Partial Molar Volumes in Aqueous Mixtures of Nonelectrolytes. I. *t*-Butyl Alcohol

Masao SAKURAI
Department of Polymer Science, Faculty of Science, Hokkaido University, Sapporo 060
(Received April 9, 1986)

The densities of mixtures of *t*-butyl alcohol (TBA) with water (W) have been measured at various temperatures over a wide range of concentrations. From these data the apparent ($V_{\phi,2}$) and partial (V_2) molar volumes as well as partial molar expansibilities (E_2) have been evaluated for both components. The limiting partial molar volumes, V^{∞}_{TBA} and V^{∞}_{W}, were smaller than the molar volume of TBA and water, respectively, at all temperatures studied. The values of E^{∞}_{TBA} was negative at temperatures below 15 °C and the value of E_W was also negative at all temperatures. Characteristic extrema were observed for the $V_{TBA}(X_{TBA})$ and $E_{TBA}(X_{TBA})$ curves in the water-rich region and for the $V_W(X_W)$ curve in the TBA-rich region. The unusual volumetric behavior found for the TBA-water mixtures at both ends of the composition may be attributed to the formation of strong hydrogen bonding between water and TBA molecules and to the unique properties of pure water, itself (i.e., the very small size of water molecules and the existence of a cluster structure).

There have been a number of studies on the volumetric behavior of mixtures of water with nonelectrolytes. Most of them have concerned water-rich solutions and have discussed structural changes of the solvent water caused by the introduction of nonpolar groups (i.e., so-called hydrophobic hydration or iceberg formation).

In 1959 Kauzmann turned his attention to data concerning negative volume changes during the transfer of hydrocarbons from nonpolar solvents to water and pointed out that iceberg formation results in a large decrease in volume.[1] He regarded this fact as a clear indication that the structures present in an iceberg are quite different from those in ordinary ice; in other words, an iceberg has a more dense structure than that of ordinary ice. On the other hand, Némethy and Scheraga,[2] Franks,[3] and Desnoyers and Arel[4] have postulated that an iceberg has a bulky structure like ordinary ice but that the increase in the volume due to iceberg formation can be largely overcome by the loss of free space due to the filling of solutes in the cavities of the iceberg. At present the latter interpretation appears to be generally accepted by many authors.

In any event, however, they have assumed *a priori* that the volume change accompanying iceberg formation can be estimated directly from measurements of the volume change during the transfer of nonpolar solutes from a nonpolar medium to water. This is apparently an oversimplified assumption. A volume change upon mixing two liquids can arise from a variety of origins. In their review article Handa and Benson[5] pointed out the following factors: (1) Differences in the sizes and shapes of the component molecules, (2) differences in the intermolecular interaction energy, (3) structural changes, and (4) the formation of new chemical species. In my opinion, many authors have overestimated factor (3) in order to interpret the unusual volumetric behavior of aqueous mixtures. It should be noted, furthermore, that the exact nature of icebergs has remained obscure; consequently, the volume change accompanying iceberg formation is still open to question. As has been claimed by Hvidt[6] and Nakajima et al.,[7] there is no explicit evidence as to whether iceberg formation results in an increase or decrease in volume.

It is well known that many unusual thermodynamic and spectroscopic properties have been observed for dilute aqueous solutions of *t*-butyl alcohol (TBA).[3,8,9] These have, in general, been interpreted in terms of an iceberg formed around the *t*-butyl group in water. Thus, TBA has been regarded as a typical hydrophobic structure-maker, although TBA is completely miscible with water in any proportion at room temperature (i.e., very hydrophilic in nature).

While many authors have reported the partial molar volumes of TBA in aqueous solutions,[10-18] precise studies of water dissolved in TBA (i.e., the partial molar volume of water in the TBA-rich region) are scare. It would be interesting to investigate the behavior of water in the absence of the characteristic structure of liquid water in order to clarify the interactions between water and TBA. The purpose of this study is to present precise density data regarding TBA-water mixtures at various temperatures over the whole concentration range, whenever possible, and to discuss the partial molar volume behavior at both ends of the concentration range.

Experimental

The solution densities, ρ, were measured using an oscillating-tube densimeter (DMA 60) that was described earlier.[19] In this study, two measuring cells (DMA 601) were used under the operation of a phase locked loop (PLL) mode in order to minimize the drift of period measurements. In most case the solutions were prepared by successive additions of a concentrated solution or a pure solute to a known quantity of solvent. The addition was carried out by

weight in a mixing chamber connected to the measuring cell with a teflon tube and a flow pump.

For very dilute solutions of water in TBA, the measurements were carried out as before.[20] The water concentration was determined with an automatic Karl-Fischer titration apparatus (Hiramuma, AQ 3) immediately after density measurements for each solution.

Water and TBA were purified as before,[20] the latter being further purified by fractional crystallization. No trace of impurities in the TBA was detected using gas chromatography.

Results and Discussion

In a mixture of components 1 and 2, the apparent molar volume of the component 2, $V_{\phi,2}$, is given by

$$V_{\phi,2} = X_1M_1(\rho_1^*-\rho)/X_2\rho_1^*\rho + M_2/\rho, \quad (1)$$

where X and M are the mole fraction and the molar mass of the component 1 or 2 and ρ_1^* is the density of component 1. The density of water, ρ_w^*, was taken from Kell.[21] The density of pure TBA, ρ_{TBA}^*, was determined by extrapolating the ρ values to infinite dilution. The estimated values of ρ_{TBA}^* are 0.77940, 0.77529, 0.77008, 0.76476, and 0.75937 g cm^{-3} at 26, 30, 35, 40, and 45 °C, respectively.

In Fig. 1 the apparent molar volumes of TBA, $V_{\phi,TBA}$, at 25 °C are compared with various values from the literature and generally show good agreement. In particular, the values in extremely dilute solutions given by Franks and Smith[12] are in excellent agreement with the present data within the experi-

mental uncertainty of the density measurement: $\delta\rho=\pm 2\times 10^{-6}$ g cm^{-3}.

Limiting Partial Molar Volume. For very dilute solutions, the apparent molar volume of solute 2 can be represented by a linear form:

$$V_{\phi,2} = V_2^\infty + A_2 m, \quad (2)$$

where V_2^∞ is the limiting partial molar volume of component 2, A_2 an empirical constant, and m the molality. The results for TBA in water and for water in TBA are plotted in Figs. 2 and 3, respectively, and the parameters of Eq. 2 are summarized in Table 1. The value of V_{TBA}^∞ at 25 °C is in good agreement with that from the literature: 87.82,[12] 87.90,[13] 87.73,[14] and 87.76 cm^3 mol^{-1}.[15] No precise V_W^∞ data were available with which the presented results could be compared.

The temperature dependence of V_{TBA}^∞ is shown in Fig. 4, including the results for *n*-butyl alcohol (NBA) solutions obtained by Nakajima et al.[7] The values of V_{BA}^∞ are smaller than the molar volumes of neat butyl alcohols, V_{BA}^*, at all temperatures. Figure 5 shows the temperature dependence of the excess limiting partial molar volume defined by

$$V_{BA}^E = V_{BA}^\infty - V_{BA}^*. \quad (3)$$

The values of V_{TBA}^* below 25 °C were evaluated from the temperature dependence of the densities of neat TBA. As described in the Introduction, a negative V_2^E has, in general, been regarded as a characteristic of iceberg formation.[1-4,8,9] If this is relevant the negative V_2^E would have to be reduced as the temperature is raised, since water structural effects become progressively reduced with increasing temperature. Thus, Kauzmann[1] has explained the larger negative values of V_2^E at lower temperatures for aliphatic hydrocarbon in water reported by

35	88.20	−1.68			
45	88.75	−1.26			

Masterton;[22] he had explained his results in terms of a break down of the water structure around hydrocarbons. On the contrary, Fig. 5 shows that the value of V^E_{BA}, as well as for many other alcohols, becomes very strongly negative as the temperature is increised. This is more significant for V^E_{TBA} than V^E_{NBA}.

Evidently, a complicated situation can take place through an assumption that the observed volume change in the transfer of nonpolar solutes from nonpolar medium to water is taken just as the volume change accompanying iceberg formation. Volume changes must arise from a number of factors, not only from iceberg formation even in aqueous systems.

The large negative V^E_2 observed for aqueous systems can be well explained in terms of the unique properties of solvent water itself, not the water-structural change caused by the introduction of solutes. Recently, Lee[23] investigated the partial molar volume based on a hard-sphere mixture model and clearly showed that the negative volume change is due to the small size of water molecules. This is the same conclusion that was postulated earlier by Assarsson and Eirich.[24] On the basis of the scaled particle theory, French and Criss[25] wrote: "The small V_2 values of nonelectrolytes in water are understandable in light of the low compressibility of water. Structural considerations are not neccessary." In addition, the linear correlation between the partial molar volumes of solutes and the compressibility coefficients of solvents has been illustrated by Hamilton and Stokes[26] and Dack.[27] That is to say, the volume of liquids is primarily given by the repulsive forces of hard spheres. Therefore, the greatest part of the negative V^E_2 observed for aqueous systems can be ascribed to the fact that the free volume in water or in dilute aqueous mixtures is considerably smaller than that in most organic systems, while the solute-solvent hydrogen bonding probably plays a role in the volume change for polar mixtures. Thus, the negative temperature dependence of V^E_{BA} (Fig. 5) can be interpreted in terms of the difference in the expansibilities of neat butyl alcohols and aqueous butyl alcohol solutions. The pronounced effect for TBA, compared to NBA, can also be explained by the fact that the expansivity of neat TBA (α=1.294 kk^{-1} at 25 °C) is much larger than that of neat NBA (α=0.948 kK^{-1} at 25 °C).

On the basis of the thermodynamic relation

$$(\partial C_p/\partial P)_T = -T(\partial^2 V/\partial T^2)_p, \quad (4)$$

Hepler[28] has postulated a criterion for discriminating between solutes in water as being "structure maker" or "structure breaker." It is well known that the limiting partial molar expansibility, $E^\infty_2(=\partial V^\infty_2/\partial T)$, of various alcohols in water greatly decreases with decreasing temperature (that is $\partial^2 V^\infty_2/\partial T^2>0$; therefore, alcohols have been regarded as structure makers), and it is in some cases negative at low temperatures.[7,15,29] In fact, Fig. 4 shows that the $V^\infty_{TBA}(T)$ curve passes through a minimum at about 15 °C. The results coincide with a prediction from the fact that the temperature of maximum density (TMD) of dilute TBA solutions is higher than that of pure water (3.98 °C).[30,31] The TMD of D_2O (11.23 °C) is higher than that of H_2O; this is one piece of evidence for supporting the idea that D_2O is more structured than H_2O at ordinary temperatures.[32] In analogy with this consideration, it is possible to consider that the introduction of TBA brings about a solvent water with more structure. Such a consideration leads us to the idea that iceberg formation is accompanied by a positive volume change;[6,7,33] this is in conflict with the generally accepted view.

However, structural considerations based on the sign of $\partial^2 V_2/\partial T^2$ or the shift in TMD also lead to the conclusion that benzene has little influence on the structure of water and that aliphatic hydrocarbon is a structure breaker.[28,30] This conclusion may be essentially in conflict with the definition of an iceberg. Furthermore, it should be noted that an anomalous negative expansibility has been observed even for the organic solvent systems described below.

The limiting partial molar volumes of water, V^∞_W, in TBA are plotted as a function of temperature in Fig. 6, together with V^∞_W in the other three isomeric butyl alcohols.[20,34] The values of V^∞_W are always smaller than the molar volume of water, V^*_W. This is probably due to a large V^*_W resulting from the water cluster, in addition to the factors operating in V^E_2 for aqueous solutions as pointed out before. It is of interest that for four butyl alcohol solvents the V^∞_W in TBA alone decreases monotonously as the temperature is increased. Such a negative E^∞_2 behavior in organic solvents has been also observed for urea in methanol[26]

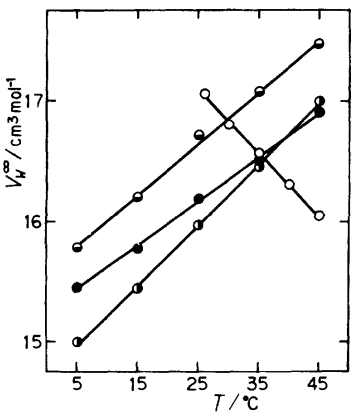

Fig. 6. Limiting partial molar volumes of water in four isomeric butanols.
○: TBA, ●: NBA,[20] ◑: isobutyl alcohol,[34] ◒: s-butyl alcohol.[34]

and water in methanol,[20] but is highly pronounced for the present system. Needless to say, in the absence of the water structure in the TBA-rich region, the volumetric behavior is not explicable by the structural change of water. Both the negative E^{∞}_{TBA} and E^{∞}_{W} may arise from a more effective packing due to a difference in the size and the strong hydrogen bonding between water and TBA molecules.

Concentration Dependence of Apparent and Partial Molar Volumes. The empirical constant A_2 of Eq. 2 is associated with solute-solute interactions. The values of A_{TBA} and A_W estimated from Figs. 2 and 3, respectively, are plotted in Fig. 7; this includes, for comparison, the values for NBA-water mixtures.[7,20] For dilute aqueous alcohol solutions the A_2 value is negative and becomes more negative with increasing the size of the hydrocarbon group and decreasing the temperature.[7,14] Therefore, such a negative A_2 value has, in general, been ascribed to iceberg formation.[4] As can be seen from Fig. 7, the A_{BA} values for aqueous TBA and NBA solutions are comparable with each other at all temperatures, while it has often been considered that the structural effect of TBA is much larger than that of NBA.[9] The absolute values of A_W are very small compared to those of A_{BA}. As will be described below, the variation of A_2 values with the size of solutes may mostly depend on the molar scale employed in Eq. 2. This problem is closely associated with the difference in the molality range in which Eq. 2 holds for an aqueous TBA solution (Fig. 2) and for a solution of water in TBA (Fig. 3).

From the $V_{\phi,2}$ values, the partial molar volume of component 2 at finite concentrations is given by

$$V_2 = V_{\phi,2} + X_1X_2(\partial V_{\phi,2}/\partial X_2)_{T,P} \quad (5)$$

The values of $(\partial V_{\phi,2}/\partial X_2)_{T,P}$ were evaluated by a local fitting procedure[35] in which five consecutive values of $V_{\phi,2}$ were represented by a quadratic equation in a certain mole fraction range.

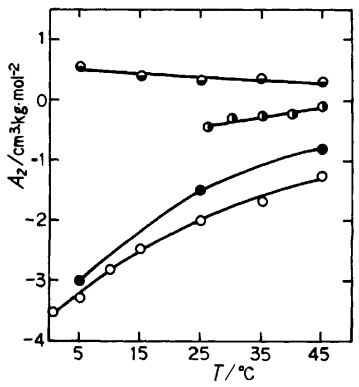

Fig. 7. Coefficient A_2 of Eq. 2 as a function of temperature.
○: TBA in water, ●: NBA in water,[7] ◑: water in TBA, ◒: water in NBA.[20]

Figure 8 shows the concentration dependences of the apparent and partial molar volumes of TBA and water over the whole mole fraction range at 35 °C. As is well known, the $V_{TBA}(X_{TBA})$ curve has a sharp minimum at a very low mole fraction. It is worth noting that the $V_W(X_W)$ curve also has a minimum, though not so outstanding compared to that for V_{TBA}. This obscure minimum in the $V_W(X_W)$ curve is apparently due to a comparison based on the molar scale. When the molar masses of the two components in binary mixtures differ significantly (M_{TBA} is about 4 times M_W), it may be better to compare the extent of the volume change based on the unit-mass scale rather than the molar scale. Figure 9 illustrates the apparent and partial specific volumes of TBA and water as a function of the weight fraction of TBA. The depth and the position of the two minima are comparable with each other. Thus, the volumetric behavior of the TBA-water mixture is unusual at both ends of the

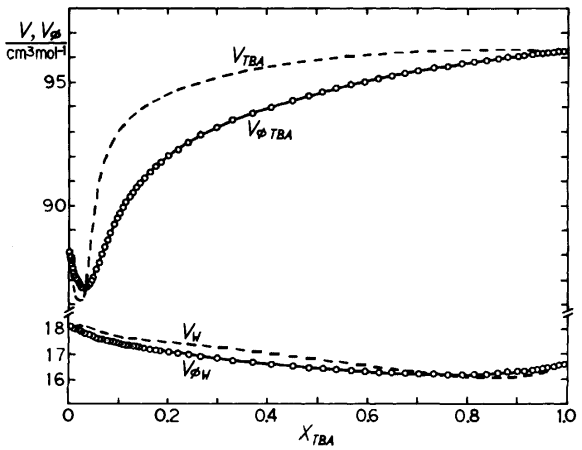

Fig. 8. Apparent and partial molar volumes of TBA and water in their mixtures as a function of mole fraction of TBA.

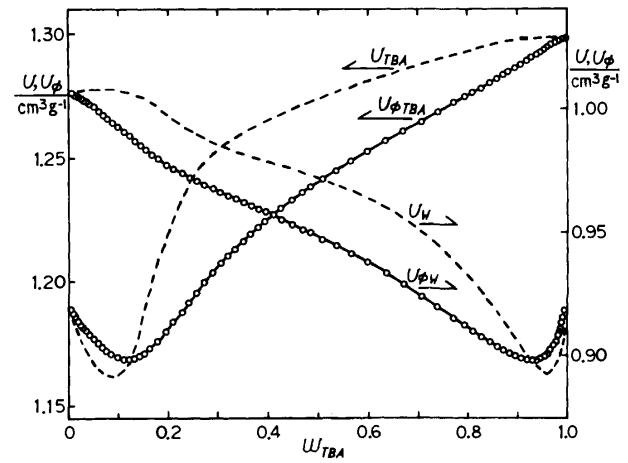

Fig. 9. Apparent and partial specific volumes of TBA and water in their mixtures as a function of weight fraction of TBA.

concentration range.

In Fig. 10 are shown the concentration dependences of V_{TBA} in the water-rich region at various temperatures. The appearance of the characteristic minimum in dilute aqueous solutions has also been associated with iceberg formation on the basis of the fact that it becomes more pronounced and shifts to a lower concentration as the alkyl group increases in size.[3,8] As can be seen from Fig. 10, the minimum is similarly more pronounced but occurs at a higher concentration as the temperature is lowered. On the other hand, Nakagawa et al.[36] have reported that the increase in the pressure also causes a more pronounced minimum and shifts it to a higher concentration. That is to say, such a minimum behavior is affected in a similar manner by a decrease in the temperature and by an increase in the pressure, both of which bring about a decrease in the volume in the usual way. The explanation of the minimum by using iceberg formation is, therefore, not consistent since iceberg formation may be less significant with both the increases in the temperature and the pressure.

It is worth noting that a similar behavior is found for the $V_W(X_W)$ curves in Fig. 11, where the minimum is also very pronounced and shifts to a higher concentration with decreasing temperature. A minimum in the $V_W(X_W)$ curve has been observed in tetrahydrofuran,[37] but not in *n*-alcohols.[20]

The appearance of a minimum in the $V_2(X_2)$ curve at a certain concentration means that the packing of the component molecules takes place more effectively up to this concentration. The exact nature of such a packing effect is not clear since the concentration dependence is a very complex phenomenon and is attributable to various types of solute-solvent and solute-solute interactions, which may include the destruction of self-associations in water and in TBA and the formation of hydrogen-bonded associations between water and TBA molecules.

Figure 12 shows the partial molar expansibilities, $E_2(=\partial V_2/\partial T)$, of TBA and water at 40 °C over the whole mole fraction range. The $E_{TBA}(X_{TBA})$ curve is characterized by a remarkable maximum and an

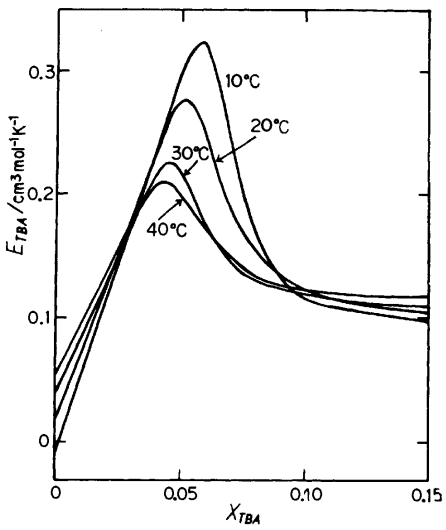

Fig. 13. Partial molar expansibilities of TBA in the water-rich region at various temperatures.

indistinct minimum at low X_{TBA}. The variation of the maximum with temperature is shown in Fig. 13. The maximum is more pronounced and occurs at higher concentration as the temperature is decreased. These are analogous to the minimum behavior in V_{TBA} (Fig. 10). However, it is noteworthy that the concentration of the maximum in E_{TBA} is higher than that for the minimum in V_{TBA}; i.e., the position of the E_{TBA} maximum coincides with that where V_{TBA} increases abruptly beyond the minimum with increasing concentration.

On the other hand, no extremum is found for the $E_W(X_W)$ curve in the TBA-rich regions. Consequently, the appearance of the E_{TBA} maximum may be associated with the destruction of the water structure. The expansibility of dilute aqueous TBA solutions is unusually small through the existence of the cluster structure of water initially present in solvent water. As the concentration is increased, the water cluster is progressively disrupted and the expansibility of the solution increases most steeply at the concentration referring to the E_{TBA} maximum. A further addition of TBA may extinguish most of the bulky water structure, and the volumetric behavior of the solution approximates more and more closely to that of neat TBA. In fact, Fig. 8 and 12 show that the values of V_{TBA} and E_{TBA} slightly depend on the mole fraction for $X_{TBA}>0.1$ and are comparable to those for neat TBA.

Conclusion

The characteristic volumetric behavior observed for dilute aqueous TBA solutions has been generally interpreted in terms of iceberg formation around the *t*-butyl group. The present study clearly shows that some anomalies can be found for the TBA–water mixture at both ends of the concentration. This fact confirms my suspicion that the volumetric behavior of aqueous TBA solutions may be irrelevant to iceberg formation. The peculiarity of the TBA–water mixture may be mainly attributed to the very small radius of water molecules, strong hydrogen-bonding between water and TBA molecules, and the cluster structure of pure water; not to iceberg formation by the introduction of TBA molecules.

The author wishes to thank Dr. Nobumichi Ohno, Akita National College of Technology, for drawing his attention to this problem. Financial support of this work which came from a Grant-in-Aid for Scientific Research by the Ministry of Education, Science and Culture is gratefully acknowledged.

Band Shape of Photoelectron Spectrum and Potential Energy Curve for Alkylamine

Masao TAKAHASHI,* Iwao WATANABE, and Shigero IKEDA

Department of Chemistry, Faculty of Science, Osaka University,
Toyonaka, Osaka 560
(Received May 6, 1986)

Accurate measurements of UPS and ab initio potential energy calculations have been carried out for ammonia and several alkylamines to interpret the band shape of the UPS. Theoretical photoelectron band shape was obtained by a simple Franck-Condon approach. The calculation predicted very well the alkyl substitution effects on the ionization potentials and on the band widths of the first bands in UPS for the alkylamines. The following conclusions were obtained by comparing these theoretical photoelectron bands with experimental ones. The threshold ionization potential observed in the UPS is not always thermodynamically adiabatic ionization energy, but it can be subject to hot bands. Adiabatic ionization potential I_{Pa} of ammonia is concluded to be 10.08 eV. And the values of I_{Pa} for a series of alkylamines are evaluated by taking account of molecular vibrational frequency for the neutral state.

Though numerous investigations on UV photoelectron spectra (UPS) for free molecules have been executed, most of them have been concerned only with their ionization energies. We have been interested in the information obtainable from the band shape of the UPS. Our attention has been paid to the first band of the UPS corresponding to the ionization of a HOMO electron which must play the most important role with respect to the chemical reactivity of the molecule. The band shape of the UPS is related to the degree of distortion in the molecular structure after the photoionization, viz., the larger the distortion, the wider the band width.[1] The distortion also occurs after one-electron oxidation in solution, so that the degree of distortion must affect kinetics of electrochemical oxidation reaction. We obtained accurate UPS for a series of alkylamines,[2] and found that the band width of the first band for amine molecule correlates with one of the kinetic parameters, transfer coefficient (symmetry factor), for electrochemical oxidation reaction in solution and qualitatively showed that both the band width and the transfer coefficient reflect the character of potential energy curves for neutral and cationic state.[3]

Nitrogen skeleton of amine of the neutral state is known to be pyramidal[4,5] and that of the cationic state planar.[6,7] Thus the equilibrium structure of the amine cation radical differs substantially from that of the neutral one. It results in a broad first band in the UPS with a long vibrational progression though the HOMO, from which an electron is removed, is a nonbonding orbital consisting mainly of nitrogen 2p orbital. In order to discuss the band feature of the UPS, the Franck-Condon factor for the transition from the neutral to cationic potential energy surface is necessary. The Franck-Condon factors were calculated and reported for simple molecules[8,9] by many workers. The calculations for ammonia were also performed and the first band of its UPS was theoretically obtained.[10] However the potential energy surfaces of neutral alkylamines and the corresponding cation radicals are far more complex and have not yet been calculated.

One must also pay attention to whether the adiabatic ionization potential, I_{Pa}, can be determined from the UPS for the molecule which undergoes large change in its geometry after the photoionization process. For ammonia it remains uncertain whether the first peak in the vibrational progression for the first band corresponds to I_{Pa} or not.[6b,11] It is known that the photoionization processes corresponding to I_{Pa} are intrinsically unobservable for water dimer molecule[12] and van der Waals molecules composed of inert gas atoms.[9]

We carried out ab initio MO calculations for ammonia, mono-, di-, and trimethylamine and mono-, di-, and triethylamine, with several different geometries both for the neutral and cationic states and obtained potential energy curves on the deformation coordinate of the bending vibration. Theoretical photoelectron band can be derived from the potential energy curves by using a simple Franck-Condon approach. The band shape of UPS theoretically obtained will be compared with the experimental UPS data to test the validity of the present approach. The effects of the alkyl substitution on the band shape and ionization potentials are also studied.

Experimental

The experimental setup for the UPS measurements has been presented elsewhere[2] and will be outlined here. The ionization energy scale was calibrated with either argon (I_P=15.759 eV) or xenon (I_P=12.130 eV) used as an internal reference. The instrumental resolution was 20—30 meV. The spectrometer was kept at about 300 K and the temperature of the ionization chamber was higher by about 20 K because of the heat of a helium discharge lamp. For a low vapor pressure sample of tripentylamine the spectrometer was heated to 307 K to obtain sufficient vapor pressure. The spectral data for the first bands corresponding

to the ionization of HOMO electron were accumulated more than 25 times. All the samples were commercial products and the samples obtained in the form of aqueous solutions were evaporated from the solution by adding sodium hydroxide.

Vertical ionization potential I_{Pv} was read at the maximum of the most intense vibrational component of the first band when vibrational progressions were well resolved. Threshold ionization potential I_{Pth} was read at the first vibrational peak of the band. For the molecule which displays no vibrational fine structure, I_{Pv} was read at the maximum of the band, and I_{Pth} was determined as follows. We took the point where the spectral intensity was 1% of the band maximum over the threshold region as the onset of the band. Then the I_{Pth} was obtained by adding 0.15 eV to the onset. 0.15 eV (0.148±0.017 eV) is the average distance between the onset and the first vibrational peak of the band for those molecules which display vibrational progressions. Bandwidth δ was determined from the full width at half-maximum (FWHM) of the first band. When the band displayed vibrational fine structure, the δ was read from the FWHM of the envelope connecting vibrational peaks. Though the accuracies of I_P and δ depend on the band shape, we believe that they are better than 0.02 eV.

Computational Procedure

In the present work, we performed ab initio MO calculations for ammonia, mono-, di-, and trimethylamine, *N,N*-dimethylethylamine and mono-, di-, and triethylamine. Calculations were carried out using the Gaussian 80 program and the IMSPACK program[13] with the minimal STO-3G basis set. For the cationic state, the open-shell calculations were performed with an unrestricted Hartree-Fock (UHF) procedure included in the programs.

The geometries for both neutral and cationic states were optimized by means of gradient method included in the Gaussian 80 program. The full-geometry optimizations were carried out except for diethylamine, *N,N*-dimethylethylamine and triethylamine, for which the structural parameters within ethyl group were fixed to the values optimized for ethylamine. The symmetries used for the calculations are; C_{3v} for ammonia and trimethylamine, C_3 for triethylamine, and C_s for all the others and also ammonia and trimethylamine. The optimized geometries are described in Fig. 1, and the structural parameters obtained are listed in Table 1. The bond lengths and angles are in good agreement with those obtained experimentally and calculated by others.[14]

As indicated in Table 1, the change in geometry of the cation radical from the neutral molecule is

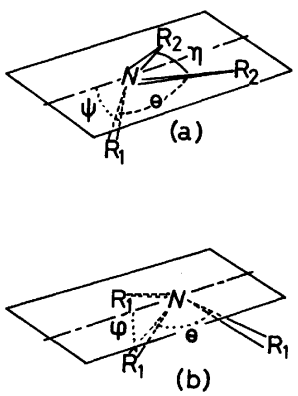

Fig. 2. Deformation angles and internal coordinates. R_1 and R_2 denote H, CH_3, or C_2H_5. (a) for C_s symmetry and (b) for C_3 and C_{3v}.

ψ and ϕ are the angles defined in Fig. 2. Values in parenthesis are calculated for the planar form, i.e. ψ or $\phi=0°$. The following parameters are fixed for the neutral and the cationic state respectively, for diethylamine (H_2-C_1; 0.1093 and 0.1096, H_3-C_2; 0.1086 and 0.1087, H_2-C_1-N; 110.5 and 105.6, H_3-C_2-C_1; 110.5 and 110.0) and for triethylamine(C_1-H_1; 0.1093 and 0.1096, C_2-H_2; 0.1086 and 0.1087, H_1-C_1-N; 110.5 and 105.6, H_2-C_2-C_1; 110.5 and 110.0), and are fixed for both the neutral and the cationic states for *N,N*-dimethylethylamine (C_1-H_1; 0.1090, C_2-H_2; 0.1090, C_3-H_3; 0.1090, H_1-C_1-N; 110.0, H_2-C_2-C_1; 109.5, H_3-C_3-N; 110.0).

remarkable only in ψ or ϕ, which denotes the deformation angle as shown in Fig. 2. The first band of the UPS for the alkylamine has a very strong vibrational progression which corresponds to the deformation vibration. Thus we chose a potential energy curve on the coordinate of ψ or ϕ, for the calculation of theoretical band of the UPS. Potential energy curves were also calculated by using the angles HNH for methylamine and CNC for dimethylamine as the reaction coordinates. During the calculations other structural parameters were fixed at the optimized values for the neutral state.

Results and Discussion

Observed Spectra. The He(I) photoelectron spectra of various alkylamines were previously reported.[2] The report includes their expanded first bands which are broad and are ascribable to the photoionization of a 2p non-bonding electron on nitrogen. Vibrational progressions are observed in the first bands for all the primary amines. The first bands for some of the secondary and tertiary amines also have vibrational structures. The vibrational frequencies listed in Table 2 are to be comparable to the ones for the neutral state and will be discussed in the following section. The vibrational structures are composed almost entirely of angle deformation mode and the other vibrational modes are only slightly observable, e.g., in the case of ammonia.[6b,11]

The I_{Pv} and the I_{Pth} for alkylamines decrease in the order of primary, secondary and tertiary amine as shown in Fig. 3. They also decrease with the length of alkyl group from methyl to propyl and level off. The successive decrease in ionization potential up to

Experimental values for the cationic state are collected in this work, see also Ref. 2. a) Refs. 4 and 15a. b) Ref. 33. c) Ref. 34. d) Ref. 35. e) Vibrational mode corresponding to ψ. f) Observed in Raman spectrum, taken from Ref. 36. g) Vibrational mode corresponding to η. h) Ref. 19.

propyl substitution indicates that for the amine with smaller alkyl groups, the cationic state is stabilized to a greater extent than the neutral state by the introduction of a longer alkyl group. It is a case for a series of aliphatic alcohols, in which the I_P values continue to decrease up to butyl substitution.[29] It seems that oxygen atom being more electronegative than nitrogen exhibits electron-attracting effect extending to longer range in alcohol than that in amine.

The half width δ of the first band decreases in the order of primary, secondary, and tertiary amine as shown in Fig. 4. The systematic decrease of δ with the length of alkyl group is also indicated. However there is unexpected behavior of I_P shown in the same figure that the value of $\Delta I_{Pv,th}$, the difference between I_{Pv} and I_{Pth}, does not exhibit such trend against the alkyl substitution. We will discuss the behavior of $\Delta I_{Pv,th}$ in the following section.

Potential Energy Curves. The potential energy curves calculated for the neutral and cationic state are shown in Figs. 5 and 6. The potential energy V used in this paper is referred to the minimum of the total energy for the neutral state. Potential energy curves shown in Fig. 5 are obtained by varying ψ under C_s symmetry and those in Fig. 6a by varying ϕ under symmetry of C_{3v} for ammonia and trimethylamine and C_3 for triethylamine.

Though the potential energy curves for neutral methylamine (2) and ethylamine (5) almost overlap as shown in Fig. 5, the curve for ethylamine cation radical is steeper than that for methylamine cation radical, and this is due to the fixed geometry within the ethyl group. Same trend is seen in the case of dimethylamine (3) or diethylamine (6).

As can be seen in Fig. 5, trimethylamine (4) and *N*,*N*-dimethylethylamine (7) have steeper curves at the larger $|\psi|$ for both the neutral and the cationic state. This is considered to be due to the steric hindrance of the bulky substituent group.

The geometries optimized for neutral ammonia and the methyl amines with planar nitrogen skeleton are included in Table 1. Obvious difference in CN and/or HN bond lengths exists between the molecules with the pyramidal and the planar nitrogen skeletons. These bonds are longer in the pyramidal form than in the planar form. The differences in total energy between the pyramidal and the planar form for the neutral state are 0.48, 0.45, 0.42, and 0.45 eV for am monia, methylamine, dimethylamine, and trimeth-

ylamine, respectivery. The differences corresponding to the amino inversion barrier are larger than those previously reported.[5a, 30] The barriers determined from Figs. 5 and 6a are even higher because the geometries at ψ or ϕ=0° are not energetically optimized.[31] Furthermore neglect of configuration interaction (CI) and lack of superior basis sets may well make the potential energy curves calculated here different from the actual ones. However, the fact that the MO calculations predict the drastic change on ψ or ϕ coordinate after the ionization suggests that the most important part of the intrinsic characters of the vibration induced by photoionization are describable with the present potential energy curves.

Potential energies as a function of the angle η were also calculated for methylamine and dimethylamine and are given in Fig. 6b. Although the value of η for each cation radical with the most stable geometry in the figure is different by about 10 degrees from that for the optimized geometry of neutral molecule, the curves for cation radical and neutral molecule are similar indicating that the deformation in η after the photoionization is small.

Band Shape of the Theoretical Photoelectron Spectrum. In order to obtain an envelope of a theoretical photoelectron band, we have carried out a following simple approach. First of all, we connected ψ or ϕ with an internal coordinate θ. A harmonic oscillator approximation on $V(\theta)$ gives a force constant and then a vibrational frequency is calculated by use of Willson's ***GF*** matrix method.[32] A wave function Ψ for the harmonic vibration is also calculated. Although it is well-known that an unharmonicity exists in the deformational vibration of amine at the large amplitude, we have neglected the unharmonic terms because of the simplicity of the calculation. Next, assuming a Boltzmann distribution at 320 K which is the temperature of the ionization chamber, the population p_i on each vibrational state i is obtained. The calculated frequencies and the populations are collected in Table 2 together with the experimental frequencies for ammonia and mono-, di-, and trimethylamine. Values of calculated frequencies are not in agreement with experimental ones. However, the following facts indicate that the essential property of molecular vibration in alkylamines concerned remains in the present potential energy curves; both experiment and calculation are in agreement on the point that the NH_2 wagging frequency is lower than the symmetric NH_2 deformational frequency for methylamine and that the CNC skeletal deformational frequency is lower than the a′ N–H deformational frequency for dimethylamine.

Now the theoretical photoelectron band *f* shown in Fig. 7 is obtained as follows. The curve *c*, Ψ_0^2, is projected on the potential energy curve *a* for cation radical and weighted with p_0 for the v''=0 state. This gives us the photoelectron spectrum intensity corresponding to the ionization from v''=0. Then the photoelectron spectrum *f* is obtained as the accumulation of all the ionizations from the vibrational states whose population is larger than 1%. In Fig. 8 are shown the theoretical photoelectron spectra for amines calculated in this work. In the figure, each spectrum is shifted in energy so that the maximum corresponding to I_{Pv} comes on the same position on abscissa. It is assumed for the simplicity of the

theoretical treatment that the vibrational levels for the cationic state are continuous. This is not correct from the quantum chemical point of view. However because the vibrational symmetries for the neutral and cationic molecules are same, the curve obtained in this manner should be comparable to the envelope of the experimental photoelectron spectrum. In Fig. 8 are also shown the theoretical photoelectron bands arising from the vibration on η for methylamine and dimethylamine. Both of them are sharp and I_{Pth} is equal or close to I_{Pv}. This indicates that this kind of vibration less contributes to the band shape.

The band width δ and threshold energy I_{Pth} are determined from the theoretical photoelectron bands. The I_{Pth} is read at the onset whose intensity is 1% of the band maximum. Table 3 contains the theoretical values for δ, I_{Pth}, I_{Pa}, and I_{Pv}, together with experimental ones. The $I_{Pv}(\Delta SCF)$ is defined as a difference in total energy between the neutral and the cationic state with the same geometry which is the most stable for the neutral state. The I_{Pa} is defined as a difference in minimum total energy between the neutral and the cationic state each with the most stable geometry.

The calculated values of I_{Pth} are always larger than those of calculated I_{Pa}. This owes to the fact that the I_{Pa} is the difference in total energy between optimized geometries for the neutral and cationic state, while the I_{Pth} is evaluated by use of the potential energy curves as a function of only ψ or ϕ. That makes the total energy for cation radical at the minimum-energy point on the potential energy curve more unstable than that with the optimized geometry.[31] The theoretical values of I_{Pv}, I_{Pa}, and I_{Pth} are underestimated, and if a constant value of 3.1 eV is added to the theoretical values of I_{Pv}, they are in excellent agreement with the experimental ones. The calculations also predict the values of δ very well as shown in Fig. 9 in which the theoretical and experimental values are compared.

Band Width. The band width and the band shape depend on the following factors: (i) The difference in geometry between the neutral and cationic molecule each with the most stable geometry; (ii) the vibrational wave function for the neutral state which is based on the feature of the potential energy curve for the neutral state; (iii) the slope of the potential energy curve for the cationic state.

The calculated δ must be underestimated because the potential energy at minimum on the potential energy curve for cation radical is higher than that for the cation radical with the optimized geometry,[31] i.e., the potential energy curve for cation radical should be steeper. For ammonia and trimethylamine we have obtained the theoretical photoelectron band by two methods. One is the use of the potential energy curve for C_{3v} symmetry and the other is the use of C_s symmetry, i.e., the potential energy curve obtained as a function of ψ, while fixing the angle η to the value for the optimized geometry for the neutral state (1b and 4b in Fig. 8). δ's evaluated under the C_s symmetry have reproduced the experimental values more poorly

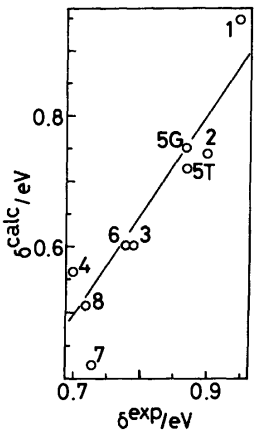

Fig. 9. Comparison between experimental and calculated δ. The notations are the same as in Table 3. G; gauche conformation. T; trans conformation.

than those under the C_{3v} symmetry. This is chiefly due to the fixed angle η.

As shown in Fig. 9 the deviation from the correlation line between experimental and calculated values is large for the case of *N,N*-dimethylethylamine. δ for this amine is quite underestimated because of the fixed CNC skeleton the same as the case of trimethylamine calculated under C_s symmetry. There is some limitation in the present method to estimate band width of the UPS, because the potential energy curve used is a cross section of potential energy hypersurface taken only on a single coordinate on which the change after the photoionization is greatest.

Threshold Ionization Potential and Potential Energy Curve. The I_{Pth} mainly depends on the next three factors: (I) The difference in the geometry between the neutral molecule and the cation radical each with the most stable structure; (II) the population on each vibrational level for the neutral state; (III) the value of vibrational probability density Ψ_0^2 for the neutral state with the geometry similar to the equilibrium geometry for the cationic state. When the difference for (I) is large, I_{Pa} may well be smaller than I_{Pth} and intrinsically undetectable in UPS. While the larger population on a higher vibrational level causes larger probability of hot band. When the value for (III) is large, I_{Pa} should be detectable. Note that even if the value for (I) is large, the large value for (III) makes I_{Pa} detectable.

It is interesting that although it is impossible to predict the values of $\Delta I_{Pv,th}$ accurately from the theoretical potential energy curves, the values of δ are predicted excellently from the curves as shown in Fig. 9 (except *N,N*-dimethylethylamine). This implies that the present potential energy curve for cation radical is distorted only around the equilibrium geometry for cation radical. With respect to *N,N*-dimethylethylamine, both δ and $\Delta I_{Pv,th}$ deviate from the correlation between experimental and calculated values. Thus the slope on the calculated curve for *N,N*-dimethylethylamine cation radical is gentler than the actual curve.

While I_P and δ systematically vary in the order of primary, secondary and tertiary amine, $\Delta I_{Pv,th}$ does not. This can be interpreted as follows. The populations on the higher vibrational levels for the neutral state increase in the order of primary, secondary and tertiary amine, since the vibrational frequency decreases in the same order. On the other hand the probability density Ψ_0^2 at the most stable geometry of cation radical decreases in the order of primary, secondary and tertiary amine. The two opposing factors result in the unsystematic order of $\Delta I_{Pv,th}$ as shown in Fig. 4.

Determination of Adiabatic Ionization Potential. The first ionization peak 10.075 eV in the UPS of ammonia, observed also by several other workers,[6b,7,11] has been regarded as the hot band.[6b,7] Population on $v''=1$ is, however, 1% as listed in Table 2, and the ratio of Ψ_1^2 to Ψ_0^2 at the equibrium geometry of ammonia cation radical is very small. Thus 0←1 ionization peak, i.e., hot band, should be indiscernible in the UPS. If the first peak were the 0←1 ionization peak, intensity of the first peak should be a few hundredth of that of the second peak according to Boltzmann distribution, since ionization cross section for the same vibrational mode is similar. The ratio of the first peak height to the second in the UPS is 0.24 and is too large to assign the first peak to 0←1 ionization peak. Then we conclude that the first peak is not the 0←1 but the 0←0 ionization peak, and that I_{Pa} is 10.08 eV. As for primary amines, the frequency of deformation vibration of ψ, viz., NH_2 wagging vibration, is in the range of 850—750 cm^{-1} from the infrared spectra of liquid phase,[36] so the population on $v''=1$ should be 2—4%. Peak height of the first peak in the vibrational progression in the first band for methylamine and ethylamine, compared to that of the second peak, however, is too large to assign the first peak to 0←1 ionization peak. Therefore the first peaks for methylamine and ethylamine pertain to the 0←0 ionization peak and the I_{Pa}'s are 8.95 and 8.78 eV, respectively.

Now we estimate I_{Pa}'s for mono-, di-, and trimethylamine and the ethylamines by use of I_{Pa}^{calcd} calculated here and experimental I_{Pth}^{exp}. I_{Pa}^{calcd} is largely underestimated because of the neglect of CI and the lack of superior basis set. So is I_{Pv}^{calcd}, but one expects that this is somewhat canceled out in the difference $\Delta I_{Pv,a}^{calcd}(=I_{Pv}^{calcd}-I_{Pa}^{calcd})$. $\Delta I_{Pv,a}^{corr}$ is obtained by adding 0.30 eV to $\Delta I_{Pv,a}^{calcd}$. The correction of 0.30 eV gives $\Delta I_{Pv,a}^{calcd}$ equal to $\Delta I_{Pv,th}^{exp}$ for methylamine and ethylamine. Finally I_{Pa} is estimated by subtracting $\Delta I_{Pv,a}^{corr}$ from I_{Pv}^{exp}. The values of I_{Pa} are included in Table 3 together with $\Delta I_{Pv,a}^{calcd}$ and $\Delta I_{Pv,a}^{corr}$. The difference between I_{Pa} and I_{Pth}^{exp} are 0.12 and 0.16 eV for trimethylamine and triethylamine, respectively. These values indicate that the hot band should be observable and that the hot band can be at least 0←2 ionization peak if considered that the frequency of the vibration of ϕ for neutral trimethylamine and triethylamine is about 0.05 eV.[36] For diethylamine the difference between I_{Pa} and I_{Pth}^{exp} is 0.05 eV, and this indicates that the hot band may be observable, or that the difference is only the error produced in the calculation because the frequency of the vibration of ψ is about 0.09 eV.[36] The difference for dimethylamine is 0.09 eV, and the hot band, 0←1 ionization peak, may exist. However, the hot band should not be observabvle, if the population p_1 and probability density Ψ_1^2 of the neutral state at the equilibrium geometry of the cation radical are considered. The hot band of dimethylamine may be due to the coupling of the vibration of ψ with other

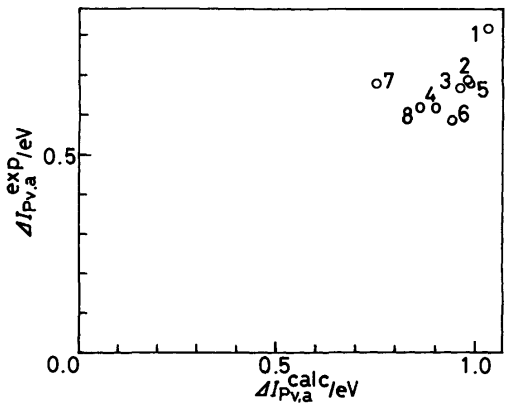

Fig. 10. Comparison between experimental and calculated $\Delta I_{Pv,a}$. The notations are the same as in Table 3.

vibrations.

According to the discussions one can estimate the thermodynamic I_{Pa} by combining photoelectron spectroscopic I_{Pth} and vibrational energy. Assuming that 0←1 and 0←2 ionizations are observable for the secondary and the tertiary amines, respectively, the values for I_{Pa} are obtained by adding 0.09 eV to I_{Pth} for the secondary and 0.10 eV for the tertiary amines and are listed in Table 3. By using the I_{Pa} obtained in this manner, we can obtain the values of $\Delta I_{Pv,a}^{exp}$, which are compared with the theoretical $\Delta I_{Pv,a}$'s in Fig. 10. The correlation indicates that 0.3 eV subtraction from the theoretical value predicts the experimental one excellently, except for ammonia, triethylamine and *N,N*-dimethylethylamine. This result also supports the present determination of the thermodynamic I_{Pa} for amines.

The authors wish to thank Professor Takayuki Fueno and Dr. Kizashi Yamaguchi, Department of Chemistry, Faculty of Engineering Science, Osaka University for the computer program of the IMSPACK revised for the computer in Osaka University. The calculations were carried out using HITAC M-200H at the computer center of IMS (Institute for Molecular Science) and ACOS NEAC 1000 at the computation center, Osaka University.

14) The calculated bond lengths and angles for ammonia, and mono-, di-, and trimethylamine agree with the experimental values[4,15-19] within a few hundredths of an angstrom and within a few degrees. The structural parameters for ethylamine are similar to those used in Ref. 20b. For mono-, di-, and triethylamine, the calculated conformations of the neutral state are in agreement with the result of experiment as follows. Most stable conformation of ethylamine has been reported to be either G (gauche) conformation with respect to the lone pair of the nitrogen,[20] or T (trans) conformation.[21] We have found that the G conformation is the most stable. However, the energy difference between these two conformations is only 8 meV which is less than the noise level of the computational technique, which is also stated in Ref. 5b. Diethylamine takes TT (trans-trans) conformation, i.e., each ethyl group has a methyl group at trans position with respect to the other ethyl group.[22] Triethylamine takes G'G'G' conformation, i.e., each of the methyl group comes to the gauche position against the lone pair and other ethyl groups.[23] While another stable conformations were reported to be present,[23,24] we have taken the conformation of this molecule as G'G'G' which is the result of the present geometry optimization. The structural parameters for the neutral ammonia and mono-, di-, and trimethylamine are in good agreement with those calculated by others.[5,25-27] The conformations calculated by L. Radom et al.[28] for the neutral methylamine, dimethylamine and ethylamine are in reasonable agreement with the present results. For ethylamine cation radical the difference in total energy between T conformation and G conformation has been only 3 meV.

(Received May 10, 1986)

The addition of talc powder in an ethanolic solution of mandelic acid gave a large change of its optical rotation. It was confirmed by absorption spectrography, thin-layer chromatography, and gas chromatography that mandelic acid was racemized at the surface of the talc powder. The IR spectra showed that racemization took place when mandelate anions adsorved weakly at the surface of the talc. It was concluded that the H atom at the C atom in the second position of a mandelate anion was adsorbed at a basic site of the talc surface to deprotonate and also that the deprotonation was enhanced by the interaction between the carboxyl group and an acidic site.

Racemization of an optically active substance is of great interest with regard to the origin of life. Furthermore, racemization is of practical importance in pharmaceutical technology. In the case of such substances as amino acids, only one enantiomer is physiologically active. The inactive enantiomer can be converted into the active enantiomer by racemization.

Previously, the authors reported mechanochemical racemization of L-leucine in the presence of such an inorganic powder as talc.[1] This paper deals with the racemization of optically active mandelic acids in suspensions of talc.

Experimental

The materials used were *S*(+)-mandelic acid [*S*(+)-α-hydroxyphenylacetic acid] and *R*(−)-mandelic acid purchased from Aldrich Chemical Co. The samples of inorganic powder used were kaolin (acid washed, American standard) of Fisher Scientific Company, talc of Sanko Seiyaku Co., SiO_2 (precipitated) of Koso Chemicals Co., and γ-Al_2O_3 of Nishio Kogyo Co. The following samples were prepared:

$Talc_{AA}$: Talc was set aside in a vapor of acetic acid at a room temperature for more than 2 d, it was then washed with ethanol several times and dried at 60 °C.

$Talc_{TEA}$: Talc was set aside in a vapor of triethylamine at a room temperature for more than 2 d, it was then washed with ethanol several times and dried at 60 °C.

Inorganic Powder-M: After the suspension of the inorganic powder in an ethanol solution of mandelic acid had been set aside at 5 °C for more than 1 d, the supernatant was removed and the precipitation was dried at 60 °C. Ethanol, 2-propanol, 2-butanol, and formic acid were of guaranteed grade. Dioxane and cyclohexane, both of a guaranteed grade, were dried with molecular sieves 4A of Wako Pure Chemicals Industries, Ltd.

A certain amount of inorganic powder was added to the flask containing 30 ml of a mandelic acid solution, and the following processes were carried out at 5 °C or 20 °C; (i) the mixture was set aside after a vigorous shaking, (ii) it was stirred at 190 rpm., or (iii) it was stirred at 380 rpm. An aliquot of these suspensions was taken into a test tube at several intervals. (iv) Separately, 3—5 ml of an ethanol solution of mandelic acid were added to a test tube containing a certain amount of inorganic powder. The test tube was shaken vigorously, and then set aside at 5 °C for 1 h. The optical rotation of the supernatants obtained by centrifuging these suspensions were measured with a JASCO digital polarimeter (Model DIP-140). The absorption spectra of these supernatants were obtained using a Hitachi recording spectrophotometer (Model 340). The concentrated solutions of the supernatants were developed on thin layers of silica gel with a solvent system of 2-butanol-2-propanol-formic acid-water (15:15:4:10).[2] Gas chromatographic determination of the trimethylsilyl derivatives of mandelic acid in the supernatant was carried out at 170 °C with a Shimadzu gas chromatograph (Model 6A), using a column containing 10% SE 52 chromosorb W 60/80 mesh treated with AW-HMDS of Shimadzu Seisakusho.[3] IR spectra were measured with a JASCO diffraction granting infrared spectrophotometer (Model A-2). The Hammett's acidity function, H_0, and basicity function, H_0', for inorganic powder were obtained by the indicator method.[4]

Results and Discussion

Racemization of Mandelic Acid at the Surface of Talc Powder. In Figs. 1 and 2, α is the optical rotation of the supernatant obtained by centrifuging an ethanolic suspension of mandelic acid and talc. The value of $|\alpha|$ decreased immediately after adding talc to the solution of the optically active mandelic acid at 5 °C, though the value remained constant after the lapse of more than 10 min. Figure 3 shows the effect of talc on the absorption spectra of an ethanol solution of mandelic acid. The absorbance around 250—260 nm increased on addition of talc. According to many studies concerning the degradation of mandelic acid on oxidation or γ-irradiation, the main products are benzaldehyde, benzoic acid, and phenylglyoxylic acid.[5] On fractionating these solutions by thin-layer chromatography, benzoic acid was confirmed to be formed, but no spot corresponding to any product other than benzoic acid was observed. The areas of ΔABD, S_{252}, and ΔBCE, S_{257}, were not changed by adding talc. The concentrations of mandelic acid

in the solutions were determined using gas chromatography. The concentrations in the supernatants in Fig. 3 were identical with the concentration in the original solution. These results show that degradation and adsorption of mandelic acid at the surface of talc are negligible. It is also confirmed that optically active mandelic acids are racemized at the surface of talc, though the diastereomers of these active forms were not separated because of the difficulty in synthesis.

Effect of the Polarity of Solvents. In Table 1, α_0 is the optical rotation of the original mandelic acid solution, and $\Delta\alpha$ is equal to $\alpha_0-\alpha$. The value of $|\Delta\alpha|$ obtained by adding a mandelic acid solution to a suspension of talc, which had been stirred for more than 10 min, was smaller than the value obtained by adding talc to a mandelic acid solution. This fact shows that solvent molecules and mandelic acid molecules compete with each other for the surface of the talc. Bubbling nitrogen gas during stirring did not show any effect on $|\Delta\alpha|$; this fact shows that oxygen has little effect on racemization. The effect of the polarity of solvents on racemization was investigated, using the mixtures of various ratios of dioxane and cyclohexane at 20 °C. Here, $(\overline{S}/S_0)$ stands for $1/2\{(S_{252}/S_{252,0})+(S_{257}/S_{257,0})\}$, where $S_{252,0}$ and $S_{257,0}$ are S_{252} and S_{257} for original solutions, respectively. $(\overline{S}/S_0)$ was proportional to the concentration of mandelic acid determined by gas chromatography. As is shown in Table 1, $(\overline{S}/S_0)$ decreased on interaction with talc and this tendency became greater with decrease in the polarity of the solvent. Probably, the adsorption of mandelic acid on the surface of talc is greater in the solvent of lower polarity. The racemization percentage, R, is defined as $[\{(\overline{S}/S_0)-(\alpha/\alpha_0)\}/(\overline{S}/S_0)]\times100$. As is shown in Table 1, racemization does not take place in the suspension containing 5 v/v% of dioxane, though R is 4—15% in the suspension containing more than 10 v/v% of

dioxane. This suggests that racemization is an ionic reaction.

Complex Formation. It is clear from Figs. 4 and 5 that Eq. 1 is applicable;

$$\Delta\alpha = K' W_T{}^n C^m, \quad 0<m, n<1, \tag{1}$$

where K' is a constant, W_T the amount of talc added to the suspension, and C the concentration of mandelic acid in the original solution. It is assumed that a complex M-T is formed between mandelic acid, M, and talc, T, as is shown in Eq. 2, and that Eq. 3 is applied;

$$\text{M+T} \rightleftarrows \text{M-T}, \quad K = [\text{M-T}]/[\text{M}][\text{T}], \tag{2}$$

$$\Delta\alpha \propto [\text{M-T}] \propto [\text{M}][\text{T}], \tag{3}$$

where [M] and [M-T] are the concentrations of M and M-T, respectively, [T] is the amount of T, and K a constant. In this case, Eqs. 4 and 5 are applied;

$$C = [\text{M}] + [\text{M-T}], \tag{4}$$

$$W_T = [\text{T}] + [\text{M-T}]. \tag{5}$$

Equation 6 is obtained from the above equations;

$$\Delta\alpha = K''\{C/(1+K[\text{M}])\}\{W_T/(1+K[\text{T}])\}, \tag{6}$$

where K'' is a constant. Equation 1 is similar to Eq. 6. This suggests that complex formation between mandelic acid and talc participates in racemization. As is shown in Table 1, the value of R in ethanol at 20 °C was lower than the value at 5 °C. Probably, dissociation of the complex is more remarkable at 20 °C than at 5 °C.

Active Sites at the Surface of Talc. Fukui et al. reported that both acidic and basic sites participated in dehydration of 2-propanol at the surface of talc.[6] Table 2 shows the values of Hammett's acidity function, H_0, and basicity function, H_0', for various talcs obtained by the indicator method.[4] Acidic sites with H_0 smaller than the pK_a value of mandelic acid (3.7 at 25 °C) are absent at the surface of $talc_{TEA}$. Basic sites are expected to be absent at the surface of $talc_{AA}$. On adding these talcs to an ethanolic solution of

Samples of No. 3, 5, 7, 9, and 11 were prepared using $R(-)$-mandelic acid.

mandelic acid at 5 °C, $|\alpha|$ and $(\bar{S}/S_0)$ decreased; this is considered to be due to the adsorption of mandelic acid at the surface of these talcs, as the shape of the absorption spectra was changed only slightly. Comparison between α/α_0 and $(\bar{S}/S_0)$ revealed that mandelic acid was not racemized at the surface of these talcs, as is shown in Table 2. It is judged from these results that both acidic and basic sites take part in racemization.

Addition of Various Inorganic Powders. On adding kaolin and γ-Al_2O_3 to an ethanolic solution of mandelic acid at 5 °C, $|\alpha|$ and $(\bar{S}/S_0)$ decreased; this is considered to be due to the adsorption of mandelic acid on these powders. Addition of SiO_2 had little influence on α. Comparison between α/α_0 and $(\bar{S}/S_0)$ revealed that racemization is slight at the surface of these powder. (Table 2) It is also clear from Table 2 that acidic sites, whose H_0 value is nearly equal to or smaller than the pK_a value of mandelic acid, exist at the surface of kaolin, talc and SiO_2. It is reported by many workers that basic sites exist at the surface of these powders.[6,7] It is also clarified in Table 2 that basic sites exist at the surface of γ-Al_2O_3.

Figure 6 shows the IR spectra of the various powders. In the spectra of kaolin-M, the band of the hydroxyl group at 3420 cm^{-1} was weak and the band of C=O was observed at 1730 cm^{-1}, though the band for mandelic acid was found at 1720 cm^{-1}. In the spectra of γ-Al_2O_3-M, no band was observed at 3420 cm^{-1} and a new band was found around 3200 cm^{-1}. No band was observed around 1720 cm^{-1} and the absorbance around 1600 cm^{-1} seemed to increase. In the spectra of $talc_{AA}$-M and $talc_{TEA}$-M, the band of C=O was at 1730 cm^{-1} and, in addition a new band was found at 1580 cm^{-1} in the spectra of talc-M, though the band of the hydroxyl group was at 3420 cm^{-1} in these spectra. In the spectra of SiO_2-M, the bands of mandelic acid in these regions were not

Scheme 2.

distinguished clearly from broad and strong bands of the adsorbed water, though a small shoulder was observed around 1720 cm^{-1}.

Singurel[8] investigated the IR spectra of mandelic acid in carbon tetrachloride or in KBr pellets. He pointed out that the C=O vibrations at 1718 cm^{-1} and 1762 cm^{-1} belonged to the dimer and monomer, respectively. In the spectra of KBr pellets, a wide and intense absorption range between 2400 cm^{-1} and 3200 cm^{-1} was assigned to carboxylic OH groups of dimer molecules connected by hydrogen bonds and a band around 3400 cm^{-1} to the hydroxyl group. When a proton acceptor complexed with the COOH group of mandelic acid, the C=O band was observed between the monomer and dimer bands. Khadikar et al.[9] investigated the IR spectra of bivalent metal complexes of mandelic acid. The hydroxyl group frequency was observed around 3260 cm^{-1}, and the stretching frequency of the COO^- group occured around 1600 cm^{-1}. They concluded that chelation took place involving coordination of hydroxyl and carboxyl groups of mandelic acid.

The above facts suggest that the hydroxyl group of mandelic acid interacts readily with the surface of γ-Al_2O_3. It interacts only weakly with the surface of kaolin, and does not interact at all with the surface of the various talcs. The COOH group interacts with a proton acceptor at the surface of kaolin and the various talcs. The COO^- group of mandelate anions also interacts with the surface of talc. The COO^- group coordinates with the surface of γ-Al_2O_3. These results show that racemization takes place in the mandelate anion, whose hydroxyl groups are free; it weakly interacts with the surface of the inorganic powders.

Mechanism of Racemization. Maggio et al.[10] studied the mechanism of the action of mandelate racemase, using the EPR and NMR techniquss. They showed that this enzyme bonded with Mn^{2+} to which a water molecule liganded, and concluded that deprotonation from the C atom at the second position of a mandelate anion was enhanced by hydrogen bonding of COO^- with the ligand water, as is shown in Scheme 1. It is concluded from the above results that the H atom at the C atom in the second position of a mandelate anion interacts with the basic site at the surface of talc and that deprotonation is enhanced by interaction between the carboxyl group and the acidic site, as is shown in Scheme 2.

Difference between Racemization of *S*-Isomer and that of *R*-Isomer. The decrease in α for the solution of the *S*-isomer by adding talc powder was little influenced by the stirring velocity. On the contrary, the value of $|\Delta\alpha|$ decreased with the decrease in stirring velocity in the case of *R*-isomer, though the value at the stirring velocity at 380 rpm was identical with the value for *S*-isomer. (Figs. 1 and 2) The value of $|\alpha|$ for the solution containing 6.6×10^{-3} M of *R*-isomer did not decrease on adding talc by the process of (iv), though the value for the solution containing 6.6×10^{-2} M of *R*-isomer decreased. (Fig. 4) These results suggest that talc has a chiral surface.

Partial Specific Compressibility and Its Relation to Solvation of Solute Based on Measurements of Suspension System

Hiroyasu NOMURA,* Fumio KAWAIZUMI, and Takeshi IIDA
Department of Chemical Engineering, School of Engineering, Nagoya University,
Chikusa-ku, Nagoya 464
(Received May 20, 1986)

The relation between limiting partial specific compressibility, $\bar{\kappa}_2^0$, and solvation of solute was reviewed and determination of $\bar{\kappa}_2^0$ was carried out in different types of solutions; ideal binary mixtures, such as benzene-toluene, and suspension systems of polystyrene latex and colloidal silica. In ideal mixture and polystyrene latex systems, the partial specific compressibility and limiting partial specific volume of each solute were equal to the corresponding value of the solute itself. The $\bar{\kappa}_2^0$ of the colloidal silica decreased from a positive to negative value with increasing pH of the media, showing strong hydration in alkaline solution.

In the last two decades compressibility measurement of solution has become quite familiar to many workers who are interested in solute-solvent interaction. Increase of attention to the compressibility in solution chemistry is ascribed to the appearance of commercial apparatus for ultrasonic velocity measurement and also to the development of molecular dynamical study of solution stimulated by computer simulation and various experimental techniques. As is well-known, the compressibility of solution is related to the radial distribution function of the molecules composing solutions.[1]

It goes without mentioning here the important role played by compressibility measurements in the estimation of amount of hydration of electrolytes which go back to the pioneering work of Passynski done as early as in 1938.[2] In his treatment, Passynski assumed that the compressibility of ionic solute and water molecules hydrated to the solute be incompressible. This hydration model, though simplified, is reasonable, since solvent molecules around ionic solute are subject to very strong electric field, namely they are electrostricted and their compressibility should be very small in comparison with that of bulk solvent.

On the other hand, for more general discussion of solute-solvent interaction from the point of solution compressibility, Nomura and Miyahara,[3] using a realistic model of solvated polymer molecule in solution, defined the limiting partial specific compressibility of solute, $\bar{\kappa}_2^0$, about twenty years ago. Since then, Miyahara and his coworkers determined the values of $\bar{\kappa}_2^0$ of many kinds of polymers in various conditions.[4] The solvation model proposed by them (abbreviated as N-M solvation model) can be extended to solutes other than polymers and amounts of solvent molecules bound to the solutes were determined for such systems as dextran in water[5] and in the mixed solvent of water-ethanol,[6] and cyclodextrin in the same mixed solvent.[7] Moreover, the N-M solvation model is useful in estimating the compressibility of certain kind of solute, for example polysaccharide, by means of ethanol-precipitation technique proposed originally by Shiio et al.[8]

As will be seen later in the present paper, the relation between $\bar{\kappa}_2^0$ and the amount of solvation is based basically on the assumption that the solvated or hydrated molecules make ideal solution with the solvent or water. This assumption is the same as that used in determination of the amount of hydrated water for electrolytes[9] and saccharides[10] from respective activity data. In spite of a number of papers dealing with the parameter $\bar{\kappa}_2^0$ reported by Miyahara's school,[3-7] direct experimental confirmation of the proposed relation of $\bar{\kappa}_2^0$ with the N-M solvation model using well-defined solute species is scare, except for one paper.[11] Considering recent increasing attention to the solution compressibility and importance of the information deduced therefrom, we found it appropriate to re-examine at this time the relation between the parameter $\bar{\kappa}_2^0$ and compressibility of solute in a more rigorous way. For this purpose we have undertaken the measurements of compressibility for the systems for which the compressibility of solute can be defined without any ambiguity.

The systems investigated are the ideal binary mixtures and the suspension systems. The formers are toluene-benzene, and -*m*-xylene, toluene being considered as solvent, while the latters are the solutions of monodisperse polystyrene latex and those of colloidal silica. As for the compressibility of suspension system, Urick[12] and Fukutomi and Wada[13] estimated the compressibility of a suspensoid from compressibility data for a dispersed phase and dispersion media.

Definition and Model

We briefly discuss compressibility of liquids and solutions and review the N-M solvation model.[3]

Definition of the Limiting Partial Specific Compressibility. The limiting partial specific compressibility of solute, $\bar{\kappa}_2^0$, is defined in the following equation:[3]

$$\bar{\kappa}_2^0 \equiv -\frac{1}{\bar{v}_2^0}\left(\frac{\partial \bar{v}_2}{\partial p}\right)_{s,0}, \qquad (1)$$

where $\bar{v}_2^0$ is the limiting partial specific volume of the solute. The subscripts zero and s refer respectively to the state at infinite dilution and the isentropic condition. An alternative definition of $\bar{\kappa}_2^0$ is

$$\bar{\kappa}_2^0 \equiv \frac{1}{\bar{v}_2^0}\left(\frac{\partial \kappa}{\partial x}\right)_0 + \kappa_1, \tag{2}$$

where κ is the compressibility and x is the concentration of solute expressed in g cm^{-3} of solution. In the present paper the subscripts 1 and 2 always refer to the solvent and solute, respectively. The quantity $\bar{\kappa}_2^0$ is evaluated from extrapolation of the data of compressibility κ and density d of solution in a following way;

$$\bar{\kappa}_2^0 = -\frac{\kappa_1}{\bar{v}_2^0}\lim_{x\to 0} K_x, \tag{3}$$

$$K_x = \left(\frac{d-x}{d_1} - \frac{\kappa}{\kappa_1}\right)\frac{1}{x},$$

Compressibility concerned here is that under adiabatic condition and is obtained from the well-known Laplace equation:

$$\kappa = \frac{1}{du^2}, \tag{4}$$

u being ultrasonic velocity in the solution. The parameter K_x is related to the apparent molar adiabatic compressibility $K_{s\phi}(=-(\partial\phi_v/\partial p)_s)$ by the equation,

$$K_x = -\frac{K_{s\phi}}{\kappa_1 M}, \tag{5}$$

where M is the molar mass of the solute.

Statistical Mechanical Expression of $\bar{\kappa}_2^0$. In order to have microscopic information on the solute-solvent interaction from the data of compressibility of solution, a statistical mechanical expression of $\bar{\kappa}_2^0$ is earnestly required. However, to derive statistical mechanical expression is a very hard task, since compressibility is directly related to the volume of the system under considerations. The only one theory available and based on the statistical mechanical treatment is the theory proposed by Kirkwood and Buff.[1] Using their theory, the limiting partial specific compressibility can be expressed as follows:

$$(\kappa_{2,T}^0 - \kappa_{1,T}) = \frac{1}{\bar{v}_2^0}[G_{112}^0 - G_{111}^0 + G_{11}^{0,2} - G_{12}^{0,2}] - \frac{v_1}{\bar{v}_2^0}[G_{11}^0 - G_{12}^0], \tag{6}$$

$$G_{1j}^0 = \int [g_{1j}^{(2)0}(r_{1j}) - 1]\mathrm{d}v, \tag{7}$$

$$G_{1jk}^0 = \iint [g_{1jk}^{(3)0}(r_{12}, r_{13}) - g_{1j}^{(2)0}(r_{12}) - g_{1k}^{(2)0}(r_{13}) - g_{jk}^{(2)0}(r_{23}) + 2]\mathrm{d}v_{12}\mathrm{d}v_{13}, \tag{8}$$

where the suffix T is used to refer to an isothermal condition and $g_{ij}^{(2)}(r_{ij})$ and $g_{ijk}^{(3)}(r_{ij}, r_{jk})$ are respectively the pair and triple distribution function in binary solution system. Comparison of Eqs. 6 and 2 shows what kind of information we can deduce from the values of $\bar{\kappa}_2^0$. The terms $[G_{112}^0 - G_{111}^0]$ and $[G_{11}^0 - G_{12}^0]$ are closely related to the solvation of solute and they can be estimated from the experimental data. Unfortunately, at present, we can not go any further into discussion of compressibility on molecular level starting from the values of the $[G_{112}^0 - G_{111}^0]$ and $[G_{11}^0 - G_{12}^0]$ terms. We, therefore, ought to rely upon a proper model in order to discuss the solute-solvent interaction in terms of compressibility data.

$\bar{\kappa}_2^0$ and the N-M Solvation Model. The proposed N-M solvation model is schematically represented in our previous paper.[3] In this model, we have assumed that the solvated or hydrated molecules make ideal solution with the solvent or water, and the so-called structure breaking region in the Frank-Wen model[14] is wholly ignored. If the volume additivity holds even after solvation for such solvated molecules in solution, then the total volume of solution V is given by

$$V = (n_1 - n_s n_2)v_1 + n_2(v_2 + n_s v_s), \tag{9}$$

where v_1, v_2, and v_s are the specific volume of the bulk solvent, solute and solvent in the solvation region, and n_s is the gram number of solvent in the solvation region per one gram of solute. In dilute solution, we may consider the n_s to be independent of the concentration of solute.

The partial specific volume of the solute is given by the differentiation of V with respect to solute concentration:

$$\bar{v}_2 = \left(\frac{\partial V}{\partial n_2}\right)_{n_1} = v_2 + n_s(v_s - v_1). \tag{10}$$

On taking the pressure derivative of Eq. 9 under the condition of constant entropy, we obtain the following relation according to the definition of $\bar{\kappa}_2^0$ shown in Eq. 1:

$$\bar{\kappa}_2^0 = \frac{v_2}{\bar{v}_2^0}\kappa_2 + \frac{n_s}{\bar{v}_2^0}(v_s\kappa_s - v_1\kappa_1). \tag{11}$$

If the solution concerned behaves non-ideally but so long as the volume contraction due to the solvation is negligible in order of magnitude, we can assume the relation below:

$$v_s \simeq v_1 \quad \text{and} \quad \bar{v}_2^0 \simeq v_2. \tag{12}$$

Equation 11 can then be written as

$$\bar{\kappa}_2^0 = \kappa_2 + \frac{n_s v_1}{\bar{v}_2^0}(\kappa_s - \kappa_1). \tag{13}$$

In case where no solvation occurs; i.e. $n_s=0$ and/or $\kappa_s=\kappa_1$. Equation 13 is reduced to an equation

$$\bar{\kappa}_2^0 = \kappa_2. \tag{14}$$

In more general cases in which the compressibility of solvation layer κ_s is taken into account, the amount of solvation can be calculated as follows:

$$v_1 n_s = \bar{v}_2^0 \frac{\bar{\kappa}_2^0 - \kappa_2}{\kappa_s - \kappa_1}. \quad (15)$$

For electrolytic solutes in solution, especially in aqueous solution, we can safely assume $\kappa_2=0$ and $\kappa_s=0$, as done by Passynski.[2] Then, we have from Eqs. 3 and 15

$$n_s = \frac{1}{v_1} \lim_{x \to 0} K_x. \quad (16)$$

If Eq. 9 is directly differentiated with respect to pressure and both quantities κ_2 and κ_s are assumed to be zero, as for the case of electrolytic solute, we have

$$n_s = \frac{n_1}{n_2}\left(1 - \frac{\kappa}{\kappa_1}\frac{V}{n_1 v_1}\right). \quad (17)$$

This equation is essentially the same as that proposed by Passynski.[2]

If the N-M solvation model is applied to the liquid-liquid mixtures where solute molecules interact negligibly with the surrounding solvent, the $\bar{\kappa}_2^0$ values should agree with the adiabatic compressibility of the solute itself in pure liquid state. Moreover, in ideal suspension system, the relation 14 should hold. As the adiabatic compressibility and specific volume of the suspensoid in solid state are defined and evaluated unequivocally, comparisons of the $\bar{\kappa}_2^0$ with κ_2 and $\bar{v}_2^0$ with v_2 are highly meaningful.

Experimental

Samples. Sample liquids *m*-xylene, benzene, and toluene used were all commercial products, spectral grade, of Nakarai Chemicals Co., Ltd. and they were used after purification by fractional distillation. Polystyrene latexes used were courteously supplied from Nippon Synthetic Rubber Co., Ltd. and their diameters were determined by the dynamic light scattering method using a spectrometer Coulter Model N4 as to be 246 (monodisperse), 123 (monodisperse), and 84±20 nm. The ζ-potentials, which serve as a measure of surface charge density, fall between −66 and −74 mV for the three latex samples mentioned above. The values were determined by a ζ-potentiometer Pen KEW 3000.

The colloidal silicas used in this work are commercial products Snowtex S, 20, and 20L supplied from Nissan Chemicals Co., Ltd. Particle size distribution was determined from the photographs taken by an electron microscope. The mean diameter of the sample Snowtexes are 8.1±2.9, 14.6±4.4, and 42.7±15.0 nm, respectively.

Measurements. The adiabatic compressibility of the sample solutions were determined from the measurements of ultrasonic velocities and densities of solutions. The former measurements were carried out using an ultrasonic interferometer operating at constant frequency of 5.000008 MHz, while the latters were done by means of a conventional Ostwald pycnometer of 20 cm^3. The procedure of sound velocity measurement and its accuracy is described in details elsewhere.[15]

Preparation of Sample Solutions. The original commercial products of colloidal silica Snowtex have the pH values about 10. Adjustment of the pH of colloidal silica solution was attained in two steps; first, making the colloidal silica pass through the ion-exchange resin (mixed bed, Amberlite IRA-400 and IR-120), then adding small quantity of solutions of HCl to raise the pH of colloidal silica solution to a desired pH value. The ion-exchanged colloidal solution has the pH values equal to 2—3 and this pH region corresponds to the isoelectric point of the colloidal silica.[16] Colloidal silica is unstable in the neutral pH region and if the solution is kept standing in the neutral pH region for one night, then the colloidal silica shows gelation. Therefore, measurements are difficult in the pH ranges 5—7.

Content of silica and polystyrene latexes in each colloidal solution and suspension was determined from the weight of solid residue left after drying the sample solution.

All measurements were carried out at 25 °C.

Results and Discussion

To illustrate the accuracy of extrapolation and also to confirm our assumptions, $(d-x)/d_1$, and κ/κ_1 are plotted against x for the typical examples of ideal

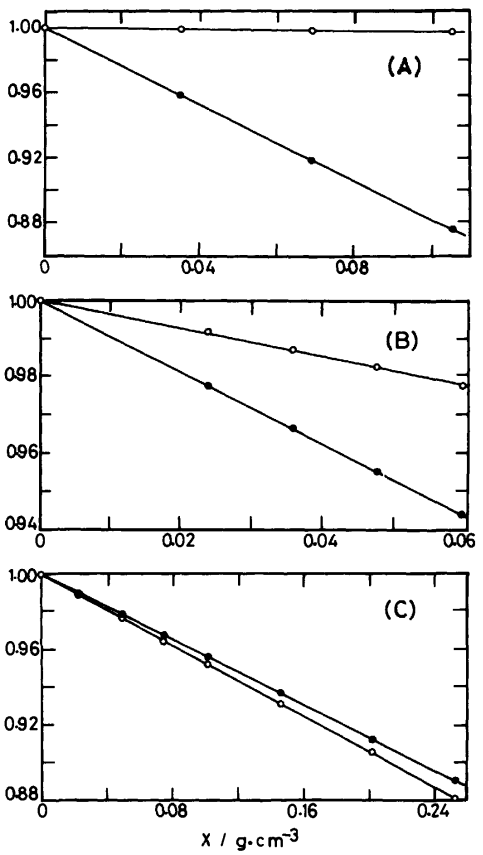

Fig. 1. $(d-x)/d_1$ and κ/κ_1 plotted against concentration X; ● $(d-x)/d_1$, ○ k/k_1.

binary mixtures of *m*-xylene-toluene, suspension of polystyrene latexes and silica sol, respectively in Fig. 1. As is seen in Fig. 1, linear relations were observed for both quantities in the concentration ranges investigated, that is, the value of K_x is independent of concentration. The limiting value of K_x was estimated from the slopes of these two lines. Values of $\bar{\kappa}_2^0$ are obtained by Eq. 3.

Values of $\bar{\kappa}_2^0$ in the Ideal Mixture. It is well-known that benzene, *m*-xylene, and styrene form ideal solution with toluene. In Table 1, the values of $\bar{\kappa}_2^0$ and $\bar{v}_2^0$ are compared respectively with κ_2 and v_2 for the solutes benzene, *m*-xylene, and styrene dissolved in toluene. As is seen Table 1, the relations $\bar{v}_2^0=v_2$ and $\bar{\kappa}_2^0=\kappa_2$ hold obviously, as predicted from Eqs. 12 and 14 for these systems. Consequently, in these mixtures no specific interactions are working between solute and solvent molecules.

Values of $\bar{\kappa}_2^0$ of Suspensoids. The results obtained from the ultrasonic velocity and density measurements of suspensions of various monodisperse polystyrene latexes are summarized in Table 2.

Although the values are scattering to some extent, the average values of $\bar{v}_2^0$ and $\bar{\kappa}_2^0$ are 0.941 $cm^3\,g^{-1}$ and 25.3×10^{-11} Pa^{-1}, respectively. The specific volume and compressibility of solid polystyrene are 0.953 and 24×10^{-11}, respectively at 20 °C in the same unit as above.[17] Therefore, the relation expressed as Eqs. 12 and 14 are retained in the suspension system in which particle diameters of suspensoid are ranging from 84 to 400 nm. It may be expressed that the smaller the diameter of suspensoid particle, the larger will be the surface effects in the values of $\bar{\kappa}_2^0$ which reflect the interaction between the surface of the particle and solvent molecules. However, down to the diameter 80 nm of the suspensoid, no appreciable surface effect was observed.

Values of $\bar{\kappa}_2^0$ and $\bar{v}_2^0$ of the Colloidal Silica Samples. The limiting partial specific compressibilities of electrolytes in aqueous solutions are mostly negative, for example, $\bar{\kappa}_2^0(KCl)=-162\times10^{-11}$ Pa^{-1} at 25 °C. This corresponds to hydration arising from very strong electrostrictive force. The colloidal silica is a sort of sols. It is stabilized by the electric repulsive force acting among colloidal particles and at the same time contributing to the formation of hydration layer around the particles. The colloidal silica can be taken as a model system of large hard sphere solute placed in a homogenious media.

The pH dependences of $\bar{\kappa}_2^0$ and $\bar{v}_2^0$ of colloidal silica sols are shown in Figs. 2 and 3, respectively. In these figures both quantities decrease with increasing pH value of the media. As will be seen below, these observations are interpreted in terms of the strong

Table 1. Comparison of the Values of $\bar{\kappa}_2^0$ and $\bar{v}_2^0$ in Toluene with the Compressibility Values in Pure State at 25 °C

hydration in alkaline region.

A number of silanol radicals -SiOH are distributed on the surface of colloidal silica particles and these silanol radicals are dissociated to a degree following the pH of the media. The silanol radical works similarly as an amphoteric electrolyte and its isoelectric point lies around pH 2. Therefore, in the higher pH region, the surface of the colloidal silica is charged positively like a cation. Somewhat different behaviors are observed in Figs. 2 and 3, depending on the particle size; in alkaline pH region the values of $\bar{\kappa}_2^0$ and $\bar{v}_2^0$ become smaller with decreasing particle size. However, in this work no examination was attempted to measure the surface charge density of each colloidal silica particle, as mentioned in the preceding chapter. At present it seems legitimate to postpone the detailed discussion concerning the particle size dependence until we have sufficient knowledge on this subject.

Following values[18] have been given for the values of κ_2 and v_2 of silica in bulk state at 25 °C.

$$\kappa_2 = 2.70 \times 10^{-11}\ \mathrm{Pa^{-1}} \text{ and } v_2 = 0.543\ \mathrm{cm^3\ g^{-1}}$$

In Fig. 3, the values of $\bar{v}_2^0$ in low pH region are close to the above mentioned specific volume of solid quartz. The fact that $\bar{v}_2^0 = v_2$ is equivalent to set $n_s = 0$ in Eq. 10.

This means that colloidal silica is not hydrated in acidic pH region. On the contrary, decrease of $\bar{v}_2^0$ with pH of the colloidal system suggests that $v_1 > v_s$ in Eq. 10 and that the term n_s increases with the pH value.

In correspondence to Fig. 3, the values of $\bar{\kappa}_2^0$ in acidic region are positive and a little larger than the compressibility of fused quartz as illustrated in Fig. 2, while they decrease to be negative in alkaline solutions. These variations correspond to $v_s\kappa_s < v_1\kappa_1$ in Eq. 11 or 13. As described just above, the relation $v_s < v_1$ holds. Therefore, the water molecules in hydration layer seem to be less compressible than those in bulk phase. In alkaline region where the relations $\bar{\kappa}_2^0 < \kappa_2$ and $\bar{v}_2^0 < v_2$ are observed, colloidal silica particles are doubtlessly hydrated. Evaluation of the parameters n_s and v_s is possible on solving simultaneously Eqs. 10 and 11. In doing so, a proper value must be assumed for the value of κ_s. The two cases were considered; $\kappa_s = 0$ and $\kappa_s = 11.1 \times 10^{-11}\ \mathrm{Pa^{-1}}$. The latter refers to the compressibility of hexagonal ice. The differences $\bar{v}_2^0 - v_2$ and $\bar{\kappa}_2^0 - \kappa_2$ used in this evaluation are significant to one or at most two figures and self-consistent, i.e. reasonable both for v_s and n_s, results were obtained only for the colloidal solutions with pH >8.5. Accuracy of the evaluation prevents detailed analysis of the results given in Table 3. However, the average values of v_s seems too small in view of the size of colloidal particles and the estimated electrostriction volume of ions in water.[19,20]

The authors are pleased to thank Nippon Synthetic Rubber Co., Ltd. and Nissan Chemicals Co., Ltd. for supplying them, respectively, polystyrene latex and colloidal silica with the data sheet of physicochemical analysis of these samples.

Phenomenological Relationship between the Fluidity and Tracer-Diffusion in Concentrated Electrolyte Solutions

Kazuko TANAKA* and Reita TAMAMUSHI†
The Institute of Physical and Chemical Research, Wako, Saitama 351-01
†Fukushima University, Matsukawa, Fukushima 960-12
(Received May 27, 1986)

An attempt has been made to correlate the mobility of component species with the fluidity of the solution over a wide range of concentration in aqueous solutions. A good linear correlation was observed between the relative fluidity and the relative tracer-diffusion coefficient of Cl^- in aqueous solutions of LiCl, NaCl, $MgCl_2$, $CaCl_2$, and $NiCl_2$, particularly at higher concentrations over 2 mol kg^{-1}. The correlation for the cations was very similar to that of water in aqueous solutions of such electrolytes. The feature of these plots presents that the structural properties of concentrated electrolyte solutions are reflected on these correlations.

In recent years, much attention has been paid to physicochemical properties of concentrated electrolyte solutions; a considerable amount of experimental data have been accumulated for transport processes in aqueous electrolyte solutions of varying compositions. However, many of the features of these experimental results still remain unexplained mainly because of a lack of appropriate theories and models which can be applied up to very high concentrations.

Since very early studies of transport phenomena in solution some simple correlations have been expected and examined between the velocity of a particle and the fluidity of the medium in which the particle moves, and the examination of so-called Stokes–Einstein equation[1] is still continuing.[2,3,4] Many of such correlations are empirical in nature, nevertheless they are expected to be useful to gain an insight into the nature of interactions among moving particles and the structure of the solution.

In electrolyte solutions the Stokes-Einstein equation is expected to be applicable to solutions at infinite dilution or very dilute solutions where the solution is assumed to be ideal, and have been examined by using limiting values of diffusion coefficients and molar ionic conductivities at infinite dilution.[5,6] Most of the previous studies have concerned the transport behaviour of only one component existing in the solution. In case of multicomponent solutions, however, it is important to study the transport properties of each component in the same solution. Among various transport properties only the tracer diffusion can provide the individual mobility data of each component.

In the present study, we have collected reliable tracer-diffusion data from the literature given in Table 1, and examined the correlation between the diffusion coefficients and fluidity of the solution for each individual component. Although no simple correlations may be expected between the mobility and fluidity in real solutions of finite concentrations, we have found that a substantial body of the experimental data reveals significant relationships between the mobility and fluidity in aqueous electrolyte solutions of very high concentrations.

Table 1. Sources of the Diffusion and Viscosity Data Used

Electrolyte	Tracer	Reference	
		Diffusion	Viscosity
LiCl	Li^+	(7), (8)	(29)
	Cl^-	(7), (8), (12)	
	H_2O	(8), (10)	
NaCl	Na^+	(9), (11)	(29)
	Cl^-	(12), (13)	
	H_2O	(14), (15)	
KCl	K^+	(7), (16)	(29)
	Cl^-, H_2O	(7), (12), (18)	
	H_2O	(17), (18)	
CsCl	Cs^+, Cl^-, H_2O	(18)	(29)
$MgCl_2$	Mg^{2+}, Cl^-	(19)	(29)
	H_2O	(15)	
$CaCl_2$	Ca^{2+}	(20)	(29)
	Cl^-	(20), (21)	
	H_2O	(17)	
$NiCl_2$	Ni^{2+}, Cl^-, H_2O	(22)	(26)
$CdCl_2$	Cd^{2+}, Cl^-, H_2O	(23)	(27)
CdI_2	Cd^{2+}, I^-, H_2O	(24)	(27)
R_4NBr	R_4N^+, Br^-, H_2O	(25)	(28)

The concentration dependence of tracer diffusion coefficients $D(Cl^-)$ of chloride ions in several aqueous electrolyte solutions is given in Fig. 1, in which relative diffusion coefficients as defined by $D_r(Cl^-)= D(Cl^-)/D^0(Cl^-)$ where $D^0(Cl^-)$ is the limiting diffusion coefficient calculated from the limiting ionic conductivity of Cl^- by the Nernst equation,[30] are plotted as a function of electrolyte concentration. This figure clearly demonstrates that the rate of diffusion of chloride ion is very much affected by the cations present in the solution. In KCl and CsCl solutions chloride ions diffuse faster than in LiCl and NaCl solutions, and the rate of diffusion decreases with increasing electrolyte concentration more rapidly in solutions of divalent cations than in solutions of

monovalent cations. The corresponding plot for relative fluidity $\phi_r=\phi/\phi^0$, (ϕ^0, the fluidity of pure solvent) is shown in Fig. 2. A comparison of Figs. 1 and 2 shows that the concentration dependence of tracer diffusion coefficients of Cl^- is very similar to that of fluidity of the solution, which gives us an indication that there seems to be some empirical correlation between relative tracer-diffusion coefficient of chloride ions and the relative fluidity of the solution.

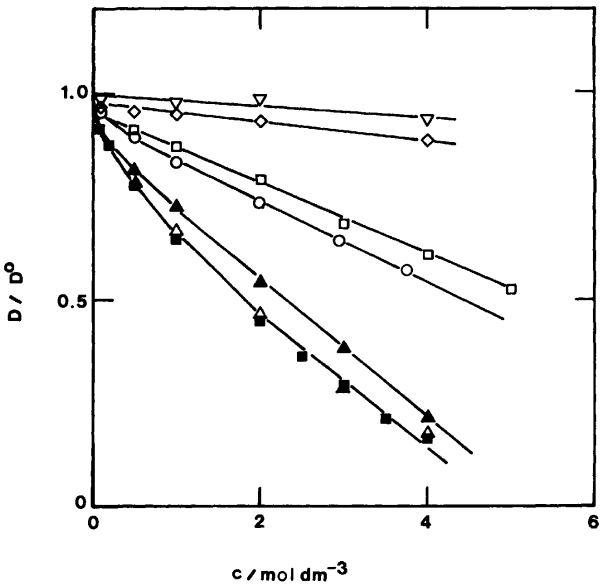

Fig. 1. Concentration dependence of the relative diffusion coefficients of Cl^- in aqueous solutions of LiCl (○), NaCl(□), KCl(◇), CsCl(▽), $MgCl_2$(△), $CaCl_2$ (▲) and $NiCl_2$(■) at 25 °C.

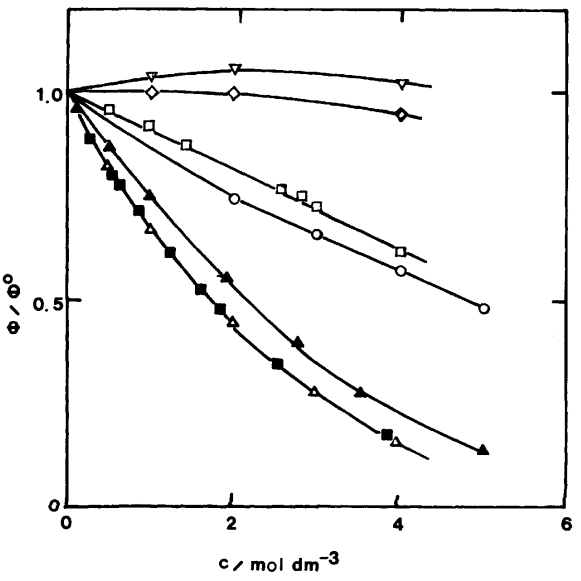

Fig. 2. Concentration dependence of relative fluidities of the aqueous electrolyte solutions (25 °C) given in Fig. 1; symbols are the same as those used in Fig. 1.

In Fig. 3, the relative tracer diffusion coefficients of chloride ion are plotted against the relative fluidity of the solutions, where the diagonal line represents the relation,

$$D(Cl^-)/D^0(Cl^-) = \phi/\phi^0. \quad (1)$$

A striking feature of this plot is that the experimental points for concentrated solutions (≥2 mol kg^{-1}) of LiCl, NaCl, $MgCl_2$, $CaCl_2$, and $NiCl_2$ (hereafter, these electrolytes will be called the LiCl-type for the sake of simplicity) are on or very close to the diagonal line, while those points for medium and low concentrations (0.5—2.0 mol kg^{-1}) lie slightly below the line.

The present empirical finding suggests that in concentrated solutions, the LiCl-type electrolytes affect the chloride ion diffusion and the fluidity of the solutions in a similar manner, which may be interpreted in terms of the structural aspect of chloride ions in the solution. In this respect, it seems worthwhile to note the neutron diffraction studies by Enderby's group which show that the geometric arrangement of water molecules around chloride ions is independent of concentration and also counter cations for a wide variety of electrolytes.[31]

Let us now examine the D_r vs. ϕ_r plot for the tracer-diffusion of cations and water (Figs. 4 and 5, respectively) in aqueous solutions of the LiCl-type electrolytes. As can be seen from Fig. 4, the experimental points for the cations at lower concentrations are close to the diagonal line, whereas most of the points at higher concentrations lie above the line, suggesting that the retardation of the diffusion rates of these cations is less than that expected from the decrease in fluidity of the solution.

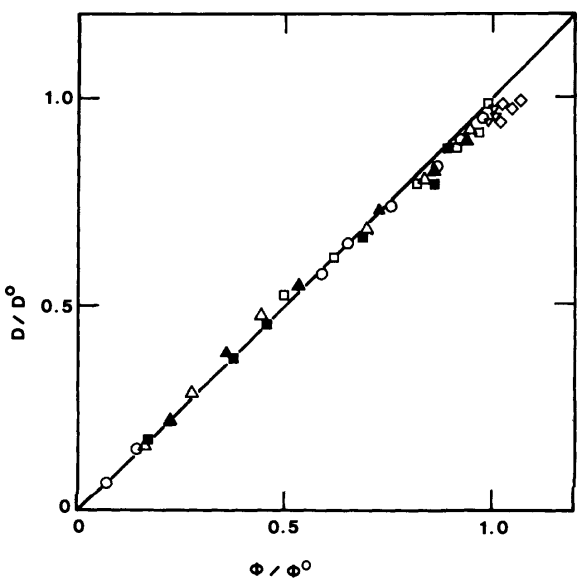

Fig. 3. D_r vs. ϕ_r plots for Cl^- in the solutions of LiCl (○), NaCl(□), KCl(▽), CsCl(◇), $MgCl_2$(△), $CaCl_2$ (▲) and $NiCl_2$(■) at 25 °C.

It should be noticed that most of the experimental points are on the same curve irrespective of the kind of cations.

The tracer diffusion of water in aqueous solutions of the LiCl-type electrolytes behaves very similarly to that of the cations (compare Figs. 4 and 5). This result may give a qualitative explanation that the above-mentioned behavior is associated with the strong interaction of water molecules with the cations in solutions of the LiCl-type electrolytes.

Relative diffusion coefficient vs. relative fluidity relationships for aqueous solutions of KCl and CsCl are different from those observed with the LiCl-type electrolytes. In the case of KCl and CsCl solutions, the fluidity and diffusion coefficient do not change very much with concentration; fluidity first increases and then decreases slightly with increasing concentration (see Fig. 2) and the increase in fluidity is more pronounced for CsCl at lower temperatures. The experimental points for these electrolyte solutions are located in the region corresponding to $\phi_r=1$ and $D_r=1$ of the D_r vs. ϕ_r diagram (see Figs. 3, 4, and 5). The points for the cations and chloride ion are always below the diagonal line. The observed transport behaviour of KCl and CsCl solutions may be related to the fact that K^+ and Cs^+ ions have large crystallographic radii and low charge densities so that

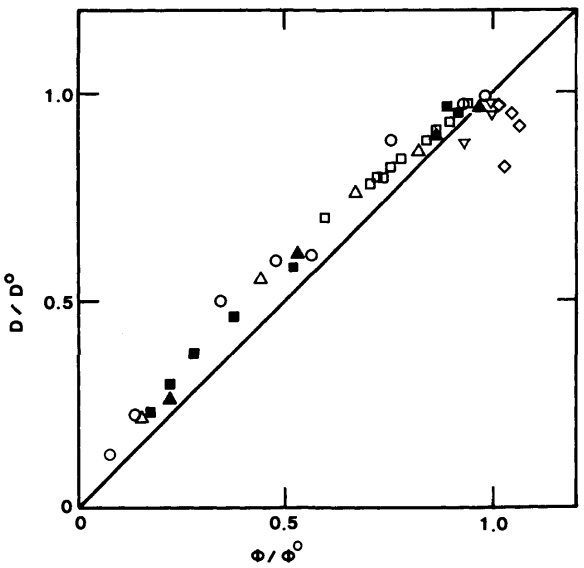

Fig. 4. D_r vs. ϕ_r plots for cations of the solutions given in Fig. 3.

they cause weaker hydration.

Examples of the D_r vs. ϕ_r plots for aqueous solutions of tetraalkylammonium bromides which cause the so-called hydrophobic hydration, are given in Figs. 6, 7, and 8. For bromide ions all the experimental points lie on the same curve regardless of their counter tetraalkylammonium cations (Fig. 6); the correlation is similar to that observed for chloride ions in solutions of the LiCl-type electrolytes, although the linear relationship represented by Eq. 1 is satisfied at rather smaller relative fluidities ($\phi_r<0.5$) than in the case of the chloride ions of small electrolytes. Among the points for tetraalkylammonium cations, those for tetramethylammonium cation fall below the diagonal line, whereas those points for the other tetraalkylammonium cations are on or above the line (Fig. 7). The water diffusion in these solutions exhibits more complicated behavior (Fig. 8), and will not be discussed in detail until more experimental data have been available.

The D_r vs. ϕ_r relationships for aqueous solutions of cadmium chloride and iodides (Fig. 9) are examples where cations and anions have strong specific interactions such as complex formation. The most characteristic behavior of such systems can be seen on the correlation for the anions; all the points are far below the diagonal line, indicating that the anions in these solutions diffuse much slower than would be expected from the fluidity by Eq. 1. This transport behavior may be mainly ascribed to the specific ion-ion interaction, as a result of which the chloride and iodide ions are travelling together with cadmium ions whose diffusion coefficients are about one-third of the anions.

In this paper, we have demonstrated that different types of solute-solvent interactions exhibit different diffusion vs. fluidity correlations. The D_r vs. ϕ_r plots may not be adequate to study of validity of the Stokes-Einstein equation, and the correlations we found are entirely empirical. We believe, however, that the correlations will provide some fundamental information on the nature of ion-solvent interactions and structural properties of ions in concentrated electrolyte solutions. It is hoped that the empirical correlations presented in this paper could be explained by the future development of theories and models of concentrated electrolyte solutions.

The Effect of Phosphoric Acid Treatment on the Catalytic Property of Niobic Acid

Susumu Okazaki,* Masao Kurimata, Tokio Iizuka,† and Kozo Tanabe†
Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Hitachi 316
†Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received June 2, 1986)

The effects of the treatment of niobic acid with phosphoric acid, sulfuric acid, and hydrofluoric acid on its surface area, structure, acidic property, and catalytic activity have been studied. The treatment with phosphoric acid was found to be most effective for maintaining a large surface area and a large amount of strong acid sites and for preventing niobic acid from crystallizing even after the heat treatment at higher temperatures above 600 °C. The XPS study revealed that a large amount of phosphorous exists on niobic acid after high temperature heat treatment. In accordance with these results, niobic acid treated with phosphoric acid and heat-treated at higher temperatures exhibited high catalytic activities for methanol conversion and ethylene hydration, whereas the activities of niobic acid containing no phophoric acid were very low when heat-treated at high temperatures.

Recently, niobic acid ($Nb_2O_5 \cdot nH_2O$) is known to have a strong acidic property and catalytic activity towards acid-catalyzed reactions such as ethylene hydration,[1] esterification of acid with alcohols,[2] butene isomerization[3] etc. even on the heat treatment at lower temperatures (100—200 °C). However, on the heat treatment at higher temperatures (550 °C), niobic acid decomposes to become a crystalline niobium oxide and loses its acidic property and catalytic activity.[3]

On the other hand, it is known that the addition of SO_4^{2-} or F^- ions to a metal oxide such as Al_2O_3 or TiO_2 enhances the acidity of the metal oxide and that the addition of SO_4^{2-} prevents TiO_2 from changing to stable rutile crystals.[4]

Thus, in this study, the effect of the treatment of niobic acid with various acids, especially phosphoric acid, was examined for the purpose of strengthening the solid acidity of niobic acid even after the treatment at high temperatures. The conversion of methanol and the hydration of ethylene were tested to measure the effect of acid treatment on the catalytic activity of niobic acid.

Experimental

Catalyst Preparation. Niobic acid (AD-135) supplied by CBMM was dried in air at 120 °C for 6 h. For the preparations of acid-treated samples, niobic acid (10 g) was immersed in 30 ml of an acid solution prepared so as to have a given concentration (0.05, 0.25, 0.5, and 2.5 mol dm^{-3} of HF; 0.5 mol dm^{-3} of H_2SO_4; 0.25, 0.5, and 1 mol dm^{-3} of H_3PO_4). The suspension of niobic acid was allowed to stand for 48 h, then the sample was evaporated to dryness in air at 120 °C. The dried sample was calcined at various temperatures.

Surface Acidity and Specific Surface Area. The amount of surface acidic sites was measured by butylamine titration method, using various Hammett indicators. The BET method was used to measure the specific surface areas. Constant-volume adsorption of N_2 was carried out at 78 K for the sample having a particle size of 14—20 mesh.

TG-DTA, XRD, and XPS Measurements. For the measurement of TG-DTA, untreated and acid treated niobic acid, all dried at 120 °C, were used in an amount of 2.0 g each. The programmed temperature was raised at a rate of 10 °C min^{-1} up to 800 °C. The XRD experiments were done by using copper as the target and nickel as the filter. Some of the samples of untreated and acid treated niobic acid were subjected to XPS measurement for the surface composition after heat treatment at 400 °C or 600 °C. The Ar ion sputtering for 5 or 15 min was used to know the composition of several inner layers.

Methanol Conversion Reaction and Hydration of Ethylene. The methanol conversion was carried out at 400 °C, under normal pressure using a conventional flow reactor. One gram of catalyst, having a particle size of 14 to 20 mesh was fixed in the reactor and heat-treated in He stream at 400 °C for 1 h. The methanol feed was passed through a preheater at a constant rate of 1.8 ml h^{-1} by means of a microfeeder so that methanol was vaporized and led into the reactor by He carrier gas at a rate of 60 ml min^{-1}. The product gas was analyzed by gas chromatography. The reaction procedure of ethylene hydration was the same as reported previously.[3]

Results and Discussion

Surface Acidity. The acidity change of acid treated and untreated niobic acid after heating at various temperatures was summarized in Table 1. On the untreated niobic acid, strong acid sites of $H_o \leq -5.6$ appeared when samples were heat-treated at 200 or 300 °C. However, such strong acid sites were not found for the samples heat-treated at higher temperatures. In addition, the weaker acid sites of $1.5 \geq H_o > -5.6$ decreased with the rise of treatment temperature. The decrease of acid sites has been ascribed to the crystallization of Nb_2O_5.[3]

When niobic acid was treated with HF of concentration being 0.5 mol dm^{-3} or below, the amount of the weaker acid sites increased from 0.23 to 0.35—0.38 mmol dm^{-3}, whereas there was no change or somewhat decrease in the amount of the strong acid sites. However, the strong acid sites on HF treated sample remained after heat treatment at 400 °C in contrast with the case of untreated niobic acid. After

the treatment with HF of higher concentration, the acid sites on niobic acid decreased drastically.

If a niobic acid was treated with 0.5 mol dm^{-3} H_2SO_4, the acidity increased remarkably and the strong acid sites were retained even after the heat treatment at 400 °C. It is known that some metal oxides such as ZrO_2, TiO_2, and Fe_2O_3 show solid super acidity ($H_o \leq -12$) after the treatment with H_2SO_4 followed by the heat treatment at 500—600 °C.[5] However, on the surface of niobic acid, the strong acidity ($H_o \leq -5.6$) diminished after heating at 500—600 °C.

Figure 1 shows the surface acidity of niobic acid treated similarly with 1.0 mol dm^{-3} of phosphoric acid and then heat-treated at various temperatures. It is observed that the phosphoric acid treatment retains relatively large amount of strong acid sites. Surface treatment with 0.5 mol dm^{-3} of phosphoric acid enhances the surface acidity similarly to that with 1.0 mol dm^{-3} of phosphoric acid.

Figure 2 shows the relationship between the temperatures of heat treatment and the amounts of strong acid sites ($-5.6 \geq H_o > -8.2$) of niobic acid untreated or treated with acids. As obvious from this figure, the treatment with phosphoric acid differs from the treatment with other acids in that the strong acid amount is fairly retained at 600 °C and even 800 °C. As can be seen from a comparison of Fig. 1 with Fig. 2, the acid amount retained at 600 °C or higher temperature does not depend on the concentration of phosphoric acid.

As described above, the niobic acid treated with phosphoric acid does not lose strong acidity even after the heat treatment at high temperatures. This fact is considered to be due to the nonvolatile polyphosphate formed by the condensation of phosphoric acid on and near the surface of niobic acid. The ability of niobic acid to retain strong acidity at high temperature is not changed by the phosphoric acid concentration, and this fact indicates that a polyphosphate layer is formed in an amount enough to cover the full surface even when phosphoric acid is used at a relatively low concentration such as 0.5 mol dm^{-3}.

TG-DTA and XRD. TG-DTA was conducted to obtain an information about thermal stability of acid

treated niobic acid. Figure 3 shows the TG-DTA patterns of the untreated niobic acid and phosphoric acid or sulfuric acid treated samples. At and near 200 °C, it shows a weak and dull endothermic peak. According to Sen et al., niobic acid has a composition of $3Nb_2O_5 \cdot 4H_2O$ at 150 °C and $3Nb_2O_5 \cdot H_2O$ at 300 °C.[6] Therefore, the peak around 200 °C is attributable to a partial elimination of water of crystallization. TG showed little change when untreated and H_3PO_4-treated samples were heated to temperatures ranging from 300 to 800 °C. However, DTA shows a sharp exothermic peak around 550 °C. This peak has been attributed to the transformation of niobic acid to crystalline niobium oxide.[3] The sharp exothermic peak near 550 °C is characteristic of niobium oxide. The crystallization of niobium oxide was prevented considerably by the addition of sulfuric acid or phosphoric acid. In DTA, the exothermic peak grew blunt and shifted to the higher temperature region. As found especially in H_3PO_4-treated samples, the effect becomes more remarkable with the increase in the treatment concentration. With a concentration of 1 mol dm^{-3} phosphoric acid, the exothermic peak is no longer observed. Sulfuric acid treatment also showed the similar effect, but TG showed the weight decrease at 600 °C or higher. This is probably due to the elimination of SO_3. Along with this elimination, the acidity of niobic acid rapidly decreased (See Fig. 2). In contrast, niobic acid treated with phosphoric acid did not show any weight loss due to the decomposition and retained the strong acid sites even after the heat treatment at high temperature.

In Fig. 4 are shown XRD patterns of untreated and acid treated niobic acid. After heating at 400 °C or below, samples showed only very broad peaks at about 30° (d=2.08 Å) and about 55° (1.67 Å). When heat-treated at higher temperatures, sharp peaks were observed on untreated niobic acid. The sample treated with sulfuric acid and heat-treated at 600 °C gave the peaks similar to those on untreated samples heated at 600 °C, but the peak strength was somewhat lower. At 800 °C, new peaks appear at 23.7° and 25.0°, but there is no change in main peaks. On the other hand, the diffraction peaks of the samples treated with phosphoric acid had quite low strength. Even after the heat treatment at 800 °C, the peaks were not so sharp. Thus, the treatment with phosphoric acid proves to be especially effective in preventing the crystallization of niobium oxide.

Surface Area. Samples untreated or treated with sulfuric or phosphoric acid were examined for the relationship between specific surface areas and heat treatment temperatures. As is shown in Fig. 5, the surface area of the untreated sample sharply drops between 400 and 600 °C. This decrease in surface area is due to the crystallization of niobium oxide occurring around 550 °C. Furthermore, the extremely small surface area observed at 800 °C suggests that the crystallization has been completed at this temperature. In the case of sulfuric acid treated niobic acid, the surface area was constant up to 600 °C, but drastically decreased after heating at 800 °C. The sample treated with phosphoric acid had lower surface area at 200 °C than that of the untreated niobic acid, but it showed the lowest extent of decrease with the rise of temperature. After heat treatment at 800 °C, the

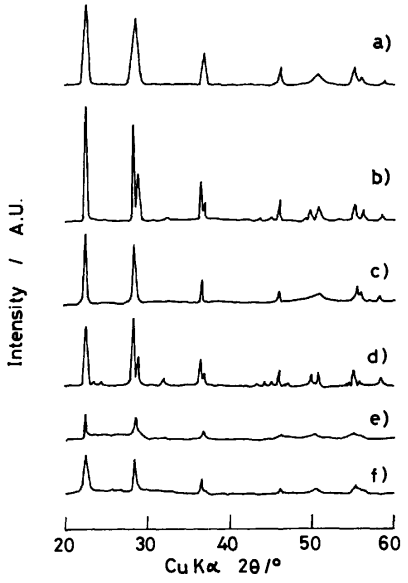

Fig. 4. XRD patterns.
a) Niobic acid heat-treated at 600 °C, b) niobic acid heat-treated at 800 °C, c) H_2SO_4-treated niobic acid, after heat-treated at 600 °C, d) H_2SO_4-treated niobic acid, after heat-treated at 800 °C, e) H_3PO_4-treated niobic acid, after heat-treated at 600 °C, f) H_3PO_4-treated niobic acid, after heat-treated at 800 °C. The concentrations of the H_2SO_4 and H_3PO_4 used for the treatment were 0.5 mol dm^{-3}.

sample retained a relatively large surface area of 33 $m^2 g^{-1}$. Thus, the effect of phosphoric acid treatment is remarkable to maintain the large surface area of niobic acid.

Surface Composition. The XPS study was made to obtain an information about surface composition of niobic acid. Surfaces of untreated and phosphoric acid treated samples were etched for 0, 5, and 15 min. In Table 2, the surface compositions determined by XPS are shown. The untreated sample gave a Nb/O atomic ratio of 27/73 regardless of heat treatment temperature. This ratio is roughly equal to the theoretical Nb/O value of Nb_2O_5 (29/71). After heating at 400 °C, the Nb/O ratio slightly increased as the time of Ar^+ etching became longer. After 15 min of etching, the observed value reached the theoretical value. On the other hand, after heating at 600 °C, the Nb/O ratio sharply increased along with the etching. This indicates that Nb atoms are regularly arranged on stable and strong grids and are difficult to eliminate on etching; therefore oxygen atoms are preferentially eliminated.

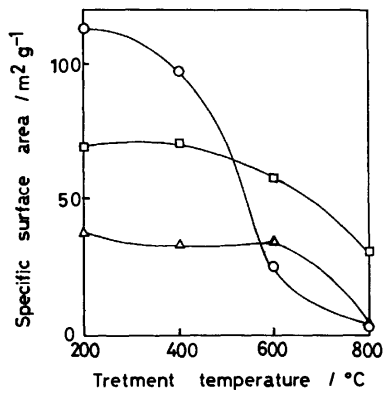

Fig. 5. Specific surface area of niobic acid.
○: Before acid treatment, △: after treatment with 0.5 mol dm^{-3} H_2SO_4, □: after treatment with 0.5 mol dm^{-3} H_3PO_4.

As regards the samples treated with phosphoric acid, the P/Nb ratio at 600 °C is slightly lower than that at 400 °C, indicating a possibility of the loss of P component and crystallization during the heat treatment at high temperatures. Even in this case, a P/Nb ratio close to 0.5 enables us to expect that a considerable part of surface layer will be covered with phosphoric acid (probably in the form of polyphosphate). Even when the sample was heat-treated at 600 °C, a relatively high P value of 6 atomic% is retained. This indicates that phosphoric acid penetrates to inner layers of niobic acid.

Catalytic Activity in Methanol Conversion. The product distribution of methanol conversion is shown in Table 3. Though the main product was dimethylether (DME), a considerable amount of methane formed over niobic acid heat-treated at 400 °C. After heating at 600 °C, which is higher than the crystallization temperature of niobium oxide, the activity decreased and especially methane formation was

All these catalysts were heat-treated at 220 °C under evacuation for 1 h (for untreated or H_3PO_4-treated niobic acid) or about 5 min (for solid phosphoric acid) before use as a catalyst.

depressed.

On the other hand, the catalytic activity of niobic acid treated with phosphoric acid was not so sensitive to the heat-treatment temperature. Besides DME and methane, small amounts of olefin were formed in this reaction. The olefin formation was promoted more effectively by the niobic acid treated with phosphoric acid compared with the untreated sample after heat-treated at 600 °C. It is known that the olefin formation is promoted only by strong acid sites,[7] whereas the DME formation may be promoted by weak ones. So, the results described above suggest that strong acid sites should be formed and retained on niobic acid treated with phosphoric acid even after the heat treatment at higher temperature (600 °C).

Catalytic Activity in Ethylene Hydration. A gas-phase reaction was carried out in a circulation system at 220 °C to examine the catalytic activity of niobic acid treated with 0.5 mol dm^{-3} of phophoric acid in ethylene hydration reaction. The results obtained are shown in Fig. 6. For comparison, the previously reported results[1] obtained under the same reaction conditions for solid phosphoric acid and untreated niobic acid are also shown here. The untreated niobic acid has a higher catalytic activity than conventionally used solid phosphoric acid. It should be noted, however, that the activity is fairly low during the initial period of reaction. In contrast, niobic acid treated with phosphoric acid showed a high activity from the beginning. It is especially noted that, when the H_3PO_4-treated catalyst was heated at 500 °C in a vacuum, and then used in the reaction, the catalytic activity increased remarkably. This fact is in contrast to the case of untreated niobic acid which showed low activity when evacuated at 500 °C. Namely, the phosphoric acid treatment seems to be the reason for maintaining the catalytic activity even after the heat treatment at a high temperature such as 500 °C. In these ethylene hydration reactions, the heat treatments were carried out under evacuation, since they were attempted in the circulation system to use the niobic acid catalyst immediately after the treatment. However, it was confirmed that the heat treatment under atomospheric pressure affected the surface acidity and the catalytic activity of niobic acid, almost similarly to the heat treatment under evacuation. Thus, the H_3PO_4-treated catalyst has the advantage that the deactivated one can be recovered by heat treatment.

In the 1st-run reaction, the catalyst treated with 1 mol dm^{-3} phosphoric acid showed a higher activity than the sample treated with 0.5 mol dm^{-3} acid. However, in the second run reaction, the activity of the catalyst evacuated at 500 °C remained constant and independent of the concentration of phosphoric acid. As previously noted, the strong acid amount of niobic acid heat-treated at high temperatures remains roughly constant regardless of the concentration of phosphoric acid used for the treatment. Since the catalytic activity of H_3PO_4-treated catalyst is remarkably higher than that of solid phosphoric acid, it is speculated that phosphoric acid is not simply polymerized, but is condensed with niobium on the surface of niobium oxide and that for this reason, the H_3PO_4-treated catalyst works effectively to promote the reaction.

The authors are indebted to CBMM Ltd. for their providing the niobic acid samples and financial support on the present work.

Interaction between Dodecyltrimethylammonium Chloride and DNA

Keishiro SHIRAHAMA,* Koji TAKASHIMA, and Noboru TAKISAWA
Department of Chemistry, Faculty of Science and Engineering, Saga University, Saga 840
(Received June 12, 1986)

Binding of dodecyltrimethylammonium cation to calf thymus DNA was studied by using the surfactant-selective electrode as a function of added electrolyte concentration at various temperatures. Binding is highly cooperative and biphasic. An abruptly occurring binding attains a slight shoulder within a very narrow equilibrium concentration range followed by a further augmentation in binding, as the equilibrium concentration is increased. Temperature caused relatively small shift in binding isotherm, but a distinct inversion point was found around 27 °C. Above this temperature the isotherm shifts to the left and then to the right below it. Analogous binding studies as above were repeated with heat-denatured DNA, which binds the surfactant with higher intrinsic affinity but less cooperatively than the intact DNA. A fluorescent probe, pyrene, was employed to assess the microenvironmental polarity of pyrene in DNA before and after surfactant binding. The surfactant-DNA complex has a hydrophobic region akin to ordinary micelle.

Partition of a ligand molecule (ion) between a macromolecule and aqueous phase is very important and attractive phenomena. Actually a number of investigations on such molecular interactions have been published to cover synthetic as well as biological systems.[1-4] Binding isotherm among many others is a clear-cut evidence of interaction between ligand and macromolecule, and will allow not only qualitative but also quantitative interpretation of the phenomena by the help of statistical mechanics and other physical methods.

We also have studied some macromolecule-ligand systems in which ionic surfactants take part of the ligands.[5-12] Deoxyribonucleic acid (DNA) is viewed as a long cylinder with phosphate groups spirally arrayed on the surface, and thus has driven researchers to work on surfactant binding.[12-14] In a previous paper,[12] interaction between DNA and cationic surfactant, *N*-dodecylpyridinium halides, was reported. In the present work, dodecyltrimethylammonium chloride was used in place of the pyridinium analog to see if there is any difference in binding behavior. A fluorescence probe, pyrene was employed to assess the microenvironment of pyrene in DNA–surfactant complex. Binding studies were extended to thermally denatured DNA in the added electrolyte solutions of various concentrations at temperatures. These binding behaviors were semiquantitatively expressed in terms of one-dimensional Ising model.

Experimental

Materials. Dodecyltrimethylammonium chloride (Tokyo Kasei Co.) was recrystallized from acetone three times. The critical micelle concentration as measured by an electric conductivity method is 20.5 mM in water at 25 °C. Calf thymus DNA (Sigma, sodium salt) is the same sample as used before.[12] Thermal denaturation was carried out by heating DNA solution at 85 °C for 5 min.

Binding Isotherm. Propionyl-α-cyclodextrin electrode which had previously been used[11,12] responded also to dodecyltrimethylammonium cation as seen in Fig. 1, where a straight line has a slope of 59 mV per 10 fold concentration difference, or the Nernstian response. In the presence of DNA, however, there appeared a deviation from the linearity which was caused by a partial uptake of surfactant by DNA.

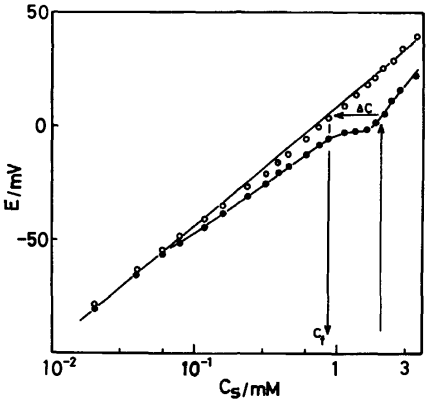

Fig. 1. Potentiometric titration of dodecyltrimethylammonium chloride in 20 mM NaCl at 25 °C. ○: without and ●: with DNA. See text for C_s, C_f, and ΔC.

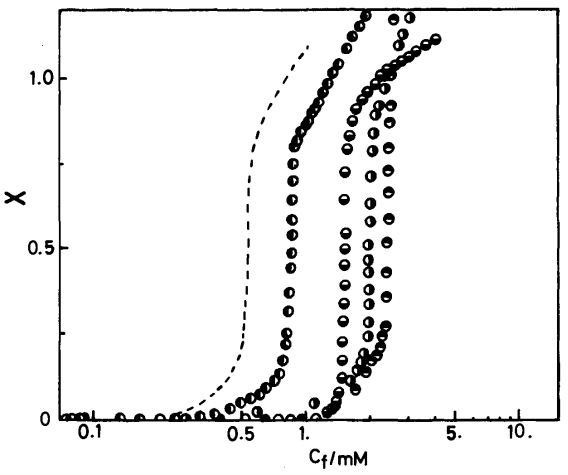

Fig. 2. Binding isotherms of dodecyltrimethylammonium chloride–DNA system at 25 °C. NaCl concentrations ◐: 20, ◒: 40, ◑: 80, and ◓: 160 mM, the dashed line for *N*-dodecylpyridinium chloride for comparison.

No hysterisis was observed when the potentiometric titration without DNA was repeated after the binding run. Following the arrows indicated in Fig. 1, an amount of binding, $\Delta C=C_s-C_f$, and an equilibrium concentration, C_f are easily obtained. A binding isotherm is built up by plotting a degree of binding, $X=\Delta C/$(total concentration of phosphate groups in DNA) vs. $\log C_f$ as shown in Fig. 2.

Fluorescent Probe Method. Emission spectrum from pyrene in the surfactant and/or DNA solution was recorded on a fluorescence spectrophotometer (Shimadzu RF-510).

We conveniently use the notation, 1 M=1 mol dm^{-3} throughout the paper.

Results and Discussion

Binding to Intact DNA. All the binding isotherms are characteristic of cooperative nature as well as biphasic. An abrupt appearance and completion of the first step binding is followed by the second step binding. It is clear that added NaCl causes the first binding shift to the right along the C_f axis as seen in Fig. 2. As for the second one, the effect of added electrolyte seems reversed. All these features are the same as observed previously with the DNA-*N*-dodecylpyridinium system and can be interpreted in the same manner. The first step binding is a process where DNA discharges and added electrolyte shields the electrostatic field attractive to surfactant cations leading to decreased binding affinity. On the other hand, in the second step binding, charge is built up on DNA on binding the surfactants with their hydrocarbon tails in contact with each other on DNA and with their charged head groups exposed toward the aqueous bulk phase. In Fig. 2, the binding isotherm of *N*-dodecylpyridinium Cl-DNA system (20 mM NaCl, 25 °C)[12] is shown by a dashed line for comparison. The equilibrium concentration at $X=0.5$ are 0.54 mM for *N*-dodecylpyridinium and 0.64 mM for dodecyltrimethylammonium, respectively. This difference, $RT\ln(0.64/0.54)=0.42$ kJ mol^{-1}, should be ascribed to the different structures of ionic head groups of the two kinds of surfactants. A positive charge delocalized throughout a flat pyridinium ring can approach a phosphate group on DNA much closer than that of trimethylammonio group gaining more electrostatic interaction energy.

Figure 3 shows binding isotherms at four temperatures. The temperature effect is small and even an inversion temperature is found around 27 °C, which is slightly higher than the one (23 °C) found with the pyridinium analog in the previous study.[12]

Binding to Thermally Denatured DNA. Figures 4 and 5 display binding isotherms for thermally denatured DNA. Binding begins at an equilibrium concentration lower than in intact DNA solution, and increases with less steep slope. This means that

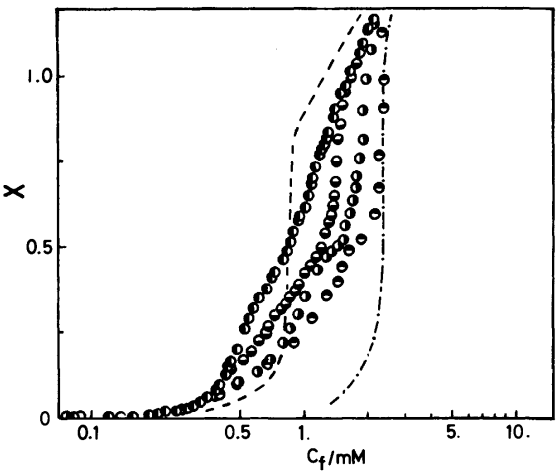

Fig. 4. Binding isotherms of dodecyltrimethylammonium chloride-heat denatured DNA system at 25 °C. NaCl concentrations: ◐: 20, ◒: 40, ◑: 80, and ◓: 160 mM. The dashed and chain lines for intact DNA in 20 and 160 mM NaCl at 25 °C, respectively.

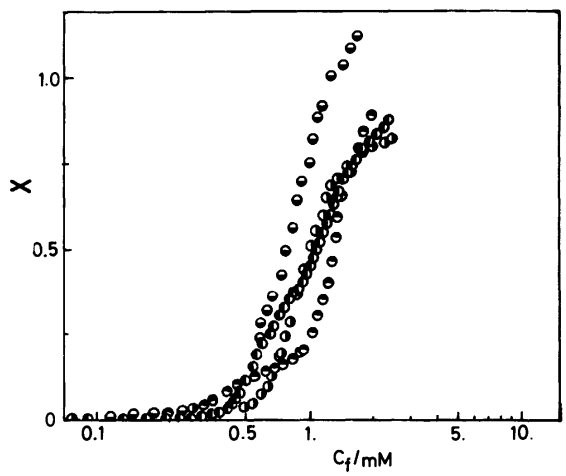

Fig. 5. Binding isotherms of dodecyltrimethylammonium chloride-heat denatured DNA system in 20 mM NaCl at various temperatures(°C); ◓: 15, ◐: 25, ◒: 35, and ◑: 45.

additional binding affinity is gained by contact between alkyl chains of bound surfactants and hydrophobic moiety of DNA which has been exposed to the aqueous phase by thermal denaturation. Randomized array of phosphate groups as a result of heat denaturation causes less effective interaction between alkyl chains of bound surfactants leading to a lower cooperativity, or a less steep growth of binding. It is to be noted that the binding isotherm overlaps that of not-heat-treated DNA (dashed and chained lines in Fig. 5) around $X=1$. This strongly indicates that the surfactant-DNA complex assumes the same dissolved state as the thermally denatured DNA does near the endpoint of surfactant titration, in other words, the cationic surfactant denaturates the DNA. Electrostatic shielding effect decreases the binding affinity in these systems, too.

In Fig. 5, the effect of temperature on the binding to the denatured DNA is shown. Here again an inversion temperature is observed around 27 °C: binding isotherm shifts to the left from 15 °C up to the inversion temperature, and moves back at 45 °C to the right. Regular structure of intact DNA may not be prerequisite for the inversion temperature phenomena, which is similar to a minimum found in a critical micelle concentration-temperature plot.[15-17]

Fluorescence from Pyrene. Fluorescence from pyrene provides significant information about microenvironment surrounding the molecule.[18] Figure 6 shows how relative fluorescence intensity at $\lambda=391$ nm, I_r, varies with the surfactant concentration. In the absence of DNA, and below cmc, I_r decreases. This means that fluorescence from pyrene molecules in aqueous environment is quenched on encounter with the cationic surfactant monomers. The pyrene molecules are, however, getting free from the quenching as soon as micelle formation begins. Pyrene molecules now find micelles where the quantum yield for fluorescence is enhanced. In the presence of DNA, I_r is much smaller than the one without DNA. When pyrene molecules are under the influence of DNA, they are probably intercalated between bases, and the quantum yield is very low.[19] However the fluorescence intensity is enhanced in parallel with the surfactant binding as seen in Fig. 6, where a dashed line shows the surfactant binding isotherm. That pyrene molecules are transferred to some hydrophobic micelle-like region in surfactant-DNA complex is suggested from comparison of curves (a) and (b).

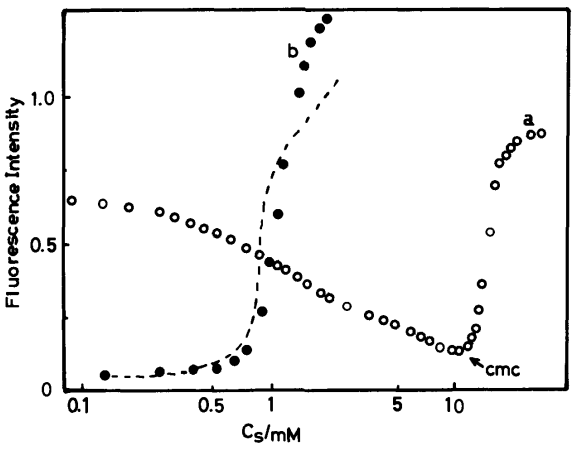

Fig. 6. Fluorescence intensity (in arbitrary unit) of pyrene ($\lambda=391$ nm) as a function of dodecyltrimethylammonium chloride concentration (in 20 mM NaCl at 25 °C). ○: Without and ●: with DNA. The dashed line shows a synchronized binding.

Ising Model. All these binding features will be semiquantitatively expressed in terms of statistical thermodynamics. Phosphate groups are taken as a one dimentional array of binding sites, on which the surfactant molecules are bound with their hydrocarbon chains in contact with each other. The partition function of the system is written as,

$$Z = aM^n a^* \tag{1}$$

with

$$M = \begin{pmatrix} 1 & 1 \\ s/u & s \end{pmatrix},\ a = (1,1),\ a^* = \begin{pmatrix} 1 \\ 0 \end{pmatrix},\ \text{and}\ s = KuC_f,$$

where K is equilibrium constant for a process that a surfactant is transferred from the aqueous bulk phase to an isolated binding site on DNA, and u an equilibrium constant of aggregation among bound surfactants, or cooperativity parameter.

When n is very large, Eq. 1 produces compact and useful expressions,[20] among which the following equations are convenient to extract thermodynamic informations,

$$X = \mathrm{dln}\, Z/\mathrm{dln}\, C_f = \{1-(1-s)/\sqrt{(1-s)^2+4s/u}\}/2 \tag{2}$$

$$K = 1/C_f(X=0.5)u, \tag{3}$$

where $C_f(X=0.5)$ is an equilibrium concentration assuring $X=0.5$. Lower halves of binding isotherms were fitted to Eq. 2 to calculate the value of u in conformity with the Manning's notion that electrostatic potential at polyelectrolyte surface remains relatively constant so long as the surface charge density is high enough.[21,22] The thermodynamic parameters thus obtained are shown in Figs. 7 and 8. It is noted in Fig. 7 that u increases, while K decreases with increasing the added electrolyte concentration. The value of u should be kept constant irrespective of added salt concentration, since it is an equilibrium constant for aggregation process of bound surfactants which are no longer charged. With increase in the amount of binding, electrostatic potential is reduced, although there may be a sort of compensation by the Manning's ion-condensation mechanism. This potential reduction brings about a negative cooperativity. The anticooperativity decreases with increase in added electrolyte concentration, as seen in Fig. 7,

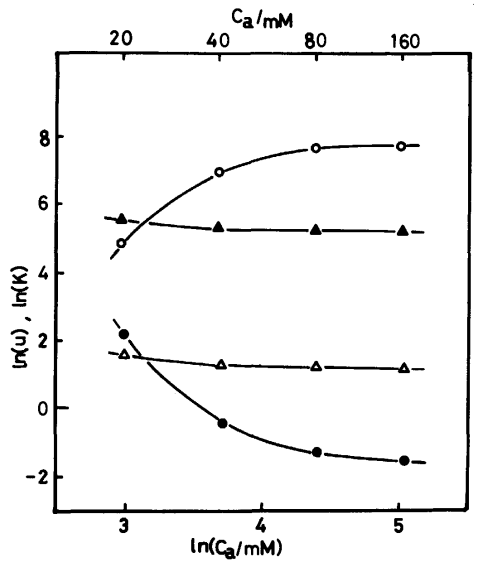

Fig. 7. ln u and ln K vs. ln C_a, where C_a is added NaCl concentration. ○: u and ●: K for intact DNA, and △: u and ▲: K for heat-denatured DNA.

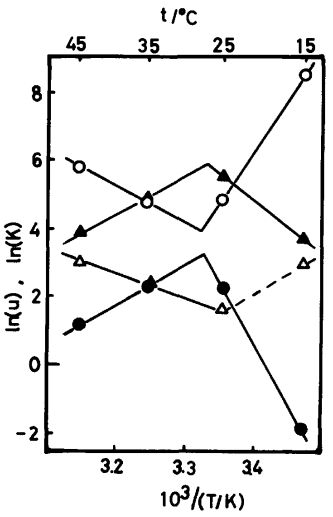

Fig. 8. ln u and ln K vs. $1/T$. ○: u and ●: K for intact DNA, and △: u and ▲: K for heat-denatured DNA.

where the effect of added electrolyte is almost saturated when C_a is as much as 160 mM. Figure 7 also shows the thermodynamic parameters for the thermally denatured DNA. Very low u and high K values may be responsible for the disordered phosphate array and exposed hydrophobic moieties of DNA as a result of heat denaturation as explained above.

Temperature dependence on the binding behavior is reflected on plots of ln u and ln K vs. $1/T$ in Fig. 8, where distinct reversal in the temperature dependence is observed around 26—27 °C, for both intact and heat-denatured DNA. Below the inversion temperature, K increases while u decreases with increasing temperature, and vice versa above it. Inversion in the temperature dependence in surfactant binding is also found for DNA[12] and dextran sulfate.[23] These phenomena are reminiscent of the similar minima found in cmc[15–17] as well as solubilities of some organic compounds in water.[24] Detailed studies on water structure and hydrophobic hydration are required before these inversion phenomena are fully understood.

Gross effect of added surfactant is to denature DNA which has ordinarily highly ordered structure. Proteins are also denatured by addition of surfactants, and the modes of action are very much complicated as well as diverse, reflecting the complexity of protein structures of primary, secondary, and higher orders.[25,26] In contrast, binding mode is simpler than that of proteins, and DNA behaves much like synthetic polyelectrolytes in binding surfactants.[8,11,23] However there is a distinct difference in DNA which undergoes an drastic order-disorder transition, while synthetic polymers will not show such a conformation change.

We thank Prof. Mitsuru Tanaka of Fukuoka University for providing the DNA sample.

Time-Resolved Unimolecular Reactions of Pyridine Ions by Means of Trapped-Ion Mass Spectrometry

Ryuichi ARAKAWA* and Yozaburo YOSHIKAWA
Institute of Chemistry, College of General Education, Osaka University,
Toyonaka, Osaka 560
(Received June 16, 1986)

The electron-impact ionization-efficiency curves for the $C_5H_5N^{+\cdot} \rightarrow C_4H_4^{+\cdot} + HCN$ dissociation have been measured as a function of the ion-source-residence time by means of trapped-ion mass spectrometry (TIMS). The ionization-efficiency curves for residence times of 5 and 700 μs were fitted by QET calculation, assuming dissociation-rate models. A kinetic shift of 0.3 eV was observed from the time-dependent appearance energy measurements. The fragmentation of metastable ions was first sampled for the ion-source residence time of 0—100 μs. The preferable rate model was determined by the analysis of the ionization-efficiency curves and the metastable ion fragmentations. Time-resolved kinetic energy releases for pyridine and perdeuteriopyridine have been explained in terms of excess energy drop of metastable ions with their lifetime.

The $C_4H_4^+$ ion is one of the major fragments from benzene and pyridine in their mass spectra. The appearance energy of the pyridine reaction (Eq. 1) has been measured by a wide variety of experimental techniques.[1-5]

$$C_5H_5N^{+\cdot} \longrightarrow C_4H_4^{+\cdot} + HCN. \quad (1)$$

One of the main problems in these measurements is the so-called "kinetic shift," the excess energy required to produce a detectable dissociation of a polyatomic ion. Ion-trapping techniques are favored for clarifying this kind of problem. There have been two reports of experimental results for the dissociation of trapped pyridine ions. One was the study of Rosenstock et al.[6] by means of photoion-photoelectron coincidence (PIPECO) mass spectrometry, with a variable ion-source-residence time. The dissociation threshold energy at 0 K was determined by their detailed analysis of time-dependent breakdown curves obtained from the first derivative of photoionization curves with a microsecond ion-residence time. The other was studied by Lifshitz[7] using trapped ion mass spectrometry, with a millisecond ion-storage time. The second derivative of electron-impact ionization curves produced the breakdown curves.

In these two studies, a shift observed for time-resolved breakdown curves was used for evaluating the kinetic shift. The measurements of the breakdown curve shift give us less erroneous information about the kinetic shift than conventional appearance energy measurements for metastable ions, e. g., a semilog plot. This is because metastable ions usually have quite a low intensity relative to the normal ion intensity. Compared with the PIPECO experiment, the TIMS experiment can easily change the ion-residence time from zero to several milliseconds, so that unimolecular reactions of rate constants ranging from 10^2 to 10^5 s^{-1} can be observed. However, its energy definition for ionized precursors is rather uncertain because of electron-impact ionization.

Recently, the fragmentation of the bromobenzene ion to the phenyl cation has been studied by Lifshitz and her co-workers[8] using time-resolved photoionization mass spectrometry (TPIMS). Photoionization efficiency (PIE) curves at ion-residence times of 2 m s and 6 μs have been, for the first time, measured and compared with the calculated PIE curves near the threshold energy. A critical appearance energy was determined from the calculation of the quasi-equilibrium theory(QET). The TPIMS technique has employed a cylindrical ion-trap chamber to store ions over milliseconds, because the variable-time PIPECO technique limits ion-source-residence time to a microsecond time scale.

In the present work, electron-impact ionization efficiency (EIE) curves for the pyridine reaction (Eq. 1) have been measured as a function of the ion-source-residence time. Then, we observed a shift of time-resolved daughter EIE curves near the threshold energy, although the electron-impact energy had an spread of ≈1 eV. The EIE curves moved to a lower energy side with an increase in the ion-residence time. The time-resolved EIE curves will be analyzed by QET calculation using two available unimolecular rate models. The EIE curve can be expressed in the mathematical form of double integrations of breakdown curves, while the PIE calculation involves a single integration of breakdown curves with respect to energy. A difficulty in the EIE curve calculation is to estimate the internal energy distribution of parent ions ionized with a variable incident electron energy. Here, we estimated the internal energy distribution on the basis of the threshold behavior of the electron ionization. In addition, the energy spread of incident electrons should be convoluted for the EIE calculation.

The metastable peak intensity and the kinetic energy release have not been measured for a wide range of ion-source-residence times. Two rate models for the pyridine reaction (Eq. 1) have been reported using the PIPECO technique.[3,6] We will discuss the

validity of these rate models by analyzing the time-resolved metastable ion fragmentation, because its fragmentation depends greatly on the unimolecular rate constant. Moreover, the time-resolved kinetic-energy-release measurement can closely test an empirical relation between the kinetic energy release and the internal excess energy of precursor ions.

Experimental

The ion trapping technique employed has been described in detail by Herod and Harrison[9] and by Lifshitz.[10] Ions were produced when a negative pulse was applied to a Rhenium filament. A continuous 5-eV electron beam, forming a negative potential well, was used to trap the ions. The well-depth should be greater than the thermal kinetic energy of the trapped ions.[11] A small negative bias on a repeller plate is also necessary for effective trapping. At a known delay time after the ionizing pulse, a positive pulse, 6 μs in duration and 6 eV in height, was applied to a repeller electrode to remove ions for mass analysis. The ion-trapping efficiency was examined by the use of Kr or pyridine ions. These ions were stored up to several milliseconds without any serious decrease in the trapped-ion concentration. An ionizing pulse 2 μs in duration was applied to the filament at 1-ms intervals. The nominal electron energy was varied by changing the pulse height applied to the filament.

A home-built tandem mass spectrometer[12] was used to measure the fragment-ion abundance and the kinetic-energy release in the metastable ion dissociation. Fragment ions produced by unimolecular decomposition occurring in the second-field free region between two magnets were detected by means of a pulse-counting method. Their intensities were then analyzed by means of a microcomputer. The temperature of the ion source was 423 K. The ion-accelerating voltage was 1.5 kV. The ion-source pressure was kept at 2×10^{-6} Torr (1 Torr=133.32 Pa). The collisional induced reaction were negligible, because the pressure in the field-free region was always less than 1×10^{-6} Torr. The samples of pyridine and perdeuteriopyridine (99% atom D; MERCK) were commercially obtained.

Results and Discussion

Time-Resolved EIE Curves and Appearance Energies. Figure 1 displays the EIE curves of daughter-($C_4H_4^+$) and parent($C_5H_5N^+$) ions for the delay times of 5 and 700 μs. The EIE data have been accumulated for several hours because of low counting rates near the reaction onset. A kinetic shift of about 0.3 eV was observed near the onset. In the previous TIMS experiment,[7] the normalized second derivatives of the experimental EIE curves yielded the breakdown curves. A crossing point of daughter and parent fractions in the breakdown curve moved with the delay time, and its shift was compared with that of the QET calculation. The breakdown curves have a width of a few eV at the nominal electron energy. Thus, it should be emphasized that time-resolved EIE curves, as well as the PIE curves in the TPIMS analysis, should be analyzed in a narrow energy range above the onset.

The time-resolved EIE of the daughter ion at a nominal electron energy, V, can be written in this form:

$$\mathrm{EIE}(V,t) = c\int_0^\infty m(E_t-V) \times\left[\int_{AE_o}^{E_t} f(E_t,E)(1-\exp(-k(E)t))dE\right]dE_t. \quad (2)$$

Here, c is the constant; t is the ion residence time; $m(E_t-V)$ is the instrumental-electron energy distribution; E_t is the total electron energy, defined as V plus the energy of the electron emitted from the filament; $f(E_t,E)$ is the internal energy distribution at the electron-impact energy, E_t; E is the internal energy of the parent ion; $k(E)$ is the unimolecular rate constant, and AE_o is the appearance energy at 0 K.

Morrison has proposed that the EIE second derivatives for inert gases yield the electron-energy distribution, reversed with respect to the energy scale.[13] In the present case, the $m(E_t-V)$ distribution was obtained by differentiating the experimental helium EIE. The half-width of $m(E_t-V)$ was found to be 0.8 eV. From the threshold law of ionization,[14] the internal energy distribution is given by $f(E_t,E)=p(E)\cdot(E_t-E)^{K-1}$, where $p(E)$ is the energy deposition function; the exponent K gives the number of electrons that leave the collision complex; $K=1$ for

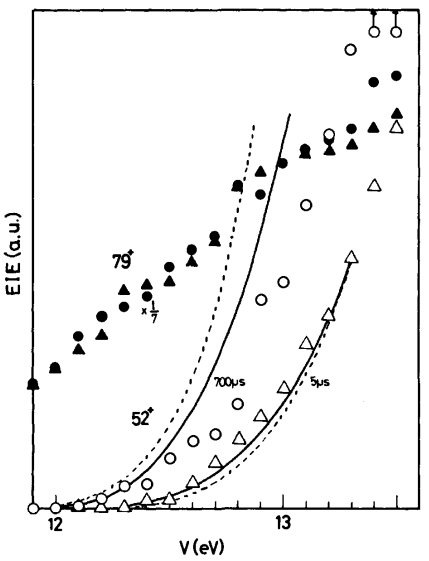

Fig. 1. Time-resolved electron ionization efficiency (EIE) curves measured with a 0.1 eV step of the nominal electron energy V. Experimental EIEs plotted on an arbitrary unit: ○, △, $C_4H_4^+$ fragment (52^+) for the delay times of $t=700$ and 5 μs, respectively; ●, ▲, parent ion (79^+). The EIE calculations based on the two available $k(E)$ models: ——, Eland et al.[3]; ----, Rosenstock et al.[6]. The calculated EIE curves were normalized at $V=13.3$ eV for the 5 μs curve.

photon impact, and $K=2$ for electron impact. The first derivative of the total PIE reported by Goffart et al.[15] was assumed to represent the $p(E)$ function upon ionization by electron impact. The mean vibrational energy of the pyridine molecules was 0.13 eV at 423 K. This thermal distribution was not considered in the EIE calculation, because the thermal effect was much less than the broad $m(E_i-V)$ distribution.

The experimental EIE curves were fitted using the two rate models proposed by Eland et al.,[3] $k_E(E)$, and by Rosenstock et al.,[6] $k_R(E)$. The $k_E(E)$ model has a tight transition state to fit their experimental $k(E)$ with the threshold energy of $AE_O=11.8$ eV. $k_R(E)$ is a loose model having $AE_O=12.15$ eV, which fits the measured crossover shift and the crossover energy of the breakdown curves. As a result, $k_R(E)$ has a somewhat steeper energy dependence than does $k_E(E)$.

The short delay time of 5 μs corresponds to the actual reaction time of 8 μs in the ion source. Figure 1 indicates that agreement with the experimental EIE curves is better for the $k_E(E)$ model than for the $k_R(E)$ model. This is consistent with the breakdown curve results[7] for fitting the experimental crossover shift for delay times of 5 and 1000 μs. From the time-resolved EIE calculation, the shift near the onset proved to depend only on the magnitude of $k(E)$ and to increase as the rate decreased. These results were actually due to the term of $1-\exp(-k(E)t)$ in Eq. 2. The $k_R(E)$ rate model, therefore, yielded a larger EIE shift than the $k_E(E)$ model, as is shown in Fig. 1; the rate constant near the threshold is smaller for $k_R(E)$ than for $k_E(E)$, because the $k_R(E)$ model has a higher reaction threshold. Thus, the amount of EIE shift is principally affected by the AE_O value.

The appearance energies, AE, of the $C_4X_4^+$ (X=H,D) ion, measured as a function of the delay time for pyridine and deuteriopyridine, are shown in Fig. 2. The convenient procedure for AE determination has been described by Burgers and Holmes[16] and by Gefen and Lifshitz.[17] On the basis of this procedure, we obtained the experimental AE value at a known delay time by comparing the EIE intensity of the fragment with that of a reference over a narrow range of ionizing-electron energies. The EIE comparison is usually made at the energy of ≈2 eV, far from the real onset, where the EIE intensity is statistically sufficient. The EIE curve for pyridine ions was employed as a reference. The ionization energy of pyridine (9.36 eV) was obtained by calibration with the ionization energies of benzene (9.24 eV)[18] and methyl acetate (10.27 eV).[2]

Lifshitz[7] has calculated the dependence of the delay time on the appearance energies using an equation for a minimum detectable ion signal developed by Gordon and Reid.[19] We recalculated the AE curve with the $k_E(E)$ rate model, as is shown in Fig. 2. The experimental AE of the $C_4H_4^+$ ion levels off at $AE=12.1\pm0.1$ eV. The kinetic shift of 0.3 eV for the $C_4H_4^+$ fragment was obtained from the AE gap between short and long reaction times. This AE gap agreed with the calculated one. In the present AE measurement, the EIE comparison was made at around $V=14$ eV. On the other hand, the time-resolved EIE measurement due to data accumulation produced an EIE shift of ≈0.3 eV at the lower energy of $V=12.5$ eV, as is shown in Fig. 1. Hence, it is worth

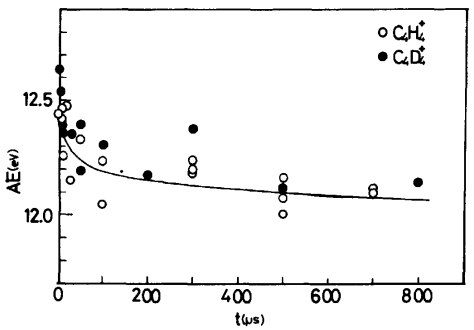

Fig. 2. Time dependent appearance energies AE for the reaction $C_5X_5N^{+\cdot}\rightarrow C_4X_4^{+\cdot}+XCN$(X=H, D). Experimental AEs at the ion source temperature of 423 K are indicated by open circles (X=H) and filled (X=D). The smooth line is the calculated AE for $C_4H_4^+$ using the rate model of Eland et al. Procedure for time-dependent AE calculation has in detail been described in Ref. 17. The minimum daughter concentration was calculated by setting $AE=12.5$ eV for $t=0$ μs. Since the detection sensitivity was independent of the delay time, AE for given delay time was then determined so as to produce the same concentration as calculated for $t=0$ μs.

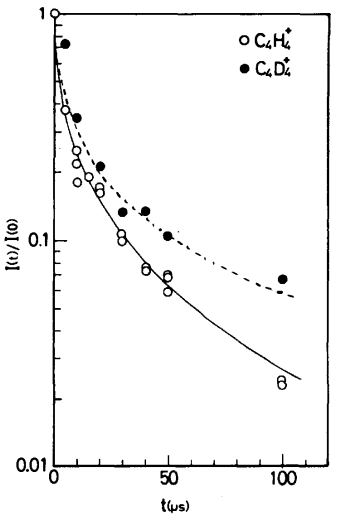

Fig. 3. The metastable ion abundances $I(t)$ for $C_4H_4^+$ (○) and $C_4D_4^+$ (●) measured as a function of delay times when $V=20$ eV. The data are nomalized at $t=0$ μs. The solid and dashed curves are the calculated $I(t)$ for $C_4H_4^+$ using the rate models of $k_E(E)$ and $k_R(E)$, respectively.

noting that the EIE shift measured is rather independent of the detection sensitivity of EIE. Finally, the rate model of Eland et al. is the preferable model for fitting the time-resolved EIE and AE curves. The AE values for the $C_4D_4^+$ fragment, as a whole, have a tendency to exceed those for the $C_4H_4^+$ fragment. The AE_0 value for perdeuteriopyridine was estimated by applying a zero-point vibrational energy correction[5]; at most, it proved 0.1 eV greater than that for pyridine.

Fragmentation of Metastable Ions. The relative abundance of the $C_4X_4^+$ resulting from the metastable transition of $C_5X_5N^+$ (X=H,D) was measured in the range of t=0—100 μs, as is shown in Fig. 3. For example, the $C_4H_4^+$ fraction relative to the parent ion was 3.1×10^{-2} at t=0 μs. The fragment abundance, $I(t)$, is given[20] by:

$$I(t) = c\int_0^\infty m(E_t-V) \times\left[\int_{AE_0}^{E_t} f(E_t-E)w(E)(k(E)/k_t(E))dE\right]dE_t, \quad (3)$$

where $k_t(E)=k(E)+k_n(E)$ is the total decay rate, $k_n(E)$ is a nondissociative rate such as the infrared radiative decay and the collisional relaxation in the ion source, and $w(E)=\exp(-k_t(E)t_1)-\exp(-k_t(E)t_2)$ is a fraction of the metastable-ion dissociation. (t_2-t_1) is the time ions spend in the second field-free region, where metastable ions are produced; $t_1=6.8+t$ and $t_2=11.8+t$ μs. The $I(t)$ curves for the $C_4H_4^+$ fragment were calculated with two $k(E)$ models in the case of $k_n(E)=0$. The calculated curve for the $k_E(E)$ model is in good agreement with the experimental curve, as is shown in Fig. 3. In this manner, the measurements of the time-resolved metastable peak abundances enable us to determine the $k(E)$ model, because the $I(t)$ curve is dependent on a rising steepness of $k(E)$. The rates corresponding to a peak of the $w(E)$ function when t=0 and 100 μs are $k(E)=1.1\times10^5$ and 9.1×10^3 s^{-1} respectively. These rates mainly contribute to the metastable fragmentation.

The approximate collisional relaxation rate is given by the Langevin ion-molecule reaction theory.[21] The relaxation rate of a bimolecular reaction is 80 s^{-1} at the present sample density if the polarizability of benzene, 10.3×10^{-24} cm^3, is taken as that of pyridine. Dunbar[22] has suggested that an upper limit on the lifetime of metastable-ion decomposition is determined by the competing relaxation of the infrared radiative cooling. This upper limit lies in the range of 15—60 s^{-1} for polyatomic molecules. The effects of the radiative decay on time-resolved PIE curves have been discussed in the case of a bromobenzene reaction.[8]

The nondissociative rate, $k_n(E)$, is, at most, 150 s^{-1}, as has been estimated above. This amount of $k_n(E)$ proved to have no effect on the quantity of metastable-ion fragmentation. For $k(E)\leq10^3$ s^{-1}, small values of $k_t(E)t_1$ and $k_t(E)t_2$ lead to $w(E)k(E)/k_t(E)\simeq(t_2-t_1)k(E)$ in Eq. 3. For $k(E)>10^3$ s^{-1}, $k_n(E)$ is negligible compared with $k(E)$. Thus, $I(t)$ is independent of $k_n(E)$.

Figure 4 represents the fragmentations of the metastable $C_4X_4^+$ ion by the loss of a hydrogen atom and a hydrogen molecule. The relative intensity of the two channels is nearly equal throughout the delay time.

Time-Resolved Kinetic Energy Release (KER). A metastable peak shape and its width are a very sensitive measure of the KER in unimolecular reactions.[23] In principle, a reaction with a large kinetic shift should show a large change in the KER with a increase in the metastable-ion lifetime. This has been demonstrated by Gefen and Lifshitz[17] in the case of iodobenzene. The KER value T, as determined by the peak analysis,[24] is given by:

$$T = m_1^2HV/(16m_2^3m_3)d^2 \quad (4)$$

Here, m_1 is the mass of the parent ion; m_2 and m_3 are the mass of the fragment ion and the neutral respectively; HV is the ion-accelerating voltage, and d is the peak width of the metastable ion, corrected by the normal peak width in units of the atomic mass. The experimental KER values at a half maximum, $T_{1/2}$, are listed in Tables 1 and 2. The error limits represent the standard deviation of several runs.

A simple method for the evaluation of the average KER $\langle T\rangle$ for a Gaussian-type metastable peak was described by Holmes and Osborne.[25] The $\langle T\rangle$ values were obtained from their relationship between the $\langle T\rangle/T_{1/2}$ ratio and the peak shape parameter n(=1.8 for the present case), which had itself been derived from width ratios at the given peak heights. Accord-

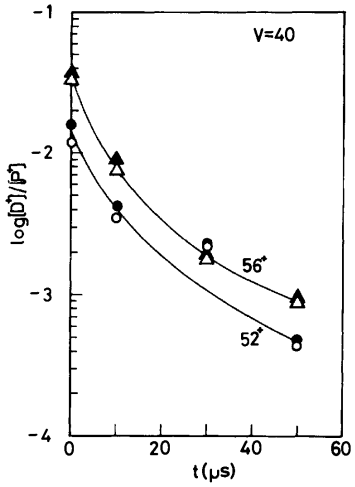

Fig. 4. Time-resolved abundances produced by two parallel fragmentations by X and X_2 loss from $C_4H_4^+$ (X=H, D) precursors. Symbols represent fragments by the H(○), H_2 (●), D (△), and D_2 (▲) loss. The abundances relative to the parent, $[D^+]/[P^+]$ at V= 40 eV are plotted on a logarithmic scale. The lines are for easy comparison.

Table 1. Time-Resolved Kinetic Energy Releases $T_{1/2}$ for the Pyridine Metastable Transition of $C_5X_5N^{+\cdot} \longrightarrow C_4X_4^{+\cdot} + XCN(X=H, D)$

$t/\mu s$	X=H			X=D		
	$T_{1/2}$/meV	E^*/eV[a]	E_p/eV[b]	$T_{1/2}$/meV	E^*/eV	E_p/eV[c]
0	49±10	1.5±0.3	0.90	53	1.6	1.2
5	41±8	1.3±0.3				
10	29	0.9	0.80	43	1.3	1.0
20	23	0.7

40	8	0.3				
50	8	0.3	0.65	33	1.0	0.85
100	0		0.60	35	1.0	0.80

a) E^* represents the excess energy of metastable ions above the reaction threshold, which was obtained from the experimental $T_{1/2}$ values according to the relation of Haney and Franklin.[26] b) E_p is the peak energy for the $w(E)$ function above the threshold. It corresponds to the $k(E_p)=\ln(t_2/t_1)/(t_2-t_1)$ rate, where t_1 and t_2 are respectively, the entrance and the exit time in the second field-free region. The $k(E)$ model of Eland et al. was used for this calculation. c) The unimolecular rate constant for deuteriopyridine was obtained by directly computing the harmonic oscillator eigenstate sums and densities. The vibrational frequencies used were given in Ref. 5.

Table 2. Time-Resolved Kinetic Energy Releases $T_{1/2}$ for $C_4X_3^+$ and $C_4X_2^+$ Fragments from Metastable $C_4X_4^+$(X=H, D) Ions

$t/\mu s$	$T_{1/2}$/meV			
	$-H$[a]	$-H_2$	$-D$	$-D_2$
0	90±15	330±50	180	400
10	0	160	180	330
20	0	220	—	—
30	0	100	140	200
50	—	—	100	200

a) The notation of $-H$ represents the hydrogen atom loss.

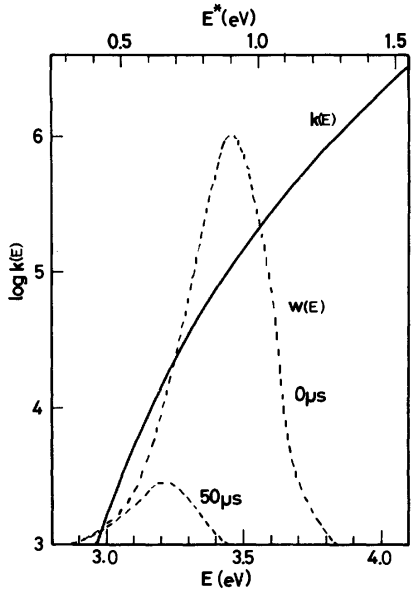

Fig. 5. The relationship of $k(E)$ and $w(E)$ for the pyridine reaction. $k(E)$ indicates the unimolecular rate constant of Eland et al. The $w(E)$ functions, as defined in Eq. 3, for delay times of $t=0$ and 50 μs are linearly plotted on an arbitrary unit vs. the internal energy E above ionization threshold. E^*(upper scale) represents the excess energy above reaction threshold.

ing to the empirical formula of Haney and Franklin,[26] $\langle T\rangle=E^*/(0.44N)$, the average KER $\langle T\rangle$ is related to the excess energy(E^*) of metastable ions above the threshold. Here, N is the number of vibrational degrees of freedom of the parent ion. $\langle T\rangle$ should approach zero as E^* approaches zero if there is no reverse activation energy. The excess energies estimated from the experimental $T_{1/2}$ values are given in Table 1.

Generally, the KER value decreases with the lifetime of metastable ions. The fragmentation takes place only for metastable ions with a limited range of excess energy, as defined by the $w(E)$ function in Eq. 3. The $w(E)$ curves for $t=0$ and 50 μs were calculated with the $k_E(E)$ model, as shown in Fig. 5. The increase in the delay time lowers the peak position of the $w(E)$ curve. A peak energy E_P of $w(E)$ above the threshold can be representative of the average internal energy, compared with E^*. The E^* values for every delay time in Table 1 are estimated to have the error limit of ≈0.3 eV. The experimental E^* values are roughly reproduced by the calculated E_P values, except at $t=0$ μs. The reaction of deuteriopyridine has slower rate constants than that of pyridine. This causes the larger KERs for deuteriopyridine than for pyridine; The excess energy of decomposing ions declines consistently with the increase in the rate constant. Strictly speaking, the metastable peak should be analyzed by taking the internal energy distribution into account. An sttempt to determine time-resolved KERs for pyridine has been made in a previous TIMS

study.[7] A rough estimate of the maximum KER ratio at delay times of 0 and 100 μs was $T_{max}(0\ \mu s)/T_{max}(100\ \mu s)=3.5$. The maximum KER, which reflects the internal excess energy, was obtained from the widths at the base of the peaks above the noise level. This KER ratio is far beyond the calculated E_P ratio of 1.5 between $t=0$ and 100 μs.

Table 2 represents time-resolved KERs by the X and X_2 loss of the metastable $C_4X_4^+$ ion. Our KER values of $T_{1/2}=90$ and 330 meV for $C_4H_4^+$ at $t=0$ μs are comparable to those of $T_{1/2}=49$ and 399 mV[27] respectively. As in the pyridine reaction, the $C_4D_4^+$ reaction always has a greater KER than the $C_4H_4^+$.

The present study has advanced understanding of the unimolecular decomposition of pyridine ions. The reaction rate model of Eland et al. proved to be best for time-resolved measurements of both the EIE curve and the metastable peak. In particular, the analysis of the EIE shift near onset permitted a determination of the AE_0 threshold energy, whereas the measurement of the metastable-ion fragmentation was effective for evaluating the rising steepness of $k(E)$. The empirical formula of Haney and Franklin was not ruled out by the present time-resolved KER measurements with the metastable-ion lifetime of 0—100 μs.

We wish to thank Professor C. Lifshitz, Department of Physical Chemistry, The Hebrew University of Jerusalem, for her helpful discussions and advice.

(Received June 24, 1986)

Vapor-phase amination of cyclohexanol with ammonia over silica-supported platinum and other platinum group metal (Ru, Rh, Pd, Ir) catalysts has been studied. Cyclohexylamine and aniline are the main products. Platinum is the most active metal, although there is not much difference in the activity between platinum and other metals. The reaction is suggested to proceed as follows. The first step, which is rate-determining, is the dehydrogenation of cyclohexanol to cyclohexanone intermediate, from which cyclohexylamine and aniline are formed in the parallel process via cyclohexylideneamine. From reaction-rate measurements on Pt/SiO_2 catalysts with different Pt particle size, the amination reaction has been found to be structure-insensitive. The catalytic activity decreases with time on stream probably because of the deposit of carbonacious or polymeric materials on the catalyst surface.

The amination of cyclohexanol to cyclohexylamine with ammonia has been carried out over various acidic catalysts such as ThO_2[1] and Al_2O_3.[2] In addition, supported or unsupported metal catalysts are also effective for this reaction. For example, Raney Ni, Co, Cu,[3,4] and Cu–Zn oxide catalysts[5] were used for the vapor-phase amination, and reduced Ni catalysts[6] for the liquid-phase amination.

Recently, it has been found that the reaction of cyclohexanol and ammonia over platinum group metal catalysts gives aniline by simultaneous amination and dehydrogenation. Baker[7] obtained aniline in high selectivity by vapor-phase reaction of cyclohexanol/NH_3/H_2 over Pt/C catalysts. Carrubba and Golden[8] used Pt/SiO_2 for the same reaction. Moreover, modified Pd/Al_2O_3 catalysts are also useful for aniline formation according to an European patent.[9] Richardson and Lu[10] studied dehydrogenation and amination of cyclohexanol over a commercial Pt/SiO_2 catalyst by changing contact time and reaction time and speculated a possible reaction pathway. However, no study has been made on the basic nature of cyclohexanol amination over platinum group metal catalysts, which is useful information to develop high-performance catalysts.

In this paper, the catalytic activity and selectivity of silica-supported platinum group metals for the vapor-phase cyclohexanol amination is first investigated. Then, the reaction mechanism is examined by changing reaction conditions or performing related reactions. Structure sensitivity of the reaction is also studied by changing metal particle size. Finally, catalyst deactivation is discussed.

Experimental

Preparation of Catalysts. All the catalyst samples used in this study were prepared by impregnation of silica (Davison #57) with an aqueous solution of metal chloride salts ($RuCl_3 \cdot H_2O$, $RhCl_3 \cdot 3H_2O$, $PdCl_2$, $IrCl_4 \cdot H_2O$, $H_2PtCl_6 \cdot 6H_2O$). The samples were then dried with a rotary evaporator (353 K 1 h, 383 K 1 h) and finally reduced in flowing hydrogen (773 K 3 h).

Characterization of Catalysts. In order to know the percentage metal exposed or dispersion (for fresh catalysts), hydrogen chemisorption measurements were performed at room temperature in the pressure range of 5—30 kPa with a conventional volumetric adsorption system. Catalyst samples reduced at 723 K were outgassed for 1 h at the same temperature before the measurements. The chemisorption values were determined by extrapolating the linear portion of adsorption isotherms to zero pressure except for Pd/SiO_2. In the case of Pd/SiO_2, the chemisorption value was taken as the difference between the first adsorption value and the backsorption value measured after evacuation at room temperature for 10 min, in order to eliminate the contribution of hydride formation.[11] Percentage metal exposed or dispersion was calculated from the chemisorption value on the assumption that one hydrogen atom is chemisorbed on each metal atom at the surface. Then, metal particle size was calculated by using the following equation, assuming a spherical shape.[12]

$$d = 6V/AD \quad (1)$$

where d is the metal particle size, D is the dispersion, V is the volume occupied by a metal atom in the bulk, and A is the effective average area occupied by a metal atom in the surface.

Reaction Procedures. The amination reactions were carried out with a continuous flow reactor at atmospheric pressure. Cyclohexanol was pumped by a motor-driven syringe to the preheating zone of the reactor. Ammonia from a cylinder was dried through a potassium hydroxide column and mixed with hydrogen before entering the reactor. The reactant gas flow was 24 mmol h^{-1} of cyclohexanol, 98 mmol h^{-1} of ammonia, and 98 mmol h^{-1} of hydrogen. The reaction products were trapped by bubbling into a ice-cold trap containing 2-propanol as the solvent and *N,N*-dimethylaniline as the internal standard for analysis.

Catalysts placed in the reactor were first reduced in flowing hydrogen at 723 K for 30 min and the temperature was lowered to the reaction temperature. Then, ammonia and cyclohexanol were fed. The products were analyzed by a gas chromatograph with a 3-m column of Silicone DC-

a) Reaction temperature: 493 K. b) L is the metal loading. c) D is the metal dispersion.

550 operating from 378 K to 468 K at a rate of 10 K min^{-1}. Product yield (Y), cyclohexanol conversion (C), product selectivity (S), and turnover rate of formation (TOR) were calculated on the cyclohexanol basis from the following equations.

$$Y/\% = \frac{\text{Product produced/mol}}{\text{Cyclohexanol fed/mol}} \times 100 \quad (2)$$

$$C = \text{Total product yields} \quad (3)$$

$$S/\% = \frac{\text{Product yield}}{\text{Cyclohexanol conversion}} \times 100 \quad (4)$$

$$TOR/\text{s}^{-1} = \frac{\text{Product produced/mol s}^{-1}}{\text{Amount of Surface catalyst metal atoms/mol}} \quad (5)$$

As carbon balance was fairly good, Eq. 3 is not a bad selection for the calculation of cyclohexanol conversion. The catalyst amount was controlled so that the conversion was less than 10% in most cases.

Results and Discussion

Catalytic Activity and Selectivity of Platinum Group Metals. Table 1 summarizes the reaction results on silica-supported platinum group metal catalysts. The loading of these metals was approximately fixed at 5 wt%. As catalyst deactivation was observed, initial activity values are taken in Table 1. The main products were cyclohexylamine and aniline. The by-products detected were cyclohexane, benzene, dicyclohexylamine, and *N*-cyclohexylaniline. As will be discussed later, the last two products are considered as the condensation products of two cyclohexylamine molecules, and one aniline and one cyclohexylamine molecule, respectively.

The most active catalyst is Pt/SiO_2 because the conversion per unit weight was the largest. It also gave the largest total turnover rate. However, the difference between Pt and Rh, the least active metal, is within one order of magnitude. With respect to selectivity, aniline was barely formed on Ru or Ir, showing that these two metals have little activity for dehydrogenation to aniline. On the other hand, aniline formation was observed on Rh, Pd, and Pt, among which Pd showed the highest selectivity to aniline. This nature of catalyst metals agrees very much with the work by Ono and Ishida on phenol amination,[13] where aniline was formed in high selectivity on Pd, Pt, and Ph/Al_2O_3 while aniline was not detected on Ru/Al_2O_3. Another point to be noted is that the elimination of amino or hydroxyl group was observed on Rh and Pt, resulting in the formation of cyclohexane and benzene.

Taking high activity into consideration, all the following studies were done with Pt/SiO_2.

Effect of Reaction Conditions. The effect of reaction temperature on cyclohexanol amination was examined in the temperature range of 478—539 K and

is shown in Fig. 1. Both cyclohexylamine and aniline yield increased with temperature. But the selectivity shifts to aniline at high temperatures. Therefore, high temperature is desirable for aniline formation. In fact, Richardson et al.[10] obtained aniline in high selectivity at 573 K.

In Fig. 2 is shown the effect of contact time on the conversion and yield. The yield of each product increased almost proportionally with contact time within the range to 3.5 g h mol^{-1}. The selectivity change with contact time is plotted in Fig. 3, which shows that the selectivity to dicyclohexylamine increases and that to cyclohexylamine decreases. This suggests that the former originates by condensation reaction of two molecules of the latter. Similarly, *N*-cyclohexylaniline is thought to be formed by condensation of cyclohexylamine and aniline, although this conclution is not so clear as in the case of dicyclohexylamine.

When the yield of these dimers is divided and added to their component compounds (cyclohexylamine and aniline), the selectivity does not change much within the whole range of the experiment. This result indicates that cyclohexylamine and aniline are formed from cyclohexanol not in the consecutive process but in the parallel process.

Reaction Mechanism. In order to elucidate the reaction mechanism, several related reactions were performed. The results are summerized in Table 2. First, when cyclohexanol and hydrogen were passed over Pt/SiO_2 with inert N_2 instead of NH_3, cyclohexanone was formed as the only product, the cyclohexanol conversion being almost the same. Next, cyclohexanone was fed instead of cyclohexanol in the amination reaction. In this case, the conversion was much larger, but the product distribution was almost the same except for the ratio of monomers to dimers. Therefore, it is inferred that amination of cyclohexanone is a facile reaction, producing the same products in the same selectivity as the amination of cyclohexanol. In order to examine the formation pathway of cyclohexylamine or aniline, cyclohexylamine or aniline was passed at 493 K over Pt/SiO_2 in an atmosphere of ammonia and hydrogen. It was found that cyclohexylamine is not formed from aniline and the reverse reaction occurs to only a little extent. This means that conversion from cyclohexylamine to aniline is a difficult reaction under these

reaction conditions or vice versa. Therefore, these two compounds are considered to originate not in the consecutive process but in the parallel process. It is unlikely that cyclohexylamine and aniline are in equilibrium. Ono and Ishida[13] pointed out that cyclohexylamine and aniline are formed in equilibrium in the case of phenol amination at 523 K. The difference may be attributed to different catalysts and reaction conditions.

From these results, a reaction scheme represented by Fig. 4 can be given. The first step, which is rate-determining, is the dehydrogenation of cyclohexanol to cyclohexanone intermediate. Then, cyclohexylamine and aniline are formed simultaneously via cyclohexylideneamine by amination of cyclohexanone. The presence of cyclohexylideneamine intermediate has been proposed and proved in studies on amination reactions[13,14] or hydrogenation of aniline.[15]

Structure Sensitivity. Catalytic reactions on metal catalysts can be classified into two groups, one is structure-sensitive and the other structure-insensitive, depending on the manner how the catalytic activity is influenced by metal particle size or crystallographic plane.[16] To investigate structure sensitivity of this amination reaction, six Pt/SiO_2 catalysts with different Pt particle size were prepared by changing Pt loading from about 0.30 to 6.5 wt%. With decreasing Pt loading, Pt dispersion increased from 16 to 73% and Pt particle size decreased consequently from 7.2 to 1.6 nm. The reaction results are shown in Table 3. It was found that catalytic activity per surface metal atom and product selectivity do not change much with Pt particle size. Therefore, it can be concluded that cyclohexanol amination on Pt/SiO_2 is a structure-insensitive reaction. This conclusion is also supported by the result of Table 1 that the catalytic activity is not so sensitive to the nature of the catalyst metal.[17] Most of hydrogenation and dehydrogenation reactions have been found to be structure-insensitive. Therefore, this amination reaction can be expected to be structure-insensitive because the rate-determining step is the dehydrogenation of cyclohexanol to cyclohexanone. Thus, improving metal dispersion has no more effect than making metal surface area larger.

Strictly speaking, however, the product distribution seems to be affected by Pt particle size, because the selectivity to aniline decreased and the selectivity to

6.5	16	7.2	0.071	5.39	90.23	50.94(56.5)	6.49(7.2)	5.06(5.6)	2.27(2.5)	25.48(28.2)

a) Reaction temperature: 493 K. b) L is the Pt loading. c) D is the Pt dispersion. d) d is the Pt particle size.

cyclohexane plus benzene increased with Pt particle size, as can be seen from Table 3. Especilally on 6.5% Pt/SiO_2, considerable elimination of amino or hydroxyl group was observed, resulting in 28% selectivity to cyclohexane plus benzene. Hence, highly dispersed Pt/SiO_2 is favorable for obtaining aniline in higher selectivity.

Deactivation of Catalysts. Figure 5 shows a typical change of the product yield with time on stream. The yield of each product dropped with time especially at the beginning of the reaction. It should be noted, however, that the product selectivity remains unchanged. Considering that this reaction is structure-insensitive, it is suggested that the number of surface Pt atoms decreases as the catalyst deactivation proceeds. In fact, Table 4 indicates that the catalyst deactivation is closely related to the decrease of

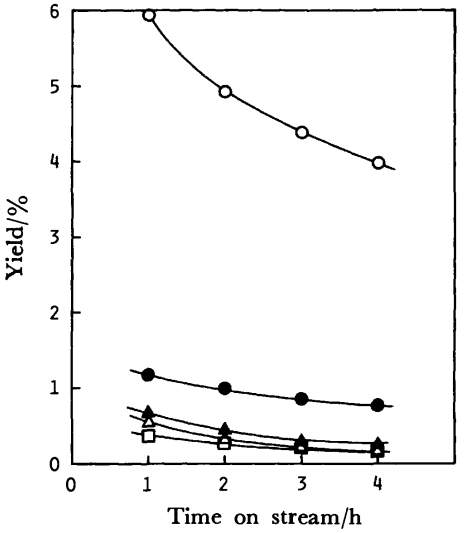

Fig. 5. Change in the product yield with time on stream in cyclohexanol amination at 493 K on 0.50% Pt/SiO_2. ○: Cyclohexylamine, ●: aniline, △: dicyclohexylamine, ▲: *N*-cyclohexylaniline, □: cyclohexane+benzene.

Table 4. Change in Percentage Pt Exposed by Reaction[a]

	Fresh	Used
0.30	73	36
0.50	63	35
0.99	49	35
2.9	22	19
6.5	16	14

a) Catalyst amount: 1.8 g. Reactions conditions: 523 K, 5 h. b) L is the Pt loading. c) D is the percentage Pt exposed, which is equal to Pt dispersion for fresh catalysts.

percentage Pt exposed, and that the extent of decrease is larger as the Pt loading is smaller.

Deactivation may be caused by sintering or surface fouling by carbonaceous or polymeric materials. In the case of this reaction, surface fouling is more likely because the catalyst weight increased by 10% after performing amination reaction. This conclution agrees with the work by Richardson and Lu.[10] However, regeneration of the deactivated catalysts by calcination with air and/or hydrogen has been unsuccessful so far.

A High Resolution ^{23}Na NMR Study of Sodium Complexes with Ionophores in Solution. Stability of Complexes as Viewed from Displacements of ^{23}Na Chemical Shifts as Referred to Those in the Solid State

Hazime Saitô* and Ryoko Tabeta
Biophysics Division, National Cancer Center Research Institute,
Tsukiji 5-Chome, Chuo-ku, Tokyo 104
(Received June 26, 1986)

We have recorded ^{23}Na NMR spectra of sodium complexes with naturally occurring and synthetic ionophores in chloroform and methanol solution, to gain insight into conformational stability of these complexes as examined from the displacements of ^{23}Na chemical shifts with respect to those in the solid state. Interestingly, the ^{23}Na chemical shifts of sodium complexes with monensin and tetranactin obtained in chloroform solution are very close to those in the solid, as a result of adopting similar conformation between the solid and solution. For the rest of complexes, however, the ^{23}Na NMR signals are displaced downfield in solution as compared with those of the solid state. Such downfield shifts are well interpreted in terms of the presence of conformational fluctuation and/or sodium ions interacting with solvent or anions. Therefore, downfield displacement is more significant in methanol which can be good ligand molecules. The presence of fluctuation-induced quadrupole coupling constants is consistent with our view about ^{23}Na chemical shifts. These quadrupole interactions were reduced in methanol solution, owing to the presence of exchange with solvents.

It is well-recognized that ionic permeability of alkaline cations in biological or artificial membranes is strongly enhanced by the presence of naturally occurring or synthetic ionophores.[1-4] This phenomenon can be interpreted in terms of a mobile carrier model of ionophores in which most important step is complexation of metal ions to these ionophores at interface and interior of membrane lipids.[2] These ligand molecules should undergo marked conformational change to achieve stability and ion selectivity for particular metal ions. Nevertheless, it has not yet been fully explored whether or not conformations of these ionophores in the crystalline state are retained in the liquid phase or membrane-bound state because of lack in suitable experimental means. One of the most promising new approach to this end is to examine displacements of the conformation-dependent ^{13}C chemical shifts (up to 8 ppm) which are varied upon particular conformations, as manifested from our previous high-resolution solid-state ^{13}C NMR studies of a variety of crystalline free and complexed ionophores.[5-8]

Alternatively, we can utilize ^{23}Na chemical shifts of sodium complexes in solution as compared with those of the solid state. For this purpose, we have recently demonstrated that ^{23}Na chemical shifts of solid sodium salts and complexes are significantly displaced (up to 60 ppm) depending on a variety of anions or ligand molecules and the Na–O interatomic distances,[9,10] as determined by magic angle spinning (MAS) method. The advantage of recording ^{23}Na NMR spectra in the solid state is that NMR signals of the individual species of the ion–ion, ion-solvent, and ion-ligand interactions were observed separately in the solid state, free from any chemical exchange process as encountered in solution. For the latter, extensive conventional high-resolution ^{23}Na NMR studies have been performed to obtain the kinetic and thermodynamic data of complexation in solution[11-25] although separate observation of such species is difficult owing to the presence of fast chemical exchange. Accordingly, use of these solid-state ^{23}Na NMR data provides one unambiguous reference data to assess whether or not conformations achieved in the solid state are retained in solution or membrane-bound state. For this purpose, it seems to be essential to utilize solvent of lower polarity such as chloroform to reproduce hydrophobic environment as in interior of biomembranes, although previous ^{23}Na NMR study by Haynes et al.[12] was mainly conducted for sodium complexes in methanol solution owing to the encountered difficulty in recording substantially broadened spectra in chloroform.

In this paper, we aimed to compare ^{23}Na chemical shifts of sodium complexes with some naturally occurring (valinomycin, nonactin, tetranactin, monensin, and lasalocid) and synthetic (cryptands 22, 221, 222, and 18-crown-6) ionophores (see Fig. 1) in chloroform and methanol solution with those obtained in the solid state previously reported.[10] Surprisingly, we noted that the linewidths of ^{23}Na NMR signals in these systems are substantially increased (up to 2.2 kHz for the complex with valinomycin). In addition, the ^{23}Na chemical shifts of monensin and tetranactin in chloroform solution were very close to the data of solid state, indicating the similarity of conformations between the solid and solution. Nevertheless, solid-state conformations are not retained for the rest of complexes in chloroform and methanol solution, because of the presence of rapid conformational fluctuation and ligand ex-

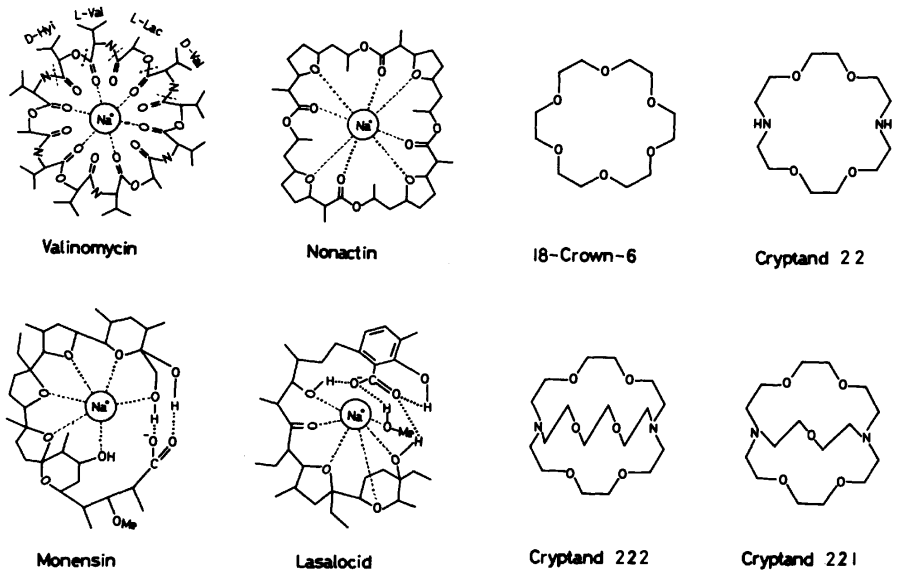

Fig. 1. Schematic representation of some sodium complexes with naturally occurring and synthetic ionophores.

change between the ionophores and solvent molecules.

Experimental

Sodium complexes of valinomycin (Sigma Chemical Company, MI, USA), nonactin (Boehringer-Mannheim GmbH, Germany), and tetranactin (Chugai Pharmaceutical Co. Ltd., Tokyo) (see Fig. 1) were prepared from ethyl acetate solution containing 10% excess NaSCN as described previously.[7] Complex formation was confirmed by the characteristic changes of ^{13}C NMR signals in the crystalline complexes as determined by the cross polarization-magic angle spinning (CP-MAS) NMR method.[7,8] Monensin (Na salt) and lasalocid (Na salt) were purchased from Sigma Chemical Company, MI, USA. These samples were recrystallized from diethyl ether-petroleum ether (1:1) containing small amount of acetone or methanol. Cryptands 22, 221, and 222 were purchased from Aldrich Chemical Company, WI, USA. 18-Crown-6 (18C6) was purchased from Aldrich Chemical Company, WI, USA. Sodium complexes with these cryptands and 18C6 were prepared by the method previously reported.[8]

High-resolution ^{23}Na NMR spectra were recorded on a Bruker CXP-300 spectrometer operating at 79.35 MHz. The crystalline complexes obtained by the procedure described above were dissolved (10 mg ml^{-1}) in deuterated chloroform (Merck Company, Germany) or methanol solution and transferred to 10 mm o.d. quartz NMR sample tubes (Shigemi Standard Joint Company, Tokyo), to avoid undesirable intense signal arising from standard Pyrex sample tubes. Spectral width and data points were usually taken as 10 kHz and 4 K, respectively. To record extremely broadened ^{23}Na NMR signal from the sodium complex with valinomycin, we utilized spectral width 25 kHz and data point 1 K. Free induction decays were accumulated usually 100—500 times. We further confirmed that the observed ^{23}Na signals did not arise from empty sample tube. ^{23}Na chemical shifts were referred to the resonance peak of 1 M† NaCl solution. Proton-decoupled ^{13}C NMR spectra were recorded on the same spectrometer operating at 75.46 MHz. ^{13}C spin-lattice relaxation times were measured for the same samples observed for ^{23}Na NMR spectra by the standard pulse-sequence of the inversion recovery.

Results

Figure 2 illustrates high-resolution ^{23}Na NMR spectra of some sodium complexes with naturally occurring ionophores in chloroform solution. Generally, the ^{23}Na NMR peaks of these sodium complexes were resonated at higher field region than the reference peak of 1 M NaCl solution. In particular, the ^{23}Na NMR peak of Na^+-tetranactin complex appears at the highermost peak-position (−27.8±0.3 ppm). Obviously, ^{23}Na NMR signals of complexes with lasalocid, monensin and valinomycin in chloroform solution are significantly broadened (up to 2200 Hz) but those of nonactin and tetranactin are not. By contrast, these signals were considerably narrowed in methanol solution and the extent of displacements of peaks was significantly reduced in methanol solution, as shown in Fig. 3. Note that relative peak position was also altered between chloroform and methanol solution. In a similar manner, Figs. 4 and 5 summarize ^{23}Na NMR spectra of some sodium complexes with synthetic ionophores in chloroform and methanol solution, respectively. In chloroform solution, a ^{23}Na NMR signal of very low intensity is clearly seen at the peak position of 1 M NaCl solution (Fig. 4). Undoubtedly, this peak arose from the ^{23}Na

† 1 M=1 mol dm^{-3}.

222	1.4 (1.7)[b]	1.0 (1.3)[b]	2.1×10^{-11}		1145±53
221	2.1 (2.4)[b]	1.7 (1.9)[b]	1.7×10^{-11}		1370±83
18C6	1.9 (2.4)[b]	2.4 (3.1)[b]	2.2×10^{-11}		1094

a) Averaged value of several T_1 values from different peak positions. b) Calculated based on the T_1 value of 1.85 s (Ref. 18).

ion coordinated to either anion or water molecules present in trace amount in chloroform (slow chemical exchange). No such a peak was seen in methanol solution, because of the presence of rapid ligand exchange between the ionophores and solvents, if any. The relative peak positions in both the solvent systems were also altered. Table 1 summarizes these ^{23}Na chemical shifts and linewidths, together with those obtained in the solid state. We summarize ^{13}C spin-lattice relaxation times of these complexes measured in chloroform solultion in Table 2 (spectra not shown).

Discussion

^{23}Na Chemical Shifts. As demonstrated in our previous papers,[9,10] the ^{23}Na chemical shifts of sodium salts and complexes in the solid state are strongly influenced by a variety of anions and ligand moieties (C=O, OH, or ether), and Na-O distance. Interestingly, the Na-O distances of the sodium complexes with ionophores studied in this paper are usually longer than those of open-chain ligand molecules to be able to take optimal configuration.[26] As a result, it appears that the ^{23}Na NMR signals of these complexes are resonated at a higher field position by about 10—20 ppm, as compared with those complexes with open-chain ligand molecules.[10] As a clue for an explanation of this trend, it has been mentioned that the ^{23}Na chemical shifts are strongly influenced by the extent of electron transfer from the ligand molecule to a 3p orbital of the central metal cation, which in turn induces downfield displacement of peaks through contribution of paramagnetic shielding effect.[11a] Otherwise, it is impossible to account for the displacement of peaks as large as 60 ppm by means of the diamagnetic shielding term alone which is caused by 2s electrons of Na atom. In fact, we showed on the basis of an ab initio molecular orbital calculation that the extent of electron transfer

from ligand molecule to a 3p orbital could be increased when the Na–O distance is decreased until 2.5 Å: under these conditions, ^{23}Na NMR signal would be displaced downfield together with a decrease of the Na–O distance.[10]

By contrast, interpretation of the ^{23}Na chemical shifts in solution state is much complicated, because the observed ^{23}Na shift, δ_{obsd}, consists of time-averaged values of the following several contributions:

$$\delta_{obsd} = p_1\delta_{complex} + p_2\delta_{solvent} + p_3\delta_{ion}$$
$$p_1 + p_2 + p_3 = 1 \quad (1)$$

where $\delta_{complex}$, $\delta_{solvent}$, and δ_{ion} stand for the ^{23}Na chemical shifts of the sodium ions interacting with the ionophores, solvent molecules, and anions, respectively. To be used for reference data of $\delta_{complex}$, $\delta_{solvent}$, and δ_{ion} values, we have already recorded ^{23}Na NMR spectra of a variety of corresponding crystalline samples by high-resolution solid-state ^{23}Na NMR method, as pointed out previously.[9,10] It is cautioned, however, that these data obtained in the solid state are not necessary the same as those in solution, if molecular conformation achieved in the solid is not always retained in solution state. This will happen for a variety of complexes in which the Na–O distance of the complex is much larger than the sum of crystallographic radii of sodium (0.99 Å) and oxygen (1.40 Å) atoms as in the case of Na^+-valinomycin[10] and/or resultant conformational fixation of ligand molecule by metal-binding is not sufficient in solution. In such cases, it is conceivable that the Na–O bond distance would be instantaneously decreased to gain more effective ion-dipolar interaction as a result of thermal fluctuation of ligand moiety, leading to the downfield displacement of the ^{23}Na NMR peaks in view of the data as mentioned above. Then, the $\delta_{complex}$ value obtained in the solid could be modified to some extent. At the same time a plausible instantaneous decrease in the cation–anion distance during thermal fluctuation of ligand molecules would also cause downfield displacement of ^{23}Na peaks, although anions in crystalline sodium complexes are not in the vicinity of sodium ions and do not affect the ^{23}Na NMR peak position in the complexes.[10]

In chloroform solution, contribution from $\delta_{solvent}$ can be neglected because chloroform is not served as ligand molecules for the cation.. It is emphasized that peaks from the remaining two factors, $\delta_{complex}$ and δ_{ion}, are independently observed or at least in slow exchange in chloroform solution, as seen as two separate peaks in Fig. 4. Therefore, it is expected that the ^{23}Na chemical shifts of the complexes in chloroform solution should be the same as those observed in the solid, if there exists no conformational change between these two systems, as in the sodium complexes with monensin and tetranactin (Table 1). This finding is consistent with our previous data concerning with the similarity of the conformation-dependent ^{13}C chemical shifts of ligand molecules between the solid and solution.[7,27]

Nevertheless, it is obvious from Table 1 that the ^{23}Na NMR peaks are displaced downfield in chloroform solution for the rest of complexes (valinomycin, lasalocid, nonactin, 22, 221, 222, and 18C6). This observation strongly suggests that molecular conformation of these complexes could be effectively distorted by thermal fluctuation of ligand molecules in solution, because downfield displacements of peaks were noted in chloroform solution, consistent with our view as described above. In fact, such a downfield displacement of ^{23}Na NMR peaks in solution is most significant for the complex with valinomycin (15.6 ppm). As to Na^+-valinomycin complex, no detailed data of molecular conformation in the solid state are available from X-ray diffraction study. However, we previously demonstrated on the basis of the conformation-dependent ^{13}C chemical shifts[7] that conformation of Na^+-valinomycin complex in the solid state is not significantly different from that of K^+-valinomycin.[26] Nevertheless, the size of cavity with the Na–O distances[28] 2.69—2.83 Å, which is optimal for K^+ ion (1.33 Å), seems to be too large to accommodate smaller sodium ion (0.99 Å). As a result, acquired stabilization energy of the ion-dipolar interaction will be decreased for the sodium complex than that of the potassium complex. This is one of reasons why ionic selectivity of K^+ ion is larger than that of Na^+ ion by 1.7×10^4.[3] Accordingly, the above-mentioned conformation achieved in the solid state might be easily deformed to gain more favorable interaction energy by the metal-ligand interaction. Obviously, such a deformation of ligand molecule from the octahedral symmetry[28] would result in creation of a large electric field gradient around the sodium ion, thermal fluctuation of which is responsible for the extensive line broadening of the ^{23}Na NMR signal in solution.

On the contrary, it was previously shown by X-ray diffraction studies of K^+- and Na^+-complexed nonactin and tetranactin[29] that the cubic coordination by eight equidistant oxygen atoms obtained in the K^+ complexes (K^+–O: 2.8—2.9 Å) is deformed in the Na^+ complexes (Na–C=O: 2.40—2.45 Å. Na–O(ether): 2.74—2.83 Å).[30–32] In spite of such a close conformational similarity between the two types of sodium complexes, there appears a substantial difference in stability of such complexes in chloroform solultion, as manifested from the difference of ^{23}Na chemical shifts between the solid and solution: Na^+-tetranactin is stable, while Na^+-nonactin is not. This observation is again consistent with our previous high-resolution solid-state ^{13}C NMR study of Na^+-nonactin complex in which ^{13}C chemical shifts of the C=O carbons are substantially displaced upfield in chloroform solution

as compared with those of the solid, by reflecting instability of the complex.[7] In a similar manner to that of Na^+-valinomycin complex, the downfield displacement of ^{23}Na signal could be explained by the presence of conformational flexibility which would modify either the Na-O or Na-anion distances. Consistent with this view, nonactin molecule is more flexible than tetranactin in the sodium complexes, as manifested from the observed differences in the ^{13}C spin-lattice relaxation times (and resultant correlation times), as described later (see Table 2).

Lasalocid[33-35] and monensin[36,37] are charged carboxyl ionophores in which there is no symmetry around the sodium ion, because sodium ion is coordinated by ether, hydroxyl or carboxyl groups, as depicted schematically in Fig. 1. In addition to the monomeric form[35] of the sodium complex of lasalocid in which methanol is also complexed, dimeric form is also known to exist both in the solid[33,34] and nonpolar solvent[38,39] such as cyclohexane. The structure of the dimeric form consists of a sandwich type in which the cation resides in a cavity between the two ionophores.[33,34] Thus, a plausible conversion from the monomeric crystalline form to the dimeric form or thermal fluctuation of ligand molecules in chloroform solution could nicely account for the downfield displacement (by 5.0 ppm) of peaks by going from the solid to chloroform solution (see Table 1).

In a similar manner, ^{23}Na chemical shifts of sodium complexes with cryptands and 18C6 in chloroform are resonated downfield as compared with those of the solid state. Obviously, similar explanation to these downfield shifts applies straightforwardly to these samples by taking into account of flexibility of this class of compounds. In this connection, it is interesting to note that deviation of the ^{13}C chemical shifts in chloroform solution from those in the solid is most significant in Na^+-221 complex,[8] as compared with the sodium complexes with 22 and 222. In parallel with this observation, the downfield displacement of ^{23}Na NMR signal is most pronounced in the complex with 221.

In methanol solution, the ^{23}Na NMR signal of the above-mentioned complexes are substantially displaced downfield, due to the presence of ligand-exchange process with solvent molecules. Among them, significant displacements of ^{23}Na NMR signals in the complexes with monensin and tetranactin are noteworthy (11.7 and 15.1 ppm, respectively). Naturally, the original conformations of these complexes achieved both in the solid and chloroform solution are not any more retained in methanol solution. In this connection, it is interesting that the ^{23}Na chemical shifts of sodium complexes with cryptands and 18C6 are not strongly different between solutions of chloroform and methanol.

^{23}Na NMR Linewidths. Surprisingly, the linewidth of ^{23}Na NMR signal of Na^+-valinomycin complex in chloroform solution is in the same order of magnitude observed in the solid state, as summarized in Table 1. On the contrary, the linewidths of the other complexes are reduced to 1/3—1/20 of the solid state. As pointed out in the previous section, location of the sodium ion within the cavity of asymmetric electric field gradient creates strong field gradient eq. Thus, the interaction of this field gradient with the nuclear quadrupole moment eQ produces the efficient pathway of nuclear relaxation.

Under the condition of extreme narrowing ($w^2\tau_C^2 \ll 1$), the linewidth $W_{1/2}$ is written as,[40]

$$W_{1/2} = 1/\pi T_2 = 2\pi/5(e^2qQ/h)^2\tau_C \quad (2)$$

where w and τ_C are Larmor frequency and the correlation time which characterizes the fluctuation of the electric field gradient, respectively, e^2qQ/h is the quadrupole coupling constant. The correlation time τ_C can be independently determined by measurement of the ^{13}C spin-lattice relaxation time (T_1),[41]

$$1/T_1 = N\hbar^2\gamma_C^2\gamma_H^2 r^{-6}\tau_C \quad (3)$$

where N is number of proton(s) attached to carbon nuclei in question, γ_C and γ_H are gyromagnetic ratio of the carbon and proton, respectively, and r is the C–H distance.

By combination of Eqs. 2 and 3,[42] it is now possible to calculate the quadrupole coupling constant e^2qQ/h, which is a very important parameter to determine the linewidths of ^{23}Na NMR signals, from a knowledge of the correlation time τ_C, as deduced by the ^{13}C spin-lattice relaxation times. As listed in Table 2, the quadrupole coupling constants of some complexes in chloroform solution are in parallel with the degree of asymmetry in the electric environment of sodium atoms. It is now possible to estimate ^{23}Na NMR linewidths of these complexes under various situation, if correlation times of molecular tumbling are known. For instance, ^{23}Na NMR linewidths of these complexes incorporated in biological membranes are estimated as 0.5—50 kHz on the basis of Eq. 2 using the quadrupole coupling constant 2 MHz and correlation times 10^{-8}—10^{-10} s.[43] Accordingly, it appears that ^{23}Na NMR spectra of these complexes might be substantially broadened in biomembranes. To make this situation worse, presence of slower collective motion tends to further broaden linewidth ($T_2 \ll T_1$).[43] In fact, we were not successful in recording ^{23}Na NMR spectra of these ionophores incorporated into sonicated lipid bilayers of egg phosphatidylcholine (unpublished finding).

Strictly speaking, the correlation times τ_C in methanol solution might be different from those in

chloroform. However, we neglected such a difference to qualitatively estimate the quadrupole coupling constants. Further, it is also desirable to remove residual oxygen molecules, by freezing-and-thawing, to obtain reliable spin-lattice relaxation times longer than about 1000 ms. Instead, we used published T_1 value[18] of 18C6 under the conditions of degassing to evaluate the quadrupole coupling constants of some sodium complexes with cryptands and 18C6, as shown in the parentheses of Table 2. Interestingly, the estimated quadrupole coupling constants of sodium complexes with cryptands and 18C6 (in parentheses of Table 2) by this treatment became larger than those of the naturally occurring ionophores, reflecting inherent asymmetric nature of the complexes.

When ligand-exchange process occurs as in methanol solution, the ^{23}Na NMR linewidths are substantially decreased, as summarized in Table 1. Analogous to the expression of the ^{23}Na chemical shifts given in Eq. 1, the observed quadrupole coupling constant $(e^2qQ/h)_{obsd}$ is given by Eq. 4.

$$(e^2qQ/h)_{obsd} = p_1(e^2qQ/h)_{complex} + p_2(e^2qQ/h)_{solvent} + p_3(e^2qQ/h)_{ion}, \quad (4)$$

where subscripts, complex, solvent and ion, have the same meaning as those described already. If we can neglect fractions of sodium complexes of mixed ligands with ionophores and solvents, the second and third terms $(e^2qQ/h)_{solvent}$ and $(e^2qQ/h)_{ion}$ become nearly zero because of symmetric property. Therefore, the linewidths will be reduced in proportion to the fraction of the complexed species. In particular, such reduction of the linewidth is remarkable from 2200 Hz to 70 Hz in methanol for the complex with valinomycin. Thus, it is likely that sodium ion in this case is not mainly coordinated to valinomycin but to methanol. For the complexes with other ionophores, this trend is not drastic as in the case of the above-mentioned valinomycin but is still significant.

In conclusion, we have demonstrated that comparison of high-resolution ^{23}Na NMR spectra of sodium complexes in solution with those obtained in the solid is very useful to reveal conformational stability of these complexes in solution, as a complementary means to ^{13}C NMR spectroscopy utilizing the conformation-dependent ^{13}C chemical shifts.

We are grateful to Chugai Pharmaceutical Co. Ltd., Tokyo for generous gift of tetranactin.

Formulation of Enthalpy, Entropy, and Volume Changes Accompanying Association Reaction in Solution in Terms of Molecular Distribution Functions

Yosuke YOSHIMURA* and Masaru NAKAHARA*
Department of Chemistry, Faculty of Science, Kyoto University,

(Received June 27, 1986)

The equilibrium constant of the chemical reaction in solution is formulated by means of the distribution function at the semiclassical level. The equivalence of the present expression and the traditional one that is based on the standard chemical affinity is proved. The changes of the thermodynamic quantities (enthalpy, entropy, and volume) at constasnt temperature and pressure are expressed on the basis of the present formulation. They are composed of the following three terms: (i) the internal change, (ii) the translational change, and (iii) the solvation change. Each term is evaluated for the dimerization of nitrogen dioxide. It is shown that the volume change is a good measure for the solvation change because it does not contain the internal change. Since the solvation change is explicitly expressed by means of the radial distribution function and its temperature or pressure derivative in an explicit manner, it is useful for discussing the solvent effect on the chemical reaction from the point of view of the liquid structure.

Our molecular understanding of chemical reactions is much less advanced in the liquid phase than in the gas phase because of the presence of many-body interactions characteristic of the liquid phase; most fundamental theories have been developed primarily for the gas-phase reaction which is free from complicated intermolecular interactions due to solvent. It is desired to improve the situation by applying statistical thermodynamics of liquids to reacting systems. We concentrate on the molecular interpretation of the widely used thermodynamic and activation parameters, such as enthalpy, entropy, and volume changes accompanying the chemical reaction in the condensed phase; these parameters are obtainable from the application of thermodynamics and transition state theory to the experimental study on the effect of temperature and pressure on the equilibrium and rate constants for the liquid-phase reaction.[1] We take advantage of the present knowledge of the liquid state at equilibrium in order to provide a theoretical framework or perspective for the molecular interpretation of the thermodynamic and activation parameters which have been used to characterize the mechanism of the reaction in solution.

It is still an open problem how the liquid structure of solvent influences the thermodynamic and activation parameters associated with chemical reactions in solution. When we consider this problem, it is of primary importance to clearly define what we mean by the solvent liquid structure. The radial distribution function is meaningful in this respect. In the previous papers,[2,3] we have successfully applied the distribution function theory of liquids to the problem of reaction and activation volumes to unveil the molecular aspects of the volume properties. This potential approach is extended here to apply to enthalpy and entropy changes to have an insight into the solvent effect on these macroscopic quantities from a molecular point of view; this kind of generalization is not yet completely fulfilled after such a new direction has been suggested by Chandler and co-workers[4-6] and followed by some others.[2,3,7] In the present work we intend to examine the macroscopic reaction parameters mentioned above beyond the primitive view that their changes are nothing more than a difference between the reactant and the product (or transition) states.

One of the merits of the distribution function theory is the capability of continuously treating a reaction process starting just from the reactant state as in the MO calculation of the potential energy supersurface. In the present approach, the transition and product states are represented by the configuration where the coordinates of the atoms involved in the reactants are specified. Thus we can regard the chemical reaction as a continuous variation of the distribution (configuration or arrangement) of constituent atoms or groups composing the reactant molecules; in the liquid-phase reaction, not only the reactants but also the third bodies like solvent molecules have to be included in the definition of the distribution. In the distribution function theory, we define a probability (density) of finding a configuration that varies with the extent (or coordinates) of a reaction, and its equilibrium and rate constans are given in terms of such probabilities. Since the distribution function theory is applicable to both the liquid and the gas phases, it enables us to disclose the key role of solvent molecules in differentiating the liquid-phase reaction from the gas-phase one.

Molecular Model for Association Reaction in Solution

Consider a reversible association reaction in solution at infinite dilution where two spherical molecules A and B form the adduct C in an excessive

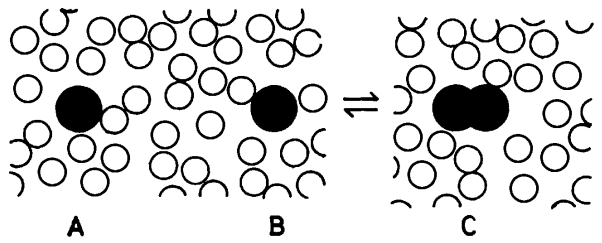

Fig. 1. Model of the bimolecular association reaction in solution illustrated in a two-dimensional way. The white circles denote the solvent molecules and the black the reactants.

amount of solvent as shown in Fig. 1. The potential energy Φ of the reaction system is assumed to be given by the pairwise additive intermolecular potentials u_{ij} as

$$\Phi = \sum u_{ij}, \tag{1}$$

where the pair potential u_{ij} is assumed to act only in the short range between the ith and jth species. The pair potential between the reactants A and B corresponds to the "potential energy supersurface" of the association reaction.

In the present paper, we neglect the quantum effect on the intramolecular behavior of the product molecule C because it is not easy to incorporate this effect into the distribution function formalism; the system is described here at the semiclassical level in the sense that the difference between the energy states is small enough compared with the thermal energy.

The behavior of the model system in the semiclassical limit can be predicted when we specify the form of the potential energy functions in the above scheme; here, however, we are concerned not with the numerical calculation but with the formalism. There remains another fundamental problem as to how to identify the product molecule C. There can be two ways to define C. One may define the product C as a molecular pair when the distance r between A and B lies between l and $l+\varepsilon$; here l and ε can be defined in an arbitrary manner independent of the environments, and l corresponds to the "bond length" when ε is in a sufficiently small range. The other may define C as a molecular pair which has the highest population at a value of r in the ensemble. We take the former definition for the sake of convenience.

Equilibrium Constant in Terms of Distribution Function

Expression for Equilibrium Constant. Since the total number N_C of the product C is the number of the molecular pair A-B which lies between l and $l+\varepsilon$ as described above, it is evaluated by using the radial distribution function $g_{AB}(r)$ as[2]

$$N_C = V\int n_A n_B g_{AB}(r)\cdot\chi(r)4\pi r^2 dr, \tag{2}$$

where V, n_A, n_B, and $\chi(r)$ denote the volume of the system, the number densities of A and B, and the characteristic function for identifying C, respectively. The explicit form of $\chi(r)$ is given here as

$$\chi(r) = \begin{cases} 1 & l \leqq r \leqq l+\varepsilon \\ 0 & r<l \text{ or } r>l+\varepsilon, \end{cases} \tag{3}$$

where ε is the distance in the range of which the molecular pair is recognized as the product C. When ε is small enough, Eq. 2 is written as

$$n_C = n_A n_B g_{AB}(l)\cdot\delta, \tag{4}$$

where n_C is the number density of C and δ is $4\pi l^2\varepsilon$. Since the concentrations of the reactants are at infinite dilution, n_C is negligibly small compared with n_A or n_B, and hence the equilibrium constant K is given as

$$K = n_C/n_A n_B = g_{AB}(l)\cdot\delta. \tag{5}$$

This simple expression is important because the molecular nature of solvent and solute molecules is taken into account in a natural manner.[8,9]

Equation 5 can be easily extended to the association between the same molecules, i.e., A=B, or the aggregation among a number of molecules. In the former case, Eq. 5 is rewritten as

$$K = n_C/n_A^2 = \frac{1}{2}g_{AA}(l)\cdot\delta, \tag{6}$$

where the factor 1/2 is necessary to avoid the double counting of the molecular pair in Eq. 2.

Radial Distribution Function in Terms of Cavity Distribution Function. Since the potential energy of the system is pairwise additive, the radial distribution function is expressed as the product of the Boltzmann factor for the "bond energy" $u_{AB}(l)$ at a fixed distance l and the cavity distribution function $y_{AB}(l)$ which is defined as[4]

$$g_{AB}(l) = \exp(-u_{AB}(l)/kT)\cdot y_{AB}(l), \tag{7}$$

where k and T are the Boltzmann constant and the temperature, respectively. The solute-solvent interactions are included in the cavity distribution function; the cavity distribution function is the radial distribution function between the hypothetical molecules which have no interactions between themselves and have interactions as usual with the solvent molecules. The cavity distribution function is introduced to represent the indirect interactions between A and B through the solvent molecules. The direct interaction $u_{AB}(l)$ between reactant molecules is separated unambiguously from the radial distribution function so that we may abstract the effect of the solvent-solvent interaction on the thermodynamic quantities of our interest.

Comparison of Distribution Function and Partition Function Expressions

Standard Chemical Affinity. The traditional scheme for treating the changes in the thermodynamic quantities is based on the standard chemical affinity A^0.[10] The standard chemical affinity is defined as

$$A^0 = -\sum \nu_i \mu_i^0, \tag{8}$$

where μ_i^0 is the standard chemical potential of species i; i runs for all the reactants ($\nu_i<0$) and the product ($\nu_i>0$); the symbol ^{0} denotes the standard state. The equilibrium constant K is related to the standard chemical affinity as follows:

$$A^0 = kT \ln K - \sum \nu_i kT \ln c^0, \tag{9}$$

where c^0 is the concentration of the standard state that is conventionally taken to be unity in most cases. The thermodynamic changes, such as enthalpy, entropy, and volume are derived by differentiating the standard chemical affinity. Furthermore, the standard chemical affinity is expressed by the partition functions Z_R^0 and Z_P^0 for the reactants and products, respectively, as

$$A^0 = kT \ln (Z_P^0/Z_R^0). \tag{10}$$

Thus we can diagnose the changes in the thermodynamic quantities by dividing into the contributions from each degree of freedom as shown below. However, the traditional treatment does not tell us the significance of the liquid structure on the chemical reaction. In this chapter, we try to find a relationship between the present and traditional schemes based on the distribution function and the partition function, respectively; remember that the liquid structure of solvent is taken into account in an explicit manner in the former approach.

Components of Standard Chemical Affinity. The standard chemical affinity of the model association reaction is composed of several factors, such as the translational, rotational, and vibrational degrees of freedom of the molecules involved in the reaction and the solute–solvent interactions. First, we briefly review the traditional formulation of the standard chemical affinity in terms of partition functions. The contributions of the solute–solvent interactions to the standard chemical potentials of A, B, and C in solution are considered to be expressed by the corresponding standard chemical potential for the process of their transfer from the ideal gas into the solvent. These are called the solvation free energies, and denoted as α_A, α_B, and α_C for A, B, and C, respectively. The internal degrees of freedom are assumed here to be unperturbed by this process. In consequence, we have the following expressions of the standard chemical potentials for species A, B, and C:

$$\mu_A^0 = kT \ln \left[\left(\frac{h^2}{2\pi m_A kT} \right)^{3/2} c^0 \right] + \alpha_A, \tag{11}$$

$$\mu_B^0 = kT \ln \left[\left(\frac{h^2}{2\pi m_B kT} \right)^{3/2} c^0 \right] + \alpha_B, \tag{12}$$

$$\mu_C^0 = -kT \ln Z_{int} + kT \ln \left[\left(\frac{h^2}{2\pi (m_A+m_B) kT} \right)^{3/2} c^0 \right] + \alpha_C, \tag{13}$$

where h, and m_A, and m_B are Planck's constant and the masses of A and B, respectively, and Z_{int} is the partition function for the internal degree of freedom. Using Eqs. 11—13 we have the standard chemical affinity in the form

$$A^0 = -\mu_C^0 + (\mu_A^0+\mu_B^0) = kT \ln Z_{int} + kT \ln (\lambda^3 c^0) - \Delta\alpha, \tag{14}$$

where

$$\lambda = (h^2/2\pi m_r kT)^{1/2}, \tag{15}$$

$$m_r = m_A m_B/(m_A+m_B), \tag{16}$$

$$\Delta\alpha = \alpha_C - (\alpha_A+\alpha_B). \tag{17}$$

Here we call the first term in Eq. 14 the internal contribution, the second the translational contribution, and the third the solvation contribution. Such a simple expression for the chemical affinity comes from the fact that the translational contribution is the same in the gas and liquid phases at the semiclassical level and the assumption that the internal structure of the molecule is unchanged by the solvation.

Comparison of Distribution Function and Partition Function Approaches. Although at first sight, Eqs. 5 and 14 seem to have no relation, the semiclassical expressions for the internal partition functions lead to a simple relation between them. The first term on the right-hand side of Eq. 14 comes from the following three factors; the rotational and vibrational degrees of freedom of the associated molecule C and the difference in the zero point of the energy between reactants A and B and product C. The last factor is equal to the bond energy $u_{AB}(l)$ that is negative in sign contrary to the convention. Hence it follows that

$$kT \ln Z_{int} = kT \ln Z^{rot} + kT \ln Z^{vib} - u_{AB}(l), \tag{18}$$

where Z^{rot} and Z^{vib} denote the partition functions of the rotational and vibrational motions of C, respectively.

The rotational partition function in the semiclassical approximation is written as

$$Z^{rot} = \frac{1}{s} \lambda^{-2} \cdot 4\pi l^2, \tag{19}$$

where s is the symmetry number of the associated molecule C, and the vibrational partition function as

$$Z^{vib} = \lambda^{-1} \varepsilon. \tag{20}$$

In the semiclassical approximation, the rotational

partition function is equivalent to the partition function of the two-dimensional translational motion for the particle of the mass m_r in an area $4\pi l^2$ (which is the surface area of the sphere of the radius l), and the vibrational partition function is equivalent to the partition function of the one dimensional translational motion of the particle in a length ε. Thus the internal partition function is written as

$$Z_{\text{int}} = \frac{1}{s}\lambda^{-3}4\pi l^2\varepsilon \cdot \exp\left(-u_{AB}(l)/kT\right). \tag{21}$$

When Eqs. 18—20 are used in Eq. 14 the standard chemical affinity is written as

$$A^0 = kT\ln\left(c^0 \cdot 4\pi l^2\varepsilon\right) - kT\ln s - u_{AB}(l) - \Delta\alpha. \tag{22}$$

This equation can be interpreted thermodynamically by considering a process by which the associated molecule C is formed. Suppose a gas mixture of the reactants A and B at the standard state the concentration of which is c^0. The first term on the right-hand side of Eq. 22 is the change due to the compression of reactant A (or B) from the free space to the concentration $1/(4\pi l^2\varepsilon)$ in the restricted space around B (or A); $4\pi l^2\varepsilon$ is the volume where one of the reactants can move in the neighborhood of the other. If A and B are the same, only either A or B is involved in the initial gas mixture at the standard state (the concentration c^0), so that the concentration of the resultant C is one half of c^0. Therefore, it is necessary to add $kT\ln 2$ to bring the product gas C into the standard state. This correction is made through the symmetry number s=2. Finally, the reversible work $\Delta\alpha$ accompanying the transfer of the product from the gas phase into the solvent is added as shown in Eq. 22.

According to Eq. 9, the equilibrium constant is expressed by the standard chemical affinity and the sum of the stoichiometric number -1 ($-\nu_A=-\nu_B=\nu_C=1$). Putting Eq. 22 into Eq. 9 we obtain

$$K = \frac{1}{s}\exp\left(-(u_{AB}(l)+\Delta\alpha)/kT\right)\cdot 4\pi l^2\varepsilon. \tag{23}$$

Comparison of Eqs. 5 and 23 leads to the following equation:

$$y_{AB}(l) = \exp\left(-\Delta\alpha/kT\right). \tag{24}$$

This equation is also derivable from the fact that $-kT\ln y_{AB}(l)$ is equal to the reversible work accompanying the approach of A and B at a large separation to the distance l[4]; this is called the potential of mean force by the solvent molecules and equivalent to the difference of the solvation free energy $\Delta\alpha$. In the classical scheme, the change $\Delta\alpha$ due to solvation is treated as the standard chemical affinity associated with the formation or the destruction of the solvation shell. This is contained naturally in the cavity distribution function treated here.

Free Volume Theory vs. Distribution Function Theory. Let us inspect the relation between the present framework based on the distribution function theory and the old one based on the free volume theory. It has been asserted by some authors[1b,11] that the difference in the equilibrium constant between the gas and the liquid phases arises from the restriction of the translational freedom in the liquid phase, and that the "free volume" is useful as a measure of the restriction. In this framework, the chemical potential change is simply written as

$$A^0 = A^0(\text{ideal}) + kT\ln\left(v^0 v_C^f/v_A^f v_B^f\right), \tag{25}$$

where A^0(ideal) is the standard chemical affinity without the solute–solvent interaction that is equal to the standard chemical affinity in the ideal gas, and v^0 and v_X^f are the volume per particle $1/c^0$ and the free volume per particle X, respectively. Although the free volume is often claimed to be ambiguous, its concept can be made clear by the present molecular approach as shown below.

According to Eq. 25, the reversible work α_X introduced into Eqs. 11—13 is expressed as

$$\alpha_X = -kT\ln\left(v_X^f/v^0\right). \tag{26}$$

Putting Eq. 26 into Eq. 24, we obtain the relation

$$y_{AB}(l) = v^0 v_C^f/v_A^f v_B^f \tag{27}$$

$$= p_C/p_A p_B, \tag{28}$$

where p_X is the ratio of v_X^f to v^0. Suppose dissolution of solute X into the solvent. The probability of the allowed occupation of an arbitrary place in the solvent is assumed to be equal to the ratio p_X of the free volume to the total volume. The cavity distribution function at a distance l is the ratio of the probability of finding the A–B pair at the distance l to that of finding the pair without correlation between A and B; the former and the latter probabilities are given by p_C and $p_A p_B$, respectively. Thus we can explain Eq. 25 in the probabilistic manner.

Components of Changes in Thermodynamic Quantities and Their Significance

The formulation in the previous section enables us to divide the changes of the thermodynamic quantities into the following three terms in an additive manner: (i) the change due to the direct interaction between the reactants which brings about the internal degree of freedom of the product (called the "internal change"), (ii) the change due to the translational motion (called the "translational change"), and (iii) the change due to the indirect interactions between the reactants through the solvent molecules (called the "solvation change"). The term "solvation" is used here in a broad sense, whereas it is often used for strong

solute-solvent interactions. In this section, we clarify the significance of each component of the enthalpy, entropy, and volume changes accompanying the association reaction proceeding under isobaric conditions. Numerical value for each component in an actual system is shown in the Appendix to see the relative importance.

Internal Contribution. The internal change in the chemical potential is represented by the first term in Eq. 14. Differentiation of the term leads to the following expressions:

$$\Delta\bar{H}^0(\text{int}) = u_{AB}(l) + \frac{3}{2}kT, \tag{29}$$

$$\Delta\bar{S}^0(\text{int}) = k\ln(\lambda^{-3}\cdot 4\pi l^2\varepsilon) + \frac{3}{2}k, \tag{30}$$

$$\Delta\bar{V}^0(\text{int}) = 0. \tag{31}$$

The internal changes are the same both in the ideal gas and in solution according to the present model. The first term in the enthalpy change is the pair potential change between the reactants. And the second term due to the energy of the internal degree of freedom of the associated molecule that is equal to $(3/2)kT$ as expected from the equipartition law of energy.[12]

Different aspects are shown by the internal enthalpy and entropy changes. While the enthalpy change depends on the strength of the bond, $u_{AB}(l)$, the entropy change depends on the "softness" of the bond, ε. Though the semiclassical term $(3/2)kT$ in the enthalpy change arises from the internal motion which is attributed to the "softness" of the A-B bond, the contribution of the term is usually small (3.7 kJ mol^{-1} at 25 °C) compared with the bond energy. Thus the standard chemical affinity is meaningfully split into the enthalpy and the entropy changes.

It is interesting that the internal contribution does not appear in the volume change. The present result discloses that whatever the internal change takes place the volume change is not observed without the solute-solvent interactions not the direct interaction betwee the solute and the vessel. Thus the "intrinsic volume change" has no real physical meaning, as referred to previously.[3]

Translational Contribution. The translational chemical potential change is represented by the second term in Eq. 14. Differentiation of this term leads to the following expressions:

$$\Delta\bar{H}^0(\text{trans}) = -\frac{3}{2}kT - \alpha_p kT^2, \tag{32}$$

$$\Delta\bar{S}^0(\text{trans}) = k\ln(\lambda^3 c^0) - \frac{3}{2}k - \alpha_p kT, \tag{33}$$

$$\Delta\bar{V}^0(\text{trans}) = -\kappa_T kT, \tag{34}$$

where α_p and k_T are the isobaric expansibility and the isothermal compressibility of the solvent, respectively. Since these translational changes are determined not only by the momentum of the molecule but also by the direct interaction between the molecule and the container's walls,[11] these equations contain the response function of the volume of the system with respect to the temperature (α_p) or the pressure (κ_T) as shown by the last term on the right hand-side of each equation.[13,14] These terms have been treated as the "correction term" in calculating the change of the thermodynamic quantity from the equilibrium constant expressed in molarity.[1a] The role of the last terms in Eqs. 32—34 was pointed out in a different manner in the "noninteracting solution"[11] where the solute molecule had only the translational degree of freedom in the container. We have previously elucidated the significance of the translational volume change on the basis of the virial theorem.[3,15]

Solvation Contribution. The solvation contribution to the standard chemical affinity is represented by the third term in Eq. 14. Differentiation of this term leads to the following expressions:

$$\Delta\bar{H}^0(\text{solv}) = kT^2\left(\frac{\partial\ln y_{AB}(l)}{\partial T}\right)_P, \tag{35}$$

$$\Delta\bar{S}^0(\text{solv}) = k\ln y_{AB}(l) + kT\left(\frac{\partial\ln y_{AB}(l)}{\partial T}\right)_P, \tag{36}$$

$$\Delta\bar{V}^0(\text{solv}) = -kT\left(\frac{\partial\ln y_{AB}(l)}{\partial P}\right)_T. \tag{37}$$

These formal expressions tell us that the solvation changes are determined by the liquid structure through the temperature or pressure derivative of the cavity distribution function. Comparison of Eqs. 29—37 reveals that the volume change is a more direct measure of the solvent effect than are the chemical affinity, and the entropy and enthalpy changes because the volume change is independent of the internal structure of the associated molecule C except for the bond length which is assumed to be unaffected by the environments.

The nature of the solvation change is more complicated than that of the internal of the translational change, which results from the fact that the cavity distribution function is determined by multibody interactions among the molecules. If the density of the solvent is small enough, the expansion of the cavity distribution function in powers of density can be truncated to the first several terms and served for a rigorous discussion of their explicit form of Eqs 35—37, an example is shown elsewhere[3] for the volume change in the dilute gas. But such a treatment breaks down in usual liquids where multibody interactions are dominant. Hence we should explore the liquid structure in a more sophisticated manner to establish a solid basis for the treatment of the solvation effects on the chemical reaction; e.g., such "extra-thermodynamic" relation-

ships as linear free energy relationship and the entropy-enthalpy compensation may be obtained along this line. The present-day liquid theory[16] will be useful for justifying the extra-thermodynamic rules empirically found. Our work along this line will appear in near future.

Appendix

Evaluation of the Internal, Traslational, and Solvation Contributions in an Actual System. Although the theoretical framework presented here is insufficient for understanding the molecular nature of the chemical reaction because of the complexity of the internal structure in the actual reaction system, at least, the translational and solvation contributions can be elucidated. The relative weights of the internal, translational, and solvation contributions vary from one thermodynamic quantity to another. Here, we show the significance of the three components in the changes of the thermodynamic quantities, enthalpy, entropy, and volume in an association reaction.

The dimerization of nitrogen dioxide in solution

$$2NO_2 \rightleftharpoons N_2O_4, \tag{38}$$

is a prototype association reaction studied experimentally[17-20] and theoretically[4,6] in both the gas and liquid phases. Although this reaction is complicated enough as referred to above, the translational and solvation contributions can be estimated by applying the experimental imformation in the present formulation.

We adopt the experimental data for the enthalpy and entropy changes in carbon tetrachloride which are obtained by measuring the solution susceptibility,[18] while there exists a discrepancy in the experimental data.[18,19] The isothermal compressibility and the isobaric expansibility are taken from Ref. 21.

The evaluated values for the three components at 25 °C and 1 atm (1 atm=1.013×10^5 Pa) are summarized in Table 1. The largest contribution to the entropy change comes from the translational change. If the internal freedom exists only in the associated molecule as in the present model, the internal entropy change is expected to be positive. However, since both nitrogen dioxide and dinitrogen tetroxide molecules have the internal freedom, the dimerization reaction may have the negative internal entropy change as shown in Table 1; the largest contribution to the internal entropy change comes from the rotational entropy change that is calculated here as -55 J K^{-1} mol^{-1}. The internal contribution plays the most important role in the enthalpy change. The volume change is dominated by the solvation change, and the translational volume change is rather small in solution, though the translational contribution to the volume change is dominant in the gas phase where the volume change amounts to -24 dm^3 mol^{-1}.

Table 1. Values of the Components of Changes of the Thermodynamic Quantities Accompanying the Dimerization of Nitrogen Dioxide in Carbon Tetrachloride at 25 °C and 1 atm[a,b]

	Internal	Translational	Solvation
$\Delta\bar{H}^0$ (kJ mol^{-1})	-50.9	-4.6	-5.6
$\Delta\bar{S}^0$ (J K^{-1} mol^{-1})	-28	-116	$+11$
$\Delta\bar{V}^0$ (cm^3 mol^{-1})	0	-3	-20

a) The standard state is taken to be 1 mol dm^{-3}. b) The internal changes of the enthalpy and entropy, which are assumed to be the same in the gas and the liquid phases, are calculated from the data of the gas-phase reaction[17] by subtracting the translational changes which are obtained from Eqs. 34 and 35. The experimental data of the volume change is obtained from Ref. 20.

The entropy change has been used in the characterization of the chemical reaction in solution with such a view that the entropy change (activation entropy) reflects the "softness" or "randomness" of the product (transition state). As shown here, however, the entropy change accompanying the association reaction contains a large amount of translational contribution which is independent of the molecular parameters except for the mass. Thus we must subtrac the translational contribution before discussing the mechanism of the association or addition reaction in terms of the entropy change.

8) When we ignore the ion charge in the Fuoss equation for ion-pair formation,[9] the equilibrium constant is given by

$$K = \frac{4\pi}{3}a^3,$$

where a is the center-to-center distance between the two contact spheres. This equation has no real physical meaning, and should read better as

$$K = 4\pi a^2 \varepsilon,$$

which is equal to Eq. 5 when $g(a)$ is assumed to be unity.

12) Since the Hamiltonian for the internal motion of C can be regarded to be independent of the coordinates, the energy partitioned is $(3/2)kT$. If the Hamiltonian depends on the coordinates, this is not the case; e.g., the harmonic oscillator shares an energy of $2kT$.
13) The translational volume change arises from the translational pressure change $(-kT/V)$ under the isochoric condition,[3] and the last terms of the translational enthalpy and entropy changes are attributed to the translational volume change. The enthalpy and entropy changes under isochoric condition are reduced to the following[14]:

$$(\Delta\bar{U}^0)_{T,V} = \Delta\bar{H}^0 - (\alpha_P/\kappa_T)T\Delta\bar{V}^0,$$
$$(\Delta\bar{S}^0)_{T,V} = \Delta\bar{S}^0 - (\alpha_P/\kappa_T)\Delta\bar{V}^0,$$

where $(\Delta\bar{U}^0)_{T,V}$ is the internal energy change under isochoric condition. When the translational volume change $k_T kT$ is used in the last terms of the above equations, they become equal to the corresponding term in Eqs. 32 and 33. Thus it is verified that the last terms in Eqs. 32 and 33 are attributed to the change of the direct interaction between the molecule and the container's walls.

(Received July 5, 1986)

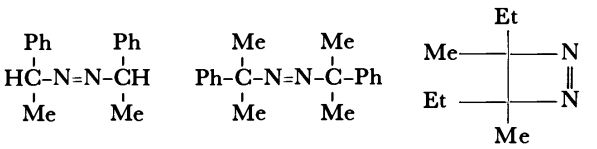
The mechanism of the decomposition of α,α′-azocumene and 2,2′-di-*p*-tolyl-2,2′-azopropane was studied by means of laser flash photolysis (λ=347 nm) and the optical absorption of 1-methyl-1-phenylethyl (α-cumyl) and α-cumyldiazenyl radicals was observed. The α-cumyl radicals were formed in two modes, a fast mode occurring during the flash and a slow mode after the flash. The ratio of the optical densities pertaining to the two modes depended on the absorbed dose rate. The higher the absorbed dose per flash, the more dominant was the fast mode. The transient band at λ=285 nm which decayed simultaneously with the grow- in of the α-cumyl radicals was assigned to α-cumyldiazenyl radicals. The experimental results strongly suggested the occurrence of the stepwise decomposition mechanism. The dose rate dependent kinetics of the slow formation process was explained in terms of the competition between the unimolecular decomposition and the dimerization of α-cumyldiazenyl radicals. The rate constants of the decomposition and the dimerization were estimated to be 1.1×10^5 s^{-1} and 5×10^9 M^{-1} s^{-1}, respectively.

Azo compounds are well-known as very effective initiators for the free radical polymerization of vinyl compounds.[1] Both thermal and photochemical decomposition reactions of azo alkanes were studied by several workers, and two mechanisms were discussed: simultaneous scission of the two C-N bonds (Eq. 1)[2] and stepwise cleavage of the C-N bonds involving the diazenyl radical as a transient (Eq. 2).[3]

$$R_1\text{-}N{=}N\text{-}R_2 \longrightarrow R_1\cdot + N_2 + \cdot R_2 \quad (1)$$

$$R_1\text{-}N{=}N\text{-}R_2 \longrightarrow R_1\text{-}N{=}N\cdot + \cdot R_2 \longrightarrow R_1\cdot + N_2 + \cdot R_2 \quad (2)$$

As far as *thermolysis* is concerned, Engel[4] arrived at the conclusion that "azoalkane thermolysis seems to proceed by a continuum of mechanisms between 1 and 2; the more unsymmetrical the azo compound the more unsymmetrically it cleaves." Actually, evidence for a concerted two bond cleavage according to reaction 1 was obtained for the thermolysis of symmetrical azo compounds: 1,1′-diphenylazoethane,[5] α,α′-azocumene,[6,7] and a cyclic azoalkane:[8]



1,1′-diphenylazoethane | α,α′-azocumene | dl-3,4-diethyl-3,4-dimethyldiazetine

On the other hand, the occurrence of the heat-induced stepwise decomposition according to reaction 2 was evidenced in the case of *cis*-1,1′-azoadamantane, a symmetrical compound.[9] Dannenberg and Rocklin[10] carried out a theoretical study on the thermolysis of trans-azoethane, also a symmetrical compound, and arrived at the conclusion that the initial step is trans → cis isomerization which is followed by dissociation into diazenyl and ethyl radicals.

The mechanism of the *photolysis* of azo compounds was studied by relatively few researchers up to now. Porter et al.[11] postulated a stepwise mechanism based on their work with unsymmetrical compounds such as Ph-N=N-C(CH$_3$)$_2$Ph and Ph$_2$CH-N=N-CH$_2$Ph. Upon irradiation *trans*-1-(1,1-dimethylallylazo)alkanes of the type R-N=N-C(CH$_3$)$_2$CH=CH$_2$ with UV light (337 nm) evidence was obtained by Engel and Gerth[12] for the intermediacy of thermally labile cis-isomers. Diazenyl radicals were found to play "a more general role" in the decomposition of the cis isomers with R equal to phenyl, methyl, cyclohexyl, ethyl etc. In these cases the recombination of diazenyl and 1,1′-dimethylallyl radicals (occurring at the allylic site) was observed. However, with the symmetrical compound (R: H$_2$C=CHC(CH$_3$)$_2$) this turn-around reaction was not observed.

Rather recently, the photofragmentation of azomethane in the vapor phase was studied.[13] In this case, the fragmentation was complete within 2 ns and by coherent anti-Stokes Raman spectroscopy the nascent vibrational distribution appeared consistent with a theoretical prediction of stepwise bond scission.

The present paper describes results obtained upon the laser flash photolysis of α,α′-azocumenes in solution. These compounds were selected because, in spite of their UV band at 367 nm, they possess an absorption window between 270 and 340 nm. This enabled us to observe the absorption of transient species, i.e., 1-methyl-1-phenylethyl (α-cumyl, hereafter) and diazenyl radicals. As will be shown below

the photolysis of the α,α′-azocumenes occurred according to the stepwise mechanism.

Experimental

Materials. α,α′-Azocumene (AC) and 2,2′-di-*p*-tolyl-2,2′-azopropane (DMAC) were synthesized by a procedure described in the literature.[14] Cyclohexane of Uvasol(R) quality was obtained from E. Merck and was used without further purification.

Irradiations. Solutions of α,α′-azocumenes freed from oxygen by bubbling with purified argon were irradiated by 347 nm laser flashes of a ruby laser operated in conjunction with a frequency doubler. The flash duration was about 20 ns.

Actinometry was performed with benzene solutions of benzophenone (1.15×10^{-3} M†) containing naphthalene (1.03×10^{-1} M). The absorbed dose per flash was calculated from the concentration of naphthalene triplets formed by energy transfer from benzophenone with $\varepsilon_{T\text{-}T}=1.32\times10^{4}$ M^{-1} cm^{-1} at 425 nm[15] and $\phi(T)=1$. The maximum laser output was 4.5×10^{-4} Einstein per dm^3. The laser beam diameter was 0.6 cm at the sample position.

Results

Figure 1 shows transient absorption spectra with peaks at 272, 310, and 322 nm of a solution of AC in cyclohexane (4.7×10^{-3} M) photolyzed with an absorbed dose of 7.9×10^{-5} E l^{-1}.* These peaks were observed immediately at the end of the flash. The peaks at 272 and 322 nm grew-in further after the pulse. The three bands, which were also observed with DMAC in cyclohexane solution, are similar to those reported for benzyl,[16] *o*-, *m*-, *p*-methylbenzyl[17] and cumyl radicals.[18] They are, therefore, assigned to α-cumyl and 1-methyl-1-(*p*-tolyl)ethyl radicals, for AC and DMAC, respectively.

In addition to the absorption of α-cumyl radicals, a fast decaying transient absorption was observed in the region between 270 and 305 nm. The difference

spectrum obtained by subtracting spectrum (b) from spectrum (a) in Fig. 1 is shown in Fig. 2. It has an absorption maximum at 285 nm.

Figure 3 shows kinetic traces recorded at 290 and 322 nm at an absorbed dose of 7.8×10^{-5} E l^{-1}. As can be seen from Fig. 3a, the absorption at 322 nm was formed to some extent during the flash. It increased further within about 5 μs and then decreased, as is shown in Fig. 3b. At 290 nm, on the other hand, the absorption formed during the flash decreased steadily after the flash.

Figure 4 shows kinetic traces obtained at 322 nm at various absorbed doses. It can be seen that with increasing absorbed dose the initial absorption increased while the extent of the grow-in absorption did not increase. Moreover, the grow-in rate depended significantly on the absorbed dose per flash. At $D_{absd}=2\times10^{-5}$ E l^{-1}, for example, the absorption increased until 10 μs but, at $D_{absd}=1.4\times10^{-4}$ E l^{-1}, only until 2 μs after the flash. The decay of the 322 nm band dose not fit first order or second order kinetics. However, the half lifetime slightly decreased with increasing absorbed dose, suggesting the occurrence of radical-radical reactions as will be dealt with in the next section. A similar kinetic behavior was observed with DMAC. In Fig. 5 the initial optical density (OD_0) and the maximum optical density (OD_{max}) at 322 nm were plotted against the absorbed dose per flash. Straight lines passing through the origin were obtained for OD_0 but not for OD_{max}. From the slope of the straight line (OD_0 vs. D_{absd}) the following $\phi\varepsilon$ values were

calculated for the α-cumyl radicals produced during the flash: 1630 and 1280 M^{-1} cm^{-1} for AC and DMAC, respectively.

Discussion

Engel and Steel have shown that the triplet-sensitized decomposition of AC (ϕ=0.31) occurs as efficient as the direct photolysis (0.36).[19] This fact suggests the intermediacy of the triplet AC in C-N bond scission.

For many azo compounds, it is well-known that the cis-isomers undergo remarkably facile thermal decomposition. *cis*-AC produced by UV irradiation of *trans*-AC in a poly(methyl methacrylate) matrix at −196 °C had a half lifetime of the order of 10 min at −100 °C,[20] while *trans*-AC has a lifetime of 20 min in toluene at 69 °C.[14] Thus, photoinduced trans-cis isomerization and the thermal instability of *cis*-AC suggest the intermediacy of *cis*-AC in decomposition. The present experimental results show that there exist two sources for α-cumyl radical production. On the basis of the fast mode of the α-cumyl radical formation that was completed during the laser pulse, it is assumed that both the triplet and the cis-isomer of α,α′-azocumene at room temperature have lifetimes much shorter than the laser pulse width of 20 ns.

The experimental results of the photolysis of α,α′-azocumenes in cyclohexane can be accounted for by the following equations:

$$\text{Ph-C(CH}_3)_2\text{-N=N-C(CH}_3)_2\text{-Ph} \longrightarrow \text{Ph-C(CH}_3)_2\text{-N=N}\cdot + \cdot\text{C(CH}_3)_2\text{-Ph} \quad (3)$$

$$\text{Ph-C(CH}_3)_2\text{-N=N}\cdot \longrightarrow \text{Ph-C(CH}_3)_2\cdot + \text{N}_2 \quad (4)$$

$$\text{Ph-C(CH}_3)_2\text{-N=N}\cdot + \text{Ph-C(CH}_3)_2\text{-N=N}\cdot \longrightarrow \text{Ph-C(CH}_3)_2\text{-N=N-N=N-C(CH}_3)_2\text{-Ph} \quad (5)$$

$$\text{Ph-C(CH}_3)_2\cdot \longrightarrow \text{product} \quad (6)$$

$$\text{Ph-C(CH}_3)_2\cdot + \text{Ph-C(CH}_3)_2\cdot \longrightarrow \text{product} \quad (7)$$

Figure 6 shows a plot of the ratio OD_{max}/OD_0 vs. the absorbed dose per flash which corresponds to the absorbed dose rate. It seems that both curves (obtained with AC and DMAC, respectively) are approaching the value of two on extrapolation of the absorbed dose rate to zero. At low absorbed dose rates the ratio of the concentrations of α-cumyl radicals formed by reaction 3, i.e., during the pulse, and reaction 4, i.e., after the pulse, is expected to be unity because the dimerization reaction 5 cannot compete with the unimolecular decomposition of diazenyl radicals according to reaction 4. This condition results in OD_{max}/OD_0=2. Reaction 6 stands for the reaction of α-cumyl radicals with intact α,α′-azocumene, the solvent and impurities.

To estimate the individual rate constants, a series of kinetic traces obtained within a wide range of absorbed doses (2×10^{-5}—1.5×10^{-4} E l^{-1}, see Fig. 4)

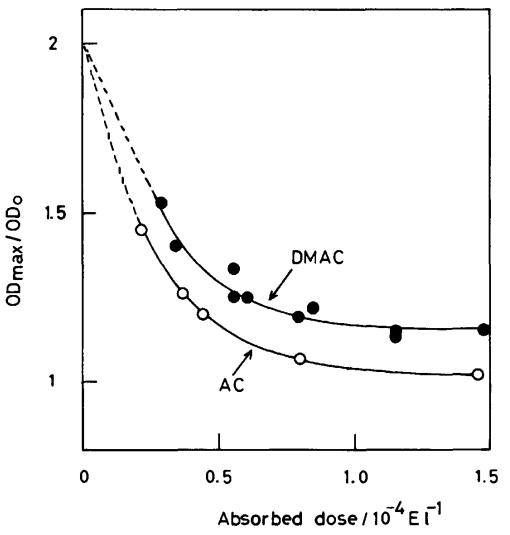

Fig. 6. Absorbed dose dependence of OD_{max}/OD_0 at 322 nm for α,α′-azocumene (○) and 2,2′-di-*p*-tolyl-2,2′-azopropane (●).

were simulated with the aid of a personal computer.

One can write equations for the rate of disappearance of the α-cumyldiazenyl radicals and the α-cumyl radicals:

$$-dA/dt = k_4A + 2k_5A^2 \quad (8)$$

$$-dB/dt = -k_4A + k_6B + 2k_7B^2 \quad (9)$$

where A and B represent the instantaneous concentrations of the α-cumyldiazenyl radicals and α-cumyl radicals respectively.

Equation 8 can be resolved to give[21]

$$\ln\{A_0(k_4+2k_5A)/A(k_4+2k_5A_0)\} = k_4t, \quad (10)$$

where A_0 is the initial concentration of the α-cumyldiazenyl radicals produced by reaction 3. Equation 10 may be rearranged to give

$$A = A_0k_4/\{(k_4+2k_5A_0)\exp(k_4t)-2k_5A_0\}. \quad (11)$$

By substituting this value for A into Eq. 9, we obtain

$$dB/dt = A_0k_4^2/\{(k_4+2k_5A_0)\exp(k_4t)-2k_5A_0\} - k_6B - 2k_7B^2. \quad (12)$$

This differential equation can be solved numerically by the Runge-Kutta method,[22] with the condition A_0=B_0 at t=0, where B_0 is the initial concentration of the α-cumyl radicals.

To estimate values of A_0 and B_0 one has to know the extinction coefficient of the α-cumyl radical at 322 nm. According to Nelsen and Bartlett[14] the quantum yield of the photodecomposition of α,α′-azocumene in benzene at 26.3 °C is 0.6. This rather high value very probably dose not only refer to scission of C-N bonds according to reactions 1 and 2 but also to other AC consuming reactions. For the

present case it appears more relevant to refer to the quantum yield of N_2 formation in order to estimate the quantum yield of α-cumyl radicals formed according to reactions 1 and 2. $\phi(N_2)=0.36$ has been determined by Engel and Steel[19] in the photolysis of AC in benzene. Dividing the slope of the straight line in Fig. 5a by 0.36 yields $\varepsilon(322\text{ nm})=4500\ M^{-1}\ cm^{-1}$ for AC. This extinction coefficient is quite similar to those obtained for *o*-, *m*-, *p*-methylbenzyl radicals which fall in the range 3000—6000.[17]

An iterative curve fitting procedure on the basis of Eq. 12 was applied to the experimental kinetic traces of Fig. 4. The solid lines in Fig. 4 are best fits obtained with the following rate constants: $k_4=1.1\times10^5\ s^{-1}$, $k_5=5\times10^9\ M^{-1}\ s^{-1}$, $k_6=1.65\times10^4\ s^{-1}$, and $k_7=1.8\times10^8\ M^{-1}\ s^{-1}$. With these rate constants the kinetic traces observed with DMAC in cyclohexane could also be reproduced. The unimolecular decay rate constant of the α-cumyldiazenyl radical k_4 can be compared with rate constants $(1.8—330)\times10^5\ s^{-1}$ obtained for substituted phenyldiazenyl radicals in water/*t*-butyl alcohol mixture.[23] The dimerization rate constant of the α-cumyldiazenyl radical is the same as that obtained for the phenyldiazenyl radical.[23]

The full line in Fig. 3 is the simulated kinetic trace representing the absorbances of both the α-cumyldiazenyl radical and the α-cumyl radical on the assumption that extinction coefficients at 290 nm are equal to 2000 and 2600 $M^{-1}\ cm^{-1}$, respectively. The difference between the experimental and the simulated curves might be explained on the basis of strongly absorbing products formed in the dimerization of α-cumyl radicals. According to Skinner et al.[24] the dimerization of α-cumyl radicals gives the following distribution of isomers: 1,2-diphenylethane:*o*-semibenzene:*p*-semibenzene=1:0.1:0.2.[24] The *p*-semibenzene is characterized by its strong UV absorption band peaked at 262 nm in cyclohexane and the extinction coefficient is estimated to be 25000—40000 $M^{-1}\ cm^{-1}$. From the spectrum of p-semibenzene the extinction coefficient at 290 nm can be estimated to be about 3500—6000 $M^{-1}\ cm^{-1}$.[24] Thus we can expect a contribution of about 10% of p-semibenzene to the transient absorption at 290 nm which compares well with the difference shown in Fig. 3c.

In conclusion, the present results clearly indicate the stepwise decomposition of α,α'-azocumenes on photolysis. This contrasts strongly the conclusion arrived at in the thermolysis studies,[6,7] where it is shown that on heating α,α'-azocumene is decomposed by a concerted process according to reaction 1. It can be conjectured that upon UV irradiation an electronically excited repulsive state is produced resulting in the occurrence of rapid fragmentation. This problem could probably be solved by a highly time-resolved flash photolysis technique.

The authors are grateful to Dr. G. Beck for maintaining the flash photolysis set-up and to Dr. J. Lilie for assisting in the computer evaluation of the data. M. K. and Y. K. wish to express their sincere appreciation to Professor Shun-ichi Nozakura, Osaka University, for his encouragement.

The Pulse-Photoconductivity of Poly(1-vinylpyrene)

Akira ITAYA* and Ken-ichi OKAMOTO
Department of Chemical Engineering, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
(Received July 7, 1986)

The migration of electronic excitation energy, the steady-state photoconductivity, the hole-drift mobility and the carrier-photogeneration efficiency of holes in poly(1-vinylpyrene)(PVPy) films were investigated and compared with those in poly(*N*-vinylcarbazole)(PVCz) films. Although the concentration of the excimer-forming sites in PVPy films was about twenty times as large as that in PVCz films, the magnitude of the steady-state photoconductivity of PVPy was comparable to that of PVCz. The hole mobility in PVPy films was about one-half as large as that in PVCz films. The electric field and temperature dependence of the mobility fit Gill's empirical equation. The carrier-photogeneration efficiency, ϕ, of PVPy was larger than that of PVCz. The filed dependence of ϕ of PVPy for all the excitation bands was in good agreement with the Onsager theory of geminate recombination. The high photoconductivity of PVPy could be explained on the basis of these results.

A number of papers have appeared in the literature concerning carrier-photogeneration and charge transport in both aromatic vinyl polymers and molecularly-doped polymers from theoretical and practical standpoints.[1] It has been revealed that the concentration of excimer-forming sites is one of the important factors determining the magnitude of the photoconductivity; that is, the excimer-forming sites act as traps of both singlet excitation energy and hole carriers.[2,3]

Considerable data on the photoconductivity of poly(*N*-vinylcarbazole)(PVCz) have been accumulated because of an interest in highly photoconductive polymers.[4,5] *N*-Ethylcarbazole, which is a monomeric model compound of PVCz, shows no excimer fluorescence in either concentrated fluid solutions or the solid state[6] and is a typical compound which forms no excimer. On the other hand, 1-ethylpyrene shows an excimer fluorescence in concentrated fluid solutions and is a typical compound which forms an excimer. Poly(1-vinylpyrene) (PVPy) almost exclusively shows the excimer fluorescence in dilute solutions[7,8] and is, therefore, expected to have a high concentration of the excimer-forming sites in solid films.

In the present paper, the pulse photoconductivity of PVPy has been investigated in comparison with that of PVCz, poly(5-vinylbenzo[*b*]carbazole) (P5VBCz) and poly(7-vinylbenzo[*c*]carbazole) (P7VBCz).

Experimental

The PVPy was prepared by the polymerization of a 0.15 M†† toluene solution of purified 1-vinylpyrene in the presence of 2 mol% $BF_3 \cdot OEt_2$ under a nitrogen atmosphere at −35 °C for 1 h and was purified by reprecipitation from a tetrahydrofuran solution with methanol two times. The sample was stored in tubes within an argon atmosphere in the dark. Films were cast on NESA-coated conductive quartz plates from a chloroform solution containing 0.5% ethanol and were dried in vacuo. A semitransparent gold electrode with a typical area of 1 cm^2 was evaporated on a film to prepare a sandwich-type cell. Polymer-film thickness was determined from the weight and density (1.22 g cm^{-3}) of a film with a certain known area and/or by a capacitive method. The dielectric constant, ε, of the films was determined to be 3.28 from capacitance measurements at the frequency of 1 KHz at 298 K.

The fluorescence spectra and the steady-state photocurrent were measured with the apparatus described in a previous paper.[9,10]

The drift mobility and the carrier-photogeneration efficiency of holes were measured with the apparatus described in a previous paper by means of a conventional time-of-flight method in a vacuum of 2.6×10^{-3} Pa.[4,5] A 3 μs light pulse from an air-gap flash was irradiated onto a sample through appropriate narrow band-pass filters. The precautions described in a previous paper were taken in all the procedures in order to obtain reproducible results.[4]

Results and Discussion

Concentration of Excimer-Forming Sites. The fluorescence spectrum of PVPy films is composed of only one component and is assigned to the excimer fluorescence.[7,8] In PVPy films doped with dimethyl terephthalate (DMTP), where a long-range single-step energy transfer is impossible, the host fluorescence is significantly quenched (Fig. 1). The application of a random-hopping model of monomer-exciton migration to the quenching process of the host-sensitized energy transfer gives the concentration of trap sites (excimer-forming sites and non-fluorescent trap sites) for the singlet exciton migration.[2,11] The concentration of the trap sites in PVPy films was dependent on the excitation wavelength used in the quenching experiment and was 8.6×10^{-2} and 4.9×10^{-2} mol mol^{-1} basic unit for the 345 and 379 nm excitation,

* Present address: Department of Polymer Science and Engineering, Kyoto Institute of Technology, Matsugasaki, Kyoto 606.

†† 1 M=1 mol dm^{-3}.

respectively.

It has been reported that the process of photooxidation of PVCz films proceeds near the surface of films.[4,12] The absorption coefficient of 345 nm in the ^1L_a band (1.9×10^5 cm^{-1}) of PVPy films is about twenty times as large as that of 379 nm in the ^1L_b band (7.8×10^3 cm^{-1}) and 90% of the exciting light of 345 and 379 nm was absorbed within layers of less than 0.12 and 3.0 μm in depth, respectively. Therefore, the higher concentration of trap site obtained for the 345 nm excitation may be attributable to a high concentration of nonfluorescent photooxidation products. If the concentration of excimer-forming sites in PVPy films is taken to be 4.9×10^{-2} mol mol^{-1} basic unit, it is about twenty times as large as the value for PVCz films (2.7×10^{-3} mol mol^{-1} basic unit).[11]

Steady-State Photocurrent. Photocurrents with positive and negative electrode illumination of PVPy films (abbreviated to i_{ph}^+ and i_{ph}^-, respectively) showed a superlinearity on applied voltage in fields higher than ca. 70 and 130 kV cm^{-1}, respectively, although they were proportional to the applied voltage in the lower field. This field dependence of i_{ph}^+ is quite similar to that of PVCz.[13] Both i_{ph}^+ and i_{ph}^- of PVPy were always proportional to the light intensity (10^{11}—10^{13} photons cm^{-2} s^{-1}) in every wavelength region over the whole range of the applied voltage. The spectral dependence of the photocurrent (Fig. 2) was obtained by normalizing the observed photocurrent values to the values for a constant light intensity of 1×10^{13} photons cm^{-2} s^{-1}, according to the light-intensity dependence. This spectral dependence of i_{ph}^+ corresponds symbatically to the absorption spectrum, but that of i_{ph}^- does antibatically to the spectrum. This behavior of PVPy is also quite similar to that of PVCz in the field higher than 10^4 V cm^{-1}.[13] The magnitude of i_{ph}^+ is larger than that of i_{ph}^- in the UV wavelength region shorter than 385 nm (the absorption edge of the thick film), although they are nearly equal to each other in the wavelength region longer than 385 nm. The magnitude of both i_{ph}^- and i_{ph}^+ of PVPy was almost the same as that of PVCz.[13] Considering the difference in the concentration of excimer-forming sites between PVPy and PVCz, this result is noteworthy.

Hole-Drift Mobility. A transient photoresponse was detected for the positive electrode illumination and was attributed to hole transport. In the transient-response curve, a shoulder corresponding to a transit time (t_r) was observed above about 338 K. When no shoulder of the transient response curve was observed, the transit time (t_r*) was determined from the bilogarithmic plots, based on the theory of Scher and Montroll.[14] The hole-drift mobilities calculated from t_r and t_r* were abbreviated as μ_p and μ_p*, respectively.

Figure 3 shows the absorption spectrum of a PVPy thin film and the transmittance of the band-pass filters used. The hole-drift mobility was independent of the excitation bands of ^1L_a, ^1B_b, and ^1B_a. The results mentioned below concerning the hole mobility were obtained by the excitation of the ^1L_a absorption band.

Figure 4 shows the electric field dependence of the hole mobility of PVPy at 338 K. The results for PVCz, P5VBCz, and P7VBCz samples are also shown for the sake of a comparison. The straight lines in plots of log μ against the square root of the electric field show that the Poole-Frenkel type relation holds for these polymers. At 338 K and 9×10^4 V cm^{-1}, the hole mobility of PVPy was about one-half as large as that of PVCz and was larger than those of P5VBCz and P7VBCz. The monomeric model compounds of

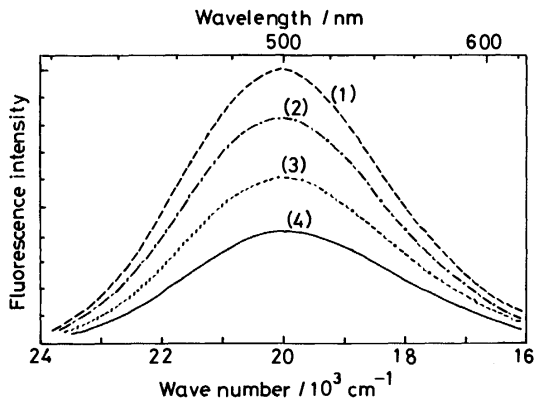

Fig. 1. Fluorescence spectra of PVPy films doped with DMTP at room temperature. DMTP concentration; (1): 0, (2): 1.20×10^{-2}, (3): 3.00×10^{-2}, (4): 7.50×10^{-2} (mol/VPy unit mol). Excitation wavelength; 379 nm.

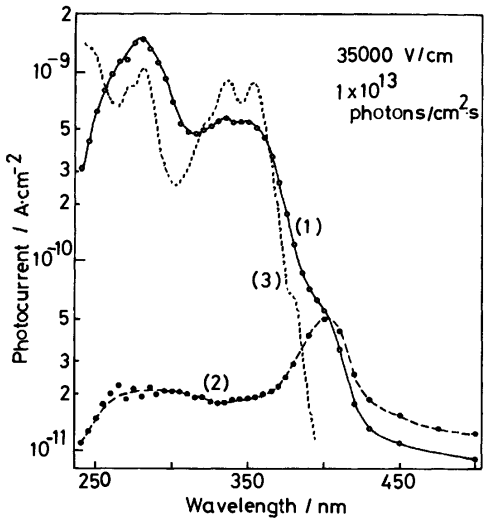

Fig. 2. Spectral dependence of steady-state photocurrent of PVPy in a high vacuum under 35000 V cm^{-1} at room temperature (1) i_{ph}^+ (2) i_{ph}^-. Absorption spectrum of PVPy films is shown by curve (3).

P5VBCz and P7VBCz also show no excimer fluorescence in concentrated solutions[15] and, therefore, these polymers are expected to have a low concentration of excimer-forming sites in films as well as PVCz. Therefore, the magnitude of the hole mobility is not simply related to the concentration of excimer-forming sites.

Figure 5 shows the temperature dependence of the hole mobility of PVPy and PVCz under various electric fields. The electric field dependence of the activation energies, ΔE_a, of PVPy, PVCz, P5VBCz, and P7VBCz is shown in Fig. 6. These figures indicate that the hole mobility of PVPy also follows Gill's empirical equation,[16] as is the case with carbazolyl- and benzocarbazolyl-pendant polymers:[5,16,17]

$$\mu_p = \mu_0 \exp\{-(\Delta E_0 - \beta\sqrt{E})/kT_{eff}\} \quad (1)$$

$$1/T_{eff} = 1/T - 1/T_0 \quad (2)$$

where k is the Boltzmann constant; E, the electric field; T, the film temperature, and μ_0, ΔE_0, T_0, and β; the characteristic parameters. The values of the parameters obtained are listed in Table 1. Remarkable differences in parameter values between PVPy and PVCz were found in μ_0 and T_0. The T_0 value of PVPy

a) *: Values were determined from μ_p*.

was much lower than that of PVCz and close to those of the benzocarbazolyl-pendant polymers. It has been suggested that T_0 is related to the freezing-in temperature of the micro motion of chromophores themselves acting as hopping sites; their micro motion destroys some structural traps preventing the hole transport and promotes the transport and that T_0 is the transition temperature from the glassy state to the supercooled liquid state in the hole-transport phenomena.[5,18] The pyrenyl chromophores connected to a skeletal chain at the 1-position have unsymmetric molecular structure, being different from carbazolyl chromophores connected to skeletal chain at the 9-position. Therefore, the packing between chromophores in PVPy may be loose as compared with chromophores in PVCz and the pyrenyl chromophores may tend to move to destroy the structual traps at lower temperatures.

The μ_0 value of PVPy was much smaller than that of PVCz by a factor of ca. 20 and close to those of the benzocarbazolyl-pendant polymers. It has been reported that the μ_0 value is related to a molecular interaction between chromophores[16] and is close to the value of the trap-free drift mobility.[19,20] Although a sample with a high value of T_0 tends to have a high value of μ_0, it is noted that the μ_0 value of PVCz is extremely high among the aromatic vinyl polymers investigated. Therefore, PVCz is considered to be a special case and the molecular interaction between carbazolyl chromophores in PVCz is considered to be very strong with regard to hole transport.

The value of the exponential term related to the temperature in Eq. 1 is larger for PVPy than for PVCz. However, the μ_0 value is much lower for PVPy than for PVCz. Consequently, the mobility of PVPy is one-half as large as that of PVCz. Although the concentration of excimer-forming sites in PVPy films is about twenty times as large as that in PVCz films, the difference in the mobility between PVPy and PVCz is small. This is considered to be attributed to the low T_0 value caused by the loose packing between chromophores in PVPy.

Carrier-Photogeneration Efficiency. In order to excite the ^1L_a, ^1B_b, and ^1B_a absorption bands, narrow band-pass filters of 340, 280, and 240 nm were used, respectively (Fig. 3). Figure 7 shows the field dependence of the carrier-photogeneration efficiency, ϕ, of PVPy for the various excitation bands, including that of PVCz for the sake of comparisons. The ϕ increases in the order of the ^1L_a, ^1B_b, and ^1B_a bands, as is the case of PVCz.

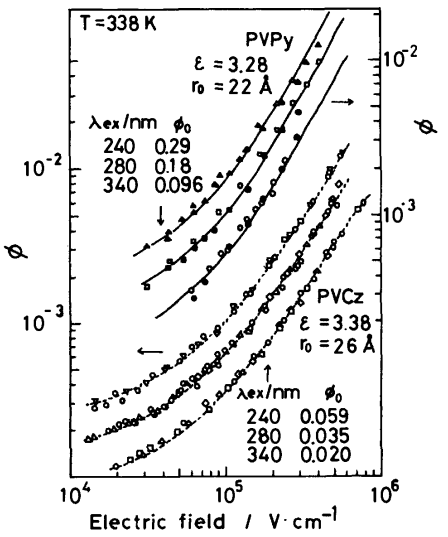

Fig. 7. Field dependence of the carrier-photogeneration efficiency in PVPy and PVCz films for various excitation bands. The solid lines were calculated from Eq. 3 with r_0 and ϕ_0 values presented in the figure.

The ϕ is given as the product of a primary yield, ϕ_0, of a bound electron-hole pair with an interionic separation of r_0 and the dissociation probability, P(E):[4]

$$\phi = \phi_0 \cdot P(E). \quad (3)$$

The P(E) is given by the Onsager theory[21] as the function of r_0. The solid lines in Fig. 7 were calculated from Eq. 3 with r_0 of 22 Å and with ϕ_0 of 0.096, 0.18, and 0.29 for the ^1L_a, ^1B_b, and ^1B_a bands, respectively. They are in good agreement with the experimental data. The carrier-photogeneration efficiency of PVCz fit also the Onsager theory with both ϕ_0 values increasing from 0.02 to 0.059 and a constant r_0 value of 26 Å.[4] Therefore, the carrier-photogeneration mechanism of PVPy is considered to be the same as that of PVCz.[4,11] That is, the extrinsic carrier-photogeneration via nonrelaxed exciplexes formed between singlet excitons and acceptor-like impurities or photooxidation products is also predominant in PVPy films for all the excitation bands.

The ϕ_0 values of PVPy are about five times as large as those of PVCz, although the concentration of excimer-forming sites of PVPy is higher than that of PVCz. This indicates that the concentration of acceptor-like impurities and/or photooxidation products is much higher for PVPy than for PVCz under these experimental conditions. Judging from that the

excimer-forming site is susceptible to photooxidation[12] and also that a PVPy film has a fairly low ionization potential (7.13 eV), concentration of photooxidation products in a PVPy film seems to be higher than that in a PVCz film. It has been reported for PVCz that the ϕ_0 value is higher for the excitation band having higher absorption coefficient,[4] because the concentration of photooxidation products becomes higher on going from the bulk to the surface. The similar concentration profile of the photooxidation products is also held in PVPy films, as indicated by the above-mentioned results of the singlet energy migration. The absorption coefficient of the ^1L_a band of PVPy (2.4×10^5 cm^{-1}) is larger than those of the ^1L_b and ^1L_a bands of PVCz (5×10^4 cm^{-1} and 1.5×10^5 cm^{-1}, respectively). Therefore, the large ϕ_0 value of PVPy is attributed to both the excitation of the film surface including photooxidation products in very high concentrations and the low ionization potential of a PVPy film.

In conclusion, the carrier-photogeneration efficiency of PVPy is twice as large as that of PVCz. On the other hand, the hole-drift mobility of PVPy is one-half as large as that of PVCz. Consequently, there is no significant difference in the steady-state photocurrent between PVPy and PVCz.

The cost of the present investigation was partly defrayed by the Grant-in-Aid from the Japanese Ministry of Education, Science, and Culture to AI(60550627). KO wishes to acknowledge the financial support of the Mita Kogyo Co. Ltd., for this work.

Effects of Surfactants and Surface Treatment on Aqueous Dispersion of Silicon Carbide

Kenjiro MEGURO, Takahisa USHIDA, Tetsuya HIRAOKA, and Kunio ESUMI*
Department of Applied Chemistry and Institute of Colloid and Interface Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received July 9, 1986)

The effects of the addition of surfactants and of the surface treatment upon the aqueous dispersion of silicon carbide were examined. In the case of β-SiC, the addition of nonionic surfactants having relatively longer lengths of hydrocarbon and oxyethylene chain to the β-SiC treated with a silane coupling agent enhanced the dispersion stability. On the other hand, the lack of a difference for the dispersion stability was observed between a silane coupling treated α-SiC and an untreated one by the addition of surfactants. These differences in the surface property of two kinds of SiC were confirmed by measuring the zeta potential and the heat of immersion in water.

In recent years particle-reinforced composites have become attractive for many fields because of their excellent properties. Particularly, interest in electrodeposited composite coatings has increased rapidly. The purposes for composite plating are improved abrasion resistance, friction resistance, corrosion resistance, functional plating and so on. The detailed properties and applications of such plating have been reported.[1-5] From many studies, it has been confirmed[6,7] that agitation and current density are two major factors that affect the rate of entrapment of electrodeposite composite plating.

Besides, it is important to disperse the component particles in the plating solution in order to obtain a homogeneous surface of composite plating. The dispersion of solid particles in an aqueous solution is often considerably influenced by the addition of a small amount of water-soluble substances. The dispersion effect by nonionic ethoxylated surfactants[8-10] is dependent on their chemical structure and on the kind of particles to be dispersed. Since nonionic ethoxylated surfactants have both hydrophilic and hydrophobic parts, it is expected that their adsorption behavior will be affected not only by their affinity to solids, but also by the affinity to the medium in the suspensions. It is also suggested that the adsorption of nonionic surfactants is strong when either the particle or medium is polar and the other is nonpolar.

In this study, interactions between treated silicon carbide with a silane coupling agent or an untreated one and nonionic surfactants in an aqueous solution of high concentration of electrolytes were investigated by measuring the zeta-potential, the particle size, the turbidity and the heat of immersion from the standpoint of basic electrodeposited composite plating.

Experimental

Materials. α-SiC was provided from Showa Denkou Co., Ltd., and β-SiC from Ibiden Co., Ltd.

The physical properties of silicon carbides are as follows: a density of 3.2 g cm^{-3} and a specific surface area of 9.5 m^2 g^{-1} for α-SiC and 3.2, 17.0 for β-SiC,

The nonionic surfactants were obtained from Nikko Chemical Co., Ltd.; their types and structural formula are

$C_{16}H_{33}$-O-$(CH_2CH_2O)_n$H (BC-*n*),
$C_{22}H_{45}$-O-$(CH_2CH_2O)_n$H (BB-*n*),
$C_{18}H_{35}$-O-$(CH_2CH_2O)_n$H (BO-*n*), and
$C_{18}H_{37}$-CO-O-$(CH_2CH_2O)_n$H (MYS-*n*),

where *n* indicates the mole number of oxyethylene units included in the surfactant.

Sodium dodecyl sulfate was provided from Wako Pure Chemical Industrial Ltd. and purified by recrystallization from ethanol.

Sodium chloride, calcium chloride and aluminum chloride were of commercial high pure grade reagents.

A nickel sulfamate aqueous solution was used as the plating solution. It was provided by the Electroplating Engineers of Japan Ltd.

The treatment of silicon carbide was carried out with a 5 w% solution of trimethylchlorosilane (TMCS), provided by Chisso Co., Ltd., in isopropyl alcohol by stirring for 2 h. After the treatment, the silicon carbide was washed five times with pure isopropyl alcohol. Then, the treated powder was dried for 2 h at 140 °C.

The water used in all experiments was purified by passing it through an ion-exchanged column followed by filtration in a Milli-Q Water Purification System.

Apparatus and Procedure. 0.5 g of silicon carbide was added to a nonionic surfactant solution (1 L) with a high electrolyte concentration and agitated with an ultrasonic bath for 10 min. Then, after shaking for 1 h at 25 °C, the absorbance of the suspension was recorded every 5 min during 1 h at 500 nm by means of a Hitachi 220-A-type double-beam spectrophotometer using 0.2-cm cells at 25 °C.

The stability of the suspension can be expressed as

$$[O.D]_t/[O.D]_5,$$

where $[O.D]_5$ is the absorbance after 5 min and $[O.D]_t$ is the absorbance after *t* minutes.

The heat of immersion in water for these samples was measured using a calorimeter (Tokyo Rikou Co., Ltd.) at 25 °C: after silicon carbide was placed into a glass ample tube and evacuated at 1×10^{-2} Torr for 1 h, the glass ample tube was sealed and set in a calorimeter with water, until it reached thermal equilibrium at 25 °C. Then, the glass

ample tube was broken and the silicon carbide was immersed in water. The liberated heat was recorded and calibrated by the normal procedure.

The zeta-potential of silicon carbide was measured by an electrophoresis apparatus Laser Zee TM Model 500 (PEN KEM, Inc.). The mean particle size was measured by a particle sizer (Malvern Co., Ltd.).

The pH of the silicon carbide suspension was measured using a pH meter 130 (Corning Co., Ltd.).

The surface of silicon carbide was measured by FTIR-ATR (Japan Spectroscopic Co. Ltd.).

Results and Discussion

1. Dispersion of Silicon Carbide in Aqueous Solution. Variations in the zeta-potential of α-SiC and β-SiC as a function of pH are given in Fig. 1. The silicon carbide particles had a positive charge at a low pH; their charges became negative with an increase in the pH. The isoelectric point of α-SiC was found to be in the vicinity of pH 2.3, and of β-SiC in the vicinity of pH 5. The pH of dispersion (0.5 g L^{-1}) of α-SiC and β-SiC in pure water was 5.6, at which the zeta potential of α-SiC was about -30 mV, and of β-SiC was about -7 mV, and their mean particle sizes were about 470 and 7300 nm, respectively.

Variations in the zeta-potential of silicon carbide with the concentration of each electrolyte solution are given in Fig. 2. The zeta-potential of silicon carbide in aqueous solution was altered from negative to zero by the addition of an electrolyte. By a further addition of the electrolyte, the charge of the particles became positive. In the case of aluminum chloride, upon a further addition, the charge of the particles again became zero.

On the other hand, the zeta-potential became high with the valency of cationic ions. Accordingly, the isoelectric point (i.e.p.) of silicon carbide was remarkably shifted to the low concentration with an increase in the valency of cationic ions.

It was found that both α-SiC and β-SiC had the highest positive charge by the addition of 1×10^{-4} M† $AlCl_3$. At this concentration, the absorbance of dispersion of α-SiC was initially 0.73, but greatly decreased to 0.01 after 24 h, while that of β-SiC gradually decreased from 1.45 to 0.85.

Variations in the zeta-potential of α-SiC and β-SiC

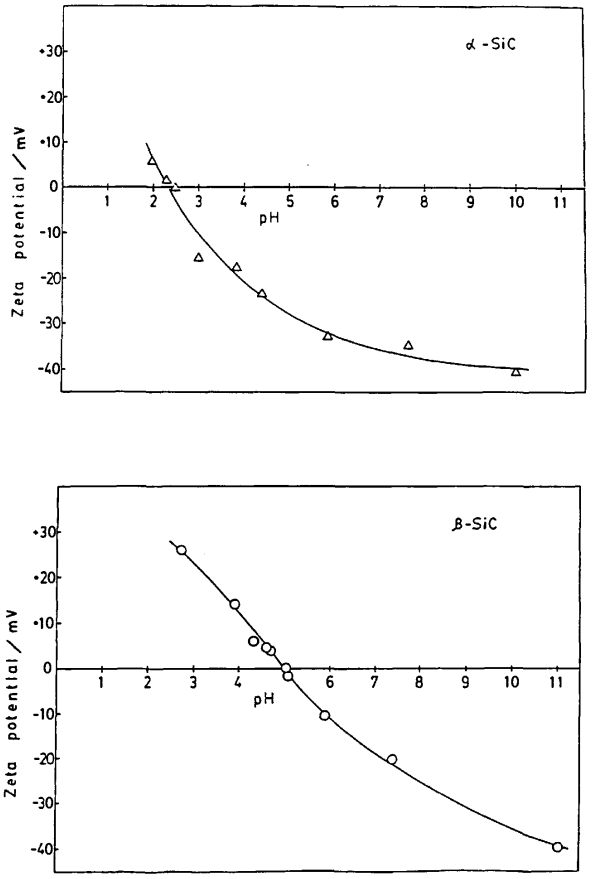

Fig. 1. Variation in zeta potential of silicon carbide as a function of pH.

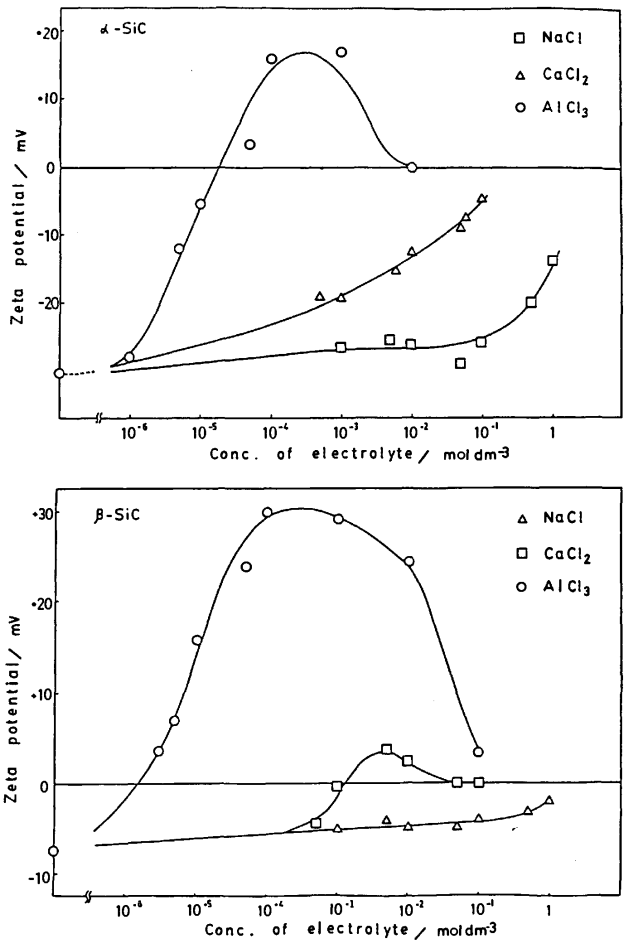

Fig. 2. Variation in zeta potential of silicon carbide with concentration of electrolyte.

† 1 M=1 mol dm^{-3}.

having a positive charge in a 1×10^{-4} M $AlCl_3$ aqueous solution with the concentration of an anionic surfactant (SDS) are given in Fig. 3. Particles of α-SiC and β-SiC had a positive charge during the initial state, and the mean particle sizes of α-SiC and β-SiC were about 800 and 300 nm, respectively. These positive charges of α-SiC and β-SiC decreased to zero upon the addition of a small amount of SDS whose concentrations were 2×10^{-4} and 5×10^{-4} M, respectively. Then, the SiC flocculated and the mean particle sizes of those flocculate were about 4000 and 5000 nm, respectively. Upon a further addition of SDS, α-SiC and β-SiC became negatively charged, and the flocs redispersed again. This resulted in a mean particle sizes of about 600 and 250 nm, respectively.

From these results, the processes of flocculation and redispersion of silicon carbide were observed by the addition of SDS. The stability of the dispersion of silicon carbide by the addition of 1×10^{-2} M SDS was altered as follows: The absorbance of the α-SiC suspension was initially 0.86 but decreased to 0.46 after 24 h, while that of β-SiC suspension gradually decreased from 1.44 to 1.00.

The absorbance at 500 nm for a suspension of α-SiC and β-SiC, which had flocculated by addition of SDS, changed with the concentration of added nonionic surfactant (BB-n). The results given in Fig. 4 show

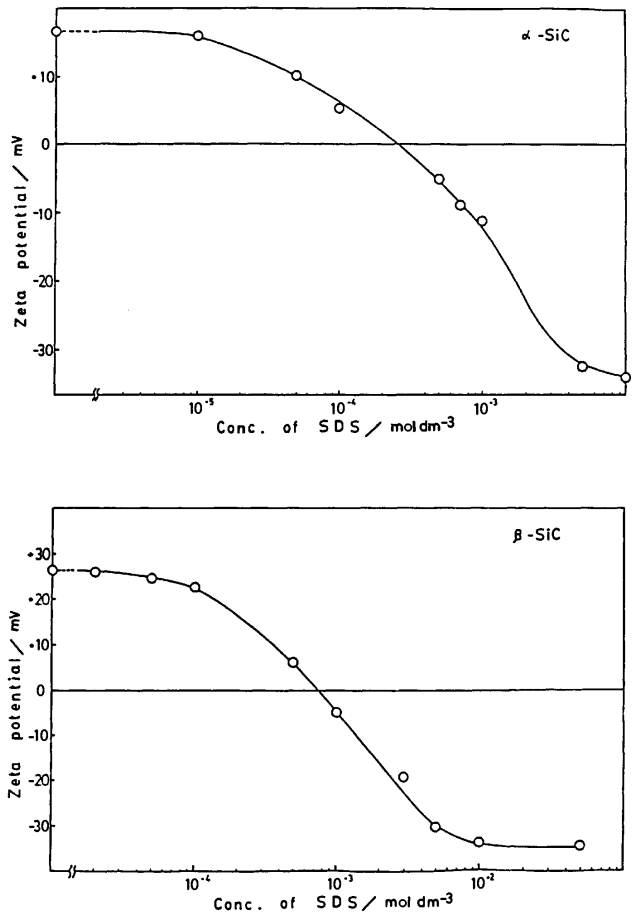

Fig. 3. Variation in zeta potential of silicon carbide in $AlCl_3$ solution(1×10^{-3} M) with a concentration of SDS.

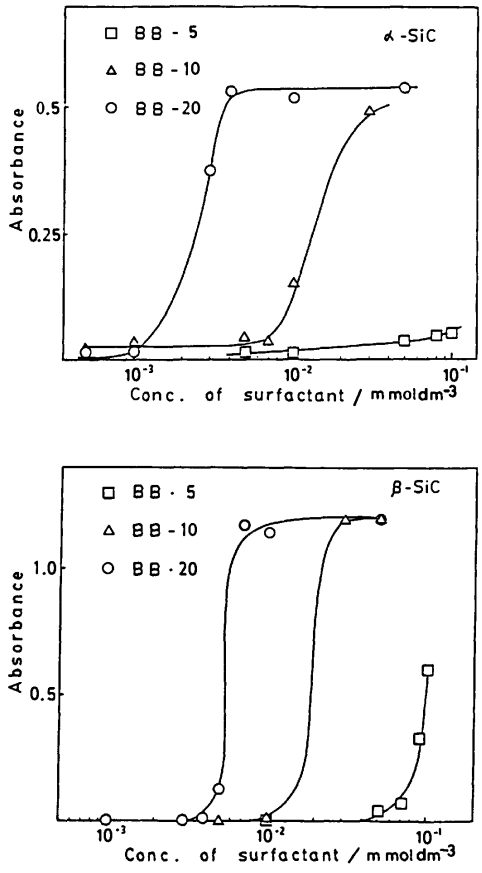

Fig. 4. Variation in absorbance for silicon carbide suspension, flocculated by addition of SDS, with addition of BB-5, BB-10, and BB-20.

Table 1. Dispersion Stability of Silicon Carbide

Sample	α-SiC		β-SiC	
	$[O.D]_0$	$[O.D]_{1d}{}^{a)}/[O.D]_0$	$[O.D]_0$	$[O.D]_{1d}{}^{a)}/[O.D]_0$
$AlCl_3$	0.73	0.01	1.45	0.59
$AlCl_3$+SDS	0.86	0.54	1.44	0.69
$AlCl_3$+SDS+BB-20	0.92	0.58	1.53	0.78

a) 1d indicates 1 day.

that the absorbance increases and becomes constant with the addition of BB-5, BB-10, and BB-20, indicating that a redispersion of α-SiC and β-SiC could be attained. A well redispersion was obtained by a smaller addition of a nonionic surfactant which had a longer oxyethylene chain, at which the mean particle sizes of α-SiC and β-SiC were about 800 and 310 nm, respectively. However, the addition of BB-5, scarcely gave a well redispersion.

The mechanisms of flocculation and redispersion can be explained in terms of a "two-fold adsorption layer," similar to that suggested earlier[11-14] That is, silicon carbide becomes positively charged in an aqueous aluminum chloride solution, providing a well dispersed state characterized by a minimum in the mean particle size and a maximum in the zeta-potential. By the addition of low concentrations of SDS, the particles are discharged and the size of flocculated particles increases. As the hydrocarbon chains of SDS are oriented outward, the particles become hydrophobic and flocculation takes place. On a further addition of SDS, the adsorption of this surfactant occurs by a chain interaction resulting in a two-fold layer with the ionized groups of the second layer oriented towards the solution. Accordingly, the particles become recharged and a redispersion is achieved due to the electric repulsion. A redispersion upon the addition of nonionic surfactants, on the other hand, is most likely due to a steric hindrance between the adsorbed nonionic surfactant molecules.

Table 1 shows the above results for the stability of dispersion. It is recognized that the positive charged particles flocculated by the addition of SDS are redispersed by the addition of a nonionic surfactant which has relatively longer lengths of the oxyethylene chain (BB-20); also, the stability of redispersion is remarkably enhanced.

2. Dispersion of Silicon Carbide in Aqueous Solution with High Concentration of Electrolyte. A well dispersion stability of silicon carbide treated with SDS and BB-20 was not obtained in a 0.1-M $AlCl_3$ aqueous solution since the zeta-potentials of α-SiC

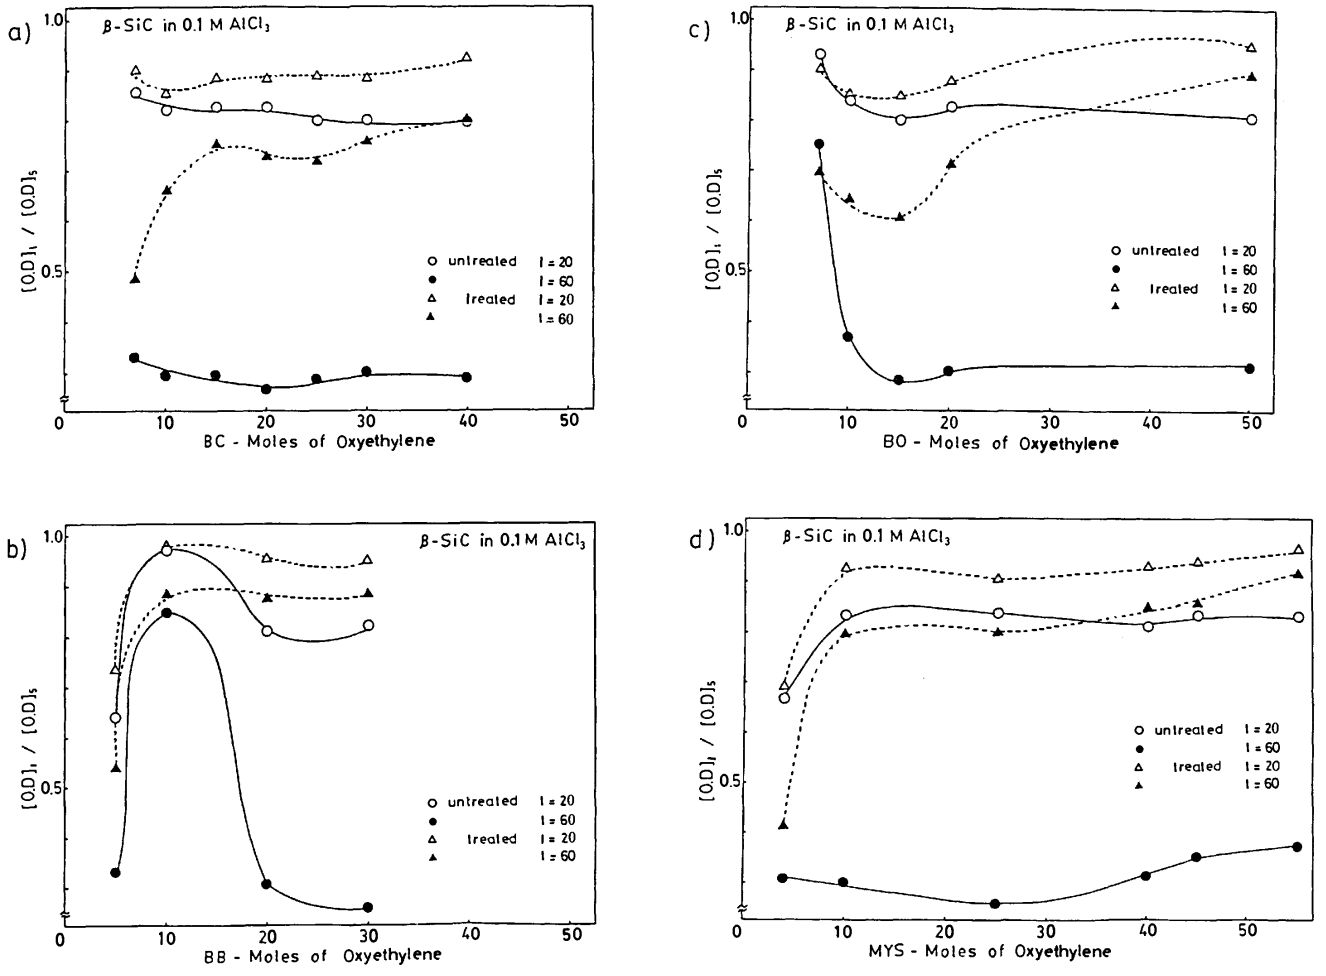

Fig. 5. Variation in $[0.D]_t/[0.D]_5$ of treated and untreated β-SiC with mole of oxyethylene included in nonionic surfactants in 0.1 M $AlCl_3$ aqueous solution.

and β-SiC are almost zero in a 0.1-M $AlCl_3$ aqueous solution or a 1-M $CaCl_2$ aqueous solution and the adsorption of SDS and BB-20 hardly occurred on the surface of silicon carbide. Therefore, a surface treatment of silicon carbide by a silane coupling agent was performed and the effect was examined. Variations in $[O.D]_t/[O.D]_5$ of TMCS-treated α-SiC and untreated α-SiC with the mole of oxyethylene included in each nonionic surfactants in a 0.1-M $AlCl_3$ aqueous solution were measured. Particularly, a well dispersion stability by the addition of BC-*n* or BB-*n* or MYS-*n* (n=10), and BO-*n* (n=7) was obtained. However, the effects of treatments with TMCS were not observed.

The results for TMCS-treated β-SiC and untreated β-SiC are given in Figs. 5 (a-d). In the case of β-SiC, the addition of nonionic surfactants, which had longer lengths of hydrocarbon and oxyethylene chains enhanced a dispersion stability of the treated sample significantly.

Similar results to that of α-SiC and β-SiC were also obtained in a 1.0-M $CaCl_2$ aqueous solution.

It was recognized through an FTIR-ATR measurement that silanol group exists on the surface of silicon carbide. Therefore, the reaction of trimethylchlorosilane with silanol would occur in the following manner[15-17]:

$$\text{-}\overset{|}{\underset{|}{\text{Si}}}\text{-OH} + (CH_3)_3SiCl \longrightarrow \text{-SiOSi}(CH_3)_3 + HCl.$$

Table 2 shows the immersional heat into water of untreated α-SiC, TMCS-treated α-SiC, untreated β-SiC and TMCS-treated β-SiC. In the case of β-SiC, by the reaction with TMCS, the heat was reduced, indicating that the surface of silicon carbide becomes appreciably hydrophobic under the treatment. As for α-SiC, the lack of difference in the heat between untreated α-SiC and TMCS-treated α-SiC implies that the surface of silicon carbide is not covered with TMCS.

As a general rule, interactions at water-solid surfaces are due to the van der Waals force, hydrogen bonding of water to hydroxyl groups and an electrostatic force (proportional to the surface charge). The hydrophilicity of a solid surface is mainly due to the latter two forces. Therefore, the dispersion stability of silicon carbide in water can be improved by the addition of an electrolyte, an anionic surfactant and a nonionic surfactant.

Table 2. Heat of Immersion of Silicon Carbide in Water ($J\,m^{-2}$) at 25 °C

	α-SiC	β-SiC
Untreated	0.20	0.17
TMCS-treated	0.19	0.11

However, in an aqueous solution with a high electrolyte concentraiton, silicon carbide hardly disperses, because the forces for adsorption of surfactants are very weak when particles are discharged due to a depression of electric double layer.

On the other hand, with an increase in the amount of the combined trimethylsilyl group, the silicon carbide particles start to float on the water surface without surfactants, and obviously reveal the surface hydrophobicity. Therefore, the mechanisms of dispersion of TMCS-treated β-SiC is explained as follows: the hydrocarbon chain of nonionic surfactants is oriented to the hydrophobic surface of TMCS-treated β-SiC. The force of adsorption is stronger between the surface and the hydrocarbon chain when the surface of β-SiC becomes hydrophobic. Accordingly, a well dispersed state is obtained when the length of the oxyethylene chain of a nonionic surfactant is relatively longer, even in an aqueous solution with a high electrolyte concentration.

For an application of electrodeposition, the SiC dispersion in a nickel sulfamate aqueous solution (plating bath) was studied. The results were similar to those for a in 1.0-M $CaCl_2$ aqueous solution or a 0.1-M $AlCl_3$ aqueous solution. Furthermore, the proportion of co-deposit TMCS-treated β-SiC on the plating surface to the concentration of TMCS-treated β-SiC in a plating bath by the addition of BC-40 or without BC-40 is given in Fig. 6. From this result, it is apparent that the amount of co-deposit after treatment with TMCS increases twice that without the treatment. Thus, the above result demonstrates that the dispersion of SiC is an important factor for an electrodeposite composite.

The authors are indebted to the Electroplating Engineers of Japan Ltd. for their help with the electroplating study.

Surface Characterization of Silica Modified with Aminosilane Compounds

Seiichi KONDO,* Tatsuo ISHIKAWA, Naoki YAMAGAMI, Kiyotaka YOSHIOKA, and Yoshiko NAKAHARA†
School of Chemistry, Osaka University of Education, 4-88 Minamikawahori-cho, Tennoji-ku, Osaka 543
†Government Industrial Research Institute, Osaka, Midorigaoka, Ikeda 563
(Received July 14, 1986)

Adsorption behaviors, IR spectroscopy and surface electric properties were studied on the surfaces of well-defined mesoporous silica gels modified with triethoxy(3-aminopropyl)silane (TAS) and [3-(dimethylamino)propyl]diethoxymethylsilane (DDS). Surface free silanol groups react with ethoxyl groups of these compounds rigidly. Isoelectric points and points of zero charge of modified silicas shift from pH 3 of pure material to alkali, but DDS-modified silica gels dissolve themselves in aqueous phase because of their strong alkali environment.

Silica gels modified with a large variety of silane derivatives are used for the liquid/solid and gas/solid adsorption chromatography,[1] and there are substantial studies such as states of modifications and adsorption behaviors.[2,3] However, the surfaces of silica gels in these studies were usually not well-characterized in view of, for example, the species and population of surface silanol groups which are substituted with various modifying agents and thence the degree of surface coverage of functional groups per unit area. Therefore, there are still some ambiguities on the state of modified compounds on the surface. On this point of view, surface characterization of ethoxylated mesoporous silica gels was carried out in this laboratory with the result that one ethanol molecule reacts with one free silanol group which covers the surface with a population of 3/nm^2.[4]

The purpose of this report is to clarify details of surface modification with coupling agents which have plural number of reacting functional groups per molecule such as triethoxy(3-aminopropyl)silane (TAS) and [3-(dimethylamino)propyl]diethoxymethylsilane (DDS) by means of well-characterized mesoporous silica gels as a starting material.

Experimental

Materials. Thin transparent plates of mesoporous silica gels of about 0.1 to 0.05 mm thick were made as mentioned elsewhere.[4] Specific surface areas (A_s), pore volumes (V_p) and mean pore radii (r_p) of sample S1 were 718 m^2 g^{-1} 0.63 cm^3 g^{-1} and 1.8 nm respectively. Surfaces of these materials were modified with TAS and DDS by immersing the material in toluene solution of these coupling agents in various concentrations relative to total amount of free hydroxyl groups in these silica gels, and by warming at 323 K for 5 h. The products were washed with toluene and ethanol and dried in vacuo at room temperature.

Adsorption Properties. Specific surface areas, pore volumes and mean pore radii were obtained from nitrogen isotherms using B. E. T. and Cranston-Inkley equations.

IR Spectroscopy. Ft-nir spectrometer of Digilab FTS15E with a PbSe detector was used with 2 cm^{-1} resolution, in the range from room temperature to about 1000 K in vacuo.

Chemical Analysis. The amount of carbon and nitrogen atoms contained in modified samples was measured both by simultaneous TG-DTA and by CHN elements analyzer of Yanagimoto Co. Total number of OH groups, N_{OH}/nm^2, being obtained from ignition loss between 423 and 1373 K were 7.2 and 6.5 for S1 and S2 sillca gels respectively.

Surface Electric Charges. ζ Potentials were measured with ground powders suspended and pH-equilibrated in water by means of ζ meter of Penkem Co. model 501. Points of zero charges (pzc) were estimated from pH change caused by adding a known amount of hydrogen chloride or potassium hydroxide to the solution obtained by immersing 100 mg of powdered samples in the 0.1 mol l^{-1} solution of potassium chloride under nitrogen gas stream at 302.3 K.

Results and Discussion

The nitrogen adsorption isotherms of original and modified samples with TAS are typical to mesoporous materials as is shown in Fig. 1 in which N_n is the number of nitrogen atoms of TAS reacted with the surface per unit surface area and is equal to the

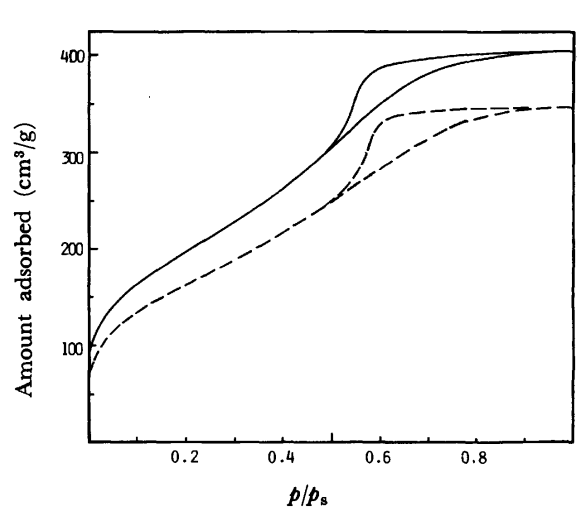

Fig. 1. The nitrogen adsorption isotherms of sample S1 (full line) and that modified with TAS to N_n= 0.49/nm^2 (broken line).

number of modified functional groups. Pore sizes are fairly uniform looking from pore size distribution curves in Fig. 2 with smaller maximum for larger amount of modification with TAS. Specific surface areas (A_s $m^2 g^{-1}$) and pore volumes (V_p $ml\ g^{-1}$) being computed from nitrogen gas adsorption isotherms of sample S2 decreased as the degree of modification with TAS and DDS was increased, whereas it was rather unusual to see that mean pore radii (r_p nm) did not decrease significantly as is seen in Table 1. The same tendency was observed with sample Sl.

The monolayer capacity of adsorbed water decreases by increasing degree of modification, such as from 4.7 water molecules/nm^2 to 1.5/nm^2 on sample modified with DDS to N_n=0.7. This shows that the sample became less hydrophilic by DDS modification, which was also true in case of TAS modification.

The reaction of these coupling agents on silica surface proceeds further to give the amount reacted much higher than monolayer of these substituted functional groups such as N_n=1.0. The ratio of nitrogen atoms to carbon atoms contained in silica gels after reaction was nearly equal to 0.7:3.0, as is seen in Fig. 3. This value is smaller than the ratio of these atoms in one molecule (1.0:3.0). This indicates that roughly one out of three ethoxy groups of a molecule did not react with surface silanol groups, the reason for which was explained by IR spectroscopy as is mentioned later. A_s, V_p, and r_p become smaller because of pore filling. However, the amount of these agents enough to cover the surface and form monolayer can not be precisely estimated from these results only.

Original mesoporous silica gels have mainly three types of silanol groups such as free silanol groups having a surface concentration of about 3/nm, inner OH groups and interparticle hydrogen-bonded silanol groups whose wave numbers are 3740, 3670 and about 3500 cm^{-1} respectively as was discussed elsewhere,[4] and as is partly seen in the ir spectra of unmodified sample Sl in Fig. 4. After modifying this sample with TAS and DDS, the absorbance of OH fundamental stretching band of free silanol groups decreases, and C-H and N-H bands in case of TAS increased. The absorbances of N-H band in case of TAS were proportional to the amount of nitrogen atoms contained in the sample, but free OH band disappears at nearly N_n=0.7 as is seen in Fig. 5. This was also true in case of DDS. This may be interpreted as that roughly two surface free silanol groups reacted with TAS or DDS, which agrees with the above mentioned result. The amino or dimethylamino groups of the substituted functional groups may be hydrogen-bonded to the

remaining one free silanol group as follows.

Thus, free silanol band disappeared and all three free silanol groups per nm² might have been used to form a monomolecular layer of functional groups. Modifying functional groups more than monolayer seem to react with each other forming some kind of polymers and lie over these modified surfaces to fill pores.

ζ Potentials and pzc were mearsured on these original and modified samples as the function of pH. The values of isoelectric points (iep) and pzc of the same sample agreed well to each other and were higher by increasing the amount of modification. Surface electric charges changed greatly by amine

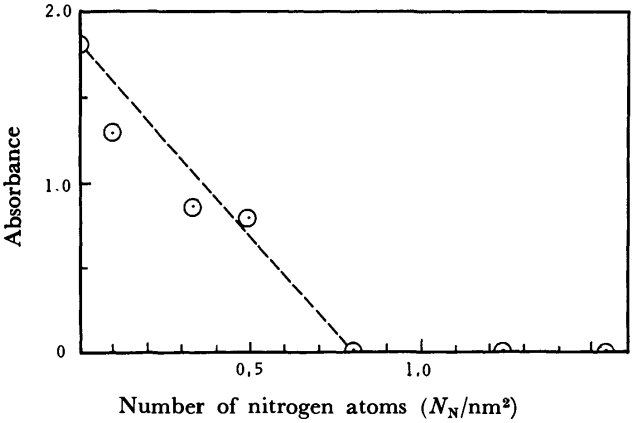

Fig. 5. The absorbance of O–H band as a function of number of nitrogen atoms contained in sample S1.

modification as one can expect. The iep and pzc of TAS modified samples were both about 8.0 and were stable for a prolonged period of time. On the other hand, initial values of iep and pzc of the DDS modified sample were equal to about 9.8 which is much higher than that of TAS, but went down to about 8.5 in 1 d. In this case, particles of this material dispersed in distilled water at room temperature are dissolved and disappeared after a few hours under microscope because of high pH produced by strong basicity of its surface. The free OH band emerged again after immersing this DDS-modified material in distilled water for several hours. These materials absorb alkyl halides irreversibly as is reported elsewhere.[5]

^{81}Br Nuclear Quadrupole Resonance of Cs_2ZnBr_4 and Crystal Stability of Compounds of A_2MX_4 Type

Hirokazu NAKAYAMA,† Nobuo NAKAMURA, and Hideaki CHIHARA*
Department of Chemistry, Faculty of Science, Osaka University,
Toyonaka, Osaka 560
(Received July 16, 1986)

The temperature dependences of ^{81}Br nuclear quadrupole resonance frequencies and quadrupolar relaxation times of Cs_2ZnBr_4 were measured. The librational motion of $[ZnBr_4]^{2-}$ about the Zn–Br axis parallel to the a axis in the crystal is more active than those about the other axes. The reason why this compound shows no phase transition can be accounted for by the molecular packing, especially the packing of $[ZnBr_4]^{2-}$ along the a axis. General examination of the relative size of cation/anion in the class of compounds of A_2MX_4 type led to a criterion which may be used to rationalize existence and absence of a phase transition.

A large number of A_2MX_4 type of compounds crystallize in the isomorphous structure with the space group *Pnma* and undergo analogous sequence of phase transitions. Among them much attention has recently been focused on Rb_2ZnBr_4 and Rb_2ZnCl_4 from experimental and theoretical points of view because they assume typical incommensurate structure in certain temperature regions. Cs_2HgBr_4[1] and Cs_2CdBr_4[2] also belong to this group and have interested us as they[3–6] show similar successive phase transitions from the normal room temperature phase to the phase of incommensurate structure and then to the commensurate phase on further cooling. We studied the microscopic structure of the incommensurate phases of these latter two materials by relating the nuclear quadrupole resonance results with a model calculation of the electric field gradients at the bromine sites.[7]

Cs_2ZnBr_4 also has the A_2MX_4 composition and crystallizes in the *Pnma* structure.[8] However no phase transition has been found in this compound so far.[3] These facts suggest that the structural stability of this type of compounds depends on a very intricate balance of interatomic forces and that the phase transition phenomena have to occur when such an intricate balance is destroyed. Hence it will be of great interest to uncover a factor or factors which govern the crystal stability and the cooperative phase change phenomena of such series of materials.

This paper is aimed first at deducing some information about the feature of the molecular motion in Cs_2ZnBr_4 from the temperature dependence of nuclear quadrupole resonance frequencies and spin-lattice relaxation times. The second purpose is to pin down the physical properties that determine the crystal structure and trigger the phase transition of these materials.

† Present address: Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560.

Experimental

Crystalline Cs_2ZnBr_4[8] was obtained by slow evaporation of aqueous solution of the stoichiometric amounts of CsBr and $ZnBr_2$ at room temperature. The sample was recrystallized twice from aqueous solution, ground and sealed in an ampule with helium gas for the NQR measurements.

The ^{81}Br NQR signal was observed with a home-built pulsed FT spectrometer based on a MATEC spectrometer. The matching unit was placed in the cryostat in order to make impedance matching easy. Details of the apparatus and its operation were reported elsewhere.[9]

The temperature dependence was determined by using a simple cryostat with liquid nitrogen as the refrigerant. The temperature, kept constant to within ±0.1 K during the NQR measurements, was measured with Chromel P-Constantan thermocouples.

Results and Discussion

Cs_2ZnBr_4. The temperature dependence of the nuclear quadrupole resonance frequencies is shown in Fig. 1. There are three resonance lines in the temperature range between 77 and 300 K in accordance with the X-ray structure data.[8] Our frequency data agree with those by Plesko et al.[3] within 100 kHz in the temperature range measured. We may assign the three resonance lines ν_1, ν_2, and ν_3 to the bromine 1, 2, and 3 in the structure data[8] respectively by reference to the NQR data of the isomorphous Cs_2CdBr_4.[6] One sees from this figure that the temperature coefficient of the resonance line at the site 1 is only $-2\,kHz\,K^{-1}$ in comparison with -6.5 kHz for the line at the site 2, indicating that the librational motion of the $[ZnBr_4]^{2-}$ tetrahedron is highly anisotropic. Since the direction of the bond between the bromine at the site 1 and the central metal almost coincides with the crystallographic a-axis, the above fact means that only the libration of the anion about the a-axis is highly excited. This interpretation is also supported by the relaxation time measurements. The temperature dependence of the ^{81}Br spin-lattice relaxation time, T_1, is shown in Fig. 2. The relaxation rate, T_1^{-1}, obeys the T^2 law[10] for all the

lines between 77 and 300 K, indicating that the relaxation of the bromine nuclei at all the sites is governed by the librational motion of the $[ZnBr_4]^{2-}$ tetrahedron. According to the theory of the quadrupolar relaxation[10] due to vibration,

$$T_1^{-1}(\nu_1) : T_1^{-1}(\nu_2) : T_1^{-1}(\nu_3) = \nu_1^2 : \nu_2^2 : \nu_3^2$$

holds if the molecular or the ionic motion is isotropic. Hence, the relaxation time of the ν_1 line would be the shortest if the isotropic anionic librations were excited. The experimental T_1 of the ν_1 is, however, more than twice as long as those of the other two lines, which supports again that the libration about the a-axis, which does not essentially affect the T_1 for ν_1, is sufficiently excited but those about the other axes have only small amplitudes.

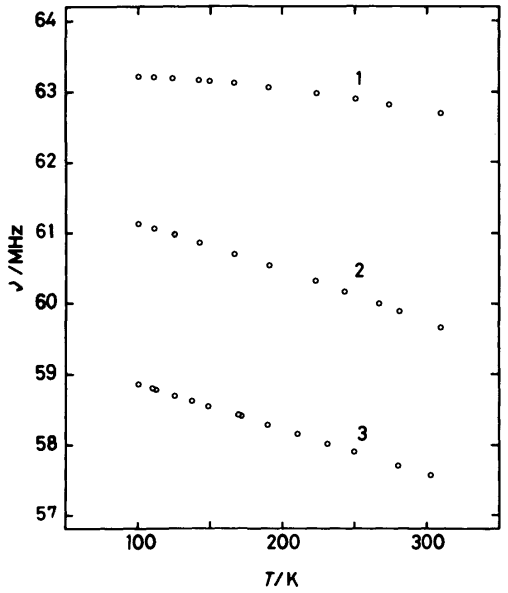

Fig. 1. Temperature dependence of ^{81}Br NQR frequencies in Cs_2ZnBr_4.

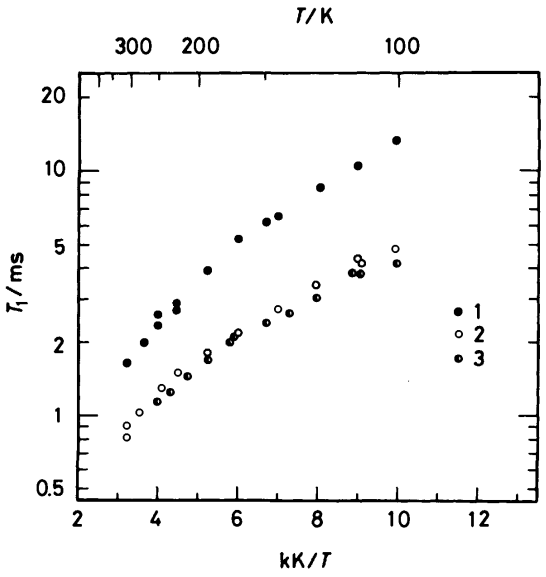

Fig. 2. Temperature dependence of ^{81}Br NQR spin-lattice relaxation times in Cs_2ZnBr_4.

In a previous paper[7] we showed that in Cs_2MBr_4 (M=Hg, Cd) the librational motion of the $[MBr_4]^{2-}$ (M=Cd, Hg) tetrahedron about the a-axis is highly excited in their normal phases and that such anisotropic libration is responsible for the phase transition to the incommensurate phase in which the rotational displacement of the anions about the a-axis generates the incommensurate wave along the a-axis.

Thus, we see that the compounds Cs_2MBr_4 (M=Hg, Cd) and Cs_2ZnBr_4 have a common feature; i.e., the librational mode is highly excited about the a-axis in the *Pnma* phase of each substance and it may be the cause of existence or non-existence of successive phase transitions in these isomorphous substances.

Phase Relation and Stability of A_2MX_4 Structure. The compounds Cs_2CdBr_4[3,5,6] and Cs_2HgBr_4[1,3-5] show successive phase transitions and become incommensurate in a certain temperature region. Their structures and phase transitions such as the transition temperature, the length and distance of the incommensurate wave vectors and the phase relation below T_c, etc., are very similar to each other. On the other hand, Cs_2ZnBr_4[3] shows no phase transition although its crystal structure[8] at room temperature is isomorphous to Cs_2HgBr_4[1] and Cs_2CdBr_4,[2] and these three compounds show common characteristic as mentioned in the preceding section. In an attempt to uncover a factor or factors which govern the phase relations and the stability of the *Pnma* structure, a comparison will be made of the structural characteristics of a variety of A_2MX_4 type compounds.

The space group of the highest temperature phase of each of A_2MX_4 type compounds (A=K, Na, Rb, Cs; B=Hg, Cd, Zn, Co, Mn, Cu; X=Cl, Br, I)[1,2,8,11-25] is listed in Table 1. From this table two interesting

CoI_4		$P2_1/m$[22]	$P2_1/m$[22]	*Pnma*[22]

properties can be extracted.

1) The compounds that have the common cation and the anion of almost the same size crystallize in the same space group irrespective of the chemical species of metallic element. A_2CoX_4 and A_2ZnX_4 have the same space group when A and X are common. Thus the space group of both Cs_2CoCl_4 and Cs_2ZnCl_4 is *Pnma* and the space group of Rb_2CoI_4 and Rb_2ZnI_4 is $P2_1/m$. Moreover, the lattice constants in A_2CoX_4 and A_2ZnX_4 are almost the same as shown in Table 2. The same relation can be seen between A_2HgBr_4 and A_2CdBr_4.

Table 2. Space Group and Lattice Parameters of A_2ZnX_4 and A_2CoX_4

2) The relative size of the cation and the complex anion governs the space group of the highest temperature phase. Those are the properties that

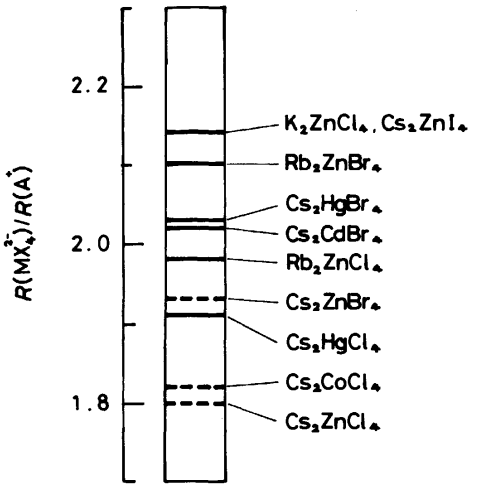

Fig. 3. Ratio of the effective radius of the complex anion $[MX_4]^{2-}$ to the radius of cation A^+ for various compounds.
——: Indicates a compound which has one or more phase transitions.
- - -: Indicates a compound which has no phase transition.

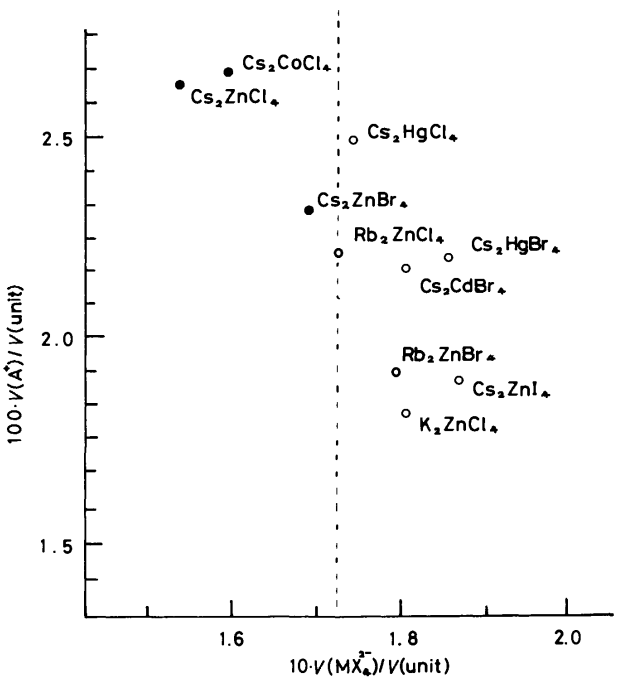

Fig. 4. The effective volume of the complex anion $[MX_4]^{2-}$ is plotted against the volume of the cation A^+ both reduced by the volume of the unit cell.
●: Indicates a compound which has phase transitions.
○: Indicates a compound which has no phase transition.

determine not only the crystal structure but also the phase relation. Table 3[1,3-6,26-31] suggests that the key factor for the highest temperature phase to undergo a phase transition into an incommensurate phase is the relative size of the cation and the complex anion. In order to show that it is the key factor in a more quantitative manner, the relative sizes of the cation and the anion were calculated for each of these compounds and the result is shown in Fig. 3. The ionic radii of the cations were taken from reference 32 as 1.52 Å for K^+, 1.66 Å for Rb^+ and 1.81 Å for Cs^+. The ionic radii of $[MX_4]^{2-}$ complex anions were obtained by adding interatomic distance of M–X and the atomic radius of the X atom. The ratios between the ionic radii, $R([MX_4]^{2-})/R(A^+)$, calculated from these data are arranged in Fig. 3, where the solid lines represent compounds which undergo a phase transition or transitions and the broken lines those without any transition. This graph shows that the compounds with the ratio value between 1.9 and 2.2 show a phase transition except for slight displacement of Cs_2ZnBr_4. If, on the other hand, the volume occupied by a cation is plotted against the volume occupied by a complex anion, both reduced by the unit cell volume (Fig. 4), the compounds for which $V([MX_4]^{2-})/V$(unit cell) is larger than 0.172 undergo at least one phase transition almost independent of the value of $V(A^+)/V$(unit cell). It thus seems that $V([MX_4]^{2-})/V$(unit cell)=0.172 is the critical value for A_2MX_4 type compounds; it serves as a gross criterion for distinguishing whether a compound with A_2MX_4 type structure undergoes any phase transition or not.

We saw in the preceding section that the anisotropic interaction plays an important role in the phase transition phenomena in the A_2MX_4 type of substances. In order to search for an anisotropic property

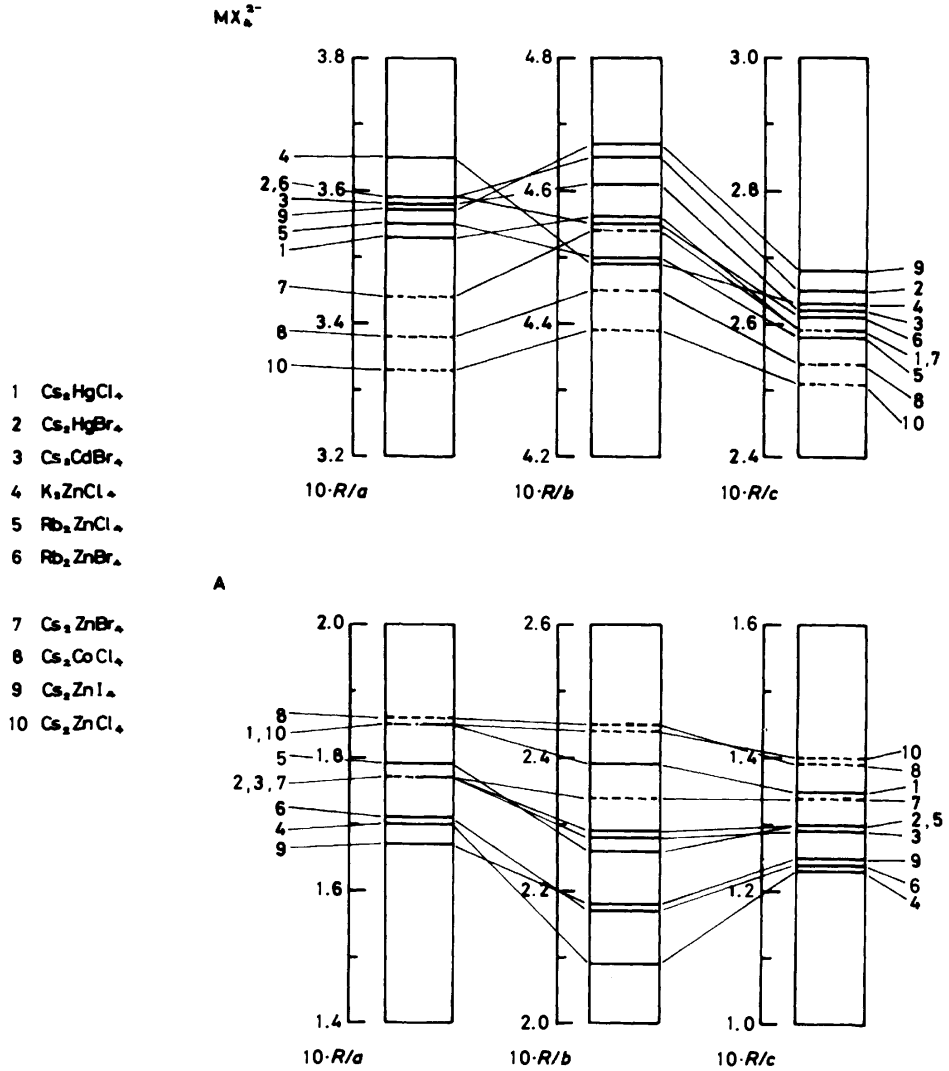

Fig. 5. Ratio of the radius of the complex anion $[MX_4]^{2-}$ and that of the cation A^+ to the individual lattice constants in various compounds are shown in the upper and the lower figures, respectively.
– – –: Indicates a compound which has no phase transition.

governing the crystal stability, we arranged the ionic radius $R(A^+)$ or $R([MX_4]^{2-})$ reduced by each of the lattice constants in the order of their magnitude as shown in Fig. 5. The compounds with and without any phase transition are highlighted by the solid and broken lines, respectively. These diagrams suggest that the compounds composed of a small cation and a large complex anion undergo a phase change. Especially, this tendency is distinct in regard to the quantity $R([MX_4]^{2-})/a$, i.e. the compounds with this ratio greater than 0.35 undergo some kind of phase transition. This finding is very important in that the compounds which possess an incommensurate phase show the incommensurate wave vector directed in the a-axis. Even the compounds that do not have an incommensurate phase show tripled unit cell in the a axis direction in the low temperature phase. We can therefore state that the ionic interaction along the a-axis mainly govern the stability of a particular crystal structure with regard to incommensurate modulation.

In this way we can interpret the fact that both Cs_2HgBr_4 and Cs_2CdBr_4 undergo successive phase transitions while the isomorphous Cs_2ZnBr_4 doesn't exhibit any phase transition: The anisotropic interaction along the crystallographic a-axis in Cs_2ZnBr_4 is small whereas in the former two compounds a strong cooperative interaction exists along the a-axis and may drive these materials to undergoing phase transitions on cooling.

We can now use our finding to predict the phase transition of the A_2MX_4 type of materials, i.e., a compound of A_2MX_4 type in which the value of $R([MX_4]^{2-})/a$ is slightly smaller than 0.35 is a candidate which undergoes a phase transition at high pressure because external pressure will increase this ratio up to 0.35 and then the original structure may become less stable.

Multinuclear Solid-State NMR Study of Dehydration of Na-Y Type Zeolites

Shigenobu HAYASHI, Kikuko HAYAMIZU, and Osamu YAMAMOTO
National Chemical Laboratory for Industry, Tsukuba, Ibaraki 305
(Received July 22, 1986)

High-resolution solid-state NMR spectra of ^{23}Na, ^{27}Al, and ^{29}Si nuclei were measured for dehydrated Na-Y type zeolites as well as undehydrated and rehydrated samples using magic angle sample spinning technique. ^{1}H NMR spectra, X-ray diffraction patterns, and thermal properties were measured as well. ^{23}Na NMR results indicate that there are three types of Na sites with different symmetries in the faujasite framework; two types with high and slightly low symmetries are detected by NMR, while the third cannot because of its very low symmetry. Na ions in high-symmetry sites are moved into slightly-low and very-low-symmetry sites by the dehydration. On the other hand, the Na ions in the amorphous region are located in low and very-low-symmetry sites. ^{27}Al and ^{29}Si NMR lines are broadened by the dehydration, due to the distortion of AlO_4 tetrahedra and the interaction with ^{27}Al nuclei, respectively. The ^{29}Si spin-lattice relaxation time becomes longer by the dehydration, which indicates that water molecules play some role in the relaxation.

Zeolites are crystalline aluminosilicates with many pores inside it. SiO_4 and AlO_4 tetrahedra are connected by sharing their oxygen atoms, and positive ions and water are located in the cage constructed by the SiO_4 and AlO_4 tetrahedra. The structures and properties of zeolites are largely influenced by the water molecules.

High-resolution solid-state NMR has been extensively used to study the structure of zeolites in recent years.[1] ^{29}Si NMR can distinguish Si atoms in zeolites according as the number of Al atoms coordinating to the Si atoms through oxygen atoms.[2] ^{27}Al NMR can resolve four-coordinated and six-coordinated Al,[3] i.e., lattice and extra-lattice Al. A number of NMR spectra have been measured for various zeolites so far, and comparisons have been made between them. But even if the network structures are the same, it is possible that the spectra are different depending on the hydration state. Actually, spectral changes caused by thermal treatment have been reported for the ^{29}Si spectra of ZSM-5[4] and the ^{27}Al spectra of ZSM-5 and H-Y zeolites[5,6] No extensive studies, however, have been published up to now.

In the present work, ^{23}Na, ^{27}Al, and ^{29}Si NMR spectra have been measured for dehydrated Na-Y zeolites as well as undehydrated and rehydrated samples, using magic-angle sample-spinning (MAS) technique,[7]) to study the effect of the hydration state on the NMR spectra. ^{1}H NMR spectra, X-ray diffraction pattern, and thermal properties were measured as well. Changes of the microscopic structure shown by the NMR results are discussed in relation to the hydration state. Since the NMR spectra have been measured for several nuclei in the same samples, the relations between the spectra of different nuclei are also discussed.

Experimental

Materials. Na-Y zeolite, coded JRC-Z-Y4.8, was supplied by Sansho-Shokubai-Iinkai, Catalysis Society of Japan. Dehydration was carried out in air at elevated temperatures. Dehydrated samples are called DE400, DE600, and DE800, which were dehydrated at 400 °C for 4 h, at 600 °C for 5 h, and at 800 °C for 5 h, respectively. Rehydration was performed by contacting the dehydrated samples with an excess of liquid water at room temperature for 2.5 d, after which the sample was dried at 70 °C for 1 d. Rehydrated samples are called RExxx, whose xxx denotes the dehydration temperature.

Measurements. High-resolution solid-state NMR spectra were measured by a JEOL FX-200 pulsed spectrometer equipped with an accessary for MAS. The resonance frequencies were 52.80, 52.00, and 39.60 MHz for ^{23}Na, ^{27}Al, and ^{29}Si nuclei, respectively. An ordinary one-pulse cycle was used under a MAS condition with a spinning speed of about 3.5 kHz. ^{1}H NMR spectra were also measured by a Bruker CXP-100 pulsed spectrometer, operating at a resonance frequency of 90.03 MHz and using the ordinary one-pulse cycle. Shift values are referred to NaCl aqueous solution for the ^{23}Na spectra (The shift of solid NaCl was 6.7 ppm with respect to this standard.), to $AlCl_3$ aqueous solution for the ^{27}Al spectra, and to tetramethylsilane for the ^{29}Si and ^{1}H spectra. All the measurements were carried out at room temperature.

Powder X-ray diffraction patterns were measured by a Rigaku Geiger-flex diffractometer, and thermal analysis was performed by a Rigaku Thermoflex.

Results

^{23}Na NMR. Figure 1 shows ^{23}Na MAS NMR spectra of undehydrated and dehydrated samples. Since the maximum intensity of the central line ($m=1/2\rightarrow-1/2$) of half-integer spins is obtained at a flip angle of $\pi/(2I+1)$(I :spin number),[8] the flip angle of the excitation pulse was set at $\pi/4$ for ^{23}Na spin ($I=3/2$). The undehydrated sample has a symmetric peak at -12 ppm with a 1.2-kHz width. On the other hand, DE400 and DE600 have asymmetric line shapes, whose tops are located at the same position as the undehydrated sample. DE800 shows a markedly different line shape centered at -28 ppm with a

2.8-kHz width. The spectral intensities per unit sample weight are 20% for DE400 and DE600 and 40% for DE800 with respect to the undehydrated sample.

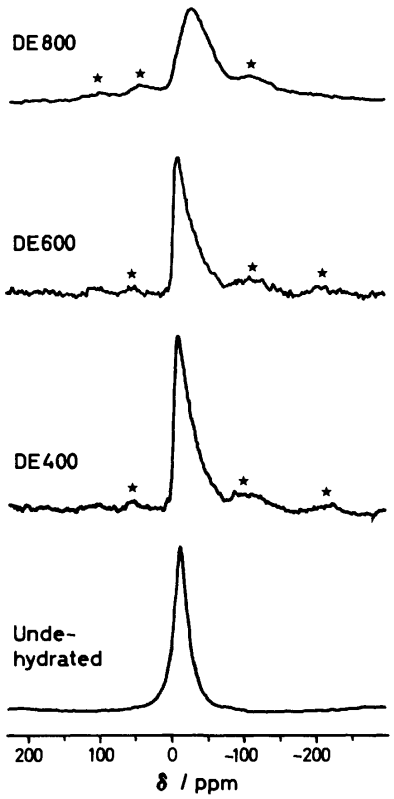

Fig. 1. ^{23}Na MAS NMR spectra of undehydrated and dehydrated Na–Y zeolites. The flip angle of the excitation pulse was $\pi/4$ and the recycle time was 1 s. The intensity is not normalized, and the mark ★ denotes spinning sideband.

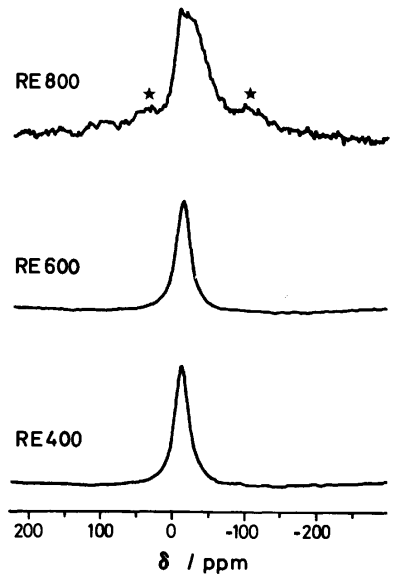

Fig. 2. ^{23}Na MAS NMR spectra of rehydrated Na–Y zeolites under the same measuring conditions as in Fig. 1.

Figure 2 shows the spectra of rehydrated samples. The spectra of RE400 and RE600 agree with that of the undehydrated sample, while the spectrum of RE800 is a superposition of the spectra of DE800 and the undehydrated sample.

Table 1. Summary of ^{23}Na and ^{27}Al MAS NMR

Sample	^{23}Na NMR[a]		^{27}Al NMR[b]	
	Peak	FWHM[c]	Peak	FWHM[c]
	ppm	kHz	ppm	kHz
Undehydrated	−12	1.2	53	1.0
DE400	−10	1.4	45	2.6
DE600	−11	1.4	42	2.7
DE800	−28	2.8	45	2.1
RE400	−13	1.2	51	1.3
RE600	−15	1.2	51	1.3
RE800	−11, −21	2.7	47	2.1

a) Resonance frequency of 52.80 MHz. b) Resonance frequency of 52.00 MHz. c) Full width at half-maximum.

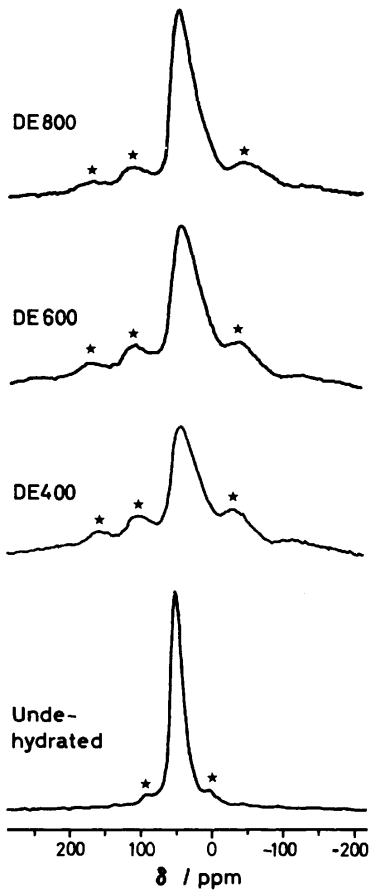

Fig. 3. ^{27}Al MAS NMR spectra of undehydrated and dehydrated Na–Y zeolites with the flip angle of $\pi/6$ and the recycle time of 1 s. The intensity is not normalized, and the mark ★ denotes spinning sideband.

The results are summarized in Table 1.

^{27}Al NMR. Figure 3 shows ^{27}Al MAS NMR spectra of the undehydrated and dehydrated samples. The undehydrated sample has a peak at 53 ppm with a 1.0-kHz width. DE400, DE600, and DE800 have a peak at about 45 ppm with a width of about 2.6 kHz, and their total intensities per unit sample weight decrease to the extent of 80—90% of that of the undehydrated sample. For the rehydrated samples, RE400 and RE600 have spectra similar to the undehydrated sample, while RE800 shows a spectrum similar to DE800. The results are usmmarized in Table 1.

^{29}Si NMR. Figure 4 shows ^{29}Si MAS NMR spectra of the undehydrated and dehydrated samples. The undehydrated sample has four peaks at −88.7, −93.7, −99.3, and −105.1 ppm, which are attributed to Si(3Al), Si(2Al), Si(1Al), and Si(OAl), respectively, in which Si(nAl) denotes the Si atom coordinated by n aluminum atoms and (4-n) silicon atoms through oxygen atoms. Assuming that Loewenstein's rule[9] is valid, the [Si]/[Al] ratio of the faujasite framework is estimated to be 2.75 using the equation in Ref. 10. The T_1 value is 6.3±0.7 s for all the four peaks. DE400 has four peaks also, but their widths are wider than those in the undehydrated sample, resulting in lower resolution. The two peaks assigned to Si(3Al) and Si(2Al) are shifted in the higher-field direction by about 1.5 ppm compared to those of the undehydrated sample, while other two peaks are not shifted. DE600 has the same line shape as DE400, and the line shape is independent of the recycle time, which indicates that the four peaks have the same T_1 value. The T_1 value is 13±3 s, longer than that of the undehydrated sample. DE800 has a negligible fine structure, and the total linewidth is broader than that of DE600.

Figure 5 shows the spectra of the rehydrated samples. RE400 and RE600 have the same spectra as the undehydrated sample. On the other hand, RE800 has a little fine structure, and the whole line shape is similar to the sum of the spectra of DE600 and DE800.

^{1}H NMR. ^{1}H results are summarized in Table 2. The undehydrated sample contains a large amount of water, whose proton shows a peak at 5.0 ppm with a 0.22-kHz width. The ^{1}H nuclei are in a motionally-narrowed state. On the other hand, the DE samples

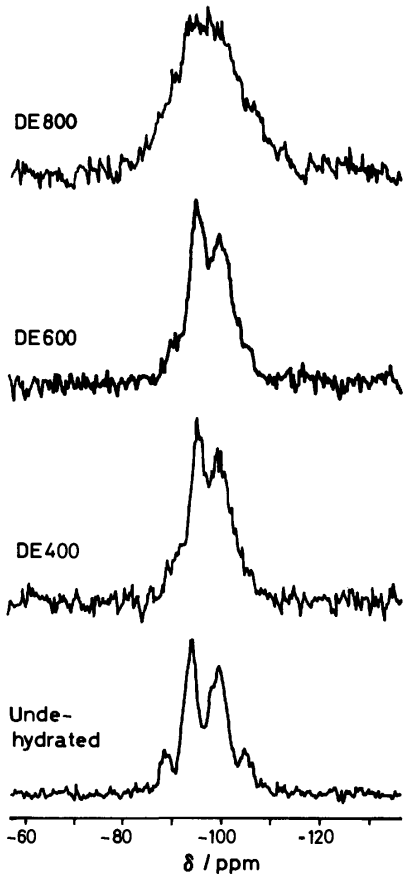

Fig. 4. ^{29}Si MAS NMR spectra of undehydrated and dehydrated Na-Y zeolites with the flip angle of about $\pi/2$ and the recycle time of 10 s. The intensity is not normalized.

Table 2. ^{1}H NMR Results

Sample	Peak / ppm	FWHM / kHz	C_H[a)]
Undehydrated	5.0	0.22	100
DE400	12	2.50	3.2
DE600	8.6	0.92	1.9
DE800	4.2	0.34	2.8

a) Relative hydrogen content with respect to the unit cell of the framework.

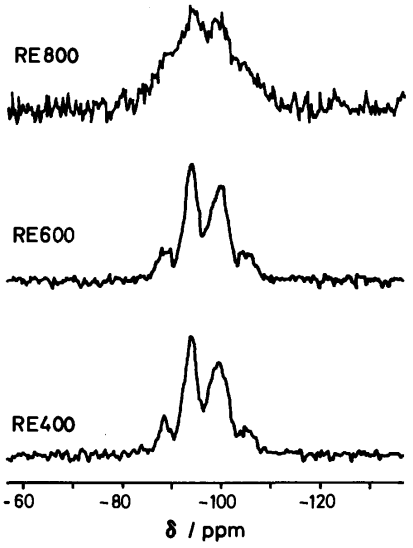

Fig. 5. ^{29}Si MAS NMR spectra of rehydrated Na-Y zeolites under the same measuring conditions as in Fig. 4.

lose most of their water. Though DE800 has a higher hydrogen content than DE600, it is probably caused by the absorption of water from atmospheric moisture after the dehydration process. The motionally-narrowed line which (0.34 kHz) of DE800 supports that the hydrogen is present in the form of mobile H_2O.

X-Ray Diffraction. The undehydrated sample shows a typical pattern of faujasite framework. Some peaks of the faujasite framework split into doublet in the pattern of DE400, indicating the lowering of the crystal symmetry. On the other hand, DE600 has the same pattern as the undehydrated sample, recovering the crystal symmetry. DE800 has a broad peak in addition to the pattern of the faujasite framework, which demonstrates that the framework structure is partially decomposed.

Thermal Analysis. Most of water molecules were desorbed in the temperature range between 35 and 350 °C, whose weight is 24.4% of the undehydrated sample. Weight decreased gradually up to 900°C, and finally 25.1% of the weight was lost.

Discussion

The DE samples lose most of their water, as demonstrated by ^{1}H NMR. X-Ray diffraction results indicate that DE400 and DE600 retain their network structure, while DE800 is a mixture of the faujasite network and an amorphous silica-alumina. Rehydration can reproduce the undehydrated state from DE400 and DE600, while it cannot from DE800, which is clearly demonstrated by ^{23}Na, ^{27}Al, and ^{29}Si NMR results.

^{23}Na NMR. Since ^{23}Na spin has quadrupole moment, the linewidth of the central line is broadened mainly by second-order quadrupole interaction,[11,12] reflecting coordination symmetry of the Na ion. The spectrum of the undehydrated sample shows a sharp line at −12 ppm without any spinning sidebands, which indicates that the Na ions are located in high-symmetry sites, coordinated by water molecules. On the other hand, the spectra of DE400 and DE600 have asymmetric line shapes and are accompanied by many spinning sidebands, suggesting that the Na ions are located in slightly-low-symmetry sites. The Na ions lose water molecules coordinating to themselves by the dehydration, as shown by the ^{1}H NMR results, and they approach to the framework atoms. Thus the coordination symmetry of the Na ions becomes slightly lower. The spectrum of DE800 shows a broad line centered at −28 ppm with many spinning sidebands, demonstrating that the Na ions are located in low-symmetry sites. It must be noted that a small shoulder is observed at about −10 ppm in the spectra of DE800, which can be ascribed to the Na ions in the faujasite framework left undecomposed.

By the rehydration, the Na ions in DE400 and DE600 recover their site symmetry, coordinated by water molecules. On the other hand, the spectrum of RE800 is composed of two lines centered at about −10 and −30 ppm. A part of Na ions in DE800 recover their symmetry, which are considered to be located not in the amorphous region but in the faujasite framework.

Consequently, three kinds of Na ions are observed with different site-symmetries. The difference in the signal position is originated from second-order quadrupole shift[12] and/or chemical shift.

The total signal intensities are largely reduced by the dehydration. Though the quadrupole interaction reduces the signal intensity,[13] the observed large reduction indicates the presence of undetectable nuclei, which are considered to be located at sites with very low symmetry. A simplified calculation suggests that 85 at% of Na ions are not observed in DE400 and DE600, while 70 at% in DE800.

A simple model is presented which can express the correlation between the Na sites and the NMR spectra. In the faujasite framework there are three kinds of occupied sites with different symmetries. The Na ions in the first site are coordinated by water molecules and have high symmetry, producing the narrow NMR line at −12 ppm without sidebands. The second site has slightly low symmetry, giving the asymmetric line at −10 ppm with many spinning sidebands, and the third site has very low symmetry, giving no detectable line. Only the first site is occupied in the hydrated state, while Na ions are distributed over the second and third sites in the dehydrated state. On the other hand, the amorphous region has low-symmetry sites and the third sites. The Na ions in this region cannot be hydrated to form symmetrical Na–H_2O clusters, probably because the ions are trapped on sites having an insufficient space for the cluster.

^{27}Al NMR. ^{27}Al spectra have only one peak which can be attributed to four-coordinated Al. DE400 and DE600 have larger linewidths than the undehydrated sample, which is considered to be broadened by second-order quadrupole effect. The AlO_4 tetrahedra is considered to be distorted by the approach of Na ions on dehydration. The approach of Na ions to the AlO_4 tetrahedra also gives rise to the lowering of Na site symmetry, as described above.

The broadening of the ^{27}Al resonance line on dehydration has been reported for H-ZSM-5 and H-Y, but in the case of Na-ZSM-5 the broadening is so large that the resonance line disappears.[5,6] On the contrary, a signal can be observed in the present case of Na-Y, but the intensity corresponding to 30–40 at% of Al atoms decreases. The decrease is partly explained by the increase in quadrupole interaction which reduces the intensity of the central line. Thus the value of 30—40 at% is only the upper limit of the

undetected Al atoms.

Rehydration can reproduce the ^{27}Al spectrum, since Na ions are removed from the neighborhood of the AlO_4 tetrahedra by coordination of water molecules. On the other hand, the spectrum of DE800 does not change by the rehydration, although DE800 indicates the same line shape and intensity as DE400 and DE600. The symmetry of the AlO_4 tetrahedra in DE800 is lowered by the decomposition of the network, not only by the neighboring Na ions.

^{29}Si NMR. The width of each Si(nAl) line is broadened by the dehydration, which is caused by dipolar interaction with ^{27}Al perturbed by its quadrupole interaction and/or chemical shift dispersion. Line broadening of a $I=1/2$ spin bonded to a $I \geqq 1$ spin has been reported for ^{13}C spectra of α-carbon atoms in amino acids.[14] The increase of electric field gradient on the Al nuclei makes the ^{29}Si resonance line broader in the present case. Chemical shift dispersion may be produced by lowering of the crystal symmetry. The results of X-ray diffraction and ^{29}Si NMR however indicate that the crystal symmetry does not influence the line width very much in this case, as explained below. Although DE400 has an X-ray diffraction pattern with lower crystal symmetry than the undehydrated sample and DE600, the ^{29}Si NMR spectra of DE400 and DE600 agree with each other. Furthermore, the ^{29}Si spectra of DE600 and the undehydrated sample are different in spite that they have the same X-ray diffraction pattern.

The peaks ascribed to Si(3Al) and Si(2Al) are shifted towards higher field by the dehydration. The shift is considered to be caused by the interaction with Al, since the shift is only observed for the Si atom coordinated by more than one Al atom.

In the case of ZSM-5 the ^{29}Si spectral structure is not directly correlated with the hydration state.[4] Heat treatment causes line narrowing instead of broadening, which is attributed to temoval of lattice defects such as Si-OH. This behavior is different from the present results of Na-Y. Since the Na-Y sample has a much higher Al content than ZSM-5, the ^{29}Si NMR spectrum of Na-Y is inevitably influenced by the Al nuclei.

By heating at 800 °C, the network structure is broken, and the amorphous part produces a broad ^{29}Si line without any fine structure. The structure cannot be reconstructed by the rehydration, so that the spectrum of the amorphous part does not change. Though RE800 shows a little fine structure, it is produced by a crystalline part left undecomposed.

The T_1 value of ^{29}Si nuclei is also changed by the dehydration, though the network structure retains. The mechanism of the ^{29}Si relaxation is not established now, but paramagnetic impurities have been reported to have some role in the relaxation.[15] From the present study, it can be concluded that water in the cage plays some role in the ^{29}Si relaxation. Water molecules are considered to be a transport medium of paramagnetic impurities.

In summary, ^{23}Na, ^{27}Al, and ^{29}Si MAS NMR spectra can reflect the hydration state of Y-type zeolites very well. Line shape, position, and width of the spectra and spin-lattice relaxation time are changed by dehydration and hydration treatments.

The authors acknowledge useful discussion to Dr. Shigemitsu Shin and Dr. Kunio Suzuki of this Laboratory. They also acknowledge the supply of the material to Catalysis Society of Japan, and the thermal analysis to Rigaku Denki Co. Ltd. Thanks are also expressed to the referee for his useful comments.

The Phase Transition of 1,4-Dialkyl-1,4-diazoniabicyclo[2.2.2]octane Dibromides, C_n-DABCO-C_{n+1}-Br_2 ($10 \leqq n \leqq 17$)

Kengo IMAMURA, Takashi NOGAMI,* and Yasuhiko SHIROTA
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received July 26, 1986)

The phase transitions of 1,4-dialkyl-1,4-diazoniabicyclo[2.2.2]octane dibromide (bis(quaternary alkyl bromide salts) of DABCO) in which the difference in the carbon numbers of the two alkyl groups is one, were studied on the basis of measurements of differential scanning calorimetry, infrared absorption spectroscopy, and bromide-anion conductivities. The DSC measurements showed that an endothermic transition occurred at T_{c1} when the sample was heated from room temperature. An exothermic transition occurred at T_{c2}($T_{c2}<T_{c1}$) when the sample was cooled after it had been heated above T_{c1}. The transition temperatures (T_{c1} and T_{c2}), the transition enthalpies, and the transition entropies increased as the increase in the alkyl-chain lengths. T_{c1} was found to be governed by the even numbers of the alkyl group. The temperature dependence of the IR absorption spectra showed that the *trans*-zigzag conformation of the alkyl chain was destroyed by a conformational change above T_{c1}, and that the annealed sample existed as a metastable phase. The temperature dependence of the bromide-anion conductivities showed abrupt increases in the conductivities by three orders of magnitude at around the transition temperatures. The temperatures of the conductivity jump of the virgin samples were usually higher than those of the annealed samples. The differences in these two temperatures tended to become smaller as the increase in the alkyl-chain lengths. This fact can be explained as that the solid-state properties of the unsymmetric bis(quaternary salts) of DABCO tend to resemble those of the symmetric bis(quaternary salts) of DABCO as the increase in the alkyl-chain lengths.

A series of 1,4-dialkyl-1,4-diazoniabicyclo[2.2.2]octane dihalides (denoted as bis(quaternary salts) of DABCO) were found to exhibit phase transitions above room temperature by us.[1-4] The phase transition was studied by means of a DSC, IR absorption spectra, and a study of halide-anion conductivities. The phase transition of the symmetric bis(quaternary salts) was quite different from that of the unsymmetric bis(quaternary salts). In the case of the symmetric salts, almost a reversible transition was observed.[1,2] On the other hand, the unsymmetric salts were converted to the metastable phase when they were heated above the transition temperature, and then cooled.[3,4] The thermodynamic properties of the unsymmetric salts were explained by free energy-temperature relation. Some of the unsymmetric salts showed the conversion from the metastable phase to the stable phase during several days when they were kept at room temperature. The larger the difference in the carbon numbers of the two alkyl groups attached to DABCO nitrogens, the faster was the conversion rate from the metastable phase to the stable phase.[4] When the difference in the carbon numbers of the two alkyl groups was two, the conversion rates were too slow to be followed.[3] If we designate the bis(quaternary alkyl halide salt) of DABCO by the halide anion and by the numbers of the alkyl carbons (see Refs. 3 and 4),[5] the thermodynamic properties of the symmetric salts, C_n-DABCO-C_n-X_2 (X=Cl, Br, and I; $10 \leqq n \leqq 22$),[1,2] are quite different from those of the unsymmetric salts, C_n-DABCO-C_{n+2}-Br_2 ($10 \leqq n \leqq 16$)[3] and C_{10}-DABCO-C_n-Br_2 ($13 \leqq n \leqq 22$).[4] Thus, the phase transitions of a series of the unsymmetric salts, C_n-DABCO-C_{n+1}-Br_2, are interesting, because they seem to belong to the borderline of the different behaviors of the phase transitions. We studied the phase transitions of the bis(quaternary alkyl bromide salts) of DABCO, C_n-DABCO-C_{n+1}-Br_2 ($10 \leqq n \leqq 17$), by means of DSC, IR absorption spectra, and the measurements of the bromide-anion conductivities. The materials studied are shown in Fig. 1.

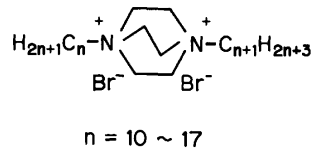

Fig. 1. Unsymmetric bis(quaternary alkyl bromide salts) of DABCO, C_n-DABCO-C_{n+1}-Br_2.

Experimental

Syntheses of Unsymmetric Bis(quaternary salts) of DABCO. The unsymmetric salt of DABCO was synthesized by two steps of the reactions, i.e., a synthesis of the mono(quaternary salt) by the reaction of DABCO with an equimolar amount of alkyl bromide, followed by a reaction of the resultant mono(quaternary salt) with another alkyl bromide. Detailed procedures were described previously.[3,4] All of the materials were recrystallized four or five times. The solvents of the recrystallization are acetonitrile for C_n-DABCO-C_{n+1}-Br_2 ($10 \leqq n \leqq 14$) and ethanol for C_n-DABCO-C_{n+1}-Br_2 ($15 \leqq n \leqq 17$) respectively.

Measurements. The DSC, the bromide-anion conductivities, and the IR absorption spectra were measured by the methods described previously.[2-4]

Results and Discussion

DSC Measurements. The DSC measurements were made while changing the temperature by 5 °C min^{-1}. When virgin samples[6] were heated from room temperature, endothermic signals ($\Delta H_{en,1}$) were obtained at T_{c1}. C_{11}-DABCO-C_{12}-Br_2 and C_n-DABCO-C_{n+1}-Br_2 (n=10, 13, and 15) showed three and two endothermic signals respectively. On the other hand, C_n-DABCO-C_{n+1}-Br_2 (n=12, 14, 16, and 17) showed only one endothermic signal. When the samples were cooled after they had once been heated above T_{c1}, all of them showed one exothermic signal ($\Delta H_{ex,1}$) at T_{c2} which was lower than T_{c1}; $T_{c1}>T_{c2}$. The succeeding heating-cooling cycles showed reproducible endothermic ($\Delta H_{en,2}$) and exothermic ($\Delta H_{ex,1}$) signals at around T_{c2}. The absolute values of $\Delta H_{ex,1}$ and $\Delta H_{en,2}$ were equal within the experimental error. Figure 2 shows the observed thermogram of C_{10}-DABCO-C_{11}-Br_2 as a typical example. The endothermic signals $\Delta H_{en,1}$ were usually broader[7] than $\Delta H_{en,2}$ for all of the materials studied. The observation of at least two transition temperatures (T_{c1} and T_{c2}) can be explained by the free energy-temperature relation as described before.[3,4] According to this, the sample exists as a metastable phase (C_M) when it is heated above T_{c1} and then cooled. Even if the sample was left at room temperature for weeks after it had been heated above T_{c1}, it showed endothermic ($\Delta H_{en,2}$) and exothermic ($\Delta H_{ex,1}$) signals at around T_{c2}. This fact shows that the potential barrier from the C_M phase to the stable phase (C_L) is too high for the C_M phase to go back to the C_L phase. Similar phenomena were also observed for C_n-DABCO-C_{n+2}-Br_2 ($10 \leqq n \leqq 16$).[3] This is consistent with the previous observation[3,4] that the conversion rate from C_M to C_L becomes slower as the decrease in the differences in the carbon numbers of the two alkyl chains attached to DABCO nitrogens. Part of Table 1 shows some materials, T_{c1}, T_{c2}, $\Delta H_{en,1}$,[8] ΔS_1 ($=\Delta H_{en,1}/T_{c1}$),[8] $\Delta H_{en,2}$, and ΔS_2 ($=\Delta H_{en,2}/T_{c2}$). Here ΔS_1 and ΔS_2 denote the transition entropies at T_{c1} and T_{c2} respectively. Since the virgin samples of C_n-DABCO-C_{n+1}-Br_2 (n=10, 11, 13, 15) showed more than one transitions, all of the transition temperatures and the corresponding transition enthalpies and transition entropies are shown for these materials in this table. The transition temperatures were obtained by the onsets of the endothermic signals. Figure 3 plots the transition temperatures (T_{c1} and T_{c2}) against the carbon numbers (n) of the alkyl groups of C_n-DABCO-C_{n+1}-Br_2. The transition temperatures of the symmetric salts, C_n-DABCO-C_n-Br_2 and C_{n+1}-DABCO-C_{n+1}-Br_2,[2] are also plotted for the sake of comparison. The following characteristics can be seen from Fig. 3. (1) The transition temperatures tend to increase as the increase in the alkyl-chain length. (2) The separation between T_{c1} and T_{c2} becomes smaller as the increase in the alkyl-chain length. (3)

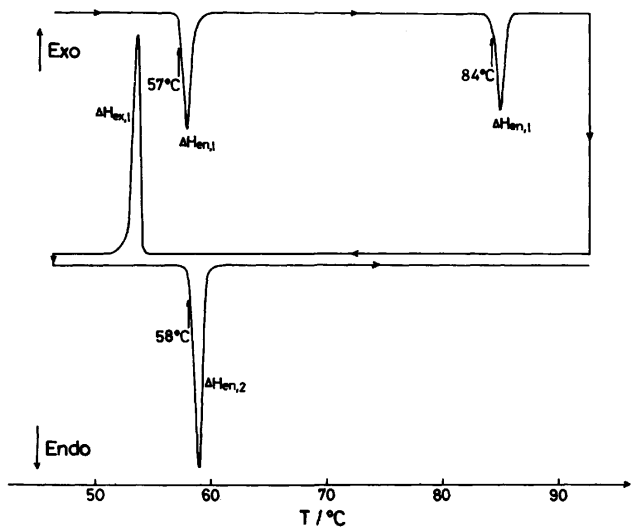

Fig. 2. DSC thermogram of C_{10}-DABCO-C_{11}-Br_2. Note that the sum of the two endothermic heats of transition ($\Delta H_{en,1}$) is close to the value of $\Delta H_{en,2}$.

Table 1. Materials, and the Transition Temperatures, Transition Enthalpies, Transition Entropies, and the Ratios of the Bromide-Anion Conductivities Before and After the Transitions

Materials	T_{c1} / °C	$\Delta H_{en,1}$ / kJ mol^{-1}	ΔS_1 / J/(mol deg)	σ_h/σ_1[a]	T_{c2} / °C	$\Delta H_{en,2}$ / kJ mol^{-1}	ΔS_2 / J/(mol deg)	σ_h/σ_1[b]
C_{10}-DABCO-C_{11}-Br_2	57, 84	27.1, 22.6	82, 63	820, 4[c]	58	48.9	148	1900
C_{11}-DABCO-C_{12}-Br_2	69, 77, 82	16.2, 22.7, 25.8	47, 65, 73	4500	65	51.7	153	2100
C_{12}-DABCO-C_{13}-Br_2	77	62.3	178	6000	72	59.7	173	5800
C_{13}-DABCO-C_{14}-Br_2	86, 87	69.3	193	1600	78	68.0	194	1500

a) For the virgin samples. b) For the annealed samples. c) As shown in Fig. 6, two steps of the conductivity jumps were observed.

T_{c1}'s of C_n-DABCO-C_{n+1}-Br_2[9] are close to either the corresponding transition temperatures of C_n-DABCO-C_n-Br_2 or those of C_{n+1}-DABCO-C_{n+1}-Br_2. It is noteworthy that T_{c1}'s of C_n-DABCO-C_{n+1}-Br_2 (n= odd number) and those of C_n-DABCO-C_{n+1}-Br_2 (n=even number) are close to the transition temperatures of C_{n+1}-DABCO-C_{n+1}-Br_2 and C_n-DABCO-C_n-Br_2 respectively.[10]

The characteristic (1) above can be explained as follows. Since the phase transition is caused mainly by a conformational change in the alkyl groups,[2-4] a parallel relation between the transition temperature and the alkyl-chain length arises from an increase in the van der Waals force between molecules as the increase in the alkyl-chain length. The characteristic (2) can be explained as follows. The molecular shape of the unsymmetric bis(quaternary salt) of DABCO tends to resemble that of the symmetric salt as the increase in the alkyl-chain length. Thus, C_{17}-DABCO-C_{18}-Br_2 showed reversible transition (only one transition temperature) like the cases of the symmetric bis(quaternary alkyl halide salts) of DABCO.[1,2] Although the characteristic (3) is interesting, the reason is as yet not clear. Since the present materials possess both even and odd numbers of the alkyl carbons, the following expression (3)′ is simpler for the characteristic (3). (3)′ The transition temperature (T_{c1}) of C_n-DABCO-C_{n+1}-Br_2 is determined by the alkyl group of the even numbers of carbons, and it is close to that of the corresponding symmetric salt possessing the same (even) number of alkyl carbons.

Figure 4 plots the transition enthalpies ($\Delta H_{en,1}$ and $\Delta H_{en,2}$) against the carbon numbers (n) of the alkyl groups of C_n-DABCO-C_{n+1}-Br_2. This figure also shows similar plots of the transition enthalpies of the symmetric bis(quaternary salts),[2] C_n-DABCO-C_n-Br_2 and C_{n+1}-DABCO-C_{n+1}-Br_2, for the sake of comparison. The dotted circles of C_n-DABCO-C_{n+1}-Br_2 (n=10, 11) mean the sums of the transition enthalpies ($\Delta H_{en,1}$) of these materials. The following three characteristics can be seen from Fig. 4. (1) Both $\Delta H_{en,2}$ and $\Delta H_{en,1}$ tend to increase as the increase in the alkyl-chain length. (2) $\Delta H_{en,1}$'s are close to $\Delta H_{en,2}$'s for

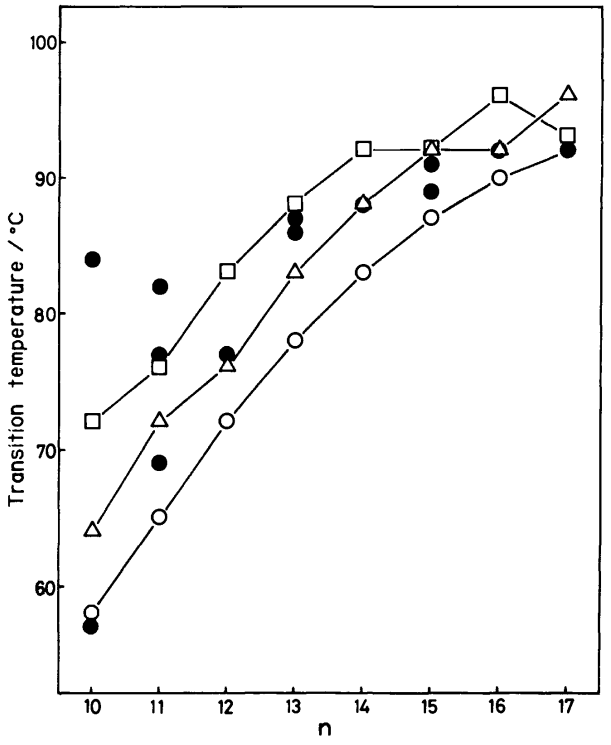

Fig. 3. The plot of the transition temperatures (T_{c1} and T_{c2}) against the carbon numbers (n) of alkyl group of C_n-DABCO-C_{n+1}-Br_2. The transition temperatures of the symmetric salts, C_n-DABCO-C_n-Br_2 and C_{n+1}-DABCO-C_{n+1}-Br_2, are also plotted for the sake of comparison.
●: T_{c1} of C_n-DABCO-C_{n+1}-Br_2, ○: T_{c2} of C_n-DABCO-C_{n+1}-Br_2. △: T_c of C_n-DABCO-C_n-Br_2, □: T_c of C_{n+1}-DABCO-C_{n+1}-Br_2.

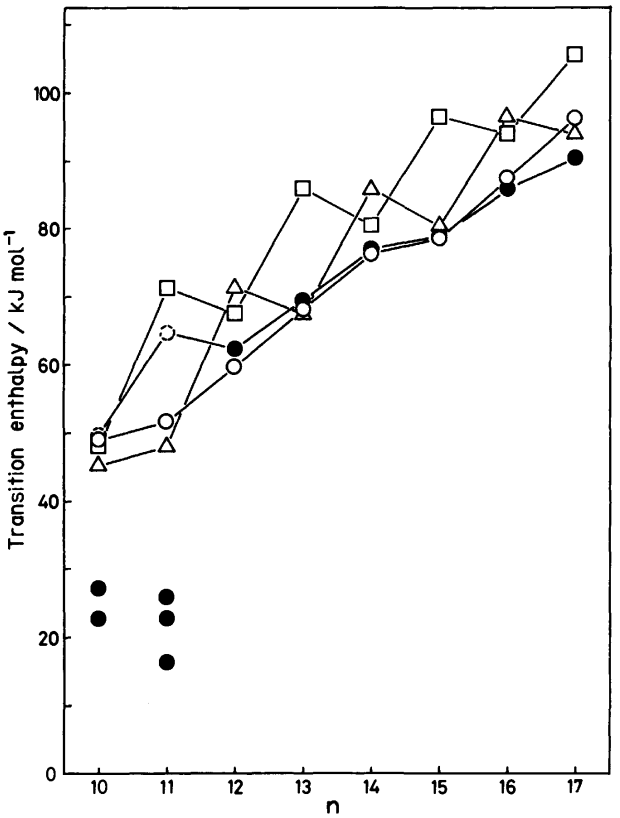

Fig. 4. The plot of the transition enthalpies ($\Delta H_{en,1}$ and $\Delta H_{en,2}$) against the carbon numbers (n) of alkyl group of C_n-DABCO-C_{n+1}-Br_2. The transition enthalpies of the symmetric salts, C_n-DABCO-C_n-Br_2 and C_{n+1}-DABCO-C_{n+1}-Br_2, are also plotted for the sake of comparison. Dotted circles mean the sum of the two transition enthaplies ($\Delta H_{en,1}$)for C_{10}-DABCO-C_{11}-Br_2 and that of the three transition enthalpies ($\Delta H_{en,1}$) for C_{11}-DABCO-C_{12}-Br_2.
●: $\Delta H_{en,1}$ of C_n-DABCO-C_{n+1}-Br_2, ○: $\Delta H_{en,2}$ of C_n-DABCO-C_{n+1}-Br_2. △: ΔH of C_n-DABCO-C_n-Br_2, □: ΔH of C_{n+1}-DABCO-C_{n+1}-Br_2.

C_n-DABCO-C_{n+1}-Br_2 ($12 \leqq n \leqq 17$). In the case of C_{10}-DABCO-C_{11}-Br_2, the sum of the two transition enthalpies ($\Delta H_{en,1}$) is close to $\Delta H_{en,2}$ (see also Fig. 2). (3) Comparison of $\Delta H_{en,2}$'s with the transition enthalpies of the symmetric salts gives the following rules: $\Delta H_{en,2}$'s of C_n-DABCO-C_{n+1}-Br_2 (n=odd number) are close to the transition enthalpies of the corresponding symmetric salts, C_n-DABCO-C_n-Br_2; if n is an even number, the following order holds except for C_{10}-DABCO-C_{11}-Br_2 (ΔH for C_n-DABCO-C_n-Br_2 > ΔH for C_{n+1}-DABCO-C_{n+1}-Br_2 > $\Delta H_{en,2}$ for C_n-DABCO-C_{n+1}-Br_2). Figure 5 plots the transition entropies (ΔS_1 and ΔS_2) against the carbon numbers (n) of the alkyl group of C_n-DABCO-C_{n+1}-Br_2. This figure also shows similar plots of the transition entropies of the symmetric bis(quaternary salts),[2,3] C_n-DABCO-C_n-Br_2 and C_{n+1}-DABCO-C_{n+1}-Br_2, for the sake of comparison. The dotted circles of C_n-DABCO-C_{n+1}-Br_2 (n=10, 11) mean the sum of the transition entropies (ΔS_1) of these materials. From Fig. 5, the characteristics (1)—(3) above of the transition enthalpies also hold in the cases of the transition entropies. From the Boltzmann relation, $\Delta S = R \ln W$, the numbers of sites (W) above the transition temperatures were estimated to be in the range of 300—5.7×10^{13} for the virgin and the annealed samples.[6,11] The large values of W suggest that the conformational change occurs at the every carbon site of the alkyl groups.

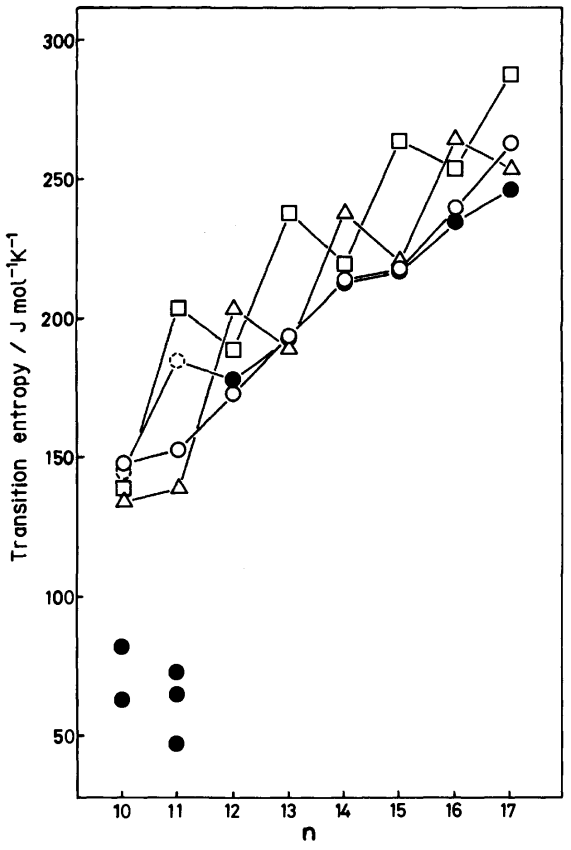

Fig. 5. The plot of the transition entropies (ΔS_1 and ΔS_2) against the carbon numbers (n) of alkyl group of C_n-DABCO-C_{n+1}-Br_2 ($\Delta S_1 = \Delta H_{en,1}/T_{c1}$, $\Delta S_2 = \Delta H_{en,2}/T_{c2}$). The transition entropies of the symmetric salts, C_n-DABCO-C_n-Br_2 and C_{n+1}-DABCO-C_{n+1}-Br_2, are also plotted for the sake of comparison. Dotted circles mean the sum of the two transition entropies for C_{10}-DABCO-C_{11}-Br_2 and that of the three transition entropies for C_{11}-DABCO-C_{12}-Br_2 respectively.
●: ΔS_1 of C_n-DABCO-C_{n+1}-Br_2, ○: ΔS_2 of C_n-DABCO-C_{n+1}-Br_2. △: ΔS of C_n-DABCO-C_n-Br_2, □: ΔS of C_{n+1}-DABCO-C_{n+1}-Br_2.

The characteristic (1) for the transition enthalpies is explained by the increase in the van der Waals force between molecules as the increase in the alkyl-chain length. The characteristic (1) for the transition entropies could be explained as follows. Since the phase transition is mainly caused by a conformational change in the alkyl group, the number of the sites after the transition increase as the increase in the alkyl-chain length. This gives rise to an increase in the transition entropies as an increase in the alkyl-chain length. The characteristic (2) for the transition enthalpies and entropies suggests that the structure of the C_M phase is not very different from that of the C_L phase. Since the difference in the numbers of the alkyl carbons is one in the present materials, their thermodynamic properties resemble those of the symmetric salts which have shown no clear indication of the presence of the metastable phase. The characteristic (2) is in common with the cases of the unsymmetric salts, C_n-DABCO-C_{n+2}-Br_2,[3] but is in sharp contrast to the cases of the unsymmetric salts, C_{10}-DABCO-C_n-Br_2.[4] In the latter cases, $\Delta H_{en,1}$ and ΔS_1 were larger than $\Delta H_{en,2}$ and ΔS_2 respectively. These facts show that the structural difference between C_L and C_M is small for C_n-DABCO-C_{n+1}-Br_2 and C_n-DABCO-C_{n+2}-Br_2, and that it tends to become larger with an increase in the alkyl-chain length. It is noteworthy that the sum of the two transition enthalpies ($\Delta H_{en,1}$) and that of the two transition entropies (ΔS_1) are close to $\Delta H_{en,2}$ and ΔS_2, respectively, in C_{10}-DABCO-C_{11}-Br_2. However, these relations do not hold in the case of C_{11}-DABCO-C_{12}-Br_2; the sums of the transition enthalpies and the transition entropies are larger than $\Delta H_{en,2}$ and ΔS_2 respectively. In order to clarify the thermodynamic properties described above, the determinations of the crystal structures of the present materials seem to be crucial.

Infrared Absorption Spectroscopy. The temperature dependence of the infrared absorption spectra of C_{13}-DABCO-C_{14}-Br_2 was measured as an example in order to obtain more information regarding the phase transition. It showed a similar change in the IR spectra as has been observed in the cases of the unsymmetric bis(quaternary alkyl bromide salts) of DABCO.[3,4] The virgin sample exhibited band

progressions originating from 720 cm^{-1}. This is the evidence for the *trans*-zigzag conformation of the alkyl groups. The band progressions suddenly disappeared at T_{c1} when the sample was heated from room temperature, and they appeared again at T_{c2} upon cooling the sample. This fact shows that the *trans*-zigzag conformation of the alkyl group is destroyed in the high temperature phase, and that the annealed sample[6] exists as a metastable phase. This is consistent with the DSC results. The detailed

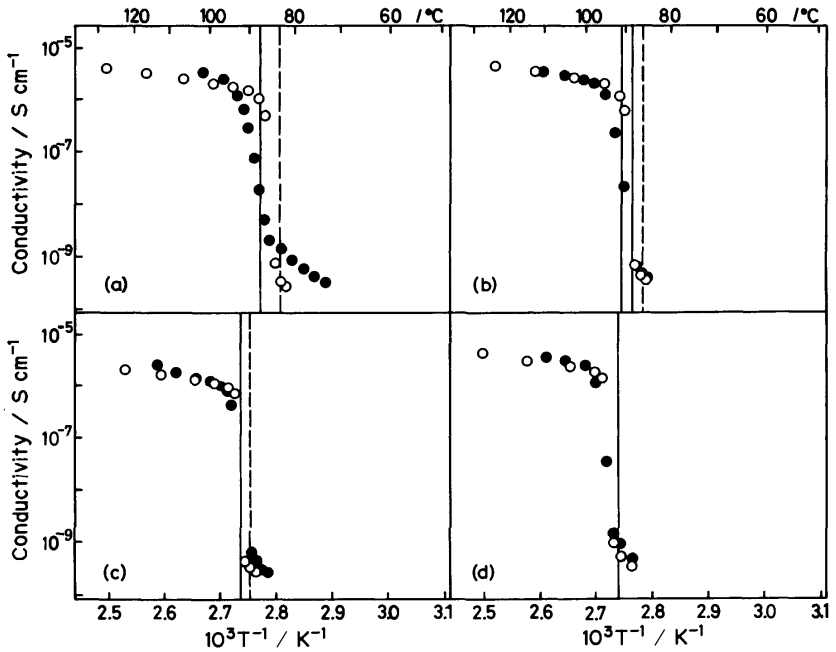

Fig. 7. Temperature dependence of the bromide-anion conductivities of C_n-DABCO-C_{n+1}-Br_2 ($14 \leqq n \leqq 17$) (●: virgin sample, ○: annealed sample). The vertical solid- and dotted-lines represent T_{c1} and T_{c2} respectively.
(a) $n=14$, (b) $n=15$, (c) $n=16$, (d) $n=17$.

discussion was given in the previous papers.[3,4]

Bromide-Anion Conductivities. All of the samples were confirmed to be bromide-anion conductors by the method described previously.[1] The bromide-anion conductivities were measured for the compressed pellet sample by an AC impedance method.[1-4] The conductivities of the virgin samples[6] were measured first by heating the sample slowly (0.5 °C min^{-1}) from room temperature across T_{c1}. The sample was then allowed to cool to room temperature, and the conductivities of the annealed sample[6] were measured by heating the sample again. Figures 6 and 7 show the temperature dependences of the bromide-anion conductivities of C_n-DABCO-C_{n+1}-Br_2 ($10 \leqq n \leqq 13$) and C_n-DABCO-C_{n+1}-Br_2 ($14 \leqq n \leqq 17$) respectively. Each figure shows both conductivities of the virgin and the annealed samples . The vertical solid- and dotted-lines represent T_{c1} and T_{c2} respectively. The conductivities less than 10^{-9} S cm^{-1} were below the limit of our measurements. All of the samples showed abrupt increases in the bromide-anion conductivities by three orders of magnitude at around the transition temperatures; the virgin and the annealed samples showed the conductivity jumps at around T_{c1} and T_{c2} respectively. Table 1 shows the ratios of the conductivities before (σ_l) and after (σ_h) the transition for the virgin and the annealed samples. They were found to be in the range of 1000 to 6000 for the virgin samples and in that of 1800 to 5800 for the annealed samples. The conductivity jump (σ_h/σ_l=6000) of C_{12}-DABCO-C_{13}-Br_2 is the largest of all of the materials studied hitherto.[2-4] To see closely Figs. 6 and 7, the following three characteristics are noteworthy. (1) The difference in the temperatures of the conductivity jumps between the virgin and the annealed samples tends to become smaller as the increase in the alkyl-chain lengths. (2) The conductivity jump becomes sharper as the increase in the alkyl-chain lengths. (3) Although the conductivities are quite different below the transition temperatures, they are almost similar above the transition temperatures with the activation energies of about 30 kJ mol^{-1}.

The characteristics (1) and (2) above are consistent with the results of the DSC measurements; the thermodynamic properties of the unsymmetric salts tend to resemble those of the symmetric salts as the increase in the alkyl-chain lengths. Since the symmetric salts showed only slight hysteresis of the conductivity jumps,[2] the characteristic (1) can be understood as a natural phenomenon. The characteristic (2) can also be deduced from the sharp conductivity jumps observed for the symmetric salts.[1,2] The characteristic (3) is a common phenomenon of all of the bis(quaternary alkyl halide salts) of DABCO, irrespective of the symmetric and unsymmetric salts, and it was discussed before.[2] From Figs. 6 and 7 and Table 1, it can not be said generally whether the virgin samples exhibit larger conductivity jumps than the annealed samples or not. The conductivity jump is caused by the formation of a large number of voids as a result of the conformational movement of the alkyl groups above the transition temperature.

Figures 6 and 7 also show the relations between the conductivity jumps and the transition temperatures (T_{c1} and T_{c2}). T_{c2}'s were located at the onsets of the conductivity jumps of the annealed samples except for C_{11}-DABCO-C_{12}-Br_2. T_{c1}'s were also located at the onsets of the conductivity jumps of the virgin samples for C_n-DABCO-C_{n+1}-Br_2(n=10, 11, 12, 17). However, T_{c1}'s were located at around the middle points of the conductivity jumps of the virgin samples for C_n-DABCO-C_{n+1}-Br_2(n=13, 14, 15, 16). The second T_{c1} of C_{10}-DABCO-C_{11}-Br_2 corresponds to the second conductivity jump. The second and the third T_{c1}'s of C_{11}-DABCO-C_{12}-Br_2 were located at around the end points of the conductivity jump. Although the complex behaviors of the relations between T_{c1}'s and the conductivity jumps are as yet not clear, they will reflect the difference in the formations of the voids as a result of the conformational change in the alkyl groups.

Summary. The phase transitions of bis(quaternary alkyl bromide salts) of DABCO, C_n-DABCO-C_{n+1}-Br_2 ($10 \leqq n \leqq 17$), were studied by means of the DSC, the infrared absorption spectroscopy, and the measurements of the bromide-anion conductivities. As described in the Introduction, these materials seem to belong to the borderline of the solid-state properties between the symmetric and unsymmetric bis(quaternary salts) which have been studied previously.[1-4] As expected, the present materials showed both properties of the symmetric and the unsymmetric salts as will be shown below. (1) C_n-DABCO-C_{n+1}-Br_2 showed at least two transition temperatures (T_{c1} and T_{c2}), and the annealed samples were found to be converted to the metastable phase by the DSC and the IR absorption spectra. These properties are similar to the cases of the unsymmetric salts.[3,4] (2) The separation between T_{c1} and T_{c2} tends to become smaller with an increase in the alkyl-chain length. C_{17}-DABCO-C_{18}-Br_2, which has the longest alkyl groups of the present materials, showed only one transition temperature; this is similar to the cases of the symmetric salts.[1,2] These facts show that the thermodynamic properties of C_n-DABCO-C_{n+1}-Br_2 tend to resemble those of the symmetric salts as the increase in the alkyl-chain length. (3) T_{c1}'s are close to the transition temperatures of the corresponding symmetric salts. It is especially interesting that T_{c1} is governed by the alkyl group possessing even number of carbons. (4) $\Delta H_{en,1}$'s and ΔS_1's are close to $\Delta H_{en,2}$ and ΔS_2 respectively. These facts suggest that the structure of

the metastable phase (C_M) is not very different from that of the low temperature phase (C_L). This is interesting in connection with the following observations; the symmetric salts did not show any presence of the C_M phase, but the unsymmetric salts showed C_M phase; when the difference in the carbon numbers of the two alkyl groups is larger than two, the structure of the C_M phase was assumed to be quite different from that of the C_L phase, unlike the cases of the present materials. Thus, C_n-DABCO-C_{n+1}-Br_2 can be said to possess intervening properties between the symmetric and unsymmetric salts. (5) The measurements of the bromide-anion conductivities revealed that conductivity jumps occurred at around T_{c1} and T_{c2} for the virgin and the annealed samples respectively. These phenomena are similar to the cases of the unsymmetric salts.[2,3] However, the differences in the two temperatures of the conductivity jumps tend to become smaller, and the conductivity jumps, themselves, tend to become sharper with an increase in the alkyl-chain lengths. These facts show that the temperature dependences of the bromide-anion conductivities tend to resemble those of the symmetric salts as the increase in the alkyl-chain lengths. The conductivity jump of C_{12}-DABCO-C_{13}-Br_2 was the largest of all of the materials studied hitherto.

We are grateful to Professor Shigekazu Kusabayashi and Dr. Shunsuke Takenaka, Faculty of Engineering, Osaka University, for the use of the DSC apparatus.

5) For example, 1-decyl-4-undecyl-1,4-diazoniabicyclo-[2.2.2]octane dibromide is abbreviated as C_{10}-DABCO-C_{11}-Br_2.

6) The virgin and the annealed samples mean the sample synthesized and the sample heated above T_{c1} at least once respectively.

7) The widths of all of the endothermic signals, $\Delta H_{en,2}$, were found to lie within 5 °C. However, those of the $\Delta H_{en,1}$ were broader than 5 °C, and are as follows: 5 °C and 5 °C, corresponding to two transitions for n=10; 11 °C, 8 °C, and 8 °C, corresponding to three transitions for n=11; 15 °C for n=12; 10 °C for n=13; 11 °C for n=14; 7 °C for n=15; 8 °C for n=16; 5 °C for n=17.

8) The two endothermic signals of C_n-DABCO-C_{n+1}-Br_2 (n=13, 15) were not separated well because of the proximity of the two transition temperatures. Thus, $\Delta H_{en,1}$'s were obtained by the total enthalpies of the two transitions, and ΔS_1 by dividing $\Delta H_{en,1}$ with the average transition temperatures (T_{c1}(average)=86.5°C for n=13, and T_{c1} (average)=90 °C for n=15).

9) The virgin samples of C_n-DABCO-C_{n+1}-Br_2 (n=11, 13, 15) possess more than one transition temperatures (T_{c1}). The second transition temperatures of these materials are close to the transition temperatures of the corresponding symmetric DABCO salts.

10) The characteristic (3) does not hold in the case of C_{10}-DABCO-C_{11}-Br_2. It showed large separation of the two transition temperatures (T_{c1}=57 °C, 84 °C).

11) The estimated numbers of sites (W) of C_n-DABCO-C_{n+1}-Br_2 above the transition temperatures are as follows. Virgin samples: 1.9×10^4 and 2000, corresponding to two transitions for n=10; 300, 2400, and 6200, corresponding to three transitions for n=11; 2×10^9 for n=12; 1.2×10^{10} for n=13; 1.3×10^{11} for n=14; 2.1×10^{11} for n=15; 1.8×10^{12} for n=16; 8.1×10^{12} for n=17. Annealed samples: 5.2×10^7 for n=10; 9.8×10^7 for n=11; 1.1×10^9 for n=12; 1.3×10^{10} for n=13; 1.5×10^{11} for n=14; 2.4×10^{11} for n=15; 3.7×10^{12} for n=16; 5.7×10^{13} for n=17.

(Received May 24, 1986)

Four geometrical isomers of [Co(mida)(edma)] were prepared in the first time and their structures were determined on the basis of their visible and UV absorption spectral data. Three of the isomers were optically resolved by the use of a column containing QAE-Sephadex of the $Sb_2(d\text{-}tart)_2^{2-}$ form. Absolute configurations of the facially chelated isomers of [Co(mida)(edma)] were determined by measuring the ^1H NMR spectra of the optically resolved isomers with an asymmetric carbon-containing edma (obtained from the stereospecifically deuterated $(-)_{543}^{CD}$ C_2-*trans*(O)-$[Co(edma)_2]^{2+}$). Absolute configuations of the facially chelated isomers of [Co(ida)(edma)] were determined on the basis of their CD spectral data.

Either [Co(ida)(edma)] or [Co(mida)(edma)] (ida=iminodiacetato; edma=ethylenediamine-*N*-acetato; and mida=*N*-methyliminodiacetato) provides four geometrical isomers,[1] as shown in Fig. 1. In the present paper, chromatographic methods to separate and to resolve the isomers of [Co(ida)(edma)] and [Co(mida)-(edma)] which are uncharged complexes will be described.

The absolute configuration of the complex containing edma is closely related to the chirality of the asymmetric nitrogen arising from coordination of the ligand. The determination of the chirality of the asymmetric nitrogen make it possible to determine the absolute configuration of the edma chiral complex. On this basis, a ^1H NMR method to determine the absolute configurations of the isomers of $[Co(edma)_2]^+$ was reported in the previous paper.[2] In the present paper, we report on a modification of the method to determine the absolute configurations, which was applied to the isomers of [Co(mida)(edma)].

Experimental

Ligands. *N*-Methyliminodiacetic acid (H_2mida) and ethylenediamine-*N*-acetic acid (Hedma) were synthesized as described in the previous papers.[3-5]

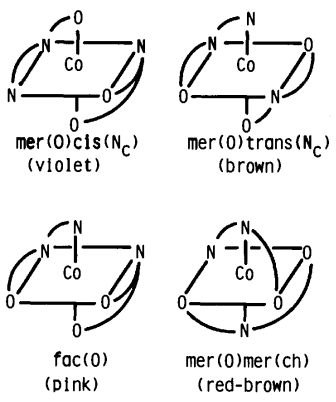

Fig. 1. The four geometrical isomers of [Co(ida)-(edma)] or [Co(mida)(edma)].

Preparation of the Complexes. Four Geometrical Isomers of the [Co(mida)(edma)] Complexes: A solution containing 2.4 g of $CoCl_2 \cdot 6H_2O$, 1.5 g of *N*-methyliminodiacetic acid (H_2mida) and 2.3 g of ethylenediamine-*N*-acetic acid dihydrochloride dihydrate (Hedma·2HCl·$2H_2O$) in 100 cm^3 of water was adjusted to pH 5 with a 2 mol dm^{-3} NaOH solution. The pH being kept constant at 5, 24 g of PbO_2 was stirred into the solution in small portions at 30 °C. After 1 h, the insoluble materials were removed by filtration. A solution containing neutral complexes was obtained by passing the filtrate through a QAE-Sephadex (SO_4^{2-} form) column and then an SP-Sephadex (K^+ form) column (eluent: water). This solution was evaporated to about 10 cm^3 and poured onto an SP-Sephadex (K^+ form) column. A band adsorbed on the column was separated into three parts by recyclic development with water: the first was an overlapped band (brown and red-brown); the second a violet band; and the third a pink band. Crude violet crystals were obtained by addition of methanol to the concentrated solution of the second eluant. Crude pink crystals were obtained by the same method as for the violet crystals. The solution obtained from the first part was acidified with a few drops of acetic acid and then concentrated under reduced pressure. Methanol was added to the concentrated solution. Brown crystals (unresolved) were deposited and were filtered off. The filtrate was evaporated almost to dryness to remove methanol and diluted with a small amount of water. The solution was repeatedly developed on a QAE-Sephadex column ($Sb_2(d\text{-}tart)_2^{2-}$ form; eluent: water), $(+)_{561}^{CD}$-brown (resolved; trace amount), red-brown (unresolved), and $(-)_{561}^{CD}$-brown band (resolved; trace amount) were separated (in the order of elution). The red-brown eluant (acidified with acetic acid) was concentrated under reduced pressure, and then acetone was added to the concentrated solution to obtain crude red-brown crystals. Each of the brown (unresolved), violet, and pink isomers was recrystallized from water by adding methanol and the red-brown isomer was next recrystallized from methanol by adding acetone. Yields of the isomers: the brown (unresolved), 420 mg; the violet, 650 mg; the red-brown, 10 mg; and the pink, 130 mg. Anal. Found for the brown isomer: C, 30.92; H, 5.64; N, 12.10%. Found for the red-brown isomer: C, 31.07; H, 5.46; N, 11.94%. Calcd for [Co(mida)(edma)]·$1.5H_2O$=$C_9H_{19}N_3O_{7.5}Co$: C, 31.05; H, 5.50; N, 12.07%. Found for the violet isomer: C, 31.74; H, 5.33; N, 12.31%. Calcd for [Co(mida)(edma)]·H_2O=$C_9H_{18}N_3O_7Co$: C, 31.87; H, 5.35;

N, 12.39%.

Four Geometrical Isomers of [Co(ida)(edma)]: These isomers were prepared according to the method reported in the previous paper.[1]

Optical Resolution. Isomers of [Co(ida)(edma)]: The racemic brown isomer of [Co(ida)(edma)] (ca. 50 mg) was dissolved in a small amount of warm water. The solution was poured onto a QAE-Sephadex column ($Sb_2(d\text{-}tart)_2^{2-}$ form, 3.7 cm×70 cm) and the adsorbed band developed with water. Developing was repeated on the same column using a micropump until the adsorbed band completely separated into two bands (recycle-times: 2). The earlier eluted isomer was $(+)_{565}^{CD}$ and the later eluted was $(-)_{565}^{CD}$. Each eluting solution from the two bands was concentrated to a small volume under reduced pressure at 35—40 °C. A crude complex was obtained by adding methanol to the concentrated solution: it was recrystallized from water by addition of methanol. The violet isomer of [Co(ida)(edma)] was resolved by the same method as that described above (recycle-times: 4). The earlier eluted isomer was $(+)_{563}^{CD}$ and the later eluted was $(-)_{563}^{CD}$. Though the pink isomer was chromatographed by the same method as that described for the brown isomer, the adsorbed band of the isomer was not separated into two bands upon 40 recycle-times. However, the faster eluted part showed (−) CD sign at 554 nm and the later one did (+). Fine needle crystals were obtained by adding methanol to each of the concentrated solutions. Found for $(+)_{565}^{CD}$ brown isomer: C 31.20; H, 4.55; N, 13.74%. Calcd for [Co(ida)(edma)]=$C_8H_{14}N_3O_6Co$: C, 31.28; H, 4.59; N, 13.68%. Found for $(+)_{563}^{CD}$ violet isomer: C, 29.41; H, 5.05; N, 12.89%. Calcd for [Co(ida)(edma)]·H_2O: C, 29.55; H, 4.96; N, 12.92%.

Isomers of [Co(mida)(edma)]: The brown and pink isomers of [Co(mida)(edma)] were resolved by the same method as that used for [Co(ida)(edma)]. The recycle times to attain complete separation of the enantiomers of the brown isomers were 5 and those of the pink isomer were 8. The earlier eluted bands of the brown and pink isomers showed (+) CD sign at 561 nm and at 565 nm, respectively. The resolution of the violet isomer was incomplete on the chromatograph using a QAE-Sephadex column ($Sb_2(d\text{-}tart)_2^{2-}$ form). However, it separated into enantiomers by 15 times recyclic development on a Sephadex G-10 column. Found for $(+)_{561}^{CD}$ brown isomer: C, 31.79; H, 5.51; N, 12.39%. Found for $(-)_{572}^{CD}$ violet isomer: C, 31.84; H, 5.35; N, 12.34%. Calcd for [Co(mida)(edma)]·H_2O=$C_9H_{18}N_3O_7Co$: C, 31.87; H, 5.35; N, 12.39%. Found for $(+)_{565}^{CD}$ pink isomer: C, 30.22; H, 5.70 N, 11.77%. Calcd for [Co(mida)(edma)]·$2H_2O$: C, 30.26; H, 5.64; N, 11.76%.

Determination of the Absolute Configuration of [Co(mida)(edma)]. A buffer solution (pH 10) was prepared by adding a suitable amount of 2 mol dm^{-3} DCl-D_2O to a solution containing 530 mg of Na_2CO_3 in 50 cm^3 of D_2O. About 1.0 g of $(-)_{543}^{CD}$ ($\Delta\Lambda\Delta(N_R,N_R)$) C_2-*trans*(O)-[Co(edma)$_2$]Cl·$2H_2O$[2] was dissolved into the buffer solution. The stereospecific deuteration reaction on the coordinating edma was allowed to proceed (40 °C, 25 min) and then stopped as described in the previous paper[1] (being adjusted the pH of the solution to 5 by addition of 1 mol dm^{-3} HCl). The complex solution was mixed with 10 g of zinc powder to reduce the central cobalt(III) and the mixture was stirred for 5 min. After the excess of zinc was filtered off, 0.64 g of $CoCl_2·6H_2O$ and 0.79 g of H_2mida were added to the filtrate and then the pH of the solution was adjusted to 5 with 2 mol dm^{-3} NaOH solution. After 15 g of PbO_2 was added to the solution, the mixture was stirred for 30 min at room temperature and the reactant solution was filtered. The filtrate was treated on a column chromatograph as described for separation of the racemic isomers of [Co(mida)(edma)]. Each facially chelated isomer so obtained was resolved into enantiomeric isomers by the chromatographic method described in the previous section. The ^1H NMR spectra of these isomers are illustrated in Fig. 5.

Spectral Measurements. The visible and UV absorption and CD spectra were recorded on a Hitachi 557 spectrophotometer and a JASCO J-22 spectropolarimeter in aqueous solutions, respectively. ^1H NMR spectra were recorded on a JEOL MH-100 spectrometer using DSS as an internal standard in D_2O or 0.1 mol dm^{-3} DCl-D_2O solutions.

Results and Discussion

Structural Assignments for the Isomers of [Co(mida)(edma)]. Each of the [Co(ida)(edma)] and [Co(mida)(edma)] complexes provides four geometrical isomers, as shown in Fig. 1. The structural assignments for the geometrical isomers of the former complex have been reported in the previous paper:[1] violet, *mer*(O)*cis*(N_c); brown, *mer*(O)*trans*(N_c); red-brown, *mer*(O)*mer*(ch); and pink, *fac*(O). The isomeric structures of the latter complex can be assigned by comparing their absorption spectra with those of the isomers of [Co(ida)(edma)]: violet, *mer*(O)*cis*(N_c); brown, *mer*(O)*trans*(N_c); red-brown, *mer*(O)*mer*(ch); and pink, *fac*(O) (Figs. 2 and 3). These assignments are also supported by the observation that the CD spectral behavior of an isomer of [Co(ida)-(edma)] is similar to that of the corresponding isomer of [Co(mida)(edma)] (vide infra).

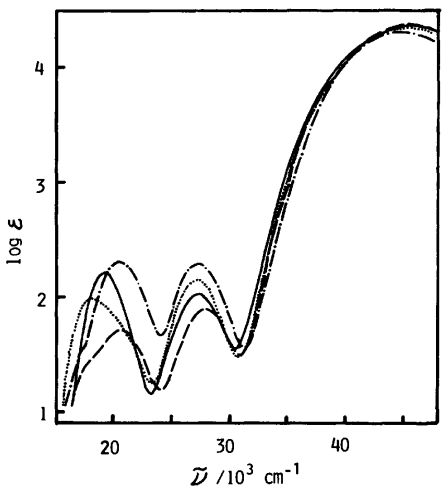

Fig. 2. Absorption spectra of [Co(ida)(edma)] in water: violet (·····), brown (– – –), pink (——), and red-brown (—·—).

^{1}H NMR Spectra. Table 1 shows the ^{1}H NMR data of the glycinate methylene protons of the edma complexes. The ^{1}H NMR spectra of the isomers which contain facially coordinating edma were measured in 0.1 mol dm^{-3} DCl-D_2O and in D_2O. The glycinate-ring (G-ring) signal for each isomer was observed as four peaks (an AB quartet) in D_2O, but it appeared as eight peaks in DCl because of the J_{H_a,H_b}, $J_{N\text{-}H,H_a}$, and $J_{N\text{-}H,H_b}$ couplings (Table 1). The $J_{N\text{-}H,H_b}$ and $J_{N\text{-}H,H_a}$ values are ca. 8 Hz's (for the peaks at lower field) and 1 Hz's (for those at higher field), respectively. On the basis of the Karplus equation,[6] the following assignments are possible: the dihedral angles of the proton resonating at higher field against the N-H proton (H-C-N-H) is about 90°, and the proton can be assigned to H_a (inside; Fig. 4 (A)). The angle of the proton (which is assigned to H_b (outside)) resonating at lower field is about 30°. Similar assignments for the G-ring methylene protons have been made for the isomers of $[Co(edma)_2]^{2+}$ [2] and for edda-Co(III) complexes.[7,8] When the N-H proton on the facially coordinating edma was deuterated, the signal of the G-ring methylene protons appeared as an AB quartet.

The G-ring methylene protons in the facially coordinating edma are known to be stereospecifically deuterated.[2,9-13] A new singlet appeared between the two higher-field peaks of the AB quartet, with intensity loss of the AB quartet. In other words, the deuteration rates are different between the two protons; the deuteration of the higher-field proton is much slower than that of the lower-field one. (The new singlet signal disappeared after a long period). Sudmeier and Occupati[9] found that the deuteration of the inside proton of the facial G-ring is slower than that of the outside proton for the edda-Co(III) complexes. The application of this to the present edma complexes leads to the conclusion that the two lower-field peaks of the AB quartet arise from the outside proton which is easily deuterated, while the two higher field peaks arise from the inside proton. These assignments are consistent with those made by the Karplus equation mentioned above.

Correlation between the Absolute Configuration Around the Cobalt Center and the Chirality of Asymmetric Nitrogen. When the edma ligand coor-

Geometrical Isomer	δ		J_{H_a,H_b} /Hz	$J_{N\text{-}H,H_a}$ /Hz	$J_{N\text{-}H,H_b}$ /Hz
	H_a	H_b			
mer(O)*cis*(N_c)	3.18	4.14	18	0	8
mer(O)*trans*(N_c)	3.40	4.22	18	0	8
fac(O)	3.15	4.00	18	2	9
mer(O)*mer*(ch)	3.84	3.84	—	7	9

Table 2. Possible Configurations and CD Signs of [Co(mida)(edma)] Complexes Containing Facially Coordinating edma

Geometrical Isomer	Possible Configuration		CD sign
	around cobalt(III)	asymmetric nitrogen	
mer(O)*cis*(N_c)	*ΛΔΛ*	N_S	$(+)^{CD}_{573}$
(violet)	*ΔΛΔ*	N_R	$(-)^{CD}_{573}$
mer(O)*trans*(N_c)	*ΔΛ*	N_S	$(+)^{CD}_{561}$
(brown)	*ΛΔ*	N_R	$(-)^{CD}_{561}$
fac(O)	*ΛΔΛ*	N_R	$(+)^{CD}_{565}$
(pink)	*ΔΛΔ*	N_S	$(-)^{CD}_{565}$

dinates to a cobalt(III) ion in the facial form, the secondary nitrogen (C-NH-C) becomes an asymmetric center (Fig. 4).[2] Where a geometrical structure of the edma complex is given, the absolute configuration around the cobalt(III) is restricted by the chirality of the asymmetric nitrogen. For example, in the *fac*(O) isomer of [Co(mida)(edma)], if the asymmetric nitrogen has R chirality (N_R), the absolute configuration around the cobalt(III) is *ΔΔΔ*. The correlation between the configurations around cobalt(III) and the chirality of asymmetric nitrogen is shown in Table 2.

Determination of Absolute Configurations by ^{1}H NMR. An outline of the method to determine the absolute configurations is illustrated in Fig. 4. The $(-)^{CD}_{543}$ C_2-*trans*(O)-$[Co(edma)_2]^{2+}$ isomer, the structure of which was determined in the previous work, has the configuration *ΔΔΔ*(N_R,N_R).[2] One of the G-ring $-CH_2-$ protons in this complex is stereospecifically deuterated in basic D_2O. When the outside proton (H_b in Fig. 4 (A)) was deuterated, the methylene carbon becomes an asymmetric center with the S chirality (C_S) (Fig. 4 (B)). Using this edma which contains C_S (edma(C_S)), the isomers of [Co(mida)(edma(C_S))] were prepared and resolved as described in the experimental section. In that experimental procedure, the C_S chirality was retained but the N_R chirality was not retained (yielded a 1:1 mixture of N_R and N_S). It is noteworthy that, when the nitrogen atom of the facially coordinating edma(C_S) takes N_R chirality, the undeuterated proton (-CHD-) occupies an inside position (Fig. 4 (C)). (When edma(C_S) takes N_S chirality, the -CHD- proton occupies an outside position.) In $(+)^{CD}_{561}$ *mer*(O)*trans*(N_c)-[Co(mida)(edma(C_S))], the NMR signal of G-ring -CHD- in edma(C_S)

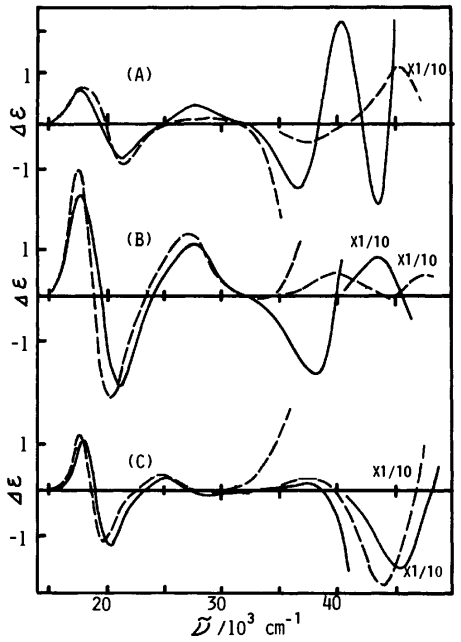

Fig. 6. CD spectra of the isomers of [Co(ida)(edma)] (——) and [Co(mida)(edma)] (– – –). (A) brown isomers of $(+)^{CD}_{565}$ [Co(ida)(edma)] and $(+)^{CD}_{561}$ [Co(mida)(edma)]; (B) violet isomers of $(+)^{CD}_{568}$ [Co(ida)(edma)] and $(+)^{CD}_{572}$ [Co(mida)(edma)]; and (C) pink isomers of $(+)^{CD}_{554}$ [Co(ida)(edma)] and $(+)^{CD}_{588}$ [Co(mida)(edma)].

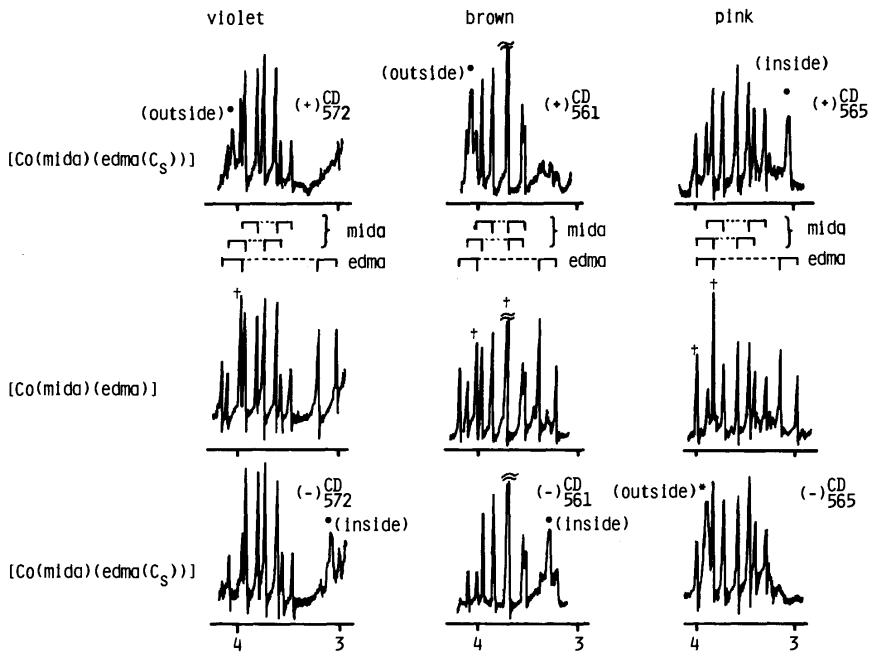

Fig. 5. ^{1}H NMR spectra of the optically active isomers of [Co(mida)(edma(C_S))] and those of the undeuterated isomers of [Co(mida)(edma)]. (Asterisked peaks: G-ring -CHD- of edma. Daggered peaks: Overlapped peaks.)

appeared at the chemical shift that corresponds to the outside proton (H_b; lower field) (Fig. 5). Accordingly, the chirality of the asymmetric nitrogen is N_S in $(+)^{CD}_{561}$ *mer*(O)*trans*(N_c)-[Co(mida)(edma(C_S))]. On the other hand, in $(-)^{CD}_{561}$ *mer*(O)*trans*(N_c)-[Co(mida)(edma(C_S))] the signal of -CHD- appeared at higher field (corresponding to the inside proton). This isomer should have N_R chirality. In a similar manner, the absolute configurations of three isomers of [Co(mida)-(edma)] were determined. These are summarized in Table 2 and Fig. 5.

CD Spectra of the Complexes. The CD spectra of the complexes examined are illustrated in Fig. 6. The facially chelated isomers of [Co(ida)(edma)] show similar CD patterns in the first and second band regions to those of the corresponding isomers (with the same colors) of [Co(mida)(edma)] except that the CD bands of the violet and pink isomers of [Co(mida)(edma)] shift slightly to the lower energy side than those of the corresponding isomers of [Co(ida)(edma)]. No shift was observed in the CD bands of the brown isomer of [Co(mida)(edma)]. Since the violet and pink isomers belong to *cis*(N_c) type isomers (violet, *mer*(O)*cis*(N_c); pink, *fac*(O) (Fig. 1)), steric compression between the methyl group of mida and the ethylene or methylene groups of edma is large in these isomers. The shift to the lower energy side results from this compression. Such compression is not expected in the brown isomer (*trans*(N_c) type) of [Co(mida)(edma)].

The first absorption bands of the *fac*(O)-[Co(N_3)-(O_3)] type complexes are sharp but those of *mer*(O)-[Co(N_3)(O_3)] are broad or not sharp with accompanying shoulder bands.[14,15] However, both isomers show two CD bands with opposite signs in the first absorption band region. This may be a general feature of the bis(terdentate)cobalt(III) type complex containing five membered chelate rings, even though the vicinal CD from the ligand may make the feature vague. The u-fac isomers of $[Co(ida)_2]^-$[16] and $[Co(dien)_2]^{3+}$[17] also show similar spectral patterns in the first absorption band region.

The $(+)^{CD}_{572}$ *ΔΔΔ* *mer*(O)*cis*(N_c)-[Co(mida)(edma)] gives two component CD bands with (+) and (−) signs at the lower and higher energy sides in the first absorption band region and the intensities (absolute values) are larger than those of $(+)^{CD}_{565}$ *fac*(O)-[Co(mida)(edma)]. The low CD intensities of the *fac*(O) isomer may result from one of the following two reasons: (1) although the *fac*(O) isomer has *ΔΔΔ* configuration the same as the *mer*(O)*cis*(N_c) isomer does, the N_R chirality of the coordinating edma in the *fac*(O) isomer is different from the N_S chirality in the *mer*(O)*cis*(N_c); (2) the split of the CD components in the first absorption band is smaller in the *fac*(O) isomer than in the *mer*(O)*cis*(N_c).

The CD intensities of $(+)^{CD}_{561}$ *mer*(O)*trans*(N_c) are the smallest among three resolved isomers of [Co(mida)-(edma)]. As this isomer has *Δ* and *Λ*-configurational ring pair, the CD contribution from the configurational effect is the smallest among three isomers and the vicinal CD from the N_S is dominant in this isomer.

Crystal Structures of Bis(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)cobalt(III) Iodide and Tricyano(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)-cobalt(III) Monohydrate

Minoru Ishii,* Michiko Umehara, and Masayoshi Nakahara
Department of Chemistry, Faculty of Science, Rikkyo (St. Paul's) University,
Nishiikebukuro 3, Toshima-ku, Tokyo 171
(Received June 13, 1986)

The crystal structures of bis(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)cobalt(III) iodide (**1**) and tricyano(*r*-1,*c*-3*c*-5-cyclohexanetriamine)cobalt(III) monohydrate (**2**) were determined by the X-ray diffraction technique. **1** is monoclinic with space group *A*2/*a*,[1] *a*=10.437(2), *b*=16.131(2), *c*=12.486(2) Å, and *β*=94.36(3)°, and **2** is orthorhombic with space group *Pbca*, *a*=12.599(1), *b*=16.818(2), and *c*=11.659(1) Å, the final *R* values for **1** and **2** were 0.048 and 0.045, respectively. In both the complexes, all six-membered chelate rings formed by the *r*-1,*c*-3,*c*-5-cyclohexanetriamine ligand and central cobalt atom assume chair conformations. The presence of the six-membered chelate rings does not introduce. much distortion on the octahedral geometry of the chromophores. These findings are in fair agreement with spectroscopic data on these complexes.

r-1,*c*-3,*c*-5-Cyclohexanetriamine (Fig. 1; abbreviated as chta) can act as a terdentate ligand and coordinate to the central metal in only one topological way (facial). Two kinds of complexes containing chta ligand, $[Co(chta)_2]^{3+}$ [2] and $[CoX_3(chta)]$[3] (X=CN^-, Cl^-, and CH_3COO^-), have been prepared. It is expected that a chta ligand coordinates to form a triplet six-membered ring, leading to existence of three six-membered chelate rings in $[CoX_3(chta)]$ (X=CN^-, Cl^-, and CH_3COO^-) and that of six in $[Co(chta)_2]^{3+}$. The d-d absorption bands of cobalt(III) complexes shift to the lower energy side as the number of chelate rings increases.[4] Rather large shifts were observed also for complexes of the type $[Co(triamine)_2]^{3+}$: for example, 19400 and 27200 cm^{-1} for $[Co(dpt)_2]^{3+}$ (dpt=bis(3-aminopropyl)amine)[5] and 21800 and 30000 cm^{-1} for *s*-*fac*-$[Co(dien)_2]^{3+}$ (dien=diethylenetriamine).[6] Although their band maxima are in lower energy sides than those of five-membered chelate polyamine complexes, they are located quite close to those of the corresponding ammine complexes: $[Co(chta)_2]Cl_3$, 20900 and 29200 cm^{-1},[2] $[Co(NH_3)_6]Cl_3$, 20960 and 29400 cm^{-1},[7] $[Co(CN)_3(chta)]$, 26300 and 33000 cm^{-1},[3] *fac*-$[Co(CN)_3(NH_3)_3]$, 26300 and 33000 cm^{-1}.[8] These facts suggest that the chta chelate assumes a undistorted structure in the complex. A study with scaled models has suggested that the chta ligand can build up a robust structure with the central atom. This work deals with the molecular structures of bis(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)cobalt(III) iodide, $[Co(chta)_2]I_3$,[9] and tricyano(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)cobalt(III) monohydrate, $[Co(CN)_3(chta)]\cdot H_2O$.

Experimental

Both the complexes were prepared according to the literatures.[2,3] The crystal of $[Co(chta)_2]I_3$ is of orange-red hexagonal prism and that of $[Co(CN)_3(chta)]\cdot H_2O$ is of yellow cube. Anal. for $[Co(chta)_2]I_3$. Found: C, 20.45; H, 4.32; N, 11.88; I, 54.54%. Calcd for $CoC_{12}H_{30}N_6I_3$: C, 20.65; H, 4.34; N, 12.04; I, 54.54%. Anal. for $[Co(CN)_3(chta)]\cdot H_2O$. Found: C, 37.44; H, 6.03; N, 28.95%. Calcd for $CoC_9H_{17}N_6O$: C, 38.04; H, 6.03; N, 29.57%. Specific gravities were determined by the floating method. Lattice constants were first approximately determined from Weissenberg photographs obtained with Cu *Kα* radiation and then refined. Crystal data of both the complexes are listed in Table 1. Intensities were collected on a Rigaku AFC-5 four-circle diffractometer (Josai University) with graphite-monochromated Mo *Kα* radiation (*λ*=0.7107 Å) up to 2*θ*=60°, the *θ*—2*θ* scan technique being employed. The usual corrections for Lorentz and polarization effects were made with both the crystals, and further corrections for absorption and

extinction were made with $[Co(chta)_2]I_3$. Calculations were carried out on a Univac 1100 computer at the Rikkyo University Computer Center and partially on a HITAC 200 H computer at the Computer Center of the University of Tokyo.

Crystal Structure Determination. **a) $[Co(chta)_2]I_3$:** The observed systematic absence of $h\,k\,l$ for $k+l=2n+1$ and $h\,0\,l$ for $h=2n+1$ indicated that possible space groups would be $A2/a$ or Aa. Then, two refinements were carried out independently by assuming the two space groups.[10] In the case of Aa, some C–C and C–N bond lengths were abnormal and the coordinates and temperature factors had unusually high values, whereas no anomalies were found in the case of $A2/a$. Independent 2794 reflections with $|F_o|>3\sigma(|F_o|)$ were used for structure determination. The structure was solved by the heavy-atom method with a local version of UNICS.[11] The final refinement was carried out by using the full-matrix least squares program LINUS[12] with anisotropic temperature factors for non-hydrogen atoms and isotropic ones for hydrogen atoms. The final R and R_2 values were 0.048 and 0.055,[13] respectively. The positions of all hydrogen atoms were determined from the difference-Fourier map.

b) $[Co(CN)_3(chta)]\cdot H_2O$: From the observed systematic absence of $0\,k\,l$ for $k=2n+1$, $h\,0\,l$ for $l=2n+1$, and $h\,k\,0$ for $h=2n+1$, the space group was uniquely determined to be $Pbca$. Independent 2674 reflections with $|F_o|>3\sigma(|F_o|)$ were used. The structure was solved by the Patterson-Fourier method with UNICS.[11] The refinement was carried out by using the block-diagonal least squares program HBLS IV. With anisotropic temperature factors for non-hydrogen atoms and isotropic ones for hydrogen atoms, the final R and R_2 values were 0.045 and 0.049, respectively. Fourteen of fifteen hydrogen atoms, except those of the water molecule, were located from the difference-Fourier map. The position of the remaining hydrogen atom was determined theoretically.

The final atomic parameters and temperature factors of both the complexes are given in Tables 2 and 3.[14]

Results and Discussion

Projections of the crystal structures of $[Co(chta)_2]I_3$ along the b axis and of $[Co(CN)_3(chta)]\cdot H_2O$ along the c axis are shown in Figs. 2 and 3. Perspective drawings of the complexes are shown in Figs. 4 and 5.

In both the complexes, the chta ligands are spanned on a face of an octahedron, that is, they coordinate in the facial positions, as expected.

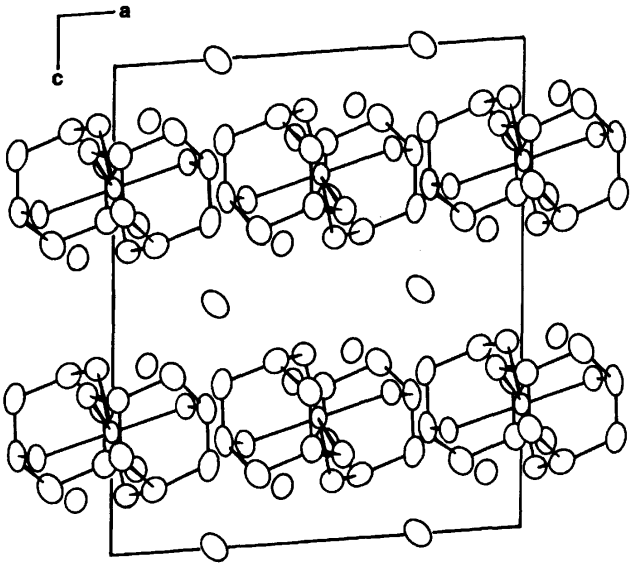

Fig. 2. Crystal structure of $[Co(chta)_2]I_3$ projected along the b-axis.

Bond distances and angles within the complex ion and molecule are listed in Tables 4 and 5, together with estimated standard deviations. Between both the complexes there are no remarkable differences with respect to the chta chelate. The Co-N(amine) bond distances which range from 1.948(6) to 2.010(3) Å are similar to those of some CoN_6 complexes with six-membered chelate rings.[15,16] These values are also in good agreement with the Co-N(NH_3) bond lengths of the corresponding ammine complexes (2.01 Å for *fac*-$[Co(CN)_3(NH_3)_3]$[8] and 1.979(1) Å for $[Co(NH_3)_6][Cr(CN)_6]$). The angles N(amine)-Co-N(amine) in the

chta chelate, close to 90°, are in agreement with those of analogous complexes.[15] Between both the complexes there is few difference in bond length and angle with respect to the triplet six-membered chelate rings, in contrast to the case of $[Co(diamine)_3]^{3+}$ complexes containing six-membered chelate rings.[15,16] The C-N(amine) and C-C bond distances are normal as such single bonds. The N(amine)-C-C angles are also normal as regular tetrahedral angles, but the Co-N(amine)-C ones are larger than those angles. Thus, these six-membered chelate rings are significantly flattened out. Absolute values of deviations from the plane Co-N-N(in chelate) are 0.91—0.96 Å (C(1)) and 0.56—0.62 Å (C(2)) for $[Co(chta)_2]^{3+}$ and 0.90—0.97 Å (C4A) and 0.53—0.67 Å (C5A) for $[Co(CN)_3(chta)]$. These six-membered rings assume more stable and less undistorted chair conformations than $[Co(tn)_3]^{3+}$[17] (Fig. 6). In complex $[Co(CN)_3(chta)]$, the Co-C-(cyano) and C-N(cyano) bond lengths agree with those of $[Co(CN)_3(NH_3)_3]$.[8] The C(cyano)-Co-C-(cyano) angles are smaller than 90°. The dihedral angle between the opposite N-N-N planes in $[Co(chta)_2]^{3+}$ is 0° as deduced necessarily from this symmetry, and that between the N-N-N and C-C-C planes in $[Co(CN)_3(chta)]$ is smaller than 1°. The octahedra of the CoN_6 and CoN_3C_3 chromophores are compressed or elongated along the quasi-threefold axes only slightly; the distance between the upper and lower triangles (2.292—2.297 Å) agrees with that estimated for a regular octahedron (2.294 Å).

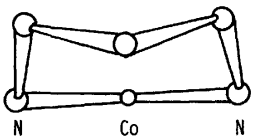

Fig. 6. Conformation of chta chelate ring.

These facts suggest that the distortion of the chromphores, although six-membered rings are formed by the chta ligands, is fairly alleviated by to the presence of the chta itself and that the octahedra retain approximately the O_h symmetry. The structures of the complex and ion, as determined in this work, are in good agreement with the speculations based on the absorption spectra.

Magnetic Properties of Some Molybdenum(V) Dimeric Coordination Compounds with Terminal Oxo-Ligands and Di-μ-oxo-, Di-μ-sulfido- or μ-Oxo-μ-sulfido- Bridges

Hanako KOBAYASHI,* Takashi SHIBAHARA,† and Norikiyo URYŪ††

††Department of Applied Science, Faculty of Engineering, Kyushu University, Higashi-ku, Fukuoka 812
(Received June 18, 1986)

Magnetic susceptibilities and electron spin resonances of Mo(V) dimers, $Cs_2[Mo_2O_2S_2(ox)_2(H_2O)_2]\cdot 2H_2O$, $Ba[Mo_2O_4(ox)_2(H_2O)_2]\cdot 3H_2O$, $(pyH)_4[Mo_2O_2S_2(NCS)_6]$, $(pyH)_4[Mo_2O_4(NCS)_6]\cdot H_2O$ and $(pyH)_4[Mo_2O_3S(NCS)_6]$ were observed at temperatures from 2 K to room temperature. The paramagnetic part of the magnetic susceptibilities of these compounds was small and approached zero with decreasing temperature. Under an applied magnetic field strength of 40 kOe, the susceptibilities had temperature independent regions but the spin susceptibilities derived from the electron spin resonances, observed at a magnetic flux density of about 3000 G, showed temperature dependences like antiferromagnetic dimers. This discrepancy was explained by a quasi alternating linear chain antiferromagnetic model. The corrections of the diamagnetic susceptibilities are discussed.

Molybdenum coordination compounds with sulfur containing ligands are found in many enzyme systems. The magnetic properties of such molybdenum coordination compounds are of interest because the mechanism of enzyme activity is strongly correlated with their magnetism. Within a limited moiety of molybdenum coordination compounds, that is, a Mo(V) dimeric ion with double bridges of oxygen or sulfur, there are many residual problems. A salt $[C_5H_5MoO_2]_2$,[1] which has oxygen double bridges, is known to be diamagnetic from NMR observations. On the other hand, $Na_2[Mo_2O_4(edta)]\cdot 4H_2O$[2] and $Ba[MoO_2(ox)]_2\cdot 5H_2O$,[3] both are oxygen double bridged, are reported to be paramagnetic. A salt sulfur-bridged $Na_2[Mo_2O_2S_2(histidine)_2]\cdot H_2O$,[4] which seems to be similar to $Na_2[Mo_2O_4(edta)]\cdot 4H_2O$ from the view point of magnetism, is diamagnetic and $Ba[Mo_2O_4(C_2O_4)_2]\cdot 5H_2O$[5] is considered to be diamagnetic. The molecular and crystal structures of paramagnetic $(pyH)_4[Mo_2O_4(NCS)_6]\cdot H_2O$ were analyzed by Jezowska-Trzebiatowska et al.[6] together with several related coordination compounds. She reported the molar magnetic susceptibilities of $(pyH)_4[Mo_2O_4(NCS)_6]$ in the range $(74—281)\times 10^{-6}$ CGSemu at room temperature.[7] The magnetic susceptibility of $(pyH)_4[Mo_2O_4(NCS)_6]$ reported by Mitchell and Williams,[2] is paramagnetic with a value of 157×10^{-6} (CGSemu) at 120 K and 147×10^{-6} (CGSemu) at 293 K. We have synthesized its homologous series $[Mo_2O_3S(NCS)_6]$ and $[Mo_2O_2S_2(NCS)_6]$ salts[8] and observed their magnetic susceptibilities and electron paramagnetic resonances, together with those of $[Mo_2O_4(NCS)_6]$ salt.[6] The two dimeric salts $[Mo_2O_2S_2(ox)_2(H_2O)_2]$ and $[Mo_2O_4(ox)_2(H_2O)_2]$ also were prepared and measured to examine some common properties among  , or  skelton.

Experimental

Preparation of Samples. Caesium di-μ-sulfido-bis[aquaoxalatooxomolybdate(V)] dihydrate ($Cs_2[Mo_2O_2S_2(ox)_2(H_2O)_2]\cdot 2H_2O$ (**1**)) and barium di-μ-oxo-bis[aquaoxalatooxomolybdate(V)] trihydrate ($Ba[Mo_2O_4(ox)_2(H_2O)_2]\cdot 3H_2O$ (**2**)) were prepared following Refs. 5, 9, and 10. Pyridinium di-μ-sulfido-bis[tris(isothiocyanato)oxomolybdate(V)] ($(pyH)_4[Mo_2O_2S_2(NCS)_6]$ (**3**)) and pyridinium di-μ-oxo-bis[tris(isothiocyanato)oxomolybdate(V)]monohydrate ($(pyH)_4[Mo_2O_4(NCS)_6]\cdot H_2O$ (**4**)) were prepared by the method reported in Refs. 6,7, and 11. Pyridinium μ-oxo-μ-sulfido-bis[tris(isothiocyanato)oxomolybdate(V)]($(pyH)_4[Mo_2O_3S(NCS)_6]$ (**5**)) was prepared following the method in Ref. 8. Chemical analysis results were: Found: N, 14.64; C, 32.51; H, 2.36%. Calcd for **3**: N, 14.64; C, 32.64; H, 2.53%. Found: N, 15.11; C, 33.26; H, 2.57%. Calcd for **4**: N, 14.86; C, 33.12; H, 2.78%. Found: N, 14.87; C, 33.29; H, 2.50%. Calcd for **5**: N, 14.89; C, 33.19; H, 2.57%.

Measurements of Magnetic Properties. Magnetic susceptibilities of samples **1**,**2**,**3**,**4**, and **5** were observed on powders in the temperature range from about 2 K to about 280 K by a magnetic balance (Oxford Instruments) of the Faraday method, which applies magnetic fields of a constant strength and a homogeneous gradient.[12,13] In order to prevent the powder sample from changing water content, it was put into a quartz cell together with minimum amount of liquid paraffin of special grade sufficient to cover the powder. The absolute values of the measured magnetic susceptibilities were small. Therefore, a constant magnetic field of 4×10^4 Oe and an inhomogeneous magnetic field with gradient of 390 Oe cm^{-1} were mainly used. The thermometer is fixed to the cryostat wall. The measurements of the $[Cr(NH_3)_6]Cl_3$ powder, which is paramagnetic in the temperature range from about 2 to 280 K, were made to correct the thermometer indications. For each measurement the sample cell site in the cryostat was checked, as were the pressures of the heat exchange gas and the time schedules of the temperature variation to get precise magnetic susceptibilities.

Electron spin resonances were observed on powder

samples and in CH_3CN solutions by a JEOL PE-3X with a microwave oscillator ES-SCXA. A thin-wall quartz cell was used. For CH_3CN solutions, signals were recorded with 1000 G/32 min scanning under 10 G modulation and input power of 0.8 mW. For powder samples measurements in the temperature range from about 2 K to 200—300 K were made using an Oxford Instruments' cryostat. Observations were made at 1000 G/40 min or 1000 G/16 min scanning rate under 1 or 10 G modulation with input power of 0.8 mW or 10^{-2} mW. The thermometer at the cryostat was calibrated by measurements of a Au(Co)-Cu thermocouple set at the sample position at a range of temperature variation made under the same conditions of changing rates and pressure of the atmosphere with the sample measurements. The magnetic flux densities were checked by diluted $Mn^{II}O$ hyperfine interaction signals and the H_1 effect measurements were also checked by the diluted $Mn^{II}O$ marker. The "H_1 effects" were observed in a range of input powers from 10^{-3} to 20 mW.

Units. The nonrationalized CGSemu are used in the present paper. The relations between the SI and the CGSemu systems on the units used in this paper are listed in Ref. 14.

Results and Discussion

Magnetic Susceptibility. The molybdenum complex ions of samples **1**,**3**, and **5** have the structures shown in Fig. 1. The structures of samples **2** and **4** are considered to be similar to **1** and **3**, respectively.

The measured magnetic susceptibilities of samples **3**, **4**, and **5** were corrected for diamagnetism following Pascal's law. As no absorption was observed in the wavenumber region of the spectra below 10^4 cm^{-1}, no correction for the temperature independent paramagnetism was made. The molar magnetic susceptibilities of samples **3**, **4**, and **5** at room temperature obtained in this way were 1.7×10^{-4}, -0.27×10^{-4}, and -4.4×10^{-4} cm^3, respectively. However, the electron paramagnetic resonances observed on all the three samples in the temperature range from about 2 to 280 K showed that they were paramagnetic, and the results of chemical analyses and molecular structure analyses by X-ray diffraction,[6,8] also established that the three were dimers of Mo (V), which may have $S=1/2$ spin on each Mo ion. The values of the molar magnetic susceptibilities reported above show that they need more corrections for diamagnetic susceptibilities, namely, at least the corrections of anisotropic diamagnetic susceptibilities due to the looped structures, that is, the pyridinium ion and the  ,  or  structures. Lonsdale[15] showed that the aromatic rings gave rise to anisotropic diamagnetic susceptibilities. An aromatic π-bonding structure with an effective radius r has an anisotropic diamagnetic susceptibility of $\chi_{ring}=(-Ne^2/4mC^2)\sum_p r^2$, where N is the Avogadro number, p is the number of p-electrons in the π-bonding loop and other symbols have their usual meanings. The unit of χ_{ring} is CGSemu except e and r which are CGSesu and Å respectively. The projections of the area of π-bonding looped structures on the planes perpendicular to the external manetic field directions of the samples were calculated in order to estimate the anisotropic diamagnetic susceptibilities. For the pyridinium ion, which is analogous to benzene, 6 electrons were taken as mobile electrons under the applied magnetic field. For the  group, the following electronic

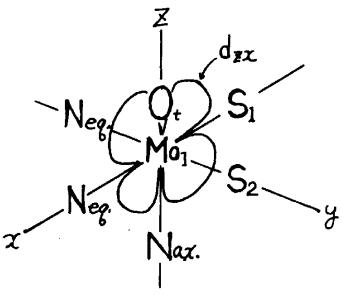

Fig. 2. Axes of atomic orbitals.

structure is assumed; a Mo^{5+} ion is basically six-coordinated with σ-bonding by two p-electrons from each bridged S^{2-} ion, two p-electrons from a terminal O^{2-} ion, two p-electrons from each equatorial N and two p-electrons from an axial N. If x, y, and z axes are taken as in Fig. 2, π-bondings are made up between d_{zx} of Mo_1 and p_z of S_1, and d_{yz} of Mo_1 and p_z of S_2, and, through the dimeric structure, a linked π-bonding is constructed. The π-bonding is a bound state like that in the aromatic benzene ring, but in this case the π-electrons might not be as mobile as those of the aromatic π-electrons. Thus, when the magnetic field is applied, four p_z-electrons of S-double bridges and two paramagnetic 4d electrons of two Mo^{5+} circulate along the π-bonding. The four p_z-electrons will contribute to the diamagnetism and two 4d electrons will effectively contribute to the paramagnetism; they have a spin of 1/2 respectively and would have super-exchange interactions of antiferromagnetic through the diamagnetic electrons as is predicted from the temperature dependence of the magnetic susceptibility derived from the ESR experiments as will be seen later. The electronic structure mentioned above is the simplest assumption for the Larmor rotation. The terminal O^{2-} would be coordinated to the Mo by four additional 2p-electrons, that is, between the Mo and the terminal O^{2-}, the bond order would therefore be higher than two. If so, the p orbitals might overlap with d_{zx} and d_{yz} of Mo. When the four $3p_z$-electrons which originally belonged to the bridged S^{2-} ions rotate in the external magnetic field, eight 2p-electrons from two terminal O^{2-} ions and four p-type electrons from the equatorial two N atoms, where sp hybridization is considered, would also be brought into the π-bonding rotation. This is because the $2p_z$ orbitals of the equatorial two N atoms are overlapped with d_{yz} and d_{zx} respectively. If this extended π-bonding is assumed, a total of 16 electrons will rotate along the linkage. If sp hybridizations are assumed in the bridged S^{2-}, four additional electrons, making a total of 20 might contribute to the anisotropic dia-

The former value is the case of 4 mobile p-electrons and the latter value is of 16 mobile p-electrons.

magnetism. For the  and  structures, the mobile electrons were similarly considered. The anisotropic diamagnetic molar susceptibilities are shown together with atomic diamagnetic susceptibilities in Table 1. The molar magnetic susceptibilities corrected for the diamagnetic susceptibilities are shown in Fig. 3.

The corrected value of sample **4** is in the same order value with that measured by Mitchell and Williams[2] for $(pyH)_4[Mo_2O_4(NCS)_6]$. Jezowska-Trzebiatowska et al.[7] measured more than five pyridinium salts of di-μ-oxo- and μ-oxo-μ-(sulfido, perchlorate, oxalato, or etc.)-bis[oxomolybdate(V)], the molar magnetic susceptibilities of which are in the same region with our data at room temperature. The temperature dependence of the molar magnetic susceptibilities of samples **3**, **4**, and **5** under the applied magnetic field of 40 kOe is roughly as follows. At very low temperature the molar magnetic suseptibilities increase exponentially with rising temperature from small values, reaching a maximum around 10—20 K, and retaining the same magnitude up to room temperature. This temperature dependence at very low temperatures shows that it can be expressed in the form of $\exp(E/kT)$, where E is an activation energy and E/k would be about 10—20 K (k: Boltzmann's const.= 1.380662×10^{-16} erg K^{-1}). The susceptibilities seem to decrease to zero at absolute zero K showing that the spins condense to a spin singlet state rather than to a long range ordered state. On the other hand from the temperature independent susceptibilities at higher temperatures we infer the existence of an ordered state. The isolated dimer spin system does not have any ordered state, and therefore an alternating linear chain system[16] or some other dimeric systems with

Results are listed in Table 2), (b): $(pyH)_4[Mo_2O_4(NCS)_6]\cdot H_2O$ (**4**) in CH_3CN solution at room temperature (Experimental conditions: 9.456 GHz, 0.8 mW, 3400±500 G/32 min scanning, and 10 G moduration. Results are listed in Table 2), (c): $(pyH)_4[Mo_2O_3S(NCS)_6]$ (**5**) in CH_3CN solution (Experimental conditions: 9.456 GHz, 0.8 mW, 3400±500 G/64 min scanning and 10 G moduration. Results are listed in Table 2).

interactions among the dimers should be present. As shown in Figs. 4 and 5, samples **1** and **2** showed similar and clearer temperature dependence of the magnetic susceptibilities with those of sample **3**. The effective Bohr magneton numbers of the samples at 100 K were **1**:1.6, **2**:1.5, **3**:0.45, and **4**:0.21, respectively. Sample **5** was diamagnetic after the above diamagnetic corrections.

Electron Spin Resonance. The electron spin resonances were first observed to see if the samples are paramagnetic or not. All the samples showed paramagnetic resonances in the temperature region from 2 K to room temperature, in spite of the diamagnetic static susceptibility of sample **5**. As mentioned in the section of the experimental the electron paramagnetic resonances were observed under unusual conditions. In Fig. 6, the magnetic susceptibilities derived from the ESR signals at room temperature divided by the magnetic susceptibilities of the diluted Mn^{2+} compounds used as a reference of the ESR signals were plotted for the ESR input powers. All the samples showed decreasing intensities with increasing input powers, namely, a saturation effect called the "H_1 effect" was observed. Input power of 10^{-3} m W does not give the maximum signal intensity. This H_1 effect might be the reason why they reported that no ESR was observed in some Mo(V) dimeric coordination compounds.[6] The values of H_1 were not measured, but as at the same input power the diluted Mn^{2+} compound did not show any saturation. We believe that the input power of 0.8 mW was less than several G^2 as H_1^2. Which of T_1, T_2, or, both of T_1 and T_2 are responsible for the ESR signal saturations cannot be decided, but this effect is never found in the reports of ESR of Mo(V) monomer, then, the "H_1 effect" would arise from the dimeric structures of the samples. The distances between the Mo(V) ions in the dimers are about 2.5—2.8 Å, but the effective superexchange interactions between the paired Mo(V) ions might be small, making T_2 long, alternatively spins in the π-molecular orbitals might have a large relaxation time to the lattice of the bath.

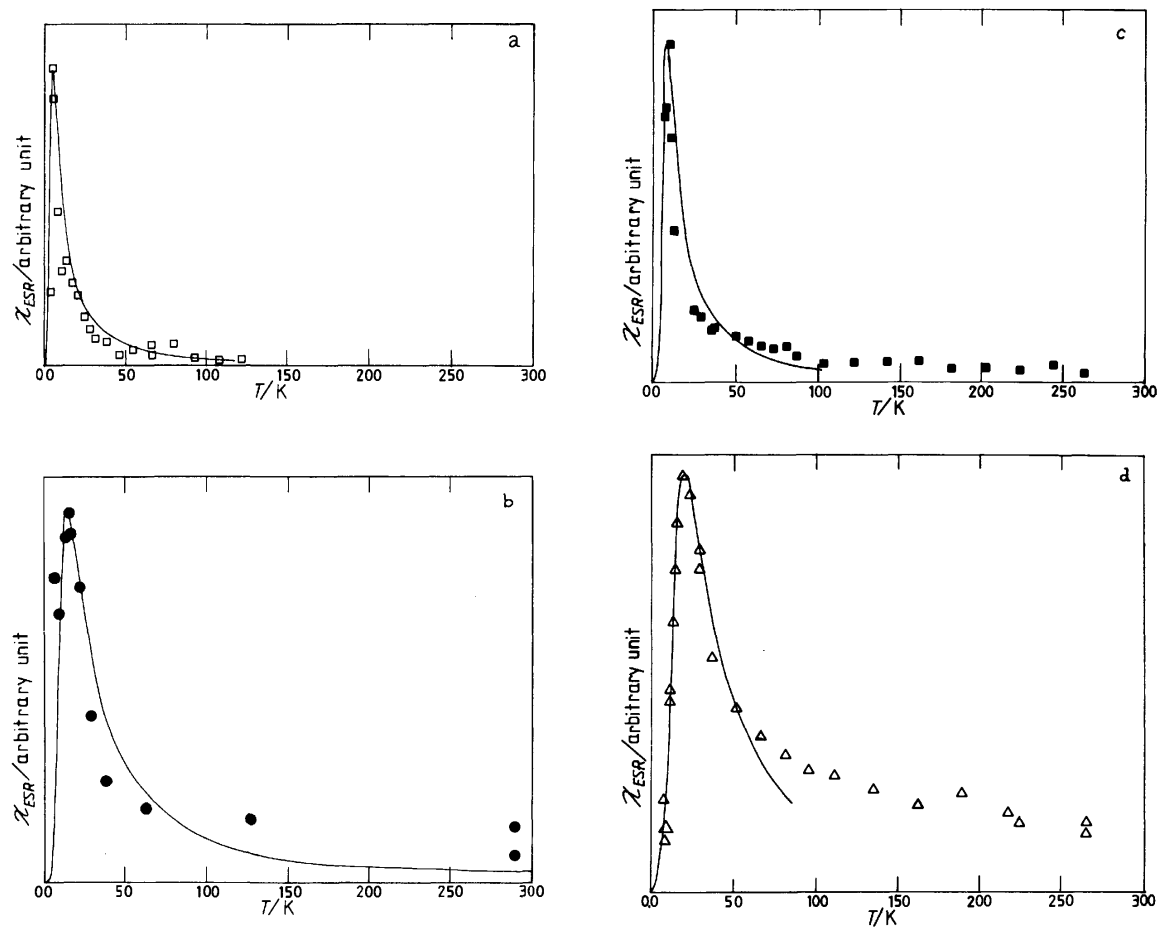

Fig. 8. Spin susceptibilities deduced from the ESR derivative curves versus temperatures. (a): Ba-$[Mo_2O_4(ox)_2(H_2O)_2]\cdot 3H_2O$ (**2**) (□: Experimental values and the thin curve is a fitted $B_2T^{-3/2}\exp(-20/T^2)$). (b): $(pyH)_4[Mo_2O_2S_2(NCS)_6]$ (**3**) (●: Experimental values and the thin curve is a fitted $B_3T^{-3/2}\exp(-160/T^2)$), (c): $(pyH)_4[Mo_2O_4(NCS)_6]\cdot H_2O$ (**4**) (■: Experimental values and the thin curve is a fitted $B_4T^{-3/2}\exp(-40/T^2)$), (d): $(pyH)_4[Mo_2O_3S(NCS)_6]$ (**5**) (△: Experimental values and the thin curve is a fitted $B_5T^{-3/2}\exp(-260/T^2)$).

In Fig. 7, ESR derivative curves of samples **3**, **4**, and **5** in CH_3CN solutions at room temperature are shown, of which averaged g-values, H_{msl}'s (separation of maximum slope) and the hyperfine interaction splittings observed at 0.8 mW input power are listed in Table 2. The hyperfine interaction splittings were observed also on powder samples as listed in Table 3 together with g-values and H_{msl}'s. The ESR signals of samples **3**, **4**, and **5** showed isotropic g-values. Samples **1** and **2** showed g-values of axial anisotropy. Relative intensities of g_1,g_2, and g_3 signals of sample **2** showed temperature dependences.

In Fig. 8, the spin susceptibilities obtained from the ESR signals by integration of the derivative curves of samples, **2**, **3**, **4**, and **5** respectively are shown in arbitrary units in the temperature region from 2 K to room temperature. The values at low temperatures seem to decrease to zero with decreasing temperatures. The spin susceptibilities have maxima at rather low temperatures; at higher temperatures they decrease with increasing temperature. This behavior is that of dimer spins or alternating linear spins[16] or ladder model spins,[16] though the peaks of the maxima are too steep to fit the theoretical dimer or alternating linear chain models. The different temperature dependences of a static magnetic susceptibility and a dynamic magnetic susceptibility are known as characteristic of the itinerant ferromagnetism in the theory on the weak ferromagnetic metals.[17] This is an attractive theory having various suggestive ideas. However in our samples, the itinerant interactions are limited within the π-molecular orbitals, therefore it

a) Ref. 6.

should not be considered in the present case.

Alternating Linear Chain Magnet Model. The arrangements of the molecules in the crystals of the five dimer samples were investigated.[5,8] Their space groups, lattice constants, numbers of Mo in a unit cell, distances between two Mo's of intra dimer and between a Mo and the nearest Mo in the nearest neighbour dimer, effective areas of the π-orbitals containing two Mo's and the π-orbital of pyridinium ion are listed in Table 3. In sample **1**,[8] the dimer complex ions make linear chains along the *c* axis, but it is not distinctly so, rather it should be said the dimer complex ions make two dimensional arrangements on the *bc* planes. Sample **2** has a spiral structure along the *c* axis where the molecular axes of the three dimer complex ions in a unit cell point in different directions consistent with the complx *g*-values observed in the ESR. Samples **3** and **5** have linear chains of the dimer complex ions along the *b* axis respectively. The details of sample **4** are not yet clear, but the five dimer samples are considered as magnetically alternating linear chains or dimers having low dimensional magnetic interactions among them.

The magnetic ordered state induced by the applied magnetic field was experimentally found on an alternating linear chain compound $Cu(NO_3)_2 \cdot 2.5H_2O$ by Amaya et al. and discussed by Tachiki et al., Bonner et al., and others.[16] In Fig. 9, a phase diagram of the alternating linear chain of Heisenberg spins proposed by Bonner is shown. She considers that the ordered SF(spin flop) phase has a temperature independent magnetic susceptibility and at lower applied magnetic fields than the SF phase region the spins behave as an alternating linear chain. She reported the results of the exact calculations of the magnetic and thermal properties of the alternating linear chain of a finite number of spins up to 10 and extended them to the infinite number of spins. On the other hand, she gave a rough temperature dependence of the magnetic susceptibility of the alternating linear chain under applied magnetic fields lower than the critical SF phase field as $\chi = T^{-1/2}\exp(-\Delta E_1/kT)$. This is a good approximation at low temperatures. As desctribed above, samples **1**, **2**, **3**, and **4** measured at 40 kOe of an applied magnetic field and sample **5** measured at 10 kOe of an applied field showed temperature independent magnetic susceptibilities at higher temperatures than some temperatures characteristic to each sample. If the molar magnetic susceptibilities at temperatures above the constant values under the applied magnetic fields are expressed as C_i, where the base line is set at the value of zero K, the molar magnetic susceptibilities of the samples **1**, **2**, **3**, **4**, and **5** under the magnetic fields are $C_1\exp(-0.2/T)$, $C_2\exp(-0.2/T)$, $C_3\exp(-5/T)$, $C_4\exp(-30/T)$, and $C_5\exp(-10/T)$, respectively, which are shown in Figs. 4,5, and 3 a,b, and c. It can be assumed that the samples take ordered states under high applied magnetic fields having the magnetic susceptibilities of the C_i's. If the spins are localized at atomic sites the magnetic susceptibilities will take the values of the ordered states as soon as the magnetic fields are applied at a low temperature. However the Mo(V) spins in the present samples are in the π-bonding linked orbitals. When the magnetic field is applied for the measurements at a low temperature, the mobile electrons and electron spins will begin the Larmor rotations. The rotations of the spins will attenuate with rising temperature to some velocities characteristic to each linked orbital and the spins will gradually take the ordered state values following the temperature dependences as shown in the graphs. The rotations of the nonmagnetic electrons will not have this temperature dependence. The electron spin resonances were observed at the magnetic flux densities of about 3000±15 G. The observed temperature dependences of the spin susceptibilities derived from the ESR signals show that 3000±15 G is lower than the critical fields of the SF ordered states, but the Larmor rotation will similarly affect the mobile electrons when the magnetic field is applied. At least the temperature dependence of the alternating linear chain magnetic susceptibilities of the five samples might have a term $\exp(-\Delta E'/T^2)$ instead of the Bonner's term $\exp(-\Delta E_1/T)$. The fitted magnetic susceptibilities to the experimental values of samples **2**, **3**, **4**, and **5** were $B_2T^{-3/2}\exp(-20/T^2)$, $B_3T^{-3/2}\exp(-160/T^2)$, $B_4T^{-3/2}\exp(-40/T^2)$, and $B_5T^{-3/2}\exp(-260/T^2)$, respectively, where B_i's are arbitrary constants. These fitted curves are drawn in Fig. 8 a, b, c, and d. The term T^{-1} multiplied to the Bonner's term $T^{-1/2}$ might come from the rf field. We cannot decide whether this temperature dependence comes from an isothermal effect or from some relaxation effect due to

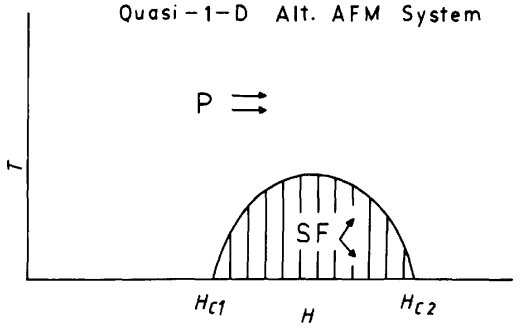

Fig. 9. A phase diagram of the quasi-1D alternating antiferromagnetic Heisenberg spins from Ref. 16. P $\rightleftarrows$ shows paramagnetic phase under applied magnatic field, SF$\rightleftarrows$ shows spin flopped phase of magnetic ordered phase induced by applied magnetic field; H_{c1} and H_{c2} are the critical magnetic fields at zero temperature.

the method of ESR measurements. The curves of the fitted magnetic susceptibilities agree with the experimental curves at low temperatures, but at temperatures higher than the susceptibility maximum, the fittings become poorer with rising temperature as the curves never approach the Curie-Weiss type temperature dependence. The static magnetic susceptibility of sample **4** shows a different behavior. Its Larmor rotation effect is $C_4\exp(-30/T)$ as mentioned above. Then before the spins reach the ordered state value the behavior as an alternating linear chain with the rotation effect appears with a fitted formula $C_{41}T^{-1/2}\exp(-14/T^2)$, as shown in Fig. 3. Sample **5** showed negative susceptibility after the above-mentioned atomic (Pascal) and molecular (π-orbital) orbital diamagnetism corrections have been applied. This sample was measured at an applied field of 40 kOe in the lower temperature region and at 10 kOe above 100 K. In the lower temperature region an alternating linear chain type susceptibility fitted to $C_{51}T^{-1/2}\exp(-60/T^2)$ is observed. For the superexchange interaction parameter J between two paramagnetic ions of spin 1/2 with double bridges each through one anion path are known to show a larger value than one hundred K, if it is expressed as $|J|/k$. For the present samples, if the exponential term of the spin susceptibilities derived from ESR signals indicates the band gap energy, then the superexchange interaction parameters of samples **2**, **3**, **4**, and **5** are $|-100|$, $|-32|$, $|-1.3|$, and $|-26|$K, respectively, where the rotation effects are removed. These values are small, though they are not inconsistent with the "H_1 effect".

The problem remains that sample **5** is diamagnetic after all the above-mentioned diamagnetic corrections have been applied. There may be some diamagnetism with large absolute values, not only in the sample **5** but in all the samples. The atomic daimagnetic susceptibility is $\chi=(-Ne^2/6mc^2)$ $(\sum_i r_i^2)$, which was deduced from Larmor's theorem by Langevin and Pauli, [18] that is, the Larmor's rotation in the atomic core is considered as the ideal one, where electrons rotate along an orbital on a plane energy level. This assumption is used in the case of benzene π-orbital by Lonsdale. The static magnetic susceptibility is $\chi=M/H$, where M is magnetization and H is magnetic field strength, when the magnetic induction B is defined as $B=\mu H=H+4\pi M$, $\chi=(\mu-1)/4\pi$. When the sample is a superconductor, B is zero, that is, permeability μ should be zero. We consider, here, for normal substances, therefore, $0<\mu$. On the other hand, we consider diamagnetism, therefore, χ should be negative, that is $\mu<1$. When the electrons obey the ideal Larmor's theorem, $\chi\fallingdotseq-10^{-6}\,\mathrm{cm}^3$, that is $1-\mu=+10^{-6}\times4\pi$, namely, B/H is very near to 1. In the present samples, when a magnetic field is applied, mobile electrons circulate along molecular orbitals which are  , or  , or  . In the above-mentioned corrections we have assumed ideal Larmor rotations, but, the results show us that the assumptions used were not suitable. B/H may be much smller than 1 and the samples may have diamagnetic susceptibilities with large absolute values. If so the symmetry of the molecular orbital of sample **5** is lower than those of samples **3** and **4**, and has diamagnetic susceptibility with the largest absolute value. This is consistent with the above considerations. Another possibility for the diamagnetism with a large absolute value, was proposed by Ginzburg[19] concerning the diamagnetism of CuCl and CdS. The diamagnetism would be due to the toroidal moment. He did not discuss coordination compounds, but if ring structures with mobile electrons take a toroidal coil arrangement in a crystal, the toroidal moment will appear. That possibility cannot be denied in samples **3**, **4**, and **5**.

The authors wish to express their sincere thanks to Professor Minoru Kinoshita and Dr, Tadashi Sugano, the University of Tokyo, for the valuable discussions all over this work. The authors wish to express their thanks to the Institute for Molecular Science, Okazaki, and the Institute for Solid State Physics, the University of Tokyo, for the measurements of the magnetic susceptibilities and Professor Tadamasa Shida, Kyoto University, for the observations of the electron spin resonances. One of the authors(H. K.) would like to thank Professor Ikuji Tsujikawa, Dr. Yoshitami Ajiro, and Dr. Kiminori Ushida, Kyoto University, for the valuable discussions and Dr. Keisaku Kimura and Mr. Shunji Bandow, Institute for Molecular Science, for their thoughtful advice and helps with the measurements.

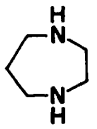
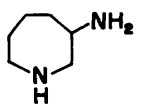
(Received July 11, 1986)

A series of copper(II) complexes of (*S*)-3-aminohexahydroazepine (abbreviated as *S*-ahaz) were prepared. The molecular structure of bromobis[(*S*)-3-aminohexahydroazepine]copper(II) perchlorate, [CuBr(*S*-ahaz)$_2$]-ClO$_4$, was determined using single-crystal X-ray diffraction method. The complex crystallizes is space group $P2_12_12_1$ with a=13.449(6), b=17.411(11), c=7.937(2) Å, and Z=4. The structure was solved by the direct method and refined by the least squares to R value of 0.068 for 1853 unique reflections. The Cu^{2+} ion has the square-pyramidal five-coordination geometry with four nitrogen atoms as basal donors and a bromide as an apical donor. The structures of other copper(II) complexes of *S*-ahaz were assigned on the basis of the above X-ray analysis result, together with electronic spectral and conductivity measurements. The complexes having the formula Cu(*S*-ahaz)$_2$X(ClO$_4$) (X$^-$=Cl$^-$, I$^-$, NCS$^-$, ONO$^-$) were assigned to have square-pyramidal five-coordinated structures. The *S*-ahaz complexes Cu(*S*-ahaz)$_2$X$_2$ (X$^-$=Cl$^-$, Br$^-$, NO$_3^-$) were also considered to have similar five-coordination geometries, while the complexes Cu(*S*-ahaz)$_2$X$_2$ (X$^-$=ClO$_4^-$, BF$_4^-$) to be four-coordinated in the crystalline state.



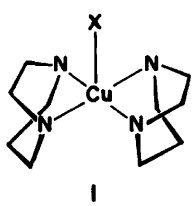
(1)



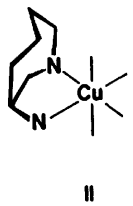
(2)

Musker and collaborators reported that 1,4-diazacycloheptane (**1**), abbreviated as dach, acts as a bidentate ligand for certain transition metal ions.[1,2] The structure of the copper(II) complex obtained from dach and Cu(NO$_3$)$_2$·6H$_2$O was determined by an X-ray crystallographic study,[3] which revealed that two Cu^{II} species, [Cu(NO$_3$)(dach)$_2$]$^+$ and [Cu(H$_2$O)(dach)$_2$]$^{2+}$, with square-pyramidal five-coordination geometries, were involved in the crystal. The molecular structure of [CuX(dach)$_2$]$^{n+}$ (X=NO$_3^-$ or H$_2$O), illustrated in Fig. 1 (I), indicated that the access of another monodentate ligand to the sixth coordination site is sterically blocked by the ligand methylene chains.

3-Aminohexahydroazepine (**2**), abbreviated hereafter as ahaz, is a unique chiral 1,2-diamine having C- and N-substituents which are fused into a seven-membered mono-azaheterocycle, while dach can be regarded as an *N*,*N*'-disubstituted 1,2-ethanediamine. If ahaz acts as a bidentate ligand for a metal ion, the ring carbon chain is required to orient nearly perpendicular to the five-membered chelate ring as in Fig. 1 (II). The ring carbon chain of ahaz should hang over the central metal ion in a similar manner as that of dach. Therefore, the coordination of a further ligand to the apical site should be significantly restricted for ahaz complexes due also to steric interactions with the ring methylenes.



I



II

Fig. 1. The five-coordinated structure of [CuX(dach)$_2$]$^{n+}$ ion (I),[3] and a possible structure of ahaz coordinating to a metal ion, (II).

It seems interesting to compare the stereochemical and other properties of metal complexes of ahaz with those of dach. This paper describes the results on the preparation and stereochemical properties of copper(II) complexes of the optically active form of ahaz, i.e., (*S*)-3-aminohexahydroazepine (=S-ahaz), and, further, those of the X-ray structural analysis of a square-pyramidal copper(II) complex of *S*-ahaz, [CuBr(*S*-ahaz)$_2$]ClO$_4$.

Experimental

Measurements. Visible reflectance and absorption spectra were recorded with a Hitachi 340 spectrophotometer. Infrared spectra were obtained with a Jasco IRA-2 spectrophotometer. Electric conductivities were measured by a Toa Electronics CM-20A conductivity meter. Magnetic susceptibilities were measured at room temperature using a Shimadzu MB-100 magnetic balance (Faraday method). Optical rotations were measured with a Jasco DIP-360 polarimeter.

(*S*)-3-Aminohexahydroazepine (*S*-ahaz). To a suspension of lithium tetrahydridoaluminate (17.5 g) in dry tetrahydrofuran (THF, 400 cm^3) was added (*S*)-3-aminohexahydro-2-azepinone hydrochloride (25.0 g) in small

portions with stirring. The mixture was stirred and heated under reflux for 24 h, and then cooled to room temperature. To the mixture was added water (33 cm^3) drop by drop with stirring, and the resultant slurry was heated under reflux for 1 h. The cooled slurry was filtered off, and the solid mass was washed with THF. The solid was stirred with THF (150 cm^3) under reflux for 1 h, filtered, and washed as above. All the filtrates and washings were united, neutralized with dilute hydrochloric acid, and rotary-evaporated. The oily residue was dissolved in water (100 cm^3), and solid sodium hydroxide was added in small portions to make the mixture strong alkaline. The amine which separated from the aqueous layer was extracted with diethyl ether (total 250 cm^3), and the extracts were combined and dried over solid potassium hydroxide. The solvent was removed under reduced pressure, and the residual amine was distilled under reduced pressure. Bp, 92 °C/23 mmHg (3066 Pa). Yield; 9.5 g. α_{obsd} (neat, 589.3 nm, 1 cm cell)=−0.167°±0.002°.

In the same manner, (*S*)-3-aminohexahydro-2-azepinone prepared from L-lysine methyl ester dihydrochloride by the reported method,[4] was converted to *S*-ahaz. The product thus obtained was slightly racemized. α_{obsd} (neat, 589.3 nm, 1 cm cell)=−0.150°±0.002°.

(*RS*)-3-Aminohexahydroazepine (*RS*-ahaz). This was obtained by the same procedure for preparing *S*-ahaz, except the use of (*RS*)-3-aminohexahydro-2-azepinone hydrochloride in place of the *S*-enantiomer.

Preparation of Cu(*S*-ahaz)$_2$X$_2$ (X^-=ClO_4^-, NO_3^-, Cl^-, and Br^-). $CuX_2 \cdot nH_2O$ (5 mmol) dissolved in ethanol (5—10 cm^3) was added drop by drop to an ethanol solution (5 cm^3) of *S*-ahaz (11 mmol). Diethyl ether was added to complete the precipitation of copper(II) complex. The crystals formed were collected, washed with diethyl ether, and air-dried. The crude product was recrystallized from hot methanol.

Cu(*S*-ahaz)$_2$(BF_4)$_2$ was obtained similarly using 45% aqueous solution of Cu(BF_4)$_2$. Diethyl ether (100 cm^3) was added to an aqueous ethanol solution of the crude product to induce the precipitation of the complex. The analytical data of copper(II) complexes are given in Table 1.

Preparation of Cu(*S*-ahaz)$_2$X(ClO_4) (X^-=Cl^-, Br^-, I^-, NCS^-, and ONO^-). To a methanol solution of Cu(*S*-ahaz)$_2$(ClO_4)$_2$ (0.93 g; 2 mmol) was added a methanol solution of LiX(X^-=Cl^-, Br^-, or I^-) or NaX(X^-=NCS^- or NO_2^-) (3 mmol). The crystals which appeared were collected, and washed with methanol and diethyl ether. The product was recrystallized from methanol-water mixture (3:1 v/v). Table 1 lists the analytical data of the heteroanion[5] complexes obtained as above.

X-Ray Diffraction Analysis. A violet needle crystal, 0.20×0.38×0.57 mm, was used for the X-ray analysis. Diffraction data were collected on a Rigaku AFC-5 four-circle diffractometer with graphite-monochromatized Mo $K\alpha$ radiation (λ=0.71073 Å) at 296 K. Unit cell parameters were derived from a least squares fit of 16 2θ values in the range $20° < 2\theta < 30°$

Crystal Data. $C_{12}H_{28}BrClCuN_4O_4$, M=471.28, Orthorhombic, a=13.449(6), b=17.411(11), c=7.937(2) Å, U=1859(2) Å^3, space group $P2_12_12_1$, Z=4, D_m=1.66 (298 K), D_x=1.684 g cm^{-3}, $F(000)$=964, μ(Mo $K\alpha$)=3.47 mm^{-1}. Data were collected by ω and ω—2θ (2θ>30°) scan mode and at scan rate, 4.0° min^{-1}. The three standard reflections were monitored every 150 reflections and their intensities varied by<0.06. A total 1906 reflections obtained in the range of 2θ<55°, of which 1853 independent reflections with $|F_o| > 3\sigma(|F_o|)$ were used for the structure determination. The intensities data were corrected for Lorentz and polarization factors, but not for absorption.

Solution and Refinement. The structure was solved by the direct method, and was refined by using a block diagonal least-squares procedure based on $|F_o|$. Unit weight was used for all reflections. H-Atom coordinates were generated assuming the standard bond lengths and angles. All non-hydrogen atoms are anisotropic and H atoms are isotropic (321 parameters). The final indices R ($=(|F_o|-|F_c|)/|F_o|$) and R_w ($=[w(|F_o|-|F_c|)^2/w|F_o|^2]^{1/2}$) were 0.068 and 0.079 respectively. The largest shift to error value on the final cycle is 0.13. The maximum height in the final difference Fourier maps was 1.8 e Å^{-3} near the disordered perchlorate, O(3).

Atomic scattering factors are taken from International

a) The calculated values are in parentheses. b) Obtained for nitromethane solution (4×10^{-4} mol dm^{-3}) at 19 °C. c) The orange-red complex of racemic ahaz.

Tables for X-ray Crystallography.[6] The crystallographic calculations were performed on a FACOM M-380 computer of The Institute of Physical and Chemical Research using program MULTAN 78[7] and the UNICS III program system.[8] Their positional parameters for non-hydrogen atoms are listed in Table 2.[9]

Results

Isolation of Violet and Orange-Red Forms of $Cu(ahaz)_2(ClO_4)_2$. In our first examination, we prepared the ligand *S*-ahaz by lithium tetrahydridoaluminate reduction of (*S*)-3-aminohexahydro-2-azepinone (**3**), which was obtained via the cyclization of methyl L-lysinate[4] (Scheme 1). The copper(II)

complex obtained from the above-mentioned ahaz (α_{obsd} (neat, 598.3 nm, 1 cm cell)=−0.150°±0.002°) and $Cu(ClO_4)_2\cdot 6H_2O$ consisted of two crystalline forms of different color, the dominant violet and the minor orange-red ones. Because the latter was less soluble than the former, they could be separated from each other by recrystallization from methanol.

In spite of the clear difference in their color, the elemental analysis results of these two forms agreed adequately with the expected values for the formula $C_{12}H_{28}Cl_2CuN_4O_8=Cu(C_6H_{14}N_2)_2(ClO_4)_2$. Electric conductivity measurements showed that they dissociated as bi-univalent electrolites in nitromethane. Further, magnetic susceptibility measurements suggested that both were mononuclear Cu^{II} species. The electric conductivity and magnetic susceptibility data of copper(II) complexes of ahaz are also summarized in Table 1.

A remarkable distinction between the two forms, which could be noticed finally with a surprise, was that the orange-red form was optically inactive, while the violet one optically active. Thus, the violet crystals evidently involve the optically active ahaz, the chiral carbon center of which should assume the *S*-configuration, because the starting material of the present ligand was L-lysine (Scheme 1). On the other hand, the orange-red form was thought to include the racemic ahaz. These results indicated that *S*-ahaz employed here was partially racemized.

To confirm the difference between copper(II) complexes caused by employing either the racemate or the optically-active *S*-enantiomer as the ligand, we synthesized both modifications of ahaz. The enantiomerically pure *S*-ahaz was prepared from the pure (*S*)-3-aminohexahydro-2-azepinone hydrochloride ((**3**)·HCl) (Scheme 1). The optically-pure *S*-ahaz showed an optical rotation α_{obsd} (neat, 589.3 nm, 1 cm cell)=−0.167°±0.002°, and gave rise to only the violet form. On the other hand, the orange-red form was the sole product for the reaction of *RS*-ahaz (*RS*-ahaz=racemic ahaz) with $Cu(ClO_4)_2$. These observations confirm that the violet form involves the pure *S*-antipode of ahaz.

Preparation of Copper(II) Complexes of *S*-ahaz. It was observed that the homo-anion[10] copper(II) complexes of *S*-ahaz, $Cu(S\text{-ahaz})_2X_2$, obtained by mixing $CuX_2\cdot nH_2O$ and twice the molar of *S*-ahaz were violet ($X^-=ClO_4^-$, BF_4^-, NO_3^-) or blue-violet ($X^-=Br^-$, Cl^-). As these complexes gave no single crystals suitable for X-ray structural analysis, their exact structures have not been clarified yet. The circular dichroism spectral feature of the S-ahaz complex has been reported.[11]

The hetero-anion[5] copper(II) complexes of *S*-ahaz having the formula $Cu(C_6H_{13}N_2)_2X(ClO_4)$ were obtained by either of the following two methods; (i) the addition of an excess amount of LiX ($X^-=Cl^-$, Br^-, I^-)

or NaX (X^-=NCS^-, NO_2^-) to a methanol solution of $Cu(S\text{-ahaz})_2(ClO_4)_2$ (Eq. 1), and (ii) the addition of $LiClO_4$ to a methanol solution of $Cu(S\text{-ahaz})_2X_2$ (X^-=Cl^-, Br^-) (Eq. 2).

$$Cu(S\text{-ahaz})_2(ClO_4)_2 + MX \rightarrow Cu(S\text{-ahaz})_2X(ClO_4) + MClO_4 \quad (1)$$

(M^+=Li^+ or Na^+; X^-=Cl^-, Br^-, I^-, NCS^-, ONO^-)

$$Cu(S\text{-ahaz})_2X_2 + LiClO_4 \rightarrow Cu(S\text{-ahaz})_2X(ClO_4) + LiX \quad (2)$$

(X^-=Cl^-, Br^-)

These hetero-anion complexes formed well-developed single crystals so that the molecular structure of the bromo complex, $Cu(S\text{-ahaz})_2Br(ClO_4)$, was determined using the single-crystal X-ray diffraction method.

The Molecular Structure of Bromobis[(*S*)-3-aminohexahydroazepine]copper(II) Ion. Figure 2 shows the perspective views of the complex cation, $[CuBr(S\text{-ahaz})_2]^+$. The selected bond parameters are listed in Table 3. The absolute configuration of the complex were assigned from the known absolute configuration of the ligand as an internal reference. The complex ion has a square-pyramidal structure with the bromide at the apex. Two *S*-ahaz ligands coordinate to Cu^{2+} ion in the trans fashion, and, expectedly, the seven-membered rings orient perpendicular to the CuN_4 basal plane. The seven-membered rings extend toward the same side of the basal plane, and disturb obviously the access of additional ligand to the sixth coordination site.

It is noticeable that the seven-membered ring of *S*-ahaz depicted on the left side of the structure in Fig.2 with the non-primed atoms N(1), C(2), ···N(8) has a different conformation from that of the right side *S*-ahaz with the primed atoms N(1)′, C(2)′, ···N(8)′. In spite that the seven-membered rings of both *S*-ahaz adopt the preferred twist-chair conformation,[12] the cyclic sequence of dihedral angles in the non-primed *S*-ahaz is different from that of the primed one as shown in Fig. 3. This is the reason for that the complex ion lacks the true C_2 symmetry. Both five-membered chelate rings take the λ conformation, though the chelate of the primed ligand is deformed to an envelope. The coordinating secondary asymmetric nitrogen center adopts the *R*-configuration.

O(2)-Cl-O(4)	109(2)		
O(3)-Cl-O(4)	103(2)		

The three possible N-O hydrogen-bond distances are 3.20 [N(8)—O(1^{i})], 3.07 [N(1)—O(4^{ii})], and 3.22 Å [N—O(1^{iii})]. The symmetry codes are (i) $x-1/2$, $-y+1/2$, $-z$, (ii) x, y, z, and (iii) $x-1/2$, $-y+1/2$, $-z+1$. There are no particularly short intermolecular distances.

Discussion

Square-Pyramidal Geometry of [CuBr(*S*-ahaz)$_2$]$^{2+}$ Ion. As has been described, one of the apical coordination site of Cu^{2+} ion in the title complex is effectively shielded from the coordination of a ligand by the seven-membered ring of *S*-ahaz. Similar five-coordination geometries of copper(II) complexes containing diamine ligands were established for [CuX(dach)$_2$]$^{n+}$ (X=NO_3^- or H_2O)[3] and [CuCl(1,3-dach)$_2$]$^+$ (1,3-dach=*cis*-1,3-cyclohexanediamine).[13] In the case of 1,3-dach complex, the methylene chains of the ligands shield one of the apical coordination sites in a closely similar manner to that of *S*-ahaz or dach.[13]

It was indicated for a number of copper(II) complexes with square-pyramidal coordination that the ratio of the apical Cu-X distance to the mean value of in-plane bond lengths (ca. 2.0 Å), i.e., (Cu-N/Cu-X), is 0.83 on an average, which is correlated to the geometry and/or electronic energy level.[14,15] The value of the present complex is 0.72, indicating that the Cu-Br distance is fairly longer than the average value for typical square-pyramidal configuration, and that the bromide ion binds to Cu^{2+} rather weakly. Concomitantly, the deviation of Cu^{2+} from the basal plane is very small (0.0097 Å).

Stereochemistries of Hetero-Anion Copper(II) Complexes of *S*-ahaz. Figure 4 shows the possible geometries of *S*-ahaz complex in which four amino nitrogen atoms occupy the basal coordination plane. The secondary (or primary) amino groups of the diamines are located in the cis relationship for (III) and in the trans fashion for (IV). The seven-membered rings are depicted in a twist-chair conformation, though certain other conformations will be plausible as well. The methylene chain of the ligand should strictly prevent the anion coordination at the apical site close to it, so that the cis isomer is necessary to take the four-coordination geometry (III), while the trans isomer may adopt either four- or five-coordination depending on the coordinating abilities of the anion present, since one of the apical sites in (IV) is not blocked by the ring methylenes. When the fifth coordination site of (IV) is occupied by a monodentate ligand, a square pyramidal five-coordination geometry (V) is effected. The X-ray diffraction study on [CuBr(*S*-ahaz)$_2$]ClO_4 clearly indicates the presence of such geometry as (V).

The hetero-anion complexes of *S*-ahaz other than [CuBr(*S*-ahaz)$_2$]ClO_4 were blue-violet, and their

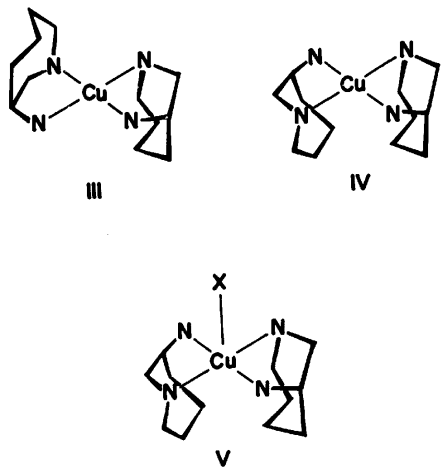

Fig. 4. Possible geometries of *S*-ahaz complexes. The four-coordinated cis form, (III); the four-coordinated trans form, (IV); the five-coordinated trans form (V). (X represents a coordinating anion).

reflectance spectra resembled one another as shown in Fig. 5 (see also Table 4). Further, all these complexes were found to dissociate uni-univalently in nitromethane (Table 1). This indicates that the halides or pseudohalides (NCS^-, ONO^-) with relatively high coordinating ability enter into the fifth coordination site to give rise to the complexes having the five-coordination structure (V) in a way similar to the $[CuBr(S\text{-ahaz})_2]^+$ ion. We concluded, therefore, that the hetero-anion complexes are thoroughly five-coordinated, and can be formulated as $[CuX(S\text{-ahaz})_2]ClO_4$ ($X^-=Cl^-$ etc.).

a) R; reflectance spectra. A; obtained for nitromethane solution using 5 cm cells. B; obtained for methanol solution using 5 cm cells.

The infrared spectra of $[CuX(S\text{-ahaz})_2]ClO_4$ ($X^-=NCS^-$ and NO_2^-) were examined to clarify the coordination mode of these ambidentate anions. The complex with NCS^- showed bands at 2070 cm^{-1} for $\nu(CN)$ and at 856 cm^{-1} for $\nu(CS)$, and no band around 720—690 cm^{-1}. These are characteristic for the N-coordination of NCS^- ion.[16] The NO_2^- complex has bands at 1464 and 1452 cm^{-1} for $\nu(N=O)$ and at 1058 cm^{-1} for $\nu(N-O)$, indicative of the O-coordination of the NO_2^- group.[16]

Musker and Hussain described the preparation of hetero-anion complexes $[CuX(dach)_2]ClO_4$ ($X^-=Cl^-$, Br^-, NCS^-), and postulated their structures to be five-coordinated on the basis of electronic spectral and conductivity data.[1] The evidence of the square-pyramidal five-coordination geometry (Fig. 1 (I)) was provided by the X-ray analysis study on $[Cu(dach)_2(NO_3)]NO_3$,[3] which suggested that the other hetero-anion complexes of dach also took square pyramidal structures.

Stereochemistries of Homo-Anion Copper(II) Complexes of *S*-ahaz. The above-mentioned structure determination of $[CuBr(S\text{-ahaz})_2]ClO_4$ could imply the possible stereochemistries of the complex ions in $Cu(S\text{-ahaz})_2X_2$. Since the reflectance spectra of these complexes (Fig. 6 and Table 4) showed no significant change from those of the hetero-anion complexes, it seems likely that all the complexes adopt five-coordinated structures such as (V). However, these complexes were found to be classified into two groups on the basis of their conductivity behaviors.

The first group, which involves $Cu(S\text{-ahaz})_2X_2$ ($X^-=Cl^-$, Br^-, and NO_3^-), are uni-univalent electrolites in nitromethane, indicating that the complex ions have five-coordinated structures $[CuX(S\text{-ahaz})_2]^+$ in

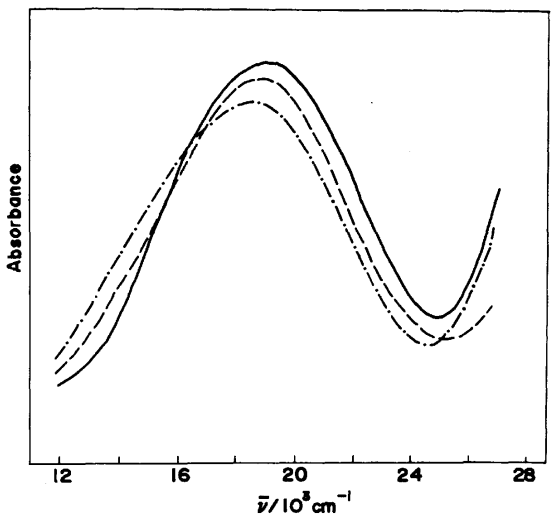

Fig. 6. Reflectance spectra of $Cu(S\text{-ahaz})_2X_2$: $X^-=ClO_4^-$ (——), $X^-=Cl^-$ (— —), $X^-=Br^-$ (—·—).

nitromethane solution. Because the rapid rearrangement and exchange of ligands are generally effected for labile copper(II) complexes in solution, it is difficult on the basis of conductivity and spectral data alone to determine unambiguously whether the crystalline state structures of these *S*-ahaz complexes are five-coordinated square-pyramidal as (V) or four-coordinated as (IV). Nevertheless we consider it to be more likely that these complexes adopt the structures (V) in a similar manner as $[CuBr(S\text{-ahaz})_2]ClO_4$ and can be formulated as $[CuX(S\text{-ahaz})_2]X$, because of that for most metal complexes such anions as halides tend to coordinate to the central metal ion in the crystalline state.

The second group, which involves the complexes with relatively weak coordinating anions as ClO_4^- and BF_4^-, were found to dissociate uni-bivalently in nitromethane. This indicates no coordination of the anion to Cu^{2+} in solution, and suggests that the interaction between the anions and Cu^{2+} for these complexes is negligible, or, if any, very weak even in the crystalline state. We supposed, therefore, that these two may adopt four-coordination structures, either (III) or (IV), and the complexes be formulated as $[Cu(S\text{-ahaz})_2]X_2$ ($X^-=ClO_4^-$, BF_4^-). We have not obtained any direct evidence of the above presumption yet, but a helpful information for considering the stereochemistry of above complexes is provided by the structural determination study of $[Cu(deen)_2](ClO_4)_2$ (deen=*N*,*N*-diethyl-1,2-ethanediamine).[17]

It is well-known that $[Cu(deen)_2]X_2$ exhibits reversible thermochromism between the red lower temperature form and the blue higher temperature form, when X^- is of low coordinating ability as ClO_4^- and BF_4^-.[17-22]. The structural change which may accompany with the color change had been studied from various aspects,[17,19-22] and conclusively demonstrated was that the most apparent stereochemical change in the course of the transformation from the red to blue form is the coformational inversion of one of the deen chelates.[17]

The red form has a strictly four-coordinated structure illustrated as (VI) in Fig. 7, in which the chelates assume the opposite conformation with each other.[17] On the other hand, the structure of the complex ion in the blue form can be depicted by (VII) in Fig. 7 or its antipode, where the chiralities of both chelate conformations are the same and the complex ion has a two-fold rotation axis perpendicular to the CuN_4 plane.[17] The coordination of perchlorate group to Cu^{2+} ion was indicated not to take place in the blue form, since the interatomic distance of Cu-O is not shorter than 4 Å.[17] This means that the color change mentioned above does not necessary mean the transformation from four to five coordination around Cu^{2+}. It is interesting to note that the stereochemical features of (VII), the presence of a two-fold rotation axis perpendicular to the CuN_4 plane and the identical chiralities of the conformation of both chelates, are same as those of (IV), one of the possible structures for $[Cu(S\text{-ahaz})_2]X_2$ ($X^-=ClO_4^-$, BF_4^-). We consider, therefore, that the S-ahaz complexes of perchlorate series ($X^-=ClO_4^-$, BF_4^-) has the four-coordination geometry (IV), and can be formulated as $[Cu(S\text{-ahaz})_2]X_2$.

The structure of the orange-red complex containing *RS*-ahaz is remained unsolved in the present paper. The structure determination of this and related complexes will be presented in a following paper.

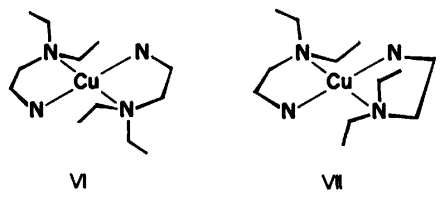

Fig. 7. Structures of $[Cu(deen)_2]^{2+}$ ion in the red form, (IV), and in the blue form, (VII).[16]

The authors wish to thank Dr. Yutaka Fukuda of Ochanomizu University for his help in obtaining the magnetic susceptibility data, and to Toray Co. for supplying the samples of (*S*)- and (*RS*)-3-amino-hexahydro-2-azepinone hydrochloride.

Comparative Studies of 2-, 3-, and 4-Pyridylpalladium(II) Complexes: Synthesis and Properties

Kiyoshi Isobe,* Yukio Nakamura, Toshio Miwa, and Shinichi Kawaguchi†
Department of Chemistry, Faculty of Science, Osaka City University,
Sumiyoshi-ku, Osaka 558
†School of Medicine(Premedical Bldg.), Kinki University,
Sayama-cho, Minamikawachi-gun, Osaka 589
(Received July 12, 1986)

Oxidative addition reactions of bromopyridines to tetrakis(triphenylphosphine)palladium(0) gave [{PdBr(2-pyridyl)(PPh_3)$_2$}] (**1b**), *trans*-[PdBr(3-pyridyl)(PPh_3)$_2$] (**2b**), and *trans*-[PdBr(4-pyridyl)(PPh_3)$_2$] (**3b**), which were converted on treatment with triethylphosphine to *trans*-[PdBr(2-, 3-, and 4-pyridyl)(PEt_3)$_2$] complexes (**1d**, **2d**, **3d**, respectively). Titration with perchloric acid in dioxane–water (1:1 by volume) indicated the basicity sequence of these complexes: 2-pyridyl≫4-pyridyl>3-pyridyl. The bromide ligand in **1b**—**3b** can readily be replaced by Cl^-, I^-, N_3^-, NCO^-, and NCS^-. In each corresponding series the relative thermal stability is in the sequence of 2-pyridyl>4-pyridyl>3-pyridyl. The pyridyl complexes containing triphenylphosphine react with carbon monoxide at ambient temperature and pressure to afford acyl complexes, which produce the corresponding esters by reactions with methanol. They also act as catalysts for cross coupling reactions of bromopyridines.

Oxidative addition of organic halides to palladium(0) complexes is one of the most convenient methods to prepare the σ bonded organopalladium(II) complexes.[1] In a previous paper we have reported on the 2-pyridylpalladium(II) complexes which were prepared by the reactions of 2-halopyridines with tetrakis(triphenylphosphine)palladium(0), $Pd(PPh_3)_4$.[2] Although the 2-pyridylnickel(II) complexes, [{NiX(C_5H_4N-C^2)(PPh_3)$_2$}] (X=halide and pseudohalide ligands), are quite stable, the corresponding 3-pyridyl complex [{NiCl(C_5H_4N-C^3)(PPh_3)}$_2$] is less stable and the 4-pyridyl complex has not been prepared.[3] On the contrary, stable 3- and 4-pyridyl palladium(II) complexes have been obtained. This paper reports on the comparative studies of these complexes. A preliminary account and X-ray molecular structures of these compounds have appeared.[4]

Experimental

Unless otherwise stated, air-sensitive materials were handled under a nitrogen atmosphere. Solvents used in these experiments were redistilled in nitrogen, and vessels and reagents were also purged with nitrogen. Dioxane was distilled over Linde molecular sieves 4A before use through a fractionating column.

Commercial reagents such as halopyridines, tertiary phosphines, Grignard reagents, and carbon monoxide were used without further purification. 4-Bromopyridine was freed from its hydrogen chloride adduct by action of triethylamine. The starting complex $Pd(PPh_3)_4$ was prepared by Coulson's method.[5] The dinuclear 2-pyridyl complexes [{PdX(C_5H_4N-C^2)(PPh_3)}$_2$], X=Cl (1a) and Br (1b) were prepared by the reactions of $Pd(PPh_3)_4$ with 2-chloro- and 2-bromopyridines as described already.[2]

Preparation of the *trans*-Bromo(3- and 4-pyridyl)bis(triphenylphosphine)palladium(II) Complexes, *trans*-[PdBr(C_5H_4N-C^3, and -C^4)(PPh_3)$_2$] (2b and 3b, respectively). 3-Bromo- or 4-bromopyridine (3.95 g, 25.0 mmol) was added to a solution of $Pd(PPh_3)_4$ (4.21 g, 3.63 mmol) in toluene (50 cm^3) and the mixture was allowed to react at 90 °C for 4 h. A white precipitate of 2b separated out in a 90% yield from the reaction mixture after standing for 5 h at room temperature. In the case of **3b**, the solution was concentrated to ca. 25 cm^3 and kept in a refrigerator for 24 h to deposit a white precipitate in a 73% yield.

Preparation of the *trans*-Halogeno- and *trans*-Pseudohalogeno(3- and 4-pyridyl)bis(triphenylphosphine)palladium(II) Complexes, *trans*-[PdX(C_5H_4N-C^3)(PPh_3)$_2$] with Cl (2a), I (2c), N_3 (2f), NCO (2g) and NCS (2h) as X and *trans*-[PdX(C_5H_4N-C^4)(PPh_3)$_2$] with Cl (3a), I (3c), N_3 (3f), NCO (3g), and NCS (3h) as X. Methanol (10 cm^3) was added to a solution of **2b** or **3b** (0.151 g, 0.190 mmol) in dichloromethane (30 cm^3). To this solution was added a methanol solution of ten times molar amount of sodium chloride (0.112 g), iodide (0.283 g), azide (0.121 g), cyanate (0.122 g), or thiocyanate (0.151 g). In the case of sodium chloride or cyanate, a mixture (15 cm^3) of methanol and water (2:1 by volume) was used because of their poor solubilities in methanol. After the reaction at 40 °C for 1 h (for 72 h in the case of NaCl), dichloromethane was distilled away under reduced pressure to deposit a white precipitate, which was recrystallized from dichloromethane–methanol. The yields were 85 (**2a**), 84 (**2b**), 65 (**2f**), 60 (**2g**), 81 (**2h**), 75 (**3a**), 93 (**3c**), 71 (**3f**), 68 (**3g**), and 78% (**3h**), respectively.

Preparation of the *trans*-Bromo(2-, 3-, and 4-pyridyl)bis(triethylphosphine)palladium(II) Complexes, *trans*-[PdBr(C_5H_4N-C^2, -C^3, and -C^4)(PEt_3)$_2$] (1d, 2d, and 3d, respectively). Triethylphosphine (0.340 g, 2.88 mmol) was added to a suspension of **1b** (0.611 g, 0.580 mmol), **2b** (0.915 g, 1.16 mmol), or **3b** (0.915 g, 1.16 mmol) in diethyl ether (30 cm^3) and the mixture was stirred at room temperature for 24, 5, and 5 h, respectively, to result in a clear colorless solution. After concentration to 5 cm^3, petroleum ether (20 cm^3) was added and the mixture was kept at −78, 0, and 0 °C, respectively, to precipitate white crystals in 30 (**1d**), 65 (**2d**), and 75% (**3d**) yields. Complexes **2d** and **3d** were recrystallized from diethyl ether–petroleum ether. Complex **1d** was dissolved in a mixture of water and methanol to be freed from triphenylphosphine and then recrystallized from petroleum ether. In order to prevent oxidation of triethylphosphine, preparation and purification of these

complexes were carried out under an argon atmosphere.

Preparation of *trans*-Bromo(2-, 3-, and 4-pyridylium)bis(triethylphosphine)palladium(II) 2,4-Dinitrophenolates, *trans*-[PdBr(C_5H_4NH-C^2, -C^3, and -C^4)(PEt_3)$_2$][2,4-$(NO_2)_2C_6H_3O$] (1e, 2e, and 3e, respectively). A dichloromethane solution (5 cm^3) of 2,4-dinitrophenol (0.0730 g, 0.395 mmol) was added to a solution of **1d**, **2d**, or **3d** (0.198 g, 0.395 mmol) in dichloromethane (5 cm^3) to convert the colorless solution to yellow instantaneously. Diethyl ether (10 cm^3) was added to the solution and the mixture was kept at 0 °C for 3 h to precipitate yellow crystals in 61, 64, and 63% yields, respectively, which were recrystallized from dichloromethane-diethyl ether.

Preparation of the *trans*-Bromo(3- and 4- pyridylcarbonyl)bis(triphenylphosphine)palladium(II) Complexes, *trans*-[PdBr(C_5H_4N-C^3-CO and -C^4-CO)(PPh_3)$_2$] (2i and 3i, respectively). Carbon monoxide was passed for 5 h through a solution of **2b** or **3b** (0.118 g, 0.150 mmol) in tetrahydrofuran at room temperature to convert the colorless solution to yellow. The solution was concentrated to 20 cm^3 by evaporation under reduced pressure. After addition of diethyl ether (60 cm^3), the mixture was left standing at room temperature for 24 h to obtain yellow crystals of **2i** and **3i** in 80 and 81% yields, respectively, which were recrystallized from dichloromethane–diethyl ether.

Reactions of the Acyl Complexes 2i and 3i with Methanol. Methanol (10 cm^3) was added to a solution of **2i** or **3i** (0.131 g, 0.160 mmol) in dichloromethane (20 cm^3) with changing color of the solution from yellow to red and finally to brown. After standing for 24 h, the solvent was distilled away to dryness under reduced pressure and the residue was extracted with diethyl ether. The solvent was vaporized again and the residue was dissolved in dichloromethane-d_2 and identified by the ^1H NMR assay to be methyl nicotinate and isonicotinate, respectively.

pH Titration of Complexes 1d, 2d, and 3d. To a solution of **1d** or **2d** (0.0879 g, 0.176 mmol) in dioxane (10 cm^3) was added an aqueous solution (10 cm^3) of sodium perchlorate which had been adjusted to μ=0.2, and the mixture containing the complex in 8.78×10^{-3} mol dm^{-3} was kept at 25.0±0.2 °C under a nitrogen atmosphere. Dioxane and an aqueous solution of perchloric acid (9.43×10^{-3} mol dm^{-3}) adjusted to μ=0.2 with sodium perchlorate were added from separate burettes to the sample solution.

Each time exactly the same volumes of titrants were added and the mixture was stirred for several minutes before recording the pH value. Standardization of the perchloric acid solution had been performed in advance with a standard solution of sodium carbonate dried at 200 °C using a mixture of Bromocresol Green and Methyl Red as an indicator. For comparison pyridine dissolved in a mixture of dioxane and water (1:1 by volume) was also titrated in a similar manner as above.

Unfortunately titration of **3d** in this way was not successful, since it is soluble in a mixture of dioxane and water (1:1 by volume) but not in the presence of sodium perchlorate to adjust the ionic strength. In order to compare relative basicities of **1d**, **2d**, and **3d**, titration as above was carried out in the absence of sodium perchlorate.

Measurements. Infrared spectra were taken in Nujol or hexachlorobutadiene mull on JASCO IR-E (4000—650 cm^{-1}), Hitachi EPI-L (700—200 cm^{-1}), and FIS-3 (400—30 cm^{-1}) spectrophotometers. ^1H NMR spectra were measured at 100 MHz in CD_2Cl_2 with Me_4Si as internal reference by means of a JEOL JNM MH-100 spectrometer. A JEOL JNM FX-100 instrument was used to record ^{13}C NMR spectra in $CDCl_3$ with Me_4Si as external reference at 25.0 MHz. Gas-chromatograms were obtained with a Yanagimoto G-180 instrument using nitrogen as a carrier gas through a Silicone DC-550 column, samples being injected at 200 °C. A Beckman Century SS-1 pH meter was used for titration together with glass and calomel electrodes. The Beckman buffer solution at pH 7.00 was used at 25 °C to calibrate the pH meter. The molecular weight was determined by vapor pressure osmometry in dichloromethane at 25 °C with an instrument manufactured by Knauer in Berlin, West Germany. The decomposition temperature was measured in a capilary tube under nitrogen.

Results and Discussion

Tetrakis(triphenylphosphine)nickel(0) reacts with 2- and 3-halopyridines promptly at room temperature to afford the 2- and 3-pyridylnickel(II) complexes.[3] Although the former is stable, the latter complex is not so stable as to allow full characterization and the 4-pyridyl complex has not yet been obtained. On the other hand, the reactions of $Pd(PPh_3)_4$ with 2-, 3-, and 4-bromopyridines did not proceed appreciably at room temperature, but occurred in toluene at 90 °C and completed after 4 h to form stable complexes. The 2-pyridylpalladium(II) complex is yellow and dinuclear as was reported previously,[2] while the 3- and 4-pyridyl complexes are white and mononuclear. The triphenylphosphine ligands in these complexes are readily replaced by triethylphosphine, an excess amount of which gives the mononuclear 2-pyridyl complex ultimately. Table 1 lists the complexes prepared in this study.

Halogeno Pyridyl Complexes. The analytical and molecular-weight data in Table 1 indicate that complexes **1d**, **2a—d**, and **3a—d** are all mononuclear. As is seen in Table 2, decomposition temperature of these complexes is high. In the cases of 2-pyridyl nickel(II)[3] and palladium(II)[2] complexes, the relative thermal stability of halogeno complexes was in the sequence of Cl>Br>I. The same sequence holds for the 4-pyridyl complexes **3a—c**, but in the case of 3-pyridyl complexes the bromo complex **2b** decomposes at appreciably higher temperature than the chloro complex **2a** does.

Among complexes containing the same halogeno ligand, the 4-pyridyl complexes are more stable than the corresponding 3-pyridyl complexes. The triethylphosphine complexes having distinct melting points show the decomposition temperature in the sequence of 2-pyridyl(**1d**)>4-pyridyl(**3d**)>3-pyridyl(**2d**).

Infrared spectra of these complexes show a single ν(Pd-P) band in the 410—430 cm^{-1} region in conformity with the presumed trans structure and the ν(Pd-Cl):ν(Pd-Br):ν(Pd-I) ratio is 1:0.75:0.59 for

2a—**c**, resembling to that for the 2-pyridyl complexes (1:0.75:0.55),[2a] although the corresponding ratio (1:0.62:0.50) for **3a**—**c** is a little smaller.

The methyl protons in **1d**, **2d**, and **3d** resonate at 1.0—1.1 ppm as a 1:4:6:4:1 quintet (J=ca. 9 Hz), indicating the trans arrangement of the triethylphosphine ligands.[6] As is listed in Table 3, the ring protons of the triphenylphosphine ligands in **2a** and **3a** exhibit two multiplets at about 7.4 and 7.6 ppm, the former being assigned to the meta and para protons, and the latter to the ortho protons.[7]

The NMR signals attributable to the pyridine-ring protons in **1d**, **2d**, and **3d** are shown in Fig. 1. The ring protons of 2-substituted pyridines such as methyl-, ethyl-, methoxy-, and chloropyridines show an ABB'X pattern, H^3 and H^5 resonating at the highest field with almost the same chemical shifts, and H^4 and H^6 at lower fields in this sequence.[8] In the case of complex **1d**, the $PdBr(PEt_3)_2$ moiety attached to C^2 effects the strongest influence on H^3, of which the signal shifts to lower field to overlap with that of H^4. Thus the signal at the highest field is assigned to H^5

Table 1. Analytical Data for the σ-Pyridyl Palladium(II) Complexes

and that at the lowest field to H^6. The ABMX pattern of the ring proton signals from **2d** is similar to that from methyl nicotinate,[8,9] and four signals are assigned as is seen in Fig. 1. The 4-pyridyl complex **3d** has the highest symmetry and exhibits only two doublets, of which the higher-field one is attributed to H^3 and H^5, and the lower-field one to H^2 and H^6. Assignment of signals from pyridine ring protons in **2a** and **3a** was made by reference to **2d** and **3d**, respectively.

Table 4 lists the ^{13}C NMR data from complexes **1d**, **2d**, and **3d**. The methyl and methylene carbons of triethylphosphine resonate at about 8 and 15 ppm, respectively, and the latter signal appears as a triplet with J(C-P)=ca. 13 Hz, indicating the trans arrangement of the two phosphine ligands.[10] Assignment of the pyridine-ring carbons was made based on both the completely and selectively ^1H-decoupled studies as well as measurements without ^1H-decoupling.

Figure 2 shows the ^{13}C NMR spectra of **1d**, **2d**, and **3d** under ^1H-decoupled (A_1, B_1, and C_1) and nondecoupled (A_2, B_2, and C_2) conditions. The ^1J(C-H) values given therein were determined by spectral measurements without proton irradiation. The triplet signal at 179.7 ppm lacks in ^1H-coupling and assigned to C^2 in **1d**. All of the other signals for pyridine-ring carbons exhibit ^1H-coupling (A_2). Irradiation at the resonance frequency of H^6 (8.3 ppm) reduced only the doublet at 149.1 ppm to a singlet, which is then assigned to C^6. In a similar way the 117.5 ppm signal was attributed to C^5. The remaining two signals at 133.3 and 132.5 ppm are so close to each other that the spin-decoupling method is not applicable. However the triplet at 133.3 ppm is assigned to C^3 because of its coupling to ^{31}P, since the carbon atoms adjacent (ortho) to the quaternary carbon bonded to the metal in **2d** and **3d** showed coupling to ^{31}P (Fig. 2 and Table 4).

In a similar manner the $^{13}C\{^1H\}$ spectra of **2d** (B_1) and **3d** (C_1) in Fig. 2 were assigned to each pyridine-ring carbon. It is worth noting that the value of ^1J(C-H) decreases with the distance of the carbon from the nitrogen atom in the sequence of $^1J(C^2\text{-}H)>{}^1J(C^3\text{-}H)>{}^1J(C^4\text{-}H)$ and $^1J(C^6\text{-}H)>{}^1J(C^5\text{-}H)>{}^1J(C^4\text{-}H)$. This is analogous to the situation observed for free pyridine.[11] All of the spectral data obtained for **1d**, **2d**, and **3d** are consistent with their trans structures which were confirmed by X-ray analysis.[4]

Compared with the ^{13}C shieldings for uncoordinated pyridine carbons (C^2, 149.7; C^3, 123.6; C^4, 135.5 ppm),[12] ring carbons in **1d**, **2d**, and **3d** show the following tendency. (i) The carbon atom bonded to palladium shows a very large down-field shift of ca. 30 ppm. (ii) The carbon atoms adjacent to the quaternary carbon also shift to lower field by 6–10 ppm, appearing as triplets due to coupling to ^{31}P as does the metal-bonded carbon. (iii) Carbons at the meta position of the quaternary carbon suffer the least effect on coordination, showing up-field shift less than 3 ppm. (iv) Carbons at the para position of the quaternary carbon also experience up-field shift by about 6 ppm.

Substituent effect similar to (i) has been reported for monosubstituded benzenes[13,14] and pyridines,[12,15] showing that the quaternary carbon is susceptible

Table 2. Decomposition Temperatures and Some FIR Data

a) Data for uncoordinated pyridine from Ref. 10 and 11.

to the inductive, resonance, and anisotropic effects of the substituent.[16] However, variation in shielding for the present complexes is the highest among values reported so far. Thus the ^{13}C shieldings of the benzene-ring carbons in *trans*-$[Pt(C_6H_5)L(AsMe_3)_2]PF_6$ with various neutral ligands as L show a quite similar pattern to (i)—(iv) above,[17] but the extent of downfield shift for the carbon bonded to platinum is not so large as the present case.

The deshielding effect on the adjacent carbons (ii) may be attributed to the anisotropic effect by the palladium moiety rather than σ, π-inductive and resonance effects.[16,17] The $PtX(PEt_3)_2$ group with a variety of negative ligands as X, when bound to fluorobenzene, was said to be an electron donor in both the inductive and resonance senses.[6] On the other hand a bonding model was proposed for *trans*-$[Pt(C_6H_5)L(AsMe_3)_2]PF_6$ in which σ rather than π interactions are dominant in the phenyl-platinum bond,[17] whereas evidence was presented supporting the presence of significant π interactions between platinum and an aryl ligand in a series of complexes of the type *trans*-$[PtX(C_6H_5)(PEt_3)_2]$.[16] The effects (iii) and (iv) in the present case may be due to inductive and/or resonance effects of palladium.

The pyridine ring carbons in **2b** and **3b** except C^4 in **2b** resonate at lower fields than corresponding carbons in **2d** and **3d** (Table 4). These results may be related to the lower electron-donating ability of palladium in **2b** and **3b** than that in **2d** and **3d**, respectively, caused by lower basicity and higher π-acceptability of triphenylphosphine compared with triethylphosphine. Ring carbons of the triphenylphosphine ligands in **2b** resonate in a usual region, appearing as triplets except the para carbon in conformity with the proposed trans configuration. The chemical shifts and the coupling constants for carbons in the triphenylphoshine ligands in **3b** are very close to those for **2b** (Table 4).

pH Titration of the *trans*-Bromo(2-, 3-, and 4-pyridyl)bis(triethylphosphine)palladium(II) Complexes. Complexes **1d** and **2d** as well as pyridine are readily soluble in dioxane-water (1:1 by volume) adjusted to μ=0.1 with sodium perchlorate, and were titrated with perchloric acid. Complex **3d**, on the other hand, is enough soluble in dioxane-water only in the absence of sodium perchlorate and titration was carried out under these conditions to compare the basicity of **3d** with that of **1d** and **2d**. Titration curves at μ=0.1 are shown in Fig. 3. In a mixture of dioxane and water the reading of a pH meter is usually 0.10 higher than the true value of $-\log[H^+]$ in the whole range.[18] The pK_a values of the conjugate acids of **1d**, **2d**, and py were calculated to be 8.04, 5.47 and 4.47, respectively, by using corrected values of $[H^+]$. Thus the basicity of **1d** is ca. 3700 times higher than that of uncoordinated pyridine, indicating substantial charge donation from the $PdBr(PEt_3)_2$ moiety to nitrogen.

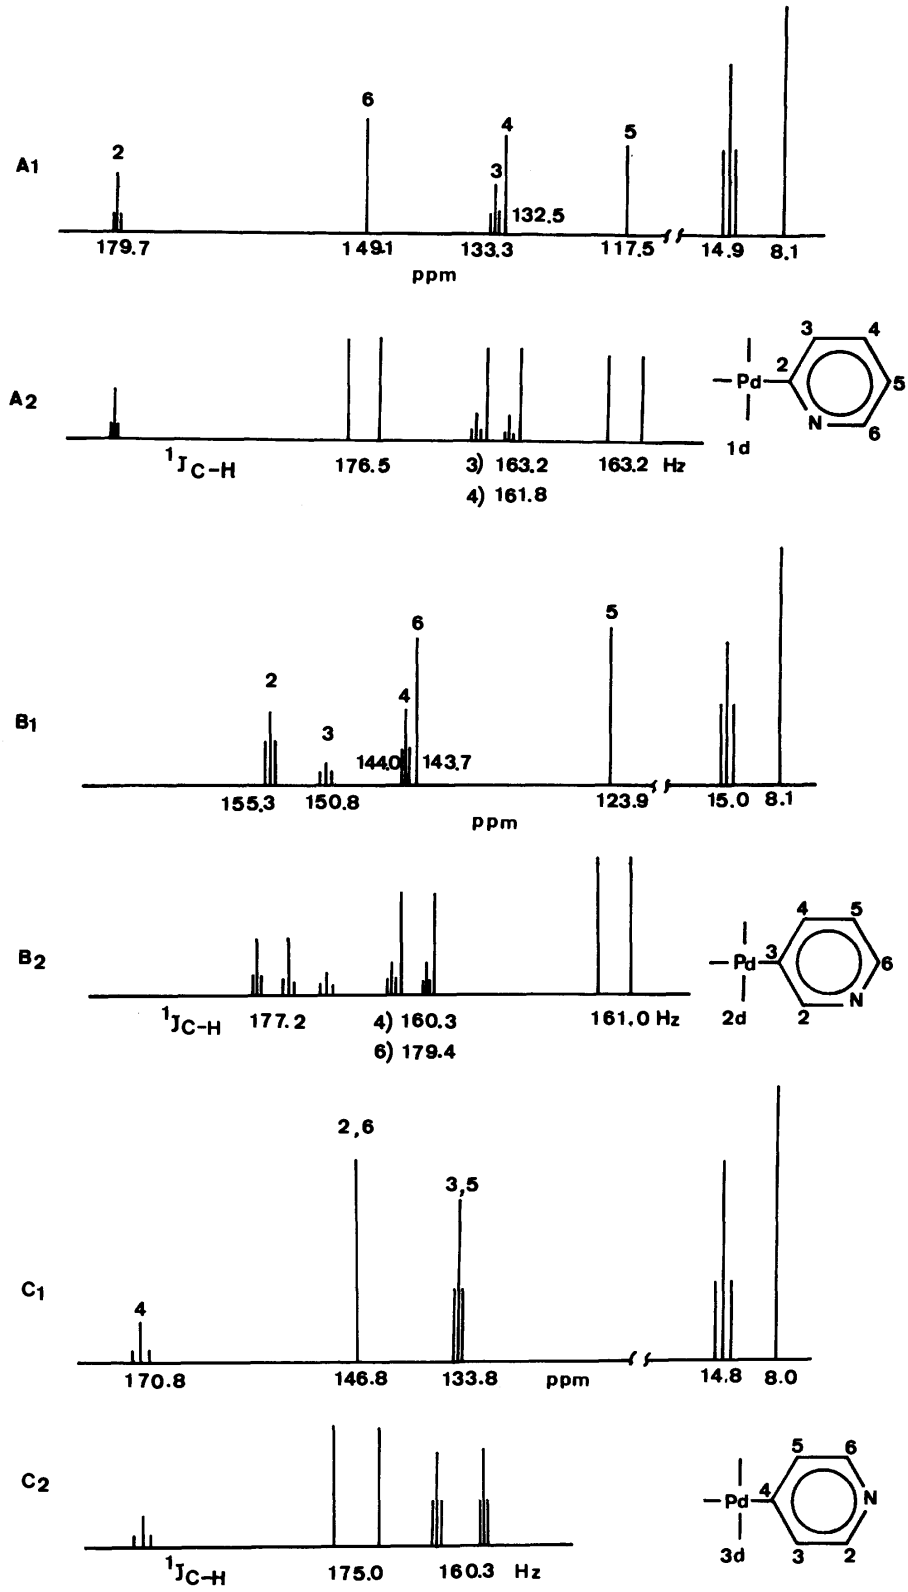

Fig. 2. ^{13}C NMR spectra at 25.0 MHz in $CDCl_3$ of *trans*-[PdBr(C_5H_4N-C^2, C^3, and C^4)(PEt_3)$_2$] (**1d**, **2d**, and **3d**, respectively) under ^1H-decoupled (A_1, B_1, and C_1) and nondecoupled (A_2, B_2, and C_2) conditions, the chemical shift being given in ppm from external Me_4Si and the ^1J(C–H) in Hz.

Titration in the absence of supporting electrolytes gave the pK_a values of 7.44, 5.01, and 5.38 to **1d**, **2d**, and **3d**. Thus the relative basicity is in the sequence of 2-pyridyl (**1d**)>4-pyridyl (**3d**)>3-pyridyl (**2d**).

The enhancement of basicity of pyridine by substitution with electron-donating groups such as CH_3 and NH_2 also depends upon the position attached on the ring and is in the sequence of 4>2>3.[19] The relative basicities of the present complexes do not follow this sequence and may not be rationalized only by simple inductive effect as applied to the methyl and amino substituents. The charge density donated by the $PdBr(PEt_3)_2$ substituent attached to C^2 seems not to be dissipated throughout the ring but to be accumulated at the adjacent nitrogen. The extraordinarily large ^3J(C-P) value of 7.3 at C^3 in **1d** as compared with ^3J(C-P) values for carbons adjacent to the quaternary carbons in **2d** and **3d** might be brought by a similar mechanism.

Johnson and Winterton[20] also found that the pK_a values of pyridinium salts with the $CH_2Co(CN)_5^{3-}$ substituent depend on the position of substitution, decreasing in the sequence of 2(10.6)>4(9.2)>3(8.3). In order to compare the bonding parameters and distribution of charge densities in **1d**, **2d**, and **3d**, X-ray analysis and MO calculations of these complexes have been carried out and the results were reported previously.[4]

Pyridylium Complexes. An equimolar amount of 2,4-dinitrophenol reacts with **1d**, **2d**, and **3d** to afford adducts **1e**, **2e**, and **3e**, respectively. Fig. 4 compares the IR bands related to the $\rangle C{=}\overset{+}{N}\langle_{H}$ group of these complexes and pyridinium 2,4-dinitrophenolate(A). The frequencies of vibration due to the iminium group in **1e** and **3e** are appreciably higher than those for **A** and **2e** which are comparable.

The NH^+ proton in these complexes resonates at substantially lower field than that of **A** does. When compared at a constant concentration of 0.409 mol dm^{-3}, the chemical shifts were 14.76, 13.14, 14.07, and 11.03 ppm for **1e**, **2e**, **3e**, and **A**, respectively, though they varied somewhat with concentration. (The OH proton of free 2,4-dinitrophenol resonates at 10.94 ppm.)

On adduct formation the pyridine-ring protons in the complexes show large down-field shifts (Table 3) and the phenol-ring protons do large up-field shifts compared with those in a free molecule (H^3, 9.06; H^5, 8.43; H^6, 7.34 ppm). The extent of variation is much larger than that for **A** in which the pyridine-ring protons resonate at 8.97 (H^2 and H^6), 7.36 (H^3 and H^5), and 7.78 (H^4) ppm, the phenol-ring protons appearing at 8.97 (H^3), 8.42 (H^5), and 7.31 (H^6) ppm. These IR and ^1H NMR evidences indicate that proton is more strongly interacting with nitrogen in these adducts than in **A** probably in the sequence of 2-pyridyl(**1e**)>4-pyridyl(**3e**)>3-pyridyl(**2e**)>**A**.

Pseudohalogeno Pyridyl Complexes. The pseudohalogeno 3- and 4-pyridyl complexes **2f—h** and **3f—h** were derived in high yields from **2b** and **3b**, respectivery, by ligand substitution with pseudohalides. Analytical and molecular-weight data in Table 1 as well as single ν(Pd-P) bands in the 420—435 cm^{-1} region (Table 5) indicate that these complexes have the trans mononuclear structure. Frequencies of the ν(CN) and ν(CS) vibrations observed for **2h** and **3h** indicate that each NCS ligand in these complexes is

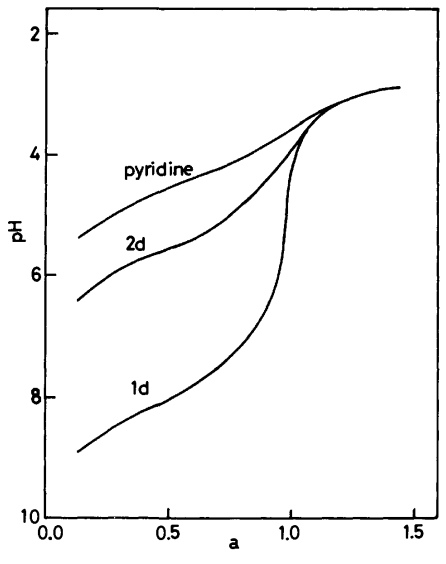

Fig. 3. pH Titration of *trans*-[PdBr(C_5H_4N-C^2 and C^3)$(PEt_3)_2$] (**1d** and **2d**, respectively) and pyridine with perchloric acid in dioxane-water (1 : 1 by volume) at 25.0 °C and μ=0.1 ($NaClO_4$) under nitrogen. The absissa gives the mole ratio of (acid added/complex): a.

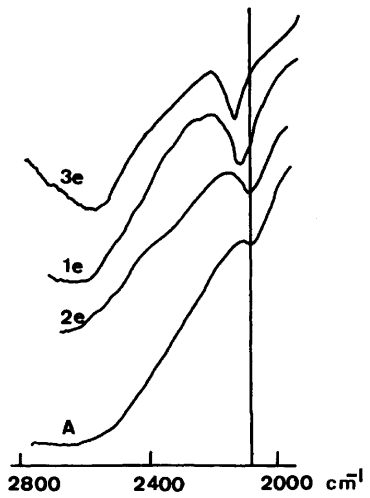

Fig. 4. IR spectra in the 2000—2800 cm^{-1} region of pyridinium 2,4-dinitrophenolate (**A**) and *trans*-[PdBr(C_5H_4NH-C^2, C^3, and C^4)$(PEt_3)_2$][2,4-$(NO_2)_2$-C_6H_3O (**1e**, **2e**, and **3e**, respectively) in Nujol.

Table 5. Characteristic IR in Nujol(cm^{-1}) for the Pseudohalogeno Complexes[a)]

Complex	ν(CN) or ν_a(NNN)	ν(CY) or ν_b(NNN)	δ(NCY) or δ(NNN)	ν(Pd-P)

3h	2080 vs	818 m	b)	423 m

a) Y=O or S. b) Indiscernible.

N-bonded.[21] Preliminary X-ray analysis has confirmed the proposed molecular structure of **2h** unequivocally.[22]

Similarly the ν(CN), ν(CO), and δ(NCO) frequencies for the cyanate ligand in **2g** and **3g** (Table 5) are in the range assigned to N-bonding.[21] In accordance with the fact that each of the pseudohalides in **2f—h** and **3f—h** is bound to palladium through the same donor atom, the chemical shifts of pyridine-ring protons in **2f—h** and **3f—h** completely coincide with each other, respectively, in the range of experimental error (Table 3).

The *trans*-Bromo(3- and 4-pyridylcarbonyl)bis(triphenylphosphine)palladium(II) Complexes. Complexes **2b** and **3b** reacted with carbon monoxide in THF at room temperature to give the insertion products **2i** and **3i**. The analytical and molecular-weight data in Table 1 as well as the single ν(Pd-P) band at 427 and 430 cm^{-1} for **2i** and **3i**, respectively, suggest that they are mononuclear complexes of trans structure. The ν(CO) bands are observed at 1642(**2i**) and 1644(**3i**) cm^{-1}, respectively. Both of these complexes readily reacted with methanol in the absence of base to produce methyl nicotinate (CH_3, 3.98 s; H^2, 9.20d; H^4, 8.20 m; H^5, 7.35 m; H^6, 8.85 m ppm) and isonicotinate (CH_3, 4.00 s; H^2, H^6, 8.80 d; H^3, H^5, 7.90 d ppm) in 48 and 54% yields, respectively. As was reported in a previous paper,[2a] $[PdBr(C_5H_3(6\text{-}Cl)N\text{-}C^2)(PPh_3)_2]$ is also carbonylated. It may be interesting from the standpoint of organic synthesis that one carbon unit can easily be added to any carbon of pyridine. It should also be noted that the corresponding triethylphosphine complexes **1d**, **2d**, and **3d** are not carbonylated. The Pd-C bonds in these complexes seem again to be more stable and/or more inert than those in the corresponding triphenylphosphine complexes.

Cross Coupling Reactions. Catalysis of the 2-pyridyl palladium(II) complexes on the cross coupling reactions of 2-chloro- and 2,6-dichloropyridines with methylmagnesium bromide was reported in a previous paper.[2a] Now one-hundredth molar amount of **2b** and **3b** were found to promote the reactions of 3- and 4-bromopyridines with methylmagnesium bromide in refluxing THF to give 3- and 4-methylpyridines in 12 and 6% yields, respectively, although the reactions did not occur at room temperature. Further improvement in yields may be desirable to make these catalytic reactions useful in organic synthesis.

We wish to thank Mr. Junichi Gohda for elemental analyses.

The Crystal and Molecular Structure of the Hydrated Light Lanthanoid(III) Chloroacetates, $[\{M(ClCH_2CO_2)_3\}_3(H_2O)_5]_n$, (M=La, Pr, Nd, and Eu)

Takashi Imai, Mamoru Shimoi, and Akira Ouchi*
Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153
(Received May 19, 1986)

The crystal and molecular structures of the hydrated lanthanum(III), neodymium(III), and europium(III) chloroacetates indicated in the title were determined by the single-crystal X-ray diffraction method; these three salts as well as the praseodymium(III) salt are apparently isomorphous. By the same synthetic technique, gadolinium(III) or heavier lanthanoid(III) did not give the isomorphous salts. Their crystals are monoclinic with the space group of $P2_1/c$, and the cell constants of the neodymium(III) salt, for example, are, a=14.805(4), b=18.765(4), c=14.403(5) Å, β=95.13(3)°. There are crystallographically independent three kinds of nine-coordinated metal atoms: Nd(1), Nd(2), and Nd(3). Among them, Nd(1) and Nd(2) are best approximated as being in a tricapped trigonal prism geometry. The Nd(3) is best regarded as being in a monocapped square-antiprism geometry, although one more additional oxygen atom, O(35), approaches one side face. In the lanthanum(III) complex, O(35) is thought to be ligated to La(3), while in the europium(III) complex O(35) is perfectly removed from Eu(III), being accompanied by a change in the coordination geometry of the ligand. In the crystal, the metal atoms are bridged by carboxylato ligands, forming polymeric chains approximately along [−110] or [110] axis. There are no carboxylato bridges between respective chains, although there are some hydrogen-bondings linking them with each other.

The variety of the coordinating structures of metal carboxylates, where the metal atoms are linked by the ligands, is one of the interesting thèmes of structural chemistry.[1] Especially, the lanthanoid(III) carboxylates are found to form many kinds of the chain structures where the carboxylate ions act as the bridges between the metal atoms.[2-9] Although the lanthanoid formate can make a two-dimensional polymeric structure,[10] the carboxylates generally form a dimer or a linear polymeric chain.[4]

In the case of cerium(III) acetate, it is in a polymeric form, where the respective pairs of the metal atoms, being nine-coordinated in a tricapped trigonal prism geometry, are bridged by three acetato ligands.[7] On the other hand, the holmium(III) acetate is in a dimer form, in which the metal atom is nine-coordinated, being bridged by two carboxylate ions.[6]

The neodymium(III) (methylthio)acetate has the nine-coordinated neodymium(III) atoms in the tricapped trigonal prism geometry, being bridged by two to four carboxylato ligands into a linear polymeric chain.[2] On the other hand, in the case of ytterbium(III) (methylthio)acetate, which is also in a linear polymeric form, respective pairs of side-by-side metal atoms are linked only with one carboxylate ion.[9]

From these results, we deduced that the size of the central metal ion as well as the substituted groups on the carboxylato ligands are the reasons for forming such a variety of the linkages in the polymeric structure.

This time, we have obtained the chloroacetates of a series of the lanthanoid elements, which were expected to have some characteristic structures. Moreover, the type of complexes indicated in the title could be obtained only for lanthanum(III) to europium(III), while gadolinium(III) and heavier lanthanoids did not give isomorphous complexes. Therefore, some effect of the central metal-ionic size to its structure is also expected to be found even in the series of the isomorphous complexes, as in cases of the tetraacetatolanthanoidates(III),[4] and of lanthanoid(III) *m*-hydroxybenzoates.[3] For these reasons, the authors have tried to determine the structures of the series of the complexes by the single-crystal X-ray diffraction method.

Experimental

Synthesis of Neodymium(III) Chloroacetate, $[\{Nd(ClCH_2CO_2)_3\}_3(H_2O)_5]$, and Its Isomorphous Complexes. Freshly obtained neodymium(III) hydroxide, by mixing solutions of neodymium(III) chloride hexahydrate (0.72 g, 2.0 mmol) and excess sodium hydroxide, was mixed with chloroacetic acid (0.57 g, 6.0 mmol). After stirring several minutes, the obtained aqueous solution was filtered and the filtrate was left standing for several days in a silica gel desiccator; care was taken that the solution did not become dry. The deposited crystals were filtered off and washed with a small portion of water. They were then dried in open air overnight and kept in a sealed bottle, where they remained stable. Yield: 0.55 g, 60%. Some additional lot, about 0.2 g, was obtained from the residual mother liquor, which almost had the same purity.

By applying the same synthetic technique, lanthanum(III), praseodymium(III), and europium(III) salts, which are apparently isomorphous with each other, were obtained almost in the same yield. Anal. ($M_3C_{18}H_{28}O_{23}Cl_9$) M, C, H. (where M=La, Pr, Nd, or Eu).

When this synthetic method was applied to obtain gadolinium(III) or heavier lanthanoid(III) salts, triclinic-type crystals were obtained instead. Chemical analyses

showed that they also include 5/3 molecules of water per one metal atom and are isomorphous with each other.

Although our synthetic results regarding the title complexes are reproducible, the compositions as well as the crystallographic data (obtained by the X-ray powder diffraction method) of the lanthanoid(III) chloroacetates shown in a reference,[11] did not agree with our results. Probably, the crystallizing conditions and, consequently, the number of the included water molecules of the salts were different from each other.

Single-Crystal X-Ray Analysis. From the crystallographic data obtained by the single-crystal X-ray diffraction method, the lanthanum(III), praseodymium(III), neodymium(III), and europium(III) chloroacetates indicated in the title are apparently isomorphous, although (as shown later) there are some discrepancies in their detailed structures. They are monoclinic with the space group $P2_1/c$, $Z=4$ (for the title formula; twelve metal atoms are included in one unit cell). Their crystallographic data are shown in Table 1 and some other experimental conditions are tabulated in Table 2. The reflections shown in Table 2 were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer with graphite monochromated Mo $K\alpha$ radiation (scan speed was 4° min^{-1} (θ)), the ω—2θ scan technique being employed.

Structure Determination. The structure of the neodymium(III) complex was solved by the heavy-atom method. The positions of the metal and some ligated oxygen atoms were deduced from a three-dimensional Patterson map, while all the other non-hydrogen atoms were located by means of successive Fourier syntheses and refined by the block-diagonal least-squares method. In the last cycle of the refinement with anisotropic temperature factors for all atoms, all the parameter shifts were less than one-third of the corresponding standard deviations. The structures of the isomorphous complexes were solved by starting with the final parameters of the neodymium(III) complex and were refined in the same way. All of their parameters converged in the same grade.

All the calculations were carried out on a HITAC M-280H apparatus at the Computer Center of the University of Tokyo, using the local version of the UNICS program.[12] The atomic scattering factors were taken from Ref. 13.

Infrared Spectrum Measurements. Their infrared spectra were obtained by means of a JASCO 202-A grating infrared spectrophotometer, using Nujol or hexachloro-1,3-butadiene mull.

Results and Discussion

The final atomic parameters of the complex are listed in Table 3 (1—3), while selected bond lengths and bond angles as well as some interatomic distances (which are thought to be the hydrogen-bonding types) are tabulated in Table 4.[14] A perspective drawings of the neodymium(III) complex around the metal atoms (Nd(1), Nd(2), and Nd(3)) as well as the numbering scheme of the atoms are shown in Figs. 1—3, and the crystal packing diagram in Fig. 4, respectively.

a) The equivalent isotropic temperature factors were computed using the following expression: $B_{eq}=4/3(B_{11}a^2+B_{22}b^2+B_{33}c^2+B_{13}ac\cos\beta)$. The B_{ij}'s are defined by: $T=\exp[-(h^2B_{11}+k^2B_{22}+l^2B_{33}+2klB_{23}+2hlB_{13}+2hkB_{12})]$.

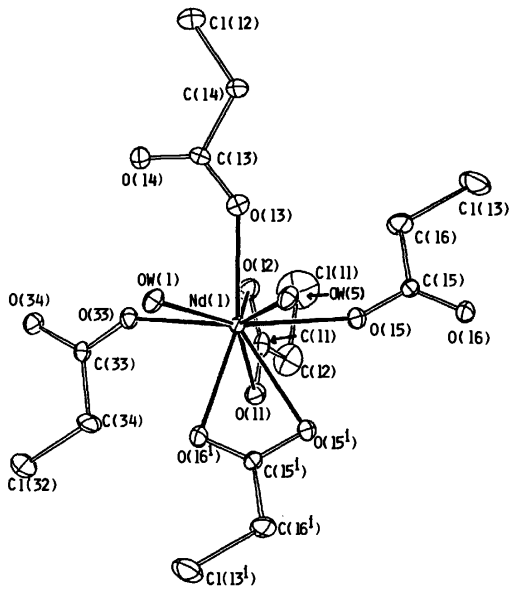

Fig. 1. A perspective drawing of the complex around Nd(1) atom with the numbering scheme of the atoms.

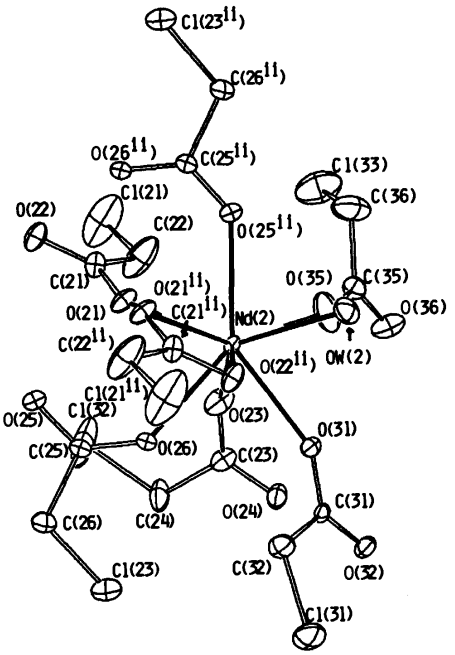

Fig. 2. A perspective drawing of the complex around Nd(2) atom with the numbering scheme of the atoms.

Schematic presentations to show the coordination geometries of the ligating atoms around the Nd(1), Nd(2), and Nd(3) atoms are shown in Figs. 5.1, 5.2, and 5.3. As shown in these figures, in the neodymium-(III) complex, Nd(1) and Nd(2) atoms are approximately in a tricapped trigonal prism geometry. The Nd(3) atom is regarded as being in a monocapped square-antiprism geometry,[15] however other than these nine oxygen atoms, another oxygen atom, O(35), also approaches the metal atom above one side face of the square-antiprism, Nd(3)···O(35)=3.009(8) Å, although the distance is much longer than the other Nd-O bond lengths of this complex.[15]

As shown in Table 5, the average of eighteen Nd-O bond lengths around the Nd(1) and Nd(2) atoms is 2.493 Å, while that of nine Nd-O bond lengths around the Nd(3) atom is 2.553 Å. The former is about the same as the sum of the radii of the tervalent Nd (Coordination number (CN)=9) and O (Valence (Val)=2−, CN=2) ions, 2.51 Å;[16] however the latter is too long. It is rather near to the sum of the Nd(CN=10) and O ions, 2.56 Å (see the footnote g of Table 5). Concerning their lengths, the Nd-O bonds around the Nd(3) atom are like those of ten-coordination. This fact is probably because the O(35) atom, which is not very far from the coordination area around the metal atom, giving some steric hindrance effect to the other coordinated ligands.

The respective Nd-O bond lengths around the Nd(1) or Nd(2), and Nd(3) atoms are distributed in the ranges shown in Table 5 by the ratios of the maximum and minimum values to the average lengths, respectively. In the high-coordination-number geometries, such a discrepancy regarding the respective M-O bond lengths around one metal atom is sometimes found.

The coordinating carboxylate ions found in the neodymium(III) complex are classified into three groups, depending on their forms (as previously shown in Ref. 4). The **A**-, **B**-, and **C**-type ions (as

follows) are schematically given in Fig. 6.

(**A**) Chelating ion: The ion **11**,[17] belongs to this group. Its COM and CO'M angles are 93.5(3) and 93.4(5)°, which are normal (in the range of 90—95°) for this group ions.[4]

(**B**) *Z,Z*-Type bridging bidentate ions: (*syn-syn* type bridge according to the classification by Chatteric.[18]) The ions **12**, **22**, and **23** belong to this group. In the standard form of this type ion, 2(M-O')/(M-O+M'-O') is about 1.6—1.7, the angles MO'C and M'OC, and COM and CO'M' are about 60 and 135—150°, respectively. The bond lengths and angles of these ions are found to be in the normal ranges, respectively, although C(23)-O(24)-Nd(3) is an exception (123.3(5)°).

(**C**) Tridentate-type bridging ions: (One oxygen atom of a carboxylato chelate around a metal atom is also bonded to another metal atom, consequently as a whole the ligand acts as a tridentate.) Ions **21**, **13**, **31**, **32**, and **33** are the members. In the typical form, the bond lengths (M-O, M-O', and M'-O') as well as the bond angles (MOC and MO'C, about 90—100°) are about the same, respectively, and the angle M'O'C is in the range 140—150°. Bonds O'-M' and C-O are at the opposite sides of the C-O' bond from each other. As previously shown,[4] many of the actually found ligands of this type are deformed from the ideal shape. When it deforms, the M-O' length as well as the COM angle increase, while the CO'M angle decreases. In this complex, the type of ligands deforms approximately in the given order. Their bond lengths and bond angles are compared with each other in Table 6, where the corresponding data regarding those of the lanthanum(III) and europium(III) complexes are also shown. As shown in the Table, for ion **21** of the neodymium(III) complex (which is almost in the standard form) the M-O' length is not much different from that of M-O and M'-O' and angles MOC and MO'C are within the normal range. On the other hand, in cases of the other deformed ligands, the bond lengths and bond angles deviate as mentioned above. The deformation in the form of the tridentate-type ligand is thought to tend toward the *Z,E*-type bidentate one (where M-O and C-O' bonds are at the same side of the C-O bond, while M'-O' and C-O bonds are at the opposite sides of the C-O' bond from each other, respectively). Angles COM and CO'M' are in the range 140—145° (CO'M is about 60°) and M-O' length is about 1.6- to 1.7-times the average of the M-O and M'-O' lengths in standard *Z,E*-type bidentate ion.[4] Therefore, even the most deviated ion, **33**, of the neodymium(III) complex is far from the normal *Z,E*-type bidentate.

The coordination type of the respective carboxylate ions, their bridging positions as well as the number of the intermetallic bridges are schematically shown in Fig. 7. As shown in this figure, the pairs of the

b) The sum of the Shannon's ionic radii.[16] The valence of the central metal is 3+, and its coordination number *n* is shown by CN=*n*. c) Average of the 18 M-O bond lengths around M(1) and M(2) atoms. d) Average of written numbers of the M-O bond lengths around M(3) atom. (In the case of 9, M(3)-O(35) one is rejected.) e) The shortest (shown by min) or the longest (shown by max) M-O bond length around the M(1) and M(2) atoms is divided by the average of all the M-O bond lengths around the metal atoms. f) The written bond length is divided by the average M-O bond length around M(3) atom, where "av(M(3), 9)" means the average of nine M-O bond lengths excluding M(3)-O(35), while "av(M(3), 10)" that of all ten bond lengths around the metal atom. g) As Shannon did not give the ionic radii of neodymium(III) and europium(III) in ten-coordination, the values 0.05 Å longer than the corresponding nine-coordination radii are tentatively adopted.

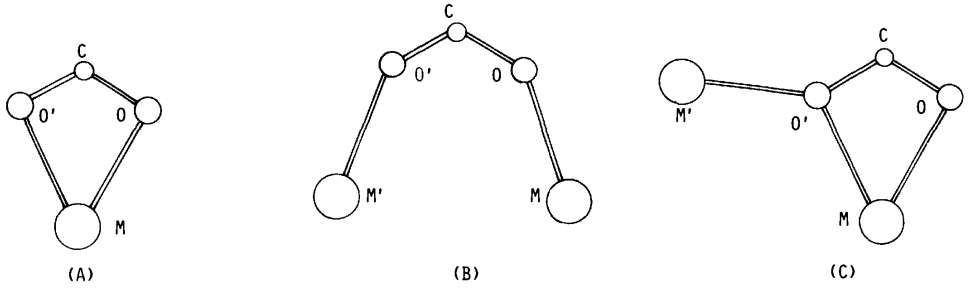

Fig. 6. Schematic presentation of the three types of ligands.

neodymium(III) atoms, Nd(1^{i}) and Nd(1), Nd(1) and Nd(3), Nd(3) and Nd(2), and Nd(2) and Nd(2^{ii}) (where the key to the symmetry operations: i, $1-x$, $-y$, $-z$; ii, $-x$, $1-y$, $-z$) are bridged by: two **C**-type ions; one **B**-and one **C**-type ion; one **B**-, one **C**- and one extremely deformed **C**-type ion; and two **B**- and two **C**-type ions, respectively. The respective inter-metal-atomic distances are: 4.315(1), 4.764(1), 4.352(1), and 4.060(1) Å. Therefore, judging from these data, the effect of a **C**-type bridge to shorten the intermetallic distance is greater than that of a **B**-type bridge.

Thus, the metal atoms in the complex are arranged in the order of ···Nd(1^{i})···Nd(1)···Nd(3)···Nd(2)···Nd(2^{ii})···, approximately along [−110] axis, although in a zig-zag way. The next chain on the *z*-axis direction, ···Nd(1^{iv})···Nd(1^{iii})···Nd(3^{iii})···Nd(2^{iii})···Nd(2^{v})···, (where the key to the symmetry operations: iii, x, $0.5-y$, $0.5+z$; iv $1-x$ $0.5+y$, $0.5-z$; v, $-x$, $-0.5+y$, $0.5-z$), is laid along [110] axis. Thus, the polymeric chains along both axes are aligned alternately. Between these side-by-side chains, no coordinated carboxylato bridges are found, though some hydrogen bondings are expected to exist (as shown by some interatomic distances in Table 4).

The structures of the lanthanum(III) and europium-(III) complexes resemble that of the neodymium(III) complex. However, there are some differences between them (mentioned below) regarding their detailed structures.

In the lanthanum(III) complex, an average of eighteen La-O bond lengths around the La(1) and La(2) atoms is 2.549 Å; this is slightly shorter than the

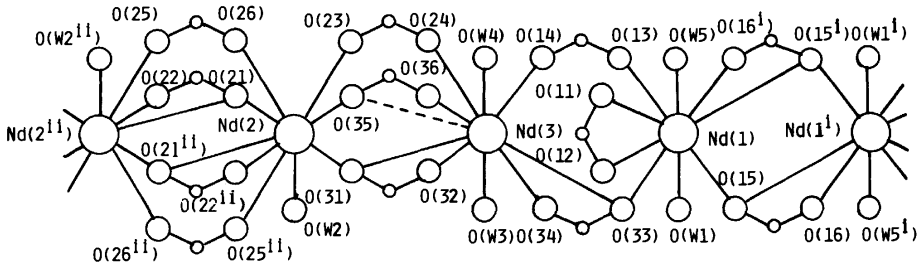

Fig. 7. Schematic presentation of the bridgings between the metal atoms. (Key to the symmetric operations: i, $1.0-x$, $-y$, $-z$; ii, $-x$, $1.0-y$, $-z$).

h) The nominations of the atoms shown in this Table are the same as those of Fig. 6(C).

sum of the tervalent La(CN=9) and O ionic radii, 2.57 Å.[16] The average of ten La–O bond lengths, including La(3)–O(35), around the La(3) atom is 2.638 Å; this is almost the same as the sum of the tervalent La(CN=10) and O ionic radii, 2.62 Å[16] (the average of nine La–O lengths, excluding La(3)–O(35), is 2.612 Å, which is not much different from the latter sum, too).

The corresponding La–O bonds, except La(3)–O(35), are all longer than the respective Nd–O bonds; the differences between them are in the range of 0.028—0.068 Å around the M(1) and M(2) atoms, and 0.017—0.082 Å around the M(3) atom. The relatively long La(3)–O(35) distance is, on the contrary, 0.137 Å shorter than that of the neodymium(III) complex. Even other than this bond, La(1^{i})–O(15), La(3)–O(31), and La(3)–O(33), which are relatively long, are also not very elongated when the central metal atom is changed from neodymium(III) to lanthanum(III). Consequently, the range between the shortest and the longest M–O bond lengths of the lanthanum(III) complex is widened in the neodymium(III) complex (Table 5).

Table 6 gives a comparison of the respective tridentate-type ions of the neodymium(III) complex with the corresponding ones of lanthanum(III) complex; the deviations from the ideal values of the relative M–O′ lengths, and of the MOC as well as MO′C angles are a little greater in the neodymium(III) complex.

As the ionic radius of the neodymium(III) is shorter than that of lanthanum(III), due to the lanthanoid contraction effect, the spherical area around the neodymium(III) atom to be occupied by the ligating atoms is smaller than that of the lanthanum(III) ion. Therefore, in the neodymium (III) complex, there are more steric interactions between the ligating atoms and between the ligand molecules. These steric hindrance effects work unequally on the respective ligands. Consequently, the respective M–O bond lengths do not decrease equally, and the M–O bond lengths of the neodymium(III) complex disperse over a wider range.

Of course, even in the lanthanum(III) complex, as the restrictions such as the bonding directions of the respective ligating atoms, and the definite distance between each pair of the oxygen atoms of the same ligand still remain, the discrepancy of the respective La–O bond lengths and the deformation of the coordination geometries around the respective metal atoms are also found.

Although the disproportional changes of several M–O bond lengths are found when the central metal atom of the lanthanum(III) complex is substituted by the neodymium(III) atom; no change of the bonding type of the ligands is found. This kind of the unequal bond-length change in a series of the isomorphous complexes was also reported in a series of guanidinium tetraacetatolanthanoidates(III).[4]

In the europium(III) complex, an average eighteen Eu–O bond lengths around the Eu(1) and Eu(2) atoms is 2.462 Å; this is about the same as the sum of the tervalent Eu(CN=9) and O ionic radii: 2.47 Å.[16] However, the differences between the respective Eu–O and the corresponding Nd–O bond lengths distribute over a wider range than those between the Nd–O and La–O lengths: 0.079—−0.019 Å (negative value means that the Eu–O is longer). The relatively long Nd–O bonds, such as Nd(1^{i})–O(15) and Nd(2^{ii})–O(25), are rather elongated in the europium(III) complex. On the other hand, some M–O bonds other than the elongated type of the same ligand are greatly shortened: M(1^{i})–O(16) and M(2)–O(21) are the examples.

The Eu(3) atom is regarded as being nine-coordinated. The average of the nine Eu–O bond lengths around it is 2.476 Å; this is about the same as the sum of the radii of tervalent Eu(CN=9) and O ions. No such discrepancy, as was found in the lanthanum(III) or the neodymium(III) complexes, was recognized. From this aspect, the Eu(3) atom is in pure nine-coordination geometry. Around the Eu(3) atom, except Eu(3)–O(35), all the Eu–O lengths are shorter than the corresponding Nd–O lengths of the neodymium(III) complex by 0.002 to 0.261 Å.

The general tendency of the change of the M–O bond lengths around the Eu(3) atom is about the same as that around the Eu(1) and Eu(2) atoms, although in more drastic way. The distance Eu(3)···O(35) is 0.969 Å longer than that of the neodymium(III) complex; consequently the O(35) atom of the europium(III) complex is perfectly out of the bonding distance. Moreover, it is thought to be even out of the sterically affecting region around the metal atom. On the other hand, the bond Eu(3)–O(36) is extremely short, 2.285(9) Å, although almost the same short Nd–O bond (2.312(10) Å) was already found in another polymeric-type carboxylato complex of neodymium(III).[2] Such disproportional changes of the M–O bond lengths of the same ligands are also found in ions **31**, and **32**. As shown in Table 4 (compared with the corresponding ions of the neodymium(III) complex), in the ion **31** the shorter bond is very shortened, while the longer one is shortened only a little, in the europium(III) complex. On the other hand, in the ion **32** the longer bond is more shortened.

According to the data shown in Table 6, four tridentate-type ions (except **33**) of the europium(III) complex are found to be in the forms approximately the same as the corresponding ones of the neodymium-(III) or lanthanum(III) complexes; the grade of their deviations from the respective values of the standard types are not much different from those of the former two complexes.

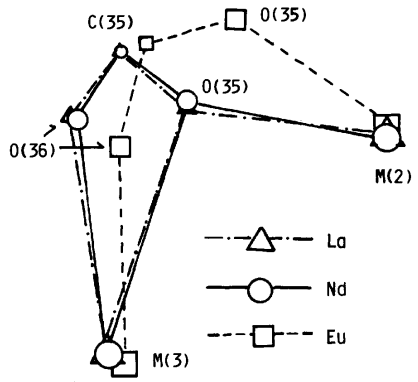

Fig. 8. The projection of **33** and the bonded metal atoms of the complexes to the (001) plane. The origin of the unit cell, the a-axis, and the scaling in length are taken commonly.

On the other hand (as shown in Fig. 8) in ion **33** of the europium(III) complex, bonds O(35)-Eu(2) and O(36)-C(35) are at the same side of bond C(35)-O(35) (*Z*-type), while the corresponding bonds of the neodymium(III) and lanthanum(III) complexes are at the opposite sides of the C(35)-O(35) bond from each other (*E*-type). As shown in Table 6, in the europium(III) complex, the bond length ratio 2(M-O')/(M-O+M'-O'), and the bond angles C(35)-O(36)-Eu(3) (COM) and C(35)-O(35)-Eu(2) (CO'M') are in the respective standard ranges of the *Z,Z*-type ion, while in those of the other two complexes the values are in the range of the tridentate-type ion, although they are a little deviated.

Thus, in the europium(III) complex, there are not only the unequal change of the respective M-O bond lengths, but also the change of the type of the coordinating ligand, depending on the change of the atomic number (i.e., the ionic size of the central metal atom). This is the first example of this kind of the discrepancy of the structure in the series of the apparently isomorphous lanthanoid complexes.

Such change of the M-O bond lengths in the complex of the smaller size metal causes some stress on the coordination geometry around the metal atom; also, the degree of the stress should affect the stability of the complex. As a result, in an europium(III) complex, the modification of the ligand form also took place, although its apparent crystal system did not change yet.

The infrared spectra of the series of the complexes were examined, and we found continuous changes in the intensities of the ν_{as}(COO) peaks as well as of the splitting of the ν_s(COO) band, depending on the increase of the metal atomic number.

The main peak of the ν_{as}(COO) band of lanthanum(III) and praseodymium(III) complexes appeared at about 1580 cm^{-1}, together with small shoulders at about 1565 and 1605 cm^{-1}, while in the neodymium(III) complex, both of the 1565 and 1580 cm^{-1} peaks were dominant (former one is stronger). On the other hand, in the europium(III) complex, only the 1565 cm^{-1} peak was dominant together with a new small peak at 1650 cm^{-1}; no shoulders could be recognized at 1580 and 1605 cm^{-1}.

The ν_s(COO) band of the lanthanum(III) and praseodymium(III) complexes appears at 1415 cm^{-1} as a broad peak, while in the neodymium(III) and europium(III) complexes, the peak splits clearly into three equal height ones at 1396, 1420, and 1440 cm^{-1}.

Although at present, it is impossible to assign these peaks exactly, at least we can deduce that there are some changes in the bonding modes (not only the continuous change of bond strengths) of the carboxylate ions. This depends on the increase in the atomic number of the central metal atom; this fact may correspond with the X-ray analysis results mentioned above.

The authors wish to thank Shin-Etsu Chemical Ind. Co. Ltd., for presenting us with the highly pure lanthanoid oxides.

15) Although in many papers each coordination geometry (where the coordination number is higher than 7) around the lanthanoid or such heavy metal atom is approximated to some type, generally it is only an approximation and it is deformed from the ideal shape. Some other geometry may also be applicable in place of the written one. In the title complex, for the geometry of Nd(1) and Nd(2) atoms, the tricapped trigonal-prism is thought to be the best approximation, although they are deformed. When the geometry is assumed as schematically shown in Fig. 5 as 5.1 and 5.2, the dihedral angles between the side rectangulars are within the range of 55.8 to 63.5°, while those between the planes of the both end triangles and of the side rectangulars are within the range of 77.4 to 99.2°. The dihedral angles between two end triangle planes are 21.2 and 17.0°. Around the Nd(3) atom, if the O(33) and O(35) atoms are rejected, the coordination geometry of the metal atom is regarded as a deformed dodecahedron, where the atoms [O(32), O(34), O(W4), and O(36)] and [O(24), O(31), O(14), and O(W3)] are on the apexes of the both trapezia, respectively. Moreover, if only the O(35) is rejected, a tricapped trigonal-prism geometry can be adopted, where both end triangles are [O(36), O(W3), and O(14)] and [O(24), O(32), and O(34)], while O(W4), O(33), and O(31) are capped above the respective faces.

However, as the O(35) atom only in the lanthanum(III) complex is not very far from the metal atom (compared with the other ligated oxygen atoms), it is preferable to adopt a common structure available to all three complexes which includes the O(35) atom. In the two above-mentioned geometries, we cannot give any reasonable position around the assumed polyhedron to the O(35) atom. On the other hand, if we assume the *cis*-bicapped square-antiprism geometry around the M(3) atom, we can consider it reasonable as a cap above one side face, although the geometry is deformed to some grade. Moreover, as the monocapped square-antiprism is a more common geometry, we can imagine an additional capping atom above a side face, O(35), is less strongly ligated.

16) R. D. Shannon, *Acta Crystallogr., Sect. A*, **32**, 751 (1976). The presented ionic radii are as follows (the valence of the metals is 3+, and of oxygen ion 2−; the coordination numbers of the metal ions (8, 9, or 10) are shown by the respective numbers (unit is in *l*/Å): r_{La}, 8=1.160, 9=1.216, 10=1.27 Å; r_{Nd}, 8=1.109, 9=1.163 Å; r_{Eu}, 8=1.066, 9=1.120 Å; r_O, 2=1.35 Å.

17) Hereafter, each carboxylate ion is numbered according to that of the chlorine atom in it; ions ***n*1**, ***n*2**, and ***n*3** (where ***n***=1, 2, and 3) include the carboxylato group atoms of C(n1), O(n1), O(n2); C(n3), O(n3), O(n4); and C(n5), O(n5), O(n6), respectively.

The Crystal and Molecular Structure of Heavy Lanthanoid(III) Chloroacetates in the Hydrated Form, $[M_3(ClCH_2CO_2)_9(H_2O)_4]_n \cdot nH_2O$ (M=Gd, Dy, Er, and Yb)

Yoshihiko SUGITA and Akira OUCHI*
Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153
(Received July 21, 1986)

The crystal and molecular structures of the chloroacetato complexes of gadolinium(III), erbium(III), and ytterbium(III) indicated in the title were determined by the single-crystal X-ray diffraction method. In addition to these three complexes, the isomorphous dysprosium(III) salt was also obtained. Their chemical composition, $M_3L_9 \cdot 5H_2O$ (where M=Gd, Dy, Er, or Yb; HL=chloroacetic acid), is the same as that of the light lanthanoid(III) (La—Eu) chloroacetates, though the latter crystals are monoclinic. The cell constants of the ytterbium(III) salt, for example, are: triclinic, space group $P\bar{1}$, a=13.278(10), b=13.624(6), c=12.067(4) Å α=96.62(3), β=100.68(5), γ=67.40(4)°, Z=2 (including 6 metal atoms). There are three kinds of crystallographically independent metal atoms; Yb(1), Yb(2), and Yb(3): Yb(1) and Yb(2) are octa-coordinated (square-antiprism geometry) and Yb(3) is ennea-coordinated (monocapped square-antiprism geometry). Two oxygen atoms around the last type of the metal atom are the more separated in the higher atomic-number lanthanoid(III) complex, while the other M-O bond lengths decrease, depending on the increase of the metal atomic number. The metal atoms are bridged by carboxylate ions in a chair form along the [111] axis, though in a way different from that of the light lanthanoid(III) complexes.

The variety of the coordination geometries of the central metal atom as well as the carboxylate ions in the lanthanoid carboxylate complexes are one of the interesting thème of structural chemistry.[1] Among them, chloroacetates of light lanthanoid(III) (La through Eu) were found to have a complicated linear polymeric structure bridged by carboxylate ions.[2]

Using the same synthetic technique, the chloroacetates of heavy lanthanoid(III) (Gd through Yb) in the hydrated form were obtained. From a preliminary check of their single crystals by the X-ray diffraction method, they were found to be isomorphous with each other since their cell constants resemble each other. However, their crystal system is triclinic, not monoclinic like that of the light lanthanoid(III) salts, though the results of their chemical analyses show that the heavy and light lanthanoid(III) chloroacetates have the same chemical composition: $ML_3 \cdot 5/3\ H_2O$ (where M=Gd, Dy, Er, or Yb, as well as La, Pr, Nd, or Eu; HL=chloroacetic acid).[2]

It was recognized in many other cases that the crystals of the complexes of the heavy and light lanthanoids(III) are different from each other, even when the used synthetic technique is the same. For example, in the case of acetates, the cerium(III) salt is in a linear polymeric structure, while the holmium-(III) salt is in a dimer form.[3,4] In cases of the Lewis base (L') adducts of tris(O,O'-dialkyl dithiophosphato)lanthanoid(III) ($Ln(R_2dtp)_3$), light and heavy lanthanoids(III) gave $[Ln(R_2dtp)_3L'_2]$ and $[Ln(R_2dtp)_2L'_3][R_2dtp]$ type complexes, respectively. The border of both series of complexes exists between praseodymium and neodymium in the case of the triphenylphosphine oxide adducts,[5] and at gadolinium in the case of the benzamide adducts (both types of adducts were obtained for gadolinium).[6,7]

Therefore, it is interesting to examine the difference in the structures between the light and heavy lanthanoid(III) complexes of the same ligand; we have determined the crystal and molecular structures of the latter complexes by the X-ray diffraction technique using their single crystals.

Experimental

Synthesis of Ytterbium(III) Chloroacetate, $[Yb_3(ClCH_2CO_2)_9(H_2O)_4] \cdot H_2O$, and Its Isomorphous Complexes. The synthetic technique is about the same as that for the neodymium(III) salt.[2] Ytterbium(III) hydroxide was obtained by mixing aqueous solutions of ytterbium(III) chloride (obtained by dissolving ytterbium(III) oxide (Yb_2O_3, 0.39 g, 1.0 mmol) in excess of hydrochloric acid), and of excess sodium hydroxide. After the ytterbium hydroxide and chloroacetic acid (0.57 g, 6.0 mmol) were mixed and stirred for several minutes, the obtained solution was filtered and the filtrate was left standing in a silica gel desiccator for several days. About two-thirds of the water was removed and crystals were deposited. They were first separated and dried in the open air overnight and then kept in a sealed glass bottle. They were stable there at least for several months. Yield: 0.75 g, 78%.

Applying the same technique, gadolinium(III), dysprosium(III), and erbium(III) salts, which were isomorphous with each other, were obtained in about the same yield. Anal. ($M_3L_9 \cdot 5H_2O = M_3C_{18}H_{28}O_{23}Cl_9$), M, C, H (where M=Gd, Dy, Er, or Yb).

It was reported that the number of water molecules in the lanthanoid chloroacetates $ML_3 \cdot n'H_2O$ were: n'=4 for the Ho salt, 5 for the Er salt, and 3 for the Tm, Yb and Lu salts.[8] However, according to our synthetic method, only one type of crystal, $M_3L_9 \cdot 5H_2O$, could be obtained for the heavy lanthanoids(III).

Single-Crystal X-Ray Analysis. The crystals used for the analysis were obtained by the above-mentioned syntheses. From the crystallographic data obtained by the single-

crystal X-ray diffraction technique, the four above-mentioned chloroacetates were all found to be isomorphous with each other. They are triclinic with the space group of $P\bar{1}$, Z=2 (for the title formula with n=1; six metal atoms are included in a unit cell).

Their crystallographic data are given in Table 1 and some experimental conditions to obtain the intensity data are tabulated in Table 2. The reflections were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer with graphite monochromated Mo $K\alpha$ radiation (the scan speed was 4° min^{-1} (θ)), using the ω—2θ scan technique.

Structure Determination. The structure of the ytterbium(III) complex was solved by the heavy-atom method. The positions of the metal and some oxygen atoms were deduced from a three-dimensional Patterson map; the other non-hydrogen atoms were located successively by repeated Fourier syntheses. Their positional, isotropic and then anisotropic thermal parameters were refined by a block-diagonal least-squares method. At the last cycle of the refinement with anisotropic temperature factors for all non-hydrogen atoms, all the parameter shifts were less than one-third of the corresponding standard deviations. The structures of the isomorphous complexes were solved starting with the final parameters of the ytterbium(III) complex, and were refined in the same way. All the hydrogen atoms were fixed at the calculated positions assuming their C-H bond lengths to be 1.08 Å and their B_{iso}'s to be 8.0.

As shown in Table 3, the temperature factors of Cl(22), Cl(31), Cl(32), and Cl(33) atoms of all the complexes are large, and the apparent bond lengths of their C(36)-Cl(33) are a little too short. Attempts to determine the disorders of these atoms (i.e., to divide each atomic position into two with respective appropriate occupancy factors for them) were not successful; all the trials did not give any improvement to their temperature factors and to their R value. It is likely that these atoms are distributed in a wide region around the most probable position. Thus, these chlorine atoms as well as some carbon atoms of the ligands which take their positions far from the central metal atom are not well fixed; such position ambiguity regarding some ligand atoms was often encountered in structure determinations of some lanthanoid(III) complexes.[2,6,7,9-11]

All the calculations were carried out on a HITAC M-680H at the Computer Center of the University of Tokyo using a local version of the UNICS program.[12] The atomic scattering factors were taken from Ref. 13.

Infrared Spectrum Measurements. Their infrared spectra were obtained by means of a JASCO 202A grating infrared spectrophotometer using Nujol and hexachloro-1,3-butadiene mull.

Results and Discussion

The final atomic parameters and their equivalent thermal parameters of the complexes are listed in

a) The equivalent isotropic temperature factors were computed using the following expression: $B_{eq}=4/3(B_{11}a^2+B_{22}b^2+B_{33}c^2+B_{12}ab\cos\gamma+B_{13}ac\cos\beta+B_{23}bc\cos\alpha)$. The B_{ij}'s are defined by: $T=\exp[-(h^2B_{11}+k^2B_{22}+l^2B_{33}+2hlB_{23}+2hlB_{13}+2hkB_{12})]$.

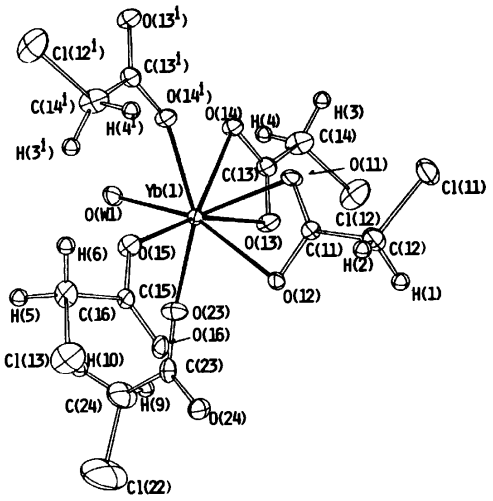

Fig. 1. A perspective drawing of the complex around Yb(1).[15]

Table 3 (3.1—3.3), while selected bond lengths and angles are given in Table 4.[14] Perspective drawings of the ytterbium(III) complex around the metal atoms (Yb(1), Yb(2), and Yb(3)) as well as the numbering scheme of the atoms are shown in Figs. 1—3 and the crystal packing diagram in Fig. 4, respectively.

Schematic presentations of the coordination geometries of the ligating atoms around the Yb(1), Yb(2), and Yb(3) atoms are shown in Fig. 5 (5.1—5.3), respectively.

The structures of these complexes are completely different from those of the light lanthanoid(III) complexes, as mentioned in the following paragraph.

In these complexes, one water oxygen atom is not coordinated to any metal atoms, though all of the water molecules are coordinated in the light lanthanoid(III) salts. The coordination numbers of the metal atoms of the title complexes are smaller than those of the light lanthanoid(III) ones; there are two octa- and one ennea-coordinated metal atoms in the former complexes, while two ennea- and one deca- (or ennea-) coordinated metal atoms in the latter complexes.

The Yb(1) and Yb(2) atoms are octa-coordinated (square-antiprism geometry) while the Yb(3) atom is ennea-coordinated (monocapped square-antiprism geo-

metry). Table 4 compares the gadolinium(III), erbium(III), and ytterbium(III) complexes with each other. It can be seen that the respective M–O bond lengths, except for M(3)–O(31), and M(3)–O(33^{ii}),[15] decrease in the order of the metal atomic number, due to a decrease in the metal atomic radius.

The observed lengths of the M–O bonds of these complexes are distributed relatively over a wide range; no clear difference between the lengths to the carboxylato oxygen and to the water oxygen atoms could be found. The average M–O bond lengths around M(1) and M(2) atoms are 2.397(2.246–2.572), 2.343(2.186—2.529), and 2.325(2.174—2.516) Å for the gadolinium, erbium, and ytterbium complexes, respectively. These are comparable to the respective sums of Shannon's ionic radii of the metals (Valence(Val)=3+, Coordination number(CN)=8) and oxygen (Val=2−, CN=2); the calculated M–O bond lengths, where M=Gd, Er, and Yb, are 2.40, 2.35, and 2.34 Å in the order.[16]

The average of the nine M–O bond lengths around the M(3) atom is 2.471(2.273—2.802), 2.426(2.221—2.853), and 2.419(2.206—2.897) Å, for the gadolinium, erbium, and ytterbium complexes, respectively. These

(5.1) (5.2) (5.3)

Fig. 5. Schematic presentation of the complex with the numbering scheme of the ligated oxygen atoms: 5.1, 5.2, and 5.3 show the coordination geometries around Yb(1), Yb(2), and Yb(3) atoms, respectively.[15]

are slightly longer than the respective sums of the ionic radii of metal(Val=3+, CN=9) and oxygen; the calculated M–O bond lengths, where M=Gd, Er, and Yb, are 2.46, 2.41, and 2.39 Å.[16] Except for the two long bonds, M(3)–O(31) and M(3)–O(33^{ii}), the average lengths of the other seven M–O bonds around the M(3) atom are 2.394, 2.337, and 2.318 Å, respectively, for the three complexes. These are much longer than the respective sums of the ionic radii of the metal (Val=3+, CN=7) and oxygen; 2.35, 2.295, and 2.275 Å for M=Gd, Er, and Yb. Consequently, around the M(3) atom, it is better to adopt the ennea-coordination geometry.

In the series of lanthanoid(III) elements, its ionic radius decreases depending on the increase of their atomic number due to the lanthanoid contraction effect. Therefore, the coordination area to be occupied by the ligating atoms around each metal atom decreases depending on the increase of the atomic number, too. In such case, the weakly ligating atoms, such as O(31) and O(33^{ii}), are kept further away than the other coordinating atoms, while the other M–O lengths decrease.[2]

All the carboxylate ions in the complex are coordinated to the metal atoms, and their coordination geometries are classified into three types (as follows). The chelating-type ions, found in the light lanthanoid(III) salts, were not found in the heavy lanthanoid(III) complexes, while the unidentate-type ions were not found in the former.

(**A**) Unidentate type: The ion **35**,[17] is type one. The O(35) atom is ligated to the M(3) atom, while the O(36) atom is not coordinated to any metal atom; but it is hydrogen-bonded with a water oxygen atom, O(W4), which is ligated to the M(3) atom. The bond lengths O(35)–C(35) and O(36)–C(35) are not very different from each other, and the C=O double bond of the carboxyl group is probably not very localized.

(**B**) *Z,Z*-Type bidentate bridging type: Ions **15**, **21**, **23**, and **25** are members.[17] Although the MOC angles of this type ion in the standard form should be in the range 140—150°, some of the determined angles of the title complexes are out of the range, and the differences between both the M–O bond lengths of the same ligands are relatively large: in the ytterbium(III) complex, for example, they are in the range 0.065—0.146 Å. Therefore, the deformation of this type ion is thought to be greater than those of the light lanthanoid(III) complexes.

(**C**) Tridentate type:[18] The ideal form of this type ion is that the carboxyl group COO′ makes a chelate ring with a metal atom M. At the same time, one oxygen atom, O′, approaches another metal atom, M′. Ions **11**, **13**, **31**, and **33**,[17] are members (where the more deformed one is written the later). In the most deformed ones, **31** and **33**,[17] the M–O′ bond lengths are much longer than M–O or M′–O′ bond lengths of the complex. However, as shown in Table 4, their MOC angles are in the range 101—109°, while the angles MO′C are in the range 82—89°. Therefore, their deformations are not the range-out ones of this type ion. The change of the coordination type, found in an europium(III) complex in the series of light lanthanoid(III) complexes,[2] could not be found.

Respective types and numbers of the bridges between the metal atoms are schematically shown in Fig. 6, and the intermetallic distances are shown in Table 4. As shown in the Figure, the pairs of metal atoms, M(1^{i})···M(1) and M(3)···M(3^{ii}) are bridged by two tridentate type ions, while M(1)···M(2) and M(2)···M(3) by one tridentate type and two *Z,Z*-type bidentate bridging type ions, respectively. No clear relation was found between the numbers as well as the types of the bridging ions and the intermetallic distances.

The metal atoms are lined in a linear polymeric chain of Yb(1^{i})···Yb(1)···Yb(2)···Yb(3)···Yb(3^{ii})···, which spans approximately along [111] axis. Thus, in the heavy lanthanoid(III) complexes, all the polymeric chains are parallel, though in the light lanthanoid-(III) salts, two kinds of the lines along [110] and [−110] are alternately placed. As shown in Table 4, there are some hydrogen bondings through a coordinated water oxygen and O(36) as well as

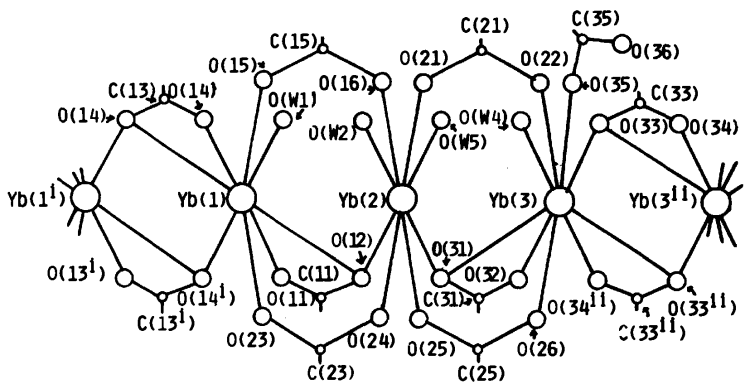

Fig. 6. Schematic presentation of the bridgings between the metal atoms.[15]

O(W3) atoms to the side-by-side chains; however, no carboxylato bridgings between them were found.

This kind of the complicated bridging is also found in various other lanthanoid(III) carboxylates.[2,19]

The general feature of the infrared spectra of the gadolinium, dysprosium, erbium, and ytterbium chloroacetates are about the same, although it is different from those of the light lanthanoid(III) chloroacetates.[2] As the ν_{as}(COO) band, two strong peaks appeared at 1570 and 1620 cm^{-1}, with smaller peaks at 1620—1630 and at 1650—1660 cm^{-1}. As the ν_s(COO) band, two strong peaks appeared at 1398 and 1440 cm^{-1}, with two shoulders at both sides of the main peaks. The maximum wavenumbers of these peaks of the four complexes are not very different from each other.

The authors wish to thank the Shin-Etsu Chemical Ind. Co., Ltd., for presenting us with the highly pure lanthanoid oxides.

The Syntheses and the X-Ray Crystal Structure of Tetramethylammonium Tetrakis- and Tris(thiocyanato)cadmates(II), $[(CH_3)_4N]_2[Cd(SCN)_4]$ and $[(CH_3)_4N][Cd(SCN)_3]$

(Received July 31, 1986)

The crystal and molecular structure of the two new thiocyanatocadmate(II) complexes indicated in the title were determined by the single-crystal X-ray-diffraction technique. $[(CH_3)_4N]_2[Cd(SCN)_4]$ (**1**) is triclinic, with a space group of $P\bar{1}$; a=7.300(2), b=13.019(4), c=5.8920(9) Å, α=96.32(2), β=93.080(18), γ=104.63(2)°, and Z=1, while $[(CH_3)_4N][Cd(SCN)_3]$ (**2**) is orthorhombic with a space group of $Pna2_1$; a=10.506(3), b=13.797(5), c=9.4506(18) Å, Z=4. In both complexes, the cadmium atom is in an octahedral geometry. In **1**, the metal atom is at the center of symmetry, and respective pairs of side-by-side metal atoms are bridged by two thiocyanate (SCN) ions, where one SCN ion is *S*-coordinated and the other is *N*-coordinated to the same-side metal atom. Also bonded with two nitrogen atoms of unidentate SCN ions, the metal atom is 4*N*2*S*-hexa-coordinated, and they line up along the c-axis in a polymeric form. In **2**, respective pairs of side-by-side metal atoms are bridged by three SCN ions, two of those SCN ions being *S*-coordinated, and one *N*-coordinated, to the same-side metal atom; each metal atom is 3*S*3*N*-hexa-coordinated, and the chain of the polymeric complex lines up along the a-axis. The tetramethylammonium ions bond with the polymeric complex only by the ionic bonding. The final R values obtained are **1**=0.039 and **2**=0.050.

It was already known that some thiocyanate complexes of cadmium(II) are in the polymeric form. For example, cadmium(II) thiocyanate itself is in a three-dimensional polymeric form, where each cadmium(II) atom is 4*S*2*N*-hexa-coordinated, being in an octachedral geometry.[1] It is also well-known that some Lewis base adducts of cadmium(II) thiocyanate are in the linear polymeric form, where respective pairs of the side-by-side cadmium(II) atoms are bridged by two thiocyanate (SCN) ions[2-5] or by the base molecules.[6] The cesium salt of tris(thiocyanato)cadmate(II) has a three-dimensional polymeric structure, where the two kinds of cadmium(II) atoms are 6*S*- and 6*N*-hexa-coordinated, while its rubidium salt has a two-dimensional polymeric structure, where the two kinds of cadmium(II) atoms are 4*N*2*S*- and 2*N*4*S*-hexa-coordinated.[7] On the other hand, in $K_2[Cd(SCN)_4]\cdot 2H_2O$, the tetrakis(thiocyanato)cadmate(II) ions are discrete; the cadmium atom is 2*N*4*S*-hexa-coordinated although the octahedron around the metal atom is deformed.[8]

From these results, the bridging structure of the thiocyanatocadmate(II) can be expected to depending on the kind of counter cation. As the rubidium and cesium salts have the respective types of polymeric structures, it can also be expected that, if a different kind of counter cation is introduced, some complex with another type of polymeric structure will be obtained. From this expectation, we started the syntheses of some tetraalkylammonium salts of the thiocyanatocadmate(II), and have thus obtained the title complexes; their crystal and molecular structures were determined by the single-crystal X-ray-diffraction technique.

Experimental

Syntheses of Tetramethylammonium Tetrakis(thiocyanato)cadmate(II) (1), and Tetramethylammonium Tris(thiocyanato)cadmate(II) (2). The cadmium(II) thiocyanate (**3**) and tetramethylammonium thiocyanate (**4**) were obtained by metathetical reactions between the respective chlorides and potassium thiocyanate in a methanol medium, as in cases of the other thiocyanates.[9]

To synthesize Complex **1**, the solutions of **3** and **4** in the mol ratio of 1:2 (**3**, 0.57 g, 2.5 mmol in 20 cm³ of acetone; **4**, 0.66 g, 5.0 mmol in 10 cm³ of acetone) were mixed and left standing overnight at the ambient temperature. Crystals of **1** were thus deposited. Yield, 0.68 g; 1.38 mmol, 58%.

To obtain Complex **2**, aqueous solutions of equimol amounts of **3** and **4** (0.57 g (2.5 mmol) and 0.33 g (2.5 mmol), respectively, in 10 cm³ of water) were mixed and left standing overnight in a silica gel desiccator. Crystals of **2** were thus deposited. Yield, 0.37 g; 1.03 mmol, 41%. An additional lot, which was almost of the same purity, was also obtained from the filtrate.

Intensity Data Collection. The crystallographic data of both complexes are listed in Table 1, while some of the experimental conditions used to obtain the intensity data are tabulated in Table 2. The reflections were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer, with graphite-monochromated Mo $K\alpha$ radiation (the scan speed was 4° min⁻¹ (θ), and the ω—2θ scan-technique was employed).

Structure Determination. Their structures were solved by the heavy-atom method. The positions of the metal and sulfur atoms were deduced from the three-dimensional Patterson map; the other non-hydrogen atoms were located by means of successive Fourier syntheses. Their positional, isotropic, and then anisotropic thermal parameters were refined by means of a block-diagonal least-squares method. Eight hydrogen atoms of **1** were found on the difference

Fourier map, while the other hydrogen atoms were situated at their respective positions assuming C-H=1.08 Å and B_{iso}=6.0. In the final cycle, all the hydrogen atoms were fixed. The positions of any hydrogen atoms of **2** were not determined exactly on the difference Fourier map, and so we gave up adding their parameters to the calculation.

All the calculations were carried out on a HITAC M 680H computer at the Computer Center of the University of Tokyo, using a local version of the UNICS program.[10] The atomic scattering factors were taken from Ref. 11.

Infrared Spectrum Measurements. The infrared spectra of the samples were obtained by means of a JASCO 202A grating infrared spectrophotometer, using Nujol and hexachloro-1,3-butadiene mulls.

Results and Discussion

The final atomic parameters of the non-hydrogen atoms of **1** and **2** are listed in Table 3 as 3.1 and 3.2, while the bond lengths and bond angles of **1** and **2** are tabulated in Table 4 and Table 5 respectively.[12] Perspective drawings of the skeleton of the polymeric chains of Complexes **1** and **2**, together with the numbering scheme of the atoms, are shown in Figs, 1 and 3 respectively. The crystal packing diagrams of **1** and **2** are shown in Figs. 2 and 4.

In **1**, the cadmium(II) atom is at the center of symmetry and is 4*N*2*S*-hexa-coordinated, being in a slightly deformed octahedral geometry. Two nitrogen atoms of unidentate SCN ions, two nitrogen atoms, and two sulfur atoms of the respective bridging SCN ions are coordinated. The Cd-N bond lengths of the unidentate SCN (Cd-N(2)=2.357(3) Å) is longer than that of the bridging SCN (Cd-N(1)=2.269(2) Å), but both of them are shorter than the sum of Shannon's ionic radii, 2.41 Å.[13] This is probably because the assumed valence of the nitrogen atom is not appropriate, for the charge on the SCN ion is much delocalized. The observed Cd-S bond length is 2.742(1) Å (Cd-S(1^i)), about the same as the sum of Shannon's ionic radii, 2.79 Å.[13] These values are not much different from the respective values of Lewis base adducts of the cadmium(II) thiocyanate, which have the same type of doubly bridged SCN ions in their polymeric structures.[2-5] The Cd-N(1)-C(1), Cd-N(2)-C(2), and Cd-S(1^i)-C(1^i) angles are 165.8(2), 158.0(2), and 98.65(8)° respectively, while the average

a) Reflections with $|F_o|>3\sigma(|F_o|)$ were used. b) $R=\Sigma||F_o|-|F_c||/\Sigma|F_o|$; $R_{weight}=[\Sigma(|F_o|-|F_c|)^2/\Sigma wF_o^2]^{1/2}$, where $w=1/[\{\Sigma(|F_o|)\}^2+(F_{weight}\times F_o)^2]$, $F_{weight}=0.015$. c) $S=[\Sigma w(|F_o|-|F_c|)^2/(N_o-N_p)]^{1/2}$, where N_o=number of reflections and N_p=number of parameters.

of the S-C-N angle of the SCN ions is 178.6°. Both of the Cd-N-C angles can be said to be almost in the normal range, because in other thiocyante complexes, the M-N-C (SCN) bond angles have been shown to be 160—180°.[14]

The respective pairs of the neighboring cadmium(II) atoms are bridged by two SCN ions; one of them is *S*-coordinated, and the other is *N*-coordinated, to the same-side metal atom, thus forming a polymeric linear chain structure along the [001] axis. Thus, it has been shown that the tetrakis(thiocyanato)cadmate ion in its tetramethylammonium salt takes a linear

polymeric chain structure, while its potassium salt has discrete anions, although the latter is in a dihydrate form.[8]

In **2**, the cadmium(II) atom is *3N3S*-hexacoordinated, being in a slightly deformed octahedral geometry, where three nitrogen atoms and, accordingly three sulfur atoms, also- are in the *fac*-configuration; around one metal atom, each sulfur atom is at the *trans*-position of a nitrogen atom. The average Cd-S and Cd-N bond lengths are 2.720 and 2.334 Å respectively. Therefore, the average values are not very different from the respective values of **1** or from the Lewis base adducts of cadmium(II) thiocyanate, although as is shown in Table 5, the respective Cd-N bond lengths as well as Cd-S bond lengths of **2** are a little different from each other. However, all of them are shorter than the respective sums of Shannon's ionic radii; 2.41 and 2.79 Å.[13] The average bond angles of Cd-N-C, Cd-S-C, and S-C-N are 148.5, 95.7, and 170.4° respectively. Although the angles of the latter two are not much different from the corresponding values of **1**, nor from those of the Lewis base adducts of cadmium(II) thiocyanate,[2-5] the Cd-N-C angles of **2**, especially Cd-N(2)-C(2) and Cd-N(3)-C(3), are much smaller than the normal value.[14] This structural deformation is probably caused by the mutual steric interaction of the

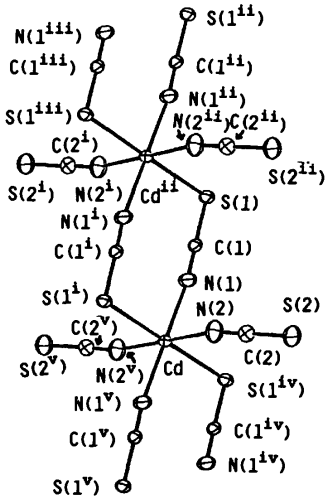

Fig. 1. A perspective drawing of the structure of $[(CH_3)_4N]_2[Cd(SCN)_4]$, with the numbering scheme of the atoms. Key to the symmetry operations: i, $-x$, $-y$, $1-z$; ii, x, y, $1+z$; iii, $-x$, $-y$, $2-z$; iv, x, y, $-1+z$; v, $-x$, $-y$, $-z$.

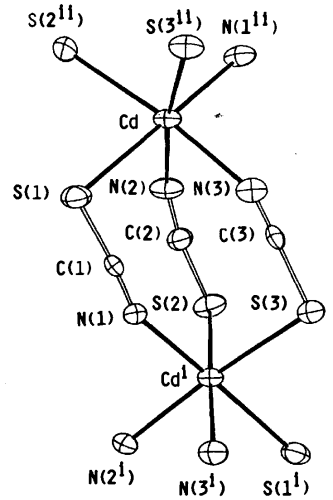

Fig. 3. A perspective drawing of the structure of $[(CH_3)_4N][Cd(SCN)_3]$, with the numbering scheme of the atoms. Key to the symmetry operations: i, $0.5+x$, $0.5-y$, z; ii, $-0.5+x$, $0.5-y$, z.

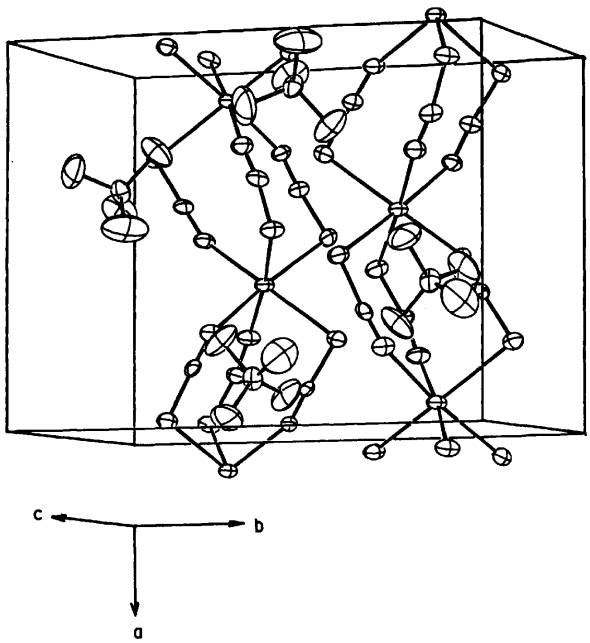

Fig. 4. Crystal packing diagram of $[(CH_3)_4N][Cd(SCN)_3]$.

respective SCN ions in a limited packing space of the crystal, thus forming such a type of triple chain.

The respective pairs of the neighboring cadmium(II) atoms are bridged by three SCN ions, where one of them is *N*-coordinated, and the other two are *S*-coordinated to a one-side metal atom. Thus, in **2**, the side-by-side metal atoms are triply bridged by three SCN ions, thus forming a polymeric linear chain structure along the [100] axis, although in a zig-zag way.

Although many kinds of bridging structures have been found in cadmium(II) thiocyanate complexes, no such triply bridged one has yet been found; this is a new type of polymeric chain of the thiocyanate ions.

The tetramethylammonium ions in **1** and **2** are not bridged, but are isolated from the complex chain; only mutual electrostatic interaction is expected.

In the infrared spectrum of **1**, the ν(CN) and δ(SCN) bands appear as doublets: the maximum wavenumbers are 2070, 2105(s), and 453, 464(m) cm^{-1} respectively, although the ν(CS) band at 768(w) cm^{-1} is found to be a singlet. On the. other hand, in the spectrum of **2**, the ν(CN), δ(SCN), and ν(CS) bands are all singlet; their maximum wave numbers are 2100(s), 460(m), and 758(w) cm^{-1} respectively. These facts may be due to the existence of two kinds of SCN ions in **1**, as has been shown by the structure analysis, while the bond strengths of the three SCN ions in **2** are not very different from each other. The absorption bands of the tetramethylammonium ion are found at 1480(s), 1378(s), and 941(s) cm^{-1}; they are about the same in the spectra of **1** and **2**.

Reactions of 3-(2-Methyl-1,3-dioxolan-2-yl)tropolone Methyl Ethers with Hydrazines, Thiourea, Guanidine, and Amidines

Kimiaki IMAFUKU,* Yosuke KIKUCHI,† and Bing-Zhu YIN††
Department of Chemistry, Faculty of Science, Kumamoto University,
Kurokami, Kumamoto 860
(Received May 16, 1986)

3-(2-Methyl-1,3-dioxolan-2-yl)tropolone, prepared from 3-acetyltropolone, was methylated with diazomethane to afford 2-methoxy-3-(2-methyl-1,3-dioxolan-2-yl)tropone (**3a**) and 2-methoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**3b**). The methyl ether **3a** reacted with hydrazine to afford 2-hydrazono-3-(2-methyl-1,3-dioxolan-2-yl)-3,5-cycloheptadien-1-one and 3-methyl-1,8-dihydrocycloheptapyrazol-8-one. The reaction with methylhydrazine afforded 3-(2-methyl-1,3-dioxolan-2-yl)-2-methylhydrazono-3,5-cycloheptadien-1-one and 1,3- and 2,3-dimethyl-dihydrocycloheptapyrazol-8-ones. Another methyl ether **3b** reacted with hydrazine to afford 2-hydrazino-7-(2-methyl-1,3-dioxolan-2-yl)tropone, while the reaction with methylhydrazine gave 2-(2-methyl-1,3-dioxolan-2-yl)-7-(2-methylhydrazino)tropone, 2-(2-methyl-1,3-dioxolan-2-yl)-7-(1-methylhydrazino)tropone, and 1,3-dimethyl-8-methylhydrazono-1,8-dihydrocycloheptapyrazole. On the other hand, the methyl ether **3a** reacted with guanidine, acetamidine, and benzamidine to give 4-(2-methyl-1,3-dioxolan-2-yl)-2-amino-, 2-methyl-, and 2-phenylcycloheptimidazole, respectively. The reaction of the methyl ether **3b** also gave the same products. The reaction of **3b** with thiourea afforded 2-mercapto-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole but **3a** resulted in the rearrangement to ethyl 2-(2-methyl-1,3-dioxolan-2-yl)benzoate.

We found that 3-acetyltropolone is useful as starting material for the synthesis of heterocycle-fused troponoid compounds, because it has β-diketone structure.[1] On the other hand, the acetyl group not only enhances the reactivity of the tropolone nucleus but also becomes the reaction center for nucleophilic reactions. For example, 3-acetyltropolone and its methyl ether reacted with hydrazines to give 1,8-dihydrocycloheptapyrazol-8-one derivatives.[2-4] We also reported reactions of 3-acetyltropolone methyl ethers, 2-acetyl-7-methoxytropone and 3-acetyl-2-methoxytropone, with guanidine and amidines.[5] In these reactions, we found that the former produced the usual cycloheptimidazole derivatives but the latter produced 9*H*-cyclohepta[*d*]pyrimidine derivatives.

In the present work, 3-acetyltropolone (**1**) reacted with ethylene glycol in the presence of *p*-toluenesulfonic acid to afford 3-(2-methyl-1,3-dioxolan-2-yl)tropolone (**2**), which was methylated with diazomethane to give two isomeric methyl ethers, 2-methoxy-3-(2-methyl-1,3-dioxolan-2-yl)tropone (**3a**) and 2-methoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**3b**). All of the other isomers, 2-methoxy-4-, -5-, and -6-(2-methyl-1,3-dioxolan-2-yl)tropones, have been reported.[6]

Furthermore, we describe reactions of 2-methoxy-3-(2-methyl-1,3-dioxolan-2-yl)tropone and 2-methoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**3a** and **3b**) with hydrazines, urea, thiourea, guanidine, and amidines.

Results and Discussion

Synthesis of 3-(2-Methyl-1,3-dioxolan-2-yl)tropolone (2) and Its Methyl Ethers (3a and 3b). 3-Acetyltropolone (**1**)[2] reacted with ethylene glycol in dry benzene in the presence of *p*-toluenesulfonic acid to give 3-(2-methyl-1,3-dioxolan-2-yl)tropolone (**2**) as colorless prisms. Ketalization was confirmed by spectral data, such as a disappearance of the acetyl carbonyl absorption in the IR spectrum and the appearance of an ethylenedioxy resonance as an A_2B_2 pattern in the ^1H NMR spectrum.

Methylation of **2** with diazomethane gave two isomeric methyl ethers as crystals which were determined to be 2-methoxy-3-(2-methyl-1,3-dioxolan-2-yl)tropone (**3a**) (mp 80—81 °C) and 2-methoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**3b**) (mp 121—122 °C) by their spectral data.

Reactions with Hydrazine. It is well known that reactive troponoids, such as 2-methoxy-, 2-tosyloxy-, and 2-chlorotropones, react with hydrazine to afford 2-hydrazinotropones.[7] Previously, it was reported that 2-methoxy-4-, -5-, and -6-(2-methyl-1,3-dioxolan-2-yl)tropones reacted with hydrazine to afford, respectively, 2-hydrazino-4-, -5-, and -6-(2-methyl-1,3-dioxolan-2-yl)tropones.[6]

A solution of 2-methoxy-3-(2-methyl-1,3-dioxolan-2-yl)tropone (**3a**) and hydrazine hydrate in methanol was refluxed for 1 h to afford 2-hydrazono-3-(2-methyl-1,3-dioxolan-2-yl)-3,5-cycloheptadien-1-one (**4**) and 3-methyl-1,8-dihydrocycloheptapyrazol-8-one (**5**)[2] in 19 and 36% yields, respectively. The former is a tautomer of 2-hydrazino-3-(2-methyl-1,3-dioxolan-2-yl)tropone. Its structure was determined by its spectral data. The ^1H NMR spectrum shows peaks at δ 1.84 (3H, s) for CH_3, 3.01 (2H, d, J=6 Hz) for 7-CH_2, 3.5—4.2 (4H, m) for OCH_2CH_2O, 5.71 (1H, dt, J=9.5 and

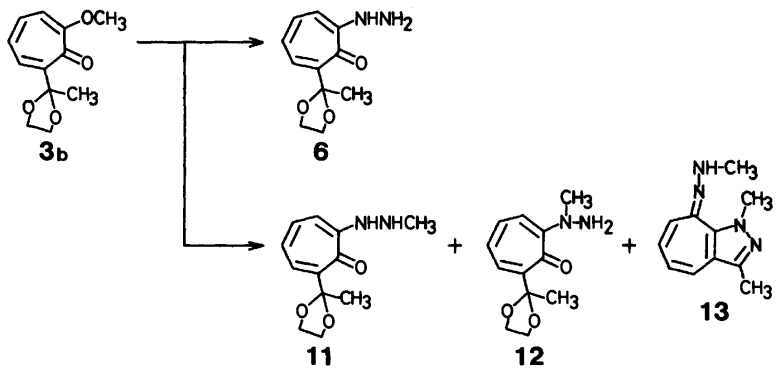

Scheme 3.

6 Hz) for H-6, 6.21 (1H, dd, J=9.5 and 5.5 Hz) for H-5, 6.67 (1H, d, J=5.5 Hz) for H-4, and 10.5 (2H, br) for NH_2. The UV spectrum is different from those of 2-hydrazino-4-, -5-, and -6-(2-methyl-1,3-dioxolan-2-yl)tropones.[6] It is thought that the tropone ring cannot maintain a planar hydrazino-substituted structure by steric hindrance of the vicinal bulky 2-methyl-1,3-dioxolan-2-yl group at the 3-position and, thus, tautomerized to a non-planar hydrazono-substituted structure.

The 2-methyl-1,3-dioxolan-2-yl group in compound **4** was hydrolyzed with 2 M (1 M=1 mol dm^{-3}) hydrochloric acid and did not give 3-acetyl-2-hydrazinotropone but, rather, its cyclized product **5** in 89% yield.

Another methyl ether **3b** in methanol was refluxed for 6 h with hydrazine hydrate to give 2-hydrazino-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**6**) in 74% yield; it was determined by its elemental analysis and spectral data. The UV spectrum is similar to those of its isomers, 2-hydrazino-4-, -5-, and -6-(2-methyl-1,3-dioxolan-2-yl)tropones. Thus, all of the isomers have been obtained except for 2-hydrazino-3-(2-methyl-1,3-dioxolan-2-yl)tropone, which exsists in tautomeric form, 2-hydrazono-3-(2-methyl-1,3-dioxolan-2-yl)-3,5-cycloheptadien-1-one (**4**).

Reactions with Methylhydrazine. A solution of the methyl ether **3a** and methylhydrazine in methanol was refluxed for 8 h to afford 3-(2-methyl-1,3-dioxolan-2-yl)-2-methylhydrazono-3,5-cycloheptadien-1-

one (**7**), 2-methylamino-3-(2-methyl-1,3-dioxolan-2-yl)tropone (**8**), 1,3-dimethyl-1,8-dihydrocycloheptapyrazol-8-one (**9**)[3] and 2,3-dimethyl-2,8-dihydrocycloheptapyrazol-8-one (**10**)[3] in 7, 9, 3, and 13% yields, respectively. Product **7** was isolated as a tautomer of 3-(2-methyl-1,3-dioxolan-2-yl)-2-(2-methylhydrazino)tropone. Its structure was determined by its spectral data. The UV spectrum is similar to that of compound **4**. The ^{1}H NMR spectrum also shows a similar pattern. The methylene protons at the 7-position was observed at δ 2.91 as a doublet peak (J=7 Hz). Compound **7** was heated with 2 M hydrochloric acid on a water bath to afford the cyclized product **10** in 91% yield. Compound **8** was also confirmed spectroscopically. Methyl ether **3a** reacted with methylamine to give the same product **8** in 10% yield.

A mixture of methyl ether **3b** and methylhydrazine in methanol was refluxed for 24 h to afford 2-(2-methyl-1,3-dioxolan-2-yl)-7-(2-methylhydrazino)tropone (**11**), 2-(2-methyl-1,3-dioxolan-2-yl)-7-(1-methylhydrazino)tropone (**12**), and 1,3-dimethyl-8-methylhydrazono-1,8-dihydrocycloheptapyrazole (**13**)[3] in 31, 29, and 8% yields, respectively. Compound **11** was determined by its spectral data. The UV spectrum is similar to that of compound **6**. The structure of the compound **12** was also confirmed by its spectral data. The ^{1}H NMR spectrum shows peaks at δ 1.90 (3H, s) for C-CH_3, 3.32 (3H, s) for N-CH_3, 3.5—4.2 (4H, m) for OCH_2CH_2O, 4.2 (2H, br) for NH_2, 6.2—7.2 (3H, m) for H-4,5,6, and 7.43 (1H, dd, J=9 and 2 Hz) for H-3. Previously, we reported that similar-type compounds could be obtained by the reactions of 2-tosyloxy- and 2-chlorotropones with methylhydrazine.[8]

Reactions with Urea and Thiourea. It is well known that 2-methoxytropones react with guanidine and thiourea to afford cycloheptimidazole derivatives.[9,10] However, reactions with urea do not give cycloheptimidazole, except for the case of 4-(*p*-nitrostyryl)tropolone methyl ethers.[11] Reactions of both methyl ethers of 3-acetyltropolone with urea gave 2-acetylbenzoic acid as a rearrangement product.

A mixture of the methyl ether **3a** and urea in absolute ethanol was refluxed for 1 h in the presence of sodium ethoxide to afford the rearrangement product, ethyl 2-(2-methyl-1,3-dioxolan-2-yl)benzoate (**14**), in 83% yield. Its IR spectrum shows an ester carbonyl absorption at 1720 cm^{-1}. The ethyl group in the ester and the ethylenedioxy group were confirmed by the ^{1}H NMR spectrum.

The reaction of **3b** with urea in the presence of sodium ethoxide gave 3-(2-methyl-1,3-dioxolan-2-yl)tropolone (**2**) as a hydrolysis product and 2-ethoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**15**) as the alkoxy-exchanged product in 45 and 47% yields, respectively. For the latter, the introduction of an ethoxyl group into the 2-position was confirmed by the ^{1}H NMR spectrum. The UV spectrum is very similar to that of the methyl ether **3b**.

The methyl ether **3a** was heated in the presence of sodium ethoxide to give **14** in 82% yield. In a similar manner, **3b** gave **2** and **15** in 22 and 61% yields, respectively. The use of potassium hydroxide instead of sodium ethoxide gave also similar results. Namely, **3a** gave **14** in 72% yield, while **3b** gave **2** and **15** in 21 and 44% yields, respectively. Thus, these results show that urea does not participate in the reactions. This type of rearrangement with alkali or alkoxide is well known.[12,13]

A solution of **3a** and thiourea was refluxed for 2 h in the presence of sodium ethoxide gave a rearrangement product **14** in 80% yield. On the other hand, the

Table 1. Reactions of 3-(2-Methyl-1,3-dioxolan-2-yl)tropolone Methyl Ethers (**3a** and **3b**)

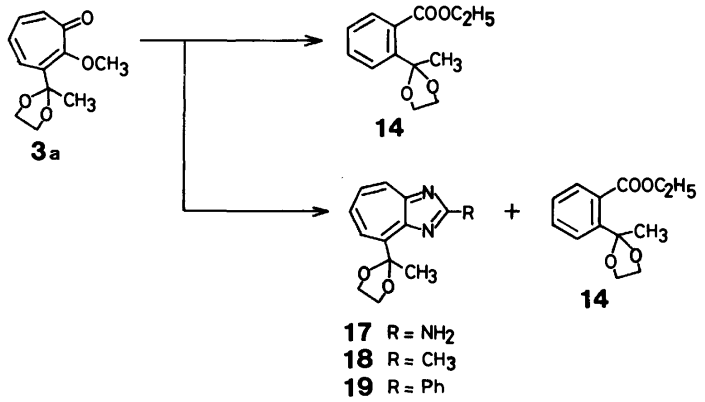
a) Hydrate. b) Hydrochloride. c) Carbonate.

reaction of **3b** afforded 2-mercapto-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole (**16**) as reddish-orange prisms in 81% yield. Its UV spectrum [235 (log ε 4.26), 256 (4.53), 313 (3.88), and 450 nm (4.26)] is very similar to those of isomers, 5-(2-methyl-1,3-dioxolan-2-yl)- [227 (log ε 4.26), 253 (4.55), 310 (3.78), and 440 nm (4.23)] and 6-(2-methyl-1,3-dioxolan-2-yl)-2-mercaptocycloheptimidazole [230 (log ε 4.64), 305 (3.84), 440 nm (4.37)].[14]

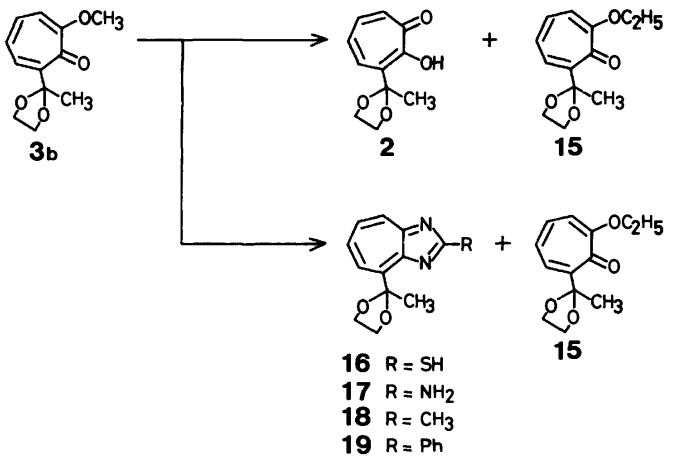
Reactions with Guanidine. A mixture of the methyl ether **3a** and guanidine hydrochloride in absolute ethanol was refluxed for 2 h in the presence of potassium hydroxide to give 2-amino-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole (**17**) as yellow prisms in 5% yield, in addition to the rearrangement product **14** in 64% yield. The UV spectrum of the former is very similar to those of isomeric 2-amino-5- and -6-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazoles.[14] The ^{1}H NMR spectrum shows peaks at δ 2.07 (3H, s) for CH_3, 3.7—4.3 (4H, m) for OCH_2CH_2O, 7.2—7.8 (2H, m) for H-6 and -7, 7.60 (2H, br) for NH_2, 7.97 (1H, dm, J=9 Hz) for H-5, and 8.30 (1H, dd, J=10 and 2.5 Hz) for H-8. On the other hand, the reaction of **3a** with guanidine carbonate improved the yield of **17** to 21%. The cycloheptimidazole **17** was hydrolyzed to afford 4-acetyl-2-aminocycloheptimidazole (**20**)[5] in 83% yield.

The reaction of **3b** with guanidine hydrochloride gave cycloheptimidazole **17** and the alkoxy-exchanged product **15** in 62 and 21% yields, respectively.

Reactions with Amidines. A mixture of methyl ether **3a** and acetamidine hydrochloride in absolute ethanol was refluxed for 2 h in the presence of sodium ethoxide to afford 2-methyl-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole (**18**) as yellow prisms and the rearrangement product **14** in 4 and 78% yields, respectively. The ^{1}H NMR spectrum of the former shows two singlet peaks at δ 2.44 for the 2-CH_3 and 2.95 for the acetal CH_3 and three multiplet peaks at δ 3.7—4.4 for the OCH_2CH_2O, 7.75—8.15 for H-6 and -7, and 8.3—8.8 for H-5 and -8 protons. In the UV spectrum, four absorption bands were observed at 228 (log ε 4.42), 260 (4.62), 323 (4.01), and 399 nm (3.14). The reaction of the methyl ether **3b** with acetamidine afforded the same cycloheptimidazole **18** and the alkoxy-exchanged product **15** in 30 and 11% yields, respectively. The cycloheptimidazole **18** was decomposed by heating with dilute hydrochloric acid and



Scheme 4.



Scheme 5.

did not give the hydrolysis product, 4-acetyl-2-methylcycloheptimidazole.

With benzamidine, the reaction of **3a** gave 4-(2-methyl-1,3-dioxolan-2-yl)-2-phenylcycloheptimidazole (**19**) as yellow needles and the rearrangement product **14** in 14 and 45% yields, respectively. The UV spectrum of the former exhibits the absorption bands at 259 (log ε 4.53), 277 sh (4.46), 356 sh (4.39), 366 (4.40), and 415 nm sh (3.25). Compound **19** was hydrolyzed with dilute hydrochloric acid to afford 4-acetyl-2-phenylcycloheptimidazole (**21**)[5] in 65% yield.

Methyl ether **3b** also reacted with benzamidine to give the cycloheptimidazole **19** and the alkoxy-exchanged product **15** in 69 and 4% yields, respectively.

Experimental

Measurements. The melting points were determined with a Yanagimoto MP-S2 apparatus and are uncorrected. The IR spectra were taken on a JASCO A-102 spectrophotometer, and the UV spectra on a Hitachi EPS-3T spectrophotometer. The ^{1}H NMR spectra were recorded with a Hitachi-Perkin-Elmer R-24 spectrometer (60 MHz). The high-resolution mass spectra were obtained with a JEOL DX-300 apparatus.

3-(2-Methyl-1,3-dioxolan-2-yl)tropolone (2). A mixture of 3-acetyltropolone (**1**) (3.76 g, 20 mmol) and ethylene glycol (40 ml) in dry benzene (120 ml) was refluxed under stirring in the presence of *p*-toluenesulfonic acid (0.4 g). As water produced in the reaction was removed by azeotropic distillation with benzene, dry benzene (1000 ml) was gradually added into the reaction mixture. After refluxing for 10 h, the reaction mixture was diluted with water and extracted with benzene. The benzene extract was washed with water. The evaporation residue from the extract yielded 3-(2-methyl-1,3-dioxolan-2-yl)tropolone (**2**) (3.4 g, 71%) as colorless prisms (from benzene–hexane): Mp 86—87 °C; IR ($CHCl_3$) 1600 cm^{-1} (C=O); UV (CH_3OH) 247 (log ε 4.38), 253 sh (4.30), 310 sh (3.78), 324 (3.88), 362 (3.84), 376 (3.82), 404 nm sh (3.00); ^{1}H NMR ($CDCl_3$) δ=1.85 (3H, s, CH_3), 3.7—4.3 (4H, m, OCH_2CH_2O), 6.8—7.5 (3H, m), 8.00 (1H, dm, *J*=9 Hz, H-7), 9.50 (1H, br, OH). Found: C, 63.61; H, 5.84%. Calcd for $C_{11}H_{12}O_4$: C, 63.45; H, 5.81%.

Methylation of 3-(2-Methyl-1,3-dixolan-2-yl)tropolone (2). To a solution of **2** (5.2 g, 25 mmol) in chloroform (50 ml), an ethereal solution of diazomethane was added dropwise until the resulting mixture gave no colorlation with an iron(III) chloride solution. After removing the solvent, the residue was chromatographed on a Wakogel C-100 column (600 g) using ethyl acetate as an eluant. The evaporation residue from the former fractions was twice rechromatographed on four Wakogel B-10 plates (30×30 cm) with chloroform to give 2-methoxy-3-(2-methyl-1,3-dioxolan-2-yl)tropone (**3a**) (1.9 g, 34%) as pale yellow crystals (from benzene–hexane): Mp 80—81 °C; IR ($CHCl_3$) 1580 cm^{-1} (C=O); UV (CH_3OH) 239 (log ε 4.21), 330 nm (3.82); ^{1}H NMR ($CDCl_3$) δ=1.71 (3H, s, CH_3), 3.75—4.1 (4H, m, OCH_2CH_2O), 3.89 (3H, s, OCH_3), 6.6—7.3 (3H, m), 7.50 (1H, dm, *J*=10 Hz, H-7). Found: C, 64.75; H, 6.53%. Calcd for $C_{12}H_{14}O_4$: C, 64.85; H, 6.53%. The evaporation residue from the latter fractions gave 2-methoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (**3b**) (2.9 g, 52%) as colorless prisms (from benzene–hexane): Mp 121—122 °C; IR ($CHCl_3$) 1600 cm^{-1} (C=O); UV (CH_3OH) 243 (log ε 4.18), 308 sh (3.70), 322 (3.74), 345 sh (3.69), 355 nm (3.68); ^{1}H NMR ($CDCl_3$) δ=1.88 (3H, s, CH_3), 3.8—4.1 (4H, m, OCH_2CH_2O), 3.88 (3H, s, OCH_3), 6.4—7.45 (3H, m), 7.75 (1H, d, *J*=10 Hz, H-3). Found: C, 65.05; H, 6.30%. Calcd for $C_{12}H_{14}O_4$: C, 64.85; H, 6.35%.

General Procedure for the Reactions of the Methyl Ethers (3a and 3b) with Hydrazines. A solution of the methyl ether **3a** or **3b** (444 mg, 2 mmol) and the reagent (4 mmol) in methanol (20 ml) was refluxed. After removing the solvent, the residue was triturated with water and extracted with chloroform. The products were separated by chromatography on Wakogel B-10 plates (30×30 cm) with ethyl acetate. These results are summarized in Table 1.

2-Hydrazono-3-(2-methyl-1,3-dioxolan-2-yl)-3,5-cycloheptadien-1-one (4): Yellow crystals (from benzene–hexane); mp 120 °C (decomp); IR ($CHCl_3$) 3440 (NH), 3370 (NH), 1600 cm^{-1} (C=O); UV (CH_3OH) 281 (log ε 3.65), 335 nm (3.72); ^{1}H NMR ($CDCl_3$) δ=1.84 (3H, s, CH_3), 3.01 (2H, d, *J*=6 Hz, 7-CH_2), 3.5—4.2 (4H, m, OCH_2CH_2O), 5.71 (1H, dt, *J*=9.5, 6 Hz, H-6), 6.21 (1H, dd, *J*=9.5, 5.5 Hz, H-5), 6.67 (1H, d, *J*=5.5 Hz, H-4), 10.5 (2H, br, NH_2). Found: *m/z* 222.0971. Calcd for $C_{11}H_{14}N_2O_3$: M, 222.1004.

3-Methyl-1,8-dihydrocycloheptapyrazol-8-one (5): Orange plates; mp 183—184 °C (lit,[2] 183—184 °C).

2-Hydrazino-7-(2-methyl-1,3-dioxolan-2-yl)tropone (6): Orange needles (from benzene–hexane); mp 161 °C (decomp); IR ($CHCl_3$) 3300 (NH), 3240 (NH), 1600 cm^{-1} (C=O); UV (CH_3OH) 232 (log ε 4.39), 343 (4.11), 410 nm (4.09); ^{1}H NMR ($CDCl_3$) δ=1.90 (3H, s, CH_3), 3.5—4.5 (4H, m, OCH_2CH_2O), 6.60 (1H, ddd, *J*=12, 9, 3 Hz, H-4), 7.0—7.4 (2H, m, H-5,6), 7.81 (1H, d, *J*=9 Hz, H-3), 8.8 (1H, br, NH). Found: C, 59.43; H, 6.52; N, 12.41%. Calcd for $C_{11}H_{14}N_2O_3$: C, 59.45; H, 6.35; N, 12.60%.

3-(2-Methyl-1,3-dioxolan-2-yl)-2-methylhydrazono-3,5-cycloheptadien-1-one (7): Yellow oil; IR ($CHCl_3$) 3450 (NH), 1640 cm^{-1} (C=O); UV (CH_3OH) 216 (log ε 4.23), 287 (3.86), 350 nm (4.02); ^{1}H NMR ($CDCl_3$) δ=1.82 (3H, s, *C*-CH_3), 2.91 (2H, d, *J*=7 Hz, 7-CH_2), 3.33 (3H, s, *N*-CH_3), 3.5—4.2 (4H, m, OCH_2CH_2O), 5.69 (1H, dt, *J*=9.5, 6 Hz, H-6), 6.18 (1H, dd, *J*=9.5, 5.5 Hz, H-5), 6.55 (1H, d, *J*=5.5 Hz, H-4), 12.95 (1H, br, NH). Found: *m/z* 236.1071. Calcd for $C_{12}H_{16}N_2O_3$: M, 236.1161.

2-Methylamino-3-(2-methyl-1,3-dioxolan-2-yl)tropone (8): Pale yellow needles (from benzene–hexane); mp 125—126 °C; IR ($CHCl_3$) 3300 (NH), 1600 cm^{-1} (C=O); UV (CH_3OH) 212 (log ε 3.88), 256 (4.37), 342 (4.04), 412 nm (3.96); ^{1}H NMR ($CDCl_3$) δ=1.06 (3H, s, *C*-CH_3), 2.97 (3H, d, *J*=6 Hz, *N*-CH_3), 3.5—4.2 (4H, m, OCH_2CH_2O), 6.3—7.6 (5H, m, H-4,5,6+NH). Found: *m/z* 221.1013. Calcd for $C_{12}H_{15}N_2O_3$: M, 221.1052.

1,3-Dimethyl-1,8-dihydrocycloheptapyrazol-8-one (9): Pale yellow needles; mp 100—101 °C (lit,[3] 96—98 °C).

2,3-Dimethyl-2,8-dihydrocycloheptapyrazol-8-one (10): Pale yellow needles; mp 178—180 °C (lit,[3] 178—179 °C).

2-(2-Methyl-1,3-dioxolan-2-yl)-7-(2-methylhydrazino)tropone (11): Yellow needles (from benzene–hexane); mp 151 °C (decomp); IR ($CHCl_3$) 3260 (NH), 1590 cm^{-1} (C=O); UV (CH_3OH) 247 (log ε 4.13), 344 (4.27), 412 nm (4.05); ^{1}H NMR ($CDCl_3$) δ=1.80 (3H, s, *C*-CH_3), 2.62 (3H, s,

N-CH_3), 3.5—4.2 (4H, m, OCH_2CH_2O), 4.09 (1H, br, NH), 6.55 (1H, ddd, J=12, 9, 3 Hz, H-4), 6.9—7.3 (2H, m, H-5,6), 7.71 (1H, d, J=9 Hz, H-3), 8.6 (1H, br, NH). Found: m/z 236.1063. Calcd for $C_{12}H_{16}N_2O_3$: M, 236.1161.

2-(2-Methyl-1,3-dioxolan-2-yl)-7-(1-methylhydrazino)tropone (12): Yellow plates (from benzene-hexane); mp 149 °C (decomp); IR ($CHCl_3$) 3500 (NH), 3300 (NH), 1600 cm^{-1} (C=O); UV (CH_3OH) 216 (log ε 4.13), 260 (4.17), 355 (4.08), 422 nm (3.86); ^1H NMR ($CDCl_3$) δ=1.90 (3H, s, *C*-CH_3), 3.22 (3H, s, *N*-CH_3), 3.5—4.2 (4H, m, OCH_2CH_2O), 4.2 (2H, br, NH_2), 6.2—7.2 (3H, m, H-4,5,6), 7.43 (1H, dd, J=9, 2 Hz, H-3). Found: m/z 236.1058. Calcd for $C_{12}H_{16}N_2O_3$: M, 236.1161.

1,3-Dimethyl-8-methylhydrazono-1,8-dihydrocycloheptapyrazole (13): Reddish orange needles; mp 113—114 °C (lit,[3] 112—113 °C).

Hydrolysis of the Hydrazone (4) with Hydrochloric Acid. The hydrazone **4** (111 mg, 0.5 mmol) in 2 M hydrochloric acid (5 ml) was heated for 1 h on a water bath. The mixture was diluted with water and extracted with chloroform. The extract was washed with water and dried over sodium sulfate. The evaporation of the solvent gave the cycloheptapyrazol-8-one **5** (71 mg, 89%).

Hydrolysis of the Hydrazone (6) with Hydrochloric Acid. The hydrazone **6** (118 mg, 0.5 mmol) in 2 M hydrochloric acid (5 ml) was heated for 1 h on a water bath. The mixture was worked up, as mentioned above, to give the cycloheptapyrazol-8-one **10** (80 mg, 92%).

Reaction of the Methyl Ether (3a) with Methylamine. A mixture of **3a** (122 mg, 0.5 mmol) and 40% methylamine solution (2 ml) in methanol (5 ml) was allowed to stand for 4 d at room temperature. After removing the solvent, the residue was dissolved in chloroform, washed with water, and dried over sodium sulfate. The evaporation residue from the chloroform solution was chromatographed on a Wakogel B-10 plate (30×30 cm) with ethyl acetate to afford the methylaminotropone **8** (12 mg, 10%).

General Procedure for the Reactions of the Methyl Ethers (3a and 3b) with Urea, Thiourea, Guanidine, and Amidines. A solution of the methyl ether **3a** or **3b** (222 mg, 1 mmol) in absolute ethanol (5 ml) was added a solution of the reagent (2 mmol) and the base (2 mmol) (indicated in Table 1) in absolute ethanol (5 ml). After removing the solvent, the residue was triturated with water, made slightly acidic with 10% acetic acid, and extracted with chloroform. The products were separated by chromatography on Wakogel B-10 plates (30×30 cm) with chloroform or ethyl acetate. These results are summarized in Table 1.

Ethyl 2-(2-Methyl-1,3-dioxolan-2-yl)benzoate (14): Colorless prisms (from cyclohexane); mp 49—50 °C; IR ($CHCl_3$) 1720 cm^{-1} (C=O); ^1H NMR ($CDCl_3$) δ=1.36 (3H, t, J=7 Hz, $CH_2C\underline{H}_3$), 1.78 (3H, s, CH_3), 3.4—4.2 (4H, m, OCH_2CH_2O), 4.30 (2H, q, J=7 Hz, $C\underline{H}_2CH_3$), 7.2—7.7 (4H, m). Found: C, 66.02; H, 6.83%. Calcd for $C_{13}H_{16}O_4$: C, 66.08; H, 6.65%.

2-Ethoxy-7-(2-methyl-1,3-dioxolan-2-yl)tropone (15): Colorless prisms (from benzene-hexane); mp 108—109 °C; IR ($CHCl_3$) 1620 cm^{-1} (C=O); UV (CH_3OH) 244 (log ε 4.23), 323 (3.92), 353 nm (3.86); ^1H NMR ($CDCl_3$) δ=1.50 (3H, t, J=7 Hz, $CH_2C\underline{H}_3$), 1.89 (3H, s, CH_3), 3.6—4.2 (4H, m, OCH_2CH_2O), 4.06 (2H, q, J=7 Hz, $C\underline{H}_2CH_3$), 6.5—7.25 (3H, m), 7.75 (1H, dd, J=7, 2 Hz, H-3). Found: C, 66.20; H, 6.89%. Calcd for $C_{13}H_{16}O_4$: C, 66.08; H, 6.83%.

2-Mercapto-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole (16): Reddish orange prisms (from benzene-hexane); mp 228—229 °C; UV (CH_3OH) 235 (log ε 4.26), 256 (4.53), 274 sh (4.13), 313 (3.88), 450 nm (4.26); ^1H NMR ($CDCl_3$) δ=1.75 (3H, s, CH_3), 3.7—4.4 (4H, m, OCH_2CH_2O), 7.3—8.2 (4H, m), 10.85 (1H, br, SH). Found: C, 58.32; H, 4.88; N, 10.99%. Calcd for $C_{12}H_{12}N_2O_2S$: C, 58.06; H, 4.84; N, 11.29%.

2-Amino-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole (17): Yellow prisms (from ethanol); mp 208—209 °C; UV (CH_3OH) 240 sh (log ε 4.29), 263 (4.52), 290 sh (4.01), 360 nm (4.24); ^1H NMR ($CDCl_3$) δ=2.07 (3H, s, CH_3), 3.7—4.3 (4H, m, OCH_2CH_2O), 7.2—7.8 (2H, m, H-6,7), 7.60 (2H, br, NH_2), 7.97 (1H, dm, J=9 Hz, H-5), 8.30 (1H, dd, J=10, 2.5 Hz, H-8). Found: C, 62.05; H, 5.93; N, 18.32%. Calcd for $C_{12}H_{13}N_3O_2$: C, 62.32; H, 5.67; N, 18.23%.

2-Methyl-4-(2-methyl-1,3-dioxolan-2-yl)cycloheptimidazole (18): Yellow prisms (from cyclohexane); mp 119—120 °C; UV (CH_3OH) 228 (log ε 4.42), 260 (4.62), 307 sh (3.93), 323 (4.01), 399 nm (3.14); ^1H NMR ($CDCl_3$) δ=2.14 (3H, s, CH_3), 2.95 (3H, s, 2-CH_3), 3.7—4.4 (4H, m, OCH_2CH_2O), 7.75—8.15 (2H, m, H-6,7), 8.3—8.8 (2H, m, H-5,8). Found: C, 67.78; H, 6.19; N, 12.10%. Calcd for $C_{13}H_{14}N_4O_2$: C, 67.81; H, 6.19; N, 12.17%.

4-(2-Methyl-1,3-dioxolan-2-yl)-2-phenylcycloheptimidazole (19): Yellow needles (from cyclohexane); mp 155—156 °C; UV (CH_3OH) 259 (log ε 4.53), 277 sh (4.46), 356 sh (4.39), 366 (4.40), 415 nm sh (3.25); ^1H NMR ($CDCl_3$) δ=2.28 (3H, s, CH_3), 3.6—4.2 (4H, m, OCH_2CH_2O), 7.2—7.6 (3H, m, H-3′,4′,5′), 7.65—8.0 (2H, m, H-6,7), 8.3—8.5 (1H, m, H-5), 8.55—8.9 (3H, m, H-2′,6′,8). Found: C, 74.05; H, 5.63; N, 9.52%. Calcd for $C_{18}H_{16}N_4O_2$: C, 73.95; H, 5.52; N, 9.58%.

Rearrangement of the Methyl Ether (3a) with Sodium Ethoxide or Potassium Hydroxide. (a) To a sodium ethoxide solution, prepared from sodium (28 mg, 1.2 mmol) and absolute ethanol (6 ml), was added **3a** (113 mg, 0.6 mmol). The mixture was refluxed for 30 min to give **14** (116 mg, 82%).

(b) A mixture of **3a** (266 mg, 1.2 mmol) and potassium hydroxide (67 mg, 1.2 mmol) in absolute ethanol (10 ml) was refluxed for 1 h to give **14** (204 mg, 72%).

Reaction of the Methyl Ether (3b) with Sodium Ethoxide or Potassium Hydroxide. (a) Methyl ether **3b** (222 mg, 1 mmol) in sodium ethoxide solution, prepared from sodium (46 mg, 2 mmol) and absolute ethanol (10 ml), was refluxed for 30 min to give **2** (45 mg, 22%) and **15** (145 mg, 62%).

(b) A mixture of **3b** (222 mg, 1 mmol) and potassium hydroxide (56 mg, 1 mmol) in absolute ethanol (10 ml) was refluxed for 1 h to give **2** (44 mg, 21%) and **15** (105 mg, 44%).

Hydrolysis of the Cycloheptimidazole (17). Compound **17** (231 mg, 1 mmol) in 2 M hydrochloric acid (20 ml) was heated on a water bath for 20 min. The mixture was diluted with water, neutralized with a saturated sodium hydrogencarbonate solution, and extracted with chloroform. The evaporation residue from the extract was chromatographed on a Wakogel B-10 plate (30×30 cm) with ethyl acetate to give 4-acetyl-2-aminocycloheptimidazole (**20**) (155 mg, 83%) as yellow needles (from ethanol): mp 218—219 °C (lit,[5] 213—214 °C).

Hydrolysis of the Cycloheptimidazole (19): Compound **19** (81 mg, 0.28 m mol) in 1 M hydrochloric acid (4 ml) was heated on a water bath for 20 min. The mixture was worked

up, as mentioned above, to give 4-acetyl-2-phenylcycloheptimidazole (**21**) (43 mg, 65%) as yellow needles (from cyclohexane): mp 148—149 °C (lit,[5] 142—143 °C).

We wish to thank Dr. Hiromichi Matsuura, Wakunaga Pharmaceutical Co., Ltd., for his kind measurements of the high-resolution mass spectra. The present work was partly supported by a Grant-in-Aid for Scientific Research (No. 60540336) from the Ministry of Education, Science and Culture.

Thermal Condensation in Solid State of *N*-Hydroxyalkyl-2-imidazolidinone

Choichiro SHIMASAKI,* Ryosei KANAYAMA, Hiroaki YOSHIDA, and Makoto YUGAMIDANI
Faculty of Engineering, Toyama University, Gofuku, Toyama 930
(Received May 22, 1986)

N-(1-Hydroxyalkyl)-2-imidazolidinones (**1**) were prepared by a reaction of 2-imidazolidinone with form-, acet-, propion-, and butyraldehyde. In all of these reactions, **1** were unstable and moisture-sensitive substances. The pyrolysis reaction of **1** was found to be a thermal decomposition via a condensation reaction stage after a molten state. The condensation stage obeyed 1/2- and the first-order kinetics. The kinetic data regarding the condensation reaction were evaluated by analyses of the dependences of the area of isothermal DSC curves upon the reaction time. It may be concluded that the difference provided by the reaction order and the activation parameters were caused by the number of the hydrogen atoms on the β-carbon atom adjacent to the carbon attacked the hydroxyl group of side chain in **1**. In the decomposition by electron impact of **1** and dimer of **1**, the cleavage of the five-membered ring which corresponded to the molecular-ion peak for 2-imidazolidinone (*m/z* 86) was considered to take place after a successive cleavage of the side chain. On the basis of both kinetic studies and ESR or Mass spectral observations, the dimerization mechanism is fully discussed.

Thermosetting resins are characterized by irreversible chemical and physical changes that take place during a "cure." The resin is polymerized into a substance of a three-dimensional network which is no longer soluble or fusible. Whenever basic studies regarding this resin or its chemical structures and curing reactions are investigated, a determination of the experimental conditions involves many difficulties. Recently, Ishida et al.[1] have a convenient method using computer simulation for the initial polymerization mechanism of the trimer (at most). However, a study regarding the reaction products and the mechanism of the thermal condensation for *N*-(1-hydroxyalkyl)-2-imidazolidinone (**1**) in the solid state has not yet been carried out.

2-Imidazolidinone (**2**) has many advantages over any other substituted ureas. Furthermore, **2** has two active imino groups similar to the amino groups of urea. **2** can not produce compounds which have an intermolecular ether formation such as uron. If **1** are cured at a certain temperature, the curing process must be similar to those of the main-chain formation for the urea resin. The present authors investigated the curing reaction of **1** under no alkaline and acid catalyst conditions by IR, ^{1}H and ^{13}C NMR measurements, as well as mass spectrum, ESR, and DSC measurements. DSC is a useful tool for measuring the thermally induced conformation transition of macromolecules[2] as well as the polymerization process. An application of DSC to the study of polymerization provides available information for a kinetic data, such as a reaction parameter. The present authors have already reported that **2**, 2-imidazolidinethione, and their *N*,*N*′-bis(hydroxymethyl) derivatives are of great value as thermally stable agents.[3] The object of the present work is divided into two parts: (1) The characterization and experimental verification of reactions related to the proposed process. (2) The condensation of the material and reaction mechanism to estimate the overall reaction for the monomer by a thermochemical analysis.

Experimental

Materials. The **2** (paraformaldehyde, ethanol, and methanol) were of reagent grade and were used without further purification. The acet-, propion-, and butyraldehyde were distilled before use.

Preparation of Samples. A preparation of *N*-(1-hydroxymethyl)-2-imidazolidinone (**1a**) (**2** 43 g(0.5 mol) and paraformaldehyde 15 g(0.5 mol)) was suspended in 25 ml of ethanol under a nitrogen atmosphere. The ethanol solution was controlled at pH 12 with a 2M† -NaOH aq soln. as the catalyst. After an elevation of the temperature by the reaction heat, the ethanol solution was cooled below 10 °C with ice. White crude crystals were filtered with suction and washed with cooled acetone in order to remove any solvents and the 2M-NaOH aq soln. A white crystal of **1a** was obtained by recrystallization from chroloform.

A preparation of *N*-(1-hydroxyethyl)-2-imidazolidinone (**1b**), *N*-(1-hydroxypropyl)-2-imidazolidinone (**1c**), and *N*-(1-hydroxybutyl)-2-imidazolidinone (**1d**) (*N*-substituted hydroxyalkyl derivatives such as **1b**, **1c**, and **1d**) were all prepared according to the reported method for monomethylolurea.[4]

Measurements. DSC and TG: A sample was heated at the rate 5 °C min^{-1} in air using a Rigakudenki TG-DSC apparatus.

IR spectrophotometry: An IR spectrum of the sample was recorded on a Nipponbunko IR-810 using the KBr-disc method.

Mass spectrum: A mass spectrum of the sample was taken with an ionization potential of between 20 and 70 eV using a JEOL-JMS-D300.

^{1}H and ^{13}C NMR measurements: **1a** and **1c** were dissolved in a deuterated dimethyl sulfoxide solution, and **1b** and **1d** in a deuterated chloroform solution, respectively. The ^{1}H and ^{13}C NMR spectra of each solution was taken on a JNM-FX-90-FT-NMR instrument.

ESR measurement: The ESR spectrum of the sample was

† 1 M=1 mol dm^{-3}.

taken under 50 and 100 kHz fields (modulation using a JEOL FE 3X spectrometer). The sample tube that fed **1c** was sealed in a vacuum system (10^{-3} mmHg (1 mmHg=133.322 Pa)) using a Hickman vacuum apparatus.

Paper chromatography: A one-dimensional paper chromatographic separation was carried out on the species using a developing solvent of 1-butanol–ethanol–water (4:1:2). The color was developed using a color-producing reagent of sodium pentacyanonitrosylferrate(III) and potassium hexacyanoferrate(III).[5]

Results and Discussion

Syntheses of 1. The physical properties of **1** are summarized in Table 1. As Table 1 shows, the observed values in the elemental analysis are in accord with the calculated values. The R_f values of the samples by paper chromatography increases upon increasing of the length of the alkyl group in the side chain. Similarly, the melting point of the sample rises upon increasing the molecular weight of **1** (except for **1d**). In the IR spectra, these samples do not show any change in the characteristic absorption due to ν_{C-H} at 2950 cm^{-1} increases with an increase in the length of the side chain. The NMR data of these samples indicate that the structure of **1** is in accord with that proposed in Scheme 1. In the mass spectra of these samples, the parent peak can be detected in the spectrum of **1a** at *m/z* 116. In the spectra of other samples, however, the parent peak can not be detected. The peak of $(M-H_2O)^+$ can be detected at a high intensity similar to that of the mass spectra of tertiary alcohol. The analytical and spectroscopic data regarding the structure of **1** are consistent with that proposed in Scheme 1.

Thermal Analysis. Figure 1 shows a DSC–TG curve for **1c**, as determined by a heating rate of 5 °C min^{-1}. The DSC curve exhibited two endother-

mic peaks and an exothermic peak. The first endothermic peak is attributed to the melting point. The second endothermic peak is due to the formation of a dimer; this is confirmed by the IR, mass, and NMR spectra of samples obtained before and after the second endothermic peak (described later). The final DSC peak is found over a wide temperature range, in which the sample decomposed with the evolution of gases. The TG curve shows that the pyrolysis process for a sample takes place in two stages. In Fig. 1, the first plateau of the TG curve is probably due to a condensation of the sample to a dimer compound. The other plateau corresponds to a thermal degradation and a decomposition reaction. The kinetic consideration is carried out by this condensation. First, the present authors discuss the kinetic analysis using for an example McGhie method.[6] The DSC measurements are carried out by the method in which the sample was hermetically sealed in an aluminum pan and in a DSC cell using an isothermal mode. Condensation was studied in the temperature range of 90—150 °C. Figure 2 shows typical isothermal condensation curves for **1c**. After an induction period, during which condensation occurred at a slow rate, there was a rapid increase in the endothermic heat of the condensation region (apparently obeying 1/2- and first-order kinetics). By calling the representative total area under a given isothermal curve a, and the fractional area up to the time t, x, the 1/2- and the first-order kinetics plots of $2\times[a^{1/2}-(a-x)^{1/2}]$ and $\ln[a/(a-x)]$ vs. $t-t_0$ for each curve are linear. Figures 3 and 4 show these plots for the isothermal condensation of four samples at any temperature. The data was normalized with respect to time by plotting the time after the induction period t_0. Thus, each isothermal curve yielded two important quantities, t_0 and k. The 1/2- and the first- order rate constant was obtained from the slope of the curve in Figs. 3 and 4. The rate constant for the condensation of **1** is summarized in Table 2. Second, Arrhenius plots are shown in Fig. 5. The activation energy was obtained by the slope and the frequency factor was obtained by the intercept of these lines (Fig. 5). The results of these calculations are summarized in Table 3. The reaction order of **1a** is different from the other three samples. **1b** has an activation energy about half that of **1c** or **1d** and **1b** has an activation entropy about two-times that of **1c** or **1d**. **1c** has an activation energy and the activation entropy that are the same order as **1d**. It can be assumed that the difference provided by the reaction order and the

activation parameters is caused by the number of the hydrogen atom (β-hydrogen atom) on β-carbon atom adjacent to the carbon attached to the hydroxyl group of the side chain in **1**. These compounds may be grouped, therefore, into three general classes: (1) no β-hydrogen atom (**1a**); (2) three β-hydrogen atoms (**1b**) and (3) two β-hydrogen atoms (**1c**, **1d**).

Thermal Condensation of 1. The TG analysis shows that a dehydration of the samples can be expected for the thermal condensation of **1** since the weight loss of the first plateau at the temperature range of the condensation corresponds to that of about one mole of water. The IR spectra of the condensation products show that the absorption due to ν_{C-O} at 1030 cm^{-1} decreases in intensity (Fig. 6). The ^{13}C NMR spectra of **1c** and its condensation product is given as an example in Fig. 7. This figure shows that the signal at δ 161.556 due to the carbonyl group separates into two signals, and the signal due to the α-carbon atom attached to the hydroxyl group splits after condensation. These results show that the formation process of dimer seemed to be dehydrated as intermolecular combination (Scheme 2). The mass spectra of the condensation products also support this dimer formation. The mass spectra of the condensation products are summarized in Table 4. In this Table 4 **1a**-H, **1b**-H, **1c**-H, and **1d**-H are used for symboliz-

ing the thermal condensation products of **1a**, **1b**, **1c**, and **1d**, respectively. There are no peaks due to trimer or oligomer in these mass spectra. The observed fragment ions in the mass spectra of the condensation products support the main fragmentation mechanism of the dimer by the typical representative **1c** (Fig. 8). The amount of aldehyde liberated during the thermal reaction of **1** was about 10% (in quantities of the sample fed with the flask). The elimination of the corresponding aldehyde due to the pyrolysis of **1** is a reverse reaction of *N*-hydroxyalkylation. Consequently, the pyrolysis of **1** leads to the production of **2** (10% of the amount of the samples fed with the flask). A

separation of the various mixtures into the liberated **2** could not be verified. Thus, the observed values through elemental analyses are not in full agreement with calculated ones.

Reaction Mechanism for Thermal Condensation in Solid State. Dimerization of **1a**: **1a** has a γ-lactam structure. Therefore, **1a** shows a "tautomeric change" as shown in Scheme 3. In the DSC measurement over the high-temperature range, it is expected that an activated complex is formed from two molecules of the lactim (enol isomer) of **1a** (Scheme 4). These equilibrium conditions for Scheme 4 lie far to the right, showing the reaction process during a smooth formation of the activation complex. At this equilibrium, therefore, the reaction for dimerization apparently obeys first-order kinetics. The expected process for the dimerization of **1a** is as follows.

The reaction mechanism for the dimerization of **1b**, **1c**, and **1d**: As described in the previous section, the dimerization of **1** shows first-order kinetics, whereas in **1b**, **1c**, and **1d**, the order of reaction is to the 1/2 order. It is expected that the dimerization of **1b**, **1c**, and **1d** proceeds by the same mechanism. The use of the results of ESR and mass spectra clarifies the difference in the order of the reaction. ESR measurements were carried out for **1c** at room temperature, 70, 100, 130, and 150 °C. **1c** was in a solid state at room temperature and at other temperatures melted. As Fig. 9 shows, the signal may be due to an intermediate material which participates in the thermal condensation, since this signal was observed alone at the temperature range of the thermal-condensation process. It shows that the intermediate material is considered to form at the pertinent temperature range (70—130 °C). Also, this signal deviates from 0 G to a low magnetic field, and shows a discernible shoulder at the low-magnetic-field side of the main signal. The above results do not indicate that **1c** thermally polymerizes to form the radical. Therefore, the present authors conclude that **1c** in this system forms the electron-transfer complex. After the ESR measurement of **1c** (at 100 °C), the sample tube fed with **1c** was cooled to room temperature. During the ESR measurement under these conditions, the same signal (observed at 100 °C) was reproduced in the ESR spectrum of this sample. This result seems to show that the thermal condensation stops and the resulting activity species remain unaltered. This behavior resembles ordinary very closely living polymerization regarding chemical properties. The possible structure of intermediates formed during the activated state in the course of the dimerization process for **1b**, **1c**, and **1d** is the activated complex (A) and the enol type (B) like lactim (Scheme 5).

The presence of (A) was confirmed by the ESR measurements, and (B) gave no direct evidence concering its existence in the solid state. In the melted state, however, the presence of (B) have likewise been formed in the case of cyanuric acid. By a comparison of structures (A) and (B), the hydroxyl group of (A) was easier to eliminate than that of (B). In the next step, the activated complex (C) (Scheme 5) was formed

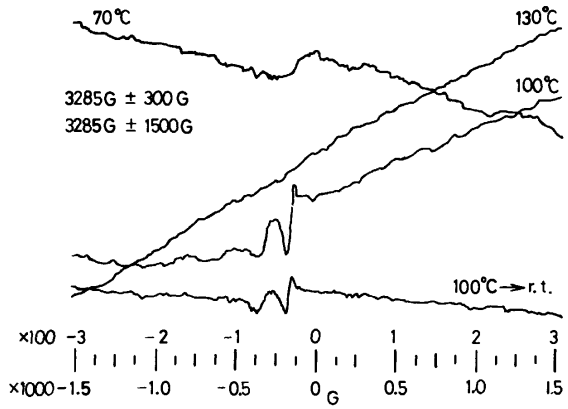

Fig. 9. ESR spectra of **1c**.

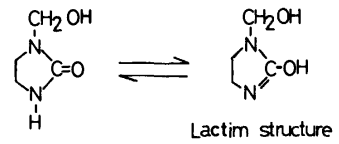
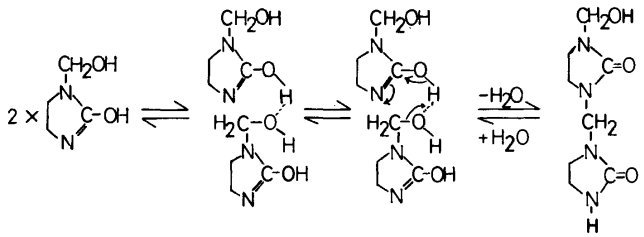
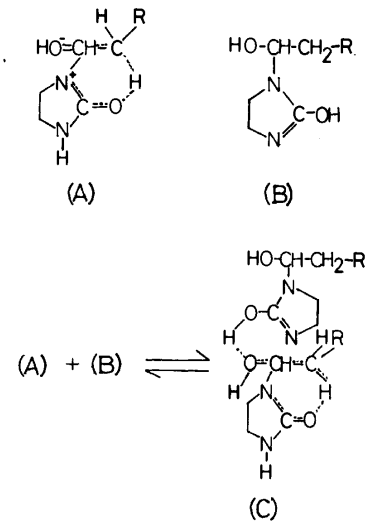


Scheme 3.



Scheme 4.



Scheme 5.

from (A) and (B). Now, on the assumption that the overall reaction of dimerization of **1** proceeds with the apparent first-order reaction (such as the dimerization of **1a**), the main conclusion to be drawn from these results is as follows. The concentration of **1**, (A), (B), and (C) are symbolized as [M], [A], [B], and [C], respectively. The equation for each process is as follows:

For the formation of (A)

$$M \rightleftharpoons A \qquad K_1[M] = [A]. \tag{1}$$

For the formation of (B)

$$M \rightleftharpoons B \qquad K_2[M] = [B]. \tag{2}$$

For the formation of (C)

$$A + B \rightleftharpoons C \qquad K_3[A][B] = [C], \tag{3}$$

where K_1, K_2, and K_3 are the equilibrium constants for each process. If the values of [A] and [B] in Eq. 3 are replaced by the corresponding expressions as Eqs. 1 and 2, it is found that

$$K_1 \cdot K_2 \cdot K_3[M]^2 = [C]. \tag{4}$$

According to the previous assumption, for an overall reaction,

$$\text{Reaction rate} = k_0[M], \tag{5}$$

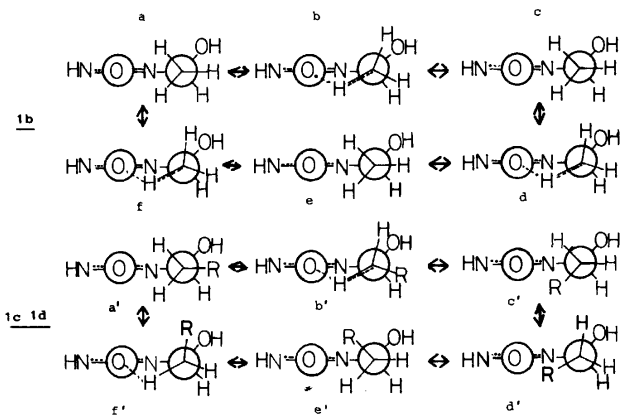


Fig. 10. Conformations of **1b**, **1c**, and **1d**.

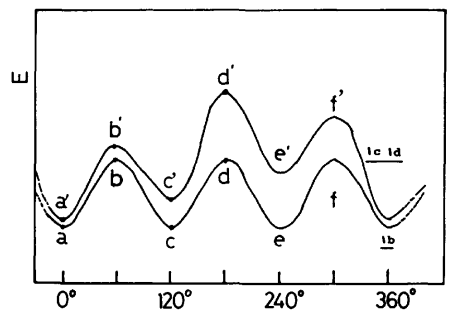

Fig. 11. Rotational energy profiles for **1b**, **1c**, and **1d**.

where k_0 is the rate constant for the overall reaction. When the value of [M] in Eq. 4 is substituted into Eq. 5,

$$\text{Reaction rate} = k_0\{1/(K_1 \cdot K_2 \cdot K_3)\}^{1/2}[C]^{1/2}. \tag{6}$$

When $k_0\{1/(K_1 \cdot K_2 \cdot K_3)\}^{1/2}$ is substituted for k, Eq. 6 becomes

$$\text{Reaction rate} = k[C]^{1/2}. \tag{7}$$

Equation 7 shows that the reaction for the dimerization of **1b**, **1c**, and **1d** proceeds by a 1/2-order reaction. This result agrees with those of the DSC measurements. It is expected for **1b**, **1c**, and **1d** that the DSC measurement was taken in order to obtain information regarding the formation of (C) to the dimer. From these results, it is clear that (A), (B), and (C) are formed during the induction period. The effect of the number of β-hydrogen atoms on the activation parameters must be discussed. **1c** and **1d** have methyl and ethyl groups on the β-carbon atom, respectively. The difference in the activation parameters between **1c** and **1d** for the dimerization is negligibly small. Therefore, the effect of these alkyl groups as the electron donor on the electron-transfer complex (A) is negligible. Figure 10 shows conformations of **1b**, and **1c** and **1d** which are concerned with a rotation about the bond between the α- and the β-carbon atoms attached to the hydroxyl group. Their interconversion processes are represented by the Newman projection formulae. The formation of the electron-transfer complex in the case of **1b** is formed at b, d, and f (Fig. 10). However, in the case of **1c** and **1d**, the formation of the electron-transfer complex is formed at b′ and f′. The formation of (A) at b, b′, d, f, and f′ should be unstable forms owing to their eclipsed geometries. This is the reason for the formation of (A), which is only at the pertinent temperature range (as shown in the ESR spectra). Figure 11 shows the rotational-energy profiles for **1b**, **1c**, and **1d**. According to these profiles, it is definite in the case of **1c** and **1d** that the rotational-energy of structures b′ and f′ is higher than that for b and f in **1b**. This is the reason for the difference in the activation parameters between **1b** and **1c** or **1d**.

We acknowledge the good advice of Prof. Eiichi Tsukurimichi and Dr. Toshiaki Yoshimura. We thank Mr. Yoshiharu Yoneyama for NMR measurements and Miss Misao Shinoda for the Mass spectra. We thank Prof. Shigeya Takeuchi for good advice regarding DSC measurement.

The Nucleophilic Reaction upon Electron-Deficient Pyridone Derivatives. VIII.[1] Novel Fragmentation of 3,5-Dinitro-2-pyridone by Primary Amine

Yasuo TOHDA,* Masahiro ARIGA, Toshihide KAWASHIMA, and Eizo MATSUMURA
Department of Chemistry, Osaka Kyoiku University,
Minamikawahoricho 4-88, Tennoji-ku, Osaka 543
(Received June 17, 1986)

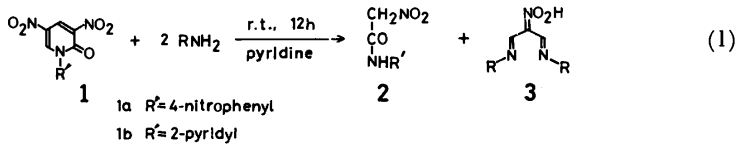
Fragmentation of 3,5-dinitro-2-pyridone (**1**) by primary amine gave nitroacetamide (**2**) and nitromalonaldehyde diimine. In the case of *N*-methyl derivative (**1c**), the reaction was completely suppressed by the product **2** to give an anionic σ-adduct of **1c** with **2**. The mechanism of the reaction was discussed.

In previous papers, we reported a ring transformation of 3,5-dinitro-2-pyridone (**1**) with various ketones into *p*-nitrophenols[2] or *p*-nitroanilines.[3] Three types of the intermediates were isolated and characterized, i.e., an anionic σ-adduct,[4] a 2-azabicyclo[3.3.1]nonane derivative,[2,3] and an α-nitro-α-(2-nitro-2,4-hexadienyl)acetamide derivative.[3] (Scheme 1) The reaction of **1** is unusual in the reactions of heteroaromatic compounds, because most ring transformations of electron-deficient heterocyclic compounds with ketones or other nucleophiles proceed through open chain intermediates rather than through such bicyclic compounds.[5] It is analogous to the reaction of 1,3,5-trinitrobenzene with acetone and diethylamine to give *N,N*-diethyl-*p*-nitroaniline,[6] because an anionic σ-adduct[7] and a bicyclo[3.3.1]nonane derivative[8] were recognized as the intermediates.

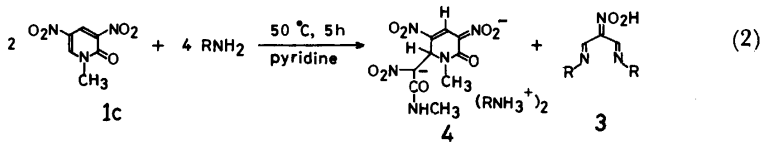
In our study on electron-deficient pyridone derivatives, we found a novel fragmentation of 3,5-dinitro-2-pyridone (**1**) by primary amine. The mechanism of the reaction which appears to be closely related to those of the above reactions will be discussed.

Results and Discussion

The reaction of 3,5-dinitro-1-(4-nitrophenyl)-2-pyridone (**1a**) with excessive aliphatic or aromatic primary amine in pyridine at room temperature gave a nitroacetamide (**2a**) and nitromalonaldehyde diimine (**3**) (Eq. 1). The aliphatic amines reacted faster and gave better yields of **2** and **3** than the aromatic amines. The reaction of **1a** with cyclohexylamine was completed within 5 min. Similarly, 1-(2-pyridyl) derivative (**1b**) reacted with these amines according to Eq. 1. On the other hand, 1-methyl derivative (**1c**) reacted with excess of the aliphatic primary amines at 50 °C to give **3** and a Michael-type adduct (**4**) as indicated in Eq. 2. No aromatic primary amines reacted with **1c** at 50 °C due to their low basicity. The results are summarized in Table 1. The structure of **3** was confirmed by comparing **3b** with an authentic sample prepared by the reaction of sodium salt of nitromalonaldehyde with *p*-anisidine. The product **4** showed characteristics of anionic σ-adduct of **1c** by the UV and ^{1}H NMR spectra.[4] The addition site of nucleophilic carbon or nitrogen is C-6 of **1c**. Chemical shifts of H-6 of **4a** (cyclohexylammonium salt) or **4b** (*t*-butylammonium salt) were found at δ of 6.2. The values are about 1 ppm lower than those of anionic σ-adducts of **1c** with usual carbon nucleophiles. This is attributed to strong diamagnetic anisotropic effect of anionic part of α-(*N*-methyl-carbamoyl)-α-nitromethylene of **4**. Coupling between H-4 and H-6 was not observed. Treatment of **4a** with hydrochloric acid gave **1c**, *N*-methyl-α-nitroacetamide (**2c**), and cyclohexylammonium chloride in 85, 45, and 90% yields, respectively. An authentic sample of **4a** was obtained by mixing its components in pyridine at room temperature. From these facts, **4** were identified as dianionic salts as indicated in Eq. 2.



(1)



(2)

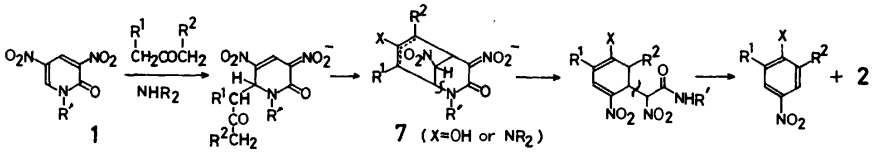
The different results between **1a**, **1b**, and **1c** can be interpreted by the hard-soft concept. **1c** is a softer electrophile than **1a** and **1b**, because **1c** is a weaker electrophile for hard amines but has stronger affinity for soft nucleophilic carbon of nitroacetamide (**2**) than **1a** and **1b**. In the case of **1c**, the reaction indicated by Eq. 1 is completely suppressed by the product **2c** which gives adduct **4** by addition to **1c**. The difference in reactivity between **1a** and **1c** explains the following facts. In the presence of excess acetone, the reaction of **1c** with cyclohexylamine at 70 °C gave *N*-cyclohexyl-*p*-nitroaniline quantitatively. The fragmentation in Eqs. 1 and 2 is thus completely suppressed by acetone nucleophile. On the other hand, in the case of the reaction of **1a** under similar conditions, competitive reactions between the fragmentation and the ring transformation occurred to give a mixture of **3a** and *N*-cyclohexyl-*p*-nitroaniline in 41 and 19% yields, respectively.

When the reaction of a mixture of **1c** and excess of cyclohexylamine (1:6 mol ratio) in pyridine-d_5 was monitored at 37 °C by ^{1}H NMR spectra, the first observable species was only an anionic σ-adduct (**5**) of **1c** with the amine; δ=3.18 (s, NCH_3), 5.68 (d, H-6, J=1.0 Hz), and 9.37 (d, H-4, J=1.0 Hz). The chemical shifts and coupling patterns were similar to those of the secondary amine adducts of **1c**.[4] As the peaks of **5** decreased slowly, the peaks of the products **3a** and **4a** increased. The change did not obey the first-order kinetics as expected from the mechanism. Neither other intermediate nor by-product was detected. Transformation of **5** to an intermediate is the rate-determining step. The pyridone **1c** also reacted with strong secondary amines such as pyrrolidine and diethylamine in pyridine-d_5 to give anionic σ-adducts immediately, but the further fragmentation did not occur under the similar conditions. On the other hand, the reactive pyridone **1a** was rapidly decom-

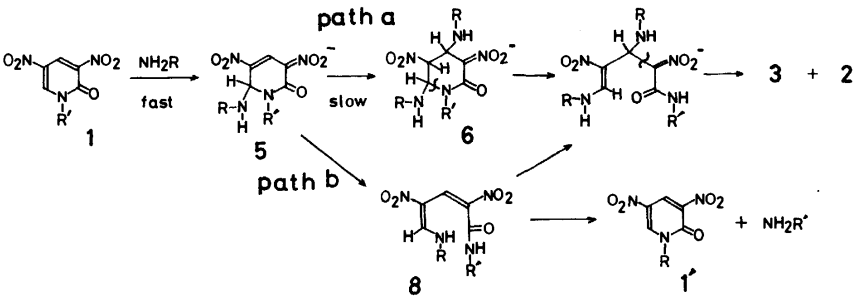
Table 1. Fragmentation of 3,5-Dinitro-2-pyridone (**1**) by Primary Amine

Substrate[a]	Amine	Reaction Temperature	Products	(Yields/%)[c]
1a	Cyclohexylamine	r.t.	**2a** (80)	**3a** (88)
1a	*p*-Anisidine	r.t.	**2a** (15)	**3b** (73)
1a	Aniline	r.t.	**2a** (0)	**3c** (59)
1b	Cyclohexylamine	r.t.	**2b'**[b] (75)	**3a** (86)
1b	*p*-Anisidine	r.t.	**2b** (56)	**3b** (82)
1b	Aniline	r.t.	**2b** (0)	**3c** (58)
1c	Cyclohexylamine	50 °C	**4a** (94)	**3a** (88)
1c	*t*-Butylamine	50 °C	**4b** (92)	**3d** (88)
1c	*p*-Anisidine	100 °C	—	**3c** (6)

a) Notations of the compounds are described in Eqs. 1 and 2. b) Isolated as a cyclohexylammonium salt. c) In the reaction of **1a** and **1b**, yields are based on Eq. 1. In the reaction of **1c**, yields are based on Eq. 2.



Scheme 1.



Scheme 2.

posed to unidentifiable products by pyrrolidine.

There are two possible courses of the reaction. The one involves a complex (**6**) formed by twofold addition of the primary amine. (Scheme 2, path a) The complex **6** corresponds to the bicyclic intermediate (**7**) in the ring transformation (Scheme 1).[2,3] Although diadduct formation such as **6** has been exemplified in the reaction of 1,3,5-trinitrobenzene and other electron-deficient aromatic systems,[9] this type of fragmentation has not been reported. Easy heterolysis of C_6–N_1 bond of **6** explains the fragmentation of **1**, whereas lack of such a bond in the diadduct of trinitrobenzene would result no fragmentation.

The alternative course which involves an open-chain intermediate (**8**) can be considered. (path b) The similar intermediate has been postulated in the reactions of 3,5-dinitro-4-pyridone with sodium salt of ethyl acetoacetate[10] or with primary amine.[11] In the latter reaction, recyclization of the open-chain intermediate gives another 4-pyridone, in which an original *N*-substituent is exchanged for the primary amine. Since such a substitution product (**1'**) was not found in the present reaction, path a is more probable than path b.

Thus the fragmentation is a characteristic reaction of 3,5-dinitro-2-pyridone (**1**) and unique reaction of electron-deficient aromatic compounds.

Experimental

The infrared spectra were measured in nujol by means of a Hitachi 260-10 spectrophotometer, ^{1}H NMR spectra by a Hitachi R-20 B spectrometer, and ultraviolet spectra by a Shimadzu UV-240 spectrophotometer.

3,5-Dinitro-(4-nitrophenyl)-2-pyridone (1a). Nitration of 1-(4-nitrophenyl)-2-pyridone with fuming nitric acid (d 1.42) at 130 °C for 7 h gave **1a** in 65% yield. Pale yellow needles (AcOH–H_2O 3:1); mp 221.5—222 °C. ^{1}H NMR (DMSO-d_6) δ=7.91 (d, 2H, J=9.1 Hz), 8.46 (d, 2H, J=9.1 Hz), 9.17 (d, 1H, J=3.1 Hz), 9.51 (d, 1H, J=3.1 Hz), IR: 1710 cm^{-1} (C=O), 1577, 1530, 1346, 1324 cm^{-1} (NO_2). Found: C, 43.10; H, 2.05; N, 18.27%. Calcd for $C_{11}H_6N_4O_7$: C, 43.15; H, 1.98; N, 18.30%.

Reaction of 1a with Cyclohexylamine. To a solution of 0.61 g of **1a** in 15 ml of pyridine 1.21 g of cyclohexylamine in 5 ml of pyridine was added at 0 °C. The mixture was allowed to stand at room temperature for 12 h. After removal of the solvent in vacuo, residual oil was extracted with hexane to give 0.49 g of the diimine **3a**; colorless needles (hexane); mp 86—87 °C. ^{1}H NMR ($CDCl_3$) δ=1.0—2.2 (m, 20H), 3.0—3.5 (m, 2H), 8.70 (s, 2H), 11.0 (broad, 1H). IR: 1650, 1600 cm^{-1} (C=N). Found: C, 64.74; H, 9.00; N, 14.99%. Calcd for $C_{15}H_{25}N_3O_2$: C, 64.48; H, 9.02; N, 15.04%. The residue was dissolved in water and slightly excess hydrochloric acid was added to the solution. Precipitates were recrystallized from ethanol to give 0.36 g of α-nitro-*N*-(4-nitrophenyl)acetamide (**2a**); pale yellow needles; decomp 177—179 °C. ^{1}H NMR (DMSO-d_6) δ=5.59 (s, 2H), 7.83 (d, 2H, J=9.2 Hz), 8.23 (d, 2H, J=9.2 Hz), 11.07 (broad s, 1H). IR: 3360 cm^{-1} (N–H), 1703 cm^{-1} (C=O). Found: C, 42.90; H, 3.17; N, 18.69%. Calcd for $C_8H_7N_3O_5$: C, 42.67; H, 3.13; N, 18.66%.

Reaction of 3,5-Dinitro-1-(2-pyridyl)-2-pyridone (1b) with *p*-Anisidine. To a solution of 0.52 g of **1b** in 15 ml of pyridine was added 0.74 g of *p*-anisidine in 5 ml of pyridine at 0 °C. The mixture was allowed to stand at room temperature for 12 h. Water was added to the mixture and resulted precipitates were recrystallized from ethanol to give 0.54 g of **3b**. Yellow needles; mp 133—135 °C. ^{1}H NMR ($CDCl_3$) δ=3.82 (s, 6H), 6.94 (d, 4H, J=9.1 Hz), 7.19 (d, 4H, J=9.1 Hz), 8.99 (s, 2H), 13.5 (broad, 1H). IR: 1642, 1563 cm^{-1} (C=N). Found: C, 62.50; H, 5.36; N, 12.74%. Calcd for $C_{17}H_{17}N_3O_4$: C, 62.37; H, 5.24; N, 12.84%. After the solvent was removed in vacuo, the residue was recrystallized from chloroform to give 0.21 g of **2a**.[2]

Similarly, nitromalonaldehyde dianil (**3c**) was obtained. Yellow needles; mp 93—95 °C. ^{1}H NMR ($CDCl_3$) δ=7.0—7.6 (m, 10H), 9.10 (s, 2H), 13.5 (broad, 1H). IR: 1650, 1567 cm^{-1} (C=N). Found: C, 67.54; H, 4.88; N, 15.47%. Calcd for $C_{15}H_{13}N_3O_2$: C, 67.40; H, 4.90; N, 15.72%.

Reaction of 1-Methyl-3,5-dinitro-2-pyridone (1c) with Cyclohexylamine. To a solution of 0.40 g of **1c** in 15 ml of pyridine 1.21 g of cyclohexylamine in 5 ml of pyridine was added. The mixture was heated at 50 °C for 3 h. After the solvent was removed in vacuo, residual oil was extracted with hexane. The extract was recrystallized from hexane to give 0.25 g of **3a**. The residue was dissolved in hot ethanol containig a few drops of cyclohexylamine. After cooling, 0.43 g of **4a** was obtained as orange powder; decomp 118—123 °C. ^{1}H NMR (DMSO-d_6) δ=0.9—2.2 (m, 20H), 2.71 (s, 3H), 2.71 (d, 3H, J=5.2 Hz), 2.4—3.2 (m, 2H), 6.20 (s, H-6), 5.8—7.0 (broad, 8H), 8.60 (s, H-4), 10.04 (broad q, 1H, J=5.2 Hz). IR: 3260, 2650, 2550 cm^{-1} (NH_3^+), 1626 cm^{-1} (C=O). UV (MeOH, 8.38×10^{-5} mol l^{-1}, ε depends on the concentration of **4a**): λ_{max} (ε) 489 nm (1.96×10^4), 302 nm (1.37×10^4). Found: C, 47.27; H, 7.30; N, 18.42%. Calcd for $C_{21}H_{39}N_7O_9$ (monohydrate): C, 47.27; H, 7.37; N, 18.38%.

Similarly **3d** and **4b** were obtained from reaction of **1c** with *t*-butylamine.

3d: Colorless needles (hexane); mp 142—143 °C. ^{1}H NMR ($CDCl_3$) δ=1.34 (s, 18H), 8.73 (s, 2H), 12.6 (broad, 1H). IR: 1640, 1592 cm^{-1} (C=N). Found: C, 58.02; H, 9.29; N, 18.43%. Calcd for $C_{11}H_{21}N_3O_2$: C, 58.12; H, 9.31; N, 18.49%.

4b: Orange powder (ethanol–*t*-butylamine); decomp 120—127 °C. ^{1}H NMR (DMSO-d_6) δ=1.24 (s, 18H), 2.70 (s, 3H), 2.71 (d, 3H, J=4.9 Hz), 6.28 (s, H-4), 6.7 (broad, 9H), 8.61 (s, H-6), 10.04 (broad q, 1H, J=4.9 Hz). IR: 2610, 2500 cm^{-1} (NH_3^+), 1627 cm^{-1} (C=O). UV (MeOH, 8.38×10^{-5} mol l^{-1}): λ_{max} (ε) 489 nm (1.71×10^4), 301 nm (1.61×10^4). Found: C, 41.83; H, 7.10; N, 20.22%. Calcd for $C_{17}H_{36}N_7O_{9,5}$ (1.5 hydrate): C, 41.63; H, 7.40; N, 19.99%.

Reaction of 1a with Cyclohexylamine in the Presence of Acetone. A solution of 0.31 g of **1a**, 0.61 g of cyclohexylamine, and 0.58 g of acetone in 20 ml of pyridine was heated at 70 °C for 3 h. The solvent was removed in vacuo and residue was treated by column-chromatograph with silica gel. Benzene elute gave 42 mg of *N*-cyclohexyl-*p*-nitroaniline; mp 99 °C; yellow needles (hexane). Chloroform elute gave 82 mg of 3-cyclohexylamino-2-nitro-2-propenal; mp 130—131 °C; pale yellow needles (hexane). Found: C, 54.58; H, 7.12; N, 14.35%. Calcd for $C_9H_{14}N_2O_3$: C, 54.53; H, 7.12; N, 14.13%. This compound was quantitatively obtained by treatment of **3a** with silica gel.

Synthesis of Shikalkin (±Shikonin) and Related Compounds[1)]

Akira TERADA,* Yasuhiro TANOUE, Akira HATADA, and Hiroshi SAKAMOTO
Department of Chemistry, Kyushu Institute of Technology, Sensui-cho, Tobata, Kitakyushu 804
(Received June 18, 1986)

The key intermediate, 2-formyl-1,4,5,8-tetramethoxynaphthalene, was prepared through 1,4,5,8-tetramethoxynaphthalene, which was obtained from 1,5-naphthalenediol via three steps or from naphthazarin via one step. A total synthesis of shikalkin and dihydroshikalkin have been accomplished with this aldehyde via a side-chain introductions with Grignard reactions and the following demethylations.

A root of *Lithospermum erythrorhizon* Sieb. et Zucc. found in Japan, China, and Korea is called Shikon and contains purple pigments (about 1 wt%) under the bark. Two kinds of Shikon are available in the market. One is called "Ko-shikon," which is the root of the above, and the other is "Nan-shikon," which is the root of *Macrotomia euchroma* Pauls. From ancient times the purple pigments have been used as dyes, which are well known as Kodaimurasaki. They can be represented by shikonin and its esters as Fig. 1.

These compounds have antiinflammatory,[4)] antibacterial,[5)] and antitumor actions,[6)] and are also used as raw materials for dyes[7)] and cosmetics.[8)]

Alkanna tinctoria in Europe contains alkannin,[9)] an enantiomer of shikonin. According to a proposal of R. Kuhn, Brockmann named the racemate shikalkin, an equimolar mixture of shikonin and alkannin. Japanese shikonin also contains 20% shikalkin.[10)]

Kuroda[11)] and Brockmann[9)] reported on shikonin's structure and a synthesis of its derivatives, but there was no report concerning the total synthesis of shikonin itself. First, Kuroda had proposed that all three hydroxyl groups in shikonin were bonded to the naphthazarin skeleton; finally, however, formula **1-a** was established by Brockmann.[9a)] Arakawa et al.[12)] showed that the absolute configuration of the α-hydroxyl group in shikonin is *R*.

Shikonin and alkannin are so labile that they must be delicately handled during their extraction.[9b, 11)] The fact that shikonin cyclizes easily by Lewis acid[13)] to cycloshikonin has posed difficulties in attempts toward its total synthesis. Until recently, cycloshikonin and cycloalkannin had been considered to possess structure **2**, but Sankawa et al.[14)] proved that the real structure was the ether **3** Fig. 2.

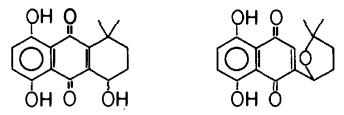
Fig. 1.

In a recent communication we reported on the total synthesis of shikalkin[(±)shikonin].[15)] The present paper describes the total synthesis in detail in addition to related compounds of shikalkin, and a new synthetic method of 1,4,5,8-tetramethoxynaphthalene.

Results and Discussion

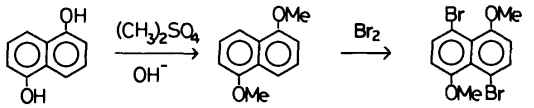
Methylation of 1,5-naphthalenediol with dimethyl sulfate provided 1,5-dimethoxynaphthalene (**4**).[16)] Bromination of **4** gave 4,8-dibromo-1,5-dimethoxynaphthalene (**5**).[17)] Zweig et al.[18)] reported that the compound **5** gave 1,4,5,8-tetramethoxynaphthalene (**6**) (19%) when treated with sodium methoxide and copper(I) oxide in DMF. By using copper(I) iodide[19)] instead of copper(I) oxide we were able to obtain **6** in a good yield (84%). The treatment of **6** with Vilsmeier reagent ($POCl_3$, DMF)[20)] gave 2-formyl-1,4,5,8-tetramethoxynaphthalene (**7**) in 99% yield.

Compound **6** was also synthesized from naphthazarin, which was easily prepared by a treatment of

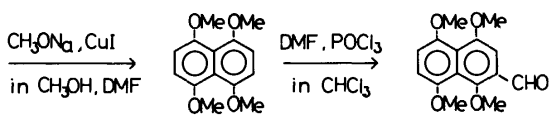


2 3

Fig. 2.



4 5



6 7

Fig. 3.

maleic anhydride with hydroquinone in a molten mixture of aluminum chloride and sodium chloride.[11b] According to Thomson's procedure, methylation of naphthazarin with methyl *p*-toluenesulfonate gave 5,8-dimethoxy-1,4-naphthoquinone (**8**) in 44% yield.[21] Reduction of the quinone **8** and methylation were simultaneously accomplished with sodium dithionite and dimethyl sulfate to give the tetramethyl ether **6** (48%). The ether **6** was also directly prepared in 44% yield from naphthazarin without the isolation of the quinone **8**.

First, the synthesis of dihydroshikalkin was tried. A treatment of the aldehyde **7** with isopentylmagnesium bromide gave 2-(1-hydroxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (**9**) (95%). Methylation of **9** with methyl iodide gave 2-(1-methoxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (**10**) (81%), which was transformed into a 1,4-naphthoquinone derivative **11** (42%)[22] by oxidation using cerium(IV) ammonium nitrate [$Ce(NH_4)_2(NO_3)_6$, CAN].[23]

Demethylation of **11** with aluminum chloride[24] gave 5,8-dihydroxy-2-(1-methoxy-4-methylpentyl)-1,4-naphthoquinone (**12**) in 49% yield. The ^1H NMR spectrum showed signals at δ 12.49 (1H), 12.59 (1H) due to phenolic hydroxyl groups whose protons form strong hydrogen bonds. The presence of a signal at δ 3.32 (3H) due to the methoxyl group suggested that no demethylation in the side chain had occurred. Therefore, a similar reaction was carried out without the protection of the hydroxyl group (shown in the scheme of Fig. 6).

Oxidation of **9** with CAN gave 2-(1-hydroxy-4-methylpentyl)-5,8-dimethoxy-1,4-naphthoquinone (**13**) (52%) as a major product. Further demethylation of the quinone **13** with aluminum chloride gave crude products, which were purified by silica-gel chromatography to afford two products.

The IR of the product eluted first barely showed a broad absorption at 3100—3700 cm^{-1}, which is similar to the spectrum of naphthazarin. The lack of a secondary alcoholic hydroxyl group was also proved by the IR spectrum which showed no C-O stretching band at 1060 cm^{-1}. The ^1H NMR spectrum showed signals at δ 12.47 (1H), 12.61 (1H) due to the phenolic hydroxyl groups; however, no signal was found at δ 3—6. Therefore, it was thought that there was no other hydroxyl group present. The mass spectrum (*m/z*, 274, M^+)[25] and the above spectral data revealed that the structure was **15**. Kyogoku et al.[26] had obtained this from the natural product. The formation mechanism of **15** will be investigated more and reported in the near future.

The product eluted next (in 48% yield) was similar to shikonin under an IR comparison. The presence of a secondary alcoholic hydroxyl group was confirmed by a broad absorption at 3050—3700 cm^{-1} and a C-O band at 1060 cm^{-1}. The ^1H NMR spectrum showed

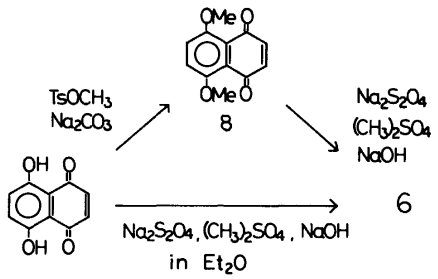


Fig. 4.

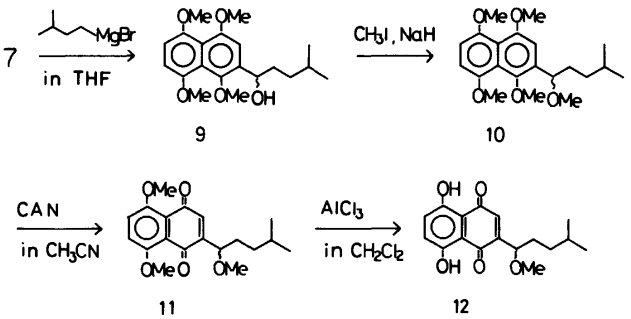

Fig. 5.

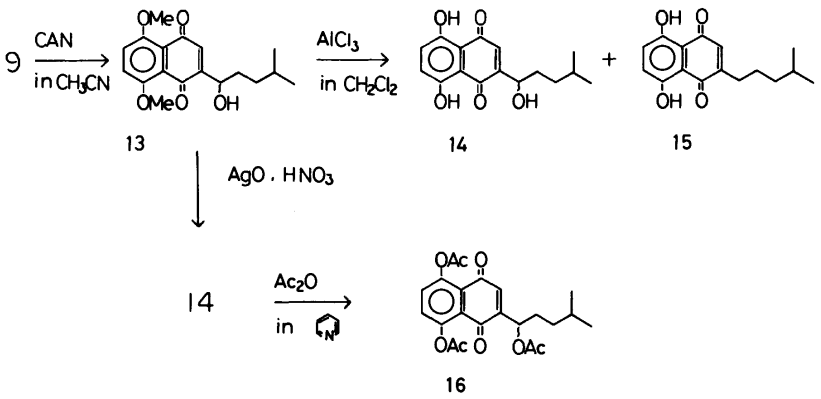

Fig. 6.

signals at δ 12.46 (1H), 12.58 (1H) due to hydrogen-bonded phenolic hydroxyl groups, and at δ 4.87 (1H) due to a proton of the methine attached to the secondary hydroxyl group. The mass spectrum of the product clearly exhibited a molecular ion peak at *m/z* 290. These data as well as an elemental analysis clearly indicated that this was the proposed dihydroshikalkin, 5,8-dihydroxy-2-(1-hydroxy-4-methylpentyl)-1,4-naphthoquinone (**14**). Sankawa et al.[6] had obtained this from the natural product.

Since demethylation using aluminum chloride is accompanied by various side reactions; Parker et al. used AgO–HNO_3[27] as a demethylation reagent. In an analogous way, demethylation of **13** with AgO–HNO_3 gave **14** in 28% yield. Treatment of **14** with acetic anhydride in pyridine afforded triacetate **16**.

The total synthesis of shikalkin is described below.

Treatment of methyl vinyl ketone with hydrogen bromide by the procedure of Gerlach et al.[28]; and acetalization with ethylene glycol in the presence of an acid catalyst gave 4-bromo-2-butanone ethylene acetal **17**. The treatment of the aldehyde **7** with the Grignard reagent of **17** afforded 2-[4,4-(ethylenedioxy)-1-hydroxypentyl]-1,4,5,8-tetramethoxynaphthalene (**18**) in 96% yield. Methylation of **18** with methyl iodide gave an ether, which was converted into 2-(1-methoxy-4-oxopentyl)-1,4,5,8-tetramethoxynaphthalene (**19**) by deacetalization in the presence of an acid. The ketone **19** was treated with methylmagnesium iodide to give 2-(1-methoxy-4-hydroxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (**20**) in 86% yield. Dehydration of the alcohol **20** with thionyl chloride in pyridine at −18 °C gave 2-(1-methoxy-4-methyl-4-pentenyl)-1,4,5,8-tetramethoxynaphthalene (**22**) and 2-(1-methoxy-4-methyl-3-pentenyl)-1,4,5,8-tetramethoxynaphthalene (**21**). The ratio of these two isomers was about 3:5 as judged by gas chromatography.

A variety of reagents such as HBr, $AlCl_3$, $(CH_3)_3SiI$, BBr_3, etc.,[29,30] are available for the demethylation of methyl ethers; however, hard reaction conditions are usually required except for BBr_3 and $(CH_3)_3SiI$. Our preliminary attempt to treat 1,4,5,8-tetramethoxynaphthalene **6** with BBr_3 at −78 °C gave the naphthazarin (**23**) in 68% yield. Then, a demethylation of **21** with BBr_3 in CH_2Cl_2 at −70—−80 °C afforded the cyclic ether **3** in 5% yield instead of the desired shikalkin **24**. A cleavage of the ether **21** with $AlCl_3$ or $(CH_3)_3SiI$ was unsuccessful.

A synthesis of shikalkin was attempted while considering the following two points: 1) that the carbon–carbon double bond of the side chain should be introduced as late as possible, and 2) the selection of a protecting group for the secondary alcoholic hydroxyl group which could be easily removed under mild conditions.

Deacetalization of **18** with an acid afforded the ketone **25** and a treatment of **25** with methylmagnesium iodide gave 2-(1,4-dihydroxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (**26**). Oxidation of **26** with CAN afforded 5,8-dimethoxy-2-(1,4-dihydroxy-4-methylpentyl)-1,4-naphthoquinone (**27**) as a major product, and further demethylation of **27** with AgO–HNO_3 yielded 5,8-dihydroxy-2-(1,4-dihydroxy-4-methylpentyl)-1,4-naphthoquinone (**28**). Acetylation of **28** with acetic anhydride in pyridine gave the

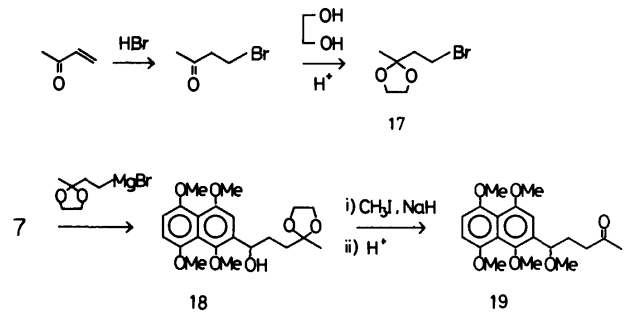

Fig. 7.

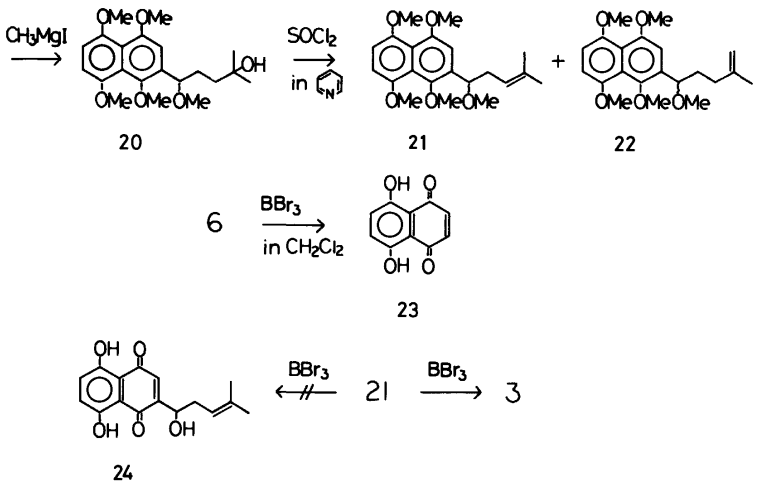

Fig. 8.

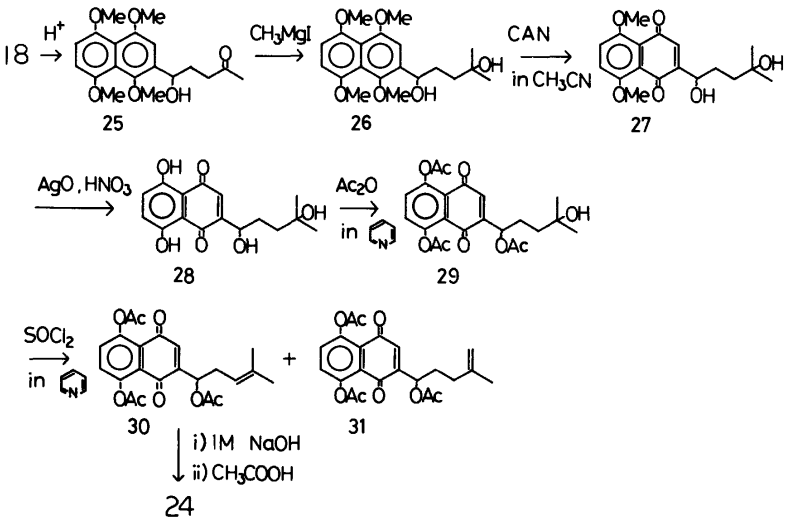

Fig. 9.

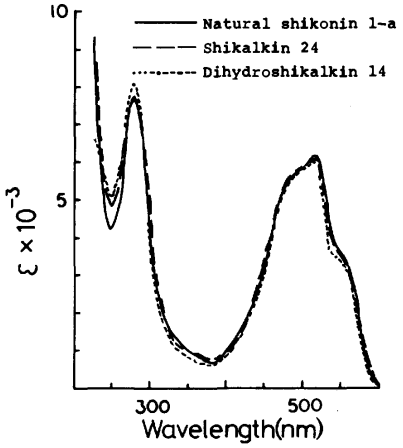

Fig. 10.

triacetate **29**. The secondary hydroxyl group of **28** was acetylated, but tertiary one was not because of a steric hindrance. The treatment of **29** with thionyl chloride in pyridine at −38 °C afforded a mixture of dehydrated compounds, **30** and **31**, in 46% yield. The ratio of these two isomers **30**:**31** was ca. 3:1 as judged by the ^{1}H NMR. Compound **30** was separated by chromatography on silica-gel and was then hydrolyzed by an alkali; and neutralization with acetic acid gave shikalkin **24** in 37% yield.

The ultraviolet spectra of natural shikonin extracted from shikon, synthetic shikalkin **24**, and dihydroshikalkin **14** are shown in Fig. 10. In the spectra of all compounds the benzenoid and quinonoid electron-transfer (E.T.) bands appear at 278 nm, and the benzenoid E.T. band at 515 nm.

Experimental

^{1}H NMR spectra were taken on a JEOL JNM-FX60 spectrometer using tetramethylsilane as an internal standard and the chemical shifts were reported in δ values. Mass spectral data were obtained with a JEOL DX-300. Infrared spectra were recorded on a Hitachi 260—30 infrared spectrometer and the UV spectra on a Shimadzu recording spectrometer UV-200S. Analytical GLC was performed on a Shimadzu GC-6A gas chromatography using Silicone SE-30. High-performance liquid chromatography (HPLC) was performed with a EYELA PLC-10 using TC-ODS 1171. Column chromatography was performed on silica gel (Wakogel C-200) and alumina (Sumitomo activated alumina, KCG-30). Melting points were determined with a Yanagimoto micromelting point apparatus and were uncorrected.

1,5-Dimethoxynaphthalene **4**, mp 181—182 °C (lit,[16] 183—184 °C) was prepared by the method of Benthey.[16]

4,8-Dibromo-1,5-dimethoxynaphthalene (5). Bromine (49.3 g, 0.32 mol) in carbon tetrachloride (50 ml) was added to a solution of 1,5-dimethoxynaphthalene (30.3 g, 0.16 mol) *in carbon tetrachloride (600 ml) at 70—71 °C. After stirring* at 70 °C for 30 min, the solution was concentrated and the residue was recrystallized from carbon tetrachloride to give 32.4 g (58%) of **5**, mp 187—189 °C (lit,[17] 187 °C). Found: C, 41.64; H, 2.93%. Calcd for $C_{12}H_{10}O_2Br_2$: C, 41.65; H, 2.91%.

1,4,5,8-Tetramethoxynaphthalene (6). A 6 from 5. A mixture of 4,8-dibromo-1,5-dimethoxynaphthalene (11 g, 32 mmol), sodium methoxide (5.7 g, 106 mmol), copper(I) iodide (20 g, 106 mmol), *N,N*-dimethylformamide (360 ml) and methanol (360 ml) was refluxed for 30 h. The cooled mixture was poured into ice water and the resulting precipitate was filtered, washed with water and dried. It was extracted with chloroform, and evaporation of the solvent gave a solid residue which was chromatographed on alumina. The fractions taken from the column were recrystallized from ligroin to give 6.66 g (84%) of **6** as white needles, mp 168.5—169 °C (lit.,[17] 167—168 °C). Found: C, 67.53; H, 6.58%. Calcd for $C_{14}H_{16}O_4$: C, 67.73; H, 6.50%.

B 6 from 8. 5,8-Dimethoxy-1,4-naphthoquinone (**8**) was prepared according to the method described in the literature.[20] To a solution of the quinone **8** (2.19 g, 10 mmol) in methanol (10 ml) was added 40% aqueous sodium hydroxide (5 ml). The solution was alternatively

treated with sodium dithionite (8.5 g, 49 mmol) in water (10 ml), and dimethyl sulfate (6 g, 49 mmol) under reflux for 8 h. After cooling, the reaction mixture was diluted with water and extracted with chloroform. The chloroform solution was washed with brine, dried, and evaporated. The residue was chromatographed on alumina and recrystallized from ligroin to give 1.20 g (48%) of **6**, mp 168—169 °C.

C. 6 from Naphthazarin. To a solution of naphthazarin (0.19 g, 1 mmol) in ether (40 ml) was added sodium dithionite (0.53 g, 3 mmol) in water (10 ml) with stirring. After 30 min, the solution was alternatively treated with sodium hydroxide (5 g) in water (10 ml) and dimethyl sulfate (7.5 g, 60 mmol) at room temperature for 3 h. To the solution was again added the above-mentioned amounts of aqueous sodium hydroxide, dimethyl sulfate and aqueous sodium dithionite; and the mixture was then stirred at room temperature for 12 h. The reaction mixture was acidified by the addition of hydrochloric acid and extracted with chloroform. After the usual work-up, column chromatography on alumina gave 0.11 g (44%) of **6**, mp 167—168 °C.

2-Formyl-1,4,5,8-tetramethoxynaphthalene (7). A solution of **6** (6.0 g, 25 mmol) in chloroform (50 ml) was added to a mixture of phosphoryl chloride (19.0 g, 125 mmol) and *N,N*-dimethylformamide (9.0 g, 125 mmol) and the mixture was refluxed for 6 h. It was then decomposed with ice water and extracted with chloroform. The chloroform solution was washed with brine and dried over anhydrous sodium sulfate. Evaporation of the solvent gave a residue which could be recrystallized from hexane-benzene to afford 6.72 g (99%) of **7** as yellow crystals, mp 124—125.5 °C. IR (KBr) 1673 (C=O), 2845, and 1067 cm^{-1} (OCH_3); MS *m/z* 276 (M^+) and 248 (M^+-CO); ^1H NMR ($CDCl_3$) δ=3.91, 3.92, 3.98, 3.99 (each s, 3H, OCH_3), 6.96, 7.00, 7.20 (3H, ArH), and 10.56 (s, 1H, CHO). Found: C, 65.44; H, 5.94%. Calcd for $C_{15}H_{16}O_5$: C, 65.21; H, 5.84%.

2-(1-Hydroxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (9). The aldehyde **7** (2.0 g, 7.3 mmol) was added to the Grignard solution of isopentylmagnesium bromide (21.9 mmol) in tetrahydrofuran (40 ml) and the mixture was stirred at room temperature for 3 h, decomposed with aqueous ammonium chloride and extracted with chloroform. The chloroform solution was treated as usual and left a crude oil. This oil was purified by alumina chromatography to give 2.4 g (95%) of **9**. IR (neat) 3470 (OH) and 1065 cm^{-1} (OCH_3); MS *m/z* 348 (M^+) and 330 (M^+-H_2O); ^1H NMR ($CDCl_3$) δ=0.83, 0.92 (6H, $2CH_3$) 1.1—1.9 (5H, $2CH_2$, CH), 2.22 (1H, OH), 3.74 (s, 3H, OCH_3), 3.89 (s, 3H, OCH_3), 3.93 (s, 6H, $2OCH_3$), 5.20 (t, 1H, -C<u>H</u>(OH)-), 6.81 (s, 2H, ArH), and 6.97 (s, 1H, ArH).

2-(1-Methoxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (10). A solution of the alcohol **9** (0.61 g, 1.76 mmol) in dry tetrahydrofuran (15 ml) was chilled to 0—5 °C, and sodium hydride (ca. 60% in oil, 0.35 g, 8.8 mmol) was added. Methyl iodide (1.25 g, 8.8 mmol) was added to this solution at 0—5 °C with strring. The mixture was allowed to stand overnight at room temperature, then poured into ice water, and extracted with chloroform. The chloroform solution was washed with brine and dried over anhydrous sodium sulfate. The solvent was removed by a rotary evaporator to give an oil. Chromatography on alumina with chloroform as an eluent gave a purified oil of **10** (0.51 g, 81%). IR (neat) 2840 and 1060 cm^{-1} (OCH_3); MS *m/z* 362 (M^+), 330, and 291; ^1H NMR ($CDCl_3$) δ=0.83, 0.91 (6H, $2CH_3$), 1.1—1.9 (m, 5H, $2CH_2$ and CH), 3.24 (s, 3H, -CH($OC\underline{H}_3$)-), 3.76, 3.90 (each s, 3H, OCH_3), 3.94 (s, 6H, $2OCH_3$), 4.78 (t, 1H, -C<u>H</u>(OCH_3)-), 6.83 (s, 2H, ArH), 6.92 (s, 1H, ArH). Found: C, 69.00; H, 8.22%. Calcd for $C_{21}H_{30}O_5$: C, 69.59; H, 8.34%.

2-(1-Methoxy-4-methylpentyl)-5,8-dimethoxy-1,4-naphthoquinone (11). A solution of the ester **10** (1.34 g, 3.7 mmol) in acetonitrile (30 ml) was cooled in an ice bath. To this solution was added a solution of cerium(IV) ammonium nitrate (6 g, 11.1 mmol) in water (10 ml). The mixture was stirred for 30 min, diluted with water, and extracted with chloroform. After working up as usual, the crude product was purified by silica-gel chromatography to yield 0.52 g (42%) of **11**, mp 97—99 °C. IR (KBr) 1655(C=O) and 1060 cm^{-1} (OCH_3); MS *m/z* 332 (M^+), 317, and 216; ^1H NMR($CDCl_3$) δ=0.82, 0.90 (6H, $2CH_3$), 1.1—2.0 (m, 5H, $2CH_2$ and CH), 3.29 (s, 3H, OCH_3), 3.97 (s, 6H, $2OCH_3$), 4.43 (t, 1H, -C<u>H</u>(OCH_3)-), 6.78 (s, 1H, quinonoid ring H), 7.32 (s, 2H, benzenoid ring H).

5,8-Dihydroxy-2-(1-methoxy-4-methylpentyl)-1,4-naphthoquinone (12). A solution of 1,4-naphthoquinone **11** (0.18 g, 0.54 mmol) in dichloromethane (8 ml) was cooled in an ice bath. Aluminum chloride (1 g, 5.4 mmol) was added to this solution and the mixture was stirred at room temperature for 1 h. The reaction mixture was decomposed by the addition of ice water and extracted with ether. The usual work-up and purification of the crude product by silica-gel chromatography gave 80 mg (49%) of **12** as a viscous oil. IR (KBr) 1610 (C=O), 1570, and 1100 cm^{-1}; MS *m/z* 304 (M^+), 277, 232, and 229; ^1H NMR ($CDCl_3$) δ=0.83, 0.92 (6H, $2CH_3$), 1.1—1.9 (m, 5H, $2CH_2$ and CH), 3.32 (s, 3H, OCH_3), 4.50 (t, 1H, -C<u>H</u>(OCH_3)-), 7.12 (s, 1H, quinonoid ring H), 7.17 (s, 2H, benzenoid ring H), 12.49 and 12.59 (each s, 1H, ArOH).

2-(1-Hydroxy-4-methylpentyl)-5,8-dimethoxy-1,4-naphthoquinone (13). A solution of the alcohol **9** (1.3 g, 3.7 mmol) in acetonitrile (15 ml) was cooled to 10—20 °C. To this solution was added dropwise a solution of cerium(IV) ammonium nitrate(5.1 g, 9.25 mmol) in water (15 ml) under stirring. The reaction mixture was stirred at room temperature for 30 min, diluted with water and extracted with chloroform. Usual work-up and chromatography on silica-gel gave two products as viscous oils. The first eluate gave 0.20 g (17%) of an isomer of **13**, 6-(1-hydroxy-4-methylpentyl)-5,8-dimethoxy-1,4-naphthoquinone. IR (KBr) 3500 (OH), 1650 (C=O), 1580, 1560, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.84, 0.93 (6H, $2CH_3$), 1—2 (m, 5H, $2CH_2$ and CH), 2.60 (broad, 1H, OH), 3.82 (s, 3H, OCH_3), 3.96 (s, 3H, OCH_3), 5.16 (m, 1H, -C<u>H</u>(OH)-), 6.77 (2H, quinonoid ring 2H), and 7.51 (s, 1H, benzenoid ring H).

The second eluate gave 0.62 g (52%) of **13**. IR (KBr) 3500 (OH), 1650 (C=O), 1580, 1560, and 1050 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.84, 0.93 (6H, $2CH_3$), 1—2 (m, 5H, $2CH_2$ and CH), 2.60 (broad, 1H, OH), 3.96 (s, 6H, $2OCH_3$), 4.70 (m, 1H, -C<u>H</u>(OH)-), 6.77 (1H, quinonoid ring H), and 7.31 (s, 2H, benzenoid ring H).

5,8-Dihydroxy-2-(1-hydroxy-4-methylpentyl)-1,4-naphthoquinone (14) and 5,8-Dihydroxy-2-(4-methylpentyl)-1,4-naphthoquinone (15). A, Demethylation with $AlCl_3$. Aluminum chloride (41 mg, 3.1 mmol) was added to a solution of the quinone **13** (98 mg, 0.31 mmol) in dichloromethane (5 ml) cooled in an ice bath. The reaction

mixture was stirred at room temperature for 1 h, decomposed by the addition of water (50 ml) and 5% aqueous oxalic acid (100 ml), and extracted with chloroform. After the usual work-up, the crude product was purified by silica-gel chromatography to yield two crystalline products: 22 mg (26%) of **15** from the first eluate, mp 55—70 °C (lit,[26] 99 °C). IR (KBr) 1609 (C=O) and 1570 cm^{-1}; MS *m/z* 274 (M^+), 205, and 204. Calcd for $C_{16}H_{18}O_4$: *m/z* 274.1205, Found: 274.1210. ^1H NMR ($CDCl_3$) δ=0.85, 0.94 (6H, $2CH_3$), 1.1—1.9 (m, 5H, $2CH_2$ and CH), 2.60 (t, 2H, *J*=7 Hz, $ArCH_2$-), 6.85 (s, 1H, quinonoid ring H), 7.20 (s, 2H, benzenoid ring H), 12.47 and 12.62 (each s, 1H, ArOH).

The second eluate gave 43 mg (48%) of **14**, mp 78—81 °C (lit,[6] 100—107 °C). IR (KBr) 3600—3100 (broad, OH), 1610 (C=O), 1570, and 1065 cm^{-1} (OH); MS Found: *m/z* 290.1143. Calcd: 290.1154. ^1H NMR ($CDCl_3$) δ=0.85, 0.95 (6H, $2CH_3$), 1.1—2.0 (m, 5H, $2CH_2$ and CH), 2.24 (broad, 1H, -CH(O<u>H</u>)-), 4.87 (t, 1H, -C<u>H</u>(OH)-), 7.14 (s, 1H, quinonoid ring H), 7.19 (s, 2H, benzenoid ring H), 12.46 and 12.58 (each s, 1H, ArOH). Found: C, 65.95; H, 6.45%. Calcd for $C_{16}H_{18}O_5$: C, 66.20; H, 6.25%.

B Demethylation with AgO-HNO_3. To a solution of the quinone **13** (1.10 g, 3.5 mmol) and AgO (4.27 g, 35 mmol) in acetone (50 ml), was added dropwise 40% HNO_3 (45 ml) at 15—20 °C over 5 min. The mixture was stirred at room temperature for 5 min and extracted with dichloromethane (100 ml). The dichloromethane solution was washed with brine and dried over Na_2SO_4. The solvent was evaporated and the crude product was purified by silica-gel chromatography to afford 0.21 g (28%) of **14**, mp 79.5—81.5 °C.

5,8-Diacetoxy-(1-acetoxy-4-methylpentyl)-1,4-naphthoquinone (16). Acetic anhydride (1 ml) was added to a solution of dihydroshikalkin **14** (65 mg, 0.224 mmol) in pyridine (2.5 ml) at 0—5 °C, and stirred at 0—5 °C for 2 h. After concentration under reduced pressure at room temperature, the crude product was chromatographed on silica-gel to give 85 mg (91%) of **16**, mp 98—100 °C. IR (KBr) 1775 (ester C=O), 1745 (ester C=O), 1667 (quinone C=O), and 1188 cm^{-1}; MS *m/z* 374, 332, 272, 229, and 43 (CH_3CO^+), and no parent peak was observed. ^1H NMR ($CDCl_3$) δ=0.83, 0.92 (6H, $2CH_3$), 1.1—1.9 (m, 5H, $2CH_2$ and CH), 2.11 (s, 3H, -CH(OCOC<u>H</u>$_3$)-), 2.43 (s, 6H, ArOAc), 5.82 (t, 1H, -C<u>H</u>(OCOCH$_3$)-), 6.65 (s, 1H, quinonoid ring H), and 7.37 (s, 2H, benzenoid ring H).

4-Bromo-2-butanone Ethylene Acetal (17). Hydrogen bromide was bubbled into a freshly distilled methyl vinyl ketone (192 g, 2.74 mol) to saturate for 5 h at −80 °C; then the solution gradually solidified. To this solution was added ethylene glycol (340 g, 5.48 mol) and *p*-toluenesulfonic acid monohydrate (10 g, 0.052 mol) at −80 °C; the mixture was then stirred at −80—−40 °C for 3 h. Acetonitrile (250 ml) was added to the mixture and the solvent was evaporated at room temperature under reduced pressure; this procedure was repeated 3 times. The solution was combined with 1 M† KOH (1000 ml) and the product was extracted with hexane. After the usual work-up, the crude product was distilled under reduced pressure to yield 143 g (28%) of **17**, bp 55—56 °C/1.5 mmHg (lit,[28] 64—68 °C/9 mmHg). Found: C, 37.06; H, 5.78%. Calcd for $C_6H_{11}O_2Br$: C, 36.95; H, 5.68%.

2-[4,4-(Ethylenedioxy)-1-hydroxypentyl]-1,4,5,8-tetramethoxynaphthalene 18. The Grignard solution of the ethylene acetal **17** (26.3 mmol) in tetrahydrofuran (30 ml) was added to the aldehyde **7** (2.4 g, 8.76 mmol) and the reaction mixture was stirred at room temperature for 3 h. After a decomposition with aqueous ammonium chloride, extraction with chloroform, and usual procedures, the crude product was purified by chromatography on alumina with chloroform to give 3.28 g (96%) of **18** as an oil. IR (neat) 3480 (OH), 2850 (OCH_3), and 1060 cm^{-1} (OCH_3); MS *m/z* 392 (M^+), 374 (M^+-H_2O), and 330; ^1H NMR ($CDCl_3$) δ=1.34 (s, 3H, CH_3), 1.6—2.2 (m, 5H, $2CH_2$ and OH), 3.76 (s, 3H, OCH_3), 3.89 (s, 3H, OCH_3), 3.94 (s, 4H, $2CH_2$), 3.96 (s, 6H, $2OCH_3$), 5.20 (t, 1H, CH), 6.82 (s, 2H, ArH), and 7.01 (s, 1H, ArH).

2-(1-Methoxy-4-oxopentyl)-1,4,5,8-tetramethoxynaphthalene (19). A solution of the alcohol **18** (3.28 g, 8.4 mmol) in dry tetrahydrofuran (30 ml) was cooled to 0—5 °C, and sodium hydride (ca. 60% in oil, 1 g, 25.2 mmol) was added. Methyl iodide (5.94 g, 25.2 mmol) was added at 0—5 °C, and the mixture was allowed to stand at room temperature overnight; then it was poured into ice water and extracted with chloroform. The chloroform solution was washed with brine and dried over Na_2SO_4. After removing the solvent an oil was obtained. To the solution of this oily product in acetone (10 ml) was added *p*-toluenesulfonic acid monohydrate (100 mg). The solution was kept in a freezer for 3 h, diluted with ice water, and extracted with chloroform. After the usual work-up, the crude product was purified by silica-gel chromatography to yield **19** (1.73 g, 57%) as an oil. IR (neat) 2850 (OCH_3), 1710 (C=O), and 1060 cm^{-1} (OCH_3); MS *m/z* 362 (M^+), and 315; ^1H NMR ($CDCl_3$) δ=2.14 (s, 3H, $COCH_3$), 2.0—2.8 (m, 4H, $2CH_2$), 3.23 (s, 3H, -CH(OC<u>H</u>$_3$)-), 3.76 (s, 3H, OCH_3), 3.89 (s, 3H, OCH_3), 3.94 (s, 6H, $2OCH_3$), 4.78 (t, 1H, CH), 6.84 (s, 2H, ArH), 6.89 (s, 1H, ArH). Found: C, 65.66; H, 7.40%. Calcd for $C_{20}H_{26}O_6$: C, 66.28; H, 7.23%.

2-(4-Hydroxy-1-methoxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (20). Methylmagnesium iodide (6.5 mmol) in ether (10 ml) was added to a solution of the ketone **19** (0.47 g, 1.3 mmol) in tetrahydrofuran (20 ml) at 0—5 °C and the mixture was stirred at room temperature for 3 h. After decomposition with aqueous ammonium chloride, extraction with chloroform, and usual procedure, a crude oil was chromatographed on alumina to afford 0.42 g (86%) of **20**. IR (neat) 3470 (OH), 2845, and 1075 cm^{-1}; MS *m/z* 378 (M^+), 360 (M^+-H_2O), and 291; ^1H NMR ($CDCl_3$) δ=1.20 (s, 6H, $2CH_3$), 1.4—2.0 (m, 4H, $2CH_2$), 2.21 (s, 1H, OH), 3.25 (s, 3H, -CH(OC<u>H</u>$_3$)-), 3.76 (s, 3H, OCH_3), 3.90 (s, 3H, OCH_3), 3.94 (s, 6H, $2OCH_3$), 4.81 (t, 1H, -C<u>H</u>(OCH_3)-), 6.83 (s, 2H, ArH), and 6.92 (s, 1H, ArH).

2-(1-Methoxy-4-methyl-3-pentenyl)-1,4,5,8-tetramethoxynaphthalene (21) and 2-(1-Methoxy-4-methyl-4-pentenyl)-1,4,5,8-tetramethoxynaphthalene (22). Alcohol **20** (191 mg, 0.51 mmol) in dry pyridine (1 ml) was treated with thionyl chloride (70 mg, 0.61 mmol) at 0—5 °C. This mixture was kept in a freezer for 17 h, diluted with ice water and extracted with chloroform. The chloroform solution was washed with dil hydrochloric acid, aqueous sodium hydrogencarbonate, brine, and dried over Na_2SO_4. The solvent removal provided a crude oil which was shown by GLC analysis to be a mixture of **21** and **22** (5:3). The chromatographic separation using alumina succeeded in giving two pure oils. The former eluate gave 62 mg of **22**. IR (neat) 1648 (C=CH_2),

† 1 M=1 mol dm^{-3}.

885 ($C=CH_2$), 1602, and 1073 cm^{-1}; MS *m/z* 306 (M^+); ^1H NMR ($CDCl_3$) δ=1.55 (s, 3H, $CH_2=C(C\underline{H}_3)$-), 1.8—2.2 (m, 4H, $2CH_2$), 3.25 (s, 3H, $CH(OC\underline{H}_3)$), 3.76 (s, 3H, OCH_3), 3.90 (s, 3H, OCH_3), 3.95 (s, 6H, $2OCH_3$), 4.73 (s, 2H, $C\underline{H}_2=C(CH_3)$-), 6.83 (s, 2H, ArH), and 6.94 (s, 1H, ArH).

The latter eluate afforded 104 mg of **21**. IR (neat) 1602, and 1073 cm^{-1}; MS *m/z* 360 (M^+), 328, and 291; ^1H NMR ($CDCl_3$) δ=1.55, 1.69 (6H, $2CH_3$), 2.50 (t, 2H, CH_2), 3.24 (s, 3H, -$CH(OC\underline{H}_3)$-), 3.75 (s, 3H, OCH_3), 3.90 (s, 3H, OCH_3), 3.95 (s, 6H, $2OCH_3$), 4.85 (t, 1H, *J*=6.6 Hz, -$C\underline{H}(OCH_3)$-), 5.26 (t, 1H, *J*=7.1 Hz, $(CH_3)_2C=C\underline{H}$-), 6.83 (s, 2H, ArH), and 6.95 (s, 1H, ArH). Found: C, 69.73; H, 7.85%. Calcd for $C_{21}H_{28}O_5$: C, 69.98; 7.83%.

5,8-Dihydroxy-1,4-naphthoquinone (Naphthazarin) (23). To a solution of 1,4,5,8-tetramethoxynaphthalene (**6**) (124 mg, 5 mmol) in dichloromethane (6 ml) was added dropwise BBr_3 (0.5 g, 20 mmol) in dichloromethane (6 ml) at −70 °C. After stirring at −70 °C for 2 h, the solution was allowed to warm to room temperature and to stand overnight. It was then poured into ice water and extracted with ether. After the usual work-up, sublimation of the crude product afforded 65 mg (68%) of pure **23**, mp 200—202 °C (lit,[31] 201—202 °C). IR (KBr) 1610 (C=O), 1565, and 1225 cm^{-1}; MS *m/z* 190 (M^+), 136, 134, and 108; ^1H NMR ($CDCl_3$) δ= 7.14 (s, 4H, ArH), and 12.39 (s, 2H, ArOH).

5,8-Dihydroxy-2-(5,5-dimethyl-2-tetrahydrofuranyl)-1,4-naphthoquinone (3). To the above obtained olefin **21** (119 mg, 0.33 mmol) dissolved in dichloromethane (2.5 ml) was added dropwise BBr_3 (248 mg, 0.99 mmol) in dichloromethane (2.5 ml) at −78 °C. After stirring at −78 °C for 2 h, the solution was allowed to warm to room temperature and to stand overnight. The solution was then poured into aqueous 1 M sodium hydroxide (30 ml) cooled in an ice bath, stirred for 1 h, and centrifuged to settle the precipitate. To the clean layer was added aqueous ammonium chloride (300 ml) and extracted with ether. After the usual work-up, column chromatography of the residue on silica gel afforded 5 mg (5%) of **3**, mp 79—80.5 °C (lit,[9a] 79—80 °C). IR (KBr) 1610 (C=O), 1570, and 1065 cm^{-1}; MS *m/z* 288 (M^+), and 219; ^1H NMR ($CDCl_3$) δ=1.36 (s, 6H, $2CH_3$), 1.80—1.85 and 2.39—2.81 (m, 4H, $2CH_2$), 5.14 (t, 1H, CH), 7.19 (s, 3H, ArH), and 12.51 (s, 2H, ArOH).

2-(1-Hydroxy-4-oxopentyl)-1,4,5,8-tetramethoxynaphthalene (25). A solution of the acetal **18** (7.53 g, 19.2 mmol) in acetone (30 ml) was cooled to 0—5 °C and *p*-toluenesulfonic acid monohydrate (250 mg) was added. The solution was kept in a refrigerator for 3 h with occasional shaking, diluted with ice water, and extracted with chloroform. After the usual work-up, the crude product was purified by chromatography of alumina to give 5.8 g (87%) of **25** as an oil. IR (neat) 3450 (OH), 1705 (C=O), 1600, and 1062 cm^{-1}; MS Found: *m/z* 348.1577. Calcd for $C_{19}H_{24}O_6$: *m/z* 348.1573. ^1H NMR ($CDCl_3$) δ=2.15 (s, 3H, $COCH_3$), 1.8—2.8 (m, 5H, $2CH_2$ and OH), 3.74 (s, 3H, OCH_3), 3.88 (s, 3H, OCH_3), 3.93 (s, 6H, $2OCH_3$), 5.21 (t, 1H, *J*=6.6 Hz, -$C\underline{H}(OH)$-), 6.81 (s, 2H, ArH), and 6.98 (s, 1H, ArH).

2-(1,4-Dihydroxy-4-methylpentyl)-1,4,5,8-tetramethoxynaphthalene (26). Methylmagnesium iodide (0.15 mol) in ether (30 ml) was added to a solution of ketone **25** (6.26 g, 0.018 mol) in tetrahydrofuran (120 ml) at 0—5 °C, and the mixture was stirred at room temperature for 3 h. After the usual procedures, the crude product was purified by alumina chromatography to afford 5.62 g (86%) of **26**. Recrystallization from ligroin-benzene (4:1) gave crystals, mp 114—115 °C. IR (KBr) 3400 (broad, OH), 1600, and 1070 cm^{-1}; MS Found: *m/z* 364.1900; Calcd: 364.1884. ^1H NMR ($CDCl_3$) δ=1.25 (s, 6H, $2CH_3$), 1.6—2.2 (m, 6H, $2CH_2$ and 2OH), 3.76, 3.89, 3.94, 3.95 (each s, 3H, OCH_3), 5.25 (t, 1H, -$C\underline{H}(OH)$-), 6.82 (s, 2H, ArH), and 7.01 (s, 1H, ArH). Found: C, 65.23; H, 7.73%. Calcd for $C_{20}H_{28}O_6$: C, 65.92; H, 7.74%.

2-(1,4-Dihydroxy-4-methylpentyl)-5,8-dimethoxy-1,4-naphthoquinone (27). A solution of cerium(IV) ammonium nitrate (7.57 g, 14 mmol) in water (25 ml) was added dropwise to a solution of the ether **26** (2.01 g, 6 mmol) in a mixed solvent of chloroform (5 ml) and acetonitrile (25 ml) at room temperature for 5 min. The mixture was stirred at room temperature for 10 min, diluted with ice water, and extracted with chloroform. After the usual work-up, the chromatography on alumina gave two products. The first eluate gave 0.28 g (15%) of an isomer of **27**, 6-(1,4-dihydroxy-4-methylpentyl)-5,8-dimethoxy-1,4-naphthoquinone, as a viscous oil. IR (KBr) 3430, 1650, 1588, and 1052 cm^{-1}; MS Found: *m/z* 334.1429. Calcd for $C_{18}H_{22}O_6$: 334.1417. ^1H NMR ($CDCl_3$) δ=1.24 (s, 6H, $2CH_3$), 1.5—2.1 (m, 4H, $2CH_2$), 2.2—2.6 (broad, 2H, OH), 3.81 (s, 3H, OCH_3), 3.99 (s, 3H, OCH_3), 5.15 (m, 1H, CH), 6.76 (s, 2H, quinonoid ring H), and 7.58 (s, 1H, benzenoid ring H).

The second eluate gave 1.29 g (70%) of **27**. Recrystallization from ligroin-benzene-chloroform mixture gave crystals, mp 127.5—130.5 °C. IR (KBr) 3430 (broad, OH), 1650 (C=O), 1588, and 1052 cm^{-1}; MS *m/z* 334 (M^+); ^1H NMR ($CDCl_3$) δ=1.24 (s, 6H, $2CH_3$), 1.5—2.1 (m, 4H, $2CH_2$), 2.2—2.6 (broad, 2H, 2OH), 3.94 (s, 6H, $2OCH_3$), 4.77 (m, 1H, CH), 6.84 (d, 1H, quinonoid ring H), and 7.29 (s, 2H, benzenoid ring H). Found: C, 64.06; H, 6.73%. Calcd for $C_{18}H_{22}O_6$: C, 64.66; H, 6.63%.

2-(1,4-Dihydroxy-4-methylpentyl)-5,8-dihydroxy-1,4-naphthoquinone (28). To a mixture of the 1,4-naphthoquinone **27** (503 mg, 1.51 mmol) and AgO (1.86 g, 15.1 mmol) in acetone (35 ml) was added 40% HNO_3 (28 ml) at 15—20 °C over 10 min. The reaction mixture was stirred at room temperature for 10 min and extracted with chloroform. The chloroform solution was washed with brine and dried over Na_2SO_4. The solvent was removed to give a crude product; this was purified by silica-gel chromatography to afford 124 mg (27%) of **28**, mp 151—152 °C. IR (KBr) 3300, 3200 (each broad, OH), 1610 (C=O), 1570, 1210, and 1080 cm^{-1}; MS Found: *m/z* 306.1079; Calcd: 306.1103. ^1H NMR ($CDCl_3$) δ=1.25 (s, 6H, $2CH_3$), 1.5—2.7 (m, 6H, $2CH_2$ and 2OH), 4.93 (t, 1H, -$C\underline{H}(OH)$-), 7.19 (s, 3H, ArH), 12.49 and 12.59 (each s, 1H, ArOH). Found: C, 62.43; H, 6.00%. Calcd for $C_{16}H_{18}O_6$: C, 62.74; H, 5.92%.

5,8-Diacetoxy-2-(1-acetoxy-4-hydroxy-4-methylpentyl)-1,4-naphthoquinone (29). Acetic anhydride (1 ml) was added to a solution of the tetraol **28** (69 mg, 0.225 mmol) in pyridine (2 ml) at 0—5 °C, and the mixture was stirred at 0—5 °C for 2 h. Excess of the reagent was removed under reduced pressure at room temperature, and the crude product was chromatographed on silica-gel to give 86 mg (88%) of the triacetate **29**. Recrystallization from ligroine-benzene gave crystals, mp 156.5—158.5 °C. IR (KBr) 3500 (broad, OH), 1770 (ester C=O), 1740 (ester C=O), 1660 (quinone C=O), and 1185 cm^{-1}; MS *m/z* 372, 371 (M^+−61),

288, 232, 219, and 43 (CH_3CO^+), and no parent peak was observed. ^1H NMR ($CDCl_3$) δ=1.20 (s, 6H, $2CH_3$), 1.4—2.4 (m, 5H, $2CH_2$ and OH), 2.12 (s, 3H, CH(OCOC$\underline{H}_3$)), 2.43 (s, 6H, ArOCOC$\underline{H}_3$), 5.87 (t, 1H, CH), 6.66 (s, 1H, ArH), and 7.37 (s, 2H, ArH). Found: C, 61.04; H, 5.57%. Calcd for $C_{22}H_{24}O_9$: C, 61.11; H, 5.59%.

5,8-Diacetoxy-2-(1-acetoxy-4-methyl-3-pentenyl)-1,4-naphthoquinone (30) and 5,8-Diacetoxy-2-(1-acetoxy-4-methyl-4-pentenyl)-1,4-naphthoquinone (31). The triacetate **29** (213 mg, 0.49 mmol) in dry pyridine (1.5 ml) was chilled to −38 °C, and thionyl chloride (70.4 mg, 0.59 mmol) was added. The mixture was stirred at −38 °C for 7 min and then poured into ice water. The reaction mixture was extracted with dichloromethane, and washed with brine, dried over Na_2SO_4, and concentrated. Column chromatography of the residue on silica-gel brought two viscous oils of **30** and **31** (3:1). The former eluate gave 23 mg (12%) of **31**. IR (KBr) 1770 (ester C=O), 1750 (ester C=O), 1665 (quinone C=O), and 888 cm^{-1} (C=C); ^1H NMR ($CDCl_3$) δ=1.56 (s, 3H, CH_2=C($C\underline{H}_3$)-), 1.9—2.5 (m, 4H, $2CH_2$), 2.09 (s, 3H, -CH(OCOC$\underline{H}_3$)-), 2.43 (s, 6H, ArOCOCH_3), 4.69 (s, 2H, $C\underline{H}_2$=C(CH_3)-), 5.87 (t, 1H, CH), 6.65 (s, 1H, ArH), and 7.37 (s, 2H, ArH).

The latter eluate afforded 70 mg (34%) of **30**. IR (KBr) 1770, 1750 (each ester C=O), and 1665 cm^{-1} (quinone C=O); ^1H NMR ($CDCl_3$) δ=1.56, 1.67 (6H, $2CH_3$), 1.9—2.5 (m, 4H, $2CH_2$), 2.09 (s, 3H, -CH(OCOC$\underline{H}_3$)-), 2.43 (s, 6H, ArOCOCH_3), 5.07 (t, 1H, $(CH_3)_2$C=C$\underline{H}$-), 5.87 (t, 1H, -C$\underline{H}$(OAc)-), 6.65 (s, 1H, ArH), and 7.37 (s, 2H, ArH).

5,8-Dihydroxy-(1-hydroxy-4-methyl-3-pentenyl)-1,4-naphthoquinone (24). The triacetate of the internal olefin **30** (63 mg, 0.15 mmol) was dissolved in aqueous 1 M sodium hydroxide (50 ml) and stirred during 3 h. The solution was filtered and the filtrate was acidified by addition of acetic acid until the solution turned red. The product was extracted with dichloromethane, washed with aqueous sodium hydrogencarbonate, brine, and dried over Na_2SO_4. The solvent was evaporated and the crude product was purified by silica-gel chromatography to afford 16 mg (37%) of **24**, mp 146—148 °C (lit,[9a] 148 °C). IR (KBr) 3400, 3100 (each broad, OH), 1613 (C=O), 1570, and 1075 cm^{-1}; MS Found: *m/z* 288.0999. Calcd: *m/z* 288.0997. ^1H NMR ($CDCl_3$) δ=1.66, 1.76 (6H, $2CH_3$), 2.1—2.9 (m, 3H, CH_2 and OH), 4.97 (t, 1H, -C$\underline{H}$(OH)-), 5.19 (t, 1H, (CH_3)C=C$\underline{H}$-), 7.20 (s, 3H, ArH), 12.49 and 12.59 (each s, 1H, ArOH). Found C, 66.34; H, 5.60%. Calcd for $C_{16}H_{16}O_5$: C, 66.66; H, 5.59%.

Isolation of Shikonin 1-a. Shikonin **1-a** was isolated from "Ko-shikon" according to the procedure described by Toribara,[9b] mp 146—147.5 °C (lit,[13] 147—149 °C). Found: C, 66.32; H, 5.66%. Calcd for $C_{16}H_{16}O_5$: C, 66.66; H, 5.59%.

We thank Mr. Takayuki Ōmori and Mr. Takeshi Hanamoto for their technical assistances, Mr. Yoshiharu Okada for the elemental analyses, Mrs. Miyako Kage for the NMR spectra, and Mrs. Keiko Yamaguchi for the MS spectra. We also thank Professor Alfred Hassner (Bar Ilan University, Israel) for reading this manuscript.

Highly Regioselective α-Addition of Alkynyl and Alkenyl Grignard Reagents to 1-Alkoxycarbonylpyridinium Salts and Its Application to Synthesis of 1-Azabicycloalkanes and (±)-Solenopsin A

Ryohei YAMAGUCHI,* Yutaka NAKAZONO, Toshitsugu MATSUKI, Ei-ichiro HATA, and Mituyosi KAWANISI
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Kyoto 606
(Received June 20, 1986)

Nucleophilic addition of a variety of alkynyl and alkenyl Grignard reagents to 1-methoxycarbonylpyridinium chloride takes place at the α-position in a highly regioselective manner to give 2-substituted 1-methoxycarbonyl-1,2-dihydropyridines exclusively, while, with alkyl Grignard reagents, a lack of the regioselectivity is observed. These results may be explained by the HSAB principle. The high α-regioselectivity is preserved in the cases of 2-substituted pyridines as well, giving 2,6-disubstituted 1,2-dihydropyridines exclusively, which can be transformed stereoselectively into *cis*- and *trans*-2,6-dialkylated piperidines. These highly regioselective α-alkynylations of 1-methoxycarbonylpyridinium salts are exploited in synthesis of 1-azabicycloalkanes as well as (±)-solenopsin A.

Nucleophilic addition of organometallic reagents to 1-acylpyridinium salts has been utilized to prepare 2- and 4-substituted 1,2- and 1,4-dihydropyridines, which have proved to be valuable synthetic intermediates for nitrogen heterocycles.[1] The regioselectivity of these reactions has been of critical importance in synthetic and mechanistic points of view. There have been several organometallic reagents which favor the γ-attack on 1-acylpyridinium salts; organocopper reagents,[2] trialkylalkynylborates,[3] enol silyl ethers,[4] and titanium enolates[5] produce regioselectively the 4-substituted 1,4-dihydropyridines.

On the other hand, only a few organometallics, i.e. Grignard[6] and organocadmium reagents,[6c] have been reported to predominantly attack on the α-position. The regioselectivity of these reactions, however, is apparently biased, because 4- and/or 3-substituted pyridines have been used as the starting material in most of the cases.

Then, we have examined the reaction of 1-methoxycarbonylpyridinium chloride itself with a variety of Grignard reagents and found that the regioselectivity is highly dependent on the nature of Grignard reagent. Thus, with alkyl Grignard reagents, 4-alkyl-1,4- and 2-alkyl-1,2-dihydropyridines are produced in variable ratios, uncovering a lack of the regioselectivity.[7,8]

In this report we describe that alkynyl and alkenyl Grignard reagents add to the α-position of the pyridinium salt in a highly regioselective manner to afford 2-substituted 1,2-dihydropyridines exclusively and that this methodology provides an easy access to the synthesis of 1-azabicycloalkanes as well as 2,6-dialkylated piperidines.[9]

Results and Discussion

When we reexamined the reaction of 1-methoxycarbonylpyridinium chloride (**1**) with butylmagnesium

Table 1. Reactions of 1-Methoxycarbonylpyridinium Chloride (**1**) with Alkyl Grignard Reagents and Other Organometallic Reagents

Entry	R	M	Temp °C	Method[a]	Yield[b] %	Ratio(2/3)[c]

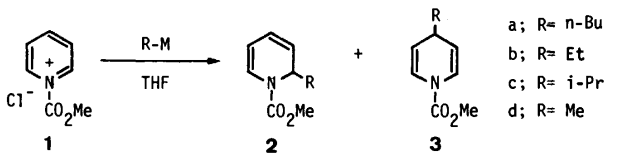
a) Method A: Methyl chloroformate was added to a mixture of pyridine and organometallic reagent in THF. Method B: **1** was preformed before adding organometallic reagent. b) Combined yield. c) Determined by GLC and/or ^{1}H NMR. d) A small amount of 5-butyl-5-nonanol was obtained. e) Prepared by adding $ZnCl_2$ to *n*-BuMgBr. f) Pentanoic anhydride was obtained. g) Taken from Ref. 2b.

bromide in THF at 0 °C according to the Fraenkel method,[6a] we found that 2-butyl-1-methoxycarbonyl-1,2-dihydropyridine (**2a**) and 4-butyl-1-methoxycarbonyl-1,4-dihydropyridine (**3a**) were produced in a ratio of 78:22, along with a small amount of 5-butyl-5-nonanol. The reaction conducted at −78 °C gave again a mixture of **2a** and **3a** in a ratio of 67:33. Since these results were inconsistent with that of Fraenkel et al., who reported the exclusive formation of **2a**, we decided to investigate the reaction of **1** with a couple of alkyl Grignard reagents as well as other organometallic reagents in more detail (Scheme 1, Table 1).



Scheme 1.

Table 1 evidently demonstrates that the regioselectivity is dependent on the character of metals. It has been suggested that the regioselectivity of the attack on the pyridinium cation by nucleophiles may be explained by the HSAB principle[10,11] (Fig. 1); with such relatively hard nucleophiles as hydroxide and amide ions the preferential α-attack (an arrow b) is observed, while with such soft ones as cyanide and enolate ions an attack on the γ-position (an arrow a) is predominant.[11] The above reactions with the organometallic reagents may be rationalized in the same context; the very soft organocopper reagents almost exclusively attack at the γ-position, as has been recently suggested by Akiba et al. (Entry 10).[2b,2c] The organozinc reagent, which is slightly harder than organocopper reagent, reveals a slightly less γ-selectivity (Entry 8). With harder alkyl Grignard reagents, both of α- and γ-attack occur in variable ratios (Entries 1—7). Furthermore, we have found that much harder organolithium reagent gives pentanoic anhydride exclusively (Entry 9), probably through the attack on the carbonyl moiety, the hardest position of the pyridinium salt (an arrow c in Fig. 1).

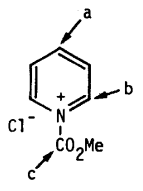


Fig. 1. Three possible positions attacked by nucleophiles.

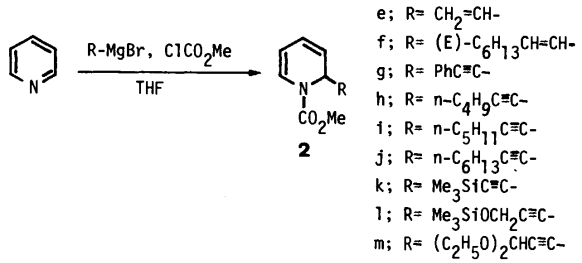
While the above results led to the conclusion that alkyl Grignard reagents generally showed no appreciable α-regioselectivity, we were interested in that, among alkyl Grignard reagents, methyl Gignard reagent showed more than the 90% of the α-addition (Entry 5). We have thought that this is because the α-regioselectivity is enhanced by harder methyl group than other alkyl ones. Accordingly, in order to obtain 2-substituted 1,2-dihydropyridine selectively which may be a potential intermediate for alkaloid synthesis,[1] we have next examined the reaction of **1** with alkynyl as well as alkenyl Grignard reagents, considering that these organic moieties are supposed to be harder than alkyl ones (Scheme 2). The results are summarized in Table 2. As is shown in Table 2, the α-regioselectivity is far better than the expected; with a variety of alkynyl and alkenyl Grignard reagents the α-attack takes place exclusively to afford 2-alkynyl- and 2-alkenyl-1,2-dihydropyridines in good to excellent yields.[12,13]



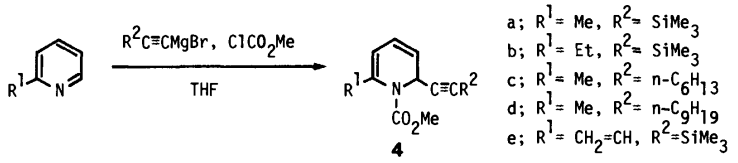
Scheme 2.

Tabe 2. Reactions of **1** with Alkynyl and Alkenyl Grignard Reagents[a]

Entry	R	Yield[b,c] %
1	CH_2=CH-	81
2	(*E*)-*n*-C_6H_{13}CH=CH-	71[d]
3	PhC≡C-	98
4	*n*-C_4H_9C≡C-	97
5	*n*-C_5H_{11}C≡C-	93
6	*n*-C_6H_{13}C≡C-	93
7	Me_3SiC≡C-	99
8	Me_3SiOCH$_2$C≡C-	98
9	$(EtO)_2$CHC≡C-	87

a) All reaction were carried out by Method A at 0° C, unless otherwise noted. b) Isolated yield. c) The α-regioselectivity was shown to be >98% by GLC and/or ^{1}H NMR analysis in all of the cases. d) The reaction was conducted at −40 °C.

To our further delight, it has been found that the above high α-regioselectivity is completely preserved in the reactions of 2-substituted pyridines (Scheme 3). The results are summarized in Table 3. Thus, reactions of 2-methyl- or 2-ethylpyridine with alkynyl Grignard reagents in the presence of methyl chloroformate proceeded in a highly regioselective manner to give exclusively 2,6-disubstituted 1-methoxycarbonyl-1,2-dihydropyridines, in spite of their steric congestion.[14]



Scheme 3.

a) All reactions carried out by Method A at 0 °C.
b) Isolated yield.

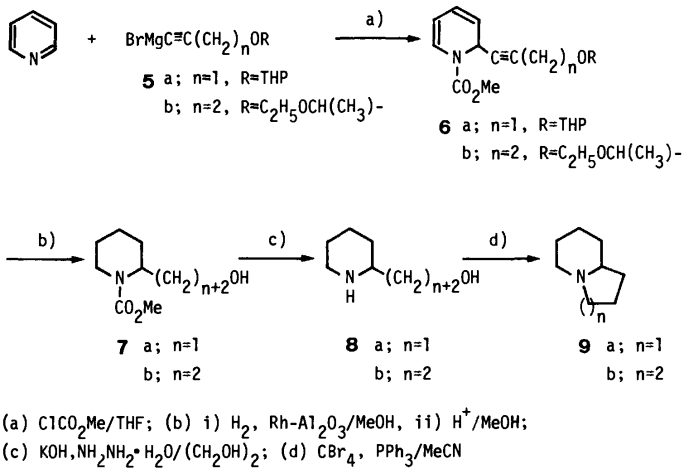
Synthesis of Indolizidine and Quinolizidine through Highly Regioselective α-Alkynylation of Pyridinium Salt. Indolizidine and quinolizidine skeletons are incorporated in a number of alkaloids and much effort has been made for constructing these systems.[15)] We describe here an application of the above reactions to synthesis of 1-azabicycloalkanes (Scheme 4).

Reactions of pyridine with alkynyl Grignard reagents possessing protected hydroxyl group **5** in the presence of methyl chloroformate gave exclusively 1-methoxycarbonyl-2-alkynyl-1,2-dihydropyridines (**6a** and **6b**), which were successively hydrogenated on Rh-Al_2O_3 and deprotected to afford 2-(3-hydroxypropyl)- and 2-(4-hydroxybutyl)piperidine derivatives (**7a** and **7b**), respectively, in good yields. Demethoxycarbonylation[16)] of **7**, followed by cyclization of the resulting amino alcohols (**8a** and **8b**) with PPh_3 and CBr_4,[17)] furnished indolizidine (**9a**) and quinolizidine (**9b**), respectively.

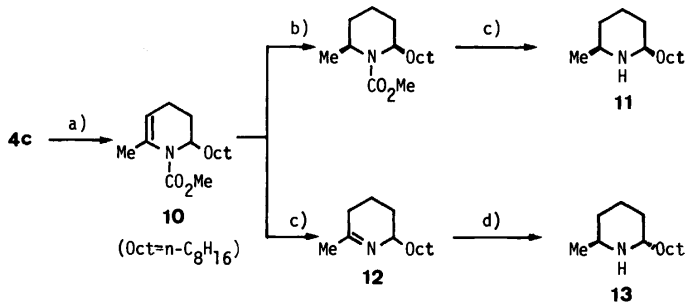
Synthesis of *cis*- and *trans*-2,6-Dialkylated Piperidines and (±)-Solenopsin A via 1-Methoxycarbonyl-2,6-disubstituted-1,2-dihydropyridines. 2,6-Dialkylated piperidines constitute the principal structure of a number of piperidine alkaloids.[18,19)] Accordingly, we next examined the stereoselective transformation of 2,6-disubstituted 1-methoxycarbonyl-1,2-dihydropyridine obtained above into *cis*- and *trans*-2,6-dialkylated piperidines and an application of this sequence to synthesis of (±)-solenopsin A, a piperidine alkaloid isolated from the venom of the fire ant.[20,21)]

At first we have found that careful hydrogenation of **4c** over 5% Pd-C can give a partially hydrogenated, crucial intermediate, 2,6-dialkylated 1,2,3,4-tetrahydropyridine (**10**) in 83% yield. Further hydrogenation of **10** over Pd-black, followed by demethoxycarbonylation with iodotrimethylsilane,[22)] afforded *cis*-2-methyl-6-octylpiperidine (**11**) exclusively (Scheme 5).

On the other hand, a cyclic imine (**12**) could be obtained, when **10** was demethoxycarbonylated with iodotrimethylsilane. According to the Yamamoto's elegant method for stereoselective reduction of this type of cyclic imine,[21a)] **12** was reduced by lithium tetrahydroaluminate in THF at −78 °C to afford *trans*-2-methyl-6-octylpiperidine (**13**), along with a small amount of the cis-isomer **11** (**13**:**11**=78:22).

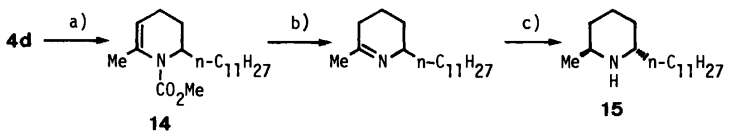


Scheme 4.



(a) H_2, Pd-C/MeOH; (b) H_2, Pd/MeOH; (c) $Me_3SiI/CHCl_3$; (d) $LiAlH_4$/THF, -78°C

Scheme 5.



(a) H_2, Pd-C/MeOH; (b) $Me_3SiI/CHCl_3$; (c) $LiAlH_4$, Me_3Al/THF, -78°C

Scheme 6.

Thus, it has been shown that 2,6-disubstituted 1,2-dihydropyridine is a versatile precursor for *cis*- and *trans*-2,6-dialkylated piperidines.[23]

Consequently, the above sequence has been applied to the regio- and stereoselective synthesis of (±)-solenopsin A, *trans*-2-methyl-6-undecylpiperidine (Scheme 6). Careful hydrogenation of **4d** over 5% Pd-C in methanol gave 1,2,3,4-tetrahydropyridine derivative (**14**). Demethoxycarbonylation of **14** followed by reduction with lithium tetrahydroaluminate in the presence of trimethylaluminium[21a] afford (±)-solenopsin A (**15**) in 90% yield based on **14**, along with a small amount of its epimer. Thus, the present route provides one of the most practical and efficient method for the synthesis of (±)-solenopsin A (43% overall yield in 4 steps from 2-methylpyridine).[24]

Experimental

All the temperatures were uncorrected. The IR spectra were obtained on a Hitachi 215 or JASCO IR-810 spectrometer. The mass spectra were taken by using a Hitachi RMS-4 mass spectrometer. The ^1H and ^{13}C NMR spectra were obtained on Varian EM-390 and CFT-20 or JEOL FX-90Q spectrometers, Me_4Si being chosen as the internal standard. Analytical GLC were carried out on a Shimadzu GC-4C gas chromatography with 10% SE-30, 10% HVSG, or 10% PEG-20M on Chromsorb W columns. The microanalyses were performed by Kyoto University Elemental Analysis Center. All the reactions were carried out under Ar atmosphere, otherwise noted. THF was distilled from benzophenone ketyl before use.

General Procedure for the Reaction of 1-Methoxycarbonylpyridinium Chloride (1) with Alkyl Grignard Reagents. Method A. To a mixture of butylmagnesium bromide (5 mL, 2.0 M†, 10.0 mmol) and pyridine (0.396 g, 5.0 mmol) in THF (7.5 mL) was added methyl chloroformate (0.473 g, 5.0 mmol) at −78 °C. The reaction mixture was stirred for 5 h and quenched by adding water (0.75 mL) at that temp. The mixture was poured onto water and extracted with CH_2Cl_2. The organic layer was washed with brine and dried (Na_2SO_4). The solvent was evaporated and the residue was passed through a short silica-gel column eluting with CH_2Cl_2 to give a mixture of **2a**[3a] and **3a**[2a] (0.966 g, 99%). The ratio of **2a** to **3a** was 67:33 by GLC analysis.

Method B. To a solution of pyridine (0.396 g, 5.0 mmol) in THF (20 mL) were added methyl chloroformate (0.473 g, 5.0 mmol) at 0 °C. The mixture was stirred for 1 h and cooled to −78 °C. To this mixture was added butylmagnesium bromide (10.0 mmol in 15 mL of THF) and the reaction mixture was stirred for 5 h. The usual work-up gave a mixture of **2a** and **3a** (0.767 g, 79%). The ratio of **2a** to **3a** was 59:41 by GLC analysis.

The reactions of **1** with other alkyl Grignard reagents were conducted in a similar manner to the above. The yields and the ratios are described in Table 1.[2a]

Reaction of 1 with Butyllithium. To a mixture of **1**, prepared from pyridine (0.158 g, 2.0 mmol) and methyl chloroformate (0.189 g, 2.0 mmol), in THF (6 mL) was added *n*-BuLi (0.64 mL, 1.56 M, 1.0 mmol) in hexane at −78 °C. After 15 min, water (0.5 mL) was added to the mixture. The usual work-up gave valeric anhydride (0.091 g, 98%).

General Procedure for the Reaction of 1 with Alkenyl and Alkynyl Grignard Reagents. To a mixture of pyridine

† 1 M=1 mol dm^{-3}.

(0.211 g, 2.7 mmol) and alkenyl or alkynyl Grignard reagent (2.7—5.0 mmol) in THF (6—10 mL) was added a solution of methyl chloroformate (0.230 g, 2.4 mmol) in THF (2 mL) dropwise under ice-cooling. After 30 min, the mixture was poured onto 1 M aq NH_4Cl and extracted with CH_2Cl_2. The organic solution was washed with water and dried (Na_2SO_4). The solvent was evaporated and the residue was passed through a short silica-gel column eluting with CH_2Cl_2 to give **2**. The yield of each product is described in Table 2.

1-Methoxycarbonyl-2-vinyl-1,2-dihydropyridine (2e): MS *m/z* (%) 165 (M^+, 36), 138 (100); IR (neat): 1715 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.68 (br d, 1H, *J*=6 Hz), 4.66—6.02 (m, 7H), 3.74 (s, 3H); ^{13}C NMR ($CDCl_3$) δ=169.7 (s), 134.6 (d), 125.2 (d), 122.0 (d), 120.5 (d), 115.1 (t), 105.4 (d), 54.1 (d), 53.1 (q). 1-Methoxycarbonyl-6-methyl-2-(1-octynyl)-1,2-dihydropyridine (4c): MS *m/z* (%) 261 (M^+, 100); IR (neat): 2220, 1720 cm^{-1}; ^1H NMR ($CDCl_3$) δ=5.36—5.94 (m, 4H), 3.73 (s, 3H), 2.15 (s, 3H), 1.90—2.28 (m, 2H), 1.05—1.57 (m, 8H), 0.85 (t, 3H, *J*=7 Hz); ^{13}C NMR ($CDCl_3$) δ=154.4 (s), 135.1 (s), 122.7 (d), 120.7 (d), 111.8 (d), 83.4 (s), 77.5 (s), 52.9 (q), 44.5 (d), 31.4 (t), 28.7 (t), 28.4 (t), 22.6 (t), 21.5 (q), 18.9 (t), 14.0 (q). Found: C, 73.50; H, 9.11%. Calcd for $C_{16}H_{23}NO_2$: C, 73.53; H, 8.87%.

1-Methoxycarbonyl-6-methyl-2-(1-undecynyl)-1,2-dihydropyridine (4d): MS *m/z* (%) 303 (M^+, 100); IR (neat): 2220, 1715 cm^{-1}; ^1H NMR ($CDCl_3$) δ=5.37—5.97 (m, 4H), 3.75 (s,

3H), 2.17 (s, 3H), 2.00—2.40 (m, 2H), 1.07—1.70 (m, 14H), 0.87 (t, 3H, J=7 Hz); ^{13}C NMR ($CDCl_3$) δ=154.4 (s), 135.0 (s), 122.7 (d), 120.6 (d), 111.8 (d), 83.4 (s), 77.3 (s), 53.0 (q), 44.3 (d), 32.0 (t), 29.6 (t), 29.3 (t), 29.2 (t), 28.8 (t), 28.7 (t), 22.8 (t), 21.5 (q), 18.8 (t), 14.1 (q). Found: C, 75.18; H, 9.92%. Calcd for $C_{19}H_{29}NO_2$: C, 75.20; H, 9.63%.

1-Methoxycarbonyl-2-trimethylsilylethynyl-6-vinyl-1,2-dihydropyridine (4e): MS m/z (%) 261 (M^+, 77), 202 (100); IR (neat): 2170, 1710, 840 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.92—6.45 (m, 7H), 3.64 (s, 3H), 0.04 (s, 9H); ^{13}C NMR ($CDCl_3$) δ=154.8 (s), 136.3 (s), 134.1 (d), 128.5 (d), 123.6 (d), 114.3 (t), 113.7 (d), 102.2 (s), 88.5 (s), 53.1 (q), 45.1 (d), 0.0 (q). Found: C, 64.19; H, 7.35%. Calcd for $C_{14}H_{19}NO_2Si$: C, 64.33; H, 7.33%.

1-Methoxycarbonyl-2-(3-hydroxypropyl)piperidine (7a). To a mixture of pyridine (1.242 g, 12.6 mmol) and 3-(2-tetrahydropyranyloxy)propynylmagnesium bromide, prepared from tetrahydro-2-(2-propynyloxy)-2*H*-pyran (1.396 g, 9.97 mmol) and ethylmagnesium bromide (6.0 mL, 1.88 M, 11.3 mmol), in THF (20 mL) was added a solution of methyl chloroformate (1.000 g, 10.5 mmol) in THF (10 mL) slowly over 1.5 h under ice-cooling. The mixture was stirred for 2 h, poured onto 10% aq NH_4Cl, and extracted with CH_2Cl_2. The organic solution was washed with water and brine, and dried (Na_2SO_4). The solvent was evaporated to give almost pure **6a**: ^{1}H NMR ($CDCl_3$) δ=6.76 (br d, 1H, J=7 Hz), 5.20—6.21 (m, 4H), 4.80 (br s, 1H), 4.27 (s, 2H), 3.83 (s, 3H), 3.47—4.02 (m, 2H), 1.30—1.97 (m, 6H); ^{13}C NMR ($CDCl_3$) δ=153.7 (s), 124.8 (d), 122.0 (d), 118.2 (d), 105.1 (d), 96.6 (d), 83.2 (t), 78.6 (s), 61.8 (t), 54.2 (t), 53.4 (q), 43.6 (d), 30.3 (t), 25.5 (t), 19.1 (t). Without purification, **6a** was dissolved in dry MeOH (15 mL) and completely hydrogenated over 5% Rh-Al_2O_3 (0. 20 g) under 8 kg cm^{-2} pressure of H_2. After the catalyst was removed by filtration through Celite, the solvent was evaporated. The residue was dissolved in dry MeOH (10 mL) and to this solution was added Amberlyst H-15 (0.15 g). The mixture was stirred at 45 °C for 1 h and Amberlyst H-15 was removed by filtration. The solvent was evaporated and the residue was purified through bulb-to-bulb distillation to give **7a** (1.621 g, 81%): Bp 110—120 °C/80 Pa; MS m/z (%) 201 (M^+, 4), 142 (100); IR (neat): 3450, 1680 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.83—4.50 (m, 2H), 3.68 (s, 3H), 3.53—3.83 (m, 2H), 2.63—3.10 (m, 1H), 2.53 (s, 1H), 1.20—1.90 (m, 10H); ^{13}C NMR ($CDCl_3$) δ=156.3 (s), 61.8 (t), 52.4 (q), 50.8 (d), 39.1 (t), 29.5 (t), 28.7 (t), 26.1 (t), 25.7 (t), 19.0 (t).

1-Methoxycarbonyl-2-(4-hydroxybutyl)piperidine (7b). To a mixture of pyridine (1.27 g, 12.9 mmol) and 4-(1-ethoxyethoxy)-1-butynylmagnesium bromide, prepared from 4-(1-ethoxyethoxy)-1-butyne (1.43 g, 10.1 mmol) and ethylmagnesium bromide (7.8 mL, 1.42 M, 11.1 mmol), in THF (20 mL) was added a solution of methyl chloroformate (1.00 g, 10.5 mmol) in THF (10 mL) slowly over 1.5 h under ice-cooling. The mixture was stirred for 2 h and the usual work-up gave **6b**: ^{1}H NMR ($CDCl_3$) δ=6.80 (br d, 1H, J=7 Hz), 5.38—6.13 (m, 4H), 4.75 (q, 1H, J=6 Hz), 3.83 (s, 3H), 3.36—3.80 (m, 4H), 2.43 (t, 2H, J=6 Hz), 1.30 (d, 3H, J=6 Hz), 1.13 (t, 3H, J=6 Hz); ^{13}C NMR ($CDCl_3$) δ=153.6 (s), 124.7 (d), 121.7 (d), 119.2 (d), 105.3 (d), 99.5 (d), 80.6 (s), 78.6 (s), 63.1 (t), 60.8 (t), 53.3 (q), 43.6 (d), 20.5 (t), 19.7 (q), 15.3 (q). Without purification, **6b** was hydrogenated in a similar manner to the above. In this case, 1-ethoxyethyl group was removed during this hydrogenation. Purification through bulb-to-bulb distillation gave **7b** (1.61 g, 75%): Bp 110—130 °C/67 Pa; IR (neat): 3400, 1690 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=3.80—4.33 (m, 2H), 3.65 (s, 3H), 3.57 (t, 2H, J=6 Hz), 2.60—3.07 (m, 2H), 1.10—1.83 (m, 12H); ^{13}C NMR ($CDCl_3$) δ=156.4 (s), 62.4 (t), 52.4 (q), 50.7 (d), 39.1 (t), 32.6 (t), 29.4 (t), 28.4 (t), 25.7 (t), 22.5 (t), 19.0 (t).

2-(3-Hydroxypropyl)piperidine (8a). A mixture of **7a** (0.699 g, 3.5 mmol), KOH (5.11 g), and 100% $NH_2NH_2 \cdot H_2O$ (0.85 mL) in ethylene glycol (26 mL) was heated under reflux for 1.5 h. The reaction mixture was poured onto water and extracted with CH_2Cl_2. The organic solution was washed with 30% aq NaOH and dried (Na_2SO_4). The solvent was evaporated to give almost pure **8a** (0.473 g, 95%): MS m/z (%) 143 (M^+, 9), 142 (100); ^{1}H NMR ($CDCl_3$) δ=3.57 (s, 2H), 3.53 (t, 2H, J=6 Hz), 2.90—3.20 (m, 1H), 2.30—2.77 (m, 2H), 0.93—1.90 (m, 14H); ^{13}C NMR ($CDCl_3$) δ=62.6 (t), 56.9 (d), 46.6 (t), 35.9 (t), 32.2 (t), 30.4 (t), 26.6 (t), 24.8 (t).

2-(4-Hydroxybutyl)piperidine (8b). A mixture of **7b** (0.263 g, 1.2 mmol), KOH (1.80 g), and 100%$NH_2NH_2 \cdot H_2O$ (0.3 mL) in ethylene glycol (9 mL) was heated under reflux for 1.5 h. The similar work-up to the above gave almost pure **8b** (0.179 g, 93%): ^{1}H NMR ($CDCl_3$) δ=3.55 (t, 2H, 6 Hz), 2.84—3.20 (m, 1H), 2.80 (br s, 2H), 2.27—2.77 (m, 2H), 0.97—1.90 (m, 12 H); ^{13}C NMR ($CDCl_3$) δ=61.5 (t), 56.8 (d), 47.0 (t), 37.0 (t), 32.9 (t), 32.8 (t), 26.4 (t), 24.8 (t), 22.2 (t).

Indolizidine (9a). A solution of **8a** (0.258 g, 1.8 mmol), PPh_3 (0.890 g, 3.3 mmol), and CBr_4 (1.320 g, 4.0 mmol) in dry CH_3CN (18 mL) was stirred at room temp overnight. The mixture was poured onto 10% aq HCl and washed with AcOEt. The aqueous layer was basified by adding 2 M aq NaOH and K_2CO_3, and extracted with ether. The organic layer was dried (K_2CO_3) and the solvent was evaporated. The residue was purified through bulb-to-bulb distillation (80 °C/6000 Pa) to give **9a** (0.130 g, 58%): Picrate, mp 229—231.5 °C (lit,[25] 233—234 °C); ^{1}H NMR ($CDCl_3$) δ=2.90—3.23 (m, 2H), 1.03—2.63 (m, 13H); ^{13}C NMR ($CDCl_3$) δ=64.4 (d), 54.3 (t), 53.2 (t), 31.1 (t), 30.6 (t), 25.6 (t), 24.7 (t), 20.7 (t).

Quinolizidine (9b). A solution of **8b** (0.164 g, 1.04 mmol), PPh_3 (0.520 g, 2.00 mmol), and CBr_4 (0.770 g, 2.33 mmol) in dry CH_3CN (11 mL) was heated under reflux for 2 h. The similar work-up to the above and purification through bulb-to-bulb distillation (80 °C/2666 Pa) gave **9b**: Picrate, mp 195—198 °C (lit,[26] 198—199 °C); ^{1}H NMR ($CDCl_3$) δ=2.60—2.97 (m, 2H), 0.90—2.23 (m, 15H); ^{13}C NMR ($CDCl_3$) δ=63.0 (d), 56.7 (t), 33.6 (t), 26.0 (t), 24.7 (t).

1-Methoxycarbonyl-6-methyl-2-octyl-1,2,3,4-tetrahydropyridine (10). A mixture of **4c** (0.783 g, 3.0 mmol) and 5% Pd-C (0.157 g) in dry MeOH (30 mL) was stirred under atmospheric pressure of H_2. The reaction was carefully monitored by TLC. As soon as the starting material disappeared, the reaction was stopped. The catalyst was removed by filtration through Celite and the solvent was evaporated. The residue was passed through a short silica-gel column eluting with hexane-CH_2Cl_2 (4:1) to give **10** (0.667 g, 83%): MS, m/z (%) 267 (M^+, 34), 196 (100); IR (neat): 1710 cm^{-1} ^{1}H NMR ($CDCl_3$) δ=4.85 (br s, 1H), 4.35 (br s, 1H), 3.66 (s, 3H), 2.00 (s, 3H), 1.10—2.10 (m, 18H), 0.87 (t, 3H, J=6 Hz); ^{13}C NMR ($CDCl_3$) δ=154.4 (s), 132.9 (s), 111.7 (d), 52.7 (d), 52.3 (q), 32.0 (t), 31.7 (t), 29.9 (t), 29.7 (t), 29.4 (t), 26.5 (t), 26.0 (t), 22.7 (t), 22.7 (q), 19.6 (t), 14.1 (q). Found: C, 75.18; H, 9.92%. Calcd for $C_{16}H_{29}NO_2$: C, 75.20; H, 9.63%.

***cis*-2-Methyl-6-octylpiperidine (11).** A mixture of **10** (0.203 g, 0.76 mmol) and Pd-black (0.02 g) in dry MeOH (5 mL) was stirred under atmospheric pressure of H_2 for 20 h. The catalyst was removed by filtration through Celite and the solvent was evaporated. The residue (0.126 g) was dissolved in dry $CHCl_3$ (2.0 mL) and to this solution was added iodotrimethylsilane (0.10 mL, 0.6 mmol). The reaction mixture was stirred at 50—60 °C for 3 h and then, after addition of MeOH (0.06 mL), at room temp for 0.5 h. The mixture was condensed under reduced pressure, diluted with 0.1 M aq NaOH, and extracted with CH_2Cl_2. The organic layer was dried (Na_2SO_4) and the solvent was evaporated to give **11** (0.103 g, 64%), which was identical with the authentic **11** prepared by a different route (vide infra).

***trans*-2-Methyl-6-octylpiperidine (13).** To a mixture of **10** (0.134 g, 0.50 mmol) in dry $CHCl_3$ (2.0 mL) was added iodotrimethylsilane (0.10 mL, 0.60 mmol). The mixture was stirred at 50—60 °C for 1.5 h and then, after addition of MeOH (0.06 mL), at room temp for 0.5 h. The mixture was condensed under reduced pressure, diluted with 0.1 M aq NaOH, and extracted with CH_2Cl_2. The solvent was evaporated to give a imine (**12**) (0.103 g): IR (neat): 1655 cm^{-1}. To a suspension of $LiAlH_4$ (0.475 g, 12.5 mmol) in THF (8.0 mL) was added a solution of **12** (0.103 g) in THF (8.0 mL) at −78 °C. The mixture was stirred at −78 °C for 1 h, −45 °C for 1 h, −20 °C for 1 h, and 0 °C for 1 h. The usual work-up and column chromatography on alumina eluting with ether gave **13**, along with a small amount of **11** (0.081 g, 70%, **13**:**11**=78:22 by GLC analysis).

Preparation of 11 and 13 by MacConell's Method.[22] To a mixture of 2,6-dimethylpyridine (2.15 g, 20 mmol) in ether (20 mL) was added PhLi in ether (17 mL, 1.33 M, 22 mmol) and the mixture was heated at reflux for 15 min. To this solution was added heptyl bromide (3.59 g, 20 mmol) over 30 min and the mixture was heated at reflux for 1 h. Usual work-up and distillation gave 2-methyl-6-octylpyridine (2.78 g, 68%). To a solution of 2-methyl-6-octylpyridine (0.48 g, 2.3 mmol) in dry EtOH (100 mL) was added Na (5.00 g, 217 mmol) in portionwise under reflux for 5 h. Usual work-up gave a mixture of **11** and **13** (0.412 g, 85%, 69:31 by GLC analysis), each of which was separated by column chromatography on alumina eluting with pentane–ether (9:1 to 0:10). **11**: MS *m/z* (%) 211 (M^+, 1), 98 (100); IR (neat): 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.30—2.80 (m, 2H), 1.14—1.86 (m, 21H), 1.03 (d, 3H, J=6 Hz), 0.87 Hz (t, 3H, J=6 Hz); ^{13}C NMR ($CDCl_3$) δ=57.4 (d), 52.7 (d), 37.7 (t), 34.8 (t), 32.6 (t), 32.0 (t), 29.7 (t), 26.1 (t), 25.1 (t), 23.2 (q), 22.7 (t), 14.1 (q). **13**: MS *m/z* (%) 211 (M^+, 1), 98 (100); IR (neat): 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.70—3.14 (m, 2H), 1.15—1.80 (m, 21H), 1.04 (d, 3H, J=6 Hz), 0.86 (t, 3H, J=6 Hz); ^{13}C NMR ($CDCl_3$) δ=51.1 (d), 46.1 (d), 34.4 (t), 33.3 (t), 32.0 (t), 31.1 (t), 29.9 (t), 29.7 (t), 29.4 (t), 26.6 (t), 22.7 (t), 21.3 (q), 19.8 (t), 14.1 (q).

1-Methoxycarbonyl-6-methyl-2-undecyl-1,2,3,4-tetrahydropyridine (14). A mixture of **4d** (0.303 g; 1.0 mmol) and 5% Pd–C (0.060 g) in dry MeOH (10 mL) was stirred under atmospheric pressure of H_2. The reaction was followed by GLC. After **4d** disappeared, the catalyst was removed by filtration through Celite and the solvent was evaporated. The residue was chromatographed on silica gel. Elution by hexane–CH_2Cl_2 (4:1) gave **14** (0.185 g, 60%): MS *m/z* (%) 309 (M^+, 31), 196 (100); IR (neat): 1715 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.87 (br s, 1H), 4.35 (br s, 1H), 3.69 (s, 3H), 2.02 (s, 3H), 1.07—2.07 (m, 24H), 0.87 (t, 3H, J=6 Hz); ^{13}C NMR ($CDCl_3$) δ=155.3 (s), 132.6 (s), 111.7 (d), 52.5 (q), 52.4 (d), 32.0 (t), 29.7 (6t), 29.4 (t), 26.4 (t), 25.8 (t), 22.7 (t), 22.7 (q), 19.5 (t), 14.1 (q). Found: C, 73.74; H, 11.40%. Calcd for $C_{19}H_{35}NO_2$: C, 74.06; H, 11.81%.

(±)-Solenopsin A, *trans*-2-Methyl-6-undecylpiperidine (15). To a mixture of **14** (0.155 g, 0.50 mmol) in dry $CHCl_3$ (2.0 mL) was added iodotrimethylsilane (0.10 mL, 0.60 mmol). The mixture was stirred at 50—60 °C for 1 h and, after addition of MeOH (0.06 mL), at room temp for 10 min. The solvent was evaporated and diluted with CH_2Cl_2. The solution was washed with 0.1 M aq NaOH and dried (Na_2SO_4). The solvent was evaporated and the residue was dissolved in THF (8.0 mL). This solution was added to a suspension of $LiAlH_4$ (0.133 g, 3.5 mmol) in THF (8.0 mL) at −78 °C. To this mixture was added trimethylaluminium in hexane (3.5 mL, 1.0 M, 3.5 mmol) and the mixture was stirred at −78 °C and warmed gradually to room temp over 2 h. Usual work-up and column chromatography on alumina eluting with ether gave **15** (0.113 g, 90%), which was shown to contain the cis-isomer (10%) by GLC analysis.[27] **15**: IR (neat): 1370 cm^{-1} (weak); ^1H NMR ($CDCl_3$) δ=2.70—3.13 (m, 2H), 1.13—1.87 (m, 27H), 1.05 (d, 3H, J=6 Hz), 0.87 (t, 3H, J=6 Hz); ^{13}C NMR ($CDCl_3$) δ=50.9 (d), 45.9 (d), 34.1 (t), 33.0 (t), 31.9 (t), 30.7 (t), 29.8 (t), 29.7 (t, 5C), 29.4 (t, 2C), 26.5 (t), 22.7 (t), 21.2 (q), 19.6 (t), 14.1 (q).

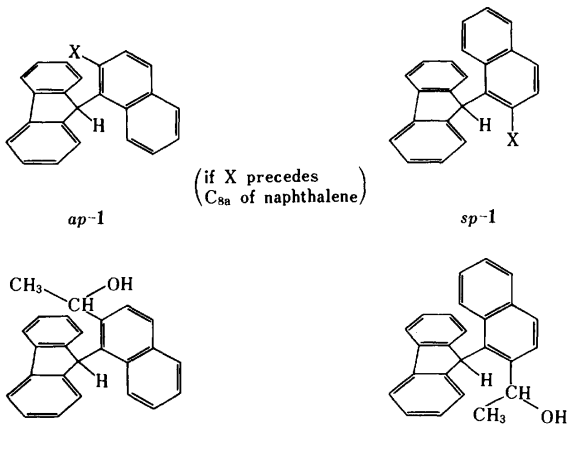
(Received June 21, 1986)

Treatment of the title compound with 70% sulfuric acid in 1,2-dimethoxyethane caused cyclization for the *ap* isomer, whereas it did dehydration to produce a vinyl compound smoothly for the *sp*. The same treatment with 10% sulfuric acid in 1,2-dimethoxyethane afforded the corresponding vinyl compounds from both rotamers. Treatment of the alcohol with thionyl chloride afforded the corresponding chloride in the case of the *sp*-alcohol, while it gave the *sp*-vinyl compound in addition to the *ap*-chloride in the case of the *ap*-alcohol. The change in solvents in the reaction of the *ap* form caused the change in the ratio of the olefin vs. the chloride: The polar solvents enhance the rates of formation of the chloride. Introduction of three deuteriums to the methyl group of the *ap*-form of the title compound suppressed the formation of the olefin to some extent. The results are explained on the grounds of steric effects in the ion-pair formation from the chlorosulfites and the contribution of the C–H stretching in the transition state of the elimination.

In previous papers of this series, it was postulated that a reaction is slow in the ap conformer of 9-arylfluorenes, one of which examples is 9-(2-substituted 1-naphthyl)fluorene (**1**), if the reaction takes a space-demanding transition state[2,3)] and that a cation formed in the benzylic position of the aryl group shows intramolecular interactions with the π-electron system of the fluorene moiety.[4)] Since 9-[2-(1-hydroxyethyl)-1-naphthyl]fluorene (**2**) should form a cationic species if treated with an acid and derivation of the alcohol to the corresponding chloride with the use of thionyl chloride should proceed with a cyclic transition state,[5)] the rotamers of compound **2** might show interesting difference in their behaviors in these reactions. Thus we investigated these reactions of the alcohol **2**. This paper is to report the results of the investigation and to discuss the origin of the difference.

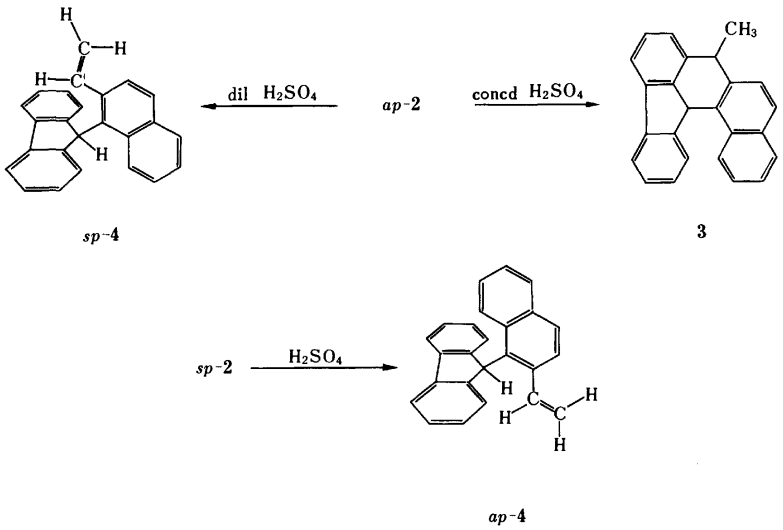


ap-1 *sp*-1

ap-2 *sp*-2

The barrier to rotation about the C_9(fluorene)-to-C_1(naphthalene) bond in the compound **2** has not been determined but may be assumed to be high enough to examine reactions without giving any complexity due to isomerization at room temperature for the following reasons. The barrier to rotation in 9-(2-methyl-1-naphthyl)fluorene (**1**: X=CH_3) is known to be ca. 29 kcal mol^{-1} (1 cal=4.18 J).[6,7)] Substitution of one of the hydrogens in the methyl group of 9-(2-methyl-1-naphthyl)fluorene does not significantly affect the barrier height (ca. 29 kcal mol^{-1}).[8)] In a series of 9-(2-substituted phenyl)fluorenes, the change in the substituent from methyl to ethyl and then to isopropyl causes a slight increase in the barrier height (16, 17, and 18 kcal mol^{-1}, respectively, for the *ap*→*sp* process).[6,9)] Similarly, 9-[2-(1-methoxycarbonylethyl)phenyl]fluorene exhibits ca. 18 kcal mol^{-1} barrier.[10)] Furthermore, the barrier to rotation in 9-[2-(α-hydroxybenzyl)-1-naphthyl]fluorene (*ap*→*sp*) is known to be ca. 30 kcal mol^{-1} at room temperature.[2b)] Thus the barrier to rotation about the C_9(fluorene)–C_1-(naphthalene) bond should be higher than 29 kcal mol^{-1}.

Reaction with Sulfuric Acid. Treatment of *ap*-**2** in 1,2-dimethoxyethane with sulfuric acid, of which concentration was high in the same solvent, afforded a product of which elemental analysis was consistent with a structure derived by dehydration of *ap*-**2**. From the ^{1}H NMR spectrum of the product and from our experience that has shown cyclization be possible for the *ap*-isomer if a cation is formed,[4)] we assigned a planar structure **3** for the product. By contrast, the *sp*-isomer afforded *ap*-9-(2-vinyl-1-naphthyl)fluorene (**4**) in good yields. If the concentration of sulfuric acid in 1,2-dimethoxyethane was low, both *ap*-**2** and *sp*-**2** afforded the respective rotamer of **4**, although the former is often contaminated by **3**.

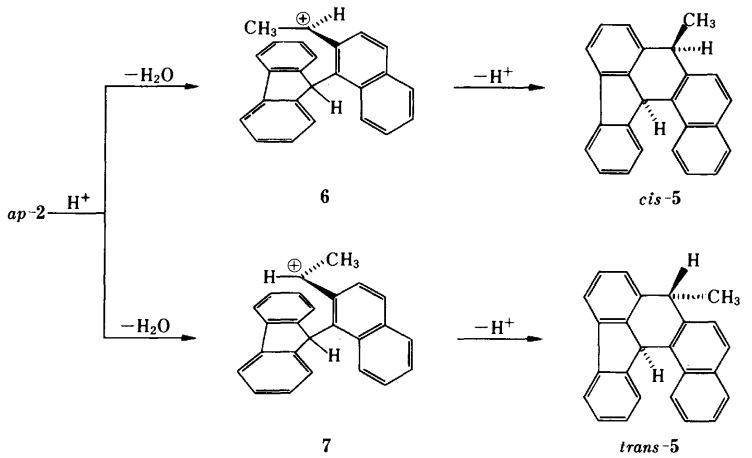


The reason for the fact that, whereas the *ap* form of **2** cyclized, *sp*-**2** failed to give any cyclized product, must be the geometry of the cation that is formed during the reaction. The cation from *sp*-**2** is in the plane of the fluorene ring. Since rotation about the C_9(fluorene)–C_1(naphthalene) bond must take place for the cation from *sp*-**2** for cyclization, of which barrier is high, deprotonation from the cation is a preferred process even in the concentrated sulfuric acid medium. In contrast, cyclization is favored in the cation from *ap*-**2** because the cationic center is very close to the π-system of the fluorene ring. It seems that, if the concentration of sulfuric acid is low, water or hydrogensulfate anion can remove a proton from the intervening cation from *ap*-**2** favorably.

If the π-participation in forming the benzylic cation from *ap*-**2** is really important, the dehydration of the *ap*-alcohol may be facilitated relative to the *sp*-alcohol, since formation of the cation is expected to be rate-determining. Competitive dehydration of *sp*-**2** and *ap*-**2** revealed that the relative rate, k_{sp}/k_{ap}, was 0.36, as determined by the formation of the olefins. Although this ratio might seem small, it must be taken as an indication that the π-participation is considerable, especially because the solvent molecules are good at stabilizing carbocations. For the cation from *ap*-**2**, solvation shell is formed by participation of the fluorene ring in addition to the solvent molecules, the latter being more favorable than the former.[4]

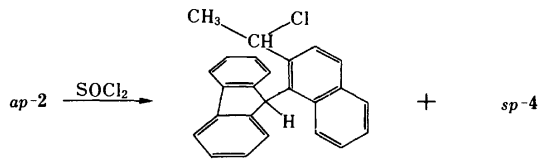
As to the stereostructure of **3**, there are two possibilities, *cis* and *trans*, with respect to the 8-H and 14c-H. For the stereochemical assignments of 9,10-dihydroanthracene derivatives, coupling constants in ^{1}H NMR are known to be useful.[11] Since the 14c-H should take the axial position because of the geometrical requirement, if the methyl group at the 8-position is equatorial, a large coupling constant between the protons in question is expected. Since they showed a small coupling constant, the ^{1}H NMR spectrum supports the stereochemistry in that the 8-H and the 14c-H are *trans* with each other.

Consideration of the reaction mechanism also supports the conclusion drawn from the ^{1}H NMR spectrum. The alcohol (**2**) will form a cationoid species when it is treated with sulfuric acid, since it is a benzylic alcohol.[12] Then there are two over-simplified reaction intermediates (**6** and **7**) possible, as

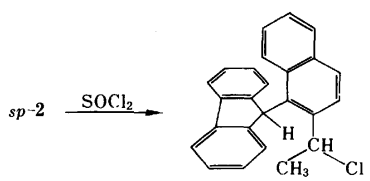


shown in the preceding page. Of the two, the one in which the methyl group is located over the fluorene ring **6** should be of high energy than the other **7** in which the hydrogen is over the fluorene ring. If cyclization takes place from **6**, the 8-H/14c-H stereochemistry is *cis*, whereas it is *trans* when cyclization takes place from **7**. Thus, *trans* stereochemistry should be favored in the product. In support of this, we observed formation of another isomer, of which ^{1}H NMR doublet signal appeared at δ 1.82 due to the methyl protons, in addition to the main product which showed the same peak at δ 1.53, in the reaction run by adding sulfuric acid to 1,2-dimethoxyethane solutions of *ap*-**2**, when temperature rose spontaneously.

Reactions with Thionyl Chloride. The reactions of the alcohol (**2**) with thionyl chloride was carried out generally as dichloromethane solutions at 0 °C. *sp*-**2** afforded the corresponding chloride (**8**) smoothly, whereas *ap*-**2** afforded *sp*-9-(2-vinyl-1-naphthyl)fluorene (**4**) in addition to the chloride (**8**). Since the reaction of 1-(2-naphthyl)ethanol under the same conditions gave the corresponding chloride only, as had been reported,[13] the anomaly is in *ap*-**2** rather than in *sp*-**2**. Formation of olefins in treatment of secondary alcohols with thionyl chloride has been reported in purely aliphatic series,[14] but not for the benzylic alcohols. We have examined whether hydrogen chloride reacted with *sp*-**4** to form *ap*-**8** and *ap*-**8** decomposed to produce *sp*-**4** under the conditions. The results were all negative. Thus the ratio *sp*-**4**/*ap*-**8** can be taken as intrinsic.



ap-**8**



sp-**8**

The formation of a chloride from a chlorosulfite ester which is derived by the reaction of an alcohol with thionyl chloride is believed to proceed via an ion pair that is produced by a cyclic transition state.[5b] The rate-determining step in the olefin formation from secondary alcohols and thionyl chloride has been deduced to be the formation of the ion pair as well from the kinetic isotope effect.[15] However, it is necessary for the chloride anion to move in the deprotonation from the methyl group in the case of *ap*-**2**. Therefore, if the elimination to form *sp*-**4** and the substitution to form *ap*-**8** are competing, solvent effects due to the polarity are expected. Thus we carried out the reactions of **2** with thionyl chloride in various solvents. The results are shown in Table 1. The olefin **4** is never found in the product of the reaction of *sp*-**2**, as far as the present method of detection concerns, but the formation of the olefin from *ap*-**2** is dependent on the polarity of the solvent used: The more polar is the solvent, the more is the chloride produced.

Table 1. Dehydration versus Chlorination in the Reaction of **2** with Thionyl Chloride

Solvent	Dielectric constant of solvent	From *ap*-alcohol (*sp*-**4**/*ap*-**8**)	From *sp*-alcohol (*ap*-**4**/*sp*-**8**)
Hexane	1.88[b]	71/29	<5/>95
Dioxane	2.21[b]	67/33	<5/>95
Dichloromethane	8.93[b]	60/40	<5/>95
Thionyl chloride	9.25[c]	38/62	<5/>95
Nitromethane	35.9[b]	20/80	<5/>95

a) Reactions were carried out with ice-cooling except for the hexane solutions which were heated at 40 °C. b) From Ref. 16. c) From Ref. 17.

In order to get further insight into the reaction, we measured ^{1}H NMR spectra of mixtures of **2** and thionyl chloride in dichloromethane at 0 °C. Surprisingly, we found signals due to the starting material and the products, the olefin **4** and/or the chloride **8**, but not those due to chlorosulfites. Whereas the signals due to **2** decreased in their intensities and those due to the products increased in their intensities, we did not observe any signals ascribable to the chlorosulfite. This means either that the rate determining step in the reaction is not the step leading to the cyclic transition state or that the chlorosulfite is highly unstable, though its decomposition is rate-determining. It is not possible to conclude which is the case from the results of the present work. The rate determining step may vary also, as the polarity of the solvent changes.

We further carried out the reaction of *ap*-**2**-methyl-d_3 under the same conditions with the protium compound in dioxane to find that the ratio *sp*-**4**/*ap*-**8** changed from 2.0 in the protium compound to 1.0 in the deuterium compound. Although it was not possible to run the kinetic studies due to the fact that the chlorosulfites were unstable and thus the kinetic isotope effects were not determined, this change in the product ratio is interesting. The results would mean that the hydrogen-abstraction step is contributing to the overall reaction rates.

The implication of the results made it necessary to reexamine the reported kinetic isotope effect.[15] Close examination of the reported rates of decomposition of

1-methylbutyl-methyl,2,2-$d_{4.3}$ chlorosulfite reveals that the isotope effects are 1.4 and 3.3 in dioxane and isooctane, respectively. The secondary α-kinetic isotope effects are normally 10—15% per deuterium for the S_Ni type ionizations.[18] While the β-kinetic isotope effects are stereochemistry-dependent, they never exceeds 2.0.[19] The data obtained for the dioxane solutions are within the range for normal ionization reactions, but those for the isooctane solutions exceeds the range of the normal ionization, if the secondary isotope effects are assumed. This would mean that solvents change the mechanisms or the contributions to the transition states of the rate-determining step considerably, because the solvent polarity affects the transition state energy.

The isotope effects on the product ratio then could be used for the diagnosis of the reaction mechanisms, since the primary isotope effects are expected to be more than 3.0 for the normal cases.[20] From the data of the solvent effects on the product ratios, it was expected that the isotope effects on the product ratio *sp*-**4**/*ap*-**8** were to be the highest in hydrocarbons. Accordingly, examination of the product ratio *sp*-**4**/*ap*-**8** in hexane would be interesting. The reaction had to be carried out at 40 °C in hexane because of its slowness, while reactions were practically complete at 0 °C in other solvents. This operation will cause reduction in the *sp*-**4**/*ap*-**8** ratio relative to the data at 0 °C in other solvents.[21] Yet the ratio was 7:3 for the protium compound, a little higher value than that obtained with the dioxane solution at 0 °C (Table 1). Thus the solvent effect on the *sp*-**4**/*ap*-**8** ratio, favoring the formation of *sp*-**4** in less polar media, is still valid. The same treatment of *ap*-**2**-methyl-d_3 in hexane gave the *sp*-**4**/*ap*-**8** ratio of 1.5, which is still higher than that obtained with the dioxane solution of the deuterium compound.

From the above results, we can conclude that 1) the olefin formation from *ap*-**2** is favored in less polar media than in more polar media and 2) the deuterium isotope effects on the product ratio is more significant in less polar media than in the more polar. Any explanation of the mechanisms must accommodate these facts together with the results that have been published.

The formation of the olefin (*sp*-**4**) from *ap*-**2** may be explained by the steric effects. Molecular models of the cyclic transition state to form an ion pair from the *ap*-chlorosulfite suggest that the transition state of the reaction receives considerable steric hindrance from the fluorene ring. In nonpolar media, the ion pair must be tight, while it is loose in polar media. This will mean that the transition state for the ion-pair formation in polar media is attained earlier than that in nonpolar media. Since the $C_\alpha \cdots Cl$ distance in this assumed transition state in nonpolar media is shorter than that in polar media, the steric effect that is received by the former must be severer than the latter. By contrast, the elimination reaction which involves the contribution of the C–H stretching will receive far less steric effect of the fluorene ring because one of the C–H bonds in the methyl group is always far from the fluorene moiety. In addition to the above, there is a factor that must be taken into account. That is, the ionic reactions, that form the chloride in this case, are generally favored in polar solvents, whereas the olefin formation should be less affected by the polarity of the media, as judged from the participation of the C–H stretching to the olefin formation, which means that the nonionic cyclic transition state is contributing. Thus we conclude that due to the factors discussed above the chloride formation becomes relatively favored in polar media, while the olefin formation is favored in nonpolar media.

Experimental

9-[2-(1-Hydroxyethyl)-1-naphthyl]fluorene (2). A solution of 2.0 g (5.9 mmol) of a rotameric mixture (ca. 1:1) of 9-(2-formyl-1-naphthyl)fluorene[2] in 150 mL of ether was added to a Grignard solution, which was prepared from 0.37 g (15 mmol) of magnesium, 1.1 mL (18 mmol) of methyl iodide, and 15 mL of ether. The mixture was stirred for several minutes and decomposed with aqueous ammonium chloride. The ether layer was separated and the aqueous layer was extracted with ether. The combined ether layer was dried over magnesium sulfate and the solvent was evaporated to afford a mixture of the rotameric alcohols. The mixture was separated by silica-gel chromatography (hexane–ether eluent) to give 1.0 g each of *sp* and *ap* rotamers, which were identical with those previously reported.[2]

ap-9-[2-(2,2,2-Trideuterio-1-hydroxyethyl)-1-naphthyl]fluorene (*ap*-**2**-methyl-d_3) was similarly prepared from methyl-d_3 iodide and the *ap*-aldehyde (**1**: X=CHO) and purified by thin-layer chromatography (3:2 dichloromethane–hexane). MS (*m/z*): 339 (M^+, $C_{25}H_{17}D_3O$), 321 (base peak, $M-CD_3$), 320 (M−HDO). ^1H NMR ($CDCl_3$) δ=3.77 (1H, s), 6.10 (1H, s), 7.1—8.0 (13H, m), 8.4—8.6 (1H, m). The OH proton signal was not detected.

Reaction with Dilute Sulfuric Acid. A solution of 1.0 g of the *sp*-alcohol (**2**) in 50 mL of 1,2-dimethoxyethane was mixed with a mixture of 10 mL of concentrated sulfuric acid and 150 mL of 1,2-dimethoxyethane with ice-cooling. The mixture was stirred for 5 d at room temperature, poured into water, and extracted with ether. The ethereal extract was washed with aqueous sodium hydrogencarbonate and dried over magnesium sulfate. After evaporation of the solvent, the residue was chromatographed on silica gel (hexane eluent). The product was recrystallized from pentane to give pure *ap*-9-(2-vinyl-1-naphthyl)fluorene (**4**), mp 119.0—119.5 °C, in 90% yield. Found: C, 94.14; H, 5.41%. Calcd for $C_{25}H_{18}$: C, 94.30; H, 5.70%. ^1H NMR ($CDCl_3$) δ=5.4—5.9 (2H, m), 5.87 (1H, s), 6.3—8.0 (15H, m).

Similar treatment of the *ap*-alcohol (**2**) with sulfuric acid afforded *sp*-olefin (**4**), mp 134.5—135.5 °C, in 85% yield. Found: C, 94.58; H, 5.41%. Calcd for $C_{25}H_{18}$: C, 94.30; H, 5.70%. ^1H NMR ($CDCl_3$) δ=4.4—5.3 (2H, m), 5.4—5.8 (1H,

m), 6.11 (1H, s), 7.1—8.0 (13H, m), 8.4—8.7 (1H, m).

Reaction with Concentrated Sulfruic Acid. A solution of 1.0 g of *ap*-alcohol (**2**) in 10 mL of 1,2-dimethoxyethane was mixed with a mixture of 30 mL of 1,2-dimethoxyethane and 30 mL of concentrated sulfuric acid and stirred overnight at room temperature. The mixture was poured into water and extracted with ether. The ethereal extract was washed with aqueous sodium hydrogencarbonate and dried over magnesium sulfate. The solvent was evaporated and the residue was chromatographed on silca gel (hexane eluent) to afford *trans*-8-methyl-8,14c-dihydrodibenz[*a*,*l*]aceanthrylene (**5**), mp 173.0—174.0 °C, in 90% yield. Found: C, 94.27; H, 5.40%. Calcd for $C_{25}H_{18}$: C, 94.30; H, 5.70%. ^{1}H NMR ($CDCl_3$) δ=1.53 (3H, d, J=7 Hz), 4.11 (1H, dq, J=1 and 7 Hz), 5.14 (1H, d, J=1 Hz), 6.9—8.8 (13H, m).

Similar treatment of the *sp*-alcohol afforded the *ap*-olefin only which was identical with that described above.

Competitive Reaction of *ap*-2 and *sp*-2 with Sulfuric Acid. A solution of 20 mg each of *ap*-**2** and *sp*-**2** in 50 mL of 1,2-dimethoxyethane was mixed with a mixture of 10 mL of concentrated sulfuric acid and 50 mL of 1,2-dimethoxyethane with ice-cooling. The whole was stirred at room temperature for 3 h and treated similarly as above thereafter. The conversion was less than 10% under the conditions. The ratio of the rotameric olefins, *sp*-**4**/*ap*-**4**, was analyzed with the use of HPLC. The HPLC instrument was a Waters M-600 Chromatograph equipped with a UV detecter at 254 nm. At a flow rate of 3.1 mL min^{-1} of hexane on a Microporasil column, the retention times were, *ap*-**4** 6.1 min and *sp*-**4** 7.1 min. The formation ratio, *sp*-**4**/*ap*-**4**, was 0.36.

Since the reaction can be assumed to be first-order in each of the substrate and sulfuric acid is used in large excess and since the reaction was discontinued at early stages, the formation ratios were taken as the relative rates of the reaction.

9-[2-(1-Chloroethyl)-1-naphthyl]fluorene](8). A solution of 100 mg (0.30 mmol) of the *sp*-alcohol in 50 mL of nitromethane was mixed with 0.5 mL (4.3 mmol) of thionyl chloride which was freshly distilled from a mixture of thionyl chloride and triphenyl phosphite, with ice-cooling. The mixture was stirred at 40 °C for 10 min and the solvent was evaporated. The residue was chromatographed on silica-gel TLC to give ca. 80% *sp*-chloride, oil, which was rather unstable. High resolution MS gave very weak M^+ peak at m/z 354.1192, whereas the calcd value for $C_{25}H_{19}{}^{35}Cl$ is 354.1175. ^{1}H NMR ($CDCl_3$) δ=2.13 (3H, d, J=7 Hz), 5.86 (1H, s), 6.00 (1H, q, J=7 Hz), 6.3—8.0 (14H, m). No impurity was detected by ^{1}H NMR spectra.

Similar treatment of the *ap*-alcohol gave a mixture of *sp*-9-(2-vinyl-1-naphthyl)fluorene and *ap*-9-[2-(1-chloroethyl)-1-naphthyl]fluorene in 18 and 72% crude yields, respectively. The *ap*-chloride, oil, was again unstable but showed a very weak M^+ peak in high resolution MS at m/z 354.1166, whereas the calcd value for $C_{25}H_{19}{}^{35}Cl$ is 354.1175. No impurity peaks were detected in the ^{1}H NMR spectra of *ap*-**8**. ^{1}H NMR ($CDCl_3$) δ=1.02 (3H, d, J=7 Hz), 4.03 (1H, q, J=7 Hz), 6.10 (1H, s), 7.0–8.0 (13H, m), 8.4–8.6 (1H, m).

Solvent Dependence of the Thionyl Chloride Reaction with the Alcohol (2). Except for hexane solutions, the following is the typical procedure. The alcohol (*ap*-**2**) (30 mg) in appropriate solvent (50 mL) was mixed with 0.5 mL of thionyl chloride, which was purified as above, with ice-cooling, and the mixture was stirred for 5 min at that temperature and then at 40 °C for 10 min. The reaction mixture was treated similarly as above and the ratios (olefin/chloride) were determined by ^{1}H NMR spectra of the products in chloroform-*d* with the use of a Varian EM-390 spectrometer.

For hexane solutions, the reaction was carried out for 10 h at 40 °C with the same ratios of the reactants and the solvent and the mixture was treated similarly as above. Under the competitive conditions, 15% of the *ap*-alcohol remained unreacted, whereas 28% of the *sp*-alcohol was found unreacted after 10 h at 40 °C, when 50 mg each of the rotameric alcohols and 0.5 mL of thionyl chloride in 80 mL of hexane were used.[22]

Reaction of *ap*-2-Methyl-d_3 with Thionyl Chloride. The reaction was carried out in either dioxane or hexane as described in the Solvent Dependence section and the product ratios were determined by ^{1}H NMR spectra. The alcohol was less reactive than the protium compound, giving 35.5% unreacted alcohol after 10 h in hexane at 40 °C. The following ^{1}H NMR spectra were recorded. *ap*-**8**-methyl-d_3: 4.01 (1H, s), 6.10 (1H, s), 7.0—8.0 (13H, m), 8.4—8.6 (1H, m). *sp*-**4**-methylene-d_2: 5.54 (1H, s), 6.10 (1H, s), 7.0—8.0 (13H, m), 8.4—8.6 (1H, m).

21) In one experiment in which thionyl chloride was added to a nitromethane solution of *ap*-**2** at room temperature followed by heating at 40 °C, no detectable amount of the olefin (*ap*-**4**) was formed. This lends support as well to the idea that the olefin formation is suppressed at a high temperature.
22) In hexane, it seems that the rate-determining step is the decomposition of the corresponding chlorosulfites, because addition of thionyl chloride to a hexane solution of *sp*-**2** caused a change in the chemical shift due to the methine proton in ^{1}H NMR spectra. However, the huge peaks due to the solvent prevented us performing any reliable, quantitative study.

Concurrent Anodic Cyanation and Methoxylation of Methylated Furans. Oxidation Potential and Reactivity, and Stereochemical Control of Addition

Kunihisa Yoshida* and Takayuki Fueno
Department of Chemistry, Faculty of Engineering Science, Osaka University, Toyonaka, Osaka 560
(Received June 23, 1986)

The potentiostatic electrooxidation of a series of methyl-substituted furans was performed in MeOH that contains NaCN at a Pt anode in a divided cell. In all instances, the 1,4-additions of cyano and/or methoxyl group(s) across the furan ring were achieved. Replacement of an aromatic hydrogen by a cyano group occurred concurrently in some cases. The relative rates of cation radicals toward two different nucleophiles (CN^- ion and the solvent MeOH (or the MeO^- ion as a result of the equilibrium between CN^- ion and the solvent MeOH)) at the electrode surface were determined from the yields of products by using the rate expressions of competitive reactions. There is a linear correlation between the relative reactivity of the furans (on a log scale) and their oxidation potential. The ratio of stereoisomers formed in an electrooxidation of 2,5-dimethylfuran (2,5-DMF) changes with addition of adsorbable compound as well as substrate concentration and this is thought to be due to the influence of concentration (or coadsorbate) on substrate orientation in the adsorption layer.

Previously we reported the electrooxidation of 2.5-dimethylfuran (2,5-DMF) in MeOH that contains NaCN.[1-4] Stereoselective 1,4-addition of cyano and/or methoxyl group(s) to the furan ring occurred. The process consists of two successive competitive reactions; the first one is addition of two different nucleophiles, CN^- ion and the solvent MeOH (or the MeO^- ion as a result of the equilibrium between CN^- and MeOH), to the 2,5-DMF cation radical and the second one is to the benzenium-type ion formed by means of an ECE process. If this system is applied to a series of sequentially substituted furans, the mode and yields of products may well reflect the competitive reactions toward each cationic intermediate. It should provide information on the relative reactivity of a series of related cations toward two competing nucleophiles at the electrode.

In an attempt to determine the relative concentrations of those two nucleophiles at the electrode from oxidation products of 1,4-dimethoxybenzene (1,4-DMB) in the same solvent-electrolyte system using a competitive technique, Weinberg and co-workers assumed that the relative rates of 1,4-DMB cation radical and of substituted benzenium ions toward two nucleophiles would be both equal to those of relatively stable carbenium ions such as triarylmethyl cations, arenediazonium ions, and tropylium ions.[5] There is, however, no foundation for such a hypothesis. The idea that the relative (if not absolute) reactivity changes with the structure is rather natural.

The present paper describes the competitive anodic cyanation and methoxylation of a series of sequentially methyl-substituted furans. The relative reactivity of furans cation radicals toward two competing nucleophiles at the electrode has been estimated by studying the products. The relative reactivity changes widely with the substrate structure, and correlates with the oxidation potential at that. Addition to the furan ring, especially the second nucleophilic addition, is sterically controlled by the electrode. The influence of substrate concentration, aromatic additive, and electrode material on the ratio of stereoisomeric products has been investigated.[6]

Results

Cyclic Voltammetry (CV). Cyclic voltammograms were recorded for each compound using a solution of 0.4 M† NaCN in MeOH. The background current with this system began to increase at potentials more anodic than 1.60 V. The E_p values are collected in Table 2. 2,5-DMF gave a single anodic peak. The electrochemical data revealed that the height of the peak varied linearly with concentration, and there was no evidence of a reversible cathodic peak for any of the furans. The current function, $i_p/v^{1/2}$, where i_p is the peak current and v is the sweep rate, decreased, and E_p shifted more positive with increasing sweep rate. Similar voltammetric data were noted for other substituted furans (Table 1). All of the preceding data are consistent with a fast chemical reaction following the electron transfer.

Product Studies. The reactions were performed potentiostatically in a divided cell with a Pt anode at room temperature. The reference electrode was an SCE. The electroreaction medium was MeOH–0.4 M NaCN. The products were isolated by preparative GLC and were identified by the elemental and ^1H NMR, IR, and mass spectroscopic analyses.

The 1,4-addition of cyano and/or methoxyl group(s) across the diene system of a furan took place for all of the molecules investigated, and besides the replacement of an aromatic hydrogen by a cyano group at a free 2 (or 5) position occurred concurrently

† 1 M=1 mol dm^{-3}.

for furans lacking the substituent on either 2 or 5 (or both) position(s). Nuclear cyanation at the 3 position also occurred slightly for 2,5-DMF. In some cases, small amounts of side-chain-methoxylation products were produced. Some of cyanation products undergo base-catalyzed reaction[5,7] in the reaction medium, yielding methyl imidates. Small amounts of 1,4-dicarbonyl compounds and their monoacetals were occasionally obtained. Structural formulas of products are shown below and the results of preparative electroreaction are given in Table 2. The Table also contains the results of both the electrooxidation of 2,5-diethylfuran (2,5-DEF) in the same solvent-electrolyte system and the electroreaction of 2,5-DMF in EtOH that contains NaCN.

Structure of Isomeric Pairs. The extensive and detailed studies on geometrical isomerism in 2,5-dihydro-2,5-dimethoxyfurans[8-11] make possible the structural assignments to isomeric pairs of the relevant 1,4-mixed addition products. The basis for the structural assignments resides in the fact that the chemical shift of a group in the 2 position of the furan ring is affected both by the other group at the 2 position and the magnetic influence exerted by the group at the 5 position that is cis to it. Thus, if a 2-methyl is cis to a 5-methoxyl (or a 5-cyano) it will resonate at lower field and raise the δ value than if it is

a) Oxidation in MeOH solvent, unless otherwise stated. The potential was set at the peak potential of the substrate. b) Peak potential from CV; Pt anode, MeOH, 0.4 M NaCN, SCE reference. Sweep rate is 0.1 V/s. Substrate concentration is 2×10^{-2} M. All voltammograms showed no cathodic peak corresponding to reversible reduction of a cation radical. c) Current efficiency. d) The remainder of the current is consumed by concurrent discharge of the solvent-electrolyte system. e) A small amount. f) Oxidation in EtOH. g) Equilibrium mixture at room temperature: cis/trans=1.5. h) Equilibrium mixture at room temperature: cis/trans=1.7.

cis to another 5-methyl (or 5-protio) group (Table 3). The same reasoning can be applied to the methoxyl peaks and permits the indicated structural assignments for the two isomers.

Stereochemical Experiments. Table 4 summarizes the isomer compositions of the products of electrooxidative cyanomethoxylation of 2,5-DMF conducted under various experimental conditions. The product mixture was analyzed in very early stages of the run to avoid the shift of the substrate concentration. Consequently, samples were withdrawn and analyzed after passage of 1 to 5% of the charge calculated for a two-electron transfer process, and the average of two or more runs was then taken to be the isomer ratio.

The reaction is sterically controlled by a Pt electrode. The ratio of the resultant stereoisomers depends on the concentration of the substrate, the highest value (3.1 : 1) being obtained in the most dilute solution. The ratio also changed with the type and concentration of aromatic additives. Among aromatic additives, 1,4-DMB and pyridine cause greater changes in the cis-to-trans ratio. On the contrary, addition of aromatic molecules such as bis(*p*-methoxyphenyl)-amine, triphenylamine, tris(*p*-bromophenyl)amine, and tri-*p*-tolylamine, of which oxidation potentials are lower than that of the substrate, prevented the reaction. These aromatic compounds are apparently inert under the present conditions even though they discharge practically. The current is consumed by the regeneration of the additive as a consequence of homogeneous electron transfer between the electrogenerated cation radical and CN^- ion.

In contrast to the Pt electrode, a vitreous C anode gives an isomer ratio approaching that of the equilibrium mixture.

Acid-Catalyed Reactions of 1,4-Mixed Addition Products. It was confirmed that neither of the isomers *cis*-**1k** and *trans*-**1k** undergoes interconversion under the reaction conditions. Both of them also remained intact on GLC. However, a trace of a strong acid converted either isomer into an equilibrium mixture of the two isomers. To obtain a value for the equilibrium isomer composition, cis-trans isomerization was carried out in MeOH in the presence of 1% CF_3COOH at 25.0 °C. The equilibrium was reached within 1 h. The equilibrium value for the ratio *cis*-**1k**:*trans*-**1k** was 1.5:1. Moreover, a temperature change had a negligible effect on the K value at 0 to 100 °C. The acid-catalyzed isomerization also occurs in other solvents such as $CHCl_3$ and CCl_4, but in EtOH it gives place to the alcohol exchange accompanying the isomerization equilibrium.

The adduct **1m**, which has a hydrogen on the 2 position geminate to a cyano group, differs in behavior. It smoothly loses MeOH to afford **2h** with a trace of CF_3COOH in $CHCl_3$.

$$\mathbf{1m} \xrightarrow{H^+/-MeOH} \mathbf{2h} \qquad (2)$$

Discussion

Mechanism. Both addition to and substitution on the furan ring are formally a 2-equiv change. Coulometry supports this experimentally. The voltammetric characteristics (Table 1) indicate that oxidation is initiated by electron transfer from the substrate molecule, followed by a fast chemical reaction. By analogy with anodic cyanation and methoxylation of other aromatic compounds,[3] the ECEC mechanism involving a cation-radical intermediate would be reasonable. The ionization potential of furan and the methylated derivatives is relatively low,[12-14] and the existence of their cation radicals has clearly been recognized in mass spectrometry[15] and studied by ESR.[16,17]

The cation radical mechanism is given in Scheme 1, illustrated for 2,3,4-trimethylfuran (2,3,4-TMF). The first step is the electron-transfer step which involves the direct discharge of the substrate. The cation radical **4** and the benzenium-type ions **5**—**8** react competitively with CN^- ion and the solvent MeOH (or the MeO^- ion as a result of the equilibrium between CN^- and MeOH). Part of **7** could undergo deprotonation to afford **2j**. We may denote rate constants as k_1, k_2,···, and k_{13}, and CEs as **1ox**, **1oy**, **1px**, **1py**, **1qx**, **1qy**, **2j**, **9x**, and **9y**. Thus **9x** and **9y**

represent the CE of product **9** formed in the first and third branches of Scheme 1, respectively. Treating the reactions in Scheme 1 as a system of competitive reactions[5,18] one can derive the following relationships.

$$\frac{k_1'}{k_2'}=\left(\frac{k_1}{k_2}\right)\left(\frac{CN^-}{MeOH}\right)=\frac{\mathbf{1ox}+\mathbf{9x}}{\mathbf{1px}+\mathbf{1qx}} \quad (3)$$

$$\frac{k_3'}{k_4'}=\left(\frac{k_3}{k_4}\right)\left(\frac{CN^-}{MeOH}\right)=\frac{\mathbf{1py}+\mathbf{2j}+\mathbf{9y}}{\mathbf{1oy}+\mathbf{1qy}} \quad (4)$$

$$\frac{k_5'}{k_6'}=\left(\frac{k_5}{k_6}\right)\left(\frac{CN^-}{MeOH}\right)=\frac{\mathbf{9x}}{\mathbf{1ox}} \quad (5)$$

$$\frac{k_7'}{k_8'}=\left(\frac{k_7}{k_8}\right)\left(\frac{CN^-}{MeOH}\right)=\frac{\mathbf{1px}}{\mathbf{1qx}} \quad (6)$$

$$\frac{k'_{10}}{k'_{11}}=\left(\frac{k_{10}}{k_{11}}\right)\left(\frac{CN^-}{MeOH}\right)=\frac{\mathbf{9y}}{\mathbf{1py}} \quad (7)$$

$$\frac{k'_{12}}{k'_{13}}=\left(\frac{k_{12}}{k_{13}}\right)\left(\frac{CN^-}{MeOH}\right)=\frac{\mathbf{1oy}}{\mathbf{1qy}} \quad (8)$$

where

$$\mathbf{9x}+\mathbf{9y}=\mathbf{9}=0.1 \quad (9)$$

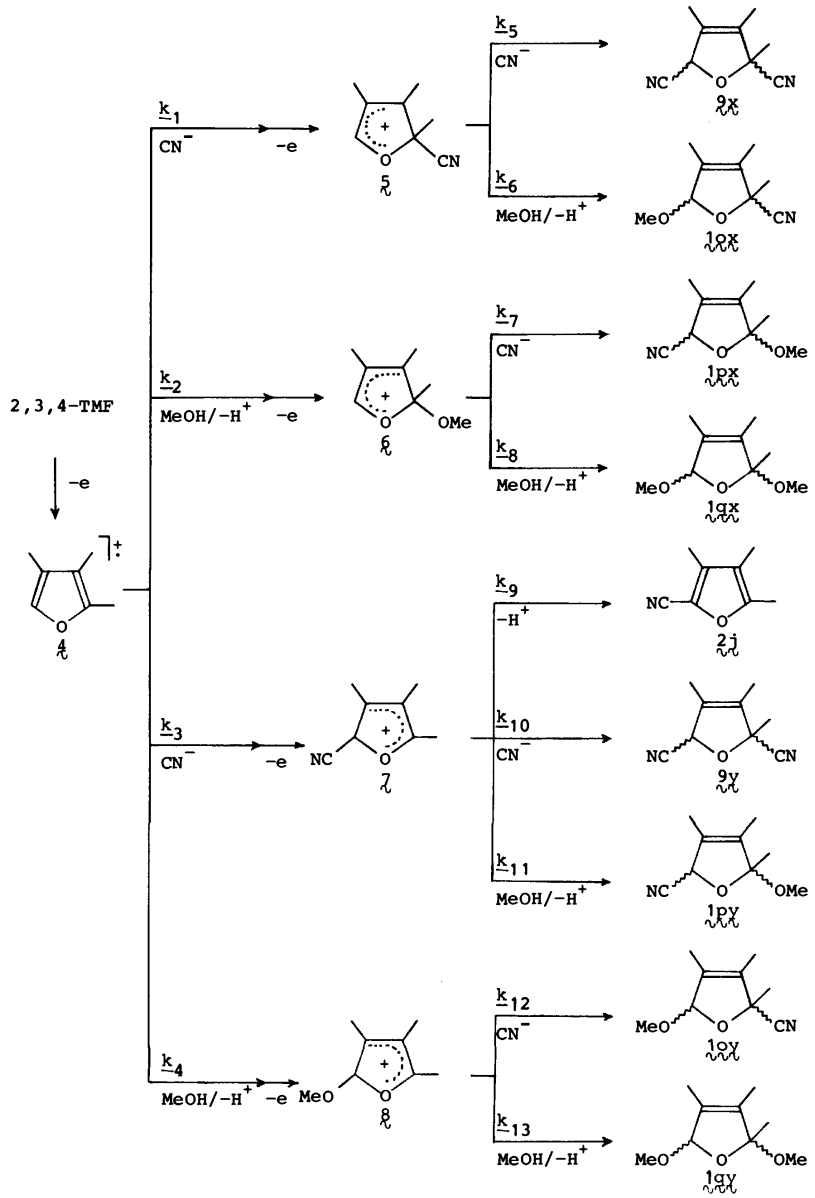
$$\mathbf{1ox}+\mathbf{1oy}=\mathbf{1o}=22 \quad (10)$$

$$\mathbf{1px}+\mathbf{1py}=\mathbf{1p}=7 \quad (11)$$

$$\mathbf{1qx}+\mathbf{1qy}=\mathbf{1q}=13 \quad (12)$$

Here $k_1'=k_1(CN^-)$, $k_2'=k_2(MeOH)$,$\cdots$, $k_{13}'=k_{13}(MeOH)$.

We would like to evaluate the relative magnitudes of k_1 and k_2. In order to solve Eqs. 3—12, it is necessary to obtain information on the relative concentration of nucleophiles in the vicinity of the electrode. In the reactions containing a fast chemical step following the electron transfer, the concentration distribution of available, i.e., physisorbed, nucleo-



Scheme 1.

philes in the electrical double layer would be kept steadily constant by the competition[19] between mass transfer and chemical reaction. Prior to this, adsorption saturation of nucleophiles at the electrode surface may bear a part in duration of the spatially constant concentration. The observed independence of the product distribution obtained on competitive anodic cyanation and methoxylation of 2,5-DMF on the bulk concentration of CN^- ion or potential[2] supports this. Accordingly, the quantity (CN^-/MeOH) should actually be designated as (CN^-/MeOH)$_E$, i.e., referring to relative steady-state concentrations of these nucleophiles in the region of solution adjacent to the anode as compared to the bulk. Furthermore, it is assumed that $k_1/k_2=k_3/k_4$, $k_5\cong k_7$, $k_6\cong k_8$, $k_{10}\cong k_{12}$, and $k_{11}\cong k_{13}$. These assumptions would be reasonable since the electronically significant part of the structures of the corresponding cationic species are identical. The 2,5-dicyano adduct **9** was not detected and thus the lowest limit (0.1% CE) of product analysis in the present experiments was allotted to **9**. Substituting the assumed values for the relative quantities k_1/k_3, we can solve Eqs. 3—12.

Likewise, the relative rate constants of the cation radicals of other methylated furans toward two different nucleophiles have been evaluated. The results obtained are shown in Table 5, together with the observed anodic peak potential. As can be seen from Table 5, methyl substitution lowers the oxidation potential of the neutral substrate while it raises the relative reactivity k_1'/k_2' of its cation radical. A plot of log relative rate constant versus anodic peak potential gives a linear relationship (Fig. 1). The cation-radical intermediates derived from compounds having lower oxidation potentials would be less reactive and hence more discriminating than the cation radicals of substrates having higher oxidation potentials. Thus, the cation radical of 2,3,4,5-tetramethylfuran (TetMF) is highly selective for nucleophiles and preferentially combines with a powerful nucleophile, that is, the CN^- ion, whereas the cation radical of 3-methylfuran (3-MF) preferentially combines with an abundant nucleophile, namely, the solvent MeOH.

Table 5. Relative Reactivity of Methylated Furans Toward Two Different Nucleophiles

Compd	E_p, V	$(k_1/k_3)^{-1}$ a)	k_1'/k_2' b)

TetMF	1.13		742

a) Assumed values. b) Average values.

The mechanism presented in Scheme 2 can also account for the electrooxidation of 2-methylated furans. The cation radical **10** could undergo deprotonation to afford an analogue of a benzylic radical intermediate, which would subsequently undergo anodic oxidation (or homogeneous electron-transfer oxidation by the cation radical **10**) to give a cation **11**, followed by nucleophilic attack by CN^- ion (or MeOH) to give a 2,5-dihydro-5-methylenefuran **12**, which should be eventually transferred to **13**. Indeed, a compound of the type of **12** is probable as a reaction intermediate: e.g., 2,5-dihydro-5-methylene-2-furancarbonitrile and its homologues are the primary products of abnormal product formation in the reaction of 2-(chloromethyl)furans with aqueous cyanide solution.[20] The final step is the homogeneous chemical reaction. If the anodic reaction followed this reaction path, the observed cis-to-trans isomer ratio in the products would be consistent with the isomer composition for the homogeneous equilibrium. However, the anodic reaction of 2,5-DMF gives a high cis-to-trans reaction compared with the equilibrium value. Thus this pathway is not important in the

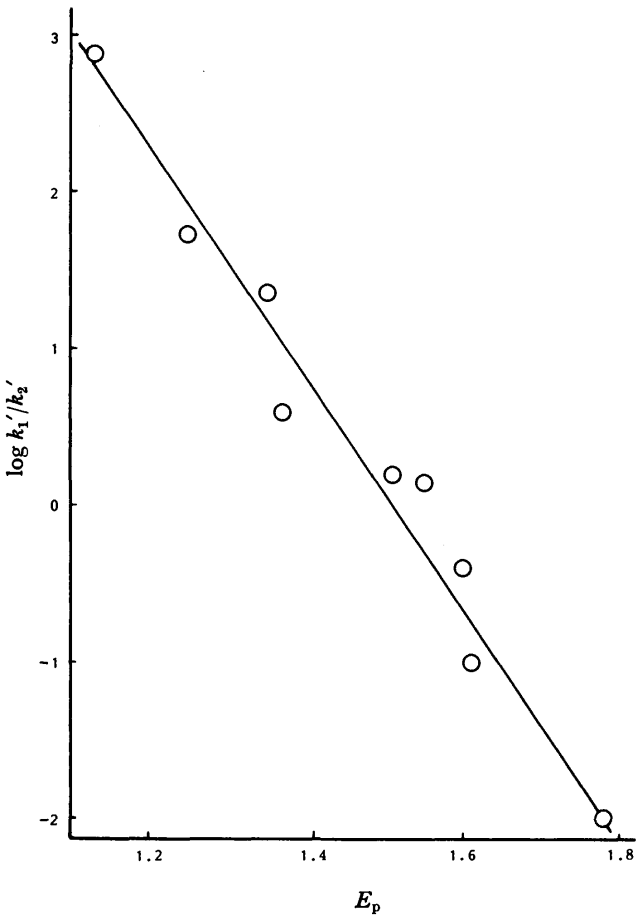

Fig. 1. Plot of log relative rate constant vs. E_p.

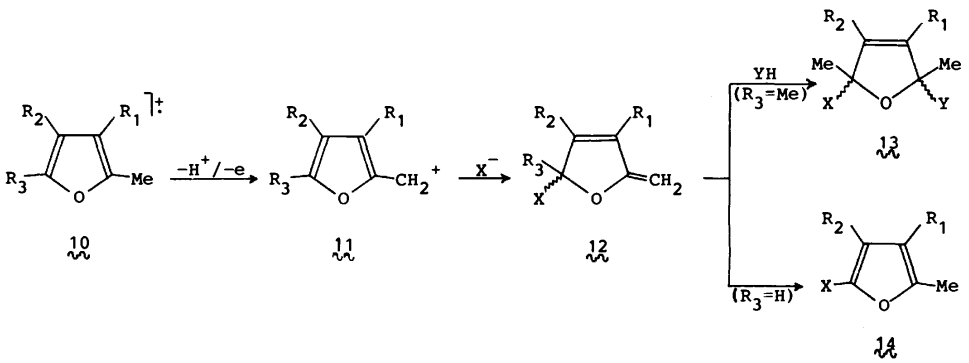
anodic reaction. Alternatively, the compound **12** could be aromatized in protic solvents for furans lacking the substituent on the 5 position (R_3=H). This mechanism was previously discussed in anodic nuclear substitution of 1,2-dimethylpyrrole and has been precluded on the basis of no incorporation of deuterium in the 2-methyl group upon the reaction in methanol-*d*.[21]

1,4-Dicarbonyl derivatives (**3**) would be formed in the acid-catalyzed ring fission[22,23] of 2-methoxyfurans obtained by either anodic nuclear methoxylation or 1,4-elimination[24,25] of MeOH element from the primary 2,5-dihydro-2,5-dimethoxyfurans.

Positional Reactivity. The values of k_1/k_3 given in Table 5 reveal the relative regioreactivity of the initial nucleophilic attack to the cation radicals of unsymmetrical methylfurans. The reaction occurs preferentially at the 2 (and 5) position. When a methyl group is attached at the 2 position, the initial nucleophilic attack occurs comparably at both 2 (ipso) and 5 (para) positions. The introduction of the methyl substituent in the 3 position activates dominantly the 2 (ortho) position.

Comparison with Electrooxidation of 1,4-DMB. Weinberg and co-workers investigated the electrooxidation of 1,4-DMB at a Pt electrode in MeOH that contains NaCN.[5] 1,4-DMB undergoes the additions of cyano and/or methoxyl group(s) across the aromatic nucleus in competition with methoxyl displacement. The CEs of *p*-methoxybenzonitrile **15** and of *p*-benzoquinone bis(dimethyl acetal) **18** are highly potential dependent, whereas the CE of 3-cyano-3,6,6-trimethoxy-1,4-cyclohexadiene **16** taken together with its base-catalyzed methanolysis product **17** is found to be independent of potential. A similar trend appears on changing the concentration of CN^- ion in the bulk solution. Curiously enough, there are discrepancies between their observations on 1,4-DMB and our previous results[2] on 2,5-DMF at the same material electrode. In the latter case, the product distribution was independent of anode potential or the bulk concentration of CN^- ion. Apparent potential dependency of the CEs of **15** and **18** in the former case may be ascribable to that, the 1,4-DMB cation radical is not adsorbed as strongly as is 2,5-DMF cation radical (or, the 1,4-DMB cation radical that reacts really with two competing nucleophiles may be formed by the homogeneous electron-transfer reaction between the primary product in the inner region and the parent uncharged molecule in the outer region), diffuses into the bulk solution which contains a greater relative concentration of MeO^- ion, and consequently produces a greater part of **18** with the decreasing in NaCN or with the lowering in anode potential.

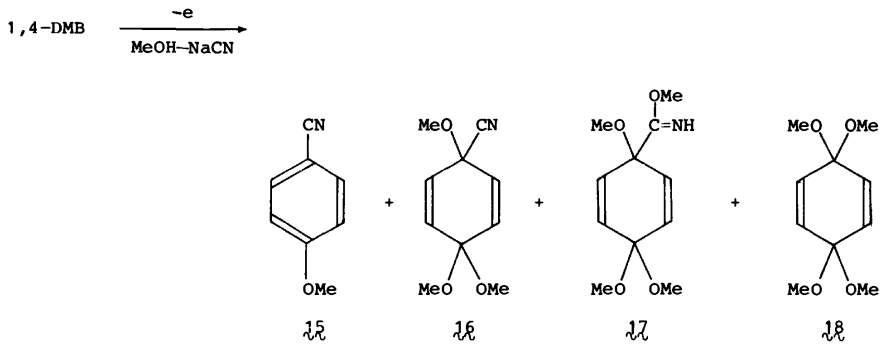
An attempt by Weinberg and co-workers[5] to determine the relative concentrations of two nucleophiles at the electrode from electrooxidation products



R_1, R_2, R_3 = H, Me

X, Y = CN, MeO

Scheme 2.



(13)

by using the rate expressions of competitive reactions met with failure. Their assumptions and results are not reasonable as mentioned previously.[26]

Stereochemical Control of Addition. The stereochemistry of electrochemical incremental reactions could be brought about by the orientation of the substrate molecule on the electrode surface during the reaction, especially in a *final* bond-formation step. The present anodic mixed 1,4-addition to 2,5-DMF is sterically controlled by the Pt electrode. The dependence observed of the ratio of the stereoisomeric products on the concentration of the substrate would be ascribable to the orientational transition which occurs as the substrate concentration is changed. The orientation of adsorbed aromatic molecules has been studied as a function of adsorbate molecular structure and its concentration.[27-29] At low concentrations, aromatic molecules generally adopt a flat orientation on the Pt surface in which the ring is more or less parallel to the electrode surface plane. Cis addition to the adsorbed furan ring would dominate. Transitions from flat to vertical (endwise or edgewise) orientations occur at higher concentrations. In the endwise orientation a C-H bond (or other substituent) of the ring is perpendicular to the surface, and in the edgewise orientation one edge is parallel and the ring is perpendicular to the surface. The ratio of isomeric products should reflect thermodynamic control.

The ratio of the stereoisomeric products also varies significantly with the addition of adsorbable compounds. Deviations from the ratio obtained in the blank experiment are explicable in terms of the changes in orientation. The changes in orientation of aromatic molecules under the influence of a surface-active anion, iodide, have recently been detected in aqueous solutions.[30] When a layer of molecules adsorbed in the planar orientation to the surface is exposed to a solution of a coadsorbate such as iodide, reorientation to an edgewise orientation occurs for most of the compounds. A similar phenomenon, that is, change of positional reactivity under aromatic additives, has been detected in other electrode reactions, for example, anodic nuclear acetoxylation of anisole.[31]

Infrared and Mass Spectral Intensity. 2-Furonitriles have a strong band in the region of the C≡N stretching vibration in IR spectra, whilst the intensity of the nitrile absorption band in nonaromatic 2,5-dihydro-2-furonitriles is very weak or undetectable. Marked declines in C≡N intensities are commonly observed when the oxygen-containing group is attached to the same carbon atom as the cyano group.[32]

The parent peaks are very weak or cannot be detected at all in the mass spectra of 2,5-dihydro-5-methoxy-2-furonitriles and of 2,5-dihydro-2,5-dimethoxyfurans. The absence of a parent peak in the mass spectrum of ethers is usually observed.[33]

Other Synthetic Method. The synthesis of a pertinent 2-cyano-5-methoxy compound by nonelectrochemical reaction of a 2,5-dimethoxy adduct (**1a**) and cyanotrimethylsilane has recently been reported.[34]

Experimental

Equipment. A JEOL FX-100 NMR spectrometer, a JASCO Model IR-E IR spectrophotometer, and a Hitachi Model RMS-4 mass spectrometer were used for structure determination.

CV was performed in a two-compartment cell in which the calomel reference electrode with an agar bridge was separated from the Pt anode and the cathode by a glass frit. The working electrode was a 1-cm Pt wire sealed in glass, and the auxiliary electrode was a Pt sheet. A Hokuto Denko HB-107A voltage scanner, HA-104 potentiostat, and Yokogawa Type 3083 XY recorder were used. All measurements were carried out at room temperature.

Controlled-potential electroreactions were performed by using a three-compartment cell (which separated the anode, cathode, and reference electrode solutions by glass frits). The anode compartment held 50 ml of anolyte, the cathode held 20 ml of catholyte, and the reference held 5 ml of an electrolyte solution. A Pt sheet (2×2 cm) anode was employed. A Pt wire was used as the cathode, and an SCE with an agar bridge as the reference. Anode potential was controlled by means of the potentiostat mentioned above.

Coulometry was carried out with a Hokuto Denko Model HF-108 A current integrator.

Materials. MeOH and NaCN were used without purification. Furan and 2-MF were obtained commercially and were purified by distillation.

3-MF was prepared by a three-step method starting with

2-methylallyl chloride and ethyl orthoformate.[35-37]

2,3-DMF was prepared by lithium aluminum hydride reduction of 3-chloromethyl-2-methylfuran,[38] which was obtained in 3 steps from chloroacetaldehyde and ethyl acetoacetate.[39]

2,4-DMF[40] was obtained by thermal decomposition of the δ-sultone[41] which was prepared by sulfonation of mesityl oxide.

2,5-DMF was prepared by dehydration of acetonylacetone according to the method of Gaertner and Tonkyn.[42]

3,4-DMF was synthesized by the hydrogenation of 3,4-bis(chloromethyl)furan[43] in the presence of Pd in barium sulfate.[44]

2,3,4-TMF was made from 3-hydroxymethyl-2,4-dimethylfuran, which was obtained by reduction of 2,4-dimethyl-3-furancarboxylic acid[45] with lithium aluminum hydride, using the procedure of Winberg, Fawcett, Mochel, and Theobald.[38]

2,3,5-TMF was prepared by a four-step procedure starting with ethyl acetoacetate and 3-chloro-2-butanone.[46]

TetMF was obtained by the dehydration of 3,4-dimethyl-2,5-hexanedione with acetic anhydride and zinc chloride.[42] 3,4-Dimethyl-2,5-hexanedione was prepared by the reaction of 2-butanone and di-*t*-butyl peroxide by a modification of the procedure of Moore.[47] Decomposition of the peroxide was accomplished by photodissociation instead of thermal decomposition. A solution of 2-butanone (250 ml) and di-*t*-butyl peroxide (25 g) was irradiated through a Pyrex filter by a 450-W high-pressure Hg vapor lamp at room temperature for 40 h. Colorless 3,4-dimethyl-2,5-hexanedione was collected at 94 °C/16 mmHg (1 mmHg=133.322 Pa), 8 g. No attempt was not made to optimize the yield.

2,5-DEF was prepared by the reaction of 2,5-bis(chloromethyl)furan[48] and methylmagnesium bromide.[49]

NMR data of furans were given in Table 6.

Authentic samples of *cis*- and *trans*-2,5-dihydro-2,5-dimethoxy-2,5-dimethylfuran were prepared by anodic methoxylation of 2,5-DMF.[11,50]

2,5-Bis(methoxymethyl)furan was prepared by the bromination of 2,5-DMF with *N*-bromosuccinimide, followed by treatment with NaOMe.[11]

2-Methoxymethyl-5-methylfuran was obtained according to the same method as above except that 1 equiv of *N*-bromosuccinimide was used.

2,5-Dimethyl-3-furancarbonitrile was prepared by reaction of 2,5-DMF and chlorosulfonyl isocyanate followed by treatment of the intermediate with *N*,*N*-dimethylformamide.[51]

General Electrooxidation Procedure. The anolyte (50 ml) was made up of the organic substrate (5 mmol) in a methanolic solution of NaCN (0.4 M). The catholyte was the same medium in the absence of the substrate. The anode and cathode compartments were kept under an atmosphere of nitrogen and the anolyte was stirred magnetically. The reaction was carried out at a controlled anode potential at room temperature. The potential was set at the peak potential of the substrate. During the run the current dropped with time and was discontinued when either 2 faradays/mol of furan added was passed or the current dropped to some low value near the original background level. To the product mixture were added internal standards for GLC analyses, the mixture was treated with water, and the organic material was extracted with ether. The ethereal solution was concentrated and analyzed by GLC using a PEG 6000 column at 65 °C. Each isomeric product was separated in pure form by preparative GLC. They were identified by the elemental and ^{1}H NMR, IR, and mass spectroscopic analyses (Table 3). The intensity of the C≡N stretching vibration in IR spectra varied with structure. Methyl imidates showed characteristic bands at the region of 3320 (NH) and 1650 cm^{-1} (C=N). *Caution*: a cyanide salt in MeOH must be handled in a fume hood, as it contains HCN as a result of the equilibrium between CN^- and the solvent MeOH.

Isomerization Equilibrium. Isomerization was carried out in MeOH (1 ml) containing either of the two isomers *cis*-**1k** and *trans*-**1k** (0.01 g) and 1% CF_3COOH as catalyst. The reaction mixture was kept at 25.0 °C by a thermostat. At specified intervals, samples were withdrawn and analyzed by GLC after neutralization with sodium carbonate.

Methanol-Incorporated Photoaddition of *N*-Methyl-1,2-naphthalenedicarboximide with Alkenes and Dienes

Yasuo KUBO,* Mariko MIHARA, and Takeo ARAKI
Department of Chemistry, Faculty of Science, Shimane University, Matsue 690
(Received June 24, 1986)

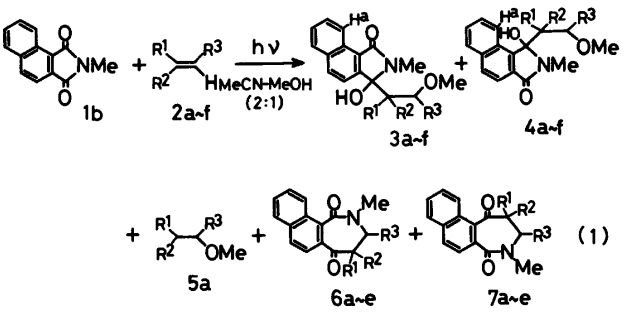
Irradiation of acetonitrile-methanol solutions of *N*-methyl-1,2-naphthalenedicarboximide (**1b**) with 1,1-diphenylethylene gave a methanol-incorporated adduct at a carbonyl carbon atom in **1b** together with 2,2-diphenylethyl methyl ether as a typical electron-transfer photosensitized product. The photoreaction of **1b** with α-methylstyrene, styrene (**2c**), or 2-methyl-2-butene in the same solvent system gave a regio-isomeric pair of a mixture of two diastereomers of methanol-incorporated adducts at carbonyl carbon atoms. The irradiation of **1b** with 2,3-dimethyl-2-butene and ethyl vinyl ether (**2h**) in benzene–methanol afforded methanol-incorporated adducts, although no reaction was observed for irradiation in acetonitrile–methanol. The irradiation of **1b** with 2,5-dimethyl-2,4-hexadiene in acetonitrile–methanol also resulted in the formation of methanol-incorporated adducts. The values of the free-energy change associated with an electron-transfer (ΔG_{et}) from the alkenes to the singlet excited state of **1b** and fluorescence quenching rate constants support the photochemical single-electron-transfer mechanism for the addition. A preferential addition at the carbonyl carbon atom in **1b** as well as that at the more sterically hindered carbonyl carbon atom in the reaction of **1b** with **2c** and **2h** is explainable on the basis of the spin densities of the radical anion of **1b** derived by a photochemical single-electron-transfer.

Recently, photoreactions involving electron-transfer processes have received much attention with regard to both synthetic and mechanistic aspects in organic photochemistry.[1] During the course of studies on the photochemistry of imides, our and other groups have found a variety of alcohol (solvent)-incorporated intramolecular cyclization[2] and intermolecular addition products[3] in the photoreactions of phthalimide-alkene systems, possibly via a single-electron-transfer processes. However, imide compounds employed in the previous investigations have been confined to phthalimides, and only little information has been reported on the effect of the arene structures of arenedicarboximides. Mazzocchi and his co-workers reported that in the photoreaction of *N*-methyl-1,8-naphthalenedicarboximide (**1a**) and α-methylstyrene (**2b**) a methanol-incorporated addition occurred solely at a naphthalene ring carbon atoms.[4] We have recently reported that in the photolyses of *N*-(3-phenylallyl)arenedicarboximides methanol-incorporated intramolecular cyclization occurs at the carbonyl carbon atom.[5] Here, we report on the results of the intermolecular photoreaction of *N*-methyl-1,2-naphthalenedicarboximide (**1b**) with alkenes and dienes in solvents containing methanol. The results show that the methanol-incorporated addition generally occurs at the carbonyl carbon atoms, in contrast to the reaction of **1a**. The effect of the arene structure of the imides is discussed on the basis of spin densities in the imide radical anions derived by the photochemical single-electron-transfer.

We have already reported the photoreactions of **1b** and alkenes in benzene.[6] The predominant reaction in benzene was an insertion of the alkene into C(=O)–N bonds of **1b**, in contrast to the fact that the predominant photoreactions of **1a** and its 2,3-isomer were cyclobutane[6a,7] and oxetane formation,[6a] respectively.

Results and Discussion

Irradiation (>320 nm) of a mixture of **1b** and 1,1-diphenylethylene (**2a**) in N_2-purged acetonitrile–methanol (2/1 v/v) gave a methanol-incorporated adduct at the carbonyl carbon atom (**3a**), 2,2-diphenylethyl methyl ether (**5a**), and two naphthoazepinediones (**6a** and **7a**) (Eq. 1 and Table 1). The



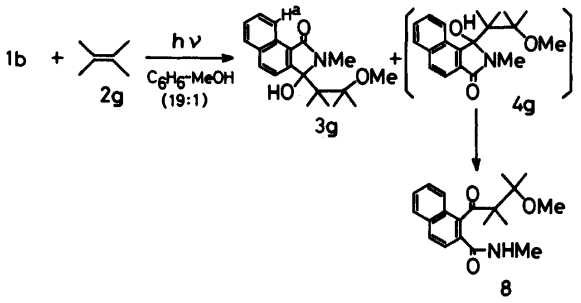
(1)

last two products (**6a** and **7a**) are the main products obtained in the photolysis of **1b** and **2a** in benzene and are formed by the insertion of **2a** into C(=O)–N bonds of **1b**.[6b] Other examples of the photoreactions of **1b** with alkenes (**2b—f**) are summarized in Table 1, which indicates that the methanol-incorporated addition to the carbonyl carbon atoms is characteristic of the reactions of **1b** with some ethylenes substituted by a phenyl group, **2b** and styrene (**2c**), and with an ethylene substituted by three alkyl groups, 2-methyl-2-butene (**2f**). No reaction was observed in the photolysis of **1b** with 1-hexene (**2d**), an ethylene substituted by one alkyl group. Only an insertion to give **6e** and **7e** was observed in the reaction with 2-

methylpropene (**2e**).[6c] The result shows that **1b** is less reactive toward a methanol-incorporated addition than *N*-methylphthalimide (**1c**) since irradiation of **1c** with **2e** gave the methanol-incorporated adduct together with the insertion product.[3d]

In the reaction with **2b**, **2c**, or **2f** a regioisomeric pair of a mixture of two diastereomers of the methanol-incorporated adduct (**3b,c,f** and **4b,c,f**) was obtained, although in the reaction with **2a** one of the regioisomers (**4a**) could not be isolated in a pure form because of the trace amount. The structures of the adducts are supported by a spectral resemblance to the benzo analogues obtained by the photoreactions of **1c**.[3d] The regiochemistry of the adducts shown in the structural formulas are deduced from the chemical shift of an aromatic proton H^a which was observed as ortho- and meta-coupled double doublets. The H^a protons in **3f** was observed in a lower field region (δ=9.18, 9.35) than those in **4f** (δ=8.62, 8.79) and the difference in chemical shift was 0.39—0.73 ppm. The molecular model examination indicates that the H^a proton in **3f** should be deshielded by the proximate lactam carbonyl group. This analysis is applicable to determination of the regiochemistry of the isomeric pairs of adducts having phenyl substituents (**3a—c** and **4b,c**), in which slight higher field shift of H^a protons compared with those in **3f** and **4f** is observed possibly due to the shielding effect of the phenyl substituent: H^a protons in **3a—c** and **4b,c** appear at δ=8.78—9.08 and at δ=8.36—8.52, respectively, and the difference in chemical shift is 0.26—0.72 ppm.

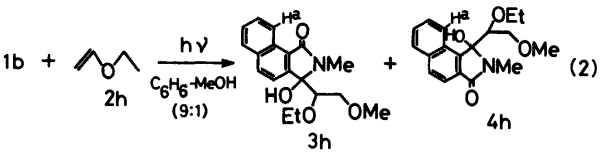
In the irradiation of **1b** (19 mM†) and 2,3-dimethyl-2-butene (**2g**, 480 mM), an ethylene substituted by four alkyl groups, in acetonitrile-methanol (2/1 v/v) no reaction was observed (at least with respect to conversion of **1b**). However, irradiation in benzene-methanol (19/1 v/v), a less-polar solvent, gave a methanol-incorporated adduct (**3g**, 32%) and **8** (14%) (Scheme 1). The keto amide structure of **8** was assigned on the basis of the spectral data: ^{1}H NMR



Scheme 1.

δ=2.90 (d, NH*Me*, coalesced to a singlet after D_2O exchange), 6.10 (br s, NH, disappeared after the D_2O exchange); IR 1678 (ketone), 1646 (amide) cm^{-1}. The regiochemistry shown in the structural formula was tentatively assigned on the basis of the assumption that **8** was derived by a ring-opening reaction which accompanied the hydrogen-migration of the initially formed **4g** (Scheme 1); it was not isolated in this system although both of the regioisomers were obtained in the other reaction systems (such as in the reaction with **2f**). Such a ring-opening reaction was reported to occur in the photoreaction of **1c** with **2g**.[3b]

A similar solvent effect to reactions with **2g** was observed in reactions with ethyl vinyl ether (**2h**). No reaction was observed during irradiation in acetonitrile-methanol (2:1 v/v), but irradiation of **1b** (19 mM) and **2h** (560 mM) in benzene-methanol (9/1 v/v) gave methanol-incorporated adducts (**3h**, 26% and **4h**, 34%) (Eq. 2). An addition at the more



sterically hindered carbonyl carbon atom in **1b** predominated, as in the reaction with **2c**.

Table 1. Yields of Photoproducts from *N*-Methyl-1,2-naphthalenedicarboximide (**1b**) and Alkenes **2a—f** in Acetonitrile-Methanol (2/1 v/v)[a]

R^1	R^2	R^3	2	[2] mM	Yield[b]/% 3	4	5	6	7

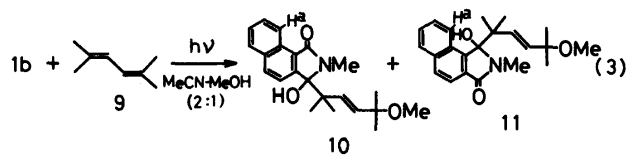
a) Reaction conditions: [**1b**] = 19 mM. b) Yields were based on consumed **1b**.

† 1 M=1 mol dm^{-3}.

As for the reaction with dienes, photoreaction with 1,3-butadiene and 2,3-dimethyl-1,3-butadiene, poorly alkyl substituted dienes, in acetonitrile–methanol (2/1 v/v) gave no methanol-incorporated adducts, but the irradiation of **1b** (19 mM) with 2,5-dimethyl-2,4-hexadiene (**9**, 360 mM) gave methanol-incorporated adducts (**10**, 43% and **11**, 27%) (Eq. 3). The trans-



configurations of the aliphatic double bonds in **10** and **11** were assigned on the basis of the large coupling constants between the vinyl hydrogens (16.7 and 16.8 Hz, respectively). This reaction is the first example of an alcohol-incorporated addition of diene to arenedicarboximide.

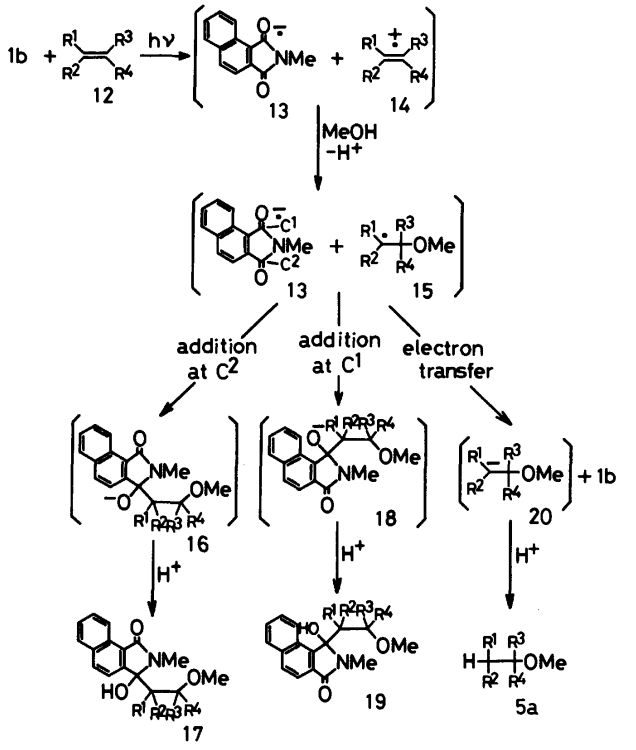
A possible mechanism which can be used to interpret the general feature of the methanol-incorporated addition is shown in Scheme 2, in which alkenes are denoted as **12**. The initial step of the reaction is a single-electron-transfer from **12** to the singlet excited state of **1b**. The approximate values of the free-energy change associated with the electron-transfer (ΔG_{et}) can be estimated[8] by using

$$\Delta G_{et} = 96.49[E(D/D^+) - E(A^-/A)] - \Delta E_{0,0}. \quad (4)$$

In this equation $E(D/D^+)$ is the oxidation potential of the alkenes, $E(A^-/A)$ is the reduction potential of **1b**, and $\Delta E_{0,0}$ is the singlet excitation energy of **1b**. With these values, we can calculate the ΔG_{et} values for reactions with **2a,d—g** (Table 2). This table shows that the methanol-incorporated addition occurs only in the cases having negative ΔG_{et} values as expected from the electron-transfer mechanism.

An addition of alkenes (**2e—g**) to air-saturated acetonitrile solutions of **1b** (1×10^{-5} M) resulted in a reduction of the fluorescence of **1b** without varying the shape and the position of the emission. Stern-Volmer plots of the fluorescence quenching by **2e—g** gave straight lines against concentration of **2e—g**. Fluorescence quenching rate constants (k_q) in acetonitrile calculated from the Stern-Volmer slopes ($k_q\tau$) using the lifetime of the fluorescence of **1b**, together with k_q values in benzene, are shown in Table 3. The k_q values in acetonitrile are larger than those in benzene. The large k_q values obtained in quenching by **2f** and **2g** in acetonitrile and by **2g** in benzene may also support the electron-transfer mechanism.

Concerning the electron-transfer mechanism, the by-product **5a** in the reaction with **2a** could be one of the typical electron-transfer photosensitized products,



Scheme 2.

Table 2. Calculated Free Energy Changes (ΔG_{et}) Associated with Electron Transfer from Alkenes **2a, d—g** to the Singlet Excited State of *N*-Methyl-1,2-naphthalenedicarboximide (**1b**)

Alkenes	$E(D/D^+)$/V	ΔG_{et}[a]/kJ mol^{-1}
2a	1.48[b]	−56.4
2d	2.64[c]	+55.4
2e	2.39[c]	+31.3
2f	1.79[c]	−26.5
2g	1.63[c]	−42.0

a) Calculated by Eq. 4: $E(A^-/A) = -1.13$ V (in 0.5 M Et_4NClO_4/acetonitrile vs. Ag/0.01 M $AgClO_4$) from Ref. 7, $\Delta E_{0,0} = 308$ kJ mol^{-1} from Ref. 6b. b) Ref. 9. c) Ref. 3b.

Table 3. Fluorescence Quenching Rate Constants (k_q) for *N*-Methyl-1,2-naphthalenedicarboximide (**1b**) and Alkenes **2d, e—g** Systems[a]

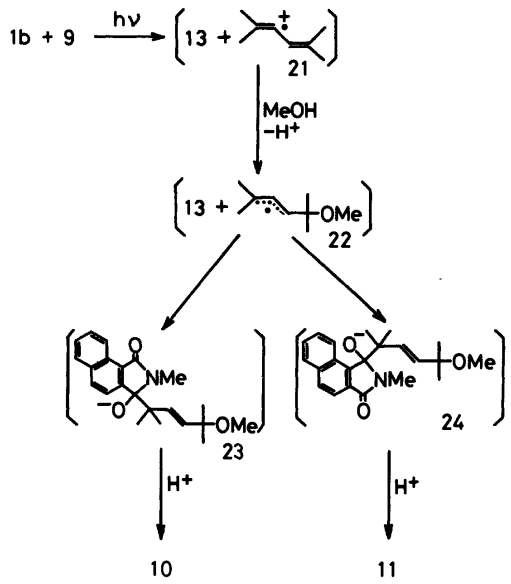
Alkenes	$k_q\tau$[b] / dm^3 mol^{-1}	k_q[c] / dm^3 mol^{-1} s^{-1}	k_q[d] / dm^3 mol^{-1} s^{-1}
2d	0	0	0
2e	0.39	7.13×10^8	5.5×10^8
2f	48.7	8.90×10^8	6.1×10^7
2g	600	1.10×10^{10}	2.8×10^9

a) Conditions: [**1b**] $= 1\times10^{-5}$ mol dm^{-3}, at 25 °C, in air-saturated acetonitrile. b) Stern-Volmer slopes for the flnorescence quenching. c) Calculated from $k_q\tau$ using the lifetime ($\tau = 54.7$ ns) of the fluorescence of **1b**. d) In air-saturated benzene from Ref. 6b.

as reported by Arnold and his co-workers.[10] The electron-transfer photosensitized addition of methanol to **2a** giving **5a** and the methanol-incorporated addition of **2a** to **1b** giving **17** and **19** appear to be closely related processes via common intermediates (**13**+**15**). A combination reaction of the two components at the carbonyl carbon atoms (C^2 and C^1) of **1b** results in the formation of **17** and **19**, and the back electron-transfer from **13** to **15** results in the formation of **1b** and **5a** (Scheme 2).

A similar electron-transfer mechanism (Scheme 3) can be used to interpret the methanol-incorporated addition of **9** to **1b**. The addition of methanol to the radical cation **21** to give a radical **22** and a radical coupling at the tertiary carbon atom of **22** has already been reported.[11]

In the reaction with **2g** and **2h** peculiar solvent effects were observed. Thus, in a polar solvent system, acetonitrile–methanol (2/1 v/v), **1b** did not change upon irradiation, but in nonpolar solvent systems, benzene–methanol, an methanol-incorporated addition was observed. These results may be interpreted on the basis of an inclusion of different reaction intermediates. There is significant interest in the mechanism of reactions proceeded by a single-electron-transfer, particularly with respect to whether contact ion pairs and solvent separated ion pairs are involved.[1b,12] Solvent-separated ion pairs should be formed in a polar solvent if a sufficient electron-transfer could occur. Thus, in reactions with electron-donating alkenes such as **2g** and **2h** the solvent separated ion pair of **13** and **14** (Scheme 2) may be formed in a polar solvent and may reproduce **1b** by reaction pathways other than the methanol-incorporated addition, and the methanol-incorporated addition may arise only from the contact ion pair formed in nonpolar solvent.



Scheme 3.

It should be emphasized here that the variation of the imide ring size caused a remarkable change in the reaction. Thus, a methanol-incorporated addition of **1b** as well as **1c**, possessing a five-membered imide ring, occurs exclusively at the carbonyl carbon atoms, while that of **1a**, possessing six-membered imide ring, occurs at the naphthalene ring carbon atom.[4] Whether the carbonyl carbon atom is attacked or the naphthalene ring carbon atom is attacked may depend on the reactivity of the respective carbon in the imide radical anion toward alkyl radicals such as **15** (Scheme 2). The relative spin density in the imide radical anion can be used as an index for the reactivity. The spin density of radical anions of 1,8-naphthalenedicarboximide (**25a**),[13] 1,2-naphthalenedicarboximide (**25b**),[5] and phthalimide (**25c**)[13] calculated by McLachlan method[14] as model compounds for radical anions of **1a**, **1b**, and **1c**, respectively, is shown in Fig. 1. That the spin density at the carbonyl carbon atom in **25a** is remarkably low compared with that at the naphthalene ring C^4 carbon atom in **25a** as well as that at the carbonyl carbon atom in **25b** and **25c** may support the preferential methanol-incorporated addition at the naphthalene ring carbon atom observed in the photoreaction of **1a**. The result that the spin density distribution in **25b** is similar to that in **25c** might account for the similar photoreaction pattern of **1b** and **1c**.

Another problem related to the spin density is which of the two types of carbonyl carbon atoms in **1b** is attacked during the methanol-incorporated addition. The spin density at the C^1 carbonyl carbon atom in a radical anion of **25b** is relatively high compared

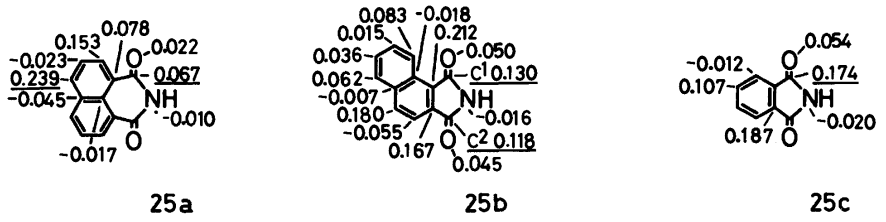


Fig. 1. Spin density of radical anions of 1,8-naphthalenedicarboximide (**25a**), 1,2-naphthalenedicarboximide (**25b**), and phthalimide (**25c**) calculated by McLachlan method.

with that at the C^2 carbon atom, although the difference in the spin density is not so large. Therefore, an addition at the C^1 carbon atom should be favorable to some extent. Since the C^1 carbonyl carbon atom is essentially more sterically hindered than the C^2 atom, the result that in the photolysis of **1b** with **2c** the yield of the products **4c** from the addition at the C^1 carbonyl carbon atom is larger than that of the products **3c** from the addition at C^2 atom may reflect the inherent preference of the addition at the C^1 atom because of the high spin density. A similar preference regarding an addition at the C^1 carbonyl carbon atom was observed in a reaction with **2h**, which was also an ethylene having only one substituent. In a series of reactions with **2c**, **2b**, and **2a**, the ratio of the products from the addition at the C^1 carbonyl carbon atom to those from the addition at the C^2 atom decreased in that order, probably due to a steric effect of the substituent of the alkenes on the addition.

Experimental

The mps were measured by a Yanagimoto micromelting-point apparatus and are uncorrected. ^{1}H NMR spectra were determined on a JEOL JNM-MH-100 (100 MHz) in $CDCl_3$ solution. IR spectra were obtained with a Hitachi 260-50 spectrophotometer. Mass spectra were measured on a JEOL JMS-DX-300 apparatus. Fluorescence spectra and the lifetimes were recorded by a Hitachi 850 spectrophotometer and a HORIBA NAES-1100 time-resolved spectrofluorometer, respectively. Microanalyses were performed on a Yanagimoto CHN corder MT-2.

Materials. *N*-Methylnaphthalene-1,2-dicarboximide (**1b**) was prepared and purified as described previously.[6b] Alkenes (**2a—h**) and dienes (**9**, 1,3-butadiene, and 2,3-dimethyl-1,3-butadiene) were commercially available and purified by distillation for liquid materials.

General Procedure for Irradiation and Product Isolation. Unless otherwise noted, UV irradiation of **1b** (19 mM) with alkenes (**2a—h**) and dienes (**9**, 1,3-butadiene, and 2,3-dimethyl-1,3-butadiene) in 25 ml of N_2 purged acetonitrile–methanol (2/1 v/v) was carried out with an Eikosha EHB-W-300 high-pressure Hg-lamp through aq $CuSO_4$ filter about 1 cm in thickness (>320 nm) at ambient temperature. The reaction was monitored by TLC (Merk, Kieselgel 60 F_{254}) analyses and ^{1}H NMR measurements. After an evaporation of the solvent, the residue was subjected to column chromatography (Wakogel C-200). Dichloromethane-ether was used as the eluant for the separation of the products. Yields were determined by measurement of the weight of the isolated products.

Irradiation of 1b and 1,1-Diphenylethylene (2a). 2,2-Diphenylethyl methyl ether (**5a**) was identical with a sample prepared by irradiation of **2a**, *p*-dicyanobenzene, and phenanthrene (sensitizer) in methanol.[15]

3-(1,1-Diphenyl-2-methoxyethyl)-3-hydroxy-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**3a**): Mp 182—185 °C; ^{1}H NMR δ=2.93 (s, 3H, NMe), 3.23 (s, 3H, OMe), 4.31 and 4.62 (ABq, J=11 Hz, 2H, CH_2), 5.78 (s, 1H, OH), 6.8—7.9 (m, 15H, Arom H), 8.79 (dd, 1H, H^a); IR (KBr) 3250 (OH), 1665 (lactam), 1428, 1108, 712 cm^{-1}. Found: C, 79.65; H, 6.03; N, 3.41%; M^+-H_2O, 405. Calcd for $C_{28}H_{25}NO_3$: C, 79.41; H, 5.95; N, 3.31%; $M-H_2O$, 405.

Irradiation of 1b and α-Methylstyrene (2b). A mixture of diastereomers of 3-hydroxy-3-(2-methoxy-1-methyl-1-phenylethyl)-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**3b**): Mp 166—172 °C; ^{1}H NMR of one diastereomer δ=1.20 (s, 3H, CMe), 2.88 (s, 3H, NMe), 3.33 (s, 3H, OMe), 3.74 and 3.93 (ABq, 2H, CH_2), 6.43 (s, 1H, OH), 7.1—8.0 (m, 10H, Arom H), 9.08 (dd, 1H, H^a); ^{1}H NMR of another diastereomer δ=1.37 (s, 3H, CMe), 2.60 (s, 3H, NMe), 3.37 (s, 3H, OMe), 3.80 (s, 2H, CH_2), 6.35 (s, 1H, OH), 7.1—8.0 (m, 10H, Arom H), 9.04 (dd, 1H, H^a); IR (KBr) 3300 (OH), 1662 (lactam), 1448, 1382, 1108, 702 cm^{-1}. Found: C, 76.63; H, 6.56; N, 3.96%; M^+-H_2O, 343. Calcd for $C_{23}H_{23}NO_3$: C, 76.43; H, 6.41; N, 3.88%; $M-H_2O$, 343.

A mixture of diastereomers of 1-hydroxy-1-(2-methoxy-1-methyl-1-phenylethyl)-2-methyl-1,2-dihydro-3*H*-benz[*e*]isoindol-3-one (**4b**): Mp 158—160 °C; ^{1}H NMR of one diastereomer δ=1.18 (s, 3H, CMe), 2.85 (s, 3H, NMe), 3.37 (s, 3H, OMe), 3.65 and 4.05 (ABq, 2H, CH_2), 5.85 (s, 1H, OH), 7.8—8.0 (m, 10H, Arom H), 8.39 (dd, 1H, H^a); ^{1}H NMR of another diastereomer δ=1.48 (s, 3H, CMe), 2.77 (s, 3H, NMe), 3.37 (s, 3H, OMe), 3.72 (s, 2H, CH_2), 5.82 (s, 1H, OH), 7.8—8.0 (m, 10H, Arom H), 8.36 (dd, 1H, H^a); IR (KBr) 3310 (OH), 1692 (lactam), 1461, 1386, 1106, 702 cm^{-1}. Found: C, 76.64; H, 6.52; N, 3.93%; M^+-H_2O, 343. Calcd for $C_{23}H_{23}NO_3$: C, 76.43; H, 6.41; N, 3.88%; $M-H_2O$, 343.

Irradiation of 1b and Styrene (2c). A mixture of diastereomers of 3-hydroxy-3-(2-methoxy-1-phenylethyl)-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**3c**): Mp 153—161 °C; ^{1}H NMR of one diastereomer δ=2.85 (s, 3H, NMe), 3.42 (s, 3H, OMe), 3.4—4.0 (m, 2H), 4.1—4.3 (m, 1H), 5.21 (s, 1H, OH), 6.4—8.1 (m, 10H, Arom H), 8.83 (dd, 1H, H^a); ^{1}H NMR of another diastereomer δ=3.06 (s, 3H, NMe), 3.21 (s, 3H, OMe), 3.4—4.0 (m, 3H), 5.21 (s, 1H, OH), 6.4—8.1 (m, 10H, Arom H), 8.78 (dd, 1H, H^a); IR (KBr) 3320 (OH), 1680 (lactam), 1424, 1384, 1120, 760, 702 cm^{-1}. Found: C, 76.25; H, 6.18; N, 4.11%; M^+-H_2O, 329. Calcd for $C_{22}H_{21}NO_3$: C, 76.06; H, 6.09; N, 4.03%; $M-H_2O$, 329.

A mixture of diastereomers of 1-hydroxy-1-(2-methoxy-1-phenylethyl)-2-methyl-1,2-dihydro-3*H*-benz[*e*]isoindol-3-one (**4c**): Mp 146—152 °C; ^{1}H NMR of one diastereomer δ=3.26 (s, 3H, NMe), 3.50 (s, 3H, OMe), 3.5—4.4 (m, 3H), 6.15 (s, 1H, OH), 6.4—8.1 (m, 10H, Arom H), 8.52 (dd, 1H, H^a); ^{1}H NMR of another diastereomer δ=2.89 (s, 3H, NMe), 3.32 (s, 3H, OMe), 3.5—4.4 (m, 3H), 6.18 (s, 1H, OH), 6.4—8.1 (m, 10H, Arom H), 8.52 (dd, 1H, H^a); IR (KBr) 3300 (OH), 1680 (lactam), 1424, 1384, 1118, 760, 702 cm^{-1}. Found: C, 76.30; H, 6.27; N, 4.14%; M^+-H_2O, 329. Calcd for $C_{22}H_{21}NO_3$: C, 76.06; H, 6.09; N, 4.03%; $M-H_2O$, 329.

Irradiation of 1b and 2-Methyl-2-butene (2f). A mixture of diastereomers of 3-(1,1-dimethyl-2-methoxypropyl)-3-hydroxy-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**3f**): Mp 148—151 °C; ^{1}H NMR of one diastereomer δ=0.52 (s, 3H, CMe), 1.18 (d, 3H, CH*Me*), 1.36 (s, 3H, CMe), 3.14 (s, 3H, NMe), 3.47 (s, 3H, OMe), 3.89 (q, 1H, C*H*Me), 6.28 (s, 1H, OH), 7.2—8.2 (m, 5H, Arom H), 9.35 (dd, 1H, H^a); ^{1}H NMR of another diastereomer δ=0.57 (s, 3H, CMe), 1.08 (d, 3H, CH*Me*), 1.25 (s, 3H, CMe), 3.09 (s, 3H, NMe), 3.30 (s, 3H, OMe), 3.75 (q, 1H, C*H*Me), 5.67 (s, 1H, OH), 7.4—8.18

(m, 5H, Arom H), 9.18 (dd, 1H, H^a); IR (KBr) 3280 (OH), 1694 (lactam), 1462, 1428, 1392, 1104 cm^{-1}. Found: C, 72.95; H, 7.54; N, 4.51%; M^+-H_2O, 295. Calcd for $C_{19}H_{23}NO_3$: C, 72.82; H, 7.40; N, 4.47%; $M-H_2O$, 295.

A mixture of diastereomers of 1-(1,1-dimethyl-2-methoxypropyl)-1-hydroxy-2-methyl-1,2-dihydro-3*H*-benz[*e*]-isoindol-3-one (**4f**): Mp 145—148 °C; ^1H NMR of one diastereomer δ=0.40 (s, 3H, CMe), 1.18 (d, 3H, CH*Me*), 1.27 (s, 3H, CMe), 3.22 (s, 3H, NMe), 3.52 (s, 3H, OMe), 3.95 (q, 1H, C*H*Me), 7.17 (s, 1H, OH), 7.5—8.1 (m, 5H, Arom H), 8.79 (dd, 1H, H^a); ^1H NMR of another diastereomer δ=0.49 (s, 3H, CMe), 0.99 (d, 3H, CH*Me*), 1.22 (s, 3H, CMe), 3.17 (s, 3H, NMe), 3.32 (s, 3H, OMe), 3.89 (q, 1H, C*H*Me), 6.71 (s, 1H, OH), 7.5—8.2 (m, 5H, Arom H), 8.62 (dd, 1H, H^a); IR (KBr) 3280 (OH), 1694 (lactam), 1376, 1122, 1102, 758 cm^{-1}. Found: C, 72.97; H, 7.54; N, 4.51%; M^+-H_2O, 295. Calcd for $C_{19}H_{23}NO_3$: C, 72.82; H, 7.40; N, 4.47%; $M-H_2O$, 295.

Irradiation of 1b and 2,3-Dimethyl-2-butene (2g). 3-Hydroxy-3-(2-methoxy-1,1,2-trimethylpropyl)-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**3g**): Mp 158—161 °C; ^1H NMR δ=0.97 (s, 3H, CMe), 1.07 (s, 6H, CMe), 1.22 (s, 3H, CMe), 3.05 (s, 3H, NMe), 3.10 (s, 3H, OMe), 4.85 (s, 1H, OH), 7.6—8.0 (m, 5H, Arom H), 9.25 (dd, 1H, H^a); IR (KBr) 3280 (OH), 1666 (lactam), 1394, 1060, 800 cm^{-1}. Found: C, 73.54; H, 7.83; N, 4.33%; M^+-H_2O, 309. Calcd for $C_{20}H_{25}NO_3$: C, 73.36; H, 7.70; N, 4.28%; $M-H_2O$, 309.

N-Methyl-1-(3-methoxy-1-oxo-2,2,3-trimethylbutyl)-2-naphthalenecarboxamide (**8**): Mp 200—202 °C; ^1H NMR δ=1.12 (s, 3H, CMe), 1.19 (s, 3H, CMe), 1.26 (s, 3H, CMe), 1.38 (s, 3H, CMe), 2.90 (d, 3H, NH*Me*), 3.15 (s, 3H, OMe), 6.10 (br s, 1H, NH), 7.4—8.0 (m, 6H, Arom H); IR (KBr) 3380 (NH), 1678 (ketone), 1646 (amide), 1538, 1298, 1058, 762 cm^{-1}. Found:C, 73.51; H, 7.82; N, 4.31%; M^+, 327. Calcd for $C_{20}H_{25}NO_3$:C, 73.36; H, 7.70; N, 4.28%; M, 327.

Irradiation of 1b and Ethyl Vinyl Ether (2h). A mixture of diastereomers of 3-(1-ethoxy-2-methoxyethyl)-3-hydroxy-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**3h**): Mp 155—158 °C; ^1H NMR of one diastereomer δ=1.29 (t, 3H, OCH_2Me), 2.99 (s, 3H, NMe), 3.11 (s, 3H, OMe), 2.9—3.5 (m, 2H), 3.6—4.2 (m, 3H), 5.53 (s, 1H, OH), 7.4—8.1 (m, 5H, Arom H), 9.07 (dd, 1H, H^a); ^1H NMR of another diastereomer δ=1.23 (t, 3H, OCH_2Me), 3.02 (s, 3H, NMe), 3.09 (s, 3H, OMe), 2.9—3.5 (m, 2H), 3.6—4.2 (m, 3H), 5.50 (s, 1H, OH), 7.4—8.1 (m, 5H, Arom H), 9.00 (dd, 1H, H^a); IR (KBr) 3320 (OH), 1665 (lactam), 1130, 1114, 702 cm^{-1}. Found: C, 68.62; H, 6.63; N, 4.54%; M^+-H_2O, 297. Calcd for $C_{18}H_{21}NO_4$: C, 68.55; H, 6.71; N, 4.44%; $M-H_2O$, 297.

One of the diastereomers of 1-(1-ethoxy-2-methoxyethyl)-1-hydroxy-2-methyl-1,2-dihydro-3*H*-benz[*e*]isoindol-3-one (**4h**): Mp 176—177 °C; ^1H NMR δ=1.41 (t, 3H, OCH_2Me), 2.96 (s, 3H, NMe), 3.11 (s, 3H, OMe), 2.7—3.4 (m, 2H), 3.6—4.2 (m, 2H), 4.45 (dd, 1H, CH), 4.82 (s, 1H, OH), 7.6—8.1 (m, 5H, Arom H), 8.35 (dd, 1H, H^a); IR (KBr) 3280 (OH), 1681 (lactam), 1428, 1392, 1115, 768 cm^{-1}. Found: C, 68.62; H, 6.88; N, 4.43%; M^+-H_2O, 297. Calcd for $C_{18}H_{21}NO_4$: C, 68.55; H, 6.71; N, 4.44%; $M-H_2O$, 297.

Another of the diastereomers of 1-(1-ethoxy-2-methoxyethyl)-1-hydroxy-2-methyl-1,2-dihydro-3*H*-benz[*e*]-isoindol-3-one (**4h**): Mp 136—139 °C; ^1H NMR δ=0.95 (t, 3H, OCH_2Me), 2.90 (s, 3H, NMe), 3.11 (s, 3H, OMe), 2.8—3.7 (m, 4H), 4.08 (dd, 1H, CH), 5.14 (s, 1H, OH), 7.3—8.0 (m, 5H, Arom H), 8.66 (dd, 1H, H^a); IR (KBr) 3280 (OH), 1682 (lactam), 1422, 1103, 1062, 702 cm^{-1}. Found: C, 68.72; H, 6.98; N, 4.51%; M^+-H_2O, 297. Calcd for $C_{18}H_{21}NO_4$: C, 68.55; H, 6.71; N, 4.44%; $M-H_2O$, 297.

Irradiation of 1b and 2,5-Dimethyl-2,4-hexadiene (9). 3-Hydroxy-3-(4-methoxy-1,1,4-trimethyl-2-pentenyl)-2-methyl-2,3-dihydro-1*H*-benz[*e*]isoindol-1-one (**10**): Mp 176—178 °C; ^1H NMR δ=0.98 (s, 3H, CMe), 1.15 (s, 3H, CMe), 1.21 (s, 3H, CMe), 1.24 (s, 3H, CMe), 2.77 (s, 3H, NMe), 3.06 (s, 3H, OMe), 3.52 (s, 1H, OH), 5.35 and 6.09 (ABq, J=16.8 Hz, 2H, CH=CH), 7.4—8.0 (m, 5H, Arom H), 9.11 (dd, 1H, H^a); IR (KBr) 3320 (OH), 1662 (lactam), 1424, 1380, 1068, 768 cm^{-1}. Found: C, 74.81; H, 7.83; N, 4.03%; M^+-H_2O, 335. Calcd for $C_{22}H_{27}NO_3$: C, 74.75; H, 7.70; N, 3.96%; $M-H_2O$, 335.

1-Hydroxy-1-(4-methoxy-1,1,4-trimethyl-2-pentenyl)-2-methyl-1,2-dihydro-3*H*-benz[*e*]isoindol-3-one (**11**): Mp 139—142 °C; ^1H NMR δ=0.88 (s, 3H, CMe), 1.09 (s, 6H, CMe), 1.14 (s, 3H, CMe), 2.79 (s, 3H, NMe), 2.97 (s, 3H, OMe), 4.46 (s, 1H, OH), 5.20 and 5.87 (ABq, J=16.7 Hz, 2H, CH=CH), 7.3—8.0 (m, 5H, Arom H), 8.58 (dd, 1H, H^a); IR (KBr) 3270 (OH), 1668 (lactam), 1422, 1384, 1070, 763 cm^{-1}. Found: C, 74.97; H, 7.84; N, 4.04%; M^+-H_2O, 335. Calcd for $C_{22}H_{27}NO_3$: C, 74.75; H, 7.70; N, 3.96%; $M-H_2O$, 335.

Asymmetric Catalytic Hydrogenations of *N*-Pyruvoyl-(*S*)-proline Esters

Toratane MUNEGUMI, Manabu FUJITA, Tetsuya MARUYAMA, Shozo SHIONO, Michiaki TAKASAKI, and Kaoru HARADA*
Department of Chemistry, The University of Tsukuba, Sakura-Mura, Niihari-Gun, Ibaraki 305
(Received June 25, 1986)

Asymmetric catalytic hydrogenations of the entitled compounds were carried out over palladium on charcoal in various solvents to afford *N*-[(*S*)-lactoyl]-(*S*)-proline esters with a d.e.(=diastereoisomeric excess) of up to 59%. The stereochemistry of the catalytic hydrogenation was explained by the "chelation mechanism." And the effects of temperature and bulkiness of the ester groups on the asymmetric induction were also described.

Many studies on homogeneous asymmetric reactions have been reported[1,2] and the stereochemical models of those asymmetric inductions have been proposed. Prelog's model[3] and Cram's model[4] are typical examples. However, there are few general stereochemical models to explain the mechanism of the asymmetric induction in the heterogeneous hydrogenations. A hypothesis which explains the stereochemistry of the heterogeneous catalytic hydrogenations of α-keto acid derivatives was proposed.[5] We speculated a five-membered cyclic intermediate with the palladium catalyst as shown in Fig. 1. Many experimental results have supported the hypothesis which was named "chelation mechanism"[5,6] as a general model for asymmetric induction in the heterogeneous catalytic hydrogenations of α-keto acid derivatives.

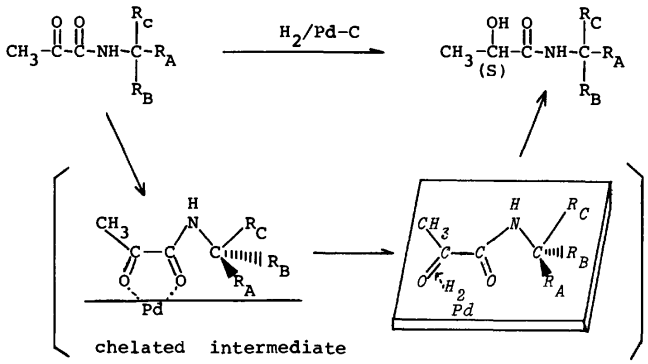

Fig. 1. Chelation mechanism in the catalytic hydrogenations of pyruvamides. R_A is bulkier than R_B.

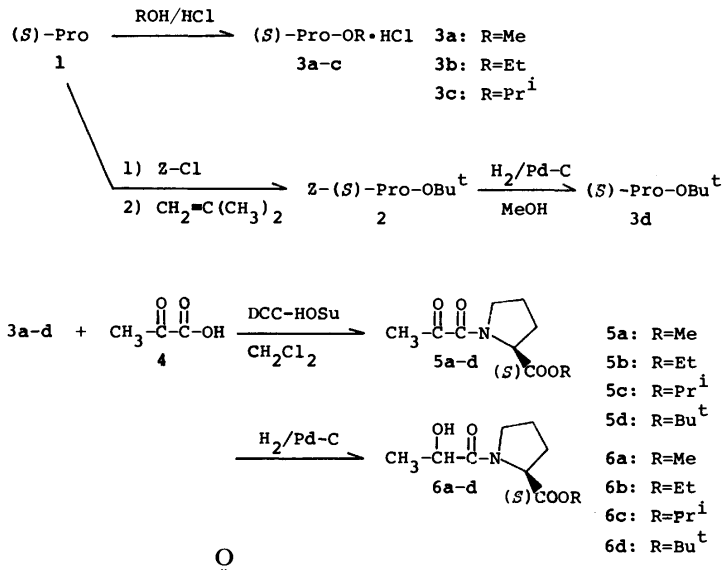
In the previous papers,[6-8] the steric courses of asymmetric catalytic hydrogenations of several chiral pyruvamides over palladium on charcoal have been explained by the "chelation mechanism."[5,6] Of these asymmetric catalytic hydrogenations, the pyruvamides which contain amino acid esters as chiral sources gave low asymmetric yields[diastereoisomeric excess (d.e.)<24%].[8] Those low asymmetric yields seemed to be caused by the free rotation around the N–C bond between the amide nitrogen and chiral carbon (Fig. 1). Thus, there would be several possible "chelation intermediates" which took different conformations, and a mixture of these conformers was catalytically hydrogenated to afford lower d.e.



Scheme 1. Z: $C_6H_5CH_2O-\overset{O}{\overset{\|}{C}}-$, Bu^t: $(CH_3)_3C-$, DCC: dicyclohexylcarbodiimide, HOSu: *N*-hydroxysuccinimide.

In this paper, we wish to report the catalytic hydrogenations of pyruvamides having the N-C bond which does not rotate. We chose *N*-pyruvoyl-(*S*)-proline esters (methyl=Me, ethyl=Et, isopropyl=Pr^i, *t*-butyl=Bu^t) as the substrates for the asymmetric catalytic hydrogenations. The *N*-pyruvoyl-(*S*)-proline esters[9,10] were prepared by the manner as shown in Scheme 1. Substrates **5a—d** were hydrogenated in various solvents (methanol=MeOH, ethanol=EtOH, isopropyl alcohol=Pr^{i}OH, *t*-butyl alcohol=Bu^{t}OH, ethyl acetate=AcOEt, and tetrahydrofuran=THF) at 30 °C over palladium on charcoal. The hydrogenations in MeOH, EtOH, Pr^{i}OH were carried out at different temperatures (−30, −10, +10, +30, 50 °C). The diastereomeric mixtures of the hydrogenation products[*N*-lactoyl-(*S*)-proline esters] were separated to each diastereomer by a gas chromatography equipped with a chiral glass capillary column (Chirasil-Val).[11] Those diastereomers were identified by comparing the retention times with those of the authentic lactamides which were prepared separately from (*S*)-lactic acid[or (*R,S*)-lactic acid] and corresponding proline esters with dicyclohexylcarbodiimide as described in the literature.[12]

Results and Discussion

Substrates **5a—d** were hydrogenated over 5% palladium on charcoal to give diastereomeric mixtures of lactamides **6a—d** using various solvents at 30 °C as shown in Scheme 1. The results of the catalytic hydrogenations are shown in Table 1. All the catalytic hydrogenations of substrates **5a—d** gave *N*-[(*S*)-lactoyl]-(*S*)-proline esters[(*S,S*)-lactamides] in excess over *N*-[(*R*)-lactoyl]-(*S*)-proline esters[(*R,S*)-lactamides].

a) Configuration of the chiral source. b) Dielectric constant of solvents. c) Diastereoisomeric excess= $[((S,S)-(R,S))/((S,S)+(R,S))]\times 100$ (%). d) Configuration of the newly formed chiral moiety.

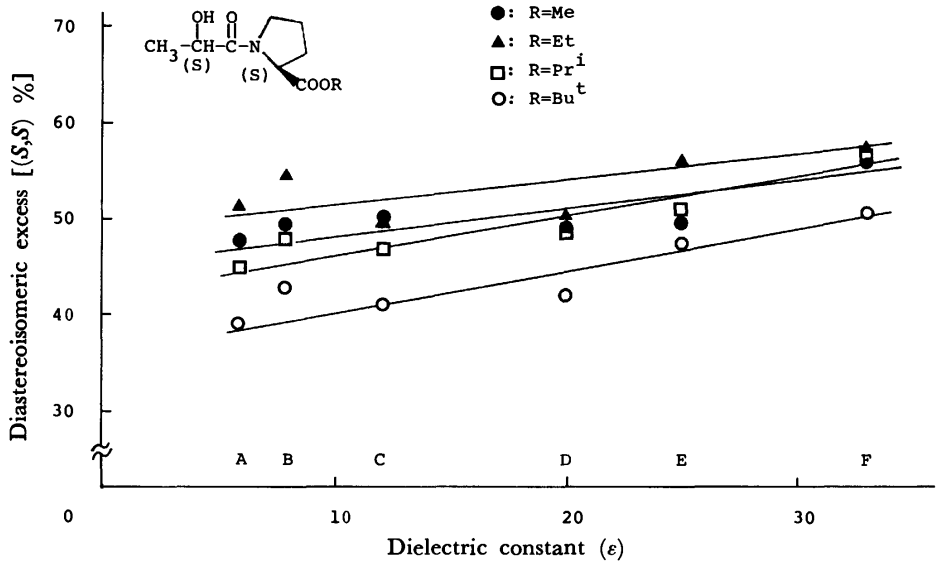

Fig. 2. Solvent effect on d.e. of hydrogenation products.
Solvent: A, AcOEt; B, THF; C, Bu^{t}OH; D, Pr^{i}OH; E, EtOH; F, MeOH.

The values of the d.e. of the asymmetric catalytic hydrogenations in Table 1 were plotted against the dielectric constants of the solvents used for the hydrogenations in Fig. 2. In most cases, the d.e. of the hydrogenation products were slightly higher in the solvents with higher dielectric constants than in the solvents with lower dielectric constants. The values of the d.e. were plotted against the bulkiness of R(Me<Et<Pr^i<Bu^t) as shown in Fig. 3. Substrate **5b** gave higher d.e. than **5a**. Substrate **5c** gave slightly lower d.e. than **5b**. Substrate **5d** gave the lowest d.e. In all solvents used, substrates **5a—d** gave (*S,S*)-lactamide in excess over (*R,S*)-lactamide with rather higher d.e. (up to 58%) than *N*-pyruvoyl-(*S*)-amino acid esters used in the previous study.[8] These results suggested that the fixation of the N-C bond gave stable conformers to make the d.e. of the resulting (*S,S*)-lactamide higher.

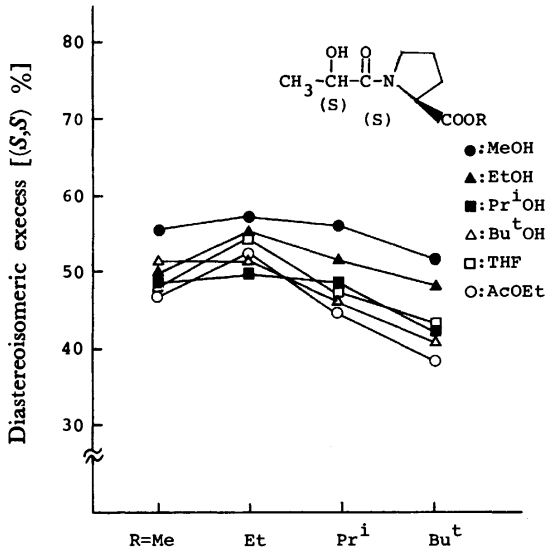

Fig. 3. Effect of bulkiness of substituent group on d.e.

There are two possible steric courses (A and B) through which substrates give (*S,S*)-lactamides in excess in the catalytic hydrogenations (Fig. 4). In the first step (A-1) of the steric course A, the two carbonyl groups take a s-trans conformation owing to their electrostatic repulsion, and the amide bond formed by pyruvic acid and proline ester moieties take a cis[13] conformation as shown in Fig. 4. The substrate molecule taking this conformation would be adsorbed on the palladium surface at the less bulky side of the molecule and be hydrogenated from the catalyst side to give (*S,S*)-lactamide. Thus, in the steric course A, the substrate molecule would be hydrogenated through one step adsorption on the palladium surface and then be hydrogenated. However, this steric course A seemed to contribute little to the asymmetric induction, because A-1 would be unstable due to the steric repulsion between $CH_3C{=}O$ and COOR group binding to the chiral center.

The steric course B which is the "chelation mechanism" could explain the stereochemistry of the catalytic hydrogenations as follows. In the first step (B-1), the substrate molecule would stand on the catalyst surface by the two carbonyl oxygens which take a s-cis conformation, and the amide bond would be trans[13] as shown in Fig. 4. This is the "chelated intermediate." In the second step(B-2), the intermediate would then be adsorbed at the less bulky side of the substrate on the catalyst. And the substrate molecule would be hydrogenated from the catalyst side to give (*S,S*)-lactamide in excess. Thus, in the steric course B, the "chelated intermediate" would be formed first between the substrate molecule and the palladium catalyst and then hydrogenated. Thus, the steric course B could explain the experimental results that (*S,S*)-lactamide was obtained in excess over (*R,S*)-lactamide with the fairly high d.e. (39—59%).

However, while the d.e. of the hydrogenation products would increase with the increase of the

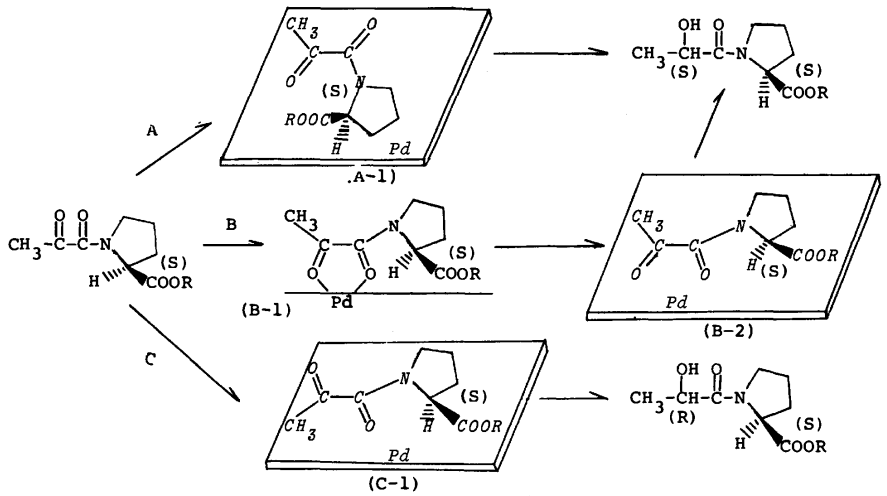

Fig. 4. Possible steric cuorses in the hydrogenations of substrates **5a—d**.

bulkiness of the ester moiety, acturely the d.e. decreased a little in the hydrogenations of substrates **5c,d** (R=Pr^i, Bu^t) as shown in Fig. 3. This could be due to the larger steric repulsion between the ester moiety of substrate **5c** or **5d** and the catalyst surface. Thus, the steric repulsion would inhibit the formation of the "chelated intermediate." And the molecular model of these substrate supported this possibility. Therefore, as the R group becomes larger, the proportion of the substrate molecule which takes other conformation as C-1 on the catalyst increased to give (*R,S*)-lactamide. And the d.e. of (*S,S*)-lactamide in the hydrogenation of substrates **5c,d** might slightly drcrease.

The hydrogenations of substrates **5a—d** were performed in MeOH, EtOH, and Pr^{i}OH at various temperatures. The results of these hydrogenations are shown in Table 2. Substrates **5a—c** gave similar d.e. at each temperature in each solvent. Substrate **5d** gave slightly higher d.e. at lower temperatures. The d.e. from **5d** reached to 59% (*S,S*) at −30 °C.

From the experimental results described above, we could conclude that the asymmetric induction of substrates **5a—d** would be explained by the chelation mechanism. And these experimental results might be useful to speculate the steric course of other heterogeneous asymmetric hydrogenation reactions.

Experimental

The melting points were uncorrected. Optical rotations were measured with a Jasco DIP-181 Digital polarimeter.

a) Configuration of the chiral sources. b) Diastereoisomeric excess. c) Configuration of the newly formed chiral moiety.

The gas chromatographic analyses were carried out with a Hitachi 163 gas chromatograph, and the peaks on the chromatograms were integrated with a Shimazu C-R3A Chromatopac. NMR spectra were measured with a Hitachi R-24 High Resolution NMR spectrometer. IR spectra were measured with a Hitachi 260-50 infrared spectrometer. Palladium on charcoal(5%) was purchased from Nippon Engelhald.

Materials. *N*-Benzyloxycarbonyl-(*S*)-proline *t*-Butyl Ester (2):[14,15] The compound **2** was prepared from *N*-benzyloxycarbonyl-(*S*)-proline(Mp 73.5—74.5 °C $[\alpha]_D^{20}$ −38.0° (*c* 1.09, MeOH)) and isobutene in dichloromethane in the presence of H_2SO_4. Yield, 93%. Mp 40—41 °C. $[\alpha]_D^{24}$ −45.3° (*c* 1.00, AcOEt).

(*S*)-Proline Methyl, Ethyl, and Isopropyl Ester Hydrochloride (3a—c): These compounds **3a—c** were prepared by the esterification of **1** with HCl in the corresponding alcohols (MeOH, EtOH, and Pr^{i}OH).

(*S*)-Proline *t*-Butyl Ester (3d): *N*-Benzyloxycarbonyl-(*S*)-proline *t*-butyl ester **2** (2.08 g, 6.8 mmol) was hydrogenated in ethyl acetate in the presence of 5% palladium on charcoal. After the catalyst was removed off, the filtrate was evaporated in vacuo to give an oily product. This oil was redissolved in ethyl acetate and was used for preparation of **5d**.

***N*-Pyruvoyl-(*S*)-proline Methyl Ester (5a):**[9] (*S*)-Proline methyl ester hydrochloride (**3a**) (3.03 g, 20 mmol) was liberated with triethylamine (1.76 g, 20 mmol) and was coupled with pyruvic acid (**4**) by using dicyclohexyl-carbodiimide (4.54 g, 22 mmol) in ethyl acetate in the presence of *N*-hydroxysuccinimide (2.76 g, 24 mmol). The reaction was carried out for two hours at 0 °C and for 24 h at room temperature. After usual work-up, an oily crude product was obtained and was purified with silica-gel column chromatography (eluting solvent: benzene-ethyl acetate (12:1)) to give 1.29 g oil (32%). $[\alpha]_D^{15}$ −76.5° (*c* 1.25, EtOH). ^{1}H NMR (CCl_4) δ=1.50—2.50 (4H, br), 2.35 (3H, d), 3.64 (3H, s), 3.50 (2H, t), 4.75 (1H, br). IR: 1630, 1700, 1730 cm^{-1}. Found: C, 54.65; H, 6.83; N, 6.76%. Calcd for $C_9H_{13}NO_4$: C, 54.26; H, 6.57; N, 6.73%.

***N*-Pyruvoyl-(*S*)-proline Esters 5b—d.**[9] Substrates **5b—d** were prepared by the similar method to prepare **5a**. The physical data are shown as follows: **5b.** $[\alpha]_D^{17}$ −75.5° (*c* 1.22, EtOH). ^{1}H NMR (CCl_4) δ=1.25 (3H, t), 1.50—2.50 (4H, br), 2.30 (3H, d), 3.60 (2H, br), 4.05 (2H, br), 4.70 (1H, br). IR, 1630, 1710, 1730 cm^{-1}. Found: C, 56.02; H, 7.13; N, 6.47%. Calcd for $C_{10}H_{13}NO_4$: C, 56.32; H, 7.09; N, 6.56%. **5c.** $[\alpha]_D^{17}$ −65.5° (*c* 1.08, EtOH). ^{1}H NMR ($CDCl_3$) δ=1.15—1.30 (6H, dd), 1.80—2.25 (4H, br), 2.32—2.38 (3H, d), 3.40—3.90 (2H, br), 4.20—4.50 (1H, br). IR, 1620, 1700, 1710 cm^{-1}. Found: C, 57.88; H, 7.60; N, 6.22%. Calcd for $C_{12}H_{19}NO_4$: C, 58,13; H, 7.54; N, 6.16%. **5d.** $[\alpha]_D^{17}$ −71.4° (*c* 1.07, AcOEt). ^{1}H NMR ($CDCl_3$) δ=1.44 (9H, s), 2.07 (4H, br), 2.40 (3H, d), 3.50—3.83 (2H, br), 4.60—4.83 (1H, br). IR, 1640, 1720—1740 cm^{-1}. Found: C, 59.81; H, 8.11; N, 6.08%. Calcd for $C_{13}H_{21}NO_4$: C, 59.73; H, 7.93; N, 5.80%.

Catalytic Hydrogenations of Substrates 5a—d. Substrates **5a—d** (0.10 mmol) were dissolved in 5 ml solvents (MeOH, EtOH, Pr^{i}OH, Bu^{t}OH, THF, and AcOEt) in the presence of 20 mg of 5% palladium on charcoal and were hydrogenated at 30 °C. After 2—7 d hydrogenations, the catalyst was filtered off and the filtrate was evaporated in vacuo to give an oily product. Chemical yields and d.e. (=diastereoisomeric excess) of the hydrogenation products were determined by using gas liquid chromatography. Catalytic hydrogenations of **5a—d** at some different temperatures (−30, −10, +10, and +50 °C) were also carried out by the same manner.

***N*-Lactoyl-(*S*)-Proline Ester 6a—d.** Authentic *N*-lactoyl-(*S*)-proline esters were prepared from (*S*)-lactic acid[or (*R*,*S*)-lactic acid] and the corresponding (*S*)-proline esters as described in the literatuere.[12]

Gas Liquid Chromatographic Analyses. All the diastereomer mixture of the hydrogenation products were not derivatized and directly separated to each diastereomer by using a Hitachi gas chromatograph with a fused glass capillary column (Chirasil-Val[11] 25 m×0.25 mm I.D.) which was purchased from Alltech Associates, Inc. Applied Science Labs. Il 60015 U.S.A. Carrier gas was helium. The column temperature during the analyses was 170 °C (constant). Flame thermionic detector was used for these analyses.

Synthesis of 1,4-Diaminocyclitol Antibiotics. I. Synthesis of 4′-Hydroxyfortimicin D

Kazuaki KANAI, Itsuki SAKAMOTO, Yasunobu MIYAMOTO, Seiichiro OGAWA,* and Tetsuo SUAMI†
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Yokohama 223
(Received June 25, 1986)

The 4′-hydroxy analog of fortimicin D has been synthesized by condensation of 4-*O*-acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,6-trideoxy-α-D-*ribo*-hexopyranosyl chloride with a partially protected aminocyclitol, 1,2:4,5-di-*N*,*O*-carbonylfortamine B, followed by deprotection.

Fortimicins are isolated from a fermentation broth of *Micromonospora olivoasterospora*,[1,2] and belong to members of 1,4-diaminocyclitol antibiotics. The structural features of the antibiotics are pseudo-disaccharides consisting of the aminocyclitol, fortamine, and the diamino sugar, 6-epipurpurosamine B. As a member of anitibiotic fortimicin-group, sporaricins,[3] istamycins,[4] sannamycins,[5] SF-2052,[6] and SF-1854[7] have been known. A number of chemical modifications has extensively been carried out, and the relationship between the structure and antimicrobial activity has gradually been made clear. However, most studies have been centered around the aminocyclitol moiety.[8] Therefore, in order to elucidate the role of the diamino sugar moiety in the antimicrobial activity, we have undertaken a modification of the amino sugar moiety.

We now describe a chemical synthesis of the 4′-hydroxy analog (**17**) of fortimicin D.[9] The synthesis involved preparation of the glycosyl chloride, 4-*O*-acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,6-trideoxy-α-*ribo*-hexopyranosyl chloride (**8**) and condensation of **8** with the partially protected aminocyclitol, 1,2:4,5-di-*N*,*O*-carbonylfortamine B (**9**).[10,11]

Results and Discussion

The glycosyl chloride **8** has been prepared by the following sequence. Methyl 2-acetamido-4,6-*O*-benzylidene-2,3-dideoxy-α-D-*ribo*-hexopyranoside (**3**)[12–15] was obtained in high yield (80%, 2 steps) from methyl 2-acetamido-4,6-*O*-benzylidene-2-deoxy-α-D-glucopyranoside (**1**)[6] by modified Barton's deoxygenation reaction.[17] Catalytic hydrogenation of methyl 2-acetamido-6-azido-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside (**4**),[18] which was accessible from **3**, gave the 6-amino derivative **5** as an acetate form in 84% yield. Hydrolysis of **5** in refluxing 2 M†† hydrochloric acid solution gave the 2,6-diamino sugar **6**, which was converted into 1,4-di-*O*-acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,6-trideoxy-D-*ribo*-hexopyranose (**7**, 55%) by treatment with 2,4-dinitrofluorobenzene and triethylamine, followed by acetylation. The chloride **8** was obtained as yellow crystals (54%) by chlorination of **7** with 15% HCl–dioxane and acetyl chloride.

Condensation of **9** with **8** in dioxane in the presence of silver trifluoromethanesulfonate afforded 28% yield of the condensate **10** as an anomeric mixture, which was directly used for the following step. *O*-Deacetylation of **10** with 0.02 M sodium hydroxide gave two products (**11**, 5% based on **9**) and (**12**, 11%). The ^{1}H NMR spectrum of **11** revealed the presence of the anomeric proton of the α-D-glycoside as a doublet at δ 5.62 (J=4.5 Hz). The spectrum of **12** showed a doublet at δ 5.15 (J=7.5 Hz) attributable to the anomeric proton of the β-D-glycoside. Removal of the dinitrophenyl group of **11** with Amberlite IRA-400 (OH^-) resin, followed by hydrolysis in refluxing 1 M sodium hydroxide solution gave, in 76% yield, 4′-hydroxyfortimicin KE (**13**), which was characterized by conversion into the hepta-*N*,*O*-acetyl derivative (**14**). Selective *N*-benzyloxycarbonylation of **13** with *N*-(benzyloxycarbonyloxy)succinimide gave 1,2′,6′-tris[*N*-(benzyloxycarbonyl)]-4′-hydroxyfortimicin KE (**15**) in 50% yield. Tetrakis[*N*-(benzyloxycarbonyl)] derivative of 4′-hydroxyfortimicin D (**16**) was obtained in 67% yield by introduction of *N*-(benzyloxycarbonyl)-glycyl group into methyl amino group at C-4 of **15** with *N*-[*N*-(benzyloxycarbonyl)glycyloxy]succinimide and triethylamine. Hydrogenolysis of **16** in ethanol containing 0.1 M hydrochloric acid in the presence of

Table 1. Antimicrobial Activity of **17** and Fortimicin A[a]

Test Organisms	**17**	Fortimicin A
Streptococcus faecalis KY4280	>100	3.1
Pseudomonas aeruginosa KY4276	50	3.1
Staphylococcus aureus KY4279	6.3	<0.05
Escherichia coli KY4271	25	0.39
Bacillus subtilis KY4273	3.1	0.1
Shigella sonnei KY4281	50	0.78
Klebsiella pneumoniae KY4275	6.3	<0.05

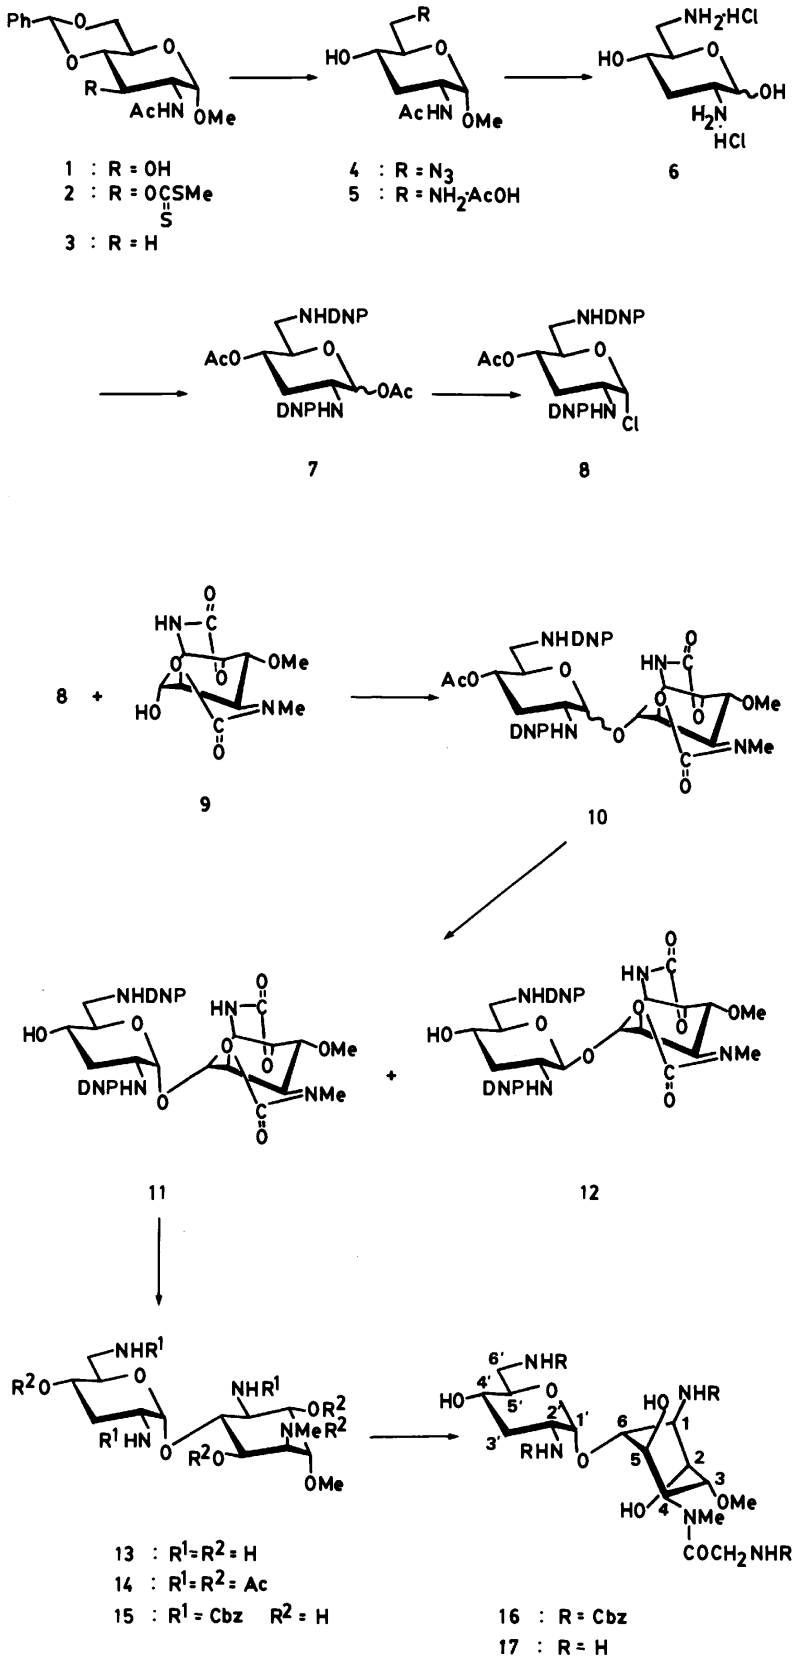
a) Minimum inhibitory concentration in μg ml^{-1}.

† Present address: Department of Chemistry, Faculty of Science and Technology, Meisei University, Hodokubo, Hino, Tokyo 191.

†† 1 M=1 mol dm^{-3}.

10% palladium on charcoal gave 4′-hydroxyfortimicin D (**17**) as the hydrochloride.

The minimum inhibitory concentrations of **17** against seven organisms were compared with those of fortimicin A (Table 1). Antimicrobial activity of **17** was lower than that of fortimicin A.



Experimental

General Procedures. Melting points were determined in capillary-tubes and are uncorrected. Optical rotations were measured on a JASCO DIP-4 polarimeter. IR and Mass spectra were recorded on Hitachi HPL-225 spectrophotometer and Hitachi M-80 and M-80A (SIMS) spectrometers, respectively. ^{1}H NMR spcetra with TMS or DSS as internal standard were recorded on Varian EM-390 (90 MHz). TLC and column chromatography were performed on Silica Gel 60F-254 (E. Merck) and Wakogel C-200, C-300 or Kieselgel 60, respectively. Concentration were carried out under reduced pressure below 40 °C.

Methyl 2-Acetamido-4,6-*O*-benzylidene-2-deoxy-3-*O*-[methylthio(thiocarbonyl)]-α-D-glucopyranoside (2). To a solution of methyl 2-acetamido-4,6-*O*-benzylidene-2-deoxy-α-D-glucopyranoside[16] (28.5 g) in *N*,*N*-dimethylformamide (400 ml), a suspension of 60% sodium hydride (5.40 g) in *N*,*N*-dimethylformamide (10 ml) and catalytic amount of imidazole were added. After stirring for 1 h at 50 °C, carbon disulfide (54 ml) was added to the mixture. After 15 min, methyl iodide (40 ml) was added and stirring was continued for 30 min. The mixture was then poured into ice water (500 ml) and extracted with chloroform (300 ml). The extracts were washed with 0.1 M hydrochloric acid, saturated aqueous $NaHCO_3$ and water, and dried. After evaporation of the solvent, the residue was crystallized from ethanol to afford **2** (29.1 g, 81%): Mp 182—183 °C; $[\alpha]_D^{14}$ −23.8° (*c* 0.93, chloroform); IR (KBr) 1665, 1520 (NHC=O), 1200 (C=S) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.92 (3H, s, NAc), 2.54 (3H, s, SMe), 3.41 (3H, s, OMe), 4.75 (1H, d, *J*=3.5 Hz, H-1), 5.53 (1H, s, C<u>H</u>C$_6$H$_5$), 5.90 (1H, d, *J*=9 Hz, NH), 6.31 (1H, t, *J*=9 Hz, H-3), 6.92—7.53 (5H, m, phenyl).

Found: C, 52.51; H, 5.56; N, 3.35; S, 15.26%. Calcd for $C_{18}H_{23}NO_6S_2$: C, 52.28; H, 5.61; N, 3.39; S, 15.51%.

Methyl 2-Acetamido-4,6-*O*-benzylidene-2,3-dideoxy-α-D-*ribo*-hexopyranoside (3). To a boiling solution of **2** (30 g) in toluene (750 ml), a solution of *n*-Bu_3SnH (38.8 ml) in toluene (62 ml) and catalytic amount of α, α′-azobisisobutyronitrile were added under nitrogen atmosphere. After 5 min, the mixture was cooled and concentrated to give a gelatinous residue, which was chromatographed on silica gel with chloroform–acetone (1:1). The fractions [R_f 0.38; toluene–acetone (3:1)] were concentrated to afford **3** (22.2 g, 99%) as an amorphous solid: Mp 248—249 °C; $[\alpha]_D^{16}$ +54.5° (*c* 1.27, chloroform), Lit.[14] mp 245 °C, $[\alpha]_D$ +55.5° (*c* 0.95).

Found: C, 62.38; H, 7.02; N, 4.55%. Calcd for $C_{16}H_{21}NO_5$: C, 62.52; H, 6.89; N, 4.56%.

Methyl 2-Acetamido-6-amino-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside Acetate (5). A solution of methyl 2-acetamido-6-azido-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside (**4**)[18] (2.62 g) in methanol (25 ml) containing acetic acid (0.1 ml) was hydrogenated with Raney nickel in the initial hydrogen pressure of 3.4 kg cm^{-2} for 17 h. The catalyst was filtered and the filtrate was concentrated to a residue, which was washed with ether to give **5** (2.52 g, 84%) as a white powder: Mp 150 °C; $[\alpha]_D^{22}$ +115° (*c* 0.65, methanol); ^{1}H NMR (CD_3OD) δ=1.97 (3H, s, NAc), 3.47 (3H, s, OMe), 4.64 (1H, d, *J*=3.3 Hz, H-1).

Found: C, 47.21; H, 7.75; N, 10.23%. Calcd for $C_9H_{18}N_2O_4 \cdot CH_3COOH$: C, 47.47; H, 7.97; N, 10.07%.

1,4-Di-*O*-acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,6-trideoxy-D-*ribo*-hexopyranose (7). A solution of **5** (9.52 g) in 2 M hydrochloric acid (200 ml) was refluxed for 4 h. The mixture was concentrated and the residue was dissolved in methanol (100 ml) and acetone (70 ml). 2,4-Dinitrofluorobenzene (17.9 g) and triethylamine (26.9 ml) were added to it under ice cooling and the mixture was stirred for 12 h at room temperature. The mixture was concentrated to half volume and partitioned between ethyl acetate (200 ml) and water (200 ml). The organic layer and the extracts (400 ml) were combined and dried. After concentration, the residue was chromatographed on silica gel with toluene–acetone (5:1) as an eluent to afford the *N*-(2,4-dinitrophenyl) derivative of **6** (14.7 g, 68%) as a yellow powder: Mp 138—139.5 °C; $[\alpha]_D^{19}$ +19.1° (*c* 1.1, acetone); IR (KBr) 1520, 1335 (NO_2) cm^{-1}. To a solution of the powder (14.6 g) in pyridine (150 ml), acetic anhydride (56 ml) was added under ice cooling and the mixture was stirred for 13 h at room temperature. The reaction solution was concentrated and the residue gave **7** (7.11 g) as a yellow powder upon addition of ethyl acetate. An additional crop of **7** (6.72 g, total yield 55%) was obtained by chromatography of the mother liquor on silica gel using toluene–acetone (8:1): Mp 190 °C (decomp); $[\alpha]_D^{25}$ +14.3° (*c* 0.34, chloroform); IR (KBr) 1745 (ester), 1525, 1340 (NO_2) cm^{-1}; ^{1}H NMR (pyridine-d_5) δ=2.12 and 2.26 (each 3H, s, OAc), 5.30 (1H, dt, *J*=5 Hz, 10 Hz, H-4), 6.63 (1/4H, d, *J*=8.5 Hz, H-1), 6.66 (3/4H, d, *J*=3.5 Hz, H-1).

Found: C, 45.55; H, 3.92; N, 14.46%. Calcd for $C_{22}H_{22}N_6O_{13}$: C, 45.68; H, 3.83; N, 14.53%.

4-*O*-Acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,6-trideoxy-α-D-*ribo*-hexopyranosyl Chloride (8). A solution of **7** (4.0 g) in 15% HCl–dioxane (175 ml) containing acetyl chloride (10 ml) was stirred at 50 °C for 4 h. The mixture was concentrated, and the residue was washed with ether and recrystallized from chloroform to afford **8** (2.10 g, 54%): Mp 127 °C (decomp); $[\alpha]_D^{17}$ +86.0° (*c* 1.66, acetone); ^{1}H NMR (acetone-d_6) δ=2.10 (3H, s, OAc), 4.80 (1H, ddt, *J*=4 Hz, 9 Hz, 12 Hz, H-2), 5.10 (1H, dt, *J*=4.5 Hz, 11.5 Hz, H-4), 6.54 (1H, d, *J*=4 Hz, H-1), 7.27 and 7.46 (each 1H, d, *J*=9 Hz, H-3 of DNP), 8.26 (2H, dd, *J*=3 Hz, 9 Hz, H-5 of DNP×2), 8.98 (2H, d, *J*=3 Hz, H-6 of DNP×2).

Found: C, 43.10; H, 3.60; N, 14.88; Cl, 6.45%. Calcd for $C_{20}H_{19}N_6O_{11}Cl$: C, 43.29; H, 3.45; N, 15.15; Cl, 6.39%.

4′-*O*-Acetyl-1,2:4,5-di-*N*,*O*-carbonyl-2′,6′-bis[*N*-(2,4-dinitrophenyl)]-fortimicin KE and -1′-epifortimicin KE (10). 1,2:4,5-Di-*N*,*O*-carbonylfortamine B (**9**)[10,11] (404 mg) was dissolved in freshly distilled dioxane (16 ml) at 100 °C. After the solution had been cooled to room temperature, **8** (1.95 g) and silver trifluoromethanesulfonate (990 mg) were added, and the mixture was stirred under argon atmosphere in the dark for 66 h. An insoluble material was filtered and washed with acetone. The filtrate was concentrated and the residual product was purified by a column chromatography using toluene–acetone (5:1). Fractions [R_f 0.33, toluene–acetone (5:2)] were concentrated to give the anomeric mixture of **10** (342 mg, 28%) and the aglycon **9** (200 mg) recovered.

1,2:4,5-Di-*N*,*O*-carbonyl-2′,6′-bis[*N*-(2,4-dinitrophenyl)]-4′-hydroxyfortimicin KE (11) and -1′-epi-4′-hydroxyfortimicin KE (12). To a solution of **10** (342 mg) in acetone (30 ml) and methanol (30 ml), 0.02 M sodium hydroxide (20 ml) was added and the mixture was stirred for 5 min. The mixture

was neutralized with Amberlite IR-120 (H^+) resin and concentrated. The residue was purified by chromatography with chloroform–acetonitrile (5:1). Fractions [R_f 0.46, chloroform–acetonitrile (3:1)] were concentrated to give **11** (58 mg, 5% based on **9**): Mp 163—167 °C; $[\alpha]_D^{23}$ +0.83° (*c* 0.84, acetone); IR (KBr) 1760 (cyclic carbamate), 1620, 1590 (aromatic), 1335 (NO_2) cm^{-1}; ^1H NMR (acetone-d_6) δ=2.86 (3H, s, NMe), 3.54 (3H, s, OMe), 5.62 (1H, d, *J*=4.5 Hz, H-1′).

Found: C, 45.49; H, 4.12; N, 14.98%. Calcd for $C_{28}H_{30}N_8O_{16}$: C, 45.78; H, 4.12; N, 15.25%.

The fractions (R_f 0.37) gave **12** (122 mg, 11% based on **9**): Mp 180—184 °C; $[\alpha]_D^{23}$ −32.2° (*c* 0.90, acetone); IR (KBr) 1760, 1620, 1590, 1335 cm^{-1}; ^1H NMR (acetone-d_6) δ=2.86 (3H, s, NMe), 3.48 (3H, s, OMe), 5.15 (1H, d, *J*=7.5 Hz, H-1′).

Found: C, 45.52; H, 4.17; N, 14.99%. Calcd for $C_{28}H_{30}N_8O_{16}$: C, 45.78; H, 4.12; N, 15.25%.

4′-Hydroxyfortimicin KE (13). A mixture of **11** (80 mg) in acetone (10 ml), methanol (10 ml) and water (5 ml), and Amberlite IRA-400 (OH^-) resin (2 ml) was stirred overnight. The resin was filtered and the filtrate was concentrated and the residue was partitioned between ethyl acetate (20 ml) and water (20 ml). The organic layer was washed with water (20 ml) and the aqueous layers were concentrated to give a syrup of *N*-de(2,4-dinitrophenyl)ated derivative of **11** (67 mg). To a refluxing solution of 1 M sodium hydroxide (10 ml), a solution of the syrup (67 mg) in water was added and the mixture was stirred for 1 h. The mixture was cooled to room temperature and neutralized with 1 M hydrochloric acid. After concentration, the residue was chromatographed on a column of Amberlite CG-50 (NH_4^+, 40 ml) resin with 0—0.16 M aq ammonia with gradient increase in concentration. Fractions [R_f 0.41, isopropyl alcohol–chloroform–concd aq ammonia (4:1:2)] were collected and concentrated to give 4′-hydroxyfortimicin KE **13** (29 mg, 76%): $[\alpha]_D^{17}$ +19.1° (*c* 0.43, water); ^1H NMR (D_2O) δ=2.72 (3H, s, NMe), 3.43 (3H, s, OMe).

1,4,2′,6′-Tetra-*N*-acetyl-2,5-di-*O*-acetyl-fortimicin KE (14). Compound **13** was acetylated in the usual way to give **14**: $[\alpha]_D^{17}$ +84.9° (*c* 0.85, methanol); IR (KBr) 1740 (ester), 1650 (NHC=O) cm^{-1}; ^1H NMR (CD_3OD) δ=1.89, 1.94, 1.96, 2.02, 2.05, 2.08 and 2.11 (each 3H, s, NAc×4 and OAc×3), 3.02, and 3.10 (3H in total, each s, NMe), 3.40 (3H, s, OMe).

Found: *m/z*, 645.2979. Calcd for $C_{28}H_{45}N_4O_{13}$: M+1, 645.2979.

1,2′,6′-Tris[*N*-(benzyloxycarbonyl)]-4′-hydroxyfortimicin KE (15). To a solution of **13** (29 mg) in water–methanol (1:2, 5 ml), *N*-(benzyloxycarbonyloxy)succinimide (64 mg) was added under ice cooling. After stirring for 3 h at 0 °C, the mixture was stirred for 20 h at room temperature. The mixture was concentrated, and the residue was extracted with chloroform (40 ml) and dried. After concentration, the residue was purified by preparative TLC with toluene–ethanol (4:1) to give **15** (31 mg, 50%): $[\alpha]_D^{21}$ +16.8° (*c* 0.30, methanol); ^1H NMR ($CDCl_3$) δ=2.30 (3H, s, NMe), 3.41 (3H, s, OMe), 5.06 (6H, s, benzyl×3), 5.28 (1H, d, *J*=3.8 Hz, H-1′), 7.31 (15H, s, phenyl×3).

Found: C, 59.89; H, 6.42; N, 7.21%. Calcd for $C_{38}H_{48}N_4O_{12}\cdot 2/3H_2O$: C, 59.68; H, 6.50; N, 7.33%.

1,2′,6′-Tris[*N*-(benzyloxycarbonyl)]-4-[*N*-[*N*-(benzyloxycarbonyl)glycyl]]-4′-hydroxyfortimicin KE (16). To a solution of **15** (18 mg) in dioxane (1.5 ml), *N*-[*N*-(benzyloxycarbonyl)-glycyloxy]succinimide (19 mg) and triethylamine (0.02 ml) were added and the mixture was stirred at 60 °C for 12 h. The mixture was cooled to room temperature and concentrated to give a residue which was extracted with chloroform (40 ml). The extract was dried and concentrated to the residue, which was purified by preparative TLC with toluene–ethanol (6:1) to give **16** (15 mg, 67%): $[\alpha]_D^{27}$ +53.0° (*c* 0.63, chloroform); ^1H NMR ($CDCl_3$) δ=2.82 (3H, s, NMe), 3.22 (3H, s, OMe), 5.07 (8H, s, benzyl×4), 7.32 (20H, s, phenyl×4).

Found: C, 60.86; H, 6.09; N, 7.16%. Calcd for $C_{48}H_{57}N_5O_{15}$: C, 61.07; H, 6.09; N, 7.42%.

4′-Hydroxyfortimicin D (17). To a solution of **16** (13.8 mg) in ethanol (3 ml), a mixture of 0.1 M hydrochloric acid (0.6 ml) and water (0.5 ml) was added. The mixture was hydrogenated in the presence of 10% palladium on charcoal (23 mg) at an initial hydrogen pressure of 3.4 kg cm^{-2} for 6 h. After removal of the catalyst, the filtrate was concentrated to afford a white solid of **17** (8.0 mg, quant.) as the hydrochloride: $[\alpha]_D^{22}$ +42.5° (*c* 0.4, water); ^1H NMR (D_2O) δ=3.13 (3H, s, NMe), 3.48 (3H, s, OMe), 4.10 (2H, bs, $COCH_2NH_2$), 5.48 (1H, d, *J*=4.8 Hz, H-1′). MS (SIMS) Found: *m/z*, 408. Calcd for $C_{16}H_{34}N_5O_7$: M+1, 408.

The authors wish to express their thanks to Drs. Kunikatsu Shirahata and Hiroshi Sano of Kyowa Hakko Co. for antibacterial assay. We also would like to thank Dr. Yoshimasa Fukuda of Meiji Seika Co. for measurement of mass spectrum, Mr. Saburo Nakada of the University for elemental analyses.

Synthesis on 1,4-Diaminocyclitol Antibiotics. II. Synthesis of 7′-Propylfortimicin A[1]

Kazuaki KANAI, Junji NISHIGAKI, Seiichiro OGAWA,* and Tetsuo SUAMI†
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Yokohama 223
(Received June 25, 1986)

7′-Propylfortimicin A has been synthesized by a condensation of newly prepared 1-*O*-acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,4,6,7,8,9,10-octadeoxy-L-*lyxo*-decopyranose with 2,5-di-*O*-benzoyl-1,4-bis-*N*-(methoxycarbonyl)fortamine B, followed by deprotection.

Since fortimicin A was discovered by Nara et al. in 1977,[2] its chemical modifications have extensively been studied.[3,4] In continuation of our study on modification of the diamino sugar moiety,[5] an extension of its sidechain would be of interest in connection with increase in its hydrophobic nature. We now describe the synthesis of 7′-propylfortimicin A (**17**).

Results and Discussion

1-*O*-Acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,4,6,7,8,9,10-octadeoxy-L-*lyxo*-decopyranose (**9**) has been prepared from the known methyl 2-acetamido-2,3,4-trideoxy-α-D-*erythro*-hexopyranoside (**1**)[6] as shown in Scheme.

Treatment of **1** with *p*-toluenesulfonyl chloride in pyridine gave the tosylate **2** in 76% yield. Displacement of the tosyloxy group with sodium iodide, followed by treatment with sodium nitrite in *N*,*N*-dimethylformamide and dimethyl sulfoxide, afforded the nitro derivative **4** in 48% yield. The nitro aldol reaction of **4** with butyraldehyde was effected in the presence of CsF in acetonitrile for 5 h at room temperature and the product was successively acetylated with acetic anhydride and BF_3 etherate to give **5** as a diastereoisomeric mixture. The reaction using KF instead of CsF resulted in a poor yield. Hydrogenation of **5** with sodium borohydride in dimethyl sulfoxide afforded a mixture of methyl 2-acetamido-2,3,4,6,7,8,9,10-octadeoxy-6-nitro-α-D-*ribo* and -β-L-*lyxo*-decopyranoside (**6**) in 41% yield based on **4**. Catalytic hydrogenation of **6** with Raney nickel in methanol, followed by *N*-acetylation with acetic anhydride, gave two products (**7**, 57% and **8**, 19%) after chromatography.

The stereochemistry at C-6 in **7** and **8** has been established by the values of specific rotations, and chemical shifts of C-7 in ^{13}C NMR spectra. The values of the specific rotations of **7** and **8**, together with those of methyl 2,6-di-*N*-acetyl-α-purpurosaminide B[7] and -6-*epi*-α-purpurosaminide B[6,8] are shown in Table 1.

† Present address: Department of Chemistry, Faculty of Science and Technology, Meisei University, Hodokubo, Hino, Tokyo 191.

From these data, we could assume that the values of specific rotations of the compounds with α-D-*ribo* configuration are more dextrorotatory than those of the corresponding β-L-*lyxo* isomers. In the ^{13}C NMR spectra on **7** and **8**, the signal of C-7 of **8** shifted upfield by 1.99 ppm compared to that of **7**. Chmielewski et al. observed this upfield shift for the related compounds, and assumed that it was due to the antiperiplanar arrangement of C-7/C-6/C-5/O-5.[9,10] In addition, the ^1H NMR spectrum of **8** revealed the H-5 signal (δ 3.60) with 6 Hz splitting, the dihedral angle around H-5 and H-6 being about 60°. The stereochemistry at C-6 of **7** and **8** has thus been confirmed as shown in Scheme.

Hydrolysis of **7** with 2 M†† hydrochloric acid, followed by successive *N*-(2,4-dinitrophenyl)ation and

†† 1 M=1 mol dm^{-3}.

O-acetylation gave **9** in 26% yield. On the other hand, the aglycon, 2,5-di-*O*-benzoyl-1,4-bis[*N*-(methoxycarbonyl)]fortamine B (**12**), has been prepared from fortimicin B in the following way. Treatment of fortimicin B with methyl chloroformate in aqueous acetone gave 1,4,2′,6′-tetrakis[*N*-(methoxycarbonyl)]-fortimicin B (**10**) in 98% yield. Benzoylation of **10** with benzoyl chloride in pyridine afforded 65% yield of the 2,5-dibenzoate (**11**), which was hydrolyzed with acetic acid containing 2 M hydrochloric acid to give the aglycon **12** in 79% yield. Judging from the ^{1}H NMR data, **12** is assumed to adopt the skew-boat form as depicted in Scheme. However, the conformations of the fortamine moieties in pseudo-disaccharides could not be deduced by analogy with these results.

Condensation of **9** with **12** in 1,2-dichloroethane in the presence of trimethylsilyl trifluoromethanesulfonate under argon gave single compound **13** in 49% yield. The ^{1}H NMR spectrum of **13** exhibited the signal of H-1′ (δ 5.28) with a small coupling constant ($J_{1',2'}$=3 Hz), supporting that the anomeric proton is equatorial of the α-D-glycoside. Hydrolysis of **13** in refluxing aqueous dioxane with barium hydroxide, followed by removal of the dinitrophenyl group with Amberlite IRA-400 (OH^-) resin, afforded 7′-propylfortimicin B (**14**) in 68% yield. The tris[*N*-(benzyloxycarbonyl)] derivative **15** was prepared in 60% yield by treatment of **14** with *N*-(benzyloxycarbonyloxy)succinimide. Treatment of **15** with *N*-[*N*-(benzyloxycarbonyl)glycyloxy]succinimide and triethylamine gave 1,4,2′,6′-tetrakis[*N*-(benzyloxycarbonyl)] derivative **16** in 86% yield. Catalytic hydrogenation of **16** in the presence of 10% palladium on charcoal gave quantitatively the free base, which was characterized as crystalline 7′-propylfortimicin A disulfate (**17**).

Table 3. Antimicrobial Activity of **17** and Fortimicin A[a)]

Test Organisms	**17**	Fortimicin A
Streptococcus faecalis KY4280	12.5	12.5
Pseudomonas aeruginosa KY4276	50.0	12.5
Staphylococcus aureus KY4279	0.4	0.4
Escherichia coli KY4271	1.6	1.6
Bacillus subtillis KY4273	0.4	0.4
Shigella sonnei KY4281	3.1	6.3
Klebsiella pneumoniae KY4275	0.4	0.4

a) Minimum inhibitory concentration in $\mu g\,ml^{-1}$.

The minimum inhibitory concentration of **17** was compared with those of fortimicin A (Table 3). 7′-propylfortimicin A (**17**) exhibited almost similar activity to that of fortimicin A against many micro organisms except *Pseudomonas*.

Experimental

General Procedures. Melting points were determined in capillary tubes and are uncorrected. Optical rotations were measured on a JASCO DIP-4 polarimeter. IR and Mass spectra were recorded on Hitachi HPL-225 spectrophotometer and Hitachi M-80 and M-80A (SIMS) spectrometers, respectively. ^{1}H NMR spectra with TMS or DSS as internal standard were recorded on Varian EM-390 (90 MHz) or JEOL FX-200 (200 MHz), and ^{13}C NMR spectra with TMS on JEOL FX-200 (50 MHz). TLC and column chromatography were performed on Silica Gel 60F-254 (E. Merck) and Kieselgel 60. Organic solutions were concentrated under reduced pressure below 40 °C.

Methyl 2-Acetamido-2,3,4-trideoxy-6-*O*-tosyl-α-D-*erythro*-hexopyranoside (2). To a solution of methyl 2-acetamido-2,3,4-trideoxy-α-D-*erythro*-hexopyranoside (**1**)[6] (1.03 g) in pyridine (20 ml), *p*-toluenesulfonyl chloride (2.50 g) was added under ice cooling and the mixture was poured into ice water (200 ml) and the solution was extracted with chloroform (200 ml). The extract was washed successively with 1 M hydrochloric acid (100 ml), saturated aqueous $NaHCO_3$ (100 ml) and water (100 ml), and dried. After concentration, the residue was chromatographed on silica gel with toluene–ethanol (10:1) to give **2** (1.38 g, 76%). Recrystallization from ethyl acetate–pentane afforded an analytical sample: Mp 98—99 °C; $[\alpha]_D^{20}$ +68.3° (*c* 1.29, chloroform); IR (KBr) 1355, 1170 (SO_2) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.39—2.05 (4H, m, H-3,4), 1.91 (3H, s, NAc), 2.43 (3H, s, Me of tosyl), 3.31 (3H, s, OMe), 4.50 (1H, d, *J*=3 Hz, H-1), 5.66 (1H, d, *J*=9 Hz, NH), 7.34 and 7.80 (each 2H, d, *J*=8.5 Hz, tosyl).

Found: C, 53.96; H, 6.44; N, 4.10; S, 8.71%. Calcd for $C_{16}H_{23}NO_6S$: C, 53.77; H, 6.49; N, 3.92; S, 8.97%.

Methyl 2-Acetamido-2,3,4,6-tetradeoxy-6-nitro-α-D-*erythro*-hexopyranoside (4). To a stirred solution of **2** (897 mg) in 2-butanone (30 ml), sodium iodide (1.50 g) was added and the mixture was refluxed for 2.5 h. The mixture was cooled to room temperature, and the solid was filtered. The filtrate was concentrated to dryness and was diluted with ethyl acetate (150 ml). The solution was washed successively with 30% aqueous sodium thiosulfate (100 ml) and water (100 ml), and dried. Evaporation of the solvent gave crude **3** (738 mg). To a solution of **3** (738 mg), without purification, in *N*,*N*-dimethylformamide (2 ml) and dimethyl sulfoxide (8 ml), sodium nitrite (938 mg) and phloroglucinol dihydrate (1.12 g) were added and the mixture was stirred for 6 d at room temperature. To the mixture, ice water (30 ml) was added and the mixture was extracted with chloroform (100 ml). The extract was washed with water (150 ml) and dried. After concentration, the residue was recrystallized from chloroform–petroleum ether to afford **4** (274 mg, 48% based on **2**): Mp 169 °C (decomp); $[\alpha]_D^{20}$ +138° (*c* 0.78, methanol); IR (KBr) 1545, 1365 (NO_2) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.89 (3H, s, NAc), 3.31 (3H, s, OMe), 4.51 (1H, d, *J*=3 Hz, H-1).

Methyl 2-Acetamido-2,3,4,6,7,8,9,10-octadeoxy-6-nitro-α-D-*ribo*- and β-L-*lyxo*-decopyranoside (6). To a solution of **4** (1.55 g) in acetonitrile (15 ml), butyraldehyde (1.20 ml) and CsF (1.01 g) were added and the mixture was stirred for 5 h at room temperature. The mixture was partitioned between ethyl acetate (20 ml) and water (20 ml). The aqueous layer

was extracted with ethyl acetate (40 ml) and the organic layer and the extract were combined, and dried. After evaporation of the solvent, a crude syrup of the condensation product (1.91 g) was obtained. To a solution of the condensate (1.91 g) in acetic anhydride (20 ml), BF_3 etherate (3 ml) was added under ice cooling. After stirring for 1 h at 0 °C, the mixture was poured into ice water (200 ml) and the solution was extracted with chloroform (300 ml). The extracts were washed successively with saturated aqueous $NaHCO_3$ (600 ml) and water (200 ml), and dried. After concentration, the residue was chromatographed on silica gel with ethyl acetate–2-butanone (10:1). Fractions [R_f 0.66, chloroform–methanol (10:1)] gave **5** (951 mg) as a syrup: IR ($CHCl_3$) 1740 (ester), 1665, 1560 (NHC=O), 1510, 1370 (NO_2) cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.95 (3H, s, NAc), 2.11 (3H, s, OAc), 3.38 and 3.40 (3H in total, each s, OMe), 4.57 (1H, d, J=3 Hz, H-1), 5.26 (1H, m, H-7), 5.72 (1H, d, J=9 Hz, NH). The fractions [R_f 0.55, chloroform–methanol (10:1)] recovered **4** (359 mg).

To a solution of **5** (951 mg) in dimethyl sulfoxide (10 ml), a suspension of sodium borohydride (250 mg) in dimethyl sulfoxide (5 ml) was added. After stirring for 1 h at room temperature, the mixture was acidified with Amberlite IR-120 (H^+) resin and partitioned between dichloromethane (100 ml) and water (100 ml). The aqueous layer was extracted with dichloromethane (200 ml). The organic layer and the extracts were combined and washed with water (200 ml), and dried. After concentration, the residue was recrystallized from chloroform–petroleum ether to afford **6** (484 mg). Chromatography of the mother liquor on silica gel with ethyl acetate–2-butanone (10:1) gave an additional crop of **6** (310 mg, total yield 41% based on **4**): Mp 110 °C (decomp); $[\alpha]_D^{27}$ +124° (c 1.0, methanol); ^1H NMR ($CDCl_3$) δ=0.91 (3H, m, H-10), 1.17—2.19 (10H, m, H-3,4,7,8,9), 1.96 (3H, s, NAc), 3.33 and 3.38 (3H in total, each s, OMe), 4.54 (1H, d, J=3 Hz, H-1), 5.70 (1H, d, J=9 Hz, NH).

Methyl 2,6-Diacetamido-2,3,4,6,7,8,9,10-octadeoxy-β-L-*lyxo*-decopyranoside (7) and α-D-*ribo*-decopyranoside (8). A solution of **6** (730 mg) in methanol (10 ml) was hydrogenated in the presence of Raney nickel at an initial hydrogen pressure of 3.4 kg cm^{-2} for 18 h. After removal of the catalyst, the filtrate was concentrated. The residue was treated with acetic anhydride (4 ml) in methanol (10 ml) for 2 h. The mixture was concentrated and was chromatographed on silica gel with toluene–ethanol (10:1). Fractions [R_f 0.45, toluene–ethanol (3:1)] gave **7** (434 mg, 57%) as an amorphous solid: Mp 224—225.5 °C; $[\alpha]_D^{22}$ +43.4° (c 1.0, methanol); ^1H NMR (CD_3OD) δ=0.90 (3H, t, J=7 Hz, H-10), 1.32 (4H, m, H-8,9), 1.43—1.89 (6H, m, H-3,4,7), 1.92 and 1.98 (each 3H, s, NAc), 3.38 (3H, s, OMe), 3.74 (1H, dt, J=3.5 Hz, 10 Hz, H-5), 3.86 (1H, dt, J=3.5 Hz, 7 Hz, H-6), 3.88 (1H, ddd, J=3.5 Hz, 5.5 Hz, 12 Hz, H-2), 4.61 (1H, d, J=3.5 Hz, H-1).

Found: C, 59.89; H, 9.24; N, 9.08%; m/z, 300.2041. Calcd for $C_{15}H_{28}N_2O_4$: C, 59.98; H, 9.40; N, 9.33%; M^+, 300.2047.

The fractions [R_f 0.41, toluene–ethanol (3:1)] gave **8** (143 mg, 19%): Mp 252.5—254 °C; $[\alpha]_D^{22}$ +147° (c 0.86, methanol); ^1H NMR (CD_3OD) δ=0.90 (3H, t, J=7 Hz, H-10), 1.27—1.83 (10H, m, H-3,4,7,8,9), 1.92 and 1.94 (each 3H, s, NAc), 3.36 (3H, s, OMe), 3.60 (1H, ddd, J=2 Hz, 6 Hz, 11 Hz, H-5), 3.76 (1H, ddd, J=3 Hz, 6 Hz, 10 Hz, H-6), 3.88 (1H, ddd, J=3.5 Hz, 6.5 Hz, 10.5 Hz, H-2), 4.60 (1H, d, J=3.5 Hz, H-1).

1-*O*-Acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,4,6,7,8,9,10-octadeoxy-L-*lyxo*-decopyranose (9). A stirred solution of **7** (430 mg) in 2 M hydrochloric acid (10 ml) was refluxed for 23 h. The mixture was cooled to room temperature and concentrated, and dried in vacuum. To a solution of the residue in methanol (15 ml) containing 2,4-dinitrofluorobenzene (0.38 ml), triethylamine (0.8 ml) was added dropwise under ice cooling. After stirring for 1 h at 0 °C, the mixture was partitioned between ethyl acetate (50 ml) and water (30 ml). The aqueous layer was extracted with ethyl acetate (80 ml), and the organic layer and the extract were combined and dried. After concentration, the residue was treated with acetic anhydride (5 ml) in pyridine (10 ml) for 4 h at room temperature. The mixture was poured into ice water (100 ml) and the solution was extracted with dichloromethane (200 ml). The extract was successively washed with 1 M hydrochloric acid (200 ml) and water (200 ml), and dried. After concentration, the residue was chromatographed on silica gel with toluene–2-butanone (50:1—30:1) to afford **9** (218 mg, 26% based on **7**) as yellow syrup: $[\alpha]_D^{24}$ −42.4° (c 1.0, chloroform); ^1H NMR ($CDCl_3$) δ=1.99 and 2.25 (3H in total, each s, OAc), 5.65 (1/4H, d, J=9 Hz, H-1β), 6.35 (3/4H, d, J=3 Hz, H-1α), 6.91 and 7.31 (each 1H, d, J=11 Hz, H-3 of DNP), 8.24 and 8.33 (each 1H, dd, J=3 Hz, 11 Hz, H-5 of DNP), 8.48 and 8.86 (each 1H, d, J=10 Hz, NH-2,6), 9.10 and 9.15 (each 1H, d, J=3 Hz, H-6 of DNP).

Found: m/z, 576.1823. Calcd for $C_{24}H_{28}N_6O_{11}$: M^+, 576.1814.

1,4,2′,6′-Tetrakis[*N*-(methoxycarbonyl)]fortimicin B (10). To a solution of fortimicin B (5.80 g) in aqueous acetone (1:1, 200 ml), anhydrous sodium carbonate (5.29 g) and methyl chloroformate (7.85 ml) were added and the mixture was stirred for 20 min under ice cooling. The mixture was concentrated and the residue was partitioned between water (150 ml) and chloroform (150 ml). The aqueous layer was extracted with chloroform (250 ml), and the organic layer and the extract were combined and dried. After concentration, the residue was washed with petroleum ether to give **10** (9.50 g, 98%): Mp 85—92 °C; $[\alpha]_D^{19}$ +63.5° (c 1.21, chloroform); ^1H NMR ($CDCl_3$) δ=1.08 (3H, d, J=6 Hz, H-7′), 3.62, 3.65, 3.70, and 3.75 (each 3H, s, Cbm), 3.00 (3H, s, NMe), 3.42 (3H, s, OMe), 4.84 (1H, d, J=3 Hz, H-1′).

2,5-Di-*O*-benzoyl-1,4,2′,6′-tetrakis[*N*-(methoxycarbonyl)]-fortimicin B (11). To a solution of **10** (1.0 g) in pyridine (10 ml), benzoyl chloride (1.2 ml) was added and the mixture was stirred for 65 h at 60 °C. After cooling to room temperature, the mixture was poured into ice water (100 ml). The mixture was extracted with ethyl acetate (200 ml) and the extract was washed successively with 1 M hydrochloric acid (100 ml), saturated aqueous $NaHCO_3$ (100 ml), and water (100 ml), and dried. After concentration, the residue was chromatographed on silica gel with chloroform–methanol (40:1). Fractions [R_f 0.58, chloroform–methanol (20:1)] were concentrated and the residue was crystallized from ether–chloroform–petroleum ether to give **11** (890 mg, 65%): Mp 115—121 °C; $[\alpha]_D^{27}$ +13.4° (c 1.19, chloroform); ^1H NMR ($CDCl_3$) δ=1.09 (3H, d, J=6 Hz, H-7′), 2.92 (3H, s,

NMe), 3.49 (3H, s, OMe), 3.55, 3.64, 3.67, and 3.77 (each 3H, s, Cbm), 5.04 (1H, d, J=3 Hz, H-1′).

Found: C, 56.13; H, 6.04; N, 6.98%. Calcd for $C_{37}H_{48}N_4O_{15}$: C, 56.34; H, 6.13; N, 7.10%.

2,5-Di-*O*-benzoyl-1,4-bis[*N*-(methoxycarbonyl)]fortamine B (12). A solution of **11** (890 mg) in acetic acid (4 ml) containing 2 M hydrochloric acid (1 ml) was stirred for 4 h at 80 °C. After cooling to room temperature, the mixture was diluted with water (20 ml). The mixture was extracted with dichloromethane (100 ml) and the extract was washed successively with saturated aqueous $NaHCO_3$ (200 ml), brine (100 ml) and water (100 ml), and dried. After concentration, the residue was chromatographed on silica gel with chloroform–methanol (99:1). Fractions [R_f 0.32, chloroform–methanol (50:1)] gave **12** (476 mg, 79%). Recrystallization from ether–petroleum ether afforded an analytical sample: mp 104—113 °C; $[\alpha]_D^{22}$ +18.0° (c 0.65, chloroform); ^{1}H NMR ($CDCl_3$) δ=3.00 (3H, s, NMe), 3.29 (1H, bs, OH-6), 3.48 (3H, s, OMe), 3.60 and 3.64 (each 3H, s, Cbm), 4.04 (1H, dd, J=3 Hz, 8 Hz, H-3), 4.28 (2H, m, H-1,6), 4.97 (1H, dd, J=5 Hz, 8 Hz, H-4), 5.29 (1H, d, J=8 Hz, NH-1), 5.69 (1H, dd, J=5 Hz, 7 Hz, H-5), 5.78 (1H, dd, J=3 Hz, 7 Hz, H-2), 7.40—7.62 (6H, m, benzoyl), 7.98—8.10 (4H, m, benzoyl).

Found: C, 58.66; H, 5.69; N, 5.16%. Calcd for $C_{26}H_{30}N_2O_{10}$: C, 58.86; H, 5.70; N, 5.28%.

2,5-Di-*O*-benzoyl-2′,6′-bis[*N*-(2,4-dinitrophenyl)]-1,4-bis-[*N*-(methoxycarbonyl)]-7′-propylfortimicin B (13). To a mixture of **9** (218 mg), **12** (200 mg), and powdered molecular sieve 4A (200 mg) in 1,2-dichloroethane (5 ml) was added trimethylsilyl trifluoromethanesulfonate (0.07 ml) and the mixture was stirred for 2 h under argon. The mixture was diluted with dichloromethane (40 ml) and an insoluble material was filtered. The filtrate was washed with saturated aqueous $NaHCO_3$ (40 ml) and water (40 ml), and dried. After concentration, the residue was chromatographed on silica gel eluting with toluene–2-butanone (50:1—20:1) to give **13** (195 mg, 49%): Mp 127—132 °C; $[\alpha]_D^{27}$ + 0.8° (c 0.4, chloroform); ^{1}H NMR ($CDCl_3$) δ=2.82 (3H, s, NMe), 3.43 (3H, s, OMe), 3.52 and 3.64 (each 3H, s, Cbm), 3.70 (2H, m, H-2′,6′), 3.95 (1H, m, H-1), 4.09 (1H, dd, J=3 Hz, 10 Hz, H-3), 4.54 (1H, m, H-6), 4.88 (1H, m, H-4), 5.18 (1H, d, J=9 Hz, NH-1), 6.28 (1H, d, J=3 Hz, H-1′), 5.44 (1H, m, H-5), 5.77 (1H, m, H-2), 6.86 and 7.02 (each 1H, d, J=9 Hz, H-3 of DNP), 7.22—7.66 (6H, m, benzoyl), 7.88 and 8.16 (each 2H, d, J=8.5 Hz, bezoyl), 8.16 and 8.28 (each 1H, dd, J=3 Hz, 9 Hz, H-5 of DNP), 8.64 (2H, m, NH-2′,6′), 9.12 and 9.14 (each 1H, d, J=3 Hz, H-6 of DNP).

Found: C, 54.65; H, 5.20; N, 10.88%. Calcd for $C_{48}H_{54}N_8O_{19}$: C, 55.07; H, 5.20; N, 10.70%.

7′-Propylfortimicin B (14). A stirred solution of **13** (204 mg) in aqueous dioxane (1:2, 15 ml) containing barium hydroxide octahydrate (3.80 g) was refluxed for 14 h. The mixture was cooled to room temperature and the solid was filtered. Carbon dioxide was introduced to the filtrate and an insoluble material was filtered. After concentration, the residue was treated with Amberlite IRA-400 (OH^-) resin (13 ml) in a mixture of water (10 ml), methanol (15 ml) and acetone (15 ml). After stirring for 15 h, the resin was filtered, and the filtrate was neutralized with 1% H_2SO_4. After concentration of the solution, the residue was chromatographed on a column of Amberlite CG-50 (NH_4^+) resin (35 ml) with 0—0.20 M aq ammonia with gradient increase in concentration. Fractions [R_f 0.60, isopropyl alcohol–chloroform–concd aq ammonia (4:1:1)] gave **14** (51 mg, 68%): $[\alpha]_D^{27}$ +8.6° (c 1.54, water); IR (KBr) 3350, 2930, 1570, 1460, 1370, 1090 cm^{-1}; ^{1}H NMR (D_2O) δ=0.89 (3H, m, H-10′), 1.20—1.90 (10H, m, H-3′,4′,7′,8′,9′), 2.40 (3H, s, NMe), 2.82—2.96 (2H, m, H-2′,6′), 3.01 (1H, t, J=9.5 Hz, H-1), 3.11 (1H, dd, J=4 Hz, 4.5 Hz, H-4), 3.48 (3H, s, OMe), 3.53 (1H, t, J=9.5 Hz, H-6), 3.69 (1H, t, J=4 Hz, H-3), 3.72 (1H, dd, J=4 Hz, 9.5 Hz, H-2), 3.82 (1H, m, H-5′), 4.01 (1H, dd, J=4.5 Hz, 9.5 Hz, H-5), 5.16 (1H, d, J=3 Hz, H-1′).

Found: C, 52.80; H, 9.14; N, 13.29%; m/z, 391. Calcd for $C_{18}H_{38}N_4O_5 \cdot 1/2H_2CO_3$: C, 52.71; H, 9.32; N, 13.29%; M+1, 391.

1,2′,6′-Tris[*N*-(benzyloxycarbonyl)]-7′-propylfortimicin B (15). To a solution of **14** (49 mg) in aqueous methanol (1:2, 6 ml), *N*-(benzyloxycarbonyloxy)succinimide (97 mg) was added under ice cooling and the mixture was stirred for 3 h at 0 °C, and stirring was continued for 23 h at room temperature. After addition of 5% aqueous $NaHCO_3$ (10 ml) to the solution, the mixture was extracted with chloroform (30 ml) and the extract was dried. After concentration, the residue was chromatographed on silica gel with chloroform–methanol (30:1) to give **15** (59 mg, 60%): $[\alpha]_D^{27}$ +11.4° (c 1.66, chloroform); ^{1}H NMR ($CDCl_3$) δ=2.26 (3H, s, NMe), 3.39 (3H, s, OMe), 5.00 (6H, bs, benzyl×3), 7.27 (15H, s, phenyl×3).

1,2′,6′-Tris[*N*-(benzyloxycarbonyl)]-4-[*N*-[*N*-(benzyloxycarbonyl)glycyl]]-7′-propylfortimicin B (16). To a solution of **15** (57 mg) in dioxane (5 ml), *N*-[*N*-(benzyloxycarbonyl)-glycyloxy]succinimide (27 mg) and triethylamine (0.01 ml) were added and the mixture was stirred for 13 h at 60 °C. After cooling to room temperature, 5% aqueous $NaHCO_3$ (20 ml) was added to the mixture and the mixture was extracted with chloroform (30 ml). The extract was washed with water (30 ml), and dried. After concentration, the residue was chromatographed on silica gel with chloroform–methanol (50:1) to give **16** (62 mg, 86%): $[\alpha]_D^{25}$ +21.2° (c 1.16, chloroform); ^{1}H NMR ($CDCl_3$) δ=2.78 (3H, s, NMe), 3.27 (3H, s, OMe), 4.78 (1H, d, J=3 Hz, H-1′), 5.06 (8H, s, benzyl×4), 7.31 (20H, s, phenyl×4).

Found: C, 63.46; H, 6.65; N, 6.87%. Calcd for $C_{52}H_{66}N_5O_{14}$: C, 63.40; H, 6.75; N, 7.11%.

7′-Propylfortimicin A (17). A solution of **16** (53 mg) in methanol (5 ml) was hydrogenated in the presence of 10% palladium on charcoal (50 mg) at an initial hydrogen pressure of 3.4 kg cm^{-2} for 4 h. The catalyst was removed and the solution was concentrated. The residue was dissolved in water and passed through a column of Amberlite IRA-400 (OH^-) resin using water as an eluent. Fractions [R_f 0.39, isopropyl alcohol–chloroform–concd aq ammonia (4:1:1)] were collected and the solution was adjusted to pH 5 with 1% H_2SO_4. The mixture was concentrated to a residue, which was recrystallized from methanol–acetone to give **17** (25 mg, 70%) as the disulfate: $[\alpha]_D^{25.5}$ +63.5° (c 0.47, water); IR (KBr) 3430, 2920, 1485, 1110, 1030 cm^{-1}; ^{1}H NMR (D_2O) δ=0.92 (3H, t, J=7 Hz, H-10′), 1.41, 1.65, and 2.02 (10H in total, each m, H-3′,4′,7′,8′,9′), 3.16 (3H, s, NMe), 3.52 (3H, s, OMe), 4.88 (1H, dd, J=2 Hz, 12 Hz, H-4), 5.33 (1H, d, J=3.5 Hz, H-1′).

Found: C, 35.72; H, 7.04; N, 9.80%; m/z, 448. Calcd for $C_{20}H_{41}N_5O_6 \cdot 2H_2SO_4 \cdot 2H_2O$: C, 35.35; H, 7.27; N, 10.30%; M+1, 448.

The authors wish to express their thanks to Drs. Kunikatsu Shirahata and Hiroshi Sano of Kyowa Hakko Co. for performing antibacterial assay. We also would like to thank Dr. Yoshimasa Fukuda and Mr. Osamu Sakanaka of Meiji Seika Co. for measurement of mass, ^{13}C and ^{1}H NMR spectra, and Mr. Saburo Nakada and Mr. Akio Takahashi of the University for elemental analyses.

A Simple and Convenient Method for the Synthesis of Iminomethylene Analogs of Peptides

Hidekazu Oyamada and Masaaki Ueki*
Department of Applied Chemistry, Science University of Tokyo,
1-3 Kagurazaka, Shinjuku-ku, Tokyo 162
(Received June 26, 1986)

The synthesis of pseudopeptides in which a part of the peptide bonds has been replaced by other isosteric bonds has been studied in order to obtain long-lasting peptide drugs and also to study the structure-activity relationships of peptides with biological activity. A simple and convenient method for the synthesis of pseudo[CH_2-NH]peptides was established by improving the conditions for the selective reduction of the peptide bond of *N*-protected dipeptide esters by borane. Among the ester residues investigated, the *t*-butyl ester gave the best result. During reactions no racemization occurred. [L-Pheψ[CH_2-NH]L-Leu$^{4-5}$]leucine-enkephalin was synthesized in good yield starting from *N*-benzyloxycarbonyl-L-phenylalanyl-L-leucine *t*-butyl ester.

Numbers of biologically active peptides which can be isolated or the sequences of which are determined by gene technical methods have been increasing. In the study of their physiological roles and their applications as drugs, native peptides have a substantial restriction due to their rapid degradation by peptidase. As a method for increasing the stability of peptides towards proteolytic enzymes, (and at the same time to determine the contribution of a specific amino acid residue to the biological activity,) syntheses of analogues with some residues replaced by unnatural amino acids such as *N*-methyl amino acids or D-amino acids have been tried with success.

As another approach to this problem, the syntheses of pseudopeptides in which a specific peptide bond is replaced by an appropriate isosteric bond stable to hydrolysis (such as CH=CH, CH_2-CO, CH_2-CH_2, CH_2-S, or CH_2-NH) have been studied. Among these isosteric bonds, the CH_2-NH bond has the characteristic that it maintains the amine function with a capacity as a hydrogen-bond donor. However, ψ[CH_2-NH]peptides have so far not been widely utilized since methods for the introduction of this bond to any desired position in a sequence of peptide have not been established. This study offers the first general method for the preparation of an *N*-protected ψ[CH_2-NH]dipeptide acid unit necessary for the synthesis of ψ[CH_2-NH]peptides.

The synthesis of ψ[CH_2-NH]peptides have been approached from two routes: 1) by direct CH_2-NH bond formation from a peptide aldehyde and a peptide ester, either through a Schiff-base formation followed by hydrogenation[1,2] or by a reductive alkylation[3] and 2) by the incorporation of a protected ψ[CH_2-NH]dipeptide acid unit by a usual peptide synthetic method.[4] The ψ[CH_2-NH]dipeptide acid units have been prepared from 2-(protected amino)ethyl tosylate[4] or halo acid[5] by a substitution reaction, or from protected dipeptide esters (either by the selective reduction of the peptide bond by borane followed by hydrolysis[6] or by reduction by sodium bis(2-methoxyethoxy)aluminium hydride followed by oxidation[4]). Most of these routes, however, can not be the general method owing to the complexity of the reactions. Only one exception, a reduction by borane, has a substantial possibility to be a general method. However, the procedure proposed by Roeske's group is not practically applicable because of the poor yield and difficulty of separation of the desired product from the by-products.[4] In this study we reinvestigated the conditions for a reduction of protected dipeptide esters by borane in order to establish a general method for the incorporation of the CH_2-NH bond in any desired position of the peptides.

A retention of asymmetry at chiral centers during the reduction and the necessity of protecting the generated secondary amine function during peptide bond elongation steps are also discussed.

Results and Discussion

Borane is known to reduce amide bonds selectively, but in the case of a protected dipeptide ester, a reduction of the ester moiety often accompanies this reaction. Roeske's group reported that a concurrent reduction of the ester bond was minimized by carrying out the reaction at −20 °C with 2 mol of BH_3 for 4—5 h. However, the fact that such selectivity is obtained only in a low conversion-stage restricted the practical application of their procedure. Then, we examined in detail the conditions for the reduction of protected dipeptide esters by borane and the effects of ester residues on the product yields.

Optimization of the conditions of the reduction of protected dipeptide esters by borane was tried by using *N*-benzyloxycarbonyl(Z)-L-phenylalanyl-L-Phenylalanine 2-methoxyethyl ester (**1a**) as a model compound.

e: X=Z, AA^1=L-Phe, AA^2=D-Leu, Y=$C(CH_3)_3$
f: X=Z, AA^1=Gly, AA^2=L-Phe, Y=$C(CH_3)_3$
g: X=Boc, AA^1=L-Phe, AA^2=L-Leu, Y=CH_3

Borane-tetrahydrofuran (THF) was added to a solution of **1a** in THF at −20 °C and then the temperature was increased to the point to be studied. After having been stirred at that temperature for an appropriate period, the remaining borane was quenched by the addition of methanol and the mixture was further treated with 1 M† HCl for 15 min to destroy boron-nitrogen bonds in products. Then, products were separated and isolated by preparative thin-layer chromatography (TLC) on silica gel. The results are summarized in Table 1 together with the results of a reduction of various kinds of protected dipeptide esters.

When the reaction temperature was raised between −5 and 0 °C, the yield of the corresponding pseudopeptide ester **2a** increased, while some part of it was further reduced to the pseudopeptide alcohol **4a** (Entries 3—5). In this case, the product of the selective reduction of the ester moiety, peptide alcohol **3a**, was not obtained. When the temperature was further raised to 30 °C, no further improvement in the conversion ratio of the starting material and yield of the desired product was obtained (Entry 6). Thus, the highest yield of the protected pseudodipeptide ester was obtained when a reduction of the protected dipeptide ester was carried out by use of 10 mol of BH_3 at 0 °C for 10 h (Entry 5).

In Entries 7—9 the effects of ester residues on the yield of the products were shown. The structure of the ester moiety has an important role in determining the ratio of the products. As expected, *t*-butyl ester (Entry 9) gave the highest yield of the desired pseudopeptide ester. However, a low yield was encountered in the case of Z-Gly-L-Phe-OBu^t, reflecting the lower reactivity of BH_3 toward α-unsubstituted amides[7] (Entry 11). On the other hand, these conditions are also applicable to *N*-*t*-butoxycarbonyl-dipeptide ester (Entry 12).

Racemization during the reduction was checked for two pseudopeptides, Z-L-Pheψ[CH_2-NH]L-Leu-OBu^t (**2d**) and Z-L-Pheψ[CH-NH]D-Leu-OBu^t (**2e**). Compounds **2d** and **2e** were deprotected by HBr in acetic acid and the free pseudodipeptides obtained were analyzed by reverse-phase HPLC.[8] Both compounds were eluted separately, and L-Pheψ[CH_2-NH]D-Leu was not detected in a sample of synthesized L-Pheψ[CH_2-NH]L-Leu. Since D-Pheψ[CH_2-NH]L-Leu, a mirror image of the L-Pheψ[CH_2-NH]D-Leu, should be eluted at the same position as L-Pheψ[CH_2-NH]D-Leu it can be concluded that racemization does not occur during the reduction at both chiral centers of the dipeptides.

In planning the synthesis of ψ[CH_2-NH]peptides by utilizing the ψ[CH_2-NH]dipeptide unit thus obtained, the necessity of protecting the secondary amine function should be considered. Most of the syntheses used so far protecting groups,[4] but syntheses without protection have also been reported.[1,2] In order to clarify this point and at the same time to determine the effect of a displacement of the peptide bond by an isosteric bond on the biological activity, we synthesized a pseudopeptide analogue of Leu-

Table 1. Reduction of *N*-Protected Dipeptide Esters **1a—g** by Borane

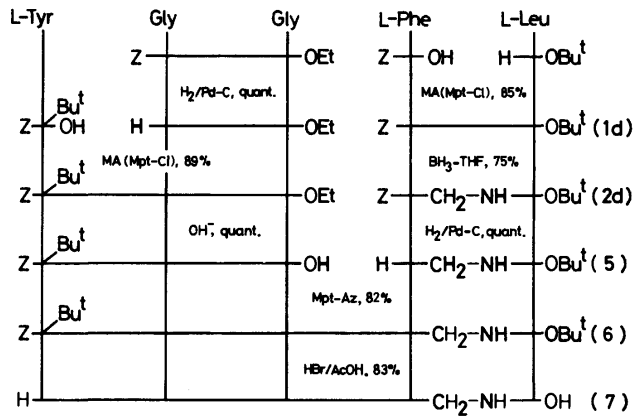
† 1 M=1 mol dm^{-3}.



Scheme 1. Synthesis of [L-Pheψ[CH_2–NH]L-Leu$^{4-5}$]-leucine-enkephalin.

enkephalin, in which a peptide bond between Phe^4 and Leu^5 residues was replaced by the CH_2–NH bond. The synthetic route is shown in Scheme 1.

The benzyloxycarbonyl group of **2d** was removed by catalytic hydrogenolysis to give H-L-Pheψ[CH_2–NH]L-Leu-OBu^t (**5**) in quantitative yield as dihydrochloride. The coupling of **5** with a protected *N*-terminal tripeptide acid unit was carried out with the use of dimethylphosphinothioic azide as a coupling reagent[9,10] to afford the desired protected pseudopentapeptide ester, Z-L-Tyr(Bu^t)-Gly-Gly-L-Pheψ-[CH_2–NH]L-Leu-OBu^t (**6**), in 82% yield. In this reaction no significant amount of side products could be detected, showing that the protection of the secondary amine function was not necessary. The removal of all the protecting groups by HBr in acetic acid, followed by purification by preparative TLC and gel chromatography on Sephadex LH-20 gave chromatographically homogeneous [L-Pheψ[CH_2–NH]L-Leu$^{4-5}$]leucine-enkephalin (**7**) in 83% yield.

Measurements of the pharmacological activity of **7** in in vitro isolated tissue preparations are now being studied. Results will be reported elsewhere.

Experimental

All the melting points were uncorrected. TLC was performed on silica-gel plates (Merck 60 GF_{254}) in the following solvent systems(v/v): chloroform-methanol (9:1, R_f^1), chloroform-methanol (49:1, R_f^2), ether-petroleum ether (1:1, R_f^3), ethyl acetate (R_f^4), chloroform-methanol-water (65:25:4, R_f^5), chloroform-methanol-acetic acid (85:25:20, R_f^6), chloroform-methanol-acetic acid (95:5:3, R_f^7), 1-butanol-acetic acid-water (4:1:1, R_f^8). Diborane solution in THF was prepared from $NaBH_4$ and boron trifluoride etherate and standardized before use. For most of the experiments the concentration was approximately 2 M in BH_3. All the stepwise syntheses of protected di- and tripeptides were mediated with the mixed anhydride method with the use of dimethylphosphinothioic chloride (Mpt-Cl) as the coupling reagent.[11]

H-L-Phe-$OCH_2CH_2OCH_3$·HCl (8) and H-L-Leu-$OCH_2CH_2OCH_3$·HCl (9): These compounds were prepared from the corresponding amino acids and 2-methoxyethanol by the usual method using thionyl chloride. **8**: Mp 173.0—175.6 °C; $[\alpha]_D^{22}$ +15.7° (*c* 2.0, abs. EtOH); **9**: Mp 124.8—125.2 °C; $[\alpha]_D^{22}$ +12.5° (*c* 2.0, abs. EtOH).

Z-L-Phe-L-Phe-$OCH_2CH_2OCH_3$ (1a): The Mpt-Cl (2.57 g, 20 mmol) was added at rt to a stirred mixture of Z-L-Phe-OH (5.99 g, 20 mmol) and triethylamine (2.79 ml, 20 mmol) in chloroform (20 ml). After 30 min, to this solution, **8** (5.20 g, 20 mmol) in chloroform (20 ml) and triethylamine (5.58 ml, 40 mmol) were added at 0 °C and the solution was stirred at rt for 11 h. All the volatile materials were removed in vacuo. The residue was taken in ethyl acetate and the solution washed in the usual manner and dried. After evaporation of the solvent, the crude material was recrystallized from ethyl acetate-petroleum ether. Yield 8.57 g (85%); mp 119.5—120.0 °C; $[\alpha]_D^{27}$ +24.8° (*c* 1.0, $CHCl_3$); R_f^2=0.60, R_f^3=0.10; ^{1}H NMR ($CDCl_3$) δ=2.9—3.2 (m, 4H), 3.3—3.7 (m, 5H), 4.1—4.9 (m, 4H), 5.0 (s, 2H), 5.3—5.6 (d, 1H), 6.3—6.7 (d, 1H), 6.9—7.4 (aromatic protons, 15H).

Found: C, 68.71; H, 6.36; N, 5.40%. Calcd for $C_{29}H_{32}O_6N_2$: C, 69.03; H, 6.39; N, 5.55%.

Z-L-Phe-L-Leu-$OCH_2CH_2OCH_3$ (1b): This compound was obtained using **9** in the same way as described above. Crude products were recrystallized from ether-petroleum ether. Yield 62%; mp 77.0—77.8 °C; $[\alpha]_D^{27}$ −4.7° (*c* 1.0, $CHCl_3$); R_f^2=0.55, R_f^3=0.13; ^{1}H NMR($CDCl_3$) δ=0.8—1.0 (d, 6H), 1.4—1.9 (m, 3H), 3.0—3.2 (d, 2H), 3.35 (s, 3H), 3.5—3.7 (t, 2H), 4.1—4.8 (m, 4H), 5.07 (s, 2H), 5.2—5.5 (broad, 1H), 6.1—6.6 (broad, 1H), 7.1—7.4 (aromatic protons, 10H).

Found: C, 66.22; H, 7.24; N, 5.96%. Calcd for $C_{26}H_{34}O_6N_2$: C, 66.36; H, 7.28; N, 5.95%.

General Procedure for the Reduction of *N*-Protected Dipeptide Esters by BH_3-THF (Table 1): Borane-THF solution (2.5—5.0 mmol) was slowly added to the stirred solution of **1** (0.5 mmol) in THF at −20 °C. The reaction mixture was stirred at an appropriate temperature for an appropriate period (see Table 1). The reaction was quenched by the addition of methanol (5 ml) and then 1 M HCl (5 ml). After stirring for 15 min, the pH of the mixture was adjusted to 7—8 by a 5% aq $NaHCO_3$ solution. After removing THF in vacuo the desired product was extracted with chloroform or ethyl acetate. The combined extracts were washed, dried and evaporated under a reduced pressure, and the residue was purified by preparative silica-gel TLC.

Reduction of Z-L-Phe-L-Phe-$OCH_2CH_2OCH_3$ (1a): The reaction was carried out according to the general procedure. The purification by TLC was performed twice using different solvent systems; ether-petroleum ether (2:1 v/v) and then chloroform-methanol (20:1 v/v). **2a** was obtained as pale-yellow crystals; mp 63.0—63.2 °C; $[\alpha]_D^{26}$ +15.2° (*c* 2.6, $CHCl_3$); R_f^2=0.57, R_f^3=0.17; ^{1}H NMR ($CDCl_3$) δ=1.77 (broad, 1H), 2.15—3.1 (m, 6H), 3.1—4.4 (m, 9H), 4.9—5.3 (m, 3H), 6.8—7.4 (aromatic protons, 15H).

Found: C, 70.88; H, 6.97; N, 5.69%. Calcd for $C_{29}H_{34}O_5N_2$: C, 71.00; H, 6.99; N, 5.71%.

4a was obtained as colorless crystals. An analytical sample was recrystallized from ethyl acetate-petroleum ether; mp 111.0—111.7 °C; $[\alpha]_D^{26}$ +16.0° (*c* 0.6, $CHCl_3$); R_f^1=

0.49, R_f^5=0.38; ^{1}H NMR ($CDCl_3$) δ=2.25 (broad, 2H), 2.5—2.9 (m, 7H), 3.1—4.2 (m, 3H), 4.9—5.3 (m, 3H), 6.9—7.4 (aromatic protons, 15H).

Found: C, 74.32; H, 7.21; N, 6.57%. Calcd for $C_{26}H_{30}O_3N_2$: C, 74.61; H, 7.23; N, 6.69%.

Reduction of Z-L-Phe-L-Leu-OCH$_2$CH$_2$OCH$_3$ (1b): The reaction of **1b** (235 mg, 0.5 mmol) was carried out according to the general procedure. Purification by TLC was performed twice using different solvent systems; ether–petroleum ether (2:1 v/v) and then chloroform–methanol (10:1 v/v) to give **2b** as pale-yellow crystals; mp 54.0—55.0 °C; $[\alpha]_D^{19}$ −16.2° (*c* 1.0, $CHCl_3$); R_f^2=0.56, R_f^3=0.25; ^{1}H NMR ($CDCl_3$) δ=0.8—1.1 (d, 6H), 1.3—1.9 (m, 4H), 2.3—3.0 (m, 4H), 3.1—4.3 (m, 9H), 5.0—5.3 (m, 3H), 7.1—7.4 (aromatic protons, 10H).

Found: C, 67.94; H, 7.88; N, 5.92%. Calcd for $C_{26}H_{36}O_5N_2$: C, 68.39; H, 7.95; N, 6.14%.

3b (10.4 mg, 5.2%) was identical with the authentic sample prepared by the reduction of Z-L-Phe-L-Phe-OMe by $NaBH_4$; mp 119.0—121.3 °C; R_f^1=0.69, R_f^4=0.74.

4b (18.7 mg, 9.7%) was obtained as colorless crystals; mp 100.7—102.0 °C; R_f^1=0.44; R_f^4=0.13; ^{1}H NMR ($CDCl_3$) δ=0.7—1.0 (m, 6H), 1.0—1.9 (m, 3H), 2.1—4.4 (m, 10H), 5.0—5.3 (m, 3H), 7.1—7.6 (aromatic protons, 10H).

Reduction of Z-L-Phe-L-Leu-OMe (1c): According to the general procedure, **1c** (213 mg, 0.5 mmol) was reduced. **2c** was obtained as colorless crystals; 133 mg (64%); mp 66.0—68.0 °C; $[\alpha]_D^{19}$ −16.7° (*c* 1.0, $CHCl_3$); R_f^2=0.68; R_f^3=0.44; ^{1}H NMR ($CDCl_3$) δ=0.8—1.1 (d, 6H), 1.2—2.0 (m, 4H), 2.2—3.4 (m, 5H), 3.6—4.2 (m, 4H), 5.0—5.2 (m, 3H), 7.0—7.4 (aromatic protons, 10H).

Found: C, 69.72; H, 7.74; N, 6.48%. Calcd for $C_{24}H_{32}O_4N_2$: C, 69.88; H, 7.82; N, 6.79%.

Reduction of Z-L-Phe-L-Leu-OBu^t (1d): According to the general procedure, **1d** (217 mg, 0.5 mmol) was reduced. **2d** was obtained as colorless oil (158 mg, 75%); $[\alpha]_D^{19}$ −13.4° (*c* 1.1, $CHCl_3$); R_f^2=0.70; R_f^3=0.48.

Found: C, 70.47; H, 8.33; N, 5.76%. Calcd for $C_{27}H_{38}O_4N_2 \cdot 1/3H_2O$: C, 70.40; H, 8.46; N, 6.08%.

The acetic acid salt of **2d** was obtained as colorless crystals: Mp 76.8—78.6 °C; $[\alpha]_D^{27}$ −7.5° (*c* 1.0, $CHCl_3$).

Found: C, 67.47; H, 8.20; N, 5.47%. Calcd for $C_{29}H_{42}O_6N_2$: C, 67.68; H, 8.23; N, 5.44%.

Reduction of Z-L-Phe-D-Leu-OBu^t (1e): According to the general procedure, **1e** (141 mg, 0.30 mmol) was reduced. TLC purification in the solvent system of ether–petroleum ether (2:3 v/v) gave **2e** as a pale-yellow oil; 67.3 mg (49%); $[\alpha]_D^{25}$ +5.3° (*c* 3.8, $CHCl_3$); R_f^2=0.69; R_f^3=0.46. ^{1}H NMR ($CDCl_3$) δ=0.8—1.1 (d, 6H), 1.2—1.9 (m, 13H), 2.3—3.2 (m, 5H), 3.6—4.1 (broad, 1H), 5.0—5.3 (m, 3H), 7.1—7.4 (aromatic protons, 10H).

Found: C, 71.29; H, 8.37; N, 6.29%. Calcd for $C_{27}H_{38}O_4N_2$: C, 71.33; H, 8.43; N, 6.16%.

Reduction of Z-Gly-L-Phe-OBu^t (1f): According to the general procedure, **1f** (170 mg, 0.41 mmol) was reduced. TLC purification using ether as a solvent gave colorless oil of **2f**; 27.2 mg (17%); $[\alpha]_D^{27}$ +6.9° (*c* 3.0, methanol); R_f^1=0.80; R_f^5=0.56. ^{1}H NMR ($CDCl_3$) δ=1.35 (s, 9H), 1.65 (s, 1H), 2.6—3.6 (m, 7H), 5.0—5.3 (m, 3H), 7.1—7.4 (aromatic protons, 10H).

Found: C, 69.07; H, 7.56; N, 7.13%. Calcd for $C_{23}H_{30}O_4N_2$: C, 69.32; H, 7.59; N, 7.03%.

Reduction of Boc-L-Phe-L-Leu-OMe (1g): According to the general procedure, **1g** (157 mg, 0.40 mmol) was reduced. TLC purification using ether then chloroform–methanol (20:1 v/v) gave **2g** as colorless crystals; 71.7 mg (47%); mp 83.0—85.0 °C; $[\alpha]_D^{26}$ −2.3° (*c* 2, $CHCl_3$); R_f^2=0.63, R_f^3=0.48; ^{1}H NMR ($CDCl_3$) δ=0.6—1.1 (m, 6H), 1.4—2.0 (m, 13H), 2.2—3.5 (m, 5H), 3.5—4.3 (m, 4H), 4.4—4.9 (broad, 1H), 7.2 (aromatic protons, 5H).

Found: C, 66.58; H, 9.00; N, 7.57%. Calcd for $C_{21}H_{34}O_4N_2$: C, 66.63; H, 9.05; N, 7.40%.

Preparation of Z-L-Tyr(Bu^t)-Gly-Gly-L-Pheψ[CH$_2$-NH]L-Leu-OBu^t (6): Compound **2d** (145 mg, 0.32 mmol) was hydrogenolyzed in the presence of 10% Pd-C (50 mg) in methanol (4 ml) containing conc HCl (0.1 ml) to give 125.6 mg (quantitative) of H-L-Pheψ[CH$_2$-NH]L-Leu-OBu^t·2HCl, which was dissolved together with Z-L-Tyr(Bu^t)-Gly-Gly-OH (155 mg, 0.32 mmol) in *N*,*N*-dimethylformamide (DMF) (1.0 ml) and triethylamine (134 μl, 0.958 mmol). To this solution (cooled at 0 °C) dimethylphosphinothioic azide (47.6 mg, 0.352 mmol) in DMF (0.3 ml) was added and the mixture was stirred at this temperature for 24 h. The solution was diluted with ethyl acetate and washed with water, a 5% aq $NaHCO_3$ solution, water and saturated NaCl solution, dried over anhydrous sodium sulfate and evaporated. The oily residue was purified by silica-gel column chromatography to give **6** as amorphous solid; 207.8 mg (82%); $[\alpha]_D^{27}$ −13.4° (*c* 1.0, methanol); R_f^4=0.44, R_f^7=0.51. ^{1}H NMR ($CDCl_3$) δ=0.7—1.8 (m, 27H), 2.1—3.2 (m, 8H), 3.3—5.1 (m, 8H), 6.3—8.0 (m, 18H).

Found: C, 66.79; H, 7.76; N, 9.10%. Calcd for $C_{44}H_{61}O_8N_5$: C, 67.07; H, 7.80; N, 8.89%.

Preparation of H-L-Tyr-Gly-Gly-L-Pheψ[CH$_2$-NH]L-Leu-OH (7): 25% HBr in acetic acid (0.4 ml) was added to a solution of **6** (54.7 mg, 0.069 mmol) in acetic acid (0.2 ml) containing anisole (0.1 ml) and the solution stirred at room temperature for 2 h. After evaporation, the residue was washed with ether by trituration. The crude product was purified by silica-gel TLC by a solvent system of chloroform–methanol–29% aqueous ammonia (65:25:4) followed by gel chromatography on Sephadex LH-20 (eluted with methanol) to give chromatographically homogeneous monohydrobromide dihydrate of **7** as amorphous solid; 38.0 mg (83%); $[\alpha]_D^{27}$ +23.0° (*c* 1.9, methanol); R_f^5=0.25, R_f^8=0.54.

Found: C, 51.01; H, 6.42; N, 10.41%. Calcd for $C_{28}H_{42}O_7N_5Br$: C, 51.06; H, 6.73; N, 10.63%.

ESR Studies of the Reaction of the Calcium Atom with Substituted Benzene Vapors[1)]

Kunio MOCHIDA* and Yasuhisa MIZUNO
Department of Chemistry, Faculty of Sciences, Gakushuin University,
1-5-1 Mejiro, Tokyo 171
(Received June 30, 1986)

The reaction of the calcium atom with substituted benzene vapors was examined by means of ESR. The anion radicals of substituted benzenes as intermediates were directly observed.

The study of metal-vapor reactions has been of considerable interest in organometallic chemistry and organic synthesis during the last few decades.[2)] With these methods, it is proving feasible to synthesize organometallic compounds which would be difficult, if not impossible, to prepare by other methods, and to study their reactive intermediates. The unstable intermediates (molecules and molecular fragments) produced by metal-vapor reactions are generally stabilized at cryogenetic temperatures in a solid matrix.

The unstable intermediates in metal-vapor reactions are mainly being examined by means of matrix infrared and Raman spectroscopy.[2)] Matrix electron spin resonance (ESR) is also potentially useful in these studies. However, there have been few reports on a convenient apparatus for high-boiling metal matrix ESR.[3)]

We previously reported the activation of the C–H bonds[4)] and C–X bonds[5)] of substituted benzenes by a calcium atom, followed by the formation of the corresponding arylcalcium hydrides and arylcalcium halides respectively. In these studies, the anion radicals of substituted benzenes were proposed to be reactive intermediates.

In this paper, we will describe the preparation of a convenient apparatus for high-boiling metal matrix ESR and also ESR studies of the reactions of the calcium atom with substituted benzene vapors using this apparatus.

Results and Discussion

In studying the activation of C–H bonds[4)] and C–X bonds[5)] of substituted benzene vapors with the calcium atom, the color of the intial products at 77 K turned green or blue, probably because of the anion radicals of substituted benzenes, depending on the aromatic compounds.

Apparatus. In order to observe directly the anion radicals of substituted benzenes produced by the reactions of the calcium atom with substituted benzene vapors, the apparatus for metal-atom matrix ESR illustrated in Fig. 1 was made. The cryostat assembly attaches directly to the assembly for metal vaporization and is pumped out as part of the complete vacuum system. Metal is vaporized using a filament of tungsten. During the vaporization of the metal, an organic substrate is introduced as vapor through an organic-substrate inlet tube. The co-condensation product of the metal atom and the organic substrate vapor condenses on a stainless-steel drum filled with liquid nitrogen. The co-condensation product of the metal-organic substrate at 77 K is transferred to the ESR tube using a scratching bar.

Miles and his co-workers have recently reported on matrix ESR in a rotating cryostat.[3)] The rotating cryostat has been used to deposit the metal atom onto the frozen layer of an organic substrate at 77 K. Our apparatus for the metal atom matrix ESR can similarly and coincidently be used to deposit the co-condensation products formed by the reactions of the metal atom with the organic-substrate vapor.

ESR Studies of Co-Condensation Products of the Calcium Atom and Substituted Benzene Vapors. The co-condensation products of the calcium atom with benzene, alkylbenzenes, and phenyltrimethylsilane respectively were examined by means of ESR. The ESR data of the products of the calcium atom and benzene (No. 1), alkylbenzenes (Nos. 2—5), and phenyltrimethylsilane (No. 6) are summarized in Table 1. Figure 2 shows the ESR spectrum of the product formed by the reaction of the calcium atom with benzene vapor. Although the spectrum is poorly

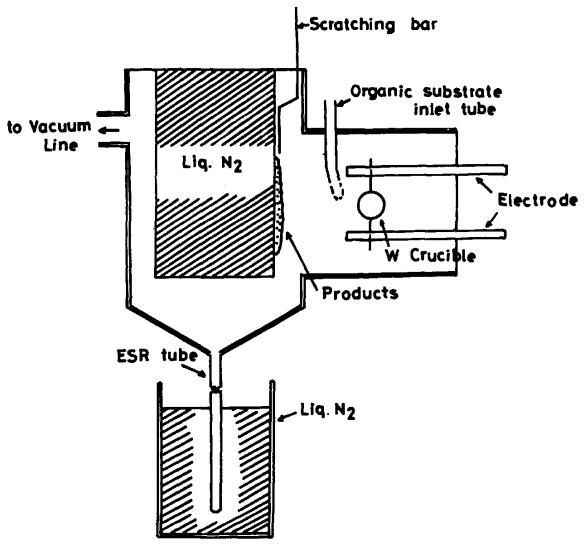

Fig. 1. The apparatus for metal atom matrix ESR.

resolved, it consists of a septet, and the line width is ca. 0.39 mT. The outermost lines of the septet are lost in the noise. The ESR spectrum of the calcium atom-benzene vapor product can safely be assigned to the benzene anion radical by comparison with that of a reference sample.[6,7] The experimental spectrum was reproduced by computer simulation, with the hyperfine splitting constants (hfsc) listed in Table 1. The signal gradually disappeared as the temperature was warmed at 0 °C. Figure 3 shows the ESR spectrum of the product by the reaction of the calcium atom with ethylbenzene vapor. The ESR spectrum is also poorly resolved, and the line width is ca. 0.56 mT. The ESR spectrum of the calcium atom-ethylbenzene vapor product can easily be assigned to the ethylbenzene anion radical by comparison with the ESR data of a reference of sample[6,7] and by computer simulation. The ESR spectra of the products formed by the reactions of the calcium atom with toluene, isopropylbenzene, *t*-butylbenzene, and phenyltrimethylsilane vapors were found to be broad singlets. Such broad singlets may result from the high concentrations of

a) The g factors were determined by reference to that of Fremy's salt (g=2.0055). b) Not resolved. c) Hfs due to the para proton was not resolved.

the reaction intermediates or from the matrix conditions. Although no hyperfine structures due to the ring protons were resolved, these signals can safely be assigned to the anion radicals of the corresponding aromatic compounds on the basis of the ESR results for benzene and ethylbenzene vapors-calcium atom described above and on the basis of the reported g factors of these anion radicals. As a typical example, Fig. 4 shows the ESR spectrum of the product formed by the reaction of the calcium atom with toluene vapor.

The co-condensation products of the calcium atom with fluorobenzene and chlorobenzene vapors respectively were also examined. The ESR spectra of the products formed by the reactions of the calcium atom with fluorobenzene and chlorobenzene vapors respectively were found to be broader singlets than those of alkylbenzene vapors. The signal for the calcium atom-fluorobenzene vapor product was stable at −60 °C. On the other hand, the signal for the calcium atom-chlorobenzene vapor product was unstable and disappeared even at −60 °C. With bromobenzene, attempts to observe the anion radical failed. Although there have been studies of halogenated aromatic compound anion radicals by means of ESR, there has been no report on g factors of fluorobenzene and chlorobenzene anion radicals.[9] No hfs constants of calcium atom-fluorobenzene vapor product or of calcium atom-chlorobenzene vapor product were obtained in this study. Therefore, we could not determine whether the signals obtained by the reactions of the calcium atom with halobenzenes were those of the corresponding anion radicals or not.

These ESR results suggest that the anion radicals of substituted benzenes are produced in the reactions of the calcium atom with substituted benzene vapors.

In this experiment, we made a convenient apparatus for high-boiling metal atom matrix ESR and observed directly by means of ESR anion radicals of substituted benzenes as reaction intermediates in the reactions of the calcium atom with substituted benzene vapors. This apparatus will give further information on reaction intermediates in metal-vapor reactions.

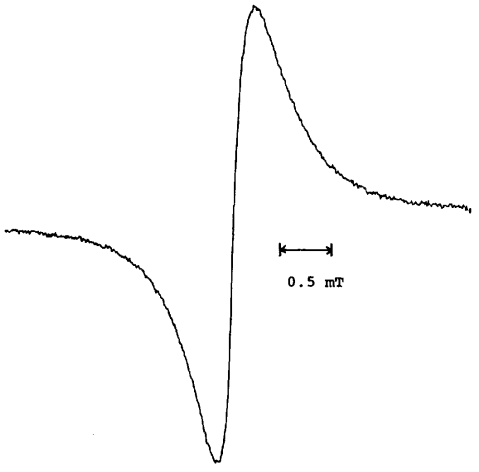

Fig. 4. The observed ESR spectrum of calcium atom-toluene vapor product at −120 °C.

Experimental

ESR Measurements. All the ESR spectra were obtained using a Varian E-9 ESR spectrometer. The field sweep of the spectrometer was calibrated with an aqueous solution of Fremy's salt (a_N=1.307 mT). The g factors were determined by reference to that of Fremy's salt (g=2.0055) using a dual cavity.

Materials. Substituted benzenes were dried and distilled prior to use.

Experimental Procedure. As a typical experiment, the reaction of the calcium atom with benzene vapor is described. Calcium metal (0.15 g, 3.7 mmol) was vaporized at a temperature of ca. 900 °C using a filament of tungsten in vacuo (ca. 5×10^{-3} Torr, 1 Torr=133.322 Pa) at a rate of ca. 20 mg min^{-1}. During the vaporization of the calcium metal, benzene (4 cm^3, 45 mmol) was introduced as vapor. The benzene vapor-calcium atom product condensed on a stainless-steel drum filled with liquid nitrogen. The product of calcium atom-benzene vapor at 77 K was transferred to the ESR tube using a scratching bar.

We wish to thank Messrs. Masayoshi Hamano, Hiroshi Miyagi, and Yuji Shimokawa of the machine shop of Gakushuin University for making the apparatus for the metal-atom matrix ESR studies. We also wish to thank Professor Tadashi Suehiro of Gakushuin University for providing the Varian E-9 ESR spectrometer. Partial financial support of this research by a Grant-in-Aid from the Ministry of Education, Science, and Culture of Japan is greatly acknowledged.

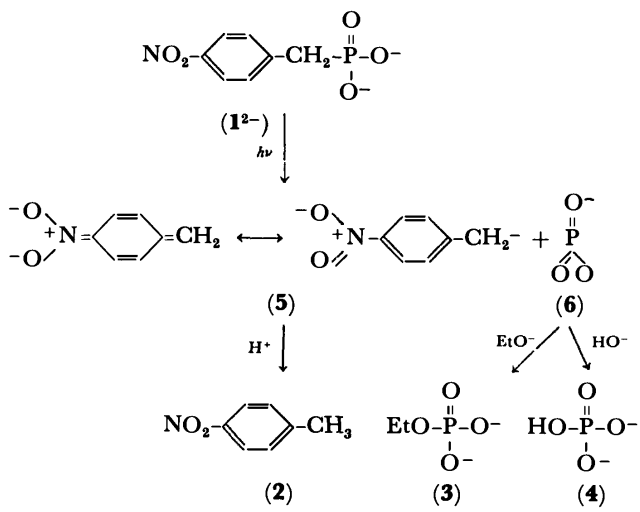
Photochemical C-P Bond Cleavage of Nitrobenzylphosphonate Ions

Yoshiki Okamoto,* Narimasa Iwamoto, Susumu Toki, and Setsuo Takamuku
The Institute of Scientific and Industrial Research, Osaka University,
Mihogaoka 8-1, Ibaraki, Osaka 567
(Received June 30, 1986)

Upon UV-irradiation, the C-P bond of *p*-nitrobenzylphosphonate ions cleaved with a quantum yield of about 0.7 in an aqueous alcohol solution to give 1,2-bis(4-nitrophenyl)ethane, *p*-nitrotoluene, orthophosphate, and alkyl dihydrogenphosphate. Whereas in an aqueous solution 1,2-bis(4-nitrophenyl)ethane was produced as a main product, in an alcohol solution only *p*-nitrotoluene was produced. This photolysis may proceed via intramolecular electron transfer from PO_3^{2-} group to nitro aromatic moiety to form an excited state, which undergoes C-P bond cleavage to give *p*-nitrobenzyl anion and monomeric metaphosphate anion as intermediates. The C-P bond cleavage of *p*-nitrobenzylphosphonate ion occurred more readily than those of *o*- and *m*-nitrobenzylphosphonate ions.

The chemical and thermal stability of C-P bond in free alkylphosphonic acid is well-known and chemical reactions involving C-P bond cleavage are not common.[1] The thermal decomposition of 2-haloalkylphosphonic acid is one of a few examples.[2] The C-P bond of this acid is easily cleaved into the fragments of 1-alkene, halide, and orthophosphate in a basic aqueous solution. The photochemical C-P bond cleavage of free phosphonic acid has not been reported before our previous letter.[3] Upon UV-irradiation of a basic 80% ethanol solution of *p*-nitrobenzylphosphonic acid (**1**), the formations of *p*-nitrotoluene (**2**), and salts of ethyl dihydrogenphosphate (**3**) and orthophosphoric acid (**4**) were observed.[3] We have suggested that this process involves an unimolecular C-P bond cleavage to give *p*-nitrobenzyl anion (**5**) and monomeric metaphosphate anion (**6**) as intermediates (Scheme 1). When anhydrous alcohol solutions of **1** containing 2 molar equivalents of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) were irradiated, alkyl dihydrogenphosphates were obtained in almost quantitative yields.[4]

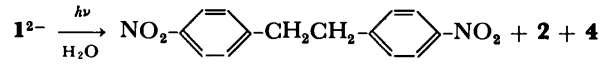
In the present paper, we will report the more detail investigation of photolysis of nitrobenzylphosphonic acids.



Scheme 1.

Results and Discussion

Photolysis of *p*-Nitrobenzylphosphonate Ion. In an aqueous solution, the absorption maximum of **1** is 290 nm at pH 5 and shifts to longer wavelength (305 nm) with increasing pH (Fig. 1). This shift may be due to an intramolecular charge transfer.[5] In an ethanol solution (containing 2 molar equivalents of DBU), this band shifts to shorter wavelength (298 nm). Upon exposure to ultraviolet light, an aqueous solution of dianion of **1** (50 mmol dm^{-3}) rapidly formed a precipitate, which was identified as 1,2-bis(4-nitrophenyl)ethane (**7**). Small amount of **2** was also detected. The quantum yield of C-P bond cleavage based on the yields of **7** and **2** was 0.86. The photolysis products and their quantum yields varied with the solvent (see below). By ^{31}P NMR observation, the quantitative yield of **4** (δ=2.6, H_2O, pH 12) was also observed after 1 h irradiation (Eq. 1).



(7) (1)

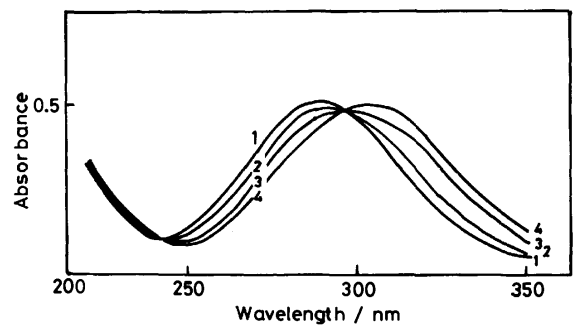


Fig. 1. Absorption spectra of **1** in an aqueous solution (5.0×10^{-2} mmol dm^{-3}) under different pH.
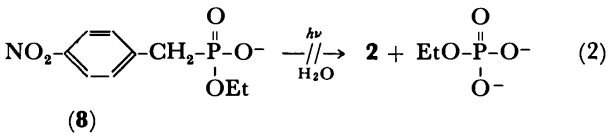
1: at pH ≈5.0, 2: at pH 6.8, 3: at pH 7.2, 4: at pH 8.0≈.

The photolysis of **1** was dependent on pH of the solution (80% EtOH) as shown in Fig. 2. The C–P bond cleavage did not occur below pH 5. It began above pH 5, which corresponds to the concentration of hydronium ion required for second ionization of **1** (pK_a^1 3.9, pK_a^2 9.3 in 80% EtOH). The yields of photolysis products **2** were constant above pH 9 (ϕ=0.76). Ethyl *p*-nitrobenzylphosphonate ion (**8**) did not undergo the C–P bond cleavage even at pH 10 (Eq. 2).



(8) (2)

Our results indicate that the undissociated or monodissociated **1** undergoes no C–P bond cleavage. The complete dissociation of the acid **1** is required for the photo-cleavage of C–P bond. Hammett σ_p constant of phosphono group ($-P(O)(OH)_2$) is 0.29, but that of complete dissociated phosphono group ($-PO_3^{2-}$) is −0.16.[6] Its electron-donor character increases by the complete dissociation. *p*-Nitrotoluene (**2**) could be produced by the reaction of **5** with H^+. This process is supported by a labelling experiment: The photolysis of $\mathbf{1}^{2-}$ in ethanol-*d*/deuterium oxide (v/v=3/2) gave *p*-nitrotoluene-*α*-*d* as a main product (81%). No phosphonic acid ($HPO(OH)_2$), resulted by homolytic C–P bond cleavage, could be detected by ^{31}P NMR observation of both the irradiated aqueous and ethanolic solutions of **1**. This photolysis was essentially the same in the presence or absence of oxygen: The yield of **4** was not be affected under bubbling of oxygen, although the yield of **2** was slightly reduced owing to a formation of *p*-nitrobenzaldehyde. Consequently, we conclude that the photolysis dose not proceed via radical mechanism, but via heterolytic C–P bond cleavage: The photoexcited **1** dianion may undergo heterolytic C–P bond cleavage to give **5** and **6**. The constancy of quantum yield of C–P bond cleavage with differences in the concentration of **1** also provides an evidence in favor of a direct C–P bond cleavage.

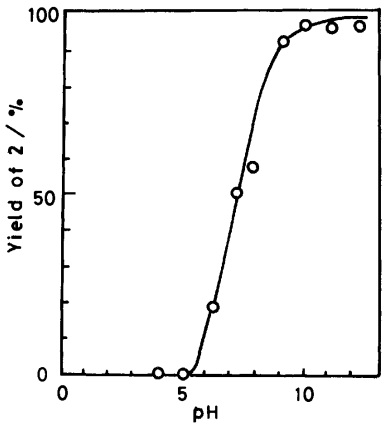


Fig. 2. Effect of pH on photolysis of **1** in 80% EtOH (50 mmol dm^{-3}, 1 h, in N_2).

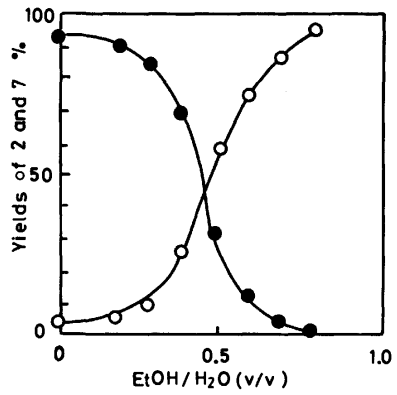

Fig. 3. Change of the product ratio **7/2** by the ratio of EtOH/H_2O (**1**, 50 mmol dm^{-3}, pH 10, 1 h, in N_2). —●—: **7**, —○—: **2**.

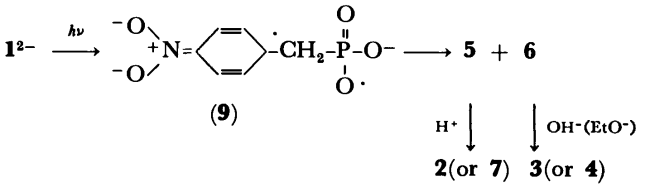
The product ratio of **7/2** decreased with an increase of the ratio of ethanol/water as shown in Fig. 3. In an anhydrous ethanol solution of **1** (containing 2 equivalents of DBU) only **2** was given (ϕ=0.50). The mechanism for the formation of **7** is not clear, and it is being investigated in more detail in our laboratory. The formation of product **7** via **5** by action of strong base on **2** in aqueous solution was reported by other investigator.[7]

Transient Intermediates. Although it is conceivable as an alternative path that **5** is formed by rapid electron transfer from phosphoranyl radical to benzyl radical after homolytic C–P bond cleavage, we can exclude this possibility by the results obtained with laser flash photolysis. The presence of two transient species was revealed by flash photolysis of an aqueous solution of $\mathbf{1}^{-2}$ with 15 ns flash of 308 nm light (Fig. 4). One is a transient species having absorption maximum at 360 nm, which is in agreement with that of **5** reported by Miller and Pobiner from the reaction of **2** with potassium *t*-butoxide in *t*-butyl alcohol.[8] The absorbance of the transient species was constant above pH 9, but below this was dependent upon the pH and at pH 5 could not be observed. The decrease of its absorbance may be comparable with the decrease of concentration of dianion of **1**. The difference of yields of the transient species in the presence or absence of oxygen was within experimental error. These results are consistent with the results from product analysis. The rate of formation of this absorption band followed first-order kinetics and the rate constant was 1.2×10^7 s^{-1} in aqueous solution (5.0×10^{-5} mol dm^{-3}, pH 12). The formation rate constant was not affected by the change of pH. In ethanol solution, the absorption maximum was identical with that in an aqueous solution, but the

formation rate constant reduced to $0.5\times10^7\ s^{-1}$. The lifetime of this transient species was very long and the decay behavior could not be followed by the ns-flash photolysis technique.

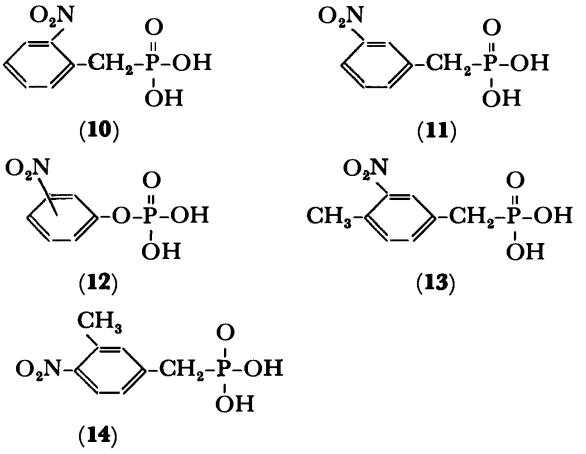
The other short-lived transient having absorption maximum at about 300 nm was also observed, although it could not be analyzed accurately, because the absorption maximum overlapped with that of **1** dianion (305 nm) (Fig. 4). This absorption band decayed together with an weak and broad absorption band at 500—800 nm. The decay rate of the latter band followed first-order kinetics and its rate constant was about $5.8\times10^6\ s^{-1}$. The decay of this transient absorption band may be correlated with the formation of 360-nm band, although there was a small difference in their rate constants. Thus, this short-lived transient intermediate may be a precursor of the 360-nm band and assigned as a diradical dianion **9** resulted by intramolecular electron transfer from PO_3^{2-} to nitro aromatic moiety (Scheme 2). Nagakura, et al. reported that radical anion of **2** has the absorption maxima at 302, 607, and 875 nm in THF.[10]

In an aqueous solution, the decay of 360-nm absorption band after short time exposure (2 s) of ultraviolet light with a high pressure mercury lamp could be observed with moderately high speed scanning using a UV spectrometer (Fig. 5). The lifetime was about 60 s, which is similar to that reported by Margerum (53 s) under the similar reaction conditions.[9] The rate constant for its absorption decay followed second-order kinetics.



Scheme 2.

Photolysis of Other Nitrobenzylphosphonate Ions. Dianions of *o*- (**10**) and *m*-nitrobenzylphosphonic acids (**11**) also exhibited a clearly promoted reactivity on illumination, but their photochemical reactivities were more less than that of *p*-derivative (Table 1). Our results do not follow the photochemical patterns observed by Havinga et al., in the solvolysis of *m*- and *p*-nitrophenyl phosphates,[11] or by Zimmerman and Somasekhara, in the solvolysis of *m*- and *p*-nitrophenyl trityl ethers:[12] Readier C-P bond cleavage of **1** do not fit the mechanisms of Zimmerman on photolysis of nitrophenyl phosphates (**12**) in which the excited state of a *m*-nitro structure is considered to be favorable and that of a *p*-nitro unfavorable, for heterolytic cleavage.[13] Other different photochemical behavior of **12** is that the bond cleavage occurs with a definite efficiency between pH 5 and 12.[11]



Whereas absorption maximum of *p*-derivatives of **12** in a basic aqueous solution is 310 nm, this band did not shift by increasing pH from 5 to 12. This fact indicates that there is no or little intramolecular charge transfer between PO_3^{-2} and nitro aromatic moiety in **12**. The electronic structure of photoexcited

Table 1. Quantum Yields of C-P Bond Cleavage of the Dianions of **11**, **10**, **1**, and *o*-, *m*-, and *p*-Nitrophenyl Phosphate (**12**)

Compound	Quantum yield
o-Nitrobenzylphosphonate dianion (**11**$^{-2}$)	0.024[a]
m-Nitrobenzylphosphonate dianion (**10**$^{-2}$)	0.039[a]
p-Nitrobenzylphosphonate dianion (**1**$^{-2}$)	0.76[a]
o-Nitrophenyl phosphate dianion	0.003[b]
m-Nitrophenyl phosphate dianion	0.05[b]
p-Nitrophenyl phosphate dianion	0.002[b]

a) Concentration 50 mmol dm^{-3}, 50% EtOH/H_2O, pH 12. b) The aqueous solutions of **12** (0.2 mmol dm^{-3}, 10 mmol dm^{-3} NaOH) were irradiated with monochromatic light of 313 nm.[11]

1 dianion may be entirely different from that of **12** anion. It is well-known that intermolecular electron transfer from an electron donor to *p*-nitrobenzyl chloride give *p*-nitrobenzyl chloride radical anion, which undergoes homolytic bond cleavage to afford *p*-nitrobenzyl radical and chloride anion.[14] In these reaction, numerious instances of light effects have been found, and some of them very large.[15] The fact that the dianion of **10** underwent C-P bond cleavage at a rate one-tenth that of **1** is readily understood in view of Geske's report that *o*-nitrotoluene is significantly more difficult to be reduced than **2**.[16] This is reasonably assumed to be due to steric hindrance to coplanarity in the ortho isomer, which lowers the reducibility of the system by tending electronically to isolate the nitro group from the ring.

Under identical photolysis conditions, dianions of (3-methyl-4-nitrophenylmethyl)phosphonic acid (**13**) and (4-methyl-2-nitrophenylmethyl)phosphonic acid (**14**) hardly underwent C-P bond cleavage.

These behaviors of photochemical C-P bond cleavage of **1** are similar to those of photochemical decarboxylation of nitrophenylacetate ions.[9]

Experimental

All mp and bp were uncorrected. Following spectrometers were used for spectral measurements: UV: Hitachi 323; Excimer laser Lambda Physik EMG 501; ^{1}H and ^{31}P NMR: Bruker WM 360.

Materials. Ethanol and other solvents were dried and distilled by the usual methods.

***p*-Nitrobenzylphosphonic Acid (1):** The acid **1** was prepared by the procedure reported previously.[3] Mp 230—232 °C. UV_{max} (H_2O, pH 12) 305 nm (ε 10,500). ^{1}H NMR (D_2O, DSS, pH 12) δ=2.98 (2H, d, J_{PH}=20 Hz), 7.1—8.1 (m, 4H). ^{31}P NMR (H_2O, 80% H_3PO_4, pH 12) δ=15.2 (t, J_{PH}=20 Hz).

***o*-Nitrobenzylphosphonic Acid (10):** After an equimolar mixture of *o*-nitrobenzyl bromide and triethyl phosphite was refluxed for 1 h, the mixture was distilled to give diethyl *o*-nitrobenzylphosphonate. Bp 160—165 °C/0.1 mmHg.† It was hydrolyzed by refluxing with hydrobromic acid for 12 h. The hydrolyzed acid **10** was recrystallized from water. Mp 190—191 °C, UV_{max} (H_2O, pH 12) 270 nm (ε 6,600). ^{1}H NMR (D_2O, DSS, pH 12) δ=3.65 (2H, d, J_{PH}=22.0), 7.1—8.0 (4H, m). Found: C, 38.56; H, 3.69; N, 6.58; P, 14.12%. Calcd for $C_7H_8NO_5P$: C, 38.72; H, 3.71; N, 6.45; P 14.27%.

***m*-Nitrobenzylphosphonic Acid (11):** The acid **11** was prepared by the same method as described above. Diethyl *m*-nitrobenzylphosphonate, bp 186—187 °C/0.5 mmHg, **11**, mp 186—187 °C. UV_{max} (H_2O, pH 12) 280 nm (ε 7,300). ^{1}H NMR (D_2O, pH 12) δ=2.84 (2H, d, J_{PH}=18.0 Hz), 7.1—8.0 (4H, m). Found: C, 38.81; H, 3.68; N, 6.38; P, 12.41%. Calcd for $C_7H_8NO_5P$: C, 38.72; H, 3.71; N, 6.45; P, 12.63%.

Ethyl *p*-Nitrobenzylphosphonate (8): The phosphonate **8** was prepared by nitration of ethyl benzylphosphonate with fuming nitric acid at 0 °C. Ethyl benzylphosphonate (mp 63—64 °C) was prepared by partial hydrolysis of diethyl

† 1 mmHg=133.3 Pa.

benzylphosphonate with 1 mol dm^{-3} NaOH 50% ethanol solution. **8**, mp 156—157 °C. UV_{max} (H_2O, pH 12) 290 nm (ε 10,600). ^1H NMR (D_2O, DSS, pH 12) δ=1.17 (t, 3H, J_{HH}=7.0 Hz), 3.10 (d, 2H, J_{PH}=20 Hz), 3.80 (quint, 2H, J_{HH}=7.0 Hz), 7.3—8.2 (m, 4H). Found: C, 44.25; H, 5.06; N, 5.69; P, 14.54%. Calcd for $C_9H_{12}NO_5P$: C, 44.09; H, 4.93; N, 5.71; P, 14.40%.

(3-Methyl-4-nitrophenylmethyl)phosphonic Acid (13): *m*-Methylbenzylphosphonic acid was nitrated with a nitric acid-sulfuric acid mixture (v/v=1:3) at 0 °C. Mp 219—220 °C. UV_{max} (H_2O, pH 12) 268 nm (ε 5,100). ^1H NMR (D_2O, DSS, pH 12) δ=2.58 (s, 3H), 3.35 (d, 2H, J_{PH}=20 Hz) 7.3—8.4 (m, 4 H). Found: C, 41.48; H, 4.27; N, 6.21; P, 13.37%. Calcd for $C_8H_{10}NO_5P$: C, 41.57; H, 4.36; N, 6.06; P, 13.40%.

(4-Methyl-3-nitrophenylmethyl)phosphonic Acid (14): *p*-Methylbenzylphosphonic acid was nitrated as described above. Mp 209—210 °C, UV_{max} (H_2O, pH 12) 274 nm (ε 3,800). ^1H NMR (D_2O, DSS, pH 12) δ=2.37 (s, 3H), 2.92 (d, 2H, J_{PH}=19 Hz), 7.0—8.0 (m, 3H). Found: C, 41.39; H, 4.18; N, 6.21; P, 13.49%. Calcd for $C_8H_{10}NO_5P$: C, 41.57; H, 4.36; N, 6.06; P, 13.40%.

Product Identification. The insoluble product was separated from the photolyzed aqueous solution of **1** by extraction with chloroform. The chloroform extract was evaporated, and the residue was recrystallized from acetone-ethanol to give **7**, pale yellow-needle (mp 181—183 °C) and it was identified by GLC with an authentic sample.

From a photolyzed ethanol solution of **1**, **2** was isolated. The ethanol was evaporated, and the residue was recrystallized from water-ethanol to give **2** (mp 51—52 °C), and identified by GLC with an authentic sample.

Typical Procedure of Photolysis. Five ml of a 50% ethanol solution of **1** (50 mmol dm^{-3}) was adjusted at pH 12 with a 10% aqueous solution of sodium hydroxide. Nitrogen was bubbled through the solution before irradiation. The solution was irradiated in a Pyrex tube (ϕ=10 mm) with a high-pressure mercury lamp (350 W) for 1 h under cooling with running water. The progress of the photolysis was directly monitored by a GLC analysis using biphenyl as an internal standard [Silicone OV-17 (2%) on Chromosorb W AW DMCS] of **2** or **7**. When the photolysis in a aqueous solution was carried out, chloroform (5 ml) was added and the mixture was shaken sufficiently. Analyses were performed on the chloroform extracts.

Photolysis of 1 in the Presence of Oxygen. The 80% ethanol solution of **1** (50 mmol dm^{-3}, pH 12) was irradiated in the same manner described above. Oxygen was bubbled into the solution during the irradiation. After irradiation, the solution was directly analyzed by GLC. *p*-Nitrobenzaldehyde, other than **2**, has been detected by comparison with an authentic sample (5.2%). As another oxidation product, a trace amount of *p*-nitrobenzyl alcohol was also detected.

Photolysis of 1 in Ethanol-*d*/Deuterium Oxide. One ml of ethanol-*d*/deuterium oxide solution (v/v=3/2) of **1** (50 mmol dm^{-3}) containing two equivalents of sodium deuteroxide was irradiated in the same manner as described above. The product was extracted with chloroform-*d*, and the extract was subjected to ^1H NMR analysis. *p*-Nitrotoluene-α-*d* [^1H NMR ($DCCl_3$, TMS) δ=2.46 (t, 2H, J_{DH}=2.2 Hz), 7.3—8.1 (m, 4H)] content in the product was 81%. When the ethanol-*d*/deuterium oxide solutions of **1** and **2** were allowed to stand for 24 h without UV-irradiation, isotopic hydrogen exchange on the methylene and the methyl groups of them could not be observed.

Measurement of the Quantum Yield. The quantum yields were determined on the basis of generated nitrotoluene and/or **7**, and chemical actinometry using 2-hexanone. The sample solutions (50 mmol dm^{-3}) were irradiated in a merry-go-round apparatus employing 313-nm monochromatic light according to the procedures previously described.[4]

Flash Photolysis. Flash photolyses were carried out by using a XeCl excimer laser Lambda Physik EMG 501 supplying 15 ns pulses of 308 nm light (energy 100 mJ/pulse). The solutions of **1** (5×10^{-2} mmol dm^{-3}, pH 12) were prepared freshly before irradiation and were deoxygenated by bubbling with argon gas. Irradiated solutions were replaced by a fresh solution for each pulse. The transmissions of samples were monitored using an optical system consisting of Xe-pulse lamp (Osram OPG 450), a monochromater (Nikon G-250), and a photomutiplier tube (Hamamatsu Photonics R928).

The authors are grateful to Mrs. Fusako Fukuda and Mr. Yoshio Takai of Material Analysis Center in the Institute of Scientific and Industrial Research, Osaka University, for the elemental analysis and the measurement of ^1H and ^{31}P NMR spectra.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 61223019 from the Ministry of Education, Science and Culture.

A Novel Method for Determining the Chelation Ability of the Cysteine-Containing Peptides with 3,4-Toluenedithiol. Application to [2Fe-2S]-Ferredoxin Model Systems

Norikazu Ueyama, Satoru Ueno, and Akira Nakamura*
Department of Macromolecular Science, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received July 2, 1986)

The chelating ability of a bidentate ligand, Cys-X-Y-Cys (X, Y=amino acid residue), in 2Fe-2S peptide model complexes was examined by a ligand-exchange method using 3,4-toluenedithiol (tdt-H_2) or *o*-xylene-α,α'-dithiol. The addition of tdt-H_2 to an *N,N*-dimethylformamide solution of $[Fe_2S_2(Z\text{-cys-Ala-Ala-cys-OMe})_2]^{2-}$ results in the cleavage pf Fe-S* (S*=inorganic sulfur) bond and in the formation of hydrogen sulfide and mononuclear Fe(III) peptide thiolate complex, $[Fe(Z\text{-cys-Ala-Ala-cys-OMe})(tdt)]^{1-}$. In the case of $[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]^{2-}$, $[Fe_2S_2(tdt)^2]^{2-}$ was obtained by the substitution of Z-Ala-Cys-OMe with the chelating reagent. On the other hand, *o*-xylene-α,α'-dithiol expels both Z-Cys-Ala-Ala-Cys-OMe and Z-Ala-Cys-OMe ligands from these complexes.

An inherent lability of teterahedrally coordinated Fe(II) or Fe(III) species in solution is manifest in the observed ease in the core extrusion from iron–sulfur proteins or in the thiolate ligand exchange of their synthetic model complexes, e.g. $[Fe_2S_2(SR)_4]^{2-}$.[1] Bridging μ-sulfido ligands are also labile in these iron complexes and interconversion among [4Fe-4S], [3Fe-4S], and [2Fe-2S] clusters has been recently found in many iron–sulfur proteins.[2] Similar changes in cluster structures are studied for some model complexes.[3] Thus, we have reported a smooth conversion of $[Fe_2S_2(peptide)_4]^{2-}$ to $[Fe_4S_4(peptide)_4]^{2-}$ upon one-electron reduction.[4] All these reactions depend on the lability of the Fe-S bonds which is important for their functions in biological systems.

The high lability of monodentate thiolate ligands in Fe(II) complexes or the instability in Fe(III) complexes has been found to decrease by effective chelation.[5] Thus, remarkable thermal stability of oxidized rubredoxin (Fe(III) state) is ascribed to the multiple chelation of the protein. In the related model complex, $[Fe(Z\text{-cys-Pro-Leu-cys-OMe})_2]^{1-,2-}$ (Z=benzyloxycarbonyl), we have found a remarkable stabilizing effect due to chelation.[6,7] In native [2Fe-2S]-ferredoxins, the oxidized state is also stable by chelation where an invariant peptide sequence, Cys-A-B-C-D-Cys-X-Y-Cys chelates in tridentate fashion.[8] Here, the Cys-X-Y-Cys part is bridging the two Fe(III) ions and Cys-A-B-C-D-Cys part is chelating.

In the previous paper we reported the chelation of a tetrapeptide Cys-X-Y-Cys to $[Fe_2S_2]^{2+}$ ion.[9] However, we could not determine whether the Cys-X-Y-Cys bridges between the two Fe(III) ions of $[Fe_2S_2]^{2+}$ or chelates to one Fe(III) ion of $[Fe_2S_2]^{2+}$.

In this paper, we describe a novel method for determination of the mode of chelation of Cys-X-Y-Cys to $[Fe_2S_2]^{2+}$ core utilizing the ligand-exchange reaction with 3,4-toluenedithiol. This reagent has been employed for attempt to extrude some inorganic clusters from iron-sulfur proteins.[10]

Experimental

All manipulations involving solvent purifications, air-sensitive iron thiolate, and peptide complexes were carried out under argon atmosphere.

Materials. 3,4-Toluenedithiol (tdt-H_2) was obtained from Nakarai Chemical Co. and used without purification. Tetrahydrofuran (THF) was purified by distillation after sufficient refluxing over sodium metal. *N,N*-Dimethylformamide (DMF) was purified by distillation under reduced pressure before use. *o*-Xylene-α,α'-dithiol (*o*-xyl-$(SH)_2$) was prepared by the literature method.[11] $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-}Bu)_4]$ (**1**), $[NEt_4]_2[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]$ (**2**),[12] and $[NEt_4]_2[Fe_2S_2(Z\text{-cys-Ala-Ala-cys-OMe})_2]$ (**3**) were synthesized by the method reported in the previous paper.[9] $[NEt_4]_2[Fe_2S_2(S_2\text{-}o\text{-xyl})_2]$ (**4**) was prepared according to the reported procedure.[13]

$[NEt_4]_2[Fe_2S_2(tdt)_2]$ (tdt=3,4-toluenedithiolate). To a solution of $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-Bu})_4]$ (200 mg, 2.5×10^{-4} mol) in acetonitrile (20 cm^3) was added 3,4-toluenedithiol (36 mg, 2.3×10^{-4} mol) with stirring at room temperature. The solution was concentrated under reduced pressure and the residue was washed with fresh THF. The powder obtained was recrystallized with acetonitrile and ether and gave black microcrystals. Found: C, 46.73; H, 7.39; N, 3.33. Calcd for $C_{30}H_{62}N_2S_6Fe_2$: C, 48.38; H, 7.04; N, 3.76. Absorption maxima (DMF); 550 nm (ε 4000), 496 nm (ε 5260), 475 nm (sh, ε 4800), 383 nm (ε 9100), and 320 nm (ε 9700). ^1H NMR spectrum; *o*-CH_3, δ=4.5; Ph-H, δ=10.2 and 10.5 (Me_2SO-d_6).

Detection of H_2S. Argon gas was bubbled into a DMF solution (2 cm^3) of $[NEt_4]_2[Fe_2S_2(Z\text{-cys-Ala-Ala-cys-OMe})_2]$ (30.3 mg, 2.1×10^{-5} mol) and the gas was vented through an 8 mM silver nitrate aqueous solution. After addition of tdt-H_2 (6.4 mg, 4×10^{-5} mol) into the DMF solution, the silver nitrate solution gave a black precipitate upon bubbling argon gas at room temperature. The black precipitate was collected with filtration. Yield 7 mg of silver sulfide (68%).

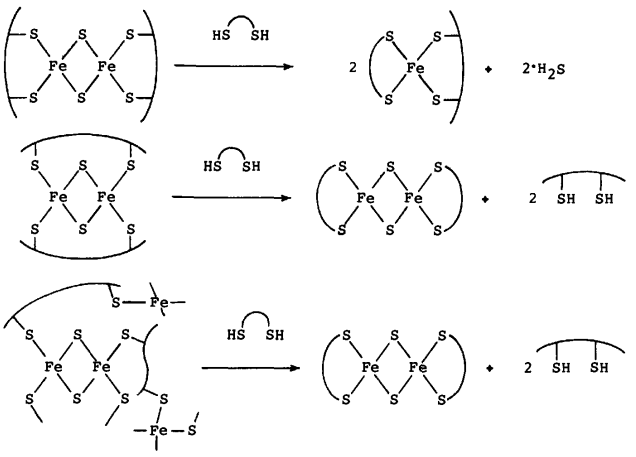
Methods. The visible spectrum (a) was obtained with a DMF solution of [2Fe-2S] complex (3×10^{-7} mol) in a

specially designed quartz 1 mm-cell equipped with stop-cocks for the measurements of visible and circular dichroism (CD) spectra. The ligand-exchange reaction (b) was carried out by the addition of a DMF solution of tdt-H_2 (3×10^{-7} mol) at room temperature. The difference visible spectra of the above systems were obtained by subtracting (a) from (b) to give a spectrum corresponding to the spectrum of a DMF solution of the authentic $[NEt_4]_2[Fe_2S_2(tdt)_2]$. The addition of *o*-xyl-$(SH)_2$ to [2Fe–2S] complexes was also carried out by the above method.

Physical Measurements. The visible spectra of the [2Fe–2S] complexes were obtained on a Jasco UVIDEC-5A spectrophotometer. CD spectra were recorded using a Jasco J-40 spectropolarimeter. The calibration of the spectropolarimeter was carried out with *epi*-androsterone in dioxane.[14] The values of ε and $\Delta\varepsilon$ were given in the unit of $M^{-1}cm^{-1}$.

Results and Discussion

Ligand-Exchange Reaction. A ligand-exchange method using 3,4-toluenedithiol (tdt-H_2) or *o*-xylene-α,α'-dithiol (*o*-xyl-$(SH)_2$) was employed to determine a chelation ability of Z–Cys–X–Y–Cys–OMe to $[Fe_2S_2]^{2+}$ core in DMF at room temperature. The proposed ligand-exchange reactions for the 2Fe–2S complexes with the dithiols are shown in the following scheme.



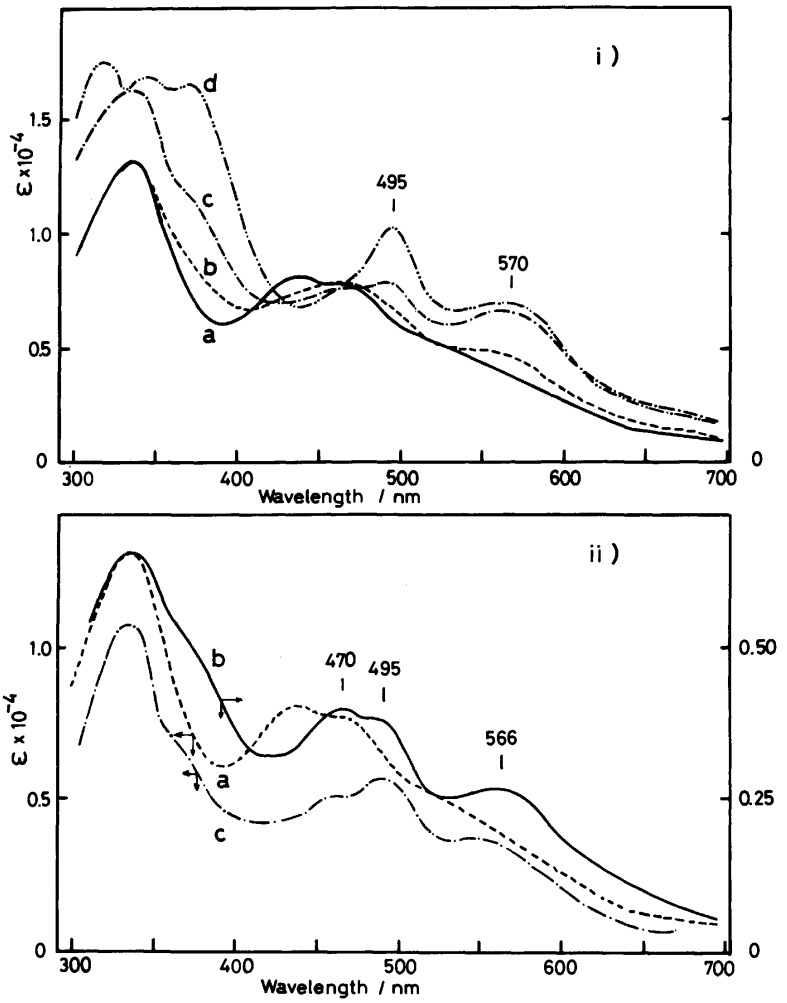


Fig. 1. Visible spectra of i) (a) a DMF solution of $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-}Bu)_4]$ at room temperature, (b) solution-(a)+tdt-H_2(1 equiv), (c) solution-(a)+tdt-H_2(2 equiv,) and (d) the solution-(a)+tdt-H_2(4 equiv) and ii) (a) a DMF solution of $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-}Bu)_4]$, (b) the difference visible spectrum of the reaction mixture of $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-}Bu)_4]$ and tdt-H_2 (1 : 1), and (c) the visible spectrum of a DMF solution of $[NEt_4]_2[Fe_2S_2(tdt)_2]$ at room temperature.

Monodentate ligand, *t*-Bu-S$^-$, in $[Fe_2S_2(S\text{-}t\text{-}Bu)_4]^{2-}$ can be easily expelled by Cys-containing peptides such as Z-Ala-Cys-OMe and Z-Cys-Ala-Ala-Cys-OMe. This ligand-exchange reaction in the following equation was utilized for the synthesis of [2Fe-2S] Cys-containing peptide complexes[9] as well as the synthesis of [4Fe-4S] peptide complexes.[15-17] The authentic $[NEt_4]_2[Fe_2S_2(tdt)_2]$ was synthesized by the same method.

$$[Fe_2S_2(S\text{-}t\text{-}Bu)_4]^{2-} \xrightarrow{RS^-} [Fe_2S_2(SR)_4]^{2-} + t\text{-BuSH} \quad (1)$$

(SR^- = $tdt^{2-}/2$, Cys-containing peptides$^-$)

Examination of Chelation of Peptide Ligands on $[Fe_2S_2]^{2+}$ Core by Ligand-Exchange Reaction with 3,4-Toluenedithiol. The dithiol readily exchanges with the monodentate ligand of [2Fe–2S] complexes as shown in $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-}Bu)_4]$ (**1**) and $[NEt_4]_2[Fe_2S_2$-(Z-Ala-cys-OMe)$_4$] (**2**).

Figure 1-i or 2 shows the visible spectra of **1** or **2** in DMF and the spectral change by the addition of various molar equivs of tdt-H_2. The addition of less than 2 equiv of tdt-H_2 to $[NEt_4]_2[Fe_2S_2(S\text{-}t\text{-}Bu)_4]$ resulted in formation of a new species giving an isosbestic point at 465 nm. The visible spectrum of the new species obtained by the addition of 1 equiv of tdt-H_2 is shown in Fig. 1-b. One of the figures shows a difference spectrum between **1** and the reaction mixture. The new species exhibits absorption maxima at 566, 495, 470, 375 (sh), and 336 nm for **1** or 566, 493, 470, 373 (sh), and 335 nm for **2** in DMF. The absorption maximum at 566 nm is assignable to a characteristic ligand-metal charge-transfer (LMCT) band for $[Fe_2S_2(SR)_4]^{2-}$ complex. The species having these absorption maxima (550, 496, 470, 370, 320 nm) was thus identified as the authentic $[Fe_2S_2(tdt)_2]^{2-}$ complex. The formation of $[Fe_2S_2(tdt)_2]^{2-}$ was observed by ^1H NMR spectrum of a reaction mixture of $[Fe_2S_2(Z\text{-cys-Ala-OMe})_4]^{2-}$ with tdt-H_2 in Me_2SO-d_6. Two broad peaks at δ 10.8 and 10.2 were found and assignable to the phenyl protons of tdt ligand, since the authentic tdt complex exhibited two Ph-H signals at δ 10.2 and 10.5 in Me_2SO-d_6. The methyl proton peaks of the ligand were overlapped with *t*-Bu peaks at δ 4.7.

The addition of tdt-H_2 to $[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]^{2-}$ results in formation of $[Fe_2S_2(tdt)_2]^{2-}$ with a smooth substitution reaction of Z-Ala-Cys-OMe with the tdt ligand. In this case, the $[Fe_2S_2]^{2+}$ core remains until the addition of over 5 equiv of tdt-H_2.

The addition of over 3—4 equivs of tdt-H_2 to **1** resulted in formation of another new species having absorption maxima at 495 nm (ε 14500), 375 nm (ε 27400), and 313 nm (ε 19500). The addition of tdt-H_2 to a DMF solution of $[Fe_2S_2(S_2\text{-}o\text{-xyl})_2]^{2-}$ (**3**) (Fig. 3) or $[Fe_2S_2(Z\text{-cys-Ala-Ala-cys-OMe})_2]^{2-}$ (**4**) (Fig. 4) at

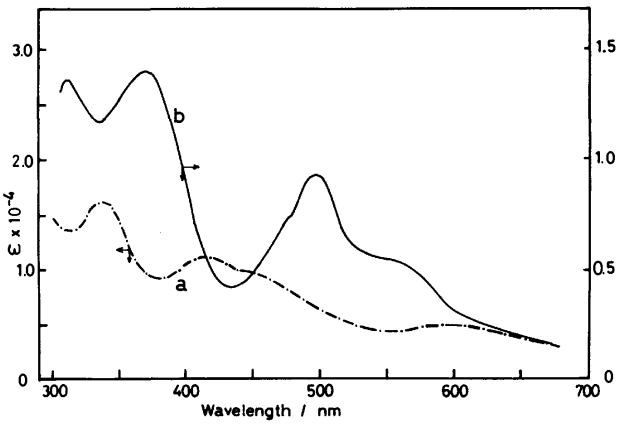

Fig. 3. Visible spectra of a) $[NEt_4]_2[Fe_2S_2(S_2\text{-}o\text{-xyl})_2]$ and b) the difference visible spectrum of the species forming from the ligand-exchange reaction (solution-(a) + tdt-H_2 (1 : 1)) in DMF at room temperature.

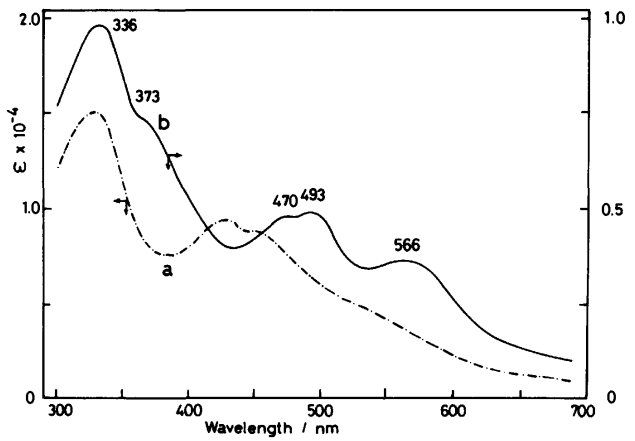

Fig. 2. Visible spectra of a) $[NEt_4]_2[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]$ and b) the difference visible spectrum of the species obtained from the ligand-exchange reaction (solution-(a) + tdt-H_2 (1 : 1)) in DMF at room temperature.

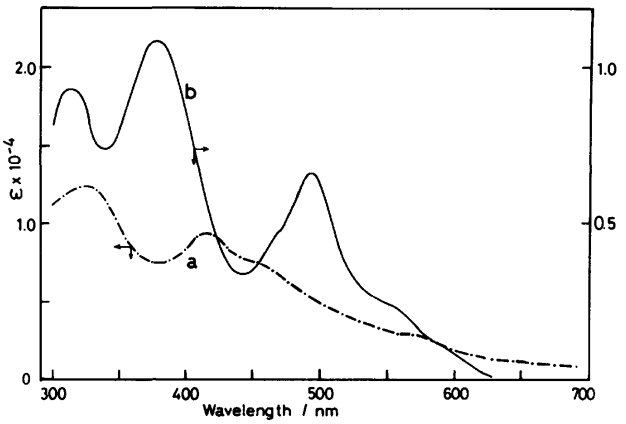

Fig. 4. Visible spectra of a) $[NEt_4]_2[Fe_2S_2(Z\text{-cys-Ala-Ala-cys-OMe})_2]$ and b) the difference visible spectrum of the species forming from the ligand-exchange reaction (solution-(a) + tdt-H_2 (1 : 1)) in DMF at room temperature.

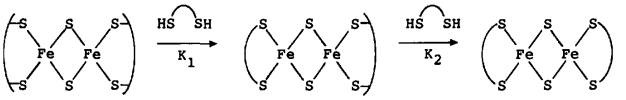
(1 : 1) molar ratio gave another species which exhibits absorption maxima at 492 nm (ε 9700), 370 nm (sh, ε 13000), and 339 nm (ε 16000). The difference spectrum of the species is shown in Fig 4-b. The chelation of two tdt ligands is expected for Fe(III), but the absorption maxima of $[Fe(tdt)_2]^{1-}$ in DMF were reported to be observed at 645 nm (ε 100), 503 nm (ε 10000), and 386 nm (ε 17000).[18] The bis(peptide)Fe(III) complex, $[Fe(Z\text{-cya-Ala-Ala-cys-OMe})_2]^{1-}$ has been found to have absorption maxima at 495 nm (ε 3400) and 353 nm (ε 5500).[5] Therefore, these two bis-chelated species are not present at (1 : 1) ratio. Then, the new species suggests the formation of [Fe(tdt)-(Z-cys-Ala-Ala-cys-OMe)]$^{1-}$. This ligand-exchange reaction gave hydrogen sulfide which was detected as silver sulfide in 68% yield. The addition of tdt-H_2 to a DMF soultion of **4** results in preferential cleavage of Fe-S* at (1 : 1) molar ratio.

Addition of *o*-Xylene-α,α′-dithiol (*o*-xyl-(SH)$_2$) to a Solution of 2Fe-2S Peptide Complex. *o*-Xyl-(SH)$_2$ is also one of effective chelating reagents for Fe(III) ion. The succesive addition of 1—5 equiv of *o*-xyl-(SH)$_2$ to a DMF solution of $[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]^{2-}$ and $[Fe_2S_2(Z\text{-cys-Ala-Ala-cys-OMe})_2]^{2-}$ showed a visible maximum at 588 nm with high-molar absorption coefficient which is assignable to a LMCT absorption maximum (ε 4800) of $[Fe_2S_2(S_2\text{-}o\text{-xyl})_2]^{2-}$ (Fig. 5). The addition of *o*-xyl-(SH)$_2$ to a solution of the peptide complexes results in formation of the same 2Fe-2S complex after the ligand substitution reaction. This titration was monitored by the CD spectral method and resulted in observation of 20% of the Δε value at 580 nm (Fig. 6). Clear isosbestic points in the CD spectra were observed at 350, 395, and 437 nm. The results indicate a monotonous substitution of Z-Cys-Ala-Ala-Cys-OMe with *o*-xyl-(SH)$_2$ giving mixed ligand [2Fe-2S] complexes as shown in the following scheme. The *K* value ($K_1 \cdot K_2$) obtained by the CD



method is 0.4 (K_1=0.2, K_2=2.0) in DMF. On the contrary, the successive addition of *o*-xyl-(SH)$_2$ to $[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]^{2-}$ results in gradual appearance of an absorption maximum at 592 nm. *K* value for the ligand-exchange reaction of $[Fe_2S_2(Z\text{-Ala-cys-OMe})_4]^{2-}$ is 0.0007 mol^2 in DMF (by the CD

method).

Chelating Ability of Z-Cys-Ala-Ala-Cys-OMe. The displacement reaction by tdt-H_2 with Cys-containing 2Fe–2S complexes in DMF was found to be different from that by *o*-xyl-$(SH)_2$. The addition of *o*-xyl-$(SH)_2$ to **1** and **2** results in formation of $[Fe_2S_2(S_2\text{-}o\text{-xyl})_2]^{2-}$ with a characteristic absorption maximum at 592 nm, which corresponds to the reported maximum at 590 nm (ε 4800) in DMF.[13] The difference between the K values (0.0007 for **2** and 0.4 mol^2 for **3**) is ascribed to the chelation effect of Z–Cys–Ala–Ala–Cys–OMe in **4**. The presence of the clear isosbestic point of the CD spectra with addtion of *o*-xyl-$(SH)_2$ to **3** indicates absence of a bridged Z–Cys–Ala–Ala–Cys–OMe ligand since the bridging ligand must be substituted first with tdt ligand. The successful employment of *o*-xyl-$(SH)_2$ for the core extrusion of [2Fe–2S]adrenal ferredoxin has already been reported.[1,10]

The addition of tdt-H_2 to a DMF solution of **2** and **3** results in the cleavage of Fe–S* bond in the $Fe_2S_2^{2+}$ core, giving $[Fe(tdt)(S_2\text{-}o\text{-xyl})]^{1-}$ or $[Fe(tdt)(Z\text{–cys–Ala–Ala–cys–OMe})]^{1-}$ with the following reaction scheme.

$$[Fe_2S_2(S_2\text{-}R)_2]^{2-} \xrightarrow{\text{tdt-}H_2} [Fe(tdt)(S_2\text{-}R)]^{1-} + H_2S \xrightarrow{\text{tdt-}H_2} 2[Fe(tdt)_2]^{1-} + (HS)_2\text{-}R \quad (2)$$

$(S_2\text{-}R^{2-} = S_2\text{-}o\text{-xyl}^{2-}$, Z-Cys-Ala-Ala-Cys-$OMe^{2-})$

Previously, we reported that $[Fe(Z\text{–cys–Ala–Ala–cys–OMe})_2]^{1-}$ exhibits CD extrema at 560 nm ($\Delta\varepsilon$ +1.3) and 500 nm ($\Delta\varepsilon$ −1.6) in DMF. The (1:1) species, $[Fe(tdt)(Z\text{–cys–Ala–Ala–cys–OMe})]^{1-}$, exhibits an absorption maximum at 494 nm (ε 12000) and CD extrema at 550 nm ($\Delta\varepsilon$ −0.6), 495 nm ($\Delta\varepsilon$ −1.0), and 335 nm ($\Delta\varepsilon$ −13.0). Formation of hydrogen sulfide was confirmed by precipitation of silver sulfide from silver nitrate. The satisfactory yield (68%) of silver sulfide indicates that the addition of tdt-H_2 to **3** preferentially cleavages the Fe–S* bonds according to the Eq 2. Averil et al. have reported the core extrusion of [2Fe–2S] adrenodoxin with tdt-H_2.[10] They speculated the formation of $[Fe(tdt)_2]^{2-}$ with addition of 19 equivs of tdt-H_2 to adrenodoxin. The reduction of $[Fe(tdt)_2]^{1-}$ should be involved in this case because the mononuclear bis(1,2-dithiolene)Fe(III) complex has a relatively positive redox potential and is easily reduced by the dithiol giving (2−) species ($[Fe^{II}(tdt)_2]^{2-}$). Our results suggest that, upon the core extrusion from iron-sulfur proteins, some of dithiols destroy a native cluster itself.

Thus we found that the addition of one equiv of tdt-H_2 to $[Fe_2S_2(SR)_4]^{2-}$ complex results in the formation of either $[Fe(tdt)(SR)_2]^{1-}$ or $[Fe_2S_2(tdt)_2]^{2-}$. The former complex is formed by cleavage of Fe–S* and the later product is obtained by the substitution of SR with tdt ligand. Thus, although we have examined only a few cases of the ligand exchange reactions for Cys-containing peptide complexes, the chelation of the peptide thiolate ligand to $[Fe_2S_2]^{2+}$ core was conveniently determined by using tdt-H_2.

In conclusion, the chelation of Z–Cys–Ala–Ala–Cys–OMe to each Fe(III) ion in the [2Fe–2S] complex is confirmed. The bridging coordination of this sequence in native [2Fe–2S]ferredoxins is thus enforced by the peptide sequence of the other parts.

Hydroxylation of Acetoxy-*p*-menthenes in the Cultured Cells of *Nicotiana tabacum*. Epoxidation of the Carbon-Carbon Double Bond

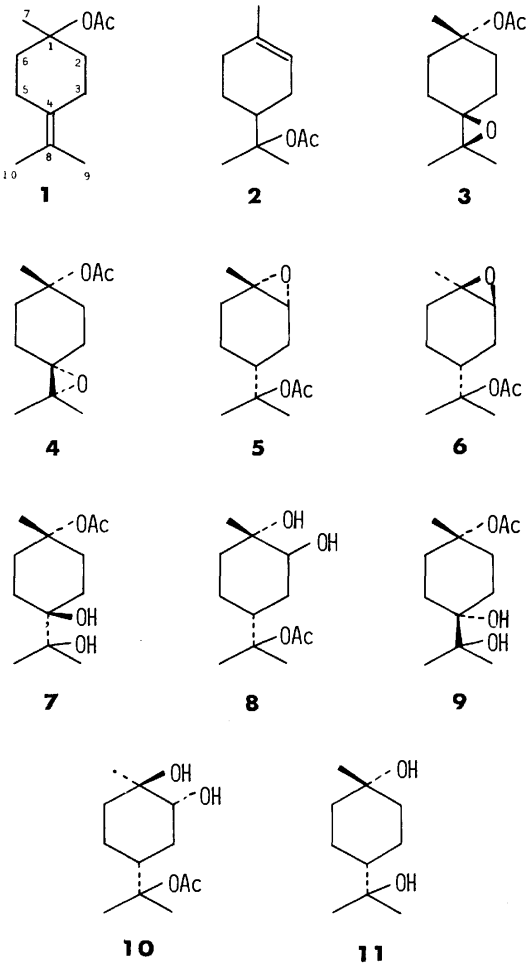
Toshifumi HIRATA, Shunsuke IZUMI, Teiji EKIDA, and Takayuki SUGA*
Department of Chemistry, Faculty of Science, Hiroshima University,
Higashisenda-machi, Naka-ku, Hiroshima 730
(Received July 7, 1986)

The process of the formation of glycols in the biotransformation of 1-acetoxy-*p*-menth-4(8)-ene and 8-acetoxy-*p*-menth-1-ene in the cultured cells of *Nicotiana tabacum* was examined. The formation of the glycols was found to result from epoxidation of the C–C double bond, followed by hydrolysis of the resulting epoxides.

Recent studies on the biotransformation of acetoxy-*p*-menthenes in the cultured cells of *Nicotiana tabacum* showed that the cells have the ability to hydroxylate regio- and stereoselectively the C–C double bond and its allylic position to yield the corresponding glycols and allyl alcohols.[1-3] Also the hydroxylation of 8-acetoxy-*p*-menth-1-ene was enantioselective;[3,4] the C–C double bond of the 4*S* enantiomer was hydroxylated in preference to the 4*R* one, whereas the hydroxylation at the allylic position was in favor of the 4*R* isomer. Such a difference in enantioselectivity in two types of the hydroxylation remarked us that the mechanism may differ from one another. We have investigated the process of hydroxylation of the C–C double bond in the cultured cells of *N. tabacum*.

Results and Discussion

Formation of Epoxides in the Biotransformation of Acetoxy-*p*-menthenes. In order to find intermediates in the hydroxylation of the C–C double bond, each of 1-acetoxy-*p*-menth-4(8)-ene (**1**) and (±)-8-acetoxy-*p*-menth-1-ene (**2**) was incubated for 2 d with a suspension of cultured cells of *N. tabacum* similarly to the manner described in our previous paper,[1] and careful TLC and GLC analyses indicated that the products were composed of unidentified products (**3**—**6**), in addition to the previously described hydroxylated products, such as *t*-1-acetoxy-*p*-menthane-*r*-4,8-diol (**7**) and 8-acetoxy-*c*-4-*p*-menthane-*r*-1,*t*-2-diol (**8**).[1,3] The unidentified products **3**—**6** were proved to be the corresponding epoxides of the acetoxy-*p*-menthenes by comparison of TLC, GLC, and GLC-MS with those of synthetic specimens described in the next section. Incubation of **1** gave *r*-1-acetoxy-*t*-4,8-epoxy-*p*-menthane (**3**) and *r*-1-acetoxy-*c*-4,8-epoxy-*p*-menthane (**4**) in 3.8 and 1.0% yields, respectively. On the other hand, incubation of **2** gave 8-acetoxy-*r*-1,*c*-2-epoxy-*c*-4-*p*-menthane (**5**) and 8-acetoxy-*r*-1,*c*-2-epoxy-*t*-4-*p*-menthane (**6**) in 2.0 and 0.1% yields, respectively.



The time-courses in the biotransformation of the acetoxy-*p*-menthenes **1** and **2** in a suspension of the cultured cells were followed. In the case of **1**, the formation of the epoxides **3** and **4** was observed at an earlier period of incubation, but their content gradually decreased with the lapse of time after incubation for 4 d, as shown in Fig. 1a. Similar phenomenon was also observed in the case of 8-acetoxy-*p*-menth-1-ene (**2**) (Fig. 1b). Such a decrease in the amount of the epoxides is probably due to further transformation to other products such as glycols, which had been the main products in the

biotransformation of the acetoxy-*p*-menthenes.[1,3]

To elucidate the conversion of the epoxides to the glycols, each of the epoxides **3**—**6** was incubated under the same conditions as described above. The remarkable formation of the corresponding glycols was observed as shown in Fig. 2. The epoxides **3** and **6** were transformed to a single product, *t*-1-acetoxy-*p*-menthane-*r*-4,8-diol (**7**) and 8-acetoxy-*c*-4-*p*-menthane-*r*-1,*t*-2-diol (**8**), respectively, whereas the epoxides **4** and **5** gave a mixture of glycols, the glycol (**7**) and *c*-1-acetoxy-*p*-menthane-*r*-4,8-diol (**9**) in a ratio of 1:6 from **4** and the glycol **8** and 8-acetoxy-*t*-4-*p*-menthane-*r*-1,*t*-2-diol (**10**) in a ratio of 4:1 from **5**. Exclusive formation of the glycol **8** in the conversion of the epoxide **6** indicates occurrence of the cleavage of the epoxy ring at only C-1 and not at C-2. Such an exclusive conversion is probably due to the difference in the stability of intermediate cations in the transition state, as indicated by the MO calculation[5] that the total energy of the cation having a positive charge at C-1 is lower by 26 kcal† mol^{-1} than that of the cation at C-2. The transformation of the epoxides to the glycols was also found when the epoxides were treated with Murashige and Skoog's solution[6] used as culture medium. These findings clearly indicate that the epoxides are chemically converted to the corresponding glycols with this solution. The rate of the transformation of the epoxide **6** to the glycol **8** was very fast, as shown in Fig. 2d; this may be responsible for a little accumulation of the epoxide **6** in the biotransformation of **2**.

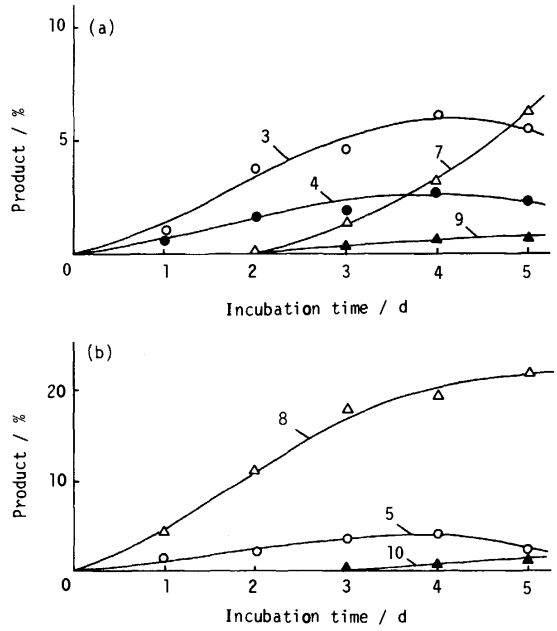


Fig. 1. Formation of the epoxides **3**—**5** and the glycols **7**—**10** in the biotransformation of (a) 1-acetoxy-*p*-meth-4(8)-ene (**1**) and (b) 8-acetoxy-*p*-menth-1-ene (**2**) in the cultured cells of *N. tabacum*.

The transformation of the acetoxy-*p*-menthenes to glycols in the cultured cells of *N. tabacum* was thus found to involve epoxidation of the double bond by a biological process, followed by hydrolysis of the resulting epoxides by a chemical one.

Structure Elucidation of the Synthetic Epoxides. For identification of the stereochemical structures of the epoxides produced in the biotransformation of the

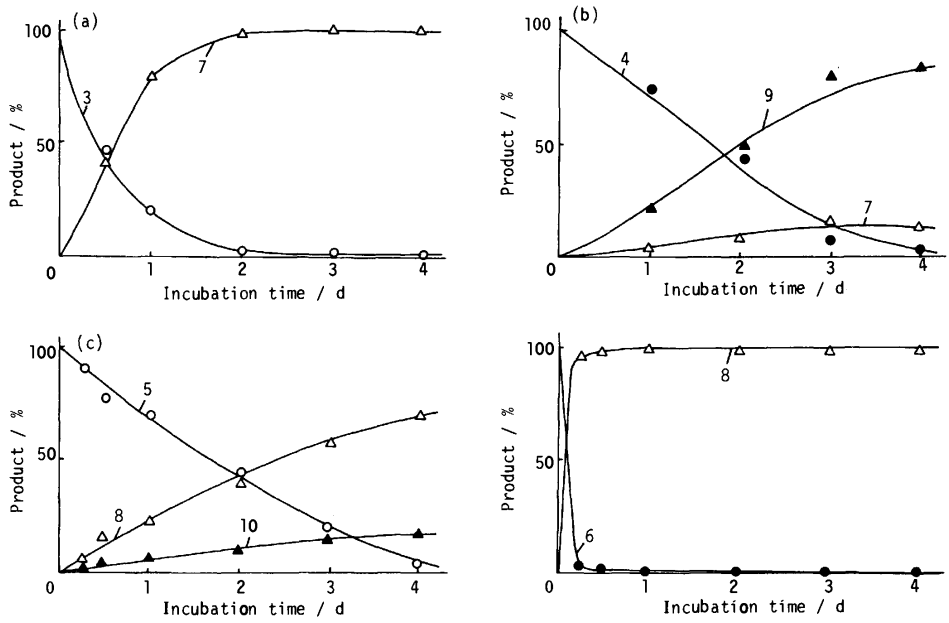

Fig. 2. The time-courses in the biotransformation of (a) *r*-1-acetoxy-*t*-4,8-epoxy-*p*-menthane (**3**), (b) *r*-1-acetoxy-*c*-4,8-epoxy-*p*-menthane (**4**), (c) 8-acetoxy-*r*-1,*c*-2-epoxy-*c*-4-*p*-menthane (**5**) and 8-acetoxy-*r*-1,*c*-2-epoxy-*t*-4-*p*-menthane (**6**) in the cultured cells of *N. tabacum*.

† 1 cal=4.184 J.

acetoxy-*p*-menthenes in the cultured cells, epoxides were prepared from **1** and **2** by epoxidation with *m*-chloroperbenzoic acid to determine their relative spatial arrangements between the epoxy ring and the 1-acetoxyl and 1-acetoxy-1-methylethyl groups, as described below. Epoxidation of **1** gave a 3:7 mixture of epoxides A and B which were identical with the products **4** and **3** in the biotransformation of **1**, respectively, in all respects of their spectra and chromatographic behavior. The fragmentation pattern in the mass spectrum of the epoxide A was quite similar to that of the epoxide B; this implies the epoxide A to be a geometrical isomer of the epoxide B. The epoxides A and B exhibited the ^{1}H NMR signals at δ 1.36 and 1.33, respectively, due to a tertiary *gem*-dimethyl group, instead of the signal (δ 1.67) due to the methyl groups attached to the 4(8)-double bond of **1**. Accordingly, the epoxides A and B were suggested to be 4,8-epoxides of **1**. However, these spectral data did not give any reliable informations for determining the relative orientation between the epoxy ring and the 1-acetoxyl group in the epoxides. The structure of the epoxide A was finally determined by X-ray crystallography. An ORTEP drawing[7] of the epoxide A is given in Fig. 3; the epoxy ring was found to be cis to the acetoxyl group. The epoxide A was thus established to be *r*-1-acetoxy-*c*-4,8-epoxy-*p*-menthane (**4**). Therefore, the epoxide B should be *r*-1-acetoxy-*t*-4,8-epoxy-*p*-menthane (**3**).

Epoxidation of **2** gave a 9:11 mixture of epoxides C and D which were identical with the epoxides **5** and **6** in the biotransformation of **2**, respectively. The relative orientation between the epoxy ring and the 1-acetoxy-1-methylethyl group in these epoxides was evidenced by ^{1}H NMR spectral analysis as described below. On the basis of Karplus's equation[8] and the ^{1}H NMR data reported for limonene 1,2-oxide,[9] ^{1}H–^{1}H coupling patterns for the C-2 proton of both the epoxides were predicted to be a doublet (J=4—7 Hz) for a *cis*-epoxide and a broad singlet or a triplet (J=0—2 Hz) for a *trans*-epoxide. The observed signals were a doublet (J=4.6 Hz) at δ 2.81 for the epoxide C and a broad singlet at δ 2.87 for the epoxide D; this observation suggests the relative orientation between the epoxy ring and the 1-acetoxy-1-methylethyl group in the epoxide C to be cis and that of the epoxide D to be trans. The suggested structure for the epoxide C was supported by the formation of *c*-4-*p*-menthane-*r*-1,8-diol (**11**)[10] on reduction with lithium aluminum hydride. The epoxides C and D were thus established to be 8-acetoxy-*r*-1,*c*-2-epoxy-*c*-4-*p*-menthane (**5**) and 8-acetoxy-*r*-1,*c*-2-epoxy-*t*-4-*p*-menthane (**6**), respectively. All the epoxides prepared above were used as authentic samples for the purpose of identification.

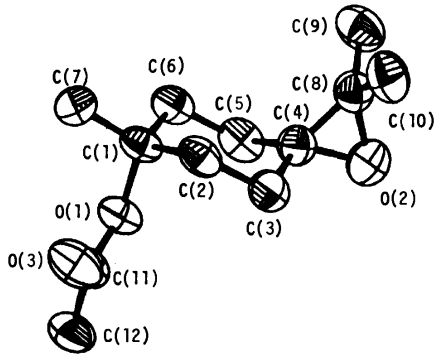

Fig. 3. ORTEP drawing of the epoxide A.

Experimental

Analytical TLC and preparative TLC were carried out on 0.25 mm and 0.75 mm thick silica-gel plates (Merck silica gel 60, GF_{254}), respectively. GLC analyses were performed on a Shimadzu GC-6A gas chromatograph equipped with an FID and a glass column (3 mm×2 m) packed with 15% DEGS and 2% OV-17 on Chromosorb W (AW-DMCS; 80—100 mesh) by programming the column temperature at 100—200 °C with a rate of 3 °C min^{-1} for DEGS and at 90—250 °C with a rate of 2 °C min^{-1} for OV-17. GLC-MS were recorded on a Shimadzu QP-1000 mass spectrometer which was equipped with an EI ion source operating at 70 eV and installed with a gas chromatograph equipped with an OV-17 column operating at 80—200 °C with a rate of 3 °C min^{-1}.

Substrate. 1-Acetoxy-*p*-menth-4(8)-ene (**1**) [IR ν_{max} (film) 1740 cm^{-1} (ester C=O); ^{1}H NMR ($CDCl_3$) δ=1.49 (3H, s, 7-Me), 1.67 (6H, bs, 9- and 10-Me), and 1.98 (3H, s, OAc); *m/z* (rel intensity) 136 (M$^+$—AcOH, 80%), 121 (100), and 93 (65)] was prepared from limonene (Ogawa Perfumery Co. Ltd.), according to the procedure described in our previous paper.[1]

(±)-8-Acetoxy-*p*-menth-1-ene (**2**) [IR ν_{max} (film) 1730 cm^{-1} (ester C=O); ^{1}H NMR ($CDCl_3$) δ=1.43 (6H, s, 9- and 10-Me), 1.64 (3H, bs, 7-Me), 1.96 (3H, s, OAc), and 5.32 (1H, bs, >C=CH-); *m/z* (rel intensity) 136 (M$^+$—AcOH, 85%), 121 (100), and 93 (63)] was prepared from (±)-*p*-menth-1-en-8-ol (*α*-terpineol) (Takasago Perfumery Co. Ltd.) by acetylation, followed by chromatography on a silica-gel column with hexane-ethyl acetate (97:3, v/v). Both the substrates used were >99.5% pure on GLC.

Incubation of Acetoxy-*p*-menthenes 1 and 2 in a Suspension of the Cultured Cells. A suspension of the cultured cells of *N. tabacum* "Bright Yellow" were prepared as described in our previous paper;[1] the cells were cultured in each 300-ml conical flask containing 100 ml of Murashige and Skoog's solution.[6] To the flask containing a suspension of the cultured cells, 10 mg of the substrate, such as 1-acetoxy-*p*-menth-4(8)-ene (**1**) and (±)-8-acetoxy-*p*-menth-1-ene (**2**), were administered; the total amount of the substrate used was 100 mg. The mixture was incubated at 25 °C for 2 d on a rotary shaker (70 rpm) in the dark. The cultured mixture was worked up in a manner similar to that described in our previous paper.[1] An incubation product obtained was subjected to the repeated TLC with hexane-ethyl acetate (7:3 and 1:1, v/v). Constituents of the product were identified by comparing their TLC, GLC, and GLC-MS with those of authentic specimens.

Time-Courses in the Biotransformation of Acetoxy-*p*-menthenes 1 and 2 and Epoxides 3—6. Each of the substrates was administered to a suspension of the precultured cells in each flask, as described above. A part of the incubation mixture (10 ml) was pipetted out and extracted with ether at a regular time interval. Each ether extract was dissolved in ethyl acetate and then subjected to GLC. The products were identified by comparison (co-GLC and GLC-MS) with authentic samples.[1,3] Yields of the products were determined on the basis of the peak areas on GLC and are expressed as the relative percent for the total amount of a whole reaction product extracted. The time-courses in the biotransformation are given in Figs. 1 and 2.

Treatment of Acetoxy-*p*-menthenes 1 and 2 and Epoxides 3—6 with Murashige and Skoog's Solution. Each of the substrates (10 mg) were shaken with 100 ml of Murashige and Skoog's solution (pH 5.8) at 25 °C for 4 d in the dark. A reaction mixture was extracted with ether to give an oily substance, which was subjected to TLC, GLC, and GLC-MS. The oily substance was composed of only the unchanged acetoxy-*p*-menthene in both the cases of the acetoxy-*p*-menthenes **1** and **2**.

The epoxides **3—6** were completely converted to the corresponding glycols. These glycols were identified by comparison of their TLC, GLC, and GLC-MS with those of authentic samples.[1,3] Each of the oily substances (9 and 10 mg) obtained in the reactions of **3** and **6** with Murashige and Skoog's solution was composed of only *t*-1-acetoxy-*p*-menthane-*r*-4,8-diol (**7**) and 8-acetoxy-*c*-4-*p*-menthane-*r*-1,*t*-2-diol (**8**), respectively, by GLC and GLC-MS analyses. In the case of the epoxide **4**, the oily substance (10 mg) was composed of the glycol **7** and *c*-1-acetoxy-*p*-menthane-*r*-4,8-diol (**9**) in a ratio of 1:6 on the basis of the peak areas on GLC. On the other hand, the oily substance (9 mg) from the epoxide **5** was composed of the glycol **8** and 8-acetoxy-*t*-4-*p*-menthane-*r*-1,*t*-2-diol (**10**) in a ratio of 4:1. The time-courses of the conversion of the epoxides **3—6** to the corresponding glycols in Murashige and Skoog's solution were quite similar to those in the case of the transformation of the epoxides in a suspension of the cultured cells (Fig. 2).

Table 1. Final Atomic Coordinates and Thermal Parameters of the Epoxide **4** with Standard Deviations in Parentheses

Atom	$10^4 x$	$10^4 y$	$10^4 z$	B_{eq}[a)]/Å^2
C(1)	6117 (7)	4790 (9)	1682 (4)	4.2

a) $B_{eq}=(B_{11}+B_{22}+B_{33})/3$.

Preparation of Authentic Samples. i) *r*-1-Acetoxy-*t*-4,8-epoxy-*p*-menthane (**3**) and *r*-1-acetoxy-*c*-4,8-epoxy-*p*-menthane (**4**). Following the procedure described in the reference,[11] 1-acetoxy-*p*-menth-4(8)-ene (**1**) (66 mg) dissolved in dichloromethane (4 ml) was epoxidized with *m*-chloroperbenzoic acid (75 mg) at 0 °C for 4 h. The reaction mixture, after working-up as usual, was subjected to preparative TLC with hexane-ethyl acetate (9:1, v/v) to afford the epoxide **3** [35 mg; IR ν_{max} (film) 1730 cm^{-1} (ester C=O); ^{1}H NMR ($CDCl_3$) δ=1.33 (6H, s, 9- and 10-Me), 1.54 (3H, s, 7-Me), and 2.02 (3H, s, OAc); *m/z* (rel intensity) 152 (M^+—AcOH, 6), 110 (45), and 79 (100)] and the epoxide **4** [15 mg; mp 86.5—87.0 °C, IR ν_{max} (film) 1735 cm^{-1} (ester C=O); ^{1}H NMR ($CDCl_3$) δ=1.36 (6H, s, 9- and 10-Me), 1.54 (3H, s, 7-Me), and 2.04 (3H, s, OAc); *m/z* (rel. intensity) 152 (M^+—AcOH, 2), 110 (44), and 79 (100)].

ii) 8-Acetoxy-*r*-1,*c*-2-epoxy-*c*-4-*p*-menthane (**5**) and 8-acetoxy-*r*-1,*c*-2-epoxy-*t*-4-*p*-menthane (**6**). Epoxidation of 8-acetoxy-*p*-menth-1-ene (**2**) (1.02 g) with *m*-chloroperbenzoic acid (1.2 g) in dichloromethane (25 ml) at 5 °C for 4 h, followed by working-up in the same manner as above, gave the epoxide **5** [269 mg; IR ν_{max} (film) 1729 (ester C=O); ^{1}H NMR ($CDCl_3$) δ=1.23 (3H, s, 9-Me), 1.29 (3H, s, 9-Me), 1.31 (3H, s, 10-Me), 1.88 (3H, s, OAc), and 2.81 (1H, d, *J*=4.6 Hz, 2-H); *m/z* (rel intensity) 152 (M^+—AcOH, 8), 137 (7), 126 (21), and 43 (100)] and the epoxide **6** [335 mg; IR ν_{max} (film) 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.26 (3H, s, 7-Me), 1.38 (6H, s, 9- and 10-Me), 1.88 (3H, s, OAc), and 2.87 (1H, bs, 2-H); *m/z* (rel intensity) 152 (M^+—AcOH, 5), 137 (7), 126 (25), and 43 (100)].

Reduction of the Epoxide 5. The epoxide **5** (10 mg) dissolved in ether (2 ml) was refluxed with a suspension of $LiAlH_4$ (10 mg) in ether (2 ml) for 30 min. The reaction mixture, after working-up as usual, gave a crude product (6 mg). This crude product, after PTLC with hexane-ethyl acetate (7:3, v/v), gave *c*-4-*p*-menthane-*r*-1,8-diol (**11**):[10] 6 mg; mp and mmp 105—106 °C (lit,[12] mp 104—105 °C); IR ν_{max} (film) 3450 cm^{-1} (OH); ^{1}H NMR ($CDCl_3$) δ=1.18 (6H, s, 9- and 10-Me) and 1.21 (3H, s, 7-Me); *m/z* (rel intensity) 136 (M^+-2H_2O, 1), 96 (23), and 81 (100).

X-Ray Crystallographic Analysis of the Epoxide 4. The X-ray crystallographic analysis was performed on a Syntex R3 diffractometer using graphite-monochromated Mo $K\alpha$ radiation. The crystal analyzed was 0.62 mm×0.35 mm×0.87 mm in size. Crystal data: $C_{12}H_{20}O_3$, monoclinic, a=10.891 (5), b=7.747 (7), c=15.112 (8) Å, β=108.47 (4)°, U=1209.4 Å^3, Z=4, D_c=1.17 g cm^{-3}, D_m=1.20 g cm^{-3}, μ(Mo $K\alpha$)=0.9 cm^{-1}, space group $P2_1/c$. A total of 1316 reflections were collected by ω-scan ($2\theta_{max}$=50.0) and used in the structure determination. The phases of 204 reflections with $|E|>1.30$ were determined by MULTAN.[13] An E map for the best solution yielded positions for all non-hydrogen atoms. Anisotropic refinement for carbon and oxygen atoms and isotropic refinement for hydrogen atom by full-matrix least-squares calculation reduced the R index finally to 0.042. Final atomic coordinates are shown in Table 1. The lists of anisotropic thermal parameters and final structure factors have been deposited as Document No. 8718 at the Office of the Editor of the Chemical Society of Japan.

We acknowledge the assistance of Mr. Hidetoshi Sugimoto in the incubation of 1-acetoxy-4,8-epoxy-*p*-menthanes with the cultured cells and Messrs. Kiyotaka Munesada, Akira Nishikawa, and Satoru Murakami in the preparation of the authentic samples of 1-acetoxy-4,8-epoxy-*p*-menthanes. We thank Takasago Perfumery Co., Ltd. for a gift of the sample of α-terpineol and Ogawa Perfumery Co., Ltd., for a gift of the sample of limonene. The present work was supported in part by Grant-in-Aids for Developmental Scientific Research No. 57840030 (1982) and No. 59840013 (1984) from the Ministry of Education, Science and Culture.

Radical Switch Reaction. A Novel Reaction between Two Free Radicals in a Solvent Cage

Michio KOBAYASHI,* Michiko GOTOH, and Masato YOSHIDA
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received July 10, 1986)

Studies on the thermal decomposition of *t*-butyl phenylazo sulfone suggested the occurrence of a radical switch reaction, a novel type of reaction between two radicals. A primary geminate radical pair, *t*-butanesulfonyl and phenyl radical pair, exchange sulfur dioxide to form a new radical pair consisting of *t*-butyl and benzenesulfonyl radicals. The generation of benzenesulfonyl radical was confirmed by its ESR spectrum and the isolation of products containing a benzenesulfonyl group.

The thermal decomposition of arylazo aryl sulfones (Ar-N=N-SO_2Ar') can be considered to be initiated by the homolytic cleavage of the S-N bond to give a diazenyl radical and a sulfonyl radical; the diazenyl radical further decomposes to an aryl radical and nitrogen.[1-5] In continuing studies on the decomposition mechanism of azo sulfones, we are interested in the decomposition of *t*-butyl phenylazo sulfone (Ph-N=N-SO_2-*t*-Bu **1**). Since the 1,1-dimethylethanesulfonyl radical, which is expected to be generated by homolytic cleavage of the S-N bond of **1**, is known to decompose readily to a *t*-butyl radical and sulfur dioxide,[6] the mechanism and products of the decomposition of **1** may be different from that of arylazo aryl sulfones. During the study of the decomposition mechanism of **1** by product analysis, chemically induced dynamic nuclear polarization (CIDNP) and ESR, we have observed the occurrence of a new type of reaction between two geminate radicals in a solvent cage. The results will be described in this paper.

Results and Discussion

The rate constant of the decomposition of the azo sulfone **1** was determined in benzene in the presence of 3 mol of pyridine per mol of **1**; pyridine was added in order to suppress the autocatalyzed decomposition of **1** by acidic products.[2] The reaction was monitored by UV absorption at 296 nm. The rate was found to be first order in **1**. The observed first order rate constants were 48.3 (65.2 °C), 23.3 (60.2 °C), 8.84 (55.2 °C), and 6.05×10^{-5} s^{-1} (50.8 °C). Activation parameters estimated from these value are ΔH^*=133.7 kJ mol^{-1} and ΔS^*=126.7 J K^{-1} mol^{-1}.

The products of decomposition of **1** under these conditions are summarized below.

Detection of biphenyl among the products suggested the generation of a phenyl free radical. This was further confirmed by the examination of the orientation in the phenylation of the aromatic ring in the thermal decomposition of **1** in nitrobenzene: The isomer ratio of the nitrobiphenyl produced was *o*-72.2%; *m*- 5.2%; *p*- 22.6%. The total yield of nitrobiphenyls amounted to 28%. The isomer distribution (*o,p*-orientation) is the characteristic of homolytic

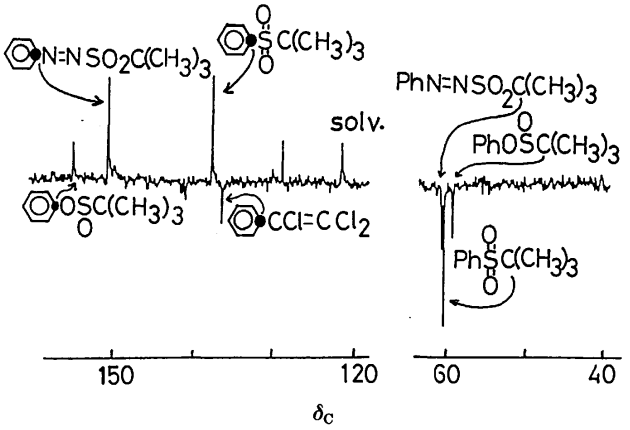

Fig. 1. The CIDNP spectra obtained in the thermal decomposition of azo sulfone **1** in tetrachloroethylene.

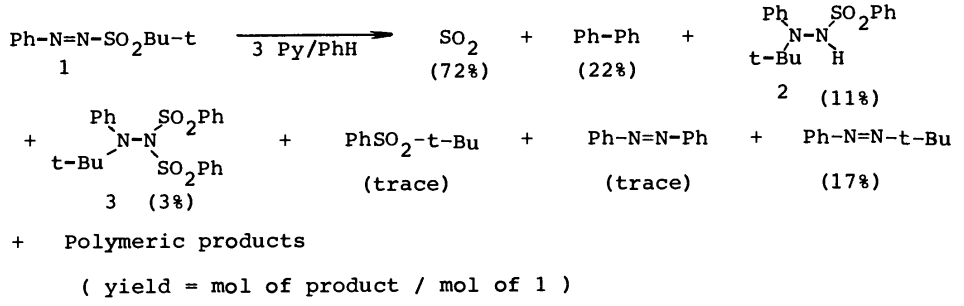
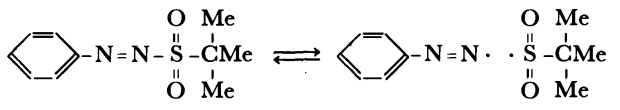


Scheme 1.

substitution by the phenyl radical.[7] The production of sulfur dioxide indicates the generation of the 1,1-dimethylethanesulfonyl radical followed by rapid decomposition to sulfur dioxide and a *t*-butyl radical.

We further examined the decomposition of azo sulfone **1** using the ^{13}C-CIDNP technique. When **1** was decomposed in tetrachloroethylene in a ^{13}C-NMR probe, several ^{13}C-CIDNP signals were observed as shown in Fig. 1. The enhanced absorption of C_1 and the emission signal of C_α of azo sulfone **1** itself indicates that the first step of the decomposition of **1** to give phenyldiazenyl-sulfonyl radical pair is reversible as shown in Eq. 1.

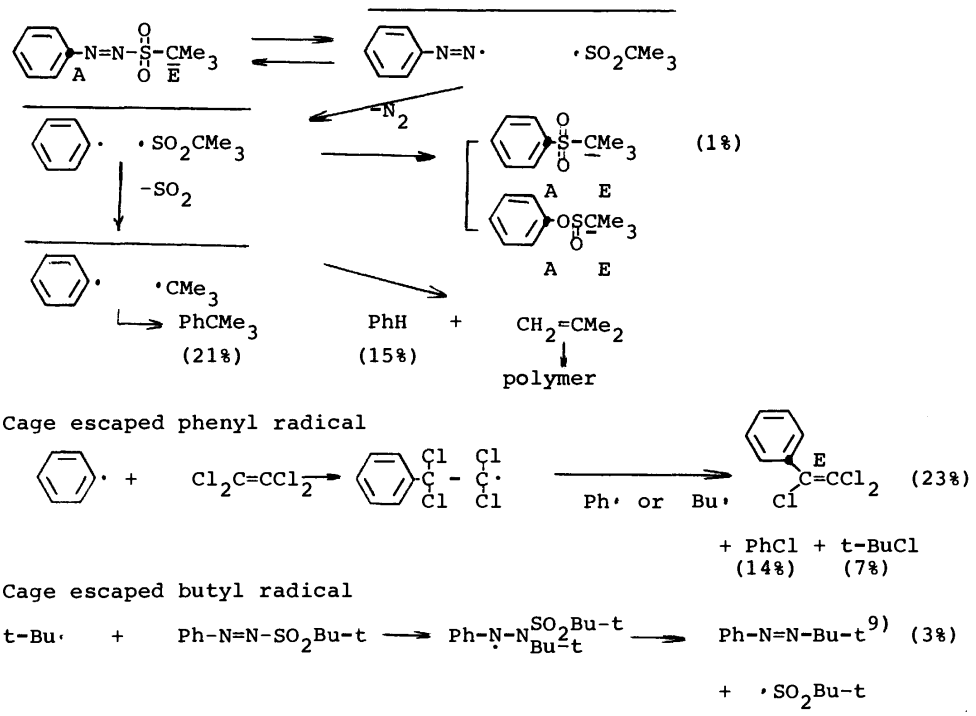


(1)

The mode of the CIDNP signals attributable to *t*-butyl phenyl sulfone and phenyl 1,1-dimethylethanesulfinate was also characteristic of the cage recombination products.[8] This suggests that in the second step, the primary geminate radical pair consisting of the phenyldiazenyl and 1,1-dimethylethanesulfonyl radicals decomposes to form a secondary radical pair consisting of phenyl and 1,1-dimethylethanesulfonyl radicals.

A considerable degree of a spin selection must occur in this radical pair before recombination or diffusion out of the solvent cage. Since the sulfonyl radical is ambident, recombination of these radicals in the solvent cage may give both sulfone and sulfinic ester. Although phenyl 1,1-dimethylethanesulfinate is unstable and could not be isolated as such among the final products of the decomposition of **1**, the ^{13}C-CIDNP spectrum shown in Fig. 1 cleary indicates that sulfinic ester is produced as the cage product during the thermal decomposition of **1**. In the previous paper,[1] we reported that the arenesulfonyl radical was ambident and acted either as a S- or O-centered radical.[5] Now the 1,1-dimethylethanesulfonyl radical is also shown to behave as a S- and O-centered radical.

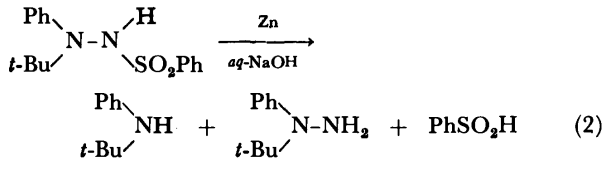
Although considerable amounts of *t*-butylbenzene and benzene were detected among the decomposition products, they did not exhibit the CIDNP signals. The formation of *t*-butylbenzene and benzene indicates that the 1,1-dimethylethanesulfonyl radical decomposes to a *t*-butyl radical and sulfur dioxide in the third step to give the *t*-butyl and phenyl radical pair in the solvent cage. This radical pair may give *t*-butylbenzene as a recombination product, and benzene and isobutene as disproportionation products. Failure to observe CIDNP signals due to *t*-butylbenzene or benzene may be explained by the small difference between the *g* values of the phenyl and *t*-butyl radicals. Results of CIDNP studies of the decomposition of **1** in tetrachloroethylene are summarized in Scheme 2.



Compound **3** was also isolated in a yield of 1%.
· or — shows the polarized carbons. A: enhanced absorption, E: emission signal.

Scheme 2.

The above-mentioned results obtained by product analysis and CIDNP technique are those expected from the usual homolytic decomposition of an azo sulfone. A remarkable result was the isolation of some unexpected products, phenylsulfonylhydrazine **2** and **3**, in considerable yields. The products were characterized by ^{1}H, ^{13}C-NMR, IR, and MS spectra. In order further to confirm the structure of **2**, it was reduced by zinc dust in aq. NaOH. The production of *N*-(*t*-butyl)phenylamine and benzenesulfinic acid is consistent with the structure suggested by the spectral data.



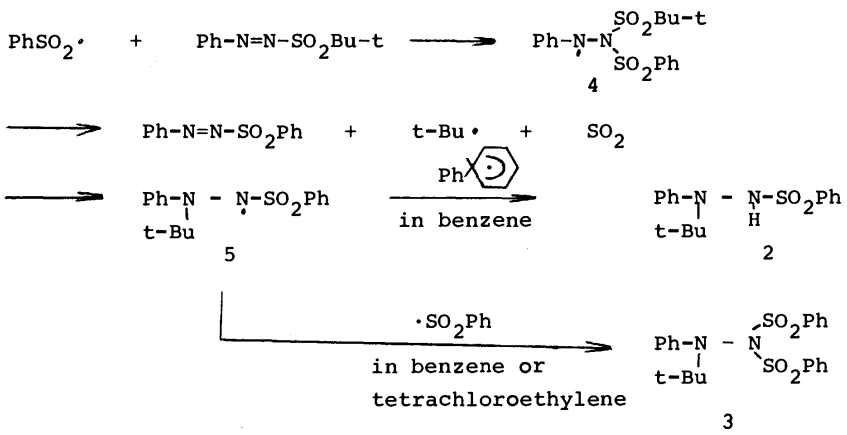
(2)

Formation of these phenylsulfonylhydrazine indicates the generation of benzenesulfonyl radical ($PhSO_2\cdot$) during the decomposition of **1**. Once sulfur dioxide splits off from 1,1-dimethylethanesulfonyl radical and diffuses out of the cage, the likelyhood of an encounter with a phenyl radical must be very small. As a phenyl radical is very reactive, a cage escaped phenyl radical should react with solvent benzene to give biphenyl before an encounter with sulfur dioxide. Thus, the only chance for the generation of a benzenesulfonyl radical is the recombination of the geminate phenyl radical and sulfur dioxide within the solvent cage.

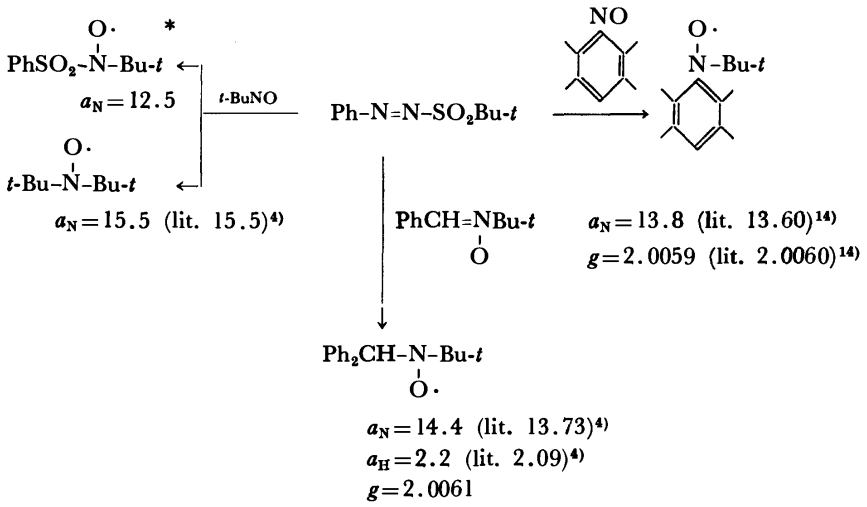
(3)

This exchange of sulfur dioxide between phenyl and 1,1-dimethylethanesulfonyl radicals to give benzenesulfonyl and *t*-butyl radical pair is a new type of reaction between two free radicals, which has no precedent. The driving force of this radical switch reaction must be the higher thermal stability of benzenesulfonyl radical than the 1,1-dimethylethanesulfonyl radical. The reaction of an aryl radical and sulfur dioxide to give a sulfonyl radical is well known, so the recombination of a phenyl radical and sulfur dioxide within the cage is plausible. Formation of **2** and **3** may be explained as shown in Scheme 3. The addition of a free radical to an N=N double bond to form a relatively stable hydrazyl radical (>N–N–Ar) must be thermally an easy process, although it has received little attention.[5,10,11] The addition of a benzenesulfonyl radical to the N=N bond of azo sulfone **1** will give the hydrazyl radical **4**, which may decompose to afford phenylazo phenyl sulfone and a *t*-butyl radical. The *t*-butyl radical then further attacks the azo sulfone to give the radical **5**. The radical **5** substituted by both electron-donor and -acceptor groups is expected to be rather stable (captodative substituent effect).[12,13] The hydrazyl radical **5** may give hydrazine **2** and **3** in benzene; in tetrachloroethylene it will give **3**. The hydrogen source for the formation of **2** should be a cyclohexadienyl radical formed by the addition of a phenyl radical to the solvent benzene.

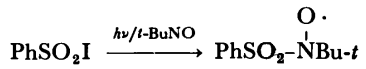
Phenyl, butyl, and benzenesulfonyl radicals escape from the solvent cage. These radicals could be trapped by spin trapping reagents such as nitrosodurene, 2-nitroso-2-methylpropane, or *N*-(*t*-butyl)-α-phenylnitrone to give nitroxide radicals which may be detected by ESR. As shown in Scheme 4, the formation of the benzenesulfonyl radical along with *t*-butyl and phenyl radicals was verified by spin trapping.



Scheme 3.



* The signal was assigned by the comparison with that obtained from benzenesulfonyl iodide and 2-nitroso-2-methylpropane under photo-irradiation.



Scheme 4.

Experimental

Materials. Azo sulfone **1** was prepared from benzenediazonium tetrafluoroborate and sodium 1,1-dimethylethanesulfinate in water and recrystallized from hexane-benzene. Mp 65—66 °C (decomp), ^{1}H-NMR ($CDCl_3$) δ_H=1.63 (9H, s), 7.32—7.90 (5H, m), Found: C, 52.98; H, 6.31; N, 12.43%. Calcd for $C_{10}H_{14}N_2SO_2$: C, 53.08; H, 6.24; N, 12.43%. *t*-Butyl phenyl sulfone was prepared by the oxidation with hydrogen peroxide of *t*-butyl phenyl sulfide which was synthesized from isobutene and thiophenol. ^{13}C-NMR (Cl_2C=CCl_2) δ_C=23.0, 58.2, 127.6, 129.9, 132.0, 135.9.

Product Analysis of Thermal Decomposition of 1 in Benzene. After the decomposition was completed, the reaction mixture was washed with water. The organic layer was dried over magnesium sulfate and evaporated to give the oily residue, which was subjected to column chromatography. Sulfur dioxide was determined by the iodometric titration with a standard sodium thiosulfate solution.

Product Analysis of Thermal Decomposition of 1 in Tetrachoroethylene. The yields of the products shown in Scheme 2 were determined by gas chromatography except the sulfone, yield of which was an isolated yield by column chromatography.

CIDNP Spectra. A solution of **1** (1 mmol) and pyridine (3 mmol) in 10 cm^3 tetrachloroethylene was inserted in an NMR probe which had been heated at 100 °C, and ^{13}C NMR was measured: pulse flipping angle 45°; data points 8192; accumulation 30, pulse interval 2 s. A JEOL Fx-60 FT NMR spectrometer was used. The CIDNP signals were assigned by comparison with the chemical shifts of the authentic samples. The chemical shifts of the sulfinate were estimated from the related compounds. The sign of the net polarization as calculated according to Kaptein's rule agreed with the observed one.[8]

Spectral Data of 2 and 3. **2**: Mp 140 °C (decomp) ^{1}H-NMR ($CDCl_3$) δ=1.10 (s, 9H), 6.80—7.70 (m, 15H), ^{13}C-NMR ($CDCl_3$) δ=27.4, 59.8, 115.8, 116.3, 126.2, 128.3, 128.8, 132.7, IR 3240 (NH), 1323, 1160 cm^{-1} (SO_2), MS *m/z* 305, 304 (M^+), 163 (base), 107, 77, 57. Found: C, 63.06; H, 6.68; N, 9.19%. (Received July 16, 1986)

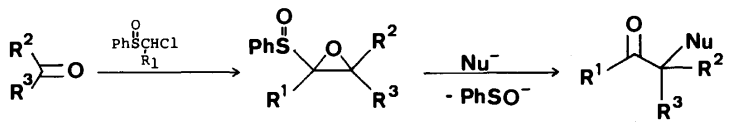
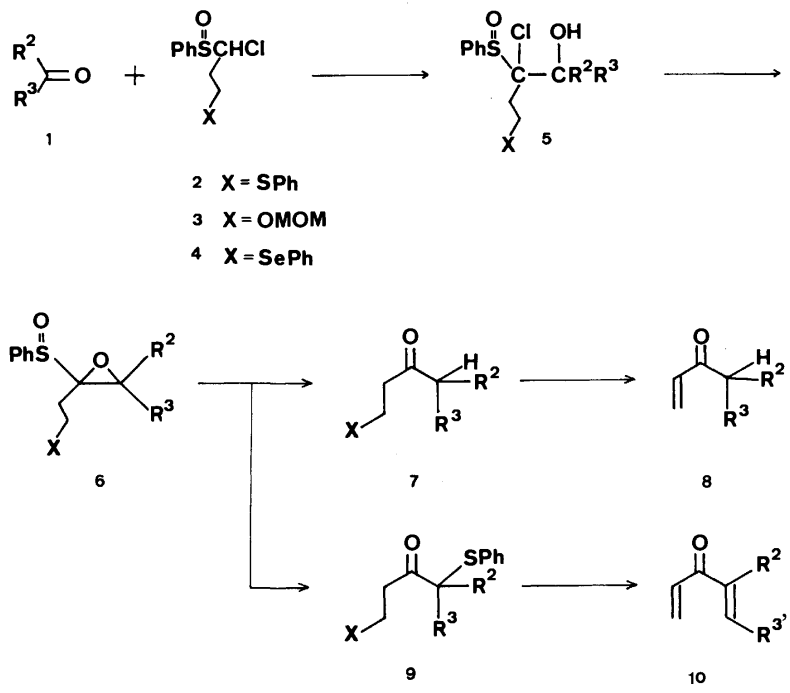
The α,β-epoxy sulfoxides easily derived from carbonyl compounds and 1-chloro-3-phenylthiopropyl phenyl sulfoxide were treated with sodium benzeneselenolate to give β-phenylthio carbonyl compounds in excellent yields. The phenylthio group was oxidized to the sulfinyl group and was then treated with a base to afford alkyl vinyl ketones in quite good yields. This reaction presents a novel method for the preparation of alkyl vinyl ketones from carbonyl compounds by three-carbon homologation. The treatment of α,β-epoxy sulfoxides mentioned above with benzenethiolate gave α,β′-bis(phenylthio) ketones. The elimination of the both thio groups afforded divinyl ketones.

α,β-Unsaturated carbonyl compounds have received much attention for long time regarding synthetic organic reactions. They are quite useful as the dienophiles in the Diels-Alder reactions[2] and as the acceptors of Michael-type reactions.[3] Among the α,β-unsaturated carbonyl compounds, alkyl vinyl ketones and divinyl ketones are most important in the chemistry of carbon-carbon bond formation. Many methods have already been reported for the synthesis of vinyl ketones. The most widely used one is a two-carbon homologation method; one is the reaction of a vinylmetalic reagent, such as vinyllithium with carboxylic acids,[4] or with aldehydes followed by oxidation;[5] the other is a palladium-catalyzed acylation of alkenylzinc,[6] alkenyltin,[7] or alkenylcopper.[8] Another method for the synthesis of vinyl ketones is three-carbon homologation; one is the alkylation of alkyl halides or the addition of carbonyl



Scheme 1.



Scheme 2.

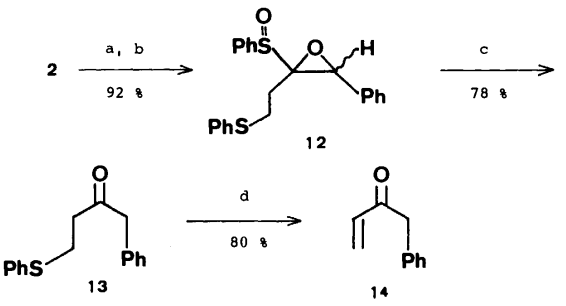
compounds with vinyl ketone anion equivalents (acyl anion equivalent)[9] and the other is a coupling of the α,β-unsaturated carboxylic acid chloride with transition-metal reagents[10] or with alkyltin[11] or alkyl iodides[12] by promotion of palladium. On the other hand, an excellent method for the synthesis of divinyl ketones was recently reported by Stille.[13]

Recently, we reported[14] a new method for the homologation of carbonyl compounds through α,β-epoxy sulfoxides upon a treatment with nucleophiles (Scheme 1). In these reactions if R_1 is to be a vinyl group or its equivalent this sequence must lead to a novel synthetic method for the preparation of alkyl vinyl ketones from carbonyl compounds by three-carbon homologation. In this paper we report a novel and versatile method for a synthesis of alkyl vinyl ketones **8** and divinyl ketones **10** from carbonyl compounds (**1**) and 1-chloro-3-phenylthiopropyl phenyl sulfoxide (**2**) as a three-carbon homologating agent through α,β-epoxy sulfoxides **6**.[15] The whole sequence is shown in Scheme 2.

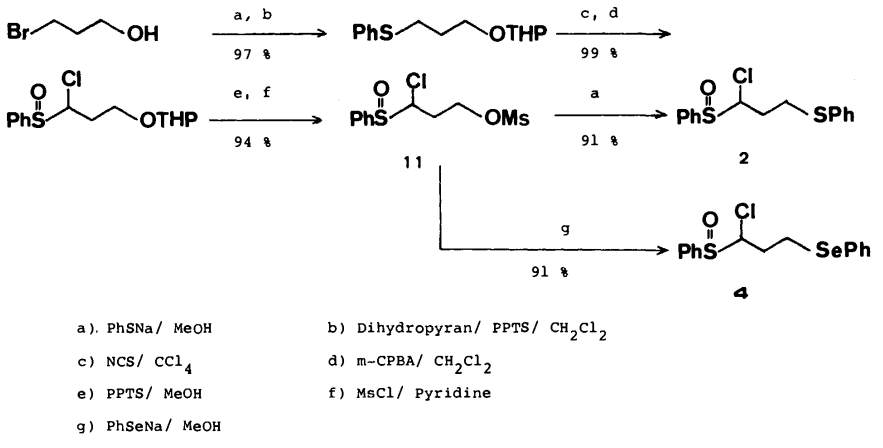
Results and Discussion

A Synthesis of Alkyl Vinyl Ketones from Carbonyl Compounds Through α,β-Epoxy Sulfoxides by the Use of 1-Chloro-3-phenylthiopropyl Phenyl Sulfoxide as Three-Carbon Homologating Agent. As the three-carbon homologating agents, we selected three kinds of 3-substituted 1-chloropropyl phenyl sulfoxides **2**—**4**. 1-Chloro-3-phenylthiopropyl phenyl sulfoxide (**2**) was synthesized from 3-bromo-1-propanol via **11** in very good overall yields as shown in Scheme 3. Addition of **2** with benzaldehyde followed by treatment with a slight excess potassium *t*-butoxide in *t*-butyl alcohol gave the desired **12** in 92% yield. A treatment of **12** with excess sodium benzeneselenolate[14a] afforded β-phenylthio ketone **13** in 78% yield without any problem. Next, the sulfur group of **13** was oxidized with one equivalent of *m*-chloroperbenzoic acid (*m*-CPBA) to give the desired sulfoxide. In this reaction, we observed some vinyl ketone **14** during the work-up stage (alkali washing of the etheral extract of the product). On the basis of this observation we established the conditions of the derivation of β-phenylthio ketone to the vinyl ketone as follows. β-Phenylthio ketone (0.2 mmol) was treated with 1.1 equivalent of *m*-CPBA in CH_2Cl_2 (2 ml) at −60 °C for 20 min. Ether (4 ml) and 10% sodium hydroxide (4 ml) was added to the reaction mixture and the whole (two phases) was vigorously stirred at room temperature. In this one-pot oxidation β-elimination sequence the β-phenylthio ketone **13** gave the desired vinyl ketone **14** in 80% overall yield. A thermal elimination of the sulfinyl group[16] was also possible; however, we found that an alkaline treatment was much more convenient owing to higher yields and a one-pot operation.

The results of the preparation of alkyl vinyl ketones from α,β-epoxy sulfoxides are summarized in Table 1. As shown in the Table, various kinds of aldehydes and ketones were converted to alkyl vinyl ketones through the α,β-epoxy sulfoxides in good overall yields. The reaction time for the elimination of the phenylsulfinyl group was dependent on the substrate varied from 15 min to 2 d. It is noteworthy that this kind of reductive three-carbon homologation has been



Scheme 4.



Scheme 3.

reported by Murai et al.[17] by using allylsilane chemistry; however, their procedure was reported to be useful only when unhindered aldehydes, not ketones, were used. In contrast with their results, the present method is quite useful for various kinds of aldehydes and ketones.

At the same time, we studied this vinyl ketone synthesis by using the three carbon homologating agents having a methoxymethoxy group or a phenylseleno group as the leaving group. 1-Chloro-3-(methoxymethoxy)propyl phenyl sulfoxide (**3**) was synthesized from 3-bromo-1-propanol in good overall yield (Scheme 5). The addition of **3** with benzaldehyde followed by a treatment with excess aqueous potassium hydroxide gave the α,β-epoxy sulfoxide **15** in quantitative yield; this was treated with sodium benzeneselenolate and afforded the desired ketone **16** having a leaving group at β-position.

Several acidic or basic conditions for the elimination of the methoxymethoxy group of **16** were tried; however, only disappointing results were obtained. For instance, a treatment of **16** with *p*-toluenesulfonic acid in benzene at 40 °C for 2.5 h or with 10% aqueous potassium hydroxide in benzene at room temperature for 3 h gave **14** in 33 and 24% yields, respectively.

Next, 1-chloro-3-(phenylseleno)propyl phenyl sulfoxide (**4**) was synthesized from **11** (Scheme 3). The addition of **4** with 4,4-(ethylenedioxy)cyclohexanone

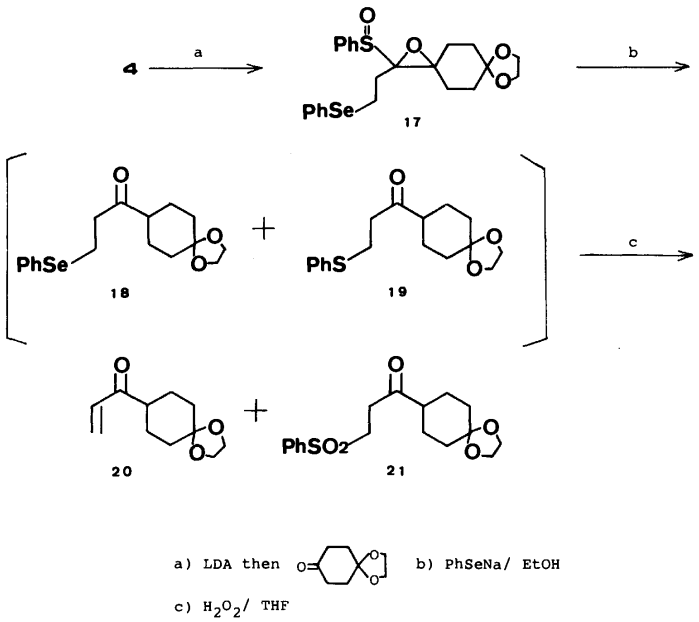
a) Reaction time for the alkaline treatment. b) Isolated purified yield.

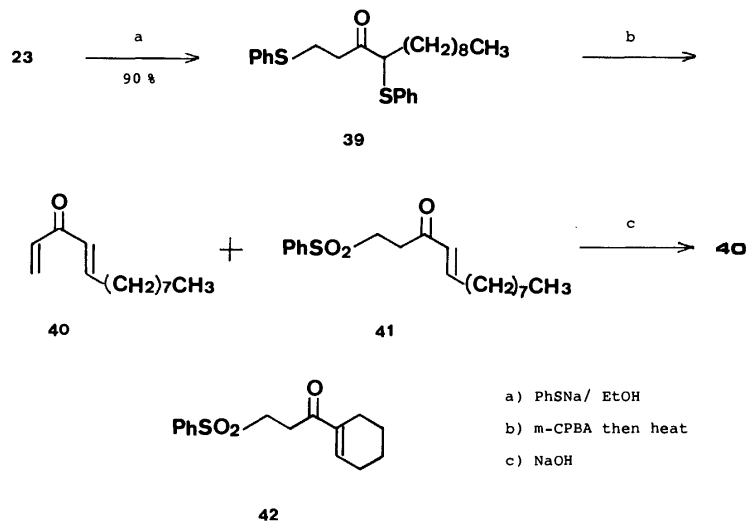
was carried out in the usual way but in this case, after the addition of **4** with ketone, an elevation of the reaction temperature from −78 °C to room temperature gave the desired **17** in 74% yield.

We came across a problem in next step. A treatment of **17** with excess sodium benzeneselenolate in refluxing ethanol for 1 h gave an unseparable mixture of the desired seleno ketone **18** and an undesired thio ketone **19**. This was confirmed from the fact that the oxidation of the mixture with hydrogen peroxide[18] gave the vinyl ketone **20** and the sulfone **21** in a ratio of about 2 to 5.

A Synthesis of Divinyl Ketones from Carbonyl Compounds with Three-Carbon Homologation. As already reported, a treatment of α,β-epoxy sulfoxides with a thiolate gave α-sulfenylated ketones in good yields.[14b] In the case of the α,β-epoxy sulfoxides **23**—**27** this reaction should afford α,β′-bis(phenylthio) ketones; these compounds must give divinyl ketones by the elimination of both phenylthio groups. First of all, a treatment of the α,β-epoxy sulfoxide **23** with sodium benzenethiolate, prepared from thiophenol and sodium hydride in ethanol, gave a rather complex mixture in which some amount of the desired bis(phenylthio) ketone **39** was observed. This complexity of this reaction was thought to be due to the strong basicity of the conditions. Based on this consideration, sodium benzenethiolate was prepared from diphenyl disulfide by the reduction with sodium borohydride in refluxing ethanol for 30 min. Treatment of **23** with thus obtained sodium benzenethiolate in this solution at 0 °C for 1 h gave the desired



Scheme 6.



Scheme 7.

bis(phenylthio) ketone **39** as a sole product in 90% yield. This method for the sulfenylation was used throughout this study. Similar kinds of differences of the two conditions as mentioned above were reported by Liotta et al.[19] in the selenolate case.

A successive oxidation followed by pyrolytic elimination was our initial plan for the conversion of **39** to the desired divinyl ketone **40**. Bis(phenylthio) ketone **39** was oxidized with two equivalents of *m*-CPBA at −40 °C. The product, bis(phenylsulfinylated) ketone, was roughly purified by silica-gel column chromatography and heated in refluxing toluene for 15 min. In this reaction the desired **40** (66%) and the unexpected sulfone **41** (26%) were obtained. Finally, this mixture was treated with a base (as described for the synthesis of alkyl vinyl ketones) to give pure divinyl detone **40** in 79% yield. The oxidant for the formation of this sulfone was not determined certainly, but was thought to be the eliminated sulfinate. In the case of the bis(phenylthio) ketone derived from the α,β-epoxy sulfoxide **25**, the yield of the sulfone **42** came up to 50%. The results of the preparation of various kinds of divinyl ketones from α,β-epoxy sulfoxides through bis(phenylthio) ketones is shown in Table 2.

In conclusion, a novel and versatile procedure for the synthesis of vinyl and divinyl ketones from carbonyl compounds with three-carbon homologation was realized. As these unsaturated ketones are quite useful as the building blocks of compounds having a complex carbon framework, especially divinyl ketones are good precursors for cyclopentenone derivatives by Nazarov type cyclization;[20] the procedure presented in this paper contributes to the synthesis of complex natural products as well.

Experimental

All melting points are uncorrected. Infrared (IR) spectra were measured directly on a NaCl plate or in KBr disks with a Hitachi 215 spectrometer. ^{1}H Nuclear magnetic resonance (NMR) spectra were measured in a $CDCl_3$ solution with a JEOL FX-100 spectrometer using Me_4Si as an internal standard. Ultraviolet (UV) spectra were measured with a Hitachi 200 spectrometer. Electron-impact mass spectra (MS) were obtained on a Hitachi M-80 double-focusing spectrometer at 70 eV by direct insertion. Silica-gel BW-127 ZH (Fuji-Devison) containing 2% fluoresence reagent 254 and quartz column were used for column chromatography and the products having UV absorption were detected by UV irradiation.

1-Chloro-3-(methylsulfonyloxy)propyl Phenyl Sulfoxide (11). To a solution of sodium benzenethiolate (21 mmol) in MeOH (30 ml) was added 3-bromo-1-propanol (1.8 g; 20 mmol); the mixture was stirred under N_2 at room temperature for 45 min. Excess NH_4Cl was added and the MeOH was evaporated; then, the residue was extracted with ether. The product was distilled (bp 130 °C/2 mmHg (1 mmHg=133.322 Pa)) to give 3.36 g (99%) of 3-phenylthio-1-propanol as a colorless oil. IR (neat): 3350 (OH) cm^{-1}; ^{1}H NMR δ=1.89 (2H, quintet, J=7 Hz), 3.06 (2H, t, J=7 Hz), 3.78 (2H, t, J=7 Hz), 7.0—7.5 (5H, m). 3-Phenylthio-1-propanol (3.36 g; 20 mmol) was treated with dihydropyran (2.7 ml; 30 mmol) and pyridinium *p*-toluenesulfonate (PPTS) (250 mg; 1 mmol) in CH_2Cl_2 (20 ml) at room temperature for 1 h. After the workup according to Miyashita's procedure[21] the product was distilled (bp 150 °C/2 mmHg) to afford 4.9 g (97%) of 1-phenylthio-3-(tetrahydro-2-pyranyloxy)propane as a colorless oil. ^{1}H NMR δ=3.07 (2H, t, J=7 Hz), 4.58 (1H, bs). This sulfide (5.05 g; 20 mmol) was added to a suspension of NCS (21 mmol) in 40 ml of CCl_4 and the reaction mixture was stirred at room temperature for 2 h. The precipitate was filtered off and the filtrate was evaporated. The residue was dissolved in 60 ml of CH_2Cl_2 and cooled to −50 °C and *m*-CPBA (21 mmol) was added to the solution and stirred for

Table 2. Preparation of Divinyl Ketones from α,β-Epoxy Sulfoxides through Bis(phenylthio)ketones

1 h. The reaction mixture was diluted with 60 ml of CH_2Cl_2 and the whole was washed, successively, with 10% NaOH and sat. NH_4Cl. The usual work-up gave a crude product, which was purified by silica-gel column chromatography to afford 5.99 g (99%) of 1-chloro-3-(tetrahydro-2-pyranyloxy)-propyl phenyl sulfoxide (diastereomeric mixture) as a colorless oil. IR (neat): 1050, 1035 (SO) cm^{-1}. This product (769 mg; 2.54 mmol) was dissolved in 20 ml of MeOH and 64 mg of PPTS was added. The mixture was stirred at 50 °C for 2 h. After the usual work-up[21] 557 mg (99%) of the alcohol was obtained as a colorless oil. IR (neat): 3400 (OH), 1050 (SO) cm^{-1}. To a solution of the alcohol (3.17 g; 14.5 mmol) in 13 ml of pyridine was added methanesulfonyl chloride (2.3 ml; 29 mmol) at 0 °C and the solution was stirred for 1 h. The reaction mixture was diluted with benzene and washed, successively, with 10% HCl, sat. $NaHCO_3$, and sat. NH_4Cl. The product was purified by silica-gel column chromatography to give the desired **11** (4.06 g; 94%) as a colorless oil. IR (neat): 1360, 1180 (SO_2), 1050 (SO) cm^{-1}; ^1H NMR δ=2.0—2.9 (2H, m), 3.03, 3.07 (each s, OSO_2CH_3); MS *m/z* (%): 171 ([M−PhSO]$^+$, 21), 79 (42), 77 (57), 75 (100).

1-Chloro-3-phenylthiopropyl Phenyl Sulfoxide (2). To a solution of sodium benzenethiolate (14.4 mmol) in 21 ml of MeOH was added a solution of **11** (4.06 g; 13.7 mmol) in MeOH (5 ml). The reaction mixture was stirred at room temperature for 3 h. Excess NH_4Cl was added to the mixture and the MeOH was evaporated. The product was purified by the usual way to give 3.64 g (86%) of **2** as a colorless oil (diastereomeric mixture) and 0.24 g (6%) of recovered **11**. IR (neat): 1060 (SO) cm^{-1}; ^1H NMR δ=1.8—2.7 (2H, m), 2.8—3.4 (2H, m), 4.07 (dd, *J*=9, 4 Hz), 4.83 (dd, *J*=10, 4 Hz), 7.1—7.8 (10H, m); MS *m/z* (%): 310 (M$^+$, 8), 185 ([M−PhSO]$^+$, 28), 149 (32), 123 (100); Found: *m/z* 310.0237. Calcd for $C_{15}H_{15}ClOS_2$: M, 310.0251.

1,2-Epoxy-1-phenyl-2-phenylsulfinyl-4-phenylthiobutane (12). To a solution of LDA (2.1 mmol) in 9 ml of THF at −60 °C was added a solution of **2** (2 mmol) in 1 ml of THF dropwise with stirring. The stirring was continued for 15 min; then, 0.22 ml (2.1 mmol) of benzaldehyde was added. After 5 min the reaction was quenched by sat. aq NH_4Cl and the whole was extracted with benzene. The usual workup gave chlorohydrin-L[14a] and chlorohydrin-P[14a] in 43 and 54% yields, respectively. Chlorohydrin-L: Colorless oil; IR (neat): 3330 (OH), 1050 (SO) cm^{-1}; ^1H NMR δ=2.2—3.5 (4H, m), 5.00 (1H, s), 7.1—8.0 (15H, m); MS *m/z* (%): 290 ([M−PhSOH]$^+$, 35), 180 (27), 145 (46), 117 (77), 77 (100). Chlorohydrin-P: Colorless prisms; mp 112—114 °C (benzene-hexane); IR (KBr): 3350 (OH), 1040 (SO) cm^{-1}; ^1H NMR δ=1.6—3.1 (4H, m), 5.17 (1H, d, *J*=3 Hz), 7.0—7.8 (15H, m); MS *m/z* (%): 290 ([M−PhSOH]$^+$, 61), 180 (56), 145 (73), 117 (100); Found: C, 63.55; H, 5.04; Cl, 8.42; S, 15.53%. Calcd for $C_{22}H_{21}ClO_2S_2$: C, 63.37; H, 5.08; Cl, 8.50; S, 15.38%. To a solution of the chlorohydrin-L (1.10 g; 2.36 mmol) in 2 ml of benzene and 12 ml of *t*-BuOH was added a suspension of *t*-BuOK (234 mg; 3.03 mmol) in 2 ml of *t*-BuOH at room temperature with stirring. The reaction was quenched after 5 min by adding NH_4Cl and the solvent was evaporated. The residue was dissolved with benzene. After the usual workup, the product was purified by silica gel column chromatography to give 1.03 g (99%) of **12-L** as a colorless oil. IR (neat): 1055 (SO) cm^{-1}; ^1H NMR δ=1.5—2.1 (2H, m), 2.3—3.1 (2H, m), 4.82 (1H, s), 6.9—7.8 15H, m); MS *m/z* (%): 256 (33), 255 ([M−PhSO]$^+$, 18), 199 (38), 123 ([M-$C_{15}H_{13}O_2S$]$^+$, 100). **12-P**: Yield 92%; IR (neat): 1050 (SO) cm^{-1}; ^1H NMR δ=1.7—3.2 (4H, m), 4.53 (1H, s), 7.0—7.8 (15H, m); MS *m/z* (%): 199 (3), 125 (8), 109 ([M−$C_{16}H_{15}O_2S$]$^+$, 7), 78 (100).

1-Phenyl-4-phenylthio-2-butanone (13). To a suspension of diphenyl diselenide (1.46 g; 4.65 mmol) in 9 ml of EtOH was added $NaBH_4$ (353 mg; 9.3 mmol) by portions with stirring at room temperature. After vigorous hydrogen gas evolution ceased, the solution was cooled in an ice bath and a solution of **12** (0.93 mmol) in 0.5 ml of EtOH was added. The reaction mixture was stirred at 0 °C under N_2 for 20 min then the reaction was quenched by sat. aq NH_4Cl and then the EtOH was evaporated. The residue was extracted with benzene. After the usual workup, the product was purified by silica-gel column chromatography to give **13** in 78% yield as a colorless oil. IR (neat): 1720 (CO) cm^{-1}; ^1H NMR δ=2.7—2.9 (2H, m), 3.0—3.2 (2H, m), 3.70 (2H, s), 7.1—7.4 (10H, m); MS *m/z* (%): 256 (M$^+$, 65), 165 ([M−$PhCH_2$]$^+$, 23), 137 ([M−C_8H_7O]$^+$, 62), 123 ([M−C_9H_9O]$^+$, 100); Found: *m/z* 256.0914. Calcd for $C_{16}H_{16}OS$: M, 256.0920.

Oxidation of 13 with *m*-CPBA Followed by Treatment with Alkali. To a solution of **13** (48 mg; 0.91 mmol) in 2 ml of CH_2Cl_2 was added 44 mg (0.21 mmol) of *m*-CPBA at −60 °C with stirring. The stirring was continued for 20 min and then ether (4 ml) and 10% NaOH (4 ml) were added to the reaction mixture. This was vigorously stirred at room temperature for 1.5 h. The reaction mixture was neutralized by NH_4Cl and the whole was extracted with CH_2Cl_2, washed and dried. After the usual workup, the product was purified by silica-gel column chromatography to afford 22 mg (80%) of 1-phenyl-3-buten-2-one (**14**) as a colorless oil. IR (neat): 1690, 1670 (CO), 1615 (C=C) cm^{-1}; ^1H NMR δ=3.91 (2H, s), 5.85 (1H, dd, *J*=8, 3.5 Hz), 6.36 (1H, dd, *J*=18, 3.5 Hz), 6.45 (1H, dd, *J*=18, 8 Hz), 7.1—7.5 (5H, m); UV λ_{max}^{EtOH} 210, 256 nm; MS *m/z* (%): 146 (M$^+$, 21), 118 ([M−CO]$^+$, 13), 91 ([M−C_3H_3O]$^+$, 64), 55 (100); Found: *m/z* 146.0734. Calcd for $C_{10}H_{10}O$: M, 146.0731.

1-Chloro-3-(methoxymethoxy)propyl Phenyl Sulfoxide (3). Chloromethyl methyl ether (3.8 ml; 50 mmol) was added to a solution of 3-bromo-1-propanol (1.4 g; 10 mmol), *N,N*-diisopropylethylamine (5 ml; 29 mmol) in THF (0.5 ml) at 0 °C and the mixture was stirred at 0 °C for 30 min. The reaction mixture was poured into a mixture of ice and diluted HCl and the whole was extracted with ether. The ether extract was washed with sat. aq $NaHCO_3$, dried over Na_2SO_4 and the ether was evaporated. The residue was distilled (bp 100 °C/2 mmHg) to give 1.63 g (88%) of 1-bromo-3-(methoxy)methoxypropane as a colorless oil. ^1H NMR δ=2.10 (2H, quintet, *J*=6 Hz), 3.30 (3H, s), 3.45, 3.60 (each 2H, t, *J*=6 Hz), 4.55 (2H, s). This bromide (1 g; 5.5 mmol) was added to a solution of sodium benzenethiolate (6 mmol) in 6 ml of dry EtOH and the mixture was stirred at room temperature for 1.5 h under an N_2 atmosphere. The reaction mixture was neutralized by NH_4Cl and the EtOH was evaporated. The residue was dissolved with benzene and washed, successively, with 5% NaOH and sat. NH_4Cl. The product was distilled (bp 130 °C/2 mmHg) to give 1.07 g (92%) of 1-(methoxy)methoxy-3-phenylthiopropane as a colorless oil. ^1H NMR δ=1.95

(2H, quintet, J=6 Hz), 3.00 (2H, t, J=6 Hz), 3.31 (3H, s), 3.60 (2H, t, J=6 Hz), 4.55 (2H, s), 7.0—7.5 (5H, m). This product (1.07 g; 5 mmol) was chlorinated then oxidized according to the procedure described for the synthesis of **11** to afford 1.25 g (94%) of **3** as a colorless oil (diastereomeric mixture). IR (neat): 1050 (SO) cm^{-1}; ^1H NMR δ=3.28, 3.30 (each s, CH_3), 3.72 (m), 4.53, 4.55 (each s, $-OCH_2O-$).

1,2-Epoxy-4-(methoxymethoxy)-1-phenyl-2-phenylsulfinylbutane (15). Addition of **3** with benzaldehyde according to the procedure described for the synthesis of **12** gave two chlorohydrins. Chlorohydrin-L: Yield 40%, colorless prisms (benzene-hexane) mp 116—118 °C; IR (KBr): 3220 (OH), 1035, 1025 (SO) cm^{-1}; ^1H NMR δ=3.35 (3H, s), 4.60 (2H, s), 5.00 (1H, s), 7.25 (5H, s), 7.4—8.0 (5H, m). Chlorohydrin-P: Yield 60%, colorless prisms (AcOEt-hexane) mp 85 °C (decomp); IR (KBr): 3310 (OH), 1065, 1035, 1015 (SO) cm^{-1}; ^1H NMR δ=3.29 (3H, s), 4.47 (2H, s), 5.20 (1H, s), 7.2—7.8 (10H, m). **15-L**: Yield 99%, colorless oil, IR (neat): 1050 (SO) cm^{-1}; ^1H NMR δ=1.24—2.05 (2H, m), 3.29 (3H, s), 3.45 (2H, m), 4.49 (2H, s), 4.91 (1H, s), 7.10—7.94 (10H, m); MS m/z (%): 271 ([M−$C_2H_5O_2$]$^+$, 0.1), 207 ([M−PhSO]$^+$, 0.4), 125 (5), 91 (9), 45 (100). **15-P**: Yield 98%, colorless oil, IR (neat): 1050 (SO) cm^{-1}; ^1H NMR δ= 1.58—1.90 (1H, m), 2.47—2.78 (1H, m), 3.34 (3H, s), 3.56 (2H, t, J=6 Hz), 4.56 (2H, s), 4.61 (1H, s), 7.24—7.75 (10H, m); MS m/z (%): 271 ([M−$C_2H_5O_2$]$^+$, 0.1), 207 ([M−PhSO]$^+$, 0.4), 125 (3), 45 (100).

4-(Methoxymethoxy)-1-phenyl-2-butanone (16). The α,β-epoxy sulfoxide **15** was treated with sodium benzeneselenolate as described above to give **16** in 91% yield as a colorless oil. IR (neat): 1720, 1715 (CO) cm^{-1}; ^1H NMR δ=2.71 (2H, t, J=6 Hz), 3.33 (3H, s), 3.72 (2H, s), 3.76 (2H, t, J=6 Hz), 4.56 (2H, s), 7.0—7.4 (5H, m); MS m/z (%): 208 (M$^+$, 0.3), 177 ([M-CH_3O]$^+$, 2), 117 ([M−$PhCH_2$]$^+$, 16), 91 (51), 45 (100); Found: m/z 208.1092. Calcd for $C_{12}H_{16}O_3$: M, 208.1098.

Treatment of 16 with Acid or Base. Acidic conditions: A solution of **16** (35 mg) and p-TsOH·$2H_2O$ (3.2 mg) in 1.7 ml of benzene was stirred at 40 °C under N_2 for 2.5 h. The mixture was passed through a short pad of Na_2CO_3 and the product was purified by silica-gel column chromatography to give 8 mg (33%) of **14** as a colorless oil. Basic conditions: A mixture of **16** (42 mg) in 2 ml of benzene and 1.5 ml of 10% KOH was vigorously stirred at room temperature for 3 h to give 7 mg (24%) of **14** and several by-products.

1-Chloro-3-phenylselenopropyl Phenyl Sulfoxide (4). To a suspension of diphenyl diselenide (815 mg; 2.61 mmol) in 15 ml of MeOH was added $NaBH_4$ (200 mg; 5.23 mmol) by portions with stirring. After vigorous hydrogen gas evolution ceased, a solution of **11** (1.41 g; 4.75 mmol) in 2 ml of MeOH was added and the reaction mixture was stirred at room temperature for 2 h. Excess NH_4Cl was added and the MeOH was evaporated. After the usual work-up, the product was purified by silica-gel column chromatography to give 1.54 g (91%) of **4** as a colorless oil (diastereomeric mixture). IR (neat): 1055 (SO) cm^{-1}; ^1H NMR δ=2.0—2.7 (2H, m), 2.8—3.4 (2H, m), 4.69, 4.82 (each dd, J=9, 4 Hz), 7.1—7.8 (5H, m); MS m/z (%): 358 (M$^+$, 13), 233 ([M−PhSO]$^+$, 30), 201 ([M−PhSe]$^+$, 25), 171 (54), 101 (95), 77 (100).

2″-Phenylsulfinyl-2″-(2-phenylseleno)ethyldispiro[1,3-dioxolane-2,1′-cyclohexane-4′,1″-oxirane] (17). To a LDA (3.5 mmol) solution in THF (30 ml) at −78 °C was added a solution of **4** (118 g; 3.3 mmol) in 2 ml of THF dropwise with stirring. The stirring was continued for 30 min then a solution of 4,4-(ethylenedioxy)cyclohexanone (0.77 g; 5 mmol) in THF was added. After 5 min the cooling bath was removed and the mixture was stirred at room temperature for 1 h. Sat. aq NH_4Cl was added to the reaction mixture and the whole was extracted with benzene. After the usual work-up, the product was purified by silica-gel column chromatography to give 1.17 g (74%) of **17** as a colorless oil. In this reaction 0.28 g (24%) of **4** was recovered. IR (neat): 1145, 1100, 1090 (COC), 1050 (SO) cm^{-1}; ^1H NMR δ=1.1—2.9 (12H, m), 4.00 (4H, s), 7.1—7.7 (10H, m); MS m/z (%): 352 ([M−PhSO]$^+$, 27), 297 (25), 157 (34), 99 (100).

8-(1-Oxo-2-propenyl)-1,4-dioxaspiro[4.5]decane (20) and 8-(1-Oxo-3-phenylsulfonylpropyl)-1,4-dioxaspiro[4.5]decane (21). To a solution of sodium benzeneselenolate (5 mmol) in 9 ml of EtOH was added a solution of **17** (238 mg; 0.5 mmol) in 1 ml of EtOH and the mixture was refluxed for 1 h under N_2. Excess NH_4Cl was added and the EtOH was evaporated. The residue was extracted with benzene. After the usual work-up, te products were purified by silica-gel column chromatography to give 146 mg of unseparable mixture of **18** and **19**. IR (neat): 1715 (CO) cm^{-1}; MS m/z (%): 354 (M$^+$; $C_{17}H_{22}O_3Se$; 3), 306 (M$^+$; $C_{17}H_{22}O_3S$; 26), 99 (100). To a solution of the mixture (53 mg) in 1.5 ml of THF was added 35% H_2O_2 (0.5 ml) and the mixture was stirred at room temperature for 30 min. The whole was extracted with ether and washed, dried over Na_2SO_4. The products were separated by silica-gel column chromatography to afford 9 mg of **20** and 39 mg of **21**. **20**: Colorless oil; IR (neat): 1705, 1685 (CO), 1625 (C=C) cm^{-1}; UV λ_{max}^{EtOH} 214 nm; ^1H NMR δ=1.4—2.0 (8H, m), 2.5—2.8 (1H, m), 3.97 (4H, s), 5.77 (1H, dd, J=9, 3 Hz), 6.32 (1H, dd, J=18, 3 Hz), 6.50 (1H, dd, J=18, 9 Hz); MS m/z (%): 196 (M$^+$, 0.5), 168 ([M−C_2H_4]$^+$, 4), 141 ([M−C_3H_3O]$^+$, 4) 99 (100). **21**: Colorless prisms (benzene-hexane); mp 102—104.5 °C; IR (KBr): 1715 (CO), 1310 (SO_2) cm^{-1}; ^1H NMR δ=1.4—2.0 (8H, m), 2.2—2.6 (1H, m), 2.9—3.1 (2H, m), 3.3—3.5 (2H, m), 3.96 (4H, s), 7.4—8.0 (5H, m); MS m/z (%): 338 (M$^+$, trace), 197 ([M−$PhSO_2$]$^+$, 18), 141 ([M−$C_9H_9O_3S$]$^+$, 11), 99 (100); Found: C, 60.54; H, 6.53; S, 9.41%. Calcd for $C_{17}H_{22}O_5S$: C, 60.34; H, 6.55; S, 9.47%.

α,β-Epoxy Sulfoxides 22—27. All α,β-epoxy sulfoxides **22—27** were synthesized from **2** and carbonyl compounds as described for **12**.

1,2-Epoxy-1-(4-chlorophenyl)-2-phenylsulfinyl-4-phenylthiobutane (22). Chlorohydrin-L: Colorless oil; yield 42%; IR (neat): 3330 (OH), 1050 (SO) cm^{-1}; ^1H NMR δ=2.0—3.5 (4H, m), 4.91 (1H, s), 7.0—8.9 (14H, m), Chlorohydrin-P: Colorless powder: yield 42%; IR (KBr): 3490 (OH), 1050 (SO) cm^{-1}; ^1H NMR δ=1.6—3.1 (4H, m), 5.18 (1H, s), 7.0—7.7 (14H, m), **22-L**: Colorless oil; yield 86%; IR (neat): 1090, 1050 (SO) cm^{-1}; ^1H NMR δ=1.3—3.1 (4H, m), 4.72 (1H, s), 6.9—7.7 (14H, m); MS m/z (%): 414 (M$^+$, trace), 398 ([M−O]$^+$, 1.6), 341 (0.7), 289 (47), 233 (75), 125 (100). **22-P**: Colorless oil; yield 89%; IR (neat): 1090, 1050 (SO) cm^{-1}; ^1H NMR δ=1.6—3.1 (4H, m), 4.45 (1H, s), 7.0—7.7 (14H, m); MS m/z (%): 288 ([M−C_6H_6SO]$^+$, 12), 233 (100).

3,4-Epoxy-3-phenylsulfinyl-1-phenylthiotridecane (23). Chlorohydrin: Diastereomeric mixture; colorless oil; IR (neat): 3350 (OH), 1045 (SO) cm^{-1}; ^1H NMR δ=0.88, 0.90 (each t, J=7 Hz), 7.2—7.9 (10H, m); MS m/z (%): 340

([M−PhSOH]$^+$, 23), 230 (23), 284 (23), 110 (100). Less polar **23**: Colorless oil; yield 36%; IR (neat): 1055 (SO) cm^{-1}; ^{1}H NMR δ=0.90 (3H, bt, J=6 Hz), 1.0—3.1 (20H, m), 3.32 (1H, t, J=7 Hz), 7.1—7.8 (10H, m); MS m/z (%): 304 ([M−PhSOH]$^+$, 5), 249 (34), 218 (25), 186 (31), 125 (100). More polar **23**: Colorless oil; yield 45%; IR (neat): 1045 (SO) cm^{-1}; ^{1}H NMR δ=0.90 (3H, bt, J=6 Hz), 1.0—3.1 (20H, m), 3.67 (1H, m), 7.1—7.7 (10H, m); MS m/z (%): 305 ([M−PhSO]$^+$, 52), 249 (69), 123 (100).

1-Cyclohexyl-1,2-epoxy-2-phenylsulfinyl-4-phenylthiobutane (24). Chlorohydrin: Diastereomeric mixture; colorless oil; yield 95%; IR (neat): 3370 (OH), 1055 (SO) cm^{-1}; MS m/z (%): 296 ([M−PhSOH]$^+$, 15), 126 (53), 110 (100). Less polar **24**: Colorless oil; yield 38%; IR (neat): 1050 (SO) cm^{-1}; ^{1}H NMR δ=1.0—3.0 (15H, m), 3.04 (1H, d, J=8 Hz), 7.1—7.8 (10H, m); MS m/z (%): 386 (M$^+$, 0.2), 261 (23), 205 (31), 123 (100). More polar **24**: Colorless oil; yield 32%; IR (neat): 1055 (SO) cm^{-1}; ^{1}H NMR δ=0.8—3.4 (15H, m), 3.44 (1H, d, J=8 Hz), 7.1—8.0 (10H, m); MS m/z (%): 386 (M$^+$, trace), 261 (11), 185 (19), 123 (100).

2′-Phenylsulfinyl-2′-(2-phenylthioethyl)spiro[cyclohexane-1,1′-oxirane] (25). Chlorohydrin: Colorless plate; mp 100—102 °C (benzene-hexane); yield 77%; IR (KBr): 3210 (OH), 1030 (SO) cm^{-1}; ^{1}H NMR δ=0.8—3.2 (14H, m), 7.1—7.8 (10H, m); MS m/z (%): 282 ([M−PhSOH]$^+$, 28), 126 (31), 110 (100); Found: C, 61.65; H, 6.09; Cl, 8.60; S, 15.59%. Calcd for $C_{21}H_{25}ClO_2S_2$: C, 61.67; H, 6.16; Cl, 8.67; S, 15.68%. Epoxy sulfoxide **25**: Colorless prisms; mp 86—87 °C (benzene-hexane); yield 93%; IR (KBr): 1050 (SO) cm^{-1}; ^{1}H NMR δ=1.3—2.9 (14H, m), 7.1—7.7 (10H, m); MS m/z (%): 372 (M$^+$, trace), 247 ([M−PhSO]$^+$, 43), 123 (100); Found: C, 67.87; H, 6.46; S, 17.30% m/z 372.1191. Calcd for $C_{21}H_{24}O_2S_2$: C, 67.70; H, 6.49; S, 17.21% M, 372.1216.

2″-Phenylsulfinyl-2″-(2-phenylthioethyl)dispiro[1,3-dioxrane-2,1′-cyclohexane-4′,1″-oxirane] (26). Chlorohydrin: Colorless oil; yield 94%; IR (neat): 3400 (OH), 1040 (SO) cm^{-1}; ^{1}H NMR δ=1.4—3.2 (12H, m), 3.98 (4H, s), 7.1—7.8 (10H, m); MS m/z (%): 340 ([M−PhSOH]$^+$, 26), 203 (22), 99 (100). Epoxy sulfoxide **26**: Colorless oil; yield 99%; IR (neat): 1100 (COC), 1050 (SO) cm^{-1}; ^{1}H NMR δ=1.2—3.0 (12H, m), 4.02 (4H, s), 7.1—7.7 (10H, m); MS m/z (%): 414 ([M−O]$^+$, 0.2), 305 ([M−PhS]$^+$, 54), 249 (73), 99 (100).

2′-Phenylsulfinyl-2′-(2-phenylthio)ethylspiro[cycloheptane-1,1′-oxirane] (27). Chlorohydrin: Colorless oil; yield 97%; IR (neat): 3410 (OH), 1050 (SO) cm^{-1}; ^{1}H NMR δ=1.2—3.1 (16H, m), 7.1—7.8 (10H, m); MS m/z (%): 296 ([M−PhSOH]$^+$, 19), 278 (4), 234 (17), 186 (34), 149 (19), 125 (100). Epoxy sulfoxide **27**: Colorless oil; yield 68%; IR (neat): 1090, 1050 (SO) cm^{-1}; ^{1}H NMR δ=1.3—3.0 (16H, m), 7.0—7.7 (10H, m); MS m/z (%): 261 ([M−PhSO]$^+$, 17), 205 (100).

1-(4-Chlorophenyl)-4-phenylthio-2-butanone (28). Colorless crystals (EtOH-hexane); mp 52—55 °C; IR (KBr): 1720 (CO) cm^{-1}; ^{1}H NMR δ=1.64—1.85 (2H, m), 3.00—3.20 (2H, m), 3.62 (2H, s), 6.95—7.32 (9H, m); MS m/z (%): 290 (M$^+$, 38), 165 (25), 137 (64), 123 (100); Found: m/z 290.0526. Calcd for $C_{16}H_{15}OClS$: M, 290.0530.

1-Phenylthio-3-tridecanone (29). Colorless oil; IR (neat): 1715 (CO) cm^{-1}; ^{1}H NMR δ=0.89 (3H, bt, J=7 Hz), 1.1—1.7 (16H, m), 2.40 (2H, t, J=8 Hz), 2.75 (2H, m), 3.18 (2H, m), 7.2—7.4 (5H, m); MS m/z (%): 306 (M$^+$, 58), 165 (22), 137 (65), 123 (100).

1-Cyclohexyl-4-phenylthio-2-butanone (30). Colorless oil; IR (neat): 1720 (CO) cm^{-1}; ^{1}H NMR δ=0.5—2.1 (11H, m), 2.18 (2H, d, J=7 Hz), 2.72 (2H, m), 3.16 (2H, m), 7.1—7.4 (5H, m); MS m/z (%): 262 (M$^+$, 57), 137 (41), 125 (72), 109 (35), 97 (60), 55 (100).

1-Cyclohexyl-3-phenylthio-1-propanone (31). Colorless oil; IR (neat): 1715 (CO) cm^{-1}; ^{1}H NMR δ=0.8—2.0 (10H, m), 2.1—2.3 (1H, m), 2.6—2.9 (2H, m), 3.0—3.3 (2H, m), 7.1—7.6 (5H, m); MS m/z (%): 248 (M$^+$, 77), 191 (14), 165 (17), 137 (49), 123 (51), 109 (42), 83 (100); Found: m/z 248.1221. Calcd for $C_{15}H_{20}OS$: M, 248.1233.

8-(1-Oxo-3-phenylthiopropyl)-1,4-dioxaspiro[4.5]decane (32). Colorless oil; IR (neat): 1715 (CO) cm^{-1}; ^{1}H NMR δ=1.3—2.0 (8H, m), 2.1—2.5 (1H, m), 2.7—2.9 (2H, m), 3.0—3.3 (2H, m), 3.96 (4H, s), 7.1—7.4 (5H, m); MS m/z (%): 306 (M$^+$, 30), 192 (12), 169 (6), 137 (7), 123 (14), 99 (100); Found m/z 306.1291. Calcd for $C_{17}H_{22}O_3S$: M, 306.1288.

1-Cycloheptyl-3-phenylthio-1-propanone (33). Colorless oil; IR (neat): 1710 (CO) cm^{-1}; ^{1}H NMR δ=1.2—2.0 (12H, m), 2.3—2.6 (1H, m), 2.6—2.9 (2H, m), 3.0—3.2 (2H, m), 7.0—7.6 (5H, m); MS m/z (%): 262 (M$^+$, 95), 180 (6), 165 (23), 137 (58), 123 (70), 97 (87), 55 (100); Found: m/z 262.1372. Calcd for $C_{16}H_{22}OS$: M, 262.1389.

1-(4-Chlorophenyl)-3-buten-2-one (34). Colorless oil; IR (neat): 1690 (CO), 1620 (C=C) cm^{-1}; ^{1}H NMR δ=3.83 (2H, s), 5.85 (1H, dd, J=8, 3.5 Hz), 6.28 (1H, dd, J=17.5, 3.5 Hz), 6.37 (1H, dd, J=17.5, 8 Hz), UV λ_{max}^{EtOH} 218.5 nm; MS m/z (%): 180 (M$^+$, 24), 125 ([M−C_3H_3O]$^+$, 43), 55 ([M−C_7H_6Cl]$^+$, 100); Found: m/z 180.0333. Calcd for $C_{10}H_9OCl$: M, 180.0341.

1-Tridecen-3-one (35). Colorless oil; IR (neat): 1705, 1690 (CO), 1620 (C=C) cm^{-1}; ^{1}H NMR δ=0.89 (3H, t, J=7 Hz), 1.0—1.8 (16H, m), 2.61 (2H, t, J=7 Hz), 5.83 (1H, dd, J=9, 3 Hz), 6.26 (1H, dd, J=17.5, 3 Hz), 6.40 (1H, dd, J=17.5, 9 Hz); UV λ_{max}^{EtOH} 212 nm, MS m/z (%): 196 (M$^+$, 2), 167 ([M−C_2H_5]$^+$, 11), 139 ([M−C_4H_9]$^+$, 12), 70 ([M−C_9H_{18}]$^+$, 100); Found: m/z 196.1820. Calcd for $C_{13}H_{24}O$: M, 196.1825.

1-Cyclohexyl-3-buten-2-one (36). Colorless oil; IR (neat): 1700, 1685 (CO), 1620 (C=C) cm^{-1}; ^{1}H NMR δ=0.6—2.1 (11H, m), 2.47 (2H, d, J=7 Hz), 5.83 (1H, dd, J=9, 3 Hz), 6.23 (1H, dd, J=17.5, 3 Hz), 6.40 (1H, dd, J=17.5, 9 Hz); UV λ_{max}^{EtOH} 213 nm; MS m/z (%): 152 (M$^+$, 17), 134 ([M$^+$−H_2O]$^+$, 4), 109 ([M−C_3H_3O]$^+$, 18), 70 (100); Found: m/z 152.1182. Calcd for $C_{10}H_{16}O$: M, 152.1200.

1-Cyclohexyl-2-propen-1-one (37). Colorless oil; IR (neat): 1700, 1680 (CO), 1620 (C=C) cm^{-1}; ^{1}H NMR δ=1.0—2.0 (10H, m), 2.4—2.8 (1H, m), 5.77 (1H, dd, J=9, 3 Hz), 6.36 (1H, dd, J=18, 3 Hz), 6.45 (1H, dd, J=18, 9 Hz); UV λ_{max}^{EtOH} 212 nm.

1-Cycolheptyl-2-propen-1-one (38). Colorless oil; IR (neat): 1700, 1680 (CO), 1615 (C=C) cm^{-1}; ^{1}H NMR δ=1.1—2.1 (12H, m), 2.6—2.9 (1H, m), 5.71 (1H, dd, J=9, 3 Hz), 6.22 (1H, dd, J=18, 3 Hz), 6.38 (1H, dd, J=18, 9 Hz); UV λ_{max}^{EtOH} 212.5 nm; MS m/z (%): 152 (M$^+$, 7), 123 (10), 97 ([M−C_3H_3O]$^+$, 26), 55 ([M−C_7H_{13}]$^+$, 100).

General Procedure for the Preparation of Divinyl Ketones from α,β-Epoxy Sulfoxides Through Bis(phenylthio) Ketones. A synthesis of (*E*)-1,4-tridecadien-3-one (**40**) is described. A solution of diphenyl disulfide (660 mg; 3 mmol) and $NaBH_4$ (230 mg; 6 mmol) in 11 ml of dry EtOH was refluxed under N_2 for 30 min. This solution was cooled in an ice bath and a solution of **23** (260 mg; 0.6 mmol) in 1 ml of EtOH was added. The whole mixture was stirred at 0 °C for 1 h. The reaction was quenched by adding NH_4Cl

and the EtOH was evaporated. The residue was extracted with benzene and the organic layer was washed with sat. aq NH_4Cl and dried over Na_2SO_4. The product was purified by slilca-gel column chromatography to afford 226 mg (90%) of **39** as a colorless oil. IR (neat): 1710 (CO) cm^{-1}; ^1H NMR δ=0.88 (3H, bt, J=7 Hz), 1.0—2.0 (16H, m), 2.8—3.3 (4H, m), 3.62 (1H, t, J=7 Hz), 7.1—7.4 (10H, m); MS m/z (%): 414 (M^+, 6), 304 ([M−PhSH]$^+$, 10), 249 ([M−C_9H_9OS]$^+$, 100). To a solution of **39** (66 mg; 0.16 mmol) in 3 ml of CH_2Cl_2 at −40 °C was added *m*-CPBA (0.35 mmol) and the mixture was stirred for 5 min. The whole mixture was treated with short silica-gel column chromatography to remove the excess *m*-CPBA and *m*-chlorobenzoic acid. The crude product was heated in refluxing toluene (6 ml) for 15 min. The reaction mixture was cooled to room temperature and ether (6 ml) and 10% NaOH (3 ml) were added. The whole mixture (two phases) was vigorously stirred at room temperature for 1 d. The product was extracted with benzene and after the usual workup and silica-gel column chromatography, 24.5 mg (79%) of **40** was obtained as a colorless oil. IR (neat): 1670 (CO), 1640, 1620 (C=C) cm^{-1}; ^1H NMR δ=0.89 (3H, bt, J=7 Hz), 1.0—1.8 (12H, m), 2.1—2.4 (2H, m), 5.83 (1H, dd, J=10, 2 Hz), 6.32 (1H, dd, J=17.5, 2 Hz), 6.37 (1H, dt, J=16, 1.5 Hz), 6.70 (1H, dd, J=17.5, 10 Hz), 6.99 (1H, dt, J=16, 6.5 Hz); MS m/z (%): 194 (M^+, 2), 167 ([M−C_2H_4]$^+$, 9), 124 (16), 109 (32), 83 (63), 55 ([M−$C_{10}H_{19}$]$^+$, 100); Found: m/z 194.1641. Calcd for $C_{13}H_{22}O$: M, 194.1668.

(*E*)-1-Phenylsulfonyl-4-tridecen-3-one (41). Colorless oil; IR (neat): 1680 (CO), 1635 (C=C), 1310, 1155 (SO_2) cm^{-1}; ^1H NMR δ=0.89 (3H, bt, J=6.5 Hz), 1.0—1.7 (12H, m), 2.0—2.4 (2H, m), 2.96—3.20 (2H, m), 3.36—3.56 (2H, m), 6.09 (1H, dt, J=16, 1.5 Hz), 6.82 (1H, dt, J=16, 7 Hz), 7.4—8.1 (5H, m).

1-(1-Cyclohexenyl)-3-phenylsulfonyl-1-propanone (42). Colorless oil; IR (neat): 1665 (CO), 1305, 1150 (SO_2) cm^{-1}; ^1H NMR δ=1.40—1.80 (4H, m), 1.90—2.40 (4H, m), 2.96—3.25 (2H, m), 3.26—3.55 (2H, m), 6.90 (1H, m), 7.35—8.05 (5H, m); MS m/z (%): 278 (M^+, 14), 136 ([M−$PhSO_2H$]$^+$, 100), 109 (94).

1-(1-Cyclohexenyl)-2-propen-1-one (43). α,β′-Bis(phenylthio) ketone: Colorless oil; IR (neat): 1695 (CO) cm^{-1}; ^1H NMR δ=1.0—2.0 (10H, m), 3.12 (4H, m), 7.0—7.4 (10H, m); MS m/z (%): 356 (M^+, 6), 248 (6), 191 ([M−C_9H_9OS]$^+$, 86), 110 ([M−$C_{15}H_{18}OS$]$^+$, 100). **43**: Colorless oil; IR (neat): 1660 (CO), 1635, 1610 (C=C) cm^{-1}; ^1H NMR δ=1.64 (4H, m), 2.25 (4H, m), 5.65 (1H, dd, J=10.5, 2 Hz), 6.20 (1H, dd, J=17, 2 Hz), 6.90 (1H, m), 6.91 (1H, dd, J=17, 10.5 Hz); UV λ_{max}^{EtOH} 248.5 nm; MS m/z (%): 136 (M^+, 67), 108 ([M−C_2H_2]$^+$, 53), 81 ([M−C_3H_3O]$^+$, 100).

8-(1-Oxo-2-propenyl)-1,4-dioxaspiro[4.5]dec-7-ene (44). α,β′-Bis(phenylthio) ketone: Colorless oil; IR (neat): 1690 (CO), 1090 (COC) cm^{-1}; ^1H NMR δ=1.2—2.2 (8H, m), 2.9—3.4 (4H, m), 3.96 (4H, bs), 7.1—7.5 (10H, m); MS m/z (%): 414 (M^+, 13), 249 ([M−C_9H_9OS]$^+$, 100). **44**: Colorless oil; IR (neat): 1665 (CO), 1645, 1610 (C=C) cm^{-1}; ^1H NMR δ=1.82 (2H, bt, J=6 Hz), 2.4—2.7 (4H, m), 4.04 (4H, s), 5.73 (1H, dd, J=10.5, 2 Hz), 6.26 (1H, dd, J=17, 2 Hz), 6.83 (1H, m), 6.96 (1H, dd, J=17, 10.5 Hz); UV λ_{max}^{EtOH} 248.5 nm; MS m/z (%): 194 (M^+, 16), 86 ([M−C_7H_8O]$^+$, 100), Found: m/z 194.0940. Calcd for $C_{11}H_{14}O_3$: M, 194.0941.

1-(1-Cycloheptenyl)-2-propen-1-one (45). α,β′-Bis(phenylthio) ketone: Colorless oil; IR (neat): 1700 (CO) cm^{-1}; ^1H NMR δ=1.2—2.2 (12H, m), 3.0—3.4 (4H, m), 7.1—7.5 (10H, m); MS m/z (%): 370 (M^+, 5), 262 (44), 205 ([M−C_9H_9OS]$^+$, 100). To a solution of this bis(phenylthio) ketone (66 mg; 0.18 mmol) in 4 ml of CH_2Cl_2 at −70 °C was added *m*-CPBA (0.38 mmol) and stirred for 5 min. The cooling bath was removed and the mixture was stirred at room temperature for 2 h. To the reaction mixture was added ether (5 ml) and 10% NaOH (4 ml) and the whole (two phases) was vigorously stirred under N_2 for 1 d. The usual work-up and purification by silica-gel column chromatography gave **45** (20.6 mg; 77%) as a colorless oil. IR (neat): 1660 (CO), 1635, 1610 (C=C) cm^{-1}; ^1H NMR δ=1.3—2.0 (6H, m), 2.2—2.7 (4H, m), 5.72 (1H, dd, J=10, 2 Hz), 6.23 (1H, dd, J=17, 2 Hz), 6.95 (1H, dd, J=17, 10 Hz), 7.10 (1H, t, J=6 Hz); UV λ_{max}^{EtOH} 255 nm; MS m/z (%): 150 (M^+, 60), 135 (27), 95 (100); Found: m/z 150.1030. Calcd for $C_{10}H_{14}O$: M, 150.1043.

The authors are grateful to Dr. Sei-ichi. Saito, Tanabe Seiyaku Co. for the elemental analysis and Miss Noriko Sawabe, Mrs. Noriko Yamatani, and Miss Mutsumi Ohne of this laboratory for the NMR and mass spectral measurements.

(Received July 19, 1986)

The carbon-skeleton rearrangements as catalyzed by heptamethyl cobyrinate perchlorate, [Cob(II)7C1ester]-ClO_4, were investigated under electrochemical conditions. The controlled-potential electrolysis of 2,2-bis(ethoxycarbonyl)-1-bromopropane, which is considered to be a model substrate for methylmalonyl-CoA mutase, was catalyzed by [Cob(II)7C1ester]ClO_4 in *N,N*-dimethylformamide to give the rearrangement product, 1,2-bis(ethoxycarbonyl)propane, as a major one at −1.5 V vs. SCE in the presence of acetic acid and at potentials more cathodic than −1.8 V vs. SCE without acetic acid in the dark. The electrochemical carbon-skeleton rearrangement was postulated to proceed via formation of anionic intermediates. The electrolyses of 1-bromo-2-cyano-2-ethoxycarbonylpropane, 2-acetyl-1-bromo-2-ethoxycarbonylpropane, and 1-bromo-2-[(ethylthio)carbonyl]propane with [Cob(II)7C1ester]ClO_4 also afforded the corresponding carbon-skeleton rearrangement products. The results indicated that substrates with two electron-withdrawing groups placed on the β-carbon atom with combinations of one carboxylic ester and one of carboxylic ester, acetyl, and cyano moieties readily gave the corresponding rearrangement products which were derived from individual migration of the substituent groups. Substrates with only one of the electron-withdrawing groups, carboxylic ester, acetyl, and cyano, did not give any rearrangement product, but a substrate with one thioester group afforded the corresponding rearrangement product. The migratory aptitude of electron-withdrawing groups was found to decrease in the order: COSR>COR>COOR>CN. Both electronic character and steric bulkiness of the migrating groups are apparently reflected on this tendency, even though relative contributions of these effects are much dependent on the nature of β-substituents.

We have previously prepared the cobalt complex of 1,19-dimethyl-A,D-didehydrocorrin (Hbdhc), having additional double bonds at peripheral positions and an additional angular methyl group as compared with the parent corrinoid, and investigated its structural properties in connection with vitamin B_{12} chemistry.[1,2] The bdhc complex is quite analogous to the corrinoid as far as electronic properties are concerned on the basis of its spectroscopic, electrochemical, and axial coordination behavior. On the other hand, the angular methyl groups in the complex exert an unusually large steric effect in the bimolecular reactions of Co^{I}(bdhc) with alkyl donors which result in the formation of an alkyl–cobalt bond. Even though the bdhc complex is considered to be a good B_{12} model, it does not catalyze the 1,2-migration reaction observed with vitamin B_{12}. This is indeed originated from the steric repulsion effect provided by the angular methyl group which prevents an alkyl fragment initially formed through the Co–C cleavage from staying close to the nuclear cobalt. In order to improve this stereochemical situation, it became necessary to develop another good vitamin B_{12} model.

Various cobalt complexes have been synthesized as model complexes,[3] but all of those complexes cannot be qualified as favorable model complexes in the light of the following aspects. (i) Redox behavior of the central cobalt, which is mainly controlled by basicity of an equatorial ligand, must be similar to that for the naturally occurring vitamin B_{12}. (ii) Electronic properties must be equivalent to those of the natural B_{12}, which are provided by the corrin ring with eight double bonds and the direct bond between A and D rings. (iii) The steric effects, which are caused by the methyl moiety and the hydrogen atom at C(1) and C(19) positions in the corrin ring, respectively, and by four propanamides and three acetamides placed at the α- and β-peripheral sites, respectively, must be retained by model complexes.

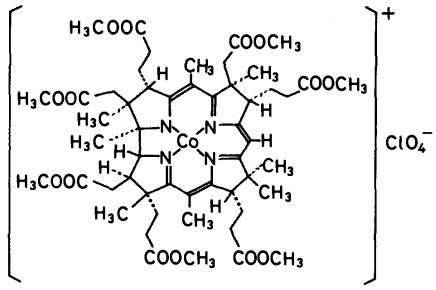
In order to simulate various functions of vitamin B_{12} as exerted in the hydrophobic active sites of enzymes concerned, we have been dealing with hydrophobic vitamin B_{12} derivatives which have ester groups in place of the peripheral amide moieties of the naturally occurring vitamin B_{12}.[4-12] These modified cobalt complexes satisfy all the above requirements and are readily soluble in a wide range of organic solvents.

Most of the vitamin B_{12} model reactions so far carried out are concerned merely with cleavage of the Co–C bond of the corresponding alkylated complexes[13] and cannot be regarded as catalytic ones.[14] Because the alkylated complexes in these reactions were prepared from cobalt complexes and alkyl halides in the presence of chemical reductants such as $NaBH_4$, it was difficult to establish the catalytic cycle and to eliminate an undesirable effect caused by reductants on the reaction. In order to overcome these

† Contribution No. 840 from this Department.

difficulties and set up clean reaction systems, we have adopted electrochemical means for reduction.[11] Recently, electrochemical reactions catalyzed by vitamin B_{12} derivatives or model complexes have been carried out rather extensively,[15-20] but catalytic isomerization reactions accompanied with the carbon-skeleton rearrangement, which are considered to be typical coenzyme B_{12}-dependent enzymatic reactions, have not been successfully performed yet.

In the present work, we have carried out the rearrangement reactions by electrochemical means for the first time as catalyzed by heptamethyl cobyrinate perchlorate, [Cob(II)7C$_1$ester]ClO_4, and reaction mechanisms involved in the electrolyses were clarified by means of various spectroscopic methods. Furthermore, we studied the migratory aptitude of functional groups in the carbon-skeleton rearrangement by employing several substrates having electron-withdrawing groups such as carboxylic ester, thioester, acetyl, and cyano moieties.



[Cob(III)7C$_1$ester]ClO_4

Results and Discussion

We have previously pointed out that [Cob(II)7C$_1$ester]ClO_4 is readily reduced to the univalent cobalt species of highly nucleophilic character by electrochemical means in nonaqueous media,[5] and catalytic reaction cycles shown in Scheme 1 were established. An alkylated complex, generated by the reaction between a univalent cobalt complex and an alkyl halide (RX), is generally decomposed by photolysis[10] or electrolysis to afford reduction and/or rearrangement products. First, we adopted 2,2-bis(ethoxycarbonyl)-1-bromopropane (**1**) which is considered to be a model substrate for methylmalonyl-CoA mutase. This bromide was originally used by Rétey et al. as a model substrate,[21] but Tada et al. reported that the photochemical decomposition of the corresponding alkylated cobaloxime complex gave only the reduction product, 2,2-bis(ethoxycarbonyl)-propane, and the rearrangement product, 1,2-bis-(ethoxycarbonyl)propane, was not detected.[22] Furthermore, the ethoxycarbonyl group of this substrate does not migrate during the reaction with tributyltin hydride which acts to generate the corresponding free radical in the course of the reaction without a cobalt complex.[23]

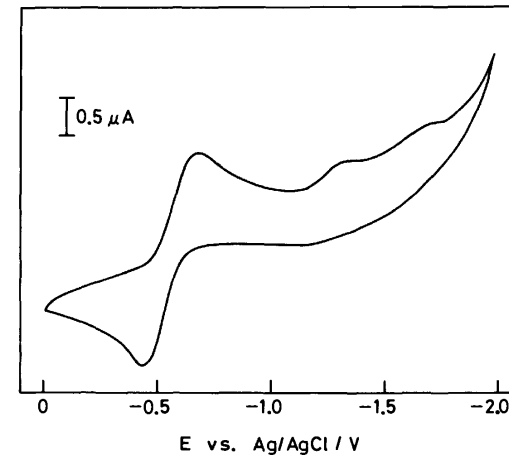


Fig. 1. Cyclic voltammogram of [Cob(II)7C$_1$ester]ClO_4 (7.2×10^{-4} mol dm^{-3}) in DMF containing 2,2-bis(ethoxycarbonyl)-1-bromopropane (0.10 mol dm^{-3}) and TBAF (0.10 mol dm^{-3}) at 20±2 °C in the dark; sweep rate, 100 mV s^{-1}.

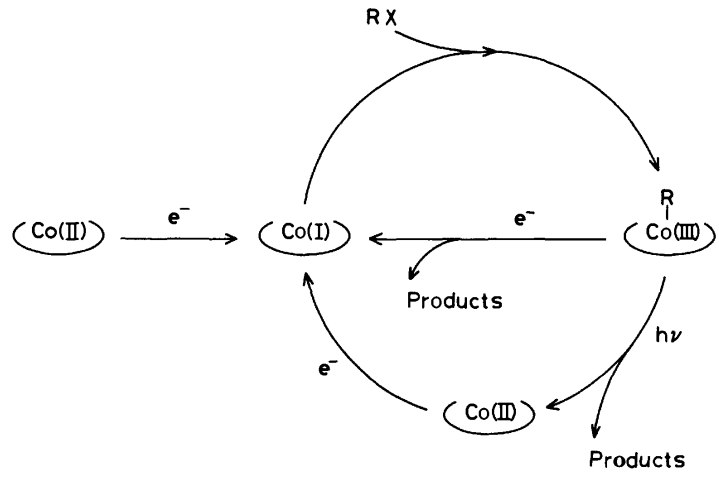
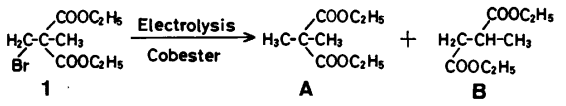


Scheme 1.

Redox Behavior. The redox behavior of [Cob(II)-7C$_1$ester]ClO_4 in *N*,*N*-dimethylformamide (DMF) containing 2,2-bis(ethoxycarbonyl)-1-bromopropane in a large excess and tetrabutylammonium tetrafluoroborate (TBAF) as a supporting electrolyte was examined by means of cyclic voltammetry as shown in Fig. 1.[12] The redox potential for the Co(II)/Co(I) couple on [Cob(II)7C$_1$ester]ClO_4 in DMF was observed at −0.56 V vs. Ag/AgCl in the presence of the alkyl bromide, while the corresponding potential in DMF was observed at −0.58 V vs. Ag/AgCl (−0.61 V vs. SCE) without the alkyl bromide.[5] An irreversible reduction peak was observed at ca. −1.3 V vs. Ag/AgCl and assigned to the formation of the one-electron reduction intermediate of the alkylated complex, which was generated by the reaction between the Co^I species and the alkyl halide. This value is in agreement with the one for heptamethyl methylaquacobyrinate perchlorate, [$(CH_3)(H_2O)$Cob(III)7C$_1$-ester]ClO_4, in DMF; −1.29 V vs. Ag/AgCl (−1.32 V vs. SCE). Its cathodic peak current was small in comparison with that for Co(II)/Co(I) due to the slow rate of reaction between the Co^I species and the substrate. In addition, the second irreversible reduction peak was observed at ca. −1.8 V vs. Ag/AgCl. This peak was assigned to the formation of the two-electron reduction intermediate of the alkylated complex as confirmed by coulometry and controlled-potential electrolysis described below. The first reduction peak for substrate **1** was observed at −2.7 V vs. Ag/AgCl by cyclic voltammetry in DMF without the hydrophobic vitamin B_{12}, so that the peaks observed in the range of −2.0—0 V vs. Ag/AgCl are not originated from the substrate itself. Consequently, the electrochemical behavior shown in Fig. 1 is consistent with the reduction processes shown in Scheme 5, indicating generation of mutually different intermediates by the electrolysis at −1.0, −1.5, and −2.0 V vs. SCE.[24]

Catalytic Reaction. The electrolysis of 2,2-bis(ethoxycarbonyl)-1-bromopropane was carried out upon addition of [Cob(II)7C$_1$ester]ClO_4 under various conditions. The following findings were obtained on the basis of the product analyses given in Table 1 (refer to Eq. 1). (i) At −1.0 V vs. SCE: products were



(1)

obtained only when the reaction mixture was irradiated with the visible light, and the major product was the reduced one (**A** in Eq. 1). (ii) At −1.5 V vs. SCE in the dark: the rearrangement product (**B** in Eq. 1) was the major one when an efficient proton source such as acetic acid or propionic acid was added,[25] while the reduction product (**A**) was largely obtained when 2-propanol was added or without any additive. (iii) At −1.5 V vs. SCE under irradiation with the visible light: the major product was the reduced one even in the presence of acetic acid. (iv) At potentials more cathodic than −1.8 V vs. SCE in the dark: the rearrangement product (**B**) was largely obtained even in the absence of acetic acid. The catalysis was very efficient at −2.0 V vs. SCE, so that the rearrangement product was obtained in yields

Table 1. Product Analyses for Controlled-Potential Electrolysis of 2,2-Bis(ethoxycarbonyl)-1-bromopropane as Catalyzed by Hydrophobic Vitamin B_{12}[a]

Entry	Electrolysis conditions					Yield/%[e]

a) Electrolysis was carried out in a two-compartment cell equipped with Pt electrodes at 20±2 °C under argon atmosphere. Starting solutions composed of: [Cob(II)7C$_1$ester]ClO_4, 30 mg (2.6×10^{-5} mol): 2,2-bis(ethoxycarbonyl)-1-bromopropane, 1.0 g (3.8×10^{-3} mol); 30 mL of DMF containing 0.50 mol dm^{-3} TBAF. b) Irradiated with a 300-W tungsten lamp from a distance of 50 cm. c) CH_3COOH, 0.50 g (8.3×10^{-3} mol); C_2H_5COOH, 0.61 g (8.3×10^{-3} mol); $(CH_3)_2CHOH$, 0.50 g (8.3×10^{-3} mol). d) Electrical charge passed per mol of the substrate. e) Based on an initial amount of the substrate; the rest was the unreacted substrate (a small amount of $(CH_3CO_2)CH_2C(CH_3)(CO_2C_2H_5)_2$ was obtained when CH_3COOH was added); analyzed by GLC. Recovery of the catalyst: 80—90% at −1.0 V; 60—70% at −1.5 V; ca. 50% at −1.8 and −2.0 V vs. SCE.

equivalent to 100—110 times as much as a molar quantity of the hydrophobic vitamin B_{12} after 2 h of the reaction.

Reaction Mechanisms. The reaction mechanisms for controlled-potential electrolyses were investigated by means of electronic spectroscopy, product analyses, and coulometry as well as by the spin-trapping ESR technique.

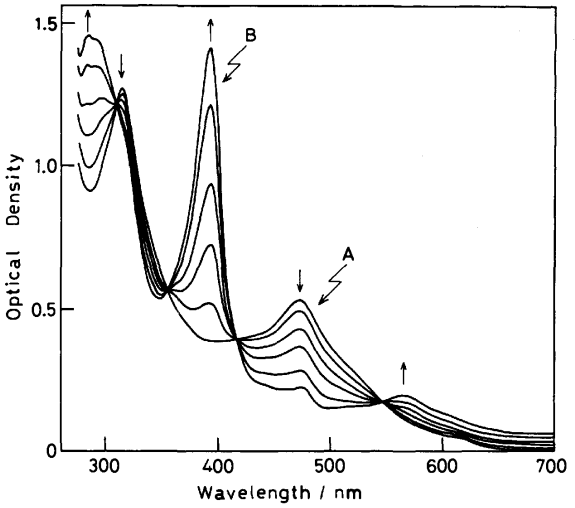

Fig. 2. Spectral change during electrochemical reduction of [Cob(II)7C$_1$ester]ClO_4 (5.2×10^{-5} mol dm^{-3}) in DMF containing 0.20 mol dm^{-3} TBAF at -1.0 V vs. SCE and 20.5 ± 0.1 °C: A, [Cob(II)7C$_1$ester]ClO_4; B, Cob(I)7C$_1$ester. Trends of spectral change with time are shown by arrows.

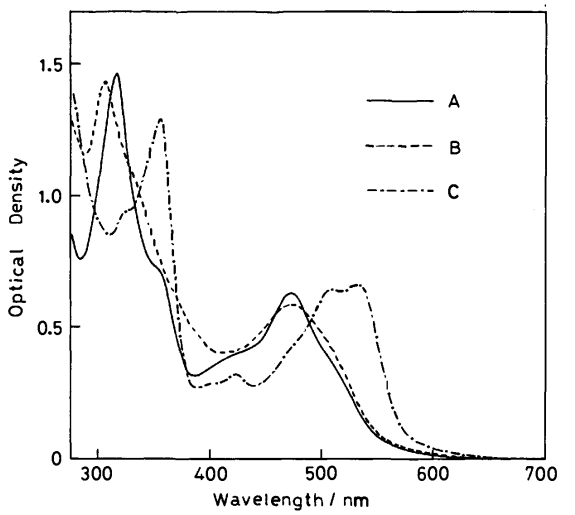

Fig. 3. Electronic spectra observed for a DMF solution containing [Cob(II)7C$_1$ester]ClO_4 (5.2×10^{-5} mol dm^{-3}), 2,2-bis(ethoxycarbonyl)-1-bromopropane (1.5×10^{-2} mol dm^{-3}), TBAF (0.20 mol dm^{-3}), and acetic acid (1.2×10^{-2} mol dm^{-3}) at 20.5 ± 0.1 °C under the following conditions: A, before electrolysis under argon atmosphere; B, electrolysis at -1.0 V vs. SCE under argon atmosphere; C, sample B being irradiated with a 150-W tungsten lamp from a distance of 20 cm for 1 min under aerobic conditions.

(a) Electrolysis at -1.0 V vs. SCE. The controlled-potential electrolysis was followed by electronic spectroscopy. [Cob(II)7C$_1$ester]ClO_4 was reduced to Cob(I)7C$_1$ester, having an absorption maximum at 394 nm as shown in Fig. 2, when the electrolysis was carried out at -1.0 V vs. SCE in the absence of an alkyl halide. When the electrolysis with 2,2-bis(ethoxycarbonyl)-1-bromopropane was carried out at -1.0 V vs. SCE in the dark, [Cob(II)7C$_1$ester]ClO_4 was transformed into the corresponding alkylated complex with absorption maxima at 305 and 474 nm (curve B in Fig. 3). Upon irradiation of this complex with the visible light for a short period of time under aerobic conditions, the electronic spectrum indicated cleavage of the Co-C bond[10] (curve C in Fig. 3). These spectral changes apparently reflect the fact that the alkylated complex is formed at -1.0 V vs. SCE and subsequently decomposed under irradiation conditions.

The reaction was also examined by the spin-trapping technique with α-phenyl-*N*-(*t*-butyl)nitrone (PBN).[26] An ESR spectrum for the PBN spin adduct formed in the course of electrolysis at -1.0 V vs. SCE is shown in Fig. 4. An ESR signal was not observed in the dark (A in Fig. 4), but clear signals for the PBN spin adduct (A_N=14.9 G, A_H=2.7 G; 10^4G=1 T) were detected upon irradiation with the visible light under anaerobic conditions (B in Fig. 4). The identical signals were observed in the absence of acetic acid. The result indicates that the radical species is generated as the intermediate under irradiation conditions.

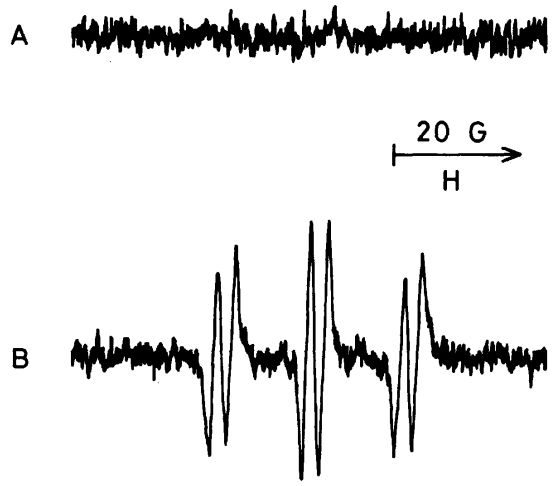

Fig. 4. ESR spectra observed during electrolysis (at -1.0 V vs. SCE) of a DMF solution containing [Cob(II)7C$_1$ester]ClO_4 (2.4×10^{-3} mol dm^{-3}), 2,2-bis-(ethoxycarbonyl)-1-bromopropane(0.29 mol dm^{-3}),PBN (0.12 mol dm^{-3}), acetic acid (0.56 mol dm^{-3}), and TBAF (0.10 mol dm^{-3}) at room temperature: A, in the dark; B, irradiated with a 300-W tungsten lamp from a distance of 60 cm.

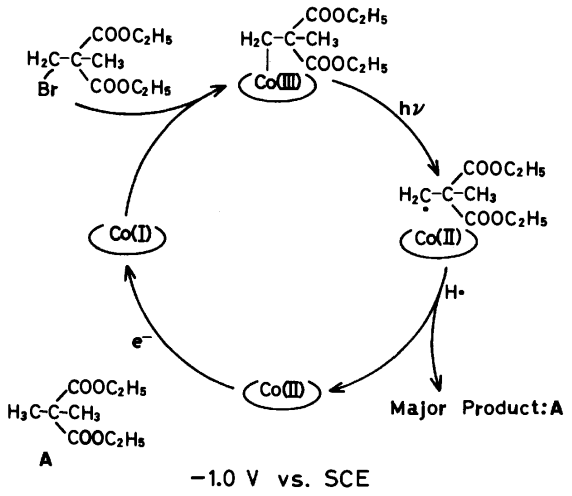
In the light of the spectral measurements and the product analyses for the electrolysis at −1.0 V vs. SCE, a reaction cycle takes place as shown in Scheme 2. The Co^{II} complex is first converted into the Co^{I} species by the electrochemical reduction. The alkylated complex is formed in the second place by the reaction of the super-nucleophilic Co^{I} species with 2,2-bis(ethoxycarbonyl)-1-bromopropane. The complex is then decomposed by the visible light to give the Co^{II} species and the alkyl radical. The radical species abstracts a hydrogen atom to afford the reduction product (**A**), and the Co^{II} complex repeatedly acts as a mediator.



Scheme 2.

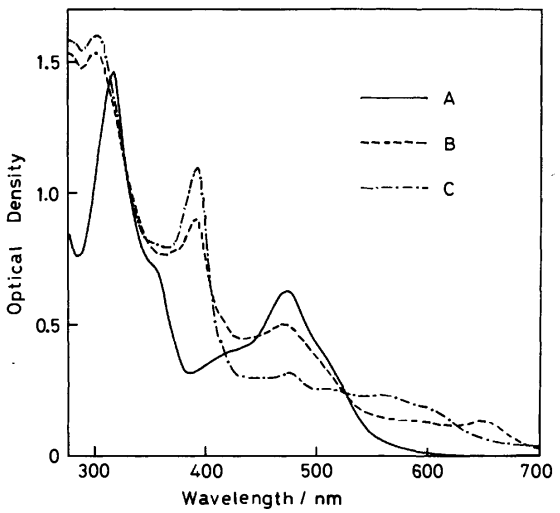


Fig. 5. Electronic spectra observed steadily during electrolysis of a DMF solution containing [Cob(II)7C_1-ester]ClO_4 (5.2×10^{-5} mol dm^{-3}), 2,2-bis(ethoxycarbonyl)-1-bromopropane (1.5×10^{-2} mol dm^{-3}), TBAF (0.20 mol dm^{-3}), and acetic acid (1.2×10^{-2} mol dm^{-3}) at 20.5±0.1 °C: A, before electrolysis; B, at −1.5 V vs. SCE; C, at −1.5 V vs. SCE without acetic acid.

(b) Electrolysis at −1.5 V vs. SCE. When the electrolysis was carried out at −1.5 V vs. SCE, absorption maxima were observed at 280, 302, 391, and 474 nm (curve B in Fig. 5). The spectrum indicates the formation of the alkylated complex and Cob(I)7C_1-ester. A similar spectral change was observed even in the absence of acetic acid (curve C in Fig. 5), but the absorbance intensity originated from Cob(I)7C_1ester was greater than that observed in the presence of acetic acid. These spectral features indicate that the alkylated complex is electrochemically decomposed at −1.5 V vs. SCE.

The electrolysis reaction without irradiation was also examined by the spin-trapping technique. ESR spectra for the PBN spin adducts formed in the course of electrolysis in the dark are shown in Fig. 6. ESR signals attributable to the PBN spin adducts were clearly observed (A in Fig. 6), while the signal intensities became much weaker upon addition of acetic acid (B in Fig. 6). Spin Hamiltonian parameters for the spin adducts are as follows: A_N=14.9 G, A_H=2.7 G; A_N=14.3 G, A_H=6.3 G. Only a single radical species with the former set of parameters was detected at the initial stage of the electrolysis. These values are identical with those observed for the electrolysis at −1.0 V vs. SCE under irradiation conditions. The latter set of parameters was assigned to another species formed in some secondary reactions. The result confirms that the radical species is generated as the electrolysis intermediate at −1.5 V vs. SCE without acetic acid while an efficient proton source such as acetic acid inhibits the formation of the radical species to a large extent.

A relationship between electrical quantity and

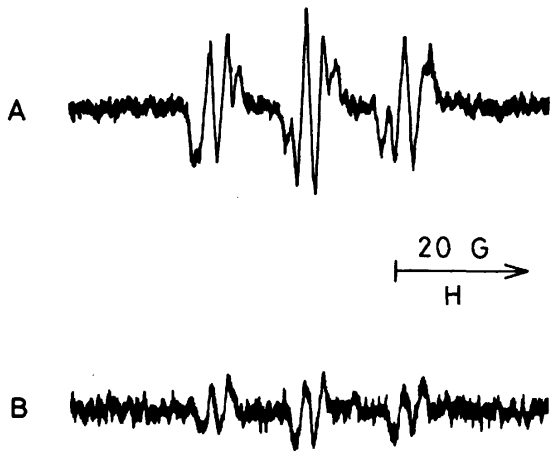

Fig. 6. ESR spectra observed during electrolysis (at −1.5 V vs. SCE) of a DMF solution containing [Cob(II)7C_1ester]ClO_4 (1.7×10^{-3} mol dm^{-3}), 2,2-bis(ethoxycarbonyl)-1-bromopropane (0.25 mol dm^{-3}), PBN (0.10 mol dm^{-3}), and TBAF (0.10 mol dm^{-3}) at room temperature in the dark: A, without acetic acid; B, in the presence of acetic acid (0.56 mol dm^{-3}).

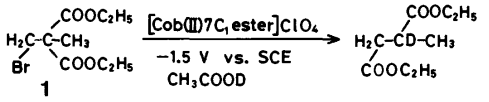
product yield at the initial stage of electrolysis in the dark without acetic acid at −1.5 V vs. SCE is shown in Fig. 7. The reciprocal value (n) of the slope gives a number of electrons needed for the reaction; n=1.2 indicates one-electron reduction.

In order to identify the role of acetic acid, the electrolysis was carried out in the presence of the deuterated acetic acid (CH_3COOD) at −1.5 V vs. SCE in the dark. The product analysis by means of ^{1}H-NMR and mass spectral measurements clarified that the rearrangement product containing one deuterium, $(H_5C_2O_2C)CH_2CD(CH_3)(CO_2C_2H_5)$, was primarily obtained (refer to Eq. 2).[27] Its isotopic purity was



(2)

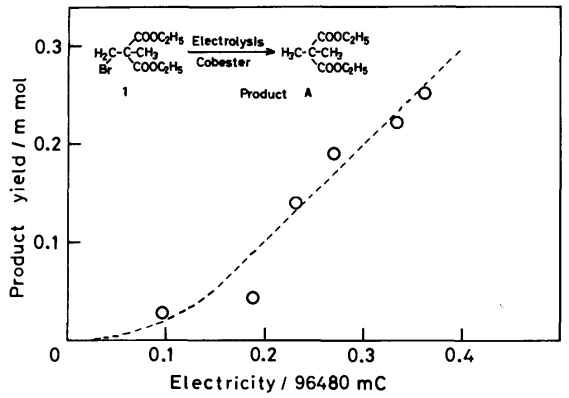


Fig. 7. Relationship between quantity of electricity and yield of the reduction product, 2,2-bis(ethoxycarbonyl)-propane, for electrolysis at −1.5 V vs. SCE and 20± 2 °C in the dark. Initial solution: [Cob(II)7C$_1$ester]-ClO_4, 30 mg (2.6×10^{-5} mol); 2,2-bis(ethoxycarbonyl)-1-bromopropane, 1.0 g (3.8×10^{-3} mol); 30 mL of DMF containing 0.50 mol dm^{-3} TBAF.

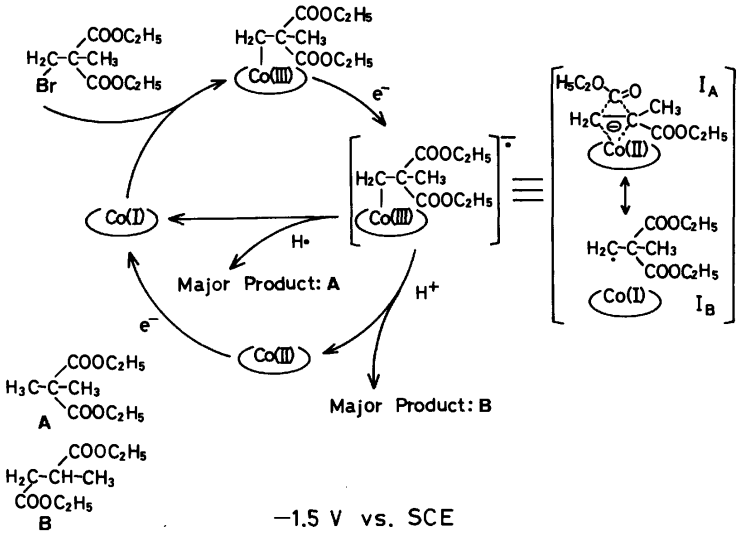
estimated to be 55—60%D. Even when CD_3COOD was used, the isotopic purity remained the same. Reasons for the formation of the product without deuterium may be given as follows: (i) proton-exchange between the deuterated acetic acid and a trace amount of water involved in DMF takes place;[28,29] (ii) proton donation from formic acid formed by decomposition of DMF occurs;[28] (iii) a proton is abstracted from the quaternary ammonium salt, the supporting electrolyte (Hofmann elimination).[30] The electrochemical carbon-skeleton rearrangement is postulated here to proceed via formation of an anionic intermediate, and the proton from acetic acid attacks on the β-carbon of the substrate bound to the hydrophobic vitamin B_{12}.

In the light of the above results, the electrolysis at −1.5 V vs. SCE proceeds via reaction cycles shown in Scheme 3. The mechanism for alkylation of the hydrophobic vitamin B_{12} is identical with that at −1.0 V vs. SCE (vide supra). The alkylated complex is then reduced to the one-electron reduction intermediate at −1.5 V vs. SCE in the dark. The electronic structure for the intermediate seems to be represented by two canonical forms I_A and I_B (Scheme 3). The proton attack on the β-carbon of the substrate induces the carbon-skeleton rearrangement, followed by the cobalt-carbon bond cleavage. On the other hand, the one-electron reduction intermediate is spontaneously decomposed to afford the Co^{I} chelate and the alkyl radical in the absence of an efficient proton source. The reduction product (**A**) is mainly produced from the alkyl radical by rapid abstraction of the hydrogen atom.

(c) Electrolysis at −2.0 V vs. SCE. When the electrolysis was carried out at −1.8 V vs. SCE, the absorbance originated from Cob(I)7C$_1$ester was more intense than that observed during the electrolysis at −1.5 V vs. SCE (Fig. 8). The alkylated complex was



Scheme 3.

decomposed to the Co^{I} complex at potentials more cathodic than −1.8 V vs. SCE in the dark, since the Co^{I} species was steadily observed by electronic spectroscopy during the electrolysis. The spin-trapping technique was not applicable to the electrolysis at −2.0 V vs. SCE, because spin adducts were formed to a limited extent by electrolysis of the substrate itself even in the case without the hydrophobic vitamin B_{12}.

A relationship between electrical quantity and product yield for the electrolysis at −2.0 V vs. SCE in the dark is shown in Fig. 9; the n value of 2.3 indicates the electrolysis takes place via two-electron reduction (line C). Thus, the reaction at −2.0 V vs. SCE must proceed through a cycle shown in Scheme 4. The alkylated complex, which is generated in a manner as observed at −1.0 V vs. SCE, is converted into the two-electron reduction intermediate in the dark. This intermediate is decomposed to the Co^{I} chelate and the anionic species, and rearrangement product is obtained from the latter.

(d) Overall feature of electrolysis mechanisms. The formation conditions for the reduction and rearrangement products in the electrolysis of 2,2-bis(ethoxycarbonyl)-1-bromopropane as catalyzed by the hydrophobic vitamin B_{12} are summarized in Scheme 5. The rearrangement product is obtained primarily from the anionic intermediates, I_A and I_C, while the simple reduction product is mainly

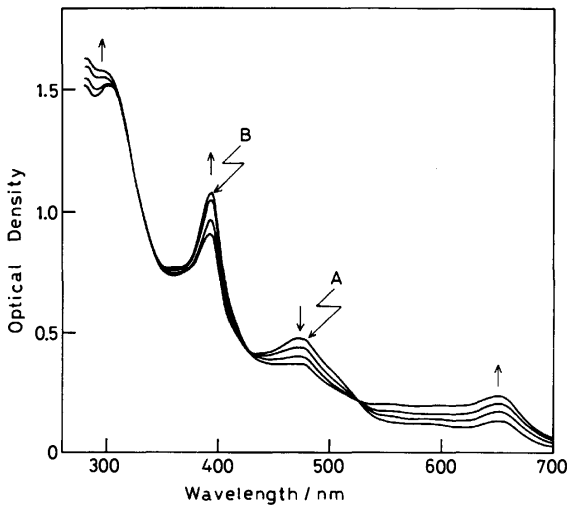


Fig. 8. Electronic spectra observed during electrolysis of a DMF solution containing [Cob(II)$7C_1$ester]ClO_4 (5.2×10^{-5} mol dm^{-3}), 2,2-bis(ethoxycarbonyl)-1-bromopropane (1.5×10^{-2} mol dm^{-3}), TBAF (0.20 mol dm^{-3}), and acetic acid (1.2×10^{-2} mol dm^{-3}) at 20.5 ±0.1 °C: A, steady state at −1.5 V vs. SCE; B, steady state at −1.8 V vs. SCE (electrolysis potential was reset at −1.8 V vs. SCE after state A was attained; trends of spectral change are shown by arrows).

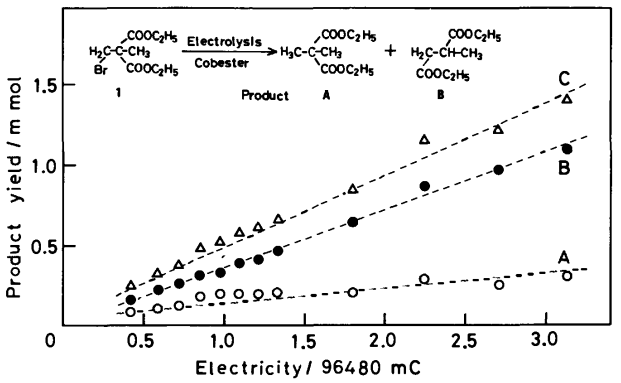

Fig. 9. Relationships between quantity of electricity and product yield for electrolysis at −2.0 V vs. SCE and 20±2 °C in the dark: A, yield of the reduction product, 2,2-bis(ethoxycarbonyl)propane; B, yield of the rearrangement product, 1,2-bis(ethoxycarbonyl)-propane; C, total yield. Initial solution: [Cob(II)-$7C_1$ester]ClO_4, 30 mg (2.6×10^{-5} mol); 2,2-bis(ethoxycarbonyl)-1-bromopropane, 1.0 g (3.8×10^{-3} mol); 30 mL of DMF containing 0.50 mol dm^{-3} TBAF.

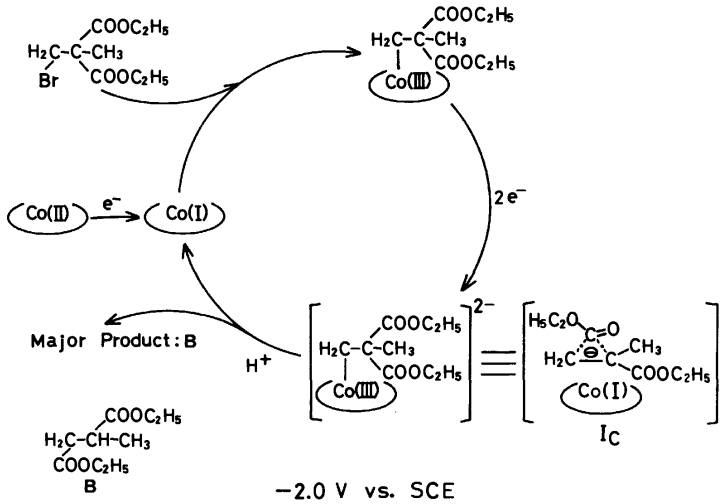

Scheme 4.

produced from the radical species. In particular, the two-electron reduction intermediate (Ic) is more effective in affording the rearrangement product. Since the identical radical species, which is produced by the reaction of the present substrate with tributyltin hydride[23] or by the photolysis of the present substrate bound to cobaloxime,[22] does not give the rearrangement product, the anionic reaction intermediates are the primary source for the rearrangement product. The present study demonstrates the first example of the rearrangement as catalyzed by a vitamin B_{12} model under electrochemical conditions.

Electrolyses of Various Substrates. In order to make further characterization of the catalytic proficiency of the hydrophobic vitamin B_{12} and clarify the migratory aptitude of functional groups in the electrochemical rearrangement reaction, other substrates were also used here. These substrates and the corresponding products are shown in Eqs. 3—8. All the substrates showed their first reduction peaks at -2.7 ± 0.1 V vs. Ag/AgCl as confirmed by cyclic voltammetry.

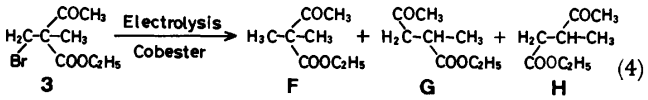
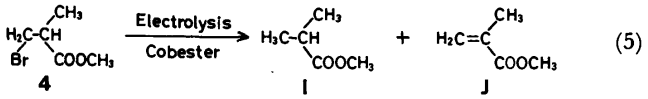
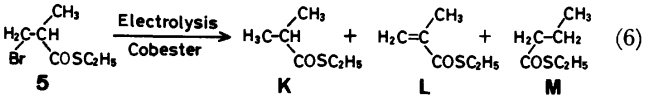
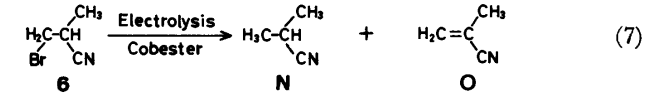
4	−2.0	In the dark	None	2.0	8	28—32	2—3	60—64

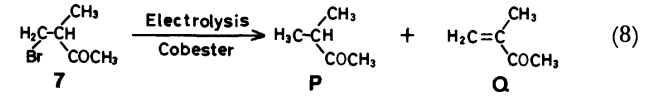
a) Electrolysis was carried out in a two-compartment cell equipped with Pt electrodes at 20 ± 2 °C under argon atmosphere. Starting solutions composed of: [Cob(II)7C$_1$ester]ClO_4, 30 mg (2.6×10^{-5} mol); 1-bromo-2-cyano-2-ethoxycarbonylpropane, 1.0 g (4.5×10^{-3} mol); 30 mL of DMF containing 0.50 mol dm^{-3} TBAF. b) Irradiated with a 300-W tungsten lamp from a distance of 50 cm. c) CH_3COOH, 0.50 g (8.3×10^{-3} mol). d) Electrical charge passed per mol of the substrate. e) Based on an initial amount of the substrate; the rest was the unreacted substrate (a small amount of $(CH_3CO_2)CH_2C(CH_3)(CO_2C_2H_5)(CN)$ was obtained when CH_3COOH was added); analyzed by GLC. Recovery of the catalyst: 80—90% at −1.0 V; 60—70% at −1.5 V; ca. 50% at −2.0 V vs. SCE.











(a) Substrates with two electron-withdrawing groups. The product analyses for the electrolyses of 1-bromo-2-cyano-2-ethoxycarbonylpropane (**2**) and 2-acetyl-1-bromo-2-ethoxycarbonylpropane (**3**) are respectively shown in Tables 2 and 3. The following findings are based on the product analyses for the reaction with substrate **2** (Table 2; refer to Eq. 3). (i) At −1.0 V vs. SCE: products were obtained only when the reaction mixture was irradiated with the visible light, and the major product was the reduced one, 2-cyano-2-ethoxycarbonylpropane (**C**). (ii) At −1.5 V vs. SCE in the dark: the ester-migrated product, 2-cyano-1-ethoxycarbonylpropane (**E**), was the major one when acetic acid was added, while the reduction product (**C**) was largely obtained without any proton source. (iii) At −2.0 V vs. SCE in the dark: the rearrangement product (**E**) was the major one even in the absence of a proton source. (iv) The ester-migrated product (**E**) was produced more readily than the cyano-migrated one, 1-cyano-2-ethoxycarbonylpropane (**D**), under all the conditions; **E**:**D**=96:4.

The following results provide the basis for clarification of the reaction mechanisms concerned. (i) As for cyclic voltammetry performed in DMF on the alkylated complex[31] derived from the hydrophobic vitamin B_{12} and **2**, the first reduction wave was observed at −1.25 V vs. Ag/AgCl and the second one at −1.80 V vs. Ag/AgCl. (ii) On the basis of the relation between electrical quantity and product yield, one-electron reduction (n=1.1) and two-electron reduction (n=2.0) took place at −1.5 and −2.0 V vs. SCE, respectively. (iii) When CH_3COOD was used as a proton source at −1.5 V vs. SCE in the dark, the rearrangement product containing one deuterium, $(H_5C_2O_2C)CH_2CD(CH_3)(CN)$, was obtained as the major product. Its isotopic purity was estimated to be 50—60%D. These results are comparable to those obtained for the reaction with **1**. It may be concluded that the electrolyses of **2** catalyzed by the hydrophobic vitamin B_{12} proceed via formation of intermediates identical in electronic nature with those given in Scheme 5. It became apparent that the ester group has a higher tendency to migrate than the cyano group. This is in contrast with a previous result reported by Rétey et al.,[32] showing that the cyano-migrated product was obtained as a major one by photolysis of the alkylated complex derived from cobalamin and **2**. They concluded that the cyano group has a somewhat higher tendency to migrate than the ethoxycarbonyl group. Since their experimental conditions allow to generate primarily the radical species, the migratory aptitude of cyano and ester groups seems to become reversed under the present conditions which allow to give the anionic intermediates.

The electrolysis of substrate **3** gave the following

Table 3. Product Analyses for Controlled-Potential Electrolysis of 2-Acetyl-1-bromo-2-ethoxycarbonylpropane as Catalyzed by Hydrophobic Vitamin B_{12}[a]

Entry	Electrolysis conditions					Yield/%[e]		
	Potential V vs. SCE	Irradiation[b]	Additive[c]	Charge[d] F mol^{-1}	Period h	**F**	**G**	**H**
1	−1.0	Irradiation	None	1.0	20	2—3	7—10	Trace
2	−1.5	In the dark	None	1.0	20	10—13	53—60	ca. 1
3	−1.5	In the dark	CH_3COOH	3.0	10	15—20	73—83	ca. 1
4	−2.0	In the dark	None	2.0	12	2—5	90—93	3—4

a) Electrolysis was carried out in a two-compartment cell equipped with Pt electrodes at 20±2 °C under argon atmosphere. Starting solutions composed of: [Cob(II)7C_1ester]ClO_4, 30 mg (2.6×10^{-5} mol); 2-acetyl-1-bromo-2-ethoxycarbonylpropane, 1.0 g (4.2×10^{-3} mol); 30 mL of DMF containing 0.50 mol dm^{-3} TBAF. b) Irradiated with a 300-W tungsten lamp from a distance of 50 cm. c) CH_3COOH, 0.50 g (8.3×10^{-3} mol). d) Electrical charge passed per mol of the substrate. e) Based on an initial amount of the substrate; the rest was the unreacted substrate (a small amount of $(CH_3CO_2)CH_2C(CH_3)(COCH_3)(CO_2C_2H_5)$ was obtained when CH_3COOH was added); analyzed by GLC. The catalyst was recovered to the same extents as given in Table 2.

results on the basis of product analyses (Table 3; refer to Eq. 4). (i) The major product was the acetyl-migrated one, 1-acetyl-2-ethoxycarbonylpropane (**G**) under all the electrolysis conditions such as at −1.0 V vs. SCE under irradiation with the visible light, at −1.5 V vs. SCE in the dark with or without acetic acid, and at −2.0 V vs. SCE in the dark. (ii) A proportion of the rearrangement products was the highest under the electrolysis conditions at −2.0 V vs. SCE. (iii) The acetyl-migrated product (**G**) was much more favorably obtained than the ester-migrated one, 2-acetyl-1-ethoxycarbonylpropane (**H**), under all the conditions. These results are different from those for the electrolysis of **1** and indicate that the acetyl group can also migrate via a radical mechanism. This concept is in agreement with previous results which demonstrate that the acetyl group very readily undergoes the 1,2-migration via formation of radical intermediates.[22,33]

The following results may give some insight into the reaction mechanism. (i) The second reduction wave for the alkylated complex was scarcely detected by cyclic voltammetry carried out on [Cob(II)7C$_1$-ester]ClO$_4$ in DMF containing **3** in a large excess. The corresponding alkylated complex was quite labile and could not be isolated by ordinary procedures.[9,34] (ii) Numbers (n) of electrons consumed during the electrolysis was 1.3 and 1.6 at −1.5 and −2.0 V vs. SCE, respectively. (iii) When CH$_3$COOD was used as a proton source at −1.5 V vs. SCE in the dark, the rearrangement product containing one deuterium on the β-carbon was obtained as the major product.[35]

It is not apparent from the above results if the electrolysis at −2.0 V vs. SCE proceeds along with two-electron reduction or not so. The reaction mechanism for the electrolysis of **3** catalyzed by the hydrophobic vitamin B$_{12}$ may be different from that given in Scheme 5, but the detail is not clear at present. The acetyl group may also migrate via a radical mechanism, but the acetyl-migrated rearrangement reaction proceeds much favorably as the electrolysis potential becomes more cathodic.

(b) Substrates with only one electron-withdrawing group. The electrolyses of 1-bromo-2-methoxycarbonylpropane (**4**), 1-bromo-2-[(ethylthio)carbonyl]propane (**5**), 1-bromo-2-cyanopropane (**6**), and 1-bromo-2-acetylpropane (**7**), each with only one electron-withdrawing group, were carried out in the same manner. The β-elimination products were obtained primarily; 2-methoxycarbonylpropene (**J**), 2-cyanopropene (**O**), and 2-acetylpropene (**Q**) from substrates **4**, **6**, and **7**, respectively (refer to Eqs. 5, 7, and 8). Only the electrolysis of substrate **5**, having one thioester group on the β-carbon, afforded the corresponding rearrangement product, 1-[(ethylthio)carbonyl]propane (**M**) as shown in Table 4 (refer to Eq. 6). (i) At −1.5 V vs. SCE in the dark: the reduction product, 2-[(ethylthio)carbonyl]propane (**K**) was the major one without any additive, while the rearrangement one (**M**) was obtained when acetic acid was added. (ii) At −2.0 V vs. SCE in the drak: the rearrangement product (**M**) was dominantly obtained even in the absence of acetic acid. (iii) The β-elimination product, 2-[(ethylthio)carbonyl]-1-propene (**L**), was also largely obtained under the conditions that allow the formation of **M**. Thus, the rearrangement reaction during the electrolysis of **5** must proceed via reaction mechanisms similar to those given in Scheme 5.

(c) Migratory aptitude. The following aspects became apparent for the electrolyses of substrates **1**—**7**. (i) Substrates with two electron-withdrawing groups on the β-carbon atom tend to give the corresponding rearrangement products which are derived from individual migration of the groups (refer to Eqs. 1, 3, and 4). (ii) Substrates with only one of the electron-withdrawing groups do not give the rearrangement products (refer to Eqs. 5, 7, and 8), except for the substrate with one thioester group (refer to Eq. 6). The sulfur atom with d-orbitals seems to stabilize the anionic intermediates which subsequently afford the rearrangement product. (iii) The rearrangement reaction readily proceeds under the electrolysis

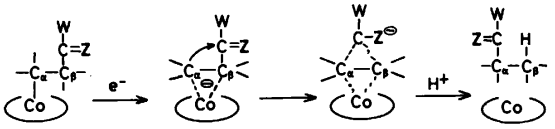
Table 4. Product Analyses for Controlled-Potential Electrolysis of 1-Bromo-2-[(ethylthio)carbonyl]-propane as Catalyzed by Hydrophobic Vitamin B$_{12}$[a]

Entry	Electrolysis conditions				Yield/%[d]		
	Potential / V vs. SCE	Additive[b]	Charge[c] / F mol^{-1}	Period / h	**K**	**L**	**M**
1	−1.5	None	1.0	5	37—41	ca. 1	ca. 1
2	−1.5	CH$_3$COOH	1.0	3	8—16	7—13	15—21
3	−2.0	None	2.0	3	18—22	22—28	33—41

a) Electrolysis was carried out in a two-compartment cell equipped with Pt electrodes at 20±2 °C under argon atmosphere in the dark. Starting solutions composed of: [Cob(II)7C$_1$ester]ClO$_4$, 6 mg (4.4×10^{-6} mol); 1-bromo-2-[(ethylthio)carbonyl]propane, 200 mg (9.0×10^{-4} mol); 7 mL of DMF containing 0.50 mol dm^{-3} TBAF. b) CH$_3$COOH, 0.10 g (1.7×10^{-3} mol). c) Electrical charge passed per mol of the substrate. d) Based on an initial amount of the substrate; the rest was the unreacted substrate; analyzed by GLC. The catalyst was recovered to the same extents as given in Table 2.

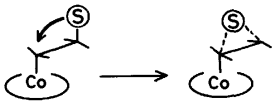
conditions which allow the formation of anionic intermediates.

In the light of the above results, the migratory aptitude of electron-withdrawing groups decreases in the following sequence: COSR>COR>COOR>CN. Both electronic character and steric bulkiness of the migrating groups must be responsible for this tendency. For the formation of the *quasi*-cyclopropane ring in the intermediate stage shown in Scheme 5, attack of the α-carbanion on the β-substituent group is progressively enhanced as the substituent becomes more electron-withdrawing (refer to Eq. 9).



(9)

Stabilization of the anionic intermediates may be achieved through delocalization of negative charge within the *quasi*-cyclopropane ring, and its extent controls the migratory aptitude. On the other hand, a more bulky substituent on the β-carbon atom must be placed at the *anti*-position to the cobalt atom when the alkylated complex is formed (refer to Eq. 10) so



(10)

that such a bulky group readily migrates via formation of the *quasi*-cyclopropane ring. Relative contributions of both electronic and steric effects are much dependent on the nature of β-substituents.

Conclusion. The present study demonstrates for the first time the carbon-skeleton rearrangements catalyzed by a vitamin B_{12} model under electrochemical conditions. The carbon-skeleton rearrangement was postulated to proceed via formation of the anionic intermediates. In the light of the reactions with various substrates, the migratory aptitude of functional groups was clarified. However, it is not relevant to apply these mechanisms directly to the corresponding vitamin B_{12}-dependent enzymatic reactions, since the reduction potential as high as -2.0 V vs. SCE would not be expected in vivo. The rearrangement reaction is generally considered to proceed via radical mechanisms in vivo, but the nature of such radical species must be different from those in homogeneous solution. The reactivity of radical species may be subjected to change by the microenvironmental properties provided by apoenzymes at the reaction sites. In this regard, we have studied the catalytic behavior of the hydrophobic vitamin B_{12} in apoenzyme models such as hydrophobic cyclophanes and bilayer membranes.[34,36]

In the light of the present study, it became apparent that the rearrangement reactions of model substrates readily proceed under stronger reduction conditions. Hydrophobic vitamin B_{12}'s are expected to be widely utilized as specific catalysts for fine organic syntheses via the 1,2-migration process of various functional groups.

Experimental

General Analyses and Measurements. Elemental analyses were performed at the Microanalysis Center of Kyushu University. IR spectra were taken on a JASCO IR-810 infrared spectrophotometer, while electronic absorption spectra were recorded on a Hitachi 340 spectrophotometer. ESR spectra were obtained on a JEOL JES-ME3 X-band spectrometer equipped with a 100 kHz field modulation unit; a standard MgO/Mn^{II} sample calibrated with a NMR magnetometer was employed for calibration of the magnetic field. ^{1}H-NMR spectra were taken on a Hitachi R-24B or a JEOL JNM-FX100 spectrometer, and mass spectroscopic analyses were performed on a JEOL JMS-01SG-2 spectrometer.[37] Cyclic voltammograms were obtained on a Yanaco P-8 polarograph or an apparatus composed of a Hokuto Denko HA-501 potentiostat/galvanostat and a Hokuto Denko HB-104 function generator. An applied potential between the working and reference electrodes in the electrolysis was maintained constant with a Hokuto Denko HA-305 potentiostat/galvanostat and the electrical quantity was recorded on a Hokuto Denko HF-201 coulomb/ampere-hour meter. GLC analyses were carried out on a Shimadzu GC-4C or a Shimadzu GC-9A apparatus equipped with a Shimadzu C-R3A-FFC chromatopac.

Cyclic Voltammetry. An elecrtochemical cell similar to that reported in literature[38] was used and equipped with platinum wire of 0.5-mm diameter as working and auxiliary electrodes. A saturated calomel electrode (SCE) or an Ag/AgCl electrode was served as a reference which was separated from a bulk electrolyte solution by a salt bridge prepared with benzylidene-D-sorbitol[39] and a DMF solution of tetrabutylammonium tetrafluoroborate (TBAF; supporting electrolyte) (5.0×10^{-2} mol dm^{-3}). DMF solutions containing the cobalt complex, TBAF, and the inside of the cell were maintained under argon atmosphere throughout each measurement. All measurements were carried out at 20 ± 2 °C, and the scan rate was varied in a range from 10 through 200 mV s^{-1}. Half-wave potentials ($E_{1/2}$) and anodic and cathodic currents were evaluated according to the method described previously.[40]

Catalytic Reactions. The electrolyses of various substrates were carried out upon addition of [Cob(II)7C$_1$ester]-ClO_4 in a cylindrical three-electrode cell which was divided into two internal compartments with a single sheet of microporous polypropylene membrane and equipped with platinum mesh as working and auxiliary electrodes (Fig. 10). A DMF solution of [Cob(II)7C$_1$ester]ClO_4, a substrate, an additive, and TBAF was subjected to electrolysis at an appropriate controlled-potential under argon atmosphere. Then, the reaction mixture was distilled in vacuo and analyzed for products by means of GLC. Identification of the reaction products was performed by coinjection of the distilled sample and the corresponding authentic samples into columns of Silicone DC-550, Silicone SE-30, and Dioctyl phthalate. A capillary column of Polyethylene

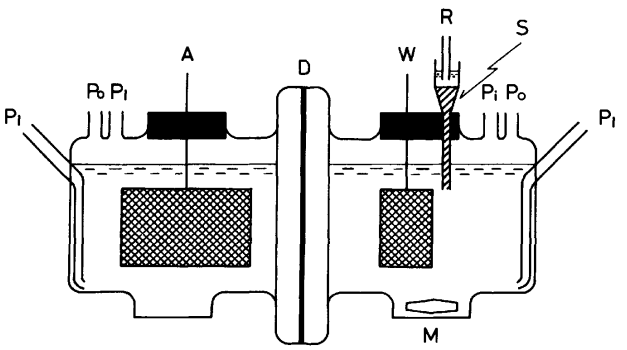


Fig. 10. Three-electrode cell for controlled-potential electrolysis: A, auxiliary electrode (Pt mesh); D, diaphram(Duragard: microporous polypropylene membrane); M, magnetic stirrer; P_i, inert gas inlet; P_o, inert gas outlet; R, reference electrode (SCE); S, salt bridge (prepared with benzylidene-D-sorbitol and a nonaqueous solution of TBAF); W, working electrode (Pt mesh).

Glycol-20M was used for identification of isomers having similar structures such as **D** and **E** or **G** and **H**. Each product separated by preparative GLC on Silicone DC-550 was identified by means of ^{1}H-NMR and mass spectroscopy.

Spectroscopic Measurements. Controlled-potential electrolyses under various conditions were carried out in a three-electrode cell modified for electronic and ESR spectral measurements, as described previously.[40] An applied potential between the working and reference electrodes was maintained constant with a conventional potentiostat and monitored with a Takeda Riken TR-6656 digital multimeter.

Materials. Heptamethyl dicyanocobyrinate, $(CN)_2$Cob(III)7C$_1$ester, was derived from cyanocobalamin after the method of Werthemann et al.[41] Preparation of [Cob(II)7C$_1$ester]ClO_4 from $(CN)_2$Cob(III)7C$_1$ester has been described previously.[4] Tetrabutylammonium tetrafluoroborate (TBAF) was prepared after the reported procedure.[42] α-Phenyl-*N*-(*t*-butyl)nitrone (PBN) as a spin-trapping agent, CH_3COOD (98 atom %D) (both from Aldrich Chemical Co., U.S.A.), and CD_3COOD (99.6 atom %D) of Commissariat á l'Enerqie Atomique, France were used as supplied. *N,N*-Dimethylformamide (DMF) was dried and purified just before use according to the standard procedure.[28] The substrates were prepared by the following procedures.

2,2-Bis(ethoxycarbonyl)-1-bromopropane (1). A solution of diethyl methylmalonate (11.2 g, 0.064 mol) in dry benzene (40 mL) and subsequently a solution of dibromomethane (16.0 g, 0.092 mol) in dry DMF (40 mL) were added dropwise to a suspension of sodium hydride (1.54 g, 0.064 mol) in dry benzene (20 mL) with vigorous stirring at room temperature under nitrogen atmosphere. After the reaction mixture being stirred for 2 h at room temperature, a saturated aqueous ammonium chloride (100 mL) was added to it. The resulting product was extracted with diethyl ether (100 mL×2), and the extract was washed with distilled water and dried over sodium sulfate. The product was recovered by distillation under reduced pressure (75—76 °C/5.3 Pa), and its purity was confirmed by GLC: Yield 12.0 g (70%); IR (neat) 1735 cm^{-1} (ester C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.30 (6H, t, $CH_2C\underline{H}_3$), 1.50 (3H, s, CH_3), 3.80 (2H, s, CH_2Br), and 4.20 (4H, q, $C\underline{H}_2CH_3$).

Found: C, 40.60; H, 5.68%. Calcd for $C_9H_{15}BrO_4$: C, 40.47; H, 5.66%.

1-Bromo-2-cyano-2-ethoxycarbonylpropane (2). This compound was derived from 1-cyano-1-ethoxycarbonylethane[43] (16.2 g, 0.128 mol) in a manner similar to that described above. The product was recovered by distillation under reduced pressure (80—90 °C/40—66 Pa) and further purified by preparative GLC on Silicone DC-550: Yield 16.2 g (68%); IR (neat) 2240 (C≡N) and 1740 cm^{-1} (ester C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.16 (3H, t, $CH_2C\underline{H}_3$), 1.54 (3H, s, CH_3), 3.46 (2H, m, CH_2Br), and 4.12 (2H, q, $C\underline{H}_2CH_3$).

Found: C, 38.42; H, 4.54; N, 6.52%. Calcd for $C_7H_{10}BrNO_2$: C, 38.20; H, 4.58; N, 6.36%.

2-Acetyl-1-bromo-2-ethoxycarbonylpropane (3). This substrate was prepared from ethyl 2-methylacetoacetate[44] (20 g, 0.14 mol) in a manner similar to that described above. The product was recovered by distillation under reduced pressure (70—72 °C/102 Pa) and purified further by preparative GLC on Silicone DC-550: Yield 12 g (36%); IR (neat) 1740 (ester C=O) and 1720 cm^{-1} (ketone C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.18 (3H, t, $CH_2C\underline{H}_3$), 1.41 (3H, s, CH_3), 2.10 (3H, s, $COCH_3$), 3.61 (2H, s, CH_2Br), and 4.13 (2H, q, $C\underline{H}_2CH_3$).

Found: C, 40.41; H, 5.36%. Calcd for $C_8H_{13}BrO_3$: C, 40.53; H, 5.53%.

1-Bromo-2-methoxycarbonylpropane (4). 3-Bromo-2-methylpropionic acid (51.3 g, 0.31 mol), which was obtained by the reaction of methacrylic acid with hydrogen bromide in acetic acid,[45] was esterified with methanol (100 mL) containing sulfuric acid (1 mL). The product was extracted with diethyl ether and recovered from the extract by distillation under reduced pressure (72.5—73.0 °C/2530 Pa): Yield 50.0 g (90%); IR (neat) 1750 cm^{-1} (ester C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.28 (3H, d, CH_3), 2.84 (1H, m, CH), 3.47 (2H, m, CH_2Br), and 3.66 (3H, s, CO_2CH_3).

Found: C, 33.27; H, 4.98%. Calcd for $C_5H_9BrO_2$: C, 33.17; H, 5.01%.

1-Bromo-2-[(ethylthio)carbonyl]propane (5). This was prepared according to a reported procedure.[1]

1-Bromo-2-cyanopropane (6). This compound was prepared by the reaction of 2-cyanopropene (15.0 g, 0.22 mol) with 30%(w/w) hydrogen bromide in acetic acid (100 mL) in a usual manner,[45] bp 35—40 °C/107 Pa: Yield 17.0 g (51%); IR (neat) 2240 cm^{-1} (C≡N); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.44 (3H, d, CH_3), 3.10 (1H, m, CH), and 3.45 (2H, d, CH_2Br).

Found: C, 32.46; H, 4.11; N, 9.38%. Calcd for C_4H_6BrN: C, 32.46; H, 4.09; N, 9.46%.

1-Bromo-2-acetylpropane (7). This substrate was prepared by the reaction of 2-acetylpropene (5.0 g, 0.059 mol) with hydrogen bromide in methanol,[45] bp 60 °C/2670 Pa: Yield 1.0 g (10%); IR (neat) 1705 cm^{-1} (ketone C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.18 (3H, d, CH_3), 2.20 (3H, s, $COCH_3$) 2.29 (1H, m, CH), and 3.51 (2H, m, CH_2Br). This compound was so labile that its elemental analysis was not possible.

Authentic Samples. 2,2-Bis(ethoxycarbonyl)propane (**A**), 2-methoxycarbonylpropane (**I**), 2-methoxycarbonylpropene (**J**), 2-cyanopropane (**N**), 2-cyanopropene (**O**), 2-acetylpropane (**P**), and 2-acetylpropene (**Q**) were purchased from Nakarai Chemicals and purified by distillation before use; confirmed to be sufficiently pure by ^{1}H-NMR and GLC.

2-Cyano-1-ethoxycarbonylpropane (**E**),[46] 2-acetyl-2-ethoxycarbonylpropane (**F**),[44] 1-acetyl-2-ethoxycarbonylpropane (**G**),[47,48] 2-acetyl-1-ethoxycarbonylpropane (**H**),[47] 2-[(ethylthio)carbonyl]propane (**K**),[1] 2-[(ethylthio)carbonyl]-1-propene (**L**),[1] and 1-[(ethylthio)carbonyl]propane (**M**),[1] were prepared according to the methods described in literatures and confirmed to be sufficiently pure by ^{1}H-NMR and GLC.

1,2-Bis(ethoxycarbonyl)propane (B). This compound was derived from the corresponding carboxylic acid (10 g, 0.08 mol) by refluxing it in ethanol containing sulfuric acid, bp 74—75 °C/670 Pa: Yield 7.8 g (54%); IR (neat) 1735 cm^{-1} (ester C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.25 (6H, t, $CH_2C\underline{H}_3$), 1.30 (3H, d, CH_3), 2.60 (2H, m, CH_2), 2.90 (1H, m, CH), and 4.20 (4H, q, $C\underline{H}_2CH_3$).

2-Cyano-2-ethoxycarbonylpropane (C). This was obtained by the reaction of 1-cyano-1-ethoxycarbonylethane (5.0 g, 0.039 mol) with methyl iodide in a manner similar to that adopted for the preparation of **1**, bp 95 °C/4000 Pa: Yield 3.0 g (54%); IR (neat) 2240 (C≡N) and 1740 cm^{-1} (ester C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.30 (3H, t, $CH_2C\underline{H}_3$), 1.58 (6H, s, CH_3), and 4.18 (2H, q, $C\underline{H}_2CH_3$).

2-Cyano-1-ethoxycarbonylpropane (D). This compound was prepared by the reaction of 1-bromo-2-ethoxycarbonylpropane (5.0 g, 0.026 mol) with potassium cyanide (2.5 g, 0.038 mol) in a manner similar to that reported previously,[43] bp 85 °C/4000 Pa: Yield 0.30 g (10%); IR (neat) 2240 (C≡N) and 1735 cm^{-1} (ester C=O); ^{1}H-NMR ($CDCl_3$, TMS) δ=1.28 (3H, t, $CH_2C\underline{H}_3$), 1.32 (3H, d, CH_3), 2.62 (2H, br s, CH_2), 2.70 (1H, m, CH), and 4.12 (2H, q, $C\underline{H}_2CH_3$).

We wish to thank Mr. Hideki Horiuchi, glassworker of our department, for his skill in preparing specific three-electrode cells used for catalytic reactions, electronic and ESR spectroscopy, and cyclic voltammetry.

Synthesis of Hexahydroindenones through a Diels-Alder Cycloaddition and Nazarov Cyclization Sequence of Triene Alcohols

Eiji WADA, Isamu FUJIWARA, Shuji KANEMASA, and Otohiko TSUGE*
Research Institute of Industrial Science, and Department of Molecular Science and Technology, Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, Kasugakoen, Kasuga 816
(Received June 26, 1986)

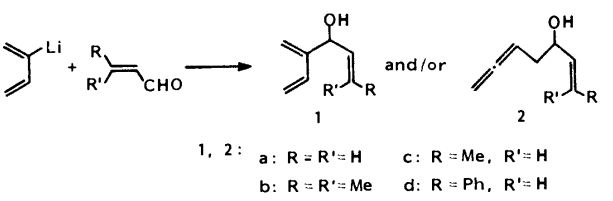
The Diels-Alder cycloaddition of 4-methylene-1,5-hexadien-3-ols with olefinic dienophiles such as dimethyl maleate, fumarate, and *N*-methylmaleimide produces 1-(1-cyclohexenyl)-2-propen-1-ols. These diene alcohols are oxidized with activated manganese(IV) oxide to give dienones, which are then treated with acid catalysts to undergo ready electrocyclization leading to hexahydroindenones with functional groups. Stereoselectivity at the electrocyclization step is found to depend upon the stereostructures of cyclohexene skeleton of the dienones as well as the reaction conditions.

2-Lithio-1,3-butadiene serves as a reagent which introduces a 1-methylene-2-propenyl unit into carbonyls by a regioselective nucleophilic addition.[1] In the preceding paper, we have already demonstrated that 1-aryl-2-methylene-3-buten-1-ols thus prepared undergo a sequence of Diels-Alder cycloaddition with electron-deficient olefins and acid-catalyzed cyclization leading to tetrahydrofluorene skeletons.[2] This sequence belongs to a new [6.5] annelation method to a benzene ring, while [6.6] annelation processes to acyclic and cyclic ketones have been established through stepwise sequence of two Diels-Alder reactions on 1-methylene-2-propenyl carbinols.[3]

The present article presents a new version of [6.5] annelation method by a sequence of two ring-forming reactions: The Diels-Alder cycloaddition of 4-methylene-1,5-hexadien-3-ols with olefins, oxidation of the diene alcohols as cycloadducts into dienones, and subsequent Nazarov cyclization. Although Nazarov reaction has been long utilized as a key reaction for natural product synthesis,[4] there are only limited examples known for the cyclization of dienones which are carrying several carbonyl functionalities.[5]

Results and Discussion

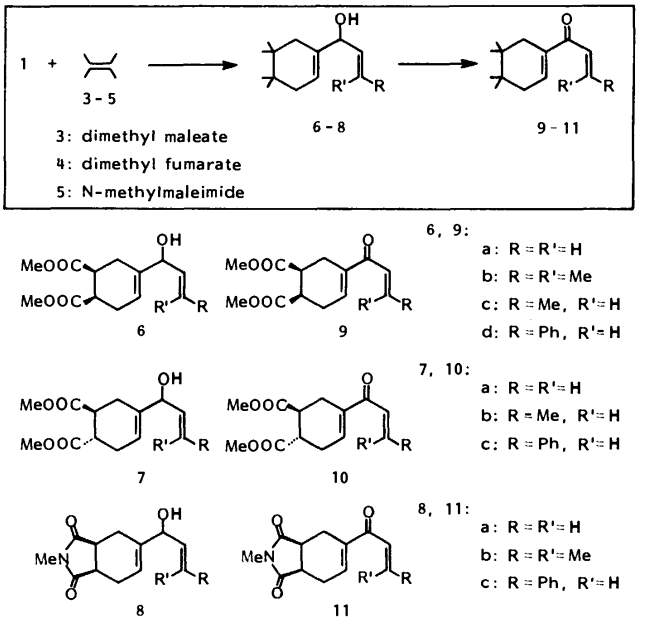
4-Methylene-1,5-hexadien-3-ols (**1**) as starting materials in the present work can be readily prepared from the regioselective reactions of 2-lithio-1,3-butadiene with 2-alkenals (Scheme 1).[1] Although some of the triene alcohols **1** were contaminated by a small amount of their isomers, 1,5,6-heptatrien-3-ols (**2**), these mixtures were able to be used for the following Diels–Alder cycloadditions without serious trouble. After the cycloaddition was over, the allene alcohols **2** were recovered unchanged and easily separated from the cycloadducts by column chromatography over silica gel.



Scheme 1.

The triene alcohols **1a—d** were employed in the Diels-Alder reactions with dienophiles such as dimethyl maleate (**3**), dimethyl fumarate (**4**), and *N*-methylmaleimide (**5**). The reactions took place smoothly under reflux in benzene to give excellent yields of cycloadducts **6—8** as mixtures of two diastereomers (Scheme 2 and Table 1).

The oxidation of 1,4-pentadien-3-ols into pentadienones is not a well-studied transformation[6] and this oxidation should be done with care because pentadienones as products are, in general, labile compounds. We used activated manganese(IV) oxide for this purpose since its versatility in the oxidation of allyl alcohol has been well-achieved.[7] Thus, the diene



Scheme 2.

alcohols **6**—**8** were successfully oxidized with activated manganese(IV) oxide in dichloromethane at room temperature to give satisfactory yields of dienones **9**—**11** as unstable compounds (Scheme 2 and Table 2).

Although details will be discussed later, electrocyclization of the dienones **9**—**11** afforded two types of enones (tetrasubstituted endo olefins **12**, **14**, and trisubstituted exo olefins **13**, **15**) as cyclized products depending upon the reaction conditions as well as the structure of starting dienones **9**—**11** (Scheme 3). In all cases, no trace of the other cyclopentenones, double-bond isomers of **12** and **14**, was even detected. This is consistent with the reported examples for the electrocyclizations of dienones including cyclohexene moiety as an olefin part.[5,8,9]

a) All reactions were carried out in dichloromethane. b) Molar ratio (DA: diene alcohols **6**—**8**). c) Isolated yield. d) The starting material **8a** was recovered in 16% yield.

A wide variety of acid catalysts including both Brønsted and Lewis acids have served in the electrocyclization of dienones and their equivalents.[5] We hoped to avoid the use of aqueous acids since the dienones **9**—**11** are all bearing some substituents sensitive to hydrolysis and since aqueous acids sometimes cause abnormal cyclization.[10] In addition, a cyclization procedure under mild conditions was desired, under which stereoselective cyclization would be achieved and acid-catalyzed epimerization of the cyclized products would be suppressed.

First we tested the electrocyclization of the dienone **9a** in the presence of *p*-toluenesulfonic acid (*p*-TsOH). This reaction gave 55% of expected product **12a** when heated under reflux in benzene for 4.5 h, but the reaction temperature and time are both unacceptable. So, some Lewis acid catalysts were examined in dichloromethane (Table 3); gallium(III) chloride was found much more effective than some other Lewis acids such as titanium(IV) chloride, aluminum(III) chloride, tin(IV) chloride, boron trifluoride, and trimethylsilyl trifluoromethanesulfonate. For example, the cyclization was completed within 30 min below 0 °C to give 73% of **12a** when two equimolar amounts of gallium(III) chloride were employed.

Other maleate cycloadducts **9b**—**d** underwent smooth cyclization in the presence of gallium(III) chloride to give tetrasubstituted olefins **12b**—**d** and/or trisubstituted olefins **13b**—**d**, both with high stereoselectivities (Scheme 4 and Table 4). In each case, the crude reaction mixture was found to be consisting of two major products by TLC and ^1H NMR spectrum, one of which was identical with **12**. When this

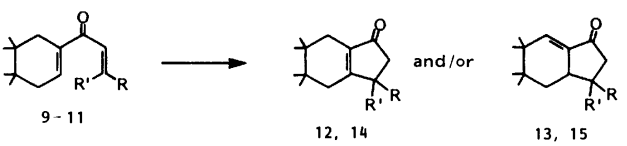
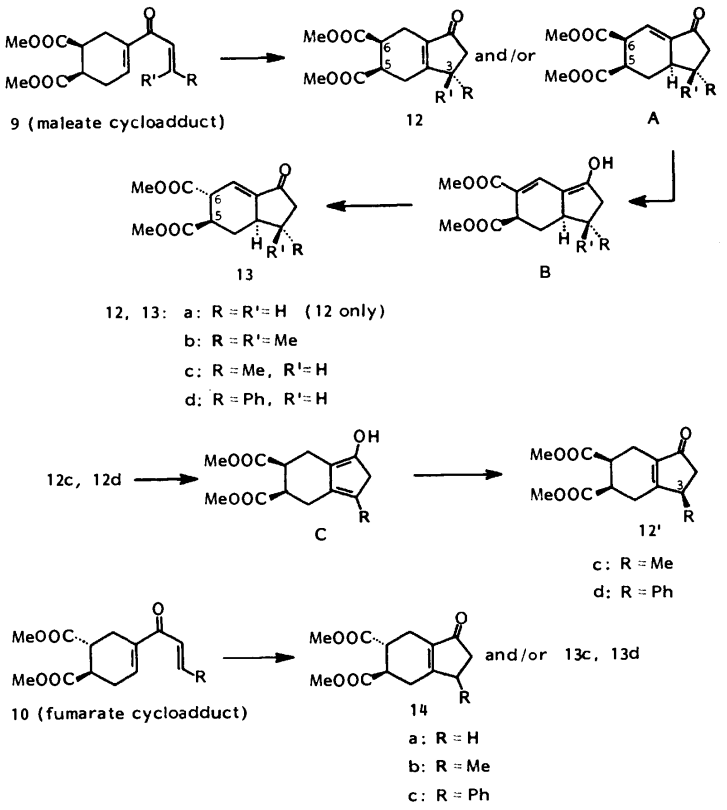


Scheme 3.

mixture was subjected to column chromatography over silica gel, the other product **A** completely isomerized into **13** which was also obtained from the electrocyclization of fumarate cycloadducts **10** as will be mentioned below. It is thus clear that the unstable primary products **A** and **13** are carrying cis and trans two adjacent ester groups, respectively.

Fumarate cycloadducts **10a—c** were similarly treated with gallium(III) chloride under the conditions listed in Table 4 to give tetrasubstituted olefins **14** together with aforementioned trisubstituted olefins **13c** and **13d**.

Structures of **12**, **13**, and **14** were determined mainly on the basis of spectral data except that the stereochemistry at the 3-positions of **12** and **13** could not be assigned only on their spectroscopic basis. Therefore, mechanistic consideration was taken into account. In the preceding paper,[2] we found that



Scheme 4.

a) DCM: dichloromethane; BZ: benzene; T: toluene. b) Isolated yield. The isomer ratios were determined by ^1H NMR. c) A 1:1 mixture of stereoisomers.

dimethyl 4-(α-hydroxybenzyl)-4-cyclohexene-1,2-dicarboxylates underwent highly stereoselective electrocyclization leading to dimethyl 3,4a-*cis*-1*H*-2,3,4,4a-tetrahydrofluorene-2,3-dicarboxylate. The high stereoselectivity observed above in the Nazarov cyclization of maleate cycloadducts **9** presumably resulted in the same manner (Fig. 1): Pentadienyl cation **D** as an intermediate cyclizes through one of two possible conrotatory rotations to form allyl anion **E** which is sterically less hindered than the isomeric anion derived by the other rotation. Deprotonation of **E** at the 3a- or 7-position leads to **12** or **A**, respectively. Thus, the substituent R in **9** becomes cis to 5-H.

Small couplings of J_{5-6} (3.6 Hz) indicates the validity of 5,6-cis geometry of tetrasubstituted olefins **12** derived from **9**. On the other hand, trans configuration of epimerized products **13** is confirmed by relatively large couplings of J_{5-6} (10.0 Hz). One of

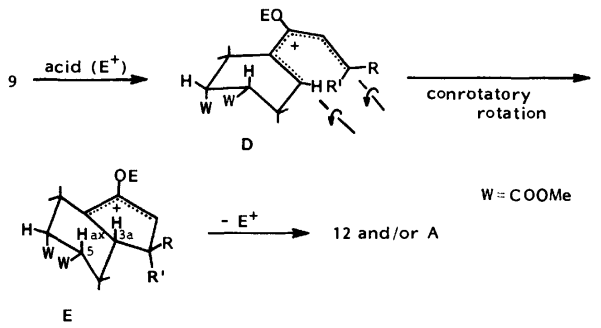

Fig. 1. Stereoselective cyclization of maleate cycloadducts **9** through conrotatory rotation of pentadienyl cation **D**.

4-methylene hydrogens of **13b** couples with two adjacent methine hydrogens (3a-H and 5-H) with 12.0 Hz of diaxial couplings, indicating 3a,5-cis structure (Fig. 2). The stereostructures of tetrasubstituted olefins **14b** and **14c** derived from fumarate cycloadducts **10b** and **10c** could not be assigned by spectral data.

The aforementioned ready epimerization at the 6-position of a trisubstituted olefin **A** probably took place through an acid-catalyzed dienolization (via **B**, Scheme 4). Contrary to the highly stereoselective electrocyclization of **9** in the presence of gallium(III) chloride, similar cyclizations with *p*-TsOH occurred in a nonstereoselective fashion. For example, a mixture of two stereoisomers **12c+12c′** (1:1) or **12d+12d′** (1:1) was obtained when the cyclization of **9c** or **9d** was carried out under reflux in benzene or toluene with *p*-TsOH, respectively (Table 4). As **12d** was found to isomerize into **12d′** in the presence of *p*-TsOH under comparable conditions, it is easily understood that **12d** undergoes a similar acid-catalyzed epimerization via dienol **C** (Scheme 4).

Even in the presence of gallium(III) chloride, maleimide cycloadducts **11** experienced nonstereoselective cyclization giving trisubstituted olefins **15** and/or **15′** (Scheme 5 and Table 4). This selectivity looks the same to that previously observed on the related cyclization.[2] No formation of tetrasubstituted olefins may be due to the serious steric hindrance anticipated to exist in the folded conformation of cyclohexene ring. The structures of **15** and **15′** were confirmed mainly on the basis of ^{1}H NMR data which were already shown in Fig. 2. The axial hydrogen (8-H_{ax}) of **15c** couples with both 7a-H and 8a-H with

large coupling (10.0 and 12.5 Hz), whereas 8-H_{ax} of **15c'** shows a small coupling constant toward 8a-H (6.0 Hz).

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 Hz), a JEOL FX-100 instrument (100 MHz), or Bruker AM 360 (360 MHz), and ^{13}C NMR on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. GC-Mass spectra as well as high resolution mass spectra (HRMS) were also obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck) or of aluminum oxide 60 F-254 type-E (Merck); visualization was with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20×180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Preparative high-performance liquid chromatography (HPLC) was performed on a Kusano KHLC-201 apparatus with a UV-detector Uvilog-III using a column (22×300 mm) packed with silica gel (Wakogel LC-50H). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with a flame ionization detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×5000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

Materials and Solvents. 4-Methylene-1,5-hexadien-3-ol (**1a**), 6-methyl-3-methylene-1,5-heptadien-4-ol (**1b**), *trans*-3-methylene-1,5-heptadien-4-ol (**1c**), and *trans*-4-methylene-1-phenyl-1,5-hexadien-3-ol (**1d**) were prepared from 2-lithio-1,3-butadiene and the corresponding aldehydes according to the reported method.[1] Although some of these triene alcohols **1** were often contaminated by the corresponding allene alcohols **2**, the mixtures were used for the following Diels-Alder reactions without purification. Gallium(III) chloride was prepared from metal gallium and dry hydrogen chloride and purified by distillation.

General Procedure for the Diels-Alder Reactions of Triene Alcohols 1 with Olefinic Dienophiles 3—5 Leading to Cycloadducts 6—8. Triene alcohols **1a—d** were heated under reflux in dry benzene with a slightly excess amount of dimethyl maleate (**3**), dimethyl fumarate (**4**), or *N*-methylmaleimide (**5**) under the reaction conditions listed in Table 1. The benzene was evaporated in vacuo and the residue was chromatographed over silica gel with hexane-ethyl acetate (4:1 to 1:3 v/v) or hexane-diethyl ether (1:1 v/v) to give cycloadducts **6—8** which were all mixtures of two diastereomers. The results are summarized in Table 1.

6a: Colorless liquid; IR (neat) 3400 and 1750 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.2—3.2 (7H, m, CH_2, CH, and OH), 3.66 (6H, s, COOMe), 4.48 (1H, br d, J=5.5 Hz, CHOH), 5.10 (1H, dt, J=10.0, 1.5, and 1.5 Hz, =CH_2 (cis)), 5.25 (1H, dt, J=17.5, 1.5, and 1.5 Hz, =CH_2 (trans)), 5.70 (1H, br s, 2-H), and 5.82 (1H, ddd, J=17.5, 10.0, and 5.5 Hz, CH=); ^{13}C NMR ($CDCl_3$) δ=24.83, 25.01, 25.48, 25.60 (each t, 3- and 6-C), 39.75, 39.86, 39.98 (each d, 4- and 5-C), 51.84 (q, COOMe), 76.09, 76.27 (each d, -CHOH-), 115.25 (t, =CH_2), 120.71, 120.88 (each d), 137.09, 137.20 (each s, 1-C), 138.61, 138.79 (each d), and 173.55 (s, COOMe); MS *m/z* (rel intensity, %) 236 (M^+−18, 9), 176 (52), 117 (100), and 79 (20).

Found: C, 61.45; H, 7.13%. Calcd for $C_{13}H_{18}O_5$: C, 61.40; H, 7.13%.

6b: Unstable colorless liquid; IR (neat) 3500 and 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.1—3.2 (7H, m, CH_2, CH, and OH), 2.69, 2.73 (each 3H, d, J=1.0 Hz, =CMe_2), 3.65, 3.68 (6H, each s, COOMe), 4.70 (1H, d, J=9.0 Hz, CHOH), 5.18 (1H, br d, J=9.0 Hz, CH=), and 5.66 (1H, br s, 2-H); ^{13}C NMR ($CDCl_3$) δ=18.30, 18.53 (each q, =CMe_2), 25.12, 25.35, 25.71, 25.88 (each t, 3- and 6-C), 40.09, 40.12 (each d, 4- and 5-C), 51.95 (q, COOMe), 71.89, 72.01 (each d, CHOH), 119.19, 119.60 (each t, =CH_2), 125.89, 126.24 (each d), 133.65, 135.19, 135.83, 138.48 (each s), 173.77, and 173.95 (each s, COOMe); MS *m/z* (rel intensity, %) 282 (M^+, 2), 264 (19), 204 (26), 145 (100), 91 (30), 83 (27), 79 (29), and 77 (23).

6c: Colorless liquid; IR (neat) 3500 and 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.70 (3H, d, J=6.0 Hz, =CHMe), 2.3—2.6 (5H, m, CH_2 and OH), 2.9—3.2 (2H, m, CH), 3.65 (6H, s, COOMe), 4.40 (1H, br d, J=5.5 Hz, CHOH), and 5.3—5.8 (3H, m, CH=); ^{13}C NMR ($CDCl_3$) δ=17.69 (q, =CHMe), 25.14, 25.48, 25.63 (each t, 3- and 6-C), 39.81, 40.06 (each d, 4- and 5-C), 51.80 (q, COOMe), 75.92 (d, CHOH), 119.83, 120.11, 127.28, 131.77, 131.96 (each d), 137.81 (s, 1-C), and 173.57 (s, COOMe); MS *m/z* (rel intensity, %) 268 (M^+, 1), 250 (22), 191 (20), 190 (44), 131 (100), and 69 (20).

Found: C, 62.71; H, 7.46%. Calcd for $C_{14}H_{20}O_5$: C, 62.67; H, 7.51%.

6d: Pale yellow liquid; IR (neat) 3400 and 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.1—3.2 (7H, m, CH_2, CH, and OH), 3.56, 3.60 (each 3H, s, COOMe), 4.02 (1H, br d, J=6.0 Hz, CHOH), 5.72 (1H, br s, 2-H), 6.14 (1H, dd, J=16.0 and 6.0 Hz, CH=), 6.54 (1H, dd, J=16.0 and 3.0 Hz, =CHPh), and 7.0—7.2 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=25.05, 25.58 (each t, 3- and 6-C), 39.72, 39.91 (each d, 4- and 5-C), 51.80 (q, COOMe), 75.87 (d, CHOH), 120.66, 126.41, 127.48, 128.45, 130.26, 130.50 (each d), 136.64, 137.32, 137.42 (each s), 173.48, and 173.57 (each s, COOMe); MS *m/z* (rel intensity, %) 330 (M^+, 8), 312 (26), 270 (35), 211 (19), 194 (25), 193 (100), 178 (21), 131 (21), 115 (65), 105 (22), 103 (26), 91 (58), 79 (25), and 77 (34).

Found: C, 68.88; H, 6.77%. Calcd for $C_{19}H_{22}O_5$: C, 69.07; H, 6.71%.

7a: Colorless liquid; IR (neat) 3450 and 1725 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.0—2.5 (5H, m, CH_2 and OH), 2.7—3.0 (2H, m, CH), 3.66 (6H, s, COOMe), 4.50 (1H, br d, J=5.5 Hz, CHOH), 5.15 (1H, dt, J=10.0, 1.5, and 1.5 Hz, =CH_2 (cis)), 5.26 (1H, dt, J=17.5, 1.5, and 1.5 Hz, =CH_2 (trans)), 5.74 (1H, br s, 2-H), and 5.83 (1H, ddd, J=17.5, 10.0,

and 5.5 Hz, CH=); ^{13}C NMR ($CDCl_3$) δ=26.76, 27.00, 27.63, 27.78 (each t, 3- and 6-C), 41.27, 41.42 (each d, 4- and 5-C), 51.90 (q, COOMe), 75.82 (d, CHOH), 115.54, 115.64 (each t, =CH_2), 120.27, 120.75 (each d), 136.98, 137.27 (each s, 1-C), 138.44, 138.64 (each d), and 175.09 (s, COOMe); MS *m/z* (rel intensity, %) 236 (M^+−18, 3), 204 (32), 177 (20), 176 (84), 117 (100), 91 (21), 79 (33), and 77 (19).

General Procedure for Oxidation of Diene Alcohols 6—8 with Activated Mangnese(IV) Oxide Leading to Dienones 9—11. Diene alcohols **6—8** and activated manganese(IV) oxide were stirred in dry dichloromethane (10—20 ml per 1 mmol of the alcohols) at room temperature under the reaction conditions listed in Table 2. The oxide was filtered off through Celite 545 and the filtrate was evaporated in vacuo. The residue was chromatographed over silica gel with hexane-ethyl acetate (1 : 1 to 2 : 1 v/v) to give **9—11**. The results are summarized in Table 2.

9a: Colorless liquid; IR (neat) 1730 and 1650 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.4—3.3 (6H, m, CH_2 and CH), 3.67, 3.69 (each 3H, s, COOMe), 5.72 (1H, dd, *J*=10.5 and 2.0 Hz, =CH_2 (cis)), 6.24 (1H, dd, *J*=17.1 and 2.0 Hz, =CH_2 (trans)), 6.89 (1H, m, 2-H), and 6.94 (1H, dd, *J*=17.1 and 10.5 Hz, CH=); ^{13}C NMR ($CDCl_3$) δ=24.42, 26.54 (each t, 3- and 6-C), 39.16, 39.45 (each d, 4- and 5-C), 52.02 (q, COOMe), 128.34 (t, =CH_2), 131.10 (d, COCH=), 137.32 (s, 1-C), 138.20 (d, 2-C), 172.92, 173.01 (each s, COOMe), and 190.16 (s, CO); MS *m/z* (rel intensity, %) 252 (M^+, 19), 221 (24), 220 (17), 192 (35), 133 (100), 105 (16), and 77 (29).

General Procedure for Acid-Catalyzed Electrocyclic Reaction of Dienones 9—11 Leading to 12—15. Use of *p*-toluenesulfonic acid as a catalyst: To a solution of *p*-toluenesulfonic acid in dry benzene or toluene (15—20 ml per 1 mmol of substrate) was added a dienone. The mixture was heated under reflux for the reaction time listed in Table 4. After cooled to room temperature, the resulting mixture was poured into ice water and extracted with diethyl ether. The ether extract was dried over anhydrous magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with hexane-ethyl acetate (4:1 to 1:2 v/v). Use of gallium(III) chloride: A dienone in dichloromethane was slowly added at −20 °C to a solution of freshly prepared gallium(III) chloride in dry dichloromethane (20—30 ml per 1 mmol of substrate). After the reaction was completed (checked on TLC), the mixture was poured into ice water. The same separation procedure as above gave the cyclized products **12—15**. All the results are listed in Table 4.

12a: Colorless liquid; IR (neat) 1730, 1690, and 1650 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.4—2.5 (2H, m), 2.5—2.6 (2H, m), 2.6—2.7 (3H, m) 2.94 (1H, dd, J=19.8 and 7.2 Hz, one of 4-H), 3.10 (1H, ddd, J=7.2, 6.3, and 3.6 Hz, 5-H), 3.21 (1H, dt, J=5.8, 5.8, and 3.6 Hz, 6-H), 3.65, and 3.68 (each 3H, s, COOMe); ^{13}C NMR ($CDCl_3$) δ=21.31, 28.77, 29.41 (each t, 3-, 4-, and 7-C), 34.52 (t, 2-C), 39.34, 39.98 (each d, 5- and 6-C), 51.84 (q, COOMe), 136.27 (s, 7a-C), 170.61 (s, 3a-C), 172.61,

172.72 (each s, COOMe1/2 and 207.37 (s, 1-C); MS *m/z* (rel intensity, %) 252 (M^+, 38), 221 (23), 193 (39), 192 (23), 133 (100), 105 (43), and 91 (36).

Found: C, 61.96; H, 6.54%. Calcd for $C_{13}H_{16}O_5$: C, 61.89; H, 6.39%.

12b: Colorless liquid; IR (neat) 1725, 1680, and 1650 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.17, 1.20 (each 3H, s, 3-Me), 2.30 (2H, br s, 2-H), 2.43 (1H, ddt, J=18.2, 6.0, 2.0, and 2.0 Hz, one of 4-H), 2.57 (1H, br dd, J=19.7 and 6.5 Hz, one of 7-H), 2.63 (1H, ddd, J=18.2, 6.0, and 2.0 Hz, the other of 4-H), 2.86 (1H, ddd, J=19.7, 6.5, and 2.0 Hz, the other of 7-H), 3.10 (1H, dt, J=6.5, 6.5, and 3.6 Hz, 6-H), 3.15 (1H, dt, J=6.0, 6.0, and 3.6 Hz, 5-H), 3.66, and 3.68 (each 3H, s, COOMe); ^{13}C NMR ($CDCl_3$) δ=21.31, 23.84 (each t, 4- and 7-C), 26.60 (q, 3-Me), 39.45, 40.39 (each d, 5- and 6-C), 40.57 (s, 3-C), 51.37 (t, 2-C), 51.96, 52.08 (each q, COOMe), 134.33 (s, 7a-C), 172.72, 172.84 (each s, COOMe), 177.54 (s, 3a-C), and 205.96 (s, 1-C); MS *m/z* (rel intensity, %) 280 (M^+, 30), 240 (21), 221 (40), 209 (22), 161 (58), 121 (100), 119 (30), 105 (19), and 42 (71).

Found: C, 64.13; H, 7.28%. Calcd for $C_{15}H_{20}O_5$: C, 64.27; H, 7.19%.

12c: Colorless liquid; IR (neat) 1730, 1700, and 1650 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.15 (3H, d, J=7.1 Hz, 3-Me), 1.99 (1H, dd, J=18.5 and 2.9 Hz, one of 2-H), 2.43 (1H, ddd, J=18.0, 6.0, and 2.2 Hz, one of 4-H), 2.50 (1H, ddd, J=19.0, 6.8, and 2.0 Hz, one of 7-H), 2.64 (1H, dd J=18.0 and 6.0 Hz, the other of 4-H), 2.65 (1H, dd, J=18.5 and 6.8 Hz, the other of 2-H), 2.76 (1H, m, 3-H), 2.78 (1H, dd, J=19.0, and 6.8 Hz, the other of 7-H), 3.15 (1H, dt, J=6.0, 6.0, and 3.6 Hz, 5-H), 3.20 (1H, dt, J=6.8, 6.8, and 3.6 Hz, 6-H), 3.63, and 3.66 (each 3H, s, COOMe); ^{13}C NMR ($CDCl_3$) δ=18.67 (q, 3-Me), 21.49, 26.71 (each t, 4- and 7-C), 35.93 (d, 3-C), 39.51, 40.27 (each d, 5- and 6-C), 43.65 (t, 2-C), 51.96, 52.08 (each q, COOMe), 135.74 (s, 7a-C), 172.77, 174.42, 174.66 (each s, COOMe and 3a-C), and 206.60 (s, 1-C); MS *m/z* (rel intensity, %) 266 (M^+, 8), 207 (21), 206 (21), 148 (100), 119 (20), 105 (66), 91 (42), and 77 (31).

Found: C, 62.92; H, 6.94%. Calcd for $C_{14}H_{18}O_5$: C, 63.15; H, 6.82%.

12c' could not be separated from the mixture with **12c**. Its formation was confirmed by the appearance of additional peaks in ^{13}C NMR ($CDCl_3$) δ=21.31 (t) and 135.86 (s, 7a-C).

12d: Colorless liquid; IR (neat) 1730, 1700, 1650, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.35 (1H, dd, J=19.0 and 5.9 Hz, one of 4-H), 2.42 (1H, dd, J=19.0 and 2.2 Hz, one of 2-H), 2.58 (1H, ddd, J=17.8, 6.5, and 2.1 Hz, one of 7-H), 2.70 (1H, dd, J=19.0 and 5.9 Hz, the other of 4-H), 2.77 (1H, ddd, J=17.8, 6.5, and 2.1 Hz, the other of 7-H), 2.95 (1H, dd, J=19.0 and 6.9 Hz, the other of 2-H), 3.01 (1H, dt, J=6.5, 6.5, and 3.6 Hz, 6-H), 3.19 (1H, dt, J=5.9, 5.9, and 3.6 Hz, 5-H), 3.68, 3.69 (each 3H, s, COOMe), 3.85 (1H, dd, J=6.9 and 2.2 Hz, 3-H), and 7.1—7.4 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=21.55, 26.95 (each t, 4- and 7-C), 39.45, 40.28 (each d, 5- and 6-C), 45.03 (t, 2-C), 47.50 (d, 3-C), 52.08 (q, COOMe), 127.17, 129.05 (each d), 136.91, 141.14 (each s), 172.43, 172.67, 172.84 (each s, COOMe and 3a-C), and 206.66 (s, 1-C).

Found: C, 69.53; H, 6.35%. Calcd for $C_{19}H_{20}O_5$: C, 69.50; H, 6.14%.

12d': Colorless prisms (diethyl ether-hexane); mp 86—87 °C; IR (KBr) 1730, 1700, 1650, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.36 (1H, dd, J=18.9 and 2.2 Hz, one of 2-H), 2.45 (1H, dd, J=19.7 and 6.2 Hz, one of 4-H), 2.56 (1H, ddd, J=18.0, 5.9, and 2.0 Hz, one of 7-H), 2.60 (1H, dd, J=19.7 and 6.8 Hz, the other of 4-H), 2.84 (1H, ddt, J=18.0, 5.9, 2.0, and 2.0 Hz, the other of 7-H), 2.95 (1H, dd, J=18.9 and 6.9 Hz, the other of 2-H), 3.11 (1H, ddd, J=6.8, 6.2, and 3.6 Hz, 5-H), 3.20 (1H, dt, J=5.9, 5.9, and 3.6 Hz, 6-H), 3.63, 3.68 (each 3H, s, COOMe), 3.87 (1H, dd, J=6.9 and 2.2 Hz, 3-H), and 7.0—7.3 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=21.64, 27.24 (each t, 4- and 7-C), 39.57, 40.37 (each d, 5- and 6-C), 45.37 (t, 2-C), 47.52 (d, 3-C), 51.95 (q, COOMe), 127.23, 128.89 (each d), 137.62, 141.02 (each s), 171.87, 172.51, 172.75 (each s, COOMe and 3a-C), and 207.00 (s, 1-C); MS *m/z* (rel intensity, %) 328 (M^+, 86), 297 (22), 269 (49), 268 (30), 209 (100), 167 (49), 165 (28), 103 (22), 77 (22), and 59 (95).

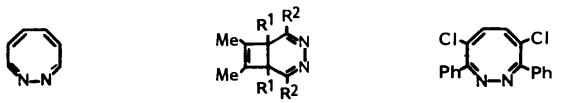
(Received June 28, 1986)

Nucleophilic substitution of 4,7-dichloro-3,8-diphenyl-1,2-diazocine with arenethiols gave stable 4-arylthio-7-chloro- and/or 4,7-bis(arylthio)-1,2-diazocines. Unsymmetrical 4,7-bis(arylthio)- and 4-acetoxy-7-phenylthio-1,2-diazocines were also prepared from 4-chloro-7-phenylthio-1,2-diazocine. Thermolysis of all the diazocines afforded only arylthio-substituted pyridines with extrusion of benzonitrile.

1,2-Diazacycloocta-2,4,6,8-tetraenes (1,2-diazocines) free of benzo groups were not known until Trost et al.[1] succeeded in an elegant synthesis of the parent 1,2-diazocine (**1**), which decomposed slowly in solution at room temperature and rapidly neat. However, experiments that might have yielded substituted monocyclic 1,2-diazocines, in which compound **2** had been pyrolyzed, failed to give stable eight-membered rings, for although these probably formed, under the conditions of their preparation they seemingly valence tautomerized and extruded nitrogen, giving substituted benzene instead.[2]



1 2 3

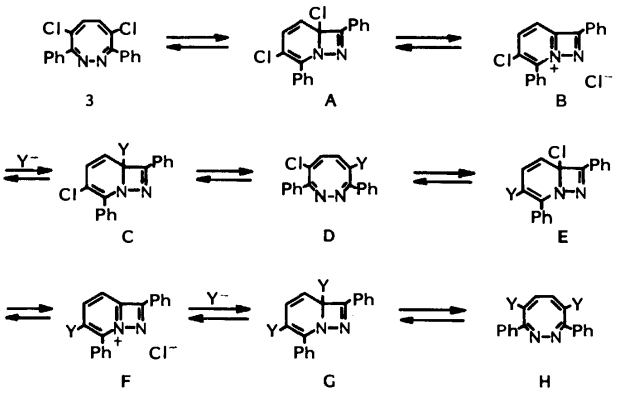
We have recently reported[3] a convenient method for the synthesis of 4,7-dichloro-3,8-diphenyl-1,2-diazocine (**3**), which is the first example of stable substituted monocyclic 1,2-diazocine, via a chlorination-dehydrochlorination sequence starting from readily available 3,8-diphenyl-1,2-diazacycloocta-2,8-diene,[4] and the conversion of **3** into stable mono(acyloxy)- and bis(acyloxy)-1,2-diazocines by nucleophilic substitutions of chlorine atoms on **3** with carboxylate anions. In addition, it has been found that in contrast to the parent 1,2-diazocine (**1**), which thermally decomposed to benzene and pyridine with comparable rates,[1] these stable 1,2-diazocines had been pyrolyzed to give only pyridines with the extrusion of benzonitrile: This provided a new route for the synthesis of chloro- and acyloxy-substituted pyridines which are difficult to prepare by other methods.

Nucleophilic substitutions of chlorine atoms on the 1,2-diazocine (**3**) with a carboxylate anion (Y=OCOR) can be understood by the processes as illustrated in Scheme 1. The 1,2-diazocine (**3**) is thermally isomerized into its valence isomer (**A**), which gives a mono(acyloxy)-1,2-diazocine (**D**) through the process **B**→**C**, and then the 1,2-diazocine (**D**) is similarly converted into a bis(acyloxy)-1,2-diazocine (**H**) via the processes **E**→**F**→**G**.[3]

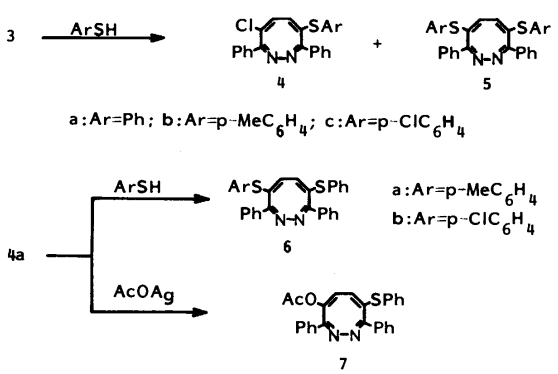
Thus, it is indicated that a route to new 4,7-disubstituted 1,2-diazocines is opened by the reaction of 4,7-dichloro-1,2-diazocine (**3**) with various nucleophiles. In this paper we describe the synthesis of arylthio-substituted 1,2-diazocines, and their thermolysis leading to pyridines.

Results and Discussion

Synthesis of Arylthio-Substituted 1,2-Diazocines. Although the reaction of 4,7-dichloro-1,2-diazocine (**3**) with sodium benzenethiolate in benzene under reflux gave the expected 4-chloro-7-phenylthio- (**4a**) and 4,7-



Scheme 1.

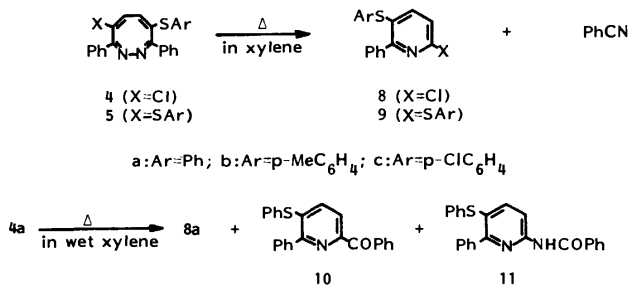


Scheme 2.

bis(phenylthio)-1,2-diazocine (**5a**), the reaction using benzenethiol in place of the thiolate brought about more satisfactory results. When heated with four equivalents of benzenethiol under similar conditions, **3** was converted into a mixture of **4a** and **5a** in good yield, whose relative yields depended upon the reaction time. Similarly, the 1,2-diazocine (**3**) reacted with *p*-methyl- and *p*-chlorobenzenethiol to give the corresponding mono(arylthio)- (**4b** and **4c**) and bis-(arylthio)-1,2-diazocines (**5b** and **5c**), respectively.[5] The results are given in Table 1.

In the reaction of mono(phenylthio)-1,2-diazocine (**4a**) with *p*-substituted benzenethiols under similar conditions, the corresponding unsymmetrical bis-(arylthio)-1,2-diazocines (**6a** and **6b**) were obtained in good yields, respectively. A longer reaction time was required for the preparation of **6a** than for **6b** (Table 1). Also, the 1,2-diazocine (**4a**) reacted with silver acetate in refluxing benzene to give 4-acetoxy-7-phenylthio-1,2-diazocine (**7**) (Scheme 2). Structural elucidation of all the 1,2-diazocines (**4**—**7**) was accomplished on the basis of spectral data.

Thermolysis of Arylthio-Substituted 1,2-Diazocines. It is evident that the mono(arylthio)- (**4**) and bis(arylthio)-1,2-diazocines (**5**) are thermally isomerized into their valence isomers, diazabicyclooctatrienes like **E** and **G** (Y=ArS), respectively (Scheme 1). Thus, in analogy with acyloxy-substituted 1,2-diazocines,[3] thermolysis of the 1,2-diazocines (**4** and **5**) can be expected to afford mono(arylthio)- and bis(arylthio)-substituted pyridines with the extrusion of benzonitrile, respectively.



Scheme 3.

In fact, the 1,2-diazocines (**4** and **5**) decomposed in dry xylene under reflux to give the corresponding 3-arylthio-6-chloro-2-phenylpyridine (**8**) and 3,6-bis-(arylthio)-2-phenylpyridines (**9**) in good yields respectively, together with benzonitrile (Table 2). On the other hand, when heated in wet xylene under reflux for 6 h, the 1,2-diazocine (**4a**) afforded the pyridine (**8a**), 6-benzoyl-2-phenyl-3-phenylthiopyridine (**10**), and 6-benzoylamino-2-phenyl-3-phenylthiopyridine (**11**) in 12, 63, and 7% yields, respectively (Scheme 3): This is closely similar to the formation of 3,6-dichloro-2-phenyl-, 6-benzoyl-3-chloro-2-phenyl-, and 6-benzoyl-amino-3-chloro-2-phenylpyridine in the thermolysis of 4,7-dichloro-1,2-diazocine (**3**) in wet toluene.[3]

The structures of pyridines (**8**—**11**) were confirmed on the basis of spectral data as well as on the chemical conversions.

The mono(phenylthio)pyridine (**8a**) was allowed to react with sodium methoxide in methanol under reflux to give 6-methoxy-2-phenyl-3-phenylthiopyridine (**12**), which on heating with hydrobromic acid was converted into a mixture of 6-phenyl-2-pyridone (**13**)[6] and diphenyl disulfide. The pyridone (**13**) was

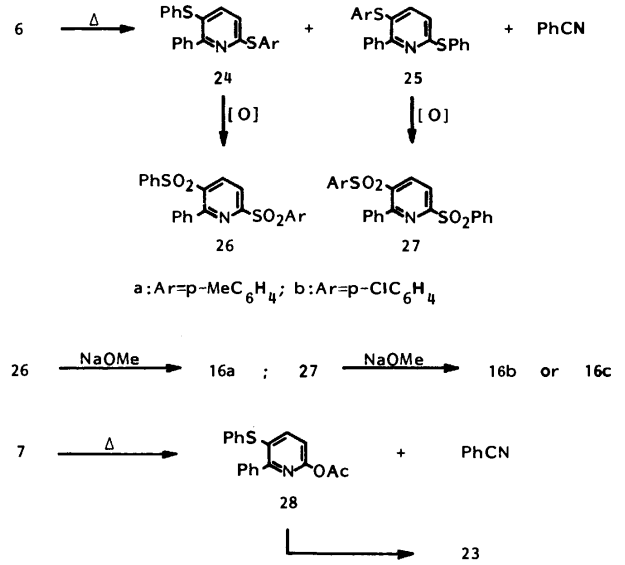
identical with an authentic sample prepared from hydrolysis of 2-acetoxy-6-phenylpyridine.[7]

Oxidations of the mono(arylthio)- (**8**) and bis(arylthio)pyridines (**9**) with potassium permanganate in acetic acid or 35% hydrogen peroxide gave the corresponding mono(arylsulfonyl) (**14**) and bis(arylsulfonyl)pyridines (**15**) in good yields, respectively. On treatment with sodium methoxide in methanol under reflux, both the pyridines (**14** and **15**) were converted into the same 3-arylsulfonyl-6-methoxy-2-phenylpyridines (**16**). When heated with hydrobromic acid, 6-methoxy-2-phenyl-3-phenylsulfonylpyridine (**16a**) was converted into 6-phenyl-5-phenylsulfonyl-2-pyridone (**17**) (Scheme 4).

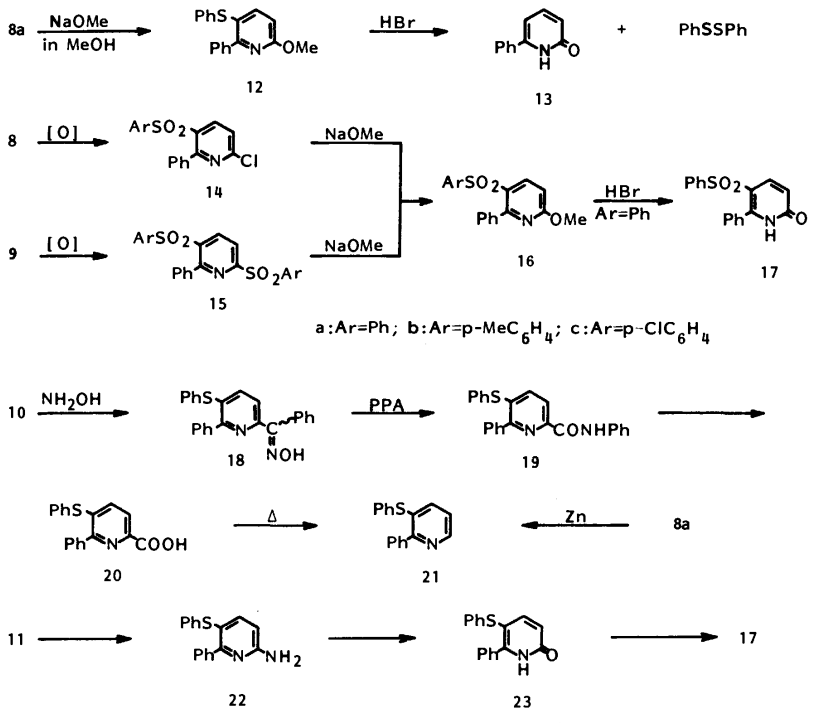
On the other hand, the reaction of the benzoylpyridine (**10**) with hydroxylamine afforded a mixture of stereoisomeric oximes (**18**), which on the Beckmann rearrangement using polyphosphoric acid gave 2-phenyl-6-phenylcarbamoyl-3-phenylthiopyridine (**19**) in good yield. Hydrolysis of the pyridine (**19**) gave 6-phenyl-5-phenylthio-2-pyridinecarboxylic acid (**20**), which on heating at 230—250 °C was converted into 2-phenyl-3-phenylthiopyridine (**21**). The pyridine (**21**) was also obtained by the reduction of the pyridine (**8a**) with zinc dust in acetic acid.

Hydrolysis of the (benzoylamino)pyridine (**11**) with an ethanolic alkali solution gave 6-amino-2-phenyl-3-phenylthiopyridine (**22**), which was then converted, by diazotization, into 6-phenyl-5-phenylthio-2-pyridone (**23**). Oxidation of the pyridone (**23**) gave the phenylsulfonylpyridone (**17**).

Next, thermolysis of unsymmetrical bis(arylthio)-1,2-diazocines (**6**) was investigated. In dry xylene under reflux for 5 h, the 4-(*p*-methylphenylthio)-7-phenylthio-1,2-diazocine (**6a**) gave benzonitrile and oil, which consisted of a 1:1 mixture of 6-(*p*-methylphenylthio)-2-phenyl-3-phenylthio- (**24a**) and 3-(*p*-methylphenylthio)-2-phenyl-6-phenylthiopyridine (**25a**), in 78 and 68% yields, respectively. Although it was very difficult to isolate pure **24a** and **25a** from the mixture, the formation of **24a** and **25a** was confirmed by the conversion, via the corresponding bis(arylsulfonyl)pyridines (**26a** and **27a**),



Scheme 5.



Scheme 4.

into the methoxypyridines (**17a** and **17b**), respectively.

Similarly, thermolysis of the 4-(*p*-chlorophenylthio)-7-phenylthio-1,2-diazocine (**6b**) afforded benzonitrile and a mixture of 6-(*p*-chlorophenylthio)-2-phenyl-3-phenylthio- (**24b**) and 3-(*p*-chlorophenylthio)-2-phenyl-6-phenylthiopyridine (**25b**) in 76 and 84% yields, respectively. The pyridines (**24b** and **25b**) were again converted into the methoxypyridines (**17a** and **17c**) via the corresponding bis(arylsulfonyl)pyridines (**26b** and **27b**), respectively (Scheme 5).

Thermolysis of the 4-acetoxy-7-phenylthio-1,2-diazocine (**7**) was performed under similar conditions: Benzonitrile and 6-acetoxy-2-phenyl-3-phenylthiopyridine (**28**) were obtained in 69 and 87% yields, respectively. The acetoxypyridine (**28**) was readily converted into the pyridone (**23**) on an ethanolic alkali hydrolysis.

Experimental

IR spectra were obtained on a JASCO A-302 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-24 or a JEOL FX-100 instrument, and ^{13}C NMR spectra were measured on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical shifts are expressed in parts per million downfield from tetramethylsilane. Mass spectra were taken with a Hitachi RMU-6L spectrometer at 70 eV ionization energy. Elemental analyses were performed on a Yanaco MT 2 CHN corder instrument.

Reaction of Dichloro-1,2-diazocine (3) with Sodium Benzenethiolate. A solution of benzenethiol (1.10 g, 10 mmol) in methanol (10 ml) was added to a solution of sodium methoxide in methanol, which was prepared from metallic sodium (0.3 g) and methanol (10 ml), and then the resultant mixture was concentrated in vacuo to leave sodium benzenethiolate as white powder. A solution of 1.08 g (3.3 mmol) of the dichloro-1,2-diazocine (**3**) in benzene (50 ml) was refluxed with the thiolate for 5 h. The reaction mixture was washed with water, and the benzene layer was concentrated in vacuo, and the residue was chromatographed on silica gel using benzene–hexane (3:7) as an eluent to give 0.17 g (15%) of unreacted **3**, 0.42 g (38%) of the mono(phenylthio)-1,2-diazocine (**4a**) and 0.23 g (17%) of the bis(phenylthio)-1,2-diazocine (**5a**).

4a: Mp 143—144 °C (decomp); colorless needles; ^{1}H NMR ($CDCl_3$) δ=6.17, 6.49 (each 1H, d, =CH, J=4.8 Hz), 7.10—7.50 (13H, m), 7.51—7.80 (2H, m); MS m/z 402, 400 (M^+). Found: C, 71.98; H, 4.26; N, 7.11%. Calcd for $C_{24}H_{17}N_2SCl$: C, 71.90; H, 4.27; N, 6.99%.

5a: Mp 156—157 °C; colorless needles; ^{1}H NMR ($CDCl_3$) δ=6.27 (2H, s, =CH), 7.00—7.50 (16H, m), 7.51—7.70 (4H, m); ^{13}C NMR ($CDCl_3$) δ=153.47 (s), 137.56 (s), 134.80 (s), 132.80 (s), 131.80, 129.99, 129.16, 128.34, 128.22 (each d); MS m/z 474 (M^+). Found: C, 75.80; H, 4.62; N, 6.08%. Calcd for $C_{30}H_{22}N_2S_2$: C, 75.92; H, 4.67; N, 5.90%.

Reaction of 3 with Arenethiols. i) With Benzenethiol. After a solution of **3** (0.65 g, 2 mmol) and benzenethiol (0.88 g, 8 mmol) in benzene (50 ml) was refluxed for 6 h, the reaction mixture was washed with a 10% aqueous sodium hydroxide solution, and then water. The benzene layer was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 20 mg (3%) of unreacted **3**, 0.52 g (65%) of **4a** and 0.30 g (32%) of **5a**. The result of the reaction for 18 h is shown in Table 1.

ii) With *p*-Methylbenzenethiol. A solution of **3** (0.65 g, 2 mmol) in benzene (30 ml) refluxed with *p*-methylbenzenethiol (1.0 g, 8 mmol) for 4 h. Similar work-up of the reaction mixture gave 0.18 g (28%) of unreacted **3**, 0.49 g (59%) of the mono(*p*-methylphenylthio)-1,2-diazocine (**4b**), and 0.12 g (12%) of the bis(*p*-methylphenylthio)-1,2-diazocine (**5b**). The result of the reaction for 18 h is given in Table 1.

4b: Mp 131—132 °C; colorless prisms; ^{1}H NMR ($CDCl_3$) δ=2.28 (3H, s), 6.10, 6.50 (each 1H, d, =CH, J=4.2 Hz), 6.80—7.80 (14H, m); MS m/z, 416, 414 (M^+). Found: C, 72.48; H, 4.46; N, 6.70%. Calcd for $C_{25}H_{19}N_2SCl$: C, 72.36; H, 4.62; N, 6.75%.

5b: Mp 172—173 °C; colorless needles; ^{1}H NMR ($CDCl_3$) δ=2.26 (6H, s), 6.20 (2H, s, =CH), 6.80—7.80 (18H, m); MS m/z 502 (M^+). Found: C, 76.58; H, 5.26; N, 5.34%. Calcd for $C_{32}H_{26}N_2S_2$: C, 76.45; H, 5.21; N, 5.57%.

iii) With *p*-Chlorobenzenethiol. A solution of **3** (1.2 g, 3.68 mmol) in benzene (30 ml) was refluxed with *p*-chlorobenzenethiol (1.59 g, 11 mmol) for 7 h. Similar work-up gave 0.68 g (43%) of the mono(*p*-chlorophenylthio)-1,2-diazocine (**4c**) and 0.67 g (34%) of the bis(*p*-chlorophenylthio)-1,2-diazocine (**5c**).

4c: Mp 99—101 °C; colorless needles; ^{1}H NMR ($CDCl_3$) δ=6.18, 6.42 (each 1H, d, =CH, J=4.2 Hz), 7.03 (4H, s), 7.16—7.86 (10H, m); MS m/z 438, 436, 434 (M^+). Found: C, 66.39; H, 3.78; N, 6.56%. Calcd for $C_{24}H_{16}N_2SCl_2$: C, 66.21; H, 3.70; N, 6.43%.

5c: Mp 196—197 °C (decomp); yellow needles; ^{1}H NMR ($CDCl_3$) δ=6.32 (2H, s, =CH), 7.15 (8H, s), 7.20—7.70 (10H, m); MS m/z 546, 544, 542 (M^+). Found: C, 66.57; H, 3.46; N, 4.92%. Calcd for $C_{30}H_{20}N_2S_2Cl_2$: C, 66.29; H, 3.71; N, 5.15%.

4-(*p*-Methylphenylthio)-7-phenylthio-1,2-diazocine (6a). A solution of 1.0 g (2.5 mmol) of the mono(phenylthio)-1,2-diazocine (**4a**) in benzene (50 ml) was refluxed with *p*-methylbenzenethiol (1.0 g, 8.1 mmol) for 24 h. Similar work-up gave 0.95 g (78%) of the diazocine (**6a**): Mp 132—133 °C; colorless needles; ^{1}H NMR ($CDCl_3$) δ=2.22 (3H, s), 6.15, 6.24 (each 1H, d, =CH, J=4.2 Hz), 6.75—7.90 (19H, m); MS m/z 488 (M^+). Found: C, 76.02; H, 4.90; N, 5.82%. Calcd for $C_{31}H_{24}N_2S_2$: C, 76.20; H, 4.95; N, 5.73%.

The result of the reaction for 7 h is given in Table 1.

4-(*p*-Chlorophenylthio)-7-phenylthio-1,2-diazocine (6b). A solution of 0.64 g (1.6 mmol) of the diazocine (**4a**) in benzene (30 ml) was refluxed with *p*-chlorobenzenethiol (0.35 g, 2.4 mmol) for 7 h. Similar work-up afforded 50 mg (8%) of unreacted **4a** and 0.61 g (75%) of the diazocine (**6b**): Mp 129—130 °C; yellow needles; ^{1}H NMR ($CDCl_3$) δ=6.30, 6.37 (each 1H, d, =CH, J=4.2 Hz), 7.03—7.73 (19H, m); MS m/z 510, 508 (M^+). Found: C, 70.68; H, 3.94; N, 5.61%. Calcd for $C_{30}H_{21}N_2S_2Cl$: C, 70.78; H, 4.16; N, 5.50%.

4-Acetoxy-7-phenylthio-1,2-diazocine (7). A solution of 1.0 g (2.5 mmol) of the diazocine (**4a**) in benzene (50 ml) was refluxed with silver acetate (2.0 g, 12 mmol) for 20 h. The reaction mixture was filtered, and the precipitate was washed with benzene (50ml). The combined benzene solution was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 0.2 g (20%) of

unreacted **4a** and 0.65 g (61%) of the diazocine (**7**): Mp 161—163 °C (decomp); colorless needles; ^{1}H NMR ($CDCl_3$) δ=1.95 (3H, s), 6.25 (2H, s, =CH), 7.20—7.90 (15H, m); MS *m/z* 425 (M^+). Found: C, 73.31; H, 4.51; N, 6.74%. Calcd for $C_{26}H_{20}N_2O_2S$: C, 73.56; H, 4.75; N, 6.60%.

Thermolysis of 4-Chloro-7-phenylthio-1,2-diazocine (4a). i) In Dry Xylene. A solution of **4a** (1.60 g, 4 mmol) in dry xylene (20 ml) was refluxed for 5 h. The reaction mixture was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 0.38 g (93%) of benzonitrile and 0.89 g (75%) of 6-chloro-2-phenyl-3-phenylthiopyridine (**8a**).

8a: Oil; ^{1}H NMR ($CDCl_3$) δ=7.06, 7.53 (each 1H, d, PyH, *J*=8.0 Hz), 7.20—7.90 (10H, m); MS *m/z* 299, 297 (M^+). Found: C, 68.85; H, 4.05; N, 4.91%. Calcd for $C_{17}H_{12}NSCl$: C, 68.56; H, 4.06; N, 4.70%.

Thermolysis of 4-chloro-7-(*p*-methylphenylthio)- (**4b**) and 4-chloro-7-(*p*-chlorophenylthio)-1,2-diazocine (**4c**) under similar conditions afforded 6-chloro-3-(*p*-methylphenylthio)-2-phenyl- (**8b**) and 6-chloro-3-(*p*-chlorophenylthio)-2-phenylpyridine (**8c**) together with benzonitrile, respectively. The results are shown in Table 2.

8b: Oil; ^{1}H NMR ($CDCl_3$) δ=2.31 (3H, s), 6.98 (1H, d, PyH, *J*=8.4 Hz), 7.02—7.82 (10H, m, ArH and PyH); MS *m/z* 311 (M^+). Found: C, 69.54; H, 4.34; N, 4.65%. Calcd for $C_{18}H_{14}NSCl$: C, 69.33; H, 4.53; N, 4.49%.

8c: Oil; ^{1}H NMR ($CDCl_3$) δ=7.08 (1H, d, PyH, *J*=8.4 Hz), 7.10—7.80 (10H, m, ArH and PyH); MS *m/z* 335, 333, 331 (M^+). Found: C, 61.20; H, 3.61; N, 4.08%. Calcd for $C_{17}H_{11}NSCl_2$: C, 61.45; H, 3.34; N, 4.22%.

ii) In Wet Xylene. A solution of **4a** (1.60 g, 4 mmol) in xylene (20 ml) containing 3 drops of water was refluxed for 6 h. Similar work-up and chromatography (silica gel, benzene) of the pyrolysate gave 0.14 g (12%) of the pyridine (**8a**), 0.92 g (63%) of 6-benzoyl-2-phenyl-3-phenylthiopyridine (**10**) and 0.11 g (7%) of 6-benzoylamino-2-phenyl-3-phenylthiopyridine (**11**).

10: Mp 120—121 °C; colorless prisms; IR (KBr) 1646 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=7.21 (5H, s), 7.65, 8.23 (each 1H, d, PyH, *J*=8.2 Hz), 7.30—7.65 (8H, m), 7.80—8.02 (2H, m); MS *m/z* 367 (M^+). Found: C, 78.32; H, 4.59; N, 3.50%. Calcd for $C_{24}H_{17}NOS$: C, 78.44; H, 4.66; N, 3.81%.

11: Mp 120—121 °C; yellow prisms; IR (KBr) 3300, 3200, 1655 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=7.04—8.04 (16H, m, ArH and PyH), 8.29 (1H, d, PyH, *J*=8.4 Hz), 8.74 (1H, broad, NH); MS *m/z* 382 (M^+). Found: C, 75.14; H, 4.91; N, 7.10%. Calcd for $C_{24}H_{18}N_2OS$: C, 75.36; H, 4.74; N, 7.33%.

Thermolysis of 4,7-Bis(phenylthio)-1,2-diazocine (5a). A solution of 0.95 g (2 mmol) of the diazocine (**5a**) in dry xylene (20 ml) was refluxed for 6 h. Similar work-up and chromatography (silica gel, benzene) of the pyrolysate gave 0.19 g (93%) of benzonitrile and 0.63 g (85%) of 3,6-bis(phenylthio)-2-phenylpyridine (**9a**).

9a: Mp 77—78 °C; colorless prisms; ^{1}H NMR ($CDCl_3$) δ=6.61 (1H, d, PyH, *J*=7.2 Hz), 7.10—7.80 (16H, m, ArH and PyH); MS *m/z* 371 (M^+). Found: C, 74.40; H, 4.31; N, 3.79%. Calcd for $C_{23}H_{17}NS_2$: C, 74.35; H, 4.61; N, 3.77%.

Similar thermolysis of 4,7-bis(*p*-methylphenylthio)- (**5b**) and 4,7-bis(*p*-chlorophenylthio)-1,2-diazocine (**5c**) afforded 3,6-bis(*p*-methylphenylthio)-2-phenyl- (**9b**) and 3,6-bis(*p*-chlorophenylthio)-2-phenylpyridine (**9c**), together with benzonitrile, respectively. The results are given in Table 2.

9b: Mp 102—103 °C; colorless prisms; ^{1}H NMR ($CDCl_3$) δ=2.29, 2.45 (each 3H, s), 6.57 (1H, d, PyH, *J*=8.4 Hz), 7.02—8.03 (14H, m, ArH and PyH); MS *m/z* 399 (M^+). Found: C, 74.97; H, 5.51; N, 3.53%. Calcd for $C_{25}H_{21}NS_2$: C, 75.14; H, 5.30; N, 3.51%.

9c: Oil; ^{1}H NMR ($CDCl_3$) δ=6.67 (1H, d, PyH, *J*=8.4 Hz), 7.10—7.70 (14H, m, ArH and PyH); MS *m/z* 443, 441, 439 (M^+). Found: C, 62.81; H, 3.17; N, 3.20%. Calcd for $C_{23}H_{15}NS_2Cl_2$: C, 62.72; H, 3.43; N, 3.18%.

6-Methoxy-2-phenyl-3-phenylthiopyridine (12). In a solution of sodium methoxide in methanol, which was prepared from metallic sodium (1.0 g) in methanol (30 ml), 0.5 g (1.7 mmol) of the pyridine (**8a**) was heated under reflux for 5 h. The reaction mixture was poured into water (100 ml), and the mixture was extracted with benzene (50 ml×2). The extract was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 0.41 g (82%) of the methoxypyridine (**12**): Mp 68—69 °C; colorless prisms; ^{1}H NMR ($CDCl_3$) δ=3.85 (3H, s), 6.54, 7.48 (each 1H, d, PyH, *J*=8.4 Hz), 7.13—7.38 (3H, m), 7.02 (5H, s), 7.53—7.73 (2H, m); MS *m/z* 293 (M^+). Found: C, 73.58; H, 5.02; N, 4.60%. Calcd for $C_{18}H_{15}NOS$: C, 73.69; H, 5.15; N, 4.77%.

Conversion of the Methoxypyridine (12) into 6-Phenyl-2-pyridone (13). A suspension of 0.15 g (0.5 mmol) of the pyridine (**12**) in 48% hydrobromic acid (1 ml) was heated under reflux for 4 h. To the reaction mixture was added water (10 ml), and the mixture was extracted with benzene. The benzene extract was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 30 mg (27%) of diphenyl disulfide which was identical with an authentic sample. An aqueous acidic layer was alkalized with an aqueous sodium carbonate solution to precipitate 40 mg (46%) of the pyridine (**13**), mp 196—197 °C (lit,[6] mp 197 °C), which was identical with an authentic sample prepared from hydrolysis of 2-acetoxy-6-phenylpyridine.[7]

6-Chloro-2-phenyl-3-phenylsulfonylpyridine (14a). To a stirred solution of 0.3 g (1 mmol) of the phenylthiopyridine (**8a**) in acetic acid (30 ml), added slowly a 6.6% aqueous potassium permanganate solution at room temperature; when about 5 ml of the permanganate solution was added, reddish violet color of the reaction mixture did not disappear. A 10% aqueous sodium hydrogensulfite solution (10 ml) was added to the colored solution, and then the resultant clear solution was poured into water (50 ml) to give a precipitate. Filtration and recrystallization of the precipitate from petroleum ether to give 0.27 g (82%) of the phenylsulfonylpyridine (**14a**): Mp 131—133 °C; colorless needles; IR (KBr) 1320 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=7.05—7.45 (10H, m), 7.47, 8.65 (each 1H, d, PyH, *J*=8.4 Hz); ^{13}C NMR ($CDCl_3$) δ=159.75, 154.40, 139.67, 139.32, 136.44, 133.81, 129.57, 129.22, 128.52, 127.87, 127.64, 123.17; MS *m/z* 331, 329 (M^+). Found: C, 61.75; H, 3.97; N, 4.43%. Cacld for $C_{17}H_{12}NO_2SCl$: C, 61.91; H, 3.67; N, 4.25%.

Similar oxidations of *p*-methylphenylthio- (**8b**) and *p*-chlorophenylthiopyridine (**8c**) gave the corresponding arylsulfonylpyridines **14b** and **14c** in 61 and 76% yields, respectively.

14b: Mp 143—145 °C; colorless needles; IR (KBr) 1320 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.33 (3H, s), 6.95—7.45 (9H, m), 7.51, 8.62 (each 1H, d, PyH, *J*=8.4 Hz); MS *m/z* 345, 343 (M^+). Found: C, 62.66; H, 3.91; N, 3.78%. Calcd for

$C_{18}H_{14}NO_2SCl$: C, 62.88; H, 4.10; N, 4.07%.

14c: Mp 149—150 °C; colorless needles; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.13—7.43 (9H, m), 7.55, 8.65 (each 1H, d, PyH, J=8.4 Hz); MS m/z 367, 365, 363 (M^+). Found: C, 56.27; H, 2.99; N, 3.61%. Calcd for $C_{17}H_{11}NO_2SCl_2$: C, 56.06; H, 3.04; N, 3.85%.

3,6-Bis(phenylsulfonyl)-2-phenylpyridine (15a). i) A solution of 0.50 g (1.4 mmol) of the bis(phenylthio)pyridine (**9a**) in acetic acid (30 ml) was refluxed with 35% hydrogen peroxide (5 ml) for 3 h. After it had been cooled to room temperature, water (100 ml) was added to it. The mixture was extracted with benzene (50 ml×2), and the extract was concentrated in vacuo to leave a residue which was recrystallized from petroleum ether to give 0.48 g (81%) of the pyridine (**15a**): Mp 187—189 °C; yellow needles; IR (KBr) 1320 cm^{-1}: ^1H NMR ($CDCl_3$) δ=7.20—7.72 (13H, m), 7.96—8.01 (2H, m), 8.32, 8.88 (each 1H, d, PyH, J=8.4 Hz); ^{13}C NMR ($CDCl_3$) δ=160.98, 159.75, 140.20, 139.55, 138.56, 136.33, 134.22, 133.51, 129.87, 129.39, 129.10, 128.63, 128.05, 127.52, 120.30; MS m/z 371 ($M^+ - SO_2$). Found: C, 63.51; H, 4.17; N, 3.28%. Cacld for $C_{23}H_{17}NO_4S_2$: C, 63.43; H, 3.93; N, 3.22%.

ii) A 6.6% aqueous potassium permanganate solution was slowly added, at room temperature, to a stirred solution of 0.37 g (1 mmol) of the pyridine (**9a**) in acetic acid (30 ml); when about 9 ml of the permanganate solution was added, reddish violet color of the reaction mixture did not disappear. After a 10% aqueous sodium hydrogensulfite solution (20 ml) was added to the reaction mixture, the resultant clear solution was poured into water (50 ml) to give a precipitate. Filtration and recrystallization of the precipitate from petroleum ether to give 0.28 g (64%) of the pyridine (**15a**).

Similar oxidations of the bis(*p*-methylphenylthio)- (**9b**) and bis(*p*-chlorophenylthio)pyridine (**9c**) with potassium permanganate in acetic acid gave the corresponding bis(arylsulfonyl)pyridines **15b** and **15c** in 69 and 76% yields, respectively.

15b: Mp 231—232 °C; colorless needles; IR (KBr) 1330 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.31, 2.39 (each 3H, s), 6.91—7.46 (11H, m), 7.71—8.01 (2H, m), 8.26, 8.86 (each 1H, d, PyH, J=8.4 Hz); MS m/z 399 ($M^+ - SO_2$). Found: C, 64.66; H, 4.70; N, 3.28%. Calcd for $C_{25}H_{21}NO_4S_2$: C, 64.77; H, 4.57; N, 3.02%.

15c: Mp 227—228 °C; colorless needles; IR (KBr) 1330 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.02—7.62 (11H, m), 7.82—8.02 (2H, m), 8.30, 8.88 (each 1H, d, PyH, J=8.4 Hz); MS m/z 443, 441, 439 ($M^+ - SO_2$). Found: C, 54.72; H, 2.79; N, 2.70%. Calcd for $C_{23}H_{15}NO_4S_2Cl_2$: C, 54.77; H, 3.00; N, 2.78%.

6-Methoxy-2-phenyl-3-phenylsulfonylpyridine (16a). i) In a solution of sodium methoxide in methanol, which was prepared from metallic sodium (1.0 g) in methanol (30 ml), 0.66 g (2 mmol) of the pyridine (**14a**) was refluxed for 5 h. The mixture was poured into water (100 ml), and extracted with benzene (50 ml×2). The benzene extract was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 0.52 g (80%) of the pyridine (**16a**): Mp 84—85 °C; yellow prisms; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.90 (3H, s), 6.84, 8.52 (each 1H, d, PyH, J=8.4 Hz), 7.10—7.50 (10H, m); MS m/z 325 (M^+). Found: C, 66.51; H, 4.89; N, 4.33%. Calcd for $C_{18}H_{15}NO_3S$: C, 66.44; H, 4.65; N, 4.31%.

ii) In a solution of sodium methoxide in methanol, which was prepared from metallic sodium (0.5 g) in methanol (30 ml), 0.40 g (0.9 mmol) of the pyridine (**15a**) was refluxed for 5 h. Similar work-up and chromatography (silica gel, benzene) of the residue gave 0.22 g (75%) of the pyridine (**16a**).

The bis(*p*-methylphenylsulfonyl)- (**15b**) and bis(*p*-chlorophenylsulfonyl)pyridine (**15c**) reacted with sodium methoxide in methanol under similar conditions to give the corresponding methoxypyridines **16b** and **16c** in 67 and 70% yields, respectively.

16b: Mp 107—108 °C; colorless prisms; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.32 (3H, s), 3.92 (3H, s, OCH_3), 6.83, 8.50 (each 1H, d, PyH, J=8.4 Hz), 6.95—7.35 (9H, m); MS m/z 339 (M^+). Found: C, 67.41; H, 4.99; N, 4.34. Calcd for $C_{19}H_{17}NO_3S$: C, 67.23; H, 5.05; N, 4.13%.

16c: Mp 143—144 °C; colorless prisms; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.90 (3H, s), 6.79, 8.46 (each 1H, d, PyH, J=8.4 Hz), 7.02—7.30 (9H, m); MS m/z 361, 359 (M^+). Found: C, 59.87; H, 3.79; N, 3.74%. Calcd for $C_{18}H_{14}NO_3SCl$: C, 60.08; H, 3.92; N, 3.89%.

6-Phenyl-5-phenylsulfonyl-2-pyridone (17). A suspension of 0.16 g (0.5 mmol) of the methoxypyridine (**16a**) in 48% hydrobromic acid (4 ml) was refluxed for 4 h; during which time it turned into a clear solution. When it had been cooled to room temperature, crystals separated out. The crystals were filtered and washed well with a 10% aqueous sodium carbonate solution, and recrystallized from ethyl acetate to give 60 mg (40%) of the pyridone (**17**): Mp 267—268 °C; colorless needles; IR (KBr) 2700—3100, 1660, 1650, 1300 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.41, 8.15 (each 1H, d, PyH, J=11.0 Hz), 7.10—7.50 (10H, m); MS m/z 311 (M^+). Found: C, 65.31; H, 4.00; N, 4.63%. Calcd for $C_{17}H_{13}NO_3S$: C, 65.58; H, 4.21; N, 4.50%.

Conversion of 6-Benzoyl-2-phenyl-3-phenylthiopyridine (10) into 2-Phenyl-6-phenylcarbamoyl-3-phenylthiopyridine (19). A solution of 0.49 g of the benzoylpyridine (**10**) in ethanol (30 ml) was refluxed with an aqueous hydroxylamine solution, which was prepared by the treatment of hydroxylamine hydrochloride (1.5 g) with a 7% aqueous sodium hydroxide solution (10 ml), for 2 h. The reaction mixture was poured into water (100 ml), and the resultant mixture was acidified with hydrochloric acid, and then extracted with chloroform (50 ml×2). The chloroform extract was concentrated in vacuo, and the residue was chromatographed (silica gel, chloroform) to give 0.27 g (54%) of a mixture of isomeric oximes (**18**). Without further purification, a mixture of oximes (**18**) was used for the Beckmann rearrangement: 0.3 g (0.8 mmol) of the oximes (**18**) was heated with polyphosphoric acid (3 ml) at 90—100 °C for 2 h. The mixture was poured into water (50 ml), and extracted with chloroform (30 ml×2). The extract was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 0.24 g (88%) of the phenylcarbamoylpyridine (**19**).

19: Mp 145—146 °C; yellow prisms; IR (KBr) 3250, 1735 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.33, 7.90 (each 1H, d, PyH, J=8.4 Hz), 7.41—7.70 (15H, m), 8.93 (1H, broad, NH); MS m/z 382 (M^+). Found: C, 75.49; H, 4.65; N, 7.12%. Calcd for $C_{24}H_{18}N_2OS$: C, 75.36; H, 4.74; N, 7.33%.

2-Phenyl-3-phenylthiopyridine (21). i) From the Phenylcarbamoylpyridine (19). A suspension of 0.3 g (0.8 mmol)

of the pyridine (**19**) in an ethanolic potassium hydroxide solution, which was prepared from potassium hydroxide (0.5 g) in ethanol (20 ml), was refluxed for 3 h. The mixture was poured into water (20 ml) and extracted with benzene (20 ml×2). The aqueous layer was acidified with hydrochloric acid, and extracted with chloroform (30 ml×2). The chloroform extract was concentrated in vacuo to give 0.15 g (61%) of 6-phenyl-5-phenylthio-2-pyridinecarboxylic acid (**20**). After 0.2 g of the carboxylic acid (**20**) was heated at 230—250 °C for 15 min, the product was purified by chromatography (silica gel, benzene) to give 60 mg (35%) of the pyridine (**21**).

20: Mp 141—142 °C; colorless prisms; IR (KBr) 2800—3050, 1700 cm^{-1}; MS *m/z* 307 (M^+). Found: C, 70.51; H, 4.33; N, 4.44%. Calcd for $C_{18}H_{13}NO_2S$: C, 70.33; H, 4.26; N, 4.56%.

21: Oil; ^1H NMR ($CDCl_3$) δ=7.01 (1H, dd, PyH(β), J=4.8, 8.0 Hz), 7.39 (1H, dd, PyH(γ), J=1.2, 8.0 Hz), 7.20—7.55 (8H, m), 7.55—7.80 (2H, m), 8.45 (1H, dd, PyH(α), J=1.2, 4.8 Hz); MS *m/z* 263 (M^+). Found: C, 77.80; H, 4.68; N, 5.26%. Calcd for $C_{17}H_{13}NS$: C, 77.53; H, 4.98; N, 5.32%.

ii) From 6-Chloro-2-phenyl-3-phenylthiopyridine (8a). A solution of 0.23 g (0.8 mmol) of the chloropyridine (**8a**) in acetic acid (20 ml) was refluxed with zinc dust (1.5 g) for 8 h. The hot reaction mixture was filtered and the precipitate was washed with benzene (30 ml). The filtrate was poured into water (100 ml), and the resultant mixture was extracted with benzene (50 ml). The benzene extract was concentrated in vacuo and the residue was chromatographed (silica gel, benzene) to give 0.1 g (49%) of the pyridine (**21**).

6-Amino-2-phenyl-3-phenylthiopyridine (22). In a 10% ethanolic potassium hydroxide solution (20 ml) was heated 0.1 g of the (benzoylamino)pyridine (**11**) under reflux for 4 h. After the reaction mixture was concentrated in vacuo, the residue was triturated with water (10 ml), and then extracted with chloroform (30 ml). The extract was concentrated in vacuo, and the residue was chromatographed (silica gel, chloroform) to give 30 mg (41%) of the aminopyridine (**22**): Mp 177—178 °C; yellow needles; IR (KBr) 3460, 3300, 2950, 1635 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.66 (2H, broad, NH_2). 6.41, 7.52 (each 1H, d, PyH, J=8.4 Hz), 6.96—7.56 (10H, m); MS *m/z* 278 (M^+). Found: C, 73.20; H, 4.79; N, 9.80%. Cacld for $C_{17}H_{14}N_2S$: C, 73.35; H, 5.07; N, 10.06%.

6-Phenyl-5-phenylthio-2-pyridone (23). After diazotization of 0.1 g of the aminopyridine (**22**) with sodium nitrite (50 mg) in aqueous sulfuric acid (conc sulfuric acid (1 ml) and water (10 ml)) was carried out at 0—5 °C, the reaction mixture was heated at 50—60 °C for 1 h. Water (10 ml) was added to the mixture and the mixture was extracted with chloroform (20 ml×2). The extract was concentrated in vacuo, and the residue was chromatographed (silica gel, chloroform) to give 30 mg (30%) of the pyridone (**23**): Mp 206—208 °C; colorless needles; IR (KBr) 2700—3100, 1640 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.43 (1H, d, PyH, J=9.0 Hz), 7.00—7.60 (11H, m, ArH and PyH); MS *m/z* 279 (M^+). Found: C, 73.29; H, 4.41; N, 5.26%. Calcd for $C_{17}H_{13}NOS$: C, 73.10; H, 4.69; N, 5.01%.

Oxidation of the Pyridone (23). A solution of 0.1 g of the pyridone (**23**) in acetic acid (20 ml) was heated with 35% hydrogen peroxide (2 ml) under reflux for 3 h. The reaction mixture was concentrated in vacuo, and the residue was chromatographed (silica gel, chloroform–ethyl acetate (7:3)) to give 50 mg (45%) of the phenylsulfonylpyridone (**17**).

Thermolysis of the 4-(*p*-Methylphenylthio)-7-phenylthio-1,2-diazocine (6a). A solution of 0.73 g (1.5 mmol) of the 1,2-diazocine (**6a**) in dry xylene (20 ml) was refluxed for 5 h. The mixture was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 0.12 g (78%) of benzonitrile and 0.39 g (63%) of a mixture of 6-(*p*-methylphenylthio)-2-phenyl-3-phenylthio- (**24a**) and 3-(*p*-methylphenylthio)-2-phenyl-6-phenylthiopyridine (**25a**) whose ratio was found to be 1:1 on the basis of ^1H NMR spectrum (δ=2.28, 2.34 (each s, CH_3)). It was very difficult to isolate pure **24a** and **25a** from the mixture.

Oxidation of the Mixture of 24a and 25a. A 6.6% aqueous potassium permanganate solution was slowly added, at room temperature, to a stirred solution of 0.17 g (0.4 mmol) of the mixture of **24a** and **25a** in acetic acid (30 ml); when about 6 ml of the permanganate solution was added, reddish violet color of the reaction mixture did not disappear. After a 10% aqueous sodium hydrogensulfite solution (12 ml) was added to the reaction mixture, the resultant clear solution was poured into water (50 ml) to give 0.14 g (71%) of a 1:1 mixture of 6-(*p*-methylphenylsulfonyl)-2-phenyl-3-phenylsulfonyl- (**26a**) and 3-(*p*-methylphenylsulfonyl)-2-phenyl-6-phenylsulfonylpyridine (**27a**): Mp 171—176 °C; ^1H NMR ($CDCl_3$) δ=2.29, 2.37 (each s, CH_3, relative intensity 1:1). Again it was very difficult to isolate pure **26a** and **27a** from the mixture.

Conversion of the Mixture of 26a and 27a into the Methoxypyridines 16a and 16b. In a solution of sodium methoxide in methanol, which was prepared from metallic sodium (0.5 g) in methanol (30 ml), 0.14 g (0.3 mmol) of the mixture of **26a** and **27a** was heated under reflux for 5 h. The reaction mixture was poured into water (50 ml), and the mixture was extracted with benzene (50 ml×2). The extract was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 30 mg (30%) of 6-methoxy-2-phenyl-3-phenylsulfonylpyridine (**16a**) and 40 mg (36%) of 6-methoxy-3-(*p*-methylphenylsulfonyl)-2-phenylpyridine (**16b**), respectively.

Thermolysis of 4-(*p*-Chlorophenylthio)-7-phenylthio-1,2-diazocine (6b). A solution of 0.69 g (1.4 mmol) of the 1,2-diazocine (**6b**) in dry xylene (20 ml) was refluxed for 5 h. Similar work-up and chromatography (silica gel, benzene) of the residue gave 0.13 g (76%) of benzonitrile and 0.46 g (84%) of a mixture of 6-(*p*-chlorophenylthio)-2-phenyl-3-phenylthio- (**24b**) and 3-(*p*-chlorophenylthio)-2-phenyl-6-phenylthiopyridine (**25b**). Since it was very difficult to isolate pure **24b** and **25b**, the mixture was subjected to oxidation. A similar oxidation of 0.27 g of the mixture of **24b** and **25b** with potassium permanganate in acetic acid gave 0.14 g (45%) of 6-(*p*-chlorophenylsulfonyl)-2-phenyl-3-phenylsulfonylpyridine (**26b**) and 70 mg (23%) of 3-(*p*-chlorophenylsulfonyl)-2-phenyl-6-phenylsulfonylpyridine (**27b**), respectively.

26b: Mp 183—185 °C; colorless needles; IR (KBr) 1325 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.00—7.60 (6H, m), 7.80—8.10 (2H, m), 8.29, 8.86 (each 1H, d, PyH, J=8.4 Hz); MS *m/z* 407, 405 (M^+-SO_2). Found: C, 58.82; H, 3.58; N, 3.10%. Calcd for $C_{23}H_{16}NO_4S_2Cl$: C, 58.78; H, 3.43; N, 2.98%.

The sulfonylpyridines **26b** and **27b** reacted with sodium methoxide in methanol to give the methoxypyridines **16a** and **16c**, respectively.

Thermolysis of the 4-Acetoxy-7-phenylthio-1,2-diazocine

(**7**). A solution of 1.0 g (2.4 mmol) of the 1,2-diazocine (**7**) in dry xylene (20 ml) was refluxed for 5 h. Similar work-up and chromatography (silica gel, benzene) of the residue gave 0.17 g (69%) of benzonitrile and 0.66 g (87%) of 6-acetoxy-2-phenyl-3-phenylthiopyridine (**28**).

28: Oil; IR (neat) 1760 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.30 (3H, s), 6.87, 7.45 (each 1H, d, PyH, J=7.8 Hz), 7.20—7.70 (10H, m); MS m/z 321 (M^+). Found: C, 71.23; H, 4.66; N, 4.23%. Calcd for $C_{19}H_{15}NO_2S$: C, 71.00; H, 4.70; N, 4.36%.

Hydrolysis of the Acetoxypyridine (28) to the Pyridone (23). A solution of 0.5 g (1.6 mmol) of the pyridine (**28**) in an ethanolic alkali solution (sodium hydrogencarbonate (1.0 g) in ethanol (50 ml)) was refluxed for 4 h. After the mixture was concentrated in vacuo, the residue was triturated with water (30 ml), and extracted with chloroform (30 ml×2). The extract was concentrated in vacuo, and the residue was chromatographed (silica gel, chloroform) to give 0.27 g (62%) of the pyridone (**23**).

(Received July 24, 1986)

Nucleophilic substitution of 4,7-dichloro-3,8-diphenyl-1,2-diazocine with benzenesulfinate gave stable 7-chloro-4-phenylsulfonyl- and 4,7-bis(phenylsulfonyl)-1,2-diazocine. The 4-mono(arylsulfonyl)- and 4,7-bis-(arylsulfonyl)-1,2-diazocines were obtained by oxidation of the corresponding mono(arylthio)- and bis(arylthio)-1,2-diazocines, respectively. 4-Phenylsulfonyl-7-phenylthio-1,2-diazocine was also prepared. Thermolysis of all the diazocines gave only pyridine derivatives, and the feature of the thermolysis was also described.

Although Trost et al.[1] succeeded in an elegant synthesis of 1,2-diazacycloocta-2,4,6,8-tetraene, the parent 1,2-diazocine, substituted monocyclic 1,2-diazocines were not known until we reported the synthesis of stable 4,7-disubstituted 3,8-diphenyl-1,2-diazocines: 4,7-Dichloro-3,8-diphenyl-1,2-diazocine (**1**),[2] which can be readily obtained through a chlorination–dehydrochlorination sequence starting from 3,8-diphenyl-1,2-diazacycloocta-2,8-diene,[3] reacted with nucleophiles such as carboxylate anions[2] and arenethiols[4] to give the corresponding 4-substituted and 4,7-disubstituted 1,2-diazocines. In addition, it has been found that in contrast to the parent 1,2-diazocine, which decomposed slowly in solution at room temperature and rapidly neat to benzene and pyridine with comparable rates,[1] thermolysis of these stable 1,2-diazocines in refluxing toluene or xylene gave only pyridines with the extrusion of benzonitrile. This provided a new route for the synthesis of 3,6-disubstituted 2-phenylpyridines.

In order to obtain further information on thermal behavior of stable 1,2-diazocines, we have investigated the preparation of 1,2-diazocines bearing electron-withdrawing arenesulfonyl groups in place of electron-donating groups such as acyloxy[2] and arylthio groups,[4] and their thermolysis.

Results and Discussion

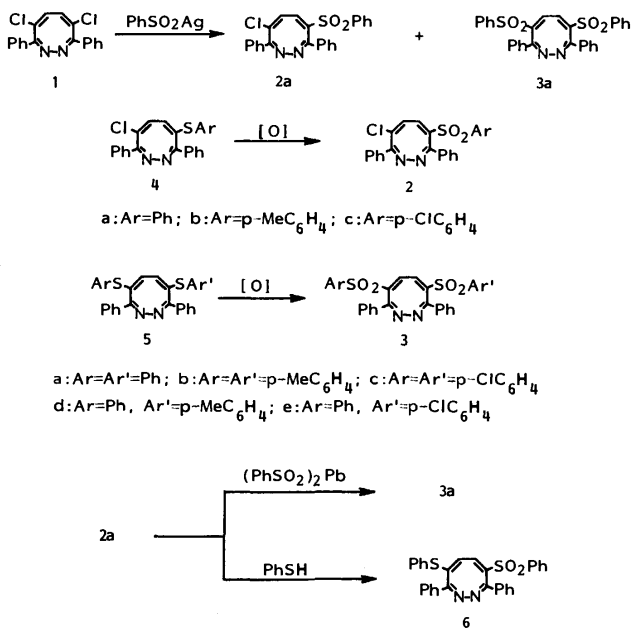
Preparation of Arylsulfonyl-Substituted 1,2-Diazocines. As expected, the dichloro-1,2-diazocine (**1**) reacted with two equivalents of silver benzenesulfinate in benzene under reflux for 6 h to give 7-chloro-3,8-diphenyl-4-phenylsulfonyl- (**2a**) and 4,7-bis(phenylsulfonyl)-3,8-diphenyl-1,2-diazocine (**3a**) in 83 and 3% yields, respectively. It has been found, however, that oxidations of the 4-arylthio-7-chloro- (**4a—c**)[4] and 4,7-bis(arylthio)-1,2-diazocines (**5a—e**)[4] with potassium permanganate or hydrogen peroxide in acetic acid afforded the corresponding mono(arylsulfonyl)-, **2a—c**, and bis(arylsulfonyl)-1,2-diazocines, **3a—e**, in fairly good yields, respectively (Scheme 1).

On the other hand, 3,8-diphenyl-4-phenylsulfonyl-7-phenylthio-1,2-diazocine (**6**) was obtained from the reaction of the mono(phenylsulfonyl)-1,2-diazocine (**2a**) with benzenethiol or the reaction of the mono(phenylthio)-1,2-diazocine (**4a**) with lead benzenesulfinate in benzene under reflux, respectively.

Structural elucidation of all the 1,2-diazocines, **2**, **3**, and **6**, was accomplished on the basis of spectral data.

Thermolysis of Arylsulfonyl-Substituted 1,2-Diazocines. We have first investigated the thermolysis of the mono(arylsulfonyl)-1,2-diazocines (**2**). When a solution of the phenylsulfonyl-1,2-diazocine (**2a**) in dry xylene was heated under reflux for 5 h, three pyridines, 3-chloro-2-phenyl-6-phenylsulfonyl- (**7a**), 6-benzoyl-2-phenyl-3-phenylsulfonyl- (**8a**), and 6-benzoyl-3-chloro-2-phenylpyridine (**9**) were isolated together with benzonitrile in small amounts.

Thermolysis of the (*p*-tolylsulfonyl)- (**2b**) and (*p*-chlorophenylsulfonyl)-1,2-diazocine (**2c**) under simi-



Scheme 1.

lar conditions gave the corresponding 6-arylsulfonyl-3-chloro-2-phenyl- (**7b** and **7c**), 3-arylsulfonyl-6-benzoyl-2-phenylpyridines (**8b** and **8c**) and the pyridine **9**, accompanied by trace amounts of benzonitrile, respectively (Scheme 2).

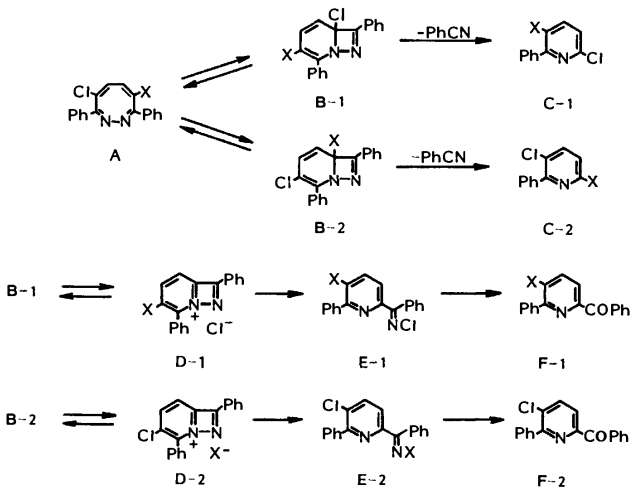
The structures of the pyridines, **7** and **8**, were confirmed on the basis of spectral data. In addition, the reaction of the pyridines, **7a—c**, with sodium methoxide in methanol afforded the same product, 3-chloro-6-methoxy-2-phenylpyridine (**10**), which was identical with an authentic sample prepared from 3,6-dichloro-2-phenylpyridine (**11**).[2] The pyridine **8a** was also obtained by the oxidation of 6-benzoyl-2-phenyl-3-phenylthiopyridine (**12**).[4] The pyridine **9** was identical with the product obtained from the thermolysis of the dichloro-1,2-diazocine (**1**) in wet toluene under reflux.[2]

As reported previously,[2,4] 4,7-disubstituted 3,8-diphenyl-1,2-diazocines are thermally isomerized into their valence isomers, diazabicyclooctatrienes. In the case of unsymmetrically 4,7-disubstituted 1,2-diazocines **A**, two valence isomers, **B-1** and **B-2**, are possible. 4-Acyloxy-7-chloro-[2] and 4-arylthio-7-chloro-1,2-diazocines[4] are exclusivly isomerized into their valence isomers **B-1** (X=OCOR and SAr), which decomposed into the corresponding 6-chloropyridines **C-1** (X=OCOR and SAr) with the extrusion of benzonitrile, respectively (Scheme 3).

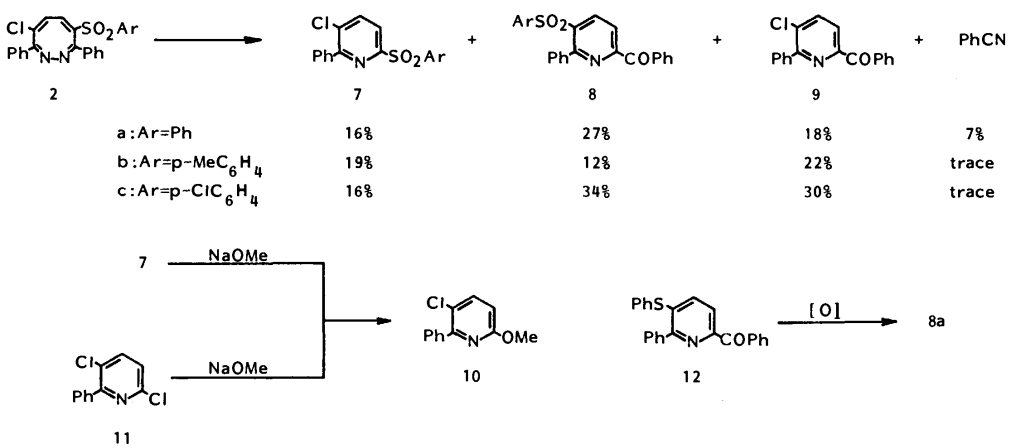
As illustrated in Scheme 2, however, the mode of decomposition of the arylsulfonyl-substituted 1,2-diazocines (**2**) is somewhat different from those of the acyloxy- and arylthio-substituted 1,2-diazocines. The 1,2-diazocines **2** seem to be preferentially isomerized into **B-2** (X=SO_2Ar) rather than **B-1** (X=SO_2Ar). It is evident that the pyridines, **7** and **9**, are derived from the **B-2**: The extrusion of benzonitrile from the **B-2** gives the pyridines **7**, and the pyridine **9** corresponds to the hydrolytic compounds **F-2** (X=SO_2Ar) of the imidoylpyridines **E-2** (X=SO_2Ar) arising from ring opening of the azonia intermediates **D-2** (X=SO_2Ar).[5]

In analogy with the formation of **9**, the pyridines **8** form via the processes, **B-1**→**D-1**→**E-1**→**F-1** (each X=SO_2Ar) (Scheme 3). Taking into account the formation of the pyridines, **8** and **9**, it should be emphasized that the arenesulfonyl group suppresses the extrusion of benzonitrile from the valence isomers, **B-1** and **B-2**, respectively.

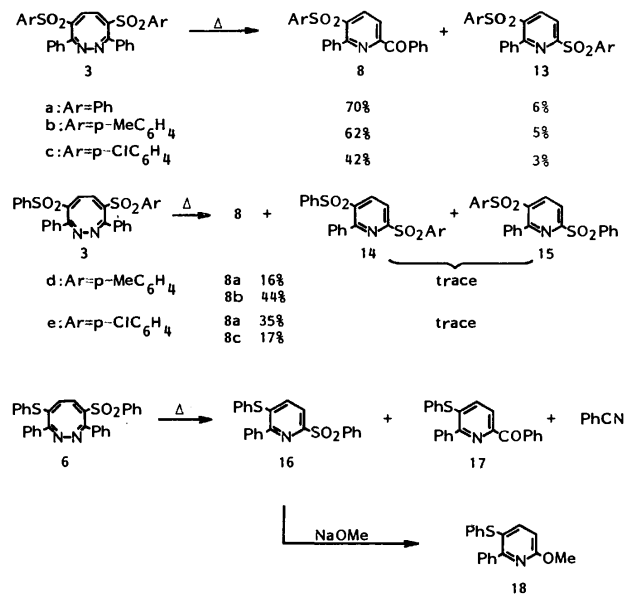
Next, the thermolysis of the bis(arylsulfonyl)-1,2-diazocines (**3**) was carried out under similar conditions. The symmetrical bis(arylsulfonyl)-1,2-diazocines (**3a—c**) gave the corresponding 3-arylsulfonyl-6-benzoyl-2-phenylpyridines (**8a—c**) as the main products, together with small amounts of the corresponding 3,6-bis(arylsulfonyl)-2-phenylpyridines (**13a—c**),[4] respectively (Scheme 4). In the thermolysis of the unsymmetrical bis(arylsulfonyl)-1,2-diazocine (**3d** or **3e**), two 3-arylsulfonyl-6-benzoyl-2-phenylpyridines (**8a** and **8b**) or (**8a** and **8c**) were obtained together with trace amounts of a mixture of the corresponding 6-arylsulfonyl-2-phenyl-3-phenylsulfonyl- (**14**) and 3-arylsulfonyl-2-phenyl-6-phenylsulfonylpyridine (**15**), respectively.



Scheme 3.

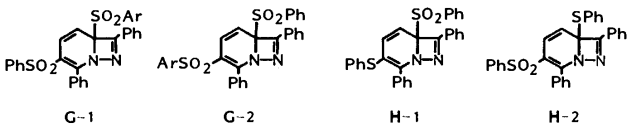


Scheme 2.



Scheme 4.

When the 4-phenylsulfonyl-7-phenylthio-1,2-diazocine (**6**) was pyrolyzed under similar conditions, 2-phenyl-6-phenylsulfonyl-3-phenylthio- (**16**) and 6-benzoyl-2-phenyl-3-phenylthiopyridine (**17**)[4] were obtained together with benzonitrile. The pyridine **16** was converted into 6-methoxy-2-phenyl-3-phenylthiopyridine (**18**)[4] (Scheme 4).



On the basis of the results shown in Scheme 4, it is clear that the unsymmetrical bis(arylsulfonyl)-1,2-diazocines (**3d** and **3e**) decomposed via two possible valence isomers, **G-1** and **G-2**. However, the decomposition of **3d** occurs somewhat more preferentially via **G-2** than **G-1**, and the reverse in **3e**. On the other hand, the 1,2-diazocine **6** exclusively decomposes via **H-1**, but not **H-2**.

Experimental

IR spectra were obtained on a JASCO A-302 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-24 or a JEOL FX-100 instrument, and ^{13}C NMR spectra were measured on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical shifts are expressed in parts per million downfield from tetramethylsilane. Mass spectra were taken with a Hitachi RMU-6L spectrometer at 70 eV ionization energy. Elementary analyses were performed on a Yanaco MT 2 CHN corder instrument.

Reaction of the Dichloro-1,2-diazocine (1) with Silver Benzenesulfinate. A solution of the diazocine **1**[2] (1.3 g, 4mmol) in benzene (50 ml) was refluxed with silver benzenesulfinate (2.0 g, 8 mmol) for 6 h. The reaction mixture was filtered, and the precipitate was washed with benzene (50 ml). The combined benzene solution was concentrated in vacuo, and the residue was chromatographed on silica gel to give 1.42 g (83%) of the mono(phenylsulfonyl)-1,2-diazocine (**2a**) (from benzene elution) and 60 mg (3%) of the bis(phenylsulfonyl)-1,2-diazocine (**3a**).

2a: Mp 180—181 °C (decomp); colorless needles; IR (KBr) *1320 cm^{-1}*; ^{1}H NMR (CDCl$_3$) *δ=6.60 (1H, d, =CH, J=4.2 Hz)*, 7.20—7.80 (16H, m, =CH and ArH); ^{13}C NMR (CDCl$_3$) δ=149.29, 148.36, 142.61, 141.61, 139.90, 133.86, 132.21 (each s), 131.22, 130.63, 130.16, 128.58, 128.39, 128.11, 127.69; MS *m/z* 434, 432 (M$^+$). Found: C, 66.58; H, 3.87; N, 6.38%. Calcd for $C_{24}H_{17}N_2O_2SCl$: C, 66.58; H, 3.96; N, 6.47%.

3a: Mp 227—229 °C (decomp); colorless needles; IR (KBr) 1320 cm^{-1}; ^{1}H NMR (CDCl$_3$) δ=7.75 (2H, s, =CH), 7.40—7.70 (20H, m); MS *m/z* 538 (M$^+$). Found: C, 66.83; H, 4.05; N, 5.42%. Calcd for $C_{30}H_{22}N_2O_4S_2$: C, 66.89; H, 4.12; N, 5.20%.

Oxidation of the 4-Arylthio-7-chloro-1,2-diazocines (4). Typical run is illustrated for the phenylthiodiazocine **4a**.

i) With Hydrogen Peroxide: A solution of 0.8 g (2 mmol) of **4a**[4] in acetic acid (30 ml) was refluxed with 35% hydrogen peroxide (10 ml) for 1.5 h. The reaction mixture was poured into water (50 ml) to precipitate solid, which on recrystallization from benzene gave 0.52 g (60%) of the mono(phenylsulfonyl)-1,2-diazocine (**2a**).

ii) With Potassium Permanganate. A 6.6% aqueous potassium permanganate solution was slowly added, at room temperature, to a stirred solution of 0.8 g (2 mmol) of **4a** in acetic acid (40 ml); when about 8 ml of the permanganate solution was added, reddish violet color of the reaction mixture did not disappear. After a 10% aqueous sodium hydrogensulfite solution (18 ml) was added to the reaction mixture, the resultant clear solution was poured into water (50 ml) to give 0.5 g (58%) of **2a**.

Similar oxidations of the 4-chloro-7-(*p*-methylphenylthio)- (**4b**)[4] and 4-chloro-7-(*p*-chlorophenylthio)-1,2-diazocine (**4c**)[4] with potassium permanganate in acetic acid gave the corresponding mono(arylsulfonyl)-1,2-diazocines **2b** and **2c** in 50 and 58% yields, respectively.

2b: Mp 186—188 °C (decomp); colorless needles; IR (KBr) 1320 cm^{-1}; ^{1}H NMR (CDCl$_3$) δ=2.32 (3H, s), 6.67 (1H, d, =CH, *J*=4.2 Hz), 6.98—7.80 (15H, m, =CH and ArH); MS *m/z* 449, 446 (M$^+$). Found: C, 67.29; H, 4.01; N, 6.16%. Calcd for $C_{25}H_{19}N_2O_2SCl$: C, 67.18; H, 4.29; N, 6.27%.

2c: Mp 177—179 °C (decomp); colorless needles; IR (KBr) 1330 cm^{-1}; ^{1}H NMR (CDCl$_3$) δ=6.64 (1H, d, =CH, *J*=4.2 Hz), 7.01—7.71 (15H, m, =CH and ArH); MS *m/z* 470, 468, 466 (M$^+$). Found: C, 61.80; H, 3.61; N, 5.76%. Calcd for $C_{24}H_{16}N_2O_2SCl_2$: C, 61.67; H, 3.45; N, 5.99%.

Oxidation of the 4,7-Bis(arylthio)-1,2-diazocines (5). Typical run is illustrated for the bis(phenylthio)diazocine **5a**.

i) With Hydrogen Peroxide. A solution of 0.95 g (2 mmol) of **5a**[4] in acetic acid (30 ml) was refluxed with 35% hydrogen peroxide (10 ml) for 1.5 h. The reaction mixture was poured into water (50 ml) to precipitate solid, which on recrystallization from petroleum ether gave 0.68 g (63%) of the bis(phenylsulfonyl)-1,2-diazocine (**3a**).

ii) With Potassium Permanganate. To a stirred solution of **5a** (0.5 g, 1 mmol) in acetic acid (40 ml), a 6.6%

aqueous potassium permanganate solution was slowly added at room temperature; when about 9 ml of the permanganate solution was added, reddish violet color of the reaction mixture did not disappear. After a 10% aqueous sodium hydrogensulfite solution (20 ml) was added to the reaction mixture, the resultant clear solution was poured into water (50 ml) to give 0.41 g (76%) of **3a**.

Similar oxidations of the bis(*p*-methylphenylthio)- (**5b**)[4] and bis(*p*-chlorophenylthio)-1,2-diazocine (**5c**)[4] with potas sium permanganate in acetic acid gave the bis(*p*-tolylsulfonyl)- (**3b**) and bis(*p*-chlorophenylsulfonyl)-1,2-diazocine (**3c**) in 62 and 53% yields, respectively.

3b: Mp 245—247 °C (decomp); colorless needles; IR (KBr) 1320 cm^{-1}; MS *m/z* 566 (M^+). Found: C, 68.15; H, 4.50; N, 4.91%. Calcd for $C_{32}H_{26}N_2O_4S_2$: C, 67.82; H, 4.62; N, 4.94%.

3c: Mp 173—174 °C (decomp); colorless needles; IR (KBr) 1330 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.64 (2H, s, =CH), 7.02—7.57 (18H, m); MS *m/z* 610, 608, 606 (M^+). Found: C, 59.53; H, 3.11; N, 4.86%. Calcd for $C_{30}H_{20}N_2O_4S_2Cl_2$: C, 59.31; H, 3.32; N, 4.61%.

4-Phenylsulfonyl-7-phenylthio-1,2-diazocine (6). i) A solution of 0.58 g (1.3 mmol) of the mono(phenylsulfonyl)-1,2-diazocine (**2a**) in benzene (30 ml) was refluxed with 0.33 g (3 mmol) of benzenethiol for 4 h. After the reaction mixture was washed with a 10% aqueous sodium hydroxide solution and then water, the benzene solution was concentrated in vacuo to leave the residue. Chromatography (silica gel, benzene) of the residue gave 0.45 g (78%) of unreacted **2a** and 0.14 g(21%) of the 1,2-diazocine **6**.

ii) A solution of 0.8 g (2 mmol) of the phenylthiodiazocine **4a** in benzene (50 ml) was heated with 1.0 g (2 mmol) of lead benzenesulfinate under reflux for 18 h. The reaction mixture was filtered, and the precipitate was washed with benzene (30 ml). The combined benzene solution was concentrated in vacuo, and chromatography (silica gel, benzene) of the residue afforded 0.17 g (21%) of unreacted **4a** and 0.52 g (51%) of **6**.

6: Mp 203—204 °C (decomp); colorless needles; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.20 (1H, d, =CH, *J*=4.2 Hz), 7.01—7.81 (21H, m, -CH and ArH); MS *m/z* 506 (M^+). Found: C, 69.97; H, 4.09; N, 5.75%. Calcd for $C_{30}H_{22}N_2O_2S_2$: C, 71.12; H, 4.38; N, 5.53%.

Thermolysis of the 7-Chloro-4-phenylsulfonyl-1,2-diazocine (2a). A solution of 1.0 g (2.3 mmol) of **2a** in dry xylene (20 ml) was refluxed for 5h. The reaction mixture was concentrated in vacuo, and the residue was chromatographed (silica gel, benzene) to give 20 mg (7%) of benzonitrile, 0.12 g (16%) of 3-chloro-2-phenyl-6-phenylsulfonylpyridine (**7a**), 0.25 g (27%) of 6-benzoyl-2-phenyl-3-phenylsulfonylpyridine (**8a**), and 0.12 g (18%) of 6-benzoyl-3-chloro-2-phenylpyridine (**9**), mp 119—120 °C (lit.[2] mp 119—120 °C).

7a: Mp 132—133 °C; yellow prisms; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.97, 8.05 (each 1H, d, PyH, *J*=8.4 Hz), 7.32—7.82 (8H, m), 7.97—8.22 (2H, m); ^{13}C NMR ($CDCl_3$) δ=156.98, 156.46, 139.50, 138.61, 136.33, 133.86, 133.63, 129.57, 129.58, 129.05, 127.99, 121.06; MS *m/z* 267, 265 (M^+-SO_2). Found: C, 61.82; H, 3.56; N, 4.07%. Calcd for $C_{17}H_{12}NO_2SCl$: C, 61.91; H, 3.67; N, 4.25%.

8a: Mp 159—160 °C; yellow needles; IR (KBr) 1665, 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.11, 8.86 (each 1H, d, PyH, *J*=8.2 Hz), 7.10—7.60 (13H, m), 7.97—8.12 (2H, m); ^{13}C NMR ($CDCl_3$) δ=191.87, 157.81, 157.40, 139.14, 138.88, 138.20, 137.15, 135.09, 133.39, 133.16, 130.98, 129.63, 128.87, 128.52, 128.16, 127.87, 127.45, 122.70; MS *m/z* 399 (M^+). Found: C, 71.95; H, 4.51; N, 3.65%. Calcd for $C_{24}H_{17}NO_3S$: C, 72.16; H, 4.29; N, 3.51%.

Thermolysis of the 4-Chloro-7-(*p*-tolylsulfonyl)-1,2-diazocine (2b). A solution of 0.7 g (1.6 mmol) of **2b** in dry xylene (20 ml) was refluxed for 5h. Similar work-up and chromatography (silica gel, benzene) of the pyrolysate gave trace amounts of benzonitrile, 0.1 g (19%) of 3-chloro-2-phenyl-6-(*p*-tolylsulfonyl)pyridine (**7b**), 80 mg (12%) of 6-benzoyl-2-phenyl-3-(*p*-tolylsulfonyl)pyridine (**8b**), and 0.1 g (22%) of the pyridine **9**.

7b: 142—143 °C; colorless needles; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.40 (3H, s), 7.33—7.83 (8H, m, PyH and ArH) 7.83—8.13 (3H, m, PyH and ArH); MS *m/z* 281, 279 (M^+-SO_2). Found: C, 63.01; H, 4.26; N, 4.33%. Calcd for $C_{18}H_{14}NO_2SCl$: C, 62.88; H, 4.10; N, 4.07%.

8b: Mp 163—164 °C; colorless prisms; IR (KBr) 1655, 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.33 (3H, s), 8.06, 8.81 (each 1H, d, PyH, *J*=8.4 Hz), 6.76—7.56 (12H, m), 7.86—8.16 (2H, m): MS *m/z* 413 (M^+). Found: C, 72.37; H, 4.50; N, 3.43%. Calcd for $C_{25}H_{19}NO_3S$: C, 72.62; H, 4.63; N, 3.39%.

Thermolysis of the 4-Chloro-7-(*p*-chlorophenylsulfonyl)-1,2diazocine (2c). A solution of 0.8 g (1.7 mmol) of **2c** in dry xylene (20 ml) was refluxed for 5 h. Similar work-up and chromatography (silica gel, benzene) of the pyrolysate gave trace amounts of benzonitrile, 0.1 g (16%) of 3-chloro-6-(*p*-chlorophenylsulfonyl)-2-phenylpyridine (**7c**), 0.25 g (34%) of 6-benzoyl-3-(*p*-chlorophenylsulfonyl)-2-phenylpyridine (**8c**), and 0.15 g (30%) of the pyridine **9**.

7c: Mp 132—133 °C; colorless needles; IR (KBr) 1320 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.29—7.69 (8H, m, PyH and ArH), 7.94—8.19 (3H, m, PyH and ArH); MS *m/z* 303, 301, 299 (M^+-SO_2). Found: C, 56.06; H, 3.04; N, 3.85%. Calcd for $C_{17}H_{11}NO_2SCl_2$: C, 55.77; H, 3.21; N, 3.69%.

8c: Mp 147—148 °C; colorless needles; IR (KBr) 1660, 1330 cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.13, 8.85 (each 1H, d, PyH, *J*=8.4 Hz), 7.09—7.59 (12H, m), 7.78—8.19 (2H, m); MS *m/z* 435, 433 (M^+). Found: C, 66.21; H, 3.60; N, 3.49%. Calcd for $C_{24}H_{18}NO_3SCl$: C, 66.43; H, 3.72; N, 3.23%.

Conversion of the 3-Chloro-2-phenyl-6-phenylsulfonylpyridine (7a) to 3-Chloro-6-methoxy-2-phenylpyridine (10). The pyridine **7a** (0.2 g, 0.6 mmol) was heated in a solution of sodium methoxide in methanol, which was prepared from metallic sodium (0.5 g) in methanol (20 ml), under reflux for 5 h. The reaction mixture was poured into water (50 ml), and the mixture was extracted with benzene (50 ml×2). The benzene extract was concentrated in vacuo, and chromatography (silica gel, benzene) of the residue gave 0.1 g (76%) of the pyridine **10**.

10: Oil; ^1H NMR ($CDCl_3$) δ=3.89 (3H, s), 6.59, 7.52 (each 1H, d, PyH, *J*=8.4 Hz), 7.27—7.52 (3H, m), 7.67—7.87 (2H, m); MS *m/z* 221, 219 (M^+). Found: C, 65.37; H, 4.62; N, 6.51%. Calcd for $C_{12}H_{10}NOCl$: C, 65.61; H, 4.59; N, 6.38%.

Similar treatments of 3-chloro-2-phenyl-6-(*p*-tolylsulfonyl)- (**7b**) and 3-chloro-6-(*p*-chlorophenylsulfonyl)-2-phenylpyridine (**7c**) with sodium methoxide in methanol afforded the pyridine **10** in 67 and 50% yields, respectively. The pyridine **10** was identical with the product from the reaction of 3,6-dichloro-2-phenylpyridine (**11**)[2] with sodium

methoxide in methanol under similar conditions.

Thermolysis of the Symmetrical Bis(arylsulfonyl)-1,2-diazocines. Typical run is illustrated for the bis(phenylsulfonyl)-1,2-diazocine (**3a**). A solution of **3a** (1.0 g, 1.9 mmol) in dry xylene (20 ml) was refluxed for 5 h. The reaction mixture was concentrated in vacuo, and the residue was chromatographed on silica gel to give 0.52 g (70%) of the pyridine **8a** (from benzene elution) and 50 mg (6%) of 3,6-bis(phenylsulfonyl)-2-phenylpyridine (**13a**), mp 187—189 °C (lit,[4] mp 187—189 °C) (from chloroform elution).

Thermolysis of the bis(*p*-tolylsulfonyl)- (**3b**) or bis(*p*-chlorophenylsulfonyl)-1,2-diazocine (**3c**) in dry xylene under similar conditions gave the pyridine **8b** and 3,6-bis(*p*-tolylsulfonyl)-2-phenylpyridine (**13b**), mp 231—232 °C (lit,[4] mp 231—232 °C), or the pyridine **8c** and 3,6-bis(*p*-chlorophenylsulfonyl)-2-phenylpyridine (**13c**), mp 227—228 °C (lit,[4] mp 227—228 °C), respectively. The results are shown in Scheme 4.

Thermolysis of the Unsymmetrical Bis(arylsulfonyl)-1,2-diazocines. A solution of 0.7 g (1.3 mmol) of the 4-phenylsulfonyl-7-(*p*-tolylsulfonyl)-1,2-diazocine (**3d**) in dry xylene (20 ml) was refluxed for 5 h. The reaction mixture was concentrated in vacuo, and the pyrolysate was chromatographed on silica gel to give 80 mg (16%) of **8a** and 0.23 g (44%) of **8b** (each from benzene elution), together with 10 mg of a mixture of 2-phenyl-3-phenylsulfonyl-6-(*p*-tolylsulfonyl)- (**14**) and 2-phenyl-6-phenylsulfonyl-3-(*p*-tolylsulfonyl)pyridine (**15**) (each Ar=*p*-MeC_6H_4) (from chloroform elution) whose ratio was not determined.

In the thermolysis of the 7-(*p*-chlorophenylsulfonyl)-4-phenylsulfonyl-1,2-diazocine (**3e**) under similar thermolytic conditions, two benzoylpyridines, **8a** and **8c**, were obtained accompanied by small amounts of a mixture of two the corresponding 3,6-bis(arylsulfonyl)-2-phenylpyridines, **14** and **15** (Ar=*p*-ClC_6H_4). whose ratio was not determined (See Scheme 4).

Thermolysis of the 4-Phenylsulfonyl-7-phenylthio-1,2-diazocine (6). A solution of **6** (0.6 g, 1.2 mmol) in dry xylene (20 ml) was refluxed for 5 h. Similar work-up and chromatography (silica gel, benzene) of the pyrolysate gave 60 mg (49%) of benzonitrile, 0.3 g (63%) of 2-phenyl-6-phenylsulfonyl-3-phenylthiopyridine (**16**), and 0.1 g (23%) of 6-benzoyl-2-phenyl-3-phenylthiopyridine (**17**), mp 120—121 °C (lit,[4] mp 120—121 °C). The pyridine **16** was converted into 6-methoxy-2-phenyl-3-phenylthiopyridine (**18**), mp 68—69 °C (lit,[4] mp 68—69 °C).

16: Mp 143—145 °C; colorless prisms; ^1H NMR ($CDCl_3$) δ=7.1—8.3 (m, PyH and ArH); MS *m/z* 399 (M^+-SO_2). Found: C, 68.17; H, 4.15; N, 3.67%. Calcd for $C_{23}H_{17}NO_2S_2$: C, 68.46; H, 4.25; N, 3.47%.

(Received July 25, 1986)

Photoirradiation of coumarin and tetrachloroethylene with a high-pressure mercury lamp through Pyrex filter in the presence of benzene and benzophenone gave cross cycloadduct (**3**) in a moderate yield. By treatment with bases or nucleophiles at room temperature, **3** underwent ring-contraction reaction through lactone-opening, cyclobutene formation, and intramolecular S_N2' displacement to yield dichlorocyclobuta[*b*]-benzofurancarboxylic derivatives exclusively. By use of a non-nucleophilic base, 3-(trichloroethenyl)coumarin was alternatively obtained through [2+2] cycloreversion of cyclobutene intermediate in a good yield.

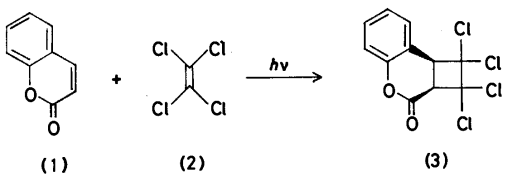
[2+2] Photocycloadducts of olefins occasionally have particular reactivities based on their strain arisen from the highly restricted geometry. For example, we have reported the highly enhanced reactivities of coumarin dimers and their lactone-opened derivatives,[2)] and their application to polymer synthesis and polymer reaction.[3)] Our continuing studies on [2+2] photocycloadducts led us to investigate the reaction of the compounds having dissymmetrical structures. Recently, we carried out cross photocycloaddition reaction of coumarin (**1**) and tetrachloroethylene (**2**) with an expectation that cyclobutane-fused pyrone compounds would undergo easily lactone-opening reaction to lead some attractive reactions such as ring-expansion and rearrangement.[4)] The reaction of the obtained cross photocycloadduct, 1,1,2,2-tetrachloro-1α,2α,2aα,8bα-tetrahydro-3*H*-cyclobuta[*c*][1]benzopyran-3-one (**3**), with nucleophiles or bases resulted in the ring-contraction or cycloreversion to give two types of compounds. One is dichlorocyclobuta[*b*]benzofuran-2a-carboxylic derivatives (**6**), which would be yielded via lactone-opening, cyclobutene formation, and intramolecular S_N2' displacement. The other is 3-(trichloroethenyl)coumarin (**9**) obtained by cycloreversion of the cyclobutene intermediate.

In this paper, we wish to report these reactions in detail with the X-ray structural analysis of the new type of compound having 4,5,6-fused ring system.

Results and Discussion

The cross photocycloaddition between coumarin (**1**) and tetrachloroethylene (**2**) was undertaken by irradiation with the light of a high-pressure mercury lamp. When the irradiation was carried out in the absence of benzene, the photoreaction did not proceed at all. Moreover, when benzophenone was not present, the formation of homodimers of coumarin, anti head-to-head, anti head-to-tail, and syn head-to-head coumarin dimers, overcame the production of cross cycloadduct (**3**). Accordingly, for the synthesis of **3** in a high yield, presence of both benzene and benzophenone was proved to be essential. Under the optimum conditions, 52% conversion to **3** and 39% isolated yield were achieved (Scheme 1).

Treatment of **3** with methanol at room temperature gave simply lactone-opened derivative **4a** as a sole product (Run 1), which would be obtained in analogy with the lactone-opening reaction of coumarin dimers.[2a)] When the reaction was undertaken at reflux temperature, cyclobutene compound **5a** and 3-(trichloroethenyl)coumarin (**9**) were formed (Runs 2 and 3). Though easy relactonization of cyclobutanecarboxylate **4a** to lactone **3** on heating or under acidic conditions such as contact with silica gel disturbed the isolation, the formation of **4a** was ascertained by ^{1}H and ^{13}C NMR spectra of the reaction mixture, which showed two doublets of cyclobutane ring protons [δ=4.49 and 4.89 (J=10 Hz), in $CDCl_3$] and four peaks of cyclobutane ring carbons [δ=51.9 (d), 59.0 (d), 89.2 (s), and 93.0 (s), in $CDCl_3$], together with other peaks appearing in the reasonable regions for **4a**. Isolation of cyclobutenecarboxylate **5a** was also unsuccessful, because of the spontaneous transformation to trichloroethenylcoumarin (**9**). The formation of **5a** was also confirmed by the ^{1}H NMR spectrum of the reaction mixture, which showed singlet for methoxyl protons (3H) at δ=3.81, singlet for cyclobutene ring proton (1H) at δ=5.07, and multiplet for aromatic protons



Scheme 1.

(4H) at δ=6.75—6.95.

However, when butylamine or an alkali was used, two types of compounds (**5** and **6**) were obtained in the ratio depending on the basicity and/or the amount of the nucleophile used. Simply lactone-opened derivatives **4b**, **4c** were not detected. This result indicates that in the reaction of **3** with butylamine or an alkali, lactone-opening reaction initially took place to produce cyclobutanecarboxylic derivatives **4**, followed by immediate dehydrochlorination reaction yielding cyclobutenes **5**, and finally intramolecular S_N2' displacement occurred by the attack of the phenolate anion on the sp^2 carbon of the cyclobutene ring.

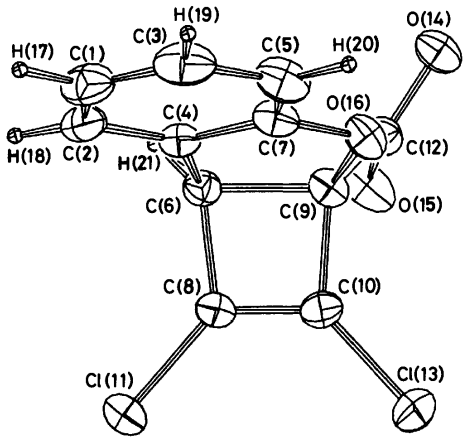


Fig. 1. Perspective view of cyclobutabenzofurancarboxylic acid (**6c**) drawn by ORTEP[12] program. Atoms (except hydrogen) are shown by ellipsoids of 30% probability.

The intramolecular S_N2' displacement for ring closure was more influenced by the basicity of the nucleophile than the cyclobutene formation (Runs 5—11). The reaction mentioned above resulted finally in an almost quantitative contraction of the cyclobutenefused benzofuran systems (Runs 7, 9, and 11).

Reactions of **3** with nucleophiles or bases are summarized in Table 1.

The structures of these compounds were determined by ^1H and ^{13}C NMR spectra, IR spectra, and elemental analyses. The structure of cyclobutabenzofurancarboxylic acid (**6c**) was confirmed by X-ray analysis. The perspective view is shown in Fig. 1, and the atomic coordinates, the bond lengths, and the bond angles are shown in Tables 2—4.

As methanol has not enough basicity, in the reaction with **3** at room temperature methanol did not act other than a weak nucleophile and there existed an equilibrium between lactone-opened and -closed compounds. Then a mixture of lactone **3** and ester **4a** was obtained. But when the reaction mixture was heated at methanol reflux temperature, thermal dehydrochlorination of cyclobutanecarboxylate **4a** would occur to give cyclobutenecarboxylate **5a**. At such high temperature, by further [2+2] cycloreversion the plausible intermediate, methyl *cis*-3-(2-hydroxyphenyl)-2-(trichloroethenyl)-2-propenoate (**7a**), would be gradually formed from **5a**. Then, **7a** should smoothly undergo thermal or acid-catalyzed relactonization to give trichloroethenylcoumarin (**9**) without formation of cyclobutabenzofuran **6a**, because methanol cannot produce phenolate anion from

phenolic hydroxyl group.

The exclusive formation of **9** was performed by treatment of **3** with triethylamine. As triethylamine has not nucleophilicity, the six-membered lactone-ring should be maintained all over the reaction steps. Then, by dehydrochlorination plausible 6,6,4-fused ring intermediate **8**, which is considered to be very unstable because of its highly restricted structure, would be formed, and immediate cycloreversion to **9** should exclusively proceed in a similar manner to the dehydrochlorination and cyclocleavage reactions of the photoadduct of cyclohexanone and dichloroethylene.[5]

On the contrary, the reaction path from cyclobutenecarboxylate **5a** to **9** via cyclobutene **8** seems unsuitable, since heating *N*-butylcyclobutenecarboxamide (**5b**) in benzene afforded **9** exclusively. The spontaneous lactonization of *cis*-cinnamamide derivative **7b** is reasonable, but the formation of very unstable 6,6,4-fused ring compound (**8**) together with cleavage of amide linkage looks very disadvantageous, and under such drastic conditions [2+2] cycloreversion of cyclobutene **5b** to diene **7** must proceed far rapidly.

The overall feature of these reactions is summarized in Scheme 2.

By the reactions mentioned above, cyclobutenecarboxylic derivatives fused benzofuran ring (**6**) were readily obtained through three sequential stepwise

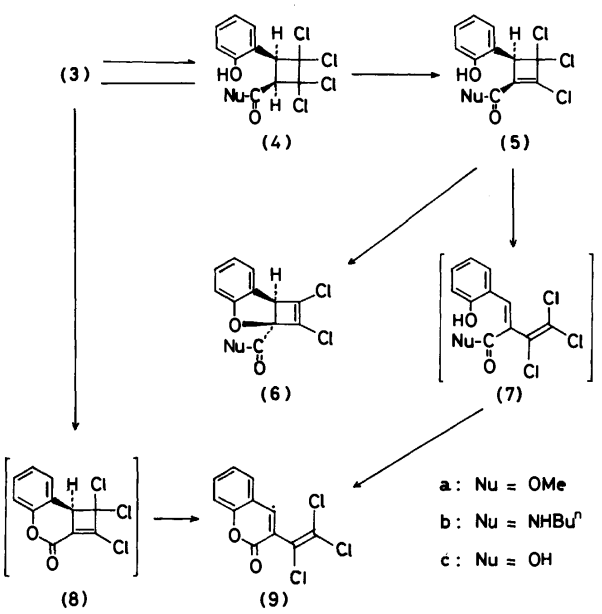

Scheme 2.

reactions, and trichloroethenyl lactone (**9**) was easily prepared by dehydrochlorination and cycloreversion. In addition, both of these reactions proceeded under very mild conditions with high yields. The syntheses of cyclobutene-fused benzofuran systems were reported by Tinnemans and Neckers[6] along with a large number of reports about the 4,5,6-fused ring systems of nitrogen and sulfur analogues.[7] According to their method the cyclobutene-fused benzofurans were synthesized by the cross photocycloaddition between benzofurans and an alkyne, but initial photoadducts easily underwent photoisomerization, resulting in the formation of complicated mixtures of the rearranged isomers. By contrast, cyclobutabenzofurans **6b**, **6c** were formed exclusively from cyclobuta[1]benzopyran-3-one **3**, which was readily prepared as a pure material in an adequate yield. In addition, compared to the related nucleophilic and/or thermal ring transformation reactions of pyrone derivatives to give furans,[8] the ring contraction of **3** proceeded under mild conditions even when butylamine was used as a nucleophile at room temperature. For the occurrence of this ring contraction, the ring-opening reaction must occur before dehydrochlorination, and the S_N2' displacement must proceed much faster than the [2+2] cycloreversion. If either reaction is slow, a considerable amount of trichloroethenylcoumarin (**9**) would be formed. Thus, this result clearly shows the highly enhanced ring-opening tendency of the lactone ring of cross cycloadduct **3**. This high reactivity is considered to be attributed to the strain of the lactone rings which is brought about by cyclobutanation. Although under such weakly basic conditions, the equilibrium between the phenolic hydroxyl group and the phenolate anion does not favor the phenolate anion; the neighboring group effect. should permit the nucleophilic attack of the phenolate anion to proceed so rapid that it competes effectively with the thermal cycloreversion.

Experimental

All melting points were measured on a MELTEMP micro melting point apparatus and are uncorrected. IR and NMR spectra were recorded on a JASCO IR-810 spectrophotometer and JEOL GX-400 nuclear magnetic spectrometric instrument, respectively. Photoirradiation was undertaken with an Eiko-sha EHB-WI(F)-500 high-pressure mercury lamp (500 W).

All the reagents and solvents were purified by the methods described in the literature.[9] Anti head-to-head, anti head-to-tail, and syn head-to-head coumarin dimers were prepared according to the methods described in the literature,[10] and used as authentic samples for the identification and the quantification of the photoproducts by ^{1}H NMR spectroscopy.

Unless specified otherwise, the following experimental conditions were used. The reactions were carried out under an argon atmosphere. The extracts were washed with saturated aqueous sodium chloride before drying. The solution was dried overnight and the desiccant was removed by filtration. The solvents were taken off on a flash evaporator at the temperature below 10 °C. The conversions were determined by ^{1}H NMR spectrum of the reaction mixture in $CDCl_3$. Separations of the products by column chromatography were carried out using silica gel (Wako-gel C-200, 100—200 mesh). The chemical shifts in ^{1}H and ^{13}C NMR spectra were referred to tetramethylsilane (TMS) signals.

Synthesis of 1,1,2,2-Tetrachloro-1α,2α,2aα,8bβ-tetrahydro-3*H*-cyclobuta[*c*][1]benzopyran-3-one (3): 14.54 g (0.10 mol) of coumarin (**1**) and 3.14 g (0.017 mol) of benzophenone were dissolved in a mixture of tetrachloroethylene (**2**) (633.6 g, 3.82 mol) and benzene (36.0 g). The solution was irradiated with the 500 W high-pressure mercury lamp through Pyrex filter for 28.5 h. On the basis of ^{1}H NMR spectrum of the reaction mixture, 42% of **1** was found to convert to **3**, accompanying 13% of anti head-to-head coumarin dimer and a trace amount (less than 0.5%) of syn head-to-head coumarin dimer. No other product could be detected. After concentration of the reaction mixture under reduced pressure, silica-gel column chromatographic separation using benzene as an eluant gave 9.52 g (30.5%) of **3**: Mp 144—145 °C; IR (KBr) 1770 (C=O), 930 (cyclobutane), 820, 805, 775, 745, 700 cm^{-1}; ^{1}H NMR (400 MHz $CDCl_3$) δ=4.22 (1H, d, J=10 Hz, cyclobutane ring proton), 4.59 (1H, d, J=10 Hz, cyclobutane ring proton), 7.07—7.43 (4H, m, aromatic protons); ^{13}C NMR (100 MHz $CDCl_3$) δ=50.7 (d), 50.8 (d), 89.8 (s), 93.9 (s), 114.3 (s), 117.5 (d), 125.2 (d), 129.5 (d), 131.0 (d), 151.6 (s), 158.9 (s); Found: C, 42.23; H, 2.06; Cl, 45.04%. Calcd for $C_{11}H_6Cl_4O_2$: C, 42.35; H, 1.93; Cl, 45.46%.

When 7.27 g (50 mmol) of coumarin (**1**) was irradiated for 141 h under same conditions described above, 39% (5.97 g) of **3** was obtained (conversion was 52%).

Reaction of Cross Adduct (3) with Methanol at Room Temperature: A solution of **3** (156 mg, 0.5 mmol) in methanol (100 ml) was stirred for 240 h at room temperature,

followed by evaporation of excess methanol. The ^{1}H NMR spectrum of the residue thus obtained in $CDCl_3$ showed a singlet of methoxyl protons (δ=3.83, 3H), two doublets of cyclobutane ring protons (δ=4.49 and 4.89, each 1H, J=10 Hz), and a multiplet for aromatic ring protons (δ=6.70—7.30, 4H) together with the peaks of **3**. In its ^{13}C NMR spectrum in $CDCl_3$, four carbons of cyclobutane ring [δ=51.9 (d), 59.0 (d), 89.2 (s), and 93.0 (s)], a methoxyl carbon [δ=51.8 (q)], aromatic carbons [δ=115.1 (d), 119.9 (s), 120.2 (d), 128.7 (d), 128.8 (d), and 153.5 (s)], and a carbonyl carbon [166.6 (s)] were observed. These NMR data were consistent with the structure of methyl 2,2,3,3-tetrachloro-*c*-4-(2-hydroxyphenyl)-*r*-1-cyclobutanecarboxylate (**4a**). Based on the integration intensities in the ^{1}H NMR spectrum, content of ester **4a** was calculated to be 52% and that of **3** to be 48%. But isolation of **4a** was unsuccessful since relactonization took place easily on silica-gel column or on standing at room temperature.

Reaction of Cross Cycloadduct (3) with Methanol at Reflux Temperature: **3** (156 mg, 0.5 mmol) was dissolved in methanol (70 ml) at room temperature, and the solution was stirred for 60 h at reflux temperature. The solution was concentrated under reduced pressure to yield a solid. On the basis of the ^{1}H NMR spectrum of the solid thus obtained, it was confirmed that 21% of **3** converted to cyclobutanecarboxylate **4a**, 12% to cyclobutenecarboxylate **5a**, and 19% to trichloroethenylcoumarin (**9**). Chromatography on silica gel using benzene as an eluant afforded **5a** (20 mg, 14%), along with a mixture of starting material (**3**) and **9**. Data for cyclobutene **5a**; ^{1}H NMR ($CDCl_3$) δ=3.81 (3H, s, OMe), 5.07 (1H, s, cyclobutene ring proton), and 6.75—6.95 (4H, m, aromatic protons). On silica-gel column, **4a** was considered to be decomposed to **5a** or lactone **3**, and resulted cyclobutenecarboxylate **5a** was also very unstable and spontaneously decomposed to **9** on standing at room temperature. So elemental analysis and measurement of mp were unsuccessful.

***N*-Butyl-2,3,3-trichloro-4-(2-hydroxyphenyl)-1-cyclobutenecarboxamide (5b):** Butylamine (73 mg, 1.0 mmol) was added to a stirred acetone solution (10 ml) of **3** (156 mg, 0.5 mmol) at room temperature. After stirring for 1 h, the solution was poured into 1 M† HCl (20 ml), and extracted with benzene (50 ml×3). The extracts were combined, dried ($MgSO_4$), and concentrated to leave viscous liquid, which was washed with chloroform (10 ml×3) to give cyclobutenecarboxamide **5b** (116 mg, 67%): glass; IR (KBr) 1655 (amide I), 1530 (amide II), 760, 595 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.95 [3H, t, J=7.5 Hz, $(CH_2)_3CH_3$], 1.20—1.80 (4H, m, $CH_2CH_2CH_2CH_3$), 3.29—3.50 [2H, m, $NCH_2(CH_2)_2CH_3$], 5.15 (s, 1H, cyclobutene ring proton), 6.14 (1H, br s, NH), 6.60—7.25 (4H, m, aromatic protons), 7.96 (1H, br s, ArOH); ^{13}C NMR ($CDCl_3$) δ=13.7 (q), 20.0 (t), 31.3 (t), 39.5 (t), 59.3 (d), 84.5 (s), 115.3 (d), 119.6 (d), 120.5 (s), 128.3 (d), 129.8 (d), 134.3 (s), 134.8 (s), 155.2 (s), 160.0 (s); Elemental analysis was unsuccessful since cyclobutene **5b** was transformed to trichloroethenylcoumarin (**9**) on a silica-gel column.

2,3,3-Trichloro-4-(2-hydroxyphenyl)-1-cyclobutenecarboxylic Acid (5c): To a stirred solution of **3** (156 mg, 0.5 mmol) in acetone (10 ml), 10 ml of sodium hydrogencarbonate (1 M) was added at room temperature. After stirring at room temperature for 42 h, the reaction mixture was poured into 15 ml of 1 M HCl and extracted with benzene (50 ml×3). The extracts were combined, dried ($MgSO_4$), and concentrated to yield a white powder, which was washed with chloroform (10 ml×3) to give cyclobutenecarboxylic acid (**5c**) (46 mg, 31%): mp 132°C (decomp.); IR (KBr) 1705 (C=O), 885, 740, 600 cm^{-1}; ^{1}H NMR [$(CD_3)_2SO$] δ=4.97 (1H, s, cyclobutene ring proton), 6.67—6.90 (3H, m, aromatic protons), 7.15—7.20 (1H, m, aromatic proton), 9.89 (1H, s, NH), 13.8 (1H, br s, CO_2H); ^{13}C NMR [$(CD_3)_2CO$] δ=60.8 (d), 85.9 (s), 115.9 (d), 120.2 (d), 122.1 (s), 129.6 (d), 130.5 (d), 133.8 (s), 140.3 (s), 156.9 (s), and 161.2 (s); Elemental analysis was unsuccessful because cyclobutenecarboxylic acid (**5c**) was transformed to **9** on a silica-gel column.

***N*-Butyl-1,2-Dichloro-2aα,7bα-dihydrocyclobuta[*b*]benzofuran-2a-carboxamide (6b):** Butylamine (365 mg, 5.0 mmol) was added to a stirred acetone solution (10 ml) of **3** (156 mg, 0.5 mmol) at room temperature. After stirring for 1.5 h, the solution was poured into 1 M HCl (7.5 ml), and extracted with benzene (50 ml×3). The extracts were combined, dried ($MgSO_4$), and concentrated to give a white solid. The crude product was recrystallized from hexane to give cyclobutabenzofurancarboxamide (**6b**) as needles (150 mg, 96%): Mp 94—95°C; IR (KBr) 1665 (amide I), 1555 (amide II), 875, 740, 635 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.94 (3H, t, J=7.5 Hz, $(CH_2)_3CH_3$), 1.31—1.41 (2H, m, $CH_2CH_2CH_2CH_3$), 1.50—1.60 (2H, m, $CH_2CH_2CH_2CH_3$), 3.26—3.36 (1H, m, $CH_2CH_2CH_2CH_3$), 3.38—3.48 (1H, m, $CH_2CH_2CH_2CH_3$), 4.62 (1H, s, cyclobutene ring proton), 6.68 (1H, br s, NH), 6.96—7.06 (2H, m, aromatic protons), 7.26—7.34 (2H, m, aromatic protons); ^{13}C NMR ($CDCl_3$) δ=13.7 (q), 20.0 (t), 31.5 (t), 39.4 (t), 58.9 (d), 91.4 (s), 112.3 (d), 122.4 (d), 124.4 (s), 124.6 (s), 125.2 (d), 129.8 (d), 136.7 (s), 161.1 (s), 165.1 (s); Found: C, 57.43; H, 4.74; N, 4.53; Cl, 22.71%. Calcd for $C_{15}H_{15}Cl_2NO_2$: C, 57.71; H, 4.84; N, 4.49; Cl, 22.71%.

1,2-Dichloro-2aα,7aα-dihydrocyclobuta[*b*]benzofuran-2a-carboxylic Acid (6c): To a stirred methanol solution (50 ml) of **3** (189 mg, 0.61 mmol) aqueous sodium hydroxide (1 M, 6.1 ml) was added at room temperature. After stirring for 1 h at room temperature, the solution was poured into 1 M HCl (20 ml), and extracted with benzene (50 ml×3). The extracts were combined, dried ($MgSO_4$), and concentrated under reduced pressure, and the residue was recrystallized from benzene-hexane to afford white blocks of cyclobutabenzofurancarboxylic acid (**6c**) (140 mg, 90%): Mp 144°C (decomp); IR (KBr) 1730, 1700 (C=O and cyclobutene), 750 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=4.66 (1H, s, cyclobutene ring proton), 6.98—7.04 (2H, m, aromatic protons), 7.24—7.30 (2H, m, aromatic protons), 9.46 (1H, s, CO_2H); ^{13}C NMR ($CDCl_3$) δ=60.27 (d), 89.8 (s), 113.3 (d), 123.0 (d), 124.7 (s), 125.0 (s), 125.8 (d), 130.9 (d), 138.3 (s), 162.1 (s), 172.5 (s); Found: C, 51.53; H, 2.50; Cl, 26.99%. Calcd for $C_{11}H_6O_3Cl_2$: C, 51.39; H, 2.35; Cl, 27.58%.

3-(Trichloroethenyl)coumarin (9): Triethylamine (730 mg, 7.2 mmol) was added to a stirred benzene solution (20 ml) of **3** (50 mg, 0.16 mmol) at room temperature. After stirring at room temperature for 15 min, reaction mixture was poured into 1 M HCl (40 ml) and extracted with benzene (50 ml×3). The extracts were combined, dried ($MgSO_4$), and concentrated under reduced pressure to leave a white solid (39.4 mg), which was purified on a silica-gel column using

† 1 M=1 mol dm^{-3}.

benzene as an eluant to give pure **9** as white powder (36.2 mg, 82%). Recrystallization from hexane gave needles: Mp 129—130 °C; IR (KBr) 1725, 1700 (pyrone ring), 890, 815, 770 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.32—7.40 (2H, m, aromatic protons), 7.54—7.65 (2H, m, aromatic protons), 7.87 (1H, s, olefinic proton); ^{13}C NMR ($CDCl_3$) δ=117.6 (d), 118.9 (s), 124.2 (s), 124.6 (s), 124.7 (s), 125.6 (d), 129.3 (d), 133.9 (d), 145.4 (d), 154.8 (s), 158.0 (s); Found: C, 47.78; H, 1.98; Cl, 38.64%. Calcd for $C_{11}H_5Cl_3O_2$: C, 47.95; H, 1.83; Cl, 38.60%.

Crystallographic Measurement of Cyclobutabenzofurancarboxylic Acid (6c): Crystal Data. $C_{11}H_6Cl_2O_3$, M=257.1. Monoclinic, a=18.814(10), b=6.688(5), c=8.825(5) Å, β=92.38(5)°, V=1109 Å^3, space group $P2_1/n$, Z=4, D_x=1.538 g cm^{-3}, μ for Cu $K\alpha$=52.9 cm^{-1}.

The crystal of approximate dimensions 0.25×0.20×0.35 mm was mounted on a Philips PW1100 diffractometer and the integrated intensities were measured by a 2θ—θ scan method using graphite monochromated Cu $K\alpha$ radiation. 2042 Independent reflections were measured as above the 2σ(I) level out of 2542 theoretically possible ones in the 2θ range 6° through 156°. The intensities were corrected for Lorentz and polarization factors but not for absorption.

The crystal structure was determined by the direct method[11] and refined by the block-diagonal-matrix least-squares calculations. The R value was reduced to 0.067 for 2042 observed structure factors including 5 hydrogen atoms which were located on a difference electron-density map and assessed isotropic temperature factors. The carboxyl group may be protonated at O(15) since C(12)-O(15) is longer than C(12)-O(14) and C(9)-C(12)-O(15) is quite smaller than C(9)-C(12)-O(14), but this hydrogen atom was not found in the difference map.

The complete F_o—F_c data are deposited as Document No. 8715 at the Office of the Editor of Bull. Chem. Soc. Jpn.

Syntheses of 23-C-Substituted Derivatives of Mycaminosyl Tylonolide and 4′-Deoxymycaminosyl Tylonolide[1)]

Shuichi SAKAMOTO, Norio KAJIKAWA, Tsutomu TSUCHIYA,* and Sumio UMEZAWA
Institute of Bioorganic Chemistry, 1614 Ida, Nakahara-ku, Kawasaki 211
(Received July 26, 1986)

23-C-Substituted derivatives of mycaminosyl tylonolide (MT) and 4′-deoxymycaminosyl tylonolide (DT) have been prepared by the reaction of protected 23-aldehyde derivatives, 2′,4′-di-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-23-deoxy-23-oxomycaminosyl tylonolide diethyl acetal (**5**) and 2′-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-23,4′-dideoxy-23-oxomycaminosyl tylonolide diethyl acetal (**26**), with several Grignard reagents and methyllithium. The final products were (23*S*)- and (23*R*)-23-C-methyl (**13a, 13b**), -ethyl (**14a, 14b**), -butyl (**15a, 15b**), -phenyl (**16b, 16a**), -allyl (**17a, 17b**), -vinyl (**18a, 18b**), -ethynyl (**19b, 19a**) derivatives of MT, and (23*S*)- and (23*R*)-23-C-methyl (**28a, 28b**), -vinyl (**29a, 29b**), and -ethynyl (**30b, 30a**) derivatives of DT. Their configurations at 23-position were determined by the NOE difference spectroscopy on **13a** and **13b**.

As previously reported,[2)] 23-dialkylamino-23-deoxymycaminosyl tylonolides and their 4′-deoxy analogs had considerable antibacterial activities against both Gram-positive and -negative bacteria. Since, generally, macrolide antibiotics are active only against Gram-positive bacteria, the species of the substituents at C-23 of mycaminosyl tylonolides seem important in terms of antibacterial spectrum. This prompted us to modify the substituents at C-23 with new ones. This paper describes[1)] the syntheses of 23-C-alkyl and 23-C-aryl derivatives of mycaminosyl tylonolide (MT) and 4′-deoxymycaminosyl tylonolide[3)] (DT) by way of the C-23- aldehyde intermediates.

2′,4′-Di-*O*-acetylmycaminosyl tylonolide diethyl acetal[3)] (**1**) was treated with *t*-butylchlorodimethylsilane in the presence of imidazole in *N*,*N*-dimethylformamide (DMF), whereupon the 3,23-di-*O*-silyl derivative (**2**) was obtained almost quantitatively with slight amount of 23-*O*-silyl derivative **3**. Selective removal of the 23-*O*-silyl group of **2** was carried out by treatment with tetrabutylammonium fluoride in oxolane. The *O*-silyl protection proved to be superior to *O*-tetrahydrofuranylation, -tetrahydropyranylation, or -methoxymethylation, because the 3,23-di(acetal) derivatives prepared were difficult to remove selectively their 23-*O*-protecting groups. Oxidation of the resulting 23-hydroxy compound **4** was examined with several reagents; pyridinium chlorochromate (PCC) oxidized the dimethylamino group in addition to the 23-hydroxyl group, dimethyl sulfoxide (DMSO)–acetic anhydride gave a large amount of 23-*O*-(methylthiomethyl) by-product, DMSO-$(COCl)_2$ in the presence of triethylamine (Swern oxidation) gave a large amount of open-macrolactone compound **6**, and only DMSO–dicyclohexylcarbodiimide (DCC) in

TBS: *t*-butyldimethylsilyl

the presence of pyridinium trifluoroacetate gave the desired product **5** in high yield with slight **6**. The isolated **5** was unstable and readily converted to **6** by β-elimination in the presence of base such as triethylamine or its own basicity caused by 3′-dimethylamino group. The ^{1}H-NMR spectrum of **6** showed, by the decoupling method, that **6** had a new double bond between C-14 and C-15, and was a mixture of two geometrical isomers (the ratio being changed between 2:3—2:1 depending upon the slight change in experimental conditions; but the cause was not pursued). Methylation of **6** with diazomethane gave the corresponding esters **7a** and **7b** proving the presence of a carboxylic acid in **6**.

We next tried to prepare the unprotected 23-oxo derivative (**10**) of MT from **5**. De-*O*-acetylation of **5** in an usual manner[3] (in methanol, 50 °C, 24 h), however, gave the desired de-*O*-acetyl derivative (**9**) in only low yield, possibly by the presence of the unstable 23-aldehyde group. We therefore converted **4** to the 3-*O*-silyl-2′,4′-diol (**8**) which was oxidized by the DMSO–DCC method as described above to afford the 23-oxo derivative (**9**) in a moderate yield (50%). Removal of the acetal and 3-*O*-silyl protecting groups with 5% hydrofluoric acid in acetonitrile gave the 23-oxo compound **10** in a low yield. Efforts to improve the yield were unsuccessful. The presence of two aldehyde groups in **10** was proved by the ^{1}H-NMR spectrum, the signal of the new 23-CHO proton being appeared at δ 9.69.

Methylation of **5** with methylmagnesium bromide in oxolane gave the two 23-C-methyl derivatives (*S* and *R*) in low yields with several by-products including the reduction product **4**; formation of this kind of reduction product **4** sometimes occurs in the reaction with the Grignard reagent. The low yields of the methyl products **11a**, **11b** may be resulted from the partial reaction of the carbonyl group at C-9 of **5** with the Grignard reagent as well as opening of the macrolactone ring during the reaction. In the ^{1}H-NMR spectra, the major product **11a** showed new methyl signals (doublet) at δ 1.12, and the minor (**11b**), at δ 1.22. Since **4** was produced from **5** with limited amount of sodium cyanotrihydroborate, the same R-configuration[4,5] at C-14 of **11a,b** with that of MT was concluded. This was supported by the ^{1}H-NMR spectra of **11a** and **11b**, in that both $J_{13,14}$ and $J_{14,15}$ showed, respectively, almost identical values with those of MT.[5] When **5** was methylated with methyllithium in ether, **11a** was obtained in a better yield. Methanolysis of **11a** and **11b** gave the deacetyl derivatives (**12a** and **12b**), which were led, by deblocking with hydrochloric acid in acetonitrile, to the final 23-C-methyl products **13a**, **13b**.

In the ^{1}H-NMR spectra of **13a** and **13b**, the signals of Me-24 appeared at δ 1.15 and 1.24 (each doublet), respectively, and the methyl configurations were determined by the NOE difference spectroscopy[6] (Fig. 1). Irradiation at δ 1.15 (Me-24) of **13a** caused pronounced positive signal enhancements of H-13, -14, and -23 (the signals of H-5′ were also slightly enhanced possibly by the simultaneous irradiation of Me-6′), whereas irradiation at δ 1.24 (Me-24; Me-21 and Me-6′ were also irradiated simultaneously inevitably) of **13b** caused similar enhancements of H-13, -15, and -23, as well as those of H-10 and 5′. The sharp difference between **13a** and **13b** was that **13a** gave enhancement of H-14, and **13b**, H-15. To satisfy the above result on **13a**, the Me-24 should come stereochemically to the position to bisect the projection angle formed by the C(13)–C(14) and C(14)–H(14) sides (Fig. 1). On the other hand, the small value of $J_{14,23}$(=2 Hz) indicates that H-23 should take gauche (not antiperiplanar) position with respect

* Absolute configuration at C-23 by Cahn-Ingold-Prelog specifications.

to H-14 (the projection angle of H(14)-C(14)-C(23)-H(23) should be 68° according to a literature[7]). This conclusion was also supported by another NOE experiment: irradiation of H-23 of **13a** caused positive signal enhancement only of H-14 (12.6%). These results indicate that the absolute configuration at C-23 of **13a** is *S*. In the case of **13b**, the Me-24 was concluded to take the position to bisect the projection angle formed by the C(13)-C(14) and C(14)-C(15) sides. Again from the $J_{14,23}$ value (=6 HZ), the gauche relationship between H-14 and H-23 is concluded (the projection angle of H(14)-C(14)-C(23)-H(23) should be 50°[7]). This conclusion was also supported by another NOE experiment: irradiation of H-23 of **13b** caused positive signal enhancements of H-14 (5%) and H-15 (8%). The absolute configuration at C-23 of **13b** is, therefore, determined to be *R*. Another aspect worthy to mention was that, in **13b**, NOE was observed (not clear in **13a**) between Me-21 and H-10, suggesting close spatial relationship between them.

Other 23-C-substituted derivatives of MT were prepared by treatment of **5** with several other Grignard reagents, that is, ethyl-, butyl-, phenyl-, allyl-, vinyl-, and ethynylmagnesium bromides. In all cases two

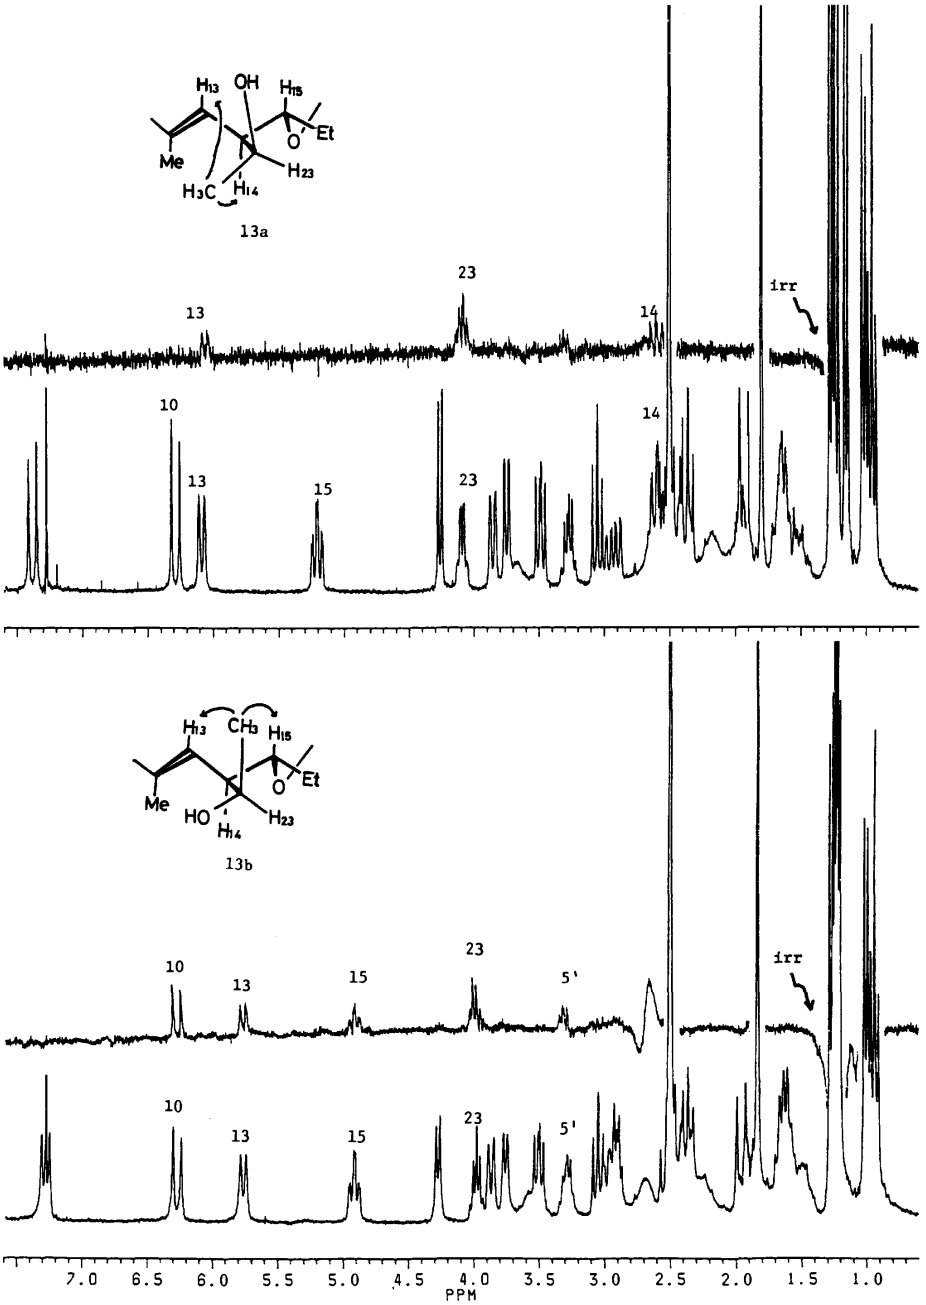

Fig. 1.

products, namely, (*S*)- and (*R*)-23-C-ethyl (**14a**, **14b**), (*S*)- and (*R*)-23-C-butyl (**15a**, **15b**), (*R*)- and (*S*)-23-C-phenyl (**16a**, **16b**), (*S*)- and (*R*)-23-C-allyl (**17a**, **17b**), (*S*)- and (*R*)-23-C-vinyl (**18a**, **18b**), and (*R*)- and (*S*)-23-C-ethynyl derivatives (**19a**, **19b**) of mycaminosyl tylonolide (MT) were produced with by-products accompanied. These products were purified by column chromatography, but with difficulty owing to their close mobilities between products and by-products. The faster-moving products (compounds attached "**a**" to the numbers) had, in all cases, small $J_{14,23}$ values (2—3 Hz) in their ^{1}H-NMR spectra, being the same with the value of **13a**, and the slower-moving (compounds attached "**b**" to the numbers), larger $J_{14,23}$ values (5.5—6.8 Hz), being the same with the value of **13b**. These data are shown in Table 1 with some chemical shifts. The absolute configurations at C-23 of the faster- and slower-moving products were, therefore, specified L and D, respectively, independent of the RS specifications by Cahn-Ingold-Prelog. The fact that L-isomers were always predominating except for the ethynyl derivatives (**19a**,**b**) will be reasonable from the Felkins model[8] describing the approach of the Grignard reagent to a carbonyl carbon (Fig. 2).

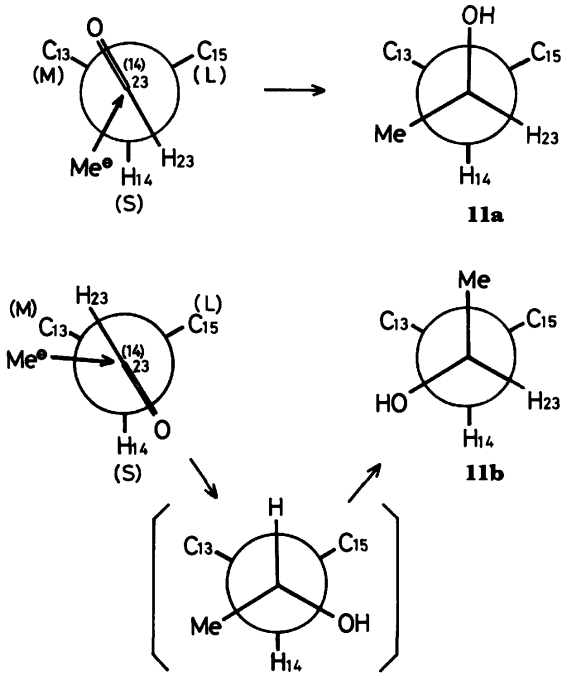

Fig. 2.

The 4′-deoxy analogs (DT-series) of the above MT-series having 23-C-methyl (**28a**,**b**), -vinyl (**29a**,**b**), and -ethynyl (**30a**,**b**) groups were next prepared. In order to remove the C-4′ hydroxyl group before 23-C-alkylation, **2** was solvolyzed with hot methanol, and the 2′,4′-diol (**20**) was treated with phenylmethanesulfonyl chloride. The 4′-*O*-benzylsulfonyl derivative (**21**) was then treated with sodium iodide in 2-butanone, and the 4′-iodo derivative (**22**) was reduced

a) Measured at room temperature; 50 °C for compounds MT, **15a** and **15b**. b) Abbreviations: all=allyl, vin=vinyl, and eth=ethynyl. c) Multiplicities of H-23 were dq (for 23-L products) and quintet (23-D products).

with tributylstannane to give the 4′-deoxy derivative (**23**). The above reaction sequence is fundamentally the same with the procedure previously reported.[3] Acetylation of **23** gave the 2′-*O*-acetyl-4′-deoxy derivative (**24**). The all-protected derivative was then subjected to the procedure described in the MT-series, that is, 23-de-*O*-silylation (to give **25**), oxidation (to give the 23-oxo derivative, **26**), alkylation with methylmagnesium bromide or the other Grignard reagents (to give **27a**, **27b**, and other 23-C-alkyl derivatives), and deblocking to give the final products (**28a,b**, **29a,b**, and **30a,b**). Elemental analyses of the products are shown in Table 2 with some other data.

Antibacterial spectra[1] of these products showed diverse activity results, but D-series products always had stronger activities than those of the corresponding L-isomers. Compound **10** showed markedly decreased antibacterial activity.

Experimental

General. Grignard reagents (MeMgBr, EtMgBr, *n*-BuMgBr, PhMgBr, AllylMgBr) were purchased from Tokyo Kasei Kogyo Co., Ltd., and methyllithium (1.5 M solution in diethyl ether 1 M=1 mol dm^{-3}), from Aldrich Chem. Co. Thin-layer chromatography (TLC) was carried out on kieselgel 60 F-254 silica gel (E. Merck) with detection by spraying with sulfuric acid, followed by slight heating. Column chromatography was performed on Wakogel C-200 or Kieselgel 60, 230—400 mesh (E. Merck). Optical rotations were measured with a Perkin-Elmer 241 polarimeter. ^{1}H-NMR spectra were recorded at 250 MHz at room temperature, unless otherwise stated, in the FT mode with a Bruker WM 250 spectrometer, or at 90 MHz with a Varian EM-390 spectrometer.

2′,4′-Di-*O*-acetyl-3,23-bis(*O*-*t*-butyldimethylsilyl)mycaminosyl Tylonolide Diethyl Acetal (2). To a mixture of **1**[3] (22.5 g) and imidazole (12.1 g) in dry *N*,*N*-dimethylformamide (23 ml) was added *t*-butylchlorodimethylsilane (22.4 g) and the solution was heated at 75 °C overnight. Evaporation with several additions of xylene gave a residue, that was extracted with benzene (2 L). The solution was washed with saturated aqueous sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid (29 g). The solid showed, on TLC with toluene–ethyl acetate (2:1), spots at R_f 0.7 (**2**), 0.65 (trace, **3**), and 0 (cf **1**: R_f=0.15). An analytical sample of **2** was prepared by silica-gel column chromatography with toluene–ethyl acetate (3:1), $[\alpha]_D^{22}$ −11° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04, 0.03, 0.04, and 0.17 (each 3H s, $SiMe_2$×2), 0.87 (18H s, Si-*t*Bu×2), 1.78 (3H s with slight splittings, Me-22), 2.06 and 2.07 (each 3H s Ac×2), 2.34 (6H s, NMe_2), 3.67 (2H, H-23a,b), 3.98 (1H sl. br d, $J_{2b,3}$[7] ≈6.5 Hz, H-3), 4.35 (1H br d, *J*≈7.5 Hz, H-1′), 4.75 (1H t, J=10 Hz, H-4′), 4.89 (1H dd, *J*=7.5 and 10 Hz, H-2′), 5.78 (1H d, $J_{13,14}$=10.5 Hz, H-13), 6.25 (1H d, $J_{10,11}$=15 Hz, H-10), 7.18 (1H d, H-11).

a) Based on **4** or **25** and after purification; the 23-L and 23-D products were, respectively, purified in the same manner; in **13b** and **14b**, however, the yields were estimated from the mixture of the product and MT owing to difficulty of separation.

AcX2), 2.34 (6H s, NMe_2), ≈3.68 (H-23a,b), 3.78 (1H dd, $J_{3,OH}$≈4.5, $J_{2b,3}$=10 Hz, H-3), 4.40 (1H d, J=7.5 Hz, H-1'), 4.77 (1H t, H-4'), 4.91 (1H dd, H-2'), 5.87 (1H d, H-13), 6.31 (1H d, H-10), 7.25 (1H d, H-11); Irradiation at δ 2.46 (dd, H-2b)[7] collapsed the double doublets of H-3 to a doublet.

Found: C, 62.22; H, 8.99; N, 1.42%. Calcd for $C_{45}H_{79}NO_{13}Si$: C, 62.14; H, 9.09; N, 1.61%.

2',4'-Di-*O*-acetyl-3-*O*-*t*-butyldimethylsilylmycaminosyl Tylonolide Diethyl Acetal (4). To an ice-cold solution of crude **2** (29 g) in oxolane (290 ml) was added a M solution (29.5 ml) of tetrabutylammonium fluoride (1 moler equivalent for **2**) in oxolane (the solution contained <5% of water, Aldrich Chem. Co., Wisconsin, U.S.A.), and the solution was kept at room temperature for 1 h. On cheking by TLC with toluene–ethyl acetate (1:1), the solution showed a major spot at R_f 0.45. Evaporation gave a residue, that was extracted with benzene (1 L). The organic solution was washed with saturated aqueous sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated. The residue was chromatographed on a silica-gel column with toluene–ethyl acetate (3:2) to give a solid of **4**, 19.7 g (72% from **1**); $[\alpha]_D^{22}$ −10° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.175 (each 3H s, $SiMe_2$), 0.87 (9H s, Si-*t*-Bu), 1.82 (3H, Me-22), 2.06 and 2.07 (each 3H s, AcX2), 2.34 (6H s, NMe_2), 3.98 (1H d, $J_{2b,3}$=7 Hz, H-3), 4.35 (1H br d, H-1'), 4.74 (1H t, H-4'), 4.89 (1H dd, H-2'), 5.74 (1H d, H-13), 6.28 (1H d, H-10), 7.18 (1H d, H-11).

Found: C, 62.35; H, 8.98; N, 1.53%. Calcd for $C_{45}H_{79}NO_{13}Si$: C, 62.14; H, 9.09; N, 1.61%.

2',4'-Di-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-23-deoxy-23-oxomycaminosyl Tylonolide Diethyl Acetal (5). A mixture of **4** (2.24 g), pyridinium trifluoroacetate (747 mg) and dicyclohexylcarbodiimide (2.13 g) in benzene–dimethyl sulfoxide (1:1, 45 ml) was stirred at room temperature overnight. Oxalic acid dihydrate (1.95 g) in 1,4-dioxane (22.5 ml) was added and the mixture was stirred for 30 min. The resulting precipitates were filtered off with aid of benzene, and the organic solution was concentrated. The residue was extracted with benzene and the solution was thoroughly washed with saturated aqueous sodium hydrogencarbonate (to remove dimethyl sulfoxide), saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated. The residue showed, on TLC with toluene–ethyl acetate (1:1), two spots at R_f 0.55 (**5**) and R_f 0.3 (minor, **6**). Column chromatography of the residue with toluene–ethyl acetate (2:1→1:1) gave solids of **5**, 1.93 g (86%) and **6**, 0.32 g (14%).

5: $[\alpha]_D^{22}$ −40° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.17 (each 3H s, $SiMe_2$), 0.88 (9H s, Si-*t*-Bu), 1.85 (3H, Me-22), 2.07 and 2.08 (each 3H s, AcX2), 2.36 (6H s, NMe_2), 3.57 (1H dt, H-14), 3.99 (1H d, H-3), 4.37 (1H d, H-1'), 4.75 (1H t, H-4'), 4.89 (1H dd, H-2'), 5.25 (1H dt, H-15), 5.77 (1H d, H-13), 6.33 (1H d, H-10), 7.18 (1H d, H-11), 9.67 (1H d, H-23); $J_{2b,3}$=7,5, $J_{10,11}$=16, $J_{13,14}$=10, $J_{14,15}$=9, $J_{14,23}$=3.8, $J_{15,16a}$=9.5, $J_{15,16b}$=2.5, $J_{1',2'}$=7.5 Hz. Irradiation of H-14 collapsed the double triplets of H-15 to a broadened doublet, and the doublets of H-13 and H-23 to a singlet, respectively. Irradiation of H-23 collapsed the double triplets of H-14 to a triplet.

Found: C, 62.24; H, 8.77; N, 1.49%. Calcd for $C_{45}H_{77}NO_{13}Si$: C, 62.28; H, 8.88; N, 1.61%.

6: $[\alpha]_D^{25}$ −32° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$; the ratio of the components of **6** changed (A/B=2/1—2/3) depending on the experimental conditions, on which no study was carried out): δ=0.06 (for A/2) and 0.09 (A/2 +B) (6H in total, each s, $SiMe_2$), 0.90 (9H d, Si-*t*-Bu), 1.25(B) and 1.69(A) (3H in total, each s with small splittings, Me-22), 2.06 (6H s, AcX2), 2.34 (6H s, NMe_2), ≈2.3 (H-16), ≈2.5 (H-2), 3.96 (1H m, H-3), 4.38 (1H d, H-1'), 4.59 (1H m, H-20), 4.74 (1H t, H-4'), 4.90 (1H dd, H-2'), 6.26(B) and 6.28(A) (1H in total, each d, H-10), 6.36 (1H sl. br s, H-13), 6.69(A) and 6.72(B) (1H in total, each t, H-15), 7.11(B) and 7.33(A) (1H in total, each d, H-11), 9.44(A) and 9.46(B) (1H in total, each s, H-23); $J_{10,11}$=15.5, $J_{13,16}$≦1, $J_{15,16a}$=$J_{15,16a}$=7.5 Hz. Irradiation of H-16 collapsed the triplet of H-15 to a singlet and sharpened the broad singlet of H-13. Irradiation of H-13 sharpened the signals of both H-16 and H-23.

Esterification of 6 (obtained by a run) with Diazomethane (to give 7a and 7b). To a solution of **6** (65.4 mg) in chloroform (0.65 ml) was added 0.3 M diazomethane in ether (1.8 ml) and the solution was kept at room temperature for 1 h. The solution showed, on TLC with toluene–ethyl acetate (2:1), two spots at R_f 0.35 and R_f 0.25. Evaporation gave a residue, that was subjected to column chromatography with hexane–ethyl acetate (4:1→2:1) to give solids of **7a** (R_f=0.35), 25.4 mg (38%) and **7b** (R_f=0.25), 19.5 mg (29%).

7a: ^{1}H-NMR ($CDCl_3$) δ=0.04 and 0.08 (each 3H s, $SiMe_2$), 0.89 (9H s, Si-*t*-Bu), 2.04 and 2.06 (each 3H s, AcX 2), 2.25 (2H quintet, H-16), 2.34 (6H s, NMe_2), a set of eight signals typical for the AB part of an ABX system centered at 2.50 (2H, J=6.75 and 15 Hz, H-2a,b), 3.67 (3H s, CO_2Me), 4.03 (1H m, H-3), 4.40 (1H d, J=7.5 Hz, H-1'), 4.55 (1H m, H-20), 4.72 (1H t, H-4'), 4.89 (1H dd, H-2'), 6.25 (1H sl. br s, H-13), 6.35 (1H d, H-10), 6.67 (1H sl, br t, H-15), 7.11 (1H d, H-11), 9.46 (1H s, H-23); $J_{10,11}$=15.5, $J_{15,16a}$=$J_{15,16b}$=7.5 Hz.

7b: ^{1}H-NMR ($CDCl_3$) δ=0.04 and 0.08 (each 3H s, $SiMe_2$), 0.89 (9H s, Si-*t*-Bu), 2.05 (6H s, AcX2), 2.27 (2H quintet, H-16), 2.34 (6H s, NMe_2), 2.52 (2H, H-2a,b), 3.69 (3H s, CO_2Me), 4.05 (1H, br, H-3), 4.41 (1H d, H-1'), 4.58 (1H t, H-20), 4.72 (1H t, H-4'), 4.89 (1H dd, H-2'), 6.27 1H d, H-10), 6.35 (1H sl. br s, H-13), 6.63 (1H t, $J_{15,16a}$=$J_{15,16b}$=7.5 Hz, H-15), 7.32 (1H d, H-11), 9.46 (1H s, H-23).

In the 250 MHz ^{1}H shift-correlated 2D NMR spectrum, Me-17 could be correlated to H-16, and the latter, to H-15.

3-*O*-*t*-Butyldimethylsilylmycaminosyl Tylonolide Diethyl Acetal (8). A solution of **4** (100 mg) in methanol (2 ml) was heated at 50 °C for 24 h. Evaporation was followed by extraction of the residue with chloroform. The organic solution was washed with saturated aqueosu sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid of **8**, 89 mg (98%); $[\alpha]_D^{22}$ −2° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.18 (each 3H s, $SiMe_2$), 0.85 (9H s, Si-*t*-Bu), 0.93 (3H t, Me-17), 0.99 (3H d, Me-18), 1,83 (3H, Me-22), 2.50 (6H s, NMe_2), 3.03 (1H t, H-4'), 3,53 (1H dd, H-2'), 4.02 (1H sl. br d, H-3), 4.27 (1H sl. br d, H-1'), 4.73 (1H br dd, H-20), 4.90 (1H dt, H-15), 5.77 (1H d, H-13), 6.27 (1H d, H-10), 7.21 (1H d, H-11); $J_{2b,3}$=6, $J_{4,18}$=7, $J_{10,11}$=16, $J_{13,14}$=10, $J_{14,15}$=$J_{15,16a}$=9, $J_{15,16b}$=2.5, $J_{1',2'}$=6.5, $J_{2'3'}$=$J_{3'4'}$=$J_{4'5'}$=10Hz.

Found: C, 62.77; H, 9.41; N, 1.71%. Calcd for $C_{41}H_{75}NO_{11}Si$: C, 62.68; H, 9.55; N, 1.78%.

3'-*O*-*t*-Butyldimethylsilyl-23-deoxy-23-oxomycaminosyl

Tylonolide Diethyl Acetal (9). From 5. A solution of **5** (22.2 mg) in methanol (0.1 ml) was heated at 50 °C for 24 h. TLC (chloroform–methanol–28% aqueous ammonia= 10:1:0.1) of the reaction mixture showed two spots at R_f 0.3 (**9**) and R_f 0.01 (major). Evaporation was followed by extraction of the residue with chloroform. The solution was washed with saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated. The residue was chromatographed on a silica-gel column with chloroform–methanol–28% aqueous ammonia (20:1:0.1) to give a solid of **9**, 6.9 mg (34%).

From 8. A mixture of **8** (300 mg), pyridinium trifluoroacetate (74 mg) and dicyclohexylcarbodiimide (315 mg) in benzene–dimethyl sulfoxide (1:1, 6 ml) was stirred at room temperature overnight. The solution showed, on TLC with chloroform–methanol–28% aqueous ammonia (10:1:0.1), a spot at R_f 0.3 (major, **9**) with several minors. The solution was then treated as usual to give, after chromatography (chloroform–methanol–28% aqueous ammonia=10:1:0.1), a solid of **9**, 150 mg (50%); $[\alpha]_D^{23}$ −40° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.16 (each 3H s, $SiMe_2$), 0.89 (9H s, Si-*t*-Bu), 1.85 (3H d, $J\approx1$ Hz, Me-22), 2.56 (6H s, NMe_2), 4.02 (1H d, H-3), 4.35 (1H d, H-1′), 5.25 (1H dt, H-15), 5.78 (1H d, H-13), 6.32 (1H d, H-10), 7.19 (1H d, H-11), 9.66 (1H d, H-23); $J_{14,15}\approx9$, $J_{14,23}$=3.8 Hz.

Found: C, 62.53; H, 9.13; N, 1.90%. Calcd for $C_{41}H_{73}NO_{11}Si$: C, 62.83; H, 9.32; N, 1.42%.

23-Deoxy-23-oxomycaminosyl Tylonolide (10). To a solution of **9** (20 mg) in acetonitrile (0.1 ml) in a silicone vessel was added 10% aqueous hydrofluoric acid (0.1 ml) and the solution was kept at 27 °C overnight. The solution showed, on TLC with chloroform–methanol–28% aqueous ammonia (5:1:0.1), spots at R_f 0.38 (**10**) and R_f 0. Afrer addition of saturated aqueous sodium hydrogencarbonate (0.5 ml), the reaction mixture was extracted with chloroform. The organic solutioon was washed with saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated. The residue was chromatographed over silica gel with chloroform–methanol (7:1) to give an unstable solid of **10**, 3.9 mg (26%); $[\alpha]_D^{22}$ −60° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=0.96 (3H t, Me-17), 1.02 (3H d, Me-18), 1.22 (3H d, Me-21), 1.27 (3H d, Me-6′), 1.87 (3H d, $J\approx1$ Hz, Me-22), 1.96 (1H d, H-2a), 2.40 (1H t, H-3′), 2.52 (6H s, NMe_2), 2.56 (1H dd, H-2b), 2.96 (1H ddd, H-19b), 3.07 (1H t, H-4′), 3.27 (1H m, H-5′), 3.49 (1H dd, H-2′), 3.65 (1H dt, H-14), 3.74 (1H dd, H-5), 3.87 (1H d, H-3), 4.27 (1H d, H-1′), 5.30 (1H dt, H-15), 5.83 (1H d, H-13), 6.36 (1H d, H-10), 7.31 (1H d, H-11), 9.69 (1H d, H-23), 9.71 (1H s, H-20); $J_{13,14}$= $J_{14,15}$=10, $J_{14,23}$=3.8 Hz; other *J* values were almost the same with those of the related compounds reported.[7] Irradiation of H-14 collapsed the double triplets of H-15 to double doublets, and the doublets of H-13 and H-23 to a singlet, respectively.

Found: C, 61.47; H, 8.41; N, 2.44%. Calcd for $C_{31}H_{49}NO_{10}\cdot1/2\ H_2O$: C, 61.59; H, 8.28; N, 2.32%.

(23*S*)- and (23*R*)-2′4′-Di-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-23-C-methylmycaminosyl Tylonolide Diethyl Acetal (11a, 11b). Procedure A. To a cold (−78 °C) solution of **5** (570 mg) in oxolane (7 ml) was added methylmagnesium bromide (1 ml of M solution in oxolane) and the mixture was stirred at the temperature for 1.5 h, then kept at room temperature for 1 h. The reaction mixture was poured into an ice-cold half-saturated aqueous ammonium chloride (30 ml) and extracted with chloroform. The organic solution combined was washed with saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a residue. Silica-gel column chromatography of the residue with toluene–ethyl acetate (2:1) gave, from the earlier fractions, a solid of **11a**, 236 mg (36%), and from the later, a mixture of **11b** and **4**, 114 mg, the both compounds had the same mobility on chromatogram.

11a: $[\alpha]_D^{21}$ −10° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.18 (each 3H s, $SiMe_2$), 0.87 (9H s, Si-*t*Bu), 1.12 (3H d, Me-24), 1.78 (3H short-spaced d, Me-22), 2.06 and 2.08 (each 3H s, Ac×2), 2.35 (6H s, NMe_2), 2.45 (1H dd, $J_{2,3}$=7, $J_{2a,b}$=19 Hz, H-2b), 2.49 (1H dt, H-14), 2.73 (1H t, H-3′), 3.98 (1H br d, H-3), 4.10 (H-23), 4.36 (1H br d, H-1′), 4.68 (1H, br, H-20), 4.75 (1H t, H-4′), 4.89 (1H dd, H-2′), 5.13 (1H dt, H-15), 5.96 (1H d, H-13), 6.27 (1H d, H-10), 7.23 (1H d, H-11); $J_{13,14}$=10, $J_{14,15}$=9, $J_{14,23}$=2.5, $J_{23,Me\text{-}24}$=7 Hz. Irradiation of H-23 collapsed the doublet of Me-24 and the double triplets of H-14 to a singlet and a triplet, respectively.

Found: C, 62.59; H, 9.17; N, 1.67%. Calcd for $C_{46}H_{80}NO_{13}Si$: C, 62.59; H, 9.07; N, 1.59%.

11b: $[\alpha]_D^{21}$ +11° (*c* 1, $CHCl_3$); ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.18 (each 3H s, $SiMe_2$), 0.87 (9H s, Si-*t*Bu), 1.22 (3H d, Me-24), 1.83 (3H short-spaced d, Me-22), 2.06 and 2.07 (each 3H s, Ac×2), 2.34 (6H s, NMe_2), 2.47 (1H dd, H-2b), 2.73 (1H t, H-3′), 2.88 (1H dt, H-14), 3.98 (1H br d, H-3), 3.98 (1H br d, H-23), 4.35 (1H d, H-1′), 4.68 (1H, br, H-20), 4.75 (1H t, H-4′), 4.85 (1H, H-15), 4.89 (1H dd, H-2′), 5.73 (1H d, H-13), 6.27 (1H d, H-10), 7.18 (1H d, H-11); $J_{13,14}$=$J_{14,15}$=10, $J_{14,23}$=6, $J_{23,Me\text{-}24}$=6.5 Hz. Irradiation at δ=3.98 collapsed the doublet of Me-24 and double triplets of H-14 to a singlet and a triplet, respectively.

Procedure B. To a cold (−78 °C) solution of **5** (310 mg) in dry diethyl ether (3.1 ml) was added methyllithium (0.25 ml of 1.5 M solution in diethyl ether) and the mixture was stirred in the cold for 1.5 h, then the resulting yellow suspension was kept at room temperature for 1 h. Work-up as described for Procedure A gave a crude mixture. Silica-gel column chromatography of the mixture with toluene–ethyl acetate (2:1→1:1) gave solids of **11a**, 140 mg (44%) and **11b**, 36 mg (≈11%, slightly contaminated with **4**).

(23*S*)-23-C-Methylmycaminosyl Tylonolide (13a). A solution of **11a** (236 mg) in methanol (2.4 ml) was heated at 50 °C overnight. Evaporation gave a solid of **12a**. To a solution of the solid in acetonitrile (1.2 ml) was added M aqueous hydrochloric acid (1.2 ml) and the solution was kept at 37 °C overnight. On TLC with chloroform–methanol–28% aqueous ammonia (9:1:0.1), the solution showed a spot (R_f=0.23). Addition of saturated aqueous sodium hydrogencarbonate (10 ml) was followed by extraction of the mixture with chloroform. The organic solution isolated was washed with saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid (178 mg). Silica-gel column chromatography with chloroform–methanol–28% aqueous ammonia (20:1:0.1→10:1:0.1) gave a solid of **13a**, 121 mg (74%).

13a: ^{1}H-NMR ($CDCl_3$) δ=1.15 (3H d, Me-24), 1.27 (3H d, Me-6′), 2.36 (1H t, J=10 Hz, H-3′), 2.93 (1H ddd, J=1.5, 10, and 17.5 Hz, H-19b), 3.05 (1H t, J=10 Hz, H-4′), 3.27 (1H m, H-5′), 3.49 (1H dd, H-2′), 3.75 (1H d, H-5), 3.86 (1H sl. br d, H-3), 4.26 (1H d, J=7.5 Hz, H-1′), 9.69 (1H

s, H-20); $J_{13,14}$=10.8, $J_{14,15}=J_{15,16a}$=9.5, $J_{15,16b}$=3, $J_{23,Me\cdot24}$= 7.5 Hz. Irradiation of H-14 collapsed the signals of H-13, H-15, and H-23 to a singlet, a broad doublet, and a quartet, respectively. Irradiation of H-23 collapsed the doublet of Me-24 to a singlet.

(23*R*)-23-C-Methylmycaminosyl Tylonolide (13b). A solution of crude **11b** (114 mg obtained by Procedure A) was treated as described for **13a** and the products were twice chromatographed (to remove MT accompanied) as described, to give solids of **13b**, 39 mg (7.8% from **4**) and mycaminosyl tylonolide (19 mg).

13b: ^{1}H-NMR ($CDCl_3$) δ=1.24 (3H d, Me-24), 1.27 (3H d, Me-6'), 2.37 (1H t, H-3'), 3.05 (1H t, H-4'), 3.28 (1H m, H-5'), 3.50 (1H dd, H-2'), 3.76 (1H d, H-5), 3.87 (1H d, H-3), 4.28 (1H d, H-1'), 9.70 (1H s, H-20); $J_{13,14}$=10.5, $J_{14,15}=J_{15,16a}$=9.0, $J_{15,16b}$=3, $J_{23,Me\cdot24}\approx$6 Hz. Irradiation of H-23 collapsed the signals of H-14 and Me-24 to a triplet and a singlet, respectively.

General Procedure for the Syntheses of 14a,b—19a,b. A mixture of **4** (900 mg), pyridinium trifluoroacetate (300 mg) and dicyclohexylcarbodiimide (850 mg) in benzene–dimethyl sulfoxide (1:1 18 ml) was stirred at room temperature for **6 h** and the mixture was treated as described for **5** to give, without chromatography, a crude product (900 mg). To a cold (−78 °C) solution of the product in dry oxolane (9 ml) was added ethylmagnesium bromide (0.8 ml of 3 M solution in ether; for the preparation of **14a,b**), butylmagnesium bromide (1.2 ml of 2 M solution in oxolane, for **15a,b**), phenylmagnesium bromide (1.2 ml of 2 M solution in oxolane, for **16a,b**), allylmagnesium bromide (2.4 ml of M solution in ether, for **17a,b**), vinylmagnesium bromide [prepared from magnesium turnings (960 mg) and vinyl bromide (3.5 ml) in oxolane (20 ml) and used 2 ml of this solution; for **18a,b**] or ethynylmagnesium bromide [prepared by dropwise addition of EtMgBr (5 ml of 3 M solution in ether) to acetylene saturated in oxolane (10 ml) at 0—5 °C and used 4 ml of this red solution; for **19a,b**], and the mixture was kept at −78 °C for 1 h (at 0—5 °C for **19**), then kept at room temperature for 1 h. Work-up as described for **11a,b** gave, after column chromatography with toluene–ethyl acetate (2:1), a mixture of reaction products. Each product mixture was then methanolized and hydrolyzed as described for **13a** to give, after column chromatography with chloroform–methanol–28% aqueous ammonia (20:1:0.1→10:1:0.1), a final set of products as the solids of **14a,b—19a,b** (see Table 2).

3,23-Bis(*O*-*t*-butyldimethylsilyl)-4'-deoxymycaminosyl Tylonolide Diethyl Acetal (23). A solution of **2** (14.4 g) in methanol (144 ml) was heated at 50 °C overnight. Evaporation gave a residue, that was extracted with chloroform. The organic solution was washed with saturated aqueous sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid of **20** (12.7 g, 96%). To a cold (−40 °C) solution of the solid (12.7 g) in pyridine (127 ml) was added phenylmethanesulfonyl chloride (2.7 g initially, and 1.38 g after 1 hour) and the solution was kept at −40 °C for 5.5 h in total. After addition of water (0.5 ml), the solution was concentrated to give a residue, that was extracted with chloroform. The organic solution was washed with saturated aqueous sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated. The residue showed, on TLC with toluene–ethyl acetate (2:1), a spot at R_f 0.65 (major, **21**) with trace spots of R_f 0.8 and R_f 0. A mixture of the residue and sodium iodide (4.2 g) in 2-butanone (127 ml) was heated at 80 °C for 1 h. TLC (toluene–ethyl acetate 2:1) of the solution showed a spot (**22**) of the same R_f value with that of **21**. Filtration followed by evaporation gave a solid, that was extracted with benzene. The organic solution was washed with 0.1 M aqueous sodium thiosulfate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid. To a solution of the solid in benzene (127 ml) was added tributylstannane (12.3 g) and the solution was refluxed for 9 h. TLC (cyclohexane–acetone 7:4) of the solution showed a major spot at R_f 0.25 (**23**). Evaporation gave a syrup, that was twice chromatographed over silica gel with chloroform–methanol (20:1) to give solids of **23**, 10.3 g (82%) and **20**, 0.31 g. **23**: $[\alpha]_D^{20}$ −7° (*c* 1, $CHCl_3$).

^{1}H-NMR ($CDCl_3$) δ=−0.05, 0.02, 0.03, and 0.18 (each 3H s, $SiMe_2$×2), 1.78 (3H d, Me-22), 2.28 (6H s, NMe_2), 4.00 (1H d, H-3), 4.24 (1H d, H-1'), 4.75 (1H m, H-20), 4.93 (1H dt, H-15), 5.79 (1H d, H-13), 6.26 (1H d, H-10), 7.20 (1H d, H-11).

Found: C, 63.68; H, 9.81; N, 1.79%. Calcd for $C_{47}H_{88}NO_{10}Si_2$: C, 63.95, H, 9.98; N, 1.59%.

2'-*O*-Acetyl-3,23-bis(*O*-*t*-butyldimethylsilyl)-4'-deoxymycaminosyl Tylonolide Diethyl Acetal (24). A mixture of **23** (8.56 g) and acetic anhydride (1.17 ml) in acetonitrile (86 ml) was kept at room temperature for 6 h. Evaporation with several additions of toluene gave a residue, that was extracted with chloroform. The organic solution was washed with saturated aqueous sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a residue. Silica-gel column chromatography with toluene–ethyl acetate (1:1→1:2) gave a solid of **24**, 7.42 g. (82%); $[\alpha]_D^{22}$ +1° (*c* 1, $CHCl_3$).

^{1}H-NMR ($CDCl_3$) δ=−0.05, 0.03, 0.05, and 0.18 (each 3H s, SiM_2×2), 1.78 (3H d, Me-22), 2.08 (3H s, Ac), 2.27 (6H s, NMe_2), 4.28 (1H d, H-1'), ≈4.7 (2H, H-2', 20), 4.93 (1H dt, H-15), 5.78 (1H d, H-13), 6.25 (1H d, H-10), 7.19 (1H d, H-11).

Found: C, 63.49; H, 9.68; N, 1.48%. Calcd for $C_{49}H_{90}NO_{11}Si_2$: C, 63.63; H, 9.74; N, 1.52%.

2'-*O*-Acetyl-3-*O*-*t*-butyldimethylsilyl-4'-deoxymycaminosyl Tylonolide Diethyl Acetal (25). To an ice-cold solution of **24** (7.3 g) in oxolane (73 ml) was added a M solution of tetrabutylammonium fluoride in oxolane (8.7 ml) and the mixture was kept at room temperature for 2 h. Work-up as described for **24** gave a crude product, having, on TLC (chloroform–acetone 1:1), a single spot (R_f 0.5). It was purified by column chromatography with chloroform–acetone (6:5) to give a solid of **25**, 6 g (93%); $[\alpha]_D^{20}$ +4° (*c* 1, $CHCl_3$).

^{1}H-NMR ($CDCl_3$) δ=−0.05 and 0.18 (each 3H s, $SiMe_2$), 1.82 (3H s, Me-22), 2.08 (3H s, Ac), 2.27 (6H s, NMe_2), 4.29 (1H d, H-1'), ≈4.75 (2H, H-2', 20), 4.89 (1H dt, H-15), 5.75 (1H d, H-13), 6.30 (1H d, H-10), 7.18 (1H d, H-11).

Found: C, 62.80; H, 9.21; N, 1.80%. Calcd for $C_{43}H_{77}NO_{11}Si\cdot1/2\ H_2O$: C, 62.93; H, 9.51; N, 1.71%.

(23*S*)- and (23*R*)-2'-*O*-Acetyl-3-*O*-*t*-butyldimethylsilyl-4'-deoxy-23-C-methylmycaminosyl Tylonolide Diethyl Acetal (27a, 27b). To a solution of **25** (900 mg) in benzene–dimethyl sulfoxide (1:1, 18 ml) were added pyridinium tri-

fluoroacetate (230 mg) and dicyclohexylcarbodiimide (914 mg) and the mixture was stirred at room temperature for 4 h. After addition of oxalic acid dihydrate (372 mg) in 1,4-dioxane (9 ml), the mixture was stirred for 1 h. Filtration followed by concentration of the solution gave a syrup. A benzene solution of the syrup was washed with saturated aqueous sodium hydrogencarbonate, saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid, 900 mg; TLC: R_f 0.5 with toluene–acetone (3:2). The ^{1}H-NMR spectrum (90 MHz, in $CDCl_3$) of this solid showed a doublet ($J_{14,23}$=3 Hz) at δ 9.75 (CHO at C-23).

To a cold (−78 °C) solution of the solid (900 mg) in dry oxolane (9 ml) was added methylmagnesium bromide in oxolane (1.6 ml of M solution) and the solution was kept at −78 °C for 1 h. The reaction mixture was poured into an ice-cold half-saturated aqueous ammonium chloride (30 ml) and extracted with chloroform. The organic solution was washed with saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated to give a solid, that showed several spots including R_f 0.47 (major, **27a**) and 0.41 (minor, **27b** and **25**) on TLC with toluene–acetone (3:2). Column chromatography with toluene–acetone (4:1→1:1) gave solids of crude **27a**, 384 mg (≈42%) and **27b**, 131 mg (contaminated with **25**).

27a: ^{1}H-NMR ($CDCl_3$) δ=−0.04 and 0.18 (each 3H s, $SiMe_2$), 1.12 (3H d, $J_{23,Me\text{-}24}$=7.5 Hz, Me-24), 1.78 (3H d, Me-22), 2.09 (3H s, Ac), 2.26 (6H s, NMe_2), 2.47 (1H m, H-14), 4.09 (1H dq, $J_{14,23}$=2.5 Hz, H-23), 5.14 (1H dt, H-15).

27b: ^{1}H-NMR ($CDCl_3$; the signals for **25** were not recorded) δ=1.20 (3H d, $J_{23,Me\text{-}24}$=6 Hz, Me-24), 2.09 (3H s, Ac), 2.89 (1H m, H-14), 4.30 (1H d, H-1′).

(23*S*)- and (23*R*)-4′-Deoxy-23-C-methylmycaminosyl Tylonolide (28a, 28b). A solution of **27a** (384 mg) in methanol (7 ml) was heated at 50 °C overnight. Evaporation gave a residue of the deacetylated product. To a solution of the residue in acetonitrile (1.5 ml) was added M aqueous hydrochloric acid (1.5 ml) and the solution was kept at 37 °C overnight. After addition of saturated aqueous sodium hydrogencarbonate (10 ml), the mixture was extracted with chloroform. The organic solution was washed with saturated aqueous sodium sulfate, dried (Na_2SO_4), and evaporated. Column chromatography of the residue with chloroform–methanol–28% aqueous ammonia (15:1:0.1) gave a solid of **28a**, 130 mg (50% from **27a**). Compound **27b** (131 mg) was likewise treated as described above to give, after column chromatography, solids of **28b**, 47 mg (7% from **25**) and DT, 20 mg.

General Procedure for the Syntheses of 29a,b and 30a,b. A mixture of **25** (900 mg), dicyclohexylcarbodiimide (914 mg), and pyridinium trifluoroacetate (230 mg) in benzene–dimethyl sulfoxide (1;1, 18 ml) was stirred at room temperature overnight. Work-up as described for **27a,b** gave the final products.

We are grateful to Mrs. Yukiko Otsuka and Miss Yoshiko Koyama of our Institute for measurements of the NMR spectra, to Mr. Saburo Nakada of Keio University for elemental analysis, and to Mrs. Machiko Yamazoe for preparation of the manuscript.

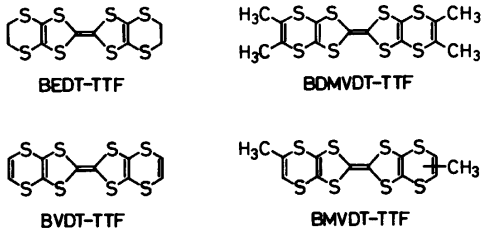
(Received July 28, 1986)

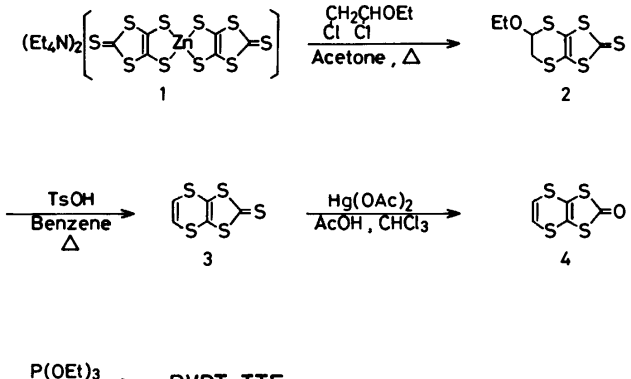
Bis(vinylenedithio)tetrathiafulvalene (BVDT-TTF) and bis(methylvinylenedithio)tetrathiafulvalene (BMVDT-TTF) were synthesized as attractive donor molecules for highly conductive organic salts. These molecules have analogous structures to BEDT-TTF, but are expected to possess more planar structures. They have higher oxidation potentials than BEDT-TTF. The synthetic method of BVDT-TTF by using a phase-transfer catalyst was also studied.

Bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) is known to give superconductive organic salts.[1,2] BEDT-TTF salts possess a two-dimensional electrical-conductivity character due to the presence of eight sulfur atoms in the donor molecule. Since BEDT-TTF has two ethylene units at both sides of the molecule, it is nonplanar.[3] One of the important factors for donor and acceptor molecules which give highly conductive salts is their planar structures. A replacement of the ethylene units of BEDT-TTF with carbon–carbon double bonds would give an attractive donor molecule since it has an analogous structure to BEDT-TTF and is expected to possess a more planar structure. The IBM group has reported the syntheses of bis(vinylenedithio)tetrathiafulvalene (BVDT-TTF) and bis(dimethylvinylenedithio)tetrathiafulvalene (BDMVDT-TTF) without a detailed description of the synthetic procedures.[4] They synthesized these donor molecules, starting from a reaction of 1,3,4,6-tetrathiapentalene-2,5-dione with a phase-transfer catalyst and Na_2CO_3. We also synthesized BDMVDT-TTF[5] by a different route. We have now synthesized BVDT-TTF and bis(methylvinylenedithio)tetrathiafulvalene (BMVDT-TTF) by different routes from those of the IBM group. The IBM method is assumed to be broadly applicable to the syntheses of the related donor molecules, and deserves to be studied in detail. We synthesized 4,5-(vinylenedithio)-1,3-dithiol-2-one, which is a precursor to BVDT-TTF, by the method reported by the IBM group. Since no detailed synthetic procedure has been disclosed for this method, and some researchers claim that this method is difficult,[6] it will be worth describing the synthetic procedures. We found that our method is superior to the IBM method.



Results and Discussion

Synthesis of BVDT-TTF. BVDT-TTF was synthesized by four reaction steps (Scheme 1). The synthesis of the starting material, $(Et_4N)_2[Zn(dmit)_2]$ (**1**),[7] was made by the reported method.[8] The synthesis of 4,5-(ethoxyethylenedithio)-1,3-dithiole-2-thione (**2**) was made by a reaction of **1** with 1,2-dichloroethyl ethyl ether in refluxing acetone. A dilution method is crucial for the synthesis of **2**, since its yield was poor without the dilution method. An elimination reaction of ethanol from **2** was made by refluxing a benzene solution of **2** and anhydrous *p*-toluenesulfonic acid to give 4,5-(vinylenedithio)-1,3-dithiole-2-thione (**3**). Since the coupling reaction of **3** with triethyl phosphite gave BVDT-TTF in low yield, **3** was converted to 4,5-(vinylenedithio)-1,3-dithiol-2-



Scheme 1.

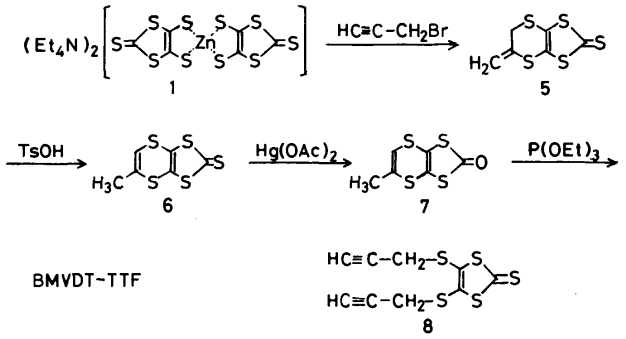
† Present address: Department of Environment and Safety Engineering, Faculty of Engineering, Fukui Institute of Technology, Gakuencho, Fukui 910.

one (**4**) by treating with mercury(II) acetate. The coupling reaction of **4** was made by heating it in neat triethyl phosphite, and BVDT-TTF was obtained as red needles. The cyclic voltammetry of BVDT-TTF in THF (0.1 M n-Bu_4NClO_4, Pt electrode, 20 mV s^{-1}) exhibited one wave: $E_{1/2}$=0.83 V vs SCE. This value was higher than those of the BEDT-TTF observed in THF ($E_{1/2}(1)$=0.69 V, $E_{1/2}(2)$=0.82 V vs SCE).

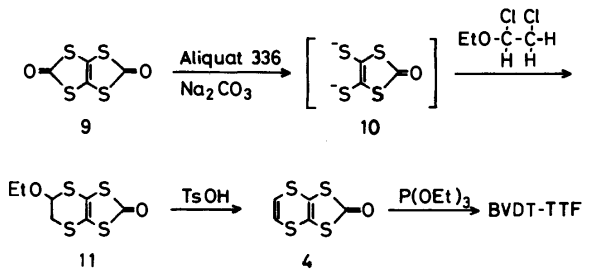
Synthesis of BMVDT-TTF. BMVDT-TTF was also synthesized by a four step reaction (Scheme 2). Reaction of **1** with propargyl bromide in refluxing acetone gave 4,5-(2-methylene-1,2-ethanediyldithio)-1,3-dithiole-2-thione (**5**). The dilution method is also crucial for this reaction. Without this method, two successive substitution reactions occurred to give 4,5-bis(propargylthio)-1,3-dithiole-2-thione (**8**) as the main product (judging from the mass and IR spectra). Product **5** was isomerized to 4,5-(methylvinylenedithio)-1,3-dithiole-2-thione (**6**) by treating **5** with p-toluenesulfonic acid monohydrate in toluene. Since the coupling reaction of **6** with neat triethyl phosphite gave BMVDT-TTF in low yield (16%), **6** was converted to 4,5-(methylvinylenedithio)-1,3-dithiol-2-one (**7**) by treating with mercury(II) acetate. The coupling reaction of **7** with neat triethyl phosphite gave BMVDT-TTF as light-yellow needles. The cyclic voltammetry of BMVDT-TTF in THF also gave one redox wave ($E_{1/2}$=0.80 V vs. SCE). This value was also higher than those of BEDT-TTF.

Synthesis of BVDT-TTF by Using Phase-Transfer Catalyst. Since the IBM group has disclosed no detailed synthetic procedure for the syntheses of BVDT-TTF and the related donor molecules,[4] we studied the synthetic conditions of BVDT-TTF by their method. The reaction route is shown in Scheme 3. The synthesis of 1,3,4,6-tetrathiapentalene-2,5-dione (**9**) was made by the reported method.[9] A benzene/water solution containing **9**, Aliquat 336,[10] and sodium carbonate was stirred at 40—45 °C to give 2-oxo-1,3-dithiole-4,5-dithiolate (**10**) in benzene phase. Then, the aqueous phase was eliminated by a syringe. Without the elimination of the aqueous phase, another carbonyl group also reacted to give tetrathiolate. The reaction of **10** with 1,2-dichloroethyl ethyl ether gave 4,5-(ethoxyethylenedithio)-1,3-dithiol-2-one (**11**). The elimination of ethanol from **11** was made by treating with p-toluenesulfonic acid in chlorobenzene to give **4**, which is a precursor to BVDT-TTF.

We have studied two different synthetic routes of BVDT-TTF (Schemes 1 and 3). Comparing these methods, the method shown in Scheme 1 is better than that in Scheme 3 from the following reasons. (1) The starting material, $(Et_4N)_2[Zn(dmit)_2]$,[7] in Scheme 1 can be obtained on a large scale (about 150 g) in one day. Therefore, the succeeding synthesis can be made on a large scale. On the other hand, a large-scale synthesis of **9** is not only difficult, but its synthesis requires several days. Although **9** can be commercially obtained, it is expensive. Furthermore, **9** sensitizes and produces skin rashes on some individuals. (2) All of the reaction products in Scheme 1 can be easily purified by recrystallization or chromatography. On the other hand, the product in Scheme 3 must be purified by column chromatography, followed by recrystallization, mainly due to the contamination of Aliquat 336. Thus, a much longer time is required for the purification. The loss of the product during these procedures is also a serious problem.



Scheme 2.



Scheme 3.

Experimental

The reaction was made under a nitrogen atmosphere, except for the syntheses of **4** and **7**. In the following reactions, second crops of **2**, **3**, **4**, BVDT-TTF, **5**, **6**, **7**, and BMVDT-TTF could be obtained by concentrating the mother solutions of the recrystallizations.

4,5-(Ethoxyethylenedithio)-1,3-dithiole-2-thione (2). A two-liter flask containing 1.7 l of acetone was equipped with two dropping funnels. The funnels contained an acetone solution (200 ml) of **1** (25 g) and an acetone solution (100 ml) of 1,2-dichloroethyl ethyl ether (10 g), respectively. After refluxing the acetone in the flask, the acetone solutions of **1** and 1,2-dichloroethyl ethyl ether were simultaneously dropped into the flask with vigorous stirring for a 3-h period; the solution was then refluxed for another 21 h. After cooling to room temperature, an orange precipitate was filtered off, and the acetone in the filtrate was evaporated. The residue was extracted with benzene, washed with water, dried over Na_2SO_4, recrystallized from acetonitrile, and then from the mixed solvent of hexane and

chloroform (2:1) to give yellowish-brown needles of **2** (9.3 g, 50% yield based on **1**). Mp 108 °C. Found: C, 2.89; H, 31.19; S, 59.78%. Calcd for $C_7H_8OS_5$: C, 3.00; H, 31.32; S, 59.72%. MS *m/z* 268 (M^+).

4,5-(Vinylenedithio)-1,3-dithiole-2-thione (3). The azeotropic distillation of 100 ml of benzene from the benzene solution (105 ml) of *p*-toluenesulfonic acid monohydrate ($TsOH \cdot H_2O$, 7.086 g) eliminated water in the solution. Benzene (895 ml) was added to the solution, and 100 ml of benzene was distilled again. After the benzene solution of TsOH was refluxed, a benzene solution (200 ml) of **2** (5 g) was added from a dropping funnel. The solution was refluxed for 24 h with vigorous stirring. The reddish-yellow solution gradually became dark brown. After cooling to room temperature, the solution was washed with water, then with aqueous $NaHCO_3$, finally with water, and dried over Na_2SO_4. After evaporating the benzene, the residue was chromatographed on silica gel by using benzene as an eluent. The second red fraction contained **3**. It was chromatographed again on silica gel by using hexane and chloroform (2:1) to give pure **3** as yellow powders (890 mg, 23.7%). Mp 143—144 °C. Found: C, 27.09; H, 0.85; S, 71.91%. Calcd for $C_5H_2S_5$: C, 27.01; H, 0.85; S, 71.91%. MS *m/z* 222 (M^+). ^{1}H-NMR (CS_2) δ=6.63 (s).

4,5-(Vinylenedithio)-1,3-dithiol-2-one (4). To the chloroform solution (30 ml) of **3** (300 mg) was added 30 ml of acetic acid and 1.075 g of mercury(II) acetate; the solution was stirred for 20 min at room temperature. A white precipitate was filtered off, and the filtrate was washed with water, then with aqueous $NaHCO_3$, finally with water, and dried over Na_2SO_4. After evaporating the solvent, the residue was chromatographed on silica gel by using hexane and chloroform (1:1) as an eluent. The second orange fraction gave **4** as pale yellow powders (158 mg, 57%). Mp 99 °C. Found: C, 29.02; H, 0.91; S, 61.94%. Calcd for $C_5H_2OS_4$: C, 29.11; H, 0.91; S, 62.15%. MS *m/z* 206 (M^+). ^{1}H-NMR (CS_2) δ=6.59 (s).

Bis(vinylenedithio)tetrathiafulvalene (BVDT-TTF). Two hundred mg of **4** was added to 5 ml of triethyl phosphite (freshly distilled), and the solution was stirred for 2 h at 100—105 °C. After cooling to room temperature, the precipitate was collected, washed with methyl alcohol, and dried to give BVDT-TTF (132 mg, 72%). It was recrystallized from chloroform to give red needles of BVDT-TTF. Mp 227 °C (decomp). Found: C, 31.85; H, 1.02; S, 67.13%. Calcd for $C_{10}H_4S_8$: C, 31.56; H, 1.06; S, 67.38%. MS *m/z* 380 (M^+). ^{1}H-NMR (CS_2) δ=6.5 (s). λ_{max}^{THF} (log ε): 316 nm (3.83), 340 nm (3.84).

4,5-(2-Methylene-1,2-ethanediyldithio)-1,3-dithiole-2-thione (5). To the refluxing acetone (480 ml) was added (dropwise) an acetone solution (60 ml) of **1** (7.19 g) and acetone solution (30 ml) of propargyl bromide (2.38 g) simultaneously for a 8-h period. The solution was refluxed for another 18 h. The residue was filtered off, acetone was evaporated, and the oil was extracted with benzene. It was washed with water, dried over Na_2SO_4, and chromatographed on silica gel by using hexane and chloroform (4:1) as an eluent. The first yellow fraction contained **5** and **8**. It was chromatographed again on silica gel by using hexane and chloroform (6:1) as an eluent, and the first fraction gave **5** (802 mg, 17%). It was recrystallized from acetonitrile to give orange needles. Mp 114—116 °C. Found: C, 30.50; H, 1.61; S, 67.62%. Calcd for $C_6H_4S_5$: C, 30.49; H, 1.71; S, 67.81%. MS *m/z* 236 (M^+). ^{1}H-NMR (CS_2) δ=3.71 (2H, s), 5.29 (1H, s), 5.39 (1H, s).

4,5-(Methylvinylenedithio)-1,3-dithiole-2-thione (6). A toluene solution (50 ml) of **5** (250 mg) and *p*-toluenesulfonic acid monohydrate ($TsOH \cdot H_2O$, 0.4 g) was refluxed for 1 h, and TsOH was filtered off. The filtrate was washed with water and dried over Na_2SO_4. After evaporating the solvent, **6** was extracted with acetonitrile. It was recrystallized from acetonitrile to give **6** as orange needles (150 mg, 61%). Mp 103 °C. Found: C, 30.50; H, 1.61; S, 67.62%. Calcd for $C_6H_4S_5$: C, 30.49; H, 1.71; S, 67.81%. MS *m/z* 236 (M^+). ^{1}H-NMR (CS_2) δ=2.20 (3H, s), 6.18 (1H, s).

4,5-(Methylvinylenedithio)-1,3-dithiol-2-one (7). Mercury(II) acetate (0.34 g) and **6** (0.1 g) was added to the mixed solvent of chloroform (10 ml) and acetic acid (10 ml), and the solution was stirred for 15 min at room temperature. A white precipitate was filtered off and the filtrate was washed with water, then with aqueous $NaHCO_3$, finally with water, and dried over Na_2SO_4. It was chromatographed on silica gel by using the mixed solvent of hexane and chloroform (1:1). The first pale yellow fraction gave **7** (75 mg, 80%). Recrystallization from methanol gave analytically pure **7**. Mp 80.5—81 °C. Found: C, 32.64; H, 1.85; S, 58.17%. Calcd for $C_6H_4OS_4$: C, 32.71; H, 1.83; S, 58.20%. MS *m/z* 220 (M^+). ^{1}H-NMR (CS_2) δ=2.20 (3H, s), 6.12 (1H, s).

Bis(methylvinylenedithio)tetrathiafulvalene (BMVDT-TTF). To triethyl phosphite (8 ml, freshly distilled) was added 0.2 g of **7**, and the mixture was stirred for 2 h at 110 °C. The yellow product was collected (157 mg, 92%), washed with methyl alcohol, and recrystallized from chloroform to give BMVDT-TTF as yellow needles. Mp: gradually decomposes at around 204 °C. Found: C, 35.12; H, 2.11; S, 61.74%. Calcd for $C_{10}H_8S_8$: C, 35.27; H, 1.97; S, 62.76%. MS *m/z* 408 (M^+). ^{1}H-NMR (CS_2) δ=2.12 (3H, s), 6.03 (1H, s). λ_{max}^{THF} (log ε): 316 nm (3.69), 342 nm (3.69).

4,5-(Ethoxyethylenedithio)-1,3-dithiol-2-one (11). A four-necked flask containing **9** (624 mg, 3 mmol), Na_2CO_3 (636 mg, 6 mmol), benzene (40 ml), and water (40 ml) was equipped with two dropping funnels, which contained a benzene solution (40 ml) of Aliquat 336 (2.5 g) and benzene solution (40 ml) of 1,2-dichloroethyl ethyl ether (429 mg, 3 mmol), respectively. The solution in the reaction vessel was heated to 40—45 °C, and a benzene solution of Aliquat 336 was dropped for a 40-min period with vigorous stirring, then stirred for another 20 min. After cooling to room temperature, the aqueous phase was eliminated by a syringe. The dithiolate (**10**) was produced as a reddish benzene solution. The benzene solution of 1,2-dichloroethyl ethyl ether was then added dropwise to the above solution for a 30-min period with stirring at room temperature, and the solution was stirred for another 90 min at 40—45 °C. Filtration of the solution, followed by the evaporation of the solvent, gave dark red oil. It was extracted with benzene, washed with water, and dried over Na_2SO_4. After evaporating the benzene, the residue was chromatographed on silica gel by using a mixed solvent of hexane and chloroform (4:1) as an eluent. The second yellow fraction contained almost pure **11** as a reddish-yellow oil (454 mg, 60%). MS *m/z* 252 (M^+). It was difficult to purify **11** completely by repeated chromatographies due to the contamination of Aliquat 336. Thus, the crude product was

used directly in the next step of the reaction.

4,5-(Vinylenedithio)-1,3-dithiol-2-one (4) from 11. To *p*-toluenesulfonic acid monohydrate (5.538 g) was added the mixed solvent of benzene (80 ml) and chlorobenzene (80 ml). An azeotropic distillation of benzene eliminated any water in the solution. A chlorobenzene solution (10 ml) of **11** (1.157 g) was added to the above solution and was then refluxed for 4 h. After cooling to room temperature, the solution was washed with water and dried over Na_2SO_4. After evaporating chlorobenzene, the residue was chromatographed on silica gel by using a mixed solvent of hexane and chloroform (1 : 1) as an eluent. The first yellow fraction gave **4** (234 mg, 25%), which was recrystallized from acetonitrile to give light yellow needles. Mp 99.5—100.5 °C. Found: C, 29.19; H, 0.92; S, 61.26%. Calcd for $C_5H_2S_4O$: C, 29.11; H, 0.98; S, 62.15%. MS *m/z* 206 (M^+). ^{1}H-NMR (CS_2) δ=6.60.

Battle River Coal Liquefaction and Its Co-Processing with Tar-Sand Bitumen

Ryoichi Yoshida,* Makoto Miyazawa,† and Yosuke Maekawa
Government Industrial Development Laboratory, Hokkaido, 2-Jo 17-Chome, Tsukisamu-Higashi, Toyohira-ku, Sapporo 004
†Nippon Kokan K. K., 1-1 Minamiwatarida-cho, Kawasaki-ku, Kawasaki 210
(Received February 24, 1986)

Battle River coal from Canada shows an excellent applicability to liquefaction. At 450 °C, anthracene oil and Cold Lake tar-sand bitumen show the solvent effect as a vehicle oil in the initial stage of liquefaction. A definite advantage is gained by tar-sand bitumen co-processing, where hydrogen consumption is comparatively lower than that of anthracene oil derived from coal to produce a similar yield of oil.

As part of a study program of coals from the Pan-Pacific Basin area at the Government Industrial Development Laboratory, Hokkaido, their basic properties[1] and their reaction characteristics in liquefaction[2,3] have been studied. In a previous paper,[2] the behavior during liquefaction of Wandoan coal, Australian subbituminous coal, was investigated. As to Battle River coal, Canadian subbituminous coal, the liquefaction test by a 0.1 T/D continuous plant was carried out.[3,4] However, the detailed behavior during liquefaction is not sufficiently understood.

In the present paper, the reactivity in the liquefaction of Battle River coal from Canada was studied without vehicle oil and with tar-sand bitumen from Cold Lake, Canada, and anthracene oil derived from coal as vehicle oil in a batch autoclave in order to obtain fundamental data on the liquefaction and co-processing characteristics.

Experimental

The analytical data of Battle River coal, anthracene oil, and tar-sand bitumen are shown in Table 1. The experimental procedure and reaction conditions of coal liquefaction in a shaking-type, 500 ml autoclave are given in detail elsewhere.[2,5] In the experiments of coal liquefaction, 10 g of Battle River coal, 1 g of a dry red-mud catalyst, 0.1 g of sulfur as a promoter, and 15 g of vehicle oil were charged in an authoclave. The initial pressure of hydrogen was adjusted to reach a reaction pressure of 220—230 kg cm^{-2}. The reaction temperature was 400 °C or 450 °C. Liquid and solid products were extracted with hexane and toluene successively, and they were separated into 3 fractions: a hexane-soluble fraction (oil), a hexane-insoluble/toluene-soluble fraction (asphaltene), and a toluene insoluble fraction (unreacted coal). The coal conversion was calculated on the basis of the unreacted coal.

Results and Discussion

Battle River coal (Fig. 1) and tar-sand bitumen (Fig. 2), were hydrogenated, respectively, with red-mud and sulfur without vehicle oil. In the liquefaction of the Battle River coal (Fig. 1), the conversion and the asphaltene yield at 400 °C tend to increase with an increase in the reaction time. The conversion reaches the equilibrium value at 450 °C, where the asphaltene yield decreases, and the gas yield, oil yield, and hydrogen consumption increase, with the increase in the reaction time. These results show that the secondary hydrogenolysis of the products occurs at 450 °C. Such a reaction trend is similar to that of Wandoan coal reported in a previous paper.[2] However, the conversion of Battle River coal is 96 wt% daf at 450 °C and at 60—120 min, higher by about 3 wt% daf than that of Wandoan coal under the same reaction conditions.

The results of the hydrogenolysis of tar-sand bitumen itself as a blank run are shown in Fig. 2. As has been reported in a previous paper,[2] the whole quantity of original anthracene oil is soluble in hexane, i.e., oil; hence, the whole quantity of the products after hydrogenolysis is also soluble in hexane. However, original tar-sand bitumen contains 15 wt% of the hexane insoluble/toluene soluble fraction, i.e., asphaltene. After hydrogenolysis, 3.3—

Table 1. Analysis of Sample Coal and Vehicle Oils

Coal and vehicle	Ultimate analysis/wt%					Atomic ratio		
	C	H	N	O	S	H/C	N/C	O/C
Battle River coal	70.0[a)]	4.7[a)]	1.7[a)]	23.1[a)]	0.6[a)]	0.80	0.021	0.247
Anthracene oil	90.0	6.2	1.1	2.4	0.3	0.83	0.011	0.020
Cold Lake tar-sand bitumen	83.7	11.4	0.3	0.6	4.0	1.64	0.003	0.005

a) d.a.f. coal basis. b) Proximate analysis of Battle River coal/wt%, Moisture: 11.9, Ash: 10.1, Volatile Matter: 34.1, Fixed Carbon: 43.3.

5.4 wt% of asphaltene remains in the products at 400 °C, while 0.6—2.1 wt% of asphaltene remains in the products at 450 °C. The hydrogen consumption is ca. 0.5 wt%[2] and is almost constant during the hydrogenolysis of anthracene oil, but when tar-sand bitumen is hydrogenated, the hydrogen consumption tends to increase with the increase in the reaction time; especially at 450 °C, it increases from 1 to 3 wt%. Regarding the gaseous products, the formation of hydrogen sulfide from tar-sand bitumen is remarkable and at 400 °C exceeds that of hydrocarbon gases, such as methane, ethane, and propane. No carbon monoxide or carbon dioxide formation was observed.

Figure 3 shows the results of the liquefaction of Battle River coal with anthracene oil and with tar-sand bitumen co-processing. The product yields are calculated as the difference between blank runs and those charged with coal. In this experiment, the effect of vehicle oil on the reactivity of the liquefaction of Battle River coal was examined. The conversion in the initial stage at 400 °C is about 30 wt% daf without vehicle oil (Fig. 1) and with tar-sand bitumen (Fig. 3), while it is about 80 wt% daf with anthracene oil (Fig. 3).

At 450 °C, the conversion, the asphaltene yield, and the oil yield in the initial stage up to the reaction time of 60 min show differences depending on the nature of the vehicle oil (tar-sand bitumen or anthracene oil) and on the presence or the absence of the vehicle oil. The effect of vehicle oil on the initial stage of liquefaction is clearly observed. Anthracene oil and tar-sand bitumen are different in the degree of the effect of vehicle oil in the initial stage; tar-sand bitumen contains more resins, asphaltene, and the heavy fraction boiling off above 400 °C, which should make it more viscous than anthracene oil, as is shown in Table 2. The fluidity of the reactants must be less in the initial stage when vehicle oil is tar-sand bitumen. Therefore, the reactivity of the reactants must be less.[6] However, as the reaction time and reaction temperature increase, the tar-sand bitumen decomposes (Fig. 2) and/or its viscosity must drop substantially. Therefore, as vehicle oil tar-sand bitumen shows an effect comparable to that of

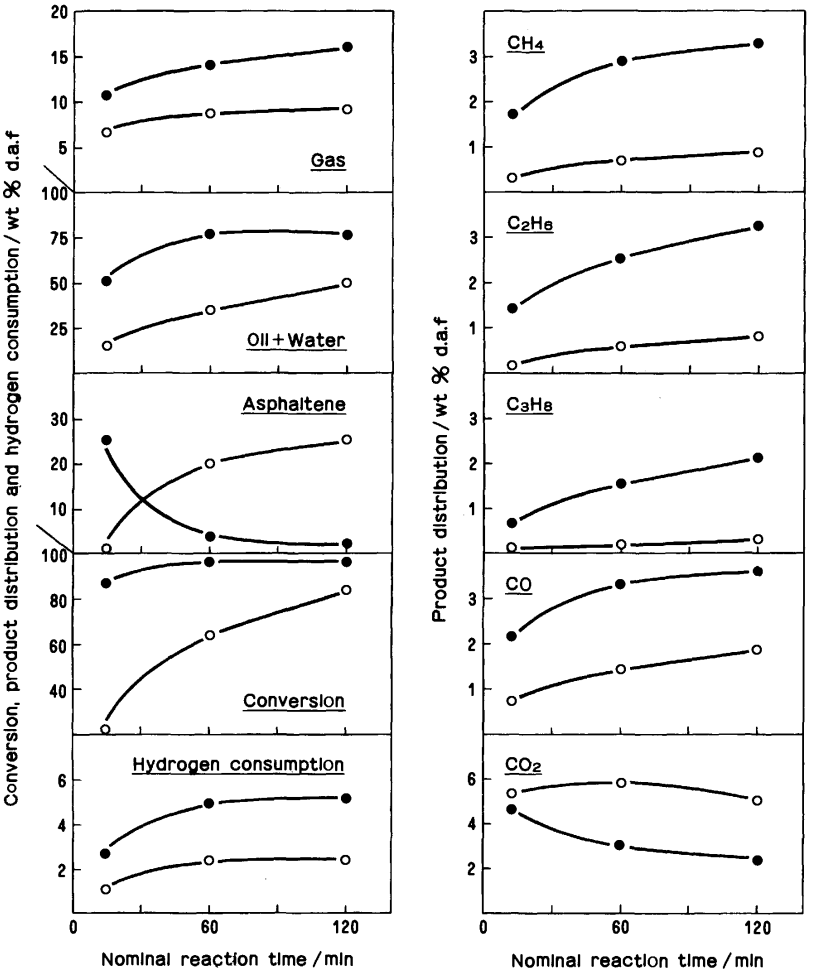

Fig. 1. Conversion, product distribution and hydrogen consumption vs. nominal reaction time on Battle River coal hydrogenolysis with red-mud/sulfur catalyst. ○: 400 °C, ●: 450 °C.

anthracene oil at 450 °C, as has been reported by Moschopedis.[7] Hydrogen consumption and gas formation are the highest with anthracene oil, and they increase with an increase in the reaction time; subsequently, the oil yield tends to decrease. When tar-sand bitumen is used, the hydrogen consumption is lower and is considered to be the effect of hydrogen sulfide.[8-10] Hydrogen sulfide starts to decompose to hydrogen and sulfur above 400 °C, and it is easily decomposed to hydrogen and sulfur in the presence of iron sulfide.[8] The hydrogen formed immediately after the decomposition of hydrogen sulfide can be more active than normal hydrogen, and the hydrocracking ability and the hydrogen-donor ability may play some role in the coal conversion.[8-10] The lower formation of gaseous products is remarkable.

In Table 3, the analytical data of the hexane-soluble fraction are shown. The hexane-soluble fraction in Table 3 is a mixture of the hexane-soluble fraction from Battle River coal and vehicle oil. In the presence of tar-sand bitumen, the hydrogen contents in the hexane-soluble fraction produced are higher than the

450	119	86.2	9.7	1.1	1.6	1.5	1.35	0.011	0.014	0.007

hydrogen contents in the hexane-soluble fraction produced when anthracene oil was used. The H/C atomic ratio in the hexane-soluble fraction produced from co-processing with tar-sand bitumen is 1.4 to 1.6, higher by 1.4 to 1.7 times than the H/C atomic ratio in the hexane-soluble fraction produced when anthracene oil was used. Tar-sand bitumen seems to be associated with the lowering of the nitrogen content and the oxygen content in the hexane-soluble fraction. However, the sulfur in tar-sand bitumen was probably transferred to the hexane-soluble fraction.

Conclusion

In summary, Battle River coal shows an excellent reactivity to liquefaction, for the maximum conversion attainable is ca. 90 wt% daf at 400 °C and ca. 96 wt% daf at 450 °C. In the presence of anthracene oil as the vehicle oil, Battle River coal shows a liquefaction behavior similar to that of Wandoan coal. At 400 °C, anthracene oil is excellent as a vehicle oil to facilitate the liquefaction reaction during the heating period up to 400 °C. The conversion at 400 °C and 16 min reaches about 80 wt% daf. When tar-sand bitumen is used as the vehicle oil at 400 °C, the conversion shows a change, depending on the reaction time, similar to the conversion change in the case of no vehicle oil. Tar-sand bitumen shows the effect of vehicle oil on the increase in the oil yield. At 450 °C, anthracene oil and tar-sand bitumen show the effect of vehicle oil in the initial stage up to 60 min, and they facilitate the increase in the conversion and the oil yield and the decrease in the asphaltene yield. When tar-sand bitumen is used, it may be surmised that the conversion of tar-sand bitumen itself proceeds and that, at the same time, the conversion of coal-derived asphaltene to the oil fraction is also facilitated at 450 °C.

Structure, Properties, and Na^+ Transport Membrane of Polyelectrolyte Complexes Consisting of Glycol Chitosan and Poly(vinyl sulfate)

Yasuo KIKUCHI* and Naoji KUBOTA
Department of Environmental Chemistry and Engineering, Faculty of Engineering, Oita University, Dannoharu, Oita 870-11
(Received April 28, 1986)

Glycol chitosan (GC) was allowed to react with poly(vinyl sulfate) (PVSK) to form many different water-insoluble polyelectrolyte complexes (PECs) in aqueous solution at various hydrogen ion concentrations. According to elemental analyses, IR spectroscopy, and solubilities of PECs, molecular structures of each PEC depend on $[H^+]$. This result is attributable to change with $[H^+]$ in the degree of dissociation and conformation of GC and PVSK. PEC membranes were made by casting solutions of all kinds of PECs, and transport phenomena through a membrane of the PEC prepared in a solution of 4 v/v% HCl were investigated under various conditions. The transport ratio of Na^+ and the electric potential difference between the left and right sides of the membrane were measured, with a result that the higher value the membrane potential difference was long allowed to maintain, the higher the transport ratio became. According to this result, the driving force of transport is dependent on the membrane potential, Donnan potential and diffusion potential, between both sides of the membrane. The Cl^- exclusion (Donnan exclusion), however, is small due to the small cation-exchange capacity, so that the membrane potential difference is caused to decrease rather rapidly by Cl^- permeation.

Polyelectrolyte complexes (PECs) are expected to find many-sided applications[1-3] because of the diversity of their structures and properties. For example, PECs may be prepared in the form of cationic or anionic as well as neutral polymer complex because of the applicability of a variety of components, mixing ratios, and solvent pHs, and may be cast into membranes with various ion-exchange capacities (0—2 mequiv g^{-1} dry membrane).[4] Consequently, when PEC membranes with high permeability[5] are used, it is possible to control the active transport of alkali metal and halide ions, of which a great number of studies have recently been made.[6-11] Investigation on PEC membrane is, however, confined almost to synthetic polymers, and there have been only a few papers on PEC membranes of naturally occurring polysaccharides. We have already reported that PEC membranes of glycol chitosan–poly(vinyl sulfate),[12] methyl glycol chitosan–(carboxymethyl)dextran–poly(vinyl sulfate),[13] and [2-(diethylamino)ethyl]dextran hydrochloride–(carboxymethyl)dextran–poly(vinyl sulfate)[14] systems are capable of active and selective transport of alkali metal ions.

This paper deals with chemical reactions of glycol chitosan (GC) with poly(vinyl sulfate) (PVSK) and general characteristics of resulting PECs. In addition, a description will be made on active transport of Na^+ through a membrane of PEC prepared in 4v/v% HCl solution, with particular reference to the relationship between transport ratio and membrane potential.

Experimental

Glycol chitosan (GC) (nitrogen content, 6.09%; intrinsic viscosity, 1.68 dl g^{-1} in 1 mol dm^{-3} NaCl solution at 25 °C) as a polycation and poly(vinyl sulfate) (PVSK) (sulfur content, 18.67%; intrinsic viscosity, 0.66 dl g^{-1} in 1 mol dm^{-3} NaCl solution at 25 °C) as a polyanion were used to prepare PECs. Sodium poly(*p*-styrenesulfonate) (NaSS) and poly(*p*-styrenesulfonic acid) (HSS) with molecular weights 1.0×10^4 and 5.0×10^5 were adopted in the active transport experiment. Reactions were run in 7, 4, and 1% HCl, at pHs 2.0, 4.5, 6.5, 11.0, and 13.0, and in 5% NaOH, considering that the degree of dissociation of polyelectrolytes and their conformation are influenced by hydrogen ion concentration. GC solution (2 g dm^{-3}) was added dropwise to PVSK solution (2 g dm^{-3}) and vice versa, for the adjustment to the same $[H^+]$, at a rate of 50 cm^3/30 min with stirring at ca. 22 °C. Water-insoluble PECs were thus obtained. After 30 min, the precipitate was separated by centrifugation. Then, it was washed with methanol, and dried in vacuo at room temperature until there occurred no further decrease in weight. Estimation of the nitrogen in PEC was carried out by the Kjeldahl method, and quantitative analysis of sulfur was performed at the Institute of Physical and Chemical Research. IR spectra of PEC in a KBr pellet were taken with a Hitachi 285 spectrophotometer. The miscibility of GC, PVSK, or PEC with the ternary solvent system, NaBr/acetone/water, was examined as previously described.[15]

PEC membrane was obtained from a PEC prepared in 4% HCl solution by casting. The method of casting into membrane and the experimental conditions were described in a previous paper.[12] A diaphragm type cell, made of poly(methyl methacrylate) and consisting of two chambers, was used in the active transport experiment for Na^+. After well washing with water, the PEC membrane was fixed tightly with silicone rubber between both chambers of the cell having an effective area of 4.0 cm^2. In the right-side chamber of the cell was placed 25 cm^3 of 0.1 mol dm^{-3} NaOH solution, and simultaneously 25 cm^3 of HCl (or HSS) solution of one of various concentrations containing 0.1 mol dm^{-3} NaCl (or 0.1 mol dm^{-3} NaSS unit) in the left-side chamber. The cell was then put in a thermostat controlled at 30 °C. At proper intervals, 0.1 cm^3 samples

from both the side chambers of the cell were withdrawn and analyzed for the concentration of Na^+ with an atomic absorption spectrophotometer (Shimadzu AA-640). At the same time, the concentration of Cl^- was determined by volumetric titration with $Hg(NO_3)_2$, and the concentration of SS^- from the absorbance at 260 nm (Hitachi 100-10 spectrophotometer). The electric potential difference between the left and right sides of the membrane was obtained by measurement with a Horiba F-7 potentiometer and Ag-AgCl electrodes. The ion-exchange capacity of the membrane was determined as follows.[16] The PEC membrane was first immersed in 1 mol dm^{-3} HCl solution. After washing with water, this membrane was in turn immersed in 30 cm^3 of 1 mol dm^{-3} NaCl solution three times every two hours. After washing with water again, washings and immersing solvents were titrated with 0.05 mol dm^{-3} NaOH solution. The ion-exchange capacity was evaluated by dividing the measured value by the dry membrane weight.

Results and Discussion

Polyelectrolyte Complex. Figure 1 shows the dependence, upon hydrogen ion concentration, of the molar ratio of the reacting groups in PVSK and GC in a reaction mixture solution at the start and end of coagulation of PEC. The molar ratio, S(PVSK)/N(GC), increased with increasing $[H^+]$ and no coagulation was observed in solutions of lower $[H^+]$ than pH 6.5, i.e., larger amounts of PVSK solution were necessary to coagulate GC solution containing PEC as the hydrogen ion concentration was increased. The reason for above is that the degree of dissociation of GC decreases with decreasing $[H^+]$ and reaches zero eventually, whereas that of PVSK remains unchanged. In the pH 6.5 solution, the following strange phenomenon was observed. A coagulation occurred when PVSK solution was added to GC solution, while none when GC solution was added to PVSK solution. A probable reason for this phenomenon is that the concentration of PEC and the ionic strength in the reaction mixture for which PVSK solution was added to GC solution, were initially higher than those in the reaction mixture for which GC solution was added to PVSK solution.[3] Further investigation on this point should be made. Experimental conditions, yields of products, and results of elemental analyses for each PEC prepared after coagulation are given in Table 1. As seen in Table 1, the sulfur and nitrogen contents in the PECs which reflect the molar ratio of PVSK to GC are roughly equal, except for the PEC prepared in pH 6.5 solution. As a result, it appears that the reactions proceeded in the same manner when PEC was prepared after coagulation in the solutions of

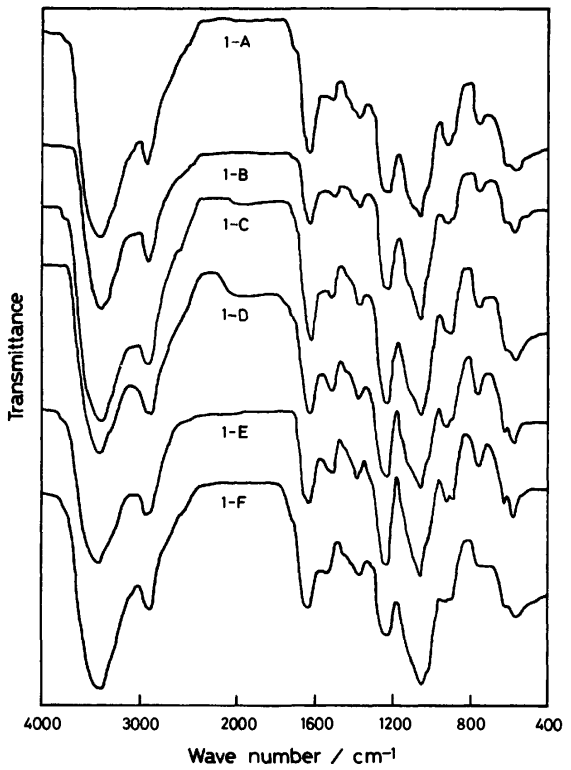

Fig. 2. IR spectra of the PEC. Sample codes correspond to those in Table 1.

$[H^+]$>pH 6.5. Thus, the hydrogen ion concentration in this system plays an important role in determining the ratio of PVSK/GC in the PEC.

Since the IR spectra of the PECs prepared in the cases where PVSK solution was added to GC solution are identical with those in the cases where GC solution was added to PVSK solution, only the former are shown in Fig. 2. The IR spectra of the PECs are almost the same as that of a mixture of PVSK and GC, differing from one another only in details. The absorption band at 1540 cm^{-1} assigned to $-NH_3^+$ in GC is present in all PECs, whereas that assigned to $-NH_2$ which should appear at 1590 cm^{-1} is absent. The absorption bands at 1230 and 800—600 cm^{-1}, which are also present in each PEC, are assigned to $-OSO_3^-$ in PVSK. The intensity of these absorptions is nearly equal in all PECs except the one prepared in pH 6.5 solution, whose absorbances at 1230 and 800—600 cm^{-1} are weak. These results imply that the PECs were produced in the same way, and this viewpoint coincides with the result of elemental analyses in Table 1. Furthermore, the absorption bands around 3500 cm^{-1} assigned to -OH groups are found in every PEC, and this proves that inter- and intramolecular hydrogen bonds between -OH groups are formed. These IR spectra have revealed that the PECs prepared in 7% HCl—pH 4.5 solutions consist of a greater fraction of PVSK, whereas the PVSK contents in the PECs prepared in pH 6.5 solution are low.

PECs are insoluble in general organic solvents, e.g., *N,N*-dimethylformamide, *N,N*-dimethylacetamide, and dimethyl sulfoxide, but soluble in ternary solvent mixtures, e.g., NaBr/acetone/H_2O and $CaCl_2$/1,4-dioxane/H_2O, and also in 36% HCl solution without heating. Phase diagrams were obtained for all kinds of PECs in the system of NaBr/acetone/H_2O and are shown in Fig. 3. There is a small region in the solvent composition field where PEC remains in the solution to form a homogeneous, viscous sirup. The miscibility limit of each PEC is approximately constant except for the PEC prepared in the solution of pH 6.5.

These experimental results support the concept that the PECs prepared in 7% HCl—pH 4.5 solutions have common constituents and similar compositions, but that the PEC prepared in pH 6.5 solution is different from them. This concept is in turn reduced to the dependence that the degree of dissociation of GC and PVSK changes with $[H^+]$.

Polyelectrolyte Complex Membrane. The membrane obtained by casting the PEC prepared in 4% HCl solution was adopted for the study on the transport of alkali metal ion Na^+, because this membrane was most stable in acidic and alkaline solutions. The concentrations of Na^+ in the left- and right-side chambers of the cell were set the same initially. The left-side chamber contained HCl as well, while the right-side chamber NaOH. Figure 4 shows concentration changes for Na^+, Cl^-, and H^+ with time in both the side chambers containing 0.1 mol dm^{-3} HCl. Despite the fact that both the sides of the membrane were originally equal in the concentration of Na^+, an increase of Na^+ in the left side was observed and the change in the right side was quite reverse. This suggests that the active transport of Na^+ took place from the right side, alkaline solution, to the left side, acidic solution, through the membrane. The concentration of Na^+ in the left side increased up to a maximum, and then decreased with the passage of time. This back transport of concentrated Na^+ is due to decrease in the hydrogen ion concentration difference between both sides of the membrane and to the permeation of Cl^-. The ratios of the transported ions are calculated by

$$\text{Transport ratio } (\%) = \frac{[Na^+]_{max} - [Na^+]_0}{[Na^+]_0} \times 100, \quad (1)$$

where $[Na^+]_{max}$ is the mole number of Na^+ in the left-side chamber at the maximum, and $[Na^+]_0$ is the mean of the initial mole numbers of Na^+ in both the side chambers. The dependence of the transport ratio of Na^+ on the concentration of H^+ in the left-side chamber is shown in Fig. 5. The transport ratio corresponds to the $[H^+]$, and it is high at $[H^+]$ above pH 1.0, whereas low at $[H^+]$ below pH 2.0. Hence, it is thought that the driving force for the transport of Na^+ will be the hydrogen ion concentration difference between both the side chambers which causes an electric potential gradient. Accordingly, the membrane potential difference needs to be measured. Figure 6 indicates that the membrane potential difference gets greater as the concentration of HCl in the left side is increased, and this tendency is consistent with the result in Fig. 5. The membrane potential difference, however, decreases with time. This decrease in the potential difference is not only due to the transport of Na^+ from the right to left side

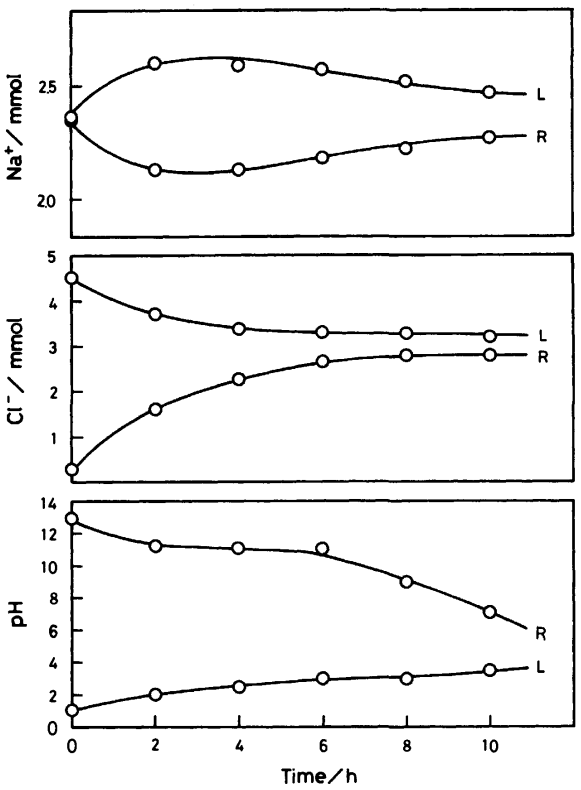

Fig. 4. Changes in the concentration of Na^+, Cl^-, and H^+ at the active transport

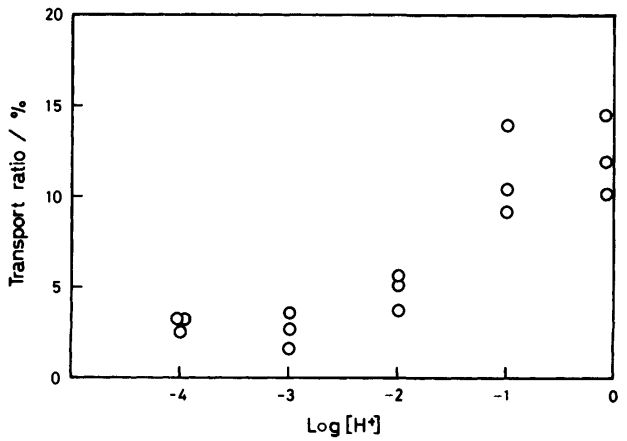

Fig. 5. Effect of the hydrogen ion concentration on the transport ratio of Na^+ in the case HCl was used.

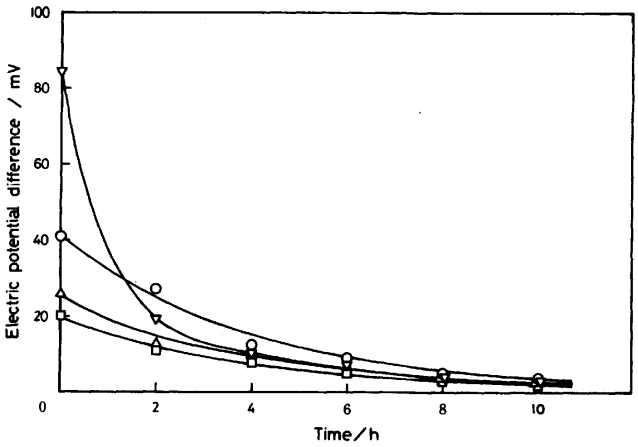

Fig. 6. Changes of the electric potential difference with time. ▽: 1 mol dm^{-3} HCl, ○: 0.1 mol dm^{-3} HCl, △: 0.01 mol dm^{-3} HCl, □: 0.001 and 0.0001 mol dm^{-3} HCl.

but also due to the permeation of Cl^- from the left to right side. As shown in Fig. 4, this Cl^- permeation is large, so that an investigation on the transport in cases where all negative charges are kept fixed in the left side of the membrane, was attempted, results obtained being analyzed in the light of the above conclusion.

The results in the case where HSS and NaSS were adopted instead of HCl and NaCl, respectively, are shown in Figs. 7 and 8. The transport ratios were evaluated by Eq. 1 by taking into consideration the transfer of water based on the Donnan osmosis. The concentration of Na^+ in the left-side chamber increased and that in the right-side one decreased with the passage of time in a similar manner as in the case of HCl. On the other hand, the concentration of SS^- was unchanged, in contrast with Cl^- in the case of HCl. Moreover, the transport ratios of Na^+ were much larger than those in the case of HCl, as shown in Fig. 8. This is compatible with the assumption that the membrane potential difference would be maintained for a long time because SS^- is kept fixed well in the left side of the membrane. This assumption is supported by the result in Fig. 9. The membrane potential difference was maintained for more than 24 h.

Therefore, on the basis of the results described above we speculate that the transport of Na^+ will be effected in the following manner. The PEC membrane is considered to be a sort of charged membrane for which the functional groups of $-OSO_3^-$ in PVSK are responsible. The permeation phenomena in the case where a charged membrane is used or a certain ion is fixed in one side of the membrane, is explained in terms of the Donnan membrane equilibrium. It is difficult to analyze such a system as in this study comprising many kinds of ions. However, on the assumption that the membrane potential is the concentration membrane potential raised by HCl or HSS, the membrane potential $\Delta\phi$ can be regarded as the sum of the Donnan potentials $\Delta\phi_{Don,L}$ and $\Delta\phi_{Don,R}$ at the two solution-membrane interfaces and the diffusion potential $\Delta\phi_{Dif}$ in the membrane.[17] Tentative membrane potential and transfer of Na^+ deduced

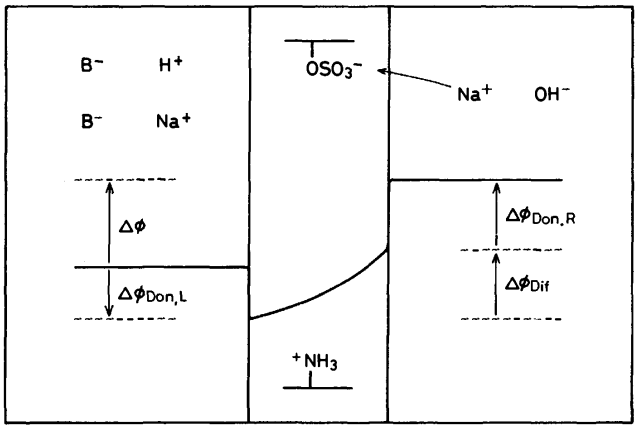

Fig. 10. Schematic representation of the membrane potential.

from the conclusions described above are illustrated in Fig. 10. In this system, the membrane surface potential is low because PEC membrane is anionic, and the potential in the membrane increases in the direction toward the right because of the large mobility of H^+. Thus, as a result, the right side is higher than the left side in electric potential. Na^+ was transported from the right to left side, i.e., from the alkaline to acidic side, through the membrane in accord with the gradient of electric potential. It seems that $-OSO_3^-$ groups in the membrane serve as carriers for Na^+.[8] However, the Donnan exclusion for Cl^- is small due to the small cation-exchange capacity (0.14 mequiv g^{-1} dry membrane) and there are $-N^+$ groups in the membrane capable of attracting Cl^-, so that the membrane potential difference is not maintained constant so long by Cl^- permeation. Then, the transport ratio of Na^+ seems low in the case of HCl. In the case of HSS, on the contrary, $\Delta\phi_{Don,L}$ and $\Delta\phi_{Dif}$ are larger than those in the case of HCl for the fixed SS^-, although $\Delta\phi_{Don,R}$ is equal; moreover, the maintenance time of constant membrane potential difference is long. Therefore, the transport of Na^+ in accord with the membrane potential gradient is appreciable.

Neutralization Dialysis for Deionization

Manabu IGAWA,* Kiyoyuki ECHIZENYA, Takashi HAYASHITA, and Manabu SENO†
Department of Applied Chemistry, Faculty of Engineering, Kanagawa University,
Rokkakubashi, Kanagawa-ku Yokohama 221
†Institute of Industrial Science, The University of Tokyo,
Roppongi, Minato-ku, Tokyo 106
(Received June 30, 1986)

In neutralization dialysis, cations are exchanged with protons across a cation-exchange membrane, while anions are exchanged with hydroxide ions across an anion-exchange membrane, and the effective deionization and the neutralization occur simultaneously on the base of Donnan equilibrium. The ion-exchange membranes are much more permeable to the electrolytes than the nonelectrolytes and their mutual separation is possible by this method.

Donnan dialysis is an ion-exchange membrane process based on Donnan equilibrium[1] and it has been used for salt enrichment.[2-5] Recently, we proposed a novel deionization method based on the principle of Donnan dialysis by the simultaneous use of a cation-exchange membrane and an anion-exchange membrane.[6] When a salt solution is separated from an acid solution with a cation-exchange membrane and from a base solution with an anion-exchange membrane, the cations in the salt solution are exchanged with protons, while the anions are exchanged with hydroxide ions, and deionization and neutralization occur simultaneously. This process can be called "neutralization dialysis," because salts are transported rapidly across the membrane by the great concentration gradients of protons and hydroxide ions caused by neutralization in the deionization compartment. Neutralization dialysis is a simple, continuous, and very effective process and its principle must also play an important role in biomembranes. Active transports coupled with proton antiport have been reported as the model of biomembranes,[7] but the ion transport will be enhanced much when it is coupled with neutralization reaction. This method will be quite profitable for desalination because of requiring a low energy and low cost and it may be able to substitute this deionization process for the ion-exchange process on ion-exchange resin. The ion-exchange membranes are much more permeable to electrolytes than nonelectrolytes and their complete mutual separation will be also reported in this report.

Experimental

The neutralization-dialysis cell, which is similar to the macromosaic cell,[8] and the schematic ion transport are shown in Fig. 1. Each compartment is 0.5 mm thick with a 2×10 cm^2 area. The solutions in deionization compartment D, in acid compartment A, and in base compartment B were cycled from respective reservoirs with tube pumps at a rate of 40 cm min^{-1}. The ion-exchange membranes in the cell were Selemion AMV and CMV(Asahi Glass Co., Ltd.). In the dialysis experiment, 3 cm^3 samples were collected from the solution of compartment D at a regular interval and the cation concentration, the specific resistance, and pH were measured with an atomic absorption spectrophotometer, a conductance cell, and a pH meter, respectively. The separation of electrolytes from nonelectrolytes was investigated with a mixed aqueous solution of potassium chloride and methyl alcohol. The concentration of methyl alcohol was measured with a total organic carbon analyzer.

Results and Discussion

A deionization experiment was carried out with the neutralization-dialysis cell and Fig. 2 shows the changes with time of the cation concentration, pH, and the specific resistance of the solution in compartment D. The ion concentration decreased and the specific resistance increased rapidly with time, and a deionized water with a specific resistance of 1 MΩ cm were obtained after 1.5 h.

In this process, Donnan equilibrium is set up across a membrane after an ample time and the ratios of the

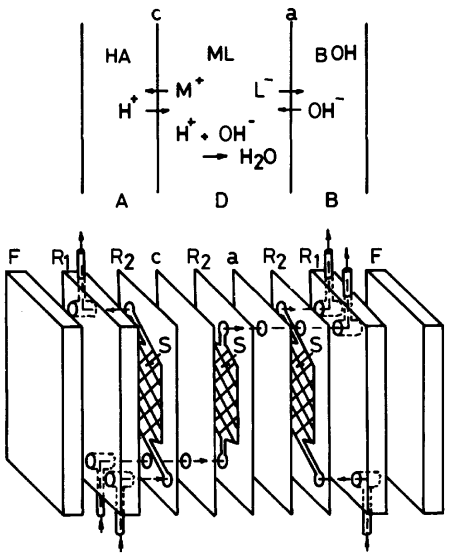

Fig. 1. Neutralization-dialysis cell and the schematic ion transport. a: Anion-exchange membrane, c: cation-exchange membrane. R_1 and R_2: silicone rubber sheet, S: spacer, F: acrylic resin frame.

ion concentrations in each compartment become

$$C_A^M/C_A^H = C_D^M/C_D^H, \quad (1)$$

$$C_B^L/C_B^{OH} = C_D^L/C_D^{OH}, \quad (2)$$

From the standpoint of thermodynamics, activities should be used for describing Donnan equilibrium but activity coefficients are assumed to be unity and concentrations are used in these equations for simplifying the discussion. In the equations, C is concentration, M, L, H, and OH are a monovalent cation, a monovalent anion, proton, and hydroxide ion, respectively, and A, B, and D are symbols of the compartments. When the volume of the acid solution is equal to that of the base solution and $C_A^H=C_B^{OH}$, $C_A^M=C_B^L$ and $C_D^M=C_D^L$. The material balance for the metal ion is

$$C_A^M V_A + C_D^M V_D = C_{0,D}^M V_D + C_{0,A}^M V_A, \quad (3)$$

where the amount of the ion in the cation-exchange membrane is ignored, and V and C_0 show the volume and the initial metal ion concentration of the solutions, respectively. From Eqs. 1 and 3, the final concentration of the metal ion in the deionization compartment is

$$C_D^M = (C_{0,D}^M V_D + C_{0,A}^M V_A)/(C_A^H V_A/C_D^H + V_D). \quad (4)$$

Since protons and hydroxide ions combine to be water and their concentrations become 10^{-7} mol dm^{-3} ideally in compartment D, the equilibrated concentration in compartment D is calculated to be 3.8×10^{-10} mol dm^{-3} according to this equation in the case of Fig. 2. The pH decreased appreciably in the initial stage of the dialysis as shown in Fig. 2, because the transport rate of protons in the cation-exchange membrane differs from that of hydroxide ions in the anion-exchange membrane. Sulfuric acid and calcium hydroxide were used for acid and base in this experiment to decrease the leakage of co-ions across the membrane because polyvalent co-ions repel ion-exchange membranes strongly, but it can not be ignored in highly deionized solution.

In neutralization dialysis, the diffusion flux of metal ion across the membrane, J_M can be derived as the function of the ion concentration in the bulk solution. The ion flux is proportional to the concentration difference in the membrane as generally recognized[9] and it is

$$J_M = P(\bar{C}_D^M - \bar{C}_A^M), \quad (5)$$

where P, C_D^M, and C_A^M are the permeation constant, the concentration in the membrane adjacent to the deionization compartment, and that adjacent to the acid compartment, respectively.[4] The ion-exchange equilibriums apply at the interfaces of the membranes and the equilibrium constant, K is

$$K = (\bar{C}_A^M/C_A^M)/(\bar{C}_A^H/C_A^H) = (\bar{C}_D^M/C_D^M)/(\bar{C}_D^H/C_D^H), \quad (6)$$

where K is assumed to be constant on either side of the membrane. When the concentration of the exchangeable cation in the cation-exchange membrane is shown as C_{ex}, the relationship between each ion concentration in the membrane is

$$\bar{C}_A^M + \bar{C}_A^H = \bar{C}_D^M + \bar{C}_D^H = C_{ex}. \quad (7)$$

From Eqs. 5—7, J_M is expressed as the function of the ion concentration in the bulk solution by

$$J_M = C_{ex}P[1/(1+C_D^H/KC_D^M) - 1/(1+C_A^H/KC_A^M)]. \quad (8)$$

According to this equation, it is predicted that J_M increases with increasing the ratio of C_A^H to C_A^M and becomes zero when Donnan equilibrium is attained across the membrane as shown in Eq. 1. J_M also increases with the decrease of C_D^H but the optimum value of C_D^H is 10^{-7} mol dm^{-3} because the anion flux can be also described in the same form as Eq. 8 and it should be equal to J_M for the most efficient

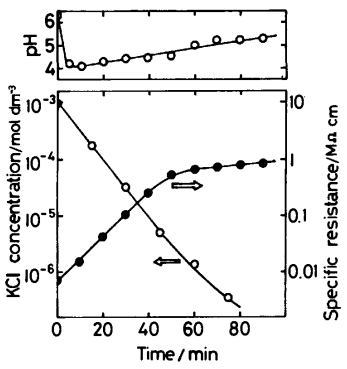

Fig. 2. Deionization by neutralization dialysis. Compartment A, 0.01 mol dm^{-3} H_2SO_4 (1 dm^3). Compartment B, 0.01 mol dm^{-3} $Ca(OH)_2$ (1 dm^3). Compartment D, 0.001 mol dm^{-3} KCl (75 cm^3).

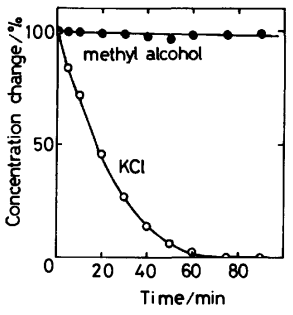

Fig. 3. Separation of potassium chloride from methyl alcohol. Compartment D, 0.1 mol dm^{-3} methyl alcohol+0.01 mol dm^{-3} KCl aqueous solution (100 cm^3). The other experimental conditions are the same as those of Fig. 2.

deionization.

The deionization capability was also confirmed when KCl was initially added to both acid and base solutions to be 0.1 mol dm^{-3} in the case of Fig. 2. The permeation rate decreased and the time taken to reach 10% of the initial concentration of the deionization compartment becomes about 5 times longer, but KCl was transported against its concentration difference as expected by above equations.

A dialytic separation of potassium chloride from methyl alcohol was also tried in this system and the result is shown in Fig. 3. The concentration change of methyl alcohol could be ignored (within 2%), while potassium chloride was effectively removed and its concentration became 0.2% of the initial concentration after 1.5 h. Since permeabilities of nonelectrolytes decreases rapidly with the increase of the molecular weight,[8] the loss of nonelectrolytes during the dialysis is much smaller in almost all the case than that showm in Fig. 3. A dialytic deionization of a mixed solution of electrolytes and nonelectrolytes is achieved effectively in this process.

Polymer-Protected Metal Complex for Gas Separation. III. Water-Resistivity of Polystyrene Resin-Supported Aluminium Copper(I) Chloride as Solid Carbon Monoxide Adsorbent[1)]

Hidefumi HIRAI,* Susumu HARA, and Makoto KOMIYAMA
Department of Industrial Chemistry, Faculty of Engineering, The University of Tokyo, Hongo, Bunkyo-ku, Tokyo 113
(Received July 14, 1986)

Solid adsorbents of carbon monoxide are prepared from aluminium chloride, copper(I) chloride, and a macroreticular type polystyrene resin by use of various solvents, and their resistivities against water vapor are investigated. The adsorbing capacities of the adsorbents prepared by use of carbon disulfide and dichloromethane remain virtually unchanged even after repeated (3—5 times) contacts of the adsorbents with nitrogen gas containing 10 mol% water with respect to the charged copper(I) chloride (water contents: 5600 and 4600 ppm). The adsorbents obtained with the use of benzene and toluene as preparation solvents, however, exhibit small but gradual decreases in the adsorbing capacities on the repeated contacts with nitrogen gas containing water. Scanning electron microscopy and energy dispersive X-ray microanalysis on the water-resistant adsorbents, prepared with the use of carbon disulfide and dichloromethane, show that the active species for the adsorption, aluminium copper(I) chloride, uniformly distributes in the beads of the polystyrene resin without formation of aggregates. Almost all of aluminium copper(I) chloride is located in the apolar microporosities of the polystyrene resin here, and is effectively protected from water vapor.

Carbon monoxide (CO), which is one of the most important raw materials in chemical industry,[2)] is usually obtained as gas mixtures with hydrogen, nitrogen, oxygen, methane, carbon dioxide, and water vapor.[3)] Thus, CO must be separated from the gas mixtures prior to effective utilization.

In previous papers,[4,5)] the authors reported that toluene solutions of polystyrene-protected aluminium copper(I) chloride ($AlCuCl_4$) reversibly absorbed CO under mild conditions. These absorbents were stable against water vapor, and thus were applicable to separation of CO from gas mixtures containing considerable amounts of water vapor. In the absence of the polystyrene, however, $AlCuCl_4$ in toluene was rapidly deactivated by water vapor due to irreversible reaction of $AlCuCl_4$ with water.[6)]

Furthermore, the authors succeeded in the preparation of the macroreticular type cross-linked polystyrene resin-supported $AlCuCl_4$ as solid adsorbents for CO.[1,7,8)] With the use of them, separations of CO from gas mixtures were successfully achieved both by pressure-swing method and by thermal-swing method.

This paper reports on the resistivities against water vapor for the macroreticular type polystyrene resin-supported $AlCuCl_4$. Effects of preparation solvents on the water-resistivities of the adsorbents are described. Furthermore, the results of scanning electron microscopy and energy dispersive X-ray microanalysis on the surface and the cross-section of the adsorbents are shown. The mechanism of water-resistivities is discussed in terms of the microstructures of the adsorbents.

Experimental

Materials. A macroreticular type cross-linked polystyrene resin (8:2 styrene–divinylbenzene copolymer; 20—50 mesh; 296—740 μm in diameter; average pore diameter 9 nm; surface area 300 $m^2 g^{-1}$)[9)] was obtained from Bio-Rad Laboratories (Bio-Beads SM-2). The resin was successively washed with the following solvents under the specified conditions: aqueous hydrochloric acid solution, 4 mol dm^{-3}, 55 °C, 2 h; aqueous sodium hydroxide solution, 2 mol dm^{-3}, 55 °C, 2 h; distilled water, 55 °C, 2 h; methanol, room temperature, 1 h; dichloromethane, room temperature, 1 h.

Aluminium chloride was purified by sublimation. Copper(I) chloride was reprecipitated from a concentrated aqueous hydrochloric acid solution by the addition of distilled water, followed by washing successively with ethanol and diethyl ether, and then dried overnight in vacuo at 100 °C.

Carbon disulfide and dichloromethane were dried over diphosphorus pentaoxide and were distilled. Toluene and benzene were distilled after being dried over metallic sodium.

Carbon monoxide and nitrogen, which had purities of 99.95 and 99.999%, respectively, were passed through columns of molecular sieve 3A immediately before use.

Preparation of CO Adsorbents. The solid CO adsorbents were prepared by refluxing aluminium chloride, copper(I) chloride, and the macroreticular type polystyrene resin in various solvents under dry nitrogen.[8)] Charged molar ratios of aluminium chloride and styryl residue in the resin, respectively, to copper(I) chloride were 1.0 and 1.2. After 6 h, the solvents were removed from the mixtures by evaporation at 4 mmHg (1 mmHg=133.3 Pa) for 4—6 h. Evaporation temperature was gradually elevated from room temperature to 80 °C, as the evaporation proceeded.

Adsorption and Desorption of CO. The adsorption of CO by the adsorbent, continuously stirred by use of a magnetic stirrer, was carried out at 25 °C, 1 atm, and was

followed by measuring the uptake of CO with the use of a gas burette.[8]

The desorption of adsorbed CO was achieved by subjecting the adsorbent to a reduced pressure (7 mmHg) at 25 °C for 10 min.

Contacts of CO Adsorbents with Water Vapor. The contacts of the adsorbents with water vapor were effected by circulating 10 dm^3 of nitrogen gas, which contained 10 mol% water to the charged CuCl, over the adsorbents at 25 °C for 10 min by use of a gas-circulating pump. The contents of water were in the range of 4600—6100 ppm. During the contacts, the adsorbents were stirred using a magnetic stirrer. The nitrogen containing water vapor was prepared by the introduction of distilled water into 10 dm^3 of evacuated vessel using a microsyringe, followed by the addition of dry nitrogen in an amount required to make the total pressure atmospheric.

Effects of contacts of the adsorbents with dry nitrogen, in place of nitrogen containing water vapor, were investigated in similar ways in order to evaluate precisely the effects of water vapor on the capacities of the adsorbents.

Scanning Electron Microscopy and Energy Dispersive X-Ray Microanalysis on CO Adsorbents. Scanning electron microscopy and the energy dispersive X-ray microanalysis were simultaneously carried out by use of a system composed of a Hitachi model S-550 scanning electron microscope and a KEVEX model 7000-75 energy dispersive X-ray spectrometer.[10] Data analysis was made on a DEC type PDP 11/34 mini computer.

The specimens for the analysis of the cross-sections of the beads of the adsorbents were prepared by embedding the beads in an epoxy resin. The resultant composites were scraped with sand paper so that the cross-sections of the beads could be analyzed. Alternatively, the beads of the adsorbents were divided into two parts by using a stainless steel blade, and were used for the analysis.

Results

Effect of Water Vapor on Adsorbing Ability of Macroreticular Type Polystyrene Resin-Supported Aluminium Copper(I) Chloride Prepared Using Carbon Disulfide As Solvent. Open circles in Fig. 1 show the adsorption of CO at 25 °C, 1 atm by the adsorbent prepared from 3.03 g (22.7 mmol) of aluminium chloride ($AlCl_3$), 2.25 g (22.7 mmol) of copper(I) chloride (CuCl), and 2.84 g (26.1 mequiv. of styryl residue) of the macroreticular type cross-linked polystyrene resin (divinylbenzene content 20%) by use of 20 cm^3 of carbon disulfide as solvent. The adsorption is rapid and the equilibrium molar ratio of the adsorbed CO to the charged CuCl is 1.07. The amount of adsorbed CO per 1 g of the adsorbent is 67 cm^3 (standard temperature and pressure).

After the first adsorption, the adsorbent is contacted with 10 dm^3 of dry nitrogen at 25 °C for 10 min, and then is subjected to a reduced pressure (7 mmHg) at 25 °C for 10 min. In the second adsorption, the adsorbent promptly adsorbs CO and the equilibrium molar ratio of adsorbed CO to the charged CuCl is 0.54, as shown by the solid circles in Fig. 1.

The open triangles in Fig. 1 depict the third adsorption of CO. Before the adsorption, the adsorbent is contacted with nitrogen containing 10 mol% water to the charged CuCl (water content: 5600 ppm) for 10 min, and is kept at 7 mmHg, 25 °C for 10 min. The equilibrium molar ratio of the adsorbed CO to the charged CuCl is 0.54, which is identical with the value in the second adsorption. In the fourth, the fifth, the sixth, and the seventh adsorptions, the time courses of CO adsorptions are virtually the same as those for the second and the third adsorptions. Prior to each of these adsorptions, the adsorbent is contacted with nitrogen containing 10 mol% water (water content: 5600 ppm).

Water Resistivities of CO Adsorbents Prepared by Use of Various Solvents. Figure 2 depicts the plots of the CO adsorbing capacities of the adsorbents as functions of numbers of repeated adsorptions of CO. Prior to each of the third and the later adsorptions, the adsorbents are contacted with nitrogen containing 10 mol% water with respect to the charged CuCl, as indicated by the arrows. Before the second adsorptions the adsorbents are contacted with dry nitrogen.

In the first adsorptions, all the adsorbents, prepared by use of carbon disulfide, dichloromethane, toluene, and benzene, adsorb CO approximately equimolar to the charged CuCl.

The adsorbing capacity of the adsorbent prepared by use of carbon disulfide remains constant at 0.54 in the second to the seventh adsorption (see the open circles). Thus, no measurable decrease in the capacity

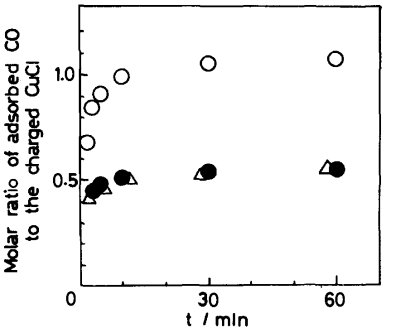

Fig. 1. Adsorption of CO at 25 °C, 1 atm by the adsorbent prepared from the macroreticular type (divinylbenzene content 20%) polystyrene resin, $AlCl_3$, and CuCl by use of carbon disulfide as solvent: the first adsorption (○), the second adsorption (●), and the third adsorption (△); the desorptions of CO were carried out by subjecting the adsorbent to a reduced pressure (7 mmHg) at 25 °C for 10 min; prior to the third adsorption, the adsorbent was contacted with 10 dm^3 of nitrogen containing 10 mol% water to the charged CuCl (water content 5600 ppm) at 25 °C for 10 min; the adsorbent was prepared from 3.03 g (22.7 mmol) of $AlCl_3$, 2.25 g (22.7 mmol) of CuCl, and 2.84 g (26.1 mequiv. in styryl residue) of the polystyrene resin with the use of 20 cm^3 of carbon disulfide.

is perceived even after five times of the contacts of the adsorbent with nitrogen containing water vapor. The capacity of the adsorbent prepared using dichloromethane is also unchanged after three times of the contacts with nitrogen containing water vapor (the closed circles). In contrast, the CO adsorbing capacities of the adsorbents prepared by use of toluene and benzene as solvents gradually decrease on the contacts with water vapor, as depicted by the open triangles and the closed triangles, respectively.

The differences between the adsorbing capacities in the first adsorptions and those in the second adsorptions are ascribed to the amounts of CO adsorbed in equilibria under the desorption conditions employed (7 mmHg at 25 °C for 10 min), as described in the previous paper.[8] When the CO adsorption-desorption cycles are repeated without the contacts of the adsorbents with water vapor, the adsorbing capacities of all the four adsorbents in the third and the later adsorptions are identical with the values in the corresponding second adsorptions.[8]

Scanning Electron Microscopy (SEM) on Surface of CO Adsorbents. Figure 3 depicts the SEM photographs of the surface of the adsorbents. The surface of the adsorbent prepared using carbon disulfide as solvent is smooth and deposition of metal salts is hardly detected, as exhibited by the photograph (a). On the surface of the adsorbent prepared with the use of toluene as solvent, however, depositions of considerable amount of metal salts are clearly observed (the photograph (b)).

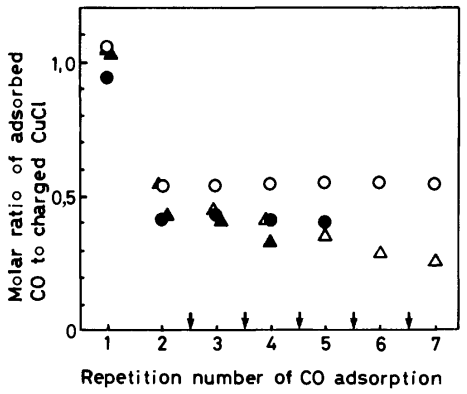

Fig. 2. Effects of water vapor on the CO adsorbing capacities at 25 °C, 1 atm for the adsorbents prepared from the macroreticular type polystyrene resin, $AlCl_3$, and CuCl by use of carbon disulfide (○), dichloromethane (●), toluene (△), and benzene (▲) as solvents: the arrows refer to the contacts of the adsorbents with nitrogen containing 10 mol% water to the charged CuCl at 25 °C for 10 min; the desorptions of CO were carried out by subjecting the adsorbents to a reduced pressure (7 mmHg) at 25 °C for 10 min.

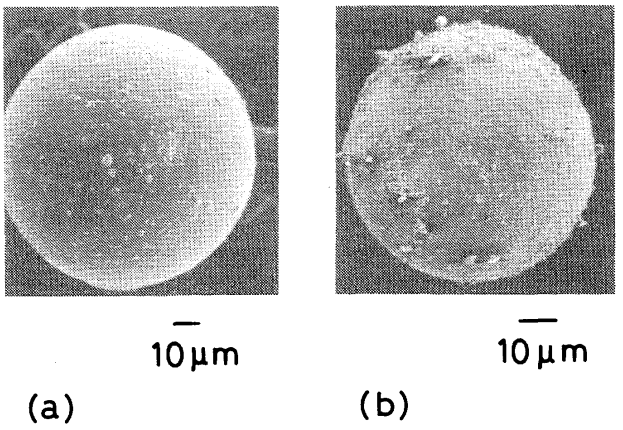

Fig. 3. SEM photographs of the surface of the CO adsorbents prepared from the macroreticular type polystyrene resin, $AlCl_3$, and CuCl by use of (a) carbon disulfide and (b) toluene as solvents.

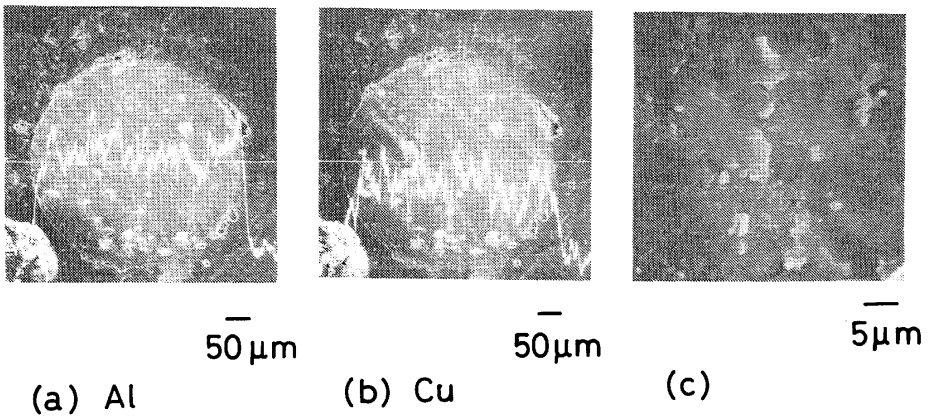

Fig. 4. SEM photographs as well as distributions of Al and Cu atoms for the cross-section of the CO adsorbent prepared from the macroreticular type polystyrene resin, $AlCl_3$, and CuCl by use of carbon disulfide as solvent: the waved lines show the distributions of (a) Al atoms and (b) Cu atoms along the corresponding white straight lines.

Scanning Electron Microscopy (SEM) and Energy Dispersive X-Ray Microanalysis on Cross-Sections of Beads of CO Adsorbents. Figures 4—6 depict SEM photographs of the cross-sections of the beads of the adsorbents. The waved lines refer to the distributions of Al and Cu atoms along the corresponding white straight lines on the cross-sections of the beads.

For the adsorbent prepared by use of carbon disulfide, both Al atoms and Cu atoms uniformly distribute in the cross-section of the bead, as shown by the waved lines in the photographs (a) and (b) in Fig. 4. Even at a larger magnitude of magnification (the photograph (c) in Fig. 4), no depositions of metal salts are detected.

In the adsorbent obtained with the use of toluene, Al atoms exist largely on or near the surface of the bead, as depicted in the photograph (a) in Fig. 5. The Cu atoms, however, are abundantly present in the inner portion of the bead with small population near the surface of the bead (the photograph (b) in Fig. 5). Thus, the distributions of Al and Cu atoms are different from each other. In addition, many granules are perceived mostly in the inner portion of the bead.

Figure 6 shows SEM photographs of the inner portion of the bead prepared with the use of toluene. Here, the middle parts of the cross-section of the bead in Fig. 5 (a) and (b) are analyzed at larger magnitudes of magnification. A number of crystalline deposits are observed in the photographs (a) and (b), while highly grown columnar crystals are seen in the photograph (c).

As depicted by the waved line in Fig. 6 (b), the distribution of the Cu atoms exhibits maxima at the positions where the crystalline deposits are present on the white straight line. In contrast, the distribution of the Al atoms shows minima at the positions of the deposits (Fig. 6 (a)). Thus, most of the Al atoms are located in the portions where no deposits exist. The X-ray microanalysis on one of the deposits, which involves signals from the region of diameter around 1—2 μm, has showed that the atomic ratio of Cu, Cl, and Al is 37.5:57.6:4.9.

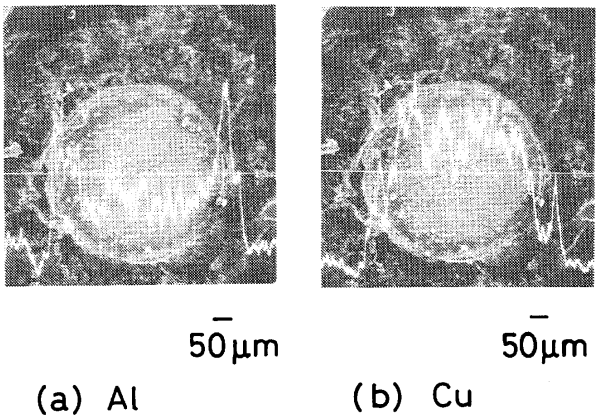

Fig. 5. SEM photographs as well as distributions of Al and Cu atoms for the cross section of the CO adsorbent prepared from the macroreticular type polystyrene resin, $AlCl_3$, and CuCl by use of toluene as solvent: The waved lines show the distributions of (a) Al atoms and (b) Cu atoms along the corresponding white straight lines.

Discussion

Water-Resistivity of Macroreticular Type Polystyrene Resin-Supported $AlCuCl_4$ As CO Adsorbent. The macroreticular type polystyrene resin-supported

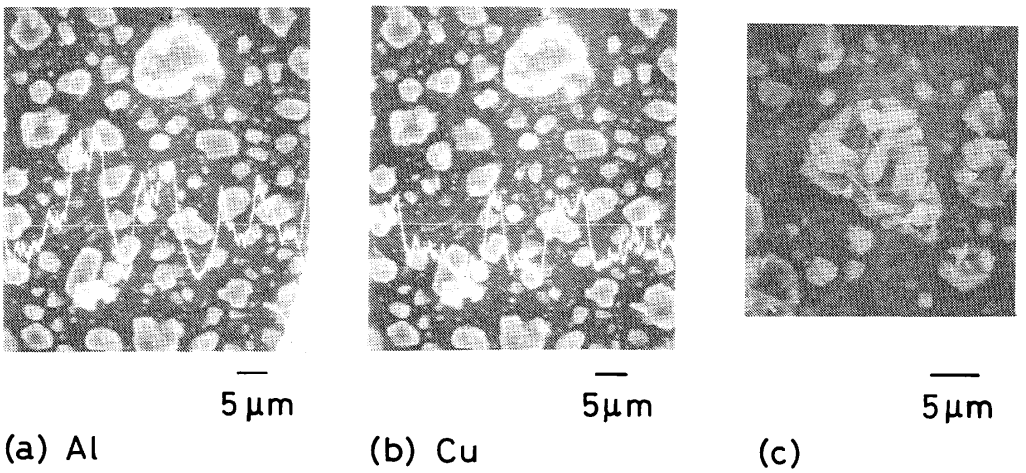

Fig. 6. SEM photographs as well as distributions of Al and Cu atoms for the inner portions of the bead of the CO adsorbent prepared from the macroreticular type polystyrene resin, $AlCl_3$, and CuCl by use of toluene as solvent: The middle parts of the cross-section of the bead in Fig. 5 (a) and (b), where many fine deposits of metal salts are observed, are analyzed at larger magnitudes of magnification; the waved lines refer to the distributions of (a) Al and (b) Cu atoms along the corresponding white straight lines.

$AlCuCl_4$ is stable against water vapor, as shown in Fig. 2, when carbon disulfide and dichloromethane are used as preparation solvents. No measurable decreases in the adsorbing capacities are observed after five and three repeated contacts of the adsorbents (total periods of contacts 50 and 30 min) with nitrogen containing 5600 and 4600 ppm of water, respectively. The water-resistivities of these adsorbents are quite important from the viewpoints of practical applications, since almost all of the CO sources in industry contain considerable amounts of water vapor.

These results are highly in contrast with the fact that the CO absorbing abilities of toluene solutions of $AlCuCl_4$ rapidly and significantly decrease on the contacts with water vapor.[4-6] Thus, CO separation processes using these liquid absorbents require pretreatments of feed gas to reduce the amount of water vapor to 1 ppm or smaller.[6] The water-resistivities of the present solid CO adsorbents are definitely attributable to protection of $AlCuCl_4$ by the polystyrene resin. As shown previously,[4,5] linear polystyrene exhibits effective protection of $AlCuCl_4$ from water vapor in toluene, resulting in water-resistant liquid CO absorbents.

In contrast to the water-resistivities of the adsorbents prepared by use of carbon disulfide and dichloromethane, the capacities of the adsorbents prepared by using toluene and benzene gradually decrease on the repeated contacts with water vapor (Fig. 2). The CO adsorbing and desorbing abilities of solid of $AlCuCl_4$ without the polystyrene resin are small.[8]

Microstructures of CO Adsorbents Prepared by Use of Various Solvents. In the polystyrene-supported $AlCuCl_4$ prepared by use of carbon disulfide as solvent, $AlCuCl_4$ uniformly disperses without formation of aggregates in the beads of the polystyrene resins (Fig. 4).

With the use of toluene as preparation solvent, however, the distribution of Cu atoms and that of Al atoms in the adsorbents are different from each other, and many deposits are formed in the beads (Fig. 5). The deposits are assignable to solid of CuCl on the basis of the atomic ratio (37.5:57.6:4.9) of Cu, Cl, and Al atoms. Both the deviation of the ratio (1.54) of Cl to Cu from the theoretical value (1.0) for CuCl and the presence of small amount of Al atoms are associated with the fact that the ratio has been determined by the analysis on a region of diameter around 1—2 μm. Thus the analysis involves signals from the parts other than the deposit, which are abundant in $AlCl_3$ (see Fig. 6 (a)), in addition to the signals from the deposit. Subtraction of three times (14.7) of the observed value (4.9) for Al atom from that (57.6) for Cl atom results in an estimated value (42.9) for Cl atom which exists in fact in the deposit. This subtraction is based on the assumption that all the Al atoms are present in the forms of $AlCl_3$. The ratio of the estimated value (42.9) for Cl atom to the observed value (37.5) for Cu atom is 1.14, which is close to the theoretical value (1.0) for CuCl.

The significant dependence of the distributions of the metal salts in the CO adsorbents on the preparation solvents is attributable to differences in the solubilities of the salts in the solvents. All the four solvents used, carbon disulfide, dichloromethane, benzene, and toluene, are good solvents for polystyrene.

When CuCl, $AlCl_3$, and the polystyrene resin are refluxed in carbon disulfide or dichloromethane, $AlCuCl_4$, formed in situ in the reaction mixtures, promptly penetrates into the polystyrene beads due to formation of molecular complexes between the double salt and the aromatic rings of the polystyrene resin. The amounts of $AlCuCl_4$ in the liquid phase after refluxing are virtually none.[8] Both carbon disulfide and dichloromethane are poor solvents for $AlCuCl_4$, $AlCl_3$, and CuCl. In the resin, $AlCuCl_4$ is located in the microporosities, and interacts with multiple aromatic rings there. Location of the $AlCuCl_4$ on the surface of the macroporosities of the resin in the adsorbents is energetically less favorable, since the number of the aromatic rings which can interact with one molecule of the double salt is smaller. On the subsequent evaporation of the liquid phase, homogeneous and molecular dispersion of $AlCuCl_4$ in the microporosities of the beads is achieved.

These arguments are supported by the finding[11] of strong charge-transfer bands having absorption maxima around 460 nm for the toluene solutions of $AlCuCl_4$ containing linear polystyrene. In the absence of the polystyrene, such charge-transfer bands were not detected at all.

On refluxing CuCl, $AlCl_3$, and the polystyrene resin in toluene or benzene, however, the $AlCuCl_4$ is present both in the polystyrene beads and in the liquid phase, since $AlCuCl_4$ effectively dissolves in benzene and toluene due to molecular complex formations with the aromatic solvents.[12,13] On the evaporation, most of the $AlCuCl_4$ in the liquid phase precipitates either on the surface of the macroporosities or on the surface of the beads.

The formation of deposits of CuCl in the beads of the adsorbents prepared with these aromatic solvents (Figs. 5 and 6) is probably associated with decomposition of some portion of $AlCuCl_4$ in the liquid phase to $AlCl_3$ and CuCl on the evaporation. Here, the CuCl aggregates each other to crystalline solids, and the $AlCl_3$ forms molecular complexes[14] with the aromatic rings around the macroporosities. As the evaporation proceeds still more, a part of the $AlCl_3$ dissolves in the solvents which are subsequently drawn out of the innermore parts of the beads. These $AlCl_3$ molecules gradually move towards the outside of the beads

together with the solvents, and at the final stage of the evaporation they precipitate either on the surface of the polystyrene beads or in the vicinity of their surface. The CuCl, which shows virtually no solubility in the solvents, retains the crystalline forms. These arguments are consistent with the large population of Al atoms on and near the surface of the beads (Fig. 5 (a)) and with the large population of Cu atoms in the inner portion of the beads (Fig. 5 (b)).

Mechanism of Water-Resistivities of CO Adsorbents. For the adsorbents prepared by use of carbon disulfide and dichloromethane as solvents, most of the $AlCuCl_4$ is located in the microporosities of the polystyrene resin. Inside of the microporosities, composed of aromatic rings and methylene residues, is highly apolar and the concentration of water vapor there is quite small even when the adsorbents are present under the atmosphere containing considerable amounts of water vapor. In addition, the aromatic rings interacting with the $AlCuCl_4$ in the microporosities prevent the access of water vapor to the double salt by steric hindrance. These effects, both of which suppress the irreversible reaction between the $AlCuCl_4$ and water, function cooperatively, giving rise to the water-resistivities of the adsorbents.

Rather small water-resistivities of the adsorbents prepared with the use of toluene and benzene are ascribed to location of some of $AlCuCl_4$ on the surface of the beads of the polystyrene resin and on the surface of macroporosities. These $AlCuCl_4$ molecules without sufficient protection by the aromatic rings of the polystyrene are rapidly deactivated with water vapor due to irreversible reaction.[5,6]

The above arguments are supported by the fact that the catalytic activity of $AlCl_3$ incorporated in a gel type polystyrene resin remains intact even after the resin-$AlCl_3$ composites are washed with water.[15] Porosity of gel type polystyrene resin exists only in swollen states in good solvents.[16]

The proposed mechanism for the water-resistivities of the present adsorbents is consistent with that for the water-resistivities of the toluene solutions of the linear polystyrene-protected $AlCuCl_4$ as liquid CO absorbents.[5] There, $AlCuCl_4$ is effectively protected by the adjacent aromatic rings of linear polystyrenes from water vapor.

In conclusion, water-resistant solid adsorbents for carbon monoxide, the macroreticular type polystyrene resin-supported aluminium copper(I) chloride, are prepared from copper(I) chloride, aluminium chloride, and the resin. The use of solvents such as carbon disulfide and dichloromethane, which are good solvents for the resin and poor solvents for the double salt, is essential for the adsorbents to be sufficiently stable against water vapor.

The authors wish to express their thanks to Mr. Shigeru Ohtsuka and Mr. Mitsuhiro Adachi at the University of Tokyo for the assistance in the scanning electron microscopy and the energy dispersive X-ray microanalysis.

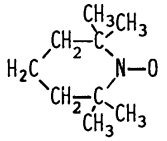
A Kinetic Study of Pressure Effect upon an Outer Sphere Electron-Transfer Reaction Involving Free Radicals

Masahiro EBIHARA, Yoichi SASAKI,† Shozo TERO-KUBOTA, and Kazuo SAITO*
Coordination Chemistry Laboratories, Institute for Molecular Science, Myodaiji, Okazaki 444
(Received July 14, 1986)

Synopsis. Volume of activation for the redox reaction between $[(en)_2Co^{III}(\mu\text{-}NH_2,O_2^{(-)})Co^{III}(en)_2]^{4+}$ (en, ethylenediamine) and 2,2,6,6-tatramethyl-1-piperidinyloxyl radical is zero. The result endorses our previous discussion that the changes in solvation and in intrinsic volume of reactants are respectively responsible for determining the precursor and transition state.

Usefulness of pressure effect for elucidating the reaction mechanism of electron-transfer reactions has been widely understood,[1-3] but experimental data are available only for limited variety of redox pairs.[4] When the charge sign of the oxidant and reductant is different from each other, the equilibrium constant for the precursor formation K_{os} and the electron-transfer rate constant k_e are kinetically analyzed.[5-8] Hence the molar volume change accompanied by the precursor formation ΔV°_{os} and the activation volume of the electron-transfer stage $\Delta V^{\neq}_e$ are individually known, particularly when the charge numbers are high.[4,9-11] We have discussed that the ΔV°_{os} is mostly governed by the environmental effect, i.e. the observed positive values are due to the release of hydrated water molecules in the second hydration sphere on the formation of precursor ion pair.[10] Such a consideration may be endorsed by use of a reductant without charge. We have chosen 2,2,6,6-tetramethyl-1-pyperidinyloxyl (TMPNO) which is soluble in water and stable in air as reductant and binuclear cobalt(III) complex doubly bridged by hyperoxide and amide as oxidant. This paramagnetic complex has its localized unpaired electron at the hyperoxide moiety and the two Co^{III} atoms have low spin configuration, which is retained in the reduced form, diamagnetic μ-peroxo-μ-amido bridged species. Hence the change in overall structure before and after the redox reaction is expected to be very small. The stoichiometry of the reaction is as follows.

$$[(en)_2Co^{III}(\mu\text{-}NH_2, O_2^{(-)})Co^{III}(en)_2]^{4+} + \text{TMPNO radical} \longrightarrow [(en)_2Co^{III}(\mu\text{-}NH_2, O_2^{(2-)})Co^{III}(en)_2]^{3+} + \text{TMPNO cation}$$



2,2,6,6-tetramethyl-1-pyperidinyloxyl (TMPNO)

Table 1. Kinetic Data for the Redox Reaction between $[(en)_2Co^{III}(\mu\text{-}NH_2, O_2^{(-)})Co^{III}(en)_2]^{4+}$ and 2,2,6,6-Tetramethyl-1-piperidinyloxyl Radical in Aqueous Solution

Experimental

The oxidant was synthesized by the known method[12] in pure chloride form. Commercial TMPNO was sublimed in vacuo. pH Titration gave no sign of protonation at pH 2 to 11. The standard redox potentials for TMPNO· to $TMPNO^+ + e^-$ are +0.478 and +0.475 V vs. SCE at ionic strengths 0.1 and 0.5 M (NaCl), respectively. The pH was adjusted with acetate buffer (acetate concentration 0.01 M) or perchloric acid to 2.85 to 5.00. The ionic strength was adjusted to 0.1 and 0.5 M with sodium perchlorate (M=mol dm^{-3}).

The kinetics were followed at 4.8 to 24.8 °C under the following conditions: [oxidant]=(0.73 to 7.3)×10^{-5} M, [reductant]=(2.0 to 10.0)×10^{-4} M. A Union Giken Stopped-flow spectrophotometer was used for the kinetic measurement. The pressure effect was measured (up to 200 MPa) by a High Pressure Stopped-flow Apparatus FIT 3 exploited in Department of Chemistry, Nagoya University.[13] The pressure was measured with a strain-type gauge calibrated with a standard Heize gauge. The pressure remained constant within less than 1 MPa.

Results

When the kinetics were followed by this method at 306 nm (absorption peak of the oxidant) in the presence of a large excess of the reductant, the pseudo first order plots with respect to the oxidant concentration were linear for more than three half period of the reaction. The first order rate constant is independent of the initial concentration of the oxidant and proportional to that of reductant.

$$\text{Rate} = k_{obsd}[\mu\text{-}NH_2, O_2^{(-)}][\text{TMPNO}]$$

Table I shows that the rate constant is independent of

† Present address: Department of Chemistry, Faculty of Science, Tohoku University, Sendai 980.

the pH and the buffering agent. It increases significantly with increase in ionic strength. The activation parameters included in the Table clearly indicate that the volume of activation is zero (Fig. 1) and so is the activation entropy. Ligand substitution of the oxidant complex is very slow under the given conditions.

Discussion

It is generally understood that the influence of ionic strength upon reaction rates is feasible in the precursor formation stage rather than in the electron-transfer stage.[7] The observed increase in k_{obsd} with ionic strength can be interpreted that the interaction between the oxidant in less strongly hydrated form and the reductant results in effective precursor. Since the reductant is a chargeless radical, this fact implies that the precursor formation will not bring about significant change in the solvation state of the precursor formation, to make the ΔV°_{os} almost zero. Since $\Delta V^{*}_{obsd}=\Delta V^{\circ}_{os}+\Delta V^{*}_{e}$, the volume of activation at the electron-transfer stage is also very likely near to zero.

Consideration on the basis of crystallographic data of $[(en)_2Co^{III}(\mu\text{-}NH_2,O_2^{(-)})Co^{III}(en)_2]^{4+}$,[14] $[(en)_2Co^{III}(\mu\text{-}NH_2,\ O_2^{(2-)})Co^{III}(en)_2]^{3+}$,[15] TMPNO,[16] and its oxidized cation[17] indicates that the change in molar volume of these species is not significant. The Co–Co distances of the hyperoxide- and peroxide bridged species are 3.25 and 3.27 Å, and the configuration of ethylenediamine ligand around Co^{III} as well as the Co–N distance is very similar to each other. The Co–O–O–Co moiety has planar (O–O 1.36 Å) and gauche (1.48 Å) structure, respectively, but the transition from O_2^- to O_2^{2-} will proceed without siginificant change in structure of that part. TMPNO and its oxidized cation have almost equal bond distances to each other including N–O (1.296 and 1.19 Å, respectively). The angles of N–O bond to the C–N–C plane of piperidine are 19.4 and 0°, respectively, but they are within the four methyl groups on 2- and 6- position and the small angle change will not cause big change in molar volumes of the two species. Thus the change in intrinsic molar volume of the oxidant and reductant on electron transfer will be very small. This fact indicates that the change in solvation state around the precursor will not be appreciable since the ΔV^{*}_{e} is near to zero. This consideration is supported by the very small absolute value of activation entropy.

When an electron is transferred from the chargeless TMPNO to the +4 oxidant in the precursor, a change in dipole moment may be expected, which could increase the hydration around the precursor, because +4 vs. 0 pair could give stronger hydration than +3 vs. +1 pair does. If this effect gave significant contribution to increase ΔV^{*}_{e} value, there should be some other contribution to compensate the increase in volume of the system. Careful examination of the molar volumes of participating species as well as the hydration around them did not suggest any possibility of decrease in volume of the system. Hence we conclude that in the present system both ΔV°_{os} and ΔV^{*}_{e} will be near to zero. The present result seems to support our previous conclusion that the contributions of change in solvation sphere and in the intrinsic volume of the reactants are respectively responsible for determining the precursor and the transition state of redox systems involving charged oxidant and reductant.

Synopsis. The molecular structure of the title complex, $(+)^{CD}_{550}\cdot(+)^{CD}_{370}$-[Co(aese)(tn)$_2$](ClO$_4$)$_2$, has been determined by the X-ray analysis. This isomer having the Λ configuration takes S configuration for the sulfur donor atom and one of the two 1,3-propanediamine chelate rings takes a chair form and the other an asymmetric skew-boat one.

In the previous papers,[2,3] we reported the preparation and the spectro- and stereochemical properties of the [Co(aese)(diamine)$_2$]$^{2+}$-type complexes, where the aese denotes 2-aminoethanesulfenate and the diamine is 1,2-ethanediamine (en) and 1,3-propanediamine (tn). In *Λ*-[Co(aese)(en)$_2$]$^{2+}$ generated by the oxidation reaction of *Λ*-[Co(2-aminoethanethiolato)(en)$_2$]$^{2+}$ with hydrogen peroxide, the formation ratio of the two isomers, *Λ*-(*R*) and *Λ*-(*S*),[4] is about 3:1.[2] While, the formation ratio of the two isomers for *Λ*-[Co(aese)-(tn)$_2$]$^{2+}$ obtained from a similar oxidation reaction is *Λ*-(*R*):*Λ*-(*S*)≈5:6.[3] In order to elucidate the difference in these formatiom ratios between the en and tn complexes, we determined in this work the molecular structure of $(+)^{CD}_{550}\cdot(+)^{CD}_{370}$-[Co(aese)(tn)$_2$](ClO$_4$)$_2$ by the X-ray diffraction method. The structure of the present tn complex is discussed in comparison with that of the corresponding [Co(aese)(en)$_2$]$^{2+}$ complex.[5]

Experimental

X-Ray Data Collection. $(+)^{CD}_{550}\cdot(+)^{CD}_{370}$-[Co(aese)(tn)$_2$]-(ClO$_4$)$_2$ was prepared by the method of the literature.[3] The resultant precipitate of the $(+)^{CD}_{550}\cdot(+)^{CD}_{370}$ isomer was collected by filtration. When the filtrate was kept in a refrigerator for 2 h, fairly large needle crystals, which showed the identical absorption and CD spectra with the $(+)^{CD}_{550}\cdot(+)^{CD}_{370}$ isomer, were obtained. The unit cell parameters and intensity data for the single crystal (ca. 0.18×0.24×1.00 mm^3) were measured on a Rigaku-denki four-circle diffractometer (AFC-5) with graphite-monochromatized Mo *Kα* radiation. The systematic absence led to either the space groups $P6_1$ or $P6_5$, which could not be determined by using the anomalous scattering factors for the Mo *Kα* radiation. Taking the absolute configuration based on the CD spectral behavior into consideration,[3] the space group is tentatively determined to be $P6_5$. The crystal data are as follows; $C_8H_{26}N_5O_9SCl_2Co$, a=9.367(1), c=37.878 (15) Å, V=2878.5(13) Å^3, hexagonal, $P6_5$, D_m=1.73 g cm^{-3}, D_x=1.724 g cm^{-3}, Z=6, and μ(Mo *Kα*)=13.6 cm^{-1}.

The intensity data were collected by a ω—2θ scan technique up to 2θ=60° with a scan rate of 3° min^{-1}. During the cource of the data collection, three reflections were monitored every 40 reflections. The intensity data were converted to F_o data in the usual manner. Absorption corrections were not applied. A total of 1020 indepedent reflections with $F_o > 3\sigma(|F_o|)$ were considered as 'observed' and used for the structure analysis.

Determination of Crystal Structure. The position of the cobalt atom was obtained from a three-dimensional Patterson function. Difference Fourier maps, based on the cobalt position, revealed all the non-hydrogen atoms. The structure was refined by a full-matrix least-squares refinement of the positional and anisotropic thermal parameters of all the non-hydrogen atoms (program RFINE by L. W. Finger was used[6]). The neutral atomic scattering factors for the non-hydrogen atoms were taken from the literature.[7] The final R and R_w values are 0.089 and 0.079, respectively. The final positional parameters and equivalent isotropic temperature factors for the non-hydrogen atoms are listed in Table 1. Tables of structure factors, anisotropic temperature factors, and bond lengths and angles are kept at the Chemical Society of Japan (Document No. 8714).

Results and Discussion

The perspective drawing of $(+)^{CD}_{550}\cdot(+)^{CD}_{370}$-[Co(aese)-(tn)$_2$]$^{2+}$ is shown in Fig. 1. The coordination geometry

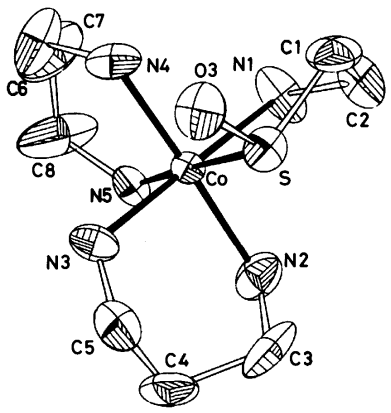

Fig. 1. A perspective drawing of $(+)_{550}^{CD}\cdot(+)_{370}^{CD}$-[Co(aese)$(tn)_2]^{2+}$ with the numbering scheme of the atoms.

around the cobalt atom is approximately octahedral. The 2-aminoethanesulfenate coordinates to the cobalt atom with the nitrogen and sulfur atoms. The asymmetric sulfur donor atom in $(+)_{550}^{CD}\cdot(+)_{370}^{CD}$-[Co(aese)$(tn)_2]^{2+}$ takes the (*S*) configuration for the Λ configuration which was suggested from the CD spectral behavior.[3] The five-membered chelate ring of the coordinated aese ligand, S-C1-C2-N1, takes the reasonable gauche form with a δ conformation (Fig. 1).[8] The six-membered 1,3-propanediamine chelate ring N2-C3-C4-C5-N3, takes the chair conformation, as in the case of the tn ligand in $[Co(tn)_3]^{3+}$,[9] $[Co(X)_2(tn)_2]^{n+}$ ($(X)_2$=$(NCS)_2$[10,11] and 2,4-pentanedionato (acac)[12]), and $[Co(en)_2(tn)]^{3+}$.[13] The other tn chelate ring, N4-C6-C7-C8-N5, however, has the asymmetric skew-boat form (Fig. 1). This irregular conformation seems to be caused by the intramolecular hydrogen bond between the sulfenato oxygen atom, O3, and the nitrogen atom, N4, of the amino group, because the distance between the oxygen atom and nitrogen one is 2.986 Å.

The coordination angles in the tn chelate rings, N2-Co-N3 and N4-Co-N5, are 90.6° and 93.4°, respectively, which are slightly smaller than those found in $(-)_{589}$-$[Co(tn)_3]^{3+}$ (mean 94.5°)[9] and $(-)_{589}$-$[Co(acac)(tn)_2]^{2+}$ (mean 96°).[12] The average bond lengths of Co-N2, Co-N3, and Co-N4, where the nitrogen atoms are cis position to the sulfur donor atom, is 1.991 Å, and this value is in consistent with that of Co-N in other (1,3-propanediamine)cobalt(III) complexes.[9-13] On the other hand, the trans Co-N5 bond length (2.074 Å) is longer than the average cis Co-N one. A similar trans effect has been observed in the bis(1,2-ethanediamine)cobalt(III) complexes with a coordinated sulfenato sulfur atom; $[Co(aese)(en)_2]^{2+}$[5] and [Co(L-cysteinesulfenato-*N*,*S*)$(en)_2]^{2+}$.[14] The bond lengths and angles associated with the aese ligand are similar to those of the corresponding bis(1,2-ethanediamine) complex,[5] although the Co-S bond length (2.199 Å) is somewhat shorter and Co-N1 one (2.033 Å) somewhat longer than those in $[Co(aese)(en)_2]^{2+}$ (Co-S=2.253 Å and Co-N=1.987 Å).

In *Λ*-(*S*)-$[Co(aese)(tn)_2]^{2+}$ (Fig. 1), the tn chelate ring, of which amine proton may participate in an intramolecular hydrogen bond with the oxygen atom of the aese ligand, takes the asymmetric skew-boat form, although the other tn chelate ring takes a chair form, as in the case of the tn chelate rings in $[Co(tn)_3]^{3+}$,[9] $[Co(X)_2(tn)_2]^{n+}$ ($(X)_2$=$(NCS)_2$[10,11] and acac[12]), and $[Co(en)_2(tn)]^{3+}$.[13] The Λ-(*R*) tn isomer can also be expected to take a similar intramolecular hydrogen bond to the Λ-(*S*) isomer because of the flexibility of the tn chelate ring. This stereochemical similarity of the Λ-(*R*) and Λ-(*S*) tn isomers is probably related to the fact that the two isomers are formed in roughly equal amounts. In crystal of *Λ*-(*R*)-$[Co(aese)(en)_2]^{2+}$,[5] both of the aese and en chelate rings, which take a lel conformation (δ conformation), form a similar intramolecular hydrogen bond to the Λ-(*S*) tn isomer. While, molecular model constructions reveal that the Λ-(*S*) en isomer can not be expected to have such interaction as the Λ-(*R*) en isomer because of the rigidity of the five-membered chelate rings. The stereochemical difference between the two Λ-$[Co(aese)(en)_2]^{2+}$ isomers suggests that the Λ-(*R*) isomer is more abundantly formed by the intramolecular hydrogen bond than the Λ-(*S*) isomer. In other words, the difference in the formation ratio between the isomers, (*R*) and (*S*), of *Λ*-$[Co(aese)(en)_2]^{2+}$ and those of *Λ*-$[Co(aese)(tn)_2]^{2+}$ is considered to be associated with that in the flexibility of the tn or en chelate ring and simultaneously with that in the formation of the intramolecular hydrogen bond.

(Received July 7, 1986)

Synopsis. In the presence of the optically active amino alcohol-borane complex, an oxime ether was reduced with various hydride reducing agents to give a chiral primary amine of high optical purity. Catalytic use of the chiral complex was also investigated.

We have reported previously that a tetrahydrofuran (THF) solution of a chiral reducing agent prepared from an optically active amino alcohol and borane reduced ketones and ketone oxime *O*-alkyl ethers quantitatively with high enantioselectivity to give optically active secondary alcohols[1] and primary amines,[2] respectively. In most studies for asymmetric reduction, a stoichiometric amount of chiral metal hydrides has been required. For the practical purpose, catalytic use of the expensive chiral auxiliary has been intensely desired as well as high enantioselectivity of the reaction.[4] In this context, we studied the catalytic behaviour of the chiral amino alcohol-borane complex in the reduction of oxime ethers.

The optically active amino alcohol such as **1** reacted with an excess borane in THF to generate hydrogen. After evaporation of unreacted free borane and THF under reduced pressure at room temperature, chiral complex was obtained as a white powder. Although this chiral complex has a B-H bond which was easily detected by infra-red spectroscopy (2500 cm^{-1}) and hydrogen evolution by acid hydrolysis, a THF solution of this white powder could not reduce any oxime ether within one day at room temperature. However, interesingly, when THF-borane (1:1) was added to the mixture of a THF solution of the chiral complex and acetophenone *O*-methyl oxime, optically pure (*S*)-1-phenylethylamine was obtained quantitatively in 20 h at room temperature, after hydrolysis (Table 1, Run 1). In the presence of the above chiral complex prepared from **1** and borane, the oxime ether was reduced asymmetrically also with metal hydrides such as lithium alminum hydride ($LiAlH_4$) and aluminum hydride (AlH_3) in place of borane. The reduction with sodium borohydride did not proceed due to its low reactivity. Results are summarized in Table 1.

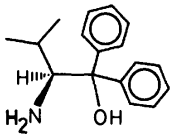
On the basis of these results, catalytic use of the chiral complex was investigated. For example, in the presence of 1 equiv of the chiral complex, 1 equiv of acetophenone *O*-benzyl oxime was reduced asymmetrically in a THF solution containing excess of free borane (4 equiv) to give (*S*)-1-phenylethylamine of 95% ee (see Experimental). Under the same conditions, 4 equiv of the oxime ether could also be reduced to give the chiral amine in 90% ee. These results show that the reduction is catalyzed by the chiral complex. The chiral complex would interact with the oxime ether to accelerate the borane reduction and induce asymmetry. Indeed, borane alone reduced the oxime ether slowly in THF at ambient temperatute. Even 10 equiv of the oxime ether was reduced quantitatively with 10 equiv of borane in the presence of only 1 equiv of the chiral complex to give the chiral amine (52%ee). This somewhat low enantioselectivity indicates that the reduction of the oxime ethers with free borane proceeded competitively when a small amount of the chiral complex was employed. To use the chiral complex more effectively, the following procedure was attempted. After asymmetric reduction of 5 mmol of acetophenone *O*-methyl oxime with borane in the presence of the chiral complex prepared from 5 mmol of the chiral amino alcohol, another 5 mmol of the oxime ether and borane was introduced again without work-up procedure. Overall, 10 mmol of the oxime ether may interact with the chiral complex successively. Isolated 9 mmol of the amine exhibited 85% of the optical purity. This result demonstrates that the chiral complex induces the asymmetric reduction also for the borane reduction of the second added substrate. The successive asymmetric reduction of the oxime ether was repeated five times. Total amount of the amine isolated was 43 mmol by use of only 5 mmol of the complex, optical purity of the amine being 67% ee. A gradual decrease of enantioselectivity would be caused by the accumulation of chiral amino borane after asymmetric reduction of the oxime ether.

Table 1. Enantioselective Reduction of Acetophenone *O*-Methyloxime in the Presence of Chiral Complex Prepared from **1** and Borane

Run	Reducing agent	I-Phenylethylamine			
		Yield/% (Isolated)	$[\alpha]_D^{22}$	%ee[a]	Config.[a]
1	BH_3	90	−40.3	100	S
2	$NaBH_4$	0	—	—	—
3	$LiAlH_4$	85	−30.6	76	S
4	AlH_3	79	−17.7	44	S

a) Values for maximum rotation and configuration taken from Ref. 7).

Although the exact structure of the chiral complex was not clear, this complex possessed interesting characteristics in the asymmetric reduction of oxime ethers; (1) The reduction with borane was accelerated by the presence of the complex. (2) The complex itself could not reduce oxime ether. (3) The high level of asymmetry was induced by the complex. (4) By the use of small amount of the complex, more than stoichiometric amount of the oxime ether was reduced asymmetrically. Consequently, we supposed tentatively that this chiral complex prepared from optcally active amino alcohol and borane may be a chiral catalyst, not a reagent, for asymmetric reduction of oxime ethers. The realization of higher efficiency of the chiral catalyst is now under investigation.



1

Experimental

All reactions were carried out under a nitrogen atmosphere. GLPC analyses were carried out on a Yanaco G180 gas chromatograph with a 3 m×3 mm column packed with PEG20 M on Diasolid L. Optical rotations were measured on a JASCO DIP-140 digital polarimeter using a 1 cm or 10 cm thermostated microcell. ^{1}H NMR spectra were taken in $CDCl_3$ (internal Me_4Si) on a JEOL JNM-PMX 60 or a JEOL JNM-GX 270 spectrometer. Melting points were determined on a Yanagimoto micromelting point apparatus.

Materials. Tetrahydrofuran (THF) was dried over sodium wire and distilled over $LiAlH_4$ and stored under nitrogen. AlH_3 was prepared by adding the theoretical quantity of 100% sulfuric acid to the standardized THF solution of $LiAlH_4$.[5] Borane was prepared by the reaction of $NaBH_4$ with diethyl ether–trifluoroborane (1:1) according to the procedure of Brown.[6] (*S*)-(−)-2-amino-3-methyl-1,1,-diphenyl-1-butanol (**1**) and acetophenone oxime *O*-alkyl ethers were prepared by previously described procedures.[2]

Enantioselective Reduction of Acetophenone *O*-Methyloxime with $LiAlH_4$ in the Presence of 1-Borane Complex. A solution of borane (20 mmol) in THF (10 ml) was added to a solution of **1** (10 mmol) at 0 °C during ca. 20 min. The resulting solution was stirred at 0 °C for 8 h. The excess of free borane and solvent were evaporated off in vac. at room temperature to give a white solid (the chiral complex). The chiral complex was dissolved in dry THF (20 ml) and acetophenone *O*-methyl oxime (10 mmol) in THF (5 ml) was then added dropwise at 0 °C. After addition was complete a THF solution of $LiAlH_4$ (10 mmol) was added at 0 °C. The reaction mixture was warmed to room temperature, stirred for 24 h, and then decomposed by the dropwise addition of Na_2SO_4 saturated water and 2M HCl(1 M=1 mol dm^{-3}). After hydrolysis, evaporation of THF deposited the **1**-HCl as a white solid, which was collected on a glass filter and washed with water. The aqueous acid extract was shaken with ether, cooled, made basic with aqueous ammonia, and extracted with ether. The ether layer was dried ($MgSO_4$) and evaporated to give a colorless oil which upon distillation (bulb-to-bulb) furnished 1-phenylethylamine: 85% yield. This was characterized by IR and ^{1}H NMR spectroscopy and shown to be homogeneous by GLPC analysis. The optical rotation was $[\alpha]_D^{22}$ −30.6° (neat)(lit,[7] $[\alpha]_D^{22}$ −40.3° (neat)). The optical yield, 76%, was calculated by the observed optical rotation and the kwown maximum rotation of 1-phenylethylamine.

Enantioselective Reduction of Acetophenone *O*-Benzyloxime with Borane in the Presence of 1-Borane Complex. A THF solution of the chiral complex was prepared from **1** (10 mmol) and borane (20 mmol) according to the above procedure. To the solution, a solution of acetophenone *O*-benzyl oxime (10 mmol) in THF (5 ml) was added and then borane (40 mmol) was added dropwise at 0 °C. The reaction mixture was warmed to room temperature and stirred for 24 h. After hydrolysis with 2M HCl, **1**-HCl was filtered off and benzyl alcohol was extracted. The aqueous layer was basified with aqueous ammonia and extracted with ether. The ether layer was dried ($MgSO_4$) and evaporated to give a colorless oil which upon distillation (bulb-to-bulb) furnished (*S*)-1-phenylethylamine: 80% yield, $[\alpha]_D^{22}$ −38.3°, 95% ee.

Regioselective Addition of Organic Chlorides to Epoxides in the Presence of Quaternary Ammonium Chloride

Xue-Ping GU, Isao IKEDA, and Mitsuo OKAHARA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka 2-1, Suita, Osaka 565
(Received July 9, 1986)

Synopsis. By a reaction of epoxides with organic chlorides in the presence of dodecyltrimethylammonium chloride as a catalyst, a series of 2-substituted 1-(chloromethyl)ethyl ethers were synthesized regioselectively in high yields under mild conditions.

Epoxides are useful materials in organic synthetic chemistry and industry based on its active epoxy ring, and many kinds of reactions with various reagents have been widely utilized. However, the reaction of epoxides with organic halides had not attracted much attention until the reaction with chloroacetate was reported, where the effect of a catalyst on this reaction was studied.[1] In the course of the investigation regarding the reactivity of epichlorohydrin under phase-transfer catalytic conditions,[2] we found that dodecyltrimethylammonium chloride is a very effective catalyst for the preparation of a wide variety of 2-substituted 1-(chloromethyl)ethyl ethers by the reactions of epoxides with various organic chlorides under mild conditions.

There are several reports concerning the application of 2-substituted 1-(chloromethyl)ethyl ethers. For example, 2-chloro-1-(chloromethyl)ethyl ethers can afford the corresponding azetidines by reactions with primary amines,[3] and are also used to modify the properties of rubber or cellulose.[4-7] At present, we found that 2-chloro-1-(chloromethyl)ethyl methoxymethyl ether (**3a**) is a very effective acetonylation reagent to convert a series of hydroxyl compounds to the corresponding acetonyl ethers.[8]

The reaction may proceed via the intermediate of 2-substituted 1-(chloromethyl)ethoxide as shown in Scheme 1, where Q^+ represents quaternary ammonium ion.

Several novel 2-substituted 1-(chloromethyl)ethyl ethers were synthesized in good yields using dodecyltrimethylammonium chloride as a catalyst. The synthetic conditions and results are shown in Table 1. Products are characterized by spectral and elemental analyses. In the mass spectra, all products gave the characteristic fragment peak based on the elimination of chloromethyl group, and no fragment peak based on dehydrochlorination appeared, showing that this addition reaction of organic chlorides to epoxide in the presence of dodecyltrimethylammonium chloride is regioselective, regardless of substitution group in the substrate epoxide within this experiment.

In the case of methallyl chloride with epichlorohydrin, no reaction proceeded at 85 °C. In the reaction of chloroacetone with epichlorohydrin, 2-chloro-1-(chloromethyl)ethanol was isolated in 57% yield as the main product rather than the anticipated 2-chloro-1-

Table 1. Synthesis of 2-Substituted 1-(Chloromethyl)ethyl Ethers

(chloromethyl)ethyl acetonyl ether, possibly due to the too acidic methyl or methylene group of chloroacetone.

Experimental

General Procedure for Preparation of 2-Substituted 1-(Chloromethyl)ethyl Ethers. 2-Chloro-1-(chloromethyl)ethyl Methoxymethyl Ether (3a): The mixture of chloromethyl methyl ether 24.6 g (0.30 mol), epichlorohydrin 31.4 g (0.36 mol) and dodecyltrimethylammonium chloride 3.9 g (0.015 mol) is stirred with a magnetic stirrer at 30 °C for 20 h. Then, by fractional distillation at reduced pressure, **3a** was obtained as a colorless liquid; yield: 48.3 g (93%); bp 94—95 °C/30 Torr (1 Torr=133.322 Pa). A GLC of the reaction product showed only one peak, except for excess epichlorohydrin. Another run of the same reaction was carried out at 50 °C for 3 h, yielding 74% of **3a**. Without the catalyst, the yield of **3a** was only 18%, even after a prolonged reaction time (48 h) at 30 °C. ^{1}H NMR ($CDCl_3$) δ=3.42 (s, 3H), 3.70—3.76 (d, 4H), 3.88—4.10 (m, 1H), 4.75 (s, 2H); MS, *m/z* (rel intensity) 173 (M^++1), 171 (M^+−1), 123 (12), 75 (12), 45 (100); IR (neat) 2970, 1460, 1170, 1060, 923, 770 cm^{-1}. Found: C, 34.66; H, 5.98; Cl, 41.14%. Calcd for $C_5H_{10}Cl_2O_2$: C, 34.71; H, 5.83; Cl, 40.97%.

1-(Chloromethyl)tridecyl Methoxymethyl Ether (3b): Synthesized by the reaction of 1,2-epoxytetradecane (0.1 mol) and chloromethyl methyl ether (0.11 mol); bp 100 °C/0.05 Torr (Kugelrohr distillation). ^{1}H NMR ($CDCl_3$) δ=0.80—1.00 (t, 3H), 1.10—1.80 (m, 22H), 3.40 (s, 3H), 3.46—3.65 (d, 2H), 3.65—3.80 (m, 1H), 4.74 (s, 2H); MS, *m/z* (rel intensity) 243 (5), 45 (100); IR (neat) 2950, 1050 cm^{-1}. Found: C, 65.57; H, 11.52; Cl, 11.98%. Calcd for $C_{16}H_{33}ClO_2$: C, 65.61; H, 11.36, Cl, 12.10%.

1-Chloromethyl-2-(decyloxy)ethyl Methoxymethyl Ether (3c): Synthesized by the reaction of decyl glycidyl ether (0.1 mol) and chloromethyl methyl ether (0.11 mol); bp 115 °C/0.04 Torr. ^{1}H NMR ($CDCl_3$) δ=0.76—1.10 (t, 3H), 1.06—1.80 (m, 16H), 3.40 (s, 3H), 3.42—3.80 (m, 6H), 3.80—4.00 (m, 1H), 4.74 (s, 2H); MS, *m/z* (rel intensity) 294 (12), 57 (52), 45 (100); IR (neat) 2950, 1110, 1040 cm^{-1}. Found: C, 60.93; H, 10.87; Cl, 11.82%. Calcd for $C_{15}H_{31}ClO_3$: C, 61.10; H, 10.60; Cl, 12.02%.

1-Chloromethyl-2-(phenylthio)ethyl Methoxymethyl Ether (3d): Synthesized by the reaction of phenyl glycidyl sulfide (0.1 mol) and chloromethyl methyl ether (0.11 mol); bp 90 °C/0.01 Torr. ^{1}H NMR ($CDCl_3$) δ=3.10—3.30 (d, 2H), 3.40 (s, 3H), 3.60—3.80 (d, 2H), 3.80—4.00 (m, 1H), 4.78 (s, 2H); MS, *m/z* (rel intensity) 246 (M^+), 123 (61), 45 (100); IR (neat) 2950, 1590, 1460, 1440, 1160, 1110, 1040 cm^{-1}. Found: C, 53.52; H, 6.08%. Calcd for $C_{11}H_{15}ClO_2S$: C, 53.54; H, 6.13%.

2-Chloro-1-(chloromethyl)ethyl Trimethylsilyl Ether (3e): Synthesized by the reaction of epichlorohydrin (0.11 mol) and chlorotrimethylsilane (0.1 mol); bp 81 °C/20 Torr. ^{1}H NMR ($CDCl_3$) δ=0.10 (s, 9H), 3.40—3.60 (q, 4H), 3.80—4.00 (m, 1H); MS, *m/z* (rel intensity) 185 (24), 151 (47), 93 (100) 73 (62); IR (neat) 2950, 1250, 1100, 840 cm^{-1}. Found: C, 35.62; H, 7.03; Cl, 35.17%. Calcd for $C_6H_{14}Cl_2OSi$: C, 35.82; H, 7.01; Cl, 35.24%.

2-Chloro-1-(chloromethyl)ethyl Ethoxymethyl Ether (3f): Synthesized by the reaction of epichlorohydrin (0.11 mol) and chloromethyl ethyl ether (0.1 mol); bp 85 °C/20 Torr. ^{1}H NMR ($CDCl_3$) δ=1.14—1.26 (t, 3H), 3.56—3.90 (m, 6H), 3.90—4.12 (m, 1H), 4.80 (s, 2H); MS, *m/z* (rel intensity) 187 (M^++1), 185 (M^+−1), 137 (14), 75 (14), 59 (100), 31 (32); IR (neat) 3000, 2900, 1450, 1140, 1060, 770 cm^{-1}. Found: C, 38.24; H, 6.47; Cl, 37.70%. Calcd for $C_6H_{12}Cl_2O_2$: C, 38.52; H, 6.47; Cl, 37.90%.

2-Chloro-1-(chloromethyl)ethyl Benzoate (3g): Synthesized by the reaction of epichlorohydrin (0.11 mol) and benzoyl chloride (0.1 mol); bp 89 °C/0.02 Torr. ^{1}H NMR ($CDCl_3$) δ=3.84—3.92 (d, 4H), 5.32—5.52 (m, 1H), 7.24—7.68 (m, 3H), 8.00—8.16 (m, 2H); MS, *m/z* (rel intensity) 234 (M^+), 232 (M^+), 123 (34), 122 (49), 105 (100); IR (neat) 1730, 1295, 1122, 730 cm^{-1}. Found: C, 51.48; H, 4.40; Cl, 30.20%. Calcd for $C_{10}H_{10}Cl_2O_2$: C, 51.53; H, 4.30; Cl, 30.40%.

2-Chloro-1-(chloromethyl)ethyl Methoxycarbonylmethyl Ether (3h): Synthesized by the reaction of epichlorohydrin (0.11 mol) and chloroacetic acid methyl ester (0.1 mol); bp 78 °C/0.02 Torr. ^{1}H NMR ($CDCl_3$) δ=3.72—4.00 (m, 8H), 4.30 (s, 2H); MS, *m/z* (rel intensity) 201 (M^++1), 199 (M^+−1), 151 (46), 93 (100), 75 (45); IR (neat) 2975, 1760, 1440, 1230 cm^{-1}. Anal. Calcd for $C_6H_{10}Cl_2O_3$: C, 35.84; H, 5.01; Cl, 35.26%. Found: C, 36.06; H, 5.07; Cl, 35.07%.

Benzyl 2-Chloro-1-(chloromethyl)ethyl Ether (3i): Synthesized by the reaction of epichlorohydrin (0.12 mol) and benzyl chloride (0.1 mol); bp 80 °C/0.05 Torr. ^{1}H NMR ($CDCl_3$) δ=3.60—4.00 (m, 5H), 4.68 (s, 2H), 7.16 (s, 5H); MS, *m/z* (rel intensity) 220 (M^+), 218 (M^+), 91 (100); IR (neat) 2800, 1460, 1120, 1090, 760, 720 cm^{-1}. Found: C, 54.43; H, 5.70; Cl, 32.17%. Calcd for $C_{10}H_{12}Cl_2O$: C, 54.81; H, 5.52; Cl, 32.35%.

Mechanism of Photochemical Reaction from Benzyl Chloride to Toluene in Solution

Takeshi TAKEMURA* and Masahisa FUJITA
Research Institute of Applied Electricity, Hokkaido University, Sapporo 060
(Received June 25, 1986)

Synopsis. The photochemical reaction from benzyl chloride to toluene has been investigated in rigid glasses and fluid solutions. The experimental results indicate that toluene formation from benzyl chloride in 2-methylpentane proceeds via hot benzyl radicals or higher triplet states that are isoenegitic to the vibrationless level of the S_1 state of BzCl and proceeds negligibly from stable benzyl radicals.

Benzyl chloride (BzCl) is photochemically very active and its photochemistry has been widely studied.[1-4] Although it is known that upon irradiation with UV light, BzCl in alkane solvents yields a variety of photochemical products, several problems for the reaction mechanism remain unsettled, especially concerning intermediates in the excited state leading to photoproducts. This note is concerned with the mechanism of the photochemical reaction from BzCl to toluene, which was believed to proceed via benzyl radicals (Bz radicals) as a reaction intermediate.[1-4]

On the other hand, it is difficult to observe any emission of the fluorescence and phosphorescence of BzCl in the usual organic solvents at any temperature.[1,5-7] This suggests that the lifetime of the S_1 state of BzCl in solution is very short (less than 10^{-12} s; cf. Results and Discussion) and that the T_1 state is poorly populated because the intersystem crossing rate from the S_1 state to an excited triplet state is unlikely to be as fast as 10^{12} s^{-1}. Accordingly, the photochemistry of BzCl in solution is considered to proceed exclusively from the S_1 state and/or from the higher triplet states. This consideration corresponds to the results by Cristol and Bindel, who indicated that the photoreaction of BzCl in *t*-butyl alcohol occurs via a short-lived upper state, S_1, or a higher triplet state.[2]

In this study, we attempt to elucidate the photochemical processes concerning the formation of toluene from BzCl as a prototype of the homolytic photochemical reaction and to reveal the energy-relaxation processes in the excited states of BzCl as a series of studies on those of halogenated benzenes.[7-11]

Experimental

Benzyl chloride (Wako Chemical Co.) was purified by repeated vaccum distillations. 2-Methylpentane (Tokyo Kasei Co.) was purified after the method described in a previous paper.[8] Absorption and emission spectra were measured, respectively, with a Hitachi 228 spectrophotometer and a high-sensitivity fluorescence and phosphorescence spectrophotometer by means of the photon-counting technique using a Hamamatsu R585 photomultiplier. Unless otherwise stated, the photochemical experiments were made at 77 K using 1-cm square quartz cell and irradiation was carried out at 265 nm with a bandwidth of 10 nm by the use of light from a 150-W xenon arc passed through a monochromator.

Upon irradiation of BzCl in 2-methylpentane (2-MP) at 77 K, the contents of Bz radicals and toluene produced are quantitatively obtained by monitoring the fluorescence of Bz radicals and the phosphorescence of toluene. In measurements of the fluorescence of Bz radicals and of the phosphorescence of toluene, the excitations were carried out at an absorption band of 318 nm for Bz radicals and at a band of 254 nm for toluene (with a bandwidth of 2 nm). The concentrations of BzCl in 2-MP examined were in the range 10^{-4}—10^{-5} M.

Results and Discussion

Upon irradiation with a UV light shorter than 270 nm, BzCl in 2-MP at 77 K reacts to form Bz radicals and toluene. Bz radicals show a structured fluorescence spectrum commencing at 465 nm and has a very strong absorption band at 318 nm. Therefore, the formation of Bz radicals can be quantitatively observed by monitoring the fluorescence spectrum excited at 318 nm. Toluene produced can also be detected by monitoring the phosphorescence of toluene by means of time-resolved spectroscopy.[8,9] The fluorescence from toluene can not be used as a quantitative measure of toluene because of the very low concentration of toluene produced and because of interference from the Raman scattering light due to solvents. It should be noted here that the fluorescence of BzCl could not be detected within our experimental accuracies (the quantum yield is less than 10^{-5}).

Also, no phosphorescence from BzCl could be observed. Fresh BzCl in 2-MP at 77 K did not show any emission with a lifetime longer than 10^{-3} s (the quantum yield is less than 10^{-5}). Although no fresh BzCl showed a structured emission spectrum starting at 390 nm with a lifetime of 3—5 ms, which is similar to the phosphorescence spectrum reported in Ref. 5, it was found from the excitation spectrum of the

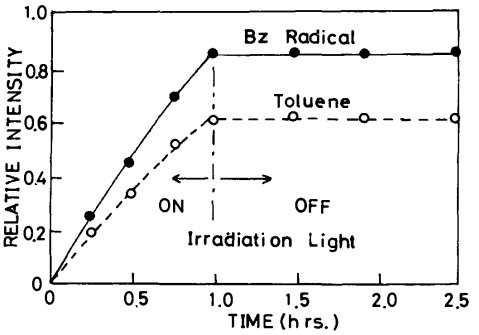

Fig. 1. Plots of the fluorescence intensities of Bz radicals (-●—●-) and the phosphorescence intensities of toluene (-○- -○-) as a function of the time with and without irradiation light of 265 nm of BzCl in 2-MP at 77 K.

emission that the emission is due to an impurity: maybe benzaldehyde. The emission with a lifetime of 2 s (produced by irradiation) can be attributed to toluene on the basis of the phosphorescence and its excitation spectra.

In Fig. 1 the fluorescence intensities of Bz radicals and the phosphorescence intensities of toluene are plotted as a function of the time with and without irradiation of BzCl in 2-MP at 77 K with a light of 265 nm. The concentrations of Bz radicals and toluene increase with the irradiation time and show no change for at least 3 h after irradiation. This is consistent with the observation that stable Bz radicals ("stable" means Bz radicals are in the vibrationless level in the ground state) in rigid glass solutions at 77 K react negligibly with solvents.[1)]

Figure 2 shows the formation rates of Bz radicals and toluene against the intensities of the irradiation light, indicating that each of the rates is linear to the light intensities under experimental conditions; that is, the photoreaction from BzCl to toluene as well as to Bz radicals is a one-photon process.

Now we are in a position to consider the mechanism regarding the photoreaction from BzCl to toluene. On the basis of the experimental results described above, we can give three mechanisms as candidates of a plausible path for the toluene formation from BzCl: (1) a reaction of toluene←stable Bz radical involves an appropriate orientation between the Bz radical and solvent molecules concerned and is accompanied by considerable amounts of the activation energy; (2) stable Bz radicals react with alkyl radicals produced by the reaction between the solvent and the chlorine atom (comes photochemically from BzCl) to form toluene with a negligible amount of the activation energy; and (3) toluene arises from a hot Bz radical or a higher triplet state isoenergitic to the vibrationless level of the S_1 state of BzCl and arises negligibly from stable Bz radicals. Mechanisms (1) and (2) involve the concentrations of stable Bz radicals, while (3) does not.

In order to decide which mechanism is acceptable, it is desirable to examine the oxygen effect on the photochemical reaction in question in a fluid solution. The lifetime of Bz radicals is found to be considerably long in a degassed alkane solvent and decreases with an increase in the concentration of oxygen.[1)] Accordingly, if the photochemical reaction in the fluid solution was influenced by aeration, mechanism (3) would be excluded from a possible mechanism. On the contrary, if the aeration effect on the reaction in the fluid solution is negligible, the contributions from (1) and (2) are less for the photochemistry in interest, and (3) is favorable.

BzCl in 2-MP at room temperature was irradiated for 3 h under deaerated and aerated conditions; then, the phosphorescence of toluene produced was quantitatively observed at 77 K. For both samples, deaerated and aerated solutions, the contents of the toluene produced by irradiation were almost equal to each other within our experimental accuracies. That is, the effect of oxygen on the reaction could not be clearly observed. The experimental results also showed that the toluene formation under fluid conditions was not in an order of magnitude appreciably different from those in rigid glass at 77 K. These facts indicate that the reaction of interest had no appreciable amounts of activation energy and involved no relatively long-lived species as intermediates (such as stable Bz radicals and the T_1 state of BzCl). In addition, the fact that the rate of the toluene formation is linear against the intensity of the irradiation light (as described before), excludes mechanism (2) from a possible path for the photoreaction.

Thus, the experimental results described above lead us to the conclusion that the photochemical reaction from BzCl to toluene proceeds via a very short-lived Bz radical (hot Bz radical) as the reaction intermediate and does not via stable Bz radicals and the T_1 state of BzCl. That is, hot Bz radicals produced from the S_1 state or the isoenergitic higher triplet state transform into toluene during the very short lifetime. These reaction processes seem to correspond to the mechanism of the heterolytic photoreaction of BzCl in *t*-butyl alcohol which is considered to occur via the short-lived S_1 state or a higher triplet state.[2)]

Figure 3 schematically shows the photochemical mechanism proposed. For BzCl in 2-MP, the lifetime of the S_1 state can be estimated to be shorter than one picosecond from the fluorescence quantum yield ($\leqslant 10^{-5}$) and radiative lifetime ($\approx 10^{-7}$ s estimated from the oscillator strength of S_0—S_1 absorption). This indicates that the S_1 state deactivates dominantly

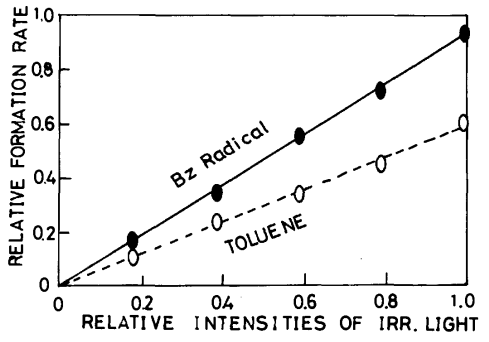

Fig. 2. Plots of the formation rates of Bz radicals (-●—●-) and of toluene (-O- -O-) against the intensities of the irradiation light.

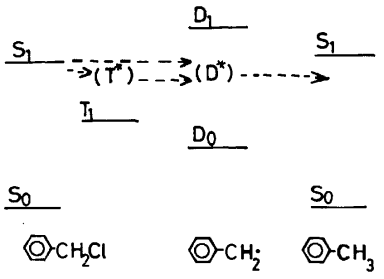

Fig. 3. Possible mechanism for photochemical reaction from BzCl to toluene in alkane solvent. The reaction proceeds along arrows in competition with vibrational relaxations.

to the radical formation directly or to higher triplet states. Although we could not decide whether the hot Bz radicals were formed directly from the S_1 state or via a higher triplet state, hot Bz radicals are actually regarded as being produced almost directly from the S_1 state.[12]

Finally, we shall show the results of a photochemical reaction for benzyl bromide (BzBr). BzBr also shows no fluorescence and phosphorescence under any condition and gives almost no Bz radicals. However, toluene is considerably produced from BzBr in 2-MP at 77 K upon irradiation with UV light. This seems to give some evidence that the photochemical process of toluene formation proceeds along the mechanism shown in Fig. 3.

Crystal Structure of the Mixed-Stacked Salt of Bis(ethylenedithio)-tetrathiafulvalene (BEDT-TTF) and Tetracyanoquinodimethane (TCNQ)

Takehiko Mori* and Hiroo Inokuchi
Institute for Molecular Science, Okazaki 444
(Received July 17, 1986)

Synopsis. The crystal structure of the monoclinic form of (BEDT-TTF)(TCNQ) is determined by X-ray analysis. The donor (BEDT-TTF) and the acceptor (TCNQ) molecules are planar and form alternating stacks.

Recently the discoveries of superconductivity have aroused much interest in BEDT-TTF complexes. Although the organic superconductors based on BEDT-TTF have been found among the salts with inorganic anions such as ReO_4^-, I_3^-, IBr_2^-, and AuI_2^-,[1] the conventional type of charge-transfer complex (BEDT-TTF)(TCNQ) was already prepared as early as 1978 when BEDT-TTF was first synthesized,[2] and this complex has been reported to be highly conductive by the measurements on compressed samples.[2,3] On the way to characterize this complex by means of the X-ray analysis and the measurements of physical properties by using single crystals, we found two different types of crystals: The monoclinic form and the triclinic form. The triclinic form of (BEDT-TTF)(TCNQ) is composed of segregated stacks, where TCNQ molecules are stacked face to face, while BEDT-TTF molecules are arranged side by side along the TCNQ stacks. This complex shows comparatively high conductivity and undergoes a characteristic metal-insulator transition around room temperature.[4] In the present paper we report the crystal structure of the other form, the monoclinic form of (BEDT-TTF)(TCNQ).

Experimental

Single crystals for structure analysis were obtained by the direct reaction of the donor and the acceptor in various organic solvent.[4] The donor and the acceptor were dissolved together in a hot organic solvent such as 1,1,1- and 1,1,2-trichloroethane, 1,2-dichloroethane, and THF, and the solution was allowed to evaporate at room temperature. By keeping for several weeks, black crystals of the complex in the form of elongated plates were grown. The triclinic form was obtained together with the monoclinic form from the same solution, and it was difficult to control reaction conditions so as to obtain only one form. Since these two forms were quite similar in shape, they were only distinguished by X-ray investigations.

Crystal Data. $C_{22}H_{12}N_4S_8$, F.W. 588.89, monoclinic, space group $P2_1/n$, a=23.897(4), b=7.327(2), c=7.053(2) Å, β=98.37(2), U=1221.8(5) Å^3, Z=2, D_x=1.601 gcm^{-1}, and μ(Mo $K\alpha$)=7.23 cm^{-1}. Intensity data were measured by the θ—2θ scan technique on a Rigaku AFC-5R automated four-circle diffractometer with graphite-monochromatized Mo $K\alpha$ radiation ($2\theta<60°$) and corrected for usual Lorentz and polarization effects, but not for the absorption. The structure was solved by the direct method and refined by the block-diagonal least-squares procedure to an R value of 0.052, by using 2294 independent reflections ($|F_o|>3\sigma(|F_o|)$). Anisotropic thermal parameters were adopted for all non-hydrogen atoms, and the hydrogen atoms were refined isotropically.

Results and Discussion

The atomic coordinates are listed in Table 1.[5] The crystal sturcture is shown in Fig. 1. The donors and the acceptors are stacked alternately along the b axis (the crystal long axis). Each molecule is present on an inversion center. The donor and the acceptor molecules are planar (see Fig. 1). As shown in Table 2, the planarity of BEDT-TTF is as good as those observed in the BEDT-TTF salts with various inorganic anions; the deviation of each atom from the optimal plane is within 0.04 Å except the terminal ethylene groups. This contrasts with the nonplanar structure of the neutral molecule.[6]

It is noteworthy that BEDT-TTF and TCNQ form either segregated (the triclinic form) or mixed (the monoclinic form) stacks with the same 1:1 composition. This is largely related to the similar molecular size. The rectangle of the outer sulfur atoms of BEDT-TTF, 9.6×3.7=36 Å^2 has almost the same size as that of TCNQ, 8.5×4.1=35 Å^2. In this context, the terminal ethylene group of BEDT-TTF plays an exceptional role, because there is no overlap between this part and TCNQ (Fig. 1) due to the steric repulsion of this out-of-plane aliphatic moiety.

C (10)-N (1)	1.14	1.14	1.17

The molecular geometry is depicted in Fig. 2. In order to estimate the degree of charge transfer, η, the molecular geometries of the constituents are analyzed in comparison with the molecular geometries in which the degrees of charge transfer are evident from their composition (Table 3). As for BEDT-TTF, the central C=C bond length and the C(1)-S(1) bond length are between those of $\eta=0$ and $\eta=1/2$ species. On the other hand, since the population of the LUMO of TCNQ is largest on C(8) and C(9),[9] the bond lengths associated with these atoms are sensitive to η; these bond lengths are also between $\eta=0$ and $\eta=1/2$. As a whole, we can conclude the degree of charge transfer to be between $\eta=0$ and $\eta=1/2$, probably about $\eta=0.2$—0.3.

The electrical resistivity measured by the usual four-probe method is in the order of 10^6 Ωcm. Saito et al. have briefly mentioned two forms of (BEDT-TTF)(TCNQ); one affords a broad infrared spectrum and the other affords a sharp spectrum.[3] The broad

spectrum is considered to be that of the triclinic form, and is associated with its high conductivity. On the other hand, the sharp spectrum is that of the present low-conductive monoclinic form.

Viscosity Behavior of Poly(2-vinylpyridine) of a Low Molecular Weight

Masafumi YOSHIDA,* Kikuo ITOH, Noriyuki SAKAMOTO, and Shizuo ARICHI
Department of Chemistry, Faculty of General Education, Kumamoto University, Kurokami 40-1, Kumamoto 860
(Received May 28, 1986)

Synopsis. For the data of the limiting viscosity number of poly(2-vinylpyridine) of a low molecular weight M_w=2.26—0.21×10⁴ in benzene and methanol, the value of the thickness parameter, b, and the energy difference, E, between the gauche and trans state were discussed in terms of the theory of Rossi and Perico. It is possible to use this theory for the viscosity data in the molecular weight range of 0.35—1.30×10⁴. The values of E and b were thus estimated; E depended on the nature of the solvent for this polymer, while b was constant (0.3 nm). The temperature dependence of the calculated limiting viscosity number, $d\ln[\eta]/dT$, in benzene and dioxane was discussed, together with the measured values.

In the relation of the limiting viscosity number and the molecular weight for the range of low molecular weights, the equation $[\eta]=KM^{0.5}$ holds. Here, the constant, K, is independent of the nature of a solvent.[1] For poly(2-vinylpyridine), the present authors previously reported that the constant, K, is equal to the value of Flory's K_θ, which is itself related to the unperturbed mean-square radius gyration of the chain molecule.[2] Consequently, it was deduced that it was possible to evaluate the characteristic ratio from the measurement of the limiting viscosity number for a low molecular weight.

On the other hand, according to the precepts of statistical mechanics, the properties of chain molecules should be evaluated by averaging all the conformations generated by varying all angles and all bond lengths to the extent permitted by the chain structure. The subsequent calculation for a long chain, is indeed formidable, but they can be greatly abbreviated though the adoption of a rotation angle.[3] Furthermore, Rossi and Perico reported the theoretical treatment of a short-chain polymer.[4] They showed that the limiting viscosity number of a short-chain polymer could be evaluated from a model of the independent hindered rotation by introducing b, a thickness parameter.

In this paper, the energy difference, E, between the gauche and trans states and thickness parameter, b, will be discussed on the basis of the limiting viscosity number for the low-molecular-weight range of poly(2-vinylpyridine) in benzene and methanol, using the theory of Rossi and Perico.[4] These values in several solvents will then be evaluated, and the temperature dependence of the calculated limiting viscosity number will be discussed.

Experimental

Poly(2-vinylpyridine) was polymerized, with butyllithium as the initiator, in tetrahydrofuran at −27 °C for the BL-sample, while A-1-V was polymerized with $\alpha\alpha'$-azobisisobutyronitrile in benzene at 25 °C. The polymer samples were obtained by the method of fractional precipitation. Benzene and petroleum ether were used as solvent and precipitant. The limiting viscosity number was measured with a Ubbelohode-type viscometer.

The weight average molecular weight of the polymer fraction was determined with a Fica-50 automatic light scattering photometer in methanol at 25 °C for scattered angles of 30—150°. The measurement of the specific refractive-index increment was carried out by the use of a Shimadzu-DR-3-type differential refractometer.

Results and Discussion

The relation of the limiting viscosity number and the molecular weight for short chain polymers was represented by the theory of Rossi and Perico.[4] The relation was as follows:

$$[\eta] = \phi 6^{3/2}(R_s^3/M)$$
$$R_s = \langle s^2\rangle_0^{1/2} + b$$

Table 1. Results from the Calculation and the Viscosity Measurements

Sample	$M_w \times 10^{-3}$	N_c[a]	$\langle s^2\rangle_{0,\,calcd}^{1/2}$[b] nm	Benzene $[\eta]_{calcd}$	Benzene $[\eta]_{meas}$	$\langle s^2\rangle_{0,\,calcd}^{1/2}$[c] nm	Methanol $[\eta]_{calcd}$	Methanol $[\eta]_{meas}$

a) Bond number of the polymer chain. b) and c) A root mean-square radius gyration for E=1.0 and 1.15 kcal mol^{-1} respectively. (1 cal=4.184 J).

where ϕ was a hydrodynamic parameter and was constant (2.87×10^{21}) for the number of monomeric units $N_c>20$; M was the molecular weight. $<s^2>_0$ was a mean-square radius gyration and was calculated for the chain with an independent bond rotational potential according to the rotational-isomer method[5]; b was the thickness of the polymer chain.

The limiting viscosity number for a low molecular weight was calculated by choosing the appropriate values of E and b yielding the best-fitting point. In Table 1 the calculated results are shown, together with the measured values, which have been reported before in benzene and methanol at 25 °C.[2] The calculated values were in very good agreement with all the measured values except with the data of BL-6-2 in methanol and with those of BL-6-9 in both solvents. The value of E is 1.0 kcal mol^{-1} in benzene and 1.15 kcal mol^{-1} in methanol. As to the disagreement with the value of E in benzene and methanol, it is possible to explain it as follows. The specific interaction between poly(2-vinylpyridine) and a solvent was investigated; alcohol is solvated to the pyridine nitrogen of this polymer through hydrogen bonding. However, there has been no report of the specific interaction in benzene for this polymer. On the other hand, the value of b is the same, 0.3 nm, in both solvents (the size of the pyridine ring: 0.3 nm). This value is reasonable. Furthermore, the relation of the calculated limiting viscosity number and the molecular weight is represented by the Mark-Houwink-Sakurada empirical equation: $[\eta]_\theta=K_\theta M^{0.5}$ That is, E is affected by the nature of a solvent, but b is independent of this polymer.

As to the discrepancy between the calculated and measured viscosity data of BL-6-2 in methanol and BL-6-9 in both solvents, it may be explained that, for the former, the theory of Rossi and Perico can not be accepted because of the presence of the excluded volume;[2] as for the latter, it is difficult to determine the accurate limiting viscosity number for very a low viscosity.

From the above conclusion that b is independent of the nature of a solvent, it is possible to evaluate E from one point of the limiting viscosity number over the suitable-molecular weight range: 3500—13000 for this polymer. Consequently, the value of E is calculated from the data of BL-6-7 in ethyl methyl ketone and dioxane and from those of A-1-V ($M_w=7.87\times10^3$) in ethanol and chloroform.[7] The value of E in ethyl methyl ketone and dioxane, which are very poor solvent for this polymer, are 0.95 and 1.05 kcal mol^{-1} respectively. On the other hand, in ethanol, E is 1.15 kcal mol^{-1} and in chloroform, 1.25 kcal mol^{-1}.

The Temperature Dependence of the Limiting Viscosity Number. The temperature coefficient of the limiting viscosity number for poly(2-vinylpyridine) was previously reported from the temperature dependence on the limiting viscosity number.[2] Therefore, the limiting viscosity number could be calculated from the above equation at several temperatures. Table 2 shows the results of the calculated limiting viscosity numbers together with the measured limiting viscosity numbers (BL-6-7) in benzene, dioxane and ethyl methyl ketone at several temperatures. It is found that the calculated values agreed with the respective measured values. The values of the temperature coefficient of the limiting viscosity numbers, as calculated by means of the method of least squares, are -5.1×10^{-3} in dioxane, -4.9×10^{-3} in benzene, and -4.6×10^{-3} in ethyl metyl ketone. On the other hand, the measured values are -4.5×10^{-3} in dioxane, -3.9×10^{-3} in benzene, and -3.7×10^{-3} in ethyl methyl ketone. From the agreement with the calculated and measured limiting viscosity number and/or these temperature coefficients, it is considered that the theory of Rossi and Perico is acceptable and that the E and b values for the low-molecular-weight poly(2-vinylpyridine) are reasonable.

Flory's K_θ value of the polymer was indirectly determined in a non-θ-solvent using an extrapolation method based on the two-parameter theory for a dilute solution. Flory's K_θ or K value of a low molecular weight for a non-polar polymer is independent of the nature of a solvent at the same temperature; E and b are constant. The solvent effect on Flory's K_θ value of a polar polymer has also been investigated.[7]

The results of the investigation of poly(4-vinylpyridine) by Hirai and Yanagida indicate that the hydrogen bonding and solvation for the side chain of a polymer must result in an increase in the values of E and b.[8] The values of E and b are 1.1—1.3 kcal mol^{-1} and 0.45—0.67 nm respectively for poly(4-vinylpyridine). The values of E and b for that polymer are a little larger than those for the present observation, and b is variable.

Table 2. Results from the Calculation and the Viscosity Measurements at Several Temperature

Temperature °C	Dioxane		Benzene		Ethyl methyl ketone	
	$[\eta]^{a)}_{calcd}$	$[\eta]_{meas}$	$[\eta]^{b)}_{calcd}$	$[\eta]_{meas}$	$[\eta]^{c)}_{calcd}$	$[\eta]_{meas}$
20	0.0618	0.0627	0.0570	0.0575	0.0526	0.0532
25	0.0601	0.0611	0.0555	0.0568	0.0512	0.0529
30	0.0584	0.0588	0.0540	0.0560	0.0500	0.0518
35.1	0.0569	0.0580	0.0526	0.0556	0.0487	0.0507
45	0.0541	0.0564	0.0502	0.0538	0.0466	0.0498
60	0.0504	0.0520	0.0469	0.0489	0.0437	0.0459

a) $E=1.05$ kcal mol^{-1}. b) $E=1.0$ kcal mol^{-1}. c) $E=0.95$ kcal mol^{-1}.

Now, the steric factor, σ, which is defined as the ratio between the actual steric hindrance, assuming a free rotation, is obtained from Flory's K_θ value. The effect of the substituent volume of the polymer chain on the value of is quite small-for example, polypropylene; 1.76, and polyisobutylene 1.80.[9] That is, the effect of the increase in the substituent volume, which results in the hydrobonding or solvation of this polymer, may not have an effect on σ or on Flory's K_θ value. This is perhaps to be explained by the fact that, in a polymer chain, a huge group of atoms corresponding to the remaining part of the chain is always attached to the carbon atom being considered; therefore, the substituent volume may have only a minor effect on the hindering potential for rotation about the C-C bond. In other words, it is suitable that b is constant and that the nature of the solvent affects the rotation of the chain.

In conclusion, the results of the above calculation suggest that the value of E and b can be evaluated from the limiting viscosity number of the low molecular weight for poly(2-vinylpyridine) in the range of 3500—13000 according to the theory of Rossi and Perico,[4] and that E is affected by the nature of a solvent, while b is constant.

The Structure of μ-Aquabis(μ-trichloroacetato)bis[aquabis(trichloroacetato)-erbium(III)] Hydrate, $[\{Er(CCl_3CO_2)_2(H_2O)\}_2(CCl_3CO_2)_2(H_2O)]_n \cdot nH_2O$

Takashi IMAI and Akira OUCHI*
Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153
(Received June 21, 1986)

Synopsis. The structure of the title complex has been determined by the single-crystal X-ray diffraction method. A crystal of $Er_2C_{12}H_8O_{16}Cl_{18}$, F. W. 1380.86 is triclinic, with the space group of $P\bar{1}$, a=12.787(8), b=15.209(7), c=11.685(7) Å, α=102.24(5), β=114.43(5), γ=70.59(4)°, Z=2 (for the dimer formula), D_x=2.36, D_m=2.34(3) Mg m^{-3}, and μ(Mo $K\alpha$)=5.74 mm^{-1}. All the carboxylate ions act as bidentate bridges, and each pair of the side-by-side metal atoms is bridged by four carboxylate ions, or by two carboxylate ions and one water-oxygen atom, alternately, forming a polymeric chain approximately parallel to the [011] axis. The chains are arrayed in layers parallel to the (100) plane, and the respective layers are separated by the trichloromethyl groups.

We have reported previously about the lanthanoid(III) 2-naphthalenesulfonate enneahydrate, where the crystal is composed of alternate layers of hydrophilic metal cores and hydrophobic naphthalene rings.[1] However, such a layer structure was not always found, even when the ligand has a large hydrocarbon group in it; for example, in neodymium(III) 1-hydroxy-2-naphthoate–water–ethanol (1/2/2), the ligand-metal cores are surrounded by naphthalene rings.[2]

As the layer structure is very interesting, we have been trying to find another example. Along this line, the title complex was chosen, because the trichloromethyl groups in the ligands were also expected to act as a hydrophobic part.

Moreover, as many lanthanoid(III) carboxylates have a complicated polymeric form in their crystals,[3,4] it is interesting to compare the structure of the title complex with them. Therefore, its crystal and molecular structure has been determined by the X-ray-diffraction method using a single crystal.

Experimental

Preparation of μ-Aquabis(μ-trichloroacetato)bis[aquabis(trichloroacetato)erbium(III)] Hydrate. Wet erbium(III) hydroxide, freshly prepared from an hydrochloric acid solution of erbium(III) oxide (0.38 g, containing 2.0 mmol of Er(III)) and an excess of sodium hydroxide, was treated with trichloroacetic acid (0.98 g, 6.0 mmol). The aqueous solution thus obtained (about 8 cm^3) was left standing in a desiccator over silica gel for several days at the ambient temperature; about two-thirds of the water was then removed, and crystals were deposited. They were filtered and washed with a little water. Yield: 0.62 g, 45%. Although the crystals were stable in a sealed bottle for several months, they easily lost a part of the water in the open air.

The dysprosium(III) complex, which is thought to be isomorphous, is also obtained by the same technique. (a=12.818(15), b=15.247(16), c=11.648(12) Å, α=102.01(9), β=114.62(9), γ=70.99(9)°, U=1950(4) Å^3).

Anal. ($M_2C_{12}H_8O_{16}Cl_{18}$) M=Er or Dy, C, H.

Single-crystal X-Ray Analysis. A crystal with dimensions of 0.25×0.25×0.15 mm^3 was used for the measurement after its edges have been ground off. The reflections within the range of $3°<2\theta<50°$ were collected on a Rigaku AFC-6A four-circle automated X-ray diffractometer with Mo $K\alpha$ radiation, employing the ω—2θ scan technique. Of the 6957 independent reflections, 4642 reflections with $|F_o|>3\sigma(|F_o|)$ were used for the refinement. The intensities were corrected for the Lorentz and polarization factors, but no correction was made for the absorption and extinction. All the calculations were carried out on a HITAC M-280H computer at the Computer Center of the University of Tokyo, using the local version of UNICS.[5] The scattering factors were taken from Ref. 6.

Structure Determination. The structure was solved by the heavy-atom method, and all the non-hydrogen atoms were found. However, as the temperature factors of the five chlorine atoms were found to be large, at the final step of the refinement their positions were fixed assuming their B_{iso} value to be 15.0. The final R value thus obtained, by applying the anisotropic temperature factors for the other atoms, was 0.084.[7] Although the thermal parameters of some chlorine atoms of this complex are found to be abnormally large, the same kind of positional ambiguities of some atoms are also found in the structural determination of some lanthanoid(III) complexes,[8–11] with regard to some carbon atoms of the hydrocarbon groups, or even some sulfur atoms which are apart from the central metal core and are in the hydrophobic moiety in the crystal.

Results and Discussion

Some selected bond lengths and bond angles are tabulated in Table 1.[12] The respective perspective drawings of the complex around Er(1) and Er(2) atoms are shown in Figs. 1 and 2; a schematic presentation to show the coordination geometries around the metal atoms as well as the bridging modes, in Fig. 3, and the crystal packing diagram, in Fig. 4.

All the metal atoms are octa-coordinated and are in the square-antiprism geometry. The Er–O bond lengths of the carboxylato oxygen atoms are 2.28 Å on the average (maximum, Er(1)–O(16^i)=2.387(13) and minimum, Er(2)–O(21)=2.227(17) Å),[13] while the Er–O(water) bond lengths are longer than they (2.45 Å on the average, except the Er(2)–O(W2)). The Er(2)–O(W2) is the longest one (3.10(2) Å), and this bond is thought to be very weak.

All the carboxylato ligands act as Z,Z-type bidentate bridges.[3] Their COM angles of the carboxyl groups are about 140—147°, except for some abnormal ones in **15** and **25**.[14]

One oxygen atom, O(W4) is not ligated with any

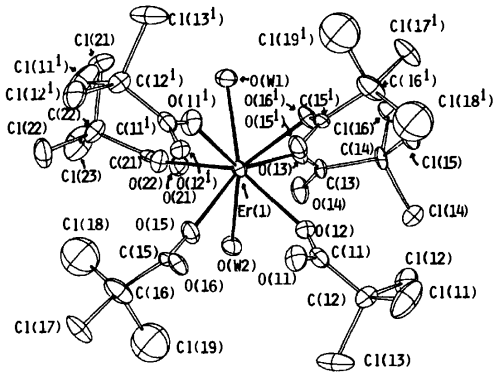

Fig. 1. A perspective drawing of the complex around Er(1) atom, with the numbering scheme of the atoms.[13]

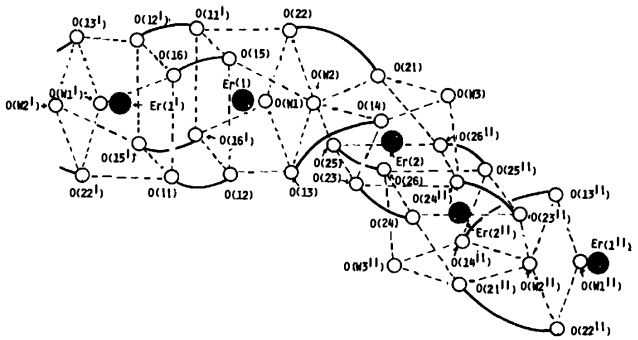

Fig. 3. Schematic presentation to show the coordination geometries around the metal atoms, as well as the bridgings between them.[13]

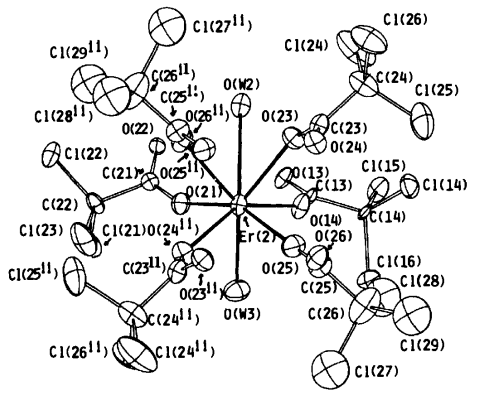

Fig. 2. A perspective drawing of the complex around Er(2) atom, with the numbering scheme of the atoms.[13]

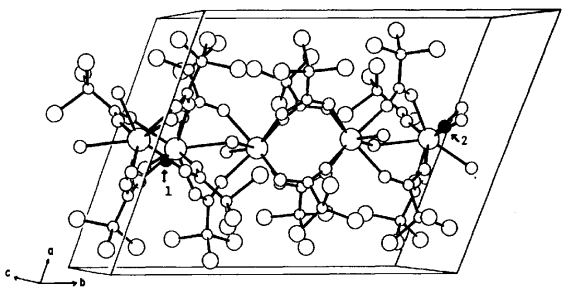

Fig. 4. Crystal packing diagram of the complex. ● atoms are: 1, O(W4); 2, O($W4^{II}$).[13]

metal atom, but it is hydrogen-bonded with O(W1), O(W3), and O(W1^{iii}) atoms.[13]

As is shown in Fig. 3, Er(1^{i})···Er(1), and Er(2)···Er(2^{ii}) are bridged by four carboxylate ions, while Er(1)···Er(2) is bridged by two carboxylate ions and one water oxygen atom O(W2), although Er(2)–O(W2) is a little too long. The dihedral angles of the respective pairs of the square planes above and below the Er(1) and Er(2) atom are 2.8 and 4.8° respectively, while that of the two squares joined by O(W2) is 62.3°. The intermetallic distances of Er(1^{i})···Er(1), Er(1)···Er(2), and Er(2)···Er(2^{ii}) are 4.430(4), 4.823(3), and 4.267(3) Å respectively, and they are aligned approximately along the [011] axis.

As is shown in Fig. 4, the polymeric chains are arrayed in a layer parallel to the (100) plane, and the chlorine atoms of the ligands take positions in the parallel layes on both sides of it. Thus, the layer structure of this complex resemble that of lanthanoid(III) 2-naphthalenesulfonate;[1] the hydrophobic-trichloromethyl group layers act as those of the naphthalene-ring layers of the latter complex.

The authors are greatly obliged to the Shin-Etsu Chemical Ind. Co., Ltd., for presenting them with highly pure lanthanoid oxides.

(Received June 26, 1986)

Synopsis. Dysprosium platinum and palladium bronzes, DyM_3X_4 (M=Pt or Pd; X=O, S, Se, or Te) were synthesized, except for $DyPt_3S_4$, by a solid state technique. They were found to have a high electric conductivity with ρ=0.3—2.6×10^{-5} Ω cm and among them, the oxide bronzes crystallized in $Na_xPt_3O_4$ type structure. The platinum oxide bronzes in particular showed a high activity for the methanol electrooxidation as compared with ordinary platinum electrodes.

Metal bronzes can be candidates for electrode materials,[1] since they often show a good electric conductivity and some of them possess a high corrosion resistivity in acid or alkali solutions. Shannon et al.[2] have tested a series of $M'_xPt_3O_4$ (M'=Li, Na, Mg, Ca, Zn, Cd, Co, and Ni), and found them promising as brine electrolyzer anodes or H_2-O_2 fuel cell electrocatalysts. Recently, rare earth palladium sulfide analogues of the platinum oxide bronzes, $LnPd_3S_4$(Ln=rare earth elements), have been reported by Keszler and Ibers.[3]

Methanol electrooxidation characteristics of platinum electrodes in acid solution are known to be considerably influenced by a trace amount of foreigen elements.[4] Among them, rare earth elements, typically dysprosium, have been reported to possess a significant degree of activity enhancement effect on the reaction.[4c] In this note, dysprosium platinum or palladium bronzes are prepared and the electric and electrocatalytic properties were studied.

Experimental

Preparation Method. The rare earth platinum (or palladium) bronzes were prepared by a solid state technique: Appropriate amounts of Dy_2O_3 and PtO_2 (or PdO) for oxygen bronzes or elemental Dy, Pt (or Pd), and X' (X'=S, Se, or Te) for other chalcogenide analogues were mixed. The former was heated at 773 K under oxygen stream for 40 h and the latter in an evacuated silica tube at 1073 K for 60 h. A structural analysis of the samples prepared was performed by X-ray diffraction (XRD) using monochrmatized Mo $K\alpha$ radiation (λ=0.70926 Å) and the atomic ratio was checked by X-ray fluorescent spectroscopy.

Electrical and Electrochemical Measurements. The electric resistivity of the sintered samples were measured using a four probe method in air at room temperature. The methanol electrooxidation experiments were carried out according to the method described elsewhere.[5]

X-Ray Photoelectron Spectroscopy Measurements. The XPS signals were obtained with an ESCA VG-III apparatus using Al $K\alpha$ radiation.

Results and Discussion

Preparation of Bronzes. The samples obtained were found to give powder XRD patterns different from those of the raw materials, except for the case of the Dy-Pt-S mixture. The XRD data have indicated that the oxides are crystallized in a $Na_xPt_3O_4$ type structure (cubic, $Pm3n$).[6] Preparation of the rare earth platinum or palladium oxide bronzes is the first case reported in so far as we know. The XRD data are listed in Table 1 and the phase relations are summarized in Table 2, together with those of the other chalcogenide systems Dy-M-X'. Since the oxide samples have been mixed with the remaining Dy_2O_3 and Pt (or Pd and PdO) or the reaction has not been stoichiometrically achieved, they are expected to be of the form $Dy_xM_3O_4$ with $x\leqq1$ and not DyM_3O_4. The lattice constants of the platinum and palladium oxide bronzes were determined by a least-square treatment to be a=5.665(3) and 5.651(2) Å, respectively. The

observed fact that the lattice constant of the platinum oxide bronze is about 0.2% larger than that of palladium appears to be reasonable from the difference between their ionic radii.

The crystal structure of $Dy_xM_3O_4$ is shown in Fig. 1. Each Dy atom is located in the hole of M_3O_4 framework and is surrounded by 8 O atoms. The M_3O_4 framework consists of M–O bonds of which each M or O atom is linked to 4 O and 3 M atoms with 1.998—2.003 Å. Particularly, the M and O atoms form a coplanar square or a triangle configuration with O atoms and M, respectively, which allow the chemical bonds between M and O atoms via interactions of their dsp^2 and sp^2 hybrid orbitals, etc. These covalently bonded atom groups must be closely related to their electrical properties as described later.

For the sulfide systems, the Dy-Pt-S specimen gives only those XRD patterns which are derived from PtS. Thus, no bronze was likely to be formed under the experimental conditions employed. Exceptionally, however, the palladium sulfide bronze, $DyPd_3S_4$ was formed in a single phase, which did not contain starting materials as impurities. The crystal data [cubic, a=6.646(2) Å] corresponded with that of the lanthanum analogue [cubic, a=6.7394(1) Å][3] which is isostructural with $Na_xPt_3O_4$ as well as the above oxide bronzes.

On the other hand, the selenide and telluride specimens showed new XRD patterns (Table 3) which were not assigned as that of the $Na_xPt_3O_4$ type bronze nor of other selenides or tellurides of Dy, Pt, and Pd; their structures were not determined. However, since they showed a high electric conductivity characteristic of bronzes as described later and the atomic ratio determined by the X-ray fluorescent spectra agreed with that in the starting mixtures, the new XRD patterns might be derived from the DyM_3X_4 type bronzes.

Electric Conductivity. The specific resistivity data of the specimens are summarized in Table 2. They were found to be good electric conductors (ρ=0.3—2.6×10^{-5} Ω cm), except for the specimen in the Dy–Pt–S system (ρ=1.1×10^{-3} Ω cm). The results seem to be in harmony with their phase formations: The high conductivity is realized with the formation of bronzes whilie the Dy–Pt–S mixture [of which the major phase is PtS (semiconductor)] has low conductivity. Along this line, the formation of bronzes in the selenide and telluride systems may be suggested from their high conductivity, although their structure has not been identified by the XRD method.

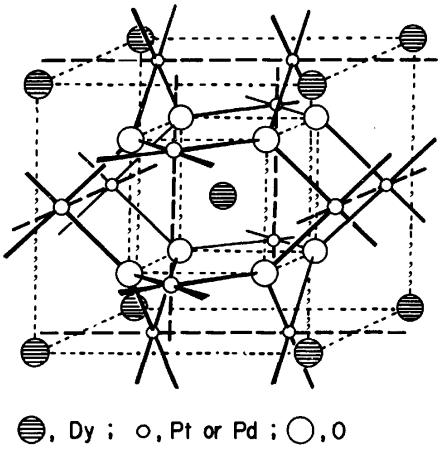

Fig. 1. Crystal structure of $Dy_xM_3O_4$ (M=Pt or Pd) based on the $Na_xPt_3O_4$ structure.[6]

X-Ray Photoelectron Spectroscopy. Typical XPS spectra of $Dy_xPt_3Se_4$ are shown in Fig. 2. The spectrum derived from Se 3 d electrons consisted of two bands at 52.8 and 57.1 eV, which might be assigned to those of Se^{2-} and Se^{4+} ions, respectively. The Pt 4f electrons gave two sets of XPS signals at 70.9—74.2 and 73.6—77.0 eV, which might be attributed to neutral Pt atoms and Pt^{2+} ions, respectively. Since H_2SeO_3 and Pt have never been detected on the XRD pattern of $DyPt_3Se_4$, such ionic species are likely to be formed only near the surface by hydrolysis with moisture in air. For the dysprosium, a broad band at about 153.0 eV was observed which might be originated from the 4d electrons of Dy^{3+} ions. Similar valence relations among the elements were also observed on the other bronzes. Thus, the DyM_3X_4

bronzes generally consist of the elements of Dy^{III}, M^{II}, and X^{-II}. Accordingly, these bronzes can generally be formulated as $[DyM_3X_4+e^-]$ and the resulting electrons are presumably sent to the conduction bands formed by the covalently bonded M_3O_4 framework. This model of supplying electrons can perhaps describe their metallic conductivity.

Methanol Electrooxidation Characteristics. The oxide bronzes, particularly $Dy_xPt_3O_4$, were found to have a high level of catalytic activity for the methanol electrooxidation. The other chalcogenide analogues were, however, unstable in acid solutions. The Tafel relation observed on a $Dy_xPt_3O_4$ electrode with the roughness factor (R_F; the value was determined by amounts of the under-potential hydrogen adsorption) of 630 is shown in Fig. 3, together with that of a platinized Pt (pt-Pt) electrode (R_F=120); the large R_F value of the bronze may be caused by the dissolution of one of the starting material, viz. Dy_2O_3, existed as an impurity in the bronze. The electrode showed the rest potential around 0.35 V (RHE) which was more negative, and hence suggested a better catalytic activity, than that of Pt itself at which it was usually 0.40—0.45 V. Indeed, the specific activity per true unit surface area of $Dy_xPt_3O_4$ was observed to be about one order of magnitude higher than that of ordinary Pt electrode.

Kinetic Studies on Dehydrogenation Reaction of 5,6-Dihydro-2,4(1*H*,3*H*)-pyrimidinediones in Aqueous Solution Induced by Argon Arc Plasma or Hydrogen-Oxygen Flame

Hiroshi NARAOKA, Michiaki TAKASAKI, Shinya NOMOTO, and Kaoru HARADA*
Department of Chemistry, University of Tsukuba, Sakura, Niihari, Ibaraki 305
(Received June 13, 1986)

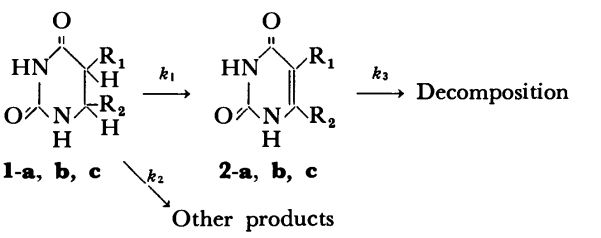
Synopsis. 5,6-Dihydro-2,4(1*H*,3*H*)-pyrimidinediones underwent dehydrogenation at the 5- and 6-position producing 2,4(1*H*,3*H*)-pyrimidinediones in aqueous solution induced by argon arc plasma or flames. From consideration based on the kinetic study of this reaction, it was found that abstraction of a hydrogen atom took place preferentially at the 6-position of the dihydropyrimidinediones.

Although various types of plasma chemistry have been reported,[1] most of these are chemical reactions in the gaseous phase or onto the solid phase. Few organic reactions in aqueous solution using plasma have been performed except for contact glow discharge electrolysis.[2] We recently reported a few aqueous-phase reactions induced by argon arc plasma or flames.[3-5] When argon arc plasma or flames of various gases mixed with oxygen were kept in contact with aqueous solution containing organic compounds, a very powerful and clean oxidation reaction took place without adding any oxidizing agent. For example, aliphatic amines were oxidized to amino acids,[3] and direct hydroxylation of aromatic rings proceeded in aqueous solution of phenyl-containing amino acids.[4] The active oxidizing species could be hydroxyl radicals which exist in flames, or which are produced by dissociation of water by high energy argon arc plasma.

In the present study, it was found that 5,6-dihydro-2,4(1*H*,3*H*)-pyrimidinediones underwent dehydrogenation at the 5- and 6-position producing 2,4(1*H*,3*H*)-pyrimidinediones in aqueous solution induced by argon arc plasma or flames. This paper reports the kinetics of the dehydrogenation and the reaction mechanism.

Results and Discussion

The substrates used here were 5,6-dihydro-5-methyl-2,4(1*H*,3*H*)-pyrimidinedione (**1a**), 5.6-dihydro-2,4(1*H*, 3*H*)-pyrimidinedione (**1b**) and 5,6-dihydro-6-methyl-2,4(1*H*,3*H*)-pyrimidinedione (**1c**) (Scheme 1). The time courses of the yield of product (**2c**) and the decay curves of the substrate (**1c**) are shown in Figs. 1 and 2, which were obtained by using argon arc plasma and hydrogen-oxygen flame, respectively. The yields of pyrimidinediones increased with the reaction time and then decreased because of the decomposition of the products. Table 1 shows the maximum yield and its reaction time for each substrate. The order of the maximum yields of the products are as follows: **2c>2b>2a**, in both energy sources.



1a, 2a: $R_1=CH_3$, $R_2=H$ **1b, 2b**: $R_1=H$, $R_2=H$ **1c, 2c**: $R_1=H$, $R_2=CH_3$

Scheme 1.

Table 1. Maximum Yields and Thier Reaction Times for Each Substrate and the Energy Source

	1a-2a	**1b-2b**	**1c-2c**
Ar arc plasma	1.0% (40 min)	2.3% (60 min)	6.8% (40 min)
H_2-O_2 flame	2.4% (60 min)	4.0% (100 min)	6.4% (60 min)

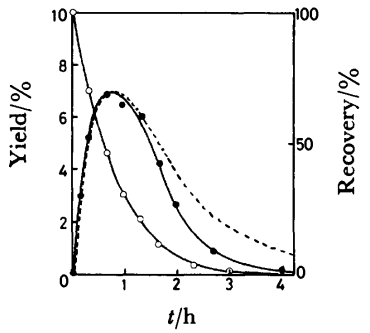


Fig. 1. The time course of the yield of **2c** through dehydrogenation reaction of **1c** by argon arc plasma; (○—○) **1c**, (●—●) **2c**.

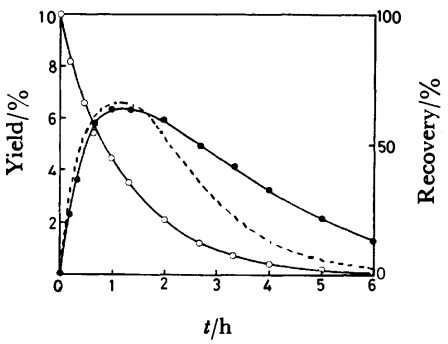

Fig. 2. The time course of the yield of **2c** through dehydrogenation reaction of **1c** by hydrogen-oxygen flame; (○—○) **1c**, (●—●) **2c**.

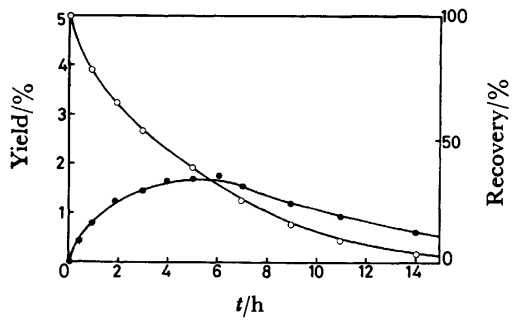

Fig. 3. The time course of the yield of **2b** through dehydrogenation reaction of **1b** by acetylene–oxygen flame; (O—O) **1b**, (●—●) **2b**.

This dehydrogenation reaction could proceed by the action of hydroxyl radicals, which were produced through dissociation of water molecule by high energy argon arc plasma, or transferred into the aqueous reaction mixture from the flames.[3–5] The dehydrogenation reaction was also effected by an acetylene(C_2H_2)–oxygen flame instead of a hydrogen–oxygen flame (Fig. 3). The rate of the dehydrogenation reaction with this flame was lower than that with a hydrogen–oxygen flame. This could be due to the lower hydroxyl radical abundunce in the acetylene–oxygen flame.

This reaction proceeded as a first-order reaction with respect to the decay of the substrate. This result was attributed to the large number of active species provided. Accordingly, it was also confirmed that the decay of the product proceeded as a first-order reaction from individual experiments. The reaction pathway could be explained as shown in Scheme 1, where k_1+k_2 and k_3 are the rate constants for the decay of the substrate and the product, respectively. The rate expression for the reaction is given by

$$\frac{d[P]}{dt} = k_1[DHP_0]e^{-(k_1+k_2)t} - k_3[P], \quad (1)$$

where [P] represents the concentration of the product, and [DHP_0] stands for the concentration of the substrate at t=0. Eq. 1 gives

$$[P] = -\frac{k_1}{k_1+k_2}[DHP_0](e^{-(k_1+k_2)t}-1) - k_3\int_0^t [P]dt. \quad (2)$$

The value of k_1+k_2, k_3, and k_1 are shown in Table 2. The theoretical curves are represented in Fig. 1 and Fig. 2 by dotted line, using Eq. 3 which is obtained from Eq. 1.

$$[P] = \frac{k_1}{k_3-k_1-k_2}[DHP_0](e^{-(k_1+k_2)t}-e^{-k_3t}). \quad (3)$$

The value of $k_1/(k_1+k_2)$, which represents the ratio of the dehydrogenation reaction, are shown in Table 2. It is apparent that the ratio of $k_1/(k_1+k_2)$ on **1c** was higher than that of others. These results show that the dehydrogenation reaction of **1c** took place easier than the others.

It has been known that the radical abstraction of a hydrogen atom is observed at the site with higher electron density.[6] For the substrates used, the electron density is lower at the 5-position than at the 6-position owing to the electron-withdrawing effect of a carbonyl group at the 4-position. In addition, in the case of **1c**, the electron density at the 6-position should be highest owing to the inductive effect of the methyl group.

Based on the considerations mentioned above, the experimental results suggest that the preferential redical abstraction took place at the 6-position. Therefore, **1c** had the highest value of $k_1/(k_1+k_2)$.

The chemical reactions in aqueous solution induced by flames or argon arc plasma are a new type of chemistry. The reaction is also interesting from the chemical evolutionary point of view. The reaction could be regarded as a model for the solar plasma-induced reaction in the primitive hydrosphere, when the primitive Earth had no magnetic field and low atmospheric pressure.

Table 2. Rate Constants of Dehydrogenation Reaction for Each Substrate and Energy Source

Substrates	Rate constants (min^{-1})			$k_1/(k_1+k_2)$
	k_1+k_2[a]	k_3[b]	k_1[c]	
1a–2a*	2.02×10^{-2}	2.14×10^{-2}	6.38×10^{-4}	0.032
1b–2b*	2.11×10^{-2}	2.04×10^{-2}	1.07×10^{-3}	0.028
1c–2c*	1.97×10^{-2}	2.06×10^{-2}	3.73×10^{-3}	0.19
1a–2a**	1.33×10^{-2}	3.03×10^{-2}	1.21×10^{-3}	0.096
1b–2b**	1.25×10^{-2}	2.94×10^{-2}	1.63×10^{-3}	0.16
1c–2c**	1.27×10^{-2}	2.76×10^{-2}	3.59×10^{-3}	0.28

* Ar arc plasma. ** H_2–O_2 flame.

a) The values k_1+k_2 were obtained from the data up to 80 min after the begining of the reaction for both argon arc plasma and hydrogen-oxygen flame. b) The values k_3 were obtained from the data up to 80 min or 40 min after the begining of the reaction for argon arc plasma or hydrogen-oxygen flame, respectively. c) Using Eq. 2, the values of k_1 were estimated by averaging the values of each 20 min after 20 min up to 80 min or 180 min of the reaction, carried out by argon arc plasma or hydrogen-oxygen flame, respectively. The term $\int_0^t [P]dt$ was estimated by the area of the figure in comparison with that of a standard.

Experimental

Materials. Compound **1b** was prepared by the method of Dakin.[7] Other substrates were commercial products. Their purities were checked by high performance liquid chromatography (HPLC).

Apparatus and Procedures. The apparatus used is shown in Fig. 4. The plasma torch used for the plasma induced reaction was a non-transferred type plasma torch (Nippon Welling Co., Wellpen NP-7). The conditions to produce plasma jet were: argon, 1.5 dm^3 min^{-1}; electric current, 40 A; electric voltage, 15 V. The plasma torch was immersed into the solution of the substrate 1 cm below the surface and the plasma jet was directly applied into the solution. The flame used in the dehydrogenation reaction was a hydrogen–oxygen flame, and the flow rates of gas

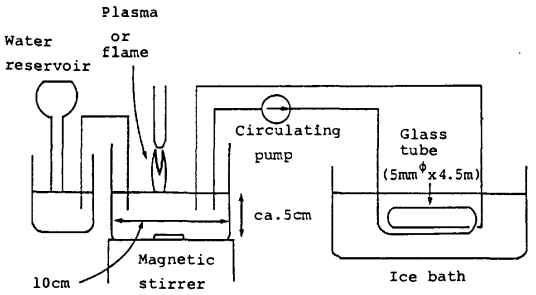

Fig. 4. Apparatus for the plasma- or flame-induced reaction.

($dm^3\ min^{-1}$) were 1.5 (hydrogen) and 0.8 (oxygen). A flame from a burner nozzle was blown onto the solution 3 cm above the surface. The temperature of the solution was kept at 40—50 °C throughout the reaction by circulating the solution through a glass tube immersed in an ice bath. The concentration of the substrates were 2.5×10^{-2} mol dm^{-3} and the volumes of the reaction mixture were 0.3 and 0.5 dm^3 for the flame and plasma, respectively. At appropriate time intervals, 0.5 ml aliquots of the solution were withdrawn and analyzed with HPLC. The column used for HPLC was Finepak C_{18} (JASCO 4.6 mm i.d.×25 cm; eluent: H_2O–CH_3OH) and UV detector (230 nm) was used. Quantitative analyses were carried out by comparison with authentic samples.

Preparation and Structures of Acetylene Adducts of 4,6-*O*-Isopropylidene- and 4-*O*-Acetyl-6-*O*-triphenylmethyl-1,5-anhydro-2-deoxy-D-*erythro*-hex-1-en-3-uloses[1)]

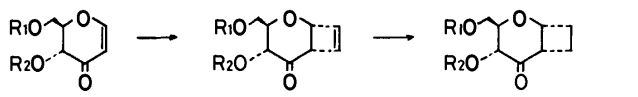
Synopsis. Cyclobutene adducts were formed stereoselectively in good yields by the irradiation of acetone solutions of 4,6-*O*-isopropylidene- and 4-*O*-acetyl-6-*O*-triphenylmethyl-1,5-anhydro-2-deoxy-D-*erythro*-hex-1-en-3-uloses, derived from D-glucal triacetate, in the presence of acetylene. The stereochemistry at the ring junction was achieved by a single-crystal X-ray analysis and a chemical correlation with the derived compounds.

Carbohydrate enones can be used to produce chiral compounds with four- and six-membered rings by the photochemical addition and Diels–Alder reaction of olefins, although in certain cases there are problems of regio- and stereochemical-selectivity in cycloadduct formation. In recent reports,[2)] Fraser-Reid et al. have demonstrated that annulated pyranosids obtained from carbohydrate α-enones can be converted into a variety of natural products and analogues. We have been concerned with the use of an enone system in pyranone compounds in order to prepare thermal and photochemical cycloadducts, e.g., the Diels–Alder adducts[3)] of methyl 2-oxo-2*H*-pyran-5-carboxylate with isoprene and the acetylene adducts[1)] of 7-methoxychromone, which are rearranged to cyclic skeletons and transformed into aromatic compounds.[1,4)] In the present investigation, conversions of carbohydrates into the chiral pyranone compounds and the use of their enone systems in cycloaddition reactions have been studied. This paper describes how photochemical reactions of 4,6-*O*-isopropylidene- and 4-*O*-acetyl-6-*O*-triphenylmethyl-1,5-anhydro-2-deoxy-D-*erythro*-hex-1-en-3-uloses (**1** and **2**), derived from readily available D-glucal triacetate,[5)] with acetylene gave stereoselectively the optically active cyclobutene adducts (**3** and **4**); the stereochemistry of the products was revealed by a single-crystal X-ray analysis and a chemical correlation.

Irradiation of **1** in an acetone solution saturated with a stream of acetylene by means of a 500-W high-pressure mercury lamp afforded [2+2]-cycloadduct (**3**) as a single compound in 81% yield. The single-crystal X-ray analysis confirmed the syn relationship of the cyclobutene ring to the proton at the C-5 position,[6)]



1 $R_1+R_2=C(CH_3)_2$ 3 $R_1+R_2=C(CH_3)_2$ 5 $R_1=H$, $R_2=Ac$
2 $R_1=CPh_3$, $R_2=Ac$ 4 $R_1=CPh_3$, $R_2=Ac$ 6 $R_1=CPh_3$, $R_2=Ac$

8 $R_1+R_2=C(CH_3)_2$

Scheme 1.

indicating that acetylene approaches from the least hindered side of the molecule. Under similar conditions, enone **2** underwent a photochemical cycloaddition with acetylene to give the same type adduct (**4**) in 75% yield. The structural proof of **4** was based on a chemical correlation with **3**. That is, treatment of **4** with H_2 over Pd-C followed by deacetylation of the resulting cyclobutane acetate (**5**) afforded cyclobutane diol (**7**), which was identical in all respects with the product obtained from **3** (Scheme 1). Thus, the stereoselectivity of these cycloadditions seems to derive from the steric influence of the isopropylidene and triphenylmethyl substituents that blocks approach of acetylene from the β-face of the enone molecules.

As an application, we have examined the photochemical behavior of **3** and **4** having a bicyclic β,γ-unsaturated ketone system.[8)] When both **3** and **4** were irradiated in acetone and acetonitrile, the photoreduction products **8** and **6** were obtained in detectable amounts (27 and 20% yields), which were identical with the samples prepared by isopropylidenation of **7** and isolated from catalytic hydrogenation of **4**, respectively.

Experimental

Melting points are uncorrected. IR spectra were measured in $CHCl_3$ with a Hitachi 260-50 spectrophotometer. ^1H and ^{13}C NMR spectral data were obtained in $CDCl_3$ on a JEOL JNM-PMX 60 spectrometer and a JEOL JNM-FX 60 Fourier transform spectrometer, respectively. Chemical shifts are

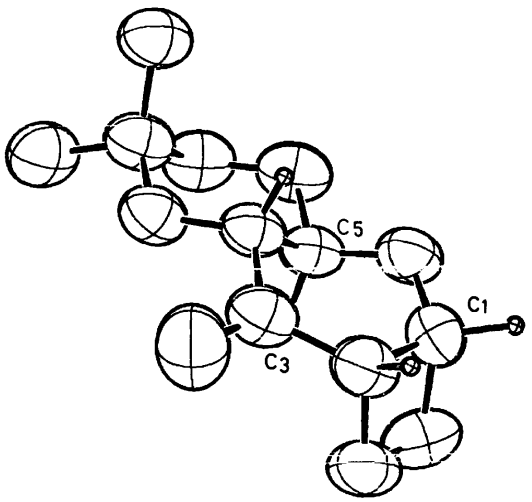

Fig. 1. ORTEP drawing of the molecular structure of **3**.[7)]

reported in δ values (ppm) downfield from an internal TMS reference. The mass spectra were measured with a JEOL JMS-D 300S spectrometer. Optical rotations were taken on a JASCO DIP-SL polarimeter. X-Ray diffraction data were obtained on an Enraf-Nonius CAD-4 automated four-circle diffractometer with a SDP program package. All irradiations were carried out with a 500-W high-pressure mercury lamp (Eikosha EHB-WI-500).

Photoaddition of Acetylene to 4,6-*O*-Isopropylidene- and 4-*O*-Acetyl-6-*O*-triphenylmethyl-1,5-anhydro-2-deoxy-D-*erythro*-hex-1-en-3-uloses (1 and 2). (a) To 1. A solution of **1** (120 mg) in dry acetone (250 ml) was irradiated through a Pyrex filter at room temperature for 30 min under a continuous introduction of acetylene. The removal of the solvent under reduced pressure and chromatography of the residue on silica gel using hexane-ethyl acetate (4:1) as eluent gave **3** (112 mg, 81% yield); mp 117—118.5 °C (hexane-ethyl acetate); $[\alpha]_D^{24}$ +103° (*c* 0.54 in EtOH); IR: 1725, 1390, 1380, and 1125 cm^{-1}; ^1H NMR δ=1.51 (6H, s, -C(CH$_3$)$_2$), 3.7—4.4 (5H, m), 5.14 (1H, d, *J*=2 Hz, -OCHCH=), and 6.2—6.4 (2H, m, -CH=CH-); ^{13}C NMR δ=18.6, 28.6, 55.9, 62.4, 63.2, 75.4, 77.6, 100.2, 137.0, 140.0, and 200.1; MS: *m/z* 210 (M^+); Found: C, 62.85; H, 6.92%. Calcd for $C_{11}H_{14}O_4$: C, 62.84; H, 6.71%.

(b) To 2. A solution of **2** (200 mg) in dry acetone (600 ml) was irradiated through a Pyrex filter at room temperature for 30 min under a continuous introduction of acetylene. After removing the solvent, the residue was subjected to column chromatography on silica gel using hexane-ethyl acetate (9:1) as eluent to afford **4** (158 mg, 75% yield); mp 157—158 °C (hexane-acetone); $[\alpha]_D^{24}$ +187° (*c* 0.53 in EtOH); IR: 1745, 1720, and 1600 cm^{-1}; ^1H NMR δ=1.78 (3H, s, OAc), 2.97 and 3.36 (each 1H, dd, *J*=3 and 10 Hz, -CH$_2$OCPh$_3$), 3.66 (1H, d, *J*=4 Hz, -COCH-), 4.10 (1H, dt, *J*=3 and 10 Hz, Ph$_3$COCH$_2$CH-), 5.05 (1H, d, *J*=4 Hz, -OCHCH=), 5.23 (1H, d, *J*=10 Hz, -CHOAc), 6.08 (2H, s, -CH=CH-), and 7.0—7.5 (15H, m, 3×Ph); ^{13}C NMR δ=20.3, 55.9, 62.1, 69.5, 74.9, 127.0, 127.1, 127.9, 128.8, 129.7, 137.0, 140.9, 143.6, 169.1, and 200.3; MS: *m/z* 454 (M^+); Found: C, 76.57; H, 5.91%. Calcd for $C_{29}H_{26}O_5$: C, 76.63; H, 5.77%.

Conversion of 3 and 4 to 7. (a) From 3. A mixture of **3** (100 mg) and 5% Pd-C (25 mg) in ethanol (15 ml) was stirred under a hydrogen atmosphere at room temperature for 90 min until it absorbed ca. 18 ml of H_2. The catalyst was removed by filtration and the solvent was evaporated to give an oil (100 mg); this was chromatographed on silica gel using benzene-ethyl acetate (1:1) as eluent to afford **7** (colorless oil, 80 mg). IR: 3600, 3500, and 1715 cm^{-1}; ^1H NMR δ=1.6—2.6 (4H, m, -CH$_2$CH$_2$-), 2.84 (2H, bs, 2×OH), 3.0—3.6 (1H, m, -COCH-), 3.72 (1H, dd, *J*=3 and 10 Hz, -OCHCH$_2$OH), 3.91 (2H, d, *J*=3 Hz, -CH$_2$OH), 4.37 (1H, d, *J*=10 Hz, -CHOH), and 4.90 (1H, dd, *J*=8 and 15 Hz, -OCH-); MS: *m/z* 173 ([M+1]$^+$).

Isopropylidene Derivative (8) of 7. *p*-Toluenesulfonic acid (43 mg) was added to a mixed solution of **7** (110 mg), 2,2-dimethoxypropane (10 ml) and dry *N*,*N*-dimethylformamide (0.5 ml), and then the mixture was stirred at room temperature for 50 min. A usual work-up and purification by silica-gel column chromatography (hexane-ethyl acetate, 9:1) gave **8** in 32% yield; mp 138—139 °C (hexane-ethyl acetate); IR: 1730, 1390, and 1380 cm^{-1}; ^1H NMR δ=1.54 (6H, s, -C(CH$_3$)$_2$), 1.7—2.7 (4H, m, -CH$_2$CH$_2$-), 3.0—3.5 (1H, m, -COCH-), 3.8—4.5 (2H, m, -OCHCHO-), 3.93 (2H, d, *J*=3 Hz, -OCH$_2$-), and 4.84 (1H, dd, *J*=8 and 15 Hz, -OCH-); MS: *m/z* 212 (M^+); Found: C, 62.24; H, 7.75%. Calcd for $C_{11}H_{16}O_4$: C, 62.25; H, 7.60%.

(b) From 4. A mixture of **4** (200 mg) and 5% Pd-C (120 mg) in ethyl acetate (20 ml) was stirred with H_2 at room temperature for 17 min. After ca. 20 ml of H_2 had been consumed, a similar work-up to that described above gave 210 mg of oily product, which was chromatographed on silica gel using hexane-ethyl acetate (98:2, 95:5, and 50:50) as developing agent to afford triphenylmethanol (75 mg), **6** (65 mg), and **5** (60 mg) in the order of elution. **5**: Colorless oil; IR: 3580, 3500, 1740, and 1720 cm^{-1}; ^1H NMR δ=1.5—2.7 (4H, m, -CH$_2$CH$_2$-), 2.21 (3H, s, OAc), 3.0—3.4 (2H, m, -COCH- and OH), 3.80 (2H, d, *J*=2 Hz, -CH$_2$OH), 4.07 (1H, dt, *J*=2 and 10 Hz, -CHCH$_2$OH), 4.87 (1H, dd, *J*=7 and 15 Hz, -OCH-), and 5.23 (1H, d, *J*=10 Hz, -CHOAc). **6**: Mp 130—131 °C (ethanol); IR: 1740, 1730, 1600, 1490, and 1450 cm^{-1}; ^1H NMR δ=1.90 (3H, s, OAc), 1.5—3.3 (5H, m, -CH$_2$CH$_2$- and -COCH-), 3.11 and 3.42 (each 1H, dd, *J*=3 and 10 Hz, -CH$_2$OCPh$_3$), 4.01 (1H, dt, *J*=3 and 10 Hz, Ph$_3$COCH$_2$CH-), 4.81 (1H, dd, *J*=8 and 14 Hz, -OCH-), and 5.34 (1H, d, *J*=10 Hz, -CHOAc). Alkaline hydrolysis of **5** (25 mg of **5**, 5 ml of methanol, 55 mg of Na_2CO_3, and stirring at room temperature for 25 h) gave **7** which was identical with the above material.

Irradiation of 3. A solution of **3** (203 mg) in anhydrous acetone (500 ml) was irradiated through a Pyrex filter at room temperature for 60 min. After removing the solvent, the residue was chromatographed on silica gel using hexane-ethyl acetate (7:3) as an eluent to afford **8** (55 mg, 27% yield); this was identical in all respects with the sample prepared by isopropylidenation of **7**.

Irradiation of 4. Irradiation of a solution of **4** (200 mg) in anhydrous acetonitrile (600 ml) through a Pyrex filter at room temperature for 30 min, followed by a silica-gel column chromatographic work-up of the residual oil using hexane-ethyl acetate (95:5) as an eluent afforded **6** (40 mg, 20% yield); this was identical with the compound previously obtained from the catalytic hydrogenation of **4**.

We wish to thank the Research Center for Material Analysis in Miyazaki University for the NMR and MS measurements and the X-ray crystallographic analyses.

Kinetic Studies on the Oxidation of Thiols by Coenzyme PQQ

Shinobu ITOH, Nobuyuki KATO, Minae MURE, and Yoshiki OHSHIRO*
Department of Applied Chemistry, Faculty of Engineering, Osaka University,
Yamadaoka 2-1, Suita, Osaka 565
(Received July 14, 1986)

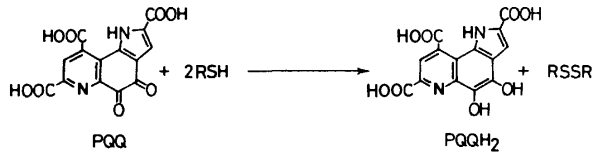
Synopsis. Kinetic studies on the oxidation of thiols by coenzyme PQQ are carried out under anaerobic conditions. A bell shaped pH-rate profile having a maximum rate at around pK_a of the thiol is observed. The rate-determining step changes between acidic and basic sides of the profile indicating the existence of at least one intermediate in the course of the reaction.

Mercapto groups are important in biological systems due to the widespread occurrence of this functional group in many proteins and in natural compounds such as glutathione, cysteine, coenzyme A, and lipoic acid. In particular, reversible oxidation-reduction to the disulfide stage is an essential process in such systems, and thus mechanistic details on the oxidation of thiols by flavins have been demonstrated.[1,2] On the other hand, we have found that coenzyme PQQ (4,5-dihydro-4,5-dioxo-1*H*-pyrrolo[2,3-*f*]-quinoline-2,7,9-tricarboxylic acid) is an efficient catalyst in air oxidation of thiols.[3] In this paper, we wish to report the kinetic studies on the reaction between PQQ and thiols.[4]

Results and Discussion

Treatment of PQQ (3.4×10^{-2} mmol) and 10-fold excess of benzenethiol in 20% CH_3CN neutral aqueous solution under anaerobic conditions gave $PQQH_2$ (4,5-dihydroxy-1*H*-pyrrolo[2,3-*f*]quinoline-2,7,9-tricarboxylic acid, 84%) and diphenyl disulfide (99% based on PQQ) as shown in Eq. 1. This reaction was followed spectrophotometrically under pseudo-first-order conditions ([PQQ] ≪ [PhSH], Fig. 1). PQQ was reduced rapidly to $PQQH_2$ with isosbestic points at 274, 336, and 399 nm at pH* 4.65 (see Experimental), and the reaction followed pseudo-first-order rate law up to 90% conversion (Fig. 2). When the concentration of the thiol was kept constant and the pH* was varied using 0.05 M acetate, phosphate, and carbonate (containing 20% CH_3CN, μ=0.2 with KCl), it was found that a plot of log k_{obsd} vs. pH* exhibited a "bell-shaped curve" (Fig. 3). Interestingly, the reaction was found to be first-order in benzenethiol concentration at the acidic side of the bell-shaped curve (pH* 6.3), while it was second-order in benzenethiol concentration at the basic conditions (pH* 9.9) as shown in Fig. 4. This result shows an evidence for a change in rate-determining step between the acidic and the basic conditions. This implies the existence of at least one intermediate, and all one-step mechanisms such as a net hydride transfer may be ruled out.

From these results, we assume the following reaction path (Eq. 2).



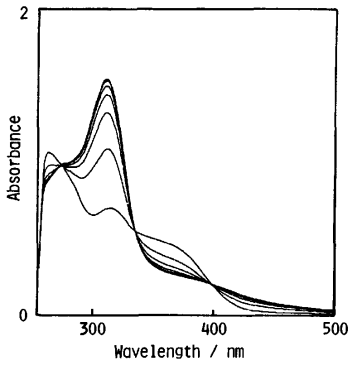


Fig. 1. Sepctral change along the progress of the oxidation of PhSH (4.0×10^{-3} M) by PQQ (4.0×10^{-5} M) in 0.05 M acetate buffer (pH* 4.65, μ=0.2 with KCl, 20% CH_3CN) at 30 °C under anaerobic conditions.

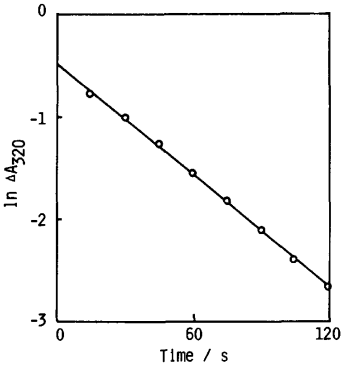

Fig. 2. Pseudo-first-order plot for the oxidation of PhSH by PQQ at pH* 4.65.

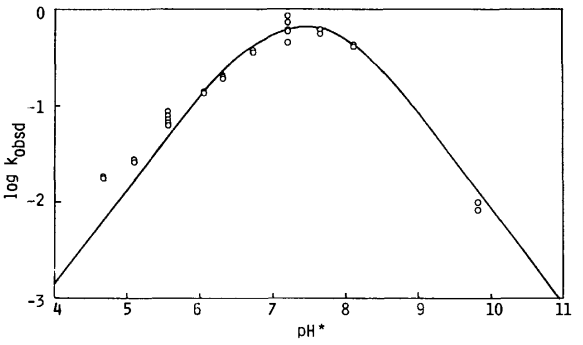

Fig. 3. The pH-rate profile for the oxidation of PhSH by PQQ.

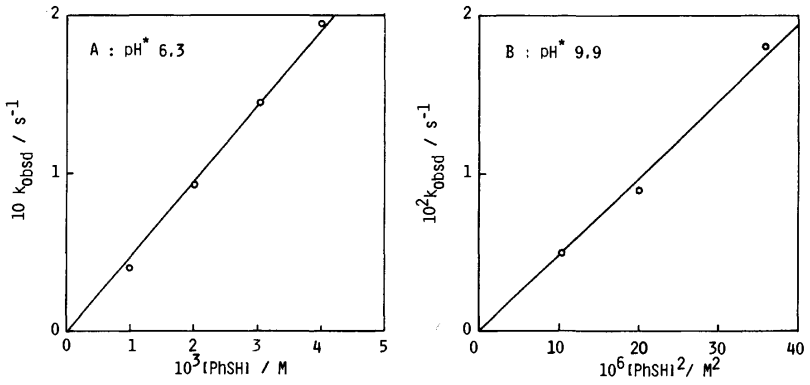

Fig. 4. Dependence of k_{obsd} on benzenethiol concentration at pH* 6.3 (A) and 9.9 (B).

$$PQQ \underset{k_{-1}}{\overset{k_1[RS^-]}{\rightleftharpoons}} I^- \underset{k_{-H}}{\overset{k_H[H^+]}{\rightleftharpoons}} IH \xrightarrow{k_2[RS^-]} PQQH^- + RSSR \quad (2)$$

(I: intermediate)

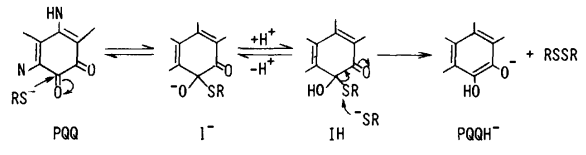
If it is assumed that protonation of I^- occurs rapidly relative to the establishment of the PQQ-I^- equilibrium ($k_H[H^+] \gg k_{-1}$), the rate law can be given as

$$k_{obsd} = \frac{k_1 k_2 K_a^2 a_H [RSH]_T^2}{k_{-1} K_H (K_a + a_H)^2 + k_2 K_a a_H (K_a + a_H)[RSH]_T} \quad (3)$$

where K_a is the apparent dissociation constant of benzenethiol and K_H is k_{-H}/k_H. Curve-fitting of Eq. 3 (solid line in Fig. 3) by using pK_a value (6.9) determined by spectrophotometric titration under the kinetic conditions provides the following values; k_1=325 $M^{-1}s^{-1}$, $k_2/k_{-1}K_H$=1.6×10^{10} M^{-2}. Using these values, kinetic behaviors mentioned above can be explained with this equation. Namely, under acidic conditions ($K_a \ll a_H$), Eq. 3 can be simplified to Eq. 4 in which k_{obsd} is proportional to $[RSH]_T$ and a_H^{-1}, respectively. On the other hand, under basic conditions ($K_a \gg a_H$), Eq. 5 is an approximated form where k_{obsd} is proportional to $[RSH]_T^2$ and a_H, respectively. Aliphatic thiols such as 2-mercaptoethanol, cysteine, and 1,4-butanedithiol were also oxidized rapidly at around their pK_as as shown in Table.

$$k_{obsd} = k_1 a_H^{-1} K_a [RSH]_T \quad (4)$$

$$k_{obsd} = k_1 k_2 k_{-1}^{-1} K_H^{-1} a_H [RSH]_T^2 \quad (5)$$



Scheme

From buffer dilution studies (0.1—0.5 M at pH* 6.3 and 9.9), it could be concluded that the oxidation of benzenethiol by PQQ is not subject to buffer catalysis. One of the possible mechanism is that involving C-5 attack of the thiolate ion followed by breakdown to reduced PQQ and the corresponding disulfide as shown in Scheme. In this mechanism, the first thiolate ion attack to the quinone is the rate-determining step under the acidic conditions, while the breakdown step is rate-determining under the basic conditions. It is well-known that C-5 quinone carbonyl of PQQ is easily attacked by nucleophiles.[5] Jencks and his co-worker have demonstrated that the addition of a thiolate ion to carbonyl group shows no general acid catalysis.[6] So there may be no general acid catalysis in the first thiolate ion attack to the quinone carbonyl. Further, the acid-base dissociation constant of the quinol group of $PQQH_2$ is determined to be 7.08×10^{-10} M (pK_a 9.15) by spectrophotometric titration. Thus, the breakdown step would not also be subject to general acid catalysis.

Table 1. Pseudo-First-Order Rate Constants for the Oxidation of Thiols by Coenzyme PQQ[a]

Thiol	pK_a	pH*	k_{obsd}/s^{-1} [b]
PhSH	6.9	7.2	6.5×10^{-1}
$HOCH_2CH_2SH$	9.7	9.8	8.1×10^{-2}
$HS(CH_2)_4SH$[c]	10.3	9.1	3.3×10^{-1}
$HOOCCH(NH_2)CH_2SH$	8.5	8.1	3.4×10^{-2}

a) [PQQ]=4.0×10^{-5} M, [thiol]=4.0×10^{-3} M, 0.05 M buffer solution (μ=0.2 with KCl, containing 20% CH_3CN) at 30 °C under anaerobic conditions. b) Average values of 3—5 kinetic runs. c) In 40% CH_3CN buffer solution.

Alternatively, free radical mechanism (one-electron transfer; I^-=PQQ^-) may be applicable since stepwise one electron oxidation of thiols is well documented.[7] In that case, however, the reactions at all pH region investigated should be first-order in benzenethiol concentration, since the PQQ semiquinone radical is well-known to be unstable to disproportionate rapidly to PQQ and $PQQH_2$ under these aqueous conditions.[8] If the PQQ semiquinone radical should be comparably stable, kinetics indicative of autocatalytic process would be observed. From these considerations, the ionic mechanism (Scheme) is preferable for the present oxidation.

Experimental

Kinetics. Kinetic measurements for the oxidation of thiols by PQQ were carried out under anaerobic pseudo-first-order conditions. An anaerobic 20% acetonitrile aqueous solution (1.5 ml) containing a thiol (8.0×10^{-3} M) was mixed with 1.5 ml of a 20% acetonitrile buffer solution (0.05 M acetate, phosphate, and carbonate, μ=0.2 with KCl) containing PQQ (8.0×10^{-5} M) under anaerobic conditions in a Thunberg cuvette. The reaction was followed by monitoring the appearance of $PQQH_2$ at 320 nm at 30 °C (Shimadzu UV-240 spectrophotometer equipped with a temperature controlled cell holder, Shimadzu TCC-240). The pH* is a corrected pH value by adding 0.11 to measured pH value in an aqueous buffer solution containing 20% CH_3CN.[9]

The present work was partially supported by a Grant-in-Aid for Co-operative Research (No. 60304027) from the Ministry of Education, Science, and Culture to which our thanks are due.

Influences of Lewis Acids on the Photochemical Cyclodimerization of Cyclopentenone

Takuji OGAWA,* Yoshiyuki MASUI, Shoshi OJIMA, and Hitomi SUZUKI*
Department of Chemistry, Faculty of Science, Ehime University, Bunkyo-cho, Matsuyama 790
(Received February 5, 1986)

Synopsis. In the presence of tin(IV) chloride, photochemical dimerization of cyclopentenone gave a cis-transoid-cis head-to-head dimer as predominant product. Other Lewis acids such as zinc(II) bromide, boron trifluoride etherate, tin(II) chloride, and silver(I) trifluoromethylsulfonate, however, showed little influence. Tris-(2,2,6,6-tetramethyl-3,5-heptanedionato)lanthanum(III) and tris(2,2,6,6-tetramethyl-3,5-heptanedionato)europium(III) affected regiochemistry of the reaction in a way to favor a head-to-tail dimer.

Photochemical (2+2) cycloaddition of cyclopentenones to form tricyclic ring systems has been widely used for the synthesis of natural products.[1] Since these tricyclic compounds are of difficult access via ordinary ionic reactions, photochemical route appears to be more attractive for their preparation. However, photochemical (2+2) cycloaddition is generally known to be difficult to control its regio- and/or stereochemistry and many possible isomers are formed together. In order to improve the selectivity, micellar effect[2] and salt effect[3] have been studied, but no satisfactory results have been obtained as yet. We thought that the coordinative ability of Lewis acids or lanthanoid complexes to carbonyl oxygen may be exploited to control the mode of photochemical cyclodimerization of cyclopentenon in solution.

Results and Discussion

Dry dichloromethane solutions containing 0.6 mol dm^{-3} cyclopentenone (**1**) and various amounts of tin(IV) chloride(**2**) were irradiated using a merry-go-round apparatus with a high-pressure mercury lamp under a nitrogen atmosphere. Product analyses were performed by gas chromatographic comparison with authentic samples[4] and typical results are tabulated in Table 1.

Table 1. Effect of $SnCl_4$ on the Photochemical Dimerization of Cyclopentenone

Eu(thd)$_3$(0.05)	23	20/80

a) Mole ratio of the Lewis acid/cyclopentenone.
Tf=trifluoromethanesulfonate
thd=2,2,6,6-tetramethyl-3,5-heptanedionato

mole ratio (**2**/**1**) changed from zero to 0.53, the HH/HT ratios finally rising up to ca. 9.

Effect of **2** on the photodegradation of the dimers was also studied. No matter whether **2** was present or not, HH dimer was degraded faster than HT dimer (Table 2). Thus, the observed improvement of the selectivity cannot simply be attributed to the preferential degradation of HT dimer by **2**.

Total yields (HH+HT) were not so high and decreased as the conversion increased. It was because that the dimers underwent further photochemical reactions by absorbing light competitively with cyclopentenone.

With an expectation to increase yields by suppression of decomposition of the dimers, cyclopentenone solution was irradiated through $CuSO_4$ filter. HH dimer had the absorption maximum at 300 nm ($\varepsilon \fallingdotseq 60$) and $CuSO_4$ filter cut off lights shorter than 310 nm. As shown in Table 2, $CuSO_4$ filter suppressed the decomposition, although small amounts of dimers decomposed because of a small overlap of absorption edge of the dimers around 310—320 nm and light through $CuSO_4$ filter. However, the yields of dimers did not increase by using $CuSO_4$ filter, because absorption of cyclopentenone shifted to the shorter wavelength by coordination with **2** (Fig. 1) and cyclopentenone coordinate with **2** was not absorb light through $CuSO_4$ filter efficiently.

Effects of other Lewis acids such as zinc(II) bromide, boron trifluoride etherate, tin(II) chloride, and silver(I) trifluoromethanesulfonate were also examined in THF solutions. However, no significant influence of these Lewis acids was observed (Table 3). Acidity of these Lewis acids may be too weak to form such a rigid complex with **1** as to effect the regiochemistry.

When a low concentration of tris(2,2,6,6-tetramethyl-3,5-heptanedionato)lanthanum(III) ($La(thd)_3$; **3**) or tris(2,2,6,6-tetramethyl-3,5-heptanedionato)europium(III) ($Eu(thd)_3$; **4**) was added to the solution of **1** (mole ratio **3**/**1** or **4**/**1**=0.05), the ratio of regioisomers (HH/HT) decreased a little (Table 3). Addition of the increasing amount of **3** or **4** to the solution resulted in the formation of a complex of **1** with **3** or **4** which did not liberate **1** or its dimers at all under the conditions employed.

The results mentioned above are quite different from those observed in the cases of aromatic enones (cinnamate[5a] and coumarin[5b]). In the case of coumarin the quantum yield was highest when 0.125 equiv of boron trifluoride was present, and the predominant dimer was head-to-head in the absence of the Lewis acid, and head-to-tail in the presence of boron trifluoride. It is believed that the excited complex of coumarin with boron trifluoride reacts with another molecule of coumarin at the ground state, leading to the observed dependence of quantum yields on concentration.[5]

Contrarily, in the case of cyclopentenone small amounts of **2** (**2**/**1**=0.1—0.2) were not effective, and the addition of about 0.5 mol of **2** to 1 mol of **1** was necessary to achieve high HH/HT ratio (Table 1). Furthermore, the regiochemistry changed from head-to-tail to head-to-head by the addition of **2**. These results can be explained by an assumption that two molecules of cyclopentenone coordinate on one tin(IV) chloride from one side through the carbonyl oxygen atom and the photochemical dimerization occurs within the complex thus formed. Formation of 1:2 complex of **2** with **1** was supported by UV absorptivity change of **1** in the presence of various mole ratio of **2** (Fig. 2). The 1:2 complex formation is in consistent with the favored head-to-head regiochemistry in the presence of **2**, because the most favored conformation of two molecules of **1** in the complex would give the head-to-head dimer.

If the photochemical reaction occurs between the Lewis acid complex of **1** and non-coordinated **1**, the effect should be observed even at low Lewis acid/cyclopentenone ratio as was the case with coumarin. Coordinated cyclopentenone would be unable to react with ground state cyclopentenone by two reasons; small absorptivity of coordinated cyclopentenone as is shown in Fig. 1 and steric crowding around the tin(IV) atom.

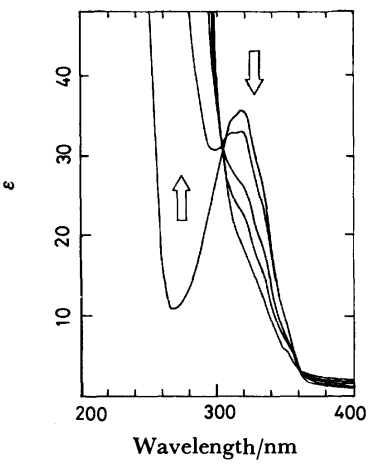

Fig. 1. UV absorption spectra of cyclopentenone in the presence of tin(IV) chloride.[a]
a) Arrows indicate the direction of spectral changes observed when 0.0 to ca. 0.5 mol ratio of $SnCl_4$ was added to a CH_2Cl_2 solution of cyclopentenone.

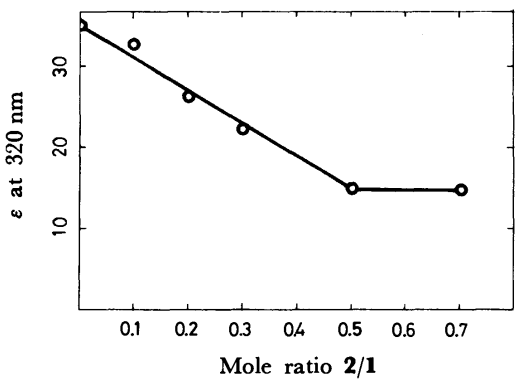

Fig. 2. Absorptivity change of **1** at 320 nm by adding various mole ratio of **2**.

Experimental

Materials. Cyclopentenone was prepared according to the reported method.[6] Tin(II) chloride, zinc(II) bromide, boron trifluoride etherate and silver(I) trifluoromethanesulfonate were commercial products and used as such. Lanthanoid complexes were prepared according to the literature method.[7] Dichloromethane was dried over P_2O_5, distilled under nitrogen, and stored with molecular sieves 3A.

Irradiation of Solutions. About 6 mmol of **1** and the Lewis acid were dissolved in 10 dm^{-3} of dry dichloromethane and were irradiatd under a nitrogen atmosphere in Pyrex tubes, using a 300-W high-pressure mercury arc lamp. In instances where equal irradiation of several samples was required, a merry-go-round apparatus was used.

Products Analyses. Dimer ratios and relative yields were analyzed by gas chromatography, using a 20% PEG-6000 (1 m) or 25% DEGS (1 m) column, and xanthone was used as an internal standard. Column temperature was 170 °C. Retention times of samples were as follows. In the case of PEG-6000: **1**, 11 min; HT, 27 min; HH, 38 min. In the case of DEGS: **1**, 3 min; HT, 6 min; HH, 9 min.

Syntheses of Steroidal *trans*-Iodo Acetates

C. Akira HORIUCHI* and J. Yasuo SATOH
Department of Chemistry, Rikkyo (St. Paul's) University, Nishi-Ikebukuro, Toshima-ku, Tokyo 171
(Received June 27, 1986)

Synopsis. The reaction of the following steroidal olefins with iodine–copper(II) acetate in acetic acid afforded the corresponding steroidal *trans*-iodo acetates: 5α-cholest-1-, -2-, and -3-ene; and 5β-cholest-1-, -2-, and -3-ene.

trans-1-Iodo-2-acetates are important as intermediates of Prévost reaction. There have been known many procedures for syntheses of *trans*-1-iodo-2-acetates, namely, *trans*-addition to olefins using iodine–silver(I) acetate,[1] *N*-iodosuccinimide–acetic acid,[2] iodine–mercury(II) acetate,[3] and iodine–thallium acetate.[4] Recently, Georgoulis and Valery[5] reported a convenient procedure for the preparation of vicinal alkoxy-iodoalkanes from alkene by means of copper(II) acetate and iodine. In part of the paper, they mentioned that the reaction of cyclohexene with iodine–copper(II) acetate in acetic acid yielded *trans*-iodo(acetoxy)cyclohexane.

We have been investigating a novel iodination method using iodine–copper(II) acetate; and as early steps in this research project, we have already reported the α-iodination of ketones;[6] the regioselective iodination of estradiol, estriol, and estrone;[7a,7b] a convenient procedure for iodination of electron-rich aromatic compounds;[8] and α-iodination of carboxylic acid.[9]

Now in the present paper, we would like to report that the reaction of the following steroidal olefins readily yielded the corresponding steroidal *trans*-iodo acetates: 5α-cholest-1- (**1**), -2- (**2**), and -3-ene (**3**); and 5β-cholest-1- (**4**), -2- (**5**), and -3-ene (**6**).

The reaction of 5α-cholest-1-ene (**1**) with iodine–copper(II) acetate in acetic acid at 60 °C for 10 h yielded the *trans*-iodo acetate (**7**), mp 113—114 °C. The NMR spectrum of **7** showed two multiplets due to the C_1- and C_2-proton at δ 4.46 (W/2=6.0 Hz) and 5.45 ppm (W/2=6.0 Hz), respectively. From this spectrum, however, it would not be determined the structure of **7**; and so the following procedure was carried out: The iodo acetate (**7**) was reduced with lithium aluminium hydride to give the 2β-hydroxyl derivative (**18**). By treating the iodo acetate (**7**) with potassium hydroxide, the 1β, 2β-epoxide (**13**) was obtained. From these results an acetoxyl group and an iodine atom of the iodo acetate were shown to be *trans*; this led to a 1α-iodo-2β-acetoxy-5α-cholestane structure for this iodo acetate. Similarly, 5α-cholest-2-ene (**2**) gave the 3α-iodo-2β-acetoxy derivative (**8**) (85%).[10] In the case of 5α-cholest-3-ene (**3**), a needle crystalline material (**9**), mp 83—85 °C was obtained. This product was presumed to be 3α-iodo-4β-acetoxy-5α-chlolestane on the basis of the NMR spectral data. The iodo acetate (**9**) was then converted to the 3β,4β-epoxide (**14**). The reaction of **9** with lithium aluminium hydride gave the 4β-ol derivative (**19**). Similarly, the reaction of 5β-cholest-1- (**4**) and -2-ene (**5**) gave 1β-iodo-2α-acetoxy- (**10**) and 3β-iodo-2α-acetoxy derivatives (**11**), respectively. These structures were determined from the NMR spectra and the chemical methods described above. The reaction of 5β-cholest-3-ene (**6**) gave *trans*-iodo acetate (**12**); mp 125—126 °C. The NMR spectrum showed a triplet (J=10.5 Hz) and a multiplet (W/2=15 Hz) at δ 4.50 and δ 5.02, respectively. By treating **12** with potassium hydroxide according to the method above, 3α, 4α-epoxide (**17**) was obtained. From this fact, *trans*-iodo acetate (**12**) was confirmed to be 4β-iodo-3α-acetoxy-5β-cholestane.

Moreover, the reaction is applicable to the synthesis of hindered *cis*-diols. The *trans*-iodo acetate (**8**) was converted with *m*-chloroperbenzoic acid to give 2β-acetoxy-5α-cholestan-3β-ol (**22**) (90%). Then the hydrolysis of **22** afforded the 2β,3β-diol (**23**) in good yield.

Thus, on the basis of all of the foregoing results, it can be concluded that the reagent used in this work [iodine–copper(II) acetate in acetic acid] is applicable to the steroidal olefins. In the reactions of 5α- and 5β-steroidal olefins with this reagent, the products in the case of the 5α-steroidal olefins were the α-iodo-β-acetoxy derivatives, in which the iodine attacked from the α-face; while the products in the case of the 5β-olefins were the β-iodo-α-acetoxy derivatives, in which the iodine attacked from the β-face. These results are also in agreement with the facts that the

α-face of 5α-steroidal olefins is less hindered than the β-face, and that the β-face of 5β-steroidal olefins is less hindered than the α-face.

Experimental

All the melting points are uncorrected. The IR and NMR spectra were measured using a Hitachi model 215 grating infrared spectrometer and a nuclear magnetic resonance spectrometer, Hitachi-Perkin Elmer R-20A, in carbon tetrachloride and deuteriochloroform, with TMS as the internal standard.

General Procedure. A mixture of steroidal olefin (1.349×10^{-3} mol), copper(II) acetate monohydrate (1.349×10^{-3} mol), iodine (1.349×10^{-3} mol), and acetic acid (50 ml) was stirred at 55—60 °C. After 10—30 h, the reaction mixture turned to brown; and then it was filtered to remove copper(I) iodide produced. The filtrate was taken up in ether, and the ether extracts were washed with sodium hydrogencarbonate solution and with water, and then dried and evaporated. Crystallization of the residue from ethanol gave *trans*-iodo acetate.

Confirmation of Configuration of 1α-Iodo-2β-acetoxy-5α-cholestane (7). The *trans*-iodo acetate (**7**) (180 mg) in dry ether (18 ml) was treated with lithium aluminium hydride (13 mg). After the usual work-up, the resulting oil, on crystallization from ethanol, gave 5α-cholestan-2β-ol (**18**) (140 mg), mp 161—163 °C (154—155 °C[16]).

The *trans*-iodo acetate (**7**) (20 mg) in ethanol was treated with potassium hydroxide. After the usual work-up, the resulting oil, on crystallization from ethanol, yielded 1β,2β-epoxy-5α-cholestane (**13**) (9 mg), mp 93—94 °C (94—95 °C[16]).

Confirmation of Configuration of 3α-Iodo-4β-acetoxy-5α-cholestane (9). By practically the same method as that in the case of **7** above, **9** (40 mg) was converted to 5α-cholestan-4β-ol (**19**) (17 mg), mp 131—133 °C (132—135 °C[17]) and 3β,4β-epoxy-5α-cholestane (**14**) (16 mg), mp 96—98 °C (98—99 °C[18]) respectively.

Confirmation of Configuration of 1β-Iodo-2α-acetoxy-5β-cholestane (10). The *trans*-iodo acetate (**10**) (70 mg) in dry ether was treated with lithium aluminium hydride. After the usual work-up, the resulting oil, on crystallization from ethanol, gave 5β-cholestan-2α-ol (**20**) (41 mg), mp 105—106 °C (106—107 °C[19]).

The *trans*-iodo acetate (**10**) (70 mg) in ethanol (10 ml) was treated with potassium hydroxide (76 mg). After the usual work-up, the resulting oil, on crystallization from ethanol, gave 1α,2α-epoxy-5β-cholestane (**15**) (45 mg); IR (KBr): 847 cm^{-1}, ^1H NMR (CCl_4) δ=2.63 (1H, d, J=3.6 Hz) and 3.05 (1H, m, W/2=6.75 Hz).

Found: C, 83.43; H, 11.89%. Calcd for $C_{27}H_{46}O$; C, 83.87 H, 11.99%.

Confirmation of Configuration of 3β-Iodo-2α-acetoxy-5β-cholestane (11). The *trans*-iodo acetate (**11**) (30 mg) in dry ether was treated with lithium aluminium hydride. After the usual work-up, the resulting oil, on crystallization from ethanol gave 5β-cholestan-2α-ol (**20**) (17 mg), mp 105—106 °C (106—107 °C[19]). The *trans*-iodo acetate (**11**) (70 mg) in ethanol was treated with potassium hydroxide. After the usual work-up, crystallization of the residue from ethanol gave 2α,3α-epoxy-5β-cholestane (**16**) (38 mg), mp 74—76 °C; IR (KBr): 810 and 800 cm^{-1}, ^1H NMR (CCl_4) δ=2.75—3.10 (2H, m).

Found: C, 83.50; H, 11.90%. Calcd for $C_{27}H_{46}O$; C, 83.87 H, 11.99%.

Confirmation of Configuration of 4β-Iodo-3α-acetoxy-5β-cholestane (12). By practically the same method as that in the case of **11** above, **12** (40 mg) was converted to 5β-cholestan-3α-ol (**21**) (14 mg), mp 113—115 °C (107—108 °C[20]) and 3α,4α-epoxy-5β-cholestane (**17**) (18 mg), mp 53—55 °C (55—56 °C[21]), respectively.

The Reaction of 2β-Acetoxy-3β-iodo-5α-cholestane (8) with *m*-Chloroperbenzoic Acid. A mixture of **8** (200 mg) in

methylene dichloride (20 ml) and *m*-chloroperbenzoic acid (137 mg) was stirred at room temperature for 4 h. After the usual work-up, the resulting oil, on crystallization from ethanol, 2β-acetoxy-5α-cholestan-3β-ol (**22**) (144 mg), mp 136—137 °C (136—138 °C[22]).

Hydrolysis of 2β-Acetoxy-5α-cholestan-3β-ol (22). A mixture of **22** (100 mg) in methanol (10 ml) and potassium hydroxide (10 mg) in water (0.5 ml) was refluxed for 0.5 h. After evaporation of the reaction mixture, the residue was dissolved in ether. The ethereal solution was washed with water, dried, and evaporated. Crystallization of the residue from methanol gave plates of **23** (90 mg), mp 174—177 °C (175—176 °C[22]).

We are indebted to Toyo Jozo Co., Ltd. for the elemental analyses.

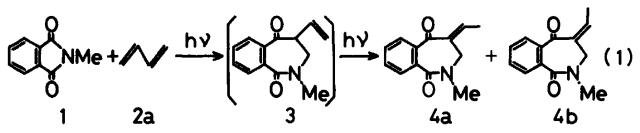
Photoreactions of *N*-Methyl-1,2-naphthalenedicarboximide with Dienes. Formation of Naphthazepinediones and Their Secondary Reactions

Yasuo KUBO,* Rie TODA, and Takeo ARAKI
Department of Chemistry, Faculty of Science, Shimane University, Matsue, Shimane 690
(Received June 24, 1986)

Synopsis. In the photolysis of a benzene solution of *N*-methyl-1,2-naphthalenedicarboximide (**5**) in the presence of dienes, i.e., 2,3-dimethyl-1,3-butadiene and 1,3-butadiene, insertion of one of the double bond in the dienes into a C(=O)-N bond of **5** was observed to give naphthazepinediones. These products were found to convert further into cyclobutanes and α,β-unsaturated ketones via photochemical intramolecular cycloaddition and via hydrogen migration, respectively.

In recent years, the photochemistry of imides has been the subject of intensive investigations.[1] A characteristic photoreaction of arenedicarboximides in the presence of alkenes is the insertion of the alkene into a C(=O)-N bond of the imide moiety.[2] Concerning the reactions with dienes, Mazzocchi and his co-workers have reported that the photoreaction of *N*-methylphthalimide (**1**) with, for example, 1,3-butadiene (**2a**) gives **4a** and **4b** by insertion of one of the double bonds in **2a** into a C(=O)-N bond of **1** (**1**+**2a**→**3**) and successive photochemical hydrogen-migration (**3**→**4a**+**4b**) (Eq. 1).[2a,f]

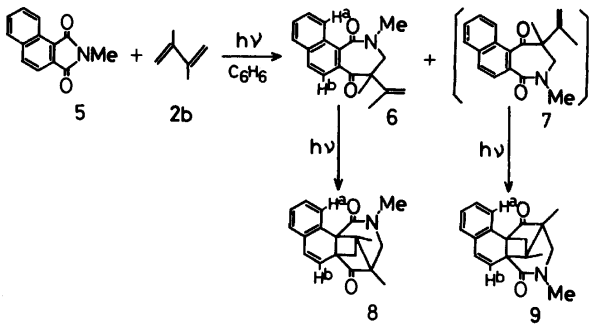


1 2a 3 4a 4b (1)

systematic investigation of the photochemistry of arenedicarboximides with alkenes, we have established that the arene structure played a crucial role in determining the reaction pathways.[3] This paper describes the photoreactions of *N*-methyl-1,2-naphthalenedicarboximide (**5**) with dienes in benzene. The predominant reaction of **5** with dienes is found to be insertion of one of the double bonds in the dienes into a C(=O)-N bond of **5** (naphthazepinedione formation). New types of secondary reactions are observed at the same time.

Results and Discussion

Irradiation of a benzene solution of **5** (10 mM, 1 M=1 mol dm^{-3}) and 2,3-dimethyl-1,3-butadiene (**2b**) (100 mM) by a light of >320 nm (aq $CuSO_4$ filter) for a short time gave naphthazepinedione (**6**, 27%) and two regio-isomeric cyclobutanes (**8**, 17% and **9**, 38%) (Scheme 1). Prolonged irradiation of the same system gave only **8** (42%) and **9** (40%), and irradiation of **6** alone in benzene afforded **8** quantitatively. These results clearly show that **8** is a secondary photoproduct of **6**. Although **7** could not be isolated, product **9** seems to be formed similarly from the corresponding



5 2b 6 7 8 9

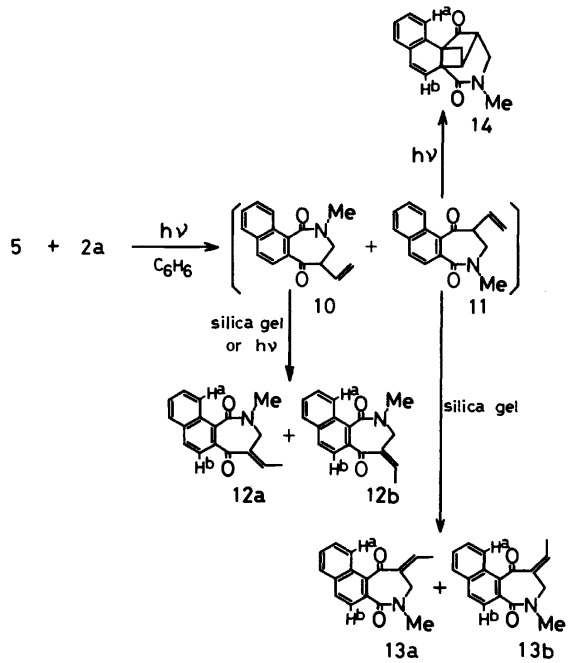
Scheme 1.

precursor **7** which is more reactive than **6** under the photochemical conditions used.

The structure of **6** was supported by the spectral resemblance to the analogous naphthazepinediones obtained by the photoreactions of **5** with alkenes.[3b] The regiochemistry was deduced mainly from the chemical shift of H^b, which generally appeared at a lower field region than that of H^a in such a regio-isomer.[3b] The structures of **8** and **9** were assigned on the basis of IR and ^{1}H NMR spectra. The IR spectra of **8** and **9** show characteristic five-membered carbonyl absorption bands at 1758 and 1762 cm^{-1}, respectively. The H^a signal of **8** shifted considerably to a lower field (δ=7.95) than that of **9**, probably due to the deshielding effect of the lactam carbonyl group. Molecular model examination shows that the five-membered carbonyl groups in **8** and **9** are fixed in configurations where no anisotropic effects of the carbonyl groups exerts on H^a and H^b.

After irradiation of a benzene solution of **5** (10 mM) and **2a** (100 mM) for a short time, chromatography of the resultant mixtures on silica-gel column gave a mixture of **12a** and **12b** (45%, isomer-ratio=2.9:1) and a mixture of **13a** and **13b** (40%, isomer-ratio=2.6:1), respectively (Scheme 2). These products were only weakly observed in the ^{1}H NMR spectrum of the original mixture before chromatography. Judged from the ^{1}H NMR spectra of the original mixtures, the main products seem to be **10** and **11** (not isolated) because of their spectral resemblance to the naphthazepinediones obtained by the reactions of **5** with alkenes.[3b] These results may indicate that the initially formed **10** and **11** were converted by silica-gel treatment to a mixture of **12a** and **12b**, and a mixture of **13a** and **13b**, respectively.

On the other hand, prolonged irradiation of **5** and **2a** gave a mixture of **12a** and **12b** (38%, isomer-



Scheme 2.

ratio=2.0:1), and **14** (33%) together with a trace amount of a mixture of **13a** and **13b**. In this case, the ^{1}H NMR spectrum of the irradiation mixture was a simple combination of those of the isolated products, indicating that the unchanged products were isolated by chromatography.

The structures of **12a,b** and **13a,b** were supported by the spectral resemblance to the benzo analogues.[2a,f] The regiochemistry was deduced from the chemical shifts of H^a and H^b as in the case of the regiochemistry-determination of the naphthazepinediones obtained by the reactions of **5** with alkenes.[3b] The structure of **14** was supported by the spectral resemblance to **9**.

The photoreaction of **5** and 2,5-dimethyl-2,4-hexadiene (**2c**) was slow and only gave a mixture of unidentified minor products.

The results obtained here indicate that the insertion of one of the double bonds in dienes into a C(=O)–N bond of **5** is a predominant reaction in the photoreaction of **5** with dienes. The predominance of the insertion is a characteristic nature of the excited state of **5**, since no significant predominance was observed in the reactions of *N*-methyl-1,8- and -2,3-naphthalenedicarboximides with dienes.[3c] In the present system a new type of secondary photoreaction is found, i.e., intramolecular cycloaddition, which was not observed in the reaction of the benzo analogue. The hydrogen-migration (**10**→**12a,b**) is found to occur by the action of silica gel as well as by already known photochemical process. The photochemical pathways from **10** and **11** were strongly structure-dependent, i.e., β-naphthyl ketone (**10**) or α-naphthyl ketone (**11**) structure determines whether hydrogen-migration (**10**→**12a,b**) or cycloaddition (**11**→**14**) is favored.

Experimental

The mps were measured by a Yanagimoto micromelting point apparatus, and are uncorrected. ^{1}H NMR spectra were determined on a JEOL JNM-MH-100 (100 MHz) in $CDCl_3$ solution. IR spectra were obtained with a Hitachi 260-50 spectrophotometer. Mass spectra were measured on a JEOL JMS-DX-300 apparatus. Microanalyses were performed on a Yanagimoto CHN corder MT-2.

Materials. *N*-Methyl-1,2-naphthalenedicarboximide (**5**) was prepared and purified as previously described.[3b] Dienes (**2a—c**) were commercially available and **2b,c** were purified by distillation.

General Procedure for Irradiation and Product Isolation. UV irradiation of 25 cm^3 of N_2 purged benzene solutions containing 10 mM of **5** and 100 mM of dienes (**2a—c**) was carried out with an Eikosha EHB-W-300 high-pressure Hg-lamp through aq $CuSO_4$ filter about 1 cm in thickness (>320 nm) at ambient temperature. The reaction was monitored by ^{1}H NMR measurements. After evaporation of the solvent, the residue was subjected to column chromatography (Wakogel C-200). Dichloromethane-ether was used as the eluant for the separation of the products.

Irradiation of 5 and 2,3-Dimethyl-1,3-butadiene (2b). 4-Isopropenyl-2,4-dimethyl-3,4-dihydro-1*H*-naphth[1,2-*c*]-azepine-1,5(2*H*)-dione (**6**): Mp 145—148 °C; ^{1}H NMR δ=1.55 (s, 3H, CMe), 1.87 (s, 3H, =CMe), 3.28 (s, 3H, NMe), 3.27 and 4.38 (ABq, *J*=14 Hz, 2H, CH_2), 4.84 and 5.08 (br s, 2H, $=CH_2$), 7.4—7.7 (m, 2H, Arom H), 7.7—8.1 (m, 3H, Arom H), 8.12 (d, 1H, H^b); IR (KBr) 1698 (ketone), 1643 (lactam), 1482, 1406, 1384, 1080 cm^{-1}. (Received June 24, 1986)

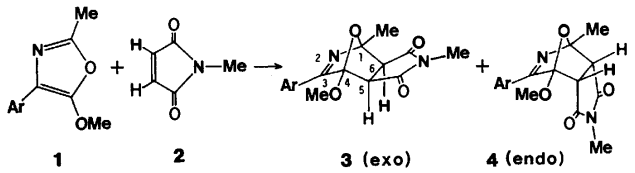
Synopsis. The molecular structure of the exo-Diels-Alder adduct of 5-methoxy-2-methyl-4-(*p*-nitrophenyl)oxazole with *N*-methylmaleimide was determined by X-ray analysis. The crystals are triclinic, space group $P\bar{1}$, with a=9.160(2), b=11.182(2), c=8.816(1) Å, α=92.39(1), β=116.47(1), γ=100.60(1)°, Z=2, D_x=1.455 Mg m^{-3}, D_m=1.458 Mg m^{-3}, μ(Cu $K\alpha$)=9.76 cm^{-1}. The configuration of the exo-adduct is consistent with that predicted on the basis of the NMR data.

The Diels–Alder reaction is one of the most useful reactions in organic synthesis, and widely studied for the preparation of six-membered compounds.[1] Oxazoles have a conjugate azadiene system and are available for the diene component of the Diels–Alder reaction to prepare nitrogen-containing bicyclic compounds.[2,3] In these cycloadditions, the determination of the stereochemistry of the adducts is indispensable from the synthetic and mechanistic view points. However, because of the extreme unstability of the Diels–Alder adducts of oxazoles, no structural determination has been studied yet. The authors have reported that the reaction of 5-methoxy-2-methyl-4-(*p*-nitrophenyl)oxazole (**1**) and *N*-methylmaleimide (**2**) gave two adducts, **3** and **4**, in 32 and 58% yields, respectively.[3] The structures of **3** and **4** were



1 **2** **3 (exo)** **4 (endo)**

Ar=p-$NO_2C_6H_4$

determined tentatively to exo- and endo-adducts on the basis of NMR spectra. The high-field shift of N–CH_3 signal of the adduct (**4**) at δ 2.55, in comparison with that of **3** at δ 3.04, was attributed to the shielding effect of *p*-nitrophenyl group located near the N–CH_3. In this manner **4** was assumed to have endo-structure and **3** to have exo-structure.[3] In order to confirm the above assumption we performed X-ray analysis of the adduct. Of these two adducts endo-adduct (**4**) was found difficult to obtain good crystals for X-ray analysis because of its unstability owing to the retro-Diels–Alder reaction.

Experimental

The Diels–Alder reaction of **1** and *N*-methylmaleimide was carried out by the method previously described.[3] Colorless crystals of the exo-adduct (**3**) were obtained by the several recrystallizations from a mixed solvent of benzene and hexane after the separation of the reaction products by silica-gel column chromatography.

The cell dimensions and diffraction intensities were measured on a Rigaku four-circle diffractometer with Ni-filtered Cu $K\alpha$ radiation. Among 2338 independent reflections with 2θ values up to 120°, 2294 with $|F_o|>0$ were used for the structure determination. No correction was made for absorption.

The structure was solved by the MULTAN 80 program.[4] The positions of the hydrogen atoms were obtained from the difference Fourier synthesis. The structural parameters were obtained by the block-diagonal least-squares method. Anisotropic thermal parameters were applied to the non-hydrogen atoms and isotropic parameters, to the hydrogen atoms. The final R values was 0.046. The function minimized was $\sum w(|F_o|-|F_c|)^2$ with the following weighting scheme: $w=(\sigma^2(F_o)+0.0072|F_o|+0.0009|F_o|^2)^{-1}$.

All the atomic scattering factors were taken from the "International Tables for X-Ray Crystallography".[5] The computations were carried out on an ACOS-850 computer at the Crystallographic Research Center, Institute for Protein Research Laboratory, Osaka University, using "The

Universal Crystallographic Computing System-Osaka".[6] Table 1 lists the final atomic coordinates with equivalent isotropic temperature factors.[7]

Results and Discussion

Molecular Structure. The perspective view of the adduct (**3**) determined by the X-ray analysis is depicted in Fig. 1. The molecule has the exo-structure as has

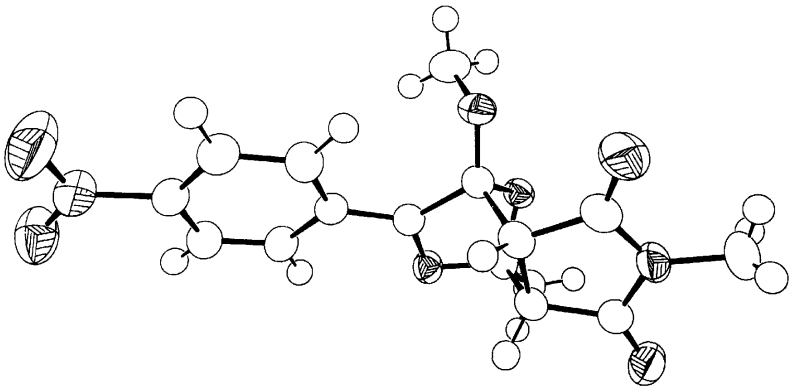

Fig. 1. Perspective view of the exo-adduct (**3**).

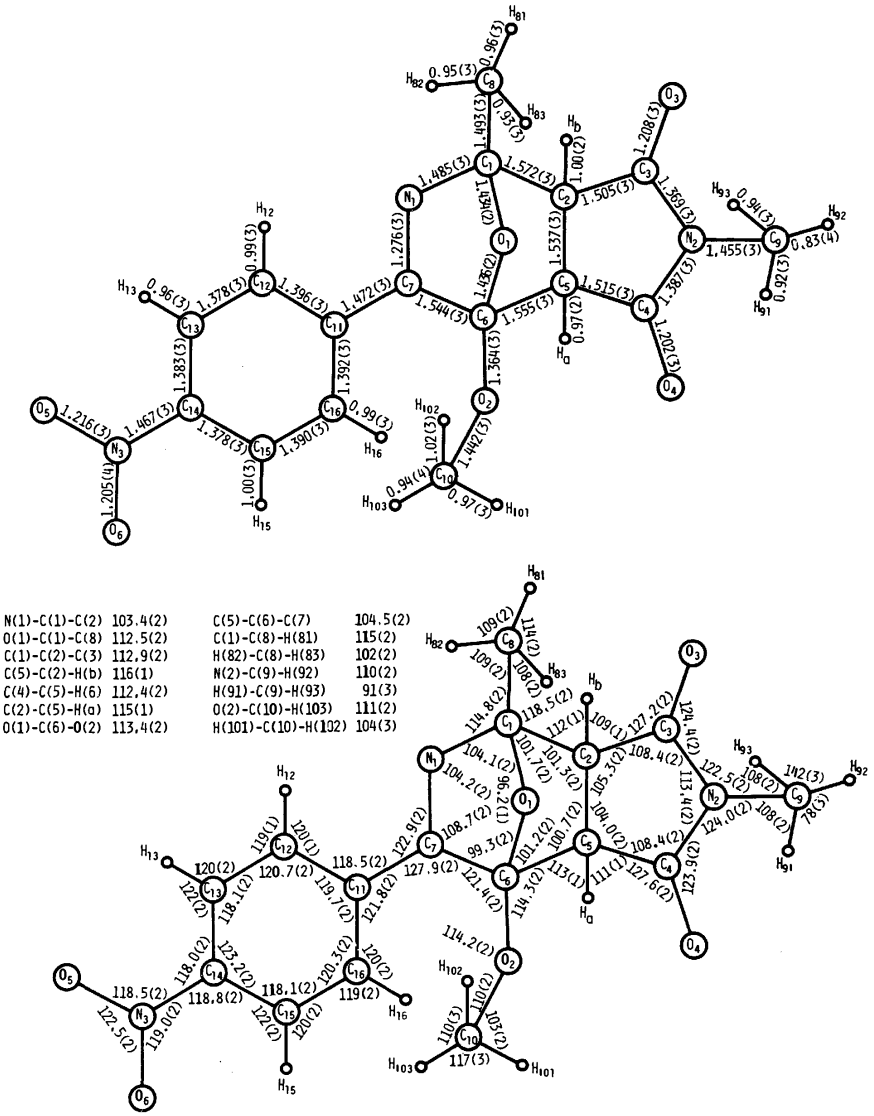

Fig. 2. Bond lengths (l/Å) and angles (ϕ/°).

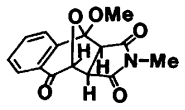
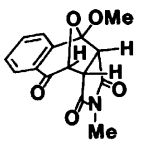
been deduced on the basis of the NMR data. Bond distances and angles are given in Fig. 2.

The bond lengths and bond angles of *N*-methyltetrahydrofuran-3,4-dicarboximide ring system of the adduct (**3**) agree fairly well with those of the corresponding parts of the exo-(**5**) and endo-adduct (**6**) between *N*-methylmaleimide and 1-methoxy-2-benzopyrylium-4-olate[8] except for the following points. The bond lengthes, O(1)–C(1) and O(1)–C(6) of **3** are equal within the limits of experimental errors, while the differences between the corresponding bonds in the exo- and endo-adducts (**5** and **6**) are regarded as significant. The observation that the C(1)–O(1)–C(6) bond angle (96.2°) of **3** is smaller than those of **5** (104.1°) and **6** (105.0°) may be ascribed to the difference of the ring system which consists of a five-membered ring in **3** in contrast to a six-membered rings in **5** and **6**.



5



6

There is no appreciable interaction between the hydrogen atoms of the methoxyl group and the bridged oxygen atom, while the corresponding intramolecular distances in the exo-2:1-adduct between 1-methoxy-2-benzopyrylium-4-olate and acenaphthylene are shorter than the van der Waals distance.[10] The intramolecular distance (2.49 Å) between imide-carbonyl oxygen O(4) and one of the *N*-methyl hydrogen H(91) is shorter than the van der Waals distance. The torsion angle C(13)–C(14)–N(3)–O(5) is 6°, which is comparable to some of the corresponding torsion angles of the nitrobenzene derivatives.[11]

Coupling Constant and Ring-Current Effect. The coupling constant between the vicinal protons of the exo-adduct (**3**) $J_{5,6}$=6.3 Hz is consistent with the calculated value (8.19 Hz) according to the Karplus's Equation.[9] The distance (4.40 Å) between imide-methyl group and bridged oxygen in **3** is far enough to cause the anisotropic deshielding effect of bridged oxygen on chemical shift of *N*-methyl group. In fact, chemical shift of *N*-methyl of **3**, δ 3.04, is quite similar to the value of *N*-methylsuccinimide (δ 2.98). Therefore, the value of chemical shift (δ 2.55) of the endo-adduct (**4**) may be attributed to the anisotropic shielding effect of a *p*-nitrophenyl group located near the *N*-methyl group; that is distance between the *N*-methyl carbon and the center of phenyl group is approximated to 4.5 Å by the CPK model inspection of **4**.

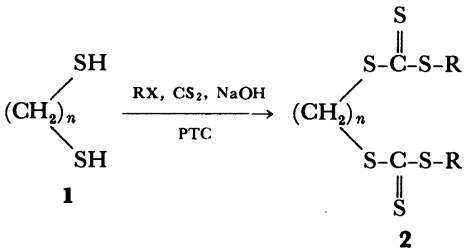
(Received July 4, 1986)

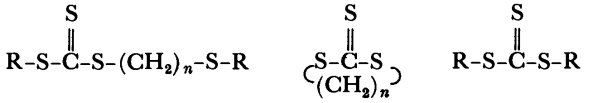
Synopsis. Alkanediyl bis(alkyl trithiocarbonate)s were conveniently synthesized by treating alkanedithiols with alkyl halides and carbon disulfide in the presence of a phase-transfer catalyst.

It is known that trithiocarbonates, R-S-C(=S)-S-R, exhibit insecticidal and fungicidal activities.[1] Therefore, many chemists have investigated the synthesis of trithiocarbonates, for example, by reactions of (i)sodium trithiocarbonate with alkyl halides,[2] (ii) thiophosgene with benzenethiols,[3] (iii)arylchlorodithioformates with alkanethiols,[4] (iv)lithium alkyltrithiocarbonates derived from lithio 2-alkylthio-1,3-dithiolanes with alkyl halides,[5] and (v)alkanethiols and haloalkanenitriles with carbon disulfide in the presence of tetrabutylammonium sulfate.[6] Recently, we also reported the one-pot synthesis of alkyl aryl trithiocarbonates by treating thiols with alkyl halides and carbon disulfide in the presence of a phase-transfer catalyst.[7] However, bis(trithiocarbonate)s, R-S-C(=S)-S-$(CH_2)_n$-S-C(=S)-S-R, which may have synthetic potential due to the presence of two trithiocarbonate groups are yet difficult to obtain. To our knowledge, there have been only two reports on the preparation of two 1,2-ethanediyl bis(alkyltrithiocarbonate)s from 2,2′-[1,2-ethanediylbis(thio)]bis[1,3-dithiolane].[8] Here, we wish to report a convenient preparation of (*S*,*S*′-)alkanediyl bis(alkyl trithiocarbonate)s (**2**) from α,ω-alkanedithiols (**1**) with alkyl halides and carbon disulfide in the presence of a phase-transfer catalyst (PTC) (Eq. 1).



1 **2** (1)

Since a marked difference was not observed in the use of other catalysts, we employed trioctylmethylammonium chloride as a phase-transfer catalyst. Various (*S*,*S*′-)alkanediyl bis(alkyl trithiocarbonate)s (**2aa**–**2de**) were synthesized from α,ω-alkanedithiols (**1**), for example, 1,2-ethane-, 1,3-propane- and 1,6-hexanedithiols, in good yields as shown in Table 1. The absence of PTC resulted in a poor yield of (*S*,*S*′-)alkanediyl bis(alkyl trithiocarbonate)s (**2**). All reactions proceeded smoothly at an ambient temperature.



3 **4** **5**

The use of alkyl iodides rather than bromides gave better results (Runs 5—6). Bulky alkyl iodides such as isopropyl iodide did not yield the desired (*S*,*S*′-)alkanediyl bis(alkyl trithiocarbonate)(**2**) (Run 10). It is noted that 1,6-hexanedithiol gave **2** selectively. Bis(trithiocarbonate)s **2ab**–**2ac** and **2ba**–**2de** obtained by this method were new compounds.

This novel method for the preparation of (*S*,*S*′-) alkanediyl bis(alkyl trithiocarbonate)s is convenient, and has synthetic utility.

Experimental

All Melting points were uncorrected. ^{1}H NMR spectra were measured with a HITACHI R-20B, using tetramethylsilane as internal standard. IR spectra were obtained on a JASCO-G spectrophotometer. Elemental analysis were determined with YANAGIMOTO MT-3.

General Procedure. To a solution of α,ω-alkanedithiol (**1**) (3.5 mmol) and sodium hydroxide (10.5 mmol) in water (5 ml), carbon disulfide (10.5 mmol) and trioctylmethylammonium chloride (0.07 mmol) was added and then stirred at 10—30 °C for 2 h. Alkyl halide (10.5 mmol) in benzene (5 ml) was added to the solution and further stirring was continued at the temperature for 3 h. After completion of the reaction benzene layer was washed with water and then dried on sodium sulfate. Yellow oil obtained by evaporation of benzene was chromatographed on silica gel using chloroform as eluent, to give the desired (*S*,*S*′-)alkanediyl bis(alkyl trithiocarbonate)s (**2**) together with by-products (**3**, **4**, and **5**). The structure of the products were characterized by ^{1}H NMR, IR, MS, and elemental analysis.

1,4-Butanediyl Bis(methyl trithiocarbonate) 2ca: Mp 54.9 °C; IR (KBr) 2900, 1407, 1065, and 820 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.78 (t, 4H, 6.0 Hz, CH_2), 2.69 (s, 6H, CH_3) and 3.36 (t, 4H, 6.0 Hz, CH_2); Found: C, 31.81; H, 4.44%. Calcd for $C_8H_{14}S_6$: C, 31.76; H, 4.66%.

1,4-Butanediyl Bis(ethyl trithiocarbonate) 2cb: Mp 34.0 °C; IR (KBr) 2920, 1448, 1073, 1022, and 815 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (t, 6H, 7.2 Hz, CH_3), 1.78 (m, 4H, CH_2), 3.15—3.52 (m, 4H, CH_2) and 3.33 (q, 4H, 7.2 Hz, CH_2); Found: C, 36.64; H, 5.49%. Calcd for $C_{10}H_{18}S_6$: C, 36.33; H, 5.49%.

1,4-Butanediyl Bis(propyl trithiocarbonate) 2cc: Mp 27.4 °C; IR (KBr) 2930, 1448, 1075, 1022, and 810 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.92 (t, 6H, 7.0 Hz, CH_3), 1.63 (sextet, 4H, 7.0 Hz, CH_2), 1.72 (t, 4H, 7.0 Hz, CH_2), 3.28 (t, 4H, 7.0 Hz, CH_2) and 3.31 (t, 4H, 7.0 Hz, CH_2); Found: C, 40.19; H, 5.94%. Calcd for $C_{12}H_{22}S_6$: C, 40.18; H, 6.18%.

1,4-Butanediyl Bis(methoxycarbonylmethyl trithiocarbonate) 2cd: Mp 66.2 °C; IR (KBr) 2860, 1746, 1165, and 1070 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.80 (m, 4H, CH_2), 3.40 (m, 4H, CH_2), 3.74 (s, 6H, CH_3) and 4.15 (s, 4H, CH_2); Found: C, 34.65; H, 4.14%. Calcd for $C_{12}H_{18}O_4S_6$: C, 34.43; H, 4.33%.

1,4-Butanediyl Bis(benzyl trithiocarbonate) 2ce: Mp 95.5 °C; IR (KBr) 3010, 2900, 1452, 1052, 810, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.79 (m, 4H, CH_2), 3.39 (t, 4H, 6.5 Hz, CH_2), 4.60 (s, 4H, CH_2) and 7.38 (s, 10H, arom); Found: C, 52.53; H, 4.85%. Calcd for $C_{20}H_{22}S_6$: C, 52.58; H, 4.88%.

1,6-Hexanediyl Bis(methyl trithiocarbonate) 2da: Mp 72.0 °C; IR (KBr) 2900, 1409, 1262, 1064, and 808 cm^{-1};

^{1}H NMR ($CDCl_3$) δ=1.54 (m, 8H, CH_2), 2.77 (s, 6H, CH_3) and 3.39 (t, 4H, 8.0 Hz, CH_2); Found: C, 36.12; H, 5.32%. Calcd for $C_{10}H_{18}S_6$: C, 36.33; H, 5.49%.

1,6-Hexanediyl Bis(ethyl trithiocarbonate) 2db: Mp 42.0 °C; IR (KBr) 2910, 1410, 1250, 1089, and 838 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.32 (t, 6H, 7.2 Hz, CH_3), 1.44 (m, 8H, CH_2), 3.37 (q, 4H, 7.2 Hz, CH_2) and 3.35 (m, 4H, CH_2); Found: C, 40.39; H, 6.11%. Calcd for $C_{12}H_{22}S_6$: C, 40.19; H, 6.18%.

1,6-Hexanediyl Bis(propyl trithiocarbonate) 2dc: Mp 46.0 °C; IR (KBr) 2900, 1416, 1228, 1060, and 815 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.02 (t, 6H, 7.0 Hz, CH_3), 1.53 (m, 8H, CH_2), 1.69 (sextet, 4H, 7.0 Hz, CH_2) and 3.35 (t, 8H, 7.0 Hz, CH_2); Found: C, 43.12; H, 6.65%. Calcd for $C_{14}H_{26}S_6$: C, 43.48; H, 6.78%.

1,6-Hexanediyl Bis(methoxycarbonylmethyl trithiocarbonate) 2dd: Mp 63.0 °C; IR (KBr) 2780, 1747, 1165, and 1076 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.50 (m, 8H, CH_2), 3.37 (t, 4H, CH_2), 3.74 (s, 6H, CH_3) and 4.17 (s, 4H, CH_2); Found: C, 37.40; H, 4.85%. Calcd for $C_{14}H_{22}O_4S_6$: C, 37.64; H, 4.96%.

1,6-Hexanediyl Bis(benzyl trithiocarbonate) 2de: Mp 86.0 °C; IR (KBr) 3010, 2920, 1454, 1060, 822, 798, and 701 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.50 (bs, 8H, CH_2), 3.35 (t, 4H, 7.0 Hz, CH_2), 4.60 (s, 4H, CH_2) and 7.28 (s, 10H, arom); Found: C, 54.62; H, 5.49%. Calcd for $C_{22}H_{26}S_6$: C, 54.73; H, 5.43%.

Methyl 2-(Methylthio)ethyl Trithiocarbonate 3aa: Oil; IR (neat) 2900, 1410, 1055, 1040, and 810 cm^{-1}: ^{1}H NMR ($CDCl_3$) δ=2.17 (s, 3H, CH_3), 2.74 (s, 3H, CH_3), 2.70 (t, 2H, 7.8 Hz, CH_2) and 3.59 (t, 2H, 7.8 Hz, CH_2); Found: C, 30.04; H, 4.83%. Calcd for $C_5H_{10}S_4$: C, 30.28; H, 5.08%.

Ethyl 2-(Ethylthio)ethyl Trithiocarbonate 3ab: Oil; IR (neat) 2900, 1450, 1252, 1070, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.28 (t, 3H, 7.2 Hz, CH_3), 1.37 (t, 3H, 7.2 Hz, CH_3), 2.63 (q, 2H, 7.2 Hz, CH_2), 2.78 (t, 2H, 4.8 Hz, CH_2), 3.36 (q, 2H, 7.2 Hz, CH_2) and 3.56 (t, 2H, 4.8 Hz, CH_2); Found: C, 36.84; H, 6.12%. Calcd for $C_7H_{14}S_4$: C, 37.13; H, 6.23%.

Propyl 2-(Propylthio)ethyl Trithiocarbonate 3ac: Oil; IR (neat) 2900, 1054, 1039, and 808 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.99 (t, 3H, 6.8 Hz, CH_3), 1.01 (t, 3H, 6.8 Hz, CH_3), 1.62 (m, 2H, 6.8, 7.2 Hz, CH_2), 1.72 (m, 2H, 6.8, 7.2 Hz, CH_2), 2.54 (t, 2H, 7.2 Hz, CH_2), 2,80 (m, 2H, CH_2), 3.31 (t, 2H, 7.2 Hz, CH_2) and 3.50 (m, 2H, CH_2); Found: C, 42.21; H, 6.84%. Calcd for $C_9H_{18}S_4$: C, 42.48; H, 7.13%.

Methyl 3-(Methylthio)propyl Trithiocarbonate 3ba: Oil; IR (neat) 2880, 1417, 1070, and 812 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.03 (s, 3H, CH_3), 2.53 (quint, 2H, 7.0 Hz, CH_2), 2.72 (s, 3H, CH_3) and 3.46 (t, 4H, 7.0 Hz, CH_2); Found: C, 33.77; H, 5.53%. Calcd for $C_6H_{12}S_4$: C, 33.93; H, 5.70%.

Ethyl 3-(Ethylthio)propyl Trithiocarbonate 3bb: Oil; IR (neat) 2900, 1445, 1250, 1075, 1025, and 815 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.22 (t, 3H, 7.0 Hz, CH_3), 1.34 (t, 3H, 7.0 Hz, CH_3), 1.92 (quint, 2H, 7.5 Hz, CH_2), 2.41 (t, 2H, 7.5 Hz, CH_2), 2.49 (q, 2H, 7.0 Hz, CH_2), 3.34 (q, 2H, 7.0 Hz, CH_2) and 3.44 (t, 2H, 7.5 Hz, CH_2); Found: C, 39.77; H, 6.56%. Calcd for $C_8H_{16}S_4$: C, 39.96; H, 6.71%.

Propyl 3-(Propylthio)propyl Trithiocarbonate 3bc: Oil; IR (neat) 2900, 1440, 1060, 1040, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.03 (t, 6H, 6.8 Hz, CH_3), 1.50—2.90 (m, 8H, 6.8, 7.0 Hz, CH_2), 3.32 (t, 4H, 7.0 Hz, CH_2) and 3.43 (t, 4H, 7.0 Hz, CH_2); Found: C, 44.61; H, 7.59%. Calcd for $C_{10}H_{20}S_4$: C, 44.73; H, 7.51%.

Benzyl 3-(Benzylthio)propyl Trithiocarbonate 3be: Oil; IR (neat) 3020, 2880, 1498, 1060, 798, and 694 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.00 (quint, 2H, 7.0 Hz, CH_2), 3.04 (t, 2H, 7.0 Hz, CH_2), 3.42 (t, 2H, 7.0 Hz, CH_2), 4.16 (s, 2H, CH_2), 4.54 (s, 2H, CH_2) and 7.18—7.21 (m, 10H, arom); Found: C, 59.33; H, 5.43%. Calcd for $C_{18}H_{20}S_4$: C, 59.30; H, 5.53%.

Methyl 4-(Methylthio)butyl Trithiocarbonate 3ca: Oil; IR (neat) 2920, 1420, 1065, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.67—1.84 (m, 4H, CH_2), 1.96 (s, 3H, CH_3), 2.40 (t, 2H, 7.0 Hz, CH_2), 2.66 (s, 3H, CH_3) and 3.32 (t, 2H, 7.0 Hz, CH_2); Found: C, 37.38; H, 6.18%. Calcd for $C_7H_{14}S_4$: C, 37.13; H, 6.23%.

Ethyl 4-(Ethylthio)butyl Trithiocarbonate 3cb: Oil; IR (neat) 2950, 1450, 1075, 1022, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.16 (t, 3H, 7.0 Hz, CH_3), 1.29 (t, 3H, 7.0 Hz, CH_3), 1.70 (m, 4H, CH_2), 2.41 (q, 2H, 7.0 Hz, CH_2), 2.42 (t, 2H, 7.0 Hz, CH_2), 3.29 (q, 2H, 7.0 Hz, CH_2) and 3.30 (t, 2H, 7.0 Hz, CH_2); Found: C, 42.28; H, 6.96%. Calcd for $C_9H_{18}S_4$: C, 42.48; H, 7.13%.

Propyl 4-(Propylthio)butyl Trithiocarbonate 3cc: Oil; IR (neat) 2920, 1455, 1060, 1038, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.02 (t, 3H, CH_3), 1.28 (t, 3H, CH_3), 1.83 (m, 8H, CH_2), 2.80 (m, 2H, CH_2) and 3.39 (m, 6H, CH_2); MS (13.5 eV) *m/z* 283 (M^+), 239, 164, 120, and 43.

Methoxycarbonylmethyl 4-(Methoxycarbonylmethylthio)-butyl Trithiocarbonate 3cd: Mp 43.0 °C; IR (KBr) 2840, 1740, 1430, 1060, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.84 (m, 4H, CH_2), 3.44 (m, 4H, CH_2), 3.74 (s, 3H, CH_3), 3.76 (s, 3H, CH_3), 4.20 (s, 2H, CH_2) and 4.31 (s, 2H, CH_2); MS (10 eV) *m/z* 343 (M^+), 254, 193, 160, 91, and 74.

Benzyl 4-(Benzylthio)butyl Trithiocarbonate 3ce: Oil; IR (neat) 3020, 2900, 1450, 1060, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.63 (m, 4H, CH_2), 2.30 (m, 2H, CH_2), 3.26 (m, 2H, CH_2), 3.58 (s, 2H, CH_2), 4.52 (s, 2H, CH_2) and 7.17 (s, 10H, arom); Found: C, 60.57; H, 5.89%. Calcd for $C_{19}H_{22}S_4$: C, 60.27; H, 5.86%.

Effect of $Ru_3(CO)_{12}$ and Triisopropylphosphine on the Catalytic Activity of CO Hydrogenation by $Co_2(CO)_8$

(Received June 24, 1986)

Synopsis. A catalyst system, containing $Co_2(CO)_8$ coupled with $Ru_3(CO)_{12}$ and triisopropylphosphine($(i\text{-Pr})_3P$), was found to be effective for the ethylene glycol formation by homogeneous hydrogenation of CO: The most active catalyst, the activity of glycol formation of which was ca. 3 times higher than that of $Co_2(CO)_8$ alone, was obtained at phosphorus:Co:Ru ratio of 2:1:1.

Many efforts have been made to prepare ethylene glycol directly from syngas ($CO+H_2$) using homogeneous catalyst of Group 8 metals.[1] Rhodium,[1b,c] ruthenium,[1a,b,c] and cobalt[1b,c] metals are particularly favorable. Recently, it has been reported that the use of mixed metals, Rh and Ru, as catalyst precursors results in an improved catalytic activity.[2]

We have reported a direct synthesis of the glycol from syngas, where $Co_2(CO)_8$ in toluene solvent is employed under the standard conditions of 1800 atm (180 MPa) and 230 °C.[3] Also, we have found that, in the cobalt-catalyzed glycol production from formaldehyde and syngas, the addition of $Ru_3(CO)_{12}$ is effective for enhancing the glycol productivity.[4] The addition of phosphines has proved to be effective in the case of Rh-amide catalyst.[5] These findings prompt us to try Co-Ru or Co-Ru-P mixed catalysts for the hydrogenation of CO to give ethylene glycol under high pressure and high temperature. Now we describe here some of our results.

Results and Discussion

Some typical examples are shown in Fig. 1, where total amount of metals is held constant at 0.4 (Co+Ru) mmol. In our system involving cobalt coupled with ruthenium and triisopropylphosphine-($(i\text{-Pr})_3P$), ethylene glycol (EG), methanol (MeOH), and methyl formate (MF) are mainly produced with a small amount of ethanol (EtOH) (See Table 1). The results are summarized as follows:

i) A small but clear synergism was observed in the absence of $(i\text{-Pr})_3P$(●).

ii) The addition of $(i\text{-Pr})_3P$ resulted in enhancing the CO hydrogenation activity of Co–Ru system (○): The most active catalyst, the cativity of glycol formation of which was ca. 3 times higher than that of $Co_2(CO)_8$ alone, was obtained at phosphorus:Co:Ru ratio of 2:1:1. Further addition of the phosphine reduced the glycol formation. The effectiveness of other phosphines was in the order: $(i\text{-Pr})_3P(1.59)$>$(n\text{-Bu})_3P(1.14)$>$Cy_3P(0.93)$(Cy:cyclohexyl)>none(0.55)>

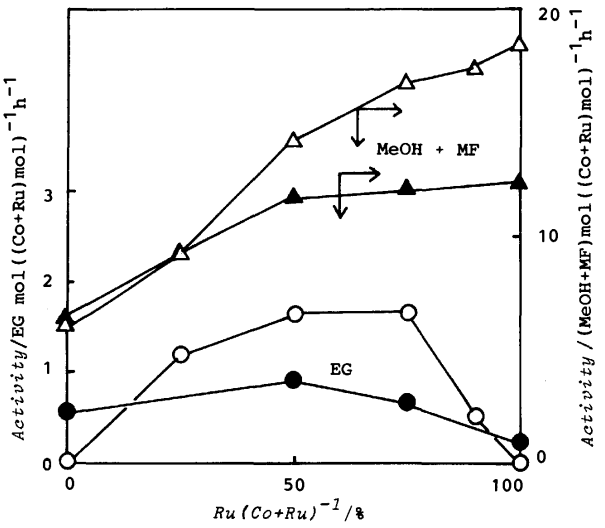

Fig. 1. CO hydrogenation activity vs. ruthenium mole fraction. Co+Ru=0.4 mmol, $(i\text{-Pr})_3P$ 0.4 mmol, dioxane 20 ml, 270 °C, 5 h, 1000 atm, $H_2/CO=1$.

Table 1. Effect of H_2/CO Ratio under 2000 atm[a]

H_2/CO Ratio	T/°C	Product/mmol				N_{EG}[b]	Sel.$_{EG}$[c]	N_{C_1}[d]
		MeOH	MF	EtOH	EG	mol/g-atom. h	%	mol/g-atom. h
1	270	3.95	4.4	0.01	3.03	22.8	42	62.8
2	270	8.78	4.46	0.09	4.23	31.8	39	99.5
3	270	11.2	3.49	0.01	2.49	18.7	25	111
1	250	0.79	1.53	0.01	1.27	9.5	52	17.4
3	250	3.18	2.05	0.01	1.96	14.7	43	39.3

a) Conditions: $Co_2(CO)_8$ 0.0335 mmol, $Ru_3(CO)_{12}$ 0.0223 mmol, $(i\text{-Pr})_3P$ 0.133 mmol, toluene 7 ml, 2000 atm, 1 h. b) Turnover frequency relative to the total amounts of Co and Ru. c) Sel.$_{EG}$=2EG×100/(MeOH+MF+2(EG+EtOH)). d) MeOH+MF.

$(PhO)_3P(0.25)>Ph_3P(0.07)>Cy_2P(CH_2)_2PCy_2(0.012)$(Cy: cyclohexyl)(numerical values refer to turnover frequency of the glycol (N_{EG})). It was found for the first time that the addition of ruthenium-phosphine was effective for the cobalt-catalyzed CO hydrogenation.[6]

iii) After the reaction, the data of which is shown in Fig. 1, each catalyst solution, which is pale red-brown color, is truly homogeneous. Isotope-labelling studies using dioxane-d_8 conclusively demonstrated that the glycol was primary product and not solvent-derived by hydrogenation of dioxane.

iv) Replacement of $Ru_3(CO)_{12}$ by other metal carbonyls such as $Re_2(CO)_{10}$, $Mo(CO)_6$, $Fe(CO)_5$, and $Cr(CO)_6$ resulted in negative effects on the activity, whereas $Rh_4(CO)_{12}$ promoted the reaction, but the extent was less than $Ru_3(CO)_{12}$. Catalytic behaviors of Co-Ru-P system were examined, in comparison with $Co_2(CO)_8$ alone. For Co-Ru-P (1:1:2) system, the pressure dependence of the glycol formation was greater than fourth-order, while that for C_1-(MeOH+MF) formation process was in the vicinity of first- to second-order, as shown in Fig. 2 (○,△). Analogous dependences were observed in the cobalt catalyst (Fig. 2, ●, ▲). The glycol formation increased with either increases in partial pressure of H_2 or CO; the C_1 formation increased with the increase in P_{H2} and decreased with the increase in P_{CO}. Similar trends were obtained for $Co_2(CO)_8$. The activity of Co-Ru-P system was affected by the initial H_2/CO ratio (Table 1): The maximum activity was achieved at the ratio of 2 at 270 °C. The activation energy for the glycol formation was 105 kJ mol^{-1} and that for C_1 products was 142 kJ mol^{-1}, in the case of Co-Ru-P in toluene solvent under 2000 atm.[7] For $Co_2(CO)_8$ alone in the same solvent, the energies for glycol and C_1 have been found to be 100 and 138 kJ mol^{-1}, respectively.[3]

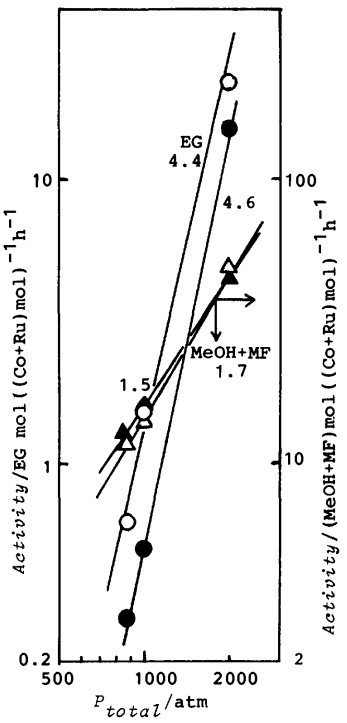

Fig. 2. Effect of total pressure.
toluene 7 ml, 270 °C, 5 h, $H_2/CO=1$.
○△ $Co_2(CO)_8$ 0.1 mmol, $Ru_3(CO)_{12}$ 0.0667 mmol, $(i\text{-Pr})_3P$ 0.4 mmol, ●▲ $Co_2(CO)_8$ 0.2 mmol.

The IR spectroscopic measurements were undertaken under the conditions of 20 atm at room temperature.[8] The hexane solution of Co-Ru-P system exhibited IR absorptions characteristic of $Co_2(CO)_8$(2075 m, 2045 m, 2025 s, 1857 m cm^{-1})[9], $Ru(CO)_5$(2040 s, 2002 s cm^{-1}),[10] and $Ru(CO)_4[(i\text{-Pr})_3P]$ (1982 m, 1940 vs cm^{-1}).[11,12] Mixed cobalt-ruthenium carbonyl cluster species[13] were not detected. For comparison, the Ru-P system, the spectra of which showed $Ru(CO)_5$ and $Ru(CO)_4[(i\text{-Pr})_3P]$[14], possessed high productivity of C_1 compounds but not glycol (Fig. 1) and, on the other hand, the Co-Ru system, exhibiting $Co_2(CO)_8$ and $Ru(CO)_5$ carbonyl bands,[14] was favorable in the glycol formation but a little inferior to the Co-Ru-P system (Fig. 1). There findings demonstrate that the presence of $Co_2(CO)_8$ species seems to be essential for the glycol formation and that the presences of both $Ru(CO)_5$ and $Ru(CO)_4[(i\text{-Pr})_3P]$ contribute to the enhancement of total catalytic activity.

Experimental

Materials. Phosphines, solvents, and $Ru_3(CO)_{12}$ were obtained commercially and used with no further purification. $Co_2(CO)_8$ was prepared according to an usual procedure.

Reaction Procedure. A catalyst solution containing $Co_2(CO)_8$, $Ru_3(CO)_{12}$, and phosphine in solvent was placed in a Hastelloy C(100 ml)- or Inconnel(20 ml)-autoclave, which was subsequently charged with syngas ($H_2/CO=1$). After the reaction, the reaction vessel was cooled to room temperature and the solution was analyzed by GLC. IR spectra were measured with a JEOL A-302 type spectrometer.

12) UV spectra of the solution at atmospheric pressure were also consistent with the presence of $Co_2(CO)_8$(350 nm) and the absence of cluster $Ru_3(CO)_{12}$(390 nm). We also observed a weak IR band of $Co_2(CO)_7$[(i-Pr)$_3$P](1994 cm^{-1}).[10] But little glycol is generated in $Co_2(CO)_8$/(i-Pr)$_3$P system under the conditions (Fig. 1).

13) W. L. Gladfelter, G. L. Geoffroy, and J. C. Calabrese, *Inorg. Chem*, **19**, 2569 (1980). Also, the UV spectra under 80 atm at ambient temp. exhibited no cluster absorptions.

14) In the Ru/(i-Pr)$_3$P system, $Ru_3(CO)_{12}$ species was not present and, on the contrary, the cluster was present in Co-Ru system (UV spectra).

Interaction between Copper(I) Chloride and Active Carbon in Active Carbon-Supported Copper(I) Chloride as Solid Carbon Monoxide Adsorbent

Hidefumi HIRAI,* Keiichiro WADA, and Makoto KOMIYAMA

7-3-1, Hongo, Tokyo 113
(Received July 14, 1986)

Synopsis. Magnetic susceptibility (-4.7×10^{-9} m^3 kg^{-1}) of the carbon monoxide adsorbent prepared from 10.0 g of active carbon and 1.4 g of copper(I) chloride is in paramagnetic side with respect to the value (-10.1×10^{-9} m^3 kg^{-1}) estimated from the susceptibilities of the components. Almost all the copper atoms are in their monovalent states, as shown by X-ray photoelectron spectroscopy. These results have indicated specific interaction between active carbon and copper(I) chloride in the adsorbent.

Separation of carbon monoxide from gas mixtures is an important process in industry, since carbon monoxide is usually obtained as mixtures with nitrogen, hydrogen, methane, and carbon dioxide.[1]

In previous papers,[2,3] the authors showed that the active carbon-supported copper(I) chloride rapidly and reversibly adsorbed carbon monoxide under mild conditions. The adsorbing capacities of the adsorbents were much larger than the sum of the capacities of the active carbon and copper(I) chloride, indicating some interaction between them in the adsorbents.

This paper reports the results of magnetic susceptibility measurements and X-ray photoelectron spectroscopy on the active carbon-supported copper(I) chloride, which shed light on the interaction between active carbon and copper(I) chloride in the adsorbents.

Experimental

Active carbon was purchased from Kureha Chemical Industries Co. (BAC G-70R, Lot No. 810117; beads of average diameter ca 0.7 mm) and was subjected to a reduced pressure (6 mmHg) at 200 °C for 5 h immediately before use. The active carbon-supported copper(I) chloride was prepared by stirring 10.0 g of the active carbon in 15 cm^3 of aqueous hydrochloric acid solution (3 mol dm^{-3}) containing various amounts of copper(I) chloride at room temperature for 1 h, followed by the removal of the liquid phase at 6 mmHg, 100 °C.[2,3] The amount of copper(I) chloride supported onto the active carbon was determined by atomic absorption spectroscopy.

Magnetic susceptibilities were measured at room temperature by use of a CAHN Instrument Co. Model RG Automatic Electrobalance, which took advantage of the Gouy's method.[4] The permanent magnetic field, the magnetic field gradient, and the balance sensitivity were 5 kG (1 G=10^{-4} T), 4.841×10^6 G^2 cm^{-1}, and 0.1 μg, respectively. Specimens (100—500 mg) were charged into Pyrex glass vessels of diameter 8 mm and depth 10 mm under nitrogen. The susceptibilities of the specimens were determined by subtraction of the susceptibilities for the vessels without the specimens from the values for the vessels with them.

X-Ray photoelectron spectra were measured on a Shimadzu Electron Spectrometer ESCA 750 with Mg X-ray anode. Chemical shifts were determined by use of the $4f_{7/2}$ band of metallic gold at 84.0 eV as reference.

Results and Discussion

Figure 1 depicts the X-ray photoelectron spectra for the Cu_{2p} region of the active carbon-supported copper(I) chloride as carbon monoxide adsorbents, copper(I) chloride, and copper(II) chloride. The adsorbents exhibit spectra (a and b) having two bands at 933 and 953 eV, which are virtually identical with that (c) of copper(I) chloride. The spectra of the adsorbents, however, are significantly different from that (d) of copper(II) chloride, which shows four bands at 937, 944, 957, and 964 eV. Thus, almost all the copper atoms in the adsorbents are present in the monovalent states.

Table 1 lists the mass magnetic susceptibility of the adsorbent (Active Carbon/CuCl) composed of 10.0 g of the active carbon (Active Carbon) and 1.4 g of copper(I) chloride (CuCl) together with the values of the components. All of the adsorbent, the active carbon, and copper(I) chloride are diamagnetic, as shown by the negative values of the susceptibilities. The absolute value (4.7×10^{-9} m^3 kg^{-1}) of the susceptibility of the adsorbent is considerably smaller than that (10.1×10^{-9} m^3 kg^{-1}) estimated from the susceptibilities (-11.0×10^{-9} and -3.9×10^{-9} m^3 kg^{-1}, respec-

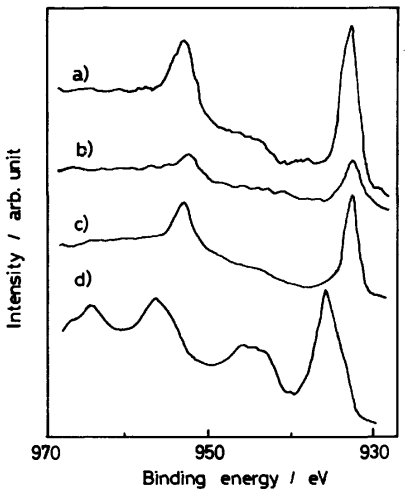

Fig. 1. X-Ray photoelectron spectra in the Cu_{2p} region for (a) the adsorbent prepared from 2.5 g of copper(I) chloride and 10.0 g of the active carbon, (b) the adsorbent prepared from 1.5 g of copper(I) chloride and 10.0 g of the active carbon, (c) solid of copper(I) chloride, and (d) solid of copper(II) chloride.

Table 1. Mass Magnetic Susceptibility of the Carbon Monoxide Adsorbent Prepared from 10.0 g of the Active Carbon and 1.4 g of Copper(I) Chloride as well as the Values for the Components

Specimen	Magnetic susceptibility[a] 10^{-9} m^3 kg^{-1}

Active carbon	−11.0
CuCl	−3.9

a) Negative signs refer to diamagnetic properties.

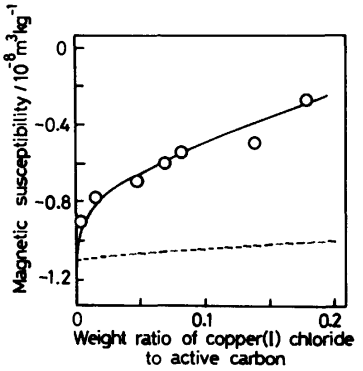

Fig. 2. Plot of mass magnetic susceptibility of the carbon monoxide adsorbent prepared from the active carbon and copper(I) chloride against the weight ratio of copper(I) chloride to the active carbon: the negative signs in the susceptibilities refer to diamagnetic properties; the broken line is a theoretical line evaluated from the susceptibilities of the components under the assumption that the additivity rule is valid.

tively) of the active carbon and copper(I) chloride under the assumption that the additivity rule is applicable here. In the rule proposed by Wiedemann,[5] the susceptibility is expressed by linear combination of the values of the components with the use of weight fractions as coefficients. This indicates that some paramagnetic species are formed by the interaction between the active carbon and copper(I) chloride.

The open circles in Fig. 2 depict the plot of the mass magnetic susceptibility for the adsorbent composed of the active carbon and copper(I) chloride as a function of the weight ratio of copper(I) chloride to the active carbon. The broken line refers to theoretical values evaluated by use of the additivity rule. All the experimental points are located in considerably paramagnetic sides with respect to the theoretical line. The magnitude of the deviation of the experimental point from the theoretical line significantly increases with increase in the weight ratio of copper(I) chloride to the active carbon.

These results show that some electronic interaction is operative between the active carbon and copper(I) chloride in the adsorbent. The interaction is probably associated with formation of pi-type complex between them. Electron donation from the active carbon to the copper(I) chloride as well as back donation from the copper atoms to the active carbon results in unpaired electrons both on the copper atoms and in the condensed aromatic rings of the active carbon, giving rise to the increase in the paramagnetic characters of the adsorbents.

These arguments are supported by the formation of pi-complexes between copper(I) ion and various olefins.[6] In the present adsorbents almost all the copper(I) chloride are present in their monomeric or dimeric forms.[3]

Virtually the same X-ray photoelectron spectra (a and b in Fig. 1) of the adsorbents with that (c) of copper(I) chloride is ascribed to rather small dependence of the chemical shifts of copper(I) ions on their chemical circumstances. The chemical shifts of Cu_{2p} bands for the complexes between copper(I) chloride and various ligands are identical with each other within 1.6 eV.[7]

The interaction between copper(I) chloride and active carbon in the adsorbents has been also examined by electron spin resonance spectroscopy. Detection of signals from the paramagnetic species in the adsorbents, however, has not been successful yet, probably due to both effective shielding of them from magnetic field by the active carbon and background signals from the active carbon.

High dispersion of copper(I) chloride on the surface of the active carbon in the active carbon-supported copper(I) chloride, which is essential for the large adsorbing ability of the adsorbents,[3] is attributable to the specific interaction between the active carbon and the copper(I) chloride. Without the interaction, copper(I) chloride is promptly bound each other through chlorine bridges, forming aggregates with minimal adsorbing capacities. In addition, decreases of the electron densities in the d-orbitals of the copper(I) ions, due to back donation from them to the active carbon, suppress back donation from the copper atoms to carbon monoxide. This weakens coordination bonds between the carbon monoxide and the copper(I) ions in the adsorbents, resulting in the effective desorption of the adsorbed carbon monoxide under mild conditions.

In conclusion, the magnetic susceptibility measurements as well as X-ray photoelectron spectroscopy have showed specific interaction between active carbon and copper(I) chloride in the active carbon-supported copper(I) chloride as solid carbon monoxide adsorbents. Effective and reversible adsorptions of carbon monoxide by the adsorbents are ascribed to the interaction.

The authors would like to thank Prof. Shunichi Kobayashi at the University of Tokyo for his help in the measurements of magnetic susceptibilities.

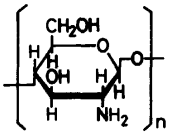
Adsorption of Cu^{2+} or Hg^{2+} Ion on Resins Prepared by Crosslinking Metal-Complexed Chitosans

Kazuya OHGA* Yoshiaki KURAUCHI, and Hiroshi YANASE
Department of Environmental Chemistry and Engineering, Faculty of Engineering, Oita University, Dannoharu, Oita 870-11
(Received June 21, 1986)

Synopsis. Crosslinking metal-complexed chitosans (metal ions=Cu(II), Cd(II), Zn(II), Ni(II), and Fe(III)) with (chloromethyl)oxirane yields resins having higher abilities to adsorb Cu^{2+} than a resin obtained from chitosan in the absence of metal ion. Resins from Cd(II)-chitosan complex can act as effective adsorbents for Hg^{2+}; their Langmuir's adsorption parameters depend on the quantity of (chloromethyl)oxirane used.

Chitosan has been used as an effective coagulating



Chitosan

agent in activated sludge plants and for recovering proteins from food processing factories. This inexpensive polysaccharide can also act as an adsorbent for transition metal ions through chelation,[1-7] in which the amino group of the 2-amino-2-deoxy-D-glucose (glucosamine) unit plays an important role. The amino group is also responsible for dissolution of chitosan in acidic media.[2,3,5,7] This is one serious disadvantage from the practical viewpoint; thus, we attempted to crosslink chitosan with (chloromethyl)oxirane.[8] However, the crosslinking resulted in significant lowering of adsorptive activity, as will be described later. In the present paper, we describe that this problem can be largely overcome by crosslinking metal-complexed chitosan. Central metal ions of complexes are most likely to protect the amino group effective for the adsorption against the attack of the crosslinking agent and, at the same time, to preserve adsorption domains.

Experimental

Chitosan (Tokyo Kasei) was purified through gelation of its aqueous acetic acid solution with KOH, lyophilized, and sufficiently dried in vacuo (<0.13 Pa) for 2 d. The other reagents were of reagent or higher grade and used without further purification. All solutions were prepared with distilled, deionized water.

Preparation of Crosslinked Chitosan. Chitosan (5 g) was crosslinked with (chloromethyl)oxirane (2.9 g, equimolar to the glucosamine unit on the assumption that the chitosan is deacetylated completely[9]) accoding to the procedure reported by Noguchi et al.[10] The resin (NM-R) obtained was dried in vacuo (<0.13 Pa) to a constant weight 6.5 g.

Crosslinking of Metal-Complexed Chitosans. A 0.2 mol dm^{-3} NaOH solution was added dropwise to a 0.3 mol dm^{-3} acetic acid solution (40 cm^3) containing chitosan (500 mg) and a metal chloride ($CuCl_2$, $CdCl_2$, $ZnCl_2$, $NiCl_2$, or $FeCl_3$, equimolar to the glucosamine unit) with vigorous stirring to get a gelatinous metal-complexed chitosan.[5] The addition of the NaOH solution was stopped just before the solution pH got abruptly increased. The gel isolated after centrifugation was crosslinked with (chloromethyl)oxirane (2.9 g, ten times the molar quantity of the glucosamine unit) by the above method. The resin obtained was washed with 1.2 mol dm^{-3} HCl and 0.3 mol dm^{-3} acetic acid repeatedly to remove the metal ion and uncrosslinked chitosan, except for the Fe(III) complex which required conc. HCl to get rid of Fe^{3+} ion completely. The metal-free resin was washed subsequently with 0.2 mol dm^{-3} NaOH and with deionized water to neutral pH, and then dried similarly to the chitosan resin prepared in the absence of metal ion. The yields of the resins from the Cu(II)-, Cd(II)-, Ni(II)-, Zn(II)-, or Fe(III)-complex (abbreviated as Cu-R, Cd-R, Ni-R, Zn-R, or Fe-R, respectively) were 479, 477, 489, 487, and 250 mg, respectively. Likewise, crosslinking of the Cd(II) complex at (chloromethyl)oxirane/glucosamine unit molar ratios of 0.5, 1.0, 4.0, and 6.0 gave resins Cd-$R_{0.5}$, Cd-R_1, Cd-R_4, and Cd-R_6 in yields of 368, 394, 432, and 456 mg, respectively.

Equilibrium Adsorption Test. The resin was ground and sieved to 100—200 mesh size. After having been dried to constant weight, the sieved resin (10 mg) was placed in glass test tubes (16.5×165 mm), to which were added 0.05 mol dm^{-3} acetic acid/sodium acetate buffer solution (pH 5.0, 5 cm^3) containing a metal chloride (0.500—5.00 mmol dm^{-3} for Cu^{2+} or 1.00—8.00 mmol dm^{-3} for Hg^{2+}). The mixture was shaken at a shaking rate of ca. 110 strokes/min at 30.0±0.1 °C for 24 h. The equilibrated mixture was centrifuged, and then the supernatant solution was analyzed for the metal ion by atomic absorption spectrophotometry (Shimadzu AA-640-12). Hg^{2+} ion was determined by the cold vapor technique (Shimadzu mercury vaporizer unit MVU-1A). The quantity of metal ion adsorbed by the resin was obtained by subtracting the concentration in the supernatant solution from the initial concentration. A commercially available chelate resin, Chelex 100 (100—200 mesh; water content 68.8%), was also used for comparison.

Results and Discussion

Adsorption of Cu^{2+}. The ability of NM-R (the chitosan resin obtained in the absence of metal ion) to adsorb Cu^{2+} was first examined but no appreciable adsorption was observed. The resins prepared by crosslinking the metal-complexed chitosans adsorbed Cu^{2+} effectively. As Fig. 1 shows, the experimental isotherms obey the Langmuir equation, $C_{eq}/X=1/X_m b+C_{eq}/X_m$, where C_{eq} and X represent the equilibrium concentration of Cu^{2+} and the quantity of Cu^{2+} adsorbed, respectively. Adsorption parameters, binding constants b, and the quantities, X_m, of adsorbed Cu^{2+} ion with which the resins are saturated, are evaluated from the intercepts and slopes. The numerical data are summarized in Table 1, together

Table 1. Parameters for Cu^{2+} Adsorption

Adsorption parameters	Resins[a]					
	Cu-R	Cd-R	Zn-R	Ni-R	Fe-R	Chelex 100
X_m/mmol g^{-1}	1.4	1.2	0.92	0.78	0.67	2.3
b/$mmol^{-1}$ dm^3	1.1	1.1	1.0	0.51	0.73	1.9

a) Chitosan resins were prepared by crosslinking at a (chloromethyl)oxirane/glucosamine unit molar ratio of 10.

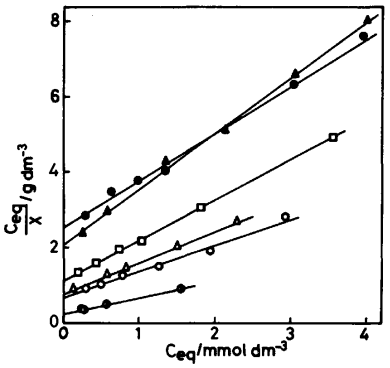


Fig. 1. Adsorption isotherms of Cu^{2+} on Cu-R(○), Cd-R(△), Zn-R(□), Ni-R(●), Fe-R(▲), and Chelex 100(◑) at 30.0 °C.

Table 2. Parameters for Hg^{2+} Adsorption

Adsorption parameters	Resins					
	Cd-R	Cu-R	Fe-R	Ni-R	NM-R[a]	Chelex 100
X_m/mmol g^{-1}	1.6	1.5	1.3	1.1	0.85	1.5
b/$mmol^{-1}$ dm^3	2.6	0.98	0.51	0.56	1.6	2.4

a) Prepared by crosslinking with (chloromethyl)oxirane of equimolar quantity to the glucosamine unit. For the other chitosan resins, see the footnote in Table 1.

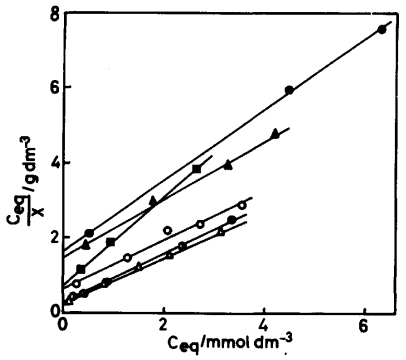

Fig. 2. Adsorption isotherms of Hg^{2+} on Cu-R(○), Cd-R(△), Ni-R(●), Fe-R(▲), NM-R(■), and Chelex 100(◑) at 30.0 °C. C_{eq} and X represent the equilibrium concentration of Hg^{2+} and the quantity of Hg^{2+} adsorbed, respectively.

with those for the commercial resin, Chelex 100. The quantities of Cu^{2+} uptake on the chitosan resins steeply decrease below pH 3, probably due to the protonation of the amino gourp of the glucosamine unit prevailing over its coordination to Cu^{2+}. The adsorption behavior was thus investigated at pH 5.0 where the precipitate of copper(II) hydroxide is not formed.

It is important to note here that lowering of the adsorption ability of parent chitosan by crosslinking was so small when the Cu(II)–chitosan complex (for resin (Cu-R), which of the chitosan resins has the largest adsorption parameters) was used; the uptake of Cu^{2+} from 5 cm^3 of an unbuffered solution ($[Cu^{2+}]=1.17$ mmol dm^{-3}) onto Cu-R or chitosan powder (10 mg) were 52 and 62%, respectively, at adsorption equilibrium. Thus, the central metal ions of the chitosan complexes serve to retain the adsorption ability of chitosan. This suggests that the metal ions can successfully leave domains available for the adsorption upon the removal of the ions from the resins. It is probable that the coordination of the amino groups to the metal ions leads to crosslinking between the hydroxyl groups so that the amino groups survive in the adsorption domains. Moreover, the fact that Cu-R has the largest adsorption parameters of the chitosan resins used, supports the idea that the Cu^{2+} ion in the complex serves, to some extent, as a template ion.[11] The parameters for Cd-R, comparable to those for Cu-R, can be explained in terms of the large ionic radius of Cd^{2+}.

Table 1 also demonstrates that the abilities of the chitosan resins to adsorb Cu^{2+} are lower than that of Chelex 100. However, it should be emphasized that, for the adsorption of Hg^{2+}, Cd-R was found to possess a high ability comparable to that of Chelex 100 known as an excellent chelating resin for Hg^{2+},[6] as will be mentioned in the following subsection.

Adsorption of Hg^{2+}. The isotherms for Hg^{2+} adsorption are also of Langmuir's type as shown in Fig. 2. The parameters obtained are summarized in Table 2.

Of the metal ions used for complexing with chitosan, Cd^{2+} has the largest ionic radius, so that Cd-R could be expected to have the greatest advantage for the adsorption of Hg^{2+} having a large ionic radius. This anticipation has been embodied by the large adsorption parameters of Cd-R, especially by its quite large binding constant comparable to that of Chelex 100.

NM-R has a moderate ability to adsorb Hg^{2+}. This adsorption behavior, different from the case of the Cu^{2+} adsorption, seems due to the coordination to Hg^{2+} of the hydroxyl groups and the ethereal oxygen atoms originating from the parent chitosan and (chloromethyl)oxirane. Thus, in the case of the resins from the metal–chitosan complexes also it is necessary to take into account the participation of these oxygen atoms.

Figure 3 and Table 3 are for the resins prepared by crosslinking the Cd(II)–chitosan complex with reduced quantities of (chloromethyl)oxirane. As Fig. 3

Table 3. Parameters for the Adsorption of Hg^{2+} on Resins Prepared by Crosslinking the Cd(II)-Chitosan Complex with Different Quantities of (Chloromethyl)oxirane

Adsorption parameters	Resins[a]			
	Cd-R_6	Cd-R_4	Cd-R_1	Cd-$R_{0.5}$
X_m/mmol g^{-1}	1.8	1.9	2.5	2.6
b/mmol^{-1} dm^3	1.8	1.7	1.5	1.2

a) The numbers appearing after Cd-R denote the molar ratio of the (chloromethyl)oxirane used for crosslinking to the glucosamine unit.

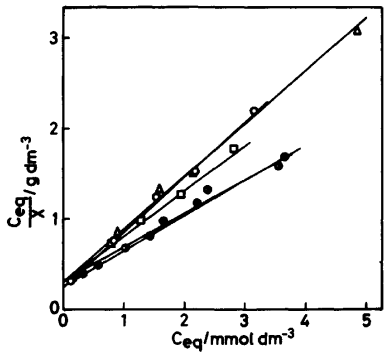

Fig. 3. Adsorption isotherms of Hg^{2+} on Cd-R_6(△), Cd-R_4(□), Cd-R_1(●), and Cd-$R_{0.5}$(◑) at 30.0 °C. For comparison, the isotherm for Cd-R(○) was plotted again. For C_{eq} and X, see the footnote in Fig. 2.

shows, Cd-R_4, Cd-R_1, and Cd-$R_{0.5}$ adsorb Hg^{2+} in larger quantities than Cd-R_6 and Cd-R do. Table 3 indicates that the X_m value progressively increases with decrease in the amount of (chloromethyl)oxirane used. The b value, on the contrary, tends to decrease. Thus, the above improvement of the adsorption ability by use of reduced quantities of oxirane, for which the resulting reduced degree of crosslinking is most probably responsible, is due to the increment in the X_m value prevailing over the decrement in the b value. The X_m value of Cd-R_1 is three times as large as that of NM-R (Table 2), which was crosslinked with the same molar quantity of (chloromethyl)oxirane as Cd-R_1. This again verifies the effectiveness of the central ion, Cd^{2+}, for leaving the domains available for the adsorption of Hg^{2+}.

Separation of Cu^{2+}, Hg^{2+}, and Cd^{2+} Ions. A great difference in the b value was observed between the adsorptions of Cu^{2+} and Hg^{2+} on the Cd-R resin (Tables 1 and 2). Moreover, Cd^{2+} was not adsorbed appreciably on Cd-R or Cd-R_6 under the same conditions as those for the Cu^{2+} or Hg^{2+} adsorption. These findings suggest that a selective separation of Cu^{2+}, Hg^{2+}, and Cd^{2+} ions is feasible by using an appropriate resin obtainable from the Cd(II)-complexed chitosan. Figure 4 illustrates that this separation may be achieved with 95—100% recovery by using a small column (8.0 cm×0.4 cm i.d.) containing 40 mg of Cd-R_6. The following solutions were successively used as eluents: 0.05 mol dm^{-3} acetate buffer, 1.00 mmol dm^{-3} HNO_3, and 0.5 mol dm^{-3} HNO_3. In addition, almost the same chromatograms were obtained when the metal ions were loaded into the column again after complete washing with deionized water, which indicates an effective durability in repeated use.

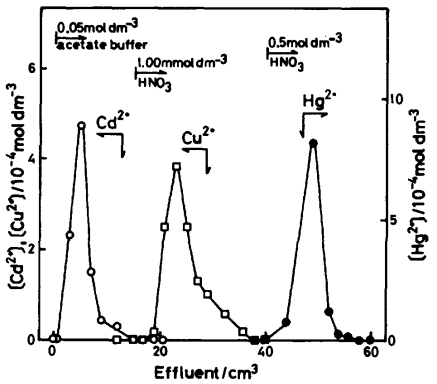

Fig. 4. Separation of Cd^{2+}, Cu^{2+}, and Hg^{2+} ions with a Cd-R_6 column (8.0 cm × 0.4 cm i.d., 40 mg of Cd-R_6). The quantities of the metal ions loaded were 2 μmol for Cd^{2+}, 3 μmol for Cu^{2+}, and 4 μmol for Hg^{2+}. The flow rate was 2 cm^3/h.

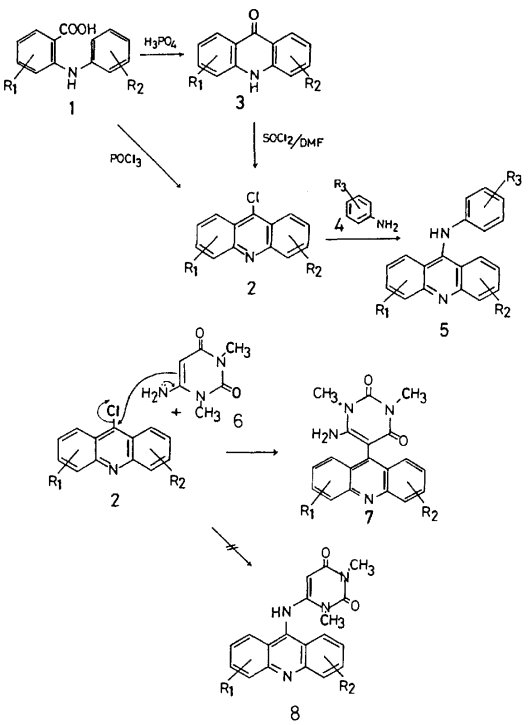
Acridine Derivatives. I. Molecular Structure of the Novel Acridinyl-Substituted Uracil, 5-(9-Acridinyl)-6-amino-1,3-dimethyluracil

Michio Kimura
Niigata College of Pharmacy, 5829 Kamishin'ei-cho, Niigata 950-21
(Received April 25, 1986)

The reaction of enamine between 9-chloroacridines and 6-aminouracil derivatives give novel acridine substituted uracils, the structures of which have been determined by means of an X-ray analysis of 5-(acridin-9-yl)-6-amino-1,3-dimethyluracil hydrochloride dihydrate, $C_{19}H_{16}N_4O_2 \cdot HCl \cdot 2H_2O$. The crystal is triclinic with a space group $P\bar{1}$; also, $a=8.763(3)$, $b=16.130(9)$, $c=7.620(2)$ Å, $\alpha=117.51(4)$, $\beta=83.81(3)$, $\gamma=94.21(4)°$, $Z=2$, $V=949.3$ Å^3, $D_c=1.16$ g cm^{-3}, and $\mu=5.30$ cm^{-1} for Cu $K\alpha$. The structure was solved by a direct method and refined by a block-diagonal least-squares procedure: $R=0.074$ for 2810 reflections with $|F_o|>3\sigma(|F_o|)$. The crystal is composed of the title compound, chloride anion, and two molecules of water held together by hydrogen bonds (described in Table 4).

DNA has a reversible-binding ability for accepting planar molecules which can be inserted between the base pairs of a double helix.[1-4] Most intercalators are mutagens or compounds that have some significant biological and physicochemical properties.[5-9] It is thus of considerable interest to find new type intercalators and to understand the detailed manner of their binding modes within the confines of a double-helical structure. The recent synthesis and study of the 9-anilinoacridines (**5**) (Scheme 1)[10-19] which have antibacterial, antimalarial, mutagenic and carcinogenic properties by intercalating to DNA have encouraged us to investigate a synthesis of novel acridine derivatives and their molecular geometries. During this work the author observed the reaction of enamine between 9-chloroacridines (**2**) and 6-aminouracil derivative (**6**); this gives novel acridinyl-substituted uracils (**7**) instead of 6-(9-acridinylamino)uracils (**8**) corresponding to 9-anilinoacridines (**5**). In order to establish the structure of **7**, the title compound ($R_1=R_2=H$) was chosen for X-ray diffraction studies. The preparation of the novel acridinyl-substituted uracils, (**7**) shown in Scheme 1, followed general procedures: Jourdan-Ullmann condensation of an appropriate 2-chlorobenzoic acid and an aromatic amine formed an *N*-arylanthranilic acid (**1**). The acridine ring formation was carried out in many cases with $POCl_3$ in order to provide 9-chloroacridines (**2**)[20] directly; these were then coupled with the appropriate 6-aminouracil derivatives. When ring formation with $POCl_3$ was not desirable, this reaction was effected with either H_2SO_4, polyphosphoric acid (PPA), or polyphosphate ester (PPE) to give the 9(10*H*)-acridinones (**3**). These were then converted to the desired 9-chloroacridines (**2**) with $SOCl_2$/DMF.[21]

This paper is concerned about the molecular structure of 5-(9-acridinyl)-6-amino-1,3-dimethyluracil (**7**, $R_1=R_2=H$) obtained by means of an X-ray diffraction of its hydrochloride dihydrate.



Scheme 1. Substituents R_1, R_2 and R_3 are alkyl, alkoxy, amino, nitro and methylsulfonylamino etc.[15]

Experimental

Preparation of 5-(9-Acridinyl)-6-amino-1,3-dimethyluracil. A mixture of 9-chloroacridine (1.0 g, 0.0047 moles) and 6-amino-1,3-dimethyluracil (0.73 g, 0.0047 moles) in 50 cm^3 of ethanol was stirred at room temperature for 20 h. At the end of this period the resulting red solid was filtered off and recrystallized from MeOH-H_2O (5 : 1 v/v) to give yellow crystals (1.33 g, 85%). Mp > 300 °C; TLC ($CHCl_3$ as an eluent) R_f=0.09; IR (KBr): 3500, 3170, 1690, 1640, 1580, 1500 cm^{-1}; ^{1}H NMR (DMSO) δ=3.24 (s, 3H), 3.46 (s, 3H), 6.65 (s, NH_2), 7.67—8.67 (m, 8H of acridine); MS *m/z* (rel intensity): 332 (M^+, 31), 174 (31), 141 (31), 97 (41), 81 (81), 70 (98), 57 (100).

Suitable crystals for X-ray investigation were obtained by a slow evaporation of an EtOH-H_2O solution added a drop of concd HCl at room temperature.

Collection and Reduction of Data. The crystal used for the X-ray study had approximate dimensions of 0.20×0.25×0.20 mm. The unit cell parameters at room temperature

were refined by least-squares using the Bragg angles (Cu $K\alpha$, λ=1.54178 Å) of 24 reflections ($30°<2\theta<40°$). The crystal data are given in Table 1. Intensity data were collected at room temperature on a Rigaku AFC diffractometer utilizing nickel-filtered Cu $K\alpha$ radiation. The θ—2θ scan mode was employed. The scan rate was 5° min^{-1} in θ, and the scan range in θ was varied by 1.2+0.15° tanθ. Background were counted for 7 s at both ends of the scan with an offset of 50% of the scan range from the calculated position of the $K\alpha$ peak. A total of 3479 unique reflections of the type $\pm h$, $\pm k$, l were measured in the range $2\theta<125°$. The intensities of three standard reflections measured after every 57 reflections dropped by an average of a few percent over the period of data collection; however, no correction was applied for this fluctuation. Lorentz and polarization corrections were applied but no absorption correction was applied (μ=5.30 cm^{-1} for Cu $K\alpha$). Standard deviations in the intensities, $\sigma(|F_o|)$, were derived directly from counting statistics.

Solution and Refinement of the Structure. The structure was solved by direct methods using *MULTAN* 78[22] to calculate phases for the 300 $|E|$ values with $|E|>1.50$. The E map computed from the phase set with the largest combined figure of merit (2.62) revealed all non-hydrogen atoms except for two oxygen atoms of water and one chlorine atom. The subsequent difference Fourier map readily gave the remaining atoms. Atomic parameters were refined by the block-diagonal least-squares procedure. The function minimized was $\sum w(|F_o|-|F_c|)^2$, where w was taken as $1/\sigma^2(F_o)$. All of the hydrogen atoms could be readily located from a difference Fourier map. During further refinement, anisotropic and isotropic thermal parameters were included for the non-hydrogen and hydrogen atoms, respectively. The refinement converged to a conventional $R=\sum||F_o|-|F_c||/\sum|F_o|$ of 0.057 and a weighted $R_w=\sum w(|F_o|-|F_c|)^2/\sum w|F_o|^2)^{1/2}$ of 0.079 with a GOF of 1.49 (Quality of fit=$[\sum w(|F_o|-|F_c|)^2/(N_{obsd}-N_{para})]^{1/2}$). The refinement was completed when the largest shift in any parameters among the non-hydrogen atoms was 0.05σ; the largest shift for hydrogen atoms was 0.08σ. The largest peak in the final difference map, 0.2 $eÅ^{-3}$, was located near the chlorine atom. Atomic scattering factors were taken from those of "International Tables for X-Ray Crystallography."[23] Mathematical and computational details are noted elsewhere.[24] Calculations were carried ouy by using the *UNICS*[25] program system on an ACOS 850 computer at the Crystallographic Research Center, Institute for Protein Research, Osaka University, and an ACOS 900 computer at Computation Center of Niigata University. The final positional parameters* of non-hydrogen and hydrogen atoms with equivalent isotropic and isotropic temperature factors are given in Table 2.

Discussion

The estimated structure of the title compound has shown the novel acridine derivative substituted by uracil, which is obtained by the interesting reaction of the enamine of 9-chloroacridine and biological important uracil. The molecular structure and the atom labeling are illustrated by an ORTEP drawing in Fig. 1.[31] The bond lengths and angles are given in Table 3,

* Tables of anisotropic thermal parameters, coordinates of hydrogen atoms, least-squares planes, and the observed and calculated structure factors are kept as Document No. 8717 at the Chemical Society of Japan.

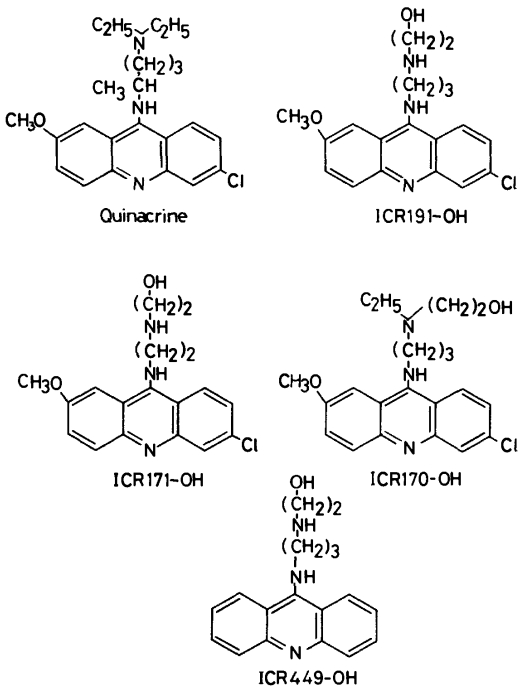

Fig. 2. Formulae of quinacrine and ICR series compounds.

together with estimated standard deviations. The average C-C distances of two benzene rings of acridine nucleus are 1.401 and 1.400 Å, respectively, while that of the C-N distances of the acridine nucleus is 1.358 Å. On the other hand, the uracil ring has average values of 1.386 Å in the C-N bond and 1.229 Å in the C=O bond. These values are normal, and the bond distances of the two benzene rings of acridine nucleus are exactly equivalent within experimental error. As shown in Fig. 1, the molecule consists of two planar portions. The derivatives from the least-squares planes through portions of the molecule are calculated and, the dihedral angle between the least-squares planes defined by the acridine ring and the uracil ring is 108.0°. The calculated dihedral angle is 2.5° between the best planes through the outer rings of the acridine ring system; these are compared with values of 8° for quinacrine,[26] 4.9° for ICR-191-OH,[27] 7.5° for ICR-171-OH,[28] 10.7°for ICR-170-OH,[29] and 12.5° for ICR-449-OH.[30] The formulate of the above ICR compounds are shown in Fig. 2. In these series of acridines, it seems that the more potent biological activities, such as antitumor and mutagenic activity,

are caused by the flatter ring systems and better stacking ring systems as intercalators to DNA.

Hydrogen-bond distances and bond angles are given in Table 4. The molecules in the unit cell are connected by three-dimentional networks of hydrogen-bonds, composed of seven hydrogen atoms originating from atoms N25, O26, O27 and protonated N10, and corresponding hydrogen bonding acceptors (Fig. 3). That is, there are the hydrogen-bonds of 2.813 (9) Å between the water oxygen atom O27 and another water oxygen O26, and 2.939 (8) Å between the water oxygen atom O26 and the oxygen atom O21 of the uracil ring. Water oxygen atom O27 is also connected by oxygen O23 of the uracil ring and nitrogen atom N25 of the adjacent molecule by the hydrogen-bonds, 3.005 (8) and 2.870 (7) Å, respectively. On the other hand, the chloride anion has a hydrogen bonding interaction (3.093 (4) Å) with the protonated nitrogen atom N10 on which is also met a hydrogen atom (N10 ··· H=0.94 (8) Å).

In a similar synthetic method, the novel acridinyl-substituted uracils related to the title compound were also prepared. For those compounds, all the analytical and spectroscopic data are in accordance with the given structures (Scheme 1). The interesting physicochemical and biological properties of these compounds are expected, such as antitumor activity and their binding characteristics to DNA and to synthetic polynucleotide. The application of this reaction to other 6-aminouracil derivatives and nucleotide bases makes us such that we can find potent biologically active compounds as intercalators. Studies concerning the above topics are now in progress and results will be published in due course.

The author is grateful to Professor Masao Kakudo, Himeji Institute of Technology, and Professor Yukiteru Katsube and the staff of Crystallographic Research Center, Institute for Protein Research, Osaka University, for the use of diffractometer and ACOS 850 computer.

The liquid-phase hydration of acrylonitrile to acrylamide was examined over a manganese dioxide catalyst at 65 °C. When the catalysts were treated at 110—500 °C, both the acidity and the reaction activity of the catalysts decreased at temperatures above 110 °C. The reduction of the solid acidity of heat-treated samples decreased the catalytic activity of the catalysts. It was confirmed that the solid acidity of manganese dioxide was derived from acidic hydroxyl groups on the catalyst surface through their dispersion in water. A good relationship between the number of surface hydroxyl groups and the catalytic activity of the manganese dioxide was observed; its hydration ability was depressed by the addition of an aqueous base as a NaOH solution. These results show that the acidic surface hydroxyl group of a manganese dioxide catalyst is the active site of acrylonitrile hydration. The kinetic behavior of both acrylonitrile and water was examined and the reaction rate showed both first and zero orders with respect to the acrylonitrile and water concentration, respectively. The hydration mechanism of acrylonitrile on the manganese dioxide catalyst is discussed.

In our previous papers,[1,2] it was reported that the heterogeneous hydration of acrylonitrile (AN) proceeded on various metal oxide catalysts in the liquid-phase. The hydration selectivity to the reaction products (acrylamide (AA), ethylene cyanohydrin and bis-(2-cyanoethyl) ether) was governed by the solid acid-base properties in the liquid phase. The acidic metal oxide catalysts selectively hydrated the C≡N triple bond of an AN molecule and only AA formed, while the basic metal oxide catalysts hydrated the C=C double bond rather than C≡N. AA is an especially useful material among those three products owing to such industrial uses as paper-strengthening agents, flocculants and crude-oil recovery agents. For AA production, manganese dioxide (MnO_2) was the most effective catalyst among the metal oxides since it exhibits a selectivity to AA.

The high catalytic ability of MnO_2 is well-known. A few examples include the oxidation of CO,[3,4] hydrocarbons[5,6] and the decomposition of H_2O_2.[7,8] Furthermore, since MnO_2 prepared by an electrolytic oxidation method has been used as a depolarizer of drycells, the surface properties of MnO_2 also have been studied by many investigators.[9-12] Regarding the catalytic abilities of MnO_2 on the liquid-phase hydration of AN to AA, they have been scarcely clarified. This study, therefore, aims to clarify the properties at the active sites of a MnO_2 catalyst as well as the hydration mechanism.

Experimental

Catalyst Preparation. A MnO_2 catalyst produced from the electrolytic oxidation of manganeous sulfate was supplied by Toyo Soda Manuf. Co. It was preheated at 110—500 °C for 1 h in air and then used for the hydration. MnO_2 catalysts having a differential surface coverage of Zn^{2+} ions were also prepared by an ion exchange of Zn^{2+} and the hydroxyl group on the MnO_2 samples preheated at 110 °C. The surface area was determined by the BET method. The crystal structure was identified by using the X-ray diffraction method.

Activity Measurement. The liquid-phase hydration of AN was carried out in a batch reactor system. Ordinary experimental conditions were as follows: reaction temperature of 65 °C, 6-h reaction time, 2.5-g catalyst, purified AN 8.5 and 100 ml of H_2O. A detailed description of the procedure was described in a previous paper.[2] The inhibition effects of the additives were examined by the addition of HNO_3, NaOH, AA, or acrylic acid in the reaction system suspended with a MnO_2 sample. After the reaction temperature reached 65 °C, AA was added.

Surface Hydroxyl Group. The amount of hydroxyl groups on the MnO_2 surface was determined in accordance with the manner described by Kozawa;[9,13,14] this method can be described as follows: a preheated MnO_2 sample (1.0 g) was placed into an Erlenmeyer flask with glass stopper, into which 25 ml of the zinc solution was poured. The zinc solution was prepared as follows: two moles of NH_4Cl and 0.1 mol of ZnO were dissolved in one liter of water and then adjusted to a pH of 7.0 by the addition of aqueous ammonia. The resulting suspension was shaken with the use of a vibrator for 12 h; it was then allowed to stand for 1 h. A portion of the supernatant solution was titrated by the EDTA method. The difference between the amount of Zn^{2+} adsorbed in this procedure and that consumed by the original solution corresponds to the number of Zn^{2+} ions. Another portion of the supernatant solution was titrated with a standard solution of HCl (0.01 mol dm^{-3}) using Methyl Orange as an indicator for determining the amount of released H^+. The difference between the amount of HCl consumed in this titration and that consumed by the original solution corresponds to the number of hydrogen ions released by the ion-exchange reaction.

Amount of AN Adsorbed. A preheated MnO_2 sample (2.5 g) was placed into an Erlenmeyer flask with a glass stopper; then, 100 ml of 2.5 wt% AN aqueous solution was poured into the flask. After stirring for 6 h, the sample was allowed to stand for 40 h at room temperature and was then kept at 40 °C for 4 h. The amount of adsorbed AN was determined from the difference of the concentration of AN before and after adsorption. The concentration of AN was measured by gas chromatography.

Acidic Properties. The surface acidity of MnO_2 samples was determined by an indicator titration method using

Table 2. Amount of Adsorbed Zn^{2+} and Released H^+ Ion by the Ion-Exchange Reaction on the Manganese Dioxide Samples

Sample No.	Calcination temp(°C)	Amount of adsorbed Zn^{2+} (mmol g^{-1})	Amount of released H^+ (mmol g^{-1})	H^+/Zn^{2+} ratio	Amount of Surface OH groups (mmol g^{-1})[a]
1	110	0.26	0.54	2.1	0.52
2	200	0.23	0.44	1.9	0.46
3	300	0.19	0.40	2.1	0.38
4	400	0.07	0.14	2.0	0.14
5	500	0.05	0.11	2.2	0.10

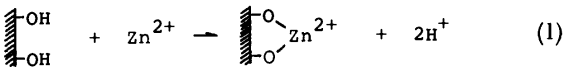
a) Double molar quantity of the adsorbed Zn^{2+} was defined as the amount of surface OH groups on the MnO_2 samples on the basis of Kozawa's results.[9]

Methyl Red (pK_a=+4.8) as the indicator. The equi-acid-base point of MnO_2 samples, representing the solid acid-base properties of a metal oxide dispersed in water, was determined by a pH-shift method.[15] A detailed description of the procedure for both acidic property measurements was given in previous papers.[2,17]

Results and Discussion

Acidic Properties and Catalytic Activity. In one previous paper,[16] we reported that a large number of moderate-strength acid sites was present on the MnO_2 surface. The relationship between the acidic properties and the catalytic abilities of MnO_2 on the liquid-phase hydration of AN was investigated. As shown in Table 1, the catalytic activity (conversion of AN after a 6-h reaction) of MnO_2 catalysts decreased upon increasing the calcination temperature. A heat treatment of the catalysts simultaneously led to a reduction of both the specific surface area and the solid acidities, indicated by acid amounts at pK_a=4.8 and values of their equi-acid-base point. However, transformations of the crystal structure by heat treatments could not be observed, although the crystal growth was observed. The stability of the structure was also supported from the fact that neither the endothermic nor the exothermic peak was observed by a DTA analysis until 500°C. Therefore, it was concluded that the reduction of the catalytic activity by the heat-treatment was caused by a decrease in the acidic property of the catalysis accompanying a specific surface-area loss.

Surface Hydroxyl Groups. On the MnO_2 surface cation-exchangeable hydroxyl groups are present.[9,10] It was confirmed in a previous study[17] that the surface hydroxyl group had remained on the sample, even under a heat-treatment at 500°C. The number of surface hydroxyl groups on the MnO_2 dispersed in water was determined by the cation-exchange method. The obtained results are shown in Table 2. The number of adsorbed Zn^{2+} and released H^+ ions decreased upon increasing the heat-treatment temperature. The amount of released H^+ was twice that of adsorbed Zn^{2+}. This simple integral ratio indicates that a single Zn^{2+} ion exchanges with two H^+ ions of the surface hydroxyl groups as follows:



(1)

Therefore, a double molar quantity of the adsorbed Zn^{2+} was defined as the amount of surface hydroxyl groups on the MnO_2 samples.

The relation between the catalytic activity and the amount of surface hydroxyl groups of MnO_2 treated at 110—500°C was examined. The catalytic activity was directly proportional to the amount of surface hydroxyl groups (Fig. 1); the relationship between them can be described by

$$\text{ANconv.} = a[\text{-OH}]_s, \quad (2)$$

where a and $[\text{-OH}]_s$ are the constant of proportionality and the number of surface hydroxyl groups, respectively. The value of the correlation coefficient of a was determined to be 0.997. This result suggests that the acidic hydroxyl groups on the surface are the active sites for AN hydration.

The poisoning effects were examined. As shown in Fig. 2, the conversion of AN on the MnO_2 catalysts

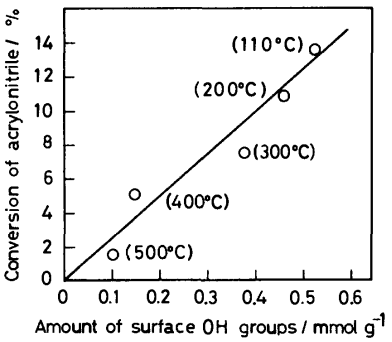


Fig. 1. Relationship between the conversion of acrylonitrile and amount of surface hydroxyl groups of the MnO_2 catalysts heat-treated at various temperature. The values in parentheses is that of calcination temperature. Reaction conditions are the same as those in Table 1.

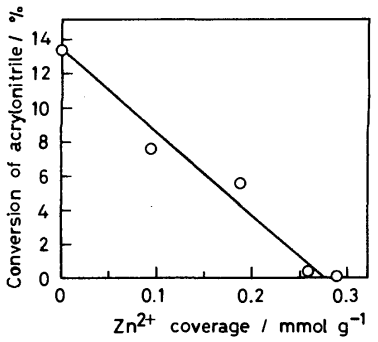

Fig. 2. Relationship between the conversion of acrylonitrile and surface covarage of Zn^{2+} ion on the MnO_2 catalysts treated at 110°C.

Table 3. Poisoning Effect of the Additives to MnO_2 Catalyst on the Hydration of Acrylonitrile[a)]

Additive	Nitrile conv(%)	Amide sel(%)
Blank	13.3	100
HNO_3 0.2 mmol	13.0	100
0.4 mmol	13.8	100
0.6 mmol	13.5	100
NaOH 0.2 mmol	12.2	100
0.4 mmol	10.1	90.6
0.6 mmol	7.1	73.1

a) Reaction conditions are the same as those in Table 1.

coated with various amounts of Zn^{2+} linearly decreased upon increasing the surface coverage of adsorbed Zn^{2+}. When acid or alkali was added to an AN solution the catalytic activity changed as shown in Table 3. The addition of HNO_3 had little effect on the catalytic activity and selectivity to AA; in the case of the addition of NaOH the catalytic abilities of MnO_2 decreased.

Consequently, we could conclude that the active site of a MnO_2 catalyst on the liquid-phase hydration of AN to AA is the acidic surface hydroxyl group.

Hydration Mechanism. The number of AN molecules adsorbed on the preheated MnO_2 samples was shown in Fig. 3. A good relationship between the number of adsorbed AN molecules and surface hydroxyl groups was observed with a slope of unity. Therefore, we concluded that an AN molecule adsorbs on a surface hydroxyl group.

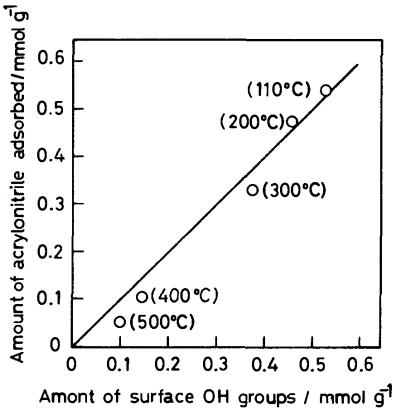

Fig. 3. Relationship between the amount of both adsorbed acrylonitrile and surface hydroxyl group of the MnO_2 catalysts treated at various temperature. Adsorption temperature: 40°C

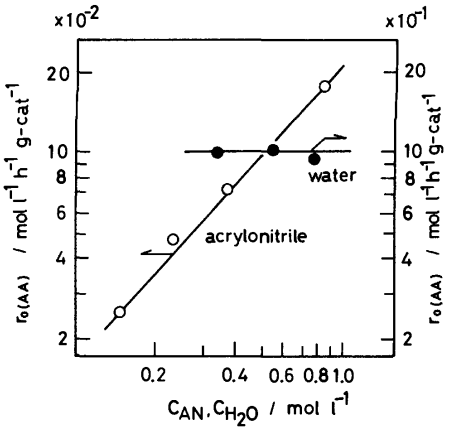

Fig. 4. Dependence on the concentration of acrylonitrile or water.
Reaction temperature: 65°C

The dependence of AN and the water concentration on the hydration rate of AN was examined and the results are given in Fig. 4. From this figure, the dependence on the concentration of each reactant was first order to the AN concentration and zero order to water. Consequently, the rate equation can be given as

$$r = k[\mathrm{AN}]^{1.0}[\mathrm{H_2O}]^{0}, \quad (3)$$

where k, [AN] and [H_2O] show a rate constant, concentration of AN and water, respectively. The rate equation shows that excess water is adsorbed on the catalyst surface and that its concentration on the surface is constant during hydration. The reaction between the adsorbed AN and adsorbed water is rate-determining. In addition, since the conversion of AN is proportional to the number of hydroxyl groups on the cata-

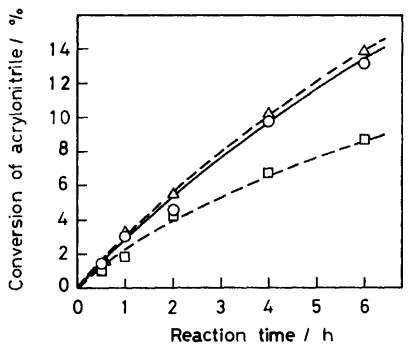

Fig. 5. Effect of additives.
(□): Acrylamide, (△): acrylic acid, (○): no addition
Reaction temperature: 65°C.

lyst surface, the equation can be rewritten as

$$r'=k'[\mathrm{AN}]^{1.0}[\mathrm{H_2O}]^{0}[\mathrm{-OH}]_{s}^{1.0}. \quad (4)$$

The catalytic abilities of MnO_2 were retarded by the addition of AA (Fig. 5). Thus, these results suggest that an accumulation of AA takes place on the MnO_2 surface during hydration in a batch reactor, retarding the reaction.

On the basis of the results described above, the hydration mechanism of AN to AA on the MnO_2 catalyst was postulated (Fig. 6). An acidic hydroxyl group exists on a Mn^{4+} ion of the MnO_2 surface and is surrounded by a large number of water molecules (see Fig. 6 (I)). An AN molecule first adsorbs on an acidic hydroxyl group (Fig. 6 (II)); then, a covalent coordination through N (2s) lone-pair electrons of a C≡N bond by the electrostatic force of attraction will take place on the surface hydroxyl group of MnO_2. Then, a hydroxide anion supplied from the surrounding water attacks the carbonium ion of the C≡N bond, whereas the residual proton adsorbs on Mn-$O^{\ominus}$ to regenerate hydroxyl group (III→IV). An amide group is formed by a 2,4-shift reaction of the precusor in the tautomerism system; then AA desorbs from the site (V). In this manner the liquid-phase hydration of AN to AA on the acidic hydroxyl group of MnO_2 will catalytically proceed as a Langmuir-Hinshelwood-type reaction mechanism.

Conclusion

The results of the liquid-phase hydration of AN to AA on a MnO_2 catalyst can be summarized as follows:

(1) The catalytic activity is proportional to the amount of the acidic surface hydroxyl group.

(2) An AN molecule adsorbs on a surface hydroxyl group.

(3) The reaction order is first-order with respect to AN and zero-order with respect to the water concentration, respectively.

(4) AA inhibits AN hydration.

It is concluded that active site of a MnO_2 catalyst is the acidic surface hydroxyl group and that hydration

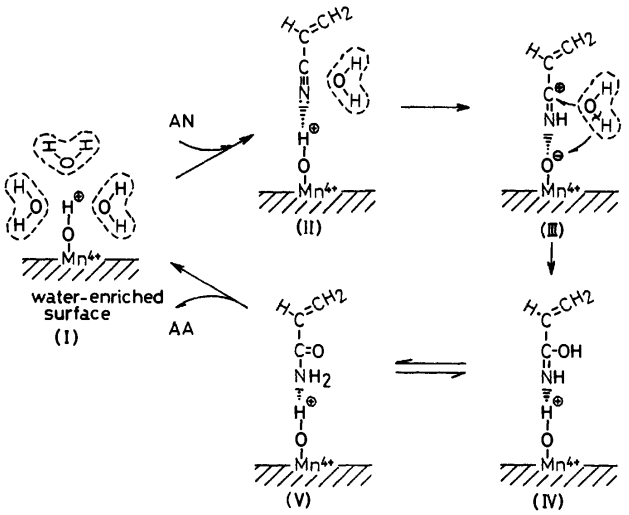

Fig. 6. Hydration scheme of acrylonitrile to acrylamide.

proceeds through a Langmuir-Hinshelwood-type mechanism between adsorbed AN and adsorbed water.

The authors greatly thanks the Toyo Soda Manuf. Co., Ltd. for supplying the MnO_2 sample.

The Solvation Effect on the Reactions in Solution. I. The Solvation Model for the Interpretation of Entropy Changes in the Complex Formation of Dichlorodimethylstannane with Pyridine

Hideaki FUJIWARA,* Hiroyuki ARAKAWA, Saburo MURATA, Ikuzi OHTAKU, Motoko ISHII, and Yoshio SASAKI
Faculty of Pharmaceutical Sciences, Osaka University, 1-6 Yamada-Oka, Suita, Osaka 565
(Received July 9, 1986)

A complex-formation reaction has been studied for the Me_2SnCl_2 plus pyridine system in dimethyl phthalate (DMP) and dioctyl phthalate (DOP) by means of titration calorimetry. The resulting entropy changes in the reactions of A+B=AB and AB+B=AB_2, with A=Me_2SnCl_2 and B=pyridine, were compared with those calculated for the gas-phase reactions. The values in solution amounted only to 1/3—1/4 of the gas-phase values. Correction for the entropy of solution of each component failed to explain the observed values in the absence of a strong solvation. The solvation model is presented to allow for such a discrepancy, assuming a strong solvation for Me_2SnCl_2 as well as for the 1 : 1 pyridine complex by definite numbers of solvents. To test the applicability of the model, calculations were made based on molecular statistical thermodynamics. The results obtained were reasonable, indicating that a free molecule, Me_2SnCl_2, is solvated by 1.3 molecules of the solvent of DMP, which are released about half by half on the formation of the 1 : 1 and 1 : 2 complexes with pyridine.

Entropy changes upon reactions are generally expressed as the sum of the standard entropies of the products minus those of the starting materials. The standard entropy is equal to the (absolute) entropy of the compound in its standard state at an arbitrary temperature. Based on this concept, entropies of reactions have been calculated from the entropies of relevant compounds, which are either measured as thermodynamic third-law entropies in a calorimetric experiment or estimated statistically from the molecular theory for thermodynamic functions. The calculated entropies usually coincide well with those observed for gas-phase reactions, proving the thermodynamic third law. However, reactions in a solution are almost always accompanied by changes in solvation which affect the entropy change to a great extent. Therefore, solvation is essential for a full understanding of the entropy changes in a solution. In other words, entropy changes can be expected to offer important information regarding the solvation phenomena.

Hitherto, the thermodynamic aspects of reactions in solution have attracted attention mostly in terms of the enthalpy. The well-known Hammett substituent constants have been derived assuming a major contribution from the enthalpy term to the free energy change as a result of a negligible entropy term or a proportional enthalpy-entropy relationship. Some other empirical treatments, such as Drago's *E* and *C* parameters[1] and Gutmann's donor number,[2] have been developed for the enthalpy term in relation to acid-base reactions. Also, a classification of Pearson's hard and soft acids and bases (HSAB)[3] has been discussed quantum chemically[4] in relation to the enthalpy term, although the idea first came from a classification of the free energy changes. In contrast to this, the entropy term has long been overlooked in the discussion of the thermodynamic profiles. Hitherto, ion-pair formation has been discussed with regard to the entropy term, and the entropy of hydration has been obtained for different ion pairs.[5]

The present authors have previously reported that entropy changes upon the complex formation of some chloromethylstannanes with Lewis bases, as measured in halogenated hydrocarbon solvents, amount to only 1/3 of those estimated in the gas phase.[6,7] These results have been interpreted to indicate the release of a definite number of solvent molecules from the solvation sphere upon the complex formation. To take the solvation effect into consideration more exactly, in the present study the entropy term is discussed on the basis of thermochemical cycle. The solvents used are substituted phthalates, for which the entropies of solution can be measured by means of the gas-liquid chromatography.

Experimental

The Me_2SnCl_2 (Tokyo Kasei Co.) was purified by sublimation under a reduced pressure. The pyridine was dried over CaH_2 and distilled in a dry box. The dimethyl phthalate (DMP) and dioctyl phthalate (DOP) were distilled under reduced pressure in a dry box. Alkylbenzenes from commercial sources were used for the gas-liquid chromatography without further purification. The calorimetric titration experiments were performed on a Tronac 550 isothermal/isoperibol calorimeter under an isothermal mode. The details of this experiment were the same as those in Ref. 7. The gas-chromatographic retention data were collected on a Yanagimoto T-1880 gas chromatograph with a TCD detector. The column temperature was measured with a copper-constantan thermocouple. DMP and DOP were coated on 60/80 mesh Chromosorb W AW-DMCS (25 wt%). The temperature ranges measured were from 50 to 70 °C for DMP and from 85 to 135 °C for DOP. The retention data were extrapolated to the vanishing amount of the injection for each solute at each temperature.

Results

Our analysis of the calorimetric titration data is summarized in Table 1 for the complex formation of

Table 1. Analysis of Calorimetric Titration Data for the Me_2SnCl_2+Pyridine System in Dimethyl and Dioctyl Phthalates (DMP and DOP) at 25 °C

Solvent	K_1[a]	K_2[a]	$-\Delta H_1$[b]	$-\Delta H_2$[b]	$-\Delta S_1$[c]	$-\Delta S_2$[c]
DMP	26.7±0.7	4.0±0.2	30.8±0.3	30.7±2.5	76.1±0.9	91.4±8.2
DOP	22.4±0.8	3.8±0.2	32.5±2.1	34.9±0.3	83.3±7.1	106.0±2.1

a) $dm^3 mol^{-1}$. b) $kJ mol^{-1}$. c) $J K^{-1} mol^{-1}$.

Me_2SnCl_2 with pyridine in DMP and DOP. The successive formation of 1 : 1 and 1 : 2 complexes (Eqs. 1 and 2) has already been concluded from the analysis of the NMR[8] and of the calorimetric[9] titration data.

$$A+B=AB \qquad K_1,\ \Delta H_1,\ \Delta S_1 \tag{1}$$

$$AB+B=AB_2 \qquad K_2,\ \Delta H_2,\ \Delta S_2 \tag{2}$$

Table 1 shows that DMP and DOP resemble each other as solvents. Besides these two, the phthalates $C_6H_4(COOR)_2$ with R=C_2H_5, C_4H_9, C_7H_{15}, and C_9H_{19} were also tested, but the results showed no clear dependence on the carbon number in R.

The entropy of solution, which is necessary for the comparison of the entropies of reactions in solution and those in the gas phase, was derived from the retention data in gas-liquid chromatography. The basic equation used is as follows;[10]

$$\ln(V_g^0)+\ln(T\rho/273.15)=-\Delta H^s/RT+\Delta S^s/R, \tag{3}$$

where V_g^0 is the specific retention volume, T is the column temperature, ρ is the density of the liquid phase, and ΔH^S and ΔS^S are the enthalpy and entropy of solution, respectively. From the data of benzene, toluene, and ethyl-, propyl-, and isopropylbenzenes, the following relations were obtained between ΔS^S and the thermodynamic third-law entropy, $S^0_{298}(g)$:

$$\Delta S^s=-0.093\,S^0_{298}(g)-9.0 \qquad r=0.998 \text{ in DOP}, \tag{4}$$
$$(0.002)\quad(8.5)$$

$$\Delta S^s=-0.097\,S^0_{298}(g)+7.4 \qquad r=0.985 \text{ in DMP}. \tag{5}$$
$$(0.007)\quad(2.6)$$

Here, the values of $S^0_{289}(g)$ have been taken from Ref. 11. In Eqs. 4 and 5, r is the correlation coefficient and the standard errors are listed in parentheses.

Discussion

In the discussion of entropy changes upon complex-formation reactions in solution, rigorous calculation is very difficult because solvation contributes a great deal to the entropy of each component and because some physical properties, e.g., the fundamental vibrations at low frequencies and the physical properties of the complex especially, are frequently lacking. However, any discussion of the entropy changes in solution can be expected to disclose solvation phenomena in the reaction process. In this section, first, the entropy of reaction is estimated without assuming any specific solvation for each component; it will be compared with the experimental values.

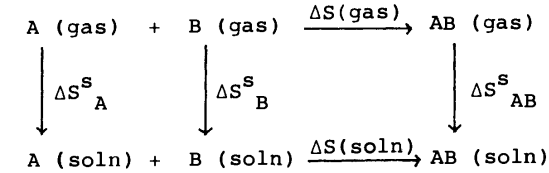

Fig. 1. A complex formation reaction of A+B=AB in gas phase and in solution. ΔS^s is the entropy of solution of each component.

i) Estimation of the Entropy Changes Assuming No Specific Solvation. For a simple reaction of A+B=AB, a thermochemical cycle will be given such as the one shown in Fig. 1. Generally, Eq. 6 holds for the gas-phase reaction, and a thermochemical consideration leads to Eq. 7:

$$\Delta S^0(gas)=S^0_{AB}(gas)-S^0_A(gas)-S^0_B(gas), \tag{6}$$

$$\Delta S^0(soln)=\Delta S^0(gas)+(\Delta S^s_{AB}-\Delta S^s_A-\Delta S^s_B). \tag{7}$$

In Eq. 6, $S^0_{AB}(gas)$, $S^0_A(gas)$, and $S^0_B(gas)$ are the standard entropies of AB, A, and B respectively in the gas phase at a standard state. Recently, Wertz proposed a simple relation between the entropy of solution, ΔS^S, and the thermodynamic third-law entropy, $S^0_{298}(g)$; he based this relation on a discussion of relatively simple molecules which interact only weakly with the solvent,[12] i.e.:

$$\Delta S^s=a\,S^0_{298}(g)+b. \tag{8}$$

The coefficents, a and b, in this equation were later reported to change slightly depending on the type of compound.[13] Here, it is clear that the entropy of solution of each component is actually non-vanishing, even if it does not interact strongly with the solvent. In the present case, Eq. 7 is converted to Eq. 9 (see Appendix 1).

$$\Delta S^0_{calcd}(soln)=(1+a)\,\Delta S^0(gas)-b-aR\ln 24.5 \tag{9}$$

where $\Delta S^0_{calcd}(soln)$ means $\Delta S^0(soln)$ as calculated from $S^0(gas)$ and Wertz's equation, $S^0(gas)$ being obtained from an experiment in the gas phase or from the molecular statistical method described above. Equation 9 is applicable to both steps of Eqs. 1 and 2 in the present study, but the coefficients a and b remain undetermined because of the unavailable third-law entropies in the gaseous and liquid states of DMP and DOP. To determine these coefficients, the entropies of solution were measured by means of gas-liquid chro-

matography for some hydrocarbons which interact only weakly with the phthalates (Eqs. 4 and 5). In this way, Eq. 9 proved to be Eqs. 10 and 11 in DOP and DMP, respectively for the reactions of both Eqs. 1 and 2:

$$\Delta S_{calcd}(soln) = 0.907\,\Delta S^0(gas) + 11.5 \quad \text{in DOP,} \quad (10)$$

$$\Delta S_{calcd}(soln) = 0.903\,\Delta S^0(gas) - 4.8 \quad \text{in DMP.} \quad (11)$$

Here, ΔS^0(gas) means S^0_{AB}(gas)-S^0_A(gas)-S^0_B(gas) and ΔS^0_{AB2}(gas)-S^0_{AB}(gas)-S^0_B(gas). In the present study, ΔS^0(gas) is obtained by means of the molecular statistical calculation (Appendix 2). As a first approximation, the vibrational part of the entropies was omitted in the calculation of ΔS^0(gas), for the contributions from the products and the starting materials were almost the same. Although detailed structural parameters are not required for the discussion below because of the minor dependence of the calculated entropies on the structural changes, references are cited for Me_2SnCl_2,[14] pyridine,[15] and $Me_2SnCl_2 \cdot (pyridine)_2$.[16] As for the 1:1 complex, two configurations were assumed, where either pyridine or the Cl group is located at an equatorial position besides the two methyl groups.[17] However, the resulting entropies were virtually unchanged. The comparison of the calculated values with the experimental value shown in Table 2 shows that the correction from the entropy of solution of each component is small and does not explain the difference between the entropies observed in solution and those calculated for the gas-phase reaction. Therefore, a model assuming no specific solvation fails to explain the results in the present study. Where, then, does this difference come from? If it were possible to measure ΔS^S for the AB complex similarly to those of A and B, ΔS^0(soln) could be estimated according to Eq. 7. However, this is impossible because of the labile character of the complex. For reference, the entropies of solution were measured for several methylstannanes (Table 3). These entropies decreased with an increase in the acidity of the stannanes: Me_4Sn exhibits no discernible tendency toward acid, whereas the acidity increases from Me_3SnCl to Me_2SnCl_2. Hence, this decrease is attributed to the increased solvation for the stannanes with increased acidity. In the following, a solvation model is presented which allows for the effect of strong solvation on the entropy of solution and helps to interpret the experimental entropies of reactions in solution measured above.

ii) Solvation Model for the Interpretation of Entropy Changes in Solution. In Fig. 2 a solvation model is depicted for the reactions of A+B=AB and AB+B=AB_2, where A and AB are strongly solvated by m and n molecules of the solvent respectively, whereas AB_2, in which the tin atom possesses a coordination number of six, and B are not solvated, or are only weakly solvated, so that their entropies of solution are expressed by the Wertz-type equation. From a consideration of the

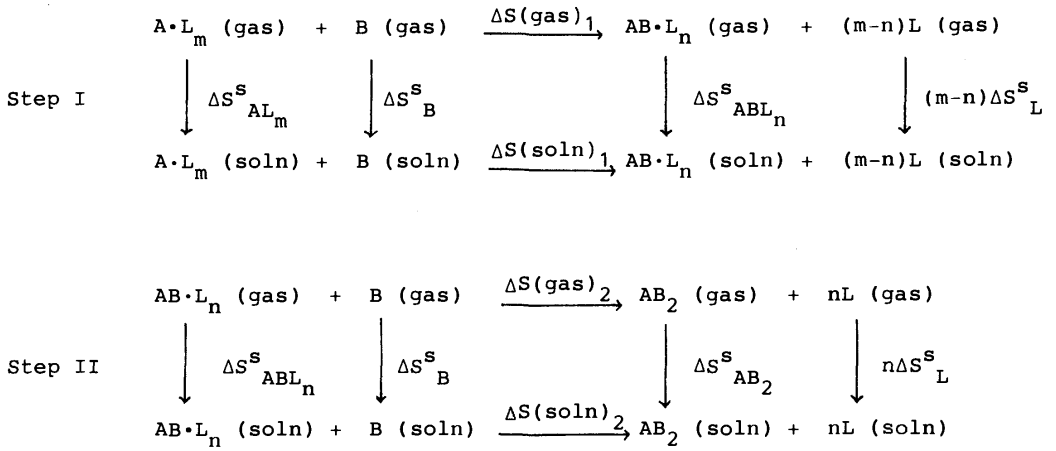

Fig. 2. The solvation model for the reactions of A+B=AB and AB+B=AB_2. A and AB are solvated strongly by m and n molecules of the solvent L, respectively.

thermochemical cycles in Fig. 2, the following equations are derived:

$$\Delta S^0(\text{soln})_1 = \Delta S^0(\text{gas})_1 + \Delta S^s_{ABL_n} + (m-n)\Delta S^s_L - (\Delta S^s_{AL_m} + \Delta S^s_B), \quad (12)$$

$$\Delta S^0(\text{soln})_2 = \Delta S^0(\text{gas})_2 + \Delta S^s_{AB_2} + n\Delta S^s_L - (\Delta S^s_{ABL_n} + \Delta S^s_B). \quad (13)$$

The substitution of Eq. A2 into Eqs. 12 and 13 leads to:

$$\Delta S^0(\text{soln})_1 = (1+a)\Delta S^0(\text{gas})_1 + (m-n-1)(b+aR\ln 24.5), \quad (14)$$

$$\Delta S^0(\text{soln})_2 = (1+a)\Delta S^0(\text{gas})_2 + (n-1)(b+aR\ln 24.5). \quad (15)$$

Here,

$$\Delta S^0(\text{gas})_1 = S^0_{ABL_n}(\text{gas}) + (m-n)S^0_L(\text{gas}) - S^0_{AL_m}(\text{gas}) - S^0_B(\text{gas}), \quad (16)$$

$$\Delta S^0(\text{gas})_2 = S^0_{AB_2}(\text{gas}) + nS^0_L(\text{gas}) - S^0_{ABL_n}(\text{gas}) - S^0_B(\text{gas}), \quad (17)$$

holds; also, the following equations hold when an additivity rule is assumed for the entropy of the strongly solvated species:

$$S^0_{AL_m}(\text{gas}) = S^0_A(\text{gas}) + m\{S^0_{AL}(\text{gas}) - S^0_A(\text{gas})\}, \quad (18)$$

$$S^0_{ABL_n}(\text{gas}) = S^0_{AB}(\text{gas}) + n\{S^0_{ABL}(\text{gas}) - S^0_{AB}(\text{gas})\}. \quad (19)$$

By substituting Eqs. 18 and 19 into 16 and 17, we obtain:

$$\Delta S^0(\text{gas})_1 = \Delta S^0_{AB}(\text{gas}) + n\Delta S^0_{ABL}(\text{gas}) - m\Delta S^0_{AL}(\text{gas}), \quad (20)$$

$$\Delta S^0(\text{gas})_2 = \Delta S^0_{AB_2}(\text{gas}) - n\Delta S^0_{ABL}(\text{gas}), \quad (21)$$

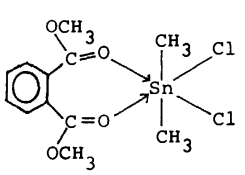
where, $\Delta S^0_{AB}(\text{gas}) = S^0_{AB}(\text{gas}) - S^0_A(\text{gas}) - S^0_B(\text{gas})$, $\Delta S^0_{ABL}(\text{gas}) = S^0_{ABL}(\text{gas}) - S^0_{AB}(\text{gas}) - S^0_L(\text{gas})$, $\Delta S^0_{AL}(\text{gas}) = S^0_{AL}(\text{gas}) - S^0_A(\text{gas}) - S^0_L(\text{gas})$, and $\Delta S^0_{AB_2}(\text{gas}) = S^0_{AB_2}(\text{gas}) - S^0_{AB}(\text{gas}) - S^0_B(\text{gas})$. Then, Eqs. 14 and 15 turn out to be:

$$\Delta S^0(\text{soln})_1 = (1+a)\Delta S^0_{AB}(\text{gas}) + n\Delta S^0_{ABL}(\text{gas}) - m\Delta S^0_{AL}(\text{gas}) + (m-n-1)(b+aR\ln 24.5), \quad (22)$$

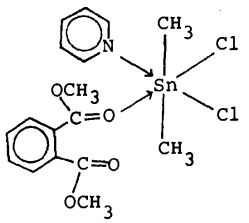
$$\Delta S^0(\text{soln})_2 = (1+a)\Delta S^0_{AB_2}(\text{gas}) - n\Delta S^0_{ABL}(\text{gas}) + (n-1)(b+aR\ln 24.5). \quad (23)$$

The rearrangement of Eqs. 22 and 23 gives these expressions for m and n:

$$m = \frac{\Delta S^0(\text{soln})_1 - (1+a)\{\Delta S^0_{AB}(\text{gas}) + n\Delta S^0_{ABL}(\text{gas})\} + (n+1)(b+aR\ln 24.5)}{-(1+a)\Delta S^0_{AL}(\text{gas}) + (b+aR\ln 24.5)}, \quad (24)$$



[Me_2SnCl_2·DMP]



[Me_2SnCl_2·Py·DMP]

Fig. 3. Structures assumed as the strongly solvated species.

$$n = \frac{\Delta S^0(\text{soln})_2 - (1+a)\Delta S^0_{AB_2}(\text{gas}) + (b+aR\ln 24.5)}{-(1+a)\Delta S^0_{ABL}(\text{gas}) + (b+aR\ln 24.5)}, \quad (25)$$

Therefore, n can be determined from Eq. 25, the value of which will enable m to be determined from Eq. 24. In making these calculations, $\Delta S^0(\text{soln})_1$ and $\Delta S^0(\text{soln})_2$ can be replaced by experimental values, but definite structures need be assigned to AL and ABL in order to calculate the entropy of these strongly solvated species. The structures shown in Fig. 3 were assumed for the case of L=DMP. The molecular structures of pyridine[15] and DMP were taken to be the same in both free and complexed states, and also the structural data of the Me_2SnCl_2·(*N*,*N*-dimethylformamide)$_2$[18] complex was used for the Sn····O=C distance and angle in Me_2SnCl_2·DMP. The structure of DMP was determined on the basis of the standard bond lengths[19] and angles for sp^2 and sp^3 hybridization. Calculations were also performed under somewhat different structures for the complexes (e.g., a cis configuration with regard to the two Cl groups in Me_2SnCl_2·(pyridine)$_2$ or Me_2SnCl_2·pyridine·DMP), but the resulting entropies showed no discernible changes. In this way, m=1.34 and n=0.70 were obtained. This means that, when judged from the point of view of the entropy change, a free molecule of Me_2SnCl_2 is solvated by ca. 1.3 molecules of DMP, half of which are released when the 1 : 1 and 1 : 2 complexes are each formed with pyridine. As for the molecular structures of these strongly solvated species, the structures shown in Fig. 3 can be imagined. However, in the case of the solvated Me_2SnCl_2·pyridine complex, the solvent (DMP) molecule needs be either in a rapid exchange between the solvated state and a released state or in a rather weak solvation to make the averaged solvation number equal to 0.7. This number is probable since the tin atom is already coordinated by a strong base of pyridine before solvation occurs with a relatively weak base of DMP. Also, Me_2SnCl_2·DMP is solvated by an extra 0.3 molecule of DMP, on the average. This situation may be explained by a partial contribution from a solvated structure where two DMP molecules are involved.

iii) An Effect of the Entropy of Vibration in the Solvation Model. New vibrational degrees of freedom contribute to the entropy of reaction when new

chemical bonds are formed between the two participant molecules, leading to a complex. This number is six when one bond is formed to make a new complex, but such a vibrational term has been reported to be nontrivial from a comparison of the calculated sum of the translational and rotational entropies with the experimental total entropy for several gas-phase reactions.[20] When a linear relationship is assumed between the vibrational term, $\Delta S^0_{vib}(gas)$, and log μ according to Ref. 20, μ being the reduced mass of the complex, Eq. 26 is obtained from the data in the reference, excluding the complexes with a cyclic structure:

$$\Delta S^0_{vib}(gas) = 35.4 \log \mu - 20.4. \quad (24)$$

When this equation was used to estimate the vibrational terms in $\Delta S^0(gas)_1$, $\Delta S^0(gas)_2$, $\Delta S^0_{AL}(gas)$, and $\Delta S^0_{ABL}(gas)$, the latter values decreased by ca. 16% in absolute value and m=1.25 and n=0.65 resulted. That is, the conclusion given in this section does not change considerably even if the vibrational term is included in the calculation.

Appendix 1

Correction of Eq. 8 for the difference in standard states.

In Eq. 8, ΔS^s corresponds to the entropy changes of a gas at unit atm, and a and b are constants, which are determined from the entropies and other physical properties of the solvent. In the present study, the equilibrium constant is given in units of mol dm^{-3}: hence, ΔS^0(soln) and ΔS^0(gas) are given on that basis also, the standard state corresponding to a unit mol dm^{-3}. As this contrast, the third-law entropy, $S^0_{298}(g)$, is expressed relative to a standard state of 25 °C and 1 atm. Therefore, the gas-phase entropy, S^0(gas), in Eq. 6, which corresponds to a unit mol dm^{-3} at 25 °C, is connected with the $S^0_{298}(g)$ by the following equation under an ideal gas assumption:

$$S^0(gas) = S^0_{298}(g) - R \ln 24.5. \quad (A1)$$

Hence, Eq. 8 is converted to Eq. A2 for the present purposes:

$$\Delta S^s = a S^0(gas) + b + aR \ln 24.5, \quad (A2)$$

since ΔS^s itself does not change on this conversion of the standard state. The substitution of Eqs. 6 and A2 into Eq. 7 leads to Eq. 9.

Appendix 2

Calculation of entropies according to molecular statistical thermodynamics.

The entropy of a molecule is composed of several parts (translational, rotational, vibrational, and internal-rotational ones); i.e., $S = S_{tr} + S_{rot} + S_{vib} + S_{ir}$. Each part relates to the physical properties of the molecule:[21]

$$S_{tr} = R(1.5 \ln M + 2.5 \ln T - \ln P - 1.1650), \quad (A3)$$

$$S_{rot} = R(0.5 \ln I_A I_B I_C + 1.5 \ln T - \ln \sigma - 2.7106), \quad (A4)$$

$$S_{rot} = R(\ln I + \ln T - \ln \sigma - 2.1886) \text{ for linear molecules}, \quad (A5)$$

$$S_{vib} = R \sum_i [(\theta_i/T)\exp(-\theta_i/T)/\{1-\exp(-\theta_i/T)\} - \ln\{1-\exp(-\theta_i/T)\}], \quad \theta_i = h\nu_i/k, \quad (A6)$$

$$S_{ir} = S_{fir} - (S_f - S), \quad (A7)$$

where R is the gas constant, M is the molecular weight, T is the absolute temperature, h is Planck's constant, k is the Boltzmann constant, ν_1 is the wavenumber, and P is the pressure in atm, equal to 1/24.5 atm for an ideal gas of unit mol dm^{-3} at 25 °C. $I_A I_B I_C$ in Eq. A4 is the product of the principal moments of inertia and is calculated simply by using the moments of inertia with regard to any Cartesian axes x, y, or z, which go through the center of gravity:

$$I_A I_B I_C = \begin{vmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{xy} & I_{yy} & -I_{yz} \\ -I_{xz} & -I_{yz} & I_{zz} \end{vmatrix} \quad (A8)$$

where $I_{xx} = \sum m_i(y_i^2 + z_i^2)$ and $I_{xy} = \sum m_i x_i y_i$.

σ is the symmetry number, which is equal to the number of rotational operations by which the molecule remains the same as before when all the atoms are numbered. Thus, the accurate calculation of entropies is feasible according to the above formalism. Some computer programs have also published,[22] in which several refinements such as "vibrational anharmonicity" are included.

Cationic Motions and Phase Transitions in $[(CH_3)_4N]GaBr_4$ Crystals as Studied by ^1H NMR and Differential Thermal Analysis Techniques

Setsuko SATO and Daiyu NAKAMURA*
Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464
(Received August 6, 1986)

Two phase transitions were located for solid $[(CH_3)_4N]GaBr_4$ at 404 and 138 K. The temperature dependences of ^1H NMR spin-lattice relaxation times were determined mainly at 20 MHz. A shallow ^1H T_1 minimum appearing at ca. 400 K and a deep one below ca. 250 K were observed. The latter minimum could be explained by the occurrence of the overall reorientation of the cation as a whole with an activation energy of 14.5 kJ mol^{-1}. The shallow ^1H T_1 minimum may come from temperature dependent quadrupolar relaxation of bromine nuclei through the dipolar relaxation of the second kind.

Dynamical behavior of tetramethylammonium, $(tetMA)^+$, cations in various crystalline salts has been extensively studied mainly using ^1H NMR techniques,[1–13] because of several motional modes of the cation expected to be activated with increasing temperature. The motions of the cation which contribute to ^1H spin-lattice relaxation time, T_1, around room temperature were shown in various solids to be random reorientation of the CH_3 groups about each C–N bond axis by 120°, i.e., the CH_3 C_3 reorientation, and the overall reorientation of the cations about the center of gravity.

In some crystals such as (tetMA)X (X=Cl, Br, I),[3] the above two kinds of motional modes are activated successively at well-separated temperatures. However, it is shown from our NMR studies on $(tetMA)_2MX_6$[10,11] and $(tetMA)_2CdX_4$[12] type complexes and some clathrate hydrates of (tetMA)OH[13] that the above reorientational processes of the cation do not necessarily take place step by step distinctly with changing temperature. The present investigation of the motion of $(tetMA)^+$ cations in $(tetMA)GaBr_4$ crystals has been undertaken to find an example of crystals in which the cation performs a different type of motions from those already clarified.

Experimental

At first, we carried out synthetic experiments to obtain $(tetMA)_2Ga_2Br_6$ according to the method described in literature[14] except adding bromine. The synthetic procedure was as follows. Granular gallium was dissolved in hydrobromic acid involving bromine in a temperature range of 70—80 °C. When (tetMA)Br was added to the resulting solution, a white precipitate was obtained from the hot solution. When the solution was cooled to room temperature, the precipitate completely dissolved. The precipitate obtained at higher temperatures was $(tetMA)GaBr_4$ in contrast to the product reported in the literature.[14] The existence of $[GaX_4]^-$ (X= Cl, Br) had been reported elsewhere.[15,16] Purification was made by successive recrystallizations from a warm hydrobromic acid solution and finally from a CH_3NO_2 solution. Anal. Calcd for $[(CH_3)_4N]GaBr_4$: C, 10.4; H, 2.6%. Found: C, 10.4; H, 2.6%. The sample prepared was further identified by taking far IR spectra. The $\tilde{\nu}_3$ band of $[GaBr_4]^-$ was observed at 273 cm^{-1} with a shoulder at 280 cm^{-1} as already reported for the same complex.[16]

^1H T_1 was measured at various temperatures by use of pulsed NMR spectrometers already reported[10,17] at the Larmor frequencies of 20 and 10.5 (partly) MHz. The conventional inversion method to observe free induction decay signals was employed to determine T_1 values. Differential thermal analysis (DTA) experiments were carried out with a homemade apparatus already described.[18] Temperatures in the above two kinds of experiments were determined employing a copper vs. constantan thermocouple and could be estimated to be accurate within ±1 K. The 2nd moments of ^1H NMR absorptions were determined by means of a JEOL-MW-40S spectrometer at several temperatures measured with an accuracy of ±3 K.

Results and Discussion

Since many kinds of crystals involving $(tetMA)^+$ cations are known to exhibit structural phase transition in their solid phase,[3–7,9–13] we carried out the experiments of DTA. When the sample at room temperature was cooled to 80 K, no heat anomaly could be detected as shown in Fig. 1. However, a broad and small endothermic anomaly was recorded at ca. 138 K with increasing temperature fairly rapidly (≈3.4 K min^{-1}). When the sample was heated from room temperature, an endothermic anomaly showing marked thermal hysteresis appeared at 404 K. Accordingly, it can be concluded that $(tetMA)GaBr_4$ crystals undergo a first order phase transition at 404 K and an unusual small phase transition at ca. 138 K.

The temperature dependences of ^1H T_1 observed at 20 MHz in a temperature range of 96—440 K and at 10.5 MHz between 246 and 435 K are shown in Fig. 2.

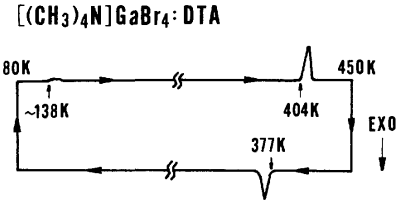

Fig. 1. Differential thermal analysis curves recorded for $[(CH_3)_4N]GaBr_4$.

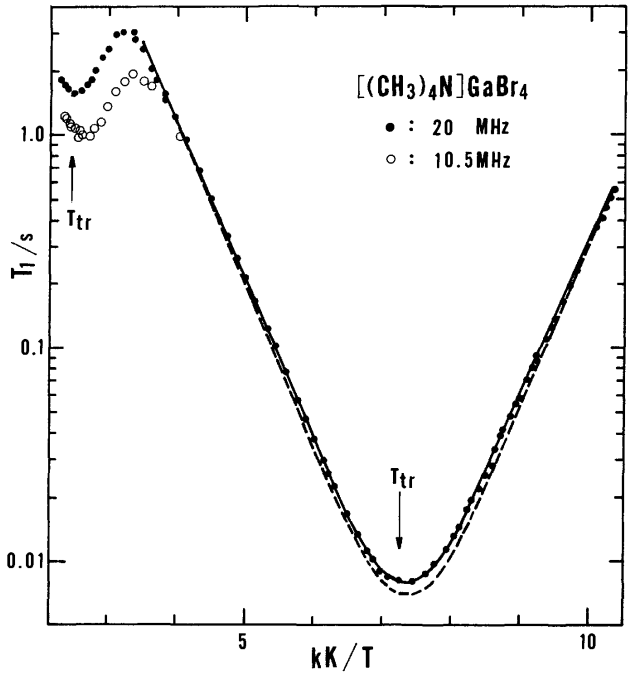

Fig. 2. Temperature dependence of ^1H T_1 observed for $[(CH_3)_4N]GaBr_4$ at 20 (●) and 10.5 (○) MHz. Solid and broken lines indicate the calculated curves using the BPP theory and the Takeda et al. method, respectively. T_{tr} indicates the phase transition temperatures determined from differential thermal analysis.

Below ca. 250 K, ^1H T_1 values determined formed a deep V-shaped curve, the minimum value of which was 8 ms obtained at ca. 135 K. On the other hand, ^1H T_1 values observed above ca. 250 K deviated from the V-shaped curve with increasing temperature and yielded a maximum around 310 K, above which temperature a very shallow T_1 minimum was obtained at ca. 400 K when observation was made at the Larmor frequency of 20 MHz. In this paper we mainly discuss about the T_1 curve having the deep minimum.

To assign the deep T_1 minimum to the motional mode of the cation, we determined the ^1H NMR 2nd moment, M_2, at several temperatures. The results are as follows: 24 G^2 at 77 K, 0.4 G^2 at 135, 167, and 215 K, 0.3_6 G^2 at 298 K, and 0.3_4 G^2 at 425 K. The rigid lattice M_2 value of an isolated $(tetMA)^+$ cation was calculated in a previous report[10] as 26.72 G^2 by use of the geometrical data reported by Andrew and Canepa.[1] For the present complex, the M_2 value observed at 77 K is very near to and only slightly smaller than the rigid lattice value. This suggests that the motions of the cation in $(tetMA)GaBr_4$ crystals are almost frozen at 77 K. On the other hand, very sharp ^1H NMR absorption lines were recorded above 135 K, indicating that the cations perform isotropic reorientation in the crystal. Accordingly, the deep T_1 minimum can be attributed to the isotropic reorientation, i.e., the C_2 and C_3 reorientations of the whole cation with or without the CH_3 C_3 reorientation of the four CH_3 groups.

According to the BPP theory,[19] T_1 due to magnetic dipolar relaxation mechanism can be written as

$$T_1^{-1} = C\left(\frac{\tau}{1+\omega^2\tau^2} + \frac{4\tau}{1+4\omega^2\tau^2}\right). \quad (1)$$

Here, ω, C, and τ represent the angular Larmor frequency employed, the motional constant, and the correlation time for the motion, respectively. By assuming the Arrhenius relation for the correlation time, one has

$$\tau = \tau_0 \exp(E_a/RT), \quad (2)$$

where τ_0 is the correlation time at the limit of infinite temperature and E_a is the activation energy for the motion.

^1H T_1 values observed below ca. 250 K were fitted to Eqs. 1 and 2 using E_a and the T_1 minimum values determined experimentally. The values of E_a and the T_1 minimum were 14.5 kJ mol^{-1} and 8 ms, respectively. The calculated BPP curve agrees very well with the observed data, suggesting that the motion of the cation can be described by a single motional mode, possibly the isotropic overall reorientation of the cation as a whole. However, we cannot say whether or not the CH_3 C_3 reorientation is involved in the cationic motional process giving rise to the deep T_1 minimum. The present type of motional process activated for $(tetMA)^+$ cations is a unique example in various crystalline salts containing the cation ever studied.

To confirm the adequacy of the above interpretation of the deep T_1 minimum obtained, we calculated quantitatively the T_1 curve based on the more general method developed by Takeda et al.,[20] which has been successfully employed for the analysis of the T_1 data obtained for some $(tetMA)^+$ salts of cadmium(II) complexes[12] and also clathrate hydrates of (tetMA)OH.[13]

In this calculation, each ^1H-^1H vector involved in the CH_3 C_3 reorientation, the cationic reorientation about its C_3 axes, and that about its C_2 axes was assumed to jump at the rates of ω_{CH_3}, ω_3, and ω_2, respectively, which gave transition matrices for intramethyl and intermethyl ^1H-^1H vectors. The transition matrices constructed at a given temperature were diagonalized numerically, where ω_{CH_3}, ω_3, and ω_2 were given as reciprocals of τ values expressed by Eq. 2 with E_a and τ_0 taken as adjustable parameters. For ω_3 and ω_2, the same E_a but the different τ_0 values were assumed. To obtain good agreement between the observed values and the calculated curve, the E_a value of $14._8$ kJ mol^{-1} was employed, which is slightly different from the foregoing value obtained from the BPP analysis. The bond lengths of C-H and C-N were assumed to be 1.09 and 1.50 Å, respectively, according to Albert et al.,[3] while the all bond angles of the cation to be tetrahedral. The present geometry is thought to be more suitable to check the adequacy of the above discussion than that of Andrew and Canepa[1] because the present com-

plex will form loosely packed crystals in contrast to those of (tetMA)X (X=Cl, Br, I) studied by Albert et al.[3] The calculated curve with the values of E_a=14.8 kJ mol^{-1} and τ_0=1.3×10^{-13} s for the all reorientations of the CH_3 C_3 and the whole cationic C_2 and C_3 is shown in Fig. 2. The calculated curve explains still fairly well the observed values although the T_1 minimum calculated is slightly smaller than the observed one.

In the above calculation, we assumed that the CH_3 C_3 and the overall cationic reorientations are activated simultaneously with the same E_a value. However, it is possible to assume alternatively that the overall reorientation of the cations occurs from lower temperatures with E_a similar to the above value whereas the CH_3 C_3 reorientation is activated at higher temperatures with a larger E_a value. In other words, we regarded the cation itself as in a rigid state with no CH_3 C_3 reorientation in the present temperature region. Even in this case, the same calculated T_1 curve could be obtained by taking very large E_a for the CH_3 C_3 process such as 50 kJ mol^{-1}.

When the cation keeping the four CH_3 groups in rigid performs overall reorientation rapidly, ^{1}H-^{1}H dipole interactions in the cation are completely averaged out. This means that any M_2 reduction does not occur even if the CH_3 C_3 reorientation is activated at a temperature higher than the T_1 minimum temperature at ca. 135 K. Therefore, we can say for this complex that the CH_3 C_3 reorientation occurs rapidly enough at the T_1 minimum temperature with the same E_a of 14.8 kJ mol^{-1} as that of the overall reorientation or at a higher temperature than ca. 135 K, and we cannot determine which is the true situation for this complex.

The present E_a value for the overall reorientation of the cation is very small indicating that the cation experiences a weak crystal field. Previously, we observed the small-angle reorientation of each CH_3 group of the cation in a lower temperature region of some hexahalometallates(IV) forming high symmetric crystals.[10,11] In these crystals, the cation also undergoes weak crystal field. For the present complex, however, we did not detect the small-angle reorientation of the CH_3 groups.

Since no structural data of the (tetMA)$GaBr_4$ crystal were available, we took X-ray powder patterns at room temperature by means of a Model VD-1A X-ray diffractometer from Shimadzu Seisakusho Co. However, the patterns shown in Fig. 3 could not be explained in terms of a cubic or a tetragonal crystal system indicating that (tetMA)$GaBr_4$ forms a crystal structure of lower symmetry. From the appearance of a shoulder for the IR $\bar{\nu}_3$ band of $[GaBr_4]^-$ in solid (tetMA)$GaBr_4$,[16] it can be said that the complex anion is located on a site having lower symmetry than cubic. Accordingly, it is highly probable that the cation is also located on a lower symmetry site. This may be the reason why the small-angle reorientation was not observed in the present complex.

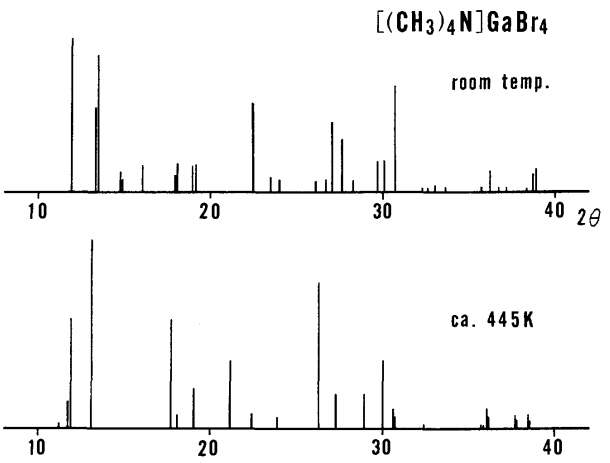

Fig. 3. X-Ray powder patterns taken at room temperature and at ca. 445 K for $[(CH_3)_4N]GaBr_4$.

In the higher temperature region above room temperature, (tetMA)$GaBr_4$ yielded a first order phase transition at 404 K. To know something about the crystal structure of the high temperature phase, we took X-ray powder patterns at ca. 445 K and obtained simpler patterns than those recorded at room temperature as shown in Fig. 3. The strong diffraction lines can be approximately interpreted in terms of a cubic structure with a lattice constant of ca. 15 Å. Since those strong lines have very weak side lines unexplainable by the cubic system, however, the crystal structure might belong to a less symmetric system, possibly a monoclinic one which is very close to the cubic system. It is very interesting that the phase transition did not give any detectable influence on the temperature dependence of ^{1}H T_1. This suggests that the motional state of the cation is not directly altered above and below the phase transition.

To obtain information for the characterization of the shallow T_1 minimum, we observed ^{1}H T_1 by a different Larmor frequency of 10.5 MHz as shown in Fig. 2. ^{1}H T_1 observed at both frequencies showed a clear frequency dependence in a temperature region of the shallow T_1 minimum. However, the ratios of T_1 values determined at the two frequencies measured at a given temperature were not ω^2 but nearly ω. This indicates that the relaxation mechanism yielding the shallow minimum cannot be attributed to the simple BPP type. Also the 2nd moment at 425 K was almost the same as that at room temperature, this is, no drastic decrease of the 2nd moment was found. The facts indicate that this T_1 minimum cannot be explained through a simple dipolar relaxation mechanism such as the self-diffusion of the cations. In a previous paper,[12] a ^{1}H T_1 decrease with increasing temperature observed at higher temperatures for (tetMA)$_2CdBr_4$ and (tetMA)$_2CdI_4$ was attributed to the ^{1}H relaxation through magnetic interactions between ^{1}H and halogen nuclei, where the quadrupolar relaxation of bro-

mine and iodine nuclei, respectively, is very fast because of a fluctuating electric field gradient possibly by the molecular or anionic reorientation. This relaxation mechanism named as dipolar relaxation of the second kind[21] may be the main origin for the present shallow T_1 minimum. The appearance of the T_1 minimum suggests that $[GaBr_4]^-$ reorients more rapidly than $[CdBr_4]^{2-}$ in almost the same high temperature region.

^{1}H NMR Studies on the Motion of Cations in the Three Solid Phases of Methylammonium Perchlorate Including Cationic Self-Diffusion in Its Highest-Temperature Solid Phase

Hiroyuki Ishida, Ryuichi Ikeda, and Daiyu Nakamura*
Department of Chemistry, Faculty of Science, Nagoya University, Chikusa-ku, Nagoya 464
(Received August 25, 1986)

The temperature dependences of the second moment of ^{1}H NMR absorptions, the ^{1}H spin-lattice relaxation time, T_1, and the ^{1}H spin-spin relaxation time, T_2, of $CH_3NH_3ClO_4$ ($CH_3ND_3ClO_4$) were observed in the three solid phases existing over a wide range of temperature. In the phase I stable above 451 K, the onset of the isotropic reorientation as well as the self-diffusion of the cations with the activation energy of 36 kJ mol^{-1} was observed. In the phase II stable between 451 and 321 K, no remarkable change in the motional state of the cation was observed, but the dynamical orientational disorder of perchlorate anions was expected to occur. In the phase III stable below 321 K, the correlated reorientation defined as the C_3 reorientation of the cation having the rigid structure, was observed at lower temperatures for two nonequivalent cations in the crystal with small activation energies of 4.4 and 2.0 kJ mol^{-1}. The uncorrelated reorientation in which both CH_3 and NH_3^+ groups perform C_3 reorientation independently could be observed at a higher temperature with the activation energy of 6.4 kJ mol^{-1}. Nonexponential behavior appearing in the observation of T_1 below 40 K could be explained by the presence of a contribution to ^{1}H T_1 from the rotational tunneling of the cation.

Recently, we have found the presence of highly movable methylammonium $(MA)^+$ cations performing overall reorientation as well as self-diffusion in the highest-temperature solid phase of various simple $(MA)^+$ salts, such as (MA)I,[1,2] $(MA)NO_3$,[3,4] $(MA)ClO_4$,[3] and $(MA)_2SO_4$.[5] Furthermore, we also revealed the presence of such an unusual phase for $(CH_3)_3NHNO_3$[6] and $[C(NH_2)_3]ClO_4$[7] crystals. Very recently, Jurga and Spiess confirmed the existence of the unusual phase in $(MA)ClO_4$ crystals,[8] and also they found the appearance of a similar phase in $(CH_3)_2NH_2ClO_4$[9] and $(CH_3)_3NHClO_4$[10] crystals.

From our studies carried out up to date, it can be said that these highest-temperature solid phases of the above salts bear a strong resemblance to the plastic phase,[11] which is well-known to exist in molecular solids. Similarities are as follows. Both of the present and the plastic phases contain considerably freely moving constituents, i.e., molecule-like cations and such molecules, respectively. Additionally, an unusually large entropy change which is in some cases larger than that of melting, has been observed at the phase transition to the above phases with increasing temperature.[2,4,8,12]

Stammler et al.[13] carried out the experiments of differential thermal analysis (DTA) and powder X-ray diffraction and found three solid phases for $(MA)ClO_4$ above room temperature. The room-temperature phase (the phase III) obtainable below 321 K has a monoclinic unit lattice belonging to the space group $P2_1/n$.[14] With increasing temperature, this phase transforms at 321 K into the phase II, the crystal structure of which belongs to a tetragonal system.[14] The crystal of the highest-temperature phase (the phase I) existing above 451 K has a CsCl-type cubic structure.[14] The existence of the unusual solid phase in this salt was already reported as a letter.[3]

To obtain detailed information about dynamical properties of the cations in the above three phases, the present investigation of the temperature dependences of ^{1}H spin-lattice relaxation times (T_1) above 11 K, ^{1}H spin-spin relaxation times (T_2), and ^{1}H NMR second moments (M_2) has been undertaken for $(MA)ClO_4$ and $(CH_3ND_3)ClO_4$ [hereafter abbreviated as (MA-*d*)ClO_4]. Jurga and Spiess[8] reported ^{1}H NMR results obtained above 80 K for both salts. However, their data partly disagree with ours. Therefore, we again carried out sample preparations and ^{1}H T_1 measurements very carefully and confirmed our data presented here to be reasonable.

Experimental

$(MA)ClO_4$ was synthesized by neutralizing an aqueous solution of methylamine with perchloric acid by cooling the reaction vessel with an ice-bath. The resultant solution was placed in a desiccator, and crystals were separated after slowly evaporating water. The crystals obtained were purified by performing recrystallizations twice from isopropyl alcohol. A partially deuterated analog, (MA-*d*)ClO_4, was prepared from purified $(MA)ClO_4$ by successive crystallizations made three times from heavy water. These salts are so hygroscopic that the purified samples were dried over phosphorus pentaoxide in a vacuum desiccator for several weeks. After that, the samples, which had been put in glass ampoules for the measurements of NMR and DTA, were again dried by pumping out inner gas of the ampoules for ca. 8 h at ca. 90 °C before sealing them with a small amount of helium exchange gas.

DTA curves were recorded by using a homemade apparatus already described.[15] ^{1}H T_1, ^{1}H T_2, and M_2 of ^{1}H NMR absorptions were determined by use of apparatus already reported.[16,17] The T_1 measurements below 77 K were performed by employing a cryostat newly constructed by us. The cryostat could be used for the frequency variable pulsed spectrometer[17] for the measurements of NMR relaxation times between 4.2 and ca. 100 K. The sample temperature could be roughly controlled by adjusting the pressure of helium gas put in open space between the sample probe and

a glass cylinder which was immersed in liquid helium. To obtain a given and constant temperature, electric power supplied into a heater wound on the probe was controlled by means of an Oxford model DTC2 temperature controller. When measurements were carried out with this cryostat, sample temperatures were determined by use of a gold (0.07% iron) vs. chromel thermocouple with an accuracy of ±0.2 K. For the other T_1 and T_2 measurements as well as DTA experiments, sample temperatures were measured with a copper vs. constantan thermocouple with an estimated error of ±1 K.

Results

To confirm the phase transition temperatures (T_{tr}) reported,[13] DTA curves were recorded for $(MA)ClO_4$ and $(MA\text{-}d)ClO_4$ in the temperature range of 80—460 K. When $(MA)ClO_4$ was heated, two endothermic anomalies appeared at 321 and 451 K. These temperatures agree well with the T_{tr} values determined by Stammler et al.[13] from their DTA measurements and also by Jurga and Spiess from their DSC experiments.[8] However, the higher T_{tr} of 452 K observed for $(MA\text{-}d)ClO_4$ by us was higher by as much 15 K as that reported by Jurga and Spiess,[8] although the lower T_{tr} of 321 K obtained by us for the deuterated analog agreed well with their T_{tr} of 319.7 K reported.

The M_2 values of $(MA)ClO_4$ observed at 77 K and at various temperatures between 260 and 460 K are shown in Fig. 1, where an M_2 value of $(MA\text{-}d)ClO_4$ determined at 77 K is also included. At 77 K, $(MA)ClO_4$ and $(MA\text{-}d)ClO_4$ gave M_2 of $8._0$ and $7._0$ G^2, respectively. At 260 K, $(MA)ClO_4$ still yielded a large M_2 of $7._5$ G^2. With further increasing temperature from 260 to 450 K, a gradual M_2 decrease to ca. 6 G^2 was observed. However, no discontinuous decrease in M_2 was detected at T_{tr} from the phase III to the phase II [hereafter, such T_{tr} as this will be abbreviated as T_{tr}(III→

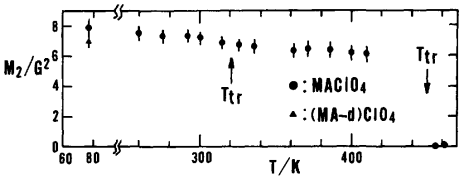

Fig. 1. ^1H NMR second moments (M_2) observed for $CH_3NH_3ClO_4$ at various temperatures. M_2 observed at 77 K for $CH_3ND_3ClO_4$ is also included. Vertical lines written on observed values are error bars estimated. T_{tr} with arrows indicates phase transition temperature.

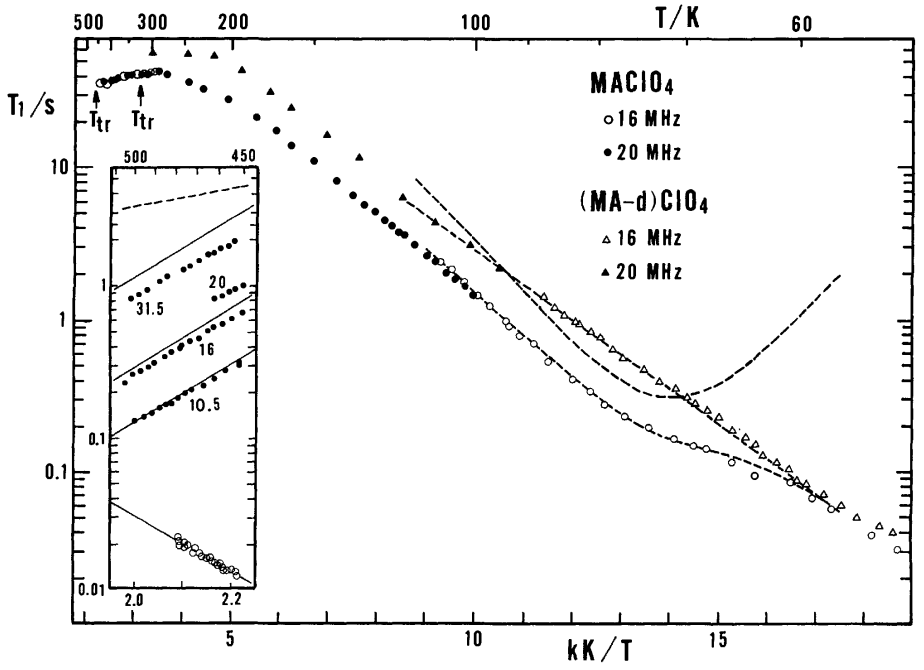

Fig. 2. Temperature dependences of ^1H T_1 observed for $CH_3NH_3ClO_4$ and $CH_3ND_3ClO_4$ at 16 and 20 MHz. A log T_1 vs. T^{-1} curve written by a broken line, which has a shallow minimum, indicates the BPP curve for the uncorrelated reorientation of the $CH_3NH_3^+$ cation, whereas a straight broken line is a hot-side fraction of the BPP curve corresponding to the correlated reorientation of the cation. The sum of the two curves is written by a broken line in agreement with the data of $CH_3NH_3ClO_4$. Temperature dependences of ^1H T_1 (●) observed at 10.5, 16, 20, and 31.5 MHz and ^1H T_2 (○) determined at 31.5 MHz for $CH_3NH_3ClO_4$ in its highest- temperature phase are shown as an inserted figure. Straight lines having negative temperature gradients denote T_{1d} derived at each Larmor frequency except 20 MHz, while the broken line indicates T_{1i}. The straight line having a positive temperature coefficient is the best-fitted line to the T_2 data observed.

II)], although Jurga and Spiess reported a clear M_2 decrease of 2.6 G^2 around 300 K.[8] At the higher T_{tr} of 451 K, M_2 decreased discontinuously to an extremely small value less than 0.05 G^2.

Temperature dependences of ^1H T_1 determined for $(MA)ClO_4$ and $(MA\text{-}d)ClO_4$ in relatively high-temperature regions are shown in Fig. 2. ^1H T_1 values of $(MA)ClO_4$ determined in the temperature ranges of 53—107 and 296—505 K at the Larmor frequency of 16 MHz and of 100—462 K at 20 MHz are depicted. For $(MA\text{-}d)ClO_4$, ^1H T_1 measurements at 16 MHz were made between 53 and 87 K, while those at 20 MHz were carried out between 95 and 300 K.

The $\log T_1$ vs. T^{-1} plots of both salts determined at 16 MHz increased with increasing temperature, and the plots extrapolated to higher temperatures agree well with those of the corresponding salts observed at 20 MHz as can be seen in Fig. 2. The $\log T_1$ value of $(MA\text{-}d)ClO_4$ increased almost linearly with decreasing T^{-1} in the present temperature range, whereas $(MA)ClO_4$ yielded a shallow T_1 minimum around 75 K. Almost the same temperature-dependence curve of ^1H T_1 observed at 20 MHz was obtained for both salts between ca. 100 and ca. 200 K.

$(MA)ClO_4$ yielded a broad T_1 maximum around 300 K, above which temperature almost the same ^1H T_1 values were observed at a given temperature for the measurements made at both Larmor frequencies of 16 and 20 MHz and the observed ^1H T_1 decreased gradually with increasing temperature up to T_{tr}. No discontinuity in the ^1H T_1 curve was observed at T_{tr} of 321 K. However, ^1H T_1 changed discontinuously at T_{tr} of 451 K, where ^1H T_2 also increased discontinuously by about three orders of magnitude.

The temperature variations of ^1H T_1 values determined for $(MA)ClO_4$ in its phase I are inserted in Fig. 2 as an enlarged figure on the T^{-1} scale. In this phase, ^1H T_1 was observed at 10.5 and 31.5 MHz in addition to the above frequencies in the temperature range of T_{tr}—ca. 500 K. With increasing temperature in the phase I, each ^1H T_1 measured at four different Larmor frequencies decreased monotonously, whereas ^1H T_2 determined at 31.5 MHz between T_{tr} and ca. 480 K increased linearly with decreasing T^{-1}. The temperature gradient of the $\log T_1$ vs. T^{-1} plots observed in this phase became gentler when the Larmor frequency employed increased.

The temperature dependences of ^1H T_1 observed for $(MA)ClO_4$ and $(MA\text{-}d)ClO_4$ in the temperature ranges of 11—110 and 18—90 K are shown in Figs. 3 and 4, respectively. Above ca. 40 K, each ^1H T_1 value of $(MA)ClO_4$ observed at 16 and 30.5 MHz yielded a deep T_1 minimum of 17 ms at 46 K and of 34 ms at 50 K, respectively. Similarly, $(MA\text{-}d)ClO_4$ gave a T_1 minimum of 31 ms at 49 K and of 53 ms at 51 K for the measurements made at 16 and 30.5 MHz, respectively.

Below ca. 40 K, nonexponential behavior was observed for the ^1H spin-lattice relaxation of both salts. If one assumes the presence of two independent relaxation processes having different relaxation times, $T_{1\ell}$ and T_{1s} ($T_{1\ell} > T_{1s}$), the ^1H magnetization $M_z(t)$ observed after each 90° pulse, where t is the time inter-

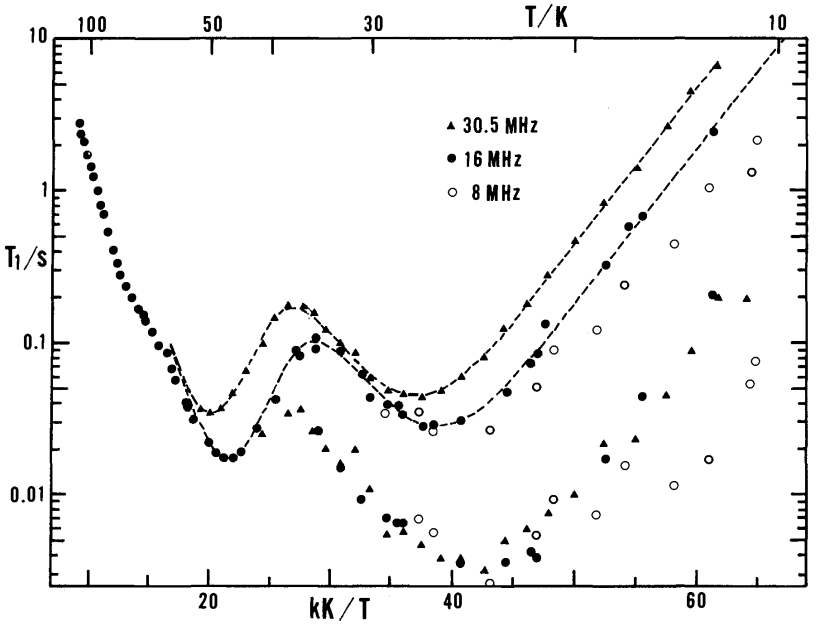

Fig. 3. Temperature dependences of ^1H T_1 observed for $CH_3NH_3ClO_4$ at 8, 16, and 30.5 MHz. Below ca. 40 K, long($T_{1\ell}$) and short (T_{1s}) components of T_1 for each Larmor frequency were obtained from nonexponential free induction decay curves observed. The sum of two independent BPP type T_1 curves corresponding to two kinds of crystallographically nonequivalent cations is written with broken lines for each frequency.

val between 180 and 90° pulses, can be given by

$$M_0 - M_z(t) = A_s \exp(-t/T_{1s}) + A_\ell \exp(-t/T_{1\ell}). \quad (1)$$

Here, M_0 denotes the M_z value under the thermal equilibrium of the spin system, i.e., $M_0 = M_z(\infty) = -M_z(0)$. To evaluate T_{1s} and $T_{1\ell}$, the $M_z(t)$ values observed at various intervals were fitted to Eq. 1 by use of the least-squares method under the condition of $A_s + A_\ell = 2M_0$. As an example, $M_z(t)$ values observed for $(MA)ClO_4$ at 19 K with the best-fitted M_z (t) recovery curve are shown in Fig. 5.

For $(MA\text{-}d)ClO_4$, it became difficult to obtain two T_1 values accurately around 40 K, because T_{1s} and $T_{1\ell}$ values come close to each other with increasing temperature. Accordingly, averaged T_1 values, T_{1av}, were evaluated from

$$T_{1av} = (t_{half})/\ln 2, \quad (2)$$

where (t_{half}) denotes the time interval t when a half-recovery value of the ^1H magnetization is reached. T_{1av} values derived from this method agree with the $T_{1\ell}$ values roughly estimated by using Eq. 1. Since these T_{1av} values were very near to the $T_{1\ell}$ curve extrapolated from the low-temperature side, T_{1av} was assumed to have the same origin of ^1H relaxation as $T_{1\ell}$ and plotted in Fig. 4.

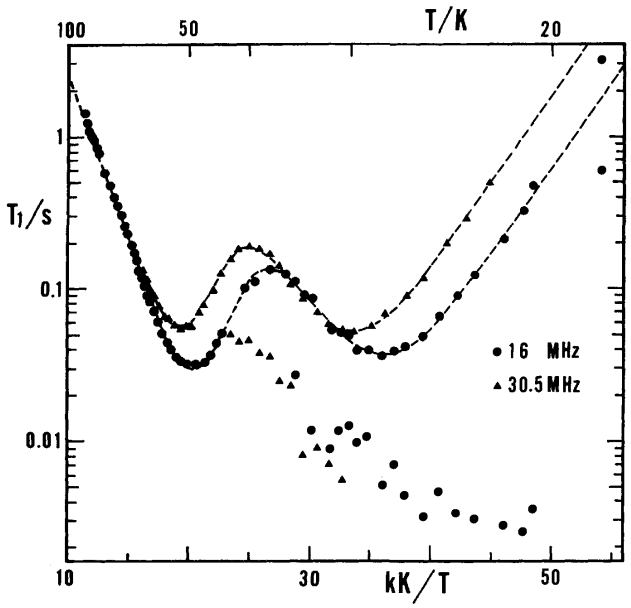

Fig. 4. Temperature dependences of ^1H T_1 observed for $CH_3ND_3ClO_4$ at 16 and 30.5 MHz. Below ca. 40 K, ^1H T_1 observed at each frequency showed nonexponential behavior and, $T_{1\ell}$ and T_{1s} could be determined as in the case of $CH_3NH_3ClO_4$ shown in Fig. 3. The sum of two different BPP curves arising from the two nonequivalent cations is indicated by broken lines calculated at each Larmor frequency. Around the high-temperature minima appeared, ^1H T_1 observed at both frequencies showed somewhat nonexponential behavior. However, it was difficult to obtain short T_1 component values accurately. Therefore, these values are omitted from the figure.

The T_1 curves of both salts thus obtained were connected smoothly to the respective T_1 curve observed in a higher-temperature region than 40 K. Each $T_{1\ell}$ curve of $(MA)ClO_4$ obtained from the measurements at 16 and 30.5 MHz exhibited a minimum of 28 ms at 26 K and 44 ms at 27 K, respectively. Similarly, $(MA\text{-}d)ClO_4$ yielded a $T_{1\ell}$ minimum of 36 ms at 28 K and 52 ms at 30 K for the measurements at 16 and 30.5 MHz, respectively. On the other hand, T_{1s} values measured at these two frequencies at a given temperature were approximately equal to each other in the temperature range where the nonexponential recovery curves could be observed for each analog. A minimum of 3.2 ms for the T_{1s} curve of $(MA)ClO_4$ could be located at 23 K, whereas no clear minimum could be found for $(MA\text{-}d)ClO_4$ down to 20 K.

Discussion

Second Moments of ^1H NMR Absorptions. According to the theoretical calculation of M_2 by use of Van Vleck's method,[18] $(MA)^+$ cations which rotate about the respective C-N bond axes give rise to ^1H M_2 of 8.9 G^2.[19,20] The fact that M_2 of 8.0 G^2 was observed for $(MA)ClO_4$ at 77 K indicates that the cations perform this motion with higher frequencies than 10^5 Hz even at 77 K.

A drastic decrease in M_2 to a value less than 0.05 G^2 at T_{tr} of 451 K clearly indicates the onset of the diffusional jumps as well as the isotropic rotation of the cations in the phase I. This is because M_2 observed in

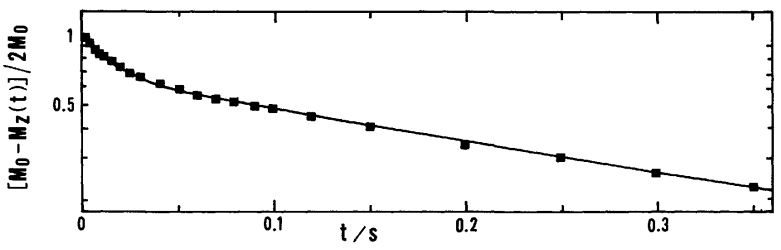

Fig. 5. ^1H magnetization recovery values, $[M_0 - M_z(t)]/2M_0$, observed for $CH_3NH_3ClO_4$ at 19 K by changing the interval time, t, between 180° and 90° pulses. M_0 denotes the thermal equilibrium value of the magnetization value. The solid line is the best fitted curve obtained by the least-squares method.

this phase is much smaller than the theoretical value of 0.8 G^2 calculated for the isotropically rotating cations in crystals using the crystal structure[13] of the phase I. A similar M_2 reduction has been already observed in some $(MA)^+$ salts.[1-6] For (MA)I[2] and $(MA)NO_3$[4] crystals, ^1H NMR and also electrical conductivity data obtained could be explained in terms of the above motional state of the cations.

Room-Temperature Phase (Phase III). (MA-*d*)ClO_4 yielded two deep minima of T_1 (including $T_{1\ell}$) below 100 K. These T_1 minima are attributable to magnetic dipolar relaxation because their frequency dependence is well explained by the BPP theory.[21] Since M_2 of 7.0 G^2 observed for this salt at 77 K is close to the theoretical value of 6.1 G^2 calculated for the cation reorienting about its C_3 axis,[19] these T_1 minima can be assigned to this motion. $(MA)ClO_4$ also showed two T_1 (including $T_{1\ell}$) minima at about the same temperatures as those of (MA-*d*)ClO_4. These results indicate the existence of two kinds of crystallographically nonequivalent $(MA)^+$ ions in the phase III crystal, in agreement with the results of X-ray diffraction analysis carried out by Zanazzi.[14] The fact that each of the T_1 and $T_{1\ell}$ minimum temperatures is approximately the same for both salts implies that the CH_3 and NH_3^+ groups in a cation have the correlation time of the C_3 reorientations very close to each other.

From the reason described below, this C_3 reorientation is attributable to the "correlated reorientation" of the cation, which has already been defined as the C_3 reorientation of the cation as a whole with keeping its rigid structure.[22] This motional mode is expected to exist for the cation in crystals where the C_3 rotation of the whole cation has a lower hindering barrier than the intracationic or internal C_3 rotation. The correlated reorientation of the $(MA)^+$ cation has been found in $(MA)_2MX_6$ (M=Sn, Te, Pt; X=Cl or Br) complexes, from the study of ^1H T_1 at lower temperatures.[22,23]

When the correlated reorientation of the cation takes place at a lower temperature, the "uncorrelated reorientation," which has been also defined before as the independent reorientation of the CH_3 and NH_3^+ groups in the identical cation,[22] is expected to occur with increasing temperature. In fact, a shallow T_1 minimum assignable to the uncorrelated reorientation was observed for the foregoing $(MA)_2MX_6$-type complexes.[22,23]

As shown in Fig. 2, $(MA)ClO_4$ gave a shallow T_1 minimum at ca. 75 K, whereas no such minimum was observed for (MA-*d*)ClO_4 in the same temperature range. The appearance of the shallow T_1 minimum is responsible for the averaging of magnetic-dipole interactions between protons belonging to the different groups in a cation, which reorient independently. Accordingly, the shallow minimum observed for $(MA)ClO_4$ can be assigned to the uncorrelated reorientation of the cation.

The ^1H T_1 curve around this minimum can be expressed as[24]

$$T_1^{-1}=(2/3)\gamma^2[\Delta M_{2c}g(\tau_c)+\Delta M_{2u}g(\tau_u)], \quad (3)$$

where

$$g(\tau)=\frac{\tau}{1+\omega^2\tau^2}+\frac{4\tau}{1+4\omega^2\tau^2}. \quad (4)$$

Here, γ, ω, and τ are the gyromagnetic ratio of a proton, the angular Larmor frequency, and the correlation time of a motion involved in the averaging of ^1H-^1H dipolar interactions, respectively. ΔM_{2c} is an M_2 reduction through the onset of the correlated reorientation of the cation from the rigid lattice M_2 value. ΔM_{2u} denotes the difference between the M_2 values for the cations performing the correlated reorientations and those having independently reorienting CH_3 and NH_3^+ groups. τ_c and τ_u indicate the correlation time for the correlated reorientation of the cation and for the uncorrelated reorientation which is the relative intracationic reorientation of the two groups, respectively. Each of these correlation times can be related to the activation energy, E_a, for the corresponding motion using the Arrhenius relationship given by

$$\tau=\tau_0\exp(E_a/RT), \quad (5)$$

where τ_0 is the correlation time at the limit of infinite temperature.

A fitting calculation of the ^1H T_1 values of $(MA)ClO_4$ observed between 57 and 110 K was carried out using the program SALS[25] at the Computation Center of Nagoya University. The best-fitted T_1 curve and the values of the unknown parameters determined from the calculation are given in Fig. 2 and Table 1, respectively. M_{2u} of 0.5 G^2 obtained agrees well with that of 0.4 G^2 calculated from the theoretical T_1 minimum for the same motion in the $(MA)_2MX_6$-type

Table 1. Activation Energy, E_a, the Correlation Time, τ_0, at the Limit of Infinite Temperature, and the Motional Mode of Methylammonium Ions in the Phases I and III of Methylammonium Perchlorates

Compound	Phase	E_a/kJ mol^{-1}	$\tau_0\times10^{13}$/s	Motional Mode (data obtained from)
$CH_3NH_3ClO_4$	III	2.0±0.2	5±3	Correlated C_3 reorient. ($T_{1\ell}$)
	III	4.4±0.1	0.8±0.1	Correlated C_3 reorient. (T_1)
	III	6.4±0.3	1.3±0.6	Uncorrelated C_3 reorient.(T_1)
	I	37±3	—	Self-diffusion (T_1)
	I	35±3	—	Self-diffusion (T_2)
$CH_3ND_3ClO_4$	III	2.2±0.2	5±3	Correlated C_3 reorient. ($T_{1\ell}$)
	III	4.4±0.1	1.3±0.1	Correlated C_3 reorient. (T_1)

complexes.[22] This means that two kinds of nonequivalent $(MA)^+$ cations existing in the crystal yielded their T_1 minima attributable to the uncorrelated reorientation at approximately the same temperature. This is expected from the foregoing discussion made on this reorientation which is hindered mostly by the intracationic potential barrier. E_a of 6.4 kJ mol^{-1} evaluated for this cationic motion in the present salt is lower than that of ca. 8 kJ mol^{-1} already reported for the same motion in $(MA)_2MX_6$-type complexes.[22] The present small E_a can be explained if the T_1 curve observed is broadened due to the presence of two different T_1 curves overlapping each other, which arise from the two nonequivalent cations, each of which gives the T_1 minimum at a little different temperature.

Next, we try to explain the ^1H T_1 and ^1H T_1 minima observed for both salts below 50 K by the BPP theory.[21] This theory predicts that the ratios of the T_1 minima observed at two different Larmor frequencies should be equal to the ratio of these frequencies. The ratios observed for the high-temperature T_1 minima, T_{1min}(30.5 MHz)/T_{1min}(16 MHz) were 1.9 and 1.8 for $(MA)ClO_4$ and (MA-*d*)ClO_4, respectively, in good agreement with the theoretical value of 1.91. On the other hand, the low-temperature T_1 minima yielded the ratios of 1.6 and 1.4 in the same order as above, which were much smaller than the theoretical value. Moreover, the squared ratios of T_1 observed at 30.5 MHz to that of 16 MHz at the same temperature on the low-temperature side of the minima were 2.5 and 2.6 for $(MA)ClO_4$ and (MA-*d*)ClO_4, respectively. These values were also much smaller than the theoretical value of 3.6 $[(30.5/16)^2]$ predicted from the BPP theory.[21]

These facts and the foregoing nonexponential T_1 behavior observed below 40 K cannot be explained by the usual mechanism, i.e., the averaging of magnetic dipolar interactions due to the cationic motions, and suggest the existence of some contribution to ^1H T_1 from the rotational tunneling of the cation in $(MA)ClO_4$ crystals.[26-28] Another fact that T_{1s} of $(MA)ClO_4$ has a minimum at 23 K, suggests that the tunneling frequency is of the order of 10^7 Hz around this temperature.[28]

Here, we roughly evaluate E_a values for the correlated reorientation of the $(MA)^+$ cation. Assuming that the T_1 and $T_{1\ell}$ curves observed at 16 MHz can be expressed by the superposition of two independent BPP curves, we have

$$T_1^{-1} = (1/2)[Cg(\tau_c) + C'g(\tau_c')], \quad (6)$$

where C and C' are the motional constants of the correlated reorientation of the two kinds of cations with the correlation times τ_c and τ_c', respectively. Equations 5 and 6 were fitted to the observed values by the least-squares method. The unknown parameters determined and the best-fitted T_1 curves are shown in Table 1 and Figs. [4, 5], respectively. The activation energies for the correlated reorientation of the cation in both salts were much smaller than the corresponding value of the uncorrelated reorientation. This supports our expectation that the whole-cation reorientation is less hindered than the intracationic reorientation of the CH_3 and NH_3^+ groups.

Intermediate Phase (Phase II). When the temperature was raised above 300 K, ^1H T_1 decreased monotonously in the phases III and II without showing any detectable anomaly at T_{tr}(III→II). Since no frequency dependence of ^1H T_1 was observed in this temperature range, this T_1 decrease cannot be attributed to magnetic dipolar relaxation. From the preceding discussion, it is apparent that the cations in $(MA)ClO_4$ crystals are considerably free. This suggests that the cations perform a rapid rotation around the C-N bond axis. Such a rapid axial rotation of the cations may give rise to spin-rotation relaxation which is known to yield frequency-independent T_1 decrease with increasing temperature even in solids.[29,30]

Jurga and Spiess have reported a clear M_2 decrease around T_{tr}(III→II) and assigned it to the onset of the precession of the cations about an axis inclined at an angle of 18° to each C-N bond axis.[8] However, neither T_1 minimum nor frequency-dependent T_1 corresponding to this M_2 decrease could be detected in the present study and also in their T_1 measurements.

If the above motional model of the cation proposed by Jurga and Spiess is considered, ^1H T_1 arising from this motion can be calculated by substituting the parameters (E_a, τ_0, and ΔM_2) of this motion given in their paper[8] into Eq. 5 and the following BPP equation[21]

$$T_1^{-1} = (\tfrac{2}{3})\gamma^2 \Delta M_2 g(\tau). \quad (7)$$

Therefore, the T_1 values roughly evaluated at the Larmor frequency of 20 MHz were ca. 16 and 1.2 s at 350 and 440 K, respectively. These results indicate that ^1H T_1 in the phase II should decrease more rapidly than the observed values with increasing temperature. Furthermore, these T_1 values should show frequency dependency due to magnetic dipolar relaxation caused by the precessional motion in contrast to the present experimental fact.

In our M_2 measurements, no marked change in M_2 was found around room temperature although a gradual decrease in M_2 with increasing temperature was found over a wide range of temperature. This M_2 decrease can be interpreted in terms of a gradual increase of the amplitude of lattice vibrations.[31,32] The activation of lattice vibrations usually gives no remarkable effect on T_1 which is consistent with our T_1 data observed in the phase II.

Jurge and Spiess[8] reported a large entropy change ΔS_{tr} (20.9 J K^{-1} mol^{-1}) of transition at T_{tr}(III→II) of 321 K for $(MA)ClO_4$, indicating that the ions forming the crystal obtain motional freedom considerably at T_{tr}(III→II). This ΔS_{tr} is larger than that (16.9 J K^{-1}

mol^{-1}) obtained at T_{tr}(II→I). However, the fact that no marked discontinuity in either ^1H T_1 or M_2 was observed at T_{tr}(III→II) indicates that the cationic motion is little affected through this transition. Accordingly, the large ΔS_{tr} observed at T_{tr}(III→II) suggests that a sudden increase in the motional freedom of ClO_4^- anions takes place at 321 K. That is, the onset of anionic rotation around each chlorine atom is expected to occur in the phase II. This expectation is consistent with the ^1H spin-lattice dipolar relaxation time, T_{1D}, data reported by Jurga and Spiess.[8] They observed a discontinuous decrease in T_{1D} at T_{tr}(III→II), and also a monotonous decrease of T_{1D} in the phase II with increasing temperature. These facts observed by them can be explained in terms of the averaging of the dipolar interactions between ^1H and ^{17}O nuclei caused by the anionic rotation.[33]

The ΔS_{tr} value of 16.9 $J K^{-1} mol^{-1}$ at T_{tr}(II→I)[8] can be compared with those of (MA)I[2] and $(MA)NO_3$[4] at the highest-temperature solid-solid phase transition. These salts perform the same kind of phase transitions as $(MA)ClO_4$ at high temperatures and transform into highly disordered crystals with a CsCl-type cubic structure. ΔS_{tr} of 15 $J K^{-1} mol^{-1}$ observed for (MA)I at T_{tr} to the ε phase[2] is comparable to that of $(MA)ClO_4$, whereas $(MA)NO_3$ gives a larger ΔS_{tr} of 28 $J K^{-1} mol^{-1}$ at the corresponding T_{tr}.[4] This ΔS_{tr} of the nitrate can be assigned to an increase in the motional freedom of both cations and anions at the phase transition. We have previously shown for the iodide, however, that only the cationic motion is responsible for the transition entropy observed.[2] Accordingly, the phase transition at 451 K occurring in $(MA)ClO_4$ crystals can be characterized mainly by the change in the motional state of the cation. This is consistent with our previous expectation that the dynamical orientational disorder of the anions will take place at the low-temperature T_{tr}.

High-Temperature Phase (Phase I). The discontinuous decrease of M_2 to a value less than 0.05 G^2 and the sudden increase of T_2 to 14 ms as well, occurring at T_{tr}(II→I), indicate the onset of the isotropic reorientation and the self-diffusion of the cations in the phase I. The log T_1 vs. T^{-1} plots of the phase I, as determined at four different Larmor frequencies shown in Fig. 2, increase almost linearly with increasing T^{-1} and the gradients against T^{-1} become gentler with increasing frequency. The T_1 behavior similar to this was also reported for the cubic phase of $(MA)NO_3$[4] and (MA)I.[2] According to the analysis of the T_1 data of these salts, the present T_1 values could also be expressed by the superposition of the two components, T_{1d} and T_{1i}, as written by

$$T_1^{-1} = T_{1d}^{-1} + T_{1i}^{-1}. \quad (8)$$

Here, T_{1d} and T_{1i} denote ^1H T_1 proportional to ω^2 and independent of ω, respectively. As the most probable origin of T_{1i}, the spin-rotation interaction due to the isotropic rotation of the cation can be considered. On the other hand, T_{1d} is assignable to the self-diffusion of the cations in agreement with the vanishingly small M_2 determined in this phase.

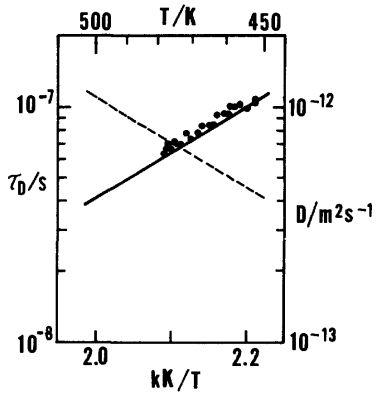

Fig. 6. The correlation times of the self-diffusion estimated from the ^1H T_2 values are shown by dots. The solid line indicates the calculated one from the T_{1d} values derived. The broken line indicates the temperature variations of the diffusion constant, D, calculated from T_{1d} values.

If the monovacancy mechanism proposed by Torrey[34] and Sholl[35] is applicable for the self-diffusion of the cations in the present crystal, we have[4]

$$T_{1d}^{-1} = (36/5)\gamma^4\hbar^2 a_0^{-6}\omega^{-2}\tau_D^{-1}(S_0 - S_1/Z). \quad (9)$$

Here, a_0, τ_D, and Z are the lattice constant of the phase I, the correlation time of the self-diffusion, and the number of the nearest neighbors in the simple cubic sublattice formed by the cations, respectively. The numerical values of S_0 and S_1 are given in Sholl's paper.[35] When we derived Eq. 9, we used the condition of $\omega\tau_D \gg 1$. By introducing ^1H T_1 values observed to Eq. 9 and using Z=6, we could estimate τ_D at various temperatures.

The diffusion constant D of the cations in the crystal can be expressed as[36]

$$D = <r^2>/6\tau_D, \quad (10)$$

where $<r^2>$ is the mean-square jump distance of the cations, which is taken as a_0^2 in the monovacancy mechanism. The values of τ_D and D calculated using the above equations are shown in Fig. 6.

τ_D can be also calculated independently from the ^1H T_2 data determined using the relation written by[4]

$$T_2^{-1} = (27/20)\gamma^4\hbar^2 a_0^{-6}\tau_D g(0). \quad (11)$$

Substituting $g(0)$=17.98[35] into Eq. 11, we obtained τ_D as shown by dots in Fig. 6. The τ_D values derived from the T_2 values agree well with the line calculated from T_{1d}.

For $(MA)^+$ cations in the highest-temperature solid phase of $(MA)ClO_4$, the D value of the order of 10^{-13} $m^2 s^{-1}$ was obtained. The same order of D for the diffusion of the same cation was also obtained in the highest-temperature solid phase of $(MA)NO_3$.[4] It is

known that many plastic crystals which are formed by neutral molecules have analogous D values of ca. 10^{-13} $m^2 s^{-1}$ observed near their melting temperatures (T_m) although they are distributed over a wide range of temperature.[36] τ_D values obtained in the phase I are very similar to those of $(MA)NO_3$ and also of the plastic crystals. By extrapolation to higher temperatures, τ_D of $(MA)ClO_4$ at T_m can be obtained from the log τ_D vs. T^{-1} curve as ca. 3×10^{-8} s. This is close to the value of 9.8×10^{-8} s evaluated for $(MA)NO_3$[4] and also to those τ_C values of the plastic crystals forming a bcc lattice, which are ca. 1×10^{-7} s on the average.[36] These facts suggest that the highest-temperature solid phase of the ionic crystals of $(MA)ClO_4$ and $(MA)NO_3$ has solid state properties similar in many respects to those of the plastic crystals.

The activation energies for the self-diffusion of the cations calculated from the T_{1d} and T_2 data employing Eq. 5 are given in Table 1. The E_a values obtained from both relaxation values agree well with each other within experimental errors. These E_a values of $(MA)ClO_4$ are very close to that (35 kJ mol^{-1}) of (MA)I for the same motion,[2] whereas they are much higher than 28 kJ mol^{-1} obtained for $(MA)NO_3$.[4] Since these phases of the three salts containing diffusive $(MA)^+$ cations have the isomorphous CsCl-type cubic structure, the E_a values obtained can be compared by considering the differences in the shape and the size of the anions. The bulky and nearly spherical ClO_4^- anions and also bulky I^- anions seem to provide higher barriers for the translational jumps of the cations than the planar NO_3^- anions.[37]

The authors express their thanks to Mr. Yoshisato Funahashi and Mr. Gunzo Takamatsu of our machine shop for the construction of the NMR cryostat usable down to liquid helium temperature.

Molecular Dynamics Simulation of Liquid Water

Kazuo TOKIWANO† and Kiyoshi ARAKAWA*
Research Institute of Applied Electricity, Hokkaido University, Sapporo 060
†Faculty of Engineering, Hokkaido University, Sapporo 060
(Received August 7, 1986)

A molecular dynamics simulation has been performed for a fluid system containing 1000 water molecules confined to a cubical box at mass density 1 g cm^{-3}, where the ST2 type intermolecular potential has been used. Newtonian equations of motion of molecules were solved according to the method of constraints proposed by Ryckaert et al. Atomic radial distribution functions and corresponding partial structure functions at 24 and 93 °C were given and compared with theoretical calculations for the pentamer-monomer mixture model and neutron diffraction data. The agreement among the three was found to be satisfactory on the whole. In order to investigate how profoundly the periodic boundary condition influences upon the calculated values, the difference between the hydrogen-bonding behavior of molecules near the boundary and that of those in the central part of the box was examined into details. The population of hydrogen bonds near the boundary was found to be about 10% lower than that in the central part including about 210 molecules. In addition to these static properties the self-diffusion process was investigated.

The study of the properties of computer model has played a very important role in the development of the theories of liquid. It has been the case in the theories of molecular fluids. With respect to liquid water, such models have provided valuable information[1,2] necessary for constructing theoretical models of the liquid.[3,4] Since the first comprehensive works by Rahman and Stillinger,[1] simulation calculations of liquid water have been performed for various potential models such as ST2, MCY etc.,[5-14] though no decisive results have been obtained until present.

The equilibrium structure of a molecular fluid is described in terms of partial structure functions, $a_{ss'}(Q)$, which is related to atom pair (s,s') correlations. Recently, we have calculated three partial structure functions, $a_{OO}(Q)$, $a_{OH}(Q)$, and $a_{HH}(Q)$,[15] according to a theoretical calculation procedure[15-17] proposed for obtaining structure factors of a fluid composed of molecular clusters of various sizes. A substantial agreement was found between the calculated and experimental values.

In order to push forward the study of the liquid structure of water further, we have attempted, here, a computer simulation study for the fluid system containing 1000 water molecules. It is straightforward to calculate the partial structure functions $a_{ss'}(Q)$ and others using computer simulation techniques. In this paper we present first the results of partial structure functions obtained from the molecular dynamics simulation. The results are compared with neutron diffraction data[17,18] and our preceding theoretical calculations for the pentamer-monomer mixture model.[15,17] Further discussions on the simulation calculation are given.

Molecular Dynamics Simulations

As a model of liquid water we used the ST2 molecules of Stillinger and Rahman.[2] Molecular dynamics simulations were performed for a system of N=1000 water molecules confined to a cubical box, being subjected to periodic boundary conditions. The mass density was fixed at 1 g cm^{-3}, so that the cube edge length was 31.03 A. In evaluating potentials and forces the interaction between two molecules was neglected when the oxygen-oxygen distance was larger than a cut-off distance r_c. The cut-off was placed at r_c=8.46 A.

Newtonian equations of motion were solved by the method of constraints described by Ryckaert et al.[19] This method was devised originally to deal with the problem of large molecules having internal degrees of freedom, and it has a general applicability. The method of constraints is based on the cartesian equations of motion of individual atoms, being simple to implement. The time increment Δt for numerical integration of the equations of motion was taken to be

$$\Delta t = 1.0 \times 10^{-16}\ \mathrm{s}.$$

To take the molecular dynamics statistical average, we utilized a period of 10000 Δt. Molecular dynamics runs were generated at two distinct temperatures, 24 and 93 °C; they correspond to fixed total energies of $-110\ \varepsilon$ and $-91\ \varepsilon$ respectively, where ε is 0.07575 kcal mol^{-1} (1 cal=4.184 J). The total energy was monitored every 10 steps of Δt, and if it had drifted by $\pm 0.04\ \varepsilon$ (on the average every 500 steps) all velocities were rescaled to recover the initial energy value.

Results and Discussion

Radial Distribution Functions. Figures 1 and 2 show the atomic radial distribution functions $g_{OO}(r)$, $g_{OH}(r)$, and $g_{HH}(r)$ obtained from the molecular dynamics runs for the ST2 model for 24 and 93 °C, respectively.

Partial Structure Functions. The partial structure functions $a_{ss'}(Q)$ are related to the atomic radial distribution functions $g_{ss'}(r)$ by the expression

$$a_{ss'}(Q) = 4\pi\rho\int_0^\infty [g_{ss'}(r) - 1] r^2 j_0(Qr)\mathrm{d}r, \qquad (1)$$

where $j_0(x)=\sin x/x$, s and s' label nucleus species, and $Q=|\vec{Q}|$ ($\vec{Q}$: the scattering vector).

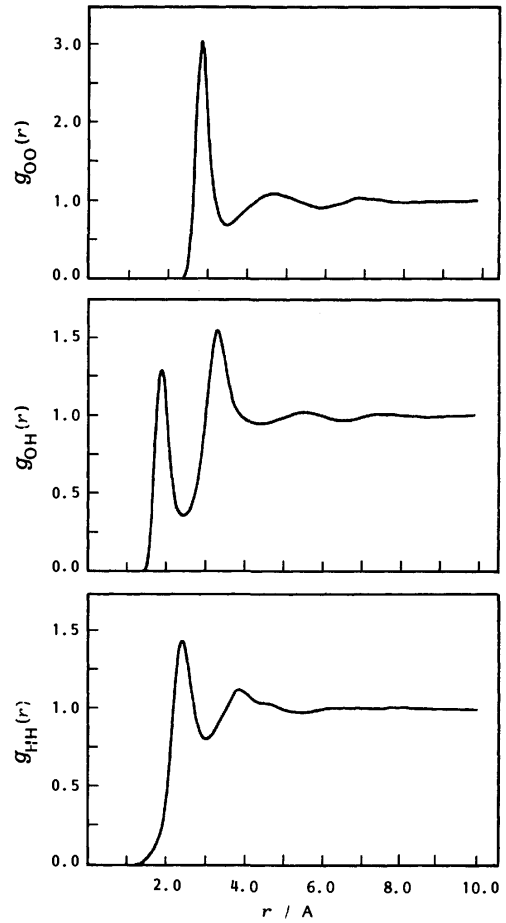

Fig. 1. Radial distribution functions at 24°C.

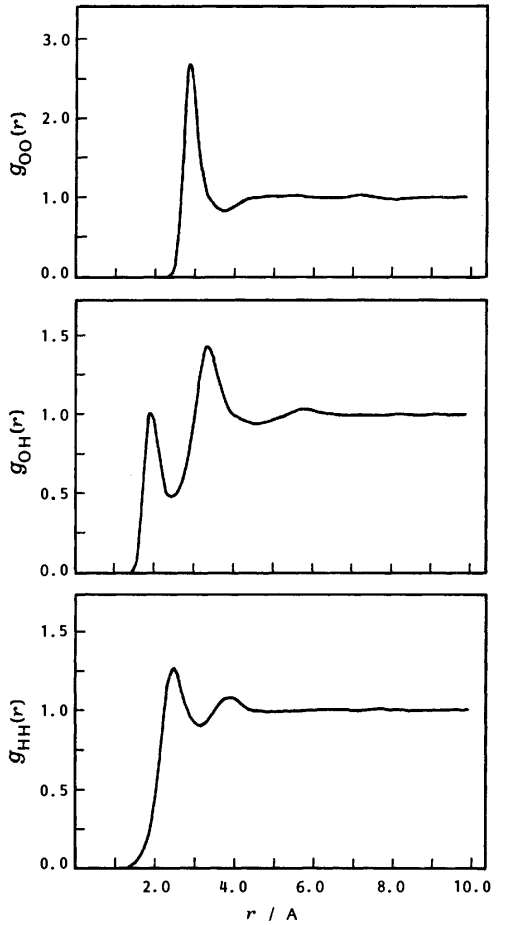

Fig. 2. Radial distribution functions at 93°C.

Now, we can calculate the partial structure functions $a_{ss'}(Q)$ for the ST2 model by using the molecular dynamics results of $g_{ss'}(r)$ given in Figs. 1 and 2. The calculated $a_{OO}(Q)$, $a_{OH}(Q)$, and $a_{HH}(Q)$ functions for 24°C are shown in Figs. 3—5, respectively, and are compared with the corresponding neutron diffraction data of Thiessen and Narten[18] as well as with the preceding theoretical calculations for the pentamer-monomer mixture model.[15] The agreement among those three is satisfactory on the whole.

We calculated the total coherent neutron structure factor $S_m(Q)$ by using the three partial structure functions $a_{ss'}(Q)$ given in Figs. 3—5. The structure factor $S_m(Q)$ is defined as a sum of partial structure factors $S_{ss'}(Q)$[15]

$$S_m(Q)=(b_O+2b_H)^{-2}[b_O^2S_{OO}(Q)+4b_Ob_HS_{OH}(Q)+4b_H^2S_{HH}(Q)], \quad (2)$$

where b_s is the coherent scattering length of nucleus s, and

$$S_{OO}(Q)=1+a_{OO}(Q),$$
$$S_{OH}(Q)=a_{OH}(Q)+Y_{OH}(Q),$$
$$S_{HH}(Q)=(1/2)+a_{HH}(Q)+(1/2)Y_{HH}(Q).$$

The $Y_{ss'}(Q)$ is generally approximated by

$$Y_{ss'}(Q)=j_0(Qr_{ss'})\exp(-\gamma_{ss'}Q^2),$$

where $r_{ss'}$ is the distance between the s and s' nuclei, and $(2\gamma_{ss'})^{1/2}$ the rms variation to the distance $r_{ss'}$. Figure 6 shows the calculated $S_m(Q)$ curve, together with the corresponding observed data[17] and the previous result for the pentamer-monomer mixture model.[17] As seen in Fig. 6, the present values are in good agreement with the observed data as well as with the ones for the pentamer-monomer mixture model.

Here, the $a_{OH}(Q)$ and $a_{HH}(Q)$ curves, shown in Figs. 4 and 5 respectively, are of particularly interest. First, taking account of experimental difficulties in determining partial structure functions, it can be said that the present $a_{OH}(Q)$ and $a_{HH}(Q)$ curves essentially reproduce the corresponding observed data, and also that the agreement between the $a_{OH}(Q)$ and $a_{HH}(Q)$ curves for the ST2 model and the pentamer-monomer mixture model is remarkably good on the whole. These results seem to show the effectiveness of the pentamer-monomer mixture model for describing the equilibrium structure of liquid water. The ST2 model has a strong tendency for water molecules to form tetrahedrally-coordinated structures. The dominance of a tetrahedral configuration as the local environment around a molecule on the average is essential for liquid water.

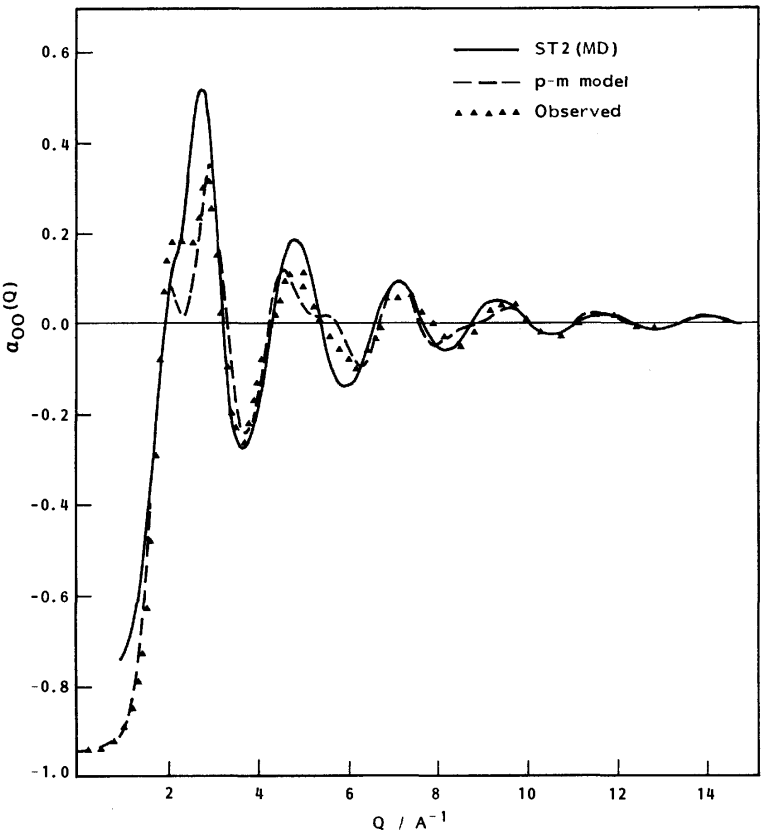

Fig. 3. O-O structure function $a_{OO}(Q)$ at 24°C in comparison with the observed data[18] and the calculated ones for pentamer-monomer mixture model (p-m model).[15]

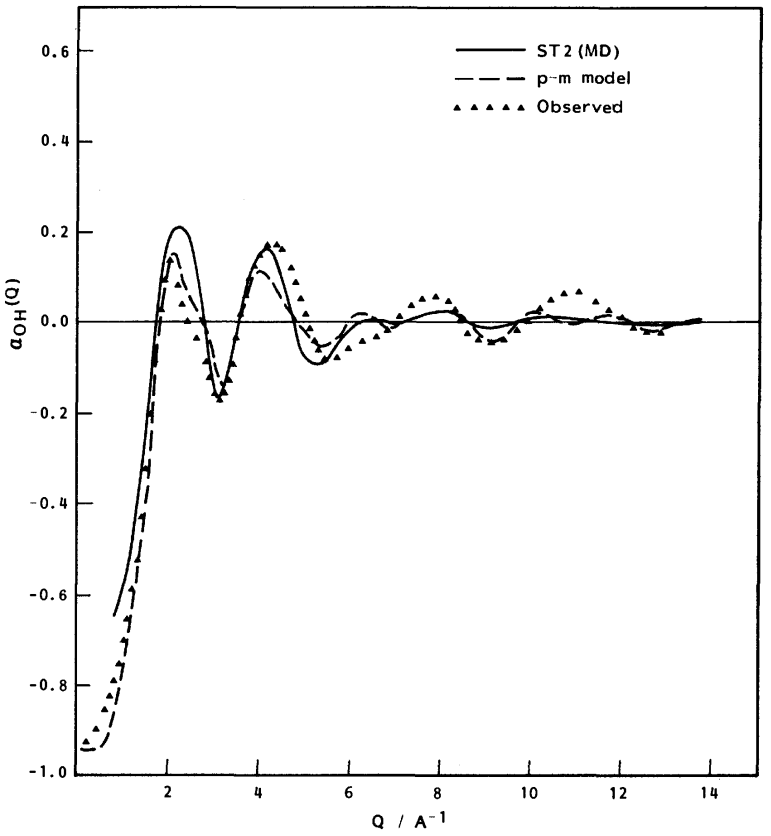

Fig. 4. O-H structure function $a_{OH}(Q)$ at 24°C in comparison with the observed data[18] and the calculated ones for pentamer-monomer mixture model.[15]

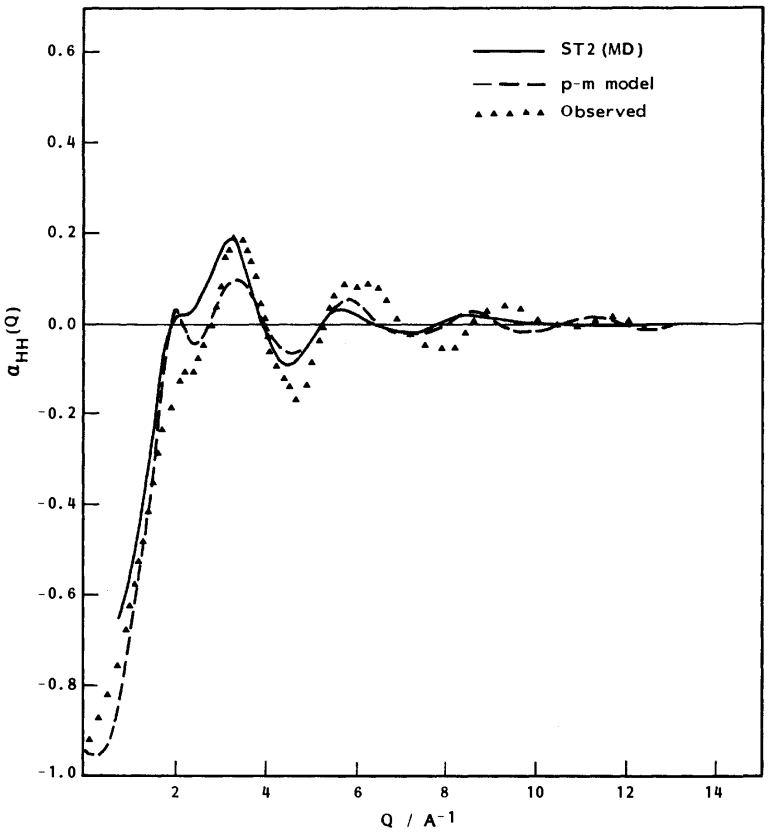

Fig. 5. H-H structure function $a_{HH}(Q)$ at 24°C in comparison with the observed data[18] and the calculated ones for pentamer-monomer mixture model.[15]

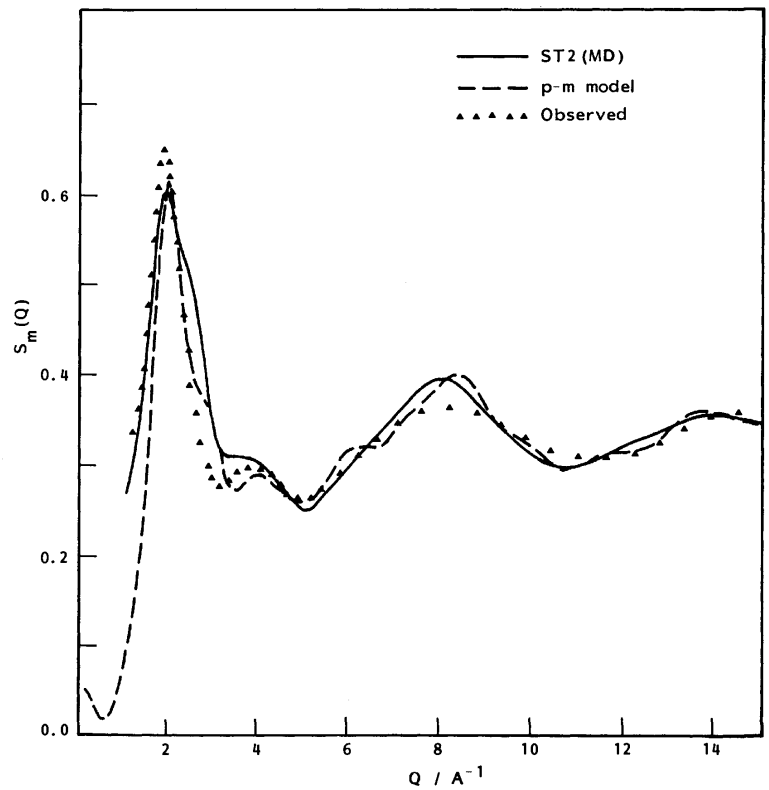

Fig. 6. Coherent neutron structure factor $S_m(Q)$ at 24°C in comparison with the observed data[17] and the calculated ones for pentamer-monomer mixture model.[17]

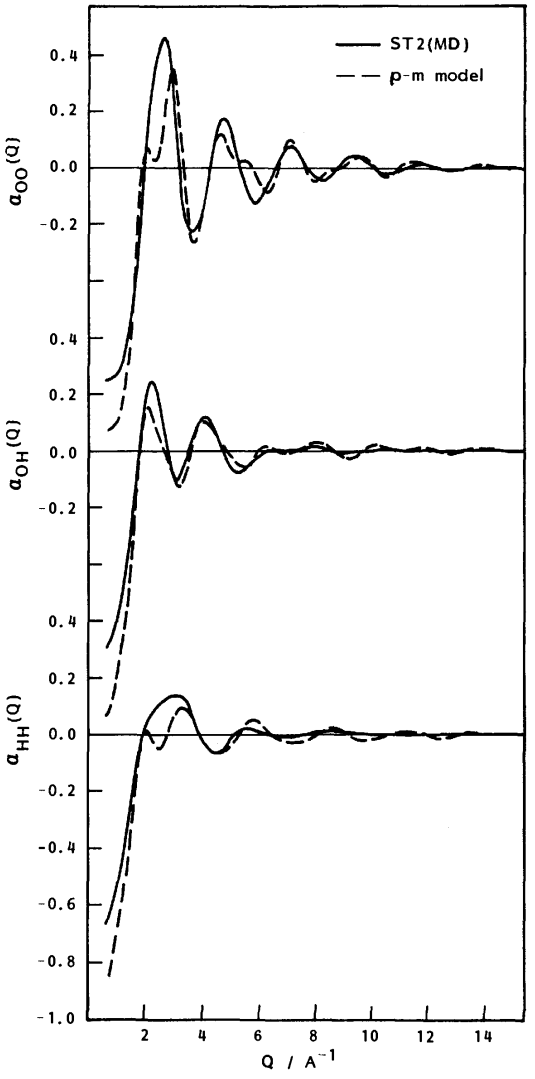

Fig. 7. Partial structure functions at 93°C in comparison with the corresponding ones calculated for pentamer-monomer mixture model.[17]

This feature should always be taken into consideration in constructing a theoretical model of water. In the pentamer-monomer mixture model, liquid water is regarded as an equilibrium mixture of the tetrahedral hydrogen-bonded pentamers and the non-hydrogen-bonded monomers.[3,17] The present results show that the pentamer-monomer mixture model can describe the overall structural properties of liquid water.

Seeing further details, some discrepancies are found for the $a_{OO}(Q)$ curves shown in Fig. 3; a double peak appears in the observed curve around Q=2.5 A^{-1}, but for the ST2 curve at 24 °C the double peak is quite less impressive and the right peak is too high. The similar situation was seen in the simulated X-ray scattering intensity curves due to Rahman and Stillinger for the BNS potential system at 34.3 °C.[1] An improvement is considered to be achieved by allowing the simulations to incorporate the nonrigidity of water molecules.[5,14]

In Fig. 7 the molecular dynamics $a_{ss'}(Q)$ curves for the ST2 system at 93 °C are given in comparison with the calculated curves for the pentamer-monomer mixture model. In Fig. 8 the $S_m(Q)$ curve for the ST2 system at 93 °C is shown, together with neutron diffraction data.[17]

Effects of the Periodic Boundary Conditions on Distributions of Hydrogen Bonds. In a molecular dynamics simulation of liquid systems, a periodic boundary condition is required in order to minimize surface effects, and the influences of artificial correlations imposed by the condition have been believed to be satisfactorily small for substantially large cells. For hydrogen-bonded fluids like water, however, there is a possibility that the periodicity condition affects the aspect of "hydrogen bonding" between molecules. In the following we examine the effects of the periodic boundary condition on distributions of hydrogen bonds.

In measuring the degree of hydrogen bonding, we follow a guideline due to Rahman and Stillinger.[1] If the interaction energy for a given pair of molecules lies below an assigned negative cut-off energy V_{HB}, the pair is hydrogen bonded and if their interaction equals or exceeds V_{HB}, they are not hydrogen bonded.

In order to see the degree of hydrogen bonding near the surface of the box, we classify molecules into two groups, and calculate separately the distributions of hydrogen bonds for each group;

$$\text{group I: } 0.2L < x_j, y_j, z_j < 0.8L$$

$$\text{group II: } x_j, y_j, z_j < 0.2L \text{ and } x_j, y_j, z_j > 0.8L$$

where L is the edge length of the cubic box and x_j, y_j, and z_j are the center of mass cartesian coordinates of molecule j.

In Fig. 9 we show the distributions of hydrogen bonds thus obtained for five different values of V_{HB}. These were determined by averaging over a period of 1000 Δt. From the comparison between the histograms for group I (about 210 molecules in the central part of the box) and those of group II (about 790 molecules near the surface), it is seen that the mean of the distribution for group II clearly shifts to lower numbers of hydrogen bonds. The population of hydrogen bonds which are destroyed near the surface is estimated roughly to be 10%. The cause of lowering of the degree of hydrogen bonding in group II is supposed as in the following. The periodic boundary condition clearly constrains the freedom of the molecules in motion near the surface of the box on the whole. This constraint subjected to the condition, probably that with respect to the rotationary degree of freedom of molecules, is considered resultantly to shift the degree of hydrogen bonding in group II to a lower magnitude than that in group I. Thus, it can be said that in the present simulation the molecules in group I (about 210 molecules) as the inner part resemble more exactly to the real water. In order to avoid such effects due to the

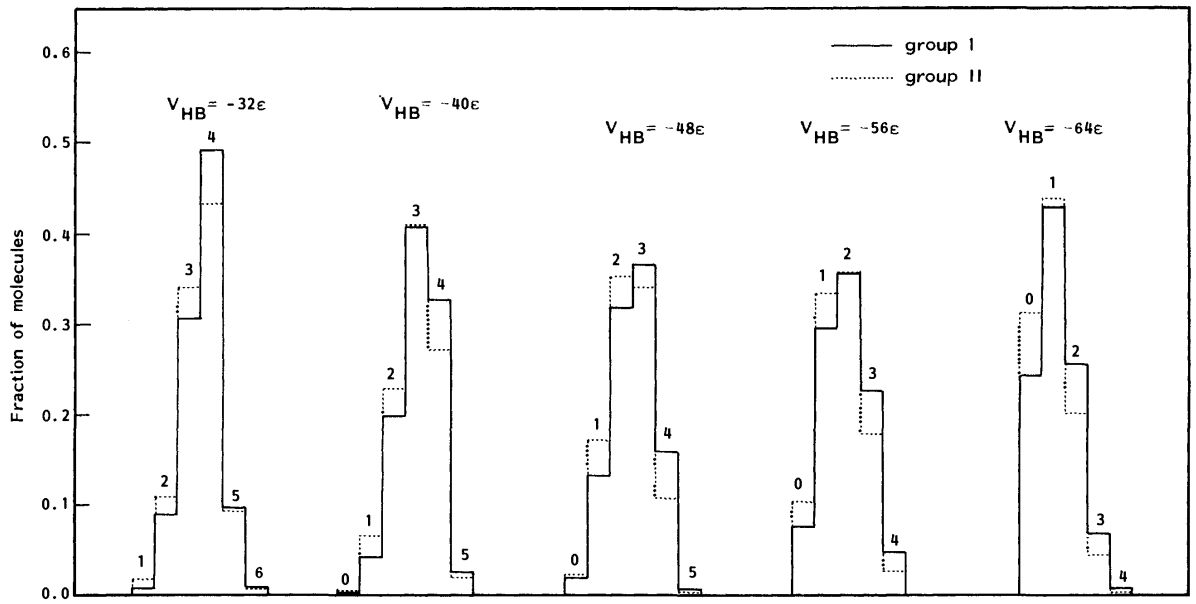

Fig. 9. Effects of periodic boundary conditions on distributions of hydrogen bonds. The results were obtained for 24°C.

periodic boundary conditions in a simulation of liquid water, the total number of molecules is desired to be as large as in the present simulation.

Self-Diffusion Process. The normalized velocity autocorrelation function for the molecular center of mass motion is given by

$$\psi(t) = <\frac{1}{N}\sum_j^N \vec{v}_j(0)\vec{v}_j(t)>/<\frac{1}{N}\sum_j^N \vec{v}_j(0)^2>, \quad (3)$$

where $\vec{v}_j$ is the center of mass velocity for molecule j. Figure 10 gives the normalized velocity autocorrelation function $\psi(t)$ at 24°C, including the simulation

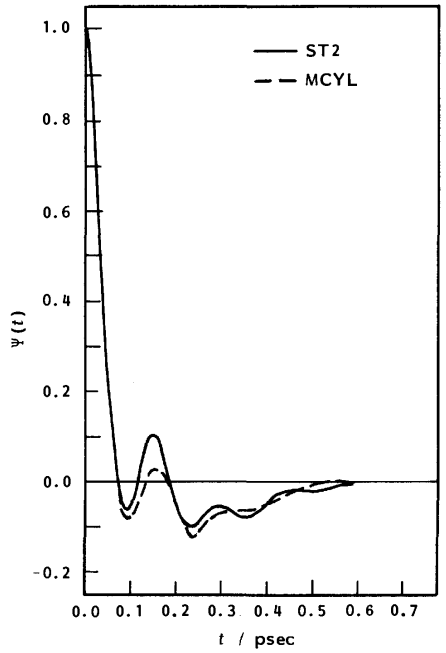

Fig.10. Velocity autocorrelation function for the molecular center of mass motion at 24°C in comparison with the ones for MCYL model given by Lie and Clementi.[14]

calculation of Lie and Clementi for the MCYL model at 27 °C.[14] The present result is consistent with the results of Stillinger and Rahman's simulations[2] expected at the corresponding temperature. Then, we find that the curves for the ST2 and MCYL models substantially resemble each other on the whole, although a more pronounced oscillatory behavior after the first negative region appears in the ST2 curve.

The self-diffusion coefficient D can be calculated by means of a Green-Kubo relation. Using the $\psi(t)$ curve given in Fig. 10, we obtain 2.8×10^{-5} cm^2s^{-1} for the ST2 model at 24 °C. This value is consistent with the results of Stillinger and Rahman extrapolated at the corresponding temperature.

An ENDOR Study of Diphenyl Nitroxide and Its Methyl Derivatives, The Effect of the Methyl Substitution

Jun YAMAUCHI,* Keiichi OKADA, and Yasuo DEGUCHI
College of Liberal Arts and Sciences, Kyoto University, Kyoto 606
(Received August 9, 1986)

The ENDOR spectra of diphenyl nitroxide (DPNO) and its monomethyl derivatives were observed in ethylbenzene at −70 °C. The agreement between the ESR and ENDOR data is generally good. The MO calculations, however, indicate a few disagreements in the case of the *m*- and *o*-methyl DPNO derivatives. The methyl substitution at the meta-position destroys the equivalency of all protons at the meta-positions, which are divided into two sets of equivalent proton groups of the same number. The ortho-substitution weakens the coplanarity of the two benzene rings and increases the number of the equivalent proton groups, which are fully resolved in the ENDOR spectrum. The steric hindrance is taken into account in the MO calculation, which can predict these slightly different coupling groups-again except for those in the meta-positions. A satisfactorily simulated spectrum of the *o*-methyl DPNO is obtained on the basis of the ENDOR data.

Previously two of the present authors (J.Y. and Y.D.) have investigated the hyperfine structures of several neutral radicals by means of the electron spin resonance (ESR).[1] In this work, diphenyl nitroxide (DPNO) and its methyl derivatives have been discussed in detail from the point of view of steric effect. The hyperfine coupling constants of the nitrogen and protons have been greatly affected in the case of the ortho-substituted compounds. The steric hindrance has weakened the coplanarity of the two benzene rings and caused a redistribution of the spin density such that the number of the equivalent proton group is increased, giving rise to complex ESR spectra. This must be one of the reasons why the ESR spectra of the ortho-methylated compounds could not be analyzed completely, whereas unambiguous analyses and assignment have been done for the other derivatives.

Electron nuclear double resonance (ENDOR) is the most useful for establishing the detailed proton hyperfine coupling constants in complicated ESR spectra.[2] Thus, the application of the ENDOR to the methylated DPNO derivatives was attempted in order to confirm the steric effect of the ortho-substituted compounds. As far as we know, there has been no such ENDOR work, not even on the parent compound DPNO. Thus, in this paper a proton ENDOR study is reported on DPNO and its monomethyl derivatives, with an emphasis placed on the *o*-methyl DPNO; the effect of the methyl substitution is also discussed.

Nitroxide radicals have previously been investigated extensively by means of ENDOR. For example, there are several works on the neutral nitroxide radicals containing aliphatic and/or aromatic substituent;[3-7] also the ^{14}N-ENDOR of the nitroxides is another interesting subject.[8-12] ESR investigations of DPNO have been made in a solid[13] and in solution.[1] DPNO shows two isotropic hyperfine coupling constants A_1=1.91 and A_2=0.82 G (1 G=10^{-4} T) in ethylbenzene.[14] These are assigned to the six equivalent protons at the ortho- and para-positions, and to the four equivalent protons at the meta-positions, respectively.[1] The para- or meta-substitution of a methyl group has little influence on the spin density distribution. Thus, the ESR spectra are easily explained by considering the increased proton number on the substituted position. Ortho-substituted DPNO, on the other hand, shows a drastic redistribution of the spin density because of strong bond-twisting.[1] Recently a short communication about a general triple resonance experiment on DPNO has been published.[14] The general triple resonance made possible the determination of the relative signs of the hyperfine coupling constants of the protons; that is, the two coupling constants, A_1 and A_2, of DPNO have opposite signs, in agreement with the earlier result.[13]

Experimental

DPNO and its derivatives are fairly unstable; thus, one should use a radical compound synthesized freshly in order to prepare a sample of its solution. Synthetic methods were described in the previous paper.[1] Solution samples for ENDOR measurements were prepared by the standard technique, using ethylbenzene as the solvent. The ESR and ENDOR spectra were recorded at −2 and −70 °C respectively for the best resolution.

The ENDOR spectrometer consists basically of a commercial JEOL FE-3X ESR spectrometer, with a JEOL ES EDX2 ENDOR accessory equipped with a TE_{011} cavity. Moreover, a broad-band ENDOR accessory equipped with a TM_{110} was built. This is similar to the one reported previously.[15] A simple block diagram is shown in Fig. 1. The TM_{110} cavity contains a silver solenoid of 20 turns (30 mm length, 7 mm o.d., made of silver wire 1 mm in diameter) directly mounted on a thin quartz tube; it is supplied with microwave power through a coupling iris which connects the cavity with the wave guide. With this device, it is easier to adjust the coupling between the cavity and the transmission line of microwave power than with the coaxial-line method. A frequency generator (Hewlett-Packard HP8601A) generates the radio-frequency, which passes through a broad-band power amplifier (ENI A300) and the solenoid. Finally, its power is dissipated in a 50 Ω oil-cooled resistor (TRIO RF DUMMY LOAD RD 300). A linear amp simultaneously sweeps the 6.5 KHz FM frequency of the oscillator and drives the *X*-axis of the *X*-*Y* recorder. The phase-sensitively detected changes of the absorbed microwave power generate the signal voltage,

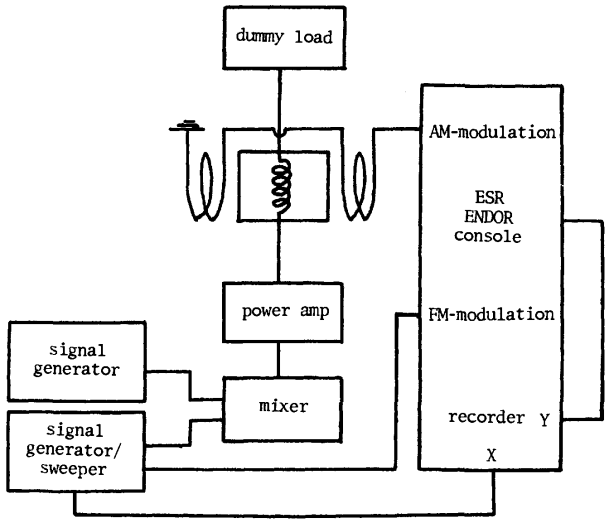

Fig. 1. A block diagram for ENDOR and triple experiments using a TM_{110} mode cavity.

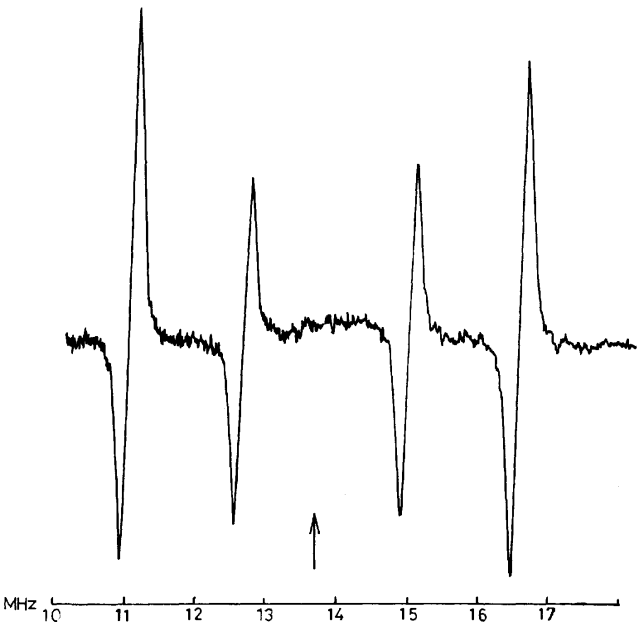

Fig. 2. ENDOR spectrum of DPNO in ethylbenzene at −70°C. The arrow indicates the frequency of free proton.

driving the Y-axis of the recorder. The ENDOR signals are observed in the systems of both TE_{011} and TM_{110} cavities. In the spectra themselves, there are no essential differences. However, the TM_{110} cavity system surely has certain advantages, as has been pointed out elsewhere[11,14-16] The ENDOR spectra shown in this paper were all recorded by means of the TM_{110} cavity.

Results

The ENDOR spectrum of DPNO is shown in Fig. 2, from which one can recognize that the protons on both benzene rings are to be classified into two different sets, such as one group of para- or ortho-protons and

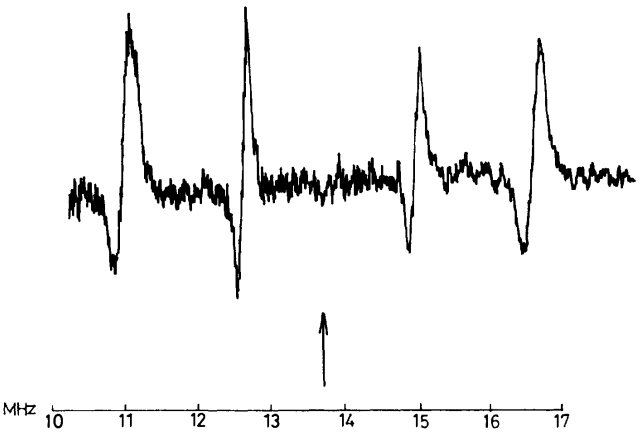

Fig. 3. ENDOR spectrum of *p*-methyl DPNO in ethylbenzene at −70°C. The arrow indicates the frequency of free proton.

another group of meta-protons. Features similar to those in DPNO appear in the cases of *p*-methyl and *m*-methyl DPNO (Figs. 3 and 4). The ortho-methylated derivative of DPNO, however, shows a fairly different appearance in its ENDOR spectrum, as is shown in Fig. 5; firstly, the overall width of the spectrum is about 8 MHz, about 2 MHz larger than that of DPNO. Secondly, the weak ENDOR absorption lines due to several sets of equivalent protons can be observed. The proton hyperfine coupling constants determined from the ENDOR spectra are summarized in Table 1, in which the data obtained from the ESR spectra are also listed for comparison. Two of the present authors (J.Y. and Y.D.) could not analyze the ESR spectrum of the *o*-methyl DPNO, but at this time the ESR spectral analysis could be made on the basis of the ENDOR results and the spectrum could be simulated using the hyperfine coupling constants listed in the table.

Discussion

The agreement between the ESR and the ENDOR data is excellent, except in the case of *o*-methyl DPNO. For further comparison, the usual MO calculations were performed. The same MO parameters as in the previous paper were employed for the simple Hückel and McLachlan methods. Thus, the theoretically calculated hyperfine coupling constant in each position is also shown in Table 1, where the McConnel relation between the spin density and the hyperfine coupling constant is applied with a proportionality constant of $|Q|=27.3$ G. The calculations also support the assignment which has been made mainly on the basis of the ESR simulation. Here a comment about *m*-methyl DPNO is appropriate. In this radical, both ESR and ENDOR assure two kinds of equivalent proton sets in the meta-positions. The inner pair of absorption lines in DPNO and its *p*-methyl derivative splits into two lines *m*-methyl DPNO, giving 814 and 577 mG splittings. These are also ascertained by the ESR simulation; 810 and 580 mG. However, the equivalent proton numbers of both hyperfine coupling constants are found to be the same, so that there is no way to assign the larger hyperfine coupling to the methyl or the other meta-protons. Deuteron substitution (for example, trideuteriomethyl substitution at the meta-position) would be necessary to solve this problem. On the other hand, the MO calculation predicts only a minor difference, less than 30 mG, between

a) A twisted angle of 45° is assumed. b) A twisted angle of 60° is assumed. c) A proportionality constant of $|Q|=27.3$ G is assumed so that the DPNO value is reprodued.

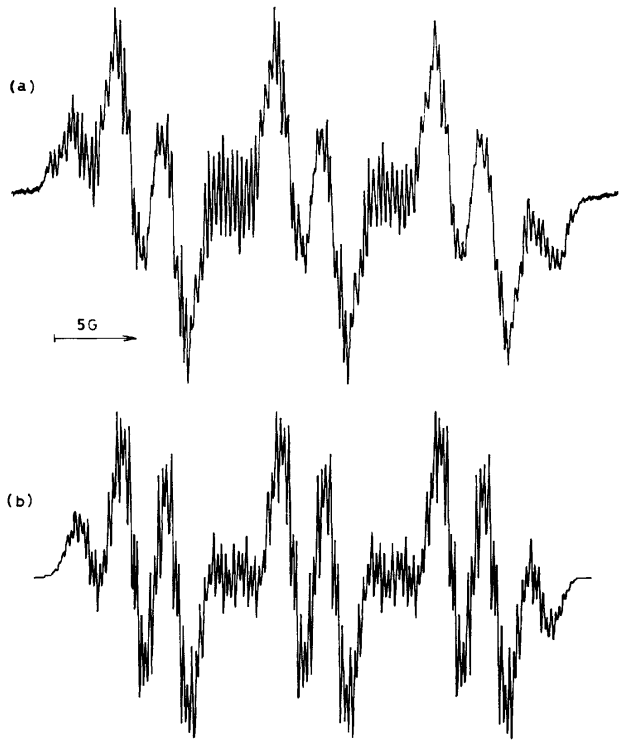

Fig. 6. ESR(a) and simulated(b) spectra of *o*-methyl DPNO.

these positions. We have no reasonable explanation about this discrepancy at present. In Table 1, therefore, the larger hyperfine coupling constant is assigned temporarily to the *m*-methyl protons, following the MO calculation.

The fact that the overall width of the ENDOR spectrum of *o*-methyl DPNO is larger than that of DPNO implies that the steric hindrance effect of the methyl group substituted at the ortho-position of the benzene ring is dominant in this case; that is, there is a greater population of electron on the N-O bond and the benzene ring of no-methyl substitution than on the twisted tolyl ring. In the earlier ESR, only the biggest proton coupling (2.70 G) was recognized except for the nitrogen one, which gave a quartet appearance in the spectrum (Fig. 6). A similar value, although the absorption line is slightly split, is also observed this time in the ENDOR spectrum (Fig. 5), from which three additional sets of equivalent protons are revealed in the smaller splitting groups. In a more highly sensitive spectrum, it seems that the smaller two groups split into two splittings further, as is shown in Fig. 5. All these slightly different values obtained experimentally can be predicted by the theoretical MO calculations, assuming the sterically hindered rotation of one phenyl ring containing the substituted methyl group away from the remaining π-electron framework, which includes the N-O nitroxide group. This assumption has been discussed in detail in the previous paper,[1] where a twisted angle of 55—60° was anticipated for a proton-methyl proton repulsion case. In Table 1 the results of the MO calculation (a twisted angle of 60° is assumed) are compared with the experimental results; the fit is excellent except for the second biggest proton coupling, which is assigned to the meta-positions of the unsubstituted benzene ring. Considering the tendency of the other protons, it is rather difficult to understand this value. The steric hindrance makes the unpaired electron highly populated on the ortho- and para-positions of the unsubstituted benzene ring. Nevertheless, the meta-proton hyperfine coupling constant increased less than 10%, whereas a 40% increase is observed in the para- and ortho-positions. On the other hand, the MO calculations show that all positions of the unsubstituted benzene ring are equally influenced to localize the unpaired electron ca. 40% more and that the calculated hyperfine coupling constants, except for this meta-position, are in good agreement with the experimental values. This quantitative singularity at the meta-position, together with the discrepancy discussed in the *m*-methyl DPNO, may be relevant to a special characteristic of the meta-positions of the benzene rings, that is, a negative spin density. A more sophisticated MO treatment and/or steric hindrance mechanism is necessary. This will be commented on in the Discussion section later. At any rate, the comparatively good agreement surely supports the validity of the steric hindrance mechanism developed in the earlier paper.[1]

The ESR simulation was carried out on the basis of the ENDOR results. DPNO and its *p*-methyl derivative are straightforward, and the *m*-methyl DPNO is almost the same. Even a stick-diagram construction can yield reliable values. It is found that the coupling constants of the *m*-methyl DPNO, 810 and 560 mG, which are assigned to the meta-positions, should be taken into account so as to produce quartet splittings. This means that three protons in each group should contribute as an equivalent proton group. Then the well-simulated spectrum can be reproduced. The assignment, however, is still ambiguous, although it is narrowly evidenced by the MO calculation. For the *o*-methyl DPNO, there are many sets of equivalent protons so that the assignment seems to be really intuitive for the smaller coupling groups. According to the MO calculation, however, the magnitude of the hyperfine coupling constants agrees well with the experimental values; thus, one can assign each hyperfine coupling so as to satisfy the order of its magnitude. Furthermore, if one takes into account several experimental facts, for instance, the facts that the ortho- and para-proton hyperfine coupling constants are almost equal and are bigger than the meta-protons, or that the unpaired electron is highly localized on the unsubstituted benzene ring, the analysis can be nearly perfect. By changing the coupling constants little by little from the ENDOR values we finally come to the simu-

lated spectrum shown in Fig. 5. Of course, a minor modification would still be necessary to complete it. Generally speaking, however, the ESR data of the sterically hindered *o*-methyl DPNO in Table 1 are considered to be reasonable.

The general triple resonance of DPNO was described in an earlier communication,[14] where it was clarified that the two hyperfine coupling groups of the meta- and para- or ortho-positions have opposite signs. Usually one may assume a positive spin density on the carbon atoms at the para- and ortho-positions and, therefore, a negative spin density at the meta-positions, as has been evidenced by several MO calculations. This means that the spin density on the carbon atoms at the meta-positions is rather small but, on the contrary, is easily influenced by many factors, for example, MO parameters, substituents, steric rotations, and solvents. Therefore, the discrepancy and the singularity observed in the meta-positions in this experiment may be attributed to these properties. To solve the problem, more precise work, such as deuteron substitution, a study of the solvent effect, and triple experiments for the methylated DPNO, will be necessary.

In conclusion, the ENDOR study supports the previous ESR work. In the para- and meta-methylated DPNO, only a few modifications of DPNO are necessary; that is, the methyl substitution in such positions results in little change in the spin density distribution. The ortho-methylated DPNO is twisted at one N–C bond, which is attached to the substituted benzene ring. The data calculated on the assumption that the twisted angle is 60° are reasonable and consistent with the spin density distribution and the steric hindrance consideration discussed previously.[1] We observed a minor but clear discrepancy and singularity in the meta-positions of the meta- or ortho-substituted DPNO.

Oxygen-17 NMR Study of the Uranyl Ion. IV.[1] ^{17}O Nuclear Magnetic Relaxation and Chemical Shifts of Uranyl Oxygen Atoms and Coordinated Water

Woo-Sik Jung, Hiroshi Tomiyasu, and Hiroshi Fukutomi*
Research Laboratory for Nuclear Reactors, Tokyo Institute of Technology,
O-okayama, Meguro-ku, Tokyo 152
(Received August 13, 1986)

^{17}O nuclear magnetic relaxation times and chemical shifts of uranyl oxygen atoms (hereafter uranyl oxygens) and solvent water have been measured with changing concentration of the uranyl ion in aqueous solution. The ^{17}O resonance of the water molecule in the first-coordination sphere is determined to be at 90.1±1.2 ppm relative to free water at 25 °C. The effective correlation time for the ^{17}O quadrupolar relaxation of the coordinated water, which corresponds to the reorientation time for the hydrated uranyl ion, is about 8.7 times that of free water. The ^{17}O spin-lattice relaxation times (T_1) of uranyl oxygens have been measured at 25 °C. From the ^{17}O T_1 values the ^{17}O nuclear quadrupole coupling constant of uranyl oxygens has been estimated to be 0.44 MHz. This small value implies the high symmetry of electron distribution around uranyl oxygens.

Although ^1H resonances of the water molecule in the first-coordination sphere of a uranyl ion (UO_2^{2+}) have been observed,[2-5] it is impossible to observe directly the ^{17}O resonance of the coordinated water even at low temperature. The ^{17}O nuclear magnetic relaxation of acidified water is dominated by a quadrupolar relaxation process,[6] which is brought about by interaction of the nuclear electric quadrupole moment with fluctuations of the electric field gradient (EFG) at the oxygen nucleus. The equality of T_1 and T_2 (spin-spin relaxation time) holds for acidic solutions of pure water. In the limit of extreme narrowing, the ^{17}O longitudinal relaxation rate follows Eq. 1,[7]

$$\frac{1}{T_1} = \frac{12\pi^2}{125}\left(1+\frac{\xi^2}{3}\right)\left(\frac{e^2qQ}{h}\right)^2\tau_c, \quad (1)$$

where ξ is an asymmetry parameter of the electric field gradient, e^2qQ/h the quadrupole coupling constant (QCC) in Hz, h the Planck constant, and τ_c the effective correlation time for molecular reorientation. Approximate estimate of τ_c for isotropic tumbling may be made by application of the modified Stokes-Einstein-Debye formula,

$$\tau_c = 4\pi r^3 f\eta/3k_BT, \quad (2)$$

where f is the Gierer-Wirtz microviscosity correction factor,[8] r the molecular radius, η the viscosity, k_B the Boltzmann constant, and T the absolute temperature.

The τ_c value is expected to increase for water coordinated to diamagnetic ions in aqueous solution, thus causing the broadening of the ^{17}O resonance. If the exchange reaction of water between free and coordinated water in the ions is very fast, a single ^{17}O resonance of water is observed, which corresponds to the average of resonances in these environments.

In order to elucidate the behavior of the coordinated water in the uranyl ion, we have measured linewidths and chemical shifts of ^{17}O resonances of solvent water with changing concentration of the uranyl ion in aqueous solution. ^{17}O relaxation times of uranyl oxygens have been also measured and an ^{17}O QCC value of uranyl oxygens has been estimated.

Experimental

Uranyl nitrate hexahydrate $UO_2(NO_3)_2\cdot 6H_2O$ was purified by the extraction into diethyl ether from ammonium nitrate solution and recrystallized twice from aqueous solution. Preparation of uranyl perchlorate pentahydrate $UO_2(ClO_4)_2\cdot 5H_2O$ and ^{17}O-enriched uranyl oxygens has been described elsewhere.[9] The concentrations of uranyl ions were calculated on the assumption that the hydration number of the uranyl ion is 5.[4] The ^{17}O NMR spectra were obtained with a JEOL JNM-FX 100 FT-NMR spectrometer operating at 13.46 MHz. The measurements were performed with a 5-mm o.d. NMR sample tube, which was immersed in a 10-mm o.d. concentric NMR tube containing $(CD_3)_2CO$ (Merck). The samples were not degassed since the presence of oxygen makes no effect on the ^{17}O linewidth.[10]

Full linewidths ($\Delta\nu$) at half height were determined by a least-squares Lorentzian lineshape-fitting procedure. The positive chemical shift is downfield relative to the reference signal. Samples for measurements of ^{17}O linewidths and spin-lattice relaxation times of uranyl oxygens were prepared by the same method as described in the previous paper.[9] The ^{17}O T_1 measurements, which were carried out at 54.10 MHz on a JEOL JNM-GX 400 FT-NMR spectrometer, were made by using the inversion recovery pulse sequence.

Results and Discussion

^{17}O Chemical Shifts of Coordinated Water. ^{17}O chemical shifts of uranyl oxygens relative to solvent water tend to decrease with increasing concentration of the uranyl ion in nitrate solution, as shown in Fig. 1. If one adopts $(CD_3)_2CO$ as a reference for ^{17}O chemical shifts, it is possible to know how the concentration of the uranyl ion affects the respective ^{17}O chemical shifts of uranyl oxygens and solvent water. An example of the results is illustrated in Fig. 2. The ^{17}O chemical shifts of uranyl oxygens increase linearly with increasing concentration of the uranyl ion, where $d\delta(^{17}O)/d[UO_2^{2+}]=1.7$ ppm m^{-1} at 25 °C. This value is larger than that for the uranyl perchlorate complex,[1] and

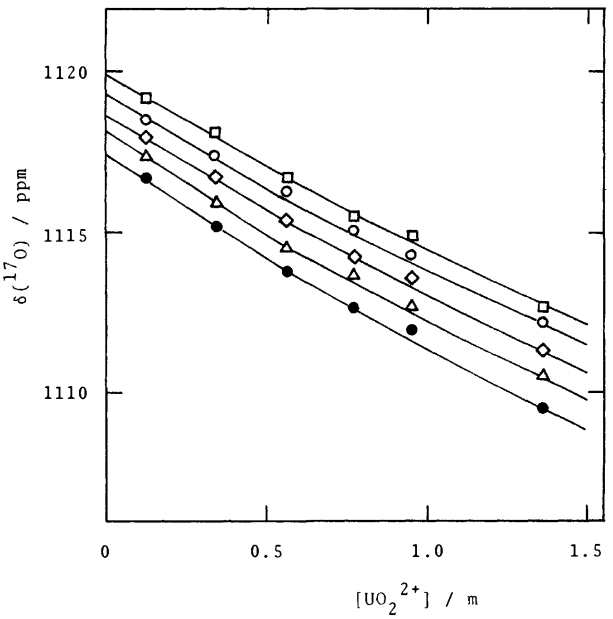

Fig. 1. Dependence of ^{17}O chemical shift of uranyl oxygens (relative to solvent water) on $[UO_2^{2+}]$ in nitrate solution at 20 (●), 25 (△), 30 (◇), 35 (○), and 40 (□)°C; 1 m=1 mol kg^{-1}.

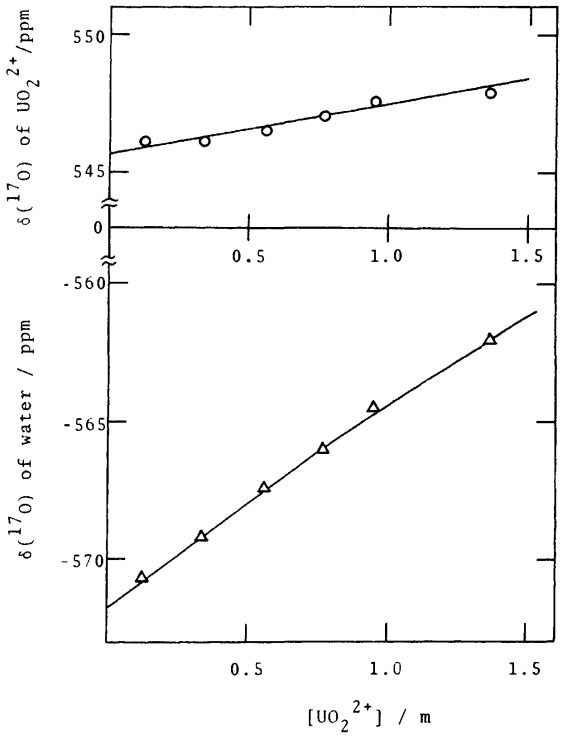

Fig. 2. Effects of $[UO_2^{2+}]$ on ^{17}O chemical shift (relative to acetone-d_6) of uranyl oxygens (○) and solvent water (△) in nitrate solution at 25°C.

this result is attributed to the formation of $UO_2NO_3^+$, the ^{17}O chemical shift of which is larger than that of UO_2^{2+} ion by 4.9 ppm at 25 °C.[1]

On the other hand, the ^{17}O resonances of solvent water shift downfield and the plot of $\delta(^{17}O)$ vs. $[UO_2^{2+}]$ deviates slightly from a linear relationship with increasing $[UO_2^{2+}]$ as shown in Fig. 2. This arises from the fact that since the exchange of water between free and coordinated water in the uranyl ion is very fast,[2,11] the observed ^{17}O resonance is the average of the resonances in these environments. The observed ^{17}O chemical shift is given by

$$\delta(^{17}O)_{obsd} = P_f\delta_f(^{17}O) + P_c\delta_c(^{17}O), \quad (3)$$

where P_f (or $\delta_f(^{17}O)$) and P_c (or $\delta_c(^{17}O)$) are mole fractions (or chemical shifts) of free and coordinated water, respectively. Assuming that the effect of NO_3^- ions on ^{17}O chemical shifts of water is negligible,[12] we calculated $\delta_f(^{17}O)$ and $\delta_c(^{17}O)$ by a nonlinear least-squares method. The results obtained are listed in Table 1. The ^{17}O chemical shifts of free water relative to $(CD_3)_2CO$ are in good agreement with the literature value.[13]

Figure 3 shows that the difference in ^{17}O chemical shift between free and coordinated water decreases with increasing temperature. Since $d\delta(^{17}O)/dT$ for

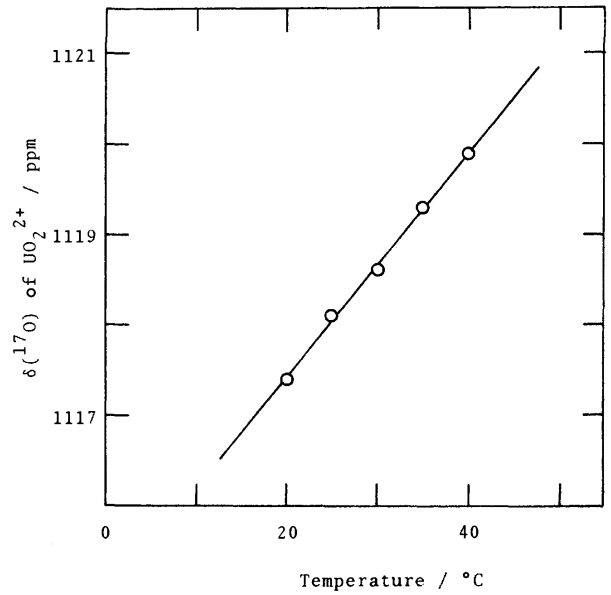

Fig. 4. Temperature dependence of ^{17}O chemical shift of uranyl oxygens (relative to pure water) at infinite dilution of the uranyl ion.

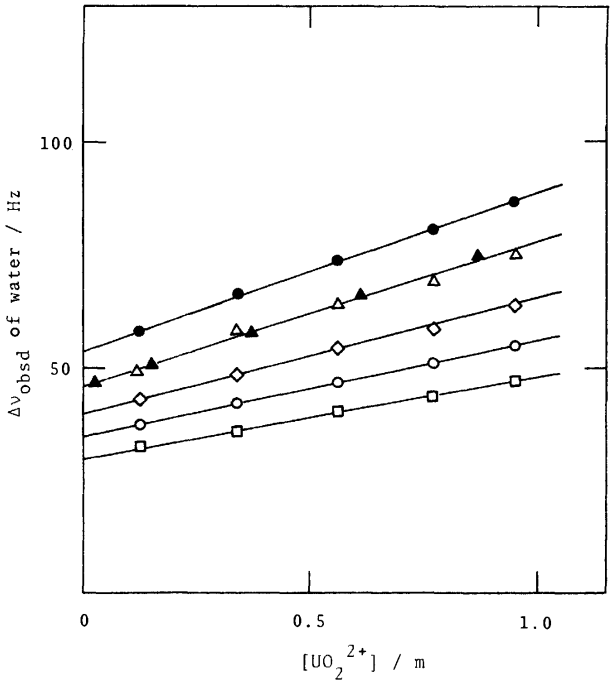

Fig. 5. Dependence of ^{17}O linewidth of solvent water on $[UO_2^{2+}]$ in nitrate solution at 20 (●), 25 (△), 30 (◇), 35 (○), and 40 (□)°C; 25°C (▲), in perchlorate solution.

pure water is −0.03 ppm °C^{-1},[12] then $d\delta(^{17}O)/dT$ for the coordinated water was calculated to be 0.52 ppm °C^{-1} from the slope in Fig. 3. The ^{17}O chemical shift of uranyl oxygens relative to free water at infinite dilution of the uranyl ion is given by (1114.9±0.1)+(0.12±0.01)×Temp (°C) as shown in Fig. 4. The second term agrees with the difference in $d\delta(^{17}O)/dT$ between uranyl oxygens (+0.087 ppm °C^{-1})[1] and pure water.

^{17}O Relaxation Times of Coordinated Water. The dependence of ^{17}O linewidth ($\Delta\nu_{obsd}$) of solvent water on $[UO_2^{2+}]$ is shown in Fig. 5. Assuming that the viscosity of the solution studied is equal to that of pure water and the rate of water exchange is slow relative to the rate of molecular reorientation,[14] $\Delta\nu_{obsd}$ is given by

$$\Delta\nu_{obsd} = P_f \Delta\nu_f + P_c \Delta\nu_c, \quad (4)$$

where $\Delta\nu_f$ and $\Delta\nu_c$ are linewidths of free and coordinated water, respectively. The values of $\Delta\nu_f$ and $\Delta\nu_c$ calculated by a nonlinear least-squares method are listed in Table 1. From the results that the values of $\Delta\nu_f$ and $\Delta\nu_c$ for the nitrate complex agree with those for the perchlorate complex within experimental errors (Fig. 5), the effect of formation of the $UO_2NO_3^+$ complex[1] on $\Delta\nu_c$ and $\Delta\nu_f$ is considered to be negligible in the concentration range studied.

Table 1 shows that the $\Delta\nu_f$ values are consistent with linewidths of pure water in the literature[15] within experimental errors and that the average ratio of $\Delta\nu_c$ to $\Delta\nu_f$, $(\Delta\nu_c/\Delta\nu_f)_{av}$, is about 8.7. Since an external charge has only a negligible effect on the ^{17}O electric field gradient of water,[16,17] the ^{17}O QCC and the asymmetry parameter of the coordinated water can be assumed to be the same as those of pure water (QCC=6.68 MHz; ξ=0.93).[16] The $(\Delta\nu_c/\Delta\nu_f)_{av}$ value should be, therefore, equal to the ratio of the tumbling time (τ_c) between coordinated and free water. The τ_c value for the coordinated water can be estimated from Eq. 2 on the assumption that the radius (3.82 Å) of the hydrated uranyl ion is taken to be the sum of the van der Waals radius (1.40 Å) of oxygen and the distance (2.42 Å)[4] between the uranium atom and the water of hydration. The estimated value of τ_c (1.9×10^{-11} s) at 25 °C for the coordinated water is longer than that (2.5×10^{-12} s) for pure water by a factor of 7.6, which is close to $(\Delta\nu_c/\Delta\nu_f)_{av}$. This supports the idea that the effective correlation time for the ^{17}O quadrupolar relaxation of the coordinated water in the uranyl ion corresponds to the reorientation time for the hydrated uranyl ion. It is worth noting that for 2+ diamagnetic ions such as Ca^{2+}, Mg^{2+}, and Cd^{2+}, τ_c for the water molecule in the first-coordination sphere corresponds to intramolecular rotation around the metal-oxygen axis.[18]

The quadrupolar relaxation rate is usually well represented by an Arrhenius-type function

$$1/T_2 = A \exp(E_Q/RT), \quad (5)$$

where E_Q is an activation energy for the reorientation. Plots of $\ln\Delta\nu_c$ or $\Delta\nu_f$ vs. $1/T$ were linear in the temperature range studied. The activation energies for free and coordinated water were determined to be 22.4±0.1 and 24.8±0.8 kJ mol^{-1}, respectively.

^{17}O Relaxation Times of Uranyl Oxygens. We measured ^{17}O T_1 relaxation times of uranyl oxygens (enriched by using $H_2{}^{17}O$ (42.1 atom%)) in aqueous

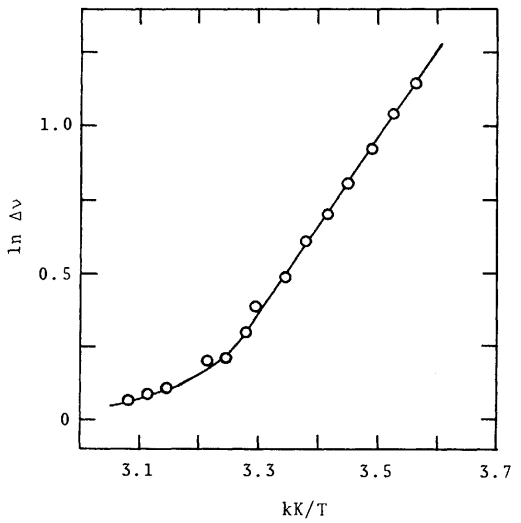

Fig. 6. A semilogarithmic plot of ^{17}O linewidths of uranyl oxygens against the reciprocal temperature. $[UO_2^{2+}]$=0.5 m and $[H^+]$=0.1 m in nitrate solution.

perchlorate solution ($H_2O:D_2O$=1:1 by weight), where $[UO_2^{2+}]$=0.098 m and $[H^+]$=0.23 m. The T_1 values were determined to be 0.245±0.001, 0.227±0.001, and 0.244±0.001 s at 25 °C for $[^{16}O=U=^{17}O]^{2+}$, $[^{17}O=U=^{17}O]^{2+}$, and $[^{18}O=U=^{17}O]^{2+}$, respectively. In view of the fact that three T_1 values become equal with increasing temperature,[19] the slightly smaller T_1 value for $[^{17}O=U=^{17}O]^{2+}$ may be attributed to overlapping of three ^{17}O resonances. When the values of 1.0 cp and 3.82 Å are taken as the viscosity of the solution studied and the molecular radius, respectively, the τ_c value for the hydrated uranyl ion was calculated to be 2.2×10^{-11} s from Eq. 2. The ^{17}O QCC of uranyl oxygens can be obtained from Eq. 1 by using values of T_1 (0.245 s) and τ_c and taking the asymmetry parameter ξ to be zero. The value obtained is 0.44 MHz, which appears to be the smallest of previously measured ^{17}O QCC values. For tetrahedral molecules such as MoO_4^-, RuO_4, and OsO_4, ^{17}O QCC's have been reported to be 0.72,[20] 1.12,[21] and 0.967 MHz,[21] respectively. The significantly small ^{17}O QCC of uranyl oxygens implies the high symmetry of the electron distribution around uranyl oxygen atoms.

We also measured ^{17}O linewidths of a $[^{16}O=U=^{17}O]^{2+}$ isotopomer in aqueous nitrate solution ($H_2O:D_2O$=1:2 by weight), where $[UO_2^{2+}]$=0.5 m and $[H^+]$=0.1 m. Figure 6 shows that an Arrhenius plot of the ^{17}O linewidth against temperature indicates a marked change in the activation energy around 40 °C. This result resembles the results of dynamic behavior of water, e.g. rotational[22] or translational processes,[23] where activation energies for both types of processes decrease with temperature. The activation energy obtained from Fig. 6 is 24.2±0.3 kJ mol^{-1} in the low-temperature range (7—35 °C). The activation energy value is very close to that for ^{17}O quadrupolar relaxation rate of the water molecule in the first-coordination sphere of the uranyl ion, indicating that there is a similarity in ^{17}O quadrupolar relaxation mechanisms between the uranyl oxygens and the coordinated water.

The authors wish to express their thanks to Dr. Kazumi Hata of JEOL, Ltd. for T_1 measurements on a JEOL JNM-GX 400 FT-NMR spectrometer.

Conductance of Potassium Iodide in Supercooled Water

Masaru NAKAHARA* and Masanobu ZENKE[1)]
Department of Chemistry, Faculty of Science, Kyoto University, Oiwake-cho, Kitashirakawa, Sakyo-ku, Kyoto 606
(Received August 22, 1986)

The conductance of potassium iodide was measured in water as a function of concentration (between 2×10^{-3} and 10^{-2} mol dm^{-3}) and temperature (between −6 and 0 °C). The effect of temperature on the mobility of such halide ions as I^- and Cl^- ions was discussed by taking the ionic residual friction coefficient $\Delta\zeta$, which was defined as the overall friction coefficient subtracted by the Stokes one for slip, instead of the conventional Walden product. We compared the experimental results with the predictions due to the Hubbard-Onsager dielectric friction theory. Of the monovalent ions so far studied, the iodide ion shows the largest negative value of $\Delta\zeta$ with the largest positive temperature coefficient; their signs are opposite to those theoretically predicted. These findings were explained in terms of the special ionic transport mechanism called the passing-through-cavities.

The conductivity measurement in electrolyte solution has made a great contribution to our understanding of the dynamic and static properties of electrolyte solution because of its high sensitivity and the availability of the single-ion property. We can probe the ion-ion and ion-solvent interactions through the concentration dependence of molar conductance and its limiting value, respectively; the latter quantity is involved in a theoretical equation of conductance to be determined experimentally. As reviewed elsewhere,[2,3)] however, our attention is now focused on the dynamics of the ion-solvent interaction as a result of the stimulation due to the recent advances in the theory of ion mobility.[4-7)]

The modern dielectric friction theory of ionic motion in solution developed by Hubbard and Onsager (HO)[4,5)] has been tested systematically against experiments on ion mobility (translational motion) under a variety of conditions in the previous papers.[8-16)] In the extensive test,[9-16)] the residual friction coefficient ($\Delta\zeta$), which is defined as the overall ionic friction coefficient subtracted by the Stokes one for slip,[9,17)] has been used successfully instead of the conventional Walden product, and led to the elucidation of the reliability and limitations of the HO theory; although the HO theory can describe the charge effect for small ions with a large surface charge density, it is unsuccessful in explaining the negative values of $\Delta\zeta$ for such medium-sized ions as the larger alkali metal and the halide ions in hydrogen-bonded solvents.

The validity of the HO theory indicates that the classical Stokes-Einstein-Walden framework for interpreting ion mobility has to be replaced by the modern HO framework as soon as possible. On the other hand, the disclosed limitations of the HO theory suggests the necessity of a new theory where the molecular nature and the liquid structure of solvent are taken into account in some manner. To explain the essential limitations of the continuum theory for ion transport, such a jump mechanism as the passing-through-cavities (PTC) has been proposed.[9-12,16)] The idea on the PTC mechanism has been hinted in the first study on conductances of the alkali metal ions in supercooled water.[9)] This important work is extended here to such halide ions as I^- and Cl^- to have more insights into the PTC mechanism.

Theoretical

We use the HO continuum model as a reference system to elucidate the effect of the solvent structure on the mechanism of ion transport process. For this purpose, first of all, we show in brief the significance of the HO theory and the procedure for its application.

Although the Stokes-Einstein-Walden (SEW) framework based on the Navier-Stokes (NS) hydrodynamic equation of motion is in general use in the interpretation of ion mobility, in principle, the NS hydrodynamic equation is inapplicable to ionic systems of our interest. HO have overcome the fundamental limitations of ordinary hydrodynamics by developing the dielectric friction theory and inventing the epoch-making electrohydrodynamic equation for migrating ions as follows:

$$\eta\nabla^2\boldsymbol{v} = \nabla p - \frac{1}{2}[\boldsymbol{E}_0\times(\nabla\times\boldsymbol{P}^*) + \boldsymbol{E}_0(\nabla\cdot\boldsymbol{P}^*)], \quad (1)$$

where η is the solvent viscosity, v the velocity field in the fluid, p the pressure, $\boldsymbol{E}_0$ the electrical field at $v=0$, and $\boldsymbol{P}^*$ the polarization deficiency. In this equation $\boldsymbol{P}^*$ expresses the departure of the orientational polarization of the Debye type from that at $v=0$ due to slow dielectric relaxation of the flowing solvent. Thus HO extended the NS hydrodynamic equation to ionic systems in a self-consistent manner by adapting the Debye dielectric relaxation theory to the flow system involving a charged sphere.

The second term on the right side of Eq. 1 represents the contribution of dielectric friction which is coupled to viscous friction. The full coupling of the two kinds of frictions renders the HO theory superior to ordinary hydrodynamics and the early dielectric friction theory[18,19)] in the treatment of ion dynamics in solution, as clearly shown elsewhere.[15,16,20,21)]

The essential difference between the modern (HO) and classical (NS) continuum models mentioned above is understandable from Eq. 1. When the charge on an ion is neglected ($\boldsymbol{E}_0=0$), Eq. 1 reduces to the

linearized form of the NS equation given by

$$\eta\nabla^2 v = \nabla p. \quad (2)$$

This equation leads to the following well-known Stokes law of the friction coefficient for a sphere with the radius R:

$$\zeta_S = 4\pi\eta R, \quad (3)$$

where ζ_S is the Stokes friction coefficient for the slip boundary condition. As mentioned elsewhere,[14] the slip boundary condition seems preferable to the stick on the molecular level, and R is usually taken to be the crystallographic radius of the ion.[22] Thus only the size effect of the solute can be handled by the NS hydrodynamic equation, whereas the charge effect as well as the size effect is treated by the HO electrohydrodynamic equation in a self-consistent manner.

The ionic friction coefficient ζ is related to the limiting conductance λ° as:

$$\zeta = |e| F/\lambda^\circ, \quad (4)$$

where F is the Faraday constant and e is the ionic charge. By using Eqs. 3 and 4 we can define the residual friction coefficient[9,17] as

$$\Delta\zeta = \zeta - \zeta_S. \quad (5)$$

Since the purely hydrodynamic friction is taken as a reference in Eq. 5, $\Delta\zeta$ reflects mainly the dielectric friction and all the other factors neglected in the primitive hydrodynamic model for ζ_S. As elucidated previously,[17] the residual friction coefficient is much more useful and meaningful than the so far widely used Walden product.

The numerical solutions to the linearized form of Eq. 1 are given in terms of the dimensionless quantity of the form

$$x = \zeta/\eta R_{HO}, \quad (6)$$

where R_{HO} denotes the Hubbard-Onsager radius, and x depends only on R and R_{HO}. A kind of solvent parameter R_{HO} is defined as

$$R_{HO} = \left[\frac{e^2}{16\pi\eta\varepsilon_0^2}(\varepsilon_0 - \varepsilon_\infty)\tau\right]^{1/4}, \quad (7)$$

where τ, ε_0 and ε_∞ are the dielectric relaxation time, the static, and high-frequency dielectric constants, respectively.

The HO theoretical value of the residual friction coefficient is expressed in the polynomial form[14,15]

$$\Delta\zeta = \eta(xR_{HO} - yR) = \eta R_{HO}\sum_{j=1}^{4} a_j (R_{HO}/R)^j, \quad (8)$$

where $y=4\pi$ for the slip boundary condition considered here and the universal coefficients are given as follows:

$$a_1 = -2.7866,$$
$$a_2 = 8.6216,$$
$$a_3 = -3.3425,$$

and

$$a_4 = 0.39550,$$

for $R/R_{HO} > 0.3$, which is satisfied by the I^- ion in water. When the physical properties of solvent involved in the HO radius expressed by Eq. 7 are all available, the HO value of the residual ionic friction coefficient $\Delta\zeta$ can be calculated for the ion characterized by the radius R and the charge e according to Eq. 8 under any conditions.

a) From Ref. 9.

Experimental

Potassium iodide of high quality was supplied by Merck. The concentrations of the dilute solutions at 5 °C were determined by weight, and their variation with temperature was corrected by using the density of water. The conductivity of water was in the range of 5×10^{-7}—$8\times10^{-7}\,s^{-1}\,cm^{-1}$ at 0 °C. Molar conductances of KI measured in this way were reproducible within ±0.1%. The physical properties of water, such as density, dielectric properties, and viscosity, used in the present work are provided elsewhere.[9,23] Details of the experimental apparatus and procedure are described in the previous paper.[23]

Results

Table 1 shows the molar conductance (Λ) of KI in water measured as a function of concentration C ($mol\,dm^{-3}$) and temperature t (°C). The limiting molar conductances Λ°($S^{-1}\,cm^2\,mol^{-1}$) summarized in Table 2 are obtained by analyzing the conductance data in Table 1 with the aid of the Fuoss-Onsager equation of conductance for unassociated electrolyte[24,25]

$$\Lambda = \Lambda^\circ - SC^{-1/2} + EC\log C + JC, \quad (9)$$

where the parameters S, E, and J have the usual meaning and depend on the temperature and the solvent properties. Our value of Λ° (KI) at 0 °C agrees with that in the literature.[26]

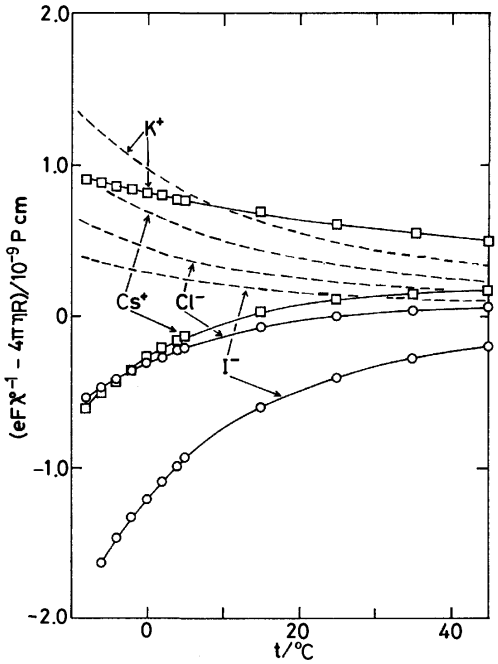

Fig. 1. Plots of the theoretical and experimental residual friction coefficients for several ions in water against temperature. The broken and full lines indicate the theoretical and experimental results, respectively. The square and circle symbols are used for the cations and anions, respectively.

As pointed out elsewhere,[9,11,23,27] the Fuoss-Onsager equation based on the sphere-in-continuum model describes well the concentration dependence of conductance in supercooled water. The validity of the continuum model for this case indicates that the relaxation and electrophoretic effects on ion mobility due to the ion-ion interactions in dilute solution can be presented in terms of the water radial distribution function that is effectively unity at a large ion-ion separation as in the continuum model. As discussed below, however, this is not the case for the ion-solvent interactions acting in the short range.

The limiting molar conductance of the iodide ion $\lambda°(I^{-1})$ listed in the fourth column of Table 2 is derived at each temperature by using the value of $\lambda°(K^+)$ previously determined;[9] the Kohlrausch law of independent migration of ions is applied. By using Eqs. 4 and 5 we have transformed the limiting ionic conductances of the iodide ion and some others[9] into the residual friction coefficients and plotted them against temperature in Fig. 1 for comparison with the HO theoretical prediction. The residual friction coefficients above 0 °C in Fig. 1 are computed from the conductance data in the literature.[26,28]

Discussion

Figure 1 shows how the HO dielectric friction theory of ion mobility predicts the temperature and ion-size dependencies of the residual friction coefficients for the medium-sized ions; the theory predicts that the positive ionic residual friction coefficient decreases with an increase in temperature and ion size. Although the K^+ ion ($R=1.33$ Å) has a negative temperature coefficient of $\Delta\zeta$ just as predicted, the I^- ($R=2.16$ Å) and Cl^- ($R=1.81$ Å) ions as well as the Cs^+ ion ($R=1.69$ Å) exhibit a positive temperature coefficient and a large negative value of $\Delta\zeta$ contrary to the theoretical prediction. Of the monovalent ions so far investigated, the iodide ion has the largest negative residual friction coefficient. However, the observed values of $\Delta\zeta$ are in the sequence $K^+ > Cs^+ > Cl^- > I^-$ in agreement with the HO prediction.

The unpredictable sign of the temperature coefficients of $\Delta\zeta$ for the medium-sized ions is originally related to their large negative values which become more negative as water is supercooled. The negative sign of $\Delta\zeta$ expressed by Eq. 5 indicates that the friction coefficients for these ions are even smaller than the lower limit (Eq. 3) set by the continuum model where the bulk properties of the solvent are used. The essential limitation of the continuum model for solvent is not ascribed to the charge effect of the ion but to the size effect because a similar limitation of the Stokes-Einstein law is found for diffusion of neutral molecules.[3,16,29,30] Thus it turns out that although the HO continuum theory is successful for small ions with a large surface charge density, it exhibits essential limitations for the medium-sized ions because of the neglect of many complicated factors in the vicinity of the ion. To explain the anomalous mobility, such a concept as the passing-through-cavities (PTC) mechanism has been introduced in the previous work.[9,10,12,16]

Figure 1 suggests that the stabilization or development of the hydrogen-bonded network in water favors the PTC mechanism. This is quite reasonable because the PTC process requires the framework formed by the hydrogen-bonded water molecules. The PTC process is assisted by such a cooperative fluctuating motion of the framework that it can reduce the potential barrier or friction for ion migration.[12] The role of the PTC mechanism increases when the extent of hydrogen bonds in water is promoted by any other factors than temperature; the PTC mechanism has so far been confirmed by changing the water structure through temperature,[9,11,12] pressure,[10-13] solvent isotope,[13] and organic cosolvent.[14,15] In this respect, this mechanism is analogous to that seen in the solid electrolyte.[31] Thus the PTC mechanism remains as a memory in the short-range order characteristic of the liquid state even after the long-range order is completely lost by melting. The corresponding limitations of the continuum model are shown also in the study of rotational motion of ions.[20]

Such an ion transport process as the PTC mechanism is expected to be important in highly viscous liquids, liquid crystals, and membranes in view of the features described above. This will be examined in our

experimental investigation in progress. Furthermore, a molecular theory of ionic or molecular diffusion in liquids is desired to be developed beyond hydrodynamics. The Wolynes molecular theory[6,7] cannot explain the negative value of $\Delta\zeta$ because it relies upon the hydrodynamic relation Eq. 3 in the expression of the friction coefficient due to the hard force-hard force correlation.

The Structure of the Cyclodextrin Complex. XIX. Crystal Structures of Hexakis(2,3,6-tri-*O*-methyl)-α-cyclodextrin Complexes with (*S*)- and (*R*)-Mandelic Acid. Chiral Recognition through the Induced-Fit Conformational Change of the Macrocyclic Ring

(Received August 23, 1986)

Hexakis(2,3,6-tri-*O*-methyl)-α-cyclodextrin (methyl-α-CDx) forms crystalline inclusion complexes with (*S*)-mandelic acid (*S*-MA) and (*R*)-mandelic acid (*R*-MA). Both crystals are monoclinic, and the space group is $P2_1$ with cell dimensions: $a=13.123(2)$, $b=23.187(4)$, $c=13.113(2)$ Å, $\beta=107.19(1)°$ for the *S*-MA complex, $a=11.624(2)$, $b=23.739(4)$, $c=13.786(2)$ Å, $\beta=106.56(1)°$ for the *R*-MA complex. The structures were solved by inspection of a Patterson map and the R-map method, and refined by the block-diagonal least-squares method to the *R*-values of 0.087 for the *S*-MA complex and 0.055 for the *R*-MA complex. In the *S*-MA complex, the methyl-α-CDx molecule, which has a *pseudo* two-fold symmetry, loosely includes the phenyl group of *S*-MA. The hydroxyl and carboxyl groups of *S*-MA protrude from the O(2), O(3) side of the methyl-α-CDx cavity and form hydrogen bonds with water molecules located outside the host cavity. The methyl-α-CDx molecule in the *R*-MA complex tightly binds the *R*-MA molecule which is deeply inserted into the host cavity. The hydroxyl group of *R*-MA is hydrogen-bonded to an O(2) oxygen atom of host methyl-α-CDx. The comparison of the two structures suggests that the complex formation induces the conformational change of the host molecule to accommodate *S*-MA or *R*-MA more suitably within the cavity.

Cyclodextrins form diastereoisomers by including optically active guests. Many attempts have been made to resolve racemic compounds by the co-precipitation with cyclodextrins.[1] Except for some cases, however, cyclodextrins are not good reagents for this purpose. Since the intramolecular cavity of cyclodextrins is round and rather symmetrical, cyclodextrins does not seem to be sensitive to the chirality of included guests, as demonstrated in our earlier reports.[2,3] α-Cyclodextrin equally includes *R* -and *S*-isomers of 1-phenylethanol although the hydroxyl group attached to the assymmetric carbon atom is disordered.[2] In the crystal of the β-cyclodextrin complex with racemic Flurbiprofen, a pair of *S*- and *R*-isomers are packed within the cavity formed by two β-cyclodextrin molecules.[3]

Recently, it has been found that the permethylation markedly changes the macrocyclic conformation of cyclodextrins.[4] Permethylated cyclodextrins also form inclusion complexes with a variety of guests, but the geometry of the host-guest interaction differs from that of the parent cyclodextrin complexes because of the different size and shape of the macrocyclic cavity. Previously, we have briefly reported that permethylated cyclodextrins recognize the chirality of mandelic acid[5] and Flurbiprofen[6,7] in the crystalline state. This paper deals with the crystal structures of hexakis(2,3,6-tri-*O*-methyl)-α-cyclodextrin (methyl-α-CDx) complexes with (*S*)-mandelic acid (*S*-MA) and (*R*)-mandelic acid (*R*-MA), and will discuss the chiral recognition through the induced-fit conformational change of methyl-α-CDx.

Experimental

Materials and Measurements. Methyl-α-CDx complexes with *S*- and *R*-MA were crystallized at 50 °C by standing aqueous solutions containing methyl-α-CDx and each isomer with ca. 1 : 1 molar ratio. Lattice parameters and diffraction intensities were measured at room temperature on a Nicolet P3/F diffractometer with graphite-monochromated Cu $K\alpha$ radiation. Lattice parameters were refined by using 25 reflections with 2θ values in the range 40—45°. By using θ—2θ scan mode, 4837 (*S*-MA complex) and 4925 (*R*-MA complex) independent reflections with $|F_o| \geqq 3\sigma(F)$ were obtained up to 118° in 2θ. No corrections were made for absorption or extinction effects.

Crystal Data: (1) *S*-MA complex, $C_{54}H_{96}O_{30}\cdot C_8H_8O_3\cdot 3H_2O$, F.W.=1431.5, monoclinic, space group $P2_1$, $Z=2$, $a=13.123(2)$, $b=23.187(4)$, $c=13.113(2)$ Å, $\beta=107.19(1)°$, $V=3812(1)$ Å^3, $D_X=1.247$ g cm^{-3}, (2) *R*-MA complex, $C_{54}H_{96}O_{30}\cdot C_8H_8O_3\cdot 2H_2O$, F.W.=1413.5, monoclinic, space group $P2_1$, $Z=2$, $a=11.624(2)$, $b=23.739(4)$, $c=13.786(2)$ Å, $\beta=106.56(1)°$, $V=3646(1)$ Å^3, $D_X=1.289$ g cm^{-3}.

Determination and Refinement of the Structure. The orientation of the molecular axis of methyl-α-CDx was easily deduced from a Patterson map in both structures. The rotation around the molecular axis and the position of the molecule in the unit cell were determined from an R-map, which was calculated by using a model structure of methyl-α-CDx having a six-fold molecular symmetry. The orientation and position of each residue were corrected by the rigid-body least-squares method. After the refinement of atomic parameters of methyl-α-CDx, the guest and water molecules were found on Fourier and difference-Fourier maps. The block-diagonal least-squares refinement of the structure, including 42 hydrogen atoms (*S*-MA complex) and 96 hydrogen atoms (*R*-MA complex), achieved the *R*-value of 0.087 for the *S*-MA complex and 0.055 for the *R*-MA complex. The quantity minimized was $\sum w(|F_o|-|F_c|)^2$, with $w=1.0$ for all the reflections. Final atomic parameters and B_{eq} values are given in Table 1. Tables of observed and calculated structure factors, anisotropic temperature factors of non-hydrogen atoms, atomic parameters of hydrogen atoms, bond dis-

tances, angles, and conformation angles are kept at The Chemical Society of Japan (Document No. 8719). The computation was carried out on a FACOM M-380 computer at the Center of the Research Information Processing System (RIPS), Agency of Industrial Science and Technology, Tsukuba.

Description of the Structure

Conformation of Methyl-α-CDx. The numbering scheme of both complexes is shown in Fig. 1. The average bond distances and angles of 2,3,6-tri-*O*-methylglucose residues are shown in Fig. 2. Table 2 gives geometrical data describing the macrocyclic conformation of methyl-α-CDx.

Methyl-α-CDx in the *S*-MA Complex: The methyl-α-CDx molecule has a *pseudo* two-fold symmetry. The conformational difference among six 2,3,6-tri-*O*-methylglucose residues is observed in the orientation of C(6)–O(6) bonds. Two O(6)–C(6) bonds (G2 and G5 residues) are in a gauche-gauche conformation, while the others show a gauche-trans conformation. All O(6)–C(9) bonds are trans to the corresponding C(5)–C(6) bond. The O(2)–C(7) bonds point away from the center of the methyl-α-CDx ring. On the other hand, the O(3)–C(8) bonds are oriented to the opposite direction, turning to the inside of the methyl-α-CDx ring. The six glycosidic oxygen atoms form a nearly regular hexagon with the radius of 4.23—4.38 Å and the O(4)···O(4′) distance of 4.24—4.36 Å (Table 2). The O(2)···O(3′) distances are longer than those found in α-cyclodextrin complexes[2] because of the steric hindrance involving C(8)H_3 methyl groups.[4] The C(8) atoms are located at a position equidistant from O(2) and O(2′) atoms with the distance of 3.12—3.52 and 3.31—3.41 Å, respectively. The G3 and G6 residues are nearly perpendicular to the plane through the six O(4) atoms. The sharp inclination of the G1 and G4 residues (the tilt-angles of 35.9 and 34.6°, respectively) is supported by the included W1 water molecule which forms the O(6, G1)···W1···O(6, G4) hydrogen-bond bridge.

Methyl-α-CDx in the *R*-MA Complex: The methyl-α-CDx ring is less symmetrical than that of the *S*-MA complex. The C(6)–O(6) bonds show also two types of orientations. The gauche-gauche conformation is found in the G4 and G6 residues, and the C(6)–O(6) bonds in the other residues are in the gauche-trans conformation. Except for the O(6, G1)–C(9, G1) bond,

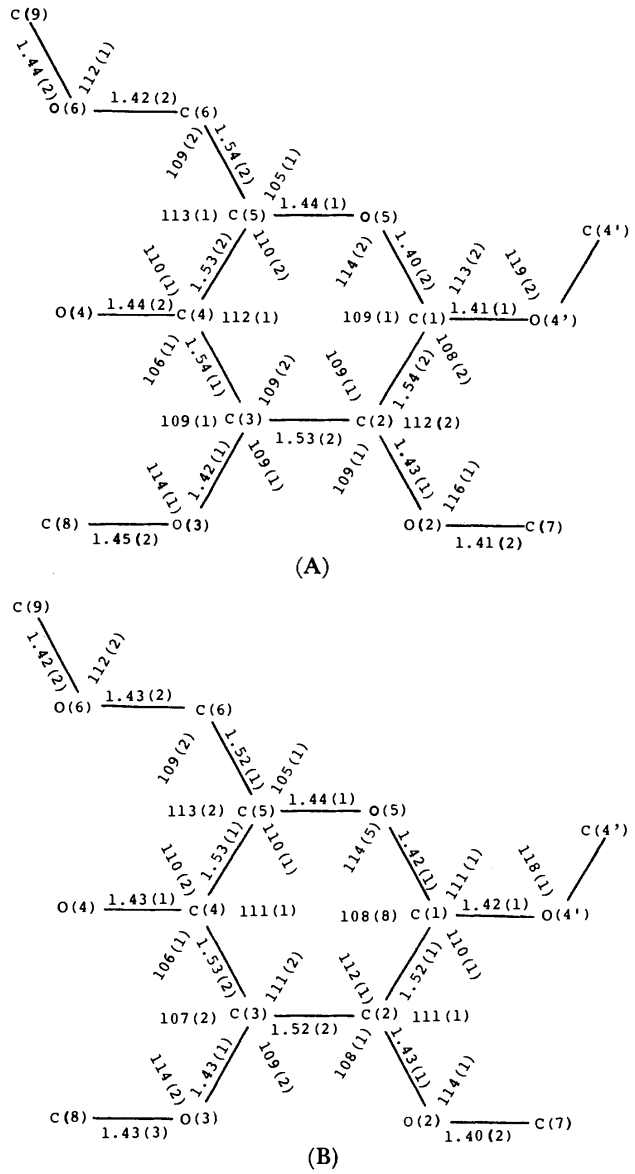

Fig. 2. Average bond distances and angles for the 2,3,6-tri-*O*-methylglucose residue in the methyl-α-CDx complexes with *S*-MA (A) and *R*-MA (B). Standard deviations given in parentheses were estimated according to $\sigma=[\sum_{i=1}^{6}(x_i-\bar{x})^2/5]^{1/2}$, where x_i is the bond distance or angle in the i-th residue and $\bar{x}$ is the average value.

all the O(6)–C(9) bonds are trans to the corresponding C(5)–C(6) bond. The O(6, G1)–C(9, G1) bond turns to the inside of the methyl-α-CDx ring, and the C(9,G1)H_3 methyl group caps the O(6) side of the cavity. The O(2)–C(7) and O(3)–C(8) bonds show the same conformations as those in the *S*-MA complex. The macrocyclic ring is rather elliptically distorted compared with the methyl-α-CDx ring in the *S*-MA complex. The diagonal O(4, G2)···O(4, G5) distance of 9.08 Å is 1 Å longer than the O(4, G1)···O(4, G4) distance (8.08 Å). The G3 and G6 residues, which face to each other, are nearly perpendicular to the plane through six O(4) atoms. The other residues incline

Table 2. Geometrical Data Describing the Macrocyclic Conformation of Methyl-α-CDx

I. Distance (l/Å) from the center of gravity of six O(4) atoms to each O(4) atom

	S-MA Complex	*R*-MA Complex
O(4, G1)	4.26	4.05
O(4, G2)	4.23	4.54
O(4, G3)	4.37	4.27
O(4, G4)	4.26	4.03
O(4, G5)	4.23	4.55
O(4, G6)	4.38	4.29
Average	4.29	4.29

II. O(4)···O(4′) distance (l/Å) between adjacent residues

	S-MA Complex	*R*-MA Complex
O(4, G1)···O(4, G2)	4.25	4.27
O(4, G1)···O(4, G6)	4.31	4.43
O(4, G2)···O(4, G3)	4.34	4.14
O(4, G3)···O(4, G4)	4.30	4.49
O(4, G4)···O(4, G5)	4.24	4.17
O(4, G5)···O(4, G6)	4.36	4.28
Average	4.30	4.30

III. O(2)···O(3′) distance (l/Å) between adjacent residues

	S-MA Complex	*R*-MA Complex
O(2, G1)···O(3, G2)	3.43	3.55
O(2, G2)···O(3, G3)	3.43	3.34
O(2, G3)···O(3, G4)	3.37	3.20
O(2, G4)···O(3, G5)	3.30	3.38
O(2, G5)···O(3, G6)	3.46	3.44
O(2, G6)···O(3, G1)	3.39	3.44
Average	3.40	3.39

IV. Deviation (d/Å) of O(4) atoms from their least-squares plane

	S-MA Complex	*R*-MA Complex
O(4, G1)	0.031	0.093
O(4, G2)	0.238	−0.153
O(4, G3)	−0.271	0.033
O(4, G4)	0.034	0.150
O(4, G5)	0.235	−0.204
O(4, G6)	−0.266	0.081
R.M.S. Deviation	0.207	0.132

V. Tilt-angle[a] (ϕ/°) of each 2,3,6-tri-*O*-methylglucose residue

	S-MA Complex	*R*-MA Complex
G1	35.9	29.3
G2	19.8	23.0
G3	7.9	1.9
G4	34.6	23.2
G5	18.7	26.6
G6	7.5	2.9
Average	20.7	17.8

a) The tilt-angle is defined as an angle made by the plane through six O(4) atoms and a plane through C(1), C(4), O(4), and O(4′) of each residue.

with their O(6) side turning to the inside of the methyl-α-CDx ring. In spite of the elliptical distortion of the methyl-α-CDx ring, the O(2)···O(3′) distances do not much differ from those of the *S*-MA complex. The

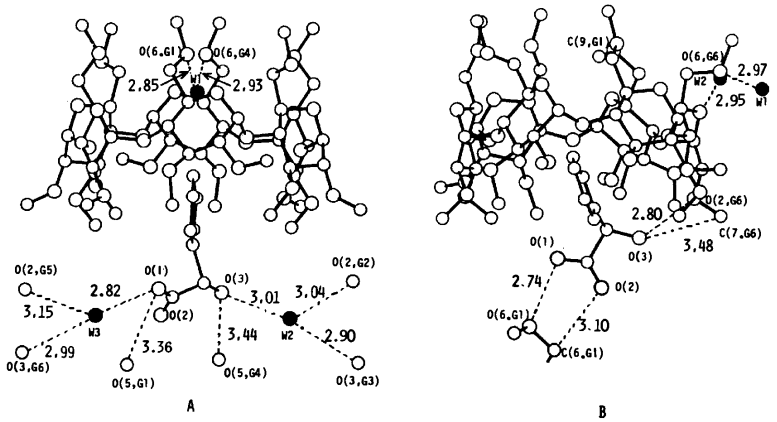

Fig. 3. The inclusion feature of the methyl-α-CDx complexes with *S*-MA (A) and *R*-MA (B). Water molecules are shown by full circles. Intermolecular contacts (Å) involving the guest and water molecules are shown by dashed lines.

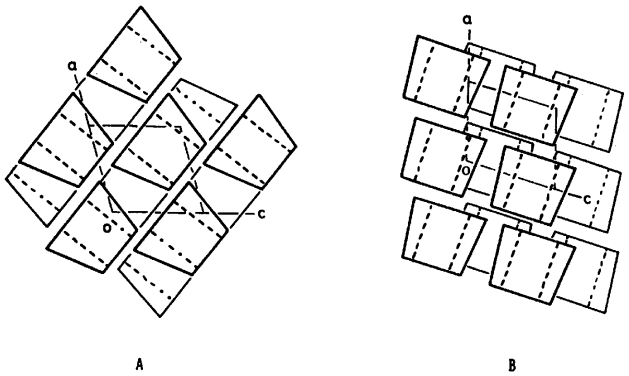

Fig. 4. Schematic drawings of the packing feature of methyl-α-CDx molecules in the crystals of the *S*-MA complex (A) and *R*-MA complex (B).

average O(2)···C(8) and O(2′)···C(8) distances (3.30 and 3.38 Å, respectively) indicate that the $C(8)H_3$ methyl group is located at an equidistant position from the two O(2) oxygen atoms.

Host-Guest Interaction. The inclusion feature of the complexes are shown in Fig. 3. In both complexes, the phenyl group is inserted into the methyl-α-CDx ring from the O(2), O(3) side, but the mode of the host-guest interaction differs between these complexes.

***S*-MA Complex:** The phenyl group is included within the host cavity parallel to the *pseudo* two-fold axis of methyl-α-CDx. The *S*-MA molecule is weakly bound at the O(2), O(3) side of the cavity, as indicated by the relatively large temperature factors of *S*-MA (Table 1), since the phenyl group is only partially inserted into the host cavity. The W1 water molecule is also included at the O(6) side of the cavity to fill the vacant space. The hydroxyl and carboxyl groups protrude outside the cavity, and form hydrogen bonds with the W2 and W3 water molecules, respectively. These water molecules are also hydrogen-bonded to oxygen atoms of adjacent methyl-α-CDx molecules.

***R*-MA Complex:** The host molecules are stacked along the a axis to form a channel-type structure, as shown in Fig. 4. The guest *R*-MA molecule is included within the methyl-α-CDx column. The phenyl group is more deeply inserted into the host cavity, and sandwiched between the G3 and G6 residues (Figs. 1 and 3). The phenyl plane makes an angle of 70.5° with the plane through six O(4) atoms. The hydroxyl group of *R*-MA is hydrogen-bonded to the O(2, G6) atom. The carboxyl group is located outside the host cavity, and forms hydrogen bond with the O(6, G1) oxygen atom of the adjacent methyl-α-CDx molecule.

Crystal Structure. The crystal structure of both complexes are shown in Figs. 5 and 6. In the *S*-MA complex, methyl-α-CDx molecules are arranged to form a layer parallel to the [10$\bar{1}$] plane (Fig. 4). Two adjacent layers are shifted by about half a molecule, forming a blick-work pattern. The O(6) side of the cavity is open to the intermolecular space of the next layer, where the W2 and W3 water molecules are located.

Methyl-α-CDx molecules in the *R*-MA complex are arranged along the a axis in a head-to-tail mode to form an endless column. The methyl-α-CDx ring is not perpendicular to the column axis, but the plane through six O(4) atoms makes an angle of 72.5° with the column axis. The guest *R*-MA molecule is arranged in the methyl-α-CDx column. Two water molecules are located outside the methyl-α-CDx column. W1 forms hydrogen bonds with O(6, G4) and O(6, G6), while W2 is hydrogen-bonded to O(5, G6).

Discussion

As shown in Figs. 1 and 3, the macrocyclic conformation of methyl-α-CDx differs depending on the included isomer. When methyl-α-CDx includes *S*-MA, the macrocyclic ring becomes symmetrical and has the *pseudo* two-fold symmetry. The symmetrical

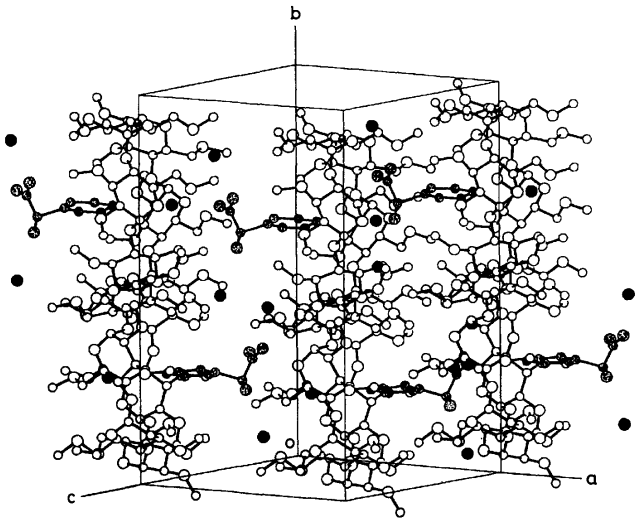

Fig. 5. The crystal structure of the methyl-α-CDx–*S*-MA complex.

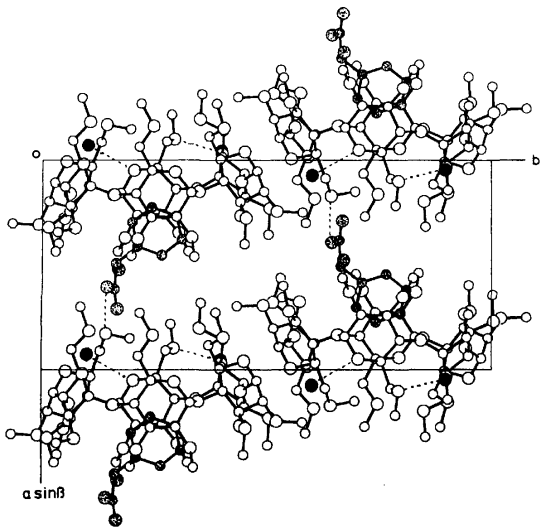

Fig. 6. The crystal structure of the methyl-α-CDx–*R*-MA complex viewed along the c axis.

cavity is favorable to accommodate the phenyl group which is located on the *pseudo* two-fold axis of methyl-α-CDx. The macrocyclic ring of the *R*-MA complex is less symmetrical and somewhat elliptically distorted. The elliptical change of the host cavity, which may be induced by the host-guest interaction, is suitable for the deep penetration of *R*-MA. The formation of the host-guest hydrogen bond between the hydroxyl group of *R*-MA and the O(2, G6) atom of methyl-α-CDx requires the inclination of *R*-MA towards the G1, G6 side of the methyl-α-CDx ring as well as the deep penetration. As the result, a long axis of the benzene ring becomes parallel to the O(4, G2)··· O(4, G5) diagonal, as shown in Fig. 1. The macrocyclic ring should become elliptical to include the phenyl group in such orientation. The methyl-α-CDx molecule seems to recognize the chirality of mandelic acid by the formation of the host-guest hydrogen bond. The hydrogen-bond formation with *S*-MA may be prevented by the steric hindrance involving methyl groups. When *R*-MA is replaced by *S*-MA, the hydroxyl group of *S*-MA should approach to the O(2) or O(3) atom of the G2 residue to form a hydrogen bond. But, such approach is blocked by the methyl group attached to the O(3, G2) atom. The hydrogen-bond formation of *S*-MA with water molecules does not require the deep penetration of *S*-MA into the host cavity.

The comparison of these structures with the α-cyclodextrin-1-phenylethanol complex[2] suggests the important role of methyl groups in the chiral recognition. Both isomers of 1-phenylethanol are equally included within the α-cyclodextrin cavity in the crystal except for the orientation of the hydroxyl group attached to the asymmetric carbon atom. The hydroxyl group of *R*- and *S*-isomers are hydrogen-bonded to the O(2)H and O(3)H hydroxyl groups of α-cyclodextrin, respectively. Such hydrogen bonding may be prevented by the methyl group attached to the O(3) oxygen atom when 1-phenylethanol is included in methyl-α-CDx. The induced-fit conformational change requires the flexibility of the macrocyclic ring. The macrocyclic ring of parent cyclodextrins is considerably rigid because of the intramolecular O(2)··· O(3′) hydrogen bond. The permethylation blocks the intramolecular hydrogen bond and makes the macrocyclic ring more flexible. The chiral recognition by permethylated cyclodextrins has been also observed in the permethylated β-cyclodextrin complexes with Flurbiprofen.[6]

The Vaporization of the Various Trace Components from Aluminoborosilicate Glass

Noriko ITOH* and Tetsurō NAKAMURA
Research Laboratory of Engineering Material, Tokyo Institute of Technology,
4259 Nagatsuta, Midori-ku, Yokohama 227
(Received February 6, 1986)

The simultaneous vaporization of dopants in aluminoborosilicate glass was investigated by means of mass spectrometry using a Knudsen cell. The detected chemical species were Na, K, Ni, Zn, Rb, Ag, Te, TeO_2, and Cs in the temperature range of 650—800 °C. Their vapor pressures were 10^{-6}—10^{-4} Pa. The activation energy of vaporization was discussed in relation to the electrostatic force between the vaporizing specie and oxygen. However, lithium, alkali-earth metal elements, alomst all the transition metal elements (such as Fe, Cr, and Ru), and rare-earth metal elements were not detected in the vapor phase, though they were contained in the glass matrix.

The glass is often heated to several hundred degrees in the process of producing and using the enamel, the glass lining, or the glass matrix containing radioactive wastes. It is an important problem how many and what constituents vaporize from the glass. Numerous investigations have been reported.[1-9] They have, however, been concerned with the gross volatility[1-5] and volatility of a specified element.[2,6-9]

In this work, Knudsen's effusion cell and a mass spectrometer were used in order to determine simultaneously about thirty kinds of chemical species vaporizing from the aluminoborosilicate glasses. The volatilities of the detected elements were estimated by mean of a scale of activation energy.

Experimental

Glass Matrices. The glass matrices were SiO_2-Al_2O_3-B_2O_3-Na_2O glasses doped with a single modifier oxide (S-series) and doped with 26—35 kinds of modifier oxides (P-series). The S-series glasses were used in order to estimate the thermodynamic parameters of the vaporization of a certain modifier ion. The experimental data concerning S1 will be excluded hereinafter because neither Sr nor SrO was detected in the vapor from the S1 glass, where the SrO was the modifier oxide. The chemical compositions are shown in Table 1. The S2, S3, and S4 glass matrices were prepared in the weight ratio of $SiO_2 : B_2O_3 : Al_2O_3 : Na_2O : M_xO_y = 1 : 0.312 : 0.0797 : 0.220 : 0.0848$.

The P-series glasses were used to observe the simultaneous vaporization of the various modifier ions from the same matrix. The P5 and P7 glasses were prepared so that their frit compositions are the same as those of the S-series glasses, i.e., the weight ratio was $SiO_2 : B_2O_3 : Al_2O_3 = 1 : 0.326 : 0.0814$, but the weight ratios of the modifier oxides were different. The frit compositions of the P6 and P8 glasses were different from those of the S-series glasses. However, most of the modifier oxides of the P6 glass have a chemical composition analogous to that of the P5 glass. On the other hand the P8 glass is analogous to the P7 glass in the composition of most of the modifier oxides. The chemical compositions are listed in Table 2 in the order of (1) the components of the frit glass, (2) the components doped in the frit glass and detected in the

*Present address: Tokyo Metropolitan Institute of Technology, 6-6 Asahigaoka, Hino, Tokyo 191.

Table 1. Composition of S2-S4 Glass Matrices (wt.%)

	S2	S3	S4
SiO_2	59.0	59.0	59.0
B_2O_3	18.3	18.3	18.3
Na_2O	13.0	13.0	13.0
Al_2O_3	4.7	4.7	4.7
Cs_2O	5.0	—	—
La_2O_3	—	5.0	—
TeO_2	—	—	5.0
Sum	100	100	100

Table 2. Composition of Aluminoborosilicate Glass (wt.%)

		P5	P6	P7	P8
I	SiO_2	43.22	47.2	43.47	48.49
	B_2O_3	14.07	13.5	14.15	18.58
	Na_2O	8.42	9.34	10.00	11.30
	Al_2O_3	3.52	2.41	3.54	2.00
II	K_2O	2.01	0.96	—	—
	NiO	0.49	0.49	0.23	—
	ZnO	2.01	0.96	3.03	—
	Rb_2O	0.15	0.15	0.11	0.12
	Ag_2O	—	—	0.02	0.02
	TeO_2	0.26	0.26	0.19	0.18
	Cs_2O	1.02	1.02	0.75	0.84
III	Fe_2O_3	7.41	7.41	2.04	2.96
	Li_2O	3.02	1.93	3.54	1.87
	CaO	2.01	0.96	3.03	1.86
	BaO	0.68	1.64	3.52	0.57

vapor phase, and (3) the components doped in the frit glass but not detected in the vapor phase.

Mass Spectrometry. The instrument used was a JEOL-1A-type mass spectrometer equipped with the Knudsen cell. The conditions of measurement were as follows:

a) Realizable limit of vapor pressure: 10^{-6}—10^{-4} Pa,
b) Deviation of ion current I: ±20%,
c) Mass resolution at m=44: 2200,
d) Ionizing electron: 27.0 kV×100 μA,
