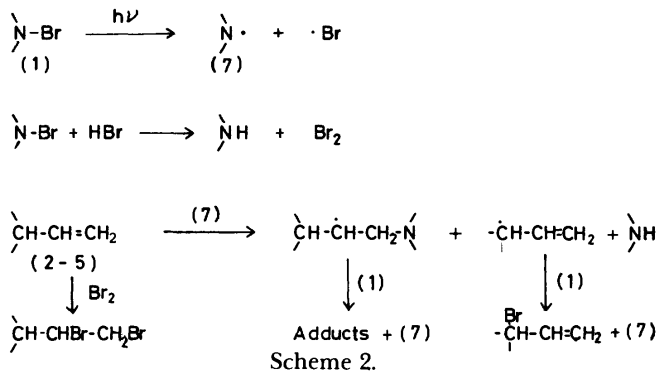
A chromatographic separation of the adduct mixtures obtained from the photoreaction of **1** with 1-hexene (**2**) gave an isomer mixture of bromine-containing 1 : 2-adducts (**2″**), an isomer mixture of hydroxyl group-containing 1 : 2-adducts (**2″(OH)**), and a hydroxyl group-containing 1 : 1-adduct (**2′(OH)**). No bromine-containing 1 : 1-adduct was obtained. Addition of 1,2-epoxybutane (a hydrogen bromide scavenger) resulted in increased yields of the adducts. The adduct mixture (**2″**) was re-chromatographed to give isomers **2″a** and **2″b**. Both **2″a** and **2″b** had two bromine atoms, and they gave similar NMR and IR spectra. Treatment of **2″a** and **2″b** by tributyltin hydride afforded identical 1,4-dihexyl-2,5-piperazinedione (**2″(H)**). NMR spectra of **2″a** and **2″b**, and their reduction product (**2″(H)**) indicated that the 2,5-dioxo-1-piperazinyl group added to the less substituted carbon atom of **2**, and that **2″a** and **2″b** are stereoisomers each other at the carbon atoms bearing bromine atoms. The hydroxyl group-containing adduct consisted of two isomers, **2″(OH)a** and **b** (in about a 3 : 4 ratio (NMR)); they hardly separated on TLC. IR spectra of **2″(OH)a**, **b** showed the presence of hydroxyl groups, and no bromine atom was contained as checked by MS; the distinct M^+-2H_2O was detected on MS spectra. The structure of **2′(OH)** was deduced by similar analysis.

The adduct mixtures obtained from the photoreactions of **1** with 2-methyl-1-pentene (**3**), 2,3-dimethyl-1-butene (**4**), and 3,3-dimethyl-1-butene (**5**) were also analyzed, and the structures of the corresponding 1 : 1-adducts (**3′**—**5′**) and 1 : 2-adducts (**3″**—**5″**) were similarly determined as given in Scheme 1. In these cases, adducts corresponding to **2′(OH)** and **2″(OH)** were not obtained.

For allylic brominations of alkenes with NBS, Goldfinger[7] pointed out that the bromine atom should be the hydrogen atom abstracting species of the chain sequence, and that the succinimido radical should be less reactive. However, evidence was reported that disclosed unexpected high reactivity of the succinimido radical in the addition reactions to olefinic double bonds.[1,3] We had also reported that the photoreaction of 1,4-dibromo-2,5-piperazinedione (**1**) with cyclohexene in acetonitrile gave a considerable amount of addition products.[6] The 1-alkenes employed in the present study gave similar adducts (Scheme 1 and Table 1). The respective bromine-containing 1 : 2-adduct consisted of two diasteromers. The 2,5-piperazinedione moieties were found to be attached to the less substituted carbon atoms of the original olefins. The direction of addition appears to be determined by the mode of addition of the 2,5-dioxo-1-piperazinyl radical (**7**) to the olefins to give more stable alkyl radicals. The stability of the



Scheme 2.

intermediate alkyl radicals is responsible for the amounts of the adducts produced (tertiary alkyl radicals from **3** and **4**, while secondary alkyl radicals from **2** and **5**). In the photoreaction with 5, no rearranged products such as 1-(3-bromo-2,3-dimethylbutyl)- or 1-(4-bromo-2,3-dimethyl-2-butyl)-2,5-piperazinedione were detected. This indicates that the addition proceeded through a radical mechanism. Steric inhibition to addition is also observed in the cases where methyl groups are present at the C_3 position of the olefins.

In the photoreaction of **1** with 1-hexene (**2**), 1-(2-hydroxyhexyl)-2,5-piperazinedione (**2′(OH)**) and a mixture of 1,4-bis(2-hydroxyhexyl)-2,5-piperazinediones (**2″(OH)a**, **b**) were produced as well as 1,4-bis(2-bromohexyl)-2,5-piperazinediones (**2″a**, **b**). Hydrolysis during chromatographic separation is considered to result in these hydroxyl group-containing adducts from corresponding bromine-containing adducts. Participation by the neighboring amide group may be responsible for facilitating the hydrolysis. Because of the bulk of the neighboring 2,5-piperazinedione moiety, this assisted hydrolysis works only in the case of the adducts produced from **2**. The presence of methyl substituents at the C_2 and/or C_3 positions of the side chains of **3″**, **4″**, and **5″** makes the *N*-participation impossible, so that no hydroxy group-containing adducts exist in the reactions with **3**, **4**, and **5**. A treatment of an acetone solution of **2″** with silica gel containing a small amount of hydrobromic acid actually yielded **2″(OH)**. To trap hydrogen bromide generated during the photoreaction, the reaction was examined in the presence of 1,2-epoxybutane. The addition of two mole equivalents of 1,2-epoxybutane results in an increased yield of the adducts, and the ratio of **2″(OH)** to **2″** is considerably reduced. This implies that the hydrolysis of **2″** is catalyzed by hydrogen bromide.

Photoreaction of **1** with electron poor olefins (methyl acrylate, stilbene, *etc*) gave few adducts even in the presence of 1,2-epoxybutane, but a considerable amount of polymers and dibromides were produced.

Experimental

The olefins and 1,2-epoxybutane were dried over Molecular Sieve 4A and distilled over copper(I) chloride prior to use. Acetonitrile was dried over calcium hydride and distilled. 1,4-Dibromo-2,5-piperazinedione (**1**) was prepared according to the procedure reported earlier.[8] IR spectra (KBr) were recorded with JASCO IR-A-1 and -3 spectrometers. NMR spectra were measured on JEOL JNM-PMX-60 and

PS-100 spectrometers using tetramethylsilane as the internal standard. Mass spectra were obtained by a Hitachi RMU-6MG and ESCO EMD-05A spectrometers. Irradiation was conducted through a Pyrex filter using an Ushio Model UI-50le high-pressure mecury arc lamp (500 W).

Reaction of 1,4-Dibromo-2,5-piperazinedione (1) with 1-Hexene (2) in the Presence of 1,2-Epoxybutane. A typical experimental procedure is described. Irradiation of a mixture containing 544 mg (2 mmol) of **1**, 1.68 g (20 mmol) of 1-hexene and 1,2-epoxybutane (288 mg, 4 mmol) in acetonitrile (10 cm^3) was carried out with stirring at the ambient temperature for 4 h. The mixture was filtered to give 2,5-piperazinedione in a 39% yield. The filtrates (2—3 runs) were combined, and after removal of the solvent the products were separated on a silica-gel column (benzene→benzene and acetone→acetone). The 1:2-adducts **2"a,b** were rechromatographed on a silica-gel column (benzene→benzene and acetone) to give a pure specimen. Yields are given in Table 1 on the basis of **1** employed. Physical constants of the isolated products are shown below.

1,4-Bis(2-bromohexyl)-2,5-piperazinedione (2"a): Mp 125—126 °C (from benzene). IR, 1670, 1490, 1430, 1340, 1250, 1190, and 950 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.9 (6H, m, CH_3), 1.0—2.0 (12H, m, $-(CH_2)_3-$), 3.1—3.8 (4H, m, $N-CH_2-$), 4.04 (2H, s, ring H), 4.12 (2H, s, ring H), and 4.2—4.5 (2H, m, -CHBr-).

Found: C, 43.43; H, 6.49%. Calcd for $C_{16}H_{28}Br_2N_2O_2$; C, 43.65; H, 6.14%.

2"b: Mp 92—93.5 °C (from benzene). IR, 1670, 1495, 1430, 1340, 1250, 1190, and 950 cm^{-1}. ^1H NMR($CDCl_3$), δ=0.9 (6H, m, CH_3), 1.0—2.1 (12H, m, $-(CH_2)_3-$), 3.1—3.8 (4H, m, $N-CH_2-$), 4.08 (2H, s, ring H), 4.19 (2H, s, ring H), and 4.3—4.6 (2H, m, -CHBr-).

Found: C, 43.05; H, 6.58%. Calcd see above.

1,4-Bis(2-hydroxyhexyl)-2,5-piperazinedione (2"(OH)a,b): A mixture of two isomers (*a*:*b*=3:4). Mp 213.5—215.0 °C (from ethanol-hexane). IR, 3400, 1650, 1510, 1425, 1345, and 1130 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.9 (6H, m, CH_3), 1.0—1.5 (12H, m, $-(CH_2)_3-$), 3.0—3.5 (4H, m, $N-CH_2-$), 3.5—3.9 (2H, m, $-C\underline{H}(OH)-$), 3.82 (2H, broad s, OH), and 4.01 (4H, s, ring H). MS (*m/z*), 278 (M^+-2H_2O), 223, 205, 145, 111, 84, and 56.

Found: C, 61.03; H, 9.83; N, 8.89%. Calcd for $C_{16}H_{30}N_2O_4$; C, 61.12; H, 9.62; N, 8.91%.

1-(2-Hydroxyhexyl)-2,5-piperazinedione (2'(OH)): Mp 219—220 °C (from ethanol-hexane). IR, 3400, 3230, 1650, 1495, 1425, 1330, and 1130 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.9 (3H, m, CH_3), 1.1—1.6 (6H, m, $-(CH_2)_3-$), 2.9—3.5 (2H, m, $N-CH_2-$), 3.5—3.9 (1H, m, $-C\underline{H}(OH)-$), 3.72 (2H, s, ring H), 3.88 (2H, s, ring H), 4.25 (1H, broad s, OH), and 7.85 (1H, s, NH). MS (*m/z*), 214 (M^+), 196 (M^+-H_2O), 157, 128, 115, and 99.

Found: C, 56.05; H, 8.65; N, 13.46%. Calcd for $C_{10}H_{18}N_2O_3$: C, 56.05; H, 8.47; N, 13.07%.

Hydrogenolysis of 1,4-Bis(2-bromohexyl)-2,5-piperazinedione (2"a, b) with Tributyltin Hydride. The compound (**2"a** or **2"b**) (149 mg, 0.34 mmol), tributyltin hydride (24 mg, 0.82 mmol), and AIBN (16 mg) were dissolved in 5 cm^3 of benzene, and the mixture was kept in an atmosphere of nitrogen at 80 °C for 3 h. The solvent was evaporated off and the residue was chromatographed on a silica-gel column using benzene-acetone (4:1) to give 1,4-dihexyl-2,5-piperazinedione (**2"(H)**) in 95% yield: Mp 85—86 °C (from benzene). IR, 1660, 1495, and 1335 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.9 (6H, m, CH_3), 0.9—2.0 (16H, m, $-(CH_2)_4-$), 3.34 (4H, t, *J*=7 Hz, $N-CH_2-$), and 3.88 (4H, s, ring H).

Found: C, 68.18; H, 10.87%. Calcd for $C_{16}H_{30}N_2O_2$: C, 68.04; H, 10.71%.

Photoadducts of 2-Methyl-1-pentene (3) with 1. 1,4-Bis(2-bromo-2-methylpentyl)-2,5-piperazinedione (3"a, b): A mixture of two isomers. Mp 111—113 °C (from benzene-hexane). IR, 1680, 1490, 1425, 1330, 1200, and 1190 cm^{-1}. ^1H NMR (C_6H_6), δ=0.9 (6H, m, CH_3), 1.2—2.1 (8H, m, $-(CH_2)_2-$), 1.70 (6H, s, $-CBr(CH_3)-$), 3.55—4.05 (4H, two AB quartets, *J*=14 and 16 Hz, $N-CH_2-$), and 4.10 (4H, s, ring H).

Found: C, 44.04; H, 6.67%. Calcd for $C_{16}H_{28}Br_2N_2O_2$: C, 43.65; H, 6.36%.

1-(2-Bromo-2-methylpentyl)-2,5-piperazinedione (3'): Mp 91.5—93 °C (from benzene-hexane). IR, 3210, 1670, 1475, 1325, and 1115 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.97 (3H, m, CH_3), 1.2—2.0 (4H, m, $-(CH_2)_2-$), 1.68 (3H, s, $CBr(CH_3)-$), 3.53 and 3.91 (center) (2H, AB quartet, *J*=15 Hz, $N-CH_2-$), 3.93 (2H, s, ring H), 4.16 and 4.31 (center) (2H, AB quartet, *J*=17 Hz, ring H), and 7.62 (1H, s, NH).

Found: C, 43.20; H, 6.15%. Calcd for $C_{10}H_{17}BrN_2O_2$: C, 43.33; H, 6.18%.

1,4-Bis(2-methylpentyl)-2,5-piperazinedione (3"(H)): Mp 88—89 °C (from hexane). IR, 1660, 1480, 1325, 1285, and 1190 cm^{-1}; ^1H NMR ($CDCl_3$), δ=0.9 (6H, m, CH_3), 0.94 (6H, s, $CH(C\underline{H}_3)-$), 1.0—1.9 (10H, m, $-(CH_2)_2-CH-$), 3.24 and 3.85 (center) (4H, AB quartet, *J*=7 Hz, $N-CH_2-$), and 3.92 (4H, s, ring H).

Found: C, 67.75; H, 10.61%. Calcd for $C_{16}H_{30}N_2O_2$: C, 68.04; H, 10.71%.

1-(2-Methylpentyl)-2,5-piperazinedione (3'(H)): Mp 121.5—123.0 °C (from hexane). IR, 3200, 1670, 1475, 1335, 1280, and 1015 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.9 (3H, m, CH_3), 0.93 (3H, s, $-CH(C\underline{H}_3)-$), 1.0—1.9 (5H, m, $-(CH_2)_2-CH-$), 3.21 and 3.83 (center) (2H, AB quartet, *J*=7 Hz, $N-CH_2-$), 3.95 (4H, s, ring H), and 7.48 (1H, s, NH).

Found: C, 60.61; H, 8.90%. Calcd for $C_{10}H_{18}N_2O_2$: C, 60.58; H, 9.15%.

Photoadducts of 2,3-Dimethyl-1-butene (4) with 1. 1,4-Bis(2-bromo-2,3-dimethylbutyl)-2,5-piperazinedione (4"a): Mp 104—105 °C (from benzene). IR, 1680, 1480, 1380, 1320, 1205, 1180, and 1030 cm^{-1}. ^1H NMR ($CDCl_3$), δ=1.10 (12H, d, *J*=6 Hz, $CH(C\underline{H}_3)_2$), 1.65 (6H, s, $CBr(CH_3)-$), 1.5—2.2 (2H, m, $-C\underline{H}(CH_3)_2$), 3.38 and 4.22 (center) (4H, AB quartet, *J*=15 Hz, $N-CH_2-$), and 4.10 and 4.58 (center) (4H, AB quartet, *J*=16 Hz, ring H).

Found: C, 43.67; H, 6.54%. Calcd for $C_{16}H_{28}Br_2N_2O_2$: C, 43.65; H, 6.36%.

4"b: Mp 109—110 °C (from benzene). IR, 1670, 1490, 1380, 1325, 1180, and 1030 cm^{-1}. ^1H NMR ($CDCl_3$), δ=1.12 (12H, d, *J*=6 Hz, $CH(C\underline{H}_3)_2$), 1.67 (6H, s, $CBr(CH_3)-$), 1.5—2.2 (2H, m, $C\underline{H}(CH_3)_2$), 3.26 and 4.23 (center) (4H, AB quartet, *J*=15 Hz, $N-CH_2-$), and 4.02 and 4.74 (center) (4H, AB quartet, *J*=17 Hz, ring H).

Found: C, 43.72; H, 6.37%. Calcd above see.

1-(2-Bromo-2,3-dimethylbutyl)-2,5-piperazinedione (4'): Mp 210 °C (dec.) (from benzene). IR, 3320, 3210, 1670, 1655, 1470, 1320, 1105, and 1020 cm^{-1}. ^1H NMR ($CDCl_3$), δ=1.08 (6H, d, *J*=6 Hz, $-CH(C\underline{H}_3)_2$), 1.66 (3H, s, $-CBr(CH_3)-$), 1.5—2.2 (1H, m, $-C\underline{H}(CH_3)_2$), 3.28 and 4.26 (center) (2H, AB quartet, *J*=15 Hz, $N-CH_2-$), 3.98 (2H, s, ring H), 3.99 and 4.61 (center) (2H, AB quartet, *J*=17 Hz, ring H), and 7.69 (1H, s, NH).

Found: C, 43.04; H, 6.18%. Calcd for $C_{10}H_{17}BrN_2O_2$: C, 43.33; H, 6.18%.

1,4-Bis(2,3-dimethylbutyl)-2,5-piperazinedione (4"(H)): Mp 70—72 °C (from benzene-hexane). IR, 1670, 1480, 1335, and 1180 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.87 (12H, m, $CH(C\underline{H}_3)_2$), 1.3—2.0 (4H, m, $-C\underline{H}(CH_3)-C\underline{H}(CH_3)_2$), 1.66 (6H, d, *J*=9 Hz, $CH(C\underline{H}_3)-$), 3.2—3.8 (4H, m, $N-CH_2-$), 3.88 (2H, s, ring H), and 4.07 (2H, s, ring H).

Found: C, 67.99; H, 10.26%. Calcd for $C_{16}H_{30}N_2O_2$: C, 68.04; H, 10.71%.

1-(2,3-Dimethylbutyl)-2,5-piperazinedione (4'(H)): Mp 163—165 °C (from benzene-hexane). IR, 3220, 1670, 1470, 1320, and 1110 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.87 (6H, m, $CH-(C\underline{H}_3)_2$), 1.3—2.1 (2H, m, $-C\underline{H}(CH_3)-C\underline{H}(CH_3)_2$), 1.63 (3H, d,

J=9 Hz, CH($C\underline{H}_3$)), 3.2—4.0 (2H, m, N-CH_2-), 3.85 (2H, s, ring H), 3.95 (2H, s, ring H), and 7.20 (1H, s, NH).

Found: C, 60.45; H, 8.80%. Calcd for $C_{10}H_{18}N_2O_2$: C, 60.58; H, 9.15%.

Photoadducts of 3,3-Dimethyl-1-butene (5) with **1**. *1,4-Bis(2-bromo-3,3-dimethylbutyl)-2,5-piperazinedione (5"a)*: Mp 226—227 °C (from benzene-acetone). IR, 1675, 1475, 1330, 1290, 1185, and 1110 cm^{-1}. ^1H NMR ($CDCl_3$), δ=1.11 (18H, s, $C(CH_3)_3$), 3.21 (2H, dd, J=11 and 15 Hz, N-CH_2-), 4.00 and 4.40 (center) (4H, AB quartet, J=16 Hz, ring H), 4.17 (2H, dd, J=2 and 15 Hz, N-CH_2-), and 4.26 (2H, dd, J=2 and 11 Hz, -CHBr-).

Found: C, 43.85; H, 6.46%. Calcd for $C_{16}H_{28}Br_2N_2O_2$: C, 43.65; H, 6.36%.

5"b: Mp 242—243 °C (from benzene-acetone). IR, 1670, 1475, 1335, 1280, 1185, and 1120 cm^{-1}. ^1H NMR ($CDCl_3$), δ=1.12 (18H, s, $C(CH_3)_3$), 3.29 (2H, dd, J=11 and 15 Hz, N-CH_2-), 3.98 and 4.42 (center) (4H, AB quartet, J=16 Hz, ring H), 4.18 (2H, dd, J=2 and 15 Hz, N-CH_2-), and 4.29 (2H, dd, J=2 and 11 Hz, -CHBr-).

Found: C, 43.85; H, 6.62%. Calcd see above.

1-(2-Bromo-3,3-dimethylbutyl)-2,5-piperazinedione (5'): Mp 177—178 °C (from benzene and acetone). IR, 3230, 1670, 1465, 1320, 1280, and 1120 cm^{-1}. ^1H NMR ($CDCl_3$), δ=1.11 (9H, s, $C(CH_3)_3$), 3.25 (1H, dd, J=11 and 15 Hz, N-CH_2-), 3.99 and 4.42 (center) (2H, AB quartet, J=17 Hz, ring H), 4.03 (2H, s, ring H), 4.23 (1H, dd, J=3 and 15 Hz, N-CH_2-), 4.31 (1H, dd, J=3 and 11 Hz, -CHBr-), and 7.00 (1H, s, NH).

Found: C, 43.84; H, 6.62%. Calcd for $C_{10}H_{17}BrN_2O_2$: C, 43.33; H, 6.18%.

1,4-Bis(3,3-dimethylbutyl)-2,5-piperazinedione (5"(H)): Mp 190—191.5 °C (from benzene-hexane). IR, 1675, 1480, 1317, and 1285 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.98 (18H, s, $C(CH_3)_3$), 1.43 (4H, m, N-CH_2-$C\underline{H}_2$-), 3.36 (4H, m, N-CH_2-), and 3.86 (4H, s, ring H).

Found: C, 67.82; H, 10.68%. Calcd for $C_{16}H_{30}N_2O_2$: C, 68.04; H, 10.71%.

1-(3,3-Dimethylbutyl)-2,5-piperazinedione (5'(H)): Mp 223.5—224.5 ° (from benzene-hexane). IR, 3240, 1670, 1475, 1320, 1285, and 1120 cm^{-1}. ^1H NMR ($CDCl_3$), δ=0.95 (9H, s, $C(CH_3)_3$), 1.42 (2H, m, N-CH_2-$C\underline{H}_2$-), 3.35 (2H, m, N-CH_2-), 3.88 (2H, s, ring H), 3.92 (2H, s, ring H), and 6.90 (1H, s, NH).

Found: C, 60.67; H, 8.94%. Calcd for $C_{10}H_{18}N_2O_2$: C, 60.58; H, 9.15%.

Photoresponsive Crown Ethers. 12. Photocontrol of Metal Ion Complexation with Thiacrown Ethers

Seiji SHINKAI,* Yoshihiro HONDA, Kaori UEDA, and Osamu MANABE*
Department of Industrial Chemistry, Faculty of Engineering, Nagasaki University, Nagasaki 852
(Received December 28, 1983)

Thiacrown ethers with a photofunctional azolinkage were synthesized to control their binding ability by an on-off light switch: They are the N_2S_4 crowns capped with 2,2′-azopyridine (**1**) or azobenzene (**2**). The cis-trans isomerism occurred reversibly by photoirradiation. The binding ability, evaluated by solvent extraction, showed that (i) the order of the affinity for Hg^{2+} is *N,N′*-dibenzoylated N_2S_4 crown (**4**)≈photoirradiated **1**>*trans*-**1**>photoirradiated **2**>*trans*-**2**, (ii) neither *trans*-**2** nor **4** shows significant affinity toward heavy metal ions such as Cu^{2+}, Co^{2+}, Ni^{2+}, and Pb^{2+}, (iii) *trans*-**1** has a slight affinity (Ex% 5.9%) for Cu^{2+},whereas photoisomerized **1** shows the remarkably enhanced affinity (Ex% 93.9%) with Cu^{2+}, and (iv) such light-induced improvement is not seen for **2**. The relatively poor binding ability of **2** and **4** is rationalized in terms of the unfavorable inside-out conformation of the N_2S_4 crown ring. The remarkable affinity change in *cis*-**1** is probably due to the cooperative contribution of the thiacrown and the azopyridine cap constructing a new ligand site. **1** was used as a carrier for Cu^{2+} transport through a liquid membrane. It was found that the rate is efficiently accelerated by UV-light irradiation.

Chemical substances which exhibit photoinduced structural changes are potential candidates not only for the storage of light energy but also as mediators for the conversion of light into other forms of energy. Further, if the structural changes occurring in the photoresponsive chromophores can be transmitted to functional molecules, the fundamental functions of photoresponsive systems in nature may be mimicked in artificial systems. Azobenzene derivatives which exhibit photoinduced reversible cis-trans isomerism have frequently been employed as photoantennae which trigger subsequent events of a number of functional molecules.[1-6]

The purpose of our investigation has been to control the functions of a crown ether family by an on-off light switch, which would lead to the photocontrol of ion-extraction and membrane transport.[7-12] We have developed two different techniques to change the binding ability of crown ethers by light. One method is to induce a conformational change in the crown ether moiety in conjugation with a photoinduced configurational change in the azobenzene moiety. A typical example is azobenzene-bridged crown ether.[7] The other method is associated with a change in the spatial position between two crown rings which leads to interconversion between 1:1 and 2:1 crown/cation complexes. The photoresponsiveness of azobis(benzocrown ether)s (so-called butterfly crown ethers) is a typical example.[8,11] It was shown that in these photoresponsive crown ethers, not only the binding ability but also the ion selectivity is markedly influenced by photoirradiation[7-14] and that in some cases an all-or-nothing change in the binding ability is observed.[15,16] By use of such photoresponsive crown ethers, we can control the ion-extraction and membrane-transport of alkali and alkaline earth metal cations by an on-off light switch. It is known that a thiacrown family exhibits an affinity toward heavy metal cations.[17,18] Thus, if one can extend the above concept to the thiacrown family, it would lead to photocontrol of the ion-binding ability toward heavy metal cations. With these objects in view, we synthesized thiacrown analogues **1**—**4** to test the photoresponsive binding of heavy metal cations.

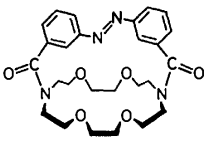
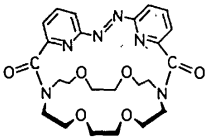
Results and Discussion

^{1}H-NMR Spectra of Capped Thiacrown Ethers. We previously synthesized azobenzene-capped and azopyridine-capped crown ethers (**5** and **6**, respectively) from 1,4,10,13-tetraoxa-7,16-diaza-18-crown-6(N_2O_4 crown).[7,12] It was found that in the ^{1}H-NMR spectra of these compounds the chemical shifts of the crown protons are sensitively affected by ring current of the aromatic rings. For example, *trans*-**5** gave two resolved peaks at 3.6—3.9 ppm (8H) and 4.1—4.8 ppm (16H), which were attributed to NCH_2 and OCH_2 of the crown ring, respectively.[7] Since the crown protons of N_2O_4 crown derivatives usually appear at 3.4—3.8 ppm as a broad single peak, the downfield shift in *trans*-**5** is ascribed to the anisotropic effect of the benzene rings.



trans-5



trans-6

A similar anisotropic effect was seen for *trans*-**1** and *trans*-**2**. In contrast to a broad single peak (2.80 ppm in $CDCl_3$) observed for the methylene protons of 1,4,10,13-tetrathia-7,16-diazacyclooctadecane (N_2S_4 crown), *trans*-**1** and *trans*-**2** gave the resolved, complex NMR spectra at 2.6—4.8 ppm (Fig. 1). The downfield chemical shifts observed at 4.6 ppm (2H) for *trans*-**1** and 3.8 ppm (4H) for *trans*-**2** would be attributed to the central methylene protons which most strongly undergo the anisotropic effect of the aromatic caps. As seen in Fig. 1, the NMR peaks of *trans*-**2** are significantly broad at 30°C and sharpened with increasing temperature. It is conceivable that the broadening effect is induced by the steric rigidity of the bicyclic *trans*-**2**. A similar temperature-dependence is seen for the crown ether analogue

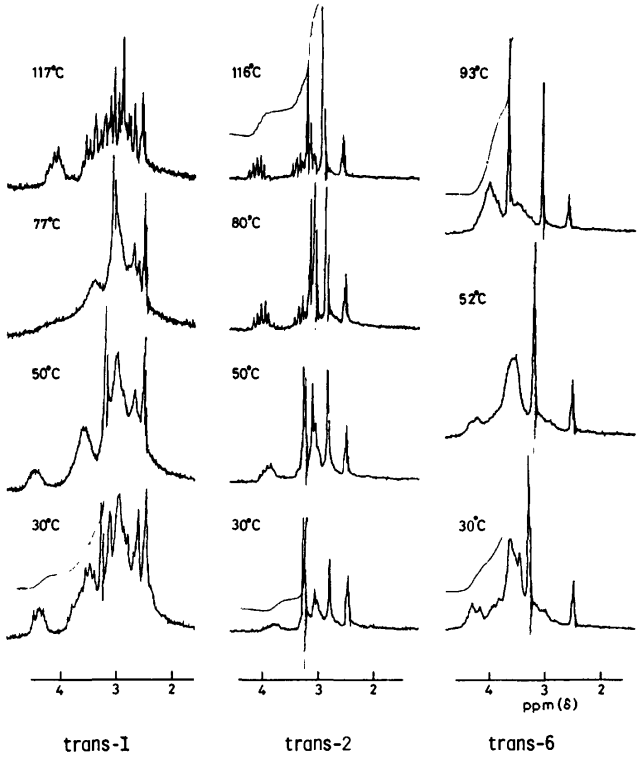


Fig. 1. Temperature dependence of the NMR spectra of *trans*-**1**, *trans*-**2**, and *trans*-**6** (solvent: Me_2SO-d_6).

trans-**6**. On the other hand, the NMR spectrum of *trans*-**1** had a peculiar temperature-dependence: The peaks at 30°C were very sharp, and with increasing temperature they once became broad at the intermediate temperature region, finally being sharpened again at 117°C. The intergral intensity of the downfield peak (around 4.6 ppm) at 30°C corresponds to two protons. The peak is once absorbed into the main absorption band at intermediate temperature and finally separated as four proton intensity at 117°C. According to recent X-ray crystallographic studies, most of thiacrown ethers show some disorder due to differences in the sulfide bond configuration.[19,20] It is likely on the basis of the above NMR data and the X-ray analysis[21] that the thiacrown ring of *trans*-**1** involves a few configurational isomers. We cannot explain readily, however, why the temperature dependences of the NMR spectra are so different between azopyridine-capped *trans*-**1** and azobenzene-capped *trans*-**2**.

Spectral Examination of Metal-Crown Interactions. In order to evaluate interactions between the thiacrown ethers and heavy metal ions, the absorption spectra were taken in methanol or *o*-dichlorobenzene(DCB)-1-butanol(*n*-BuOH) mixed solvent. The latter mixed solvent was used to compare the spectral data with the subsequent ion-extraction and thermal cis-to-trans isomerization under the consistent conditions. The results are summarized in Table 1. The absorption bands at around 325 nm and 450 nm in *trans*-**1**, *trans*-**2**, and *trans*-**3** are ascribed to π-π^* and n-π^* bands, respectively. Since **4** gives no appreciable absorption band at 300—600 nm and **2** gives no additional absorption band on the addition of heavy metal ions, a new absorption band (when it appears) can be attributed mainly to the interaction between the 2,2′-azopyridine cap with metal ions. Examination of the spectral data on *trans*-**1** and *trans*-**3** revealed that under the present conditions *trans*-**3** are capable of binding most heavy metal ions while *trans*-**1** interacts selectively with Cu^{2+} (in methanol and DCB–BuOH) and Hg^{2+} (in methanol). In these systems, the π-π^* bands shifted significantly to longer wavelength region (340—350 nm). The *trans*-**1**·Cu^{2+} complex afforded an additional, weak absorption band at around 550 nm only in

a) [metal salt]=1.00×10^{-3} M, [**1**, **2**, **3** or **4**]=2.50×10^{-5} M. "Sh" denotes the shoulder at 350—400 nm. "No" means that the spectrum is scarcely affected by added metal ions. b) [$HgCl_2$]=0.30 M. c) [$Pb(OCOCH_3)_2$]=5.51×10^{-5} M.

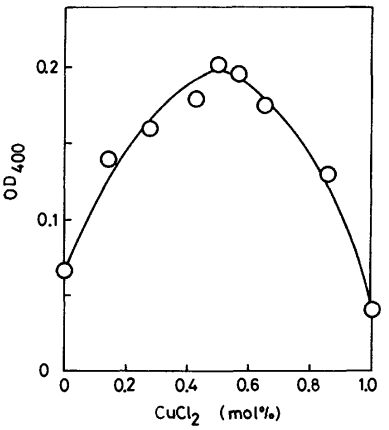

Fig. 2. Continuous variation plots of OD_{400}. 30°C, methanol (containing 9.1 vol% dioxane), [*trans*-**1**]+[$CuCl_2$]=5.01×10^{-4} M, 0.2 cm cell.

methanol. Since such an absorption band was scarcely detected for the *trans*-**3**·Cu^{2+} complex, the band may arise from the interaction of the thiacrown moiety with Cu^{2+} bound to the azopyridine moiety of *trans*-**1**. In fact, many thiacrown ethers we recently synthesized gave a new absorption band at 500—600 nm in the presence of Cu^{2+}.[22]

The binding of Cu^{2+} to *trans*-**1** was further estimated by a continuous variation method in methanol (Fig. 2). Clearly, the absorbance at 400 nm ascribable to the complex formation provided a maximum at 0.5 mol% of $CuCl_2$, indicating that *trans*-**1** forms the 1:1 complex with $CuCl_2$. Here, we tried to determine the association constants (K_t) for *trans*-**1** by a spectroscopic method. They were evaluated by using Eq. 1, which holds for the formation of a 1:1 complex under $[metal]_0 \gg [trans\text{-}1]_0$, where OD_0 and OD are the absorbances of *trans*-**1** in the absence and the presence of metal ions, respectively, and ε is the apparent molar absorption coefficient of the *trans*-**1**·metal complexes.

$$\frac{OD-OD_0}{[metal]_0} = \varepsilon K_t[trans\text{-}1]_0 - K_t OD \qquad (1)$$

In methanol solvent, new absorption maxima appeared on the addition of $CuCl_2$ and $HgCl_2$ at 353 and 342 nm, respectively (Table 1). Thus, the wavelengths at the maximum or near the maximum were used to follow the spectral changes in methanol. In DCB–BuOH mixed solvent, the addition of $CuCl_2$ developed a shoulder at around 400 nm, so that we chose the 380 nm band where the spectral change seemed most apparent. The plots of $[metal]_0$ *vs.* OD, which showed saturation curves (Fig. 3), were analyzed according to Eq. 1, resulting in good linear relationships between $(OD-OD_0)/[metal]_0$ and OD with $r>0.98$. We here assume that $HgCl_2$ also forms the 1:1 complex with *trans*-**1**. The K_t values were determined from the slopes (*i.e.*, $-K_t$) by least-squares analysis: For $CuCl_2$ K_t=8660 M^{-1} (methanol) and 686 M^{-1} (DCB-*n*-BuOH); for $HgCl_2$ 18 M^{-1} (methanol).†

Metal Ion Catalyses in the Thermal Cis-to-Trans Isomerization. **1**, **2**, and **3** in DCB-*n*-BuOH (9:1 by volume) could be isomerized to the *cis*-forms by UV-light ir-

a) Solvent: *o*-dichlorobenzene : 1-butanol=91:9 by volume, [metal salt]=1.00×10^{-3} M, [**1**]=[**3**]=3.87×10^{-5} M, [**2**]=3.24×10^{-5} M. b) $[Pb(OCOCH_3)_2]=5.51\times10^{-5}$ M.

radiation (330 nm<λ<380 nm) without degradation. We found, however, that the *cis* concentration of **2** (azobenzene-capped) at the photostationary state is high (70%), whereas those of **1** (azopyridine-capped) and **3** are only 24 and 18%, respectively. We thus looked for other wavelengths which might improve the *cis* concentrations of **1** and **3**, but failed.

It is known that some heavy metal ions can catalyze the thermal isomerization of azo-linkages,[2,23] probably because of the stabilization of the transition-state through metal ion coordination to the azo linkages. In Table 2, typical first-order rate constants in the presence of metal ions are summarized. As the rate constant for **1** (0.0765 h^{-1}) is comparable with that for **3** (0.0921 h^{-1}), steric inhibition due to the rigidity arising from the thiacrown moiety is unlikely. Similarly, the rate constant for **2** (0.0133 h^{-1}) is comparable with that for the azobenzene-capped crown ether analog (0.0562 h^{-1} at 40°C in DCB)[7]. From Table 2, most of the heavy metal ions used are capable of catalyzing the thermal isomerization and, in particular, Cu^{2+} provides the greatest catalytic effect. We thus carried

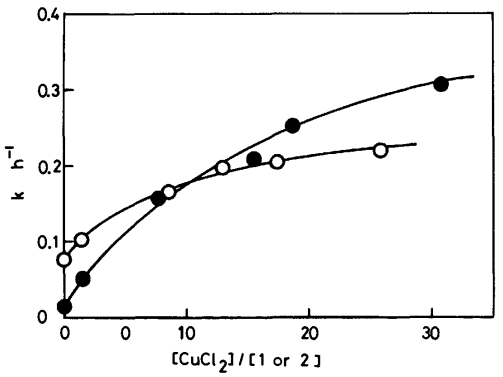

Fig. 4. Influence of added $CuCl_2$ on the thermal cis-to-trans isomerization in DCB-*n*-BuOH (9:1 by volume) at 30°C. ○ [**1**]=3.87×10⁻⁵M; ● [**2**]=3.24×10⁻⁵M.

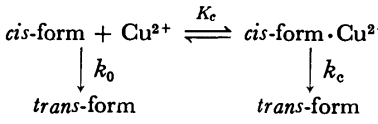
out further detailed investigation on the Cu^{2+} catalysis. In Fig. 4, the first-order rate constants for **1** and **2** are plotted against the Cu^{2+} concentration. The plots for **1** and **2** seem to afford a simple saturation curve.

The Cu^{2+}-catalyzed isomerization in Fig. 4 is expressed by Scheme 1, where K_c is the association constant with the *cis*-forms and k_0 and k are the first-order rate constants in the absence and the presence of metal ions, respectively.



Scheme 1.

K_c and k_c can be evaluated by using Eq 2,[24] which holds for the formation of a 1:1 complex under $[Cu^{2+}] \gg [cis\text{-form}]$, where $q=(k_c/k_0)-1$ and k_c is the first-order rate constant for the complex.

$$\frac{k_0}{k-k_0} = \frac{1}{qK_c}\cdot\frac{1}{[Cu^{2+}]} + \frac{1}{q} \qquad (2)$$

From the plots of $k_0/(k-k_0)$ against $[Cu^{2+}]_0^{-1}$, we determind $(qK_c)^{-1}$ (slope) and q^{-1} (intercept) by the least-squares procedure ($r>0.99$). Thus, K_c and k_c were calculated from these two terms: K_c=2190 M^{-1} and k_c=0.294 h^{-1} for *cis*-**1**: K_c=1726 M^{-1} and k_c=0.472 h^{-1} for *cis*-**2**.

The rate values show that the rate constants for the Cu^{2+}-complexes of *cis*-**1** and *cis*-**2** are greater by 3.8-fold and 34.5-fold, respectively, than those for the uncomplexed *cis*-forms. On the other hand, the K_c value for *cis*-**1** is greater by 3.2-fold than the K_t value for *trans*-**1**. Previously, we estimated the K_c value for the azopyridine-capped crown ether analog (**6**) from a similar kinetic method.[12] In **6**, the azopyridine is the main association site with Cu^{2+}, so that we considered the K_c to be the true association constant with the *cis*-form. In **1**, however, one must take the another interaction with the thiacrown moiety (at least partially) into account which would not be reflected by the kinetics. Thus, the K_c values determined here mainly reflect the interaction with the azo moietics and should be considered to be the "kinetic" association constants.

Solvent Extraction of Heavy Metal Ions. The binding ability of **1**, **2**, and **4** was estimated by solvent extraction of heavy metal ions from water to an organic phase (DCB: *n*-BuOH=4:1 by volume). We employed picrate ion (Pic) which is one of the most convenient counteranions for solvent extraction. In the extraction of Cu^{2+} and Hg^{2+}, however, the aqueous phase after the treatment gave an absorption band at around 350 nm (*vide supra*), which partially overlapped with the absorption band of picrate ion. We thus employed Methyl Orange (MO: λ_{max} 466 nm) for Cu^{2+} and Hg^{2+}. To make all the extraction data comparable, we determined the extractability (Ex%) of Hg^{2+} with picrate ion by correcting the 350 nm band, but the accuracy of the Hg^{2+}-picrate system must be somewhat inferior to others. The results, together with the detailed extraction conditions, are summarized in Table 3.

The examination of Table 3 reveals that (i) except for Hg^{2+}, **4** generally acts as a poor ligand for heavy metal ions, (ii) Hg^{2+} is bound not only to **4** but also to **1** and **2**, and the Ex%'s for **1** (but not so much for **2**) are improved by UV-light irradiation, (iii) neither **2** nor **4** binds Cu^{2+} appreciably, indicating that the small Ex% of *trans*-**1** for Cu^{2+} is probably due to the interaction with the azopyridine moiety, (iv) most significantly, the Ex% of **1** for Cu^{2+} dramatically enhanced by UV-light irradiation (5.9%→93.9%). The binding ability of **4** with Hg^{2+} can be rationalized either by the

Table 3. Influence of photoirradiation on the extraction of heavy metal ions to the organic phase(*o*-dichlorobenzene: 1-butanol=4:1 by volume) with **1**, **2**, and **4** at 30°C[a]

Crown	Counteranion	Extracted counteranion/%				
		Cu^{2+}	Hg^{2+}	Co^{2+}	Ni^{2+}	Pb^{2+}

	MO	93.9	28.1			
trans-**2**	Pic		0—3	0	0	0
	MO	0	6.8			
Photoirradiated **2**[c]	Pic		0—3	0	2.7	1.4
	MO	0	8.2			
4	Pic		22	0	1.2	0
	MO	0	30.5			

a) Extraction conditions: aqueous phase, [metal salt]=0.010M, [Pic(picric acid)]=1.00×10⁻⁴M or [MO(Methyl Orange)]=8.90×10⁻⁵M, pH 4.2—4.3 with Et_4NOH(*ca.* 10⁻⁴M); organic phase, [crown]=1.00×10⁻³M. b) *cis*-Form 27%. c) *cis*-Form 53%.

general affinity between sulfur and Hg^{2+} or by the relatively large Hg^{2+} radius. The ion radius of Hg^{2+} (1.10—1.16 Å) is comparable with that of Na^+ (1.13—1.16 Å), whereas except for that of Pb^{2+} (1.32—1.63 Å), those of other metal ions (0.76—0.84 Å) are comparable with that of Li^+ (0.73—0.88 Å). Anyway, the absence of the significant affinity for other heavy metal ions (even for Cu^{2+}) is unexpected. Recently, the crystal structure of 1,4,7,10,13,16-hexathiacyclooctadecane (hexathia analog of 18-crown-6) was reported by Harman *et al.*[20] They found the sulfur atoms in a gauche configuration in the thiacrown ether at the position where the corresponding oxygens in the conventional crown ether would be anti. As a result, the thiacrown ether has both endo- and exodentate-sulfur atoms, resulting in a tendency for bridging two metal ions rather than chelating to one as conventional crown ethers do. If **4** adopts a similar conformation in solution (and probably it does[21]), it is unlikely that the four sulfur atoms coordinate to one metal ion. The examination of the CPK model suggests that, assuming sp^3 for the amide nitrogens, the boat-form of **4** in which the four sulfur atoms can coordinate to one metal ion is highly crowded, whereas the crowding is somewhat relaxed in the chair-form in which only two sulfur atoms can coordinate to one metal ion. It seems to us, therefore, that the coordination of the four sulfur atoms of the N_2S_4 crown to one metal would be energetically unfavorable. The low association tendency of **2** with Hg^{2+} relative to **4** would be ascribed to further deformation of the thiacrown ring by the azobenzene cap. Further details of the relation between the crown structure and the metal selectivity will be described elsewhere.[21]

Finally, we would like to consider the photoirradiation effect on **1**. Based on the spectral change in the azopyridine moiety (Fig. 3), we estimated the association constants of *trans*-**1** in methanol for Cu^{2+} and Hg^{2+} to be 8660 and 18 M^{-1}, respectively. Contrary to these association constants, Hg^{2+} gave the greater Ex% values than Cu^{2+} (Table 3). The discrepancy is accommodated by taking the contribution of the thiacrown moiety into account: that is, the spectroscopically-determined association constants mainly reflect the interaction with the azoarene caps, whereas the interaction with the thiacrown moiety, which is not detected by spectroscopy, is expected for Hg^{2+}.

For the Hg^{2+}-binding to *trans*-**1**, one may consider the cooperative coordination of the thiacrown and the azopyridine-cap, because the Ex% of *trans*-**1** (Pic 18%, MO 13.8%) is significantly higher than that for *trans*-**2** (Pic 0—3%, MO 6.8%). Interestingly, we found that the Ex% of **1** for Cu^{2+} is remarkably enhanced by UV-light irradiation and a similar improvement is also seen for Hg^{2+}. When taking the low *cis* concentration (27%) in the extraction solution into account, the improvement is quite dramatic. The results strongly suggest that in *cis*-**1** the thiacrown and the azopyridine cap cooperatively build a ligation site with a strong coordination ability. At present, we can only speculate on the structure from the CPK model: the azopyridine-cap in *trans*-**1** stands vertically over the thiacrown ether plane.[21] whereas that in *cis*-**1** is almost parallel to the thiacrown plane. Therefore, one (or two) pyridine nitrogen in the *cis*-cap is directed towards two adjacent sulfur atoms in the thiacrown ring. In this case, the metal cation undergoes the cooperative coordination both from the pyridine nitrogen and the sulfur atoms. Although further study is needed to clarify the structure of the binding site, the results indicate that **1** has a dramatic photoresponsiveness in the binding to Cu^{2+}.

Table 4. Photocontrol of Cu^{2+} transport across a liquid membrane (30 °C)[a]

Condition	Transport rate/mol h^{-1}	
	Method I[b]	Method II[c]
Dark	1.4×10^{-8}	*ca.* 2×10^{-10}
UV light[d]	6.3×10^{-9}	1.2×10^{-9}
UV and visible lights[e]	7.0×10^{-9}	1.2×10^{-9}

a) The membrane phase (10 ml, *o*-dichlorobenzene: 1-butanol=4:1 by volume) : [**1**]=3.00×10^{-4} M. b) IN aqueous phae: [$CuCl_2$]=0.010 M, [picrate]=1.00×10^{-3} M, [CH_3COONH_4]=0.010 M. OUT aqueous phase: water. The rate was estimated from the absorption maximum of picrate ion. c) IN aqueous phase: [$CuCl_2$]=0.010 M. OUT aqueous phase: water. The rate was estimated from the absorption band of Cu^{2+}-PAN complex (see Experimental). d) The membrane phase was irradiated through a color glass filter (330 nm<λ<380 nm) for 10 min at intervals of 60 min. e) UV(10 min)→dark(50 min)→visible(10 min)→dark (50 min)→repeated.

Photocontrol of Cu^{2+} Transport. Since the large difference in Ex% was found for the extraction of Cu^{2+} with **1**, we attempted the photocontrol of Cu^{2+} transport across a liquid membrane at 30 °C. The results are summarized in Table 4.

When picrate ion as a counteranion was added to the IN aqueous phase (method I), the rate under UV-light irradiation was smaller than that in the dark. We observed, however, that in the transport under UV-light irradiation the membrane phase rapidly colors yellow. This indicates that Cu^{2+}-picrate salt, which is efficiently extracted with *cis*-**1** into the membrane phase, is not released to the OUT aqueous phase. We found that *cis*-**1** can be isomerized to *trans*-**1** (half-life, *ca.* 2 min at 30 °C) by irradiation of a 200-W tungsten lamp even in the presence of Cu^{2+} ion. Therefore, we alternately irradiated the membrane phase by UV and visible lights in order to facilitate the ion-release by the isomerization to *trans*-**1**, but the rate was scarcely improved.

We previously experienced that hydrophobic counteranions facilitate the ion-extraction but rather decelerate the rate of the ion-release from the membrane phase.[8] We thus carried out the Cu^{2+} transport without any hydrophobic counteranions (method II). Although the absolute values of the Cu^{2+} transport were relatively small, the rate under UV-light irradiation was significantly enhanced compared with that in the dark. Visible light had no effect on the transport rate. Probably, the rate enhancement in method II is attributed to the improved extraction efficiency by photoisomerized *cis*-**1**. In other words, the extraction of Cu^{2+} to the membrane phase from the IN aqueous phase is rate-determining through the transport system.

Conclusions. In this article we have indicated that the concept to photocontrol the chemical and

physical functions of a crown ether family can be extended to a thiacrown ether family which acts as receptors for heavy metal ions. Being different from "inactive" alkali metal ions, some kinds of heavy metal ions show various catalytic activities as seen in metalloproteins. We thus consider that the catalytic activities of heavy metal ions could be photocontrolled by use of thiacrown ethers or azacrown ethers as photoresponsive mediators. Although the frameworks of the photoresponsive thiacrown ethers are still to be improved, the results indicate that the binding ability towards heavy metal ions can be controlled, in principle, by switching the light source on and off. Further investigation is currently in progress in this laboratory.

Experimental

Materials. The preparation of 6,6′-bis(morpholinocarbonyl)-2,2′-azopyridine (**3**) was described previously.[12]

1,4,10,13-Tetrathia-7,16-diazacyclooctadecane (N_2S_4 crown) was prepared from equimolar amounts of 1,2-ethanedithiol and bis(2-bromoethyl)amine hydrobromide in ethanol in the presence of sodium ethoxide; mp 128—129 °C (lit,[25] 124 °C), yield 14%, M^+ 326. ^{1}H-NMR ($CDCl_3$, δ): NH, 2.03, 2H; NCH_2 and SCH_2, 2.80, 24H. Found: C, 43.92; H, 7.97; N, 8.53%. Calcd for $C_{12}H_{26}N_2S_4$: C, 44.13; H, 8.02; N, 8.58%.

Compound **1** was synthesized from equimolar amounts of the N_2S_4 crown and 6,6′-bis(chloroformyl)-2,2′-azopyridine according to the high dilution method in chlorobenzene in the presence of excess triethylamine. The procedure is essentially similar to that described for the synthesis of *trans*-**6**[12]: mp 249—251 °C (dec), yield 33%, M^+ 562. ^{1}H-NMR ($CDCl_3$, δ): N_2S_4 crown protons, 2.4—4.0 and 4.4—4.8, 22H and 2H, respectively; pyridine protons, 7.8—8.2, 6H. Found: C, 51.16; H, 5.23; N, 14.80%. Calcd for $C_{24}H_{30}N_6S_2O_4$: C, 51.22; H, 5.37; N, 14.93%.

Compound **2** was synthesized from equimolar amounts of the N_2S_4 crown and 3,3′-bis(chloroformyl)azobenzene in chlorobenzene in the presence of excess triethylamine. The product was purified by a TLC method (silica gel and chloroform); mp 256—258 °C, yield 24%, M^+ 560. IR (KBr disk): $\nu_{C=O}$ 1635 cm^{-1}. ^{1}H-NMR (Me_2SO-d_6, δ): N_2S_4 crown protons, 2.6—3.4 and 3.6—4.0, 20H and 4H, respectively; benzene protons, 7.64 (4H), 7.96 (2H), and 8.12 (2H). Found: C, 55.51; H, 5.74; N, 10.00%. Calcd for $C_{26}H_{32}N_4O_2S_4$: C, 55.68; H, 5.75; N, 9.99%.

Compound **4** was obtained by the treatment of the N_2S_4 crown with benzoyl chloride in benzene in the presence of excess triethylamine. The product was recrystallized from benzene; mp 105—107 °C, yield 51%, M^+ 534. Found: C, 58.16; H, 6.51; N, 4.95%. Calcd for $C_{26}H_{34}N_2O_2S_4$: C, 58.39; H, 6.41; N, 5.24%.

Miscellaneous. The method of solvent extraction and the rate determination of thermal cis-to-trans isomerization were described previously.[7-12] As a UV-light source for the trans-to-cis isomerization, a 100-W high-pressure Hg-lamp with a color glass filter (330 nm$<\lambda<$380 nm) was used.

Transport of Cu^{2+} across a liquid (DCB: *n*-BuOH=4:1 by volume) membrane with the aid of **1** was examined with a U-tube. The U-tube (10 mm diameter) was immersed in a thermostated (30 °C) water bath. The transport system consisted of 10 ml of the liquid membrane and IN and OUT aqueous phases (5 ml each). The membrane phase was stirred at a constant speed (180 rpm). When required, the tube was irradiated either by a 100-W high-pressure Hg-lamp or by a 200-W tungsten lamp. In method I, the rate of Cu^{2+} transport was estimated from the absorption maximum of picrate ion. In method II, the aliquots of the OUT aqueous phase were treated with 1-(2-pyridylazo)-2-naphthol (PAN) and the rate was determined from the absorption band at 550 nm using a calibration curve. Further details of the transport methods are recorded in footnotes to Table 4.

This research was supported by a grant from the Ministry of Education of Japan. We thank the helpful discussions of Dr. H. L. Ammon, and Dr. K. T. Douglas.

Redox-Switched Crown Ethers. 1. Redox-Coupled Control of Metal-Ionophore Interactions and Their Application to Membrane Transport[1)]

Seiji SHINKAI,* Kenichi INUZUKA, Kenzo HARA, Takaaki SONE, and Osamu MANABE*

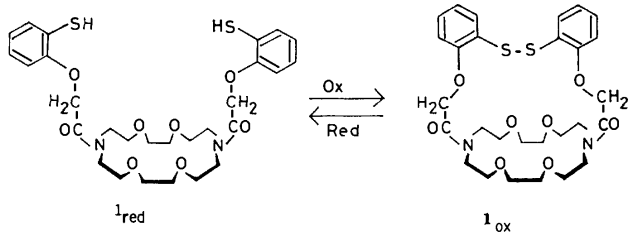
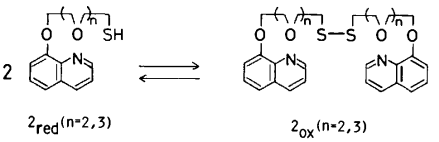
(Received January 14, 1984)

Polyether ionophores with redox-functional thiol groups were synthesized: they are a diaza-18-crown-6 with a disulfide cap that exhibits redox-responsive interconversion between crown($\mathbf{1}_{red}$) and cryptand($\mathbf{1}_{ox}$) and tri- and tetra(oxyethylene)s having a mercapto and an 8-quinolyl group as their terminal groups that feature redox-responsive interconversion between monopodands ($\mathbf{2}_{red}$) and dipodands ($\mathbf{2}_{ox}$). For Na^+ $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$ showed a similar ion affinity, but $\mathbf{1}_{ox}$ bound K^+, Rb^+, and Cs^+ more efficiently than $\mathbf{1}_{red}$ because of the coordination of the cap oxygens to the complexed metal cations. The difference was rationalized by such that "K^+ (Rb^+ and Cs^+ also) perches on the crown-ring whereas Na^+ nests in it," $\mathbf{2}_{ox}$ showed, in most cases, the ion affinity significantly higher than corresponding $\mathbf{2}_{red}$, indicating the cooperative action of the two poly(oxyethylene) chains on the ion-binding. The rate of K^+ transport with $\mathbf{2}_{red}$ across a liquid membrane was very slow but $\mathbf{2}_{ox}$ carried K^+ more efficiently. It was found that the rate of K^+ transport started with $\mathbf{2}_{red}$ is efficiently accelerated by the addition of I_2. This is due to the redox-switch of the carrier from $\mathbf{2}_{red}$ to $\mathbf{2}_{ox}$. These results suggest that the redox-functionalized ionophores provide novel applications of ion-extraction and ion-transport.

Macrocyclic polyethers contain intramolecular cavities delineated by molecular segments and are capable of specific chelation with alkali and alkaline earth metal ions. The specificity in the chelation stems from a host-guest relationship[2-4]: that is, the ion-selectivity is primarily subjected to the size and shape of the intramolecular cavities. One may thus expect that if the ring conformation or the topological ring shape can be reversibly changed in response to some input energy, it would lead to the "control" of ion-binding ability and ion-selectivity by an on-off switch. Furthermore, this is important in relation to the membrane transport phenomenon mediated by some antibiotic carriers where the reversible interconversion between the cyclic and the acyclic form of the antibiotics plays the crucial role.[5)] There are several synthetic ionophores that exhibit pH-dependent interconversion between the acyclic and the pseudo-cyclic form,[6-11)] but to the best of our knowledge there is no example for the redox-dependent acyclic-cyclic interconversion.[1)] We considered that the interconversion would be realized more directly by utilizing the reversible bond-formation and bond-scission. The most suitable candidate to this purpose would be the redox reaction of a thiol-disulfide couple, because the reversibility is excellent and the reaction occurs under mild conditions. Here, we wish to report such examples of "redox-switched" ionophores, the ion affinity of which changes in response to redox of a thiol-disulfide bond: that is, (i) a crown ether with a disulfide cap which features a crown ($\mathbf{1}_{red}$)–cryptand($\mathbf{1}_{ox}$) interconversion, and (ii) a monopodand($\mathbf{2}_{red}$)–dipodand($\mathbf{2}_{ox}$) interconversion in which two 8-quinolyl groups are linked by a disulfide bond *via* poly(oxyethylene) chains.



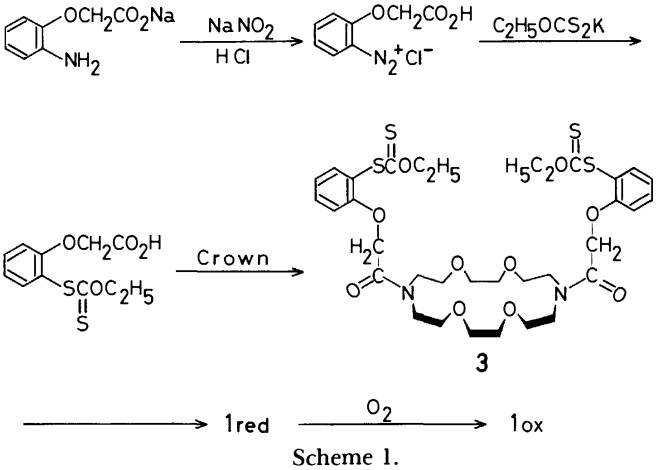
$\mathbf{1}_{red}$ $\mathbf{1}_{ox}$



$\mathbf{2}_{red}$(n=2,3) $\mathbf{2}_{ox}$(n=2,3)

Experimental

Materials. $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$ were synthesized according to a following reaction Scheme 1.



Scheme 1.

Sodium *o*-aminophenoxyacetate (18.9 g; 0.10 mol) and $NaNO_2$ (6.90 g; 0.10 mol) were dissolved in 100 ml of water. This solution was added dropwise to 60 ml of 6 M† HCl solution at 0—5 °C. After 5 min excess $NaNO_2$ was decomposed by sulfamic acid. The solution was mixed slowly with 200 ml of aqueous solution containing potassium ethyl xanthate (19.2 g; 0.12 mol) and sodium hydrogencarbonate (25.5 g; 0.30 mol) in an ice-water bath. The progress of the reaction was followed by a color test with H-acid. The solution was treated with active charcoal at room temperature. After filtration the solution was acidified to pH 1 with concd. HCl, the precipitate being recovered by filtration. The raw product (*o*-(ethoxythiocarbonylthio)phenoxyacetic acid) thus obtained was again dissolved in $NaHCO_3$ solution, treated with active charcoal, and recovered by acidification

† 1 M=1 mol dm^{-3}.

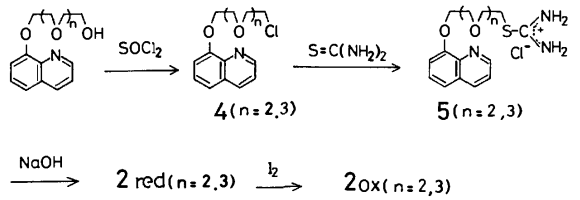
with concd. HCl; mp 119—120 °C, single spot on TLC, yield from sodium *o*-aminophenoxyacetate 30.9%. IR (KBr): $\nu_{C=O}$ 1750 cm^{-1}, ν_{C-O-C} 1090 and 1230 cm^{-1}; M$^+$ (*m/z*) 272; NMR (Me_2SO-d_6, δ): CH_3, 1.22, 3H; O-CH_2, 4.54, 2H; O-CH_2-CO, 4.73, 2H; benzene protons, 7.20, 4H. Found: C, 48.70; H, 4.46%. Calcd for $C_{11}H_{12}O_4S_2$: C, 48.51; H, 4.44%.

In 150 ml of anhydrous tetrahydrofuran (THF) *o*-(ethoxythiocarbonylthio)phenoxyacetic acid (7.20 g; 0.0264 mol) and pivaloyl chloride (3.72 g; 0.0309 mol) were reacted for 30 min at 0 °C. To the stirred solution was added dropwise a THF solution (100 ml) containing 1,4,10,13-tetraoxa-7,16-diazacyclooctadecane (3.0 g; 0.0114 mol) and triethylamine (4.8 ml; 0.034 mol). The reaction was continued for 2 h at room temperature and then refluxed for 1 h. The white precipitate formed on cooling was collected by filtration, and triethylamine hydrochloride was removed by washing with water. The remaining product (**3** in Scheme 1) was recrystallized from 1-butanol; mp 161—164 °C, yield 84.0%. IR (KBr): $\nu_{C=O}$ 1650 cm^{-1}, ν_{C-O-C} 1130 and 1230 cm^{-1}; NMR (Me_2SO-d_6, δ) CH_3, 1.19, 6H; crown protons, 3.36, 24H; O-CH_2, 4.53, 4H; O-CH_2-CO, 4.89, 4H; benzene protons, 7.20, 8H. Found: C, 53.14; H, 6.34; N, 3.50%. Calcd for $C_{34}H_{46}N_2O_{16}S_4$: C, 52.97; H, 6.01; N, 3.63%.

3 was hydrolyzed to $\mathbf{1}_{red}$. **3** (7.77 g; 0.0101 mol) was suspended in 600 ml of ethanol and mixed with 200 ml of 75 vol% ethanol solution containing NaOH (1.75 g; 0.0407 mol). The reaction mixture was refluxed under a nitrogen stream and the progress of the reaction was followed by a TLC method. After 1 h, 2-mercaptoethanol (2.0 g; 0.0256 mol) and then 3 ml of acetic acid were added. The white precipitate was obtained from the cooled solution; mp 166—168 °C, yield 85.1%. IR (KBr): $\nu_{C=O}$ 1650 cm^{-1}, ν_{C-O-C} 1130 and 1225 cm^{-1}, ν_{SH} 2580 cm^{-1}; NMR (Me_2SO-d_6, δ) SH, 3.24, 2H; crown protons, 3.54, 24H; CH_2, 4.93, 4H; benzene protons, 7.05, 8H. Found: C, 56.29; H, 6.69; N, 4.57%. Calcd for $C_{28}H_{38}N_2O_8S_2$: C, 56.55; H, 6.44; N, 4.71%.

$\mathbf{1}_{red}$ (1.0 g; 1.68×10^{-3} mol) was dissolved in 400 ml of 0.1 M KOH solution and an oxygen stream was introduced at room temperature. After 5 h, the white precipitate ($\mathbf{1}_{ox}$) was recovered by filtration and recrystallized from ethylene glycol monomethyl ether; mp 172—175 °C, yield 54.2%. IR (KBr): $\nu_{C=O}$ 1650 cm^{-1}, ν_{C-O-C} 1075 and 1220 cm^{-1}; M$^+$ (*m/z*) 592; NMR (Me_2SO-d_6, δ) crown protons, 3.51, 24H; CH_2, 4.89, 4H; benzene protons, 7.00, 8H. Found: C, 56.45; H, 6.65; N, 4.62%. Calcd for $C_{28}H_{36}N_2O_8S_2$: C, 56.74; H, 6.12; N, 4.73%.

$\mathbf{2}_{red}$ and $\mathbf{2}_{ox}$ were synthesized according to Scheme 2. Since the synthesis of **4** has been described by Hiratani *et al.*,[7,8] we here record only the analytical data.



Scheme 2.

4 (n=2); oil, single spot on TLC, yield 90.9%. IR (neat) quinoline 1500 and 1600 cm^{-1}, ν_{C-O-C} 1120 cm^{-1}; NMR ($CDCl_3$, δ) methylene protons, 3.70 (8H), 4.04 (2H), and 4.40 (2H); quinoline protons, 7.05 (1H), 7.35 (3H), 8.05 (1H), and 8.85 (1H).

4 (n=3); oil, single spot on TLC, yield 59.6%. IR (neat) quinoline 1500 and 1600 cm^{-1}, ν_{C-O-C} 1120 cm^{-1}; NMR ($CDCl_3$, δ) methylene protons, 3.65 (12H), 4.10 (2H), and 4.45 (2H); quinoline protons, 7.15 (1H), 7.40 (3H), 8.10 (1H), and 8.90 (1H).

4 (n=2) (5.13 g; 0.0173 mol) was treated with thiourea (1.45 g; 0.0190 mol) in 30 ml of ethanol at boiling temperature. The progress of the reaction was followed by a TLC method. After 40 h, the solution was epavorated to dryness and the remaining solid (**5** (n=2)) was dissolved in 100 ml of water and washed with chloroform. The aqueous solution was mixed with 20 ml of NaOH (0.69 g) solution and heated at 80 °C. After cooling the solution was adjusted to pH 6—7 with 0.1 M HCl and extracted with chloroform. The chloroform solution of $\mathbf{2}_{red}$(n=2) thus obtained was treated with I_2 to give $\mathbf{2}_{ox}$(n=2). $\mathbf{2}_{ox}$(n=2) was isolated by a preparative TLC method (silica gel and chloroform); oil, single spot on TLC, yield 43.5%. IR (neat) quinoline 1500 and 1600 cm^{-1}, ν_{C-O-C} 1120 cm^{-1}; M$^+$ (*m/z*) 584; NMR ($CDCl_3$, δ) methylene protons, 2.80 (2H), 3.65 (6H), 4.02 (2H), and 4.38 (2H); quinoline protons, 7.10 (1H), 7.36 (3H), 8.10 (1H), and 8.85 (1H). Found: C, 57.49; H, 6.33; N, 4.44; S, 10.16%. Calcd for $C_{30}H_{36}N_2O_6S_2\cdot3.35\,H_2O$: C, 57.46; H, 6.12; N, 4.47; S, 10.23%.

$\mathbf{2}_{ox}$(n=3) was similarly synthesized from **4**(n=3) *via* **5**(n=3) and $\mathbf{2}_{red}$(n=3); oil, single spot on TLC, yield 59.6%. IR (neat) quinoline 1500 and 1600 cm^{-1}, ν_{C-O-C} 1100 cm^{-1}; NMR ($CDCl_3$, δ) methylene protons, 2.90 (2H), 3.65 (10H), 4.10 (2H), and 4.45 (2H); quinoline protons, 7.18 (1H), 7.39 (3H), 8.10 (1H), and 8.92 (1H). Found: C, 59.82; H, 6.54; N, 4.01%. Calcd for $C_{34}H_{44}N_2O_8S_2$: C, 60.69; H, 6.59; N, 4.16%.

Solvent Extraction. The method of solvent extraction has been described in detail previously.[12-14] In this study, 5 ml of organic solution containing the ionophore was agitated with 5 ml of buffered aqueous solution containing alkali metal salts of 8-anilinonaphthalene-1-sulfonate (ANS). The extractability (Ex%) was estimated from the partition of ANS between the organic and the aqueous phase. Since the isolation of $\mathbf{2}_{red}$(n=2, 3) was extremely difficult, $\mathbf{2}_{red}$(n=2, 3) reduced from $\mathbf{2}_{ox}$(n=2, 3) with $Na_2S_2O_4$ was directly used for extraction. The extraction with $\mathbf{1}_{red}$ and $\mathbf{2}_{red}$(n=2, 3) was carried out under anaerobic (N_2) conditions. After determining Ex% the contents of $\mathbf{1}_{ox}$ or $\mathbf{2}_{ox}$(n=2, 3) formed during the extraction were evaluated by a TLC method using a high-speed TLC scanner (Shimadzu CS-920): usually the amounts of concomitant $\mathbf{1}_{ox}$ or $\mathbf{2}_{ox}$(n=2, 3) were negligible (less than 2%).

Membrane Transport. Transport of Na^+ and K^+ across a liquid (chloroform) membrane was carried out in a U-tube which consisted of two (IN and OUT) aqueous phases (10 ml each) and a membrane phase (40 ml). The membrane phase was stirred at a constant speed (180 rpm) and thermostated to 30 °C. The rates of K^+-transport were estimated from the absorption band of ANS (350 nm) in the OUT aqueous phase.

Results and Discussion

Comments on the Oxidation Methods. We have found that iodine is the most suitable to the oxidation of $\mathbf{2}_{rex}$ to $\mathbf{2}_{ox}$ because the reaction is very fast and occurs under mild conditions. Furthermore, the progress of the reaction can be monitored by the color change. However, it turned out to be rather unsuitable to the oxidation of $\mathbf{1}_{red}$ to $\mathbf{1}_{ox}$ because the intermolecular disulfide formation significantly competed with the intramolecular one. The TLC analysis showed that the oxidation of $\mathbf{1}_{red}$(3.36×10^{-4} mol) by iodine in 50 ml of chloroform gave mainly the polymeric products and $\mathbf{1}_{ox}$ was a minor product. We attempted the isolation of $\mathbf{1}_{ox}$ by preparative TLC but the isolated product was always contaminated with some unknown materials

TABLE 1. EXTRACTION OF ALKALI METAL SALTS OF ANS WITH $\mathbf{1}_{red}$ AND $\mathbf{1}_{ox}$ AND THEIR ASSOCIATION CONSTANTS (K_c)[a]

Ionophore	Metal	Ex%	$K_e \cdot 10^{-3}/M^{-2}$ [b]	K_c/M^{-1} [c]
$\mathbf{1}_{red}$	Na^+	39.9	3.59	756
	K^+	39.0	3.95	697
	Rb^+	31.6	2.89	416
	Cs^+	26.5	2.92	284
$\mathbf{1}_{ox}$	Na^+	40.2	3.66	771
	K^+	53.3	12.8	2250
	Rb^+	46.7	9.55	1370
	Cs^+	35.6	6.53	635

a) 30°C. Organic phase: [$\mathbf{1}_{red}$ or $\mathbf{1}_{ox}$]=4.00×10^{-3}M in *o*-dichlorobenzene: 1-butanol=80:20 by volume. Aqueous phase: pH 4.0 with MOH(0.010 M)-H_3PO_4, [MCl]=0.10 M, [ANS]=5.00×10^{-5}M. b) K_e=[$M^+A^- \cdot \mathbf{1}^*$]/[$M^+$][$A^-$][$\mathbf{1}^*$] where the asterisk and A^- refer to the species in the organic phase and the counteranion, respectively. c) K_c=[$M^+A^- \cdot \mathbf{1}^*$]/[MA*][$\mathbf{1}^*$]=$K_e/K_d$ where K_d=[MA*]/[M^+][A^-].

(probably oligomeric oxidation products).

On the other hand, O_2-oxidation of $\mathbf{1}_{red}$ in the presence of KOH gave $\mathbf{1}_{ox}$ as a main product, although the reaction was not so fast. Pure $\mathbf{1}_{ox}$ could be isolated without using the preparative TLC method. As a control experiment, we oxidized $\mathbf{1}_{red}$ by O_2 in the presence of triethylamine. Although the main product was still $\mathbf{1}_{ox}$, a considerable amount of the polymeric products was formed. These results suggest that the "template effect" of K^+ which facilitates the intramolecular disulfide formation may be operative on the oxidation process.

Solvent Extraction of Alkali Metal Cations. The binding ability of $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$ was estimated by solvent extraction of alkali metal salts of 8-anilinonaphthalene-1-sulfonate (ANS) from water to the organic phase (*o*-dichlorobenzene: 1-butanol=80:20 by volume). Alkali picrates which are frequently used for solvent extraction were not employed in the present study, because the oxidative nature of picrate ion is unfavorable to the redox treatment of the ionophores. The extractability(Ex%) was estimated by the partition of ANS between the aqueous and the organic phases. The pH of the aqueous phase was buffered to 4.0 where ANS is fully dissociated while the thiol groups of $\mathbf{1}_{red}$ are undissociated. We confirmed that both $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$ do not leak into the aqueous phase under the extraction conditions. The results are summarized in Table 1.

Examination of Table 1 reveals that (i) $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$ have the similar Ex% values for Na^+, (ii) $\mathbf{1}_{ox}$ is capable of extracting K^+, Rb^+, and Cs^+ more efficiently than $\mathbf{1}_{red}$ and (iii) the maximum Ex% is observed for the extraction of K^+ with $\mathbf{1}_{ox}$. The inspection of CPK model of $\mathbf{1}_{ox}$ suggests that two phenolic oxygens can be directed towards the crown ring, indicating the coordination ability to metal ions complexed in the crown ring. However, the oxygens are apparently far from the crown ring plane as compared with those of crypt- and 222 which exhibits a high affinity with Na^+ and K^+.[2] The expansion of the intramolecular cavity of $\mathbf{1}_{ox}$ is due to six atoms (two sulfurs and four carbons) present between the two oxygens in the disulfide cap. Conceivably, small Na^+ is deeply bound to the diaza-18-crown-6 ring, so that the two oxygens are too far to coordinate to the complexed Na^+ ion. In contrast, other alkali metal ions with relatively large ion-radii would be able to interact with the oxygens owing to the shallow-binding to the crown ring. The situation would be well expressed by "K^+ (Rb^+ and Cs^+ also) perches on the crown ring whereas Na^+ nests in it."[15]

According to the established procedure,[16-18] we estimated K_e (extraction equilibrium constants) and K_c(complexation contants). The results in Table 1 indicate again that the K_c values of $\mathbf{1}_{ox}$ for K^+, Rb^+, and Cs^+ are greater by 2—3 fold than those of $\mathbf{1}_{red}$, whereas there is no difference in the K_c for Na^+. Conceivably, $\mathbf{1}_{ox}$ is expected to act as a cryptand analogue, whereas $\mathbf{1}_{red}$ is a simple crown ether (or at most, a lariat-type crown ether).[19,20]

The absolute K_c values in Table 1 are smaller by about two orders of magnitude than those of conventional 18-crown-6 analogues.[2-4] This is due to the two amide nitrogens present in the diaza-18-crown-6 ring. We thus attempted to reduce the carbonyls in $\mathbf{1}_{red}$ to the methylene groups with B_2H_6 or $LiAlH_4$. Although we confirmed the disappearance of the carbonyls with IR, the isolation was very difficult and unsuccessful.

The redox scheme for the interconversion between $\mathbf{2}_{red}$ and $\mathbf{2}_{ox}$ can be more simplified, because one need not take the competition between intra- and intermolecular oxidations into account. The results of solvent extraction between water and chloroform are summarized in Table 2. Neither $\mathbf{2}_{red}$ nor $\mathbf{2}_{ox}$ leaked into the aqueous phase under the extraction conditions. Unfortunately, the partition of ANS to the chloroform phase was so small that we could not determine the K_d values (see footnote c to Table 1) accurately. Therefore, we determined Ex% and K_e and summarized in Table 2.

It is seen from Table 2 that (i) $\mathbf{2}_{red}(n=2)$ and $\mathbf{2}_{ox}(n=2)$ have the highest selectivity towards Na^+ while $\mathbf{2}_{red}(n=3)$ and $\mathbf{2}_{ox}(n=3)$ show the highest selectivity towards K^+ (ii) when comparing the $n=2$ series with the $n=3$ series, there is little difference in Ex% for Na^+, but Ex%'s of the $n=3$ series for K^+, Rb^+, and Cs^+ are significantly higher than those of the $n=2$ series, and (iii) most importantly, Ex%'s of $\mathbf{2}_{ox}$ are higher than $\mathbf{2}_{red}$, indicating the cooperative ion-binding by two chains of $\mathbf{2}_{ox}$. It is well known that acyclic polyethers have a relatively good ion-selectivity like cyclic polyethers.[6-11] The selectivity is particularly associated with the length of the poly(oxyethylene) chain. For example, Hiratani *et al.*[7,8] demonstrated that **6** and **7** exhibit the selectivity for Li^+ and Na^+, respectively. $\mathbf{2}_{red}(n=2)$ and $\mathbf{2}_{red}(n=3)$ which have the chain length similar to **6** and

TABLE 2. EXTRACTION OF ALKALI METAL SALTS OF ANS WITH $2_{red}(n=2, 3)$ AND $2_{ox}(n=2, 3)$ AND THEIR EXTRACTION EQUILBRIUM CONNSTANTS (K_e)[a]

Ionophore	Metal	Ex%	K_e·[b]/M^{-2}
$2_{red}(n=2)$	Li^+	4.7	16.5

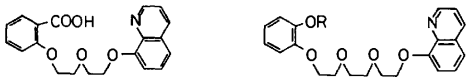
	Rb^+	9.9	36.8
	Cs^+	5.9	21.0
$2_{ox}(n=3)$	Na^+	13.3	105(52.5)
	K^+	15.6	125(61.7)
	Rb^+	12.8	100(50.1)
	Cs^+	10.8	81.6(40.7)

a) 30°C. Organic phase: $[2_{red}(n=2, 3)]=2[2_{ox}(n=2, 3)]=1.00\times10^{-2}$ M in chloroform. Aqueous phase: pH 6.0 with MOH(0.010 M)-H_3PO_4, [MCl]=0.29 M, $[ANS]=5.00\times10^{-4}$ M. b) $K_e=[M^+A^-\cdot\mathbf{2}^*]/[M^+][A^-][\mathbf{2}^*]$. The values in the parenthesis are obtained by the same equation on the basis that one quinoline chain corresponds to one ligand (*i.e.*, [ligand]=2[**2**]).



6 7

7, repectively, showed the ion-selectivity towards Na^+ and K^+, respectively. This implies that the maximum selectivity of $2_{red}(n=2)$ and $2_{red}(n=3)$ shifts a little to the larger metal cations. According to Hiratani *et al.*,[7,8] the pseudo-cyclic structures from **6** and **7** are formed so that the terminal benzene and quinoline can overlap each other. Such a stacking association of the aromatic terminal groups cannot be expected for 2_{red}. Conceivably, the sizes of the psuedo-cyclic structures of 2_{red} are somewhat greater than those of corresponding **6** and **7**.

The extraction data showed that Ex%'s of 2_{ox} are significantly greater than those of 2_{red}, indicating that the two chains in 2_{ox} act cooperatively on metal-binding. On the other hand, the ion-selectivities of 2_{ox} are similar to those of 2_{red}, indicating that the two chains in 2_{ox} would act rather independently. The apparently incompatible results may be rationalized in terms of the peculiar conformation of the central disulfide linkage. The azimuthal angle in the lowest energy conformation of diethyl disulfide is considered to be 90°, although the bulky substituents may enlarge the angle.[21] It is unconceivable, therefore, that the two chains in 2_{ox} enjoy the coplanarity around a metal ion. Probably, 2_{ox} wraps a metal cation by forming a helical structure. In fact, several podands having the coordinative terminal groups adopt helical structures to bind metal ions,[6-8,10] and the azimuthal angle of the central disulfide linkage would be rather advantageous to the helical structure. If one accepts the hypothesis, one can elucidate the enhanced Ex%'s of 2_{ox} relative to 2_{red} as well as the unchanged ion-selectivities. To obtain evidence for this, we took the NMR spectra of 2_{ox} in the presence of K^+ and Rb^+, but could not detect the appreciable change in chemical shifts probably because of the low association abilities.

TABLE 3. RATES (k) OF ION TRANSPORT THROUGH A LIQUID MEMBRANE (30°C)[a]

Run	Metal	Carrier	Transport rate / 10^{-6} mol h^{-1}
1	Na^+	$2_{red}(n=2)$	0.07
2	Na^+	$2_{ox}(n=2)$	0.09
3	Na^+	$2_{red}(n=3)$	0.06
4	Na^+	$2_{ox}(n=3)$	0.20
5	K^+	$2_{red}(n=2)$	0.10
6	K^+	$2_{ox}(n=2)$	0.18
7	K^+	$2_{red}(n=3)$	0.12
8	K^+	$2_{ox}(n=3)$	0.50
9[b]	K^+	$2_{red}(n=3)\rightarrow2_{ox}(n=3)$	0.10→0.75

a) In aqueous phase (10 ml): [MCl]=0.290 M, pH 6.0 with MOH (0.010 M)-H_3PO_4(0.011 M), $[ANS]=5.00\times10^{-3}$ M. OUT aqueous phase (10 ml): water. Membrane phase (40 ml $CHCl_3$): $[2_{red}]=2[2_{ox}]=2.00\times10^{-3}$ M. b) In order to suppress the pH change in the IN aqueous phase by added I_2 the buffer concentration is enhanced while $[K^+]$ is constant: [MCl]=0.100 M, pH 6.0 with MOH (0.200 M)-H_3PO_4 (0.114 M), $[ANS]=5.00\times10^{-3}$ M.

Ion-Transport across a Liquid Membrane. Various kinds of chemical and physical phenomena have been utilized to increase the rate of ion transport through membranes: redox energies,[22,23] light energies,[13,14,24-27] countercurrent of metal cations,[28] pH-dependent lactone cyclization,[29] *etc.*[30] Some of these systems have been applied to active transport. To the best of our knowledge, however, there exists no precedent for the ion-transport mediated by the redox interconversion of ionophores such as **1** or **2**.[31] We here demonstrate that the ion-transport rate can be changed by the redox interconversion between 2_{red} and 2_{ox}.

Table 3 shows the rates of Na^+ or K^+ transport across a liquid (chloroform) membrane. The leak of the metal ions was not detected in the absence of **2**. For $2_{red}(n=2)$ and $2_{ox}(n=2)$, the rates of Na^+ transport are similar but the rate of K^+ transport with $2_{red}(n=2)$ is significantly higher than that with 2_{red} $(n=2)$. The results are well compatible with the extraction data in Table 2: for example, Ex% of Na^+ with $2_{ox}(n=2)$(11.9%) is close to that with $2_{red}(n=2)$(8.1%), whereas Ex% of K^+ with $2_{ox}(n=2)$(11.0%) is more than two times greater than that with $2_{red}(n=2)$(4.8%). A similar trend was observed for the transport with $2_{red}(n=3)$ and $2_{ox}(n=3)$: that is $2_{ox}(n=3)$ exhibits the transport ability higher than $2_{red}(n=3)$. Figure 1 shows the plot of Ex% against the rate of ion-transport. It is clearly seen from Fig. 1 that the higher is the Ex%, the faster is the ion-transport rate. One can conclude on the basis of this fact that the ion-extraction step from the IN aqueous phase to the membrane phase, but not the ion-release step from the membrane phase to the OUT aqueous phase, is totally rate-determining.

The largest rate increase was observed for K^+ transport with $2_{ox}(n=3)/2_{red}(n=3)$(4.2-fold). We thus con-

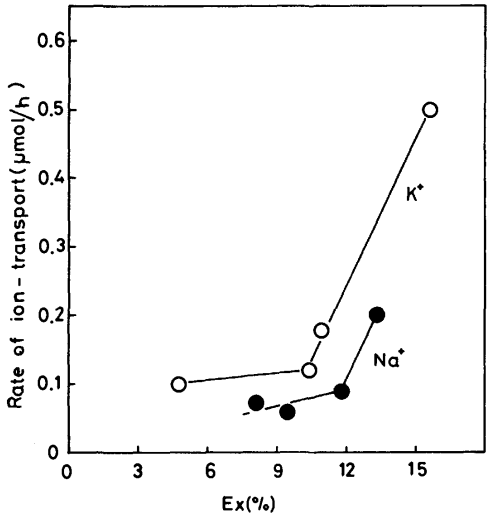


Fig. 1. Plots of rate of ion-transport *vs.* Ex%.

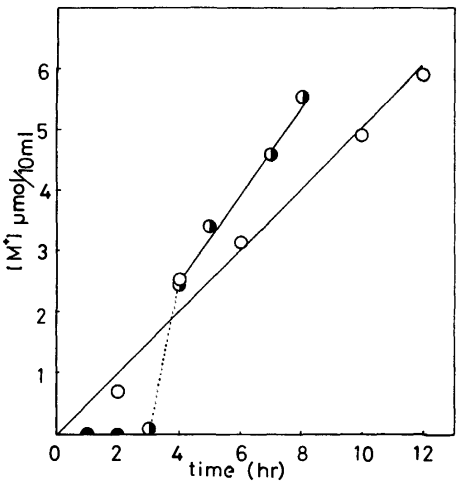

Fig. 2. Transport of K^+ across a liquid (chloroform) membrane. ○ with $\mathbf{2}_{ox}$ (n=3) (run 8 in Table 3); ●→◑ transport was started with $\mathbf{2}_{red}$ (n=3) and I_2 was added after 2 h (run 9 in Table 3).

ducted the "redox-switched" experiment with this combination. K^+ transport was started with $\mathbf{2}_{red}$ (n=3) as a carrier in the membrane phase, and iodine([I_2]= 0.5 [$\mathbf{2}_{red}$(n=3)] was added to the membrane phase after 2 h. As illustrated in Fig. 2, the rate of K^+ transport was enhanced to 7.5×10^{-7} mol h^{-1} from 1.0×10^{-7} mol h^{-1} after an induction period (about 1 h). In a separate study, we corroborated that $\mathbf{2}_{red}$(n=3) has been oxidized to $\mathbf{2}_{ox}$ (n=3) within 1 h in the membrane and that K^+ is not transported through the chloroform membrane containing only iodine. Therefore, the marked rate increase can be ascribed to the production of the capable ion-carrier (*i.e.*, $\mathbf{2}_{ox}$(n=3)) in the membrane phase by treatment with the oxidizing agent. The induction period after I_2 addition is ascribed either to the oxidation time of $\mathbf{2}_{red}$ to $\mathbf{2}_{ox}$ or to the diffusion of K^+ across the liquid membrane. The slightly greater transport rate after the oxidation relative to that with $\mathbf{2}_{ox}$ is probably due to the change in the buffer concentration. We also attempted the reverse control of K^+ transport by reducing $\mathbf{2}_{ox}$(n=3) to $\mathbf{2}_{red}$(n=3) by tributylphosphine (0.01 M=10[$\mathbf{2}_{ox}$(n=3)]). Although $\mathbf{2}_{ox}$(n=3) was reduced to $\mathbf{2}_{red}$(n=3) in 1.5 h, the K^+ increase in the OUT aqueous phase was scarcely affected for 4 h after the addition of tributylphosphine. The membrane phase contained a significant amount of K^+ extracted with $\mathbf{2}_{ox}$(n=3) before tributylphosphine addition. Conceivably, the K^+ ion was released gradually to the OUT aqueous phase even after $\mathbf{2}_{ox}$(n=3) being reduced to $\mathbf{2}_{red}$(n=3). At present, we consider that the "volume" of the membrane phase must be considerably reduced in order to achieve the rapid response of the reverse control.

Ion transport using the interconversion between $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$ may be also interesting. In this case, however, one has to pay additional attention to intra- *versus* intermolecular oxidation of $\mathbf{1}_{red}$ in the membrane phase. In addition, the difference in K_c values is not large enough to attain the efficient control of ion-transport by redox-switch. We thus did not perform the ion-transport with $\mathbf{1}_{red}$ and $\mathbf{1}_{ox}$.

Conclusions. The present system demonstrated that the ion-binding ability of redox-functionalized ionophores can be changed by the treatment with redox reagents. This is directly applicable to the control of ion transport across membranes. The novel phenomenon becomes possible because these synthetic ionophores have within the molecule both a redox-functional group and an ionophilic site. Although the framework of the present "redox-switched" functions must be further improved, we expect that this concept might be applied more generally to the control of the chemical and physical functions of synthetic ionophores by the redox energy source.

We thank Professor K. Sasaki and Dr. A. Kunai for helpful discussions. We are indebted to Miss T. Yamamichi for technical assistance.

Phosphinyl- and Phosphinothioylamino Acids and Peptides. VIII. New Practical Removal Conditions for the *S*-Mpt Group and their Application for the Synthesis of Bis[*N,N*-diallyl-[D-Ala^2, L-Leu^5]-enkephalyl]cystine

Masaaki UEKI* and Kozo SHINOZAKI

Department of Applied Chemistry, Science University of Tokyo, 1-3 Kagurazaka, Shinjuku-ku, Tokyo 162

(Received January 10, 1984)

Synthesis of bis[*N,N*-diallyl-[D-Ala^2, L-Leu^5]-enkephalyl]cystine, which is expected to be a selective opioid δ-receptor antagonist, was studied. The mercapto group of cysteine was protected by the dimethylphosphinothioyl(Mpt) group. For the removal of this group without damaging the allyl moiety, new mild removal conditions by use of KF/18-crown-6 in a solvent mixture of acetonitrile-methanol are proposed. Bis[D-Ala^2, L-Leu^5]-enkephalyl]cystine was also prepared in a similar manner.

Since the discovery of enkephalins by Hughes and Kosterlitz,[1] chemistry and biochemistry of opioid peptides have attracted the attention of many reseachers. Many analogs and derivatives have been prepared in order to develop more potent, more selective and metabolically stable ligands and also to explain the structure-activity relationship and drug-receptor interactions.[2] Of these, *N,N*-diallyl-[L-Leu^5]-enkephalin methyl ester (ICI 139462, **1**) and its metabolically more stable analog (ICI 154129, **2**) are of special interest because they showed selective antagonistic activity toward the δ-receptor, but their affinity was not sufficiently high.[3] Another interesting recent finding is that a dimeric enkephalin **3** has increased affinity and selectivity for the δ-receptor as compared with the corresponding monomer.[4] We have tried to synthesize *N,N*-diallyl-[D-Ala^2, L-Leu^5]-enkephalin dimerized at extended *C*-terminal cystine **4**. This paper describes the synthetic procedures.

[$(CH_2{=}CHCH_2)_2$L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys-OH]$_2$ **4**

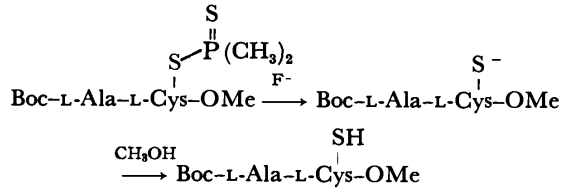
Results and Discussion

In planning the synthesis of **4**, selection of a mercapto protecting group was important. Various kinds of protecting groups for the cysteine mercapto function are now available; most of these require liquid HF or heavy metal ions for removal.[5] In the latter case, cysteine-containing peptides are generated from their thiolates by treatment with thiols. Removal conditions that may damage the double bond of the allyl group should be avoided.

Recently, we found that diphenylphosphinothioyl (Ppt)[6] and dimethylphosphinothioyl (Mpt)[7] groups, which are removed by treatment with an aqueous alkali or $AgNO_3$ solution, could be used for the protection of the mercapto group of cysteine. Independently, Horner *et al.*[8] also reported the use of the Ppt group for the same purpose and recommended its removal by unsolvated fluoride ions in dichloromethane, chloroform or tetrahydrofuran. This removal method seemed to be attractive, but it was not shown whether more polar solvents, which dissolve large peptide molecules, could also be used. We have investigated solvent effects in the removal reactions of the *S*-phosphinothioyl groups by fluoride ions.

As a preliminary experiment, a comparison was made between Mpt and Ppt groups. When 2 equivalents of tetrabutylammonium fluoride trihydrate (**5**) were added at 30 °C to a solution of Boc-L-Ala-L-Cys(Mpt)-OMe (**6**) in dichloromethane the *S*-Mpt group was cleaved instantaneously. However, removal of the *S*-Ppt group of Boc-L-Ala-L-Cys(Ppt)-OMe in the same manner took about 15 min. Based on these results, further studies were made by use of compound **6**, which carries the *S*-Mpt group. As a source of fluoride ions, KF in the presence of an equimolar amount of 18-crown-6 was also used because tetrabutylammonium fluoride trihydrate was too hygroscopic. All results are summarized in the Table 1.

The removal of the *S*-Mpt group by **5** was almost instantaneous in all aprotic solvents examined. The deprotection by KF/18-crown-6 also took place rapidly. On the contrary, the reaction in methanol was slow because of solvation of fluoride ions. Since methanol is a good solvent for large peptides, we tried the use of methanol by mixing with acetonitrile or dichloromethane and found that these mixed solvents were effective for this reaction up to the methanol content of 50%. In these solvent mixtures, no difference of cleaving abilities of tetrabutylammonium fluoride and KF-crown ether was observed. It was also noted that methanol protonated rapidly to yield the thiol form product. From these results it was concluded that the *S*-Mpt group would be useful for the synthesis of large peptides containing cysteine or cystine.



As the first application of the *S*-Mpt group involving the new removal conditions, synthesis of bis[*N,N*-diallyl-[D-Ala^2, L-Leu^5]-enkephalyl]cystine (**4**) was performed according to the scheme illustrated in Fig. 1

TABLE 1. SOLVENT EFFECTS IN REMOVAL OF *S*-PHOSPHINOTHIOYL GROUPS BY FLUORIDE IONS

Compound	Solvent	Time for complete removal (at 30°C) KF/18-crown-6	$(n\text{-}C_4H_9)_4N^+F^-$

* Tetrahydrofuran

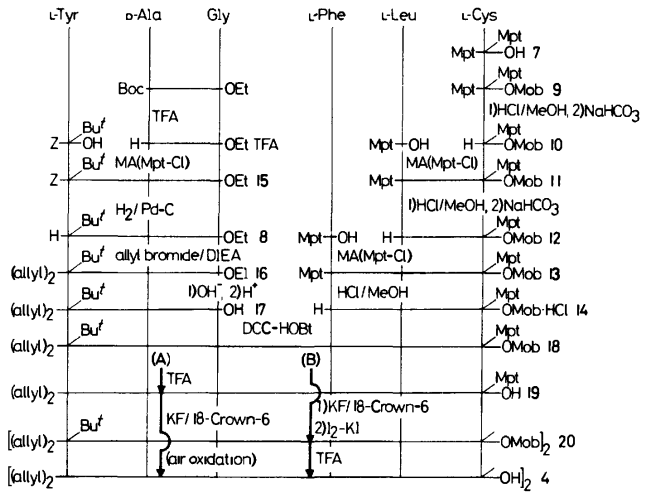

Fig. 1. Synthesis of Bis[*N*,*N*-diallyl-[D-Ala^2, L-Leu^5]-enkephalyl]cystine.

Synthesis was made by the classical method, starting with *N*,*S*-bis(Mpt)-L-cysteine (**7**).[7] **7** was esterified with *p*-methoxybenzyl alcohol in a 87% yield by use of 2 equivalents of *N*-(dimethylphosphinothioyl)imidazole.[9] From the *N*, *S*-bis-Mpt cysteine *p*-methoxybenzyl ester thus obtained, the *N*-Mpt group was selectively removed by treating with 0.4 M† HCl in methanol (3 equiv) at room temperature overnight. Succeeding couplings were performed by the Mpt-mixed anhydride method.[10] This method would allow incorporation of tyrosine moiety without protecting its phenolic hydroxyl group, but in this synthesis *t*-butyl group was introduced as a protecting group in order to avoid *O*-allylation in an *N*-allylation step. For the *N*-allylation, *N*-terminal tripeptide ester **8** was treated with excess allyl bromide in the presence of *N*,*N*-diisopropylethylamine in chloroform at room temperature for 2 d. After hydrolysis of the ethyl ester, *N*,*N*-diallyltripeptide acid **17** was coupled with *C*-terminal tripeptide ester **14** by the dicyclohexylcarbodiimide (DCC)-1-hydroxybenzotriazole (HOBt) method[11] to give protected, *N*,*N*-diallylhexapeptide ester **18** in a yield of 68%.

† 1 M=1 mol dm^{-3}.

Final deprotection required two steps: Treatment with trifluoroacetic acid (TFA) to cleave the *t*-butyl ether and *p*-methoxybenzyl ester bonds and treatment with KF/18-crown-6 to remove the *S*-Mpt group. When the *S*-Mpt group was removed at the first step, the removal conditions determined in the model experiments were effective, except that a somewhat longer reaction time (9 h) was required. After oxidation by iodine and final deprotection by TFA, the desired compound **4** was obtained. But in this case, purification by preparative thin-layer chromatography and gel chromatography in Sephadex LH-20 failed to give completely pure material, probably because of incomplete deprotection by TFA.

On the other hand, when the removal of the *S*-Mpt was performed at the final step, some difficulty was encountered, probably because the *S*-Mpt group was blocked conformationally. But when the excess reagents (10 equiv KF+4 equiv 18-crown-6) were used at higher temperature (50 °C), the removal was complete after 10 h. During these procedures, air oxidation of the product occurred to give **4** directly; this could be purified by preparative silica-gel thin-layer chromatography and gel chromatography on Sephadex LH-20.

Based on the success in the synthesis of **4**, we also prepared bis[D-Ala^2, L-Leu^5]-enkephalyl]cystine with free *N*-terminals in order to determine the effects of *N*-allylation on the pharmacological activity. In this case tyrosine was incorporated without protecting its phenolic hydroxyl group. Again, a better result was obtained when the *S*-Mpt group was removed before removal of *N*- and *C*-terminal protecting groups by TFA.

As expected, the compound **4** showed selective antagonistic activity toward the opioid δ-receptor. Additionally, the compound **4** was found to be approximately ten-fold more effective than ICI 154129 in antagonizing the δ-receptor agonists. Thus, as far as we know, the compound **4** seems to be the most potent δ antagonist.

Experimental

Thin-layer chromatography (TLC) was performed on

silica gel plates (Merck 60F_{254}) in the following solvent systems: Ether (R_f^1), ethyl acetate (R_f^2), chloroform-methanol (9:1, R_f^3), chloroform-methanol-acetic acid (95:5:3, R_f^4), chloroform-methanol-acetic acid (85:25:20, R_f^5), chloroform-methanol-water (65:25:4, R_f^6), chloroform-methanol -29% aqueous ammonia (60:30:5, R_f^7), 1-butanol-acetic acid-water (4:1:1, R_f^8).

N,S-*Bis(dimethylphosphinothioyl)*-L-*cysteine* p-*Methoxybenzyl Ester (Mpt*-L-*Cys(Mpt)*-*OMob) (9).* To a cooled solution of Mpt-L-Cys(Mpt)-OH[7] (1.53 g, 5 mmol) and *p*-methoxybenzyl alcohol (0.62 cm³, 5 mmol) in *N,N*-dimethylformamide (1 cm³) and chloroform (15 cm³), *N*-Mpt-imidazole (1.60 g, 10 mmol) was added; the solution was stirred at 0 °C for 4.5 h and at room temperature overnight. After removal of precipitates by filtration, the filtrate was evaporated *in vacuo*. The residue was dissolved in ethyl acetate. The solution was washed successively with water, an ice-cold 5% citric acid solution, water, a 5% sodium hydrogencarbonate solution, water, and a saturated sodium chloride solution, dried over anhydrous sodium sulfate, and evaporated. The oily residue was dissolved in dichloromethane and placed in a silica-gel column (2.5×37 cm). Elution with ether gave **9** as colorless oil; 1.86 g (87%). $[\alpha]_D^{26}$−5.12 ° (*c* 1, methanol); R_f^1 0.54, R_f^2 0.68. Found: C, 42.35; H, 5.93; N, 3.27; P, 14.49%. Calcd for $C_{15}H_{25}NO_3P_2S_3$: C, 42.34; H, 5.91; N, 3.29; P, 14.56%.

S-*Dimethylphosphinothioyl*-L-*cysteine* p-*Methoxybenzyl Ester Hydrochloride (H*-L-*Cys(Mpt)*-*OMob*·*HCl) (10*·*HCl).* Compound **9** (1.86 g, 4.37 mmol) was stirred with 0.4 M HCl in methanol (32.8 cm³) at 0 °C for 1 h and the mixture was kept standing at room temperature overnight. The solvent was evaporated *in vacuo* and the residue was triturated with ether. Crystalline precipitates were collected by filtration, washed with ether, and dried over P_2O_5; 1.56 g (95%). The sample was once changed to the free amine form and again precipitated from 3 M HCl in ethyl acetate (1.38 cm³); 1.17 g (72%). An analytical sample was recrystallized from hot methanol; mp 136—137 °C (decomp); $[\alpha]_D^{26}$+3.52 ° (*c* 1, methanol); R_f^4 0.23, R_f^5 0.64. Found: C, 42.38; H, 5.72; N, 3.79; P, 8.22%. Calcd for $C_{13}H_{21}NO_3PS_2Cl$: C, 42.22; H, 5.72; N, 3.79, P, 8.37%. This salt was dissolved in water and neutralized with sodium hydrogencarbonate. The solution was extracted with ethyl acetate several times. The extracts were dried and evaporated to give the free base **10** as colorless oil.

N-*Dimethylphosphinothioyl*-L-*leucyl*-S-*dimethylphosphinothioyl*-L-*cysteine* p-*Methoxybenzyl Ester (Mpt*-L-*Leu*-L-*Cys(Mpt)*-*OMob) (11).* Mpt-L-Leu-OH·DCHA[12] (1.16 g, 2.87 mmol) was dissolved in chloroform (3 cm³) and treated with Mpt-Cl (0.369 g, 2.87 mmol) at 0 °C for 40 min. To this **10** (0.957 g, 2.87 mmol) and *N,N*-diisopropylethylamine (0.50 cm³, 2.87 mmol) in chloroform (3 cm³) were added and the solution was stirred at 0 °C for 1 h. After the usual washing procedures,the product was obtained by silica-gel column chromatography as a colorless oil; 1.35 g (87%). $[\alpha]_D^{25}$−59.3 ° (*c* 1, methanol); R_f^2 0.30, R_f^3 0.67. Found: C, 46.63; H, 6.76; N, 5.15; P, 11.49%. Calcd for $C_{21}H_{36}N_2O_4P_2S_3$: C, 46.83; H, 6.74; N, 5.20; P, 11.50%.

L-*Leucyl*-S-*dimethylphosphinothioyl*-L-*cysteine* p-*Methoxybenzyl Ester (H*-L-*Leu*-L-*Cys(Mpt)*-*OMob) (12).* The Mpt group of **11** (1.23 g, 2.28 mmmol) was removed by 0.4 M HCl in methanol (28.8 cm³). After evaporation of the solvent, ether and water were added to the residue. The ether layer was separated and washed with water. The water layer and extracts were gathered, neutralized with sodium hydrogen-carbonate and extracted with ether. The extracts were dried over anhydrous sodium sulfate and evaporated to give a colorless oil; 0.967 g (95%).

N-Dimethylphosphinothioyl-L-*phenylalanyl*-L-*leucyl*-S-*dimethylphosphinothioyl*-L-*cysteine* p-*Methoxybenzyl Ester (Mpt*-L-*Phe*-L-*Leu*-L-*Cys(Mpt)*-*OMob) (13).* Mpt-L-Phe-OH·DCHA[12] (1.035 g, 2.36 mmol) was dissolved in chloroform (5 cm³) and treated with Mpt-Cl (0.303 g, 2.36 mmol) at 0 °C for 1 h. To this a solution of **12** (1.05 g, 2.36 mmol) and *N,N*-diisopropylethylamine (0.41 cm³, 2.36 mmol) in chloroform (3 cm³) was added. The solution was stirred at 0 °C for 1 h and then evaporated *in vacuo*. After the usual washing procedures the product was obtained by silica-gel column chromatography eluted by chloroform-methanol (98:2). Pure materials were obtained by recrystallization from ethyl acetate-ether as colorless crystals; 1.30 g (79%). $[\alpha]_D^{26}$−60.4 ° (*c* 1, methanol); R_f^1 0.18, R_f^2 0.67. Found: C, 52.21; H, 6.60; N, 6.11; P; 8.73%. Calcd for $C_{30}H_{45}N_3O_5P_2S_3 \cdot 1/2H_2O$: C, 52.08; H, 6.65; N, 6.07; P, 8.82%.

L-*Phenylalanyl*-L-*leucyl*-S-*dimethylphosphinothioyl*-L-*cysteine* p-*Methoxybenzyl Ester Hydrochloride (H*-L-*Phe*-L-*Leu*-L-*Cys(Mpt)*-*OMob. HCl) (14).* Compound **13** (1.43 g, 2.09 mmol) was stirred with 0.4 M HCl in methanol (15.7 cm³) at 0 °C for 1 h and the mixture was kept standing at room temperature overnight. The solvent was evaporated *in vacuo* and the residue was triturated with ether. Crystalline precipitates were collected by filtration, washed with ether and ethyl acetate and dried over P_2O_5; 1.089 g (82%). R_f^4 0.07, R_f^5 0.74.

N-*Benzyloxycarbonyl*-O-t-*butyl*-L-*tyrosyl*-D-*alanylglycine Ethyl Ester (Z*-L-*Tyr(Bu^t)*-D-*Ala*-*Gly*-*OEt) (15).* Mpt-Cl (0.257 g, 2 mmol) was added to an ice-cold stirred solution of Z-L-Tyr(Bu^t)-OH·DCHA[13] (1.105 g, 2 mmol) in chloroform (4 cm³), after which the mixture was stirred for 1 h. To this solution, a mixture of TFA·H-D-Ala-Gly-OEt (0.576 g, 2 mmol) and triethylamine (0.56 cm³, 4 mmol) in chloroform (2 cm³) and *N,N*-dimethylformamide (2 cm³) was added in several portions at 0 °C. After having been stirred at this temperature for 1 h, the solution was washed in the usual way, dried and evaporated *in vacuo*. The oily residue was dissolved in dichloromethane and placed in a silica-gel column (1.1×12 cm). Elution with ether gave **15** as a colorless oil; 0.899 g (85%).

N,N-*Diallyl*-O-t-*butyl*-L-*tyrosyl*-D-*alanylglycine Ethyl Ester ((allyl)$_2$*-L-*Tyr(Bu^t)*-D-*Ala*-*Gly*-*OEt) (16).* A mixture of **15** (0.899 g, 1.70 mmol), 10% palladium-charcoal (0.42 g), cyclohexene (15 cm³), and ethanol (30 cm³) was refluxed for 7 h. After removal of the catalyst by filtration the filtrate was evaporated *in vacuo*. The oily residue was dissolved in chloroform (15 cm³) and *N,N*-diisopropylethylamine (1.05 cm³, 6 mmol) and cooled to 0 °C. To this solution allyl bromide (8.65 cm³, 100 mmol) was added drop by drop over a period of 30 min at this temperature and the solution stirred at room temperature for 2 d. The solution was evaporated and the oily residue was shaken with ethyl acetate and water. The organic layer was separated and washed with water, a 5% sodium hydrogencarbonate solution, water and a saturated sodium chloride solution, dried over anhydrous sodium sulfate, and evaporated. The oily residue was purified by preparative silica-gel thin-layer chromatography using ether as a developing solvent. From the desired band (R_f=0.4—0.6) compound **15** was obtained as colorless oil; 0.544 g (67%). An analytical sample was obtained by rechromatography on Sephadex LH-20 (1.9×100 cm) eluted with methanol. The desired fractions were collected and evaported *in vacuo* to give **16** as colorless oil; 0.544 g (67%). $[\alpha]_D^{26}$−18.4 ° (*c* 1, methanol); R_f^2 0.45, R_f^3 0.49. Found: C, 65.92; H, 8.46; N, 8.82%. Calcd for $C_{26}H_{39}N_3O_5$: C, 65.94; H, 8.32; N, 8.87%.

N,N-*Diallyl*-O-t-*butyl*-L-*tyrosyl*-D-*alanylglycyl*-L-*phenylalanyl*-L-*leucyl*-S-*dimethylphosphinothioyl*-L-*cysteine* p-*Methoxybenzyl Ester ((allyl)$_2$*-L-*Tyr(Bu^t)*-D-*Ala*-*Gly*-L-*Phe*-L-*Leu*-L-*Cys(Mpt)*-*OMob) (18).* Compound **16** (0.492 g, 1.04 mmol) was dissolved in methanol (3 cm³). To this a 1 M aqueous NaOH solution (1.23 cm³) was added at 0 °C. After the solution had been stirred at this temperature for 30 min

and at room temperature overnight, methanol was removed *in vacuo*. The resulting solution was acidified to pH 4 by acetic acid at 0 °C. To this,Diaion HP-20 resin was added until no spot corresponding to (allyl)$_2$-L-Tyr(Bu^t)-D-Ala-Gly-OH (**17**) was detectable on TLC. The resin was filtered and washed with water until the filtrate became neutral. Elution of **16** was performed by methanol to give an amorphous solid: 0.448 g (100%).

To a suspension of **17** (0.298 g, 0.669 mmol) in chloroform (2 cm^3) and dissolved *N,N*-diisopropylethylamine (0.117 cm^3, 0.669 mmol) and **14** (0.442 g, 0.669 mmol), dicyclohexylcarbodiimide (0.138 g, 0.669 mmol) and 1-hydroxybenzotriazole (0.090 g, 0.669 mmol) were added at 0 °C. The mixture was stirred at this temperature for 1 h, and at room temperature overnight. Precipitates were filtered off and the filtrate was evaporated *in vacuo*. The solid residue was dissolved in dichloromethane and washed with water, a 5% sodium hydrogencarbonate solution, water and a saturated sodium chloride solution, dried over anhydrous sodium sulfate and evaporated. Crude materials were then purified by preparative silica-gel thin-layer chromatography using chloroform–methanol (100:1) as a developing solvent system. The desired band was eluted with dichloromethane–methanol (9:1) and the eluates evaporated *in vacuo*. The residue was again dissolved in a small volume of dichloromethane and placed in a Sephadex LH-20 column (1.9×100 cm) and eluted with methanol. The desired fractions were collected and evaporated *in vacuo* to give **18** as colorless crystals; 0.471 g (68%). An analytical sample was recrystallized from hot methanol; mp 188—190 °C; $[\alpha]_D^{26}$−20° (*c* 1, *N,N*-dimethylformamide); R_f^3 0.61, R_f^4 0.40. Found: C, 60.90; H, 7.17; N, 8.21; P, 2.63%. Calcd for $C_{52}H_{73}N_6O_9PS_2$: C, 61.16; H, 7.20; N, 8.23; P, 3.03%.

N,N-*Diallyl-*L*-tyrosyl-*D*-alanylglycyl-*L*-phenylalanyl-*L*-leucyl-S-dimethylphosphinothioyl-*L*-cysteine ((allyl)$_2$-L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys(Mpt)-OH) (19).* Trifluoroacetic acid (4 cm^3) was added to an ice-cold solution of compound **18** (0.236 g, 0.23 mmol) in dichloromethane (4 cm^3) containing anisole (0.4 cm^3). After having been kept at room temperature for 6.5 h, the solution was evaporated *in vacuo*. The solid residue was washed with ether and dissolved in methanol (10 cm^3) and water (2 cm^3). The solution was neutralized to pH 7 by addition of solid sodium hydrogencarbonate at 0 °C, and then evaporated. The residual materials were submitted to preparative silica-gel thin-layer chromatography in a solvent system of chloroform–methanol–water (65:25:4). The desired band (R_f=0.5—0.7) was eluted with methanol and evaporated *in vacuo*. The residue was dissolved again in a small volume of methanol and placed in a Sephadex LH-20 column (1.9×100 cm) and eluted with methanol. The desired fractions were collected and evaporated *in vacuo* to give **19** as colorless crystals; 0.175 g (87%). An analytical sample was recrystallized from hot methanol; mp 169—172 °C; $[\alpha]_D^{26}$+7 °(*c* 1, acetic acid); R_f^6 0.54, R_f^7 0.64. Found: C, 55.08; H, 6.61; N, 9.56; P, 3.14%. Calcd for $C_{40}H_{57}N_6O_8PS_2 \cdot 4/3H_2O$: C, 55.28; H, 6.92; N, 9.67; P, 3.56%.

*Bis(*N,N-*diallyl-*O*-t-*butyl-*L*-tyrosyl-*D*-alanylglycyl-*L*-phenylalanyl-*L*-leucyl)-*L*-cystine Bis(*p*-methoxybenzyl Ester) ((allyl)$_2$-L-Tyr(Bu^t)-D-Ala-Gly-L-Phe-L-Leu-L-Cys-OMob)$_2$ (20).*

To a solution of compound **18** (0.294 g, 0.288 mmol) in methanol (3 cm^3) and acetonitrile (3 cm^3), KF (33.5 mg, 0.576 mmol) and 18-crown-6 (0.152 g, 0.576 mmol) were added. The mixture was stirred at room temperature for 9 h and treated with 0.1 M iodine–potassium iodide in 90% methanol solution (1.6 cm^3). The yellow solution was evaporated *in vacuo*. The residue was dissolved in ethyl acetate and washed with water, a sodium thiosulfate solution, water, a 5% citric acid solution, water, a saturated sodium chloride solution, dried over anhydrous sodium sulfate, and evaporated *in vacuo*. The residue was purified by preparative silica-gel thin-layer chromatography in a solvent system of chloroform–methanol (95:5). The desired band (R_f=0.6—0.7) was eluted with methanol and evaporated *in vacuo*. The residue was again purified by gel chromatography on Sephadex LH-20 (1.9×100 cm) eluted with methanol. The desired fractions were collected and eluates evaporated *in vacuo* to yield **20** as colorless crystals; 0.237 g (88%). Mp 196—199 °C; R_f^3 0.54, R_f^4 0.29. Found: C, 64.25; H, 7.25; N, 9.00%. Calcd for $C_{100}H_{134}N_{12}O_{18}S_2 \cdot CH_3OH$: C, 64.24; H, 7.37; N, 8.90%.

*Bis(*N,N-*diallyl-*L*-tyrosyl-*D*-alanylglycyl-*L*-phenylalanycyl-*L*-leucyl)-*L*-cystine ((allyl)$_2$-L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys-OH)$_2$ (4).* *Method A*: To a solution of compound **19** (0.129 g, 0.149 mmol) in methanol (10 cm^3) and acetonitrile (10 cm^3), KF (0.083 g, 1.48 mmol) and 18-crown-6 (0.158 g, 0.595 mmol) were added. The mixture was stirred at 50 °C for 10 h and evaporated *in vacuo*. The residue was dissolved in a small volume of methanol and water and applied to a column (1.2×21 cm) of Dowex 50 W×2 (H^+ form). The resin was rinsed with water (150 cm^3) and then the desired material was eluted with a 1% aqueous ammonia solution. The crude peptide was purified by preparative silica-gel thin-layer chromatography in a solvent system of chloroform–methanol–water (65:25:4) and gel chromatography on Sephadex LH-20 (1.9×100 cm) eluted with methanol. The desired fractions were collected and evaporated *in vacuo* to yield **4** as colorless crystals; 58 mg (51%). An analytical sample was further purified by preparative silica-gel thin-layer chromatography in a solvent system of 1-butanol–acetic acid–water (4:1:1) and gel chromatography on Sephadex LH-20. Mp 198—208 °C (decomp); $[\alpha]_D^{26}$+6.7 (*c* 1, acetic acid); R_f^6 0.20, R_f^7 0.21, R_f^8 0.52. Found: C, 56.87; H, 6.67; N, 10.17%. Calcd for $C_{76}H_{102}N_{12}O_{16}S_2 \cdot 2H_2CO_3 \cdot H_2O$: C, 56.92; H, 6.61; N, 10.21%.

Method B: Compound **20** (0.236 g, 0.127 mmol) was stirred with trifluoroacetic acid (4 cm^3) containing anisole (0.8 cm^3) at 0 °C for 1 h and at room temperature over night. The solution was evaporated *in vacuo* and the residue was crystallized by triturating with ether. Crystalline precipitates were purified by preparative silica-gel thin-layer chromatopraphy using chloroform–methanol–29% aqueous ammonia (60:30:5). The desired band was eluted with methanol and the eluates were evaporated *in vacuo*. The residue was again purified by gel chromatography on Sephadex LH-20 (1.9×100 cm) eluted with methanol. The desired fractions were collected and eluates evaporated *in vacuo* to yield **4** as colorless crystals; 79 mg (41%). Mp 171—179 °C (decomp); R_f^6 0.19, R_f^7 0.22, R_f^8 0.53.

N-*(t-Butoxycarbonyl)-*L*-tyrosyl-*D*-alanylglycine Ethyl Ester (Boc-L-Tyr-D-Ala-Gly-OEt) (21).* Mpt-Cl (0.257 g, 2 mmol) was added to an ice-cold stirred solution of Boc-L-Tyr-OH (0.563 g, 2 mmol) and triethylamine (0.28 cm^3, 2 mmol) in chloroform (3 cm^3), after which the mixture was stirred for 1 h. To this solution a mixture of TFA·H-D-Ala-Gly-OEt (0.576 g, 2 mmol) and triethylamine (0.56 cm^3, 4 mmol) in *N,N*-dimethylformamide (2 cm^3) and chloroform (2 cm^3) was added in several portions at 0 °C. After having been stirred at this temperature for 1 h, the solution was washed in the usual way, dried and evaporated *in vacuo*. Solid residue was purified by preparative silica-gel thin-layer chromatography using chloroform–methanol (37:3) for development. The desired band (R_f=0.4—0.6) was eluted with chloroform–methanol (9:1) and eluates evaporated *in vacuo*. The residue was crystallized from hot ethyl acetate to give colorless crystals; 0.674 g (77%). Mp 164—166 °C; R_f^2 0.56, R_f^3 0.45.

N-*(t-Butoxycarbonyl)-*L*-tyrosyl-*D*-alanylglycine (Boc-L-Tyr-D-Ala-Gly-OH) (22).* To an ice-cold solution of **21** (0.479 g, 1.1 mmol) in methanol (3 cm^3), a 1 M aqueous NaOH solution (2.2 cm^3) was added and the solution was stirred at

0 °C for 30 min and at room temperature for 4 h. After removal of methanol *in vacuo*, the solution was acidified to pH 3 by solid citric acid at 0 °C. To this Diaion HP-20 resin was added until no spot corresponding to the product was detectable on TLC. The resin was filtered and washed with water until the filtrate became neutral. Elution of the resin with methanol and evaporation *in vacuo* of the eluates gave a chromatographically homogeneous amorphous solid; 0.430 g (95%). R_f^5 0.50, R_f^6 0.22.

N-(t-Butoxycarbonyl)-L-tyrosyl-D-alanylglycyl-L-phenylalanyl-L-leucyl-S-dimethylphosphinothioyl-L-cysteine p-Methoxybenzyl Ester (Boc-L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys(Mpt)-OMob) (23). To a mixture of **22** (0.390 g, 0.742 mmol), *N,N*-diisopropylethylamine (0.129 cm³, 0.742 mmol) and **14** (0.468 g, 0.742 mmol) in chloroform (3 cm³) and *N,N*-dimethylformamide (3 cm³), dicyclohexylcarbodiimide (0.153 g, 0.742 mmol) and 1-hydroxybenzotriazole (0.100 g, 0.742 mmol) were added at 0 °C. After the mixture was stirred at room temperature overnight, all the solvents were removed *in vacuo*. To the solid residue, dichloromethane was added, and precipitates were removed by filtration and washed. The filtrate and washings were washed as usual, dried and evaporated to give an amorphous solid. This was purified by preparative silica-gel thin-layer chromatography, using chloroform–methanol (9:1) as a developing solvent. The desired band (R_f=0.5—0.7) was eluted with methanol and eluates were evaporated *in vacuo*. The residue was dissolved again in a small volume of methanol and this mixture was placed in a Sephadex LH-20 column (1.9×100 cm), which was eluted with methanol. The desired fractions were collected and evaporated *in vacuo* to give colorless crystals; 0.560 g (76%). Mp 141—145 °C; R_f^3 0.60, R_f^4 0.18. Found: C, 57.63; H, 6.70; N, 8.60%. Calcd for $C_{47}H_{65}N_6O_{11}PS_2$: C, 57.30; H, 6.65; N, 8.53%.

L-Tyrosyl-D-alanylglycyl-L-phenylalanyl-L-leucyl-S-dimethylphosphinothioyl-L-cysteine (H-L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys(Mpt)-OH) (24). Trifluoroacetic acid (3 cm³) was added to an ice-cold solution of compound **23** (0.200 g, 0.203 mmol) in dichloromethane (2 cm³) containing anisole (0.3 cm³). After having been kept at room temperature overnight, the solution was evaporated *in vacuo*. The solid residue was washed with ether and purified by preparative silica-gel thin-layer chromatography using chloroform–methanol–29% aqueous ammonia (60:30:5). The desired band (R_f=0.3—0.5) was dissolved again in a small volume of acetic acid and the mixture was placed in a Sephadex LH-20 column (1.9×100 cm), which was eluted with methanol. The desired fractions were collected and evaporated *in vacuo* to give **24** as colorless crystals: 0.0991 g(63%). R_f^6 0.56, R_f^7 0.47. Found: C, 52.62; H, 6.57; N, 10.45%. Calcd for $C_{34}H_{49}N_6O_8PS_2 \cdot CH_3OH \cdot 1/4H_2O$: C, 52.45; H, 6.72; N, 10.49%.

Bis(N-(t-butoxycarbonyl)-L-tyrosyl-D-alanylglycyl-L-phenylalanyl-L-leucyl)-L-cystine Bis(p-methoxybenzyl Ester) (Boc-L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys-OMob)₂ (25). To a solution of compound **23** (0.201 g, 0.204 mmol) in methanol (4 cm³) and acetonitrile (4 cm³), KF (0.0237 g, 0.407 mmol) and 18-crown-6 (0.108 g, 0.407 mmol) were added. After having been stirred at room temperature for 9 h, the mixture was treated with 0.1 M iodine–potassium iodide solution in 90% methanol (2.3 cm³) and evaporated *in vacuo*. The residue was dissolved in ethyl acetate and water. The organic layer was separated and washed with water, a sodium thiosulfate solution, water, a 5% citric acid solution, water and a saturated sodium chloride solution, dried over anhydrous sodium sulfate, and evaporated. The residue was purified by preparative silica-gel thin-layer chromatography by using chloroform–methanol (9:1). The desired band (R_f=0.5—0.6) was eluted with methanol and the eluates were evaporated *in vacuo*. The residue was further purified by preparative silica-gel thin-layer chromatography using chloroform–methanol (95:5) and gel chromatography on Sephadex LH-20 (1.9×100 cm) eluting with methanol. The desired fractions were collected and the eluates were evaporated *in vacuo* to yield **25** as colorless crystals; 0.136 g(74%). Mp 195—198 °C; R_f^3 0.55, R_f^4 0.07. Found: C, 58.83; H, 6.64; N, 9.14%. Calcd for $C_{90}H_{118}N_{12}O_{22}S_2 \cdot 3H_2O$; C, 58.80; H, 6.80; N, 9.14%.

Bis(L-tyrosyl-D-alanylglycyl-L-phenylalanyl-L-leucyl)-L-cystine (H-L-Tyr-D-Ala-Gly-L-Phe-L-Leu-L-Cys-OH)₂ (26). Method A: To a solution of compound **24** (0.136 g, 0.178 mmol) in methanol (10 cm³) and acetonitrile (10 cm³), KF (0.124 g, 2.135 mmol) and 18-crown-6 (0.282 g, 1.067 mmol) were added. The mixture was stirred at 50 °C for 9 h and then evaporated *in vacuo*. The residue was dissolved in water (20 cm³) and to this Diaion HP-20 resin was added. The resin was filtered and washed with water (200 cm³). Elution of **26** was performed by methanol and eluates were evaporated. The residue was subjected to preparative silica-gel thin-layer chromatography using chloroform–methanol–water (65:25:4). The desired band (R_f=0.2—0.3) was eluted with methanol and the eluates were evaporated *in vacuo*. The residue was dissolved in a small volume of methanol and placed in a Sephadex LH-20 column (1.9×100 cm), which was eluted with methanol. The desired fractions were collected and evaporated *in vacuo* to give **26** as colorless crystals; 55.3 mg(46%). R_f^6 0.25, R_f^7 0.07, R_f^8 0.54.

Method B: Compound 25 (0.129 g, 0.072 mmol) was dissolved in TFA (4 cm³) containing anisole (0.4 cm³). The solution was stirred at 0 °C for 4 h and evaporated *in vacuo*. The residue was triturated with ether to give crystals, which were dissolved in a small volume of methanol and subjected to preparative silica-gel thin-layer chromatography using chloroform–methanol–29% aqueous ammonia (60:30:5). The desired band was eluted with methanol and the eluates were evaporated *in vacuo*. The residue was again dissolved in a small volume of methanol and water and placed in a column (1.2×20 cm) of Dowex 1×2 ion-exchange resin (acetate form), which was eluted with a 1% acetic acid solution. The eluates were evaporated and the residue was purified by gel chromatograhy on Sephadex LH-20 (1.9×100 cm), eluting with methanol. The desired fractions were collected and evaporated *in vacuo* to give colorless crystals; 44.5 mg (45%). Mp 198—202 °C (decomp); R_f^6 0.25, R_f^7 0.06, R_f^8 0.56. Found: C, 53.52; H, 6.22; N, 11.49%. Calcd for $C_{64}H_{86}O_{16}N_{12}S_2 \cdot 1/2H_2O$: C, 53.68, H, 6.21; N, 11.38%.

The authors wish to thank Professor Tetsuo Oka (Tokai University) for the biological activity measurements and for his encouragement throughout this work.

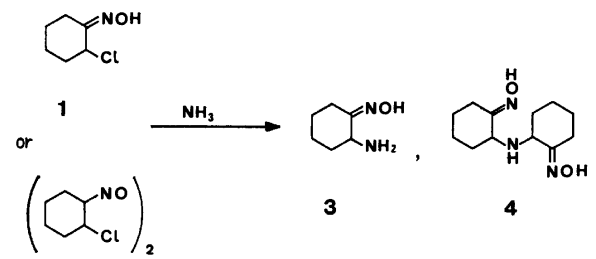
(Received January 9, 1984)

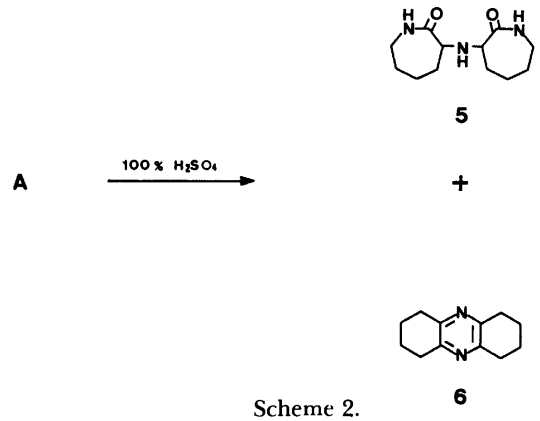
The structure of the dimeric oxime compound obtained by the reaction of 2-chlorocyclohexanone oxime or 1-chloro-2-nitrosocyclohexane dimer with stoichiometrical ammonia was established to be 14-oxa-7,15,16-triazatetracyclo[11.2.1.$0^{1,6}$.$0^{8,13}$]hexadecan-16-ol by spectroscopic methods and X-ray crystallography; the result leads to a revision of the previously proposed structure, bis(2-hydroxyiminocyclohexyl)amine.

2-Aminocycloalkanone oxime can be obtained by the reaction of 2-chlorocycloalkanone oxime or its dimer, 1-chloro-2-nitrosocycloalkane dimer, with a large excess of ammonia.[1] In the commercial chemico-enzymatic process[2] used to prepare L-lysine, 2-aminocyclohexanone oxime (**3**) is produced in large scale from 2-chlorocyclohexanone oxime (**1**) or 1-chloro-2-nitrosocyclohexane dimer (**2**). The structure of the principal by-product of the reaction (hereinafter named "compound **A**") was proposed to be bis(2-hydroxyiminocyclohexyl) amine (**4**) by Ohno *et al.*[3] and J. Beger *et al.*[4] (Scheme 1). However, while we were engaged in the further study of this reaction, we had some doubts about the chemical structure of compound **A**. Thus we have attempted the detailed instrumental analysis of compound **A** and its analog to elucidate the proper chemical structure.

The following experimental results may give support to assigning structure **4** to compound **A**. (i) In the reaction of **1** or **2** with ammonia, compound **A** increases with the decrease in the molar ratio of ammonia. Thus it is inferred from analogy with the reaction of alkyl halide and ammonia that compound **A** is an oxime having a imino group. (ii) 1,2,3,4,6,7,8,9-octahydrophenazine (**6**) was obtained as a major product when compound **A** was heated in acidic or alkaline aqueous solution. Moreover, bis(perhydro-2-oxo-3-azepinyl)amine (**5**), a plausible product from **4**, was formed as a major product by the Beckmann rearrangement of compound **A** in 100% sulfuric acid (Scheme 2). (iii) Compound **A** is obtainable in high yield by the reaction of **1** and **3**. (iv) The elemental analysis of compound **A** gave the empirical formula $C_{12}H_{21}N_3O_2$. However, when the properties of compound **A** are compared with those of **3**, the following different points are found: (v) The pattern of IR spectrum does not resemble to that of **3**. Particularly, the absorption at 1670 cm^{-1} arising from oxime group was missing in the spectrum of compound **A**. (vi) Compound **A** is only sparingly soluble in such solvents as chloroform and alcohols, while **3** is fairly soluble in them. (vii) The rate of the salt exchange reaction of compound **A** with ammonium chloride is lower than that of **3**. (viii) Compound **A** was formed by heating **3** with ammonia, but the reverse reaction did not proceed. Therefore, it is doubtful whether compound **A** and **3** have analogous functional groups or not.



Scheme 1.



Scheme 2.

Accordingly, we synthesized a reference compound and compared the data from instrumental analyses of the compound with those of compound **A** to elucidate the proper structure. We found that the reaction of 2-chlorocyclohexanone oxime or 1-chloro-2-nitrosocyclohexane dimer with stoichiometrical ammonia yields dimeric cyclohexanone oxime, 14-oxa-7,15,16-triazatetracyclo[11.2.1.$0^{1,6}$.$0^{8,13}$]hexadecan-16-ol.

Results and Discussion

2-Chlorocyclohexanone oxime (**1**) or 1-chloro-2-nitrosocyclohexane dimer (**2**) was treated with stoichiometrical ammonium chloride in a two-phase solvent system containing organic and aqueous alkaline layers to produce compound **A**. **1** or **2** was also reacted with stoichiometrical methylamine hydrochloride to produce compound **B**. 2-(methylamino)cyclohexanone oxime was obtained by the reaction of **1** or **2** with excess methylamine in organic solvents such as benzene and chloroform.

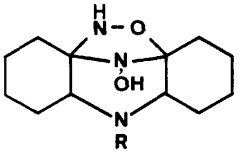
The structures of compound **A** and **B** were studied in the following procedure.

The elemental analyses gave the empirical formulae $C_{12}H_{21}N_3O_2$ and $C_{13}H_{23}N_3O_2$ to compounds **A** and **B**, respectively. Though ^{1}H-NMR spectrum of compound

A was not obtained due to its poor solubility, two kinds of protons exchangeable with deuterium in deuterium oxide were observed at δ=6.1 and 7.8 in the spectrum of compound **B**. ^{13}C-NMR spectra of both compounds showed analogous peak-patterns, the peaks to be noticed being observed at δ=100, 86, 60 (2 carbon atoms) in compound **A** and at δ=99, 85, 68, 63 in compound **B**. The peaks at δ=99—100 and 85—86 are reasonably assigned to quarternary carbon atoms, and the remaining peaks at δ=60—68 are also reasonably assigned to carbon atoms adjacent to the amino group. Thus, it is inferred that both compounds have two quarternary carbon atoms of considerably different natures and two similar carbon atoms adjacent to the amino group. Moreover, since no peaks were observed in the field lower than 100, it is suggested that neither of them has an oxime group.

In the IR spectra of both compounds, no absorption at 1670 cm^{-1} arising from oxime group was observed, but the bands due to amino groups and hydroxyl groups were observed at 3200—3100 cm^{-1}. Mass spectra of both compounds showed the fragment peaks at m/z $(M-17)^+$ resulting from the elimination of a hydroxyl radical, but no other useful information was obtained from them.

From these observations, we assigned 14-oxa-7,15,16-triazatetracyclo[11.2.1.0^{1,6}.0^{8,13}]hexadecan-16-ol (**7**) and 7-methyl-14-oxa-7,15,16-triazatetracyclo[11.2.1.0^{1,6}.0^{8,13}] hexadecan-16-ol (**8**) to the structures of compounds **A** and **B**, and the structure of **7** was definitely confirmed by X-ray diffraction analysis.



7 R = H
8 R = CH_3

The crystallographic structure of **7** is shown in Fig. 1. The atomic positional parameters are listed in Table 1 and Table 2 presents some of more important bond lengths and angles. The molecule has a fused ring structure. The two outer cyclohexane rings are attached equatorially to the central six-membered heterocyclic ring and is in a chair conformation. The bonding pattern within the three six-membered ring is normal with an average C–C bond length of 1.528 Å and C–N bond length of 1.471 Å. The longest of these, C(1)–C(6), 1.543 (3) Å and C(7)–C(12), 1.550(3) Å, can be ascribed to the high degree of substitution on these C atoms. The bond angle, C(1)–N(2)–C(12), is much less, 100.1(1)°, than expected as the effect of the ring strain of attached five-membered ring and has probably resulted in the long N(2)–O(2) length of 1.458(2) Å found at this point. The sum of the valency angles around N(2) is 314.6°. The dihedral angles between C(1)–C(6)–C(7)–C(12) and C(1)–C(3)–C(4)–C(6) and between C(1)–C(6)–C(7)–C(12)

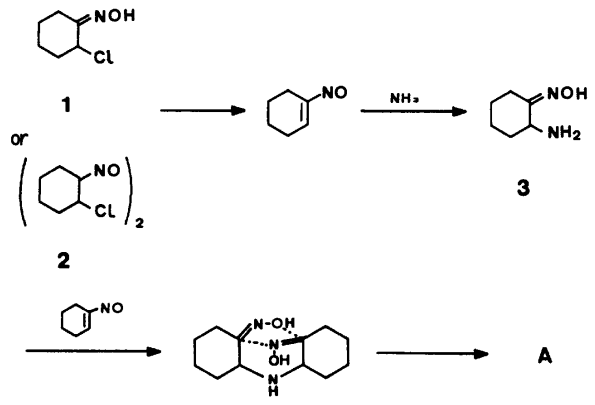
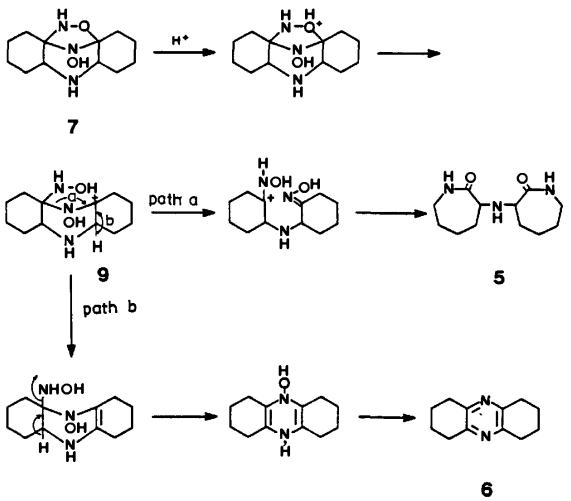
and C(7)–C(9)–C(10)–C(12) are 11.5(1)° and 7.4(1)°, respectively. O(1) and N(3) atoms axially attached to the C(1) and C(12) atoms respectively make five membered ring with the atom N(2) by an envelope conformation, with this atom 0.610(5) Å out of plane of the remaining four ring atoms. Figure 2 displays the packing. The molecules are linked by two types of intermolecular hydrogen bonds, such that the crystal contains an infinite two-dimensional net perpendicular to the b axis. One hydrogen bond exists between N(3)–H(N3) and N(1) of the molecules related by the c glide plane in the direction of a, the second between O(2)–H(O2) and N(3) of the successive molecules along the c. Thus each molecule is hydrogen bonded to four neighboring molecules. The plate-like morphology of the crystal parallels the orientation of the hydrogen-bonded nets. The hydrogen bond distances and angles are: N(3)···N(1), 3.158(2); H(N3)···N(1), 2.22(2) Å; N(3)–H(N3)···N(1), 163(2)°; O(2)···N(3), 2.807(2); H(O2)···N(3), 1.85(3) Å; O(2)–H(O2)···N(3), 170(3)°.

We speculate that this moderately complicated compound was formed by the reaction mechanism shown in Scheme 3. Hydrogen chloride was eliminated from **1** or **2** to give nitrosocyclohexene, and this was converted to **3** by addition of ammonia. When the molar ratio of ammonia was low, **3** reacted with another intermediary nitrosocyclohexene to give **4**. Spontaneous intramolecular 1,3-dipolar addition reaction between two oxime groups gave 14-oxa-7,15,16-triazatetracyclo-[11.2.1.$0^{1,6}$.$0^{8,13}$] hexadecan-16-ol (**7**).

A plausible mechanism for the formation of bislactam (**5**) and octahydrophenazine (**6**) are also illustrated in Scheme 4. Compound **7** was protonated in an acidic medium to produce a common intermediate (**9**). In 100% sulfuric acid, bislactam (**5**) was obtained by the



Scheme 3.



Scheme 4.

Beckmann rearrangement (path a). On the other hand, when **7** was heated in an acidic aqueous solution, **6** was formed by the elimination of hydroxylamino radical from **9** (path b).

Experimental

General. Melting points are uncorrected. The IR and mass spectra were recorded on Shimadzu IR-40 and Hitachi RMU-7M spectrometers respectively. ^{1}H-NMR and ^{13}C-NMR specra were recorded on Hitachi R-24B (60 MHz) spectrometer and JEOL FX-90Q pulse FT spectrometer (22.49 MHz) using TMS as internal standard.

Preparation of 2-Chlorocyclohexanone Oxime (1) and 1-Chloro-2-nitrosocyclohexane Dimer (2). **1** and **2** were prepared by the methods described in the patent.[5]

Preparation of 2-Aminocyclohexanone Oxime (3). In a 500 ml stainless steel autoclave, a mixture of 1-chloro-2-nitrosocyclohexane dimer (14.8 g, 0.05 mol), ammonia (170 g, 10 mol) and methanol 100 ml was heated at 70 °C. After 1 h, ammonia and methanol were removed under reduced pressure to give 15.7 g of crude 2-aminocyclohexanone oxime hydrochloride (95.3%). The crude product was purified by recrystallization from water to give (14.9 g, 90.6%) of 2-aminocyclohexanone oxime hydrochloride as white crystals; mp 212.0—213.0 °C. Found: C, 43.85; H, 8.00; N, 17.16; Cl, 21.49 %. Calcd for $C_6H_{13}N_2OCl$: C, 43.77; H, 8.02; N, 17.02; Cl, 21.53 %.

Preparation of 2-(Methylamino)cyclohexanone Oxime. To a solution of 1-chloro-2-nitrosocyclohexane dimer (14.8 g, 0.05 mol) in benzene (100 ml) was added dropwise at 60 °C a solution of methylamine (6.2 g, 0.2 mol) in benzene (50 ml) during 1 h, and the reaction mixture was heated at 60 °C for an additional 1 h. After the reaction, the mixture was cooled to room temperature and washed with a 100 ml portion of 10% sodium hydroxide. The benzene layer was dried over anhydrous magnesium sulfate, and benzene was removed under reduced pressure to give crude 13.5 g of 2-(methylamino)-cyclohexanone oxime (94.9%). The crude product was purified by recrystallization from methanol to give 10.8 g of 2-(methylamino)cyclohexanone oxime as white crystals (75.9%); mp 103—104 °C. Found: C, 59.18; H, 9.83; N, 19.75%. Calcd for $C_7H_{14}N_2O$: C, 59.12; H, 9.93; N, 19.71%.

Preparation of 14-Oxa-7,15,16-triazatetracyclo[11.2.1.0^{1,6}.0^{8,13}]-hexadecan-16-ol (7). To a mixture of 1-chloro-2-nitrosocyclohexane dimer (14.8 g, 0.05 mol), dichloromethane (200 ml), and 2 mol dm^{-3} sodium hydroxyde solution (100 ml) was added dropwise at room temperature a solution of ammonium chloride (5.4 g, 0.1 mol) in water (50 ml) during 30 min. The reaction mixture was stirred for an additional 2 h. A crystalline material suspended in the reaction mixture was filtered and washed with water. The crude product was purified by recrystallization from ethanol to give 11.3 g (94.6%) of **7** as a white solid; mp 186—187 °C. ^{1}H-NMR (CD_3COOD) δ=1.3—2.2 (m 12H), 2.2—2.6 (t 4H), 3.4—3.8 (m 2H). ^{13}C-NMR CD_3COOD δ=22.5, 23.1, 23.6, 24.3, 27.2, 27.6, 28.7, 60.3, 60.4, 85.6, 100.0. IR (KBr): 3280, 3120, 2940, 2870, 1480, 1450, 1120, 958, 942, 905, 898, 860, 820, 795 cm^{-1}. Found: C, 60.58; H, 8.81; N, 17.69%. Calcd for $C_{12}H_{21}N_3O_2$: C, 60.23; H, 8.85; N, 17.56%.

Preparation of 7-Methyl-14-oxa-7,15,16-triazatetracyclo[11.2.1.-0^{1,6}.0^{8,13}]hexadecan-16-ol (8). In a similar manner to the above, **8** was prepared from methylamine hydrochloride in 90.7% yield; white solid; mp 157—158 °C. ^{1}H-NMR (DMSO-d_6) δ=1.0—2.0 (m 16H), 2.0—2.3 (m 2H), 2.1 (s 3H), 5.9—6.1 (1H), 7.8 (1H). ^{13}C-NMR ($CDCl_3$) δ=22.5, 23.0, 24.1, 27.8, 28.1, 29.2, 29.6, 36.4, 37.9, 62.6, 67.9, 85.0, 99.1. IR (KBr): 3210, 3100, 2930, 2850, 2770, 1450, 1360, 1350, 1260, 1250, 1190, 1150, 1120, 1040, 980, 950, 930, 900, 870, 830, 790, 700 cm^{-1}. Found: C, 61.77; H, 9.03; N, 16.62%. Calcd for $C_{13}H_{23}N_3O_2$: C, 61.63; H, 9.15; N, 16.59%.

Preparation of 1,2,3,4,6,7,8,9-Octahydrophenazine (6). A mixture of 14-oxa-7,15,16-triazatetracyclo[11.2.1.0^{1,6}.0^{8,13}] hexadecan-16-ol (**7**) (23.9 g, 0.1 mol) and 1 mol dm^{-3} sulfuric acid (100 ml) was heated at 60 °C. After 3 h, the reaction mixture was cooled to room temperature and adjusted to pH 10 with 2 mol dm^{-3} sodium hydroxide solution. The solution was extracted with three 100 ml portions of benzene and then dried over anhydrous magnesium sulfate. After removal of the benzene, the residue was distilled under reduced pressure, and the fraction at 128 °C/1.6 mmHg was collected; mp 108—109 °C. ^{1}H-NMR ($CDCl_3$) δ=1.6—2.2 (8H), 2.6—3.1 (8H). IR (KBr): 2920, 2860, 1460, 1430, 1420, 1390, 1335, 1240, 1210, 1190, 1130, 1120, 1070, 1060, 980, 925, 890, 870, 816, 750 cm^{-1}. Found: C, 76.30; H, 8.43; N, 14.67%. Calcd for $C_{12}H_{16}N_2$: C, 76.56; H, 8.57; N, 14.88%.

Preparation of Bis(perhydro-2-oxo-3-azepinyl)amine (5). To 100% sulfuric acid (98 g, 1 mol) was added at 60 °C 14oxa-7, 15, 16-triazatetracyclo[11.2.1.0^{1,6}.0^{8,13}]hexadecan-16-ol (23.9 g, 0.1 mol) over 30 min. The reaction mixture was heated at 60 °C for an additional 1 h. After the reaction mixture was cooled to 10—20 °C, water (200 ml) was added at 0—5 °C. The resulting solution was adjusted to pH 10 with 30% sodium hydroxide solution and was extracted with three 300 ml portions of chloroform; then the chloroform extract was dried over anhydrous magnesium sulfate. After removal of the chloroform, the residue was distilled under reduced pressure, and the fraction at 220 °C/0.25 mmHg was collected. ^{1}H-NMR (DMSO-d_6) δ=1.2—2.4 (12H), 2.5 (NH), 2.9—3.4 (4H), 4.0—4.5 (2H), 8.0—8.6 (-NH-C(=O)-, 2H). IR (KBr): 3300, 3200, 3070, 2970, 2920, 2840, 1660, 1470, 1450, 1420, 1380, 1350, 1320, 1300, 1260, 1150, 1130, 1110, 980, 970, 820 cm^{-1}. Found: C, 60.56; H, 8.51; N, 17.79%. Calcd for $C_{12}H_{21}N_3O_2$: C, 60.23; H, 8.85; N, 17.56%.

X-Ray Crystal Structure Determination. Crystal data: $C_{12}H_{21}N_3O_2$, Mr=239.32, monoclinic, $P2_1/c$, a=6.022(1), b=19.245(4), c=10.560(1) Å, β=95.94(1)°, V=1217.4 Å^3, Dm=1.298, Dx=1.306 Mg m^{-3}, Z=4, F(000)=520, μ(Cu $K\alpha$)=0.74 mm^{-1}, the final R was 0.0464 for 2022 unique reflections.

Crystals of compound **7** suitable for X-ray diffraction were obtained upon recrystallization from an ethanol solution. Preliminary film work revealed the material to be monoclinic with systematic absences (h0l, $l=2n+1$; 0k0, $k=2n+1$) strongly indicative of the centrosymmetric space group C_{2h}^5 $-P2_1/c$. The density was measured by flotation in chloroform-cyclohexane solution. The unit cell parameters were obtained by least-squares from 2θ values for 15 reflections measured on a diffractometer. The intensities of 2022 (1990 non-zero) independent reflections were collected on a Rigaku automatic four-circle diffractometer up to an angle of 2θ=125° with graphite monochromated Cu $K\alpha$ radiation, using the $2\theta-\omega$ scan technique and scan range of $(0.8+0.142\tan\theta)°(\omega)$. The scan speed and the background counting time were 10°/min and 3s at each terminus of the scans for $0°<2\theta\leqq 80°$, 5°/min and 6s for $80°<2\theta\leqq 100°$, and 2°/min, 15s for $110°<2\theta\leqq 125°$. Three standard reflections were measured every 100 measurements with no significant deterioration in intensity. Lorentz and polarization correction were applied, but not that for absorption.

The structure was solved with the MULTAN 78 program[6] which located all the non-hydrogen atoms. Isotropic and anisotropic block-diagonal least-squares refinement with HBLS VI program[7] reduced R to 0.070. A difference synthesis at this stage clearly indicated all H atoms, which were included in the refinement with isotropic temperature factors. In the refinement, the function minimized was $\sum\omega(|F_o|-|F_c|)^2$

with $\omega=[\sigma^2(F_o)+a|F_o|+b|F_o|^2]^{-1}$ for $F_o\neq 0$ and $\omega=c$ for $F_o=0$, where $\sigma(F_o)$ is the standard deviation based on counting statistics. Final refinement ($a=0.0006$, $b=5.7428$ and $c=0.01379$) gave $R=0.0464$ ($\omega R=0.0639$) for all reflections and $R=0.0459$ for non-zero reflections. No significant peaks were observed in the final difference map, except for a few peaks of *ca* 0.3 eÅ^{-3}. All calculations were performed with the UNICS programs on a FACOM M-200 computer.[8]

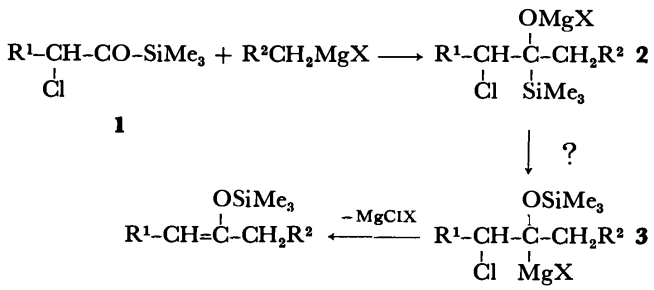
Reactions of 2-Chloroacyltrimethylsilanes with Grignard Reagents. Preparation of 3-(Trimethylsilyl)-2-alkanones and 2-(Trimethylsilyl)-1-alkanols[1)]

Toshio SATO,† Kazuhisa MATSUMOTO, Toru ABE, and Isao KUWAJIMA*
Department of Chemistry, Tokyo Institute of Technology, Meguro, Tokyo 152, Japan
(Received January 11, 1984)

Reactions of 2-chloroacyltrimethylsilanes with Grignard reagents have been examined. Thus, treatment with methylmagnesium iodide affords the corresponding 3-(trimethylsilyl)-2-alkanones through an initial addition followed by removal of chloride anion and 1,2-rearrangement of silyl group. In contrast, the reaction proceeds with 2 equiv of the Grignard reagents bearing β-hydrogen to give 2-(trimethylsilyl)-1-alkanols, where initial reduction of the silylcarbonyl group followed by such rearrangement and addition of the Grignard reagents to the resulting 2-(trimethylsilyl)alkanals have been proposed.

Enol silyl ethers have recently been employed as one of the most promising nucleophiles in organic synthesis.[2)] Use of this class of compounds has allowed regioselective introduction of a variety of functional groups or carbon chain onto α-carbons of the carbonyl compounds. For regioselective preparation of enol silyl ethers from the corresponding ketones, difference of thermodynamically and kinetically favorable enolates has usually been utilized to reflect their geometries to those of enol silyl ethers.[3)] Based on these features, various methods have been developed for regioselective synthesis of enol silyl ethers, but there have been still encountered several difficulties on occasions where such difference is very small or negligible. In order to explore a new methodology for regioselective synthesis of enol silyl ethers,[4)] we have examined the reaction of 2-chloroacyltrimetylsilanes **1** with Grignard reagents, assuming that the initially formed adduct **2** undergoes 1,2-rearrangement[5)] of silyl group from carbon to oxygen to yield **3**. The resulting **3** may be converted to the corresponding enol silyl ethers regiospecifically through removal of magnesium halides as shown in Scheme 1.



Scheme 1.

Results and Discussion

The requisite 2-chloroacyltrimethylsilanes **1** can be prepared in excellent yields by treating the corresponding enol silyl ethers of acyltrimethylsilanes[6)] with an equimolar amount of chlorine in carbon tetrachloride at ambident temperature (see Table 1). Direct chlorination of acyltrimethylsilanes is also employable, but formation of a small amount of dichlorides accompanies as by-products.[7)]

†Present address: Chemistry Department of Resources, Mie University, Tsu, Mie 514.

$$R^1\text{-CH=C(OSiMe}_3\text{)-SiMe}_3 + Cl_2 \longrightarrow R^1\text{CH(Cl)-CO-SiMe}_3$$

b) *n*-C_6H_{13}	89	92
c) $C_6H_5CH_2$	87	87
d) CH_2=CH-$(CH_2)_7$	82	85

In contrary to our assumption, treatment of 2-chlorohexanoyltrimethylsilane with an equimolar amount of methylmagnesium iodide in tetrahydrofuran (THF) at −78 °C has never afforded the expected enol silyl ether, but its isomer, 3-trimethylsilyl-2-heptanone has been isolated in 91% yield (Eq. 1). Other chlorides also afforded the corresponding 3-(trimethylsilyl)-2-alkanones **4** in excellent yields (Table 2). Similar reactions were also examined with methyllithium, but afforded much less satisfactory results.

$$\mathbf{1} + CH_3MgI \longrightarrow \mathbf{2}(R^2\text{=H,X=I}) \longrightarrow R^1\text{CH(SiMe}_3\text{)-CO-CH}_3 \quad \mathbf{4} \quad (1)$$

TABLE 2. PREPARATION OF 3-(TRIMETHYLSILYL)-2-ALKANONES **4**

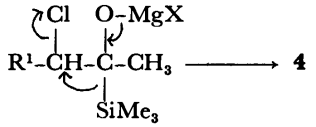
R¹	Yield/%
a) *n*-C_4H_9	91
b) *n*-C_6H_{13}	90
c) $C_6H_5CH_2$	98
d) CH_2=CH-$(CH_2)_7$	91

Similarly, 2-methyl-1-propenylmagnesium bromide afforded the corresponding unsaturated silyl ketone **4e** in 72% yield.

$$C_4H_9\text{-CH(Cl)-CO-SiMe}_3 + (CH_3)_2C\text{=CHMgBr} \longrightarrow C_4H_9\text{-CH(SiMe}_3\text{)-CO-CH=C(CH}_3\text{)}_2 \quad \mathbf{4e}$$

These results have clearly indicated that transfer of silyl group to the neighboring carbon atom takes place preferentially even under such mild reaction conditions. Intermediary formation of α,β-epoxysilane can

be ruled out because Mg^{2+} cation induced rearrangement of such material should afford the corresponding 2-halo-2-(trimethylsilyl)-3-alkanol as reported.[8] Instead, the reaction is considered to proceed through removal of chloride anion from the initially formed alkoxide **2** followed by rearrangement of trimethylsilyl group to the resulting cationic site to afford **4**. We have found no evidence on the question whether these processes occur successively or in concerted manner, but both of them are expected to be greatly favored. The first stage may be facilitated by σ-π interaction with the neighboring silyl group[9] and the second one may be accelerated by the aid of an anionic character of O–Mg bond. A combination of these three factors is considered to induce this characteristic transformation so efficiently.



In contrast, on using Grignard reagents bearing β-hydrogen in the reaction with **1**, 2 equiv of the Grignard reagent are required to complete a conversion, and 2-(trimethylsilyl)-1-alkanol **5** has been obtained in place of **4**. For example, the reaction of **1** ($R^1=C_6H_5CH_2$) with 1 equiv of hexylmagnesium bromide resulted in formation of a mixture of **5** ($R^1=C_6H_5CH_2$, $R^2=C_4H_9$, 39%) and 3-phenylpropanal (18%) together with the recovered starting material (17%), whereas use of 2 equiv of the Grignard reagent led to the exclusive formation of the corresponding **5**.

In connection with this transformation, it has been reported by Brook *et al.*[10] that in stead of an addition reaction, acylsilanes undergo reduction preferentially to yield 2-(trimethylsilyl)-1-alkanols on treating with Grignard reagents bearing β-hydrogen. Similarly, it appears to be reasonable to assume that the corresponding alkoxide **6** is formed as an initial product in this case. Then, **6** may undergo the same type of transformation to yield the corresponding 2-(trimethylsilyl)alkanal **7**, which reacts further with the Grignard reagent to give **5** as shown in Eq. 2. Higher reactivity of an aldehyde function to such nucleophiles has made it very difficult to isolate 7. Although several attempts to isolate **7** have failed, formation of 3-phenylpropanal in the above experiment supports **7** as a plausible intermediate.

According to Cram's rule,[11,12] selective formation of erythro isomer **5** has been expected in the reaction of **7** with Grignard reagents because trimethylsilyl group should behave as much more bulky one than most of alkyl groups. Hudrlik *et al.* recently described threo selective reduction of 2-(trimethylsilyl)alkanones with

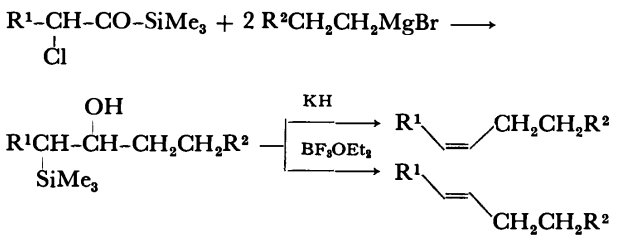
diisobutylaluminium hydride (DIBAL) and stereoselective conversion of the resulting alcohols to (*E*)- and (*Z*)-olefins under the influence of base and Lewis acid, respectively.[12a]

In order to confirm stereochemical outcome of this addition reaction, 2-chlorohexanoyltrimethylsilane was treated with 2.2 equiv of butylmagnesium bromide in THF at −78 °C for 30 min, and the corresponding **5** ($R^1=C_4H_9$, $R^2=C_2H_5$) was isolated in 85% yield. As expected, on treating with potassium hydride and boron trifluoride etherate, the resulting alcohol **5** afforded (*E*)- and (*Z*)-5-decene, respectively, in highly stereo-controlled manner as shown in the following equation. These results apparently verified highly selective formation of erythro isomer **5** in the present one-pot procedure.



Yield of olefins/% ($Z:E$)

R^1	R^2	KH	$BF_3\cdot OEt_2$
C_4H_9	C_2H_5	82 (96:4)	85 (5:95)
C_2H_5	C_6H_5	89 (96:4)	78 (6:94)

In summary, use of 2-chloroacyltrimethylsilanes has made it feasible to prepare 3-(trimethylsilyl)-2-alkanones or 2-(trimethylsilyl)-1-alkanols, depending on the Grignard reagent employed, in completely regiocontrolled manner. The latter alcohols can be oxidized to the corresponding silyl ketones[12a] in good yield.

Although we failed to explore a method for regiospecific preparation of enol silyl ethers by a sequence described above,[13] these silyl ketones[12,14] obtained undergo a facile isomerization to the corresponding enol silyl ethers regiospecifically.[15] Further, these silyl ketones themselves have been proved to be especially useful for regioselective aldol formation because the silyl group has played dual roles for selective generation of two types of enolates as described already.[16]

Experimental

General Methods. Boiling points are uncorrected. Infrared (IR) spectra were recorded on a Hitachi EPI-G3 spectrometer; absorptions are reported in reciprocal centimeters. Proton nuclear magnetic resonance spectra (^1H NMR) were obtained on a Hitachi R-24B spectrometer; chemi-

cal shifts (δ) are expressed in part per million downfield from tetramethylsilane. Analytical gas-liquid chromatography (GLC) was performed on a Hitachi 163 instrument with a flame ionization detector and nitrogen carrier gas (1.0—1.3 kg/cm^2) using a OV-101 fused silica 20 m capillary column (Hitachi Chemi-Column). Microanalysis were performed with a Perkin-Elmer 240 at the Micro-analytical Laboratory, Tokyo Institute of Technology.

Reactions involving air- or moisture-sensitive compounds were carried out in appropriate round-bottomed flasks with stirring bars under nitrogen or argon atmosphere. Bulb-to-bulb distillation was performed with a Büchi Kugelrohr apparatus.

Preparative thin-layer chromatography (TLC) was carried out on glass plates (20×20 cm) coated with Merck silica gel PF 254 (1 mm thick).

Hexane was distilled from sodium. Ether and tetrahydrofuran (THF) were distilled from sodium-benzophenone ketyl immediately before use.

Materials. Enol trimethylsilyl ethers of acyltrimethylsilanes were prepared from the corresponding enol trimethylsilyl ethers of benzenethiol or methanethiol esters according to the procedure developed in our laboratory.[6]

Preparation of 2-Chloro- or 2-Bromoacyltrimethylsilanes. General Procedure: An enol trimethylsilyl ether of acyltrimethylsilane (1 mmol) in carbon tetrachloride (1.5 ml) was added to a carbon tetrachloride (4.5 ml) solution of chlorine or bromine (1.1 mmol) at −20 °C and it was stirred for 5—10 min at that temperature under argon. Then, the solvent was removed on a rotary evaporator, and the residual oil was separated by preparative TLC using a mixture of hexane and ether (5:1) as a solvent to give the title compound.

2-Chlorohexanoyltrimethylsilane **1a**: IR(neat): 1650, 1250, 855 cm^{-1}; NMR(CCl_4) δ=0.30 (s, 9H), 0.77—2.33 (m, 9H), 4.11 (t, J=6 Hz, 1H); Calcd for $C_9H_{19}OClSi$: C, 52.27; H, 9.26. Found: C, 52.40; H, 9.05.

2-Bromohexanoyltrimethylsilane **1a'**: IR (neat): 1652, 1250, 855 cm^{-1}; NMR(CCl_4) δ=0.40 (s, 9H), 0.76—2.33 (m, 9H), 4.33 (t, J=7 Hz, 1H); Calcd for $C_9H_{19}OBrSi$: C, 43.03; H, 7.62. Found: C, 43.21; H, 7.50.

2-Chlorooctanoyltrimethylsilane **1b**: IR (neat): 1650, 1250, 855 cm^{-1}; NMR(CCl_4) δ=0.33 (s, 9H), 0.66—2.43 (m, 13H), 4.15 (t, J=5 Hz, 1H); Calcd for $C_{11}H_{23}OClSi$: C, 52.26; H, 9.87. Found: 52.43; H, 9.59.

2-Bromooctanoyltrimethylsilane **1b'**: IR (neat): 1650, 1250, 855 cm^{-1}; NMR(CCl_4) δ=0.33 (s, 9H), 0.66—2.43 (m, 13H), 4.37 (t, J=7 Hz, 1H).

2-Chloro-3-phenylpropionyltrimethylsilane **1c**: IR (neat): 1645, 1250, 845 cm^{-1}; NMR(CCl_4) δ=0.33 (s, 9H), 2.99 (dd, J=14 and 8 Hz, 1H), 3.40 (dd, J=14 and 6 Hz, 1H), 4.50 (dd, J=8 and 6 Hz, 1H), 7.20 (s, 5H); Calcd for $C_{12}H_{17}OClSi$: C, 59.85; H, 7.12. Found: C, 60.06; H, 6.97.

2-Bromo-3-phenylpropionyltrimethylsilane **1c'**. IR (neat): 1640, 1250, 845 cm^{-1}; NMR (CCl_4) δ=0.20 (s, 9H), 3.05 (dd, J=14 and 7 Hz, 1H), 3.53 (dd, J=14 and 7 Hz, 1H), 4.70 (t, J=7 Hz, 1H), 7.23 (s, 5H).

2-Chloro-10-undecenoyltrimethylsilane **1d**: IR (neat): 1652, 1250, 855 cm^{-1}; NMR(CCl_4) δ=0.30 (s, 9H), 1.15—2.25 (m, 14H), 4.23 (t, J=6 Hz, 1H), 4.94 (d, J=13 Hz, 1H), 4.99 (d, J=17 Hz, 1H), 5.78 (m, 1H); Calcd for $C_{14}H_{27}OClSi$: C, 61.17; H, 9.90. Found: C, 61.05; H, 10.08.

2-Bromo-10-undecenoyltrimethylsilane **1d'**. IR (neat): 1651, 1250, 855 cm^{-1}; NMR(CCl_4) δ=0.30 (s, 9H), 1.00—2.50 (m, 14H), 4.40 (t, J=6 Hz, 1H), 4.94 (d, J=13 Hz, 1H), 4.99 (d, J=17 Hz, 1H), 5.78 (m, 1H).

The Reaction of 2-Chloroacyltrimethylsilane with Methylmagnesium Iodide. General Procedure: An ethereal solution of methylmagnesium iodide (21.8 ml of 0.95 M solution (1 M=1 mol dm^{-3})) was added to a THF (20 ml) solution of 2-chloroacyltrimethylsilane (20 mmol) at −78 °C and it was stirred for 30 min at that temperature under argon. Hexane (200 ml) pre-cooled to −60 °C was added directly to the reaction mixture and the resulting solution was washed with satd aq NH_4Cl (20 ml). After drying the organic layer with anhyd $MgSO_4$ and removal of the solvent, fractional distillation of the residual oil gave the corresponding 3-(trimethylsilyl)-2-alkanone.

3-(Trimethylsilyl)-2-heptanone **4a**: Bp 78—83 °C/5 mmHg (1 mmHg≈133.322 Pa); IR (neat): 2950, 2920, 2845, 1693, 1253, 843 cm^{-1}; NMR (CCl_4) δ=−0.11 (s, 9H), 1.63—4.70 (m, 9H), 1.83 (s, 3H), 2.06—2.43 (m, 1H); Calcd for $C_{10}H_{22}OSi$: C, 64.45; H, 11.90. Found: C, 64.28; H, 12.13.

3-(Trimethylsilyl)-2-nonanone **4b**: Bp 86—90 °C/2 mmHg; IR (neat): 2950, 2920, 2845, 1693, 1253, 843 cm^{-1}; NMR (CCl_4) δ=−0.10 (s, 9H), 0.57—1.60 (m, 16H), 1.87 (s, 3H), 2.13—2.50 (m, 1H); Calcd for $C_{12}H_{26}OSi$: C, 67.22; H, 12.22. Found: C, 67.09; H, 12.07.

4-Phenyl-3-(trimethylsilyl)-2-butanone **4c**: Bp 117—120 °C/1 mmHg; IR (neat): 3020, 1920, 1690, 1605, 1497, 1255, 845 cm^{-1}; NMR (CCl_4) δ=0.00 (s, 9H), 1.77 (s, 3H), 2.35—3.38 (m, 3H), 7.05 (s, 5H); Calcd for $C_{13}H_{20}OSi$: C, 70.85; H, 9.15. Found: C, 70.62; H, 9.03.

3-(Trimethylsilyl)-11-dodecen-2-one **4d**: Bp. 117—120 °C/1 mmHg; IR (neat): 3070, 2925, 2850, 1695, 1645, 1255, 985, 910, 840 cm^{-1}; NMR (CCl_4) δ=−0.11 (s, 9H), 0.90—1.40 (m, 12H), 1.75—2.40 (m, 3H), 4.87 (d, J=11 Hz, 1H), 4.92 (d, J=16 Hz, 1H), 5.12—6.00 (m, 1H); Calcd for $C_{15}H_{30}OSi$: C, 70.79; H, 11.88. Found: C, 70.92; H, 12.03.

2-Methyl-5-(trimethylsilyl)-2-nonen-4-one **4e**: IR (neat): 1670, 1620 cm^{-1}; NMR (CCl_4) δ=0.07 (s, 9H), 0.70—1.50 (m, 9H), 1.70—2.40 (m, 2H), 1.87 (s, 3H), 2.13 (s, 3H), 5.90 (m, 1H).

The Reaction of 2-Chloroacyltrimethylsilane with a Grignard Reagent Bearing β-Hydrogen. General Procedure: An ethereal solution of the Grignard reagent (5.2 mmol) was added to a THF (2.5 ml) solution of 2-chloroacyltrimethylsilane (2.5 mmol) at −78 °C and it was stirred for 30 min at that temperature. Then, the reaction mixture was quenched with satd aq NH_4Cl and the aqueous layer was extracted with ether. After drying the combined extracts over anhyd $MgSO_4$ and removal of the solvent, purification of the residual oil with TLC using a mixture of hexane and ether (20:1) afforded the corresponding 2-(trimethylsilyl)-1-alkanol.

5-(Trimethylsilyl)-6-dodecanol **5b**: IR (neat): 3440, 2950, 2920, 1240, 836 cm^{-1}; NMR (CCl_4) δ=−0.07 (s, 9H), 0.7—1.62 (m, 23H), 2.06 (br s, 1H), 3.63 (m, 1H); Calcd for $C_{15}H_{34}OSi$: C, 69.69; H, 13.26. Found: C, 69.42; H, 13.38.

6-(Trimethylsilyl)-7-tetradecanol **5c**: IR (neat): 3450, 2920, 2850, 1247, 836 cm^{-1}; NMR (CCl_4) δ=0.03 (s, 9H), 0.77—1.73 (m, 27H), 1.97 (br s, 1H), 3.77 (m, 1H); Calcd for $C_{17}H_{38}OSi$: C, 71.25; H, 13.37. Found: C, 71.07; H, 13.16.

1-Phenyl-2-(trimethylsilyl)-3-heptanol **5d**: IR (neat): 3430, 1250, 840 cm^{-1}; NMR (CCl_4) δ=0.10 (s, 9H), 0.90—1.80 (m, 11H), 2.83 (d, J=7 Hz, 2H), 3.85 (m, 1H), 7.26 (s, 5H).

1-Phenyl-2-(trimethylsilyl)-3-nonanol **5e**: IR (neat): 3450, 3060, 3030, 3000, 2940, 2900, 2835, 1600, 1490, 1245, 835 cm^{-1}; NMR (CCl_4) δ=0.03 (s, 9H), 0.7—1.9 (m, 14H), 2.01 (br s, 1H), 2.95 (d, J=7 Hz, 2H), 3.95 (m, 1H), 7.38 (s, 5H); Calcd for $C_{18}H_{32}OSi$: C, 73.90; H, 11.03. Found: C, 73.68; H, 10.89.

Found: C, 73.33; H, 13.04.

Conversion of 6-(Trimethylsilyl)-5-decanol to (E)- and (Z)-5-Decene. 2-Chlorohexanoyltrimethylsilane (412 mg, 2 mmol) was treated with butylmagnesium bromide (4.4 mmol) in a

similar manner as described above and 6-(trimethylsilyl)-5-decanol **5a** (462 mg, 85%) was obtained. IR (neat): 3450, 2960, 1680, 835 cm^{-1}; NMR(CCl_4) δ=−0.06 (s, 9H), 0.77—1.67 (m, 19H), 3.70 (m, 1H). To a THF (2 ml) solution of the alcohol **5a** (230 mg, 1 mmol) was added KH (3 mmol) in THF (1 ml) at 0 °C and it was stirred for 1 h at room temperature. Then, the reaction mixture was quenched with sat aq NH_4Cl and the aqueous layer was extracted with ether. The combined extracts were dried over anhyd $MgSO_4$, and the resulting solution was analyzed by GLC using decane as an internal standard, which showed formation of a mixture of (*E*)- and (*Z*)-5-decene in 82% yield. Ratio of (*E*)- to (*Z*)-isomer was determined to be 4:96 by comparison with the authentic sample.

The same alcohol (216 mg, 0.94 mmol) was treated with BF_3OEt_2 (0.4 ml) in dichloromethane (5 ml) at room temperature for 1 h. Similar analysis of the reaction mixture indicated formation of (*E*)- and (*Z*)-5-decene in 85% yield in a ratio of 95:5, respectively.

Axially Dissymmetric Bis(aminophosphine)s Derived from 2,2′-Diamino-1,1′-binaphthyl. Synthesis and Application to Rhodium(I)-Catalyzed Asymmetric Hydrogenations[1)]

Sotaro MIYANO,* Masayoshi NAWA, Akira MORI, and Harukichi HASHIMOTO
Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Aramaki-Aoba 980
(Received January 13, 1984)

Axially dissymmetric bisphosphine ligands, (*R*)- and (*S*)-2,2′-bis(diphenylphosphinoamino)-1,1′-binaphthyl (BDPAB) and (*R*)-2,2′-bis[*N*-(diphenylphosphino)methylamino]-1,1′-binaphthyl (Me-BDPAB) were conveniently prepared from 2,2′-diamino-1,1′-binaphthyl. The rhodium(I)-catalyzed asymmetric hydrogenation of α-acylamidoacrylic acids and esters gave the corresponding amino acids of up to 95% optical purity. The sign of the centro-chirality of the product amino acids was always the same to that of the axial chirality of the ligand in both cases of BDPAB and Me-BDPAB.

Asymmetric hydrogenation of prochiral olefins catalyzed by rhodium(I)-chiral phosphine complexes has been widely studied.[2)] Although the mechanism of the hydrogenation has recently been greatly clarified,[3)] there has still been continuing interest in the synthesis of novel chiral phosphine ligands,[4)] as subtle variations in ligand structure not only greatly affect the optical yields but sometimes alter even the absolute configuration of the preferential products. Some of these ligands have shown enantioselectivity which rivals that of enzymic reactions. However, the synthesis and isolation of many of chiral phosphines require tedious manipulations, imposing some restrictions to their wide use. In this regard, aminophosphines have recently attracting much interest because they can be readily prepared and show high stereoselectivity in the rhodium-catalyzed asymmetric hydrogenation.[5)]

Axially dissymmetric 1,1′-binaphthyl moiety has proved to be highly desirable asymmetry-inducing unit because of its structural rigidity and simplicity, resistance to racemization, and above all, effectiveness of chiral recognition.[6)] Three research groups have reported chiral bisphosphine ligands, **1a** (NAPHOS),[7)] **1b**,[8)] and **2** (BINAP),[9)] which contain the atropisomeric 1,1′-binaphthyl residue as the chiral element for use in the rhodium-catalyzed asymmetric hydrogenation of prochiral olefins. Recently a biphenyl phosphine **3** (MABP) has appeared.[10)]

d -X- = $-N(CH_3)-$ (Me-BDPAB)

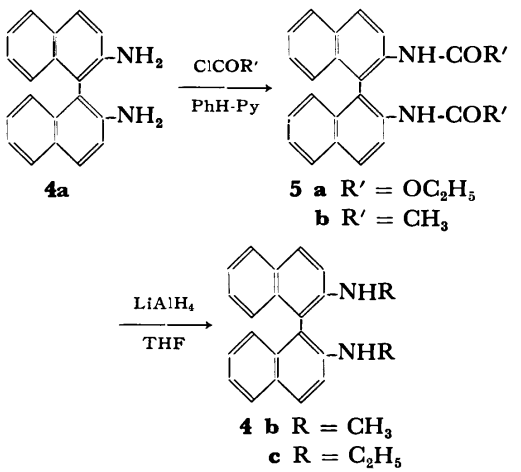
2 (BINAP) **3** (MABP)

We ourselves have reported briefly a facile synthesis of (*R*)- and (*S*)-2,2′-bis(diphenylphosphinoamino)-1,1′-binaphthyl (**1c**, hereafter abbreviated as BDPAB) and asymmetric hydrogenation of α-acylamidoacrylic acids and esters by use of Rh(I)–BDPAB complexes.[1)] In this paper, we wish to report the results we have obtained in the course of this investigation including the synthesis of 2,2′-bis[*N*-(diphenylphosphino)methylamino]-1,1′-binaphthyl (**1d**, Me-BDPAB).

Results and Discussion

Synthesis of 2,2′-Diamino-1,1′-binaphthyls. According to the method reported briefly by Clemo and Dawson,[11)] 2-naphthol was converted to 2,2′-diamino-1,1′-binaphthyl (**4a**) by heating with hydrazine hydrate to 170—180 °C in a sealed vessel, and then treating with hot aq HCl. Although the yield of the diamine was not so much good (less than 40% at our hand) and the formation of carcinogenic 2-naphthylamine as a by-product requires careful handling of the reaction mixture, the procedure seems to be the one of choice because of operational simplicity and inexpensive starting materials.[12)] Both enantiomers of the diamine (**4a**) were readily obtained by the method of Kuhn and Goldfinger using *d*-camphorsulfonic acid as the resolving agent.[12)]

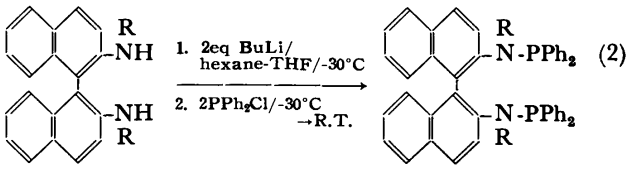
Preparation of 2,2′-bis(methylamino)- and 2,2′-bis(ethylamino)-1,1′-binaphthyl (**4b** and **4c**) is summarized in Eq. 1. Treatment of parent diamine **4a** with



4a **5 a** R′ = OC_2H_5, **b** R′ = CH_3 **4 b** R = CH_3, **c** R = C_2H_5 (1)

ethyl chloroformate in benzene-pyridine gave 2,2′-bis(ethoxycarbonylamino)-1,1′-binaphthyl (**5a**), which was then boiled with lithium aluminium hydride (LAH) in THF to give **4b**. By using (*R*)- or (*S*)-**4a**, the corresponding atropisomeric **4b** was obtained. Similar treatment of diamine **4a** with acetyl chloride and then reduction with LAH gave *N*-ethyl analogue, **4c**.

Synthesis of 2,2′-Bis(diphenylphosphinoamino)-1,1′-binaphthyls. At first, diamine **4a** was treated with diphenylphosphinous chloride in THF in the presence of triethylamine or pyridine according to the conventional procedure,[5] but no detectable amount of phosphinated amine was resulted. Then, racemic **4a** was *N,N′*-dilithiated with stoichiometric amount of butyllithium in THF–hexane at −30 °C followed by treatment with diphenylphosphinous chloride; BDPAB **1c** was obtained as white crystals in a 75% yield (Eq. 2). Similar treatment of (*R*)- and (*S*)-**4a** gave the corresponding (*R*)- and (*S*)-BDPAB, respectively. The (*R*)-BDPAB was recrystallized twice from ethanol–benzene to show $[\alpha]_D^{23}$+27.2° in benzene. Significant racemization of the axial dissymmetry is ruled out considering the high asymmetric induction in the Rh(I)-catalyzed hydrogenation of (*Z*)-α-benzamidocinnamic acid (*vide infra*).



4 a R = H
b R = CH_3

1 c R = H (BDPAB)
d R = CH_3 (Me-BDPAB)

N-Methyl analogue of BDPAB, 2,2′-bis[*N*-(diphenylphosphino)methylamino]-1, 1′-binaphthyl (**1d**, Me-BDPAB), was prepared from **4b** by the similar procedure. (*R*)-Me-BDPAB was obtainable by use of (*R*)-**4b**. *N*-Ethylamine **4c**, however, did not afford the (ethylamino)phosphine (Et-BDPAB) even under somewhat forcing conditions. This was unexpected result at first, but inspection of CPK molecular models suggests that replacement of *N*-ethyl for *N*-methyl substituent imposes rather severe steric bulk on the amide anion due to the steric repulsion against naphthalene nucleus, and thus inhibits the nucleophilic attack to phosphorous center.

Asymmetric Hydrogenation. Generally, chiral catalysts were prepared just prior to the hydrogenation by mixing $[Rh(olefin)_2Cl]_2$ with 2.2 molar amount of one of the chiral bis(aminophosphine)s in the presence or absence of sodium tetraphenylborate under an inert atmosphere. Hydrogenation of several olefinic substrates was carried out in a glass tube placed in an autoclave. After the reaction, products were recovered according to the literature.[13] The optical yields were determined by comparing the rotations of the isolated products with those of the reported values for the pure enantiomers.

Table 1 shows the effects of reaction variables on the hydrogenation of (*Z*)-α-acetamidocinnamic acid using (*R*)- or (*S*)-BDPAB as the ligand. Reaction medium significantly affected the catalyst activity and optical yield. Solvent comprised of a 1:2 mixture of benzene and methanol or ethanol gave good results; the hydrogenation proceeded almost quantitatively at initial hydrogen pressure of 30 kg/cm² at ambient temperature with high optical yield. In such solvent system, the active catalyst seemed to be a cationic rhodium(I) species,[14] as was demonstrated from the fact that comparable result was obtained by using [Rh(COD)(*R*)-BDPAB]$^+BF_4^-$ as the catalyst. The optical yield was rather insensitive to the hydrogenation pressure, while addition of triethylamine was harmful to chiral recognition.[15]

Table 2 summarizes the results of the hydrogenation of several olefinic substrates. High optical yields (80—95%) were obtained with (*R*)- and (*S*)-BDPAB ligand in the hydrogenation of α-acetamidoacrylic acids **6a**—**6c**, ester **6e**, and itaconic acid **6g**. Comparison of these results with those reported by Tamao *et al.*[7] and by Grubbs and DeVries[8] shows that among bisphosphine ligands **1** which apparently form a nine-membered chelate ring, BDPAB (**1c**) is superior to NAPHOS (**1a**) or phosphite **1b** in chiral recognition in the hydrogenation of dehydroamino acids. Although the conversion was low, an appreciable optical yields were obtained with (*E*)-α-methylcinnamic acid. Simple olefin **6h** reacted completely but gave poor optical yields.

Recent studies on the mechanism of asymmetric hydrogenation of dehydroamino acids have demonstrated that thermodynamic and kinetic profiles of the process must be clarified before correlating catalyst structure to the product conformation.[3] It is widely accepted, however, that a chiral ligand which can fix rigid complex catalyst is essential for effective

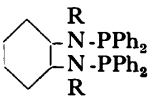
dissymmetric discrimination, and here we would like to point out some structural features of the BDPAB ligand.

It is noted that the hydrogenation of (*Z*)-dehydroamino acids **6a**—**6e** using (*R*)-BDPAB ligand always gave (*R*)-α-amino acids preferentially, and (*S*)-BDPAB preferred (*S*)-counterparts. Similar ligand-product relationship in chirality is reported in the hydrogenation of **6b** with (*S*)-NAPHOS.[7] Examination of CPK molecular models suggests that (*R*)-BDPAB confines rigid nine-membered chelate ring with square planar Rh(I) containing hardly flexible 1,1′-binaphthyl skeleton, arraying four phenyl rings in an alternating edge-face manner as is observed in the seven-membered (*R*,*R*)-DIOP-Rh(I) complex of nearly δ-conformation.

On the other hand, Miyashita *et al.* have shown that BINAP ligand (**2**) fixes seven-membered chelate ring of λ-skew-boat conformation, and that (*R*)- and (*S*)-BINAP induce (*S*)- and (*R*)-chirality, respectively, in the Rh(I)-catalyzed hydrogenation of (*Z*)-α-acylamidoacrylic acids. That is, the sense of asymmetric induction is quite opposite between BDPAB and BINAP. It is surprising that MABP (**3**),[10] which seems to form closely related Rh(I)-complex to BDPAB, also gave opposite enantioselection in the hydrogenation of (*Z*)-α-acetamidoacrylic acid to *N*-acetylalanine, and at present we have no idea to explain these results.

It has been reported that *N*-methylation of 1,2-bis(diphenylphosphinoamino)ethane-type ligand such as **7a** to **7b** causes inversion of the chiral stereoselectivity on the Rh(I)-catalyzed hydrogenation of α-acetamidoacrylic acids.[5d,5e] This drastic change in stereoselectivity has been explained from the structural studies of the complexes including X-ray analysis that the helical orientation of the phenyl rings of the ligand would be inverted by *N*-methyl groups in the aminophosphine when coordinated to rhodium.[16]



7 a R = H
b R = CH_3

In all cases examined, however, hydrogenation with (*R*)-Me-BDPAB ligand gave reduction products of the same chirality to those obtained with (*R*)-BDPAB ligand, although the effects of *N*-methylation on optical yields were different from substrate to substrate (Table 2). It seems that the rigid 1,1′-binaphthyl skeleton is mostly responsible for the overall structure

of BDPAB-type ligand regardless of the presence or absence of *N*-methyl substituents.

Experimental

Measurements. IR spectra were obtained on a Shimadzu IR 430 spectrophotometer. NMR spectra were determined on a Hitachi R-24A instrument using hexamethyldisiloxane as an internal standard. Mass spectra were recorded on a JEOR-D 300 double focussing mass spectrometer with direct sample injection. Optical rotations were recorded on a Union PM-101 automatic digital polarimeter. Melting points were corrected.

Materials. Following commercial materials were recrystallized or distilled before use; α-acetamidoacrylic acid (**6a**) (mp 185—186 °C), (*Z*)-α-acetamidocinnamic acid (**6b**) (mp 185—187 °C (H_2O)), and itaconic acid (**6g**) (mp 169.5—171.5 °C (EtOH)). (*Z*)-α-Benzamidocinnamic acid (**6c**) (mp 229—231 °C),[17] (*E*)-α-methylcinnamic acid (**6f**) (mp 81—81.5 °C),[18] 2-phenyl-1-butene (**6h**) (bp 66—67 °C/20 mmHg†)[19] were prepared by standard methods. Methyl (*Z*)-α-acetamidocinnamate (**6d**) (mp 122.5—124 °C (MeOH)) and methyl (*Z*)-α-benzamidocinnamate (**6e**) (mp 140—141 °C (MeOH)) were obtained by the reaction of diazomethane with **6b** and **6c**, respectively. $[Rh(cyclooctene)_2Cl]_2$[20] and $[Rh(COD)Cl]_2$[21] were prepared according to the literature. Commercial BuLi in hexane (*ca.* 15% solution) was titrated before use.[22] Solvents were purified as usual under nitrogen. All reactions involving phosphines were routinely performed under an inert atmosphere of nitrogen or argon.

2,2'-Diamino-1,1'-binaphthyl (4a). Clemo and Dawson's procedure[11] was utilized as follows: 2-Naphthol (40.0 g, 0.278 mol) and 8.8 ml of hydrazine hydrate (80% solution, *ca.* 0.14 mol) were heated in a *ca.* 90 ml inner-volume stainless steel autoclave at 170—180 °C for 48 h. After the vessel was cooled, it was opened and the contents were remelted by heating. The yellowish viscous material was poured into a 2-necked round-bottom flask containing 600 ml of 1:1 HCl. To the flask were attached mechanical stirrer and a reflux condenser. The stirred mixture was heated at reflux, during which time brown tarry matter appeared. After standing for a while, supernatant liquid was siphoned off. Similar hot extraction was repeated 3 times by using 300 ml of 1:1 HCl each time. The combined HCl extracts were made alkaline by cautious addition of NaOH pellets with ice-cooling. The mixture was boiled and filtered while hot. Then, the precipitate was boiled in 500 ml of water and filtered hot; the procedure was repeated several times to thoroughly remove 2-naphthylamine. The precipitate was dissolved in a 400 ml of 2 M†† HCl, filtered hot from activated charcoal. The filtrate was made alkaline with 10% NaOH; formed precipitate was filtered off and dried *in vacuo*, 14.4 g (36.6%), mp 187—188 °C. Recrystallization from ethanol-acetone gave a pure sample of mp 193.2—194.3 °C (lit,[23] mp 193 °C); IR (KBr): 3450, 3300, 3100, 1610, 1500, 1430, 1380, 1350, 1280, 810, and 750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.5 (4H, br), 6.9—7.3 (8H, m), and 7.5—7.8 (4H, m). Found: C, 84.41; H, 5.67; N, 9.72%. Calcd for $C_{20}H_{16}N_2$: C, 84.48; H, 5.67; N, 9.85%.

Resolution of 4a. The method was Kuhn and Goldfinger's,[12] while control of temperature seemed important to obtain fine precipitate of the less soluble diastereomer salt. (±)-Diamine (**4a**) (10.5 g, 36.9 mmol) was dissolved in 300 ml of chlorobenzene with warming up to 70 °C. To the stirred solution kept at *ca.* 50 °C was added slowly a solution of *d*-camphorsulfonic acid monohydrate (8.4 g, 34 mmol) in ethanol (60 ml). By the end of the addition, fine white crystals began to deposit. The mixture was stirred till it reached to room temperature, and then allowed to stand overnight. The precipitate was filtered off, washed with chlorobenzene (50 ml×3), and dried *in vacuo* to give (*d*)-(*d*)-salt, $[\alpha]_D^{23}$+101 ° (*c* 0.86, py) (lit,[23] $[\alpha]_D^{19}$+103.6 ° (*c* 1.05, py)); IR (KBr): 3450, 3300, 1740, 1130, and 1030 cm^{-1}. The salt was dissolved in 60 ml of pyridine, and poured into 500 ml of water to give white suspension. Solid was collected by filtration, dissolved in 200 ml of 2 M HCl, decolorized with activated charcoal, and filtered. The filtrate was made alkaline with aq NH_3 to give white precipitate, which was recovered by filtration, dried, and recrystallized from ethanol-benzene to give 4.50 g (86%) of (*R*)-(+)-**4a**; mp 245—246 °C (lit,[24] mp 245 °C); $[\alpha]_D^{22}$+157.4 ° (*c* 0.712, py) (lit,[23] $[\alpha]_D^{21-22}$ +151.7 ° (*c* 0.5-1, py)). A weak, but somewhat broad IR absorption at 1105 cm^{-1} of (±)-**4a** was missing in (*R*)-**4a**. Found: C, 84.29; H, 5.63; N, 9.45%.

The above chlorobenzene-ethanol filtrate which contained more soluble (*d*)-(*l*)-salt was evaporated *in vacuo* to leave brown residue, which was treated as above to liberate free (*S*)-(−)-base. The crude material was recrystallized twice from ethanol-benzene, 2.5 g (48%), mp 244—246 °C, $[\alpha]_D^{23}$−153.0 ° (*c* 0.758, py). Found: C, 84.50; H, 5.77; N, 9.53%.

2,2'-Bis(ethoxycarbonylamino)-1,1'-binaphthyl (5a). To a stirred, water-chilled solution of racemic **4a** (3.95 g, 13.9 mmol) in benzene (80 ml) and pyridine (10 ml) was added dropwise a solution of ethyl chloroformate (3.75 g, 34.6 mmol) in benzene (20 ml). After the addition was complete, the mixture was stirred for 2 h at ambient temperature. The reaction was quenched by adding 100 ml of 10% NaOH. The resulting organic layer and benzene extracts (50 ml×2) from the aqueous layer were combined, washed with water and dried over $MgSO_4$. The solvents were evaporated *in vacuo*, and resulting residue was recrystallized from ethanol-acetone to give 3.77 g of diester **5a** (63.3%); mp 155—156 °C; IR (KBr): 3400, 3300, 2900, 1720, 1600, 1490, 1210, 1090, 820, and 740 cm^{-1}; ^1H NMR (acetone-d_6) δ=1.0 (6H, t, *J*=6.8 Hz), 2.7 (2H, s), 3.9 (4H, q, *J*=6.8 Hz), 6.8—7.5 (8H, m), and 7.6—8.3 (4H, m). Found: C, 72.95; H, 5.71; N, 6.20%. Calcd for $C_{26}H_{24}O_4N_2$: C, 72.88; H, 5.65; N, 6.54%.

(R)-(+)-5a: Similar treatment of (*R*)-(+)-**4a** (2.2 g, 7.7 mmol) gave (*R*)-(+)-**5a**, 2.2 g (67%), mp 70—72 °C, $[\alpha]_D^{23}$+68.5° (*c* 1.23, THF).

2,2'-Bis(methylamino)-1,1'-binaphthyl (4b). To a stirred suspension of LAH (4 g) in 100 ml of THF was added dropwise a solution of **5a** (7.6 g, 17.7 mmol) in 50 ml of THF. The mixture was heated at reflux for 3 h. The reaction mixture was cooled in an ice-bath and the remaining hydride was carefully quenched by dropwise addition of water (5 ml) and then 15% NaOH (5 ml). A white precipitate was filtered off and thoroughly washed with ether. The combined filtrate and ether washings were washed with water, dried over Na_2SO_4 overnight. After the solvents were evaporated under reduced pressure, the residue was recrystallized from ethanol-benzene, 4.5 g (81%); mp 149—151 °C; IR (KBr): 3400, 1620, 1600, 1500, 1420, 1340, 1300, 1170, 1150, 810, and 750 cm^{-1}. ^1H NMR (acetone-d_6) δ=2.7 (6H, d, *J*=6.0 Hz), 3.9 (2H, br), 6.5—7.3 (8H, m), and 7.3—8.0 (4H, m). Found: C, 84.37; H, 6.40; N, 8.96%. Calcd for $C_{22}H_{20}N_2$: C, 84.58; H, 6.45; N, 8.97%.

(R)-(+)-4b: The (*R*)-(+)−**5a** (1.53 g, 3.56 mmol) was treated with LAH (0.9 g) in 50 ml of THF and worked up as above. After removal of volatiles *in vacuo*, the residue was recrystallized from ethanol to give (*R*)-(+)-**4b**, 0.73 g (66%), mp 143—144 °C, $[\alpha]_D^{23}$+182 ° (*c* 1.09, PhH). Found: C, 84.21; H, 6.59; N, 8.82%.

2,2'-Bis(ethylamino)-1,1'-binaphthyl (4c). A mixture of diamine **4a** (1.2 g, 4.2 mmol) and acetyl chloride (1.1 g,

† 1 mmHg≈133.322 Pa.

†† 1 M=1 mol dm^{-3}

14 mmol) in benzene (40 ml) and pyridine (8 ml) was stirred overnight at ambient temperature. Organic residue obtained after usual workup was recrystallized from ethanol to give a 1.22 g sample (79% yield) of 2,2'-bis(acetamido)-1,1'-binaphthyl **5b**, mp 235—235.5 °C; IR (KBr): 3300, 1670, 1600, 1490, 1420, 1270, 820, and 740 cm^{-1}. ^1H NMR ($CDCl_3$+DMSO-d_6) δ=1.7 (6H, s) and 6.5—8.3 (14H, m); MS (70 eV), *m/z* (%) 369 (M+1, 3.0) and 368 (M^+, 10.5). Found: C, 78.13; H, 5.60; N, 7.65%. Calcd for $C_{24}H_{20}N_2O_2$: C, 78.24; H, 5.47; N, 7.60%.

A mixture of **5b** (0.50 g, 1.4 mmol) and LAH (0.3 g) was boiled in 35 ml of THF for 3 h. The mixture was worked up as was stated in the synthesis of **4b**. Recrystallization from ethanol gave 0.25 g of **4c** (54%), mp 127.5—128 °C; IR (KBr): 3400, 2900, 1610, 1600, 1480, 1410, 1320, 1290, 1140, 800, and 740 cm^{-1}: ^1H NMR ($CDCl_3$) δ=0.95 (6H, t, *J*=7.0 Hz), 3.1 (4H, q, *J*=7.0 Hz), 3.9 (2H, br), and 6.5—8.0 (12H, m); MS (70 eV), *m/z* (%), 341 (M+1, 8.8) and 340 (M^+, 29.8). Found: C, 84.21; H, 6.88; N, 8.03%. Calcd for $C_{24}H_{24}N_2$: C, 84.67; H, 7.11; N, 8.23%.

2,2'-Bis(diphenylphosphinoamino)-1,1'-binaphthyl (1c, BDPAB). In a 100 ml, three-necked round-bottom flask equipped with a magnetic stirrer, a thermometer, a pressure equilibrating dropping funnel, and a reflux condenser topped with nitrogen inlet was placed racemic **4a** (1.55 g, 5.45 mmol). The whole system was purged with nitrogen. After the amine had been dissolved in 50 ml of THF, the solution was cooled to −30—−32 °C in a methanol-Dry Ice bath. To the cooled solution was added dropwise a hexane solution (8.8 ml) of 1.30 M BuLi (11.4 mmol) over 40 min. After the addition, the mixture was stirred at −30 °C for 20 min. To the stirred mixture kept at −28—−30 °C was added dropwise a solution of diphenylphosphinous chloride (2.46 g, 11.2 mmol) dissolved in 10 ml of THF over 40 min. Stirring was continued for another 1 h. Then the cooling bath was removed, and the mixture was stirred overnight at ambient temperature. Lithium chloride precipitated was filtered off under nitrogen, and then volatiles were evaporated *in vacuo* to leave yellowish resinous residue. This was digested with portions of warm ethanol (*ca.* 30 ml×3) to give white solid. Recrystallization from ethanol-benzene gave white crystals, 2.58 g (72.6%); mp 164—165 °C; IR (KBr): 3330, 3030, 1610, 1590, 1500, 1460, 1430, 1390, 1340, 1270, 1240, 980, 810, 740, 730, and 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.4 and 4.6 (2H, br), and 6.6—7.4 and 6.5—7.9 (32H, m); MS (70 eV), *m/z* (%), 654 (M+2, 6.3), 653 (M+1, 26.5), and 652 (M^+, 52.2). Found: C, 80.48; H, 5.12; N, 4.33%. Calcd for $C_{44}H_{34}N_2P_2$: C, 80.97; H, 5.25; N, 4.29; P, 9.49%.

(R)-(+)-BDPAB: The diamine (*R*)-**4a** (2.16 g, 7.59 mmol) was treated as above to give (*R*)-(+)-BDPAB, 3.3 g (67%), mp 153—155 °C (PhH–EtOH); $[\alpha]_D^{23}$+26.1° (*c* 1.14, PhH). The product was again recrystallized from ethanol-benzene to increase the rotation to $[\alpha]_D^{23}$+27.2° (*c* 1.14, PhH), mp 154—155 °C. Subsequent recrystallization did not change the rotation. Found: C, 80.66; H, 5.19; N, 4.42%.

(S)-(−)-BDPAB: A sample of (*S*)-(−)-**4a** of $[\alpha]_D$ −153.0° gave diphosphine (*S*)-(−)-BDPAB of $[\alpha]_D^{23}$−25.8° (*c* 0.776, PhH) after two recrystallization from ethanol-benzene, mp 152—153 °C, the optical purity of which was estimated to be 95% on the basis of the maximum rotation of (*R*)-(+)-BDPAB of $[\alpha]_D$ +27.2°. Found: C, 80.93; H, 5.38; N, 4.59%.

2,2'-Bis[N-(diphenylphosphino)methylamino]-1,1'-binaphthyl (Me-BDPAB). According to the procedure used for the synthesis of BDPAB, **4b** (0.50 g, 1.6 mmol) was treated with BuLi (3.36 mmol), and then with diphenylphosphinous chloride (0.74 g, 3.3 mmol). Recrystallization from ethanol-benzene gave fine crystals, 0.60 g (56.2%), mp 159—161 °C; IR (KBr): 3050, 2800, 1615, 1590, 1500, 1470, 1430, 1350, 1325, 1270, 1240, 1090, 960, 930, 740, 695, and 495 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.5 (6H, s) and 6.6—8.0 (32H, m); MS (70 eV), *m/z* (%), 682 (M+2, 2.9), 681 (M+1, 9.7), and 680 (M^+, 33.8). Found: C, 81.05; H, 5.68; N, 3.99%. Calcd for $C_{46}H_{38}N_2P_2$: C, 81.16; H, 5.63; N, 4.12; P, 9.10%.

(R)-(−)-Me-BDPAB: A sample of (*R*)-(+)-**4b** of $[\alpha]_D$+182° (0.63 g, 2.0 mmol) was treated with BuLi (4.2 mmol) and then with diphenylphosphinous chloride (0.93 g, 4.2 mmol) as above. After the reaction, the filtrate was evaporated *in vacuo*; the residue was freed from LiCl by dissolution in benzene and filtration. The benzene filtrate was evaporated *in vacuo* to give yellowish powder, 0.65 g (48%), mp 68—71 °C, $[\alpha]_D^{23}$ −20.7° (*c* 1.26, PhH). IR and ^1H NMR spectra were identical to those of the racemic phosphine. Found: C, 80.62; H, 5.96; N, 3.51%. Attempts to recrystallize the optically active phosphine by varying solvents were unsuccesful.

Attempted Preparation of 2,2'-Bis[N-(diphenylphosphino)-ethylamino]-1,1'-binaphthyl (Et-BDPAB). Diamine **4c** (0.23 g, 0.68 mmol) was treated with BuLi (1.4 mmol), and then with diphenylphosphinous chloride (0.35 g, 1.6 mmol) as above. After usual workup, almost all of the diamine was recovered unchanged. In an another attempt, after the reaction mixture had been stirred overnight at ambient temperature, it was finally refluxed for 2 h, while no appreciable aminophosphine was obtained.

Preparation of Hydrogenation Catalysts. Catalyst A, (1/2 [Rh(olefin)$_2$Cl]$_2$+1.1BDPAB): The catalyst was prepared just prior to the hydrogenation by the reaction of [Rh(COD)Cl]$_2$ or [Rh(cyclooctene)$_2$Cl]$_2$ with a chiral diphosphine in benzene ([diphosphine]/[Rh] (mol/mol)=1.1). Typically, 17 mg (2.4×10^{-2} mmol) of [Rh(cyclooctene)$_2$Cl]$_2$ and 35 mg (5.4×10^{-2} mmol) of (*R*)-BDPAB in 4 ml of benzene was stirred at room temperature for 20 min under argon. The clear wine-red catalyst solution was transferred under rigorous exclusion of air to a reaction vessel, which contained an olefinic substrate (*vide infra*), by a hypodermic syringe.

Catalyst B, (1/2[Rh(COD)Cl]$_2$+1.1BDPAB+3NaBPh$_4$): Typically, (*R*)-BDPAB (35 mg, 5.4×10^{-2} mmol) in benzene (2 ml) was added to a methanol solution (2 ml) of [Rh(COD)Cl]$_2$ (12 mg, 2.4×10^{-2} mmol). The solution was stirred for 15 min, to which was added $NaBPh_4$ (48 mg, 14×10^{-2} mmol) in 2 ml of MeOH. The mixture was stirred for 10 min before it was transferred to a hydrogenation vessel.

Catalyst C, ([Rh(COD)(R)-BDPAB]$^+$BF$_4^-$): To a warm benzene solution (2 ml) of (*R*)-BDPAB (0.79 g, 1.2 mmol) was added [Rh(COD)Cl]$_2$ (0.28 g, 0.57 mmol) in MeOH (5 ml). After the mixture was stirred at 30—35 °C for 2 h, $NaBF_4$ (0.43 g, 3.9 mmol) in H_2O (4 ml) was added over 2 h period. The two-layer mixture was allowed to stand for 5 days at room temperature. Precipitated [Rh(COD)(*R*)-BDPAB]$^+BF_4^-$ was collected, 0.99 g (89%).

Hydrogenation Procedure. A reaction in a benzene-methanol solution is representative. The hydrogenation was carried out in a glass tube (*ca.* 30 ml volume) placed in a 100 ml inner-volume autoclave. After the glass tube was charged with an olefinic substrate (0.45—0.50 g), the whole system was evacuated and refilled with argon several times. The substrate was dissolved in 4 ml of methanol, and to the stirred solution was added a catalyst solution. If necessary, another benzene and/or methanol were added to adjust the solvent volume. The whole system was purged thoroughly with hydrogen, and it was charged to initial hydrogen pressure of 30 kg/cm^2. After the reaction mixture had been stirred at room temperature for 24 h, whole contents in the glass tube was transferred to a flask and solvents were removed *in vacuo*.

N-Acyl amino acids were recovered by the literature procedure.[13] 2-Methyl-3-phenylpropionic acid was isolated by preparative TLC (silica gel, ethyl acetate–aq NH_3 (trace)). *N*-Acyl amino acid esters were recovered by TLC (silica gel,

ethyl acetate–hexane (1.5/1). Hydrogenation products were characterized by IR and NMR spectra.[13]

The Effect of Ethylene Glycol on the Thermal Denaturation of Ribonuclease A and Chymotrypsinogen A as Measured by Differential Scanning Calorimetry

Yukihisa FUJITA* and Yukinao NODA

Department of Chemistry, Hyogo College of Medicine, Mukogawa, Nishinomiya, Hyogo 663

(Received January 21, 1984)

The thermal denaturation of ribonuclease A(RNase A) and chymotrypsinogen A in aqueous solutions of ethylene glycol (EG) was investigated by differential scanning calorimetry at several pH values in the acidic region. The calorimetric enthalpies of denaturation, ΔH_d, of these proteins increased monotonously with increasing the EG concentration under all the conditions studied. These proteins, however, differed from one another in the variation of the denaturation temperature, T_d, with the addition of EG. The T_d of chemotrypsinogen decreased slightly with an increase in EG concentration under all the conditions, producing a greater effect at high pH. The T_d of RNase A, on the other hand, was almost independent of the EG content at pH 3.8, while at pH 2 and 3, the T_d increased slightly with increasing the EG concentration and decreased slightly at pH 5. That is, EG stabilized or unstabilized these proteins against thermal denaturation, in a way which seemed to be dependent on temperature rather than the pH. The standard thermodynamic parameters for denaturation, $\Delta G°$, $\Delta H°$, and $\Delta S°$, which were calculated using T_d and ΔH_d and assuming a constant heat capacity change, suggested that the slight increase or decrease in $\Delta G°$ induced by EG is attributed to whether $\Delta H°$ increases as much as $\Delta S°$ does or not. These results may be explained on the basis of the effect of EG on the solvation around hydrophobic groups of the protein. The EG effect may depends on the structural properties of proteins such as hydrophobicity and polarity, as well as on temperature.

The structural stability of proteins is extensively controlled by the interactions between the protein and surrounding solvent molecules. Various substances stabilize or unstabilize the native structure of proteins when added to aqueous protein solutions as a reflection of their effect on the water structure around the protein.[1-4] Polyhydric alcohols such as glycerol and sorbitol prevent the lose of enzymatic activities[5,6] and raise the thermal transition temperature of proteins. This stabilizing effect had been attributed to a lessened hydrogen bond-rupturing capacities of the medium.[7] Recently, Gekko and coinvestigators[10-13] concluded from extensive studies that the protein stabilization by polyhydric alcohols is due to a preferential hydration effect which strengthens the hydrophobic interactions of the protein. The preferential hydration of proteins in the presence of polyhydric alcohols has been directly shown from equilibrium dialysis[14] and densimetric experiments.[12] On the other hand, monohydric alcohols unstabilize the native structure of proteins. This may be attributed to the perturbation of the characteristic water structure around the protein molecule and to the direct interactions with the protein.[1-3] These alcohols are preferentially bound to protein in alcohol-water mixtures, which is accompanied by a protein dehydration.[14,15] These studies imply that any substance which trends to maintain or increase the hydration of proteins stabilizes a protein and, to the contrary, any substance which is bound to and dehydrates the protein unstabilizes the native structure of proteins.

According to this hypothesis, ethylene glycol (EG)** would have a stabilizing effect on the native structure of proteins, since a number of proteins are preferentially hydrated in EG-water mixtures.[14,16] Actually there have been many observations which show the protein stabilization induced by EG. For example, we reported previously that the denaturation temperature and enthalpy of lysozyme are higher in aqueous EG solutions at pH 2 than in aqueous solution at the same pH.[17] The stabilization of ribonuclease A (RNase A) and lysozyme by the addition of EG has been also shown by Gerlsma and Stuur.[8] However, there have been some contradictory observations concerning the EG effect on the thermal stability of proteins. The thermal transition temperatures of chymotrypsinogen and ovalbumin were depressed by the addition of EG.[7,9] Furthermore, a lowering of the denaturation temperatures of RNase A and lysozyme by EG has been shown at high pH in the acidic region,[2,10] which is in contrast with Gerlsma and Stuur's and our observations for the same proteins. These observations attracted our attention to a systematic examination of the EG effect on the thermal stability of proteins.

Differential scanning calorimetry (DSC) is a useful tool for measuring the thermally induced conformational transition of biological macromolecules such as proteins and nucleic acids. An application of DSC to the study of protein denaturation provides the available thermodynamic information on the unfolding process of proteins. This may contribute greatly to an understanding of the nature and magnitude of the forces that stabilize the native structure of proteins. Recent studies have been reviewed by Biltonen and Freire[18] and by Privalov.[19] We have been investigating the effect of various substances on the thermal stability of globular proteins by means of DSC.

A study of the thermal denaturation of ribonuclease A (RNase A) and chymotrypsinogen A in aqueous EG solutions at several acidic pH values was carried out by DSC; this paper reports the results. These proteins were chosen because they differ greatly in hydrophobicity and polarity and because their thermal denaturation had been investigated extensively in the past.

Experimental

Materials. Bovine pancreatic ribonuclease A (five-times recrystallized, type I-A) and chymotrypsinogen A (six-

** Abbreviations used: DSC, differential scanning calorimetry; EG, ethylene glycol; RNase A, ribonuclease A (bovine pancreatic, EC 3.1.4.22).

times recrystallized, type II) were purchased from Sigma Chemical Co. Ethylene glycol was purified by distillation under reduced pressure. Other chemicals were reagent grade products from Wako Pure Chemical Industries. In the case of RNase A, the experiments were carried out in either 0.05 mol dm^{-3} glycine buffer–EG mixtures adjusted to pH 2, 3, and 3.8 or 0.05 mol dm^{-3} acetate buffer–EG mixtures adjusted to pH 5 with 1 mol dm^{-3} HCl as measured by a Horiba f-7ss pH meter standardized at pH 4 in aqueous solution. In the case of chymotrypsinogen A, either 0.01 mol dm^{-3} glycine (at pH 2 and 3) or 0.01 mol dm^{-3} acetate buffer (at pH 4) was used to minimize aggregation of the denatured protein. The protein solutions were subjected to extensive dialysis against the solvent at 4 °C prior to making DSC measurements. Protein concentrations were determined spectrophotometrically on a Hitachi 323 automatic spectrophotometer. The extinction coefficients were assumed to be 7.38 at 277 nm[20] and 20.3 at 282 nm[21] for a 10 mg cm^{-3} aueous solution of RNase A and chymotrypsinogen A, respectively. The coefficients were corrected for each mixed solvent by the method of Lee *et al.*[22]

DSC measurements. The thermal denaturation of these proteins was measured on a Seiko Instruments & Electronics SSC-560U differential scanning calorimeter (conduction type) at a heating rate of 1 K min^{-1} and at protein concentrations of 8—12 mg cm^{-3} for RNase A and 15—19 mg cm^{-3} for chymotrypsinogen A. The sample solutions (0.06 cm^3) were hermetically sealed in a silver vessel. An equal amount of the solvent was used as reference material. The DSC apparatus was calibrated using gallium, benzophenone, palmitic acid, and naphthalene. The area between the transition peak and a base line fitted by inspection was measured with a planimeter and converted to the calorimetric enthalpy of denaturation, ΔH_d, using the calibration constant, 2.29 mJ mV^{-1}s^{-1}, and the molecular weight of 13 700 for RNase A and 25 700 for chymotrypsinogen A. The denaturation temperature, T_d, was estimated from the temperature at which the area under the transition peak was divided into halves, since the area is proportional to the amount denatured. The difference between the T_d obtained and the temperature of maximal heat flow did not exceed 0.5 K in every measurement because of the symmetrical nature of the transition peak.

Results and Discussion

Representative DSC scans for the thermal denaturation of RNase A in aqueous EG solutions at pH 3 are shown in Fig. 1. The DSC curves shown correspond to denaturation of a protein solution of 10 mg cm^{-3} in EG concentrations of 0 and 4.64 mol dm^{-3}. At pH 3, the addition of EG to a aqueous solution of RNase A induces a slight shift of the transition peak toward high temperature and an increase of the peak area. In the case of RNase A, although the temperature width of the transition peak, 20—22 K, was hardly influenced by the variation of pH or by the addition of EG, the shift of the transition peak induced by EG was dependent on the pH. On the other hand, the transition peak of chymotrypsinogen A was slightly shifted a toward low temperature by the addition of EG and the peak area slightly increased under all the conditions studied. Moreover, the temperature width of the transition peak became smaller in going from low pH to high pH, consistent with the observation by Brandts[23] in the spectrophotometric experiments; the temperature width of 22—24 K at pH 2 decreased to 16—19 K at pH 4.

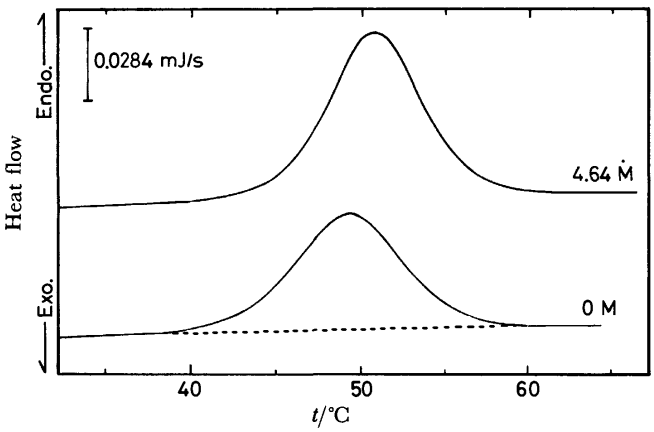

Fig. 1. DSC curves for the thermal denaturation of RNase A in aqueous EG solutions at pH 3. Protein concentration is a 10 mg cm^{-3} and EG concentrations are 0 and 4.64 mol dm^{-3}. The dotted line shows the base line assumed in the transition region for the determination of the thermodynamic parameters of denaturation.

As seen in the figure, the DSC curves obtained exhibit that there is a difference in the heat capacity between the native and denatured states of these proteins; this has been observed for many proteins including the proteins.[19] Therefore, one of the major problem for estimating exactly the thermodynamic parameters of denaturation is how to determine a suitable base line in the transition region. Some estimations of ΔH_d were made by using the base line obtained by extrapolation of the base lines for native and denatured states to the denaturation temperature. However, the ΔH_d obtained by such a procedure was not significntly different from that estimated using a linear base line fitted by inspection. Under our conditions, relatively low protein concentration, the exact heat capacity change upon denaturation seems to be considerably difficult for the DSC apparatus used to determine directly in the individual scan. In this experiment, therefore, we employed a linear base line fitted to the difference of the base lines before and after the transition. Although the thermal denaturation of these proteins has been shown to be a reversible two-state process in aqueous solution,[23–26] the reversibility for the denaturation in EG–water mixtures was checked by reheating the protein solution after rapidly cooling from the first scan. In each solvent composition, there were no significant variations in the position of the transition peak and in the peak area on reheating, indicating that the denaturation of these proteins is almost reversible in EG–water mixtures. In addition, the denaturation temperature was scarcely influenced by heating rates slower than 1 K min^{-1}, allowing equilibrium analysis of the data.

The values of T_d and ΔH_d obtained in EG–water mixtures at different pH values are listed in Table 1. These thermodynamic parameters were evaluated as the average value of five and more experiments. The T_d values have experimental errors of ± 0.1 °C and the ΔH_d values have maximum expected errors of $\pm 5\%$ including errors in sample preparation, calibration constant, and reproducibility. For RNase A, the ΔH_d values in aqueous buffers at different pH in the range

2 to 5 are in agreement with those obtained by Tsong *et al.*[24] and Privalov *et al.*[25] from calorimetric experiments at similar pH values, while the T_d values at low pH are higher than the data of theirs and those at high pH are slightly lower. However, Jacobson and Turner[26] have recently reported considerably higher T_d values from DSC measurements at pH 4.1 and 5.0. Although the reason for the differences in T_d is not clear at present, a number of factors such as protein concentration, ionic strength, buffer, purity of the protein sample (contamination), or heating rate could contribute to the differences. For example, the heating rate used by Jacobson and Turner[26] is considerably higher than that used in this experiment. In addition, Tsong *et al.*[24] have reported that the T_d of RNase A increases with an increase in protein concentration. The T_d and ΔH_d values of chymotrypsinogen A in aqueous buffer solutions at pH 2, 3, and 4 are in accord with previous values obtained by Jackson and Brandts[27] and Privalov *et al.*[28] at similar pH values. Figure 2 represents the temperature dependence of the denaturation enthalpy in aqueous buffer without EG. As has been pointed out by Privalov,[19] ΔH_d is a linear function of T_d, with slope equal to the heat capacity change, ΔC_p^d, on denaturation. The values of ΔC_p^d obtained from the slope of the graph, 4.57 kJ K^{-1} mol^{-1} for RNase A and 14.0 kJ K^{-1} mol^{-1} for chymotrypsinogen A, are in very good agreement with those calculated using the data of Privalov *et al.*[24,27] for the thermal denaturation of these proteins in aqueous solutions of varying the pH. A similar value for chymotrypsinogen has been obtained by Biltonen *et al.*[29] from the heat capacities of the native and denatured states of the protein.

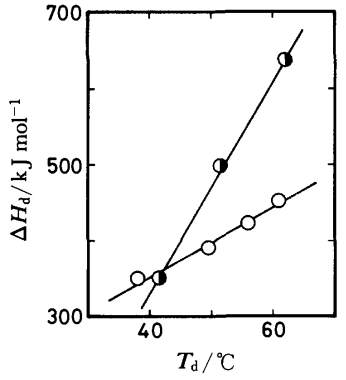

Fig. 2. Dependence of the denaturation enthalpies of RNase A(○) and chymotrypsinogen A(◑) in aqueous buffer without EG on the denaturation temperature.

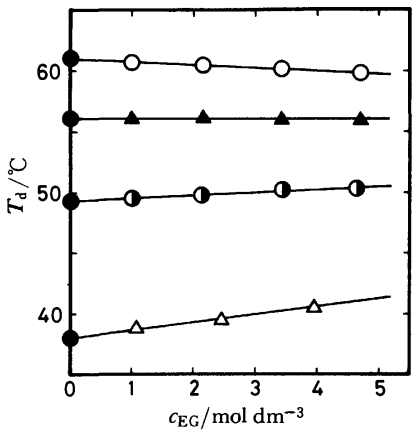

Fig. 3. Variation of the denaturation temperature of RNase A with the EG concentration at pH 2(△), 3(◑), 3.8(▲), and 5(○).
The symbol ● refers to the buffer solution without EG.

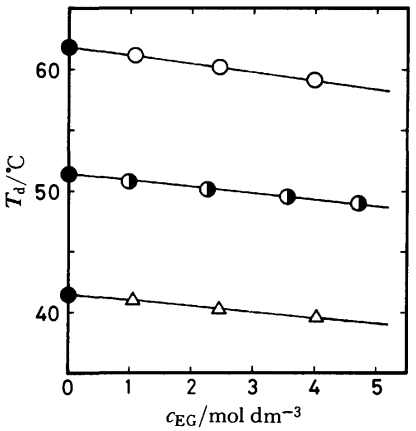

Fig. 4. Variation of the denaturation temperature of chymotrypsinogen A with the EG concentration at pH 2(△), 3(◑), and 4(○).

Figures 3 and 4 show the dependence of the denaturation temperature of RNase A and chymotrypsinogen A on the EG concentration, respectively. It is obvious from Fig. 3 that at pH 3.8 the T_d of RNase is almost independent of the EG content, while the T_d increases slightly with increasing the EG concentration at pH 2 and 3 and decreases slightly at pH 5. Similar results on the EG-induced change in T_d at low pH have been reported by Gerlsma and Stuur. EG stabilizes RNase A against thermal denaturation at low pH but unstabilizes or denatures the protein at high pH in the pH region studied. As show in Fig. 4, on the other hand, the T_d of chymotrypsinogen A is depressed by the addition of EG under all the conditions and the lowering of T_d appears to become more pronounced with increasing the pH and the corresponding T_d. That is, EG has a thermally unstabilizing effect on the protein in the pH 2 to 4 region. These results suggest that the EG-induced effect on the thermal stability of these proteins is dependent on the pH or temperature. However, it is unlikely that the EG effect depends directly on the pH, since the effect on the two proteins differs from each other at identical

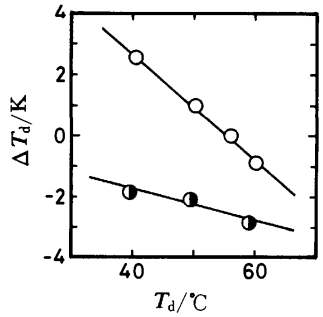

Fig. 5. Dependence of the variation of T_d induced by addition of 4 mol dm^{-3} EG, ΔT_d, of RNase A(○) and chymotrypsinogen A(◑) on the denaturation temperature.

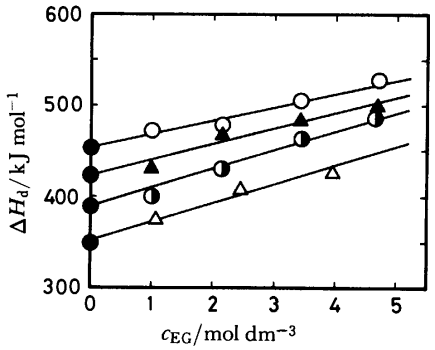

Fig. 6. Variation of the denaturation enthalpy of RNase A with the EG concentration at pH 2(△), 3(◑), 3.8(▲), and 5(○).

pH of 2 and 3 and the T_d of these proteins increases monotonously with increasing the pH in the acidic region. Therefore, the variation of T_d with the addition of EG of 4 mol dm^{-3}, ΔT_d, which is evaluated from a linear dependence of T_d on EG concentration, is plotted as a function of the corresponding temperature in Fig. 5. For both proteins, the ΔT_d appears to be a linear function of temperature, meaning that the EG-induced effect may be directly dependent on temperature.

The dependence of the denaturation enthalpy of RNase A on the EG concentration is shown in Fig. 6. Under all the conditions, ΔT_d increases almost linearly with increasing the EG concentration. Such behavior of ΔH_d was also observed for chymotrypsinogen A, though the degree of the change in ΔH_d with EG was slightly smaller for the protein than for RNase A. As shown in Table 1, the denaturation entropies at the denaturation temperature, $\Delta S_d(=\Delta H_d/T_d)$, of these proteins also increase monotonously with an increase in the concentration of EG. This means that the observed increase (or decrease) in T_d occurs because ΔH_d increases (or does not increase) as much as ΔS_d does upon the addition of EG.

The plot of ΔH_d as a function of ΔS_d gives a linear relationship, presented in Fig. 7, indicating that the EG-induced effect on the thermal stability of these proteins is closely related to the water structure around the protein molecule.[30] The compensation temperatures, which are defined as the slopes of the graph, are 375 and 364 K for RNase A and chymotrypsinogen A, respectively. Although these values are consider-

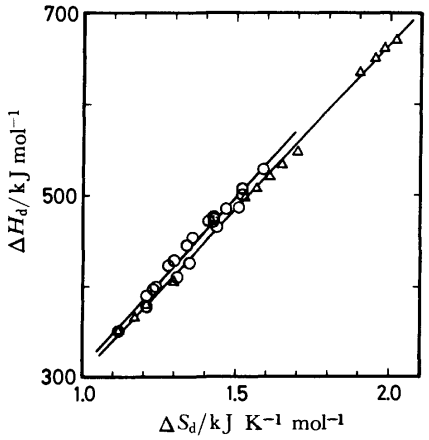

Fig. 7. Enthalpy-entropy compensation plots for the thermal denaturation of RNase A(○) and chymotrypsinogen A(△) in EG-water mixtures.

ably higher than the temperature range of 250 to 320 K observed for many processes, the value for RNase is in good agreement with the compensation temperature deduced from the results obtained for denaturants such as urea and guanidine hydrochloride.[31]

A more definite estimation of the effect of EG on the protein stability may be given by the comparison of the thermodynamic functions of denaturation, $\Delta G°$, $\Delta H°$, and $\Delta S°$, at identical temperatures. Assuming that the heat capacity change, ΔC_p^d, on denaturation is independent of temperature, standard thermodynamic parameters of denaturation at any temperature, T, can be calculated with T_d and ΔH_d by the equations:[32,33]

$$\Delta H° = \Delta H_d - \Delta C_p^d(T_d - T)$$
$$\Delta S° = \Delta H_d/T_d - \Delta C_p^d \ln (T_d/T)$$
$$\Delta G° = \Delta H° - T\Delta S°$$

Unfortunately, ΔC_p^d in each solvent composition can not be accurately determined in the present study. Thus the ΔC_p^d values of these proteins in mixed solvents were assumed to be identical with those in aqueous buffer, 4.57 kJ K^{-1} mol^{-1} for RNase A and 14.0 kJ K^{-1} mol^{-1} for chymotrypsinogen A, which were estimated from the linear temperature dependence of the ΔH_d in this experiment. This assumption will not cause significant error in standard thermodynamic parameters of denaturation when T is close to T_d, since ΔC_p^d does not seem to be largely affected by additions of EG. Therefore, these parameters were calculated at several temperatures in the transition region. Figure 8 represents the variation of $\Delta G°$, $\Delta H°$, and $\Delta S°$ calculated at 48 °C with the EG concentration at pH 3. It is evident that the $\Delta H°$ and $\Delta S°$ for both proteins are increasing functions of EG concentration, indicating that the enthalpy and entropy of transfer of denatured protein from water to aqueous EG are larger than those of native protein. On the other hand, although the variation induced by addition of EG is very small, the $\Delta G°$ for RNase increases obviously with increasing EG concentration, but that for chymotrypsinogen decreases. These findings suggest that the thermal stabilization of RNase by EG is dominantly produced by an enthalpic rather than an entropic effect. However, the unstabilization of chymotrypsinogen by EG may be attributed to the fact

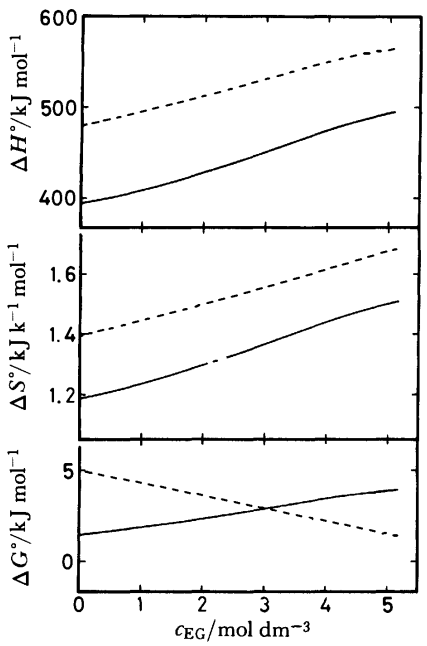

Fig. 8. Variation of the standard thermodynamic parameters of denaturation calculated at 48°C of RNase A (——) and chymotrypsinogen A (----) with the EG concentration.

that $\Delta H°$ does not increase as much as $\Delta S°$ does upon addition of EG. Therefore, the slight increase or decrease in $\Delta G°$ upon addition of EG is produced from the delicate balance between the increased $\Delta H°$ and $\Delta S°$, which may be affected by numerous factors such as temperature and the nature of the protein surface. These findings seem to offer direct evidence for regarding protein stabilization and denaturation (unstabilization) as a thermodynamically continuous phenomenon. The observed increase in $\Delta H°$ and $\Delta S°$ is similar to the observations by Brandts[23] that, at a given temperature, $\Delta H°$ and $\Delta S°$ are much larger for the denaturation of chymotrypsinogen in ethanol-water mixtures than in water. Such a trend of $\Delta H°$ has been also found for the thermal denaturation of RNase A in the same solvent system.[34]

The $\Delta G°$ values for RNase A and chymotrypsinogen A in water and aqueous EG are presented as a function of temperature in the transition region in Figs. 9 and 10, respectively. In the case of RNase, as can be seen from Fig. 9, the $\Delta G°$-temperature curves for these solutions cross at about 55 °C, corresponding roughly to the denaturation temperature of the protein at pH 3.8, which is almost independent of the pH. This means that, at temperatures lower than about 55 °C, EG is quite effective in increasing $\Delta G°$, that is, it stabilizes RNase against thermal denaturation while, at higher temperatures, it behaves as a rather unstabilizing (denaturing) agent for the protein. In the case of chymotrypsinogen, on the other hand, although the dotted line shown in Fig. 10 is the extrapolation of the curve, the crossing of the $\Delta G°$-temperature curves appears to occur at about 35 °C, which is considerably lower than that for RNase. The protein stabilization induced by polyhydric alcohols has been explained as a strengthening of the intramolecular hydrophobic

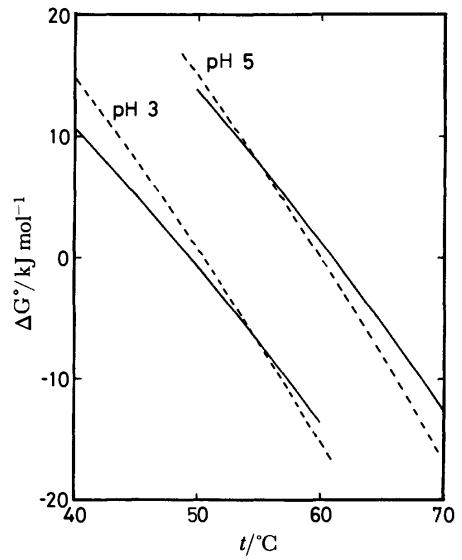

Fig. 9. Variation of $\Delta G°$ of RNase A in water (——) and aqueous EG (----) at pH 3 and 5 with temperature in the transition region.
EG concentrations are 4.64 mol dm^{-3} at pH 3 and 4.70 mol dm^{-3} at pH 5.

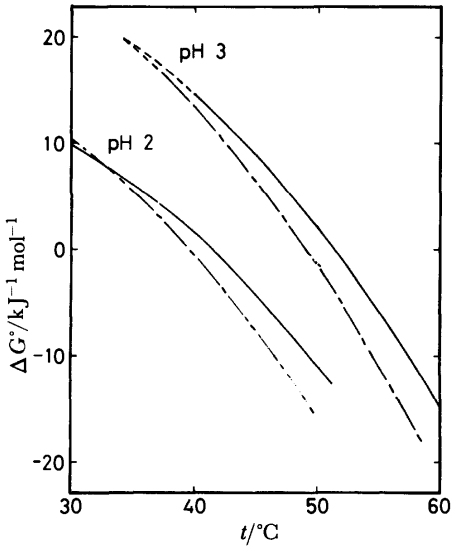

Fig. 10. Variation of $\Delta G°$ of chymotrypsinogen A in water (——) and aqueous EG (-—) at pH 2 and 3 with temperature in the transition region.
EG concentrations are 4.03 mol dm^{-3} at pH 2 and 4.70 mol dm^{-3} at pH 3. The dotted line shows the extrapolation of the curve.

interaction of the protein.[10-13] The conformational stability of proteins in aqueous medium is viewed, at present, as a result primarily of the pressure which water exerts on nonpolar residues, compressing them into the interior of the molecule. An enhancement of the hydrophobic effect in medium by addition of EG at low temperature would render more unfavorable the exposure to solvent of nonpolar groups buried in the interior of native protein. The pronounced relationship between temperature and the EG-induced effect on the thermal stability of these proteins may be explained on the basis of a solvent ordering effect, similar to that proposed by Brandts and Hunt[34] for the stabilizing effect of ethanol at low temperatures and low ethanol concentrations. According to their hypothesis, the mechanism is closely connected with the solvation which forms about exposed nonpolar groups at low temperature and with the disruption of the solvation structure which occurs as the temperature is increased. Ethanol or EG added may replace ordered water molecules around exposed hydrophobic groups, both solvent components becoming part of the solvation which surrounds the nonpolar side chains of the protein. In the case of ethanol, this structure is disrupted at low temperatures, permitting the formation of hydrophobic contacts between the nonpolar moiety of the alcohol and the nonpolar groups of the protein and leading to the denaturation of the protein. In the case of EG, however, such a solvation around the exposed nonpolar groups of a protein should remain intact up to relatively high temperature, at least near 55 °C for RNase and near 35 °C for chymotrypsinogen, since the hydrophobicity of EG is considerably smaller than that of ethanol. Furthermore, the interaction of the EG with the exposed nonpolar groups of proteins is not direct, as would be in the case of hydrophobic interactions, but it occurs indirectly through the strong interaction of EG molecule with the water of hydration around the nonpolar groups of the protein.

There is an important difference between RNase A and chymotrypsinogen A in the observed effect of EG on the thermal denaturation. These proteins differ greatly in the molecular parameters. The average hydrophobicity and polarity are 870 cal (1 cal=4.184 J) per residue and 1.73 for RNase A and 1040 cal per residue and 0.83 for chymotrypsinogen A.[35] RNase A is one of the most hydrophilic globular proteins and the content of nonpolar amino acid residues is very low, 49 residues per molecule. On the other hand, chymotrypsinogen A has high hydrophobicity and contains 112 nonpolar amino acids per molecule. Although it has been shown by Brandts and Hunt[34] that the fraction of the total number of residues which unfold during denaturation is smaller for chymotrypsinogen than for RNase, the number of newly exposed nonpolar groups following denaturation would be considerably larger in chymotrypsinogen than in RNase. Addition of EG seems to give rise to a decrease in the heat capacity of solvation of nonpolar groups.[34,36] Such a effect should be greater for chymotrypsinogen A than for RNase A. This may be partially responsible for the result that the observed decrease in $\Delta G°$ for chymotrypsinogen A upon addition of EG occurs because $\Delta H°$ does not increase as much as $\Delta S°$ does.

Cycloadditions of Trifluoroacetonitrile Oxide with Olefins and Acetylenes

Kiyoshi TANAKA,* Hideyuki MASUDA, and Keiryo MITSUHASHI
Department of Industrial Chemistry, College of Technology, Seikei University, Musashino-shi, Tokyo 180
(Received January 24, 1984)

The regio- and stereoselectivity of the cycloadditions of trifluoroacetonitrile oxide (**1**) with olefins and acetylenes were described. The oxide **1**, generated *in situ* from trifluoroacetohydroximoyl bromide etherate in the presence of triethylamine, reacted with various monosubstituted olefins and acetylenes to give exclusively 5-substituted 3-trifluoromethyl-2-isoxazolines and -isoxazoles, respectively, whereas **1** cyclized with 1,2-disubstituted olefins and acetylenes to result in the formation of a mixture of two regioisomeric products. On the other hand, the cycloaddition of **1** with (*Z*)-β-methylstyrene afforded a mixture consisting of two regioisomeric isoxazolines retaining *Z*-configuration and one diastereoisomeric isoxazoline.

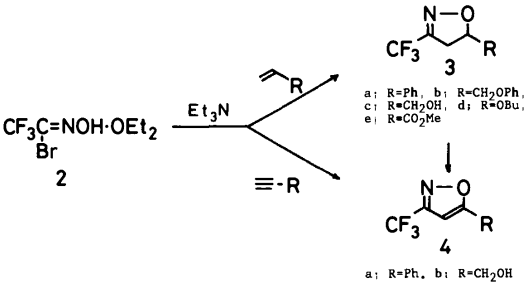
A number of heterocyclic compounds bearing a fluorine or trifluoromethyl group are known to be effective pharmaceutically and agrochemically,[1] but the introduction of such a fluorine group into heterocyclic rings has been limited.[2] As a part of research on applications of the fluorinated 1,3-dipolar compounds as building blocks of heterocycles with fluorine groups,[3] we remarked trifluoroacetonitrile oxide (**1**). Although only one report described the cycloadditions of the nitrile oxide **1**, liberated from trifluoroacetohydroximoyl chloride, the dipolarophiles employed were limited to the reactive ones such as acetylenic and enol ethers.[4] In the present paper, we wish to report that the oxide **1**, generated from trifluoroacetohydroximoyl bromide etherate (**2**), cyclizes with various olefins and acetylenes to give the corresponding 3-trifluoromethyl-2-isoxazolines and -isoxazoles,[5] and also to describe the regio- and stereoselectivity of the cycloadditions.

$$CF_3C \equiv N \rightarrow O$$

1

The bromide **2** was prepared by bromination of trifluoroacetaldehyde oxime[6] which was readily obtained from trifluoroacetaldehyde hydrate and hydroxylamine hydrochloride.

The reactions of **2** with monosubstituted olefins such as styrene, allyloxybenzene, allyl alcohol, and butoxyethylene proceeded smoothly in the presence of triethylamine at room temperature to afford exclusively 5-substituted 3-trifluoromethyl-2-isoxazolines **3** in good yields. Similarly, **2** was allowed to react with methyl acrylate, an olefin bearing electron-withdrawing group, to give only 5-methoxycarbonylisoxazoline in appreciable yield (Table 1). The structure of these 3-trifluoromethyl-2-isoxazolines was determined on the basis of the comparable chemical shifts of 5-methine and 4-methylene protons to those of 3-phenyl analogues reported in the literatures[7] and the existence of the H–F couplings between 4-methylene protons and trifluoromethyl group. Similarly, the oxide **1** readily underwent the cycloadditions with monosubstituted acetylenes. The reaction of **2** with phenylacetylene gave exclusively 5-phenyl-3-trifluoromethylisoxazole (**4a**) in excellent yield, where the alternative 1,3-addition product described in the reaction of benzonitrile oxide[8] was not detected at all. A similar reaction with 2-propyn-1-ol also gave **4b** in moderate yield and, however, that with methyl propiolate resulted in a tar-like matter. Dehydrogenation of **3a** with 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ) was so sluggish that only 12% of **4a** was obtained (Scheme 1).



Scheme 1.

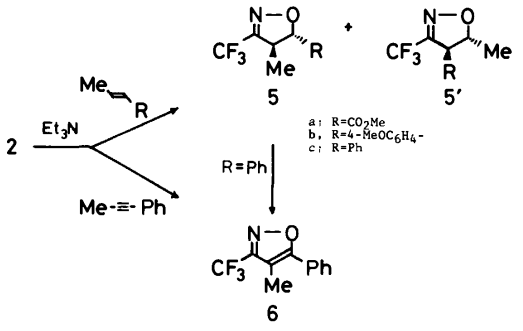
3d	89	45—46/2(78—80/10)[c]	1625	—		—	
3e	82	76—77/6(64—66/3)[c]	1635	—		—	
4a	93	[44—45.5]	1610	$C_{10}H_6NOF_3$	56.35 (56.56)	2.84 (2.38)	6.57 (6.83)
4b	38	75—77/6	1603	$C_5H_4NO_2F_3$			8.38 (8.33)

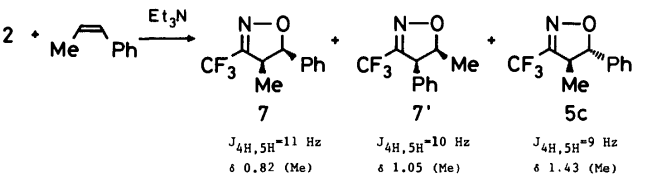
a) Isolated yield. b) Besides **3a**, a trace of 1,1,1-trifluoro-4-phenyl-3-buten-2-one oxime was obtained. c) See ref. 4).

On the other hand, the cycloadditions of **1** with 1,2-disubstituted olefins under the similar conditions produced a mixture of regioisomeric products. The reaction with methyl crotonate gave a mixture of 4-methylisoxazoline **5a** and 5-methyl isomer **5a'** in 39% yield (**5a**/**5a'** ratio of 43/57). The cycloaddition with 1-methoxy-4-(1-propenyl)benzene proceeded more easily to give a mixture of **5b** and **5b'** in 87% yield (**5b**/**5b'** ratio of 93/7). Similarly, from the reaction with (*E*)-*β*-methylstyrene, 66% yield of a mixture of **5c** and **5c'** was obtained (**5c**/**5c'** ratio of 86/14). The cycloaddition with 1,2-disubstituted acetylene such as 1-phenyl-1-propyne, however, proceeded regioselectively to afford only **6** in 23% yield. The formation of its regioisomer was not observed at all. The structure of **6** is supported by the fact that dehydrogenation of **5c** with chromium trioxide gave **6** in 47% yield (Scheme 2).



Scheme 2.

The stereoselectivity of the cycloaddition of **1** was next investigated. Since (*Z*)-stilbene and dimethyl maleate usually employed for such a purpose were both unreactive toward **1**, the reaction with (*Z*)-*β*-methylstyrene including 3% of its *E*-isomer was carried out, giving a mixture of two regioisomers with retention of *Z*-configuration, **7** and **7'**, and diastereoisomer of **7**, **5c**, in 30% yield (**7**/**7'**/**5c** ratio of 10/5/3). The stereochemical assignments are based on ^{1}H NMR spectra. The *Z*-configuration of **7** and **7'** is supported by both the more shielded methyl protons[9] and the bigger coupling constants between 4- and 5-methine protons[7b] in **7** and **7'** as compared to **5c** (Scheme 3). In the reaction mixture, 3% of (*E*)-*β*-methylstyrene was still present and, on further treatment of the reaction products with triethylamine, the ratio of **7**/**7'**/**5c** was found to be unchanged. These results indicate that **5c** may be directly led from (*Z*)-*β*-methylstyrene.



Scheme 3.

As a conclusion, the regioselectivity of the cycloadditions of **1** toward monosubstituted olefins and acetylenes, affording exclusively 5-substituted isoxazolines and isoxazoles, is similar to that of benzonitrile oxide,[7] whereas the tendency toward 1,2-disubstituted olefins is somewhat different. Summarized for comparison are the regioselective results of benzonitrile oxide,[7b,10] cyanogen *N*-oxide,[10] and benzenesulfonyl cyanide *N*-oxide[11] (Table 2). Trifluoromethyl group favors the formation of 4-methylisoxazolines **5**, compared with benzonitrile oxide, and its effect on the regioselectivity seems to be almost equal to that of cyano group. It also turns out that the regioselectivity depends on the configuration of the olefins used, namely, (*E*)-*β*-methylstyrene is more regioselective than (*Z*)-*β*-methylstyrene. It is also found that the cycloaddition proceeds with high stereoselectivity. However, the formation of the diastereoisomer **5c** in the case of (*Z*)-*β*-methylstyrene suggests that the partial inversion of the *Z*-configuration takes place during course of the cycloaddition, pointing out the possibility of the partial lack of the concerted process.

Experimental

All melting and boiling points are uncorrected. The IR spectra were recorded on a JASCO IRA-1 spectrometer. The ^{1}H and ^{19}F NMR spectra were measured with a JEOL JNM-PMX 60 spectrometer and a Hitachi R-24F spectrometer using an internal tetramethylsilane (TMS) and an external trifluoroacetic acid as a standard, respectively, the chemical shifts being given in *δ* ppm downfield. The MS spectra were obtained on a Finnigan 3300E GC-MS spectrometer operating at 120 eV.

Preparation of **2**. The previously reported procedures were modified for the preparations of trifluoroacetaldehyde hydrate and its oxime.[12] To a suspension of 7.6 g (0.20 mol) of lithium aluminium hydride in 500 ml of diethyl ether, dried over calcium chloride, was added dropwise a solution of 30.0 g (0.26 mol) of trifluoroacetic acid in 400 ml of diethyl ether holding the temperature below 5 °C. The mixture was stirred at 0 °C for an additional 1 h. To the mixture were added 18 ml of methanol, 16 ml of water, and 32 ml of concd

sulfuric acid and then diethyl ether layer was separated. Water was added to the residual mixture and the mixture was extracted twice with diethyl ether. The combined ethereal extracts were washed with brine, dried over magnesium sulfate, and evaporated under reduced pressure to leave 33.9 g of crude trifluoroacetaldehyde hydrate.

To a mixture of 33.9 g of thus-obtained crude trifluoroacetaldehyde hydrate, 50 ml of methanol, 50 ml of water, 50 g of ice, and 20.3 g of hydroxylamine hydrochloride, was added dropwise 44 g of 50% aqueous sodium hydroxide. Then the temperature of the mixture was maintained below 35 °C. After stirring at room temperature for 10 h, the mixture was washed with diethyl ether, acidified to pH 6 with concd hydrochloric acid, and extracted twice with diethyl ether. The extracts were washed with water and brine, dried over magnesium sulfate, and distilled to give 28.3 g of trifluoroacetaldehyde oxime including small amount of diethyl ether (boiling range 78—79 °C).

Holding the temperature below 40 °C, a solution of 44.6 g of *N*-bromosuccinimide in 125 ml of *N,N*-dimethylformamide (DMF) was added dropwise to a solution of 28.3 g of trifluoroacetaldehyde oxime in 50 ml of DMF. After stirring at room temperature for 3 h, the mixture was poured into 400 ml of cold water and extracted with diethyl ether. The extracts were washed with water and brine, dried over magnesium sulfate, and distilled to afford 29.9 g of **2**; bp 115 °C (lit, bp 52—55 °C/72 mmHg (1 mmHg≈133.322 Pa))[13], 43% yield based on trifluoroacetic acid, ^{19}F NMR ($CDCl_3$) δ= 10.5 (s) and 10.3 (s), MS (*m/z*) 191 and 193 (M^+-Et_2O), 171 and 173 ($M^+-Et_2O\cdot HF$), and 111 (CF_3CNO^+).

Reactions of 2 with Monosubstituted Olefins. Triethylamine (4.89 g, 48.4 mmol) diluted with 20 ml of toluene was added to a solution of 6.45 g (24.2 mmol) of **2** and 7.55 g (72.6 mmol) of styrene in 50 ml of toluene over a period of 1 h and the mixture was stirred at room temperature for additional 10 h. After excess hexane ws added to the reaction mixture, the resulting salt (4.51 g) was collected on a filter. The filtrate was washed with water and brine, dried over magnesium sulfate, and evaporated to leave crude **3a** which was purified by distillation under reduced pressure to give 4.35 g (84%) of pure **3a**, ^{1}H NMR ($CDCl_3$) δ=3.07 (ddq, 1H), 3.57 (ddq, 1H), 5.76 (dd, 1H), and 7.30 (m, 5H).

Similarly, **3c**, **3d**, and **3e** were obtained and their ^{1}H NMR data are as follows; **3c**, ($CDCl_3$) δ=2.83 (br.s, 1H), 3.07 (m, 1H), 3.25 (m, 1H), 3.58 (dd, 1H), 3.90 (dd, 1H), and 4.93 (tdd, 1H), **3d**, (CCl_4) δ=0.95 (t, 3H), 1.15—1.80 (m, 4H), 2.85 (dm, 1H), 3.25 (dm, 1H), 3.30—4.05 (m, 2H), and 5.66 (dd, 1H), **3e**, (CCl_4) δ=3.33 (m, 1H), 3.50 (m, 1H), 3.77 (s, 3H), and 5.17 (dd, 1H).

The isoxazoline **3b** was also obtained from the reaction of **2** with 1.5 equiv of allyloxybenzene and the successive isolation by column chromatography (silica gel, hexane–ethyl acetate, 9:1). Thus-obtained **3b** was further recrystallized from hexane to give the white needles **3b**, ^{1}H NMR (CCl_4) δ=3.10 (m, 1H), 3.27 (m, 1H), 3.97 (d, 2H), 5.02 (tt, 1H), and 6.85—7.27 (m, 5H).

Reactions of 2 with Monosubstituted Acetylenes. In a similar manner, crude **4a** was obtained and purified by column chromatography (silica gel, hexane) followed by recrystallization from hexane, ^{1}H NMR (CCl_4) δ=6.67 (s, 1H) and 7.28—7.90 (m, 5H), whereas **4b** was purified by distillation under reduced pressure, ^{1}H NMR ($CDCl_3$) δ= 3.67 (br.s, 1H), 4.85 (s, 2H), and 6.56 (s, 1H).

Dehydrogenation of 3a to 4a. A solution of 1.00 g (4.65 mmol) of **3a** and 1.06 g (4.65 mmol) of DDQ in 10 ml of toluene was refluxed for 2 d. Diethyl ether was added to the reaction mixture and the resulting mixture was washed with water and brine, dried over magnesium sulfate, and evaporated under reduced pressure to leave oily matter which was submitted to short column chromatography (silica gel, hexane) to give 0.84 g of a mixture of **3a** and **4a** in the ratio of 86/14, according to ^{1}H NMR analysis. The isoxazole **4a** was separated by preparative GLC and its IR and ^{1}H NMR data are consistent with those obtained above.

Reactions of 2 with 1,2-Disubstituted Olefins. To a solution of 1.81 g (6.8 mmol) of **2** and 2.04 g (20.4 mmol) of methyl crotonate in 15 ml of toluene, was added dropwise a solution of 1.37 g (13.6 mmol) of triethylamine in 5 ml of toluene over a 75 min period and the mixture was stirred at room temperature for additional 15 h. The similar procedure described above gave 1.03 g of the white salt and the oily matter which was submitted to distillation (boiling range, 73—75 °C/5 mmHg) to produce 0.42 g (29%) of a mixture of **5a** and **5a'** in the ratio of 43/57 (^{19}F NMR analysis). The isoxazolines **5a** and **5a'** were isolated by preparative GLC, **5a** ^{1}H NMR (CCl_4) δ=1.43 (d, 3H), 3.70 (dq, 1H), 3.82 (s, 3H), and 4.67 (d, 1H), ^{19}F NMR (CCl_4) δ=14.3, **5a'**, ^{1}H NMR (CCl_4) δ=1.47 (d, 3H), 3.73 (dq, 1H), 3.78 (s, 3H), and 5.07 (dq, 1H), ^{19}F NMR (CCl_4) δ=14.7.

Found: N, 6.58%. Calcd for $C_7H_8NO_3F_3$: N, 6.63% (for a mixture of **5a** and **5a'**).

Similarly, a mixture of **5b** and **5b'** in the ratio of 93/7 was collected by distillation (boiling range. 115—119 °C/1 mmHg) and each isomer was isolated by preparative GLC, **5b**, ^{1}H NMR (CCl_4) δ=1.40 (d, J=7 Hz, 3H), 3.38 (dqm, 1H). 3.78 (s, 3H), 5.10 (d, J=9 Hz, 1H), and 6.7—7.2 (A_2X_2, 4H), IR (film) 1610 cm^{-1} (C≡N), **5b'**, ^{1}H NMR (CCl_4) δ=1.40 (d, J=7 Hz, 3H), 3.77 (s, 3H), 3.90 (dm, J=7 Hz, 1H), 4.67 (dq, 1H), 6.8—7.1 (A_2X_2, 4H), IR (film) 1610 cm^{-1} (C=N).

Found: N, 5.36%. Calcd for $C_{12}H_{12}NO_2F_3$: N, 5.40% (for a mixture of **5b** and **5b'**).

A mixture of **5c** and **5c'** in the ratio of 86/14 was also collected by distillation (boiling range, 87—92 °C/4 mmHg) in 66% yield, **5c**, ^{1}H NMR (CCl_4) δ=1.43 (d, J=7 Hz, 3H), 3.40 (dqm, 1H), 5.17 (d, J=9 Hz, 1H), and 7.3 (s, 5H), IR (film) 1620 cm^{-1} (C=N), **5c'**, ^{1}H NMR (CCl_4) δ=1.43 (d, J=7 Hz, 3H), 3.90 (dm, J=6 Hz, 1H), 4.67 (dq, 1H), and 6.9—7.3 (m, 5H), IR (film) 1610 cm^{-1} (C=N).

Found: N, 6.12%. Calcd for $C_{11}H_{10}NOF_3$: N, 6.11% (for a mixture of **5c** and **5c'**).

Reaction of 2 with 1-Phenyl-1-propyne. In a similar manner to the above, crude **6** was obtained and purified by column chromatography (silica gel, hexane) followed by recrystallization from hexane, mp, 69—69.5 °C, ^{1}H NMR ($CDCl_3$) δ=2.30 (s, 3H) and 7.4—7.8 (m, 5H), IR (KBr) 1615 cm^{-1} (C=N).

Found: C, 57.91; H, 3.45; N, 6.07%. Calcd for $C_{11}H_8NOF_3$: C, 58.16; H, 3.55; N, 6.17%.

Dehydrogenation of 5c to 6. A solution of 430 mg (1.88 mmol) of **5c**, 500 mg of chromium trioxide, and 3 drops of concd sulfuric acid in 10 ml of acetic acid was refluxed for 40 min and evaporated under reduced pressure. The resulting mixture was extracted with diethyl ether and extracts were washed with water and brine, dried over magnesium sulfate, and evaporated under reduced pressure to leave crude **6** which was purified by column chromatography (silica gel, hexane–ethyl acetate, 10:1) to give 200 mg (47%) of the white solid **6**, mp, 67.5—69.5 °C.

Reaction of 2 with (Z)-β-Methylstyrene. (*Z*)-β-Methylstyrene was obtained by hydrogenation with Lindlar catalyst according to the previously reported procedure.[14] The reaction of **2** with 1.3 equiv of (*Z*)-β-methylstyrene was carried out in a similar manner and a mixture of **7**, **7'**, and **5c** in the ratio of 10/5/3 (^{1}H NMR analysis) was collected in 30% yield by column chromatography (silica gel, hexane–ethyl acetate, 3:1). Each isomer was separated by preparative GLC, **7**, ^{1}H NMR (CCl_4) δ=0.82 (d, J=8 Hz, 3H), 3.60 (dqm, 1H), 5.73 (d, J=11 Hz, 1H), and 7.1—7.4 (m, 5H), IR (film)

1618 cm^{-1} (C=N), **7'**, ^1H NMR (CCl_4) δ=1.05 (d, J=6 Hz, 3H), 4.22 (d, J=10 Hz, 1H), 4.90 (dq, 1H), and 6.9—7.7 (m, 5H), IR (film) 1610 cm^{-1} (C=N). Spectral data of **5c** are consistent with those obtained above.

Found: N, 5.83%. Calcd for $C_{11}H_{10}NOF_3$: N, 6.11% (for a mixture of **7** and **7'**).

Preparation of 13-Substituted 8*H*-Dibenzo[*a*,*g*]quinolizin-8-ones by Intramolecular Wittig-Horner Reaction of Dialkyl 2-(*o*-Acylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonates

Kin-ya AKIBA,† Yoshio NEGISHI, and Naoki INAMOTO*
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo 113
(Received January 27, 1984)

Dialkyl 2-(*o*-acylbenzoyl)-1,2-dihydro-1-isoquinolyl-phosphonates (**1**) were prepared by reactions of isoquinoline, *o*-acylbenzoyl chloride, and trialkyl phosphites. Treatment of **1** with lithium diisopropylamide gave 13-substituted 8*H*-dibenzo[*a*,*g*]quinolizin-8-ones by intramolecular Wittig-Horner reaction. Especially, 13-alkoxy and dimethylamino derivatives were obtained in good yields. A similar reaction of dimethyl 1-[*o*-(methoxycarbonyl)benzoyl]-1,2-dihydro-2-quinolylphosphonate was also described.

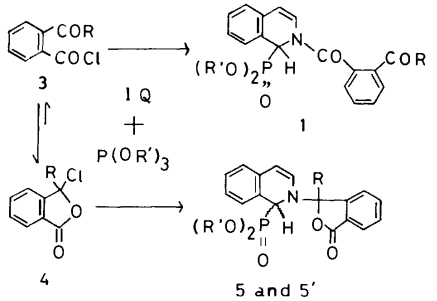
As a general method to introduce substituents into heteroaromatics, we recently reported preparation of a variety of heterocyclic phosphonates from the corresponding heteroaromatic cations and their use for carbonyl olefination to afford heterocycles containing *exo*-methylene groups.[1]

This method was extended to isoquinolinium salts, and it was found that dimethyl 2-isopropoxycarbonyl-1,2-dihydro-1-isoquinolylphosphonate, prepared from isoquinoline, isopropyl chloroformate, and trimethyl phosphite, afforded the corresponding 1-*exo*-methylene compounds by the Wittig-Horner reaction with various aldehydes, and the *exo*-methylene compounds thus obtained were readily converted to 1-substituted isoquinolines with hydrogen chloride.[2]

This paper describes on preparation of dialkyl 2-(*o*-acylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonates (**1**) and their intramolecular Wittig-Horner reaction to afford 13-substituted 8*H*-dibenzo[*a*,*g*]quinolizin-8-ones (**2**).[3]

Results and Discussion

Synthesis of Dialkyl 2-(o-Acylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonates (1). *o*-Aroylbenzoyl chlorides were used as acylating reagent of isoquinoline, but it is known that *o*-benzoylbenzoyl chloride (**3a**) exists as the tautomeric form, 3-chloro-3-phenylphthalide (**4a**)[4] which is unsuitable for the synthesis of **1a**.



a: R = Ph, R′ = Me
b: R = *p*-MeC$_6$H$_4$, R′ = Me
c: R = MeO, R′ = Me
d: R = EtO, R′ = Me
c′: R = MeO, R′ = Et
d′: R = EtO, R′ = Et
e: R = Me$_2$N, R′ = Me
f: R = PhCH$_2$S, R′ = Me

Therefore, in order to increase the contribution of **3a** and to obtain **1a** as much as possible, a solution of isoquinoline (IQ) was added dropwise to a heated solution of **4a**, followed by addition of trimethyl phosphite. The results are shown in Table 1.

As seen in Table 1, the products were a mixture of the expected phosphonate (**1a**) and undesirable diastereomeric phosphonates (**5a** and **5′a**), 3-phenyl-3-(1-dimethoxyphosphinyl-1,2-dihydro-2-isoquinolyl)-phthalides, derived directly from **4a**.

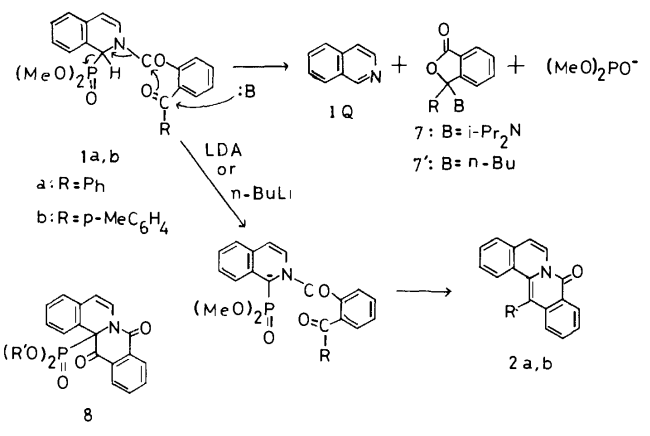
It was found that the best yield of **1a** was obtained by use of a more dilute solution in propiononitrile as solvent. Under similar conditions **1b** was also prepared in good yield (see Table 1).

Although **5′b** could not be isolated in a pure state, the isomer which has higher melting point and larger J_{PCH} value was regarded as **5** and the other as **5′**.

On the other hand, since phthalic monoesters, monoamides, or monothioester gave only the corresponding chlorides **3c—f**, **1c—f** were prepared by usual method[5] in the absence of sodium iodide in 64—87% yields, except for **1f** (8.2% yield).

Dimethyl 1-[*o*-(methoxycarbonyl)benzoyl]-1,2-dihydro-2-quinolylphosphonate (**6**) was prepared by a similar method in 60% yield.

Intramolecular Wittig-Horner Reactions. Reactions of the phosphonates **1a**, **b** with lithium diisopropylamide (LDA) geve not only the expected 13-aryl-8*H*-dibenzo[*a*,*g*]quinolizin-8-ones (**2a**, **b**) but also phthalides (**7**) and a considerable amount of IQ.



†Present address: Department of Chemistry, Faculty of Science, Hiroshima University, Higashisenda-machi, Hiroshima 730.

Table 1. Preparation of **1a** and **1b**

Solvent	Temp/°C	Concn/M[a]		Total yield/%	Ratio of 1:5:5'[b]
		4	IQ		
MeCN	82 (refl)	**a** 1.1	3.8	86	48:22:30
PhMe	111 (refl)	**a** 0.7	0.34	6.6	55:0:45
PhCN	120—130	**a** 0.3	0.36	20	80:5:15
EtCN	98 (refl)	**a** 0.3	0.33	81	76:9:15

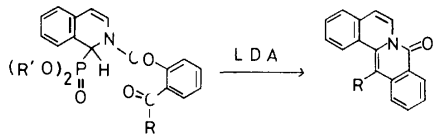
1f	LDA	**2f** (3.0)		

a) Quenched with ethanol.

Formation of **7** and IQ is attributed to a nucleophilic attack of diisopropylamide anion toward the aroyl carbonyl group of **1a**, **b**. In fact, use of more nucleophilic butyllithium as base resulted in a low yield of **2** and a higher yield of **7'** (see Table 2).



1c-f 2c-f

On the other hand, *o*-(alkoxycarbonyl)benzoyl phosphonates (**1c**, **d**, **c'**, **d'**) gave the corresponding **2c**, **d** in good yields (see Table 2), through the intramolecular Wittig-Horner reaction at the esteric carbonyl group. Formation of **2c**, **d** irrespective of kinds of the phosphonate esters or alcohols as quencher indicates no contribution of a β-keto phosphonate (**8**), which is formed by usual acylation of carbanion with ester. No formation of **8** is attributed to a relief of steric congestion and formation of an extended conjugate system in **2**.

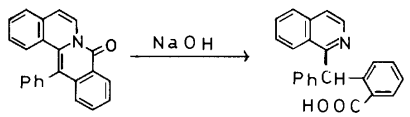
There are a few reports on the intermolecular or intramolecular Wittig reaction at esteric carbonyl group of formate,[6] oxalate,[6] acetate,[7,8] benzoate,[8] oxomalonate (methylenemalonate),[9] and carbonate.[10]

Furthermore, *o*-(dimethylcarbamoyl)benzoyl phosphonate (**1e**) gave 13-dimethylamino derivative (**2e**) in 67% yield, through the intramolecular Wittig-Horner reaction at amidic carbonyl group. Recently, a similar intramolecular Wittig reaction at amidic carbonyl in *o*-(acylamino)benzylidenetriphenylphosphorane has been reported.[11]

Good yields of **2c—e** from **1c—e** are attributed to a prevention of side reactions by electron-donating effect of alkoxyl and dimethylamino groups.

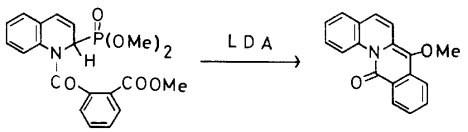
In the case of **1f**, yield of **2f** was very poor (3%), probably because benzylthio group is a good leaving group as indicated by formation of benzyl methyl sulfide (42%), which is probably formed *via* reaction between two leaving groups, α-toluenethiolate and dimethyl phosphate anions.

The structures of **2** were determined by comparison of the spectral data with analogous compounds,[12-14] and by alkaline hydrolysis of **2a** to 1-[α-(*o*-carboxyphenyl)benzyl]isoquinoline (**9**).



2a 9

A similar reaction of **6** with LDA gave 7-methoxy-12*H*-dibenzo[*b*,*f*]quinolizin-12-one (**10**) in 54% yield.



6 10

Experimental

All the melting points are uncorrected. IR spectra were measured with a Hitachi 260-30 spectrophotometer, ^{1}H NMR spectra with a Hitachi R-20B spectrometer using TMS as an internal standard and MS with a Hitachi RMU-6L mass spectrometer at 70 eV.

Synthesis of Dimethyl 2-(o-Benzoylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonate (1a). A mixture of anhyd *o*-benzoylbenzoic acid[15] (1.04 g, 4.6 mmol) and $SOCl_2$ (0.87 ml, 12 mmol) was stirred at room temp until the reaction mixture became clear, and excess $SOCl_2$ was removed *in vacuo*. The residue (**4a**) in dry EtCN (10 ml) was refluxed under nitrogen. IQ (0.59 g, 4.6 mmol) in dry EtCN (13 ml) and then trimethyl phosphite (0.54 ml, 4.6 mmol) were added dropwise to the above refluxing soln, and the refluxing was continued for 1 h. After removal of the solvent, 4% aq $NaHCO_3$ (100 ml) was added to the residue and the mixture was extracted with CH_2Cl_2. The extract was washed with aq NaCl and dried ($MgSO_4$). Removal of the solvent gave a colorless mixture of **1a**, **5a**, and **5'a** (16:2:3; 1.64 g, 81% in total). Only **5a** was isolated by column chromatography (Al_2O_3, Et_2O). The residual mixture was separated by recrystallization. **1a**: Mp

157.1—157.9°C (from EtOAc-hexane); IR (KBr) 1670, 1620, and 1255 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.56, 3.66 (6H, 2d, J_{POCH}=10.2 Hz), 5.85 (1H, d, J=7.8 Hz), 6.07 (1H, d, J_{PCH}=18 Hz), 6.40 (1H, d, J=7.8 Hz), and 6.9—7.8 (13H, m); MS m/z (rel intensity) 447 (M^+; 0.3) and 209 (100). Synthesis of Dimethyl 2-[o-(p-Toluoyl)benzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1b). o-(*p*-Toluoyl)benzoic acid[16] was dried at 90°C overnight. A mixture of the anhyd acid (1.12 g, 4.7 mmol) and $SOCl_2$ (1.0 ml, 14 mmol) was treated similarly to that of **1a**. Then dry EtCN (30 ml), IQ (0.60 g, 4.7 mmol) in EtCN (15 ml), and trimethyl phosphite (0.55 ml, 4.7 mmol) were successively added. A similar treatment gave a colorless mixture of **1b**, **5b**, and **5'b** (9:2:2; 1.99 g, 93% in total). **5b** was isolated by column chromatography (Al_2O_3, Et_2O). **1b** was isolated by crystallization from the mixture of **1b** and **5'b**, the latter of which could not be isolated in pure state. **1b**: Mp 157.1—157.8°C (from EtOAc-hexane); IR (KBr) 1660, 1625, and 1260 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.32 (3H, s), 3.54, 3.66 (6H, 2d, J_{POCH}=10.5 Hz), 5.84 (1H, d, J=7.8 Hz), 6.05 (1H, d, J_{PCH}=18.6 Hz), 6.40 (1H, d, J=7.8 Hz), 7.0—7.3 (6H, m), and 7.45—7.7 (6H, m); MS m/z (rel intensity) 461 (M^+; 0.3) and 233 (100). Found: C, 67.46; H, 5.05; N, 3.14%. Calcd for $C_{26}H_{24}NO_5P$: C, 67.67; H, 5.24; N, 3.04%. **5b**: Mp 176.0—176.8°C (from EtOAc); IR (KBr) 1770, 1635, and 1260 cm^{-1}, ^1H NMR ($CDCl_3$) δ=2.33 (3H, s), 3.57, 3.59 (6H, 2d, J=10.5 Hz), 4.67 (1H, dd, J_{PCH}=19.8 Hz, J=0.9 Hz), 5.92 (1H, d, J=7.8 Hz), 6.11 (1H, dd, J=7.8 Hz, 0.9 Hz), 6.7—7.3 (6H, m), and 7.5—8.1 (6H, m); MS m/z (rel intensity) 461 (M^+; 0.2) and 223 (100). Synthesis of Dimethyl 2-[o-(Methoxycarbonyl)benzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1c). A mixture of methyl hydrogen phthalate[17] (1.78 g, 9.9 mmol) and $SOCl_2$ (5.0 ml, 69 mmol) was refluxed for 1 h. Excess $SOCl_2$ was evaporated and completely removed by repeating three times addition of dry benzene (2.5 ml each) and distillation. To the resulting chloride (**3c**) in an ice bath, MeCN (5 ml), IQ (1.28 g, 9.9 mmol) in MeCN (7 ml) and trimethyl phosphite (1.17 ml, 9.9 mmol) were added successively and the mixture was refluxed for 10 min. After removal of the solvent, 2% aq $NaHCO_3$ (50 ml) was added to the residue and the mixture was extracted with CH_2Cl_2. The extract was washed with aq NaCl and dried ($MgSO_4$). Removal of the solvent gave **1c** (3.3 g, 8.21 mmol) in 83% yield as colorless crystals, mp 154.1—154.6°C (from EtOAc); IR (neat) 1725, 1665, 1630, and 1260 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.59 (3H, s), 3.63, 3.75 (6H, 2d, J_{POCH} =10.5 Hz), 5.83 (1H, d, J=7.8 Hz), 6.15 (1H, d, J=7.8 Hz), 6.51 (1H, d, J_{PCH}=17.4 Hz), 7.0—7.8 (7H, m), and 8.0—8.3 (1H, m); MS m/z (rel intensity) 401 (M^+; 0.3) and 163 (100). Found: C, 59.99; H, 5.08; N, 3.59%. Calcd for $C_{20}H_{20}NO_6P$: C, 59.85; H, 5.02; N, 3.49%.

Synthesis of Diethyl 2-[o-(Methoxycarbonyl)benzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1c'). This compd was prepared by a similar method to that of **1c** in 87% yield as colorless crystals, mp 91.9—92.6°C (from Et_2O-hexane); IR (KBr) 1720, 1660, 1620, and 1255 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.20, 1.25 (6H, 2t, J=6.6 Hz), 3.52 (3H, s), 3.7—4.5 (4H, m), 5.76 (1H, d, J=7.5 Hz), 6.12 (1H, d, J=7.5 Hz), 6.45 (1H, d, J_{PCH}=18.0 Hz), 6.9—7.7 (7H, m), and 7.95—8.15 (1H, m); MS m/z (rel intensity) 429 (M^+; 0.3) and 163 (100). Found: C, 61.41; H, 5.51; N, 3.26%. Calcd for $C_{22}H_{24}NO_6P$: C, 61.54; H, 5.63; N, 3.26%.

Synthesis of Dimethyl 2-[o-(Ethoxycarbonyl)benzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1d). This compd was prepared by a similar method to that of **1c** in 80% yield as colorless crystals, mp 113.9—114.4°C (from Et_2O-hexane); IR (KBr) 1720, 1675, 1630, and 1270 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.02 (3H, t, J=6.9 Hz), 3.60, 3.73 (6H, 2d, J_{POCH}=10.8 Hz), 4.04, 4.07 (2H, 2q, J=6.9 Hz), 5.77 (1H, d, J=7.8 Hz), 6.13 (1H, d, J=7.8 Hz), 6.49 (1H, d, J_{PCH}=17.4 Hz), 6.9—7.7 (7H, m), and 8.0—8.15 (1H, m); MS m/z (rel intensity) 415 (M^+; 0.5), 177 (86), and 149 (100). Found: C, 60.68; H, 5.22; N, 3.46%. Calcd for $C_{21}H_{22}NO_6P$: C, 60.72; H, 5.34; N, 3.37%.

Synthesis of Diethyl 2-[o-(Ethoxycarbonyl)benzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1d'). This compd was prepared by a similar method to that of **1c** in 64% yield as colorless crystals, mp 96.4—97.1°C (from EtOAc); IR (KBr) 1720, 1665, 1630, and 1260 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.00 (3H, t, J=6.6 Hz), 1.20, 1.26 (6H, t, J=6.6 Hz), 4.03 (2H, q, J=6.6 Hz), 3.6—4.5 (4H, m), 5.75 (1H, d, J=7.8 Hz), 6.14 (1H, d, J=7.8 Hz), 6.47 (1H, d, J_{PCH}=17.4 Hz), 6.9—7.8 (7H, m), and 8.0—8.15 (1H, m); MS m/z 443 (M^+; 0.5), 177 (100), and 149 (94). Found: C, 62.22; H, 6.00; N, 3.20%. Calcd for $C_{23}H_{26}NO_6P$: C, 62.30; H, 5.91; N, 3.16%.

Synthesis of Dimethyl 2-[o-(Dimethylcarbamoyl)benzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1e). A mixture of *N,N*-dimethylphthalamic acid[18] (1.90 g, 9.8 mmol) and $SOCl_2$ (5.0 ml, 69 mmol) was refluxed for 1 h, and excess $SOCl_2$ was evaporated. After addition of dry benzene (5 ml) and evaporation, MeCN (10 ml) was added to the chloride (**3e**). IQ (1.28 g, 9.9 mmol) in MeCN (2 ml) was added to the refluxing suspension and after 10 min trimethyl phosphite (1.16 ml, 9.8 mmol) was added. The refluxing was continued for 10 min. After usual work-up, **1e** was obtained in 78% yield (3.2 g, 7.72 mmol) as colorless crystals, mp 131.7—132.5°C (from EtOAc-hexane (1:1)); IR (KBr) 1660, 1650, 1625, and 1260 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.92 (6H, br s), 3.55, 3.71 (6H, 2d, J_{POCH}=10.8 Hz), 5.84 (1H, d, J=7.8 Hz), 6.30 (1H, d, J_{PCH}=16.8 Hz), 6.47 (1H, d, J=7.8 Hz), and 7.0—7.6 (8H, m); MS m/z (rel intensity) 414 (M^+; 0.75) and 176 (100). Found: C, 60.64; H, 5.60; N, 6.83%. Calcd for $C_{21}H_{23}N_2O_5P$: C, 60.87; H, 5.59; N, 6.76%.

Synthesis of Dimethyl 2-[o-(Benzylthio)carbonylbenzoyl]-1,2-dihydro-1-isoquinolylphosphonate (1f). A mixture of *S*-benzyl o-carboxythiobenzoate[19] (3.72 g, 13.7 mmol) and $SOCl_2$ (7 ml) was refluxed for 1 h and excess $SOCl_2$ was removed *in vacuo*. To the residue was added dry benzene (3.5 ml) and the mixture was evaporated. This treatment was repeated twice. To the residue were added MeCN (10 ml), IQ (1.77 g, 13.7 mmol) in MeCN (5 ml), and trimethyl phosphite (1.62 ml, 13.7 mmol) successively. After refluxing for 10 min, MeCN was removed *in vacuo*, to the residue were added a small amount of ether and a trace of EtOAc, and ppt thus obtained (phthalic anhydride, 0.564 g) was filtered off. To the filtrate was added 3% aq $NaHCO_3$, and the mixture was extracted with CH_2Cl_2. The extract was washed with aq NaCl, dried ($MgSO_4$), and evaporated. The residue (5.12 g) was dissolved in CH_2Cl_2 (50 ml), successively washed with 2M aq HCl, 5% aq Na_2CO_3, and aq NaCl, dried ($MgSO_4$), and evaporated. The residue (2.83 g) was subjected to dry column chromatography (DCC; Al_2O_3, Et_2O) to afford **1f** (0.55 g, 1.12 mmol, 8.2%) as colorless crystals, mp 152—154°C (from EtOAc-hexane (1:1));

IR (KBr) 1660, 1620, and 1245 cm^{-1}; ^1H NMR ($CDCl_3$) δ= 3.55, 3.67 (6H, 2d, J_{POCH}=10.8 Hz), 4.05 (2H, s), 5.70 (1H, d, J=7.8 Hz), 6.10 (1H, d, J=7.8 Hz), 6.41 (1H, d, J_{PCH}=16.2 Hz), 6.9—7.7 (12H, m), and 7.8—8.3 (1H, m); MS *m/z* (rel intensity) 493 (M^+; 0.0008) and 91 (100). Found: C, 63.41; H, 4.74; N, 3.02%. Calcd for $C_{26}H_{24}NO_5PS$: C, 63.28; H, 4.90; N, 2.84%.

Synthesis of Dimethyl 1-[o-(Methoxycarbonyl)benzoyl]-1,2-dihydro-2-quinolylphosphonate (6). MeCN (2 ml) was added to acid chloride prepared from methyl hydrogen phthalate (1.81 g, 10.0 mmol) and $SOCl_2$ (5 ml) similarly to preparation of **1c**. To the above soln, quinoline (1.30 g, 10.1 mmol) in MeCN (7 ml), trimethyl phosphite (1.18 ml, 10.0 mmol), and NaI (2 g, 13 mmol) were successively added at 0°C with stirring, and the mixture was heated at 50°C with stirring for 10 min. After removal of the solvent, 2% aq $NaHCO_3$ (50 ml) was added to the residue, the mixture was extracted with CH_2Cl_2, the extract was washed with aq NaCl, dried ($MgSO_4$), and evaporated. The residue (3.05 g) was subjected to DCC (Al_2O_3, Et_2O) to give **6** (2.40 g, 5.98 mmol, 60% yield) as pale yellow oil; IR (neat) 1730, 1660, and 1300—1265 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.53, 3.75 (6H, 2d, J_{POCH}= 10.2 Hz), 3.83 (3H, s), and 5.8—8.2 (10H, m). Analytically pure sample could not be obtained because of a difficulty of purification. Therefore, crude material was used in the reaction.

Intramolecular Wittig-Horner Reaction. General Procedure Using LDA: The reaction was performed under nitrogen atmosphere. To phosphonate (**1**; 3.0 mmol) in tetrahydrofuran (THF) (20 ml) was added a LDA soln (3.5 mmol) in THF (5 ml) at −70°C. After stirred for 0.5 h, the temperature was gradually raised to room temp and kept at about 40°C for 0.5 h. After addition of methanol (3—6 ml), the solvent was removed and water (70 ml) was added to the residue. After usual work-up, the residue was separated or purified by column chromatography (SiO_2, Et_2O).

Reaction of 1a: **2a** (31%), IQ (41%), and **7a** (6%) were isolated. **2a**: Yellow crystals, mp 211.1—211.7°C (from CH_2Cl_2-Et_2O); IR (KBr) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.70 (1H, d, J= 8.1 Hz), 6.8—7.6 (12H, m), 8.6—8.7 (1H, m), and 8.67 (1H, d, J=8.1 Hz); MS *m/z* (rel intensity) 321 (M^+; 100). Found: C, 86.01; H, 4.69; N, 4.34%. Calcd for $C_{23}H_{15}NO$: C, 85.96; H, 4.70; N, 4.36%. **7a**: Colorless crystals, mp 126—128°C; IR (neat) 1750 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.03, 1.11 (12H, 2d, J=6.6 Hz), 3.27 (2H, sept, J=6.6 Hz), and 70—7.7 (9H, m). Found: *m/z* 309.1718. Calcd for $C_{20}H_{23}NO_2$: M, 309.1728.

The reaction of **1a** with *n*-BuLi gave IQ (53%) and a mixture of **2a** (isolated yield 9.4%) and **7'a** (could not be purified, 22% yield; IR (neat) 1760 cm^{-1}).

Reaction of 1b: A mixture of **2b** and an unidentified compd, IQ (46%), and **7b** (6%) (^1H NMR ($CDCl_3$) (partly) δ=1.02, 1.09 (12H, 2d, J=6.6 Hz), 2.21 (3H, s), 3.36 (2H, sept, J=6.6 Hz)) were obtained. Twice recrystallizations gave **2b** (4.5%) as yellow crystals, mp 215.2—215.9°C (from CH_2Cl_2-Et_2O); IR (KBr) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.50 (3H, s), 6.74 (1H, d, J=7.8 Hz), 6.9—7.7 (1H, m), 8.5—8.8 (1H, m), and 8.70 (1H, d, J=7.8 Hz); MS *m/z* (rel intensity) 335 (M^+; 100). Found: C, 85.66; H, 5.03; N, 4.21%. Calcd for $C_{24}H_{17}NO$: C, 85.95; H, 5.11; N, 4.18%.

Reaction of 1c: **2c** was obtained in 76% yield as yellow crystals, mp 143.8—144.7°C (from CH_2Cl_2-Et_2O); IR (KBr) 1650 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.83 (3H, s), 6.72 (1H, d,) J= 7.8 Hz), 7.3—8.2 (6H, m), 8.65 (1H, d, J=7.8 Hz), 8.55—8.80 (1H, dm, J=8 Hz), and 9.10—9.40 (1H, m); MS *m/z* (rel intensity) 275 (M^+; 19) and 260 (100). Found: C, 78.82; H, 4.48; N, 5.11%. Calcd for $C_{18}H_{13}NO_2$: C, 78.53; H, 4.76; N, 5.09%.

Reaction of **1c'** also gave **2c** in 66% yield.

Reaction of 1d: **2d** was obtained in 67% yield as yellow crystals, mp 181.7—182.3°C (from CH_2Cl_2-Et_2O); IR (KBr) 1650 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.50 (3H, t, J=6.9 Hz), 3.87 (2H, q, J=6.9 Hz), 6.63 (1H, d, J=7.8 Hz), 7.3—8.1 (6H, m), 8.55 (1H, d, J=7.8 Hz), 8.5—8.65 (1H, dm, J=8 Hz), and 9.0—9.3 (1H, m); MS *m/z* (rel intensity) 289 (M^+; 15) and 260 (100). Found: C, 78.58; H, 4.98; N, 4.82%. Calcd for $C_{19}H_{15}NO_2$: C, 78.87; H, 5.23; N, 4.84%.

Reaction of **1d'** also gave **2d** in 75% yield.

Reaction of 1e: **2e** was obtained in 67% yield as yellow crystals, mp 144.4—145.7°C (from CH_2Cl_2-Et_2O); IR (KBr) 1655 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.00 (6H, s), 6.67 (1H, d, J= 7.8 Hz), 7.35—7.65 (4H, m), 7.7—7.95 (2H, m), 8.60 (1H, d, J= 7.8 Hz), 8.55—8.75 (1H, dm, J=8 Hz), and 8.85—9.15 (1H, m); MS *m/z* (rel intensity) 288 (M^+; 100) and 273 (84). Found: C, 79.41; H, 5.29; N, 9.67%. Calcd for $C_{19}H_{16}N_2O$: C, 79.14; H, 5.59; N, 9.72%.

Reaction of 1f: The residue (234 mg) from reaction of **1f** (0.435 g, 0.882 mmol) was subjected to column chromatography (Al_2O_3, Et_2O-hexane (1:2)) to separate benzyl methyl sulfide (51 mg, 0.37 mmol, 42% yield) and crude **2f**. Pure **2f** was isolated by treatment with ether, 9.7 mg (0.026 mmol, 3.0%), yellow crystals, mp 115—118°C (from EtOAc-hexane); IR (KBr) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.68 (2H, s), 6.68 (1H, d, J= 7.8 Hz), 6.6—7.0 (4H, m), 7.2—7.7 (5H, m), 7.87 (1H, td, J=7.7 Hz, 1.7 Hz), 8.47 (1H, d, J=7.8 Hz), 8.61 (1H, d, J=10 Hz), 8.71 (1H, d, J=9.3 Hz), and 9.05—9.2 (1H, m); MS *m/z* (rel intensity) 367 (M^+; 0.9) and 276 (100). Found: C, 78.21; H, 4.92; N, 3.55%. Calcd for $C_{24}H_{17}NOS$: C, 78.45; H, 4.66; N, 3.81%.

Reaction of 6: **10** was obtained in 54% yield as yellow crystals (gradually decompose in soln), mp 299.5—301.2°C (decomp) (from CH_2Cl_2-Et_2O); IR (KBr) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.86 (3H, s), 6.94 (1H, s), 7.05—8.05 (7H, m), 8.6—8.8 (1H, m), and 9.35—9.65 (1H, m), MS *m/z* (rel intensity) 275 (M^+; 17), 260 (88), and 49 (100). Found: C, 78.73; H, 4.99; N, 5.34%. Calcd for $C_{18}H_{13}NO_2$: C, 78.53; H, 4.76; N, 5.09%.

Hydrolysis of 2a: A mixture of aq NaOH (20%; 2.4 ml) and **2a** (42.4 mg, 0.132 mmol) in EtOH (22 ml) was refluxed under nitrogen for 8 h. The reaction mixture was neutralized with dilute HCl and EtOH was evaporated. After addition of water (30 ml) to the residue, the mixture was extracted with CH_2Cl_2. The extract was dried ($MgSO_4$) and evaporated to give 1-[α-(*o*-carboxyphenyl)benzyl]isoquinoline (**9**) (37.1 mg, 83% yield), colorless crystals, mp 191—193°C (decomp) (from CH_2Cl_2-CCl_4); IR (KBr) 3100—2300 and 1705 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.9—7.4 (10H, m), 7.6—7.9 (1H, m), 8.3—8.45 (1H, m), and 8.35 (1H, d, J=5.7 Hz); MS *m/z* (rel intensity) 339 (M^+; 30), 321 (100), and 294 (66). Found: C, 81.43; H, 4.82; N, 4.21%. Calcd for $C_{23}H_{17}NO_2$: C, 81.40; H, 5.05; N, 4.13%.

Facile Synthesis of (2*R*,3*R*)-Phenylalanine-2,3-d_2 and NMR Study on Deuterated Gramicidin S[1]

Kenjiro TANIMURA, Tetsuo KATO,* Michinori WAKI, Sannamu LEE, Yasushi KODERA,† and Nobuo IZUMIYA

Laboratory of Biochemistry, Faculty of Science, Kyushu University 33, Higashi-ku, Fukuoka 812
†*Department of Chemistry, Faculty of Science, Fukuoka University, Jonan-ku, Fukuoka 814-01*

(Received January 30, 1984)

(2*R*,3*R*)-Phenylalanine-2,3-d_2 (D-Phe*) was synthesized through catalytic reduction of *cyclo*(-(*Z*)-2,3-dehydrophenylalanyl-D-alanyl-) under an atmosphere of $^2H_2$ and successive acid hydrolysis in the yield of 80% in high chiral induction. The D-Phe* thus obtained was used for synthesis of [D-Phe*$^{4,4'}$] gramicidin S (GS*). The ^{1}H NMR spectrum of GS* in DMSO-d_6 showed a sharp singlet at 2.98 ppm for the (3*S*)-proton of D-Phe* residue. It has been proposed that among rotamers of D-Phe aromatic side chain in GS the one with $\kappa_1=180°$ is predominant. The present observation provides sound evidence for assignments of D-Phe β-protons based on the proposal.

Selectively deuterated amino acid is important for studying conformations of biologically active peptides and proteins. Kirby and Michael[2] synthesized 3-deuterated aromatic amino acids by catalytic hydrogenation of *trans*-α-acylaminocinnamic acid-β-*d* derivatives and subsequent deacylation with acylase. Kainosho and Ajisaka[3] synthesized selectively deuterated L-amino acids by use of enzyme and studied conformations of the amino acids in aqueous solutions. Nagai and Kobayashi[4] used α-chymotrypsin instead of acylase and obtained both diastereomers, (2*S*,3*R*)-*N*-acetyl-L-phenylalanine-3-*d* and (2*R*,3*R*)-*N*-acetyl-D-phenylalanine-3-*d* ethyl ester in the yield of 6% each. The prefixes L and D are used here to clarify configuration at the α-center. These deuterated amino acids were used to the synthesis and conformational studies of [Met^5]enkephalin.[5,6] In every case, optical resolution was inevitable at the final stage in the amino acid synthesis, lowering the yields of deuterated products.

Izumiya *et al.*[7,8] recently developed a new method for synthesizing optically active amino acids, that is, catalytic hydrogenation of dipeptide anhydrides containing a dehydroamino acid residue and an L- or D-amino acid residue. They observed that the condensation of *cyclo*(-*N*-acetyl-glycyl-*N*-acetyl-L-alanyl-) with benzaldehyde exclusively yielded *cyclo*(-2,3-dehydrophenylalanyl-*N*-acetyl-L-alanyl-) of *Z* configuration. Deacetylation with hydrazine, catalytic hydrogenation in the presence of Pd black, and successive acid hydrolysis yielded L-phenylalanine in high chiral inductiction, 97.0%.[9]

This paper deals with the synthesis of (2*R*,3*R*)-phenylalanine-2,3-d_2 as an example of facile synthesis of the selectively deuterated and optically active aromatic amino acid. We also report the synthesis and ^{1}H NMR analysis of gramicidin S containing two residues of the deuterated D-phenylalanine.

Results and Discussion

Synthesis of (2R,3R)-Phenylalanine-2,3-d$_2$ (D-Phe).* (2*R*,3*R*)-Phenylalanine-2,3-d_2 was synthesized in a manner similar to that described for L-phenylalanine.[9] *cyclo*(-ΔPhe-D-Ala-) (**3**)[10] was catalytically reduced under an atmosphere of $^2H_2$ to give *cyclo*(-(2*R*,3*R*)-Phe-2,3-d_2-D-Ala-) (**4**) in an excellent yield. Chiral induction was estimated as 98.8% by HPLC. Compound **4** was hydrolyzed to give (2*R*,3*R*)-phenylalanine-2,3-d_2 (D-Phe*) (**5**); no L-isomer was detected by the modified Manning-Moore method.[11,12] Content of deuterium was estimated to be 90%±10% by use of ^{1}H NMR spectroscopy. As the chirality at α-center was so high, H–D exchange at the α-center should be, if any, negligible. Therefore, some 10% hydrogen observed in ^{1}H NMR spectrum was attributed to contamination in the course of deuteration. Stereochemistry of β-center was assigned to be *R* according to the literature[2] and results of previous experiments.[7-9] Kirby and Michael showed that hydrogenation of *trans*-α-acylaminocinnamic acid derivatives proceeded in *cis* configuration insensitive to variation of substituents and catalysts with at least 95% chirality.[2] In case of dehydrodipeptide anhydrides, rigid planar structure of the substrates favored highly chiral hydrogenation.[7-9] The ^{1}H NMR spectrum of D-Phe* (**5**) in TFA-*d* showed a singlet at δ=3.37 with an intensity of 1 H and another singlet at 3.58 with 0.1 H. The latter signal was attributed to βCH proton contaminated in deuteration. Exact chiral induction at the β-center was not determined.

Synthesis of [(2R,3R)-D-Phe-2,3-d$_2^{4,4'}$]gramicidin S (GS).* The deuterated D-phenylalanine thus obtained was used for the synthesis of gramicidin S (GS). ^{1}H NMR study on the synthetic deuterio-GS should give useful information on confirming the conformation of GS. Figure 1 shows the route for the synthesis. Boc-pentapeptide acid (**13**) was converted to the active ester, which was treated with TFA to remove the Boc group. The pentapeptide active ester thus obtained was subjected to cyclization in pyridine to give a mixture of desired [L-Orn(Z)$^{2,2'}$, D-Phe*$^{4,4'}$]gramicidin S (Z_2GS*) (**14**) and a by-product (cyclic monomer) which was removed by Sephadex LH-20 column chromatography. Compound **14** was hydrogenolyzed to give [D-Phe*$^{4,4'}$]-gramicidin S (GS*) (**15**). A part of **15** was used to prepare [L-Orn-(Boc)$^{2,2'}$, D-Phe*$^{4,4'}$]gramicidin S ((Boc)$_2$GS*) (**16**).

^{1}H NMR Study on Gramicidin S and Related Peptides. Figure 2 shows 90 MHz ^{1}H NMR spectra of **14** (a), Z_2GS (b), **15**·2HCl (c), and GS·2HCl (d). In Fig. 2 (a) and (c), each βCH signal in D-Phe* resonates as a sharp singlet. This indicates that highly stereoselective deuteration proceeded not only at α-center but also at β-center.

In regard to side chain conformation of GS, Dygert

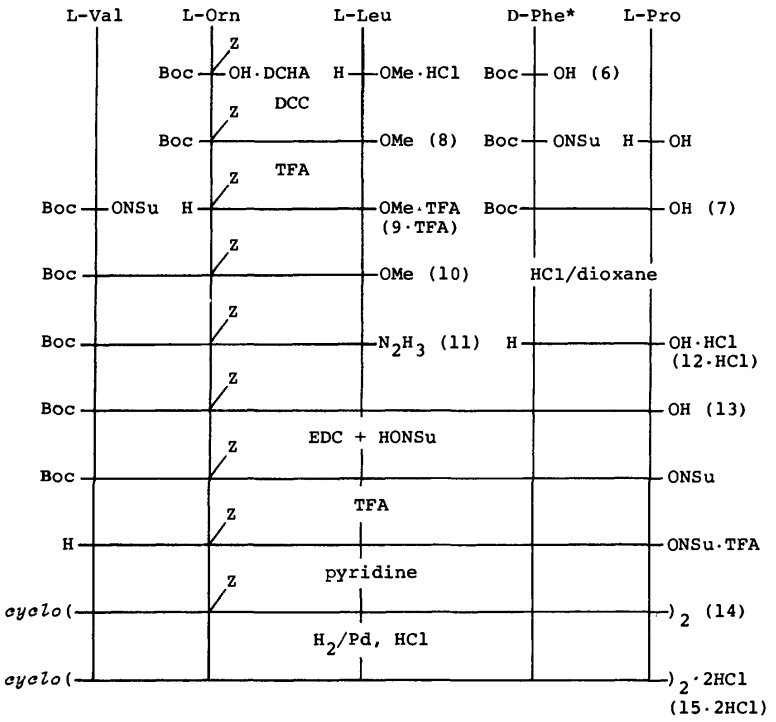

Fig. 1. Synthesis of deuterated gramicidin S.

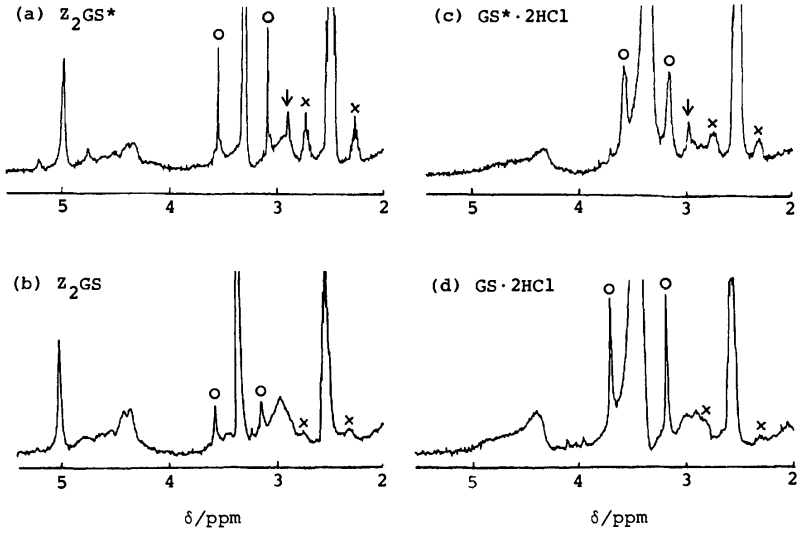

Fig. 2. 90 MHz ^{1}H NMR spectra of gramicidin S and related derivatives. Satelite of HDO (O); satelite of DMSO (X). Arrows in (a) and (c) indicate (3S)-proton signals.

et al.[13] proposed the D-Phe side chain conformation with $\kappa_1=180°$ to be most stable conformation as shown in Fig. 3. Rae and Scheraga[14] supported this proposal on the basis of ^{1}H NMR results. Assuming this D-Phe side chain conformation, Jones *et al.*[15] assigned the chemical shifts of D-Phe $H_{\beta 1}$ and $H_{\beta 2}$ protons in GS in CD_3OD solution as $\delta=3.04$ and 2.96, respectively. Krauss and Chan[16] also assigned them as $\delta=3.10$ and 2.96 in CD_3OD, and 2.97 and 2.88 in DMSO-d_6 solution. Figure 2 (c) shows that the (3S)-proton in GS* resonated at $\delta=2.98$ in DMSO-d_6 solution. As the protons named $H_{\beta 1}$ and $H_{\beta 2}$ correspond to *pro-S* and *pro-R*, respectively, this result agreed quite well with the assignments by Jones *et al.*[15] and by Krauss and

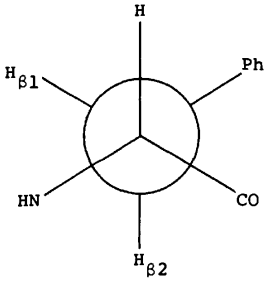

Fig. 3. Conformation for D-Phe side chain with $\kappa_1=180°$.

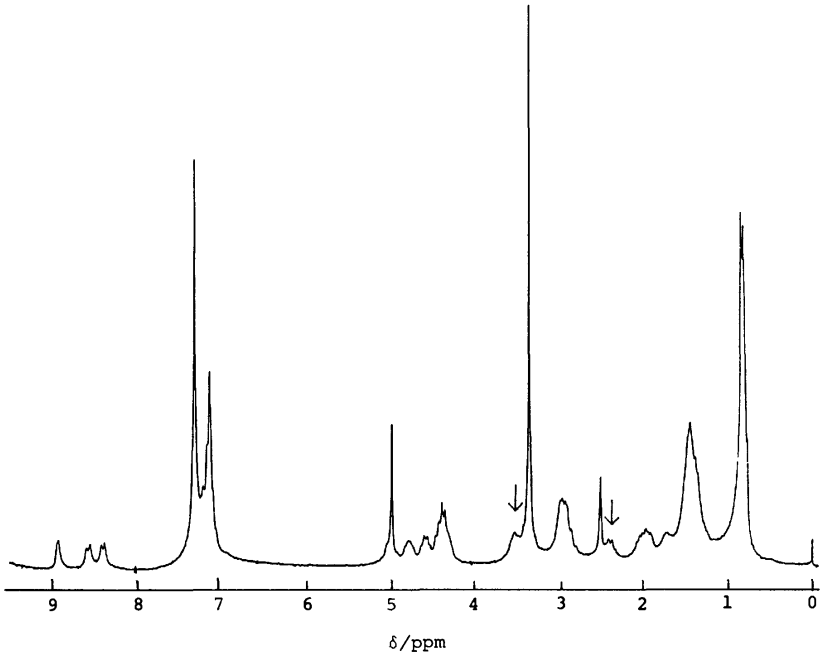

Fig. 4. 200 MHz ^{1}H NMR spectrum of bis(benzyloxycarbonyl)gramicidin S. Arrows indicate δCH_2-proton signals in L-Pro residues.

Chan.[16] Thus, our experimental results provided sound evidence for their assignments and the conformation of D-Phe side chain in GS with $\kappa_1=180°$.

Figures 2 (b) and (d) show that signals of L-Orn δ CH_2 and D-Phe βCH_2 overlap and appear as broad multiplets at about δ=2.9—3.0. The shape of the multiplets in (b) differs from that in (d), suggesting some chemical shift change between GS and Z_2GS. Similarly, the sharp singlet of D-Phe* (3S)-proton in Fig. 2 (a) resonates at δ=2.90 but the same singlet resonates at 2.98 in Fig. 2 (c). Benzyloxycarbonylation of GS* induced some 0.08 upfield shift of the (3S)-proton signal. Krauss and Chan[16] proposed the conformation of GS with intramolecular hydrogen bonds between L-Orn δNH and D-Phe C=O. If Z_2GS holds the same conformation, steric crowding around the D-Phe-L-Pro peptide bonds may be expected because bulky Z groups approach D-Phe side chains. However, 200 MHz ^{1}H NMR spectrum of Z_2GS (Fig. 4) showed that a δCH signal of L-Pro resonates at δ=2.40, indicating proximity of the D-Phe side chain to the pyrrolidine ring.[14] This means that the D-Phe side chain in Z_2GS maintains the orientation with $\kappa_1=180°$ in spite of possible steric crowding. The upfield shift of (3S)-proton of D-Phe* in Z_2GS* should be explained in terms of shielding effect due to the near-by Z group. Interestingly, the D-Phe* (3S)-proton in $(Boc)_2$GS* resonates at δ=2.93, showing minute difference between the aromatic and alkyl urethane groups in inducing chemical shift change of D-Phe (3S)-signal.

Experimental

All the melting points are uncorrected. TLC was carried out on silica gel G (Merck) with following solvent systems, the ratio in parentheses after each system being shown by volume: R_f^1, $CHCl_3$-MeOH (5:1); R_f^2, *n*-BuOH-AcOH-pyridine-water (4:1:1:2); R_f^3, $CHCl_3$-MeOH-AcOH (50:10:2). Optical rotations were measured on a Union high sensitivity polarimeter PM-71. HPLC was carried out on a Hitachi 635A liquid chromatograph and samples were detected at 210 nm absorption.

Synthesis of (2R,3R)-Phenylalanine-2,3-d_2. cyclo*(-ΔPhe-D-Ala-) (3)*: Z-Gly-D-Ala-OMe (**1**) was synthesized from Z-Gly-OH and H-D-Ala-OMe·HCl following the procedure for L-isomer;[8] yield of **1**, 86%; mp 91—93 °C; $[\alpha]_D^{23}$+20.6° (*c* 1, DMF). Reported values for L-isomer, mp 64—69 °C; $[\alpha]_D^{20}$ −21.0° (*c* 1, DMF).[8] Compound **1** in a mixture of MeOH and AcOH was hydrogenolyzed and then the filtrate was evaporated. The residue in *s*-BuOH which contains AcOH (0.1 M(1 M=1 mol dm^{-3})) was treated as described in the literature;[17] yield of *cyclo*(-Gly-D-Ala-) (**2**), 96%; mp 241—242 °C (dec); $[\alpha]_D^{21}$+21.4 (*c* 0.5, DMF). Reported values for L-isomer, mp 228—230 °C; $[\alpha]_D^{20}$−21.3° (*c* 1, DMF).[8] Possible polymorphism may explain high melting points of **1** and **2** compared to those of L-isomer. Compound **2** was converted to *cyclo*(-(*Z*)-ΔPhe-D-Ala-) (**3**) as described for L-isomer;[9] yield, 61%; mp 241—245 °C (dec); $[\alpha]_D^{21}$+18.0° (*c* 1, DMF). Reported values for L-isomer, mp 246—248 °C; $[\alpha]_D^{20}$−19.2° (*c* 1, DMF).

cyclo*(-(2R, 3R)-Phe-2, 3-*d_2*-D-Ala-) (4)*: Compound **3** (864 mg, 4 mmol) dissolved in DMF (150 ml) was deuterated in the presence of Pd black under an atmosphere of $^2H_2$ for 3 d at 0° and *ca.* 1 atm. Crystals precipitated in the course of reduction were crushed occasionally and dissolved in DMF with short-time heating. After filtration of Pd black, the solution was evaporated and the residue was collected with the aid of ether; yield, 845 mg (97%); R_f^1 0.82. The extent (98.8%) of chiral induction was determined by HPLC as described in the later section.

(2R,3R)-Phenylalaine-2,3-d_2 *(D-Phe*) (5)*: Compound **4** (437 mg, 2 mmol) was hydrolyzed in 6 M HCl (8 ml) at 110 °C for 4.5 h and the solution was evaporated. The residue was dissolved in water (100 ml) and the solution was treated for 90 min at room temperature with charcoal (9 g) which had been treated with 5% AcOH (120 ml) for 90 min.[18] After filtration, the charcoal was extracted with an aqueous solution (100 ml) containing 5% phenol and 20% AcOH, and

the extraction was repeated twice more. Combined extract was thoroughly washed with ether, diluted with water, and the solution was applied to a column of Dowex 50 (H^+ form) (0.9×8 cm). The column was washed with water, eluted with 1 M NH_4OH, and the eluate was evaporated. The residue (D-Phe*) was recrystallized from hot water-acetone; yield, 264 mg (80%); mp 240—243 °C; R_f^2 0.60. Optical purity was ascertained by the modified Manning-Moore procedure;[10,11] no L-phenylalanine was detected. Content of deuterium was estimated to be 90%±10% by the comparison of signal intensity of ^1H NMR spectra.

Separation of cyclo*(-Phe-Ala-) Diastereomers with HPLC.* The extent of chiral induction after deuteration of **3** was determined by the HPLC. Experimental conditions for separation of the diastereomers were as follows: Column, Li-Chrosorb RP-18 (4×150 mm); solvent, water-CH_3CN (8:1); flow rate, 1.2 ml/min; pressure, 180 kg/cm²; elution time, 7.5 min for *cyclo*(-L-Phe-D-Ala-) and 10.2 min for *cyclo*(-D-Phe-D-Ala-).

Synthesis of [(2R,3R)-Phe-2,3-$d_2^{4,4'}$]gramicidin S (GS).*

Boc-D-Phe-OH·DCHA (6·DCHA)*: Compound **5** was treated with $(Boc)_2O$[19] and the oily **6** was converted to crystalline DCHA salt; yield, 97%; mp 210—215 °C (dec); $[\alpha]_D^{26}$−26.9 (*c* 1, MeOH). Reported values for protio L-isomer, mp 210—212 °C; $[\alpha]_D^{27}$+29.2 (*c* 1, MeOH).[20]

Boc-D-Phe-L-Pro-OH (7)*: An oily Boc-D-Phe*-OH obtained from **6**·DCHA was converted to Boc-D-Phe*-ONSu by treatment with DCC and HONSu. This Boc-D-Phe*-ONSu was coupled with H-L-Pro-OH in the usual manner; yield, 74%; mp 167—170 °C; R_f^1 0.55. Reported value for protio **7**, R_f^1 0.54.[21]

Boc-L-Orn(Z)-L-Leu-OMe (8): To a chilled solution of Boc-L-Orn(Z)-OH·DCHA (3.83 g, 7 mmol) and H-L-Leu-OMe·HCl (1.27 g, 7 mmol) in CH_2Cl_2 (28 ml), was added DCC (1.44 g, 7 mmol), and the mixture was stirred at 0 °C overnight. After filtration, the solution was evaporated. The residue was dissolved in EtOAc, and the solution was washed with water, 10% citric acid, 4% $NaHCO_3$, and water, and dried (Na_2SO_4). After evaporation, the residue was crystallized by the addition of ether and petroleum ether; yield, 3.17 g (92%); mp 85—88 °C; $[\alpha]_D^{21}$−12.4 (*c* 1, DMF); R_f^1 0.79.

Found: C, 61.01; H, 8.04; N, 8.59%. Calcd for $C_{25}H_{39}O_7N_3$: C, 60.83; H, 7.96; N, 8.51%.

H-L-Orn(Z)-L-Leu-OMe·TFA (9·TFA): Compound **8** (2.96 g, 6 mmol) was treated with TFA (30 ml) at 0 °C for 20 min and the solution was evaporated. The oily residue was treated with ether and petroleum ether. Crystals were collected and washed with ether; yield, 2.49 g (83%); R_f^2 0.82. This was used to the next step without further purification.

Boc-L-Val-L-Orn(Z)-L-Leu-OMe (10): Into a solution of **9**·TFA (1.77 g, 3.5 mmol) in a mixture of tetrahydrofuran (7 ml) and NEt_3 (0.49 ml, 3.5 mmol), was added Boc-L-Val-ONSu (1.77 g, 3.5 mmol) at 0 °C. The mixture was stirred at room temperature overnight, evaporated, and diluted with EtOAc. The solution was treated as described for **8**; yield, 1.88 g (91%); mp 147—149 °C; $[\alpha]_D^{20}$−16.0° (*c* 1, DMF); R_f^1 0.71.

Found: C, 60.89; H, 8.25; N, 9.66%. Calcd for $C_{30}H_{48}O_8N_4$: C, 60.79; H, 8.16; N, 9.45%.

Boc-L-Val-L-Orn(Z)-L-Leu-N_2H_3 (11). Into a solution of **10** (1.78 g, 3 mmol) in DMF (6 ml), was added hydrazine hydrate (1.5 ml, 30 mmol). The mixture was left to stand at room temperature overnight. After the addition of water, precipitated crystals were collected, washed with water, and dried. Recrystallization from DMF-ether gave 1.40 g (79%); mp 199—200 °C; $[\alpha]_D^{20}$−15.2° (*c* 1, DMF); R_f^1 0.67.

Found: C, 58.66; H, 8.23; N, 14.37%. Calcd for $C_{29}H_{48}O_7N_6$: C, 58.76; H, 8.16; N, 14.18%.

H-D-Phe-L-Pro-OH·HCl (12·HCl)*: Compound **7** (176 mg, 0.48 mmol) was treated with 3.6 M HCl in dioxane (2.6 ml, 9.6 mmol) for 1 h and the solution was evaporated. The product was collected with the aid of ether; yield, 146 mg (100%); R_f^3 0.26. This was used to the next step without further purification.

Boc-L-Val-L-Orn(Z)-L-Leu-D-Phe-L-Pro-OH (13)*: Compound **11** (237 mg, 0.4 mmol) was changed to Boc-tripeptide azide with isopentyl nitrite following the literature.[22] The azide was coupled with **12**·HCl (146 mg, 0.48 mmol) in the usual manner; yield, 66 mg (20%); R_f^2 0.82. Reported value for protio **13**, R_f^2 0.82.[23]

cyclo*(-L-Val-L-Orn(Z)-L-Leu-D-Phe*-L-Pro-)₂ (Z_2GS*) (14)*: Into a chilled solution of **13** (105 mg, 0.11 mmol) in a mixture of DMF (0.5 ml) and CH_2Cl_2 (0.5 ml), were added HONSu (30 mg, 0.26 mmol) and EDC·HCl (50 mg, 0.26 mmol) at 0 °C. After being stirred at room temperature overnight, the solution was treated with cold water, and the precipitate (Boc-pentapeptide-ONSu) was collected. After drying, the precipitate was treated with TFA (1.3 ml) for 30 min and then evaporated. The residue (H-pentapeptide-ONSu·TFA) was dissolved in DMF (3 ml) and the solution was added dropwise into pyridine (40 ml) at room temperature. After 3 d, the mixture was evaporated and the residue was dissolved in MeOH. The solution was passed through Amberlyst 15 and A27 columns (1.8×3.5 cm each), washed with MeOH, and evaporated. Crude product (56 mg) was dissolved in MeOH and the solution was applied on a Sephadex LH-20 column (2×84 cm) and eluted with MeOH. Fractions containing **14** were evaporated; yield, 25.5 mg (28%); R_f^2 0.96. Reported value for protio Z_2GS, R_f^2 0.96.[24]

cyclo*(-L-Val-L-Orn-L-Leu-D-Phe*-L-Pro-)₂·2HCl (GS*·2HCl) (15·2HCl)*: A portion (5 mg) of **14** was dissolved in MeOH (4 ml) containing 40 µl of 0.3 M HCl in dioxane, the solution was hydrogenolyzed, and the filtrate was evaporated to give 4.0 mg of **15**·2HCl; R_f^1 0.74.

cyclo*(-L-Val-L-Orn(Boc)-L-Leu-D-Phe*-L-Pro-)₂ ($(Boc)_2GS$*) (16)*: A portion (3.0 mg) of **15**·2HCl was dissolved in a mixture of DMF (0.3 ml) and NEt_3 (2.0 µl) and treated with $(Boc)_2O$ (1.3 mg, 0.006 mmol) for 2 h. The mixture was evaporated and diluted with EtOAc. The solution was washed with water, dried, and evaporated to remain 2.8 mg of **16**; R_f^1 0.76.

^1H NMR spectroscopy. ^1H NMR spectra were recorded in DMSO-d_6 solution on a JEOL FX-90Q spectrometer or a JEOL FX-200 spectrometer at 29 °C. Tetramethylsilane was used as an internal reference; sample concentration, 10—30 mg/ml. The spectra obtained are shown in Figs. 2 and 4.

Preparation and Properties of AzaTCNQ⁻ Anion Salts and Mixed AzaTCNQ⁻/TCNQ⁻ Salts of *N*-Alkylpyridinium and Related Cations

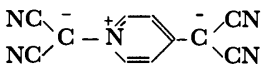
Hirohisa TANAKA, Gen-etsu MATSUBAYASHI, and Toshio TANAKA*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565

(Received January 31, 1984)

The [Cation]⁺ATCNQ⁻ type salts were prepared, where ATCNQ⁻ is (4-dicyanomethyl-1-pyridinio)-dicyanomethanide anion, so-called AzaTCNQ⁻ anion, and [Cation]⁺ are *N*-alkylpyridinium, 4-cyano-*N*-alkylpyridinium, (4-methyl-1-pyrazinio)dicyanomethanide, *N*-alkylquinolinium (alkyl=Me and Et), *N*-methylacridinium, and *N*-methylphenazinium. Electrical resistivities of these salts as compacted samples fall in the range 10^6—10^9 Ωcm at 25 °C. The mixed ATCNQ⁻/TCNQ⁻ salts (TCNQ⁻=7,7,8,8-tetracyano-*p*-quinodimethan radical anion) of *N*-alkylpyridinium and -quinolinium cations also were prepared; [Cation]⁺(ATCNQ⁻)$_{0.1}$(TCNQ⁻)$_{0.9}$ ([Cation]⁺=*N*-methylpyridinium, *N*-ethylpyridinium, and *N*-ethylquinolinium) and [*N*-methylquinolinium]⁺(ATCNQ⁻)$_{0.17}$(TCNQ⁻)$_{0.83}$ whose electrical resistivities (10^4—10^6 Ωcm at 25 °C) are somewhat smaller than those of the corresponding TCNQ⁻ salts. Stackings of ATCNQ⁻ and TCNQ⁻ anions are discussed on the basis of electronic reflectance and ESR spectra. The [Cation]⁺ATCNQ⁻ salts react with iodine in hexane to give [Cation]⁺ATCNQ⁻·I*x* ([Cation]⁺=*N*-methyl- and *N*-ethylpyridinium and -quinolinium; *x*=3.2—3.9). They exhibit electrical resistivities of 10^4—10^6 Ωcm at 25 °C, which are lower by the 10^2—10^3 order than the resistivities of the undoped [Cation]⁺ATCNQ⁻ salts.

Although the ATCNQ⁻ anion (**I**) (4-dicyanomethyl-



I

1-pyridinio)dicyanomethanide anion; so-called Aza-TCNQ⁻ anion) has a diamagnetic property with a $\bar{C}$–$\overset{+}{N}$ ylide bonding, the geometry is very similar to that of the TCNQ⁻ radical anion.[1,2] It would, therefore, be of interest to compare the properties of ATCNQ⁻ salts with those of the corresponding TCNQ⁻ radical anion salts. Thus, we reported previously the preparation and electrical resistivities of [Rh(RNC)$_4$]⁺ATCNQ⁻, and the corresponding mixed ATCNQ⁻/TCNQ⁻ and ATCNQ⁻/TCNQ⁻ /TCNQ salts (R=C_6H_5, 2,6-$Me_2C_6H_3$, and 2,4,6-$Me_3C_6H_2$) together with the crystal structure of [Rh(2,6-$Me_2C_6H_3NC)_4$]⁺ATCNQ⁻.[1] The present work was undertaken to elucidate the properties of the ATCNQ⁻ salts with organic cations having various reduction potentials.

This paper reports the preparation and electrical resistivities of several ATCNQ⁻ and mixed ATCNQ⁻/TCNQ⁻ salts with various organic cations (**1**—**9**) as well as salts obtained by the reaction of [Cation]⁺-ATCNQ⁻ salts with iodine. Interactions between the ATCNQ⁻ anion and the cations and between the ATCNQ⁻ anion and the TCNQ⁻ radical anion are discussed on the basis of electronic spectra and spin concentrations.

(**8**) (**9**)

Experimental

Materials. To a nitrobenzene (55 cm³) solution of (1-pyrazinio)dicyanomethanide[3] (0.55 g, 3.8 mmol) was added dimethyl sulfate (3.4 g, 27 mmol), and the mixture was stirred at room temperature for 4 d. The resulting precipitate was collected by filtration and recrystallized from methanol/benzene (1:1 v/v) to give orange needles of (4-methyl-1-pyrazinio)dicyanomethanide methyl sulfate in a 45% yield; mp 166—168 °C. Found: C, 39.82; H, 3.81; N, 20.13%. Calcd for $C_9H_{10}N_4O_4S$: C, 40.00; H, 3.73; N, 20.73%.

N-Ethylpyridinium bromide, *N*-methylpyridinium, *N*-alkylquinolinium, and 4-cyano-*N*-alkylpyridinium iodides (alkyl=Me and Et), and *N*-methylacridinium and *N*-methylphenazinium methyl sulfates were prepared by reactions of the corresponding base with an excess amount of alkyl halides or dimethyl sulfate according to the literature.[4] *N*-Alkylpyridinium and *N*-alkylquinolinium TCNQ⁻ salts (alkyl=Me and Et) were obtained by reactions of the corresponding pyridinium and quinolinium iodides with Li⁺TCNQ⁻ in methanol.[5] K⁺ATCNQ⁻ was prepared as described previously.[1]

Preparation of ATCNQ⁻ Salts. All the manipulations were carried out under nitrogen atmosphere. To a boiling aqueous (30 cm³) solution of K⁺ATCNQ⁻ (0.20 g, 0.82 mmol) was added *N*-methylpyridinium iodide (1.94 g, 8.8 mmol) in water (3 cm³). The mixture was allowed to stand in a refrigerator overnight to afford microcrystals of *N*-methylpyridinium ATCNQ⁻ salt (**1a**), which was collected by filtration and dried *in vacuo*, 52% yield. Similarly, the reactions of 4-cyano-*N*-methylpyridinium, 4-cyano-*N*-ethylpyridinium, *N*-methylquinolinium, and *N*-ethylquinolinium iodides with K⁺ATCNQ⁻ in water afforded the corresponding ATCNQ⁻ salts; **3a**, **4a**, **6a**, and **7a** in 52, 69, 40, and 48% yields, respectively. (4-Methyl-1-pyrazinio)dicyanomethanide, *N*-methylacridinium , and *N*-methylphenazinium-ATCNQ⁻ salts (**5a**, **8a**, and **9a**) were prepared in 46, 44, and 32% yields, respectively, by reactions of the corresponding pyrazinium dicyanomethylide, acridinium, and phenazinium methyl sulfates with K⁺ATCNQ⁻ in water.

An acetonitrile (300 cm³) solution containing K⁺ATCNQ⁻

(0.61 g, 2.5 mmol) and *N*-ethylpyridinium bromide (2.0 g, 11 mmol) was allowed to stand in a refrigerator overnight. A precipitate (KBr) was filtered off and the filtrate was evaporated to dryness under reduced pressure. The resulting solid was recrystallized from ethanol to afford needles of *N*-ethylpyridinium ATCNQ⁻ salt (**2a**) in a 46% yield.

Preparation of Mixed ATCNQ⁻/TCNQ⁻ Salts. An ethanol (40 cm³) solution containing **1a** (0.17 g, 0.55 mmol) and Li⁺TCNQ⁻ (0.12 g, 0.57 mmol) was allowed to stand in a refrigerator for one week to afford microcrystals of [*N*-methylpyridinium]⁺(ATCNQ⁻)$_{0.1}$ (TCNQ⁻)$_{0.9}$ (**1b**), which was collected by filtration and dried *in vacuo*, 58% yield. The mole ratio of ATCNQ⁻/TCNQ⁻ in the salt was determined from the electronic absorption spectrum in acetonitrile. Analogous reactions of **2a**, **6a**, and **7a** with Li⁺TCNQ⁻ in ethanol gave [*N*-ethylpyridinium]⁺(ATCNQ⁻)$_{0.1}$ (TCNQ⁻)$_{0.9}$ (**2b**), [*N*-methylquinolinium]⁺(ATCNQ⁻)$_{0.17}$ (TCNQ⁻)$_{0.83}$ (**6b**), and [*N*-ethylquinolinium]⁺(ATCNQ⁻)$_{0.1}$ (TCNQ⁻)$_{0.9}$ (**7b**) in 45, 28, and 73% yields, respectively.

Reactions of ATCNQ⁻ Salts with Iodine. Finely powdered **1a** (0.042 g, 0.14 mmol) was suspended in a hexane (25 cm³) solution of iodine (0.080 g, 0.28 mmol), and the mixture was stirred at room temperature under nitrogen atmosphere for 1 d. The resulting solid, [*N*-methylpyridinium]⁺ATCNQ⁻·$I_{3.2}$ (**1c**), was collected by filtration and dried *in vacuo*. Similar reactions of **2a**, **6a**, and **7a** with iodine in hexane gave the [Cation]⁺ATCNQ⁻·I_x salts (**2c**, **6c**, and **7c**; x=3.5 or 3.9).

Properties and analyses for the ATCNQ⁻ and the mixed ATCNQ⁻/TCNQ⁻ salts as well as the [Cation]⁺ATCNQ⁻·I_x salts are summarized in Table 1.

Physical Measurements. Electrical resistivities as compacted samples and electronic absorption spectra were measured as described previously.[6] Electronic reflectance spectra were recorded on a Hitachi 340 spectrophotometer equipped with a Hitachi NIR (near IR) or R-10A (UV and visible) integrating sphere unit. Cyclic voltammetric measurements were performed in acetonitrile using tetrabutylammonium perchlorate as a supporting electrolyte, as described elsewhere.[7] Spin concentrations of the ATCNQ⁻, the mixed ATCNQ⁻/TCNQ⁻, and the TCNQ⁻ salts as well as the ATCNQ⁻·I_x salts were determined at room temperature by comparing integrated signal intensities of the samples with that of 2,2-diphenyl-1-picrylhydrazyl (DPPH).

Results and Discussion

Electrical Properties. The temperature dependence of specific resistivities indicates that all the salts behave as typical semiconductors in the temperature range measured; 0—85 °C for [Cation]⁺ATCNQ⁻, 15—50 °C for the mixed ATCNQ⁻/TCNQ⁻ salts, and 0—20 °C for [Cation]⁺ATCNQ⁻·I_x(x=3.2—3.9).

Table 1. Properties and analyses of the ATCNQ⁻ salts

No.	Salt	Color[a]	Mp (dec.) θ_m/°C	Found (Calcd)[b] %C	%H	%N

7a/**7d**[a]	3.3×10^{8}	b	b

a) The mole ratios of **1a**/**1d**, **2a**/**2d**, **6a**/**6d**, and **7a**/**7d** are the same as those of **1b**, **2b**, **6b**, and **7b**. b) Not measured.

Specific resistivities at 25 °C ($\rho_{25°C}$) and the activation energies (E_a) calculated from the equation $\rho=\rho_0\exp(E_a/kT)$ are listed in Table 2, which involves also the $\rho_{25°C}$ and E_a values of the [Cation]⁺TCNQ⁻ salts and their mixtures with [Cation]⁺ATCNQ⁻, as well as spin concentrations of the salts obtained from ESR spectra. Salts of the [Cation]⁺ATCNQ⁻ type (**1a—9a**) exhibit fairly large $\rho_{25°C}$ values, which may be suggestive of an alternative ATCNQ⁻/[Cation]⁺ stack in the solid state.

The mixed ATCNQ⁻/TCNQ⁻ salts **1b**, **6b**, and **7b** except for **2b** display somewhat smaller $\rho_{25°C}$ and E_a values than the corresponding TCNQ⁻ salts in which the TCNQ⁻ radical anion assumes a columnar structure.[8] In addition, all the mixed salts are more conductive than the mixtures of the ATCNQ⁻ and TCNQ⁻ salts with the same ATCNQ⁻/TCNQ⁻ mole ratios as those in the respective mixed ATCNQ⁻/TCNQ⁻ salts. These results suggest the incorporation of the ATCNQ⁻ anion into the TCNQ⁻ radical anion column. Such an incorporation may bring about a disorder in the TCNQ⁻ column, which may be responsible for rather lower E_a Values of the mixed ATCNQ⁻/TCNQ⁻ salts than those of the TCNQ⁻ salts, as reported for $(TMTTF)_x(TMTSF)_{1-x}(TCNQ)$ (x= 0.005 and 0.03; TMTTF=tetramethyltetrathiafulvalene and TMTSF=tetramethyltetraselenafulvalene),[9] $(TTF)_x(TSF)_{1-x}(TCNQ)$ (x=0—1; TTF= tetrathiafulvalene and TSF=tetraselenafulvalene),[10] $(TMTSF)_2(ClO_4)_{0.95}(IO_4)_{0.05}$,[9] and $(TSF)(MTCNQ)_{0.1}(TCNQ)_{0.9}$(MTCNQ=methyltetracyanoquinodimethan).[11]

The temperature dependence of specific resistivities of the [Cation]⁺ATCNQ⁻·I_x salts is illustrated in Fig. 1. Although the plots of $\log\rho$ *vs.* $1/T$ give a linear relationship below 30 or 20 °C, they deviate from the straight lines above this temperature. The $\log\rho-1/T$ relations of **1c**, **6c**, and **7c**, however, had a reproducible nature in the range of 20—35 °C, while all the [Cation]⁺ATCNQ⁻·I_x salts decomposed above 35 °C.

Electronic Spectra and Magnetic Properties. Figure 2 shows the electronic reflectance spectra of K⁺-ATCNQ⁻ and **7a—7c**. The shoulder-like band around 23000 cm⁻¹ observed for K⁺ATCNQ⁻ (dotted line in Fig. 2), which corresponds to the absorption band at 22000 cm⁻¹ in acetonitrile, is due to the intramolecular charge transfer (CT) transition arising from the $\bar{C}$–$\overset{+}{N}$ ylide bond.[1] Salt **7a** also exhibits this band around 23000 cm⁻¹ (solid line in Fig. 2). Other several strong absorptions in the frequency region higher than 20000 cm⁻¹ observed for **7a** are ascribed to transitions within the ATCNQ⁻ anion or the cation. It should be noted that **7a** displays a band at 17500 cm⁻¹, which may be due to an electronic interaction between the ATCNQ⁻ anion and the cation, since both K⁺ATCNQ⁻ and *N*-ethylquinolinium perchlorate show no band in this region. Such a new band was observed also in the reflectance spectra of the other [Cation]⁺ATCNQ⁻ salts. The frequency of the band maxima (ν_{max}) newly appeared in the [Cation]⁺ATCNQ⁻ salts are listed in Table 3, together with cathode

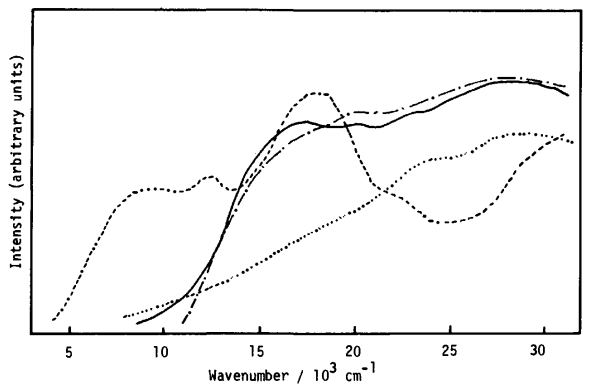

Fig. 2. Powder reflectance spectra of K⁺ATCNQ⁻ (·····), [C_9H_7N-Et]⁺ATCNQ⁻ (7a, ——), [C_9H_7N-Et]⁺(ATCNQ⁻)$_{0.1}$(TCNQ⁻)$_{0.9}$ (7b, ------), and [C_9H_7N-Et]⁺ATCNQ⁻·$I_{3.9}$ (7c, -·-·-).

peak potentials (E_{cp}) of the counter cations determined from cyclic voltammetry. There can be seen an approximate linear relation between ν_{max} and E_{cp} as shown in Fig. 3; ν_{max} decreases with the positive shift of E_{cp}, suggesting that the band is due to an intermolecular CT transition from the ATCNQ⁻ anion to the counter cations. The smaller difference between the anode peak potential of ATCNQ⁻ (0.54 V *vs.* SCE in acetonitrile)[1] and the E_{cp} value of a counter cation is expected to cause more effective CT. Although there has been observed no signal in the ESR spectra of **1a**—**4a**, **6a**, and **7a**, salts **5a**, **8a**, and **9a** displayed a weak ESR signal in the solid state, whose *g* values were essentially the same as that of DPPH (g=2.0037). Based on the signal intensities in comparing with that of DPPH, spin concentrations of **9a**, **5a**, and **8a** at room temperature were estimated 7.5, 0.3, and 0.032%, respectively,

TABLE 3. CT BAND MAXIMA (ν_{max}) OF THE ATCNQ⁻ SALTS AND CATHODE PEAK POTENTIALS (E_{cp}) OF THE COUNTER CATIONS

Salt	ν_{max} / cm⁻¹	E_{cp} / V *vs.* SCE
2a	21000	−1.36
1a	20500	−1.28
7a	17500	−0.92
6a	19500	−0.86
3a	19200	−0.76
4a	17900	−0.70
8a	15300	−0.41
5a	14700	−0.25
9a	10000	−0.11

which indicates a radical formation caused by a stronger CT in these salts.

The reflectance spectrum of **7b** shows a band around 9500 cm⁻¹ (broken line in Fig. 2), which can be assigned to the CT transition between TCNQ⁻ radical anions as observed for simple salts such as Na⁺TCNQ⁻, Rb⁺TCNQ⁻ and [morpholinium]⁺TCNQ⁻.[8] In accordance with this, a strong band appears around 18000 cm⁻¹, which is the blueshifted LE_1 band characteristic of the dimeric interaction of the TCNQ⁻ radical anions. On the other hand, a weak band observed at 12000 cm⁻¹ is ascribed to the TCNQ⁻ radical anion monomer.[8] Salts **1b**, **2b**, and **6b** gave essentially the same spectra as **7b**. Thus, these mixed ATCNQ⁻/TCNQ⁻ salts are suggested to contain predominantly TCNQ⁻ radical anions with the dimeric interaction and small amounts of the ATCNQ⁻ anion seem to prevent the TCNQ⁻/TCNQ⁻ interaction, resulting in the formation of a part of monomeric TCNQ⁻. Although the TCNQ⁻ simple salts (**1d**, **2d**, **6d**, and **7d**) in which the TCNQ⁻ radical anion may have the dimeric interactionon[8] exhibited very weak signals, the mixed ATCNQ⁻/TCNQ⁻ salts displayed a sharp ESR signal (g=2.0037) with moderate intensities, resulting in much larger spin concentrations in the mixed ATCNQ⁻/TCNQ⁻ salts than in the TCNQ⁻ salts (Table 2). This is consistent with the assumption that the ATCNQ⁻ anions may prevent the dimeric

interaction between the $TCNQ^{-}$ radical anions in the mixed $ATCNQ^{-}/TCNQ^{-}$ salts.

The iodine-doped salts, **1c**, **2c**, **6c**, and **7c**, exhibited essentially the same IR absorption spectra as those of the undoped salts, **1a**, **2a**, **6a**, and **7a**, respectively, suggesting that the dopant has little effect on the skeletons of either cationic or anionic moieties. In the electronic reflectance spectra, however, the band due to the CT transition between $ATCNQ^{-}$ and the cation ($\approx 17000\,cm^{-1}$) is weakened (dot-dash line in Fig. 2). Thus, the introduction of iodine to the $ATCNQ^{-}$ salts seems to reduce the CT interaction between $ATCNQ^{-}$ and the cation. It is noted that the spin concentrations of **1c**, **2c**, **6c**, and **7c** obtained from ESR signal intensities are small (Table 2). Only a small portion of the $ATCNQ^{-}$ anion may, therefore, be oxidized by iodine; most of iodine as a dopant would remain as I_2 in the crystals. Small amounts of the oxidized $ATCNQ^{\cdot}$ radical may contribute to the conductivities of **1c**, **2c**, **6c**, and **7c**, which are 10^2—10^3 greater than those of **1a**, **2a**, **6a**, and **7a**, respectively.

Synthetic Studies on Quinoxaline Antibiotics. II.[1] Synthesis of Triostin A[2]

Masaru SHIN,* Ken INOUYE, and Hideo OTSUKA
Shionogi Research Laboratories, Shionogi & Co., Ltd., Fukushima-ku, Osaka 553
(Received February 3, 1984)

Triostin A, a cyclic octadepsipeptide, was synthesized with Z-D-Ser[Boc-Ala-MeCys(Bzl)-MeVal]-OH and Z-D-Ser[H-Ala-MeCys(Bzl)-MeVal]-OTce as key intermediates.† The synthetic antibiotic was compared with natural triostin A in terms of chromatographic behaviors, NMR spectra, and antimicrobial activity to establish their identity. The NMR data on *S,S'*-dibenzyldihydrotriostin A showed that this intermediate lacking the disulfide linkage also existed as two conformers in chloroform. This observation excludes the possibility that the conformer equilibrium known to occur with triostin A is a consequence of the reversed chirality of the disulfide bond.

Triostin A[3] is a member of the triostin family of the quinoxaline antibiotics.[4] The triostins were isolated and structure-elucidated in these Laboratories.[3] The quinomycins[5] which constitute another family of quinoxaline antibiotics are represented by echinomycin[6] (or quinomycin A[5]). In contrast to the quinomycins which are produced by widely distributed streptomycetes, the triostins have ever been found only in a strain of *Streptomyces aureus*.[7] The quinoxaline antibiotics possess antibacterial[5] and cytotoxic[4,8] activities. They are known to bind DNA as bifunctional intercalating agents[9] and thereby inhibit RNA synthesis.[10] Triostin A is characterized by its cyclic octadepsipeptide structure with a cross-bridged disulfide linkage (Fig. 1).[3b,11] It contains an *N,N'*-dimethyl-L-cystine residue and two sets of D-serine, L-alanine, and *N*-methyl-L-valine residues. The 2-quinoxalinylcarbonyl (Qxc) moiety is attached to the amino group of the D-serine residues. Recent NMR studies have shown that triostin A exists as a mixture of two conformers in deuteriochloroform.[11,12] Kalman *et al.*[13] have postulated that occurrence of the two conformers is a consequence of the reversal of chirality of the disulfide bond, while Kyogoku *et al.*[14] attributed it to the *cis-trans* isomerization of the *N*-methyl peptide bonds. The former possibility has recently been ruled out because it was found that the *S,S'*-dibenzyl derivative of dihydrotriostin A (reduced form of triostin A) also had two conformers.[15]

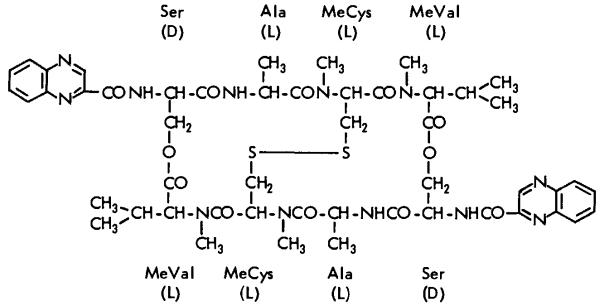

Fig. 1. Structure of Triostin A.

The synthesis of triostin A[16] and of some analogs[17,18] has been reported by Olsen *et al.* In a previous paper[1] we reported the synthesis of 2-quinoxalinylcarbonyl tetradepsipeptide derivatives of the types, Qxc-D-Ser(R^1-MeVal)-Ala-MeCys(Bzl)-OR^2 and Qxc-D-Ser[R^1-MeCys(Bzl)-MeVal]-Ala-OR^2 (R^1=Z, Bpoc, or H; R^2=Bu^t or H), but in the subsequent studies these derivatives proved to be poor intermediates for the synthesis of triostin A. The present paper describes our total synthesis of triostin A, performed with Z-D-Ser[Boc-Ala-MeCys(Bzl)-MeVal]-OH (**1**) and Z-D-Ser[H-Ala-MeCys(Bzl)-MeVal]-OTce (**2**) as key intermediates.

Figure 2 illustrates the procedure for the synthesis of the two tetradepsipeptide derivatives **1** and **2**. The starting material Z-D-Ser(Bu^t)-OH (**3**) was prepared as described for the corresponding L-isomer.[19] Com-

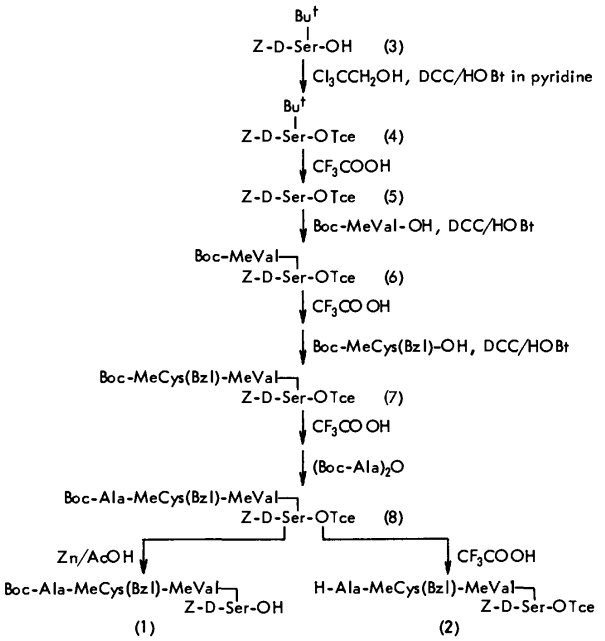

Fig. 2. Synthesis of tetradepsipeptide intermediates.

†Abbreviations used are those recommended by the IUPAC-IUB Commission on Biochemical Nomenclature [*Biochemistry*, **11**, 1726 (1972)] and include: MeCys, N-methyl-L-cysteine, MeVal; *N*-methyl-L-valine; Boc, *t*-butoxycarbonyl; Boc-SDP, *O-t*-butyl *S*-(4,6-dimethyl-2-pyrimidinyl) thiocarbonate; Bpoc, 1-(4-biphenylyl)-1-methylethoxycarbonyl; Qxc, 2-quinoxalinylcarbonyl; Z, benzyloxycarbonyl; Z(OMe), 4-methoxybenzyloxycarbonyl; Z(OMe)-SDP, *O-p*-methoxybenzyl *S*-(4,6-dimethyl-2-pyrimidinyl)thiocarbonate; Bu^t, *t*-butyl; Bzl, benzyl; Tce, 2,2,2-trichloroethyl; HOBt, 1-hydroxybenzotriazole; HONp, 4-nitrophenol; HOSu, *N*-hydroxysuccinimide; CDI, *N,N'*-carbonyldiimidazole; DCC, dicyclohexylcarbodiimide; DCU, *N,N'*-dicyclohexylurea; EDC, 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide; DPPA, diphenylphosphorazidate; AcOH, acetic acid; TFA, trifluoroacetic acid; DCHA, dicyclohexylamine; DIEA, *N,N*-diisopropylethylamine; TEA, triethylamine; DMF, *N,N*-dimethylformamide; and THF, tetrahydrofuran.

pound **3** was esterified with 2,2,2-trichloroethanol (HOTce)[20] by the action of DCC in the presence of HOBt to give **4**. The yield of the Tce ester was as high as 97% when pyridine was used as a solvent. To remove the Bu^t group compound **4** was treated with TFA and the resulting Z-D-Ser-OTce (**5**) was coupled with Boc-MeVal-OH by the use of DCC-HOBt in pyridine[16] to give depsipeptide **6** in 60—70% yields. In the absence of HOBt the yield of **6** was 35% and the formation of *N*-acylurea was predominant (62%). Compound **6** was, after removal of the Boc group with TFA, coupled with Boc-MeCys(Bzl)-OH by the DCC-HOBt method[21] to give **7** in 70—80% yields. Compound **7** was also synthesized using Z(OMe)-MeVal-OH in place of Boc-MeVal-OH. Removal of the Boc group from **7** was followed by the incorporation of Boc-Ala to give **8**, in which the symmetrical anhydride $(Boc\text{-}Ala)_2O$ proved to be a good acylating agent, whereas the usual DCC-mediated coupling with Boc-Ala-OH failed to furnish the desired compound. When acylated with the mixed anhydride derived from Boc-Ala-OH and isobutyl chloroformate, Z-D-Ser[isobutoxycarbonyl-MeCys(Bzl)-MeVal]-OTce was the sole product (90%). The protected tetradepsipeptide (**8**) thus obtained in a 70% yield was treated with either Zn in 90% AcOH[22] to remove the Tce group or TFA to remove the Boc group, giving the key compounds **1** and **2**, respectively. The removal of the Tce group was complete within 3 h and compound **1** was obtained in a 90% yield. Further steps leading to the formation of triostin A are shown in Fig. 3.

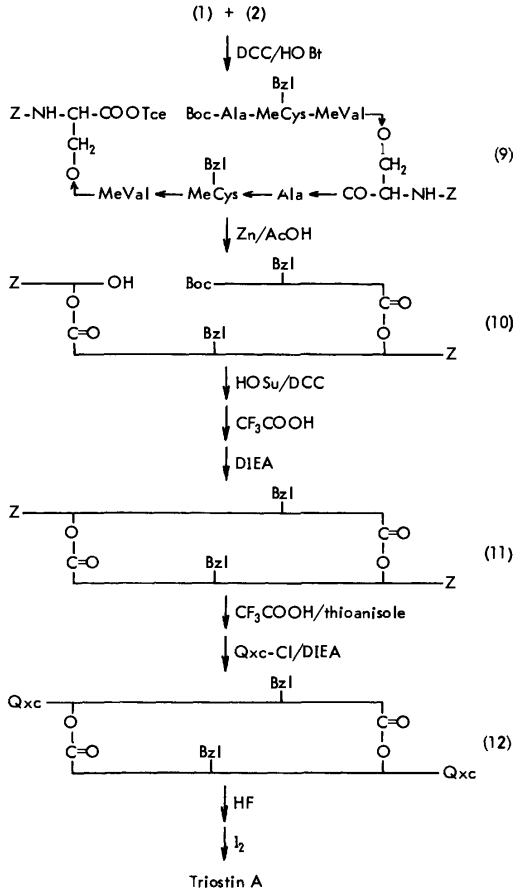

Fig. 3. Synthesis of triostin A.

The coupling of **1** and **2** with DCC-HOBt in THF afforded the linear octadepsipeptide (**9**) in 82—92% yields. Compound **9** was then treated with Zn in 90% AcOH to effect the complete removal of the Tce group giving **10** in yields higher than 90%. For the subsequent cyclization compound **10** was converted into the *N*-hydroxysuccinimide ester in the usual manner except for using HOSu and DCC in large excess and, after removal of the Boc group with TFA, the active ester was dissolved in a large volume of ethyl acetate. The cyclization was then initiated by the addition of DIEA under conditions of high dilution (0.2 mmol peptide/l). The progress of the reaction was monitored by high-performance liquid chromatography (HPLC) on a μ-Porasil column with 2-propanol-hexane (5:95) as solvent to show that the reaction was complete within 3 h. Cyclic octadepsipeptide **11** was isolated in pure form in 58% yield from **10** (mean for seven trials). The ^{1}H-NMR spectrum and the field desorption mass spectrum of **11** were consistent with the proposed structure. Conversion of **11** to *S,S'*-dibenzyl-dihydrotriostin A (**12**) was effected by selective removal of the Z group with TFA-thioanisole,[23] and the subsequent acylation with Qxc-Cl[24] or Qxc-ONp[1] in the presence of triethylamine. The yield of **12** was 28—37% as estimated by HPLC. The crude product was purified on silica-gel columns to give a pure preparation of **12** in an over-all yield of 13—22% from **11**. Compound **12** was treated with HF-anisole at 25 °C for 30 min to remove the benzyl groups, followed by treatment with iodine in methanol[25] to form the disulfide bond. The crude product was purified by silica-gel column chromatography and by recrystallization affording triostin A in a 20% yield from **12**. The synthetic antibiotic thus obtained was indistinguishable from natural triostin A in TLC and in HPLC (Fig. 5). The identity of natural and synthetic preparations was also confirmed by their superimposable 360 MHz ^{1}H-NMR spectra (Fig. 4). Synthetic triostin A was as active as natural triostin A when assayed for antimicrobial activity against *Bacillus subtilis* PCI-219. The minimum effective concentration was 0.5 μg/ml.

In 1978 Chakravarty and Olsen[16] briefly reported the first synthesis of triostin A, in which they used tetradepsipeptide fragments, Z-D-Ser[R-MeCys(Bam)-MeVal]-Ala-OH (I: R=Boc, II: R=H; Bam=benzamidomethyl), as intermediates to prepare their cyclic octadepsipeptide (III). Fragment couplings are usually susceptible to racemization at the *C*-terminal amino acid of the carboxyl component. In this case, therefore, racemization could occur at the Ala residue during the formation of a linear octadepsipeptide from I and II, and also in the subsequent cyclization leading to III. In fact, Olsen and collaborators[17] observed that a linear octadepsipeptide, an intermediate to des-*N*-tetramethyltriostin A, derived from Z-D-Ser[Boc-Cys(Acm)-Val]-Ala-OH and Z-D-Ser[H-Cys(Acm)-Val]-Ala-OTce (Acm=acetamidomethyl) by the EDC-HOBt method contained 6.4% of D-alanine. This means that 25.6% racemization had occurred to the Ala residue involved in the coupling reaction. This racemization was a problem in their synthesis of triostin A and analogs, although they suggested that the diaste-

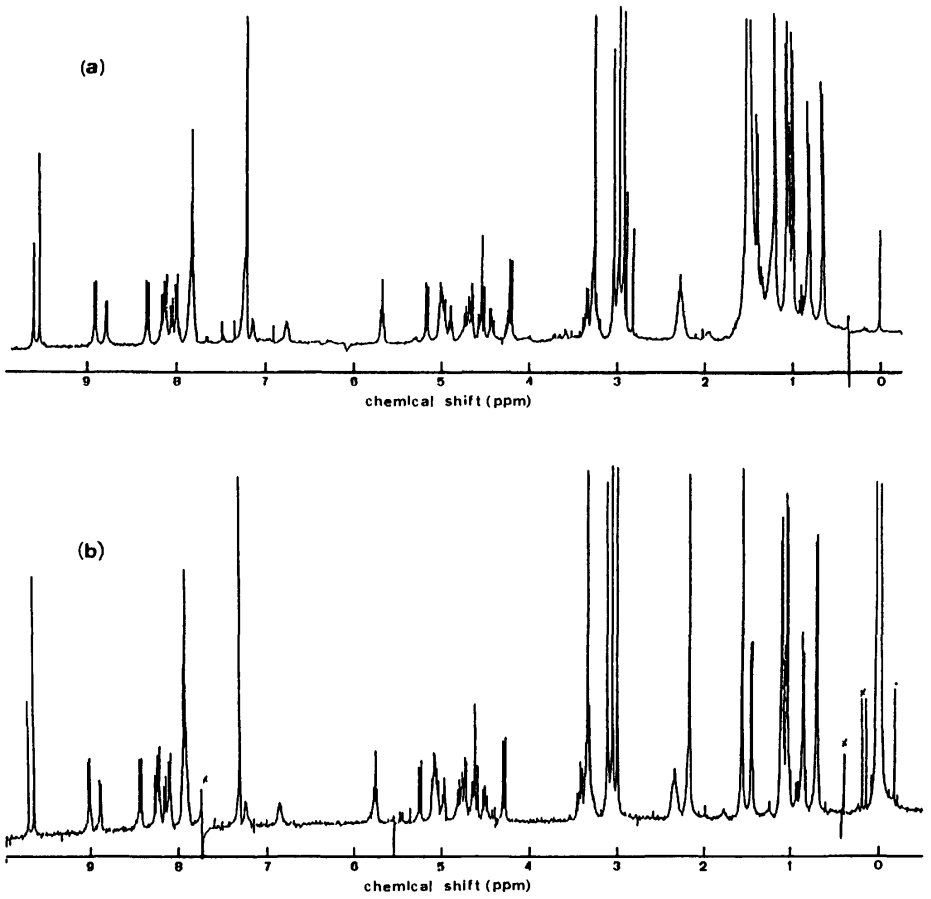

Fig. 4. 360 MHz ^{1}H-NMR spectra of (a) synthetic and (b) natural preparations of triostin A in $CDCl_3$.

reoisomeric impurity could largely be removed during purification. In our present synthesis of triostin A, the coupling of two tetradepsipeptides **1** and **2**, and the subsequent cyslization of the linear octadepsipeptide (**10**) were both performed by activation of the carboxyl function of the *O*-acylated Z-D-serine, Z-D-Ser(R)-OH (R=Boc-peptide group), to form a normal Ser-Ala bond, as shown in Fig. 2 and Fig. 3. This new approach should not only eliminate the danger of racemization, but also make the coupling reaction easier to proceed than what involves the *N*-methylamino acid.

Chakravarty and Olsen[16] stated that the removal of the Tce group from a depsipeptide of the type Z-D-Ser(R)-Ala-OTce (R=Boc-peptide) with zinc in acetic acid was incomplete (65%) in the case of tetradepsipeptide and it was practically impossible in the case of octadepsipeptide. In our synthesis (Fig. 2 and Fig. 3), on the other hand, the complete removal of the Tce group from a depsideptide of the type Z-D-Ser(R)-OTce (R=Boc-peptide) was readily achieved in both tetradepsipeptide **8** and octadepsipeptide **9** by the treatment with zinc in 90% acetic acid, suggesting that the Tce ester of the D-serine in **8** and **9** is exposed to the molecular surface, whereas the alanine ester in Olsen's intermediates is rather buried, especially in the case of the octadepsipeptide.

The cyclization of linear octadepsipeptide **10** was performed by the *N*-hydroxysuccinimide ester method as described above. Table 1 represents the results of the test experiment, in which the data show that the formation of cyclic peptide **11** from **10** is remarkably increased as the peptide concentration is decreased. This is naturally because the undesired formation of oligomers should be suppressed by lowering the concentration, while the intramolecular cyclization is independent of concentration. As is seen in Table 1, the yield of cyclic peptide **11** does not depend on the solvent used, we therefore employed ethyl acetate as solvent in the cyclization reaction of a preparative scale. Chakravarty and Olsen[16] synthesized a cyclic octadepsipeptide as intermediate to triostin A by one-step cyclization of the corresponding linear peptide with both *C*- and *N*-terminals unprotected, in which the yield of the cyclic peptide was 22% when the EDC-HOSu method and a peptide concentration of *ca.* 2.5 mmol/l were employed. In the case of cyclization leading to des-*N*-tetramethyltriostin A (nortriostin A) analogs,[17,18] however, higher yields up to 55% have been reported. In the present work we also tried this one-step method. Compound **10** was treated with TFA to remove the Boc group and the resulting material (2 mmol/l in THE or DMF) was treated with 5 or 10 equiv of DCC-HOBt, EDC-HOBt, or CDI at 25 °C, or with 5 equiv of DPPA[26] at 5 °C in the presence of DIEA (1 equiv). Among these the DPPA method gave the best result, producing cyclic peptide **11** in 24% yield as estimated by HPLC. The DCC-HOBt method pro-

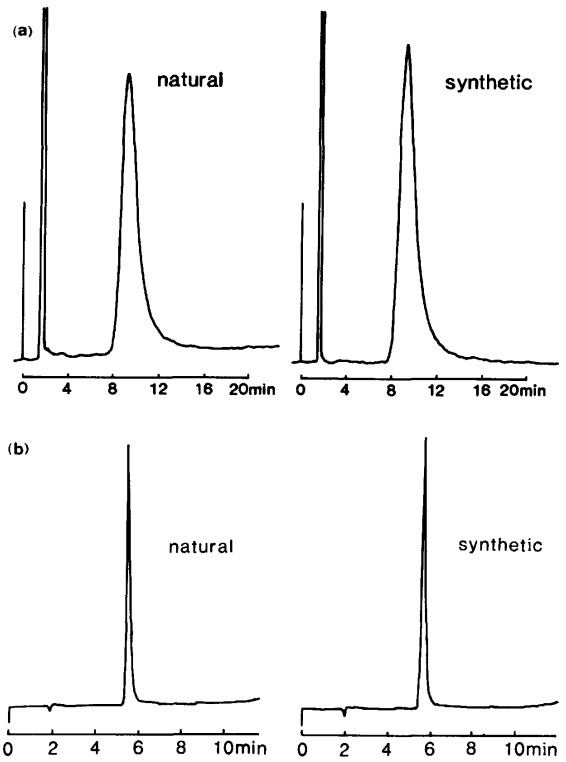

Fig. 5. HPLC profiles of synthetic and natural preparations of triostin A. (a) Column: m-Porasil, 30 cm×3.9 mm ID; solvent: 2-propanol-hexane (27.5:72.5); flow rate: 2 ml/min; detection: at 220 nm. (b) Column: Hypersil $3C_{18}$, 10 cm×6.0 mm ID; solvent: a linear gradient (20 min) of 50—90% CH_3CN in 0.1 M (1 M=1 mol dm^{-3}) triethylammonium acetate (pH 7.0); flow rate: 1 ml/min; detection: at 243 nm.

TABLE 1. CONCENTRATION DEPENDECY OF CYCLIZATION REACTION IN THE CONVERSION OF **10** TO **11**[a]

Concentration of peptide (mmol/l)	Solvent	Yield[b] (%)
20	EtOAc	13
2	EtOAc	39
0.2	EtOAc	56
20	DMF	12
2	DMF	42(31)[c]
0.2	DMF	58

a) The cyclization was carried out at 25 °C for 3 h and monitored by HPLC under the following conditions: column: μ-Porasil (Waters), 30 cm×3.9 mm ID; solvent: 2-propanol-hexane (5:95, v/v); flow rate: 2 ml/min; detection: at 220 nm and 243 nm. b) Overall yield of **11** from **10** (see Fig. 3). c) In the presence of HOBt (20 mmol/l).

duced **11** in 12, 19, and 14% yields when the peptide concentrations were 10, 2, and 0.4 mmol/l, respectively. These low yields may be ascribed to the peptide concentrations employed, which must have been lower than adequate for the activation of the linear peptide and, at the same time, too high to prevent the undesired intermolecular reaction of the activated peptide. In fact, the occurrence of a larger amount of by-products was observed in the one-step method than in the two-step cyclization by the active ester method.

The selective removal of the Z groups from **11** by the treatment with TFA-thioanisole was based on the "push-pull" mechanism described by Kiso *et al.*[23] Preliminary tests were performed with Z-Cys(Bzl)-OH, Z-MeCys(Bzl)-OH, Z-D-Ser[isobutoxycarbonyl-MeCys-(Bzl)-MeVal]-OTce, and Qxc-D-Ser(Z-MeVal)-Ala-MeCys(Bzl)-OH[1] as model compounds to show that in every case the Z group was completely removed in 4—6 h at 25 °C without appreciable cleavage of the *S*-benzyl group. The similar conditions (25 °C, 6 h) could be applied to compound **11** to give the N^{α}-free intermediate (*S,S'*-dibenzyldihydroapotriostin A) without any difficulties. The subsequent quinoxalylcarbonylation leading to **12** was carried out with 50—100% excess of Qxc-Cl and a minimum amount of TEA to minimize the O→N acyl shift at the D-Ser residue.

Compound **12** obtained above is the *S,S'*-dibenzyl derivative of dihydrotriostin A and lacks the disulfide bond. The ^{1}H-NMR data for **12** clearly show, however, that this compound still has two conformations in $CDCl_3$ as does triostin A itself. This evidence now excludes the possibility, postulated by Kalman *et al.*,[13] that the conformer isomerism of triostin A is resulted from the reversal of chirality of the disulfide bond.

Experimental

Thin-layer chromatography (TLC) was performed on silica-gel plates (precoated Kieselgel 60 F_{254}, Merck) with the following solvent systems (ratios by volume): A, chloroform-methanol (95:5); B, chloroform-methanol-acetic acid (95:5:3); C, benzene-ethyl acetate (90:10); D, benzene-ethyl acetate (70:30); E, benzene-ethyl acetate-acetic acid (70:30:3). Spots were revealed by UV, ninhydrin staining or by charring with sulfuric acid. For column chromatography, prepacked silica-gel columns (Lobar, size B or C, Merck) were mostly used. High-performance liquid chromatography (HPLC) was carried out on a Waters Associates Model 6000A solvent delivery system, equipped with a Waters U6K injector and a Japan Spectroscopic UVIDEC 100-II variable wavelength UV detector. Proton NMR spectra were recorded on a Varian T-60 NMR spectrometer operated at 60 MHz and/or a Bruker WM 360 wb NMR spectrometer at 360 MHz.

D-Serine was purchased from Fluka AG, Buchs, Switzerland, 2-methylquinoxaline from Aldrich Chemical Co., Inc., Milwaukee, WI, U.S.A., Boc-SDP and Z(OMe)-SDP from Protein Research Foundation, Osaka, diphenylphosphorazidate (DPPA) from Nakarai Chemicals, Ltd., Kyoto, and 2,2,2-trichloroethanol (TceOH) from Tokyo Kasei Kogyo Co., Ltd., Tokyo. *N*-Methyl-L-valine,[27] *N*-methyl-*S*-benzyl-L-cysteine,[28] quinoxaline-2-carboxylic acid (Qxc-OH),[6b] and 2-quinoxalinylcarbonyl chloride (Qxc-Cl)[24] were synthesized according to the literature. 4-Nitrophenyl quinoxaline-2-carboxylate (Qxc-ONp) was prepared as described previously.[1]

Z-D-Ser(Bu^t)-OH (3). This compound was prepared basically following the procedure described for the L-isomer;[19] mp 81—84 °C, $[\alpha]_D^{24}$ −18.5±0.6° (*c* 1.0, ethanol). Lit, for the L-isomer:[20] mp 83.5—85 °C, $[\alpha]_D^{23}$ +22.0° (*c* 1, ethanol). Found: C, 61.19; H, 7.19; N, 4.73%. Calcd for $C_{15}H_{21}NO_5$: C, 61.00; H, 7.17; N, 4.74%.

Z-D-Ser(Bu^t)-OTce (4). To a solution of **3** (14.8 g, 50 mmol), Tce-OH (8.22 g, 55 mmol), and HOBt (7.43 g, 55 mmol) in pyridine (100 ml) was added DCC (11.4 g,

55 mmol) and the mixture was stirred at 0—5 °C overnight. After removal of the separated DCU by filtration, the filtrate was evaporated *in vacuo*. The resulting material was dissolved in ethyl acetate and the solution was washed consecutively with ice-cold M hydrochloric acid, water, 5% sodium hydrogencarbonate, and water, dried over magnesium sulfate, and evaporated *in vacuo*. The residue (23 g) was subjected to chromatography on a column (6.0×28 cm) of silicagel (350 g, Kieselgel 60, Merck) with chloroform as solvent. The fractions containing the desired material, as monitored by TLC with benzene-ethyl acetate (90:10) as solvent, were collected and evaporated *in vacuo* to give a sirupy residue, which crystallized upon prolonged standing *in vacuo*; 20.8 g (97%), mp 67—70 °C, $[\alpha]_D^{25}$ +8.4±0.5° (*c* 1.0, methanol). TLC: homogeneous in system D. Found: C, 47.79; H, 5.23; N, 3.27; Cl, 24.90%. Calcd for $C_{17}H_{22}NO_5Cl_3$: C, 47.85; H, 5.20; N, 3.28; Cl, 24.92%.

Z-D-Ser-OTce (5). Compound **4** (4.27 g, 10 mmol) was treated with TFA (20 ml) at 25 °C for 30 min. After evaporation of the TFA *in vacuo* the residue was dissolved in ethyl acetate and the solution was washed with 5% sodium hydrogencarbonate and water, dried over magnesium sulfate, and evaporated *in vacuo*. The oily residue was subjected to a Lobar column (size C) with chloroform-methanol (95:5) as solvent. The chromatography was repeated twice and the fractions containing the desired compound as a single component were collected. Removal of the solvent *in vacuo* yielded **5** as a sirupy residue; 2.97 g (80%), $[\alpha]_D^{25}$ +14.9±0.5° (*c* 1.2, methanol). TLC: homogeneous in system A. Found: C, 42.31; H, 3.78; N, 3.75; Cl, 28.44%. Calcd for $C_{13}H_{14}NO_5Cl_3$: C, 42.13; H, 3.81; N, 3.78; Cl, 28.70%.

Boc-MeVal-OH Piperidine Salt. To a suspension of *N*-methyl-L-valine (9.18 g, 70 mmol) in water (40 ml) containing TEA (22.3 ml, 160 mmol) was added a solution of Boc-SDP (25.2 g, 105 mmol) in dioxane (40 ml) and the mixture was stirred at 25 °C overnight. After addition of ice-cold M sodium hydroxide (100 ml) and washing with ether, the aqueous solution was then acidified with ice-cold M hydrochloric acid. The product separated was taken into ethyl acetate and the organic solution was washed with water, dried over magnesium sulfate and evaporated *in vacuo*. The resulting oil was dissolved in ether and to this was added piperidine (5.02 g, 59 mmol). After evaporation of the ether the residue was crystallized from petroleum ether (16.4 g, 74%). Recrystallization from ethyl acetate-petroleum ether afforded a pure preparation of the desired compound; 13.0 g (59%), mp 97—99 °C, $[\alpha]_D^{25}$ −69.9±1.1° (*c* 1.0, methanol). Found: C, 60.24; H, 10.08; N, 8.52%. Calcd for $C_{11}H_{21}NO_4 \cdot C_5H_{11}N$: C, 60.73; H, 10.19; N, 8.85%.

The same compound was obtained in 54% yield with Boc-N_3 as acylating agent.[29]

Z(OMe)-MeVal-OH Piperidine Salt. *N*-Methyl-L-valine (2.62 g, 20 mmol) was acylated with Z(OMe)-SDP (7.61 g, 25 mmol) as in the corresponding Boc-derivative to give the desired compound; 3.98 g (52%), mp 92—93 °C, $[\alpha]_D^{22}$ −62.7±1.0° (*c* 1.0, methanol). Found: C, 63.36; H, 8.65; N, 7.20%. Calcd. for $C_{15}H_{21}NO_5 \cdot C_5H_{11}N$: C, 63.14; H, 8.48; N, 7.36%.

Boc-MeCys(Bzl)-OH DCHA Salt. *N*-Methyl-*S*-benzyl-L-cysteine (13.5 g, 60 mmol) was acylated with Boc-SDP in water-dioxane (1:2) in a manner similar to that described for Boc-MeVal-OH to give the desired compound as the DCHA salt (28.5 g). The crude product was purified by repeated recrystallization from ethyl acetate-petroleum ether; 24.6 g (81%), mp 104—105 °C, $[\alpha]_D^{24.5}$ −56.0±1.0° (*c* 1, methanol). Found: C, 66.27; H, 9.27; N, 5.39; S, 6.47%. Calcd for $C_{16}H_{23}NO_4S \cdot C_{12}H_{23}N$: C, 66.37; H, 9.15; N, 5.53; S, 6.33%.

Z-D-Ser(Boc-MeVal)-OTce (6). The piperidine salt of Boc-MeVal-OH (2.78 g, 8.8 mmol) was converted into the free acid by the treatment with Dowex 50W×8 (H^+ form) in 50% ethanol at 25 °C for 30 min. Boc-MeVal-OH obtained was dissolved in pyridine (25 ml) together with **5** (2.96 g, 8 mmol) and HOBt (1.19 g, 8.8 mmol), and to this was added a solution of DCC (1.82 g, 8.8 mmol) in pyridine (2 ml) at 0 °C. The mixture was stirred at 4 °C overnight, followed by evaporation *in vacuo*. The residue was dissolved in ethyl acetate and, after removal of precipitates by filtration, the solution was washed consecutively with ice-cold M hydrochloric acid, water, 5% sodium hydrogencarbonate and water, dried over magnesium sulfate and evaporated *in vacuo* to give an oil (5.1 g). The crude product was subjected to chromatography on a Lobar column (size C) with chloroform-methanol (99:1) as solvent. The fractions containing the desired material, as monitored by TLC with system C, were collected and evaporated *in vacuo*. The partially purified material was repeatedly chromatographed on Lobar columns with benzene-ethyl acetate systems as solvent to give **6** as an oil; 3.21 g (69%), $[\alpha]_D^{25}$ −28.3±0.5° (*c* 1.4, methanol). TLC: homogeneous in systems A and C. Found: C, 49.40; H, 5.82; N, 4.72; Cl, 18.19%. Calcd for $C_{24}H_{33}N_2O_8Cl_3$: C, 49.37; H, 5.70; N, 4.80; Cl, 18.22%.

Z-D-Ser[Z(OMe)-MeVal]-OTce (6a). Compound **6a** was synthesized as described for **6** except for the use of Z(OMe)-MeVal-OH in place of Boc-MeVal-OH; yield 74% (oil), $[\alpha]_D^{24}$ −24.1±0.6° (*c* 1.0, methanol). TLC: homogeneous in systems A and D. Found: C, 51.64; H, 5.19; N, 4.27; Cl, 16.16%. Calcd for $C_{28}H_{33}N_2O_9Cl_3$: C, 51.90; H, 5.13; N, 4.32; Cl, 16.42%.

Z-D-Ser[Boc-MeCys(Bzl)-MeVal]-OTce (7). *a) From 6.* Compound **6** (7.30 g, 12.5 mmol) was treated with TFA (30 ml) at 25 °C for 30 min, followed by evaporation *in vacuo*. The resulting oil was dissolved in ethyl acetate and the solution was washed with 5% sodium hydrogencarbonate, dried over magnesium sulfate, and evaporated *in vacuo*. The residue was dissolved in THF (25 ml) together with Boc-MeCys(Bzl)-OH, derived from the DCHA salt (6.97 g, 13.8 mmol) by the treatment with Dowex 50W×8 (H^+ form) in 50% ethanol, and HOBt (1.86 g, 13.8 mmol), and after addition of DCC (2.84 g, 13.8 mmol) the mixture was stirred at 4 °C overnight. The reaction mixture was then worked up in the usual manner to give a crude product (10.5 g) which was repeatedly chromatographed on a Lobar column (size C) with chloroform-methanol (95:5) and benzene-ethyl acetate (9:1) as solvent. The fractions containing the desired product as a single component were collected and evaporated *in vacuo* to give **7** as an oil; 7.47 g (76%), $[\alpha]_D^{27}$ −81.8±1.1° (*c* 1.1, methanol). TLC: homogeneous in systems A and D. Found: C, 52.95; H, 5.99; N, 5.22; S, 4.27; Cl, 13.33%. Calcd for $C_{35}H_{46}N_3O_9SCl_3$: C, 53.13; H, 5.86; N, 5.31; S, 4.05; Cl, 13.44%.

b) From 6a. Compound **7** was also synthesized from **6a** in basically the same manner as described in a); 74%(oil), $[\alpha]_D^{25.5}$ −81.1±1.1° (*c* 1.1, methanol). Found: C, 52.76; H, 5.86; N, 5.14; S, 4.41; Cl, 13.37%.

Z-D-Ser[Boc-Ala-MeCys(Bzl)-MeVal]-OTce (8). Boc-Ala-OH (1.70 g, 9 mmol) was treated with DCC (0.93 g, 4.5 mmol) in THF at 0—5 °C for 2 h. Removal of the separated DCU by filtration afforded a solution of $(Boc\text{-}Ala)_2O$. On the other hand, compound **7** (2.37 g, 3.0 mmol) was treated with TFA (12 ml) at 25 °C for 30 min, followed by evaporation *in vacuo*. The residue was, after being dried over potassium hydroxide pellets under reduced pressure, dissolved in THF and the solution was chilled at 0 °C. To this were then added DIEA (2.5 ml) and the solution of $(Boc\text{-}Ala)_2O$ obtained above. The mixture was stirred at 0—5 °C overnight and then worked up in the usual manner. The crude preparation of **8** was chromatographed on a Lobar column

(size C) with benzene–ethyl acetate (8:2) as solvent. The fractions containing the desired material were pooled and evaporated *in vacuo* to give **8** as amorphous solid; 2.00 g (77%), $[\alpha]_D^{25.5}$ −96.5±1.4° (*c* 1.0, methanol). TLC: homogeneous in systems A and D. Found: C, 52.81; H, 6.02; N, 6.35; S, 3.95; Cl, 12.55%. Calcd for $C_{38}H_{51}N_4O_{10}SCl_3$: C, 52.93; H, 5.96; N, 6.50; S, 3.72; Cl, 12.33%.

Unexpected Formation of Z-D-Ser[isobutoxycarbonyl-MeCys-(Bzl)-MeVal]-OTce. Boc-Ala-OH (0.23 g, 1.2 mmol) was dissolved in anhydrous THF (3 ml) and DIEA (0.21 ml, 1.2 mmol) was added. The solution was chilled to −10 °C and to this was added isobutyl chloroformate (0.16 ml, 1.2 mmol). The mixture was stirred for 1 min, after which there was added a solution of Z-D-Ser[H-MeCys(Bzl)-MeVal]-OTce TFA salt derived from **7** by the treatment with TFA as described in the prepation of **8**. The reaction mixture was stirred at 5 °C overnight and then worked up as usual. The crude product was chromatographed on a Lobar column (size B) with benzene–ethyl acetate (9:1) as solvent. The fractions containing the major product as a single component were collected, washed with water, and evaporated *in vacuo* to give an oily material; 0.71 g (90% as Z-D-Ser[isobutoxycarbonyl-MeCys(Bzl)-MeVal]-OTce), $[\alpha]_D^{25.5}$ −84.6±1.2° (*c* 1.0, methanol). TLC: homogeneous in systems A and D. Found: C, 52.83; H, 5.99; N, 5.20; S, 4.44; Cl, 13.34%. Calcd for $C_{35}H_{46}N_3O_9SCl_3$: C, 53.13; H, 5.86; N, 5.31; S, 4.05; Cl, 13.44%.

Z-D-Ser[Boc-Ala-MeCys(Bzl)-MeVal]-OH (1). Compound **8** (2.59 g, 3.0 mmol) was dissolved in 90% acetic acid (66 ml) and chilled in an ice-bath. To this was added zinc powder (9.8 g) and the mixture was stirred at 0 °C for 3 h. After the excess zinc had been filtered off, the filtrate was evaporated *in vacuo*. To the residue was added ethyl acetate and the mixture was washed with M hydrochloric acid and with water, dried over magnesium sulfate, and evaporated *in vacuo* to give a solid residue (1.6 g). The crude product was purified on a column of silica gel (110 g, Kieselgel H, Merck) with chloroform–methanol–acetic acid (99:1:1) as solvent to give compound **1** as amorphous solid; 1.97 g (90%), $[\alpha]_D^{25}$ −124.9±0.6° (*c* 1.0, methanol). TLC: homogeneous in systems B and E. Found: C, 59.16; H, 6.90; N, 7.67; S, 4.39%. Calcd for $C_{36}H_{50}N_4O_{10}S$: C, 59.42; H, 7.21; N, 7.68; S, 4.42%.

Z-D-Ser{Z-D-Ser[Boc-Ala-MeCys(Bzl)-MeVal]-Ala-MeCys-(Bzl)-MeVal}-OTce (9). Compound **8** (2.16 g, 2.5 mmol) was treated with TFA (25 ml) at 25 °C for 30 min, followed by evaporation *in vacuo*. The oily residue was dissolved in ethyl acetate and the solution was shaken with ice-cold 50% potassium carbonate, dried over magnesium sulfate and evaporated *in vacuo* to give Z-D-Ser[H-Ala-MeCys(Bzl)-MeVal]-OTce (**2**) as an oil. Compound **2** was dissolved in THF (50 ml) together with compound **1** (1.83 g, 2.5 mmol) and HOBt (0.51 g, 3.75 mmol) and to this solution was added DCC (0.77 g, 3.75 mmol) at 0 °C. The mixture was stirred at 5 °C overnight and then worked up in the usual manner. The crude product was chromatographed on a silica-gel column (Kieselgel 60, 5×16 cm) with chloroform–methanol (99:1) and then on a Lobar column (size C) with benzene–ethyl acetate (9:1) as solvent to give the linear octadepsipeptide (**9**) as amorphous solid; 3.21 g (87%), $[\alpha]_D^{25}$ −115.0±1.5° (*c* 1.0, methanol). TLC: homogeneous in systems A, B, D, and E. Found: C, 55.97; H, 6.25; N, 7.52; S, 4.65; Cl, 7.40%. Calcd for $C_{69}H_{91}N_8O_{17}S_2Cl_3$: C, 56.19; H, 6.22; N, 7.60; S, 4.35; Cl, 7.21%.

Z-D-Ser{Z-D-Ser[Boc-Ala-MeCys(Bzl)-MeVal]-Ala-MeCys-(Bzl)-MeVal}-OH (10). To a solution of **9** (3.54 g, 2.4 mmol) in 90% acetic acid (120 ml) was added zinc powder (7.85 g) at 0 °C and the mixture was stirred at 0 °C for 3 h. After removal of the excess zinc by filtration the solvent was evaporated *in vacuo*. The resulting oily residue was dissolved in ethyl acetate, washed with ice-cold M hydrochloric acid and water, dried over magnesium sulfate, and evaporated *in vacuo* to give a solid residue. This crude product was chromatographed on a silica-gel column (Kieselgel H, 6×20 cm) with chloroform–methanol–acetic acid (98:2:0.5) as solvent. The fractions containing the desired material were pooled, washed with water, dried over magnesium sulfate, and evaporated *in vacuo* to give **10** as amorphous solid; 3.03 g (94%), $[\alpha]_D^{25}$ −132.2±1.8° (*c* 1.0, methanol). TLC: homogeneous in systems B and E. Found: C, 59.88; H, 6.87; N, 8.11; S, 4.78%. Calcd for $C_{67}H_{90}N_8O_{17}S_2$: C, 59.89; H, 6.75; N, 8.34; S, 4.64%.

{Z-D-Ser[Z-D-Ser-Ala-MeCys(Bzl)-MeVal]-Ala-MeCys(Bzl)-MeVal}Dilactone, N,N′-Z$_2$-S,S′-Bzl$_2$-Dihydroapotriostin A (11). *a) By the Active Ester Method.* Compound **10** (0.269 g, 0.2 mmol) and HOSu (0.230 g, 2 mmol) were dissolved in THF (6 ml) and chilled in an ice-bath. To this was added DCC (0.413 g, 2 mmol) and the mixture was stirred at 0—5 °C for 3 h and at 25 °C for 2 h. The DCU which had formed was filtered off and the filtrate was evaporated *in vacuo* to give a residue which was then treated with TFA (10 ml) at 25 °C for 30 min, followed by evaporation *in vacuo*. The residue was, after being dried over sodium hydroxide pellets *in vacuo*, dissolved in ethyl acetate (1000 ml) and to this was added DIEA until the solution became neutral as checked with a piece of wetted pH indicator paper (Whatman). The reaction mixture was stirred at 25 °C for 3 h and, after concentration to a small volume, washed with M hydrochloric acid, water, and 5% sodium hydrogencarbonate, dried over magnesium sulfate, and evaporated *in vacuo*. The same cyclization reaction was carried out six times with 0.285 mmol each of compound **10** as starting material. The resulting crude product combined (4.4 g from 1.91 mmol of **10**) was chromatographed on a column (4×49 cm) of silica-gel (270 g, Kieselgel 60) with chloroform–methanol (98:2) as solvent. The fractions containing the desired material were combined and evaporated *in vacuo*. The residue was rechromatographed on a Lobar column (size C) with benzene–ethyl acetate (1:1) to give the title compound as amorphous solid; 1.36 g (58%), $[\alpha]_D^{23}$ −124.8±3.1° (*c* 0.5, methanol). NMR ($CDCl_3$, 360 MHz) δ=0.51 (d, 6H, MeVal γ- or γ′-CH_3), 0.71 (d, 6H, MeVal γ- or γ′-CH_3), 0.74 (d, 6H, Ala β-CH_3), 2.18 (m, 2H, MeVal β-CH), 2.47, 2.53 (m, 4H, MeCys β- and β′-CH_2), 2.82 (s, 6H, N-CH_3), 2.88 (s, 6H, N-CH_3), 3.42 (d, 2H, Bzl S-CH), 3.50 (d, 2H, MeVal α-CH), 3.67 (d, 2H, Bzl S-CH), 4.59 (m, 2H, Ser β-CH_2), 4.74 (m, 2H, Ala α-CH), 4.75 (m, 2H, Ser β-CH_2), 4.87 (m, 2H, Ser α-CH), 4.91 (d, 2H, Bzl O-CH_2), 5.40 (d, 2H, Bzl O-CH_2), 5.57 (m, 2H, MeCys α-CH), 7.2—7.4 (m, 20H, Bzl aromatic), 7.71 (d, 2H, Ala NH), and 8.22 (d, 2H, Ser NH). FD-MS: M^+ 1224. TLC: homogeneous in systems A and D. Found: C, 60.09; H, 6.57; N, 9.00; S, 4.85%. Calcd for $C_{62}H_{80}N_8O_{14}S_2$: C, 60.77; H, 6.58; N, 9.14; S, 5.23%.

b) By the DCC-HOBt Method. To a solution of **10** (0.336 g, 0.25 mmol) in dioxane (2.5 ml) was added 4 M hydrogen chloride in dioxane (10 ml) and the mixture was kept at 25 °C for 60 min, followed by evaporation *in vacuo*. The oily residue was dissolved in THF (125 ml) and to this were added HOBt (0.338 g, 2.5 mmol) and DIEA (0.09 ml, 0.5 mmol). After the subsequent addition of DCC (0.516 g, 2.5 mmol), the mixture was stirred at 25 °C for 44 h and then evaporated *in vacuo*. The residue was dissolved in ethyl acetate and the solution was filtered off and evaporated. The crude product was purified on a column (3.3×16 cm) of silica gel (50 g, Kieselgel H) with chloroform–methanol (95:5) as solvent. Rechromatography on a Lobar column (size B) in benzene–ethyl acetate (1:1) yielded **11** as amorphous solid; 0.064 g (21%), mp 100—102 °C, $[\alpha]_D^{25}$ −123.9±3.1° (*c* 0.5, methanol). Found: C, 60.73; H, 6.29; N, 8.84; S, 5.37%.

c) By the DPPA Method. Compound **10** (0.269 g, 0.2 mmol) was treated with hydrogen chloride in dioxane in the same manner as described above. The product was dissolved in DMF (100 ml) and chilled in ice. To this were then added DIEA (0.24 ml, 1.4 mmol) and DPPA (0.275 g, 1.0 mmol) and the mixture was stirred at 0 °C for 6 h. The crude product was purified on silica-gel columns in almost the same manner as described in b) to give purified **11** as amorphous solid; 0.053 g (22%), $[\alpha]_D^{22}$ −125.7±3.3° (*c* 0.5, methanol). Found: C, 60.28; H, 6.73; N, 8.66; S, 5.57%.

{Qxc-D-Ser[QxC-D-Ser-Ala-MeCys(Bzl)-MeVal]-Ala-MeCys-(Bzl)-MeVal}Dilactone, S,S'-Bzl$_2$-Dihydrotriostin A (12). Compound **11** (123 mg, 0.1 mmol) and thioanisole (1.2 ml) were dissolved in TFA (12 ml) and the mixture was kept at 25 °C for 6 h. Evaporation of the TFA *in vacuo* afforded an oily residue, which was dried over sodium hydroxide pellets *in vacuo*. The residue was then precipitated from ether-petroleum ether to give the TFA salt of *S,S'*-dibenzyldihydroapotriostin A as amorphous solid. TEA (0.028 ml, 0.2 mmol) was added to a stirred ice-cold solution of this solid in DMF (1 ml) and to this were then added Qxc-Cl (58 mg, 0.3 mmol) and TEA (0.056 ml, 0.4 mmol) simultaneously in three equal portions over 30 min. The reaction mixture was stirred at 0 °C for 6 h. The formation of **12** was 27, 30, 34, 36, and 37% at reaction time of 1, 2, 3, 4, and 6 h, respectively, as monitored by HPLC (Waters μ-Porasil, 3.9×300 mm; 2-propanol-hexane (27.5:72.5)). After dilution with ethyl acetate the mixture was successively washed with M hydrochloric acid, water, and 5% sodium hydrogencarbonate, dried over magnesium sulfate, and evaporated *in vacuo*. The residue was chromatographed on a column (1.7×22 cm) of silica-gel (20 g, Kieselgel H) with chloroform-methanol (99:1) and repeatedly rechromatographed on a Lobar column (size A) with ethyl acetate and with chloroform-methanol (99:1) as solvent. The resulting material was dissolved in ethyl acetate and the solution was washed with water, dried over magnesium sulfate and evaporated *in vacuo* to afford a pure preparation of **12**; 0.028 g (22%), $[\alpha]_D^{22.5}$ −152.6±1.9° (*c* 1.0, chloroform). NMR ($CDCl_3$, 360 MHz; I=conformer I, II=conformer II); δ=0.67 (d, 6H, MeVal γ- or γ'-CH_3, I), 0.78 (d, 6H, MeVal γ- or γ'-CH_3, I), 0.83 (d, 6H, MeVal γ- or γ'-CH_3, II), 1.09 (d, 6H, MeVal γ- or γ'-CH_3, II), 1.28 (d, 6H, Ala β-CH_3, I), 1.38 (d, 6H, Ala β-CH_3, II), 2.19 (m, 2H, MeVal β-CH, I), 2.36 (m, 2H, MeVal β-CH, II), 2.66, 2.67 (m, 4H, MeCys β- and β'-CH_2, I), 2.92, 2.99 (m, 4H, MeCys β- and β'-CH_2, II), 2.81, 2.89, 3.03, 3.12 (s, 12H, N-CH_3, I and II), 3.54, 3.80 (m, 8H, Bzl S-CH_2, I and II), 3.92 (m, 2H, MeVal α-CH, I), 4.38 (m, 2H, Ser β-CH_2, II), 4.41 (m, 2H, Ser β-CH_2, I), 4.59 (m, 2H, Ser β'-CH_2, II), 4.82 (m, 2H, Ala α-CH, II), 4.85 (m, 2H, Ser β'-CH_2, I), 5.02 (m, 2H, Ala α-CH, I), 5.13 (m, 2H, MeVal α-CH, II), 5.25 (m, 2H, Ser α-CH, I), 5.39 (m, 2H, MeCys α-CH, I), 7.07 (d, 2H, Ala NH, II), 7.2—7.4 (m, 10H, Bzl aromatic, I and II), 7.81, 7.89, 8.11, 8.22 (m, 8H, Qxc, I and II), 8.46 (d, 2H, Ala NH, I), 8.77 (d, 2H, Ser NH, II), 8.80 (d, 2H, Ser NH, I), 9.62 (s, 2H, Qxc 3-CH, I), and 9.67 (s, 2H, Qxc 3-CH, II). TLC: homogeneous in system A. Found: C, 59.43; H, 6.01; N, 12.82; S, 5.32%. Calcd for $C_{64}H_{76}N_{12}O_{12}S_2 \cdot H_2O$: C, 59.70; H, 6.11; N, 13.05; S, 4.98%.

Triostin A. Compound **12** (38.1 mg, 0.03 mmol) was treated with HF (6 ml) in the presence of anisole (0.3 ml) at 25 °C for 60 min. After the HF had been removed by evaporation, the residue was dissolved in methanol (30 ml) and the solution was neutralized with TEA. To this was added a solution of iodine (39 mg, 0.15 mmol) in methanol (2 ml) and the mixture was stirred at 25 °C for 2 h. The excess iodine was discharged with M sodium thiosulfate, in which the pH was kept neutral by the addition of 10% ascorbic acid. After removal of the solvent by evaporation *in vacuo*, the residue was purified on a silica-gel column (Kieselgel H, 1.7×23.5 cm) with chloroform-methanol (98:2) as solvent. The fractions containing the desired product were pooled and evaporated *in vacuo*. The resulting residue (9.8 mg) was crystallized from carbon tetrachloride-ethanol and recrystallized twice from dichloromethane-ethanol to afford pure triostin A; 7.0 mg (20%), mp 222—223 °C, $[\alpha]_D^{21.5}$ −151.9±19.8° (*c* 0.1, chloroform). The authentic sample of natural triostin A showed mp 220—223 °C. Lit. for natural triostin A:[3b,11] mp 245—248 °C dec, $[\alpha]_D^{23.5}$ −157±2° (*c* 0.97, chloroform). Lit, for synthetic triostin A:[16] mp 239—243 °C dec, $[\alpha]_D^{25}$ −154° (*c* 1.0, chlorofororm). λ_{max}^{MeOH} 243 nm (log ε 4.92), 317 nm (4.15), 325 nm (4.16). NMR: see Fig. 4. TLC: homogeneous in system A. HPLC: see Fig. 5. Found: C, 51.99; H, 5.89; N, 14.36; S, 6.05%. Calcd for $C_{50}H_{62}N_{12}O_{12}S_2 \cdot 3.5H_2O$: C, 52.21; H, 6.05; N, 14.61; S, 5.57%.

The authors express their sincere thanks to Professor Yoshimasa Kyogoku and Dr. Naoki Higuchi, Institute for Protein Research, Osaka University, for measurements and analysis of 360 MHz NMR spectra. Thanks are also due to Dr. Jun'ichi Shoji, Shionogi Research Laboratories, for generous gift of natural triostin A and for help with microbiological assays.

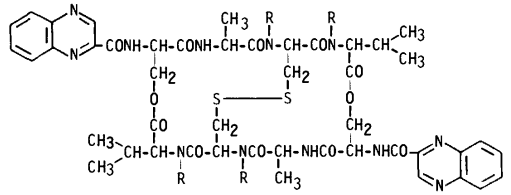
(Recieved February 3, 1984)

Nortriostin A, which is an analog of a cyclic octadepsipeptide antibiotic triostin A and contains one cystine and two valine residues substituted for the *N,N'*-dimethylcystine and *N*-methylvaline residues of the antibiotic, was synthesized with Z-D-Ser[Boc-Ala-Cys(MeBzl)-Val]-OH and Z-D-Ser[H-Ala-Cys(MeBzl)-Val]-OTce as key intermediates.††† The synthetic analog showed no antimicrobial activity at a concentration of 100 μg/ml and was found to exist as a single structure in solution as examined by ^{1}H-NMR spectroscopy. The latter observation suggests that the conformer equilibrium known to occur with triostin A is a consequence of the presence of *N*-methyl peptide bonds in the antibiotic molecule.

In the preceding paper we described the total synthesis of triostin A, a member of the triostin family of the quinoxaline antibiotics, with *S,S'*-dibenzyldihydrotriostin A as intermediate.[1] Triostin A is known to have two interconvertible conformations in solution and their occurrence has been explained by two possibilities: 1) the reversal of the chirality around the disulfide bond,[2] and 2) the *cis-trans* isomerization of the *N*-methyl peptide bonds.[3] The first possibility has recently been ruled out, because the presence of the two conformers was also shown with *S,S'*-dibenzyldihydrotriostin A which lacks the disulfide bond.[1,4] In the present work the des-*N*-tetramethyl analog of triostin A (we propose the name "nortriostin A" for des-N-tetramethyltriostin A.[5] For structure, see Fig. 1) was synthesized and its NMR pattern was compared with that of triostin A to elucidate the second possibility. The synthesis of nortriostin A was carried out in essentially the same manner as described for triostin A,[1] except that the *N*-methyl-L-cysteine and *N*-methyl-L-valine as starting materials were replaced by cysteine and valine, respectively, and the 4-methylbenzyl group[6] in place of the benzyl group was employed for the mercapto-group protection.



Triostin A: R=CH$_3$

Nortriostin A: R=H

Fig. 1. Triostin A and nortriostin A.

Z-D-Ser-OTce[1] was allowed to react in pyridine in the presence of HOBt with the symmetrical anhydride $(Boc\text{-}Val)_2O$, which had been prepared in advance from Boc-Val-OH by the action of DCC, to give a depsipeptide Z-D-Ser(Boc-Val)-OTce (**3**) in a 90% yield. Compound **3** could also be prepared by the direct coupling of Boc-Val-OH and Z-D-Ser-OTce with DCC in the presence of HOBt, but the yield was as low as 66%. Compound **3** was treated with TFA to remove the Boc group and then coupled with Boc-Cys(MeBzl)-OH (**2**) by the DCC-HOBt method[7] to give Z-D-Ser[Boc-Cys(MeBzl)-Val]-OTce (**4**) in 78% yield. Compound **4** was treated with TFA and the resulting product was coupled with the previously prepared

†† Present address: Suntory Research Center of Applied Microbiology, Shimamoto-cho, Mishima, Osaka 618.

††† Abbreviations used are those recommended by the IUPAC-IUB Commission on Biochemical Nomenclature (*Biochemistry*, **11**, 1726 (1972)) and include: MeCys, *N*-methyl-L-cysteine; MeVal, *N*-methyl-L-valine; Boc, *t*-butoxycarbonyl; Boc-SDP, *O-t*-butyl *S*-(4,6-dimethyl-2-pyrimidinyl) thiocarbonate; Qxc, 2-quinoxalylcarbonyl; Z, benzyloxycarbonyl; MeBzl, 4-methylbenzyl; Bzl, benzyl; Tce, 2,2,2-trichloroethyl; HOBt, 1-hydroxybenzotriazole; HOSu, *N*-hydroxysuccinimide; DCC, dicyclohexylcarbodiimide; DCU, *N,N'*-dicyclohexylurea; AcOH, acetic acid; TFA, trifluoroacetic acid; DIEA, *N,N*-diisopropylethylamine; TEA, triethylamine; DMF, *N,N*-dimethylformamide; and THF, tetrahydrofuran.

$(Boc\text{-}Ala)_2O$ in the presence of DIEA to produce tetradepsipeptide **5** (for structures of compounds **5**—**14**, see Fig. 2) in 66% yield.

One portion of the key intermediate **5** was treated with zinc in 90% acetic acid to remove the Tce ester giving **6** in a yield of 89%. Another portion of **5** was treated with TFA to remove the Boc group giving **7**. Compounds **6** and **7** were then coupled with DCC-HOBt to obtain the linear octadepsipeptide **8** in 72% yield. The treatment of **8** with zinc in 90% acetic acid at 0 °C for 3 h resulted in complete removal of the Tce ester giving **9** in 84% yield. Compound **9** was coupled to HOSu with DCC and the resulting active ester (**10**) was treated with TFA to give **11** as the TFA salt. For cyclization a DMF solution of **11** was diluted with ethyl acetate to a concentration of 0.2 mmol/l and neutralized with DIEA to initiate the reaction. The cyclic octadepsipeptide (**12**) was thus obtained in 48% yield. The ^{1}H-NMR spectrum and field desorption mass spectrum of **12** were consistent with the proposed structure.

The selective removal of the Z group from **12** by the TFA–thioanisole treatment[1,8] and the subsequent acylation with Qxc-Cl gave **13** as amorphous solid in 40% yield. The MeBzl groups on the Cys residues showed no sign of cleavage during the TFA–thioanisole treatment, but they were readily removed by the treatment with HF at 0 °C for 60 min in the presence of anisole to furnish dihydronortriostin A (**14**), which was, upon treatment with iodine in methanol[9] followed by silica-gel column chromatography and recrystallization, converted into nortriostin A (Fig. 1) in a yield of 40%.

Nortriostin A thus obtained was homogeneous in TLC in different solvent systems. The sufficient purity was also shown by HPLC on a μ-Porasil column in acetonitrile–2-propanol (95:5, v/v) and by reversed-phase HPLC on a Nucleosil $5C_{18}$ column in acetonitrile–10 mM (1M=1 mol dm^{-3}) phosphoric acid (50:50, v/v). The ^{1}H-NMR spectrum was consistent with the proposed structure when analyzed with reference to the spectra of natural[10] and synthetic[1] preparations of triostin A. As assayed for the inhibition of growth of *Bacillus subtilis* PCI-219, nortriostin A was found to be inactive even at a concentration of 100 μg/ml in contrast to triostin A, which was highly active at a level of 0.5 μg/ml.

The first synthesis of nortriostin A was described by Olsen and his associates in 1978,[5] in which they used the depsipeptide of the type Z-D-Ser(R^1)-Ala-OR^2 (R^1=Boc (or H)-Cys(Acm)-Val, R^2=H or Tce, Acm=acetamidomethyl) as intermediate. In this synthesis a problem was the occurrence of some racemization at the Ala residue involved in the fragment coupling and the subsequent cyclization reactions. In their recent report Olsen and his collaborators have synthesized nortriostin A from the depsipeptide of the type Z-D-Ser(R^1)-OR^2 (R^1=Boc (or H)-Ala-Cys(Acm)-Val, R^2=H or Bpa, Bpa=*p*-bromophenacyl).[11] Independently, we also used the latter type of intermediates in our synthesis of triostin A itself,[1] and in the present synthesis of nortriostin A as described above. In these syntheses the coupling of the two tetradepsipeptide intermediates and the subsequent cyclization were performed by activation of the carboxyl function of the Z-D-Ser-OH moiety. Therefore, little or no racemization was expected to occur at the Ser residue under ordinary coupling conditions. However, Olsen and his collaborators suggested the possibility of racemization of the D-Ser residues, based on the findings that the carbodiimide-mediated acylation of Z-D-Ser-OBpa with Boc-Val-OH in the presence of 4-(dimethylamino)pyridine and the acidolytic removal of the Boc group from Z-D-Ser[Boc-Ala-Cys(Acm)-Val]-OBpa followed by neutralization with sodium hydrogencarbonate were both accompanied by some formation of a dehydroalanine derivative Z-ΔAla-OBpa.[11] The Bpa ester was introduced in place of the Tce ester, which had been used in the form Z-D-Ser(R^1)-Ala-OTce in their previous synthesis of nortriostin A, because they were not able to prepare Z-D-Ser-OTce from Z-D-Ser-OH and HOTce by the DCC procedure. We also failed in this attempt but found that the esterification was readily achieved by using Z-D-Ser(Bu^t)-OH in place of Z-D-Ser-OH to give Z-D-Ser(Bu^t)-OTce, from which Z-D-Ser-OTce was derived by the TFA treatment.[1] Z-D-Ser-OTce was used as starting material in our synthesis of triostin A[1] and in the present synthesis of nortriostin A as described. Although the Tce group seems to be more favorable than the Bpa group because of the general trend that the former group is cleaved more readily than the latter under the reductive conditions, there is no available information as to whether the Tce group differs from the Bpa group regard to the effect on the dehydroalanine formation. At least we have no positive evidence for the formation of any dehydroalanine derivatives and for the occurrence of recemization.

The ^{1}H-NMR spectrum of nortriostin A was measured in deuteriochloroform to show that the hydrogens at position 3 of the two quinoxaline rings gave a single peak, indicating that nortriostin A, which differs from triostin A only by the absence of the *N*-methyl groups, exists as a single structure in solution. On the other hand, we have demonstrated that *S,S'*-dibenzyl-dihydrotriostin A, a derivative of triostin A which lacks the disulfide linkage but has the *N*-methyl peptide bonds, exists as two conformers.[1,4] These observations strongly support the view that the conformer equilibrium, which usually occurs with triostin A, is a consequence of the *cis-trans* isomerization of the *N*-methyl peptide bonds.[12]

Experimental

Thin-layer chromatography (TLC) was performed on silica-gel plates (precoated Kieselgel $60F_{254}$, Merck) with the following solvent systems (ratios by volume): A, chloroform–methanol (95:5); B, chloroform–methanol (90:10); C, chloroform–methanol–acetic acid (95:5:3); D, benzene–ethyl acetate (7:3). For detection the plates were subjected to ninhydrin staining or to sulfuric acid charring. Column chromatography was performed on prepacked columns (Lobar, size B or C, Merck) or home-made columns (Kieselgel 60, Merck). High-performance liquid chromatography (HPLC) was carried out on a Waters Associates Model 6000A solvent delivery system, equipped with a Waters U6K injector and a Japan Spectroscopic UVIDEC-100-II variable

wavelength UV detector. Proton NMR spectra were measured on a Bruker WM 360 wb NMR spectrometer operated at 360 MHz.

S-4-Methylbenzyl-cysteine (1). This compound was synthesized according to the literature;[6] mp 212—214 °C dec, $[\alpha]_D^{22}$ −4.1±1.4°, $[\alpha]_{365}^{22}$ +9.8±1.6° (*c* 0.3, M hydrochloric acid), $[\alpha]_D^{22}$ +23.7±0.9°, $[\alpha]_{365}^{22}$ +96.1±1.3° (*c* 1.0, M sodium hydroxide). Lit,[6] mp 209—211 °C dec.

Boc-Cys(MeBzl)-OH (2). To a solution of compound **1** (7.89 g, 35 mmol) and TEA (11 ml, 79 mmol) in dioxane-water (1:1, 40 ml) was added Boc-SDP (12.62 g, 53 mmol) and the mixture was stirred at 30 °C for 15 h. After addition of M sodium hydroxide (60 ml) at 0 °C the mixture was extracted twice with ether. The aqueous phase was then acidified with ice-cold M hydrochloric acid. The resulting oily precipitate was taken into ethyl acetate and the solution was washed with water, dried over magnesium sulfate and evaporated *in vacuo* to give an oil which was solidified by the addition of petroleum ether. Recrystallization from ethyl acetate-petroleum ether gave **2** as needles; 10.8 g (95%), mp 76—77 °C, $[\alpha]_D^{19}$−41.7±0.8 (*c* 1.0, acetic acid). Found: C, 58.89; H, 6.98; N, 4.25; S, 9.83%. Calcd for $C_{16}H_{23}NO_4S$: C, 59.05; H, 7.12; N, 4.30; S, 9.85%.

Z-D-Ser(Boc-Val)-OTce (3). *a) With (Boc-Val)$_2$O*: Boc-Val-OH (5.87 g, 27 mmol) was treated with DCC (5.57 g, 27 mmol) in pyridine at 0 °C for 60 min. To this was added a solution of Z-D-Ser-OTce (5.00 g, 13.5 mmol)[1] and HOBt (2.74 g, 20 mmol) in pyridine (10 ml) and the mixture was stirred at 5 °C for 20 h. The DCU which had formed was filtered off and the filtrate was evaporated *in vacuo* to give a residue, which was dissolved in ethyl acetate, and washed with ice-cold M hydrochloric acid, 5% sodium hydrogencarbonate and water. The solution was, after being dried over magnesium sulfate, evaporated *in vacuo* to give a crude preparation of **3** as an oil. The crude product was subjected to chromatography on a silica-gel column with chloroform-methanol (98:2) as solvent. The fractions containing the desired material were pooled and evaporated *in vacuo*. The residue was rechromatographed twice on a Lobar column (size B) with benzene-ethyl acetate (95:5) as solvent. Evaporation of the combined fractions containing the desired material as a single component gave a pure preparation of **3** as an oil; 7.46 g (97%), $[\alpha]_D^{21}$ +3.8±0.4° (*c* 1.0, methanol). TLC: homogeneous in systems A and D. Found: C, 48.77; H, 5.65; N, 4.85; Cl, 18.56%. Calcd for $C_{23}H_{31}N_2O_8Cl_3$: C, 48.48; H, 5.48; N, 4.92; Cl, 18.66%.

b) By the DCC-HOBt method. To an ice-cold solution of Boc-Val-OH (1.05 g, 4.8 mmol), Z-D-Ser-OTce (1.63 g, 4.4 mmol) and HOBt (0.65 g, 4.8 mmol) in pyridine (13 ml) was added DCC (1.00 g, 4.8 mmol) and the mixture was stirred at 5 °C overnight. The DCU which had formed was filtered off and the filtrate was evaporated *in vacuo*. The resulting oil was dissolved in ethyl acetate and this was washed with ice-cold M hydrochloric acid and 5% sodium hydrogencarbonate, dried over magnesium sulfate and evaporated *in vacuo*. The crude product thus obtained was purified on silica-gel columns as described above in a) to afford **3** as an oil; 1.65 g (66%), $[\alpha]_D^{23}$ +2.0±0.4° (*c* 1.0, methanol).

Z-D-Ser[Boc-Cys(MeBzl)-Val]-OTce (4). Compound **3** (6.84 g, 12 mmol) was treated with TFA (36 ml) at 25 °C for 40 min, followed by evaporation *in vacuo*. The resulting oil was dissolved in ethyl acetate and the solution was washed with 5% sodium hydrogencarbonate, dried over magnesium sulfate and evaporated *in vacuo*. The residue was dissolved in THF (70 ml) together with Boc-Cys(MeBzl)-OH (4.69 g, 14 mmol) and HOBt (1.95 g, 14 mmol). After addition of DCC (2.97 g, 14 mmol) at 0 °C, the mixture was stirred at the same temperature for 3 h and at 25 °C for 1 h. The reaction mixture was worked up in the usual manner to give a crude product which was repeatedly chromatographed on Lobar columns (size C) with chloroform-methanol (99:1) and benzene-ethyl acetate (8:2) as solvents to give **4** as amorphous solid; 7.31 g (78%) $[\alpha]_D^{22}$ −12.0±0.5° (*c* 1.0, methanol). TLC: homogeneous in systems A and D. Found: C, 52.38; H, 5.79; N, 5.19; S, 4.37; Cl, 13.13%. Calcd for $C_{34}H_{44}N_3O_9Cl_3S$: C, 52.55; H, 5.71; N, 5.41; S, 4.13; Cl, 13.69%.

Z-D-Ser[Boc-Ala-Cys(MeBzl)-Val]-OTce (5). Boc-Ala-OH (5.11 g, 27 mmol) was allowed to react with DCC (2.79 g, 13.5 mmol) in THF (30 ml) at 0 °C for 2 h. Removal of the separated DCU by filtration afforded a solution of (Boc-Ala)$_2$O. On the other hand, compound **4** (6.99 g, 9 mmol) was treated with TFA (27 ml) at 25 °C for 30 min, followed by evaporation *in vacuo*. The oily residue was, after being dried over sodium hydroxide pellets *in vacuo*, dissolved in THF (20 ml). The ice-cold solution was then combined with the (Boc-Ala)$_2$O obtained above and this was neutralized by the addition of DIEA. The mixture was then stirred at 5 °C overnight and worked up in the usual manner. The crude product was subjected to chromatography on a silica-gel column (Kieselgel 60, 6×33 cm) with chloroform-methanol (99:1) as solvent. The fractions containing the desired material were collected and evaporated *in vacuo*. Repeated rechromatography on a Lobar column (size C) with chloroform-methanol (99:1) and benzene-ethyl acetate (85:15 and 50:50) as solvents afforded a pure preparation of **5** as amorphous solid; 5.05 g (66%), $[\alpha]_D^{22}$ −25.1±0.7° (*c* 1.0, methanol). TLC: homogeneous in systems A, C, and D. Found: C, 52.46; H, 6.00; N, 6.80; S, 4.05; Cl, 11.82%. Calcd for $C_{37}H_{49}N_4O_{10}SCl_3$: C, 52.39; H, 5.82; N, 6.61; S, 3.78; Cl, 12.54%.

Z-D-Ser[Boc-Ala-Cys(MeBzl)-Val]-OH (6). Compound **5** (3.82 g, 4.5 mmol) in 90% acetic acid (135 ml) was treated with zinc powder 14.7 g) at 0 °C for 3 h. After the excess zinc had been filtered off, the filtrate was evaporated *in vacuo* and the residue dissolved in ethyl acetate was washed with ice-cold M hydrochloric acid and water, dried over magnesium sulfate and evaporated *in vacuo*. The resulting material was chromatographed on silica-gel columns (Kieselgel 60) with chloroform-methanol-acetic acid systems (95:5:0.5 and 98:2:1) as solvent to give a pure preparation of **6** as amorphous solid; 2.91 g (89%), $[\alpha]_D^{22}$−36.0±0.7° (*c* 1.0, methanol). TLC: homogeneous in system C. Found: C, 57.76; H, 6.79; N, 7.53; S, 4.53%. Calcd for $C_{35}H_{48}N_4O_{10}S\cdot 1/2H_2O$: C, 57.91; H, 6.80; N, 7.72; S, 4.42%.

Z-D-Ser{Z-D-Ser[Boc-Ala-Cys(MeBzl)-Val]-Ala-Cys(MeBzl)-Val}-OTce (8). Copound **5** (2.38 g, 2.8 mmol) was treated with TFA (28 ml) at 25 °C for 30 min, followed by evaporation *in vacuo*. The oily residue was dissolved in ethyl acetate and the solution was shaken with ice-cold 50% potassium carbonate, dried over magnesium sulfate and evaporated *in vacuo* to produce Z-D-Ser[H-Ala-Cys(MeBzl)-Val]-OTce (**7**) as an oil. This was then dissolved in THF (56 ml) together with compound **6** (2.03 g, 2.8 mmol) and HOBt (0.57 g, 4.2 mmol). The mixture was chilled in an ice-bath and, after addition of DCC (0.87 g, 4.2 mmol), stirred for 5 h at 0 °C and 1 h at 25 °C. The DCU which had formed was filtered off and the solvent was evaporated *in vacuo*. The solid residue was chromatographed on silica-gel columns (Kieselgel 60 and Kieselgel H) with chloroform-methanol (98:2) as solvent, followed by precipitation from methanol-ether to give a pure preparation of **8** as amorphous solid; 2.90 g (72%), mp 178—179 C°, $[\alpha]_D^{23}$ −41.4±0.8° (*c* 1.0, methanol). TLC: homogeneous in system B and in ethyl acetate. Found: C, 56.04; H, 6.11; N, 7.94; S, 4.68; Cl, 6.55%. Calcd for $C_{67}H_{87}N_8O_{17}S_2Cl_3$: C, 55.61; H, 6.06; N, 7.74; S, 4.43; Cl, 7.35%.

Z-D-Ser{Z-D-Ser[Boc-Ala-Cys(MeBzl)-Val]-Ala-Cys(MeBzl)-Val}-OH (9). Compound **8** (2.60 g, 1.8 mmol) was treated with zinc (5.88 g) in 90% acetic acid (280 ml) at 0 °C

for 3 h. After removal of the excess zinc by filtration the solvent was evaporated *in vacuo*. The residue was dissolved in chloroform–methanol (98:2) and the solution was washed with ice-cold M hydrochloric acid and water, dried over magnesium sulfate, and evaporated *in vacuo*. The crude product (2.34 g) was chromatographed on a silica-gel column (Kieselgel 60, 3.2×28 cm) with chloroform–methanol–acetic acid (98:2:0.5 and 95:5:0.5) as solvent to give **9** as glassy mass; 2.00 g (84%), mp 176—178 °C, $[\alpha]_D^{23}$ −62.7±1.0° (*c* 1.0, chloroform). Found: C, 58.98; H, 6.51; N, 8.31; S, 5.04%. Calcd for $C_{65}H_{86}N_8O_{17}S_2$: C, 59.34; H, 6.59; N, 8.52; S, 4.87%.

{Z-D-Ser[Z-D-Ser-Ala-Cys(MeBzl)-Val]-Ala-Cys(MeBzl)-Val}-Dilactone, N,N′-Z_2-S,S′-$MeBzl_2$-dihydroaponortriostin A (12). Compound **9** (0.132 g, 0.1 mmol) and HOSu (0.115 g, 1 mmol) were dissolved in DMF (1 ml). To this solution was added DCC (0.206 g, 1 mmol) at 0 °C and the mixture was stirred at 0 °C for 3 h and then at 25 °C for 2 h. The precipitates which formed upon addition of ether were filtered off and dried *in vacuo* to give the HOSu ester (**10**, Fig. 2). Compound **10** was treated with TFA (5 ml) at 25 °C for 30 min and the resulting **11** was precipitated by the addition of ether. These precipitates were dissolved in DMF (5 ml) and the solution was diluted with ethyl acetate (500 ml). To this was added DIEA until the solution became neutral and the mixture was stirred at 25 °C for 5 h. After removal of the solvent by evaporation *in vacuo*, the residue was dissolved in chloroform–methanol (98:2) and this was washed with M hydrochloric acid and 5% sodium hydrogencarbonate, dried over magnesium sulfate and evaporated *in vacuo*. The curde product was repeatedly chromatographed on a Lobar column (size A) with chloroform–methanol (98:2). The fractions containing the desired product as single component were pooled and evaporated *in vacuo* to afford **12** as amorphous solid; 58 mg (48%), mp 246—248 °C, $[\alpha]_D^{23}$ −76.3±1.2° (*c* 1.0, chloroform). NMR ($CDCl_3$, 360 MHz, 37 °C) δ=0.82 (d, 6H, Val γ- and γ′-CH_3), 0.84 (d, 6H, Val γ- and γ′-CH_3), 1.14 (d, 6H, Ala β-CH_3), 2.25 (m, 2H, Val β-CH), 2.28 (s, 6H, MeBzl-CH_3), 2.78 (m, 4H, Cys β- and β′-CH_2), 3.60 (s, 4H, MeBzl-CH_2), 4.23 (m, 2H, Ser β-CH_2), 4.27 (m, 2H, Ala α-CH), 4.44 (m, 2H, Ser α-CH), 4.56 (m, 2H, Ser β′-CH_2), 4.60 (m, 2H, Val α-CH), 4.63 (m, 2H, Cys α-CH), 5.12 (q, 4H, Bzl-CH_2), 6.28 (d, 2H, Ser NH), 6.30 (d, 2H, Cys NH), 6.96 (s, 2H, Ala NH), 7.11—7.33 (m, 18H, aromatic), and 7.87 (d, 2H, Val NH). Found: C, 59.80; H, 6.48; N, 9.14; S, 5.56%. Calcd for $C_{60}H_{76}N_8O_{14}S_2$: C, 60.18; H, 6.40; N, 9.36; S, 5.36%.

{Qxc-D-Ser[Qxc-D-Ser-Ala-Cys(MeBzl)-Val]-Ala-Cys(MeBzl)-Val}Dilactone, S,S′-$MeBzl_2$-dihydronortriostin A (13). Compound **12** (0.240 g, 0.2 mmol) and thioanisole (2.5 ml) were dissolved in TFA (25 ml) and the mixture was kept at 25 °C for 5 h, followed by evaporation *in vacuo*. The residue was triturated with ether to give amorphous precipitates, which were filtered off and dried *in vacuo* (0.28 g). These precipitates were dissolved in DMF (2 ml). To the stirred ice-cold solution were added 2-quinoxalinylcarbonyl chloride (Qxc-Cl, 0.077 g, 0.4 mmol) and TEA (0.14 ml, 1 mmol) and the reaction was allowed to proceed at 0 °C for 3 h and at 25 °C for 1 h. The solvent was evaporated *in vacuo*. The residue was dissolved in chloroform–methanol (98:2) and the solution was washed with M hydrochloric acid, dried over magnesium sulfate and evaporated *in vacuo*. The resulting material was chromatographed three times on silica-gel columns (Kieselgel H) with chloroform–methanol (98:2) to give **13** as amorphous solid; 102 mg (40%), mp 221—224 °C, $[\alpha]_D^{23.5}$ −113.8±3.8° (*c* 0.25, chloroform–methanol (98:2)). $\lambda_{max}^{CH_3CN}$ 242.5 nm (ε 77 300), 316 nm (ε 12 100), 325 nm (ε 11 900). NMR ($CDCl_3$, 360 MHz, 37 °C) δ=0.94 (m, 12H, Val γ- and γ′-CH_3), 1.41 (d, 6H, Ala β-CH_3), 2.26 (d, 6H, MeBzl CH_3), 2.37 (m, 2H, Val β-CH), 2.81 (m, 4H, Cys β- and β′-CH_2), 3.67 (m, 4H, MeBzl CH_2), 4.40 (m, 2H, Ala α-CH), 4.42 (m, 2H, Ser β′-CH_2), 4.62 (m, 2H, Ser β′-CH_2), 4.82 (m, 2H, Ser α-CH), 4.85 (m, 2H, Val α-CH), 5.20 (m, 2H, Cys α-CH), 6.56 (m, 2H, Cys NH), 7.01 (d, 2H, Ala NH), 7.12, 7.25 (m, 8H, aromatic), 7.87, 8.21 (m, 8H, Qxc), 8.12 (m, 2H, Val NH), 8.80 (d, 2H, Ser NH), and 9.63 (s, 2H, Qxc 3-CH), TLC: homogeneous in system B. Found: C, 58.04; H, 5.84; N, 12.99; S, 5.40%. Calcd for $C_{62}H_{72}N_{12}O_{12}S_2 \cdot 2H_2O$: C, 58.29; H, 5.68; N, 13.16; S, 5.02%.

Nortriostin A. Compound **13** (62 mg, 0.05 mmol) was treated with HF (10 ml) in the presence of anisole (0.5 ml) at 0 °C for 60 min. After removal of the HF by evaporation, the residue was dissolved in methanol (50 ml) and the solution was neutralized with TEA. To this was added a solution of iodine (66 mg, 0.25 mmol) in methanol and the mixture was stirred at 25 °C for 2 h. The excess iodine was discharged with 10% ascorbic acid and the solvent was removed by evaporation *in vacuo*. The residue was dissolved in chloroform–methanol (98:2) and the solution was washed with water, dried, and evaporated *in vacuo*. The resulting material was chromatographed two times on silica-gel columns (Kieselgel H) with chloroform–methanol (95:5). The fractions containing the desired product were collected and evaporated *in vacuo*. The residue was dissolved in chloroform–methanol (98:2, 1 ml) and to this was added ether (5 ml) to separate crystalline precipitates, which were filtered off, washed with ether, and dried *in vacuo* to give nortriostin A in pure state; 20 mg (39%), mp 213—215 °C, $[\alpha]_D^{20}$ −50.3±4.9° (*c* 0.1, chloroform). $\lambda_{max}^{CH_3CN}$ 242.5 nm (ε 89 600), 316 nm (ε 14 500), 326 nm (ε 14 200). NMR ($CDCl_3$ 360 MHz) δ=1.12 (d, 6H, Val γ- or γ′-CH_3), 1.16 (d, 6H, Val γ- or γ′-CH_3), 1.38 (d, 6H, Ala β-CH_3), 2.54 (m, 2H, Val β-CH), 2.93 (m, 4H, Cys β- and β′-CH_2), 4.45 (m, 2H, Ala α-CH), 4.65 (d, 2H, Ser β-CH_2), 4.84 (m, 2H, Val α-CH), 4.88 (m, 2H, Ser α-CH), 5.00 (d, 2H, Ser β′-CH_2), 5.68 (m, 2H, Cys α-CH), 6.30 (d, 2H, Ala NH), 6.54 (d, 2H, Cys NH), 7.92 (m, Qxc), 8.11 (d, Qxc), 8.25 (d, Qxc), 8.56 (d, 2H, Val NH), 8.79 (d, 2H, Ser NH), and 9.67 (s, 2H, Qxc 3-CH). Amino acid ratios in acid hydrolysate: Ser 0.92, Ala 1.06, Val 1.00, Cys not determined. Found: C, 50.40; H, 5.20; N, 15.15; S. 6.41%. Calcd for $C_{46}H_{54}N_{12}O_{12}S_2 \cdot 3.5H_2O$: C, 50.49; H, 5.62; N, 15.36; S, 5.86%.

The Reactions of Nitrile Oxides with Methoxy *p*-Benzoquinones

Tohru HAYAKAWA, Koji ARAKI, and Shinsaku SHIRAISHI*
Institute of Industrial Science, The University of Tokyo, Roppongi, Minato-ku, Tokyo 106
(Received February 6, 1984)

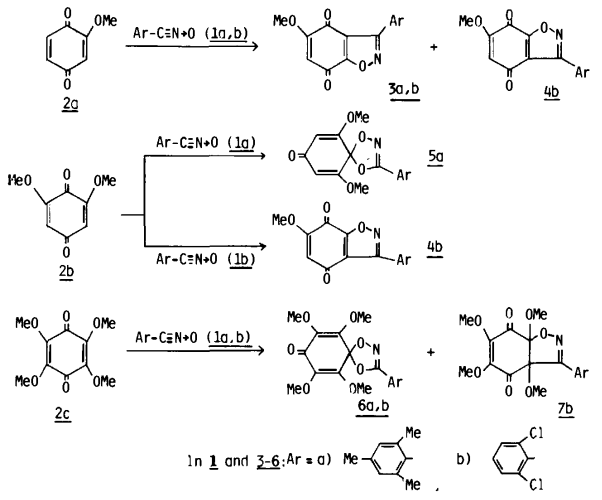
The 1,3-dipolar cycloaddition reactions of nitrile oxides with methoxy *p*-benzoquinones are discussed in terms of FMO theory. The unusual reaction pattern of methoxy *p*-benzoquinones with nitrile oxides is interpreted by considering both antibonding secondary orbital interaction and SHOMO(quinone)-LUMO (nitrile oxide) interaction.

In the previous paper[1] we reported the site- and regio-selective reactions of nitrile oxides with substituted *p*-benzoquinones by means of the FMO theory, showing the correlation between the reaction modes and two types of FMO interactions. The quinones were shown to be classified into two groups; one is a group giving C=O adducts, the reactions of which are chiefly governed by HOMO (nitrile oxide)-LUMO (quinone) interaction, and the other is that giving C=C adducts, the reactions of wihch are chiefly governed by LUMO (nitrile oxide)-HOMO (quinone) interaction. The critical energy difference of the two interactions determining the reaction mode of the quinones was roughly estimated to be about 4 eV. Steric effect was a minor factor but could not be disregarded. However, the reaction of 2,6-dichlorobenzonitrile oxide with tetramethoxy-*p*-benzoquinone, which gives both C=O and C=C adducts, could not be clearly understood even by considering the steric effect. In order to rationalize the reaction pattern, we studied the reactions of nitrile oxides with other methoxy *p*-benzoquinones and the effect of methoxyl groups is discussed in terms of FMO theory. The unusual reaction pattern of methoxy quinones was shown to be interpreted by considering both the antibonding secondary orbital interaction and MO interaction involving SHOMO's of the quinones.

Results and Discussion

The results of the reactions of nitrile oxides with methoxy *p*-benzoquinones, such as 2-methoxy-*p*-benzoquinone (**2a**) and 2,6-dimethoxy-*p*-benzoquinone (**2b**) are shown in Scheme 1 together with the result of those with tetramethoxy-*p*-benzoquinone (**2c**). As nitrile oxides, 2,4,6-trimethylbenzonitrile oxide (**1a**) and 2,6-dichlorobenzonitrile oxide (**1b**) were used. The characterization data of the reaction pruducts are described in experimental section.

The reaction of **1b** with **2a** gave two regio isomeric C=C adducts, **3b** and **4b**, which were formed by addition onto the same reaction site, unsubstituted side, but in different orientation. This is a notable contrast to the reaction with 2-methyl-*p*-benzoquinone which gave two 1:1-C=C adducts formed by addition onto different reaction site (2,3- and 5,6-position) each other.[1] The formation ratio of the regio isomers **3b** and **4b** was about 3:2 from the results of ^{1}H NMR spectrum of the reaction product. The olefinic proton of **3b** resonates as a singlet at about 0.1 ppm lower field than



Scheme 1.

TABLE 1. ENERGY LEVELS AND COEFFICIENTS OF FMO OF METHOXY *p*-BENZOQUINONES

Quinone	FMO	ε(eV)	C_1	C_2	C_3	C_4	C_5	C_6	O_1	O_2	O_3	O_4	O_5	O_6

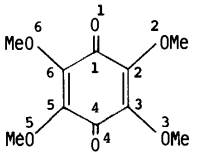
	HOMO	−6.08	0.05	−0.30	−0.32	0.05	−0.30	−0.32	0.32	0.33	0.34	0.32	0.33	0.34
	SHOMO	−6.15	−0.02	−0.34	−0.36	0.02	0.34	0.36	−0.03	0.39	0.36	0.03	−0.39	−0.36

a) The numbering of the atoms is following.



that of **4b**. The preparative separation of the two regio isomers was successfully effected by thin-layer chromatography. The reaction of **1a** with **2a** gave only one C=C adduct formed by addition onto 5,6-position in the orientation as shown in the Scheme 1.

The reaction of **2b** with **1a** has been known to give only C=O adduct,[2] while the reaction with **1b** gave exclusively the isoxazoloquinone **4b**, which was shown to be the same compound as the minor product in the reaction of **1b** with **2a**. In the reactions with **2c**, **1a** gave only C=O adduct, while **1b** gave both C=O and C=C adducts as reported before.[1,2] The difference in the modes of the reactions of **1a** and **1b** will be tried to be accounted in terms of FMO theory.

We list in Table 1 the energy values and FMO coefficients of methoxy *p*-benzoquinones calculated by *ab initio* method with STO-3G basis set[3] and in Table 2 those of nitrile oxides.[1] The geometry of quinone moiety of **2a** is that of *p*-benzoquinone[4] and that of substituent is standard one by Pople and Gordon.[5] The geometry of **2b** is that of X-ray result.[6] The substituent conformation was the most stable one by computation of the same manner described in the previous paper.[1]

The energy difference between LUMO (nitrile oxides)–HOMO (quinones) and HOMO (nitrile oxides)–LUMO (quinones) interaction is listed in Table 3. According to the energetical analysis described in the previous paper,[1] it may be predicted that the quinone **2b** will give a C=C adduct in either reaction of **1a** or **1b**. As mentioned above, however, the C=C adduct was obtained only in the reaction with **1b** and not with **1a** where C=O adduct was obtained. In addition, the high site-selectivity in the reactions is notable.

Considering the LUMO (nitrile oxide)–HOMO (quinone) interaction, one notes that the magnitude of the HOMO coefficients of the oxygen atoms of the methoxyl groups of methoxy *p*-benzoquinones is much larger than that of the carbon atoms of methyl groups of structurally similar methyl *p*-benzoquinones.[1] When nitrile oxides attack the methoxy-substituted C=C bond of the quinones, LUMO of nitrile oxides will experience an antibonding secondary orbital interaction with the oxygen orbital as shown in Fig 1. This antibonding secondary orbital interaction will decrease the net LUMO (nitrile oxide)-HOMO (quinone) overlapping to such an extent as the selectivity in the reactions may be significantly influenced. The importance of the antibonding secondary orbital interaction of methoxyl groups to the selectivity in the Diels-Alder reactions was pointed out by Tegmo-Larsson *et al.*[7] In this case, the interaction acts a role to reduce or diminish the primary orbital interaction. Gordon *et al.* rationalized the difference in the regio-selectivity between the 1,3-dipolar cycloaddition reactions of a nitrone with acrylonitrile and propiolonitrile by considering the secondary orbital interactions,[8] where the interaction acts to enhance or cooperate with the primary orbital interaction.

The quinone **2a** has two different C=C bonds. The carbon atoms of 2- and 3-positions have larger HOMO coefficients than those of 5- and 6-positions. Nevertheless the most efficient orbitals overlapping expected to be obtained in the interaction with the C=C of 2,3-position, no adduct added on the 2,3-position was obtained. This experimental result can not be rationalized by considering only the steric effect referred in the reaction with 2-methyl-*p*-benzoquinone,[1] but can be rationalized well by considering the secondary antibonding orbital interaction with the oxygen HOMO orbital of the methoxyl group.

In the reaction of **1a** with **2b**, HOMO (**1a**)-LUMO (**2b**) interaction becomes more important than the LUMO (**1a**)–HOMO (**2b**) interaction due to the antibonding secondary interactions as described above, and C=O addition occured exclusively. The kinetic data support this interpretation. The reaction rate of **2b** with **1a** is 10—100 times slower than those of other C=O addition reactions.[9] This is rationalized by the larger energy gap between HOMO (**1a**) and LUMO (**2b**). The addition across to the C=O bond of methoxy-substituted side is well understood by considering the larger LUMO coefficient magnitude of the carbon and oxygen atoms of the carbonyl.

The SHOMO's of methoxy-substituted quinones, especially those of **2b** and **2c**, lies close to that of HOMO, the energy difference being far less than 1 eV, while that of the other quinones being more than 1 eV. Therefore, in the reaction of **1b** with **2b**, LUMO (**1b**)–SHOMO (**2b**) interaction becomes more important and effects to increase net orbital overlapping, though SHOHO has also large coefficient on oxygen of methoxyl group. SHOMO does not act a role in favor of C=O addition because the coefficient on carbonyl group is zero.

The reaction with **2c** is also rationslized in terms of the same interactions mentioned above. Because of the antibonding secondary orbital intersction with

Table 2. Energy levels and coefficients of FMO of nitrile oxides

Nitrile oxide	FMO	ε(eV)	C_α[a]	C	N	O
1a	LUMO	5.58	0.50	0.27	−0.42	0.28
	HOMO	−6.12	−0.32	0.41	0.21	−0.69
1b	LUMO	4.43	0.55	0.22	−0.40	0.29
	HOMO	−6.89	−0.24	0.46	0.18	−0.73

1b	1.12	0.15	−0.62

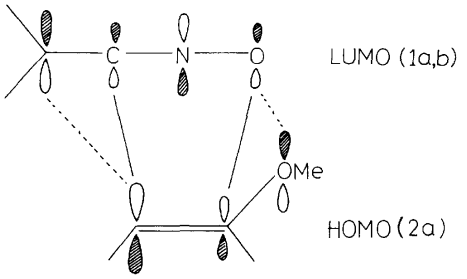

Fig. 1.

the oxygen atoms of methoxyl substituents acting to reduce the LUMO (**1a**)–HOMO (**2c**) overlapping, HOMO (**1a**)–LUMO (**2c**) interaction comes to be dominant to lead the C=O adduct formation in the reaction of **1a**. While in the reaction with **1b**, LUMO (**1b**)–SHOMO (**2c**) interaction favors C=C adduct formation due to the very small energy difference between SHOMO and HOMO of **2c** as shown in Table 1.

In the Diels-Alder reactions the role of the secondary orbtal interaction is widely recognized and applied, but in the 1,3-dipolar cycloaddition reactions not so much.[10] In this study it becomes clear that the antibonding secondary orbital interaction with oxygen atom of methoxyl substituent is the factor to control the site- and regio-selectivity in the cycloaddition reactions of nitrile oxides with methoxy *p*-benzoquinones. Moreover, it is shown that SHOMO becomes important in the interaction with the LUMO of the attacking reagent, when SHOMO lies close to HOMO.

Experimental

Melting points were measured using a micro-melting-point measuring apparatus (Yazawa Co., Ltd.) and are uncorrected. Column chromatography was conducted on silica gel (Wako gel C-200) with benzene as an eluent. IR spectra were recorded with a JASCO IRA-1 spectrophotometer. ^{1}H NMR spectra were measured in $CDCl_3$ with a JEOL JNM MH-100 spectrometer, and chemical shifts were reported in ppm from internal tetramethylsilane. Mass spectra were recorded with a Hitachi RMU-7L high resolution mass spectrometer.

Materials. 2,4,6-Trimethylbenzonitrile oxide (**1a**) and 2,6-dichlorobenzonitrile oxide (**1b**) were prepared by the method of Grundmann.[11] 2-Methoxy-*p*-benzoquinone (**2a**) was prepared by the method of Jeffreys.[12] 2,6-Dimethoxy-*p*-benzoquinone (**2b**) was prepared by the method of Will.[13]

*Reaction of 2,4,6-Trimethylbenzonitrile Oxide (1a) with 2-Methoxy-*p*-benzoquinone (2a).* A solution of 0.484 g (3 mmol) of **1a** and 0.829 g (6 mmol) of **2a** in 100 ml benzene was stirred for about 5 d at room temperature. Solvent was then evaporated under reduced pressure, and the residue was subjected to column chromatography. The first fraction gave 3-mesityl-5-methoxy-1,2-benzisoxazole-4,7-dione, **3a**, (0.62 g 69%), which was recrystallized from benzene–hexane. Mp 196—197 °C. IR (KBr) 1660 and 1690 cm^{-1} ($\nu_{C=O}$). ^{1}H NMR ($CDCl_3$) δ=2.09 (s, 6H, mesityl *o*-methyl), 2.36 (s, 3H, mesityl *p*-methyl), 3.89 (s, 3H, methoxyl methyl), 6.02 (s, 1H, olefinic), and 6.96 (s, 2H, aromatic)

Found: C, 68.78; H, 5.09; N, 4.88%. Calcd for $C_{17}H_{13}N_1O_4$: C, 68.68; H, 5.09; N, 4.71%.

*Reaction of 2,6-Dichlorobenzonitrile Oxide (1b) with 2-Methoxy-*p*-benzoquinone (2a).* The reaction was conducted and worked up in the same manner as the above. The second fraction gave a mixture of the regio-isomer, **3b** and **4b**, (0.41 g 44%). The NMR spectrum of the product revealed this to be a mixture of two C=C adducts. The signals at 6.05 and 5.94 due to the olefinic proton of the two adducts was in the ratio of 3:2. The product was separated by thin-layer chromatography with benzene–hexane 1:1 mixture as an eluent. 3-(2,6-Dichlorophenyl)-6-methoxy-1,2-benzisoxazole-4,7-dione, **4b**, was obtained from the first fraction zone, and recrystallized from benzene–hexane. Mp 190—193 °C. IR (KBr) 1660 and 1720 cm^{-1} ($\nu_{C=O}$). ^{1}H NMR ($CDCl_3$) δ=3.90 (s, 3H, methoxyl methyl), 5.94 (s, 1H, olefinic), and 7.43 (s, 3H, aromatic).

Found: C, 51.98; H, 2.14; N, 4.46%. Calcd for $C_{14}H_7N_1O_4Cl_2$: C, 51.88; H, 2.18; N, 4.32%.

The second fraction gave 3-(2,6-dichlorophenyl)-5-methoxy-1,2-benzisoxazole-4,7-dione, **3b**, which was recrystallized from benzene–hexane. Mp 181—182 °C. IR (KBr) 1670 and 1710 cm^{-1} ($\nu_{C=O}$). ^{1}H NMR ($CDCl_3$) δ=3.94 (s, 3H, methoxyl methyl), 6.05 (s, 1H, olefinic), and 7.47 (s, 3H, aromatic).

Found: C, 51.95; H. 2.10; N, 4.40%. Calcd for $C_{14}H_7N_1O_4Cl_2$: C, 51.88; H, 2.18; N, 4.32%.

*Reaction of 2,6-Dichlorobenzonitrile Oxide (1b) with 2,6-Dimethoxy-*p*-benzoquinone (2b).* A solutuion of 0.49 g (2.5 mmol) of **1b** and 0.42 g (2.5 mmol) of **2b** in 50 ml benzene was stirred for several days at room temperature and the solvent was evaporated under reduced pressure. The residue was worked up with column chromatography to give **4b**, (0.58 g 71%). The recrystallization was carried out from benzene–hexane.

Restricted Rotation Involving the Tetrahedral Carbon. LV. Differential Effects of the *peri*-Substituents on the Rotational Barriers in 9-Ethyl-, 9-Allyl-, and 9-Benzyltriptycenes[1]

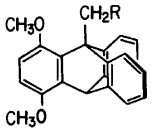
Gaku YAMAMOTO and Michinori ŌKI*

Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113

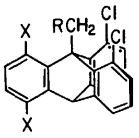
(Received February 14, 1984)

Energy barriers to rotation about the bridgehead-to-substituent bond in 9-ethyl-, 9-allyl-, and 9-benzyltriptycene derivatives with varying degrees of *peri*-substitution were studied by dynamic NMR and in one case by the classical kinetic method. In the singly *peri*-substituted series (1,4-dimethoxy derivatives) the barrier decreases in the order of 9-ethyl>9-allyl>9-benzyl. In the doubly *peri*-substituted series (1,8-dichloro derivatives) the barriers are alike irrespective of the 9-substituent, and in the triply *peri*-substituted series (1,4-dimethyl-8,13-dichloro derivatives) the barrier decreases in the order of 9-benzyl>9-allyl>9-ethyl. The reversal of the trend on the change in *peri*-substitution patterns may be explained on the basis of the change in the interaction between the *peri*- and 9-substituents in both the ground and the transition states.

Our recent ^{1}H NMR investigation on 9-benzyl-1,4-dimethoxytriptycene (**1c**) revealed that the free energy of activation, $\Delta G_c^{\ddagger}$, for the rotational isomerization (*ap*→±*sc*) was 11.9 kcal mol^{-1} (1 cal=4.184 J).[2] Meanwhile Nakanishi *et al.* reported the $\Delta G^{\ddagger}$ value of 13.8 kcal mol^{-1} for the same process in 9-ethyl-1,4-dimethoxytriptycene (**1a**) obtained by ^{13}C dynamic NMR study.[3] The higher barrier in the 9-ethyl derivative (**1a**) than in the 9-benzyl one (**1c**) made us to expect



1



2 X=H
3 X=CH$_3$

a: R = CH$_3$
b: R = CH=CH$_2$
c: R = C$_6$H$_5$
d: R = 3,5-(CH$_3$)$_2$C$_6$H$_5$

that atropisomerism could be realized in a triply *peri*-substituted 9-ethyltriptycene such as **3a**, because the corresponding 9-(3,5-dimethylbenzyl) derivative (**3d**) had been shown to afford stable atropisomers with the free energy of activation for the *ap*→±*sc* isomerization of 25.3 kcal mol^{-1}.[4] To our surprise, **3a** showed a far lower barrier to rotation than expected, as will be discussed in this article. These findings urged us to study in some detail how the rotational barrier in 9-*prim*-alkyltriptycene derivatives might depend on the pattern of *peri*-substitution and the β-group in the 9-substituent. We chose ethyl, allyl, and benzyl groups as the 9-substituent, and 1-methoxy, 1,8-dichloro, and 1,8-dichloro-13-methyl as the representative of the single, double, and triple *peri*-substitution, respectively. Therefore we prepared compounds **2a**—**2c** and **3a**—**3c**, and studied the rotational barriers in these compounds.

Results

Syntheses. A Grignard reagent prepared from ethyl iodide, allyl bromide, or benzyl chloride was treated with 1,8-dichloroanthrone and the resulted alcohol was dehydrated to give 9-ethyl-, 9-allyl-, or 9-benzyl-1,8-dichloroanthracene (**4a**—**4c**). Reactions of benzyne and 3,6-dimethylbenzyne generated *in situ*

TABLE 1. ^{1}H HMR SPECTRAL DATA IN CDCl$_3$[a]

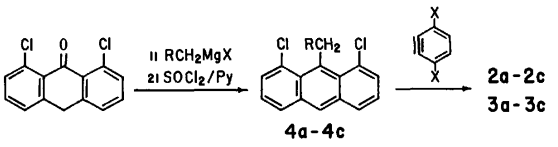
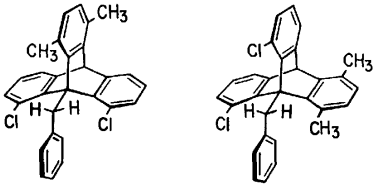
a) Obtained at *ca.* 35 °C except for **2a**, for which the data at −4 °C are given. Aromatic protons are not included. Chemical shifts are given in δ; s: singlet, d: doublet, t: triplet, q: quartet, m: multiplet, dq: double quartet, dm: double multiplet. In parentheses are coupling constants in Hz. b) In **3a** and **3b**, the signal pair with larger chemical shift differences are tentatively assigned to 1-CH$_3$. c) Apparent double doublet. d) Obscured by overlap with the vinyl protons. e) Obtained from the equilibrated mixture of atropisomers.

from the corresponding anthranilic acids with the anthracenes (**4a—4c**) gave the desired triptycene derivatives (**2a—2c** and **3a—3c**).[5] ^{1}H NMR spectral data of the triptycenes obtained are compiled in Table 1.



The analogy of compound **3d**[4] predicts that the *ap* atropisomer of **3c** would be stereoselectively formed under kinetically controlled conditions in the reaction of **4c** with 3,6-dimethylbenzyne, but actually a *ca.* 1:1 mixture of *ap*-**3c** and ±*sc*-**3c** was obtained probably due

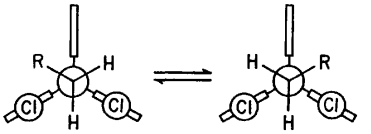


ap-**3c** ±*sc*-**3c**

to the high reaction temperature and the long reaction time. Column chromatography of the rotamer mixture of **3c** afforded a pure sample of ±*sc*-**3c** as this isomer was eluted faster than *ap*-**3c**. The *ap* isomer was concentrated up to 85%.

Classical Kinetic Measurements on 3c. The rotational barrier in **3c** seemed to be too high to be studied by dynamic NMR and was obtained by classical kinetics in the temperature range of 49—69 °C. An *ap*-enriched sample of **3c** in chloroform-*d* was placed in the NMR probe which had been preheated at a constant temperature and the change in the relative intensities of the 1- and/or 4-methyl proton signals was followed. The change was analyzed as a first-order reversible reaction and the rate constant for the *ap*→±*sc* isomerization was calculated. The rate constants thus obtained at four temperatures and the Eyring parameters therefrom are given in Table 2.

Dynamic NMR Studies on 2a—2c. ^{1}H NMR spectra of the 1,8-dichloro derivatives (**2a—2c**) at room temperature indicate that these compounds exist solely as ±*sc* rotamers and the +*sc* ⇌ −*sc* interconversion is slow on the NMR time scale. On raising the temperature, the signal due to the diastereotopic methylene protons broadened and coalesced into an isochronous



+*sc*-**2** −*sc*-**2**

signal. Rate constants at coalescence temperatures (T_c) were estimated by the use of Eq. 1,[6]

$$k_c = \frac{\pi}{\sqrt{2}}(\Delta\nu_{AB}^2 + 6J_{AB}^2)^{1/2} \quad (1)$$

where $\Delta\nu_{AB}$ is the chemical shift difference between the diastereotopic methylene protons and J_{AB} is the geminal coupling constant. The spectra at T_c for **2a** and **2c** were reproduced by theoretical calculations affording rate constants at T_c which are very similar to those from Eq. 1. This means that Eq. 1 can satis-

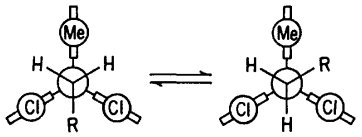
a) Kinetic parameters refer to the *ap*→±*sc* process for **1a—1c** and **3a—3c** taking the degeneracy of ±*sc* rotamers into account and to the +*sc*⇌−*sc* process for **2a—2c**. b) In parentheses are the geminal coupling constants in Hz. c) Reliable to ±0.1 kcal mol^{-1} except for **2b**, for which the value is reliable to ±0.3 kcal mol^{-1}. d) Values at T_c unless otherwise noted. e) $K = [\pm sc]/[ap]$. f) Ref. 3. g) Ref. 2. h) Obtained by the classical kinetic method. See Table 2.

factorily predict k_c for $ABX_3 \rightleftharpoons BAX_3$ exchange as manifested in **2a** and this is probably because $\Delta\nu_{AB}$ is sufficiently large (67.3 Hz). In case of **2b**, the spectra were too complex to be theoretically simulated, but the coalsecence temperature was definitely identified. Success of Eq. 1 in predicting k_c for **2a** would justify the use of the equation also for **2b**, although allowance should be made for the inaccuracy of $\Delta\nu_{AB}$ and J_{AB} values because of the overlap of the signals. The kinetic data thus obtained for the $+sc \rightleftharpoons -sc$ process in **2a—2c** are given in Table 3.

Dynamic NMR Studies on 3a and 3b. ^{1}H NMR spectra of **3a** and **3b** indicated that both compounds



ap-**3** ±*sc*-**3**

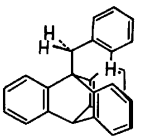
exist as two rotamers, *ap* and ±*sc*. The relative populations of the rotamers were determined by integrating the 1- and/or 4-methyl signals and the rotamer assignment was made by carefully inspecting the methylene proton signals which appeared as complex multiplets because of the couplings with the methyl or the vinyl protons: the methylene protons are enantiotopic in *ap* and diastereotopic in ±*sc*. From the coalescence phenomena exhibited by the 1- and 4-methyl signals[7] the rate constants at T_c for the *ap*→±*sc* process in these compounds were obtained by the use of the graphical method according to Jaeschke *et al.*[8] and are shown in Table 3.

Dynamic NMR Study on 1b. Although our earlier study on the low temperature NMR of **1b** has shown that the ±*sc*/*ap* ratio at −32 °C is 0.7 in chloroform-*d*,[9] dynamic NMR measurements to obtain the rotational barrier had not been made. The methoxyl signals were not suitable as a DNMR probe not only because the chemical shift differences between the rotamers are very small but also because the signals overlap with the allylic methylene signals at low temperatures. The signal ascribed to the aromatic protons at 2- and 3-positions appears as a sharp singlet isolated from the other aromatic signals at room temperature in dichloromethane-d_2 which splits into two singlets at low temperatures. This indicates that the chemical shifts of the 2- and the 3-protons coincide with each other throughout the temperature range examined. Therefore this signal was used as a DNMR probe and the rate constant at T_c for the *ap*→±*sc* process was obtained by the graphical method.[8] The kinetic data obtained are also included in Table 3.

Discussion

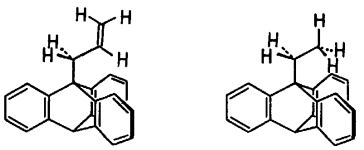
The singly *peri*-substituted 9-allyl compound (**1b**) shows the energy barrier to the *ap*→±*sc* isomerization of 13.8kcal mol^{-1}, which ranks between the barrier in the 9-ethyl compound (**1a**) and the one in the 9-benzyl compound (**1c**) but is close to the value for **1a**. The energy barrier to the *ap*→±*sc* process in the triply *peri*-substituted 9-benzyl compound (**3c**) is very similar to that in **3d** reported before,[4] and this may be reasonable becuase the *m*-methyl groups should not significantly affect the barrier. It is rather unexpected that the rotational barrier found in the triply *peri*-substituted 9-ethyl compound (**3a**) is *ca.* 5 kcal mol^{-1} lower than that in the corresponding 9-benzyl compound (**3c**). The barrier in the 9-allyl derivative **3b** is somewhat higher than that in **3a** but still far lower than that in **3c**. This trend of the barrier heights, 9-benzyl>9-allyl>9-ethyl, is just the reverse of that found in the singly *peri*-substituted series (**1a—1c**). In the doubly *peri*-substituted series, *i.e.* the 1,8-dichloro compounds (**2a—2c**), the barriers to the $+sc \rightleftharpoons -sc$ interconversion are rather similar among the compounds.

As the energy barrier is the difference between the ground and the transition states, the energy situations in both states should be considered. In the ground state conformation of 9-benzyltriptycene derivatives, the phenyl group lies coplanar with the bridgehead-to-substituent bond, constituting a static gear system with a three-toothed and a two-toothed wheels as shown by **5** for 9-benzyltriptycene.[4b] Several of the



5

previous experimental results[4b] as well as molecular model considerations suggest the presence of a considerable steric interaction between the triptycene skeleton and the inner *o*-hydrogen of the phenyl group. Meanwhile, 9-allyl- and 9-ethyltriptycenes seem to suffer no such interactions judging from the probable ground state conformations **6** and **7**. We can therefore specu-



6 **7**

late that the ground state energy level is considerably higher in 9-benzyltriptycene than in 9-allyl or 9-ethyltriptycene. Introduction of *peri*-substituents would destabilize the ground state irrespective of the 9-substituent. The degree of destabilization in the

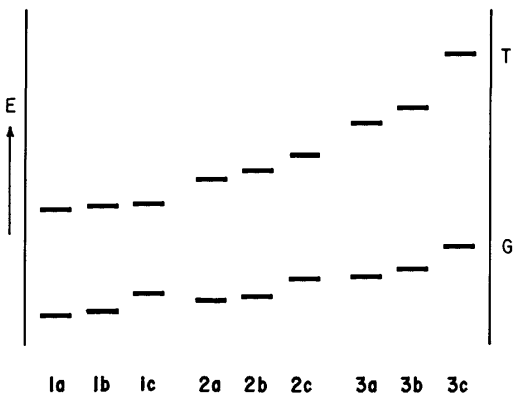


Fig. 1. Schematic energy diagram of the ground (G) and the transition (T) states. The energy scale is arbitrary.

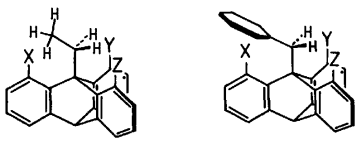
ground state should be larger in 9-benzyl derivatives than in 9-allyl and 9-ethyl ones because of the intrinsic instability of 9-benzyltriptycene.

Although information on the transition states can not be obtained experimentally, some aspects of transition state energies may be discussed on the basis of the energy barriers obtained experimentally and the ground state energies discussed above: The energy diagram of the compounds may be shcematically drawn as shown in Fig. 1. From the diagram it is clearly seen that the destabilization in the transition state on going from the singly to the triply *peri*-substituted derivative is more effective in the 9-benzyl series than that in the 9-ethyl or the 9-allyl series.

These situations may be understood to some extent by the examination of the transition state conformations (**8** and **9**). Hereafter the behavior of the



8

9

9-ethyl and the 9-benzyl compounds will be discussed; the 9-allyl compounds will behave like something between the two. Molecular model considerations reveal the difference in the probable transition state structure between the two series of compounds. In the 9-ethyl compounds (**8**), the methyl group interacts with the group X (H or Cl) at the edge, *i. e.* the methyl group does not reach the C–X bond axis with the methyl carbon ···X distance of 1.5 Å and the C–X···C angle of *ca.* 130° when X=H from the Dreiding model, while in the 9-benzyl compounds, the phenyl group extends over the group X, X being buried in the π-cloud of the benzene ring with X···benzene ring distance of 1.2 Å when X=H. In the actual molecules these distances should be larger because of the angular deformation.

In the singly *peri*-substituted compounds (X=Y=H, Z=OCH_3), the energy levels of **8** and **9** may be similar judging from the higher ground state energy level and the smaller energy barrier in **1c** than in **1a** (Fig. 1). In the doubly *peri*-substituted compounds (X=H, Y=Z=Cl) the two *peri*-chloro groups buttress the 9-substituent toward the *peri*-hydrogen both in the ground and the transition states. Destabilization due to the buttressing effect should naturally be larger in the transition state than in the ground state and the transition state **9** should be more strongly destabilized than **8** on the basis of the geometrical situations discussed above: the buttressing effect prevents angular deformations which relieve the steric strain caused by the β-group and X. This deduction is consistent with the larger increase of the energy barrier in the 9-benzyl series (**1c**→**2c**) than in the 9-ethyl series (**1a**→**2a**). In the triply *peri*-substituted compounds (X=Y=Cl, Z=CH_3), **9** should be far more strongly destabilized than **8**, because now a chloro group instead of a hydrogen interacts with the β-group of the 9-substituent and also the methylene group is buttressed by 8-chloro and 13-methyl groups.

Therefore, the order of the barrier heights in the singly *peri*-substituted compounds, 9-ethyl>9-allyl>9-benzyl, is mainly ascribed to the differences in the ground state energy. In the doubly *peri*-substituted compounds, the change in the transition state may parallel that in the ground state. In the triply *peri*-substituted compounds the difference in the transition state energy is most responsible for the order of the barrier heights.

Another intriguing feature is the rotameric equilibrium in the compounds examined. The equilibrium constant in **1b**, 0.65, is very similar to that in **1a**, suggesting that the main factor governing the both equilibria is the same, *i.e.* steric. The large preference for the $\pm sc$ rotamer in **1c** has been ascribed to an attractive interaction between the 1-methoxyl and the phenyl groups overwhelming the steric effect.[10] Almost exclusive existence of the $\pm sc$ rotamers in **2a**—**2c** can be understood on the basis of the steric effects. Among **3a**—**3c**, the 9-allyl (**3b**) and the 9-benzyl (**3c**) compounds behave similarly with each other and differently from the 9-ethyl compound (**3a**). The *ap* rotamers would be sterically favored on the basis of the generally accepted van der Waals radii of the *peri*-substituent (1.80 Å for Cl and 2.0 Å for methyl[11]), as manifested in **3a**. A hypothetical C–H···π interaction between the 1-methyl and the vinyl or the phenyl group might shift the equilibrium in favor of the $\pm sc$ rotamer in **3b** and **3c**.[12]

Experimental

Melting points are not corrected. ^{1}H NMR spectra at ambient temperature of *ca.* 35 °C were recorded on a Varian EM-390 (90 MHz) or a Hitachi R-20B (60 MHz) spectrometer in chloroform-*d* solutions with tetramethylsilane as the internal reference. Variable temperature ^{1}H NMR spectra were obtained on the R-20B spectrometer in 5—8% (w/v) solutions in dichloromethane-d_2 (**1b**), chloroform-*d* (**2a**—**2c** and **3c**), or chlorobenzene (**3a** and **3b**). Temperatures were calibrated using methanol and ethylene glycol samples.[13] Theoretical spectra were obtained on a Hitachi M-280H computer system at the Computer Center of the University of Tokyo using a modified verson of the DNMR program by Binsch.[14] Kinetic studies on **3c** were made following the procedure described before for **3d**.[4b]

1,8-Dichloro-9-ethylanthracene (4a). To an ethereal solution of the Grignard reagent prepared from 2.0 mL of ethyl iodide was added portionwise 2.63 g (10.0 mmol) of powdery 1,8-dichloroanthrone[15] and the mixture was stirred at room temperature for 1 h and treated with aqueous ammonium chloride to give 1,8-dichloro-9-ethyl-9,10-dihydro-9-anthrol [(^{1}H NMR ($CDCl_3$), δ=0.42 (3H, t, J=7.5 Hz), 2.75 (2H, q, J=7.5 Hz), 3.73 (1H, br s), 4.01 (2H, s), 6.9—7.5 (6H, m)]. The alcohol was treated with 4 mL of thionyl chloride and 7 mL of pyridine in 30 mL of ether under reflux for 15 min. The reaction mixture was washed with water, dried over magnesium sulfate, and concentrated. Column chromatography (alumina, hexane–dichloromethane) of the residue followed by recrystallization from tetrahydrofuran-hexane gave 1.64 g (60%) of **4a** as yellow granules, mp 101—102 °C. Found: C, 69.65; H, 4.12; Cl, 25.94%. Calcd for $C_{16}H_{12}Cl_2$: C, 69.84; H, 4.40; Cl, 25.76%. ^{1}H NMR ($CDCl_3$), δ=0.97 (3H, t, J=7.1 Hz), 4.18 (2H, q, J=7.1 Hz), 7.0—7.9 (6H, m), 8.12 (1H, s).

9-Allyl-1,8-dichloroanthracene (4b). Similarly as above, the reaction of 1,8-dichloroanthrone with the Grignard

reagent prepared from allyl bromide gave 9-allyl-1,8-dichloro-9,10-dihydro-9-anthrol [^{1}H NMR ($CDCl_3$), δ=3.51 (2H, br d), 3.92 (1H, br s), 3.98 (2H, s), 4.4—5.5 (3H, m), 7.0—7.5 (6H, m)], which was treated with thionyl chloride and pyridine to give 9-allyl-1,8-dichloroanthracene (**4b**) in 78% yield, mp 88—89 °C (from tetrahydrofuran-hexane). Found: C, 70.93; H, 4.10; Cl, 24.84%. Calcd for $C_{17}H_{12}Cl_2$: C, 71.10; H, 4.21; Cl, 24.69%. ^{1}H NMR ($CDCl_3$), δ=4.3—5.1 (2H, m), 5.4—6.2 (1H, m), 7.0—8.0 (6H, m).

General Procedure for the Synthesis of the Triptycenes. To a boiling solution of 1.5 mmol of an anthracene in 20 mL of 1,2-dimethoxyethane (DME) were added dropwise a solution of 2.5 mmol of an anthranilic acid in 10 mL of DME and a solution of 1.0 mL of isopentyl nitrite in 5 mL of DME, so that a considerable excess of isopentyl nitrite was always present in the reaction mixture. The mixture was heated under reflux for 1 h and concentrated. Column chromatography of the residue on alumina with hexane as the eluent followed by recrystallization from tetrahydrofuran-hexane gave the desired triptycene.

*1,8-Dichloro-9-ethyltriptycene (**2a**),* mp 231—232 °C, was prepared from **4a** and anthranilic acid in 53% yield. Found: C, 75.22; H, 4.29; Cl, 20.34%. Calcd for $C_{22}H_{16}Cl_2$: C, 75.22; H, 4.59; Cl, 20.19%.

*9-Allyl-1,8-dichlorotriptycene (**2b**),* mp 192—194 °C, was prepared from **4b** and anthranilic acid in 27% yield. Found: C, 76.18; H, 4.28; Cl, 19.61%. Calcd for $C_{23}H_{16}Cl_2$: C, 76.04; H, 4.44; Cl, 19.52%.

*8,13-Dichloro-9-ethyl-1,4-dimethyltriptycene (**3a**),* mp 251—252 °C, was prepared from **4a** and 3,6-dimethylanthranilic acid[16] in 78% yield. Found: C, 75.80; H, 5.10; Cl, 18.72%. Calcd for $C_{24}H_{20}Cl_2$: C, 75.99; H, 5.31; Cl, 18.69%.

*9-Allyl-8,13-dichloro-1,4-dimethyltriptycene (**3b**),* mp 233—235 °C, was prepared from **4b** and 3,6-dimethylanthranilic acid in 48% yield. Found: C, 76.75; H, 5.13; Cl, 18.21%. Calcd for $C_{25}H_{20}Cl_2$: C, 76.73; H, 5.15; Cl, 18.12%.

*9-Benzyl-8,13-dichloro-1,4-dimethyltriptycene (**3c**).* To a boiling solution of 9-benzyl-1,8-dichloroanthracene (**4c**)[4] and 1.5 mL of isopentyl nitrite in 30 mL of dichloromethane was added dropwise a solution of 1.15 g (6.9 mmol) of 3,6-dimethylanthranilic acid in 20 mL of tetrahydrofuran and the mixture was heated under reflux for 2 h. Column chromatography (alumina, hexane-dichloromethane) gave 890 mg (54%) of **3c** as *ca.* 1:1 mixture of the *ap* and ±*sc* rotamers. Earlier fractions of the column chromatography of the rotamer mixture on alumina with hexane as the eluent gave a pure sample of ±*sc*-**3c**, mp 208—210 °C. Found: C, 79.03; H, 5.00; Cl, 15.55%. Calcd for $C_{29}H_{22}Cl_2$: C, 78.91; H, 5.02; Cl, 16.06%. Later fractions of the chromatography gave a sample containing 85% at best of the *ap* rotamer.

Dynamic NMR as a Nondestructive Method for the Determination of Rates of Dissociation. V. Proton Affinities of *p*-Substituted *N,N*-Dibenzylanilines in Aprotic Solvents[1,2]

Michinori Ōki,* Manabu Ohira, Yasuhiro Yoshioka, Toshiari Morita, Hiroshi Kihara, and Nobuo Nakamura

Department of Chemistry, Faculty of Science, The University of Tokyo, Bunkyo-ku, Tokyo 113

(Received March 2, 1984)

Rates of proton exchange between *p*-substituted *N,N*-dibenzylanilinium ion and chloride ion in chloroform-*d* and acetonitrile-d_3 were determined by the dynamic NMR technique. Comparison of the kinetic proton affinity of the anilines in the aprotic solvents with the proton affinity of anilines in the gas phase and the basicity in water revealed that they could be linearly correlated. The feature of the kinetic data was a large positive entropy of activation which can be ascribed to the change from an ionic ground state to a covalent transition state. The entropy of activation was somewhat smaller in acetonitrile-d_3 than in chloroform-*d*. This was attributed to the change in the stage of the transition state for the exchange. A small amount of water which could not be removed easily from the aprotic solvents was proved not to harm the results.

Basicities of amines in water are well documented.[3] In recent years, proton affinity of amines in the gas phase was studied by the ion cyclotron resonance technique or high pressure mass spectrometry.[4] The results were treated thermodynamically to understand the basicity of amines in aqueous solutions by taking the solvation energy into consideration.[5] The correlation between the gas phase proton affinity and the basicity in water could be examined in detail due to the wealth of literatures on the latter. However, basicity data of amines in aprotic solvents are rather few. Therefore, the understanding of basicities in aprotic solvents requires experimental data which can be obtained by variety of methods.

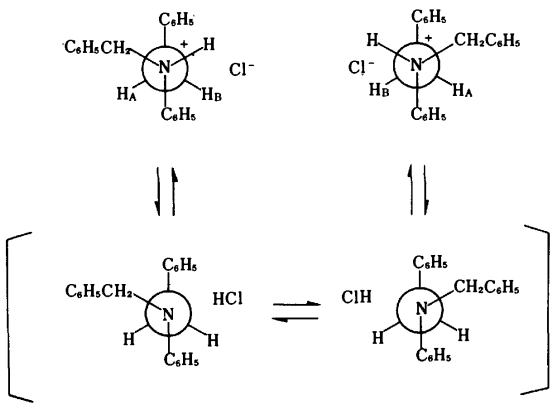
The dynamic NMR technique had been playing some role in measuring the basicity of amines in various solvents. Grunwald, Lowenstein, and Meiboom pioneered in this area by showing that the methyl proton signal of methylamine in strongly acidic media was a quartet due to coupling with $-NH_3^+$ protons but it coalesced and became a singlet when the pH of the solution was raised.[6] Saunders and Yamada followed this work to study the rates of proton exchange and nitrogen inversion in *N,N*-dibenzylmethylamine.[7] This technique now becomes widely applicable and Delpuech and collaborators have studied the rates of inversion of various amines in acidic aqueous media.[8] They further elaborated the study in the area of acidic dimethyl sulfoxide solutions.[9] There exist some ambiguities in the exchange in aqueous solutions and strongly polar media: The acceptor of proton can be the free amine, the solvent, and the anion which is derived from the acid, though the free amine is assumed to be the acceptor in these cases. This may be one of the reasons for which the technique has a shortcoming.[10]

The rates of proton exchange of ammonium salts with bases in nonaqueous solutions have been reported in some instances other than dimethyl sulfoxide. Reynolds and Schaefer found that *N,N*-dibenzylmethylamine in trifluoroacetic acid did not show the disappearance of the coupling between NH^+ and CH.[11] This is reasonable because trifluoroacetic acid is a strong acid and trifluoroacetate anion exists as a very dilute solution. As is expected, Delpuech and Gay reported that the proton exchange takes place in a solution of *N*-methylpiperidine derivatives in formic acid.[12] Menger *et al.* determined the rates of proton exchange between *N,N*-dimethylcyclohexylammonium ion and pyridine in the presence of excess of the latter in chloroform-*d* by the dynamic NMR method.[13] Perrin and Wang reexamined the case.[14] Determination of the rates of proton transfer in trisubstituted methanes-triethylamine systems[15] may be considered another area of application of this technique.

We have demonstrated that topomerization by dissociation could be used for determination of the rates of dissociation. Thus dissociation of some organic halides was studied by this technique.[16] This technique is unique in the sense that the rates of dissociation can be determined in the absence of foreign materials, contrasting with the applications cited above which needed excess of either acids or proton accepting bases. Thus it will be possible to see "intrinsic" acidity of an ammonium ion in aprotic solvents by this method.

To observe topomerization by dissociation by dynamic NMR, the compound in question should fulfill the following requirements: 1) The presence of a pair of diastereotopic protons and 2) the site exchange on dissociation. We have found that *N,N*-dibenzylaniline hydrochloride satisfies the conditions and the rates of dissociation of the anilinium ion are suitable for the dynamic NMR study.[2] The principle of the topomerization processes may be written as in Scheme 1.

The benzylic protons are diastereotopic as far as the anilinium proton sticks to the nitrogen atom. When the proton dissociates, the amine inverts, and reprotonation takes place, the whole process corresponds to topomerization and exchange of the sites takes place. Since the free energy of activation for inversion of *N,N*-dibenzylmethylamine is 6.6 kcal/mol (1 cal= 4.184 J),[17] that for inversion of *N,N*-dibenzylaniline must be smaller than this value. Thus if the dynamic NMR technique affords the free energy of activation for the topomerization much higher than 6 kcal/mol, it will mean that we are looking at the proton exchange rates. It was indeed the case as will be discussed later. Then we obtain proton affinity of *N,N*-dibenzylaniline



Scheme 1.

as free energy of activation or other kinetic parameters.

Being driven by the success in determining the kinetics, we extended the work to *p*-substituted *N,N*-dibenzylanilines to compare the proton affinity in aprotic solvents with that in the gas phase and the basicity in water. This paper describes the results and discusses the proton affinity of *p*-substituted *N,N*-dibenzylanilines in aprotic solvents together with some points which were important for obtaining reliable data.

Experimental

N,N-Dibenzylaniline is commercially available from Tokyo Kasei Co. and was used as received. It could be purified by recrystallization from ethanol, if necessary. ^{1}H NMR ($CDCl_3$) δ=4.57 (4H, s), 6.6—7.3 (15H, br s).

N,N-*Dibenzyl*-p-*methoxyaniline*. A mixture of 10.0 g (80 mmol) of *p*-methoxyaniline, 23 mL (200 mmol) of benzyl chloride and 20 g of potassium carbonate were heated at 100 °C for 5 h with stirring. The reaction mixture was poured into water and the organic compounds were extracted with ether. After evaporation of the solvent, the residue was recrystallized from ethanol to give 83.4% of the desired compound, mp 80.7 °C (lit,[18,19] mp 81—82 °C). ^{1}H NMR ($CDCl_3$) δ=3.71 (3H, s), 4.53 (4H, s), 6.70 (4H, s), 7.27 (10H, br s).

N,N-*Dibenzyl*-p-*nitroaniline*, mp 131.9 °C, was similarly prepared by heating *p*-nitroaniline and benzyl chloride at 150 °C for 7 d and was purified by recrystallization from hexane-dichloromethane. Found: C, 75.36; H, 5.72; N, 8.54%. Calcd for $C_{20}H_{18}N_2O_2$: C, 75.45; H, 5.69; N. 8.79%. ^{1}H NMR ($CDCl_3$) δ=4.76 (4H, s), 6.72 and 8.08 (4H, ABq, J= 9.6 Hz), 7.1—7.6 (10H, m).

N,N-*Dibenzyl*-p-*chloroaniline*, mp 104.5 °C, was prepared similarly. Found: C, 78.11; H, 5.80; N, 4.54; Cl, 11.55%. Calcd for $C_{20}H_{18}ClN$: C, 78.03; H, 5.89; N, 4.55; Cl, 11.51%. ^{1}H NMR ($CDCl_3$) δ=4.58 (4H, s), 6.60 and 7.03 (4H, ABq, J= 9.5 Hz), 7.1—7.4 (10H, br s).

N,N-*Dibenzyl*-p-*methylaniline*, mp 55.3 °C, was prepared from 2.1 g of *p*-methylaniline and 4.5 g of benzyl chloride in 20 mL of dioxane and 3 g of potassium carbonate by heating for 4 d. Found: C, 87.89; H, 7.08; N, 5.02%. Calcd for $C_{21}H_{21}N$: C, 87.76; H, 7.36; N, 4.87%. ^{1}H NMR ($CDCl_3$) δ= 2.20 (3H, s), 4.57 (4H, s), 6.63 and 6.93 (4H, ABq, J=10 Hz), 7.1—7.4 (10H, br s).

Hydrochlorides. The *N,N*-dibenzylanilines were dissolved in benzene and dry hydrogen chloride was introduced to the solution. The precipitate was collected (it was necessary for the methoxy compound to concentrate the solution) and recrystallized from either hexane-dichloromethane or hexane-tetrahydrofuran. They exhibited the following ^{1}H NMR spectra ($CDCl_3$) δ (only the *p*-substituent given). H, 4.77 (br s), 7.1—7.6 (15H, m); CH_3O, 3.67 (3H, s), 4.64 (4H, br s), 6.7—8.2 (14H, m); Cl, 4.66 (4H, s), 6.8—7.6 (14H, m); CH_3, 2.16 (3H, s), 4.65 (4H, s), 6.8—7.6 (14H, m).

N,N-Dibenzyl-*p*-nitroaniline hydrochloride lost hydrogen chloride on drying.

Dynamic NMR Measurement, Analysis, and Kinetic Parameters. Samples were dissolved in appropriate solvents to make up 30—70 mM solutions unless otherwise stated. ^{1}H NMR spectra were recorded on a JEOL FX-60 spectrometer which operated at 60 MHz. Data were accumulated 500—1000 times. Temperatures were directly read by a thermocouple. The total line shape analysis was performed with the use of a modified Binsch program.[20] The chemical shift differences and coupling constants of the AB protons were checked at several temperatures, where the exchange rate was negligibly small, and were found to be constant within the experimental error. The disappearance of coupling between the NH^+ and CH_2 protons were treated by assuming that J_{AX} and J_{BX} were inversely proportional to the rate constant. T_2 was estimated to be 0.1—0.2 s and treated as a variant, taking into account the line width of tetramethylsilane, together with the rate constant. The AB part of ABX (strictly speaking AA'BB'X) showed different line widths for the A and B protons, as are seen in Fig. 1, due to the different magnitude of couplings with the X proton. Typical values for the coupling constants (J_{AB}, J_{AX}, and J_{BX} and the chemical shift differences ($\Delta\nu_{AB}$) are compiled in Table 1. They differ to some extent by concentrations. The calculated and the observed spectra were compared by the visual fitting. The agreement between the two spectra was excellent.

The rate constant (s^{-1}) used for the calculation of activation parameters shown in Table 4 and 5 are as follows (*p*-substituent, solvent, and temperatures in °C in parentheses given).

p-CH_3O($CDCl_3$): 18.0 (8.1), 23.4 (10.3), 31.8 (12.5), 38.0 (14.7), 50.0 (16.9), 66.6 (19.1) 90.6 (21.3), 118 (23.5)

Table 1. Chemical shift differences ($\Delta\nu_{AB}$) and coupling constants (J_{AB}, J_{AX}, and J_{BX}) of *N,N*-dibenzylanilinium chlorides at low temperatures

p-Substituent	Solvent	$\Delta\nu_{AB}$/Hz	J_{AB}/Hz	J_{AX}/Hz	J_{BX}/Hz
CH_3O	$CDCl_3$	25.4	−12.6	3.7	7.8
	CD_3CN	22.0	−12.9	3.7	7.8
CH_3	$CDCl_3$	24.0	−13.1	3.2	7.0
	CD_3CN	22.7	−12.9	3.9	7.8
H	$CDCl_3$	25.9	−12.6	3.8	7.5
	CD_3CN	23.3	−12.8	3.7	8.1
Cl[a)]	$CDCl_3$	24.8	−12.9	3.4	7.1

a) The coupling constsnts of this entry are those of hydrobromide which were diverted to the hydrochloride because the latter compound showed evidence of exchange, though slow, at the lowest temperature attainable in this solvent.

p-$CH_3O(CD_3CN)$: 14.0(2.3), 19.0(4.9), 29.0(8.8), 41.9(11.9), 47.0(13.6), 57.0(14.9) 74.0(17.1)
p-$CH_3(CDCl_3)$: 12.0(−7.0), 17.0(−4.1), 20.0 (−3.5), 27.0(−1.1), 29.0(−0.6), 33.0(0.5), 48.0(3.1), 60.0(5.0), 84.0(7.9), 92.0(8.5), 122(11.0)
p-$CH_3(CD_3CN)$: 18.0(−5.2), 28.2(−2.0), 38.0 (0.6), 51.0(3.2), 62.0(4.9), 84.0 (7.5)
$H(CDCl_3)$: 13.4(−9.5), 25.0(−7.4), 35.4 (−5.1), 47.0(−2.9), 62.5(−0.7), 84.0(1.5), 110(3.7)
$H(CD_3CN)$: 32.0(−9.5), 54.0(−5.1), 93.0 (−0.7), 180(3.7)
p-$Cl(CDCl_3)$: 13.0(−27.8), 16.0(−25.8) 22.0 (−23.8), 29.0(−22.0), 41.0 (−19.6), 60.0(−17.9).

Results and Discussion

In Fig. 1 are shown temperature dependent spectra of the AB part of ABX signals of N,N-dibenzyl-p-methoxyaniline hydrochloride in chloroform-d together with the calculated. This was chosen because those of N,N-dibenzylaniline hydrochloride were given in a preliminary note.[2]

Although we observe the change in line shapes of the benzylic protons, the dynamic process needs proton acceptors. Since the solvents are not basic in the normal sense, we may neglect the possibility that solvent molecules act as proton acceptors. There are three possible acceptors: chloride ion, free amine, and water. Since water in the solvent was found not easily removable, we turned our attention to the effect of water. Two methodologies were used. First we observed the NH^+ proton signal at δ *ca.* 14 and followed the line shape at temperatures where the coalescence of the CH_2 proton signal took place. No change was observed. If water in the system were the proton acceptor, coalescence of the NH^+ signal with that of water would have been observed. Secondly, we examined the rates of topomerization in chloroform-d, which was carefully dried and to which water was intentionally added.

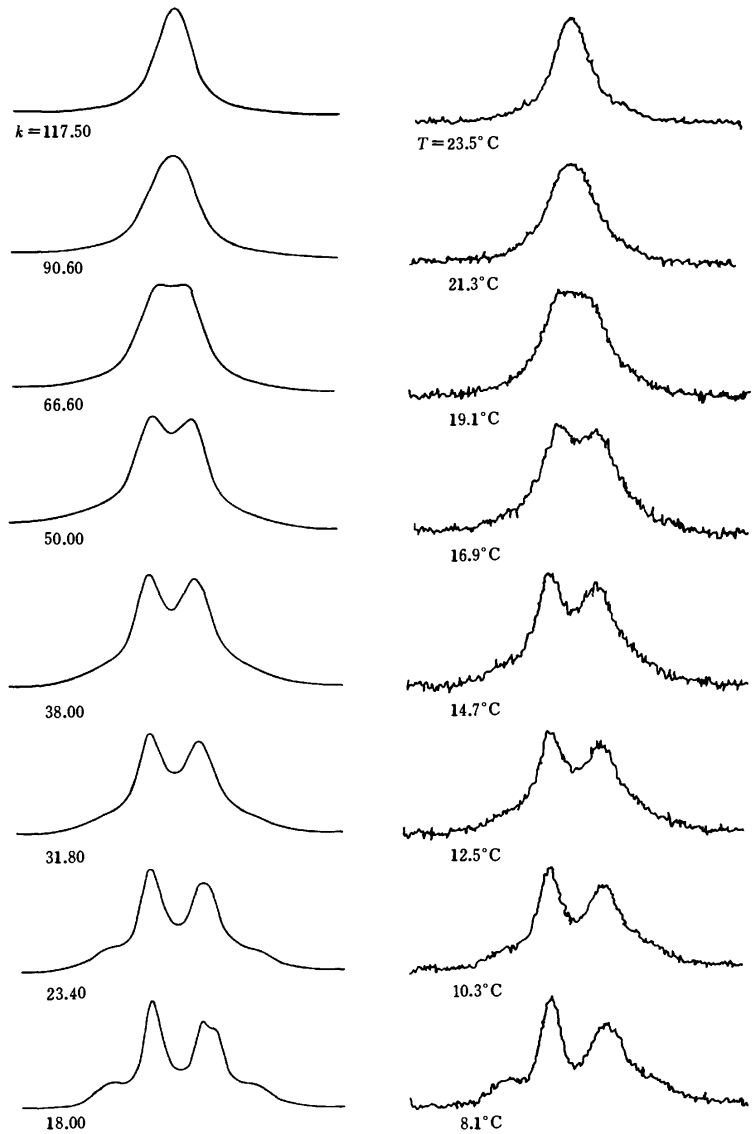


Fig. 1. Calculated and observed spectra of the AB part of ABX signals of N,N-dibenzyl-p-methoxyaniline hydrochloride in chloroform-d.

Table 2. Effect of water in the system on the kinetic parameters of proton-exchange in *N,N*-dibenzylanilinium chloride in chloroform-*d*

The results are compared in Table 2, where chloroform-*d* containing 5.4 mmol L^{-1} of water is the commercially available and is used as such. As are seen in Table 2, if water was intentionally added, the correlation coefficient in the Eyring plot became inferior and consequently the errors involved became large. Yet the free energy of activation is reproduced. We ran the similar determination of rates of dissociation in the methoxy compound with various concentrations of water. No effect of the water was observed. Therefore, as far as we use ordinary chloroform-*d*, the data are reliable. These results also rejects the possibility that water is the proton acceptor in the system.

If the free amine which exists in a minute amount in the system accepts proton, we should be able to observe the concentration effects. The data are collected at three concentrations and are summarized in Table 3. It may seem that the free energy of activation increases as the concentration increases. However, we do not believe that the tendency is significant because of the experimental errors which do not appear here. If free amine accepts proton, the rates of exchange of proton must increase as the concentration increases, contrary to the data shown in Table 3. Therefore, we conclude that the amine in the system, if any, is not the proton acceptor.

These two lines of evidence establish that the chloride ion in the system is the proton acceptor. From the concentration effect, we may conclude that the chloride ion, which exists as an ion pair with the anilinium ion, accepts proton in the process which is observed by the present technique.

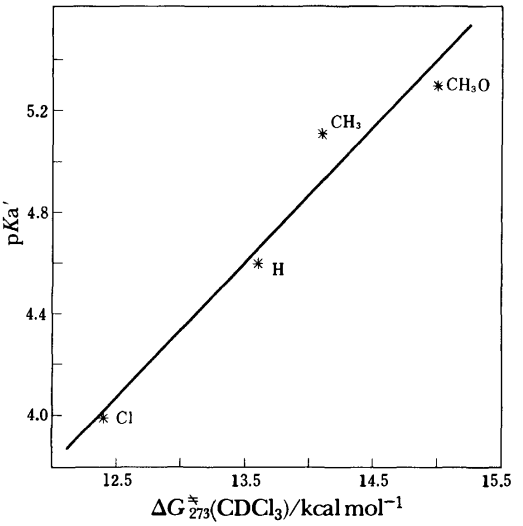

Fig. 2. Correlation between pK_a' values of *p*-substituted *N,N*-dimethylanilines and free energies of activation for the proton exchange of *p*-substituted *N,N*-dibenzylanilinium chlorides in chloroform-*d*.

Having established that the kinetic proton affinity of *N,N*-dibenzylaniline can be obtained by this technique, we turned our attention to the substituent effects. The study in this area will contribute to the genral understanding of acid-base properties of amines in aprotic solvents which are often important in organic chemistry. The results are compiled in Table 4. The results are in good agreement with the expectation from basicities in water: the *p*-methoxy compound is the strongest base and the chloro compound is the weakest of the four. It is unfortunate that the nitro compound failed to give stable hydrochloride but, if it could, the free energy of activation for the proton exchange of the compound must have been still smaller.

The feature of the data is a very large positive entropy of activation. Since the dissociation of a covalent compound into ionic species is known to be accompanied by a large negative entropy of activation,[21] the reaction studied here, from the ionic to the covalent, can be accompanied by positive entropy of activation. The freedom of motion of solvent molecules is cited to be responsible to the phenomena. The increase in entropy of activation seems to become large when we go from an electron-donating substituent to an electron-withdrawing one. If this trend is significant, that will mean that the transition state for the exchange is less covalent in the electron-rich compound than in the electron-poor one. That is the transition state is earlier in the former than in the latter. The enthalpy of activation varies little but there is a tendency that an electron-rich amine shows a large value.

It should be of interest to compare the proton affinity of the *N,N*-dibenzylanilines obtained here with those in water and in the gas phase. Hammett plot yielded a good linear relationship, the correlation coefficient being 0.979 and ρ being 3.59. Fig. 2 illustrates the relationship between the free energy of activation and the pK_a' values reported for *N,N*-dimethylanilines.[22] The correlation coefficient is 0.996. Since the proton

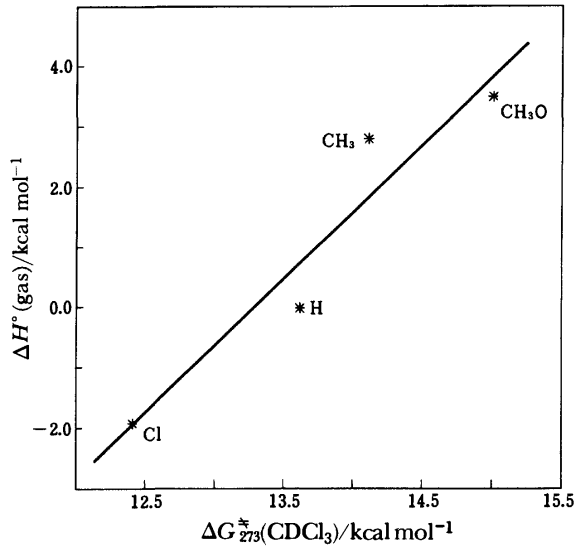

Fig. 3. Enthalpies of isodesmic process, $C_6H_5NH_3^+ + p\text{-}XC_6H_4NH_2 \rightleftharpoons C_6H_5NH_2 + p\text{-}XC_6H_4NH_3^+$ in the gas phase *vs.* free energies of activation for the proton exchange of *p*-substituted *N,N*-dibenzylanilinium chlorides in chloroform-*d*.

affinity of anilines in the gas phase is linearly correlated with the pK_a in water,[23] it will be no wonder to obtain a linear relationship between the proton affinity in the gas phase and that in the aprotic solvent. Figure 3 illustrates the result. The correlation coefficient is 0.958. Although it is known that the gas-phase proton affinity is quite different from the basicity in water when the structures of bases change,[4c] the proton affinity of substituted anilines in chloroform, at least, can be linearly correlated with the basicity in water and the proton affinity in the gas phase.

In order to get into further insight, we have tried to change the solvent. Acetone-d_6 was found to exchange proton with NH^+ and tetrahydrofuran was a poor solvent for the anilinium chloride. Acetonitrile-d_3 could afford data of 3 compounds, although the solubility of the chloro compound was too low to be practical in the measurement. The kinetic data are compiled in Table 5. The data have similar trends which are pointed out in the above sections on the behaviors in chloroform-*d* except some points discussed below.

Comparison of the data in acetonitrile-d_3 and those in chloroform-*d* reveals some interesting points. First of all, the solvent effect is not so dramatic as is expected from the change in dielectric constants. One might have expected that dissociation in acetonitrile should be slower than in chloroform because the ionic ground state is stabilized in the former. However, this similarity of the rates of dissociation in the two solvents is a mere coincidence at or near temperatures where coalescence of the signals takes place. When we divide the activation parameters into enthalpy of activation and entropy of activation, difference is clear. This may be one of the examples of enthalpy-entropy compensation effect.[24] Both enthalpy and entropy of activation with the chloroform solutions are larger than those with acetonitrile solutions. Possibly the transition state for the proton exchange in acetonitrile becomes earlier than that in chloroform because the ionic ground state is stabilized and the transition state is like the ground state in the former. The smaller entropy of activation in acetonitrile solutions than that in chloroform supports the idea. Thus we conclude that the transition state for the proton exchange in these aprotic solvents becomes early as the proton afinity of the base and the dielectric constant of the solvent increase. The rationale for the phenomena on the molecular basis undoubtedly includes the polar nature and/or hydrogen-bonding ability of the molecule but there may remain some others which are not clear at the moment.

(Received February 21, 1984)

2-Benzoylalkanoates **1** undergo photoreduction with 2-propanol. The photoreduction products are classified into three types according to their origin: the homo-pinacol-type products **2**, **5**, **7**, and **8**, the mixed-pinacol-type product **3**, and the β-hydroxy ester **6**. The product distribution is affected by α-methyl substitution. The α-methyl substitution decreases the percentage of the homo-pinacol-type products and increases the percentage of the β-hydroxy ester.

Synthetic[1] and mechanistic[2] aspects of the photoreduction of aryl alkyl ketones have been extensively investigated, and work has also been done on the photoreduction of α-dicarbonyl compounds.[3] A number of α-substituted acetophenones form pinacols upon irradiation in 2-propanol or other suitable hydrogen-donating solvents.[4] However, little attention has been given to the photoreduction of β-dicarbonyl compounds. Singh and Kagan reported[5] that ethyl acetoacetate undergoes photoreduction with alcohols to give 4,5-dihydro-4-hydroxy-2(3*H*)-furanones *via* mixed pinacols. We report here that 2-benzoyl-alkanoates **1** undergo photoreduction with 2-propanol to give the homo- and the mixed-pinacol-type products, and the β-hydroxy ester, and that the course of the photoreduction is affected by α-methyl substituents.

Results and Discussion

Irradiation of ethyl benzoylacetate (**1a**) in 2-propanol with a high-pressure mercury lamp under nitrogen yielded *meso*- and *dl*-diethyl-3,4-dihydroxy-3,4-diphenyladipates (*meso*-**2a** and *dl*-**2a**) and 4,5-dihydro-4-hydroxy-5,5-dimethyl-4-phenyl-2(3*H*)-furanone (**3a**) in 34, 32, and 6% yields, respectively. The diastereomeric pinacols *meso*-**2a** and *dl*-**2a** could be isolated by silica-gel chromatography. These compounds *meso*-**2a**, *dl*-**2a**[6] and **3a**[7] were identified by comparison with authentic samples. The dihydro-2(3*H*)-furanone **3a** can best be explained as the *secondary* product derived from an initially formed mixed pinacol **4a**. No formation of the mixed pinacol is observed in acetophenone

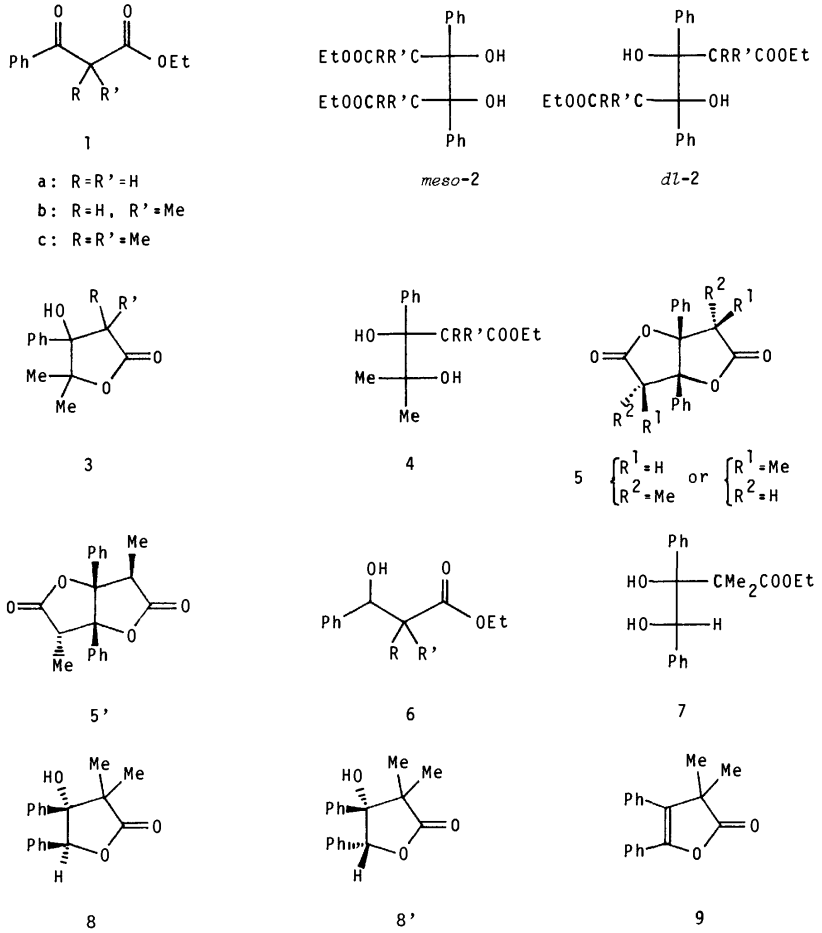

Fig. 1.

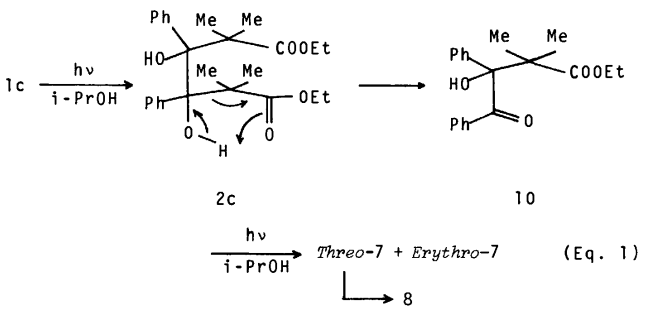
Table 1. Yields of the products in photolysis of **1a**, **1b**, and **1c**

Starting compound	Homo-pinacol-type product (Yield/%)								Mixed-pinacol-type product (Yield/%)	β-Hydroxy ester (Yield/%)
	meso-**2**	*dl*-**2**	**5**	**5′**	**7**	**8**	**8′**	Total	**3**	**6**
1a	34	32	—	—	—	—	—	66	6	—
1b	5	—	12	10	—	—	—	27	—	7
1c	—	—	—	—	7	11	1	19	14	27

photoreduction by 2-propanol.[2] Both the adipates and the dihydro-2(3*H*)-furanone formations were efficiently quenched by 1,3-pentadiene, and ethyl 2-naphthoylacetate, which is expected to have the lowest triplet with π,π^* configuration, gave no photoreduction products under the same conditions. Therefore, both the adipates and the dihydro-2(3*H*)-furanone arise from the n,π^* triplet state of the benzoylacetate **1a**.

Irradiation of ethyl 2-benzoylpropionate (**1b**) under the same conditions gave *meso*-diethyl-3,4-dihydroxy-2,5-dimethyl-3,4-diphenyladipate (**2b**), 4,8-dimethyl-1,5-diphenyl-2,6-dioxa-bicyclo[3.3.0]octane-3,7-diones (**5** and **5′**), and ethyl 3-hydroxy-2-methyl-3-phenylpropanoate (**6b**) in 5, 22 (**5**: 12, **5′**: 10), and 7% yields, respectively. The structure of **2b** was deduced from its spectroscopic and analytical data. The *meso*- and/or *dl*-isomers seem to be produced from photoreduction of the ester **1b**. However, the isolated photoproduct **2b** is deduced to be one of the isomers because the compound has a sharp melting point (184—185 °C) and shows a simple NMR spectrum. The pinacol **2b** is elucidated to have the *meso*-configuration because no dilactones were formed when the pinacol **2b** was heated at 240 °C for 30 min. The *dl*-**2a** lactonizes easily by heating, while *meso*-**2a** does not.[6] The *dl*-**2b** seems to cyclize to give dilactones **5** and **5′** under the experimental conditions. The geometry of the dilactones from *dl*-**2b** must be *cis* with respect to two phenyl groups. The stereoisomeric dilactones **5** and **5′** could be isolated by silica-gel chromatography. The IR spectra of **5** and **5′** showed the characteristic absorptions of a five-membered lactone at 1800 and 1790 cm^{-1}, respectively. The ^1H NMR signals of the two methyl groups in **5** appeared at δ 1.24 while those signals in **5′** were observed at δ 1.18 and 1.20. The methyl groups in **5** are equivalent and are either *cis* or *trans* to the neighboring phenyl group. On the other hand, one methyl group in **5′** might be *cis* to the neighboring phenyl group and the other might be *trans*. The ^{13}C NMR spectra also support the assignment of **5** and **5′**. The β-hydroxy ester **6b** was identified by direct comparison with an authentic sample.[8] This type of the product is found in acetophenone photoreduction with 2-propanol.[2] No products derived from a mixed pinacol were isolated; however, the possibility of their presence in small amounts cannot be eliminated.

Irradiation of ethyl 2-benzoyl-2-methylpropanoate (**1c**) under the same conditions gave 4,5-dihydro-4-hydroxy-3,3,5,5-tetramethyl-4-phenyl-2(3*H*)-furanone (**3c**), ethyl 3-hydroxy-2,2-dimethyl-3-phenylpropanoate (**6c**), ethyl 3,4-dihydroxy-2,2-dimethyl-3,4-diphenylbutanoate (**7**), and 4,5-dihydro-4-hydroxy-3,3-dimethyl-4,5-diphenyl-2(3*H*)-furanones (**8** and **8′**) in 14, 27, 7, and 12 (**8**: 11, **8′**: 1) % yields, respectively. The hydroxy ester **6c** was identified by comparison with an authentic sample.[9] The structural assignment of **3c** was based on its spectroscopic and analytical data. The IR spectrum of **3c** showed a γ-lactone carbonyl band at 1760 cm^{-1} and hydroxy bands at 3600 and 3400 cm^{-1}. The ^1H NMR spectrum showed four methyl singlets at δ 1.04, 1.20, 1.45, and 1.60. The lactone **3c** seems to be the *secondary* product derived from an initially formed mixed pinacol **4c**. In the photoreduction of isobutyrophenone or pivalophenone by 2-propanol, no mixed pinacols are found.[2] The structures of **7**, **8**, and **8′** were deduced from their spectroscopic and analytical data and further supported by the chemical evidence. The hydroxy lactone **8′** underwent dehydration to give 3,3-dimethyl-4,5-diphenyl-2(3*H*)-furanone (**9**) by heating in dioxane in the presence of *p*-toluenesulfonic acid, while the lactone **8** was recovered under the same conditions. Therefore, the hydroxyl group should be *trans* in **8′** and *cis* in **8** to the C_5-hydrogen atom. The dihydroxy ester **7** cyclized to give the lactone **8′** when the ester was heated at 250°C for 15 min. No isomeric lactone **8** could be detected. This fact suggests that the dihydroxy ester **7** has an *erythro*-geometry. The ester **7** seems to be produced from the homo-pinacol *meso*-**2c** and/or dl-**2c** *via* a phenyl ketone **10**, though these intermediates could not be isolated (Eq. 1). Elimination of ethyl 2-



Scheme 1.

methylpropanoate from the pinacol **2c** probably occurs easily owing to the steric compression. Photoreduction of the ketone **10** will give the *erythro*-dihydroxy ester **7** and its *threo*-isomer. The IR absorption at 1690 cm^{-1} in the *erythro*-ester **7** suggests the presence of the intramolecular hydrogen bonding between the carbonyl group and the C_3-hydroxyl group. The hydrogen bonding is also expected in the *threo*-isomer. The rate of lactonization of these dihydroxy esters might be enhanced by the participation of the C_3-hydroxyl group because of the decrease in electron density at the carbonyl carbon atom. The *threo*-isomer is probably reactive enough to lactonize easily to give **8**. However, the *erythro*-isomer is stable under the experimental conditions. The stability of the *erythro*-isomer may be explained in terms of the lack of the participation of the C_3-hydroxyl group in the early stage of the transition

state,because of steric repulsive interaction between the C_4-phenyl and the C_3-hydroxyl group. The C_4-phenyl group must be eclipse to the C_3-hydroxyl group in the transition state.

Photoreduction products from 2-benzoylalkanoates **1a**, **1b**, and **1c** are classified into three types according to their origin: the homo-pinacol-type products **2**, **4**, **7**, **8**, and **8′**, the mixed-pinacol-type product **3**, and the β-hydroxy ester **6**. The total yield of the homo-pinacol-type products decreases upon α-methyl substitution, while that of the hydroxy ester increases upon the substitution. These results can be explained in terms of an increment of the steric hindrance in free radical combination.

Experimental

All melting points were uncorrected. The IR spectra were recorded on a JASCO IRA-2 spectrometer. The ^1H and ^{13}C NMR spectra were measured on a JEOL FX-90Q spectrometer using TMS as an internal standard. The mass spectra were obtained with a JEOL JMS-OlSG-2 spectrometer. Irradiations were carried out with an Ushio 450 W high-pressure mercury lamp or a Rikoh Kagaku 100 W high-pressure mercury lamp with a water-cooled Pyrex jacket.

Chemicals. Ethyl benzoylacetate (**1a**) from Tokyo Kasei Kogyo Co. was purified by distillation. Ethyl 2-benzoylpropanoate (**1b**),[9] ethyl 2-benzoyl-2-methylpropanoate (**1c**),[10] and ethyl 2-naphthoylacetate[11] were pepared according to the reported methods.

Photoreaction of 1a. A solution of **1a** (1.018 g, 5.30 mmol) in 2-propanol (60 cm^3) was irradiated for 30 h under nitrogen with a 450 W high-pressure mercury lamp. After removal of the solvent, the residue was chromatographed on silica gel. Elution with benzene–ethyl acetate (10:1) gave *meso*-**2a** (348 mg, 34%), *dl*-**2a** (330 mg, 32%), and **3a** (63 mg, 6%). The spectroscopic data of *meso*-**2a**, *dl*-**2a**, and **3a** were identical with those of the authentic samples.[6,7]

Photoreaction of 1b. A solution of **1b** (1.200 g, 5.83 mmol) in 2-propanol (120 cm^3) was irradiated for 3.5 h with a 100 W high-pressure mercury lamp. The usual work-up gave the unreacted ester **1b** (300 mg), *meso*-**2b** (46 mg, 5%), **5** (110 mg, 12%), **5′** (90 mg, 10%), and *threo/erythro* 1:1 mixture of **6b** (65 mg, 7%). The spectroscopic data of **6b** were identical with those of the authentic sample.[8] *meso*-**2b** mp 184—185 °C; IR ($CHCl_3$) 3500 and 1700 cm^{-1}; ^1H NMR ($CDCl_3$) δ= 0.59 (6H, d, J=7.0 Hz, CH_3), 0.78 (6H, t, J=7.2 Hz, CH_3), 3.55 (2H, q, J=7.0 Hz, CH), 3.56 (4H, q, J=7.2 Hz, CH_2), 3.86 (1H, s, OH), *ca.* 7.10—7.30 (6H, m, aromatic), and *ca.* 7.50—7.70 (4H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=1.36 (q, 4C), 46.8 (d, 2C), 60.2 (t, 2C), 79.7 (s, 2C), 127.1 (d, 8C), 128.3 (d, 2C), 144.8 (s, 2C), and 176.7 (s, 2C). Found: C, 69.28; H, 7.21%. Calcd for $C_{24}H_{30}O_6$: C, 69.54; H, 7.30%. **5** mp 191—192 °C; IR ($CHCl_3$) 1800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.24 (6H, d, J=7.2 Hz, CH_3), 3.30 (2H, q, J=7.2 Hz, CH), *ca.* 6.65—7.00 (4H, m, aromatic), and *ca.* 7.00—7.40 (6H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=7.6 (q, 2C), 43.4 (d, 2C), 93.4 (s, 2C), 126.0 (d, 4C), 128.5 (d, 4C), 129.1 (d, 2C), 132.4 (s, 2C), and 174.5 (s, 2C); MS m/z 322 (M^+). Found: C, 74.35; H, 5.62%. Calcd for $C_{20}H_{18}O_4$: C, 74.51; H, 5.62%. **5′** mp 167—168 °C; IR ($CHCl_3$) 1790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.18 (3H, d, J=8.4 Hz, CH_3), 1.20 (3H, d, J=7.2 Hz, CH_3), 3.11 (1H, q, J=8.4 Hz, CH), 3.17 (1H, q, J=8.4 Hz, CH), and *ca.* 6.60—7.40 (10H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=7.9 (q), 14.8 (q), 44.5 (d), 47.5 (d), 92.6 (s), 94.8 (s), 126.8 (d, 2C), 127.4 (d, 2C), 127.6 (d, 2C), 128.5 (d, 2C), 129.0 (d), 129.4 (d), 131.4 (s), 133.8 (s), 173.8 (s), and 176.2 (s). Found: C, 74.38; H, 5.62%. Calcd for $C_{20}H_{18}O_4$: C, 74.51; H, 5.62%.

Photoreaction of 1c. A solution of **1c** (4.000 g, 18.18 mmol) in 2-propanol (400 cm^3) was irradiated for 12 h with a 450 W high-pressure mercury lamp. The usual work-up gave the unreacted ester **1c** (2.164 g), **3c** (260 mg, 14%), **6c** (500 mg, 27%), **7** (125 mg, 7%), **8** (195 mg, 11%), and **8′** (20 mg, 1%). The spectroscopic data of **6c** was identical with those of the authentic sample.[9] **3c** mp 151—152 °C; IR ($CHCl_3$) 3600, 3400, and 1760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.04 (3H, s, CH_3), 1.20 (3H, s, CH_3), 1.45 (3H, s, CH_3), 1.60 (3H, s, CH_3), 2.31 (1H, s, OH), and *ca.* 7.15—7.50 (5H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=23.5 (q), 23.9 (q), 26.0 (q), 27.0 (q), 48.6 (s), 83.7 (s), 88.3 (s), 126.6 (d, 2C), 127.6 (d, 2C), 127.8 (d), 140.5 (s), and 181.0 (s). Found: C, 71.53; H, 7.69%. Calcd for $C_{14}H_{18}O_3$: C, 71.77; H, 7.74%. **7** mp 106—107 °C; IR ($CHCl_3$) 3600, 3450, and 1690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.94 (3H, s, CH_3), 1.05 (3H, t, J=7.0 Hz, CH_3), 1.32 (3H, s, CH_3), 2.76 (1H, d, J= 7.0 Hz, OH, D_2O exchangeable), *ca.* 3.10—3.70 (2H, m, CH_2), 5.32 (1H, d, J=7.0 Hz, CH), 5.64 (1H, s, OH, D_2O exchangeable), and *ca.* 7.20—7.80 (10H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=13.5 (q), 20.6 (q), 25.0 (q), 47.5 (s), 61.2 (t), 76.2 (d), 82.5 (s), 127.3 (d), 127.4 (d, 2C), 127.7 (d, 2C), 128.0 (d), 128.3 (d, 2C), 129.2 (d, 2C), 140.0 (s), 140.1 (s), and 178.2 (s). Found: C, 73.03; H, 7.25%. Calcd for $C_{20}H_{24}O_4$: C, 73.14; H, 7.37%. **8** mp 169—170 °C; IR ($CHCl_3$) 3550 and 1775 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.08 (3H, s, CH_3), 1.23 (3H, s, CH_3), 1.54 (1H, s, OH), 6.24 (1H, s, CH), and *ca.* 7.20—7.65 (10H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=16.2 (q), 22.8 (q), 49.7 (s), 81.8 (d), 83.3 (s), 126.8 (d, 3C), 128.3 (d, 3C), 128.6 (d, 2C), 128.8 (d, 2C), 133.0 (s), 137.3 (s), and 179.7 (s); MS m/z (rel intensity) 282 (M^+, 3), 148 (100), 133 (21), 105 (40), and 77 (19). Found: C, 76.51; H, 6.36%. Calcd for $C_{18}H_{18}O_3$: C, 76.57; H, 6.43%. **8′** mp 207—208 °C (lit,[12] 210—212 °C); IR ($CHCl_3$) 3450 and 1775 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.94 (3H, s, CH_3), 1.56 (3H, s, CH_3), 2.44 (1H, s, OH), 5.76 (1H, s, CH), and *ca.* 6.90—7.40 (10H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=19.6 (q), 21.9 (q), 48.9 (s), 84.7 (s), 85.1 (d), 125.4 (d, 2C), 125.6 (d, 2C), 127.5 (d, 2C), 127.8 (d, 2C), 127.9 (d, 2C), 134.7 (s), 138.3 (s), and 179.9 (s); MS m/z (rel intensity) 282 (M^+ 2), 148 (100), 134 (19), 105 (26), and 77 (10). Found: C, 76.53; H, 6.42%. Calcd for $C_{18}H_{18}O_3$: C, 76.57; H, 6.43%.

Dehydration of 8′. A solution of 23.0 mg of **8′** and 35 mg of *p*-toluenesulfonic acid in 11 cm^3 of dioxane was heated under reflux for 50 h. The solvent was evaporated, and the residue was extracted with ether. After the usual work-up, the reaction mixture was chromatographed on silica gel to give 18.8 mg (89%) of 3,3-dimethyl-4,5-diphenyl-2(3*H*)-furanone (**9**): mp 107—108 °C; IR ($CHCl_3$) 1800 cm^{-1}; ^1H-NMR ($CDCl_3$) δ=1.36 (6H, s, CH_3) and *ca.* 7.10—7.50 (10H, m, aromatic); ^{13}C NMR ($CDCl_3$) δ=23.4 (q, 2C), 48.1 (s), 123.9 (s), 126.9 (d, 3C), 128.2 (d, 3C), 128.8 (s), 129.0 (d, 2C), 129.7 (d, 2C), 132.6 (s), 145.4 (s), and 181.0 (s). Found: C, 81.88; H, 6.04%. Calcd for $C_{18}H_{16}O_2$: C, 81.79; H, 6.10%.

Thermolysis of 7. The dihydroxy ester **7** (8.8 mg) was sealed in a Pyrex tube, and heated at 250 °C for 15 min. The ^1H NMR analysis showed that the thermolysis mixture consists of ethanol, ethyl 2-methylpropanoate, benzoin, and dihydro-2(3*H*)-furanone **8′** in a 1:1:1:1 ratio.

Optical Resolution of DL-Valine, DL-Leucine, and DL-Isoleucine by Formation of Adduct with L-Phenylalanine

Tadashi SHIRAIWA,* Akihiko IKAWA, Keiji SAKAGUCHI, and Hidemoto KUROKAWA
Faculty of Engineering, Kansai University, Yamate-cho, Suita-shi, Osaka 564
(Received March 7, 1984)

An alkaline solution containing L-phenylalanine (L-Phe) and one of DL-valine, DL-leucine, and DL-isoleucine is allowed to selectively form a precipitate composed of L-Phe and the aliphatic D-amino acid by adjusting the pH of initial solution to around 5.5 with hydrochloric acid. ^{1}H NMR spectra in deuterium oxide, elemental analyses, and infrared spectra of the precipitates indicate that they are adducts of the aliphatic D-amino acid and L-Phe in the molar ratio of 1:1. The free aliphatic D-amino acids with high optical purity (84—100%) may be recovered from the adducts in 49—63% yield. An attempt was made to obtain both the aliphatic D- and L-amino acids by using an aqueous solution containig the aliphatic DL-amino acid and L-Phe as an initial solution. The aliphatic L-amino acids obtained had optical purity of 47—85%.

A number of studies have been reported on optical resolution of DL-amino acids, and most of them have employed the preferential crystallization procedure.[1-8] Although the advantages of this procedure have been well recognized,[9,10] it should be noted that a racemate crystallizes as a conglomerate from a racemic solution and not as a racemic compound. Most of free DL-amino acids form racemic compounds and have no properties suitable for this procedure. Therefore, many of optical resolutions by this procedure have been carried out in the form of salts[3,6] or their derivatives such as *N*-acyl compounds.[1,2,4,5,7,8] Free optically active amino acids are recovered by hydrolysis of resolved derivatives, and the process may result in lowering of yield and partial racemization.

The diastereomeric procedure has also been employed for the optical resolution of DL-amino acids,[11-15] which does not require the racemate to be a conglomerate. However, since free DL-amino acids scarcely form salts with ordinary optically active organic acids or bases, their derivatives, such as *N*-acyl compounds and esters,[11-15] have been resolved by this procedure. Therefore, this procedure may have a disadvantage similar to that of the preferential crystallization procedure. In order to overcome this disadvantage, the free D- or L-amino acid should selectively form a salt or adduct with an optically active compound, and the free optically active amino acid should be easy to be recovered from the resolved salt or adduct.

Since it is possible to regard a DL-amino acids as an adduct composed of a pair of enantiomers, one enantiomer may form an adduct with an optically active amino acid. This paper describes an attempt to resolve aliphatic DL-amino acids, DL-valine (abbreviated as DL-Val), DL-leucine (DL-Leu), and DL-isoleucine (DL-Ile), *via* formation of adduct with L-phenylalanine (L-Phe). An alkaline solution containing the aliphatic DL-amino acid and L-Phe selectively gave a crystalline adduct of the aliphatic D-amino acid with L-Phe when the pH of the initial solution was adjusted to around 5.5 with hydrochloric acid. The free aliphatic D-amino acids were easy to be recovered from the adducts since active carbon is capable of adsorbing L-Phe and scarcely Val, Leu, or Ile.[16] The optical resolution of DL-Val, DL-Leu, and DL-Ile has been achieved with these ideas, and D-Val, D-Leu, and D-Ile with high optical purity (84—100%) were obtained in 49—63% yield. It was attemted to obtain the aliphatic D- and L-amino acids by using an aqueous solution as an initial solution, and the L-amino acids with optical purity of 47—85% were also obtained.

Experimental

Amino Acids. DL-Val and DL-Ile were purchased from Nakarai Chemicals, Ltd., and DL-Leu and L-Phe from Wako Pure Chemicals Ind. These amino acids were recrystallized from water. The specific rotation of the recrystallized L-Phe was $[\alpha]_D^{20}$ −4.5° (*c* 1.0, 5 mol dm^{-3} HCl) ($[\alpha]_D^{20}$ −4.5° (*c* 1.0, 5 mol dm^{-3} HCl)).[17]

Optical Resolution of DL-Valine. Procedure I: Equimolar amounts (0.01 mol) of L-Phe and DL-Val were dissolved in 20 cm^3 of 1 mol dm^{-3} aqueous sodium hydroxide and 10 cm^3 of water. The pH was adjusted to around 5.5 with 1 mol dm^{-3} hydrochloric acid. After adding 80 cm^3 ethanol, the solution was stirred for 90 min at room temperature. The precipitate (I-**1**) formed was collected by filtration. The filtrate was concentrated to 20 cm^3 under reduced pressure at around 40 °C, and the precipitate (I-**2**) deposited on cooling the solution at 0 °C for 45 min was filtered off.

Procedure II: A solution containing equimolar amounts (0.01 mol) of L-Phe and DL-Val in 150 cm^3 of water was concentrated to 40 cm^3 under reduced pressure at around 40 °C. The precipitate (II-**1**) formed was collected by filtration. After adding 20 cm^3 of ethanol to the filtrate, the solution was allowed to stand overnight at 0 °C. The precipitate (II-**2**) formed was collected by filtration. To the filtrate was added 160 cm^3 of ethanol and the solution was concentrated to 30 cm^3. The precipitate (II-**3**) deposited after cooling overnight at 0 °C was collected by filtration. The filtrate was evaporated to dryness under reduced pressure at around 40 °C, and the residue (II-**4**) was obtained.

Optical Resolution of DL-Leucine. Procedure I: Equimolar amounts (0.01 mol) of L-Phe and DL-Leu were dissolved in 20 cm^3 of 1 mol dm^{-3} aqueous sodium hydroxide and 40 cm^3 of water. The pH was adjusted to around 5.5 with 1 mol dm^{-3} hydrochloric acid. The solution was concentrated to 30 cm^3, and the precipitate (I-**1**) formed was collected by filtration. After adding 20 cm^3 of ethanol to the filtrate, the solution was concentrated to 20 cm^3. The precipitate (I-**2**) formed was filtered off.

Procedure II: Equimolar amounts (0.01 mol) of L-Phe and DL-Leu were added to 200 cm^3 of water and dissolved at around 60 °C. The solution was concentrated to 100 cm^3, and the precipitate (II-**1**) deposited after cooling overnight at 0 °C was collected by filtration. The filtrate was concentrated to 30 cm^3, and the precipitate (II-**2**) formed was collected by filtration. After adding 20 cm^3 of ethanol to the filtrate, the

solution was allowed to stand overnight at 0 °C, and the precipitate (II-3) formed was collected by filtration. The filtrate was evaporated to dryness under reduced pressure, and the residue (II-4) was obtained.

Optical Resolution of DL-*Isoleucine.* *Procedure I*: Equimolar amounts (0.01 mol) of L-Phe and DL-Ile were dissolved in 20 cm^3 of 1 mol dm^{-3} aqueous sodium hydroxide and 30 cm^3 of water. The pH was adjusted to around 5.5 with 1 mol dm^{-3} hydrochloric acid. The solution was concentrated to 20 cm^3, and the preciptitate (I-1) formed was collected by filtration. After adding 150 cm^3 of ethanol to the filtrate, the solution was stirred for 60 min at room temperature, and the precipitate (I-2) formed was filtered off.

Procedure II: A solution containing equimolar amounts (0.01 mol) of L-Phe and DL-Ile in 200 cm^3 of water was concentrated to 50 cm^3. The solution was allowed to stand overnight at 0 °C, and the precipitate (II-1) formed was collected by filtration. After adding 100 cm^3 of ethanol to the filtrate, the solution was stirred for 60 min at room temperature, and the precipitate (II-2) formed was collected by filtration. The filtrate was concentrated to 25 cm^3 and the solution was allowed to stand overnight at 0 °C. The precipitate (II-3) formed was collected by filtration. The filtrate was evaporated to dryness under reduced pressure, and the residue (II-4) was obtained.

Preparation of Free Aliphatic Amino Acids. The precipitates obtained in the above procedures were dissolved in a minimum amount of water. To the aqueous solution was added active carbon, and the mixture was shaken for 3 h at room temperature. The mixture was filtered, and the filtrate was evaporated to dryness under reduced pressure at around 40 °C. The ^1H NMR spectrum of the residue was measured without recrystallization, and it was confirmed that the residue was the free aliphatic amino acid and was free from L-Phe. The optical purities of the free aliphatic amino acids obtained were determined on the basis of the specific rotations of the corresponding L-amino acids.[17]

Preparation of Adducts. L-Phe (0.005 mol) and 0.01 mol of DL-Val, DL-Leu or DL-Ile were dissolved in 15 cm^3 of 1 mol dm^{-3} aqueous sodium hydroxide. Only to the alkaline solution containing L-Phe and DL-Leu was added 30 cm^3 of water. The pH of the alkaline solutions was adjusted to around 5.5 with 1 mol dm^{-3} hydrochloric acid at 0, 25, or 50 °C. From the solution containing L-Phe and DL-Leu, a precipitate appeared after a stirring for several minutes. From the solution containing L-Phe and DL-Val or DL-Ile, a precipitate was deposited by adding an appropriate amount of ethanol. After stirring for 5—120 min at the respective temperatures, the precipitates were filtered off and the ^1H NMR spectra were measured without recrystallization. The precipitates were treated with active carbon in a similar manner as above.

The adduct composed of L-Phe and D-Val with optical purity of 100%. Found: C, 59.34; H, 7.93; N, 9.95. Calcd for $C_{14}H_{22}N_2O_4$: C, 59.56; H, 7.85; N, 9.92. $[\alpha]_D^{20}$ −14.6 ° (*c* 0.50, 5 mol dm^{-3} HCl).

The adduct composed of L-Phe and D-Leu with optical purity of 100%. Found: C, 60.50; H, 8.19; N, 9.45. Calcd for $C_{15}H_{24}N_2O_4$: C, 60.79; H, 8.16; N, 9.45. $[\alpha]_D^{20}$ −9.5 ° (*c* 0.50, 5 mol dm^{-3} HCl).

The adduct composed of L-Phe and D-Ile with optical purity of 96.8%. Found: C, 60.49; H, 8.23; N, 9.44. Calcd for $C_{15}H_{24}N_2O_4$: C, 60.79; H, 8.16; N, 9.45. $[\alpha]_D^{20}$ −19.8 ° (*c* 0.50, 5 mol dm^{-3} HCl).

Measurements. Specific rotations were measured with a Union Giken high sensitivity PM-101 digital polarimeter in 5 mol dm^{-3} hydrochloric acid by using a 0.5 dm path length quartz cell. ^1H NMR spectra were recorded on a JEOL JNM-PMX 60 NMR spectrometer in deuterium oxide. Infrared spectra were obtained in the range 4000—400 cm^{-1} with a JASCO A-102 infrared spectrophotometer by the KBr disk method.

Results and Discussion

Formation of Adducts. The adducts of Val, Leu, and Ile with L-Phe were prepared under several conditions as given in Table 1. The adducts were determined by elemental analyses and ^1H NMR spectra in deuterium oxide and found to be composed of equimolar amounts of L-Phe and the aliphatic amino acid. Aqueous solutions of each adduct were treated with active carbon to remove L-Phe by adsorption.[16] The recovered free aliphatic amino acids were of D-configuration, and those obtained under the prescribed conditions had optical purity of about 100%. The results indicate that the alkaline solution containing the aliphatic DL-amino acid and L-Phe selectively give

a) The amount of aliphatic DL-amino acids consumed by reaction was 0.01 mol and that of L-Phe was 0.005 mol. b) $[\alpha]_D^{20}$ (*c* 1.00, 5 mol dm^{-3} HCl). c) Yield(%)=(Yield(g)×100)/(1/2) (Reacted amount of DL-amino acid).

a crystalline adduct of the aliphatic D-amino acid with L-Phe.

Infrared Spectra. Infrared spectra of the adducts of the aliphatic D-amino acids with L-Phe were measured and were compared with those of the free DL- and L-amino acids. The spectral patterns are similar to those of the free DL-amino acids, different from those of the free L-amino acids. The bands due to groups COO^- and NH_3^+ were assigned as such since it is considered that the groups are most strongly influenced by formation of the adducts. The band at about 2950 cm^{-1} was assigned to the NH streching, the band at about 1625 cm^{-1} (shoulder) to the antisymmetric NH deformation, and the band at about 1500 cm^{-1} to the symmetric NH deformation. The antisymmetric CO band (ν_{CO}(as)) appears at about 1590 cm^{-1}, and the symmetric band at 1410 cm^{-1}. A most significant difference in the spectra is noticed between the ν_{CO}(as)'s of the adducts and L-Phe. The ν_{CO}(as) of L-Phe appears at 1558 cm^{-1}, whereas the spectra of the adducts have no bands in the range 1570—1530 cm^{-1}. The ν_{CO}(as)'s of the adducts are observed at wave number positions similarly to that of DL-Phe (1585 cm^{-1}). These results suggest that the interaction between the aliphatic D-amino acid and L-Phe in the adduct is analogous to that between a pair of the enantiomers in the DL-amino acid, and that these adducts are not mere mixtues of the aliphatic D-amino acid and L-Phe.

Optical Resolutions. The optical resolution of DL-Val, DL-Leu, and DL-Ile was achieved at room temperature by using two kinds of procedures (I and II). The results are given in Tables 2, 3, and 4. The precipitate numbers in these tables have been defined in the experimental section.

In procedure I, an alkaline solution containing equimolar amounts of L-Phe and the aliphatic DL-amino acid was used as an initial solution. The ^1H NMR spectra of precipitates **I-1** and **I-2** indicated that these precipitates are composed of equimolar amounts of L-Phe and the aliphatic amino acid. The Val, Leu, and Ile from the precipitates are of D-configuration, and the aliphatic D-amino acids with optical purity of 84—100% were obtained in 49—63% yield. After these precipitates were filtered off, sodium chloride was

also deposited with the mixture of the amino acids by further concentrating the filtrate or adding ethanol. Since it was tedious to remove sodium chloride, no attempt was made to obtain the aliphatic L-amino acids.

In procedure II, an aqueous solution containing only equimolar amounts of L-Phe and the aliphatic DL-amino acid was used as an initial solution, and it was attempted to obtain both the aliphatic D- and L-amino acids.

In the optical resolution of DL-Val by this procedure, the ^1H NMR spectrum and specific rotation indicated that precipitate II-**1** is L-Phe ($[\alpha]_D^{20}$ −4.4° (*c* 0.50, 5 mol dm^{-3} HCl)); L-Phe is allowed to crystallize first since the solubility of DL-Val is much higher than that of L-Phe. Precipitate II-**2** is composed of equimolar amounts of L-Phe and Val. The Val from this precipitate is of D-configuration, and was recovered in 51.2% yield with optical purity of 98.3%. Precipitates II-**3** and II-**4** are composed of Val and L-Phe in the molar ratio of around 1.8:1. L-Val was recovered from precipitate II-**4**, and was obtained in 34.8% yield, with optical purity of 85.4%.

In the optical resolution of DL-Leu by procedure II, precipitates II-**1** and II-**2** are composed of equimolar amounts of L-Phe and Leu. The D-Leu from these precipitates had over 95% optical purity, and was obtained in 60% total yield. L-Leu with optical purity of 47.5% was obtained from precipitate II-**4** in 52.6% yield. Precipitate II-**4** is composed of Leu and L-Phe in the molar ratio of 0.8:1.

In the optical resolution of DL-Ile by procedure II, precipitate II-**1** deposited from the initial solution is composed of Ile and L-Phe in the molar ratio of about 0.6:1, and precipitate II-**2** in 1:1. However, the D-Ile from these precipitates had high optical purity (81.7 and 93.3%), and the total yield was 47.8%. The molar amount of Ile contained in precipitates II-**3** and II-**4** was about 1.8 times that of L-Phe. The L-Ile from precipitate II-**4** had an optical purity of 68.1% and was obtained in 42.1% yield.

The above results indicate that it is possible to resolve DL-Val, DL-Leu, and DL-Ile *via* formation of adducts with L-Phe.

Manufacturing Process of Sodium Hydroxide and Nitric Acid from Thermochemically Split Sodium Nitrate

Norio TAKEUCHI

Energy Chemistry Division, National Chemical Laboratory for Industry, Tsukuba Research Center, Yatabe, Ibaraki 305

(Received September 21, 1983)

For the manufacture of sodium hydroxide and nitric acid a new thermochemical process of splitting sodium nitrate has been proposed which consists of (i) splitting of sodium nitrate by iron(III) oxide, (ii) hydrolysis of sodium ferrate, and (iii) absorption of nitrogen dioxide into water. Key reactions (i) and (ii) have experimentally been verified. The overall heat requirement for the process is discussed on the basis of a material and heat flow-sheet of the process constructed.

Electricity has been rising in cost in many countries, particularly in Japan, since the first and second international rises in the price of crude oil. As a result, new energy-saving processes have been required for the manufacture of sodium hydroxide in place of the conventional electrolytic process of sodium chloride which consumes much electric energy.

There were two industrially practised processes of manufacturing sodium hydroxide except the conventional electrolytic process. Both of them used Na_2CO_3 as a raw material. As generally known, one of them was the oldest manufacturing process of NaOH that utilized a double decomposition reaction between Na_2CO_3 and $Ca(OH)_2$. Although this process was simple, it could only produce a dilute aqueous solution of NaOH with a poor conversion rate from carbonate to hydroxide. For instance, it produced a sodium hydroxide solution of 10—11 wt% with a conversion rate of about 90%. The other process was called the Löwig process.[1] This consisted of two reactions, one producing sodium ferrate through an interaction between Na_2CO_3 and Fe_2O_3 and the other being a hydrolysis of sodium ferrate to produce NaOH. The Löwig process had two merits: the first was that Fe_2O_3 used in the process could be reused without being consumed; the second was that a sodium hydroxide solution of about 30 wt% formed was industrially available. However, this process released CO_2 into the atmosphere. This is not preferable nowadays from a viewpoint of the prevention of global atmospheric pollution.

The process to be proposed in this study will neither release any gases into the atmosphere, nor produce any unnecessary by-products. The sodium hydroxide aqueous solution to be formed is industrially available in the respect of concentration, as with the Löwig process. In addition, the raw materials for this process are only $NaNO_3$ and H_2O. As generally known, $NaNO_3$ is contained in large quantity in Chile saltpeter which is an abundant natural resource in Chile and Peru.

The thermochemical splitting process of $NaNO_3$ proposed here is composed of the three chemical reactions

$$NaNO_3 + 1/2Fe_2O_3 \longrightarrow NaFeO_2 + NO_2 + 1/4O_2, \quad (1)$$

$$NaFeO_2 + 1/2H_2O \longrightarrow NaOH + 1/2Fe_2O_3, \quad (2)$$

$$NO_2 + 1/4O_2 + 1/2H_2O \longrightarrow HNO_3, \quad (3)$$

which sequence leads to the overall reaction

$$NaNO_3 + H_2O \longrightarrow NaOH + HNO_3. \quad (4)$$

Fe_2O_3 circulates between Reactions 1 and 2. Reaction 3 is the same as the absorption step of NO_2 into water in the current manufacturing process of nitric acid.

The object of the present work is divided into two: (1) Characterization and experimental verification of the reactions concerning the proposed process, and (2) construction of the material and heat flow-sheet to estimate the overall heat requirement for the manufacture of NaOH and HNO_3 by this thermochemical process.

Reaction Characteristics and Experimental Verification

Reaction 1. Thermal Analysis: Mixtures of $NaNO_3 + xFe_2O_3$ (x=0—1.0) were analyzed by DTA from 25 to 1000 °C in a stream of nitrogen at a heating rate of 300 °C/h. Every mixture used for the thermal analysis was 100 mg in a shape of powder. Powdered iron(III) oxide used was identified with hematite by X-ray diffraction pattern, and its particle size was 75—105 μm for 64 wt% and less than 46 μm for the rest. DTA curves were obtained by use of a differential thermal analyzer (Type TA3-L, Chyo Balance Corporation, Japan). Results are shown in Fig. 1. The endothermic peaks at 278 and 308 °C on every DTA curve in Fig. 1 correspond to the transition and fusion of $NaNO_3$.[2] Every curve shows a gradual endothermic peak over 400 °C which shifts to higher temperatures with increasing content of $NaNO_3$ in mixtures. The peaks for the mixtures at 600—700 °C indicate the end of reaction more clearly than the peak for pure $NaNO_3$. Both pure $NaNO_3$ and the mixtures, however, have similar patterns in their DTA curves. Therefore, it is estimated from

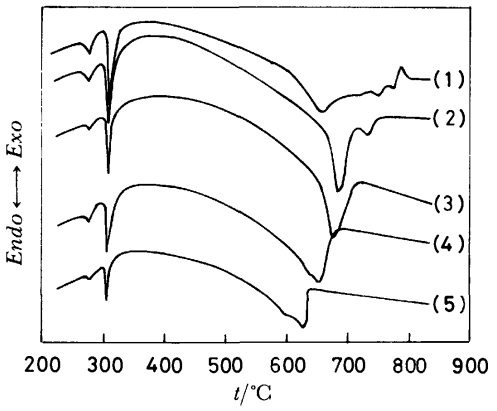

Fig. 1. DTA curves for mixtures of $NaNO_3$ and Fe_2O_3.
Heating rate: 5 °C/min, Atmosphere: N_2 50 ml/min.
$NaNO_3/Fe_2O_3$=(1): pure $NaNO_3$, (2): 2.5, (3): 2.0, (4): 1.5, (5): 1.0.

the thermal analysis that Reaction 1 is essentially a decomposition of $NaNO_3$ in conjunction with Fe_2O_3.

X-Ray Analysis: In order to grasp the outline of Reaction 1, an X-ray analysis was conducted with the solid phase. Mixed samples of $NaNO_3$ and Fe_2O_3 with various molar ratios ($NaNO_3/Fe_2O_3$=1.0, 1.5, 2.0, and 2.5) were heated in a platinum boat in an atmosphere of air at 950, 1000, and 1050 K. Each of solid residues was examined by X-ray analysis. X-Ray diffraction patterns were obtained by use of an X-ray diffractometer (Type Geigerflex RAD-III A, Rigaku Denki Corporation, Japan).

The solid residues obtained at 1050 K from every mixture showed only the X-ray pattern of $NaFeO_2$ except the unchanged Fe_2O_3. The solid residues obtained at 950 and 1000 K from the mixtures with molar ratios $NaNO_3/Fe_2O_3$=2.0 and 2.5 showed the X-ray patterns of both Na_3FeO_3 and $NaFeO_2$. $NaFeO_2$ may be regarded as the general component of the solid residues formed at 1050 K from the mixtures with molar ratios less than 2.0 of $NaNO_3/Fe_2O_3$, as far as the results of X-ray analysis is concerned.

Conversion Rate: Conversion rates from $NaNO_3$ to $NaFeO_2$ were determined at various reaction times. With the apparatus shown in Fig. 2, a mixture with a molar ratio $NaNO_3/Fe_2O_3$=2.0 in a platinum boat was heated in still or flowing air of 500 ml/min at 1 atm for a prescribed time. Then the solid residue in the platinum boat was hydrolyzed in boiling water to form NaOH. The amount in mole of the determined NaOH was regarded as equivalent to that of the $NaFeO_2$ formed by Reaction 1. The NaOH formed was determined by neutralization.

Results are shown in Figs. 3 and 4. As shown in Fig. 3, the reaction proceeds in still air at 1050 K faster than at 950 and 1000 K. In flowing air, however, as seen from Fig. 4, the reaction rate increased at 950 and 1000 K but was almost the same at 1050 K as in still air. This is because the total pressure of evolved vapor is more than 1 atm at 1050 K, whereas it is below 1 atm at 950 and 1000 K. The conversion rate does not reach 100% in either of the atmospheres of still and flowing airs at 1 atm. The maximum conversion rate is 95—96% in all the experimental conditions of this study.

In order to disclose the reason, amounts of evolved gas with Reaction 1 were determined.

Evolved Gas: About 2 g of a mixture ($NaNO_3/Fe_2O_3$=2.0 in molar ratio) in a platinum boat was heated for 30 min at 1050 K in an atmosphere of flowing O_2 and the evolved gas was allowed to be absorbed into 450 ml of 0.26 mol/l NaOH aqueous solution as shown in Fig. 2. The amount of the residual sodium hydroxide in the solution after the absorption of evolved gas was determined by neutralization. The solid residue in the platinum boat was hydrolyzed, and the NaOH formed was determined. According to the equilibrium constants[3] of the reaction $NO+1/2O_2 \rightleftarrows NO_2$, the species of nitrogen oxide in the evolved gas is NO at 1050 K but is NO_2 together with a large quantity of O_2 at room temperature where the gas is absorbed. Thus, the amount of absorbed NO_2 in coexistence with O_2 was compared with the initial amount of $NaNO_3$ for the determination of conversion rate on the basis of evolved NO_2. The result is shown in Fig. 5. As is clear from Fig. 5, the conversion rate on the basis of evolved NO_2 is almost 100% over the range 50—400 ml/min of oxygen flow, whereas that on the basis of formed NaOH is about 96% at the maximum. The drop in conversion rate at 500 ml/min of O_2 flow in Fig. 5 may be due to the fact that

NO_2 goes out of the absorbing solution with the flowing O_2 without being absorbed into the solution.

Reaction 2 (Hydrolysis of $NaFeO_2$). As already clarified by X-ray analysis, the general component of solid residue with Reaction 1 is $NaFeO_2$ at 1050 K at molar ratios less than 2.0 of $NaNO_3/Fe_2O_3$. Therefore, this study is focused on the hydrolysis of $NaFeO_2$ formed at 1050 K with Reaction 1.

Three samples of $NaFeO_2$ were hydrolyzed for the purpose of determining the maximum yield of NaOH from $NaFeO_2$. They were prepared at 1050 K in the respective molar ratios of $NaNO_3/Fe_2O_3$=1.0, 1.5, and 2.0.

Each sample of 1.3 g was added into a water of about 100 g and the suspended solution was boiled off down to half the volume with evaporation of water. After cooling, OH^- and CO_3^{2-} in the suspended solution were analyzed with an automatic titrator. As a result of this analysis, it was concluded that 95.4—96.4% of $NaFeO_2$ is converted to NaOH by hydrolysis with all the samples prepared from the mixtures with molar ratios $NaNO_3/Fe_2O_3$=1.0, 1.5, and 2.0, if 100% of the initial $NaNO_3$ is assumed to have been converted to $NaFeO_2$ in every preparation of the $NaFeO_2$ samples. In order to detect undecomposed $NaFeO_2$, an X-ray analysis was conducted on dry samples of solid residues after hydrolysis of $NaFeO_2$. However, any X-ray diffraction patterns assignable to sodium ferrate were not found; all the samples showed only the X-ray diffraction pattern of hematite.

For the purpose of investigating the mass balance of sodium with respect to Reactions 1 and 2, sodium was determined in three samples: (1) A solid residue from Reaction 1, (2) a solid residue after the hydrolysis of Reaction 2, and (3) solid sticks on the quartz tube wall and the SiO_2 powders around the platinum boat containing reactants for Reaction 1. The SiO_2 powders were used for catching vaporized $NaNO_3$, because $NaNO_3$ reacts with SiO_2.[2] The determination of sodium was conducted by flame emittion photometry after extraction of sodium ion into the aqueous solutions by decomposing the solids with hydrochloric acid, hydrofluoric acid, and perchloric acid. As a result, it was revealed that 95.4—96.4% of the sodium contained in the initial sodium nitrate forms $NaFeO_2$ which is easily hydrolyzed, and that 1.6—1.7% of the sodium coexists with Fe_2O_3 without forming NaOH after the hydrolysis of $NaFeO_2$. The residual percentage 1.9—3.0% of sodium is regarded as the $NaNO_3$ which vaporized without reacting with Fe_2O_3 during the heating step from room temperature to the reaction temperature. The vaporized $NaNO_3$ is probably caught during passage through the column packed with Fe_2O_3, because the sodium from vaporized $NaNO_3$ was detected in solid sticks on the quartz tube wall and the SiO_2 powders around the platinum boat. This vaporized $NaNO_3$ will, however, be regarded as lost in the later discussion of this paper, because it was not recovered in this study.

The hydrolysis rate of $NaFeO_2$ as a function of reaction time was also measured as shown in Fig. 6. A sample containing 0.2 g $NaFeO_2$ and 20 g water in a Teflon bottle was shaken and warmed in an oil bath at a constant controlled in temperature within ±0.1 °C. As seen from Fig. 6, features of hydrolysis rate with respect to reaction time are similar above 60 °C in that it takes as short as 30 min to reach the maximum hydrolysis rate. On the other hand, the hydrolysis of $NaFeO_2$ proceeds rather slowly below 50 °C. At any cases, the maximum hydrolysis rate is more than 98% in view of the already-stated fact that 1.9—3.0% of sodium in the initial $NaNO_3$ will not form $NaFeO_2$ in the step of preparation of the $NaFeO_2$ samples due to the vaporization of $NaNO_3$.

It is industrially important to clarify the achievable concentration of the sodium hydroxide aqueous solution obtainable by means of the hydrolysis of $NaFeO_2$. Figure 7 shows concentrations of sodium hydroxide aqueous solutions obtained with varied hydrolysis periods. In this experiment, the expected amount of water was added to each $NaFeO_2$ sample so that a sodium hydroxide solution of 50 wt% might be formed when the $NaFeO_2$ sample was perfectly hydrolyzed. The sodium hydroxide solutions were determined in concentration after they had been separated from iron(III) oxide by filtration with paper filters. As shown in Fig. 7, the concentration of sodium hydroxide solution reaches about 25 wt% at about 15 min from the start of hydrolysis, slowly increasing up to 28.5 wt% at 80 min from the start. Thus, these results suggests that the industrially achievable concentration of sodium hydroxide solution would be 25—28 wt%.

Reaction 3 (Production of HNO_3). The formation of nitric acid according to Eq. 3 is well known and quite similar to the absorption step of nitrogen dioxide into water in the current manufacturing process of nitric acid. This absorption step of nitrogen dioxide is successfully practical in many factories manufacturing nitric acid all over the world.

Thermodynamic Calculation

The enthalpy change (ΔH°_{298}), entropy change (ΔS°_{298}), and free energy change (ΔG°) for each of the reactions involved in the present process were calculated based on thermochemical data.[4,5] The results are shown in Table 1 and Fig. 8.

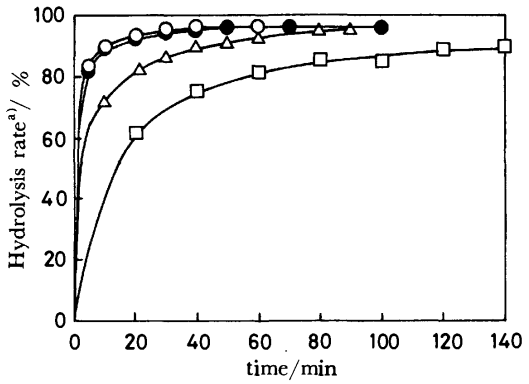

Fig. 6. Hydrolysis rates of $NaFeO_2$ with time at the various temperatures.

($NaFeO_2$ and H_2O were initially mixed so that about 50 wt% NaOH aqueous solution might be formed after 100% of $NaFeO_2$ was hydrolyzed)

Material and Heat Flow-sheet

An estimated material and heat flow-sheet for this process is shown in Fig. 9. In Fig. 9, R, E, and S refer to the reactor, heat exchanger, and separator, respectively. The other notations are as follows: the enthalpy change of reaction (ΔH°_T), the Gibbs free energy change (ΔG°_T), the heat input for heating the reactants ($Q_r=\Delta H^\circ_T-\Delta H^\circ_{298}$), and the heat output for cooling the products ($Q_P=\Delta H^\circ_T-\Delta H^\circ_{298}$).

The following assumptions were made for the construction of the flow-sheet:

$NaNO_3$ will be perfectly converted to $NaFeO_2$ with the stoichiometric ratio between $NaNO_3$ and Fe_2O_3. Q_P at E1 contains the reaction heat of $NO+1/2O_2\rightarrow NO_2$. The conversion rate for $NaFeO_2$ to NaOH will pessimistically be 95% at a molar ratio $H_2O/NaFeO_2=6.5$ for the formation of 27 wt% sodium hydroxide aqueous solution. ΔG°_{343} and ΔH°_{343} at R2 contain the free energy and enthalpy changes for the dissolution[6] of NaOH into H_2O. The conversion rate for NO_2 to HNO_3 will be 100% at 298 K. The concentration of nitric acid aqueous solution formed will be 64%. Therefore, the heat of dilution from 100 to 64 wt% of nitric acid solution is contained in ΔH°_{298} at R3. The heat unit in the flow-sheet is kcal.

Heat Requirement. The heat requirement (Q_{req}) for the process was calculated by using the equation[7-9] formulated on the basis of the flow-sheet in

Table 1. Enthalpy, entropy, and free energy changes (ΔH°_{298}, ΔS°_{298}, and ΔG°) for reaction 1—3[a]

a) Heat required in manufacturing 27 wt% NaOH aqueous solution containing NaOH of 1.000 ton, and 64 wt% HNO_3 aqueous solution containing HNO_3 of 1.658 ton.

$$Q_{req} = \sum(\Delta H_T^\circ + Q_r) - \sum Q_p \times R_i \quad (5)$$

Fig. 9, where R_i represents the ratio for the thermal regeneration. Figure 10 shows the change of the heat requirement with values of R_i. The heat requirement in Fig. 10 represents values applicable to a manufacture of 1.000 t of NaOH and 1.658 t of HNO_3. The energy required for the separation and transportation of materials in the process is neglected in the calculation of heat requirement.

The theoretical heat requirement for the manufacture of NaOH is calculated as 10.2 kcal/mol[10] the case of the electrolysis process of NaCl. Here, the heat of 10.2 kcal/mol does not include the heat required for the manufacture of accompanying Cl_2 with NaOH. If the fossil fuel equivalent to electrical energy is assumed to be three times the amount of the electrical energy delivered to the electrolysis process of NaCl, the theoretical heat requirement for the manufacture of NaOH is 0.765×10^6 kcal/*t*-NaOH. On the other hand, nitric acid is mostly manufactured *via* oxidation of ammonia. Ammonia is currently synthesized *via* the reaction between hydrogen from naphtha and nitrogen from air. The heat requirement for this synthesis is expected to be 4.03×10^6 kcal/*t*-NH_3.[11] The heat requirement for the manufacture of HNO_3 from NH_3 is assumed to be negligibly small in this discussion. Thus, the overall heat requirement for the manufacture of 1.658 t of HNO_3 is 1.80×10^6 kcal. As a result, the total heat requirement for the manufacture of 1.000 t of NaOH and 1.658 t of HNO_3 is estimated to be at least 2.56×10^6 kcal for the current manufacturing processes of NaOH and HNO_3. This value of heat requirement corresponds approximately to the case of thermal regeneration of as low as 5% in the process of this study, as is clear from Fig. 10. If thermal regeneration is practised to more than 5% in this thermochemical process, this process might be a more energy-saving process than the current manufacturing processes of NaOH and HNO_3.

Conclusion

1) A new thermochemical process for manufacture of NaOH and HNO_3 from $NaNO_3$ has successfully been devised which essentially comprises a combination of a splitting of $NaNO_3$ by Fe_2O_3 and a hydrolysis of $NaFeO_2$.

2) The feasibility of the two key reactions, (i) the splitting of $NaNO_3$ by Fe_2O_3 and (ii) the hydrolysis of $NaFeO_2$, has experimentally been verified. The conversion rate is 100% for reaction (i) at 1050 K and more than 98% for reaction (ii) at 343 K. Sufficiently high reaction rates are available for both the reactions.

3) A material and heat flow-sheet of the process has been constructed which is simple as shown in Fig. 9.

4) This proposed thermochemical process is expected to be more energy-saving than the current processes of manufacturing NaOH and HNO_3, if heat regeneration is practised to more than 5% in the process of this study.

Conduction Band Formation through the Temporary Anion States in Organic Solids

Kenzo HIRAOKA* and Masaji NARA
Faculty of Engineering, Yamanashi University, Takeda-4, Kofu 400, Japan
(Received August 5, 1983)

The transmission of low-energy electrons (0—15 eV) through thin films of benzene, toluene, pyridine, aniline, styrene, and cyclohexene was studied. The electron transmission spectra of all the aromatic compounds studied are like each other in their forms. The energies of several prominent peaks in the electron transmission spectra are in good agreement with those of temporary anion states measured in the gas phase. It is suggested that vacant orbitals of free molecules form conduction bands in molecular crystals.

Recently our group[1-7] and Sanche *et al.*[8-10] reported a simple method for measuring the electronic levels of molecules condensed on a metal surface at low temperature. A sample film was bombarded by a beam of low-energy electrons, and the current transmitted through the film (I_t) was measured as a function of the incident electron energy (eV_i). The electron transmission spectra, recorded as dI_t/dV_i *vs.* eV_i, were found useful for the detection of optically forbidden electronic transitions[1] and the determination of energies of lowest conduction bands for many orgnic solids.[2-7]

The temporary anion states of organic compounds in the gas phase have been studied by electron transmission spectroscopy.[11-17] Jordan and Burrow observed the vertical temporary anion states at 1.15 and 4.85 eV for benzene, at 1.11 and 4.88 eV for toluene, and at 0.19, 0.90, 1.67, 3.37, and 4.72 eV for naphthalene.[11] In the electron transmission spectra of solids, peaks at ≈1.1 and ≈4.8 eV for benzene and toluene[2,4] and peaks at 1.6, 3.3 and 4.8 eV for naphthalene,[4] are observed. Peak energies of the transmission spectra are in agreement with the energies of temporary anion states measured by Jordan and Burrow. This suggests that peaks observed in the transmission spectra of these solids are originated from the temporary anion states.[4]

In our previous papers,[5,7] the peak positions in the transmission spectra for solid normal alkanes were connected with onset energies of conduction bands with high density of states. In this work, we give a further evidence that vacant orbitals of free molecules form conduction bands in organic insulators.

Experimental

The experimental procedure has been described elsewhere.[2] All samples were Tokyo Kasei extra pure products. The film thickness was controlled by the deposition time under the constant vapor pressure at 1.3×10^{-5} Pa.

Results

Transmission spectra for pyridine are shown in Fig. 1. The film thickness was changed from 2 to 16 langmuir (L).† The spectra for the 2 to 8 L films were almost identical. Comparing the transmission spectra of pyridine and monosubstituted benzenes with those of benzene, a marked similarity is observed, at least below 8 eV.

As described in our previous papers,[2,4] the electron energy calibration was made by comparing the transmission spectra with spectroscopic data obtained in the gas phase. Solid and gas phase data are in good agreement for benzene, toluene, pyridine, and naphthalene. Recently we measured the electron impact luminescence excitation spectra of a benzene thin film and verified that the assignment of peaks in the transmission spectrum of benzene was correct.[6]

Electronic excitation of molecules takes place in 10^{-15}—10^{-16} s. An excited molecule in the solid immediately polarizes surrounding molecules. The excitation energy in the solid is generally smaller than that in the gas phase by the difference of interaction energies for the ground and excited states *D*. Thus peak energies of the transmission spectra calibrated

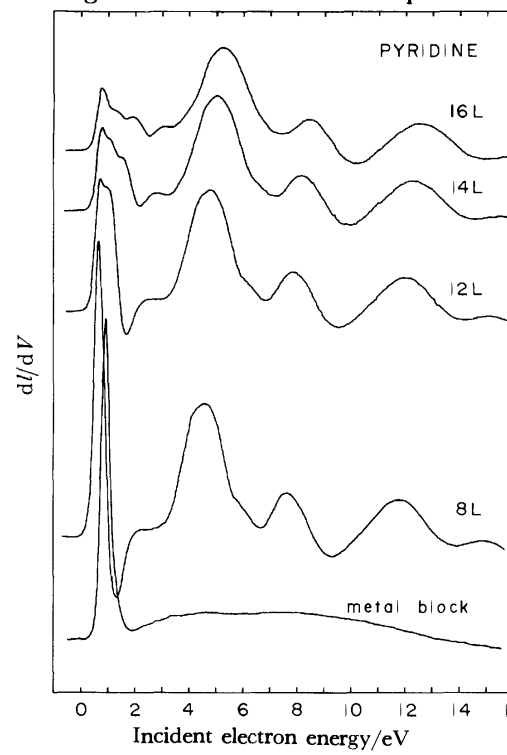

Fig. 1. The transmision spectra for pyridine. The electron energy scale was calibrated for the spectrum of an 8 L thick film. For films thicker than 8 L, all peaks including two new ones but the first peak uniformly shifted because of charging of the film. This shift was generally observed when the film was charged by electrons.

† The amount of the gas admitted in the vacuum chamber is expressed in langmuir units (1 L=1.33×10^{-4} Pa s).

by the gas-phase data would be overestimated by an amount of D. In molecular crystals the magnitude of D is known to be of the order of 1000 cm^{-1}.[35]

The peak energies of the transmission spectra for pyridine are in good agreement with those of the threshold electron-impact excitation spectrum measured in the gas phase by Van Veen and Plantenga[17] (see Table 1). The assignment of peaks above ≈7 eV is difficult because the ionization of molecules in the film obscures the spectra in this energy region.

When a pyridine film thicker than 8 L suffered charging, all peaks in the spectrum except the first one uniformly shifted and the first peak decreased with the appearance of two new peaks nearby as shown in Fig. 1. The peak energies of these two were determined to be 0.7 and 1.3 eV from the spectral shift. These levels correspond to the temporary anion states (shape resonances) of pyridine at 0.62 and 1.20 eV observed in the gas phase by Nenner and Schulz.[18] For another temporary anion state at 4.58 eV observed by them, a large peak was also observed near the value in the transmission spectra.

Table 1. The comparison of peak energies (eV) in transmission spectra with energy levels obtained with other spectroscopic methods and the estimated V_0 values

	Electron transmission (present work)	Energy level		V_0

Figure 2 depicts the transmission spectra of cyclohexene, benzene, toluene, aniline, pyridine, and styrene. The spectrum of cyclohexene showed a decrease of the first peak and an appearance of a second peak with increasing sample deposition. This means that the lowest conduction band energy V_0 is positive for cyclohexene and negative for other aromatic compounds.[2,4] Because the second peak approximately corresponds to the lowest conduction band energy for a compound with positive V_0,[4] the second peak of the transmission spectrum of cyclohexene can be assigned to the zero of the energy of electrons in the solid. The electron energy scale for benzene, toluene, and pyridine was calibrated using spectroscopic data.[17,19–21] The energy scale for aniline and styrene was calibrated by comparing energies of peaks indicated in the transmission spectra with those of temporary anion states measured by Jordan and Burrow.[11] They are also compared with other spectroscopic data in Table 1 and Fig. 3.

By the calibration of electron-energy scale for the electron transmission spectra described above, the lowest conduction band energies V_0 can be estimated from the amounts of positive shifts of the transmission spectra.[4] The estimated V_0 values are listed in

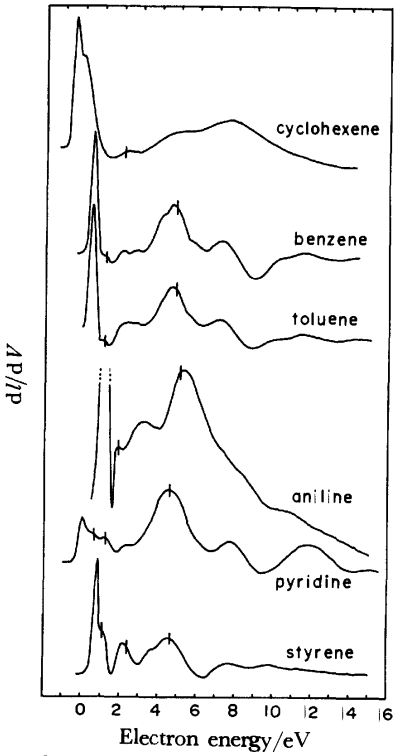

Fig. 2. The transmission spectra for cyclohexene, benzene, toluene, aniline, pyridine, and styrene. The film thickness is 16 L for pyridine and 10 L for the other compounds. The zero of the electron energy scale corresponds to the lowest conduction band energy except for pyridine. Positions of temporary anion states messured in the gas phase were indicated.[11]

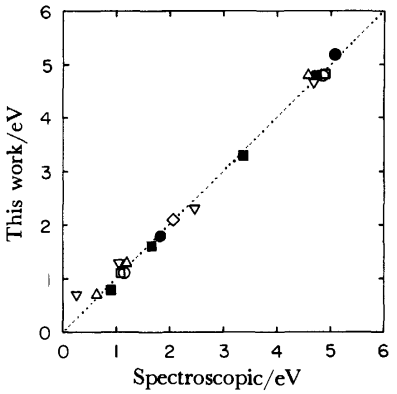

Fig. 3. The comparison of peak energies in the electron transmission spectra with temporary anion states measured in the gas phase.[11]. ○; benzene, □; toluene, △; pyridine, ●; aniline, ▽; styrene, ■; naphthalene, ◇; cyclohexene.

the last column of Table 1. The experimental error was estimated to be around ±0.3 eV. Riga *et al.*[25] compared the ESCA valence band spectra of solid polyacenes with gas phase UPS results, and obtained the V_0 values for solid benzene and naphthalene as -0.1 ± 0.2 and -1.4 ± 0.2 eV, respectively, which are fairly in good agreement with our values.

Discussion

Despite a good agreement of peak energies, there is a marked difference in their relative intensity between the transmission spectra and the threshold electron impact excitation spectra of aromatic compounds in the gas phase.[2-4,17] In the transmission spectra, peaks at about the same energies of temporary anion states are generally larger than those assigned for the exciton formation.[2,4,6,26-28] For example, excitonic peaks of pyridine observed at 4.1 ($^3A_1$) and 6.3 eV ($^1A_1$) are weaker than peaks at 0.7, 1.3, and 4.8 eV which are assigned to the temporary anion states. A large peak in the transmission spectra is due to sharp increase in the transmitted electron current at its energy. In our previous papers,[4-7] it was suggested that the transmission spectra reflect the profile of conduction bands and their peaks might correspond to the onsets of conduction bands with high density of states. Large peaks in the transmission spectra at the energies of temporary anion states suggest that the vacant orbitals of free molecules form unoccupied conduction bands when molecules are condensed.

Figure 4 shows the transmission spectra of benzene and styrene measured in the gas[11] and solid phases. The π_1^* and π_2^* states in the gas phase spectra have vibrational structures, unlike π_3^* and π_4^* states, their lifetimes ($\geq10^{-14}$ s) being longer than those of the latter (10^{-14}—10^{-15} s)[11]. It is notable that the short-lived temporary anion states (π_3^* and π_4^*) give the larger and broader peaks in the transmission spectra than long lived-states (π_1^* and π_2^*). This may be understood as follows. When an electron is taken in a resonant state of antibonding nature in a molecule, the nuclei will oscillate along a potential well with a large equilibrium internuclear distance. Thus, the molecule suffers vibrational excitation due to the resonance. The

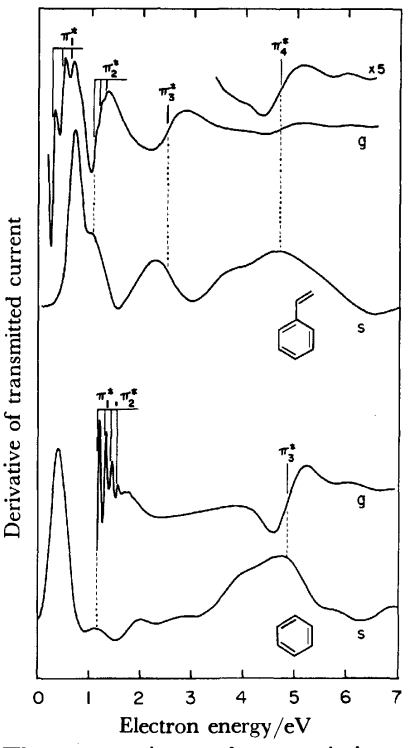

Fig. 4. The comparison of transmission spectra measured in the gas (g)[11] and solid (s) phases for benzene and styrene.

degree of excitation is a function of spatial displacement of the nuclei in the temporary anion, hence it depends upon a lifetime of the intermediate state. Through the formation of long-lived π_1^* and π_2^* states for solid benzene and toluene, a primary electron would have much chance to suffer inelastic scattering. On the contrary, short-lived π_3^* and π_4^* states are less involved in the vibrational excitation. Besides, an electron with an excess energy of a few eV may have a mean free path $l\leq37$ nm[29,30] in the solids. Under the circumstances, an electron generated by autoionization of a short-lived temporary anion may be delocalized in the initial phase and characterized by a wave vector k. In this case, an electron would propagate coherently in the solid and contribute to the increase of the transmitted electron current.

In principle, no level below the vacuum level is observed with the electron transmission experiment. For instance, the band originated from the π_1^* state of styrene cannot be detected in the transmission spectrum (Fig. 4). However, this band could be observed when the film suffered charging by electrons. Two new peaks were also observed for a charged pyridine film as described before. For compounds with negative V_0 values, one might examine some levels below the vacuum level by charging the films as much as $|V_0|$.

The energy of the lowest conduction band V_0 listed in Table 1 corresponds to the ground state energy of quasi-free electrons in the condensed phase. The theoretical model for the estimation of V_0 was given by Springett *et al.*[31] The second lowest conduction bands for benzene and toluene, for instance, are observed at 1.1 eV with respect to the lowest conduction band. These bands were generated from the lowest vacant molecular orbitals of free molecules as already

described.

For benzene, two peaks at 2.0 and 2.8 eV remain to be explained. In this energy region, unresolved peaks are also observed for toluene, aniline, octylbenzene,[4] biphenyl,[32] and pyridine. Because energies of these peaks are lower than the first excitonic levels, these peaks may also be due to the conduction bands. Since any kind of vacant molecular orbitals can contribute to the formation of conduction bands,[33] the origin of these bands could be the vacant molecular orbitals. Possible candidates for the formation of these bands are vacant C-C, C-H, and Rydberg orbitals. Although Jordan and Burrow could observe the transient anions associated with C-Cl* orbitals,[34] those associated with vacant C-C, C-H, and Rydberg orbitals have never been observed due to their very short lifetimes, and no comparison with the transmission spectra can be made at the present stage.

Stimulating discussions with Professor Yusei Maruyama of Institute for Molecular Science are gratefully acknowledged.

Redox Behavior and Electrochromic Properties of Polypyrrole Films in Aqueous Solutions

Susumu KUWABATA, Hiroshi YONEYAMA,* and Hideo TAMURA

Department of Applied Chemisrty, Faculty of Engineering, Osaka University, Yamada-oka 2-1, Suita, Osaka 565

(Received September 29, 1983)

Polypyrrole films prepared by anodic polymerization of pyrrole on Pt or SnO_2-coated glass show redox behavior in aqueous electrolyte solutions containing a supporting electrolyte alone. Transfer of electrolyte anions into and from the film is involved in the redox reaction similarly with acetonitrile solutions already reported. Insertion of divalent anions into the film occurs in two steps but that of monovalent anions in one step, as judged from corresponding cyclic voltammograms. The change in film color which occurs in the redox reaction of the film was investigated in detail as a function of electrode potential and the charge consumed in the redox reaction. Polypyrrole is a promising material for electrochromic display devices.

Recently many reports have been published concerning electrochemical properties of electroconductive polymers. Among them, polypyrrole has been studied most extensively. Except for earlier reports by Weiss *et al.*,[1-3] most of electrochemical studies have been conducted on films prepared by anodic polymerization of pyrrole in an acetonitrile medium. According to Diaz *et al.*[4-9] polypyrrole-coated Pt electrodes show redox behavior in acetonitrile solutions: Insertion of anionic species into films and elimination of inserted anions from films occur in the oxidation and reduction of films, respectively; the oxidized film contains 0.25 mol of anions in 1 mol of pyrrole rings and exhibits high conductivity. Use was made of this property to stabilize unstable semiconductor electrodes such as *n*-Si and *n*-GaAs in aqueous solutions by coating electrode surface with thin polypyrrole films.[10-15]

Concerning electrochemical properties of polypyrrole films in aqueous solutions, redox behavior of several electroactive species such as $[Fe(CN)_6]^{3-/4-}$ and ferrocene/ferricenium has been investigated by use of Pt or Ta as the electrode substrate and it has been found that the polymer films serve as inert electrodes like Pt electrodes.[7,16-18] Their photoelectrochemical properties were also investigated in relation to the conduction mechanisms.[18] We have studied electrochemical properties of polypyrrole films in aqueous solutions containing a supporting electrolyte alone and found that the films exhibit redox behavior like those reported in acetonitrile solutions. In this paper electrochemical properties of polypyrrole films in aqueous solutions will be reported with particular reference to their redox behavior. Furthermore, it will be shown that the color of polypyrrole films changes with redox behavior. Preliminary results will also be presented on the application to electrochromic display devices which have been obtained with stable inorganic oxides such as WO_3[19-23] and organic materials such as phthalocyanines.[24] The color change of polymer-coated electrodes during the course of their polarization has been described with several polymers,[8,25,26] but no systematic study with focusing on the application to electrochromic display devices seems to have conducted.

Experimental

Preparation of Polypyrrole. Redox reactions of polypyrrole were investigated with its film prepared on a Pt substrate. For this purpose, a flat Pt plate was mounted on a Teflon electrode holder having an exposed electrode area of 1 cm^2. An anodic polymerization of pyrrole was carried out in an N_2 atmosphere in acetonitrile containing 0.1 mol dm^{-3} pyrrole and 0.3 mol dm^{-3} $LiClO_4$ at 0.3 mA cm^{-2} for 2 min. By this procedure polypyrrole of *ca.* 90 nm thickness was deposited on the Pt as determined with a multi-reflection interferometer (Mizojiri Kogaku, Model 2). The electrode prepared in this manner is denoted here by PPy/Pt. For the purpose of elemental analysis the film was prepared on a Pt electrode having a large area of *ca.* 20 cm^2 under the same conditions as described above except for the electrolysis time which was 20 min, and was teared away from the substrate. The film thickness in this case was *ca.* 220 nm.

Measurements of electrochromic properties of polypyrrole were carried out with a film prepared on a SnO_2-coated glass electrode. The SnO_2-coated glass electrode was prepared in this laboratory by pyrolysis of a spray mixture of 3 mol dm^{-3} $SnCl_4$, 0.15 mol dm^{-3} $SbCl_5$, and 1.5 mol dm^{-3} HCl,[27] and its area was 3.5 cm^2. An electrical lead wire was attached to its round rim with silver-epoxy by coating it first with epoxy resin and then with silicone rubber adhesive. The SnO_2-coated glass electrode prepared in this manner had an exposed area of *ca.* 3 cm^2, which was used as the substrate for the deposition of polypyrrole. The deposition was performed under the same conditions as in the case of PPy/Pt and the prepared electrode will be denoted here by PPy/OTE.

Electrochemical Measurements. Measurements were carried out in a Pyrex beaker type cell. A saturated calomel electrode (SCE) served as a reference electrode. Cyclic voltammograms were obtained by use of a potentiostat (Hokuto Denko HA-104), a function-generator (Hokuto Denko HB-104), and an X-Y recorder (Yokogawa Electric Inc. 3077). An electronic coulometer (Hokuto Denko HF-201) was used as required. For measurements of resistivity of polypyrrole films the four-probe method[28] was applied to a film sample which had been teared away from PPy/Pt by use of an adhesive tape.

Electron Probe X-Ray Microanalysis of Polypyrrole Films. A qualitative analysis of anions contained in polypyrrole films was performed to obtain direct information on the anion transfer into and from films which occur in the course of redox reaction of PPy/Pt electrodes. An energy dispersive electron probe X-ray microanalyzer (EPMA) (Horiba EMAX-1500E) connected to a scanning electron microscope (Hitachi S-450) served for this purpose.

Measurements of Electrochromic Properties. A PPy/OTE working electrode and a counter electrode (*ca.* 1 cm^2 Pt plate) were set in a quartz cell (20×10×40H mm). The cell was connected to a reference electrode (SCE) with a salt bridge and set in an UV-visible spectro-photometer (Shimadzu MPS-5000). The absorbance of polypyrrole films was measured *in situ* in the course of polarization measurements.

Results and Discussion

Redox Behavior of Polypyrrole in Aqueous Solutions. Cyclic voltammograms of PPy/Pt electrodes in 0.5 mol dm^{-3} KCl or 0.5 mol dm^{-3} Na_2SO_4 are shown in Fig. 1. Well-defined peaks are seen both in the anodic and cathodic potential scans. Peak currents increase linearly with increasing sweep rate from 20 to 100 mV s^{-1}, suggesting that these peaks are due to electrochemical reactions of the film itself.[29] In the KCl solution the anodic and cathodic peaks appear at −0.35 and −0.15 V, respectively, and the peak potentials are eventually invariant with sweep rate. On the other hand, two anodic peaks appear in the Na_2SO_4 solution, though the cathodic behavior is almost the same as in the KCl solution. The first peak like a shoulder appears at −0.44 V, whereas the more marked second peak shows a tendency to shift its potential towards the positive direction with increasing sweep rate.

Cyclic voltammograms were obtained in other kinds of electrolytes. The peak potential and current of the cyclic voltammograms obtained at the sweep rate of 50 mV s^{-1} are shown in Table 1. In the case of appearence of two anodic peaks, the peak potential and current at the lower potential are given with the subscript pa-1 and those at the higher potential with pa-2. When only one anodic peak appears the values are given in the column of pa-1. As recognized from this Table, monovalent anions give one anodic peak, while divalint anions give two peaks. The peak potential and current of cathodic waves are little influenced by the kind of electrolyte anions, whereas different situations can be seen in the anodic waves.

The $E_{pa\text{-}1}$ observed in divalent anions is more negative than $E_{pa\text{-}1}$ observed in monovalent anions, but $E_{pa\text{-}2}$ is more positive than the latter. Voltammograms obtained in individual solution were not remarkably varied in the temperature range 0—80° C. It is suggested from cyclic voltammograms obtained in the presence of divalent anions that the oxidation in this case occurs in two steps: In the first step, the surface of polypyrrole film may be oxidized weakly by attracting anions onto the polymer surface; in the following step, anions may be inserted into the film and an oxidation of the film occurs simultaneously. It is seen in Table 1 that $E_{pa\text{-}2}$ depends on the kind of anions; sulfate and hydrophosphate ions give nearly the same $E_{pa\text{-}2}$ except for Li_2SO_4, whereas WO_4^{2-} gives more anodic $E_{pa\text{-}2}$. The discrepancy in the values of $E_{pa\text{-}2}$ seems to be closely related to ionic radii of the anions[30] to be incorporated into the film. The ionic radii of hydrated HPO_4^{2-} and SO_4^{2-} are *ca.* 4 Å, while that of WO_4^{2-} is *ca.* 5 Å. If this difference is serious, it is then suggested that the larger the ionic radius of anions, the more anodic potentials are needed for the incorporation of anions into the film to take place. Experiments aiming at the verification of this hypothesis is in progress and will be reported in future. As to the monovalent anions given in Table 1, the ionic radii of Cl^-, Br^-, and I^- are *ca.* 3 Å and that of ClO_4^{2-} is 3.5 Å, which are smaller than those of the

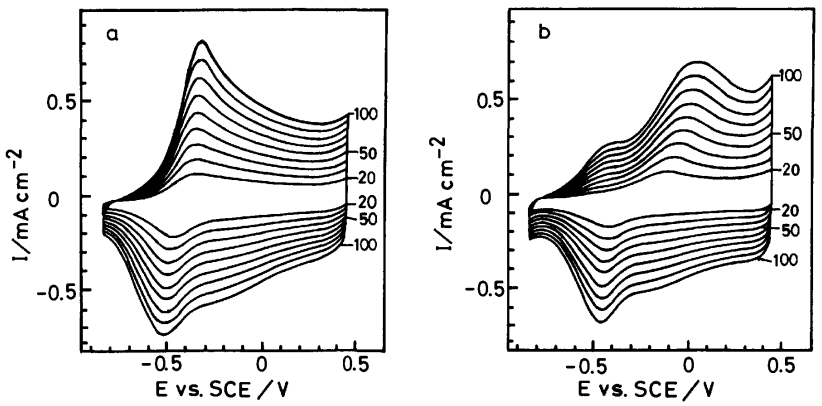

Fig. 1. Cyclic voltammograms of PPy/Pt electrodes at various sweep rates in an interval of dE/dt=10 mV s^{-1}. The number denotes the sweep rate in mV s^{-1}.

TABLE 1. PEAK POTENTIALS AND CURRENTS OF CYCLIC VOLTAMMOGRAMS OF PPy/Pt ELECTRODES OBTAINED AT dE/dt=50 mV s^{-1} IN A VARIETY OF ELECTROLYTES

Electrolyte[a]	E_{pa-1}/V	E_{pa-2}/V	E_{PC}/V	i_{pa-1}/mA	i_{pa-2}/mA	i_{PC}/mA
0.5 M KCl	−0.31		−0.47	0.36		−0.41
0.5 M KBr	−0.32		−0.46	0.34		−0.38
0.5 M KI	−0.29		−0.56	0.41		−0.36
0.5 M $LiClO_4$	−0.31		−0.48	0.39		−0.30
0.5 M Na_2SO_4	−0.44	0.04	−0.46	0.12	0.35	−0.34
0.5 M K_2SO_4	−0.45	0.02	−0.48	0.09	0.36	−0.35
0.5 M Li_2SO_4	−0.42	0.21	−0.44	0.07	0.38	−0.41
0.5 M Na_2HPO_4	−0.42	0.02	−0.36	0.13	0.41	−0.45
0.5 M Na_2WO_4	−0.42	0.45	−0.49	0.13	0.40	−0.43

a) 1 M=1 mol dm^{-3}.

divalent ions used, and the smaller size of monovalent anions may make the peak potential less positive than the $E_{pa\text{-}2}$ obtained for the divalent anions. In connection to this hypothesis, it seems important to notice that the onset potential of film oxidation is eventually the same between the monovalent and divalent ions.

Effects of the electrolyte concentration on cyclic voltammograms were investigated in KCl solutions. According to the results obtained, the peak potentials and currents were not appreciably varied with the concentration of electrolytes as long as it was higher than 10^{-3} mol dm^{-3}. In more dilute solutions, however, the voltammograms were deformed owing to IR drop in the electrolyte.[31]

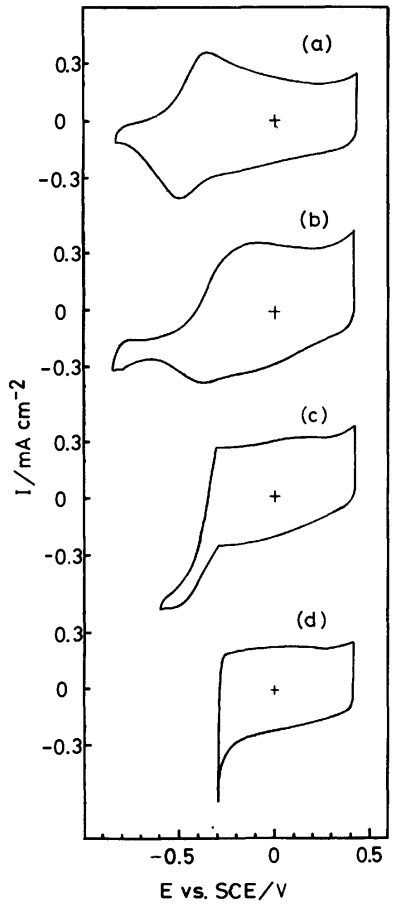

Fig. 2. Effects of solution pH on cyclic voltammograms of PPy/Pt electrodes in 1 mol dm^{-3} chloride solutions.
pH=(a) 5.5, (b) 2.0, (c) 1.5, (d) 0.6. dE/dt=50 mV s^{-1}.

Figure 2 shows effects of pH on the redox behavior of polypyrrole. The concentration of Cl^- anions was kept constant in this case. As noticed from Fig.2, the redox behavior appears in solutions having pH values higher than 2.0. In solutions of lower pH, hydrogen evolution becomes predominant, resulting in shadowing the redox behavior of polypyrrole itself.

It was reported in acetonitrile solutions[8] that the redox behavior is due to anion insertion into polypyrrole films and elimination of inserted anions from the film. In order to confirm whether or not this is true in aqueous solutions, anionic species in the film were analyzed by EPMA. The results are shown in Fig. 3. Figure 3-(a) is the spectrum of a PPy/Pt electrode prepared in the acetonitrile solution. A peak assignable to chlorine is seen, which gives the evidence that ClO_4^- is inserted into the film in the course of anodic polymerization. This electrode was kept in 0.5 mol dm^{-3} KI aqueous solution for 2 min at −0.85 V which is enough to cause the cathodic process of redox reaction, and then washed with water. Then the chlorine peak disappeared, as shown in Fig. 3-(b). When this sample was again kept for 2 min in the same solution at 0.45 V *vs.* SCE to cause the anodic process of redox reaction, peaks of iodine appeared as shown in Fig. 3-(c). Similar results of the occurrence of replacement of anionic species were obtained in other electrolytes such as KBr, Na_2SO_4, and Na_2HPO_4. Thus, it is evident that the redox reaction is accompanied with the anion transfer into and from the film.

Resistivity measurements and elemental analyses on polypyrrole films were carried out both for the original film prepared in the acetonitrile solution and for films polarized afterwards in 0.5 mol dm^{-3} KCl aqueous solution for 2 min at −0.85, 0, or 0.45 V *vs.* SCE.

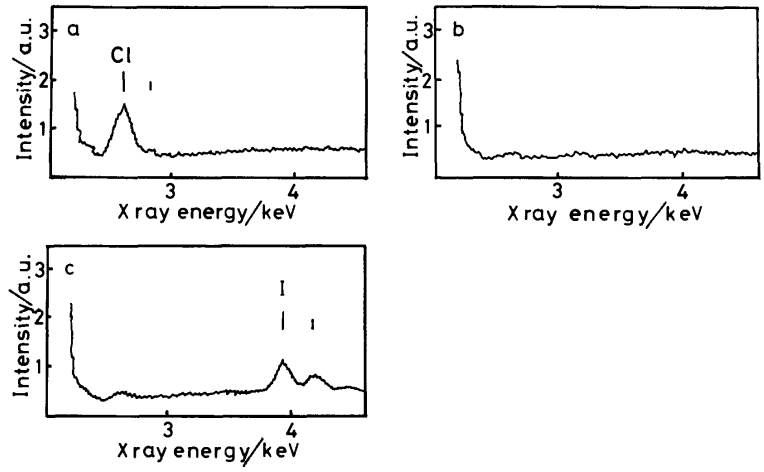

Fig. 3. EPMA spectra of PPy/Pt electrodes. (a) Original electrode prepared in 0.1 mol dm^{-3} $LiClO_4$/acetonitrile. (b) Reduced at −0.85 V *vs.* SCE in a 0.5 mol dm^{-3} KI aqueous solution for 2 min. (c) Successively oxidized at 0.45 V *vs.* SCE in the same solution for 2 min.

Prior to the measurements and analyses films were washed thoroughly with twice distilled water. The value of resistivity was found to be invariable for a few days in air. The observed results are shown in Table 2. In this table, the results of elemental analyses are given in relative molar ratio of each element to nitrogen. As expected, the original film has a low resistivity. When this film was polarized at −0.85 V in 0.5 mol dm^{-3} KCl aqueous solution, an elimination of a large part of the inserted ClO_4^- occurs and the resisitivity is enhanced. With an increase in anodic polarization, the incorporation of Cl^- anions into the film becomes appreciable as expected. Simultaneously, the resistivity becomes lowered. Judging from the results from the elemental analyses, the inserion of Cl^- is not completed at 0 V *vs.* SCE which is enough positive to the peak potential of voltammogram (see Fig. 1-(a)). It is noticed in the voltammogram that relatively large anodic currents flow in the potential region betweeen 0 and 0.45 V. At a glance, they seem to be attributable to capacitive currents,[9] but according to the results obtained that the content of Cl^- was increased by changing the polarization potential from 0 to 0.45 V *vs.*SCE, anodic oxidation of polypyrrole with insertion of anions still occurs in this potential region.

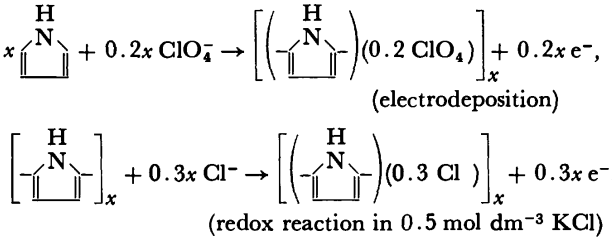
Another interesting point to be noticed is that the molar ratio of Cl^- was higher for the film polarized at 0.45 V in 0.5 mol dm^{-3} KCl than for the original film which contained the incorporated ClO_4^-. This result suggests that the charge involved in the redox process in 0.5 mol dm^{-3} KCl is higher than the excess charge retained in the film in the course of anodic polymerization of pyrrole. According to a literature,[8] 2.25 mol of electrons are involved in the electropolymerization of 1 mol of pyrrole, and 2 mol of electrons are consumed in the polymer chain formation. The extra amount of electrons is consumed in the ionization of film and the equivalent amount of anions is incorporated at that time. Judging from the results given in Table 2, our sample had an excess charge of 0.2 mol per mol of pyrrole when prepared in the acetonitrile solution, but more than 0.25 mol of electrons were found to be involved in the aqueous redox processes, as described below.

Table 2. Elemental analysis and resistivity of polypyrrole films polarized at different potentials in a 0.5 mol dm^{-3} KCl aqueous solution

E	Molar ratio to nitrogen				Resistivity
V *vs.* SCE	C	H	N	Cl	ohm cm
−0.85	4.06	3.33	1.00	0.03	3.9×10^{4}
0.00	4.03	3.28	1.00	0.15	1.2×10^{-2}
0.45	4.04	3.30	1.00	0.30	3.2×10^{-3}
Original	4.02	3.29	1.00	0.20	3.8×10^{-3}

According to the results with the original sample given in Table 2, 2.2 mol of electrons per mol of pyrrole are involved in the deposition of polypyrrole, whereas the results with the film polarized at 0.45 V suggest that 0.3 mol of eletrons can be used in the aqueous redox processes. The amount of charge consumed in the preparation of the PPy/Pt electrode was 36 mC cm^{-2}. When this sample was subjected to an anodic potential sweep from −0.8 to 0.4 V under the same conditions as chosen in the experiment shown in Fig. 1-(a), the charge of 4.8 mC cm^{-2} was consumed. Therefore, if such an assumption is made that 0.3 mol of electrons is involved in the aqueous redox processes, the charge capable of participating in the redox processes will be 36 mC cm$^{-2}\times0.3/2.2=4.9$ mC cm^{-2}, which is in fair agreement with the charge obtained in the course of anodic sweep.

These results undoubtedly support the validity of the reactions



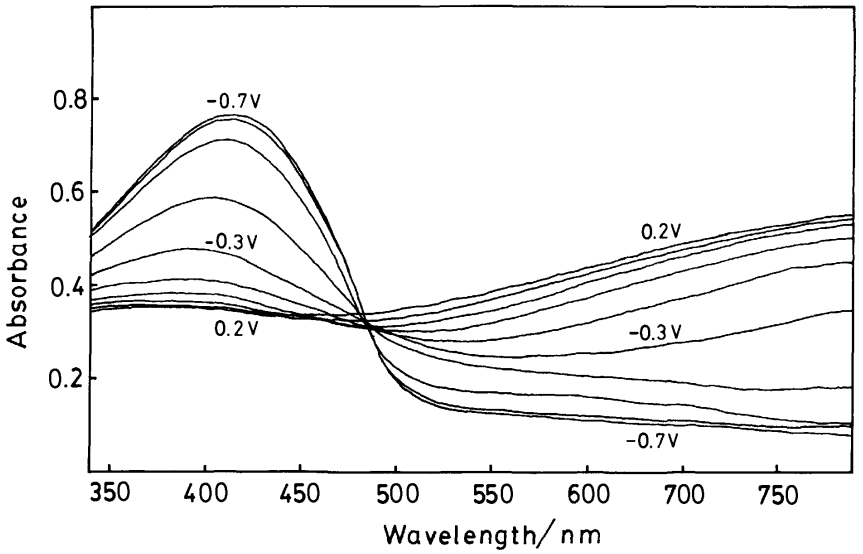


Fig. 4. Absorption spectra of a PPy/OTE electrode obtained *in situ* at different potentials in a 0.1 V interval in 0.5 mol dm^{-3} KCl.

Resistivity measurements were carried out for polypyrrole films prepared in the presence of other kinds of anions and almost the same values as shown in Table 2 were obtained. Judging from these results, electrical properties are primarily determined by charged conditions of polypyrrole which are controlled not by the kind but by the amount of incorporated anions.

Electrochromic Properties of Polypyrrole. It was reported[8,26] that the color of polypyrrole is variable with redox behavior in acetonitrile solutions. It was found that the same was true in aqueous solutions. The color change is reproducible and seems to be applicable to electrochromic display devices.

Visible absorption spectra of a PPy/OTE electrode, obtained under steady states at several different potentials, are shown in Fig. 4. Polymer films with incorporated Cl^- exhibit a brown-black color and show no appreciable absorption peaks. However, when the film is reduced, it turns yellow as recognized from an increase in absorption at wavelengths shorter than 500 nm. The absorption is thought to be assignable to the π-π^* transition of polypyrrole.[18] The coloring occurs noticeably at −0.1 V *vs.* SCE and is enhanced with an increase in cathodic potential up to −0.7 V, beyond which no appreciable increase in absorbance appears.

The change in the absorbance of polypyrrole films with electrolysis charge was pursued *in situ* in 0.5 mol dm^{-3} KCl. The films used were those prepared by anodic oxidation at 0.3 mA cm^{-2} for 2, 4, or 6 min in acetonitrile containing 0.1 mol dm^{-3} pyrrole and 0.3 mol dm^{-3} $LiClO_4$ and were initially reduced at −0.7 V in the solution for measurement. The absorbance of these films was then measured *in situ* during the course of anodic oxidation at 0.3 mA cm^{-2}. Results are given in Fig. 5-(a) as a function of the quantity of electricity consumed in the oxidation. The electrode potential values of the film in the initial and final stages (−0.7 and 0.4 V) and an intermediate stage (−0.2 V) are also given in the figure. In the final stage almost all the charges capable of being retained must have been accumulated in the film, as judged from the results given in Table 2. Fig. 5-(b) shows absorbances at these potetials as a function of the quantity of electricity consumed in the film preparation (Q_d) which is a measure of the film thickness. It is seen from this figure that the absorbance is proportional to the film thickness.

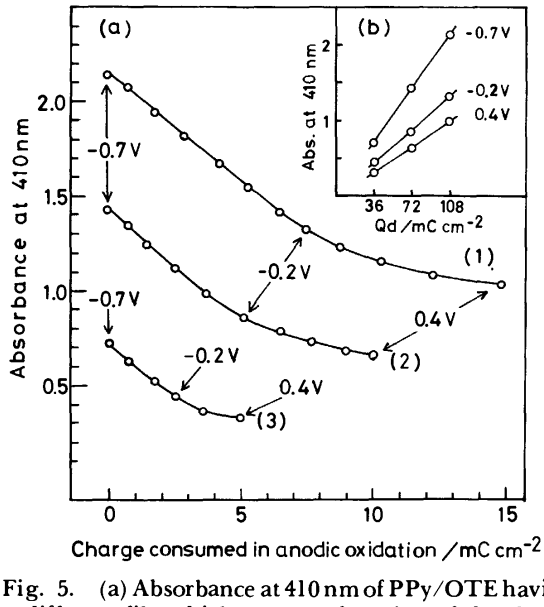

Fig. 5. (a) Absorbance at 410 nm of PPy/OTE having different film thickness as a function of the charge consumed in anodic oxidation at 0.3 mA cm^{-2} in 0.5 mol dm^{-3} KCl. (b) Absorbance at 410 nm of PPy/OTE at −0.7 V, −0.2 V, −0.4 V, in 0.5 mol dm^{-3} as a function of charge consumed for film preparation (Q_d).
The film preparation was carried out in acetonitrile containing 0.1 mol dm^{-3} pyrrole and 0.3 mol dm^{-3} $LiClO_4$ at 0.3 mA cm^{-2} for 2 min (Q=36 mC cm^{-2}) (1), for 4 min (Q_d=72 mC cm^{-2}) (2), and for 6 min (Q_d=108 mC cm^{-2}) (3).

According to Fig. 5-(a), for the films different in thickness linear relations with the same gradient are established between the absorbance and the charge consumed in the anodic oxidation of film in 0.5 mol dm^{-3} KCl as long as the electrode potential is more negative than −0.2 V. However, the rate of absorbance change becomes declined at potentials positive to −0.2 V. This behavior is in qualitatively agreement with the results shown in Fig. 4. The quantity of electricity consumed in the linear part is half the total charge capable of being stored, although with this amount of charge the absorbance at 410 nm changes by *ca.* 80% of the total change.

Relations for the linear part in Fig. 5-(a) are formulated as follows:

$$Abs = -0.119Q_c + 0.72 \text{ (for } Q_d = 36 \text{ mC cm}^{-2}), \quad (1)$$

$$Abs = -0.121Q_c + 1.44 \text{ (for } Q_d = 72 \text{ mC cm}^{-2}), \quad (2)$$

$$Abs = -0.120Q_c + 2.16 \text{ (for } Q_d = 108 \text{ mC cm}^{-2}), \quad (3)$$

where *Abs* denotes the absorbance at 410 nm and Q_c the charge consumed in the anodic oxidation. Since the absorbance is proportional to the quantity of electricity consumed in the film preparation, these equations may reduce to one equation

$$Abs = -0.12Q_c + 0.02Q_d. \quad (4)$$

Since the total amount of charge capable of being stored is $0.3/2.2 \times Q_d$ as stated above and half the charge is involved in the linear portion of the absorbance change (from −0.7 to −0.2 V), the upper limit of Q_c in the above equation is then $0.07Q_d$.

Cyclic voltammograms and absorbances at 410 nm of a PPy/OTE electrode are shown in Fig. 6 for the cases of 0.5 mol dm^{-3} KCl and 0.5 mol dm^{-3} Na_2SO_4. In the KCl solution the absorbance changes quite smoothly with variation in electrode potentials and the change in absorbance shows a hysteresis in the direction of potential sweep. A similar trend of change in absorbance appears also in the Na_2SO_4 solution. In both solutions the absorbance *vs.* potential relations show inflections at the potentials where the voltammograms show their peaks. Thus, two inflections are noticed in the voltammograms obtained on the anodic potential scan in 0.5 mol dm^{-3} Na_2SO_4. These results are closely related to the fact that the change in absorbance is brought about by the redox processes of polypyrrole.

Response behavior of absorbance to pulsed poten-

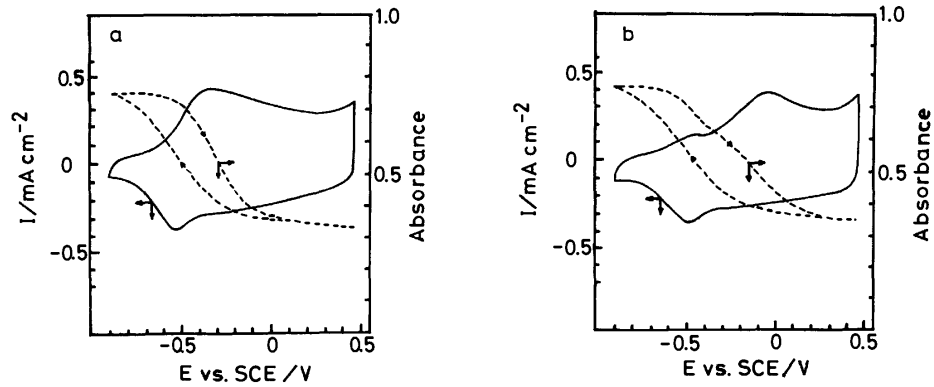

Fig. 6. Change in absorbance at 410 nm obtained *in situ* in the measurements of cyclic voltammograms. (a) in 0.5 mol dm^{-3} KCl (b) in 0.5 mol dm^{-3} Na_2SO_4. dE/dt=50 mV s^{-1}.

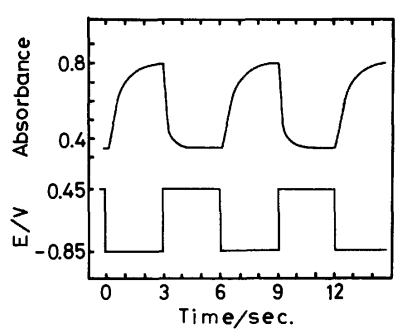

Fig. 7. Response behaviors of the absorbance change of the PPy/OTE electrode to repeated potential pulses of −0.85 V and 0.45 V *vs.* SCE in 0.5 mol dm^{-3} KCl. Absorbance was measured at 410 nm.

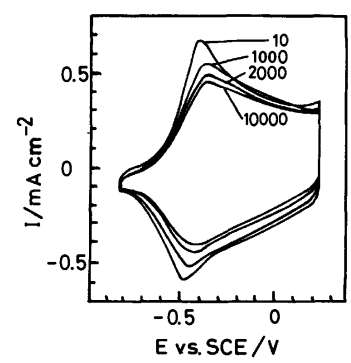

Fig. 8. Change in cyclic voltammograms of PPy/Pt electrode with the number of potential sweep cycles in 0.5 mol dm^{-3} KCl. The number in the figure denotes the cycle number. dE/dt=50 mV s^{-1}.

tials were investigated in 0.5 mol dm^{-3} KCl at 410 nm with a potential pulse of −0.85 or 0.45 V. Results are shown in Fig. 7. The response to the anodic pulse is faster than that to the cathodic one. The slowness of the cathodic response must be related to the fact that the polymer becomes resistive on application of −0.85 V. However, improvement of the response will be possible by appropriate choice of the film thickness, electrode area, and conductive substrate. Stability tests on the redox processes of polypyrrole were investigated in 0.5 mol dm^{-3} KCl with the PPy/Pt electrode. Results are shown in Fig. 8. The shape of voltammograms taken at the sweep rate of 100 mV s^{-1} becomes ill-defined with an increase in potential sweep cycles, but no appreciable change in film color is noticed to the naked eye during 10000 potential sweeps. These results suggest that polypyrrole is a promising candidate as a material for electrochromic display devices.

Basic Behaviors and Properties of the Electrodeposited Polyaniline

Akira KITANI,* Jinko IZUMI, Jun YANO, Yasuyuki HIROMOTO, and Kazuo SASAKI
Department of Applied Chemistry, Faculty of Engineering, Hiroshima University, Saijo-cho, Higashi-Hiroshima 724
(Received November 4, 1983)

Basic behaviors and properties of polyaniline(PA) deposited anodically on platinum electrodes have been studied on the following points. 1) Effect of the mode of electrolysis and supporting electrolytes in the film forming process. 2) Characteristics of charging-discharging processes. 3) Electric conductivity and elemental composition of PA. The different modes of electrolysis do not affect the characteristics of the PA electrode obtained. The growth rate of PA film is 2.7—2.8 times faster in sulfuric acid than in perchloric, nitric or hydrochloric acid. It is indicated that there are two types of doping; one is associated with the acid-base equilibrium between amino or imino group in the film and proton in the solution and the other is associated with the excess charge in the film produced by anodic oxidation. The electric conductivity of PA markedly decreases by the immersion in alkali solutions. The release of doped anion from PA by treating with an alkali solution is confirmed by the elemental analysis. The amount of anions occluded by the electrochemical doping process is determined to be 0.25—0.29 per monomer unit.

Polyaniline (PA) film as a typical electroconductive organic polymer has been first prepared by Diaz and Logan[1] by means of anodic oxidation of aniline in aqueous sulfuric acid. They used platinum as the anode electrode and the polymer film was deposited on it. Recently, Noufi and his coworkers[2] showed that the deposition of PA film is possible onto the surface of several semiconductor electrodes such as Cd-chalcogenides, Si, GaAs, and GaP. Since the latter materials are corrosive in aqueous media, the polymer coating will provide a new mean of the corrosion protection.

In contrast to polypyrrole[3], another representative conducting polymer, studies on polyaniline are very limited and, as far as we are aware, only two papers which are mentioned above have been published in the past. We thus attempted to study the basic characters of polyaniline in more detail.

Experimental

Electrode substrate used was a platinum wire having geometry of 1 mm in diameter and 10 mm in length ($S=ca.$ 0.3 cm^2). Only for the determination of doped anions released from the film, a platinum plate having surface area of *ca.* 8 cm^2 was used. Although two types of electrolysis, repeated potential cycling and controlled potential electrolysis, were employed in the film forming process, the most of measurements were made with PA electrode (PAE) prepared by potential cycling. The potential cycling was repeated usually 40 to 50 times in sulfuric acid solutions. Other details of electrochemical measurements are given at appropriate positions in the following description.

Electric conductivity of PA films was measured with the four-probe method described by van der Pauw.[4] Specimens used for the conductivity measurement were prepared by pressing the powdery product obtained by potentiostatic electrolysis.

All the potential values cited in this paper are those referred to a saturated calomel electrode. All experiments were carried out at room temperature.

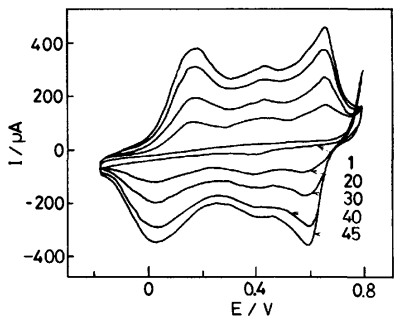

Fig. 1. Change of voltammograms in the preparation of polyaniline film by repeated potential cycling between −0.2 and 0.8 V. Numerical figure attached to each curve indicate number of potential cycle.
Solution: 0.1 M H_2SO_4+0.1 M aniline.
Sweep rate: 100 mV·s^{-1}.

Results and Discussion

1. Preparation of Polyaniline Film. Polyaniline film electrodes (PAE) were prepared in two different ways, repeated potential cycling and constant potential electrolysis. Figure 1 indicates the cyclic voltammogram observed with a platinum electrode immersed in 0.1 M H_2SO_4 containing 0.1 M aniline (1 M=1 mol dm^{-3}). The redox charge of polyaniline film continued to grow by the repetition of potential cycling. The cathodic charge in Fig. 1 increased linearly with the number of potential cycling. This indicates that the growth of polyaniline film is proportional to the number of potential cycling.

The possibility of preparing the film with constant potential electrolysis was next studied in 0.1 M H_2SO_4

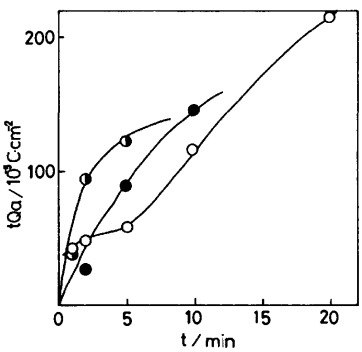

Fig. 2. Change in total anodic charge against the duration of constant potential electrolysis.
Electrode potential: 0.8 [●], 1.0 [○], 1.2 [◑] V.
Solution: 0.1 M H_2SO_4+0.1 M aniline.

containing 0.1 M aniline. The electrolyses were carried out at 0.8, 1.0, and 1.2 V, and the transient current was recorded for each measurement. After finishing the electrolysis, the electrode was subjected to the cathodic potential sweep to determine the charge associated with the redox reaction of the film itself, Qr.

The rate of aniline oxidation is a complicated function of the electrode potential. The total anodic charge, tQa, rapidly and monotonously approached to a saturation value at 0.8 and 1.2 V. Contrarily, at 1.0 V, the tQa-time curve made a step, where tQa almost ceased to increase, and again increased gradually. These are shown in Fig. 2.

Regardless of the electrode potential a tight thin film first appeared on the platinum surface and soon after that a powdery, non-adhesive structure which finally falls down from the electrode grew over the film surface. Inside of this massive structure, the thin film seems to grow progressively as far as tQa continues to increase. In fact, when Qr's were plotted against the time of anodic treatment, the curve forms were entirely similar to those shown in Fig. 2. The cyclic voltammograms exhibited by two PAE's prepared by the constant potential electrolysis and the potential cycling were almost the same and no practical difference was observed.

Although the constant potential electrolysis is complicated by the intervention of the powdery product, it is undoubted that a tight film of definite thickness is also obtained by this method. It should be also noted that by pressing the powdery product we can easily prepare a film or a pellet without spoiling electrode activity.

The effect of supporting electrolytes in the film forming process was studied. PAE was prepared by continuous potential cycling. The increase of doping charge per unit cycle, which is assumed as a measure of the rate of film growth, is listed in Table 1 to see the effect of electrolytes on the rate of film growth. It is indicated that the growth rate of PA film is extraneously faster in sulfuric acid. This may be partly attributed to the bivalency of sulfate anion.

The surface structure of PA film was observed by scanning electron microscopy. It was found that the film prepared in perchloric acid is rather smooth compared to that prepared in sulfuric acid.

2. Charging and Discharging Behavior. In the cyclic voltammograms of PAE in solutions containing no aniline, it is generally observed that the charge consumed in the anodic half cycle is exactly compensated in the succeeding cathodic half cycle. This was also the case, even though aniline was present in the solution, when PA film had already been grown enough after a number of potential cycling (Fig. 1). This indicates that, with a PAE having a thicker film, the film growth is slow enough and the charge consumed for it becomes negligible compared with the charge associated with the redox reaction of the film itself.

TABLE 1. EFFECT OF SUPPORTING ELECTROLYTES IN THE FILM PREPARATION PROCESS

Acid	No. of cycle	Doping charge	Doping charge/cycle
			mC cm^{-2}
0.1 M H_2SO_4	45	6.15	0.137
0.2 M $HClO_4$	80	3.85	0.0481
	135	6.33	0.0469
0.2 M HCl	135	6.30	0.0466
0.2 M HNO_3	200	10.2	0.0510

Potential cycling was repeated between −0.2 and 0.8 V at 0.1 V.s^{-1}.

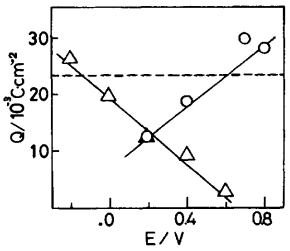

Fig. 3. Redox charge determined by potential step technique as a function of electrode potential.
○: determined from anodic going step from −0.2 V.
△: determined from cathodic going step from 0.8 V.
PAE used for this figure was prepared in 0.1 M H_2SO_4 and measurements were made in aniline free 0.1 H_2SO_4.

In order to see the nature of the charging and discharging reactions of the film more precisely, we employed the potential step technique. Figure 3 shows the results. Anodic charge in this figure was determined from the current decay at a given potential stepped up from the cathodic limiting potential (−0.2 V). Similarly, cathodic charge was determined by stepping down the potential from the anodic limiting potential (0.8 V). It is seen that both the anodic and cathodic charges are linear functions of the electrode potential showing that a PA film has a character of an electric condensor in the sense that the relation Q=CV holds.

Diaz and Logan[1] assumed that the charging-discharging processes of PA are the elimination-addition reactions of proton.

$$(C_6H_5N)_n = (C_6H_4N)_n + nH^+ + ne.$$

There is, however, another possibility of ingress and degress of anionic species in and out of the film as are known with polypyrrole.[3] We shall call this as the doping and undoping reactions.

$$(C_6H_4N)_n + pX^- = (C_6H_4N)_n^{p+}pX^- + pe.$$

In order to confirm the true mechanism, the cathodic dissolution of sulfate anions from the PA film was studied qualitatively. A PAE prepared in sulfuric acid was subjected to the cathodic reduction at −0.2 V in 0.1 M HCl containing $BaCl_2$. By this treatment it was observed that a white cloud grew at the film surface and spread gradually into the solution. The same subject was also studied by using benzenesulfonate as the doping anion. A PAE, which was made free from dopant by cathodic treatment, was oxidized at 0.8 V in 0.1 M benzenesulfonic acid. The PAE thus obtained was washed with water and then reduced at −0.2 V in sulfuric acid for 3 min. The dissolution of benzenesulfonate was confirmed by uv absorption spectra. It is indisputable that benzenesulfonate does dope into the film structue.

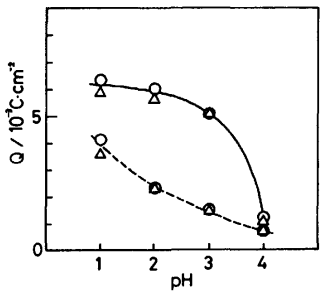

Fig. 4. Effect of the solution pH on the doping capacity.
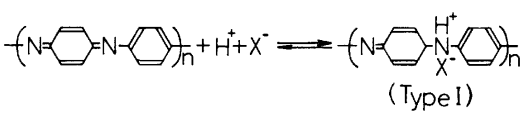
Full line was obtained with PAE prepared in 0.1 M H_2SO_4 while broken line was obtained with PAE prepared in 0.2 M $HClO_4$.
△: anodic charge. ○: cathodic charge.

At present, it is not clear whether the charging-discharging process of PAE is of solely doping and undoping reactions. The possibility that the proton elimination mechanism is occurring simultaneously with the doping mechanism cannot be ruled out. Although the detailed mechanism is uncertain, it is undoubted that the doping mechanism is operating during the redox process of PAE. Another information concerning the amount of anions in the polymer structure was also obtained by the elemental analysis of PA, and will be discussed in the succeeding section.

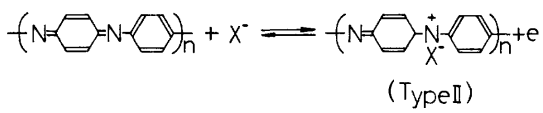
3. Effect of the Solution pH. Figure 4 shows the effect of the solution pH on the doping charge of PAE. It is seen that the doping charge decreases with increasing pH and diminishes at about pH=4. Diaz and Logan[1] were aware of this fact and attributed to the difference of nucleophilicity of solvents without any further discussion. This behavior may be related to the acid-base equilibrium of amino or imino nitrogen in the film with proton in the solution. With the increase of the solution pH, the equilibrium will shift towards the deprotonation of amino or imino nitrogen. The deprotonated film seems to lose its electric conductivity. This is the reason why PAE is only active in acidic environments.

In fact, the electric conductivity of a film prepared in H_2SO_4 was decreased from 4.0 $\Omega^{-1}cm^{-1}$ (doped state) to 0.26 $\Omega^{-1}cm^{-1}$ (undoped state). When, however, the same film was immersed to an alkaline solution (0.1 M NaOH) the conductivity decreased to an unmeasurable value. The release of doped anion from powdery polyaniline by treating with an alkali solution was also confirmed by elemental analysis. Results will be described in detail in the succeeding section.

From the results described above, it can be concluded that there are two types of anions occluded in the film structure; one neutralizes protonic charges associated with the acid-base equilibrium (Type I) and the other



(Type I)



(Type II)

compensates the excess plus charges produced by anodic oxidation of film structure (doping process, Type II). The portioning of these two types of anions is an interesting problem to be studied in future studies.

4. Electric Conductivity. In aqueous solutions, PAE is electroactive only in acidic environments. In solutions of pH>4, no appreciable charge transfer reaction across the PAE/solution interface takes place. This was attributed to the loss of the electric conductivity of the film due to the deprotonation caused by the acid-base equilibrium. This sort of deactivation will occur only in the surface layer, so long as the time of contact with water is limited.

In order to confirm this view further, a PAE prepared in a sulfuric acid solution was transferred to an acetonitrile solution containing $NaClO_4$ as the supporting electrolyte to take voltammograms. Prior to transferring the electrode, the electrode was rinsed in an aqueous 0.1 M K_2SO_4 solution for 15 min and was washed with water and acetonitrile successively. Voltammograms shown in Fig. 5 were taken periodically as indicated in the figure caption. One can see that the electrode becomes inactive by the water treatment but recovers its activity gradually. Dashed curve in this figure stands for the electrode which has been washed merely with acetonitrile without rinsing in water. The recovery of the electrode activity may be related to the slow diffusion of protons from the inside of the film to its outer surface.

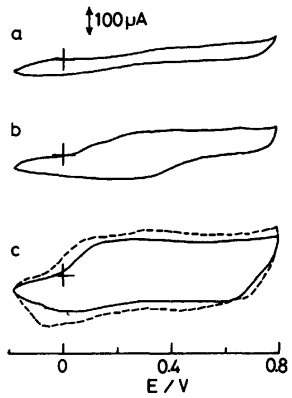


Fig. 5. Recovery of doping capacity during the immersion in acetonitrile.
PAE used was first rinsed in neutral K_2SO_4 solution for 15 min and was transferred into an acetonitrile solution.
a: just after the transfer, b: after 50 min, c: after 2 d.
Broken curve was taken by voiding the rinsing in K_2SO_4 solution.

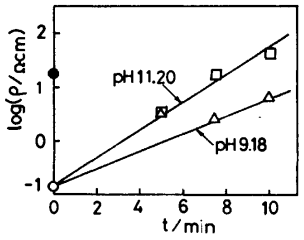

Fig. 6. Change of specific resistance of doped polyaniline with immersing time in alkaline solutions.

Table 2. Elemental analysis of polyaniline powder prepared in perchloric acid

$C_6H_wN_x\ y$(dopant) $z(H_2O)$

Sample	W	X	Type I $y_I(HClO_4)$	Type II $y_{II}(ClO_4^-)$	Z
I(Oxidized form)	3.9_7	0.97	0.85*	0.29	2.35
II(Reduced form)	3.8_8	0.96	0.98	—	1.85
III(Deprotonated form)	4.7_7	0.98	—	0.29	0.16

* Caluculated from the total amount of dopants (y=1.14) and y_{II}.

The change of electric conductivity by the immersion in alkali solutions (pH=9.13 and 11.20) was measured with four probe method.[4] In this experiment PA powder prepared potentiostatically at 0.8 V in perchloric acid was pressed to form a pallet. Logarithum of specific resistance of doped polymer changed almost linearly with the immersion time as shown in Fig. 6. It is thus possible to control the conductivity of PA from conducting to semiconducting states by changing the immersion time and/or pH of the solution.

Full circle located on the ordinate stands for the resistivity of PA which was subjected to a prolonged cathodic undoping. It is worth noting that an appreciable conductivity is still retained by the reduced PA. This indicates that the electric conductivity of the PA film is largely determined by the amount of anions brought into the film by acid-base equilibrium.

5. Elemental Composition of PA. In the preceding section, we concluded that there are two types of dopants in the film; one is to neutralize protonic charges associated with acid-base equilibrium (Type I) and the other is to compensate the positive charges produced by anodic oxidation (Type II). In order to obtain informations concerning the amounts of Type I and Type II dopants the elemental analysis of PA was carried out.

Three kinds of different samples were prepared for this. The first sample was a massive PAE which was prepared by constant potential electrolysis at 0.8 V (Sample I, oxidized form). The same sample was further treated by cathodic reduction at 0 V (Sample II, reduced form). The third sample was basically the same as Sample I but was immersed in a 0.1 M NaOH solution for 2 h (Sample III, deprotonated sample). The amount of anions in Sample III should give the amount of Type II dopant. In all cases, the samples were scratched off from the electrode substrate and they were weighed and subjected to the elemental analysis. Results are summarized in Table 2, where w, x, y, and z are the numerals appearing in the assumed formula $C_6H_wN_x\cdot y$(Dopant)$\cdot z(H_2O)$, y_I and y_{II} discriminate the types of dopant.

The y_{II} value can also be determined by calculation if we know the initial weight of a given sample and the charge required for its cathodic reduction. The value thus determined was 0.25 which is in a good agreement with the value determined by elemental analysis, 0.29. The y_I value determined with Sample II should equal to x, if all of the nitrogen atoms of PA participate the acid-base equilibrium. The data confirms this expectation. The existence of water in PA should be correlated with the hydration of doping ions. A drastic change in z value appeared in Sample III may, perhaps, be an indication of that the hydration occurs predominantly to protons rather than anionic species.

The apparent formula of aniline moeity was determined to be C_6H_4N for both oxidized and reduced forms. By considering the amount of Type II doping is 0.25—0.29 per monomer unit, the overall polymerization reaction can be expressed as follows.

$$4n(C_6H_7N) \longrightarrow (C_6H_4N)_n^{+} + 12H^+ + 13e.$$

The hydrogen content of the deprotonated sample was somewhat larger than that of oxidized form. The reason is unknown now, but may be partly related to the partial hydrolysis catalyzed by base.

Qualitatively, similar results were obtained for the samples prepared in H_2SO_4. The total amount of dopants (assumed as SO_4^{2-}) was 1.13, 0.81, and 0.16 for oxidized, reduced, and deprotonated samples, respectively. Quantitative discussion is rather difficult because there is a possibility of existing as both monovalent and divalent anions, HSO_4^- and SO_4^{2-} being doped simultaneously.

This work was supportcd by Grant 57850257 supplied by the Ministry of Education, Science and Culture. The authors wish to express their thanks to Mr. Makoto Ogasawara for the measurement of elemental composition of PA.

Electronic Spectra of $(DBTTF)_3 \cdot SnBr_6$ Complex

Masashi TANAKA,* Kohji KAMIYA,† Jiro TANAKA,† and Shizuaki MURATA
Department of Chemistry, College of General Education, Nagoya University, Nagoya 464
†*Department of Chemistry, Faculty of Science, Nagoya University, Nagoya 464*
(Received February 17, 1984)

The polarized reflection spectra of $(DBTTF)_3 \cdot SnBr_6$ complex have been measured and the absorption spectra have been determined by the simulation of the observed reflection spectra. The 4000 cm^{-1} band polarized parallel to the stacking axis has been assigned to the charge resonance(CR) band. The theoretical analysis of the electronic structure of $(DBTTF)_3 \cdot SnBr_6$ complex has been made for the explanation of the energy and absorption intensity of the CR band.

Organic charge transfer radical salts of the electron donor TTF (tetrathiafulvalene) and the electron acceptor such as TCNQ (tetracyano-*p*-quinodimethane) display the high electrical conductivties.[1,2] These organic conductors show the special feature of their crystal structures. That is, electrons and holes are delocalized along segregated stacks of the cation donor and anion acceptor free radicals. Therefore, the presence of donor and acceptor stacks causes considerable complexities of solid state properties of organic conductors and there has been a considerable interest in the studies on their highly anisotropic electrical, optical, and magnetic properties. The optical properties of such pseudo-one-dimensional materials were analyzed by Hubbard Hamiltonian as was shown in our earlier paper on TCNQ complexes.[3] On the other hand, after the high conductivity was observed using a four-probe method in single crystals of TTF-TCNQ, many donors and acceptors were synthesized and the preparation of organic metal was intended. Dibenzotetrathiafulvalene (DBTTF) is one of them and the direct oxidation of DBTTF by halogens and metal halides were reported to yield complexes such as $(DBTTF)_2 \cdot I_3$,[4] $(DBTTF)_8 \cdot (SnCl_6)_3$,[5] and $(DBTTF)_3 \cdot SnBr_6$.[5]

In this paper, we report the polarized reflection spectra of $(DBTTF)_3 \cdot SnBr_6$ complex and the theoretical analysis of the new electronic structure found in the $(DBTTF)_3 \cdot SnBr_6$ system.

Experimental

DBTTF was prepared by Nakayama's method[6] and the crystal of $(DBTTF)_3 \cdot SnBr_6$ complex was prepared by the diffusion of DBTTF and $SnBr_4$ molecules in acetonitrile solution. Reflection spectra at the normal incidence were measured over a range of 4000—25000 cm^{-1} with a reflection microspectrophotometer made in our laboratory and all computations were carried out on a FACOM-M382 computer at the NAGOYA university computation center.

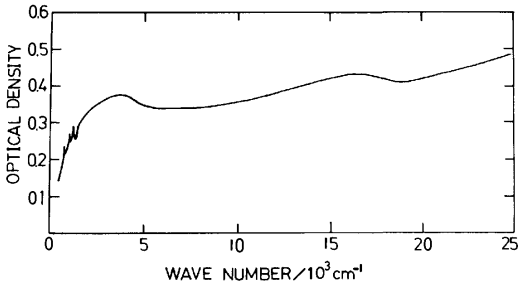

Fig. 1. Absorption spectrum of $DBTTF_3 \cdot SnBr_6$ complex in KBr disk.

Results and Discussion

The absorption spectrum of $(DBTTF)_3 \cdot SnBr_6$ complex in KBr disk is depicted in Fig. 1. The first band is located in the region of 4000 cm^{-1} and the threshold of this band overlaps with a few vibrational bands. The second band is observed at 15000 cm^{-1}.

$(DBTTF)_3 \cdot SnBr_6$ complex forms orthorhombic crystals of space group Pnn2 having two complexes in a unit cell. Projection onto the (100) plane is shown in Fig. 2.[7] The characteristic of the structure of the complex shows the stacking layer of the anion ($SnBr_6^-$) and the molecule DBTTF. Each layer elongates along the direction of the crystalline axis c, and the period along the layers consists of 1 and 3 units of $SnBr_6^-$ and DBTTF, respectively. For the molecule of DBTTF, the center of molecule is located along the direction of two-fold axis and the molecular plane is perpendicular to the stacking axis. Two of DBTTF molecules (molecules 1 and 2) overlaps each other completely, but one of them (molecule 3) has the configuration twisted for the other two molecules.

The polarized reflection spectra shown in Fig. 3 indicate that the 4000 cm^{-1} band observed in the c axis spectrum can be assigned to the band having the transition moment parallel to the intermolecular direction and the 15000 cm^{-1} band is due to the intramolecular transition of DBTTF cation radical.[8] Whole behavior of the observed reflection spectra is similar to that of $(DBTTF)_8 \cdot (SnCl_6)_3$ crystal except for the reflectivity value of 4000 cm^{-1} band ($R \simeq 80\%$).[9]

The reflectivity R can be expressed by the following

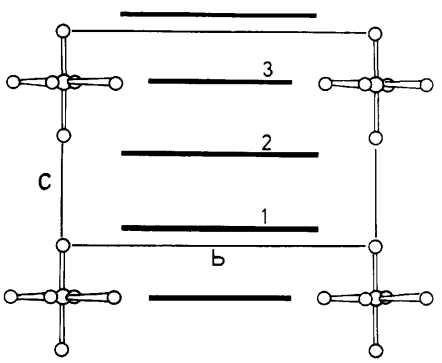

Fig. 2. Projection onto the (100) plane of the crystal of $DBTTF_3 \cdot SnBr_6$ complex.[7]

equations,[10]

$$R = \frac{1 + |\varepsilon| - \sqrt{2(|\varepsilon| + \varepsilon_1)}}{1 + |\varepsilon| + \sqrt{2(|\varepsilon| + \varepsilon_2)}}, \quad (1)$$

and

$$\varepsilon(\omega) = \varepsilon_1(\omega) + i\,\varepsilon_2(\omega) = \varepsilon_{core} + \sum_j \frac{\Omega_j^2}{\omega_j^2 - \omega^2 - i\,\omega\,\gamma_j}, \quad (2)$$

where $|\varepsilon| = \sqrt{\varepsilon_1(\omega)^2 + \varepsilon_2(\omega)^2}$. The parameters Ω_j, ω_j, and γ_j can be determined by the best fit of the calculated reflection values to the observed spectra. The obtained parameters are shown in Table 1 and the best fit curves are plotted in Fig. 3 for comparison with the experimental curves. The absorption coefficient $\alpha(\omega)$ based on these parameters can be obtained by the next equations.[11]

$$\alpha(\omega) = \frac{4\pi}{c\,n(\omega)}\omega\,\varepsilon_2(\omega), \quad (3)$$

and

$$n(\omega)^2 = \frac{1}{2}[\sqrt{\varepsilon_1(\omega)^2 + \varepsilon_2(\omega)^2} + \varepsilon_1(\omega)]. \quad (4)$$

The obtained absorption spectra are described in Fig. 4

Table 1. Dielectric parameters of the Lorentz fits of reflectivity data for $(DBTTF)_3 \cdot SnBr_6$

	//c spectrum	⊥c spectrum	
ε_{core}	2.94	3.10	
Ω_j/cm^{-1}	8700	9000	18500
ω_j/cm^{-1}	3800	15800	28000
γ_j/cm^{-1}	1910	4900	20000

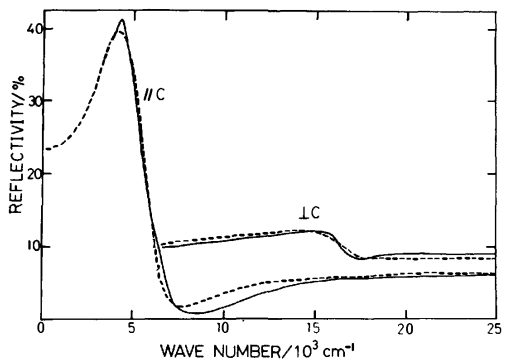

Fig. 3. Observed and calculated reflection spectra of the crystal of $DBTTF_3 \cdot SnBr_6$ complex (——: observed, ----: calculated).

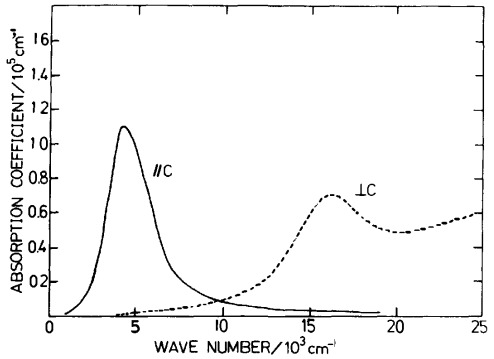

Fig. 4. Calculated absorption spectra of the crystal of $DBTTF_3 \cdot SnBr_6$ complex.

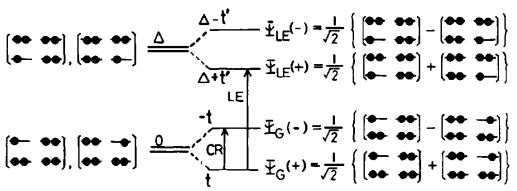

Fig. 5. Energy diagram of $DBTTF_3 \cdot SnBr_6$ complex.

and the oscillator strength f of the 4000 cm^{-1} band is estimated to be 0.3 by using the equation

$$f = \frac{m_e}{2\pi^2 N e^2}\int \omega \cdot \varepsilon_2(\omega)\,d\omega, \quad (5)$$

where N is the number density (2.49×10^{21} cm^{-3}) of $DBTTF \cdot SnBr_6$ complex in the crystal and m_e the electron mass. In order to explain the absorption intensity of the 4000 cm^{-1} band, $(DBTTF)_3 \cdot SnBr_6$ complex is proposed to have the electronic structure shown in Fig. 5. That is, the π-electron can transfer between the molecules 1 and 2 in the unit cell, although it can not move between the molecules 1 and 3, or 2 and 3. This model can be supported by the feature of the molecular overlap as is noted in the earlier paragraph. Accordingly, the DBTTF cation radical is either of the molecules 1 and 2.[7] Then, the ground configuration functions of $(DBTTF)_3 \cdot SnBr_6$ complex can be written as follows,

$$\Psi_{G,1} = a_{1,m}|HF>, \quad (6)$$

and

$$\Psi_{G,2} = a_{2,m}|HF>. \quad (7)$$

Here, $|HF>$ means the Hartree-Fock wavefunction of the neutral trimer $(DBTTF)_3$. $a_{1,m}$ and $a_{2,m}$ are the annihilation operators of the highest occupied molecular orbital ($\phi_{1,m}$ and $\phi_{2,m}$) of the molecules 1 and 2, respectively. On the other hand, the locally excited configurations of the cation radical can be expressed in the following equations,

$$\Psi_{LE,1} = a_{1,m-1}|HF>, \quad (8)$$

and

$$\Psi_{LE,2} = a_{2,m-1}|HF>, \quad (9)$$

where $a_{1,m-1}$ and $a_{2,m-1}$ are the annihilation operators of the next highest occupied orbitals ($\phi_{1,m-1}$ and $\phi_{2,m-1}$).

The wave functions and the energies of the ground state $\psi_G(+)$ and the lowest excited state $\psi_G(-)$ are given as the solution of the modified Hubbard Hamiltonian[3] in the next equations,

$$E_G(+) = t_{m,m},\ \Psi_G(+) = \frac{1}{\sqrt{2}}\{\Psi_{G,1} + \Psi_{G,2}\}, \quad (10)$$

$$E_G(-) = -t_{m,m},\ \Psi_G(-) = \frac{1}{\sqrt{2}}\{\Psi_{G,1} - \Psi_{G,2}\}, \quad (11)$$

where $t_{m,m}$ is the transfer integral between $\phi_{1,m}$ and $\phi_{2,m}$. The transition moment between $\psi_G(+)$ and $\psi_G(-)$ is given as follows,

$$<\Psi_G(+)|\mathbf{M}|\Psi_G(-)> = \frac{1}{2}\{<\phi_{1,m}|e\boldsymbol{r}|\phi_{1,m}> - <\phi_{2,m}|e\boldsymbol{r}|\phi_{2,m}>\} = \frac{e}{2}\boldsymbol{R}_{12}. \quad (12)$$

Here, $\boldsymbol{R}_{12}$ is the difference between the position vectors of the center of the molecules 1 and 2 and $\boldsymbol{R}_{12}$=3.58 A.[7] Then, the theoretical oscillator strength f^{theor} can be estimated as follows,

$$f^{theor} = 3 \times 1.085 \times 10^{11} E_{CR} |\boldsymbol{R}_{12}|^2/4 \simeq 0.4, \quad (13)$$

where $E_{CR}=2t_{m,m}$ is the transition energy in cm^{-1} ($\simeq$4000 cm^{-1}). The calculated value ($f^{theor}\simeq 0.4$) can be comparable with the observed one ($f\simeq 0.3$). Therefore, the 4000 cm^{-1} band can be called the charge resonance band (CR) corresponding to the transition from the state $\psi_G(+)$ to the state $\psi_G(-)$ as is depicted in Fig. 5. $(DBTTF)_3 \cdot SnBr_6$ complex is the first example of the one-dimensional complex having such electronic structure which is different from the dimer, alternant and island types shown in our earlier paper.[3]

Intramolecular Interactions in the Ground and Excited States of 1,3-Bichromophoric Propanes in the Aqueous Cyclodextrin Solutions

Michiya ITOH* and Yoshihisa FUJIWARA
Faculty of Pharmaceutical Sciences, Kanazawa University, Takara-machi, Kanazawa 920
(Received March 12, 1984)

The enhanced fluorescence of several 1,3-bichromophoric propanes in aqueous cyclodextrin solutions has been investigated by the steady-state fluorescence spectra and fluorescence lifetimes. 1-(9,10-Dicyano-2-anthryl)-3-(1- and 2-naphthyl)propanes exhibit the intramolecular charge transfer complex fluorescence generated in the ground state in the presence of γ-cyclodextrin. Two bichromophoric propanes, 1,3-di-2-naphthylpropane and 1-(1-naphthyl)-3-(2-naphthyl)propane, in the aqueous β- and γ-cyclodextrin solutions show not only the intramolecular excimer but also the ground state complex fluorescences, though the ground state complex formation of dinaphthylpropane has never been observed in the homogeneous solution even at low temperature. The intramolecular interactions in the ground and excited states seem to be attributable to their intramolecularly geometrical restriction in the extraordinary nonpolar cavity of the cyclodextrins.

The photochemical and photoinduced interactions of organic molecules have been recently studied in the cyclodextrin inclusion systems. Ueno *et al.*[1] reported one host-two guest complex between γ-cyclodextrin (γ-CDx) and sodium 1-naphthylacetate exhibiting excimer fluorescence. The large cavity of γ-CDx is capable of including two molecules of 1-naphthylacetate which shows the characteristic excimer fluorescence, whereas the cavity of α- and β-CDx is too small to accomodate two guest molecules. Recently, Turro *et al.*[2] reported the enhanced intramolecular excimer formation of 1,3-bichromophoric propanes (BC) in the aqueous β- and γ-CDx solutions. They suggested that a stable CDx and BC complex is formed exhibiting excimer fluorescence in cases where the correspondence of the size and shape of the eclipsed conformation of BC system and the cavity of CDx is high and the ratio of excimer and monomer fluorescence intensities is much greater in these cases than in homogeneous solutions. In these so called excimer fluorescence, however, no information of the dynamic process of the excimer formation in the CDx cavity was presented; whether the fluorescence is attributable to the real excimer or to the excited state of the ground state complex in the CDx cavity is not obvious.

This paper presents the intramolecular ground state complex fluorescence of 1-(9,10-dicyano-2-anthryl)-3-(1- and 2-naphthyl) propanes (βα- and ββ-DCAN),[3] and the ground state complex fluorescence as well as the excimer of 1,3-dinaphthylpropanes in the aqueous CDx solutions. The ground state complex formation in the CDx cavity is prevailing to the intramolecular excimer in 1,3-di-2-naphthylpropane (ββ-DNP), while the excimer formation is significant in 1-(1-naphthyl)-3-(2-naphthyl)propane(βα-DNP)[4,5] The intramolecular ground state complex and excimer formations are discussed in terms of the dynamic process of the intramolecular interaction of BC moieties in the CDx cavity both in the ground and excited states.

Experimental

Cyclodextrins (Nakarai Chem.) were recystallized three times from water. The 1,3-bichromophoric compounds were prepared and purified by the methods reported in the previous papers.[3-5] Ion exchanged and distilled water was used. An aqueous CDx solutions of BC compounds were prepared by filtration through a micropore filter (Fuji Film Co. pore size 0.22 μm) after sonification for about 10 min. Absorption and fluorescence spectra were measured by a Hitachi 323 and MPF-4 spectrophotometers, respectively. Fluorescence decay curves were obtained by using the Ortec Single Photon Counting system with the PRA 510 nanosecond light pulser. The triple or double exponential decay was analyzed by the following equation,

$$I(t) = A_1 \exp(-t/\tau_1) + A_2 \exp(-t/\tau_2) + (1-A_1-A_2)\exp(-t/\tau_3), \quad (1)$$

where A_i and t_i are pre-exponential factor and fluorescence lifetime, respectively. The data analysis for the above equation was performed by a computer simulated deconvolution.[6] The criterion for the "best fit" was the minimum sum (Q) of the squares of the difference between observed (D_i) and calculated (D_i') data; an actual allowance was $Q<0.0001$. $Q=\sum_i^n (D_i-D_i')^2/n$, where n is the number of data, D_i and D_i' were normalized to 1.

Results and Discussion

The Ground State Complex Formation of DCAN in the Aqueous CDx Solution. Two 1,3-bichromophoric compounds, ββ- and βα-DCAN are completely insoluble in aqueous solution exhibiting no fluorescence. By adding γ-CDx in the aqueous solution, the

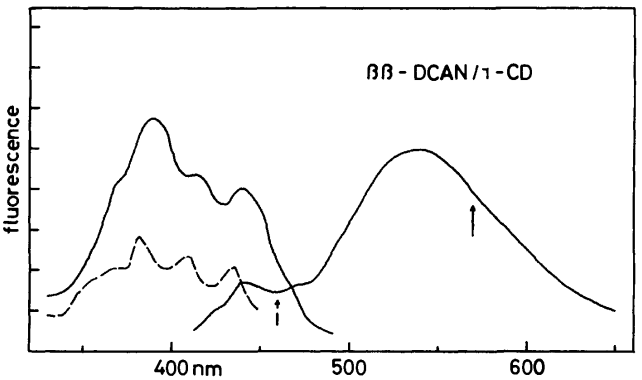

Fig. 1. Fluorescence (uncorrected, excited at 360 nm) and excitation spectra of the γ-CDx solution (10^{-2} mol dm^{-3}) of ββ-DCAN (1.8×10^{-7} mol dm^{-3}) at room temperature. The excitation spectra were monitored at 570 nm (——) and 460 nm (------).

fluorescence spectra were observed as shown in Fig. 1, where the solution was filtrated by micropore filter for removing microcrystals. However, no fluorescence was detected in the α- and β-CDx solutions. The fluorescence spectrum of this γ-CDx solution of ββ-DCAN exhibits a long wavelength fluorescence at 500—570 nm in addition to the 9,10-dicyanoanthryl moiety (DCA moiety) fluorescence at 430—500 nm at room temperature. The excitation spectrum of the former fluorescence is different from that of the latter and from the absorption spectrum of an ethanol solution of this compound. The excitation spectrum of the former long wavelength fluorescence is very similar to that of the ground state complex fluorescence observed in the 3-methylpentane (MP) solution at low temperature reported previously.[3] The MP solutions of ββ- and βα-DCAN show the ground state complex fluorescence at 500—570 nm at low temperature as well as the exciplex fluorescence at room temperature.[3] Further, the absorption spectra of the MP solution confirmed the ground state complex formation at low temperature. Therefore, the long wavelength fluorescence of the aqueous γ-CDx solution of ββ-DCAN may be ascribed not to the exciplex but to the ground state complex in the CDx cavity, though the ground state complex formation cannot be confirmed by the absorption spectra because of too weak absorption intensity. The similar ground state complex fluorescence was observed in the γ-CDx solution of βα-DCAN, whose fluorescence and excitation spectra are shown in Fig. 2. If the ≈550 nm fluorescence consists of the ground state complex and the exciplex fluorescence superimposed, the decay curve might be expressed by four or three components of exponential. However, the double exponential decay was observed throughout 450—580 nm region, though the ratio of the short lifetime component to the long was much larger at 430—530 nm than >530 nm. Therefore, the long wavelength and long lifetime fluorescence may be attributable mostly to the ground state complex mentioned above, even if a possibility of the small contribution of the exciplex fluorescence cannot entirely be removed at the present stage. The fluorescence lifetimes obtained in the aeration and deaeration are summarized in Table 1.

The fluorescence intensity ratio of the complex and DCA moiety is greater in ββ- than βα-DCAN. Further, the intensity ratio of the long lifetime component to the short one shows also a similar trend (Table 1). These facts suggest that the ground state complex formation is more significant in the former. The different fluorescence behavior between two compounds in γ-CDx solutions is well consistent with that of the enthalpy change of the complex formation in the MP solution at low temperature ($-\Delta H$=3.8 kcal mol^{-1} for ββ-DCAN and 2.6 kcal mol^{-1} for βα-DCAN, 1 kcal mol^{-1}=4.184 kJ mol^{-1}).[3] As mentioned above, these bichromophoric compounds form the ground state complex only in the nonpolar solvent such as MP at low temperature. Then, the experimental results obtained in the aqueous CDx solutions demonstrate that the inner cavity of CDx provide us with an extraordinary nonpolar and structurally restricted environment for the intramolecular interactions. The difference of the fluorescence behavior of the intramolecular ground state complex formation between ββ- and βα-DCAN may be attributable to the conformational difference of the complex formation in the CDx cavity as well as their inherent enthalpy change for the complex formation. The fluorescence lifetimes of the complex and the DCA moiety are almost invariant in the aeration and deaeration of the CDx solution, as summarized in Table 1. It seems that the excited state of the ground state complex in the CDx cavity are protected from the oxygen quenching as suggested by Turro *et al.*[2]

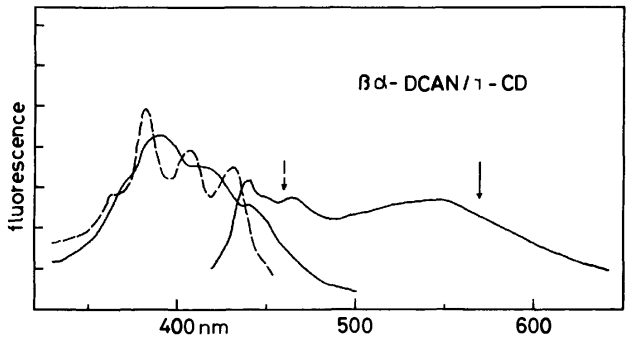

Fig. 2. Fluorescence (uncorrected, excited at 360 nm) and excitation spectra of the γ-CDx solution (10^{-2} mol dm^{-3}) of βα-DCAN (1.5×10^{-7} mol dm^{-3}). The excitation spectra were monitored at 570 nm (——) and at 460 nm (------).

Intramolecular Excimer and Ground State Complex Formations of DNP in the CDx Solutions. The aqueous β- and γ-CDx solutions of ββ-DNP show the long wavelength fluorescence in addition to the naphthyl moiety. The former fluorescence excitation spectra shown in Fig. 3 is in longer wavelength region than that of the naphthyl moiety and also the longest wavelength absorption band of DNP.[5] Therefore, it seems that the 400 nm fluorescence is ascribed to the intramolecular ground state complex of ββ-DNP in the CDx cavity. Further, the γ-CDx solution of ββ-DNP shows a similar fluorescence to that of β-CDx solution, as shown in Fig. 3(b). However, the excitation spectrum of this fluorescence shows only a faint red shift from that of the naphthyl moiety. The red shifted excitation spectrum seems to suggest that the ≈400 nm fluorescence consists of the superimposed spectra of the intramolecular excimer and ground state complex in the β-CDx solution. The fluorescence decay curves of 370—450 nm of ββ-DNP in the β- and γ-CDx solutions are shown in Figs. 4 and 5. The decay curve with-

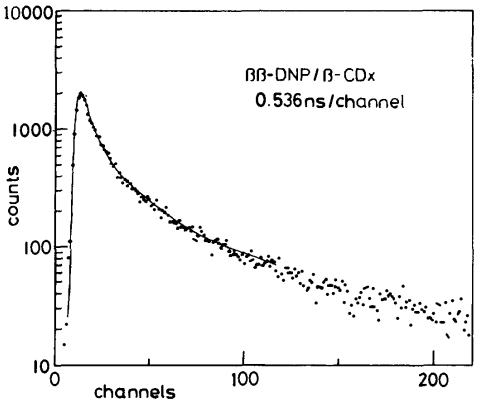

Fig. 4. Fluorescence decay curve of the long wavelength fluorescence (collected at 370—450 nm) of the β-CDx solution of $\beta\beta$-DNP (3.7×10^{-6} mol dm^{-3}) at room temperature. The curve shows the calculated decay based on the data shown in Table 2.

out fluorescence rise cannot be analyzed as a double exponential by any combination of parameters (τ_1, τ_2, A_1, and A_2 in Eq. 1), though decay curves look like a double exponential decay. The decay curves shown in Figs. 4 and 5 were analyzed as a triple exponential decay by the computer simulation, whose decay times are two short lifetimes and a long one as summarized in Table 2.

The aqueous β- and γ-CDx solutions of $\beta\alpha$-DNP exhibit remarkably enhanced fluorescence as shown in Fig. 6. A weak fluorescence ($\lambda_{max}\approx400$ nm) in β-CDx solution and a rather strong fluorescence (≈375 nm) in γ-CDx solution were observed in addition to the naphthyl moiety fluorescence. These fluorescence excitation spectra of both solutions shows rather similar to that of the naphthyl moiety fluorescence. Therefore, it seems that these fluorescence are mostly attributable to the intramolecular excimer of these compounds. The flurescence rise in the long wavelength fluores-

	γ	1.6 (50%)	26.4 (18%)	107.3	1.6 (50%)	25.8 (19%)	93.8

$I(t)=A_1\exp(-t/\tau_1)+A_2\exp(-t/\tau_2)+(1-A_1-A_2)\exp(-t/\tau_3)$. Data in bracket are fraction of components. Errors are approximately ±5%.

cence decay curve of the β-CDx solution of $\beta\alpha$-DNP was observed in the excitation at 230 nm, though a small amount of the short decay component due to the naphthyl moiety sounds to be superimposed on the fluorescence rise. Upon excitation at 290 nm, however, no fluorescence rise was observed in this solution. Further, neither fluorescence in the excitation at 290 nm nor at 230 nm was detected in the γ-CDx solution of $\beta\alpha$-DNP. The lack of the fluorescence rise may be attributable to the involvement of the ground state complex fluorescence in the decay curve of the excimer. On the analogy of the ground state complex in $\beta\beta$-DNP, there may be a weak absorption band hidden by the absorption band due to the naphthyl moiety in this 290—330 nm region. The decay curves were analyzed also as a triple exponential decay without rise, as shown in Figs. 7 and 8, whose decay times are summarized in Table 2.

These results in the CDx solutions demonstrate that the intramolecular excimer and the ground state complex formations take place both in the β- and γ-CDx solutions of $\beta\alpha$- and $\beta\beta$-DNP, though the excimer formation is more significant in $\beta\alpha$-DNP than in $\beta\beta$-DNP. If the intramolecular excimer and ground state complex fluorescences can be observed in the almost same wavelength region (≈400 nm) and if the naphthyl moiety fluorescence may be overlapped in this re-

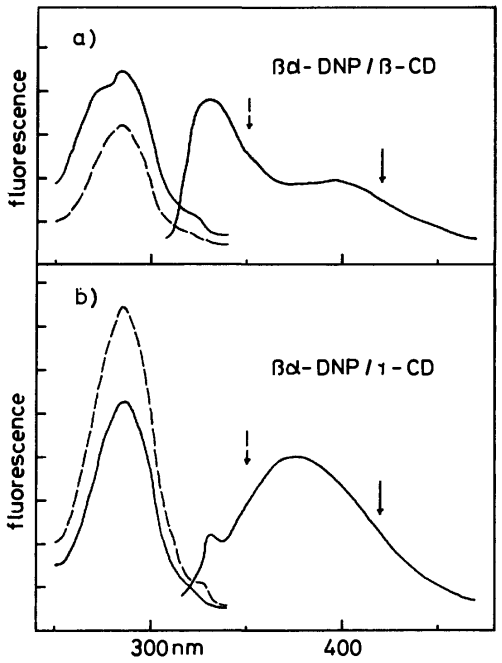

Fig. 6. Fluorescence (uncorrected, excited at 305 nm) and excitation spectra of the β- and γ-CDx (5×10^{-3} mol dm^{-3}) of $\beta\alpha$-DNP (3.7×10^{-6} mol dm^{-3}) at room temperature. The excitation spectra were monitored at 420 nm (——) and at 350 nm (------).

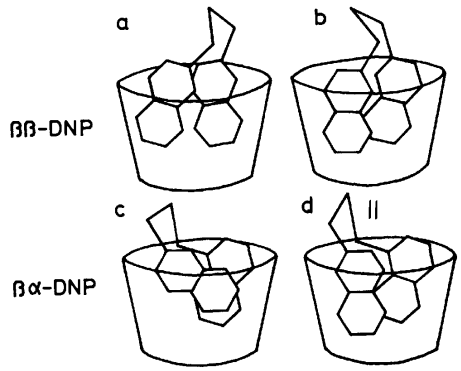

Fig. 10. Illustrated conformations of the ground state complex and/or excimer of $\beta\alpha$- and $\beta\beta$-DNP in the CDx cavity.

gion, four fluorescence decay components should be observed; two long time decay may be ascribed to the excimer and the ground state complex while two short ones to the naphthyl moiety fluorescence. However, the decay curve of the ≈400 nm fluorescence was analyzed approximately as three component decays, as mentioned above. If the excimer and ground state complex fluorescence spectra may show the approximately same fluorescence lifetime each other, the long lifetime decay due to the excimer and the ground state complex and two short lifetimes due to the naphthyl moiety may be observed. According to the well known reaction scheme as shown in Fig. 9, the shortest decay time (1—2 ns) of the naphthyl moiety fluorescence may be ascribed to the naphthyl moiety in the excited state equilibrium forming the excimer, while the decay time of 8—25 ns to that in the equilibrium with the ground state complex formation.

Turro *et al.*[2] reported the intramolecular excimer formation of $\alpha\alpha$-DNP in aqueous β- and γ-CDx solutions. The favor sturcture was proposed to be eclipsed and buried in the cavity of the CDx, where the long axes of naphthyl moieties are parallel each other. However, it is not obvious whether the structures of the fluorescent state of the ground state complex and the excimer are identical or different from each other. In the intermolecular electron donor acceptor systems, the identical fluorescent state of the exciplex and the ground state complex was evidenced as mentioned above.[7-9] However, no evidence for the identical fluorescent state of the excimer and the ground state complex has been reported, because there is no appro-

priate system exhibiting both excimer and ground state complex fluorescences . According to the geometrical allowance of the bichromophoric propanes in the CDx cavity, two each conformations of both $\beta\alpha$- and $\beta\beta$-DNP concerning with two naphthyl moieties may be considered, as shown in Fig. 10. The two closed conformers cannot be interchangeable in the small CDx cavity. If the excimer and ground state complex fluorescences may emit from an identical fluorescent state, both $\beta\alpha$- and $\beta\beta$-DNP may show similar excimer and ground state complex fluorescences, otherwise may show either the former or the latter fluorescence. However, $\beta\beta$-DNP is more favorable for the ground state complex, while $\beta\alpha$-DNP more favorable for the excimer mentioned above. Therefore, it is likely that the excimer is not identical with the fluorescent state of the ground state complex, though their fluorescence states cannot be assigned to the particular structure shown in Fig. 10.

The Complex Formation of Organomercury with 8-Quinolinol

Joji KUNIYA,* Kunishige NAITO, and Shinsuke TAKEI
Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Nakanarusawa-cho, Hitachi 316
(Received May 13, 1983)

Organomercury(II)(RHg^+, R; ethyl, *n*-propyl, *n*-butyl) forms two kinds of water-soluble complexes, RHgq and RHg(q)$(OH)^-$, with 8-quinolinol(oxine Hq). These complex-formation reactions are studied by means of spectrophotometry, and the formation constants of these complexes, RHgOH, RHgOAc, and RHg(OH)$(OAc)^-$, in 4 %(v/v) ethanol at the ionic strength of 0.1 are determined. Reliable results are obtained for ethylmercury(II) and *n*-propylmercury(II) complexes.

There have been several reports and patents[1] on the reactions of alkyl- and arylmercury(II) (RHg^+) with 8-quinolinol (oxine Hq) in an aqueous solution, and in those reports the reaction product has been reported to be RHgq. However, complex-formation reactions have not yet been studied in detail.

In this study, complex-formation reactions of ethyl-, *n*-propyl-, and *n*-butyl-mercury(II) ($EtHg^+$, *n*-$PrHg^+$, *n*-$BuHg^+$) with 8-quinolinol in an aqueous solution have been investigated by means of spectrophotometry, and two kinds of water-soluble complexes, one of which is extractable into a nonpolar solvent such as benzene, have been found to be formed. Generally, 8-quinolinol forms water-insoluble complexes with all metals except alkali metals, therefore, the reactions of RHg^+ with 8-quinolinol are very interesting.

Experimental

1. Reagent. RHg^+ Solution: To a suspension of the desired amount of RHgBr synthesized by the Grignard reaction[2] in water 1.5 times the equivalent of Ag_2O freshly prepared from $AgNO_3$ was added, after which the solution was stirred for several days by use of a magnetic stirrer. After the complete precipitaton of the AgBr, the solution was made up to 0.1 M (1 M=1 mol dm^{-3}) in OH^- by the addition of solid NaOH and then left to stand overnight to ensure the quantitative precipitation of the dissolved Ag^+. Then after the filtration of the AgBr and the excess Ag_2O (to prevent the dissolution of Ag_2O the precipitate was not washed), the filtrate was neutralized with perchloric acid and diluted to about 5×10^{-2} M in RHg^+ with a pH of about 3. The standardization of the stock solution was done by the decomposition of RHg^+ on heating with nitric acid, followed by the gravimetric determination of Hg^{2+} as HgS. The stock solution was used after a 10-fold dilution with deionized water.

8-Quinolinol Solution: Guaranteed-reagent-grade 8-quinolinol was used as the ethanolic solution. This solution could not be used for over 3 d.

In this work, commercially available guaranteed-reagent-grade acetic acid, sodium acetate, and sodium perchlorate were used without further purification. The ethanol was purified by distillation as usual.

2. Aparatus. The absorption spectrum of a solution was measured with a Shimadzu MPS-50 recording spectrophotometer and a Hitachi 124 double-beam spectrophotometer. A Hitachi-Horiba F-5 pH meter was used for the pH measurement of a solution.

3. Experimental Procedure. To a 25.00-cm^3 measuring flask, desired amounts of RHg^+, acetic acid, sodium acetate, sodium perchlorate, and 8-quinolinol solutions were added, and then deionized water was added to bring the solution to the mark. The ionic strength of the solution was maintained at 0.1. Spectrophotometric and pH measurements were made on the solution after 1.5 h. Separately, the same measurements were made on the blank solution.

Results snd Discussion

By the addition of 8-quinolinol to an aqueous solution of $EtHg^+$, yellow coloration is obtained at a pH value above 5. The solution shows absorption maxima at 340 and 395 nm, and with an increase in the pH of the solution the absorbance at 340 nm decreases and that at 395 nm increases, as shown in Fig. 1. These spectra are different from that of the free 8-quinolinol solution in this pH range. Therefore, $EtHg^+$ is considered to form two kinds of complexes with 8-quinolinol, with the sbsorption maxima at 340 and 395 nm respectively. Both *n*-$PrHg^+$ and *n*-$BuHg^+$ with 8-quinolinol show the same coloration, and the wavelength at the absorption maximum is the same as that of $EtHg^+$ complexes. Hereafter, complexes with the absorption maxima at 340 and 395 nm will be denoted as Complexes **I** and **II** respectively.

In this study, 8-quinolinol is added as an ethanolic solution. Moreover, it is observed that the absorbance of each complex decreases with an increase in the concentration of ethanol, especially in the higher concentration range. Therefore, in this work the concentration of ethanol is fixed at 4% (v/v), and the effect of the concentration of ethanol on the complex formation is not studied.

The absorbance of complex solutions of RHg^+ with 8-quinolinol at 340 and 395 nm increases with stand-

pH: 1; 4.45, 2; 4.98, 3; 5.16, 4; 5.50, 5; 5.96, 6; 7.85.

ing and shows a constant value after standing for 1.5 h when RHg^+ is added in an excess to 8-quinolinol in a molar ratio, but the absorbance of the *n*-$BuHg^+$ complex solution decreases upon standing for over 5 h. Therefore, the measurement of the absorbance of complex solutions is made after they have stood for 1.5 h in a dark place.

The molar ratio of RHg^+ to 8-quinolinol in Complexes **I** and **II** is found by the continuous variation method to be 1 : 1 regardless of the kind of alkyl group.

At 340 and 395 nm, Complexes **I** and **II** and free 8-quinolinol show absroption. Therefore, the concentrations of Complexes **I** and **II** formed under the various conditions necessary to obtain the formation constants of these complexes are determined from the absorbance of the complex solution measured at 340 and 395 nm and the molar absorption coefficients of both complexes and 8-quinolinol at both wavelengths (the values for 8-quinolinol are the apparent ones at various pHs). The molar absorption coefficients of both complexes at 340 and 395 nm are determined as follows.

In Fig. 2 the absorbance of the $EtHg^+$–8-quinolinol solution at 340 nm is shown to be constant at pH values from 3.2 to 4.2, while that at 395 nm begins to increase at a pH of about 4.0. Moreover, the absorbance of the solution buffered with sodium acetate and acetic acid at 340 nm is lower than that of an unbuffered sodium perchlorate and perchloric acid solution. These findings show that 8-quinolinol forms Complex **I** with $EtHg^+$ quantitatively at pH values from 3.2 to 4.0 and that the acetate ion interferes with the formation of the complex. However, the interference from OAc^- is not observed when the concentration of OAc^- is lower than 5×10^{-3} M under the present conditions. From these results the molar absorption coefficients of Complex **I** at 340 and 395 nm are determined from the absorbance at these wavelengths when the molar ratio of $EtHg^+$ to 8-quinolinol is higher than 10 and when the pH values from 3.2 to 4.0 in the buffered solution in which the concentration of OAc^- is lower than 5×10^{-3} M. The molar absorption coefficients of the *n*-$PrHg^+$ and *n*-$BuHg^+$ Complex **I** at 340 and 395 nm are determined by similar procedures.

The absorbance of the RHg^+ Complex **II** at 340 and 395 nm are found to be constant in borate buffer solutions at pH values from 8 to 10, and the molar ratio of RHg^+ to 8-quinolinol is higher than 10. Therefore, the molar absorption coefficients of each complex at both wavelengths are determined from the absorbance measured under the conditions mentioned above.

In Table 1 the molar absorption coefficients of the RHg^+ Complexes **I** and **II** at the absorption maximum are tabulated. The variation in the value of the coefficient with the kind of alkyl group is small.

From the experimental results obtained above, the complex formation reactions may be analysed as follows.

The complex formation reactions of the **I** and **II** complexes can be written as follows:

$$RHg^+ + q^- + mY^{n-} = RHg(q)(Y)_m^{mn-}, \quad (1)$$

$$K = \frac{[RHg(q)(Y)_m^{mn-}]}{[RHg^+][q][Y^{n-}]^m}, \quad (2)$$

where Y^{n-} is an arbitrary anion in the solution which can combine with RHg^+ (hereafter, the charge of an ion will be omitted for the sake of simplicity). Moreover, the total concentration of RHg^+, C_M°, is shown as follows when the polynuclear complexes of RHg^+ are considered to be absent:

$$C_M^\circ = [RHg] + \sum [RHg(q)(Y)_m] + [RHgOH] + [RHg(OH)_2] + \cdots + [RHgA] + [RHg(A)_2] + \cdots + [RHg(OH)(A)] + \cdots. \quad (3)$$

Table 1. Molar absorption coefficients of RHg^+ complexes **I** and **II**

RHg^+	Molar absorption coefficients $cm^{-1}mol^{-1}dm^3$	
	Complex **I** (340 nm)	Complex **II** (395 nm)
$EtHg^+$	2700	2370
n-$PrHg^+$	2690	2320
n-$BuHg^+$	2730	2400

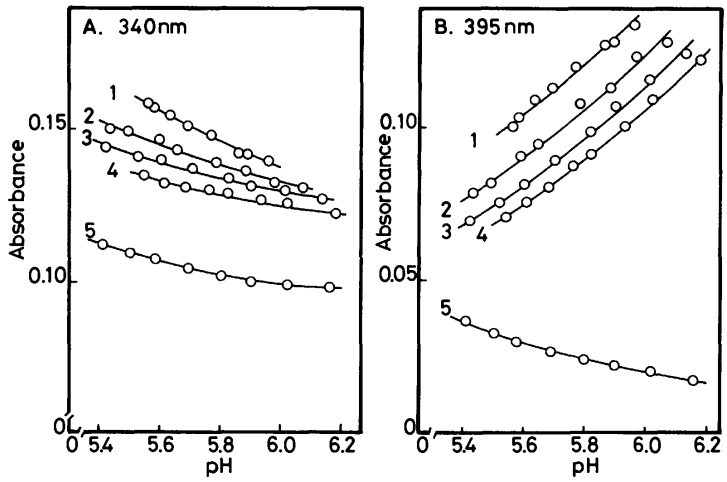

Fig. 2. pH Dependence of absorbance of $EtHg^+$–8-quinolinol complexes at 340 and 395 nm.
C_M°; 3.60×10^{-4} M, C_L°; 2.00×10^{-4} M.
[OAc]: 1; 2.00×10^{-3} M, 2; 6.00×10^{-3} M, 3; 1.00×10^{-2} M, 4; 1.40×10^{-2} M, 5; blank solution, [OAc]; 1.00×10^{-2} M.

Then:

$$C_M^\circ - \sum[RHg(q)(Y)_m] = C_M = [RHg](1+\beta_1[OH] + \beta_2[OH]^2 +\cdots+ \beta_1'[A] + \beta_2'[A]^2 +\cdots+ \beta_1''[OH][A] +\cdots = [RHg]\alpha, \quad (4)$$

where the β's are the formation constants of the respective complexes and where A represents the anions, except for OH^-, in the solution which can combine with RHg^+.

Similarly, the total concentration of 8-quinolinol, C_L°, can be written as follows:

$$C_L^\circ = \sum[RH(q)(Y)_m] + [H_2q] + [Hq] + [q]. \quad (5)$$

Then:

$$C_L^\circ - \sum[RHg(q)(Y)_m] = C_L = [q]\left(\frac{[H]^2}{k_1k_2} + \frac{[H]}{k_2} + 1\right) = [q]\gamma, \quad (6)$$

where k_1 and k_2 are the step-by-step acid-dissociation constants of 8-quinolinol; in this work, $pk_1=4.96$ and $pk_2=9.68$, values obtained under the present experimental conditions.

From (2), (4), and (6), (7), and (8) are introduced:

$$\frac{[RHg(q)(Y)_m]\alpha\gamma}{C_MC_L[Y]^m} = K'\frac{\alpha\gamma}{[Y]^m}, \quad (7)$$

$$K' = \frac{[RHg(q)(Y)_m]}{C_MC_L}.$$

$$\frac{[Y]^m}{K'\gamma} = \frac{\alpha}{K} = \frac{1}{K}(1+\beta_1[OH]+\beta_2[OH]^2+\cdots + \beta_1'[A] + \beta_2'[A]^2 +\cdots+ \beta_1''[OH][A] +\cdots$$

$$= \frac{1}{K}(1+\beta_1[OH]+\beta_2[OH]^2+\cdots) + \frac{1}{K}(\beta_1'+\beta_1''[OH]+\cdots)[A] + \frac{\beta_2'}{K}[A]^2 +\cdots. \quad (8)$$

In (7), C_M and C_L can be obtained from the total concentrations of RHg^+ and 8-quiolinol and the experimentally determined concentrations of Complexes **I** and **II** as shown in (4) and (6). Therefore, the value of K' for each complex can be determined experimentally. Moreover, the value of γ is calculated from the pH of the solution and from k_1 and k_2 as shown in (6).

In this study, the anions in the solution are OH^-, OAc^-, and ClO_4^-, and the complex formation of RHg^+ with ClO_4^- is not observed. Judging from the results in (4) and (8) it is necesssry to consider only OAc^- as A. Therefore, (8) indicates that the $[Y]^m/K'\gamma$ values which are obtained from the experimental results at a constant pH and at various concentrations of OAc^- are linear or quardratic against [OAc] when Y and m corresponding to (1) are utilized. Moreover, as the intercepts of straight lines or quadratic curves are functions of [OH], the K and β's are determined by plotting the values of the intercepts against [OH]. Similarly, the slopes of the straight lines or the coefficients of the [OAc] of the quadratic curves are functions of [OH]; therefore, the β' and β'' constants are determined by plotting the values of the slopes or coefficients of [OAc]. By these treatments, complex-formation reactions are studied.

In the treatments described above, polynuclear complexes of RHg^+ are neglected and the K' of each complex is assumed to be independent of the concentration of RHg^+. Under the conditions where pH= 5.4—6.2, $[OAc]=1.00\times10^{-2}$ M and $C_L^\circ=1.00\times10^{-4}$ M, the K' values of both Complexes, **I** and **II**, for $EtHg^+$ and n-$PrHg^+$ are found to be independent of C_M° when C_M° is 2.00×10^{-4} M or below. However, for the n-$BuHg^+$–8-quinolinol system it is necessary to maintain the total concentration of n-$BuHg^+$ at 1.3×10^{-4} M or below, even when $C_L^\circ=2.00\times10^{-4}$ M.

Figures 3 **A** and **B** show the variation in the K' values of $EtHg^+$ complexes with the pH under various concentrations of OAc^-. Both K' values decrease with

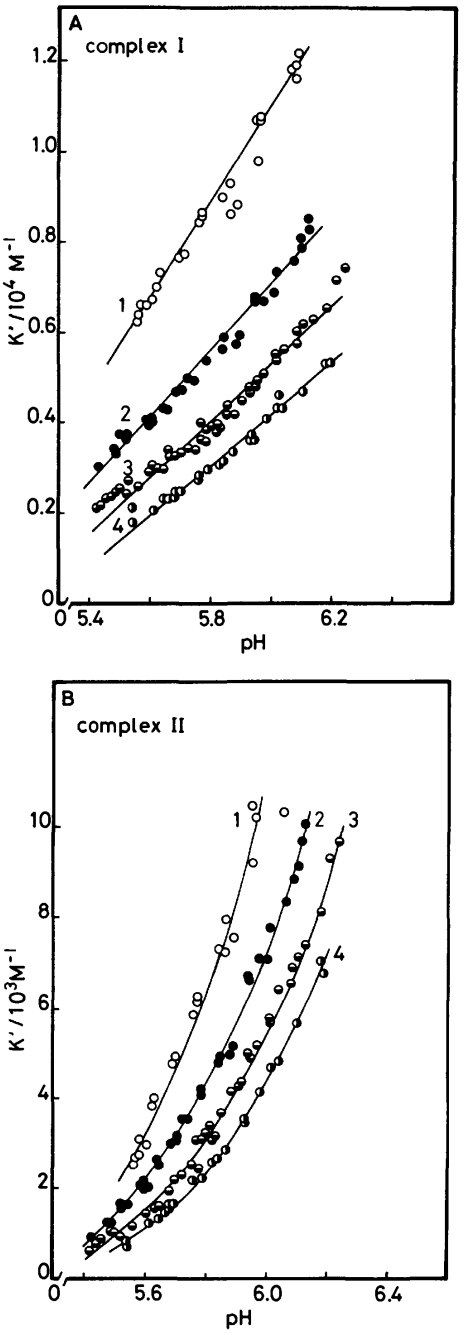

Fig. 3. pH Dependence of K' values of $EtHg^+$ complexes **I** and **II** under various concentrations of OAc^-.
[OAc]: 1; 2.00×10^{-3} M, 2; 6.00×10^{-3} M, 3; 1.00×10^{-2} M, 4; 1.40×10^{-2} M.

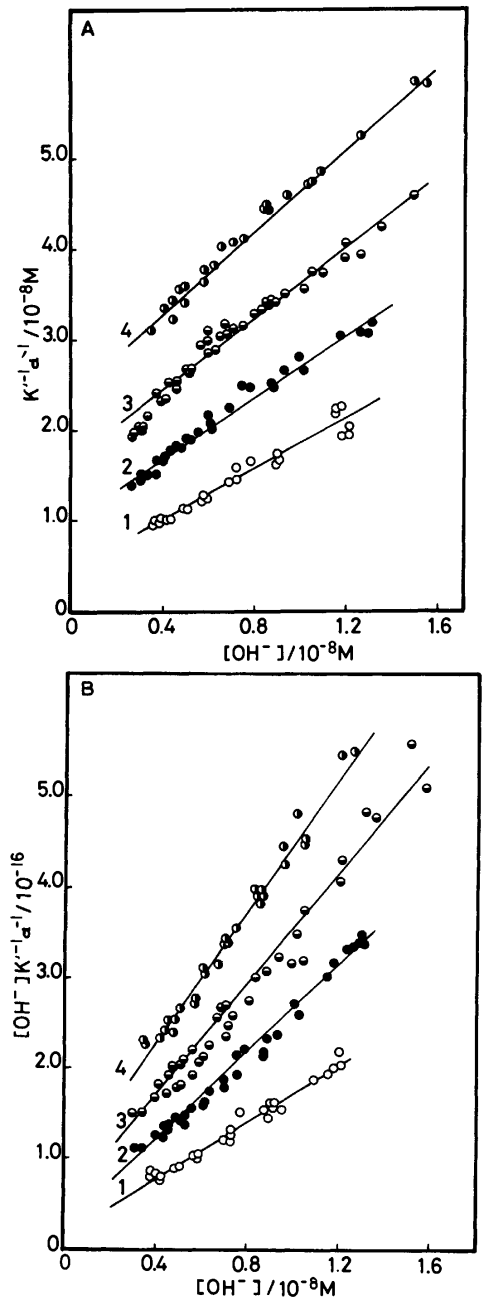

Fig. 4. **A**: Plot of $1/K'_a$ of $EtHg^+$ complex **I** against [OH].
B: Plot of $[OH]/K'_a$ of $EtHg^+$ complex **II** against [OH].
[OAc]: 1; 2.00×10^{-3}M, 2; 6.00×10^{-3}M, 3; 1.00×10^{-2}M, 4; 1.40×10^{-2}M.

an increase in the concentration of OAc^-; this result indicates that OAc^- interferes with the formation of complexes and that these complexes do not contain OAc^-. From this finding, OH^- is found to be Y in (1). In the following study, the K' values of each complex at various pHs are obtained by the treatment of the results shown in Fig. 3 as straight lines and quadratic curves and by interpolation. Then, from the results shown in Fig. 3, $[OH]^m/K'r$ is plotted against [OAc] by the use of the K' values of each complex and γ at various pHs; as shown in Figs. 4 **A** and **B**, straight lines are obtained for Complexes **I** and **II** when $m=0$ and 1 are utilized respectively. These results indicate that the Complexes of $EtHg^+$ **I** and **II** are EtHgq and EtHg(q)$(OH)^-$ respectively.

Moreover, the values of the intercept and slope of the straight lines shown in Figs. 4 **A** and **B** at various [OH] values are found to be linear against [OH]. The linear relations of the intercept and slope to [OH] indicate that $EtHg^+$ forms EtHgOH, EtHgOAc, and EtHg$(OH)(OAc)^-$ respectively. The formation constants of EtHgq, EtHg(q)$(OH)^-$, EtHgOH, EtHgOAc, and EtHg$(OH)(OAc)^-$ are determined from (8). Similar results are obtained for *n*-$PrHg^+$ and *n*-$BuHg^+$–8-quinolinol systems. The results obtained are tabulated in Table 2.

In Table 2, the formation constants of $EtHg^+$ and *n*-$PrHg^+$ complexes obtained separately by the method described above show a good agreement. Also the formation constant of EtHgOH, β_1, obtained in this work shows a good agreement with that previously reported by Waugh *et al.* These results indicate that the analytical method of complex-formation reactions presented here is reasonable and that the formation constants of $EtHg^+$ and *n*-$PrHg^+$ here estsblished are reliable. However, the formation constants of *n*-$BuHg^+$ with OH^- and OAc^- obtained separately show less agreement. Those results suggest that the formation of polynuclear complexes of *n*-$BuHg^+$ with OH^- affects the complex-formation reactions with 8-quinolinol. Therefore, in order to determine reliable formation constants of *n*-$BuHg^+$ complexes with 8-quinolinol, the OH^- and OAc^- setting of the experimental conditions is important to prevent polynuclear hydroxo complexes.

The Extraction of Organomercury with 8-Quinolinol into Benzene

Takao SUGIMOTO, Kunishige NAITO, and Shinsuke TAKEI*

Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Nakanarusawa-cho, Hitachi 316

(Received May 13, 1983)

The extraction of organomercury(II)(RHg^+, R; ethyl, *n*-propyl, *n*-butyl, phenyl) with 8-quinolinol into benzene has been studied by means of spectrophotometry. This study confirmed that there was no co-extraction of electrically neutral species RHgOH by its investigation of the effect of the pH on the extraction of ethylmercury(II) chloride into benzene. Moreover, it was found that RHg^+ forms 1:1 complexes with both HPO_4^{2-} and PO_4^{3-}. The formation constants of these complexes and of hydroxo complexes have been determined.

Organomercury(II) (RHg^+) forms two kinds of water-soluble complexes with 8-quinolinol (oxine, Hq), and one of these can be extracted into an inert solvent such as benzene. The formation of water-soluble complexes of ethylmercury(II) ($EtHg^+$), *n*-propylmercury(II) (*n*-$PrHg^+$), and *n*-butylmercury(II) (*n*-$BuHg^+$) with 8-quinolinol has previously been reported.[1] In this work, the extraction of 8-quinolinates of $EtHg^+$, *n*-$PrHg^+$, *n*-$BuHg^+$, and phenylmercury(II) ($PhHg^+$) into benzene, together with the complex formation of $EtHg^+$ with Cl^- and its extraction into benzene and the complex formation of RHg^+ with OH^- and phosphate ions, has been investigated by means of spectrophotometry.

Experimental

1. Reagent and Apparatus. Organic Solvents. The benzene and carbon tetrachloride, reagent-grade, were purified by distillation.

Dithizone Solution in Carbon Tetrachloride: The purified dithizone solution in carbon tetrachloride was prepared by the usual method.[2]

RHg^+ Solution: All the RHg^+ solutions used were prepared and standardized by the method previously reported.[1]

All the other reagents used in this work were guaranteed-reagent-grade and were used without further purification.

A Shimadzu MPS-50 recording spectrophotometer and a Hitachi 124 double-beam spectrophotometer were used for the measurements of the absorption spectra and the absorbance of the solutions. A Hitachi-Horiba F-5 pH meter was used for the measurement of the pH of an aqueous solution.

2. Experimental Procedures. a. Extraction of EtHgCl into Benzene: The extraciton of $EtHg^+$ as dithizonate into carbon tetrachloride has been reported to be unaffected by the Cl^- and the pH under the experimental conditions applied in this work.[3] Then, after the extraction of EtHgCl from 10.00 cm^3 of an aqueous solution into 10.00 cm^3 of benzene, an aliquot amount of the aqueous solution was taken and $EtHg^+$ was extracted as dithizonate by the addition of a dithizone solution on the solution and shaking. Also, from the absorbance of dithizone in excess at 620 nm, the $EtHg^+$ was determined and the distribution ratio of $EtHg^+$ was obtained.

b. Extraction of RHg^+ 8-Quinolinate: Into a glass-stoppered test tube, desired amounts of NaH_2PO_4, Na_2HPO_4, and RHg^+ solutions were taken and deionized water was then added to make the solution up to 10.00 cm^3. To this solution 10.00 cm^3 of an 8-quinolinol solution in benzene was added, after which the solution was shaken for 30 min. After this solution had been separated into two layers, the absorbance of the organic solution at the absorption peak of the complex and the pH of the aqueous solution were measured.

Results and Discussion

The complex of RHg^+ with 8-quinolinol is extracted into benzene at a pH above about 5. In order to analyse the extraction reaction, it is necessary to ascertain whether or not the electrically neutral species RHgOH can be extracted into benzene. The extraction of methylmercury(II) and $PhHg^+$ halides from an acidic solution into nonpolar solvents has been studied;[4] then by the investigation of the effect of the pH of the extraction of EtHgCl, the extraction of EtHgOH was studied.

In Fig. 1, the distribution ratio of $EtHg^+$ increases with increase in the initial concentration of Cl^-; the

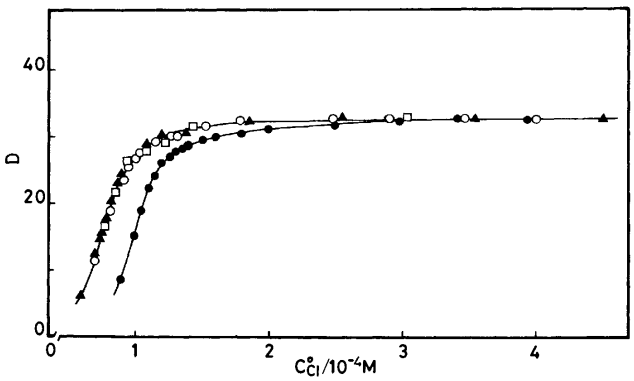

Fig. 1. Variation of distribution ratio of $EtHg^+$ with initial concentration of Cl^-.
●: pH; 1.0, C°_M; 1.07×10^{-4} M (1 M=1 mol dm^{-3}), ○: pH; 1.1, ▲: pH; 1.6, □: pH; 2.0, C°_M; 7.66×10^{-5} M.

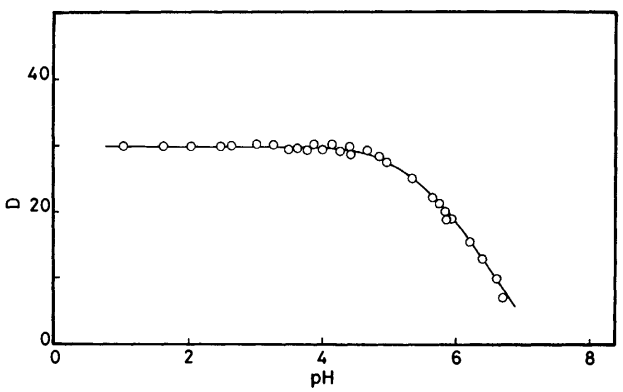

Fig. 2. Variation of distribution ratio of $EtHg^+$ with pH.
C°_M; 7.66×10^{-5} M, C°_{Cl}; 1.20×10^{-4} M.

higher distribution ratio is obtained when the initial concentration of RHg^+ is low. However, at higher concentrations of Cl^-, the same distibution ratio is obtained regardless of the intial concentration of $EtHg^+$.

Moreover, as is shown in Fig. 2, the distribution ratio of $EtHg^+$ decreases with the rise in the pH above 4.

These experimental results may be explained as follows. The distribution ratio D of $EtHg^+$ is written as follows;

$$D = \frac{[MCl]_o + [MOH]_o}{[M]+[MCl]+[MCl_2]+\cdots+[MOH]+[M(OH)_2]+\cdots} = \frac{p\beta_1[Cl] + p'\beta_1'[OH]}{1+\beta_1[Cl]+\beta_2[Cl]^2+\cdots+\beta_1'[OH]+\beta_2'[OH]^2+\cdots}, \quad (1)$$

where M represents $EtHg^+$, where β's are respective complex-formation constants, and where p and p' are the distribution constants of EtHgCl and EtHgOH respectively (the charges of the ions are omitted for the sake of simplicity).

In the experimental range shown in Fig. 1 the distribution ratio of $EtHg^+$ is independent of the pH; therefore, the formation of complexes with OH^- and the distribution of EtHgOH can be neglected, and (1) becomes;

$$\frac{1}{D} = \frac{1}{p} + \frac{1}{p\beta_1[Cl]} + \frac{\beta_2}{p\beta_1}[Cl] + \cdots. \quad (2)$$

From (2) it is found that the plot of $1/D$ against $1/[Cl]$ gives a straight line when the main species of the $EtHg^+$ complex with Cl^- is EtHgCl, whereas the plot of $1/D$ against [Cl] gives a straight line or a quadratic curve when $EtHg^+$ forms higher complexes such as $EtHgCl_2^-$ and $EtHgCl_3^{2-}$ with Cl^-.

Figure 3 shows that the plot of $1/D$ against $1/[Cl]$, in which [Cl] is the equilibrium concentration of Cl^- corrected to the distribution of Cl^- into benzene as EtHgCl, gives a straight line. On the other hand, the plot of $1/D$ against [Cl] gives a quadratic curve with negative coefficients. These results indicate that the main species formed in the aqueous layer in the experimental range is EtHgCl. From the reciprocal of the intercept and the slope of the straight line shown in Fig. 3 the distribution constant and the formation constant of EtHgCl are obtained as 33 ± 1 and $(2.7\pm0.5)\times10^5$ respectively. The formation constant of EtHgCl is almost the same as those of methylmercury(II) and

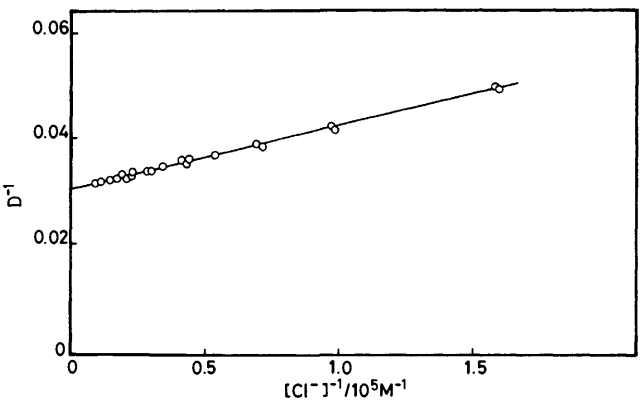

Fig. 3. Plot of 1/D of $EtHg^+$ against 1/[Cl].

PhHg$^+$ chlorides reported previously,[4] and no large variation with the R combined with Hg can be observed. The results shown in Fig. 2 seem to indicate that the distribution of EtHgOH in benzene is negligible. Then, from (1) the following relation is introduced;

$$\frac{1}{D} = \frac{1}{p} + \frac{1}{p\beta_1[Cl]} + \frac{\beta_1'[OH]}{p\beta_1[Cl]} + \frac{\beta_2'[OH]^2}{p\beta_1[Cl]} + \cdots. \quad (3)$$

By using the values of p and β_1 obtained above and the assumption that, in this experimental range, $EtHg^+$ forms a 1:1 complex only with OH^-, the value of β_1' is calculated from the experimental results shown in Fig. 2 and (3). By this treatment $\beta_1'=(1.7\pm0.1)\times10^9$ is obtained; this value shows fairly good agreement with that reported by Waugh *et al.*[5]

Therefore, it may be concluded that the distribution of EtHgOH in benzene is negligible and that, in this experiemntal range, $EtHg^+$ forms a 1:1 complex predominantly with OH^-. From these results, the extraction of the RHg^+ complex with 8-quinolinol into benzene is analysed on the assumption that the distribution of RHgOH in benzene is negligible, regardless of the R.

The absorption maxima of benzene solutions of the $EtHg^+$, *n*-$PrHg^+$, and *n*-$BuHg^+$ complexes and that of the $PhHg^+$ complex are observed at 378 nm and 375 nm respectively; therefore, the variation in the wavelength at the absorption peak with R is vary small. The absorption of free 8-quinolinol in benzene at the absorption maxima of the complexes is negligible.

The molar ratio of RHg^+ to 8-quinolinol in the complex is found by the continuous-variation method to be 1:1, regardless of the R.

At the peak wavelength, the absorbance of the extract of the RHg^+ complex from borate buffer solutions of pH values from 9.0 to 10.0 in the presence of an excess of 8-quinolinol shows constant value. Therefore, from the absorbance measured under the conditions shown above, the molar absorption coefficient of the complex solution at the peak wavelength is determined and the following results are obtained; $EtHg^+$ complex: 3.00×10^3; *n*-$PrHg^+$ complex: 3.04×10^3; *n*-

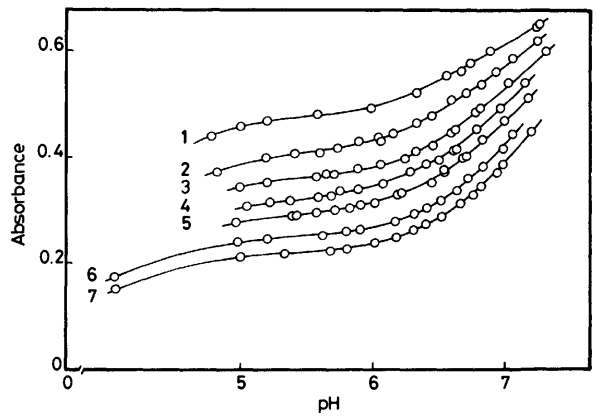

Fig. 4. Variation of the absorbance of $EtHg^+$–8-quinolinol complex in benzene with pH under various concentrations of phosphate.

Total concentration of phosphate: 1; 0.02 M, 2; 0.03 M, 3; 0.04 M, 4; 0.05 M, 5; 0.06 M, 6; 0.08 M, 7; 0.10 M.

$BuHg^+$ complex: 3.03×10^3; $PhHg^+$ complex: 3.20×10^3. The variation in the molar absorption coefficient of the complexes with the R is very small except for the $PhHg^+$ complex, which shows a higher value.

Figure 4 shows the variation in the absorbance of the $EtHg^+$ complex extracts from phosphate buffer solutions in various concentrations with the pH. Similar results are obtained in other RHg^+ systems. In this work, the initial concentration of RHg^+ is made as high as possible in order to minimise the effect of the co-extraction of the RHg^+ complexes with, *e.g.*, the Cl^- contained as an impurity in the reagents used. However, in the present experimental range the distribution ratio of RHg^+ is independent of the initial concentration of RHg^+; therefore, the formation of polynuclear complexes of RHg^+ is considered to be negligible.

The experimental results shown in Fig. 4 may be analysed as follows.

The extraction of RHg^+ with 8-quinolinol can be written as;

$$RHg^+ + q^- = RHgq_{(o)}, \tag{4}$$

$$K_{ex} = \frac{[RHgq]_o}{[RHg][q]}. \tag{5}$$

As has been mentioned above, RHgOH is not distributed into benzene, and the distribution of complexes of RHg^+ with phosphate ions are found to be negligible, therefore, the distribution ratio D of RHg^+ can be written as;

$$D = \frac{[RHgq]_o}{C_M^\circ - [RHgq]_o}, \tag{6}$$

$$\begin{aligned} C_M^\circ - [RHgq]_o = C_M &= [RHg] + [RHgOH] \\ &+ [RHg(OH)_2] + \cdots + [RHgH_2PO_4] + \cdots \\ &+ [RHgHPO_4] + \cdots + [RHgPO_4] + \cdots \\ &+ [RHgq] + [RHg(q)(OH)] + \cdots \\ &= [RHg](1 + \beta_1'[OH] + \beta_2'[OH]^2 + \cdots \\ &+ K_1[H_2PO_4] + \cdots + K_1'[HPO_4] + \cdots \\ &+ K_1''[PO_4] + \cdots + K_f[q] + K_c[q][OH] + \cdots) \\ &= [RHg]\gamma, \end{aligned} \tag{7}$$

where C_M° is the initial concentration of RHg^+ in the aqueous solution and where the β's and K's are the formation constants of the respective complexes. From the measurement of the absorbance of the aqueous layer after extraction, $RHg(q)(OH)^-$ is found to be absent[1] and [RHgq] is considered to be negligible; therefore, in (7), the terms corresponding to [RHg(q)(OH)] and [RHgq] are omitted. The total concentration of 8-quinolinol, C_L°, can be written as follows;

$$\begin{aligned} C_L^\circ &= [H_2q] + [Hq] + [q] + [RHgq] \\ &+ [RHg(q)(OH)] + [Hq]_o + [RHgq]_o. \end{aligned}$$

As [RHgq] and [RHg(q)(OH)] can be neglected;

$$\begin{aligned} C_L^\circ - [RHgq]_o = C_L &= [H_2q] + [Hq] + [q] + [Hq]_o \\ &= [q]\left(\frac{[H]^2}{k_1k_2} + \frac{[H]}{k_2} + 1 + \frac{p''[H]}{k_2}\right) = [q]\,\alpha. \end{aligned} \tag{8}$$

From (5), (7), and (8), (9) is obtained;

$$K_{ex} = \frac{[RHgq]_o\,\alpha\gamma}{C_M C_L} = K_{ex}'\,\alpha\gamma \quad \frac{1}{K_{ex}'\alpha} = \frac{\gamma}{K_{ex}}. \tag{9}$$

In (9). K_{ex}' can be determined experimentally and the value of γ can be obtained from the step-by-step acid-dissociation constants of 8-quinolinol ($pk_1=5.13$, $pk_2=9.66$[6]), the distribution constant of 8-quinolinol between aqueous and benzene layers p'' ($p''=10^{2.44}$[7]), and the pH of the aqueous layer measured. From (7), the right-hand side of (9) becomes;

$$\begin{aligned} \frac{\gamma}{K_{ex}} &= \frac{1}{K_{ex}}(1 + \beta_1'[OH] + \beta_2'[CH]^2 + \cdots) \\ &+ \frac{1}{K_{ex}}(K_1[H_2PO_4] + K_1'[HPO_4] + K_1''[PO_4] + \cdots \\ &= \frac{1}{K_{ex}} f[OH] + \frac{[PO_4]}{K_{ex}}\left(\frac{K_1[H]^2}{k_2'k_3'} + \frac{K_1'[H]}{k_3'} + K_1'' + \cdots\right) \end{aligned} \tag{10}$$

$$= \frac{1}{K_{ex}} f[OH] + \frac{[HPO_4]}{k_{ex}}\left(\frac{K_1[H]}{k_2'} + K_1' + \frac{K_1''k_3'}{[H]} + \cdots\right), \tag{11}$$

where f[OH] represents the coefficient of $1/K_{ex}$ of the first term on the right-hand side and where k_2' and k_3' are the respective acid-dissociation constants of phosphoric acid ($pk_2'=6.71$, $pk_3'=11.8$[8]).

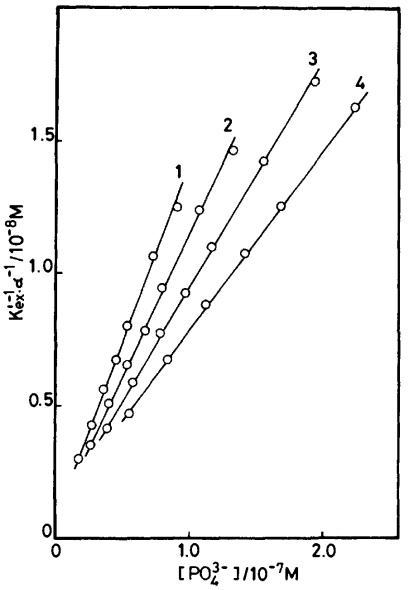

Fig. 5. Plot of $1/K_{ex}'$ a of $EtHg^+$–8-quinolinol complex against $[PO_4]$.

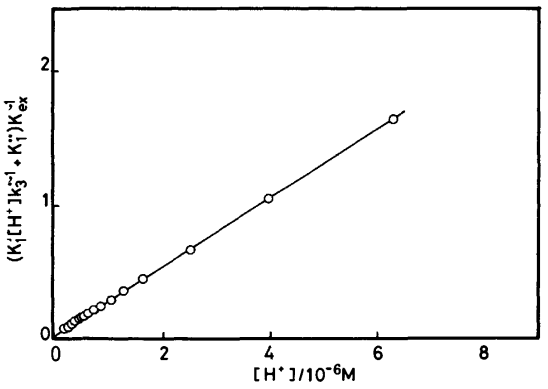

Fig. 6. Plot of Values of the slope of straight lines shown in Fig. 5 against [H].

TABLE 1. FORMATION CONSTANTS OF RHg^+ COMPLEXES

RHg^+	K_{ex}	β_1'	K_1'	K_1''
$EtHg^+$	$2.9\pm0.5\times10^{10}$	$1.7\pm0.3\times10^{9}$	$1.2\pm0.2\times10^{4}$	$2.8\pm0.7\times10^{8}$
n-$PrHg^+$	$1.4\pm0.5\times10^{11}$	$1.6\pm0.5\times10^{9}$	$1.4\pm0.3\times10^{4}$	$1.1\pm0.4\times10^{8}$
n-$BuHg^+$	$7.6\pm1.1\times10^{11}$	$1.1\pm0.1\times10^{9}$	$1.8\pm0.2\times10^{4}$	$2.7\pm0.6\times10^{8}$
$PhHg^+$	$2.0\pm0.7\times10^{13}$	$9.6\pm3.6\times10^{9}$	$1.8\pm0.4\times10^{5}$	$3.1\pm1.1\times10^{9}$

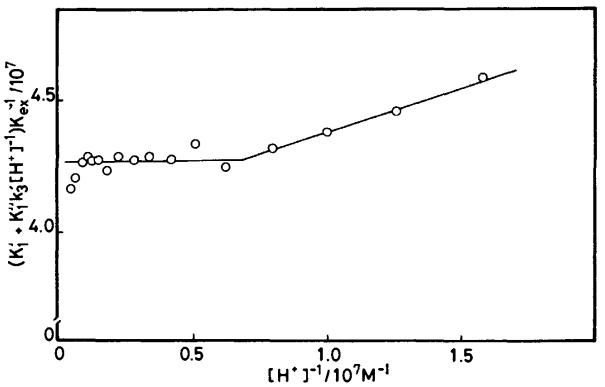

Fig. 7. Plot of values of the slope of straight lines obtained by plot of $1/K_{ex}'$ a of $EtHg^+$ complex *vs.* $[HPO_4]$ against $1/[H]$.

Equations (9), (10), and (11) indicate that $1/K_{ex}'\ \alpha$ at a constant pH is linear against $[PO_4]$ and $[HPO_4]$ and that the values of the intercept of both straight lines obtained at the same pH are equal. Moreover, intercepts of both straight lines are functions of [OH]; then, by plots of the value of the intercept against [OH], the hydroxo complexes of RHg^+ formed in the experimental range and the three constants K_{ex}, k_1' and k_2' are determined. On the other hand, the β values of the slopes of the straight lines obtained by the plot of $1/K_{ex}'\ \alpha$ against $[HPO_4]$ and $[PO_4]$ are functions of [H]; then, by plots of the values of the slope against [H] or $1/[H]$ complexes of RHg^+ with $H_2PO_4^-$, HPO_4^{2-}, and PO_4^{3-} and the formation constants of these complexes are determined on the bases of (10) and (11).

By these considerations, the experimental results shown in Fig. 4 are analysed. First, Fig. 5 shows the plot of $1/K_{ex}'\ \alpha$ of $EtHg^+$ against $[PO_4]$. A similar good linearity is obtained by the plot of $1/K_{ex}'\ \alpha$ against $[HPO_4]$, and the values of the intercept of both straight lines at the same [OH] show a good agreement with in a probable error of $\pm10\%$.

Moreover, the values of the intercept obtained from Fig. 5 are found to be linear against [OH]. This indicates that, in this experimental range, $EtHg^+$ forms a 1:1 complex with OH^- predominantly. In Table 1, the values of K_{ex} and β_1' obtained from this result on the basis of (10) are tabulated.

Figure 6 shows the plot of the value of the slope of the straight line shown in Fig. 5 against [H]. The good linearity indicates that there is no formation of a complex of $EtHg^+$ with $H_2PO_4^-$. The absence of the $EtHg^+$-$H_2PO_4^-$ complex is confirmed by the result that the values of the slopes of the straight lines obtained by a plot of $1/K_{ex}'\ \alpha$ against $[HPO_4]$ are linear against $1/[H]$ on the basis of (11), as shown in Fig. 7.

In Fig. 7, the slope of the straight line is zero below pH 6.8; therefore, below this pH the formation of $EtHgPO_4^{2-}$ is considered to be negligible. Figures 6 and 7 indicate that, in order to determine more precise values of the intercept and the slope of the straight line, the plot of $1/K_{ex}'\ \alpha$ against $[PO_4]$ is more suitable than that of $1/K_{ex}'\ \alpha$ against $[HPO_4]$. Therefore, in Table 1 the values of K_1' and K_1'' obtained by the treatment of the results shown in Fig. 6 by the least-squares method and by the use of the value of K_{ex} determined above are tabulated.

Similar results are obtained from the n-$PrHg^+$, n-$BuHg^+$, and $PhHg^+$ 8-quinolinate extraction systems. The results of the determinations are tabulated in Table 1. However, as shown in Fig. 8, plots corresponding to Fig. 6 in the $PhHg^+$ system give a curve; therefore, possibility of the formation of higher complexes of $PhHg^+$ with OH^- can not be neglected. It is found though, that the treatment of the whole curve as a quadratic curve does not give reasonable values of K_{ex}, β_1', and β_2'. Therefore, by the treatment of the region from a to b in Fig. 8 as a straight line, K_{ex} and β_2' are determined from the intercept and slope of this straight line.

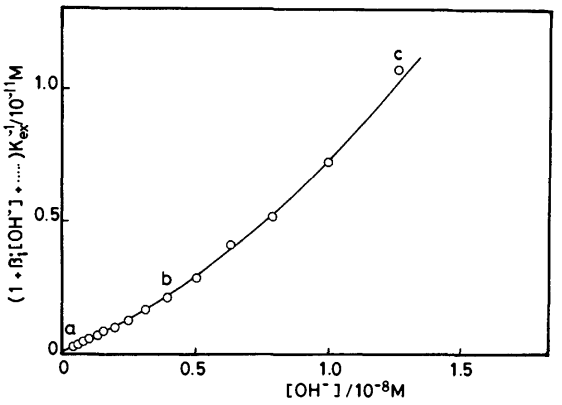

Fig. 8. Plot of values of the intercept of straight lines obtained by plot of $1/K_{ex}'$ a of $PhHg^+$ complex *vs.* $[PO_4]$ against [OH].

The formation of a 1:1 complex of methylmercury(II) with HPO_4^{2-} has been studied by Schwarzenbach *et al.*[9] and by Ingman *et al.*[10], but the formation of a complex of RHg^+ with PO_4^{3-} has not been reported previously. However, the formation constant of EtHgOH obtained here shows a good agreement with that reported previously[5] and that obtained by the study of the extraction of EtHgCl reported in this article. These results indicate that the method of analyzing a reaction presented here is reasonable. Therefore, it seems certain that RHg^+ forms complexes with both HPO_4^{2-} and PO_4^{3-}.

As has been mentioned above, $PhHg^+$ is considered to form higher complexes with OH^- in the present

experimental range, but those higher hydroxo-complex-formation reactions can not be studied in detail. However, the formation constant of PhHgOH obtained here agrees well with that obtained by Waugh *et al.*[5], 1.0×10^{10}. This indicates that $PhHg^+$ forms a 1 : 1 complex with OH^- predominantly in the region from *a* to *b*, that is at pH values from 4.8 to 5.8.

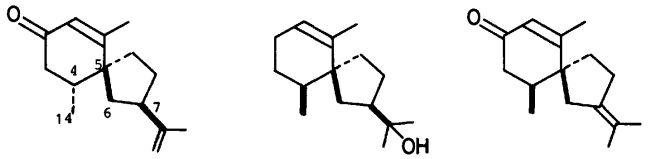
A General Synthetic Approach of Spirovetivanes. The Synthesis of (±)-Solavetivone, (±)-Hinesol, and Related Compounds[1]

Akio MURAI,* Shingo SATO, and Tadashi MASAMUNE*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received February 6, 1984)

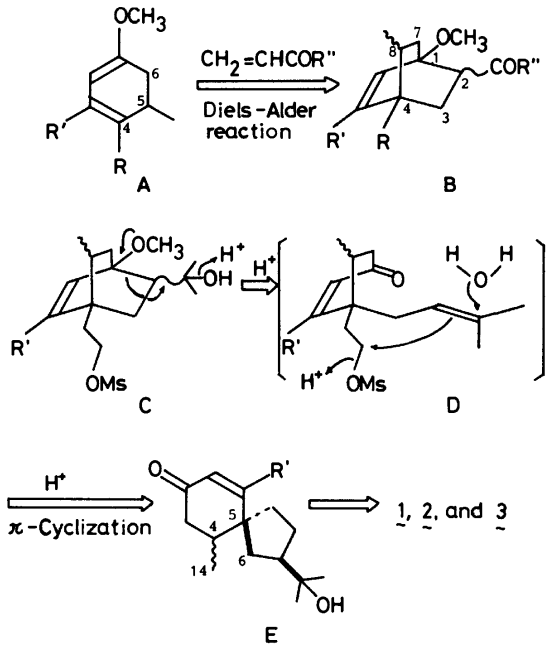
The synthetic procedure leading to preparation of representative compounds, (±)-solavetivone and (±)-hinesol, of two classes of spirovetivanes, is described. The procedure involves Diels-Alder reaction of 4-substituted 5,6-dihydro-3,5-dimethylanisoles with methyl acrylate and π-cyclization of 4-(2-mesyloxyethyl)-4-prenyl-2-cyclohexen-1-one as key steps (Scheme 1).

Naturally occurring spirovetivanes are divided into two classes based on the relative configuration between the C-4–C-14 and C-5–C-6 bonds:[2,3] one class consists of a number of sesquiterpenes, represented by solavetivone and oxylubimin and isolated as stress compounds[4] from diseased potato tubers, possesses the *trans* configuration concerning the relevant bonds, while the other,[3,5] including hinesol, β-vetivone, and others isolated from vetiver oil, takes the *cis*-configuration. While considerable attention has been directed towards synthesis[3] of these sesquiterpenes owing to the characteristic skeleton, most of the works have been limited to the preparation of spirovetivanes belonging to the latter class. Only recently, Yamada,[6] Iwata,[7] and coworkers reported the synthesis of (±)-solavetivone, one of the simplest spirovetivanes of the former class. We have also searched a general procedure leading to the preparation of both classes of spirovetivanes and succeeded in the synthesis of (±)-solavetivone[8] (±)-(**1**), (±)-hinesol[5] (±)-(**2**), (±)-β-vetivone[5] (±)-(**3**), and close analogues. The result was published in a preliminary communication,[9] and its details are described in this paper.



1 **2** **3**

Our synthetic plan involves two key steps as shown in Scheme 1: (i) Diels-Alder reaction of 4-substituted 3,5-dimethyl-5,6-dihydroanisoles (A) with methyl acrylate or its equivalents, giving cycloadducts (B), and (ii) π-cyclization[10] between the primary cationic carbon atom and prenyl double bond of the intermediates (D) derived from B *via* C. The *syn*- and *anti*-configurations of the C-8-methyl group in respect to the C-2–C-3 bond in B correspond to the *cis*- and *trans*-configurations between the C-5–C-6 and C-4–C-14-bonds in the spirovetivanes (E). If each of the *syn*- and *anti*-adducts is prepared stereoselectively under suitable conditions (step i), the respective classes of spirovetivanes would be synthesized effectively. On the other hand, there seem not to be any precedents for ring closure by the relevant π-cyclization (step ii). If the cyclization proceeds smoothly, examination of the Dreiding model indicates that the desirable spirovetivones (E) with the (4*SR*,7*SR*)-isopropyl moiety would be produced stereoselectively.



Scheme 1.

The starting diene (**4**), corresponding to A in Scheme 1, was prepared as follows. 3,5-Dimethylanisole was reacted with bromine in the presence of iron metal to give its 4-bromoanisole (**5**) (85%), which on reflux with magnesium turnings and allyl bromide in ether formed its Grignard reagent. Treatment of the reagent with allyl bromide afforded 4-allyldimethylanisole (**6**) (83% from **5**), which was converted by oxidation according to the Lemieux-Johnson procedure[10] followed by acetalization of the resulting aldehyde (**7**) into the corresponding acetal (**8**) (77% from **6**). The Birch reduction of **8** gave rise to the 3,6-dihydroanisole (**9**) (85%), which was isomerized by heating at 140 °C to yield the 5,6-dihydroanisole (**4**) (72% from **8**).

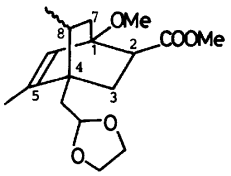
5 R=Br-
6 R=CH_2-CH=CH_2
7 R=CH_2CHO
8 R=CH_2CH<O, O>

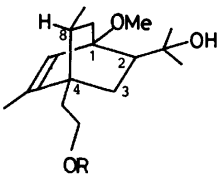
Diels-Alder reactions of the dihydroanisoles were carried out under various conditions.[11] Treatment of the 1,4-diene (**9**) with methyl acrylate in the presence of dichloromaleic anhydride (DCMA)[12] and 2,6-di-*t*-butyl-*p*-cresol (BHT) at 85 °C for 14 d produced a mixture (77% based on the recovered **9**) of four stereoisomeric cycloadducts differing in the configuration at C-2 (2-*endo*- and 2-*exo*-$COOCH_3$) and C-8 (8-*syn*- and 8-*anti*-CH_3 to the C-2–C-3 bond). The product was a 6.6:1.0 mixture of the *endo* (**10**) and exo adducts (**11**), which were separated by chromatography. Each of the adducts (**10**) and (**11**) was estimated to be a 2.0:1.0 mixture of the *syn* and *anti* isomers. The configuration of **10** and **11** was assigned on the basis of the chemical shifts of the signals due to the C-2–H [δ 2.87 (dd, J=9.5 and 5 Hz) and 2.72 (ddd, J=10, 5, and 1 Hz, long-range coupling with 7-*anti*–H=1 Hz) for the *endo* and *exo* adducts]. The ratio of the *syn* and *anti* adducts was deduced from the relative intensity of the C-8–CH_3 [δ 1.04 (d, J=6 Hz, *endo*) and 0.96 (d, J=6 Hz, *exo*) for the *syn* adducts, and δ 0.87 (d, J=6 Hz, *endo*) and 0.75 (d, J=6 Hz, *exo*) for the *anti* adducts]. The cycloaddition, when carried out in ether at 20 °C and at 15000 atm (1 atm=101325 Pa) for 2 d, afforded a 3.2:1.0 (by NMR) mixture (65% based on the recovered **9**) of the *syn-endo* and *anti-endo* adducts (**10**) as the isolable products.[11] On the other hand, treatment of the 1,3-diene (**4**) with methyl acrylate at high temperature (190 °C) afforded a 0.9:1.0 (by NMR) mixture (75%) of the *syn* and *anti* adducts, each being a 2.0:1.0 mixture of the *endo* and *exo* isomers.[11] These results indicate that (i) in contrast to exclusive production of the *anti* adducts in the reactions with 4-unsubstituted[13] and 4-methyl dines,[14] introduction of ethyl and substituted ethyl groups into C-4 of the starting diene led to formation of the *syn* isomers, and (ii) ratios of the *syn*- isomers to the corresponding *anti*-isomers in the latter reactions increased with lowering temperature.

The *endo* adducts (**10**) (a 3.2:1.0 mixture of the *syn* and *anti* adducts) were transformed by a three-step process [(i) acid hydrolysis, (ii) hydride reduction, and (iii) treatment with methyllithium] into the corresponding bicyclooctene diols, which were separated easily to give the *syn-endo* (**12**) and *anti-endo* diols (**13**) in 60 and 15% yields, respectively [δ 1.06 (3H, d, J=7 Hz, 8-CH_3) for **12**, and δ 0.74 (3H, d, J=6 Hz) for **13**]. Likewise, the aforementioned 0.9:1.0 mixture of the *syn* and *anti* adducts were separated easily by chromatography into the *endo* (**10**) and *exo* adducts (**11**), which were treated in the same manner as mentioned above to give the corresponding diols. These diols were separated by chromatography to give the *syn-endo* (**12**), and *anti-endo* isomers (**13**) in 33 and 37% yields (from **10**), and the *syn-exo* (**14**) and *anti-exo* isomers (**15**) in 30 and 33% yield (from **11**), respectively [δ 0.98 (3H, d, J=7 Hz, 8-CH_3) for **14**, and δ 0.75 (3H, d, J=7 Hz) for **15**]. These bicyclooctenediols (**12**)—(**15**) were converted by treatment with methanesulfonyl chloride into the respective methanesulfonates (**12a**)—(**15a**).

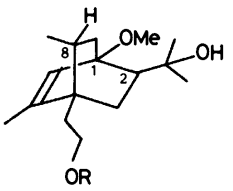
Attempts to convert the *syn-endo* mesylate (**12a**) into the spirovetivanes (**16**) and (**17**) were examined



10 2-endo-COOMe
11 2-exo-COOMe



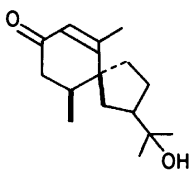
12 2-endo-$C(Me)_2OH$, R=H
12a 2-endo-$C(Me)_2OH$, R=Ms
14 2-exo-$C(Me)_2OH$, R=H
14a 2-exo-$C(Me)_2OH$, R=Ms



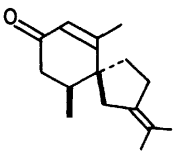
13 2-endo-$C(Me)_2OH$, R=H
13a 2-endo-$C(Me)_2OH$, R=Ms
15 2-exo-$C(Me)_2OH$, R=H
15a 2-exo-$C(Me)_2OH$, R=Ms

under various conditions: *e.g.*, tin(IV) chloride in dichloromethane at −78 °C, acetic acid at 110 °C, formic acid at 50 °C, and others. Finally, treatment of **12a** with oxalic acid (10 mol equiv) in 33% aqueous acetone at 85 °C for 4 h effected formation of the skeletone in question, giving two spirovetivanes (**16**), mp 38—41 °C, and (**17**), mp 121—123 °C, in 60 and 27% yields, respectively, in which the C-4–C-14 and C-5–C-6 bonds were oriented *cis* each other. Careful treatment of **12a** with formic acid at room temperature for 30 min gave prenylcyclohexenone (**18**), which on treatment under the same conditions as mentioned above gave **16** and **17** in 58 and 37% yields, respectively. The other *syn* adduct (**14a**) was also submitted to the same cyclization, giving **16** and **17** in 58 and 20% yields, respectively.

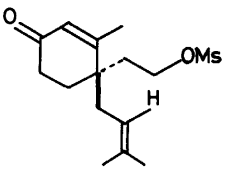
The π-cyclization must have taken place by attack of the prenyl double bond towards the primary cationic carbon atom formed by removal of the mesyloxyl group. It is noted that the isomer (**19**) differing from **16** in the C-7 configuration could not be detected by careful examination of IR and NMR spectra, and by GLC analysis. This high stereoselectivity for formation of the (4*SR*,7*SR*)-asymmetric center could be rationalized in terms of the relative stability of two conformers (**18A**) and (**18B**) with maximum overlap between the π-orbitals of the relevant primary cationic carbon atom and the prenyl double bond (Scheme 2). This seems to be the first example for such stereoselective ring closure.



16 (7SR)-$C(Me)_2OH$
19 (7RS)-$C(Me)_2OH$

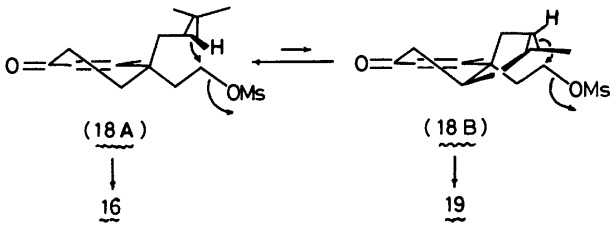


17



18

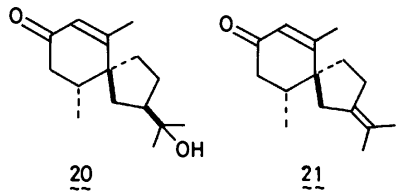
The spirovetivanes (**16**) and (**17**) were identified as authentic samples[5] of (±)-hinesolone and (±)-β-vetivone (**3**), respectively. The former could be trans-



Scheme 2.

formed according to the procedures developed by Dauben and coworkers[5] into (±)-hinesol (**2**) and (±)-β-vetispirene. The present result constitutes a new synthetic pathway to the spirovetivanes isolated from vetiver oil.

The same treatment of the *anti-endo* mesylate (**13a**) in aqueous acetone produced two spirovetivanes (**20**), oil, and (**21**), mp 52—55 °C, with *trans*-oriented C-4–C-14 and C-5–C-6 bonds in 63 and 23% yields, respectively. Likewise, the *anti-exo* isomer (**15a**) afforded **20** and **21** in 69 and 26% yields, respectively. The latter (**21**) was identified as "10-epi-β-vetivone" by comparison of the spectral data with the reported ones.[15] Dehydration of **20** proceeded smoothly by heating with pyridine-modified alumina (Woelm, neutral) at 220 °C for 8 min[16] to give an isopropenyl compound, oil, in 60% yield, which formed its *syn*-, mp 107.5—109 °C, and *anti*-2,4-dinitrophenylhydrazones, mp 137—138 °C. It is emphasized that no isopropylidene derivative was detected in the dehydration product. The compound was identified as (±)-solavetivone by direct comparison with natural solavetivone (**1**) (MS, IR, NMR, and TLC). The present synthesis of (±)-solavetivone involves 12 steps with an overall yield of 3.2% from 3,5-dimethylanisole.



Experimental

All the melting and boiling points were uncorrected. The homogeneity of each compound was always checked by TLC over silica gel (Wakogel B-5F) with various solvent systems, and the spots were developed with cerium(IV) sulfate in dil sulfuric acid and/or concd sulfuric acid. The IR and NMR (100 MHz) spectra were measured in liquid state for oil and in chloroform for solid, and in [^{2}H]chloroform, respectively, unless otherwise stated. The abbreviations "s, d, t, m, and br," in the NMR spectra denote "singlet, doublet, triplet, multiplet and broad," respectively. Solvents and reagents were dried and distilled before use: diethyl ether and tetrahydrofuran (THF) (over sodium ketyl radical); benzene and carbon tetrachloride (CCl_4) (over phosphorus(V) oxide); triethylamine (over calcium hydride).

4-Bromo-3,5-dimethylanisole (5). To a solution of 3,5-dimethylanisole (82 g) in CCl_4 (600 ml) and iron powder (0.4 g) at −40—30 °C was added dropwise a solution of bromine (34 ml, 0.66 mol) in CCl_4 (200 ml) over a 3 h period. The solution was stirred for 2 h at the same temperature, and poured into 400 ml of ice and water, and extracted with dichloromethane, repeatedly. The combined organic solution was washed with 5% aqueous sodium hydrogencarbonate ($NaHCO_3$) and water, dried (Na_2SO_4), and concentrated *in vacuo* to leave an oil, which was distilled under reduced pressure to give **5** (110 g, 85%); bp 123—125 °C/15 Torr (1 Torr=133.322 Pa); MS, *m/z* 214 (M^+, base); IR, 1570, 1230, 1193, 1160, 1074, and 1015 cm^{-1}; NMR (CCl_4), δ 2.33 (6H, s), 3.69 (3H, s), and 6.53 (2H, s). Found: C, 50.56; H, 5.28%. Calcd for $C_9H_{11}OBr$: C, 50.26; H, 5.16%.

4-Allyl-3,5-dimethylanisole (6). To a solution of 2,6-dimethyl-4-methoxyphenylmagnesium bromide, prepared from **5** (35 g), magnesium turnings (4 g) and allyl bromide (1.2 ml) in ether (200 ml) under reflux with stirring for 18 h, was added a solution of allyl bromide (30 ml) in ether (60 ml) at room temperature under argon atmosphere. The solution was stirred under reflux for 16 h and then cooled to 0 °C. To the solution was added 2M† hydrochloric acid (50 ml) to dissolve the remaining magnesium metal. The resulting mixture was poured into saturated brine (200 ml) and extracted with ether, repeatedly. The organic layer was washed with 5% aq $NaHCO_3$ and saturated brine, dried and concentrated, and the resiude was distilled to give **6** (24.09 g): bp 112—130 °C/15 Torr; MS, *m/z* 176 (M^+, base); IR, 3080, 1640, 998, and 915 cm^{-1}; NMR (CCl_4), δ 2.21 (6H, s), 3.25 (2H, dt, *J*=5.5 and 1.8 Hz), 3.68 (3H, s), 4.69 (1H, ddt, *J*=17, 1.9, and 1.8 Hz), 4.82 (1H, ddt, *J*=10, 5.5, and 1.9 Hz), 5.82 (1H, ddt, *J*=17, 10, and 5.5 Hz), and 6.42 (2H, s). Found: C, 81.64; H, 9.06%. Calcd for $C_{12}H_{16}O$: C, 81.77; H, 9.15%.

4-(2,2-Ethylenedioxyethyl)-3,5-dimethylanisole (8). To a solution of **6** (20 g) in THF (400 ml) at room temperature was added a 0.16 M solution (4 ml) of osmium tetraoxide in THF, and the solution was stirred vigorously for 15 min. To the solution was added an aqueous solution (520 ml) containing sodium periodate (58 g) at 0 °C over a 3 h period. The resulting mixture was stirred at room temperature for 10 h, and precipitates formed were removed by filtration. The filtrate was concentrated *in vacuo* to remove THF and extracted with ethyl acetate, repeatedly. The acetate solution was washed with 5% aq sodium hydrogensulfite, water and saturated brine, dried and evaporated to leave 2,6-dimethyl-4-methoxyphenylacetaldehyde (**7**) (21.57 g); IR, 2840 and 1725 cm^{-1}; NMR (CCl_4), δ 2.23 (6H, s), 3.54 (2H, d, *J*=2 Hz), 3.72 (3H, s), 6.50 (2H, s), 9.45 (1H, t, *J*=2 Hz). This compound was used for the next reaction without further purification.

The aldehyde (**7**) (21.57 g), ethylene glycol (11 g) and *p*-toluenesulfonic acid monohydrate (2 g) were dissolved in benzene (400 ml), and the solution was stirred under reflux for 15 h, water being removed continuously by a Dean-Stark tube. The reaction mixture was cooled to room temperature, and poured into saturated brine (300 ml) and extracted with ethyl acetate (EtOAc), repeatedly. The organic layer was washed with 5% aq $NaHCO_3$ and saturated brine, dried, and then evaporated. The crude residue was crystallized from hexane (350 ml), filtered, and washed with hexane–ether (1:1) to give **8** (11.68 g). The filtrate was concentrated and separated by chromatography over alumina (300 g) with benzene to give a crystalline substance **8** (7.17 g), mp 79—81 °C (from ether); MS, *m/z* 222 (M^+); IR (Nujol), 1610, 1185, 1130, 1020, 930, 870, and 837 cm^{-1}; NMR (CCl_4), δ 2.27 (6H, s), 2.86 (2H, d, *J*=5 Hz), 3.66 (3H, s), 3.7 (4H, m), 4.82 (1H, t, *J*=5 Hz), and 6.40 (2H, s). Found: C, 79.14; H, 8.04%. Calcd for $C_{13}H_{18}O_3$: C, 70.24; H, 8.16%.

4-(2,2-Ethylenedioxyethyl)-3,5-dimethyl-3,6-dihydroanisole (9) and its 5,6-Dihydro Isomer (4). i) To a stirred mixture of **8** (7.55 g) in THF (400 ml) and liquid ammonia (700 ml), dried over potassium hydroxide pellets, was added small pieces of lithium (10 g) for 30 min. The mixture was stirred for 2 h

† 1 M=1 mol dm^{-3}.

and treated with absolute ethanol (100 ml) for 40 min. The resulting mixture, after removal of the ammonia followed by addition of ice-cooled water (500 ml), was concentrated, extracted with ether, dried, and evaporated to leave an oily residue, which on distillation gave **9** (6.475 g): bp 105—107°C/1 Torr; MS, *m/z* 224 (M^+); IR, 1701 and 1664 cm^{-1}; NMR, δ 1.08 (3H, d, J=7 Hz), 1.71 (3H, s), 3.51 (3H, s), 4.60 (1H, d, J=4 Hz), and 4.89 (1H, t, J=5 Hz).

ii) The reduction of **8** (10 g) was carrried out in the same manner as mentioned above except distillation. The crude 3,6-dihydroanisole (**9**) was heated at 140°C/29 Torr for 10 h and then distilled to give **4** (7.15 g): bp 152—160°C/13 Torr; UV (EtOH), 277 nm (ε 5000); MS, *m/z* 224 (M^+); IR, 1670, and 1645 cm^{-1}; NMR, δ 0.92 (3H, d, J=7 Hz), 1.79 (3H, s), 3.56 (3H, s), 4.77 (1H, t, J=1 Hz), and 4.88 (1H, t, J=5 Hz).

Diels-Alder Reaction. Method A; The Cycloadditon at 90°C and 1 atm: A mixture of **9** (13.32 g), DCMA (20 mg) and BHT (3 g) in methyl acrylate (80 ml) and benzene (40 ml) was heated at 90°C under argon at atmospheric pressure for 14 d. The red reaction mixture was distilled to remove excess of methyl acrylate and benzene. The syrupy residue was poured into 2M aqueous sodium hydroxide (NaOH) (300 ml), and extracted with ether (4×200 ml). The combined extracts were washed with saturated brine, dried, evaporated, and chromatographed over alumina (200 g) with benzene to give the crude starting diene (**9**, 23.6 g) and a mixture (11.79 g) of the adducts. The crude diene was distilled under reduced pressure to yield the pure starting diene (4.87 g). The crude mixture of the adducts was separated by chromatography over silica gel (400 g) with benzene and ethyl acetate (8:1) to give a mixture of the *exo*-adducts (1.20 g) and the endo-adducts (7.80 g) in 77% yield (based on the consumed starting diene): *endo* adducts (**10**); oil, MS, *m/z* 310 (M^+) and 224; IR, 1741, 1643, 1170, 1112, and 1100 cm^{-1}; NMR, δ 1.04 and 0.87 (2H, and 1H, each d, J=6 Hz), 1.87 and 1.80 (2H and 1H, each d, J=1 Hz), 2.87 (1H, dd, J=9.5 and 5 Hz), 3.32 and 3.64 (each 3H, s), 3.9 (4H, m), 4.93 and 4.98 (0.67 H and 0.33 H, each t, J=4 Hz), and 5.89 (1H, br s, W_H=7 Hz): *exo* adducts (**11**); oil, MS, *m/z* 310 (M^+) and 224; IR, 1738, 1642, 1194, 1130, and 1095 cm^{-1}; NMR, δ 0.96 (2H, d, J=6 Hz), 0.75 (1H, d, J=6 Hz), 1.81 and 1.75 (2H and 1H, each d, J=1 Hz), 2.72 (1H, ddd, J=10, 5, and 1 Hz), 3.35 and 3.66 (each 3H, s), 3.9 (4H, m), 4.93 and 4.89 (0.67 H and 0.33 H, each t, J=5 Hz), and 6.03 (1H, br s, W_H=6 Hz).

Method B; The Cycloaddition Under High Pressure: The Teflon tube (ϕ 8.1×35 mm) filled with the 1,4-diene (**4**) (452 mg), methyl acrylate (230 mg, freshly distilled), BHT (14 mg) and ether (0.5 ml) was kept in a high pressure apparatus, and the cycloaddition was performed at 15000 atm at room temperature for 2 d. The syrupy mixture was evaporated and the residue was separated by chromatography over alumina (19 g) with benzene to give the strating diene (131 mg) and the cycloadducts (190 mg, 65% based on the recovered diene), which was a 3.2:1.0 (by NMR) inseparable mixture (**10**) of the *syn-endo* and *anti-endo* adducts: oil; MS, *m/z* 310 (M^+) and 224 (retro Diels-Alder fragment); IR, 1741, 1643, 1170, 1112, and 1100 cm^{-1}; NMR, δ 1.04 (2.29 H, d, J=6 Hz), 0.87 (0.71 H, d, J=6 Hz), 1.87 (2.29 H, d, J=1 Hz), 1.80 (0.71 H, d, J=1 Hz), 2.87 (1H, dd, J=9.5 and 5 Hz), 3.32 and 3.64 (each 3H, s), 3.9 (4H, m), 4.93 (0.76 H, t, J=4 Hz), 4.98 (0.25 H, t, J=4 Hz), and 5.89 (1H, s).

Method C; The Cycloaddition at 190°C: A mixture of **9** (147 mg), DCMA (2 mg) and BHT (5 mg) in methyl acrylate (1.4 ml) was heated at 190°C for 4 d in a sealed tube. The reaction mixture was dissolved in ethyl acetate (50 ml) and evaporated to leave a tarry residue, which was purified by chromatography over silica gel (30 g) with ethyl acetate and benzene, giving a 0.9:1.0 (by NMR) mixture (**11**, 28 mg) of *syn-exo* and *anti-exo* adducts and a 0.9:1.0 mixture (**10**, 89 mg) of *syn-endo* and *anti-endo* adducts.

2-[2-(1-Hydroxy-1-methylethyl)-1-methoxy-5,8-dimethylbicyclo-[2.2.2]oct-5-en-4-yl]ethanols (12)—(15)[17] *and their Mesylates (12a)—(15a)*. i) A mixture of the *endo* adducts (**10**, 285 mg), prepared by method B, and 2M hydrochloric acid (6 ml) in ether (12 ml) was stirred at 40°C for 15 h. The aqueous layer was separated, saturated with sodium chloride and extracted with ethyl acetate (3×50 ml). The combined extracts were washed with 5% aqueous $NaHCO_3$ and saturated brine, dried and evaporated to give the corresponding bicyclooctene aldehyde (273 mg): oil, MS, *m/z* 266 (M^+); IR, 2730, 1738, 1728, 1650, 1370, 1200, 1179, and 1100 cm^{-1}; NMR (CCl_4), δ 1.16 (0.76H, d, J=6 Hz), 0.88 (0.24H, d, J=6 Hz), 1.81 (3H, s), 2.65 (1.52H, dd, J=8 and 2 Hz), 2.51 (0.48H, dd, J=8 and 1 Hz), 2.80 (1H, dd, J=9.5 and 5 Hz), 3.26 (3H, s), 3.58 (3H, s), 5.78 (0.76H, s), 5.83 (0.24H, s), 9.78 (0.76H, t, J=2 Hz), and 9.84 (0.24H, t, J=1 Hz). The aldehyde was used for the next reaction without further purification.

ii) To a solution of the aldehyde (170 mg) in methanol (5 ml) at 0°C was added sodium borohydride (100 mg). The mixture was stirred for 1 h, and evaporated to leave an oily residue, which was poured into saturated brine and extracted with ethyl acetate, repeatedly. The combined extracts were washed with 5% aqueous $NaHCO_3$ and saturated brine, dried, and evaporated to give an oil, which was purified by chromatography over silica gel (15 g) with benzene and ethyl acetate (3:1) to yield a 3.2:1.0 (by NMR) mixture of the *syn-endo* and *anti-endo* alcohols (223 mg): MS, *m/z* 268 (M^+), 182 and 151 (base): IR, 3460, 1730, 1460, 1192, 1170 1082 and 1030 cm^{-1}; NMR (CCl_4), δ 0.84 (0.7H, d, J=6 Hz), 1.00 (2.3H, d, J=6 Hz), 1.86 (2.3H, d, J=1 Hz), 1.81 (0.7H, d, J=1 Hz), 2.72 (1H, dd, J=10 and 6 Hz), 3.22 (3H, s), 3.59 (3H, s), 3.63 (1.52H, t, J=8 Hz), 3.62 (0.48H, t, J=8 Hz), 5.71 (0.76H, br s, W_H=7 Hz), and 5.72 (0.24H, br s, W_H=6 Hz).

iii) To a stirred solution of the *endo* alcohols (222 mg) in dry ether (25 ml) at room temperature was added 1.2 M methyllithium in ether (15 ml), prepared from methyl iodide (8.5 ml) and lithium (2.2 g) in ether (80 ml). After the solution was cooled at 0°C for 2 h, water (10 ml) was added carefully to the solution. The ether layer was separated, and the aqueous layer was extracted with ethyl acetate repeatedly. The combined ether and acetate extracts were washed with saturated brine, dried, and evaporated. The residue was purified by chromatography over silica gel (15 g) with benzene and ethyl acetate (3:2) to give two diols. The less polar one, which was identified as 8-*syn*-methyl-*endo* diol (**12**, 147 mg), exhibited the following physical properties: mp 101—103°C (from ether); MS, *m/z* 268 (M^+), 182, and 151 (base); IR (Nujol), 3450, 1648, 1470, 1092 and 1055 cm^{-1}; NMR, δ 0.98 (6H, s), 1.06 (3H, d, J=7 Hz), 1.81 (1H, d, J=1 Hz), 3.36 (3H, s), 3.67 (2H, t, J=8 Hz), and 5.89 (1H, br s, W_H=6 Hz). Found: C, 71.95; H, 10.33%. Calcd for $C_{16}H_{28}O_3$: C, 71.60; H, 10.52%. The more polar diol was identified as 8-*anti*-methyl-*endo* diol (**13**, 37 mg); MS, *m/z* 253 (M^+−15), 182, and 151 (base); IR, 3450, 1642, 1090, 1075 and 1040 cm^{-1}; NMR, δ 0.74 (3H, d, J=6 Hz), 0.92 (6H, s), 1.75 (3H, d, J=6 Hz), 1.88 (2H, t, J=8 Hz), 3.36 (3H, s), 3.73 (2H, t, J=8 Hz), and 5.91 (1H, br s, W_H=7 Hz). Found: *m/z* 253.1789. Calcd for $C_{15}H_{25}O_3$: M-CH_3, 253.1804.

iv) The *endo* (**10**, 7.64 g) and *exo* (**11**, 1.12 g) adducts, prepared by method A, were transformed according to the aforementioned three-step process [(i) 2M hydrochloric acid and ether (2:1), 40°C, 15 h, (ii) sodium borohydride in methanol, 0°C, 1 h, and (iii) methyllithium in ether, room temperature, 2 h] into the corresponding bicyclooctene diols, respectively. The *endo* diols were separated by chromatography to give **12** (3.559 g) and **13** (1.063 g), and the *exo* diols were likewise purified to yield *syn-exo* (**14**, 0.44 g) and *anti-exo* diols (**15**, 0.218 g). The latter compounds (**14**) and (**15**) showed the following spectra. **14**; MS, *m/z* 253 (M^+-15), 182, and 151 (base); IR, 3460, 1645, 1400, 1090 and

1043 cm^{-1}; NMR, δ 0.98 (3H, d, J=6 Hz), 1.10 and 1.26 (each 3H, s), 1.81 (3H, d, J=1 Hz), 3.33 (3H, s), 3.72 (2H, t, J=8 Hz), and 6.08 (1H, br s). Found: C, 72.03; H, 10.40%. Calcd for $C_{16}H_{28}O_3$: C, 71.60; H, 10.52%. **15**; MS, m/z 253 (M^+-15), 182, and 151 (base); IR, 3450, 1648, 1092, and 1050 cm^{-1}; NMR, δ 0.75 (3H, d, J=6 Hz), 1.02 and 1.24 (each 3H, s), 1.73 (3H, d, J=1 Hz), 3.32 (3H, s), 3.72 (2H, t, J=8 Hz), and 6.07 (1H, br s). Found: m/z 253.1819. Calcd for $C_{15}H_{25}O_3$: M-CH_3, 253.1804.

v) To a stirred solution of **12** (704 mg) in dry dichloromethane (140 ml) containing triethylamine (0.6 ml, 1.5 mol equiv) cooled at −78°C was added methanesulfonyl chloride (0.23 ml, 1.1 mol equiv) under nitrogen. The resulting mixture was stirred for 10 min, mixed with water (10 ml), and warmed to room temperature. The mixture was poured into 5% aqueous $NaHCO_3$ (10 ml) and extracted with ethyl acetate (4×30 ml). The combined extracts were washed with 5% aqueous $NaHCO_3$ and saturated brine, dried, and evaporated to give a crude *syn-endo* mesylate (**12a**) in quantitative yield (1.075 g): MS, m/z 346 (M^+), 260, 151, and 149 (base); IR, 3505, 1645, 1360, 1180, 1090, 980, and 950 cm^{-1}; NMR, δ 0.89 (6H, s), 1.08 (3H, d, J=6 Hz), 1.83 (3H, d, J=1 Hz), 2.93 and 3.39 (each 3H, s), 4.21 (2H, t, J=8 Hz), and 5.92 (1H, br s). The crude mesylate was used for the next reaction without further purification. Three other diols (**13**)—(**15**) were converted in the respective monomesylates (**13a**)—(**15a**) almost quantitatively. **13a**, oil, MS, m/z 346 (M^+), 260, 151, 149, and 136 (base); IR, 3500, 1645, 1355, 1185, 1093, 980, and 954 cm^{-1}; NMR, δ 0.78 (3H, d, J=6 Hz), 0.90 (6H, s), 1.77 (3H, d, J=1 Hz), 2.95 and 3.38 (each 3H, s), 4.24 (2H, t, J=8 Hz), and 5.94 (1H, br s): **14a**, oil, MS, m/z 346 (M^+), 260, 151, and 149 (base); IR, 3495, 1643, 1353, 1192, 1090, 976, and 948 cm^{-1}; NMR, δ 1.01 and 1.25 (each 3H, s), 1.04 (3H, d, J=7 Hz), 1.81 (3H, d, J=1 Hz), 2.92 and 3.32 (each 3H, s), 4.22 (2H, t, J=8 Hz), and 6.07 (1H, br s): **15a**, oil, MS, m/z 346 (M^+), 260, 151, 149, and 136 (base); IR, 3500, 2645, 1350, 1193, 1087, 985, and 953 cm^{-1}; NMR, δ 0.73 (3H, d, J=6 Hz), 1.08 and 1.32 (each 3H, s), 4.33 (2H, t, J=8 Hz), and 6.14 (2H, br s).

π-Cyclization Reactions. i) A mixture of **12a** (234 mg) in formic acid (99%, 14 ml) was stirred at room temperature for 30 min. The mixture was poured into ice-water (160 ml), neutralized by addition of solid sodium carbonate, and extracted with ether (4×100 ml). The organic layer was washed with 5% aq $NaHCO_3$ (2×50 ml), dried and evaporated to leave a crude prenylcyclohexenone mesylate (**18**, 220 mg): oil; IR, 1670, 1616, 1360 and 118 cm^{-1}; NMR, δ 1.06 (3H, d, J=6 Hz), 1.62 (3H, br s), 1.76 (3H, br s), 1.98 (3H, br s), 2.94 (3H, s), 4.06 (2H, t, J=8 Hz), 5.11 (1H, t, J=7 Hz), and 5.89 (1H, br s, W_H=6 Hz).

A solution of the crude **18** (142 mg) and oxalic acid dihydrate (150 mg, 10 mol equiv), water (6 ml) and acetone (3 ml) was stirred at 85°C for 4 h. The mixture was poured into 5% aqueous $NaHCO_3$ (40 ml), which was saturated with sodium chloride, and extracted with ethyl acetate (5×50 ml). The extracts were washed with 5% aq $NaHCO_3$ and saturated brine, dried, and evaporated. The residue was purified by chromatography over silica gel (5 g) with ethyl acetate and benzene to give two spirovetivanes (**16**, 41 mg) and (**17**, 23 mg), which were identified as (±)-hinesolone[5] and (±)-β-vetivone[5] (**3**) respectively. **16**, mp 121—123°C (from diisopropyl ether), and 116—120°C (from CCl_4) (lit,[5] 115—119°C); MS, m/z 218 (M^+-18, base); IR (CCl_4), 3640, 3475, 1665, and 1615 cm^{-1}; NMR (CCl_4), δ 1.01 (3H, d J=7 Hz), 1.24 (6H, s), 1.97 (3H, s), and 5.75 (1H, br s, W_H=6 Hz). Found: C, 76.15; H, 10.29%. Calcd for $C_{15}H_{24}O_2$: C, 76.22; H, 10.24%. **17** [(±)-β-vetivone], mp 38—41°C (from pentane), (lit,[7] 43.5—57°C); MS, m/z 218 (M^+, base); IR (CCl_4), 1680, 1618, 1383, 1350 and 1295 m^{-1}; NMR (CCl_4), δ 0.97 (3H, d, J=6 Hz), 1.62 and 1.64 (each 3H, br s), 1.87 (3H, s), and 5.65 (1H, br s, W_H=6 Hz). Found: C, 82.73; H, 10.11%. Calcd for $C_{15}H_{22}O$: C, 82.51; H, 10.16%.

ii) A mixture of **12a** (148 mg) in acetone (3 ml) and oxalic acid dihydrate (135 mg) in water (6 ml) was stirred at 85°C for 4 h. The reaction mixture was worked up as mentioned above to yield **16** (46 mg) and **17** (19 mg) in 60 and 27% yields, respectively.

iii) Treatment of **14a** (293 mg) with oxalic acid under the same manner as mentioned above [oxalic acid (720 mg) in water (14 ml) and acetone (7 ml), 85°C, 4 h] afforded **16** (117 mg) and **17** (54 mg) in 58 and 29% yields, respectively.

iv) A mixture of **13a** (697 mg) in acetone (12 ml) and oxalic acid dihydrate (1.58 g) in water (30 ml) was stirred at 85°C for 4.5 h. After being cooled, the mixture was concentrated to remove acetone, and extracted with ethyl acetate (4×100 ml). The combined extracts were washed with saturated brine, dried, evaporated, and purified by chromatography over silica gel (40 g) with benzene and ethyl acetate to give two spirovetivanes (**20**) and (**21**) in 63% (278 mg) and 23% (93 mg) yields, respectively, the latter (**21**) being identified as (±)-10-epi-β-vetivone.[15] **20**, oil; MS, m/z 218 (M^+-18, base); IR, 3480, 1668, 1615, 1383, and 946 cm^{-1}; NMR (CCl_4), δ 0.97 (3H, d, J=7 Hz), 1.18 and 1.95 (6H, and 3H, each s), and 5.65 (1H, br s). Found: C, 76.58; H, 10.13%. Calcd for $C_{15}H_{24}O_2$: C, 76.22; H, 10.24%. **21** [(±)-10-Epi-β-vetivone], mp 52—55°C (from pentane), (lit,[15] 53—54.5°C); MS, m/z 218 (M^+, base); IR (CCl_4), 1681, 1620, and 1386 cm^{-1}; NMR (CCl_4), δ 0.98 (3H, d, J=6 Hz), 1.61 and 1.62 (each 3H, s), and 5.66 (1H, br s). Found: C, 82.76; H, 10.05%. Calcd for $C_{15}H_{22}O$: C, 82.51; H, 10.16%.

v) The *anti-exo* mesylate (**15a**, 67 mg) was treated with oxalic acid (165 mg) in acetone (1.7 ml) and water (3.2 ml) at 85°C for 3 h to give two spirovetivanes (**20**) and (**21**) in 69 (26 mg) and 26% (9 mg) yields, respectively.

(±)-Solavetivone (1). In a glass tube, 11-hydroxysolavetivone (**20**, 50 mg) was finely mixed with pyridine-modified alumina[9] (0.2 g), prepared from neutral alumina (10 g, Woelm, activity grade I) and pyridine (0.2 ml) by stirring under reduced pressure (0.3 Torr) at room temperature for 6 h. The mixture was heated at 220°C (bath temperature) for 8 min under argon, cooled, and poured into ether (30 ml) and triethylamine (5 ml). The whole mixture was stirred for 2 h, and filtered through Celite, concentrated, and chromatographed over silica gel (3 g) with benzene to afford 26 mg (60%) of an isopropenyl compound, oil; MS, m/z 218 (M^+, base); IR, 3100, 1675, 1615, and 855 cm^{-1}; NMR, δ 1.00 (3H, d, J=7 Hz), 1.75 and 1.93 (each 3H, s), 4.74 (2H, s), and 5.74 (1H, s). Found: C, 82.67; H, 10.12%. Calcd for $C_{15}H_{22}O$: C, 82.51; H, 10.16%. The compound was identified as (±)-solavetivone (**1**) by direct comparison with natural solavetivone (MS, IR, NMR, and TLC).

To a solution of (±)-solavetivone (17 mg) in aq methanol (1 ml) at room temperature was added a solution (0.5 ml) of 2,4-dinitrophenylhydrazine (2,4-DNP), prepared from 2,4-DNP (1.0 g) in water (16 ml), 95% ethanol (18 ml), and concd sulfuric acid (3.7 ml). The mixture was stirred for 10 min, and filtrated to leave a red mass, which was dissolved in ether and filtrated. The ether filtrate was concentrated and purified by preparative TLC over silica gel with benzene followed by recrystallization from aqueous methanol to give two 2,4-dinitrophenylhydrazones (**1a**, 10 mg) and (**1b**, 5.5 mg). **1a**, mp 107.5—109°C; NMR, δ 0.99 (3H, d, J=6 Hz), 1.75 and 1.95 (each 3H, s), 4.73 (2H, s), and 6.02 (1H, s). Natural; mp 126°C, NMR, δ 0.99 (3H, d, J=6 Hz), 1.75 and 1.95 (each 3H, s), 4.73 (2H, s), and 6.04 (1H, s). **1b**, mp 137—138° C; NMR, δ 0.96 (3H, d, J=6 Hz), 1.76 and 2.03 (each 3H, s), 4.73 (2H, s), and 6.24 (1H, s). Natural; mp 137°C, NMR, δ 0.97 (3H, d, J=6 Hz), 1.76 and 2.03 (each 3H, s), 4.75 (2H, s), and 6.21 (1H, s).

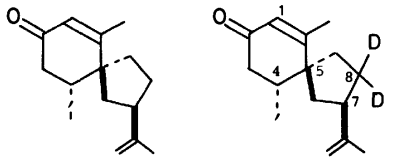
17) These compounds should be designated as 2-[3-(1-hydroxy-1-methylethyl)-4-methoxy-6,7-dimethylbicyclo[2.2.2]-oct-5-enyl]ethanols according to the IUPAC numbering rule. However, in order to avoid confusion, we used the same numbering for all bicyclo[2.2.2]octane derivatives as that for B in Scheme 1 in this paper.

Efficient Synthesis of (±)-Solavetivone and (±)-[8,8-$^2H_2$]Solavetivone[1]

Akio MURAI,* Shingo SATO, and Tadashi MASAMUNE*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received February 6, 1984)

An alternative and efficient synthesis of the title compounds is described. The synthesis involves cycloaddition of 2-methylene-4-methoxy-6-methyl-4-cyclohexenylacetonitrile with methyl vinyl ketone as a key step.

The title sesquiterpene, solavetivone[2] (**1**) is a representative member of the spirovetivane phytoalexins in the genus *Solanum* and has been considered to play an important role in the biosynthetic pathway[3] leading to formation of rishitin, one of the major phytoalexins in the family Solanaceae.[4] While attempts to elucidate this biosynthetic pathway have been made by several groups,[4] the requisite studies with labelled solavetivone have not been performed yet. In the preceding paper we described a general synthetic procedure leading to preparation of representative compounds, (±)-**1** and (±)-hinesol, of two classes of natural spirovetivanes.[1] However the overall yield (3.2%) of (±)-**1** was not always satisfactory for the present biosynthetic studies. This synthetic procedure involved cycloaddition of 4-substituted 3,5-dimethyldihydroanisoles with methyl acrylate, which controlled the relative configuration between the C-4–C-14 and C-5–C-6 bonds in spirovetivanes.[1,5] This stereochemical control in cycloaddition for preferential preparation of (±)-**1** has been improved by introducing a cyanomethyl group to C-4 of the relevant dihydroanisole. The group was less bulky than an ethyl group and converted into desirable functional groups. The result was recently published in preliminary communications,[6] and its details are described in the present paper.

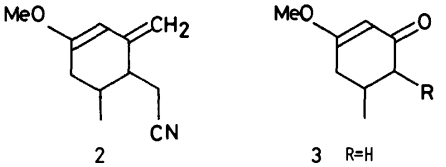


1 [8,8-$^2H_2$] **1**

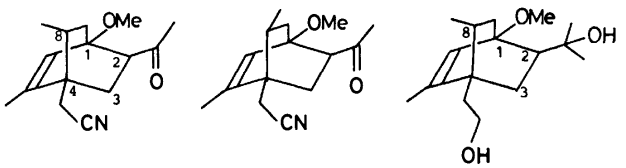
The dihydroanisole (**2**) in question, equivalent to 4-methoxy-2,6-dimethyl-3-cyclohexenylacetonitrile, was prepared from readily available 3-methoxy-5-methyl-2-cyclohexenone[7] (**3**). Treatment of **3** with lithium diisopropylamide in tetrahydrofuran (THF) followed by addition of chloroacetonitrile in a 1:1 mixture of THF and hexamethylphosphoric triamide (HMPA) afforded 4-methoxy-6-methyl-2-oxo-3-cyclohexenylacetonitrile (**4**), which on the Wittig reaction with methylenetriphenylphosphorane in dimethyl sulfoxide (DMSO) was converted into **2** in 80% yield (from **3**).

The cycloaddition of **2** was carried out with methyl vinyl ketone in benzene in the presence of dichloromaleic anhydride (DCMA) and 2,6-di-*t*-butyl-*p*-cresol (BHT) under reflux for 3 d, when a mixture of four stereoisomeric cycloadducts differing in the configurations at C-2 and C-8 was obtained in 76% yield (based on the recovered **2**). The mixture was estimated by the NMR spectrum[1] to consist of a 2.7:1.0 mixture of the *endo* and *exo* adducts, each being a 3.5:1.0 mixture of the 8-*anti*- and 8-*syn*-methyl (in respect to the C-2–C-3 bond) isomers. Indeed, the mixture was separated by repeated chromatography over silica gel to give the *anti-endo* (**5**) [δ 0.79 (3H, d, J=6 Hz, 8-CH_3) and 3.02 (1H, dd, J=10 and 6 Hz, 2-H)], *anti-exo* (**6**) [δ 0.73 (3H, d, J=6 Hz) and 2.87 (1H, ddd, J=11, 6, and 1 Hz, long-range coupling between 2-*endo*-H and 7-*anti*-H=1 Hz)], *syn-endo* (**7**) [δ 1.06 (3H, d, J=6 Hz) and 2.99 (1H, dd, J=10 and 6 Hz)], and *syn-exo* adducts (**8**) [δ 1.14 (3H, d, J=6 Hz) and 2.87 (1H, ddd, J=11, 6, and 1 Hz)] in 43, 16, 12, and 4.5% yields, respectively. The result evidently indicated that the cycloaddition proceeded with predominant formation of the desirable *anti* isomers.

The *anti-endo* (**5**) and *anti-exo* adducts (**6**) were transformed by a three-step process [(i) treatment with methyllithium in ether, (ii) reduction with diisobutylaluminium hydride (DIBAH) in ether, and (iii) reduction with sodium borohydride ($NaBH_4$) in THF–water (2:1)] into the corresponding diols (**9**) and (**10**) in 96 and 75% yields, respectively. These diols were identified as the known intermediates[8] for synthesis of (±)-**1** and were smoothly converted into (±)-solavetivone by the procedure described into the preceding paper.[1] The present synthesis involved 9 steps and the overall yield was 16.6%.



2 **3** R=H **4** R=CH_2CN



5 2-endo-Ac **6** 2-exo-Ac **7** 2-endo-Ac **8** 2-exo-Ac **9** 2-endo-$C(Me)_2OH$ **10** 2-exo-$C(Me)_2OH$

Preparation of the title deuterium-labelled (±)-solavetivone (±)-[8,8-$^2H_2$] (**1**) started with oxidation of the *anti-endo* bicyclooctene diol (**9**) with Jones reagent[9] into the corresponding acid (**11**) (88%). The acid (**11**) was transformed into the corresponding deuterated diol (**12**) according to the following procedure [(i) ethyl chloroformate and triethylamine in THF and (ii) reduction with sodium borodeuteride ($NaBD_4$, ^2H-content, over 98%) in water].[10] The resulting diol (**12**) exhibited the spectra practically identical with those of **9** with exception of the parent peaks

in the mass spectrum and the C-D stretching bands near 2200 cm^{-1} in the IR spectrum. The diol (**12**) was converted with methanesulfonyl chloride and triethylamine in dichloromethane into the monomesylate (**12a**), which was submitted to ring opening and ring closure (π-cyclization) under the reported conditions[1] [10 mol equiv oxalic acid in 33% aq acetone, 85°C, 4h], giving two spirovetivanes (**13**) and (**14**) in 58 and 13% yields (from **12**), respectively. The former underwent dehydration by heating with pyridine-modified alumina[11] to give its isopropenyl compound (±)-[8,8-$^2H_2$](**1**) in 64% yield. The deuterated compound revealed the spectra differing from those of (±)-solavetivone only in the following: MS, *m/z* 220 (M^+, 57%) and 218 (M^+−2, 0%) [8,8-$^2H_2$ content, *ca.* 100%]; IR, 2200 and 2100 cm^{-1}. This compound with two deuterium atoms at the inactive site (C-8) of (±)-solavetivone has been found to be effective for elucidation of the relevant biosynthetic pathway.[6b]

Experimental

All the melting and boiling points were uncorrected. The homogeneity of each compound was always checked by TLC over silica gel (Wakogel B-5F) with various solvent systems, and the spots were developed with concd sulfuric acid. The IR and NMR (100 MHz) spectra were measured in liquid state for oil and in chloroform for solid, and in [^{2}H]chloroform, respectively, unless otherwise stated. The abbreviations "s, d, t, m, and br" in the NMR spectra denote "singlet, doublet, triplet, multiplet, and broad," respectively.

4-Methoxy-6-methyl-2-oxo-3-cyclohexenylacetonitrile (4). To a solution of lithium diisopropylamide, prepared from diisopropylamine (11.5 ml) and 1.5 M butyllithium in hexane (55 ml), in THF (75 ml) at −78°C was added 3-methoxy-5-methyl-2-cyclohexenone (**3**) (10.5 g) in THF (80 ml) under nitrogen over a 20 min period. After being stirred for 15 min, the mixture was added to a solution of HMPA (19.5 ml) and THF (20 ml), and the whole mixture was again stirred for 15 min. To the mixture was added chloroacetonitrile (7.5 ml), and the mixture was warmed gradually to room temperature over a 12 h period under stirring. The solution was poured into saturated brine (200 ml), and extracted with ethyl acetate (EtOAc). The combined extracts were washed with water (200 ml), dried, and concentrated to leave an oily residue, which was separated by chromatography over silica gel (120 g) with benzene and ethyl acetate. The material eluted was recrystallized from ether to give **4** (7.78 g, 58%, 94% based on the recovered starting material), mp 95—97°C; MS, *m/z* 179 (M^+); IR, 2225, 1650, 1610, 1390, 1235, 1168, 1006, and 840 cm^{-1}; NMR (CCl_4), δ 1.18 (2.5H, d, J=6 Hz), 0.96 (0.5H, d, J=6 Hz), 3.64 (3H, s), 5.30 (0.83H, s), and 5.22 (0.17H, s). Found: *m/z* 179.0956. Calcd for $C_{10}H_{13}NO_2$: M, 179.0946.

4-Methoxy-6-methyl-2-methylene-3-cyclohexenylacetonitrile (2). A solution of sodium methylsulfinylmethanide in DMSO was prepared by heating a mixture of sodium hydride (1.07 g as a 60% oil dispersion), washed with hexane, and DMSO (12 ml) at 75—80°C for 30 min under nitrogen. To this solution was added dropwise methyltriphenylphosphonium iodide (8.14 g) in DMSO (20 ml) at 10°C for 10 min, and the mixture was stirred at room temperature for 20 min. Compound **4** (3.00 g) in DMSO (15 ml) was added to this mixture at room temperature during 10 min. The whole suspension was stirred at room temperature for 14 h and then at 45°C for 7.5 h under stirring. The reaction mixture was cooled, poured into 5% aq sodium hydrogencarbonate ($NaHCO_3$, 100 ml) and extracted with ether (4×100 ml). The ether solution was washed with 5% aq $NaHCO_3$, dried, and evaporated to give a reddish syrup, which was separated by chromatography over alumina (180 g) with benzene to afford **2** [1.757 g, 71% based on the recovered starting material (0.505 g)], oil; MS, *m/z* 177 (M^+) and 162 (base); IR, 3080, 2220, 1646, 1608, 1220, 1167, 873 cm^{-1}; NMR (CCl_4), δ 0.99 (3H, d, J=6 Hz), 3.54 (3H, s), 4.72 (2H, s), and 5.17 (1H, s). Found: *m/z* 177.1158. Calcd for $C_{11}H_{15}NO$: M, 177.1153.

(2-Acetyl-1-methoxy-5,8-dimethylbicyclo[2.2.2]oct-5-en-4-yl)-acetonitrile (5)—(8).[12] Compound **2** (1.57 g) was refluxed with methyl vinyl ketone (20 ml), DCMA (10 mg) and BHT (0.1 g) in benzene (20 ml) for 3 d under argon atmosphere. The reaction mixture was concentrated *in vacuo*, and dissolved in ethyl acetate (300 ml). The solution was washed with 2M hydrochloric acid (HCl) (2×40 ml) and 5% aq $NaHCO_3$, dried, and evaporated. The residue was separated by careful chromatography over silica gel (200 g) with benzene and ethyl acetate to give three fractions (total 1.317 g, 60%; 76% based on the recovered starting material).

The first fraction (161 mg) eluted early was a 1:1 (by NMR) mixture of the *syn-exo* and *anti-exo* adducts, and was recrystallised from diisopropyl ether to afford the *syn-exo* adduct (**8**) (47 mg), and the filtrate concentrated gave the *anti-exo* adduct (**6**), (75 mg). The second fraction (296 mg) was a 2:1 (by NMR) mixture of the *anti-exo* and *anti-endo* adducts. The third fraction (850 mg) was a 3:1 (by NMR) mixture of the *anti-endo* and *syn-endo* adducts, and again purified by rechromatography over silica gel (30 g) with benzene-ether (10:1) to afford the *anti-endo* (**5**) (442 mg) and *syn-endo* adducts (**7**) (75 mg).

Each of the adducts exhibited the following physical properties: **8**, mp 103—109°C (from ether); MS, *m/z* 247 (M^+), 177, and 162 (base); IR, 2230, 1710, and 1095 cm^{-1}; NMR, δ 1.14 (3H, d, J=6 Hz), 1.91 (3H, d, J=1 Hz), 2.19 (3H, s), 2.40 (2H, s), 2.87 (1H, ddd, J=11, 6, and 1 Hz), 3.30 (3H, s), 6.07 (1H, br s, W_H=7 Hz). Found: *m/z* 247.1581. Calcd for $C_{15}H_{21}NO_2$: M, 247.1571. **6**, oil; MS, *m/z* 247 (M^+), 177, and 162 (base); IR, 2230, 1718, and 1100 cm^{-1}; NMR, δ 0.73 (3H, d, J=6 Hz), 1.82 (3H, d, J=1 Hz), 2.22 (3H, s), 2.48 and 2.67 (each 1H, d, J=16 Hz), 2.96 (1H, ddd, J=12, 5, and 1.5 Hz), 3.34 (3H, s), 6.12 (1H, br s, W_H=7 Hz). Found: *m/z* 247.1569. Calcd for $C_{15}H_{21}NO_2$: M, 247.1571. **5**, mp 64—67°C (from diisopropyl ether); MS, *m/z* 247 (M^+), 177, and 162 (base); IR, 2230, 1715, 1650, and 1095 cm^{-1}; NMR, δ 0.79 (3H, d, J=6 Hz), 1.78 (3H, d, J=1 Hz), 2.14 (3H, s), 2.63 (2H, s), 3.02 (1H, dd, J=10 and 6 Hz), 3.30 (3H, s), 5.88 (1H, br s, W_H=7 Hz). Found *m/z* 247.1571. Calcd for $C_{15}H_{21}NO_2$: M, 247.1571. **7**, mp 66—67°C (from diisopropyl ether); MS, *m/z* 247 (M^+), 177, and 162 (base); IR, 2225, 1715, 1645, and 1097 cm^{-1}; NMR, δ 1.06 (3H, d, J=6 Hz), 1.95 (3H, d, J=6 Hz), 2.13 (3H, s), 2.40, and 2.56 (each 1H, d, J=16 Hz), 2.99 (1H, dd, J=10 and 6 Hz), 3.30 (3H, s), and 5.82 (1H, br s, W_H=7 Hz). Found: *m/z* 247.1588. Calcd for $C_{15}H_{21}NO_2$: M, 247.1571.

2-[2-(1-Hydroxy-1-methylethyl)-1-methoxy-5,8-dimethylbiocyclo-[2.2.2]oct-5-en-4-yl]ethanols (9) and (10).[12] i) To a stirred solution of the *anti-endo* keto nitrile (**5**) (300 mg) in dry ether (16 ml) at −78°C was added a 1.0 M† methyllithium solution

† 1 M=1 mol dm^{-3}.

in ether (1.82 ml), prepared from methyl iodide (1.6 ml) and lithium (0.4 g) in ether (25 ml). The mixture was stirred for 1 h, poured into water (30 ml), and extracted with ethyl acetate (4×50 ml). The organic layer was washed with saturated brine, dried, and concentrated. The residue was separated by chromatography over silica gel (15 g) with benzene–ethyl acetate (5:1) to afford the starting ketone (59 mg) and hydroxy nitrile (258 mg), oil; MS, *m/z* 263 (M^+), 248, 245, and 177 (base); IR, 3520, 2225, and 1090 cm^{-1}; NMR, δ 0.88 (3H, d, J=6 Hz), 1.00 (6H, s), 1.78 (3H, d, J=1 Hz), 2.58 (2H, s), 3.37 (3H, s), and 6.03 (1H, br s, W_H=7 Hz).

To a stirred solution of the hydroxy nitrile (248 mg, 0.94 mmol) in ether (20 ml) at 0°C under nitrogen was added a 1.55 M solution of DIBAH in hexane (2.44 ml). The mixture was stirred at 0°C for 1 h, mixed with 2 M HCl (5 ml), and stirred for 15 min. The mixture was extracted with ethyl acetate and then worked up as usual to give hydroxy aldehyde (276 mg); IR, 3525 and 1722 cm^{-1}. The aldehyde was used for the next reaction without further purification.

To a mixture of the aldehyde (276 mg) in THF (10 ml) and water (5 ml) at 0°C was added $NaBH_4$ (50 mg) with stirring, and the mixture was stirred for 15 min and then nuetralized with 2 M HCl. The mixture was concentrated *in vacuo* to remove THF, poured into saturated brine, and extracted with ethyl acetate (3×60 ml). The combined extracts were washed with 2 M HCl, 5% aq $NaHCO_3$ and saturated brine, dried, and evaporated to leave an oily residue, which was separated by chromatography over silica gel (14 g) with benzene–ethyl acetate (3:2) to give the starting hydroxy nitrile (83 mg, 33%) and **9** (159 mg, 63%), the latter being identical with the *anti-endo* diol prepared in the previous paper.[1]

ii) The keto nitrile (**6**), (78 mg, 0.316 mmol) was transformed into hydroxy nitrile (64 mg, 77%) in the same manner as mentioned above, oil; MS, *m/z* 263 (M^+), 248, and 177 (base); IR, 3520, 2240, 1645, and 1072 cm^{-1}; NMR, δ 0.87 (3H, d, J=6 Hz), 1.11, and 1.34 (each 3H, s), 1.75 (3H, d, J=1 Hz), 2.56 (2H, s), 3.33 (3H, s) , and 6.17 (1H, br s, W_H=7 Hz).

To a solution of the hydroxy nitrile (63 mg, 0.24 mmol) in ether (6 ml) at 0°C under nitrogen was added a 1.5 M DIBAH solution in hexane (0.7 ml). The mixture was stirred for 2.5 h and worked up as usual to give crude aldehyde (63 mg).

The reduction of the aldehyde (63 mg) under the same conditions as mentioned above [$NaBH_4$ (10 mg) in THF (2.5 ml) and water (1 ml), 0°C, 15 min] afforded crude diol (66 mg), which was separated by chromatography over silica gel (4 g) with benzene–ethyl acetate (3:2) to afford an oily *anti-exo* diol (**10**), (50 mg, 78%). The *exo* diol (**10**) was identical with the *anti-exo* diol, prepared in the previous paper.[1]

(±)-[8.8-$^2H_2$]solavetivone (±)-[8.8-$^2H_2$] (1). i) To a solution of bicyclooctene diol (**9**) (1.67 g) in acetone (100 ml) at 0°C was added Jones reagent (10 ml), and the mixture was stirred for 2 h. When isopropyl alcohol (10 ml) was added to the mixture, green precipitates appeared and were removed by filtration through Celite. The filtrate was concentrated *in vacuo* to leave an oily residue, which was dissolved in ether (100 ml), and washed with 5% aq $NaHCO_3$ (3×30 ml), dried, and concentrated to give the starting diol (**9**) (233 mg). On the other hand, the aq $NaHCO_3$ solution was acidified to pH 2 with 2 M HCl and extracted with chloroform (3×100 ml). The chloroform extracts were dried and evaporated to afford crude acid (1.25 g), oil; IR, 3450, 1730, 1650, 1400, 1390, 1160, and 1090 cm^{-1}; NMR, δ 0.89 (3H, d, J=6 Hz), 1.01 and 1.74 (6H, and 3H, each s), 2.50 and 2.64 (each 1H, d, J=15 Hz), 3.34 and 5.93 (3H and 1H, each s). The acid was used for the next reaction without further purification.

ii) To a mixture of the acid (2.46 g) in THF (50 ml) and triethylamine (Et_3N) (1.5 ml, 1.2 mol equiv) at 0°C was added a solution of ethyl chloroformate (1.0 ml, 1.2 mol equiv) in THF (5 ml) over a 15 min period. The mixture was stirred for 4 h, and the precipitates were removed by filtration and washed with dry THF. The filtrate and THF washings were used for the next reaction.

iii) To a solution of $NaBD_4$ (0.87 g) (^2H content, over 98%) in water (20 ml) at 20°C was added the aforementioned, combined, THF solution over a 50 min period. The mixture was stirred for 5 h, neutralized with 2 M HCl, and concentrated. The residue was extracted with ethyl acetate (4×100 ml), washed with 10% aq sodium hydroxide, dried, evaporated, and separated by chromatography over silica gel (80 g) with benzene–ethyl acetate (1:1) to afford deuterated diol (**12**) (1.65 g), oil; MS, *m/z* 270 (M^+), 255, 184, and 151 (base); IR, 3475, 2190, 2098, 1648, 1400, 1385, 1098, and 1085 cm^{-1}; NMR, δ 0.74 (3H, d, J=6 Hz), 0.98 and 1.74 (6H and 3H, each s), 3.36 (3H, s), and 5.95 (1H, s).

iv) To a mixture of **12** (553 mg) and Et_3N (0.43 ml, 1.5 mol equiv) in dichloromethane (10 ml) at −78°C under nitrogen was added methanesulfonyl chloride (0.17 ml, 1.1 mol equiv) and the solution was stirred for 20 min. The mixture was poured into 5% aq $NaHCO_3$ (50 ml) and extracted with ether (4×70 ml). The ether solution was washed with 5% aq $NaHCO_3$ and saturated brine, dried, and evaporated *in vacuo* to give the corresponding mesylate (705 mg), which was immediatedly used for the next reaction.

v) A mixture of the mesylate (705 mg) and oxalic acid dihydrate (1.66 g) in water (33 ml) and acetone (12 ml) was heated at 85°C for 4 h under stirring. The mixture was neutralized with solid $NaHCO_3$, concentrated, and extracted with ethyl acetate (4×70 ml). The acetate solution was worked up as usual to leave an oily residue, which was separated by chromatography over silica gel (24 g) with benzene–ethyl acetate (3:1) to afford **13** (281 mg) and **14** (60 mg): **13**, oil; MS, *m/z* 238 (M^+), 220 (M^+−18, 28%), and 218 (0%); IR, 3450, 2200, 2100, 1670, 1615, and 1385 cm^{-1}; NMR, δ 0.96 (3H, d, J=7 Hz), 1.22 and 1.94 (6H and 3H, each s), 5.72 (1H, s).

A mixture of **13** (52 mg) and pyridine-modified alumina (0.2 g), prepared from alumina (Woelm, neutral, activity II-III, 10 g) and pyridine (0.2 ml) with stirring at room temperature at 1.6 Torr (1 Torr≈133.322 Pa) for 5 h, was heated in a glass tube at 220°C for 8 min under argon. The residue was dissolved in ether (40 ml) and Et_3N (5 ml), and stirred for 5 h under nitrogen. The mixture was concentrated and purified by chromatography over silica gel (3 g) with benzene–ethyl acetate (20:1) to afford (±)-[8.8-$^2H_2$]**1** (31 mg), oil; MS, *m/z* 220 (M^+, 57.1%), 218 (M^+−2, ~0%), 205 (12.7%), 192 (12.2%), 178 (44.2%), and 136 (base); IR, 3090, 2200, 2100, 1680, 1654, 1619, and 885 cm^{-1}; NMR, δ 1.00 (3H, d, J=7 Hz), 1.76 and 1.94 (each 3H, s), 4.73 (2H, s), and 5.75 (1H, s).

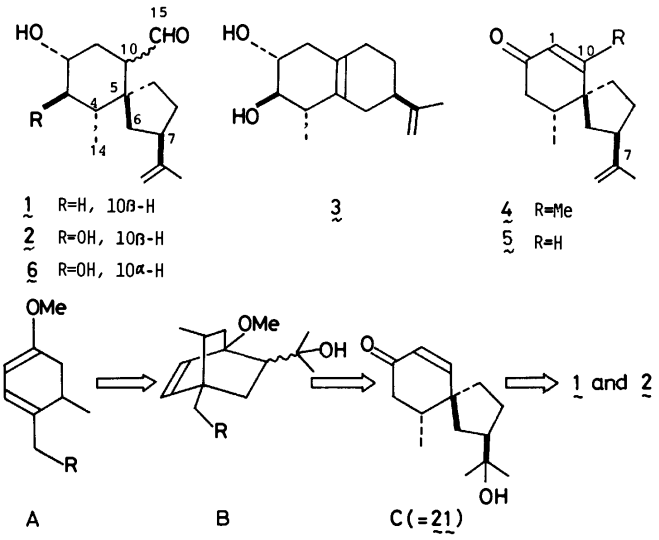
12) Compounds (**5**)—(**8**) should be designated as (3-acetyl-4-methoxy-6,7-dimethylbicyclo[2.2.2]oct-5-enyl)acetonitrile, and those (**9**) and (**10**) as 2-[3-(1-hydroxy-1-methylethyl)1-4-methoxy-6,7-dimethylbicyclo[2.2.2]oct-5-enyl]-ethanols, respectively, according to the IUPAC numbering rule. However, in this paper we used the same numbering for these bicyclo[2.2.2]octane derivatives as that for the corresponding compounds in the preceding paper.

Total Synthesis of (±)-Lubimin and (±)-Oxylubimin. I. Synthesis of (±)-15-Norsolavetivone and Related Compounds[1]

Akio MURAI,* Shingo SATO, and Tadashi MASAMUNE*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received February 6, 1984)

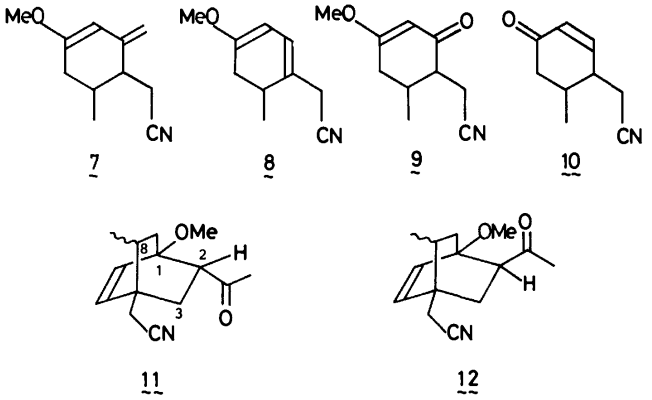
The total synthesis of (±)-15-norsolavetivone, a key intermediate in the synthesis of oxygenated spirovetivane stress metabolites, is described.

The title compounds, lubimin[2] (**1**) and oxylubimin[2] (**2**), are representative members of a group of the spirovetivane sesquiterpenes, which are produced with rishitin[3] (**3**) by potato tubers infected with fungi and qualified as phytoalexins.[4,5] These stress metabolites are biosynthetic intermediates[6] in the major pathway from acetic acid to **3** *via* solavetivone (**4**) and are characterized structurally by the presence of five and six asymmetric centers in the spiro[4.5]decane system as well as the *trans*-disposed C-4–C-14 and C-5–C-6 bonds. Total synthesis of these highly oxygenated spirovetivane phytoalexins has recently been performed according to the synthetic plan shown in Scheme 1, which is divided into two parts: Synthesis of (±)-15-norsolavetivone (±)-(**5**) and related compounds (C in Scheme 1) as key intermediates, and their transformation into (±)-**1**, (±)-**2**, and related compounds such as (±)-10-epioxylubimin[7] (±)-(**6**). The result was published in two preliminary communications.[8] In the present paper the details of the synthesis of (±)-**5** are described.



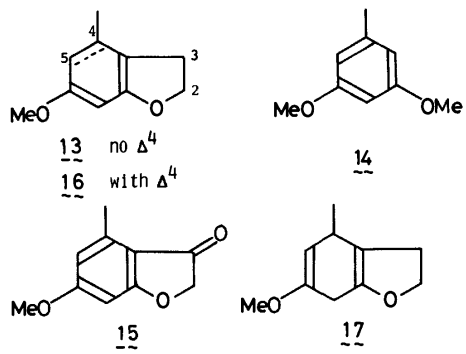
Scheme 1.

In the preceding paper[1] we reported efficient synthesis of (±)-**4**, which started with cycloaddition of 4-methoxy-6-methyl-2-methylene-3-cyclohexenylacetonitrile (**7**) with methyl vinyl ketone. The successful result led us consider that 4-methoxy-6-methyl-1,3-cyclohexadienylacetonitrile (**8**) would be one of the suitable starting materials for the present synthesis. The compound (**8**) was prepared as follows. Reduction of 4-methoxy-6-methyl-2-oxo-3-cyclohexenylacetonitrile[1] (**9**) with sodium hydrotrimethoxyborate[9] followed by acid treatment afforded 4-oxo-6-methyl-2-cyclohexenylacetonitrile (**10**) (70%), which on treatment with 2,2-dimethoxypropane and *p*-toluenesulfonic acid (TsOH) in *N*,*N*-dimethylformamide[10] (DMF) formed the aimed dihydroanisole (**8**) in 55% yield. Cycloaddition of **8** with methyl vinyl ketone at 150°C furnished a mixture of four stereoisomeric adducts, which was separated by chromatography to give the *endo* (**11**) and *exo* adducts (**12**) in 54 and 13% yields, respectively. The NMR spectra revealed that each of the adducts consisted of a 2.5:1.0 mixture of *anti* and *syn* isomers (see Experimental). These results indicated that the overall yield of the expected *anti*-bicyclooctene (B in Scheme 1) was only 18% from 3-methoxy-5-methyl-2-cyclohexenone,[1] a precursor of **9**. The low yield and low stereoselectivity in cycloaddition prompted us to search for another starting material.



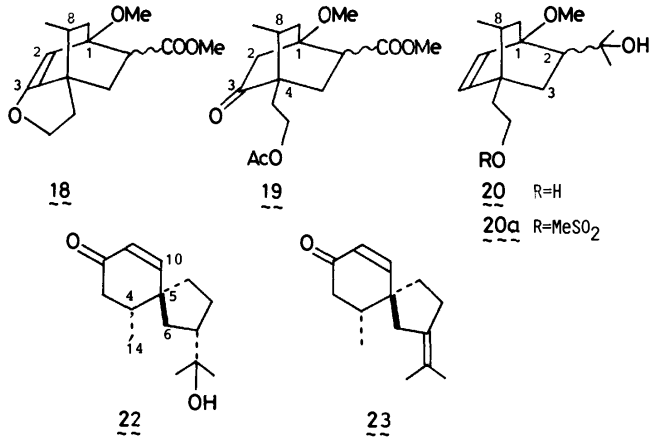
Our previous study[11] indicated that the cycloaddition of 4-substituted 3,5-dimethyldihydroanisoles with methyl acrylate varied, depending on the bulkiness of the 4-substituents. Thus 6-methoxy-4-methyl-2,3,4,5-tetrahydrobenzofuran (**13**) was selected as another suitable diene (A in Scheme 1) for the relevant cycloaddition. The compound (**13**) was prepared from commercially available orcinol dimethyl ether (**14**) as follows. Friedel-Crafts acylation of **14** with chloroacetyl chloride and aluminium chloride gave 2,3-dihydrobenzofuran-3-one (**15**), which on reduction with sodium borohydride ($NaBH_4$) in a mixture of tetrahydrofuran (THF) and methanol followed by hydrogenolysis over 10% palladium–charcoal in the same solvent mixture afforded 6-methoxy-4-methyl-2,3-dihydrobenzofuran (**16**) in 99% yield. The benzofuran (**16**), when submitted to the Birch reduction, was converted into its dihydro derivative (**17**), equivalent to the conjugate diene (**13**), in 81% yield.

The cycloaddition of **17** with methyl acrylate at 150°C in the presence of dichloromaleic anhydride (DCMA) proceeded as expected, giving only a 3:2 mixture of *syn*-8-methyl-6-*endo*-methoxycarbonyl- and *syn*-8-methyl-6-*exo*-methoxycarbonylbicyclo[2.2.2] oc-

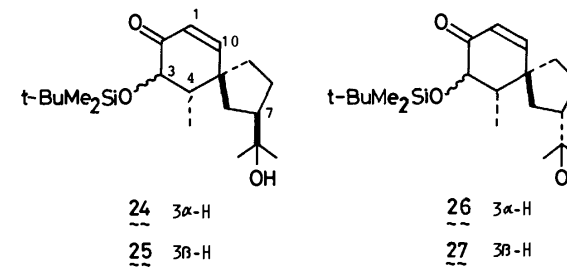


tene adducts (**18**) in 70% yields: *syn-endo* isomer, δ 0.83 (1.8H, s, 8-CH_3) and 4.91 (0.6H, s, 2-H); *syn-exo* isomer, δ 0.86 (1.2H, s) and 5.12 (0.4H, s). Hydrolysis of the mixture (**18**) with oxalic acid in aqueous methanol followed by acetylation furnished keto acetates (**19**) in 70% yield. Treatment of **19** with *p*-tolylsulfonylhydrazine and concd hydrochloric acid in THF under reflux gave its tosylhydrazones (~100%), which were converted under the Shapiro conditions[12] with excess of methylithium into *anti*-8-methylbicyclo[2.2.2]octene diols (**20**) in 71% yield.

Treatment of the diols (**20**), after monomesylation under the usual conditions, with oxalic acid (10 mol equiv) in a 1:5 heterogeneous mixture of water and methyl isobutyl ketone at 130°C for 8 h effected successive cleavage of the C-1–C-2 bond and ring closure[13] to give a mixture of three 15-norsolavetivanes with the *trans*-oriented C-4–C-14 and C-5–C-6 bonds, from which 11-hydroxy-15-norsolavetivane (**21**=C) with a (4*SR*, 7*SR*)-isopropyl moiety was isolated in 35% yield along with its (4*SR*, 7*RS*)-epimer (**22**) (25%) and a 7-isopropylidene derivative (**23**) (30%) by preparative HPLC over μ-Porasil. The relevant reactions, when carried out under the same conditions as those for solavetivones[13] (oxalic acid in a 2:1 homogeneous mixture of water and acetone) led to formation of **21**, **22**, and **23** in 16, 38, and 16% yields, respectively. These results strongly suggested that the bulkiness of the methyl group at C-10 controls conformations of the transition state in the ring closure[14] in question. The spirovetivane (**21**) underwent smooth dehydration on treatment with pyridine–modified alumina[16] to give (±)-15-norsolavetivone (±)-**5** in 68% yield. The synthesis of (±)-5 involved 11 steps and the overall yield was 5.7% from the orcinol (**14**).



The relative configuration at C-7 in the 15-norspirovetivanes (**21**) and (**22**) was assigned tentatively on the basis of the following facts. Treatment of **21** with lithium diisopropylamide (LDA) in a mixture of THF and hexamethylphosphoric triamide (HMPA) and then with *t*-butyldimethylsilyl chloride in THF, followed by oxidation with perbenzoic acid in hexane,[15] furnished a mixture of the 3,4-diequatorial 3-silyl ether (**24**) and its 3-epimer (**25**), which were separated easily by chromatography in 51 and 25% yields, respectively: **24**, δ 3.89 (1H, d, J=11 Hz, 3-H), 5.78 and 6.80 (each 1H, d, J=10 Hz, 1- and 10-H); **25**, δ 4.40 (1H, d, J=4 Hz), 5.81 and 6.60 (each 1H, d, J=10 Hz). The same treatment of **22** afforded the corresponding 3,4-diequatorial 3-silyl ether (**26**) and its 3-epimer (**27**) in 50 and 26% yields, respectively: **26**, δ 3.90 (1H, d, J=11 Hz, 3-H), 5.72 and 6.67 (each 1H, J=10 Hz, 1- and 10-H); **27**, δ 4.41 (1H, d, J=11 Hz), 5.81 and 6.62 (each 1H, d, J=10 Hz). The observed difference in chemical shift (Δδ 0.13) of the proton at C-10 between **24** and **26** was explained well by the difference of the configuration at C-7; namely, the cyclohexane rings in **24** and **26** would take a half-chair conformation owing to the bulky 3-silyloxyl group (equatorial). Thus the hydroxyl group in the C-7 isopropyl moiety would be situated near the hydrogen atom at C-10 only in **24** and hence would deshield the proton in question. A definite assignment was provided by transformation of the 10-hydroxy-15-norspirovetivanes (**21**) and (**24**) into natural spirovetivanes.[16]



Experimental

All the melting and boiling points were uncorrected. The homogeneity of each compound was always checked by TLC over silica gel (Wakogel B-5F) with various solvent systems, and the spots were developed with concd sulfuric acid (H_2SO_4). The IR and NMR (100 MHz) spectra were measured in liquid state for oil and chloroform for solid, and in [^{2}H]-chloroform, respectively, unless otherwise stated. The preparative HPLC was carried out on Waters Associates Model 6000 A, and the column chromatography over silica gel (Kieselgel 60) or aluminium oxide (Aluminumoxide 90), respectively. The following solvents were dried and distilled before use: diethyl ether and THF (from sodium ketyl radical), benzene, carbon tetrachloride, carbon disulfide, and hexane (from phosphorus (V) oxide); triethylamine, DMF, 1,2-dimethoxyethane (DME), HMPA, and dimethyl sulfoxide (DMSO) (from calcium hydride), and ethanol (from magnesium).

4-Oxo-6-methyl-3-cyclohexenylacetonitrile (10). To a suspension of sodium hydride (3.4 g, 60% in oil) in refluxing THF (120 ml) was added freshly distilled methyl borate (7.31 ml, 64 mmol) under nitrogen over a 20 min period. The mixture was stirred for 30 min and cooled to room temperature. A solution of 4-methoxy-6-methyl-2-oxo-3-cyclo-

hexenylacetonitrile (**9**) (2.86 g, 16 mmol), prepared in the preceding paper,[1] in THF (20 ml) was added to the mixture, and stirred for an additional 24 h. To the reaction mixture at 0 °C was added 10% aq H_2SO_4 (20 ml). The whole mixture was stirred for 20 min, concentrated *in vacuo*, poured into 50 ml of saturated brine, and extracted with ethyl acetate (4×100 ml). The combined extracts were washed with 10% aq H_2SO_4 and saturated brine, dried, evaporated, and separated by chromatography over silica gel (120 g) with benzene to give **10** (1.463 g, 70% yield, based on the consumed **9**), oil; MS, *m/z* 149 (M^+); IR, 2220, 1685, and 1615 cm^{-1}; NMR, δ 1.17 (3H, d, J=6 Hz), 6.08 and 6.80 (each 1H, d, J=10 Hz). Found: 149.0844. Calcd for $C_9H_{11}NO$: M, 149.0841.

4-Methoxy-6-methyl-1,3-cyclohexadienylacetonitrile (8). A mixture of **10** (1.412 g), 2,2-dimethoxypropane (12 ml), *p*-TsOH (20 mg), methanol (0.2 ml) and DMF (12 ml) was refluxed under nitrogen for 19 h. The mixture was cooled, poured into aqueous sodium hydrogencarbonate ($NaHCO_3$) (30 ml), and extracted with ether (3×100 ml). The combined extracts were washed with 5% aq $NaHCO_3$, saturated brine, and dried over potassium carbonate and sodium sulfate. The extracts was concentrated and separated by chromatography over alumina (120 g) with benzene to give **8** [559 mg, 36% yield (55% yield, based on the recovered **10**)], oil; MS, *m/z* 163 (M^+), 148, and 108 (base): IR, 2225, 1670, 1610, and 1255 cm^{-1}; NMR, δ 1.04 (3H, d, J=6 Hz), 1.96 (1H, dd, J=16, 4 Hz), 2.3~2.8 (2H, m), 3.01 (2H, s), 3.54 (3H, s), 4.82 and 5.84 (each 1H, d, J=7 Hz). Found: *m/z* 163.0990. Calcd for $C_{10}H_{13}NO$: M, 163.0994.

Cycloaddition of 8. A mixture of **8** (160 mg) and 2,6-di-*t*-butyl-*p*-cresol (BHT) (5 mg) in methyl vinyl ketone (1 ml) was heated in a sealed tube at 150 °C for 2 d. The reaction mixture was cooled and evaporated to leave an oily residue, which was dissolved in ethyl acetate (50 ml). The mixture was washed with 2 M† hydrochloric acid (HCl) (2×20 ml), 5% aq $NaHCO_3$, saturated brine, dried, evaporated, and separated by chromatography over silica gel (20 g) with benzene–ethyl acetate to give a mixture of *anti*- and *syn-endo* adducts (**11**) (122 mg, 54%) and a mixture of the corresponding *exo*-adducts (**12**) (29 mg, 13%), each being a 2.5:1.0 mixture of *anti*- and *syn*-8-methylbicyclooctenes: **11**; MS, *m/z* 233 (M^+); IR, 2225, 1716, 1180, and 1110 cm^{-1}; NMR, δ 0.84 and 1.04 (2.14H and 0.86H, each d, J=6 Hz), 2.16 (3H, s), 2.62 and 2.48 (1.43H and 0.57, each s), 3.08 and 2.98 (0.72H and 0.28H, each dd, J=10 and 6 Hz), 3.32 (3H, s), 5.83 and 6.27 (each 0.72H, d, J=9 Hz), 6.18 and 6.24 (each 0.28H, d, J=9 Hz); **12**, oil; MS, *m/z* 233 (M^+); IR 2230, 1713, 1180, and 1108 cm^{-1}; NMR, δ 0.78 and 1.11 (2.14H and 0.86H, each d, J=6 Hz), 2.23 and 2.21 (2.14H and 0.86H, each s), 3.34 and 3.32 (2.14H and 0.86H, each s), 5.89 and 6.45 (each 0.72H, d, J=8 Hz), 6.17 and 6.45 (each 0.28H, d, J=8 Hz).

6-Methoxy-4-methyl-2,3-dihydrobenzofuran (16). To a solution of orcinol dimethyl ether (16.74 g, 0.11 mmol) in carbon disufide (110 ml) was added at 0 °C carefully powdered aluminium chloride (14.8 g, 0.11 mmol) with vigorous stirring and then at room temperature a solution of chloroacetyl chloride (9 ml, 0.11 mmol) in carbon disulfide (55 ml) over a 1 h period. The mixture was stirred under reflux for 7 h, distilled to remove the solvent, and cooled with an ice-water bath. To the residue were added chloroform (200 ml), ice-water (100 ml) and 2 M HCl, successively. The mixture was stirred for 40 min at 0 °C, when the residue was dissolved. The aqueous layer was separated and the chloroform extracts were washed with 2 M HCl (100 ml) and water (2×100 ml), dried, and concentrated to leave an oily residue, which crystallized on addition of diisopropyl ether (200 ml). Recrystallization from diisopropyl ether gave 6-methoxy-4-methyl-2,3-dihydrobenzofuran-3-one (**15**). (12.09 g, 62%), mp 123—124 °C; MS, *m/z* 178 (M^+, base); IR (Nujol), 1702, 1620, 1590, 1280, 1190, 1150, and 1080 cm^{-1}; NMR, δ 2.55 (3H, s), 3.85 (3H, s), 4.57 and 6.36 (each 2H, s). Found: C, 67.33%; H, 5.82%. Calcd for $C_{10}H_{10}O_3$: C, 67.40%; H, 5.66%. The filtrate was concentrated and purified by chromatography over silica gel (300 g) with benzene and ethyl acetate to give the starting orcinol dimethyl ether (0.52 g, 3%), **15** (2.25 g, 8.1%), and 3,5-dimethoxy-2-(chloroacetyl)toluene (2.05 g, 8.1%), mp 69—70.5 °C (from diisopropyl ether); MS, *m/z* 230 (M^++2), 228 (M^+), and 179 (base); IR (Nujol), 1701, 1605, 1575, 1330, 1155, and 1102 cm^{-1}; NMR, δ 2.27 and 3.80 (3H and 6H, each s), 4.49 (2H, s), 6.27 and 6.31 (each 1H, d, J=1 Hz). Found: C, 57.72; H, 5.71%. Calcd for $C_{11}H_{13}O_3Cl$: C, 57.77; H, 5.73%.

The chloroacetyl compound was transformed into **15** as follows. A mixture of the compound (13.3 g, 0.058 mmol) and powdered aluminium chloride (8.6 g) in carbon disulfide (150 ml) was heated under reflux for 22 h. After removal of the solvent and cooling at 0 °C, the residue was worked up as described above to give **15** (10.06 g, 97%).

ii) To a solution of **15** (12.09 g) in THF (250 ml) and methanol (150 ml) was added $NaBH_4$ (8 g) in four portions at 0 °C, and the mixture was stirred for an additional 1.5 h. To the reaction mixture was added acetone (100 ml), and the mixture was concentrated *in vacuo*. The residue was poured into a mixture of saturated brine (200 ml) and 5% aq $NaHCO_3$ (100 ml), and extracted with ethyl acetate (3×200 ml) and the combined extracts were washed with water (3×50 ml), dried, and evaporated to give a crystalline residue. Recrystallization from methanol afforded an analytical sample: mp 67—68 °C; MS, *m/z*, 180 (M^+) and 162 (base); IR (Nujol), 3240, 1623, 1603, 1200, and 1141 cm^{-1}; NMR, δ 2.35 and 3.74 (each 3H, s), 4.43 (1H, d, J=3 Hz), 4.45 (1H, d, J=5 Hz), 5.23 (1H, dd, J=5 and 3 Hz), 6.23 and 6.26 (each 1H, s). Found: C, 66.75; H, 6.70%. Calcd for $C_{10}H_{12}O_3$: C, 66.56; H, 6.71%. The crude residue was used for the next reaction without further purification.

A solution of the crude alcohol in THF (200 ml) and ethanol (200 ml) was treated with hydrogen over 4 g of 10% palladium on charcoal at room temperature under atmospheric pressure, until uptake of hydrogen ceased. The solution was filtered through Celite and concentrated under reduced pressure. The residue was recrystallized from methanol to give **16** (8.366 g), mp 54.5—56.5 °C; MS, *m/z* 164 (M^+, base); IR (Nujol), 1628, 1605, 1204, and 1140 cm^{-1}; NMR, δ 2.22 (3H, s), 3.05 (2H, t, J=8 Hz), 3.75 (3H, s), 4.57 (2H, t, J=8 Hz), and 6.23 (2H, s). Found: C, 73.34; H, 7.25%. Calcd for $C_{10}H_{12}O_2$: C, 73.14; H, 7.37%.

6-Methoxy-4-methyl-2,3,4,7-tetrahydrobenzofuran (17). To a mixture of **16** (15 g) in dry ether (700 ml) and liquid NH_3 (2 l) at −33 °C was added small pieces of lithium (28 g) over a 30 min period. The mixture was stirred for 2 h, and, after addition of 260 ml of ethanol over a 1 h period, was warmed to evaporate ammonia. The residue was mixed with water (1.4 l) at 0 °C, saturated with sodium chloride, and extracted with ether (5×300 ml). The combined ether extracts were washed with water (2×200 ml), dried, evaporated, and separated by chromatography over alumina (300 g) with benzene to leave **17** (12.3 g, 81%), oil; MS, *m/z* 166 (M^+) and 151 (base); IR, 1732, 1664, 1404, 1232, and 1164 cm^{-1}; NMR (CCl_4), δ 1.05 (3H, d, J=7 Hz), 3.50 (3H, s), 4.27 (2H, t, J=9 Hz), 4.47 (1H, d, J=4 Hz). Found: *m/z* 166.0982. Calcd for $C_{10}H_{14}O_2$: M, 166.0994.

2-(1-Methoxy-6-methoxycarbonyl-8-syn-methyl-3-oxobicyclo-[2.2.2]oct-4-yl)ethyl Acetate (19).[17] i) A mixture of **17** (50 g), methyl acrylate (120 ml), dichloromaleic anhydride (1 g), and BHT (2.5 g) was heated in an autoclave at 150 °C under argon atmosphere for 5 d. The mixture was dissolved in benzene

† 1 M=1 mol dm^{-3}.

(100 ml), concentrated, and separated by chromatography over alumina (2.4 kg) with benzene to afford a mixture of adducts (**18**) (52.90 g, 70%), oil; MS, *m/z* 252 (M^+), 221, 166, and 151 (base); IR, 1733, 1680, 1207, and 1172 cm^{-1}; NMR, δ 0.83 and 0.86 (1.8H and 1.2H, each d, J=6 Hz, 8-CH_3), 2.92 (1H, m, 6-H), 3.33 and 3.37 (1.8H and 1.2H, each s, 1-OCH_3), 4.91 and 5.12 (0.6H and 0.4H, each s, *endo*- and *exo*-2-H). The mixture of the adducts was used for the next reaction without further purification.

ii) A mixture of the adducts (**18**) (52.90 g), oxalic acid (300 g as dihydrate) in methanol (850 ml) and water (1.7 l) was stirred at room temperature for 2 h, and neutralized with solid sodium carbonate. The mixture was stirred for an additional 30 min, and concentrated *in vacuo*. The residue was saturated with sodium chloride, and extracted with ethyl acetate (4×500 ml). The combined acetate extracts were washed with saturated brine, dried, evaporated, and separated by chromatography over silica gel (2.0 kg) with benzene–ethyl acetate (3:2) to give keto alcohols (39.18 g). The mixture of *endo* and *exo* keto alcohols was used for the next reaction without further separation. However, an analytical sample of each alcohol was obtained by careful column chromatography. *exo*-Keto alcohol, oil; MS, *m/z* 270 (M^+), 184, 166, and 151 (base); IR, 3480, 1730, 1720, 1202, 1183, and 1116 cm^{-1}; NMR, δ 0.84 (3H, d, J=6 Hz), 3.06 (1H, ddd, J=10, 6, and 3 Hz), 3.28 (3H, s), 3.66 (2H, t, J=7 Hz), and 3.75 (3H, s). Found: C, 61.85; H, 8.25%. Calcd for $C_{14}H_{22}O_5$: C, 62.20; H, 8.20%. *endo*-Keto alcohol, oil; MS, *m/z* 270 (M^+), 184, 166, and 151 (base); IR, 3476, 1725, 1200, 1174, and 1113 cm^{-1}; NMR, δ 0.85 (3H, d, J=6 Hz), 2.92 (1H, dd, J=8 and 5 Hz), 3.25 (3H, s), 3.63 (2H, t, J=7 Hz), and 3.71 (3H, s). Found: C, 61.77; H, 8.26%. Clacd for $C_{14}H_{22}O_5$: C, 62.20; H, 8.20%.

iii) A mixture of the keto alcohols (30.2 g) in dry pyridine (300 ml) and acetic anhydride (120 ml) was stirred at 20°C under nitrogen for 23 h. The mixture was mixed with ethanol (100 ml) stirred for 30 min at 20°C, and concentrated at 50 °C *in vacuo* (15 Torr) (1 Torr=133.322 Pa). The residue was poured into ice-water (200 ml), and extracted with ethyl acetate (3×250 ml). The combined acetate extracts were washed with 2 M HCl (4×100 ml), dried, evaporated, and saparated by column chromatography over silica gel (200 g) with benzene–ethyl acetate (7:1) afforded **19** (30.54 g, 97% based on the recovered starting material), oil; MS, *m/z* 312 (M^+); IR, 1732, 1249, 1205, 1117, and 1115 cm^{-1}; NMR, δ 2.02 (3H, s), 3.25 and 3.24 (1.8H and 1.2H, each s), 3.70 and 3.73 (1.8H and 1.2H, each s), and 4.06 (2H, t, J=7 Hz).

*2-[2-(1-Hydroxy-1-methylethyl]-1-methoxy-8-*anti-*methylbicyclo-[2.2.2]oct-3-en-4-yl]ethanol (**20**)*[17] *and its monomesylate (**20a**).* i) A mixture of **19** (4.303 g, 0.014 mmol), *p*-tolylsulfonylhydrazine (2.73 g, 0.015 mmol) and concd HCl (0.5 ml) in THF (190 ml) was stirred under reflux for 20 h. The reaction mixture was cooled, concentrated *in vacuo*, and dried at 20°C for 10 h under reduced pressure (3 Torr), giving the crude hydrazone (7.30 g), amorphous: IR ($CHCl_3$), 3540, 3225, 1728, 1598, 1440, 1374, 1340, 1248, 1168, 1098, 1040, and 815 cm^{-1}.

To a solution of the crude tosyl hydrazone (7.30 g) in dry THF (600 ml) at 0°C under nitrogen was added a 1 M solution of methyllithium in ether (210 ml, 15 mol equiv), prepared from methyl iodide (160 ml) and lithium (40 g) in ether (250 ml), over a 1 h period. The mixture was heated at 35°C for 19 h, cooled, mixed carefully with water (100 ml) at 0°C, and concentrated to remove THF *in vacuo*. The residue was poured into saturated brine (400 ml), and extracted with ethyl acetate (4×200 ml). The combined extracts were washed with saturated brine (2×100 ml), dried, evaporated, and separated by chromatography over silica gel (250 g) with benzene–ethyl acetate (2:1) to yield **20** (2.479 g, 71% from **19**), oil; MS, *m/z* 254 (M^+), 239, and 236; IR, 3473, 1384, 1173, 1101, and 1050 cm^{-1}; NMR, δ 0.78 and 0.76 (1.8H and 1.2H, each d, J=7 Hz), 1.00 (3.6H, s), 1.10 and 1.34 (total 2.4H, each s), 3.39 and 3.37 (1.8H and 1.2H, each s), 3.75 (2H, t, J=7.5 Hz), 5.82 and 6.28 (each 0.6H, d, J=9 Hz), 5.74 and 6.44 (each 0.4H, d, J=9 Hz).

ii) To a solution of **20** (13.70 g, 0.054 mol), and triethylamine (12.8 ml, 1.7 mol equiv) in dichloromethane (270 ml) at −78°C under nitrogen was added methanesulfonyl chloride (4.7 ml, 1.1 mol equiv). The mixture was stirred for 15 min, mixed with 5% aq $NaHCO_3$ (20 ml), and warmed to room temperature. The mixture was again poured into 5% aq $NaHCO_3$ (200 ml), when the dichloromethane layer was separated. The aqueous layer was extracted with ethyl acetate (3×20 ml). The dichloromethane and acetate extracts were combined, washed with 5% aq $NaHCO_3$ (70 ml) and saturated brine (70 ml), dried, and concentrated to give crude monomesylates (**20a**), which were used for the next reaction.

*Norsolavetivanes (**21**), (**22**), and (**23**).* i) A mixture of **20a** (71 mg) and oxalic acid dihydrate (252 mg) in methyl isobutyl ketone (20 ml) and water (4 ml) was stirred at 130°C for 8 h. After being cooled and neutralized with solid sodium carbonate at 0°C, the mixture was poured into saturated brine and extracted with ethyl acetate (4×50 ml). The extracts were washed, dried, concentrated, and separated by chromatography over silica gel (6 g) with benzene–ethyl acetate (2:1) to give a mixture (18 mg, 60% based on the consumed starting material) of 15-nor-11-hydroxy-solavetivanes (**21**) and (**22**) and its isopropylidene analogue (**23**) (8.1 mg, 30%), oil; MS, *m/z* 204 (M^+); IR, 1685, 1362, and 1182 cm^{-1}; NMR, δ 0.99 (3H, d, J=7 Hz), 1.63 (6H, s), 5.85 and 6.71 (each 1H, d, J=10 Hz). Found: *m/z* 204.1550. Calcd for $C_{14}H_{20}O$: M, 204.1515. A mixture of **21** and **22** was separated by HPLC [Waters, μ-Porasil, eluted with hexane–ether (1:1) 5 ml/min] to give **21** (10.3 mg, 35%) and **22** (7.4 mg, 25%): **21**, R_t=28 min, oil; MS, *m/z* 222 (M^+); IR, 3495, 1678, 1383, 1362, 1178, and 944 cm^{-1}; NMR, δ 1.00 (3H, d, J=6 Hz), 1.21 (6H, s), 5.78 and 6.74 (each 1H, d, J=10 Hz). Found: *m/z* 222.1617. Calcd for $C_{14}H_{22}O_2$: M, 222.1620. **22**, R_t=23 min, oil; MS, *m/z* 222 (M^+); IR, 3490, 1680, 1614, 1387, 1140, and 940 cm^{-1}; NMR, δ 1.01 (3H, d, J=6 Hz), 1.22 (6H, s), 5.79 and 6.76 (each 1H, d, J=10 Hz). Found: *m/z* 222.1624. Calcd for $C_{14}H_{22}O_2$: M, 222.1620.

ii) A mixture of **20a** (106 mg) and oxalic acid dihydrate (282 mg) in acetone (3 ml) and water (6 ml) was stirred at 90°C for 8 h. The reaction mixture was worked up as described above to give a mixture (81 mg, 54%) of **21**, **22**, and **23** (21 mg, 16%). The mixture was separated by HPLC as described above to give **21** (24 mg, 16%) and **22** (57 mg, 38%).

*15-Norsolavetivone (**5**).* Compound **21** (165 mg) was mixed with pyridine-modified alumina (0.5 g), prepared from neutral alumina (Woelm, activity grade I) and pyridine withstirring under reduced pressure (0.3 Torr) at room temperature for 6 h. The mixture was heated in a glass tube at 220°C (bath temperature) for 8 min under argon, cooled, poured into ether (100 ml) and triethylamine (15 ml), and stirred for 3 h. The mixture was filtrated through Celite, concentrated, and separated by chromatography over silica gel (10 g) with benzene to afford **5** (75 mg, 68% yield based on the recovered starting material), oil; MS, *m/z* 204 (M^+) and 162; IR, 3090, 1687, 1650, and 890 $^{-1}$; NMR, δ 1.01 (3H, d, J=6 Hz), 1.73 (3H, s), 4.70 (2H, s), 5.78 and 6.70 (each 1H, d, J=10 Hz). Found: *m/z* 204.1499. Calcd for $C_{14}H_{20}O$: M, 204.1502.

*3-t-Butyldimethylsiloxy-11-hydroxy-2-oxo-15-nor-$\Delta^{1(10)}$-solavetivanes (**24**)—(**27**).* i) To a solution of LDA (1.5 mmol), prepared from diisopropylamine (0.21 ml, 1.51 mmol) in THF (5 ml) and 1.5 M butyllithium (1.5 mmol) in hexane (1 ml), was added **21** (134 mg, 0.6 mmol) in THF (3 ml) and

HMPA (0.26 ml) at −78°C under nitrogen, and the mixture was stirred for 30 min. A solution of *t*-butyldimethylchlorosilane (226 mg, 1.5 mmol) in THF (1 ml) was added to the mixture, and the whole mixture was warmed to room temperature and stirred for an additional 1 h. The mixture was shaken with ether (20 ml) and water (0.5 ml), dried, and concentrated to give an oily residue (426 mg). On the other hand, a solution of perbenzoic acid (96 mg, 0.72 mmol) in dry hexane was stirred at 0°C for 20 min. To this solution was added a solution of the oily residue (426 mg) in hexane (5 ml) at −15 °C. The mixture was warmed to room temperature, stirred for 1.5 h, poured into 30 ml of saturated brine, and extracted with ethyl acetate (4×50 ml). The combined extracts were washed with 5% aq $NaHCO_3$ (2×20 ml), dried, and evaporated to leave an oily residue, which was separated by chromatography over silica gel (10 g) with benzene–ethyl acetate (15:1) to afford **24** (91.5 mg) and **25** (45 mg) in 51 and 25% yields (based on the consumed starting material), respectively. **24**, oil; MS, *m/z* 337 (M^+-15); IR, 3620, 3450, 1698, 1615, 1257, 1145, 867, and 840 cm^{-1}; NMR, δ 1.08 (3H, d, J=7 Hz), 1.24 (6H, s), 3.89 (1H, d, J=11 Hz), 5.78 and 6.80 (each 1H, d, J=10 Hz). Found: C, 68.32; H, 10.13%. Calcd for $C_{20}H_{36}O_3Si$: C, 68.13; H, 10.29%. **25**, oil; MS, *m/z* 337 (M^+-15); IR, 3500, 1700, and 1260 cm^{-1}; NMR, δ 0.99 (3H, d, J=6 Hz), 1.23 (6H, s), 4.40 (1H, d, J=6 Hz), 5.81 and 6.60 (each 1H, d, J=10 Hz). Found: C, 68.45; H, 10.11%. Calcd for $C_{20}H_{36}O_3Si$: C, 68.13; H, 10.29%.

ii) Siloxylation of **21** (122 mg) was carried out under the same conditions as descrived above to give **26** (97 mg, 50%), and **27** (50 mg, 26%). **26**, oil; MS, *m/z* 337 (M^+-15); IR, 3625, 3470, 1700, 1620, 1150, 870, and 840 m^{-1}; NMR, δ 1.09 (3H, d, J=7 Hz), 1.22 (6H, s), 3.90 (1H, d, J=11 Hz), 5.72 and 6.67 (each 1H, d, J=10 Hz). Found: C, 68.41; H, 10.11%. Calcd for $C_{20}H_{36}O_3Si$: C, 68.13; H, 10.29%. **27**, oil; MS, *m/z* 337 (M^+-15), IR, 3495, 1700, 1260, 1150, 880, and 840 cm^{-1}; NMR, δ 0.94 (3H, d, J=6 Hz), 1.23 (6H, s), 4.41 (1H, d, J=4 Hz), 5.81 and 6.62 (each 1H, d, J=10 Hz). Found: C, 68.35; H, 10.15%. Calcd for $C_{20}H_{36}O_3Si$: C, 68.13; H, 10.29%.

17) Compounds **19** and **20** should be designated as 2-(4-methoxy-5-methoxycarbonyl-7-*syn*-methyl-2-oxobicyclo-[2.2.2]octyl)ethyl acetate and 2-[3-(1-Hydroxy-4-methylethyl)-7-*anti*-methylbicyclo[2.2.2]oct-5-enyl]ethanol, respectively according to the IUPAC numbering rule. However, in this paper we used the same numbering for these compounds as that for 16 (C-1, carbon atom bearing the methoxyl group).

Total Synthesis of (±)-Lubimin and (±)-Oxylubimin. II. Transformation of (±)-15-Norsolavetivanes into (±)-Lubimin, (±)-Oxylubimin, and Related Compounds[1]

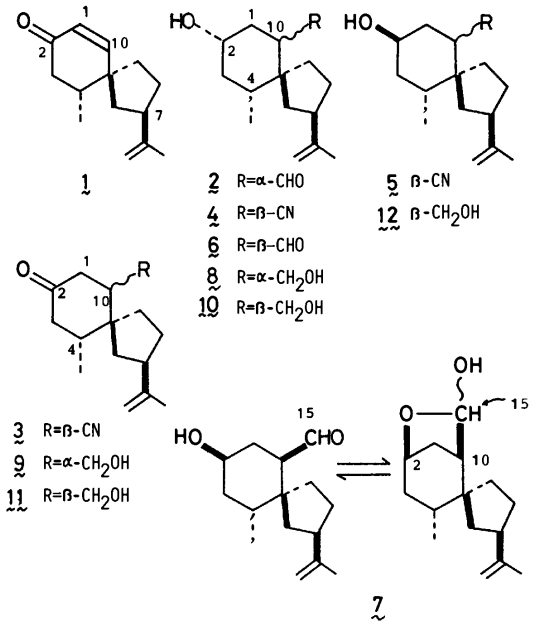
Akio MURAI,* Shingo SATO, and Tadashi MASAMUNE*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received February 6, 1984)

The transformation of (±)-15-norsolavetivone and related compounds, into (±)-lubimin and (±)-oxylubimin, which constitutes the total synthesis of these highly oxygenated spirovetivane phytoalexins, is described.

In the preceding paper we reported the synthesis of (±)-15-norsolavetivone and its oxygenated derivatives from orcinol dimethyl ether. Transformation of these compounds into the title natural compounds has recently been completed, and the result was published in a preliminary communication.[2] In the present paper details of the transformation are described.

Conversion of (±)-15-norsolavetivone (**1**) into (±)-lubimin (**2**) was commenced with hydrocyanation by a modification of Nagata's conditions.[3] The reaction proceeded regio- and stereo-selectively, giving 10-cyano-15-norsolavetiv-11-en-2-one (**3**) as the sole isolable product in 81% yield. The NMR spectrum of **3** [δ 2.61 (2H, d, J=6 Hz, 1-H) and 3.10 (1H, t, J=6 Hz, 10-H)] indicated that the cyano ketone (**3**) is a mixture of rapidly equilibrating conformers, and hence the 10-cyano and 4-methyl groups are oriented *trans* each other. Reduction of **3** with the ammonia-borane complex in aqueous mixture[4] afforded a 2:1 mixture of 2-*equatorial*- (**4**) and 2-*axial*-hydroxy-10-*axial*-cyano-15-norsolavetivenes (**5**), which were easily separated by chromatography in 60 and 30% yields, respectively. In accordance with the assigned structures, the compounds (**4**) and (**5**) exhibited the following NMR spectra: **4**, δ 2.74 (1H, t, J=4 Hz, 10-H) and 3.97 (1H, br m, W_H=25 Hz, 2-H); **5**, δ 2.77 (1H, t, J=4 Hz) and 3.92 (1H, br m, W_H=12 Hz). These nitriles (**4**) and (**5**), when treated with diisobutylaluminium hydride in ether, were converted into the corresponding aldehydes (**6**) and (**7**) in 93 and 74% yields, respectively. The latter (**7**) was isolated as a 1:3 inseparable mixture of the hydroxy aldehyde and its acetal, as revealed by the IR and NMR spectra: IR, 3630, 3450, 2730, and 1719 cm^{-1}; NMR, δ 4.02 (0.25H, m, W_H=10 Hz, 2-H), 4.33 (0.75H, m, W_H= 16 Hz, 2-H), 5.18 (0.75H, br s, 15-H), and 9.73 (0.25H, br s, W_H=6 Hz, 15-H). These compounds (**6**) and (**7**) were identified as (±)-10-epilubimin[5] and (±)-2-epi-10-epilubimin[6] by direct comparison of the synthetic and natural samples (MS, IR, NMR, and TLC). After repeated epimerization[5] of **6** with base, (±)-lubimin (**2**) was isolated in an overall yield of 2.1% from orcinol dimethyl ether. Since lubimin (**2**) has been transformed into lubiminol[5b,7] (**8**) and isolubimin[5b,7,8] (**9**), 10-epilubimin (**6**) into 10-epilubiminol[5] (**10**) and 10-epiisolubimin[5,6,9] (**11**), and 2-epi-10-epi-lubimin (**7**) into 2-epi-10-epilubiminol[5b,6] (**12**), respectively, the present transformation implies the synthesis of these natural spirovetivane stress metabolites.

The synthesis of (±)-oxylubimin (**13**) was performed in the same manner as that of (±)-lubimin (**2**), starting with the 3-*t*-butyldimethylsilyl ether (**14**) of



(3*SR*,4*RS*,7*SR*)-3,11-dihydroxy-15-norspirovetiv-1(10)-en-2-one, which had been prepared previously.[1,10] Hydrocyanation of **14** under the same conditions[3a] as that of 15-norsolavetivone (**1**) led only to regioselective formation of a mixture of the corresponding 10-*equatorial*- (**15**) and 10-*axial*-cyano-15 norsolavetivenes (**16**), which were separated easily by chromatogarphy in 44 and 32% yields, respectively. The NMR spectra of these compounds [**15**, δ 2.88 (1H, dd, J=12 and 4.5 Hz, 10-H) and 3.77 (1H, d, J=11 Hz, 3-H); **16**, δ 3.05 (1H, t, J=5 Hz) and 3.76 (1H, d, J=11 Hz)] supported the assigned configurations. Reduction of the cyano ketones (**15**) and (**16**) with the ammonia-borane complex[4] proceeded stereoselectively, in contrast with that of **3**, giving the corresponding 2-alcohols, which were converted into the respective 2,3-bis(*t*-butyldimethylsilyl) ethers (**17**) and (**18**) in 80 and 58% yields. The NMR spectra of these ethers [**17**, δ 2.58 (1H, dd, J=9 and 4 Hz, 10-H), 3.26 (1H, t, J=7 Hz, 3-H), and 3.50 (1H, m, W_H=20 Hz, 2-H); **18**, 3.10 (1H, dd, J=12 and 4 Hz), 3.52 (1H, t, J=4 Hz), and 3.72 (1H, m, W_H=12 Hz)] suggested that the A ring of **17** would probably take a deformed chair conformation with 2,3-diequatorial hydroxyl and 10-equatorial cyano groups, while **18** would adopt a slightly deformed one with 2,3-diaxial hydroxyl and 10-equatorial cyano groups owing to the bulkiness of the silyl groups. This assignment to the conformation was revealed clearly for the following compounds. Compounds **17** and **18**, when treated with

pyridine-modified alumina[10] at 220°C underwent dehydration to give the corresponding isopropenyl derivatives (**19**) and (**20**) in 74 and 75% yields, respectively. The NMR spectra [**19**, δ 2.48 (1H, dd, J=12 and 4 Hz, 10-H), 3.16 (1H, t, J=9 Hz, 3-H), and 3.44 (1H, m, W_H=20 Hz, 2-H); **20**, δ 3.05 (1H, dd, J=12 and 4 Hz), 3.50 (1H, t, J=4 Hz), and 3.69 (1H, m, W_H=14 Hz)] indicated that these compounds would be represented by conformations **19A** and **20A**. Removal of the silyl groups of **19** and **20** with hydrofluoric acid[12] afforded 10-*equatorial*- (**21**) and 10-*axial*-cyano-2,3-di-(*equatorial*-hydroxy)-15-norsolvetiv-11-enes (**22**) in 91 and 63% yields, respectively: **21**, δ 2.53 (1H, dd, J=12 and 4 Hz, 10-H), 2.97 (1H, t, J=11 Hz, 3-H), and 3.36 (1H, W_H=24 Hz); **22**, δ 2.66 (1H, t, J=4 Hz), 2.99 (1H, t, J=11 Hz), and 3.74 (1H, m, W_H=21 Hz). The compounds (**21**) and (**22**), when treated with diisobutylaluminium hydride in 1,2-dimethoxyethane, was converted into the corresponding aldehydes in 58 and 68% yields, which were identified as (±)-oxylubimin[12] (**13**) and (±)-10-epioxylubimin[12] (**23**), respectively, by direct comparison of the synthetic and natural samples. After repeated epimerization of **23**, the overall yield of (±)-oxylubimin amounted to 0.82% from orcinol dimethyl ether. The present result constitutes the first total synthesis of highly oxygenated spirovetivane phytoalexins.

Experimental

A general procedure was described in the preceding paper.[1]

10-Cyano-15-norsolavetiv-11-en-2-one (3). To a solution of **1** (68 mg) in tetrahydrofuran (THF) (2 ml) at 0°C was added a solution of hydrogen cyanide (HCN) and triethylaluminium (Et_3Al), prepared from Et_3Al in hexane (15% w/w, Tokyo-Kasei) (1.5 ml) and 0.91 M† HCN in THF (1.2 ml) at 0°C for 5 min under stirring. The mixture was warmed to room temperature and stirred for 4 h. The mixture was mixed with 2 M hydrochloric acid (HCl) (2 ml) at 0°C and stirred for 20 min, and poured into saturated brine (30 ml), and extracted with ethyl acetate (4×40 ml). The acetate extracts were washed with 2 M aq sodium hydroxide (NaOH) (2×20 ml) and saturated brine, dried, evaporated, and separated by chromatography over silica gel (5 g) with benzene to afford **3** (58 mg), oil; MS, m/z 231 (M^+); IR, 3090, 2210, 1722, 1648, and 890 cm^{-1}; NMR, δ 0.99 (3H, d, J=6 Hz), 1.76 (3H, s), 2.61 (2H, d, J=6 Hz), 3.10 (1H, t, J=6 Hz), and 4.75 (2H, s). Found: m/z 231.1594. Calcd for $C_{15}H_{21}NO$: M, 231.1621.

10-Cyano-15-norsolavetiv-11-en-2-ols (4) and (5). To a mixture of **3** (30 mg) in methanol (3 ml) and water (1.5 ml) was added the ammonia-borane complex (5 mg). The mixture was stirred at 20°C for 2 h, poured into 2 M HCl (1 ml), and stirred for 20 min. The mixture was extracted with ethyl acetate (4×30 ml), dried, evaporated, and separated by chromatography over silica gel (3 g) with benzene–ethyl acetate (8:1) to give 2α-alcohol (**4**) (18 mg) and 2β-alcohol (**5**) (9 mg). **4**, oil; MS, m/z 233 (M^+); IR, 3460, 3096, 2215, 1650, and 890 cm^{-1}; NMR, δ 0.96 (3H, d, J=6 Hz), 1.71 (3H, s), 2.74 (1H, t, J=4 Hz), 3.97 (1H, br m, W_H=25 Hz), 4.66 (2H, s). Found: m/z 233.1755. Calcd for $C_{15}H_{23}NO$: M, 233.1776. **5**, oil; MS, m/z 233 (M^+); IR, 3460, 3090, 2215, 1648, and 888 cm^{-1}; NMR, δ 0.95 (3H, d, J=6 Hz), 1.71 (3H, s), 2.77 (1H, t, J=4 Hz), 3.92 (1H, br m, W_H=12 Hz), and 4.67 (2H, s). Found: m/z 233.1820. Calcd for $C_{15}H_{23}NO$: M, 233.1776.

(±)-2-Epi-10-epilubimin (7) and (±)-10-Epilubimin (6). To a solution of **5** (5 mg) in ether (4 ml) at 0°C was added 1.7 M diisobutylaluminium hydride in hexane (0.14 ml), and the mixture was stirred for 4 h at the temperature. The reaction was quenched by saturated brine, and extracted with ethyl acetate (4×200 ml). The extracts were washed with 2 M HCl and saturated brine, dried, evaporated and separated by chromatography to give **7** (3.7 mg), oil; MS, m/z 236 (M^+); IR, 3630, 3450, 3090, 2730, 1719, 1649, 1036, 1000, and 895 cm^{-1}; NMR (CCl_4), δ 0.87 (3H, d, J=6 Hz), 1.71 (3H, s), 4.02 (0.25H, m, W_H=10 Hz), 4.33 (0.75H, m, W_H=16 Hz), 4.63 (2H, s), 5.18 (0.75H, s), and 9.73 (0.25H, m, W_H=8 Hz). Found: m/z 236.1785. Calcd for $C_{15}H_{24}O_2$: M, 236.1777. Natural; NMR (CCl_4), δ 0.88 (3H, d, J=6 Hz), 1.72 (3H, s), 4.02 (0.25H, m, W_H=10 Hz), 4.32 (0.75H, br m, W_H=16 Hz), 4.64 (2H, s), 5.20 (0.75H, s), and 9.74 (0.25H, m, W_H=8 Hz).

Reduction of **4** (7 mg) was carried out under the same conditions as described above to give **6** (6.5 mg), oil; MS, m/z 236 (M^+), 218, and 205; IR, 3630, 3450, 3090, 1715, 1648, 1115, 1090, and 895 cm^{-1}; NMR, δ 0.95 (3H, d, J=7 Hz), 1.73 (3H, s), 3.72 (1H, m, W_H=24 Hz), 4.69 (2H, s), and 9.85 (1H, s). Found: m/z 236.1758. Calcd for $C_{15}H_{24}O_2$: M, 236.1777. Natural; NMR, δ 0.95 (3H, d, J=7 Hz), 1.73 (3H, s), 3.71 (1H, m, W_H=25 Hz), 4.69 (2H, s), and 9.85 (1H, s).

10-Cyano-3,10-dihydroxy-15-norsolavetiv-2-one 3-t-butyldimethylsilyl Ethers (15) and (16). To a solution of **14** (40 mg, 0.11 mmol) in THF (1 ml) at 0°C under nitrogen was added a solution of Et_3Al–HCN in THF, prepared from Et_3Al (0.55 mmol) in hexane (10% w/w) (0.55 ml) and 1.3 M

† 1 M=1 mol dm^{-3}.

HCN (0.33 mmol) in THF (0.25 ml) at 0°C for 5 min, and the mixture was stirred for 14 h at room temperature. The reaction mixture was poured into 2 M HCl (20 ml), and extracted with ethyl acetate (4×30 ml). The extracts were washed with 2 M aqueous NaOH (2×20 ml) and saturated brine (20 ml), dried, evaporated, and separated by chromatography over silica gel (4 g) with benzene–ethyl acetate (10:1) to give **15** (19 mg) and **16** (14 mg), respectively. **15**, mp 110—112°C (from hexane–diisopropyl ether) (1:1); MS, *m/z* 364 (M^+-15); IR, 3625, 3480, 2220, 1735, 1145, 865, and 840 cm^{-1}; NMR, δ 1.12 (3H, d, J=6 Hz), 1.23 (6H, s), 2.72 (1H, t, J=12 Hz), 2.75 (1H, dd, J=12 and 4.5 Hz), 2.88 (1H, dd, J=12 and 4.5 Hz), 3.77 (1H, d, J=11 Hz). Found: C, 66.57; H, 9.81; N, 3.91%. Calcd for $C_{21}H_{37}O_3NSi$: C, 66.44; H, 9.82; N, 3.69%. **16**, mp 132.5—133.5°C (from diisopropyl ether); MS, *m/z* 379 (M^+); IR, 3620, 3480, 2210, 1753, 1135, 860, and 840 cm^{-1}; NMR, δ 1.10 (3H, d, J=6 Hz), 1.23 (6H, s), 2.69 (2H, d, J=5 Hz), 3.05 (1H, t, J=5 Hz), and 3.76 (1H, d, J=11 Hz). Found: C, 66.16; H, 9.80; N, 3.84%. Calcd for $C_{21}H_{37}O_3NSi$: C, 66.44; H, 9.82; N, 3.69%.

(2SR,3SR,4RS,7SR,10RS)-10-Cyano-15-norsolavetivane-2,3,10-triol 2,3-Bis(t-butyldimethylsilyl) ether (17) and its 10-Epimer (18). i) A mixture of **15** (149 mg) and the ammonia–borone complex (14 mg) in methanol (6 ml) and water (3 ml) was stirred at room temperature for 2 h under nitrogen. To the mixture was added 2 M HCl (4 ml), and the whole mixture was concentrated *in vacuo*. The residue was extracted with ethyl acetate (4×30 ml), and the extracts were washed with 2 M HCl (1×20 ml) and saturated brine (20 ml), dried, and evaporated. The residue was separated by chromatography over silica gel (10 g) with benzene–ethyl acetate (2:1) to give triol (120 mg), mp 139—140°C (from hexane–ether, 1:1); MS, *m/z* 366 (M^+-15), and 348; IR, 3625, 3445, 2205, 1475, 1257, 1100, 1060, and 840 cm^{-1}; NMR, δ 1.00 (3H, d, J=6 Hz), 1.21 (6H, s), 2.53 (1H, dd, J=12 and 4 Hz), 3.01 (1H, t, J=11 Hz), and 3.34 (1H, br m, W_H=22 Hz).

A mixture of the triol (61 mg), *t*-butyldimethylchlorosilane (96 mg), and imidazole (86 mg) in *N,N*-dimethylformamide (0.6 ml) was heated at 50°C under argon for 48 h. The reaction mixture was poured into saturated brine (20 ml), and extracted with ethyl acetate (4×40 ml). The combined extracts were washed with saturated brine, dried, evaporated, and separated by chromatography over silica gel (8 g) with benzene–ethyl acetate (15:1) to give **17** (70 mg), mp 129—130°C (from diisopropyl ether); MS, *m/z* 480 (M^+-15); IR, 3630, 3460, 2215, 1120, and 840 cm^{-1}; NMR, δ 1.10 (3H, d, J=6 Hz), 1.20 (6H, s), 2.58 (1H, dd, J=9 and 4 Hz), 3.26 (1H, t, J=7 Hz), and 3.50 (1H, m, W_H=20 Hz). Found: C, 65.73; H, 10.63; N, 2.62%. Calcd for $C_{27}H_{35}O_3NSi_2$: C, 65.40; H, 10.77; N, 2.82%.

ii) Reduction of **16** (136 mg) under the same conditions as described above afforded the epimeric triol (101 mg), mp 181—182°C (from ethyl acetate); MS, *m/z* 366 (M^+-15); IR, 3630, 3460, 2210, 1480, 1265, 1100, and 842 cm^{-1}; NMR, δ 0.98 (3H, d, J=6 Hz), 1.19 (6H, s), 2.69 (1H, t, J=4 Hz), 3.04 (1H, t, J=11 Hz), and 3.72 (1H, m, W_H=22 Hz).

Silylation of the triol (70 mg) was carried out under the same conditions as described above to give **18** (71 mg), mp 85—87°C (from hexane); MS, *m/z* 480 (M^+-15); IR, 3620, 3500, 2220, 1090, 870, and 840 cm^{-1}; NMR, δ 1.02 (3H, d, J=7.5 Hz), 1.21 (6H, s), 3.10 (1H, dd, J=12 and 4 Hz), 3.52 (1H, t, J=4 Hz), and 3.72 (1H, m, W_H=12 Hz). Found C, 65.73; H, 10.46; N, 2.70%. Calcd for $C_{27}H_{53}O_3NSi_2$: C, 65.40; H, 10.77; N, 2.82%.

(2SR,3SR,4RS,7SR,10RS)-10-Cyano-15-norsolavetiv-11-ene-2,3-diol 2,3-Bis(t-butyldimethylsilyl) ether (19) and its 10-Epimer (20). i) A suspension of **17** (41 mg) and pyridine-modified alumina (0.25 g) in 1,3,5-triisopropylbenzene (0.3 ml) was heated at 220°C under argon for 30 min. The mixture was dissolved in ether (40 ml) and triethylamine (5 ml), stirred at room temperature under nitrogen for 5 h, and filtered through Celite. The filtrate was concentrated, and purified by chromatography over silica gel (7 g) with hexane–benzene (1:5) to give **19** (23.5 mg) (74% based on the consumed starting material), amorphous; MS, *m/z* 462 (M^+-15); IR, 3090, 2210, 1648, 1263, 1120, 890, and 840 cm^{-1}; NMR, δ 1.05 (3H, d, J=6 Hz), 1.72 (3H, s), 2.48 (1H, dd, J=12 and 4 Hz), 3.16 (1H, t, J=9 Hz), 3.44 (1H, m, W_H=20 Hz) and 4.68 (2H, s).

ii) Dehydration of **18** (57 mg) was carried out under the same conditions as described above to give **20** (32 mg) (75% based on the recovered starting material), amorphous; MS, *m/z* 477 (M^+); IR, 3085, 2215, 1650, 1270, 1095, 1015, 870, and 840 cm^{-1}; NMR, δ 1.01 (3H, d, J=6 Hz), 1.72 (3H, s), 3.05 (1H, dd, J=12 and 4 Hz), 3.50 (1H, t, J=4 Hz), 3.69 (1H, m, W_H=14 Hz), and 4.66 (1H, br s, W_H=7 Hz).

(2SR,3SR,4RS,7SR,10RS)-10-Cyano-15-norsolavetiv-11-ene-2,3-diol (21) and its 10-Epimer (22). i) A mixture of **19** (19 mg) and 46% hydrofluoric acid (0.35 ml) in THF (0.6 ml) and acetonitrile (0.3 ml) was stirred at room temperature for 6 h. Triethylamine (0.5 ml) was then added to the reaction mixture. The whole mixture was concentrated, and purified by chromatography over silica gel (2 g) with benzene–ethyl acetate (1:1) to give **21** (9 mg), mp 159—160°C (from ether); MS, *m/z* 249 (M^+); IR, 3600, 3450, 3080, 2215, 1646, and 895 cm^{-1}; NMR, δ 1.07 (3H, d, J=6 Hz), 1.74 (3H, s), 2.53 (1H, dd, J=12 and 4 Hz), 2.97 (1H, t, J=11 Hz), 3.36 (1H, m, W_H=24 Hz), and 4.72 (2H, s). Found: C, 72.51; H, 9.19; N, 5.50%. Calcd for $C_{15}H_{23}O_2N$: C, 72.25; H, 9.30; N, 5.61%.

ii) Desilylation of **20** (31 mg) was carried out under the same conditions as described above to give **21** (10 mg), mp 102—103°C (from ether); MS, *m/z* 249 (M^+); IR, 3600, 3450, 3090, 2220, 1650, and 895 cm^{-1}; NMR, δ 1.07 (3H, d, J=6 Hz), 1.72 (3H, s), 2.66 (1H, t, J=4 Hz), 2.99 (1H, t, J=11 Hz), 3.74 (1H, m, W_H=21 Hz), and 4.70 (2H, s). Found: C, 72.53; H, 9.20; N, 5.43%. Calcd for $C_{15}H_{23}O_2N$: C, 72.25; H, 9.30; N, 5.61%.

(±)-Oxylubimin (13). To a solution of **21** (8.5 mg) in 1,2-dimethoxyethane (1 ml) was added 1.7 M diisobutylaluminium hydride in hexane (0.4 ml) at room temperature. The mixture was stirred for 12 h, mixed with 2 M HCl (2 ml) at 0°C, poured into saturated brine (10 ml), and extracted with ethyl acetate (4×30 ml). The combined acetate extracts were washed with 5% aqueous sodium hydrogencarbonate (10 ml), and saturated brine, dried, concentrated, and separated by chromatography over silica gel (2 g) with benzene–ethyl acetate (2:1) to give **13** (5 mg), mp 79—81°C (from diisopropyl ether); MS, *m/z* 252 (M^+) and 234; IR, 3600, 3440, 3080, 2725, 1720, 1645, and 894 cm^{-1}; NMR, δ 1.05 (3H, d, J=6 Hz), 1.68 (3H, s), 3.00 (1H, t, J=9 Hz), 3.42 (1H, m, W_H=22 Hz), 4.65 (2H, s), and 10.00 (1H, d, J=2 Hz). Found: C, 71.54; H, 9.67%. Calcd for $C_{15}H_{24}O_3$: C, 71.39; H, 9.59%. Natural, mp 85—86°C (from diisopropyl ether); IR, 3600, 3440, 3080, 2727, 1720, 1646, and 894 cm^{-1}; NMR, δ 1.05 (3H, d, J=6 Hz), 1.69 (3H, s), 3.00 (1H, t, J=9 Hz), 3.43 (1H, m, W_H=23 Hz), 4.66 (2H, s), and 10.02 (1H, d, J=2 Hz).

(±)-10-Epioxylubimin (23). Reduction of **22** (9.5 mg) was carried out under the same conditions as described above to give **23** (6.5 mg), mp 121—123°C (from diisopropyl ether); MS, *m/z* 252 (M^+) and 234; IR, 3600, 3445, 3085, 2730, 1720, 1648, and 897 cm^{-1}; NMR, δ 1.05 (3H, d, J=6 Hz), 1.70 (3H, s), 3.03 (1H, t, J=9 Hz), 3.40 (1H, m, W_H=20 Hz), 4.66 (2H, s), and 10.04 (1H, s). Found: C, 71.27; H, 9.65%. Calcd for $C_{15}H_{24}O_3$: C, 71.39; H, 9.59%. Natural, mp 123—124°C (from diisopropyl ether); IR, 3600, 3445, 3085, 2730, 1719, 1647, and 895 cm^{-1}; NMR, δ 1.06 (3H, d, J=6 Hz), 1.71 (3H, s), 3.02 (1H, t, J=9 Hz), 3.41 (1H, m, W_H=20 Hz), 4.66 (2H, s), and 10.04 (1H, s).

Kinetics and Mechanism of Dissociation of (Acetylacetonato)[*N*-(*o*-carboxyphenyl)iminodiacetato]chromate(III) Ion in Acidic Media

Chinmay CHATTERJEE* and Aya Singh BALI

Chemistry Department, Indian Institute of Technology, Powai Bombay 400076, India

(Received Junuary 20, 1983)

Acid-catalyzed dissociation of (acetylacetonato) [*N*-(*o*-carboxyphenyl) iminodiacetato]chromate(III) ion has been studied kinetically in aqueous perchloric acid media over a temperature range (60—80 °C). Under these conditions the reaction occurs by two concurrent paths according to the following rate law: Rate= k_1[complex]+k_2[complex][H$^+$], where k_1 and k_2 are the appropriate rate constants for the spontaneous and acid-catalyzed pathways, respectively Analysis of the rate data corresponding to the rate constants k_1 and k_2 suggests solvent assisted dissociation of the complex and its conjugate acid for the two paths, respectively, and that the opening of the chelate ring is rate determining.

The amino carboxylate ligands have donor groups similar to the more common amino acid residues. Hence the ligand substitution at chromium(III) in amino carboxylate environments have considerable physiological significance. Ogino[1] and Sykes[2] have suggested that the addition of a free $-CH_2COOH$, $-CH_2COO^-$, or $-CH_2CH_2OH$ in an associative intramolecular step is responsible for the kinetic lability of [CrY(H_2O)]^n complexes towards the addition of unidentate X^- donor. Guardalabene *et al.*[3] reported similar pendant group assistance for the acid-catalyzed aquation of the 2,4-pentanedionato chelate ligand ($acac^-$) from [Cr(hedta) (acac)]$^-$ (hedta: hydrogenethylenediamine-*N,N,N',N'*-tetraacetate) whereas the acid-catalyzed aquation of [Cr(edda)(acac)] (edda: ethylenediamine *N,N*-diacetate) exhibited normal reactivity. In contrast to the extensive study of the acid-catalyzed dissociation of octahedral chromium(III) carboxylato chelates[4-7], limited data exist for the corresponding β-diketonato[3,8,9] complexes. It is well known[10] that metal acetylacetone ring possesses quasi-aromatic character which in turn reflects their exceptional stability and relative inertness. A mixed ligand octahedral complex of chromium(III) with carboxymethyl derivative of anthranilic acid (*N*-(*o*-carboxyphenyl)iminodiacetic acid, H_3 atda) as aromatic amino acid and acetylacetone has been described in the literature.[11] The kinetic studies of dissociation of the title complex appeared to be worthy of investigation for the following reasons:

(a) In order to examine the relative reactivity of aromatic amino acid and acetylacetone as coordinating ligand towards acid solution.

(b) Comparison of kinetic data of $acac^-$ release from Cr(tetradentateaminopolycarboxylate)$(acac)^-$ type complexes with and without pendant group.

Experimental

Materials and Reagents. Diaqua[*N*-(*o*-carboxyphenyl) iminodiacetato]chormium(III) trihydrate, Cr(atda) $(H_2O)_2\cdot 3H_2O$ and potassium (acetylacetonato)[*N*-(*o*-carboxyphenyl) iminodiacetato]chromate(III), K[Cr(atda)(acac)] were prepared following the method described in the literature.[11] The purity of the sample was checked by elemental analysis.

Found: C, 33.80; N, 3.52; H, 4.67%. Calcd for [Cr $(C_{11}H_8NO_6)(H_2O)_2]\cdot 3H_2O$: C, 33,67; N, 3,57; H. 4.59%. Found: C, 43.70; N, 3.12; H, 3.43%. Calcd for K $[Cr(C_{11}H_8NO_6)(C_5H_7O_2)]$: C, 43.64; N, 3.18; H, 3.41%. The positions and intensities of the d-d bands corresponding to $^4A_{2g}\rightarrow{}^4T_{2g}$ and $^4A_{2g}\rightarrow{}^4T_{1g}$ transitions in a pseudo-octahedral ligand field for both the complexes matched very well with the reported data.[11] Other chemicals used were of reagent grade purity or prepared in the pure state by suitable methods. Sodium perchlorate was used to adjust the ionic strength of the medium.

Kinetic Measurements. The aquation rates were monitored spectrophotometrically using a Varian Superscan 3 and a Toshniwal UV-visible spectrophotometer. Spectral examination of the experimental solutions revealed that under the conditions of acidity employed for the study the metal acetylacetone bond was found to undergo dissociation in preference to aromatic amino acid, atda, leading to diaqua product, [Cr(atda)$(H_2O)_2$]. The enhanced kinetic stability exhibited by aromatic amino acid can be ascribed to the effect of presence of more number of chelate rings in ligated amino acid in comparison to only one six membered (acetylacetonato) metal ring. The course of the aquation reaction in dilute perchloric acid (0.02—0.2 mol dm^{-3}) at an ionic strength 1.0 mol dm^{-3} was followed by observing the decrease in absorbance at 400 nm, where the absorbances of the reacting complex and the product differ appreciably. To follow the reaction a solution containing requisite quantities of perchloric acid and sodium perchlorate (for adjustment of ionic strength to 1.0 mol dm^{-3}) was thermostatted at the experimental temperature. After attainment of thermal equilibrium, the requisite quantity of the complex, K[Cr(atda)(acac)], was added and the solution was thoroughly mixed and diluted to a definite volume with water thermostatted at the experimental temperature. An aliquot was immediately withdrawn from this reaction mixture using a pipette jacketed with ice to quench the reaction and its absorbance was measured at 400 nm. This was repeated at subsequent time intervals. The experimental conditions were so chosen that pseudo-first order rate law was applicable and plots of log $(A_0-A_\infty)/(A_t-A_\infty)$ *versus* time (t) were linear for at least three to four half-lives and passing through the origin with $A_t=A_\infty$ at $10t_{1/2}$. The preliminary spectral observation of the reacting solutions after digesting for at least ten half-lives agreed well with spectra of the corresponding diaqua product, [Cr(atda)$(H_2O)_2$], indicating the absence of any complication due to reverse anation reaction of aqua complex.

Results and Discussions

Values of k_{obsd} (the first order rate constants) were determined at 50.0±0.1, 60.0±0.1, 70.0±0.1, and

TABLE 1. KINETIC PARAMETERS FOR AQUATION OF (ACETYLACETONATO)[*N*(*o*-CARBOXYPHENYL)-IMINODIACETATO]CHROMATE(III) ION (μ=1.0 mol dm^{-3})

(μ=0.1 mol dm^{-3})		
70.0±0.1	7.98±0.28	8.15±0.43

80.0±0.1 °C, for acid concentration 0.02—0.2 mol dm^{-3} at an ionic strength 1.0 mol dm^{-3} and have been found to vary with acid concentration in a manner which suggests that the dissociation of the title complex proceeds in accordance with the following rate law:

$$\text{Rate} = k_1[\text{complex}] + k_2[\text{complex}][H^+], \quad (1)$$

where k_1 stands for the first order rate constant for the uncatalyzed and k_2, second order rate constant describing the acid-catalyzed pathways, respectively. Using least squares method k_1 and k_2 values at different temperatures have been determined from the linear plot of k_{obsd} *versus* acid concentration (Fig. 1) and are listed in Table 1 along with the activation parameters ΔH^* and ΔS^* values evaluated using the Eyring equation. Sequence of changes consistent with the kinetic results are depicted below:

$$[Cr(atda)(acac)]^- + H_2O \xrightarrow[\text{slow}]{k_1} [Cr(atda)(-acac)(H_2O)]^-$$

$$[Cr(atda)(-acac)(H_2O)]^- \xrightarrow{+H_2O,\ \text{rapid}} [Cr(atda)(H_2O)_2] + acac^-$$

$$acac^- + H^+ \xrightarrow{\text{fast}} acacH$$

$$[Cr(atda)(acac)]^+ + H^+ \overset{K}{\rightleftharpoons} [Cr(atda)(acacH^+)]^- \quad \text{(conjugate acid)}$$

$$[Cr(atda)(acacH^+)]^- \xrightarrow[+H_2O]{k_2'} [Cr(atda)(-acacH)(H_2O)]$$

$$[Cr(atda)(-acacH)(H_2O)] \xrightarrow{+H_2O,\ \text{rapid}} [Cr(atda)(H_2O)_2] + acacH,$$

where -acac and -acacH stand for the ligand and its protonated form, respectively, functioning as monodentate ligand. The catalytic rate constant k_2 is related to k_2' and K by the relation

$$k_2 = \frac{Kk_2'}{1+K[H^+]}, \quad (2)$$

under the present experimental conditions $K[H^+] \ll 1$ as evident from the linearity of the plot of k_{obsd} *versus* $[H^+]$ even at highest perchloric acid concentration. Hence Eq. 2 reduces to $k_2 = K k_2'$. The activation parameters corresponding to k_2 thus involve both rate constants and equilibrium constants. Guardalabene *et al.*[3] studied the acid-catalyzed aquation of Hacac from [Cr(hedta)(acac)]$^-$ and [Cr(edda)(acac)] complexes. An accelerated rate of about 10^3 relative to [Cr(acac)$_3$] is observed for [Cr(hedta)(acac)]$^-$ complex whereas normal behaviour is found for [Cr(edda)(acac)] system. The pendant group effect for labilizing the release of acetylacetone has been proposed to account for the 10^3 enhancement. In both the cases rupture of Cr–O bond has been proposed to take place in the transition state similar to what has been suggested for the [Cr(acac)$_3$] system.[8] Since the present system under investigation does not possess any pendant carboxylato group, as a result no intramolecular assistance is observed. Similarity in reactivity of the present system with those of [Cr(acac)$_3$] and [Cr(edda)(acac)] thus substantiates the influence of pendant group in enhancement of rate.

The magnitude and sign of the activation parameters corresponding to uncatalyzed and acid-catalyzed paths in the present system is found to be comparable with those reported for [Cr(acac)$_3$]. It is thus logical to conclude that the reactions corresponding to rate constants k_1 and k_2 respectively in the present system proceed by mechanisms identical to those operative in the [Cr(acac)$_3$] system where acid independent step is suggested to involves a simple dissociation of [Cr (atda) (acac)]$^-$ complex, while the acid-catalyzed path involve a dissociation of the conjugate acid formed by protonation in a rapid pre-equilibrium step. Both rate-determining dissociations for uncatalyzed and acid-catalyzed paths in the present system thus involve a one-ended dissociation of a acetylacetonato chelate ring with the simultaneous entry of a molecule of water into the coordination sphere of chromium(III), followed by the rupture of a second Cr–O bond of the unidentate functioning acetylacetone ligand in a much faster process with a simultaneous entry of another molecule of water leading to [Cr(atda) (H$_2$O)$_2$] product. Structural,[12] spectral,[13] and chemical evidence[14] suggests that orbitals of π symmetry are involved in extensive electron delocalization and pseudoaromaticity, within the planar six-membered chelate ring of metal acetylacetonato complex. This special bonding is reflected in its relative kinetic inertness. Cleavage of one of the metal–acetylacetone bond of the chelate ring would destroy the π conjugation thus facilitating the rupture of the second metal–O bond as suggested in the above scheme. The magnitude of the rate constant corresponding to acid-catalyzed path, k_2', can be estimated in the following manner. Linearity of the plots in Fig. 1 indicates $1 \gg K[H^+]$ at $[H^+]=0.2$ mol dm^{-3}, leading to $K \ll 5$. Thus the value of k_2' is greater than 3.5×10^{-5} s^{-1} at 50.0 °C. In conformity with the proposed scheme, the rate constant corresponding to acid-catalyzed path is observed to be much higher than that of uncatalyzed process (Table 1). This can be ascribed to the fact that the acid-catalyzed path is suggested to involve the protonation of the chelated acetylacetone ligand thereby putting a formal positive charge on ligand oxygen atom .As

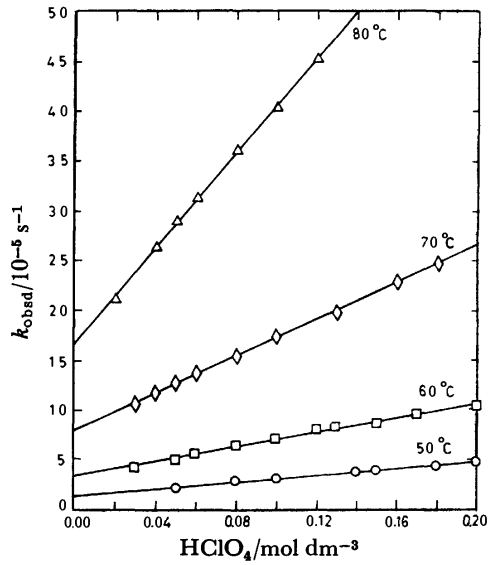

Fig. 1. Effect of acid concentration on k_{obsd} at different temperatures (Complex, 0.002 mol dm^{-3}; μ, 1.0 mol dm^{-3}).

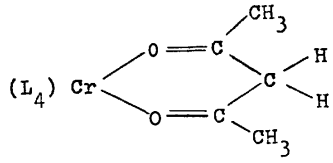
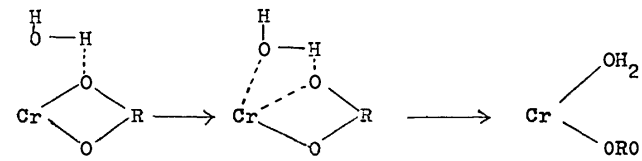
a consequence of strong bonding between oxygen atom of the acetylacetone and H^+ ion in the protonated from of the complex (conjugate acid) further weakens the Cr–O bond and thus accounting for a greater lability for the fission of the bond as is indicated by the higher rate for the acid-catalyzed path. A similar trend has been observed in other acetylacetonato complexes of chromium(III).[4,8,9] Alternative pathways for acid catalysis may involve the association of the scavenging proton at the central carbon of the leaving Hacac giving rise to the following structure:



However, the above alternative scheme would leave keto groups as ligands which seems to be less probable.[15] In absence of conclusive evidence the alternative scheme cannot be excluded unambigously. The activation enthalpies corresponding to acid-catalyzed paths for [Cr(acac)$_3$], and [Cr (atda) (acac)]$^-$ are 20.2 kcal mol^{-1} and 19.2 kcal mol^{-1}, respectively. Comparable activation enthalpies clearly suggests that the total cost of bond adjustments is similar in two paths for Cr–O bond rupture. Similarity in activation parameters, ΔH^* and ΔS^* values (Table 1) for spontaneous and acid-catalyzed path seem to suggest that same type of mechanism is operative in the transition state for both the processes. As in the case of [Cr(acac)$_3$] system,[8] the entropy of activation corresponding to k_1 and k_2 in the present system has been found to be highly negative. The high negative ΔS^* values for k_1 and k_2 are compatible with processes in which participation of a molecule of water hydrogen bonded to ligand in the rate-determining step is important,[16] suggesting an assisted dissociative mechanism as depicted below, which also accounts for the low ΔH^* values:



(Transition state)

where ORO stands for acac or acacH as the case may be. As in the case of [Cr(acac)$_3$] system, the entropy of activation, ΔS^* corresponding to uncatalyzed path for the present system is observed to be more negative than that of acid-catalyzed path. The relatively less negative value of ΔS^* for the H^+ dependent path is evidently due to the highly negative ΔS^* term for the dissociation of the chromium(III)–ligand bond being partly compensated by the positive ΔS^* term (also contributing to the overall ΔS^* for k_2) expected for the protonation pre-equilibrium, since this will lead to release of water molecules from the solvation spheres of aqueous H^+ ion. The effect of ionic strength on the rate of aquation has been studied and the values of k_1 and k_2 evaluated from a plot of k_{obsd} *vs.* [$HClO_4$] are presented in Table 1. Table 1 reveals that under otherwise identical conditions the uncatalyzed rate constant remained unaffected by the variation of ionic strength of the medium in accordance with the proposed mechanism. In contrast to the expected trend the value of k_2 is found to decrease slightly with decrease in ionic strength of the medium the reason of which is not clear at the present moment.

A Study on Some Simple and Mixed Ligand *N,N*-Disubstituted Dithiocarbamates of Thallium(III)

G. Soundararajan and M. Subbaiyan*

Department of Analytical Chemistry, University of Madras, A. C. College Campus, Guindy, Madras 600025, Tamil 1 Nadu, India

(Received September 9, 1982)

Neutral tris (*N,N*-disubstituted dithiocarbamato) thallium (III) ((Tl(III)) has been prepared from acyclic dimethylamine, diethylamine, dipropylamine, dibutylamine, *N*-methylaniline, dibenzylamine, and from piperidine. Mixed ligand dithiocarbamates were found to form by ligand exchange reactions while mixing the simple, symmetric chelates in nonpolar solvents and got separated on preparative TLC layers of silica gel. These chelates were characterised by elemental analyses, IR, ^{1}H NMR, and electronic spectral studies.

Ligand exchange reaction and the formation of corresponding mixed ligand complexes have been reported by some authors for neutral *N,N*-disubstituted dithiocarbamates of some transition elements.[1-4] HPLC[1] and ^{1}H NMR[5] studies have shown that the rate of ligand exchange among the bis-chelates with square planar structure (with vacant axial positions) is faster than in tris-chelates with octahedral structure. The ligand exchange among neutral non-transition metal dithiocarbamates has so far not been studied in detail except the report of Stary and Ruzicka[6] about the formation of dithiocarbamate–dithizone mixed ligand complexes in solution for some Group V-a metalloids. It is also found that works dealing with tris(*N,N*-disubstituted dithiocarbamato)thallium(III) complexes are rare[7] than those of thallium(I) dithiocarbamates. Though Usatenko and Kucenko[8] speak of the relative instability of thallium(III) dithiocarbamates, solvent extraction studies[9] provide them with greater extraction and formation constants. Literature survey revealed that dimethyl and diethyl dithiocarbamates[10-13] of thallium(III) alone have been studied in some detail.

This work reports the preparation and characterisation of some simple symmetric tris (dithiocarbamate)s of thallium(III) from dipropylamine, dibutylamine, dibenzylamine, *N*-methylaniline, and piperidine. This also reports the formation of mixed ligand dithiocarbamates of thallium(III) from symmetric chelates in nonpolar solvents, their separation on preparative TLC layers and characterization.

Experimental

Sodium salts of the *N,N*-disubstituted dithiocarbamic acids were prepared from dimethylamine, diethylamine (BDH samples), dipropylamine (Fluka AG), dibutylamine (Merck-Schuchardt), *N*-methylaniline (BDH), dibenzylamine (KL), and from piperidine (Riedel) following the standard procedure.[7] At 0—5°C, amine, carbon disulfide (both in dioxane) and sodium hydroxide in minimum quantity of water were mixed in equimolar proportions with constant mechanical stirring. The sodium salts formed as white solids were separated by filtration and recrystallized from 2-propanol. Good yields were obtained in dioxane medium than in acetone (reported recently[14] while this work was in progress).

Thallium(III) tris (dithiocarbamate)s were prepared by mixing the metal ion (Tl(III) prepared from Tl(I) as reported[15]) and sodium salt of the ligand in aqueous solutions in 1:3 molar ratio. The yellowish orange solids precipitated were repeatedly washed with water, dried and recrystallized from chloroform.

Preparation of Mixed Ligand Complexes

20 mM (1M=1 mol dm^{-3}) of a thallium(III) dithiocarbamate (which is to be present in greater proportions) in 40 ml benzene was mixed with 10 mM (in 20 ml benzene) of another thallium(III) dithiocarbamate with different *N*-alkyl substituents and stirred well magnetically for 30 min at room temperature (29 °C). Mixed ligand chelates were formed in solution by the ligand exchange reaction among the symmetric chelates, and the following equilibrium was established.

$$2Tl(S_2CNR_2)_3 + Tl(S_2CNR_2')_3 \rightleftharpoons 3Tl(S_2CNR_2)_2(S_2CNR_2').$$

The resulting solution was concentrated under low pressure (0.1 Torr, 1 Torr≈133.322 Pa), spotted on preparative TLC plates (50 to 60 μl of solution per spot) and developed with xylene as the mobile phase. After development, the TLC layers corresponding to the mixed ligand complexes were scrapped off, extracted with minimum quantity of xylene or CCl_4 under inert atmosphere and the solvent was removed in a vacuum evaporator to get the shiny orange crystals of mixed ligand complexes.

Molecular weights were determined cryoscopically in benzene. Elemental analyses (C and H) were performed with a Perkin-Elmer (model 240 B) analyzer. Nitrogen was estimarted by micro Kjeldahl method and sulfur by gravimetry as $BaSO_4$. Electronic spectra were obtained with a Beckmann (Model 25)-UV-visible spectrophotometer in CCl_4. IR spectra were recorded with a Perkin-Elmer (model 199) spectrometer scanning the region 4000 to 200 cm^{-1} in KBr pellets. ^{1}H NMR spectra were recorded on a Varian 60 MHz instrument in CCl_4 ($CDCl_3$ in some cases) with TMS as the internal standard. Photodensitometric studies were made with Carl Zeiss, Jena (GDR) instrument and the spot areas were measured with an Angler Planimeter. Silica gel supplied by BDH were employed for preparing thin layers. All chemicals employed in this study were of analytical grade.

Results and Discussion

Dithiocarbamates of thallium(III) ion derived from dipropylamine, dibutylamine, *N*-methylaniline, dibenzylamine, and piperidine are reported for the first time. The results of the elemental analyses presented in Table 1 are in accordance with their tris-chelate chemical compositions. In solid state, these chelates are stable indefinitely, if stored in dark. However in solutions of nonpolar solvents like benzene, chloroform, *etc.*, they decompose after a week. Molecular weight determination showed the presence of monomeric species in solution. Conductivity measurements in nitrobenzene showed their neutral, nonionic character.

On mixing the individual symmetric dithiocarbamates in nonpolar solvents, the unsymmetric mixed ligand complexes are formed and equilibrium is established.

$$2TlL_3 + TlL_3' \rightleftharpoons 3TlL_2L'$$

Photodensitometric studies at 420 nm of the resolved spots on thin layers (spotting known quantities of the stirred mixture)corresponded to about 60 to 65% conversion of symmetric chelates into ternary unsymmetric chelates. The log K values for the formation of these mixed ligand complexes (K=equilibrium constant=$([TlL_2L']^3/[TlL_3]^2[TlL_3'])$ arrived at from the equilibrium concentrations are around 1.36 to 1.45. (compound F=1.36, G=1.44, H=1.41, and I=1.38). The greater log K values observed relative to the statistical value of 0.83 show the stabilization of mixed ligand complexes by solvation or entropy effects. The total area of the spots of symmetric and unsymmetric chelates on the chromatogram is almost equal with the sum of the areas of two spots of the symmetric chelates, spotted separately. The mixed ligand chelates of Tl(III) are found not so labile as other transition metal chelates reported earlier[1-3,16] facilitating their separation on preparative TLC layers. However, the pale yellow streaks observed, with active, nonpolar solvents like chloroform, dichloro methane, *etc.*, as mobile phases indicate their partial disintegration into symmetric complexes. It is also found that with increase in

solvent phase polarity, the disintegration is accelerated, *i. e.*, in the order.

xylene<toluene<benzene<chloroform<dichloromethane.....

The formation of diagonally arranged spots on two dimensional TLC plates, as reported earlier,[1] with moderately polar mobile phases containing $CHCl_3$ or CH_2Cl_2 also support their instability in polar solvents.

Since Moriyasu and Hashimoto[2] showed that ligand exchange is dependent only on statistical factor, the nonpolar solvent molecules surrounding the neutral mixed ligand chelate molecules in solution may be presumed to prevent their collision among themselves, which lead to their disintegration. The hR_f values reported in Table 2 show that these mixed ligand chelates are intermediate in their migratory behaviour with respect to their parent chelates.

Electronic Spectra. All simple and mixed ligand dithiocarbamates show strong absorptions in the UV region around 38.5×10^3 cm^{-1} due to π–π^* transition.[17] Absorption maxima in the visible region around 23.5×10^3 cm^{-1} (log ε 3.3 to 3.4) for simple chelates (n–π^* transition) are considerably broadened for mixed ligand chelates (from 23.7 to 23.4×10^3 cm^{-1}, Figs. 1 and 2 and Table 1).

s=singlet; t=triplet; q=quartet; m=multiplet.

Infrared Spectra. The characteristic absorption due to 'thioureide' bond (N=C) is observed in the region 1470 to 1490 cm^{-1}. The mixed ligand complexes show uniformly greater ν(C=N) infrared absorption frequencies corresponding to the increased flow of electron from N-atom to donor centres resulting in stronger M–S bond and more stable chelates. However, in general, for mixed ligand complexes, the dithiocarbamate group present in greater proportions determines their IR spectral characteristics. For simple chelates, the ν(C=N) frequencies are in the order diethyl->dipropyl->dibutyl->pentamethylene->dibenzyldithiocarbamates with respect to *N*-substituents.

The inductive effect of benzyl groups and the rigid heterocyclic ring structure of piperidino group[18] restrict the easy drift of electrons from N to C-atom resulting in decreased C=N bond order in their chelates. Though basic character increases from dimethylamine to dibutylamine, the increasing *N*-alkyl chain length (by mass effect) prevent[19] the electron flow from N to C-atom *via* hyperconjugation. The ν(C=S) frequencies are observed as single and strong peaks in the region 980 to 1005 cm^{-1} indicating the bidentate nature of dithiocarbamate moieties.[20] The increased ν(C=N bond order generally resulted in decreased ν(C=S) frequencies.

^1H NMR Spectra. Table 3 shows the ^1H NMR spectral data of some simple and mixed ligand dithiocarbamates of thallium(III). The α-proton signals are shifted significantly to new energy regions (mostly in downfield direction) in mixed ligand complexes in addition to the observation of new peaks for some mixed ligand chelates. The splitting of α-proton signals of methyl and benzyl groups in Tl (die. dtc)$_2$ (dibenz. dtc) (Table 3) and Tl (dime. dtc) (dibez. dtc)$_2$ observed may be due to complex stereochemical positioning of the two benzyl and methyl groups. In moderately polar $CDCl_3$+TMS solvent, the ^1H NMR signals of the mixed ligand chelates gradually get shifted to the regions as in parent chelates indicating their disintegration as discussed earlier. This observation as against that of Duffy[16] for iron(III) dithiocarbamates show the greater stability of thallium(III) mixed ligand chelates and also the importance of ^1H NMR spectra in the study of ligand exchange reactions as observed earlier.[4]

Mixed Chelates of Cadmium(II) with *N*-(2-Hydroxyethyl)ethylenediamine and Some Amino Acids

Chandra Pal Singh CHANDEL and Chand Mal GUPTA*
Department of Chemistry, University of Rajasthan, Jaipur-302004 India
(Received May 19, 1983)

An extended method of Schaap and McMasters[1] has been applied for the study of mixed-ligand complexes of Cadmium(II) with *N*-(2-hydroxyethyl) ethylenediamine (heda) and some amino acids polarographically at DME. The reduction of mixed-ligand complex at DME has been found to be reversible, and diffusion controlled at temp (30±0.5)°C and μ=1.0 M†† (KNO_3). The formation of MXY, MXY_2, and MX_2Y has been used to discuss the non-existence of MX_3 complexes, where X has been used for heda and Y for amino acids. The values of stability constants β_{01}, β_{02}, β_{03}, β_{11}, β_{12}, and β_{21} are 3.90, 6.80, 8.94, 8.85, 11.00, and 12.13 for Cd–heda–isoleucinate system, 4.30, 7.70, 9.80, 9.36, 11.75, and 12.42 for Cd–heda–glycinate system, 3.95, 6.81, 8.90, 8.35, 10.99, and 12.12 for Cd–heda–valinate system, 4.10, 7.10, 9.08, 9.02, 11.20, and 12.18 for Cd–heda–serinate system, 4.48, 8.02, 10.33, 9.55, 12.00, and 12.59 for Cd–heda–glutamate system, 4.24, 7.54, 9.54, 9.26, 11.62, and 12.33 for Cd–heda–alaninate system and 4.06, 7.06, 9.02, 9.00, 11.16, and 12.20 for Cd–heda–threoninate system respectively.

For the determination of mixed-ligand complexes where third complex does not exist in any one out of the simple systems studied, an extention has been made in the method of Schaap and McMasters.

In this communication the extended method of Schaap and McMasters has been used to discuss the mixed-ligand complex formation of cadmium(II) with *N*-(2-hydroxyethyl)ethylenediamine(heda) and isoleucinate, glycinate, valinate, serinate, glutamate, alaninate, and threoninate. The weeker ligand (amino acids) forms three complexes (MY, MY_2, and MY_3) while strong ligand (heda) does not form MX_3 complex.

A survey of literature reveals that the stability constants of the above type mixed-ligand complexes have not been evaluated to date, except our earlier studies.[3]

Theory

For a complexation reaction,

$$M + {}_iX + {}_jY \rightleftharpoons MX_iY_j.$$

Where i, j are stoichiometry numbers, X and Y are two different ligands and charges have been ignored for simplicity.

The overall stability constant β_{ij} for the above reaction is given by

$$\beta_{ij} = \frac{MX_iY_j}{M[X]^i[Y]^j}.$$

According to the method of Schaap and McMasters the formation function $F_{00}[X, Y]$ may be expressed by

$$\begin{aligned} F_{00}[X,Y] = {} & \{\beta_{00}+\beta_{01}[Y]+\beta_{02}[Y]^2+\beta_{03}[Y]^3\}[X]^0 \\ & + \{\beta_{10}+\beta_{11}[Y]+\beta_{12}[Y]^2\}[X] \\ & + \{\beta_{20}+\beta_{21}[Y]\}[X]^2 \\ & + \{\beta_{30}\}[X]^3, \end{aligned} \quad (1)$$

which may, for simplicity, be written as

$$F_{00}[X,Y] = A + B[X] + C[X]^2 + D[X]^3. \quad (2)$$

Where A, B, C, and D are constant for a given value of [Y], and have values as defined by equiv (1).

The plot of $F_{00}[X, Y]$ *vs.* [X] when extrapolated to [X]=0 on the $F_{00}[X, Y]$ axis, will give the value of the constant A which should essentially be equal to the value of $F_0[Y]$ for the simple M–Y system, as calculated by the method of DeFord and Hume. The constant B can be found similarly from the F_{10} [X, Y] function, defined as

$$\begin{aligned} F_{10}[X,Y] &= \frac{F_{00}[X,Y]-A}{[X]} \\ &= B + C[X] + D[X]^2, \end{aligned} \quad (3)$$

by obtaining the intercept from the plot of $F_{10}[X, Y]$ *vs.* [X]. Similarly, plots of $F_{20}[X, Y]$ and $F_{30}[X, Y]$ *vs.* [X] will give intercepts on $F_{20}[X, Y]$ and $F_{30}[X, Y]$ at [X]=0, as C and D respectively. The value of D should be equal (within experimental errors) to the overall stability constant of the MX_3 complex when calculated from the simple M–X system.

From the knowledge of values of B and C at two different concentrations of Y, the values of stability constants of mixed-ligand complexes MXY, MXY_2 and MX_2Y can be evaluated.

Experimental

Chemicals. *N*-(2-hydroxyethyl)ethylenediamine (heda) was obtained from Fluka A.G. (Switzerland) and serine from Merck and other amino acids from S.D.'s Chemical Co., while potassium nitrate was used as supporting electrolyte and gelatin as maxima suppressor.

Apparatus. Manual polarograph with capillary characteristics $m^{2/3}t^{1/6}=1.96\ mg^{2/3}s^{-1/2}$ in open circuit was used. Elico., Digital pH meter model Ll-120 was used to determine the pH of the solutions. The experimental technique was same as described earlier.[4]

Results

Binary Systems. The dissociation constants for *N*-(2-hydroxyethyl)ethylenediamine and amino acids were calculated by the method of Albert and Sergeant[5] which agreed well with literature.[6–8] (Table 1). The stepwise formation constants of the complexes of Cd(II) with amino acids were determined separately before

the study of the mixed-ligand system, by the method of DeFord and Hume.[2] The conditions used corresponded as closely as possible to those for the mixed systems *i.e.* ionic strength was 1.0 M (KNO_3) and temp. (303±1)K. The formation constants which are in good agreement with literature,[9–13] have been tabulated in Table 2.

Ternary Systems. The cadmium–heda–amino acid systems were studied by keeping the concentration of the weaker ligand (amino acids) constant at two different values while varying the concentration of heda in each case, the total cadmium concentration was kept at 5×10^{-4} M.

Free ligand concentration for each system has been calculated with the help of pH of the solution, pK values and amount of the ligand.

In all cases a single well-defined wave was obtained for which the plots of $-E_{de}$ *vs.* log $i/(i_d-i)$ gave a slope of (30±2) mV, indicating that the reduction is reversible and involves the transfer of two electrons. The reduction is diffusion controlled as evident by the direct proportionality of the limiting current to the square root of the effective height of mercury column.

By increasing the heda concentration, the half wave potential shifts towards more negative side and this shift is greater in the presence of the weaker ligands (amino acids) than in its absence. It signifies the formation of mixed-ligand complexes. The F_{10} function was evaluated by extending the method of Schaap and McMasters and A, B, and C were calculated by Leden's-graphical extrapolation method.[16] Stability constants

of mixed-ligand complexes have been presented in Table 3 and summarised in Schemes 1—7.

Discussion

The values of F_{20} for Cd–heda–isoleucinate are constant as 6.30×10^{10} and 2.80×10^{11} at 0.04 and 0.2 M of isoleucinate respectively (Tables 4 and 5). But these values differ appreciably with each other. Similar results have also been observed in Cd–heda–glycinate, Cd–heda–valinate, Cd–heda–serinate, Cd–heda–glutamate, Cd–heda–alaninate, and Cd–heda–threoninate. This proves the formation of maximum number of complexes, simple and mixed in each mixed-ligand system and these complexes contain more than one mixed-ligand species. It may be concluded that the formation of MXY, MXY_2 and MX_2Y mixed-ligand complexes is taking place in the solution.

With the help of Schemes 1—7 too, the formation of MXY, MXY_2, and MX_2Y may be explained. For the addition of heda to Cd(heda), Cd(ile), Cd(gly),

* $\Delta F(\%)=\frac{100}{F_{00}(\text{exptl})}[F_{00}(\text{calcd})-F_{00}(\text{exptl})]$.

Cd(val), Cd(ser), Cd(glu), Cd(ala), and Cd(thr), the log values of stability constants are 4.41, 4.95, 5.06, 4.90, 4.92, 5.07, 5.02, and 4.94 respectively. These values indicate that it is easier for heda to add Cd (amino acids) than to Cd(heda) and also that the addition of heda is slightly favoured as the stability of the Cd(amino acids) decreases. The log K values for the addition of, isoleucinate- to Cd(ile) and Cd (heda) are 2.90 and 3.46, glycinate to Cd(gly) and Cd(heda) are 3.40 and 3.97, valinate to Cd(val) and Cd(heda) are 2.86 and 3.46, serinate to Cd(ser) and Cd(heda) are 3.00 and 3.63, glutamate to Cd(glu) and Cd(heda) are 3.54 and 4.16; alaninate to Cd(ala) and Cd(heda) are 3.30 and 3.87 and threoninate to Cd(thr) and Cd(heda) are 3.00 and 3.61, indicating that the mixed-ligand complexation is favoured.

The logarithms of stability constants for the addition of isoleucinate to $Cd(heda)_2$, Cd(heda) (ile), and $Cd(ile)_2$ are 2.33, 2.15, and 2.14 respectively and show that the mixed-ligand complex formation is preferred. The other systems follow suit.

The case of mixed-ligand complex formation by the addition of amino acids to $Cd(heda)_2$ and Cd(heda) (amino acids) may easily be confirmed on the basis of statistical considerations,[14] only when the values of stability constant of $Cd(heda)_3$ complex is known. In our experimental conditions such complex has not been identified but for the understanding view point such value may be evaluated by using equations 4—6 as proposed by Watters and Dewitt:[15]

$$\beta_{11} = 2 \times 3 \times \beta_{30}^{1/3} \times \beta_{03}^{1/3}, \quad (4)$$

$$\beta_{12} = 3 \times \beta_{30}^{1/3} \times \beta_{03}^{2/3}, \quad (5)$$

$$\beta_{21} = 3 \times \beta_{30}^{2/3} \times \beta_{03}^{1/3}. \quad (6)$$

These above equations are valid strictly when mixed-ligand complexation is characterised by the statistical factor. The values of stability-constants of $Cd(heda)_3$ complex so obtained from each system are given in Table 6.

Since all these β_{30} values are much higher than the stability constants of $Cd(heda)_2$, $Cd(heda)_3$ complex must exist at maximum heda concentration. This shows that the formation of $Cd(heda)_3$ complex is favoured by statistical factors whereas it does not exist in the simple system. The formation of $Cd(heda)_3$ may be opposed by some factors like the bulky nature of heda molecule.

By calculating the disproportionation constant K^D for the equilibria,

$$2Cd(heda)(\text{amino acids}) \rightleftharpoons Cd(\text{amino acids})_2 + Cd(heda)_2,$$

the tendency of the formation of 1:1:1 mixed ligand complex should be easily expressed. For statistical reasons the value of log K^D is −0.6 but the observed values are −1.10, −1.22, −1.11, −1.18, −1.28, −1.22, and −1.14 for Cd-heda-ile, Cd-heda-gly, Cd-heda-val., Cd-heda-ser., Cd-heda-glu., Cd-heda-ala and Cd-heda-thr, respectively. More negative values of log K^D for each equilibrium show that mixed-ligand complex formation is effected by some other factors.

TABLE 6. STABILITY CONSTANTS OF $Cd(heda)_3$ BY USING WATTERS AND DEWITTS EQUATIONS

System	Using equation 4	Using equation 5	Using equation 6
Cd-heda-isoleucinate	15.58	13.69	13.01

The Reversibilities of the Adsorption and Desorption of Organic Compounds in Water

Kohei URANO,* Hisanao KANO, and Toshimasa TABATA
Department of Safety and Environmental Engineering, Yokohama National University, 156 Tokiwadai, Hodogaya-ku, Yokohama 240
(Received September 24, 1983)

Synopsis. The reversibilities of the adsorption and desorption of seventeen organic compounds in water on a granular activated carbon and a polystyrene adsorbent were examined by means of a batch-adsorption method. The adsorptions of many organic compounds were reversible, but the adsorptions of several phenolic compounds and aniline were irreversible for the activated carbon, because these compounds were adsorbed strongly on the surface of activated carbon by the π-electron combination. On the other hand, the adsorptions of all the organic compounds were reversible for the polystyrene adsorbent.

The applications of adsorption from solutions on solid adsorbents have been considerably developed and become very important in many fields,[1] such as in purification processes, water-treatment processes, and analytical methods. The reversibility of adsorption and desorption is an important characteristic of an adsorbate to consider in selecting the adsorbent and in determining the adsorption conditions in these applications. However, there have been few reports on the reversibilities of the adsorption and desorption[2] of organic compounds in water. In this report, therefore, the reversibilities of the adsorption and desorption of various organic compounds on an activated carbon or a polystyrene adsorbent are investigated.

Experimental

Seventeen organic compounds on a reagent grade were used as the adsorbates. A granular activated carbon and a polystyrene adsorbent whose properties are shown in Table 1 were used in this study.

The adsorption isotherms at 25°C were obtained by the same method as in the previous paper.[3] After measuring the equilibrium concentrations, the solutions of 50—90 cm^3 were removed from the flasks and equal amounts of pure water were added. The flasks were then again shake for 4 d at 25±0.5°C. After the equilibrium had been completely attained, the concentrations of the desorbed adsorbates were analyzed and the desorption isotherms were obtained. The reversibilities were examined by a comparison of the desorption isotherms with the adsorption isotherms. The concentrations of the adsorbates were determined from the ultraviolet absorbances and concentrations of the total organic carbon (TOC).

Results and Discussion

Adsorption on Activated Carbon. The adsorption isotherms[3] and the desorption isotherms on the activated carbon are shown in Fig. 1—3 respectively as Freundlich expressions, the logarithmic relationships between the adsorbed amount Q (mol g^{-1}) and the equilibrium concentration C (mol dm^{-3}). The two isotherms agree with one another for many compounds, such as pentanoic acid, hexanoic acid, heptanoic acid, nitrobenzene, benzaldehyde, benzonitrile, benzoic acid, *m*-hydroxybenzoic acid, *m*-hydroxybenzaldehyde, benzenesulfonic acid, *p*-methylbenzenesulfonic acid, and *p*-ethylbenzenesulfonic acid. Therefore, the adsorptions and desorptions of these compounds are reversible. On the other hand, the desorption isotherms for phenol,

Table 2. Ratios of k for desorption to adsorption, k_{ds}/k_{ads}

Adsorbent	Phenol	*m*-Cresol	*p*-Nitrophenol	Aniline
Activated carbon	1.3	1.3	1.1	1.1
Polystyrene	1.0	—	1.0	1.0

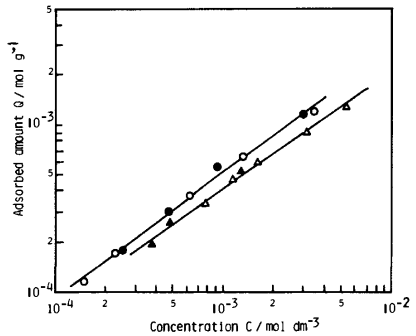

Fig. 4. Adsorption and desorption isotherms of benzoic acid and nitrobenzoic acid for polystyrene adsorbent at 25°C.
○●: Benzoic acid, △▲: *m*-nitrobenzoic acid.

m-cresol, *p*-nitrophenol, and aniline are higher and are parallel with their adsorption isotherms. Therefore, the adsorptions and the desorptions of these several phenolic compounds and aniline are irreversible. However, the values of n in the Freundlich equation, $Q=kC^{1/n}$, for the adsorption and the desorption isotherms are equal to one another. The ratios of the values of k for the desorption to the adsorption, k_{ds}/k_{ads}, show the levels of the irreversibility; they are summarized in Table 2. The ratios are large for phenol and *m*-cresol. Urano *et al.*[3] reported the energy distributions for the adsorptions of those compounds on the activated carbon and showed that the phenol and *m*-cresol adsorbed with especially high energies on the activated carbon. The adsorption energy for aniline was also slightly higher than those for the other aromatic compounds. These high adsorption energies show that those compounds combine strongly with the surface of activated carbons. It is known[2] that there are several electrophilic groups, such as the quinone group and the ketone group, on the surface of activated carbon. Since phenol, *m*-cresol, and aniline act as electron donors, these compounds may be adsorbed by the π-electron combination on the carbon surface. Urano *et al.*[3] reported that the amount of phenol adsorbed decreased with the oxidation of the activated carbon. This decrease may be due to the change in the electrophilic groups into non-electrophilic groups such as the carboxyl group with the oxidation. The reason for the reversible adsorptions of *m*-hydroxybenzoic acid and *m*-hydroxybenzaldehyde, which have a phenolic hydroxyl-group, may be that these compounds do not act as strong electron donors.

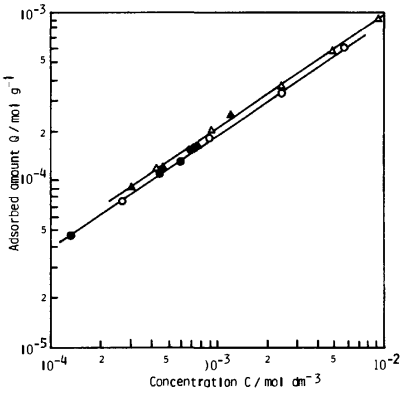

Fig. 5. Adsorption and desorption isotherms of phenol and aniline for polystyrene adsorbent at 25°C.
○●: Phenol, △▲: aniline.

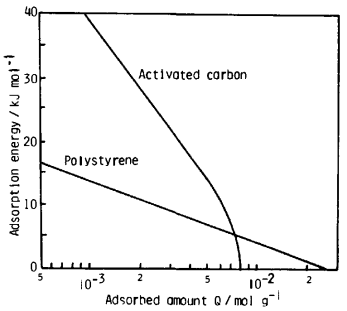

Fig. 6. Distributions of adsorption energy of phenol for activated carbon and polystyrene adsorbent at 25°C.

Adsorption on Polystyrene Adsorbent. The adsorption isotherms and the desorption isotherms on the polystyrene adsorbent are shown in Figs. 4 and 5 respectively. The adsorptions on the polystyrene adsorbent for all the organic compounds were reversible, because the polystyrene adsorbent has no active groups. The energy distribution for the adsorption of phenol on the polystyrene adsorbent was calculated by means of the following equation:[3] $Q=kC_s^{1/n}-E_{eq}/nRT$, where C_s is the saturated concentration, E_{eq} is the adsorption energy at Q, R is the gas constant, and T is the absolute temperature. It is obvious that the adsorption energy for the polystyrene adsorbent is much smaller than the energy for the activated carbon; this shows that the adsorption on the polystyrene adsorbent is completely physical.

Pentane Isomerization Activity of Halogenated Rare Earth Intermetallics

Hayao IMAMURA,* Yuzo KATO, and Susumu TSUCHIYA
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, 2557 Tokiwadai, Ube 755
(Received November 19, 1983)

Synopsis. Binary halides formed by treating $ErAl_3$ with halogen elements were subjected to an characterization as skeletal isomerization catalysts for pentane. Halogenation of $ErAl_3$ in the presence of CH_2Cl_2 or CCl_4 gives rise to superacidic binary halides as a result of formation of V-center-type sites due to excess of halogen species.

There have been various studies published of catalytic properties of solid superacids.[1-5] Recently, we have found that in the presence of halogens X_2 (X_2= Cl_2, Br_2, and I_2), rare earth- or Th-group IIIB intermetallics are readily converted into binary halides which are characterized as superacids.[6] These halogenated intermetallic compounds are exceptionally active as skeletal isomerization catalysts for pentane under mild conditions. We believe that the extreme activity is due to superacidity, but their catalytic behavior markedly varies with preparative conditions for the binary halides. To obtain information about the isomerization activity of the binary halide catalysts formed by direct halogenation of rare earth intermetallics, the present study was undertaken.

In a standard procedure for preparing the catalyst, X_2 is added to finely ground intermetallics suspended in dichloromethane (CH_2Cl_2) solvent, and the mixture is stirred to obtain the binary halide in a slurry form in dry argon under anhydrous conditions.[6] Pentane is injected to initiate the isomerization. When 2 ml of pentane was added to an $ErAl_3$ (1 mmol)-I_2 (6 mmol) system in CH_2Cl_2, the activity at 0°C was evaluated from the pentane conversion in 30 min as 61% (Table 1). On the other hand, when the isomerization was conducted without CH_2Cl_2 solvent, the catalytic activity was significantly decreased for $ErAl_3$-Cl_2 and $ErAl_3$-I_2. As shown in Table 1, however, the activity was restored to some extent by addition of a small amount of CH_2Cl_2. These observations indicate that CH_2Cl_2 used as a solvent plays an important role in the development of superacidity in the present system. NMR and element analyses for $ErAl_3$-X_2 in the presence of CH_2Cl_2 revealed that metathetic halogen exchange takes place between the halogenated $ErAl_3$ and CH_2Cl_2 along with the formation of CH_2XCl. It is supposed that this promoting action of CH_2Cl_2 on the isomerization of pentane is ascribed in part to the halogen exchange. To check this, the isomerization reaction was examined by adding Cl_2 or Br_2 to $ErAl_3$-I_2, because changes in Gibbs energy at 25°C are favorable for the halogen exchange between metal iodides and Cl_2 (or Br_2). The reaction between the iodinated $ErAl_3$ and Cl_2 could be followed gravimetrically to find $ErAl_3I_{11.6}Cl_{0.4}$, which is actually active for the isomerization (Table 1).

TABLE 1. RESULTS OF THE ISOMERIZATION OF PENTANE

Catalyst	Solvent	Additive[a]	Conversion of pentane/%
$ErAl_3$-Cl_2	CH_2Cl_2	—	25[c]
	CCl_4	—	25[c]
	—[b]	—	1.8[d]
	—[b]	CH_2Cl_2	7.6[d]
$ErAl_3$-Br_2	CH_2Cl_2	—	58[c]
	—[b]	—	5.6[d]
$ErAl_3$-I_2	CH_2Cl_2	—	61[c]
	—[b]	—	none[d]
	—[b]	CH_2Cl_2	9.0[d]
	—[b]	CCl_4	6.3[d]
	—[b]	Cl_2	1.2[d]
	—[b]	Br_2	5.3[d]

a) CH_2Cl_2: 0.5 ml, CCl_4: 0.5 ml, Br_2: 3 mmol. b) Direct contact between $ErAl_3$ and X_2 was conducted *in situ* in pentane. c) The conversion (1 mmol $ErAl_3$-6 mmol X_2, solvent: 8 ml, pentane: 2 ml) was measured at 0°C and 30 min. d) The conversion (0.5 mmol $ErAl_3$-3 mmol X_2, pentane: 10 ml) was measured at 23°C and 6 h.

In addition, it can be presumed from Table 1 that the action of CH_2Cl_2 on $ErAl_3$-Cl_2 brings about another synergism for improving the catalytic activity, besides the halogen exchange. To understand this better, the chlorination of $ErAl_3$ was examined by using gravimetric techniques: after $ErAl_3$ was allowed to react at 23°C with the stoichiometric amount of chlorine required to chlorinate the Er and Al present in the alloy, CH_2Cl_2 (190 Torr) (1 Torr=133.322 Pa) was introduced into the system in place of chlorine gas. There was a further occurrence of the reaction between the chlorinated $ErAl_3$ and CH_2Cl_2 in which a large excess of chlorine species was taken up by the resulting binary halide. Carbon tetrachloride (CCl_4) behaved quite similarly to CH_2Cl_2. As shown in Table 1, for example, $ErAl_3$-I_2 exhibited an enhancement in activity to some extent when treated with CCl_4. For $ErAl_3$-Cl_2 in CCl_4 the active catalyst was such that the binary chloride formed contains chlorine species to an extent exceeding the stoichiometric amount by a factor of 1.3.

These results lead to speculations on the generation of active sites in terms of V-center-like effects which are induced by an excess of halogen. It is recognized that for alkali halides color centers formed in the crystal structure are often associated with catalytic activities.[7] ESR studies indicated that a strong ESR signal with a g value of 2.0059 and an overall width of *ca.* 60 G is formed at room temperature when CH_2Cl_2 or CCl_4 is added to the chlorinated $ErAl_3$. The siganl intensity remained unchanged over a period of 24 h. In view of

TABLE 2. RELATIVE INTENSITIES OF ESR SIGNALS MEASURED FOR VARIOUS CATALYST SYSTEMS

Catalyst system	Relative intensity of ESR signal
$ErAl_3$-Cl_2 in CH_2Cl_2	142
$ErAl_3$-Cl_2 in CCl_4	95
$AlCl_3$ in CH_2Cl_2 (or CCl_4)	3 (2)
$ErCl_3$ in CH_2Cl_2 (or CCl_4)	0.3 (0.5)
$ErCl_3$-$AlCl_3$(1:3) in CH_2Cl_2	1

the fact that the enhancing action of CH_2Cl_2 or CCl_4 on the isomerization activity was not noticeable for a 1:3 mixture of $ErCl_3$ and $AlCl_3$ or the individual compounds, a good correlation between the ESR signal intensity and the activity may be taken to have been observed for $ErAl_3$–Cl_2 in CH_2Cl_2 or CCl_4 (Table 2). Accordingly, it is concluded for the present system that CH_2Cl_2 or CCl_4-treated $ErAl_3$–X_2, possessing V-centers due to an excess of halogen species, shows superacidity.

Experimental

The rare earth intermetallic compound $ErAl_3$ used was obtained as a commercial product from Nippon Yttrium Co. Pentane was thoroughly dehydrated with sodium wires and subsequently distilled in dry argon. Dichloromethane and carbon tetrachloride were purified by distillation in the presence of phosphorus pentaoxide. The isomerization of pentane was investigated in the liquid phase over binary halides, which had been prepared *via* reaction of $ErAl_3$ with X_2 before each run. Special care was taken to exclude water and oxygen from the system. Further details regarding the procedure for the isomerization reaction have been described elsewhere.[6]

This research was supported by the Grant-in-Aid for Scientific Research from the Ministry of Education, Culture and Science. We are grateful to Mr. Toyoharu Saito, Tokyo Institute of Technology, for carrying out the elemental analyses.

Indexing of X-Ray Powder Diffraction Data for Potassium Hexafluorovanadate(III)

Koichiro KOYAMA,* Yasuhiko HASHIMOTO, Shinichiro OMORI, and Kazuo TERAWAKI
Department of Metallurgy and Materials Science, Himeji Institute of Technology, 2167 Shosha, Himeji 671-22
(Received December 8, 1983)

Synopsis. X-Ray powder diffraction data for K_3VF_6 are presented; the α form is monoclinic with a=1.2102(1), b=1.7456(2), c=1.2007(2) nm, β=92.58(1)° at 298 K; the β form is monoclinic with a=1.714(2), b=1.237(1), c=0.5479(2) nm, β=91.49(3)° at 453 K; the γ form is tetragonal with a=1.3708(5), c=0.8752(5) nm at 483 K; the low-temperature γ form, which contains a small amount of sodium ion, is tetragonal with a=1.3570(3), c=0.8671(2) nm at 298 K.

Monoclinic; a=1.2102(1), b=1.7456(2), c=1.2007(2) nm, β=92.579(10)° at 289 K

The previous paper[1] has revealed that K_3VF_6 has four polymorphic forms and the transition points are 431, 473, and 491 K. When it contains a small amount of sodium ion, the γ and δ froms remain stable even at room temperature. This work was undertaken to present the X-ray powder diffraction data for the α, β, and γ forms, and to index their diffraction patterns.

Experimental

The potassium hexafluorovanadate(III) was prepared from V_2O_3 and KHF_2 of a special reagent grade in the manner reported previously.[1] The γ form which remains stable at room temperature—hereafter, designated the low-temperature γ form—was prepared using reagent-grade KHF_2. The X-ray diffraction pattern of the α form was taken with an X-ray diffractometer, Rigaku Denki Model SG-7, with

Tetragonal; a=1.3570(3), c=0.8671(2) nm at 298 K.

Cu K_α radiation monochromated by pyrolytic graphite at a scanning speed of 0.0167°/s (1°/min) and a chart speed of 1.67×10^{-4} m/s (10 mm/min). The X-ray diffraction patterns of the β, γ and low-temperature γ forms were taken on the same diffractometer with a Ni-filtered Cu K_α radiation at the same scanning speed and the same chart speed as for the X-ray diffraction pattern of the α form. The diffraction angles were corrected by those of silicon added to the K_3VF_6 powder as an internal standard. Indexing of the diffraction patterns was made with the aid of the computer program, Program ITO, Version 9, originally developed by Visser[2] and improved by Johnson Jr. The lattice parameters were refined by a least-squares method. The wavelengths used were 0.154178 nm (Cu K_α) for $2\theta \leqq 51°$ and 0.154051 nm (Cu K_{α_1}) for $2\theta > 51°$ respectively.

Results

Tables 1—4 show the X-ray diffraction data for the α, β, γ and low-temperature γ forms, respectively. The α form is simple monoclinic with a=1.2102(1), b=1.7456(2), c=1.2007(2) nm, β=92.58(1)° at 298 K; the β form is simple monoclinic with a=1.714(2), b=1.237(1), c=0.5479(2) nm, β=91.49(3)° at 453 K; the γ form is body-centered tetragonal with a=1.3708(5), c=0.8752(5) nm at 483 K; the low-temperature γ form is body-centered tetragonal with a=1.3570(3), c=0.8671(2) nm at 298 K.

The authors wish to express their thanks to Professor Gerald G. Johnson Jr. of the Pennsylvania State University for sending the computer program, Program ITO, Version 9.

The Catalytic Properties of the Pd/Mica Model Catalyst

Yoshio TAKASU,* Kenji KASAHARA, and Yoshiharu MATSUDA
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, 2557 Tokiwadai, Ube 755
(Received December 16, 1983)

Synopsis. The apparent activation energy of an H_2–D_2 exchange reaction on a Pd/mica model catalyst system increased with the decrease in the particle size of palladium. The activity pattern as a function of the mean particle size was of a volcano-type, with a maximum at a particle size around 1.2 nm.

The effects of the metal-particle size on the catalytic properties of supported metal catalysts have not been clearly revealed. Most of the investigations which have aimed at revealing the size effects have been performed with catalysts prepared by the impregnation method. However, they have had the following difficulties: (1) the observation of small metal particles on supports (Al_2O_3, SiO_2 or active carbon) by TEM (transmission electron microscopy) is not easy; (2) the surface cleanness of metal particles on the support cannot be well guaranteed, and (3) the application of UPS (ultraviolet photoelectron spectroscopy) to reveal the valence-band structure of catalysts is substantially impossible.

The model-catalyst method will be able to overcome those concomitant problems. Many investigations with model catalysts have been performed using an UHV (ultra-high vacuum) system; however, scarcely no experiments which have examined both metal-particle size and catalytic-activity measurements have been made.[1–6]

In this study, palladium was evaporated onto a mica sheet in an UHV system, and its catalytic activity for an H_2–D_2 exchange reaction was measured *in situ*.

Experimrental

The features of the apparatus used for the preparation of the model catalysts and for the subsequent measurements of their catalytic activities have been described elsewhere.[7] The apparatus was capable of being evecuated to the pressure of 10^{-9} Torr (1 Torr=133.3 N m^{-2}). A cleaned mica-sheet support and a TEM mesh were set in the UHV chamber. The TEM sheet mesh was composed of fine mica powder fixed on evaporated carbon film which was held on a copper sheet mesh (#400). The mount of palladium evaporated was monitored by means of a quartz-thickness monitor (ANELVA EVM-32B). A transmission electron microscope (Japan Electron Optics, JEM-200-CX, bright field) was adopted for the observation of the palladium particles on the mica-sheet support.

Results and Discussion

Figure 1 shows some typical electron micrographs of the model catalyst, in which one can see palladium particles ranging in size from the observation limit of 0.6 nm to approximately 3 nm. The mean thickness $\bar{D}$ signifies the thickness of the palladium layer if the deposits were dense and did not form any island structure. The effective surface areas of these palladium catalysts were estimated by assuming all the palladium particles to be half-spheres.

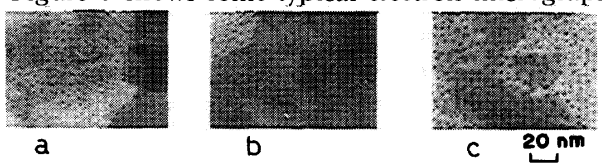

Fig. 1. Typical electron micrographs of Pd/mica model catalysts.
Mean thickness $\bar{D}$; a: 0.25 nm, b: 0.41 nm, c: 0.54 nm.

The H_2–D_2 exchange reaction on this Pd/mica model catalyst system obeyed a first-order reaction under the present experimental conditions. Figure 2 shows the specific activity towards the H_2–D_2 exchange reaction ($P_{H_2}=P_{D_2}=2.8\times10^{-2}$ Torr, 25°C) of this catalyst system as a function of the mean palladium-particle size. The activity pattern is of a "volcano" type, with a maximum at a particle size around $\bar{d}=1.2$ nm ($\bar{d}$ signifies the mean diameter of the palladium particles). Such an activity pattern has been found not only for the Pd/C and Pd/SiO_2 model catalyst systems in the H_2–D_2 exchange reaction reported elesewhere[7,8] but also for a Rh/SiO_2 powder catalyst system in benzene reduction.[9] Therefore, a hemispherical palladium particle with a diameter of 1.2 nm may be said to consist of about 30 atoms. Below $\bar{d}=1.2$ nm, the specific activity decreased rapidly with the decrease in $\bar{d}$. There-

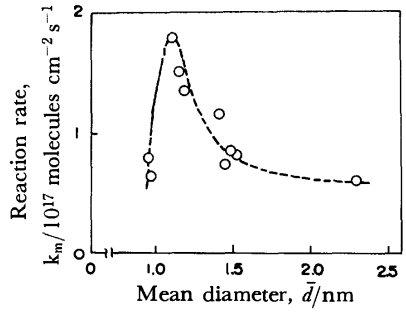

Fig. 2. Reaction rate for the H_2–D_2 exchange reaction, catalyzed by the Pd/mica catalyst, as a function of mean particle size $\bar{d}$.
Temperature: 25°C, pressure: $P_{H_2}=P_{D_2}=2.8\times10^{-2}$ Torr.

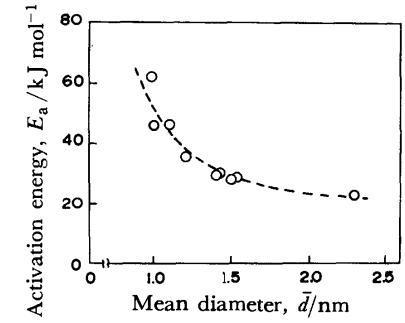

Fig. 3. Apparent activation energy for the H_2–D_2 exchange reaction, catalyzed by the Pd/mica model catalyst, as a function of mean palladium particle size $\bar{d}$.
Temperature range: 0—30°C.

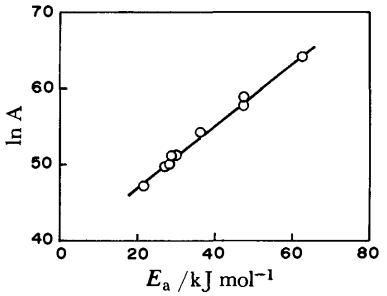

Fig. 4. Compensation effect for the H_2–D_2 exchange reaction, catalyzed by the Pd/mica model catalyst. The A means the preexponential factor in the Arrhenius equation.

fore, the contribution to the catalytic activity of the palladium particles below the observation limit of the electron microscopy (0.6 nm) must be extremely low.

Figure 3 shows the apparent activation energy of the reaction on this Pd/mica model catalyst system as a function of the mean particle size $\bar{d}$. It must be noted that the apparent activation energy gradually decreased with the increase in $\bar{d}$ from *ca.* 60 kJ mol^{-1} at $\bar{d}$ = 1.0 nm to *ca.* 20 kJ mol^{-1} at $\bar{d}$ = 2.4 nm. This tendency must not be directly affected by problems in determining the surface area of the catalyst. As with the specific activity, this tendency is analogous to the results of the Pd/C and Pd/SiO_2 model catalyst systems.[7,8] As shown in Fig. 4, a compensation effect between the apparent activation energy E_a and the preexponential factor A in the Arrenius equation exists for this H_2–D_2 reaction on the Pd/mica model catalyst system. This suggests that the reaction mechanism in this system is the same in all these palladium catalysts, while the activation energy differs.

As has been reported by many previous investigators, including us,[2,3,6] the valence band as well as the 3d levels of small particles of palladium shift to a higher binding energy from the bulk values with a decrease in the particle size. The shift of the valence band to a higher binding energy must be caused by either the intrinsic property of the very small metal particles or the support effect. The former effect has been proved by some investigators[6] on the basis of calculations; the latter effect is now under investigation by the present authors using various catalyst supports. In any event, the increase in the binding energy of the valence-band electrons in palladium particles with the decrease in the particle size must result in the decrease in the adsorption energy of hydrogen on the palladium particles. If this is the case, the increase in the apparent activation energy for the H_2–D_2 exchange reaction with the decrease in the particle size is likely to be caused by an increase in the activation energy for the dissociative adsorption of hydrogen. The rate-determining step of this H_2–D_2 exchange reaction has not been kinetically examined; however, we have pointed out that linear relationships exist between the catalytic activities of a hydrogen-recombination reaction or an H_2–D_2-exchange reaction and the amount of strongly adsorbed hydrogen (probably dissociative) on the cleaned first-transition metal wires as well as the cleaned Cu–Ni alloy plates.[10] On the other hand, the density of low-coordinated surface atoms rapidly increased with the decrease in the particle size.[11] If low-coodinated surface sites were more catalytically active than the higher-coordinated surface atoms, the catalytic activity would increase with the decrease in the particle size. However, the apparent activation energy increases with the decrease in the particle size, an activity maximum appeared at a certain particle size. In order to make a more decisive explanation, an *in-situ* investigation of adsorption and UPS studies using other supports are now being made.

We wish to thank Professor Z. Yoshii, Mr. M. Kimoto, and M. Nishimura of the Faculty of Medicine, Yamaguchi University, for their advice and help with the electron microscopy. Study of the Polymerization of Silicic Acid Adsorbed on Iron(III) Hydroxide by Trimethylsilylation-Gas Chromatography

Takushi YOKOYAMA,* Tsugio SHIMONO,† and Toshikazu TARUTANI
Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812
(Received December 21, 1983)

Synopsis. Polymerization of silicic acid adsorbed on iron (III) hydroxide from dilute monosilicic acid solutions in the concentration range 5—40 ppm (SiO_2) was studied over the pH range 6—12. Silicic acid species formed on the hydroxide were trimethylsilylated and trimethylsilyl derivatives were detected by gas chromatography. Monosilicic acid adsorbed polymerized, and dimer ($Si_2O_7^{6-}$), linear trimer ($Si_3O_{10}^{8-}$) and tetramer ($Si_4O_{13}^{10-}$), and cyclic tetramer ($Si_4O_{12}^{8-}$) were found as polymeric species.

Monosilicic acid adsorbed on or coprecipitated with iron (III) hydroxide rapidly polymerizes.[1,2] Polymerization of silicic acid adsorbed on iron (III) hydroxide has been studied by colorimetry and gel chromatography.[3] Although gel chromatography is useful to study the formation of relatively large polysilicic acids, no information is available on the formation of low-molecular-weight silicic acids such as dimer, trimer, *et al.* Lentz[4] described a chemical technique for the study of silicate structures based on trimethylsilylation of silicic acids. Trimethylsilyl (TMS) derivatives of silicic acids were isolated[5] and the method for the determination of TMS derivatives by gas chromatography was established.[6] The method proposed for the trimethylsilylation of the silicic acids assured that side reactions such as polymerization and depolymerization hardly proceed during the silylation and good reproducible results were obtained.[7] The change with time in the distribution of silicic acids in aqueous solutions was measured.[8]

In this work, the formation of low-molecular-weight silicic acid species in the early stage of polymerization of monosilicic acid adsorbed on iron (III) hydroxide was studied by trimethylsilylation-gas chromatography (TMS-GC).

Experimental

Samples and Reagents. All the reagents except hexamethyldisiloxane (HMDS; $(CH_3)_3Si\text{-}O\text{-}Si(CH_3)_3$) were of analytical reagent grade. HMDS was purified by distillation four times at 120 °C. A stock solution of monosilicic acid was prepared by dissolving silica gel (Mallinckrodt Chemical Works) in sodium hydroxide solution. A monosilicic acid solution of the desired concentration was prepared by diluting a stock solution before use. Iron(III) hydroxide was precipitated by adding sodium hydroxide solution to iron (III) chloride solution and then washed with distilled water. Iron (III) hydroxide was prepared immediately before each experiment.

Procedure. Monosilicic acid solution (0.5 dm^3) of an appropriate concentration was adjusted to the desired pH with hydrochloric acid and sodium hydroxide solution. Sodium chloride concentration was adjusted to 0.1 mol dm^{-3}. Iron (III) hydroxide (0.95×10^{-3} mol) was then introduced into the solution and the pH was readjusted. The suspension was stirred vigorously. The experiments were carried out in a thermostated bath at 25°C. After 30 min, the suspension was rapidly filtered. The concentration of monosilicic acid in the filtrate was determined by colorimetry. For the trimethylsilylation of silicic acid adsorbed on iron(III) hydroxide, the solid sample was added to a mixture of water (5 cm^3), concentrated hydrochloric acid (7.5 cm^3), 1-propanol (15 cm^3), HMDS (12 cm^3), which had been stirred for 1 h at 28°C. The mixture was then stirred for 1 h. The siloxane layer was separated from the aqueous layer and washed with water. The aqueous layer and the washed water were combined, and the water was vigorously shaken with 10 cm^3 of HMDS to extract the remaining TMS derivatives and the siloxane layer was separated and washed with water, then the two siloxane layers were combined. The siloxane layer was stirred for 4 h at room temperature in the presence of Amberlyst 15 cation-exchange regin (2 g). After filtration, the filtrate was evaporated to less than 10 cm^3 by distillation at 120—130°C, and adjusted to 10 cm^3 with isopropyl alcohol. TMS derivatives of silicic acid in the sample solution were analyzed by GC.[6]

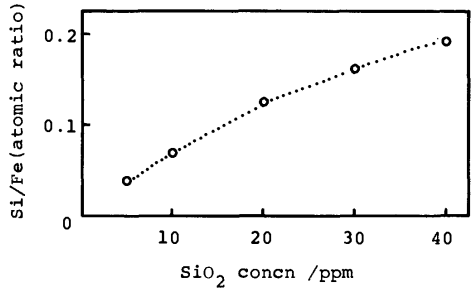

Fig. 1. Variation of Si/Fe ratio as a function of initial monosilicic acid concentration.
pH: 8.

Results and discussion

The effect of the initial concentration of monosilicic acid on the amount and polymerization of silicic acid adsorbed on iron (III) hydroxide was examined at pH 8. Figure 1 shows the variation of Si/Fe atomic ratio of monosilicic acid adsorbed to iron (III) hydroxide as a function of the initial concentration of monosilicic acid. The ratio is an indicator of the amount of silicic acid adsorbed on the hydroxide. The Si/Fe ratio increased with an increase in the initial concentration of monosilicic acid. The silicic acid adsorbed on iron (III) hydroxide was trimethylsilylated and the TMS derivatives were analyzed by GC. The results are shown in Fig. 2. Each silicic acid species is expressed in its anionic form. It was found to contain dimer ($Si_2O_7^{6-}$), linear trimer ($Si_3O_{10}^{8-}$) and tetramer ($Si_4O_{13}^{10-}$), and cyclic tetramer ($Si_4O_{12}^{8-}$) in addition to the monomer (SiO_4^{4-}). Figure 2 shows the variation of proportion of each silicic acid species as a function of the initial concentration of monosilicic acid. The proportion

† Present address: Resources and Environment protection Laboratory, Nippon Electric Co., Ltd., Takatsu-ku, Kawasaki 213.

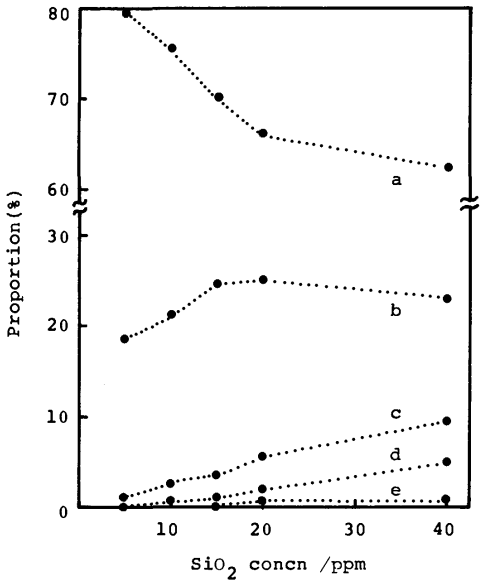

Fig. 2. Effect of initial monosilicic acid concentration on the proportion of various silicic acid species.
pH: 8.
a: SiO_4^{4-}, b: $Si_2O_7^{6-}$, c: $Si_3O_{10}^{8-}$, d: $Si_4O_{12}^{8-}$, e: $Si_4O_{13}^{10-}$.

was calculated by

$$\text{Proportion } (\%) = 100\ (p_i/\sum P_i)$$

where P_i is the peak intensity of the ith TMS derivative on the gas chromatogram. With increasing initial concentration of monosilicic acid, the proportion of monomer rapidly decreased and the proportion of the other silicic acid species increased. The results indicate that although monosilicic acid in solution at concentrations up to about 120 ppm at pH 8 does not polymerize, monosilicic acid adsorbed on iron(III) hydroxide easily polymerizes.

Adsorption of silicic acid by iron (III) hydroxide from 40 ppm (SiO_2) monosilicic acid solution and polymerization of adsorbed silicic acid was examined over the pH range 6—12. Figure 3 shows the variation of the Si/Fe ratio with pH. The maximum adsorption as a function of the pH occurred at around pH 9.5. Figure 4 shows the variation with pH of the proportion of silicic acid species. Although the linear tetramer was detected, it was not plotted in the figure because of its small amount. The polymerization of silicic acid adsorbed occurred at all the pH. It is noteworthy that monosilicic acid adsorbed on iron(III) hydroxide even in strongly alkaline solution (pH 12) polymerizes. Figure 4 suggests that the rate of polymerization of adsorbed silicic acid is most rapid at around pH 8 in the early stage of the adsorption of silicic acid, although the amount of adsorbed silicic acid is largest at around pH 9.5. In colorimetry, only monosilicic acid reacts with molybdic acid to form yellow molybdosilicic acid. As the polysilicic acid species shown in Fig. 4 depolymerize they are determined as monosilicic acid

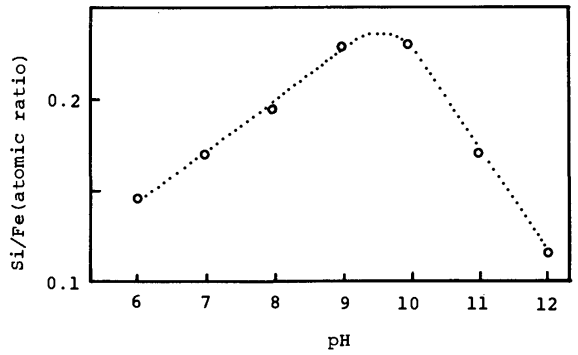

Fig. 3. Variation of Si/Fe ratio with pH.
Initial monosilicic acid concentration: 40 ppm (SiO_2).

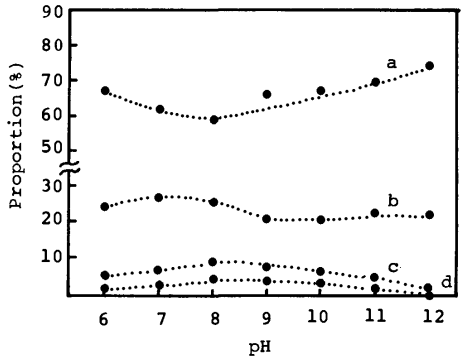

Fig. 4. Effect of pH on the proportion of various silicic acid species.
Initial monosilicic acid concentration: 40 ppm (SiO_2).

by colorimetry,[8] but the formation of such species can not be detected by colorimetry. This work indicates that TMS-GC is useful to study the early stage of the polymerization of silicic acid adsorbed on the surface of a solid.

The present work was partially supported by a Grand-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

Oxygen Isotope Shifts in ^{17}O NMR Spectra of the Uranyl Ion

Woo-Sik JUNG, Yasuhisa IKEDA, Hiroshi TOMIYASU, and Hiroshi FUKUTOMI*
Research Labortory for Nuclear Reactors, Tokyo Institute of Technology, O-okayama, Meguro-ku, Tokyo 152
(Received January 13, 1984)

Synopsis. The ^{17}O NMR spectrum of uranyl oxygens enriched with ^{17}O gave three peaks. These peaks are assigned to the signals of three isotopomers, $[^{16}O{=}U{=}^{17}O]^{2+}$, $[^{17}O{=}U{=}^{17}O]^{2+}$, and $[^{18}O{=}U{=}^{17}O]^{2+}$. Chemical shifts for the signals of $[^{17}O{=}U{=}^{17}O]^{2+}$ and $[^{18}O{=}U{=}^{17}O]^{2+}$ were -0.054 ± 0.002 and -0.108 ± 0.002 ppm relative to $[^{16}O{=}U{=}^{17}O]^{2+}$, respectively.

The study of ^{17}O NMR spectra of oxygen in a dioxouranium(VI) ion, where hereafter uranyl oxygens will be used, was first reported by Rabideau.[1] He observed an asymmetric ^{17}O NMR signal with a shoulder on the high-field side for the uranyl oxygens in 6 M (1 M = 1 mol dm^{-3}) perchloric acid solution, and two peaks in 0.2 M perchloric acid solution. Rabideau suggested that these results may be due to the formation of polynuclear species of uranyl ions. However, the formation of polynuclear species is unlikely in highly acidic solutions.[2,3] He did not take account the difference in ^{17}O enrichment in the uranyl oxygens.

In order to examine Rabideau's results, we have observed the ^{17}O NMR spectra of the uranyl ion in solutions with different acid concentrations, and the effect of ^{17}O enrichment in the uranyl oxygens on the ^{17}O NMR spectrum.

Experimental

Uranyl perchlorate pentahydrate was prepared by dissolving $UO_3{\cdot}2H_2O$ in 60% perchloric acid (Wako Pure Chemical Ind. Ltd.). The $UO_3{\cdot}2H_2O$ was prepared by using the method of Ekstrom *et al.*[4] The uranyl perchlorate pentahydrate was recrystallized from distilled water five times, and the resulting crystals were dried *in vacuo*. The abundance of ^{17}O in enriched water used was 20.5 atom % (Merck, ^{16}O: 50.4, ^{18}O: 29.1 atom %) and 42.1 atom % (Merck, ^{16}O: 26.3, ^{18}O: 31.7 atom %). Uranyl oxygens were enriched by irradiation of uranyl perchlorate solution containing ^{17}O-enriched water with a 500-W high pressure mercury lamp.[5] Samples for the NMR measurements were prepared by adding D_2O (Merck) and perchloric acid to the enriched uranyl perchlorate solution, followed by introducing the sample solution into the NMR microcell (Wilmad). The microcell was inserted in 10 mm o.d. NMR tube (Wilmad) containing reference water. Measurements of the ^{17}O NMR spectra were carried out at 13.46 MHz on a JEOL JNM-FX 100 FT-NMR spectrometer. Typical spectral settings for the measurements of ^{17}O NMR spectra are as follows: 4K data points, 90° pulse angle corresponding to *ca.* 10 μs pulse width, 500 Hz spectral width, 1.95 ms recycle delay, and normally 5000 scans. Temperature was maintained at 293±1 K.

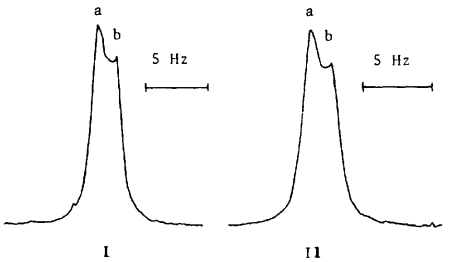

Fig. 1. ^{17}O NMR spectra of the uranyl oxygens at different acid concentrations. The uranyl oxygens were enriched by using $H_2{}^{17}O$ (20.5 atom %).
I: $[UO_2^{2+}]$=0.078 m, $[H^+]$=0.22 m, II: $[UO_2^{2+}]$=0.12 m, $[H^+]$=6.0 m.

Results and Discussion

The ^{17}O NMR spectra of the uranyl oxygens which were enriched by using $H_2{}^{17}O$ (20.5 atom %) were measured at different acid concentrations. The ^{17}O signal of uranyl oxygens was observed at *ca.* +1119 ppm[6] relative to water in 0.22 and 60 m (1 m=1 mol kg^{-1}) perchloric acid solutions. This result is in good agreement with those of earlier works.[1,7] Figure 1 shows the expanded ^{17}O signals of the uranyl oxygens, where no difference was observed in the lineshapes. The difference in chemical shifts between two peaks a and b was determined to be 0.107 ± 0.002 ppm.

The ^{17}O signal of the uranyl oxygens which were enriched by using $H_2{}^{17}O$ (42.1 atom %) was also measured in a 0.23 m perchloric acid solution, and the result is shown in Fig. 2. It is noted that the ^{17}O signal has three peaks p, q, and r, and peaks q and r are observed at -0.054 ± 0.002 and -0.108 ± 0.002 ppm from peak p, respectively. The difference in chemical shifts between two peaks a and b shown in Fig. 1 is the same as that between two peaks p and r shown in Fig. 2 within experimental errors. This result indicates that peak b corresponds to peak r.

From the results in Figs. 1 and 2, it is clear that the ^{17}O NMR lineshape of the uranyl oxygens does not depend on the acid concentration, but depends on the ^{17}O enrichment in the uranyl oxygens. This fact suggests that the change of lineshape is due to the difference in ratio of relative concentration of isotopomers of the uranyl ion, because the ratio changes with the ^{17}O enrichment in the uranyl oxygens.

As the uranyl ion has three isotopomers which are active for ^{17}O NMR, *i.e.*, $[^{16}O{=}U{=}^{17}O]^{2+}$, $[^{17}O{=}U{=}^{17}O]^{2+}$, and $[^{18}O{=}U{=}^{17}O]^{2+}$, three peaks in Fig. 2 may be assigned to these isotopomers. This deduction is supported

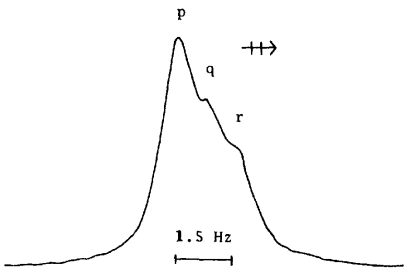

Fig. 2. ^{17}O NMR spectrum of the uranyl oxygens enriched by using $H_2{}^{17}O$ (42.1 atom %). $[UO_2^{2+}]$= 0.098 m and $[H^+]$=0.23 m.
Conditions of enrichment: each weight of $UO_2(ClO_4)_2{\cdot}5H_2O$ and $H_2{}^{17}O$ was 1.023 g and 0.3978 g, respectively.

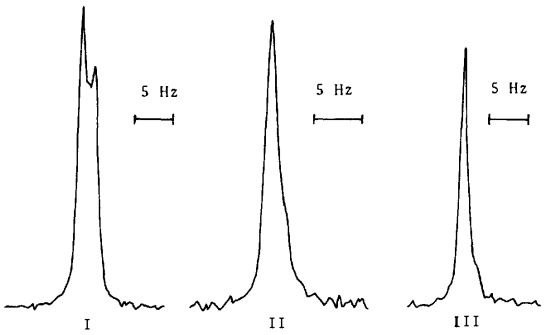

Fig. 3. Change in ^{17}O signals of the enriched uranyl oxygens by irradiation. The uranyl oxygens were enriched by using $H_2{}^{17}O$ (20.5 atom %). $[UO_2^{2+}]$= 0.065 m and $[H^+]$=3.8 m.
I: Before irradiation, II: after irradiation for 10 min, III: after irradiation for 15 min.

by the following results. Figure 3 shows the spectral change of ^{17}O signal of the uranyl oxygens by the irradiation of the enriched uranyl perchlorate solution with the mercury lamp. As is seen in Fig. 3, the intensity of the peak at high-field side decreases gradually with increasing the irradiation time. This phenomenon must be caused by oxygen exchange between the uranyl ion and bulk water, resulting in the variation of relative concentration ratio of three isotopomers. Hence, the peak at the lowest field in Fig. 3, which corresponds to peak a or p in Figs. 1 or 2, respectively, can be assigned to the signal of $[^{16}O{=}U{=}^{17}O]^{2+}$ isotopomer. The concentration of $[^{16}O{=}U{=}^{17}O]^{2+}$ is estimated to be at least ten times those of $[^{17}O{=}U{=}^{17}O]^{2+}$ and $[^{18}O{=}U{=}^{17}O]^{2+}$ at the exchange equilibrium after irradiation. Moreover, in view of the usual trend in the isotope effect on chemical shifts that the magnitude of the upfield shift is largest where the fractional change in mass upon substitution is largest,[8] peaks q and r in Fig. 2 may be assigned to the signals of $[^{17}O{=}U{=}^{17}O]^{2+}$ and $[^{18}O{=}U{=}^{17}O]^{2+}$, respectivery. As a result, peak b in Fig. 1 may be assigned to the signal of $[^{18}O{=}U{=}^{17}O]^{2+}$, since peak b corresponds to peak r as mentioned above. Although the ^{17}O signal of $[^{17}O{=}U{=}^{17}O]^{2+}$ was not able to be observed in Fig. 1, this result may arise from the fact that the relative concentration of $[^{17}O{=}U{=}^{17}O]^{2+}$ is low compared with those of $[^{16}O{=}U{=}^{17}O]^{2+}$ and $[^{18}O{=}U{=}^{17}O]^{2+}$.

From the conditions given in Fig. 2, we can calculate the probability for the occurrence of three isotopomers, assuming that oxygen isotopes are distributed statistically without the isotope effect in O=U=O bond. The ratio of probabilities is given as follows: $P_{16,17}$: $P_{17,17}$: $P_{18,17}$[9] = 0.282: 0.0676: 0.102. Therefore, the ratio of relative intensities of three isotopomers is estimated as follows: $I_{16,17}$: $I_{17,17}$: $I_{18,17}$[9] = 2.76: 1.32: 1.00. Assuming that the whole lineshape in Fig. 2 is formed by overlapping of three Lorentzian curves with the same linewidth, the best-fit calculated lineshape gives the ratio of relative intensities of three peaks p, q, and r as follows: I_p: I_q: I_r = 2.50: 1.00: 1.07. This ratio is in fair agreement with the calculated ratio of $I_{X,Y}$ from $P_{X,Y}$ values under the conditions given in Fig. 2.

It appears well established that the ^{17}O NMR spectra of uranyl oxygens have three peaks corresponding to three isotopomers of the uranyl ion, where the peak at the lowest field is assigned to the signal of $[^{16}O{=}U{=}^{17}O]^{2+}$ and the signals of $[^{17}O{=}U{=}^{17}O]^{2+}$ and $[^{18}O{=}U{=}^{17}O]^{2+}$ shift to the higher field by 0.054±0.002 and 0.108±0.002 ppm relative to $[^{16}O{=}U{=}^{17}O]^{2+}$. This result is the first finding with respect to the isotope shift through two equivalent bonds in ^{17}O NMR.

The authors with to express their thanks to Professor Gilbert Gordon of Miami University and Professor James H. Espenson of Iowa State University for helpful discussions and to Mr. Masao Nomura for the mass spectrometry of the oxygen isotopes. The present work was partially supported by a Grant-in-Aid for Scientific Research No. 57470035 from the Ministry of Education, Science and Culture.

Stereochemistry of Halogen-Metal Exchange Reaction of Vinyl Halide with Grignard Reagent

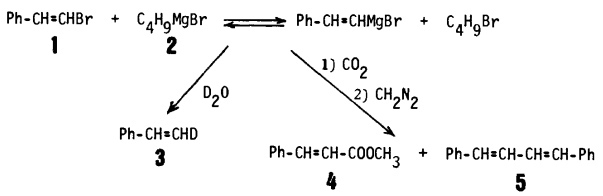
Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received October 26, 1983)

Synopsis. Halogen-magnesium exchange was confirmed to proceed with stereospecific retention of configuration in the reaction of β-bromostyrene and butylmagnesium bromide.

Vinyl Grignard reagents were formed with retention of configuration from the corresponding vinyl halides. The stereospecificities of their formation reaction, however, were widely diversed. Yoshino and his co-workers reported that *cis*- and *trans*-styrylmagnesium bromides were formed in THF with 95 and 91% retention of configuration, respectively, but the stereospecificities were lowered to 69 and 59% in diethyl ether.[1] In the formation of aliphatically substituted vinyl Grignard reagents, various degrees of configurational retention, 60—90%, depending on the substituens, were observed.[2,3] To discuss these discrete experimental results, it is necessary to confirm the stereochemistry of the halogen-metal exchange of vinyl halides with Grignard reagents. Zakharkin and his co-workers have made extensive studies on the halogen-metal exchange reactions involving Grignard reagents with ordinary alkyl and aryl halides. They concluded that the mechanism of halogen-metal exchange reaction is the same for both organomagnesium and organolithium compounds.[4] This would imply that the halogen-magnesium exchange proceeds with retention of configuration. Although there are some reports which suggest that the halogen-magnesium exchange reaction proceeds with retention of configration,[5] the exact experimental results on the stereochemistry of exchange seem to be unavailable. In this paper, we wish to report that the halogen-magnesium exchange between β-bromostyrene (**1**) and butylmagnesium bromide (**2**) does proceed with stereospecific retention of configuration.



Scheme 1.

(*E*)-**1** was treated with **2** in 1,2-dimethoxyethane (DME) at ambient temperature for 2 h. The reaction mixture was then quenched by D_2O. The isomer ratios of the resulted styrene-β-d_1 (**3**) are summarized in Table 1. As a reference experiment, the same reaction was carried out using butyllithium instead of **2**, since halogen-lithium exchange was known to proceed with complete retention of configuration.[6] The isomer ratios of **3** resulting from the halogen-magnesium and halogen-lithium exchange reactions are almost the same value. These results suggest that the halogen-magnesium exchange proceeds with highly stereospecific retention of configuration, rather like the halogen-lithium exchange does.

It has already been pointed out that an unignorable amount of hydrocarbon is also produced during the formation of Grignard reagents.[5] If undeuterated styrene was produced prior to the D_2O treatment, it should be estimated as the (*Z*)-**3** in the present analytical method. Unfortunately, the exchange reaction of (*Z*)-**1** gave only 8% of styrene, which failed to be isolated purely enough for NMR analysis, and the isomer ratio could not be determined.

Carbonation of the resulting Grignard mixture was, therefore, examined in order to obtain unequivocal results. Yields and isomer ratios of the products resulting from the exchange and carbonation reactions are summarized in Table 1. As the carbonation of Grignard reagents proceeds with complete retention of configration,[2,7] the results of these experiments clearly demonstrate that the halogen-magnesium exchange proceeds with highly stereospecific retention of configuration. (*Z*)-**1** afforded methyl (*Z*)-cinnamate (**4**) with complete retention of configuration, but the exchange of (*E*)-**1** proceeded less stereospecifically. It should be noted that the degree of configurational retention of the vinylic Grignard reagents formation usually falls upon going from *cis*- to *trans*-isomer.

TABLE 1. HALOGEN-METAL EXCHANGE REACTION OF β-BROMOSTYRENE WITH BUTYLMAGNESIUM BROMIDE

1	**2**	Product yield/%				Recovered

Carbonation						
Z (21)	42		2.0 (97/3)	7.5 (84/16)	19	52
Z (28)	84		2.7 (100/0)	20.0 (62/38)	36	11
E (21)	42		1.6 (15/85)	29.5 (0/100)	—[c]	—[c]

a) 1-Phenyl-1-hexene. b) Butyllithium hexane solution instead of **2** was used. c) Not determined.

1,4-Diphenyl-1,3-butadiene (**5**) obtained from (*E*)-**1** was (*E,E*)-isomer alone, which certainly resulted from the halogen-magnesium exchange reaction followed by the coupling with the unreacted **1**. In contrast to the (*E*)-isomer, (*Z*)-**1** gave a mixture of (*Z,Z*)- and (*E,E*)-5, although the former predominated. The coupling reaction of Grignard reagents with vinyl halides appears not to be stereospecific, since the alkylations of 1-halo-1-alkenes with Grignard reagents gave mixtures of *cis*- and *trans*-alkenes.[8] In the present case, the coupling reaction of (*Z*)-**1** with (*Z*)-stytylmagnesium bromide, formed stereospecifically from (*Z*)-**1**, may afford (*E,Z*)-**5** as well as its (*Z,Z*)-isomer. The formation of (*E,Z*)-**5** could not, however, be confirmed in the present experiments. The (*E,Z*)-isomer might be isomerised to (*E,E*)-**5** during the reaction or in the isolation process due to its instability.[9]

In THF solution, the halogen-magnesium exchange could not be observed, though it was examined in various conditions.

Experimental

All melting points and boiling points are uncorrected. IR spectra were measured with a Hitachi EPI-G2 spectrometer. ^{1}H-NMR spectra were obtained with a JEOL PMX-60 spectrometer in $CDCl_3$ using TMS as the internal standard. GLC analyses were conducted by a Hitachi 163 gas chromatograph using a 2 m column packed with PEG-20M 20% on Chromosorb-W.

Materials. The solvents were freshly distilled over lithium aluminum hydride under argon before use. (*E*)-**1** was commercially available, and (*Z*)-**1** was synthesized by the reported method.[10] Each isomer was purified by recrystallization from pentane,[1] and was confirmed to be isomerically pure by its IR and ^{1}H-NMR spectra.

Halogen-Magnesium Exchange of β-Bromostyrene with Butylmagnesium Bromide and Hydrolysis with Deuterium Oxide. A solution of **2** was prepared as usual from butyl bromide (22.5 g, 0.164 mol) and magnesium (4.0 g, 0.165 mol) in 82 ml of THF. The solution was filtered through a sintered glass funnel in order to separate it from the remaining metal, and the Grignard reagent solution prepared was used for the subsequent reactions after it was standardized by the method of Watson and Eastham.[11] To a solution of (*E*)-**1** (2.0 g, 11 mmol) in 50 ml of DME, 30 ml of the solution of **2** (40 mmol) was added. The mixture was stirred at ambient temperature for 2 h. All these procedures were carried out under argon atmosphere. The reaction mixture was quenched with 2 ml of D_2O. The mixture was then treated with aqueous ammonium chloride, extracted with ether, and distilled using a Kugelrohr apparatus to give **3**, bp 55—65 °C/30 mmHg (oven temperature; 1 mmHg≈133.322 Pa). Yield of **3**, 20.3%, was determined by GLC. The isomer ratio of the resulting 3 was estimated as *E*:*Z*=79:21 by peak integrals of the doublets at δ 5.19 (*J*=9 Hz: *cis*-β-H of (*Z*)-**3**) and at 5.62 (*J*=18 Hz: *trans*-β-H of (*E*)-**3**).[1]

Carbonation of the Exchange Reaction Mixture. To a stirred solution of (*Z*)-**1** (3.48 g, 21 mmol) in 100 ml of DME, 30 ml of the solution of **2** (42 mmol) was added. The mixture was stirred at ambient temperature in dark under argon for 20 h. The reaction mixture was poured onto a slurry of freshly powdered Dry Ice and ether with vigorous stirring. The carbonated solution was poured into a mixture of ice and hydrochloric acid and the ether layer was separated. The aqueous layer was extracted with ether and the combined ether solutions were extracted with a saturated sodium hydrogencarbonate solution. The alkaline extracts were acidified and extracted with ether. To the ether extracts, an ether solution of diazomethane was added until the mixture turned slightly yellow. After removal of the solvent, the products were submitted to GLC analysis. The ether layer of the alkaline extract was washed with saturated sodium chloride and dried. After removal of the solvent, the residual products were analyzed by GLC. The yields of the products estimated by GLC were as follows: **4**, 2.0% (*Z*:*E*=97:3); methyl 3-phenylpropionate, 0.8%; styrene, 2.4%; unreacted (*Z*)-**1**, 52.2%; **5**, 7.5% (*ZZ*:*EE*=84:16); (*Z*)-1-phenyl-1-hexene (**6**), 19.4%. The products other than **5** were identified by the comparison of their GLC retention times, IR and/or ^{1}H-NMR spectra with those of authentic samples. **5** was isolated from the product mixture and identified by its spectral data. (*Z,Z*)-**5**: mp 62.5—63.5°C (lit,[8] mp 70.5°C); its IR spectrum was superimposable with the reported one.[11] (*E,E*)-**5**: mp 142—144°C; its IR and ^{1}H-NMR spectra were completely identical with Sadtler's standard spectra.

The authors, TS and MT, are grateful to Prof. Yoshinobu Takegami for his encouragement.

A Radical-induced Extrusion Reaction of 2-(Benzylsulfonyl)tropones to 2- and 4-Benzyltropones

Hitoshi TAKESHITA,* Norihide MATSUO,† and Hiroaki MAMETSUKA
Reserch Institute of Industrial Science, 86, Kyushu University, Kasuga-koen, Kasuga, Fukuoka 816
†*Graduate School of Engineering Sciences, 39, Kyushu University, Kasuga-koen, Kasuga, Fukuoka 816*
(Received November 16, 1983)

Synopsis. Several 2-(benzylsulfonyl)tropones were thermolized to give 2- and 4-benzyltropones. The radical mechanism for the thermolysis was elucidated by a deuterium-labelling experiment.

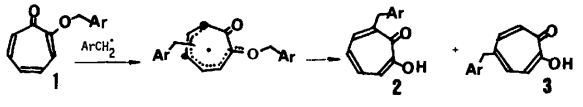
Upon thermolysis, 2-(benzyloxy)tropones (**1**) can be transformed to the 3- (**2**) and 5-benzyltropolones (**3**) in good yields *via* a radical chain reaction.[1] This behavior in the thermal reaction was unexpected, so we have undertaken the study with some other derivatives; the findings obtained from the sulfonyl derivatives will be described here.

The substrates, 2-(benzylsulfonyl)tropones (**4**), with some amounts of 2-(benzylsulfinyl)tropones (**5**), were prepared by the *m*-chloroperbenzoic acid (MCPBA)-oxidation of the crresponding 2-(benzylthio)tropones (**6**).

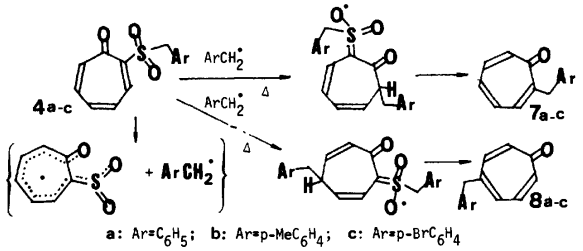
These **6** were thermally unreactive up to 195°C, where **1** caused a rearrangement to **2** and **3**, but the corresponding sulfones, **4**, have caused a new type of thermally-induced elimination: by heating at 180°C to 225°C in tetralin, 2-(benzylsulfonyl)tropone (**4a**) yielded 2-benzyltropone (**7a**), 23%, a pale yellow oil,[2] and 4-benzyltropone (**8a**), 7.5%, a pale yellow oil. The structure of **8a** was determined by chemical correlation. After a brief treatment with hydrazine hydrate in ethanol, **8a** yielded a 3:2-mixture of 2-aminotropones. By preparative thin-layer chromatography (PTLC) on silica gel, the mixture furnished 2-amino-4-benzyltropone (**9**) and 2-amino-5-benzyltropolone (**10a**),[3] which was converted to the previously prepared 5-benzyltropolone (**3a**)[1] by alkaline hydrolysis.

Two other sulfones, *p*-methyl (**4b**) and *p*-bromo (**4c**) derivatives, gave similar products upon the thermolysis.

The results of the reaction in dimethyl sulfoxide (DMSO) were different. **4b** yielded *p*-toluic acid in 65%,[4] and the radical mechanism is likely to be operative. Indeed, the thermolysis of a 1:1-mixture of **4c** and deuterio-**4a** (**4a**-*d*), which consisted of d_3, d_2-, d_1, and d_0-derivatives (19:58:20:3), in dioxane revealed an extensive cross-over recombination of two components in the mass spectra (Table 1) of the thermolysates (**7a**, **7c**, **8a**, and **8c**), to leave no ambiguity for the intermolecular path.



Scheme 1.



Scheme 2.

Consequently, the present reaction is another example of the radical substitution of benzyl group onto the tropone ring initiated by a homolysis of X–C bond of the C-2 position to form the delocalized species.

Experimental

Preparation of 2-(Benzylthio)tropone (6a). To an EtOH solution (3 cm³) of 2-mercaptotropone (200 mg) and NaOMe (100 mg), benzyl chloride (230 mg) was added and refluxed for 2 h on an oil bath. The mixture was evaporated, and the residue was chromatographed on a silica-gel column to give yellow needles, mp 98—99°C (**6a**). 237 mg (70%) [Found: C, 73.89; H, 5.38%. Calcd for $C_{14}H_{12}OS$: C, 73.65; H, 5.30%. δ[5]= 4.00 (2H, s) and 6.7—7.4 (10H, m). δ(C)=36.7, 127.5 (2C), 128.6 (2C), 128.9 (2C), 129.9, 132.6, 134.7 (2C), 136.1, 158.7, and 183.2. ν: 1615, 1555, 1460, 1385, 985, 915, 840, and 765 cm^{-1}].

2-(p-Methylbenzylthio)tropone (6b). This was prepared as colorless needles, mp 98—100.5°C [Found: C, 74.20; H, 5.79%. Calcd for $C_{15}H_{14}OS$: C, 74.35; H, 5.82%. δ=2.29 (3H, s), 3.98 (2H, s), and 6.7—7.3 (9H, m)], in 87% yield.

2-(p-Brmobenzylthio)tropone (6c). This was prepared as yellow needles, mp 133—135°C [Found: 54.46; H, 3.64%. Calcd for $C_{14}H_{11}OSBr$: C, 54.74; H, 3.61%. δ=4.02 (2H, s) and 6.8—7.5 (9H, m)], in 73% yield.

MCPBA-oxidatin of 6a. a): To a $CHCl_3$ solution (8 cm³) containing **6a** (455 mg, 2 mmol), MCPBA (740 mg, 3.4 mmol) dissolved in $CHCl_3$ (16 cm³) was added drop by drop for 4 h, and kept for an additional 24 h at 15—25°C. Then the separated crystals, MCBA, were filtered off, and the filtrate was washed with aqueous $NaHSO_3$, $NaHCO_3$, and NaCl, and dried on $MgSO_4$. Silica gel column chromatography of the organic solution afforded **4a**, 347 mg (67%), colorless needles, mp 113—114°C [Found; C, 64.83; H, 4.71%. Calcd for $C_{14}H_{12}O_3S$: C, 64.60; H, 4.65%. δ=4.90 (2H, s), 7.0—7.5 (9H, m), and 7.8—9.0 (1H, m). δ(C)=60.9, 127.6, 128.5 (2C), 128.7, 130.7 (2C), 131.5, 136.0, 139.5, 140.4, 143.7, 146.0, and 182.4. ν: 1635, 1585, 1305, 1270, 1215, 1145, 1125, and 780 cm^{-1}], and **5a**, 107 mg (22%), a colorless oil [Found: M$^+$, 244.0544. Calcd for $C_{14}H_{12}O_2S$: M$^+$, 244.0558. δ=3.95 (1H, d, J=12 Hz), 4.40 (1H, d, J=12 Hz), and 6.8—7.6 (10H, m). δ(C)=57.6, 128.0 (2C), 129.6, 130.3 (2C), 132.7, 135.5, 135.9, 137.3, 140.9, 155.9, and 183.6. ν: 1620, 1590, 1555, 1260, 1070, 1050, 875, 860, and 760 cm^{-1}].

TABLE 1. THE DEUTERIUM CONTENTS (%) IN THE PRODUCTS OF THE CROSS-OVER THERMOLYSIS OF **4a**-*d* AND **4c** DETERMINED BY MASS SPECTROMETRY

Products	d_0	d_1	d_2	d_3
7a	43.8	28.6	20.8	6.8
7c	48.9	35.8	10.4	4.9
8a	32.3	30.0	24.5	13.2
8c	35.4	26.7	22.8	15.0

b): Similarly, the oxidation of **6a** (115 mg, 0.5 mmol) in $CHCl_3$ (8 cm^3) with MCPBA (216 mg, 1.0 mmol) at 15—25°C for 24 h yielded 118 mg (91%) of **4a**.

2-(p-Methylbenzylsulfonyl)tropone (4b). This was prepared as colorless needles, mp 173—175°C [Found: C, 65.38; H, 5.12%. Calcd for $C_{15}H_{14}O_3S$: C, 65.67; H, 5.14%. δ= 2.26 (3H, s), 4.76 (2H, s), 6.8—7.3 (8H, m), and 7.83 (1H, dd, J=8, 2 Hz)], in 80% yield.

2-(p-Bromobenzylsulfonyl)tropone (4c). This was prepared as yellow needles, mp 135—137°C [Found: M^+, 337.9598 and 339.9590. Calcd for $C_{14}H_{11}O_3SBr$: M^+, 337.9612 and 339.9592. δ=4.77 (2H, s), 6.8—7.7 (8H, m), and 7.84 (1H, m)], in 99% yield.

Thermolysis of 4a. A tetralin solution (2 cm^3) of **4a** (136 mg) was heated at 215°C for 1.5 h on an oil bath under N_2 atmosphere. During the reaction, an intermittent evolution of SO_2 occurred. The mixture was then fractionated with a short silica-gel column and with PTLC to furnish **7a**, a colorless oil [Found: M^+, 196.0877. Calcd for $C_{14}H_{12}O$: M^+, 196.0888. δ=3.94 (2H, s), 6.8—7.3 (5H, m), and 7.21 (5H, s). δ(C)=40.5, 126.4, 128.5 (2C), 129.5 (2C), 132.6, 133.6, 135.4 (2C), 139.0, 140.6, 154.7, and 186.6], 24 mg (23%), which was identical with the sample prepared by the Nozoe's method,[2] and **8a**, a colorless oil [Found: M^+ 196.0889. δ=3.82 (2H, s) and 6.7—7.4 (10H, m). δ(C)=45.7, 126.9, 128.8 (2C), 128.9 (2C), 133.0, 136.2 (2C), 138.9, 140.3, 141.3, 148.2, and 187.6], 8 mg (7.5%).

The Reaction of 8a with Hydrazine Hydrate. An EtOH solution (10 cm^3) of **8a** (28 mg) was refluxed with 80% N_2H_4 hydrate (30 mg) for 2 h. Then, the mixture was fractionated with $CHCl_3$ and water, and the organic extract was purified by PTLC on silica gel to yield a yellow oil, **9**, 12 mg [Found: M^+, 211.0998. Calcd for $C_{14}H_{13}ON$: M^+, 211.0997. δ=3.88 (2H, s), 5.86 2H, m), 6.70 (1H, br. s), and 7.0—7.4 (8H, m)], and **10**, 9 mg [Found: M^+, 211.0998. δ=3.88 (2H, s), 5.82 (2H, br. s), 6.76 (1H, d, J=10 Hz), and 6.9—7.3 (8H, m)].

Hydrolysis of 10 to 3a. An EtOH solution (2 cm^3) of **10** (5 mg) and KOH (5 mg) was refluxed for 2 h. The mixture was then evaporated to dryness, acidified with dil HCl, and extracted with $CHCl_3$. Colorless needles, mp 119—120°C, 5 mg, thus obtained were identical in every respect to the previously prepared sample of **3a**.[1]

Thermolysis of 4b. A tetralin solution (5 cm^3) of **4b** (90 mg) was heated at 200°C for 1.7 h. The products isolated by PTLC were **7b**, a colorless oil, 19 mg (28%) [Found: M^+, 210.1047. Calcd for $C_{15}H_{14}O$: M^+ 210.1045. δ=2.30, 3.90 (2H, s), and 6.7—7.3 (9H, m)], and **8b**, a colorless oil, 5.5 mg (8%) [Found: M^+, 210.1043. δ=2.32 (3H, s), 3.78 (2H, s), and 6.7—7.4 (9H, m)].

Thermolysis of 4b in DMSO. A DMSO solution (0.3 cm^3) of **4b** (50 mg) was heated at 180°C for 1.5 h. The mixture was diluted with ether, and extracted with aqueous KOH to give 16 mg (65%) of colorless crystals, mp 178—179°C, which were identical with *p*-toluic acid.

Thermolysis of 4c. A tetralin solution (5 cm^3) of **4c** (170 mg) was heated at 225°C for 2 h. The products isolated by PTLC were **7c**, a colorless oil, 27 mg (20%) [Found: M^+, 274.0001 and 275.9958. Calcd for $C_{14}H_{11}OBr$: M^+, 273.9993 and 275.9973. δ=3.90 (2H, s) and 6.8—7.4 (9H, m)], and **8c**, a colorless oil, 1 mg (0.7%) [Found: M^+, 274.0009 and 275.9971. δ=3.78 (2H, s) and 6.7—7.5 (9H, m)].

Thermolysis of a 1:1-Mixture of 4a-d and 4c. A decalin solution (4 cm^3) of **4a**-*d* (123 mg) and **4c** (150 mg) was refluxed for 1.5 h on an oil bath under an N_2 stream. The mixture was then fractionated on a silica-gel column to give the thermolysates; their isotope distributions are given in Table 1.

Synopsis. Reaction of 2-phenyl-4*H*-1-benzothiopyran-4-ones and related compounds with chloromethyl methyl ether and fuming sulfuric acid gave mainly 3-chloromethyl compound, whereas chloromethylation of methoxy-substituted thioflavones took place at another position or gave tris(chloromethyl) compound. 3-(Chloromethyl)thioflavone could be easily converted into various 3-(substituted methyl)-thioflavones which showed significant antimicrobial activity against *Trichophytons*.

We have attempted to prepare some 2-phenyl-4*H*-1-benzothiopyran-4-one (thioflavone) (**1**) which would be biologically and pharmacologically effective compounds.[1,2] We now examine the introduction of specific substituent groups (chloromethyl and acetoxymethyl) into the 3-position of **1**, because the introduction of these groups into the corresponding position of 1,4-naphthoquinones[3] and 4*H*-1-benzothiopyran-4-one 1,1-dioxides[4] is required for bioactivation. However, it is well known that no chloromethylation directly occurs at the 3-position of 4*H*-1-benzothiopyran-4-ones (thiochromones).[4] 3-(Chloromethyl)thioflavone **2a** may be a key compound, one which can be efficiently converted into other pharmacologically active compounds. Few reports are available on the preparation of the title compounds. In this paper, we report the direct chloromethylation of various thioflavones and related compounds.

A common chloromethylation of thiochromone 1,1-dioxides with formaldehyde and hydrogen chloride is well known; however, the thiochromone[4] and **1a** are not chloromethylated by the same method. Chloromethylation of **1a**[6] was accomplished by use of chloromethyl methyl ether and 60% fuming sulfuric acid, which were previously applied in the chloromethylation of benzyl chloride.[5] The chloromethyl derivative was determined to be 3-(chloromethyl)thioflavone **2a** on the basis of ^{1}H-NMR spectrum, in which

Scheme 1.

a signal for a chloromethyl group appeared at δ 4.52 and a signal for a vinyl proton (δ 7.20) in the 3-position of **2a** disappeared. When the chloromethylation was carried out at 75°C, compound **3a** was isolated as the main product. 2-(Methyl)thiochromone **1b** and other thioflavones **1c—1i** were chloromethylated under the same conditions. In the case of 6-(methoxy)thioflavone **1d**, which possesses a powerful electron-donating group, chloromethylation did not take place at the 3-position, but at the 5-position. The ^{1}H-NMR signal for a chloromethyl group of product **2d** was shifted downfield to δ 5.58. On the other hand, a weak electron-donating methyl group at the same position led to 3-chloromethylated product **2c**. Methyl group and methoxycarbonyl group at the 8-position also led to 3-chloromethylated products **2h** and **2f**, respectively. Compound **3f** was isolated as a by-product. Chloromethylation of the thioflavone was also influenced by a substituent group in a phenyl group at the 2-position. Methoxyl and methyl substituent in the phenyl group led to tris(chloromethyl) compound **2e**, bis(chloromethyl) compound **2i**, and **2j**, respectively. The structure of compound **2j** was determined to be 3-(chloromethyl)-3'-(hydroxymethyl) derivative by means of its ^{1}H-NMR signal, which was shifted upfield to δ 2.44 for a OH proton of hydroxymethyl group, while the signal of the same group at the 3-position of compounds **3a**, **3b**, and **3f** appeared at δ 3.27—3.63. An electron-withdrawing nitro group at the 4'-position led to 3-chloromethyl compound **2g**. These results show that reaction of the thioflavone with chloromethyl methyl ether and fuming sulfuric acid generally gives only a 3-chloromethyated compound. The same chloromethylation of **1b**, flavone, and 2-methylchromone gave 3-chloromethyl derivatives **2b**, **4**, and **5** in 19—76% yields, respectively. New 3-(substituted methyl)thioflavones were easily prepared by reaction of **2a** with nucleophilic reagents, as shown in Scheme 1. For examples, reaction of **2a** with an excess of aniline, morpholine, bis(2-hydroxyethyl)amine, and sodium alkoxides[7] gave compounds **8—13**, respectively. The chlorine atom of a chloromethyl group of flavone derivative **4** was also converted into ethoxyl and acetoxyl group (compounds **6** and **7**) in good yields. The described method should be advantageous for direct transformation of thioflavones or flavone into their 3-(substituted methyl) derivatives.

An introduction of a chloromethyl group in the 3-position of **1a** resulted in significant antimicrobial activity against *Trichophytons* (MIC 0.195 μg/ml). 3-(Substituted methyl)thio-flavones **3a**, **9**, and **13** (MIC 0.00488—6.25 μg/ml), as well as 3-(alkoxymethyl)thioflavone **11**,[7] also exhibited activity against *Trichophytons*. On the other hand, the MIC of 3-(substituted methyl) flavones (MIC 1.56—25.0 μg/ml) became higher (*ca.* 10—200-fold) than that of the corresponding thioflavones.

Experimental

All the melting points are uncorrected. ^{1}H-NMR spectra were taken on a JEOL JNM-MH-100 spectrometer with tetramethylsilane as an internal standard. IR spectra were recorded on a Shimazu IR-420 spectrometer using KBr pellets. Elemental analyses were recorded on a Yanaco CHN recorder MT-2. Mass spectra were recorded on a Hitachi RMU-6E mass spectrometer operating at 80 eV.

2-Phenyl-4H-1-benzothiopyran-4-ones and 2-Methyl-4H-1-benzothiopyran-4-one (1a—1i). Thioflavones and 2-methylthiochromone were generally prepared by Bossert's method.[6] The physical data of new derivative **1i** are as follows. **1i**; mp 120—121°C; 1608 cm^{-1} (C=O); ^{1}H-NMR ($CDCl_3$) δ=2.42 (s, 3H, CH_3), 7.20—7.36 (m,3H), 7.48—7.70 (m, 5H), and 8.57 (m, 1H, H-5); MS m/z (rel intensity) 252 (M^+, 100), 224 (96), and 223 (26). Anal. ($C_{16}H_{12}OS$) C, H.

General Procedure for Chloromethylation. Fuming sulfuric acid (60%; 14 ml) was added dropwise to a solution of approriate thioflavone **1** (35 mmol) in chloromethyl methyl ether (56 ml) with stirring. The reaction mixture was stirred at 60°C for 24 h, and then poured into cold water. The oily precipitate soon solidified, and the resulting solid was collected and washed with water. The crude product was chromatographed on silica gel, using benzene as an eluent, to give **2**. Recrystallization from benzene/hexane (10:1) gave a pure chloromethyl derivative **2**. The yields, mp's and spectral data of **2a—2j** and **3a, b, f** are summarized in Table 1.

Table 2. Physical Data of 3-(Substituted Methyl)thioflavones

a) Isolated yield

Compounds **4** and **5** were similarly prepared from flavone[8] and 2-methylchromone,[9] respectively. Compound **4**: yield 47%; mp 155—156°C (lit,[10] 156°C). Compound **5**: yield 76%; mp 103—104°C (lit,[10] 103—108°C).

3-(Substituted Methyl)-2-phenyl-4H-1-benzothiopyran-4-ones and 3-(Substituted Methyl)-2-phenyl-4H-1-benzopyran-4-ones (6—13). A mixture of compound **2a** and appropriate amine, sodium alkoxide or sodium propionate was heated at reflux for 2—5 h in dioxane, alcohol or propionic acid. The mixture was worked up as described above to give pure compounds **8—13**. The physical data of these compounds are listed in Table 2.

Compounds **6** and **7** were similarly prepared. 3-(Ethoxymethyl)flavone **6**: yield 75%; mp 102—114°C; 1640 cm^{-1} (C=O); ^{1}H-NMR ($CDCl_3$) δ=1.31 (t, J=7 Hz, 3H, -$CH_2\underline{CH_3}$), 3.73 (q, J=7 Hz, 2H, -$\underline{CH_2}CH_3$), 4.48 (s, 2H, -CH_2O), 7.52—7.84 (m, 6H), 7.99—8.13 (m, 2H), and 8.45 (d, J=7.5 Hz, 1H, H-5). Anal. ($C_{18}H_{16}O_3$) C, H. 3-(Acetoxymethyl)flavone **7**: yield 80%; mp 118—119°C (lit,[11] 115—118°C).

Determination of in Vitro Antimicrobial Activity. The minimal inhibitory concentrations (MIC) were determined by a standard two-fold serial dilution method using agar media for *Trichophyton rubrum, Trichophyton mentagrophytes,* and *Candida albicans.*

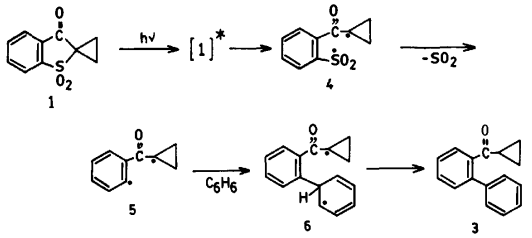
Department of Chemistry, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received November 26, 1983)

Synopsis. The photolysis of spiro[benzo[*b*]thiophene-2(3*H*),1′-cyclopropan]-3-one 1,1-dioxide (**1**) in benzene afforded 2-biphenylyl cyclopropyl ketone with extrusion of sulfur dioxide, whereas the irradiation of **1** in toluene or *p*-xylene formed photoreduced dimer and bibenzyl or 4,4′-dimethylbibenzyl, respectively. The photolysis of spiro-[benzo[*b*]thiophene-2(3*H*),1′-cyclopropan]-3-one in benzene afforded the valence isomer 2,3-dihydro[1]benzothieno[3,2-*b*]-furan.

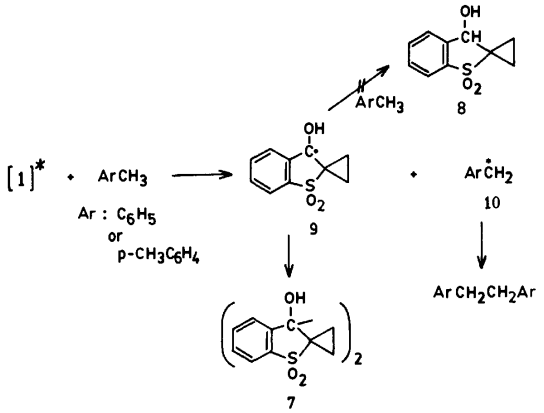
In recent years, considerable attention has been focused on the photochemistry of five-membered heterocyclic ring systems.[1] We reported that the photochemical reactions of 2-aryl-1,2-benzisothiazol-3(2*H*)-ones in benzene give dibenzo[*b*,*f*][1,4]thiazepin-10(11*H*)-ones,[2] whereas the photolyses of 2-substituted 1,2-benzisothiazol-3(2*H*)-one 1,1-dioxides in benzene give *N*-substituted *o*-phenylbenzamides with extrusion of sulfur dioxide.[3] In our systematic investigations of photochemical reactions of benzisothiazoles and their analogues, we wish to report here the photochemical behavior of spiro[benzo[*b*]thiophene-2(3*H*),1′-cyclopropan]-3-one 1,1-dioxide (**1**) and spiro[benzo[*b*]-thiophene-2(3*H*),1′-cyclopropan]-3-one (**2**). These are expected to be photoreduced at the carbonyl group and to break their bonds at spiro carbon-sulfur atom or at the highly-strained three membered ring.

When a solution containing of **1** in benzene was irradiated under argon with light of wavelength >280 nm, an extremely clean conversion to a single photoproduct occurred. This product was deduced to be 2-biphenylyl cyclopropyl ketone (**3**) on the basis of its straightforward spectral properties (see experimental section). The reaction is quite similar to the photoreactions of 2-substituted 1,2-benzisothiazol-3(2*H*)-one 1,1-dioxides in benzene,[3] and hence the reaction could be accounted for by a homolytic process *via* radical intermediates **4**, **5**, and **6**, as shown in Scheme 1.



Scheme 1.

Meanwhile, when **1** was irradiated in toluene or *p*-xylene photoreduced dimer, 3,3″-bi[spiro[benzo[*b*]-thiophene-2(3*H*),1′-cyclopropane]]3,3″-diol 1,1,1″,1″-tetraoxide (**7**) was formed with bibenzyl or 4,4′-dimethylbibenzyl, respectively, in good yield. No detectable quantities of such photoreduced alcohol as spiro-[benzo[*b*]thiophene-2(3*H*),1′-cyclopropan]-3-ol 1,1-dioxide (**8**) could be observed in the reaction mixture. The photoreaction of **1** in these solvents suggests that **1** in the photoexcited state abstracts the hydrogen atom from the methyl group of toluene or *p*-xylene to give radical **9** and benzyl (or *p*-methylbenzyl) radical (**10**) faster than a homolytic cleavage to **4** occurs. The absence of the alcohol **8** suggests that radical **9** has no ability to abstract the hydrogen atom from the methyl group of toluene or *p*-xylene and survive until a coupling reaction occurs to give dimer **7** (Scheme 2).



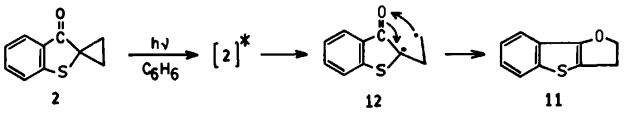
Scheme 2.

The photolysis of **1** was also carried out in 2-propanol and the photoreduced dimer **7** and pinacol were obtained. The reaction mechanism will be similar to the photolysis in toluene or *p*-xylene, involving the abstraction of the tertiary hydrogen from 2-propanol by **1** in the photoexcited state.

The photoreaction of **1** behaved in quite different manners in benzene, and in toluene, *p*-xylene, or 2-propanol. **1** in the photoexcited state abstracts a hydrogen when the solvents are hydrogen donating, whereas in benzene **1** cleaves the C–S bond homolytically, affording radical intermediates **4** and **5**. The photoreaction of 2-substituted 1,2-benzisothiazol-3(2*H*)-ones in benzene or 2-propanol, however, always included the extrusion of sulfur dioxide.[3] It is also noteworthy that **7** is the sole photoreduced product and no formation of any product like **8** is observed in the photolysis of **1**, in contrast to the reported photoreactions of phthalimides.[4]

The photoreaction of **2** in benzene afforded 2,3-dihydro[1]benzothieno[3,2-*b*]furan (**11**) as the only isolable product. The reaction mechanism will be accounted for by the homolytic reaction shown in Scheme 3.

In this case, the reaction seems to proceed *via* the homolytic cleavage of the strained cyclopropane ring affording radical **12** and the following ring construction to give **11**. The photolysis of **2** in toluene



Scheme 3.

or *p*-xylene did not form any isolable product in spite of the starting material was consumed.

Experimental

Measurements. Melting points are uncorrected. IR and UV spectra were determined on a Hitachi EPI-G2 and a Hitachi 220A spectrophotometer. The proton magnetic spectra were recorded at 60 MHz by using a Hitachi R-20B spectrometer with TMS as an internal standard in $CDCl_3$. Mass spectra were determined with a JMS-DX300 high resolution mass spectrometer. Elemental analyses were carried out by using a Perkin-Elmer 240 elemental analyzer.

Materials. Spiro[benzo[*b*]thiophene-2(3*H*),1′-cyclopropan]-3-one (**2**) was prepared from *o*-mercaptobenzoic acid (15.4 g) and α-bromo-γ-butyrolactone (20.6 g) according to the method described in the literature:[5] yield 10.5 g (65%) as colorless prisms form hexane–dichloromethane, mp 69—70°C (lit, mp 70°C).[6] IR (KBr) 1680, 1590, 1450, 1320, 1080, 980, and 740 cm^{-1}; NMR ($CDCl_3$) δ 1.3—1.9 (4H, m) and 7.2—7.9 ppm (4H, m); UV (EtOH) 367 ($\varepsilon=2.67\times10^3$), 350 ($2.60\times10^3$), 267 ($5.50\times10^3$), 258 ($6.58\times10^3$), 237 ($3.36\times10^4$), and 208 nm ($1.29\times10^5$). Spiro[benzo[*b*]thiophene-2(3*H*),1′-cyclopropan]-3-one 1,1-dioxide (**1**) was prepared by the oxidation of **2** (5.2 g) with 13.7 g of perbenzoic acid in dichloromethane at 0°C: yield 5.6 g (91%) as colorless prisms from hexane–dichloromethane, mp 198—199°C (lit, mp 202°C).[6] IR (KBr) 1720, 1590, 1460, 1315, 1300, 1155, and 990 cm^{-1}; NMR ($CDCl_3$) δ 1.30—2.00 (4H, m) and 7.40—8.10 ppm (4H, m); UV (MeOH) 292 ($\varepsilon=6.55\times10^2$), 283 ($7.74\times10^2$), 246 ($9.64\times10^3$), and 210 nm ($3.35\times10^4$).

Photolysis of 1 in Benzene. A solution containing 200 mg of **1** in 220 cm^3 of benzene was irradiated under argon with a 450W medium-pressure mercury lamp (Hanovia) through a Corex filter sleeve for 8 h. Removal of the solvent under reduced pressure left a pale-yellow oil which was subjected to the chromatography on silica gel, using benzene as the eluent. 2-Biphenylyl cyclopropyl ketone (**3**) was isolated (130 mg, 86%)[7] with 58 mg of unreacted starting material **1**. The structure of **3** was assigned based on the following data: mp 81—82°C (from hexane); IR (KBr) 3020, 1670, 1595, 1450, 1435, 1280, 1040, and 990 cm^{-1}; NMR ($CDCl_3$) δ 0.50—0.72 (2H, m), 1.00—1.16 (2H, m), 1.64—1.88 (1H, m), 7.56 (5H, s), and 7.48—7.78 ppm (4H, m); Mass (20 eV) *m/z* 222 (M^+), 194, 165, 153, 69, and 41. Found: C, 86.39; H, 6.23%. Calcd for $C_{16}H_{14}O$: C, 86.45; H, 6.35%.

Photolysis of 1 in Toluene. A solution containing 200 mg of **1** in 220 cm^3 of toluene was irradiated under argon through a Pyrex filter sleeve for 18 h. After removal of the solvent, the photolysate was subjected to the chromatography on silica gel using a 2:1 hexane–ether mixture as the eluent to give bibenzyl (62 mg, 71%) and **7** (140 mg, 70%). The structure of bibenzyl was verified by comparison with an authentic sample, and that of **7** was identified on the basis of the following data: mp 276°C (decomp); IR (KBr) 3450, 3030, 1600, 1495, 1455, 1290, 1180, 1165, 1155, 1120, 1100, 1060, 1050, and 980 cm^{-1}; NMR (CD_3SOCD_3) δ 0.91—1.6 (4H, m), 6.8—8.2 ppm (4H, m); Mass *m/z* 418 (M^+), 362, 314, 209, 152, 136, 104, and 76. Found: *m/z* 209.02719. Calcd for $C_{10}H_9O_3S$: *m/z* 209.02719.

Photolysis of 1 in p-*Xylene.* A solution containing 200 mg of **1** in 220 cm^3 of *p*-xylene was irradiated under argon through a Pyrex filter sleeve for 18 h. After evaporation of the solvent, the photolysate was subjected to the chromatography on silica gel using a hexane–ether mixture as the eluent to give 4,4′-dimethylbibenzyl (78 mg, 77%) and **7** (150 mg, 75%). The structure of 4,4′-dimethylbibenzyl was verified by comparison with an authentic sample.

Photolysis of 1 in 2-Propanol. A solution containing 200 mg of **1** in 220 cm^3 of 2-propanol was irradiated under argon through a Pyrex filter sleeve for 16 h. After removal of the solvent, the photolysate was subjected to the chromatography on silica gel using a hexane–ether as the eluent to give pinacol (41 mg, 72%) and **7** (157 mg, 78%).

Photolysis of 2 in Benzene. A solution containing of 200 mg of **2** in 220 cm^3 of benzene was irradiated under argon through a Pyrex filter for 2 h. Removal of the solvent under reduced pressure left a dark oil which was purified by thick-layer (preparative thin layer) chromatography using a 1:1 mixture of dichloromethane–benzene as the eluent. **11** (9.7 mg, 9%)[7] was isolated with 93 mg of unreacted starting material. The structure of **11** was identified by comparison with an authentic sample.[8]

The Preparation of *N*-Protected Amino Alcohols and *N*-Protected Peptide Alcohol by Reduction of the Corresponding Esters with Sodium Borohydride. An Improved Procedure Involving a Slow Addition of a Small Amount of Methanol

Kenso SOAI,* Hidekazu OYAMADA, and Masako TAKASE

Department of Applied Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162

(Received December 19, 1983)

Synopsis. Esters of *N*-protected amino acids and an *N*-protected peptide were reduced selectively to the corresponding alcohols in high yields using lesser amounts of sodium borohydride than does the conventional method by the slow addition of methanol to the mixture of ester and $NaBH_4$ in *t*-butyl alcohol or tetrahydrofuran at 50°C.

N-Protected amino alcohols (**1**) and *N*-protected peptide alcohols (**2**) have received considerable recent attention. **1** can be utilized as intermediates in the preparation of amino aldehydes,[1] which are inhibitors of proteolytic enzymes[2] and are important synthetic intermediates.[3] On the other hand, **2** are intermediates of peptide aldehydes of which biological activity is different from the corresponding peptides.[4] **2** can also be used for the determination of carboxy (*C*-) terminals of peptides.[5]

In connection with the synthesis of **1** and/or **2**, following three types of the methods have been reported: (1) Reduction of carboxylic acid by a borane–tetrahydrofuran (THF) complex.[6] In principle, this method is not applicable to the synthsis of **2**, because the borane complex is known to reduce amide groups (peptide bonds).[7] (2) Reduction of activated ester, azide, acid anhydride *etc.*[8] The procedure needs the conversion of carboxylic acids to the appropriate activated compounds, which are often sensitive toward hydroxy or mercapto groups.[9] In the synthesis from methyl or ethyl esters, an hydrolysis step from ester to acid should be additionally required. (3) Reduction of common esters such as methyl or ethyl esters. We would like to point out that carboxy (*C*-) terminal groups are often protected as methyl or ethyl esters in peptide synthesis. Direct reduction of these esters is preferable to the type (2) reaction because the hydrolysis step of the esters is not required. Reduction of these esters by lithium aluminium hydride is accompanied by the reduction of the peptide bonds.[7] Reduction by sodium borohydride ($NaBH_4$) in water[10] or in 50% aqueous ethanol[11] has been reported. However, these methods require the use of a large excess of $NaBH_4$ (4—25 mol equiv) and relatively long reaction time (3 h—2 d). Moreover, the possibility of alkaline hydrolysis of the esters is present because the solvents contain water.

During our continuing study on the stereoselectivity[12a] and chemoselectivity[12b–e] of metal borohydride reductions, we have noticed that the role of MeOH is important.

In this paper, we wish to describe a convenient method for the repid and selective reduction of esters of *N*-protected amino acid and *N*-protected peptide with $NaBH_4$. The essential part of the procedure is the addition of a small amount of MeOH to the mixture of esters and $NaBH_4$.

TABLE 1. COMPARATIVE STUDY ON THE REDUCTION OF ETHYL ESTER OF *N*-(*t*-BUTOXYCARBONYL)-L-PHENYLALANINE (**3**) WITH SODIUM BOROHYDRIDE

Solvent	Molar ratio $\frac{NaBH_4}{3}$	Temp /°C	Time /min	Yield /% of **4**
50% aqueous EtOH[a]	2.0	50—55	30	61
Slow addition of MeOH to THF	2.0	50—55	30	88

a) See Ref. 11.

In the first place, we compared the effectiveness of the present procedure with the conventional method.[11] The results are shown in Table 1. Using the ethyl ester of *t*-butoxycarbonyl-L-phenylalanine [Boc-L-Phe(OEt), **3**] as a model compound, it was reduced with $NaBH_4$ (2 mol equiv) in THF by the addition of a small amount of MeOH at 50—55°C for 30 min. The yield of Boc-L-phenylalaninol (**4**) was 88%. On the other hand, reduction of **3** in 50% aqueous EtOH[11] under the same reaction conditions (amount of $NaBH_4$, reaction temperature, time) afforded only 61% of **3** in our hands. Therefore the present procedure would seem to be superior to the conventional method.

This procedure using a slow addition of MeOH was applied to the reduction of esters of other *N*-protected amino acids and peptide. As shown in Table 2, even a hindered peptide (2*S*, 2′*S*)-(*N*-benzyloxycarbonylprolyl)-proline methyl ester was found to be reduced selectively in 84% yield. *t*-Butyl alcohol instead of THF was also effective for the conversion of esters to the corresponding alcohols.

TABLE 2. SYNTHESIS OF *N*-PROTECTED AMINO ALCOHOL (**1**) AND PEPTIDE ALCOHOL (**2**)

Ester	Alcohol **1,2**	$\frac{NaBH_4}{ester}$	Solvent[a]	Yield /%[b]	Mp or Bp θ_m or θ_b °C	$[\alpha]_D^{20}$ (*c*, solvent)
Z-L-Phe-OEt		2.5	A	94	90—91 (90—92)[c]	−41.8°[c] (1.4, EtOH)
Boc-L-Phe-OEt (**3**)	**4**	2.0	B	88	94.5	−24.6°[d] (1.1, $CHCl_3$)
Z-L-Pro-OMe		2.5	A	89	150—151/ 0.005 mmHg	−39.5°[e] (1.7, $CHCl_3$)
Z-L-Pro-L-Pro-OMe (**5**)	**6**	2.4	A	84	114—114.5	−33.5° (1.0, $CHCl_3$)

a) A; *t*-BuOH:MeOH=5:1 (v/v). B; THF:MeOH=5:1 (v/v). b) Yields of the isolated products. c) Lit, $[\alpha]_D^{20}$ −41.5°(*c* 1.4, EtOH). A.Ito, *Chem. Pharm. Bull.*, **23**, 3081(1975). d) Lit, $[\alpha]_D^{23}$ −0.80° (*c* 1.1, $CHCl_3$). See Ref. 6. e) Lit, $[\alpha]_D$ −42.4°(*c* 1.0, $CHCl_3$). J.Cassel and A.Furst, *Helv. Chim. Acta*, **59**, 1917(1976).

As described above, esters of *N*-protected amino acids and peptides were reduced selectively to the corresponding alcohols in high yields with $NaBH_4$ in THF or *t*-BuOH by the addition of a small amount of MeOH. The present procedure requires a lesser amount of $NaBH_4$ and shorter reaction time than the conventional method.[11] Moreover it avoids the possibility of the hydrolysis of the esters during the reduction in an aqueous medium,[11] neither does it require alkaline earth metal salt additives.[13]

Experimental

All of the melting points were uncorrected. Tetrahydrofuran (THF) was distilled from lithium aluminium hydride prior to use. *t*-Butyl alcohol was purchased from Kanto Chemical Co., and was used without further purification. Reagent grade methanol was dried over molecular sieves (3 Å) and used without distillation.

General Procedure. MeOH (0.8 ml) was added dropwise over a period of 20 min to a mixture of ester of *N*-protected amino acid or peptide (1.0 mmol) and $NaBH_4$ (2.0—2.5 mmol) in *t*-BuOH or THF (4 ml) at 50—55 °C. The mixture was stirred for 10—25 min, then water (2.0 ml) was added to the reaction mixture. Most of the organic solvent was evaporated under reduced pressure. Brine (3 ml) was added, and the mixture was extracted with ether (5×8 ml). The extract was washed with brine (2×3 ml), dried over anhydrous sodium sulfate, then evaporated. The residue was purified by distillation or on silica gel TLC (ethyl acetate: MeOH=15:1 as developing solvent). The physical properties of the products are summarized in Table 2. Yields of the alcohols were 84—94%. Structures of known compounds were confirmed by NMR and IR spectra.

(*2S, 2'S*)-(N-*Benzyloxycabonylprolyl*)*prolinol* (**6**). Z-L-Pro-L-Pro-OMe (**5**)[14] was reduced according to the general procedure. **6** was obtained in 84% yield. Mp 114—114.5 °C. $[\alpha]_D^{20}$ −33.5° (*c* 1.0, chloroform). ^{1}H-NMR ($CDCl_3$): δ=1.2—2.4 (m, 8H), 3.0—4.7 (m, 9H), 5.1 (s, 2H), 7.25 (s, 5H); IR: 3520, 2960, 1700, 1650, 1440, 1365, 1180 cm^{-1}; MS: *m/z* 332 (M^+). Found: C, 65.09; H, 7.30; N, 8.45%. Calcd for $C_{18}H_{24}N_2O_4$: C, 65.04; H, 7.28; N, 8.43%.

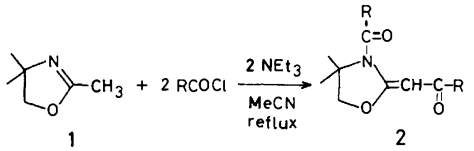
(Received December 19, 1983)

Synopsis. Acylation of 2,4,4-trimethyl-2-oxazoline with acid chlorides having no α-proton and triethylamine gave *C,N*-diacylated products. Hydrolysis of the products with potassium hydroxide gave the enols of 2-acylmethyl-oxazolines, which were selectively *C*-monoalkylated by alkyl halides.

β-Keto esters have been well known as useful starting materials for organic syntheses, and various synthetic methods of β-keto esters were developed.[1] Although 2-oxazoline is also known as the protecting group of carboxylic acids,[2] oxazoline derivatives of β-keto acids are scarcely known. Since 2-oxazoline group can be converted into a variety of functional groups more easily than esters,[3-6] the oxazoline derivatives of β-keto acids are expected to be more versatile starting materials than the corresponding β-keto esters. Here we report a convenient synthesis of this class of compounds by acylation of 2,4,4-trimethyl-2-oxazoline (**1**), which is easily obtained from acetic acid.[7]

Results and Discussion

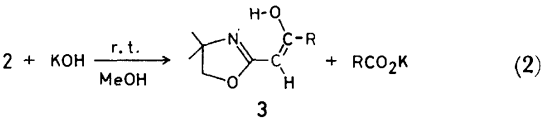
When **1** was refluxed with two equivalents of benzoyl chloride in the presence of triethylamine in acetonitrile for 3 h, diacylated product **2a** was obtained in 97% yield. By the similar treatment of **1** with other acid chlorides having no α-proton, **1** was converted into the corresponding products **2b—2d** in good yields (Eq. 1). The acid chlorides having α-protons such as acetyl and isobutyryl chlorides did not give **2** due to decomposition of the reagents under the reaction conditions. IR spectra (Table 1) of **2a—2c** show carbonyl bands at 1675—1690 cm^{-1}, which indicate that they are amides (*C,N*-diacylated products) rather than esters (*C,O*-diacylated products). NMR spectra (Table 2) of **2a—2c** suggest that they are mixtures of two geometrical isomers in the solutions. The carbonyl band of **2d** is found at higher frequency, 1750 cm^{-1}. This can be attributed to poor conjugation between the oxazoline nitrogen and the bulky pivaloyl group.



1 2 (1)

2a (R=C_6H_5) 97%, **2b** (R=$C_6H_4NO_2$-p) 99%,
2c (R=2-furyl) 82%, **2d** (R=t-C_4H_9) 90%.

The diacylated products, **2a—2c** were easily converted into unique enols (**3a—3c**) of 2-acylmethyl-2-oxazolines in good yields by treatment with excess methanolic potassium hydroxide at room temperature (Eq. 2). Hydrolysis of **2d** was carried out by refluxing with potassium hydroxide in ethanol for 30 h. The structure of **3** was determined based on the results of IR, NMR, and elemental analyses (Tables 1 and 2).



3 (2)

3a (R=C_6H_5) 93%, **3b** (R=$C_6H_4NO_2$-p) 95%,
3c (R=2-furyl) 88%,
3d (R=t-C_4H_9) 57% (under reflux in ethanol).

2-Ethyl-4,4-dimethyl-2-oxazoline was also benzoylated to **3e** (76%) by the similar treatment without isolation of intermediate **2e**. The treatment of 2-benzyl-4,4-dimethyl-2-oxazoline with benzoyl chloride and triethylamine gave **2f** (96%). Hydrolysis of **2f**

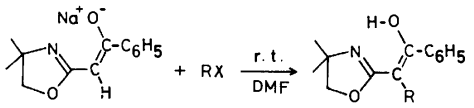
a) A and B are geometrical isomers. E is an enol isomer and K is a keto isomer. b) Crystals of the compounds consist of only this isomer. c) Measured in DMSO-d_6. d) Measured in CCl_4.

by refluxing with triethylamine in methanol for 3 h gave **3f** in 75% yield. However, a similar treatment of 2-isopropyl-4,4-dimethyl-2-oxazoline with benzoyl chloride gave a ring opening product, 2-benzoylamino-1-isobutyryloxy-2-methylpropane in 67% yield, not *C*-acylated product. The results may be interpreted in terms of lower acidity of the α-proton of the isopropyl group and its higher steric hinderance. A six-membered analogue of **1**, 2,4,4,6-tetramethyl-5,6-dihydro-4*H*-1,3-oxazine was found to be less reactive to the acylating reagent.[8]

A plausible mechanism of the formation of **2** from **1** is as follows: The 2-methyl protons of **1** are activated by quaternarization of the ring nitrogen, and subsequent abstraction of the proton by triethylamine gives a nucleophilic ketene *N,O*-acetal intermediate. The lower reactivity of the dihydrooxazine may be attributed to the more crowded nitrogen. The intermediate is *C*-acylated, and the abstraction of the second α-proton gives less nucleophilic product **2**. When **1** was treated with an equimolar amount of benzoyl chloride and triethylamine, monoacylated product **3a** was not obtained at all, and the yield of **2a** was reduced to 20%. This fact is also consistent with the above mechanism.

On treatment of sodium salt of **3a** with three molar amounts of alkyl halides in DMF at room temperature, *C*-monoalkylated products (**3e**, **3g**, and **3h**) were selectively obtained in good yields (Eq. 3). Since hydroxyl bands, not carbonyl band, are observed at about 3200 cm^{-1} in the IR spectra of **3e—3h**, they are also enols in crystals. The NMR spectra show that they are in the keto-enol equilibria in solutions. Further methylation of **3e** by the similar treatment as above gave the *C,C*-dimethylated product, **3i**, in 78% yield. However, the reaction of **3a** with excess methyl iodide and sodium ethoxide in ethanol gave neither **3e** nor **3i**, but **3a** was recovered. This fact shows that the α-protons of the 2-acylmethyl group of **3** are not so activated as those of β-keto esters. Subsequently, selective monoalkylation can be more easily achieved for **3**.



(3)

3e, **3g**, **3h**

3e (78%, RX=MeI),
3g (92%, RX=EtI; 55%, RX=EtBr),
3h (89%, RX=$C_6H_5CH_2Br$).

These results indicate that the oxazoline derivatives, **3**, of β-keto acids obtained by this method are versatile reagents for β-keto ester synthesis.

Experimental

All the melting points were uncorrected. NMR spectra were recorded on a Hitachi R-20B spectrometer. IR spectra were recorded on a Hitachi infrared spectrophotometer model 260-10. Physical properties of the oxazolines are summarized in Tables 1 and 2.

Benzoylation of 2,4,4-Trimethyl-2-oxazoline 1. Benzoyl chloride (28.4 g, 200 mmol) was added to a solution of **1** (11.3 g, 100 mmol) and triethylamine (25.3 g, 250 mmol) in acetonitrile (200 ml) at room temperature. The mixture was refluxed for 3 h, and the solvent was removed by a rotary evaporator. To the residue 100 ml of water was added and **2a** was extracted with chloroform. The organic layer was washed with 5% aqueous sodium carbonate and water, and dried over anhydrous sodium sulfate. Evaporation of the solvent yielded the crude product. Recrystallization from hexane–benzene (1:1) gave 31.1 g (97%) of pale yellow prisms (**2a**).

2-(β-Hydroxystyryl)-4,4-dimethyl-2-oxazoline (3a). To 100 ml of 1.5 M (1 M=1 mol dm^{-3}) methanolic potassium hydroxide 3.21 g (10 mmol) of **2a** was added at room temperature. After 6 h, precipitates were filtered off, and water was added to the filtrate. The mixture was extracted with chloroform and the organic layer was washed with water, and dried over anhydrous sodium sulfate. The solvent was removed by rotary evaporation and the residue was recrystallized from hexane–benzene (4:1) to give 2.02 g (93%) of colorless prisms (**3a**).

2-(β-Hydroxy-α-methylstyryl)-4,4-dimethyl-2-oxazoline (3e). To an equimolar amount of sodium ethoxide in ethanol 0.434 g (2 mmol) of **3a** was added and the solvent was removed by rotary evaporation. To the residue 0.85 g (6 mmol) of methyl iodide in 20 ml of DMF was added and the mixture was allowed to stand at room temperature for 5 h. The solvent was removed *in vacuo*, and 5% aqueous sodium carbonate was added to the residue. The mixture was extracted with chloroform. The extract was dried and the solvent was removed. The crude solid was recrystallized from hexane–benzene (4:1) to give 0.360 g (1.56 mmol) of colorless needles (**3e**).

2-(1-Benzoyl-1-methylethyl)-4,4-dimethyl-2-oxazoline (3i). Sodium salt of **3e** prepared from 0.462 g of **3e** and equimolar sodium ethoxide was treated with 0.85 g of methyl iodide in 20 ml of DMF at room temperature for 5 h. The usual workup yielded 0.426 g of colorless needles (**3i**) (87%).

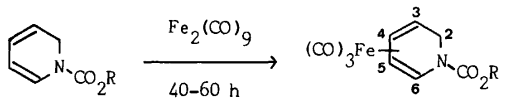
8) Reaction of 2,4,4,6-tetramethyl-5,6-dihydro-4*H*-1,3-oxazine with benzoyl chloride by the similar treatment yields the corresponding diacylated product (mp 166—167 °C) in 11% yield. Hydrolysis of the product to the corresponding enol (mp 81.5—83 °C) required refluxing with ethanolic potassium hydroxide for 5 h (yield 92%).

Convenient and Improved Synthesis of Tricarbonyl-(1,2-dihydropyridine)iron Complex

Ryohei YAMAGUCHI,* Yutaka NAKAZONO, and Mituyosi KAWANISI
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Kyoto 606
(Received January 5, 1984)

Synopsis. (*N*-Alkoxycarbonyl-1,2-dihydropyridine)-tricarbonylirons are conveniently prepared in good yields by photo-irradiation in the presence of excess pentacarbonyliron without any solvent. ^{13}C NMR spectra of the complexes are also described.

Alhough chemistry and synthetic utility of tricarbonyl(1,3-cyclohexadiene)iron complexs have been extensively studied for past several years,[1,2] there have been few investigations on the *N*-heterocyclic analogues.[3] Alper first reported the synthesis of (*N*-alkoxycarbonyl-1,2-dihydropyridine)tricarbonyliron complexes by reaction of *N*-alkoxycarbonyl-1,2-dihydropyridines (**1**) with enneacarbonyldiiron.[3a] However, the yields were relatively low [42 and 34% for *N*-methoxycarbonyl- and *N*-ethoxycarbonyl-1,2-dihydropyridines (**2a** and **2b**), respectively] and, in addition, the reaction time was exceedingly long (40—60 h).



1a R=Me **2a** R=Me (Y=42%)
1b R=Et **2b** R=Et (Y=34%)

Scheme 1.

In connection with our recent study on synthesis and reaction of 1,2-dihydropyridines,[4,5] we are interested in the tricarbonyliron complex, because 1,2-dihydropyrodines have turned out to be valuable synthetic intermediates for alkaloids and other *N*-heterocycles[4] and therefore tricarbonyl(1,2-dihydropyridine)iron complexes may find inherent utility in these fields.

Results and Discussion

At first, we tried to prepare **2a** according to Alper's procedure. However, 50% conversion of the reaction could be achieved after 65 h and the yield was 23% (46% based on the conversion) in our hands. It is highly desirable to develop more convenient and improved procedure to prepare **2**. Then, we have tried photochemical reaction of **1** with pentacarbonyliron, since in some cases photochemical reactions of simple 1,3-dienes with pentacarbonyliron have been used for the preparation of tricarbonyl(1,3-diene)iron complexes.[6] Thus, we have found that photo-irradiation of **1** in the presence of cxcess pentacarbonyliron *without any solvent* affords **2** in good yield within reasonably short reaction time. The results are summarized in Table 1.

There are a few points which should be noted here. First, the reaction time is significantly diminished in comparison with the Alper's method which requires 40—60 h. Second, the yields are higher than those of the Alpers'. Third, as the amount of pentacarbonyliron increases, the yield becomes higher. Thus, **2a** could be obtained in up to 80% yield by 18 h irradiation in the prseence of 5 fold excess of pentacarbonyliron. The reaction was clean and 90—95% of unreacted pentacarbonyliron was recovered.

TABLE 1. PHOTOCHEMICAL REACTION OF **1** WITH PENTACARBONYLIRON

$$\mathbf{1} \xrightarrow[Fe(CO)_5]{h\nu} \mathbf{2}$$

R	**1** (mmol)	$Fe(CO)_5$ (mmol)	Time/h	Yield/%
Me	10	20	28	45
Me	10	30	16	75
Me	20	100	18	80
Et	10	30	18	55

The tricarbonyl(1,2-dihydropyridine)iron complex (**2a**) thus obtained gave the correct elemental analysis and was identical with the authentic sample prepared according to the Alper's procedure in spectroscopic comparison. However, we have observed 59—59.5° for the melting point of **2a**, whereas Alper described 42—44° for it. In order to obtain further evidence for the structure of **2a**, we have measured ^{13}C NMR spectrum of **2a**, which has not been reported yet. Only one absorption due to the terminal carhonyls appears at 210.6 ppm, indicating that the three carbonyls are equivalent to each other. Three signals due to the ester carbonyl, the methyl, and the methylene carbons appear in the ordinary regions (154.0, 52.8, and 44.9 ppm, respectively). On the other hand, four signals due to the olefinic carbons are considerably shifted to the up-fieldds (83.4, 75.6, 73.0, and 56.7 ppm, respectively), as is expected by the complexation with iron carbonyl.[7] The ^{13}C NMR of **2b** also showed the similar absorptions to that of **2a**, except for the ethyl carbons instead of the methyl carbon. These ^{13}C NMR spectra clearly indicate that the tricarbonyliron moiety is coordinated to the double bonds of the dihydropyridine but not to its nitrogen atom.[6]

Since enneacarbonyldiiron is prepared from pentacarbonyliron by photo-irradiation, the present procedure provides more convenient and efficient method for synthesis of tricarbonyl(1,2-dihydropyridine)iron complex than the reported one.[3a]

Experimental

All the temperature were uncorrected. The IR spectra were obtained on a Shimadzu IR-27 spectrometer. The MS spectra were taken by using a Hitachi RMS-4 mass spectrometer. The ^1H NMR spectra were obtained on a Varine EM-360 or EM-390 spectrometer and the ^{13}C NMR spectra were obtained on a Varian CFT-20 spectrometer, TMS being chosen as the internal standard.

N-Methoxycarbonyl- and N-Ethoxycarbonyl-1,2-dihydropyridines (1a and 1b). The 1,2-dihydropyridine derivatives were prepared by the reported method.[8]

*Tricarbonyl(N-methoxycarbonyl-1,2-dihydropyridine)iron (**2a**).* A mixture of **1a** (2.78 g, 20.0 mmol) and pentacarbonyliron (19.60 g, 100 mmol) in a Pyrex tube fitted with a small rubber balloon was irradiated with stirring by means of 220 W medium pressure mercury lamp at room temperature for 18 h. The excess pentacarbonyliron was removed under reduced pressure and recovered in a Dry Ice-acetone trap (14.00 g, 89%). The residue was chromatographed on silica gel. Elution by hexane followed by benzene gave **2a** (4.47 g, 80%), which crystallized on standing in a refrigerator. **2a**: mp 59.0—59.5°C. MS *m/z* (rel intensity): 279 (M^+, 1), 251 (M^+—28, 10), 223 (M^+—56, 11), 195 (M^+—84, 18), 79 (100). IR (CCl_4): 2040, 1945, 1715 cm^{-1}. ^1H NMR $\delta(CDCl_3)$: 5.33—5.67 (2H, m, H-4 and H-5), 4.90 (1H, br s, H-6), 3.68 (3H, s, $-OCH_3$), 3.10—3.43 (2H, m, H-2 and H-3), 2.93 (1H, d. d, J=15 and 3 Hz, H-2). ^{13}C NMR $\delta(CDCl_3)$: 210.6 (s, C=O), 154.0 (s, $-CO_2-$), 83.4 (d, C-6), 75.0 (d, C-4 or C-5), 73.0 (d, C-4 or C-5), 56.7 (d, C-3), 52.8 (q, $-OCH_3$), 44.9 (t, C-2).

*Tricarbonyl(N-ethoxycarbonyl-1, 2-dihydropyridine)iron (**2b**).* A mixure of **1b** (1.53 g, 10.0 mmol) and pentacarbonyliron (5.88 g, 30.0 mmol) was irradiated in the similar manner to the above for 18 h. The excess pentacarbonyliron was removed under reduced pressure and recovered in a Dry Ice-acetone trap (3.72 g, 95%). The residue was chromatographed on silica gel. Elution by hexane followed by benzene gave **2b** (1.61 g, 55%): MS *m/z* (rel intensity): 293 (M^+, 1), 265 (M^+—28, 2), 237 (M^+—56, 2), 209 (M^+—84, 3), 80 (100). IR (neat): 2030, 1970, 1715 cm^{-1}. ^1H NMR $\delta(CDCl_3)$: 5.33—5.68 (2H, m, H-4 and H-5), 4.90 (1H, br s, H-6), 4.15 (2H, q, J=7 Hz, $-OCH_2-$), 3.13—3.46 (2H, m, H-2 and H-3), 2.93 (1H, d. d, J=15 and 3 Hz, H-2), 1.27 (3H, t, J=7 Hz, $-CH_3$). ^{13}C NMR $\delta(CDCl_3)$: 210.5 (s, CO), 153.6 (s, $-CO_2-$), 83.2 (d, C-6), 75.7 (d, C-4 or C-5), 72.9 (d, C-4 or C-5), 61.8 (t, $-OCH_2-$), 56.8 (d, C-3), 44.8 (t, C-2), 14.6 (q, $-CH_3$).

Preparation of Tetraalkyl 2,2′-Phthaloylbis[1,2-dihydro-1-isoquinolylphosphonate]s and their Reactions with Base

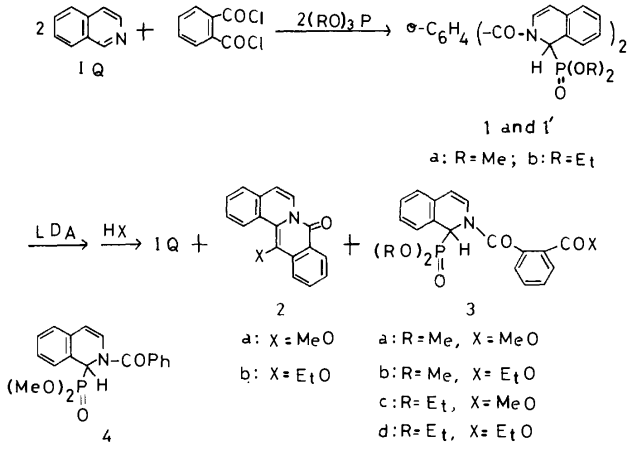
Kin-ya AKIBA,† Yoshio NEGISHI, and Naoki INAMOTO*
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo 113
(Received January 27, 1984)

Synopsis. The titled compounds were prepared and the reaction with lithium diisopropylamide followed by quenching with alcohol gave isoquinoline, 13-alkoxy-8*H*-dibenzo[*a*,*g*]quinolizin-8-ones, and dialkyl 2-(*o*-alkoxycarbonylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonates.

We reported previously preparation of 13-substituted 8*H*-dibenzo [*a*,*g*]quinolizin-8-ones (**2**) by the intramolecular Wittig-Horner reaction of dialkyl 2-(*o*-acylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonates (**3**).[1]

If the bis(phosphonate)s such as **1** are allowed to react with diketones under reaction conditions of the Wittig-Horner reaction, formation of the large-membered rings would be expected. Thus, a possibility of this type of reaction was examined.

Tetraalkyl 2,2′-Phthaloylbis [1,2-dihydro-1-isoquinolylphosphonate]s were prepared from isoquinoline (IQ), phthaloyl dichloride, and trialkyl phosphites in good yields as a diastereomeric mixtures of **1** and **1′**, where the isomers having lower melting points were regarded as **1**.

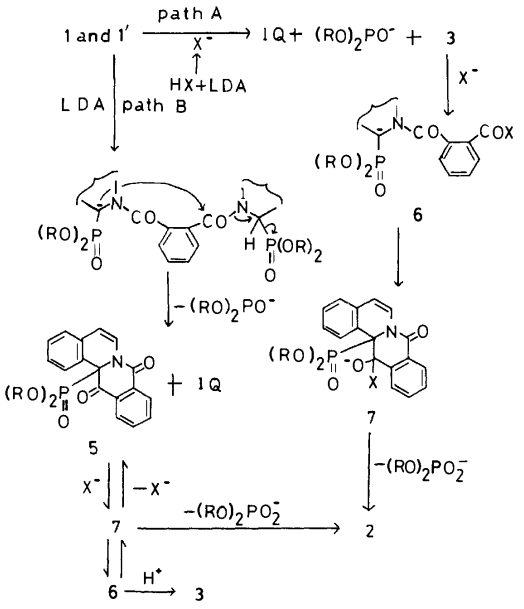


The reaction of a 1:1 mixture of **1a** and **1′a** with phthalaldehyde using two molar amounts of lithium diisopropylamide (LDA), followed by quenching with methanol, gave IQ (76%), **2a** (24%), and dimethyl 2-(*o*-methoxycarbonylbenzoyl)-1,2-dihydro-1-isoquinolylphosphonate (**3a**) (43%), indicating that phthalaldehyde did not take part in the reaction. Use of sodium methoxide (2 equiv) as a base gave mainly IQ and dimethyl phthalate.

In order to clarify the mechanism for the reaction, **1a** and **1b** were treated with LDA (1.3 equiv) at −70°C, then the reaction mixtures were quenched with alcohols, and allowed to stand at room temperature overnight. The results are summarized in Table 1, indicating that the 13-substituents in **2** are derived from the alcohols as quencher. However, the reaction of **1b** with LDA, followed by quenching with acetic acid, resulted in a quantitative recovery of a mixture of **1b** and **1′b** (5:8).

A similar reaction of dimethyl 2-benzoyl-1,2-dihydro-1-isoquinolylphosphonate (**4**)[2] as model with LDA, followed by quenching with methanol, gave a 1:1 mixture of IQ and methyl benzoate quantitatively.

From the above results, two mechanisms for formation of **2** and **3** are possible (see Scheme 1). Absence of a keto phosphonate (**5**) by quenching with acetic acid and the model experiment using **4** seem to support path A, though path B can not be ruled out completely.



Scheme 1.

Experimental

Preparation of 1a. A mixture of phthaloyl dichloride (0.44 ml, 3.06 mmol) and IQ (0.79 g, 6.12 mmol) in MeCN (5 ml) was heated at 50—60°C for 10 min. To the above soln was added trimethyl phosphite (1.08 ml, 9.14 mmol) at 0°C and the mixture was refluxed for 10 min. After addition of aq $NaHCO_3$ (3%, 50 ml), the mixture was extracted with CH_2Cl_2. The extract was washed with aq NaCl and dried ($MgSO_4$). After removel of the solvent, the residue (2.2 g) was

crystallized with ether to give a colorless mixture of **1a** and **1'a** (1.4:1; 1.55 g, 83%), which were separated by fractional recrystallization. **1a**: mp 208—209°C (from EtOAc-Et_2O); ^1H NMR ($CDCl_3$) δ=3.54, 3.59 (12H, 2d, J_{POCH}=10.8 Hz), 5.79 (2H, d, J=7.8 Hz), 6.25 (2H, d, J_{PCH}=17.7 Hz), 6.52 (2H, d, J=7.8 Hz), 6.8—7.0 (2H, m), 7.2—7.3 (6H, m), and 7.55 (4H, s); MS (70 eV) *m/z* (rel intensity) 608 (M^+; 0.5), 222 (48), and 93 (100). Found: C, 59.40; H, 4.95; N, 4.66%. Calcd for $C_{30}H_{30}N_2O_8P_2$: C, 59.21; H, 4.97; N, 4.60%. **1'a**: mp 224.9—225.8°C (from EtOAc-Et_2O); ^1H NMR ($CDCl_3$) δ=3.49, 3.67 (12H, 2d, J_{POCH}=10.8 Hz), 5.87 (2H, d, J=7.8 Hz), 6.09 (2H, d, J_{PCH}=17.7 Hz), 6.41 (2H, d, J=7.8 Hz), 7.0—7.2 (8H, m), and 7.55 (4H, s); MS (70 eV) *m/z* (rel intensity) 608 (M^+; 0.6), 222 (59), and 93 (100). Found: C, 59.48; H, 4.86; N, 4.70%.

Preparation of ***1b.*** Similarly to that of **1a**, phthaloyl dichloride (1.35 ml, 9.4 mmol), IQ (2.43 g, 18.8 mmol) in MeCN (13 ml), and triethyl phosphite (3.2 ml, 18.5 mmol) were allowed to react. On cooling the reaction mixture with ice, **1'b** precipitated (1.58 g, 25% yield). The filtrate was evaporated *in vacuo* and 3% aq $NaHCO_3$ (50 ml) was added to the residue and the mixture was extracted with CH_2Cl_2. The extract was washed with aq NaCl, dried ($MgSO_4$), and evaporated to give **1b** (4.00 g, 64% yield). **1b**: mp 168.2—169.2°C (from EtOAc-Et_2O); ^1H NMR ($CDCl_3$) δ=1.12 (6H, t, J=7.2 Hz), 1.15 (6H, t, J=7.2 Hz), 3.5—4.3 (8H, m), 5.72 (2H, d, J=7.8 Hz), 6.18 (2H, d, J_{PCH}=17.4 Hz), 6.47 (2H, d, J=7.8 Hz), 6.7—6.9 (2H, m), 7.0—7.3 (6H, m), and 7.51 (4H, m); MS (70 eV) *m/z* (rel intensity) 664 (M^+; 1.1), 398 (41), 250 (73), and 121 (100). Found: C, 61.29; H, 5.90; N, 4.19%. Calcd for $C_{34}H_{38}N_2O_8P_2$: C, 61.44; H, 5.76; N, 4.21%. **1'b**: mp 221.7—222.7°C (from EtOAc-Et_2O); ^1H NMR ($CDCl_3$) δ=1.09 (6H, t, J=6.9 Hz), 1.18 (6H, t, J=6.9 Hz), 3.5—4.3 (8H, m), 5.76 (2H, d, J=7.8 Hz), 5.95 (2H, d, J_{PCH}=16.8 Hz), 6.32 (2H, d, J=7.8 Hz), 6.8—7.2 (8H, m), and 7.56 (4H, s); MS (70 eV) *m/z* (rel intensity) 664 (M^+; 0.8), 398 (57), 250 (89), and 121 (100). Found: C, 61.14; H, 5.70; N, 4.26%.

Reaction of ***1a*** *and* ***1'a*** *in the Presence of Phthalaldehyde.* To a soln of LDA (2.38 mmol) in THF (50 ml) was added a mixture of **1a** and **1'a** (1:1) (604 mg, 0.99 mmol) at −50—−60°C and after 40 min phthalaldehyde (133 mg, 0.99 mmol) in THF (21.2 ml) was added dropwise at −65°C. After 0.5 h, the mixture was stirred at 40°C for 0.5 h and quenched with MeOH (2 ml). After filtration, the filtrate was evaporated and aq $NaHCO_3$ (2%, 50 ml) was added to the residue. The mixture was extracted with ether and then the aq layer was extracted with CH_2Cl_2. The combined extracts were washed with aq NaCl (50 ml), dried ($MgSO_4$), and evaporated. The residue (392 mg) was subjected to dry column chromatography (DCC) (SiO_2, Et_2O-hexane (1:1)) to give **2a**[1] (65 mg, 24%). IQ (97 mg, 76%), and **3a**[1] (171 mg, 43%).

Reaction of Bis(phosphonate)s (1) and LDA. General Method: To a soln of **1** (*ca.* 1 mmol) in THF (30 ml) was added at −70°C LDA (1.3 mmol) in THF (5 ml) under nitrogen atmosphere with stirring. After stirring for 0.5 h, alcohol (2 ml) was added at −70°C and the mixture was allowed to stand at room temp overnight. After removal of solvent *in vacuo*, 2% aq $NaHCO_3$ (50 ml) was added to the residue, the mixture was extracted with CH_2Cl_2, the extract was dried ($MgSO_4$), and evaporated to be subjected to DCC (SiO_2, Et_2O). The results were shown in Table 1. The products **2** and **3** were identified by the mps and spectral data.[1]

Ultrasounds in Synthetic Reactions. II. Convenient Methylenation of Carbonyl Compounds with Zinc-Diiodomethane[1]

Junzo YAMASHITA,* Yoshio INOUE, Takashi KONDO, and Harukichi HASHIMOTO
Department of Applied Chemistry, Faculty of Engineering, Tohoku University, Aramaki-Aoba, Sendai 980
(Received March 5, 1984)

Synopsis. Ultrasonic irradiation facilitates the methylenation of carbonyl compounds with zinc-diiodomethane reagent in tetrahydrofuran at room temperature.

The cyclopropanation of olefins with zinc-diiodomethane complex was first reported by Simmons and Smith,[2] and the methylenation of carbonyl compounds was also observed with this complex in the presence of an excess of zinc by Miyano, Hida, and Hashimoto of this laboratory.[3] The preparation of zinc-diiodomethane complex usually needs activated zinc-copper couple, which requires rather tedious procedure. Other methylenation procedures for aldehydes which use reagents involving Ti have been developed and given good yields, but they use highly air sensitive trimethylaluminium.[4,5] Dibromomethane-zinc-tetrachlorotitanium is a very good methylenation reagent for ketones but not for aldehydes.[5,6]

Ultrasounds have been successfully applied to accelerate a variety of organic reactions,[7] particularly those involving metals. We now wish to report that ultrasonic irradiation is also very useful for the methylenation reactions with zinc-iodomethane reagents: no chemical activation of commercial zinc powder is required, the reaction proceeds smoothly and rapidly at room temperature, and the yields are reproducible.

Experimental

Materials. Commercially available aldehydes and ketones were dried over Drierite and distilled under nitrogen atmosphere and stored for use. Tetrahydrofuran was distilled over sodium prior to use. Commercially available zinc powder was used as obtained. Commercially available diiodomethane was purified according to the known procedure.[3]

Analysis. Reaction products were identified by the retention volume on GLC and mass spectra (JEOL D300 mass spectrometer) compared with the authentic samples. The yields of products were determined by GLC. GLC was performed on a Hitachi 163 gas chromatograph (20 m glass capillary column coated with OV-17) or a Shimadzu GC 3AH gas chromatograph (Silicone DC-550 20 wt% on Diasolid M, squalane 20 wt% on Diasolid M, Silicone GE SE-52 20 wt% on Chromosorb W AW, or FFAP 10 wt% on Chromosorb W AW DMCS).

General Procedures for Methylenation Reactions. Methylenation of Benzaldehyde: To a 50 ml, 3-necked flask, which contained 1.57 g (24 mmol) of zinc powder previously dried at 100°C for 30 min under vacuum, were added 0.53 g (5 mmol) of benzaldehyde, 2.68 g (10 mmol) of diiodomethane, and 0.335 g (2.5 mmol) of durene (internal standard for GLC analysis) in 20 ml of THF, and irradiated for 20 min under nitrogen atmosphere in the water bath of an ultrasound laboratory cleaner (53 W, 41 kHz), which was maintained at room temperature. The yield of styrene was determined by GLC (FFAP 20 wt% on Chromosorb W AW DMCS at 120 °C).

Results and Discussion

The reactions of aldehydes or ketones with $Zn-CH_2I_2$ were carried out in THF at room temperature irradiated by ultrasound.

$$R_2C{=}O + CH_2I_2 \xrightarrow[\text{THF, room temp}]{\text{Zn, ultrasound}} R_2C{=}CH_2$$

The results were shown in Table 1. None or very small amount of olefins was detected when the similar reaction was carried out with ordinary magnetic stirrer instead of ultrasonic irradiation, though the longer reaction time afforded the corresponding olefin without the irradiation. The yield may be improved, for the reaction conditions are not optimum. Dibromomethane instead of diiodomethane can be used, but the longer reaction time is necessary (runs 7 and 8). Only low yields are obtained for ketones as indicated by runs 9 and 10, and this reaction is not recommended for ketones. The yields are comparable to those of previously reported procedures (40°C, 6 h in THF using activated zinc-copper couple), but the precise comparison is impossible, for the latter used 2 mol of carbonyl compounds to 1 mol of diiodomethane and the yields of olefins were based on diiodomethane.

In conclusion, the present method is a very convenient procedure for methylenation of aldehydes.

Table 1. Ultrasound-accelerated methylenation of carbonyl compounds with zinc-diiodomethane in THF at room temperature[a]

Run	Carbonyl compounds	Reaction time/min	Products	Yield %
1	Benzaldehyde	20	Styrene	70[b]
2	*p*-Methylbenzaldehyde	120	*p*-Methylstyrene	73
3	*p*-Methoxybenzaldehyde	90	*p*-Methoxystyrene	50
4	*p*-Chlorobenzaldehyde	15	*p*-Chlorostyrene	69[c]
5	1-Naphthaldehyde	120	1-Naphthylethene	54
6	Cinnamaldehyde	60	Phenylbutadiene	37
7	Heptanal	20	1-Octene	71
8	Heptanal[d]	300	1-Octene	58
9	Cyclohexanone	60	Methylenecyclohexane	18
10	Acetophenone	300	α-Methylstyrene	8

a) Reaction conditions; Zn 24 mmol, diiodomethane 10 mmol, substrate 5 mmol, THF 20 ml, room temperature. b) The yield increased to 82% when the reaction time was 60 min. c) Isolated yield was 57% (20 mmol scale). d) Dibromomethane was used instead of diiodomethane.

We would like to thank Dr. Sotaro Miyano of this laboratory for helpful discussions.

Dielectric Relaxation of Some Aliphatic Ketones in Dilute Solution

Buta SINGH
Department of Physics, Punjabi University, Patiala, India.
(Received October 7, 1983)

Synopsis. Measurements of the relative permittivity at frequency of 10 GHz, and of the refractive index, have been made at 25 °C for (a) 2-haxanone, (b) 3-hexanone, (c) 3-Methyl-2-pentanone, (d) 3,3-dimethyl-2-butanone,(e) 2-heptanone, (f) heptanal, and (g) cyclohexanone, in dilute solutions of cyclohexane, decalin, and 1,4-dioxane, Dielectric relaxation times have been evaluated. It has been concluded that in the ketones and heptanal under study, dipole reorientation occurs mainly by an intramolecular relaxation process.

Crossley[1-3] has studied some ketones at a single concentration at different frequencies and has shown that dipole reorientation occurs primarily by the intramolecular rotation of the terminal acetyl group. The present work examines the dielectric absorption of five ketones together with heptanal and cyclohexanone in three nonpolar solvents, namely, cyclohexane, decalin, and 1,4-dioxane. Viscoelastic behaviour of these polar molecules is discussed in terms of intramolecular as well as overall molecular rotations. The possibility of solute-solvent interactions between the dioxane and these molecules is also discussed.

The polar materials as well as solvents used were of purest available grade and were distilled, whereever felt necessary, before use. The measured values of the refractive indices of polar materials and solvents were in agreement with the literature values where available.

Measurements of the relative permittivity ε' and dielectric loss factor ε'' at a frequency of 10 GHz were made by the 3-db technique using a Sanders VSWR Amplifier MKIII. Six samples at different concentrations in the range 0—0.03 weight fraction were studied for each material. The refractive index was measured using an Abbe refractometer.

Results

The values of a', a'', and a_D which are, respectively the slopes[4] of the plots of ε', ε'', and n_D^2 *versus* weight fraction of the solute, are given in Table 1. These slopes a', a'', and a_D were determined within 2, 4, and 5% respectively, by least square fitting using an appropriate program on a PDP8 digital computer. Values of a_∞, the slope of the plot of the relative permittivity at infinite frequencies, ε_∞, *versus* weight fraction of the solute, were calculated using the relation $a_\infty = 1.1\ a_D$. Dielectric relaxation time τ, has been evaluated using the relation[5,6]

$$\tau = \frac{a''}{\omega(a' - a_\infty)}.$$

Discussion

Values of τ are given in Table 2 and the same are compared with the literature values where availble.

TABLE 1. VALUES OF a', a'', a_D, AND a_∞ FOR MOLECULES AT 25 °C

Cyclohexanone	9.507	5.13	+0.102	+0.112

The measured values of τ for 2-hexanone in cyclohexane and decalin and for cyclohexanone in cyclohexane are found to compare well with the literature values. Values of τ are of the same order of magnitude as the relaxation time for acetyl group rotation in aromatic molecules[8-10] (≈7 p s) and for acetone[11,12] (3.2 p s) in dilute solution and are smaller than those acticipated for overall molecular rotation. This gives an indication that dipole reorientation in ketones occurs mainly by intramolecular rotation of the terminal acetyl group. The relaxation time for 2-hexanone is almost equal to that for 3-hexanone. This indicates that the location of the carbonyl group on the hydrocarbon chain has relatively little affect on the relaxation time for hexanones. Crossley,[1] too, has made the same conclusion from the studies on nonanones and decanones. The structure of ketones can be expressed as

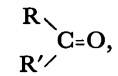

TABLE 2. VALUES OF τ, τ_{Lit}, τ_{Dec}/τ_c, AND τ_{Diox}/τ_c

Chemical	τ ps	τ_{Lit} ps	τ_{Dec} τ_c	τ_{Diox} τ_c
	Solvent cyclohexane			
2-Hexanone	4.1	4.0[1]	1.20	1.73

Heptanal	6.9	—		
Cyclohexanone	8.7	—		

and the molecule may relax either by overall molecular reorientation or by twisting around the R–C and R'–C bonds. Second type of intramolecular relaxation process appears to make a large contribution to the absorption in the ketones under study. The dielectric relaxation behaviour of diphenyl ether and related compounds is also explained by the same type of relaxation process.

The relaxation time for 3,3-dimethyl-2-butanone in cyclohexane at 25 °C is 2.8 p s., which is comparable to that for acetone in benzene at 25 °C (=3.2 p s). In this molecule the *t*-butyl group R is compact in size and, therefore, dipole reorientation occurs by twisting around the R'–C bond only.

Values of τ for 2-heptanone is only slightly longer than that for 2-hexanone and the difference increases again with the increase in the viscosity of the solvent. Also, the ratio of the relaxation times in decalin to that in cyclohexane (τ_{Dec}/τ_c) for all the compounds in the present study is $\approx$1.3 (Table 2) which is rather smaller than the ratio of the viscosities of the solvents (η_{Dec}/η_c) which is $\approx$2.5. This indicates that the contribution of the overall molecular rotation to the relaxation process is quite small. The relative contribution to the value of τ by the intramolecular rotation and overall molecular rotation and with the increased viscosity of the solvent has been discussed in detail by Crossley.[3]

The relaxation time of heptanal has been found to be almost equal to that of 2-heptanone. Also, the value of τ_{Dec}/τ_c for heptanal is comparable to those for 2-hexanone and 3-hexanone. This shows that dipole reorientation in alkanals also takes place largely by intramolecular relaxation process. The value of τ for cyclohexanone is seen to be comparable to that for 2-hexanone and 2-heptanone in all the three solvents and the values of τ_{Dec}/τ_c and τ_{Diox}/τ_c, too, are almost the same. Cyclohexanone is known to be a rigid spherical molecule. Probably the dipole reorientation of the spherical cyclohexanone molecule involves roughly the same displacement of the surrounding molecules as in the case of the segment rotations of 2-hexanone or 3-methyl-2-pentanone. This is also confirmed from dielectric relaxation studies of ketones in a polystyrene matrix,[14] where dielectric dispersion for cyclohexanone has been found to occur in the same temperature region as for the low temperature dispersion (which has been attributed to the acetyl group rotation) for 2-hexanone and 2-heptanone.

The value of τ_{Diox}/τ_c for all the molecules under study (except for 3-methyl-2-pentanone) is$\sim$1.9 (Table 2) and is much larger than η_{Diox}/η_c (=1.33). Values of τ for these molecules in 1,4-dioxane are longer when compared with those in decalin though the viscosity of the latter is almost double than the former. It is known that the ketone molecule is a resonance hybrid in which the carbon atom of the carbonyl group assumes a positive character. This positive carbonyl carbon is liable to interact strongly with the lone-pair electrons of the oxygen atom in 1,4-dioxane resulting in large values of τ. Similar results have been reported for trihaloganated esters[15] and nitroalkanes.[6]

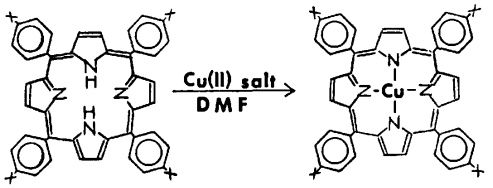
(Received July 5, 1983)

Synopsis. Using excess of acetate, chloride, bromide, and sulfate salts, the kinetics of Cu(II) incorporation in *meso*-tetrakis (4-benzyloxyphenyl) porphyrin, in DMF solution, at different temperatures, have been done. The thermodynamic parameters have been calculated and a mechanism of Cu(II) insertion proposed.

The kinetics of copper(II) incorporation in porphyrins has been reported with nitrate,[1-3] perchlorate,[4,5] acetate,[6,7] sulfate,[8] and chloride[9] salts. Glacial acetic acid,[4,7] aqueous nitric acid,[1-3] acetic acid–water,[4] acetic acid–ethanol,[9] ethanol,[6] and 2.5% dodecyl sulfate[8] were some of the solvents used. No publication has yet appeared showing the effect of different anions attached to the copper(II) on the rate of metallation in a porphyrin under same conditions. We are reporting the kinetic data and a mechanism of copper(II) insertion in *meso*-tetrakis(4-benzyloxyphenyl)porphyrin (A) in DMF solution using the chloride, bromide, sulfate and acetate salts.



Starting with freshly distilled pyrrole and 4-(benzyloxy)benzaldehyde (Aldrich Chemical Company) and following the published procedure,[10] the porphyrin A, was prepared. Analytical sample of A was made by chromatography over silica gel with dichloromethane elution. A pure sample of the copper complex, B, was also made by the literature method.[11] Both A and B gave accurate elemental analysis.[12] Analytical grade copper salts and spectroscopic grade DMF (dried over Molecular Sieve 4A) were used.

The reaction rates were followed in 1.00 cm thermostatted cells (maintained to ±0.1 or better by a Neslab RTE-3 constant temperature circulator) and monitored with a Beckman Model 25 spectrophotometer. A typical kinetic study consisted of measuring the absorbances at 518 and 642 nm[13] over a period of time of a mixture of equal volume of 2.188×10^{-3} mol/dm^3 copper salt and 5.17×10^{-5} mol/dm^3 A at a pre-equilibrated temperature against 1.094×10^{-3} mol/dm^3 copper salt blank.[14] Standard procedure was used to calculate the concentrations of A and B.[15] In DMF solution the rate of copper(II) incorporation is known to be first order with respect to porphyrin as well as metal ion concentration.[9] Since the copper (II) ion concentration has been kept much higher, pseudo-first-order rate constants were obtained from the data of this study. A plot of time (minutes *vs.* In C_o/C_t, where C_o and C_t are molar concentrations of A at zero and t minutes respectively, yielded a straight line from which the first-order-rate constants (k) were calculated. (See Table 1)

Activation energy, E_a, was obtained from the slope of a plot $1/T$ (K^{-1}) *versus* log k. Thermodynamic parameters ΔG^*, ΔH^*, and ΔS^* were calculated using standard equations.[16] (see Table 2).

The relative rates of Cu(II) incorporation are found to be sulfate > bromide > chloride > acetate. The activation energy, E_a, and enthalpy of activation, ΔH^*, are highest with acetate and lowest with sulfate; the reverse relationship is observed with free energy of activation, ΔG^*. The entropy of activation decreases in the order, acetate > chloride > bromide sulfate. These data can be rationalized with an assumption that the Cu(II) insertion in DMF proceeds in two steps as follows:

$$\text{Step 1: } 4\text{BzO-TPP-H}_2 + \text{Cu(II)} \xrightarrow{k_1} 4\text{-B}_2\text{O-TPP-H}_2\cdot\text{Cu(II)(C)}^{17}$$

$$\text{Step 2: } 4\text{BzO-TPP-H}_2\cdot\text{Cu}^{+2} \xrightarrow{k_2} 4\text{BzO-TPP-Cu} + 2\text{H}^+$$

The first step is slow formation of an unstable complex C[17] and the second step rapidly forms the product B. The rate K_1 of the slower first step is dependent upon the nature of the anion attached to the Cu(II) or the nature of anion controls the availability of Cu(II). In the solid state copper(II) sulfate pentahydrate has four water molecules and an oxygen atom from each of two sulfate anions octahedrally arranged about the Cu(II) cation.[18] In DMF solution the water ligands may be easily removed, making the Cu(II) easily available to form C. Compared to copper(II) sulfate, the chloride and the bromide have polymeric chain structures formed by planar CuX_4 groups sharing opposite edges. The distances between the chlorine atoms in the chloride are shorter than the bromine atoms in the bromide.[19] It has been postulated that in DMF solution copper(II) chloride is present as

TABLE 1. THERMODYNAMIC PARAMETERS FOR COPPER PORPHYRIN FORMATION WITH DIFFERENT COPPER SALTS

	$CuSO_4\cdot5H_2O$	$CuBr_2$	$CuCl_2\cdot2H_2O$	$Cu(OAc)_2$
ΔG^*/kJ mol^{-1}	82.09	82.89	85.35	86.78
ΔH^*/kJ mol^{-1}	56.48	63.14	65.94	81.17
ΔS^*/J mol^{-1} K^{-1}	−87.53	−69.41	−64.06	−18.12
E_a/J	58, 915	65, 639	68, 450	83, 730

Table 2. Rate constants for copper porphyrin formation with different copper salts

Copper salt	Temp/°C	k/min^{-1}
$CuSO_4 \cdot 5H_2O$	9	0.0054
	16	0.0102
	23	0.0177
	30	0.0318

	37	0.0146
	45	0.0363

[$CuCl^+ . CuCl_3^-$[9]]. If this is accepted, it is reasonable to think that copper(II) bromide in DMF solution should be present as $CuBr^+ \cdot CuBr_3^-$. The bromide species will be expected to form the complex C somewhat faster than the chloride species, because in the former the halogens are further apart from each other. Copper (II) acetate in the solid state has a dimeric structure which is expected to remain unchanged in DMF solution.[20] Therefore the Cu(II) from the dimeric acetate will be least favored, compared to sulfate, chloride and bromide, to form the complex C. The thermodynamic data (See Table 2) also suggest that the total gain in entropy due to solvation and subsequent distortion of the ordered structure of the copper salts is more than offset by the loss of entropy due to the formation of the complex C. This is most pronounced with the sulfate and least with acetate. The energy necessary to distort the geometry of the copper salts is greater than the energy released due to the formation of complex C. The difference between these two energies, *i.e.* ΔH^*, is maximum with acetate, and minimum with sulfate (see Table 2).

Two additional experiments have been performed to support the two-step mechanism proposed. The first experiment was to compare the Cu(II) incorporation in TPP-H_2[21] and TPP-D_2[21] in dry DMF solution using anhydrous copper(II) chloride at 23, 30, and 37 °C. The rates observed at these temperatures for both the compounds were identical,[22] supporting that the step 2 is not the rate limiting step.

The second experiment was to measure the Cu^{63}(II)[23] and Cu^{65}(II)[23] insertion in TPP-H_2 at 23, 30, and 37 °C in DMF. The ratio of the rate of Cu^{63}(II) to Cu^{65}(II) insertion found were 1.085(at 23 °C), 1.116 (at 30 °C), and 1.132(at 37 °C). This significant isotope effect supports the step 1 to be the rate limiting step. Our findings and conclusions are further supported by a recent report[24] on the kinetics of copper (II) incorporation into a series "picketfence" type porphyrins, dissolved in a mixture of toluene, 2-propanol, and water. It has been shown that (1) the slow step apparently involves an outersphere association (similar to our complex C) between a reactive intermediate of Cu(II) ion and the porphyrin followed by rapid metal incorporation and (2) the nature of reactive metal intermediate is responsible for the rapid metal incorporation.

Our research was supported by the NIH-MBRS Grant #RRO 8060.

(Received August 26, 1983)

Synopsis. The copolymer complexes have been synthesized from cation and/or anion resin with metal catalyst such as aluminum chloride or iron(III) chloride. Electron microprobe X-ray analysis demonstrated that aluminum and iron were distributed uniformly in the copolymer complex. The catalytic activity for esterification of dibasic organic acids was discussed and showed that copolymer complex from porous type cation exchange resin was much better catalyst than that from gel type.

Polymers have been used broadly as a supporter[1] or as a catalyst[2,3] in various organic syntheses. Some of the advantages cited include substrate stabilization, reaction selectivity, increased yield and effective separation of the products. When used as a catalyst, they are usually polymer-metal complexes formed by linking polymers to metal catalyst such as $AlCl_3$ or $FeCl_3$. Such metal complexes are no longer volatile and far less hygroscopic.[4] Furthermore, the catalyst can be reused repeatedly, because the polymer-metal complexes are stable in the air,[5] and the products are more readily separable from the bulk.

Although these metal complexes have been used extensively in pharmaceutical industry for their improved catalytic effect, there have been some difficulties in material handling and even loss of polymer complexes when they were used in styrene–divinylbenzene matrix.[6] We have used ordinary ion exchange resins to form copolymers of $AlCl_3$ or $FeCl_3$ and found that they are much better catalysts in esterification of organic acids than either cation exchange resin itself or metal catalyst. The microstructures of both $AlCl_3$ and $FeCl_3$ copolymers have been analyzed using scanning electron microscope and electron microprobe X-ray analyzer.

Aluminum chloride copolymer complex (Ⓟ-$AlCl_3$) and iron(III) chloride copolymer complex (Ⓟ-$FeCl_3$) have been prepared from anhydrous $AlCl_3$ powder and anhydrous $FeCl_3$ powder with cation and/or anion exchange resin respectively following the method of Neckers.[7] The resins used in this experiment were gel and porous types with 30—50 mesh beads. The beads were the commercial cation and/or anion exchange resin beads (gel type : DIAION SK 1B and SA 10A, porous type : DIAION PK 212 and PA 312, Mitsubishi Chemical Ltd.); These beads were treated with $AlCl_3$ and/or $FeCl_3$ for periods of 30, 60, 90, 120, 150, and 180 min.

The aluminum and iron contents of the above complexes were analyzed with atomic absorption spectrophotometer. In general, the aluminum contents of Ⓟ-$AlCl_3$ synthesized from cation exchange resin of 30—50 mesh size (gel type : SK, porous type : PK) were greater than Ⓟ-$AlCl_3$ synthesized from anion exchange resin. As shown in Table 1, the aluminum content of the porous type resin complex was the highest when it was treated with $AlCl_3$ for 30—60 min.

TABLE 1. ALUMINUM AND IRON CONTENT IN COPOLYMER COMPLEX ACCORDING TO THE VARIOUS REACTION TIMES AND TYPE OF CATION EXCHANGE RESINS

Reaction time / min	Content/mg g^{-1}			
	Al/Ⓟ-$AlCl_3$		Fe/Ⓟ-$FeCl_3$

30	0.19	0.04	0.65	0.32
60	0.19	0.07	0.80	0.53
90	0.15	0.10	0.63	0.65
120	0.12	0.07	0.53	0.52
150	0.08	0.05	—	—
180	0.06	0.04	0.55	0.48

PK; DIAION PK 212, porous type. SK; DIAION SK 1B, gel type.

But the aluminum content of the gel type resin complex was highest when the resin was treated with $AlCl_3$ for 90 min. The iron content of the complex synthesized from gel type resin was also the highest when the resin was treated with $FeCl_3$ for 90 min, while that of the complex synthesized from porous type was the highest when the resin was treated with $FeCl_3$ for 60 min. In addition, it was observed that the content of iron of the complex was four to six times as much as that of the aluminum of the complex at their maximum activities.

To investigate the microstructure of copolymer complexes, these several beads were examined in detail using energy dispersive X-ray spectrometer, scanning electron micorscope and electron microprobe X-ray analyzer.

For the microscopic analysis, samples of copolymer complex were embeded in epoxy resin and then sectioned by microtome. In the micrographs of sectioned beads, the pores of SK Ⓟ-$AlCl_3$ and SK Ⓟ-$FeCl_3$ beads appeared smaller than those of SK Ⓟ bead. The difference between these beads were also observed with the porous types. Therefore, it is suggested that Al^{3+} and Fe^{3+} of the copolymer complexes may have replaced hydrogen ion in cation exchange resin. As shown in Fig. 1 we observed the singnal intensity of aluminum and iron respectively in the electron micropobe profiles of the copolymer complex of gel type bead. These singnal intensity were also observed with porous type bead. The present results demonstrated that aluminum and iron were distributed uniformly in the copolymer complex.

The esterifications of various dibasic acids with alcohols were carried out in order to examine the catalytic effect of copolymer complexes by the method described in our previous work.[6] The reactions of various aliphatic acids with alcohols using Ⓟ-$AlCl_3$ and Ⓟ-$FeCl_3$ as catalysts in mole ratio of 1 : 1 at 120 °C for 5 h are compared with the reaction using

cation exchange resin (PSVB-SO_3H) as shown in Table 2. The reactions of aromatic and alicyclic dibasic acids with alcohols in the mole ratio of 1 : 2 were also carried out for 10 h, and the result is included in Table 2. The yields of esterifications shown in Table 2 were determined by gas chromatography. Matsumoto[8] has demonstrated previously the catalytic activity of cation exchange resin. We now have observed that the Ⓟ-$AlCl_3$ and Ⓟ-$FeCl_3$ are better catalysts in esterification. Furthermore, the Ⓟ-$AlCl_3$ is a more effective catalyst than Ⓟ-$FeCl_3$. This agrees

with the fact that $AlCl_3$ is a better catalyst than $FeCl_3$.[9] In the case of esterification of saturated aliphatic dibasic acid with ethyl alcohol, the more methylene groups in the acid, the less yield is observed. This result shows that the electron-withdrawing group at the α-position of carboxylic acid enhances esterification. In the case of maleic acid, the reaction occured more quickly than its trans isomer fumaric acid. This has also been observed in the formation of maleic anhydride.[10] As shown in Table 2, the copolymer complexes are less effective catalysts in esterification of aromatic acid and alicyclic acids than aliphatic acid. Furthermore, the copolymer complex is very stable and not fragile, so can be reused. In Table 3, the catalytic effect of the resynthesized copolymer complex is the almost same as the original one whereas, in genaral, the recycled catalyst has less activity than the original one. Generally, copolymer complexes synthesized from porous type of cation exchange resin are better catalysts in the esterification than those synthesized from gel type resin. The catalytic activity is observed proportional to the aluminum and iron contents of copolymer complexes respectively.

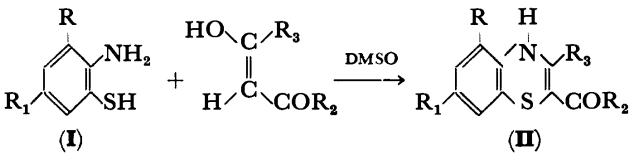
Single Step Synthesis of 4*H*-1,4-Benzothiazines

Radha Raman GUPTA,* Gopal Singh KALWANIA, and Rakesh KUMAR
Department of Chemistry, University of Rajasthan, Jaipur 302004, India
(Received October 15, 1983)

Synopsis. Single step synthesis of substituted 4*H*-1,4-benzothiazines is reported by the condensation and oxidative cyclization of substituted 2-aminobenzenethiol with β-dicarbonyl compounds in DMSO. The structures of the synthesized compounds have been confirmed by their elemental analyses and spectral studies.

4*H*-1,4-Benzothiazines resemble structurally with phenothiazines in having a fold along nitrogen sulfur axis and can be anticipated to possess biological activities like phenothiazines.[1-7] 4*H*-1,4-Benzothiazines have been prepared by the reaction of *o*-aminobenzenethiol with ethyl 2-chloroacetoacetate[8] or β-bromoketones/α,α-dimethoxy-β-bromoethane.[9] In these methods halogenated ethylacetoacetate and ketones are required, and therefore it is considered worthwhile to develop a convenient method for synthesis of 4*H*-1,4-benzothiazines involving the use of ethylacetoacetate or β-dicarbonyl compounds as such without converting them into halogenated form.

In the present communication a single step method is reported for the synthesis of hitherto unknown substituted 4*H*-1,4-benzothiazines which involve the condensation followed by oxidative cyclization of substituted 2-aminobenzenethiol with β-dicarbonyl compounds in DMSO (Scheme 1). We have used 3- and 5-substituted 2-aminobenzenethiols (1 : R=Me, Cl, MeO; R_1=Cl, Me) and β-dicarbonyl compounds such as ethylacetoacetate, dibenzoylmethane, benzoylacetone, and *p*-chlorobenzoylacetone. Two isomeric products of 4*H*- 1,4-benzothiazine may be formed theoretically, but compound (**1c**) predominates over the compound (**1d**) (identified by mass spectral studies).



R=H, CH_3, OCH_3, Cl; R_1=CH_3, Cl, H
R_2=C_6H_5, CH_3, OC_2H_5, *p*-ClC_6H_4
R_3=CH_3, C_6H_5

Scheme 1.

The infrared spectra of all the benzothiazines invariably showed an NH absorption in the region of 3200—3390 cm^{-1} and carbonyl absorption in the region of 1570—1615 cm^{-1}. The weak absorption bands in the region of 1355—1485 cm^{-1} are attributed to C–CH_3 vibrations in substituted 4*H*-1,4-benzothiazines. The bands in the region of 1600—1510 cm^{-1} are attributed to C=C stretching vibrations. A broad signal in the region of τ 1.25—1.45 was observed in all the compounds arising due to an NH proton and the multiplets in the region of τ 2.2—3.6 are due to aromatic ring protons. A singlet peak centered at τ 6.2 arising due to an OCH_3 group in methoxy derivatives was also observed. All benzoyl 4*H*-1,4-benzothiazines showed peaks at m/z=M^+—105 (with high intensity), 105 ($CO^+C_6H_5$, base peak), and 77 ($C_6H_5^+$) by the loss of a benzoyl group, but did not show any peak corresponding to the M^+–$COCH_3$ or $COCH_3^+$ moiety, proving the structure of these benzothiazines to be **1c**. The 3,5-dimethyl-2-ethoxycarbonyl derivative gave peaks at m/z=M^+–C_2H_4, M^+–OC_2H_5, and M^+–C_2H_5.

TABLE 1. PHYSICAL DATA OF SUBSTITUTED 4*H*-1,4-BENZOTHIAZINES

Experimental

All the melting points are uncorrected. The purity of the synthesized compounds was tested on the elemental analysis and thin-layer chromatography of silica gel in various non-aqueous solvents. Infrared spectra of 4*H*-1,4-benzothiazines have been scanned in KBr on Perkin-Elmer 577 grating spectrophotometer and their NMR spectra were recorded on a Perkin-Elmer R12 B spectrometer using tetramethylsilane as an internal standard. The mass spectra were recorded on a JEOL, JMSD-300 mass spectrometer at 70 eV with 100 μA ionizing current.

*Preparation of Substituted 4*H*-1,4-Benzothiazines(II)*, The substituted 2-aminobenzenethiol[10-12] (1, 0.01 mol) was added to the stirred suspension of β-dicarbonyl compound (0.01 mol) (acetylacetone, ethylacetoacetate, dibenzoylmethane, benzoylacetone, or *p*-chlorobenzoylacetone) in DMSO (5 ml) and the resulting mixture was refluxed for 1 h. The mixture was cooled down to room temperature and a solid substance separated was filtered and crystallized from methanol. The physical data are given in Table 1.

(Received July 11, 1983)

The crystal structure of the title complex has been determined by the X-ray method. The complex crystallizes in the monoclinic space group P2/c with a=24.171(9), b=14.037(3), c=24.401(9) Å, β=119.68(9)°, and Z=4. The structure was solved by the heavy-atom method and refined to R=0.094 for 3838 reflections. Two independent dimers exist with a crystallographically imposed two-fold axis in the unit cell. The two dimers are in an approximately orthogonal arrangement, and they take very similar conformations. The noticeable structural parameters are the average distances of 2.033(28) Å for Os^{IV}-N, 1.808(3) Å for Os^{IV}-O^{2-}, and 1.997(29) Å for Os^{IV}-OCH_3. The two porphinato cores bridged by a μ-oxo oxygen atom rotate around the approximately linear Os-O-Os bond (the average valence angle=178°) by 23(1)° from the eclipsed form. The porphine ring is planar within 0.10 Å, and deviation of the Os atom from the porphinato plane of the four nitrogen atoms is 0.06 Å. These results were compared, in the relation of the specific physicochemical properties in solution, with those of the corresponding Ru^{IV} complexes reported previously.

We have recently been studying the molecular and crystal structures of ruthenium(IV) porphyrins[1] as a model of quadrivalent iron porphyrins, which have received attention in relation to the structure of catalases, horseradish peroxidases, and cytochrome c peroxidases in the redox process.[2] In the recently established structures of the ruthenium(IV) porphyrins, the quadrivalent state of the metal ion was observed to be stabilized by the strong O^{2-} ligand in the axial direction, and such a structural aspect around the ruthenium(IV) ion gave a good assumption for the undetermined axial ligands around the iron(IV) ion in peroxidases. The quadrivalent osmium ion has the same number of outer-shell (d+s) electrons as the ruthenium(IV) ion, and it also forms iron(IV) porphyrin analogues. Several osmium(IV) porphyrin complexes have been obtained so far in similar reactions aimed at getting the ruthenium(IV) complexes;[1,3c] in those complexes the bivalent osmium porphyrins were oxidized to the quadrivalent state at the same time that the indole derivatives were oxidized by the molecular oxygen with the bivalent osmium porphyrins.[3] The physicochemical properties of the title complex in solution are very similar to those of the corresponding ruthenium(IV) complexes. The ^{1}H-NMR, absorption spectra, and cyclic voltammetry suggested that the osmium(IV) porphyrins formed a linear μ-oxo dimer structure as well as the ruthenium(IV) complexes. However, the osmium(IV) complex in an acid solution showed a slightly different behavior from the ruthenium(IV) complex. The μ-oxo oxygen atom had a high affinity for protons in the presence of a 1% acid such as CF_3COOH, HCl, and $HClO_4$.[3c] The cause of the high proton affinity might lie in the μ-oxo bridge structure of the osmium(IV) porphyrin dimer. A detailed comparison of the structure of the dimer with that of the ruthenium(IV) complex was of interest.

Experimental

Dark-violet plate-like crystals of the μ-oxo-bis[methoxo(octaethylporphinato)osmium(IV)] complex, $[Os^{IV}(oep)(OCH_3)]_2O$, obtained by the 2,3-dimethylindole treatment of $[Os^{II}(oep)(CO)(CH_3OH)]$ in dichloromethane,[3c] were subjected to X-ray experiments.

Crystal Data. $C_{74}H_{94}N_8O_3Os_2$, M=1522, monoclinic, space group P2/c, a=24.171(9), b=14.037(3), c=24.401(9) Å, β=119.68(9)°, U=7192(5) Å^3, Z=4, D_c=1.407 g cm^{-3}, D_m=1.40 g cm^{-3}, $F(000)$=3048, λ=0.71073 Å, μ(Mo $K\alpha$)=38.27 cm^{-1}.

The diffraction intensities were measured on a Rigaku AFC-5 diffractometer with graphite-monochromated Mo $K\alpha$ radiation. The intensity data of 4056 reflections in the $2\theta<50°$ range were collected in the ω–2θ scan mode with a scan rate of 5° min^{-1} and using a crystal with dimensions of 0.5×0.5×0.3 mm. During the course of the data collection, three reflections were monitored every 60 reflections. The intensity data were converted to the F_o data in the usual manner. Absorption correction was applied in the spherical approximation. The standard deviations $\sigma(F_o)$ were estimated by means of the counting statistics. A total of 3838 independent reflections with $F_o>3\sigma(F_o)$ were retained as observed, and used in solving and refining the structure.

The structure was solved by the heavy-atom method. The four osmium atoms were located by a sharpened Patterson synthesis. Although the systematic absences of $h0l$ for $l=2n+1$ led to two possible space groups, Pc and P2/c, the configuration was tentatively assumed to be the space group P2/c; the successive Fourier syntheses revealed the approximate structure. The block-diagonal least-squares refinement to examine the two possible space groups, P2/c and Pc, resulted in the rejection of the latter space group Pc, because it gave several abnormal bond distances and angles, and also gave non-positive temperature factors for some light atoms. Thus, a trial structure based on the space group P2/c was chosen for the further refinement. Several cycles of the block-diagonal least-squares refinement including the anisotropic thermal parameters were carried out with the weighting scheme of $w^{-1}=(\sigma^2(F_o)+(0.023F_o)^2)$. The atomic scattering factors[4a] and the anomalous dispersion terms[4b] were taken from the International Tables for X-Ray Crystallography, IV. The hydrogen atoms were included as a fixed contribution in the last cycle; their positions were assumed to be in accord with the idealized geometry (C-H=1.00 Å), and their temperature factors were assumed to be isotropic (B=8.00 Å^2). The final R value was 0.094. The final difference Fourier map showed no peak greater than 0.6 e/Å^3; most of the largest peaks were around the osmium atoms. All the computations

were performed on a FACOM M-200 computer at the Data Processing Center of Kyoto University by using the program system KPAX. The positional parameters of the non-hydrogen atoms are given in Table 1.[5]

Results and Discussion

The unit cell is comprised of four discrete μ-oxo dimers of $[Os^{IV}(oep)(OCH_3)]_2O$ (see Fig. 1). There are two independent dimers, A and B, which take an

approximately orthogonal arrangement to each other. Each dimer has a two-fold axis through the μ-oxo oxygen atom, bisecting the line joining two osmium atoms in the dimer. Thus, the asymmetric unit consists of two [Os^{IV}(oep)(OCH_3)]-O- moieties. The two independent osmium porphinato moieties have similar conformations, as is illustrated in Figs. 2(a) and (b).

The numbering scheme for the carbon and nitrogen atoms in each [Os^{IV}(oep)(OCH_3)]-O- moiety is shown in Fig. 3. The bond distances and bond angles are listed in Table 2. The average bond distances and bond angles for chemically equivalent types of the bond in the osmium octaethylporphinato skeletons are also presented in Fig. 3. The average values agree with those of the corresponding bonds in the other metalloporphyrins,[6] within the limits of experimental error.

Figure 4 presents a perspective diagram of the environment of the osmium ion, with the average bond distances and bond angles. The porphine rings are planar within 0.10 Å, and the osmium ions are displaced by 0.06Å out of the plane defined by the four porphinato nitrogen atoms. The average Os-N distance, 2.033(28) Å,[7] is normal for the quadrivalent osmium ion, and it is comparable with the bivalent Os-N distance, 2.067(2) Å, reported in [Os^{II}(oep)(pyridine)(CO)].[8] The Os^{IV}-O^{2-} distances of 1.807(3) and 1.809(3) Å are comparable with the Ru^{IV}-O^{2-} distance of 1.793(2) Å in [Ru^{IV}(oep)Cl]$_2$O,[1b] with the chloride

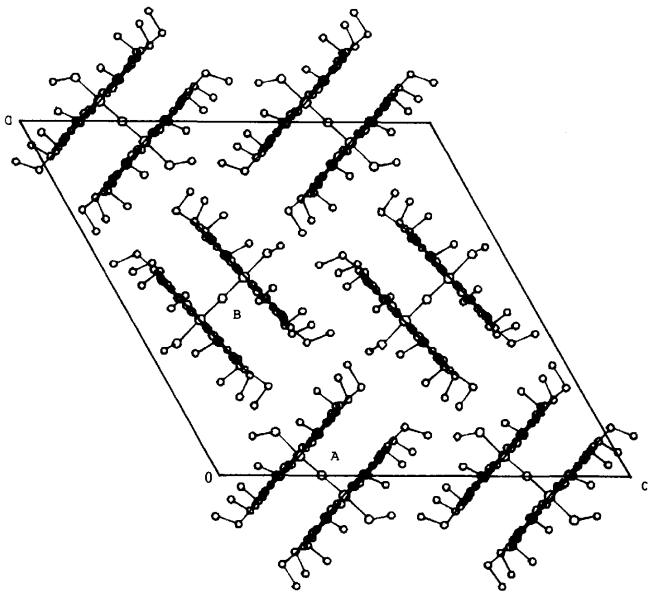

Fig. 1. Packing diagram of [Os^{IV}(oep)(OCH_3)]$_2$O crystal as viewed parallel to *b*.

atom as the external ligand, but it seems to deviate greatly from that of 1.847(13) Å in [Ru^{IV}(oep)(OH)]$_2$O.[1a] The average Os^{IV}-OCH_3 distance of 1.997(29) Å agrees with the 5% reduction of the sum of the ionic

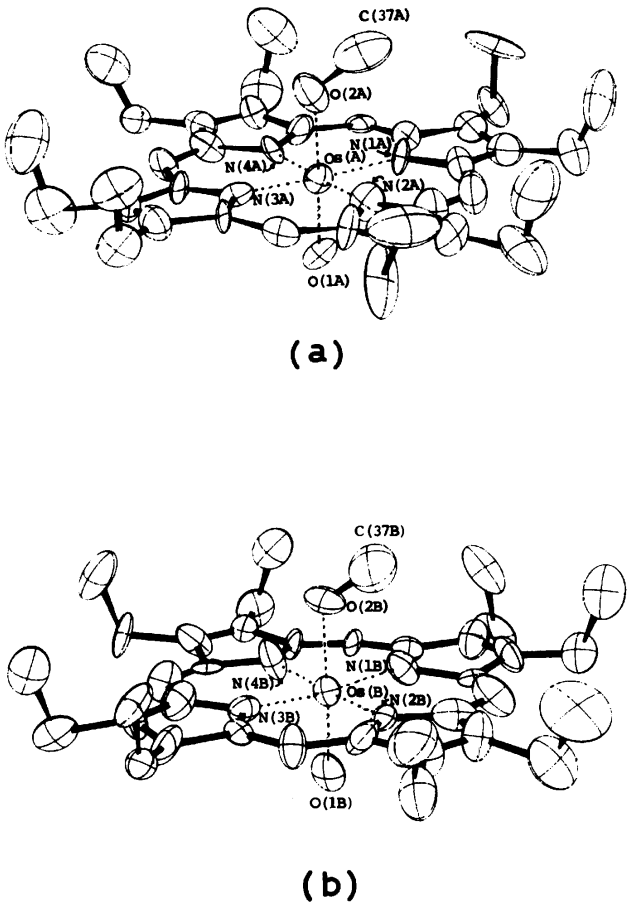

Fig. 2. Computer drawnings of the two independent osmium porphinato moieties, (a) and (b), showing 30 % probability thermal-vibration ellipsoids.

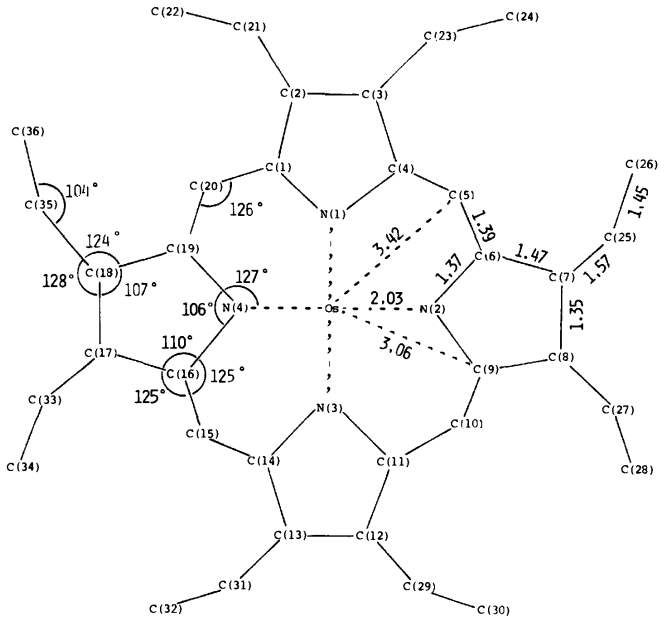

Fig. 3. Bond distances and bond angles averaged over the chemically equivalent bonds.

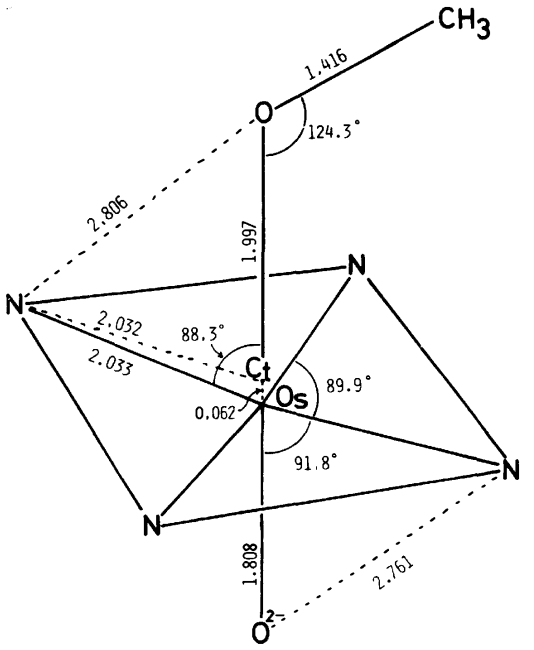

Fig. 4. Coordination sphere showing averaged bond distances and bond angles around the osmium(IV) atom in $[Os^{IV}(oep)(OCH_3)]_2O$. C_t represents the center of the porphinato skeleton.

radii,[11] 2.04 Å, due to the formation of the six-coordinate metal ion. The μ-oxo dimer consists of the two units of osmium porphyrins related by the two-fold symmetry through the O^{2-} atom. The Os–O–Os* bond has the valence angle of 178°. The two porphyrins are twisted with respect to each other so as to lie approximately midway between a staggered conformation and an eclipsed one, the N–Os–Os*–N* torsion angle being 23(1)°.[9] The average interplanar separation between the mean planes of the facing porphyrins is 3.7 Å; the closest interatomic distances are 3.60 Å for C(4A)–C(5A)* and 3.64 Å for C(11B)–C(20B)*. The binuclear porphyrin structure resembles those reported in $[Ru^{IV}(oep)(OH)]_2O$[1a] and $[Ru^{IV}(oep)Cl]_2O$,[1b] and, for the reason presented in the previous reports on the Ru^{IV} porphyrin dimers,[1] the structure is stabilized by the intramolecular π-π interactions between the face-to-face-contact porphyrins and by the $d\pi$-$p\pi$-$d\pi$ interaction in the Os^{IV}–O–Os^{IV}* bond. The diamagnetic property of this complex can also be well interpreted in terms of the π-π interactions in the Os^{IV}–O–Os^{IV}* bond system with the low-spin Os^{IV} atom.

As has been mentioned in the Introduction, the osmium-dimer complex in an acidic solution shows a high sensitivity for the protons, and the electron-donating ability of the μ-oxo bivalent anion (O^{2-}) in the Os^{IV}–O–Os^{IV} system is considerably stronger than that in the Ru^{IV}–O–Ru^{IV} system. This difference is reflected in the bond distances or bond angles around the μ-oxo oxygen. The observed Os^{IV}–O–Os^{IV} bond is almost as linear as the corresponding bonds in the ruthenium complexes,[1] in accordance with the statement of Tatsumi *et al.* that the μ-oxo dimers of d^n–d^n

($n<5$) electron systems prefer a linear M–O–M framework.[10] On the other hand, the Os^{IV}–O^{2-} distance is quite a bit smaller than the sum of the ionic radii;[11] it is also shorter than the Ru^{IV}–O^{2-} distance in $[Ru^{IV}(oep)(OH)]_2O$,[1a] although the Os^{IV}–O^{2-} distance is expected to be longer than the Ru^{IV}–O^{2-} distance from a comparison of the ionic radii of Os^{IV}(0.69 Å) and Ru^{IV}(0.65 Å) as observed in the $Os^{IV}O_2$ and $Ru^{IV}O_2$ crystals.[11,12] The short Os^{IV}–O^{2-} bond in the established structure may well account for the high sensitivity for the protons, because the shortening means a large distribution of electrons in the (Os^{IV}–O^2) π bonding orbital, and the electron-rich bonding orbital will be active for a proton.

The authors wish to thank professor Nobuo Morimoto and Dr. Katsutoshi Tomita, Faculty of Science, Kyoto University, for the use of the Rigaku AFC-5 diffracatometer.

(Received October 29, 1983)

The ultrasonic relaxation absorption has been measured in aqueous solution of dipentylamine, dihexylamine, dioctylamine, *N*-methylphenethylamine, and *N*-ethylbenzylamine in the presence of the sodium dodecyl sulfate(SDS) micelle. The relaxation absorption has been ascribed to the base equilibrium of the amines on the surface of the micelle: $RR'NH_2^+ + OH^- \underset{k_b}{\overset{k_f}{\rightleftharpoons}} RR'NH + H_2O$. The rate constants $\gamma_\pm^2 k_f$, k_b, the apparent base dissociation constant K_b ($=k_b/\gamma_\pm^2 k_f$), and the volume change in the base equilibrium ΔV were obtained, where $\gamma_\pm$ is the mean activity coefficient for $RR'NH_2^+$ and OH^-. The dependence of the rate constants on K_b revealed that, in the detailed mechanism of the base equilibrium of the amines, $\underset{(I)}{RR'NH_2^+} + OH^- \underset{k_{21}}{\overset{k_{12}}{\rightleftharpoons}} \underset{(II)}{(RR'NH_2^+ \cdots OH^-)} \underset{k_{32}}{\overset{k_{23}}{\rightleftharpoons}} \underset{(III)}{RR'NH} + H_2O$, the rate-determining step is the proton-transfer process, (II) $\rightleftharpoons$ (III). The pK_b values of the secondary amines on the surface of the SDS micelle were 0.94—1.26 smaller than the corresponding values in the aqueous solution, and the micellar effect on pK_b was smaller than that of the primary amines. From the standpoint of the micellar effect, the structures of the amines solubilized in the micelle were discussed.

Detergent micelles have been of interest as a peculiar reaction field, and many investigations[1-3] have been carried out to reveal the controlling factors in the promotion or inhibition of various reactions on the surface of the micelle. However, only relatively slow reactions have been studied with the exception of our own previous studies[4,5] of the micellar effect on a rapid base equilibrium of primary amines by the use of the ultrasonic absorption method. In those previous works[4,5] (i) kinetic parameters were obtained for the base equilibrium of primary amines on the surface of the SDS micelle, (ii) linear relationships were observed between the logarithms of the rate constants and that of the base dissociation constant, and (iii) the rate-determining step was ascribed to the proton-transfer process in the ion pair. The purposes of the present work are to study kinetically the micellar effects on the base equilibrium of the secondary amines, to compare the results with those of the primary amines, and to study especially the effect of the *N*-alkyl or aryl groups on the electrostatic interactions between the amine cation and the anionic sulfate group of the micelle forming detergent.

Experimental

The dihexylamine purchased from Tokyo Kasei and *N*-ethylbenzylamine from Aldrich were purified by distillation. The dipentylamine from Katayama Kagaku, dioctylamine from Tokyo Kasei, *N*-methylphenethylamine from Aldrich, and SDS from BDH were used without further purification.

The ultrasonic absorption measurements were performed by the pulse technique over the frequency range of 5—105 MHz. The details of the apparatus were described elsewhere.[6] The velocity of the sound was measured by the sing-around method at 1.92 MHz. The density was measured by means of a pycnometer. The pH of the solution was measured by means of a Kyoto Electronics AT-117-type potentiometer. All the pH and ultrasonic measurements were carried out under a dry nitrogen gas atmosphere at 30 °C.

Results and Discussion

The ultrasonic relaxation absorption was observed for secondary amines of various basicities in a SDS micellar solution. All the absorptions were represented by a single relaxation equation;[7,8]

$$\alpha/f^2 = A/\{1+(f/f_r)^2\} + B, \quad (1)$$

where α is the absorption coefficient, f is the frequency, f_r is the relaxation frequency, and A and B are the relaxing and nonrelaxing absorptions respectively.

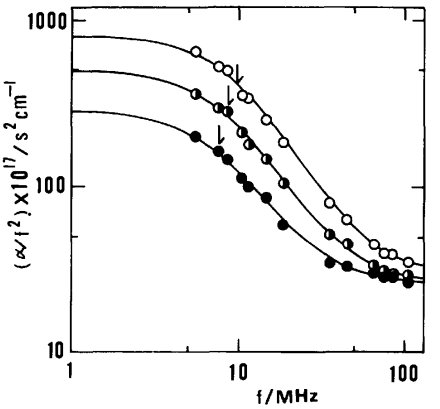

Fig. 1. Representative ultrasonic absorption spectra of the secondary amines (0.050 M†)–SDS (0.30 M) system at 30.0 °C. ○: Dipentylamine. ◑: *N*-Methylphenethylamine. ●: *N*-Ethylbenzylamine. The arrows indicate the relaxation frequency. († 1 M=1 mol dm^{-3})

Some representative absorption spectra are shown in Fig. 1. The absorption parameters obtained by fitting the data to Eq. 1 by means of a computer simulation are summarized in Table 1, along with the experimental conditions.

The ultrasonic behavior of the secondary amines in the SDS micellar solution was similar to that of the primary amines, which implies that the relaxation absorption can be assigned to the following reaction;

a) Degree of ionization.

$$RR'NH_2^+ + OH^- \underset{k_b}{\overset{k_f}{\rightleftharpoons}} RR'NH + H_2O, \quad (2)$$

where the hydrocarbon groups of an amine are solubilized in the core of the SDS micelle. The base dissociation constant, K_b^0, is given as;

$$K_b^0 = \frac{k_b}{k_f} = \frac{\gamma_\pm^2[RR'NH_2^+][OH^-]}{[RR'NH]} = \frac{\gamma_\pm^2\sigma^2 C_0}{1-\sigma}, \quad (3)$$

where σ is the degree of ionization, C_0 is the total concentration of the amine, and $\gamma_\pm$ is the mean activity coefficient. The relaxation frequency and the maximum relaxation absorption per wavelength, μ_{max}, for Reaction 2 are expressed by;[7,8]

$$2\pi f_r = \gamma_\pm^2 k_f([RR'NH_2^+] + [OH^-]) + k_b, \quad (4)$$

$$\mu_{max} = \frac{\rho u^2 \pi (\Delta V)^2}{2RT} \cdot \Gamma^{-1},$$

$$= \frac{\rho u^2 \pi (\Delta V)^2}{2RT} \cdot \frac{\sigma(1-\sigma)}{2-\sigma} \cdot C_0, \quad (5)$$

with;

$$\Gamma = [RR'NH_2^+]^{-1} + [OH^-]^{-1} + [RR'NH]^{-1}, \quad (6)$$

where ρ is the density of the solution, u is the velocity of sound, and ΔV is the volume change in the base equilibrium of the amine. Equation 4 can be rewritten as follows in terms of C_0 by using Eq. 3;

$$(2\pi f_r)^2 = 4\gamma_\pm^2 k_f k_b C_0 + k_b^2. \quad (7)$$

The experimental values of $(2\pi f_r)^2$ are plotted against C_0 in Fig. 2. The plots give a straight line, as predicted by Eq. 7; the result indicates that the relaxation absorption is due to Reaction 2. From the slope and the intercept of the straight line, the values of $\gamma_\pm^2 k_f$ and k_b respectively were obtained, and from their ratio, the apparent base dissociation constant, K_b ($=k_b/\gamma_\pm^2 k_f$), was obtained; all these parameters are listed in Table 2. The plots of μ_{max} against the Γ^{-1} calculated from the K_b obtained above and C_0 gave a straight line which goes through the point of origin of the coordinates, as shown

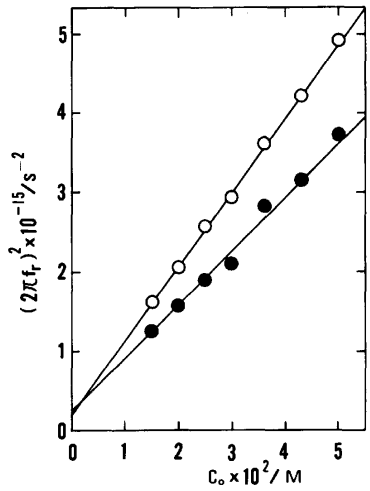

Fig. 2. Plots of $(2\pi f_r)^2$ *vs.* concentration of secondary amines in the presence of SDS (0.30 M) at 30.0 °C. ○: Dioctylamine. ●: Dipentylamine.

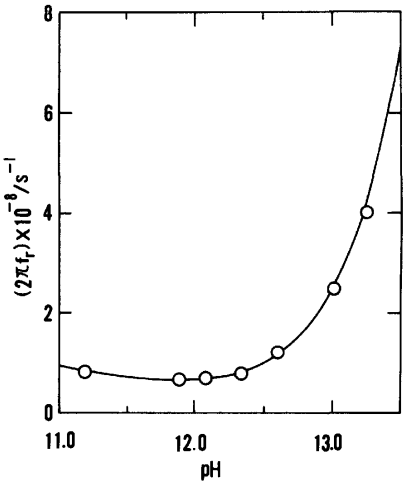

Fig. 4. pH dependence of the value of $2\pi f_r$ for the dioctylamine (0.050 M)–SDS (0.30 M) system at 30.0 °C. The solid line is the curve calculated by Eq. 4 with the values of $\gamma_{\pm}^2 k_f$, k_b, and K_b in Table 2. Circles are the experimental data.

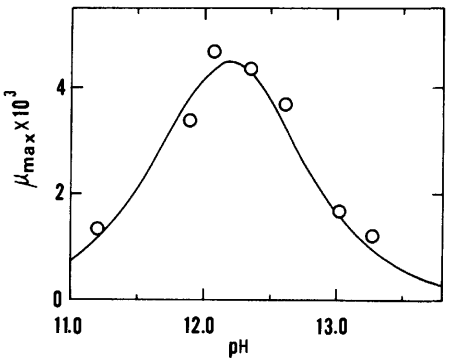

Fig. 5. pH dependence of μ_{max} for the dioctylamine (0.050 M)–SDS (0.30 M) system at 30.0 °C. The solid line is the curve calculated by Eq. 5 with the values of K_b and ΔV in Table 2. Circles are the experimental data.

in Fig. 3. A comparison with Eq. 5, also supports the idea that the relaxation absorption is due to Reaction 2. The value of ΔV was calculated from the slope of the straight line in Fig. 3.

The values of K_b can also be evaluated statically from the values of C_0 and pH in Table 1, together with the activity coefficient calculated by the use of the Davies equation;[9] they are listed in Table 2. As can be seen in the table, the value for each amine is in satisfactory agreement with that obtained above kinetically.

Further support of the assignment of the present relaxation absorption was given by the pH-dependences of the ultrasonic parameters. As a sample, the data for dioctylamine were obtained; the pH-dependences of f_r and μ_{max} are shown in Figs. 4 and 5 respectively. As can be seen in the figures, f_r and μ_{max} depend strongly on the pH, and the curves as calculated from Eqs. 3—6 by using the values of C_0, and the rate constants, K_b and ΔV obtained above express the experimental data satisfactorily. These results lead to the conclusion that the assignment of the absorption and the kinetic parameters obtained is reasonable.

The results demonstrate, among other things, the basicity dependence of the rate constants. As shown in Fig. 6, linear relationships were established for the plots of $\log \gamma_{\pm}^2 k_f$ *vs.* $\log K_b$ and $\log k_b$ *vs.* $\log K_b$. These relationships are expressed as;

$$\gamma_{\pm}^2 k_f = 10^{8.3} K_b^{-0.40} = 10^{8.3} (K_w/K_a)^{-0.40} = 10^{13.8} K_a^{0.40}, \quad (8)$$

$$k_b = 10^{8.3} K_b^{0.60}, \quad (9)$$

where K_w is the ionization constant of water and where K_a is the acid dissociation constant of an amine. These relationships are in contrast to those for the base equilibrium of amines in an aqueous solution,[10–14] where k_f is independent, while k_b is dependent on $K_b(w)$;

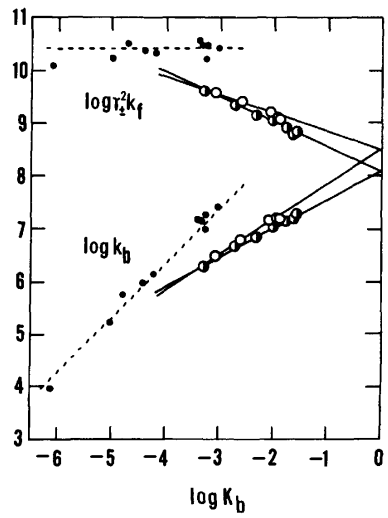

Fig. 6. Plots of the logarithms of the rate constants *vs.* $\log K_b$ for secondary amines (○) and primary amines[4,5] (◑) in the presence of SDS (0.30 M), and various amines in the absence of the micelle[11] (●).

$$k_{f(w)} = 10^{10.5}, \tag{10}$$

$$k_{b(w)} = 10^{10.5} K_{b(w)}, \tag{11}$$

where the subscript, (w), indicates the aqueous solution.

In general, the detailed mechanism of Reaction 2 has been described as;

$$\underset{\text{(I)}}{RR'NH_2^+} + OH^- \underset{k_{21}}{\overset{k_{12}}{\rightleftharpoons}} \underset{\text{(II)}}{(RR'NH_2^+\cdots OH^-)} \underset{k_{32}}{\overset{k_{23}}{\rightleftharpoons}} \underset{\text{(III)}}{RR'NH} + H_2O. \tag{12}$$

The (I)⇌(II) process is an ion pair formation and dissociation (diffusion process), and the rate constants, k_{12} and k_{21}, are dependent on the electric charge, the volume, and state of hydration, *etc.* of the ions; the proton-transfer still does not occur in the (I)⇌(II) process. Accordingly, k_{12} and k_{21} do not depend on the electron-donating (or-attracting) property of amines. On the other hand, the (II)⇌(III) process is a proton-transfer process in the ion pair, and the rate constants, k_{23} and k_{32}, are dependent mainly on the electron-donating (or-attracting) property of amines; that is k_{23} and k_{32} are dependent on K_b.

If (I)⇌(II) is the rate-determining step, the overall rate constants are expressed as;[10-14]

$$k_f = k_{12}, \tag{13}$$

$$k_b = k_{21} \cdot \frac{k_{32}}{k_{23}}. \tag{14}$$

These equations predict an independency of K_b from k_f and a linear dependency of K_b on k_b; these predictions are in good agreement with the results for the base equilibrium of amines in aqueous solutions, as seen in Eqs. 10 and 11 and in Fig. 6. However, the results of the present work, the K_b dependencies of k_f and k_b, *i.e.*, Eqs. 8 and 9, cannot be realized at all by means of Eqs. 13 and 14.

If (II)⇌(III) is the rate-determining step, on the other hand, k_f and k_b are given as follows;[5]

$$k_f = \frac{k_{12}}{k_{21}} \cdot k_{23}, \tag{15}$$

$$k_b = k_{32}. \tag{16}$$

Since (II)⇌(III) is a proton-transfer process in the ion pair, k_{23} will decrease and k_{32} will increase with an increase in K_b. Accordingly, Eqs. 15 and 16 provide a satisfactory interpretation of the K_b dependences of the rate constants in the base equilibrium of amines in a micellar solution. Then, the rate-determining step in Reaction 12 on the surface of a micelle is clarified to be the proton-transfer process in the ion pair, (II)⇌(III).

As can be seen in Eqs. 8 and 9, the kinetics of the base equilibrium of amines in the micellar system are in the form of the Brönsted catalysis law.[15] According to the Brönsted catalysis law, the right-hand side is composed of a constant and a term of a contribution of K_b, where the index (the Brönsted coefficient) expresses the degree of proton-transfer at the rate-determining step. The constant in Eqs. 8 and 9 corresponds to the rate constant of k_f (or k_b) when K_b=1; in other words, it reflects the magnitude of the activation energy of a reaction when the energy difference of the reactant and the product is zero. As can be seen in Eqs. 8—11, in the base equilibrium of amines on the surface of the SDS micelle, the value of the constant is more than two orders of magnitude smaller than that in the aqueous solution. This means that the former has a larger activation energy than the latter; the difference between them was found to be 3.0 kcal mol^{-1} by the use of the equation of $-RT$ ln $10^{8.3-10.5}$. The indices of the primary and the secondary amines in the micellar system were found to be about 0.5, which indicates that about half of the proton-transfer is performed at the rate-determining step. This fact supports the above-mentioned conclusion that the rate-determining step exists between (II) and (III) in Reaction 12.

As can be seen in Table 2, the pK_b values of the amines in an SDS micellar solution are much smaller than the corresponding values in an aqueous solution. This micellar effect on pK_b can be explained in terms of the cationic amino group being stabilized electrostatically by the surrounding anionic sulfate groups of the micelle and the dissociation of the amine being accelerated. Since the electrostatic interaction is proportional to the distance of the amino group and the anionic surface of the micelle, the difference in the pK_b values between the two solutions, ΔpK_b, will be used as a measure of the degree of penetration of an amine into the micelle. In fact, in a series of primary amines,[5] the largest of the ΔpK_b values, 1.77, was observed for octylamine, where a long alkyl chain causes the amine to be well solubilized in the micelle and causes the amino group to be close to the anionic surface of the micelle, while in the case of benzylamine, the hydrophobic group is small and the penetrates little into the micelle, and the micellar effect on pK_b is smaller, ΔpK_b=1.35. In the present study, the ΔpK_b values of the secondary amines (shown in Table 2) were smaller than those for

the primary amines, 1.35—1.77. Especially in the cases of the amines with two long alkyl groups, the ΔpK_b values were the smallest among those of the amines studied. From the standpoint of the micellar effect on pK_b, the secondary amines are not so deeply solubilized in the micelle as the primary amines because of the specific structures of the two hydrophobic groups. A similar picture can also be deduced from the kinetic results; as may be seen in Fig. 6, the K_b dependencies of k_f and k_b in the present work are a little closer to those in the aqueous solution than those for the primary amines in the SDS micellar solution. Therefore, the amino group of secondary amines might be located a little far from the anionic sulfate group of the micelle and closer to the bulk water, and the micellar effect on the base equilibrium seems to be a little smaller than that of primary amines.

In conclusion, the fundamental difference between the primary and secondary amines was not established in the reaction mechanism of the base equilibrium on the SDS micelle. However, small differences in the micellar effect on pK_b and in the K_b dependencies of the rate constants provided a picture of a little shorter penetration of the secondary amines into the SDS micelle than that of the primary amines.

The authors wish to thank the Computer Center of Kyushu University for its help in the calculation of the ultrasonic absorption parameters by means of the Facom M-200 Computer.

Kinetics of Solute-Solvent Interaction in Aqueous Solution of Butyl Carbitol by Ultrasonic Methods

Sadakatsu NISHIKAWA* and Masayuki SHIBATA
Department of Chemistry, Faculty of Science and Engineering, Saga University, Saga 840
(Received November 19, 1983)

Ultrasonic absorptions in the frequency range 4.5—220 MHz and sound velocities at 2.5 MHz were measured at 25 °C with aqueous solutions of Butyl Carbitol (diethylene glycol monobutyl ether) over the concentration range 0.497—3.00 mol dm^{-3}. Only a single relaxational process was observed and attributed to a perturbation of the equilibrium $AB \underset{k_{21}}{\overset{k_{12}}{\longleftrightarrow}} A+B$, where A is Butyl Carbitol as the solute and B is water as the solvent participating in the reaction. A data analysis has led to the estimates $k_{12}=3.4\times10^{7}$ s^{-1}, $k_{21}=2.0\times10^{8}$ dm^3 mol^{-1} s^{-1}, the standard volume change of reaction $\Delta V^\circ=0.32$ cm^3 mol^{-1}, and the standard enthalpy change $\Delta H^\circ=5.4$ kJ mol^{-1}. The effect of the hydrophobicity of solute molecules on the water structure is discussed by comparing the present results with previous ones for other aqueous nonelectrolyte solutions.

In a series of ultrasonic studies of aqueous solutions of nonelectrolytes,[1-8] we have found that different ultrasonic absorptions appear in the MHz frequency range depending upon the structure of solutes. They have been interpreted in terms of conventional relaxation theory. In order to analyze the relation between ultrasonic properties and structures of solute, a further accumulation of absorption results is desired for various nonelectrolytes over a wide frequency range and a concentration range. For this purpose, we have chosen Butyl Carbitol (diethylene glycol monobutyl ether) as a solute and have compared results obtained with those for other solutions. Another purpose of the present investigation is to elucidate why double relaxational processes have appeared in some solutions and a single process has in other solutions even when the structures of solutes are quite similar.

Experimental

Butyl Carbitol from Tokyo Kasei Co., Ltd. was distilled once under reduced pressure. No impurity was found by the gas-chromatographic method. Doubly distilled water was used as solvent. Concentrations of solutions were determined by weight.

Ultrasonic absorption coefficients were measured in the range 4.5—220 MHz by the pulse method.[9] Sound velocity was measured with an interferometer at 2.5 MHz. The temperature for measurements was 25 °C with a fluctuation within ±0.005 °C. The density of each solution was measured with a pycnometer, about 4.4 cm^3 in volume at various temperatures in order to determine thermal expansion coefficients. All ultrasonic, kinetic, and thermodynamic parameters were calculated with a microcomputer.

A complete set of ultrasonic absorption coefficients and velocities at various concentrations are available from one of the authors (S.N.) on request.

Results

No frequency dependence of α/f^2 is found in liquid Butyl Carbitol as is seen from Fig. 1, where α is the ultrasonic absorption coefficient and f is the frequency. A relaxational absorption is found at the concentrations above 0.701 mol dm^{-3}. With increasing concentration, the relaxational amplitude increases rapidly till 1.20 mol dm^{-3} and then decreases monotonously. The sound velocity in the solutions shows a maximum at around 0.804 mol dm^{-3}. Representative ultrasonic absorption spectra are shown in Fig. 1. In general, the sound absorption associated with a single relaxational process can be described by the equation

$$\alpha/f^2 = A/[1+(f/f_r)^2] + B, \quad (1)$$

where f_r is the relaxation frequency, A the relaxational amplitude, and B the background absorption. The absorptions over the concentration range 0.701—3.001 mol dm^{-3} are characteristic of a typical single relaxation. These ultrasonic parameters were determined so as to give the best fit of the experimental data to Eq. 1 by the nonlinear least mean square method. They are listed in Table 1 along with the results of the sound velocity, density, and thermal expansion coefficient as a function of analytical concentration, C_c. The values of α/f^2 calculated with the parameter thus evaluated are shown by the solid lines in Fig. 1.

a) The errors in the ultrasonic parameters are the most probable ones.

As shown in Table 1, the relaxation frequency, which is related to the relaxation time τ, shows a curious concentration dependence, that is, the presence of a minimum. If the relaxation process results from usual reactions of the solutes, such a dependence may not be observed. The relaxational absorption seems to be a characteristic of the solution. Therefore, we consider a perturbation of equilibrium associated with the interaction between solute and solvent as the cause of the absorption. It is simply represented by the formula

$$\underset{C_1}{AB} \underset{k_{21}}{\overset{k_{12}}{\longleftrightarrow}} \underset{C_2}{A} + \underset{C_3}{B}, \qquad (2)$$

where A is Butyl Carbitol, AB complex, and B water which interacts with the solute. The C_i's indicate the equilibrium concentrations of each component. In order to analyze the absorption mechanism, it is assumed that water consists of two states, *i.e.*, the hydrogen-bonded and nonhydrogen-bonded waters, and that the transition rates for these two states are too fast to be observed in our frequency range.[10] It is also assumed that the nonhydrogen-bonded water may participate in the reaction. On these assumptions, the relation between relaxation frequency and analytical concentration is derived as,[3]

$$1/\tau = 2\pi f_r = k_{21}[(C_e - \beta C_w + K_{12})^2 + 4\beta C_w K_{12}]^{1/2} \qquad (3)$$

where β is the molar fraction of the nonhydrogen-bonded water, C_w the analytical concentration of water, and K_{12} is defined as $K_{12}=k_{12}/k_{21}$. The rate and thermodynamic parameters, k_{21}, β, and K_{12}, are assumed to be independent of the concentration in the limited range studied. These parameters were determined so as to give the best fit of the observed relaxation frequencies to Eq. 3 as follows: The values of f_r obtained experimentally show a minimum at around 1 mol dm^{-3} and this result provides the relation between β and K_{12}.[3] Initially, a value of β was assumed and K_{12} was calculated. Then, the rate constant k_{21} was determined so as to fit the experimental relaxation frequencies to Eq. 3 using the least mean square method. This procedure was repeated until the value of standard deviation (S.D.) reached a minimum. In this calculation, the smallest S.D. was obtained when C_e was 1.15 mol dm^{-3}. However, the result at 3.001 mol dm^{-3} was not used since it remarkably deviates from smoothed curve. The values of relaxation frequency calculated from the parameters evaluated are shown by the solid line in Fig. 2.

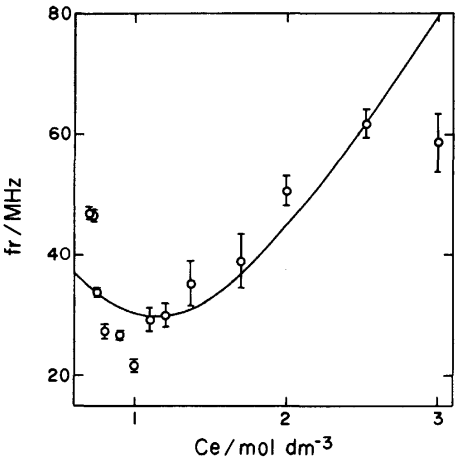

Fig. 2. Concentration dependence of the relaxation frequency for the aqueous solution of Butyl Carbitol at 25 °C. The solid line was calculated by means of Eq. (3) [S. D.=6.40 MHz].

Another parameter obtained from the measurements of the ultrasonic absorption and the velocity is a maximum excess absorption per wavelength, μ_m, which is expressed by the following equation on the assumption that the contribution of the relaxational specific heat is small:[3]

$$\mu_m = Af_r c/2 = \pi\rho c^2 \Gamma(\Delta V^\circ - \theta\Delta H^\circ/\rho C_p)^2/2RT \qquad (4)$$

where ρ is the density of solution, R the gas constant, T the absolute temperature, θ the thermal expansion coefficient, C_p the specific heat at constant pressure, ΔV° the standard volume change of the reaction, and

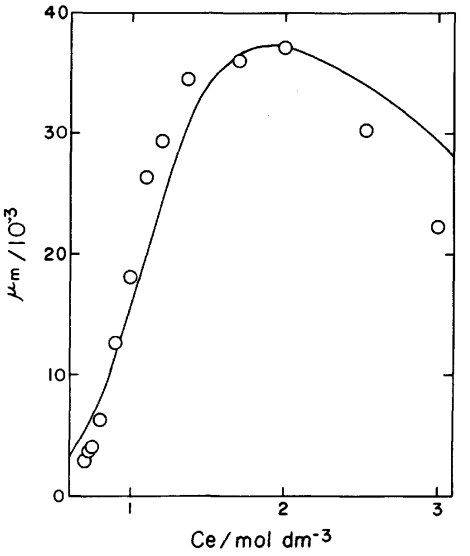

Fig. 4. Concentration dependence of the maximum excess absorption per wave length for the aqueous solution of Butyl Carbitol [S. D.=3.75×10^{-3}].

$\Delta H°$ the standard enthalpy change. The term Γ is derived for the reaction under consideration as $[1/C_1+1/C_2+1/C_3-1/(C_1+C_2+C_3)]^{-1}$. As reported in previous papers,[1,2] the concentration dependence of μ_m is controlled mainly by the term $\rho c^2\Gamma$. Precisely, however, term $\theta/\rho C_p$ depends on concentration. Therefore, we assume that the specific heat is given roughly by $C_p=2.28n_e+4.18(1-n_e)$(J deg^{-1} g^{-1}) in obtaining values of $\Delta V°$ and $\Delta H°$. Here, n_e is the molar fraction of Butyl Carbitol in the aqueous solution. The slope and intercept of $(2\mu_m RT/\pi\rho c^2\Gamma)^{1/2}$ *vs.* $\theta/\rho C_p$ plots shown in Fig. 3 provide with these values, as listed in Table 2. The concentration dependence of the density is well described by a cubic function of the analytical concentration of Butyl Carbitol as $\rho=0.99698+6.02505\times10^{-3}C_e-3.6627\times10^{-3}C_e^2+3.3096\times10^{-4}C_e^3$ (g cm^{-3}) [S. D.=2.5×10^{-4} (g cm^{-3})]; the sound velocity and thermal expansion coefficient are well expressed by the following polynomial equations: $c=1496.6+198.93C_e-179.32C_e^2+61.211C_e^3-7.5477C_e^4$ (m s^{-1}) [S.D.=2.3 (m s^{-1})] and $\theta=2.5295\times10^{-4}+2.1025\times10^{-4}C_e-2.0615\times10^{-5}C_e^2$ (deg^{-1}) [S.D.=1.1×10^{-5} (deg^{-1})]. The solid curve in Fig. 4 shows the values of μ_m which were calculated with the above thermodynamic parameters and Eq. 4.

Discussion

In order to interpret the observed relaxational process, several kinetical conditions have been applied: Firstly, even if the condition of water molecule is altered by addition of a solute, the association and dissociation processes between water molecules are too fast to be observed since their rates are estimated to be of the order of 10^{-12} s.[10] Secondly, any relaxation due to the internal rotation of solute may be ruled out because the concentration dependence of the observed relaxation frequency cannot be explained in terms of such a unimolecular reaction, and actually no relaxation phenomenon is found in pure Butyl Carbitol. Thirdly, the relaxation process due to the hydrogen bonding association of Butyl Carbitol molecules is probable. However, such a relaxation process is expected to be far beyond the MHz frequency range on the basis of estimates for various alcohols.[11,12] The high values of the background absorptions suggest the existence of such processes. Fourthly, although the association process of Butyl Carbitol molecules due to hydrophobic interaction is also conceivable, such phenomenon has been found for other ethers[1-4] with larger hydrophobic groups in lower frequency range than the observed frequency range. Finally, there is left only the relaxation process due to an interaction between ether and water molecules associated with hydrogen bonding, which has been shown to be capable of good interpretation of the experimental results in the preceding sec-

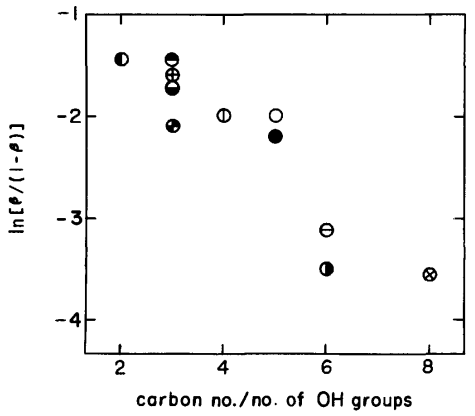

Fig. 5. Plots of the values of $\ln[\beta/(1-\beta)]$ *vs.* the carbon number per hydroxyl group for the aqueous solutions of a series of alcohols and ethers. ◐: 1,2-Butanediol, ◓: Allyl alcohol, ⊕: Isopropyl alcohol, ◒: Propyl alcohol, ◔: 1,6-Hexanediol, ⓘ: *t*-Butyl alcohol, ○: Allyl Cellosolve, ●: Propyl Cellosolve, ⊖: Isobutyl Cellosolve, ◑: Butyl Cellosolve, ⊗: Butyl Carbitol.

tion. According to our model, it is possible to estimate qualitatively the effect of Butyl Carbitol molecule on the water structure. The molar fraction β of nonhydrogen-bonded water in the aqueous solution which is calculated from Eq. 3 is listed in Table 2 along with those previously reported. The values may be taken to correspond exactly to the fraction of water capable of interacting with the solute or that of the less structured water molecules. The value for pure water is not less than 0.24.[13] On the other hand, those in the aqueous solutions are smaller than that of the water. This means that the addition of such nonelectrolytes into water causes water molecules to enter a more stabler state. This seems to be due to the hydrophobicity of the solute molecule. In order to examine its effect on the water structure we have plotted $\ln[\beta/(1-\beta)]$, which is related to the free energy change between the two states of water, against the carbon number per hydroxyl group for a series of alcohols and ethers, obtaining Fig. 5. With increasing carbon number per hydroxyl group, the value of $\ln[\beta/(1-\beta)]$ decreases, that is, the absolute value of the free energy change increases. This plot indicates that the ability to promote the water structure will increase with increasing hydrophobicity of the solute molecule.

It is interesting to note that a single relaxation process has been observed in the aqueous solution of Butyl Carbitol, whereas double relaxations are found in a solution of Butyl Cellosolve.[2] In the latter solution, one process is the same as that observed for Butyl Carbitol solution and the other, found around 7 MHz, has been attributed to a perturbation of equilibrium associated with an aggregation due to the hydrophobic interaction. The difference between the ultrasonic properties of these solutions may arise from the size of oxyethylene group, and the electrorepulsive force may affect the formation of the aggregate. This kind of difference has also been found in aqueous solutions of propyl alcohol[3] and Propyl Cellosolve.[8]

There is another interpretation for the absorption phenomenon in aqueous solutions of nonelectrolytes, which is based on the fluctuation model. Atkinson *et al.*[14-16] successfully analyzed observed absorptions in dioxiane, butylamine, and tetrahydrofuran solutions, which gave broad absorption spectra. They questioned the validity of such an approach as adopted in this report for reasons of unreliable complex formation, too slow rates for the hydrogen bonding, and inconsistent thermodynamic constants. However, as for the aqueous solution of Butyl Carbitol, a clear single relaxational absorption is observed, the simple 1-1 complex exists with equilibrium between the nonhydrogen-bonded water and single solute, the rate constant obtained corresponds to the overall process for the interaction in which the diffusion and rotation of reactants are also included, and the enthalpy change for the reaction seems reasonable because one reaction site is surrounded by many polar molecules.[17]

In conclusion, it has been elucidated from the present ultrasonic experiments for a series of alcohol and ether solutions that the ultrasonic absorption character will depend on the structure of solutes, that is, a single relaxational process occurs in solutions in which solutes have a relatively small hydrophobicity, whereas double relaxations appear with increasing hydrophobicity of solutes.

(Received December 5, 1983)

The entitled compound shows an anomalous temperature dependence of the mean-square amplitude of iron atoms derived from the Lamb-Mössbauer factor near the melting point. To clarify the anomaly, the crystal structure of this compound was determined at room temperature by X-ray diffraction. The crystal is monoclinic with space group $P2_1/c$, a=20.595(2), b=5.7909(4), c=18.840(2) Å, β=116.870(7)°, U=2004.4(3) Å^3, and Z=8. Weissenberg and oscillation photographs taken at a high temperature lead us to propose a model in which the acetylferrocene molecules rotate around the central iron atoms.

It is well-known that ferrocene undergoes an apparently second-order transition at 163.9 K from a disordered ($P2_1/a$) phase to an ordered ($F\bar{1}$, Z=16) phase.[1-3] In the low-temperature phase, the crystal consists of an ordered array of molecules, while it takes on a partial degree of rotational disorder structure above the transition point. Rotation of the cyclopentadienyl (C_p) rings has been observed in ^{1}H-NMR spectra, and ascribed to a cooperative jump-rotation, rather than a free rotation.[4]

Formylferrocene was reported by Daniel and Leadbetter to show a plastic crystal phase between 44 °C and the melting point.[5] The structure of the plastic crystal phase was assigned to a simple face-centered cubic lattice with a unit-cell parameter a=9.99 Å accompanied by an orientational disorder based on a diffuse scattering pattern.[5] Recently the structures of both the crystal and plastic phases have been determined to be orthorhombic by using single-crystal X-ray diffraction and the transition from the crystal to plastic phase has been attributed to translational molecular motions along the a axis, in accordance with the temperature dependence of the Mössbauer spectrum.[6]

1,1′,2,2′-Tetrachloroferrocene and 1,1′,2,2′,3,3′,4,4′-octachloroferrocene were also reported to exhibit a mesophase by Hedberg and Rosenberg.[7] The structure and the nature of the mesophase of 1,1′,2,2′-tetrachloroferrocene were studied using X-ray diffraction and Mössbauer spectroscopy.[8] 1,1′-Diethylferrocene was found to have a glassy state by thermal analysis, and the thermal vibration was studied by measuring the temperature dependence of the Lamb-Mössbauer factor for iron atoms.[9]

Although the critical phenomena before melting and phase transitions in ferrocene derivatives are of great interest, little is known concerning the structural features of the mesophases. It was preliminarily reported that some kind of transition occured a little below the melting points in acetyl and carboxylferrocenes.[10] In the present paper, the crystal structure of acetylferrocene was determined at room temperature by X-ray diffraction and the transitional process was investigated, based on the detailed data obtained from oscillation and Weissenberg photographs, Mössbauer spectroscopy and thermal analysis.

Experimental

Mössbauer Spectra. Acetylferrocene was prepared by the method described in Ref. 11, and purified by recrystallization and sublimation. The purity was confirmed by checking the melting point and by elemental analysis. No impurity was detected in IR, NMR, and Mössbauer spectra.

Mössbauer spectra were obtained using an Austine Science Associated Mössbauer spectrometer. Velocity calibration was carried out based on the room-temperature spectra of metallic iron. By fitting the resonance line-shape to a Lorentzian function, the Mössbauer parameters were extracted.

Low-temperature measurements were preformed using a CA thermocouple embedded in a copper sample holder in a cryostat. The precision of the temperature measurement was within approximately ±1° over a period of several hours. A high-temperature apparatus was constructed with a heater in a vaccum furnace. The samples were sealed to prevent sublimation. Temperature was checked by a CA thermocouple with precision of about ±0.1°.

Structure Determination and Refinement. Brown needle crystals of acetylferrocene were grown from a benzene-hexane solution. Although preliminary oscillation and Weissenberg photographs indicated an orthorhombic symmetry, this specimen was concluded to be a twin as described below. A single crystal of 0.30×0.25×0.35 mm was sealed in a Lindemann-glass capillary and the intensities were measured with Mo $K\alpha$ radiation monochromated by a graphite plate.

Crystal data are tabulated in Table 1. The positions of the Fe, C, and O atoms were deduced from the sharpened Patterson maps and successive Fourier syntheses. The posi-

tion of all the hydrogen atoms were deduced from difference synthesis. There are two crystallographically independent molecules I and II in a unit cell. After several cycles of refinement it turned out that the methyl groups of the two crystallographically independent molecules take two alternative sets of positions with an equal probability.

The block-diagonal least-squares program HBLS-4[12] was employed assuming anisotropic thermal parameters for the non-hydrogen atoms and isotropic thermal parameters for the hydrogen atoms. Two reflections, 210 and 102, were excluded in the refinement, since they suffered from secondary extinction. The atomic scattering factors were taken from International Tables for X-ray Crystallography (1974).[13] Unit weight was adopted for all the reflections. The R values reduced to 0.036 for 3194 independent reflections with $|F_o|>3\sigma(|F_c|)$ up to $2\theta=55°$. Final atomic parameters are given in Table 2.††

Acetylferrocene often crystallizes as a twin which pretends to have an orthorhombic unit cell as shown by dotted lines in Fig. 1, because c*sin (90-β*) is close to a*/2. There are two equivalent monoclinic components A and B described by solid and broken lines respectively, with a common b* axis; the rotation of the monoclinic component A around the c axis by 180° gives the component B.

Results and Discussion

Anomalous Mean-Square Amplitude of Iron Atom. Figure 2 shows the temperature dependence of the mean-square amplitude of the iron atoms estimated from the areal intensities of Mössbauer spectra of acetylferrocene.[10] The mean-square amplitude is proportional to the absolute temperature up to room temperature, indicating an harmonic intermolecular vibration. The value of the mean-square amplitude at room temperature by applying the high-temperature approximation[9] from 78 K to room temperature is 3.0×10^{-2} Å^2 for acetylferrocene, while the value based on the isotropic thermal factor in the X-ray diffraction study is 3.2×10^{-2} Å^2. A remarkable anomaly in the temperature dependence of the mean-square amplitude is found at temperatures a few degrees below the melt-

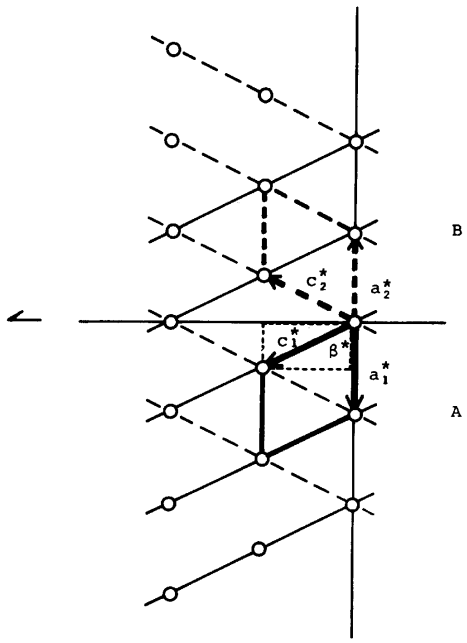

Fig. 1. Unit cell of the twinned crystal consisting of two equivalent monoclinic components looks like an orthorhombic unit cell shown by the dotted lines, because c*sin(90-β*) is close to a*.

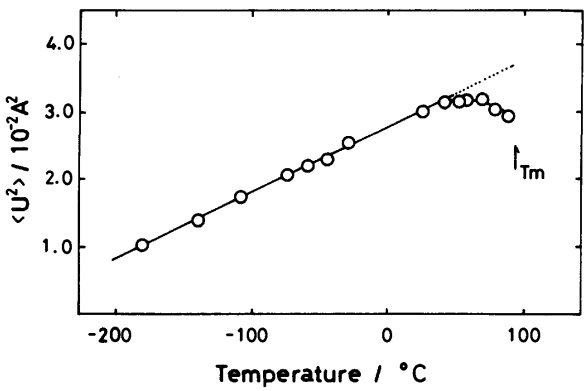

Fig. 2. Temperature dependence of the mean-square amplitude of the iron atoms in acetylferrocene.

ing point as shown in Fig. 2. The deviation from the dotted line suggests that the thermal motion cannot be explained by a simple harmonic oscillation model.

Crystal Structure. The C–C distances in the C_p rings are 1.392—1.442 Å; the Fe–C distances are 2.028—2.061 Å for the molecules I and II. These results agree with the values of the other ferrocene derivatives indicating no effect of the substituent on the Fe–C bondings.

Evidence for the reorientation in the substituent group and C_p ring of acetylferrocene has been deduced on the basis of the temperature dependence of the second moment of the ^{1}H-NMR lines.[4] The steep decrease of the line width and second moment between 50 and 210 K could be ascribed to the reorientation of the methyl groups about its triad axis and of th C_p rings about their five-fold axes of symmetry. The methyl group, unsubstituted C_p ring and substituted C_p ring, may initiate the reorientation in order of their moment of inertia with increasing temperature.

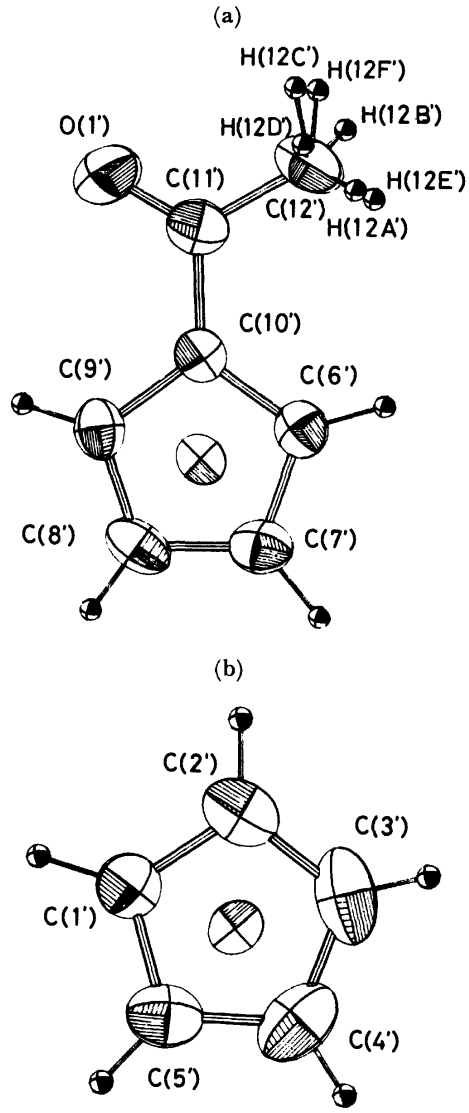

Fig. 3. Ellipsoids of the non-hydrogen atoms for molecule II are scaled at the 50 % probability. (a) substituted C_p ring and (b) unsubstituted C_p ring.

Figure 3 shows the vibrational ellipsoids of the C atoms in molecule II. A rigid-body analysis indicates that the principal libration axis of the C_p rings is nearly parallel to the five-fold molecular axis. The root-mean-square vibration amplitudes for the in-phase libration of the substituted C_p rings, 4.8° and 5.9°, are smaller than those of the unsubstituted C_p rings, 8.3° and 7.5° for molecules I and II, respectively, probably because steric hindrance of the acetyl groups reduces the thermal motion. On the other hand, the methyl hydrogen atoms in the acetyl groups take two alternative sets of positions with equal probability and the two orientations of the methyl groups are related by rotation of about 60° around the carbon–carbon bonds. The C and O atoms of the acetyl groups lie on approximately the planes of the aromatic rings owing to the existence of the complete conjugation between the acetyl groups and the C_p rings. The mean-square amplitudes of the C and O atoms in the direction perpendicular to the aromatic ring planes are about twice those estimated from the rigid-body motion, suggesting reorientation of the acetyl groups at high temperatures.

Figure 4 shows a projection of the structure along the b axis. There are two crystallographically independent molecules I and II in the unit cell. The eight iron atoms are located at *ca.* $y=1/4$ and $3/4$. A prominent feature of the crystal structure is the pairing of two molecules with respect to a center of symmetry, such as II and IV, and I and III, respectively. There is no intermolecular distance shorter than the sum of the van der Waals radii. The disordered hydrogen atoms of the methyl groups are illustrated by shaded circles.

Figure 5 shows the view of the structure perpendicular to the face (102). The C_p planes incline by about 20 degrees against the b axis in order to avoid contact with each other, and oxygen atoms are packed in the interior of the pairs. Intermolecular nearest distances are 2.29 Å between H(2)–H(12C) for the molecule I and 2.32 Å

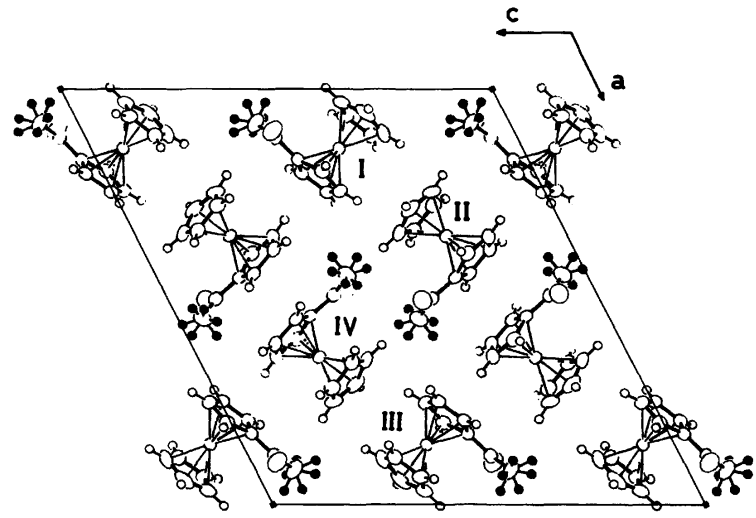

Fig. 4. Projection of the crystal structure of acetylferrocene along the b axis at room temperature. The disordered hydrogen atoms of acetyl groups are illustrated as shaded circles.

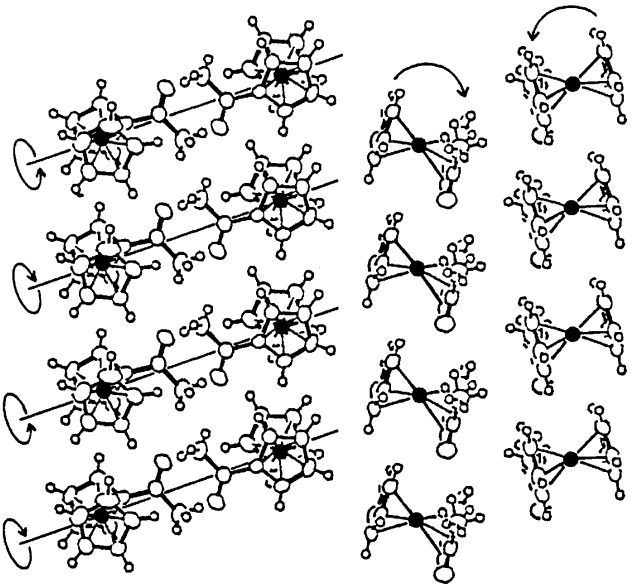

Fig. 5. View of the structure perpendicular to the face (102). The phase transition is associated with a co-operative phenomenon like in a series of rotating gears, that is, molecules reorient simultaneously around the iron-iron directions in the pairs.

between H(1′)–H(12C′) for the molecule II.

Rotational Phase Transition. Crystal specimens were heated in a stream of electrically heated air controlled with a precision of about ±0.25°. Both the Weissenberg and the oscillation photographs taken at temperatures up to the melting point (86 °C) showed that the diffraction pattern abruptly changed twice, at *ca.* 80 °C and 83 °C.

When the temperature was raised, the reflections split into two spots in the a*c* plane at *ca.* 80 °C. On increasing the temperature, the reflection intensities disappeared at *ca.* 83 °C except those corresponding to the 210, $\bar{1}12$, $\bar{3}02$, and 102 reflections in the original pattern. Those reflections are considered to be contributed largely by the iron atoms because they correspond to the planes containing the iron atoms at room temperature. Further, there appeared several additional satellite reflections along 3a*—2c* between 210 and $\bar{1}12$ as shown in Fig. 6. It was difficult to obtain the cell dimensions and the symmetry of the crystal owing to the deficiency of reflection data.

When the crystal specimen, heated once above *ca.* 83 °C, was cooled slowly back to room temperature, the Weissenberg photograph showed the same diffraction pattern as its original one or the two-fold rotated pattern. The latter photograph showed that the specimen remained as a single crystal but was rotated by 180° around the c axis with respect to the original orientation as shown in Fig. 7 by dotted lines. This indicates that the original structure, (A), shown by full lines, must be transformed into the rotated structure, (B), through a molecular motion at 83 °C. The interchange of the original structure with the resulting structure can

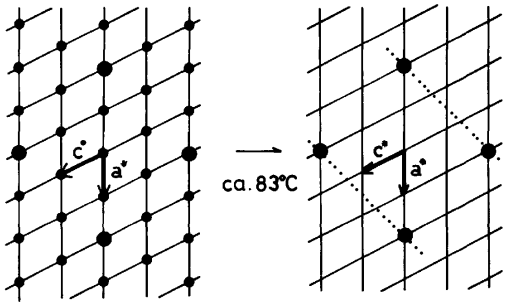

Fig. 6. Temperature dependence of Weissenberg photographs in the first layer.

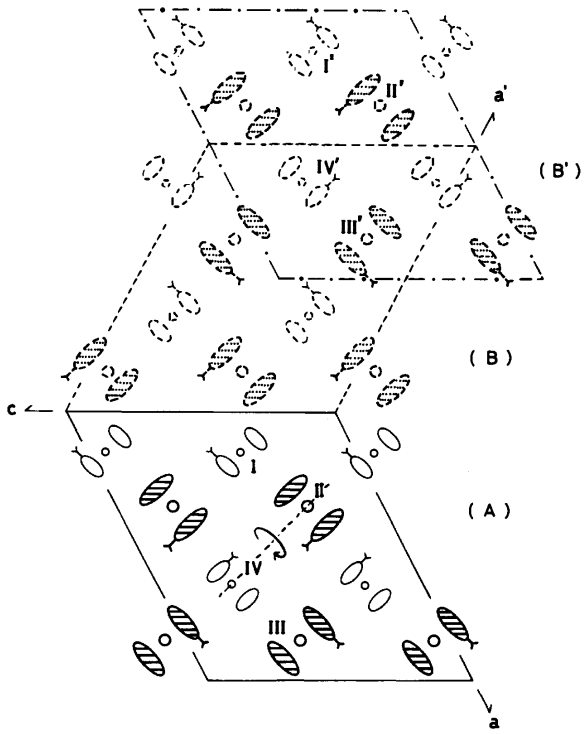

Fig. 7. Crystal structure of acetylferrocene at room temperature (A) before and (B) after heating to *ca.* 83 °C. The structure (B) shown by dotted lines is given by the rotation of the structure (A) shown by solid lines, around the c axis by 180 °, where the C_p rings are picturized with ellipses and the acetyl groups are Y-shaped symbols, and the molecular positions are expressed by different size of the ellipses and slant lines.

be interpreted in the same way as the twinning shown in Fig. 1, assuming a small potential barrier between the crystal components A and B.

These observations enable us to propose a plausible model for the phase transition at *ca.* 83 °C as follows. The structure (B′) shown by the chain lines in Fig. 7 is given by the rotation of the structure (A) around the c axis by 180° in the same way as described for the twinning of this compound. Because of the specific molecular arrangement, the crystal structure of the ferrocene

moieties in (B′) resembles that in (A) except for the position of acetyl groups; *i.e.*, molecules I, II, III, and IV correspond to molecules I′, II′, III′, and IV′, respectively. The structure (A) transforms to the structure (B′) by rotating the acetylferrocene molecules. This rotational interchange is considered to be effected by the simultaneous and cooperative rotation of pairs of adjacent molecules, such as II and IV, around the iron-iron direction in pairs as shown in Fig. 7. This model suggests that molecules jump rather than freely rotate between the two orientations, (A) and (B′), around the direction between the two adjacent iron atoms in the pairs of II and IV, and I and III, respectively, at *ca.* 83 °C. Each molecular reorientation may also be accompanied by a rotation of the acetyl group.

In the proposed model, the phase transition is assumed to be associated with a cooperative motion similar to that of a series of rotating gears as shown in Fig. 5. This model can also explain why there is no increase of the mean-square amplitude of the iron atoms with increasing temperature, as shown in Mössbauer spectra, since the central iron atoms would keep their positions in the transition state.

Mössbauer Spectra. Mössbauer spectra consist of a doublet with the isomer shift 0.40 to 0.42 mm s^{-1} and the quadrupole splitting 2.53 mm s^{-1} that reveals Fe(II) low-spin state. As shown in Fig. 8, there evidently occurs a progressive broadening above room temperature, although slight decrease of the line-width is expected in the high temperature region because of the decrease of the recoil-free fraction.

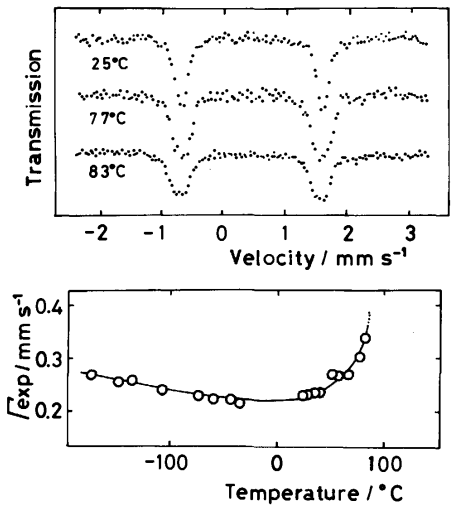

Fig. 8. Temperature dependence of the Mössbauer line-width for acetylferrocene.

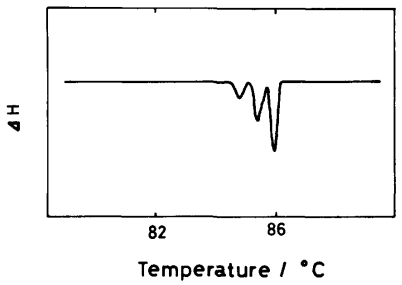

Fig. 9. Diferrential scanning calorimetric curve of acetylferrocene at heating rate 1 deg h^{-1}.

In addition to the fact of no increase of mean-square amplitude estimated by Mössbauer spectroscopy near the melting point, this behaviour may well be explained by assuming the relaxation effect of quadrupole split lines, caused by the fluctuation of the electric field gradient in the high temperature region. The process may be ascribed to a slow flipping between two equilibrium positions in the reorientational plane rather than to the rotational motion. The reorientational motion of acetylferrocene may be hindered by interaction with neighbouring molecules, for instance the steric hindrance of the acetyl groups.

Thermal Analysis. Figure 9 shows the results of Differential Scanning Calorimetry for acetylferrocene. Two endothermic peaks are observed below the melting point under an extremely slow heating rate, 1 deg h^{-1}. The peak closest to the peak of melting is ascribed to the molecular rotational phase transition, and the other peak to the rotation of acetyl groups, although further measurement are needed to justify more detailed discussion.

The authors wish to thank Prof. Yoshihiko Saito for his helpful discussions concerning the crystallographic aspects of this work and Dr. Tetsuzo Ito for creating an extended version of UNICS.

New Transport Phenomenon. Enhanced Transport into a Membrane Due to the Presence of Polyelectrolyte

Mamoru NANGO,* Shozo OHTA, Masako MAEKAWA, Akira KATAYAMA,† and Nobuhiko KUROKI
Department of Applied Chemistry, College of Engineering, University of Osaka Prefecture, Sakai 591
(Received December 6, 1983)

The transport of chromophore into a membrane in the presence of polyelectrolyte is enhanced much as it is in the presence of simple salt. The presence of polyelectrolyte with different kinds of counterions seem to modify this observed enhancement. The differences in enhanced transport into the cellulose membrane in the presence of polyelectrolyte may suggest a new model for reinterpretation of the transport phenomenon in a biological system.

In previous publications,[1,2] it has been shown by Donnan membrane equilibrium theory that the adsorption of chromophore on cotton increases with addition of polyelectrolyte in the bulk solution. Thus, the chromophore is accumulated in the internal solution of cellulose due to the presence of polyelectrolyte which is not able to enter into the pores of the cellulose. One might expect, therefore, to find progressively enhanced transport of chromophore into a cellulose membrane with addition of polyelectrolyte. We here report the effect of polyelectrolytes and their counterions on transport of chromophore into a cellulose. There have been no reports of studies concerned with the transport of simple ions and chromophores into a membrane in the presence of polyelectrolyte. Enhanced transport of chromophores into a membrane because of the presence of polyelectrolyte is similar to such enhancement in the presence of simple salt. The dependence of such transport on different kinds of counterion suggest a new type of transport phenomenon that may provide useful information for a model for transport into the cell membrane of biological systems. Specifically, the uptake of chromophore into a cellulose membrane in the presence of polyelectrolyte with different kinds of counterion on the polymer chain, when compared with the sodium salt, has been sizably enhanced to provide the basis for the above statement.

Experimental

Materials. Chromophore(C.I. Direct Yellow 12, C.I. Direct Red 2 and, C.I. Direct Blue 15) was obtained and purified as described elesewhere.[2,3] Sodium alginate(NaAlg, MW: 10,000)(Kamogawa Kasei Co.), sodium polyacrylate(NaPA, MW: 37,000), sodium polymethacrylate(PMA, MW: 260,000), and sodium polystyrenesulfonate(NaPSS, MW: 69,000) (Polyscience Co.) were purified as described eleswhere[2] and converted to different kinds of counterion(NH_4^+, K^+, and Cs^+) with the corresponding hydroxide or carbonate, respectively. The conversion of counterion was above 90% by the analysis of Hitachi 50A atomic absorption spectrophotometer. In our experiment conditions, alginate(Alg) which does not interact with chromophore or cellulose,[2] was used as the biological polyelectrolyte. Commercial cotton and cellulose membrane(cellophane film) were soaked in boiled deionized distilled water for 1 and 3 h, respectively. Then, cotton was treated with methanol and cellulose membrane was washed with deionized distilled water. Carboxyl group contents of cotton and cellulose membrane determined by iodometry were 4.00 and 62.5 meq/dg, respectively.[2,3] T. Vickerstaff indicated that the water content of cellulose and cellulose membrane were 0.22 and 0.33 l/kg, respectively, consisting with the volume term of substrate(V) (see, Eq. 4) theoretically determined.[5] The degree of dissociation constant (α) of polyelectrolytes was measured by the method of selective ion sensitive electrodes of Orion Research 94-11.

Uptake and Transport of Chromophore to Cellulose. Uptake of chromophore for cotton and cellulose membrane was carried out at temperature of 90±0.5 °C for 6 h and 25±0.5 °C for 48 h, respectively.[2] The concentration of chromophore in solution ranged from 1.004×10^{-5} to 2.164×10^{-3} mol/l. The concentration of electrolyte and polyelectrolyte ranged from 1×10^{-2} to 10×10^{-2} mol/l. Accurately weighed uptaken samples were extracted with 25% aqueous pyridine. The concentration of chromophore extracted was determined using a Hitachi 124 spectrophotometer with 25% pyridine as reference. To prevent complications arising from cis-trans formation of C.I. Direct Yellow 12, bisazo derivative, the chromophore solution was illuminated for about 1 h just before measurement.[1,2] Transport of chromophore was measured in the apparatus of Amicon ultrafiltration cell as described elesewhere.[5] To obtain the interpolated degree of dissociation constant of polyelectrolyte, uptake of C.I. Direct Yellow 12 on cotton in the presence of polyelectrolytes containing the constant concentration of sodium chloride(0.01 M, 1 M=1 mol dm^{-3}) at 25 and 90 °C was done as described in the previous paper.[2] Interaction between polyelectrolytes and chromophore used in this system was neglegible as described with previous articles.[2,6]

Results and Discussions

Figure 1 compares the uptake of C.I. Direct Yellow 12 in a cellulose membrane in the presence of the sodium salt of galacturonic acid (a model for pyranose unit in sodium alginate) with that in the presence of sodium alginate. It is obvious that the adsorption isotherm in the presence of NaAlg differs from that in the presence of galacturonic acid. Thus, the effect of NaAlg on the uptake by the cellulose membrane differs from that of small molecule electrolytes such as galacturonic acid or an inorganic salt which are able to enter into the cellulose membrane.

Figure 2 illustrates the transport of C.I. Direct Yellow 12 into a cellulose membrane in the presence of NaAlg at 25 °C. As is apparent in Fig. 2, enhanced transport of chromophore into a cellulose membrane with addition

of NaAlg was observed. Table 1 lists an example of transport of chromophore into a cellulose membrane. Transport increased progressively with addition of alginate, reaching a factor about 25 over that without NaAlg. This large enhancement may be due merely to the fact that a chromophore is accumulated inside the membrane film by a Donnan membrane-equilibrium effect.

Figure 3 illustrates the uptake of C.I. Direct Yellow 12 into a cellulose membrane in the presence of various polyelectrolytes at 90 °C. Table 1 lists an example of uptake of chromophore into a cellulose. As is apparent in Fig. 3 and in Table 1, the increase in the uptake of chromophore to cellulose for polyelectrolytes follows the order, NaAlg>NaPSS≳NaPMA≳NaPA, indicating the analogous order to the sequence of increase in the degree of dissociation constant for polyelectrolytes as described in Table 2. Figure 4 illustrates the adsorption isotherms of C.I. Direct Yellow 12 on cellulose

membrane in aqueous solutions of polyelectrolytes under conditions where sodium ion concentration is kept constant with corrected sodium ion concentration by using their measured value of dissociation constant for polyelectrolyte(see, α^* in Table 2). As is apparent in Fig. 4, the differences in the uptake of chromophore into cellulose membrane were largely reduced in comparison to those in Fig. 3. Thus, the differences in the uptake of chromophore into a cellulose membrane in aqueous solutions of various polyelectrolytes may be

due to the fact that the differences in the degree of dissociation constant for polyelectrolytes has a crucial role on the differences in the uptake of chromophore into a cellulose membrane.

For the quantitative interpretation of the degree of dissociation constant of polyelectrolyte in the bulk solution on equilibrium uptake of chromophore, the following theoretical treatment was applied to the present results as described in the previous article.[2,5] As envisaged in the adsorption model on cellulose in Fig. 5, chromophore is assumed to be adsorbed in the internal solution of cellulose(i phase). Bulk phase(σ) is assumed to penetrate into the pore of cellulose membrane and this portion of it is designated as γ. It is assumed that polyanion($P_{\bar{n}}$) is present only in the σ phase. According to Donnan membrane-equilibrium between the two phase and maintaining electrical neutrality in each phase, the standard free energy ($-\Delta\mu^\circ$) can be calculated as described in the previous article.[2,7]

According to Donnan membrane-equilibrium between two phases, the ionic concentrations are related as follows;

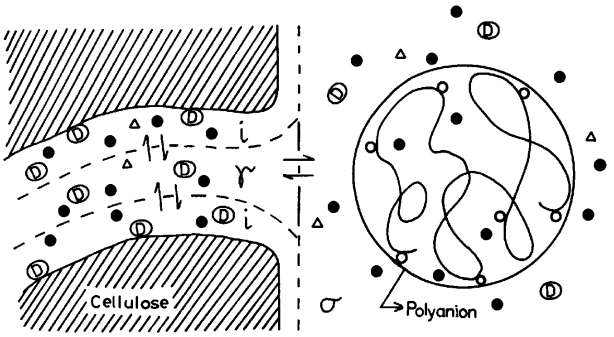

Fig. 5. Adsorption model on cellulose.
Alginate ion(polyion, $P_{\bar{n}}$) is present only in the bulk phase(σ). D, chromophore anion; ●, sodium ion (counterion of chromophore or polyelectrolyte); $P_{\bar{n}}$, alginate ion shown with pyranose unit mol; i, internal solution of cellulose; σ, bulk phase; γ, bulk phase assumed to penetrate into the pores of cellulose.

$$[Na^+]_\sigma^z[D^-]_\sigma = [Na^+]_\gamma^z[D^-]_\gamma = [Na^+]_i^z[D^-]_i \quad (1)$$

where z is the basicity of the dye(chromophore) anion and D^- is chromophore anion. For maintaining electrical neutrality in each phase,

$$\sigma \text{ phase: } [Na^+]_\sigma = z[D^-]_\sigma + \alpha[P^-]_\sigma + [Cl]_\sigma \quad (2)$$

where $\alpha[P^-]$ represents the concentration of polyanion shown with unit mol α represents the degree of ionization of polyelectrolyte to be calculated and $[Cl^-]$ represents the ionic concentration of chloride used as sodium chloride.

$$\gamma \text{ phase: } [Na^+]_\gamma = z[D^-]_\gamma + [Cl^-]_\gamma \quad (3)$$

$$i \text{ phase: } [Na^+]_i = \frac{z[D^-]_\phi}{V} + [Cl^-]_i \quad (4)$$

where V represents the volume term of i phase(cellulose membrane: 0.33 l kg^{-1}, cotton: 0.22 l kg^{-1})[5] and $[D^-]_\phi$ is the concentration of dye (chromophore) anion adsorbed into a cellulose membrane in mol kg^{-1} dry membrane.

Combination of Eqs. 1 and 3, $[Na^+]_i$ is obtained, where $[Na^+]_\phi = V[Na^+]_i$ and $[Na^+]_\phi$ is the concentration of sodium ion adsorbed in the cellulose membrane in mol kg^{-1} dry membrane.

The following equation was used to calculate the standard free energy of this uptake($\Delta\mu^\circ$).[5]

$$-\Delta\mu^\circ = RT \ln[Na^+]_\phi^z[D^-]_\phi / V^{z+1}[Na^+]_\gamma^z[D^-]_\gamma \quad (5)$$

$$= RT \ln[Na^+]_\phi^z[D^-]_\phi / V^{z+1}[Na^+]_\sigma^z[D^-]_\sigma \quad (6)$$

Thus, according to the computer simulation so that the standard free energy may has nearly constant value with various changes in the experimental conditions, the interpolated degree of dissociation constant(α) of polyelectrolyte can be obtained. Table 2 lists the interpolated degree of dissociation constant of polyelectrolyte with that measured by the method of sodium ion sensitive electrode. In addition, Table 3 lists an example of the standard free energy which has nearly constant value in these systems.

As is apparent in Table 2, the degree of dissociation constant corrected by computer simulation has fairly good agreement with that measured value by an ion

electrode, indicating that the differences in the degree of dissociation for polyelectrolytes with different kinds of ionizable groups induced the differences in the uptake of chromophore in aqueous solutions of various polyelectrolytes as described above in Fig. 1 and Table 1.

Further interesting trends of enhancement are seen in the transport of chromophore in the presence of polyelectrolytes with different kinds of counterions at 25° and 90 °C. Figure 6 illustrates the uptake of C.I. Direct Yellow 12 into a cellulose membrane in the presence of alginate with different kinds of counterions at 25 °C. Table 4 lists an example of the uptake of chromophores to cellulose in the presence of polyelectrolytes with different kinds of counterions at 25° and 90 °C. Thus, the uptake is substantially greater with the salt of potassium, cesium, and ammonium than the sodium salt. This enhanced uptake of chromophores may be due to the fact that the sodium salt of the chromophores is ion-exchanged with different kinds of counterion on the polymer chain in the bulk solution (σ) designated as in Fig. 5. The uptake by the cellulose of chromophore with different kinds of counterion in the absence of polyelectrolyte at both 25° and 90 °C is greater with the other counterion (K^+, Cs^+, and NH_4^+) than with Na^+ (Table 4).[8] Furthermore, the fact that the uptake of chromophore with different kinds of counterion in the presence of NH_4Alg at 90 °C is the same is consistent with the assumption of ion-exchange described above.

In addition, this different enhancement with different kinds of counterion in the uptake of chromophore may depend on the differences in the degree of dissociation constant of polyelectrolytes with different kinds of counterion as well as the differences in the uptake described in both Fig. 3 and Table 1.

In any event it is clear that the addition of polyelectrolytes leads to marked enhancement of uptake and ion transport into a cellulose membrane.

Ion transport into the cellulose membrane in the presence of polyelectrolytes provides an interesting model for transport in a biological system.

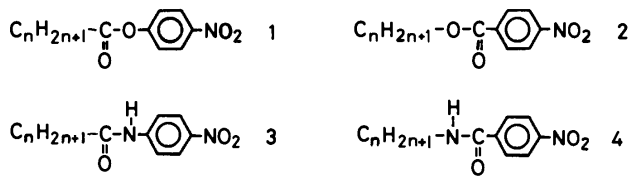
Liquid Crystal Formation in Binary Systems. X.[1] Potentially Smectogenic Behavior of Some *p*-Disubstituted Benzenes

Eiji CHINO, Yoshio MATSUNAGA,* and Mika SUZUKI
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received January 14, 1984)

Studies on binary systems with nematogenic *N*-(4-propoxybenzylidene)-4-hexylaniline revealed that 4-nitrophenyl alkanoates, alkyl 4-nitrobenzoates, *N*-(4-nitrophenyl)alkanamides, and *N*-alkyl-4-nitrobenzamides are potentially smectogenic. When the Schiff base is mixed separately with a homologous member from 4-nitrophenyl decanoate to tetradecanoate, a stable smectic A phase is induced and its maximum temperature is about 48 °C. The estimated latent transition points to this mesophase of these benzene derivatives are in the range from −25 to 10 °C. On the other hand, only metastable smectic A phases can be produced with hexyl to dodecyl 4-nitrobenzoates, the maximum temperatures being from 15 to 26 °C. While the metastable smectic B phase of the Schiff base is to some extent stabilized by the addition of the alkanoates, it is drastically depressed by the benzoates. The addition of *N*-(4-nitrophenyl)nonanamide to -dodecanamide produces a stable smectic A phase and also stabilizes the metastable smectic B phase. No smectic A phase is found in mixtures of the Schiff base with *N*-octyl- to *N*-dodecyl-4-nitrobenzamides, and the isotropic or nematic-smectic B transition point curves are almost horizontal indicating that these benzene derivatives have transitions to latent smectic B phases between 10 and 20 °C. Results obtained with some related compounds are also presented.

In one of the earlier papers of this series, we reported the induction of smectic phases by the addition of 4-alkoxynitrobenzenes to *N*-(4-propoxybenzylidene)-4-hexylaniline and the related compounds.[2] This Schiff base gives a nematic phase stable between 42 and 63 °C and a metastable smectic B phase below 21 °C. We concluded that the induction of smectic A phases in the above binary mixtures is indicative of the potentially smectogenic behavior of these *p*-disubstituted benzenes even though the upper limit of smectic temperature range is located at about −25 °C for 4-(dodecyloxy)nitrobenzene and lower for the other homologous members. With the hope of finding potentially smectogenic *p*-disubstituted benzenes with higher transition temperatures, we examined the phase diagrams of the binary systems composing of the above Schiff base and 4-nitrophenyl alkanoate (**1**), alkyl 4-nitrobenzoate (**2**), *N*-(4-nitrophenyl)alkanamide (**3**), and *N*-alkyl-4-nitrobenzamide (**4**) respectively. Esters are side chains widely shared by discogenic compounds, whereas amides were rarely studied but chosen for the present work because the $NHCOCH_3$ substituent, which can hydrogen-bond and has a strong dipole, is known to markedly enhance smectic thermal stabilities.[3]



Experimental

Materials. Homologous series of 4-nitrophenyl alkanoates and *N*-(4-nitrophenyl)alkanamides were obtained by the acylation of 4-nitrophenol and 4-nitroaniline respectively. The products will be referred to as *n*COO, NO_2, and *n*CONH, NO_2 on the basis of the substituents where *n* is the number of carbon atoms in the alkyl group. The alkyl 4-nitrobenzoates and *N*-alkyl-4-nitrobenzamides were prepared by the reaction of 4-nitrobenzoyl chloride on alcohols and alkylamines respectively. They will be abbreviated as *n*OCO, NO_2, and *n*NHCO, NO_2. These disubstituted benzenes were purified by recrystallization, distillation under reduced pressure and/or column chromatography. Hereafter, *N*-(4-propoxybenzylidene)-4-hexylaniline will be denoted by (3O, 6) designating the alkoxyl and alkyl carbon numbers for the substituents.

Measurements. The calorimetric measurements and the identification of the mesophases were made as reported in our previous paper.[2]

Results and Discussion

4-Nitrophenyl Alkanoates (nCOO, NO_2). The homologous members from decanoate to tetradecanoate (*n*=9—13) were examined. Upon mixing with (3O, 6), they produce stable smectic A phases as exemplified by the phase diagrams of the binary systems with each of 10COO, NO_2, and 12COO, NO_2 (see Figs. 1a and b). The open and shaded circles indicate the transitions recorded during the processes of heating and cooling respectively.

The phase diagrams obtained with 9COO, NO_2, and 11COO, NO_2 resemble that given in Fig. 1a; namely, the coexistence of the isotropic and smectic phases occurs over a range of temperature. In contrast, no indication of the two-phase liquid system is found with 12COO, NO_2 or with 13COO, NO_2. The maximum temperature of the smectic A-isotropic transition point curve is not much affected by the alkyl chain length throughout the studied members, that is, 47—48 °C (see Curve a in Fig. 2). It is higher by about 10 °C than the melting points of the first two homologous members, is nearly the same as those of the next two, and is lower by about 10 °C than that of the last. The extrapolation of the transition point curve to 0 mol% of (3O, 6) yields more reliable latent transition temperature when the alkyl chain is shorter as the curve is observable over a wider composition range. Such a tendency is more or less shared by most of the homologous series studied in this paper. The estimated temperature varies from −25

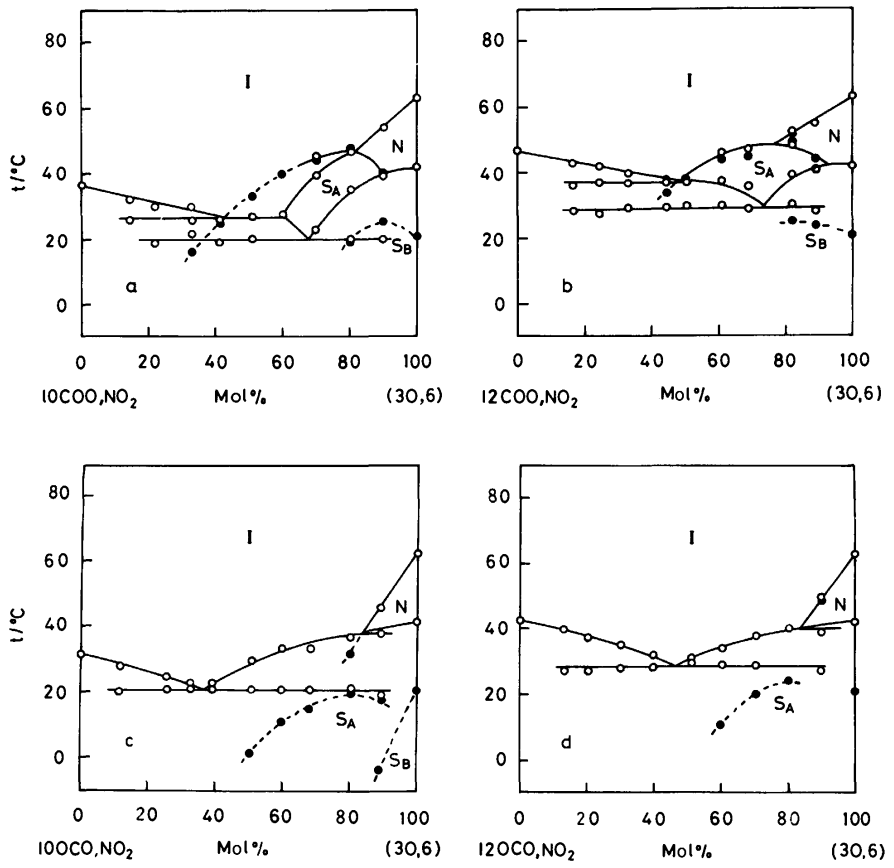


Fig. 1. Phase diagrams of (a) 10COO, NO_2–(3O, 6), (b) 12COO, NO_2–(3O, 6), (c) 10OCO, NO_2–(3O, 6), and (d) 12OCO, NO_2–(3O, 6) systems. The open and shaded circles are transitions observed in the processes of heating and cooling respectively.

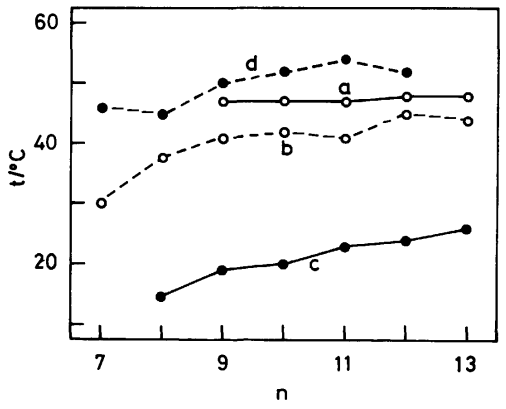

Fig. 2. Plots of the maximum temperatures of the induced smectic A phases against the length of the alkyl chain, *n*, for (a) *n*COO, NO_2–(3O, 6), (b) *n*COO, CN–(3O, 6), (c) *n*OCO, NO_2–(3O, 6), and (d) *n*CONH, NO_2–(3O, 6) systems.

to 10 °C. The values tend to be higher with the higher homologs. They are located below the melting points of *n*COO, NO_2 by 50 to 70 °C. If the isotropic melts were supercooled to such a large extent the appearance of smectic A phases of *n*COO, NO_2 could be achieved; therefore, these 4-nitrophenyl alkanoates may be considered as potential smectogens.

The monotropic smectic B phase of (3O, 6) is also stabilized by the addition of these benzene derivatives. The transition point curves are markedly convex upwards when *n* is even but not so when *n* is odd.

In order to supplement the above results, seven systems consisting of *n*COO, CN, and (3O, 6) were studied. The maximum temperatures of the smectic A-isotropic transition point curves are shown by Curve b in Fig. 2. They are slightly lower than those of the corresponding *n*COO, NO_2–(3O, 6) systems. The extrapolation of the transition point curve to 0 mol% of (3O, 6) also seems to yield lower temperatures; *e.g.*, −30 °C for 10COO, CN *vs.* −25 °C for 10COO, NO_2. As 4-cyanophenyl alkanoates have higher melting points than the 4-nitrophenyl compounds, the induced smectic A phases are metastable except for the cases *n*=9, 11, and 12. The stabilization of the smectic B phase of (3O, 6) observed with the 4-cyanophenyl esters is more remarkable than that with the 4-nitrophenyl esters. The observation made for the induced smectic A phase is consistent with the order of smectic terminal group efficiency for nitro and cyano groups given by Gray[3] but that made for the monotropic smectic B phase is in the reversed order.

Alkyl 4-Nitrobenzoates (nOCO, NO_2). The homologous series examined extends from the octyl to the tridecyl ester (*n*=8—13). When these 4-nitrobenzoates are added to (3O, 6), smectic A phases are induced in all the systems. However, they are entirely

metastable, the maximum of the isotropic-smectic A transition point curve lying in the range from 15 to 26 °C. Contrary to the alkanoates, the temperature raises with the increase of the alkyl chain length exhibiting a small but definite alternation (see Curve c in Fig. 2). The temperatures observed with 8OCO, NO_2, 9OCO, NO_2, and 11OCO, NO_2 are located above the eutectic points. For the sake of comparison with the effects of the isomeric compounds, the phase diagrams of the decyl and dodecyl ester-(3O, 6) systems are presented in Figs. 1c and d. These esters presumably have the potential to exhibit smectic A phases at temperatures as low as −65 to −40 °C. As is shown in Fig. 1c, the monotropic smectic B phase of the Schiff base shows a drastic depression on addition of 10OCO, NO_2. Furthermore, it must be noted that the slope of the nematic-isotropic transition point curve is much steeper than that observed with the 4-nitrophenyl alkanoates. Thus, the abillity to exhibit mesophases of the 4-nitrobenzoates is undoubtedly inferior to that of the above-mentioned isomerides.

It is worthwhile to note the alternation of the melting points of *n*COO, NO_2, and *n*OCO, NO_2. The former compounds melt at relatively higher temperatures when *n* is odd and the latter exhibit the opposite variation. Therefore, the melting point of *n*COO, NO_2 lies by 15 to 20 °C above that of the corresponding *n*OCO, NO_2 when *n* is odd. The difference is as small as 5 °C when *n* is even.

N-(4-Nitrophenyl)alkanamides (nCONH, NO_2). The replacement of the -O- group in the 4-nitrophenyl alkanoate with an -NH- group brings about a rise in the melting point by 30 to 40 °C depending upon *n*. When *n*=9 or more, the induced smectic A phase is enantiotropic in a certain range of composition and temperature in the binary system with (3O, 6). Even though the maximum temperatures of the transition point curves are in the range from 50 to 54 °C for these systems (see Curve d in Fig. 2), the smectic A phases are observable in the smaller ranges than those found for the *n*COO, NO_2-(3O, 6) systems. For example, the phase diagrams given in Figs. 3a and b may be compared with those in Figs. 1a and b. The observed smectic A-isotropic transition point curves are not long enough to estimate the temperatures for potential smectic A phases but suggest that they are not very different from those estimated for the 4-nitrophenyl alkanoates. As is illustrated in Fig. 3a, the monotropic smectic B phase of (3O, 6) is stabilized by the addition of 10CONH, NO_2.

In order to compare the role of a nitro group and a cyano group in the anilides on the smectogenic behavior, the system comprising 11CONH, CN, and (3O, 6) was included to the present work. The diagram is

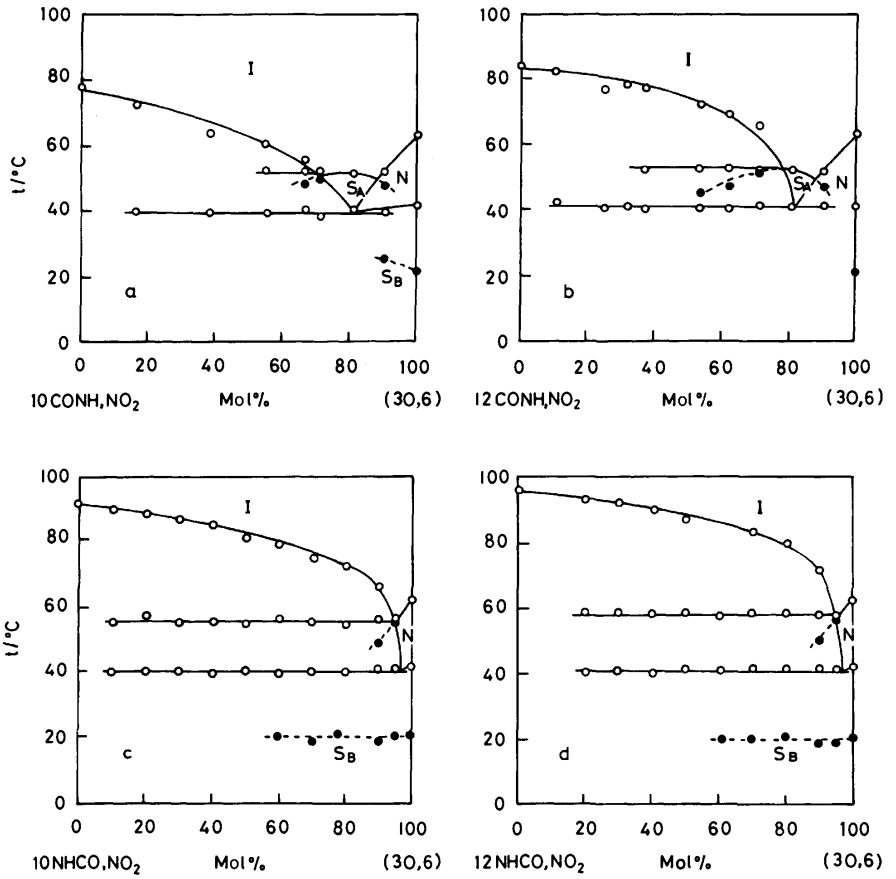

Fig. 3. Phase diagrams of (a) 10CONH, NO_2-(3O, 6), (b) 12CONH, NO_2-(3O, 6), (c) 10NHCO, NO_2-(3O, 6), and (d) 12NHCO, NO_2-(3O, 6) systems. As to the open and shaded circles, see the caption of Fig. 1.

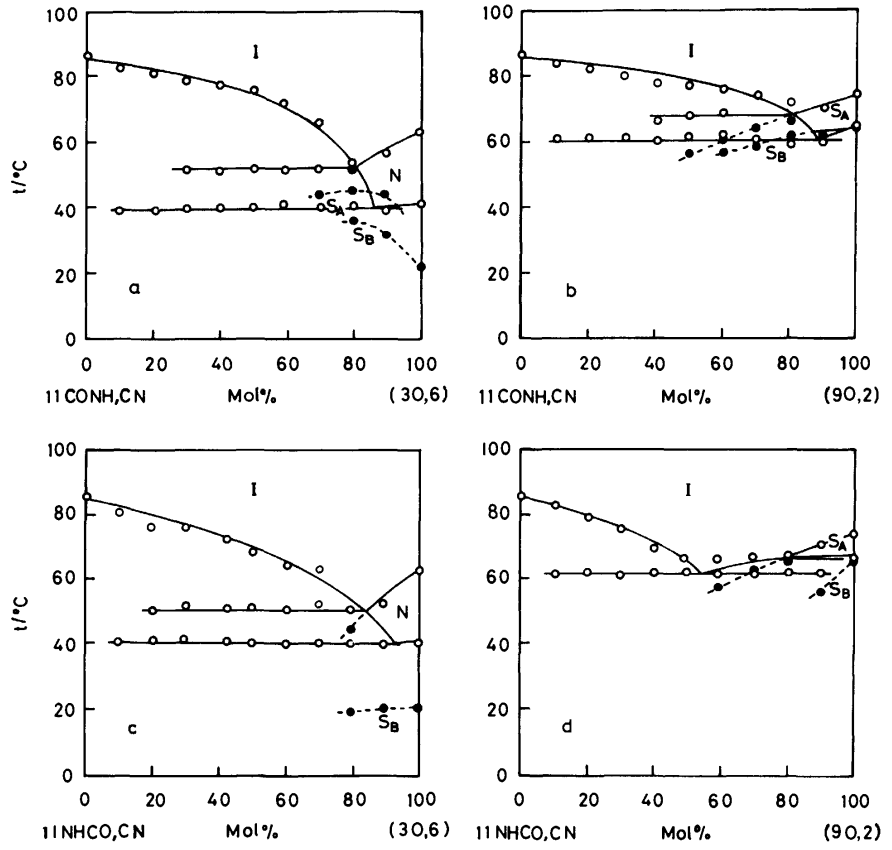

Fig. 4. Phase diagrams of (a) 11CONH, CN–(3O, 6), (b) 11CONH, CN–(9O, 2), (c) 11NHCO, CN–(3O, 6), and (d) 11NHCO, CN–(9O, 2) systems. As to the open and shaded circles, see the caption of Fig. 1.

given in Fig. 4a. A smectic A phase is induced but it is monotropic, the maximum temperature being 46 °C. This observation is in good accord with the tendency found by comparison between *n*COO, NO_2 and *n*COO, CN and also 4-alkoxynitrobenzenes and 4-alkoxybenzonitriles reported in a previous paper.[2] Moreover, it must be noted that the stabilization of the metastable smectic B phase by the cyanoanilide is much greater than that by the corresponding nitroanilide. The maximum temperature achieved by the former compound is 36 °C and that by the latter is 24 °C. This might imply that the 4-cyanoanilide has a potential smectic B phase at a relatively high temperature. This postulate is strongly supported by the phase diagram shown in Fig. 4b, where (3O, 6) is replaced by *N*-(4-nonyloxybenzylidene)-4-ethylaniline, (9O, 2), which exhibits stable smectic A and B phases. The diagram suggests that the latent smectic B phase of 11CONH, CN is located around 30 °C. This temperature is probably higher than that of the latent smectic A phase.

*N-Alkyl-4-nitrobenzamides (*n*NHCO, NO_2).* The melting points of the three compounds in this series (*n*=8, 10, and 12) are higher than those of the above isomerides as is seen from Figs. 3c and d. The effect of the change in molecular structure on the liquid crystal behavior is so remarkable that no smectic A phase is found in these mixtures. The monotropic smectic B phase is observable over a composition range as wide as 40 mol%. As the transition point curves are essentially horizontal, these 4-nitrobenzamides should have transition temperatures to latent smectic B phases between 10 and 20 °C. It may be noted that the nematic phase of the Schiff base is rapidly depressed by the presence of *n*NHCO, NO_2.

As is shown in Fig. 4c, the behavior of *N*-undecyl-4-cyanobenzamide is similar to those of the 4-nitrobenzamides described above except for the less drastic depression of the nematic phase and the limited observation of the nematic-smectic B transition point curve. The isotropic or nematic-smectic B transition point curves in Figs. 3c, 3d, and 4c are almost straight; therefore, the reason why no smectic A phase is induced by mixing with (3O, 6) may be ascribed to the absence of the thermal stability enhancement. The phase diagram prepared with (9O, 2) instead of (3O, 6) clearly demonstrates that the 4-cyanobenzamide has a transition point to a latent smectic A phase closely located to that to a latent smectic B phase (compare Fig. 4d with 4c). The observed short smectic A-smectic B transition point curve is concave upwards.

*N-(4-Nitrobenzylidene)alkylamines (*n*N=CH, NO_2).* Finally, we studied the effects of the addition of *N*-(4-nitrobenzylidene)alkylamines (*n*=9—13) as a series of the compounds involving a double bond linkage in the substituent. All the homologous members can induce smectic A phases exhibiting maximum temperatures from 40 to 41 °C. As is shown in Fig. 5, the com-

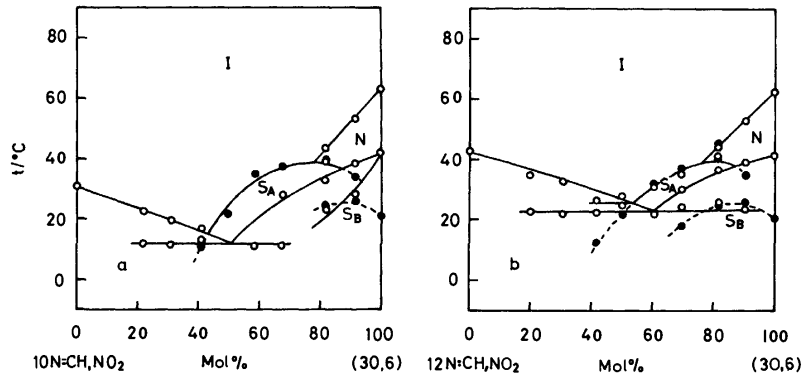

Fig. 5. Phase diagrams of (a) 10N=CH, NO_2–(3O, 6) and (b) 12N=CH, NO_2–(3O, 6) systems.
As to the open and shaded circles, see the caption of Fig. 1.

position range of the stable smectic A phase is fairly wide. The monotropic smectic B phase is appreciably stabilized. However, the latent smectic phases of these compounds are probably located at temperatures as low as −50 to −40 °C.

The above results emphasize that the particularly high transition temperatures to latent smectic phases can be achieved with the benzamides and anilides. As the suitability of the terminal substituent for liquid crystal formation may be at its most significant in simple systems we decided to extend our examination of thermal properties to a number of benzene derivatives carrying two or three of these terminal groups; namely, $C_nH_{2n+1}NHCO$ and $C_nH_{2n+1}CONH$. Some novel mesomorphic compounds have been discovered by this approach. Their properties will be the subject of the forthcoming papers.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 543001 from the Ministry of Education, Science and Culture.

Electron Paramagnetic Resonance and Optical Detection of Magnetic Resonance Studies of the Lowest Excited Triplet States of Purine, Benzimidazole, and Indazole in Benzoic Acid Host Crystals

Masayo NODA,† Shin-ichi NAGAOKA,†† and Noboru HIROTA*
Department of Chemistry, Faculty of Science, Kyoto University, Kyoto 606
(Received February 2, 1984)

The triplet states ($^3\pi\pi^*$) of purine, benzimidazole, and indazole are investigated in benzoic acid crystals by electron paramagnetic resonance (EPR) and optical detection of magnetic resonance (ODMR) techniques. Well resolved phosphorescence spectra were obtained at 4.2 K. The T_1 states of purine and benzimidazole are located at 26409 and 26536 cm^{-1}, respectively. The zero field splittings (ZFS) are D=0.1042 cm^{-1}, $|E|$=0.0608 cm^{-1} for purine, and D=0.1123 cm^{-1}, $|E|$=0.0270 cm^{-1} for benzimidazole. The decay rate constants of the triplet sublevels are determined at 1.5 K and are compared with those of indole. From the angular dependence of the EPR signals, the probable orientations of purine and benzimidazole in benzoic acid hosts are determined. From the observed hyperfine splittings (hfs) spin distribution of the T_1 state of purine is estimated. (ρ_6= 0.20, ρ_8=0.27, and ρ_2=0.12). The effects of the nitrogen substitution in the pyrole ring of indole on the ZFS and spin distribution are discussed.

The lowest excited triplet (T_1) states of purine, benzimidazole and indazole have received considerable attention because of their possible importance in photobiological processes. Numerous spectroscopic,[1-9] EPR,[10-12] ODMR, and theoretical[13-15] investigations have been attempted before, but owing to poor solubility of these molecules in nonpolar solvents and difficulties in finding good host crystals, previous investigations have been limited severely. For example, neither well resolved phosphorescence spectra nor single crystal EPR spectra of the triplet states of these molecules have been reported.[16] Zero field ODMR[17-19] experiments have been made in rigid solution, but the sublevel schemes of the T_1 states as well as their decay properties are not completely understood. Details of the spin distributions in the T_1 states are also not known for these molecules.

In the course of investigations in this laboratory, we have found that benzoic acid (BAC) is a good host for polar molecules which are difficult to dissolve into the crystals of nonpolar molecules such as durene.[20] Therefore, we have attempted to investigate the properties of the T_1 states of purine, benzimidazole, indazole and indole in the mixed crystals of BAC by means of ODMR and EPR techniques in order to elucidate the properties of their T_1 states. Well-resolved phosphorescence spectra were obtained at 4.2 K, and the decay rate constants of the triplet sublevels as well as the zero field transition energies were determined at 1.5 K. Single crystal EPR experiments were also made to determine the sublevel schemes unambiguously and to obtain information about the spin distributions. Here we discuss the phosphorescence spectra, the zero field splittings (ZFS), the hyperfine splittings (hfs) and the sublevel decay properties of these molecules. Benzimidazole, indazole, and purine are also considered as nitrogen substituted indoles, respectively. In this work it was found that the triplet properties are strongly affected by the nitrogen substitution of indole. We discuss the variations in the decay and magnetic properties in this series of molecules.

Experimental

Sample Preparation. BAC (Wako) was purified by extensive zone refining. Purine (Sigma) was purified by recrystallization from toluene followed by vacuum sublimation. Benzimidazole (Aldrich) and indole (Aldrich) were purified by vacuum sublimation. Indazole (Tokyo kasei) was recrystallized twice from water and then sublimated in vacuum. Mixed crystals of BAC with desired guest molecules were grown by the standard Bridgman method. About one percent of the guest molecule was contained in the initial melt, but the actual concentration of the guest is considered to be very low. The molecular structures of the guest molecules and the numbering systems used here are given in Fig. 1.

Phosphorescence and ODMR Experiments. Phosphorescence spectra were obtained with the ODMR setups described elsewhere.[21] The ZFS and the decay rate constants were determined by the standard ODMR[22,23] and microwave induced delayed phosphorescence (MIDP)[24] experiments made at 1.5 K. Since the sublevel lifetimes are relatively long in the present systems, the effect of the spin lattice relaxation probably cannot be neglected entirely even at 1.5 K. The experimental errors in the determination of k_y are estimated to

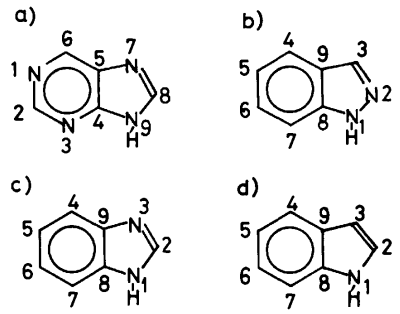

Fig. 1. Molecular structures and the numbering systems for a) purine, b) 1*H*-indazole, c) benzimidazole, d) indole.

†† Division of Chemistry, Research Institute of Applied Electricity, Hokkaido University, Sapporo 060.

be ~10% and those of k_x and k_z are ~25%. Microwave modulated phosphorescence spectra were obtained by applying the microwave at the ODMR transition frequencies and detecting the changes in the phosphorescence intensities, while the monochromator was scanned.

EPR Measurements. EPR measurements were made at 4.2 K with a JEOL JES-FE3X spectrometer with a home-built liquid helium cryostat. The experimental procedures are essentially the same as those described previously.[20] The crystal was mounted on a wedge so that the applied field rotated within the molecular plane of BAC by rotating the sample holder. The method of mounting a crystal was described elsewhere.[16]

Results and Discussion

Phosphorescence Spectra. The phosphorescence spectra of purine, benzimidazole and indazole in BAC obtained at 4.2 K are all well resolved as shown in Fig. 2. Since these molecules are expected to be in well defined configurations by forming hydrogen bonds with BAC, highly resolved spectra are probably obtained.

The O-O band of benzimidazole is very strong and is located at 376.9 nm. The frequencies of the main vibrations appearing in the phosphorescence spectra are in good agreement with the ground state vibrational frequencies determined by IR and Raman studies as shown in Table 1. As discussed in detail in a separate paper,[16] indazole in BAC exists in two tautomeric forms, 1*H*-indazole and 2*H*-indazole. The strong O-O band of the 1*H*-indazole spectrum is located at 423.9 nm. The observed vibrational frequencies are given in Table 1 together with the IR data.

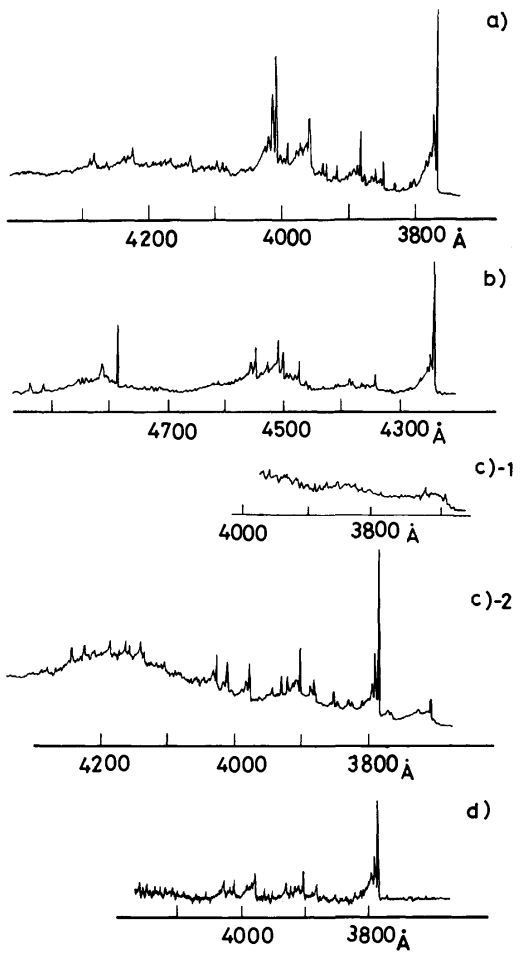

Fig. 2. Phosphorescence spectra in the mixed crystal of BAC at 4.2 K. a) benzimidazole, b) 1*H*-indazole, c)-1 benzoic acid X-trap, c)-2 purine, d) purine microwave modulated spectrum at 1.3 GHz.

The shortest wavelength band of the phosphorescence spectrum of purine in BAC appears at 368.85 nm, but the strongest band appears at 378.65 nm. The relative intensity of the former with respect to that of the latter depends on the sample preparation suggesting that the 368.85 nm band does not originate from purine. ODMR signals were observed at the bands with the wavelengths longer than 378.65 nm, but no ODMR signals were detected at the 368.85 nm band. The shorter wavelength portion of this spectrum resembles the corresponding portion of the phosphorescence spectrum of the BAC X-trap induced by anisole whose O-O band is located at 368.8 nm. (Fig. 2 c)-1) Therefore, it is concluded that the phosphorescence spectrum of purine in BAC in a superposition of the spectra coming from purine and the BAC X-trap. In order to eliminate the phosphorescence of the BAC X-trap and to obtain the genuine spectrum of purine, we have taken a microwave modulated phosphorescence spectrum. The spectrum obtained with the microwave modulation at 1.3 GHz is given in Fig. 2-d. It is seen that the spectrum has a very strong O-O band as those of benzimidazole and 1*H*-indazole. The main vibrational frequencies determined from the phosphorescence spectrum agree well with those determined from the IR and Raman spectra. (Table 1).

The strong O-O band observed here makes a striking contrast to the weak O-O bands found in the phosphorescence spectra taken in other environments, namely

The Raman and IR frequencies for purine and indazole were determined in the present work. The values for benzimidazole were taken from Ref. 35.

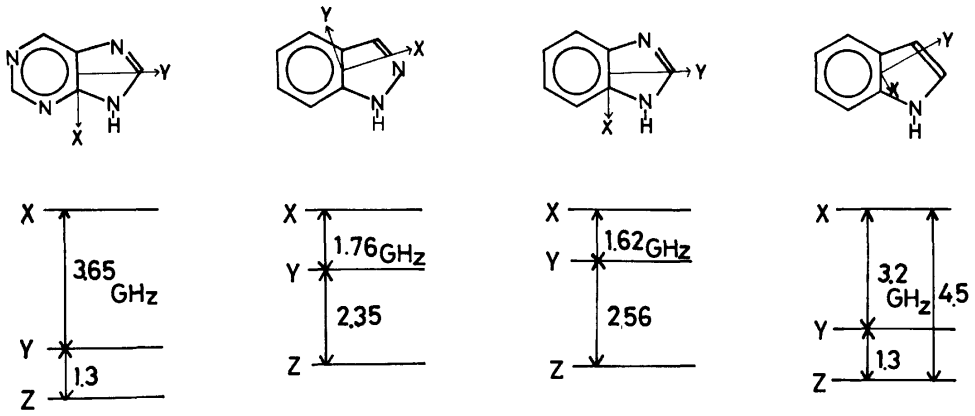

Fig. 3. Approximate direction of the principal axes of the ZFS and the sublevel schemes.

in a rare gas matrix,[8] powder,[7,9] and rigid solution.[2] The cause of this difference seems to be the following. While a well defined single site exists for purine in BAC, there are many sites with different O-O bands in other environments producing inhomogeneous broadenings of the spectra. In contrast to the sharp phosphorescence spectra of the above molecules, the spectrum of indole is very broad indicating the presence of prominent inhomogeneous broadening. The strong O-O bands and the relatively weak vibronic bands found for purine, benzimidazole, and indazole indicate that the structures of the T_1 states of these molecules are not much different from those of the ground states. The phosphorescence spectra of these three molecules are similar with the main vibronic bands at 0—780 cm^{-1}, 0—1270 cm^{-1}, and 0—1600 cm^{-1} (Table 1).

Sublevel Schemes and Zero Field Splittings. The ODMR signals were observed at 3.65 GHz and 1.30 GHz for purine, 2.56 GHz and 1.62 GHz for benzimidazole, 2.35 GHz and 1.76 GHz for 1 *H*-indazole and 4.5 GHz, 3.2 GHz, and 1.3 GHz for indole, respectively. These ODMR frequencies correspond to the transitions between the sublevels which are eigenstates of the following spin Hamiltonian;

$$\mathscr{H} = D\left(S_z^2 - \frac{1}{3}\mathbf{S}^2\right) + E(S_x^2 - S_y^2)$$

$$= -XS_x^2 - YS_y^2 - ZS_z^2, \qquad (1)$$

where $X=1/3D-E$, $Y=1/3D+E$ and $Z=-2/3D$.

Here we take the two in-plane spin axes as the X and Y axes. The Z axis is taken perpendicular to the molecular plane. The T_z sublevel is considered to be the bottom one as in the cases of other aromatic molecules. The top sublevel is taken as the X sublevel as shown in Fig. 3. We designate energies of the X, Y, and Z sublevels by T_x, T_y, and T_z, respectively.

The approximate directions of the X and Y axes were determined by the ratios of the radiative decay rate constants and the angular dependence of the EPR signals as discussed in the later sections. Whether $|T_y-T_z|>|T_x-T_y|$ or $|T_x-T_y|>|T_y-T_z|$ could not be determined from the ODMR experiments. In the former case $D>3|E|$ and in the latter $D<3|E|$. From the single crystal EPR experiments $D<3|E|$ was established previously in the case of indole, and this was also tentatively assumed for the other molecules because of the similarities of the molecular structures.[25] However, Svejda *et al.*[18] concluded $D>3|E|$ for benzimidazole from the analysis of the decay data of the ODMR signals in ethanol. It is, therefore, desirable to determine the zero field sublevel schemes unambiguously and we have examined the augular dependence of the EPR signals of benzimidazole, 1*H*-indazole and purine in BAC. The mixed crystals were mounted so that the applied field rotated in the X-Y planes, on the assumption that the guest molecules substitutionally replace the host molecules. The obtained angular dependence curves are shown in Fig. 4. Unfortunately the signals were rather weak and we were only able to observe parts of the angular dependence curves, but they are sufficient to determine whether $D>3|E|$ or $D<3|E|$. It is immediately clear from Fig. 4 that $D>3|E|$ in the case of benzimidazole and 1*H*-indazole, but $D<3|E|$ in purine. The curves obtained for benzimidazole and 1*H*-indazole are in good agreement with those predicted by solving the spin Hamiltonian

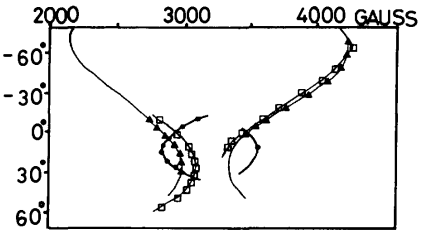

Fig. 4. Angular dependence of the EPR signals. ▲: Benzimidazole, □: 1*H*-indazole, ●: purine. The curves for benzimidazole and 1*H*-indazole are obtained by solving Eq. 2 with the ZFS determined by ODMR experiments. The curve for purine is drawn only for eye guide.

$$\mathscr{H} = \beta H \cdot g \cdot S + DS_z^2 + E(S_x^2 - S_y^2) \qquad (2)$$

with $g=2$ and the D and E values determined by the ODMR experiments. On the other hand, the agreement between the experimental and the predicted ones is poor for purine. This may be due to the deviation from the coplanarity of the guest and host molecules. The ZFS

determined in BAC are listed in Table 2 together with those determined in other hosts. The D and E values vary slightly depending on the host. $|E|$ of benzimidazole and 1H-indazole are smaller in BAC than in 1,4-dibromobenzene host (DBB), while $|E|$ of purine and indole are larger in BAC than in DBB. Though the ZFS are affected by the environment, the basic characteres of the T_1 states are considered to remain unchanged on going from one environment to the other.

Decay Properties. The relatively long lifetimes of all the molecules studied here indicate that the T_1 states are $\pi\pi^*$ in character. We have determined the total decay rate constants (k_i) and the relative radiative decay rate constants (k_i^r) of the triplet sublevels by the MIDP experiments (Table 2). In spite of the poor molecular symmetries the decay constants are remarkably sublevel dependent; k_y and k_y^r are by far the largest in each molecule. The observation that k_z is similar to k_x seems to indicate the effect of spin lattice relaxation. The sublevel decay rate constants of purine, benzimidazole, and indole in ethanol were previously estimated by Moller and Nishimura[17] from the decomposition of the decay curves obtained at 1.5 K into three components. The sublevel decay constants of benzimidazole was determined in a mixture of ethylene glycol-water (1 : 1) by Svejda, *et al.*[18] and those of indole was also determined in the neat crystal by Zuclich *et al.*[19] The values obtained in the present work are somewhat different from those reported previously.

Benzimidazole, indazole, and purine are considered to be nitrogen substituted indoles. The decay rare constants of these molecules are larger than those of indole and this is presumably due to the presence of low lying $^1n\pi^*$ and $^3n\pi^*$ states which are brought in by the nitrogen substitution. These states mix with the T_1 ($^3\pi\pi^*$) states and enhance both radiative and nonradiative decay rates. The increase in the radiative decay rate due to the $^1n\pi^*$ state is determined by the spin-orbit matrix element $\langle {}^1n\pi^*|\mathscr{H}_{so}|{}^3\pi\pi^*\rangle$, the energy separation between the $^1n\pi^*$ and $^3\pi\pi^*$ state, $E(^1n\pi^*)-E(^3\pi\pi^*)$ and the transition moment $\vec{M}(^1n\pi^*-S_o)$. The increase in the nonradiative decay rate constant is determined by the energy separations $E(^3n\pi^*)-E(S_o)$, and $E(^3n\pi^*)-E(^3\pi\pi^*)$ and the spin-orbit matrix elements $\langle {}^3n\pi^*|\mathscr{H}_{so}|S_o\rangle$ and $\langle {}^1n\pi^*|\mathscr{H}_{so}|{}^3\pi\pi^*\rangle$ as well as the matrix elements for vibronic couplings. In the present case spin-orbit matrix elements are mainly determined by the one center integral at the nitrogen atom.

When the one center integral at the nitrogen atom plays a dominant role in the relevant spin-orbit coupling matrix element for the increase in the radiative decay, the ratio of the increase in k_y^r (δk_y^r) to that in k_x^r (δk_x^r) is given by[26]

$$\delta k_y^r/\delta k_x^r = \cos^2\alpha/\sin^2\alpha \qquad (3)$$

where α is the angle between the X axis and the direction of the nitrogen lone pair orbital. A similar equation holds for the nonradiatiave decay. The data given in Table 2 show that the increases in the decay rates on going from indole to benzimidazole and 1H-indazole are mainly in k_y. Then the direction perpendicular to the lone pair orbital of the nitrogen atom must be close to the direction of the Y axes. This means that the Y axis of benzimidazole is along the direction of the long molecular axis as shown in Fig. 5, whereas that of 1H-indazole is along the short axis.

Because of the nitrogen substitution in the six-membered ring k_y of purine is larger than those of

benzimidazole and indazole. The one center integrals at the nitrogen atoms 3 and 7 are considered to be important in determining the spin-orbit matrix elements because of a smaller spin density expected at the nitrogen atom 1. The Y axis of purine is also expected to be along the long axis of the molecule.

The increase of k_y on going from indole to benzimidazole, indazole, and purine are 0.27 sec^{-1}, 0.55 sec^{-1}, and 1.8 sec^{-1}, respectively. The difference between benzimidazole and indazole may be primarily due to the increased nonradiative decay rate constant of indazole because $E(T_1)-E(S_0)$ of indazole is smaller than that of benzimidazole by ~3000 cm^{-1}. The increase in the case of purine can be attributed to the increased spin-orbit matrix element due to the inclusion of two nitrogen atoms in the six-membered ring and smaller energy separations between the $^3\pi\pi^*$ state and the $^1n\pi^*$ and $^3n\pi^*$ states.

The observed increases in the decay rate constants by the nitrogen substitution in the indole skelton are, however, rather small when we compare them with the increases found for the nitrogen substitution in naphthalene. In Table 3 we compare the increases found for the present systems with those found for a series of molecules, quinoline, isoquinoline, and quinoxaline. As seen from the Table 2 the increases are about five times smaller for the present series.

The deuteration of purine reduces the decay rate constants, with $k_y[D]/k_y[H]=0.62$. This ratio is similar to that found for quinoxaline, $k_y[D]/k_y[H]=0.6$.[24c] The reduction of the decay rate constant is due to the decrease of the nonradiative decay rate constant. In the case of quinoxaline the ratio of the radiative and the nonradiative decay rate constants, $k^r:k^{nr}$ is estimated to be 5:7.[27] As in the case of quinoxaline the nonradiative decay is considered to occupy a significant part of the total decay in the case of purine. Then it is concluded that the increases in both radiative and nonradiative decay rate constants are much larger in the naphthalane series. Since energy denominators $E(^1n\pi^*)-E(^3\pi\pi^*)$ are similar for the both series, the differences in the spin-orbit matrix elements $\langle ^1n\pi^*|\mathscr{H}_{so}|^3\pi\pi^*\rangle$ and the transition moment $\mathbf{M}$ are likely to be responsible for the differences in the radiative decay rate constants. As to the nonradiative decay the increased Franck-Condon factor due to the smaller $E(T_1)-E(S_0)$ probably enhances the nonradiative decay in the naphthalene series.

Orientations of Guest Molecules and Hyperfine Interactions. We measured the angular dependence of the EPR signals from the point at which the cleavage plane is in the direction of the applied field. At this orientation the direction of the applied field is rotated by 52° from the direction of the long axis (L axis) of BAC as shown in Fig. 5. We measure the rotation angle (β) of the applied field from this point. The Y stationary point of benzimidazole is obtained at $\beta=25°$. In the same way the Y stationary point of purine is found at $\beta=14°$. As discussed in the last section the Y directions of benzimidazole and purine are along the long axes of the molecules. Then the approximate orientations of these molecules in the BAC host are given as shown in Fig. 5. These orientations are consistent with the hydrogen bonded structures.

Hfs of purine is obtained at its Y stationary point. (Fig. 6) This hfs comes from the protons because the in-plane nitrogen hyperfine coupling constants (hfcc) are expected to be small.[28] Using a Gaussian line shape for each hyperfine component, we simulate this spectrum with three coupling constants; 7.5, 4.2, and 3.2 G as shown in Fig. 6. We consider the hfs of the protons attached to the carbons 2, 6, and 8, since the spin density at N_9 is expected to be very small. When the applied field makes an angle θ with the direction perpendicular to the C-H direction, the hfcc of a proton in the $m_s=0\leftrightarrow m_s=1$ transition is given by

$$\Delta h(\beta) = [(\rho A_{\hat{x}\hat{x}}\cos^2\theta - \rho A_{\hat{y}\hat{y}}\sin^2\theta - g_n\beta_n H)^2 + \frac{\rho^2}{4}(A_{\hat{x}\hat{x}}-A_{\hat{y}\hat{y}})^2\sin^2 2\theta]^{1/2} - g_n\beta_n H. \quad (4)$$

Here $A_{\hat{x}\hat{x}}=-36.5$ G, $A_{\hat{y}\hat{y}}=-11.5$ G, and $A_{\hat{z}\hat{z}}=-23.5$ G[29,30] are the principal values of the hyperfine tensor of a proton attached to an aromatic carbon. (x and y are perpendicular and parallel to the C-H direction in the molecular plane, respectively. $\hat{z}$ is perpendicular to the molecular plane.) Since C_6-H is nearly perpendicular to the direction of the applied field at the Y stationary point, the largest hfcc 7.5 G is likely due to the proton at position 6. $\rho_6=0.20$ is immediately

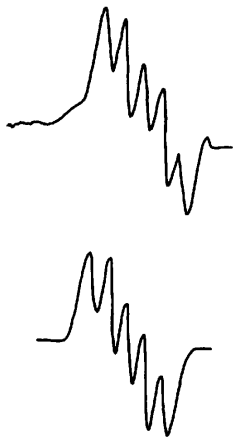

Fig. 6. Hyperfine structure in the EPR spectrum of purine in BAC. H//Y (β=0°). Upper: experimental, lower: simulated.

obtained from Eq. 4 with θ=0°. C_8–H is nearly parallel to the applied field and the hfcc is expected to be small. So we may consider the smallest hfcc 3.2 G is due to the proton at position 8. ρ_8=0.27 is obtained from Eq. 4 with θ=90°. The remaining hfcc 4.2 G is then assigned to the proton at position 2. ρ_2 is given to be 0.12 from Eq. 4 with θ=60°.

Magnetic Properties and the Nature of the Triplet States. One remarkable observation is that $|E|$ of benzimidazole and 1*H*-indazole are much smaller than that of $|E|$ of indole, despite the similarity of their structures. This indicates that the nitrogen substitution to the pyrrole ring of indole modifies the nature of the T_1 state drastically. In the previous work[25] it was shown that the ZFS and the nature of the T_1 state of indole are very similar to those of indene and benzofuran which are viewed as substituted benzenes with strongly mesomeric substituents. The large $|E|$ was attributed to a large delocalization of the unpaired electron into the -C=C- groups of the five-membered ring. On the other hand, much smaller $|E|$ values found for benzimidazole and 1 *H*-indazole indicate that the delocalization of the unpaired electron into the -C=N- groups is much less. The T_1 states of these molecules are approximately described by the excitation of an electron from the highest occupied molecular orbital (HOMO) to the lowest unoccupied molecular orbital (LUMO). The HOMO and LUMO of benzimidazole and 1*H*-indazole then must be very different from those of indole. The observed difference in the spin distributions also indicates this. It was suggested that in indole $\rho_4 \simeq \rho_8 \simeq 0.5\rho_6$, $\rho_3 < \rho_6$, and that ρ_5 and ρ_7 are small.[25] The analysis of the hfs in 1*H*-indazole indicates that ρ_4, ρ_7, and ρ_5 are large,[16] showing that the HOMO and LUMO of indole are strongly affected by the nitrogen substitution.

The ZFS and the spin distribution of purine are expected to be different from those of other in this series because of the presence of two nitrogen atoms in the six-membered ring. Here *D* is similar to those of others, but $|E|$ is very large, indicating larger spin densities in the -C=H- groups of the five-membered ring. The spin distribution in the triplet state is also very different from that of the purine anion. In the purine anion ρ_6 is very large (ρ_6=0.44),[31] but in the triplet state ρ_6 (0.20) is smaller than ρ_8 (0.27). ρ_8 in the anion is smaller than that in the triplet state. A simple π electron MO calculation indicates that the HOMO and the LUMO of purine are very different and that the spin distributions of the anion and the triplet state are very different. This expectation is born out experimentally. This difference in the spin distributions makes a marked contrast to the cases of many aromatic molecules in which the spin distributions in the triplet states are similar to those of anions.[30,32–34]

Electrochemical Properties of Adriamycin Adsorbed on a Mercury Electrode Surface

Kenji KANO, Tomonori KONSE, Naomi NISHIMURA, and Tanekazu KUBOTA*
Gifu Pharmaceutical University, 6-1 Mitahora-higashi 5-chome, Gifu 502
(Received January 26, 1984)

The electrochemical behavior of adriamycin has been studied by means of cyclic d.c. and a.c. voltammetry with a hanging mercury drop electrode, quinizarin being used as a model compound. Both adriamycin and quinizarin are strongly adsorbed on the mercury electrode with their aromatic ring planes oriented parallel to the electrode surface, and give two sets of reduction waves. The first wave, due to the quinone moieties of the adsorbed adriamycin and quinizarin, has been explained on terms of a two-step one-electron surface redox reaction. The formal standard redox potentials, semiquinone formation constants, and charge transfer rate constants of the surface redox reaction of the quinone moieties have been determined. Although the reduced form of adriamycin is not very stable chemically, it is converted to a stable and electrochemically active form for a few minutes at pH 4.54. The second wave appearing at more negative potential would be due to a kinetic or catalytic process.

Adriamycin, a member of the anthracycline antibiotics, is a highly effective antineoplastic agent.[1] The antitumor properties of the anthracyclines correlate in many case with the ability to cause the intercalative inhibition of DNA temperate functions.[1,2] Some other mechanisms, such as the generation of free radical intermediates[3] and a bioreductive covalent attachment to DNA,[4] have been suggested. Serious disadvantages of this drug are the cardiotoxicity[5] and chromosomal damage,[6] which have been shown to be associated with the inhibition of mitochondrial electron transport to bring about the generation of hydrogen peroxide, superoxide anion, and hydroxyl radicals.[7] This behavior should be in intimate correlation with the redox properties of the drugs, which then have been the subject of intensive studies.[3,8-10]

Rao *et al.*[8] have investigated the electrochemical reduction behavior of daunomycin and adriamycin. They reported two sets of reduction waves. Since their experiments were carried out at quite a high concentration by using a hanging mercury electrode, the waves reported by them seem to be attributable to the redox systems of both the adsorbed and bulk species, and the analysis of the results has been semi-quantitative. The electrochemical behavior of adsorbed adriamycin has been also reported by Molinier-Jumel *et al.*[9] on the reduction at a mercury electrode, and by Baldwin *et al.*[10a] and Chaney and Baldwin[10b] on the oxidation at a carbon paste electrode. Their analyses of the electrochemical behavior of adsorbed adriamycin have, however, remained qualitative.

Recently Kakutani and Senda[11] have presented the theory of d.c. and a.c. voltammetry for a two-step surface redox reaction. This theory has been successfully applied to explain the electrochemical behavior of adsorbed flavin mononucleotide,[12] flavin adenine dinucleotide,[13] and glucose oxidase.[14] In this study, we have investigated the electrochemical behavior of adriamycin adsorbed on a hanging mercury drop electrode by means of cyclic d.c. and a.c. voltammetry, quinizarin being used as a model compound. The wave ascribed to the quinone moiety of the adsorbed adriamycin has been interpreted by applying the above theory of the two-step surface redox reaction. The thermodynamic and kinetic properties of the electrochemical redox reaction of the adsorbed adriamycin were able to be determined. We have also investigated the second wave, which appeared at a more negative potential than in the quinone wave. The results and discussions are presented in this paper.

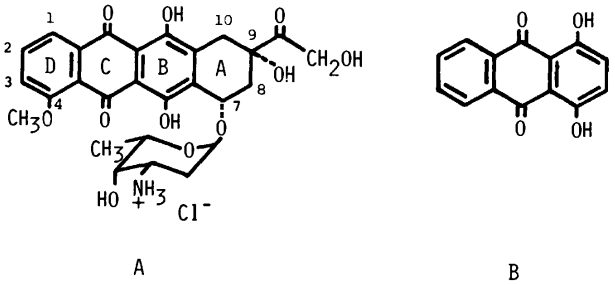

Fig. 1. Structure of adriamycin (A) and quinizarin (B).

Experimental

Chemicals. Adriamycin hydrochloride, obtained from Kyowa Hakko Kogyo Co., was used as received. The concentration of adriamycin in methanol solution was determined spectrophotometrically using $E^{1\%}_{1cm}$(495 nm)=223.[15] Quinizarin (1,4-dihydroxyanthraquinone), obtained from Ardrich Chemical Co., was purified by recrystallization from methanol. Its purity was checked by elemental analysis. Triply distilled water was used to prepare the electrolysis solution. Other chemicals were reagent grade quality.

Electrochemical Measurements. Cyclic d.c. voltammograms were recorded with a Yanagimoto P-1000 voltammetric analyzer, equipped with a Watanabe WX-4401 X-Y recorder. The a.c. voltammetric measurements were performed with a NF circuit LI-572B lock-in amplifier, equipped with the above potentiostat system. The NF circuit FG-121B function generator was used as an a.c. signal generator.

All the voltammetric measurements were made under potentiostatic conditions with a three-electrode system consisting of a Metrohm EA 290 hanging mercury drop working electrode (HMDE) with surface area 0.0187±0.0003 cm^2, a coiled platinum wire auxiliary electrode, and a Yanagimoto MR-P2 saturated calomel reference electrode (SCE). The buffer solutions of 0.2 mol dm^{-3} sodium acetate-acetic acid were used as the base solution for pH 2 to 6. The ionic strength of the base solutions was adjusted to 0.5 mol dm^{-3}

with potassium nitrate. A fresh mercury drop from the HMDE was exposed to the electrolysis solution for a given period of time, t_{exp}, at a constant d.c. potential, E_i. Then the d.c. voltage scan was started from E_i, with the scan rate v=100 mV s^{-1} for d.c. voltammetry and with v=10 mV s^{-1} for a.c. voltammetry, unless otherwise stated. In a.c. voltammetry, the amplitude of the superimposed a.c. voltage was adjusted to 10 mV peak to peak. The frequency and the amplitude of the a.c. signal were checked with a Iwatsu SS-5702 synchroscope. Electrochemical measurements were performed under nitrogen or argon atmosphere at 25.0±0.2 °C, unless otherwise noted.

Results

I. Electrochemical Behavior of Adriamycin. Figure 2 shows the cyclic d.c.voltammogram of 3.75×10^{-6} mol dm^{-3} adriamycin in a pH 4.54 acetate buffer, which was recorded after t_{exp}=3 min at E_i=−0.1 V. At such a low concentration, the current due to the redox reaction of diffusing adriamycin will be negligibly small compared with the current due to the surface redox reaction of adsorbed adriamycin. One-pair of the peak-shaped cathodic and anodic waves (I) and one irreversible cathodic wave (II) were observed at −0.45 V and −1.13 V, respectively. For the I waves, the peak potential of the anodic wave is negative by 10 mV compared with that of the cathodic one. We have studied in detail the electrochemical behavior of the I waves, which should be ascribed to the redox reaction of the quinone moiety of adriamycin adsorbed on the HMDE.

Cyclic D.c. Voltammetry of Wave I. Figure 3A shows the cyclic d.c. voltammogram of 1.46×10^{-6} mol dm^{-3} adriamycin at pH 4.54, which was recorded after t_{exp}=4 min at E_i=−0.2 V and with the switching potential, E_s=−0.7 V. A pair of cathodic and anodic waves are observed at −0.450 V. The shapes and heights of these two waves are practically identical except for the opposite current sign. The peak potential, $E_{p,I}$, and the half-peak width of the wave I, $\Delta E^{dc}_{p/2,I}$, are −0.450 V and 52 mV, respectively. Figure 3B shows the cyclic

Fig. 3. Cyclic d.c. voltammograms of 1.46×10^{-6} mol dm^{-3} adriamycin in pH 4.54 acetate buffer. Voltage scan was started after t_{exp}=4 min from (A) E_i=−0.2 V and (B) E_i=−0.7 V.

voltammogram recorded with E_i=−0.7 V, where adriamycin is adsorbed in a reduced state. As in the case of Fig. 3A, a symmetrical pair of anodic and cathodic waves is observed. However, $E_{p,I}$ of the waves in Fig. 3B is more negative by 8 mV and $\Delta E^{dc}_{p/2,I}$ is larger by 18 mV compared with those of the waves in Fig. 3A.

We performed the multicyclic voltammetry in the potential range of −0.3 to −0.7 V, with t_{exp}=10 min at 7.98×10^{-7} mol dm^{-3} adriamycin. In the multicyclic voltammetry with E_i=−0.3 V and E_s=−0.7 V, $E_{p,I}$ shifts cathodic and the peak becomes broad and resharpened as the number of cycles is increased, and in about the 40th cycle the wave reaches a steady state, where $E_{p,I}$= −0.483 V and $\Delta E^{dc}_{p/2,I}$=65 mV. On the other hand, in the multicyclic voltammetry with E_i=−0.7 V and E_s= −0.3 V, $E_{p,I}$=−0.476 V, and $\Delta E^{dc}_{p/2,I}$=73 mV for the first scan, and $E_{p,I}$ shifts cathodic and the peak becomes sharp with the increasing number of cycles. In about the 20th cycle, the wave reaches a steady state; this coincides with the steady state wave obtained in the multicyclic voltammetry with E_i=−0.3 V. These results can be interpreted as follows. The parent compound is fundamentally d.c. reversible and the peak potential is −0.450 V as written above, but the reduced form is chemically not so stable and transferred into a chemically stable other form during the time in which adriamycin was in the reduced form. The chemically stable product is also electrochemically active and shows a d.c. reversible wave, whose peak potential is −0.483 V.

In the following, we have set the E_i at a more positive potential than the peak potential by at least 150 mV. Figure 4 shows the t_{exp} dependence of the cathodic peak height, $I_{p,Ic}$, obtained with E_i=−0.2 V. At lower concentrations of adriamycin, $I_{p,Ic}$ is proportional to $[(D/r)t_{exp}+2(D/\pi)^{1/2}t_{exp}^{1/2}]$, where D is the diffusion coefficient of adriamycin, estimated by the Ilkovic equation to be 7.53×10^{-6} cm^2 s^{-1}, and r is the radius of the HMDE (3.82×10^{-2} cm in this case). The slope of the plot is also proportional to the bulk concentration of adriamycin. These results indicate the diffusion-controlled adsorption of adriamycin at the spherical electrode surface, *i.e.* at the HMDE surface.[12,16,17] The wave heights reached to a certain limit, $I^{max}_{p,Ic}$, at the relatively high concentration of adriamycin and/or

prolonged exposure of the HMDE.

Table 1 summarizes the peak heights ($I_{p,Ic}$ and $I_{p,Ia}$), the peak potentials ($E^{dc}_{p,Ic}$ and $E^{dc}_{p,Ia}$), the half-peak widths ($\Delta E^{dc}_{p/2,Ic}$ and $\Delta E^{dc}_{p/2,Ia}$), and the integrated currents *i.e.* the electricities (Q_{Ic} and Q_{Ia}) of the cathodic and anodic waves with various v. The values of Q_{Ic} and Q_{Ia} were estimated from the area under the wave. Both $I_{p,Ic}$ and $I_{p,Ia}$ are proportional to v. The $I_{p,Ic}/I_{p,Ia}$ ratio is practically unity. $E^{dc}_{p,Ic}$ and $E^{dc}_{p,Ia}$, $\Delta E^{dc}_{p/2,Ic}$ and $\Delta E^{dc}_{p/2,Ia}$, and Q_{Ic} and Q_{Ia} coincide with each other and are independent of v. Further, $I_{p,Ic}$ and $I_{p,Ia}$ are proportional to Q_{Ic} and Q_{Ia}, respectively, as shown in Fig. 5. This means that the peak height at a given v is directly proportional to the amount of the adriamycin adsorbed on the electrode surface. These results indicate that the I wave can be ascribed to the reversible surface redox reaction under the limited conditions, where the effect of the following chemical reaction can be disregarded.

At lower pH than 6, the behavior of the cyclic d.c. voltammograms of adriamycin fundamentally resembles that of the voltammograms obtained at pH 4.54, except for the peak potential. The pH dependence of the peak potential is −60 mV per pH unit in the pH range of 2 to 6, which indicates two-electron two-proton redox reaction.

A.c. Voltammetry of Wave I. In the cyclic a.c. voltammetry of adriamycin adsorbed at E_i=−0.30 V and pH 4.54, the a.c. cathodic voltammogram is practically identical in height and shape with the anodic one. So, the a.c. voltammetric behavior has been studied only for the cathodic scan. Figure 6 shows the a.c. voltammograms recorded with a.c. frequency, f, of 100 Hz after

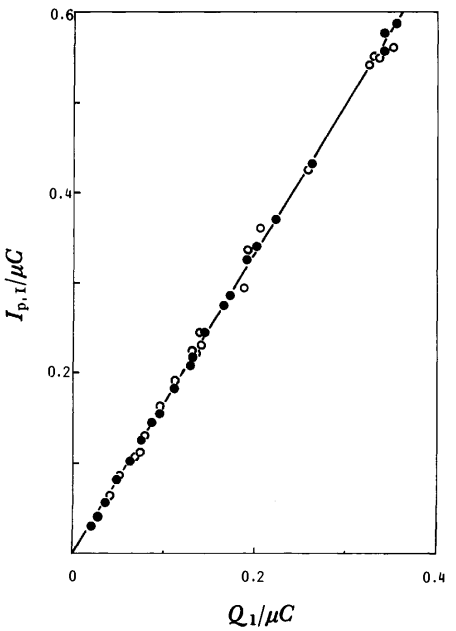

Fig. 5. Plot of the peak current against the electricity at pH 4.54. The closed and open circles correspond to the cathodic and anodic waves, respectively. E_i= −0.2 V.

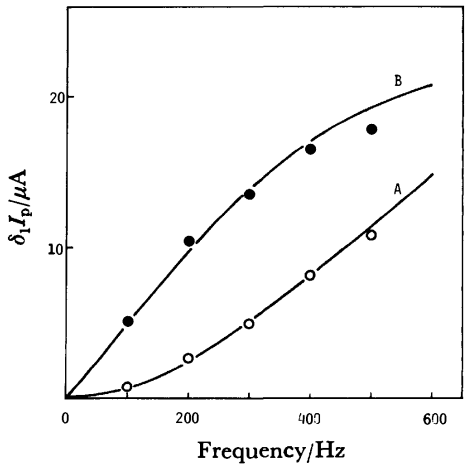

Fig. 7. Dependence of (A) $\delta_1 I_p^{real}$ and (B) $\delta_1 I_p^{imag}$ on a.c. frequency. A.c. voltammograms were recorded in pH 4.54 acetate buffer containing 1.13×10^{-6} mol dm^{-3} adriamycin after $t_{exp}=2$ min at $E_i=-0.30$ V. Solid lines represent theoretical curves[11)] calculated by using $K=0.132$, $k_{sap}=8.8\times10^{3}$ s^{-1}, and $\Gamma=4.04\times10^{-11}$ mol cm^{-2} ($\theta=0.392$).

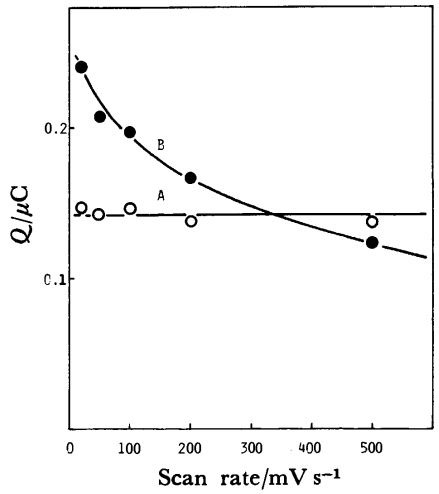

Fig. 8. Dependence of (A) Q_{Ic} and (B) Q_{II} on the scan rate in pH 4.54 acetate buffer containing 9.97×10^{-7} mol dm^{-3} adriamycin. D.c. voltammograms were recorded after $t_{exp}=3$ min at $E_i=-0.10$ V.

$t_{exp}=2$ min at $E_i=-0.3$ V in the pH 4.54 acetate buffer containing 2.16×10^{-6} mol dm^{-3} adriamycin. In all the a.c. voltammograms recorded in this study, the peak potentials of the real and the imaginary components, E_p^{real} and E_p^{imag}, are independent of the a.c. frequency between 100 and 500 Hz, and of the amount of the adsorbed adriamycin. They are also in accord with each other, and with the peak potentials of the corresponding d.c. voltammogram, as shown in Table 2. On the other hand, the peak currents, $\delta_1 I_p^{real}$ and $\delta_1 I_p^{imag}$, and the half-peak widths, $\Delta E_{p/2}^{real}$ and $\Delta E_{p/2}^{imag}$, of the real and imaginary components depend on f and on the amount of the adsorbed adriamycin, as shown in Fig. 7 and Table 2.

D.c. Voltammetry of Wave II. We have also studied the d.c. voltammetric behavior of the irreversible cathodic wave II, observed at −1.13 V with $v=100$ mV s^{-1} in a pH 4.54 acetate buffer. The peak potential of the wave II shifts cathodic by about 50 mV for the tenfold increase in the v range of 10 to 500 mV s^{-1}. The peak current of the II wave, $I_{p,II}$, grows parabolically with increasing v; here $I_{p,II}$ was obtained by subtracting the current of the base solution without adriamycin. Figure 8 shows the v dependence of the integrated current of the II wave, Q_{II}, as well as that of the cathodic wave I, Q_{Ic}, where the voltammograms were recorded with $E_i=-0.1$ V, and t_{exp} was set to be 3 min, which included the potential scanning time from E_i to the peak potential of wave II. Q_{II} decreases with increasing v. This coincides with the parabolic v dependence of $I_{p,II}$. The temperature coefficient of $I_{p,II}$ is 6.3% in the temperature range of 10 to 40 °C. These results indicate that wave II is kinetic or catalytic in character.

The current of wave II is reduced with addition of *N,N*-dimethylformamide (DMF). Curve 1 in Fig. 9 shows the dependence of $I_{p,II}$ on the amount of the added DMF. It disappears completely at the DMF concentrations beyond 20% (v/v).

II. Electrochemical Behavior of Quinizarin. Figure 10A shows the cyclic d.c. voltammogram of 3.98×10^{-6} mol dm^{-3} quinizarin in pH 4.54 acetate buffer. It was recorded after $t_{exp}=3$ min at $E_i=-0.1$ V. Just like the case of adriamycin, one pair of peak-shaped cathodic and anodic waves (I) and one irreversible cathodic wave (II) are recorded at −0.416 V and −1.095 V, respectively. However, the peak potentials of the cathodic and anodic waves I are in accord with each other, and the anodic peak current is about one-half

of the cathodic one. This I wave should be ascribed to the redox reaction of the quinone moiety of quinizarin adsorbed on the HMDE.

In the case of cyclic d.c. voltammetry starting with E_i=−0.2 V and setting the E_s in the potential range of −0.6 to −0.9 V, the shapes and heights of the cathodic and anodic waves become practically identical except for the opposite current sign (Fig. 10 B). $E_{p,I}$ and $\Delta E^{dc}_{p/2,I}$ of the wave are −0.416 and 53 mV, respectively, at pH 4.54. These values coincide well with those of the wave obtained with E_i=−0.7 V and E_s=−0.2 V. This kind of behavior of quinizarin is quite different from that of the aforementioned adriamycin, and shows that the reduced quinizarin is stable chemically, but partial desorption occurs at the more negative potential than −1.0 V. Detailed analysis of these waves in d.c. and a.c. voltammetry leads to the conclusion that the electrochemical behavior of wave I given by quinizarin is fundamentally the same as that of the d.c. reversible wave I given by adriamycin. The II wave decreases and disappears as more DMF is added, as shown in Fig. 9 (curve 2).

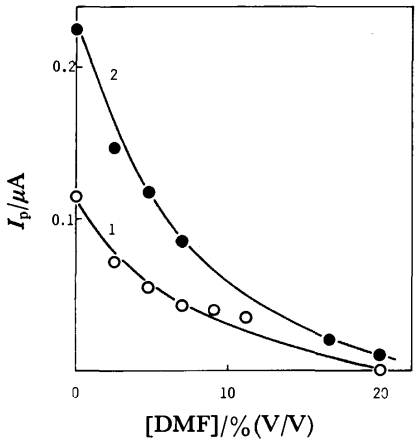

Fig. 9. Dependence of $I_{p,II}$ of (1) adriamycin and (2) quinizarin on the concentration of DMF. $C_{adriamycin}$ = 1.25×10^{-6} mol dm^{-3}, $C_{quinizarin}$ = 2.49×10^{-6} mol dm^{-3}, t_{exp}=3 min at E_i=−0.1 V.

Discussion

Adsorption of Adriamycin on Mercury Electrode Surface. The present study has revealed that adriamycin is strongly adsorbed on the HMDE surface and that the adsorption is controlled by diffusion. The peak current of the wave I is given by

$$I_p = kA\Gamma = kA[(D/r)t_{exp} + 2(D/\pi)^{1/2}t_{exp}^{1/2}]C, \quad (1)$$

where k is the proportional constant, A the electrode surface area, Γ the surface concentration of adriamycin per unit area, and C the bulk concentration of adriamycin. At large C and/or large t_{exp}, the maximum current, I_p^{max}, is obtained, so that the I_p^{max} is given by

$$I_p^{max} = kA\Gamma^{max}, \quad (2)$$

where Γ^{max} is the maximum Γ. By applying Eqs.(1) and (2) to such a plot as is shown in Fig.4, we estimated Γ^{max}=1.4×10^{-10} mol cm^{-2} at −0.2 V and at pH 4.54. The Γ and Γ^{max} values can also be estimated from the integrated current;

$$Q = nFA\Gamma \text{ and } Q^{max} = nFA\Gamma^{max}, \quad (3)$$

where n is the number of electrons transferred per molecule of adriamycin. For the I wave obtained with E_i=−0.20 V, this gives Γ^{max}=1.1×10^{-10} mol cm^{-2} at pH 4.54, by assuming n=2 (for the redox of quinone moiety). Further, when adriamycin is adsorbed at E_i=−0.65 V, where the reduced adriamycin is adsorbed, Γ^{max} is estimated to be 1.2×10^{-10} mol cm^{-2} by Eqs. (1) and (2), and 1.1×10^{-10} mol cm^{-2} by Eq. (3). The Γ^{max} values thus obtained by two different treatments agree well between the parent and reduced adriamycins, so that the adsorbed state of the reduced adriamycin is essentially the same as that of the parent adriamycin. Assuming that adriamycin is adsorbed on the electrode surface with its aromatic ring plane oriented parallel to the electrode surface and with its sugar moiety parpendicular to the electrode surface, a CPK molecular model[18] gives Γ^{max}=1.1×10^{-10} mol cm^{-2}.

The Γ^{max} value of 1.4×10^{-10} mol cm^{-2} was estimated for quinizarin by the two methods: One is the applica-

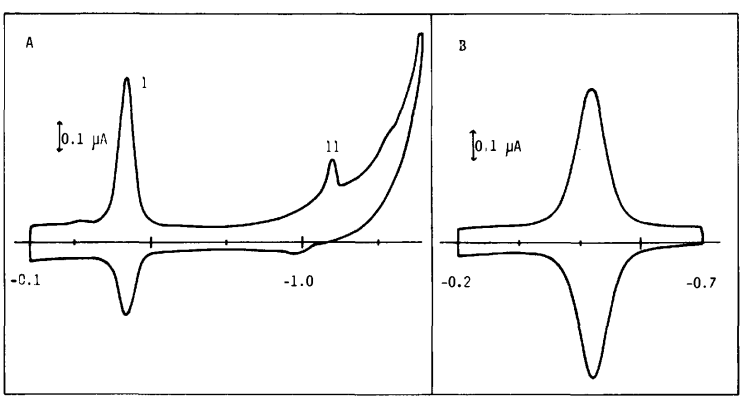

Fig. 10. Cyclic d.c. voltammograms of 3.98×10^{-6} mol dm^{-3} quinizarin in pH 4.54 acetate buffer. t_{exp}=3 min. (A) E_i=−0.1 V and E_s=−1.4 V, (B) E_i=−0.2 V and E_s=−0.7 V.

tion of Eq. (3), and the other is due to the CPK model method, where we assumed parallel orientation of its aromatic ring. The difference between Γ^{max} of adriamycin and quinizarin can be ascribed to the ring A in adriamycin, which is absent in quinizarin. In other words, the sugar moiety in the adsorbed adriamycin is directly surrounded by the solvent molecules. This conformation of the adsorbed adriamycin may be similar to that of the pyridine adduct of daunomycin in the crystal structure, in which strong hydrogen bonding is formed between the two axial oxygen groups at C_7 and C_9.[19]

Surface Redox Process of Quinone Moiety in Adsorbed Adriamycin. The I wave brought about by adriamycin adsorbed on the HMDE surface should be ascribed to the redox reaction of the quinone moiety. This wave is reversible under the conditions that the d.c. voltammogram is recorded with E_i=−0.2 V and E_s=−0.7 V. As was written in detail in the section "*Cyclic Votammetry of Wave I*" in the chapter "**Results**", the reduced form of adriamycin is not very stable, and is irreversibly transferred into other stable from, which is also capable of a reversible two-electron redox reaction. This chemical reaction would be considered as an irreversible elimination of the amino sugar moiety, giving rise to 7-deoxyadriamycinone, as stated by Rao *et al.*[8] This proposed process is supported by the fact that adriamycin is quantitatively converted into 7-deoxyaglycon by mild chemical reduction.[20] Furthermore, this reductive cleavage process is one important metabolic pathway.[21]

Let us now consider the d.c. reversible wave I produced by the parent adriamycin adsorbed at the more anodic potential side than the peak potential of wave I. The cyclic d.c. voltammetric behavior of wave I should be interpreted in terms of a two-step one-electron surface redox reaction:

$$\left.\begin{aligned} O_{ad} + e &\rightleftharpoons S_{ad} \\ S_{ad} + e &\rightleftharpoons R_{ad} \end{aligned}\right\}, \tag{4}$$

where O_{ad}, S_{ad}, and R_{ad} denote the oxidized (or parent), semiquinone and reduced from of the adsorbed adriamycin, respectively. The theory of the cyclic d.c. voltammogram and of the real and imaginary components of the a.c. current in the two-step surface redox reaction has been presented by Kakutani and Senda.[11] The theory predicts the following: If the two steps are d.c. reversible in the simplified case[22] and the semiquinone formation constant, K, is less than 16, the cathodic and anodic d.c. voltammograms may have a maximum at E'_o regardless of v and Γ. Here note that the E'_o corresponds to the standard surface redox potential of the couple O_{ad}/R_{ad}. Also, the half-peak widths, $\Delta E^{dc}_{p/2,Ic}$ and $\Delta E^{dc}_{p/2,Ia}$, will have the same value and are independent of v and Γ under the above conditions. Thus Eq. (5) is obtained:

$$\Delta E^{dc}_{p/2,Ic} = \Delta E^{dc}_{p/2,Ia} = (2RT/F)|\ln\zeta|, \tag{5}$$

where ζ is the solution of the equation, $\zeta^4-K\zeta^3+(K-4\sqrt{K}-6)\zeta^2-K\zeta+1=0$. The cathodic and anodic peak heights will be proportional to v and Γ, and are given by

$$\begin{aligned} I_{p,Ic} = I_{p,Ia} &= 2(F^2/RT)A\Gamma v/(2+\sqrt{K}) \\ &= (F/RT)Qv/(2+\sqrt{K}). \end{aligned} \tag{6}$$

Here K is defined by

$$\begin{aligned} K &= [S_{ad}]^2/[O_{ad}][R_{ad}] \\ &= \exp[(F/RT)(E'_{o1}-E'_{o2})], \end{aligned} \tag{7}$$

where E'_{o1} and E'_{o2} are the standard surface redox potentials of the couples O_{ad}/S_{ad} and S_{ad}/R_{ad}, respectively, and other symbols have their common meanings.

All experimental results obtained in this study agree well with these theoretical predictions (see Table 1 and Fig. 5), and E'_o=−0.450 V at pH 4.54. The K value at pH 4.54 has been determined to be 0.138±0.043 by Eq. (5) and 0.126±0.034 by Eq. (6). These agree well with each other.

The theory also leads to the following outcomes under the aforementioned conditions; E_p^{real} and E_p^{imag} will be independent of the a.c. frequency, f, and will coincide with E'_o. The ratio of $\delta_1 I_p^{real}$ to $\delta_1 I_p^{imag}$ at $E=E'_o$ is given by

$$(\delta_1 I_p^{real}/\delta_1 I_p^{imag})_{E=E'_o} = 2\pi f/k_{sap}(K)^{1/4} \tag{8}$$

where k_{sap} is the apparent rate constant of the first and the second charge transfer step. The present result is in line with the prediction discussed hitherto as shown in Table 2 and Fig. 11. The slope of the plot in Fig. 11 gives k_{sap} by applying the K value determined by d.c. voltammetry. The k_{sap} value has been estimated to be $8.8\times10^3\ s^{-1}$ at $\Gamma=4.04\times10^{-11}$ mol cm^{-2} ($\theta\equiv\Gamma/\Gamma^{max}$= 0.392), using K=0.132. According to the theoretical equations in the simplified case, we have calculated the half-peak widths and the peak currents of the real and imaginary components of a.c. voltammogram using the estimated values of K, k_{sap}, and Γ. Table 2 shows the experimental and theoretical values of $\Delta E_{p/2}^{real}$ and $\Delta E_{p/2}^{imag}$. Figure 7 shows the f dependence of the experimental values of a.c. peak current, where the solid lines represent the theoretical ones.

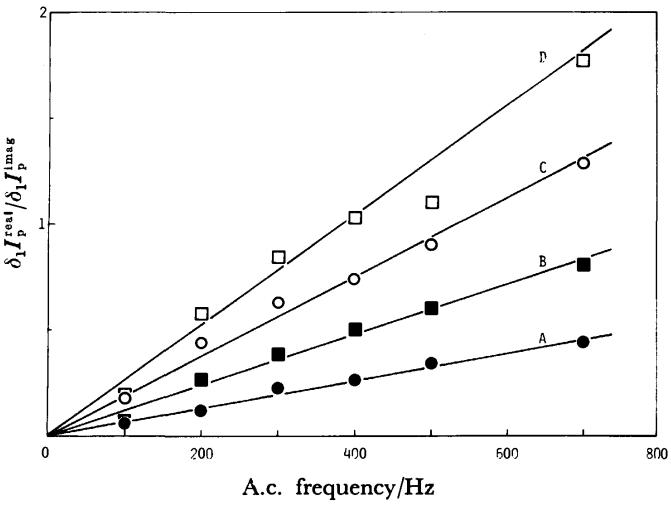

Fig. 11. Dependence of the a.c. peak current ratio, $\delta_1 I_p^{real}/\delta_1 I_p^{imag}$, on a.c. frequency at various total surface coverages of adriamycin in pH 4.54 acetate buffer. θ=(A) 0.19, (B) 0.39, (C) 0.65, and (D) 1.0.

Agreement between the experimental results and the theoretical predictions is good. The dependence of k_{sap} on the surface coverage, θ, is also given by Eq. (9)[11]

$$k_{sap} = k_{sap}(\theta \rightarrow 0)\exp(-a\theta), \quad (9)$$

where $k_{sap}(\theta \rightarrow 0)$ is the apparent rate constant at $\theta \rightarrow 0$, and a is the Frumkin's a-parameter of interaction between adsorbed molecules (a is positive for attraction and negative for repulsion). This situation is experimentally verified as shown in Fig. 12. From the slope of the plot in Fig. 12, we can estimate the a value. In conclusion, one can say that the cyclic d.c. and a.c. voltammetric behavior of the quinone moiety in the adriamycin adsorbed on the HMDE can be explained by the two-step surface redox mechanism. Now, the E'_{o1} and E'_{o2} values can be estimated by using the E'_o in Eq. (10) and the K in Eq. (7):

$$E'_o = (E'_{o1}+E'_{o2})/2. \quad (10)$$

Table 3 summarizes the above electrochemical data. We have also determined the electrochemical data of the quinone moiety of the adsorbed adriamycin at pH 2.49; these are listed in Table 3. In the range of pH lower than 6, E'_{o1} and E'_{o2} as well as E'_o shift linearly to negative with the slope of -60 mV/pH. This result indicates that each of two steps of the surface redox process involves one electron and one proton. Other electrochemical data obtained at pH 2.69 are practically identical with those obtained at pH 4.54. The electrochemical behavior of adsorbed adriamycin becomes complicated at elevated pH; this will be reported in a succeeding paper.

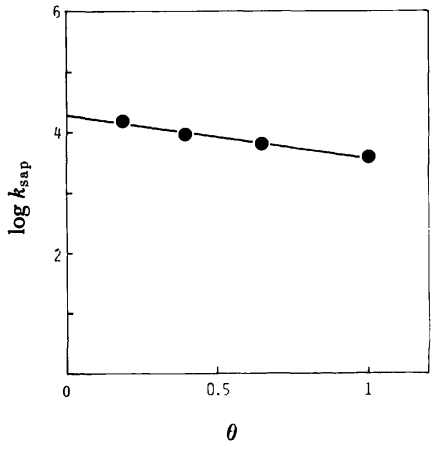

Fig. 12. Plot of log k_{sap} of adriamycin against θ at pH 4.54.

Similarly, the electrochemical behavior of the quinone moiety in the adsorbed quinizarin is explained by the above mechanism. The electrochemical data are summarized in Table 3. A decrease in $k_{sap}(\theta \rightarrow 0)$ and a-parameter is observed for quinizarin, compared with the values for adriamycin. The difference in E'_o between adriamycin and quinizarin is mainly ascribed to 4-methoxyl group of adriamycin. The K values of adriamycin and quinizarin are less than unity, indicating that the disproportionation of the adsorbed semiquinone form should be thermodynamically favorable.

Electrochemical Process in Wave II Produced by Adriamycin. The d.c. voltammetric behavior of the II wave indicates that the current has a kinetic or catalytic character. The II wave is also observed with quinizarin, but not with anthraquinone.[23] These facts suggest that the presence of two adjacent hydroquinone moieties in a molecule is essential for the appearance of the II wave. Note that the quinone moiety is reduced to the hydroquinone moiety at the potential where the II wave is observed. The process of wave II can thus be ascribed to the catalytic hydrogen evolution current catalyzed by two hydroxyl groups on adjacent benzene rings such as the oxonium compounds.[24] The fact that the II wave becomes small and disappears with the addition of DMF, an aprotic solvent, supports the proposed mechanism. Rao *et al.*[8] have ascribed this irreversible process to the reduction of the side-chain carbonyl group, on the basis of its similarily to the reduction processes of acetophenone and 1′-acetonaphtone. However, the side-chain carbonyl group of adriamycin is aliphatic and is not conjugated with the aromatic rings, differing very much from the carbonyl groups of acetophenone and 1′-acetonaphtone. In general, the reduction wave of aliphatic ketone can not be observed in the usual buffer solution.[25] Further, Rao *et al.*'s assignment can not explain the II wave produced by quinizarin, which is without the side-chain carbonyl group.

As a conclusion, the thermodynamic and kinetic information on the redox reaction of adriamycin adsorbed on a mercury electrode surface can be obtained by means of the cyclic d.c. and a.c. voltammetric study. This information would be useful in an elucidation of the action mechanism of adriamycin. The electrochemical behaviors of the adsorbed adriamycin in neutral and alkaline solutions and/or on a solid electrode will be published later.

The authors wish to express their sincere thanks to Professor Mitsugi Senda and Dr. Tadaaki Kakutani, Kyoto University, for their valuable discussions on this study.

Table 3. Electrochemical data of adriamycin and quinizarin adsorbed on a mercury electrode

Compound	pH	E'_o	E'_{o1}	E'_{o2}	K	$k_{sap}(\theta \rightarrow 0)$ / 10^4 s^{-1}	a
		V *vs.* SCE					
adriamycin	4.54	−0.450	−0.476	−0.424	0.132	1.98	1.66
adriamycin	2.69	−0.333	−0.357	−0.308	0.148	2.19	1.61
quinizarin	4.54	−0.418	−0.440	−0.396	0.178	0.73	0.94

^{13}C-NMR Studies on Conformational Equilibria in Isopropyl Methyl Ether

Kenzabu TASAKI, Yuji SASANUMA,† Isao ANDO, and Akihiro ABE*
Department of Polymer Chemistry, Faculty of Engineering, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152
(Received February 8, 1984)

The energy difference between the two rotational isomers, *i.e.*, C_S and C_I, of isopropyl methyl ether has been elucidated from the observed vicinal ^{13}C-^{1}H coupling constant. The conventional Gutowsky method based on the simple rotational isomeric state model tends to give an underestimate, especially when the energy difference is large. A more elaborate treatment, which takes account of the overall profile of the torsional potential energy curve, has been attempted. Adoption of J_T=11.0—12.0 Hz for the trans coupling gave a value of 2.2± 0.2 kcal mol^{-1} for the energy difference $E_{C_S}-E_{C_I}$. This result is consistent with the range (2.4±0.6 kcal mol^{-1}) estimated by the matrix-isolation method as reported by Nakata *et al.*

In the structural studies of polymeric chains, we occasionally encounter a stereochemical arrangement which bears some resemblance to isopropyl methyl ether. Poly[oxy(1-methylethylene)][1] $\{CH_2CH(CH_3)O\}_n$ and poly(1-methoxyethylene)[2] $\{CH_2CH(OCH_3)\}_n$ are the typical examples. The energy difference between the two rotational isomers (*i.e.*, C_S and C_I) of isopropyl methyl ether is presumed to be large due to severe steric conflicts involved in the C_S form. Any accurate value of the energy difference ΔE ($=E_{C_S}-E_{C_I}$) has not been determined experimentally. The corresponding value of ΔE for 2-methylbutane, a hydrocarbon analogue of isopropyl methyl ether, has been known[3] to be 0.8 to 0.9 kcal mol^{-1}. Considering the fact that the C–O bond length is somewhat shorter than that of the C–C bond, ΔE for isopropyl methyl ether should be much larger than the value given above. Recently Nakata, Furukawa, Hamaguchi, and Tasumi[4] applied the matrix-isolation technique to this compound: A gaseous mixture with argon was blown agaist a cold surface of CsI plate which was kept at 20 K. The characteristic Raman bands were used for detection of the two rotational isomers trapped in the argon matrix. The energy difference ΔE estimated in this manner amounts to 2.4±0.6 kcal mol^{-1} over the temperature range 20—260 °C.

In this study, we have attempted to elucidate the same energy difference from the analysis of the ^{13}C-^{1}H vicinal coupling constant determined on $^{13}CH_3OC^1H(CH_3)_2$. The information thus acquired regarding the conformation of isopropyl methyl ether will be used in the configurational studies on poly[oxy(1-methylethylene)], which is the subject of forthcoming paper.[5]

Experimental

Isopropyl methyl ether was prepared by the Williamson synthesis from isopropyl alcohol and methyl iodide. Solvents used in the NMR measurements were commercially available and used without further purification.

Natural abundance proton-coupled ^{13}C-NMR spectra were obtained at 25 MHz by using a JEOL FX-100 spectrometer equipped with FT and gated decoupling systems. In the measurements, 300 transients were accumulated with a 90° rf pulse of 13.5 μs duration. The pulse repetition time was 9 s. The Fourier-transformed spectra contain 8192 data points for a 500 Hz spectral width, yielding a resolution of 0.06 Hz. The temperature were maintained within ±1.0 °C during the measurements. A 10-mm NMR sample tube was used.

† Present address: Toray Research Center, Sonoyama, Otsu 520.

Results

The spin system of the compound may be identified as A_3BX. The vicinal coupling constant $^3J_{CH}$ (identified as J_{BX}) can be easily obtained from the ^{13}C-NMR spectrum of the methoxyl carbon. The results are summarized in Table 1. Observed values of $^3J_{CH}$ increase nearly linearly with temperature. The temperature coefficients, $d \ln {}^3J_{CH}/dT$, estimated from these data are also included in the table. The coupling constant varies slightly with polarity of the medium as manifested by a change from 3.90 in cyclohexane-d_{12} (ε=2.023) to 3.79 in dimethyl-d_6 sulfoxide (ε=46.68), both values being determined at 20 °C. Measurements were also carried out on the neat liquid. The following analysis will be mostly performed with resort to the experimental data obtained in cyclohexane-d_{12}.

Elucidation of the Torsional Potential Energy Curve and Interpretation of Results

According to the conventional Gutowsky method,[6] $^3J_{CH}$ is given by

$$^3J_{CH} = J_T f_{C_S} + J_G(1-f_{C_S}). \quad (1)$$

TABLE 1. TEMPERATURE DEPENDENCE OF THE VICINAL COUPLING CONSTANT $^3J_{CH}$ FOR THE MOIETY ^{13}C-O-C-^{1}H IN ISOPROPYL METHYL ETHER

T/deg	$^3J_{CH}$/Hz		
	in cyclohexane-d_{12}	in dimethyl-d_6 sulfoxide	neat liquid

40	3.94	3.81	3.89
60		3.88	3.93
70	3.98	3.85	4.00
80	4.00		
90		3.93	4.00
$d \ln {}^3J_{CH}/dT \times 10^3$/K	0.41	0.63	0.47

Here f_{C_s} denotes fraction of the C_S conformer:

$$f_{C_s} = \exp(-\Delta E/RT)/[2+\exp(-\Delta E/RT)], \quad (2)$$

where R is the gas constant and T the temperature. The trans (J_T) and gauche couplings (J_G) are illustrated in Fig. 1. In this simple scheme, only the energy difference between the two preferred rotational isomeric states are considered. In principle, values of J_T, J_G, and ΔE can be determined by the least-squares method from the analysis of the observed temperature dependence of $^3J_{CH}$. The experimental data listed in Table 1 were however found to be reproducible by various combinations of J_T, J_G, and ΔE. Calculations were therefore carried out for given values of ΔE. The best-fit values of J_T and J_G derived from the analysis of the observed data in cyclohexane-d_{12} are plotted against ΔE (solid curves) in Fig. 2. While J_T increases markedly with ΔE, J_G stays nearly invariable over a wide range of ΔE. It should be noted here that the assumption of discrete rotational

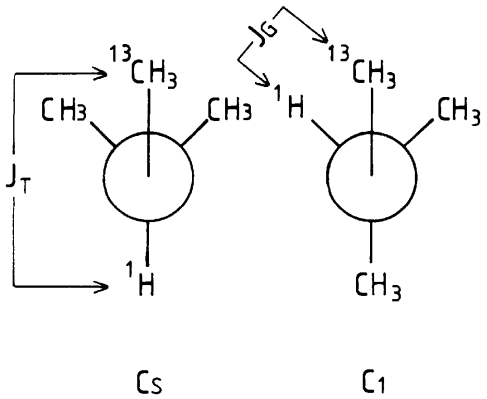

Fig. 1. Schematic representation of isomers and definition of the trans and gauche couplings.

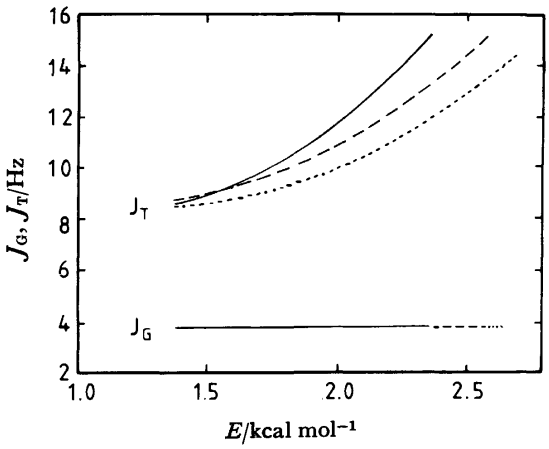

Fig. 2. Plot of best-fit values of J_T and J_G *vs.* ΔE. The results obtained according to the simple Gutowsky treatment (Eq. 1) are indicated by the solid curves. The $J(0)$ and $J(140°)$ values derived from the more elaborate scheme (Eq. 5) are used for the other curves. The height of the cis barrier ($\phi=180°$) is taken to be 1.2 and 1.8 kcal mol^{-1}, respectively, for the dotted and broken curves. The J_G *vs.* ΔE curves are all very similar and practically indistinguishable with each other: they are all represented by a solid curve.

isomeric states is, in principle, valid only when all the torsional potential energy minima are well-defined, and the energy differences among the minima are not too large.[7] Since one of the isomers (C_1) is far more stable than the other (C_S) in isopropyl methyl ether, the aforementioned criteria may not be valid in this system. In such a case, the average of $^3J_{CH}$ should be desirably determined over the entire profile of the torsional potential energy curve.

For this purpose, the potential energy curve for the internal rotation around the $(CH_3)_2CH\text{-}OCH_3$ bond was estimated by using the semiempirical energy expressions. Parameters adopted in these expressions for the three-fold torsional potentials and the 6-exp non-bonded interatomic interaction functions are identical with those used in our previous papers.[8,9] Bond lengths and bond angles used are as follows: l_{CC}=1.53 Å, l_{CO}=1.43 Å, and l_{CH}=1.10 Å; ∠CCC=∠CCH=∠OCH= 109.5°. The bond angle ∠COC was adjusted somewhat when the highly hindered C_S conformer was treated. The deformation energy for the bond angle was estimated by[9,10]

$$E(\theta) = D(\pi/180)^2(\theta-109.5)^2, \quad (3)$$

where θ is expressed in degrees, and D is set equal to 88 kcal mol^{-1}. As for the barriers situated on both sides of the C_S minimum, experimental results on *t*-butyl methyl ether $(CH_3)_3C\text{-}OCH_3$ are suggestive. The barrier to the internal rotation of this compound was reported to be 3.57 kcal mol^{-1} from IR studies in the gas phase.[11] Calculations were carried out so as to reproduce this value for the energy difference between the conformation at the top of the barrier ($\phi=\pm60°$) and that at the C_S minimum ($\phi=0$). Widening of the bond angle ∠COC was required besides adjustment of the rotation around the adjoining C–O and C–C bond. A set of values such as 116.4° and 113.0° for the bond angle ∠COC, respectively, at $\phi=\pm60°$ and 0 was found to give an energy difference as stated above. The value of ∠COC=113.0° is comparable with those observed for ether linkages carrying bulky substituents (*e.g.*, glycoside linkages in polysaccharides[12]). At the C_S minimum, the methoxyl group is situated syn to both of the terminal methyl groups. To alleviate steric conflicts between these groups, rotation angles about the adjoining C–C bonds were displaced by *ca.* 15° from the regularly staggered position. In the C_1 form, steric repulsions between the methoxyl and methyl groups can be largely reduced by the displacement ($\Delta\phi$) of the rotational minima from the regular position, *i.e.*, $\phi=\pm120°$. Locations and the energy of the C_1 minima were calculated by assuming a bond angle ∠COC= 111.5°, a similar value being adopted in the analysis of less hindered ethers.[8,9] The C_1 minima were thus estimated to occur at $\phi=\pm140°$. A displacement of $\Delta\phi=20°$ is in agreement with observations on compounds having a similar stereochemical arrangement.[13] The energy difference between the C_S and C_1 minima obtained in this manner is *ca.* 2 kcal mol^{-1}. On the same basis, the height of the barrier separating two C_1 minima was calculated to be *ca.* 1.2 kcal mol^{-1} as expressed relative to these minima. Results of these considerations are all

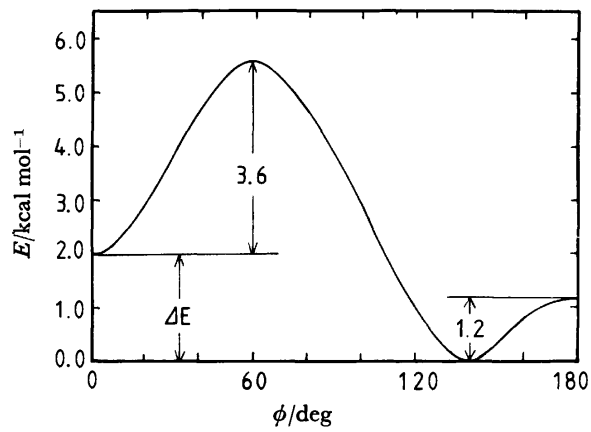

Fig. 3. Torsional potential energy curve for isopropyl methyl ether, CH_3-CH$(CH_3)_2$, estimated by using semiempirical energy calculations in consideration of experimental data on some relevant compounds. The slopes along the higher barrier are drawn by assuming trigonometric functions (see text). The value of ΔE, representing the energy difference between the two minima, will be treated as a variable in the present analysis. Numerical values are given in kcal mol^{-1}.

put together in Fig. 3, where the potential energy curve is shown as a function of ϕ. Since estimation of a reliable value of the energy is quite difficult for a highly strained conformation, trigonometric functions were assumed on both sides of the higher barrier at $\phi=\pm60°$. The slope of the curve drawn from the C_1 minimum ($\phi=\pm140°$) toward the lower barrier ($\phi=180°$) was estimated by the energy calculation.

Durig and Compton[14] deduced the profile of the potential energy curve for the internal rotation of ethyl methyl ether CH_3O-CH_2CH_3 by the analysis of vibrational spectra in the low frequency region. The potential energy barrier, associated with the conformation in which C–O eclipses C–H, resembles the barrier at $\phi=180°$ in isopropyl methyl ether. A value of 1.8 kcal mol^{-1} was estimated for the height of the barrier relative to the energy minimum in which CH_3O-CH_2CH_3 is gauche.[14] Effect arising from the choice of this value will be examined later.

The vicinal coupling constant for the moiety ^{13}C-O-C-^{1}H varies as a function of rotation angle ϕ defined for the C–O bond. The dihedral angle dependence of the coupling constant may be customarily represented by a conventional Karplus-type equation such as

$$J(\phi) = A\cos^2\phi + B\cos\phi + C. \quad (4)$$

In this expression, B is responsible for the difference between the trans and cis couplings, *i.e.*, $J(0)-J(180°)=2B$. The parameter C, which determines the $J(90°)$ value, is usually quite small. In the present treatment, we adopt a simplified expression in which C is set equal to zero. For given values of A and B, an average of the coupling constant $\langle J\rangle$ can be obtained according to the formula specified by the equation

$$\langle J\rangle = \int_0^{2\pi} J(\phi)\exp[-E(\phi)/RT]\mathrm{d}\phi \Big/ \int_0^{2\pi} \exp[-E(\phi)/RT]\mathrm{d}\phi. \quad (5)$$

Numerical computations were carried out for discrete ϕ values taken at 5° intervals. The whole process of calculations was iteratively repeated until experimental values of $^3J_{CH}$ were reproduced within the limit of uncertainty. With values of A and B so determined, $J(0)$ and $J(140°)$ were calculated for $\phi=0$ (the C_S minimum) and 140° (the C_1 minimum), respectively, from the Karplus relation (Eq. 4).

In order to elucidate a proper range of ΔE, the energy of the C_S minimum, $E(0)$, was tentatively raised or lowered in Fig. 3, the height of the barrier on both sides being kept constant (*i.e.*, $E(\pm60°)-E(0)=3.6$ kcal mol^{-1}). For each potential energy curve, a set of A and B, thus $J(0)$ and $J(140°)$, were determined. These results are indicated by the dotted curves in Fig. 2, where $J(0)$ and $J(140°)$ are adopted for J_T and J_G, respectively, and ΔE is taken to be the difference between the minimum energies for the C_S and C_1 forms. Values of J_T calculated according to the simple Gutowsky treatment based on the discrete isomeric state scheme (upper solid curve) are consistent with the results derived from the more elaborate analysis (upper dotted curve) only for very low values of ΔE (<1.5 kcal mol^{-1}). On the other hand, the J_G values are nearly unaffected by the procedure adopted in the analysis. Also shown by the broken curves in the figure are the results obtained on the basis of the torsional potential energy diagram in which the height of the barrier separating two C_1 minima is raised to 1.8 kcal mol^{-1} as suggested by Durig and Compton.[14] In this revised scheme, locations of the C_1 minima were kept unchanged at $\phi=\pm140°$, and the slope along the barrier was represented by a trigonometric function. An enhancement in the height of the torsional potential energy barrier causes some substantial upward shift in the J_T *vs.* ΔE curve (compare two curves indicated by the broken and dotted drawings). The corresponding J_G values are again indistinguishable with those derived from the other schemes.

Estimation of the Energy Difference ΔE

As is shown above, the Gutowsky analyses on the observed temperature dependence of the coupling constant $^3J_{CH}$ do not yield a unique solution for parameters J_T, J_G, and ΔE for the present compound. A reliable estimation of the J_T value is therefore required. Hamer *et al.*[15] and more recently Yamada *et al.*[16] have studied the dihedral angle dependence of the coupling constants $^3J_{CH}$ for various compounds containing the ^{13}C-O-C-^{1}H moiety. The former group deduced a value of $J(0)=6.0\pm0.5$ Hz for a variety of carbohydrate compounds, while the latter found $J(0)=6.8\pm0.7$ Hz from the analysis on cyclic compounds containing the acetal or ether linkages. These values are however apparently too low for the molecule under consideration. As is widely known, formation of a cyclic structure or introduction of electronegative substituents generally leads to a lower value of J_T.[17] For the present purpose, analyses on the observed coupling constants for the same moiety involved in some simple open-chain

methyl ethers should provide more reliable information. The coupling constants associated with the methoxyl hydrogen are reported for dimethyl ether (5.7 Hz), methyl *n*-propyl ether (5.2 Hz), and isopropyl methyl ether (5.0 Hz).[18] Since hydrogens on the terminal methyl group are all equivalent, they should be equally populated among three rotational states. Then, from the relation

$$^3J_{CH} = (1/3)(J_T+2J_G), \quad (6)$$

we estimate J_T=13.1, 11.6, and 11.0 Hz for the aforementioned compounds, respectively, by adopting a value of J_G=2.0 Hz, a standard value for an unstrained gauche coupling.[17] Adoption of an averaged value (12.0 Hz) for J_T in Fig. 2 yields ΔE=2.0, 2.2, and 2.4 kcal mol^{-1}, respectively, for the solid, broken, and dotted curves. Use of a lower value (11.0 Hz), which may also be a probable choice, gives ΔE=1.9, 2.0, and 2.2 kcal mol^{-1}, respectively. As is seen in Figure 2, the J_G value remains nearly invariable over a wide range of ΔE. A value of J_G=3.8±0.1 Hz is commonly applicable to all the models examined.

Plotted in Fig. 4 are the quantities $\langle J\rangle_T$ and $\langle J\rangle_G$ denoting respectively the averages of $J(\phi)$ over the range of ϕ associated with the Cs and C$_1$ minima: *i.e.*,

$$\langle J\rangle = z^{-1}\int_a^b J(\phi)\exp[-E(\phi)/RT]\mathrm{d}\phi, \quad (7)$$

and

$$z = \int_a^b \exp[-E(\phi)/RT]\mathrm{d}\phi, \quad (8)$$

where the interval (a,b) is taken to be (−60°, 60°) for $\langle J\rangle_T$ and (60°, 180°) for $\langle J\rangle_G$. Correspondingly, the abscissa of the figure represents the difference between the energies $\langle E_{C_s}\rangle$ and $\langle E_{C_1}\rangle$ averaged over the respective energy minimum:

$$\langle E\rangle = z^{-1}\int_a^b E(\phi)\exp[-E(\phi)/RT]\mathrm{d}\phi. \quad (9)$$

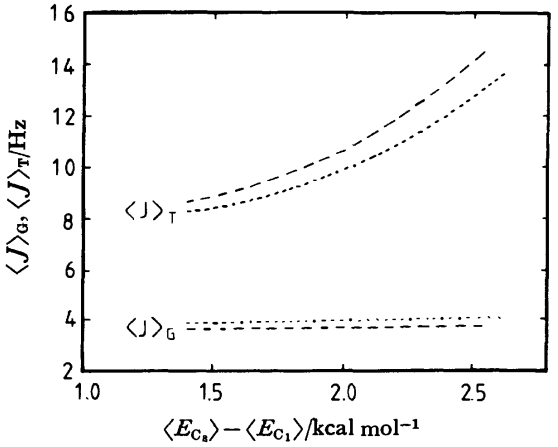

Fig. 4. The averages $\langle J\rangle_T$ and $\langle J\rangle_G$ plotted against $\langle E_{C_s}\rangle-\langle E_{C_1}\rangle$. The two curves differ with each other in the torsional potential energy curve used in the calculation. The dotted and broken curves are used to facilitate comparison with the corresponding plot in Fig. 2.

In these calculations, the integrations were again replaced by summations with discrete ϕ values taken at 5° intervals. The temperature was taken to be 20 °C. In principle, $\langle J\rangle_T$ and $\langle J\rangle_G$ evaluated in this manner should be more closely related to the parameters representing the trans and gauche couplings in the two-parameter expression. The curves drawn in Fig. 4 vary, however, very little from those given for $J(0)$ and $J(140°)$ in Fig. 2: For the ease of comparison, the broken and dotted drawings are used in common. These results arise from the fact that a small decrease in $\langle J\rangle_T$ from $J(0)$ is nearly exactly compensated by a concerted decrease in the energy term. In Fig. 4, two $\langle J\rangle_G$ curves are distinguishable with each other, but the difference is very small. Adoption of $\langle J\rangle_T$=11.0—12.0 Hz should therefore yield the same energy differences for $\langle E_{C_s}\rangle-\langle E_{C_1}\rangle$ as those (ΔE) derived above.

We finally conclude that the energy difference between the two conformers is in the range 2.2±0.2 kcal mol^{-1}. Values obtained from the simple Gutowsky treatment (1.9—2.0 kcal mol^{-1}) are a little too low. The present result is consistent with the range estimated by Nakata *et al.*[4] employing the matrix isolation technique.

Concluding Remarks

In the above treatment, the parameter C in the Karplus equation (Eq. 4) was taken to be zero. However, C is empirically known to be variable within the range ±1.0 Hz. Trial calculations indicate that use of a non-zero value for C causes only some minor modifications on the results: For the range of C given above, J_T and ΔE vary by an amount less than 0.3 Hz and 0.05 kcal mol^{-1}, respectively.

As is shown in Fig. 2, the discrepancy between the solid and either of the other two curves for J_T tends to be more enhanced as ΔE increases. At J_T=12.0 Hz, the difference amounts to 0.2 to 0.4 kcal mol^{-1} in the ΔE value. Assumption of discrete rotational isomeric states leads to a lower estimate of ΔE. In this regard, we should note some characteristic features of the torsional potential energy curve for this compound: 1) The energy difference between the Cs and C$_1$ minima is considerably high (>2 kcal mol^{-1}), 2) the height of the barrier separating the two C$_1$ minima is relatively low, and accordingly, 3) the shape of the potential well for the C$_1$ minimum is somewhat skewed. The effect arising from the latter factors is illustrated by the difference between the broken and dotted curves in Figs. 2 and 4.

Following the conventional rotational isomeric state treatment,[19] we may assign a statistical weight τ to the Cs form, the weight of unity being given to the C$_1$ state:

$$\tau = \tau_0\exp(-\Delta\langle E\rangle/RT) \quad (10)$$

where τ_0 reflects the shape of the energy minima, and $\Delta\langle E\rangle=\langle E_{C_s}\rangle-\langle E_{C_1}\rangle$. By definition, $\tau=z_{C_s}/z_{C_1}$. The partition functions z_{C_s} and z_{C_1} associated with the Cs and C$_1$ isomers, respectively, can be obtained by Eq. 8. We thus have

$$\tau = 0.88\exp(-2200/RT) \quad (11)$$

for the potential energy curve shown in Fig. 3: The temperature is taken to be 20 °C, and RT is expressed in kcal mol^{-1}. Use of the relation $f_{Cs}=\tau/(2+\tau)$ in place of Eq. 2 yields calculated values of $^3J_{CH}=3.88$ Hz and d ln $^3J_{CH}/dT=0.30\times10^{-3}$ K^{-1} for the temperature of 20 °C, values of J_T and J_G being set equal to 12.0 and 3.8 Hz, respectively. Experimental results obtained in cyclohexane-d_{12}. (*cf.* Table 1) are reasonably reproduced.

The Micellar Properties of 1-Dodecylpyridinium Chloride as Studied by the Ion-selective Electrodes

Tamaki MAEDA* and Iwao SATAKE
Department of Chemistry, Faculty of Science, Kagoshima University, Korimoto, Kagoshima 890
(Received February 23, 1984)

The surfactant ion and counterion activities of aqueous 1-dodecylpyridinium chloride with and without KCl were determined by using ion-selective electrodes. In the concentration range above the critical micelle concentration (cmc), the surfactant ion activity (a_+) was found to decrease gradually with increasing surfactant concentrations, while the reverse change was found for the counterion activity (a_-). As a result, the mean activity increased slightly but regularly with increasing concentrations. The concentration dependences of a_+ and a_- became progressively smaller as the salt concentration increased. An application of the charged phase separation model led to an apparent degree of counterion association to the micelle (β) of 0.70 regardless of the salt concentration. On the basis of these observations, the estimations were made for the concentration of monomeric surfactant ion (C_+) and the activity coefficients of counterion (γ_-) and surfactant ion (γ_+) above the cmc. The values of C_+ and γ_+ decreased appreciably, while that of γ_- increased with increasing concentrations. The value of β was also estimated from the concentration dependence of a_- and the validity of this method was discussed.

The ion-selective electrodes have widely been applied for the determination of counterion and surfactant ion activities in ionic surfactant solutions.[1-14] In most studies were used the sodium ion-sensitive glass electrodes,[2-5,7] as well as the anion-[1,6-9,14] and cation-[1,8-10,12,14] exchange membrane electrodes. In the presence of added salts, however, the liquid[11] and plastic[10,13] membrane electrodes have proved very useful because of their high selectivity for a surfactant ion over inorganic ions. It has been found that the counterion activity (a_+) in anionic surfactant solutions increases gradually with increasing surfactant concentrations through the break point at the critical micelle concentration (cmc).[1-5,7-10,12,14] According to the method advanced by Botré *et al.*,[1] an apparent degree (β) of counterion association to the micelle has been evaluated from the concentration dependence of a_+ above the cmc.[1-3,5,11] On the other hand, the surfactant ion activity (a_-) has been found to decrease monotonously with increasing surfactant concentrations above the cmc.[6-12,14] Sasaki *et al.*[7,8] and Koshinuma[9,14] have confirmed the validity of the charged phase separation model by demonstrating the constancy of $a_-a_+^{\beta}$. By ignoring the effect of micelles on the activity coefficients of monomeric ions, Sasaki *et al.*[7] and Cutler *et al.*[10] have calculated the intermicellar concentrations of counterion and surfactant ion above the cmc.

The ion-selective electrodes can also be applicable to cationic surfactant solutions, though their applications so far reported are confined mostly to anionic ones. In a previous paper,[15] we have reported that poly(vinyl chloride) membrane plasticized with bis (2-ethylhexyl) phthalate responds selectively to cationic surfactant ions, especially to 1-alkylpyridinium ion even in the presence of excess salts. The present paper is concerned with the potentiometric determination of counterion and surfactant ion activities in solution of 1-dodecylpyridinium chloride with and without added KCl.

Experimental

Materials. 1-Dodecylpyridinium chloride (DPC, Wako Pure Chemical Industry Co. Ltd.) was dissolved in hot ethanol and refluxed overnight with active carbon. After cooling the filtrate, the precipitate was purified further by repeated recrystallization from ethanol and by extraction with ether for 48 h. Potassium chloride of guaranteed grade and other chemicals of reagent grade were used without further purification.

Electromotive Force Measurements. The counterion and surfactant ion activities in DPC solutions were measured by using a chloride ion selective ceramic electrode, National IE-510103, and a poly (vinyl chloride) (PVC) membrane electrode, respectively. The following cells were constructed.

Chloride ion electrode | Sample solution (DPC, C; KCl, C_s) | 1 mol dm^{-3} NH_4NO_3 agar bridge | Reference electrode (Ag-AgCl)

Reference electrode (Ag-AgCl) | 1 mol dm^{-3} NH_4NO_3 agar bridge | Reference solution (DPC, 1×10^{-4} mol dm^{-3}) | PVC membrane | Sample solution (DPC, C; KCl, C_s) | 1 mol dm^{-3} NH_4NO_3 agar bridge | Reference electrode (Ag-AgCl)

The preparation of the PVC membrane electrode is described elsewhere.[15] The electromotive forces (EMF) of these cells were measured with an accuracy of ±0.1 mV by using a Yokogawa Universal Digital Meter Model 2502 connected to a voltage follower amplifier (input impedance≃$10^{13}\Omega$). Prior to the measurements with DPC solutions, the chloride ion electrode was calibrated with a sodium chloride solution of known activity.[16] This electrode was found to respond to the chloride ion down to 5×10^{-4} mol dm^{-3} with an ideal slope of 59.2 mV per decade change in chloride ion activity. In the case of PVC membrane electrode, the semilogarithmic plots of EMF *vs.* surfactant concentration gave a straight line with a slope of 59.1 mV in dilute concentration range below *ca.* 1×10^{-4} mol dm^{-3}. This fact suggests the Nernstian response of the PVC membrane electrode to the DPC ion.

All measurements were conducted at 25 °C. The PVC membrane was renewed after a series of experiments for a given salt concentration.

Results and Discussion

The electromotive forces (E) of the foregoing cells can be described as

$$E_+ = E_+^* - S\log(a_+/a_+^*), \quad (1)$$

$$E_- = E_-^* + S\log a_-, \quad (2)$$

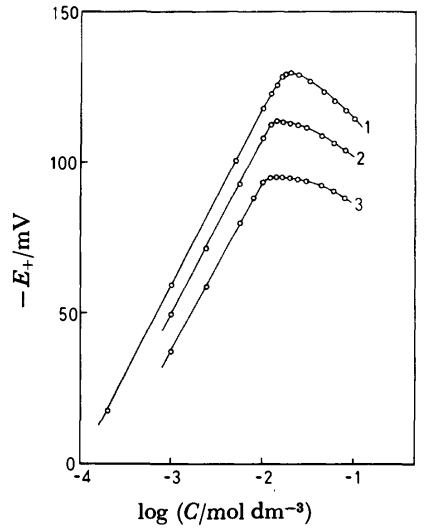

Fig. 1. The semilogarithmic plots of E_+ *vs.* C at 25 °C. 1; C_s=0, 2; C_s=0.01, 3; C_s=0.02 mol dm^{-3}. The curves 2 and 3 are displaced downward by 10 and 20 mV, respectively.

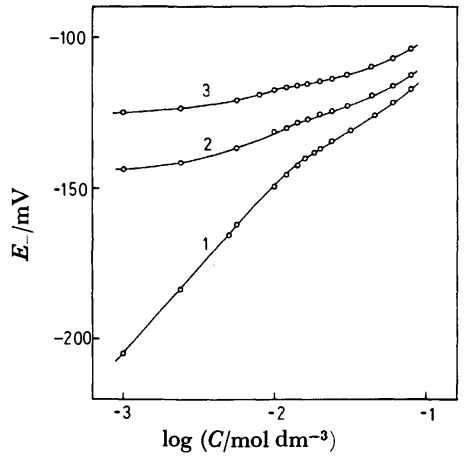

Fig. 2. The semilogarithmic plots of E_- *vs.* C at 25 °C. 1; C_s=0, 2; C_s=0.01, 3; C_s=0.02 mol dm^{-3}.

where E^a refers to the asymmetric potential of overall cell system, $E^\circ_\pm$ to the standard electrode potential, S to the Nernst slope (59.2 mV at 25 °C), and superscript r to the reference solution, respectively. In Figs. 1 and 2 are plotted E_+ and E_- against the logarithm of DPC concentration (C) in the presence and absence of KCl. The break point in these figures corresponds to the cmc (C_o) at a given salt concentration (C_s). In the concentration range above the cmc, the DPC ion activity (a_+) is seen to decrease monotonously with increasing surfactant concentrations, while the reverse is found for the chloride ion activity (a_-). As would be expected, these behaviors are similar to those of surfactant ion[6-12,14] and counter-ion[1-5,7-10,12,14] activities in anionic surfactant solutions. As can be seen from Figs. 1 and 2, the addition of KCl results in a succesive decrease in the slope of E_+ or E_- *vs.* log C plots above the cmc. Figure 3 shows the concentration dependence of $E_- - E_+$ which is a measure of the mean activity ($a_\pm$). It should be noted that

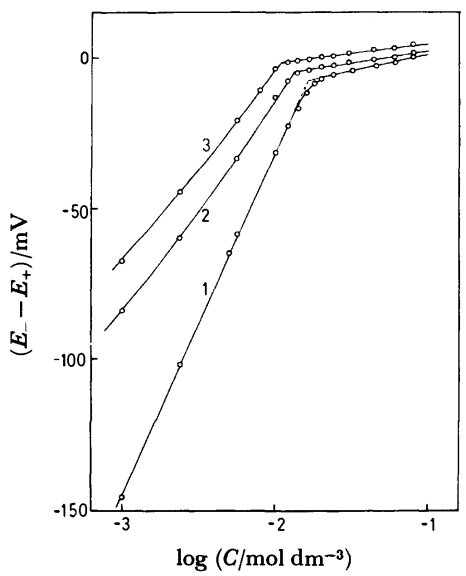

Fig. 3. The semilogarithmic plots of $E_- - E_+$ *vs.* C at 25 °C. 1; C_s=0, 2; C_s=0.01, 3; C_s=0.02 mol dm^{-3}.

the plot of $E_- - E_+$ *vs.* log C at higher surfactant concentrations than the cmc gives a straight line with a small but definite slope. Thus, we may write

$$\log(a_+a_-/a^\circ_+a^\circ_-) = [(E_- - E^\circ_-) - (E_+ - E^\circ_+)]/S = K_1\log(C/C_o), \quad (3)$$

where the superscript ° refers to the cmc. The values of K_1 and the cmc determined from the break points in Fig. 3 are summarized in Table 1. It can immediately be seen that an increase in salt concentration leads to a rapid decrease in K_1. In accord with the results obtained for anionic surfactant solutions,[7-10,12,14] these observations reveal that the mean activity of DPC above the cmc increases progressively with increasing surfactant concentrations unless an excess salt is added. For example in a salt free solution, the value of $a_\pm$ at 0.1 mol dm^{-3} is larger by a factor of 1.19 than that at the cmc.

In solutions of anionic surfactants such as sodium dodecyl sulfate (SDS)[7] and tetradecyl sulfate,[8] the charged phase separation model has been confirmed to hold over a wide concentration range above the cmc. According to this model, $a_+a^\beta_-$ should be constant at higher surfactant concentrations. It follows immediately from Eqs. 1 and 2 that

$$E_+/S = \beta(E_-/S) + \text{const.} \quad (4)$$

If β remains constant, therefore, the plot of E_+/S *vs.* E_-/S is anticipated to give a straight line with the slope of β. As is shown in Fig. 4, E_+/S depends in fact linearly on E_-/S in all cases studied, indicating that the charged phase separation model is also valid for DPC solution. It is worth noting that the value of β summarized in Table 1 is virtually independent of the added salt concentration.

In an attempt to estimate the intermicellar concentrations of surfactant ion and counterion in SDS solutions, Sasaki *et al.*[7] have assumed that the mean ionic molarities of these ions in a micellar solution and in a hypo-

Table 1. The potentiometric and micellar parameters of DPC solution at 25 °C

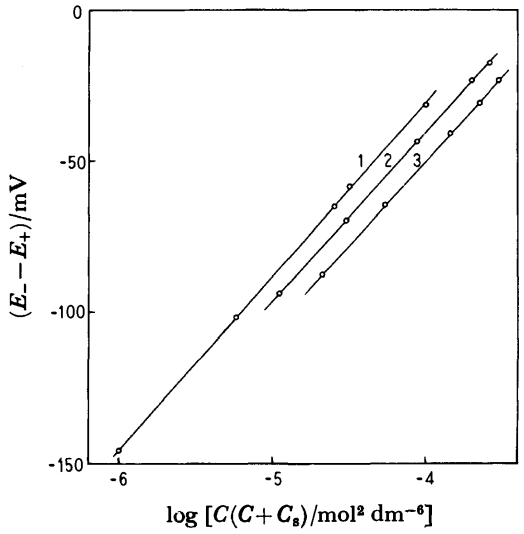

Fig. 5. Plots of $E_- - E_+$ *vs.* log$[C(C+C_s)]$ in the concentration range below the cmc at 25 °C. 1; $C_s=0$, 2; $C_s=0.01$, 3; $C_s=0.02$ mol dm^{-3}. The curves 2 and 3 are displaced downward by 10 and 20 mV, respectively.

thetical solution composing only of monomeric ions are identical with each other at a given mean activity. The same assumption was also made by Cutler *et al.*[10] in their potentiometric study of SDS solutions. Their calculation suggests that the intermicellar concentration of dodecyl sulfate ion is not constant but decreases regularly as the surfactant concentration increases.[7,10] Under the same assumption, we made the tentative estimations of the intermicellar concentration of 1-dodecylpyridinium ion (C_+) and ionic activity coefficients (γ_+, γ_-) in a bulk phase. Figure 5 shows the

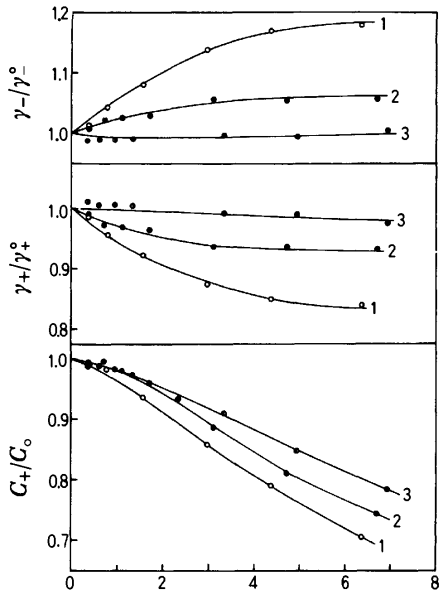

Fig. 6. The concentration dependences of C_+/C_0, $\gamma_+/\gamma_\pm^\circ$, and $\gamma_-/\gamma_\pm^\circ$ estimated from Eqs. 6, 7, and 8. 1; $C_s=0$, 2; $C_s=0.01$, 3; $C_s=0.02$ mol dm^{-3}.

change in $E_- - E_+$ with log$C_\pm^2$ in the concentration range below the cmc, where $C_\pm^2$ denotes $C(C+C_s)$. Regardless of the salt concentration, the plot is found to give a straight line, *i.e.*,

$$E_- - E_+ = \text{const.} + K_2 \log C_\pm^2. \quad (5)$$

The values of K_2 are included in Table 1. Since $C_\pm^2$ in the micellar solution is equal to $C_+[C_+ + C_s + (1-\beta)(C-C_+)]$, Eq. 5 may be rewritten as

$$(E_- - E_-^\circ) - (E_+ - E_+^\circ) = K_2 \log[C_+\{C_+ + C_s + (1-\beta)(C-C_+)\}/C_o(C_o+C_s)]. \quad (6)$$

Equation 6 allows us to estimate the change in C_+ with the surfactant concentration above the cmc. The knowledge of γ_+ and γ_- can then be obtained by substituting the following relations into Eqs. 1 and 2.

$$a_+ = \gamma_+ C_+, \quad (7)$$

$$a_- = \gamma_-[C_+ + C_s + (1-\beta)(C-C_+)]. \quad (8)$$

The values of $C_+/C_\pm^\circ$, $\gamma_+/\gamma_\pm^\circ$, and γ_-/γ_-° thus calculated are plotted in Fig. 6 as a function of $C-C_o$. An important feature of Fig. 6 is a gradual decrease in C_+ with the surfactant concentration though the deviation from C_o becomes progressively smaller as the salt concentration increases. A similar behavior has also been noted for SDS solution without added salt.[7,10] Another interesting feature of Fig. 6 is a marked de-

pendence of γ_+ and γ_- on the salt concentration. In the absence of added salt, an increase in surfactant concentration is accompanied by a decrease in the former while an anomalous increase in the latter. However, they tend eventually to level off. In the presence of 0.02 mol dm^{-3} KCl, neither γ_+ nor γ_- depends appreciably on the surfactant concentration. It is important to remember here that in the concentration range above the cmc, the total concentration of counterion in bulk phase, $C_+ + C_s + (1-\beta)(C-C_+)$, is always larger than that of coion, $C_+ + C_s$. Thus an increase in γ_-/γ_-° estimated above will be ascribed to an increase in the repulsive interaction between counterions in bulk phase compared to that at the cmc where the concentrations of counterion and coion are identical with each other.

An information about the degree of counterion association to the micelle can otherwise be obtained from the concentration dependence of counterion activity alone according to the method advanced by Botré *et al.*[1] In this treatment, it is usually assumed that the counterion activity coefficient and the concentration of monomeric surfactant ion remain constant even above the cmc.[1-3,5,11] On converting γ_- and C_+ in Eq. 8 to γ_-° and C_0 respectively and denoting β in this case by β', we have

$$\begin{aligned} a_-/a_-^\circ &= \exp[2.303(E_- - E_-^\circ)/S] \\ &= 1 + (1-\beta')(C-C_0)/(C_0+C_s) \\ &= 1 + K_3(C-C_0). \end{aligned} \tag{9}$$

In all cases studied, the plot of a_-/a_-° *vs.* $C-C_0$ gives a straight line with a slope of K_3. The values of K_3 and β' are summarized in Table 1. It can immediately be seen that the difference between β' thus estimated and β is negligibly small. We must keep in mind, however, that this agreement does not necessarily support the validity of the underlying assumption of Eq. 9, since the foregoing calculations show that both C_+ and γ_- depend appreciably on the surfactant concentration. In this connection, it is important to note that a similar relation to Eq. 9 can be derived under certain conditions even if C_+ and γ_- are dependent on the surfactant concentration. An expression of the counterion activity, Eq. 8, can formally be divided into two terms; $\gamma_-(C_+ + C_s)$ and $\gamma_-(1-\beta)(C-C_+)$. If each term is linearly dependent on the surfactant concentration, *i.e.*,

$$\gamma_-(C_+ + C_s) = \gamma_-^\circ(C_0 + C_s) + A\gamma_-^\circ(C-C_0) \tag{10}$$

and

$$\gamma_-(1-\beta)(C-C_+) = \gamma_-^\circ B(C-C_0), \tag{11}$$

we immediately have,

$$a_-/a_-^\circ = 1 + (A+B)(C-C_0)/(C_0+C_s). \tag{12}$$

This is exactly identical with Eq. 9 provided that the numerical value of $A+B$ is equal to $1-\beta'$. As is clearly shown in Fig. 7, indeed, the plots of the left hand sides of Eqs. 10 and 11 against the surfactant concentration give a straight line, respectively. In addition, the values of $A+B$ determined from Fig. 7 are in fair agreement with those of $1-\beta'$. Thus,the utility of Eq. 9 in determining the degree of counterion association to the micelle appears to rest on the fact that in micellar

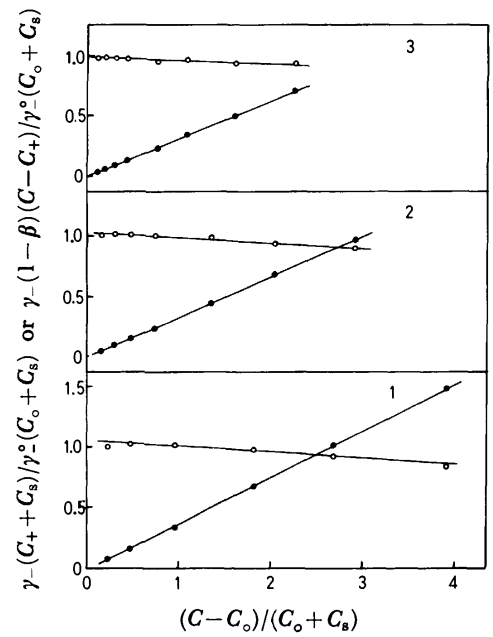

Fig. 7. The concentration dependences of the left hand sides of Eqs. 10 and 11. 1; $C_s=0$, 2; $C_s=0.01$, 3; $C_s=0.02$ mol dm^{-3}. ○; $\gamma_-(C_+ + C_s)/\gamma_-^\circ(C_0+C_s)$, ●; $\gamma_-(1-\beta)(C-C_+)/\gamma_-^\circ(C_0+C_s)$.

solution the counterion activity coefficient and the intermicellar concentration of the surfactant ion vary with the surfactant concentration so as to satisfy Eqs. 10 and 11.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 57540254 from the Ministry of Education, Science and Culture.

Analysis of Rotation-Vibration Bands of Sulfine, (CH_2SO), by FT-IR and Microwave Spectroscopy

Yoshinori KOGA,* Harutoshi TAKEO, Shigeo KONDO, Chi MATSUMURA, and Shinnosuke SAEKI
National Chemical Laboratory for Industry, Yatabe, Tsukuba, Ibaraki 305
(Received March 7, 1984)

The rotation-vibration bands of a transient molecule, sulfine, (methanethial S-oxide), have been observed by FT-IR and analyzed with the aid of microwave data, a part of which has been newly obtained in this study. The band center frequencies for ν_5 and ν_9 are determined to be 1175.75 cm^{-1} and 762.07 cm^{-1}, respectively. The good agreement between the observed and simulated band contours clarifies that the origin of these bands is sulfine.

The recent development of FT-IR spectroscopy has enabled us to observe high-resolution infrared spectra of less abundant species such as unstable molecules. If the observed rotation-vibration bands are analyzed to give reasonable values for the molecular constants, it will become evident that the spectrum is due to a particular unstable molecule. However, since many parameters are necessary for the analysis of infrared band envelopes, it is generally very difficult unless some of them have been determined previously from other sources. Since microwave spectroscopy gives the rotational and centrifugal distortion constants in the excited vibrational state as well as in the ground state, the joint study of FT-IR and microwave spectroscopy can be a powerful tool for the analysis of rotation-vibration bands. In the present study we applied this method to the analysis of the rotation-vibration bands of a transient molecule, sulfine.

The spectroscopic investigation of sulfine was first done by Block *et al.*[1] with microwave and infrared spectroscopy using flash vacuum pyrolysis of thiethane S-oxide or 1,3-dithiethane 1-oxide. The detailed analysis of the microwave spectrum of this molecule was carried out and reported by Penn and Olsen.[2] Later, the infrared spectrum of sulfine was studied by Powers *et al.*[3] using a matrix isolation method, and all the fundamental vibrations have been observed. However, only limited results on infrared spectra have been reported for gas phase sulfine.[1] They observed the two rotation-vibration bands at 1170 and 760 cm^{-1} which seemed to be due to sulfine, but they presented no support for their assignments of these bands to sulfine.

Since sulfine is produced by pyrolysis and has a fairly short lifetime, the spectra are naturally disturbed by the parent and decomposed materials. Therefore, it is very difficult to identify the spectrum unambiguously. In the present study, we observed the same two bands of sulfine in the gas phase as observed by Block *et al.* using FT-IR with relatively high resolution, and were able to identify them from the analysis of the band contours by the use of the rotational constants determined by microwave spectroscopy.

Experimental

Infrared Spectra. The infrared spectra were measured by the use of a Digilab model FTS-20C/D spectrophotometer. The optical system was modified as shown in Fig. 1. The collimated beam is taken out through the window attached to the side cover of the instrument. It is reflected by a flat mirror M_1 (80 mmϕ) and a spherical mirror M_2 (80 mmϕ and f=500 mm), and focused at the center of a gas cell. Then the image of the source is focused onto a detector by an off-axis ellipsoidal mirror M_3 (80 mmϕ, f_1=35 mm, and f_2=555 mm). The distance between the source and the detector is about 2.8 meters, and the separation between the mirrors M_2 and M_3 is about 1 meter. Thereby, a 700 mm sample cell with 40 mm diameter can be placed without disturbing the optical path. The detector, the mirrors, and the sample cell were set in the compartment covered with acrylic resin plates, and atmospheric water vapor was purged by dried air. A HgCdTe detector cooled with liquid nitrogen and a globar source were used in all measurements. The accuracy of the frequency of the FT-IR spectrometer was estimated to be better than 0.03 cm^{-1} from the comparison of the observed values for carbon monoxide with the data listed in Ref. 4.

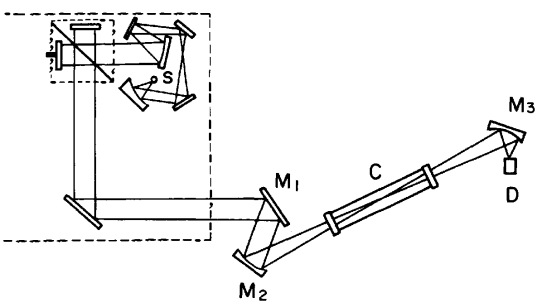

Fig. 1. Modified optical system.
S: glober, M_1: flat mirror, M_2: spherical mirror, M_3: off-axis ellipsoidal mirror, C: infrared cell, D: detector.

For the measurements of the sulfine spectrum, dimethyl sulfoxide was passed through a quartz tube heated up to 700 °C and the products of thermal decomposition were introduced into the cell and pumped through. The heated part of quartz was 20 cm long and 5 mm i.d. The pressure of dimethyl sulfoxide was carefully regulated by a needle valve and, thereby, a steady stream of the products was obtained in the flow-through system. The best sulfine spectrum was obtained at the $(CH_3)_2SO$ pressure of *ca.* 450 mTorr (1 Torr≈133.322 Pa) which was the maximum vapor pressure obtainable in the flow-through system at room temperature. The spectrum was measured at 0.1 cm^{-1} resolution using a 350 mm gas cell with 30 mm diameter and averaging over 512 scans. A triangular apodization function was used in the calculation of spectra.

In the observed spectra, C_2H_4 and SO_2 with medium intensity, along with CH_4 with strong intensity, were clearly identified. These molecules are known to be decomposition products of sulfine or dimethyl sulfoxide by the work of

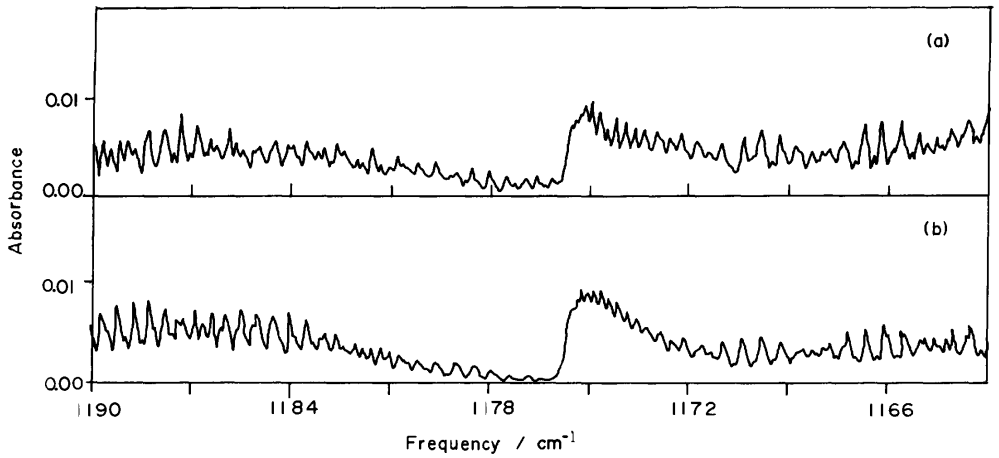

Fig. 2. Spectrum of ν_5 band of sulfine.
(a) Obsd. (b) Calcd.

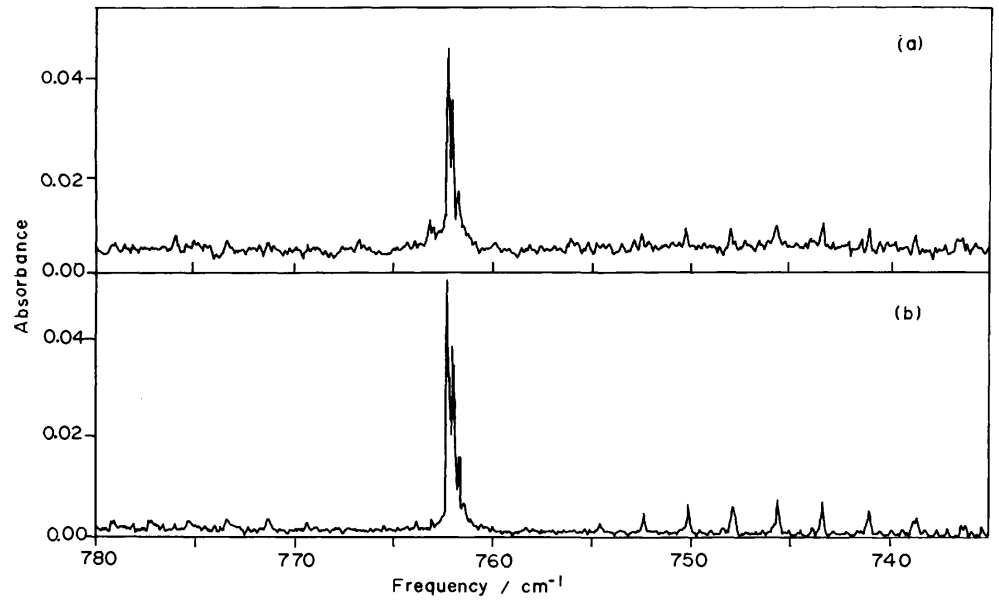

Fig. 3. Spectrum of ν_9 band of sulfine.
(a) Obsd. (b) Calcd.

Thyrion and Debecker[5] on the pyrolysis of $(CH_3)_2SO$. Besides the absorption bands due to these molecules, the rotation-vibration bands centered at 1175 cm^{-1} and 762 cm^{-1} were observed as shown in Figs. 2 and 3. These band positions agree with those reported by Block *et al.* The half-life of the molecular species giving these bands was about 25 min in the infrared cell, which was comparable with that in X-band copper waveguide cell reported by Penn and Olsen.[2] Although the lifetime of this molecule is much longer compared to the pumping speed, the strong infrared spectrum was obtained when the heated quartz tube was placed very near the inlet of the infrared cell. This suggests that this molecule tends to be lost in the narrow glass tube.

Microwave Spectra. The microwave spectrum was measured by a conventional Stark modulation spectrometer with a 3-meter X-band copper waveguide cell. The microwave sources are an HP-8672A frequency synthesizer and an HP-8690 microwave sweeper phase locked to the synthesizer. The sweeping was performed through an HP-IB system controlled by an HP-9835 desk-top computer.

The sample flow-through system was almost the same as used for the IR spectroscopy. However, the vapor pressure was optimum at about 20 mTorr. According to the results of the IR spectroscopy of matrix isolated sulfine,[3] the lowest fundamental vibration is ν_7 (394 cm^{-1}). The microwave spectrum in the excited ν_7 state was first searched for and several low-J transitions were easily identified from their characteristic Stark patterns. The spectral lines for the $2\nu_7$ state were also observed at the expected frequencies. Since the intensity of the ν_9 excited state spectrum was expected to be nearly the same as of $2\nu_7$, the assignment of the spectral lines was done by comparing them with corresponding $2\nu_7$, lines. All the observed transition frequencies and the rotational constants derived from them by least-squares fitting are listed in Table 1. Since the μ_b of sulfine is small, no b-type transitions for the vibrational satellites were observed and the A' rotational constants were not determined precisely.

Results and Discussion

The sulfine is a planar asymmetric top molecule with an asymmetry parameter $\kappa=-0.891$ and belongs to the

C_s point group. Simulation spectra for the two bands observed in this work were obtained with the computer program written for calculating the rotation-vibration spectrum of the asymmetric top molecule. The details of the program have been described elsewhere.[6] After the line positions and intensities of the individual transitions were calculated the spectrum was simulated using a Lorentz type line shape function and a triangular slit function. A comparison of the two bands observed at 1175 and 762 cm^{-1} with the simulated ones leads to their unambiguous assignment to the CSO symmetric stretching mode (ν_5) and the CH_2 wagging mode (ν_9), respectively, of sulfine. The lower part of the ν_5 band was overlapped by the ν_1 band of SO_2 produced by pyrolysis. Nevertheless, PQR-structure of sulfine was readily distinguished from the mixed spectra. In principle, the ν_5 band is expected to be an a- and b-type hybrid band. However, the observed spectrum clearly shows that this band consists mainly of a-type band because of the weak line strength of the b-type band. In the course of simulation calculation, three excited state rotational constants (A'_5, B'_5, and C'_5) and the band center ν_5 were adjusted to fit the observed spectrum, keeping the ground state rotational and centrifugal distortion constants fixed at their microwave values,[2] and the excited state centrifugal distortion constants equal to the ground state values. In the analysis of the spectrum, 44 prominent peak positions in the absorption band were chosen to use in a least-squares fit for the determination of the molecular parameters. The molecular parameters derived are listed in Table 2, and the observed and calculated frequencies along with the assignments are given in Table 3. Each of the prominent peaks is assigned to the transition which makes the largest contribution to that particular peak. In Fig. 2 the observed and simulated spectra of ν_5 band are shown. The band center is determined as 1175.75 cm^{-1} which is slightly higher than the value of 1170 cm^{-1} reported by Block *et al.*,[1] while it is fairly different from the matrix value (1165 cm^{-1}).[3]

The ν_9 band should be a c-type band which corresponds to the perpendicular band in a prolate symmetric top and, therefore, a fairly strong Q-branch is expected at its center. In Fig. 3 the observed band is compared with the calculated spectrum. It is clearly seen that this band is of typical c-type and is compatible with the vibrational mode of the CH_2 wagging as has been estimated by Powers *et al.*[3] The prominent series of $^{r,p}Q$ branches were easily assigned from comparison with the calculated spectrum, whereas ^pP, ^pR, ^rP, and ^rR in many subbands were not resolved in the present measurements. Consequently, it was difficult to determine the three excited state rotational constants of this band only from the observed spectrum. Therefore, the measurement of the microwave spectrum in the excited ν_9 state was carried out. Since the A' rotational constant obtained by microwave spectroscopy had a large uncertainty as described previously, both the A' and band center were adjusted to fit the observed infrared spectrum, keeping all the other constants fixed at the microwave values. The determined molecular constants are listed in Table 2. Table 4 compares the observed and calculated values of the prominent peaks in the ν_9 band. The band center of ν_9 thus determined is 762.07 cm^{-1} which is close to the value of 760 cm^{-1} obtained by Block *et al.* and also near the matrix value (767 cm^{-1}).

In conclusion, the good agreement between the observed and calculated spectra of the ν_5 and ν_9 bands with the reasonable molecular parameters was obtained

by the joint analysis of FT-IR and microwave spectroscopy and it definitely confirmed that the origin of these bands is the sulfine molecule. In addition, the vibrational frequencies of ν_5 and ν_9 of sulfine were determined precisely.

The Thermal Properties of Liquid Crystalline Materials Incorporating Cyanothiophene and Cyanofuran

Shiro MIYAKE, Shigekazu KUSABAYASHI, and Shunsuke TAKENAKA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 560
(Received March 10, 1984)

Some homologous series of cyanothiophene and cyanofuran compounds have been prepared. 4-Alkoxyphenyl 3-(5-bromo-2-thienyl)acrylate (**1**) and 4-alkoxyphenyl 3-(5-cyano-2-thienyl)acrylate (**2**), and 4-alkoxyphenyl 4-(5-bromo-2-furylcarbonyloxy)benzoate (**3**) and 4-alkoxyphenyl 4-(5-cyano-2-furylcarbonyloxy)benzoate (**4**) give rise to a nematic phase. For compound **4**, a smectic A phase which commences from the hexyloxy homolog has a bilayer (S_{A2}) arrangement of the molecules. The thermal stabilities of the mesophases are lower than those of the corresponding benzonitrile compounds. This arises from an increased molecular breadth around the terminal portion and the change of the dipole moment arising from the terminal cyano group bending with respect to the long molecular axis.

Liquid crystalline materials incorporating a cyanophenyl group as the terminal function are good nematogens for devices employing a twisted nematic mode. The molecules frequently give rise to very interesting phenomena such as an induced smectic A phase[1-3] or an enhancement of smectic A thermal stability[4,5] in some binary mixtures and reentrant phenomena.[6-8] In such cases, it is well known that a dipole moment arising from the terminal cyano group plays a very important role in determining the thermal behavior of the molecule.[8-10]

In this paper, we describe the preparation, and thermal and dielectric properties of cyanothiophene and cyanofuran compounds, **1**, **2**, **3**, and **4**, and some related compounds. In these series, the cyano group would occur at an angle with respect to the rotational axis of the entire molecule because of the thiophene and furan rings, and increase the molecular breadth.

Experimental

Method. The transition temperatures were determined by using a Nikon POH polarizing microscope fitted with a Mettler FP 52 heating stage and a control unit. The transition temperatures were also measured by using a Dainiseikosha SSC-560 differential scanning calorimeter. Indium (99.9%) was used as a calibration standard at a heating rate of 5 °C/min. The dielectric constants were measured by using an Andodenki TR-10 precision capacitance measurement system. The capacitor cell consisted of two indium coated glass electrodes separated by a 25 μm Mylar spacer. The cell temperature was controlled by means of a brass housing. The voltage applied was 0.4 V at 1 kHz. The alignment of molecules in the cell was achieved by applying a 1.0 T magnetic field. The capacitor cell was calibrated by highly purified benzene and acetonitrile.

Materials. 3-(5-Bromo-2-thienyl)acrylate was prepared by the reaction of 5-bromo-2-thiophenecarbaldehyde and malonic acid.[11] 3-(5-Bromo-2-thienyl) acryloyl chloride was reacted with 4-alkoxyphenols in dry benzene containing pyridine (5%), giving the homologous series of **1**. A similar reaction of 5-bromo-2-furancarbonyl chloride and 4-alkoxyphenyl 4-hydroxybenzoates[12] gave the homologous series of **3**.

4-Nonyloxyphenyl 4-(5-Cyano-2-furylcarbonyloxy)benzoate. A mixture of 4-nonyloxyphenyl 4-(5-bromo-2-furylcarbonyloxy)benzoate (3.4 g, 6.4 mmol) and copper(I) cyanide (0.86 g, 9.6 mmol) in anhydrous *N,N*-dimethylformamide (20 ml) was refluxed for 3 h.[13] After cooling, the dark brown solution was poured onto cold water (100 ml) containing ethylenediamine (8.0 g, 0.13 mol). The resulting solution was extracted with ether (50 ml×4 times). The purification was carried out by column chromatography on silica gel where a solvent mixture of pet. ether and ether (95:5) was used as an elution solvent, followed by recrystallization from absolute ethanol: 0.8 g, IR: ν_{CN}=2250 cm^{-1}. The homologous series of **2** and **4** were prepared similarly. The purity was checked by elemental analysis.

Results and Discussion

The transition temperatures for thiophene compounds **1** and **2** are summarized in Table 1. In the present study, three related compounds were prepared; 4-butylcyclohexyl 3-(5-cyano-2-thienyl)acrylate (T_{mp}=70.5 and $T_{N\cdot I}$=51.7 °C), 4-pentylcyclohexyl 3-(5-cyano-2-thienyl)acrylate (T_{mp}=85.7 and $T_{N\cdot I}$=70.2 °C), and 4-hexylphenyl 3-(5-cyano-2-thienyl)acrylate (T_{mp}=92.4 and $T_{N\cdot I}$=73.0 °C). For these compounds both melting points and nematic-isotropic transition temperatures are lower than those for series **2**.

The transition temperatures for the furan compounds **3** and **4** are summarized in Table 2. The nematic-isotropic transition temperatures reveal a familiar even-odd effect. The smectic properties for

series **4** commence from the hexyloxy homolog. In the present study, three related compounds were prepared; 4-butoxyphenyl 5-cyano-2-furancarboxylate (T_{mp}=104 °C) and 4-hexylphenyl 5-cyano-2-furancarboxylate (T_{mp}=95.5 °C), but none of them turned out to be mesogenic. 4-Hexylphenyl 4-(5-cyano-2-funylcarbonyloxy) benzoate gives rise to a nematic phase monotropically (T_{mp}=135 and T_{N-I}=129 °C). The assignment of the smectic phase for the heptyloxy homolog of series **4** was done by an examination of the isobaric diagrams shown in Fig. 1.

In the binary mixture of the heptyloxy homolog and 4-pentylphenyl 4-(4-octylbenzoyloxy)benzoate (Fig. 1a), the smectic A-nematic transition temperatures reveal a weak nonideal behavior in the range between 80 and 0 mol% of the heptyloxy homolog. However, both smectic phases are discontinuous in the range between 95 and 85 mol% of the heptyloxy homolog. A similar trend is observed in Fig. 1b. For the binary mixture of the heptyloxy homolog and 4-pentylphenyl 2-cyano-4-(4-octylbenzoyloxy)benzoate, an interesting fact is that the smectic A-nematic (isotropic) transitions show a linear correlation with additivity, whereas both smectic phases appear to be essentially immiscible. Here, it would be reasonable to assume that both nonpolar mesogens have a monolayer arrangement of the molecules in the smectic A phase. In Fig. 1c, the smectic phase of the heptyloxy homolog is also immiscible with the smectic A phase of *N*-[4-(4-octyloxybenzoyloxy)-benzylidene]-4-cyanoaniline where the molecules form a partially bilayer arrangement (S_{Ad}) in the smectic A phase.[14] For the binary phase diagram of the heptyloxy homolog and 4-pentylphenyl 4-(4-cyanobenzoyloxy)benzoate (5DB)[15] in Fig. 1d, on the other hand, both smectic phases are isomorphous, though the smectic-nematic transition temperatures show a nonideal behavior with additivity. 5DB has been known to form a bilayer arrangement (S_{A2}) of the molecules in the smectic A phase. These facts lead to the conclusion that the smectic phase of the heptyloxy homolog forms a smectic A modification with a bilayer arrangement of the molecules (S_{A2}). In Fig. 1a and 1b, the S_A-N transition temperatures show an ideal behavior in the range between 80 and 0 mol% of the heptyloxy homolog of series **4** and the apparent discontinuity in the range between 95 and 85 mol%. This indicates that the S_{A2} phase, although similar to the S_{A1} phase, is essentially different and immiscible with it and that the S_{A2} arrangement of the molecules is easily destroyed by a small amount of the nonpolar mesogens. In Fig. 1c, the rapid reduction of the S_A-N transition temperatures with increasing the composition of *N*-[4-(4-octyloxybenzoyloxy)benzylidene]-4-cyanoaniline indicates that the S_{A2} phase of the heptyloxy homolog of **4** has low affinity with the S_{Ad} phase.

From geometrical and electrical points of view, 3-(5-cyano-2-thienyl)acrylate and 5-cyano-2-furancarboxylate are very different from 3-cyanobenzoate. The geometries of cyanothiophene, cyanofuran, and benzonitrile are illustrated in Fig. 2. The cyano group in series **2** lies in the volume of a cylinder defined by rotation of the rest of the molecule about its longer molecular axis. The nematic-isotropic transition temperaturs for series **2** are lower by *ca.* 50 °C than those for the 4-alkoxyphenyl 4-cyanocinnamates,[16] whereas the cyano group does not increase the molecular breadth so much. Similarly, the nematic-isotropic transition temperatures for series **4** are lower by *ca.* 130 °C than those for the corresponding benzonitrile compounds.[15] The increased molecular breadth around the cyanofuran portion is one of the reasons for the low nematic stability. When the molecules form antiparallel correlations due to strong dipole-dipole

interaction, however, the bend of the terminal cyano group would be very unfavorable for the thermal stabilities of the mesophases, especially in the thermal stabillity of the nematic phase. The situation is shown in Fig. 3.

As a result, the bend of the cyano group would increase the breadth of the antiparallel dimer formed by the dipole-dipole interaction. The increased molecular breadth is assumed to be the other reason for the low nematic stabilities of series **2** and **4**. On the other hand, the axial separation of the molecules due to the bent geometry would reduce a repulsive interaction around the core portion. This, in turn, leads to an increase in relative thermal stability of the smectic A phase. Indeed, the ratios of the smectic A-nematic/nematic-isotropic transition temperatures for the series **4** lie in the range between 0.94 and ≈1. The values are very large compared with those for three ring compounds incorporating a cyano group at the terminal position,[17] indicating that for series **4** the thermal stabilities of the smectic A phase are relatively higher than those of the nematic phase.

From an electrical point of view, the cyano groups in series **2** and **4** are rather similar to the cyano group in 4-cyanobenzoate compounds, because a conjugation of the cyano group with the π electron system of the entire molecule generates greater polarity and polarisability, a general requisite of the mesophase stability. However, the bend of the cyano group strongly affects the dielectric behavior. The dielectric constants $\varepsilon_{/\!/}$ and $\varepsilon_{\perp}$ for the octyloxy homolog of series **2** are plotted against temperature in Fig. 4.

The dielectric anisotropy ($\Delta\varepsilon$) for the octyloxy homolog is *ca.* 1.8 at 90 °C, indicating that the anisotropy of the dipole moment arising from the cyano group is quite small. The anisotropy ($\Delta\varepsilon$) for the heptyloxy homolog of series **4** is *ca.* −3.0 at 139 °C. The negative value is expected from the theoretical calculation of the group dipole moments.[18] Therefore, the cyano groups in series **2** and **4** tend to

increse the dipolarity perpendicular to the long molecular axis, as does the cyano group in 3-cyanobenzoate compounds.

Conclusion

The terminal cyano group has a very important role in determining the thermal and dielectric properties, and the bend of the cyano group with respect to the long molecular axis results in a decrease in the thermal stabilities of the mesophases and a reduction of the dielectric anisotropy. The formation of the bilayer smectic A phase (S_{A2}) for series **4** appears to be a rare case.

The Microwave Spectrum of Acrylaldehyde Oxime

Manabu NIWASE, Kyoko KUBOTA, Kazuhiko YOSHIDA, Takeshi SAKAIZUMI, Masao ONDA, Osamu OHASHI,* and Ichiro YAMAGUCHI

Department of Chemistry, Faculty of Science and Technology, Sophia University, Chiyoda-ku, Tokyo 102

(Received March 21, 1984)

The microwave spectra of acrylaldehyde oxime and its deuterated derivative (CH_2=CH-CH=NOD) were observed in the frequency region from 8.5 to 35 GHz. The several a-type R-branch transitions in the ground vibrational state were identified and the following rotational constants in MHz were determined to be: A=34117±96, B=2363.007±0.011, and C=2210.616±0.011 for normal species and A=33950±103, B=2274.301±0.010, and C=2131.981±0.011 for deuterated species. The most plausible molecular structure to which the spectrum assigned is attributed has been deduced to be a *s-trans syn* geometrical conformer from the rotational constants experimentally determined. The dipole moment component μ_a in the ground vibrational state was determined to be 0.59 D from the Stark effects of J=2←1 transitions. The r_s coordinates of the OH hydrogen atom have been determined and the orientation of the OH bond in the molecule has been discussed.

Acrylaldehyde oxime has four possible geometrical isomers, as shown in Fig. 1, if this molecule is assumed to be planar. A theoretical study[1] has suggested that the most stable conformation of this molecule is a *s-trans E* form. Wolkowski *et al.*[2] has reported that the proton nuclear magnetic resonance spectrum of acrylaldehyde oxime showed only a *s-trans E* form to exist in a liquid state. However, the gas chromatogram and proton nuclear magnetic resonance spectrum of this molecule have indicated that this molecule has two geometrical isomers[3]: One of these isomers has an *E* form and the other one has a *Z* form. Each of these isomers has two possible rotational conformers with respect to the C-C single bond (See Fig. 1). Masuda *et al.*[3] could not conclude whether a (*Z*)-(acrylaldehyde oxime) molecule has a *s-trans Z* form or a *s-cis Z* form, or both, while the proton nuclear magnetic resonance spectrum of an (*E*)-(acrylaldehyde oxime) could be ascribed to a *s-trans E* form.

It is interesting to determine the molecular conformation of acrylaldehyde oxime, particularly of an anti isomer, in gas phase. We have observed the microwave spectra of acrylaldehyde oxime and its deuterated species and discussed its conformation and the orientation of the OH bond in this molecule.

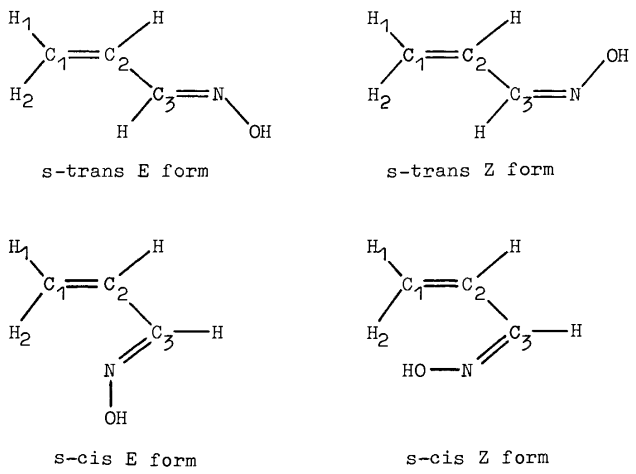

Fig. 1. Four possible geometrical isomers and the numbering of carbon and hydrogen atoms of acrylaldehyde oxime.

Experimental

Acrylaldehyde oxime was prepared and purified by Tuerck's[4] and Koral'nik's[5] methods. The deuterated species (CH_2=CH-CH=NOD) was prepared in the absorption cell itself as follows: First, the cell was flushed two or three times with D_2O vapour at room temperature. It was then pumped off for about half an hour. At the end of this time the sample of acrylaldehyde oxime was admitted into the cell. No attempt was made to separate the *E* and *Z* species; therefore, all measurements of the microwave spectrum were made with the equilibrium mixture of geometrical isomers in the absorption cell.

The microwave spectrometer used was of a conventional 100 kHz sinusoidal- and square-wave Stark modulation type with a phase sensitive detector. The spectrum was observed at 0—−10 °C or at room temperature, refreshing the sample about every half an hour.

Results and Discussion

Spectral Assignment and Conformation of Acrylaldehyde Oxime. There are four possible geometrical

Table 1. Structural parameters assumed for (*E*)-(acrylaldehyde oxime)

isomers of acrylaldehyde oxime if this molecule is assumed to be planar. The assumed structural parameters[6,7] (Table 1) of this molecule showed that three geometrical isomers except for a *s-cis Z* conformer were nearly prolate symmetric rotors. Therefore, it was expected that the a-type R-branch transition lines would be relatively intense.

For normal species, the three $J=2\leftarrow1$ transitions with $K_{-1}=0$, 1 were first observed and identified by their characteristic Stark effects. The other a-type R-branch lines of $J=3\leftarrow2$ to $J=7\leftarrow6$ transitions with $K_{-1}=0$, 1 were then observed and assigned on the basis of the result from the $J=2\leftarrow1$ transitions. The correction terms, Δ_J, Δ_{JK}, of a first-order centrifugal distortion effect has been taken into account in order to explain the transition lines with high K_{-1} value.

For deuterated species, the observation and assignment of the spectrum were made in the same way as for normal species.

The results of the analyses of the spectra for both normal and deuterated species are in Tables 2 and 3. The small inertia defects ($\Delta I=I_c-I_a-I_b$) of -0.069 and -0.052 amu·Å^2 for normal and deuterated species confirm that this molecule is planar. The comparison between the observed rotational constants and the ones calculated from the molecular models (Table 4) has led to the conclusion that the spectrum assigned in this work is ascribed to an (*E*)-(*s-trans*-acrylaldehyde oxime).

r_s *Coordinates of the Hydroxyl Hydrogen Atom.* Since the acrylaldehyde oxime molecule to which the spectrum identified in this work is ascribed has a planar *s-trans E* form, there are two possible orienta-

tions of the hydroxyl group in this molecule: One of the two orientations of OH bond is the trans position with respect to the C=N double bond and another one is the cis position (Fig. 2).

Kraitchman's equation[8] gives the r_s coordinates of the hydroxyl hydrogen atom, using the rotational constants of both the normal and deuterated species in Table 3. The results obtained are given in the second column of Table 5. The third and fourth columns give the coordinates of the hydroxyl hydrogen atom calculated from Models 1 and 2 (Fig. 2). The observed r_s coordinates are in good agreement with the ones calculated from Model 1 in which the OH bond is at the trans position with respect to the C=N double bond. This result is consistent with the orientation of the OH bond in formaldehyde oxime[7] and acetaldehyde oxime.[9,10]

Dipole Moment. The dipole moment of this molecule was determined from measurements of the Stark effects of the 2_{12}←1_{11}, 2_{02}←1_{01}, and 2_{11}←1_{10} transitions. The electric field in the absorption cell was

calibrated by measuring the Stark shifts of the J=1←0 and J=2←1 transitions of OCS with the dipole moment of 0.715121 D.[11]

The Stark coefficients experimentally determined are given in the third column of Table 6. The fourth column of Table 6 shows the results (Calcd−1) obtained by the least-squares fit, assuming the value of μ_c=0 for this planar molecule. The results given in the fifth column of Table 6 (Calcd −2) were obtained by the least-squares fit, using all three components, μ_a, μ_b, and μ_c, as parameters. Both the Stark coefficients calculated by two assumptions are in good agreement with the ones experimentally obtained (See Table 6). Table 6 shows that the value of μ_a has been determined to be 0.59 D, while the values of μ_b and μ_c are indeterminable because of their large uncertainties.

The Synthesis of Green Rust II(Fe^{III}_1-Fe^{II}_2) and Its Spontaneous Transformation into Fe_3O_4

Yutaka TAMAURA,* Takashi YOSHIDA,† and Takashi KATSURA
Department of Chemistry, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152
†*NEC Environment Engineering, Ltd., Miyamae-ku, Kawasaki 213*
(Received December 20, 1983)

Conditions for the synthesis of a pure green rust II with a definite chemical composition and its transformation reaction to Fe_3O_4 under a nitrogen atmosphere were studied. A pure green rust II with the composition of $(Fe^{3+})_1(Fe^{2+})_2(SO_4^{2-})(OH^-)_{5-2n}(O^{2-})_n$ was obtained by the air oxidation of an aqueous solution containing (0.05 mol dm^{-3}) Fe^{II} and (0.3 mol dm^{-3}) SO_4^{2-} ions at pH 6.8 and 25 °C. This iron composition differs from those estimated previously; therefore, the green rust II synthesized here is designated as green rust II(Fe^{III}_1-Fe^{II}_2). This green rust II is spontaneously transformed into Fe_3O_4 under a nitrogen atmosphere at 50—75 °C. It has been accepted that green rust II is transformed to Fe_3O_4 by oxidation. The above evidence suggests that the green rust II can be transformed into Fe_3O_4 not only by oxidation but also spontaneously without oxidants.

The atmospheric rusting of mild steel or low-alloy steel occurs when the steel surface comes into contact with atmospheric water. The Fe^{II} ion dissolved from the steel surface in the course of the rusting is oxidized by oxygen, and iron oxides and hydroxide oxides are formed. In the thin aqueous layer on the steel surface, the oxygen and water react with the iron or intermediates of the rusting process. Eventually, the steel surface is covered with oxides and hydroxide oxides(corrosion products). In the oxidation reaction of the Fe^{II} ion in the aqueous solution, the oxidation rate, the structure and composition of the initial and intermediate species, the pH, and the temperature determine what products are formed.[1-13] The influence of dissolved oxygen has been studied by Foroulis.[6] The significance of the oxidation rate of the dissolved Fe^{II} ion in the corossion of iron and steel in an aqueous solution was pointed out by Gilroy and Mayne.[7] The formation or transformation of iron oxides, hydroxide oxides, and green rusts in aqueous solutions have been studied by Kiyama,[2] Bernal *et al.*,[8] Misawa *et al.*,[1,4] and other workers.[9-13] The transformation reaction of γ-FeO(OH) to α-FeO(OH) has been studied by Schwertmann and Taylor,[9] Oosterhout,[10] and Inoue *et al.*[11] Recently, we have reported that γ-FeO(OH) is transformed to Fe_3O_4 by the adsorption of Fe^{II} ions.[12-13] Other intermediates in the corrosion process and in the oxidation of aqueous solutions containing Fe^{II} ions are greenish precipitates called "green rusts." They are formed by the air oxidation of a dissolved Fe^{II} ion in the presence of SO_4^{2-} or halogen ions, such as Cl^-, Br^-, and F^-, at neutral or slightly alkaline pH values, and are transformed to iron oxides or hydroxide oxides by further oxidation. A green rust I is formed in the presence of Cl^-, Br^-, and F^- ions, and a green rust II, in that of the SO_4^{2-} ion. Bernal *et al.*[8] reported on an X-ray crystallographic study of the green rusts. Misawa *et al.*[14,15] studied dissolved species, called "green complexes," of the Fe^{II} and Fe^{III} complexes.

This paper will describe a new reaction in which a green rust II is transformed to Fe_3O_4 without any oxidation reaction. At the beginning of this work, we undertook to prepare a green rust II with a definite chemical composition. However, the methods reported so far[2,8,14] were inadequate for the synthesis of such a green rust II. As a first report, this paper will describe the reaction conditions for the synthesis of the green rust II with a definite chemical composition, besides the new reaction. A detailed discussion of the relationship between the new reaction and the oxidation reaction of the green rust II will be presented in the subsequent paper.

Experimental

Chemicals. All the chemicals were of an analytical grade, and distilled water was used for the preparation of chemical solutions. The α- and β-FeO(OH) were perpared according to the methods of Kiyama[2] and of Kiyama and Takada[3] respectively. Fe_3O_4 and γ-FeO(OH) were synthesized by a method reported perviously.[13,16]

Apparatus. The reaction vessel used in previous papers was adopted.[16-18]

Chemical Analysis. The Fe^{II} and Fe_{total} contents were determined by means of the 2,2′-bipyridyl method[19] after dissolving the samples with a HCl solution (1:1). The Fe_{total} was determined after reducing Fe^{III} to Fe^{II} with hydroxylamine. The SO_4^{2-} content was determined using a X-ray fluorescence instrument (Toshiba X-ray Spectrometer Model AFV 777) from the intensity of sulpher in $BaSO_4$ precipitate collected on a glass fiber filter paper (Toyo Roshi GA 100 type).

Green Rust II Synthesis. A solution [0.7 dm^3, $FeSO_4 \cdot 7H_2O$ (10.0 g), Na_2SO_4 (25 g)] was oxidized with a mixed gas of air and nitrogen gas[air/N_2=1:1(atm), flow rate; 1.6 dm^3 min^{-1}] at pH 6.8±0.05 and 25 °C. During the oxidation, an alkaline solution (0.10 mol dm^{-3} NaOH) was added to maintain the reaction pH constant, and the volume of the alkaline solution consumed was read. When about 25 mol% of the Fe^{II} ion has been oxidized, nitrogen gas was passed through in place of the mixed gas; the reaction vessel was then cooled in a water bath chilled with ice. If the Fe^{II} ions are oxidized over 25 mol%, by-products such as α-FeO(OH) are produced. The greenish precipitate was collected by centrifugation under a nitrogen atmosphere, washed with a distilled water freed from oxygen (4 °C), and suspended in the distilled water (4 °C). The green rust II thus prepared is stable under a nitrogen atmosphere at a temperature below 4 °C.

For the measurement of the Fe^{II} and Fe^{III} contents of the

green rust II formed in the course of the synthesis, 0.005 dm^3 of the reaction suspension was transferred under a nitrogen atmosphere to a 0.05 dm^3 centrifuging tube chilled in ice water, and nitrogen gas was immediately flushed into the sample suspension to stop the reaction instantly. After 10 min, the sample was centrifuged under a nitrogen atmosphere at a low temperature (4 °C) at 3000 min^{-1} for 5 min. After the precipitate has been washed with cold distilled water freed from oxygen, the Fe^{II} and Fe^{III} contents were determined.

Electron Microscopy, IR Spectroscopy, and X-ray Diffractometry for the Green Rust II. A small portion of the reaction suspension was taken into a glass capillary tube whose inside was a vacuum; the capillary was then sealed and kept in cold water. The inside sample was mounted under a nitrogen atmosphere on a sample holder for electron microscopy. For the X-ray diffractometry, the precipitate obtained by centrifugation was mounted on a glass plate under a nitrogen atmosphere, and sealed with cellophane-tape to prevent oxidation. For the IR spectroscopy, the green-rust-II precipitate was washed with acetone freed from oxygen (4 °C), dried under a nitrogen atmosphere, and suspended in Nujol. The IR spectrum was taken by a Shimadzu IR spectrometer, Model IR 400, using a KBr cell under a nitrogen atmosphere.

Transformation Reaction of Green Rust II under a Nitrogen Atmosphere. The green-rust-II suspension (0.05 dm^3, 25 °C) was transferred into a 0.4-dm^3 portion of distilled water freed from oxygen. The temperature of the distilled water had been adjusted to get a given temperature after the mixing. The pH of the reaction suspension was adjusted by adding a NaOH solution during the reaction. After 4 h, the product was isolated by transferring 0.2 dm^3 of the reaction suspension to 0.1 dm^3 of an oxygen-free acetate buffer solution (pH 4.1, 0.05 mol dm^{-3}) to dissolve the Fe^{II} ions released during the transformation reaction. The product was collected by centrifugation under a nitrogen atmosphere, washed successively with oxygen-free water and acetone, and dried under a nitrogen atmosphere. The dried product was examined by means of X-ray diffractometry, electron microscopy, and IR spectroscopy. The chemical composition was determined after dissolving it with the HCl solution(1:1).

Results and Discussion

Conditions for Green Rust-II Synthesis. Curves A and A′ in Fig. 1 show the amounts of $Fe(OH)_2$ precipitate which were formed by adjusting the pH of the solutions containing Fe^{II} ions at high (Curve A; 0.3 mol dm^{-3}) and low (0.05 mol dm^{-3}) concentrations of SO_4^{2-} to those indicated in the figure at 25 °C. As may be seen here, most Fe^{II} ions dissolved at pH values below 6.8 at a high SO_4^{2-}-concentration. When a mixed gas of air and nitrogen gas was passed into the solution containing Fe^{II} ions at pH 6.8 and at a high SO_4^{2-}-concentration, the clear solution became turbid, and a greenish precipitate was formed by the oxidation of the Fe^{II} ions. Figure 2 shows the time variation of the Fe^{II} (Curve A) and Fe^{III} (Curve B) contents of the greenish precipitates formed in the course of air oxidation at pH 6.8. As can be seen here, the Fe^{II}/Fe^{III} mol ratio was maintained at nearly 2:1 during the reaction. This suggests that one mol of the Fe^{III} ions formed by oxidation combines with two mols of the Fe^{II} ions to form the greenish precipitate. The X-ray diffraction pattern of the greenish precipitate formed at an oxidation time of 40 min corresponded to that of the green rust II reported by Bernal *et al.*[8] In the IR spectrum, no bands of iron hydroxide oxides appeared, but a strong band of SO_4^{2-} (1100 cm^{-1}) and weak bands (720, 620 cm^{-1}) did appear. These results indicate the formation of the green rust II containing SO_4^{2-}. Figure 3 shows an electron micrograph of the product.

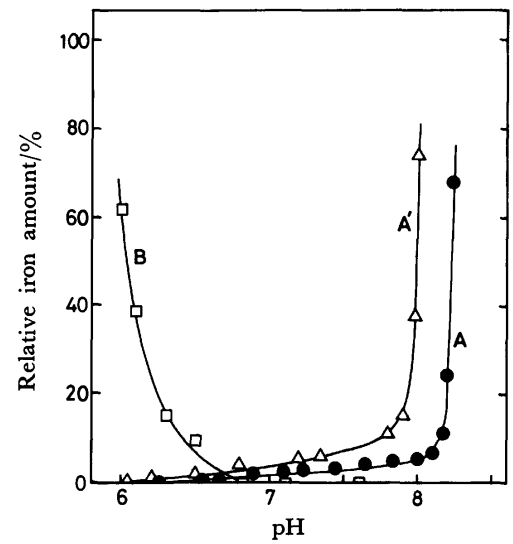

Fig. 1. The amount of $Fe(OH)_2$ precipitates which were formed by adjusting the pH of the solution containing Fe^{II} ion at high (Curve A; 0.3 mol dm^{-3}) and low (Curve A′; 0.05 mol dm^{-3}) concentrations of SO_4^{2-} to those indicated in the figure at 25 °C. The amount was estimated from the Fe^{II} in the precipitates which were formed by allowing the $Fe(OH)_2$ suspension to stand for 30 min after the addition of 0.1 mol dm^{-3} NaOH solution.
Curve B; relationship between the amount of the by-products and the reaction pH. The reaction suspension(0.05 dm^3) was taken and transferred to 0.1 dm^3 of the tartaric acid solution(10 w/v%, pH 6.0). After allowing to stand for 6 h, the amount of the total iron in the precipitate remained undissolved in the tartaric acid solution was determined.

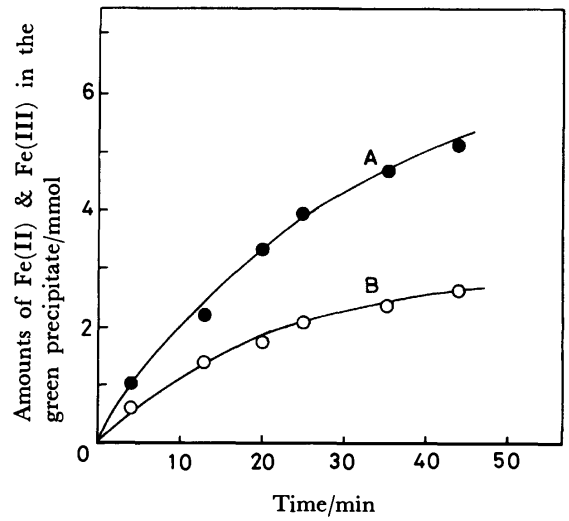

Fig. 2. The time variations of Fe^{II}(Curve A) and Fe^{III} (B) contents in the green rust II formed in the course of the synthesis.

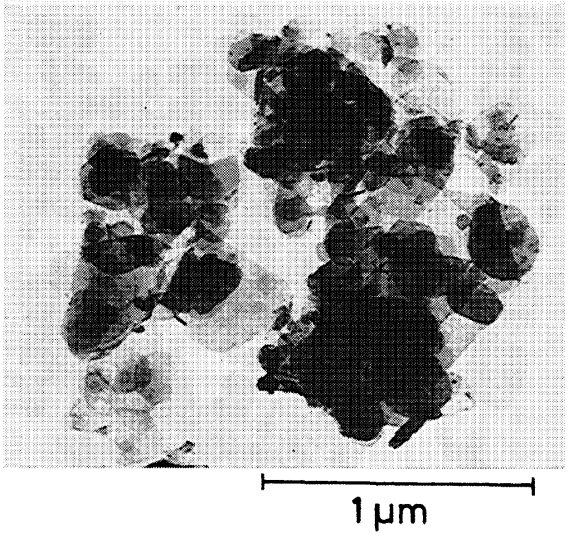

Fig. 3. Electron micrograph of the green rust II(Fe^{III}_1-Fe^{II}_2).

Table 1. Dissolution test of the green rust II, Fe_3O_4, and iron hydroxide oxides with a tartaric acid solution (10 w/v%, pH 6.0)

Iron oxides or hydroxide oxides added (7.2×10^{-4} mol; Fe_{total})	Amount of iron dissolved (mol; Fe_{total})
Green rust II	7.2×10^{-4}
Fe_3O_4	4.3×10^{-7}
α-FeOOH	2.9×10^{-7}
β-FeOOH	6.2×10^{-7}
γ-FeOOH	7.1×10^{-7}

After allowing the test suspensions to stand for 6 h under a nitrogen atmosphere, the concentration of the total iron in the supernatant was determined by the atomic-absorption method.

To ascertain the purity of the product, the green rust II obtained at pH 6.8 and at the high SO_4^{2-}-concentration was transferred to a tartaric acid solution (10 w/v%, pH 6.0), and the mixture was allowed to stand for 6 h. The green rust II dissolved completely (Table 1). However, as can be seen from the table, little of the α-, β-, and γ-FeO(OH) dissolved. This suggests that the green rust II contains no by-products such as hydroxide oxides, but is a pure green rust II. However, at pH values below 6.8 (at a high SO_4^{2-}-concentration), some by-products insoluble in the tartaric-acid solution were formed. The relationship between the amounts of the by-products and the reaction pH is given by Curve B in Fig. 1. In the IR spectrum of the by-products, key bands of α-FeO(OH) appeared strongly at 795 and 890 cm^{-1}, along with a very broad absorption over the range of 400—1000 cm^{-1}. The broad absorption could not be assigned, but it seems to be due to the Fe^{III} amorphous hydroxide oxides. Thus, the by-product can be said to be mainly composed of α-FeO(OH).

The results of the chemical analysis of the green rust II obtained at pH 6.8 and at a high SO_4^{2-}-concentration are given in Table 2, together with the OH^- amount consumed during the reaction. From the values in the table, the chemical formula can be estimated to be $(Fe^{3+})_1(Fe^{2+})_2(SO_4^{2-})(OH^-)_5$. Since Misawa *et al.*[4] suggested that green rusts contain hydroxo-bridges and oxo-bridges, the chemical formula can be generally represented by: $(Fe^{3+})_1(Fe^{2+})_2(SO_4^{2-})(OH^-)_{5-2n}(O^{2-})_n$, where n means the number of oxo-bridges. The iron composition of this green rust II is different from that estimated from the composition of the green complex II by Misawa *et al.*[15] The green rust II synthesized in the present study will hereafter be designated as green rust II(Fe^{III}_1-Fe^{II}_2).

Table 2. Results of the chemical analysis of the green rust II obtained after 30 min of air oxidation

Ions	mol	Ratio
Fe^{3+}	7.3×10^{-4}	1.0
Fe^{2+}	1.4×10^{-3}	1.9
SO_4^{2-}	6.1×10^{-4}	0.83
OH^-	3.4×10^{-3}	4.7

Equilibrium Consideration of the Formation of the Green Rust II. As may be seen in Curve B in Fig. 1, the amount of the by-product, which is mainly composed of α-FeO(OH) as has been mentioned above, increased with a decrease in the pH from 6.8 to 6.0. In the course of the reaction, Fe^{III} ions are formed by the oxidation of the Fe^{II} ions. In this pH range, the main species of the Fe^{III} ion formed by the oxidation is $Fe(OH)_2^+$, one of the hydrolysis species of the Fe^{3+} ion.[20] It is considered that α-FeO(OH) is formed by the polymerization of the $Fe(OH)_2^+$ ions. However, at pH values above 6.8, no such by-products are formed (Curve B in Fig. 1), and the green rust II is formed. This indicates that the $Fe(OH)_2^+$ ions preferentially combine with the Fe^{II} and SO_4^{2-} ions, and that they are transformed to the green rust II. Since the Fe^{2+} ion is more readily hydrolyzed into $FeOH^+$ at a higher pH in the pH range of 6—10,[20] The Fe^{II} ions which take part in the green-rust-II formation are considered to be $FeOH^+$ ions. Thus, the green rust-II formation will be written as:

$$Fe^{2+} + H_2O \rightleftharpoons FeOH^+ + H^+, \quad (1)$$

$$Fe(OH)_2^+ + 2FeOH^+ + SO_4^{2-} \rightleftharpoons (Fe^{3+})_1(Fe^{2+})_2(SO_4^{2-})(OH^-)_{5-2n}(O^{2-})_n + nH_2O. \quad (2)$$

The reversibility of Reaction (2) was also examined. When the pH of the green rust-II suspension containing a high SO_4^{2-}-concentration (0.3 mol dm^{-3}) was lowered to 5.5, the green rust II(Fe^{III}_1-Fe^{II}_2) was decomposed and a brownish precipitate was formed. In the IR spectrum of the precipitate, no key bands of iron hydroxide oxides appeared, but a very broad absorption appeared over the range of 400—1000 cm^{-1}, indicating that some amorphous precipitates of Fe^{III} were formed. Assuming that the reverse process of Reaction (2) takes place upon a lowering of the pH, it is considered that the $Fe(OH)_2^+$ ions released in the reverse process of Reaction (2) form the amorphous precipitates. How-

ever, the Fe^{II} ions released in the reverse process dissolve in the solution at pH 5.5, since their solubilities are fairly high at that pH. These considerations suggest that possibility that there exists the reverse process of Reaction (3). When the pH of the brownish suspension obtained above was raised to 8.0, a greenish precipitate was formed almost instantly. X-Ray diffractometry and chemical analysis showed that this greenish precipitate was the green rust II (Fe^{III}_1–Fe^{II}_2). Thus, the direct and reverse processes of Reaction (2) are considered to take place reversibly, and they seem to readily attain equilibrium. From Eqs. 1 and 2, the equilibrium constant for the formation of the green rust II is given by:

$$K = \frac{[H^+]^3}{[Fe(OH)_2^+][Fe^{2+}]^2[SO_4^{2-}]K_1^2K_w} \quad (3)$$

where K_1 and K_w are the hydrolysis constant of Fe^{2+} (Eq. 1) and the dissociation constant of water respectively. In the pH range of 6—7, $[Fe(OH)_2^+]$ is around 10^{-11}—10^{-12} mol dm^{-3}.[20] Equation 3 indicates that the lower values of the Fe^{2+}-concentration, the pH, and the SO_4^{2-}-concentration are unfavorable for the formation of the green rust II(Fe^{III}_1–Fe^{II}_2). When the Fe^{2+}-concentration is lowered as the oxidation reaction proceeds, Reaction (2) attains equilibrium, and the green rust II is no longer formed. The $Fe(OH)_2^+$ ions, which are formed by a further oxidation of the remaining Fe^{2+} ions, polymerize and form α-FeO(OH)(by-product). At a pH lower than 6.8, the formation of the by-product is initiated at an earlier stage of the oxidation reaction. This means that the amount of the by-products will increase with a decrease in the pH from 6.8, as is shown by Curve B in Fig. 1. When the reaction pH was further lowered to 5.5, no green rust II was formed, but only the by-products. In these experiments, the concentrations of Fe^{II} and SO_4^{2-} were 0.05 and 0.3 mol dm^{-3} respectively. For these values, the pH value of 5.5 is too small to form the green rust II in Eq. 3.

Spontaneous Transformation of the Green Rust II to Fe_3O_4 under a Nitrogen Atmosphere. When the green rust II(Fe^{III}_1–Fe^{II}_2)-suspension containing no oxidants was allowed to stand under a nitrogen atmosphere at 75 °C, the suspension spontaneously turns black, and the pH became around 7.8. Figure 4 shows the electron micrograph of the product; no particles of the green rust II are seen, but only the spherical or cubic particles characteristic of Fe_3O_4. The X-ray diffractometry, IR spectroscopy, and chemical analysis showed that the product is Fe_3O_4. In this reaction, no oxidants were used; therefore, the formation of Fe_3O_4 from the green rust II is given by:

$$2[(Fe^{3+})_1(Fe^{2+})_2(SO_4^{2-})(OH^-)_{5-2n}(O^{2-})_n] \longrightarrow$$
$$Fe_3O_4 + 3Fe^{2+} + 2SO_4^{2-} + 2(2-n)H_2O + 2OH^- \quad (4)$$

As can be seen from Eq. 4, three mols of Fe^{2+} ions and two mols of OH^- ions are released. One out of the three mols of Fe^{2+} ions will form $Fe(OH)_2$, and the remaining two be free. The pH after the mixing of the Fe^{2+} and OH^- ions at this ratio was around 7.6. This value agrees with that where the reaction pH is attained in the early stage of the reaction. At a pH around this pH value, some of the remaining Fe^{2+} ions are hydrolyzed,

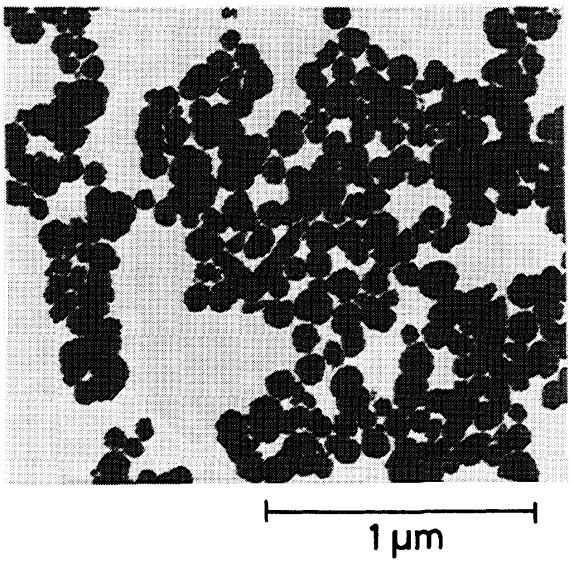

Fig. 4. Electron micrograph of the product which was obtained by allowing the green rust II(Fe^{III}_1–Fe^{II}_2)-suspension under a nitrogen atmosphere at 75 °C for 4 h. Concentrations of SO_4^{2-} and the green rust II; 0.018 mol dm^{-3} and 50 mmol dm^{-3}(Fe^{2+}), respectively.

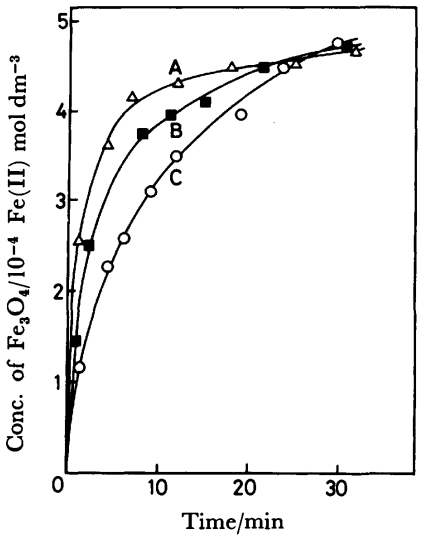

Fig. 5. The time variation of the Fe_3O_4-formation at various pH's(50 °C).
Curve A; pH 7.7, B; 9.8, and C; 10.6. Concentrations of SO_4^{2-} and the green rust II; 0.018 mol dm^{-3} and 50 mmol dm^{-3}(Fe^{2+}). The reaction suspension (0.05 dm^3) was taken and transferred to 0.1 dm^3 of the tartaric acid solution(10 w/v%, pH 6.0). After allowing to stand for 6 h, the amount of Fe^{II} in the precipitate remained undissolved in the tartaric acid solution was determined.

and the proton is released (Eq. 1). This is the cause of the gradual lowering of the pH in the transformation reaction.

Figure 5 shows the time variation in the Fe_3O_4-formation from the green rust II at various pH's(50 °C) under a nitrogen atmosphere. The reaction pH was maintained by adding an alkaline solution. As may be

Table 3. The rate of the spontaneous transformation of the green rust II into Fe_3O_4 at various temperatures under a nitrogen atmosphere

Temperature °C	Transformation rate to Fe_3O_4 (Fe^{2+} mol dm^{-3} min^{-1})
30	1.51×10^{-6}
50	6.38×10^{-5}
74	1.86×10^{-3}

The rate gradually became slow with time. The values in the table were evaluated from the tangent of the Fe_3O_4-formation curve at 0 time. Concentration of SO_4^{2-}: 0.018 mol dm^{-3}. Concentration of the green rust II: 50 mmol dm^{-3} (Fe^{2+}).

Table 4. The relationship between the concentration of the green rust II in the suspension and the rate of the spontaneous transformation of the green rust II into Fe_3O_4 under a nitrogen atmosphere at 50 °C

Green rust II conc. in the reaction suspension (Fe^{2+} mmol dm^{-3})	Transformation rate to Fe_3O_4 (Fe^{2+} mol dm^{-3} min^{-1})
4.9	7.07×10^{-6}
11	1.27×10^{-5}
25	3.36×10^{-5}

The rates were evaluated from the tangent of the Fe_3O_4-formation curve at 0 time. Concentration of SO_4^{2-}: 0.018 mol dm^{-3}.

seen here, the green rust II was transformed spontaneously to Fe_3O_4 without being oxidized, even at a pH above 7.8. However, the reaction pH affects the initial rates of the transformation reaction. The temperature and the SO_4^{2-}-concentration also affect the rate. The relationship between the initial rate and the temperature is given in Table 3. When the SO_4^{2-}-concentration became higher, the rate became slower, becoming extremely slow at 0.1 mol dm^{-3}.

The electron microscopy(Figs. 3 and 4) showed that plate particles of the green rust II are transformed to cubic or spherical particles of Fe_3O_4. This indicates that the transformation reaction proceeds through a dissolution-precipitation process. This process seems likely in view of the fact that no transformation occurred when the green rust II was dried under a nitrogen atmosphere after having been washed with a O_2-free acetone to remove as much water as possible. The transformation reaction is considered to involve the dissolution process of the green rust II. In this process, some dissolved species such as the green complex II[14] are released and transformed to Fe_3O_4 without being oxidized. If the transformation rate of the dissolved species is slower than the dissolution rate of the green rust II, the bulk solution is saturated with the dissolved species. In this case, the concentration of the dissolved species is kept constant, even though the number of particles of the green rust II in the suspension(green-rust-II concentration) is increased. This means that the rate of the Fe_3O_4-formation does not depend on the green-rust-II concentration. However, as is shown by Table 4, the rate of the Fe_3O_4-formation depends on the green-rust-II concentration. It is considered that the rate of the transformation of the dissolved species to Fe_3O_4 is fast, and that the dissolution of the green rust II is the rate-determining step of the reaction. At a higher concentration of the green rust II, the dissolution rate of the green rust II becomes faster as a result of the increase in the total surface area of the green-rust-II particles.

If the dissolved species is the green complex II with the composition of $[(Fe^{3+})(Fe^{2+})(OH^-)_x(O^{2-})_y]^{(5-2y-x)+}$,[14] the dissolution process of the green rust II is given by:

$$(Fe^{3+})_1(Fe^{2+})_2(SO_4^{2-})(OH^-)_{5-2n}(O^{2-})_n \rightleftharpoons [(Fe^{3+})(Fe^{2+})(OH^-)_{5-2n-m}(O^{2-})_n]^{m+} + Fe^{2+} + SO_4^{2-} + mOH^-, \quad (5)$$

where it is assumed that the oxo-bridges in the green rust II are transformed into the green complex II. The Fe_3O_4-formation from the green complex II may be written as:

$$2[(Fe^{3+})(Fe^{2+})(OH^-)_{5-2n-m}(O^{2-})_n]^{m+} + 2(m-1)OH^- \longrightarrow Fe_3O_4 + Fe^{2+} + 2(2-n)H_2O. \quad (6)$$

Equation 6 shows that the Fe_3O_4-formation reaction should depend largely on the reaction pH if Reaction (6) is the rate-determining step. However, as is shown by Fig. 5, the reaction rate did not increase with an increase in the reaction pH, but, rather, decreased. This suggests that the transformation step of the dissolved species to Fe_3O_4 is not the rate-determining step, as has been discussed above.

It has been accepted that green rust II is transformed to Fe_3O_4 by oxidation. However, the above evidence suggests that the green rust II can be transformed into Fe_3O_4 not only by oxidation, but also spontaneously without oxidation reaction.

The Transformation of γ-FeO(OH) to Fe_3O_4 and Green Rust II in an Aqueous Solution

Yutaka TAMAURA,* Mervelina SATURNO, Kaoru YAMADA, and Takashi KATSURA
Department of Chemistry, Tokyo Institute of Technology, Ookayama, Meguro-ku, Tokyo 152
(Received February 17, 1984)

A mechanism of the transformation of γ-FeO(OH) to Fe_3O_4 and/or green rust II in an aqueous solution containing Fe^{II} ion in the presence or absence of the SO_4^{2-} ion at 298 K is described. γ-FeO(OH) is dissolved by two mols of Fe^{II} ions adsorbed on the surface of γ-FeO(OH), and a dissolved species (DS) is formed, which is then transformed to Fe_3O_4 or green rust II. The equilibrium of the formation of green rust II from γ-FeO(OH) is represented by:

$$K = [H^+]^2/(K_h^2[Fe^{2+}]^2[SO_4^{2-}]) \qquad K = 2.14 \times 10^8,$$

where K_h is the hydrolysis constant of Fe^{2+}. This equation shows that, for a given proton concentration(pH), higher concentrations of Fe^{2+} and SO_4^{2-} ions facilitate the formation of green rust II from γ-FeO(OH). When little green rust II is formed, the DS is transformed to Fe_3O_4.

The Fe^{II} ions dissolved from the steel surface in the course of the atmospheric rusting are oxidized by oxygen, and eventually the surface is covered with rusting products of iron oxides and hydroxide oxides. Studies of the formation of iron oxides and hydroxide oxides by the air oxidation of Fe^{II} ions in an aqueous solution give useful knowledge for an understanding of the atmospheric rusting of mild steel or low-alloy steel, as reported by Kiyama,[1] Bernal *et al.*,[2] and Misawa *et al.*[3] This oxidation reaction has also been studied in relation to the formation of ferrites in aqueous solutions; ferrites are formed by the air oxidation of an $Fe(OH)_2$ suspension containing other metal ions.[4-10] In these oxidation reactions, some intermediates are formed; greenish precipitates called "green rusts" are formed in the course of the oxidation reaction.[1-3] They are transformed to γ-FeO(OH) or Fe_3O_4 by further oxidation.

Recently we have ourselves reported that a green rust (green rust II) is spontaneously transformed into Fe_3O_4 without being oxidized[11] and that γ-FeO(OH) is transformed into Fe_3O_4 by Fe^{II} ions at pH 7—11 without any oxidation reaction.[12,13] Furthermore, ferrites are formed from a suspension containing γ-FeO(OH) and Fe^{II} and other metal ions without any oxidation reaction.[14,15] These findings suggest that there are two steps in the oxidation reaction where Fe_3O_4 or ferrites are formed: 1) The oxidation step of the Fe^{II} ion, where such intermediates as green rusts and γ-FeO(OH) are formed, and 2) the transformation step of the intermediates into Fe_3O_4 or ferrites without any oxidation reaction.

In the present paper, we have studied the transformation of γ-FeO(OH) into Fe_3O_4 and/or green rust II in the presence of Fe^{II} and SO_4^{2-} ions without any oxidation reaction. The reaction mechanism of the transformation will be discussed.

Experimental

Chemicals. All the chemicals were of an analytical grade, and distilled water was used for the preparation of the chemical solutions. The NaOH solution was prepared by dissolving NaOH in distilled water through which nitrogen gas had been passed to remove the dissolved oxygen. The γ-FeO(OH) was prepared according to the method described in a previous paper.[13]

Apparatus. The reaction vessel used in a previous paper was adopted.[13] The reaction vessel was immersed in a water bath, and the reaction temperature was kept at 298±0.5 K.

Procedures. Throughout the experiments, we tried to avoid leakage of oxygen into the reaction suspension. After passing nitrogen gas through a suspension of γ-FeO(OH) (0.7 dm^3, 0.002 kmol m^{-3}) of the desired pH (8.5 or 10.0), and $Fe(OH)_2$ suspension (0.02 dm^3, 0.40 kmol m^{-3}) of that pH was added. The suspension thus obtained will be referred to as "the reaction suspension." The reaction was initiated when the $Fe(OH)_2$ suspension was added. The reaction pH was maintained at 8.5 or 10.0±0.03 by adding a sulfuric-acid solution. The amount of released OH^- was estimated from the volume of the sulfuric-acid solution consumed. The time from the addition of the $Fe(OH)_2$ suspension is referred to as "the reaction time." In the course of the reaction, 0.005-dm^3 portions of the reaction suspension were taken out at constant time intervals using a syringe and transferred to a tartaric-acid solution (10 w/v%, pH 6.0, 0.04 dm^3). After allowing the suspension thus obtained to stand for 60 min, the suspension was centrifuged at 4000 r.p.m. The precipitate was washed with the tartaric-acid solution. The Fe_3O_4 formed and the γ-FeO(OH) left unreacted do not dissolve in the tartaric-acid solution, but the intermediate green rust II(GR-II) does. The precipitate thus obtained was dissolved in a 0.002-dm^3 HCl solution (1:1). The Fe^{II} and Fe_{total} in the solution were determined. The amount of Fe_3O_4 was evaluated from the Fe^{II} concentration by assuming the stoichiometric chemical composition of Fe_3O_4. The amount of γ-FeO(OH) left unreacted was evaluated from the difference between the amount of Fe^{III} in the precipitate and Fe_3O_4. The amount of the intermediate dissolved in the tartaric-acid solution was evaluated from the difference between the amount of Fe^{III} in the initial reaction suspension and the sum of the Fe^{III} in the Fe_3O_4 and γ-FeO(OH) found in the suspension. The intermediate dissolved in the tartaric-acid solution will henceforth be referred to as "the TA-soluble intermediate."

The sample for X-ray diffractometry was prepared as follows: The precipitate obtained through the centrifugation of the reaction suspension was mounted on a glass plate under a nitrogen atomosphere and sealed with cellophane tape to prevent oxidation. For the IR spectroscopy, the precipitate was washed with oxygen-free acetone to remove as much water as possible and then dried under a nitrogen atmosphere. The IR spectra of the dried product were obtained as Nujol mulls.

Chemical Analysis. The Fe^{II} and Fe_{total} concentrations were determined by the 2,2′-bipyridyl method.[16] The Fe_{total} concentration was determined after reducing the Fe^{III} to Fe^{II} with hydroxylamine.

Results and Discussion

Dissolved Species (DS) and the TA-soluble Intermediate. As reported previously,[13] when the Fe^{II} ion was added to the γ-FeO(OH) suspension (pH 8.5) in the absence of SO_4^{2-} (Curve A in Fig. 1), γ-FeO(OH) was transformed to Fe_3O_4 (Curve C). In this reaction, γ-FeO(OH) adsorbs the Fe^{II} ion, dissolves, and it transformed to Fe_3O_4.[13] The adsorption reaction is written as:

$$\gamma\text{-FeO(OH)}(s\text{-}) + FeOH^+ \rightleftharpoons \gamma\text{-FeO(OH)}(s\text{-}FeOH^+), \quad (1)$$
(ADInt)

where *s*- is the adsorption site of γ-FeO(OH) and where ADInt is the Fe^{2+}-adsorbed intermediate.[13,17] The dissolved species formed in the dissolution step will be composed of Fe^{II} and Fe^{III} ions. The dissolution step will be given by:

$$\text{ADInt} \longrightarrow (Fe^{2+})_x(Fe^{3+})_y \text{ complex}, \quad (2)$$
(DS)

where DS means the dissolved species.

As can be seen in Fig. 2, when the SO_4^{2-} ion was present in the reaction suspension, γ-FeO(OH) (Curve A) was not transformed to Fe_3O_4 (Curve C), but to a TA-soluble intermediate (Curve B); almost all of the γ-FeO(OH) was transformed to the TA-soluble intermediate in 60 min. The X-ray diffraction pattern of the TA-soluble intermediate precipitate formed within 60 min corresponded to that of green rust II. In the IR spectrum of the precipitate, strong bands due to SO_4^{2-} appeared at 1100 and 630 cm^{-1}. These results suggest that the DS formed in the dissolution step combines with the SO_4^{2-} ion and is transformed to green rust II (GR-II).

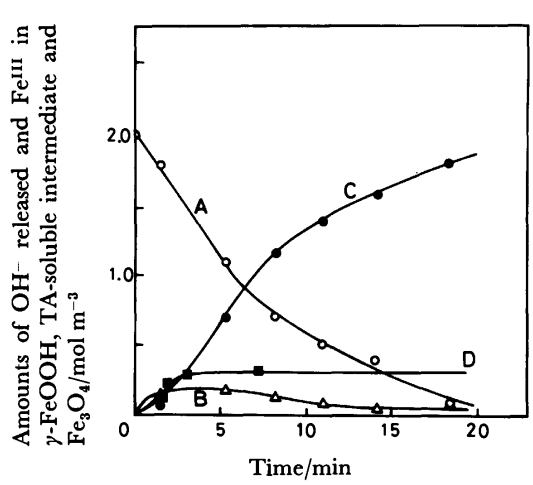

Fig. 1. The transformation of γ-FeOOH to Fe_3O_4 at pH 8.5. $Fe^{2+}/\gamma\text{-FeOOH}=3.60$, $SO_4^{2-}=0$ mol m^{-3}. Curve A; γ-FeOOH, B; TA-soluble intermediate, C; Fe_3O_4, D; OH^-.

Curves D in Figs. 1 and 2 show the release of OH^- during the formation of GR-II. These results suggest that no OH^- is released in the formation of Fe_3O_4, but only in that of GR-II. This OH^--releasing will be discussed later.

Here, we studied the effect of the Fe^{II} concentration on the formation of GR-II from γ-FeO(OH). The results are given in Figs. 3a and 3b, where the reaction pH and the concentrations of γ-FeO(OH) and SO_4^{2-} are the same as those of Fig. 2, but where the Fe^{II} concentrations in the reaction suspensions are lower than that of Fig. 2. As the Fe^{II} concentration in the reaction suspension decreased from 7.40 mol m^{-3} (Fig. 2) to 1.63 mol m^{-3} (Fig. 3b), the consumption of γ-FeO(OH) (Curve A) decreased. The relationship between the

Table 1. The effect of the Fe(II) concentration on the transformation of γ-FeOOH

Figure No.	$Fe^{2+}_{initial}$ (mol m^{-3})	γ-$FeOOH_{initial}$ (mol m^{-3})	$\frac{Fe^{2+}_{initial}}{\gamma\text{-}FeOOH_{initial}}$ (mol m^{-3})	γ-$FeOOH_{reacted}$ (mol m^{-3})	$\frac{Fe^{2+}_{initial}}{\gamma\text{-}FeOOH_{reacted}}$ (mol m^{-3})
2	7.40	2.06	3.60	1.92	3.70
3a	3.08	2.06	1.50	1.38	2.23
3b	1.67	2.06	0.81	0.68	2.46

amount of reacted γ-FeO(OH) and that of the Fe^{II} ions initially present in the reaction suspension is given in Table 1. The amount of Fe^{II} in the initial suspension is higher than the amount of γ-$FeO(OH)_{initial}$ in Figs. 2 and 3a, but lower than that in Fig. 3b (Column 4 in Table 1). The amount of γ-$FeO(OH)_{reacted}$ (Column 5) decreased as the initial amount of Fe^{II} decreased (Column 2). However, the mol ratios of $Fe^{2+}_{initial}/\gamma$-$FeO(OH)_{reacted}$ (Column 6) are approximately 2 at a $Fe^{2+}_{initial}/\gamma$-$FeO(OH)_{initial}$ ratio below 2 (column 4). This suggests that at least two mols of the Fe^{II} ions are needed to dissolve one mol of γ-FeO(OH). These results suggest that the dissolved species (DS) are composed of one Fe^{III} and two Fe^{II} ions.

Three Stages of γ-FeO(OH)-transformation Reaction. At lower Fe^{II} concentrations (Fe^{2+}/γ-$FeO(OH)_{initial}$ ratio below 2; Figs. 3a and 3b), the amount of GR-II increased, attaining its maximum as the reaction proceeded (Curve B). When the amount of GR-II became near the maximum in Figs. 3a and 3b (indicated by arrows), the Fe_3O_4 formation (Curve C) became prominent. The amount of Fe_3O_4 increased with time, accompanied by the consumption of γ-FeO(OH) (Curve A). However, as the reaction proceeded further (*cf.* Figs. 3a and 3b), the amount of GR-II decreased (slightly in Fig. 3a, but prominently in Fig. 3b). This decrease resulted in the Fe_3O_4-formation (Curve C) without any consumption of γ-FeO(OH), indicating that GR-II is transformed to Fe_3O_4.

Thus, at lower Fe^{II} concentrations (the $Fe^{2+}_{initial}/\gamma$-$FeO(OH)_{initial}$ ratio below 2), the DS is transformed to GR-II in the initial stage, and then to Fe_3O_4 in the second stage, where no further GR-II is formed. In the third stage, the transformation of GR-II to Fe_3O_4 mainly occurs.

On the other hand, at a high Fe^{II} concentration ($Fe^{2+}_{initial}/\gamma$-$FeO(OH)_{initial}$ ratio=3.60, Fig. 2), only the first-stage reaction is seen. In this case, an excess of Fe^{II} ions is present, since $Fe(OH)_2$ precipitates coexist throughout the reaction. This means that the suspension contains dissolved Fe^{II} ions, whose concentration is estimated to be about 10^{-4} kmol m^{-3} from the solubility product of $Fe(OH)_2$. On the other hand, in the case shown in Figs. 3a and 3b, since most of the Fe^{II} ions are consumed in the formation of GR-II, the concentration of the dissolved Fe^{II} ions seems to become lower than 10^{-4} kmol m^{-3} as the reaction proceeded. This lowering of the Fe^{II} concentration seems to cause the second-stage reaction. That is, in the second stage (Figs. 3a and 3b), the GR-II-formation reaction seems to attain an equilibrium as a result of the lowering of the concentration of the dissolved Fe^{II} ions.

Derivation of Empirical Formula of the Dissolved Species (DS). Since the Fe^{II} ion is adsorbed in the hydrolyzed form, $FeOH^+$, and since two mols of Fe^{II} ions seem to react with one mol of γ-FeO(OH), the adsorption step may be written as:

$$\gamma\text{-FeO(OH)}[(OH)_s(O)_s] + 2Fe(OH)_2 \rightleftharpoons \gamma\text{-FeO(OH)}[(OH)_sFeOH^+(O)_sFeOH^+] + 2OH^- \quad (3)$$
(ADInt*)

where the subscript s denotes the adsorption site. Here, it is assumed that one Fe^{II} ion is adsorbed on the OH group of γ-FeO(OH), and another, on the oxygen of the oxo-bridge of γ-FeO(OH). Since one OH^- ion takes part in the dissolution step,[13] the dissolution step may be given by:

$$ADInt^* + OH^- \longrightarrow DS. \quad (4)$$

In the absence of SO_4^{2-}, the γ-FeO(OH) is transformed to Fe_3O_4 (Fig. 1). In this reaction, it is considered that the DS is directly transformed to Fe_3O_4. Since the DS contains one Fe^{III} and two Fe^{II} ions, the Fe_3O_4-formation reaction from DS may be given by:

$$DS \longrightarrow 1/2Fe_3O_4 + 3/2Fe^{2+} + x/2OH^- + y/2H_2O. \quad (5)$$

The overall reaction obtained from Eqs. 3, 4, and 5 for the Fe_3O_4 formation from γ-FeO(OH) is written as:

$$\gamma\text{-FeO(OH)} + 2Fe(OH)_2 \longrightarrow 1/2Fe_3O_4 + 3/2Fe(OH)_2 + (x/2-2)OH^- + y/2H_2O. \quad (6)$$

or:

$$\gamma\text{-FeO(OH)} + 1/2Fe(OH)_2 \longrightarrow 1/2Fe_3O_4 + (x/2-2)OH^- + y/2H_2O \quad (6')$$

As stated previously, no OH^- is released during the Fe_3O_4 formation from γ-FeO(OH) (Curve D in Fig. 1). Therefore, $x=4$ in Eq. 6 or 6'. With $x=4$, we get $y=2$. With these x and y values, the DS composition is estimated from Eq. 5 to be $[(Fe^{2+})_2(Fe^{3+})(OH^-)_4(O^{2-})]^{1+}$.

Green Rust-II Formation Reaction from γ-FeO(OH). We know the following: The ratio of Fe^{II}/Fe^{III} in GR-II is 2;[11] the formation of one mol GR-II from one mol of γ-FeO(OH) and 2 mol of $Fe(OH)_2$ forms 2 mol of OH^- (Curves B and D in Fig. 2); the formation of GR-II from γ-FeO(OH) and $Fe(OH)_2$ requires the presence of SO_4^{2-} in the reaction suspension. In addition, GR-II is composed not of ions but of electroneutral precipitates. These findings lead to:

$$\gamma\text{-FeO(OH)} + 2Fe(OH)_2 + SO_4^{2-} \rightleftharpoons [(Fe^{2+})_2(Fe^{3+})_1O_n(OH)_{5-2n}]^{2+}\cdot SO_4^{2-} + 2OH^- + (n-1)H_2O. \quad (7)$$

If the GR-II is formed from DS in SO_4^{2-}-containing suspensions, then the reaction is given by:

$$[(Fe^{2+})_2(Fe^{3+})(OH^-)_4(O^{2-})]^+ + SO_4^{2-} \rightleftharpoons$$
(DS)
$$[(Fe^{2+})_2(Fe^{3+})_1O_n(OH^-)_{5-2n}]^{2+}\cdot SO_4^{2-}$$
(GR-II)
$$+ OH^- + (n-1)H_2O. \quad (8)$$

Equilibrium Consideration of the Green Rust-II Formation. A practical reaction for Eq. 7 is considered to be:

$$\gamma\text{-FeO(OH)} + 2FeOH^+ + SO_4^{2-} \rightleftharpoons$$
$$GR\text{-II} + (n-1)H_2O, \quad (9)$$

where it is assumed that a dissolved $FeOH^+$ ion is a reacting species for Reaction (7). Equation 9 means that $FeOH^+$ is adsorbed on γ-FeO(OH) and that GR-II is formed. The equilibrium constant, K, is given by:

$$K = 1/([FeOH^+]^2[SO_4^{2-}]) \quad (10)$$

or:

$$K = [H^+]^2/(K_h^2[Fe^{2+}]^2[SO_4^{2-}]), \quad (11)$$

where K_h is the hydrolysis constant of Fe^{2+}. Equation 11 tells that the concentrations of the dissolved Fe^{2+} and SO_4^{2-} ions and the proton (pH) affect the formation of GR-II from γ-FeO(OH). Here, we studied the effect of the SO_4^{2-} concentration. Figure 4 shows the results at a low SO_4^{2-} concentration (2.0 mol m^{-3}). As may be seen here, only the first-stage reaction (GR-II formation from γ-FeO(OH)) took place, as in the case of Fig. 2 (high SO_4^{2-} concentration; 10.0 mol m^{-3}). However, in the case of Fig. 4 (low SO_4^{2-} concentration; 2.0 mol m^{-3}), about one fourth of the γ-FeO(OH) remained unreacted, and the formation of GR-II seems to have ceased. This indicates that the formation of GR-II attained an equilibrium at a low SO_4^{2-} concentration. Since an excess of Fe^{II} ions was added, the $Fe(OH)_2$ precipitate coexisted with γ-FeO(OH) and GR-II, but the formation of GR-II did not proceed further because of a lack of dissolved SO_4^{2-}. The substitution of the solubility product of $Fe(OH)_2$ for $[Fe^{2+}]$ in Eq. 11 results in:

$$K = \left(\frac{K_w}{K_h K_{sol}}[OH^-]\right)^2[SO_4^{2-}]^{-1} \quad (12)$$

where K_w is the water-dissociation constant. The K value estimated from Eq. 12 is 2.14×10^8 for the values of $[OH^-]=10^{-5.5}$, $[SO_4^{2-}]=6.6\times10^{-4}$ kmol m^{-3}, $K_h=10^{-9.5}$,[18] and $K_{sol}=10^{-15.15}$.[18]

Table 2 summarizes the concentrations of the Fe^{II} ion calculated for various reaction conditions using Eq. 11 and the K value estimated above. The Fe^{II} concentrations evaluated at the points shown by arrows in Figs. 3a and 3b (Column 2 in Table 2) are lower than those estimated from the solubility product of $Fe(OH)_2$(Column 4). This supports the speculation that the lowering of the concentration of the dissolved Fe^{II} ion causes the cessation of the formation of GR-II from γ-FeO(OH). The Fe^{II} concentration calculated

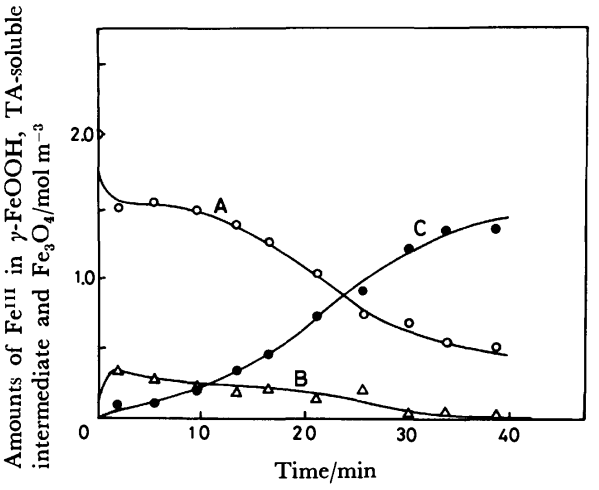

Fig. 5. The transformation of γ-FeOOH to Fe_3O_4 at pH 10.0. Fe^{2+}/γ-FeOOH=3.60, SO_4^{2-}=10.0 mol m^{-3} Curve A; γ-FeOOH, B; green rust II, C; Fe_3O_4.

TABLE 2. CONCENTRATIONS OF THE Fe(II) ION CALCULATED FOR VARIOUS REACTION CONDITIONS USING THE EQUATION $K=[H^+]^2/(K_h^2[Fe^{2+}]^2[SO_4^{2-}])$ AND $K=2.14\times10^8$

pH	Fe^{2+} Concentration Calcd (kmol m^{-3})	SO_4^{2-} Concentration (kmol m^{-3})	Fe^{2+} Concentration Evaluated from the Solubility Product of $Fe(OH)_2$ (kmol m^{-3})
8.5(Fig. 3a)	1.91×10^{-5}	9.13×10^{-3}	7.08×10^{-5}
8.5(Fig. 3b)	1.87×10^{-5}	9.48×10^{-3}	7.08×10^{-5}
10.0	5.75×10^{-7}	1.00×10^{-2} *	7.08×10^{-8}

* The Fe^{2+} concentration was calculated assuming this value, which is near those at pH 8.5.

at pH 10.0 and at a high SO_4^{2-} concentration (10.0 mol m^{-3}) is 5.75×10^{-7} kmol m^{-3}. On the other hand, the Fe^{II} concentration evaluated from the solubility product of $Fe(OH)_2$ at the same pH(10.0) is 7.08×10^{-8} kmol m^{-3}. This suggests that little GR-II is formed at the pH value of 10.0, even at a high SO_4^{2-} concentration. Figure 5 shows the results under those conditions (pH 10.0, SO_4^{2-}; 10.0 mol m^{-3}). As predicted above, the amount of GR-II was very small, and Fe_3O_4 was mainly formed (Curve C in Fig. 5). These results suggest that the DS is transformed to Fe_3O_4 when little GR-II is formed from the DS.

The Base-Catalyzed Isomerization of the (Iminodiacetato)-(*N*-methyliminodiacetato)cobaltate(III) and Bis-(iminodiacetato)cobaltate(III) Ions

Hiroshi KAWAGUCHI,* Tomoharu AMA, and Takaji YASUI
Department of Chemistry, Faculty of Science, Kochi University, Akebono-cho, Kochi 780
(Received February 16, 1984)

The isomerization reaction among three geometrical isomers of $[Co(ida)(mida)]^-$ was studied in a basic aqueous solution. It has been found that the reaction scheme is *u-fac*⇌*mer*⇌*s-fac*. The rates of these isomerization paths have been determined as the functions of pH and temperature. The rate of the *u-fac*⇌*mer* change is considerably faster than that of the *mer*⇌*s-fac* change. The CD loss of the optically active *u-fac* isomer is caused by the isomerization process of *u-fac*⇌*mer*. The isomerization of the $[Co(ida)_2]^-$ system has also been measured, and the rate data analysed according to the same scheme as that used for the $[Co(ida)(mida)]^-$ system. It is suggested that the isomerizations of the $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$ systems proceed through a conjugate-base intermediate.

Octahedral complexes containing two symmetrical terdentate ligands, such as dien, ida, and their analogs,[1] provide three possible geometrical isomers: *s-fac*, *u-fac*, and *mer* (Fig. 1). Legg and Cooke first isolated three geometrical isomers of $[Co(ida)(dien)]^+$.[2] Since then, all geometrical isomers possible in $[Co(dien)_2]^{3+}$ and $[Co(dien)(mdien)]^{3+}$ have been prepared by two groups, Keene *et al.*[3] and Kojima *et al.*[4] The series of the geometrical isomers of $[Co(ida)_2]^-$ became complete when the *mer* isomer was reported by Koine *et al.*[5] Recently, in our laboratory the *u-fac* isomers of $[Co(mida)_2]^-$ and $[Co(eida)_2]^-$, which had been considered not to form because of intramolecular repulsions, were prepared under acidic conditions,[6] and the crystal structure of *u-fac*-$K[Co(mida)_2]\cdot 1.5H_2O$ was determined by X-ray analysis.[7]

Although numerous data of the stereochemistry of the terdentate-ligand complexes have been reported,[8] few data on the rearrangement reactions (isomerization and racemization) of these complexes have been reported. Rearrangements in the octahedral complexes can occur by either of two path ways; the intramolecular pathway or the complete ligand-dissociation pathway. The major pathway of the intramolecular rearrangements involves twist and bond-rupture mechanisms, but the choice between twist and bond-rupture alternatives has seldom been unambiguous. It was hoped that the use of the terdentate-ligand complexes in mechanistic studies of rearrangement reactions might offer an opportunity of distinguishing between twist and bond-rupture alternatives, since the coupled chelate rings restrict the number of possible interconversions.

Searle *et al.* studied the isomerization of the $[Co(dien)(mdien)]^{3+}$ and $[Co(dien)_2]^{3+}$ complexes and proposed a mechanism occurring through a transient five-coordinate intermediate formed by bond-rupture.[9] The racemization rate of *mer*-$[Co(dien)_2]^{3+}$ was also measured.[10] This reaction process involves a change in the chiral disposition of two N-H bonds at the secondary nitrogen centers. Cooke has described the *u-fac*- and *s-fac*-$[Co(ida)_2]^-$ complexes as being isomerized to each other at a rate depending on the base concentration, and said that the equilibrium distribution of the isomers at room temperature was 28% *u-fac* and 72% *s-fac*.[11] Previously, we ourselves presented preliminary results concerning the reactivities of the $[Co(ida)_2]^-$, $[Co(ida)(mida)]^-$,[12] and $[Co(mida)_2]^-$ complexes.[6] In the present paper, we will describe a detailed study of the isomerization of the $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$ systems.

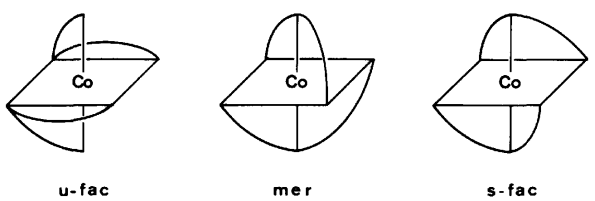

Fig. 1. Three geometrical isomers of the $[Co(L)_2]$ type complex, where L is a symmetrical terdentate ligand.

Experimental

Preparation of Complexes. The three geometrical isomers of $K[Co(ida)_2]$ and the *u-fac* and *s-fac* isomers of K-[Co(ida)(mida)] were prepared according to the method reported in our previous papers[6,12]: *s-fac*-$K[Co(ida)_2]\cdot 2H_2O$, *u-fac*-$K[Co(ida)_2]\cdot 2.5H_2O$, *mer*-$K[Co(ida)_2]\cdot H_2O$, *u-fac*-K-[Co(ida)(mida)]·$2H_2O$, and *s-fac*-$Na[Co(ida)(mida)]\cdot H_2O$.

mer-*K[Co(ida)(mida)]·0.5H₂O*: This complex was obtained by the isomerization of *u-fac*-$[Co(ida)(mida)]^-$ in a weak basic aqueous solution. Five grams of *u-fac*-K[Co-(ida)(mida)]·$2H_2O$ was dissolved in 250 cm^3 of water, after which the solution was adjusted to pH 8.4—8.5 with potassium hydroxide. An isomerization reaction was carried out at 30 °C for 40 min with constant stirring. The resulting solution was slightly acidified (pH 5—6) with acetic acid and evaporated quickly under reduced pressure at 30—35 °C until crystals of the unreacted *u-fac* isomer deposited. A large amount of methanol was added to them, and the *u-fac* isomer was filtered off. The filtrate was evaporated again, and the remaining *u-fac* isomer was removed. By repeating these procedures several times, the crude *mer* isomer was obtained. Recrystallization was carried out from a small amount of water by adding a mixture of methanol-acetone. The fine red crystals thus deposited were filtered and washed with acetone. Found: C, 28.18; H, 3,82; N, 7.27%. Calcd for K[Co(ida)(mida)]·$0.5H_2O$: C, 28.21; H, 3.42; N, 7.31%.

Optical Resolution. The *u-fac* isomers of $[Co(ida)_2]^-$

and [Co(ida)(mida)]$^-$ were resolved into optically active isomers by the methods described in our previous papers[6,12]: (+)$_{589}$-*u-fac*-K[Co(ida)(mida)]·1.5H$_2$O ($\Delta\varepsilon_{592}$=−2.52, $\Delta\varepsilon_{521}$=+2.86) and (+)$_{589}$-*u-fac*-K[Co(ida)$_2$]·H$_2$O ($\Delta\varepsilon_{588}$=−2.43, $\Delta\varepsilon_{509}$=+2.54).

Kinetic Studies. All the chemicals were of a reagent grade, and deionized water was degassed before use. The isomerization reactions were studied spectrophotochemically with the use of a Hitachi 557 spectrophotometer. The reaction vessel with jacket and the cell mounted in the cell holder of the spectrophotometer were thermostated at a constant temperature (±0.1 °C) with circulating water from a constant-temperature bath. During the experiments, the temperatures of the reaction vessel and cell were checked with a thermistor thermometer (Takara D221), and the pH of the reaction solution in the vessel by a Toa TSC-10A pH meter.

The reaction was started by stirring a buffer solution (2.0 cm^3) into the complex solution (18.0 cm^3) in the reaction vessel; *ca.* a 3-cm^3 quantity of this solution was then quickly transferred to the cell in order to record the spectral change in the suitable wave-length range at desired time-intervals. All solutions were prepared at the temperature where runs were to be made, and the following conditions were set: pH, 7.5—10.5 (Na_2HPO_4-KH_2PO_4 or Na_2CO_3-$NaHCO_3$ buffer); complex concentration, 2.8—3.0×10^{-3} mol dm^{-3}; ionic strength, 0.1 ($NaClO_4$); temperature, 25—35 °C. In the case of the isomerization between *mer* and *u-fac*, the wave-lengths chosen for kinetic study were 511 and 503 nm for the [Co(ida)(mida)]$^-$ and [Co(ida)$_2$]$^-$ systems respectively. For the isomerization from an equilibrium mixture of *u-fac* and *mer* to *s-fac*, these wave-lengths at the isosbestic points between *u-fac* and *mer* were chosen: 559 and 548 nm for the [Co(ida)(mida)]$^-$ and [Co(ida)$_2$]$^-$ systems respectively.

The rates of the loss of CD magnitude were measured by means of a JASCO J-22 spectrophotometer using the method and conditions described above.

The plots of $\ln(D_0-D_{eq})/(D_t-D_{eq})$ *vs.* the time and ln[CD magnitude] *vs.* the time gave straight lines over three times the half-lives. Analyses of the kinetic data were carried out on a NEC-8800 computer using the least-squares methods. In each of the rate analyses, the value of the standard error was within ±2% of the rate constant.

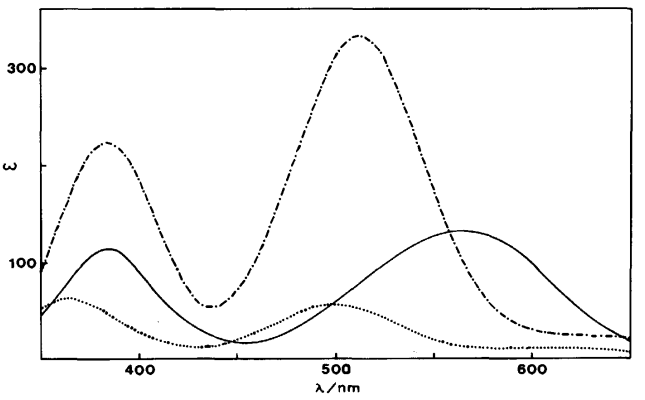

Fig. 2. Absorption spectra of three geometrical isomers of [Co(ida)(mida)]$^-$ in aqueous solution: *u-fac* (——), *mer* (—·—), and *s-fac* (·····).

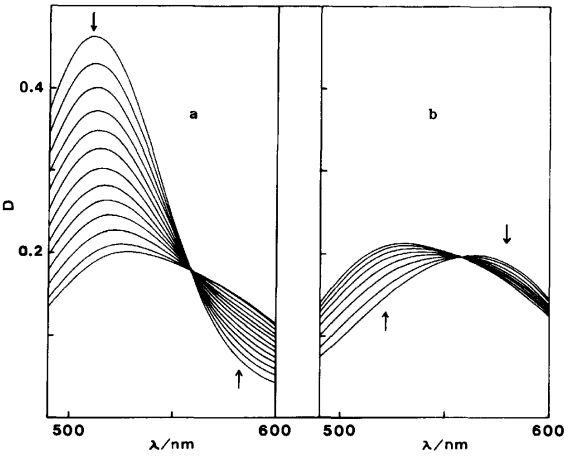

Fig. 3. The time-course changes of absorption spectra of *mer*- and *u-fac*-[Co(ida)(mida)]$^-$ in weak basic aqueous solutions at 30.0 °C. The record intervals are arbitrary: (a) *mer* (2.81×10^{-3} mol dm^{-3}), pH=8.02; (b) *u-fac* (2.98×10^{-3} mol dm^{-3}), pH=7.80.

Results and Discussion

mer-K[Co(ida)(mida)] Complex. The absorption spectrum of *mer*-[Co(ida)(mida)]$^-$, which was newly prepared, is shown in Fig. 2, together with those of the *u-fac* and *s-fac* isomers reported in a previous paper;[12] the numerical data are as follows. 1st band ($^1A_1\rightarrow{}^1T_1$), $\lambda_{sh}\simeq$625 nm ($\log\varepsilon\simeq$1.39) and λ_{max}=511 nm ($\log\varepsilon$=2.53); 2nd band ($^1A_1\leftrightarrow{}^1T_2$). λ_{max}=384 nm ($\log\varepsilon$=2.36); CT band, λ_{max}=226 nm ($\log\varepsilon$=4.29). The spectral behavior of *mer*-[Co(ida)(mida)]$^-$ is quite similar to that of *mer*-[Co(ida)$_2$]$^-$ and *mer*-[Co(mida)$_2$]$^-$. In these *mer* isomers, the 1st and 2nd absorption maxima shift to the lower-energy side in the order of [Co(ida)$_2$]$^-$<[Co(ida)(mida)]$^-$<[Co(mida)$_2$]$^-$, while the 1st and 2nd bands increase in intensity in the order of [Co(mida)$_2$]$^-$<[Co(ida)(mida)]$^-$<[Co(ida)$_2$]$^-$. These trends are in agreement with those observed in the *u-fac* isomers of [Co(ida)$_2$]$^-$, [Co(ida)(mida)]$^-$, and [Co(mida)$_2$]$^-$.[12]

As the *mer* isomers of [Co(ida)(mida)]$^-$ and [Co(ida)$_2$]$^-$ are not so stable in an aqueous solution (extremely unstable in a basic aqueous solution) and easily isomerize to the *u-fac* and/or *s-fac* isomers, the procedure of separating the *mer* isomer from the others should be carried out quickly at a low temperature. This is one of the reasons for the lower yields of *mer*-K[Co(ida)(mida)] and *mer*-K[Co(ida)$_2$]. These *mer* isomers have the dissymmetrical structure which arises from a chiral disposition of two noncoplanar ligands, but have not yet been resolved into optically active isomers. On the other hand, *mer*-[Co(mida)$_2$]$^-$ is quite stable, even in a weak basic aqueous solution, and has been resolved into optically active isomers.[5,13]

Isomerization Reactions of the [Co(ida)(mida)]$^-$ System. Figure 3 shows the spectral changes in *mer*- and *u-fac*-[Co(ida)(mida)]$^-$ in weak basic solutions. The *u-fac* isomer changed its spectrum with an isosbestic point at 559 nm, and it gave the final curve in Fig. 3-b after *ca.* 2 h. (We use the term "pseudo-equilibrium state" to describe this state.) However, after that time the intensity of the spectrum (at the pseudo-equilibrium state) began to decrease very slowly under the conditions of pH 7.80 at 30 °C. The prolonged reaction

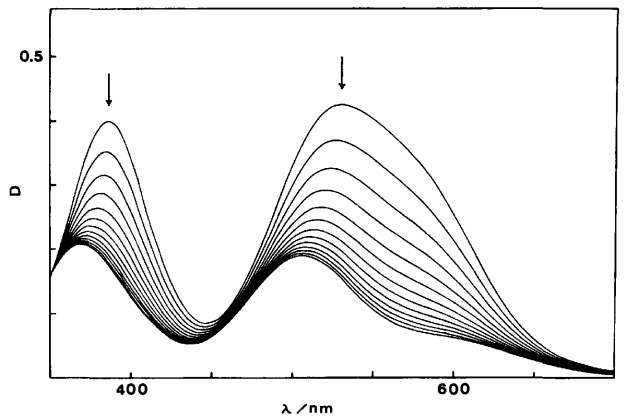

Fig. 4. The time-course change of absorption spectra of *u-fac*-[Co(ida)(mida)]$^-$ in basic aqueous solution (pH=10.10) at 30.0 °C. Record interval is 10 min.

gave the same spectral change as that shown in Fig. 4. The *mer* isomer also showed the spectral change with the passage of time in a weak basic solution, giving an isosbestic point at 559 nm (Fig. 3-a). The final curve in Fig. 3-a, recorded after *ca.* 1.5 h, is identical with that in Fig. 3-b. The subsequent spectral change was the same as that observed in the case of the *u-fac* isomer. The isosbestic point at 559 nm shown in Fig. 3 quite agrees with the point of intersection of the absorption curves of the *mer* and *u-fac* isomers in Fig. 2.

The spectral change in the second step, as shown in Fig. 4, occurred at a considerable rate in the higher-pH region (pH>10). The spectral pattern at the final equilibrium state is fairly close to that of the *s-fac* isomer. The same final spectral pattern was also observed for the final solution starting from the *s-fac* isomer. The resulting mixture at the final equilibrium state was chromatographed on a QAE-Sephadex column, but no other species except for the three geometrical isomers of [Co(ida)(mida)]$^-$ were detected. The *mer* isomer could not be clearly detected on the column chromatograph, because the *mer* isomer is present in a very small amount at the final equilibrium state and is not easily separated from the *s-fac* isomer on the QAE-Sephadex column.

With each spectral curve in Fig. 4, the intensities of absorption ($D(\lambda_x)$) at an arbitrary wave-length (λ_x) due to only *mer* and *u-fac* can be estimated using the following formulas.

$$D(\lambda_x) = D_{obsd}(\lambda_x) - \varepsilon_{s\text{-}fac}(\lambda_x)\cdot[s\text{-}fac]$$

$$D_{obsd}(559) = \varepsilon_{s\text{-}fac}(559)\cdot[s\text{-}fac] + \varepsilon_{u\text{-}fac}(559)\cdot[u\text{-}fac+mer]$$

$$[u\text{-}fac+mer]+[s\text{-}fac] = [\text{complex}]_0$$

where $[\text{complex}]_0$ is the initial concentration of the complex, where $D_{obsd}(\lambda_x)$ denotes the observed optical density at λ_x nm in Fig. 4, and where $\varepsilon(\lambda_x)$ is molar absorptivity at λ_x nm of the isomer shown as a subscript. The values of $D(\lambda_x)$ at various wave-lengths decrease in the same ratio to each other (Table 1). This suggests that the $[mer]/[u\text{-}fac]$ ratio can be regarded as constant during the isomerization reaction from the *u-fac-mer* mixture to the *s-fac* isomer except for the very first stage

Table 1. The intensities of absorption ($D(\lambda_x)$) at several wave-lengths (λ_x) attributably to only *mer*- and *u-fac*-[Co(ida)(mida)]$^-$, as calculated from the spectral data in Fig. 4

λ_x/nm	$D_t(\lambda_x)$ Time/min 10	30	60	$D_t(\lambda_x)/D_{60}(\lambda_x)$ Time/min 10	30	60
600	0.206	0.138	0.080	2.58	1.73	1
550	0.328	0.221	0.129	2.54	1.71	1
500	0.269	0.181	0.106	2.54	1.70	1
450	0.071	0.048	0.028	2.53	1.71	1
400	0.278	0.187	0.109	2.55	1.72	1

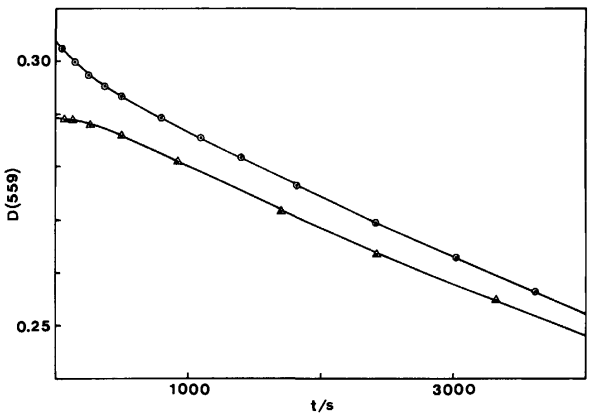

Fig. 5. The time-course changes of absorbance at 559 nm for *mer*- and *u-fac*-[Co(ida)(mida)]$^-$ in basic aqueous solutions: *mer* (—⊙—) 2.35×10^{-3} mol dm^{-3}, pH=9.09, 30.7 °C; *u-fac* (—△—△—) 2.30×10^{-3} mol dm^{-3}, pH=8.98, 30.4 °C.

of the reaction. Therefore, the reaction scheme of the isomerization reaction can be described as follows:

$$\begin{array}{ccc} & \overset{k_1'}{\rightleftharpoons} & \\ mer & & u\text{-}fac \\ & \underset{k_2'}{} & \\ & \underset{k_s'}{\downarrow}\ \uparrow\underset{k_{-s}'}{} & \\ & s\text{-}fac & \end{array} \qquad (1)$$

Thus, in order to study the isomerization of the [Co(ida)(mida)]$^-$ system, two independent experiments were carried out: The examinations of the *mer*⇌*u-fac* isomerization at pH 7.5—8.5 and of the (*mer*+*u-fac*)⇌*s-fac* isomerization at pH 9.5—10.5. The progress of the *mer*⇌*u-fac* isomerization was followed at 511 nm, and the D_t data for the analysis of kinetics were obtained during the isosbestic point at 559 nm was maintained. Each of the *mer* and *u-fac* isomers was used as a starting material under the same conditions, and the average value of D_{eq} (absorbance at the pseudo-equilibrium state) was used for the kinetic analysis.

The pseudo-first-order rate constants, k_s' and k_{-s}', can be determined from the intensity loss of absorption at 559 nm. However, it is ambiguous which isomer, *mer* or *u-fac*, in an equilibrium mixture isomerized to *s-fac*. Figure 5 shows the plots of absorbance at 559 nm

(D(559)) *vs.* the time using *mer* and *u-fac* as starting materials at pH 9 and 30 °C. In the run using *mer* as the starting material, the D(559) change in the very first stage of the reaction, where the equilibrium between *mer* and *u-fac* should not be achieved, is faster than that observed in the successive time-course. On the other hand, in the run using *u-fac* as the starting material, the initial D(559) change is slower than the subsequent change. These results support the idea that *s-fac* is produced from *mer*, and that Reaction Scheme (1) should be modified as follows:

$$\begin{array}{ccc} mer & \underset{k_2'}{\overset{k_1'}{\rightleftharpoons}} & u\text{-}fac \\ {\scriptstyle k_3'}\downarrow\uparrow{\scriptstyle k_4'} & & \\ s\text{-}fac & & \end{array} \qquad (2)$$

The relationships between the rate constants for Schemes (1) and (2) are $k_4'=k_{-s}'$ and $k_3'=(K+1)k_s'$, where K is equal to k_1'/k_2'. The pseudo-first-order and second-order rate constants for Scheme (2), k' and $k=k'/[OH^-]$, are listed in Table 2. The rate law for each isomerization path can be described as $R=k$[complex]-[OH$^-$], judging from the constancy of the k obtained in the runs with various pHs at a constant temperature (Table 2). The reaction rates for the (*mer*+*u-fac*)$\rightleftharpoons$*s-fac* change were independent of the sort of buffer (carbonate or phosphate buffer); however, an increase in the ionic strength from 0.1 to 1.0 increased the reaction rate (about 35%).

Isomerization Reactions of the [Co(ida)$_2$]$^-$ System. The *mer*-[Co(ida)$_2$]$^-$ complex showed spectral change in a weak basic solution (pH *ca.* 8.0) at 30 °C, giving an isosbestic point at 548 nm; this is consistent with the point of the intersection of the absorption curves of the *mer* and *u-fac* isomers. This implies that the spectral change is due to the *mer*→*u-fac* isomerization. After about 1.5 h, the spectra of the solution showed a nearly constant pattern (pseudo-equilibrium state), and the subsequent spectral change, which was attributed to the isomerization from a mixture of *u-fac* and *mer* to *s-fac*, was very slow under the conditions of pH *ca.* 8.0 and 30 °C. The spectral pattern at the pseudo-equilibrium state was almost identical with that of *u-fac*. Under the same conditions, the *u-fac* isomer showed a tendency of spectral change attributably to the isomerization to the *mer* isomer, but the change was very small. The equilibrium distribution of *u-fac* and *mer* is more favorable for *u-fac* than that in the case of the [Co(ida)(mida)]$^-$ complex.

In an aqueous solution buffered at pH *ca.* 10.0 at 30 °C, the isomerization from a mixture of *u-fac* and *mer* to *s-fac* occurred at a considerable speed, giving isosbestic points at about 474 and 445 nm, which are different from the points of intersection (481 and 443 nm) of the absorption curve of *u-fac* and that of *mer*. Judging from the observation of the isosbestic points, the [*mer*]:[*u-fac*] ratio can be regarded as constant in this process. The ratio ([*mer*]:[*u-fac*]=2.3:97.7) which was calculated using the molar absorptivities of three geometrical isomers at 474 nm was consistent with the ratio ([*mer*]:[*u-fac*]=1.8:98.2) calculated from the absorption data at the pseudo-equilibrium state, within the limits of experimental error.

The isomerizations of the [Co(ida)$_2$]$^-$ system were examined by the same method as that used in the case of the [Co(ida)(mida)]$^-$ system. Even though there was no obvious experimental fact supporting the idea that *s-fac* was produced from *mer*, it seems reasonable to assume that the isomerization scheme for the [Co(ida)$_2$]$^-$ system is the same as that for the [Co(ida)(mida)]$^-$ system. Thus, the data observed were analyzed according to

Each rate constant, k_n' ($n=1-4$), corresponds to that in Scheme (2). The 2nd-order rate constant, k_n, represents $k_n'/[OH^-]$.

Scheme (2). The kinetic parameters are listed in Table 2. As the reaction rates depend on the $[OH^-]$ concentrations with the first-order, the second-order rate constants can be calculated from $k=k'[OH^-]$ (Table 2).

The Loss of Optical Activities in the u-fac *Isomers.* The optically active *u-fac* isomers of the $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$ complexes lost their CD strength with the passage of time in a basic aqueous solution. The rates of CD loss in these complexes depended on the $[OH^-]$ concentration with the first-order. Therefore, the rates are described by a rate law in this form: $-d[\text{CD strength}]/dt=k_{CD}[\text{complex}][OH^-]$. The rate parameters obtained are given in Table 3. In both the $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$ complexes, the comparable values of k_{CD} with k_2 (rate constant for the *u-fac*→*mer* change) indicate that the loss of CD in the *u-fac* isomer is mainly caused by the isomerization process of *u-fac*→*mer*.

During the course of the *u-fac*→*mer* process for the systems of both $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$, the CD spectra decreased in magnitude while keeping the spectral patterns of the optically active *u-fac* isomers used as starting materials. Thus, the isoextinct points of the CD change were observed on a base line. Such CD behavior implies that the *mer* isomer produced from optically active *u-fac* is racemate, but this does not exclude the possibility that *u-fac*→*mer* change might occur through a stereospecific pathway such as *Δ-u-fac*→*mer-δ*-NH,NCH$_3$ (or *Δ-u-fac*→*mer-λ*-NH,NCH$_3$). The dissymmetrical structure of the *mer*-$[Co(ida)(mida)]^-$ or *mer*-$[Co(ida)_2]^-$ complex is due to the chirality described by the stereochemical relationship between the N-H and N-CH$_3$ bonds (or two N-H bonds) of the nitrogen atoms in the two ligands. If the rate of the inversion at the N-center (of the coordinated ida) for the *mer* structure is fast enough compared with the rate of the *u-fac*→*mer* change, the result described above may be expected. (We use the term "inversion" to describe the configurational change about a secondary nitrogen center in *mer*-$[Co(ida)(mida)]^-$ or *mer*-$[Co(ida)_2]^-$ despite the absence of asymmetry.) For the *mer*-$[Co(dien)_2]^{3+}$, $[Co(NH_3)_4(Me\text{-}en)]^{3+}$, $[Co(NH_3)_4(sar)]^{2+}$, and $[Co(en)_2(sar)]^{2+}$ complexes, the rates of the inversion at the secondary nitrogen center have been measured. The observed processes were all described by a rate law of the same form: $R=k[\text{complex}][OH^-]$. The rate constants ($k$) were $2.4\times10^2\ M^{-1}s^{-1}$ for both $[Co(dien)_2]^{3+}$ [10] (at 35.0 °C) and $[Co(NH_3)_4(Me\text{-}en)]^{3+}$ [14] (at 34.3 °C), and $1.9\times10^4\ M^{-1}s^{-1}$ and $7.32\times10^4\ M^{-1}s^{-1}$ for $[Co(NH_3)_4(sar)]^{2+}$ [15] (at 30.0 °C) and $[Co(en)_2(sar)]^{2+}$ [16] (at 30.0 °C), respectively. Therefore, for the present *mer* complexes, which have not yet been optically resolved, the rates of inversion can be expected to be sufficiently faster than the rate of *u-fac*→*mer* isomerization.

Table 3. The rate constants for the CD loss of the optically active *u-fac* isomers of the $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$ complexes in basic aqueous solutions at 30.0 °C

Complex	pH	k'_{CD} / s^{-1}	k_{CD} / $M^{-1}s^{-1}$
$[Co(ida)(mida)]^-$	8.11	1.90×10^{-4}	1.00×10^2
	9.46	4.55×10^{-3}	1.07×10^2
	10.05	1.60×10^{-2}	0.97×10^2
$[Co(ida)_2]^-$	8.15	1.89×10^{-5}	9.11
	9.76	7.61×10^{-4}	9.01
	10.05	1.53×10^{-3}	9.28

The second-order rate constant, k_{CD}, represents $k'_{CD}/[OH^-]$.

Mechanism of Isomerization Reactions. As shown in Table 2, the rate constants of the *u-fac*→*mer* change for $[Co(ida)_2]^-$ are much different from those for $[Co(ida)(mida)]^-$. The equilibrium distributions of the geometrical isomers in both the $[Co(ida)(mida)]^-$ and $[Co(ida)_2]^-$ systems are as follows (at 30 °C):

	u-fac(%)	*mer*(%)	*s-fac*(%)
$[Co(ida)(mida)]^-$	4.1	1.2	94.7
$[Co(ida)_2]^-$	29.0	0.5	70.5

These results indicate that the *u-fac* isomer in the $[Co(ida)(mida)]^-$ system is less stable than the *u-fac* isomer in the $[Co(ida)_2]^-$ system. This fact may be explained by means of the "steric effect" of the N-CH$_3$ group in the mida ligand. Through the examination of the molecular model for *u-fac*-$[Co(ida)(mida)]^-$, we can find the existence of steric repulsion between the N-CH$_3$ group of the mida ligand and the methylene group of the ida ligand. This is also supported by the ^{13}C-NMR data, in which the signals of the two α-carbons in the ida ring appear as more greatly separated doublet peaks in *u-fac*-$[Co(ida)(mida)]^-$ (Δ=2.21 ppm) than in *u-fac*-$[Co(ida)_2]^-$ (Δ=1.61 ppm).[12] The difference (Δ) in the chemical shift between the two acetate rings of an ida ligand is probably related to the difference in inter-ligand steric repulsion. The equilibrium distribution described above also shows that both the ida and mida ligands are liable to adopt the facial structure rather than the meridional one. The distribution value (29.0%) of *u-fac*-$[Co(ida)_2]^-$ is in fair agreement with that (28%) reported by Cooke.[11]

That no other species except for three geometrical isomers were detected in the isomerization reaction of the $[Co(ida)(mida)]^-$ system suggests that the ligand dissociation is not involved in the reaction; if such dissociation were involved, the reaction should provide disproportionation and/or hydrolysis products. Thus, the isomerization must involve only the intramolecular pathway. We can consider two possibilities for the intramolecular rearrangement: twist proceeding through the trigonal-prismatic transition state and bond-rupture forming a five-coordinate intermediate. (Rearrangement occurs in this intermediate and is followed by the recoordination of the $-COO^-$ group.) The *mer*⇌*s-fac* change in Scheme (2) can be sufficiently explained in terms of only the bond-rupture mechanism, whereas the *mer*⇌*u-fac* change may be described by the mechanisms of both bond-rupture and twist. The activation energies (E_a) for each process in Scheme (2) were obtained using the Arrhenius plots of the second-order rate constants in Table 2; the activation parameters calculated are given in Table 4. These

Table 4. The activation parameters for the base-catalyzed isomerization of the [Co(ida)(mida)]$^-$ and [Co(ida)$_2$]$^-$ complexes at 30 °C

	ΔH^* / kJ mol^{-1}	ΔS^* / J K^{-1} mol^{-1}
[Co(ida)(mida)]$^-$		
mer→*u-fac*	69.7±2.9	35.1± 9.7
u-fac→*mer*	75.0±3.2	42.0±10.7
mer→*s-fac*	69.5±2.0	4.0± 6.4
s-fac→*mer*	77.5±2.8	−6.9± 9.2
[Co(ida)$_2$]$^-$		
mer→*u-fac*	73.3±1.6	45.0± 5.4
u-fac→*mer*	73.3±1.7	11.6± 5.8
mer→*s-fac*	91.3±3.7	82.9±12.3
s-fac→*mer*	99.2±3.6	68.5±11.2

results do not offer any conclusive idea for determining the mechanism of the *mer*⇌*u-fac* change.

Cooke *et al.* have reported the base-catalyzed racemization of [Co(edta)]$^-$, which does not have protons on nitrogen atoms, and proposed a twist mechanism, the transient intermediate of which is a seven-coordinate species with the OH$^-$ group.[17] Also in the [Co(mida)$_2$]$^-$ system, which does not have protons on nitrogens, the *s-fac* and *mer* isomers were not isomerized; moreover, the optically active *mer* isomer was not racemized under the conditions of the present experiment. Therefore, for the present complexes with acidic secondary amine sites (ida), the base catalysis of the intramolecular isomerization pathway is more satisfactorily accounted for in terms of a rearrangement process which might proceed through the conjugate base species. The difference in activation energy between [Co(edta)]$^-$ (E_a=136.7 kJ mol^{-1}) and the present complexes may be connected with the difference in reaction mechanism between the two systems. Deprotonation seems to facilitate (1) some possibilities of nitrogen-to-cobalt pπ–dπ bonding (π stabilization) and (2) the adjustment of the bond angles at secondary amine sites which necessarily accompanies stereo change. All the experimental data for the present systems can be explained by the transient five-coordinated conjugate-base intermediate formed by bond-rupture, even though the possibility of twist mechanism should also be considered for the *u-fac*⇌*mer* change.

Studies on the Inelastic Electron Tunneling Spectroscopy of *o*-Hydroxy-, *o*-Amino-, and *o*-Mercaptobenzoic Acid on Aluminium Oxide

Hideaki MONJUSHIRO,* Katsuo MURATA, and Shigero IKEDA
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received February 27, 1984)

Inelastic electron tunneling (IET) spectra were obtained for *o*-hydroxybenzoic acid (OHBA), *o*-aminobenzoic acid (OABA) and *o*-mercaptobenzoic acid (OMBA) adsorbed on aluminium oxide (AlO_x) grown on aluminium film and were analyzed by referring IR results. OHBA is adsorbed on AlO_x with both two functional groups, carboxyl and hydroxyl radicals. In the case of OABA, the adsorption occurs mainly with carboxyl group and the interaction between amino group and AlO_x is rather weak. Mercapto group of OMBA forms two kinds of hydrogen bonding, and a dissociated species on AlO_x. These results indicate that the surface of AlO_x used in this study is highly hydrated and hydroxyl groups on the oxide are reactive with the proton donating sites of the chemical species. IET spectra of *o*-fluoro- and *o*-chlorobenzoic acid were also observed for comparison.

Inelastic electron tunneling spectroscopy (IETS) is a kind of energy loss electron spectroscopy. The principle of IETS is based on the interaction between tunneling electrons and molecules on the interface of an insulating oxide layer and the metal. An excitation mode of a molecule is obtained as a function of energy of tunneling electrons. With respect to the molecular vibrations, both infrared and Raman active modes can be observed in IETS. The details of the principle, techniques and applications of IETS have been well reviewed by several authors.[1-3] Since this spectroscopy is very sensitive, vibrational spectra of molecules adsorbed on the insulating oxide layer with submonolayer coverage could be observed.[4] Therefore IETS is applicable to the state of arts analysis for trace amounts of chemical species. One should note in this case that chemical species containing various functional groups interact with the oxidized aluminium insulating surface, leading to the partial modification of the vibrational spectra of the active sites of a free molecule. And these studies are also helpful to understand the surface property such as acidity and basicity of aluminium oxide grown on aluminium metal.

This paper presents IETS studies on the molecules of bifunctional benzene derivatives: *o*-hydroxy-, *o*-amino-, and *o*-mercaptobenzoic acid on aluminium oxide grown on aluminium film. These compounds possess two different functional groups in single molecule. Comparative analysis on the difference of molecular vibrations between IETS and IR or Raman spectra was carried out to elucidate the adsorbed structure of the proposed compounds and to analyze the reactivity of the functional groups. The study was also attempted to understand the property of the aluminium oxide utilized for IETS measurement.

Experimental

Preparation of Tunneling Junction. Tunneling junctions of Al-Al oxide-Pb sandwich structure were prepared in a specially designed home-made vacuum chamber for this study as shown in Fig. 1. The chamber was evacuated with oil diffusion pump through liquid N_2 trap as low pressure as 2×10^{-5} Pa. It consists of two rooms, an evaporation room for the preparation of metal electrodes and a sample loading room where oxidation of aluminium electrode surface and sample loading are carried out. The entire process of junction preparation was accomplished in this chamber as follows. First, aluminium was evaporated onto a thoroughly cleaned glass slide under a pressure of 5×10^{-4} Pa or below. The oxidation of aluminium film was carried out by exposing it to oxygen gas saturated with water vapor for 5 min. And then 4 μl of sample solution was dropped on the oxide. During the loading procedure, the pressure of the evaporation room was maintained below 1×10^{-3} Pa. This enabled rapid performance of next evaporation process. Lead was evaporated finally to make film strips across the aluminium strip. Loaded junctions with a resistance of 40 to 1000 ohm at room temperature with 1 mm×1 mm junction area were available for measurements of IET spectra.

Measurement of IET Spectra. IET spectra were measured by the device with circuit similar to that of Adler and Jackson[5] as shown in Fig. 2. The bias voltage (20 to 500 mV d.c.) across the junction was applied by low frequency function generator, and an a.c. modulation signal of 1.2 kHz was superimposed on the d.c. bias. The second harmonics of the modulation frequency, being proportional to d^2V/dI^2, was detected with a lock-in amplifier (NF model LI-574). Tunnel-

ing spectra were taken at liquid helium temperature 4.2 K, in a standard double glass liquid helium cryostat to obtain sufficient resolution.[1-3] Peak positions were read with digital voltmeter and the values were converted from millivolt to wavenumber with correlation of 1 mV=8.065 cm^{-1} and then a correction of $-7\ cm^{-1}$ was made to cancel out the superconducting energy gap of lead electrode. The observed line-width of the spectral peaks at half maximum was *ca.* 20 cm^{-1} with modulation voltage of 0.6 mV rms.

Chemicals. Chemicals used were obtained from Wako Pure Chemical Ind. or Nakarai Chemical Co. They were recrystallized before use. Acetone was used as solvent for sample loading.

Results and Discussion

IET Background Spectra. There appear invariably some peaks which contribute to insulating aluminium oxide and metal electrodes in IET spectra.[6] And there is a fear of observing additional peaks due to solvent molecule. In order to subtract these peaks, IET spectrum of the junction treated with acetone was compared with that obtained from the junction with sample solution. Figure 3 shows the IET spectrum obtained from the junction treated with acetone. The spectral feature is similar to that of unloaded junction and peaks due to adsorbed acetone are not present in the spectrum. Thus it is clear that acetone has no influence on the IET spectrum.

Although the surface property of aluminium oxide could be evaluated from the surface hydroxyl stretching frequency,[7] the observed hydroxyl stretching peak position in IET spectrum is thought to be shifted to lower wavenumber from substantial value due to image dipole effect of top lead electrode,[8,9] and the exact magnitude of the shift could not be estimated. However, the oxide used in this study is considered to be hydrated surface, because oxygen containing water vapor was employed to oxidize the aluminium surface at room temperature.[7]

IET Spectra of o-Substituted Benzoic Acids. The IET spectra of *o*-fluorobenzoic acid (OFBA), *o*-hydroxybenzoic acid (OHBA), and *o*-aminobenzoic acid (OABA) adsorbed on aluminium oxide are shown in Fig. 4. Figure 5 shows the IET spectra of *o*-chlorobenzoic acid (OCBA) and *o*-mercaptobenzoic acid (OMBA) adsorbed on aluminium oxide.

These spectra were obtained from junction loaded from 1 mg/cm^3 acetone solution. The observed spectral

range is from 230 to 4000 cm^{-1}. In these spectra each peak position is reproducible within experimental error of ±0.5 mV (±4 cm^{-1}). The observed values (peak positions and relative intensity) and their mode assignments are listed in Tables 1 and 2. The values of IR data (*o*-fluoro- and *o*-chlorobenzoate) are also listed for comparison. Each peak was assigned by referring to the IR and Raman spectra of *o*-disubstituted benzenes,[10,11] *o*-substituted benzoic acids and their alkali metal salts.[12]

Benzene Ring Modes: The vibrational modes of these compounds can be classified into two groups, namely the vibrational modes of benzene ring system and that of substituent groups. Since *o*-substituted benzoic acids are assigned to the C_s point group, the ring system would have 30 normal vibrations comprised of 21 a′ modes (in-plane modes) and 9 a″ modes (out of plane modes) and all modes are both IR and Raman active. Peaks observed in IET spectra of the proposed compounds could be easily identified with the corresponding normal vibrations of the related *o*-disubstituted benzene ring system. Of the expected four aromatic CH stretching modes, two or three peaks are found at a region of 3000 cm^{-1}, and the peak positions

are down-shifted from IR data of the corresponding compounds, respectively. This is presumably due to the effect of top electrode of lead.[9] At the energy region below 1620 cm^{-1}, where the peak shift is negligible, 23 peaks are observed for OCBA, 22 for OMBA, 21 for OFBA and OABA and 20 for OHBA comparing to the expected 26 peaks for normal vibrational modes. Taking into account the coincidence of the wavenumber observed and the number of the peaks below IET spectral range, almost all modes of benzene ring system are observed in IET spectra. The close agreement of the frequency of ring modes between the IETS and IR data indicates that each benzene ring of these compounds has no strong interaction with aluminium oxide surface in chemisorbed structure. On the other hand, the vibrations of substituent functional groups observed in IET spectra show significant difference from those of parent molecules. This fact implies that substituent functional groups to be deformed by junction formation and interaction with aluminium oxide surface could be expected. The bond formation and interaction between the functional groups of sample molecules and aluminium oxide will be discussed below for each compounds.

o-Hydroxybenzoic Acid (OHBA): In the IET spectrum of OHBA chemisorbed on aluminium oxide, the most characteristic mode of carboxylic acid at *ca.* 1700 cm^{-1} corresponding to the C=O stretching vibration is absent. Instead, antisymmetric stretching mode of carboxylato group; ν_a(COO) is observed at 1560 cm^{-1} as a shoulder on the side of intense peak at 1575 cm^{-1} due to benzene ring skeletal stretching mode, and its symmetric stretching mode; ν_s(COO) appears at 1410 cm^{-1} as a broad peak. This indicates that OHBA is adsorbed on aluminium oxide as carboxylate similar to other carboxylic acids.[13,14]

Another characteristic feature of the IET spectrum of OHBA is that there appear no vibrational modes corresponding to hydroxyl group. Solid OHBA has its OH stretching band at 3240 cm^{-1} and in the case of alkali metal salts of OHBA, OH stretching band appears in the range of 2500 to 2900 cm^{-1} owing to the strong intramolecular hydrogen bonding with carboxylate ion.[15] In the IET spectrum, however, no peak due to OH stretching mode is observed in the 2500 to 3600 cm^{-1} region. In-plane bending mode of OH group expected to appear at *ca.* 1200 cm^{-1} is also missing in IET spectrum. A small shoulder at 1201 cm^{-1} in IET spectrum is assigned to substituent group sensitive mode of the ring system, because similar peaks are also observed in IET spectra of OFBA and OABA. These facts imply the formation of phenolate species on aluminium oxide surface in analogy to other phenols.[16] Then, two functional groups in the single molecule of OHBA might interact with aluminium oxide surface.

Two kinds of interaction mode would be presumed for the adsorption of OHBA on aluminium oxide surface. One would coordinate to a single aluminium atom with two active sites of a molecule to form a chelate ring, and the other is the coordination of each functional group to different aluminium atoms to form a bridge structure. If both functional groups coordinate to a single aluminium atom to form a surface chelate, the carboxylato group should have unidentate structure as shown in Fig. 6 (A). It is known that in

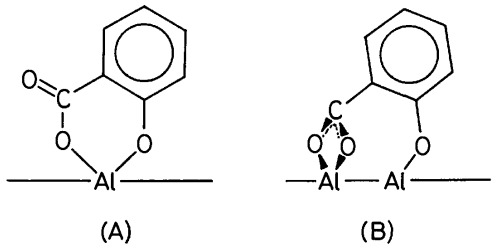

Fig. 6. Schematics of the chemisorption structure of *o*-hydroxybenzoic acid on aluminium oxide.
(A): Chelating structure, (B): bridging structure.

unidentate carboxylate, the wavenumber of ν(C=O) is higher than that of ν_a(COO$^-$) of free carboxylate ion and ν(C-O) is lower than that of ν_s(COO$^-$).[17] Peak positions for carboxylato stretching in IET spectrum of OHBA; ν_a(COO) at 1560 cm^{-1} and ν_s(COO) at 1410 cm^{-1} are in good agreement with IR data of *o*-hydroxybenzoate ion;[15,18,19] ν_a(COO$^-$) at 1546 cm^{-1} to 1593 cm^{-1} and ν_s(COO$^-$) at 1373 to 1410 cm^{-1}. Thus the carboxylato group of adsorbed OHBA is considered to be symmetrical structure like free ion and not unidentate structure. This suggests the adsorption of OHBA on aluminium oxide to form a bridge structure as shown in Fig. 6 (B).

o-Aminobenzoic Acid (OABA): Similar to the case of OHBA, in the IET spectrum of OABA, there observed no feature due to carboxyl group but carboxylato stretching modes appear at 1570 cm^{-1} and at 1405 cm^{-1}. Thus the adsorption of OABA with carboxyl group on aluminium oxide is evident to form surface carboxylate. Close similarity of those carboxylato stretching peak positions with those of OHBA indicates that surface carboxylate has symmetrical structure and chelation does not take place.

Most characteristic vibrational modes reflecting the nature of amino group is its stretching vibrations. In the case of OABA, free amino group gives symmetric and antisymmetric stretching modes in 3300 to 3500 cm^{-1} region,[20,21] amino group coordinated to metal ions such as Cu^{2+} exhibits two or three bands in 3100 to 3300 cm^{-1} region[22] and protonation of amino group would cause further down-shift of the bands. Figure 7 shows the expanded low-noise IET spectrum of OABA in the range of 2500 to 4000 cm^{-1}. Beside the peaks due to aromatic CH stretching modes at 3022 cm^{-1} and at 3062 cm^{-1} and surface OH stretching mode at *ca.* 3620 cm^{-1}, two broad and weak peaks are observed at 3350 cm^{-1} and 3480 cm^{-1}. These peaks could be assigned to symmetric and antisymmetric stretching modes of free amino group respectively. This fact implies that there are no strong interactions between amino group of OABA and aluminium oxide surface such as coordination to surface aluminium atom on the oxide or protonation by surface hydroxyl group observed for other amines by IETS.[23-25]

However, the both observed peaks corresponding to amino stretching vibrations are very broad (the linewidth at half maximum is at least 120 cm^{-1}). This suggests the existence of weak interaction between the amino group and the oxide surface. Formation of hydrogen bonding is most probable to explain the

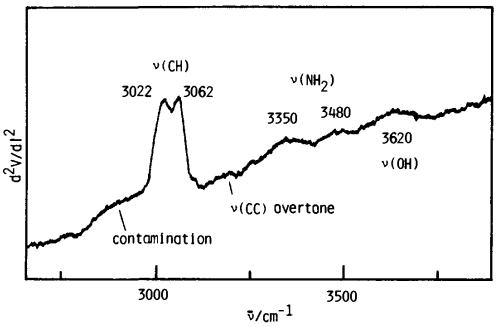

Fig. 7. Expanded IET spectrum of *o*-aminobenzoic acid adsorbed on aluminium oxide in the range of 2500 to 4000 cm^{-1}.

broadening of the amino stretching peaks. However, generally in IR spectra, hydrogen bonding causes the down-shift of corresponding stretching mode,[26] whereas IET spectrum shows no shift from free state frequency. This fact will not be explained by the simple hydrogen bonding assumption. Another modes of amino group expected to lie below 1650 cm^{-1} could not be assigned because of the complexity of the spectrum in this region. Thus further interpretations for the surface interactions between amino group and aluminium oxide surface is quite difficult in the present.

o-Mercaptobenzoic Acid (OMBA): In the IET spectrum of OMBA, there observed carboxylato stretching modes at *ca.* 1559 cm^{-1} and at 1400 cm^{-1}. Both peaks are considered to coincide with ring modes and accurate positions are not found from the spectrum. However, OMBA is considered to be adsorbed on aluminium oxide as carboxylate, because of missing of the carboxyl group vibrations. Although the IET spectrum of OMBA has been published by Hall and Hansma,[14] no data was given so far on the mercapto group frequency observed by IETS and no discussion has been done on the nature of mercapto group.

In IR spectroscopy, the free SH stretching modes of aromatic thiols generally appear near 2585 cm^{-1} and the steric and electronic effects have no influence on the SH stretching frequency.[27] In IET spectrum of OMBA, SH stretching modes appear at 2490 cm^{-1} and at 2540 cm^{-1}. The peak splitting indicates the presence of two kinds of species on the oxide. The down-shift of the peaks referred to IR data is to be due to either image dipole effect of top lead electrode[8,9] or hydrogen bonding of mercapto group. In the case of down-shift caused by top metal, the magnitude of the shift should be relate to the oscillating dipole moment strength of the mode. Whereas SH stretching mode of OMBA observed in IR spectrum is quite weak,[27] indicating a small oscillating dipole moment. Therefore the shift must be due not to the top metal effect, but to hydrogen bonding. And the both two SH stretching peaks in IET spectrum are broad on comparing with other peaks corresponding to the ring modes. This fact also supports the presence of hydrogen-bonded mercapto species on the oxide.

Hydrogen bonding of mercapto group of adsorbed OMBA could be classified into either of following three categories; (**I**) intermolecular hydrogen bonding, (**II**) intra-

molecular hydrogen bonding, and (**III**) hydrogen bonding with aluminium oxide surface. If the intermolecular hydrogen bonding(**I**) is presumed, the number of species(**I**) should be increase with increasing the surface concentration of OMBA. Consequently, the relative intensity of the peak corresponding to species(**I**) should increase. However, no correlation was found between the relative intensity of either peak at 2490 cm^{-1} or at 2540 cm^{-1} and the surface concentration of OMBA. Thus it is clear that species(**I**) is not present on the oxide.

OMBA in solid state or in solution is known to form intramolecular hydrogen bonding(**II**) between mercapto group and oxygen of carboxyl group. Mori *et al.* have studied the mercapto hydrogen bonding in solution by IR spectroscopy in detail.[27] They observed two bands in mercapto stretching wavenumber at 2558 cm^{-1} and at 2530 cm^{-1} in dilute carbon tetrachloride solution of OMBA, and assigned them to the mercapto species having hydrogen bonding with the ethoxyl and carbonyl oxygen atom, respectively. On the contrary, OMBA adsorbed on aluminium oxide forms carboxylate, and the two oxygen atoms of carboxylato group are considered to be equivalent character. Hence when the species(**II**) is formed on the oxide, only a single configuration must be allowed for OMBA and resulting in a single peak in IET spectrum. The peak position can be expected to appear at around the wavenumber between 2530 cm^{-1} and 2558 cm^{-1}. This assumption leads us to conclude the peak at 2540 cm^{-1} observed in IET spectrum to be due to the stretching mode of intramolecular hydrogen-bonding species(**II**).

The relative intensity of the peak at 2490 cm^{-1} varies by sample to sample. This variation indicates the high surface sensitivity of the interaction in nature. Thus the peak at 2490 cm^{-1} is considered to be due to mercapto group, which forms hydrogen bonding with oxide surface(**III**). Formation of hydrogen bonding between mercapto group and aluminium oxide surface has been already observed for methanethiol molecule by the use of IR spectroscopy.[28] The hydrogen-bonding species has its stretching mode at 2470 cm^{-1}. The peak position observed at 2490 cm^{-1} in IET spectrum of OMBA is close to this IR value. Therefore we assign the peak at 2490 cm^{-1} to be due to mercapto species(**III**).

In the course of the study on OMBA, we noticed that the intensity of the peak at 2490 cm^{-1} had a tendency to be stronger when the surface hydroxyl stretching peak appeared stronger in IET spectra. To make sure of this, water molecules were introduced into the complete junction by using infusion doping technique,[29] because the water infusion is expected to increase surface hydroxyl group on the oxide.

Figure 8 shows the expanded IET spectra of OMBA before(A) and after(B) infusion of water. By introducing water molecule into the junction, the peak at *ca.* 3620 cm^{-1} due to surface hydroxyl stretching mode and the peak at 2490 cm^{-1} due to mercapto species(**III**) are both intensified, although the intensities of other peaks remain unchanged. This result indicates that not only the number of surface hydroxyl group but that of mercapto group of struture(**III**) in the junction increase by water infusion. This phenomenon could be explained by assuming the presence of coordination species *via* sulfur atom to surface aluminium atom of the oxide before infusion of water. And this S-bonded species may react with water molecule introduced to form mercapto species(**III**). Consequently, there are three kinds of mercapto species on the aluminium oxide, namely intramolecular hydrogen-bonding species(**II**), species which forms hydrogen bonding with surface oxygen atom(**III**) and S-bonded species.

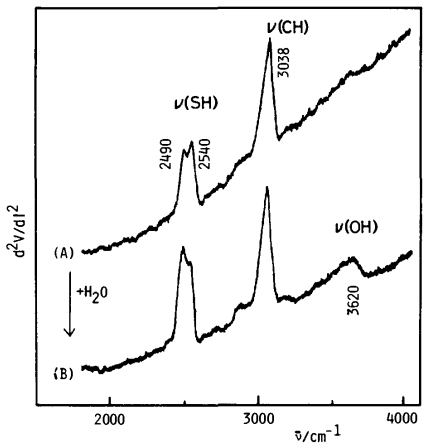

Fig. 8. Expanded IET spectrum of *o*-mercaptobenzoic acid (A): before and (B): after infusion of water.

Property of Aluminium Oxide Surface. The adsorbed feature of the proposed compounds may lead to a suggestion on the surface property of aluminium oxide grown on evaporated aluminium film. In IET spectra of *o*-substituted benzoic acids, it is found that the surface hydroxyl stretching intensity is less than that in back ground spectrum. This indicates the consumption of surface hydroxyl groups with the adsorption reaction of carboxyl group. A presumable reaction is that carboxyl group leaves proton and the proton reacts with surface hydroxyl group to form water. The water produced would be evacuated out during the junction preparation, since the vibrational modes of molecular water are absent in IET spectra. Similar surface reactions are considered to take place on the hydroxyl group of OHBA and partly on the mercapto group of OMBA with surface hydroxyl group.

As discussed above, OHBA is adsorbed on the oxide through both carboxyl and hydroxyl group to form bridge structure, and both functional groups are considered to react with surface hydroxyl groups. Therefore it is thought that there are many neighboring hydroxyl groups on the oxide used. In the case of OABA, amino group of ortho position does not coordinate to the oxidized aluminium despite the possible steric configuration. Then there must be few or no exposed aluminium ion (Lewis acid site)[30] around the carboxylate adsorption site on the oxide.

Consequently, we conclude that the surface of aluminium oxide grown by wet oxygen is highly hydrated and has many neighboring surface hydroxyl groups. The surface hydroxyl groups tend to react with Brønsted acids such as carboxyl group to form water, in other words, the oxide surface behaves as Brønsted base with respect to the proposed compounds.

Conclusion

The IETS of three kinds of *o*-substituted benzoic acid with functional groups, -OH, $-NH_2$, and -SH were studied. All compounds are adsorbed on aluminium oxide as benzoate. The second substituent functional groups show various types of interaction with the oxide surface.

The type of the adsorption reaction of these functional groups on the oxide of IET junction is specifically defined to be acid-base reaction. In this case, the oxide surface behaves as base (OH donor) and the functional groups behave as acid (H donor). The reactivity of the functional groups is the order of

$$-COOH,\ -OH > -SH \gg -NH_2.$$

The results show that the character of aluminium oxide surface utilized for IETS is quite different from that of γ-alumina, which is known to have acidic property.

On the other hand, these surface reactions affect negatively for the utilization of IETS to the identification of unknown chemical species. Further experiences to pile up more IETS data for various compounds are needed as well as the more precise analysis for the characterization of aluminium oxide of IET junction.

Synthesis and Cation-Complexing Ability of Oxo Crown Ethers Containing a Ferrocene Nucleus

Taeko IZUMI,* Takeshi TEZUKA, Sachiko YUSA, and Akira KASAHARA
Department of Applied Chemistry, Faculty of Engineering, Yamagata University, Yonezawa 992
(Received July 20, 1983)

Fifteen new oxo crown ethers having a ferrocene unit as an integral part of the ring member are reported. These oxo crown ethers were synthesized by the reaction of 1,1′-bis(chloroformyl)ferrocene with oligoethylene glycols or heterocyclic dialcohol compounds such as 2,6-bis(hydroxymethyl)pyridine by the high dilution method. Complexing ability of these compounds with alkali, alkaline earth, and transition metal cations was measured by the solvent extraction method.

Since Pedersen's pioneering work,[1] the synthesis of a great number of macrocyclic polyethers has been reported. Among them, several groups of workers[2] have described the preparation of a new type of crown ethers containing a ferrocene unit as a ring member, in which iron atom plays the role of a coordinating atom. In connection with crown ethers, attention has recently been paid to the oxo crown compounds, because some of them showed a different complexing tendency towards cations from normal crown ethers. In this report we describe the synthesis and study the complexing behavior of these ferrocenophanes with alkali, alkaline earth and transition metal picrates.

Results and Discussion

Synthesis. A large number of oxo crown compounds have been synthesized, and their properties were investigated by Bradshaw,[3-11] Vögtle,[12-14] and Kellogg.[15-18] Most of these compounds have been prepared through either the reaction between diacids and dihalides (ditosylates) of oligoethylene glycols (**1**), or the reaction between diacyl chlorides and oligoethylene glycols. Oepen and Vögtle[2a] reported that in the presence of pyridine the reaction between 1,1′-bis(chloroformyl)ferrocene (**2**) and **1** (n=1, 2, 3) in benzene led to the formation of oxo crown ethers (**3**) (n=1, 2, 3) in 29—36% yields, but no detailed spectral data were published (elemental analyses only), and 1,1′-ferrocenediyl dialcohol derivative (**4**) was not mentioned as the coproduct. They also did not refer to the formation of binuclear ferrocenophanes (**5**). In the present study, the syntheses of **3** and **5** were carried out without bases by the modification of Bradshaw's method.[9] For example, the reaction of **1** (n=1) with **2** in dry benzene led to the formation of 1,1′-bis(5-hydroxy-3-oxapentyloxycarbonyl)ferrocene (**4b**) as the main product, and 2,5,8-trioxa[9](1,1′)ferrocenophane-1,9-dione (**3b**) as the minor one. Furthermore, the reaction of **4b** with **2** afforded 2,5,8,22,25,28-hexaoxa[9.9](1,1′)-ferrocenophane-1,9,21,29-tetrone (**5b**). The results of the reactions are summarized in Tables 1 and 2.

The oxo crown ethers containing both a heteroatom such as N, O, or S and the ferrocene unit were synthesized in order to examine the influence of the electron donating heteroatoms on complexing ability of the cation. For example, the reaction of **2** with diols **6** such as 2,6-bis(hydroxymethyl)pyridine (**6a**) was carried out in the presence of the base and resulted in the formation of mononuclear ferrocenophane (**7**) and 1,1′-

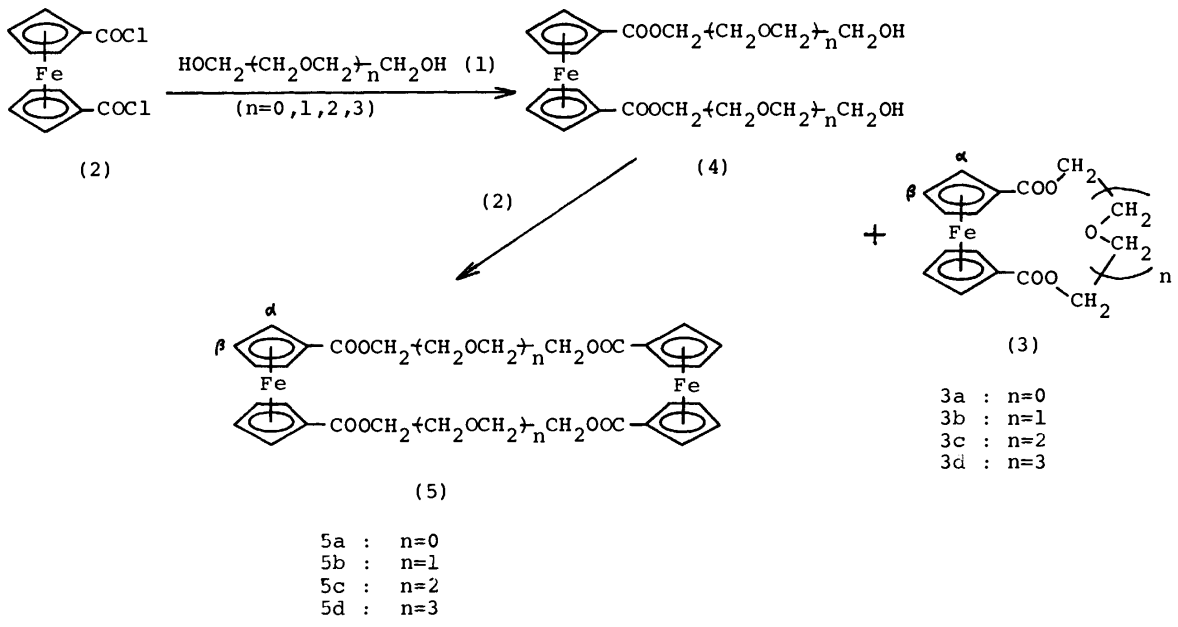

Fig. 1.

ferrocenediyl dialcohol derivative (**9**) (main product). Furthermore, the reaction of diol **9** with **2** led to the formation of **8**, but different results were obtained in the following two cases: 1,1′-Ferrocenediyl dialcohol (**9b**) was not obtained in the reaction of 2,5-bis(hydroxymethyl)furan (**6b**) with **2**, whereas, mononuclear ferrocenophane (**7b**) and binuclear ferrocenophane (**8b**) formed by the one-pot reaction. In addition, the reaction of 2,5-bis(hydroxymethyl)benzene (**6d**) with **2** gave mononuclear ferrocenophane (**7d**) and binuclear ferrocenophane (**8d**) together with 1,1′-ferrocenediyl dialcohol (**9d**). These results indicate that in most cases binuclear ferrocenophane is probably formed by the competitive reaction in the first reaction step, although the yield is extremely low ex-

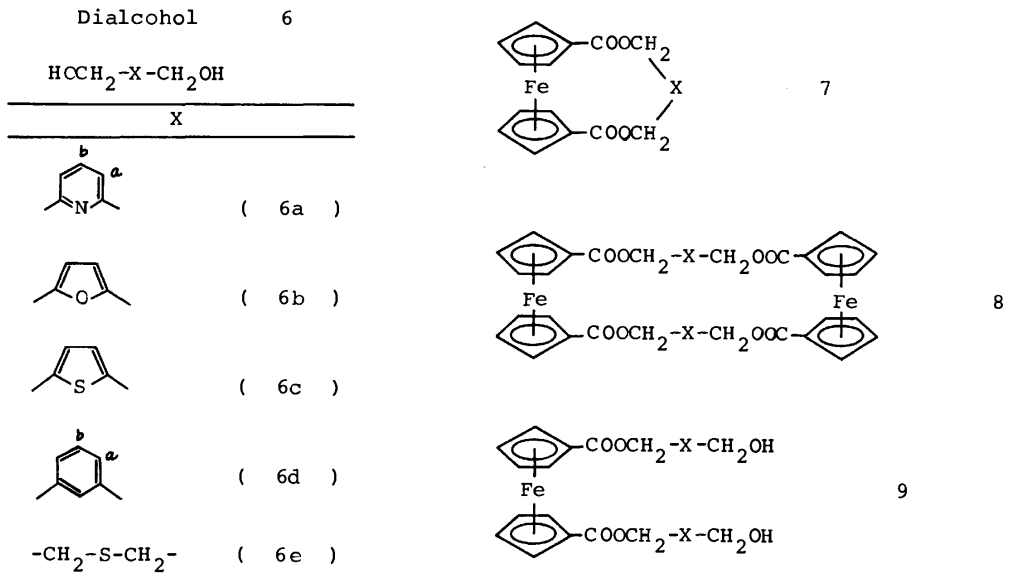

Fig. 2.

cept the above two cases. The results are summarized in Tables 3 and 4.

The structure of all ferrocenophanes thus prepared were determined on the basis of their IR, ^{1}H-NMR, and mass spectra and elemental analyses. The IR spectra of all the crown products showed the presence of an ester (1700—1720 cm^{-1}), a methylene (1460—1470 cm^{-1}), and a 1,1′-disubstituted ferrocene ring (815—840 cm^{-1}). In the ^{1}H-NMR spectra, the resonance for the α and β ring protons of the ferrocene nucleus appeared as the A_2B_2 pattern (triplet, J=4 Hz). In the ^{1}H-NMR spectra of ferrocenophane compounds, **7a—d** and **8a—d** possessing a heterocycle as a ring unit, the methylene protons are shifted to downfield by about 0.80—0.57 ppm as compared with those of **3a** and **5a**. This result was explained by the deshielding effect of the heteroaromatic (**7a—c** and **8a—c**) and aromatic rings (**7d** and **8d**).

Extraction Ability. The complexing ability of these ferrocenophanes toward alkali, alkaline earth, and transition metal cations was examined by Pedersen's extraction method.[19] The results are summarized in Table 5. As is known an increase in the number of the ester group leads to a drastic decrease of the electron donating ability of coordination sites,[20] and the presence of an ester group increases the selectivity toward alkali metal cations.[21] This tendency, however, was not observed clearly in the complexing ability of the ferrocenophanes as compared with that of polyoxaferrocenophanes.[2h,22] The ferrocenophanes (**3a—d** and **5a—d**) showed low complexing ability with alkali, alkaline earth, and transition metal cations without any difference in the extractability. Akabori *et al.*[2h,22] also reported a similar tendency in the extractability of alkali metal cations with polyoxa[*n*]ferrocenophanes prepared from 1,1′-dihydroxyferrocene and 1,1′-bis(hydroxymethyl)ferrocene. In ferrocenophanes **7e** and **8e**, it is anticipated that the incorporation of a sulfur atom (a soft atom) into the macrocycle has a strong influence on the complexing ability with transition metal ions (a soft atom) on the basis of the HSAB principle.[23] It should be emphasized that compound **8e** has a high complexing ability toward silver cation. Comparison of compound **7e** with **8e** suggests that complexing ability is influenced not only by the affinity of sulfur to a metal cation but also by the increase in the ring size. In order to know the influence of heteroatoms, extractability data of new ferrocenophanes (**7a—e** and **8a—e**) containing ferrocene and heterocyclic compound as a ring unit are listed in Table 5. These ferrocenophanes showed a poor extraction efficiency with alkali, alkaline earth, and transition metal cations, and only a small difference is found among their extractability. Compound **8a** is an exception and shows high preference toward silver ion. These results suggest that nitrogen atom has a higher affinity toward metal cations than sulfur atom (**7a** and **8a**). In Table 5, it is noteworthy that all ferrocenophanes are able to form stable complexes with silver, whereas ferrocene itself and many polyoxaferrocenophanes[2h,2j] prepared from 1,1′-dihydroxyferrocene were decomposed oxidatively by the complexed silver cation. Under acidic conditions ferrocenophanes **8a** and **8e** showed high complexing ability with mercury ion without decomposition of ferrocene nucleus. Poor complexing ability of all ferrocenophanes toward thallium ion as a transition metal cation is probably due to the nonfitness between the guest ion and the hole size of the host molecule.

a) Equal volumes of water and dichloromethane are mixed, and the concentration of picric acid is 7.0×10^{-5} M(1M=1 mol dm^{-3}). Concentration of ferrocenophane: 7.0×10^{-4} M. Concentration of metal nitrate: 0.1 M. b) Concentration of $HgNO_3\cdot H_2O$: 0.1 M in 0.6 N HNO_3.

Experimental

Materials and Measurements. All melting points are uncorrected. 1,1′-Bis(chloroformyl)ferrocene (**2**),[24] 2,5-bis(hydroxymethyl)furan,[25] and 2,5-bis(hydroxymethyl)thiophene[26] were prepared as described in the literature. The other reagents employed were commercial materials or were prepared by the usual method. All inorganic compounds were of the reagent grade. The IR, ^{1}H-NMR, mass, and electronic spectra were recorded on Hitachi 260-10, Hitachi R-22 (CW), Hitachi R-90H (FT), Hitachi RMU-6M, and Hitachi 200-10 spectrometers, respectively.

Syntheses of 3a—d. General Procedure: Under nitrogen atmosphere a solution of **2** (8.1 g, 0.026 mol) in dry benzene (200 ml) was added dropwise over 20 h to a refluxing solution of oligoethylene glycols (n=0—3) (0.052 mol) in dry benzene (200 ml). An additional 48 h period of gentle refluxing followed. After the reaction mixture was cooled to room temperature and evaporated to dryness under reduced pressure, the residue was purified by silica-gel column chromatography. The first fraction eluted with benzene gave mononuclear ferrocenophanes **3a—d**, and the second fraction eluted with chloroform gave 1,1′-ferrocene dialcohols **4a—d**. These results are summarized in Table 1.

*2,5-Dioxa[6](1,1')ferrocenophane-1,6-dione (**3a**).* ^{1}H-NMR ($CDCl_3$) δ=4.46 (t, 4H, Fc-Hβ, J=4 Hz), 4.64 (s, 4H, -C$\underline{H}_2$C$\underline{H}_2$-), 4.48 (t, 4H, Fc-Hα, J=4 Hz). IR (KBr): 3100, 2900, 1710, 1470, 1280, 820 cm^{-1}. MS (70 ev): m/z 300 (M^+). λ_{max} (CH_3OH): 455 nm (ε 290). Found: C, 55.98; H, 4.10 %. Calcd for $C_{14}H_{12}FeO_4$: C, 56.03; H, 4.03%; M, 300.09.

*2,5,8-Trioxa[9](1,1')ferrocenophane-1,9-dione (**3b**).* ^{1}H-NMR ($CDCl_3$) δ=3.83 (m, 4H, -C$\underline{H}_2$O-), 4.38 (m, 4H, -COOC$\underline{H}_2$-), 4.46 (t, 4H, Fc-Hβ, J=4 Hz), 4.71 (t, 4H, Fc-Hα, J=4 Hz). IR (KBr): 3100, 2950, 1720, 1470, 1280, 825 cm^{-1}. MS (70 eV): m/z 344 (M^+). λ_{max} (CH_3OH): 450 nm (ε 281). Found: C, 55.72; H, 4.73%. Calcd for $C_{16}H_{16}FeO_5$: C, 55.84; H, 4.69 %; M, 344.15.

*2,5,8,11-Tetraoxa[12](1,1')ferrocenophane-1,12-dione (**3c**).* ^{1}H-NMR ($CDCl_3$) δ=3.76 (s, 4H, -OC$\underline{H}_2$C$\underline{H}_2$-), 3.90 (m, 4H, -COOC$\underline{H}_2$C$\underline{H}_2$O-), 4.40 (m, 4H, -COOC$\underline{H}_2$CH$_2$O-), 4.48 (t, 4H, Fc-Hβ, J=4 Hz), 4.75 (t, 4H, Fc-Hα, J=4 Hz). IR (KBr): 3100, 2950, 1720, 1470, 1280, 825 cm^{-1}. MS (70 eV): m/z 388 (M^+). λ_{max} (CH_3OH): 452 nm (ε 339). Found: C, 55.61; H, 5.10%. Calcd for $C_{18}H_{20}FeO_6$: C, 55.69; H, 5.19%; M, 388.20.

*2,5,8,11,14-Pentaoxa[15](1,1')ferrocenophane-1,15-dione (**3d**).* ^{1}H-NMR ($CDCl_3$) δ=3.69 (s, 8H, -OC$\underline{H}_2$C$\underline{H}_2$OC$\underline{H}_2$C$\underline{H}_2$O-), 3.79 (m, 4H, -COOCH$_2$C$\underline{H}_2$-), 4.39 (m, 4H, -COOC$\underline{H}_2$CH$_2$-), 4.39 (t, 4H, Fc-Hβ, J=4 Hz), 4.78 (t, 4H, Fc-Hα, J=4 Hz). IR (KBr): 3100, 2950, 1710, 1460, 1280, 825 cm^{-1}. MS (70 eV): m/z 432 (M^+). λ_{max} (CH_3OH): 452 nm (ε 355). Found: C, 55.62; H, 5.51%. Calcd for $C_{20}H_{24}FeO_7$: C, 55.57; H, 5.60%; M, 432.25.

*Syntheses of **5a—d**.* *General Procedure*: Under nitrogen atmosphere, **2** (3.1 g, 0.01 mol) diluted with 200 ml of dry benzene was added dropwise over 20 h to the solution of 1,1'-ferrocene dialcohols **4a—d** (0.01 mol) in 200 ml of dry benzene. Additional 48 h period of gentle refluxing followed. After the removal of the solvent under reduced pressure, the residue was purified by silica-gel column chromatography. The first fraction eluted with chloroform-acetone (10:1) gave binuclear ferrocenophanes **5a—d**. The second fraction eluted with chloroform-acetone (1:1) gave an oligomer as a reddish oil. These results are summarized in Table 2.

*2,5,19,22-Tetraoxa[6.6](1,1')ferrocenophane-1,9,21,29-tetrone (**5a**).* ^{1}H-NMR (FT) ($CDCl_3$) δ=4.46 (t, 8H, Fc-Hβ, J=3.96 Hz), 4.63 (s, 8H, -C$\underline{H}_2$C$\underline{H}_2$-), 4.89 (t, 8H, Fc-Hα, J=3.96 Hz). IR (KBr): 3100, 2950, 1720, 1460, 1270, 825 cm^{-1}. MS (70 eV): m/z 600 (M^+). λ_{max} (dioxane): 448 nm (ε 510). Found: C, 55.95; H, 4.11%. Calcd for $C_{28}H_{24}Fe_2O_8$: C, 56.03; H, 4.03%; M, 600.19.

*2,5,8,22,25,28,-Hexaoxa[9.9](1,1')ferrocenophane-1,9,21,29-tetraone (**5b**).* ^{1}H-NMR (FT) ($CDCl_3$) δ=3.83—3.94 (m, 8H, -CH$_2$C$\underline{H}_2$OC$\underline{H}_2$CH$_2$-), 4.41 (t, 8H, Fc-Hβ, J=3.95 Hz), 4.39—4.48 (m, 8H, -COOC$\underline{H}_2$-), 4.82 (t, 8H, Fc-Hα, J=3.95 Hz). IR (KBr): 3100, 2950, 1715, 1470, 1280, 815 cm^{-1}. MS (70 eV): m/z 688 (M^+). λ_{max} (dioxane): 448 nm (ε 580). Found: C, 55.78; H, 4.72%. Calcd for $C_{32}H_{32}Fe_2O_{10}$: C, 55.84; H, 4.69%; M, 688.29.

*2,5,8,11,25,28,31,34-Octaoxa[12.12](1,1')ferrocenophane-1,12,24,35-tetraone (**5c**).* ^{1}H-NMR ($CDCl_3$) δ=3.69 (s, 8H, -OC$\underline{H}_2$C$\underline{H}_2$O-), 3.76—3.81 (m, 8H, -COOCH$_2$C$\underline{H}_2$O-), 4.30—4.35 (m, 8H, -COOC$\underline{H}_2$CH$_2$O-), 4.38 (t, 8H, Fc-Hβ, J=4 Hz), 4.78 (t, 8H, Fc-Hα, J=4 Hz). IR (KBr): 3100, 2950, 1710, 1470, 1280, 820 cm^{-1}. MS (70 eV): m/z 776 (M^+). λ_{max} (dioxane): 449 nm (ε 532). Found: C, 55.61; H, 5.12%. *Syntheses of **7a—e**, **8b**, **d**, and **9a**, **c**, **d**, **e**.* A solution of **2** (5.9 g, 0.019 mol) in 200 ml of dry benzene was added dropwise to a solution of **6** (0.038 mol) and triethylamine (3.8 g, 0.038 mol) in acetonitrile (250 ml) for 20 h under nitrogen atmosphere. Additional 20 h period of gentle refluxing followed. After usual work-up, the products were separated by silica-gel column chromatography. The first fraction eluted with chloroform gave mononuclear ferrocenophanes **7a—e**. The second fraction eluted with chloroform-diethyl ether (9:1) gave **8b** or **8d** from **6b** and **6d**, respectively. The third fraction eluted with chloroform-methanol (9:1) gave ferrocene dialcohols **9a**, **c**, **d**, **e**. These results are summarized in Table 3.

*Syntheses of **8a**, **c**, **d**, **e**.* Under nitrogen atmosphere, reaction of **2** (9.6 g, 0.03 mol) with ferrocene dialcohols **9a**, **c**, **d**, **e** (0.03 mol) and triethylamine (3.0 g, 0.03 mol) in dry benzene (300 ml) gave compounds **8a**, **c**, **d**, **e**, respectively.

Solvent Extraction. Solvent extraction was carried out by the similar method as described by Pedersen.[19] The dichloromethane solution contained 7×10^{-4} M (1 M=1 mol dm^{-3}) of ferrocenophane, and 1×10^{-1} M of MNO_3 (M: metal cation). Equal volumes (10 ml) of the organic and the aqueous solutions were agitated thoroughly for 10 min at room temperature (20—23 °C). After setting the solution, upper aqueous layer was withdrawn, and its electronic spectrum was measured (picrate λ_{max}: 360 nm). A similar extraction was performed with pure dichloromethane. The concentration of the picrate was determined by using the calibration curve. The extractability was calculated by the following equation:

$$\text{Extractability} = \frac{C_0 - C}{C_0} \times 100$$

C_0: Initial concentration of the picrate.
C: Concentration of the picrate after extraction.

Ruthenium Catalyzed Reduction of Nitroarenes and Azaaromatic Compounds Using Formic Acid

Yoshihisa WATANABE,* Tetsuo OHTA, Yasushi TSUJI, Takao HIYOSHI, and Yasuo TSUJI
Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received October 28, 1983)

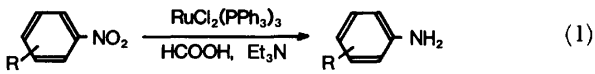
Various nitroarenes having chloro, methyl, or methoxy substituents were reduced to the corresponding aminoarenes in high yields using formic acid in the presence of a catalytic amount of $RuCl_2(PPh_3)_3$. For example, 4-chloronitrobenzene was converted in 99% conversion with 98% selectivity at 125 °C for 5 h. 4-Nitroacetophenone was reduced chemoselectively to 1-(4-nitrophenyl)ethanol in 74% isolated yield under the same reaction conditions. Formic acid could also be employed as reductant for hydrogenation of heterocyclic compounds such as quinoline, indole, and quinoxaline in the presence of the ruthenium catalyst. 2-Methylquinoline was hydrogenated to 1,2,3,4-tetrahydro-2-methylquinoline in 93% conversion with 100% selectivity.

Reduction of nitroarenes is one of the most convenient methods of producing the aminoarenes which are the primary source for various aromatic nitrogen compounds. Molecular hydrogen or hydrogen chloride is generally employed as the hydrogen source in the reaction. However, applications of other hydrogen sources have been developed. As for the reduction of nitroarenes, water was combined with carbon monoxide as the hydrogen source in the water gas shift reaction (WGSR),[1] and amines,[2] alcohols,[3] and cyclohexene[4] were employed as hydrogen donors in transfer hydrogenation.

We have been using formic acid, which is easily derived from synthesis gas, in organic synthesis and have already reported its effectiveness for hydrogenation of carbonyl compounds.[5] In this paper, we describe the reduction of nitroarenes and azaaromatic compounds with formic acid in the presence of a homogeneous ruthenium catalyst.

Results and Discussion

Reduction of Nitroarenes. Nitroarenes were reduced to aminoarenes in high yields using formic acid in the presence of a catalytic amount of $RuCl_2(PPh_3)_3$ (Eq. 1, Table 1). Nitrobenzene was converted to aniline



(1)

in 97% conversion with 97% selectivity. Methyl, methoxy, and chloro substituents at 2- or 4-position did not suppress the reaction. These observations were almost identical with the results reported by Knifton[6] who used molecular hydrogen as reductant in the presence of $RuCl_2(PPh_3)_3$. In the reduction of 4-nitroacetophenone by our system, 1-(4-nitrophenyl)ethanol was the major product, indicating that the reaction is chemoselective (Eq. 2). Knifton reported that 4-aminoacetophenone was mainly formed by molecular hydrogen in the presence of $RuCl_2(PPh_3)_3$ (A in Eq. 3)[7] and Heck also reported that 4-nitroacetophenone was reduced to 4-aminoacetophenone by use of triethylammonium formate in the presence of Pd/C (B in Eq. 3).[8] Furthermore, there have been few reports on the transition metal-catalyzed selective reduction of a carbonyl group in the presence of a nitro group. Tsuji *et al.*[9] have reported that $RuCl_2(PPh_3)_3$ catalyzed the selective reduction of benzaldehyde to benzyl alcohol in the presence of nitrobenzene by molecular hydrogen.

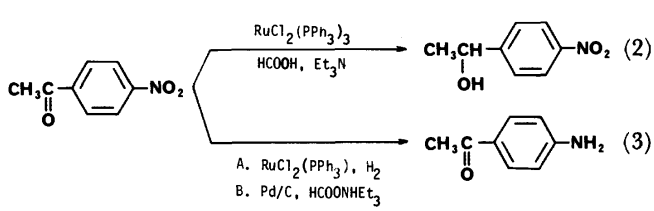


Table 1. Ruthenium-catalyzed reduction of several nitroarenes using formic acid[a]

Run	Nitroarene R=[b]	Product	Conv. of[c] nitroarene/%	Selectivity[d] to product/%
1	H	Aniline	97	97
2	2-Methyl	2-Methylaniline	99	96
3	2-Methoxy	2-Methoxyaniline	94	91
4	2-Chloro	2-Chloroaniline	100	94
5	4-Methyl	4-Methylaniline	86	96
6	4-Methoxy	4-Methoxyaniline	100	97
7	4-Chloro	4-Chloroaniline	99	98
8[e]	4-Acetyl	1-(4-Nitrophenyl)-ethanol		74[f]

a) The mixture of nitroarene (10 mmol), formic acid (33 mmol), Et_3N (35 mmol), ethanol (5 ml), and $RuCl_2(PPh_3)_3$ (0.05 mmol) was stirred at 125 °C for 5 h. b) See Eq. 1. c) Determined by GLC based on the amount of nitroarene used. d) Determined by GLC based on the conversion of nitroarene. e) Formic acid (20 mmol) was used, for 2.5 h. f) The figure in parenthesis is the isolated yield.

Figure 1 shows the pressure change during the reduction of nitrobenzene using formic acid in the presence of $RuCl_2(PPh_3)_3$. This result shows that only a little evolution of molecular hydrogen occurred in the early stage of the reaction.

This reaction proceeded without solvent with high selectivity but the use of solvent hastened the reaction. In Fig. 2, the reaction temperature *vs.* conversion of nitrobenzene is shown. The conversions were affected by the solvent employed. Over 90% conversion was attained at 125 °C in ethanol and at 180 °C in dioxane. Methanol, 2-propanol, and ethanol–benzene were also good solvents for this reaction (Table 2). Thus, alco-

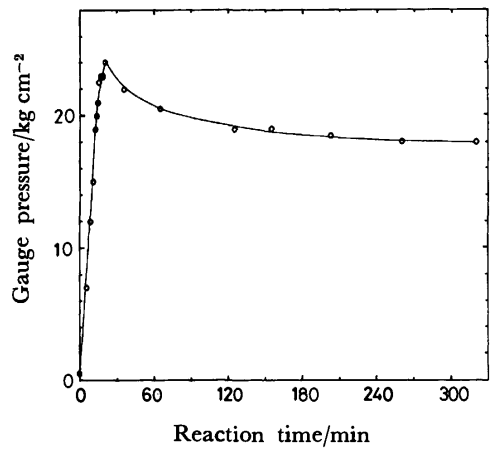

Fig. 1. Ruthenium-catalyzed Reduction of Nitrobenzene using Formic Acid. The pressure change during the reaction.
The mixture of nitrobenzene(10 mmol), formic acid (33 mmol), Et_3N (11.7 mmol), ethanol (5 ml), and $RuCl_2(PPh_3)_3$ (0.05 mmol) was heated at 125 °C in a 50 ml stainless steel autoclave.

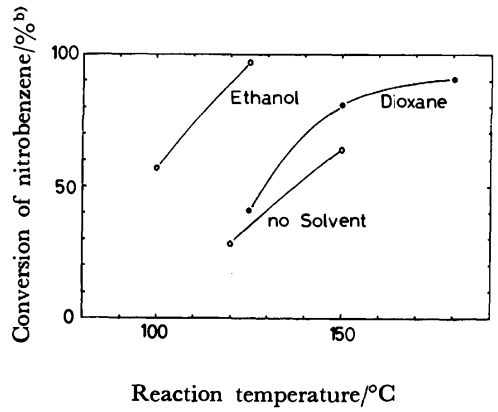

Fig. 2. Ruthenium-catalyzed Reduction of Nitrobenzene using Formic Acid.[a] Effect of Solvent.
a) The mixture of nitrobenzene(10 mmol), formic acid (33 mmol), Et_3N (35 mmol), $RuCl_2(PPh_3)_3$ (0.05 mmol) and solvent (5 ml) was heated for 5 h. b) Determined by GLC based on the amount of nitrobenzene used.

holic solvents gave good results. It is well known that alcohols are good hydrogen donor in the transfer hydrogenation. However, in the present reaction, removal of formic acid from ethanol solution gave aniline in only 2% yield. Therefore, the contribution of the transfer hydrogenation from ethanol was considered negligible in the reaction.

In the present reaction, a base was necessary for high conversion and good selectivity. Runs 14—17 indicate that the presence of triethylamine improved the conversion of nitrobenzene and the selectivity to aniline. *N*-Ethylaniline was obtained as a by-product.[10] The best result was realized in Run 17. Potassium hydroxide showed the same effect as triethylamine. However, good reproducibility was not obtained, since the reaction was heterogeneous.

Catalytic activities of several ruthenium compounds were examined, the results are listed in Table 4. $RuCl_2(PPh_3)_3$ was the most effective catalyst precursor and gave the best result. The highest turnover frequency was 350 (times/5 h) (Run 24). $RuH_2(PPh_3)_4$ and $RuHCl(PPh_3)_3$ also showed catalytic activities with triethylamine, but the conversions of nitrobenzene were

22	KOH (10.0)	2.5	94	90	10

a) The mixture of nitrobenzene (10 mmol), formic acid (33 mmol), ethanol (5 ml), $RuCl_2(PPh_3)_3$ (0.05 mmol), and the base was stirred at 125 °C. b) Determined by GLC based on the amount of nitrobenzene used. c) Determined by GLC based on the conversion of nitrobenzene. d) TMED: *N*,*N*,*N*′,*N*′-Tetramethylethylenediamine.

low without the base (Runs 27 and 29). In order to investigate the role of chloro ligand on the catalyst precursor, $Et_3N \cdot HCl$ (0.1 mmol) was combined with $RuH_2(PPh_3)_4$ in the reduction of nitrobenzene (Run 30). However this resulted in only a slight improvement of the conversion and the selectivity.

There have been several ruthenium-catalyzed reduction of nitroarene. $RuCl_2(PPh_3)_3$ and $RuHCl(PPh_3)_3$ showed good catalytic activities with molecular hydrogen.[6] $Ru_3(CO)_{12}$,[1a,c] $Ru(acac)_3$,[1a] $[Ru(COD)py_4](BPh_4)_2$,[1b] and $H_4Ru_4(CO)_{12}$[1c] were employed as catalysts under water gas shift reaction conditions (with water and carbon monoxide pressure). $RuCl_3 \cdot 3H_2O$ catalyzed the transfer hydrogenation with indoline[2] and $Ru_3(CO)_{12}$ were used in the phase transfer reaction.[11] The present reduction system using formic acid shows the same results as (or better results than) the above catalytic systems under similar reaction conditions. Furthermore, in the procedure, an excess reductant is not necessary and 1.1 equiv formic acid is sufficient for obtaining high yields of the products. Formic acid is easy to handle as compared with molecular hydrogen and after the reaction formic acid was completely decomposed into carbon dioxide and hydrogen.

TABLE 4. RUTHENIUM-CATALYZED REDUCTION OF NITROBENZENE. CATALYTIC ACTIVITIES OF SEVERAL RUTHENIUM COMPOUNDS[a]

Run	Catalyst	Conversion of[b] nitrobenzene/%	Selectivity[c] to aniline/%
23		16	31

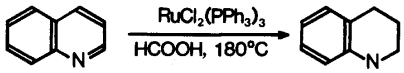
a) The mixture of nitrobenzene (10 mmol), formic acid (33 mmol), Et_3N (35 mmol), ethanol (5 ml), and a catalyst (0.05 mmol) was stirred at 125 °C for 5 h. b) Determined by GLC based on the amount of nitrobenzene used. c) Determined by GLC based on the conversion of nitrobenzene. d) Catalyst, 0.01 mmol. e) Without Et_3N. f) $Et_3N \cdot HCl$ (0.1 mmol) was added.

Reduction of Azaaromatic Compounds. Reductions of azaaromatic compounds by molecular hydrogen in the presence of the transition metal catalyst have been reported.[12] As for the ruthenium-catalyzed reaction, $RuCl_2(CO)_2(PPh_3)_2$ and $H_4Ru_4(CO)_{12}$[12d] catalyzed the reduction of quinoline derivatives. Ruthenium on carbon was used to the reduction of 2,3-benzopyrrole[12e] and the same catalyst was employed with hydrazine as the hydrogen source.[12c] Azaaromatic compounds were also reduced under WGSR conditions.[12d] The transfer hydrogenation is not applicable to azaaromatic compounds, since 1,2,3,4-tetrahydroquinoline, indoline, and their derivatives were very good hydrogen donors in the presence of transition metal catalysts.[13]



(4)

The formic acid-ruthenium catalyst was applied to the reduction of several azaaromatic compounds. The results are listed in Table 5. Formic acid was employed in stoichiometric amounts. In these reactions, different from the case of the nitroarenes, the addition of the base was not necessary for a high yield of the product. However, a higher reaction temperature was required for the high conversion (Runs 31 and 32). Thus, 1,2,3,4-tetrahydroquinoline was obtained in a reasonable yield by the reaction at 180 °C (Run 32). Prolonging the reaction time (18 h) increased the conversion. The hydrogenation occurred only at the azaaromatic ring. Other *N*-heterocyclic compounds were also hydrogenated at the *N*-heterocyclic rings (Runs 34—38). For indole derivatives, the conversions were rather low under the reaction conditions employed (Runs 36 and 37).

The highest catalytic activity was shown by

TABLE 5. RUTHENIUM-CATALYZED REDUCTION OF AZAAROMATIC COMPOUNDS USING FORMIC ACID[a]

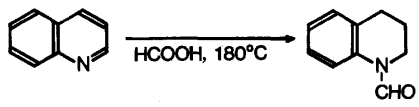
44	$RuH_2(PPh_3)_4$	12	50
45	$Ru(CO)_3(PPh_3)_2$	35	11

a) The mixture of quinoline (40 mmol), formic acid (80 mmol), and a catalyst (0.1 mmol) was stirred at 180 °C for 6 h. b) Determined by GLC based on the amount of quinoline used. c) Determined by GLC based on the conversion of quinoline. 1,2,3,4-THQ: 1,2,3,4-Tetrahydroquinoline.

$RuCl_2(PPh_3)_3$. An almost same equal activity was realized with $RuCl_3 \cdot nH_2O + 3PPh_3$ (Run 41). $Ru_3(CO)_{12}$ and $RuCl_3 \cdot nH_2O$ had some catalytic activities. However, $RuH_2(PPh_3)_4$ and $Ru(CO)_3(PPh_3)_2$ did not catalyze the reaction very much.

When the reaction was carried out with formic acid in the absence of the ruthenium catalyst, 1,2,3,4-tetrahydro-1-quinolinecarbaldehyde was isolated in only low yield (20%) (Eq. 5). This result suggests that the decomposition of formic acid is sluggish without the ruthenium catalyst.



(5)

Other aromatic compounds were employed as substrates. However, pyrene, anthracene, phenanthrene, naphthalene, 2-methylnaphthalene, anisole, and benzene were almost inactive in the present hydrogenation by $RuCl_2(PPh_3)_3$-HCOOH system at 180 °C.

Experimental

All substrates, solvents and amines were obtained from commercial products and were freshly distilled *in vacuo* or recrystallized before use. Formic acid (99%), KOH, K_2CO_3, and $NH_4 \cdot HCl$ were used without further purification. The catalysts; $RuCl_2(PPh_3)_3$,[14] $RuHCl(PPh_3)_3$,[15] $RuH_2(PPh_3)_4$,[16] $Ru_3(CO)_{12}$,[16] and $Ru(CO)_3(PPh_3)_2$[18] were prepared by methods reported in the literature.

GLC analysis was performed on a Shimadzu GC-3BT apparatus. ^1H NMR spectra were obtained at 100 MHz with a JEOL JNM FX-100 pulsed Fourier Transform spectrometer or at 300 MHz with a Nicoled NTC-300 spectrometer equipped with a 1180E computer system. The JEOL JNM FX-100 pulsed Fourier Transform spectrometer was also used to measure the 25.05 MHz ^{13}C NMR spectra. The IR spectra were measured on a Hitachi model 215 grating spectrophotometer. Elemental analyses were performed at the Microanalytical Center of Kyoto University. The mass spectra were recorded on a JMS OlSG mass spectrometer.

Reduction of Nitroarenes. A nitroarene (10 mmol), formic acid (33 mmol), a ruthenium complex (0.05 mmol), Et_3N (35 mmol), and ethanol (5 ml) as an solvent were placed in a 50 ml stainless steel autoclave with a magnetic stirring bar. The air was replaced with argon. Then the autoclave was heated to 125 °C in 20 min and held at this temperature for 5 h. The reaction was terminated by rapid cooling. The reaction products were isolated by distillation or extraction with HCl aq (10%). The identification of the products were performed by comparing the spectral data(^{13}C, ^1H NMR and IR spectra) with those of authentic samples. The conversions of the substrate and the selectivities to the products were determined by GLC (3 mmϕ×3 m column packed with 10% Versamid 900 on Neopak 1A 60—80 mesh or 5% Apiezon Grease L on Neopak 1 A 60—80 mesh) by the internal standard methods.

1-(4-Nitrophenyl)ethanol: Isolated by medium-pressure column chromatography (silica gel, Merck No.9385, hexane-ethyl acetate as the eluent). IR (neat) 3360 (ν_{OH}), 1615 and 1350 (ν_{NO_2}), 1095 (ν_{COH}), and 870 cm^{-1} (ν_{CN}). ^1H NMR ($CDCl_3$) (100 MHz) δ=1.49 (d, 3H, CH_3), 3.75 (s, 1H, OH), 4.96 (q, 1H, CH), and 6.38—8.11 (m, 4H, phenyl ring). ^{13}C NMR ($CDCl_3$) δ=25.36 (q), 69.34 (d), 123.58 (d, 2C), 126.17 (d, 2C), 146.89 (s), and 153.47 (s).

Reduction of Azaaromatic Compounds. A 100 ml stainless steel autoclave with a magnetic stirrer bar was used in the reaction. A typical reaction with quinoline and formic acid will be described here to exemplify the general procedure adopted. A mixture of quinoline (40 mmol), formic acid (80 mmol), and $RuCl_2(PPh_3)_3$ (0.1 mmol) was stirred magnetically at 180 °C under an argon atmosphere for 6 h. In the reaction with indole, 2-methylindole, and quinoxaline, benzene (20 ml) was used as solvent.

Reaction products were isolated by distillation or column chromatography (silica gel). 1,2,3,4-Tetrahydroquinoline and indoline were identified by comparing the ^1H and ^{13}C NMR spectra with those of authentic samples. 1,2,3,4-Tetrahydro-2-methylquinoline,[19] 2,3-dihydro-2-methylindole,[20] and 1,2,3,4-tetrahydroquinoxaline[21] were identified by comparison of ^1H NMR and/or IR spectra with those of the literature. These products were further confirmed by their ^{13}C NMR spectra. 1,2,3,4-Tetrahydro-4-methylquinoline was determined by ^1H and ^{13}C NMR, IR, mass spectra, and elemental analysis. The analytical data are shown below.

1,2,3,4-Tetrahydro-2-methylquinoline: ^1H NMR (300 MHz) ($CDCl_3$) δ=1.15 (d, 3H, CH_3, J=6.3 Hz), 1.55 (d of d of d of d, 1H, axial proton on 3C, J_{gem}=12.7 Hz, J=11.3, 9.9, and 5.4 Hz), 1.87 (d of d of d of d, 1H, equatorial proton on 3C, J_{gem}=12.7 Hz, J=5.6, 3.6, and 3.3 Hz), 2.68 (d of d of d, 1H, equatorial proton on 4C, J_{gem}=16.4 Hz, J=5.4 and 3.6 Hz), 2.79 (d of d of d, 1H, axial proton on 4C, J_{gem}=16.4 Hz, J=11.3 and 5.6 Hz), 3.33 (q of d of d, 1H, proton on 2C (axial), J=9.9, 6.3, and 3.3 Hz), 3.55 (s, 1H, NH), 6.42 (d of d, 1H, J=7.2 and 0.9 Hz), 6.57 (t of d, 1H, J=7.2 and 0.9 Hz), 6.92 (d, 1H, J=7.2 Hz), and 6.93 (t, 1H, J=7.2 Hz). ^{13}C NMR ($CDCl_3$): δ=22.5 (q), 26.5 (t), 30.0 (t), 47.0 (d), 113.7 (d), 116.6 (d), 120.7 (s), 126.3 (d), 128.9 (d), and 144.3 (s).

2-Methylindoline: ^{13}C NMR ($CDCl_3$) δ=22.1 (q), 37.6 (t), 55.0 (d), 108.8 (d), 118.1 (d), 124.3 (d), 126.8 (d), 128.5 (s), and 150.6 (s).

1,2,3,4-Tetrahydroquinoxaline: ^{13}C NMR ($CDCl_3$) δ=41.2 (t), 114.5 (d), 118.4 (d), and 133.6 (s).

1,2,3,4-Tetrahydro-4-methylquinoline: ^1H NMR (300 MHz) ($CDCl_3$) δ=1.22 (d, 3H, CH_3, J=7.2 Hz), 1.58 (d of d of d of d, 1H, equatorial proton on 3C, J_{gem}=12.0 Hz, J=7.0, 7.0, and 3.6 Hz), 1.88 (d of d of d of d, 1H, axial proton on 3C, J_{gem}=12.0 Hz, J=8.4, 7.0, and 4.2 Hz), 2.83 (q of d, 1H, proton on 4C, J=7.2 and 7.2 Hz), 3.11 (d of d of d, 1H, equatorial proton on 2C, J_{gem}=11.5 Hz, J=7.0 and 4.2 Hz), 3.17 (d of d of d, 1H, axial proton on 2C, J_{gem}=11.5 Hz, J=8.4 and 3.6 Hz), 3.64 (s, NH), 6.34 (d, 1H, J=7.5 Hz), 6.58 (t, 1H, J=7.5 Hz), 6.91 (t, 1H, J=7.5 Hz), and 6.99 (d, 1H, J=7.5 Hz). ^{13}C NMR

($CDCl_3$) δ=22.6 (q), 29.8 (d), 30.2 (d), 38.9 (t), 114.0 (d), 116.7 (d), 126.3 (s), 126.6 (d), 128.2 (d), and 144.1 (s). IR (neat) 3390 cm^{-1} (ν_{NH}). MS (m/z) 147 (M^+) and 132 (M^+-CH_3). Calcd for $C_{10}H_{13}N$: C, 81.58; H, 8.90; N, 9.51%. Found: C, 82.07; H, 8.94; N, 9.72%.

Reaction of Quinoline with Formic Acid without Catalyst. Quinoline (40 mmol) and formic acid (80 mmol) were stirred magnetically in a 100 ml stainless steel autoclave at 180 °C for 6 h under an argon atmosphere. The reaction product was distilled and a colorless oil was obtained.

1,2,3,4-Tetrahydro-1-quinolinecarbaldehyde: Colorless oil, bp 94—98 °C/0.07 mmHg (1 mmHg≈133.322 Pa). ^1H NMR (100 MHz) ($CDCl_3$) δ=4.82 (quint, 2H), 2.71 (t, 2H), 3.71 (t, 2H), 7.07 (s, 4H), and 8.68 (s, 1H). ^{13}C NMR ($CDCl_3$) δ=22.1 (t), 27.1 (t), 40.1 (t), 116.8 (d), 124.2 (d), 126.9 (d), 128.5 (s), 129.5 (d), 137.1 (s), and 160.7 (d). IR (neat) 1670 cm^{-1} (ν_{CO}). MS (m/z) 161 (M^+), 132 (M^+-CHO). Calcd for $C_{10}H_{11}NO$: C, 74.51; H, 6.88; N, 8.69%. Found: C, 74.81; H, 6.91; N, 8.70%.

Preferred Conformations of *cis*-4-Hydroxy-2-chromancarboxylates and Related Compounds. Molecular Force Field Interpretation

Minoru HIROTA,* Kazuhisa ABE, Masamichi SHIBATA, Hiroko SUEZAWA, Kaoru HANAYA,*,† Takashi MURAMATSU,† and Yusaku IKEGAMI††

Department of Applied Chemistry, Faculty of Engineering, Yokohama National University, Hodogaya-ku, Yokohama 240

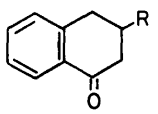
††*Chemical Research Institute of Non-Aqueous Solutions, Tohoku University, Katahira, Sendai 980*

(Received February 3, 1984)

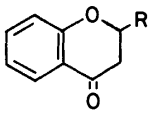
In contrast to *cis*-4-hydroxy-2-tetralincarboxylates, *cis*-4-hydroxy-2-chromancarboxylates take diaxial conformation having 4-pseudoaxial-OH and 2-axial-COOR groups preferably. The preferred conformations of these compounds were rationalized by molecular force field (MM1/MMP1) calculations on the corresponding 2-tetralin- and 2-chromancarbaldehydes as model compounds.

In connection with a series of investigations concerning the stereochemistry of catalytic hydrogenations of 4-chromanones by one of the authors (K. H.), the configuration and conformations of 4-chromanols produced by the reduction has been investigated.[1-3] The cyclohexene-like half-chair conformation has been generally accepted for the ring conformation of 3,4-dihydro-2*H*-1-benzopyrans. However, Philbin and Wheeler[4] proposed a "sofa" conformation in which all but one of the endocyclic atoms are planar. They assumed that the barrier between the sofa and the half-chair conformations is significantly low in these compounds. Contrary to this conclusion, Bolger and co-workers[5] deduced from the vicinal coupling constants of the ring protons that the dihydropyran rings of 4-benzoyloxyflavans take half-chair conformations in solution.

Hanaya and co-workers[1,6-8] found a noteworthy difference in the cis-trans ratios of the alcohols produced by the catalytic hydrogenation of 3-substituted 1-tetralones (**1**) and 2-substituted 4-chromanones (**2**) from those produced by the aluminum isopropoxide reduction of the same ketones. Thus, the *cis*-tetralols

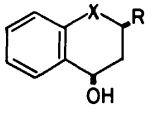


(**1**) R=CH_3, C_6H_5

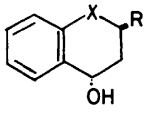


(**2**) R=CH_3, C_6H_5

(**3a**) and *cis*-chromanols (**4a**) were produced almost exclusively when the ketones (**1**) and (**2**) were hydrogenated over a Pd on charcoal or a Raney Ni catalyst, while the *trans*-alcohols (**3b**) predominated when the tetralones (**1**) were reduced by aluminum isopro-



(**3a**) X=CH_2
(**4a**) Y=O



(**3b**) X=CH_2
(**4b**) X=O

R=CH_3, C_6H_5

poxide (the Meerwein-Ponndorf reduction). The catalytic hydrogenation of ethyl 1-tetralone-3-carboxylate gave similarly ethyl *cis*-4-hydroxy-2-tetralincarboxylate, which is revealed to be the less stable epimer by equilibration carried out in the presence of aluminium isopropoxide. The configurations and conformations of these alcohols were discussed on the basis of their infrared spectra in the OH stretching region.[3,9]

On the other hand, ^{1}H NMR vicinal coupling constants are also very powerful in assigning the conformations of different torsional angles about a single bond.[10] Conformations of some 4-substituted flavans were discussed by the complete analysis of their ^{1}H NMR spectra.[5] In this investigation, the conformations of alkyl 4-hydroxy-2-chromancarboxylates and related compounds deduced from the infrared and ^{1}H NMR spectroscopic evidence are shown to be reproduced by molecular force field calculations on 4-hydroxy-2-tetralin- and 4-hydroxy-2-chromancarboxaldehydes as the model compounds.

Experimental

Preparation of the materials by reducing the corresponding ketones has previously been reported.[7,11] ^{1}H NMR spectra were measured with a Hitachi R-20 and a JEOL C-60H spectrometers.

Molecular force field calculations were carried out at the computer center of the Institute for Molecular Science and at the computer center of the University of Tokyo by use of MM1/MMP1 program originally written by Allinger and co-workers[12] and modified by Osawa.

Results and Discussion

In order to determine the preferred conformations, ^{1}H NMR spectra of *cis*- and *trans*-4-hydroxy-2-tetralincarboxylates (**5a** and **5b**), *cis*-4-hydroxy-2-chromancarboxylate (**6a**), and their acetyl derivatives (**7a**, **7b**, and **8a**) were measured in chloroform-*d* at room temperature. In addition, the spectra of the alcohols in dimethyl-d_6 sulfoxide were also measured so as to assure the assignment of H on C(4) which is geminal to the hydroxyl group. The signal of H(4) was complicated by additional spin-spin interaction with hydroxyl proton in DMSO-d_6. The results of ^{1}H NMR measurement are summarized in Table 1.

Vicinal coupling constants have been shown to be

very sensitive to the dihedral angle between the two mutually interacting ^1H nuclei. The dependency of vicinal coupling constant (J_{vic}) on dihedral angle (ϕ) was formulated by Karplus equation and similar equations[10,13,14] and proved to be useful in differentiating gauche ($\phi \approx 60°$) and anti ($\phi \approx 180°$) conformers about the C-C single bond. In the trans isomer (**5b**), the conformer carrying pseudoaxial(*a'*)-4-hydroxyl and equatorial(*e*)-2-alkoxycarbonyl groups is supposed to be predominant, since the alkoxycarbonyl group has a larger conformational free energy difference than the hydroxyl group (2.9 kJ mol^{-1} for OH and 4.6 kJ mol^{-1} for $COOCH_3$).[15] In this conformer, H(4) is pseudoequatorial and located gauche to both equatorial and axial protons on C(3)(*i. e.*, *e*-H(3) and *a*-H(3)). Vicinal coupling constants between axial and equatorial (J_{ae}) and equatorial and equatorial (J_{ee}) protons fall in the range between 2 and 3.5 Hz in the series of cyclohexane derivatives, which agrees with the observed coupling constants for **3b** and **5b**.

The cis isomers, on the other hand, are expected to take a 1,3-diequatorial (*i. e.*, equatorial-2-alkoxycarbonyl and pseudoequatorial-4-hydroxyl) conformation in the usual sense. As a consequence, a doublet of doublets is expected for H(4) due to axial-axial and axial-equatorial ^1H spin-spin interaction, since H(4) should occupy a pseudoaxial position in this conformer. In the case of *cis*-tetralin derivatives (**3a**, **5a**, and **7a**), the observed spectra are in line with the above assumption. However, the J_{vic} values of the *cis*-chroman derivatives (**6a** and **8a**) cannot adequately be interpreted by the 1,3-diequatorial conformation. In turn, slightly distorted 1,3-diaxial conformation (which has axial-2-ethoxycarbonyl and pseudoaxial-4-hydroxyl groups) or an equilibrium mixture of the diaxial and the diequatorial conformers is expected to prevail in these compounds. Thus, the triplets observed with **6a** and **8a** are explained by assuming the predominant 1,3-diaxial conformer having nearly identical J_{ae} and J_{ee} values. The coupling constants (5.0 and 4.5 Hz) seemed rather large for H(eq)-H(eq) and H(ax)-H(eq) spin-spin coupling and coexistence of a small amount of the 1,3-diequatorial conformer in a fast equilibrium with the diaxial one is expected. The coupling constant is not surprisingly large even when the 1,3-diaxial conformer alone is assumed to be present, since the J_{vic} value is calculated to be 4.1 Hz from the Lemieux's parametrization[14] of the Karplus equation assuming that the dihedral angle ϕ is 60°. Lemieux's parameters were derived empirically from the J_{vic} values of oxygen-containing six-membered rings such as 1,3-dioxane and sugars and might be suitable for the estimation of the J_{vic} values of the compounds in the chroman series.

In order to rationalize the conformational preference deduced from the observed NMR spectra, molecular force field calculations were carried out on *cis*- and *trans*-4-hydroxy-2-tetralincarbaldehydes (**9a** and **9b**, respectively) and 4-hydroxy-2-chromancarbaldehydes (**10a** and **10b**, respectively). Since the force field parameters for ester group is less trustworthy even in the revised version of MM1/MMP1 program, a model calculation replacing alkoxycarbonyl by formyl group

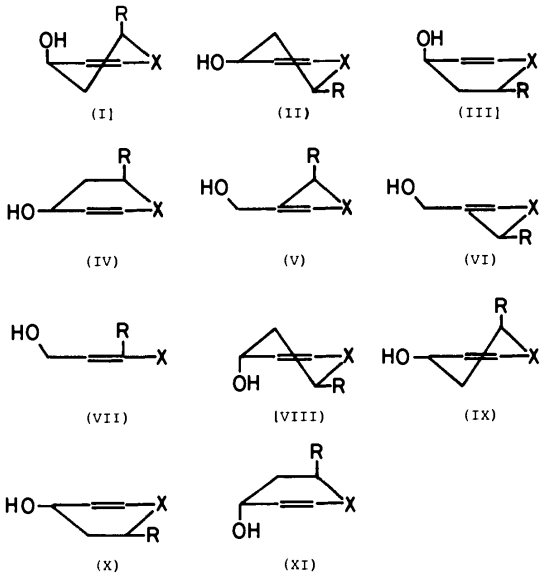

Fig. 1. Conformations selected for molecular force-field calculations. In the cases of **10a** and **10b** in Table 2 and **6a'** in Table 3, X refers to a divalent oxygen atom (O), while X is methylene group (CH_2) with the compounds **9a** and **9b** in Table 4. All coordinates were optimized whenever conformations are stable (*i. e.*, located at potential minima).

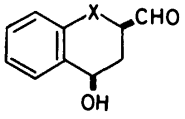
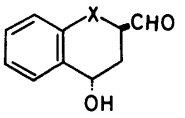
was carried out in order to predict the preferred conformations of the esters **5a** and **6a**. As to *cis*-4-hydroxy-2-chromancarbaldehyde (**10a**), the steric energies were calculated on the seven conformationsin Fig. 1: I, half-chair carrying 4*a*′-OH and 2*a*-CHO; II, half-chair carrying 4*e*′-OH and 2*e*-CHO; III, half-boat carrying 4*a*′-OH and 2*e*-CHO; IV, half-boat carrying 4*e*′-OH and 2*a*-CHO; V, sofa carrying 2*a*-CHO; VI, sofa carrying 2*e*-CHO; and VII, planar conformations (illustrated in Fig. 1). Calculated steric energies (E)



(**9a**) X=CH_2
(**10a**) X=O



(**9b**) X=CH_2
(**10b**) X=O

and their components were given in Table 2, where E_c, E_b, E_{vdw}*, E_{vdw}, E_w, and E_d denote compression (stretching) energy, bending energy, van der Waals energy due to 1,4-interaction, van der Waals energy of other than 1,4-interaction, torsional energy, and dipole interaction energy terms, respectively. E_{sb} and E_{tb} are stretch-bend and torsion-bend cross terms. Similar calculations were carried out on the following four conformations of the trans isomer **10b**: VIII, half chair carrying 4*a*′-OH and 2*e*-CHO; IX, half-chair carrying 4*e*′-OH and 2*a*-CHO; X, half-boat carrying 4*e*′-OH and 2*e*-CHO; XI, half-boat carrying 4*a*′-OH and 2*a*-CHO (illustrated in Fig. 1).

When the total steric energies (E) are compared among the conformations, half-chair conformations are always more stable than other conformations assumed in the calculations. As expected, the half-chair conformation (VIII) carrying 4*a*′-OH and 2*e*-CHO groups is the most stable conformer of the trans isomer **10b**. Quite unexpectedly, the half-chair conformation (I) carrying 4*a*′-OH and 2*a*-CHO groups is estimated to be the most stable for the cis-chroman derivative **10a** by the calculation. The dihedral angles between H(4) and two H(3)'s are calculated to be 50.8° and 68.6°. The J_{vic} values for these dihedral angles from the modified Karplus equation[16] are 5.70 and 4.64 Hz, which reproduces the experimental results for **6a** and **8a** qualitatively. However, the steric energy difference between the most and the next stable conformations is relatively small. From the energy difference (2.26 kJ mol^{-1}), **10a** is expected to exist as a mixture of the two conformers I and II in 69% and 28% abundances, respectively, at room temperature (298 K) by assuming the Boltzmann distribution a priori. Under the conditions of fast equilibrium between the conformers, a similar doublet of doublets is expected as the first order spectrum for H(4).[17] In both cases the triplet-like band shape can be explained if the central two lines is assumed to overlap to each other by broadening.

The results of force field calculations on the two half-chair conformers corresponding to I and II of methyl *cis*-4-hydroxy-2-chromancarboxylate (**6a**′), another model compound for **6a**, are also given in Table 3. As mentioned above, the force field parameters for the ester group is less trustworthy. However, the conformation I is again the most stable. The conformer I becomes more stable relative to the conformer II in this calculation, suggesting higher abundance of the diaxial conformer I. This is also in line with the triplet signal observed.

In order to find out the reason for the stability of the conformer I, the energy terms in Table 2 were examined more carefully. The dipole interaction terms concerning OH, CHO, and ring oxygen are 6.44 kJ mol^{-1} more favorable for the conformer I than for the next stable conformer II. In contrast, van der Waals interaction energy disfavors conformer I considerably when compared with that of the conformer II. Conformations other than the two half-chairs are remarkably disfavored by the contribution of larger repulsive van der Waals and torsional energy terms. After all dipole interaction energy is the most important factor in determining the most stable conformation.

In order to discuss the difference in the conformational preference observed with *cis*-4-hydroxy-2-tetralincarboxylate **5a** and its 1-oxa anolog **6a**, the steric

a) All energies are given in KJ mol^{-1}.

energies for the seven conformations I'—VII' of the model compound **9a** (corresponding to the conformation I—VII, respectively, of **10a**) were calculated as given in Table 4. The most stable conformation of **5a** is estimated to be the half-chair conformation II' in which both 4-hydroxyl and 2-carbonyl groups are equatorial by calculation. The H(4*a'*)/H(3*e*) and H(4*a'*)/H(3*a*) dihedral angles of the conformer II' were calculated to be 50.0° and 166.3°, respectively, from which the spin-spin coupling constants ($J_{a'e}$ and $J_{a'a}$) are estimated to be 5.76 and 8.96 Hz, respectively. The results reproduce the observed coupling constants fairly well. Even in the case of **9a**, the conformation I' (carrying 4*a'*-OH and 2*a*-CHO groups) is considerably favored by the contribution of dipole interaction term. The stabilizing contribution is overcome by the increase in repulsive van der Waals interaction in **9a**. Apparent difference between the molecular structure of **10a** and **9a** is the presence of pseudoaxial hydrogen atom in **9a**, which is supposed to disfavor the axial conformation of formyl group. The sums of E_{vdw} terms between ring 1-CH_2 and 2-CHO groups (inclusive of 1,4-interaction terms) are nearly identical, however. Repulsion between the axial groups causes flattening of the cyclohexene ring, which, in turn, brings about large repulsive 1,4-interaction terms between the atoms in the ring.

The next stable (diaxial) conformer (I') of the aldehyde **9a** has a steric energy only 1.46 kJ mol^{-1} higher than the most stable (diequatorial) conformer (II'). This suggests the possibility for the coexistence of conformers other than II' to a considerable extent. Infrared spectrum of ethyl *cis*-4-hydroxy-2-tetralincarboxylate **5a** shows an absorption band assignable to axial hydroxyl group at 3621 cm^{-1}, which renders a support to the presence of 4*a'*-hydroxy-2*a*-alkoxycarbonyl conformer (I').[18)]

Similarly the model calculations on the trans aldehyde **9b** showed that the half-chair conformer (VIII') carrying 2*e*-formyl and 4*a'*-hydroxyl groups is the most stable, which is again in line with the triplet signal with relatively small J_{vic} values of H(4) for the *trans*-esters **5b** and **7b**.

The molecular force field calculations were carried out by HITAC M-200H computers of the Institute for Molecular Science and, in part, of the University of Tokyo to which the authors are grateful. The authors also thank Prof. Eiji Osawa, Hokkaido University, for his permission to use the MM1/MMP1 program.

16) In general, the Karplus type equations containing only quadratic term of cosϕ tend to underestimate the J_{vic} values when the dihedral angle ϕ is near 90°. Thus the following modified equation to estimate J_{vic} was proposed by M. Karplus (*J. Am. Chem. Soc.*, **85**, 2870 (1963)):

$$J_{vic}=4.22-0.5\cos\phi+4.5\cos^2\phi$$

from which the J_{vic} values were calculated to be 5.1 Hz assuming the dihedral angle to be 60°.
17) The ring reversal from I to II causes the change in dihedral angles from 68.6° to 167.0° for a pair of coupling protons and from 50.8° to 48.5° for the other pair. Thus the J_{vic} values were calculated to be 5.74 and 5.89 Hz, respectively, from the modified Karplus equation[16] as the averages weighted by the abundances of the conformers I and II from MM.
18) Infrared absorption spectra of **5a**, **5b**, and **6a** in the OH stretching region were determined as follows: **5a**, 3621 cm^{-1}(21) and 3599 cm^{-1}(52); **5b**, 3618 cm^{-1}(63); and **6a**, 3610 cm^{-1}(42) and 3596 cm^{-1}(31). Molar absorbances in 1 mol^{-1} cm^{-1} are given in parentheses. No other absorptions were observed in the OH stretching region even with the *cis*-compounds **5a** and **6a**, which excludes the possibility of strong intramolecular hydrogen bonding. See, K. Hanaya, T. Muramatsu, S. Onodera, Y. Ikegami, and M. Hirota, *Bull. Chem. Soc. Jpn.*, **57**, 1695 (1984).

The Acid-catalyzed Decomposition of Diazo Carbonyl Compounds. II. Synthesis of 2- or 5-Heteroatom-substituted Oxazoles

Toshikazu IBATA,* Tsuyoshi YAMASHITA, Makoto KASHIUCHI, Shyuji NAKANO, and Hiroyuki NAKAWA
Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560
(Received February 8, 1984)

The BF_3-catalyzed decomposition of *m*- and *p*-substituted α-diazoacetophenones in excess of methyl thiocyanate and ethyl thiocyanate gave the corresponding 2-methylthio-, and 2-ethylthio-5-aryloxazoles, respectively in good yields along with *s*-alkyl-*n*-aroylmethylthiocarbamates and α-ethoxyacetophenones. However, yields of 2-dimethylamino-5-aryloxazoles by the reaction of dimethylcyanamide with α-diazoacetophenones were poor. 5-Dimethylamino- or 5-alkoxy-4-aryl-2-methyloxazoles were prepared by the reaction of *N,N*-dimethyl-α-(*p*-nitrophenyl)diazoacetamide or alkyl aryldiazoacetates with nitriles. When ethyl phenyldiazoacetate or methyl *p*-chlorophenyldiazoacetate were used, ketazines of alkyl arylglyoxylates were obtained together with oxazoles.

Since the early proposal of Huisgen and his coworkers in 1961,[1] syntheses of oxazoles by the reaction of diazo carbonyl compounds with nitriles have extensively been studied.[2] The oxazole derivatives have recently been paid much attention for their pharmaceutical and biological activities.[3] In our previous paper of this series, we have reported the preparation of oxazoles by the BF_3-catalyzed reaction of α-diazo carbonyl compounds with nitriles.[4] In order to confirm the generality of the reaction, synthesis of 2- or 5-heteroatom-substituted oxazoles was studied.

Results and Discussion

Synthesis of 2-Heteroatom-substituted Oxazoles. Methyl thiocyanate was used as a nitrile component to introduce a methylthio group at the 2-position of oxazole ring. Decomposition of *p*-methoxy-α-diazoacetophenone was carried out in an excess of methyl thiocyanate in the presence of BF_3–etherate at 0 °C. Silica gel column chromatography of the reaction mixture after usual workup[3] gave a colorless crystalline product along with α-ethoxy-*p*-methoxyacetophenone[4] which was identified by the comparison of its IR and NMR spectra with the authentic sample prepared by the BF_3-catalyzed decomposition of the diazoacetophenone in ethanol.[5] Result of elemental analysis and spectral data indicated that the colorless product was 2-methylthio-5-(*p*-methoxyphenyl)oxazole (**3a**: Ar=*p*-$CH_3OC_6H_4$, X=SCH_3).

Similar treatment of *p*-chloro-α-diazoacetophenone yielded 2-methylthio-5-(*p*-chlorophenyl)oxazole (**3e**: Ar=*p*-ClC_6H_4, X=SCH_3) together with *S*-methyl (*p*-chlorophenacyl)thiocarbamate (**4e**: Ar=*p*-ClC_6H_4, X=SCH_3) and α-ethoxy-*p*-chloroacetophenone (**5e**)[5] as by-products. The thiocarbamate (**4e**) has two carbonyl absorption bands at 1685, 1640 cm^{-1}, and an NH absorption at 3325 cm^{-1} in its IR spectrum. The NMR spectrum shows a singlet SCH_3 signal at δ 2.38, a doublet CH_2 signal at δ 4.79 and a broad singlet of

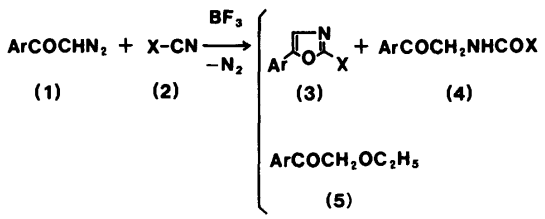
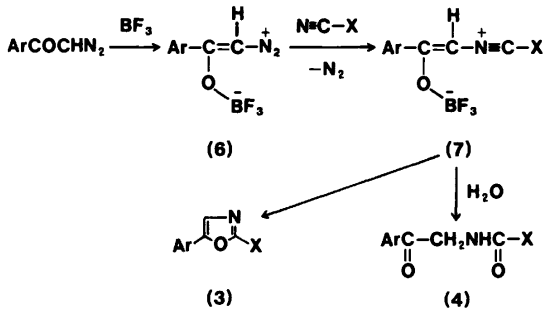
a) Isolated yield by column chromatography. b) Not investigated.

NH at δ 6.50 besides aromatic proton signals.



Other *m*- or *p*-substituted α-diazoacetophenones also gave corresponding oxazoles (**3**), thiocarbamates (**4**), and α-ethoxyacetophenones (**5**) in a similar reaction with methyl thiocyanate as is shown in Table 1. Proton NMR spectra of oxazoles (**3**) show signals of SCH_3 group in the region of δ 2.6—2.7, and that of *S*-methyl thiocarbamate (**4**) at δ 2.27—2.42. Decomposition of unsubstituted and substituted α-diazoacetophenones in the presence of ethyl thiocyanate also gave 2-ethylthio-5-aryloxazoles (3ı–ₙ: X=SC_2H_5). In these reactions, electron-attracting groups on the benzene ring of diazoacetophenones tend to increase the yields of the thiourethane derivatives. The reaction has been explained to be initiated by the attack of BF_3 on carbonyl oxygen of the diazo ketone affording diazonium betaine intermediate (**6**) which gave betaine (**7**) by attacking nitrile nitrogen under extrusion of nitrogen gas.[4] Cyclizaion of betaine (**7**) may produce oxazole (**3**). However, reaction of (**7**) with water contained in the reaction system may give thiocarbamate (**4**).[4] When aliphatic nitriles such as acetonitrile and propionitrile were used, no thiocarbamate (**4**) has been obtained unless considerable amount of water was added in the reaction system.[4]

Similarly 2-dimethylamino-5-aryloxazoles (**3**: X=N-$(CH_3)_2$) were obtained by the reaction of α-diazoacetophenones in excess of dimethylcyanamide (Table 1, run o—q). Low yields of the 2-dimethylaminooxazoles may



Scheme 1.

be attributed to the basicity of dimethylcyanamide which suppresses the catalytic activity of BF_3.

Synthesis of 5-Alkoxy-2-alkyloxazoles. Formation of 5-ethoxy-2-methyloxazole has been reported by the BF_3-catalyzed reaction of ethyl diazoacetate in acetonitrile.[4] Similar results were observed in the reactions of methyl *p*-nitrophenyldiazoacetate in acetonitrile and propionitrile to give corresponding 5-methoxy-4-(*p*-nitrophenyl)oxazoles (**9**) in high yields. However, ethyl phenyldiazoacetate and methyl *p*-chlorophenyldiazoacetate yielded ketazines of alkyl arylglyoxylates (**10**) together with the corresponding oxazoles.

The difference of the reactivity of these aryldiazoacetates is explained by the electronic effect of substituents on the phenyl ring. In the reaction of ethyl phenyldiazoacetate and methyl *p*-chlorophenyldiazoacetate, intermediate diazonium betaine (**12**) reacts either with nitrile or unreacted diazo compound competitively to give an oxazole or a ketazine respectively. However in the reaction of methyl *p*-nitrophenyldiazoacetate, electron-attracting nitro group decreased the nucleophilic reactivity of the diazo ketone toward the diazonium betaine (**12**), and consequently gave the oxazole (**9**) as a sole product by the attack on nitrile. The above mechanism is supported by the fact that the ratio of

Table 2. Yields of the reaction products of alkyl aryldiazoacetate with nitriles

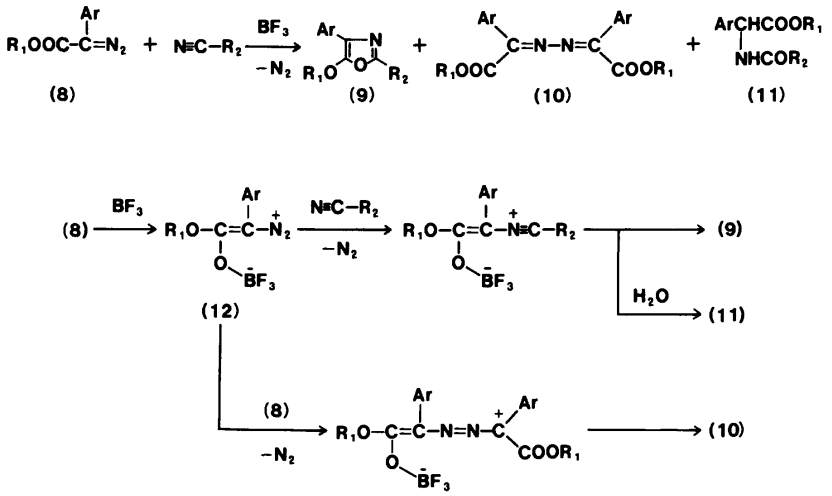
a) 10 ml of nitrile was used unless otherwise described. b) Isolated yield by column chromatography. c) 10 ml of benzene was used as a solvent, and aryldiazoacetate was added all at once. d) Reaction was carried out in absolute benzene.

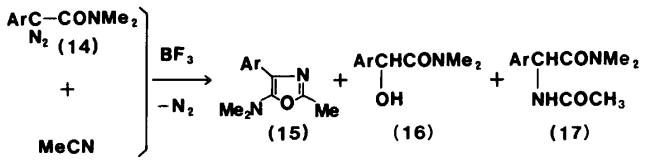


Scheme 2.

oxazole/ketazine changes depending upon the amount of acetonitrile used in the reaction of methyl *p*-chlorophenyldiazoacetate (Table 2). A similar decomposition of methyl *p*-chlorodiazoacetate in benzene without nitrile gave the ketazine (**10d**; 53%) and dimethyl bis(*p*-nitrophenyl)maleate (**13a**; 17%) and fumarate (**13b**; 26%) of which structures were determined tentatively on the basis of ester absorption of their IR spectra.

Propionitrile also showed a similar tendency to give an oxazole as a sole product in the reaction of methyl *p*-nitrophenyldiazoacetate. The BF_3-catalyzed decomposition of methyl *p*-nitrophenyldiazoacetate in methyl thiocyanate did not give the expected oxazole, 2-methylthio-5-methoxy-4-(*p*-nitrophenyl)oxazole, but gave methyl α-[(methylthio)carbonylamino]-*p*-nitrophenylacetate in 20% yield with intractable tarry product. This may be attributed to the unstability of the oxazole.

Similar treatment of *N,N*-dimethyl-α-(*p*-nitrophenyl)diazoacetamide (**14**) in excess of acetonitrile gave 5-dimethylamino-2-methyl-4-(*p*-nitrophenyl)oxazole (**15**) in 4% yield along with *N,N*-dimethyl-*p*-nitromandelamide (**16**; 39%) and *N,N*-dimethyl-α-(acetylamino)-*p*-nitrophenylacetamide (**17**; 26%).



Ar = p-$NO_2C_6H_4$

The screening tests for the several biological activities of the oxazoles obtained in these reactions are now under investigation.

Experimental

Melting points were measured with Yanagimoto Melting Point Apparatus and described without correction. The IR spectra were recorded on Hitachi Infrared Spectrometer model 260-10. The ^1H NMR spectra were recorded in $CDCl_3$ solution at 90 MHz on a Varian Spectrophotometer model EM390 using TMS as an internal standard.

Materials. Diazoacetophenones were synthesized by the reaction of corresponding acid chlorides with excess of diazomethane in the presence of triethylamine according to Newman's method.[6] Methyl *p*-nitrophenyldiazoacetate, and *N,N*-dimethyl-*p*-nitrophenyldiazoacetamide were synthesized by the diazo group transfer reaction reported by Regitz.[7] *N,N*-Dimethyl-*p*-nitrophenyldiazoacetamide (**14**): mp 123.0—123.8 °C; IR (KBr) 2080 (diazo), 1635 (C=O of diazo amide), 1493, and 1325 cm^{-1} (NO_2); NMR ($CDCl_3$) δ=3.07 (s, NCH_3) and 7.40, 8.23 (ABq, *J*=9.3 Hz, Ar). Found: C, 51.36; H, 4.36; N, 23.73%. Calcd for $C_{10}H_{11}O_3N_4$: C, 51.28; H, 4.30; N, 23.92%.

Methyl *p*-chlorophenyldiazoacetate was prepared by the modified diazo group transfer reaction using KF-alumina as a base.[8] To a solution of 4.2 g (20 mmol) of methyl *p*-chlorophenylacetate and 4.3 g (20 mmol) of TsN_3 in acetonitrile 8.6 g of $KF-Al_2O_3$ was added and the mixture was stirred for 120 h at room temperature. Reaction mixture was filtered, and solid phase was washed with benzene. The filtrate was evaporated under reduced pressure and the residue was recrystallized from pentane solution. Methyl *p*-chlorophenyldiazoacetate: Orange crystals; mp 58.5—59.0 °C; yield 87%; IR (KBr) 2080 (diazo), 1690 cm^{-1} (ester C=O); NMR ($CDCl_3$) δ=3.82 (s, OCH_3), and 7.33, 7.35 (ABq, *J*=9.0 Hz, Ar). Found: C, 51.36; H, 3.33; N, 13.25%. Calcd for $C_9H_7O_2N_2Cl$: C, 51.32; H, 3.35; N, 13.30%.

Ethyl phenyldiazoacetate was prepared by the lead tetraacetate oxidation of ethyl phenylglyoxylate hydrazone.[9] Acetonitrile, propionitrile, methyl thiocyanate, ethyl thiocyanate, and dimethyl cyanamide were used after distillation of commercial reagents.

General Procedure of the BF_3-catalyzed Reaction of Diazoacetophenones with Methyl Thiocyanate or Ethyl Thiocyanate. Diazoacetophenone (3 mmol) was added in small portions to a solution of alkyl thiocyanate (10 ml) containing BF_3-etherate (0.5 ml) at 0 °C under magnetic stirring. The reaction proceeded with vigorous evolution of nitrogen and gave gray precipitate. After the N_2 evolution ceased, the reaction mixture was poured into cold water (50 ml) saturated with $NaHCO_3$. Organic products were extracted with ether (50 ml) twice. Combined ether layer was dried over anhydrous Na_2SO_4, solvent was evaporated and then excess thiocyanate was removed by distillation under reduced pressure. The residue was separated by column chromatography using silica gel/benzene. Products were assigned on the basis of NMR and IR spectra and elemental analyses (Tables 3 and 4).

a) The signals of aromatic protons are omitted, and signals are singlet unless otherwise listed. b) Calculated values are listed in parentheses. c) All NH signals are broad singlet. d) Pure thiocyanates were not obtained. e) Besides these signals singlet signal of methyl group is at δ=2.16.

General Procedure of the BF_3-catalyzed Decomposition of Alkyl Aryldiazoacetate in the Presence of Nitriles. A 3.0 mmol of alkyl aryldiazoacetate was added in small portions into 10 ml of nitrile containing 0.5 ml of BF_3-etherate at the temperature described in the Table 2. After vigorous evolution of N_2 gas ended, the reaction mixture was poured into 100 ml of ice water saturated with $NaHCO_3$. Organic products were extracted with ether (50 ml×2). Combined ether solution was dried over Na_2SO_4, ether was removed, and then the residue was chromatographed over silica gel.

Decomposition of Methyl p-*Nitrophenyldiazoacetate in Acetonitrile.* The reaction was carried out at 50 °C by the method described above. 5-Methoxy-2-methyl-4-(*p*-nitrophenyl)oxazole (**9a**): Yellow crystals; mp 121.0—122.0 °C; yield 75%; IR (KBr) 1495 cm^{-1} (C=N); NMR ($CDCl_3$) δ=2.43 (s, CH_3), 4.13 (s, OCH_3) 7.8—8.1 (m, Ar). Found: C, 56.56; H, 4.29; N, 11.90%. Calcd for $C_{11}H_{10}O_4H_2$: C, 56.41; H, 4.30; N, 11.96%. Methyl α-acetylamino-*p*-nitrophenylacetate (**11a**): Pale yellow crystals; mp 139.0—140.5 °C; yield 5%, IR (KBr) 3380 (NH), 1735 (ester C=O), 1650 (amide C=O), 1515, 1350 cm^{-1} (NO_2); NMR ($CDCl_3$) δ=2.04 (s, CH_3), 3.74 (s, OCH_3), 5.70 (d, J=7 Hz, NCH), and 7.5—8.2 (ABq, Ar). Found: C, 52.58; H, 4.72; N, 10.89%. Calcd for $C_{11}H_{12}O_5N_2$: C, 52.38; H, 4.80; N, 11.11%.

Decomposition of Methyl p-*Nitrophenyldiazoacetate in Propionitrile.* The reaction was carried out in a similar procedure described above. 2-Ethyl-5-methoxy-4-(*p*-nitrophenyl)oxazole (**9b**): Yellow crystals; mp 96.0—97.0 °C; yield 84%; NMR ($CDCl_3$) δ=1.36 (t, J=7.5 Hz, CH_3), 2.75 (q, J=7.5 Hz, CH_2), 4.13 (s, OCH_3), and 7.92, 8.23 (ABq, J=9.0 Hz, Ar). Found: C, 58.26; H, 4.87; N, 11.27%. Calcd for $C_{12}H_{12}O_4N_2$: C, 58.06; H, 4.87; N, 11.29%. Methyl α-propionylamino-*p*-nitrophenylacetate (**11b**): Pale yellow crystals; mp 144.0—145.0 °C; Yield 6%; IR (KBr) 3325 (NH), 1732 (ester C=O), 1650 (amide C=O), and 1512, 1355 cm^{-1} (NO_2); NMR ($CDCl_3$) δ=1.17 (t, J=7.5 Hz, CH_3), 2.31 (q, J=7.5 Hz, CH_2), 3.75 (s, OCH_3), 5.69 (d, J=6.6 Hz, NCH), 6.84 (br. d, NH), 7.56, 8.20 (ABq, J=9.0, Ar). Found: C, 54.15; H, 5.22; N, 10.50%. Calcd for $C_{12}H_{14}O_5N_2$: C, 54.13; H, 5.30; N, 10.52%.

Decomposition of Methyl p-*Nitrophenyldiazoacetate in Methyl Thiocyanate.* The reaction was performed in a similar procedure described above. Excess methyl thiocyanate was removed by distillation under reduced pressure before chromatography. Methyl α-[(methylthio)carbonylamino]-*p*-nitrophenylacetate (**11c**): Colorless crystals; mp 147.0—148.3 °C; yield 15%; IR (KBr) 3325 (NH), 1730 (ester C=O), 1645 (amide C=O), and 1505, 1340 cm^{-1} (NO_2); NMR ($CDCl_3$) δ=2.30 (s, SCH_3), 3.73 (s, OCH_3), 5.64 (d, J=7.0 Hz, NCH), 7.25 (br. d, NH), and 7.5—8.1 (ABq, Ar). Found: C, 46.68; H, 4.23; N, 9.74%. Calcd for $C_{11}H_{12}O_5N_2S$: C, 46.47; H, 4.26; N, 9.86%.

Decomposition of Methyl p-*Chlorophenyldiazoacetate in Acetonitrile.* The reaction carried out at 0 °C according to the procedure described above gave two products. 4-*p*-Chlorophenyl-5-methoxy-2-methyloxazole (**9d**): Colorless crystals; mp 76.2—76.8 °C; yield 54%; NMR ($CDCl_3$) δ=2.37 (s, CH_3), 3.99 (s, OCH_3), and 7.28, 7.68 (ABq, J=9.0 Hz, Ar). Found: C, 59.08; H, 4.53; N, 6.20%. Calcd for $C_{11}H_{10}O_2NCl$: C, 59.07; H, 4.51; N, 6.26%. Methyl *p*-chlorophenylglyoxylate azine (**10d**): Yellow crystals; mp 157.0—157.5 °C; yield 29%; IR (KBr) 1740 (ester C=O), 1612 cm^{-1} (C=N); NMR ($CDCl_3$) δ=3.99 (s, OCH_3) and 7.39, 7.72 (ABq, J=9.0 Hz, Ar). Found: C, 54.96; H, 3.57; N, 7.36%. Calcd for $C_{18}H_{14}O_4N_2Cl$; C, 54.98; H, 3.59; N, 7.13%.

Decomposition of Methyl p-*Chlorophenyldiazoacetate in Benzene.* Diazoacetate (3.0 mmol) was decomposed in absolute benzene containing 0.5 ml of BF_3-etherate. Chromatography of the reaction products after the usual procedure gave the ketazine (**10d**) in 53% yield along with two white crystalline products. Dimethyl bis(*p*-chlorophenyl)-maleate (**13a**): Colorless crystals; mp 153.0—154.0 °C; yield 17%; IR (KBr) 1725 cm^{-1} (ester C=O); NMR ($CDCl_3$) δ=3.54 (s, OCH_3) and 7.36 (s, Ar). Found: C, 59.33; H, 3.81%. Calcd for $C_{18}H_{14}O_4Cl_2$: C, 59.20; H, 3.86%. Dimethyl bis(*p*-chlorophenyl)fumarate (**13b**): Colorless crystals; mp 126.0—127.0 °C; yield 26%; IR (KBr) 1715 cm^{-1} (ester C=O); NMR ($CDCl_3$) δ=3.81 (s, OCH_3) and 7.02, 7.21 (ABq, J=8.5 Hz, Ar). Found: C, 59.07; H, 3.83%. Calcd for $C_{18}H_{14}O_4Cl_2$: C, 59.20; H, 3.86%.

Decomposition of Ethyl Phenyldiazoacetate in Acetonitrile. The reaction was carried out at 10 °C in excess of acetonitrile in the presence of BF_3-etherate. Two products were obtained. 5-Ethoxy-2-methyl-4-phenyloxazole (**9e**): Colorless oil; yield

27%; NMR ($CDCl_3$) δ=1.43 (t, CH_3), 2.03 (s, CH_3), 4.45 (q, CH_2), and 7.3—8.2 (m, Ph). Ethyl phenylglyoxylate azine (**10e**): Yellow crystals; mp 143.5—144.0 °C; yield 49%; IR (KBr) 1728 (ester C=O) and 1570 cm^{-1} (C=N); NMR ($CDCl_3$) δ=1.40 (t, CH_3), 4.47 (q, OCH_2), and 7.3—7.8 (m, Ph). Found: C, 68.12; H, 5.71; N, 7.93%. Calcd for $C_{20}H_{20}O_4N_2$: C, 68.17; H, 5.72; N, 7.95%.

Decomposition of Ethyl Phenyldiazoacetate in Propionitrile. The reaction at 10 °C gave corresponding oxazole along with the ketazine (**10e**; 35%). 5-Ethoxy-2-ethyl-4-phenyloxazole (**9f**): Colorless crystals; mp 22 °C; yield 65%; NMR (CDCl) δ=1.33 (t, CH_3), 1.42 (t, CH_3), 2.70 (q, CH_2), 4.27 (q, OCH_2), and 7.1—7.9 (m, Ph). Found: C, 71.86; H, 6.94; N, 6.51%. Calcd for $C_{13}H_{15}O_2N$: 71.86; H, 6.96; N, 6.45%

Decomposition of N,N-*Dimethyl*-p-*nitrophenyldiazoacetamide (14) in Acetonitrile.* The diazoacetamide (3 mmol) was decomposed by adding in small portions into 10 ml of acetonitrile containing 1.0 ml of BF_3-etherate at 0 °C. After the usual procedure described above, silica-gel column chromatography of the reaction mixture gave three products. 5-Dimethylamino-2-methyl-4-(*p*-nitrophenyl)oxazole (**15**): Yellow crystals; mp 103—104 °C; yield 4%; IR (KBr) 1510, 1345 cm^{-1} (NO_2); NMR ($CDCl_3$) δ=2.41 (s, CH_3), 2.82 (s, NCH_3), 7.9—8.2 (ABq, Ar). Found: C, 58.13; H, 5.28; N, 17.21%. Calcd for $C_{12}H_{13}O_3N_3$: C, 58.29; H, 5.30; N, 17.00%. *N,N*-Dimethyl-*p*-nitromandelamide (**16**): Colorless crystals; mp 189—190 °C; yield 39%; IR(KBr) 3280 (OH), 1640 (amide C=O), 1515, 1355 cm^{-1} (NO_2); NMR ($CDCl_3$) δ=2.79 (s, NCH_3), 3.02 (s, NCH_3), 4.75 (d, OH), 5.26 (d, CH), 7.4—8.3 (ABq, Ar). Found: C, 53.76; H, 5.37; N, 12.29%. Calcd for $C_{10}H_{12}O_4N_2$: C, 53.57; H, 5.39; N, 12.48%. α-Acetylamino-*N,N*-dimethyl-*p*-nitrophenylacetamide (**17**): Pale yellow crystals; mp 162—163 °C; yield 26%; IR (KBr) 3325 (NH), 1640 (amide C=O), 1490, 1350 cm^{-1} (NO_2); NMR ($CDCl_3$) δ= 2.01 (s, CH_3), 2.97 (s, NCH_3), 3.00 (s, NCH_3), 5.99 (d, CH), 7.63 (br. d, NH), and 7.5—8.2 (ABq, Ar). Found: C, 54.52; H, 5.72; N, 15.72%. Calcd for $C_{12}H_{15}O_4N_3$: C, 54.33; H, 5.70; N, 15.84%.

N-Hydroxy Amides. II[1]. *N*-Benzyloxy α-Amino Acid *N*-Hydroxysuccinimide Esters and Synthesis of a Hexapeptide Having an Alternating *N*-Hydroxy Amide-Amide Sequence

Kazuyuki SHIMIZU, Kazuyuki NAKAYAMA, and Masayasu AKIYAMA*
Department of Applied Chemistry for Resources, Tokyo University of Agriculture and Technology, Koganei, Tokyo 184
(Received February 25, 1984)

Acylation of a series of *N*-benzyloxy α-amino acid derivatives with *N*,*N*-phthaloyloglycine shows that the yield decreases with increasing bulkiness of the substituent even by the acyl chloride or mixed anhydride procedure, and that the use of an excess reagent or a double acylation technique is needed to attain a good yield. The low reactivity of the benzyloxyamino group enables us to utilize *N*-benzyloxy α-amino acid *N*-hydroxysuccinimide esters without *N*-protection in the acylation of the usual amino group. In an attempt to lengthen the chain of an *N*-hydroxy peptide, a hexapeptide anilide having an *N*-hydroxy-DL-alanylglycyl sequence was synthesized *via* *N*-benzyloxy peptides. The complex forming tendency of the hexapeptide with iron(III) is examined.

Considerable effort has been directed to the synthesis of peptides having *N*-hydroxy amide bonds in the chain.[1-4] In view of the unique biological activity of naturally occurring hydroxamic acids,[5-7] the synthetic *N*-hydroxy peptides are of interest as they may serve as models for intermediates in biogenetic transformation,[8] precursors of dehydropeptides[9] and ionophoric peptides[10] as well as physiologically active substances, such as hadacidin,[11] rhodotorulic acid and ferrichromes.[6] The biological activity of the natural hydroxamic acids centers on their unique ability to chelate iron(III) for cell-membrane transport.[6] Except for a few total syntheses of natural substances,[7,12] oligopeptides with two or more *N*-hydroxy amide groups in the chain have rarely been obtained.[13] There are few general procedures for introducing the *N*-hydroxy amide bond into a peptide sequence.[3,14] *N*-Benzylozy α-amino acids have been utilized under these circumstances.[15] Previously, we reported on the use of *N*-benzyloxy α-amino acid *N*-carboxy anhydrides (*N*-benzyloxy-NCAs) for a stepwise synthesis of an *N*-benzyloxy tetrapeptide.[16] Also it was reported that polymerization of these NCAs, followed by debenzylation, led to poly(*N*-hydroxy peptide)s.[1] In this paper we describe a procedure for obtaining sequential *N*-hydroxy peptides together with the related investigations, including an examination of iron(III) chelation.

Results and Discussion

By the use of benzyloxy-NCAs, introduction of an *N*-benzyloxy α-amino acid residue into a growing peptide having the usual amino terminus has become an easy process,[16] so that a key step in the synthesis of *N*-hydroxy peptides is subsequent acylation of the terminal benzyloxyamino group. Nucleophilic reactivity of the benzyloxyamino group decreases considerably due to the inductive effect of the oxygen and steric hindrance by the benzyloxy moiety. Kolasa and Chimiak commented briefly that acylation of the *N*-benzyloxy α-amino acids with a bulky side chain was difficult,[3] but the scope and limitations of the acylation reactions have not yet been fully investigated.

Careful examination of a coupling reaction between *N*,*N*-phthaloylglycine (Pht=GlyOH) and methyl *N*-benzyloxy-DL-alaninate (DL-H(PhCH$_2$O)AlaOMe) by using a few selected coupling methods[17] gave the following results (yield of the coupling after recrystallization); acyl chloride in DMF (69%), isobutyl chloroformate (65%), *N*-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) (46%), pivaloyl chloride (40%), 1,1-carbonyldiimidazole (CDI) (37%), *N*-hydroxysuccinimide (0%): Care was taken to allow a sufficient time for each coupling procedure. These results confirm that strong activation of the acyl group is necessary to attain practical yields. Using the acyl chloride or the mixed anhydride of *N*,*N*-phthaloylglycine, acylation of a series of methyl esters of *N*-benzyloxy α-amino acids and *N*-benzyloxy dipeptides (Scheme 1) was carried out as shown in Fig. 1. The dipeptide

esters may serve as a model for growing *N*-benzloxy peptides. A decrease in the yield with increasing bulkiness of the α-substituents is clearly seen. This is ascribed to steric hindrance by the substituents. Only acyl chloride in DMF gave satisfactory results for most of the cases. The products in the acylation are summarized in Table 1. By a repetitive acylation or the use of excess reagents, these low yields may be improved (Table 2). This suggests a possibility of synthesizing longer peptides by the stepwise method.

The observation that the benzyloxyamino group did not react with the *N*-hydroxysuccinimide (HOSu) ester prompted us to utilize the benzyloxyamino acids in the

form of active esters without *N*-protection. Treatment of the *N*-benzyloxy α-amino acids with HOSu in the presence of DCC gave the corresponding active esters in good yields (Eq. 1). The esters were characterized as crystalline hydrochlorides except for that of *N*-benzyloxyglycine, which was converted into a more stable pentachlorophenyl ester (Table 3). These active esters reacted readily with methyl glycinate to afford the corresponding dipeptide methyl esters (Eq. 2 and Table 4), as did the *N*-benzyloxy-NCAs.[16]

Removal of the protective group from *N*-benzyloxy peptides is also an important step for synthesis of *N*-hydroxy peptides. Using Pht=Gly-DL-(PhCH$_2$O)-Phe-Gly-OMe as a substrate, several debenzylation procedures were tested: These are HBr in AcOH, $(CF_3CO_2)_3B$ in CF_3CO_2H, and hydrogenation with Ni or a few types of Pd catalysts. The reaction was followed by HPLC. Hydrogenation with Pd catalysts[3,14] was found to be the most satisfactory.

In order to show the usefulness of the active esters and a facile peptide chain elongation, synthesis of a hexapeptide having an *N*-hydroxyalanylglycyl sequence was carried out. Thus, DL-H(PhCH$_2$O)Ala-OSu was coupled with glycinanilide to give a benzyloxy dipeptide anilide (**6**). A reaction cycle for lengthening the benzyloxy peptide chain was performed; *viz.* acylation of the terminal benzyloxyamino group with Boc-Gly-OH by the mixed anhydride method, followed by deprotection of the Boc-group and then subsequent coupling with H(PhCH$_2$O)Ala-OSu. The cycle was repeated and finally interrupted by coupling with Ac-(PhCH$_2$O)Ala-OSu. A critical step was acylation of the benzyloxyamino group by the mixed anhydride method. To secure a practical yield, a double acylation technique was performed for this step. The resulting acetyl hexapeptide (**10**) was debenzylated by catalytic hydrogenation to give an *N*-hydroxy hexapeptide (**11**). The outline of the synthesis is shown in Fig. 2 and the data for the intermediate peptides are summarized in Table 5.

This kind of alternating sequential peptides is of interest, since it has three *N*-hydroxy peptide units and presents possibilities of holding iron(III) intramolecularly and/or intermolecularly. Natural trihydroxamic acids such as desferrioxames form stable complexes

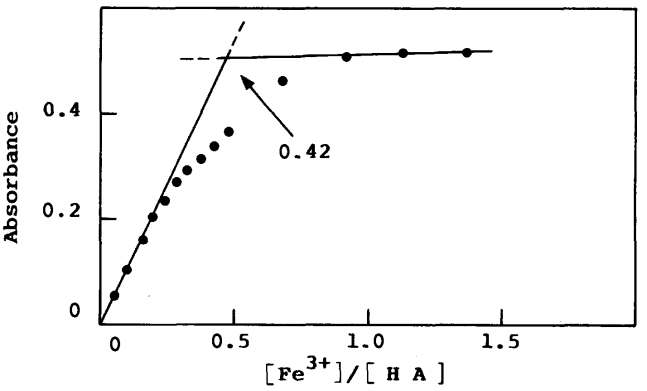

Fig. 3. Absorbance *vs.* the ratio of iron(III) to the hydroxamic acid (HA) units in 50 % aqueous DMF at pH=3 and 25 °C, ionic strength 0.1 (KNO_3). Absorbance at 463—487 nm.

with iron(III). On the other hand, little is known about the chelation tendency of synthetic *N*-hydroxy peptides.

The hexapeptide showed an intense violet color when mixed with $FeCl_3$ solution. The complex forming tendency was examined by determing the molar ratio of iron(III) to the *N*-hydroxy amide unit in 50% aq DMF solution.[1] The absorbance *vs.* the molar ratio plot (Fig. 3) reveals a curvature around an intersection of the two extrapolated straight lines. The intersection corresponds to the molar ratio of iron(III) to the *N*-hydroxy amide unit; the value being 0.33 for a 1:3 complex. A value of 0.42 was obtained for the present case, which is interpreted as a formation of an unstable complex rather than a stable 1:3 complex. This may be supported by a shift of λ_{max} to a longer wavelength (470 nm) coupled with a decrease in absorbance. It is known that a typical 1:3 complex, ferrioxamine B, shows its maximum at 420 nm while a 1:1 complex, which is usually observed for a monohydroxamic acid with iron(III) at low pH, has the maximum at 520 nm.[5] A 1:2 complex formation has been suggested for a polmyer system with λ_{max} at 466 nm[18] and also for an intermediate stage during transformation of a 1:3 complex to a 1:1 complex by an increasing acidity of the solution.[19-20] It appears that an alternating sequence of the *N*-hydroxy amide units is too dense to form a stable 1:3 complex either intramolecularly or intermolecularly.

Experimental

All the melting points are uncorrected. IR spectra were obtained with a JASCO model 403G spectrophotometer and ^1H NMR spectra were recorded on a JEOL FX200 spectrometer with TMS as internal standard. HPLC was carried out with a JASCO twincle apparatus by using a column packed with a Finepak SIL C_{18}. Microanalysis was performed in the Analytical Section, Institute of Physical and Chemical Research, Saitama. TLC was carried out by using Merck precoated silica gel 60 F_{254} plates: R_f^1, EtOAc; R_f^2, $CHCl_3$–MeOH–C_6H_6 (6:1:3); R_f^3, THF–hexane (1:1); R_f^4, $CHCl_3$–MeOH (3:1). The iron (III) complex molar ratio was determined as previously.[1] *N*-Benzyloxy-DL-amino acid methyl ester hydrochlorides ($PhCH_2ONHCH(R)CO_2Me \cdot HCl$) were obtained by treating the corresponding acid with HCL-saturated methanol: R, mp (lit,[21] mp); H, 125—126 °C (125—126 °C); Me, 130—131 °C (131—132 °C); Et. 114—116 °C (115—117 °C); *i*-Pr, 127—128 °C (127—130 °C); *i*-Bu, 115—117 °C (120—123 °C); $PhCH_2$, 119—120 °C (118—119 °C).

Coupling Methods. The following coupling procedures (a—f) were applied to the reaction of Pht=GlyOH with DL-$H(PhCH_2O)$AlaOMe; (a) acyl chloride in DMF, 3 h at −5 °C and 24 h at 25 °C; (b) mixed anhydride with $ClCO_2Bu^i$ in THF, 24 h at −15 °C and 48 h at 25 °C; (c) EEDQ in THF, 48 h at 30 °C; (d) mixed anhydride with pivaloyl chloride in THF, 48 h at 25 °C; (e) CDI in THF, 24 h at 0 °C and 24 h at 25 °C; (f) HOSu ester in THF, 72 h at 25 °C. In each case, a solution of an acyl active derivative of Pht=GlyOH was prepared either by simply dissolving the derivative or by adding an appropriate reagent to the solution of Pht=GlyOH (0.84 g, 4 mmol). To this solution was added $H(PhCH_2O)$Ala-OMe·HCl (0.982 g, 4 mmol) and Et_3N (0.404 g, 4 mmol, or 0.808 g in the case of acyl chloride). The resulting mixture was subjected to the above procedure (a—f). After evaporation of the solvent, the residue was extracted with AcOEt (100 mL) and the extract washed with 0.1 M (1 M=1 mol dm^{-3}) HCl, 5% $NaHCO_3$, and water, and then dried (Na_2SO_4). Evaporation of the solvent gave a crude product, which was recrystallized from AcOEt, mp 136—137 °C (lit,[3] mp 133—134 °C). Mp was depressed when the yield was less than 50%.

General Procedure for Acylation of N-Benzyloxy α-Amino Acid Derivatives. (A) Acyl Chloride under Schotten-Baumann Conditions: As a typical example, the preparation of Pht=Gly-DL-$(PhCH_2O)$Ala-Gly-OMe is described. To a mixture of DL-$H(PhCH_2O)$Ala-Gly-OMe·HCl (0.605 g, 2 mmol) in AcOEt (20 mL) and 5% $NaHCO_3$ (7 mL) was added Pht=Gly-Cl (0.447 g, 2 mmol) in AcOEt (20 mL) at 0—5 °C with vigorous stirring. The stirring was continued for 1 h at 5 °C and 48 h at room temperature, and AcOEt (60 mL) was added to extract the reaction products. The organic layer was washed with 0.1 M HCl, 5% Na_2CO_3, and water, and then dried over Na_2SO_4. Evaporation of the solvent gave the crude product; yield, 0.65 g (72%); mp 127—129 °C. The product was recrystallized from AcOEt–hexane to give a pure sample.

(B) Acyl Chloride in DMF: The preparation of Pht=Gly-DL-$(PhCH_2O)$Phe-Gly-OMe is given as an example. To a mixture of DL-$H(PhCH_2O)$Phe-Gly-OMe·HCl (1.13 g, 3 mmol) and Et_3N (0.61 g, 6 mmol) in DMF (30 mL) was added Pht=Gly-Cl (0.67 g, 3 mmol) in DMF (10 mL) at −10—−5 °C. After the mixture was stirred for 3 h at −5 °C and 48 h at room temperature, the solvent was removed under vacuum. The residue was dissolved in AcOEt (100 mL), and the organic layer was washed with 0.1 M HCl, 5% Na_2CO_3 and water, and dried over Na_2CO_3. Evaporation of the solvent gave a crude product, which was purified by column chromatography using Wakogel C-200; yield, 0.67 g (42%); mp 146—149 °C.

(C) Mixed Anhydride Procedure: The preparation of Pht=Gly-DL-$(PhCH_2O)$Abu-OMe is given as an example. A mixed anhydride was prepared from Pht=GlyOH (1.02 g, 5 mmol), Et_3N (0.505 g, 5 mmol) and isobutyl chloroformate (0.68 g, 5 mmol) in THF (30 mL) at −10 °C. To this was added DL-$H(PhCH_2O)$Abu-OMe·HCl (1.30 g, 5 mmol) and Et_3N (0.505 g, 5 mmol) in THF (10 mL) at −15 °C, and the mixture was stirred for 24 h at −20 °C and at 5 °C for 2 d. After evaporation of the solvent, the workup was carried out as above, to give an oily product.

N-Benzyloxy DL-*α-Amino Acid N-Hydroxysuccinimide Ester Hydrochlorides. General Procedure*: To a solution of *N*-benzyloxy α-amino acid (5 mmol) and *N*-hydroxysuccinimide (0.58 g, 5 mmol) in THF (10 mL) was added DCC (1.03 g, 5 mmol) in THF (10 mL) at 0 °C with stirring. The solution was kept for 1 h at 0 °C and for 20 h in the refri-

gerator. *N,N'*-Dicyclohexylurea (DCU) which separated was removed by filtration and the filtrate was evaporated to give a residue. It was diluted with AcOEt (20 mL) to give additional DCU. After separation of DCU, the filtrate was concentrated to give an oil or solid. This was treated with 1 M HCl in THF (20 mL) for 1 h at room temperature. Evaporation of the solvent gave the crude product. The product could be used for further coupling without purification. For an analytical sample, it was recrystallized from AcOEt-hexane.

Reactions of N-*Benzyloxy-α-amino Acid* N-*Hydroxysuccinimide Esters with H-Gly-OMe. General Procedure*: To a solution of H-Gly-OMe·HCl (0.25 g, 2 mmol) and Et_3N (0.202 g, 2 mmol) in $CHCl_3$ (10 mL), was added H($PhCH_2O$)-NHCHRCOOSu·HCl (2 mmol) and Et_3N (0.20 g, 2 mmol) in $CHCl_3$ (10 mL) at 0°C under stirring. The solution was kept for 2 h at 0°C and 1 d at room temperature. After evaporation of the solvent, the residue was diluted with AcOEt (50 mL), and the AcOEt solution was washed with 5% $NaHCO_3$ and water, and dried (Na_2SO_4). After the solvent was evaporated, the residue was treated with 2 M HCl in dioxane (3 mL) for 1 h at room temperature. Evaporation of the solvent gave the crude dipeptide hydrochloride, which was recrystallized from MeOH-ether.

*Pht=Gly-*DL*-(HO)Phe-Gly-OMe.* Pht=Gly-DL-($PhCH_2O$)Phe-Gly-OMe (2.65 g, 5 mmol), 10% Pd on carbon (0.030 g) and MeOH (10 mL) were placed in a hydrogenation apparatus. The mixture was shaken with H_2 under the atmospheric pressure for 24 h at 30 °C. The catalyst was filtered off, and the filtrate was evaporated to give the crude product. It was recrystallized from $CHCl_3$-hexane; yield, 1.93 g (88%); mp 183—184 °C (decomp). Found: C, 59.51; H, 4.76; N, 9.43. Calcd for $C_{22}H_{21}N_3O_7\cdot(1/4)H_2O$: C, 59.65; H, 4.66; N, 9.49%.

When the sample was mixed with a $FeCl_3$ solution, it gave an intense voilet color.

DL-*H($PhCH_2O$)Ala-Gly-NHPh (6).* To a solution of DL-H($PhCH_2O$)Ala-OSu·HCl (4.92 g, 15 mmol) and Et_3N (1.52 g, 15 mmol) in $CHCl_3$ (25 mL) was added H-Gly-NHPh·HCl (2.80 g, 15 mmol) in $CHCl_3$ (15 mL) containing Et_3N (1.52 g), and the mixture was stirred at room temperature. After 30 h, the mixture was washed with 5% $NaHCO_3$ and water, and dried (Na_2SO_4). Evaporation of the solvent gave the crude product, which was recrystallized from AcOEt-hexane; yield, 4.1 g (86%).

*Boc-Gly-*DL*-($PhCH_2O$)Ala-Gly-NHPh (7).* Boc-Gly-OH (0.29 g, 1.65 mmol) in THF (10 mL) containing Et_3N (0.167 g, 1.65 mmol) was converted into the mixed anhydride by adding isobutyl chloroformate (0.205 g, 1.5 mmol) in THF (5 mL) at −15 °C. To this mixture was added the dipeptide anilide (**6**) (0.491 g, 1.5 mmol) in DMF (10 mL), and the resulting mixture was stirred for 3 h at −15 °C and 12 h at 0 °C. After evaporation of the solvent, the residue was diluted with ethyl acetate (11 mL). The organic layer was washed with 5% $NaHCO_3$ and water, and dried over Na_2SO_4. Evaporation of the solvent gave the crude product (0.72 g). To ensure coupling, the crude product was subjected to the above acylation procedure two further times. The final product was chromatographed using Wakogel C-100 with EtOAc as eluant. The product obtained was 0.59 g (74% yield).

DL-*H($PhCH_2O$)Ala-Gly-*DL*-($PhCH_2O$)Ala-Gly-NHPh(8).* Boc-tripeptide anilide (**7**) (0.82 g, 1.69 mmol) was dissolved in dioxane (6 mL). To this was added 3.6 M HCl in dioxane (5 mL). The reaction mixture was stirred for 2 h at 5 °C and evaporated. The residue was triturated with ether and filtered. The product was recrystallized from MeOH-ether to give 0.60 g (85%) of the tripeptide anilide hydrochloride, mp 175—176 °C (decomp).

The tripeptide anilide hydrochloride (0.69 g, 1.65 mmol) and triethylamine (0.168 g, 1.65 mmol) were dissolved in $CHCl_3$ (15 mL). To the solution was added a solution containing H($PhCH_2O$)Ala-OSu (0.54 g, 1.65 mmol) and Et_3N (0.168 g, 1.65 mmol) in $CHCl_3$(10 mL) at 0 °C. The solution was stirred for 1 h at 0 °C and then for 24 h at room temperature. The $CHCl_3$ layer was washed with 5% $NaHCO_3$ and water, and dried (Na_2SO_4). Evaporation of the solvent gave a product (0.80 g), which was recrystallized from EtOAc-hexane; yield, 0.74 g (80%).

*Boc-Gly-*DL*-($PhCH_2O$)Ala-Gly-*DL*-($PhCH_2O$)Ala-Gly-NHPh (9).* Boc-GlyOH (0.193 g, 1.1 mmol) and Et_3N (0.113 g, 1.1 mmol) were placed in THF (10 mL) and cooled. To this was added $ClCO_2Bu^i$ (0.137 g, 1 mmol) in THF (5 mL) at −16°C. After 10 min, the tetrapeptide anilide (**8**) (0.56 g, 1 mmol) in DMF (10 mL) was added slowly to the mixed anhydride solution at −16 °C. The reaction mixture was stirred for 24 h at −16 °C, evaporated and diluted with EtOAc (40 mL). The organic layer was washed with 5% $NaHCO_3$ and water, and dried over Na_2SO_4. Evaporation of the solvent gave a residue. This residue was found to contain the starting tetrapeptide anilide; it was subjected two more times to a similar Boc-Gly mixed anhydride acylation. The crude residue thus obtained amounted to 0.84 g. It was purified by chromatography on a column of Wakogel C-100 with EtOAc as eluant by the flash technique; yield, 0.45 g (63%).

*Ac-*DL*-($PhCH_2O$)Ala-Gly-*DL*-($PhCH_2O$)Ala-Gly-*DL*-($PhCH_2O$)Ala-Gly-NHPh (10).* *Ac-*DL*-($PhCH_2O$)Ala-OSu*: To a solution of Ac-DL-($PhCH_2O$)Ala-OH (0.68 g, 2,9 mmol) and HOSu (0.33 g, 2.9 mmol) in THF (10 mL) was added DCC (0.59 g, 2.9 mmol) in THF (5 mL) at 0 °C. The solution was stirred for 1 h at 0 °C and kept in the refrigerator for 24 h. The crude product, which was obtained by the usual workup performed for a DCC reaction, was recrystallized from EtOAc-hexane; yield, 0.65 g (67%); mp 100—100.5 °C. Found: C, 57.11; H, 5.45; N, 8.35. Calcd for $C_{16}H_{18}N_2O_6$: C, 57.48; H, 5.43; N, 8.38 (%).

The pentapeptide anilide (**9**) (0.44 g, 0.61 mmol) was dissolved in dioxane (5 mL), to remove the Boc group. After the addition of 3.6 M HCl in dioxane (20 mL), the resulting solution was stirred for 2 h at room temperature and evaporated. The residue was triturated with ether, and the precipitate was filtered to give the pentapeptide anilide hydrochloride; yield, 0.346 g (86%).

The pentapeptide anilide hydrochloride (0.451 g, 0.52 mmol) and Et_3N (0.52 g, 0.52 mmol) were stirred in THF (10 mL) at 0 °C for 1 h. To this mixture was added Ac-DL-($PhCH_2O$)Ala-OSu (0.174 g, 0.52 mmol) in THF (10 mL). The reaction mixture was stirred for 48 h at 25 °C, evaporated and extracted with EtOAc (50 mL). The organic layer was washed successively with 5% $NaHCO_3$, 5% citric acid and water, and dried over Na_2SO_4. Evaporation of the solvent gave the crude product, 0.431 g (99%). The product was chromatographed on Wakogel C-200, to give a pure sample; yield, 0.325 g (75%).

*Ac-*DL*-(HO)Ala-Gly-*DL*-(HO)Ala-Gly-*DL*-(HO)Ala-Gly-NHPh (11).* The acetyl hexapeptide anilide (**10**) (0.240 g, 0.27 mmol), 10% Pd/C (0.040 g) and MeOH (20 mL) were placed in a hydrogenation apparatus, and the mixture shaken with H_2 for 72 h at 30 °C under atmospheric pressure. The catalyst was filtered off and the filtrate evaporated to give the product; yield, 0.154 g (95%). After recrystallization from MeOH, the product showed mp 191—192 °C (decomp). IR $\nu_{C=O}$, 1620—1680 cm^{-1} (-CONH- and -CON(OH)-); ^1H NMR (DMSO-d_6) δ=1.30 (9H, m, CH_3), 2.04 (3H, s, CH_3CO), 4.0 (6H, m, $-CH_2-$), 4.90 (3H, m, -CH-), 7.0—7.8 (8H, broad, -CONH- and $-C_6H_5$), 7.95 (1H, -HNPh), and 9.70 (3H, s, N-OH).

The sample gave a characteristic color when mixed with $FeCl_3$ solution.

We thank Messrs. Masayoshi Hasegawa, Masahisa Yoshimi, and Mizuhito Tani for performing some of the experiments.

Stereoelectronic and Homoconjugative Effect of Stereoselectivity. The Addition of Dichlorocarbene to 1,5-Dimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-one and Its Related Compounds

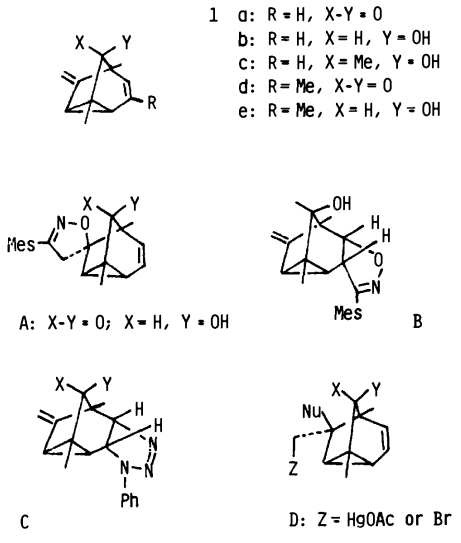
Makoto NITTA,* Shuji OKADA, and Masami KATO

Department of Chemistry, School of Science and Engineering, Waseda University, Shinjuku-ku, Tokyo 160

(Received February 25, 1984)

The reaction of dichlorocarbene with 1,5-dimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-one, its corresponding alcohol derivative, and 1,5,8-trimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-*endo*-ol occurs on the exocyclic double bond to give *exo* and *endo* adducts with preferential formation of the *exo* adduct. Dichlorocarbene addition to 1,3,5-trimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3-en-8-one (**1d**) occurs on the endocyclic double bond from the *exo* side, while the reaction occurs on the exocyclic double bond from both the *exo* and *endo* sides in the case of the corresponding alcohol derivative. The stereoselectivity or site selectivity was discussed on the basis of the stereoelectronic and homoconjugative effects as well as the steric effect of the reaction. Several chemical transformations, along with the derivation of bis adducts of dichlorocarbene, were also studied for confirmation of the structure of mono adducts. 1,3-Dipolar cycloaddition of **1d** and its dichlorocarbene adduct with mesitonitrile oxide, giving the adducts on the exocyclic double bond, was also studied to suggest a possible causative factor to control the electrophilic addition in the indicated direction.

Recently the stereoselectivities and/or site selectivities of electrophilic reactions or cycloadditions of molecules containing proximal π-bonds have been investigated.[1] In a previous paper,[2] we have shown that the 1,3-dipolar cycloadditions of mesitonitrile oxide (MNO) or phenyl azide (PA) to 1,5-dimethyl-6-methylenetricyclo-[3.2.1.$0^{2,7}$]oct-3-en-8-one (**1a**), its alcohol derivative (**1b**), and 1,5,8-trimethyl-6-methylenetricyclo[3.2.1.$0^{2,7}$]oct-3en-8-*endo*-ol (**1c**) exhibit a remarkable stereoselectivity and site selectivity to give the products of **A**, **B**, and **C**. The stereoselectivity giving *exo* adduct **A** could be ascribed to the preferential MNO(LUMO)–**1a**,**b**(HOMO) interaction. When the *exo* attack on the exocyclic double bond is sterically hindered by the methyl group at 8-position of **1c**, the addition occurs on the endocyclic double bond to give **B**. In the dipolar cycloaddition of PA, PA(LUMO)–**1a**, **b**(HOMO) interaction giving the type **A** adduct could be prohibited by the large van der Waals nonbonded interaction of the phenyl group with the C_1–C_5 bridge of **1a**,**b**, thus the adduct **C** could be obtained.

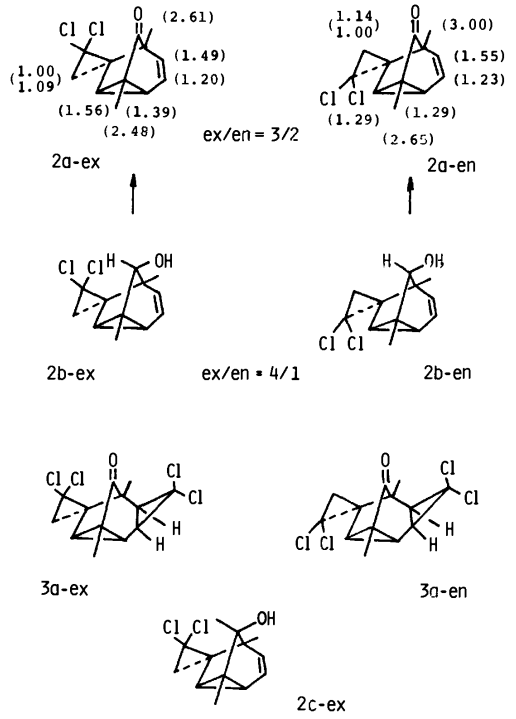


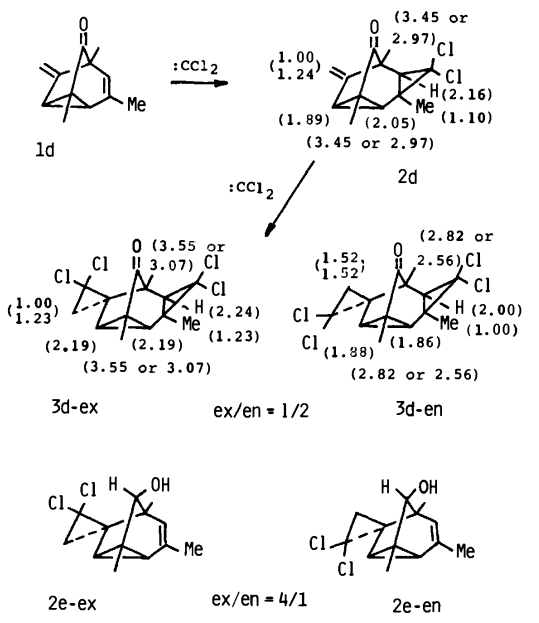
The prohibited *endo* attack of MNO and PA on the exocyclic double bond of **1a**,**b** or **1c** could be ascribed to the repulsive orbital interaction, which would be experienced with the endocyclic double bond. Similar stereoselection of electrophilic reactions such as solvomercuration, bromination and its related reaction on the exocyclic double bond of **1a**—**c** have been found to give the type D products.[3] In order to gain insight into the correlation for stereoselectivity of various electrophiles, the cheletropic reactions of dichlorocarbene with **1a**—**c** and its trimethyl analogue **1d**,**e** were investigated. In addition, 1,3-dipolar cycloadditions of **1d** and its dichlorocarbene adduct **2d** with MNO were also studied to find a plausible factor to control the stereoselectivity of 1,3-dipolar cycloaddition and dichlorocarbene addition.

Results and Discussion

The reaction of **1a**[4] with dichlorocarbene, generated by the usual phase transfer method,[5] occurred on the exocyclic double bond to give *exo* adduct **2a-ex** (48%) and *endo* adduct **2a-en** (31%) in a ratio of 3/2. A similar reaction of **1b**[6] with dichlorocarbene also afforded a mixture of two adducts, **2b-ex** (66%) and **2b-en** (16%), in a ratio of 4/1. The mixture was not separable. On oxidation with pyridinium chlorochromate, however, the mixture was converted to a mixture of **2a-ex** and **2a-en** (in a ratio of 4/1) in a 63% yield. Thus the correlation of **2a-ex** with **2b-ex** as well as **2a-en** with **2b-en** was clarified.

The structural proof for **2a-ex** and **2a-en** was based on the analytical and spectroscopic data. The stereochemical arrangement of the dichlorocarbene moiety of **2a-ex** and **2a-en** was deduced from the pseudo-contact NMR spectra obtained by using Eu(fod)$_3$. The relative downfield shifts of δ's are given in parentheses in the structural formulae.[7] The relatively large value of 1.14 for one of the methylene protons of the spirocyclopropane ring of **2a-ex**, as compared to the value of 1.01 for that of **2a-en**, could support the stereochemistry of the dichlo-





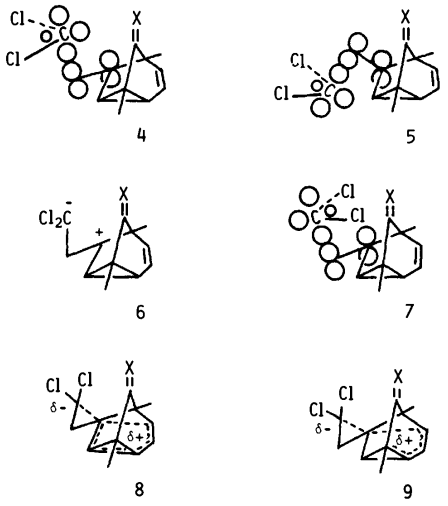
rocarbene moiety. Furthermore, in the reaction of **2a-ex** and **2a-en** with dichlorocarbene, the addition occured on the endocyclic double bond from the *exo* side giving **3a-ex** and **3a-en** respectively. The structures were deduced from the elemental analyses and the spectral data. Regarding the NMR spectra of **3a-ex** and **3a-en**, the noteworthy results include the chemical shifts of two hydrogens of dichlorocyclopropane moiety incorporated on the endocyclic double bond of **2a-ex** and **2a-en**. In the case of **3a-ex**, the key proton absorptions were seen at δ 2.37 and δ 2.50 (see Experimental). In the case of **3a-en**, however, the corresponding proton absorptions appeared at higher fields of δ 1.82 and δ 2.23. These trends are also observed for similar adducts, **2d-ex** and **2d-en** (*vide infra*). The *endo* orientation of chlorine ligand of spirocyclopropane moiety seems to cause a substantial change in long-range shielding. Assuming the *endo* attack of dichlorocarbene on the endocyclic double bond of **2a-ex** and **2a-en**, a chlorine atom comes very close to the spirocyclopropane carbon atom and the van der Waals nonbonded interaction would be very large. Consequently the *exo* attack giving **3a-ex** and **3a-ex** would be observed.

The reaction of **1c**,[8] which has a methyl group at 8-position, with dichlorocarbene afforded only **2c-ex**. This compound was also derived from the reaction of **2a-ex** with iodomethylmagnesium; thus the structure as well as the stereochemical arrangement of dichlorocyclopropane moiety could be assigned.

In contrast to the behavior of **1a**, reaction of the trimethyl analogue **1d**[4] with dichlorocarbene occurred on the endocyclic double bond from the *exo* side to give **2d**. In dichlorocarbene addition of cyclopropylethylenes, the rate enhancement caused by the methyl group has been observed.[9] The reaction of 2-cyclopropyl-1-propene proceeds 14 times faster than that of simple cyclopropylethylene itself. The methyl group at 3-position of **1d** could enhance the reactivity of the endocyclic double bond; thus only **2d** could be obtained. Furthermore the *exo* selectivity observed in the formation of **2d** may be ascribed to the steric effect of methyl group at 1- and 3-positions: the latter methyl group should come very close to the former one in the transition state.[10] The independent reaction of isolated **2d** with dichlorocarbene gave bis adducts, **3d-ex** and **3d-en** in a ratio of 1/2. The structural proof was based on elemental analyses and the spectroscopic data as well as on the pseudo-contact NMR spectra.[7]

Contrary to the reaction of **1d**, the reaction of the corresponding alcohol **1e**[6] with dichlorocarbene afforded a mixture of **2e-ex** and **2e-en** (in a ratio of 4/1) in a 60% yield. The *exo/endo* ratio is similar to that of the reaction of **1b**. The prohibited *exo* attack of dichlorocarbene on the endocyclic double bond (*cf.* the reaction of **1d**) could be explained by a steric effect of the chlorine ligand of the incorporating dichlorocarbene and OH group at 8-position. The mixture was not separable; however, the correct elemental analysis and mass spectral data were obtained. In the comparison of the NMR spectra of **2e-ex** and **2e-en**, particularly noteworthy are the chemical shifts of a hydrogen and a methyl group on the endocyclic double bond. In the case of **2e-ex**, the key proton absorptions were seen at δ 5.15 and δ 2.02, respectively (see Experimental). In the case of **2e-en**, however, these proton absorptions appeared at the higher fields of δ 4.79 and δ 1.92. This phenomenon is observed also for two protons on the endocyclic double bond in the pairs of NMR spectra of **2a-ex** (δ 6.20, 6.76) and **2a-en** (δ 5.08, 6.26). The difference of the stereochemical arrangement of chlorine atoms of the spirocyclopropane moiety may cause a substantial change in long-range shielding. Thus the structures of **2e-ex** and **2e-en** were deduced.

Regarding the stereoselection of the dichlorocarbene addition on the exocyclic double bond, *exo* adducts such as **2a,b,c-ex**, and **2e-ex**, were obtained preferentially as compared to the corresponding *endo* adducts. The

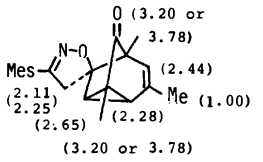


LUMO (p orbital) of the dichlorocarbene approaches the exocyclic double bond along the π axis closer to the least substituted carbon atom to form loose charge-transfer type complexes **4** and **5**, as illustrated. These could correspond closely in geometry to the valence structure **6**. The above approach was originally proposed on the basis of experimental data[12] and later on the basis of the theoretical calculations.[13] The approach of dichlorocarbene in the way illustrated as **7** could be unlikely because of a steric destabilization experienced with the chlorine ligand and the carbon skeleton in the present case. The complex **4** then collapses with rotation of the CCl_2 group to give an *exo* adduct, and **5** collapses to give an *endo* adduct.

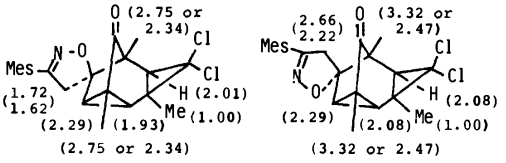
Considering the *endo* approach **5** giving an *endo* adduct, interaction of the HOMO (carbene)with the appropriate occupied orbital of endocyclic double bond could cause a destabilizing effect in the transition state, as compared to that derived from **4** giving an *exo* adduct. Consequently an *exo* adduct could be favored over an *endo* adduct for **1a-c** and **1e**.

The additional explanation for the *exo* prevalence for **1a-c** and **1e** could be a homoconjugative stabilization of the transition state. Considering the developing-charge delocalization derived from **4** giving an *exo* adduct, an interaction of type **8** is bishomocyclopentadienyl cation, which is bishomoantiaromatic in nature and undoubtedly disfavored energetically.[14] However, interaction in the way of **9** removes the energetic disadvantage present in **8** and provides for intervention of a stabilized transition state.[15] This stabilizing effect seems to be reflected in the value of *exo/endo* ratio of products derived from **1b,d** (4/1) being larger than that from **1a** (3/2), the carbonyl group in which electrons from the cyclopropane ring could be released. The high stereoselectivity for **1c** giving **2c-ex** is still ambiguous.

In the reaction of **2d**, the product ratio of **3d-ex**/**3d-en** is 1/2, which is almost a reversed value of 3/2 for **2a-ex**/**2a-en**. The *endo* prevalence for the reaction of **2d** could be explained by a low degree of intervention of the dichlorocyclopropane into the stabilising effect on the developing cationic center illustrated as **9**. Furthermore the destabilizing effect arising from the interaction of HOMO(carbene) with an occupied orbital of endocyclic double bond for **1a-c**, and **1e** seems to be large, compared to that of **2d**, in which the double bond is replaced by the cyclopropane ring. This reduced repulsive interaction for **2d** also prefers **3d-en** over **3d-ex**.



10



11-ex 11-en

The 1,3-dipolar cycloaddition of **1d** with MNO afforded only an *exo* adduct **10** as in the case of **1a**, **b**.[2] However, a similar reaction of **2d** with MNO gave two adducts, **11-ex** and **11-en**, in 71 and 6% yields. The structures of these adducts were deduced from the elemental analyses and from their spectroscopic data.[7] Thus the postulated repulsive interaction of MNO with the endocyclic double bond seems also to be larger than that of MNO with the cyclopropane bent bond.

Experimental

The melting points are uncorrected. The IR spectra were recorded on a Shimadzu IR-400 spectrometer. The mass spectral studies were conducted using a Hitachi RMU-60 spectrometer. All of the NMR spectra were recorded on a Hitachi R-25 or JEOL PS-100 spectrometer, using tetramethylsilane as the internal standard. The shift data were obtained by adding small increments of $Eu(fod)_3$ to the sample and then noting the extent to which each peak was shifted. The relative shift slopes were obtained by dividing each slope by the slope of the least shifted signal.

General Procedure for the Addition of Dichlorocarbene. To a stirred mixture of substrate, an adequate amount of chloroform, and triethylbenzylammonium chloride (TEBA), 50% (w/w) aqueous sodium hydroxide solution were added dropwise at 0 °C. In several cases, an adequate amount of dichloromethane was added to dilute the reaction mixture. After stirring for 1 h at 0 °C and 15 h at the ambient temperature, the resulting reaction mixture was poured into water and extracted with dichloromethane. After the removal of the dichloromethane, the resulting residue was purified as follows.

Reaction of 1a with Dichlorocarbene. The reaction was carried out using **1a** (1.0 g, 6.25 mmol), chloroform (1.49 g, 12.5 mmol) TEBA (30 mg), and sodium hydroxide solution (42 cm^3). The products were purified by column chromatography on Florisil using benzene as the eluent to give a mixture (1.75 g, 78%) of **2a-ex** (47%) and **2a-en** (31%) in a ratio of 3/2, which was determined by NMR spectroscopy. Repeated separation of the above mixture by TLC on silica gel using benzene-hexane (1/1) gave pure **2a-ex**. For **2a-ex**: mp 87—89 °C; IR CCl_4), 1742 cm^{-1}; NMR (CCl_4), δ=1.16 (3H, s), 1.41 (3H, s), 1.90 (2H, s), 2.17 (1H, d, J=7.5 Hz), 2.41 (1H, dxdxd, J=7.5, 5.0, 2.0 Hz), 6.20 (1H, dxd, J=7.2, 2.0 Hz), 6.76 (1H, dxd, J=7.2, 5.0 Hz); MS, m/z (rel intensity), 244 (M^+, 1),

242 (M^+, 2), 179 (100). The product **2a-en** was contaminated with **2a-ex** and the pure sample was not obtained; but the NMR spectrum was assigned as follows. For **2a-en**: NMR (CCl_4), δ=1.23 (3H, s) 1.45 (3H s), 1.54 (1H, d, J=7.5 Hz), 1.69 (1H, d, J=7.5 Hz), 1.87 (2H, m), 5.90 (1H, dxd, J=7.2, 2.0 Hz), 6.62 (1H, dxd, J=7.2, 5.0 Hz).

Reaction of 1b with Dichlorocarbene. The reaction was carried out using **1b** (500 mg, 3.1 mmol), chloroform (740 mg, 6.2 mmol), TEBA (30 mg), and sodium hydroxide solution (2.1 cm^{-3}). The products were purified by distillation to give 619 mg (82%) of a mixture of **2b-ex** (66%) and **2b-en** (16%). For **2b-ex**: NMR (CCl_4), δ=1.11 (3H, s), 1.31 (3H, s), 1.13—1.52 (2H, m), 1.55 (1H, d, J=7.2 Hz), 1.68 (1H, d, J=7.2 Hz), 3.33 (1H, s), 5.44 (1H, dxd, J=8.4, 1.7 Hz), 6.40 (1H, dxd, J=8.4, 5.4 Hz). For **2b-en**: NMR (CCl_4), δ=1.21 (3H, s), 1,39 (3H, s), 1.13—1.52 (4H, m), 3.65 (1H, s), 5.08 (1H d, J=8.2Hz) 6.26 (1H, d, J=8.2, 5.4 Hz).

Oxidtation of a Mixture of 2b-ex and 2b-en. To a stirred soltion of pyridinium chlorochromate (681 mg, 3.17 mmol) and anhydrous sodium acetate (58 mg, 0.7 mmol) in 30 cm^3 of anhydrous dichloromethane, a 4/1 mixture of **2b-ex** and **2b-en** (516 mg, 2.11 mmol) in 1 cm^3 of dichloromethane was added, followed by stirring for 10 h under a nitrogen stream. The reaction mixture was chromatographed on Florisil using dichloromethane as the eluent. The dichloromethane was evaporated and the resulting residue was distilled [bp 115—120 °C/792 Pa (bath temp)] to give a mixture (63%) of **2a-ex** and **2a-en** in a ratio of 4/1. The NMR spectrum of the mixture was identical with the authentic specimen, which was obtained from the reaction of **1a** with dichlorocarbene.

Reaction of 2a-ex with Dichlorocarbene. The reaction was carried out using **2a-ex** (150 mg, 0.62 mmol), chloroform (740 mg, 6.2 mmol), dichloromethane (0.5 cm^3), TEBA (20 mg), and sodium hydroxide solution (2.2 cm^3). The product was recrystallized from ethanol to give 144 mg (71%) of **3a-ex**: mp 149—151 °C; IR (CCl_4), 1742 cm^{-1}; NMR ($CDCl_3$), δ=1.18 (3H, s), 1.31 (3H, s), 1.52 (1H, d, J=8.3 Hz), 1.66 (1H, d, J=8.3 Hz), 1.91 (1H, d, J=6.7 Hz), 2.24 (1H, dxdxd, J=6.7, 3.3, 2.0 Hz), 2.37 (1H, dxd, J=11.1, 3.3 Hz), 2.50 (1H, dxd, J=11.1, 2.0 Hz); MS, m/z (rel intensity), 328 (M^+, 1), 326(M^+, 3), 322 (M^+, 2), 291 (100). Found: C, 47.76; H, 3.66%. Calcd for $C_{13}H_{12}OCl_4$: C, 47.89; H, 3.71%.

Reaction of the Mixture of 2a-ex and 2a-en with Dichlorocarbene. The reaction was carried out using a mixture of **2a-ex** and **2a-en** in a ratio of 3/2 (1.372 g, 5.65 mmol), chloroform (7.24 g, 60.5 mmol), TEBA (60 mg), and sodium hydroxide solution (10 cm^3). The products were separated by TLC on silica gel using benzene-hexane (1/1) to give **3a-ex** (632 mg, 34%), **3a-en** (452 mg, 25%), and a mixture of **2a-ex** and **2a-en** in a ratio of 5/2 (495 mg, 36%). For **3a-en**: mp 163—164 °C (from ethanol); IR (CCl_4), 1739 cm^{-1}; NMR ($CDCl_3$), δ=1.25 (3H, s), 1.31 (3H, s), 1.54 (1H, d, J=6.0 Hz), 1.63 (1H, d, J=6.0 Hz), 1.82 (1H, dxd, J=9.6, 2.6 Hz), 2.19 (1H, dxdxd, J=7.4, 2.6, 2.0 Hz), 2.23 (1H, dxd, J=9.6, 2.0 Hz), 2.24 (1H, d, J=7.4 Hz); MS, m/z (rel intensity), 332 (M^+, 80), 330 (M^+, 9), 328 (M^+, 9), 326 (M^+, 3), 324 (M^+, 3), 291 (100). Found: C, 47.95; H, 3.80%. Calcd for $C_{13}H_{12}OCl_2$: C, 47.89; H, 3.71%.

Reaction of 1c with Dichlorocarbene. The reaction was carried out using **1c** (300 mg, 1.7 mmol), chloroform (405 mg, 3.4 mmol), TEBA (20 mg), and sodium hydroxide solution (1.2 cm^3). The product was purified by distilation to give 315 mg (71%) of **2c-ex**: bp 118—122 °C/528 Pa (bath temp); NMR (CCl_4), δ=1.07 (3H, s), 1.09 (3H, s), 1.23 (3H, s), 1.26—1.65 (2H, m), 1.46—1.78 (2H, m), 5.52 (1H, dxd, J=8.5, 1.9 Hz), 6.42 (1H, dxd, J=8.5, 5.5 Hz); MS, m/z (rel intensity), 260 (M^+, 4), 258 (M^+, 5), 162 (100). Found: C, 59.76; H, 5.93%. Calcd for $C_{13}H_{16}OCl_2$: C, 60.25; H, 6.22%.

Independent Preparation of 2c-ex. To a stirred ethereal solution of iodomethylmagnesium, which was prepared from iodomethane (1.20 g, 8.5 mmol) and magnesium (48 mg, 1.98 mmol), a solution of **2a-ex** (120 mg, 0.49 mmol) in 5 cm^3 of ether was added dropwise over 20 min. After the addition was completed, the mixture was refluxed for 15 min. The reaction mixture was cooled and followed by addition of water and aqueous ammonium chloride. The mixture was extracted with ether and the extract was evaporated to give 106 mg (83%) of **2c-ex**: its spectral data were identical with the authenic specimen.

Reaction of 1d with Dichlorocarbene. The reaction was carried out using **1d** (507 mg, 2.91 mmol), chloroform (522 mg, 4.37 mmol), dichloromethane (1 cm^3), TEBA (30 mg), and sodium hydroxide solution (1.5 cm^3). The product was purified by TLC on silica gel using benzene as the eluent to give 664 mg (89%) of **2d**: mp 145—147 °C (from ethanol); IR (CCl_4), 1748 cm^{-1}; NMR ($CDCl_3$), δ=1.21 (3H, s), 1.24 (3H, s), 1.54 (3H, s), 1.33 (1H, d, J=2.8 Hz), 2.02 (1H, dxd, J=7.3, 2.8 Hz) 2.57 (1H, d, J=7.3 Hz), 4.73 (1H, s), 4.91 (1H, s); MS, m/z (rel intensity), 258 (M^+, 2), 256 (M^+, 3), 193 (100). Found: C, 60.48; H, 5.30%. Calcd for $C_{13}H_{17}OCl_2$: C, 60.72; H, 5.49%.

Reaction of 2d with Dichlorocarbene. The reaction was carried out using **2d** (257 mg, 1 mmol), chloroform (598 mg, 5 mmol), TEBA (20 mg), dichloromethane (1 cm^3), and sodium hydroxide solution (1.7 cm^3). The products were separated by TLC on silica gel using benzene as the eluent to give **3d-en** (160 mg, 47%) and **3d-ex** (78 mg, 22%). For **3d-ex**: mp 112—113 °C (from ethanol); IR (CCl_4), 1745 cm^{-1}; NMR (CCl_4), δ=1.10 (3H, s), 1.22 (3H, s), 1.72 (3H, s), 1.48 (1H, d, J=7.4 Hz), 1.59 (1H, d, J=7.4 Hz), 1.80 (1H, s), 1.85 (2H, broad s); MS, m/z (rel intensity), [M^+] is absent; 207 (100). Found: C, 49.45; H, 4.16%. Calcd for $C_{14}H_{14}OCl_2$: C, 49.45; H, 4.15%. For **3d-en**: mp 139—142 °C; IR (CCl_4), 1748 cm^{-1}; NMR (CCl_4), δ=1.15 (3H, s), 1.22 (3H, s), 1.53 (3H, s), 1.29 (1H, d, 8.6 Hz), 1.46 (1H, d, J=8.6 Hz), 2.21 (1H, d, J=6.8 Hz), 1.75 (1H, dxd, J=6.8, 2.4 Hz), 1.26 (1H, d, J=2.4 Hz); MS, m/z (rel intensity), [M^+] is absent; 207 (100). Found: C, 49.53; H, 3.90%. Calcd for $C_{14}H_{14}OCl_4$: C, 49.45; H, 4.15%.

Reaction of 1e with Dichlorocarbene. The reaction was carried out using **1e** (822 mg, 4.67 mmol), chloroform (837 mg, 7.0 mmol), dichloromethane (4 cm^3), TEBA (20 mg), and sodium hydroxide solution (2.3 cm^3). The purification by TLC on silica gel using benzene as the eluent gave a mixture (728 mg, 60%) of **2e-ex** (48%) and **2e-en** (12%). For a mixture of **2e-ex** and **2e-en**: MS, m/z (rel intensity), 260 (M^+, 3), 258 (M^+, 6), 106 (100). Found: C, 60.44; H, 6.43%. Calcd for $C_{13}H_{16}OCl_2$: C, 60.25; H, 6.22%. For **2e-ex**: NMR (CCl_4), δ=1.08 (3H, s), 1.33 (3H, s), 1.12—1.15 (2H, overlapping with methyl group), 1.55 (1H, d, J=7.0 Hz), 1.68 (1H, d, J=7.0 Hz), 2.02 (3H, d, J=1.4 Hz), 3.32 (1H, s), 5.15 (1H, broad s). For **2e-en**: NMR (CCl_4), δ=1.17 (3H, s), 1.41 (3H, s), 1.12—1.51 (4H, overlapping with methyl group), 1.92 (3H, d, J=1.4 Hz), 3.64 (1H, s), 4.79 (1H, broad s).

1,3-Dipolar Cycloaddition of 1d with Mesitonitrile Oxide. A solution of **1d** (174 mg, 1 mmol) and mesitonitrile oxide (161 mg, 1 mmol) in 3 cm^3 of anhydrous benzene was refluxed for 5 h. After the solvent removal *in vacuo*, the resulting residue was separated by TLC on silica gel using benzene-dichloromethane (1/1) as the eluent. The first band from the TLC plates contained 30 mg (17%) of **1d**. The second band from the TLC plates gave 271 mg (81%) of **4**: mp 123—124 °C; IR (CCl_4), 1742 cm^{-1}; NMR ($CDCl_3$), δ= 1.10 (3H, s), 1.32 (3H, s), 1.79 (3H, d, J=1.8 Hz), 1.89 (1H, dxd, J=7.5, 3.5 Hz), 2.23 (9H, broad s), 2.30 (1H, d, J=7.5 Hz), 2.94 (1H, d, J=18.5 Hz), 3.01 (1H, d, J=18.5 Hz), 5.11 (1H, dxd, J=3.5, 1.5 Hz), 6.84 (2H, s); MS, m/z (rel intensity), 335 (M^+, 19), 159 (100). Found: C, 78.58; H, 7.45; N, 3.89%. Calcd for $C_{22}H_{25}NO_2$: C,

78.77; H, 7.51; N, 4.17%.

1,3-Dipolar Cycloaddition of **2d** *with Mesitonitrile Oxide.* A solution of **2d** (257 mg, 1 mmol) and mesitonitrile oxide (161 mg, 1 mmol) in 3 cm^3 of anhydrous benzene was refluxed for 5 h. After the solvent was evaporated, the resulting residue was separated by TLC on silica gel using benzene as the eluent. The first band from the TLC plates contained 51 mg (20%) of **2d**. The second band from the TLC plates gave 27 mg (6%) of **11-en**: mp 148—149 °C; IR ($CHCl_3$), 1730 cm^{-1}; NMR ($CDCl_3$), δ=1.24 (3H, s), 1.28 (3H, s), 1.63 (1H, d, J=2.4 Hz), 1.73 (3H, s), 2.01 (1H, dxd, J=6.7, 2.4 Hz), 2.21 (6H, s), 2.24 (3H, s), 2.30 (1H, d, J=6.7 Hz), 2.89 (1H, d, J=18.4 Hz), 3.05 (1H, d, J=18.4 Hz), 6.85 (2H, s); MS, m/z (rel intensity), 421 (M^+, 1), 419 (M^+, 5), 417 (M^+, 6), 159 (100). Found: C, 65.85; H, 5.94; N, 3.55%. Calcd for $C_{23}H_{25}NO_2Cl_2$: C, 66.03; H, 6.02; N, 3.35%. The third band from the TLC plates gave 297 mg (71%) of **11-ex**: mp 186—187 °C; IR ($CHCl_3$), 1742 cm^{-1}; NMR ($CDCl_3$), δ=1.26 (3H, s), 1.29 (3H, s), 1.31 (1H, d, J=3.8 Hz), 1.58 (3H, s), 1.91 (1H, dxd, J=6.6, 3.8 Hz), 2.26 (9H, broad s), 2.35 (1H, d, J=6.6 Hz), 3.13 (1H, d, J=16.5 Hz), 3.18 (1H, d, J=16.5 Hz), 6.90 (2H, s); MS, m/z (rel intensity), 419 (M^+, 2), 417 (M^+, 3), 159 (100). Found: C, 66.09; H, 5.81; N, 3.41%. Calcd for $C_{23}H_{25}NO_2Cl_2$: C, 66.03; H, 6.02; N, 3.35%.

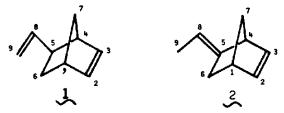
The Chemistry of Substituted Norbornenes. Reactions of 5-Vinyl-2-norbornene and 5-Ethylidene-2-norbornene with Formic Acid

Yoshiharu INOUE,* Fumio TANIMOTO, and Hisao KITANO
Research Institute for Production Development, 15, Shimogamo Morimoto-cho, Sakyo-ku, Kyoto 606
(Received November 14, 1983)

Addition of formic acid to 5-vinyl-2-norbornene(**1**) and subsequent hydrolysis afford 6-vinyl-*exo*-2-norbornanol(**5**) and 5-vinyl-*exo*-2-norbornanol(**6**). Similarly, from 5-ethylidene-2-norbornene(**2**) are formed 6-ethylidene-*exo*-2-norbornanol(**14**), 5-ethylidene-*exo*-2-norbornanol(**15**), and 6-ethyltricyclo[2.2.1.$0^{2,6}$]heptan-3-ol(**16**). The hydroboration of **2** also leads to the formation of **14** and **15**. Thus, the vinyl- and ethylidene-*exo*-norbornanols, **5**, **6**, **14**, and **15**, and the corresponding *endo*-norbornanols, **9**, **10**, **21**, and **22**, have been synthesized. A structural analysis of these products by ^{13}C NMR revealed that under certain conditions, the ethylidene group of **2** exerts a great influence upon the reactivity of the norbornenyl ring double bond. Moreover, the fact that **16** derived from the addition of formic acid to **2** consists of both *exo*- and *endo*-hydroxy epimers is inconsistent with the previous observations that the *exo*-isomer is generally the sole product in related systems.

Much less work has been done on the chemical properties of both **1** and **2** which are commercially available norbornenes having an olefinic side chain. Especially, detailed investigations concerning the reactivity difference of the two different types of double bonds in **1** and **2** have not been made so far.

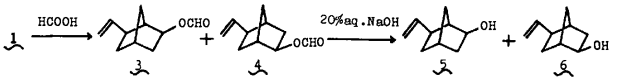


Recent studies of comparing the reactivity of the two double bonds in either **1** or **2** have clarified that the Diels-Alder reaction takes place more readily on the norbornenyl ring double bond in both **1** and **2**;[1] similarly, **2** undergoes addition of sulfur on the ring double bond,[2] whereas singlet oxygen,[3] peroxy acids,[4] and chlorosulfonyl isocyanate[5] add to **2** on the ethylidene group. On the other hand, the Prins reaction takes place on both double bonds in **2**,[6] and in addition, both **1** and **2** undergo hydroformylation on their both double bonds.[7] In any event, earlier studies as stated above have not clearly revealed the chemical behavior of both **1** and **2** from the standpoint of regio- and stereochemistry. In addition, the anticipation that the norbornanols having such an olefinic side chain could provide the intriguing reactive intermediate[4),8] has also encouraged us to initiate the current study.

The purpose of this work is to obtain a better understanding of what stereoelectronic influence is exerted on the reactivity of the norbornenyl ring double bond by participation of the unsaturated substituents, and to determine which one of the two double bonds in either **1** or **2** undergoes certain addition reactions preferentially.

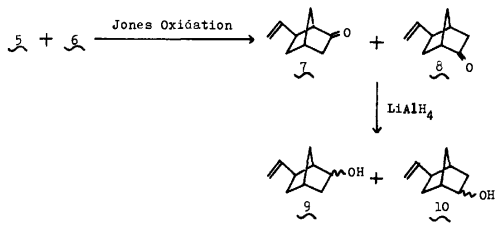
Results and Discussion

In order to prepare vinylnorbornanols from **1** and to gain further information on reactivity difference between the two double bonds in **1**, we first studied addition of formic acid to **1**, leading to the formation of a mixture of 6-vinyl-*exo*-2-norbornyl formate(**3**) and 5-vinyl-*exo*-2-norbornyl formate(**4**) in a good yield.



Here, products from the addition to the vinyl group and Wagner-Meerwein-type rearrangements *via* the bridged carbonium ion were not observed. A stereochemical assignment of the mixture of **3** and **4** was carried out by hydrolysis to a mixture of **5** and **6**, whose analysis by ^{13}C NMR showed that the hydroxyl group in both **5** and **6** exclusively occupied the *exo* position. It was also revealed that the ratio of **5** and **6** is *ca.* 1:1 by GC analysis. The result thus obtained is in accord with the earlier observation that the addition of formic acid to norbornene gives solely an *exo*-product[9], and also indicates that the vinyl group has no influence on the direction of the addition of formic acid to **1**.

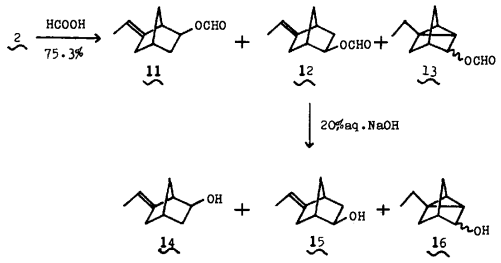
Alternatively, application of the Jones oxidation to the mixture of **5** and **6** afforded a mixture of 6-vinyl-2-norbornanone(**7**) and 5-vinyl-2-norbornanone(**8**), which was subsequently reduced by $LiAlH_4$ to form a mixture of 6-vinyl-2-norbornanol(**9**) and 5-vinyl-2-norbornanol(**10**); the ^{13}C NMR spectrum of these products was in striking contrast to that of the mixture of **5** and **6** and revealed that the mixture of **9** and **10** had 78% *endo*- and 22% *exo*-hydroxyl group.



The direct preparation of the mixture of **7** and **8** by the oxidation of the mixture of **3** and **4** was successfully conducted according to the procedure described in the case of norbornyl formate.[9]

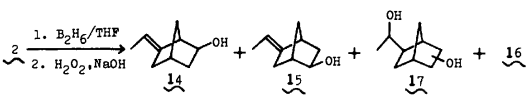
In order to achieve the synthesis of ethylidenenorbornanols from **2** and to examine the reactivity difference in the two double bonds in **2**, the addition of formic acid to **2** was carried out to give three prominent products, 6-ethylidene-*exo*-2-norbornyl formate(**11**), 5-ethylidene-*exo*-2-norbornyl formate(**12**), and 6-ethyltricyclo[2.2.1.

$0^{2,6}$]heptan-3-yl formate(**13**), in product ratio of 11+12/13=61:39.



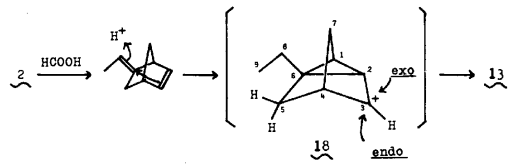
Although the three structural isomers, **11**, **12**, and **13**, can be distinguished readily by gas chromatography, isolation of pure compounds from the mixture by distillation was extremely difficult. In order to ascertain whether this reaction is stereospecific, the product mixture of **11**, **12**, and **13**, was hydrolyzed under alkaline conditions to yield a mixture of the corresponding alcohols, **14**, **15**, and **16**. The ^{13}C NMR spectrum of the alcohol mixture showed clearly that both **14** and **15** consist of 97% of the *exo* hydroxy epimer and that the ratio of **14** and **15** is 85:15. This particular positional orientation can be explained by preferential attack of H^+ upon C-2 of **2**, since C-2 (and, of course, C-8) has the richest electron density in the highest occupied frontier orbital of the homoconjugated diene system consisted of C-2, C-3, C-5, and C-8, and therefore, C-2 will be the site of attack by electrophile with its LUMO.[10]

For further study of stereochemical aspect of this reaction, an attempt was also made to prepare these compounds, **14** and **15**, by an alternative route. Thus, hydroboration-oxidation sequence was applied to **2** to provide a mixture of isomeric products, **14**, **15**, and 5-or 6-(1-hydroxyethyl)-2-norbornanol(**17**), together with *ca.* 1% of **16** unexpectedly formed.[11] Interestingly, ^{13}C NMR analysis of the mixture of **14** and **15** revealed that it consists of more than 91% of *exo*-isomer with the ratio of **14** and **15** being *ca.* 10:1. In the light of the fact that the hydroboration of norbornene gives 99.5% *exo*- and 0.5% *endo*-norbornanol,[12] we suggest that the lack of the *endo*-hydrogen at C-5 in **2** exerts a smaller steric effect on the addition of diborane to its norbornenyl ring double bond from the *endo* direction compared to norbornene, facilitating *endo* attack to increase the total amount of *endo*-products: this results in the diminished preference (~8.5%) for *exo* attack.



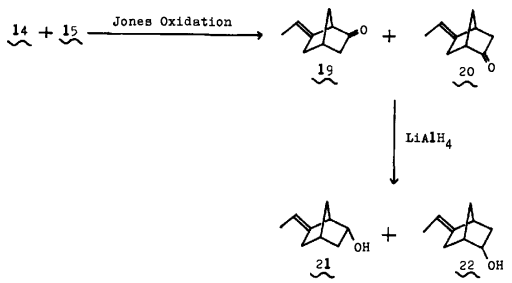
In the context of the structural investigation of the ethylidene-2-norbornanols, **14** and **15**, obtained from the two different types of methods illustrated above, preference of *exo* addition can be best explained by both the perturbation effect on the planarity of the π system[13] and the smaller steric hindrance.[11a]

Hydroboration of the mixture of **11**, **12**, and **13**, followed by distillation afforded **16**. The ^{13}C NMR spectrum of **16** revealed that it consists of 43% *exo*- and 57% *endo*-hydroxy epimers. This stereochemical outcome is surprising since most of addition reactions to norbornenyl ring double bonds proceed almost exclusively from the *exo* direction.[10,11b,11c,14] At this juncture, we propose the following mechanistic explanation; in the addition of formic acid to **2**, it is conceivable that protonation of **2** which occurs on C-8 having the richest electron density as stated above would give the carbonium ion intermediate(**18**),[15] whose molecular model suggests that the bond formation between C-2 and C-6 in **18** evidently renders the distance between C-2 and C-6 in **18** shorter than that between C-3 and C-5 in **2**.[13,16] Concurrently, the torsional strain in **18** thus generated puts C-3 and C-5 in **18** far away from each other, resulting in diminishing the steric interference induced by *endo*-hydrogen attached to C-5 toward a nucleophilic attack by formate anion at C-3 from the *endo* direction.



Alternative rationalization is that once the carbonium ion like **18** is formed, there is no need for considerations of electronic distribution governed by the molecular orbital theory, thereby giving no special preference for the direction of the addition.

Meanwhile, the mixture of **14** and **15** was oxidized by the Jones procedure to 6-ethylidene-2-norbornanone (**19**) and 5-ethylidene-2-norbornanone(**20**). Subsequent reduction with $LiAlH_4$ gave the corresponding norbornanols, **21** and **22**, whose ^{13}C NMR spectrum showed that the hydroxyl group occupied mainly the *endo* position.



Experimental

Boiling points are uncorrected. GC analyses were carried out with a Hitachi Model 163 gas chromatograph, using either (A) a 90-m, 0.25-mm i.d. stainless-steel column coated with Silicone SE-30 at a flow rate of 1.2 ml/min., or (B) a 1-m, 5-mm i.d. stainless-steel column packed with 10% Silicone SE-30 on Chromosorb W at a flow rate of 30 ml/min. Percentages indicated for each component refer to computer-calculated peak areas without correction for response, and the retention time is given as (t_R) min. for each peak. ^1H NMR spectra were recorded with a Hitachi Model R-24B, using tetramethylsilane as internal reference. Proton decoupled ^{13}C NMR spectra were obtained on a JEOL FX 90Q with $CDCl_3$ as an internal lock; absorptions are reported relative to tetramethylsilane. The ratio of each component was determined by computer-calculated line intensities without correction for response. IR spectra were obtained with a Hitachi Model 160-10 infrared spectrophotometer. Elemental ana-

lyses were performed by the Laboratory for Organic Elemental Microanalysis, Faculty of Pharmaceutical Sciences, Kyoto University.

Materials. 5-Vinyl-2-norbornene, obtained from Aldrich Chemicals Corp., and 5-ethylidene-2-norbornene, obtained from Tokyo Chemicals Corp., were vacuum distilled before use. The 5-vinyl-2-norbornene employed consists of two stereoisomers,[17] *exo*-5-vinyl-2-norbornene and *endo*-5-vinyl-2-norbornene, and was determined on the basis of ^{1}H NMR spectra and GC (column A, 80 °C) analysis to be in the ratio *exo*/*endo* of 2/3. The 5-ethylidene-2-norbornene consists of *E*- and *Z*-isomers, and it was determined on the basis of ^{13}C NMR spectrum and GC (column A, 80 °C) analysis to be in the ratio *E*/*Z* of 77/23.[18]

6-Vinyl-exo-*2-norbornyl Formate(3) and 5-Vinyl*-exo-*2-norbornyl Formate(4).* Approximately 92.0 g (2.0 mol) of 98—100% formic acid was added to 60.0 g (0.5 mol) of 5-vinyl-2-norbornene(**1**), and the mixture was stirred at about 70 °C for 4 h. After removal of excess formic acid, the residue was distilled under reduced pressure to give 52.8 g (63.6% yield) of a mixture of **3** and **4**, bp 104—105 °C (22 mmHg, 1 mmHg≈133.322 Pa), n_D^{14} 1.4821. GC(column A, 140 °C) analysis of this compound indicated that the ratio of four components (t_R 19.3, 19.9, 20.4, and 21.0 min) was 3:27:35:35. IR (neat) ν_{max} 3090, 2920, 1720, 1640, 1170 cm^{-1}; ^{1}H NMR (CCl_4) δ=7.90(s,1H), 6.00—5.40(m,1H), 5.15—4.90(m, 2H), 4.80(s, 1H), 2.40—1.35(m, 9H). Found: C, 72.20; H, 8.36; O, 19.44%. Calcd for $C_{10}H_{14}O_2$: C, 72.29; H, 8.43; O, 19.28%.

6-Vinyl-exo-*2-norbornanol(5) and 5-Vinyl*-exo-*2-norbornanol (6).* To 30.0 g (0.18 mol) of the mixture of **3** and **4** was added 36.0 g (0.18 mol) of 20% NaOH solution and 25 ml of methanol, and then the mixture was refluxed for 2 h. After removal of methanol, the residual solution was saturated with NaCl and extracted with a mixture of ether and benzene. After the extract was dried over $MgSO_4$, the solvent was evaporated. The residue was vacuum distilled to afford 24.0 g (96.6% yield) of the mixture of **5** and **6**, bp 72—73 °C (1.5 mmHg), $n_D^{18.5}$ 1.5004, whose GC (column A, 140 °C) showed to consist of three components in the yields of 5 (t_R 14.9 min.), 45 (t_R 15.4 min.), and 51 (t_R 15.7 min)%, respectively. IR (neat) ν_{max} 3350, 3090, 2920, 1640, 1100 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=6.10—5.40 (m, 1H), 5.10—4.65 (m, 2H), 3.80—3.60 (s, 1H), 2.95—2.80 (s, 1H), 2.30—1.10 (m, 9H); ^{13}C NMR ($CDCl_3$, 4 lines as C-2 for the predominant isomers) (relative intensity) 74.2 (40.7), 74.0 (22.4), 73.9 (33.1), 69.2 (3.8) ppm. Found: C, 78.14; H, 10.20; O, 11.66%. Calcd for $C_9H_{14}O$: C, 78.26; H, 10.14; O, 11.59%.

6-Vinyl-2-norbornanone(7) and 5-Vinyl-2-norbornanone(8).
Method A: A sulfuric acid solution of chromium trioxide was prepared by dissolving 5.6 g (0.056 mol) of chromium trioxide in 8 ml of water, adding 8.6 g (0.088 mol) of concentrated sulfuric acid to the solution and then diluting the mixture with 16 ml of water. This solution was then added dropwise over a period of 30 min to a solution of 11.0 g (0.080 mol) of the mixture of **5** and **6** in 50 ml of acetone with stirring below 5 °C. The mixture was stirred at a temperature below 20 °C for 3 h and then mixed with $NaHSO_3$ solution to form two layers. The lower layer was extracted with petroleum ether, and the petroleum ether layer was then combined with the upper layer previously obtained. The combined layers were washed with saturated $NaHCO_3$ solution until they turned slightly basic and then with water and dried over $MgSO_4$. After the drying agent was removed by filtration, the solvent was distilled off. The residue was distilled under reduced pressure to afford 7.3 g (67.1% yield) of the mixture of **7** and **8**, bp 68—70 °C (7.0 mmHg), $n_D^{18.5}$ 1.4883, which gave a GC (column A, 150 °C) analysis consisting of two components in the yields of 54 (t_R 15.5 min) and 46 (t_R 16.0 min)%, respectively. IR (neat) ν_{max} 3090, 2950, 2870, 1740, 1630 cm^{-1}; ^{1}H NMR (CCl_4) δ=6.20—5.50 (m, 1H), 5.20—4.80 (m, 2H), 2.75—1.60 (m, 9H). Found: C, 79.30; H, 8.87; O, 11.83%. Calcd for $C_9H_{12}O$: C, 79.41; H, 8.82; O, 11.76%.

Method B: To a solution of 10.0 g (0.060 mol) of the mixture of **3** and **4** in 25 ml of acetone was added dropwise, with stirring, 31.0 ml of 8M (1M=1 mol dm^{-3}) chromic acid solution [this solution was prepared by dissolving 10.7 g (0.107 mol) of chromium trioxide in 20 ml of water, adding 8.9 ml (0.167 mol) of concentrated sulfuric acid to the solution and then diluting this solution with 40 ml of water] while the reaction mixture was maintained at temperatures in the range of 20 to 30 °C. After being stirred at room temperature overnight, the mixture was treated with $NaHSO_3$ until the dark-brown solution turned dark-green. Thus, the solution separated into two layers and the lower layer was extracted with petroleum ether. The extract was then treated as described in Method A; as the product was obtained 6.2 g (75.7% yield) of the mixture of **7** and **8**, bp 54—55 °C (1.2 mmHg), whose physical properties and spectroscopic data proved identical to those of the compound prepared by Method A.

6-Vinyl-endo-*2-norbornanol(9) and 5-Vinyl*-endo-*2-norbornanol(10).* To the ice-cooled suspension of 0.70 g (0.018 mol) of $LiAlH_4$ in 50 ml of dry tetrahydrofuran was added dropwise, with stirring, 5.0g (0.037 mol) of the mixture of **7** and **8**. After being stirred at room temperature for 3 h, the mixture was treated with ethyl acetate to destroy excess reducing agent and then with dilute sulfuric acid solution until the solution became slightly acidic. This solution was extracted with ether and then the extract was washed with saturated $NaHCO_3$ solution, with water, and dried over $MgSO_4$. After removal of the drying agent, the solvent was distilled off. The residue was distilled under reduced pressure to yield 4.7 g (92.0% yield) of the mixture of **9** and **10**, bp 80—81 °C (2.8 mmHg), $n_D^{18.5}$ 1.5004; the GC (column A, 140 °C) showed that the ratio of three peaks (t_R 15.5, 15.7, and 15.9 min) was 26:35:39; the IR and ^{1}H NMR data are identical to those of the mixture of **5** and **6**: ^{13}C NMR ($CDCl_3$, 7 lines as C-2 for the predominant isomers) (relative intensity) 74.3 (8.1), 74.2 (9.4), 74.0 (6.1), 72.6 (31.2), 72.1 (29.3), 71.8 (22.9), 65.6 (1.1) ppm. Found: C, 78.12; H, 10.30; O, 11.58%. Calcd for $C_9H_{14}O$: C, 78.26; H, 10.14; O, 11.59%.

6-Ethylidene-exo-*2-norbornyl Formate(11), 5-Ethylidene*-exo-*2-norbornyl Formate(12), and 6-Ethyltricyclo[2.2.1.0^{2,6}]heptan-3-yl Formate(13).* To 120.0 g (1.0 mol) of **2** was added 184.0 g (8.0 mol) of 98—100% formic acid, and the mixture was stirred at 80—90 °C for 5 h. After removal of excess formic acid, the residual liquid was distilled under reduced pressure to give 125.0 g (75.3% yield) of the mixture of **11**, **12**, and **13**, bp 58—62 °C (1.8—3.0 mmHg) [lit,[4] 69—71 °C (6 mmHg)], $n_D^{18.5}$ 1.4685, whose GC (column B, 80—130 °C) showed that the ratio of two peaks (t_R 5.6 and 6.6 min) was 39:61. IR (neat) ν_{max} 3090, 2930, 2870, 1720, 1660, 1170 cm^{-1}; ^{1}H NMR (CCl_4) δ=7.90 (s, 1H), 5.50—5.25 (m, 1H), 4.80 (s, 1H), 2.80—0.75 (m, 12H). Found: C, 72.35; H, 8.40; O, 19.25%. Calcd for $C_{10}H_{14}O_2$: C, 72.29; H, 8.43; O, 19.28%.

6-Ethylidene-exo-*2-norbornanol(14), 5-Ethylidene*-exo-*2-norbornanol(15), and 6-Ethyltricyclo[2.2.1.0^{2,6}]heptan-3-ol(16).*
A mixture of 20.0 g (0.120 mol) of the ester, **11**, **12**, and **13**, and 29.0 g of 20% NaOH solution was refluxed for 2 h and then extracted with a mixture of ether and benzene. The extract was rinsed with water and then dried over $MgSO_4$. After removal of the solvent, the residue was disitilled under reduced pressure to yield 15.3 g (92.4% yield) of a mixture of **14**, **15**, and **16**, bp 65—66 °C (1.0 mmHg) [lit,[4] 82—85 °C (6 mmHg)], $n_D^{18.5}$ 1.4911, which was proved by GC (column B, 80 °C) to consist of two components in the yields of 39 (t_R

4.6 min.) and 61(t_R 6.0 min)%, respectively: IR (neat) ν_{max} 3630, 3090, 2930, 2870, 1660, 1110 cm^{-1}; ^{1}H NMR (CCl_4) δ=5.50—5.05 (m, 1H), 3.85 (s, 1H), 2.95 (s, 1H), 2.45—0.70 (m, 11H); ^{13}C NMR ($CDCl_3$, 4 lines as C-2 for the predominant isomers) (relative intensity) 78.2 (14.5), 77.1 (24.5), 73.9 (50.0), 72.8 (11.0) ppm. Found: C, 78.31; H, 10.19; O, 11.50%. Calcd for $C_9H_{14}O$: C, 78.26; H, 10.14; O, 11.59%.

*6-Ethylidene-oxo-2-norbornanol(14), 5-Ethylidene-*exo*-2-norbornanol(15), and 5-or 6-(1-Hydroxyethyl)-2-norbornanol(17).* To a solution of 72.0 g (0.600 mol) of **2** in 250 ml of dry tetrahydrofuran was added 5.0 g (0.129 mol) of solid $NaBH_4$. To the ice-cooled solution was dropwise added 14.0 ml (0.111 mol) of boron trifluoride etherate over about 30 minutes, and then the mixture was stirred at 10—20 °C for about 2 h. To the reaction mixture was added 25.2 ml of water and 34.1 ml of 3M NaOH solution, and then 34.1 ml of 30% H_2O_2 solution was dropwise added. The resultant mixture was stirred at about 50 °C for 2 h and poured into 100 ml of a mixture of ether and benzene. The mixture was washed several times with small amounts of saturated NaCl solution. The separated organic layer was dried over $MgSO_4$, and the solvent was distilled off to afford residual materials which in turn were distilled under reduced pressure to give a colorless liquid, 23.7 g of a mixture of **14**, **15**, and **16** [yield based on boron trifluoride etherate: 52%; bp 60—61 °C (0.45 mmHg)]; $n_D^{18.5}$ 1.5060, as the first fraction, and the second fraction obtained a colorless, viscous liquid, 6.4 g of **17** [yield based on boron trifluoride etherae: 37%; bp 110—113 °C (0.5 mmHg)]; $n_D^{18.5}$ 1.5022. The GC (column A, 140 °C) analysis of the mixture of **14** and **15** indicated that the ratio of three peaks (t_R 13.7, 16.2, and 16.3 min) was 1:46:53; the data for the mixture of **14** and **15** are as follows: IR (neat) ν_{max} 3630, 3090, 2930, 2870, 1660, 1115 cm^{-1}; ^{1}H NMR (CCl_4) δ=5.65—5.15 (m, 1H), 3.85 (s, 1H), 3.00 (s, 1H), 2.55—0.70 (m, 11H); ^{13}C NMR ($CDCl_3$, 4 lines as C-2 for the predominant isomers)(relative intensity) 78.4(6.7), 77.1(5.7), 74.2(79.4), 73.1(8.20) ppm. Found: C, 78.05; H, 10.08; O, 11.87%. Calcd for $C_9H_{14}O$: C, 78.26; H, 10.14; O, 11.59%.

In turn, the GC (column B, 140 °C) analysis of **17** showed a single peak (t_R 3.0 min): IR (neat) ν_{max} 3625, 2920, 2870, 1110 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.80—4.50 (s, 1H), 4.35—3.80 (m, 1H) 3.75—3.25 (m, 1H), 2.50—0.75 (m, 13H). Found: C, 69.29; H, 10.18; O, 20.53%. Calcd for $C_9H_{16}O_2$: C, 69.23; H, 10.26; O, 20.51%.

6-Ethyltricyclo[2.2.1.0^{2,6}]heptan-3-ol(16). The mixture of **11**, **12**, and **13**, 25.0 g (0.151 mol), was dissolved in 100 ml of tetrahydrofuran and to the solution was added 3.23 g (0.042 mol) of solid $NaBH_4$. To the ice-cooled solution was dropwise added, with stirring, 14.2 ml (0.056 mol) of boron trifluoride etherate. After the mixture was stirred at room temperature for 1 h and at about 50 °C for 1 h, it was treated with 8.0 ml of water, 11.0 ml of 3M NaOH solution, and then slowly with 11.0 ml of 30% H_2O_2 solution, and the mixture was stirred at about 40 °C for 2 h. The mixture was extracted with ether and the ether extract was rinsed with water, and dried over $MgSO_4$. After removal of the ether, the residue (27.5 g) was dissolved in 50 ml of methanol and treated with 20 g of 10% NaOH solution. After the mixture was stirred under reflux for 2 h, methanol was removed by distillation and the residual oil was extracted with ether. After the ether layer was washed with water and dried over Na_2SO_4, the solvent was evaporated. The residue was distilled under reduced pressure to yield 6.5 g (31.2% yield) of **16**, bp 46 °C (0.06 mmHg); $n_D^{18.5}$ 1.4855. The GC (column A, 130 °C) analysis of **16** showed to consist of two components in the yields of 43(t_R 15.6 min.) and 57(t_R 16.1 min)%, respectively. IR (neat) ν_{max} 3630, 2925, 2870, 1115 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.05 (s, 1H), 3.80 (s, 1H), 2.00—0.75 (m, 12H); ^{13}C NMR ($CDCl_3$, 2 lines as C-2 for the predominant isomers) (relative intensity) 78.2(45.5), 77.1(54.5) ppm. Found: C, 78.41; H, 10.23; O, 11.36%. Calcd for $C_9H_{14}O$: C, 78.26; H, 10.14; O, 11.59%.

6-Ethylidene-2-norbornanone(19) and 5-Ethylidene-2-norbornanone(20). To an ice-cooled solution of 5.0 g (0.036 mol) of a mixture of **14** and **15**, obtained *via* hydroboration, in 30 ml of acetone was added dropwise, with stirring 20.0 ml of 8M chromium trioxide solution prepared according to Method B previously described in this section. The chromium trioxide solution was added at such a rate that the temperature did not rise above 30 °C. After being stirred at room temperature overnight, the mixture was worked up in the identical manner to that described in Method B. The product, a mixture of **19** and **20**, was obtained by vacuum distillation as a colorless liquid [yield, 68.0%; bp 49—50 °C (0.40 mmHg)]; $n_D^{18.5}$ 1.4930, whose GC (column A, 140 °C) indicated that the ratio of three components (t_R 16.0, 16.5, and 16.8 min) was 53:2:45; IR (neat) ν_{max} 3090, 2925, 2870, 1740, 1660 cm^{-1}; ^{1}H NMR (CCl_4) δ=5.50—5.20 (m, 1H), 2.85—0.75 (m, 11H). Found: C, 79.37; H, 8.88; O, 11.75%. Calcd for $C_9H_{12}O$: C, 79.41; H, 8.82; O, 11.76%.

*6-Ethylidene-*endo*-2-norbornanol(21) and 5-Ethylidene-*endo*-2-norbornanol(22).* To a stirred ice-cooled solution of 0.5 g (0.013 mol) of $LiAlH_4$ in 30 ml of tetrahydrofuran was added dropwise 3.6 g (0.026 mol) of a mixture of **19** and **20**. After the mixture was stirred at room temperature for 2 h, the reaction was quenched by slow addition of water, acidified with 10% sulfuric acid solution, and extracted with ether. The ether layer was washed with saturated $NaHCO_3$ solution, with water, and then dried over $MgSO_4$. After removal of the drying agent, the residual liquid was subjected to vacuum distillation.

The product, a mixture of **21** and **22**, was obtained as a colorless liquid [yield, 91.0%; bp 57—58 °C (0.20 mmHg)]; $n_D^{18.5}$ 1.5050, whose GC (column A, 140 °C) showed that it consists of three components in the yields of 11(t_R 15.0 min), 70(t_R 16.5 min.), and 19(t_R 16.8 min)%, respectively. IR (neat) ν_{max} 3630, 3090, 2920, 2875, 1660, 1110 cm^{-1}; ^{1}H NMR (CCl_4) δ=5.50—4.95(m, 1H), 3.80(s, 1H), 2.95(s, 1H), 2.50—0.75(m, 11H); ^{13}C NMR ($CDCl_3$, 4 lines as C-2 for the predominant isomers) (relative intensity) 78.5(6.5), 77.2(6.8), 74.0(12.5), 73.1(1.8), 71.9(60.6), 70.9(11.9) ppm. Found: C, 78.34; H, 10.09; O, 11.57%. Calcd for $C_9H_{14}O$: C, 78.26; H, 10.14; O, 11.59%.

Assignment of ^{13}C Chemical Shifts in Substituted Norbornanols

The previous studies[19] suggest that the ^{13}C proton-decoupled NMR spectrum for the substituted norbornanols described above mainly shows resonances at 75.0—65.0 ppm characteristic of C-2, α-carbon of a hydroxyl group and lead to the conclusion that the C-2 resonances of substituted 2-norbornanols are different in an *exo-endo* pair of isomers and γ-effect generates marked chemical-shift changes. On the basis of this empirical definition, the assignment of C-2 resonances was performed on vinylnorbornanols, **5**, **6**, **9**, and **10**, ethylidene norbornanols, **14**, **15**, **21**, and **22**, and ethyltricyclanol, **16**.

Firstly, as for 6-vinyl-2-norbornanol and 5-vinyl-2-norbornanol, the characteristic shift changes of the C-2 are best interpreted on the basis of the γ-effect. Thus, the *endo*-6-vinyl group is considered to cause a relatively marked upfield shift at C-2 due to steric interac-

tion between *endo*-6-vinyl group and either *endo*-hydrogen or *endo*-hydroxyl oxygen at C-2. In the case of *exo*-6-vinyl-2-norbornanol, C-2 should show a small upfield shift. By contrast, introduction of *endo*- and *exo*-vinyl group at C-5 is not expected to cause a significant shift change at C-2. Thus, the peaks at 74.2, 74.0, and 73.9 ppm for the mixture of **5** and **6** are reasonably identified as C-2 for *exo*-6-vinyl-*exo*-2-norbornanol, *endo*-5-vinyl-*exo*-2-norbornanol, and *exo*-5-vinyl-*exo*-2-norbornanol (but not differentiated respectively) and the absorption at 69.2 ppm can be assigned to C-2 for *endo*-6-vinyl-*exo*-2-norbornanol. Since there is no absorption between 73.0 and 72.0 ppm where the *endo*-hydroxy isomers should show C-2 resonances, we can conclude that no *endo*-hydroxy isomers can be detected in the mixture of **5** and **6**.

Turning to the ^{13}C NMR spectrum of the mixture of **9** and **10**, the peaks at 74.3, 74.2, and 74.0 ppm were identified as C-2 of *exo*-6-vinyl-*exo*-2-norbornanol, *endo*-5-vinyl-*exo*-2-norbornanol, and *exo*-5-vinyl-*exo*-2-norbornanol, although they are not differentiated respectively. Three lines at 72.6, 72.1, and 71.8 ppm should belong to C-2 of *endo*-5-vinyl-*endo*-2-norbornanol, *exo*-5-vinyl-*endo*-2-norbornanol, and *exo*-6-vinyl-*endo*-2-norbornanol (but not differentiated respectively) and the remaining peak at 65.6 ppm is identified as C-2 of *endo*-6-vinyl-*endo*-2-norbornanol, whereas the characteristic absorption for C-2 of *endo*-6-vinyl-*exo*-2-norbornanol is not observed in the chemical shift range predicted on the basis of the γ-effect.

By contrast with the influence of vinyl group, especially *endo*-vinyl group, upon the ^{13}C chemical shift at C-2 of the compounds above mentioned, the ethylidene group is considered to have very little influence on chemical shift from the well-known concept that the influence of the double bond upon the chemical shift is very weak when several bonds away.[20] Thus, the ^{13}C NMR spectra of both the mixture of **14** and **15**, obtained *via* hydroboration, and of **21** and **22** are demonstrated as follows: first in the case of the mixture of **14** and **15**, the peak at 74.2 ppm was assigned to C-2 of 6-ethylidene-*exo*-2-norbornanol and the line at 73.1 ppm could be assigned to C-2 of 5-ethylidene-*exo*-2-norbornanol. Interestingly, in this case, two absorptions at 78.4 and 77.1 ppm are observed, which apparently indicates the formation of **16** whose ^{13}C NMR spectrum will be discussed later in this section. Similarly, in the case of the mixture of **21** and **22**, two absorptions at 74.0 and 73.1 ppm are identified as C-2 of 6-ethylidene-*exo*-2-norbornanol and 5-ethylidene-*exo*-2-norbornanol, respectively. The remaining two main peaks at 71.9 and 70.9 ppm are assigned to C-2 of 6-ethylidene-*endo*-2-norbornanol and 5-ethylidene-*endo*-2-norbornanol, respectively.

Analogous effort to assign the C-2 resonances of the mixture of **14** and **15**, derived from the addition of formic acid to **2**, has been made. The two peaks at 78.2 and 77.1 ppm are identified as C-2 of the two epimers of **16**. Two lines at 73.9 and 72.8 ppm are assigned to C-2 of 6-ethylidene-*exo*-2-norbornanol and 5-ethylidene-*exo*-2-norbornanol, respectively.

The simplicity in the structure of **16**, including only two epimers, allows an unambiguous assignment of C-2. Thus, the peak at 78.2 ppm is identified as C-2 of *exo*-hydroxy epimer of **16**, and hence the remaining absorption at 77.1 ppm is assigned to C-2 of *endo*-hydroxy epimer of **16**.

We wish to thank Professor Teijiro Yonezawa of Kyoto University for helpful suggestions and valuable discussions. We are also grateful to Dr. Sakae Uemura of the Institute for Chemical Research, Kyoto University, and Dr. Hiroshi Fujimoto of Kyoto University for their valuable advice.

A New Wittig Rearrangement of 2,2-Disubstituted 1,3-Dithianes

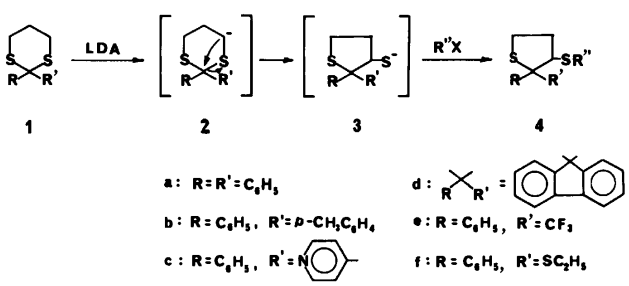
Hideyuki IKEHIRA* and Shigeo TANIMOTO*
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611
(Received January 23, 1984)

Carbanions produced by deprotonation at the ring C-4 of 2,2-disubstituted 1,3-dithianes undergo a Wittig type rearrangement to give the anions of 2,2-disubstituted tetrahydrothiophene-3-thiols. After being trapped with several alkyl halides, these afford the corresponding 2,2-disubstituted 3-(alkylthio)tetrahydrothiophenes, which are difficult to prepare by other synthetic routes.

Recently, Wilson and his co-workers[1,2] studied the reaction of 1,3-dithiane with anionic bases in the gas phase. They observed that it undergoes deprotonation at C-5, in competition with that at C-2. However, the deprotonation at C-5 is recognized only for 1,3-dithiane in the gas phase. In a solution, the deprotonation usually occurs at C-2. For example, 1,3-dithiane and its 2-alkyl derivatives easily undergo deprotonation at the ring C-2 by butyllithium or lithium diisopropylamide (LDA), leading to the formation of 2-lithio-1,3-dithianes.[3] Many examples cited in the literature demonstrate the high nucleophilicity of the 2-lithio-1,3-dithianes as well as the utility of these reagents in synthetic organic chemistry.[3] On the other hand, 2-cyclohexylidene-1,3-dithiane is deprotonated at C-4 of the 1,3-dithiane ring by butyllithium in tetrahydrofuran.[4] The ring C-4 deprotonation has also been found by Hase and Lahtinen[5] in the reaction of several 2-alkyl-2-trimethylsilylmethyl-1,3-dithianes with butyllithium in the presence of hexamethylphosphoric triamide, but it competes with side chain deprotonation. In most cases, the carbanion produced by deprotonation at the ring C-2 or C-4 of 1,3-dithiane and its derivatives is stable and does not undergo further transformation under the carbanion-forming conditions. In the last-mentioned reaction proposed by Hase and Lahtinen,[5] however, the initially formed carbanion undergoes migration of trimethylsilyl group and succeeding formation of C-2 to C(α) double bond with suprafacial expulsion of S-3 as the thiolate anion under the carbanion-forming conditions. With this background, we expected that appropriate 2,2-disubstituted 1,3-dithianes should be deprotonated at C-4 by a strong base such as butyllithium or LDA. In this paper we wish to describe such a deprotonation by LDA and the behavior of the resulting anionic species, which would be made clear by trapping them by several alkyl halides.

Results and Discussion

We have studied the reactions of several 2,2-disubstituted 1,3-dithianes (**1**), such as 2,2-diaryl-1,3-dithianes (**1a**, **1b**, **1c**, and **1d**), 2-phenyl-2-trifluoromethyl-1,3-dithiane (**1e**), and 2-ethylthio-2-phenyl-1,3-dithiane (**1f**) with LDA in tetrahydrofuran in the presence or absence of *N*, *N*, *N'*, *N'*-tetramethylethylenediamine followed by adding an appropriate alkyl halide to the reaction mixture. These reactions resulted in the high-yield formation of the corresponding 2,2-disubstituted 3-(alkylthio)tetrahydrothiophenes (**4**) after the usual work-up procedure.



It is certain that the initial deprotonation occurred at the ring C-4 of **1**, because they possess no hydrogen at the ring C-2. Presumably, the initially formed anionic species (**2**) rearranges *via* 1,2-shift of the C-2 carrying two substituents from S-3 to C-4 as well as the simultaneous S-3 thiolate expulsion to give the anions (**3**) of 2,2-disubstituted tetrahydrothiophene-3-thiols. On trapping with alkyl halides, these afford **4**. This mechanistic interpretation reveals that the reaction is a Wittig type rearrangement involving migration of carbon from sulfur to an α-carbanion. Concerning such the rearrangement of sulfide and its homologues, to our best knowledge, only three reports have been published.[6-8] We chose 2,2-diphenyl-3-(methylthio)-tetrahydrothiophene **4a** [R''=CH_3] as a representative of the obtained products **4**. We studied its ^{1}H-NMR spectrum in $CDCl_3$ by decoupling experiments involving the protons on C-3, C-4, and C-5 of **4a** [R''=CH_3]. It is obvious from Fig. 1 that **4a** [R''=CH_3] involves the $-SCH_2CH_2CH<$ system, the methylthio, and two phenyl groups. Thus, the structure of **4a** [R''=CH_3] should be supported by the decoupled spectra, together with the ^{13}C-NMR and mass spectral data and analytical data.

This observation as well as the fact that the other products also exhibit spectral properties (^{1}H-NMR, ^{13}C-NMR, and mass spectra) and analytical data in good accordance with the assigned structures supports the reasonableness of the above mechanistic interpretation. Also, the occurrence of this conversion was recognized only when both the substituents at C-2 of **1** are electron-withdrawing groups, suggesting that the migrating carbon may be C-2 of the 1,3-dithiane ring. All attempts to submit 2-alkyl-2-aryl- and 2,2-dialkyl-1,3-dithianes such as 2-methyl-2-phenyl-, 2-ethyl-2-phenyl-, 2,2-dimethyl-, and 2,2-diethyl-1,3-dithiane to the same deprotonation-alkylation sequence failed and resulted in the recovery of the starting 1,3-dithianes. Thus, it may be claimed that the occurrence

a) The products **4c** were isolated by column chromatography(silica gel, 25% ethyl acetate/chloroform). The other products were also isolated by column chromatography(silica gel, 10% ethyl acetate/hexane). All products listed in this table were a mixture of diastereomers. They were also characterized by mass spectra in addition to ^{1}H-NMR, ^{13}C-NMR, and elemental analysis. b) Decomposes during distillation under reduced pressure.
† 1 Torr≈133.322 Pa.

of this conversion requires the presence of two electron-withdrawing groups at C-2 of the 1,3-dithiane ring. Although this method is applicable only to the above-mentioned 2,2-disubstituted 1,3-dithianes such as **1**, the mild conditions required and high yields of the objective **4**, as can be seen in Table 1, make this method valuable. Tables 2 and 3 give ^{1}H- and ^{13}C-NMR spectral data of **4a—c** and **4d—f**, respectively. The analytical data of **4** are listed in Table 4.

Experimental

All 2,2-disubstituted 1,3-dithianes (**1a**, **1b**, **1c**, **1d**, and **1e**) employed in this research were prepared by the $AlCl_3$-catalyzed reaction of the corresponding ketones with 1,3-propanedithiol. The compound **1f** was prepared from 2-lithio-2-phenyl-1,3-dithiane generated by the known method and diethyl disulfide in tetrahydrofuran at low temperature. Tetrahydrofuran and *N,N,N′,N′*-tetramethylethylenediamine were dried over lithium aluminium hydride and calcium hydride respectively, and then distilled prior to use. The other reagents were commercially available and were used without further purification.

Reactions Summarized in Table 1. To lithium diisopropylamide (LDA), prepared from diisopropylamine (0.35 g, 3.5 mmol) in tetrahydrofuran (7 ml) and 1.56 molar solution (2.12 ml, 3.3 mmol) of butyllithium in hexane, was added a solution of **1** (1.3 mmol) in tetrahydrofuran (4 ml) with stirring at −78 °C. Only when **1a** and **1b** were used as the dithiane component *N,N,N′,N′*-tetramethylethylenediamine (0.41 g, 3.5 mmol) was added[9] prior to the addition of **1**. The reaction mixture was allowed to warm to −15 °C and the stirring was continued for 1 h at the same temperature. The mixture was cooled again to −78 °C, and an appropriate alkyl halide (3.3 mmol) was added with stirring. The stirring was continued for 1 h at −10—−5 °C and for 24 more hours at room temperature. The reaction mixture was quenched with water (100 ml) and a saturated aqueous solution (20 ml) of ammonium chloride, and then extracted with diethyl ether (3×60 ml). The combined ethereal extracts were dried over anhydrous magnesium sulfate and concentrated *in vacuo* to give a pale yellow residue, which was subjected to column chromatography on silica gel. The eluents used for the column chromatography are indicated as the marginal notes of Table 1.

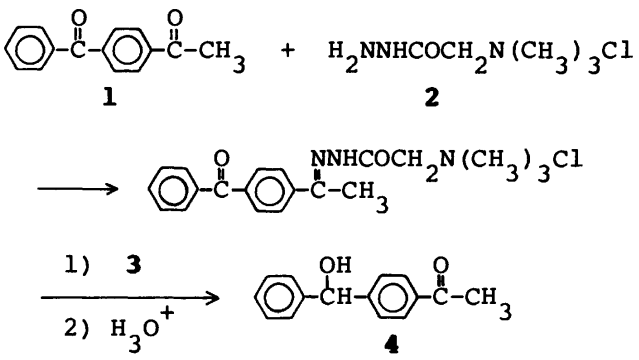
(Received February 21, 1984)

Some Girard's derivatives of 4-phenylbenzophenone were prepared in ethanol solution, in the presence of Amberlite IRC-50 as a catalyst. Supported samples of the derivatives were then prepared by addition of silica gel to the solution, followed by evaporation of the ethanol. The supported samples were reduced with lithium tri-*t*-butoxyhydroaluminate by being suspended in THF solution. Hydrolysis, followed by extraction of the product, yielded 4-acetyl-α-phenylbenzyl alcohol in an 80% selectivity. In the same way, 4-acetylbenzaldehyde yielded 1-(4-formylphenyl)ethanol in an 81% selectivity. Relatively unhindered carbonyl groups were preferentially protected. Utilization of Girard's reagents was successfully made as a protecting reagent and also as an extracting reagent of carbonyl compounds.

Many chemical reactions occur homogeneously, while various reactions occurring on solid surfaces are also known. Recently, solid adsorbents have been used as reaction media on which the reactions occur heterogeneously.[1] In almost all cases reagents were adsorbed on them, and some concepts for application of the adsorbents can be seen in the reports. In one concept, inorganic reagents such as potassium permanganate, sodium periodate, iron(III) nitrate, and iron(III) chloride were brought into an organic reaction system on solid adsorbents.[2-5] These inorganic reagents are insoluble in organic solvents, so they were adsorbed, forming monomolecular-like layers on the solid adsorbents. In addition, isolation of the products became easy by use of adsorbents, because inorganic by-products and tarry matter remain on the adsorbents.

We have reported the case in which a substrate was adsorbed.[6] Sodium hydrogensulfite adducts of carbonyl compounds are usually not soluble in organic solvents, but were stably adsorbed on silica gel and alumina in the absence of water. The adducts adsorbed on solid adsorbents could be brought into an organic reaction system. In this way, sodium hydrogensulfite was used for protection of the carbonyl groups in the organic reaction system.

From the same stand point the use of Girard's reagents for protection of carbonyl groups has been studied. Girard's reagents condense with carbonyl compounds to form water-soluble products. The carbonyl compounds are then recovered from the aqueous layer by hydrolysis or carbonyl exchange reaction.[7] While a semicarbazide hydrochloride is used to protect the carbonyl groups, Girard's reagent, a member of the substituted hydrazine group, has not been used to protect them because of the low solubilities of the derivatives in the usual organic solvents. We tried to use Girard's reagent for protection of the carbonyl groups by using it with adsorbents. As a representative of dicarbonyl compounds, 4-acetylbenzophenone (**1**) was chosen. It has two carbonyl groups. One of these, the benzoyl group, was reported not to react with Girard's reagent because of steric hindrance.[8] First, the derivative of **1** with Girard-T (**2**), α-(trimethylammonio) acetohydrazide chloride, was prepared. Then it was supported on silica gel and reduced with lithium tri-*t*-butoxyhydroaluminate (**3**). Analysis of the product showed that 4-acetyl-α-phenylbenzyl alcohol (**4**) was obtained in an 80% selectivity. Part of the results of this investigation was preliminary reported in an earlier paper,[9] and the details are given here.



Results and Discussion

Selective Protection of the Acetyl Group of 4-Acetylbenzophenone (1). The effect of reaction time on the Girard's derivative formation was examined. Equal moles of **1** and **2** were allowed to react in the presence of Amberlite IRC-50 (**5**) as a catalyst to produce the derivative. After removal of the catalyst, silica gel was added to the solution, and the ethanol was evaporated. The derivative supported on silica gel was reduced with an excess of **3**. After hydrolysis the product was analyzed. The compositions of the products were plotted against the reaction time for the derivative formation in Fig. 1. This figure shows that the products of insufficient reaction time contained considerable amount of diol, 4-(1-hydroxyethyl)-α-phenylbenzyl alcohol (**6**). This is because considerable amount of **1** was left intact and was then reduced. Figure 1 also shows that the compositions of the products attained constant values after two hours. So the selectivity for **4** was about 80%. Two hours was sufficient to complete the formation of the derivative. In this way the reaction time was determin-

ed for each substrate or pair of substrates in competitive reaction at an appropriate reaction temperature. Milder reaction conditions were adopted unless a benzoyl group was contained. As Fig. 1 shows, the products contained about 13% of the starting material, **1**, unreduced, though equal mole of **2** and sufficient amount of **3** were used. Two cases are proposed for the explanation: (1) The benzoyl group of **1** was also protected by **2**. (2) Compound **1** or the derivative on the silica gel was covered with other molecules and prohibited from reacting with **3**.

The effect of the amount of Girard-T (**2**) on the selectivity was examined. The derivatives were prepared in varying ratios of **2** to 4-acetylbenzophenone (**1**), using **5** as a catalyst, and treated in the way described above. The compositions of the products were plotted against the amounts of **2** in Fig. 2. When more than equal moles of **2** to **1** was used, 4-acetyl-α-phenylbenzyl alcohol (**4**) was obtained in about 80% selectivity. An equal mole amount of **2** was sufficient for the selective protection of the acetyl group of **1**. The benzoyl group of **1** was not protected, for more than 75% of the benzoyl group was reduced in spite of the addition of **2** in excess.

The effect of the amount of silica gel was also examined. The derivatives were prepared from equal moles of **1** and **2** as described above. Then the adsorbed samples were prepared with varying amounts of silica gel and treated with the procedure described above. The compositions of the products are plotted against the amount of silica gel in Fig. 3. This figure shows that a significant amount of unreduced **1** was recovered when the amount of silica gel was little. The figure also shows that the amount of 4-acetyl-α-phenylbenzyl alcohol (**4**) increased with increasing amount of the silica gel up to 35 times that of **1**. Not less than 10 times silica gel is required for monolayer adsorption of the derivative: this comes from a rough estimate using simple molecular models.[10] Rough agreement was obtained amoung these values. In the reaction products, **1** was contained in more than 13% selectivity in spite of employing both lithium tri-*t*-butoxyhydroaluminate (**3**) and the silica gel in excess. The benzoyl group has been proven not to be protected with **2** from the preceding experiments. Then it is considered that partial multilayer adsorption on the silica gel prevented **1** or the derivative from contact with **3**. The ionic character of the derivative may facilitate the formation of the multi layer adsorption.

Girard-P (**7**), α-(1-pyridino) acetohydrazide chloride, and rarely Girard-D (**8**), α-(dimethylammonio) acetohydrazide chloride, are also used as the condensation reagents.[7] The effectiveness of these reagents was examined according to the manner described above. As presented in Table 1, **7** was a useful reagent for protection of the acetyl group of **1**, but **8** was not.

Acetic acid (**9**), as well as Amberlite IRC-50 (**5**), is known as a catalyst for the condensation of Girard's reagents with carbonyl compounds. The effect of **9** on the selective protection was examined. As can be seen from Table 1, **9** was not a suitable reagent for the selective protection, because a significant amount of

Table 1. Selective protection of **1** with girard's reagents

6	**15**	**16**	89	95	6.7	73.3	10.9

a) Equal moles of A, B, and **2** were used. b) Combined amount of unreduced substrate and product. c) Based on recovered products. d) (Conversion of B)/(Conversion of A).

4-acetylbenzophenone (**1**) was recovered without reduction. It is difficult to remove **9** completely from the adsorbed sample because of its relatively low vapor pressure and high polarity. The incomplete reduction of **1** could be attributed to the deposit of insoluble products produced by the reaction of **9** with tri-*t*-butoxyhydroaluminate (**3**) on the silica gel surface. A calculated amount of sodium hydroxide was added to neutralize **9** and to prevent the effect after condensation reaction. Then the adsorbed sample was prepared and reduced. As shown in Table 1, no improvement was observed. Consequently **9** was proven not to be a suitable catalyst for this purpose. In contrast to **9**, **5** brought about good selectivity. Moreover **5** could be easily removed from the reaction mixture by decantation. All the following experiments were undertaken by use of **5** as the catalyst.

Celite gave good selectivity, as Table 1 shows. Alumina was another effective adsorbent for the reaction, though the selectivity decreased a little. A similar result was obtained when silica-alumina (13% or 28% Al_2O_3) was used as adsorbent.

An attempt was made to utilize the Girard's reagent for protection of the carbonyl group in an aqueous solution without using solid support. Sodium borohydride (**10**) was used, for it can reduce carbonyl groups in aqueous solution. The derivative of **1** with **2** was prepared. Reduction of the derivative with **10** in the aqueous solution yielded 4-ethyl-α-phenylbenzyl alcohol preferentially and failed to yield **4**. Reductive cleavage occurred at the carbon-nitrogen double bond of the derivative.[11] Though this attempt was unsuccessful, another reducing agent can be utilized for this procedure.

It has been confirmed that the acetyl group of 4-acetylbenzophenone (**1**) had higher reactivity with **3** than the benzoyl group. When **3** was added to the THF solution of **1**, 4-(1-hydroxyethyl) benzophenone (**11**) was produced in a maximum 68% selectivity, while 4-acetyl-α-phenylbenzyl alcohol (**4**) was produced in a 19% maximum selectivity.

Protection Selectivity of Girard-T (2) for Carbonyl Groups. 4-Acetylbenzaldehyde (**12**) and 7-oxooctanal (**13**) were chosen as representatives of dicarbonyl compounds. The selective protection of the carbonyl groups with Girard-T (**2**) was examined by the method described above. When equal moles of **12** and **2** were allowed to react, 1-(4-formylphenyl) ethanol (**14**) was obtained in an 81.0% selectivity after reduction with **3**. When equal moles of **13** and **2** were allowed to react, 7-hydroxyoctanal was obtained in an 82.1% selectivity by the same procedure. In both cases the acetyl groups which existed together with the formyl groups were reduced preferentially. On the other hand, the acetyl group of 4-acetylbenzophenone (**1**) which existed together with the benzoyl group was not reduced. The treatment of **12** with twice the number of moles of **2** gave unreduced **12** in an 80.5% selectivity after reduction with **3**, which indicates that both carbonyl groups of **12** were protected with **2**. The protection of carbonyl groups depended both on the reactivity of the carbonyl groups and on the amount of **2** used.

The protection selectivity of **2** for other carbonyl groups was examined by a competitive reaction method combining two different kinds of carbonyl compounds. Table 2 presents the results. An acetyl group was selectively protected in the presence of a benzoyl group (entry 1), as can be expected from the result of **1**. Formyl

groups in the presence of acetyl groups (entries 2 and 3), the aldehyde in the presence of an ethyl ketone (entry 4), and the methyl ketone in the presence of the ethyl ketone (entry 5) of similar molecular structures were selectively protected. 4-Phenylcyclohexanone (**15**) in the presence of 2-methyl-4-phenylcyclohexanone (**16**) was also selectively protected (entry 6). Consequently, **2** responded sensitively to the differences of steric hindrance of the carbonyl groups, and hence **2** was effective as a reagent for selective protection of the unhindered carbonyl groups.

*Application of Girard-T (**2**) as a Protective as well as an Extractive Reagent.* An experiment was undertaken in which **2** acted as a protective reagent of a carbonyl group, in addition to acting as the usual extractive reagent. To 9.4 mmol of 4-acetylbenzaldehyde (**12**), 9.4 mmol of acetophenone (**17**) was added deliberately as an impurity. To a solution of the mixture, 9.4 mmol of **2** was added; this produced the derivative in the presence of **5**. The product was washed with water. The adsorbed sample of the derivative on silica gel was prepared from the aqueous solution. After reduction with **3** followed by hydrolysis, the products were extracted with benzene. The following compounds were identified by analysis: 1-(4-formylphenyl) ethanol (**14**) (85% wt), **12** (5.6% wt), **17** (1.7% wt) and 1-phenylethanol (**18**, 6.9% wt). In this stage, about 90% of the impure substances (**17** and **18**) were removed. After purification of this product by column chromatography, 6.6 mmol (69% yield) of **14** was obtained.

Conclusion

Girard's reagents were found to be effective reagents for protection of carbonyl groups in a nonaqueous reaction system when they were used with the solid supports. The solid support was used as a reaction media on which the reaction took place. Another example can be seen in our study of protecting carbonyl groups with sodium hydrogensulfite, in which the substrates were supported on the silica gel or alumina.[6] Other examples can be seen in many cases in which the reagents were supported.[1] A solid support will provide an effective reaction environment if suitable solvents which dissolve both the substrate and reagent are not available.

Experimental

Materials. 4-Acetylbenzophenone (**1**, mp 83—84 °C),[12] 4-acetylbenzaldehyde (**12**, bp 155 °C/15 mmHg, 1 mmHg=133.322 Pa),[13] 7-oxooctanal (**13**, bp 126 °C/16 mmHg),[14] 4-phenylacetophenone (**19**, mp 121—122 °C),[15] 4-phenylcyclohexanone (**15**, mp 78 °C),[16] and 2-methyl-4-phenylcyclohexanone (**16**, mp 139 °C)[17] were prepared by the reported methods. THF was dried over calcium hydride. Lithium tri-*t*-butoxyhydroaluminate (**3**) was prepared by the reported method.[18] Silica gel and alumina were Wakogel C-200 and activated alumina 200 mesh, respectively (Wako Pure Chemical Industries, Ltd.). Finely divided Celite 545 (Johns-Manville Sales Corp.) was used. Other materials were commercial products.

Methods. *Typical Reaction:* Equal moles of **1** (44.8 mg, 0.2 mmol) and Girard-T (**2**, 33.5 mg, 0.2 mmol) were added to ethanol (1.3 mmol) suspending Amberlite IRC-50 (**5**, 10 mg) and stirred for 2 h at 70 °C. After removal of **5** by decantation silica gel (1.6 g) was added and the ethanol was evaporated under reduced pressure (*ca.* 10 mmHg) at 60 °C. After the evaporation had apparently completed, the sample was evacuated for an additional 10 min. The recovery of **1** from this adsorbed sample was 98%, and hence only a small amount of **1** was lost in this evaporation procedure. The adsorbed sample thus obtained contained a trace amount of the ethanol, but was used for further reaction as such. To a solution of **3** (2 mmol) in THF (7 cm^3), the adsorbed sample was added and well mixed for 1 h; then the mixture was hydrolyzed with dilute hydrochloric acid or treated with formaldehyde.[19] The product was extracted with benzene and analyzed by GLC or HPLC. The reactant was recovered in a 98% yield, based on the adsorbed sample. Selectivity for the formation of 4-acetyl-α-phenylbenzyl alcohol (**4**) was 79.5%.

Competitive Reaction: Typically **19** (39.2 mg, 0.2 mmol), benzophenone (36.4 mg, 0.2 mmol), and **2** (33.5 mg, 0.2 mmol) were added to ethanol (1.3 cm^3) which included **5** (10 mg) in suspension. The mixture was stirred for 2 h at 80 °C to produce the derivatives. Hereafter the sample was treated by the procedures described above.

Analysis. Reaction products were identified with the authentic samples obtained commercially or synthesized independently. Product compositions were determined by GLC or HPLC. GLC analyses were carried out on Shimadzu gas chromatographs Model GC-7A and GC-4MPTF using columns packed with 10% polyethylene glycol 20000 on Chromosorb WAW, and columns packed with 10% Apiezon grease L on Chromosorb WAW. HPLC analyses were performed on a Waters liquid chromatograph consisting of a Model 6000A pump, a Model U6K injector, and a Model 440 absorbance detector equipped with a Radial-PAK C_{18} column and a Hitachi 635A liquid chromatograph equipped with a Waters Model 440 absorbance detector and a Radial-PAK C_{18} column. Forty percent methanol in water and 25% methanol in water with 1% triethylamine adjusted at pH 7.3 with phosphoric acid were used as the mobile phase. Recoveries of the substrate from the adsorbed samples were determined by the GLC analyses above described. For the substrates bearing aromatic nuclei, the data were confirmed by UV absorbance measurement using a Hitachi 124 Spectrophotometer. The results agreed with a difference of less than 2%.

(Received March 7, 1984)

Bitter quassinoids, shinjulactones B, D, and E were isolated from *Ailanthus altissima* SWINGLE. Shinjulactone B is the first example of natural bitter principles with a 1,2-seco-1-nor-6(5→10)*abeo*-picrasane skeleton and shinjulactones D and E are a hexahydro derivative and a 6α-hydroxy derivative of ailanthone, respectively.

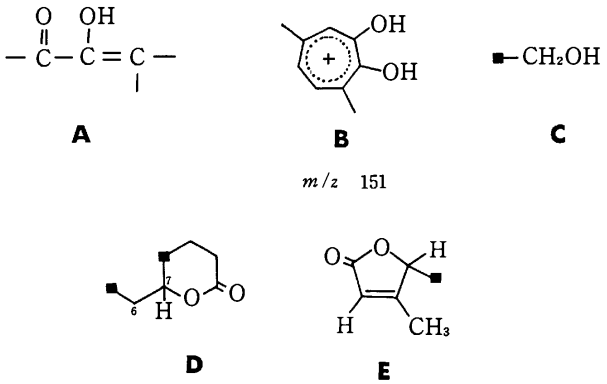
As a continuation of studies on bitter principles of Simaroubaceous plants,[2)] we have examined *Ailanthus altissima* SWINGLE and reported several new quassinoids.[1,3,4)] This paper describes the structure determination of shinjulactones B (**1**), D (**2**), and E (**3**) in detail.

Shinjulactone B (**1**) was isolated from both stem bark and root bark of the plant. The stem barks were extracted with hot water and the aqueous extract, after concentration, was continuously extracted with dichloromethane. The organic layer was evaporated to give a bitter residue, which was separated by silica-gel column chromatography. Gradient elution with methanol in chloroform gave shinjulactone B (**1**, *ca.* 0.001% yield) together with known quassinoids, amarolide 11-acetate,[5)] amarolide,[5)] shinjudilactone,[3)] and ailanthone (**4**).[4,6,7)] By the same procedure, shinjulactone B (**1**, *ca.* 0.004% yield) and shinjulactone D (**3**, *ca.* 0.001% yield) were isolated from the root bark together with known shinjulactone C,[3)] chaparrolide,[8)] and $\Delta^{13(18)}$-dehydroglaucarubolone,[9)] besides the known quassinoids mentioned above.

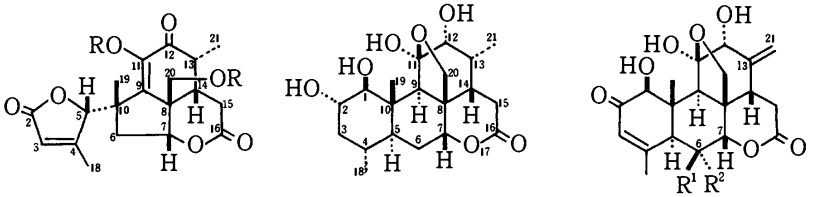
Shinjulactone B (**1**), mp 265.5—268 °C, was shown to have a norpicrasane skeleton, $C_{19}H_{22}O_7$, by high-resolution mass spectrum and elementary analysis. The IR spectrum showed the presence of hydroxyl(s) (3420 cm^{-1}), γ-lactone (1770 cm^{-1}), δ-lactone (1750 cm^{-1}), and a conjugated carbonyl (1680 cm^{-1}). The presence of a diosphenol grouping (**A**) was indicated by UV absorption maximum at 279 nm (ε 8100), which shifted to 330 nm on addition of alkali. These spectral data are similar to the observed values, 280 and 328 nm, for bruceantin in an ethanolic solution and an alkaline solution, respectively.[10)] The fact that shinjulactone B (**1**) possesses the diosphenol moiety in a ring other than A ring was inferred from the mass spectrum, in which a peak at *m/z* 151 (**B**) was not observed. This peak is characteristic of 3-hydroxy-2-oxo-3-picrasenes such as bruceantin and its congeners[10)] and 2-hydroxy-1-oxo-2-picrasenes.[10)] Instead of the peak at *m/z* 151, characteristic fragmentation peaks at *m/z* 265 $(M-C_5H_5O_2)^+$ and *m/z* 235 $(M-CH_2O-C_5H_5O_2)^+$ were observed; these peaks were not observed for normal quassinoids. The appearance of these peaks implies the presence of $C_5H_5O_2$ grouping susceptible of fragmentation on electron bombardment.

^1H and ^{13}C NMR spectra showed the presence of a tertiary methyl, a secondary methyl, a vinyl methyl, a hydroxymethyl (**C**), an olefinic proton (δ 5.95, dd), and a proton (δ 5.26) assignable to $C_{(7)}$-H on a δ-lactone terminus. On irradiation at δ 5.26, signals (δ 1.99, dd and δ 2.20, dd) due to $C_{(6)}$-H_2 changed into an AB quartet (J_{AB}=16 Hz). This observation indicates that the C-6 atom was connected with a carbon atom bearing no hydrogen atom, leading to a partial structure (**D**).

When the olefinic proton at δ 5.95 was irradiated, a doublet signal due to the vinyl methyl and a doublet



■ Carbon atom bearing no hydrogen atom



1 R=H
5 R=Ac

2

3 R^1=H R^2=OH
4 R^1=R^2=H

signal at δ 6.12 changed into singlets, respectively. On irradiation at the frequency of the vinyl methyl, an allylic coupling with J=2 Hz between the olefinic proton and the proton resonating at δ 6.12 was observed. Thus the partial structure (**E**) was proposed from these NMR measurement together with the IR absorption band due to the γ-lactone and with the $C_5H_5O_2$ moiety deduced from fragmentation of mass spectrum of **1**.

Although seven oxygen atoms of shinjulactone B (**1**) were thus characterized as shown in partial structures (**A**, **C**, **D**, and **E**), the whole structure for **1** with the norpicrasane skeleton could not be unambiguously constructed by connecting these partial structures.

Acetylation of **1** with acetic anhydride in pyridine gave a diacetate (**5**), mp 194—198 °C. Spectral information obtainable from **5** was of no use for the structure elucidation of shinjulactone B (**1**).

Unequivocal structure for shinjulactone B (**1**) was provided by X-ray diffraction analysis. A single crystal in orthorhombic space group $P2_12_12_1$ was obtained from methanol solution and the lattice parameters are a=12.594 (5), b=19.016 (8), and c=7.755 (3) Å. Four molecules of **1** and four water molecules are contained in the unit cell to give D_c=1.36 g cm^{-3}. Intensity data were collected on a Philips PW1100 automatic four-

circle diffractometer using monochromated Cu $K\alpha$ radiation. A total of 2096 independent structure factors with $F_o \geq 2.5\sigma(F_o)$ within $2\theta=156°$ were obtained by the $2\theta-\theta$ scanning mode. The structure was solved by the direct method using the MULTAN program. An E-map revealed the positions of all the non-hydrogen atoms, and the hydrogen atoms were located in a difference electron density map. The structure was refined by the block-diagonal least-squares calculations using

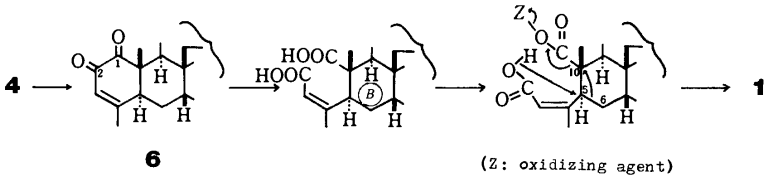

Scheme 1.

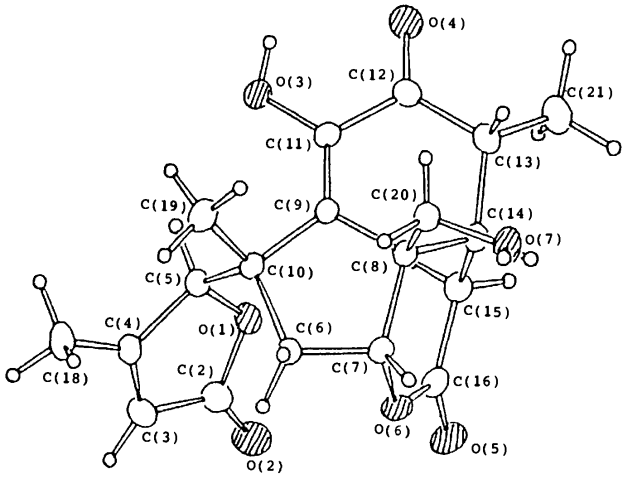

Fig. 1. Perspective view of shinjulactone B (1).[a)]
a) For clarity hydrogen atoms are represented by spheres of arbitrary radius.

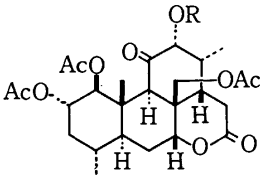
anisotropic thermal parameters for non-hydrogen atoms and isotropic ones for hydrogen atoms. The final *R* factor was 0.039. The final atomic coordinates are listed in Table 2 and bond lengths and bond angles are listed in Tables 3 and 4.[11)]

Figure 1 is a computer-generated drawing of the molecule of **1**. The structure of shinjulactone B (**1**) is thus established as (5*R*,10*S*)-11,20-dihydroxy-12,16-dioxo-1,2-seco-1-nor-6(5→10)*abeo*-picrasa-3,9(11)-dien-2,5-olide. The novel 1,2-seco-1-nor-6(5→10)*abeo*-picrasane skeleton is likely derived biogenetically from ailanthone (**4**), a major picrasane-type bitter principle in *A. altissima*. Successive oxidation of an intermediate diketone (**6**) through bond-cleavage between $C_{(1)}$ and $C_{(2)}$ and decarboxylation accompanying with a contraction of the B ring and a formation of the α,β-unsaturated γ-lactone would afford shinjulactone B (**1**) (Scheme 1). Conversion of ailanthone (**4**) into shinjulactone B (**1**) is now in progress.

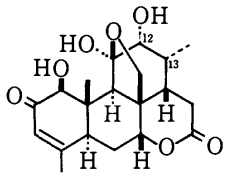
Shinjulactone D (**2**), mp 267—269 °C, was obtained together with shinjulactone B (**1**) and other known quassinoids from the aqueous extract of root bark of *A. altissima*. The molecular formula, $C_{20}H_{30}O_7$, was determined by high-resolution mass spectrum. The ^{1}H NMR spectrum was similar to that of ailanthone (**4**) except for a difference due to the absence of double bond, indicating the presence of hydroxyl(s), a δ-lactone, a tertiary methyl, two secondary methyls, and a hemiacetal group. In the mass spectrum of shinjulactone D (**2**), a fragment ion (**F**) was observed at *m/z* 268 ($C_{14}H_{20}O_5^{+\cdot}$) as a base peak. In comparison with the corresponding fragment ion at *m/z* 264 observed for ailanthone (**4**), the substitution pattern of the A ring was revealed. The UV spectrum showed no characteristic absorption maximum due to any ketone grouping. Therefore the presence of four hydroxyl groups containing a hemiacetal one was deduced. This is supported by acetylation of shinjulactone D (**2**) giving a triacetate (**7**) and tetraacetate (**8**).

The planer structure (**G**) is therefore proposed for shinjulactone D. The configuration of the hydroxyl groups at C-1, C-2, and C-12 of **2** was determined by measurement of ^{1}H and ^{13}C NMR spectra of **2**, **7**, and **8** and by proton magnetic double resonance (NMDR) measurement for **2**. In the ^{1}H NMR spectrum of **2**, signals due to three protons attached to hydroxyl-bearing carbons were observed at δ 3.59 (d, J=9 Hz), δ *ca.* 4.05 (br m), and δ 3.97 (br s), respectively. The doublet signal at δ 3.59 was assignable to H-1 and the NMDR measurement revealed the doublet signal coupled with the signal at δ 4.05 with a coupling constant, J=9 Hz, indicating a *trans*-diaxial-relationship for these protons. Thus the configurations of the vicinal hydroxyl groups were determined to be 1β-equatorial and 2α-equatorial, respectively.

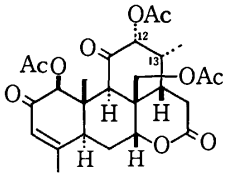
The configuration of 12-H was established as follows. The doublet signals due to 12-H were observed at δ 3.76 for a triacetate (**7**) and δ 5.03 for a tetraacetate (**8**),



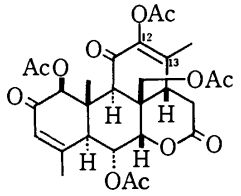
7 R=H
8 R=Ac



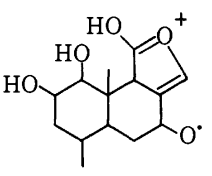
9



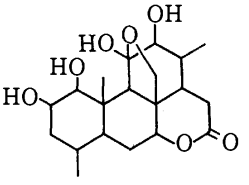
10



11



F



G

and their coupling constants were J=2.5 Hz and J=*ca.* 2 Hz, respectively. These values were almost the same as the coupling constant, J=3 Hz, observed for chaparrinone triacetate (**10**)[12] derived from chaparrinone (**9**). The observation implies that the configrations at C-12 and C-13 of shinjulactone D (**2**) are identical with those for chaparrinone (**9**) with 12β(equatorial)-H and 13β(axial)-H.

In conclusion, the structure of shinjulactone D (**2**) was established to be 11β,20-epoxy-1β,2α,11α,12α-tetrahydroxypicrasan-16-one and this compound corresponds to a perhydroailanthone derivative.

Shinjulactone E (**3**) was isolated from the stem bark of *A. altissima* collected in Hyogo Prefecture. Methanol extract was partitioned between carbon tetrachloride and water, and the aqueous layer was extracted with dichloromethane. From the organic layer, a fraction containing ailanthone as a main component was collected by silica-gel column chromatography. Minor components in the fraction were found to be chaparrinone (**9**), sitosteryl glucoside, and a new quassinoid. The new quassinoid, named shinjulactone E (**3**) was obtained by preparative TLC as amorphous solid in *ca.* 0.0001% yield. The molecular formula, $C_{20}H_{24}O_8$, was determined by high-resolution mass spectrum, indicating the presence of one more oxygen atom than that of ailanthone (**4**). The ^{1}H and ^{13}C NMR spectra showed the presence of a tertiary methyl, a vinyl methyl, an *exo*-methylene, an α,β-unsaturated carbonyl, and a lactone grouping; these observations suggest that shinjulactone E (**3**) would be a hydroxy derivative of ailanthone (**4**).

In the ^{1}H NMR spectrum of **3**, a lactone-terminus proton appeared at δ 4.87 as a doublet and a signal due to H-6 was observed at δ 4.61 as a double-doublet, resonating in lower field than that of ailanthone (**4**). Therefore the hydroxyl group was determined to be located at C-6.

On acetylation, shinjulactone E (**3**) gave a tetraacetate (**11**), mp 112—116 °C. In the ^{1}H NMR spectrum, two singlet signals due to vinyl methyls were observed at δ 1.82 and δ 2.03 together with signals due to a tertiary methyl and four acetyl groups. Seven methyl signals were observed in the ^{13}C NMR spectrum of **11**. The disappearance of the *exo*-methylene and the appearance of an additional vinyl methyl imply the occurrence of isomerization of the $C_{(13)}$–$C_{(21)}$ *exo*-double bond into an *endo*-double bond between $C_{(12)}$ and $C_{(13)}$ in the acetylation reaction to give an enol acetate.

On irradiation at δ 4.84 due to H-7, a double-doublet signal (J=11.5 and 3 Hz) at δ 5.25 due to H-6 of the tetraacetate (**11**) collapsed into a doublet, which was coupled with an α(axial)-H on C-5 with a coupling constant, $J_{5,6}$=11.5 Hz. On saturation at the frequency of H-6, the doublet signal due to H-7 changed into a singlet. Since the large coupling constant, $J_{5,6}$, suggests a *trans*-relationship between H-6 and H-5, the H-6 could be determined to be β(axial)-configuration. Therefore it is concluded that shinjulactone E (**3**) is formulated as 11β,20-epoxy-1β,6α,11α,12α-tetrahydroxypicrasa-3,13(21)-diene-2,16-dione (=6α-hydroxyailanthone) and the structure of the tetraacetate (**11**) is 1β,6α,12,20-tetraacetoxypicrasa-3,12-diene-2,11,16-trione.

Experimental[13]

Extraction and Isolation of Shinjulactones B (1) and D (2). The stem bark (11.2 kg), collected at the Botanical Gardens of Faculty of Science, the University of Tokyo in July 1979, was chipped and extracted with hot water (90 °C, 20 L) overnight. The extraction was repeated twice under the same conditions and the aqueous extracts were combined. Evaporation *in vacuo* gave a concentrated extract (*ca.* 13 L), which was divided into 8 portions and the each portion was continuously extracted with dichloromethane (1 L×2) overnight. All the extracts were combined and evaporated to give a residue (*ca.* 22 g). A part (14 g) of the residue, adsorbed on silica gel (35 g), was placed on a top of a silica-gel (700 g) column, and eluted with the following solvents in succession; $CHCl_3$ (1.4 L), 1%-MeOH in $CHCl_3$ (4.2 L), 2%-, 3%-, and 4%- (each 2.8 L), 5%- (4.2 L), 7%- (2.8 L), 10%-, and 30%-MeOH in $CHCl_3$ (each 1.4 L), and 85 fractions (each 280 mL) were collected. Elution with the 2%-MeOH in $CHCl_3$ gave amarolide 11-acetate (40 mg) and amarolide (650 mg), and elution with the 3%-MeOH in $CHCl_3$ shinjudilactone (50 mg) and ailanthone (1.3 g). Fractions 47—52 eluted with the 4%-MeOH in $CHCl_3$ gave crystals on standing, which were recrystallized from $CHCl_3$–MeOH to afford shinjulactone B (**1**; 110 mg).

The root bark (6.2 kg) was collected at the same botanical garden in August 1982. Extract with hot water was evaporated and continuously extracted with dichloromethane to give a residue (40 g), which was subjected to chromatographic separation of silica gel (2.6 kg). Amarolide 11-acetate (200 mg), amarolide (540 mg), shinjudilactone (1 g), and ailanthone (2.8 g) were eluted with 7—10%-MeOH in $CHCl_3$. Elution with 12%-MeOH in $CHCl_3$ afforded shinjulactone B (**1**; 240 mg) and 13%-MeOH in $CHCl_3$ gave shinjulactone C (130 mg) and chaparrolide (120 mg). Shinjulactone D (**2**; 50 mg) was obtained by elution with 14%-MeOH in $CHCl_3$ together with $\Delta^{13(18)}$-dehydroglaucarubolone (10 mg).

Extraction and Isolation of Shinjulactone E (3). The stem bark collected in Nishinomiya, Hyogo Prefecture, was extracted with hot methanol. The methanol extracts were concentrated and partitioned between carbon tetrachloride and water. The aqueous layer was separated and extracted with dichloromethane continuously. Organic layer was evaporated to give a residue, from which crude ailanthone was isolated by silica-gel chromatography. The crude ailanthone (10 g) was subjected to rechromatography on silica gel (300 g) eluting with 8%-MeOH in $CHCl_3$ and 30 fractions (each 75 mL) were collected. Chaparrinone (60 mg, from fr. 5), pure ailanthone (5 g, from frs. 7—10), and sitosteryl glucoside (1.5 g, from frs. 15—27) were obtained. Fractions 12—14 (82 mg) were combined and further separated by preparative TLC developed with 10%-MeOH in $CHCl_3$ and a fraction containing shinjulactone E (**3**) was obtained. Contaminated triterpenes in the fraction were separated off by crystallization from $CHCl_3$–MeOH to afford shinjulactone E (**3**; 23 mg) as amorphous solid.

Shinjulactone B (1). Prisms crystallized from $CHCl_3$–MeOH, mp 265.5—268 °C, $[\alpha]_D^{25}$ +167° (*c* 0.65, MeOH); IR (KBr) 3570, 3420, 1770, 1750, 1695, 1680, 1660, and 1635 cm^{-1}; UV (EtOH) 279 nm (ε 8100), which shifted to 330 nm on addition of alkali (pH *ca.* 11); ^{1}H NMR (Table 1); ^{13}C NMR (25.0 MHz, C_5D_5N) δ=12.3q, 16.3q, 23.8q, 28.3t, 37.4d, 39.7d, 40.4t, 48.8s, 51.6s, 64.3t, 85.2d, 87.1d, 120.4d, 138.5s, 145.1s, 167.7s, 168.8s, 171.5s, and 195.9s; MS *m/z* (%) 362 (M^+; 0.4), 344 (0.4), 332 (2.3), 265 (8.4), 235 (34), and 191 (100); Found: *m/z* 362.1395. Calcd for $C_{19}H_{22}O_7$: M 362.1365. Found: C, 60.81; H, 6.38%. Calcd for $C_{19}H_{22}O_7 \cdot 1/2H_2O$: C, 60.96; H, 6.19%.

11,20-Di-O-acetylshinjulactone B (5). A solution of

shinjulactone B (**1**; 9.3 mg) in acetic anhydride (2 mL) and pyridine (2 mL) was allowed to stand at room temperature for 2 d. The usual work-up gave a crude product, which was purified by preparative TLC developed with 8%-MeOH in $CHCl_3$ to afford diacetate (**5**; 9 mg), mp 194—198 °C (from acetone-hexane); IR (Nujol) 1770, 1750, 1720, 1685, 1660, 1640, and 1200 cm^{-1}; UV (EtOH) 240 nm (ε 8200); ^1H NMR (Table 1); ^{13}C NMR (25.0 MHz, C_5D_5N) δ=12.2q, 16.0q, 20.3q, 20.6q, 24.4q, 28.3t, 38.1d, 40.5d, 40.5t, 49.1s, 50.9s, 64.8t, 83.7d, 87.6d, 120.9d, 142.6s, 153.0s, 166.8s, 167.4s, 168.5s, 170.4s, 170.8s, and 192.0s; MS *m/z* (%) 446 (M^+; 8), 404 (40), 386 (30), 344 (45), 307 (70), 247 (90), and 177 (100); Found: *m/z* 446.1566. Calcd for $C_{23}H_{26}O_9$: M 446.1576.

Shinjulactone D (2). Mp 267—269°C (from acetone); $[\alpha]_D^{22}$ −44° (*c* 0.17, C_5H_5N); IR (KBr) 3400, 1730, 1215, and 1050 cm^{-1}; ^1H NMR (Table 1); ^{13}C NMR (67.80 MHz, C_5D_5N) δ=11.6q, 13.3q, 20.1q, 26.8t, 29.1d, 30.6t, 31.7d, 41.6s, 42.7s, 42.9d, 43.3t, 44.2d, 46.5d, 70.1d, 71.8t, 79.2d, 79.7d, 85.3d, 110.9s, and 169.9s; MS *m/z* (%) 382 (M^+; 8), 364 (3), 268 (100), and 250 (60); Found: *m/z* 382.1969. Calcd for $C_{20}H_{30}O_7$: M 382.1990.

1,2,20-Tri-O-acetylshinjulactone D (7). Shinjulactone D (**2**; 13.3 mg, crude) was acetylated with acetic anhydride (1 mL) in pyridine (2 mL) at room temperature for 20 h. The reaction product, after usual work-up, was purified by preparative TLC developed with 20%-acetone in benzene and crystallized from acetone-hexane to give a triacetate (**7**; 3.6 mg), mp 135—138 °C (sintered at 118—121 °C); IR (KBr) 3530, 2940, 1745, 1725 (sh), 1375, 1240, and 1040 cm^{-1}; ^1H NMR (Table 1); ^{13}C NMR (22.5 MHz, $CDCl_3$) δ=12.3, 13.5, 19.1, 20.7, 20.9, 21.5, 25.8, 27.2, 28.3, 35.4, 35.9, 39.0, 41.7, 43.0, 44.8, 48.2, 61.8, 70.8, 77.8, 82.3, 82.6, 170.2, 170.2, 170.4, 174.2, and 212.1; MS *m/z* (%) 508 (M^+; 13), 488 (25), 466 (8), 406 (25), 376 (42), 316 (50), and 55 (100); Found: *m/z* 508.2341. Calcd for $C_{26}H_{36}O_{10}$: M 508.2309.

1,2,12,20-Tetra-O-acetylshinjulactone D (8). Triacetate (**7**) was acetylated under the same conditions as above for 50 h to afford a tetraacetate (**8**) in almost quantitative yield, mp 129—132 °C (from acetone-hexane); IR (KBr) 1745, 1720 (sh), 1370, 1240, and 1040 cm^{-1}; ^1H NMR (Table 1); ^{13}C NMR (22.5 MHz, $CDCl_3$) δ=12.3, 13.0, 19.2, 20.7, 20.7, 20.9, 21.1, 25.6, 27.5, 27.8, 34.2, 35.9, 38.9, 41.7, 43.0, 44.3, 49.5, 61.8, 70.9, 78.1, 80.5, 80.6, 169.5, 169.6, 170.0, 170.2, 171.3, and 204.3; MS *m/z* (%) 550 (M^+; 6), 508 (20), 490 (18), 466 (25), 448 (100), 388 (65), and 328 (80); Found: *m/z* 550.2410. Calcd for $C_{28}H_{38}O_{11}$: M 550.2412.

Shinjulactone E (3). White amorphous solid, ^1H NMR (Table 1); ^{13}C NMR(22.5 MHz, C_5D_5N) δ=11.5, 26.8, 35.2, 43.7, 46.7, 48.2, 48.2, 48.5, 65.9, 71.7, 80.8, 82.0, 84.5, 110.6, 117.8, 128.1, 147.3, 165.3, 169.3, and 197.2; MS *m/z* (%) 392 (M^+; 10), 374 (50), 364 (45), 356 (20), and 314 (100); Found: *m/z* 392.1462. Calcd for $C_{20}H_{24}O_8$: M 392.1469.

1,6,12,20-Tetra-O-acetylshinjulactone E (11). Shinjulactone E (**3**; 22.6 mg, crude) was treated with acetic anhydride (0.5 mL) and pyridine (0.5 mL) in the presence of a catalytic amount of 4-(dimethylamino)pyridine at room temperature for 2.5 d. After usual work-up, purification by preparative TLC (developed with 1%-MeOH in $CHCl_3$) yielded a tetraacetate (**11**; 6.2 mg), mp 112—116 °C (from chloroform); IR (KBr) 1745, 1680, 1620, and 1235 cm^{-1}; UV (EtOH) 243 nm (ε 12000); ^1H NMR (Table 1); ^{13}C NMR (50 MHz, $CDCl_3$) δ=13.5q, 15.5q, 20.0q, 20.6q, 20.7q, 21.3q, 24.0q, 29.7t, 39.1d, 42.6s, 44.6d, 46.9s, 48.5d, 61.1t, 66.7d, 77.4d, 83.8d, 127.7s, 129.1d, 159.5s, 167.0s, 169.9s, 170.1s, 171.3s, 174.5s, 179.2s, 190.9s, and 191.7s; MS *m/z* (%) 560 (M^+; 10), 518 (65), 476 (80), 458 (50), 416 (85), 315 (90), 297 (80), and 43 (100); Found: *m/z* 560.1909. Calcd for $C_{28}H_{32}O_{12}$: M 560.1894.

The authors wish to thank Mr. Kazuhiro Matsushita of JEOL Co. Ltd. for measurement of NMR spectra.

(Received March 9, 1984)

Epoxidation of alnus-5-en-3β-yl acetate with *m*-chloroperbenzoic acid gave a 5β,6β-epoxide as a main product together with a 5α,6α-epoxide as a minor product. Treatment of the α-epoxide with $BF_3 \cdot OEt_2$ afforded a 1(10),5-diene and a mixture of 6α-hydroxy-12- and -18-ene derivatives. The 12-ene was converted into daturadiol (=olean-12-ene-3β,6β-diol).

On treatment with acid, oleanene-, lupene-, and baccharene-type triterpenes undergo backbone rearrangement generally in the opposite direction from the biogenesis and afford a number of migrated triterpenes derived from intermediate cations or their equivalent species corresponding to various biogenetic stages.

We have been investigating $BF_3 \cdot OEt_2$-catalyzed backbone rearrangement of 3β,4β-epoxyfriedelane,[2)] 3,4-epoxyshionanes,[3)] 3,4-epoxy-D:A-friedo-18β,19α*H*-lupanes,[4)] and 13,18-epoxybaccharan-3β-yl acetates,[5)] these epoxides possessing the epoxide ring on the terminal ring such as A or D ring. Epoxidation of alnus-5-en-3β-yl acetate (**1**) gives 5,6-epoxides, which on treatment with $BF_3 \cdot OEt_2$ would afford carbonium ions or their equivalents on B ring by cleavage of the epoxy ring. Now we examined behavior of the carbonium ions on B ring towards the backbone rearrangement. This paper describes the epoxidation of **1** and backbone rearrangement of epoxides catalyzed by $BF_3 \cdot OEt_2$. Conversion of dendropanoxide (**2**) into daturadiol (**3**) by utilizing these reactions is also described.

Acid treatment of dendropanoxide (**2**)[6)] gave a mixture of alnus-5-en-3β-ol (**4**) and alnus-5(10)-en-3β-ol (**5**),[7)] the former of which, after separation, was converted into its acetate (**1**). Sengupta *et al.*[8)] obtained an epoxide as the sole product by epoxidation of glut-5-en-3β-yl acetate (=alnus-5-en-3β-yl acetate (**1**)) with *m*-chloroperbenzoic acid (MCPBA) and assigned a 5α,6α-configuration to the epoxy-ring based on the steric consideration and ^1H NMR spectrum.

Epoxidation of **1** with MCPBA under the same conditions (in chloroform at 0 °C) as Sengupta's gave two epoxides. The major epoxide (**6**) was obtained in 77% yield and the minor one (**7**) in 16% yield, and the major epoxide (**6**) was found to be identical with the "Sengupta's epoxide." From the following observations, however, a question arose on the configuration of the epoxide ring which had been assigned by Sengupta. Two epoxides (**6** and **7**) were subjected to $BF_3 \cdot OEt_2$-catalyzed backbone rearrangement, respectively, and the mixtures of unsaturated hydroxy acetates were separated from the rearranged products (description on these reactions is given later). The mixture of hydroxy acetates obtained from the major epoxide (**6**) showed a broad singlet signal due to 6-H around δ 4.5 in the ^1H NMR, while that obtained from the minor epoxide (**7**) showed a broad signal due to 6-H around δ 4.0—4.1. Kocór *et al.*[9)] isolated a triterpene alcohol, daturadiol (**3**), from *Datura innoxia* MILL (Solanaceae) and reported that the monoacetate of daturadiol (**8**) (=6β-hydroxyolean-12-en-3β-yl acetate) showed a broad singlet due to 6α-H at δ 4.45 in the ^1H NMR spectrum. This implies that the broad singlet signal which appeared at *ca.* δ 4.5 is assignable to the 6α-H and, therefore, the hydroxyl group in the hydroxy acetates derived from the major epoxide (**6**) locates in β-orientation. These observations lead to the conclusion that the major epoxide (**6**), the "Sengupta's epoxide," should be a 5β,6β-epoxide and attack of the oxidizing reagent took

place preferentially from β-face of the molecule in epoxidation of alnus-5-en-3β-yl acetate (**1**).

This conclusion was supported by the epoxidation reaction of alnus-5-en-3β-ol (**4**) and its benzoate (**9**) carried out under the same conditions as above. Epoxidation of alnus-5-en-3β-ol (**4**) gave a single epoxide (**10**). On acetylation, the epoxide (**10**) yielded an acetate, which was idential with the major epoxide (**6**). On the other hand, the benzoate (**9**) was epoxidized to give α- and β-epoxides (**11** and **12**) in a 1 : 1 ratio. Since the 3α-hydrogens of alnus-5-en-3β-ol (**4**), -3β-yl acetate (**1**), and -3β-yl benzoate (**9**) were observed as triplets at δ 3.48 (t-like, J=3 Hz), δ 4.66 (J=3 Hz), and δ 4.94 (J=3 Hz), respectively, in the ^{1}H NMR spectra, the substituents at C-3β are shown to exist in an axial-conformation.

a) $B_{eq}=8\pi^2(u_1^2+u_2^2+u_3^2)/3$.

From these facts, the results obtained in these epoxidation reactions are explained reasonably as follows; in the epoxidation of alnus-5-en-3β-ol (**4**), the hydrogen-bond assisted an exclusive attack of the reagent from β-face of the molecule of **4**, while in the case of the benzoate (**9**), the attack from β-face was sterically hindered by the bulky benzoyloxyl group, resulting in a 1 : 1 ratio of the α- and β-epoxides (**11** and **12**), and in the case of the acetate (**1**), the reagent attacked preferentially from the β-side to give the β-epoxide (**6**) as the main product.

Thus the epoxide ring of the major epoxide (**6**) has been determined to exist in β-configuration. Unambiguous proof for the structure of the major epoxide (**6**) was given by single-crystal X-ray analysis. The crystals belong to orthorhombic space group $P2_12_12_1$, and the lattice parameters are a=12.618(4), b=32.776(9), and c=6.837(2) Å and D_c=1.14 g cm^{-3} with four molecules in a unit cell. Intensity data were measured on a Philips PW1100 automatic four-circle diffractometer using monochromated Cu $K\alpha$ radiation. A total of 2702, non-zero independent reflections with $3\leq\theta\leq$ 78 were obtained by $2\theta-\theta$ scanning mode. The structure was solved by the direct method using MULTAN program and was refined by the block-diagonal least-squares method. All hydrogen atoms were located on a difference electron density map. The final R-value was 0.047 assuming the anisotropic temperature factors for the non-hydrogen atoms and the isotropic ones for the hydrogen atoms. The final atomic coordinates are listed in Table 1 and bond lengths and bond angles are listed in Tables 2 and 3.[10] Figure 1 is a computer-generated perspective

drawing of the molecule of the major epoxide, 5β, 6β-epoxyalnusan-3β-yl acetate (**6**).

5α,6α-Epoxyalnusan-3β-yl acetate (**7**) was treated with $BF_3 \cdot OEt_2$ in benzene to give a complex mixture, which was separated by column chromatography into two fractions. The less polar fraction (25%) was found to consist of mainly alnusa-1(10), 5-dien-3β-yl acetate (**13**) accompanied with a small amount of an unidentified product by GLC. The authentic sample of **13** was prepared by reaction of alnus-5(10)-en-3β-yl acetate (**14**) with selenium dioxide.[11]

The polar fraction (73%) was inferred to be a mixture of Δ^{18}- and Δ^{12}-hydroxy acetates (**15** and **16**) in a ratio of 1 : 1 by spectral inspection. Two signals at δ 4.85 (0.5H) and δ 5.17 (0.5H) in the ^{1}H NMR and two fragment ions at *m/z* 177 and *m/z* 218 in the mass spectrum[12] were indicative of the presence of Δ^{18}- and Δ^{12}-oleanene derivatives. Separation of the mixture was attempted by various chromatographic techniques, but all attempts failed. The mixture of hydroxy acetates (**15** and **16**) was converted into a mixture of keto acetates (**17** and **18**), which could not be separated at all. Then the mixture of **17** and **18** was subjected to alkaline hydrolysis to give a mixture of hydroxy ketones (**19** and **20**). Separation of the mixture was attained by HPLC to afford 3β-hydroxyolean-18-en-6-one (**19**; t_R=15.7 min) and -12-en-6-one (**20**; t_R=16.3 min). 3β-Hydroxyolean-18-en-6-one (**19**), mp 217.5—219 °C, showed a molecular ion at *m/z* 440.3659 ($C_{30}H_{48}O_2$) and a fragment ion at *m/z* 177.1623 ($C_{13}H_{21}$) which is characteristic of Δ^{18}-oleanene derivatives.[12] In the ^{1}H NMR spectrum, a singlet signal appeared at δ 4.88 assignable to 19-H. On the other hand, the other hydroxy ketone (**20**) with a longer retention time showed mp 243—245 °C

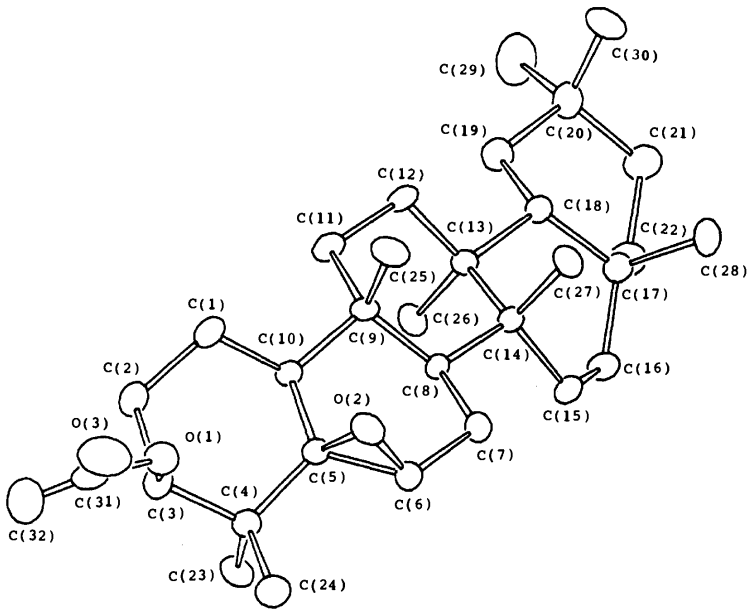

Fig. 1. Perspective view of 5β,6β-epoxyalnusan-3β-yl acetate(**6**).

(decomp), a triplet signal at δ 5.21 in the ^{1}H NMR, and a base peak at *m/z* 218.2027 ($C_{16}H_{26}$), these spectral data being compatible with 3β-hydroxyolean-12-en-6-one. Therefore the polar fraction obtained by the backbone rearrangement of the minor epoxide (**7**) was confirmed to be a mixture of 6α-hydroxyolean-18-en-3β-yl acetate (**15**) and -12-en-3β-yl acetate (**16**).

The hydroxy ketones (**19** and **20**), on acetylation, gave pure 6-oxoolean-18-en-3β-yl acetate (**17**) and -12-en-3β-yl acetate (**18**), respectively. The spectral data of the latter compound (**18**) were identical with those reported for a keto acetate derived from natural daturadiol (**3**).[9] The hydroxy ketone (**20**) was converted by lithium aluminium hydride-reduction into olean-12-ene-3β,6β-diol, spectra of which were completely identical with those of daturadiol (**3**).[9] On acetylation, the diol (**3**) gave a monoacetate (**8**), which is isomeric with the 6α-hydroxy acetate (**16**). The 6α-H of **8** appeared at δ 4.55 as a broad singlet signal in the ^{1}H NMR spectrum, from which the structural revision of "Sengupta's epoxide" had originated.

The major epoxide (**6**) was subjected to $BF_3 \cdot OEt_2$-catalyzed backbone rearrangement, followed by the usual work-up to give alnusa-1(10), 5-dien-3β-yl acetate (**13**; 3% yield) containing an unidentified diene-mixture, a hydroxy acetate (**21**; 74% yield), and a mixture (11% yield) of 6β-hydroxyolean-12-en-3β-yl acetate (**8**) and -18-en-3β-yl acetate (**22**). The new compound (**21**) showed a molecular ion peak at *m/z* 484.3934 ($C_{32}H_{52}O_3$), and the presence of a hydroxyl group, an acetoxyl group, and a trisubstituted double bond. The position of the double bond was determined by chemical conversion and ^{1}H NMR measurement. The hydroxy acetate (**21**) was dehydrated with phosphoryl chloride in pyridine to afford the diene (**13**). Oxidation of **21** with Jones reagent gave a keto acetate (**23**), whose ^{1}H NMR spectrum showed signals at δ 2.01(s, OAc), *ca.* 2.23(m, $C_{(2)}$–H_2; overlapping with $C_{(7)}$–H_2), 3.12 (br s, $C_{(5)}$–H), 4.82 (t, J=5 Hz, $C_{(3\alpha)}$–H), and 5.30(m, $C_{(1)}$–H). These spectral data suggest the presence of a 3β-acetoxy-1(10)-ene moiety, which was confirmed by a decoupling measurement of ^{1}H NMR spectrum. On irradiation around δ 2.23, the multiplet signal at δ 5.30 due to $C_{(1)}$–H changed into a doublet signal coupled with $C_{(5)}$–H (J=3 Hz) and the triplet signal at δ 4.82 due to $C_{(3\alpha)}$–H changed into a singlet. From these observations, the structure of hydroxy acetate (**21**) was determined to be 6β-hydroxyalnus-1(10)-en-3β-yl acetate.

These experiments clearly show that there was a remarkable difference in reaction behaviors between 5α,6α-epoxide (**7**) and 5β,6β-epoxide (**6**) towards the $BF_3 \cdot OEt_2$-catalyzed backbone rearrangement; the α-epoxide (**7**) gave mainly 18-ene and 12-ene derivatives (**15** and **16**; in 73% yield), while the β-epoxide (**6**) afforded 1(10)-ene and 1(10), 5-diene derivatives (**21** and **13**; in 77% yield) predominantly. One of the reasons why the backbone rearrangement of β-epoxide (**6**) did not proceed to C- and D-rings is likely to be ascribed to a steric factor. On attack of $BF_3 \cdot OEt_2$, the 5β,6β-epoxide ring would be cleaved to produce a carbonium ion on C-5, to which a migration of a hydride from C-10α would follow immediately to afford a cation at C-10. If a methyl group at C-9β migrates to the cationic center at C-10, a 1,3-diaxial steric hindrance would be brought about between the methyl group created on C-10β and a bulky BF_3-coordinated oxygen function in an axial-like configuration at C-6β. This steric hindrance might impede the backbone rearrangement of **6** towards C- and D-rings.

The conversion of dendropanoxide (**2**) into daturadiol (**3**) was thus accomplished *via* alnus-5-en-3β-yl acetate (**1**) and the 5α,6α-epoxide (**7**), which implies a formal total-synthesis of daturadiol (**3**), because a total synthesis of friedelin[13] and a conversion of friedelin into dendropanoxide (**2**)[14] have been carried out.

Experimental

General Procedures. Melting points were measured on a Mel-temp capillary melting point apparatus (Laboratory Devices) and are uncorrected. Infrared (IR) and ultraviolet absorption (UV) spectra were measured with a Hitachi 260-30 and a Hitachi 340 spectrometer, respectively. Mass (MS) spectra were run on a JEOL JMS-D300 mass spectrometer operating at 70 eV. Proton nuclear magnetic resonance (^{1}H NMR) spectra were taken in deuteriochloroform using a Varian EM 390 (90 MHz) or JEOL FX 90Q (90 MHz) spectrometer. Chemical shifts were expressed in δ downfield from tetramethylsilane as an internal standard and coupling constants in Hz. Gas-liquid chromatography (GLC) was carried out on a Shimadzu Gas Chromatograph GC-6A equipped with an FID (column: Dexsil 300GC, temperature: 270 °C, N_2: 70 mL/min). Analytical and preparative high performance liquid chromatography (HPLC) was carried out on a Waters Liquid Chromatograph ALC/GPC 202/401 at room temperature with an RI detector (column: μPORASIL 1/8″×1′, solvent: 20% ether-hexane, flow rate: 2.0 mL/min). Thin-layer chromatography (TLC) was carried out on Kieselgel 60 GF_{254} (E. Merck) and silica-gel column chromatography was done using Wakogel C-200 (Wako).

Epoxidation of Alnus-5-en-3β-yl Acetate (1). Alnus-5-en-3β-ol (**4**), prepared from dendropanoxide (**2**), was acetylated by the usual manner to give alnus-5-en-3β-yl acetate (**1**). The acetate (**1**; 290 mg) was dissolved in chloroform (12 mL) and treated with MCPBA (270 mg) at 0 °C. The usual work-up gave a residue (281 mg), which was separated by silica gel (60 g) column chromatography. Elution with benzene-ether (99:1) afforded 5α,6α-epoxide (**7**; 33 mg), mp 234—235 °C (from chloroform-acetone); IR (KBr) 1730, 1250, 1030, and 980 cm^{-1}; ^{1}H NMR δ=2.04 (3H, s) 3.23 (1H, t, J=2 Hz) and 4.88 (1H, dd, J=9 and 6 Hz); MS m/z (%) 484 (M^+; 5), 466 (10), 406 (70), 391 (37), 274 (62), 259 (68), 248 (40), 205 (89), 201 (48), 187 (72), 171 (72), and 95 (100), and 5β,6β-epoxide (**6**; 215 mg), mp 220.5—221 °C (from chloroform-acetone); IR (KBr) 1735 and 1255 cm^{-1}; ^{1}H NMR δ=2.08 (3H, s), 3.07 (1H, t, J=3 Hz), and 4.76 (1H, t, J=3 Hz); MS m/z (%) 484 (M^+; 2), 424 (7), 406 (20), 391 (11), 259 (16), 205 (38), 187 (24), and 95 (100).

Epoxidation of Alnus-5-en-3β-ol (4) and Alnus-5-en-3β-yl Benzoate (9). Alnus-5-en-3β-ol (**4**) and its benzoate (**9**) were epoxidized under the same conditions as above. The reaction product obtained from **4** was acetylated with acetic anhydride in pyridine to give 5β,6β-epoxyalnusan-3β-yl acetate (**6**) as the sole product.

The reaction product from **9** was shown to be a 1:1 mixture of 5α,6α-epoxide (**11**; ^{1}H NMR δ *ca.* 3.27, t-like; 6β-H) and 5β,6β-epoxide (**12**; ^{1}H NMR δ *ca.* 3.11, m; 6α-H) by TLC and ^{1}H NMR spectral measurement.

Backbone Rearrangement of 5α,6α-Epoxyalnusan-3β-yl Acetate (7). 5α,6α-Epoxyalnusan-3β-yl acetate (**7**; 33 mg) in benzene (6 mL) was treated with $BF_3 \cdot OEt_2$ (0.05 mL) at room temperature for 20 min. The reaction product, after addition of a saturated sodium hydrogencarbonate solution, was worked up as usual to give a residue, which was chromatographed on silica gel (8 g). Elution with benzene afforded a less polar product (8 mg; 25%) and a polar product (24 mg; 73%). The less polar product was shown to be identical with an authentic alnusa-1(10), 5-dien-3β-yl acetate (**13**; t_R=16.5 min) together with a small amount of unknown product (t_R=12.3 min) by GLC examination. The authentic sample of **13** was prepared by the dehydrogenation of alnus-5(10)-en-3β-yl acetate (**14**)[11] with selenium dioxide in boiling acetic acid. **13**: mp 207—208 °C (from chloroform-methanol); ^{1}H NMR δ=2.06 (3H, s), 4.71 (1H, dd, J=10 and 6 Hz), 5.21 (1H, m), and 5.67 (1H, t, J=4 Hz); MS m/z (%) 466 (M^+; 0.3), 406 (100), 391 (19), 274 (50), 259 (56), 205 (61), 171 (50), and 132 (65); UV (ethanol) λ_{max} (ε) 232 (14000), 238 (16000), and 245 nm (10000).

The polar product, a mixture of **15** and **16**, showed ^{1}H NMR δ=2.06 (3H, s), 4.04 (1H, m), 4.45 (1H, dd, J=9 and 6 Hz), 4.85 (0.5H, s), and 5.17 (0.5H, t, J=3 Hz); MS m/z 484 (M^+), 469, 466, 406, 391, 218 (base peak), 205, 204, 189, and 177.

Oxidation of the Mixture of Hydroxy Acetates (15 and 16). The mixture (25 mg) of **15** and **16**, dissolved in acetone (2 mL), was kept at 0 °C and oxidized with Jones reagent (0.05 mL) to give a mixture of 6-oxoolean-18-en-3β-yl acetate (**17**) and -12-en-3β-yl acetate (**18**); ^{1}H NMR δ=2.05 (3H, s), 4.41 (1H, dd, J=9 and 6 Hz), 4.90 (0.5H, s), and 5.21 (0.5H, t, J=3 Hz); MS m/z 482 (M^+), 467, 422, 407, 218 (base peak), 205, 189, and 177.

Alkaline Hydrolysis of the Mixture of Keto Acetates (17 and 18). The oxidation product (**17** and **18**), above obtained, was treated with 5% potassium hydroxide in methanol (3 mL) under a nitrogen atmosphere at room temperature for 15 h, and the usual work-up gave a mixture (18 mg) of hydroxy ketones (**19** and **20**). HPLC separation of the mixture gave a satisfactory result. 3β-Hydroxyolean-18-en-6-one (**19**; 9 mg), mp 217.5—219 °C (from chloroform-methanol), HPLC t_R=15.7 min, showed IR (film) 3450 and 1710 cm^{-1}; ^{1}H NMR δ=3.13 (1H, dd, J=9 and 6 Hz) and 4.88 (1H, s); MS m/z (%) 440 (M^+; 51), 425 (34), 205 (48), 204 (47), 189 (34), and 177 (100); high resolution MS m/z 440.3659 (Calcd for $C_{30}H_{48}O_2$: M, 440.3654) and m/z 177.1623 (Calcd for $C_{13}H_{21}$: 177.1643). 3β-Hydroxyolean-12-en-6-one (**20**; 9 mg), mp 243—245 °C (decomp) (from ether-hexane), HPLC t_R=16.3 min, showed IR (film) 3450 and 1705 cm^{-1}; ^{1}H NMR δ=3.16 (1H, dd, J=9 and 6 Hz) and 5.21 (1H, t, J=3 Hz); MS m/z (%) 440 (M^+; 20), 425 (7), 218 (100), 205 (22), 203 (26), and 189 (10); high resolution MS m/z 440.3613 (Calcd for $C_{30}H_{48}O_2$: M, 440.3653) and m/z 218.2027 (Calcd for $C_{16}H_{26}$: 218.2033).

Acetylation of 3β-Hydroxyolean-18-en-6-one (19) and -12-en-6-one (20). The Δ^{18}-hydroxy ketone (**19**; 8 mg) was acetylated with acetic anhydride in pyridine to give 6-oxoolean-18-en-3β-yl acetate (**17**; 7 mg), mp 220.5—222 °C (from ether-methanol); IR (film) 1730, 1710, and 1250 cm^{-1}; ^{1}H NMR δ=2.04 (3H, s), 4.40 (1H, dd, J=8 and 6 Hz), and 4.89 (1H, s); MS m/z (%) 482 (M^+; 77), 467 (54), 205 (84), 204 (66), 189 (59), and 177 (100); high resolution MS m/z 482.3741 (Calcd for $C_{32}H_{50}O_3$: M, 482.3758) and m/z 177.1634 (Calcd for $C_{13}H_{21}$: 177.1642).

The Δ^{12}-hydroxy ketone (**20**), on acetylation, gave 6-oxoolean-12-en-3β-yl acetate (**18**), mp 246—248 °C (from methanol); ^{1}H NMR δ=0.81, 0.89, 0.95, 0.98, and 1.00 (each 3H, s), 1.25 (6H, s), 1.30 (3H, s), 2.05 (3H, s), 4.42 (1H, t, J=7 Hz), and 5.23 (1H, t, J=3 Hz); MS m/z (%) 482 (M^+; 21), 467 (8), 218 (100), 205 (61), 203 (30), and 189 (22); high resolution MS m/z 482.3743 (Calcd for $C_{32}H_{50}O_3$: M, 482.3758) and m/z 218.1998 (Calcd for $C_{16}H_{26}$: 218.2033).

Reduction of 3β-Hydroxyolean-12-en-6-one (20). The hydroxy ketone (**20**; 9 mg) in tetrahydrofuran (1.5 mL) was treated with an excess of lithium aluminium hydride (20 mg) under reflux for 5 h and the reaction product was worked up as usual to give olean-12-ene-3β,6β-diol (**3**; 7 mg) as the sole product, mp 258—260 °C (chloroform-methanol), ^{1}H NMR δ=0.86 (3H, s), 0.90 (6H, s), 1.10, 1.13, 1.23, 1.30, and 1.35 (each 3H, s), 3.15 (1H, dd, J=8 and 6 Hz), 4.56 (1H, br s), and 5.24 (1H, t-like, J=3 Hz); MS m/z (%) 442 (M^+; 16), 218 (100), 205 (14), 203 (32), and 189 (13); high resolution MS m/z 442.3829 (Calcd for $C_{30}H_{50}O_2$: M, 442.3811) and m/z 218.2055 (Calcd for $C_{16}H_{26}$: 218.2035); these spectral data were found to be identical with those of daturadiol (**3**).[9]

Acetylation of Daturadiol (3). Daturadiol (**3**) was treated with acetic anhydride in pyridine to give daturadiol 3-monoacetate (**8**), ^{1}H NMR (FT) δ=0.84 (3H, s), 0.88 (6H, s), 0.95, 1.10, (each 3H, s), 1.26 (6H, s), 1.35 (3H, s), 2.06 (3H, s), 4.45 (1H, m), 4.55 (1H, br s), and 5.23 (1H, t, J=3 Hz); MS m/z (%) 484 (M^+; 13), 218 (100), 205 (22), 203 (24), and 189 (15).

Backbone Rearrangement of 5β,6β-Epoxyalnusan-3β-yl Acetate (6). 5β,6β-Epoxide (**6**; 168 mg) in benzene was treated with $BF_3 \cdot OEt_2$ at room temperature. After the usual work-up, the reaction product was subjected to separation by silica-gel column chromatography. Elution with benzene gave alnusa-1(10),5-dien-3β-yl acetate (**13**; 5 mg), 6β-hydroxyalnus-1(10)-en-3β-yl acetate (**21**; 125 mg), and a mixture (18 mg) of 6β-hydroxyolean-12-en-3β-yl acetate (**8**) and -18-en-3β-yl acetate (**22**). 6β-Hydroxyolean-1(10)-en-3β-yl acetate (**21**) showed mp 233—233.5 °C (from acetone–methanol); IR (KBr) 3570, 3400, 1720, and 1260 cm^{-1}; ^{1}H NMR δ =2.04 (3H, s), 4.26 (1H, br s), 5.21 (1H, dd, J=10 and 5 Hz), and 5.39 (1H, m); MS m/z 484 (M^+), 424 (base peak), 406, 391, 302, 274, 259, 205, 150, and 122; Found: m/z 484.3943. Calcd for $C_{32}H_{52}O_3$: M, 484.3917. The mixture of **8** and **22** showed IR (Nujol) 3550, 1710, 1270, and 1255 cm^{-1}; ^{1}H NMR δ=2.05 (3H, s), 4.46 (1H, m), 4.52 (1H, br s), 4.86 (0.7H, s), and 5.23 (0.3H, t-like J=3 Hz); MS m/z (%) 484 (M^+; 40), 469 (9), 391 (6), 218 (100), 205 (74), 204 (83), 189 (58), and 177 (48).

Derivatization of 6β-Hydroxyalnus-1(10)-en-3β-yl Acetate (21). Hydroxy acetate (**21**) was treated with phosphoryl chloride in pyridine to give the 1(10), 5-diene (**13**), which was shown to be identical with an authentic sample by GLC examination.

On oxidation with Jones reagent, the hydroxy acetate (**21**) afforded 6-oxoalnus-1(10)-en-3β-yl acetate (**23**), mp 199—201 °C (from benzene–methanol); ^{1}H NMR δ=2.01 (3H, s), 2.23 (m), 3.12 (1H, br s), 4.82 (1H, t, J=5 Hz) and 5.30 (1H, m); MS m/z (%) 482 (M^+; 11), 422 (62), 407 (100), 273 (14), 259 (5), 205 (9), and 149 (22); Found: m/z 482.3754. Calcd for $C_{32}H_{50}O_3$: M, 482.3759.

(Received May 2, 1984)

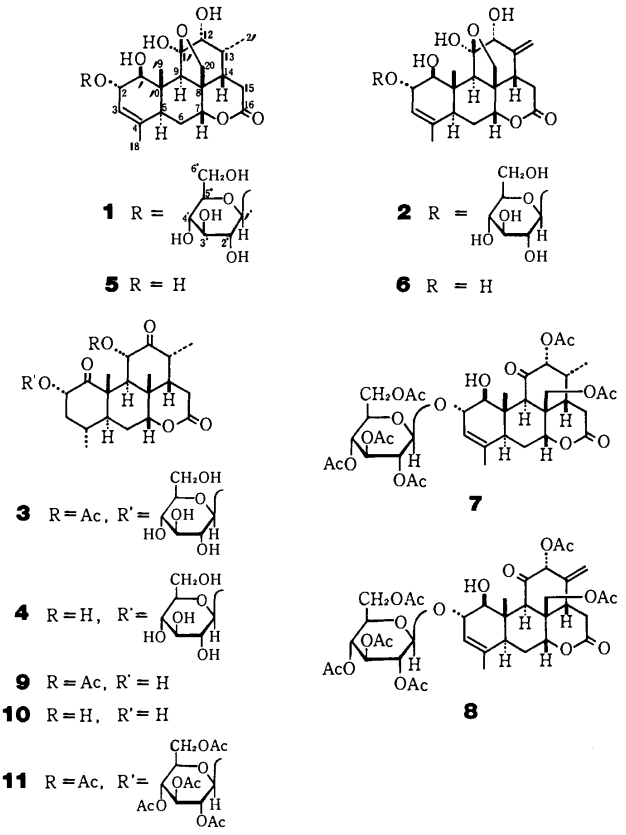
Four bitter quassinoid glycosides, shinjuglycosides A, B, C, and D were isolated from seeds of *Ailanthus altissima* SWINGLE and their structures were established to be 2-β-D-glucopyranosides of chaparrin, shinjulactone A, amarolide 11-acetate, and amarolide, respectively, from spectral data and enzymatic or acid-catalyzed hydrolysis.

Recently several quassinoid glycosides have been isolated from Simaroubaceous plants[1] and some of them have been shown to exhibit useful biological activities.[2] In our continuous studies of constituents of Simaroubaceous plants, we have investigated *Ailanthus altissima* SWINGLE (Japanese name: Shinju or Niwaurushi), and reported several new quassinoids isolated from the stem and root bark of the plant.[3,4] Now we examined bitter constituents in seeds of the plant. This paper describes isolation and structure determination of four new quassinoid glycosides named shinjuglycosides A, B, C, and D (**1**, **2**, **3**, and **4**). Although many quassinoids have been obtained from *A. altissima*, the isolation of their glycosides from the plant has not been reported yet.

Methanol extracts of seeds of *A. altissima* were defatted with hexane and partitioned between dichloromethane and water. The aqueous layer was subjected to separation by Dowex 1×2 anion exchange chromatography eluted with acetic acid in concentration of 0—2 M (1 M=1 mol dm^{-3}) linear gradient. A fraction eluted with about 0.2 M acetic acid was further purified by DEAE-Sephadex A-25 anion exchange chromatography (eluted with 0—0.5 M ammonium hydrogencarbonate linear gradient) and Sephadex G-10 gel filtration chromatography (eluted with water) to give a mixture of bitter substances. It was shown to consist of two com_ounds by ^{1}H NMR spectral measurement, but they could not be separated from each other by silicagel chromatography or reversed phase chromatography. However, they were separated by repetition of cellulose column chromatographies to give two new quassinoid glycosides, named shinjuglycoside A (**1**; *ca.* 0.015%) and shinjuglycoside B (**2**; *ca.* 0.03%).

The structure of shinjuglycoside A (**1**), mp 162—164 °C (decomp) was determined as follows. The molecular formula ($C_{26}H_{38}O_{12}$) was suggested by secondary ion mass spectrometry (SIMS) which showed the MH^+ peak at m/z 543. An abundant fragment ion at m/z 363 (MH^+-180) together with an ion at m/z 380 (M^+-162) observed in the EI mass spectrum indicated the presence of a hexose moiety. The structure of shinjuglycoside A (**1**) was inferred to be a β-D-glucoside of chaparrin (**5**)[5] from ^{1}H NMR spectrum. The sugar part was identified to be a D-glucose by the GLC examination after methanolysis and trimethylsilylation. Shinjuglycoside A (**1**) was hydrolyzed with β-glucosidase in 0.1 M acetate buffer (pH 5.0) at 37 °C for 2 weeks to afford chaparrin (**5**), which was identified by the comparison of mp, $[\alpha]_D$, IR, TLC, and ^{1}H NMR spectra with those of an authentic sample. The ^{13}C NMR spectrum of shinjuglycoside A (**1**) revealed that a signal due to C-2 of the aglycone part shifted to lower field by 9.8 ppm than that of chaparrin (**5**), indicating that the D-glucose must be attached at the C-2 position. In the ^{1}H NMR of **1**, an anomeric proton appeared at δ 5.22 as a doublet signal (J=7.6 Hz) and the coupling constants $J_{2',3'}$, $J_{3',4'}$, and $J_{4',5'}$ of the sugar part are all 8.9 Hz. Thus the structure of shinjuglycoside A (**1**) was determined to be 2-*O*-β-D-glucopyranosylchaparrin.[6]

When treated with acetic anhydride in pyridine at room temperature for 24 h, **1** gave a hexaacetyl deriva-



tive (**7**), mp 144—145 °C, which still showed the presence of hydroxyl(s) in the IR spectrum. SIMS of **7** showed an MH^+ ion at *m/z* 795 and a tetra-*O*-acetylhexose oxonium ion at *m/z* 331. In the ^1H NMR spectrum of **7**, six singlet signals due to the acetoxyl groups appeared at δ 2.02, 2.03, 2.04, 2.10, 2.17, and 2.18, and the signal of 12-H (δ 6.18, d, J=4.3 Hz) was observed at much lower field in comparison with that of **1** (δ 3.94, d, J=4.3 Hz). These findings indicate that **7** is 2′,3′,4′,6′,12,20-hexa-*O*-acetyl derivative of **1**.

The structure of shinjuglycoside B (**2**), mp 194—196 °C (decomp) was determined by the same chemical and spectral methods as those developed in **1**. Shinjuglycoside B (**2**) gave an MH^+ peak at *m/z* 541 in SIMS, indicating the molecular formula of $C_{26}H_{36}O_{12}$, and the presence of a hexose moiety was shown by fragment ions at *m/z* 378 (M^+ −162) in EI mass spectrum and at *m/z* 361 (MH^+ −180) in SIMS. Enzymatic hydrolysis of **2** gave shinjulactone A (**6**).[3] Glycosylation shift ($\Delta\delta$ 9.7) of the signal due to C-2 was observed in the ^{13}C NMR spectrum of **2**. The ^1H NMR spectrum of **2** showed an anomeric proton at δ 5.20 as a doublet signal (J=7.6 Hz) and the coupling constants of the sugar part are 8.6 Hz. Thus the structure of shinjuglycoside B (**2**) was determined to be 2-*O*-β-D-glucopyranosylshinjulactone A.

Under the same conditions as in the case of **1**, **2** also gave a hexaacetyl derivative (**8**), mp 145—148 °C. The structure of **8**, therefore, has been established to be 2′,3′,4′,6′,12,20-hexa-*O*-acetyl derivative of **2** from spectral data.

Bitter principles in the dichloromethane layer obtained by the partition (*vide supra*) were then investigated. The organic layer was separated by silica-gel column chromatography to afford four known quassinoids, amarolide,[7] chaparrinone,[8] ailanthone,[3] and chaparrin[5] in very low yields from less polar fractions. The fractions eluted with more than 20% methanol in chloroform were further subjected to separation by silica-gel column chromatography, silicic acid partition chromatography, and Sephadex G-10 gel filtration chromatography. Two new quassinoid glycosides named shinjuglycosides C (**3**) and D (**4**) were isolated in 0.005% and 0.002% yield, respectively.

Shinjuglycoside C (**3**), mp 180—185 °C, showed the presence of two secondary methyls, two tertiary

methyls, and one acetoxyl group in the 400 MHz ^{1}H NMR spectrum. Most of other protons including those attributed to a D-glucose residue were assigned (see Table 4). The molecular formula ($C_{28}H_{40}O_{12}$) was suggested by SIMS which showed the MH^+ peak at m/z 569, and an abundant fragment ion at m/z 407 ($MH^+ - 162$). The molecular formula was also supported by an intense peak observed at m/z 406 ($M^+ - 162$) in the EI mass spectrum. These spectral data suggest that shinjuglycoside C (**3**) consists of amarolide 11-acetate (**9**)[7] as an aglycone and β-D-glucopyranose as a sugar part. Acid hydrolysis of **3** with 1.5 M sulfuric acid–methanol (1:2) yielded D-glucose, and amarolide (**10**) concomitant with hydrolysis of 11-acetate moiety. The former was identified by GLC as its trimethylsilyl derivative, and the latter identified in comparison with an authentic sample by IR, ^{1}H NMR and TLC.

Shinjuglycoside D (**4**) was crystallized from methanol as colorless needles, mp 282—284 °C (decomp). The molecular formula ($C_{26}H_{38}O_{11}$) was given by SIMS which showed the $[M+Na]^+$ peak at m/z 549. The structure of **4** was suggested to be amarolide 2-β-D-glucopyranoside by the 400 MHz ^{1}H NMR spectrum (see Table 4). In the ^{13}C NMR, a glycosylation shift was observed between the signals due to C-2 of **4** and that of amarolide (**10**). Acid-hydrolysis of **4** yielded amarolide (**10**) and D-glucose, each of which was identified by the same method as described for **3**.

Acetylation of **3** and **4** afforded the same compound (**11**), mp 238 °C (from methanol–diethyl ether). In the IR spectrum of **11**, no hydroxyl was detected. In the mass spectrum (EI), the fragment ions were observed at m/z 676 ($M^+ - AcOH$) and at m/z 331 corresponding to a tetra-*O*-acetylhexose oxonium ion. In the ^{1}H NMR spectrum four methyl signals appeared at δ 0.92 (d, J=7.7, 13-CH_3), 1.05 (d, J=6.4, 4-CH_3), 1.29 (s, tertiary CH_3), and 1.54 (s, tertiary CH_3) together with five resonances due to the acetoxyl groups δ 2.01, 2.02, 2.07, 2.11, and 2.19.

Thus, the structure of **3** proves to be amarolide 11-acetate 2-β-D-glucopyranoside, and the structure of **4** to be amarolide 2-β-D-glucopyranoside.

Experimental

General Procedures. All melting points were measured on a Mel-temp capillary melting apparatus (Laboratory

devices) and uncorrected. Optical rotations were determined on a JASCO polarimeter DIP-181. Infrared (IR) spectra were measured on a Hitachi 260-30 spectrometer. Low and high resolution mass spectra (MS and HRMS, respectively) were run on a JEOL JMS-D300 mass spectrometer operating at 70 eV and secondary ion mass spectra (SIMS) on a Hitachi M-80 mass spectrometer. Proton nuclear magnetic resonance (^{1}H NMR) spectra (400 MHz) were taken using a JEOL JMN GX-400 spectrometer and carbon-13 nuclear magnetic resonance (^{13}C NMR) spectra (22.5 MHz) JEOL FX 90Q. Chemical shifts were expressed in ppm downfield from tetramethylsilane as an internal standard (δ value) and coupling constants in Hz. Thin-layer chromatography (TLC) was carried out on Kieselgel 60 GF_{254} coated in 0.25 mm or on TLC plates Kieselgel 60/Kieselgur F_{254} (E. Merck). Wakogel C-200 (Wako), Silicic acid AR (Mallincrodt), Dowex 1X2 (Dow Chemical), DEAE-Sephadex A-25, Sephadex G-10 (Pharmacia Fine Chemicals), or Cellulose microcrystalline (E. Merck) was used for column chromatography. Commercialized β-glucosidase available from Sigma Chemical Company was used.

a) Measured in C_5D_5N. b) Chemical shifts are expressed in δ-value.

Plant Materials. Seeds with pericarps of *Ailanthus altissima* Swingle were air-dried, and grinded to afford 3.7 kg of materials.

Extraction and Separation. Seeds (3.7 kg) was extracted with methanol (18 L×2) for 24 h. Extracts were concentrated, defatted with hexane, and partitioned between dichloromethane and water.

A half of the aqueous layer was concentrated to give brown tar (90 g), which was dissolved in distilled water (2 L). The aqueous solution was charged to Dowex 1×2 (OH^--form; 4.0×40 cm) and the resin was then washed with distilled water (2 L). The Dowex 1 column was then eluted with acetic acid (4 L) with 0—2 M linear gradient and 260 fractions (each 15 mL) were collected. Fractions 41—52 were combined and lyophilized to give a yellow powder (fraction A; 4.6 g).

A part of fraction A (3.6 g) was dissolved in a small amount of water and then charged to a column of DEAE-Sephadex A-25 (HCO_3^--form; 2.6×90 cm). Elution was performed with an aqueous ammonium hydrogencarbonate solution (4 L) with 0.01—0.5 M linear gradient and 400 fractions (each 10 mL) were collected. The fractions 113—157 were combined and lyophilized to give white powder (fraction B; 1.8 g). The fraction exhibited a bitter taste and was shown to be a complex mixture by TLC examination (Kieselgel 60/Kieselgur F_{254} developed with 2-propanol-conc. aqueous ammonia-water 6:1:1).

Fraction B was devided into three portions. Each portion was dissolved in a small amount of water and charged to a column of Sephadex G-10 (1.2×130 cm). Elution was performed with water, and 50 fractions (each 5 mL) were col-

Table 6. ^{1}H-NMR spectrum of 11-*O*-acetyl-2-*O*-(2′,3′,4′,6′-tetra-*O*-acetyl-β-D-glucopyranosyl)-amarolide (**11**)[a,b]

				4.21 dd	12.2, 4.9

a) δ and J are expressed in ppm and Hz, respectively. b) Measured in $CDCl_3$. c) The assignments of these signals may be reversed.

lected. The fractions 19—27, showing a bitter taste and two spots on TLC, were combined and lyophilized to give white powder (fraction C; 1.5 g).

Fraction C was applied to a Cellulose microcrystalline column (2.6×70 cm) and was eluted with acetone-water (9:1), and 50 fractions (each 15 mL) were collected. Fractions 22—27 were combined and evaporated to give shinjuglycoside A (**1**; 151 mg) and fractions 43—50 to give shinjuglycoside B (**2**; 119 mg). Fractions 28—42 (808 mg) were a mixture of shinjuglycosides A and B. A part of these fractions (578 mg) was separated by the same method to give **1** (50 mg), **2** (177 mg), and a mixture (350 mg) of **1** and **2**. This mixture was found to contain **1** and **2** in a ratio of *ca.* 1:2 by ^{1}H NMR spectral measurement.

A part (16.5 g) of the dichloromethane extract (*ca.* 60 g) obtained by the partition was separated by silica-gel column chromatography (C-200, 825 g; column A) eluted with 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 (each 1 L), 20, 40, 60% (each 2 L) methanol in chloroform, successively. Fractions of 500 mL each were collected. Fractions 25—32 (5.3 g) were combined and further separated by silica-gel column chromatography (C-200, 380 g; column B) eluted with the lower layer of a solvent mixture of chloroform-methanol-water (50:12:3). Fractions of 200 mL each were collected. Fractions 5—7 (1.4 g) of column B were subjected to separation by the silicic acid partition chromatography. Silicic acid (350 g) was mixed with water (235 mL) and packed in a column with chloroform (column C). Elution was performed with 0 (2 L), 3, 6, 9, 12, 15, 18, and 21% (each 1 L) ethanol in water-saturated chloroform. Fractions of 300 mL each were collected and monitored by TLC (ethyl acetate-methanol, 7:3). Fractions 8—13 (1.5 g) of column B were combined and also separated by silicic acid partition chromatography (silicic acid 400 g containing water 270 mL; column D). Elution was performed with the same solvent as that for column C and the effluent was collected in 200 mL-fractions.

Fractions 16—19 (175 mg) of column C were separated by column chromatography on Sephadex G-10 prepared by the same procedure as before to give shinjuglycoside C (140 mg). Fractions 27—30 (175 mg) of column D were separated to give shinjuglycoside D (80 mg) and a mixture (75 mg) of shinjuglycosides A and B by column chromatography on Sephadex G-10 prepared before.

Shinjuglycoside A (1). Amorphous solid, mp 162—164 °C (decomp); $[\alpha]_D^{21}$ +66.5° (*c* 3.79, MeOH); IR(KBr) 3400, 1720, and 1040 cm^{-1}; ^{1}H NMR (Table 1); ^{13}C NMR (Table 2); MS(SIMS) *m/z* 543 (MH^+) and 363; HRMS (EI) Found: *m/z* 380.1868. Calcd for $C_{20}H_{28}O_7$ ($M-C_6H_{10}O_5$): 380.1835.

Shinjuglycoside A Hexaacetate (7). Shinjuglycoside A (20 mg) was acetylated with pyridine (1 mL) and acetic anhydride (1 mL) for 50 h at room temperature. The usual work-up and silica-gel column chromatography afforded an amorphous solid (28 mg), mp 144—145 °C; IR (Nujol) 3550, 1750, 1240, and 1040 cm^{-1}; ^{1}H NMR (Table 3); MS (SIMS) *m/z* 795 (MH^+), 447, 405, 387, 345, 331, and 289; HRMS (EI) Found: *m/z* 674.2603. Calcd for $C_{34}H_{42}O_{14}$ ($M-C_4H_8O_4$): 674.2575.

Enzymatic Hydrolysis of 1. A mixture of **1** (64 mg) and β-glucosidase (20 mg) in 0.1 M acetate buffer (5 mL; pH 5.0) was allowed to stand for 2 weeks at 37 °C. The mixture was heated in boiling water for 10 min. After being cooled, the mixture was filtered and the filtlate was passed through a short column of Dowex 50 W (H^+). The effluent was evaporated to dryness *in vacuo*. The residue was purified by silica-gel column chromatography (C-200, 40 g, chloroform-methanol 7:3) to yield a crystalline chaparrin (18 mg).

Methanolysis of 1 and GLC Examination. A small amount of **1** in a tube was dried *in vacuo*, and 3% anhydrous HCl-MeOH (0.5 mL) was added. The tube was sealed and heated for 16 h at 80 °C. After being evaporated, the residue was trimethylsilylated by the usual method. Trimethylsilyl derivatives of methyl α-D-glucoside (t_R=6.2 min) and methyl β-D-glucoside (t_R=7.48 min) were deteacted by the GLC examination (GC-4BM, 1.5% OV-17, 1.0 m, 70 mL/min N_2, 156—245 °C, 4 °C/min).

Shinjuglycoside B (2). Amorphous solid, mp 194—196 °C; $[\alpha]_D^{20}$ +48.0° (*c* 2.77, MeOH); IR (KBr) 3400, 1720, and 1040 cm^{-1}; ^{1}H NMR (Table 1); ^{13}C NMR (Table 2); MS (SIMS) *m/z* 541 (MH^+) and 361; HRMS (EI) Found: *m/z* 378.1662. Calcd for $C_{20}H_{26}O_7$ ($M-C_6H_{10}O_5$): 378.1679.

Shinjuglycoside B Hexaacetate (8). Acetylation of **2** (35.3 mg) was carried out under the same conditions as described for **1** to give an amorphous solid (39.3 mg), mp 145—148 °C; IR (Nujol) 3550, 1740, 1220, and 1040 cm^{-1}; ^{1}H NMR (Table 3); MS (SIMS) *m/z* 793 (MH^+), 445, 403, 385, 343, 331, and 289; HRMS (EI) Found: *m/z* 672.2404. Calcd for $C_{34}H_{40}O_{14}$ ($M-C_4H_8O_4$): 672.2419.

Enzymatic Hydrolysis of 2. A mixture of shinjuglycoside B (126 mg) and β-glucosidase (50 mg) in 0.1 M acetate buffer (10 mL; pH 5.0) was treated by the same procedure as before. Shinjulactone A (**6**) was isolated and identified as the sole aglycone.

Methanolysis of **2** and GLC examination gave the same result as that obtained for **1**.

Shinjuglycoside C (3). Amorphous solid, mp 180—185 °C (decomp); $[\alpha]_D^{23}$ −37° (*c* 6.1, MeOH); IR (KBr) 3450, 1730, 1640, 1080, and 1040 cm^{-1}; ^{1}H NMR (Table 4); ^{13}C NMR (Table 5); MS (SIMS) *m/z* 569 (MH^+) and 407; HRMS (EI) Found: *m/z* 406.2005. Calcd for $C_{22}H_{30}O_7$ ($M-C_6H_{10}O_5$): 406.1992.

Acid Hydrolysis of 3. A solution of **3** (28 mg) in 1.5 M sulfuric acid-methanol (1:2, 10 mL) was refluxed for 7 h and then water (10 mL) was added. The mixture was concentrated *in vacuo* and extracted with dichloromethane three times. The combined dichloromethane layer was dried over anhydrous magnesium sulfate and evaporated to give a residue (7 mg), which was identified to be amarolide (**10**) by the comparison of IR, ^{1}H NMR and TLC with an authentic sample.

The aqueous layer obtained from the hydrolysis was passed through a short column of anion exchange resin (Amberlite IRA-400, OH^- form) and evaporated *in vacuo* to give a residue which was identified as D-glucose by GLC after trimethylsilylation.

Shinjuglycoside D (4). Colorless needles crystallized from methanol, mp 282—284 °C (decomp); $[\alpha]_D^{20}$ −42° (*c* 1.0, MeOH) IR (KBr) 3450, 1735, 1720, 1640, 1240, 1080, and 1040 cm^{-1}; ^{1}H NMR (Table 4); ^{13}C NMR (Table 5); MS (SIMS) *m/z* 549 ($[M+Na]^+$); HRMS (EI) Found: *m/z* 364.1908. Calcd for $C_{20}H_{28}O_6$ ($M-C_6H_{10}O_5$): 364.1886.

Acid Hydrolysis of 4. Hydrolysis of **4** with 1.5 M sulfuric acid-methanol (1:2) led to the isolation and identification of amarolide (**10**) and D-glucose.

11-O-Acetyl-2-O-(2′,3′,4′,6′-tetra-O-acetyl-β-D-glucopyranosyl)-amarolide (11) from 3 and 4. Shinjuglycoside C (17.8 mg) was acetylated with pyridine (1 mL) and acetic anhydride (1 mL) for 24 h at room temperature. The usual work-up and silica-gel column chromatography (C-200, 12g, ethyl acetate-dichloromethane 2:1) yielded, after crystallization from methanol-diethyl ether, a pentaacetate (**11**; 18 mg), as colorless needles, mp 238 °C; IR (Nujol) 1735, 1715, 1240, and 1040 cm^{-1}; ^{1}H NMR (Table 6); MS (EI) *m/z* (%) 676 (M^+−AcOH, 0.4), 616 (2), 556 (3), 543 (1), 514 (1), 501 (5), 483 (2), 454 (0.8), 441 (3), 390 (2), 375 (4), 348 (6), 331 (28), 271 (18), 169 (100), 109 (54), and 60 (64). HRMS (EI) Found: *m/z* 676.2741. Calcd for $C_{34}H_{44}O_{14}$ ($M-C_2H_4O_2$): 676.2732.

Under the same conditions, shinjuglycoside D was acetylated to give a crystalline residue. Recrystallization from

methanol–diethyl ether afforded **11** as colorless needles which was identified by mp, IR, ^{1}H NMR, MS, and TLC.

The authors wish to thank Dr. Teruhisa Noguchi of Suntory Biomedical Research for sample of *Ailanthus altissima*. The authors also thank Mr. Hideo Naoki of Suntory Bioorganic Research for the measurement of SIMS.

Hydrolysis of *N*-Salicylidene-2-methoxyethylamine. Intramolecular General Base Catalysis and Specific Effects of Boric Acid

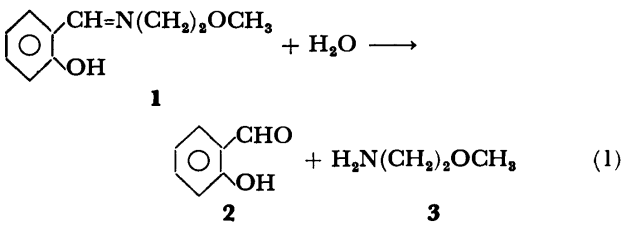
Hiroaki NAGAMATSU, Tadashi OKUYAMA,* and Takayuki FUENO
Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received March 8, 1984)

Hydrolysis of *N*-salicylidene-2-methoxyethylamine is kinetically investigated at 30 °C. Intramolecular general base catalysis by the *o*-O^- substituent takes place in the neutral pH region. Nucleophilic catalysis by morpholine was also found to be operative. Added boric acid accelerates the hydrolysis above pH 5.5 while it decelerates the hydrolysis below pH 5.5. The hydrolysis rate as the function of the boric acid concentration follows a saturation curve in harmony with a reaction sequence involving a rapid equilibrium formation of a borate-substrate complex followed by its breakdown. The morpholine catalysis is inhibited by boric acid in accord with the slow reaction of morpholine with the complex. The water reaction of the complex is considered to involve a rearrangement of the complex and an intramolecular transfer of the boron-coordinated hydroxide ion to the iminium carbon.

Boric acid greatly accelerates the hydrolysis of *N*-salicylideneaniline.[1] We have found, however, that hydrolysis of a Schiff base derived from α-hydroxyisobutyrophenone is decelerated by boric acid in acidic solution although it is accelerated in alkaline solution.[2] These effects of boric acid on the hydrolysis of hydroxy Schiff base occur through a borate-substrate complex involving a boron–hydroxyl coordination. Possible mechanisms for this reaction were presented.[1,2]

Similar accelerative effects of boric acid were also found during hydrolyses of phenyl salicylate[3] and hydroxy thiocarboxylic *S*-esters.[4] It was concluded in the latter case that the catalysis takes place through a mechanism involving an intramolecular transfer of a boron-coordinated hydroxide ion within a borate-substrate complex.[4]

In the present investigation, hydrolysis of *N*-salicylidene-2-methoxyethylamine **1** is examined in the presence of boric acid as well as morpholine. Boric acid accelerates the hydrolysis above pH 5.5 while it decelerates the hydrolysis at lower pH. Nucleophilic catalysis of the hydrolysis by morpholine is retarded by added boric acid. A detailed mechanism of the borate action is presented.



(1)

Results

Hydrolysis in the Absence of Boric Acid. Hydrolysis of Schiff base **1** was carried out at 30 °C in aqueous solution of the constant ionic strength of 0.10 maintained with KCl. The reaction was monitored by the decrease in the absorption of **1** at 275 nm. An isosbestic point was always observed at about 262 nm. The final spectra of the reaction mixtures agreed with the spectrum of salicylaldehyde **2** (λ_{max} 255 nm). The time-dependent absorbance changes obeyed the pseudo-first-order kinetics.

The hydrolysis rates were first measured without any added boric acid in usual buffer solutions of formate, acetate, and tertiary amines as well as HCl solutions in the pH range 2—12. Buffer effects were observed only below pH 6. Logarithms of the rate constants k_0 extrapolated to zero buffer concentration are plotted against pH in Fig. 1.

The pH-rate profile is quite similar to those observed for the hydrolysis of *N*-salicylideneisopropylamine[5,6] and *N*-salicylideneaniline[7] and may be interpreted in the same way (Scheme 1). The rate-determining step changes with pH from formation (pH>3) to decay (pH<3) of an α-amino alcohol intermediate. A rate increase above pH 8 must be due to the contribution from a zwitterionic from (**1**±) of **1**. The profile can be described by Eq. 2 according to Scheme 1: Equation 2 may be derived by applying the steady-state approximation to the α-amino alcohol intermediate **I**

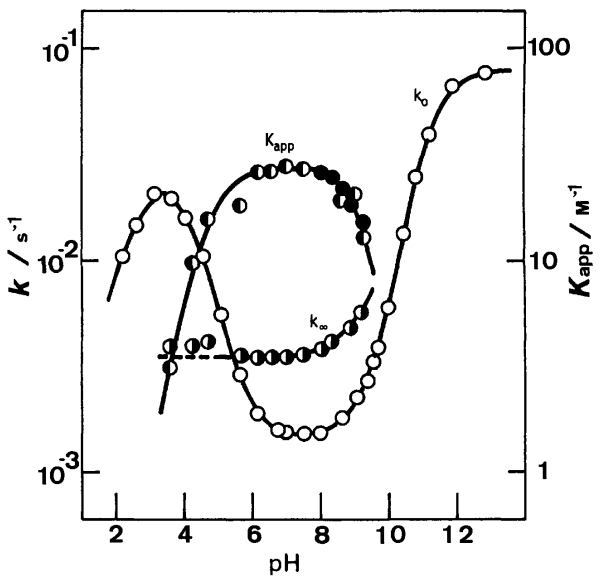


Fig. 1. pH dependences of hydrolysis rates and the equilibrium constant K_{app}. ○, k_0; ◑, k_∞; ◐, K_{app} obtained from the hydrolysis; ●, K_{app} obtained from the morpholine reaction. K_{app} refers to the right ordinate. For theoretical curves, see text.

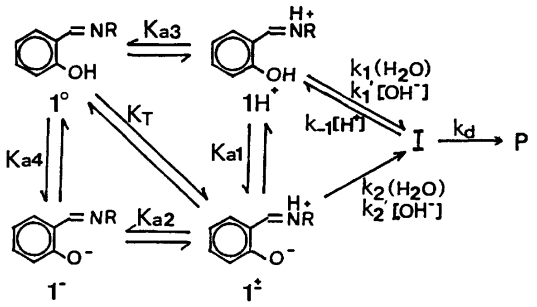


Scheme 1.

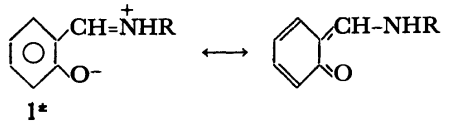
Table 1. Kinetic parameters for the hydrolysis of Schiff base **1** at 30 °C

k_1/s^{-1}	2.4×10^{-2}
k_2/s^{-1}	1.5×10^{-3}
$k_2'/M^{-1}\,s^{-1}$	3.7×10
$k_3/M^{-1}\,s^{-1}$	1.0×10^{3}
$k_4/M^{-1}\,s^{-1}$	1.6×10^{-1}
$k_M/M^{-1}\,s^{-1}$	2.7×10^{-2}
$(k_d/k_{-1})/M$	4.4×10^{-3}
K_{a1}/M (pK_{a1})	3.9×10^{-5} (4.4)
K_{a2}/M (pK_{a2})	7.0×10^{-12} (11.2)

in a usual way[5,6] with the correction for the additional equilibrium (K_T). Kinetic parameters (defined in Scheme 1) are summarized in Table 1.

$$k_0 = \frac{k_1[H^+]^2+(k_1'K_w+k_2K_{a1})[H^+]+k_2'K_{a1}K_w}{[H^+]^2+K_{a1}(1+1/K_T)[H^+]+K_{a1}K_{a2}}\cdot\frac{k_d/k_{-1}}{(k_d/k_{-1}+[H^+])} \quad (2)$$

The equilibrium constant K_T for the tautomerization $\mathbf{1}^{\circ}\rightleftharpoons\mathbf{1}^{\pm}$ is hard to determine, but it must be much greater than unity[9] in favor of zwitterion $\mathbf{1}^{\pm}$. The spectrum of **1** in aqueous solution at pH 4—11 has absorption maxima at 275 and 393 nm, which are characterstic of the iminium and phenolate functions, respectively.[8] The zwitterion $\mathbf{1}^{\pm}$ is stable owing to the contribution from the quinonoid resonance form.[9]



$\mathbf{1}^{\pm}$

Uncatalyzed (water-catalyzed) reactions observed in the neutral pH region (6.5<pH<8) can be attributed to the two kinetically indistinguishable reactions: The hydroxide reaction on the protonated substrate $\mathbf{1H}^+$ ($k_1'K_W/K_{a1}$) and the water reaction of $\mathbf{1}^{\pm}$ (k_2). If the former reaction were the main contributor to k_0, k_1' should have been $4\times10^6\ M^{-1}\,s^{-1}$,[10] which is too large (17-fold) as compared with a similar value for the hydrolysis of *N*-(*o*-methoxybenzylidene)-2-methoxyethylamine **4**.[11] The latter reaction must be the predominant reaction here and $k_2=1.5\times10^{-3}\ s^{-1}$, which is about 1/10 of k_1 and is not unreasonable in magnitude. Similar conclusions were reached before for other *N*-salicylidene amines.[6,7]

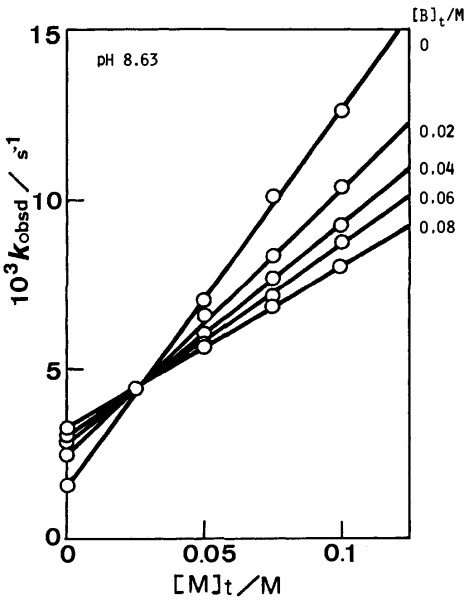


Fig. 2. Dependences of k_{obsd} on the concentration of morpholine $[M]_t$ at the concentrations of boric acid indicated.

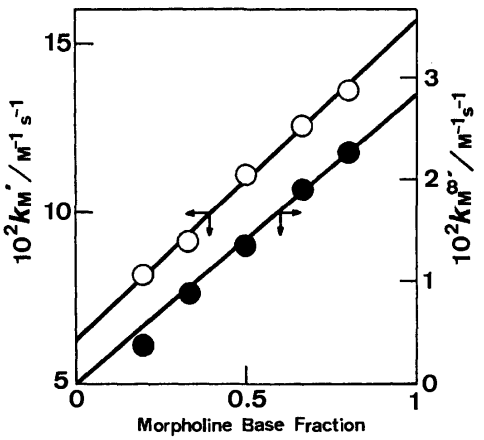

Fig. 3. Plots of k_M' (○) and $k_M^{\infty\prime}$ (●) against the base fraction of morpholine buffers.

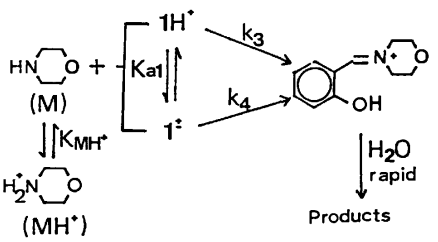
The hydrolysis of **1** was remarkably accelerated by morpholine buffer at pH 8—9.3, although tertiary amines like 1,4-diazabicyclo[2.2.2]octane and *N*,*N*-dimethyl-2-hydroxyethylamine had no effects in this pH region. Furthermore, both UV spectra of the initial and final reaction solutions were respectively the same as those observed in other normal buffer solutions. Observed rate constants k_{obsd} increased linearly with total morpholine concentration $[M]_t$ (Eq. 3) as shown in Fig. 2.

$$k_{obsd} = k_0 + k_M'[M]_t \quad (3)$$

The observed catalytic constants k_M' are plotted against the base fraction of morpholine buffer in Fig. 3. The linear correlation gives the rate constants for base and conjugate acid dependences $k_M=0.16\ M^{-1}\,s^{-1}$ and $k_{MH}=0.063\ M^{-1}\,s^{-1}$.

$$k_M' = (k_{MH}[MH^+] + k_M[M])/[M]_t \quad (4)$$



Scheme 2.

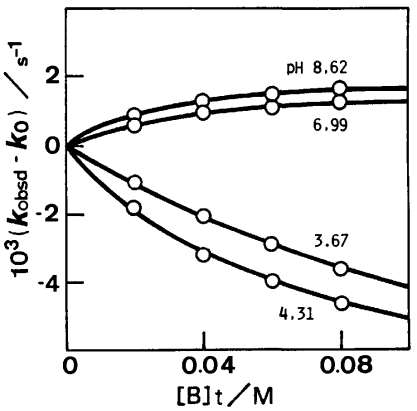


Fig. 4. Dependence of the hydrolysis rate of **1** on the boric acid concentration at pH indicated.

These accelerations must be due to the nucleophilic catalysis by morpholine. The reactive species of **1** in this nucleophilic reaction should be $\mathbf{1H^+}$ and $\mathbf{1^\pm}$, and the rate constants k_{MH} and k_M correspond to $k_3K_{MH^+}/K_{a1}$ and k_4 according to Scheme 2, respectively. Calculated values of k_3 and k_4 are given in Table 1.

Hydrolysis in the Presence of Boric Acid. When a small amount of boric acid was added to the reaction mixture, the hydrolysis was accelerated at high pH while it was decelerated at low pH. Although the spectrum of the initial solution of the substrate showed a new absorption band at 350 nm, that of the product solution was the same as that observed in the absence of boric acid. Induction periods were not observed in any kinetic runs.

Hydrolysis rates were measured with varying concentrations of boric acid at constant pH maintained with a second buffer (when necessary). The rate increased at pH>5.5 but decreased at pH<5.5 with total borate concentration $[B]_t$ as shown in Fig. 4. These changes follow a saturation curve described by Eq. 5, as observed for the hydrolysis of an α-hydroxy Schiff base.[2]

$$k_{obsd} = (k_0' + k_\infty K_{app}[B]_t)/(1 + K_{app}[B]_t) \quad (5)$$

Here, k_0' is the rate constant in the absence of boric acid and is usually equal to k_0 (negligible effects of the second buffer). The magnitude of k_∞ is greater at pH>5.5 but smaller at pH<5.5 than k_0. The curved rate dependence of Eq. 5 is consistent with a reaction sequence involving a rapid equilibrium formation of a borate-substrate complex followed by a slow breakdown of the complex to lead to the hydrolysis products.[2,12] K_{app} and k_∞ stand for the equilibrium constant for the complexation and the rate constant for the breakdown of the complex, respectively. They were evaluated from a least-squares treatment of the linear relation between k_{obsd} and $(k_{obsd}-k_0')/[B]_t$ in the same way as before.[2] The results are given in Table 2. In the pH range 4—6, where the hydrolysis is buffer-dependent, the "normal" buffer effects by boric acid must be taken into consideration. However, the general-base-catalytic acceleration by borate should be small enough to be neglected.[13] The second buffer used to maintain pH constant affects only the k_0' term but not the borate term.

Table 2. Kinetic parameters for the hydrolysis of **1** in the presence of boric acid at 30 °C

pH[a]	$10^3 k_\infty/s^{-1}$	K_{app}/M^{-1}
3.67[b]	4.0±1.5	3.4±1.0
4.31[c]	4.0±0.7	10.3±0.5
4.69[c]	4.2±1.0	15.4±0.8
5.66[d]	3.6±0.2	17.6±1.5

9.26[f]	4.9±0.2	12.9±1.3

a) pH (±0.03) were maintained with a buffer of 0.05 M. b) Formate. c) Acetate. d) 2-(*N*-Morpholino)-ethanesulfonate. e) *N*-Methylmorpholine. f) 1,4-Diazabicyclo[2.2.2]octane.

The effects of added boric acid were found also in the morpholine-catalyzed hydrolysis. When the pH and the morpholine concentration $[M]_t$ were kept constant, the rates increased at low $[M]_t$ and, in contrast, decreased at high $[M]_t$ with increasing $[B]_t$ (Fig. 5). At pH 8.6 and $[M]_t$=0.025 M, the observed rate was almost constant with varying $[B]_t$. In an opposite sense, at constant pH and $[B]_t$, the rates increased linearly with $[M]_t$ and lines (for various $[B]_t$) cross at a certain $[M]_t$ (*e.g.*, $[M]_t$=0.025 M at pH 8.6) as shown in Fig. 2. That is, in the presence of both boric acid ($[B]_t$=constant) and morpholine, k_{obsd} is described by Eq. 6.

$$k_{obsd} = k_0^B + k_M^B[M]_t \quad (6)$$

The slopes of the plots of Fig. 2, k_M^B, decreased with increasing $[B]_t$ as shown in Fig. 6. The curved dependences of $k_M^B[B]_t$ are described by Eq. 7 in the same way as Eq. 5.

$$k_M^B = (k_M + k_M^{\infty\prime}K_{app}[B]_t)/(1 + K_{app}[B]_t) \quad (7)$$

Kinetic parameters, $k_M^{\infty\prime}$ and K_{app}, obtained similarly are given in Table 3. Values of K_{app} obtained here agree well with those obtained in the absence of morpholine as shown with closed circles in Fig. 1.

The limiting rate constant $k_M^{\infty\prime}$ corresponds to that for the nucleophilic reaction of morpholine with the

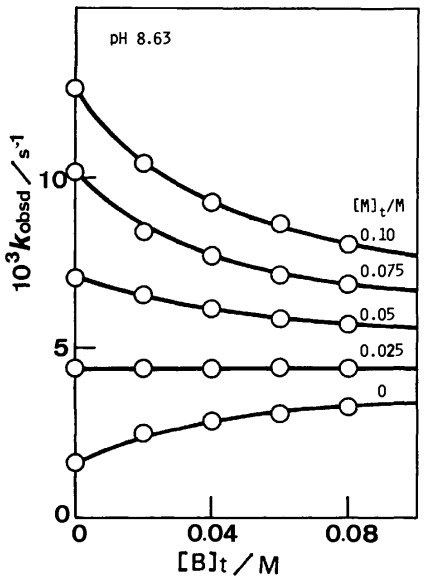

Fig. 5. Dependences of k_{obsd} on the concentration of boric acid at the concentrations of morpholine indicated.

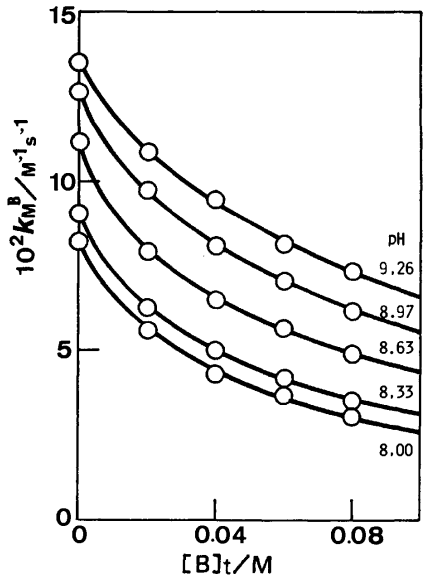

Fig. 6. Dependence of k_M^B on the boric acid concentration at pH indicated.

borate-substrate complex. The values of $k_M^{\infty\prime}$ are proportional to the base fraction of morpholine buffer as seen in Fig. 3, the slope being $k_M^{\infty}=2.7\times10^{-2}$ M^{-1} s^{-1}.

Discussion

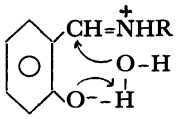
Catalysis of Hydrolysis. Hydrolysis of Schiff base **1** derived from salicylaldehyde **2** is somewhat complicated because of tautomerization of the neutral substrate $\mathbf{1}^0 \rightleftharpoons \mathbf{1}^{\pm}$. This occurs because the zwitterion $\mathbf{1}^{\pm}$ is stabilized by resonance with the quinonoid form. The increase in hydrolysis rate at alkaline pH is ascribed to the reaction of $\mathbf{1}^{\pm}$ with hydroxide ion.

The predominant reaction in the neutral pH region is the water reaction of $\mathbf{1}^{\pm}$ but not the hydroxide reaction of $\mathbf{1H}^+$ as described above. The same conclusion was reached from the lack of salt effects[7] and the substituent effect[6] observed in the hydrolysis of *N*-salicylidene amines. Failure in the observation of buffer effects in this pH region seems to be incompatible with the water reaction, which should be catalyzed by general bases, but to conform with the hydroxide reaction. However, an intramolecular general base catalysis by the *o*-O^- group may make the external catalysis unnecessary.[14]

Table 3. Kinetic parameters obtained in the presence of both morpholine and boric acid

pH[a]	$10^2 k_M^{\infty\prime}$/M^{-1} s^{-1}	K_{app}/M^{-1}
8.00	0.33±0.15	25.0±1.9
8.33	0.82±0.08	24.7±3.1
8.63	1.3±0.3	22.7±3.1
8.97	1.9±0.2	18.9±2.8
9.26	2.2±0.2	14.8±2.2

a) ±0.03.



Such an intramolecular catalysis was once considered to occur during the hydrolysis of Schiff bases derived from salicylaldehyde[15] and 3-hydroxy-4-pyridinecarbaldehyde,[16] but it was later disregarded by comparisons of the reactivities of *o*- and *p*-hydroxy as well as methoxy derivatives of *N*-benzylideneisopropylamine.[5] However, the comparisons made by the latter authors do not seem to be adequate. First of all, they attributed the predominant reaction in the neutral pH region to the hydroxide reaction of the protonated substrate and the rate constants for the hydroxide reactions of hydroxy and methoxy substrates were compared. As mentioned above, the main reaction is the water reaction of the zwitterion in the case of salicylidene derivatives.

Comparisons of rate constants for various nucleophilic reactions at iminium functions are given in Table 4. Nucleophilic reactions of *o*-methoxybenzylidene derivative $\mathbf{4}^{11}$ are involved for the reference of the comparison. The rate constants are logarithmically plotted against pK_a of the conjugate acid of the nucleophiles in Fig. 7. Three points for $\mathbf{4H}^+$ fall on a straight line of slope (β) of 0.5. Two points (H_2O and morpholine) for $\mathbf{1H}^+$ fall also in the vicinity of the same line. Three points for zwitterion $\mathbf{1}^{\pm}$ can form a line of slope of about 0.35. However, the low sensitivity in relative nucleophilicity of less reactive substrate $\mathbf{1}^{\pm}$ (compared with $\mathbf{1H}^+$ or $\mathbf{4H}^+$) is not reasonable. These points may be rationalized as follows: Hypothetical nucleophilic reactivities of $\mathbf{1}^{\pm}$ would have formed a line of β=0.5 through a point for hydroxide ion but an intramolecular base-catalyzed acceleration of morpholine and water reactions by the *o*-O^- group resulted in the positive deviations of these points (10- and 300-fold for morpholine and water) from the hypothetical line. Such deviations

TABLE 4. RATE CONSTANTS FOR NUCLEOPHILIC REACTIONS OF VARIOUS IMINIUM SPECIES ($k_{Nuc}/M^{-1}s^{-1}$) AT 30 °C

Nucleophile (pK_a)	$1H^+$	$4H^+$ [a]	1	1B
H_2O (−1.7)	4.3×10^{-4}	8.8×10^{-4}	2.7×10^{-5}	6.3×10^{-5}
Morpholine (8.6)	1.0×10^{3}	3.2×10^{2}	1.6×10^{-1}	2.7×10^{-2}
OH^- (15.7)		2.3×10^{5}	3.7×10	1.1×10^{2}

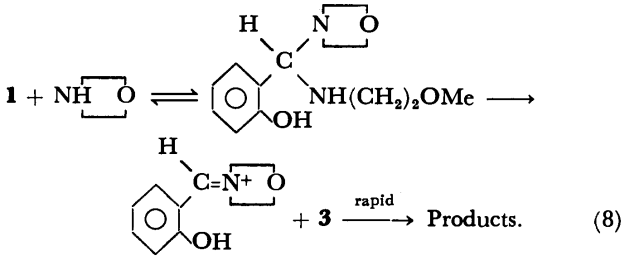
●, $4H^+$; ⊕, $1H^+$; ○, $1^\pm$; ◑, 1B.

of water reactions of the zwitterion of other *N*-salicylidene amines seemed to be observed as compared with benzylidene analogues.[5,7]

Nucleophilic catalysis of the Schiff base hydrolysis by morpholine is not unexpected since such catalysis of Schiff base formation is well known.[17] This catalysis must take place through transimination to form *N*-salicylidenemorpholinium ion, which is hydrolyzed rapidly (Eq. 8):

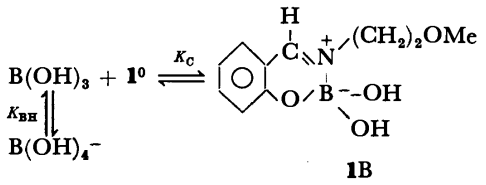


(8)

The rate-determining step of this reaction must be the initial nucleophilic reaction of morpholine with **1**. This is consistent with the observation that morpholine shows a nucleophilicity expected from the water and hydroxide reactions of $1H^+$ and $4H^+$ (Fig. 7), and is reasonable since a more basic amine is in general more readily released from a *gem*-diamine intermediate as observed during transiminations.[18] Transimination reactions are subject to buffer catalysis[18–20] and the morpholine reaction with $1^\pm$ may be facilitated by an internal catalysis by the salicylidene O^- group.

Effects of Boric Acid. The apparent equilibrium constants K_{app} for the complexation between **1** and boric acid show a bell-shaped change with pH as seen in Fig. 1. This change is described by Eq. 9, which is based on the assumption that the complex **1B** is formed from the neutral substrate 1^0 (the fraction is $(K_{a1}/K_T)[H^+]/\{[H^+]^2+K_{a1}(1+1/K_T)[H^+]+K_{a1}K_{a2}\}$) and boric acid (the fraction of acid form is $[H^+]/(K_{BH}+[H^+])$) with the equilibrium constant K_C (Eq. 10).

$$K_{app}=\frac{(K_CK_{a1}/K_T)[H^+]^2}{\{[H^+]^2+K_{a1}(1+1/K_T)[H^+]+K_{a1}K_{a2}\}(K_{BH}+[H^+])} \quad (9)$$



(10)

1B

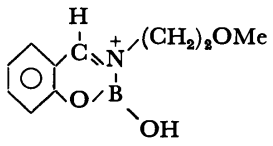
A probable structure of **1B** must involve a tetra-coordinated boron. Chelate complexes formed from polyols and boric acid involve a tetra-coordinated boron center.[21,22] Complexes of a structure similar to **1B** were isolated as diacetates from the reaction of *N*-salicylidene amines with boric acid in acetic anhydride.[23]

A theoretical curve for the bell-shaped plot of Fig. 1 is calculated with parameters given in Table 1 and $K_C/K_T=27\ M^{-1}$ according to Eq. 9, where K_T is assumed to be much geater than unity ($1+1/K_T\simeq1$). If the K_T value is in the range of 10—60,[24] $K_C=300$—$1600\ M^{-1}$. The formation constant K_C is much greater than those observed for the complexation of 1,2-diols and boric acid,[21,25] but a similar value ($K_C=435\ M^{-1}$) was obtained for complexation between an α-hydroxy Schiff base and boric acid.[2]

The limiting rate constant k_∞ refers to the breakdown of complex **1B** to give hydrolysis products. The values of k_∞ are essentially constant below pH 7.5, but increase at higher pH (Fig. 1). This pH dependence of k_∞ is accommodated by the reactions of **1B** with water and hydroxide ion (Eq. 11): $k_5=3.5\times10^{-3}\ s^{-1}$ and $k_5'=1.1\times10^2\ M^{-1}s^{-1}$.

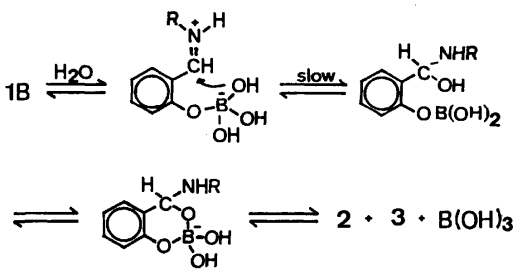
$$k_\infty=k_5+k_5'[OH^-] \quad (11)$$

A possible contribution from a cationic complex like $1B^+$ is unlikely,[26] since such a reaction was not found in the morpholine reaction. The rate constant k_M^∞ must be that for the nucleophilic reaction of morpholine with complex **1B**.



1B$^+$

Logarithms of the rate constants for the nucleophilic reactions on **1B** are plotted against pK_a for the corresponding nucleophiles with half-filled circles in Fig. 7. Points for hydroxide ion (k_5') and morpholine (k_M^∞) form a straight line of slope of 0.5, as found for the reaction with **4H**$^+$ and **1H**$^+$. However, the point for water (k_5) deviates upward by 2.5 log unit from the line. This 300-fold deviation of the k_5 point suggests that this reaction is not a simple water attack on the iminium carbon of **1B**. This water reaction is not catalyzed by a general base. Furthermore, the anomaly occurs only with water but not with morpholine. Boronic group of **1B** must participate in the reaction. A possible mechanism is presented in Scheme 3. This mechanism involves a rapid (but unfavorable) rearrangement of **1B** to an open zwitterionic complex, within which a rate-determining, intramolecular transfer of the hydroxide ion occurs from the boron to the iminium carbon. Similar reaction mechanisms have been presented for the boric acid-dependent hydrolyses of an α-hydroxy Schiff base[2] and hydroxy thiocarboxylic *S*-ester.[4]



Scheme 3.

In conclusion, boric acid decelerates the hydrolysis of **1** in the low pH region where the reaction of **1H**$^+$ predominates, while it accelerates the hydrolysis at higher pH where **1**$^\pm$ is the reactive species. The reactivities of the iminium species are in the order: **1H**$^+$> **1B**>**1**$^\pm$. The water reaction of **1**$^\pm$ is catalyzed by the internal O$^-$ group in the *ortho* position.

Experimental

Materials. Salicylaldehyde (**2**) and 2-methoxyethylamine (**3**) were commercially obtained and distilled under nitrogen. Salicylidene-2-methoxyethylamine (**1**) was prepared from **2** and **3** by the reaction of the two components at 0 °C for 1 h. After taken up with ether and dried over $MgSO_4$, the products were distilled: bp 142 °C (7 mmHg (1 mmHg≈133.322 Pa)). Other chemicals were obtained as before.[2] Glass-distilled water was used throughout.

Kinetic Measuremens. All the aqueous solutions containing appropriate amounts of boric acid and other buffers were prepared at room temperature and adjusted to an ionic strength of 0.1 with KCl. A stock solution of the substrate **1** was obtained as an acetonitrile solution of about 10^{-3} M. Reactions were started by adding 30 μl of the substrate stock solution from a microsyringe into a 3-ml buffer solution equilibrated at 30±0.1 °C in a stoppered quartz cuvette inserted in a water-jacketed cell holder. The reaction was followed by the decrease in the absorption at 275 nm on a Shimadzu UV 200 or 140 spectrophotometer. Pseudo-first-order rate constants were calculated by a modified Guggenheim method.[27] Values of the pH of buffer and reaction solutions were determined by a Hitachi-Horiba F7 pH meter.

Effects of Boric Acid on the Rate and Equilibrium of Schiff Base Formation from Salicylaldehyde

Hiroaki NAGAMATSU, Tadashi OKUYAMA,* and Takayuki FUENO
Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received April 25, 1984)

Effects of boric acid on the formation of the Schiff base from salicylaldehyde and 2-methoxyethylamine (or glycinate) were examined in aqueous solution. From the formation constants in the absence and presence of boric acid, the equilibrium constants for the borate-Schiff base complexation were determined. The structure of the complex was deduced from the UV spectral analysis. Formation of the Schiff base was found to be accelerated by boric acid (pH 7—10). A mechanism for the reaction involving the complex is presented.

Hydrolysis of Schiff bases derived from an α-hydroxy ketone[1] and salicylaldehyde[2,3] is greatly influenced by added boric acid. Intermediacy of a borate-Schiff base complex was substantiated from kinetic investigations of the hydrolysis.[1,3] Since the Schiff base formation is reversible in aqueous solution and Schiff bases are stable in the presence of an excess amount of amine, the complexation could be examined in more detail under equilibrium conditions.

In the present investigation, the formation of the Schiff base (**1**) from salicylaldehyde (**2**) has been examined under such conditions both in the absence and presence of boric acid (Scheme 1). The Schiff base formation was accelerated by added boric acid. Complexation between boric acid and **1** was analyzed and the structure of the complex was deduced on the basis of the UV spectra. A mechanism for the reaction involving the borate-Schiff base complex is presented.

Scheme 1.

Results

Schiff Base Formation in the Absence of Boric Acid. All the reactions and UV-measurements were carried out at 30 °C in aqueous solution of an ionic strength of 0.10 maintained with KCl. UV spectral data of salicylaldehyde (**2**) and its derivatives are summarized in Table 1. Spectra of Schiff bases (**1**) at higher pH were recorded under equilibrium conditions in the presence of **2** and an excess amount of amines (**3**). Appropriate corrections were made for concomitant **2** by using the formation constant K_f obtained below. The spectra in HCl solutions were obtained as an initial spectrum immediately after mixing.

When a small amount of **2** is added into an aqueous solution containing a primary amine **3**, the absortion of Schiff base **1** develops at the expense of the absorption of **2**. On the contrary, addition of **1** into the amine solution causes the Schiff base bands to diminish with simultaneous appearance of the aldehyde bands. Both changes accompany two isosbestic points at about 260 and 345 nm at lower pH(<8) and at 260 and 375 nm at higher pH(>8.5). These spectral changes are no doubt results of the equilibrium between Schiff base **1** and aldehyde **2**. *o*-Methoxybenzaldehyde (**5**) and its Schiff bases (**4**) showed similar spectral changes. The UV measurements were made in the same way.

Section. Results are summarized in Table 2.

Time-dependent changes of the absorbance gave pseudo-first-order rate constants k_{obsd}, which were not affected whether the reaction was started with **1** or **2**. The rate constant k_{obsd} linearly increased with the total amine concentration $[\mathbf{3}]_t$ (Fig. 1), but was independent of the buffer used to maintain pH constant. The observed rate constant k_{obsd} must be the sum of those for the forward and the reverse reactions (Eq. 2).

$$k_{obsd} = k_h + k_f[\mathbf{3}]_t \quad (2)$$

The intercept and the slope of the plot of k_{obsd} against $[\mathbf{3}]_t$ correspond to the rate constants for the hydrolysis (k_h) and formation (k_f) of Schiff base **1**, respectively. These rate constants obtained over pH 7—11 are summarized in Table 2. Both k_f and k_h obtained from the reaction of **2** (in the presence of **3a**) agree with those obtained from the reaction of **1a** within experimental errors. The values of k_h for the hydrolysis of **1a** are identical to those obtained previously in the absence of the amine.[3] The equilibrium constants $K_f(=k_f/k_h)$ calculated from the rate constants agree well with those

obtained spectrophotometrically, as summarized in Table 2.

Reactions in the Presence of Boric Acid. The UV spectra of **1** in the presence of boric acid were compared with those observed in its absence. On addition of boric acid, the absorbane at 393—395 nm of **1** diminished and a new absorption band appeared around 350 nm owing to the formation of a borate-Schiff base complex. The spectrum of aldehyde **2** was, however, not affected by the addition of boric acid; complexation between boric acid and **2** is negligible. The reactions involved are illustrated in Scheme 1. The apparent equilibrium constant K_f' for the Schiff base formation in the presence of boric acid can be spectrophotometrically determined in the same way as in the absence of boric acid. K_f' is defined by Eq. 3, where [**1B**] stands for the concentration of the complex **1B**. Since equilibrium constant K_{app} for the complexation is defined by Eq. 4,[3] the relation of Eq. 5 can bederived from Eqs. 3 and 4, where $[B]_t$ is total boric acid concentration.

$$K_f' = ([\mathbf{1}]+[\mathbf{1B}])/[\mathbf{2}][\mathbf{3}]_t, \quad (3)$$

$$K_{app} = [\mathbf{1B}]/[\mathbf{1}][B]_t, \quad (4)$$

$$K_f' = K_f + K_f K_{app}[B]_t. \quad (5)$$

The values of K_{app} were calculated as the ratio of the slope/intercept of the regression line of K_f' *vs.* $[B]_t$ (Fig. 2). Results are summarized in Table 3. The values of K_{app} for **1a** agree well with those obtained from the kinetic analysis of hydrolysis of **1a**.[3]

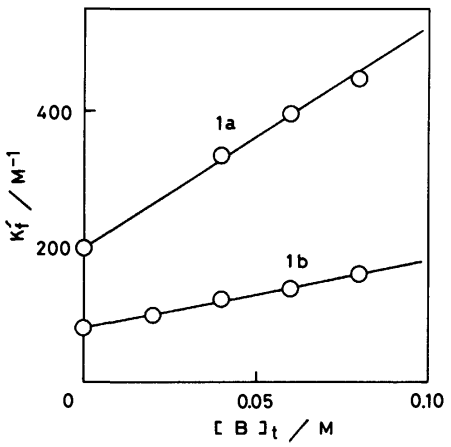

Fig. 2. Plots of K_f' against boric acid concentration at pH 8.94.

TABLE 3. EQUILIBRIUM AND RATE CONSTANTS FOR THE SCHIFF BASE FORMATION IN THE PRESENCE OF BORIC ACID[a]

pH[b]	K_{app}/M^{-1}	$k_f^B/M^{-1}s^{-1}$	$K_C/(K_T+1)/M^{-1}$

8.94	12.3 ±0.3	16.3 ±0.2	19.1
9.40	6.42 ±0.14	9.05±0.10	16.6

a) In aqueous solutions of the ionic strength of 0.10 at 30 °C. Standard deviations are given. b) ±0.03.

At a given ooncentration of boric acid $[B]_t$, the time-dependent absorbance changes followed the pseudo-first-order kinetics, and k_{obsd} increased linearly with the amine concentration $[\mathbf{3}]_t$ as observed in the absence of boric acid (Fig. 1).

$$k_{obsd} = k_h' + k_f'[\mathbf{3}]_t \quad (6)$$

The rate constant k_h' for the hydrolysis of **1a** agrees with that obtained in the absence of amine **3a**.[3] The rate

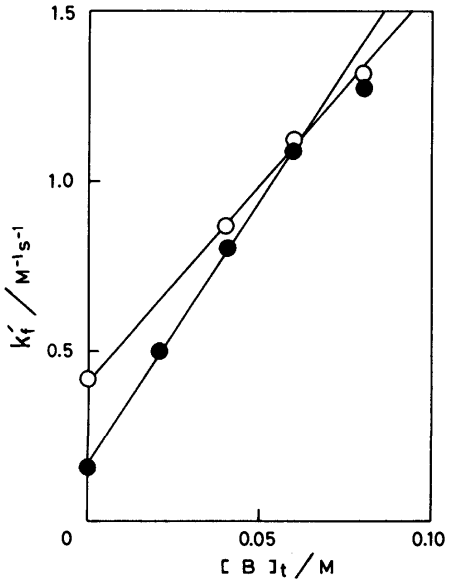

Fig. 3. Dependences of k_f' on boric acid concentration at pH 8.94 for the formation of **1a** (○) and **1b** (●).

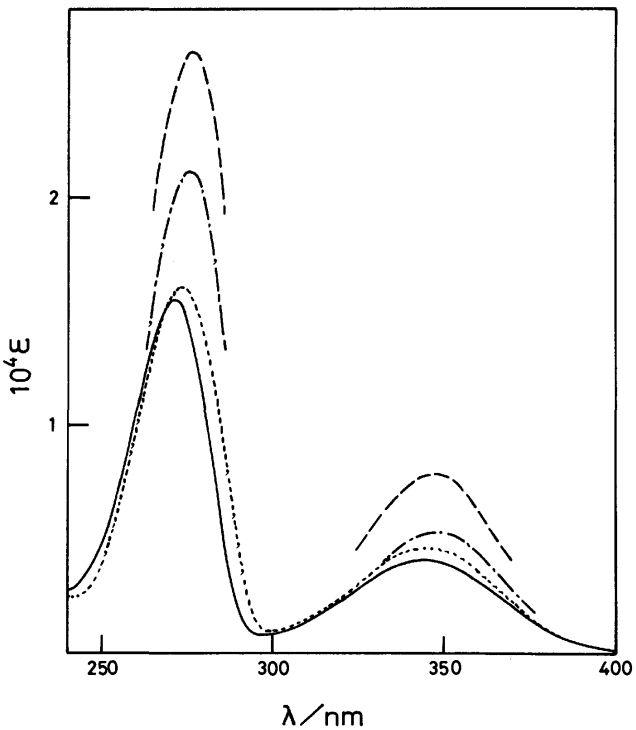

Fig. 4. UV spectra of borate complexes **1aB** (——) and **1bB** (·····) at pH 8.94. Spectra of **1aH**$^+$ (— — —) and **4aH**$^+$ (— —) are also shown.

constant k_f' for the formation of **1** increased linearly with $[B]_t$ (Fig. 3).

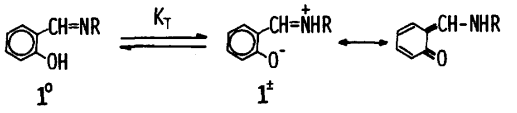
$$k_f' = k_f + k_f^B[B]_t \quad (7)$$

The intercepts of the plots of k_f' *vs.* $[B]_t$ are equal to the rate constants k_f obtained in the absence of boric acid ($[B]_t$=O). The third-order rate constants k_f^B are listed in Table 3.

Analysis of UV Spectra. The spectrum of Schiff base **1** in aqueous solution changes greatly by the addition of boric acid as mentioned above. In this aqueous solution, the complex **1B** must be present in an equilibrium concentration together with **1** and **2** as light-absorbing species (Scheme 1). Since we now know the equilibrium constants K_f and K_{app}, we can calculate the equilibrium fractions of **1**, **2**, and **1B**. The equilibrium fractions of **1aB**, **1a**, and **2** are, *e.g.*, 60, 37, and 3%, respectively, at pH 8.9, $[B]_t$=0.10 M,[4] and [3a]=0.625 M. The absorbances of **1aB** were thus calculated from the observed spectrum at every 5 nm over 240—400 nm using the extinction coefficients of **1** and **2** at each wavelength. The spectrum calculated in this way is shown in Fig. 4. The spectrum of **1bB** was also calculated in the same way. These spectra have two absorption maxima at 271(273) and 345 nm, which resemble closely those of the protonated Schiff bases **1aH**$^+$ and **4aH**$^+$ as may be seen in Fig. 4 (see also Table 1).

Discussion

UV Spectra. All the spectra of salicylaldehyde derivatives (*o*-YC_6H_4CH=X) listed in Table 1 have two absorption bands in the 250—275 and 305—395 nm regions. The iminium derivatives (X=N$^+$HR), as observed in HCl solutions, have a band at about 275 nm, while aldehyde (X=O) and the neutral imine (**4** in alkaline solution, X=NR) have a band around 255 nm. Although the spectra of **1** and **4** closely resemble each other in acid solutions, those observed in alkaline solutions are quite different. The spectra of **1** at pH 8.9 have a band typical of the iminium group (~276 nm) and largely red-shifted one (~394 nm). This feature of the spectrum of **1** conforms to the structure of the zwitterion **1**$^\pm$. The red-shift of the long-wavelength band (**1**$^\pm$ *vs.***2**$^-$) by the iminium function is generally observed; *e.g.*, **1H**$^+$ *vs.***2**^{0} and **4H**$^+$ *vs.***5**^{0}. The conclusion that the main species of *N*-salicylidene amine is the zwitterion **1**$^\pm$ in the neutral aqueous solution was previously reached from the comparisons of the spectra in aqueous and organic media.[5] This is also compatible with the kinetic results of the hydrolysis of **1a**.[3]



(8)

The tautomeric equilibrium (8) is largely shifted to the right-hand side owing to the stabilization by the quinonoid resonance.

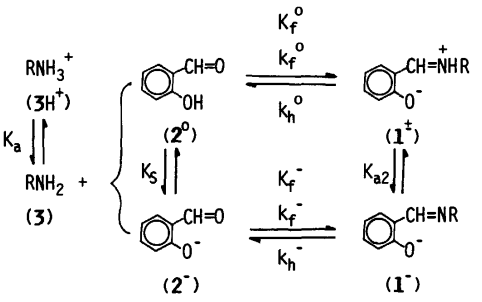
The absorption spectrum of the borate complex **1B**, as shown in Fig. 4, has two bands in the vicinity of the wavelengths characteristic of the iminium and the neutral phenolic groups. This strongly suggests the structure of **1B** involving a positive nitrogen and a neutral (phenolic) oxygen as a result of boron coordination. A reasonable structure is given in Scheme 1. Similar complexes involving a tetracoordinated boron have in fact been isolated as diacetates from the reaction of *N*-salicylidene amines with boric acid in acetic anhydride.[6] Diphenylborinate adducts have recently been found to have a similar structure.[7] It is also well-known that *N*-salicylidene amines form stable chelate complexes with various metal ions.[8,9] The UV spectra of Zn(II) and Ni(II) complexes have the absorption bands in the vicinity of 270 nm and 350 nm.[10]

Schiff Base Formation. Formation of Schiff bases occurs through a nucleophilic attack of free amine base on the carbonyl group as illustrated in Scheme 2.[11,12]

The pH-equilibrium constant profile is bell-shaped (Fig. 5) and is represented by Eq. 9 where K_a and K_S are the acid dissociation constants of ammonium ion **3H**$^+$ and salicylaldehyde **2**^{0}, respectively (pK_S 8.3).

$$K_f = \frac{K_a(K_f^0[H^+] + K_f^- K_S)}{(K_a + [H^+])(K_S + [H^+])} \quad (9)$$

Constants K_f^0 and K_f^- refer to the equilibria involving the neutral (**2**^{0}) and anionic (**2**$^-$) aldehyde, respectively.



Scheme 2.

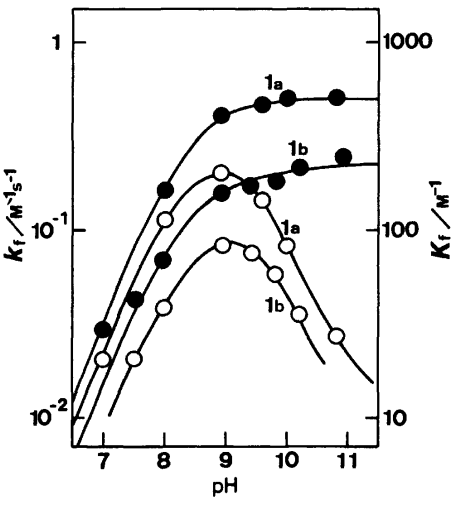


Fig. 5. pH profiles of rate constants k_f(●, left ordinate) and equilibrium constants K_f(○, right ordinate) for the formation of Schiff bases **1a** and **1b**.

The pH-rate profile also fits a similar equation (Eq. 10), although it appears to be different from the pH-K_f profile (Fig. 5).

$$k_f = \frac{K_a(k_f^0[H^+] + k_f^- K_S)}{(K_a + [H^+])(K_S + [H^+])} \quad (10)$$

The rate constant k_f^0 and k_f^- refer to the reactions of amine with $\mathbf{2}^0$ and $\mathbf{2}^-$, respectively. Theoretical curves calculated by Eqs. 9 and 10 with parameters given in Table 4 are shown in Fig. 5. The values of K_f^0 and K_f^- for **1a** satisfy the relationship $K_f^-/K_f^0 = K_{a2}/K_S$, which results from the equilibrium cycle in Scheme 2. Here, K_{a2} (7.0×10^{-12} M^{-1}) obtained during the hydrolysis kinetics[3] is used. The rate constants for the hydrolysis of **1a** can be calculated from previous results[3]: $k_h^0(k_2) = 1.5\times10^{-3}$ s^{-1} and $k_h^-(k_2'K_W/K_{a2}) = 7.8\times10^{-2}$ s^{-1}. The individual formation constants, $K_f^0(k_f^0/k_h^0) = 6.1\times10^3$ M^{-1} and $K_f^-(k_f^-/k_h^-) = 7.6$ M^{-1}, evaluated from these values agree well with those obtained spectrophotometrically. The formation constants for **1b** also agree with those reported.[9]

The equilibrium constants for the formation of Schiff base **4** corrected for the amine protonation are: **4a**, $K_f^0 = 100$ M^{-1} and **4b**, $K_f^0 = 31$ M^{-1}. These values are smaller than those (K_f^0) for *N*-salicylidene amines **1** by a factor of 10^2. The large values for **1** cannot simply be ascribed to a possible stabilization of **1** by an intramolecular hydrogen bonding. Stabilization of the Schiff base in a tautomeric form, $\mathbf{1}^{\pm}$, must be responsible for the facile formation of *N*-salicylidene amines. The zwitterionic form $\mathbf{1}^{\pm}$ is in fact a main species in neutral and weakly alkaline aqueous solutions as has been confirmed by UV spectroscopy.

The tautomeric oonstant K_T in aqueous solution is hard to estimate. If we assume that the formation constant $K_f^{0\prime}$ for the neutral Schiff base $\mathbf{1}^0$ (Scheme 3) is the same as that for the methoxy derivatives **4**, $K_T(=K_f^0/K_f^{0\prime})$ can be calculated as 60 and 116 for **1a** and **1b**, respectively.

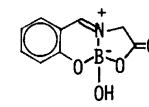
Similar evaluation for *N*-salicylideneaniline gave $K_T = 6.3$.[13] For the derivatives from less basic amines, the zwitterionic form tends to be less important. These estimations for K_T would be an upper limit in their magnitudes, as the neutral form of salicylidene derivatives **1** be stabilized by an intramolecular hydrogen bonding.

The complexation was considered to involve the neutral Schiff base and boric acid (acid form) from the bell-shaped change of K_{app} with pH.[3] With the equilibrium constant K_C for the reaction (Eq. 11), K_{app} can be expressed as Eq. 12.

$$\begin{array}{ccc} \mathbf{1}^0 + B(OH)_3 & \overset{K_C}{\rightleftharpoons} & \mathbf{1B} \\ {\scriptstyle K_T}\uparrow\downarrow & & {\scriptstyle K_{BH}}\uparrow\downarrow \\ \mathbf{1}^{\pm} & & B(OH)_4^- \end{array} \quad (11)$$

$$K_{app} = K_C[H^+]/(K_{BH} + [H^+])(K_T + 1) \quad (12)$$

Values of $K_C/(K_T+1)$ were calculated with $K_{BH} = 6.3\times10^{-10}$ M^{-1} and are given in Table 3. Average values are: $K_C/(K_T+1) = 25$ and 18 M^{-1} for **1a** and **1b**, respectively. The value for **1a** agrees reasonably well with that obtained from the hydrolysis kinetics.[3] By using the above estimated values for K_T, the K_C values are 1500 and 2100 M^{-1} for **1a** and **1b**, respectively. The carboxylato group of **1b** does not appreciably participate in the complexation. The boron–carboxylato interaction, as considered for metal-ion complex,[9] is not important. The bicyclic structure must be strained owing to the short B–O (B–N) distances.



Boric acid accelerates the Schiff base formation and the catalytic constants k_f^B change with pH taking a maximum value at pH 9. Because of the nature of the reaction, the reactive species involved must be a free amine base and boric acid (acid form). The catalytic constants k_f^B were corrected for such protonation states according to Eq. 13.

$$k_f^{B\prime} = k_f^B(K_a + [H^+])(K_{BH} + [H^+])/K_a[H^+] \quad (13)$$

The corrected constants $k_f^{B\prime}$ are plotted against the fraction of the neutral salicylaldehyde $\mathbf{2}^0$ in Fig. 6. For either of the amines, the plots seem to fit a straight line through the origin. Thus, only the neutral aldehyde $\mathbf{2}^0$ is involved in this reaction but the ionized aldehyde $\mathbf{2}^-$ is not. To be strict, the transition state for the borate-catalyzed formation of the Schiff base **1** is neutral and consists of aldehyde, amine, and boric acid. The catalytic constants k_f^{B0} corrected for the neutral aldehyde are 560 and 1100 M^{-2} s^{-1} for **3a** and **3b**, respectively, from the slopes of the plots in Fig. 6. These values correspond to accelerations of about 60- and 190-fold at $[B]_t = 1$ M.

A probable reaction sequence of the boric acid-

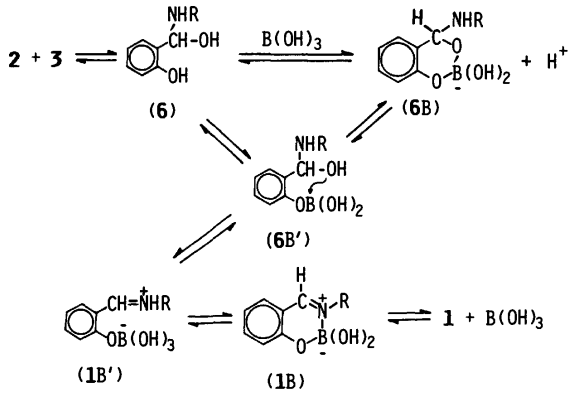
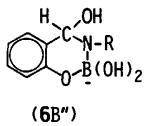


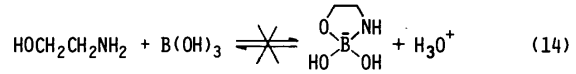
Scheme 4.

catalyzed Schiff base formation is given in Scheme 4. In alkaline pH region, formation of an α-amino alcohol intermediate (**6**) is rapid. **6** is a diol capable of forming a chelate complex (**6B**) with boric acid. However, the chelate complex cannot facilitate dehydration to lead to the Schiff base. The adduct (**6B'**) may exist in equilibrium at low concentration. Within this adduct, the hydroxyl group of the α-amino alcohol can readily transfer to the boron acceptor. The resulting zwitterion (**1B'**) rearranges to the stable borate-Schiff base complex (**1B**). This is precisely the microscopic reverse of the boric acid-assisted hydrolysis of the Schiff base.[3] Formation of a chelate complex (**6B''**) involving the amino-coordination to the boron is unlikely.



(6B")

Such complexes are not known in aqueous solution. The pH did not change when the two buffer solutions, each made from borate and 2-aminoethanol (or glycine) and adjusted at the same pH (≈9.2), were mixed (Eq. 14).



$$HOCH_2CH_2NH_2 + B(OH)_3 \rightleftharpoons + H_3O^+ \qquad (14)$$

In conclusion, the formation of *N*-salicylidene amines catalyzed by boric acid takes place through a mechanism given in Scheme 4.

Experimental

The UV measurements were carried out in a stoppered 10-mm quartz cuvette at a slitwidth of 1 nm on a Shimadzu UV 200 spectrophotometer. Some kinetic runs were also performed on a Shimadzu UV 140 spectrometer. The pH values of the buffer and reaction solutions were measured on a Hitachi-Horiba F7 pH meter.

Materials. Glycine **3b** and *o*-methoxybenzaldehyde **5** were commercially obtained. *N*-(*o*-Methoxybenzylidene)-2-methoxyethylamine **4a** was prepared in the same way as described previously for **1a**[3]: bp. 131 °C (4 mmHg).[14] All the other chemicals were obtained as before.[3]

Kinetic Measurement. All the aqueous solutions containing appropriate amounts of amine, boric acid, and buffers were prepared at room temperature and adjusted to the ionic strength of 0.10 with KCl. Reactions were started by adding 30 μl of a substrate soluion in acetonitrile from a microsyringe into 3 ml of a buffer solution equilibrated at 30±0.1 °C in a cuvette inserted in a water-jacketed cell holder. Pseudo-first-order rate constants were calculated usually by a modified Guggenheim method[15] from the time-dependent absorbance changes at 275 nm for **1**, and 335 nm at higher pH(>7) or 282 nm at lower pH(<7) for **4**. The infinite absorbances were compared occasionally between those observed and calculated.

Determination of the Formation Constant. The equilibrium constants were calculated from UV absorbance. Since amine **3** has no absorption above 220 nm, the relative concentration at equilibrium is expressed by the absorbance change: $[\mathbf{1(4)}]/[\mathbf{2(5)}]=(A_e-A_0)/(\varepsilon_1[\mathbf{2(5)}]_0-A_e)$ starting with **2(5)**, where A_0 and A_e are the absorbances at time zero and at equilibrium, and ε_1 and $[\mathbf{2}]_0$ stand for the extinction coefficient for **1** and

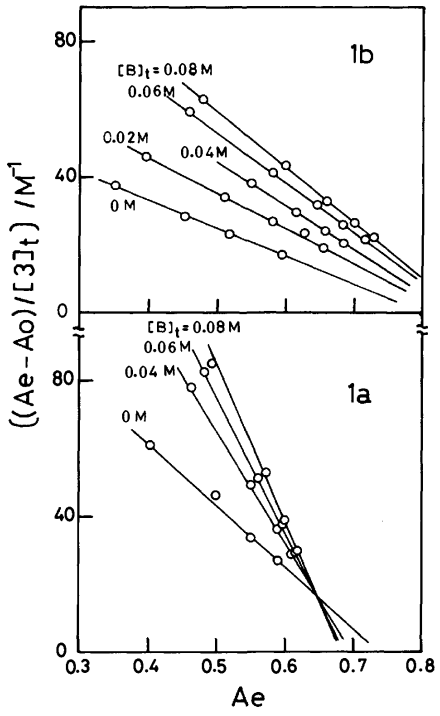


Fig. 7. Plots of $(A_e-A_o)/[3]_t$ against A_e at pH 8.94 and the boric acid concentrations indicated.

the initial concentration of **2**, respectively, or alternatively $[\mathbf{1}]/[\mathbf{2}]=(A_e-A_0)/(\varepsilon_2[1]_0-A_e)$ starting with **1** whose concentration is $[\mathbf{1}]_0$. Here ε_2 stands for the extinction coefficient for **2**. The values of $\varepsilon_1[\mathbf{2}]_0$ and $\varepsilon_2[\mathbf{1}]_0$ correspond to the limiting absorbances A_∞ at the infinite concentration of **3**. Thus the values of K_f ($=[\mathbf{1}]/[\mathbf{2}][\mathbf{3}]$) were determined from the slope of the plots of $(A_e-A_0)/[\mathbf{3}]_t$ against A_e according to Eq. 15 (Fig. 7).

$$(A_e-A_o)/[\mathbf{3}]_t = K_f(A_\infty-A_e) \quad (15)$$

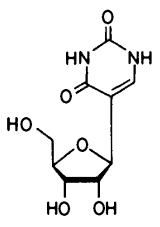
A Stereocontrolled Total Synthesis of *C*-Nucleosides[1)]

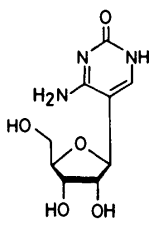
Tsuneo SATO, Yoshihiro HAYAKAWA,† and Ryoji NOYORI*
Department of Chemistry, Nagoya University, Chikusa-ku, Nagoya 464
†*Chemical Instrument Center, Nagoya University, Chikusa-ku, Nagoya 464*
(Received March 10, 1984)

A stereocontrolled, general synthesis of chiral *C*-nucleosides has been achieved through a common lactonic *C*-β-glycoside intermediate which is readily obtainable from non-carbohydrate materials. Osmium tetraoxide-catalyzed *vic*-dihydroxylation of 8-oxabicyclo[3.2.1]oct-6-en-3-one gives, after acetonidation, (1*R**,5*S**,6*S**,7*R**)-6,7-isopropylidenedioxy-8-oxabicyclo[3.2.1]octan-3-one as a single stereoisomer. Baeyer-Villiger oxidation of the ketone affords the key intermediate, 2-(2,3-*O*-isopropylidene-β-ribofuranosyl)acetic acid lactone. The optically pure lactone having the natural D configuration is obtained through optical resolution of the seco acid by the Pirkle's method followed by relactonization. α-Aminomethylenation of the lactone with *t*-$C_4H_9OCH[N(CH_3)_2]_2$ yields 2-(2,3-*O*-isopropylidene-β-D-ribofuranosyl)-2-(dimethylaminomethylene)acetic acid lactone, which undergoes base-assisted condensation with urea followed by deprotection to furnish naturally occurring pseudouridine. Analogously, construction of heterocycles using thiourea and guanidine converts the aminomethylene lactone to unnatural pyrimidine *C*-nucleosides, 2-thiopseudouridine and pseudoisocytidine, respectively. Showdomycin in natural form can be prepared by two schemes. One approach consists of ozonolysis of the α-dimethylaminomethylene lactone, Wittig reaction using $(C_6H_5)_3PCHCONH_2$, and acid hydrolysis. The second entry makes use of 2-(2,3-*O*-isopropylidene-β-D-ribofuranosyl)acetic acid lactone as the intermediate, which is converted to 2-(2,3-*O*-isopropylidene-β-D-ribofuranosyl)-2-furfurylideneacetic acid lactone by the aldol reaction with furfural and dehydration. Methanolysis of the furfurylidene lactone and *t*-butyldimethylsilylation are followed by ozonolysis, Wittig condensation with $(C_6H_5)_3PCHCONH_2$, and hydrolysis to give the maleimide *C*-nucleoside. In addition, 6-azapseudouridine and 6-aza-2-thiopseudouridine are obtainable *via* intramolecular ring closures of the semicarbazone and thiosemicarbazone of methyl 2-(2,3-*O*-isopropylidene-β-D-ribofuranosyl)glyoxylate followed by deprotections, respectively. These overall transformations are accomplishable under complete stereochemical control.

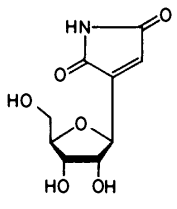
C-Nucleosides are a class of compounds which possess a carbon–carbon linkage between the carbohydrate and heterocyclic moieties, and are distinguished from ordinary *N*-nucleosides in which an anomeric carbon (C-1′ position) of the sugar is linked to the aglycon by a carbon–nitrogen bond. Since the first isolation of pseudouridine (**1**) as a minor constituent in various transfer ribonucleic acids,[2)] a number of naturally occurring *C*-nucleosides have been isolated mainly from the culture filtrates of various *Streptomyces*.[3)] The *C*-nucleosides, based on their unique structural feature, have considerable stability to chemical hydrolysis and enzymatiac destruction and, as a consequence, most of them exhibit various biological properties of interest.[4–9)]



1



2



3

The biological importance has stimulated the exploration of synthetic routes leading to natural *C*-nucleosides as well as their artificial analogues. The synthetic processes fall into the following three main categories: (1) transformation of naturally occurring *C*-nucleosides, (2) elaboration of a nitrogen heterocycle onto a suitably modified carbohydrate, and (3) total synthesis starting from non-sugar precursors. Most of the existing approaches[10)] come under the first and second categories, which seem to lack effectiveness, however, because of difficulty in access of the starting materials and poor generality in the former case, and low stereoselectivity in the latter method. The third-category type of synthesis obviously allows maximum flexibility but development of any effective approaches of this type requires some new, efficient methodologies for creation of the four asymmetric centers in the ribose skeleton as well as a strategy for stereochemical control at the anomeric center so as to maintain the β-D-glycosyl structures.[11)] This paper discloses full accounts of our stereocontrolled, general entry to *C*-nucleosides starting from inexpensive non-carbohydrate substances. The highly chiral framework is created by simple operations *via* an intermediate having C_s symmetry; the ribose skeleton is made by the efficient [3+4] cyclocoupling between polybromo ketones and furans aided by low-valent transition metals[13)] and subsequent oxidative modification of the resulting oxa bicyclic structure.

Synthesis of Pyrimidine C-Nucleosides. This synthesis starts with the bicyclic enone **4**, which is readily obtainable by reductive cyclocoupling of α,α,α′,α′-tetrabromoacetone and furan promoted by $Fe_2(CO)_9$ in benzene[14)] or Zn/Ag couple in THF,[15)] followed by debromination with Zn/Cu couple in methanol. When **4** was treated with a slight excess of 70% solution of *t*-butyl hydroperoxide in *t*-butyl alcohol containing catalytic amounts of osmium tetraoxide and aqueous tetraethylammonium hydroxide at 0—25 °C[16)] and then with anhydrous $CuSO_4$ and *p*-toluenesulfonic acid in acetone, the oxygen functions were introduced to the double bond from the less hindered side[17)] with perfect stereoselectivity to give the acetonide **5** as a single, crys-

talline isomer in 68% yield. No stereoisomer was detected in the reaction mixture. The stereoselective conversion of **4** to **5** was also accomplished in 52% yield by the osmium tetraoxide-catalyzed reaction using 30% hydrogen peroxide as the oxidizing agent. The α stereochemistry of the acetonide was established on the basis of the ^{1}H NMR spectrum which exhibited a sharp singlet at δ 3.98 due to the equivalent H_6 and H_7 protons. A Dreiding model of this rigid tricyclic system indicated that the H-C(6)-C(5)-H (or H-C(7)-C(1)-H) dihedral angle is approximately 90°, consistent with the observed ~0 Hz spin-spin coupling constant; if the acetonide had alternative β orientation with the dihedral angle of 30—40°, a 5 to 6-Hz signal splitting would be anticipated.[18] Subsequent Baeyer-Villiger oxidation of **5**,[19] giving the key intermediate **6** of an adequate *C*-β-glycoside structure, was achieved in 81% yield (94% yield based on consumed **5**) in dichloromethane at room temperature by two equiv of trifluoroperacetic acid in the presence of buffer salts of Na_2HPO_4 and disodium dihydrogen ethylenediaminetetraacetate. The oxidation proceeded only slowly by use of *m*-chloroperbenzoic acid with a catalytic amount of 4,4'-thiobis(6-*t*-butyl-3-methylphenol), and the yield was reduced to 59%. The lactone formation was confirmed by the IR absorption at 1737 cm^{-1} (C=O). Thus the keystone intermediate having a highly chiral structure can be derived facilely starting from simple and symmetrical substances, acetone and furan. The optical resolution required for natural product synthesis was effected *via* the corresponding seco acid methyl ester **7**, obtained in 95% yield by methanolysis with sodium methoxide in methanol. We found that, in this case, the Pirkle's resolution procedure[20] was far superior to the traditional method involving salt formation.[1a] Heating of an equimolar mixture of racemic **7** and (*R*)-1-(1-naphthyl)ethyl isocyanate in toluene[20] followed by chromatographic separation produced the optically active, diastereomeric carbamates **8**, $[\alpha]_D^{15}$ −3.56° (*c* 0.337, $CHCl_3$), and **9**, $[\alpha]_D^{15}$ −1.25° (*c* 0.561, $CHCl_3$), in 43% and 46% yields, respectively. The desired seco acid methyl ester, D-**7**, was liberated from **8** in 80% yield by treatment with trichlorosilane and triethylamine in benzene.[20] The transformation of D-**7** to the optically pure lactone, D-**6**, mp 161—163 °C, $[\alpha]_D^{26}$ +84° (*c* 0.63, $CHCl_3$), was then achieved according to the known procedure.[21] This resolved lactone was identical in all respects with the authentic sample prepared from D-ribose.[22]

The synthetic sequence continues by introduction of formyl or its synthetic equivalent at position α to the lactone carbonyl. After many attempts without any respectable success, a Bredereck reagent was found to be among the most effective. Thus treatment of D-**6** with

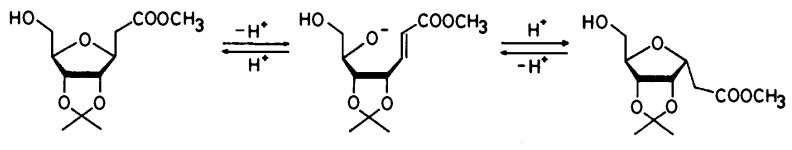
t-$C_4H_9OCH[N(CH_3)_2]_2$[25] in DMF at 60 °C afforded the dimethylaminomethylene lactone, D-**10**, in 91% yield. The product showed the IR bands [1685 and 1680 cm^{-1} (C=O), and 1595 cm^{-1} (C=C)] and a UV absorption [296 nm (ε 13,500)] characteristic of α-dimethylaminomethylene lactone structure. The ^{1}H NMR spectrum displaying two sets of two singlets at δ 2.94 and 3.16 [$N(CH_3)_2$], and 6.69 and 7.34 (=CH) indicated that the product was a 1:2 mixture of the *E*- and *Z*-olefinic isomers. It should be noted that the hydroxy ester **7**, the seco form of **6**, is stereochemically quite labile under basic conditions and, hence, formylation or related operation by conventional standard procedures causes easy isomerization through the intramolecular retro-Michael reaction/recyclization sequence,[24,26] giving the more stable α epimer **11**. Use of the lactone **6** thus has the particular advantage in preservation of the "natural" stereochemical integrity at C-1'.[27]

The aminomethylene lactone, D-**10**, appeared to serve as a common intermediate for natural and unnatural pyrimidine *C*-nucleosides. For instance, when a mix-



7 11

ture of D-**10** and urea was heated at reflux in 1 mol dm^{-1} ethanolic sodium ethoxide, there was obtained the uracil derivative, D-**12**,[29] mp 235—236 °C, $[\alpha]_D^{21}$ −18.1° (*c* 0.16, CH_3OH), in 60% yield. Removal of the isopropylidene group by exposure to 10% methanol solution of hydrogen chloride at 20 °C furnished pseudouridine (**1**), mp 243—244 °C, $[\alpha]_D^{21}$ −4.30° (*c* 0.47, H_2O), having spectral and physical properties identical with those of naturally occurring specimen. In addition, **1** is convertible to pseudocytidine (**2**),[29] a natural *C*-nucleoside, and 6-azapseudouridine (**13**),[30] an unnatural analogue, by the stereocontrolled, standard methods.

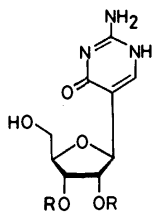
29, R^1 = $Si(CH_3)_2$-*t*-C_4H_9; R^2–R^2 = $C(CH_3)_2$; X = S
30, $R^1 = R^2$ = H; X = S



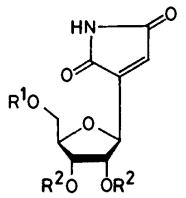
16, R–R = $C(CH_3)_2$
17, R = H

The lactone, D-**10**, underwent the sodium ethoxide-promoted condensation with thiourea in refluxing ethanol to produce the acetonide, D-**14**, $[\alpha]_D^{22}$ −8.0° (*c* 0.92, CH_3OH), in 81% yield. Subsequent deprotection with 10% solution of hydrogen chloride in methanol liberated 2-thiopseudouridine (**15**)[28] as a very hygroscopic solid in 90% yield.

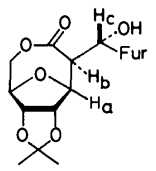
Chemotherapeutically significant pseudoisocytidine (**17**)[28,31] could be also synthesized from D-**10** in a similar manner. Thus, construction of the heterocyclic nucleus using guanidine hydrochloride and sodium ethoxide in hot ethanol gave rise to D-**16**, mp 170—174 °C, $[\alpha]_D^{22}$ −50.8° (*c* 0.73, CH_3OH), in 81% yield, methanolysis of which catalyzed by hydrogen chloride afforded hyrochloride of D-**17**, [28,31] mp 212—215 °C, $[\alpha]_D^{22}$ +14.3° (*c* 0.49 H_2O), in 93% yield.

Noteworthy is that during these all heterocycle formation-deprotection sequences no epimerization occurred at the glycosidic position.

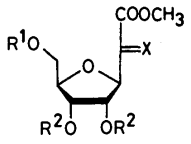
Synthesis of Showdomycin. We conceived that the lactone D-**6** or D-**10** may be useful for the synthesis of nucleosides other than pyrimidine ribo-*C*-nucleosides. The possibility of synthesis of showdomycin (**3**), a natural maleimide *C*-nucleoside,[32] was examined in two different ways. One approach used again D-**10** as the intermediate. When this lactone was exposed to ozone in ethyl acetate at −78 °C and then dimethyl sulfide at −78 °C to room temperature,[33] the labile keto lactone D-**18** was afforded, displaying a strong IR band due to the lactonic and keto carbonyls at 1732 cm^{-1} and no absorption for a conjugated olefin. This was subjected immediately to the Wittig reaction with $(C_6H_5)_3PCHCONH_2$[32a,34] in DMF to give D-**19**, mp 142—143 °C, $[\alpha]_D^{24}$ −2.31° (*c* 1.07, $CHCl_3$), in 30% yield. Removal of the isopropylidene block with aqueous trifluoroacetic acid completed the synthesis of showdomycin (**3**), mp 151—152 °C, $[\alpha]_D^{24}$ +48.7° (*c* 1.4 H_2O), which was identified by comparison with the natural product.



19, R^1 = H; R^2–R^2 = $C(CH_3)_2$
25, R^1 = $Si(CH_3)_2$-*t*-C_4H_9; R^2–R^2 = $C(CH_3)_2$



20



22, R^1 = H; R^2–R^2 = $C(CH_3)_2$; X = (*E*)-CHFur
23, R^1 = $Si(CH_3)_2$-*t*-C_4H_9; R^2–R^2 = $C(CH_3)_2$; X = (*E*)-CHFur
24, R^1 = $Si(CH_3)_2$-*t*-C_4H_9; R^2–R^2 = $C(CH_3)_2$; X = O
26, R^1 = $Si(CH_3)_2$-*t*-C_4H_9; R^2–R^2 = $C(CH_3)_2$; X = $NNHCONH_2$
28, R^1 = $Si(CH_3)_2$-*t*-C_4H_9; R^2–R^2 = $C(CH_3)_2$; X = $NNHCSNH_2$

Another entry to **3** utilizes aldol reaction of D-**6** and furfural assisted by lithium cyclohexylisopropylamide in THF at −78 °C, affording in 90% yield the adduct D-**20** (Fur=2-furyl), mp 139—141 °C, $[\alpha]_D^{21}$ +26° (*c* 2.63, $CHCl_3$). This was a single isomer and, on the basis of ^1H NMR, was revealed to have the *S* configuration at position α to the lactone carbonyl ($J_{Ha,Hb}$=5.0 Hz)[35] and the threo relationship[36] regarding the aldol moiety ($J_{Hb,Hc}$=9.0 Hz).[37] Dehydration of D-**20** was then effected by treatment with pivaloyl chloride in pyridine at 25 °C followed by heating in the same solvent at 90 °C, yielding D-**21**, mp 160—162 °C, $[\alpha]_D^{21}$ −143° (*c* 0.64, $CHCl_3$), quantitatively. The furfurylidene structure was proved by IR bands observed at 1715 (C=O) and 1627 cm^{-1} (C=C), and the ^1H NMR signal appearing as

a singlet at δ 7.24 (=CH). Ring-opening of the lactone with 0.05 mol dm^{-3} methanolic sodium methoxide at 0 °C, giving oily D-**22**, $[\alpha]_D^{21}$ +104° (*c* 2.90, $CHCl_3$), in 86% yield, followed by the silylation of the primary hydroxyl group with *t*-$C_4H_9(CH_3)_2SiCl$ and imidazole in DMF[38] gave quantitatively the methyl ester D-**23**, $[\alpha]_D^{21}$ −0.98° (*c* 0.44, $CHCl_3$), whose ^{1}H NMR data served to support its β-*C*-glycoside structure. The two isopropylidene-methyl singlets occurring at δ 1.25 and 1,56 with 0.31-ppm chemical shift difference is reminiscent of the spectral behavior of related isopropylidene ribonucleosides; the β anomers exhibit the chemical shift difference of >0.18 ppm, whereas the α anomers show the <0.10-ppm difference.[39] Ozonolysis of D-**23** in ethyl acetate at −78 °C followed by reductive workup with dimethyl sulfide yielded the unstable keto ester D-**24**, which without purification was subjected to the Wittig condensation with $(C_6H_5)_3PCHCONH_2$[32a,34] in chloroform to lead to D-**25**, $[\alpha]_D^{24}$ +2.1° (*c* 1.40, $CHCl_3$), in 29% yield (based on D-**23**). Subsequent trifluoroacetic acid-catalyzed hydrolysis produced showdomycin (**3**). Ozonolysis of the furfurylidene lactone, D-**21**, followed by the Wittig reaction also gave showdomycin acetonide, D-**19**, but only in 15% yield.

Such overall transformation have been achieved again without any epimerization at the anomeric center.

Synthesis of 1,2,4-Triazine C-Nucleosides. The keto ester D-**24** can be converted to certain 1,2,4-triazine *C*-nucleosides[40] in a stereospecific manner. For example, refluxing of a mixture of D-**24** and semicarbazide hydrochloride in aqueous methanol containing sodium acetate gave the semicarbazone D-**26**, $[\alpha]_D^{22}$ −1.6° (*c* 1.0, $CHCl_3$), in 30% yield (based on D-**23**) as a mixture of the syn and anti isomers. The isomeric ratio was assigned to be approximately 1:1 by the N–H ^{1}H NMR signals observed at δ 11.29 and 10.21,[41] respectively. Then the cyclization with 0.1 mol dm^{-3} ethanolic sodium ethoxide under reflux[42] furnished the 6-azauracil derivative, D-**27**, $[\alpha]_D^{25}$ −35.8° (*c* 8.90, $CHCl_3$), in 40% yield, hydrolysis of which gave 6-azapseudouridine (**13**),[30] mp 136—138 °C, $[\alpha]_D^{24}$ −23.4° (*c* 0.5, H_2O). In a similar fashion, treatment of D-**24** with thiosemicarbazide in refluxing methanol produced the thiosemicarbazone, D-**28**, $[\alpha]_D^{21}$ −0.71° (*c* 1.1, $CHCl_3$), in 25% yield (overall from D-**23**), which upon exposure to 0.1 mol dm^{-3} ethanolic sodium ethoxide at reflux temperature afforded D-**29**, $[\alpha]_D^{25}$ −1.4° (*c* 2.30, $CHCl_3$), in 56% yield. Deblocking of the protective groups with aqueous trifluoroacetic acid liberated 6-aza-2-thiopseudouridine (**30**),[30] mp 193—195 °C, $[\alpha]_D^{25}$ −3.5 °C(*c* 0.5, H_2O).

Conclusion. Our synthetic aim has thus in fact been realized. The salient feature of this total synthesis is use of the rigid bicyclic intermediates **4** and **6**. This allows strict stereochemical control throughout the overall transformation that consists of assembling the ribose moiety and elaboration of heterocyclic nuclei having the β configuration; the undesired stereomutation is precluded. In addition, the present route has practicability because of its directness and the ready availability of the starting materials. Of more importance is that this entry is capable of preparing various kinds of artificial *C*-nucleosides, particularly those with modified carbohydrate structures. Apparently this wide generality arises from the synthetic flexibility of the transition metal-mediated reductive cyclocoupling of appropriately substituted polybromo ketones and furan derivatives.[13,14] Analogues so far prepared by this method include various pyrimidine *C*-nucleosides containing 5′-alkylated,[43] 1′- or 4′-modified,[43a,44] 2′- or 3′-substituted,[43a,45] and 2′,3′-dialkylated ribose.[43a,46] Homo-*C*-nucleosides (homoshowdomycin,[47] homopyrazomycin,[47] and pyrimidine derivatives,[47a,48]) have been also synthesized.

We should add finally that successful examples were announced recently in preliminary disclosures for showdomycin synthesis *via* non-carbohydrate precursors, which laid on the Diels-Alder reaction between furan and an acrylic acid ester or an acetylenedicarboxylic acid derivative.[32e–g,49]

Experimental

General. Melting points uncorrected were obtained on a hot-stage apparatus. Elemental analyses were performed at the Faculty of Engineering of Nagoya University and the Fujisawa Pharmaceutical Co. Infrared (IR) spectra were recorded in a chloroform solution unless otherwise noted on a JASCO DS-402G or IRA-I spectrophotometer. Ultraviolet (UV)-visible light spectra in a stated solution were taken on a Hitachi 323 spectrophotometer. Proton nuclear magnetic resonance (^{1}H NMR) and proton decoupled ^{13}C NMR spectra were determined in a noted phase on Varian HA-100 and Varian CFT-20 instruments, respectively. Chemical shifts are given as parts per million (ppm) downfield from tetramethylsilane in δ units. In the ^{1}H NMR spectra, coupling constants are reported in hertz. Multiplicities are as follows: s; singlet, d; doublet, t; triplet, q; quartet, m; multiplet. Low-resolution mass spectra were measured on a Hitachi RMU-6C or JEOL D-100 instrument at an ionization potential of 70 eV and only a parent peak or prominent fragment peaks are described. Exact mass spectra were obtained at the Ono Pharmaceutical Co. or Institute for Molecular Science. Optical rotations were measured with a JASCO DIP-SL automatic polarimeter or a JASCO DIP-140 or 181 digital polarimeter. Analytical thin-layer chromatography (TLC) was done on a 5×2 cm of glass slide coated with 0.25-mm thickness of E. Merck Kieselgel 60 PF_{254}. For the preparative work, a 20×20 cm of glass plate coated with 1.0-mm thick layer of E. Merck Kieselgel 60 PF_{254} was employed. Use of E. Merck Kieselgel 60 (70—230 mesh) was made for column chromatography, unless otherwise state. High-performance liquid chromatography (HPLC) was achieved on a Waters 6000A instrument. All reactions in organic solutions were performed under an argon atmosphere. Concentration of solutions was carried out on a rotary evaporator under water aspirator pressures followed by a rotary oil vacuum pump. Organic solvents employed for the reactions were purified by standard procedures. *m*-Chloroperbenzoic acid was used after purification of commercially obtained material by the literature method.[53] Furfural was employed promptly after filtration through a short alumina column followed by distillation. A butyllithium–hexane solution required determination of the concentration by titration by the usual method.[54] *t*-Butoxybis(dimethylamino)methane was prepared according to the procedure of Bredereck.[25] Carbamoylmethylenetriphenylphosphorane made by the method of Trippett[34] was dried over P_2O_5 under 0.01 mmHg (1 mm Hg≈133.322 Pa) overnight before use.

(1R,5S*,6S*,7R*)-6,7-Isopropylidenedioxy-8-oxabicyclo[3.2.1]octan-3-one (5).* *A. By Oxidation with t-Butyl Hydroperoxide*: To a mixture of *t*-butyl alcohol solution (60 ml (1 ml=0.001 dm^3)) of 20% aq tetraethylammonium hydroxide (2.4 ml, 3.26 mmol) and 8-oxabicyclo[3.2.1]oct-6-en-3-one (**4**)[14,15] (3.72 g, 30 mmol) was added with vigorous stirring a 70% solution of *t*-butyl hydroperoxide in *t*-butyl alcohol (6.0 ml, 46.7 mmol) followed by a 0.02 mol dm^{-3} *t*-butyl alcohol solution of osmium tetraoxide (30 ml, 0.6 mmol) at 0 °C. The resulting yellow mixture was stirred at 0 °C for 30 min and at 20 °C for 5 h. The solution of *t*-butyl hydroperoxide (2.0 ml, 15.6 mmol), osmium tetraoxide (10 ml, 0.2 mmol), and aqueous tetraethylammonium hydroxide (1.0 ml, 1.4 mmol) were added renewedly and the reaction mixture was stirred again at 25 °C for 24 h. After quenching with 20% aq $Na_2S_2O_3$ solution (40 ml) at 0 °C, the mixture was stirred at 0 °C for 1 h. Viscous material obtained by evaporation was treated with acetone (100 ml) and the precipitates were removed by filtration through a Celite 545 pad. The filtrate was concentrated, giving an oil, which was dissolved in ethanol (50 ml) and then evaporated again. This dissolution-evaporation sequence was repeated twice more. A mixture of the resulting oil, anhydrous $CuSO_4$ (10 g, 62.7 mmol), and *p*-toluenesulfonic acid (100 mg) in acetone (100 ml) was stirred at 25 °C for 2 h. Removal of the insoluble material by filtration through a Celite 545 pad followed by concentration left an oily product, column chromatography of which with 1:1 ethyl acetate-hexane gave the acetonide **5** (4.05 g, 68%) as colorless crystals. Recrystallization from chloroform-hexane afforded an analytical sample, mp 119—121 °C: IR 1715 (C=O), 1378 and 1370 cm^{-1} (isopropylidene); ^1H NMR (benzene-d_6) δ=1.06 (s, isopropylidene CH_3), 1.47 (s, isopropylidene CH_3), 1.76 (d, J=16 Hz, $H_{2\beta}$ and $H_{4\beta}$), 2.08 (dd, J=6, 16 Hz, $H_{2\alpha}$ and $H_{4\alpha}$), 3.98 (s, H_6 and H_7), 4.23 (d, J=6 Hz, H_1 and H_5); mass spectrum m/z 198 (M^+). Anal. ($C_{10}H_{14}O_4$) C, H.

B. By Oxidation with Hydrogen Peroxide: Aqueous 30% hydrogen peroxide (100 ml, 863 mmol) was added at 0 °C over 2 h to a solution of **4** (11.6 g, 102 mmol), osmium tetraoxide (200 mg, 0.79 mmol), *t*-butyl alcohol (50 ml), and ether (50 ml) in acetone (500 ml). The reaction mixture was stirred at 20 °C for 13 h and then, after cooling to 0 °C, was quenched with $NaHSO_3$ (30 g). The resulting mixture was stirred at 20 °C for 3 h and evaporated until the volume was reduced to 50—100 ml. Extraction with ethyl acetate (200 ml×2, 100 ml) followed by concentration left an oil, which was mixed with anhydrous $CuSO_4$ (20 g, 125 mmol) and *p*-toluenesulfonic acid (50 mg) in acetone (200 ml), and stirred at 20 °C for 4 d. Removal of the insoluble solid by filtration followed by evaporation gave a viscous oil, whose column chromatography with a 1:3 to 2:1 ethyl acetate-hexane mixture as eluent afforded the colorless crystalline acetonide **5** (10.5 g, 52% yield), mp 119—121 °C.

(±)-2-(2,3-O-Isopropylidene-β-ribofuranosyl)acetic Acid Lactone (6). *A. With Trifluoroperacetic Acid*: A dichloromethane solution of trifluoroperacetic acid was prepared by mixing 90% hydrogen peroxide (9.62 ml, 255 mmol) and trifluoroacetic anhydride (43.3 ml, 305 mmol) in dichloromethane (200 ml) at 0 °C. This was added slowly with efficient stirring at 0 °C to a mixture of **5** (25.5 g, 127 mmol), Na_2HPO_4 (130 g, 915 mmol), and disodium dihydrogen ethylenediaminetetraacetate (2 g) in dichloromethane (200 ml), and the mixture was stirred at 25 °C for 12 h. After dilution with dichloromethane (200 ml) and addition of $Na_2S_2O_3 \cdot 5H_2O$ (40.5 g, 163 mmol) at 0 °C, the resulting mixture was further stirred at 25 °C for 5 h. Removal of insoluble material by filtration through a Celite 545 pad followed by evaporation produced a crude solid, which was subjected to column chromatography with a 1:1 to 3:1 ethyl acetate-hexane mixture, affording the unreacted ketone **5** (3.52 g, 14%) in the early fractions and the crystalline lactone **6** (22.1 g, 81% yield) in the late fractions. The yield of **6** based on consumed **5** was 94%. An analytical specimen of **6**, mp 146—147 °C (lit,[21] mp 140—141 °C), was collected by recrystallization from chloroform-hexane: IR 1737 cm^{-1} (C=O); ^1H NMR (benzene-d_6) δ=1.04 (s, 3 H, isopropylidne CH_3), 1.42 (s, isopropylidene CH_3), 2.16 (dd, J=3, 14 Hz, H_{2b}), 2.38 (dd, J=5.4, 14 Hz, H_{2a}), 3.10 (dd, J=3, 14 Hz, $H_{5'a}$), 3.51 (d, J=14 Hz, $H_{5'b}$), 3.96 (m, $H_{1'}$ and $H_{4'}$), 4.39 (d, J=6 Hz, $H_{2'}$), 4.58 (d, J=6 Hz, H_3); mass spectrum m/z 199 (M^+−15). Anal. ($C_{10}H_{14}O_5$) C, H.

B. With m-Chloroperbenzoic Acid: A 50-ml thick-glass tube charged with a magnetic stirring bar, **5** (2.0 g, 10 mmol), *m*-chloroperbenzoic acid (2.9 g, 16.8 mmol), sodium hydrogencarbonate (1.74 g, 20.7 mmol), and 4,4'-thiobis(6-*t*-butyl-3-methylphenol) (100 mg, 0.14 mmol) in chloroform (40 ml) was sealed and covered with an aluminum foil for shutting out the light. The ampule was immersed in a heating oil bath at 40—45 °C with stirring for 4 d. The resulting insoluble material was removed by filtration and washed with dichloromethane (20 ml). Concentration giving a yellow crystalline product followed by column chromatography with a 1:1 to 4:1 ether-hexane mixture afforded **6** (1.27 g, 59% yield) as colorless crystals, mp 146—147 °C after recrystallization. Unreacted **5** (810 mg, 41%) was recovered, hence the conversion yield was 99%.

(±)-Methyl 2-[(1S,2S*,3R*,4R*)-2,3-O-Isopropylidene-β-ribofuranosyl]acetate (7).* To a solution of the lactone **6** (200 mg, 1.00 mmol) in methanol (3 ml) was added dropwise 1 mol dm^{-3} methanolic sodium methoxide (1.20 ml) at room temperature over 5 min. Immediately after the addition was completed, the reaction mixture was quenched with 1 mol dm^{-3} solution of ammonium chloride in methanol (1.2 ml) and concentrated. The resulting residue was treated with water (5 ml) and extracted with dichloromethane (10 ml×3). The combined organic extracts were washed with brine and evaporated to give an oil, which was chromatographed on a silica-gel column (1:1 ethyl acetate-hexane) to afford **7** (233 mg, 95%) having the identical spectral data with those of the authentic sample alternatively prepared by the literature method.[24]

Methyl 5-O-(R)-1-(1-Naphthyl)ethylcarbamoyl-2-(2,3-O-isopropylidene-β-D-ribofuranosyl)acetate (8) and Methyl 5-O-(R)-1-(1-Naphthyl)ethylcarbamoyl-2-(2,3-O-bisopropylidene-β-L-ribofuranosyl)acetate (9). A mixture of **7** and (*R*)-1-(1-naphthyl)ethyl isocyanate in toluene (3 ml) was refluxed for 24 h under argon. Concentration of the resulting mixture gave a yellow oil, which was roughly purified by silica-gel column chromatography (35:65 ethyl acetate-hexane), yielding an oily mixture of the diastereomeric carbamates, **8** and **9**, (260 mg). This oil was subjected to preparative HPLC (10× 600 mm Hypersil-ODS, 40:60 H_2O-CH_3CN) to afford **8** [V_R 17.3 ml, 115 mg, 43% (86% theoretical yield)] and **9** [V_R 16.4 ml, 125 mg, 46% (92% theoretical yield)] as glassy syrups. **8**: $[\alpha]_D^{15}$ −3.56° (*c* 0.337, $CHCl_3$); IR 3440 (NH), 1730 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=1.23 (s, isopropylidene CH_3), 1.45 (s, isopropylidene CH_3), 1.56 (d, J=6.5 Hz, CHC$\underline{H}_3$), 2.5 (m, C$\underline{H}_2$COOCH$_3$), 3.56 (s, COOCH$_3$), 4.0 (m, $H_{1'}$, $H_{4'}$, and 2 $H_{5'}$), 4.4 (m, $H_{2'}$ and $H_{3'}$), 5.10 (d, J=6.5 Hz, NH), 5.50 (seven-line m, J=6.5 Hz, C$\underline{H}$NH), 7.1—8.1 (m, aromatic H). Found: m/z, 443.1936. Calcd for $C_{24}H_{29}NO_7$: 443.1942. **9**: $[\alpha]_D^{15}$ −1.25° (*c* 0.561, $CHCl_3$); IR 3440 (NH), 1730 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=1.22 (s, isopropylidene CH_3), 1.43 (s, isopropylidene CH_3), 1.53 (d, J=6.5 Hz, CHC$\underline{H}_3$), 2.47 (m, C$\underline{H}_2$COOCH$_3$), 3.50 (s, COOCH$_3$), 4.0 (m, $H_{1'}$, $H_{4'}$, and 2 $H_{5'}$), 4.4 (m, $H_{2'}$ and $H_{3'}$), 5.07 (br d, J=7 Hz, NH), 5.49 (m, C$\underline{H}$NH), 7.2—8.1 (m, aromatic H). Found: m/z, 443.1931. Calcd for $C_{24}H_{29}NO_7$: 443.1942.

Methyl 2-(2,3-O-Isopropylidene-β-D-ribofuranosyl)acetate (D-7). To a solution of **8** (83 mg, 0.19 mmol) and triethyl-

amine (46 mg, 0.45 mmol) in benzene (1.7 ml) was added trichlorosilane (31 mg, 0.23 mmol). The mixture was heated at reflux for 1 h under argon and quenched with water (3 ml). The organic layer was separated and the aqueous solution was extracted with dichloromethane (5 ml×3). The combined organic extracts were washed with brine (3 ml). Concentration gave an oil, which was subjected to column chromatography on silica gel (1:1 ethyl acetate–hexane) to give D-**7** (37 mg, 80%), $[\alpha]_D^{15}$ −6.28° (*c* 2.33, $CHCl_3$), identical in all respects with the authentic sample prepared according to the known procedure.[24]

2-(2,3-O-Isopropylidene-β-D-ribofuranosyl)-2-(dimethylaminomethylene)acetic Acid Lactone (D-10). A mixture of the lactone D-**6** (2.14 g, 10.0 mmol), *t*-butoxybis(dimethylamino)methane[25] (10 ml), and DMF (5 ml) was heated at 60 °C for 1 h. Evaporation of the resulting mixture *in vacuo* left an oily residue, which was chromatographed on a column packed with ammonia-treated silica gel. Elution with 1:1 ethyl acetate–hexane afforded a yellow syrup, D-**10** (2.45 g, 91% yield): IR 1685, 1680, 1595, 1420 cm^{-1}; UV λ_{max} (CH_3OH) 296 nm (ε 13500); mass spectrum *m/z* 269 (M^+). The ^1H NMR spectrum ($CDCl_3$) showed that the product consisted of *ca.* 2:1 mixture of *Z*- and *E*-olefinic isomers: δ=1.32 (s, isopropylidene CH_3), 1.51 (s, isopropylidene CH_3), 2.94 and 3.16 (two s's (1:2), $N(CH_3)_2$), 4.1—5.1 (m, $H_{1'}$, $H_{2'}$, $H_{3'}$, $H_{4'}$, and 2 $H_{5'}$), 6.69 and 7.34 (two s's (1:2), =CH). An analytical sample, mp 78—80 °C, was obtained by recrystallization from ether–hexane. Anal. ($C_{13}H_{19}NO_5$) C, H, N.

5-(2,3-O-Isopropylidene-β-D-ribofuranosyl)uracil (D-12). A mixture of D-**10** (4.12 g, 15.3 mmol), urea (4.59 g, 76.6 mmol), and 1 mol dm^{-3} solution of sodium ethoxide in ethanol (77 ml) was heated at reflux for 5 h under argon atmosphere. Evaporation of the reaction mixture left a residual syrup, which was dissolved in water (10 ml), and carefully neutralized by 6 mol dm^{-3} hydrochloric acid under monitoring with a pH test paper. An oil produced by concentration was diluted with ethanol (80 ml) and the insoluble material was removed by filtration. Evaporation followed by column chromatography using a 1:5 to 1:3 methanol–chloroform mixture as eluent gave the compound D-**12** (2.61 g, 60% yield), R_f 0.29 (1:5 methanol–chloroform) as slightly yellow crystals. Recrystallization from methanol–acetone–hexane produced the analytical sample, mp 235—236 °C (lit,[29] 233—234 °C), $[\alpha]_D^{21}$ −18.1° (*c* 0.16, CH_3OH): UV λ_{max} (CH_3OH) 263 nm (ε 5960), λ_{max} (0.1 mol dm^{-3} NaOH) 284 nm (ε 7110); ^1H NMR (dimethyl-d_6 sulfoxide) δ=1.27 (s, isopropylidene CH_3), 1.49 (s, isopropylidene CH_3), 3.53 (br s, 2 $H_{5'}$), 3.91 (br q, *J*=4.0 Hz, $H_{4'}$), 4.6—5.0 (m, $H_{1'}$, $H_{2'}$, $H_{3'}$, and OH), 7.55 (s, H_6), 10.93 (br s, NH), 11.14 (br s, NH); ^{13}C NMR (dimethyl-d_6 sulfoxide) δ= 25.45, 27.42, 61.74, 80.30, 81.55, 83.91, 84.33, 110.40, 112.81, 140.03, 151.05, 163.27. These physical and spectral data were superimposable on those of the authentic sample prepared by the method of literature.[29]

5-(β-D-Ribofuranosyl)uracil (Pseudouridine) (1). A mixture of solution of D-**12** (321 mg, 1.14 mmol) in methanol (5 ml) and 10% methanolic hydrogen chloride (5 ml) was stirred at 20 °C for 5 h. During this period there occurred pseudouridine (**1**) as colorless crystalline material, which was collected by filtration. A viscous residue left by concentration was dissolved in ethanol (5 ml) and evaporated. Repetition of this evaporation procedure followed by washing of the residue with ether (5 ml×3) gave additional **1**. Totally 259 mg (93%) of **1** was obtained. Recrystallization from methanol afforded an analytical sample, mp 243—244 °C (lit,[28] 221—222 °C), $[\alpha]_D^{21}$ −4.30° (*c*, 0.47, H_2O): UV λ_{max} (CH_3OH) 264 nm (ε 4750), λ_{max} (0.1 mol dm^{-3} HCl) 263 nm (ε 7560), λ_{max} (0.1 mol dm^{-3} NaOH) 285 nm (ε 7360); ^1H NMR (dimethyl-d_6 sulfoxide) δ=3.3—4.0 (m, $H_{2'}$, $H_{3'}$, $H_{4'}$, and 2 $H_{5'}$), 4.51 (d, *J*=4.0 Hz, $H_{1'}$), 4.54 (br s, 3 OH), 7.52 (d, *J*=6.0 Hz, H_6), 10.85 (d, *J*=6.0 Hz, H_1), 11.07 (br s, H_3); ^{13}C NMR (dimethyl-d_6 sulfoxide) δ=61.36, 70.62, 73.93, 78.88, 83.47, 111.05, 139.62, 150.98, 163.57. This compound showed the spectral and physical behavior identical with that of the naturally occurring specimen.

5-(2,3-O-Isopropylidene-β-D-ribofuranosyl)-2-thiouracil (D-14). A mixture of D-**10** (2.14 g, 7.96 mmol), thiourea (3.02 g, 39.8 mmol). and 1 mol dm^{-3} ethanolic sodium ethoxide (40 ml) was refluxed for 3 h under argon. Residue obtained by evaporation was dissolved in water (10 ml) and carefully neutralized with 6 mol dm^{-3} hydrochloric acid. Extraction with ethyl acetate (50 ml×5) and concentration of the combined organic layers afforded a yellow solid, which on column chromatography with a 1:30 to 1:5 methanol–chloroform mixture gave rise to D-**14** (1.93 g, 81% yield), R_f 0.65 (1:5 methanol–chloroform), as a slightly yellow foam, $[\alpha]_D^{22}$ −8.0° (*c*, 0.92, CH_3OH): UV λ_{max} (CH_3OH) 276 (ε 13930), 292 nm (12860), λ_{max} (0.1 mol dm^{-3} NaOH) 264 (ε 12920), 290 nm (10560); ^1H NMR (dimethyl-d_6 sulfoxide) δ=1.27 (s, isopropylidene CH_3), 1.49 (s, isopropylidene CH_3), 3.20 (br s, 2 $H_{5'}$), 3.91 (m, $H_{4'}$), 4.5—4.7 (m, $H_{1'}$, $H_{2'}$, and $H_{3'}$), 7.50 (s, H_6), 12.42 (br s, 2 NH); ^{13}C NMR (dimethyl-d_6 sulfoxide) δ=25.43, 27.36, 61.62, 79.94, 81.41, 84.02, 85.07, 112.84, 115.92, 139.11, 160.16, 175.39. Found: *m/z*, 300.07739. Calcd for $C_{12}H_{16}N_2O_5S$: 300.07798.

5-(β-D-Ribofuranosyl)-2-thiouracil (2-Thiopseudouridine) (D-15). A mixture of solution of D-**14** (763 mg, 2.56 mmol) in methanol (5 ml) and 10% solution of hydrogen chloride in methanol (7 ml) was stirred at 20 °C for 1 h and subsequently concentrated. The resulting residue was diluted with ethanol (7 ml) and evaporated. Dilution and evaporation sequence was repeated twice more to leave a colorless solid, which was washed with ether (7 ml×2). The solid was dried *in vacuo* producing 2-thiopseudouridine (D-**15**) (599 mg, 90% yield) as very hygroscopic, colorless crystals:[56] UV λ_{max} (CH_3OH) 275, 293 nm,[56] λ_{max} (0.1 mol dm^{-3} HCl) 274, 291 nm,[56] λ_{max} (0.1 mol dm^{-3} NaOH) 264, 284 nm;[56] ^1H NMR (dimethyl-d_6 sulfoxide) δ=3.5—4.1 (m, $H_{2'}$, $H_{3'}$, $H_{4'}$, and 2 $H_{5'}$), 4.59 (d, *J*=3.8 Hz, $H_{1'}$), 6.11 (br s, 3 OH), 7.60 (d, J=5.2 Hz, H_6), 12.28 (d, *J*=5.2 Hz, H_1), 12.37 (br s, H_3); ^{13}C NMR (dimethyl-d_6 sulfoxide) δ=62.26, 71.52, 74.76, 79.77, 84.37, 111.70, 140.58, 151.77, 164.44. The product was identical in all respects with an authentic sample of D-**15** synthesized according to the reported procedure.[28]

5-(2,3-O-Isopropylidene-β-D-ribofuranosyl)isocytosine (D-16). Guanidine hydrochloride (4.53 g, 45.5 mmol) was dissolved in 1 mol dm^{-3} solution of sodium ethoxide in ethanol (50 ml). This solution was added to D-**10** (2.45 g, 9.11 mmol) and heated at reflux for 3 h under argon. The reaction mixture was concentrated under reduced pressure and the resulting residue was dissolved in water (10 ml). After careful neutralization with 6 mol dm^{-3} hydrochloric acid by monitoring with a pH test paper, the aqueous solution was evaporated giving a viscous liquid, which was treated with ethanol (150 ml). Removal of the occurring precipitates by filtration followed by concentration gave rise to a colorless oil, which was chromatographed with a 1:30 to 1:5 methanol–chloroform mixture as eluent to produce D-**16** (2.09 g, 81% yield) as a colorless solid. Recrystallization from methanol gave an analytical specimen, mp 170—174 °C, $[\alpha]_D^{22}$ −50.8° (*c*. 0.73, CH_3OH); UV λ_{max} (CH_3OH) 226 (ε 5530), 290 nm (5390), λ_{max} (0.1 mol dm^{-3} NaOH) 233 (ε 12660), 277 nm (9860); ^1H NMR (dimethyl-d_6 sulfoxide) δ=1.27 (s, isopropylidene CH_3), 1.48 (s, isopylidene CH_3), 3.51 (br d, *J*=4.5 Hz, 2 $H_{5'}$), 3.93 (br q, *J*=3.8 Hz, $H_{4'}$), 4.5—4.9 (m, $H_{1'}$, $H_{2'}$, and $H_{3'}$), 6.97 (br s, NH_2), 7.63 (s, H_6); ^{13}C NMR (dimethyl-d_6 sulfoxide) δ=25.49, 27.52, 62.12, 81.77, 82.02, 83.57, 84.56, 112.27, 112.77, 152.81, 156.22, 163.25. Anal. ($C_{12}H_{17}N_3O_5$) C, H, N.

5-(β-D-Ribofuranosyl)isocytosine Hydrochloride (Pseudoisocytidine Hydrochloride) (Hydrochloride of D-17). To a suspension of D-**16** (1.24 g, 4.38 mmol) in methanol (10 ml) was added with efficient stirring 10% methanol solution (20 ml) of hydrogen chloride and the mixture was stirred at 20 °C for 1 h. The occurring colorless precipitates were collected by filtration. These crystals (1.14 g, 93% yield) were identified as pseudoisocytidine (D-**17**) hydrochloride by comparison of the spectral data and physical properties with the authentic sample, mp 212—215 °C (lit,[28] 215—216 °C), $[\alpha]_D^{22}$ +14.3° (*c* 0.49, H_2O): UV λ_{max} (CH_3OH) 225 (ε 9850), 290 nm (7000), λ_{max} (0.1 mol dm^{-3} NaOH) 233 (ε 9570), 277 nm (7270); ^1H NMR (dimethyl-d_6 sulfoxide) δ=3.4—4.0 (m, $H_{2'}$, $H_{3'}$, $H_{4'}$, and $H_{5'}$), 4.59 (d, *J*=2.7 Hz, $H_{1'}$), 7.83 (s, H_6), 8.53 (br s, NH_2).

2-(2,3-O-Isopropylidene-β-D-ribofuranosyl)maleimide (D-19) from D-10. To a solution of D-**10** (250 mg, 0.93 mmol) in ethyl acetate (20 ml) cooled at −78 °C was passed ozone for 10 min followed by nitrogen for 5 min. The resulting mixture was quenched by addition of dimethyl sulfide (1.0 ml, 846 mg, 13.6 mmol) and stirred at −78 °C for 1 h, at 0 °C for 3 h, and then at 20 °C for an additional 1 h. On removal of the solvent, there was left a yellow, oily material D-**18**; IR 1732 cm^{-1} (C=O), no olefinic absorption. This unstable compound was used for the subsequent reaction without further purification. To a solution of the crude product in DMF (3 ml) was added a solution of $(C_6H_5)_3PCHCONH_2$ (297 mg, 0.93 mmol) in DMF (3 ml) and the mixture was stirred at 20 °C for 1 h and at 50 °C for 2 h under argon. Evaporation under high vacuum afforded a residual oil, preparative TLC of which with ethyl acetate produced D-**19** (75.3 mg, 30% overall yield from D-**10**), mp 142—143 °C (ethyl acetate–hexane) (lit,[57] 140.5—141 °C), $[\alpha]_D^{24}$ −2.31° (*c* 1.07, $CHCl_3$). The product had identical spectral data and physical properties with those of the authentic sample prepared from natural showdomycin according to the known procedure.[57]

Preparation of Showdomycin Acetonide (D-19) from D-21. Ozone was passed through a solution of D-**21** (150 mg, 0.514 mmol) in ethyl acetate (20 ml) at −78 °C for *ca.* 10 min until the color of the solution became blue-violet. The excess ozone was removed by blowing nitrogen gas to the solution for 5 min. After quenching by addition of dimethyl sulfide (0.5 ml, 423 mg, 6.81 mmol), the mixture was stirred at −78 °C for 1 h, at 0 °C for 1 h, and at 25 °C for 1 h, and then concentrated. The resulting oil was dissolved in ethyl acetate (20 ml) and washed with brine (4 ml). The organic layer was dried over sodium sulfate and evaporated to yield a slightly yellow liquid. A mixture of this oil and $(C_6H_5)_3PCHCONH_2$ (180 mg, 0.565 mmol) in DMF (4 ml) was stirred at 25 °C for 1 h and then at 50 °C for 1 h under argon. Removal of the solvent *in vacuo* left a crude oil, whose preparative TLC with ethyl acetate produced the crystalline acetonide D-**19** (21 mg, 15% yield). Recrystallization from acetone–benzene afforded an analytical sample, mp 141—142 °C.

2-(β-D-Ribofuranosyl)maleimide (Showdomycin) (3). A mixture of D-**19** (100 mg, 0.37 mmol) and 80% aqueous trifluoroacetic acid (3 ml) was stirred at 20 °C for 10 min Evaporation *in vacuo* afforded a viscous residue, whose preparative TLC using 7:3 ethyl acetate–acetone gave rise to showdomycin (**3**) (77.9 mg, 92% yield). An analytical specimen displaying ^1H NMR and UV spectra and the optical rotation, $[\alpha]_D^{24}$ +48.7° (*c* 1.4, H_2O) (lit, +49.1°,[32f] +49.9°[57]), identical with the authentic natural product was obtained by recrystallization from acetone–benzene, mp 151—152 °C (lit, 152—153 °C,[32b] 153—154 °C,[6b] 154.5—156 °C,[32a] 160—161 °C[57]).

(2S)-2-(2,3-O-Isopropylidene-β-D-ribofuranosyl-2-[(S*)-(2-furyl)hydroxylmethyl]acetic Acid Lactone (D-20).* To a 0.3 mol dm^{-3} solution (10 ml) of lithium cyclohexylisopropylamide in THF–hexane was added at −78 °C a solution of D-**6** (500 mg, 2.3 mmol) in THF (10 ml) over 5 min with stirring. After 1.5 h, to this was added a solution of furfural (3.0 ml, 3.46 g, 36 mmol) in THF (5 ml) at −78 °C and stirring was continued for an additional 1 h. The reaction mixture was quenched with saturated aqueous oxalic acid solution (5 ml) and extracted with chloroform (100 ml, 50 ml, 30 ml). The combined organic extracts were washed with brine (10 ml), dried over sodium sulfate, and evaporated to yield a yellow crystalline product, which was subjected to column chromatography using successively a 1:1, 2:1, and 4:1 ether–hexane mixture, and finally with ether. The hydroxy lactone D-**20** (640 mg, 90% yield) was obtained as colorless crystals, mp 139—141 °C (from ethyl acetate–chloroform–hexane), $[\alpha]_D^{21}$ +26.0° (*c* 2.63, $CHCl_3$): IR 3200—3600 (OH), 1728 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=1.30 (s, isopropylidene CH_3), 1.46 (s, isopropylidene CH_3), 2.95 (d, *J*=7 Hz, OH), 3.48 (dd, *J*=5, 9 Hz, COCH), 3.97 (d, *J*=5 Hz, $H_{1'}$), 4.15 (dd, *J*=4.5, 14 Hz, $H_{5'a}$), 4.45 (dd, *J*=2.5, 4.5 Hz, $H_{4'}$), 4.55 (d, *J*=6 Hz, $H_{2'}$), 4.56 (dd, *J*=2.5, 14 Hz, $H_{5'b}$), 4.82 (d, *J*=6 Hz, $H_{3'}$), 5.25 (dd, *J*=7, 9 Hz, CHOH), 6.40 (m, furyl H_3 and H_4), 7.43 (m, furyl H_5); mass spectrum *m/z* 310 (M^+). Anal. ($C_{15}H_{18}O_7$) C, H.

2-(2,3-O-Isopropylidene-β-D-ribofuranosyl)-2-furfurylideneacetic Acid Lactone (D-21). To a cooled (0 °C) solution of D-**20** (300 mg, 0.76 mmol) in pyridine (5 ml) was added a solution of pivaloyl chloride (0.47 ml, 458 mg, 3.8 mmol) in pyridine (5 ml) over 2 min with efficient stirring under argon. After stirring at 0 °C for an additional 1 h and then at room temperature for 24 h, the reaction mixture was diluted with benzene (50 ml), washed with water (10 ml), and dried over sodium sulfate. Concentration under high vacuum (<0.01 mmHg) at room temperature for 30 min left a pale violet oil which was passed through a short silica-gel column using ether as eluent. Removal of the solvent of the filtrate gave a yellow oil, a solution of which in pyridine (15 ml) was heated at 80—90 °C for 13 h under argon. Dilution of the reaction mixture with benzene (50 ml), followed by concentration to dryness afforded a dark brown oil. The preparative TLC with 5:1 ether–hexane produced D-**21** (222 mg, 100% overall yield) as a gummy material, yielding an analytical sample by recrystallization from chloroform–hexane, mp 160—162 °C, $[\alpha]_D^{21}$ −143° (*c* 0.64, $CHCl_3$): IR 1715 (C=O), 1627 cm^{-1} (C=C), ^1H NMR ($CDCl_3$) δ=1.35 (s, isopropylidene CH_3), 1.58 (s, isopropylidene CH_3), 4.25 (m, 2 $H_{5'}$), 4.50 (m, $H_{4'}$), 4.70 (d, *J*=6 Hz, $H_{2'}$), 4.99 (d, *J*=6 Hz, $H_{3'}$), 5.74 (s, $H_{1'}$), 6.52 (dd, *J*=2, 4 Hz, furyl H_4), 6.78 (d, *J*=4 Hz, furyl H_3), 7.24 (s, COC=CH), 7.62 (d, *J*=2 Hz, furyl H_5); mass specturm *m/z* 292 (M^+). Anal. ($C_{15}H_{16}O_6$) C, H.

Methyl 2-(2,3-O-Isopropylidene-β-D-ribofuranosyl)-2-furfurylideneacetate (D-22). A solution of D-**21** (220 mg, 0.69 mmol) in methanol (7 ml) was mixed with a 90 mmol dm^{-3} methanolic sodium methoxide (10 ml) at 0 °C and stirred for 30 min. The resulting mixture was quenched by addition of an aqueous solution saturated with oxalic acid (5 ml) and extracted with chloroform (50 ml, 30 ml). The collected organic layers were washed with brine (10 ml) and dried over sodium sulfate. Evaporation *in vacuo* left an orange oil (210 mg), which was subjected to preparative TLC with 2:1 ethyl acetate–hexane, giving rise to D-**22** (190 mg, 86% yield) as a colorless liquid, $[\alpha]_D^{21}$ +104° (*c* 2.90, $CHCl_3$); IR 3620—3300 (OH), 1700 (C=O), 1635 cm^{-1} (C=C); ^1H NMR (benzene-d_6) δ=1.23 (s, isopropylidene CH_3), 1.58 (s, isopropylidene CH_3), 3.27 (s, OCH_3), 3.69 (dd, *J*=3, 12 Hz, $H_{5'a}$), 3.70 (br s, OH), 3.95 (dd, *J*=2, 12 Hz, $H_{5'b}$), 4.33 (m, $H_{4'}$), 5.13 (d, *J*=6 Hz, $H_{2'}$), 5.26 (d, *J*=6 Hz, $H_{3'}$), 5.95 (m, $H_{1'}$, and furyl H_4), 6.47 (d, *J*=3 Hz, furyl H_3), 6.93 (d, *J*=2 Hz, furyl H_5), 7.46 (s, COC=CH); mass spectrum *m/z* 324 (M^+). Anal. ($C_{16}H_{20}O_7$) C, H.

Methyl 2-[2,3-O-Isopropylidene-5-O-(t-butyldimethylsilyl)-β-D-ribofuranosyl]-2-furfurylideneacetate (D-23). A mixture

of D-**22** (190 mg, 0.59 mmol), *t*-butylchlorodimethylsilane (130 mg, 0.84 mmol), imidazole (120 mg, 1.8 mmol) in DMF (15 ml) was stirred at room temperature for 1 h. The reaction mixture was diluted with ether (50 ml) and washed with brine (10 ml). The organic layer was dried over sodium sulfate and concentrated to leave a yellow viscous oil. Preparative TLC with 1:1 ethyl acetate–hexane gave D-**23** (260 mg, 100% yield), $[\alpha]_D^{21}$ −0.98° (*c* 0.44, $CHCl_3$); IR 1710 (C=O), 1635 (C=C), 830 cm^{-1} (Si–O); ^1H NMR (benzene-d_6) δ=0.06 (s, $Si(CH_3)_2$), 0.98 (s, SiC_4H_9-*t*), 1.25 (s, isopropylidene CH_3), 1.56 (s, isopropylidene CH_3), 3.38 (s, OCH_3), 3.97 (d, *J*=6 Hz, $H_{5'a}$), 3.98 (d, *J*=5.5 Hz, $H_{5'b}$), 4.38 (q, *J*=6 Hz, $H_{4'}$), 5.02 (t, *J*=6 Hz, $H_{3'}$), 5.22 (dd, *J*=4, 6 Hz, $H_{2'}$), 5.90 (dd, *J*=2, 4 Hz, furyl H_4), 6.00 (d, *J*=4 Hz, $H_{1'}$), 6.41 (d, *J*=4 Hz, furyl H_3), 6.86 (d, *J*=2 Hz, furyl H_5), 7.44 (s, COC=CH); mass spectrum *m/z* 423 (M^+ −15). Anal. ($C_{22}H_{34}O_7Si$) C, H.

3-[2,3-O-Isopropylidene-5-O-(t-butyldimethylsilyl-β-D-ribofuranosyl]maleimide (D-25). Ozone was introduced into a solution of D-**23** (260 mg, 0.59 mmol) in dry ethyl acetate (30 ml) at −78 °C until the color of solution became blue-violet and then nitrogen gas was blown through this solution for 10 min at that temprature to remove an excess of ozone. After addition of dimethyl sulfide (1.0 ml, 846 mg, 13.6 mmol) at −78 °C, the reaction mixture was stirred at the same temperature for 1 h and for an additional 2 h under warming up to room temperature. Concentration gave a yellow crude product (430 mg), to which was added chloroform (30 ml) with vigorous shaking. Removal of the occurring precipitate by filtration through a Celite 545 pad, followed by evaporation of the filtrate left crude methyl 2-[2,3-*O*-isopropylidene-5-*O*-(*t*-butyldimethylsilyl)-β-D-ribofuranosyl]glyoxylate (D-**24**) as a yellow, viscous liquid; IR 1760 (shoulder, C=O), 1740 cm^{-1} (C=O); mass spectrum *m/z* 374 (M^+). This compound was so labile and attempted chromatography resulted in complete decomposition. Therefore this was employed in the next procedure without any purification.

A mixture of the crude D-**24** (obtained from 150 mg (0.40 mmol) of D-**32**) and $(C_6H_5)_3PCHCONH_2$ (270 mg, 0.80 mmol) in chloroform (20 ml) was stirred at room temperature. After 2 h, a solution of the phosphorane (130 mg, 0.39 mmol) in chloroform (5 ml) was added renewedly and stirring was continued for further 30 min. Concentration of the resulting mixture yielded an oily residue, which was subjected to preparative TLC with 2:1 ether–hexane, producing D-**25** (43 mg, 29% yield based on D-**23**), $[\alpha]_D^{24}$ +2.1° (*c* 1.40, $CHCl_3$); IR 3420 (NH), 1775 (C=O), 1726 (C=O), 1620 cm^{-1} (C=C); UV λ_{max} (CH_3OH) 221 nm (ε 13800); ^1H NMR ($CDCl_3$) δ=0.05 (s, $Si(CH_3)_2$), 0.85 (s, SiC_4H_9-*t*), 1.34 (s, isopropylidene CH_3) 1.59 (s, isopropylidene CH_3), 3.70 (br d, *J*=4.0 Hz, 2 $H_{5'}$), 4.20 (m, $H_{4'}$), 4.66 (m, $H_{2'}$ and $H_{3'}$), 4.82 (m, $H_{1'}$), 6.49 (t, *J*=2 Hz, H_3), 7.42 (br s, NH); mass spectrum *m/z* 368 (M^+ −15). Anal. ($C_{18}H_{29}NO_6Si$) C, H, N.

3-(β-D-Ribofuranosyl)maleimide (Showdomycin) (3). A mixture of D-**25** (130 mg, 0.339 mmol) and 80% aq trifluoroacetic acid (3 ml) was stirred at 25 °C for 10 min. Evaporation to dryness at room temperature under high vacuum (0.01 mmHg) left a white crystalline product. Column chromatography with 1:4 acetone–ethyl acetate gave showdomycin (**3**) 66 mg, 85% yield), mp 151—15 °C (acetone-benzene), which was consistent in all respects with the natural product.

Semicarbazone of Methyl 2-[2,3-O-Isopropylidene-5-O-(t-butyldimethylsilyl)-β-D-ribofuranosyl]glyoxylate (D-26). Into a cooled solution of D-**23** (720 mg, 1.70 mmol) in ethyl acetate (220 ml) at −78 °C was introduced ozone until the solution assumed blue-violet color. The solution was flushed with nitrogen gas in order to remove an excess of ozone for 10 min. The mixture was quenched with dimethyl sulfide (3.0 ml, 2.54 g, 4.08 mmol) at −78 °C and stirred at the same temperature for 1 h, at 0 °C for 1 h, and at room temperature for 1 h. Evaporation afforded a brown oil, which was dissolved in 66% aq methanol (45 ml) and to this were added semicarbazide hydrochloride (900 mg, 8.10 mmol) and sodium acetate (660 mg, 8.10 mmol). The mixture was stirred at 20 °C for 12 h and at 80 °C for 2 h, and then semicarbazide hydrochloride (600 mg, 5.40 mmol) and sodium acetate (440 mg, 5.40 mmol) were added renewedly. After stirring at 60 °C for 2 h, semicarbazide hydrochloride (300 mg, 2.70 mmol) and sodium acetate (220 mg, 2.70 mmol) in methanol (10 ml)–water (15 ml) were added again and the resulting mixture was maintained at 60 °C for an additional 2 h. An only residue obtained by concentration was treated with water (20 ml) and extracted with chloroform (150 ml, 100 ml, 50 ml). The combined organic extracts were washed with brine (20 ml) and dried over sodium sulfate. Removal of the solvent produced a viscous oil, preparative TLC of which using ethyl acetate gave D-**26** (220 mg, 30% yield from D-**23**) as an oil, $[\alpha]_D^{22}$ −1.6° (*c* 1.0, $CHCl_3$); IR 3520, 3400, 3300 (NH), 1703 (C=O), 1560 cm^{-1} (C=N); UV λ_{max} (CH_3OH) 265 nm (ε 8790); ^1H NMR ($CDCl_3$) δ=0.10 (s, $Si(CH_3)_2$), 0.89 (s, SiC_4H_9-*t*), 1.26 (s, isopropylidene CH_3), 1.29 and 1.37 (two s's, 1.5 H each, isopropylidene CH_3 of *E* or/and *Z* isomers), 3.70 (d, *J*=5 Hz, $H_{5'a}$), 3.87 (s, OCH_3), 3.6—4.0 (m, $H_{5'b}$), 4.1—5.2 (m, $H_{1'}$, $H_{2'}$, $H_{3'}$, and $H_{4'}$), 5.5—6.0 (br s, NH_2), 10.21 and 11.29 (two br s's, 0.5 H each NH of *E* or/and *Z* isomers). Anal. ($C_{18}H_{33}N_3O_7Si$) C, H, N.

6-[2,3-O-Isopropylidene-5-O-(t-butyldimethylsilyl-β-D-ribofuranosyl]-1,2,4-triazine-3,5(2H,4H)-dione (D-27). A mixture of the semicarbazone D-**26** (250 mg, 0.625 mmol) and a 0.1 mol dm^{-3} solution of sodium ethoxide in ethanol (12.5 ml, 1.25 mmol of sodium ethoxide) was refluxed for 3 h. A residual oil afforded by evaporation was dissolved in water (20 ml). The aqueous layer was acidified to pH 4 by careful addition of 0.5 mol dm^{-3} hydrochloric acid and extracted with ethyl acetate (50 ml×3). The collected organic extracts were washed with brine and dried over sodium sulfate. Removal of the solvent and the subsequent preparative TLC with 5:1 ether–chloroform produced D-**27** (100 mg, 40% yield) as an oil, $[\alpha]_D^{25}$ −35.8° (*c* 8.90, $CHCl_3$); IR 3500—3100 (NH), 1721 and 1698 cm^{-1} (C=O); UV λ_{max} (0.1 mol dm^{-3} HCl) 262 nm (ε 7420), λ_{max} (CH_3OH) 264 nm (ε 6920), λ_{max} (0.1 mol dm^{-3} NaOH) 258 (ε 5020), 293 nm (3230); ^1H NMR ($CDCl_3$) δ=0.04 (s, $Si(CH_3)_2$), 0.88 (s, SiC_4H_9-*t*), 1.37 (s, isopropylidene CH_3), 1.58 (s, isopropylidene CH_3), 3.77 (d, *J*=5 Hz, 2 $H_{5'}$), 4.20 (m, $H_{4'}$), 4.76 (dd, *J*=3, 6 Hz, $H_{2'}$), 5.0 (m, $H_{1'}$ and $H_{3'}$), 9.17 (br s, NH), 9.73 (br s, NH). Anal. ($C_{17}H_{29}N_3O_6Si$) C, H, N.

6-(β-D-Ribofuranosyl)-1,2,4-triazine-3,5(2H,4H)-dione (6-Azapseudouridine) (D-13). A mixture of D-**27** (158 mg, 0.406 mmol) and 80% aq trifluoroacetic acid (5 ml) was stirred at 25 °C for 10 min. The whole mixture was concentrated under reduced pressure to give a crystalline material. Recrystallization produced an analytical sample of D-**13** (65 mg, 63% yield) as colorless needles, mp 136—138 °C (lit,[30] 138—139 °C), $[\alpha]_D^{24}$ −23.4° (*c* 0.5, H_2O) [lit,[30] $[\alpha]_D^{25}$ −24.9° (*c* 0.5, H_2O)]; IR (KBr) 3400—3100 (NH and OH), 1720 and 1690 cm^{-1} (C=O); UV λ_{max} (CH_3OH) 264 nm (ε 6740); ^1H NMR (acetone-d_6) δ=3.0 (br s, OH), 3.54 (dd, *J*=3.3, 13.8 Hz, $H_{5'a}$), 3.74 (dd, *J*=2.7, 13.8 Hz, $H_{5'b}$), 3.97 (ddd, *J*=2.7, 3.3, 4.5 Hz, $H_{4'}$), 4.20 (dd, *J*=4.5, 5.3 Hz, $H_{2'}$), 4.45 (dd, *J*=5.3, 5.6 Hz, $H_{3'}$), 4.73 (d, *J*=5.6 Hz, $H_{1'}$), 11.70 (br s, 2 NH). These spectral and physical characters were identical with the reported ones.[30]

Thiosemicarbazone of Methyl 2-[2,3-O-Isopropylidene-5-O-(t-butyldimethylsilyl)-β-D-ribofuranosyl]glyoxylate (D-28). Through a solution of D-**23** (500 mg, 1.18 mmol) in ethyl acetate (150 ml) was blown ozone at −78 °C. When the solution took on blue color, introduction of ozone was stopped and nitrogen gas was blown into the solution at the same temperature for 5 min. The resulting colorless solution was

treated with dimethyl sulfide (2.0 ml, 1.69 g, 27.2 mmol) and then stirred at −78 °C for 1 h, at 0 °C for 1 h, and at room temperature for 1 h. Concentration gave a yellow oil, which was mixed with thiosemicarbazide (460 mg, 5.0 mmol) in methanol (25 ml) and refluxed for 12 h. After cooling, evaporation yielded a viscous oil, which was dissolved in chloroform (100 ml) and washed with water (15 ml). Concentration of the organic solution giving an orange oil, followed by preparative TLC with ether, afforded D-**28** (130 mg, 26% yield) as a colorless oil, $[\alpha]_D^{21}$ −0.71° (*c* 1.1, $CHCl_3$); IR 3520, 3380, 1731, 1715, 1582, 1465 cm^{-1}; UV λ_{max} (CH_3OH) 268 (ε 6760), 314 nm (5250); ^1H NMR ($CDCl_3$) δ=0.06 (s, $Si(CH_3)_2$), 0.87 (s, SiC_4H_9-*t*), 1.34 (br s, isopropylidene CH_3), 1.52 (br s, isopropylidene CH_3), 3.67 (s, OCH_3), 3.77 (m, 2 H5′), 4.2—4.8 (m, H1′, H2′, H3′, and H4′), 6.0—6.4 (br s, NH_2), 7.12 and 9.17 (two br s's, 0.5 H each, NH of *E* and/or *Z* isomers); mass spectrum *m/z* 447 (M^+). Anal. ($C_{18}H_{33}N_3O_6SSi$) C, H, N, S.

6-[2,3-O-Isopropylidene-5-O-(t-butyldimethylsilyl)-β-D-ribofuranosyl]-3-thioxo-2,3-dihydro-1,2,4-triazin-5(4H)-one (D-29). A mixture of D-**28** (200 mg, 0.45 mmol) and a 0.1 mol dm^{-3} solution of sodium ethoxide in ethanol (10 ml, 1.0 mmol of sodium ethoxide) was heated at reflux for 3 h and then evaporated to dryness. To a solution of the resulting dark brown liquid in water (10 ml) was added carefully 0.5 mol dm^{-3} hydrochloric acid until the pH of solution reached 4 and the aqueous layer was promptly extracted with ethyl acetate (40 ml×3). The combined organic extracts were dried over sodium sulfate and concentrated, affording a brown liquid. Preparative TLC with 1:1 ether–chloroform gave rise to D-**29** (104 mg, 56% yield) as an oil, $[\alpha]_D^{25}$ −1.4° (*c* 2.30, $CHCl_3$); IR 3500—3200 (NH), 1707 cm^{-1} (C=O); UV λ_{max} (0.1 mol dm^{-3} HCl) 213 (ε 7420), 269 nm (14100), λ_{max} (CH_3OH) 213 (ε 3720), 272 nm (12100), λ_{max} (0.1 mol dm^{-3} NaOH) 226 (ε 16200), 258 (11500), 313 nm (3230); ^1H NMR ($CDCl_3$) δ= 0.06 (s, $Si(CH_3)_2$), 0.88 (s, SiC_4H_9-*t*), 1.38 (s, isopropylidene CH_3), 1.59 (s, isopropylidene CH_3), 3.75 (d, *J*=5 Hz, 2 H5′), 4.17 (m, H4′), 4.77 (dd, *J*=3, 6 Hz, H3′), 5.0 (m, H1′ and H2′). Anal. ($C_{17}H_{29}N_3O_5SSi$) C, H, N, S.

6-(β-D-Ribofuranosyl)-3-thioxo-2,3-dihydro-1,2,4-triazin-5-(4H)-one (6-Azapseudouridine) (D-30). A mixture of D-**29** (100 mg, 0.247 mmol) and 80% aq trifluoroacetic acid (4 ml) was stirred at 25 °C for 20 min and then evaporated *in vacuo*. The resulting crude product was recrystallized from ethanol, affording an analytical specimen of D-**30** (47 mg, 70% yield) as colorless needles, mp 193—195 °C (lit,[30] 197—198 °C), $[\alpha]_D^{25}$ −3.5° (*c* 0.5, H_2O) [lit,[30] −3.7° (*c* 0.5, H_2O)]; IR (KBr) 3500—3100 (NH and OH), 1702 cm^{-1} (C=O); UV λ_{max} (0.1 mol dm^{-3} HCl) 215 (ε 10700), 269 nm (18600), λ_{max} (0.1 mol dm^{-3} NaOH) 259 (ε 13500), 313 nm (7580); ^1H NMR (acetone-d_6) δ=3.06 (br s, OH), 3.57 (dd, *J*=3.6, 12.7 Hz, H5′a), 3.83 (dd, *J*=2.5, 12.7 Hz, H5′b), 4.00 (ddd, *J*=2.5, 3.6, 4.2 Hz, H4′), 4.24 (dd, *J*=4.2, 5.7 Hz, H2′), 4.48 (dd, *J*=5.0, 5.7 Hz, H3′), 4.80 (d, *J*=5.0 Hz, H1′), 11.15 (br s, 2 NH).

Financial support by the Ministry of Education, Japanese Government, and generous gifts of D-ribose from Ajinomoto Co., pseudouridine from Kyowa Hakko Co., showdomycin from Shionogi Research Laboratory, and pseudoisocytidine hydrochloride from Dr. K. A. Watanabe of the Sloan-Kettering Institute for Cancer Research are acknowledged. We are also indebted to Mrs. R. Suzuki for her valuable contribution in some preliminary experiments.

55) The 60-MHz ^{1}H NMR analysis of this lactone in benzene-d_6 was discussed independently by Gensler and his collaborators,[21b] who commented on our previously reported result[1a] and claimed that no splitting was detected due to the geminal spin-spin coupling between two protons α to the lactone carbonyl. In fact, however, the 100-MHz spectrum showed the clear AB splitting pattern with J=14 Hz for the geminal H_{1a} and H_{1b} hydrogens. In addition, there was observed the geminal coupling, J=14 Hz, between ribose-$H_{5'a}$ and -$H_{5'b}$ protons.

56) Optical rotation and molar extinction coefficient of UV absorptions have not been measured because of the extreme hygroscopicity.

Ozonization of Phenothiazine and Its Analogues

Masaki MATSUI,* Yoshihiko MIYAMOTO, Katsuyoshi SHIBATA, and Yoshimi TAKASE
Department of Industrial Chemistry, Faculty of Engineering, Gifu University, Yanagido, Gifu 501-11
(Received March 12, 1984)

When phenothiazine and phenoxazine were ozonized in dichloromethane, the cation radicals and the ozonate anion radical were detected, whereas, in the ozonization of phenoxathiin and thianthrene, these radicals were not observed. Formation of these radicals was more favorable as greater was the polarity of the solvent and lower was the oxidation potential of the substrate. Ozonization of phenothiazine and phenoxazine in polar solvents was explained by the electron-transfer mechanism accompanied by the electrophilic ozone attack, and that of phenoxathiin and thianthrene by the electrophilic ozone attack alone.

Reactions of ozone are classified into four types; (1) a 1,3-dipole represented by the Criegee ozonolysis mechanism,[1] (2) an electrophile in the ozonization of phosphines,[2] (3) a nucleophile as was reported by Olah *et al.*,[3] and (4) an electron acceptor which was reported in the ozonization of *p*-phenylenediamines[4] and amines.[5-7]

Ozonization of phenothiazine, phenoxathiin, thianthrene, and phenoxazine which possibly involves the electron-transfer was discussed.

Experimental

General. Ozone was generated by a Nihon Ozon 0-1-2 type ozonizor. Mass spectra were recorded with Hitachi M-52 and RMU-6M spectrometers. NMR, IR, and visible spectra were recorded on a Hitachi R-24 spectrometer, a Hitachi EPI-S2 spectrometer, and a Hitachi EPS-3T spectrometer, respectively. Gas and liquid chromatography was performed on a Shimadzu 4C-PF gas chromatograh and a Japan Spectroscopic Co. Familic 100N liquid chromatograph, respectively. Melting points were measured with a Yamato MP-21 melting point apparatus. Oxidation potential was measured with Niko NPGS-301 and NPS-2 apparatuses. Purity of the materials used was confirmed by gas and liquid chromatography.

Materials. Phenothiazine (**1a**) (Nakarai Chemicals, Ltd.) was recrystallized from ethanol; mp 185.4 °C (lit, 185.1 °C);[8] MS (20 eV) *m/z* (rel intensity) 199(M^+; 100), 198 (17), 167 (41), 166 (16), and 100 (10); ^{1}H NMR (DMSO-d_6) δ=6.5—7.1 (m, 8H) and 8.51 (s, 1H); IR (KBr disk) 3300 cm^{-1} (NH). Phenoxathiin (**1b**) was synthesized according to the literature;[9] mp 55.8 °C (lit, 56.5—57.5 °C);[9] MS (20 eV) *m/z* (rel intensity) 200 (M^+; 100), 171 (25), and 168 (30). Thianthrene (**1c**) (Tokyo Chemical Industry Co., Ltd.) was recrystallized from ethanol; mp 155.0 °C (lit, 155—157 °C);[10] MS (20 eV) *m/z* (rel intensity) 216 (M^+; 100), 184 (52), and 171 (12). Phenoxazine (**1d**) (Aldrich Chemical Co., Inc.) was used without further purification; mp 156.0 °C (lit, 154.5—156.0 °C);[11] MS (20 eV) *m/z* (rel intensity) 183 (M^+; 100), 154 (31), and 127 (8); IR (KBr disk) 3380 cm^{-1} (NH). Phenothiazine 5-oxide (**2a**) was synthesized according to the literature;[12] mp 252—254 °C (lit, 251—253 °C);[12] MS (70 eV) *m/z* (rel intensity) 215 (M^+; 56), 199 (31), 186 (92), 167 (100), and 153 (25); IR (KBr disk) 3170 (NH) and 1075 cm^{-1} (S=O). Phenoxathiin 10-oxide (**2b**) was synthesized by the oxidation of phenoxathiin with an equivalent molar amount of ozone, and recrystallized from ethanol; mp 152.4 °C (lit, 153—154 °C);[13] MS (20 eV) *m/z* (rel intensity) 216 (M^+; 62), 200 (100), 187 (59), and 168 (97); IR (KBr disk) 1035 cm^{-1} (S=O). Thianthrene 5-oxide (**2c**) was synthesized by the ozonization of thianthrene and recrystallized from ethanol; mp 141.8 °C (lit, 143.0—143.5 °C);[10] MS (20 eV) *m/z* (rel intensity) 232 (M^+; 20), 216 (22), 203 (15), 184 (100), 171 (12), and 152 (8); IR (KBr disk) 1075 cm^{-1} (S=O). 3*H*-Phenothiazin-3-one (**3a**) was synthesized according to the literature;[14] mp 164—166 °C (lit, 165—166 °C);[14] MS (20 eV) *m/z* (rel intensity) 213 (M^+; 37), 185 (100), and 141 (17); IR (KBr disk) 1630 cm^{-1} (C=O). 3*H*-Phenoxazin-3-one (**3d**) was synthesized by the ozonization of phenoxazine and purified by column chromatography (silica gel, dichloromethane); mp 213—215 °C (lit, 216—217 °C);[15] MS (20 eV) *m/z* (rel intensity) 197 (M^+; 100), 169 (94), 140 (19), and 114 (16); IR (KBr disk) 1615 cm^{-1} (C=O). 2-Chlorophenothiazine (**4a**) (Tokyo Chemical Industry Co., Ltd.) was employed without further purification; mp 193.0—194.5 °C (lit, 194—195 °C);[16] MS (20 eV) *m/z* (rel intensity) 235 (39), 233 (M^+; 100), 201 (22), and 198 (56); IR (KBr disk) 3300 cm^{-1} (NH). Thianthrene 5,10-dioxides (**5c** and **5'c**) were synthesized by the ozonization of thianthrene and purified by thin layer chromatography (silica gel, dichloromethane : hexane=5:1); *trans*-Thianthrene 5,10-dioxide (**5c**); mp 276—277 °C (lit, 284 °C);[17] MS (20 eV) *m/z* (rel intensity) 248 (M^+; 53), 232 (17), 216 (43), 200 (53), 184 (100), and 171 (33); IR (KBr disk) 1085 cm^{-1} (S=O). *cis*-Thianthrene 5,10-dioxide (**5'c**); mp 234.5—235.5 °C (lit, 249 °C);[17] MS (20 eV) *m/z* (rel intensity) 248 (M^+; 35), 232 (13), 216 (54), 200 (42), 184 (100), and 171 (46); IR (KBr disk) 1075 cm^{-1} (S=O).

Ozonization Reaction. Ozonization was carried out with an ozone-nitrogen mixture. The products were identified by comparing the retention time in the gas and liquid chromatography and mass spectra with those of authentic samples. The products were determined by GLC using a 2% Silicone OV-1 column, 3 mm×1 m, programmed from 80 to 240 °C at 10 °C min^{-1}. The conditions in LC were (1) SS-10 column, 0.5 mm×0.15 m, eluted with the mixed solution (dichloromethane : ethanol=25:1) and detection at 254 nm, and (2) SS-10 column, 0.5 mm×0.15 m, eluted with the mixed solution (dichloromethane : acetone=40:1) and detection at 254 nm.

Results and Discussion

The results of the ozonization reactions are shown in Table 1. Materials employed are shown in Fig. 1.

When phenothiazine (**1a**) was ozonized in dichloromethane, phenothiazine 5-oxide (**2a**), 3*H*-phenothiazin-3-one (**3a**), and 2-chlorophenothiazine (**4a**) were detected. Since the ozonization of phenothiazine 5-oxide gave 3*H*-phenothiazin-3-one (Run 9), it was concluded that phenothiazine reacted with one molar equivalent of ozone to give phenothiazine 5-oxide and 2-chlorophenothiazine, and further ozonization gave 3*H*-phenothiazin-3-one. Though the reactivity of phenothiazine with ozone increaed with the rise of the reaction temperature, the distribution of the products was scarcely affected (Runs 1,2,3, and 4). Since chlori-

a) Ozonization was carried out with an ozone-nitrogen mixture on 0.251 mmol of phenothiazine (**1a**), 0.023 mmol of phenothiazine 5-oxide (**2a**), 2.50 mmol of phenoxathiin (**1b**), 0.926 mmol of thianthrene (**1c**), 0.216 mmol of thianthrene 5-oxide (**2c**), and 0.82 mmol of phenoxazine (**1d**) in 20 ml of solvent, respectively. b) Molar ratio. c) Yield was based on the substrate reacted with ozone.

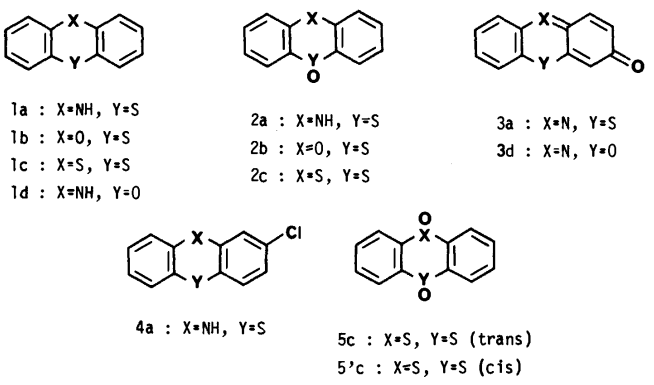

Fig. 1. Materials employed.

nated product **4a** was not formed, the yield of phenothiazine 5-oxide in acetic acid was greater than that in the chlorinated solvents (Runs 2,5, and 7). Since the yields of phenothiazine 5-oxide and 3*H*-phenothiazin-3-one in carbon tetrachloride and hexane were low compared with that in the other solvents (Runs 2,5,6,7, and 8), the electron-transfer mechanism during ozonization is suggested.

Phenoxathiin (**1b**) reacted with one molar equivalent of ozone to give phenoxathiin 10-oxide (**2b**) quantitatively. The reaction was scarcely affected by the polarity of the solvent (Runs 10 and 11).

When thianthrene (**1c**) was ozonized, thianthrene 5-oxide (**2c**), and a trace amount of *trans*-thianthrene 5,10-dioxide (**5c**) were detected. Ozonization of thianthrene 5-oxide gave *trans*-thianthrene 5,10-dioxide and *cis*-thianthrene 5,10-dioxide (**5'c**) in the ratio 97:3. The yield of thianthrene 5-oxide was scarcely affected by the solvent (Runs 12 and 13).

When phenoxazine (**1d**) was ozonized in dichloromethane, the reaction was complex and the product isolated was 3*H*-phenothiazin-3-one (**3d**), accompanied by unidentified polymers (Run 15).

When phenothiazine was ozonized in dichloromethane, the reaction mixture turned red in color. The visible absorption spectra during the reaction are shown in Fig. 2. The spectra showed the absorption maxima at 435 and 519 nm, which are close to those of the phenothiazine cation radical reported by Hason *et al.*,[18] and Brown *et al.*[19] The spectra have smaller peaks at 481 and 502 nm which are attributed to the uncharged radical.[20] Since an ozonate anion radical has been reported to undergo the hydrogen abstraction reaction,[21] cumene and triphenylmethane were added to the ozonized solution, and the mixture was allowed to stand for 0.5 h. The control experiment was also carried out. When cumene was ozonized, 2-phenyl-2-propanol was detected as was reported by Pryor *et al.*[22] However, since (1) the yield in the presence of phenothiazine (8%) was clearly greater than that in the absence of phenothiazine (trace), and (2) triphenylmethanol was not detected from the ozonized solution in the absence of phenothiazine, it was concluded that cumene and triphenylmethane reacted with the ozonate anion radicals to give 2-phenyl-2-propanol and triphenylmethanol, respectively. Since the reactivity of cumene with radicals is smaller than that of triphenylmethane,[23] yield of the ozonate anion radical with four molar equivalents of cumene gave only a trace amount of 2-phenyl-2-propanol. The result is shown in Table 2. As was expected, the ozonate anion radical was trapped in dichloromethane, chlorform, and acetic acid, in which the phenothiazine cation radical was detected (Runs 1,

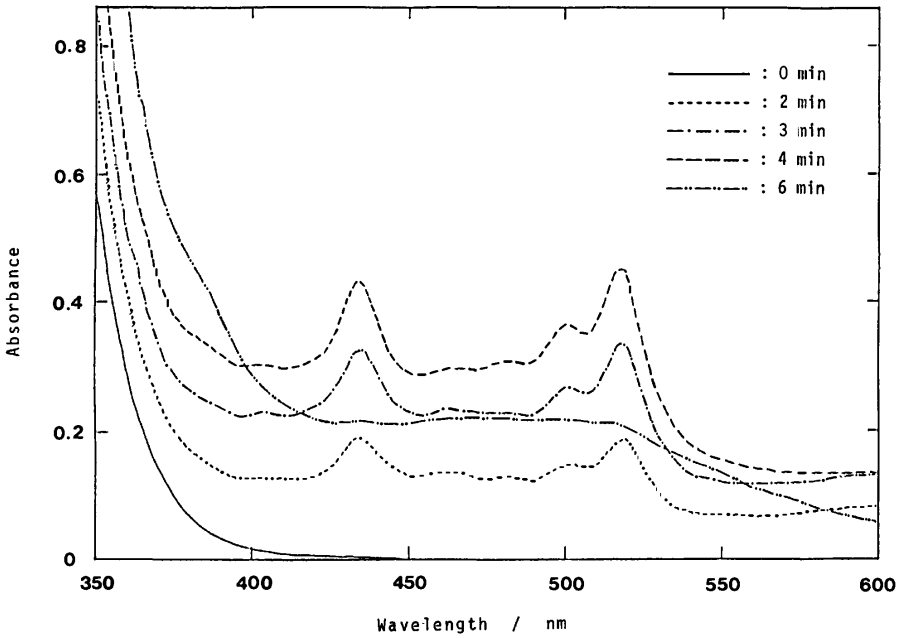

Fig. 2. Change in the visible spectrum of phenothiazine during ozonization.
Ozonization was carried out with an ozone–nitrogen mixture (ozone: 0.3 mmol, nitrogen: 50 cm^3 min^{-1}) on 0.251 mmol of phenothiazine in 50 ml of dichloromethane at 0 °C.

Table 2. Relation between the formation of a phenothiazine cation radical and the yield of the ozonate anion radical during the ozonization of phenothiazine[a)]

Run	Solvent	Formation[b)] of a cation radical	Yield[c)]/%	
			2-Phenyl-2-propanol	Triphenylmethanol
1	CH_2Cl_2	+	8	3
2	$CHCl_3$	+	7	3
3	CH_3COOH	+	7	2
4	CCl_4	−	0	0
5	C_6H_{14}[d)]	−	0	0

a) Ozonization was carried out with an ozone–nitrogen mixture (ozone: 1.0 mmol, nitrogen: 50 cm^3 min^{-1}) on 1 mmol of phenothiazine in 40 ml of solvent at 0 °C. To the ozonized solution, 140 and 4 molar equivalents of cumene and triphenylmethane were added, respectively. b) The cation radical was detected by the visible spectrum. c) Yield was based on the phenothiazine reacted. d) Ozonization was carried out with an ozone–nitrogen mixture (ozone: 0.3 mmol, nitrogen: 50 cm^3 min^{-1}) on 0.25 mmol of phenothiazine in 40 ml of solvent.

2, and 3). The greater the polarity of the solvent is, the easier is the formation of the ozonate anion radical. Such a tendency is similar to the solvent effect reported in the reaction of a superoxide ion.[24)]

Bailey *et al.* reported that *t*-butylamine cation radical produced in the ozonization underwent hydrogen abstraction reaction from 2,2,4-trimethylpentane to give 2,4,4-trimethyl-2-pentanol.[25)] However, since (1) an ozonate anion radical produced on magnesium oxide underwent hydrogen abstraction reaction,[21)] and (2) addition of cumene and triphenylmethane decreased the absorbance of phenothiazine cation radical, we have modified Bailey's mechanism, as shown in Eqs. (1)—(3),

$$O_3^{\cdot-} + RH \rightarrow R^{\cdot} + O_2 + OH^-, \quad (1)$$

$$R^{\cdot} + PTH^+ \rightarrow R^+ + RTH, \quad (2)$$

$$R^+ + OH^- \rightarrow ROH, \quad (3)$$

where RH is cumene and triphenylmethane, and PTH is phenothiazine.

Relations among oxidation potential ($E^{ox}_{1/2}$), formation of the cation radicals and yield of the ozonate anion radical in the ozonization of *N,N'*-diphenyl-*p*-phenylenediamine, phenothiazine, phenoxazine, phenoxathiin, and thianthrene are shown in Table 3. When *N,N'*-diphenyl-*p*-phenylenediamine, whose ozonization has been explained by the electron-transfer mechanism, was ozonized in dichloromethane, formation of the cation radical was observed, and the ozonate anion radical was also trapped (Run 1). In the ozonization of phenoxazine the solution turned red in color and visible spectrum showed the absorption maxima at 404 and 522 nm which are similar to that of the phenoxazine cation radical.[26)] The ozonate anion radical was also trapped in the yield of 6 and 2%, respectively (Run 3). Bailey *et al.* reported that ozonization of thianthrene in the presence of dilute sulfric acid gave the cation radical.[27)] When ozonization of phenoxathiin and thianthrene was carried out in dichloromethane, formation of the cation radicals and the ozonate anion radical were not observed (Runs 4 and 5). The result that the lower the oxidation potential is, the easier is the formation of the cation radical and the ozonate anion radical suggests that the electron-transfer process is the major path during the ozonization of phenothiazine and phenoxazine. On the other hand,

Table 3. Relations among the oxidation potential of the substrate, formation of the cation radicals, and the yield of an ozonate anion radical during ozonization[a)]

Scheme 1.

ozonization of phenoxathiin and thianthrene is explained by the electrophilic ozone attack.

The probable ozonization mechenism is shown in Scheme 1. When phenothiazine (**1a**) and phenoxazine (**1d**) are ozonized in the polar solvents, the cation radicals **6a** and **6d** are formed *via* the electron-transfer reaction. They are in equilibrium with the substrate-ozone adducts **7a** and **7d** in solution. Ozonization of phenothiazine (**1a**) in the chlorinated solvents gives 2-chlorophenothiazine (**4a**). Recombination of **6d** with the ozonate anion radical gives 3*H*-phenoxazin-3-one (**3d**). The substrate-ozone adducts **7a—d** were also formed *via* the electrophilic attack of ozone on the substrate and the adducts lose an oxygen molecule and give the S-oxides **2a—c**. Thianthrene 5-oxide (**2c**) is further ozonized to give thianthrene 5,10-dioxide (**5c**).

The authors thank Professor Teijiro Kitao of the University of Osaka Prefecture for useful discussion. The authors are grateful to Professor Yasusada Ueno and Associate Professor Hideki Minoura of Gifu University for the oxidation potential measurement.

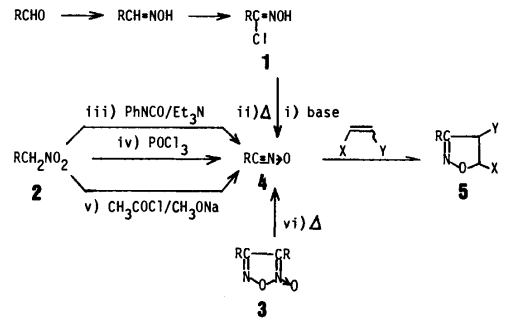
The Reaction of Primary Nitro Compounds with Dipolarophiles in the Presence of *p*-Toluenesulfonic Acid

Tomio SHIMIZU,* Yoshiyuki HAYASHI, and Kazuhiro TERAMURA
Department of Color Chemistry and Technology, Faculty of Industrial Arts, Kyoto Technical University, Matsugasaki, Sakyo-ku, Kyoto 606
(Received March 17, 1984)

3-Substituted 2-isoxazolines or isoxazoles were obtained from the reaction of primary nitro compounds [methyl nitroacetate, 2-nitro-1-phenylethanone, (nitromethyl)benzene, 1-nitropropane, and (phenylsulfonyl)-nitromethane] with dipolarophiles in refluxing mesitylene in the presence of a small amount of *p*-toluenesulfonic acid. The formation of these products can be explained in terms of 1,3-dipolar cycloaddition of nitrile oxide generated by a dehydration of the primary nitro compounds. On the other hand, 4,5-decamethylene-3-phenylsulfonyl-2-isoxazoline *N*-oxide was obtained from a similar reaction of (phenylsulfonyl)nitromethane with cyclododecene. The formation of the isoxazoline *N*-oxide can be explained on the basis of the intermediacy of 3,4-bis(phenylsulfonyl)furazan 2-oxide.

1,3-Dipolar cycloaddition reactions using nitrile oxides were one of versatile methods for the preparation of five-membered heterocycles. Many preparative methods of nitrile oxides have been known so far[1-7] (see Scheme 1) but each of these methods possesses at



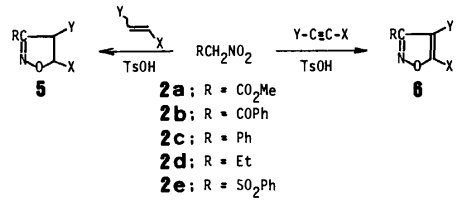
Scheme 1.

least one disadvantage; the method (i) is the most familiar one,[2] but several troublesome steps are necessary for the preparation of hydroximoyl chlorides (**1**), a precursor of nitrile oxides (**4**). On the other hand, one-step methods (iii—v)[4-6] using primary nitro compounds (**2**) which are more easily available than **1** appear to be an attractive one. However, an equimolar or an excess amount of reagents is required for the dehydration of **2**, and consequently, separation of the desired compounds from the reaction mixture is troublesome and considerable amounts of undesired by-products are formed in some cases. The present paper describes a new effective and simple method for the generation of nitrile oxides by the dehydration of **2** using a small amount of *p*-toluenesulfonic acid and the preparation of cycloadducts in the presence of dipolarophiles.

Results and Discussion

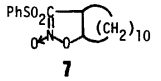
Removal of a proton from an aliphatic primary nitro compound gives a carbanion which can be alkylated (or acylated) at oxygen or carbon atom. *O*-Alkylation (or -acylation) gives nitronic esters (or anhydrides), which are generally unstable to heat and break down to a nitrile oxide, while *C*-alkylation (or acylation) gives by-products for the purpose of generation of a nitrile oxide. Acid catalyzed enolization and acid catalyzed dehydration of a hydroxyl group are well known. It is expected that a primary nitro compound would give a nitrile oxide in the presence of a trace of acid and it is shown to be the case.

The reactions between an equimolar mixture of several primary nitro compounds (**2a—e**) bearing various types of substituents and dipolarophiles were carried out in refluxing xylene or mesitylene for 6—20 h in the presence of a catalytic amount of *p*-toluenesulfonic acid. (see Eq. 1) 2-Isoxazolines (**5**) or isoxazoles (**6**) were



(1)

obtained from the reaction of **2a—e** with ethylenic or acetylenic dipolarophiles, respectively, in the yields shown in Table 1. The isolated yields in Table 1 are calculated on the reagents used. Unreacted primary nitro compounds could be recovered from the reaction mixture. The conversion of **2** to the products were over 80% in all cases shown in the Table. Though the reaction of **2a** with dipolarophiles proceeded slowly at the temperature of xylene refluxing, those of **2b—e** with dipolarophiles were too slow to be observed at this temperature. However, all of **2** reacted rapidly with dipolarophiles at the temperature of mesitylene refluxing. Formation of water was observed as the reaction proceeded. No remarkable improvement in the yields of the cycloadducts was observed after removing the water from the reaction system. On the other hand, 4,5-decamethylene-3-phenylsulfonyl-2-isoxazoline *N*-oxide (**7**) was the only isolable cycloadduct from the reaction mixture of **2e** and cyclododecene.



7

The structure of the cycloadducts (**5**, **6**, and **7**) was established on the basis of elemental analyses and spectral data (see Table 2). Physical properties of **5r**, **5s**, and

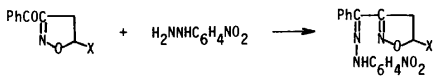
7 agreed well with those of known compounds.[8,9] The structure of oily cycloadducts (**5j** and **5m**) was further supported by conversion into crystalline hydrazones (**8**) by the reaction with *p*-nitrophenylhydrazine. (Eq. 2)

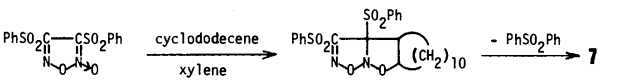


(2)

5j; X = CH_2Ph
5m; X = $C_{12}H_{25}$

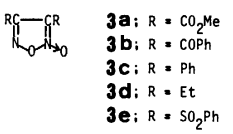
8j; X = CH_2Ph
8m; X = $C_{12}H_{25}$

Though the formation of **5** and **6** may be ascribed to the results of a direct cycloaddition reaction of nitrile oxides (**4**), generated by the dehydration of **2**, with dipolarophiles, the isolation of **7** in a particular reaction may suggest an alternative reaction mechanism for these reactions. Recently, we reported that **7** was obtained from a nitrone-type cycloaddition reaction of 3,4-bis(phenylsulfonyl)furazan 2-oxide (furoxan) (**3e**) with cyclododecene.[9] Furthermore, furazan *N*-oxides (furoxan) bearing appropriate substituents are known to undergo dissociation into to moles of nitrile oxides



3e (3)

and give isoxazolines or isoxazoles by the following cycloaddition with dipolarophiles at the temperatures over 200 °C[7] (see route vi in Scheme 1). In view of these facts, it is necessary to examine the possibility of the intervention of furoxans in the reactions reported here. Although none of pure furoxans were isolated from the reaction mixture, we examined the reaction of furoxans (**3a—e**) with dipolarophiles in mesitylene at



3a; R = CO_2Me
3b; R = COPh
3c; R = Ph
3d; R = Et
3e; R = SO_2Ph

the refluxing temperature. It was found that **3c** and **3d** were quite stable under the reaction conditions and were recovered quantitatively and that **3a** and **3b**

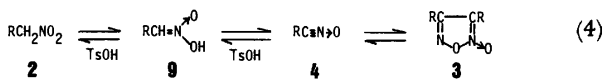
a) **5a**, **5h**, **5n**, **5r**, **5u**, and **5z** were dissolved in DMSO-d_6, the other substances were dissolved in $CDCl_3$.

underwent other types of cycloaddition reactions[9] and any trace of 3-methoxycarbonyl-2-isoxazolines or 3-benzoyl-2-isoxazolines could not be isolated from the reaction mixture. However, **5y**, **5z**, and **7** were obtained from the reaction of the furoxan **3e** with allylbenzene, allyl *p*-nitrophenyl ether, or cyclododecene, respectively, in yields similar to those from the reactions of the nitro compound **2e**. From these results, the most probable mechanism of the reaction of **2** with dipolarophiles in the presence of *p*-toluenesulfonic acid is as follows; acid-catalyst accelerates enolization of nitro compounds (**2**) into nitronic acid (**9**). Acid-catalyzed dehydration (or tosylation of the nitronic acid (**9**) followed by acid-catalyzed detosylation) gives nitrile oxides (**4**). The nitrile oxides undergo either a dimerization to furoxans (**3**) or a 1,3-dipolar cycloaddition with dipolarophiles depending on the nature of the substituents R. 1,3-Dipolar cycloadditions occur preferentially in the cases of R=CO_2Me, PhCO, Ph, and Et, and, on the other hand, a dimerization precedes the cycloaddition in the case of R=SO_2Ph. Bis-(phenylsulfonyl)furoxan (**3e**) was known to undergo two types of reactions (Eq. 3 or thermoreversion into the nitrile oxide) depending on the nature of dipolarophiles.[9]



(4)

p-Toluenesulfonic acid was the best catalyst among the examined acids, CH_3CO_2H, CF_3CO_2H, and TsOH.

It is concluded that isoxazolines or isoxazoles can be easily obtained from primary nitro compounds in a moderate yield and the method is especially effective in the reaction with dipolarophiles which have a poor reactivity toward nitrile oxides at low temperature below 100°C because our method can apply at arbitrary high temperature.

Experimental

Measurements. All melting and boiling points are uncorrected. ^{1}H NMR spectra were measured on Varian T-60 A instrument with Me_4Si as an internal standard. All new crystalline products gave correct elemental analyses (±0.3% for C, H, and N).

Materials. Methyl nitroacetate,[10] 2-nitro-1-phenylethanone,[11] (nitromethyl) benzene,[12] (phenylsulfonyl)nitromethane,[13] bis(ethoxycarbonyl)furoxan,[14] dibenzoylfuroxan,[14] diphenylfuroxan,[15] diethylfuroxan,[4] and bis(phenylsulfonyl)furoxan[16] were prepared according to the method described in the literatures. 1-Nitropropane and *p*-toluenesulfonic acid monohydrate were commercially available and were used without further purification.

Reactions of Primary Nitro Compounds with Dipolarophiles. General Procedure. A mixture of an equimolar amount (20 mmol) of primary nitro compounds and dipolarophiles and a small amount of *p*-toluenesulfonic acid monohydrate (*ca.*~100 mg) was heated to reflux in mesitylene (50 ml) for 6 h. When xylene was used for the solvent instead of mesitylene, the mixture was refluxed for 20 h. In the case of the reaction with maleimides, a small amount (*ca.* 40 mg) of hydroquinone was also added. Evaporation of the solvent and other low-boiling products from the reaction mixture in a rotary evaporator gave the crude products. Crystalline crude products were recrystallized from appropriate solvents several times and some oily crude products were chromatographed (silica gel) with chloroform to give the crystalline products or pure oily products. The other oily crude products were purified by fractional distillation. Yields and melting (or boiling) points are shown in Table 1 and the NMR spectral data are shown in Table 2; 1 mmHg≈133.322 Pa.

*Reaction of 5-Benzyl (or -Dodecyl)-3-benzoyl-2-isoxazoline (**5j** or **5m**) with* p*-Nitrophenylhydrazine.* An ethanol solution (60 ml) of **5j** (or **5m**) (5 mmol) and *p*-nitrophenylhydrazine (5 mmol) was refluxed for 4 h. The subsequent evaporation of the solvent yielded a viscous oily material which solidified upon scratching with a glass rod. Recrystallization from ethanol gave yellow crystals (**8j** or **8m**). **8j**; 54% yield, mp 165—167 °C, NMR (DMSO-d_6) δ=2.8—3.6 (m, 4H), 4.7—5.2 (m, 1H). 7.2—7.5 (m, 12H), 8.15 (d, 2H, J=9 Hz), 11.5 (s, 1H, NH). Calcd for $C_{23}H_{20}N_4O_3$: C, 68.03; H, 5.19; N, 14.43%. Found: C, 67.95; H, 5.17; N, 14.50%. **8m**; 63% yield, mp 92.5—93 °C, NMR ($CDCl_3$) δ=0.7—2.0 (m, 25H), 2.75 (dd, 1H, J=9 and 16 Hz), 3.25 (dd, 1H, J=9 and 16 Hz) 4.3—5.0 (m, 1H), 7.23 (d, 2H, J=9 Hz), 7.43 (s, 5H), 8.15 (d, 2H, J=9 Hz), 12.0 (s, 1H, NH). Calcd for $C_{28}H_{38}N_4O_3$: H, 8.00; C, 70.26; N, 11.71%. Found: H, 8.10; C, 70.47; N, 11.80%.

*Reactions of Furoxans (**3a—e**) with Dipolarophiles.* The reaction was carried out according to the method previously reported[9] except for the use of mesitylene as the solvent. From the reaction of **3e** with allylbenzene, *p*-nitrophenyl allyl ether, or cyclododecene, **5y**, **5z**, and **7** were obtained in 35, 22, and 54% yield, respectively.

Branched-chain Sugars. XXXV. The Synthesis of L-Rubranitrose (2,3,6-trideoxy-3-*C*-methyl-4-*O*-methyl-3-nitro-L-*xylo*-hexopyranose)[1]

Juji YOSHIMURA,* Toshio YASUMORI, Tatsuya KONDO, and Ken-ichi SATO
Laboratory of Chemistry for Natural Products, Faculty of Science, Tokyo Institute of Technology, Nagatsuta, Midoriku, Yokohama 227
(Received April 16, 1984)

The title compound was stereoselectively synthesized from methyl 2,6-dideoxy-4-*O*-methyl-β-L-*threo*-hexopyranosid-3-ulose (**11**) through the successive conversions; cyanomesylation, reductive spiro aziridine formation, reductive ring-opening to the methyl-branched amino sugar, oxidation to the corresponding nitro sugar.

For rubranitrose, a component of the antibiotic rubradirin,[2] the structure was reprtred to be 2,3,6-trideoxy-3-*C*-methyl-4-*O*-methyl-3-nitro-L-*xylo*-hexopyranose (**1**) from X-ray analysis and the CD spectrum,[3] in which a positive Cotton effect was observed, opposite in sign to that of L-evernitrose (**2**).[4] However, Mallams *et al.*[5] pointed out that **1** should have D-configuration, from comparison of the CD spectrum and rotational value with D-kijanose (**3**), of which the configuration was assigned by the application of Hudson's Rules of Isorotation. In a previous communication,[6] we proved the correctness of the deduction of Mallams *et al.*, by the synthesis of **1** from D-glucose. This paper describes it in detail. In our synthesis, hexopyranosid-3-ulose was converted successively into the corresponding methyl-branched nitro sugar; *i.e.* cyanomesylation of the carbonyl group, reductive spiro aziridine formation by intramolecular S_N2 substitution, reductive ring-opening into methyl-branched amino sugar, and oxidation into the corresponding nitro sugar. The series of conversions was previously used for the synthesis of **2**[7] and its enantiomer.[8] Recently, Brimacombe *et al.*[9] communicated the synthesis of **1** and its enantiomer through the inversion of configuration of *C*-4 of methyl 3-trifluoroacetamido-2,3,6-trideoxy-3-*C*-methyl-α-L- and D-*ribo*-hexopyranoside (**4**), respectively.

Results and Discussion

For the synthesis of **1** through the aforementioned pathway, methyl 2,6-dideoxy-4-*O*-methyl-β-L-*threo*-hexopyranosid-3-ulose (**11**) was considered to be the most suitable key intermediate. Treatment of methyl 4,6-*O*-benzylidene-2-deoxy-α-D-*ribo*-hexopyranoside,[10] which was obtained from D-glucose through five-step conversions, with *N*-bromosuccinimide and barium carbonate in carbon tetrachloride gave unstable methyl 4-*O*-benzoyl-6-bromo-2,6-dideoxy-α-D-*ribo*-hexopyranoside (**5**) in 92% yield. It was found that *O*-methylation of **5** in *N*,*N*-dimethylformamide with methyl iodide and silver(I) oxide is nicely accomapnied with benzoyl migration to give the corresponding 3-*O*-benzoyl-4-*O*-methyl derivative (**6**) in 90% yield. Treatment of **6** in pyridine with silver(I) fluoride[11] gave a 3:2 mixture of the corresponding hex-5-enopyranoside (**8**) and 6-fluoro-6-deoxy derivative (**7**). The mixture could not be separated, and the presence of **7** was confirmed only by ^{19}F-NMR. Compound **8** was separated, after conversion into methyl 2,6-dideoxy-4-*O*-methyl-β-L-*lyxo*-hexopyranoside (**10**) *via* the corresponding 3-benzoate (**9**) in 49% yield. Oxidation of **10** with pyridinium chlorochromate gave the crystalline key intermediate (**11**) in 65% yield.

One-flask cyanomesylation of **11** by treatment overnight with hydrogen cyanide in dry pyridine, and then with methanesulfonyl chloride for 2 d at room temperature gave methyl 3-*C*-cyano-2,6-dideoxy-3-*O*-methylsulfonyl-4-*O*-methyl-β-L-*lyxo*-hexopyranoside (**12**) as crystals in 65% yield. In order to examine the stereoselectivity of cyanomesylation under the thermodynamic conditions,[12] cyanohydrine formation was

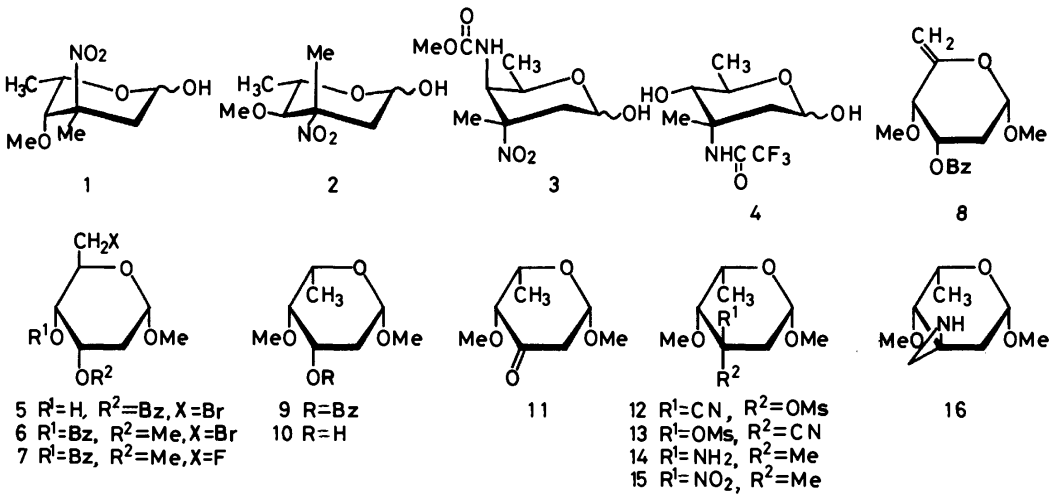

TABLE 1. ^{1}H AND ^{13}C-NMR DATA OF **1**

	Chemical shift (δ) and coupling constant (Hz) in ^{1}H-NMR							
	H-1 ($J_{1,2a}$)	H-2a ($J_{1,2e}$)	H-2e ($J_{2a,2e}$)	H-4 ($J_{4,5}$)	H-5 ($J_{5,6}$)	H-6	CMe	OMe
α-**1**	5.30 dd (2.5)	2.07 dd (3.5)	2.68 dd (14.5)	3.61 bs (1.0)	4.40 bq (6.5)	1.33 d	1.67 s	3.64 s
(Reported for α-D-**1**)	5.28 dd (2.5)	2.05 dd (3.5)	2.67 dd (14.5)	3.62 bs (<1)	4.40 bq (6.5)	1.33 d	1.67 s	3.62 s
	Chemical shift (ppm) of carbons in ^{13}C-NMR							
	C-1	*C*-2	*C*-3	*C*-4	*C*-5	*C*-6	*C*Me	OMe
α-**1**	92.51	37.17	63.45	79.65	69.84	16.79	25.84	62.69

carried out by treatment of **11** in dichloromethane with aqueous potassium cyanide and sodium hydrogencarbonate, followed by mesylation of the product in pyridine, to give a 1:4 mixture of **12** and its L-*xylo* isomer (**13**) in 83% yield. Reduction of **12** with lithium aluminium hydride gave the corresponding spiro aziridine (**16**) in 65% yield, which was converted into the methyl glycoside (**15**) of L-rubranitrose *via* the corresponding methyl-branched amino sugar (**14**) in 56% yield, by successive catalytic hydrogenolysis and oxidation with *m*-chloroperoxybenzoic acid. Hydrolysis of **15** in 0.05 M (1 M=1 mol dm^{-3}) sulfuric acid gave **1** {mp 147—148 °C, $[\alpha]_D$ −76° (*c* 0.48, ethanol, after 3 h); lit,[3] α-D-**1**: mp 150—153°, $[\alpha]_D$ +127°→ +86° (*c* 1.0, ethanol)} quantitatively. As shown in Table 1, ^{1}H-NMR parameters reveal the relative structure, and ^{13}C-NMR data indicate the presence of an equatorial *C*-methyl group.[13] Both the opposite sign of the optical rotational values and of the Cotton effect (the molar ellipticity at 285 nm of **1** in methanol was −1580; lit,[3] for β-acetate of the natural compound, +2500) between **1** and the natural product proved that the latter has the D-configuration.

Experimental

Melting points are uncorrected. Optical rotations were measured with a JASCO DIP-4 polarimeter in chloroform, and ^{1}H and ^{13}C-NMR were recorded in chloroform-*d* with JEOL PS-100 and JEOL FX-100 spectrometers, respectively, with tetramethylsilane as an internal standard, unless otherwise stated. Chemical shifts and coupling constants were recorded in δ and Hz units, respectively, and IR frequencies in cm^{-1}.

*Methyl 4-O-Benzoyl-6-bromo-2,6-dideoxy-α-D-*ribo*-hexopyranoside (5).* A suspension of methyl 4,6-*O*-benzylidene-2-deoxy-α-D-*ribo*-hexopyranoside (20 g, 75.2 mmol), *N*-bromosuccinimide (14.72 g, 82.7 mmol), and barium carbonate (80 g) in carbon tetrachloride (1.2 l) was refluxed for 2 h. The solution colored once red and then changed to colorless. The cooled reaction mixture was filtered, and the filtrate was evaporated to a half, poured into ice-water, then extracted with chloroform. The usual work-up of the extract, and purification of the product on a short column of silica gel gave **5** (22.7 g) as a sirup in 92.0% yield.

$[\alpha]_D$ +93.0° (*c* 1.0); NMR: δ=8.15—8.00 and 7.70—7.20 (m, 5H, Ph), 4.95 (dd, 1H, $J_{3,4}$=3.0, $J_{4,5}$=10.0, H-4), 4.95 (dd, 1H, $J_{1,2e}$=1.0, $J_{1,2a}$=3.6, H-1), 4.62—4.18 (m, 2H, H-3 and 5), 3.70—3.40 (m, 2H, H-6 and 6'), 3.50 (s, 3H, OMe), 2.22 (ddd, 1H, $J_{2e,3}$=3.6, H-2e), 2.04 (dt, 1H, $J_{2a,3}$=3.6, H-2a), and 1.75 (bs, 1H, OH).

Anal. ($C_{14}H_{17}O_5Br$) C, H, Br.

*Methyl 3-O-Benzoyl-6-bromo-2,6-dideoxy-4-O-methyl-α-D-*ribo*-hexopyranoside (6).* To a solution of **5** (13.8 g, 42.0 mmol) in *N*,*N*-dimethylformamide (50 ml) was added methyl iodide (17.9 g, 126 mmol) and silver(I) oxide (11.67 g, 50.4 mmol), and the mixture was stirred for 24 h at room temperature in the dark. After monitoring the disappearance of **5**, the mixture was filtered, and the filtrate was evaporated. The residual sirup was purified on a silica-gel column (benzene–aceonte 16:1) to give **6** (13.57 g) as a pale yellow sirup in 90.0% yield. $[\alpha]_D$+70.0° (*c* 1.9); NMR: δ=8.15—8.00 and 7.60—7.20 (m, 5H, Bz), 5.70 (dt, 1H, $J_{3,4}$=3.5, H-3), 4.83 (bd, $J_{1,2a}$=4.0, $J_{1,2e}$=1.0, H-1), 3.44 (dd, 1H, $J_{4,5}$=10.0, H-4), 4.24 (ddd, 1H, $J_{5,6}$=4.5, H-5), 3.90—3.60 (m, 2H, H-6 and 6'), 3.47 and 3.44 (each s, 6H, 2x OMe), 2.26 (ddd, 1H, $J_{2e,3}$=3.6, H-2e), and 1.98 (dt, 1H, $J_{2a,2e}$=15.5, $J_{2a,3}$=4.0, H-2a).

Anal. ($C_{15}H_{19}O_5Br$) C, H, Br.

Conversion of 6 into the Corresponding L-Sugar. A suspension of **6** (3.1 g, 8.64 mmol) and powdered silver(I) fluoride (3.1 g, 24.4 mmol) in dry pyridine (60 ml) was stirred for 40 h in the dark, then filtered. The filtrate was poured into ice-water, and extracted with chloroform. The extract was evaporated to give a yellow sirup, which was a 3:2 mixture of methyl 3-*O*-benzoyl-2,6-dideoxy-α-D-*erythro*-hex-5-enopyranoside (**8**) and methyl 3-*O*-benzoyl-2,6-dideoxy-6-fluoro-4-*O*-methyl-α-D-*ribo*-hexopyranoside (**7**). Because the mixture could not be separated, a solution of the mixture in methanol (36 ml) containing a few drops of acetic acid was hydrogenated in the presence of 10% palladium–carbon (383 mg) overnight, and then filtered. The filtrate was evaporated, and the dried residue was dissolved in 2M sodium hydroxide (30 ml). After stirring the solution at room temperature for 3 h, it was extracted with chloroform. Evaporation of the extract gave a yellow sirup which was fractionally crystallized from ethanol to give methyl 2,6-dideoxy-4-*O*-methyl-β-L-*lyxo*-hexopyranoside (**10**,739 mg) as white crystals in 48.6% overall yield. Mp 142.8—144 °C (ethanol); $[\alpha]_D$ +34.2° (*c* 1.0); NMR: 4.28 (dd, 1H, $J_{1,2a}$=10.0, $J_{1,2e}$=2.0, H-1), 3.90—3.30 (m, 2H, H-3 and 5), 3.64 and 3.51 (each s, 6H, 2×OMe), 3.16 (bd, 1H, $J_{3,4}$=3.6, $J_{4,5}$=<1, H-4), 2.00 (ddd, 1H, $J_{2e,3}$=5.0, $J_{2a,2e}$=12.0, H-2e), 1.67 (dt, 1H, $J_{2a,3}$= 10.0, H-2a), and 1.28 (d, 3H, H-6).

Anal. ($C_8H_{16}O_4$) C, H.

*Methyl 2,6-Dideoxy-4-O-methyl-β-L-*threo*-hexopyranosid-3-ulose (11).* A solution of **10** (500 mg, 2.84 mmol) and pyridinium chlorochromate (2.5 g, 11.6 mmol) in dichloromethane (12.5 ml) was stirred overnight at room temperature, and then evaporated roughly to dryness. The porduct was

purified directly on a silica-gel column (benzene–acetone 16:1) to give **11** (380 mg) as white crystals in 76.0% yield. Mp 38.8—40.4 °C (ethanol–hexane); $[\alpha]_D$ +92.0° (*c* 1.1); NMR: δ= 4.57 (dd, 1H, $J_{1,2a}$=8.0, $J_{1,2e}$=3.0, H-1), 3.74 (dq, 1H, $J_{4,5}$=3.0, $J_{5,6}$=6.4, H-5), 3.56 and 3.41 (each s, 6H, 2×OMe), 3.37 (m, 1H, H-4), 2.87 (dd, 1H, $J_{2a,2e}$=13.0, H-2a), 2.57 (ddd, 1H, $J_{2e,4}$= 1.0, H-2e), and 1.42 (d, 3H, H-6).

Anal. ($C_8H_{14}O_4$) C, H.

Cyanomesylation of 11. i) A solution of **11** (722 mg, 4.15 mmol) and hydrogen cyanide (170 mg, 6.19 mmol) in dry pyridine was kept at room temperature overnight, and then methanesulfonyl chloride (4.19 ml, 24.9 mmol) was added dropwise to it. The resulting solution was stirred for 2 d, diluted with chloroform, poured into ice–water, and then extracted with chloroform. The usual work-up of the extract, and purification of the product on a silica-gel column (benzene–acetone 8:1) gave methyl 3-*C*-cyano-2,6-dideoxy-3-*O*-methylsulfonyl-4-*O*-methyl-β-L-*lyxo*-hexopyranoside (**12**, 750 mg) as white plates in 64.8% yield. Mp 94.2—94.6 °C (ethanol); $[\alpha]_D$ −2.28° (*c* 1.0); NMR: δ=4.61 (dd, 1H, $J_{1,2a}$= 9.0, $J_{1,2e}$=3.0, H-1), 3.91 (dq, 1H, $J_{4,5}$=1.4, $J_{5,6}$=6.4, H-5), 3.25 (s, 3H, SMe), 3.67 (bs, 1H, H-4), 3.17 and 3.54 (each s, 6H, 2×OMe), 2.47 (ddd, 1H, $J_{2a,2e}$=12.4, $J_{2e,4}$=1.0, H-2e), 2.27 (dd, 1H, H-2a), and 1.37 (d, 3H, H-6).

Anal. ($C_{10}H_{17}O_6NS$) C, H, N, S.

ii) To a solution of **11** (210 mg, 1.2 mmol) in dichloromethane (2.8 ml) was added a solution of potassium cyanide (157 mg, 2.14 mmol) and sodium hydrogencarbonate (101 mg, 1.20 mmol) in water (1.5 ml) at 0 °C and the solution was stirred at room temperature overnight. The usual work-up of the solution gave a product, which was treated with methanesulfonyl chloride (553 mg, 4.83 mmol) to give a product, which was fractionally crystallized from ethanol to give crystals of L-*xylo* isomer (**13**) of **12**. The component in the filtrate was separated on a silica-gel column (benzene–acetone 8:1). Compound **13** and **12** were obtained in 68.3% (230 mg) and 13.7% (46 mg) yield, respectively.

13: mp 91.2—92 °C (ethanol); $[\alpha]_D$ +0.57 °C (*c* 1.5); NMR: δ=4.67 (dd, 1H, $J_{1,2a}$=9.0, $J_{1,2e}$=3.0, H-1), 4.03 (dq, 1H, $J_{4,5}$= 1.4, $J_{5,6}$=6.8, H-5), 3.76 and 3.54 (each s, 6H, 2×OMe), 3.33 (s, 3H, SMe), 3.57 (bs, 1H, H-4), 2.46 (ddd, 1H, $J_{2e,4}$=1.0, H-2e), 2.30 (dd, 1H, $J_{2a,2e}$=15.0, H-2a), 1.36 (d, 3H, H-6).

Anal. ($C_{10}H_{17}NO_6S$) C, H, N, S.

Spiro[aziridine-2,3'-(methyl 2,3,6-trideoxy-4-O-methyl-β*-*L*-xylo-hexopyranoside)] (16).* To a solution of **12** (200 mg, 0.717 mmol) in anhydrous ether (24 ml) was added lithium aluminium hydride (140 mg, 1.05 mmol), and the resulting suspension was refluxed for 2 h. The excess reagent was decomposed by addition of a small amount of water to the reaction mixture and filtered, and the precipitate was washed with ethanol. The filtrate and washings were combined and extracted with chloroform. Evaporation of the extract and purification of the product on a silica-gel column (ethanol) gave **16** (96.7 mg) as a sirup in 65.2% yield. $[\alpha]_D$ 0° (*c* 1.0); NMR: δ=4.60 (dd, 1H, $J_{1,2a}$=9.6, $J_{1,2e}$=2.5, H-1), 3.89 (dq, 1H, $J_{4,5}$=1.4, $J_{5,6}$=6.4, H-5), 3.54 (bs, 1H, H-4), 3.52 and 3.45 (each s, 6H, 2×OMe), 2.32 (dd, 1H, $J_{2a,2e}$= 13.5, H-2a), 2.35 (bs, 1H, NH), 1.90 and 1.83 (each s, 2H, NCH_2), 1.31 (d, 3H, H-6), and 1.05 (ddd 1H, $J_{2e,4}$=1.0, H-2e).

Anal. ($C_9H_{17}NO_3$) C, H, N.

Methyl 2,3,6-Trideoxy-3-C-methyl-4-O-methyl-3-nitro-β*-*L*-xylo-hexopyranoside (15).* A solution of **16** (187 mg, 1.0 mmol) in methanol (100 ml) was hydrogenolyzed under 120 atm hydrogen in the presence of Raney nickel (1.0 g) for 2 d, filtered, and then evaporated to give 3-amino-2,3,6-trideoxy-3-*C*-methyl-4-*O*-methyl-β-L-*xylo*-hexopyranoside (**14**) as a sirup, quantitatively. To a solution of the sirup in dichloromethane (3.0 ml) was added a solution of *m*-chloroperoxybenzoic acid (518 g, 3.0 mmol) in dichloromethane (3.0 ml) portionwise under refluxing, and the resulting solution was refluxed for 40 min, poured into 10% sodium sulfite solution, and then extracted with chloroform. The usual work-up of the extract, and purification of the product on a silica-gel column (benzene–acetone 6:1) gave **15** (123 mg) as a pale yellow sirup in 56.2% overall yield.

$[\alpha]_D$ −15.9° (*c* 0.8); NMR: δ=4.46 (dd, 1H, $J_{1,2a}$=9.6 $J_{1,2e}$= 2.2, H-1), 3.80—3.50 (m, 2H, H-4 and 5), 3.68 and 3.54 (each s, 6H, 2×OMe), 2.56 (ddd, 1H, $J_{2a,2e}$=14.6, $J_{2e,4}$=1.4, H-2e), 1.82 (dd, 1H, H-2a), 1.68 (s, 3H, CMe) and 1.36 (d, 3H, $J_{5,6}$= 6.0, H-6).

Anal. ($C_9H_{17}NO_5$) C, H, N.

L-Rubranitrose (1). A solution of **15** (56.7 mg, 0.26 mmol) in aq dioxane (1:1, 10.0 ml) of 0.05 M sulfuric acid was warmed at 90—95 °C for 2 h, neutralized with barium carbonate, and then filtered. The filtrate was evaporated, and the resulting sirup was purified on a silica-gel column (benzene–acetone 5:1) to give **1** (53.0 mg) as crystals in 98.0% yield. Physical properties of **1** were mentioned in Result and Discussion.

Anal. ($C_8H_{15}NO_5$) C, H, N.

Branched-chain Sugars. XXXVI. A New Synthesis of Methyl 4-*O*-Benzoyl-3-benzoylamino-2,3,6-trideoxy-3-*C*-methyl-α-L-*xylo*-hexopyranoside, a Derivative of the Branched-chain Amino Sugar of Antibiotic A35512B[1]

Toshio YASUMORI, Ken-ichi SATO, Hironobu HASHIMOTO, and Juji YOSHIMURA*
Laboratory of Chemistry for Natural Products, Faculty of Science, Tokyo Institute of Technology, Nagatsuta, Midoriku, Yokohama 227
(Received April 16, 1984)

The title compound was synthesized from methyl 4-*O*-benzyl-2,6-dideoxy-β-L-*threo*-hexopyranosid-3-ulose (**19**) through cyanomesylation, reductive spiro aziridine formation, and reductive ring-opening. When (2-methoxyethoxymethyl) group was used as the protecting group at *O*-4 of the above intermediate, it could not be removed at the final stage.

3-Amino-2,3,6-trideoxy-3-*C*-methyl-L-*xylo*-hexopyranose (**1**)[2] was found as a component of the new Gram-positive antibiotic, A35512B,[3] and characterized as the title compound (**2**).[2] In the preceding paper,[1] we have synthesized L-rubranitrose (**4**), having fundamentally the same configuration with **1**, from D-glucose. This paper describes a facile synthesis of **2** through a similar pathway. The first synthesis of **2** was accomplished from a non-carbohydrate diol obtained by fermentation of α-methylcinnamaldehyde with bakers' yeast.[4] In latter, *N*-acetyl derivative of **2** was obtained from its 4-epimeric derivative (**5**) by inversion,[5] which was derived from L-rhamnose.

Results and Discussion

In the synthesis of **4**, the coincidental migration of benzoyl group in methyl 6-bromo-2,6-dideoxy-4-*O*-benzoyl-α-D-*ribo*-hexopyranoside (**6**) with the introduction of methyl group on *O*-4, and the conversion of D-sugar to L-sugar were utilized. In the similar way, treatment of **6** with benzyl bromide and silver(I) oxide in *N*,*N*-dimethylformamide (DMF) in the dark gave the corresponding 3-*O*-benzoyl-4-*O*-benzyl derivative (**7**) in 92% yield. However, treatment of **7** in dry pyridine with silver(I) fluoride gave the 5-enopyranoside (**8**) and fluorine-substituted derivative of **7** in the ratio of 2:3, and catalytic hydrogenation of the unsaturated bond of **8** was undesirably accompanied with hydrogenolysis of 4-*O*-benzyl group to give methyl 3-*O*-benzoyl-2,6-dideoxy-β-L-*lyxo*-hexopyranoside (**9**) in 32% overall yield. Partial benzoylation of methyl 2,6-dideoxy-β-L-*lyxo*-hexopyranoside[6] gave also **9** in 85% yield, together with a small amount of the 4-benzoate (**10**) and 3,4-dibenzoate.

As was observed in the case of **6**, the benzoyl migration in equatorially oriented benzoyloxy group of **9** to the vicinal axial hydroxyl group took place very easily. Thus, the treatment of **9** with silver(I) fluoride in pyridine or with silver(I) oxide in DMF gave the corresponding 4-benzoate (**10**) quantitatively, and therefore, benzylation of **9** under the above conditions gave mainly the corresponding 4-*O*-benzoyl-3-*O*-benzyl derivative, which was confirmed by hydrogenolysis of the product into **10**. Similarly, reaction of **9** in dichloromethane with (2-methoxyethoxymethyl) chloride in the presence of *N*,*N*-diisopropylethylamine gave the corresponding 4-*O*-benzoyl-3-*O*-(2-methoxyethoxymethyl) (**11**) and 3-*O*-benzoyl-4-*O*-(2-methoxyethoxymethyl) (**12**) derivatives in the ratio of 1:1, and the mixture was *O*-debenzoylated into the corresponding 3-*O*-(2-methoxyethoxymethyl) (**13**) and 4-*O*-(2-methoxyethoxymethyl) (**14**) derivatives. These acyl migration are undesirable in the present synthesis.

Now, the reaction was accomplished under the conditions by the use of (2-methoxyethoxymethyl) triethylammonium chloride[7] to give **12** exclusively, which was then *O*-debenzoylated into **14** in 88% yield. Oxidation of **10** and **14** with pyridinium chlorochromate gave the corresponding pyranosid-3-uloses (**17** and **18**) in 91% and 98% yields, respectively. One-flask cyanomesylation of **17** and **18** under kinetic conditions[8] gave 4-*O*-benzoyl (**20**) and 4-*O*-(β-methoxyethoxymethyl) (**21**) derivatives of methyl 3-*C*-cyano-2,6-dideoxy-3-*O*-methylsulfonyl-β-L-*lyxo*-hexopyranoside in 35 and 73% yields, respectively. Reduction of **21** with lithium aluminium hydride gave the corresponding spiro aziridine (**23**) in 65% yield, which was then converted into methyl 3-benzoylamino-2,3,6-trideoxy-4-*O*-(2-methoxyethoxymethyl)-3-*C*-methyl-β-L-*xylo*-hexopyranoside

Table 1. ^{13}C-NMR chemical shifts (δ)[a] of **2**, **27**, and **28**

Carbons	**2**	**27**[b]	**28**
C-1	98.66	98.91	98.93
C-2	36.95	39.75	38.34
C-3	53.64	57.60	58.03
C-4	70.33	76.72	76.61
C-5	63.12	69.26	69.62
C-6	17.07	17.42	17.23
C-Me	22.76	23.45	23.35
O-Me	55.37	56.17	56.13
C=O	116.01	167.01	167.15
	165.58		

a) Data for benzene-carbons were omitted. b) (2-methoxyethoxymethyl) carbons from the terminal: 59.04, 68.48, 71.73, and 98.05 respectively.

(**27**) through hydrogenolysis into the corresponding methyl-branched amino sugar (**25**) followed by *N*-benzoylation. However, the 4-*O*-(2-methoxyethoxymethyl) group of **27** could not be removed. Treatment of **27** with 2-propanethiol and boron trifluoride etherate[9] gave unchanged **27**, and with zinc(II) chloride[7] in dichloromethane or with 1.5 M (1 M=1 mol dm^{-3}) methanolic hydrogen chloride[10] gave 8-(2-methoxyethoxymethoxy)-7-methyl-3-phenyl-4,6-dioxa-2-azabicyclo[3.3.1]non-2-ene (**29**) in 63 and 60% yields, respectively.

From the aforementioned result, benzyl group was chosen as the protecting group. Benzylation[11] of **9** with benzyl trichloroacetimidate and trifluoromethanesulfonic acid[12] was successfully proceeded to give the corresponding 4-*O*-benzyl derivative (**15**) in 62% yield, which was then debenzoylated to give **16**. Oxidation of **16** with pyridinium chlorochromate gave the corresponding pyranosid-3-ulose (**19**) in 84% yield. Cyanomesylation of **19** gave **22** in 65% yield, which was converted into the corresponding methyl-branched amino sugar (**26**) *via* the spiro aziridine derivative (**24**). Benzoylation of **26** in methanol gave the corresponding *N*-benzoyl derivative (**28**) quantitatively. Hydrogenolysis of **28** in methanol in the presence of palladium–carbon, followed by *O*-benzoylation of the product (**3**) in pyridine, was unexpectedly accompanied by anomerization to give **2** in 65% yield. This anomerization under neutral conditions was confirmed by repeated experiments. Physical constants of **2** thus obtained were identical with those reported for the sample obtained from antibiotic A35512B (see Experimental). In Table 1, ^{13}C-NMR data of **2**, **27**, and **28** were summarized. The results indicate the presence of an equatorially oriented methyl-group in these compounds,[13] and the substituent effects observed are rational to those have been reported.[14]

Experimental

Melting points are uncorrected. Optical rotations were measured with a JASCO DIP-4 polarimeter in chloroform, and ^{1}H and ^{13}C-NMR were recorded in chloroform-*d* with JEOL PS-100 and JEOL FX-90Q spectrometers, respectively, with tetramethylsilane as an internal standard, unless otherwise stated. Chemical shifts and coupling constants were recorded in δ (ppm) and Hz units, respectively, and IR frequencies in cm^{-1}.

*Methyl 3-O-Benzoyl-4-O-benzyl-6-bromo-2,6-dideoxy-α-*D*-ribo-hexopyranoside (7).* To a solution of methyl 4-*O*-benzoyl-6-bromo-2,6-dideoxy-α-D-*ribo*-hexopyranoside (1.61 g, 4.67 mmol) in *N*,*N*-dimethylformamide (10 ml) was added benzyl bromide (0.95 g, 5.61 mmol) and silver(I) oxide (1.32 g, 5.61 mmol), and the mixture was stirred in the dark for 24 h, filtered (after checking the consumption of the starting meterial with TLC), and the filtrate was evaporated. Purification of the residual sirup on a silica-gel column (benzene: acetone 16:1) gave **7** as a pale yellow sirup (1.87 g, 92.2%). $[\alpha]_D$ +65° (*c* 1.2); NMR: δ=8.27—7.96 and 7.86—7.04 (m, 10H, Bz and Ph), 5.79 (dt, 1H, $J_{3,4}$=3.0, H-3), 4.85 (dd, 1H, $J_{1,2a}$=4.0, $J_{1,2e}$=1.4, H-1), 4.79 and 4.47 (ABq, 2H, J_{gem}=11.0, CH_2Ph), 4.36 (m, 1H, H-5), 3.85—3.40 (m, 3H, H-4, 6, and 6′), 3.46 (s, 3H, OMe), 2.30 (ddd, 1H, $J_{2a,3}$=4.0, $J_{2a,2e}$=16.0, H-2a) and 2.00 (dt, 1H, H-2e).

Anal. ($C_{21}H_{23}O_4Br$) C, H, Br.

*Methyl 3-O-Benzoyl-2,6-dideoxy-β-*L*-lyxo-hexopyranoside (9).* i) A suspension of **7** (1.76 g, 4.2 mmol) and powdered dry silver(I) fluoride (1.55 g, 12.2 mmol) in dry pyridine (30 ml) was stirred for 40 h in the dark, poured into cold water, and then extracted with chloroform. The organic

layer was filtered, and evaporated. The residual yellow sirup contains 3-*O*-benzoyl-4-*O*-benzyl-2,6-dideoxy-α-D-*erythro*-hex-5-enopyranoside (**8**) and the substitution product; 6-fluoro-6-deoxy drivative in the ratio of 2:3. The mixture in methanol (20 ml) containing a few drops of acetic acid was hydrogenated in the presence of 10% palladium-carbon (200 mg) overnight. After monitering the disappearance of **8**, the usual work-up of the reaction mixture and purification of the product on a silica-gel column gave **9** (362 mg, 32.4%) as a yellow sirup. $[\alpha]_D$ −8.6° (*c* 1.4); NMR: δ=8.2—8.0 and 7.7—7.3 (m, 5H, Bz), 5.11 (ddd, 1H, $J_{2a,3}$=12.0, $J_{2e,3}$=6.0, H-3), 4.48 (dd, 1H, $J_{1,2a}$=8.6, $J_{1,2e}$=3.6, H-1), 3.83 (d, 1H, $J_{3,4}$=3.0, H-4), 3.65 (q, 1H, $J_{5,6}$=7.0, H-5), 3.53 (s, 3H, OMe), 2.20 (bs, 1H, OH), 2.17 (ddd, 1H, $J_{2a,2e}$=12.0, H-2e), 1.98 (dt, 1H, H-2a) and 1.35 (d, 3H, H-6).

Anal. ($C_{14}H_{18}O_5$) C, H.

ii) To a solution of methyl 2,6-dideoxy-β-L-*lyxo*-hexopyranoside[6] (4.93 g, 30.4 mmol) in dry pyridine (40 ml) was added benzoyl chloride (4.53 g, 32.2 mmol) dropwise at 0 °C, and the resulting solution was stirred overnight at room temperature. The usual work-up of the reaction mixture and purification of the product on a silica-gel column (benzene–acetone 8:1) gave **9** in 85.0% (6.88 g) yield. The residual part included 4-*O*-benzoyl (**10**) and 3,4-di-*O*-benzoyl derivatives.

*Methyl 4-O-Benzoyl-2,6-dideoxy-β-*L-lyxo-*hexopyranoside (**10**).* A suspension of **9** (130 mg, 0.488 mmol) and silver(I) oxide (2 g, 8.63 mmol) in DMF (20 ml) was stirred for 2 d at room temperature in the dark, and then filtered. The usual work-up of the filtrate gave **10** (130 mg) quantitatively. Mp. 122—124 °C (hexane–ethanol 1:1); $[\alpha]_D$ +30.3° (*c* 1.1). NMR: δ=8.3—8.0 and 7.7—7.3 (m, 5H, Bz), 5.26 (dd, 1H, $J_{3,4}$=4.0, $J_{4,5}$=1.0, H-4), 4.42 (dd, 1H, $J_{1,2a}$=9.5, $J_{1,2e}$=2.4, H-1), 4.03 (ddd, 1H, $J_{2a,3}$=12.2, $J_{2e,3}$=5.4, H-3), 3.72 (dq, $J_{5,6}$=6.7, H-5), 3.53 (s, 3H, OMe), 2.88 (bs, 1H, OH), 2.07 (ddd, 1H, $J_{2a,2e}$=12.0, H-2e), 1.84 (dt, 1H, H-2a) and 1.28 (d, 3H, H-6).

Anal. ($C_{14}H_{18}O_5$) C, H.

*(2-Methoxyethoxy) methylation of **9**.* i) A solution of **9** (172.5 mg, 0.648 mmol), (2-methoxyethoxymethyl) chloride (143 mg, 1.15 mmol), and *N*,*N*-diisopropylethylamine (167 mg, 1.29 mmol) in dichloromethane (10 ml) was stirred at room temperature overnight. The usual work-up of the reaction mixture gave a 1:1 mixture (226.8 mg) of methyl 4-*O*-benzoyl-2,6-dideoxy-3-*O*-(2-methoxyethoxymethyl)-β-L-*lyxo*-hexopyranoside (**11**) and its regioisomer (**12**) in 98.8% yield, which could not be separated in a pure state. Therefore, a solution of the mixture (226.8 mg) in methanol (10 ml) containing sodium (30 mg, 1.30 mmol) was stirred overnight at room temperature. The usual work-up of the reaction mixture gave a mixture (138.1 mg) of the corresponding 3-*O*-(2-methoxyethoxymethyl) (**13**) and 4-*O*-(2-methoxyethoxymethyl) (**14**) derivatives in 86.2% yield. Separation of the products on a silica-gel column (benzene–acetone 19:1) gave only a small amount of pure samples.

13: mp. 65—66 °C (hexane–ethanol 1:1); $[\alpha]_D$ −10.0° (*c* 0.9); NMR: δ=4.97 and 4.66 (ABq, 2H, J_{AB}=7.0, OCH_2O), 4.78 (dd, 1H, $J_{1,2a}$=3.0, $J_{1,2e}$=0.7, H-1), 4.12—3.72 (m, 3H, H-3, 4, and 5), 3.72—3.47 (m, 4H, OCH_2CH_2O), 3.40 (s, 3H, OMe), 3.33 (s, 3H, OMe in MEM), 1.92 (dd, 1H, $J_{2a,2e}$=9.0, H-2e), 1.82 (dd, 1H, H-2a), 1.32 (s, 1H, OH) and 1.23 (d, 3H, H-6).

Anal. ($C_{11}H_{22}O_6$) C, H.

14: mp 90—91 °C (hexane–ethanol 1:1); $[\alpha]_D$ −38.3° (*c* 1.1); NMR: δ=4.94 and 4.68 (ABq, 2H, J_{AB}=7.0, OCH_2O), 4.32 (dd, 1H, $J_{1,2a}$=9.6, $J_{1,2e}$=2.5, H-1), 3.91 (ddd, 1H, $J_{2a,3}$=9.6, $J_{2e,3}$=5.0, H-3), 3.56 (q, 1H, $J_{5,6}$=6.6, H-5), 3.54 (d, 1H, $J_{3,4}$=4.0, H-4), 3.47 (s, 3H, OMe), 3.76—3.48 (m, 4H, OCH_2CH_2O), 3.36 (s, 3H, OMe in MEM), 1.98 (ddd, 1H, $J_{2a,2e}$=12.0, H-2e), 1.67 (dt, 1H, H-2a), 1.92 (bs, 1H, OH), and 1.29 (d, 3H, H-6).

Anal. ($C_{11}H_{22}O_6$) C, H.

ii) A solution of **9** (162 mg, 0.608 mmol) and (2-methoxyethoxymethyl) trimethylammonium chloride (452 mg, 2.00 mmol) in acetonitrile (10 ml) was refluxed for 3h. The usual work-up of the mixture and purification of the product on a silica-gel column (benzene–acetone 19:1) gave sirupy **12** (215.6 mg) in quantitative yield. $[\alpha]_D$ +43.7° (*c* 1.5); NMR: δ=8.16—7.98 and 7.62—7.30 (m, 5H, Bz), 5.15 (ddd, 1H, $J_{2a,3}$=11.0, $J_{2e,3}$=6.0, H-3), 4.98 and 4.85 (ABq, J_{AB}=7.0, OCH_2O), 4.50 (dd, 1H, $J_{1,2a}$=8.0, $J_{1,2e}$=4.0, H-1), 3.91 (bd, $J_{3,4}$=3.0, H-4), 3.82 (q, 1H, $J_{5,6}$=6.6, H-5), 3.80—3.36 (m, 4H, OCH_2CH_2O), 3.52 (s, 3H, OMe), 3.28 (s, 3H, OMe in MEM), 2.16 (dt, 1H, $J_{2a,2e}$=11.0, H-2a), 2.03 (ddd, 1H, H-2e), and 1.37 (d, 3H, H-6).

Anal. ($C_{18}H_{26}O_7$) C, H.

O-Debenzoylation of thus obtained **12** (204 mg) with sodium methoxide by the aforementioned method gave **14** (126.1 mg) in 87.5% yield.

*Methyl 3-O-Benzoyl-4-O-benzyl-2,6-dideoxy-β-*L-lyxo-*hexopyranoside (**15**).* A solution of **9** (475 mg, 1.78 mmol) and benzyl trichloroacetimidate (1.35 g, 5.66 mmol) in cyclohexane (12 ml) and dichloromethane (6 ml) containing trifluoromethanesulfonic acid catalyst (0.72 ml of 0.435 M dichloromethane solution) was stirred for 3 d at room temperature. The usual work-up of the mixture and purification of the product on a silica-gel column (benzene–acetone 19:1) gave **15** (395 mg) as a sirup in 62.2% yield. $[\alpha]_D$ −2.4° (*c* 0.95); NMR: δ=8.16—7.96 and 7.68—7.20 (m, 10H, Bn and Bz), 5.18 (ddd, $J_{2a,3}$=11.5, $J_{2e,3}$=6.0, H-3), 4.82 and 4.62 (ABq, 2H, J_{AB}=12.0, CH_2Ph), 4.48 (dd, 1H, $J_{1,2a}$=8.4, $J_{1,2e}$=3.0, H-1), 3.68 (dd, 1H, $J_{3,4}$=3.0, H-4), 3.62 (dq, 1H, $J_{4,5}$=1.4, $J_{5,6}$=6.2, H-5), 3.53 (s, 3H, OMe), 2.26 (dt, 1H, $J_{2a,2e}$=11.5, H-2a), 2.07 (ddd, 1H, H-2e), and 1.29 (d, 3H, H-6).

Anal. ($C_{21}H_{24}O_5$) C, H.

*Methyl 4-O-Benzyl-2,6-dideoxy-β-*L-lyxo-*hexopyranoside(**16**).* A solution of **15** (350 mg, 0.982 mmol) in methanol (15 ml) containing sodium (40 mg, 1.74 mmol) was stirred overnight at room temperature. The usual work-up of the mixture and purification of the product on a silica-gel column (benzene–acetone 8:1) gave **16** (220 mg) in 88.7% yield. Mp. 63.5—64.0 °C (hexane–ethanol 1:1); $[\alpha]_D$ −9.5° (*c* 1.3); NMR: δ=7.52—7.20 (bs, 5H, Bn), 4.84 and 4.64 (ABq, 2H, J_{AB}=12.0, CH_2Ph), 4.49 (dd, 1H, $J_{1,2a}$=9.5, $J_{1,2e}$=2.6, H-1), 3.68 (ddd, $J_{2a,3}$=12.0, $J_{2e,3}$=5.4, H-3), 3.39 (dq, 1H, $J_{5,6}$=6.9, H-5), 3.48 (s, 3H, OMe), 3.42 (dd, $J_{3,4}$=3.0, $J_{4,5}$=1.4, H-4), 2.00 (bs, 1H, OH), 1.96 (ddd, 1H, $J_{2a,2e}$=9.6, H-2a), 1.68 (dt, 1H, H-2e), and 1.35 (d, 3H, H-6).

Anal. ($C_{14}H_{20}O_4$) C, H.

*Oxidation of **10**, **14**, and **16** into the Corresponding Pyranosid-3-uloses.* A suspension of **10** (435 mg, 1.63 mmol), pyridinium chlorochromate (PCC) (800 mg, 3.71 mmol) and a small amount of molecular sieves 3A in dichloromethane (15 ml) was stirred at room temperature overnight, and then filtered. The usual work-up of the filtrate, and purification of the product on a silica-gel column (benzene–acetone 8:1) gave methyl 4-*O*-benzyl-2,6-dideoxy-β-L-threohexopyranosid-3-ulose (**17**; 392 mg, 90.8%) as a sirup. $[\alpha]_D$ +20.0° (*c* 1.5); NMR: δ=8.2—8.0 and 7.7—7.3 (m, 5H, Bz), 5.35 (d, 1H, $J_{4,5}$=4.2, H-4), 4.87 (t, 1H, $J_{1,2a}$=$J_{1,2e}$=4.7, H-1), 4.24 (dq, $J_{5,6}$=6.8, H-5), 3.50 (s, 3H, OMe), 2.83 (d, 2H, H-2a and 2e) and 1.46 (d, 3H, H-6).

Anal. ($C_{14}H_{16}O_5$) C, H.

A similar oxidation of **14** (512 mg, 2.05 mmol) with PCC (912 mg, 4.23 mmol) gave the corresponding 3-ulose (**18**: 498 mg, 98.1%) as a sirup. $[\alpha]_D$ +27° (*c* 7.9); IR : 1740 cm^{-1} (C=O); NMR: δ=4.77 (s, 2H, OCH_2O), 4.63 (dd, 1H, $J_{1,2a}$=7.5, $J_{1,2e}$=3.4, H-1), 3.86 (bs, 1H, $J_{2e,4}$=1.4, H-4), 3.71 (q, $J_{5,6}$=6.2, H-5), 3.84—3.52 (m, 4H, OCH_2CH_2O), 3.53 (s, 3H, OMe), 3.39 (s, 3H, OMe in MEM), 2.90 (dd, 1H, $J_{2a,2e}$=

13.4, H-2a), 2.60 (ddd, 1H, H-2e), and 1.41 (d, 3H, H-6).

Anal. ($C_{11}H_{20}O_6$) C, H.

Oxidation of **16** (737 mg, 2.92 mmol) with PCC (1.50 g, 6.96 mmol) gave the product (**19**) (614 mg, 84.0%) as a sirup. $[\alpha]_D$ +40.4° (*c* 4.4); IR: 1740 cm^{-1} (C=O); NMR: δ=7.48—7.20 (m, 5H, Ph), 4.56 (dd, 1H, $J_{1,2a}$=8.0, $J_{1,2e}$=3.0; H-1), 4.68 and 4.36 (ABq, 2H, J_{AB}=12.0, CH_2Ph), 3.71 (dq, 1H, $J_{5,6}$=6.6, H-5), 3.51 (s, 3H, OMe), 3.46 (bd, 1H, $J_{4,5}$=2.0, H-4), 2.93 (dd, $J_{2a,2e}$=13.6, H-2a), 2.57 (ddd, 1H, $J_{2e,4}$=1.4, H-2e), and 1.37 (d, 3H, H-6).

Anal. ($C_{14}H_{18}O_4$) C, H.

Cyanomesylation of 17, 18, and 19. A solution of **17** (370 mg, 1.40 mmol) and hydrogen cyanide (50 mg, 1.85 mmol) in dry pyridine (8 ml) was stirred overnight at room temperature, and then methanesulfonyl chloride (964 mg, 8.42 mmol) was added to it. The reaction mixture was further stirred for 2 d at room temperature, poured into ice-water, and then extracted with chloroform. The usual work-up of the extract and purification of the product on a silica-gel column (benzene-acetone 19:1) gave methyl 4-*O*-benzoyl-3-*C*-cyano-2,6-dideoxy-3-*O*-methylsulfonyl-β-L-*lyxo*-hexopyranoside (**20**, 180 mg) as a sirup in 35% yield. NMR: δ=8.2—8.0 and 7.7—7.3 (m, 5H, Bz), 5.71 (s, 1H, H-4), 4.80 (dd, 1H, $J_{1,2a}$=9.3, $J_{1,2e}$=2.0, H-1), 4.22 (q, 1H, $J_{5,6}$=6.0, H-5), 3.61 (s, 3H, OMe), 3.20 (s, 3H, SMe), 2.84 (dt, 1H, $J_{2a,2e}$=12.5, $J_{2e,4}$=2.0, H-2e), 2.46 (dd, 1H, H-2a), and 1.33 (d, 3H, H-6).

Anal. ($C_{16}H_{19}O_7NS$) C, H, N.

Cyanomesylation of **18** (550 mg, 2.22 mmol) with hydrogen cyanide (200 mg, 7.40 mmol) and methanesulfonyl chloride (1382 mg, 12.06 mmol) in dry pyridine (10 ml) as above and purification of the product on a silica-gel column (benzen-acetone 14:1) gave the product (**21**, 570 mg) as a sirup in 72.8% yield. $[\alpha]_D$ +14.8° (*c* 1.3); NMR: δ=4.96 and 4.84 (ABq, 2H, J_{AB}=7.0, OCH_2O), 4.57 (dd, 1H, $J_{1,2a}$=9.2, $J_{1,2e}$=2.5, H-1), 3.95 (q, 1H, $J_{5,6}$=6.2, H-5), 3.92 (bs, 1H, H-4), 3.90—3.56 (m, 4H, OCH_2CH_2O), 3.54 (s, 3H, OMe), 3.39 (s, 3H, OMe in MEM) 3.25 (s, 3H, SMe), 2.67 (ddd, $J_{2a,2e}$=13.0, $J_{2e,4}$=1.0, H-2e), 2.31 (dd, 1H, H-2a), and 1.37 (d, 3H, H-6).

Anal. ($C_{13}H_{23}O_8NS$) C, H, N.

In a similar way, **19** (602 mg, 2.41 mmol) was cyanomesylated to give **22** (614 mg) as a sirup in 65.4% yield. $[\alpha]_D$ −4.95° (*c* 1.2); NMR: δ=7.6—7.2 (bs, 5H, Bn), 4.94 and 4.74 (ABq, 2H, J_{AB}=11.0, CH_2Ph), 4.59 (dd, 1H, $J_{1,2a}$=8.6, $J_{1,2e}$=3.0, H-1), 3.89 (q, 1H, $J_{5,6}$=6.4, H-5), 3.85 (s, 1H, H-4), 3.51 (s, 3H, OMe), 3.16 (s, 3H, SMe), 2.59 (dd, 1H, $J_{2a,2e}$= 12.4, H-2e), 2.40 (dd, 1H, H-2a), and 1.25 (d, 3H, H-6).

Anal. ($C_{16}H_{21}O_6NS$) C, H, N, S.

Spiro Aziridine Formation from 21 and 22. A suspension of **21** (447 mg, 1.26 mmol) and lithium aluminium hydride (72.0 mg, 1.90 mmol) in dry ether (55 ml) was refluxed for 2 h, and then a small amount of water was added to the reaction mixture. The mixture was filtered, and the ether solution was washed with water, dried, and evaporated. The residue was purified on a silica-gel column (ethyl acetate-ethanol 5:1) to give spiro [aziridine-2,3′-(methyl 2,3,6-trideoxy-4-*O*-(2-methoxyethoxymethyl)-β-L-*xylo*-hexopyranoside)] (**23**, 216 mg) as a sirup in 65.3% yield. $[\alpha]_D$ 0° (*c* 1.3); NMR: δ=4.88 and 4.66 (ABq, 2H, J_{AB}= 7.0, OCH_2O), 4.53 (dd, 1H, $J_{1,2a}$=9.6, $J_{1,2e}$=2.0, H-1), 3.85 (dq, 1H, $J_{5,6}$=7.0, $J_{4,5}$=1.4, H-5), 3.8—3.5 (m, 4H, OCH_2CH_2O), 3.68 (bs 1H, H-4), 3.49 (s, 3H, OMe), 3.37 (s, 3H, OMe in MEM), 2.75 (bs, 1H, NH), 2.31 (dd, 1H, $J_{2a,2e}$=13.8, H-2a), 1.07 (ddd, 1H, $J_{2e,4}$=1.3, H-2e), 1.95 and 1.75 (each s, 2H, CH_2N) and 1.29 (d, 3H, H-6).

Anal. ($C_{12}H_{23}O_5N$) C, H, N.

Similarly, **22** (460 mg, 1.29 mmol) was converted into the corresponding sirupy spiro aziridine (**24**, 210 mg) as above in 61.7% yield. $[\alpha]_D$ 0° (*c* 1.1); NMR: δ=7.5—7.2 (bs, 5H, Bn), 4.76 and 4.58 (ABq, 2H, J_{AB}=12.0, CH_2Ph), 4.60 (dd, 1H, $J_{1,2a}$=9.4, $J_{1,2e}$=2.4, H-1), 3.90 (dq, $J_{5,6}$=6.4, $J_{4,5}$=1.6, H-5), 3.53 (s, 3H, OMe), 2.55 (bs, 1H, H-4), 2.54 (bs, 1H, NH), 2.44 (dd, $J_{2a,2e}$=13.2, H-2a), 1.08 (ddd, 1H, $J_{2e,4}$=1.0, H-2e), 1.77 and 1.74 (each s, 2H, CH_2N) and 1.34 (d, 3H, H-6).

Anal. ($C_{15}H_{21}O_3N$) C, H, N.

4-O-(2-Methoxyethoxymethyl) (27) and 4-O-Benzyl (28) Derivatives of Methyl 3-Benzoylamino-2,3,6-trideoxy-3-C-methyl-β-L-xylo-hexopyranoside. A solution of **23** (180 mg, 0.689 mmol) in methanol (150 ml) was hydrogenolyzed in the presence of Raney nickel W-4 (2 ml) under 110 atm hydrogen at room temperature for 3 d and then filtered. The filtrate was evaporated, and the residue was benzoylated in pyridine (10 ml) with benzoyl chloride (226 mg, 1.61 mmol) in the usual manner to give sirupy **27** in 48.8% overall yield, after purification on a silica-gel column (benzene-acetone 8:1). $[\alpha]_D$ −18.8° (c 0.75); NMR: δ=7.76—7.56 and 7.48—7.30 (m, 5H, Bz), 5.85 (bs, 1H, NH), 4.92 and 4.82 (ABq, 2H, J_{AB}=6.5, OCH_2O), 4.58 (dd, 1H, $J_{1,2a}$=7.6, $J_{1,2e}$=4.7, H-1), 4.19 (bs, 1H, H-4), 3.93 (bq, 1H, $J_{5,6}$=6.4, H-5), 3.86—3.52 (m, 4H, OCH_2CH_2O), 3.51 (s, 3H, OMe), 3.40 (s, 3H, OMe in MEM), 1.70—2.00 (m, 2H, H-2e and 2a), 1.59 (s, 3H, CMe), and 1.30 (d, 3H, H-6).

Anal. ($C_{19}H_{29}O_6N$), C, H, N.

In a similar manner, **24** (190 mg, 0.722 mmol) was converted into **28** (193 mg) in 72.2% yield. Sirup; $[\alpha]_D$ −23.4° (*c* 1.6); NMR: 7.84—7.68 and 7.60—7.20 (m, 10H, Bn and Bz), 5.91 (bs, 1H, NH), 4.84 and 4.70 (ABq, 2H, J_{AB}=11.6, CH_2Ph), 4.60 (dd, 1H, $J_{1,2a}$=9.4, $J_{1,2e}$=3.0, H-1), 4.24 (bs, 1H, $J_{4,5}$=1.0, H-4), 3.95 (dq, $J_{5,6}$=6.4, H-5), 3.50 (s, 3H, OMe), 2.00 (dd, $J_{2a,2e}$=14.0, H-2a), 1.76 (ddd, 1H, $J_{2e,4}$=1.0, H-2e), 1.62 (s, 3H, CMe), and 1.32 (d, 3H, H-6).

Anal. ($C_{22}H_{27}O_4N$) C, H, N.

Attempted O-De (2-methoxyethoxy) methylation of 27. i) A solution of **27** (20 mg, 0.054 mmol) and zinc(II) bromide (64.5 mg, 0.286 mmol) in dichloromethane (2 ml) was stirred at room temperature overnight. The reaction mixture was washed with sodium hydrogencarbonate solution, and the usual work up, and purification of the product on a preparative TLC (benzene-acetone 14:1) gave 8-(2-methoxyethoxymethoxy)-7-methyl-3-phenyl-4,6-dioxa-2-azabicyclo[3.3.1]-non-2-ene (**29**) as a sirup in 63.3% (11.6 mg) yield. $[\alpha]_D$ −35° (*c* 1.3); NMR: δ=8.00—7.84 and 7.48—7.20 (m, 5H, Ph), 5.61 (t, 1H, $J_{1,2a}$=$J_{1,2e}$=2.0, H-1), 4.84 (s, 2H, OCH_2O), 3.90 (dq, 1H, $J_{5,6}$=6.7, $J_{4,5}$=1.8, H-5), 3.48 (bs, 1H, H-4), 3.84—3.44 (m, 4H, OCH_2CH_2O), 3.40 (s, 3H, OMe in MEM), 2.25 (dd, 1H, $J_{2a,2e}$=13.2, H-2a), 1.40 (s, 3H, CMe), 1.41 (dt, 1H, $J_{2e,4}$=1.4, H-2e), 1.20 (d, 3H, H-6).

Anal. ($C_{18}H_{25}O_5N$) C, H, N.

ii) Treatment of **27** (20 mg, 0.054 mmol) with 1.5 M hydrochloric acid in methanol (5.0 ml) for 15 min refluxing temperature gave also **29** (10.0 mg) in 59.6% yield.

Methyl 4-O-Benzoyl-3-benzoylamino-2,3,6-trideoxy-3-C-methyl-α-L-xylo-hexopyranoside (2). A solution of **28** (102 mg, 0.276 mmol) in methanol (20 ml) was hydrogenated overnight at room temperature in the presence of 10% palladium-carbon (100 mg), and then filtered. The filtrate was evaporated, and the dried residue was treated with benzoyl chloride (359 mg, 2.55 mmol) in pyridine (10 ml) at room temperature overnight. The usual work-up of the reaction mixture, and purification of the product on a silica-gel column (benzene-acetone 8:1) gave **2** (69.1 mg) in 65.3% yield.

Mp. 178—179°C (hexane-ethanol 1:1); $[\alpha]_D$ −191° (*c* 1.0, MeOH); MS: *m/z* 383 (M^+ for $C_{22}H_{25}O_5N$), 351 (M^+-CH_3OH); UV (EtOH): 231, 270, and 280 nm; CD: $\Delta\varepsilon$ 238.5=−11.3 (θ=−23.3 °M); NMR: δ=8.24—8.04, 7.90—7.80, and 7.64—7.35 (m, 10H, 2×Bz), 7.90 (bs, 1H, NH), 5.93 (bs, 1H, $J_{4,5}$=1.0, H-4), 5.00 (bd, 1H, $J_{1,2a}$=3.5, H-1), 4.33 (dq, $J_{5,6}$=6.5, H-5), 3.52

(s, 3H, OMe), 2.19 (dd, $J_{2a,2e}$=14.5, H-2a), 1.87 (bd, 1H, H-2e), 1.60 (s, 3H, CMe), and 1.15 (d, 1H, H-6). These data are identical with those of reported.[2]

(Received April 19, 1984)

A peptide with the amino acid sequence proposed for a heat-stable enterotoxin (STh) produced by a human strain SK-1 of enterotoxigenic *Escherichia coli* was synthesized by a conventional method. Synthetic STh evoked fluid secretion in suckling mice at a dose of 0.8 ng, which is similar to the effective dose of native STh. The fluid secretion was completely inhibited by antisera raised against the native toxin. Furthermore, synthetic STh showed the same ^1H-NMR spectrum and heat-stability as native STh.

Recently, we[1-3] isolated and purified two heat-stable enterotoxins (named STh and STp) that were produced by enterotoxigenic *Escherichia coli* strain SK-1 and strain 18D, respectively, originated from human patients with diarrhea. We determined the sequences of the 19 and 18 amino acid residues of these enterotoxins to be as shown in Fig. 1. Lallier *et al.*[4,5] and Ronnberg *et al.*[6] also isolated ST's from the culture supernatants of enterotoxigenic *E. coli* strain F11(P155) of porcine origin and strain C57/26C2 of human origin and determined their amino acid sequences. These sequences were identical to that of STp determined by us.[3] Our investigations[1-3,7] and those of others[4-6,8] showed that the characteristic features of these heat-stable enterotoxins were as follows: 1) STh and STp have much structural similarity except in a few N-terminal residues. 2) One-third of the amino acid residues are half-cystine residues, which are located in identical positions in the two toxins and are joined intramolecularly by disulfide linkages. 3) The minimum effective doses of the two toxins are similar in suckling mouse assays. 4) The toxicities of STh and STp are both neutralized by both anti-STh and anti-STp antisera. These findings suggested that the common amino acid sequences of STh and STp are very important for expression of their ST toxicity. However, since it is difficult to isolate much toxin from the culture supernatants of bacteria, little is known about the biological and physicochemical properties or the structure-activity relationship of ST, except that it may be involved in the guanylate cyclase–cyclic GMP system.[9-12]

This study was carried out as part of a study on the molecular conformation-activity relationship of ST to confirm the primary structure proposed for STh and to develop a method for synthesizing the large amounts of STh necessary for biological studies. The following paper[13] deals with the synthesis of several shorter analogs of STh and the structure-activity relationship of STh.

Experimental

The general experimental and analytical methods used were described in the preceding paper.[14] YMC-packed column of ODS A-324 (10×300 mm) was obtained from Yamamura Chemical Laboratory Co. Ltd. (Kyoto). LiChrosorb RP-8 (5 μm particle size) was purchased from Merck Japan and packed into a column (8×300 mm) in our laboratory. Aminopeptidase M was obtained from Protein Research Foundation (Minoh, Osaka). Synthetic peptides were hydrolyzed in 4M (1 M=1 mol dm^{-3}) methanesulfonic acid or a mixture of 6 M HCl and propionic acid (v/v, 1/1) in evacuated sealed tubes at 110 °C for 24 h, and amino acids in the hydrolysates were analyzed in a Hitachi type-835 amino acid analyzer. Native STh was isolated from the culture supernatant of enterotoxigenic *E. coli* strain SK-1 and finally purified by high-performance liquid chromatography, as described previously.[2] The abbreviations used in this paper are those recommended by the IUPAC-IUB [*J. Biol. Chem.*, **247**, 977 (1972)]. Additional abbreviations are: MBzl, *p*-methylbenzyl; TFA, trifluoroacetic acid; DMF, *N,N*-dimethylformamide; TEA, triethylamine; DMSO, dimethyl sulfoxide.

††† Present address: The Institute of Medical Science, The University of Tokyo, Shirokanedai 4-6-1, Minato-ku, Tokyo 108.

DCHA (48.1 g, 95.0 mmol) was dissolved with H-Tyr-OBzl·TosOH (54.7 g, 124 mmol) and TEA (4.00 ml) in $CHCl_3$ (1 l) and cooled below −10 °C. The solution was mixed with DCC (21.6 g, 104.5 mmol) and stirred at the same temperature for 1 h and then at room temperature overnight. The precipitate formed was filtered off and the filtrate was concentrated to a syrup under reduced pressure, dissolved in AcOEt and washed successively with 0.1 M HCl, 5% aq $NaHCO_3$, and water. The washed solution was dried over anhydrous Na_2SO_4 and concentrated under reduced pressure to a syrup, which was crystallized from AcOEt and hexane; wt 39.4 g (71.7%), mp 136—138 °C, $[\alpha]_D^{22}$ −28.1° (*c* 1.0, DMF).

Found: C, 66.83; H, 6.69; N, 4.89; S, 5.47%. Calcd for $C_{32}H_{38}O_6N_2S$: C, 66.41; H, 6.62; N, 4.84; S, 5.54%.

*Boc-Gly-Cys(MBzl)-Tyr-OBzl (**Ib**).* Compound **Ia** (39.4 g, 68.0 mmol) was dissolved in a mixture of CH_2Cl_2 (60 ml) and TFA (60 ml). The solution was stirred at room temperature for 40 min and concentrated to dryness under reduced pressure. The residue was repeatedly flushed with CH_2Cl_2 under reduced pressure to give a crystalline material, which was dissolved in DMF (500 ml). The solution was stirred with Boc-Gly-ONSu (21.3 g, 78.2 mmol) and *N*-methylmorpholine (15.0 ml) at 2—3 °C overnight. Then it was concentrated under reduced pressure to a syrup, which was dissolved in AcOEt and washed successively with 0.1 M HCl, 5% aq $NaHCO_3$ and water. The washed solution was dried over anhydrous Na_2SO_4 and then concentrated to a syrup under reduced pressure. The syrup was twice crystallized from AcOEt, ether and hexane; wt 37.4 g (86.5%), mp 79.5—81 °C, $[\alpha]_D^{22}$ −21.2° (*c* 1.0, DMF).

Found: C, 63.31; H, 6.58; N, 6.32; S, 5.13%. Calcd for $C_{34}H_{41}O_7N_3S \cdot 1/2H_2O$: C, 63.33; H, 6.57; N, 6.52; S, 4.97%.

*Boc-Cys(MBzl)-Thr-N_2H_3 (**Ic**).* Boc-Cys(MBzl)-OH·DCHA (52.8 g, 104 mmol) was dissolved with H-Thr-OEt·HCl (24.8 g, 135 mmol) and TEA (4.3 ml) in $CHCl_3$ (1 l). The solution was cooled below −10 °C, mixed with DCC (23.6 g, 114 mmol) and then stirred at the same temperature for 1 h and at room temperature overnight. The precipitate formed was filtered off and the filtrate was concentrated to a syrup under reduced pressure. The syrup was dissolved in AcOEt and washed successively with 0.1 M HCl, 5% aq $NaHCO_3$, and water. The washed solution was dried over anhydrous Na_2SO_4 and concentrated to a syrup under reduced pressure. The syrup was dissolved in EtOH (500 ml), mixed with 100% hydrazine hydrate (25.2 ml), and stirred at room temperature overnight. The gelatinous solid formed was collected with ether and reprecipitated twice from MeOH and ether; wt 37.5 g (81.9%), mp 125—127 °C, $[\alpha]_D^{22}$ −19.7° (*c* 1.0, DMF).

Found: C, 54.12; H, 7.54; N, 12.70; S, 7.15%. Calcd for $C_{20}H_{32}O_5N_4S$: C, 54.53; H, 7.32; N, 12.72; S, 7.28%.

Boc-Cys(MBzl)-Thr-Gly-Cys(MBzl)-Tyr-OBzl (1). Compound **Ib** (35.0 g, 55.0 mmol) was dissolved in TFA (100 ml) and stirred at room temperature for 1 h. The solution was concentrated to a solid under reduced pressure. Meanwhile, compound **Ic** (29.1 g, 66.0 mmol) was dissolved in DMF (150 ml) and cooled to −40—−50 °C. The solution was mixed with 4.39 M HCl in dioxane (45.1 ml) and isopentyl nitrite (9.7 ml) and stirred at −20 °C for 30 min. Then it was mixed with *N*-methylmorpholine (21.8 ml) and a solution of the above solid in DMF. The mixture was stirred at 0—2 °C overnight in a refrigerator and then concentrated to dryness under reduced pressure. The residue was dissolved in AcOEt and washed with 0.1 M HCl, 5% aq $NaHCO_3$, and water. The precipitate formed during the washing was collected and dissolved in hot EtOH and insoluble material was filtered off. The solution was concentrated under reduced pressure to a gelatinous solid, which was crystallized from EtOH; wt 38.3 g (73.7%), mp 157.5—159 °C, $[\alpha]_D^{18}$ −29.0° (*c* 1.0, DMF).

Found: C, 62.30; H, 6.72; N, 7.58; S, 6.86%. Calcd for $C_{49}H_{61}O_{10}N_5S_2$: C, 62.33; H, 6.51; N, 7.48; S, 6.79%.

*Z-Asn-Pro-Ala-OMe (**IIa**).* Z-Pro-Ala-OMe[15] (40.8 g, 122 mmol) was hydrogenated over 5% palladium-charcoal in the presence of HCl (1 equiv) in MeOH. The catalyst was filtered off and the filtrate was concentrated to dryness under reduced pressure. The residue was dissolved with Z-Asn-ONp (52.0 g, 134 mmol) and TEA (17.1 ml) in DMF (600 ml). The solution was stirred at room temperature overnight and then concentrated to a syrup under reduced pressure. The syrup was dissolved in AcOEt and washed successively with 0.1 M HCl, 5% aq $NaHCO_3$ and water. Crystals formed during the washing procedure were collected and recrystallized from a mixture of AcOEt, EtOH, and ether containing a trace amount of water; wt 39.5 g (72.2%), mp 115.5—118.5 °C, $[\alpha]_D^{22}$ −67.8° (*c* 1.0, DMF).

Found: C, 55.31; H, 6.29; N, 12.11%. Calcd for $C_{21}H_{28}O_7N_4 \cdot 1/2H_2O$: C, 55.13; H, 6.39; N, 12.25%.

*Boc-Cys(MBzl)-Cys(MBzl)-OMe (**IIb**).* Boc-Cys(MBzl)-OH·DCHA (114.0 g, 225 mmol) and H-Cys(MBzl)-OMe·HCl (62.1 g, 225 mmol) were dissolved in $CHCl_3$ (1.5 l) and cooled below −10 °C. The solution was stirred with DCC (51.1 g, 248 mmol) at the same temperature for 1 h and at room temperature overnight. The precipitate formed was filtered off and the filtrate was concentrated to an oil under reduced pressure. The oil was dissolved in AcOEt and insoluble material was filtered off. The filtrate was washed successively with 0.1 M HCl, 5% aq $NaHCO_3$, and water, and then dried over anhydrous Na_2SO_4. The dried solution was concentrated under reduced pressure to a syrup, which was crystallized from AcOEt and ether; wt 115.3 g (97.3%), mp 101—102.5 °C, $[\alpha]_D^{23}$ −52.3° (*c* 1.0, DMF).

Found: C, 61.62; H, 7.12; N, 4.94; S, 11.61%. Calcd for $C_{28}H_{38}O_5N_2S_2$: C, 61.51; H, 7.01; N, 5.12; S, 11.73%.

*Boc-Cys(MBzl)-Cys(MBzl)-N_2H_3 (**IIc**).* Compound **IIb** (115.1 g, 210 mmol) was dissolved in a mixture of DMF (200 ml) and MeOH (500 ml). Then 100% hydrazine hydrate (52.7 g) was added and the mixture was stirred at room temperature for 24 h. The precipitate formed was collected with ether; wt 109.2 g (94.9%), mp 149.5—150.5 °C, $[\alpha]_D^{23}$ −29.8° (*c* 1.0, DMF).

Found: C, 59.26; H, 7.06; N, 10.04; S, 11.60%. Calcd for $C_{27}H_{38}O_4N_4S_2$: C, 59.31; H, 7.01; N, 10.25; S, 11.73%.

*Boc-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-OMe (**IId**).* Compound **IIa** (39.5 g, 88.0 mmol) was hydrogenated over 5% palladium-charcoal in the presence of HCl (1 equiv) in MeOH (400 ml). The catalyst was filtered off and the filtrate was concentrated to a solid under reduced pressure. Meanwhile, compound **IIc** (48.1 g, 88.0 mmol) was dissolved in DMF (500 ml) and cooled below −20 °C. The solution was stirred with 4.39 M HCl in dioxane (60.1 ml) and isopentyl nitrite (13.0 ml) at the same temperature for 30 min. Then, the solution was mixed with the above solid and *N*-methylmorpholine (29.1 ml) and stirred at 4 °C for 3 d. The solution was concentrated under reduced pressure to a syrup, which was solidified in AcOEt. The solid was dissolved in $CHCl_3$, washed with water, and then dried over anhydrous Na_2SO_4. The dried solution was concentrated under reduced pressure to a syrup, which was crystallized from a mixture of $CHCl_3$, EtOH, and ether; wt 64.6 g (88.5%), mp 183 °C, $[\alpha]_D^{23}$ −65.0° (*c* 1.0, DMF).

Found: C, 57.89; H, 6.84; N, 9.98; S, 7.60%. Calcd for $C_{40}H_{56}O_9N_6S_2$: C, 57.95; H, 6.81; N, 10.14; S, 7.74%.

*Boc-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-N_2H_3 (**II**).* Compound **IId** (45.6 g, 55.0 mmol) was dissolved in DMF (500 ml). The solution was mixed with 100% hydrazine hydrate (55 ml) and stirred at room temperature overnight. The solution was concentrated under reduced pressure to a

syrup, which was triturated in ether. The solid formed was reprecipitated from hot EtOH and ether; wt 42.7 g (93.6%), mp 188.5—191 °C, $[\alpha]_D^{23}$ −54.6° (*c* 1.0, DMF).

Found: C, 55.56; H, 6.96; N, 13.23; S, 7.50%. Calcd for $C_{36}H_{56}O_8N_8S_2 \cdot H_2O$: C, 55.30; H, 6.90; N, 13.23; S, 7.59%.

Boc-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Thr-Gly-Cys(MBzl)-Tyr-OBzl (III). Compound **I** (18.9 g, 20.0 mmol) was dissolved in TFA (40 ml) and stirred at room temperature for 40 min. The solution was concentrated to a solid under reduced pressure. Meanwhile, compound **II** (19.9 g, 24.0 mmol) was suspended in DMF (80 ml), cooled below −20 °C, and mixed with 4.39 M HCl in dioxane (16.4 ml) and isopentyl nitrite (3.4 ml). The suspension gradually became clear, and was stirred at −20 °C for 60 min. Then it was mixed with *N*-methylmorpholine (7.92 ml) and a solution of the above solid in DMF (80 ml). The mixture was stirred at 0—2 °C for 4 d and then concentrated to dryness under reduced pressure. The residue was washed with a mixture of AcOEt and water and then reprecipitated from hot EtOH and ether; wt 27.9 g (85.0%), mp 199 °C (dec), $[\alpha]_D^{18}$ −51.2° (*c* 1.0, DMSO).

Found: C, 60.15; H, 6.66; N, 9.33; S, 7.96%. Calcd for $C_{83}H_{105}O_{16}N_{11}S_4 \cdot H_2O$: C, 60.09; H, 6.50; N, 9.29; S, 7.73%.

Boc-Cys(MBzl)-Cys(MBzl)-Glu(OBu^t)-Leu-OEt (IVa). Z-Glu(OBu^t)-OH·DCHA (51.9 g, 100 mmol) was dissolved with H-Leu-OEt·HCl (23.5 g, 120 mmol) and TEA (2.80 ml) in $CHCl_3$ (1 l) and cooled below −10 °C. The solution was mixed with DCC (22.7 g, 110 mmol) and stirred at the same temperature for 1 h and then at room temperature overnight. The precipitate formed was filtered off and the filtrate was concentrated to an oil under reduced pressure. The oil was dissolved in AcOEt and washed successively with 0.1 M HCl, 5% aq $NaHCO_3$, and water. The washed solution was dried over anhydrous Na_2SO_4 and concentrated to a syrup under reduced pressure. The syrup was dissolved in MeOH (500 ml) and hydrogenated over 5% palladium-charcoal in the presence of HCl (1 equiv). The catalyst was filtered off and the filtrate was concentrated to a solid under reduced pressure. Meanwhile, compound **IIc** (49.2 g, 90.0 mmol) was dissolved in DMF (400 ml) and cooled below −20 °C. The solution was stirred with 4.39 M HCl in dioxane (60 ml) and isopentyl nitrite (13.3 ml) at the same temperature for 30 min and then mixed with *N*-methylmorpholine (29.0 ml) and the above solid. The mixture was stirred at 4 °C for 24 h in a refrigerator. The precipitate formed was filtered off and the filtrate was concentrated to a syrup under reduced pressure. The syrup was solidified in water and the solid was twice recrystallized from EtOH and water and from AcOEt and hexane; wt 64.1 g (82.9%), mp 149—152 °C, $[\alpha]_D^{23}$ −26.7° (*c* 1.2, DMF).

Found: C, 61.32; H, 7.87; N, 6.52; S, 7.29%. Calcd for $C_{44}H_{66}O_9N_4S_2$: C, 61.51; H, 7.74; N, 6.52; S, 7.47%.

Boc-Cys(MBzl)-Cys(MBzl)-Glu(OBu^t)-Leu-N_2H_3 (IV). Compound **IVa** (25.7 g, 30.0 mmol) was dissolved in MeOH (400 ml) and mixed with 100% hydrazine hydrate (30 ml). The solution was stirred at room temperature for 2 d and mixed with water. The resulting precipitate was collected by filtration and reprecipitated from EtOH and ether; wt 19.9 g (78.5%), mp 204 °C (dec), $[\alpha]_D^{23}$ −19.8° (*c* 1.0, DMF).

Found: C, 59.40; H, 7.69; N, 9.74; S, 7.53%. Calcd for $C_{42}H_{64}O_8N_6S_2$: C, 59.69; H, 7.63; N, 9.94; S, 7.59%.

Boc-Cys(MBzl)-Cys(MBzl)-Glu(OBu^t)-Leu-Cys(MBzl)-Cys-(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Thr-Gly-Cys(MBzl)-Tyr-OBzl (V). Compound **III** (16.4 g, 10 mmol) was dissolved in TFA (35 ml) and stirred at room temperature for 80 min. The solution was concentrated to a solid under reduced pressure. Meanwhile, compound **IVa** (10.1 g, 12.0 mmol) was suspended in DMF (45 ml) and cooled below −20 °C. The suspension was mixed with 4.39 M HCl in dioxane (8.2 ml) and isopentyl nitrite (1.77 ml) and stirred at the same temperature for 60 min, when it gradually became clear. The resulting solution was mixed with *N*-methylmorpholine (4.0 ml) and a solution of the above solid in DMF (40 ml). The mixture was stirred at 0 °C for 4 d in a refrigerator and then concentrated to dryness under reduced pressure. The residue was collected with AcOEt, boiled in hot EtOH, cooled to room temperature, and filtered; wt 20.1 g (85.4%), mp 220 °C (dec), $[\alpha]_D^{18}$ −47.7° (*c* 1.0, DMSO).

Found: C, 60.95; H, 6.64; N, 8.75; S, 8.19%. Calcd for $C_{120}H_{157}O_{22}N_{15}S_6$: C, 61.23; H, 6.72; N, 8.92; S, 8.17%.

Z-Asn-Tyr-OEt (VIa). Z-Asn-OH (20.0 g, 75.0 mmol) was dissolved with H-Tyr-OEt·HCl (20.3 g, 82.5 mmol) and TEA (11.6 ml) in DMF (200 ml). The solution was cooled below −10 °C and mixed with HOBt (11.1 g, 82.5 mmol) and DCC (14.7 g, 71.3 mmol). The mixture was stirred at the same temperature for 1 h and at room temperature overnight. The precipitate formed was filtered off and the filtrate was concentrated to dryness under reduced pressure. The residue was washed successively with 0.1 M HCl and water and then reprecipitated from DMF and water; wt 31.6 g (96.9%), mp 170.5—172.5 °C, $[\alpha]_D^{20}$ +12.0° (*c* 1.0, DMSO).

Found: C, 60.45; H, 5.94; N, 9.05%. Calcd for $C_{23}H_{27}O_7N_3$: C, 60.39; H, 5.95; N, 9.19%.

Z-Ser-Asn-Tyr-OEt (VIb). Compound **VIa** (9.15 g, 20.0 mmol) was dissolved in MeOH (150 ml) and hydrogenated over 5% palladium-charcoal at atmospheric pressure in the presence of HCl (1 equiv). The catalyst was filtered off and the filtrate was concentrated to a solid under reduced pressure. Meanwhile, Z-Ser-N_2H_3 (5.60 g, 20.0 mmol) was dissolved in DMF (80 ml) and cooled below −20 °C. The solution was mixed with 4.39 M HCl in dioxane (13.7 ml) and isopentyl nitrite (2.95 ml) and stirred at the same temperature for 30 min. Then, the solution was mixed with *N*-methylmorpholine (6.60 ml) and the above solid, and stirred at 0—2 °C for 2 d. The precipitate formed was filtered off and the filtrate was concentrated to dryness under reduced pressure. The residue was crystallized from AcOEt and recrystallized from hot EtOH and AcOEt; wt 8.70 g (80.0%), mp 194—196 °C, $[\alpha]_D^{25}$ +6.2° (*c* 0.9, DMF).

Found: C, 57.22; H, 5.84; N, 10.21%. Calcd for $C_{26}H_{32}O_9N_4$: C, 57.35; H, 5.92; N, 10.29%.

Z-Asn-Ser-OMe (VIc). Z-Asn-OH (13.3 g, 50.0 mmol) was dissolved with H-Ser-OMe·HCl (8.60 g, 55.0 mmol) and *N*-methylmorpholine (6.05 ml) in DMF (150 ml). The solution was cooled below −10 °C and mixed with HOBt (7.4 g, 55 mmol) and DCC (9.8 g, 47.5 mmol). The mixture was stirred at the same temperature for 1 h and at room temperature overnight. The precipitate formed was filtered off and the filtrate was concentrated to crystalline material under reduced pressure. The material was recrystallized from AcOEt; wt 16.1 g (88.0%), mp 197—199 °C, $[\alpha]_D^{25}$ +8.4° (*c* 1.0, DMSO).

Found: C, 52.33; H, 5.68; N, 11.46%. Calcd for $C_{16}H_{21}O_7N_3$: C, 52.31; H, 5.76; N, 11.44%.

Z-Asn-Ser-N_2H_3 (VId). Compound **VIc** (16.0 g, 43.6 mmol) was dissolved in DMF (300 ml), mixed with 100% hydrazine hydrate (22.0 ml), and stirred at room temperature overnight. The crystalline material formed was boiled in hot EtOH and collected after cooling; wt 16.1 g (100%), mp 209 °C (dec), $[\alpha]_D^{23}$ −3.9° (*c* 1.0, DMSO).

Found: C, 47.76; H, 5.88; N, 18.97%. Calcd for $C_{15}H_{21}O_6N_5 \cdot 1/2H_2O$: C, 47.87 H, 5.89; N, 18.61%.

Z-Asn-Ser-Ser-Asn-Tyr-OEt (VIe). Compound **VIb** (8.70 g, 16.0 mmol) was hydrogenated over 5% palladium-charcoal in MeOH (100 ml). The catalyst was filtered off and the filtrate was concentrated to a solid under re-

duced pressure. Meanwhile, compound **VId** (6.50 g, 17.6 mmol) was suspended in DMF (100 ml) and cooled below −20 °C. The suspension was mixed with 4.39M HCl in dioxane (12.0 ml) and isopentyl nitrite (2.60 ml). The resulting solution was stirred at the same temperature for 30 min. The solution was mixed with *N*-methylmorpholine (5.80 ml) and the above solid. The mixture was stirred at 0 °C for 3 d and the precipitate formed was filtered off. The filtrate was concentrated under reduced pressure to a gelatinous solid, which was collected with AcOEt. Half the solid was boiled in hot EtOH and collected after cooling; wt 5.2 g (82.9%), mp 215 °C (dec), $[\alpha]_D^{23}$ +2.1° (*c* 1.0, DMSO).

Found: C, 52.05; H, 5.75; N, 12.81%. Calcd for $C_{33}H_{43}O_{13}N_7 \cdot 1/2H_2O$: C, 52.52; H, 5.88; N, 12.99%.

Z-Asn-Ser-Ser-Asn-Tyr-N_2H_3 (VI). Compound **VIe** (8.7 g, 8.0 mmol) was dissolved with 100% hydrazine hydrate (8.0 ml) in DMF (80 ml) and stirred at room temperature overnight. The resulting precipitate was collected with EtOH. The crystalline material was boiled in hot EtOH and filtered after cooling to room temperature; wt 5.0 g (93.9%), mp 207 °C (dec), $[\alpha]_D^{20}$ −9.2° (*c* 1.1, DMSO).

Found: C, 49.13; H, 5.88; N, 17.09%. Calcd for $C_{31}H_{41}O_{12}N_9 \cdot H_2O$: C, 49.66; H, 5.78; N, 16.81%.

Z-Asn-Ser-Ser-Asn-Tyr-Cys(MBzl)-Cys(MBzl)-Glu-Leu-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Thr-Gly-Cys-(MBzl)-Tyr-OBzl (VII). Compound **V** (1.18 g, 0.5 mmol) was dissolved with anisole (0.2 ml) in TFA (10 ml) and stirred at room temperature for 2 h. The solution was concentrated under reduced pressure to a syrup. Meanwhile, compound **VI** (549 mg, 0.75 mmol) was dissolved in a mixture of DMF (5 ml) and DMSO (5 ml) and cooled below −10 °C. The solution was mixed with 4.39 M HCl in dioxane (0.51 ml) and isopentyl nitrite (0.11 ml) and stirred at −10 °C for 60 min. Then, the solution was mixed with *N*-methylmorpholine (1.0 ml) and a solution of the above syrup in DMF (5 ml). The mixture was stirred at 0 °C for 10 d, concentrated under reduced pressure, and then mixed with EtOH. The precipitate formed was collected, boiled in hot EtOH, and collected after cooling to room temperature; wt 1.13 g (78.0%), mp 214 °C (dec), $[\alpha]_D^{18}$ −40.0° (*c* 1.0, DMSO). Amino acid ratio in the acid hydrolysate: Asp, 2.93 (3); Thr, 0.97 (1); Ser, 1.61 (2); Glu, 1.03 (1); Pro, 0.98 (1); Gly, 1.00 (1); Ala, 1.04 (1); 1/2Cys, not determined; Leu, 1.05 (1); Tyr, 1.93 (2).

Found: C, 58.11; H, 6.40; N, 10.41; S, 6.76%. Calcd for $C_{142}H_{178}O_{32}N_{22}S_6 \cdot H_2O$: C, 58.50; H, 6.22; N, 10.57; S, 6.60%.

Deprotection, Air-oxidation and Purification of Toxic Peptides. Compound **VII** (290 mg, 100 μmol) was treated with anhydrous liquid hydrogen fluoride (10 ml) containing anisole (0.87 ml) at 0—2 °C for 60 min. The HF-reagent was removed under reduced pressure and the residue was dissolved in 99% formic acid (3.0 ml). The solution was washed three times with hexane and diluted with water to 5×10^{-5} M concentration of the peptide. The solution was adjusted to pH 8.0 by adding aqueous ammonia and kept at room temperature for 4 d with occasional stirring. Then it was adjusted to pH *ca.* 7.0 by adding glacial acetic acid and divided into two portions, which were each applied to a column (3×25 cm) of DEAE-Sephadex A-25 (acetate form). The adsorbed material was washed with water and eluted with 1500 ml of a linear gradient of 0 to 0.5 M AcOH. Fractions with toxicity were collected and lyophilized. The lyophilized material was purified on a reversed-phase column (Merck, LiChrosorb RP-8 5 μm, 8×300 mm) by HPLC with a linear gradient of 10% to 35% acetonitrile in 0.01 M ammonium acetate (pH 5.7). Fractions of eluate with toxicity were collected and lyophilized; wt 4.90 mg (4.8%).

Aminopeptidase M Digestion of ST_h. Native or synthetic ST_h (*ca.* 100 μg) was dissolved in 0.1 M Tris HCl buffer (100 μl) at pH 7.6 and digested with aminopeptidase M (5 μg) for 30 min at 40 °C. The reaction was stopped by addition of 1 M formic acid (100 μl). The solution was directly applied to a YMC-packed column ODS A-324 (10×300 mm) and the adsorbed material was eluted with a linear-gradient of 10—45% acetonitrile in 0.05% hexafluorobutyric acid (pH 2.51).

Biological Assay. ST activity was assayed in suckling mice of 2—4 d old, as described previously.[1]

Results and Discussion

Synthesis. First the protected linear peptide **VII** with the whole amino acid sequence of ST_h was prepared, as shown in the scheme in Fig. 2. Then the protecting groups of **VII** were removed by treatment with anhydrous liquid hydrogen fluoride.[16] The free linear peptide thus obtained was spontaneously air-

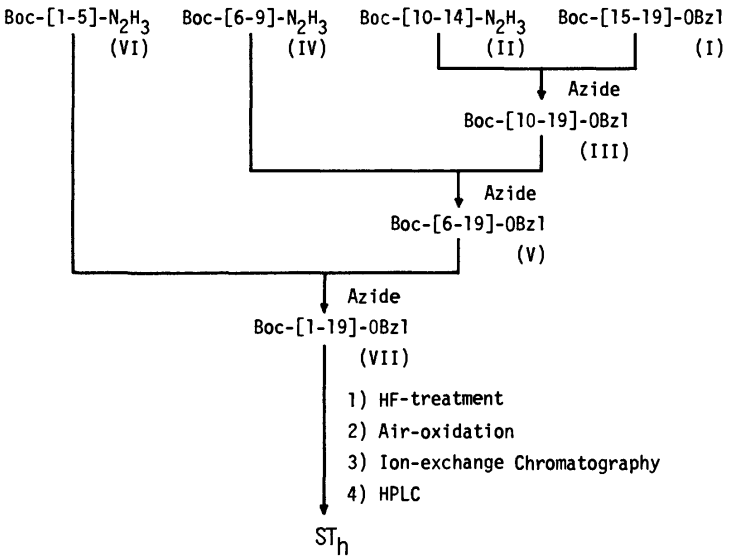

Fig. 2. Scheme for synthesis of ST_h.

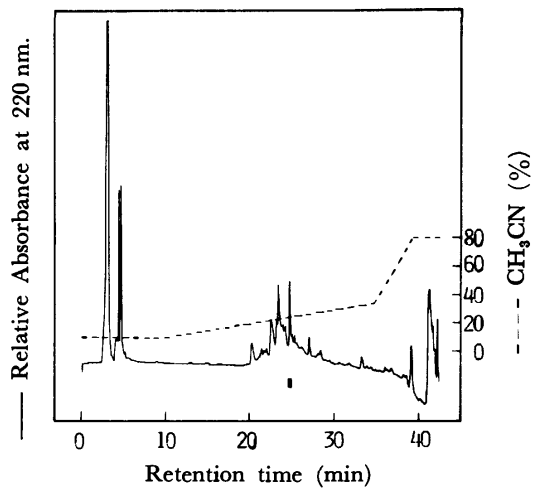

Fig. 3. HPLC profile on a LiChrosorb RP-8 column (5 μm, 4×250 mm) of HF-treated and air-oxidized solution of compound **VII**. The peak marked by a black bar showed toxicity.

oxidized in dilute solution (5×10^{-5}M) at pH 8.0 at room temperature. The air-oxidized solution was examined by high-performance liquid chromatography (HPLC) and results are shown in Fig. 3. Peak fractions were separated and toxicity of each was examined by the fluid accumulation test in suckling mice.[1] High toxicity was observed in the peak fraction shown by a black bar. This fraction was purified by ion-exchange chromatography followed by HPLC. The purified fraction had the same retention time on HPLC as native ST_h under two different conditions, as shown in Fig. 4. The yield of this fraction was 4.8% on the basis of the amount of the protected peptide **VII**. This yield was not surprisingly low, because there are 15 possible modes of formation of ST_h with three disulfide linkages from a linear peptide of ST_h and the environment for formation of disulfide linkages used in this work might be different from that in a biological system. The amino acid composition of synthetic ST_h agreed well with the theoretical one, as shown in Table 1.

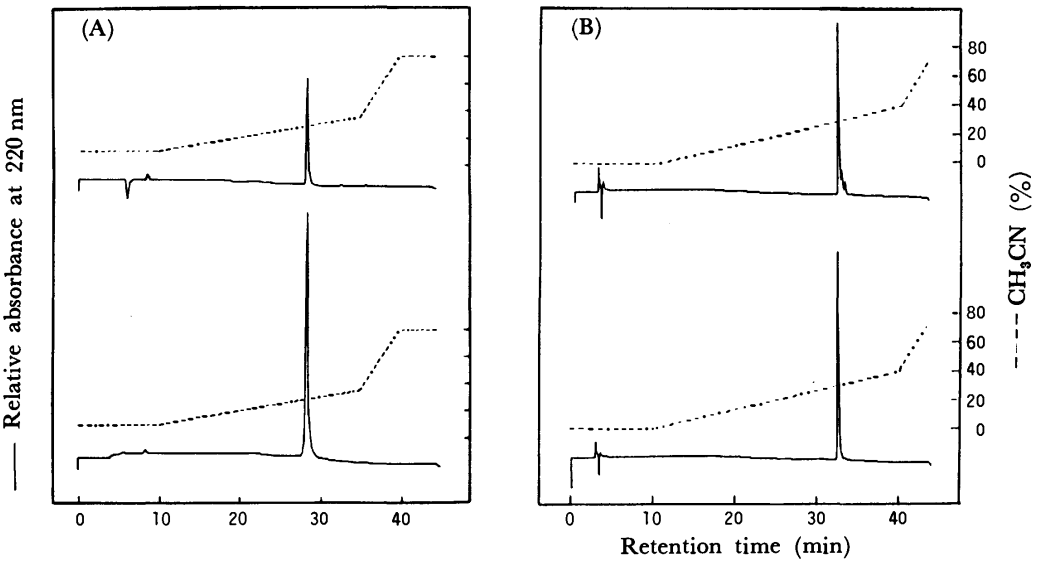

Fig. 4. HPLC profiles of native ST_h (upper) and synthetic ST_h (lower). (A) Column, LiChrosorb RP-8 (5 μm, 8×300 mm); starting solvent, 10% CH_3CN in 0.01 M $AcONH_4$ (pH 5.7). (B) Column, LiChrosorb RP-8 (5 μm, 4×250 mm); starting solvent, 10% CH_3CN in 0.05% TFA (pH 2.35).

Table 1. Amino acid compositions of synthetic and enzymatic-degraded peptides of ST_h[a]

	Synthetic			Native		
	ST_h	ST_h[3-19][b]	ST_h[4-19][b]	ST_h[c]	ST_h[3-19][d]	ST_h[4-19][d]

a) Values were calculated as mol/mol of Ala; numbers in parentheses indicate nearest integer values; b) Preparations from synthetic ST_h; c) Values cited from Ref. 2; d) Preparations from native ST_h.

Biological Activities. The toxicity of synthetic peptide ST_h was examined by the fluid accumulation test in suckling mice. The minimum effective dose of synthetic ST_h was 0.8 ng/100 μl, which was almost the same as that of native ST_h, as shown in Table 2. Furthermore, the toxicity of synthetic ST_h was neutralized not only by homologous anti-native ST_h antiserum but also by heterologous anti-native ST_p antiserum.[7]

Aminopeptidase M Digestion of Native and Synthetic ST_h. To obtain evidence that the synthetic ST_h had the same spacial structure as the native toxin, we treated synthetic and native ST_h with aminopeptidase M and compared the digests by HPLC, as shown in Fig. 5. The profile of the digest of synthetic ST_h was very similar to that of native ST_h. The peak fractions were separated and analyzed as described in the following paper.[13] The two major fractions were identified as ST_h[3-19] and ST_h[4-19], in which two and three N-terminal amino acid residues, respectively, of ST_h were removed. The minor peak fraction between undigested ST_h and ST_h[3-19] was identified as that of peptide ST_h[2-19] lacking the N-terminal Asn residue of ST_h. The same results were obtained on analysis of native ST_h, providing evidence that synthetic ST_h has the same structure as native ST_h.

Proton NMR Spectra. To confirm that synthetic peptide ST_h had the same tertiary structure as native ST_h, including the positions of disulfide linkages, we measured the 500 MHz ^{1}H-NMR spectra of synthetic and native ST_h. As shown in Fig. 6, the proton chemical shifts of synthetic ST_h were superim-

TABLE 2. BIOLOGICAL PROPERTIES OF SYNTHETIC ST_h

	Minimum effective dose (ng/100 μl)*	Neutralization by anti-native ST_h antiserum
Native ST_h	1.0	+
Synthetic ST_h	0.8	+

* Calculated from the recovery of amino acids in acid hydrolysates.

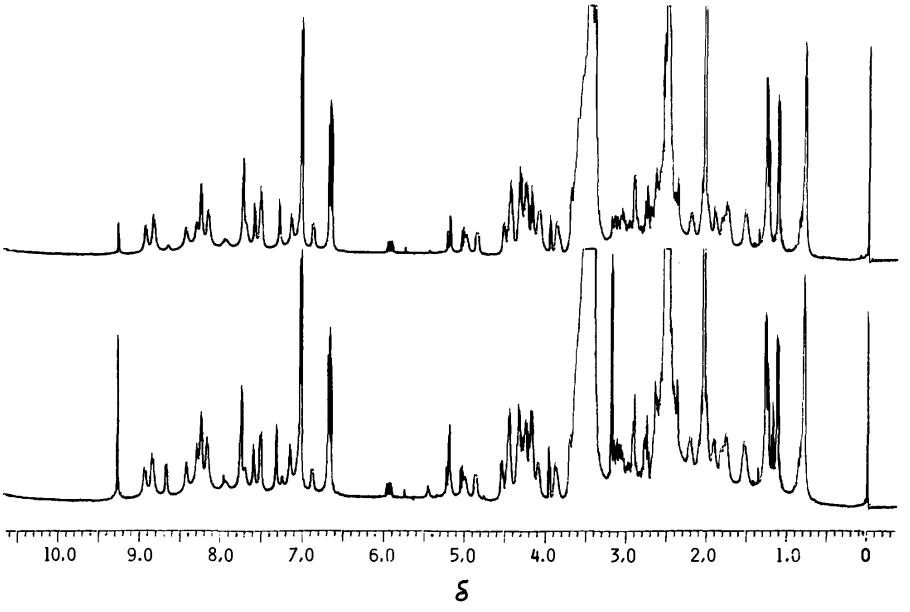

Fig. 6. 500 MHz ^{1}H-NMR spectra of synthetic ST_h (upper) and native ST_h (lower).

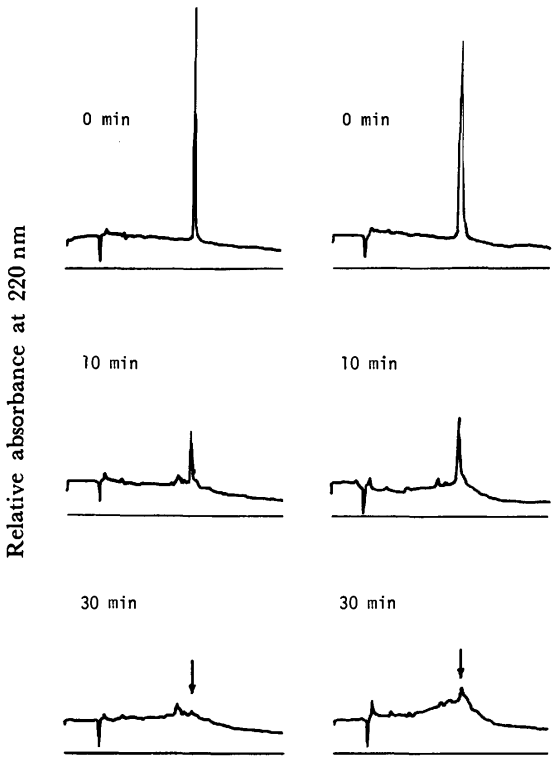

Fig. 7. HPLC profiles on a LiChrosorb RP-8 column (5 μm, 4×250 mm) of heat-treated native ST_h (left column) and synthetic ST_h (right column). The column was developed with a linear-gradient of 10 % to 35 % CH_3CN in 0.01 M $AcONH_4$ (pH 5.7) with increase of 1 %/min of CH_3CN at a flow rate of 0.5 ml/min.

posable on those of native ST_h, indicating that the synthetic peptide had the same three dimensional structure as native toxin.

Heat-stability We examined the heat-stability of synthetic ST_h by HPLC, as described previously.[17] Synthetic ST_h was confirmed to be stable on heating at 100 °C for 30 min like native ST_h, as illustrated in Fig. 7.

Thus, the synthetic ST_h obtained was found to be identical to native ST_h with respect to its physicochemical and biological properties, providing evidence that the amino acid sequence proposed for ST_h, a heat-stable enterotoxin of a human strain SK-1 of enterotoxigenic *Escherichia coli*, is correct. Furthermore, a method was developed for obtaining much toxin. The synthetic ST_h will be used for elucidating the biochemical and biological properties of ST and also for detecting ST-producing bacteria, which are very important epidemiologically.

This work was partly supported by a Grant-in-Aid for Scientific Research (No. 58122002) from the Ministry of Education, Science and Culture of Japan.

(Received April 19, 1984)

For examination of the structure-activity relationship of ST_h, five shorter analogs of ST_h lacking one to five N-terminal amino acid residues of ST_h were synthesized. The synthetic peptides were confirmed to have the same intramolecular disulfide linkages as those in native ST_h. These peptides caused fluid accumulation in the intestine of suckling mice at almost the same molar levels as that of native ST_h. The toxicities of these peptides were also neutralized by antisera raised against native ST_h. These results indicated that the toxic and antigenic sites of ST_h are both located in the amino acid sequence between the Cys residue at the 5th position from the N-terminus and the C-terminal Tyr residue.

Heat-stable enterotoxins (named ST_h and ST_p) have been isolated from various strains of enterotoxigenic *Escherichia coli* and their amino acid sequences of 19 and 18 residues, respectively, have been determined[1-7] to be as shown in Fig. 1. These toxins are very similar in primary structure and have the same amino acid sequence from the Tyr residue near the N-terminus to the Tyr residue at the C-terminus, except at position 4 from the C-terminus. Six half-cystine residues are conserved in the same relative positions and are linked intramolecularly by disulfide bonds. These facts suggest that the common sequence is important for the toxicity and heat-stability of the toxins. However, it is difficult to obtain a large amount of the toxin from the culture supernatant of the bacteria, and so apart from these suggestion from the primary structures, little is known about the biological properties of the toxin, except that it seems to act on the guanylate cyclase-cyclic GMP system.[8-11] In the preceding paper,[12] we reported a method for chemical synthesis of ST_h in large quantity. This made it possible to investigate the biochemical and biological properties of the toxin and its analogs.

As part of an investigation of the structure-activity relationship of ST_h, in this work, we synthesized several shorter analogs of ST_h. We also found that a sequence lacking the five N-terminal amino acid residues of ST_h, which is identical to that of ST_p except for the 4th residue from the C-terminus, has the same biological properties as those of native ST_h.

Experimental

The general experimental and analytical methods used were described in the preceding paper.[12] The abbreviations used in this paper are those recommended by the IUPAC-IUB [*J. Biol. Chem.*, **247**, 977 (1972)]. Additional abbreviations are: MBzl, *p*-methylbenzyl; TFA, trifluoroacetic acid; DMF, *N,N*-dimethylformamide; TEA, triethylamine; DMSO, dimethyl sulfoxide.

*Z-Ser-Ser-OMe (**Ia**).* Z-Ser-N_2H_3 (12.7 g, 50.0 mmol) was dissolved in DMF (200 ml) and cooled below −20 °C. The solution was mixed with 4.39M HCl (1M=1 mol dm^{-3}) in dioxane (34.2 ml) and isopentyl nitrite (7.40 ml), stirred at the same temperature for 30 min, and then mixed with H-Ser-OMe·HCl (8.6 g, 55 mmol) and *N*-methylmorpholine (16.5 ml). The mixture was stirred at 3 °C for 24 h in a refrigerator. The precipitate formed was removed by filtration and the filtrate was concentrated to dryness under reduced pressure. The residue was triturated and recrystallized from AcOEt; wt 13.6 g (79.9%), mp 142—142.5 °C, $[\alpha]_D^{25}$ +10.1° (*c* 1.1, DMF).

Found: C, 52.94; H, 5.89; N, 8.28%. Calcd for $C_{15}H_{20}O_7N_2$: C, 52.94; H, 5.92; N, 8.23%.

*Z-Ser-Ser-N_2H_3 (**Ib**).* Compound **Ia** (5.1 g, 15 mmol) was dissolved with 100% hydrazine hydrate (7.50 ml) in MeOH. The solution was stirred at room temperature overnight, and the precipitate formed was collected and boiled in hot MeOH. The mixture was cooled and the precipitate was collected by filtration; wt 3.6 g (70.5%), mp 205 °C (dec), $[\alpha]_D^{25}$ +16.0° (*c* 0.9, DMF).

Found: C, 48.99; H, 5.90; N, 16.40%. Calcd for $C_{14}H_{20}O_6N_4$: C, 59.41; H, 5.92; N, 16.46%.

*Z-Ser-Ser-Asn-Tyr-OEt (**Ic**).* Z-Asn-Tyr-OEt[12] (5.95 g, 13.0 mmol) was dissolved in MeOH (100 ml) and hydrogenated over 5% palladium-charcoal at atmospheric pressure. The catalyst was filtered off and the filtrate was concentrated to a solid under reduced pressure. The solid was collected with ether. Meanwhile, compound **Ib** (3.40 g, 10.0 mmol) was dissolved in DMF (80 ml) and cooled below −20 °C. The solution was mixed with 4.39M HCl in

dioxane (8.2 ml) and isopentyl nitrite (1.77 ml) and then stirred at the same temperature for 20 min. The solution was mixed with *N*-methylmorpholine (3.96 ml) and the above solution of the solid in DMF (20 ml). The solution was stirred at 2—3 °C for 3 d and concentrated to dryness under reduced pressure. The residue was triturated in AcOEt and the resulting precipitate was twice reprecipitated from EtOH and AcOEt; wt 3.2 g (50.7%), mp 180.5—183 °C, $[\alpha]_D^{25}$ +7.1° (*c* 1.1, DMF).

Found: C, 53.31; H, 5.95; N, 10.72%. Calcd for $C_{29}H_{37}O_{11}N_5 \cdot H_2O$: C, 53.62; H, 6.05; N, 10.78%.

*Z-Ser-Ser-Asn-Tyr-N_2H_3 (**Id**).* Compound **Ic** (3.5 g, 5.5 mmol) was dissolved in DMF (30 ml) and mixed with 100% hydrazine hydrate (2.75 ml). The mixture was stirred at room temperature overnight and the precipitate formed was collected with EtOH. The precipitate was boiled in EtOH, cooled to room temperature, and filtered; wt 3.3 g (92.0%), mp 218 °C (dec), $[\alpha]_D^{25}$ −6.5° (*c* 1.0, DMSO).

Found: C, 51.56; H, 5.71; N, 15.82%. Calcd for $C_{27}H_{35}O_{10}N_7 \cdot 1/2H_2O$: C, 51.75; H, 5.79; N, 15.65%.
