h: **3** (14 mg, 4%), **4** (48 mg, 26%), **5** (9 mg, 4%), **6** (3 mg, 2%), and **7** (4 mg, 3%); (iii) Reaction time, 24 h: **3** (8 mg, 2%), **4** (14 mg, 7%), **5** (14 mg, 7%), **6** (5 mg, 3%), and **7** (14 mg, 8%).

*Reaction of 3-Acetyl-2-methoxytropone (**2b**) with 1,2-Ethanediamine. (a)*: A solution of 3-acetyl-2-methoxytropone (**2b**) (357 mg, 2.0 mmol) and 1,2-ethanediamine (0.2 ml, 3.0 mmol) in methanol (10 ml) was allowed to stand for 2 h at room temperature. The reaction mixture was diluted with water and extracted with diethyl ether. After removal of the solvent, the residue was column-chromatographed on a Wakogel C-100 column (30 g) and recrystallized from diethyl ether to afford **4** (229 mg, 61%). Reaction time, 4.5 h: **4** (246 mg, 65%).

(b): A mixture of **2b** (178 mg, 1.0 mmol) and 1,2-ethanediamine (0.1 ml, 1.5 mmol) in methanol (10 ml) was refluxed and worked up, as mentioned above, to give the following results: (i) Reaction time, 30 min: **4** (152 mg, 82%), **5** (4 mg, 2%), **6** (1 mg), and **7** (3 mg, 2%); (ii) Reaction time, 2 h: **4** (91 mg, 48%), **5** (7 mg, 4%), **6** (5 mg, 3%), and **7** (8 mg, 5%); (iii) Reaction time, 8 h, **4** (3 mg, 2%), **5** (22 mg, 11%), **6** (12 mg, 7%), and **7** (20 mg, 11%).

*Treatment of the Compound (**4**) with 1,2-Ethanediamine.* A solution of the compound (**4**) (177 mg, 0.9 mmol) and 1,2-ethanediamine (0.1 ml, 1.5 mmol) in methanol (10 ml) was refluxed for 4 h. After evaporation of the solvent, the residue was thrice chromatographed on a Wakogel B-10 plate (30×30 cm²) with chloroform. The first fraction gave **5**. The second fraction was collected and rechromatographed on a Wakogel B-10 plate (30×30 cm²) with chloroform to give **5** and **7**. The third fraction gave **6**. Yields: **5** (23 mg, 12%), **6** (10 mg, 6%), and **7** (20 mg, 12%).

*Oxidation of the Compound (**4**) with Hydrogen Peroxide.* To a solution of **4** (98 mg, 0.5 mmol) in methanol (10 ml) was added 30% hydrogen peroxide aqueous solution (2 ml). The mixture was allowed to stand for 8 h at room temperature, diluted with water, and extracted with chloroform. After removal of the solvent, the residue was chromatographed on a Wakogel B-10 plate (30×30 cm²) with ethyl acetate to give **5** (3 mg, 3%), **6** (3 mg, 3%), and 8-acetyl-1,2,3,4-tetrahydro-6-quinoxalinecarbaldehyde (**8**) as semisolid (2 mg, 2%); IR ($CHCl_3$) 3390 (NH), 3270 (NH), 1690 (CHO), and 1630 cm^{-1} ($COCH_3$); ^1H NMR ($CDCl_3$) δ=2.57 (s, 3H, CH_3), 3.2—3.8 (m, 4H, $CH_2\times2$), 4.1 (br, 1H, 4-NH), 6.96 (d, 1H, J=1.5 Hz, H-5), 7.55 (d, 1H, J=1.5 Hz, H-7), 9.5 (br, 1H, 1-NH), and 9.52 (s, 1H, CHO).

*Bromination of the Compound (**4**) with NBS.* A mixture of **4** (95 mg, 0.5 mmol) and NBS (90 mg, 0.5 mmol) in benzene (10 ml) was refluxed for 30 min in the presence of benzoyl peroxide (catalytic amount). After removal of the solvent, the residue was twice chromatographed on a Wakogel B-10 plate (30×30 cm²) with ethyl acetate. The lower fraction was collected and recrystallized from benzene–hexane to afford 10 mg (7%) of 5-acetyl-9-bromo-3,4-dihydro-2*H*-cyclohepta[*b*]pyrazine (**9**) as brown plates; mp 102.5—103.5 °C; IR ($CHCl_3$) 1600 cm^{-1} (C=O); UV (CH_3OH) 245 (log ε 4.06), 252 (4.06), 270 (sh, 4.04), 380 (3.64), and 449 nm (3.82); ^1H NMR ($CDCl_3$) δ=2.45 (s, 3H, CH_3), 3.3—3.6 (m, 2H, CH_2), 3.8—4.1 (m, 2H, CH_2), 5.72 (dd, 1H, J= 10 and 8 Hz, H-7), 6.98 (d, 1H, J=10 Hz, H-8), 7.33 (d, 1H, J=8 Hz, H-6), and 10.8 (br, 1H, NH). Picrate: mp 206.5—207.5 °C (decomp). Found: C, 41.10; H, 2.90; N, 14.17%. Calcd for $C_{17}H_{14}N_5O_8Br$: C, 41.15; H, 2.84; N, 14.11%. The upper fraction was worked up, as mentioned above, to afford 11 mg (6%) of 5-acetyl-7,9-dibromo-3,4-dihydro-2*H*-cyclohepta[*b*]pyrazine (**10**) as brown prisms; mp 128 °C (decomp); IR ($CHCl_3$) 1620 cm^{-1} (C=O); UV (CH_3OH) 233 (log ε 4.13), 270 (4.07), 386 (3.75), and 461 nm (3.80); ^1H NMR ($CDCl_3$) δ=2.44 (s, 3H, CH_3), 3.2—3.5 (m, 2H, CH_2), 3.8—4.1 (m, 2H, CH_2), 7.31 (d, 1H, J= 1.5 Hz, H-8), 7.51 (d, 1H, J=1.5 Hz, H-6), and 12.1 (br, 1H, NH). Picrate: mp 154—155 °C (decomp). Found: C, 35.78; H, 2.34; N, 12.21%. Calcd for $C_{17}H_{13}N_5O_8Br_2$: C, 35.50; H, 2.28; N, 12.18%.

*Bromination of the Compound (**5**) with NBS.* A mixture of **5** (103 mg, 0.5 mmol) and NBS (89 mg, 0.5 mmol) in benzene (10 ml) was refluxed for 3 h in the presence of ben-

zoyl peroxide (catalytic amount), worked up, and twice chromatographed, as mentioned above. The upper fraction was collected and recrystallized from methanol to afford 16 mg (11%) of 8-acetyl-6-bromo-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehdye (**11**) as red needles; mp 162—163 °C; IR ($CHCl_3$) 3270 (NH), 2870 (CHO), 2770 (CHO), 1645 cm^{-1} (CHO and $COCH_3$); UV (CH_3OH) 232 (log ε 4.24), 280 (3.81), 331 (3.98), 493 (3.74), and 515 nm (sh, 3.70); ^1H NMR ($CDCl_3$) δ=2.50 (s, 3H, CH_3), 3.5—3.7 (m, 4H, $CH_2\times2$), 7.11 (s, 1H, H-7), 9.2 (br, 1H, 4-NH), 9.6 (br, 1H, 1-NH), and 10.15 (s, 1H, CHO). Found: C, 46.88; H, 3.99; N, 9.86%. Calcd for $C_{11}H_{11}N_2O_2Br$: C, 46.67; H, 3.92; N, 9.90%. The starting material (**5**) (13 mg, 17%) was recovered from the lower fraction.

*Dehydrogenation of the Compound (**5**) with DDQ.* A mixture of **5** (76 mg, 0.4 mmol) and DDQ (85 mg, 0.4 mmol) in dry benzene (15 ml) was refluxed for 8 h. After removal of the solvent, the residue was twice chromatographed on a Wakogel B-10 plate (30×30 cm^2) with chloroform. The lower fraction was recrystallized from benzene to give 13 mg (17%) of 8-acetyl-5-quinoxalinecarbaldehyde (**12**) as pale yellow needles; mp 177 °C (decomp); IR ($CHCl_3$) 1710 cm^{-1} (CHO and $COCH_3$); UV (CH_3OH) 218 (log ε 4.28), 239 (4.05), 313 (3.72), and 322 nm (sh, 3.70); ^1H NMR ($CDCl_3$) δ=2.87 (s, 3H, CH_3), 8.08 (d, 1H, J=7 Hz, H-6), 8.36 (d, 1H, J=7 Hz, H-7), 8.97 (s, 2H, H-2,3), and 11.25 (s, 1H, CHO). Found: C, 66.12; H, 4.09; N, 13.99%. Calcd for $C_{11}H_8N_2O_2$: C, 65.99; H, 4.03; N, 13.99%. The compound **5** (22 mg, 29%) was recovered from the upper fraction.

*Dehydrogenation of the Compound (**6**) with DDQ.* A mixture of **6** (94 mg, 0.5 mmol) and DDQ (228 mg, 1.0 mmol) in dry benzene (10 ml) was refluxed for 1 h and chromatographed, as mentioned above, to give 14 mg (15%) of 5-acetylquinoxaline (**13**) as pale yellow plates; mp 75—76 °C; IR ($CHCl_3$) 1700 cm^{-1} (C=O); UV (CH_3OH) 214 (log ε 4.11), 238 (3.83), 315 (sh, 3.45), and 322 nm (3.46); ^1H NMR ($CDCl_3$) δ=2.91 (s, 3H, CH_3), 7.88 (dd, 1H, J=7 and 2 Hz, H-7), 8.06 (dd, 1H, J=7 and 2 Hz, H-8), 8.22 (dd, 1H, J=7 and 2 Hz, H-6), and 8.87 (s, 2H, H-2,3). Found: C, 69.68; H, 4.73; N, 16.30%. Calcd for $C_{10}H_8N_2O$: C, 69.75; H, 4.68; N, 16.27%.

*Reaction of 2-Acetyl-7-methoxytropone (**2a**) with* N-*Methyl-1,2-ethanediamine.* *(a)*: A solution of **2a** (178 mg, 1.0 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml) was allowed to stand for 2 h at room temperature. The mixture was diluted with water and extracted with chloroform. After removal of the solvent, the residue was four-times chromatographed on two Kieselguhr G plates (30×30 cm^2) with hexane to give 163 mg (74%) of *N*-(3-acetyl-2-oxo-3,5,7-cycloheptatrienyl)-*N'*-methyl-1,2-ethanediamine (**14**) as a yellow oil; IR ($CHCl_3$) 3280 (NH), 1690 ($COCH_3$), and 1600 cm^{-1} (C=O); UV (CH_3OH) 247 (log ε 4.17), 349 (3.80), and 421 nm (3.96); ^1H NMR ($CDCl_3$) δ=1.7 (br, 1H, NH), 2.44 (br.s, 3H, *N*-CH_3), 2.55 (s, 3H, $COCH_3$), 2.7—3.1 (m, 2H, CH_2), 3.2—3.6 (m, 2H, CH_2), 6.4—6.8 (m, 2H, arom-H), 7.1—7.7 (m, 2H, arom-H), and 8.0 (br, 1H, NH). Picrate: mp 176 °C (decomp). Found: C, 47.89; H, 4.11; N, 15.27%. Calcd for $C_{18}H_{19}N_5O_9$: C, 48.11; H, 4.11; N, 15.58%.

(b): A mixture of **2a** (178 mg, 1.0 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml) was refluxed for 2 h. After removal of the solvent, the residue was four-times chromatographed on two Kieselguhr G plates (30×30 cm^2) with hexane. The lower fraction gave **14** (84 mg, 38%). The upper fraction was collected and twice rechromatographed on a Wakogel B-10 plate (30×30 cm^2) with chloroform. The first fraction gave 1 mg of 2,6-dimethyl-5,6-dihydro-4*H*-pyrrolo[1,2,3-*de*]quinoxaline (**18**) as a colorless oil; UV (CH_3OH) 223 (log ε 4.32) and 284 nm (3.84); ^1H NMR ($CDCl_3$) δ=2.19 (s, 3H, CH_3), 2.73 (s, 3H, *N*-CH_3), 2.9—3.2 (m, 2H, CH_2), 3.7—4.0 (m, 2H, CH_2), 5.89 (s, 1H, H-1), 6.03 (dd, 1H, J=4.5 and 3 Hz, H-7), 6.64 (dd, 1H, J=7 and 4.5 Hz, H-8), 6.72 (dd, 1H, J=7 and 3 Hz, H-9). Found: MS *m/e* 186.1181 (M^+). Calcd for $C_{12}H_{14}N_2$: M^+ 186.1156. The second fraction was recrystallized from hexane to give 0.6 mg of 5-acetyl-1-methyl-1,2,3,4-tetrahydroquinoxaline (**17**) as yellow needles; mp 77—78 °C; IR ($CHCl_3$) 3300 (NH) and 1630 cm^{-1} (C=O); UV (CH_3OH) 212 (log ε 4.31), 268 (3.93), and 418 nm (3.67); ^1H NMR ($CDCl_3$) δ=2.49 (s, 3H, $COCH_3$), 2.78 (s, 3H, *N*-CH_3), 3.0—3.2 (m, 2H, CH_2), 3.4—3.7 (m, 2H, CH_2), 6.47 (dd, 1H, J=7 and 6 Hz, H-7), 6.56 (dd, 1H, J=7 and 3 Hz, H-8), 7.08 (dd, 1H, J=6 and 3 Hz, H-6), and 9.1 (br, 1H, NH). Found: C, 69.45; H, 7.39; N, 14.44%. Calcd for $C_{11}H_{14}N_2O$: C, 69.45; H, 7.42; N, 14.72%. The third fraction was recrystallized from benzene–hexane to afford 25 mg (13%) of 5-acetyl-1-methyl-2,3-dihydro-1*H*-cyclohepta[*b*]pyrazine (**15**) as orange prisms; mp 134—134.5 °C; IR ($CHCl_3$) 1680 cm^{-1} (C=O); UV (CH_3OH) 259 (log ε 4.18), 379 (3.75), and 466 nm (3.93); ^1H NMR ($CDCl_3$) δ=2.35 (s, 3H, $COCH_3$), 3.12 (s, 3H, *N*-CH_3), 3.3—3.5 (m, 2H, CH_2), 3.7—4.0 (m, 2H, CH_2), 5.79 (d, 1H, J=9.5 Hz, H-9), 6.06 (dd, 1H, J=10.5 and 8.5 Hz, H-7), 6.66 (ddd, 1H, J=10.5, 9.5, and 1.5 Hz, H-8), and 7.24 (dd, 1H, J=9.5 and 1.5 Hz, H-6); ^{13}C NMR ($CDCl_3$) δ=28.53 (*CO*-CH_3), 39.81 (*N*-CH_3), 50.37 (C-2), 51.96 (C-3), 101.86, 116.80, 132.86, 134.33, 134.97 (C-5), 147.83 (C-4a), and 202.49 (C=O). Picrate: mp 151—153 °C (decomp). Found: C, 50.31; H, 3.82; N, 15.92%. Calcd for $C_{18}H_{17}N_5O_7$: C, 50.12; H, 3.97; N, 16.24%.

(c): A mixture of **2a** (178 mg, 1.0 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml) was refluxed for 24 h. The reaction mixture was worked up, as mentioned above, to give **14** (9 mg, 4%), **15** (54 mg, 27%), **17** (12 mg, 6%), **18** (17 mg, 9%), and 8-acetyl-4-methyl-1,2,3,4-tetrahydro-5-quinoxalinecarbaldehyde (**16**) (4 mg, 2%) as a red oil; IR ($CHCl_3$) 3300 (NH), 1695 (CHO), and 1640 cm^{-1} ($COCH_3$); UV (CH_3OH) 245 (log ε 4.30), 322 (3.62), and 467 nm (3.66); ^1H NMR ($CDCl_3$) δ=2.52 (s, 3H, $COCH_3$), 2.90 (s, 3H, *N*-CH_3), 3.3—3.7 (m, 4H, $CH_2\times2$), 6.94 (d, 1H, J=9 Hz, H-6), 7.40 (d, 1H, J=9 Hz, H-7), 9.1 (br, 1H, NH), and 10.25 (s, 1H, CHO). Found: MS *m/e* 218.0953 (M^+). Calcd for $C_{12}H_{14}N_2O_2$: M^+ 218.1055.

*Reaction of 3-Acetyl-2-methoxytropone (**2b**) with* N-*Methyl-1,2-ethanediamine.* *(a)*: A solution of 3-acetyl-2-methoxytropone (**2b**) (178 mg, 1.0 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml) was allowed to stand for 2 h at room temperature. The mixture was diluted with water and extracted with chloroform. After removal of the solvent, the residue was twice chromatographed on two Wakogel B-10 plates (30×30 cm^2) with ethyl acetate to afford **15** (117 mg, 58%).

(b): A mixture of **2b** (178 mg, 1.0 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml) was refluxed for 2 h. After removal of the solvent, the residue was twice chromatographed on two Wakogel B-10 plates (30×30 cm^2) with chloroform. The first, second, third, and fourth fractions gave **18** (20 mg, 10%), **17** (14 mg, 8%), **16** (2 mg), and **15** (52 mg, 26%), respectively.

(c): A mixture of **2b** (178 mg, 1.0 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml)

was refluxed for 24 h. The mixture was worked up, as mentioned above, to give **16** (2 mg), **17** (20 mg, 11%), and **18** (35 mg, 19%).

*Treatment of the Compound (**15**) with* N-*Methyl-1,2-ethanediamine.* A solution of **15** (181 mg, 0.9 mmol) and *N*-methyl-1,2-ethanediamine (0.1 ml, 1.4 mmol) in methanol (10 ml) was refluxed for 7 h. After removal of the solvent, the residue was twice chromatographed on a Wakogel B-10 plate (30×30 cm^2) with chloroform to give **16** (19 mg, 10%), **17** (32 mg, 19%), and **18** (10 mg, 6%).

*Oxidation of the Compound (**15**) with Hydrogen Peroxide.* A mixture of **15** (66 mg, 0.3 mmol) and 30% hydrogen peroxide aqueous solution (1 ml) in methanol (5 ml) was allowed to stand for 6 h at room temperature, diluted with water, and extracted with chloroform. After removal of the solvent, the residue was chromatographed on a Wakogel B-10 plate (30×30 cm^2) with ethyl acetate to give **16** (9 mg, 12%), **17** (3 mg, 5%), and 8-acetyl-4-methyl-1,2,3,4-tetrahydro-6-quinoxalinecarbaldehyde (**19**) (6 mg, 9%) as a semisolid; IR ($CHCl_3$) 3240 (NH), 1680 (CHO), and 1625 cm^{-1} ($COCH_3$); ^{1}H NMR ($CDCl_3$) $\delta=2.60$ (s, 3H, $COCH_3$), 2.95 (s, 3H, *N*-CH_3), 3.0—3.4 (m, 2H, CH_2), 3.5—3.9 (m, 2H, CH_2), 7.02 (m, 1H, H-5), 7.65 (d, 1H, $J=1.5$ Hz, H-7), and 9.65 (s, 1H, CHO).

*Methylation of the Compound (**4**) with Methyl Iodide.* A solution of **4** (188 mg, 1.0 mmol) and methyl iodide (0.2 ml, 3.0 mmol) in dry acetone (20 ml) was allowed to stand for 6 h in the presence of silver oxide (695 mg, 3.0 mmol). The mixture was filtered, concentrated, and thrice chromatographed on a Wakogel B-10 plate (30×30 cm^2) with ethyl acetate to give **15** (26 mg, 13%). The starting material (**4**) was recovered in 35% yield.

We wish to thank Dr. Tetsuo Nozoe, Professor Emeritus of Tohoku University, for his continuous encouragement. We are also grateful to Professor Hitoshi Takeshita of Kyushu University and Mr. Masanori Tsumura of Ichikawa Chemical Laboratories, Higashi-Osaka, for their kind measurements of the ^{13}C NMR and the high-resolution mass spectra, respectively.
