active esters of HODMSP·$MeSO_4^-$ are applicable to peptide synthesis, some esters of the N-protected amino acids were prepared by direct condensation using DCC in CH_3CN. These esters, thus obtained, were very soluble in water, and were able to react with amine components for the formation of the amide bond (Table 5). When they were allowed to react with amine components in $CHCl_3$, the yield of the reaction products was always good and their purities were also quite satisfactory. In addition, the removal of unreacted active ester and the hydroxy compound resulting from the reaction was easy by an extraction procedure. Furthermore, these esters were also able to react with amino acids in aqueous solution in the presence of Et_3N at room temperature. The reaction proceeded smoothly, while the reaction of the HONp or HOSu active ester required an addition of THF. The products were isolated in good yield, and were comparable with those of HONp or HOSu active ester method. When HODMSP·$MeSO_4^-$ active esters were treated with Ser, His, Glu, and Gly-Tyr as amine components in aqueous solution, every reaction afforded the *N*-α-acylpeptides selectively.

Racemization Test. Izumiya et al. established the racemization test by ion-exchange chromatography.[33] We tried to determine the exact degree of racemization in the HODMSP·$MeSO_4^-$ active ester method by the same principle as their report. As a model peptide, L-Leu-L-Asp was prepared by this method and the ratio of diastereomeric dipeptide was measured by HPLC. The result was compared with that of the HONp or HOSu active ester method (Fig. 3). Figure 3 shows that racemization in our method, if any, was not detectable as well as in other methods. A further examination of the racemization was carried out in the coupling reaction of Z-Gly-L-Ala-OH and L-Leu (Table 6). The results suggested that the HODMSP·$MeSO_4^-$ active ester method is as useful as the existing active ester method in stepwise condensation using an N-protected amino acid with a urethane-type protecting group.

Application of HODMSP·$MeSO_4^-$ Active Ester for Synthesis of Biologically Active Peptide (Synthesis of FMRFamide). In order to evaluate the utility of the HODMSP·$MeSO_4^-$ active ester method, we tried to apply it to a synthesis of a tetra peptide amide, Phe-Met-Arg-Phe-NH_2 (FMRFamide) as an example of biologically active peptides.

FMRFamide was isolated from the ganglia of the clam *Macrocallista nimbosa* by Prince and Greenberg.[34] It has diverse effects on molluscan muscles and neurones.[35] For the synthesis of FMRFamide, the method of selective acylation to the Arg residue was employed. The synthetic route is shown in Fig. 4. Boc-Met-ODMSP·$MeSO_4^-$ (**25**), which was obtained by the esterification of Boc-Met-OH with HODMSP·$MeSO_4^-$, was allowed to react with H-Arg-Phe-NH_2·2AcOH (**24**), which was obtained

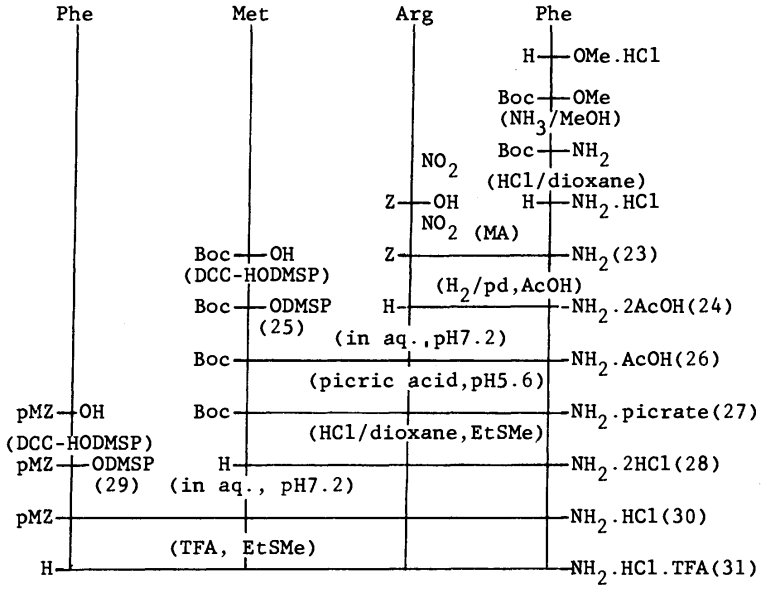

Fig. 4. Synthetic route of FMRFamide.

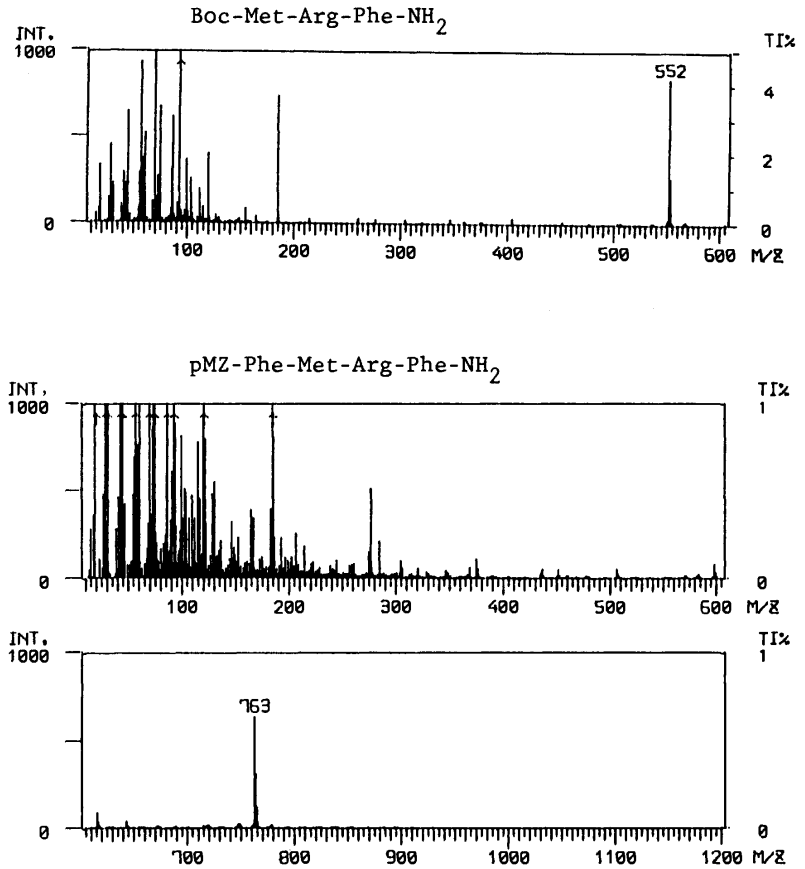

Fig. 5. Mass spectra in intermediates of FMRFamide.

from Z-Arg(NO_2)-OH and H-Phe-NH_2·2HCl by the conventional mixed anhydride method, followed by catalytic hydrogenation. The reaction proceeded on an aqueous solution with the presence of Et_3N at pH 7.2. After the isolation of Boc-Met-Arg-Phe-NH_2 as a picrate **27** by extraction with ethyl acetate from the reaction mixture, the Boc-group was removed by HCl in the presence of ethyl methyl sulfide, to yield tripeptide amide·2HCl (**28**). Then pMZ-Phe-ODMSP (**29**), which was obtained by the esterification of pMZ-Phe-OH with HODMSP·$MeSO_4^-$, was allowed to react with the tripeptide amide **28** (in the same manner as described regarding compound **26**) to yield pMZ-FMRFamide·HCl(**30**). After removing the pMZ-group of pMZ-FMRFamide (**30**) with trifluoroacetic acid in the presence of ethyl methyl sulfide, FMRFamide (**31**) was obtained. In the process of synthesizing **26** in aqueous solution, the product was not isolated, as such, owing to its high water-solubility. For this reason, this peptide was isolated and purified as a picrate. In the case of **30**, it could be extracted with ethyl acetate and purified smoothly. The homogeneity of these intermediates and the product was ascertained by TLC, elemental analysis, amino acid analysis, and mass spectra (Fig. 5).

The biological activity was measured on the anterior byssus retractor muscle of *Mytilus*, FMRFamide causes a relaxation or a contraction depending on its concentration.[36] At 10^{-8}—10^{-7} M (1 M=1 mol dm^{-3}), FMRFamide relaxes catch tension induced by acetylcholine (Ach). However, at a concentration higher than 10^{-7} M, it elicits a contraction by a direct action on the muscle fibers. From measurements of biological activity,[37] this synthesized FMRFamide was shown to possess the same activity as a natural one (Fig. 6).

All these results indicate that the HODMSP active ester method is promising for peptide syntheses in aqueous solution. We expect that our new active ester method will also be applicable for the chemical modifications of proteins.

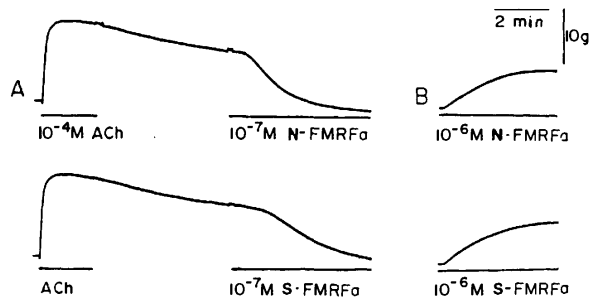

Fig. 6. Contractions and relaxations produced by synthesized FMRFamide and natural FMRFamide. A: Contractile effect, B: relaxing effect, N-FMRFa: natural FMRFamide, S-FMRFa: synthesized FMRFamide.

Experimental

All melting points were uncorrected. IR spectra were recorded on a Hitachi 269-30 infrared spectrometer. NMR spectra were measured on a Hitachi R-24B (60 MHz) spectrometer. The chemical shifts are given in δ (ppm) scale with tetramethylsilane as an internal standard. Mass spectra were obtained on a JEOL DX-300 spectrometer. The optical rotations were measured on a Union PM-101 polarimeter. TLC was carried out on Merck Silicagel G and Eastman chromagram sheet with solvent systems: R_{f_1}, 1-butanol-acetic acid-pyridine-water (4:1:1:2, v/v); R_{f_2}, $CHCl_3$-methanol (5:1, v/v); R_{f_3}, 1-butanol-acetic acid-water (3:3:2, v/v). Spots of materials possessing a free amino group on the TLC plate were detected by spraying with ninhydrin; those of amino group blocked materials were detected by spraying with 25% HBr in acetic acid and then ninhydrin. R_f spots of HODASP·X^- and its derivatives were visible with UV light. Amino acid analysis, detection of racemization, and other detection of substances were performed by HPLC using JASCO TRI ROTAR-V and UVIDEC-100V apparatus.

Preparation of HODASP·X^- and Other Phenols. **1**,[8] **8c**,[9] **8d**,[9] **9**,[10] **10**,[11] and **11**[12] were prepared by methods described in the literature. **2**—**7** and **8a**—**b** were prepared by reacting the corresponding thioether with a slight excess of dimethyl sulfate or diethyl sulfate. The reaction mixture was dissolved in ethanol; then, the ethanol solution was treated with an equimolar 70% $HClO_4$ below 5 °C. The resulting crystals were removed from the reaction mixture by filtration. The filter cake was washed with precooled ethanol and then recrystallized from ethanol or ethanol-ether. In the case of **8a** or **8d**, the ethanol solution was treated with 35% HCl or 15% HBr in place of 70% $HClO_4$. A white crystalline product was obtained. The precursor thioethers were prepared by the alkylation of the 4-mercaptophenols.

Preparation of Acylating Agents. Benzyl Carbonates: **19**[13] and **20**[14] were prepared by the methods described in the literature. **13**—**17** were prepared as follows. A mixture of the corresponding phenols and equimolar benzyloxycarbonyl chloride in CH_3CN was stirred at 5 °C. After 10 min, equimolar Et_3N was added. The reaction mixture was stirred at 5 °C for 1 h and then the precipitated triethylammonium chloride was removed from the reaction mixture by filtration. The filter cake was washed with CH_3CN, and combined filtrates were concentrated in vacuo to give the product either as a crystalline solid or as an oily residue, which was readily crystallized from ethyl acetate or ether.

13: Yield 84%; mp 68—69 °C; R_{f_3} 0.67; IR (KBr) 1762 cm^{-1} (ester C=O); ^{1}H NMR (DMSO-d_6) δ=3.15 (6H,s,-$\overset{+}{S}(CH_3)_2$), 5.28 (2H, s, -CH_2-), 7.44 (5H, s, C_6H_5), 7.63 (2H, d, J=8Hz, C_6H_4), 8.16 (2H, d, J=8Hz, C_6H_4); Found: C, 59.40; H, 5.19%; Calcd for $C_{16}H_{17}O_3SCl$: C, 59.19; H, 5.24%.

14: Yield 87%; mp 71—73 °C; R_{f_3} 0.65; IR (KBr) 1762 cm^{-1} (ester C=O); ^{1}H NMR (DMSO-d_6) δ=3.25 (6H, s, -$\overset{+}{S}(CH_3)_2$), 5.30 (2H, s, -CH_2-), 7.40 (5H, s, C_6H_5), 7.61 (2H, d, J=8Hz, C_6H_4), 8.12 (2H, d, J=8Hz, C_6H_4); Found: C, 52.21; H, 4.53%; Calcd for $C_{16}H_{17}O_3SBr$: C, 52.06; H, 4.61%.

15: Yield 72%; mp 141—143 °C; R_{f_3}, 0.54; IR (KBr) 1764 cm^{-1} (ester C=O); ^{1}H NMR (DMSO-d_6) δ=3.30 (6H, s, -$\overset{+}{S}(CH_3)_2$), 5.34 (2H, s, -CH_2-), 7.44 (5H, s, C_6H_5), 7.65 (2H, d, J=9Hz, C_6H_4), 8.15 (2H, d, J=8Hz, C_6H_4); Found: C, 49.21; H, 4.45%; Calcd for $C_{16}H_{17}O_7SCl$: C, 49.45; H, 4.37%.

16: Yield 80%; mp 155—157 °C; R_{f_3} 0.71; IR (KBr) 1770 cm^{-1} (ester C=O); ^1H NMR (DMSO-d_6) δ=2.20 (3H, s, CH_3-C_6H_5), 3.24 (6H, s, -$\overset{+}{S}(CH_3)_2$), 5.44 (2H, s, -CH_2-), 7.05—8.30 (13H, m, aromatic); Found: C, 60.31; H, 5.34%; Calcd for $C_{23}H_{24}O_6S_2$: C, 60.01; H; 5.21%.

4-Acetoxyphenyldimethylsulfonium Methylsulfate: A mixture of **8**$_d$ and equimolar acetyl chloride in CH_3CN was stirred at 5 °C. After 10 min, equimolar Et_3N was added to it. A white crystalline product was obtained (as described for the preparation of benzyl carbonates). Yield 65%; mp 91—93 °C; R_{f_3} 0.56; IR (KBr) 1750 cm^{-1} (ester C=O); ^1H NMR (DMSO-d_6) δ=2.40 (3H, s, CH_3CO), 3.30 (6H, s, -$\overset{+}{S}(CH_3)_2$), 3.41 (3H, s, CH_3SO_4), 7.45 (2H, d, J=8Hz, C_6H_4), 8.10 (2H, d, J=8Hz, C_6H_4); Found: C, 42.43; H, 5.24%; Calcd for $C_{11}H_{16}O_6S_2$: C, 42.87; H, 5.19%.

Preparation of Active Ester of N-Protected Amino Acids. A typical example is as follows. **Z-Ala-ODMSP·$MeSO_4^-$**: Z-Ala-OH (2.23 g, 10 mmol) and **8**$_d$ (2.66 g, 10 mmol) were dissolved in CH_3CN and DCC (2.66 g, 10 mmol) was added to the solution below 0°C with stirring. After stirring overnight DCurea was filtered off and the filtrate was concentrated in vacuo to give an oily residue. The oily residue was washed with ether by decantation. Yield 87%; R_{f_1} 0.82; R_{f_2} 0.25; $[\alpha]_D^{20}$ −18° (*c*1, MeOH); IR (neat) 1760 cm^{-1} (ester C=O), 1700 cm^{-1} (amide C=O). **Z-Phe-ODMSP·$MeSO_4^-$**: Yield 90%; R_{f_1} 0.77; R_{f_2} 0.41; $[\alpha]_D^{20}$ −16° (*c*1, MeOH); IR (neat) 1764 cm^{-1} (ester C=O), 1700 cm^{-1} (amide C=O). **Boc-Leu-ODMSP·$MeSO_4^-$**: Yield 88%; R_{f_1} 0.77; R_{f_2} 0.38; $[\alpha]_D^{20}$ −29° (*c*1, MeOH); IR (neat) 1762 cm^{-1} (ester C=O), 1698 cm^{-1} (amide C=O). **Z-Pro-ODMSP·$MeSO_4^-$**: Yield 90%; R_{f_1} 0.61; R_{f_2} 0.30; $[\alpha]_D^{20}$ −62° (*c*1, MeOH); IR (neat) 1760 cm^{-1} (ester C=O), 1700 cm^{-1} (amide C=O). All these active esters were obtained as an oily product.

Reaction of 17 or 18 with Amino Acids or Peptide in Aqueous Solution. In the Case of Neutral Amino Acids: Amino acids and equimolar Et_3N were dissolved in water and equimolar **17** or **18** was added to the solution at room temperature with stirring. After 4 h, 20% citric acid was added to the solution and the pH of the solution was adjusted to 3.0. The mixture was extracted with ethyl acetate. The solution was washed with water and then dried over anhydrous sodium sulfate. The filtrate was concentrated in vacuo. The oily residue was crystallized with petroleum ether. **In the Case of Arg, Ser, His, Glu, Lys, Cys, and Gly-Tyr:** Each amino acid or peptide was dissolved in water and the pH of the solution was adjusted to 6.0—9.0 by addition of Et_3N. An equimolar amount **17** was added to a stirred solution below 20 °C, the pH being maintained automatically at the starting pH with Et_3N for 7 h. In the case of Ser or Glu, 20% citric acid was added to the solution and the pH of the solution was adjusted to 3.0. The mixture was extracted with ethyl acetate. The solution was washed with water and then dried over anhydrous sodium sulfate. The filtrate was concentrated in vacuo. The oily residue was crystallized with ether and petroleum ether. In the case of Arg, His, Lys, and Cys, each product was precipitated from the solution. The crystalline product was removed from the reaction mixture by filtration. Gly-Tyr was acylated using **17** in 0.4 M phosphate buffer (Na_2HPO_4-NaH_2PO_4) at pH 6.0 and 8.0 in a similar manner to the acylation of amino acids. The product which resulted from the reaction at each pH was isolated by extraction with ethyl acetate, respectively; then, the ratio of **21** and **22** in the product was determined by HPLC (column: Lichrosob PR-18; eluent: 85% MeOH). The results of acylation of amino acids and peptide in aqueous solution are shown in Tables 3 and 4.

Preparation of Protected Peptide Using HODMSP·$MeSO_4^-$ Active Ester. Reaction in $CHCl_3$: To a solution of HODMSP·$MeSO_4^-$ active ester of N-protected amino acid in $CHCl_3$, a solution of equimolar amino acid ester and Et_3N in $CHCl_3$ was added. The reaction mixture was stirred for 7 h at room temperature. After removing the solvent in vacuo, the residue was dissolved in ethyl acetate, and the solution was washed, successively, with water and 4% citric acid. The organic solution was dried over anhydrous sodium sulfate. The solution was concentrated to an oily residue which was crystallized by addition of ether and petroleum ether. **Reaction in H_2O: (A) In the Case of Neutral Amino Acid as Amine Component:** To a solution of HODMSP·$MeSO_4^-$ active ester of N-protected amino acid in water, a solution of equimolar amino acid and Et_3N in water was added. The reaction mixture was stirred at room temperature. After 12 h, 20% citric acid was added to the solution and the pH of the solution was increased to 3.0—4.0. The mixture was extracted with ethyl acetate. The solution was washed with water and dried over anhydrous sodium sulfate. The filtrate was concentrated in vacuo. The oily residue was crystallized with ether. **(B) In the Case of Ser, Glu, His, and Gly-Tyr as Amine Component:** These peptide were prepared with HODMSP·$MeSO_4^-$ active ester of N-protected amino acid in a similar manner to the acylation of amino acid having functional group in the side chain. Z-Ala-Ser-OH, Z-Ile-Glu-OH, and Z-Pro-Gly-Tyr-OH were obtained after extraction with ethyl acetate from the reaction mixture and crystallized from ether and petroleum ether. They were recrystallized from ethyl acetate. Z-Phe-His-OH was obtained after filtration from the reaction mixture. The results of these preparations are shown in Table 5.

Preparation of Protected Peptides Using HONp or HOSu Active Ester. To a solution of HONp or HOSu active ester of N-protected amino acid in THF, a solution of equimolar amino acid and Et_3N in water was added. The reaction mixture was stirred for 7 h at room temperature. After removing THF in vacuo, the aqueous solution was extracted with ethyl acetate to remove the unreacted active ester. 20% citric acid was added to the aqueous layer and the pH was adjusted to 3.0. The resulting oily product was extracted with ethyl acetate, and then washed with water. The organic solution was dried over anhydrous sodium sulfate. The filtrate was concentrated to an oily residue which was crystallized by the addition of ether.

Determination of the Rate of Aminolysis. Into a 50 ml volumetric flask was added a solution containing 2.0 mmol of an appropriate derivative **17**, **19**, or **20** in CH_3CN. To the solution having been heated at 25 °C was added a solution of 2.4 mmol of Gly in H_2O (50 ml). At predetermined time intervals, 1 ml aliquotes of the solution

were withdrawn and diluted with distilled water (total volume, 100 ml). The consumption of Gly was measured using HPLC (column: AApack Na; eluent: 0.1 M citrate buffer, pH 3.05, 60 °C). Each point in Fig. 3 represents a mean value of three runs.

Detection of Racemization. Leu-Asp: Boc-Lue-Asp-OH was prepared using HODMSP·$MeSO_4^-$ active ester, HONp active ester, or HOSu active ester. Each Boc-Leu-Asp-OH obtained was then treated with 4 M HCl in dioxane to afford Leu-Asp. A chromatographic detection of this diastereomeric dipeptide was carried out with HPLC (column: AApack Na; eluent: 0.1 M citrate buffer, pH 3.25, 60 °C). The detection of the dipeptide was performed by OPA detection system. Authentic samples of L-Leu-L-Asp and D-Leu-L-Asp were prepared by the usual manner. **Gly-Ala-Leu:** Z-Gly-D-Ala-OH and authentic samples of H-Gly-L-Ala-L-Leu-OH and H-Gly-D-Ala-L-Leu-OH were prepared by the methods described in the literature.[33] The dipeptide (Z-Gly-L-Ala-OH) was esterified with HODMSP·$MeSO_4^-$, HONp, HOSu, or HOPcp and DCC to afford the corresponding active ester. The conditions of esterification are summarized in Table 6. Each active ester, thus obtained, was allowed to react with L-Leu at room temperature overnight to give protected tripeptide. After catalytic hydrogenation to remove the protecting group, the tripeptide was analyzed according to the procedure in Leu-Asp.

Synthesis of FMRFamide. Z·Arg(NO_2)-Phe-NH_2 (23): A solution of Z-Arg(NO_2)-OH (3.53g, 10 mmol) and NMM (1.1 ml, 10 mmol) in THF (20 ml) was chilled to −5 °C, then ECF (1 ml,10 mmol) was added to it. After 10 min, a precooled solution of H-Phe-NH_2·HCl (2.00 g, 10 mmol) and Et_3N (1.4 ml, 10 mmol) in $CHCl_3$ (20 ml) was added. The reaction mixture was refrigerated for 1 h and then allowed to stand overnight at room temperature. The reaction mixture was concentrated in vacuo, and the residue was suspended in hot methanol (50 ml). The solid was filtered and washed with methanol; yield 4.24 g (85%); mp 218—221 °C; $[\alpha]_D^{20}$ −14° (*c* 0.5, DMF); R_{f_1} 0.91; R_{f_2} 0.41; Found: C, 55.56; H, 5.70; N, 19.38%; Calcd for $C_{23}H_{29}O_6N_7$: C, 55.34; H, 5.81; N, 19.63%. **H-Arg-Phe-NH_2·2AcOH (24):** Compound **23** (2.50 g, 5 mmol) in acetic acid (10 ml) was hydrogenated in the presence of palladium black. The filtrate was concentrated in vacuo and the residue was crystallized from ether as hygroscopic crystals; yield 1.08 g (98%); $[\alpha]_D^{20}$ +9° (*c* 1, H_2O); R_{f_1} 0.41; R_{f_3} 0.75. **Boc-Met-ODMSP·$MeSO_4^-$ (25):** To a chilled solution of Boc-Met-OH (2.49 g, 10 mmol) and HODMSP·$MeSO_4^-$ (2.66 g, 10 mmol) in CH_3CN (80 ml), DCC (2.06 g, 10 mmol) was added. The reaction mixture was kept overnight at 0 °C and the DCurea which formed was filtered off. The filtrate was concentrated in vacuo, and the residual oil was washed with ether by decantation; yield 3.93 g (80%); $[\alpha]_D^{20}$ −30° (*c* 1, MeOH); R_{f_1} 0.82; R_{f_2} 0.34. **Boc-Met-Arg-Phe-NH_2·picrate (27):** Compound **24** (0.88 g, 2 mmol) was dissolved in H_2O and the pH of the solution was adjusted to 7.2 by addition of Et_3N. Boc-Met-ODMSP·$MeSO_4^-$ (0.99 g, 2 mmol) was added to the stirred solution below 20 °C, the pH being automatically maintained at 7.2 with Et_3N. After 12 h, 1% picric acid was added to the solution and the pH of the solution was adjusted to 5.6. A yellow precipitate was filtered off and it was dissolved in ethyl acetate (100 ml). The solution was successively washed with 4% sodium hydrogencarbonate, 4% citric acid and water, and then dried over anhydrous sodium sulfate. The solution was concentrated to an oily residue which was crystallized by the addition of ether. It was recrystallized from $CHCl_3$; yield 0.75 g (45%); mp 110 °C (decomp); $[\alpha]_D^{20}$ −14° (*c* 0.5, DMF); R_{f_1} 0.83; R_{f_2} 0.32; Found: C, 46.84; H, 5.81; N, 17.95%; Calcd for $C_{25}H_{41}O_5N_7S·C_6H_3N_3O_7·1/2H_2O$: C, 47.17; H, 5.70; N, 17.74%; MS *m/z* 552 (M^+H); Amino acid ratios in acid hydrolyzate: Arg 0.94, Met 0.89, Phe 1.00. **H-Met-Arg-Phe-NH_2·2HCl (28):** To a solution of **27** (0.78 g, 1 mmol) and ethyl methyl sulfide (1 ml) in dioxane (5 ml), 4.1 M HCl in dioxane (5 ml) was added. The reaction mixture was allowed to stand at room temperature. After 2 h, the solution was concentrated in vacuo. The residue was crystallized with ether; yield 0.47 g (90%); mp 140 °C (decomp); $[\alpha]_D^{20}$ +10° (*c* 0.5, H_2O); R_{f_1} 0.52; R_{f_3} 0.74; Found: C, 49.03; H, 6.87; N, 20.01%; Calcd for $C_{20}H_{33}O_3N_7S.2HCl$: C, 49.25; H, 6.97; N, 20.09%. Amino acid ratios in acid hydrolyzate: Arg 0.96, Met 0.84, Phe 1.00. **pMZ-Phe-ODMSP·$MeSO_4^-$ (29):** pMZ-Phe-OH (3.29 g, 10 mmol) and HODMSP·$MeSO_4^-$ (2.66 g, 10 mmol) were coupled by the same method as **25**. The oily product was obtained; yield of the oily product 5.20 g (90%); $[\alpha]_D^{20}$ −7° (*c* 1, MeOH); R_{f_1} 0.85; R_{f_2} 0.51. **pMZ-Phe-Met-Arg-Phe-NH_2 (30):** Compound **28** (0.52 g, 1 mmol) was dissolved in H_2O (10 mmol) and the solution was adjusted to 7.2 by addition of Et_3N. pMZ-Phe-ODMSP.$MeSO_4^-$ (0.69 g, 1.2 mmol) was added to the stirred solution below 20 °C, the pH being maintained automatically at 7.2 with Et_3N. After 12 h, the mixture was extracted with ethyl acetate (100 ml). The solution was successively washed with 4% sodium hydrogencarbonate, 4% citric acid, and water, and then dried over anhydrous sodium sulfate. The solution was concentrated to a crystalline residue. It was recrystallized from methanol; yield 0.33 g (41%); mp 190 °C (decomp); $[\alpha]_D^{20}$ −20° (*c* 0.5, DMF); R_{f_1} 0.80; R_{f_3} 0.91; Found: C, 55.91; H, 6.31; N, 13.47%; Calcd for $C_{38}H_{50}O_7N_8S·HCl·H_2O$: C, 55.87; H, 6.49; N, 13.71%. MS *m/z* 763 (M^+H); amino acid ratios in acid hydrolyzate: Arg 0.95, Met 0.87, Phe 2.00. **H-Phe-Met-Arg-Phe-NH_2 (FMRFamide)·HCl·TFA (31):** Compound **30** (0.4 g, 0.5 mmol) and ethyl methyl sulfide (0.5 ml) were dissolved in TFA (5 ml). The reaction mixture was allowed to stand at room temperature. After 2 h, the solution was concentrated in vacuo. Redox-Photosensitized Reactions. XV.[1] Photosensitized and Direct Photolytic Isomerizations of the Tetrahydro Dimers of 1-Benzylnicotinamide

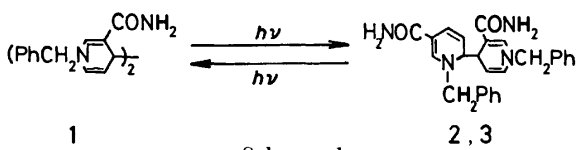
Osamu ISHITANI, Shozo YANAGIDA, Setsuo TAKAMUKU, and Chyongjin PAC*
Department of Chemical Process Engineering, Faculty of Engineering, Osaka University, Suita, Osaka 565
(Received January 16, 1987)

The photosensitization by either $[ReBr(bpy)(CO)_3]$ or $[Ru(bpy)_3]^{2+}$ (bpy=2,2′-bipyridine) resulted in the isomerization of 1,1′-dibenzyl-1,1′,4,4′-tetrahydro-4,4′-binicotinamide (**1**) and 1,1′-dibenzyl-1,1′,4,6′-tetrahydro-4,6′-binicotinamide (**2**) to give a common mixture of **1**, **2**, and the diastereoisomer of **2** (**3**) in a 2:2:1 ratio at a photostationary state, while either direct photoexcitation or thermal activation effected only the isomerization of **2** to **1** but not at all the retro isomerization.

The pyridine nucleotide coenzymes $(NAD(P)^+/NAD(P)H)$ reveal unique redox capabilities of undergoing specific transfer of a hydride equivalent (or two electrons) with a variety of substrates.[2] However, one-electron redox reactions can also very often occur with the coenzymes in the absence of oxido-reduction enzymes and particularly with their models in homogeneous solution, giving the corresponding tetrahydrobipyridines (NAD_2)[3-7] which are considered to be dead-end products incapable of undergoing two-electron redox reactions. Therefore, little has been investigated on chemical properties of NAD_2.

Nevertheless, it is certainly of chemical significance to explore chemistry of NAD_2 because of the unique dihydropyridyl structures and because of potential electron-donating nature. From this point of view, we have investigated chemical behaviors of NAD_2 using 1,1′-dibenzyltetrahydrobinicotinamides (**1**—**3**) which are selectively formed either by one-electron reduction of 1-benzylnicotinamide (BNA^+), a typical NAD^+ model, or by one-electron oxidation of 1-benzyl-1,4-dihydronicotinamide (BNAH), a typical NADH model. This paper deals with photochemical isomerizations of the 1,1′-dibenzyl-1,1′,4,4′-tetrahydro-4,4′-binicotinamide (**1**) and the diastereomeric isomers of 1,1′-dibenzyl-1,1′,4,6′-tetrahydro-4,6′-binicotinamide (**2** and **3**) (Scheme 1).



Scheme 1.

Results and Discussion

The zinc reduction of 1-benzylnicotinamide gave a mixture of the corresponding tetrahydrobinicotinamides,[3] from which one of the 4,4′-bonded diastereomers **1** and one of the 4,6′-bonded diastereomers **2** were obtained in purities enough for the present photochemical investigation, while another diastereomer of **2** (**3**) could be isolated only in a small amount. On the other hand, what appears to be the other isomer of **1**[3] was able to be detected by HPLC but not isolated because of its minor formation and difficulties of the isolation. Therefore, we used **1** and **2** as the starting materials and *N*,*N*-dimethylformamide (DMF) as the solvent.

Irradiation of a deaerated solution of **1** (2.5 mM†) and $[ReBr(bpy)(CO)_3]$ (0.8 mM) at 436 nm resulted in the isomerization of **1** to **2** and **3**, thus giving a 2:2:1 mixture of **1**, **2**, and **3** at a photostationary state (Fig. 1). The photosensitized isomerization of **2** to **1** and **3** again occurred to reach an identical photostationary state. Similarly, $[Ru(bpy)_3]^{2+}$ was effectively used as the photosensitizer for the isomerizations while the irradiation was carried at >470 nm. In all the runs, HPLC analyses showed the formation of a few common products in small amounts at retention times identical with those of the minor products in the zinc reduction of BNA^+.[3] Table 1 summarizes the photostationary-state ratios of **1**, **2**, and **3**.

The efficient photosensitized isomerization of **1** to **2**

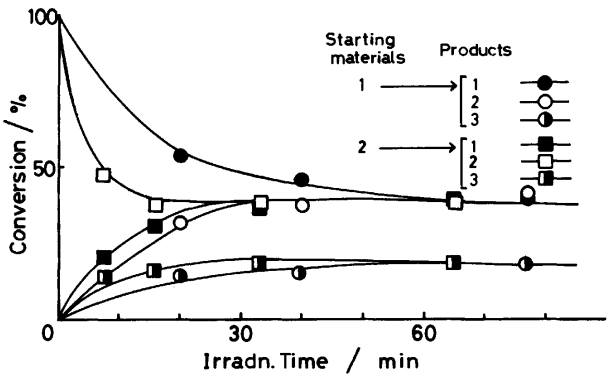


Fig. 1. Time-conversion plots for the $[ReBr(bpy)(CO)_3]$-photosensitized isomerization of **1** and **2** at 436 nm; [**1**] or [**2**]=2.5 mM and $[[ReBr(bpy)(CO)_3]]$= 0.8 mM.

1	100°C	300	56	Trace	Trace
2	60°C	960	2	78	1
2	100°C	300	14	2	1

a) For deaerated DMF solutions containing **1** or **2** (2.5 mM). b) "Photolysis" means the reactions by direct photoexcitation at 436 nm, whereas the temperatures indicate the reaction temperatures for the thermal reactions in the dark. c) Based on the **1** or **2** used.

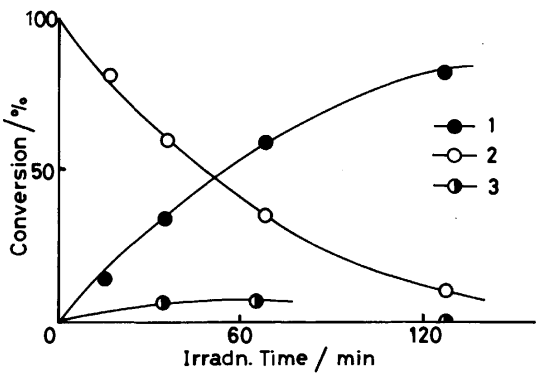

Fig. 2. Time-conversion plots for the direct photolytic isomerization of **2** at 436 nm; [**2**]=2.5 mM.

and **3** is of synthetic and mechanistic interest, since either thermal[3] or direct photoexcitation can effect the one-way isomerization from **2** to **1** for the most part. Upon heating a DMF solution of **2** at 60 or 100 °C, a reaction proceeded to give **1** only in poor yields along with substantial amounts of untractable materials, while little isomerization of **1** to either **2** or **3** occurred at 60 °C and even at 100 °C being accompanied by substantial consumption of **1**, as shown in Table 2. This means that the isomerization of **1** and **2** is only a negligible or minor pathway in the ground-state reactions. On the other hand, direct photoexcitation of **2** in DMF at 436 nm resulted in the isomerization to **1** along with very minor formation of **3** (Fig. 2), while **1** was found to be quite stable under the irradiation at 436 nm. In the excited state(s), **2** might cross to a reactive state or might give reactive intermediates while physical and chemical decays to the original ground state should predominantly occur with **1**.

For mechanistic elucidation, it shoud be noted that either chemical or electrochemical one-electron reduction of BNA^+ affords a mixture of **1**, **2**, and **3** in comparable amounts along with the other minor isomers in ratios depending on reaction conditions.[3] We also observed that a 2:2:1 mixture of **1**, **2**, and **3** is quantitatively formed by the photosensitized one-electron reduction of BNA^+ with triethylamine.[8] It is therefore conceivable that the formation of mixtures of **1**, **2**, and **3** should arise as the consequences of kinetic-controlled dimerization of the 1-benzyl-3-carbamoyldihydropyridyl radicals (BNA·), since BNA· is certainly a common intermediate in the chemical, electrochemical, and photochemical one-electron reductions of BNA^+.

These arguments strongly suggest that the photosensitized isomerizations of **1** and **2** involve BNA· as a key intermediate. In this regard, it should be

noted that the luminescence of [ReBr(bpy)(CO)$_3$] or [Ru(bpy)$_3$]$^{2+}$ is efficiently quenched by **1** and **2** at the rate constants listed in Table 1. In a previous paper,[9] we demonstrated that the luminescence of [Ru(bpy)$_3$]$^{2+}$ is quenched by BNAH at 2.0×10^8 M^{-1} s^{-1} in DMF by way of electron transfer from the quencher to the ruthenium(II) complex. Therefore, it is reasonable to assume that electron transfer from **1** and **2** to the luminescent excited-state sensitizers occurs to initiate the isomerizations, since **1** and **2** have the dihydronicotinamide chromophores. The dimeric structures of **1** and **2** imply that these compounds should be stronger electron donors compared with BNAH, a presumption being in accord with the greater quenching rate constants for **1** and **2**. Furthermore, the observation that the luminescence quenching is more efficient for [ReBr(bpy)(CO)$_3$] than for [Ru(bpy)$_3$]$^{2+}$ can be reasonably understood according to the electron-transfer mechanism, since the excited-state reduction potential of [ReBr(bpy)(CO)$_3$] is more positive by ca. 0.24 eV than that of [Ru(bpy)$_3$]$^{2+}$.[10,11] An alternative mechanism involving triplet-energy transfer from the sensitizers to **1** and **2** is unlikely to operate in the photosensitized isomerizations, since such organic triplet photosensitizers as coronene and chrysene were found to be totally ineffective.

According to the above discussion, we propose a possible mechanism for the photosensitized isomerizations in Eqs. 1—5. The key mechanistic sequence is the fragmentation of BNA$_2^{+\cdot}$ (**1**$^{+\cdot}$ and **2**$^{+\cdot}$) to BNA$\cdot$ and BNA$^+$ (Eq. 3) followed by back electron transfer from S$^{-\cdot}$ ([ReBr(bpy)(CO)$_3$]$^{-\cdot}$ or [Ru(bpy)$_3$]$^+$) to BNA$^+$ to generate BNA$\cdot$ (Eq. 4). It can be predicted that electron transfer from S$^{-\cdot}$ to BNA$^+$ (Eq. 4) rapidly occurs since the reduction potentials of [ReBr(bpy-(CO)$_3$] (-1.35 V vs. SCE in acetonitrile)[12] and [Ru-(bpy)$_3$]$^{2+}$ (-1.36 V)[13] are substantially more negative than that of BNA$^+$ (ca. -1.0 V).[14] The final products are thus formed by free-radical coupling of BNA$\cdot$ (Eq. 5). Since material balances are excellent in the photosensitized isomerizations, the fragmentation of BNA$_2^{+\cdot}$ (Eq. 3) appears to be efficient, thus predominating over Eq. 2.

$$S + BNA_2 \overset{h\nu}{\rightleftharpoons} S^{-\cdot} + BNA_2^{+\cdot} \quad (1)$$

$$BNA_2^{+\cdot} \longrightarrow \text{Others} \quad (2)$$

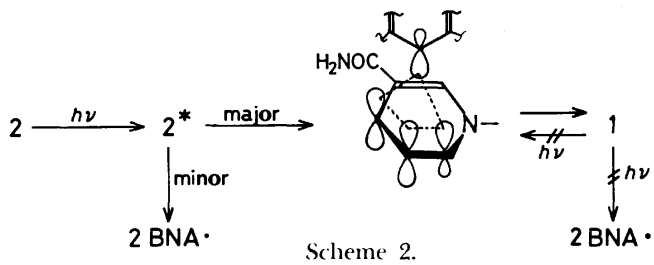
$$BNA_2^{+\cdot} \longrightarrow BNA^+ + BNA\cdot \quad (3)$$

$$S^{-\cdot} + BNA^+ \longrightarrow S + BNA\cdot \quad (4)$$

$$2BNA\cdot \longrightarrow \mathbf{1} + \mathbf{2} + \mathbf{3} \quad (5)$$

(S=[ReBr(bpy)(CO)$_3$] or [Ru(bpy)$_3$]$^{2+}$; BNA$_2$=**1**—**3**)

On the other hand, the participation of BNA$\cdot$ appears to be negligible or minor in the isomerizations of ground-state and excited-state BNA$_2$, since only the one-way isomerization from **2** to **1** can occur. Furthermore, the free-radical mechanism disagrees with the negligible formation of **3** from **2** upon either thermal activation or direct photoexcitation, since the isomerization of **2** to **3** should comparably occur, at least at an early stage of the reactions, by this mechanism. Presumably, the photoisomerization of **2** might mainly proceed via 1,3-sigmatropic migration of the 1,4-dihydropyridinyl moiety from the 6′ position to the 4′ position of the 1,6-dihydronicotinamide ring, which is an orbital-symmetry-allowed process in the excited state (Scheme 2).[15] The reverse sigmatropic migration (i.e. **1** to **2**) would be thermodynamically unfavorable. According to this mechanism, it can be reasonably understood that the thermal isomerization of **2** occurs only in poor yields, since a suprafacial 1,3-sigmatropic rearrangement is forbidden in the ground state.



Scheme 2.

Summary

It was found that the isomerizations of **1** and **2** occur upon photosensitization by [ReBr(bpy)(CO)$_3$] or [Ru(bpy)$_3$]$^{2+}$ to give a common 2:2:1 mixture of **1**, **2**, and **3** at a photostationary state. On the other hand, direct photoexcitation resulted in the one-way isomerization from **2** to **1** along with only minor formation of **3**; **1** was found to be photostable. Although **2** was reported to isomerize to **1** by thermal activation,[3] we confirmed that the isomerization can occur only as a minor pathway in the ground-state reactions.

The photosensitized isomerzations of **1** and **2** were discussed in terms of the following chemical sequences; (1) electron transfer from **1** or **2** to the luminescent excited state sensitizers, (2) bond cleavage of **1**$^{+\cdot}$ and **2**$^{+\cdot}$ to generate BNA$\cdot$ and BNA$^+$, (3) back electron transfer from the one-electron reduced sensitizers to BNA$^+$, and (4) the free-radical dimerization of BNA$\cdot$ to give a mixture of **1**, **2**, and **3** for the most part. According to this mechanism, a significant point is that both **1**$^{+\cdot}$ and **2**$^{+\cdot}$ are chemically reactive to undergo the fragmentation to BNA$\cdot$ and BNA$^+$. On the other hand, a 1,3-sigmatropic mechanism was suggested for the direct photolytic isomerization of **2** to **1**.

Experimental

Materials. The sensitizers, [ReBr(bpy)(CO)$_3$][16] and [Ru-(bpy)$_3$]Cl$_2$·6H$_2$O,[17] were prepared and purified according to

the literature methods. The preparation and isolation of **1**, **2**, and **3** was carried out according to the Ohnishi's method[3] utilizing the reduction of 1-benzyl-3-carbamoylpyridinium chloride with activated zinc powder in the presence of copper(II) sulfate. The isolated tetrahydrobipyridines, particularly **2** and **3**, were carefully recrystallized from deaerated DMF-H_2O solution below room temperature in order to avoid the contamination of untractable materials due to thermal decomposition and oxidation. The ^1H NMR spectra of the isolated samples were essentially identical with the published data.[3]

Analytical Methods. Both the disappearance and the formation of 1, **2**, and **3** were followed by HPLC, which was carried out on a Chemicosorb 7-ODS-H column with a Yanaco M-315 spectromonitor working at 355 nm. The mobile phase was a 6:4 (v/v) mixture of methanol and an NaOH-KH_2PO_4 buffer solution (pH 7) at a flow rate of 0.8 $cm^3\ min^{-1}$. A Hitachi 850 spectrofluorometer was used for luminescence-quenching experiments; the ruthenium complex (0.25 mM) in DMF was excited at 550 nm and intensities of the luminescence were monitored at 610 nm, whereas the luminescence of the rhenium complex (0.75 mM) excited at 420 nm was monitored at 600 nm.

Photoreactions. Deaerated DMF solutions of **1** or **2** (2.5 mM) in the presence or absence of the sensitizers (0.8 mM) were irradiated under cooling with water (20±2 °C), and the progress of the reactions was followed by HPLC. It was confirmed that no reaction of 1 and **2** occurred in the dark under the conditions. The $[Ru(bpy)_3]^{2+}$-photosensitized reactions were run by the irradiation with a tungsten-halogen lamp (300W) using a 1-cm pathlength filter solution of K_2CrO_4 (20 g dm^{-3}), $NaNO_3$ (200 g dm^{-3}), and NaOH (6.7 g dm^{-3}) which cuts off the light shorter than 470 nm.[9] In both the $[ReBr(bpy)(CO)_3]$-photosensitized runs and the direct photolyses, an Eikosha high-pressure mercury arc (300W) was used; the 436-nm resonance line was isolated by the passage through a 1-cm pathlength solution of $CuSO_4$ in 28% ammonium hydroxide.[18] In the $[ReBr(bpy)(CO)_3]$-photosensitized reactions, contributions of reactions due to direct light absorption of the reactants are negligible, since the optical density of the sensitizer at 436 nm is 7—8 times greater than that of each reactant and since the photosensitized reactions are much more efficient than the direct photolyses.

Thermal Reactions. Deaerated DMF solutions of **1** or **2** (2.5 mM) were heated at 60±0.5 °C or at 100±0.5 °C in a dark room. The progress of the reactions was followed by HPLC. All the procedures were done with care in order to avoid exposure of the reactant solutions to scattering light.

NAD(P)$^+$-NAD(P)H Model. 63. Regioselective Reduction of Dienoic Ketones and Aldehydes with an NAD(P)H Model on Silica Gel

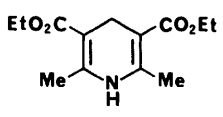
Masayuki Fujii, Kaoru Nakamura, Shinro Yasui,† Shinzaburo Oka, and Atsuyoshi Ohno*
Institute for Chemical Research, Kyoto University, Uji, Kyoto 611
†Tezukayama College, Gakuen-Minami, Nara 631
(Received January 20, 1987)

The Hantzsch ester reduces carbon-carbon double bonds in α,β-unsaturated ketones and aldehydes under the catalysis of silica gel. The 1,4-selectivity is satisfactorily high even in the reductions of polyenes conjugated to a carbonyl group. Methyl substituent at an olefinic position (α or β to the carbonyl group) retards the reduction. The reduction can be used as a useful tool in obtaining building blocks for the syntheses of terpenoids and their derivatives.

Quite a few reports have been published concerning to the mechanism of reduction with NADH, NADPH, and their analogs.[1] Stereochemistry for the reduction of carbonyl function in both biological and mimetic systems has been documented as well.[2] On the other hand, studies on synthetic application of the reduction with dihydropyridine derivatives has attracted little attention from organic chemists.[3] Namely, the mimetic reduction of carbon-carbon double bonds has been studied much less extensively than the reduction of carbon-oxygen double bonds, and reducible olefins in mimetic systems are limited to those that are substituted by a strongly electron-withdrawing substituent(s).[4] In some cases, photoirradiation is also effective for the reduction of olefins.[5] The reduction of carbon-carbon double bonds may have more value in synthetic organic chemistry than the reduction of carbon-oxygen double bonds and should be studied much more seriously.

Contrary to the mimetic systems, however, there are several biological systems that reduce carbon-carbon double bonds with the catalyses of NAD$^+$- or NADP$^+$-dependent dehydrogenases or reductases.[6] Since most NAD(P)H models so far studied have redox potentials comparable to that of NADH or NADPH[7] and these coenzymes reduce olefins in enzymatic systems, our effort should be concentrated on finding a suitable catalyst that behaves as a *mimetic enzyme* in order to undergo the organic reduction under mild conditions.

In previous papers of the series, we reported that silica gel is indeed a good catalyst for the reduction of carbon-carbon double bonds in α,β-unsaturated ketones and aldehydes,[8] and those in α-nitro olefins.[9] We now wish to report that the reduction with Hantzsch ester (HEH) in the presence of silica gel proceeds with very high chemoselectivity and regioselectivity under mild conditions, and that the reduction can be employed as a useful tool for wide variety of organic syntheses.



HEH

Experimental

Instruments. ^{1}H NMR spectra were measured at 100 and 400 MHz with a JEOL JNM-FX100 and a JEOL GX400 Fourier transform NMR spectrometers. IR spectra were recorded on a Hitachi EPI-S2 infrared spectrometer. Elemental analyses were performed with a Yanaco MT-3 elemental analyzer. Gas chromatographic data were recorded on a Yanaco G-1800 gas chromatograph (OV330, 1 m).

Materials. Hantzsch ester (HEH), and HEH-4,4-d_2 were prepared as reported in a previous paper.[10] The deuterium content in HEH-4,4-d_2 was confirmed to be 98% by 400 MHz ^{1}H NMR analysis. Citral (**3**), 2,4-nonadienal (**4c**), and β-ionone (**15**) are commercially available (Nakarai Chemicals Ltd.).

Other substrates were prepared according to literature methods.[11]

Silica gel (Nakarai Silica Gel 60, 35—70 mesh) was activated at about 80 °C in an oven for a few days. Anhydrous benzene was freshly distilled over calcium hydride immediately before the use.

Reduction of Benzylideneacetone (1a). In a 20 ml flask equipped with a magnetic stirrer and a reflux condenser, were placed 288 mg (2 mmol) of **1a**, 760 mg (3 mmol) of HEH, 2.0 g of silica gel, and 10 ml of anhydrous benzene. The mixture was heated to reflux for about 20 h under an argon atmosphere in the dark. The reaction mixture was cooled to room temperature, filtered, and washed with 30 ml of benzene. The filtrate was washed with 2 M†† hydrochloric acid (2×20 ml), water (2×20 ml), and 20 ml of brine, then dried on anhydrous sodium sulfate. Filtration and evaporation left a crude product, which was subjected to column chromatography on silica gel with benzene eluent to give 280 mg (96% yield) of the pure product, 4-phenyl-2-butanone (**2a**). The yield measured on gas chromatography was 100%.

†† 1 M=1 mol dm^{-3}.

^{1}H NMR ($CDCl_3$) δ=2.07 (s, 3H, CH_3CO), 2.74—2.81 (m, 4H, CH_2), 7.14—7.27 (m, 5H, Ph). IR (neat) 3000 (m) and 1717 (s) cm^{-1}. Found: C, 80.94; H, 8.31%. Calcd for $C_{10}H_{12}O$: C, 81.04; H, 8.31%.

Reduction of Cinnamaldehyde (1b). Reduction of 264 mg (2 mmol) of **1b** with 760 mg (3 mmol) of HEH and 2.0 g of silica gel afforded 192 mg (72% yield) of 3-phenylpropanal (**2b**). The yield on gas chromatography was 100%.

^{1}H NMR ($CDCl_3$) δ=2.64—3.04 (m, 4H, CH_2), 7.04—7.35 (m, 5H, Ph), and 9.76 (t, 1H, CHO). IR (neat) 3000 (m) and 1730 (s) cm^{-1}. Found: C, 80.38; H, 7.62%. Calcd for $C_9H_{10}O$: C, 80.56; H, 7.51%.

Reduction of Ethyl Cinnamate (1c). Starting with 2 mmol of **1c**, 3 mmol of HEH, and 2.0 g of silica gel, no product was detected, and the starting materials were obtained from the reaction mixture in 100% recovery, respectively.

Reduction of β-Nitrostyrene (1d). A mixture of 151 mg (1 mmol) of **1d**, 280 mg (1.1 mmol) of HEH, and 1.0 g of silica gel in 5 ml of anhydrous benzene was heated to reflux for 5 h under an argon atmosphere in the dark. The reaction mixture was worked up as described above giving 129 mg (84% yield) of 2-phenyl-1-nitroethane, (**2d**).

^{1}H NMR ($CDCl_3$) δ=3.30 (t, 2H, J=7 Hz, $PhCH_2$), 4.58 (t, 2H, J=7 Hz, CH_2NO_2), and 7.11—7.33 (m, 5H, Ph). IR (neat) 3000 (m), 1530 (s), and 1380 (s) cm^{-1}. Found: C, 63.90; H, 6.10; N, 9.16%. Calcd for $C_8H_9NO_2$: C, 63.56; H, 6.00; N, 9.27%.

Reduction of Citral (3). Reduction of 152 mg (1 mmol) of **3** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel under the same conditions as described above gave 103 mg (67% yield) of citronellal.

^{1}H NMR ($CDCl_3$) δ=0.97 (d, 3H, J=7 Hz, CH_3CH), 1.20—1.44 (m, 3H, $-CH_2CH(CH_3)-$), 1.60 (s, 3H, $(CH_3)_2C=$), 1.68 (s, 3H, $(CH_3)_2C=$), 2.00 (q, 2H, J=7 Hz, $-CH_2CH=$), 2.24—2.50 (m, 2H, CH_2CHO), 5.00—5.17 (m, 1H, C=CH), and 9.74 (t, 1H, J=1 Hz, CHO). IR (neat) 3000 (m) and 1740 (s) cm^{-1}. Found: C, 77.62; H, 11.74%. Calcd for $C_{10}H_{18}O$: C, 77.86; H, 11.74%.

Reduction of (3*E*,5*E*)-6-Phenyl-3,5-hexadien-2-one (4a). After the reaction of 172 mg (1 mmol) of **4a** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel in 10 ml of anhydrous benzene followed by usual work-up, column chromatography on silica gel with benzene eluent gave 153 mg (88% yield) of a mixture of two products, **5a** and **6a**. The ratio of **5a** to **6a** was determined by ^{1}H NMR analysis. The integration of signals for allylic C_α (C_3) protons (2H) in **6a** which appeared at δ 3.12 (d, J=5 Hz) and δ 3.25 (d, J=5 Hz)[12] was compared with that of signals for acetyl protons (3H) at δ 2.11 and the ratio was calculated as 73:27 (*E*:*Z* of **6a**=63:37).

^{1}H NMR ($CDCl_3$) δ=2.11 (s, CH_3CO-), 2.42—2.60 (m, CH_2 of **5a**), 3.12 (d, J=5 Hz, $-CH_2CO-$ of (*E*)-**6a**), 3.25 (d, J=5 Hz, $-CH_2CO-$ of (*Z*)-**6a**), 3.36 (d, J=5 Hz, $PhCH_2-$ of **6a**), 5.56—5.76 (m, H_β and H_γ of **6a**), 6.12 (dt, J=15, 6 Hz, H_γ of **5a**), 6.38 (d, J=15 Hz, H_δ of **5a**), and 7.04—7.41 (m, Ph). IR (neat) 3025 (m), 2925 (m), 1715 (s), and 1660 (w) cm^{-1}.

Reduction of 86 mg (0.5 mmol) of **4a** with 191 mg (0.75 mmol) of HEH-4,4-d_2 (98% purity in deuterium) and 0.5 g of silica gel afforded 75 mg of a mixture of the two products. The analysis of the 400 MHz ^{1}H NMR spectrum of the mixture revealed that the deuterium was incorporated in the 4-position of **5a** and in the 6-position of **6a**. The deuterium content in each product was 98%. The ratio of **5a**-4-*d*:**6a**-6-*d* was calculated to be 88:12.

400 MHz ^{1}H NMR ($CDCl_3$) δ=2.15 (s, CH_3CO-), 2.45 (q, J=6.8 Hz, -CHD- of **5a**-4-*d*), 2.59 (d, J=7.3 Hz, $-CH_2CO-$ of **5a**-4-*d*), 3.14 (d, J=5.9 Hz, $-CH_2CO$ of (*E*)-**6a**-6-*d*), 3.28 (d, J=7.3 Hz, $-CH_2CO-$ of (*Z*)-**6a**-6-*d*), 3.36 (bs, PhCHD- of **6a**-6-*d*), 5.60—5.72 (m, H_β and H_γ of **6a**-6-*d*), 6.18 (dd, J=16.1, 6.8 Hz, H_γ of **5a**-4-*d*), 6.40 (d, J=16.1 Hz, H_δ of **5a**-4-*d*), and 7.17—7.37 (m, Ph). IR (neat) 3030 (w), 2975 (s), 2170 (w), 1715 (s), and 1652 (w) cm^{-1}.

Reduction of (3*E*,5*E*)-3,5-Nonadien-2-one (4b). The reduction of 138 mg (1 mmol) of **4b** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel gave 132 mg (94% yield) of a mixture of two compounds, **5b** and **6b**. The ratio of **5b**:**6b** was determined as 75:25 by comparing the integration for allylic C_α (C_3) protons (2H) at δ 3.16 (d, J=7 Hz) and 3.28 (d, J=8 Hz)[12] with the integration for the whole vinylic protons at δ 5.30—6.36 (m). The ratio thus determined was consistent with the ratio of the integration for vinylic protons of **5b** at δ 5.44—5.52 to that of vinylic protons of **6b** at δ 5.31—5.40.

IR (neat) 2925 (s), 1720 (s), and 1680 (m) cm^{-1}.

Reduction of (2*E*,4*E*)-2,4-Nonadienal (4c). The reduction of 158 mg (1.0 mmol) of **4c** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel afforded 85 mg of **5c** and 21 mg of **6c** as pure compounds, respectively, after a routine column chromatography. The ratio of **5c**:**6c** was 80:20.

IR (neat) 2930 (s), 1715 (s), and 1660 (w) cm^{-1}.

Reduction of α-Methylcinnamaldehyde. The reduction of 14.6 mg (0.1 mmol) of α-methylcinnamaldehyde with 38.0 mg (0.15 mmol) of HEH, 150 mg of silica gel, and 2 ml of dry benzene gave the corresponding alcohol in 20% yield after 3 h and in 60% yield after 20 h.

Reduction of β-Methylcinnamaldehyde. The reduction of 14.6 mg (0.1 mmol) of β-methylcinnamaldehyde with 38.0 mg (0.15 mmol) of HEH was carried out under the same conditions as described above. The GLC analysis indicated that the chemical yields of the corresponding alcohol were 39% after 3 h and 79% after 20 h.

Reduction of 6-Phenyl-3,5-heptadien-2-one (7). The reduction of 186 mg (1 mmol) of **7** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel afforded 175 mg (93% yield) of a mixture of two products, **9** and **10**. The ratio of **9**:**10** was calculated to be 92:8 from the ratio of integration for the allylic C_α (C_3) protons (2H) of **10** at δ 3.09 (d, J=6 Hz) to that for the trisubstituted vinylic proton (1H) of **9** at δ 5.32—5.76 (m).

^{1}H NMR ($CDCl_3$) δ=1.28 (d, J=8 Hz, CH_3CH of **10**), 2.00 (s, CH_3CH of **9**), 2.10 (s, CH_3CO- of **9** and **10**), 2.34—2.65 (m, CH_2 of **9**), 2.58—2.86 (m, PhCH- of **10**), 3.09 (d, J=6 Hz, $-CH_2CO-$ of **10**), 5.32—5.76 (m, H_γ of **9**), 6.00—6.33 (m, H_β and H_γ of **10**), and 7.12—7.60 (m, Ph). IR (neat) 3050 (m), 2980 (s), 1715 (s), and 1680 (m) cm^{-1}.

Reduction of 6,10-Dimethyl-3,5,9-undecatrien-2-one (8). The reduction of 192 mg (1 mmol) of **8** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel afforded 167 mg (86% yield) of a mixture of two products, **11** and **12**. The ratio of **11**:**12** was calculated to be 95:5 by examining the integration for the trisubstituted vinylic protons of **11** (2H) and **12** (1H) at δ 4.96—5.20 (m), and that for allylic C_α (C_3)

protons (2H) of **12** at δ 3.09 (d, J=6 Hz). The ratio was also confirmed by comparison of the integration for trisubstituted vinylic protons of **11** and **12** and that for disubstituted vinylic protons of **12** at δ 5.38—5.59 (m).

^{1}H NMR ($CDCl_3$) δ=0.98 (d, J=6 Hz, CH_3CH of **12**), 1.58 (s, $(CH_3)_2C$= of **11** or **12**, and CH_3C of **11**), 1.67 (s, $(CH_3)_2C$= of **12** or **11**), 1.92—2.08 (m, CH_2 of **11** and **12**, and CH_3CH of **12**), 2.11 (s, CH_3CO- of **11** and **12**), 2.12—2.36 (m, CH_2 of **11**), 3.09 (d, J=6 Hz, -CH_2CO- of **12**), 4.96—5.20 (m, C=CH- of **11** and **12**), and 5.38—5.59 (m, -CH=CH- of **12**). IR (neat) 2980 (s), 1740 (s), and 1670 (m) cm^{-1}. Found: C, 80.60; H, 11.53%. Calcd for $C_{13}H_{22}O$: C, 80.35; H, 11.41%.

Preparation of Farnesol (14). Geranylacetone (**11**) (194 mg, 1 mmol) was converted into 172 mg (65% yield) of the corresponding α,β-unsaturated ester, **13**, as shown in Eq. 7.

The E:Z ratio of the new olefinic double bond was confirmed to be larger than 20:1 by ^{1}H NMR analysis; the signals for the allylic methyl protons trans to the carboethoxy group appeared at δ 2.12, whereas those cis to the carboethoxy group could not be detected at higher field.

^{1}H NMR ($CDCl_3$) δ=1.28 (t, J=7 Hz, 3H), 1.59 (s, 6H), 1.67 (s, 3H), 1.80—2.40 (m, 4H), 2.12 (s, 3H), 2.40 (t, J=6 Hz, 2H), 4.14 (q, J=7 Hz, 2H), 4.96—5.20 (m, 2H), and 5.65 (s, 1H). IR (neat) 2980 (s), 1740 (s), and 1670 (m) cm^{-1}. Found: C, 77.48; H, 10.53%. Calcd for $C_{17}H_{28}O_2$: C, 77.22; H, 10.68%.

The reduction of 150 mg (0.57 mmol) of **13** was carried out with 21.7 mg (0.28 mmol) of lithium aluminium hydride to give 111 mg (88% yield) of farnesol (**14**).

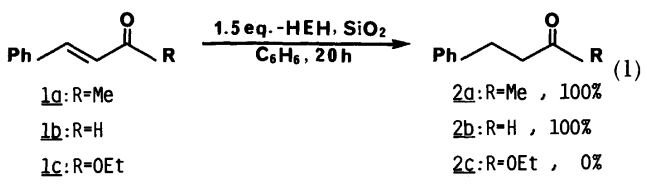
^{1}H NMR ($CDCl_3$) δ=1.60 (s, 9H), 1.68 (s, 3H), 1.82—2.36 (m, 8H), 4.15 (d, J=7 Hz, 2H), 4.97—5.24 (m, 2H), and 5.41 (t, J=7 Hz, 1H). IR (neat) 3355 (s), 2925 (s), and 1668 (m) cm^{-1}. Found: C, 81.11; H, 12.00%. Calcd for $C_{15}H_{26}O$: C, 81.02; H, 11.79%.

Reduction of β-Ionone (15). The reduction of 192 mg (1 mmol) of **15** with 380 mg (1.5 mmol) of HEH and 1.0 g of silica gel gave 136 mg of **16** as a sole product. The structure of **16** was confirmed by ^{13}C and ^{1}H NMR spectra.

^{1}H NMR ($CDCl_3$) δ=0.95 (s, 6H), 1.25—1.68 (m, 4H), 1.56 (s, 3H), 1.90 (t, J=6 Hz, 2H), 2.12—2.60 (m, 4H), and 2.13 (s, 3H). ^{13}C NMR ($CDCl_3$) δ=19.54 (q), 19.72 (q), 22.41 (t), 28.49 (q), 29.72 (t), 32.82 (t), 35.10 (s), 39.90 (t), 44.56 (t), 127.83 (s), 136.14 (s), and 208.68 (s). IR (neat) 2960 (s), 1715 (s), and 1665 (s) cm^{-1}. Found: C, 80.12; H, 11.56%. Calcd for $C_{13}H_{22}O$: C, 80.35; H, 11.41%.

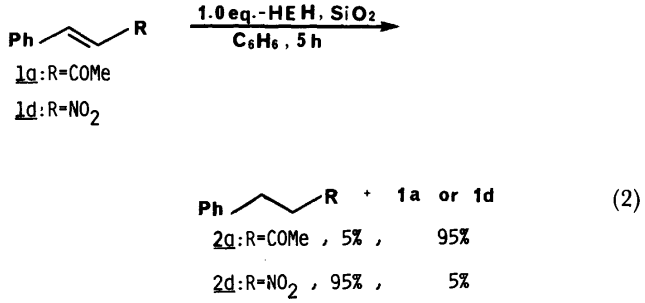
Results and Discussion

Chemoselectivity. Benzylideneacetone (**1a**) and cinnamaldehyde (**1b**) were reduced quantitatively into 4-phenyl-2-butanone (**2a**) and 1-phenylpropanal (**2b**), respectively, after 20 h at the temperature of refluxing benzene, whereas ethyl cinnamate (**1c**) remained entirely unchanged (Eq. 1). The result indicates that the reduction discriminates the carbon-carbon double



(1)

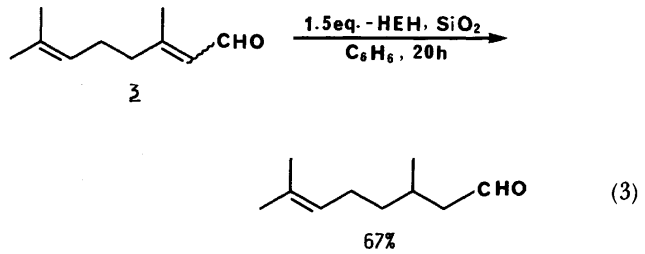
bond adjacent to a carbonyl group from that adjacent to an alkoxy-carbonyl group. The discrimination can also be seen between the double bonds adjacent to acetyl and nitro groups; under the conditions where 95% of β-nitrostyrene (**1d**) was reduced, only 5% of **1a** was converted into 4-phenyl-2-butanone (**2a**) (Eq. 2).



(2)

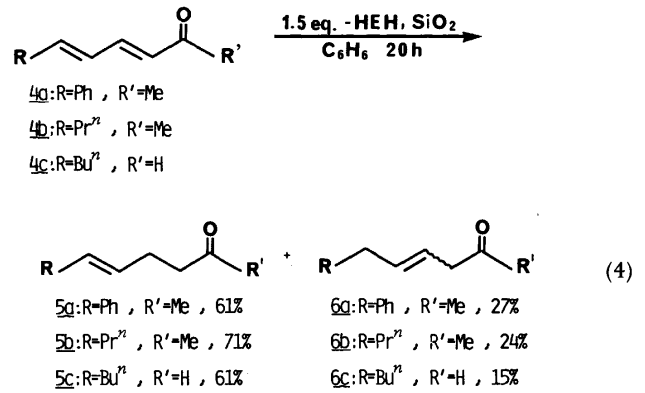
Under the same conditions, where **1b** afforded **2b** in quantitative yield, α- and β-methylcinnamaldehydes yielded the corresponding product alcohols in only 60 and 71% yields, respectively. Apparently, the methyl substituent at an olefinic position retards the reduction.

The isolated double bond is not affected by the reduction; only 1,4-reduction took place for citral (**3**) (Eq. 3).



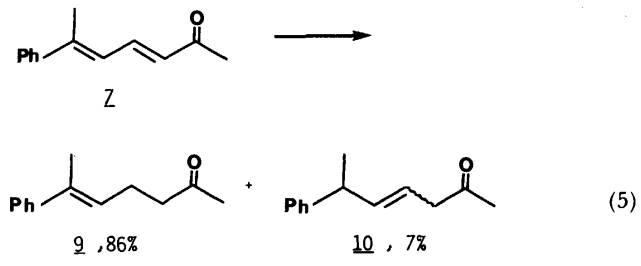
(3)

Reduction of Conjugated Dienones and Dienals. Reduction of conjugated dienoketones and aldehydes proceeded smoothly and afforded the products in good yields (Eq. 4). Although 1,4- and 1,6-type reductions are competitive here, the regioselectivity observed was reasonably satisfactory with the predominance of the 1,4-type reduction;[13] **5a**:**6a**=73:27, **5b**:**6b**=75:25, and **5c**:**6c**=80:20.

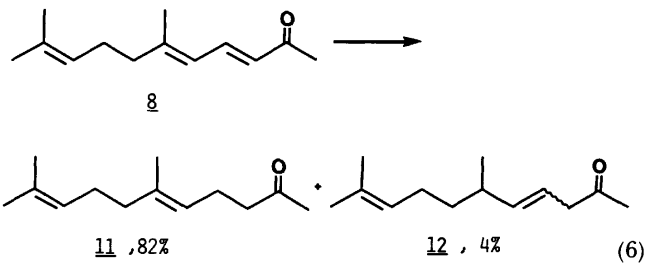


(4)

The ratio was determined by the ^1H NMR analysis comparing the sum of integration of signals for the vinylic protons with that for the allylic α-protons. The latter signal is inherent to the 1,6-reduction product, **6**, and usually appear at around δ 3.05—3.15 as a doublet. It should be noted that the predominance of the 1,4-reduction over the 1,6-reduction shows a sharp contrast to the predominant 1,6-selectivity exerted by the reduction with sodium dithionite under phase-transfer conditions[14] or with diisobutylaluminium hydride in the presence of methylcopper.[15] When the 6-position of conjugated carbon-carbon double bonds is substituted by a methyl group, the ratio of 1,4- vs. 1,6-reduction becomes much higher as a consequence of steric inhibition. For example, the reduction of 6-phenyl-3,5-heptadien-2-one (**7**) and 6,10-dimethyl-3,5,9-undecatrien-2-one (**8**) afforded **9** and **10** in 92:8 ratio and **11** and **12** in 95:5 ratio, respectively (Eqs. 5 and 6).



(5)

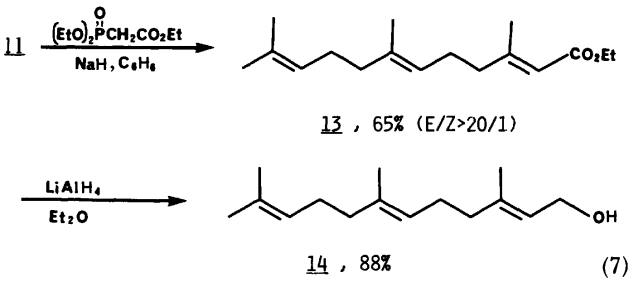


(6)

The reduction of **4a** with HEH-4,4-d_2 afforded **5a**-4-*d* and **6a**-6-*d*, which clearly demonstrated that a deuterium was directly incorporated into the 4- and 6-positions of the 1,4- and 1,6-reduction products, respectively.

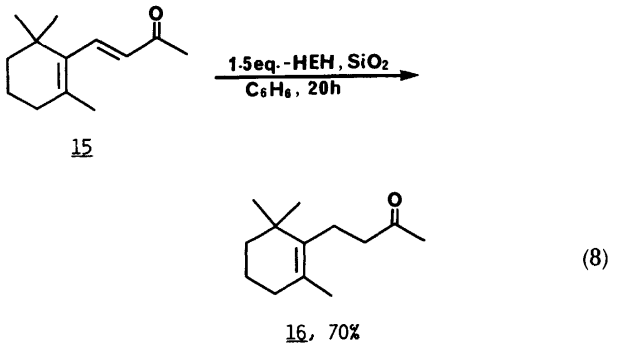
Application to Syntheses. Geranylacetone (**11**) thus obtained is an important component for the syntheses of terpenoids; a straightforward synthesis of farnesol (**14**) is one of examples (Eq. 7).[16]

The significance of the steric effect on the regioselectivity was clearly exaggerated by the reduction of β-ionone (**15**) which has three methyl groups on the cyclohexenyl moiety. In addition to the methyl



(7)

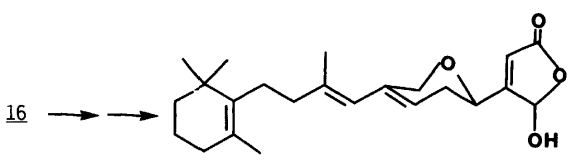
substituent on the endo-double bond, two methyl groups on the cyclohexenyl ring also plays a role to decrease the reactivity of this double bond, and the sole product obtained in this reduction is **16**, the 1,4-reduction product (Eq. 8). Recently, we came to the conclusion that the silica gel-catalyzed reduction with



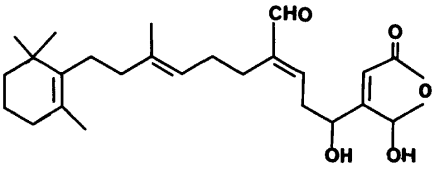
(8)

HEH proceeds with the HEH absorbed on silica gel instead of the intermediacy of a substrate-silica gel complex.[17] Consequently, the reacting HEH is sterically highly blocked by a huge silica-gel component, and a small difference in steric effects in the substrate may differentiate the reactivity of certain carbon-carbon double bond quite sensitively. A CPK molecular model shows that the axial methyl group at the 1-position of the cyclohexenyl ring of **15** prevents the (formal) hydride from attacking the endo-double bond from the axial side, whereas the attack from the equatorial side results in the 1,3-diaxial repulsion between 1- and 3-methyl groups in the product. Thus, this endo-double bond in **15** is sterically set unreactive remaining the exo-double bond as the sole reacting function.

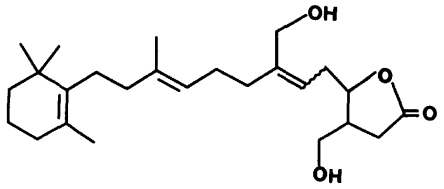
The product, **16**, is a component of natural products. For example, it is an important precursor of manoalides (Eq. 9), a series of natural marine products (e.g., 17—19) with strong biological activities.[18]



manoalide(17)



seco-manoalide(18)



(E)and(Z)-neomanoalide(19) (9)

In conclusion, HEH is a very mild reducing agent, which, in turn, can be employed as an efficient device to sharply differentiate the susceptibilities of functional groups in the reduction. Namely, it has been demonstrated that HEH on silica gel is a useful tool to synthesize γ,δ-unsaturated ketones and aldehydes that are important building blocks for the syntheses of terpenoids and other natural products.

(Received January 21, 1987)

Electrolysis of (*E,E*)-1,*n*-dibromo-2,(*n*-2)-alkadienes (*n*=12, 14) in tetrahydrofuran gave the corresponding twelve or fourteen-membered (*E,E*)-1,5-cycloalkadienes, albeit in low yields, together with (*E*)-4-vinylcycloalkenes and isomeric alkadienes. Similar electrolysis of (*Z,Z*)-1,*n*-dibromo-2,(*n*-2)-alkadienes (*n*=10, 12, 14) gave the corresponding ten, twelve, or fourteen-membered (*Z,Z*)-1,5-cycloalkadienes in 11 to 13% yields, with the accompanying formation of (*Z*)-4-vinylcycloalkenes and isomeric alkadienes.

Electroreductive cyclization of 1,3-dihalides has been reported to be useful for the preparation of substituted[1-5] and strained cyclopropanes.[1] Cyclobutane derivatives[1,4] have also been prepared by the electrochemical reduction of 1,4-dihalides. However, higher cycloalkanes have not been prepared by the electrolysis of simple aliphatic dihalides. We ourselves have previously reported that the three to seven-membered cycloalkanes are obtained by the electrochemical reductive cyclization of 1,ω-dibromides with alkoxycarbonyl groups at their terminal carbons.[6] A similar cyclization of 1,5-dibromopentanes with an electron-withdrawing group at their one termini was also reported recently.[7] As one of the extensions of our study of the electroreductive cyclization of 1,ω-dibromides we studied the preparation of even higher cycloalkanes by means of the electrochemical cyclization of (*E,E*)- or (*Z,Z*)-1,*n*-dibromo-2,(*n*-2)-alkadienes. We now report that ten, twelve, and fourteen-membered (*E,E*)- or (*Z,Z*)-1,5-cycloalkadienes can be prepared by the electrolysis of the corresponding (*E,E*)- or (*Z,Z*)-allylic dibromides, albeit in low yields.

A transition metal-catalyzed cyclization of allylic dibromides has been reported to lead generally to more stable (*E,E*)-1,5-cycloalkadiene rather than to (*Z,Z*)-dienes, regardless of the geometry of the double bonds of the starting allylic dibromides.[8,9] For the preparation of (*Z,Z*)-1,5-cycloalkadienes only a few methods have been reported, however, (*Z,Z*)-1,5-Cyclotetradecadiene was prepared by partial hydrogenation of 1,5-cyclotetradecadiynes with a Lindler catalyst.[10] (*Z,Z*)-1,5-Cyclododecadiene was formed, as one of several isomers, either in the photochemical isomerization of its (E,E)-isomer[11] or in the hydrogenation of 1,5,9-cyclododecatriene.[12] (*Z,Z*)-1,5-Cyclodecadiene was similarly formed either in the photochemical isomerization of its (E,Z)-isomer[13] or in the partial hydrogenation of cyclodecatrienes.[14] Of these (*Z,Z*)-1,5-cycloalkadienes, (*Z,Z*)-1,5-cyclododecadiene has not been isolated in a pure form and the stereochemistries of (*Z,Z*)-1,5-cyclotetradecadiene and (*Z,Z*)-1,5-cyclododecadiene have not been established in an unambiguous manner.

Results and Discussion

The starting (*E,E*)-allylic dibromides **1**, **5**, and **10** were readily prepared by reduction of the corresponding 2,(*n*-2)-alkadiyn-1,*n*-diols with lithium aluminum hydride, followed by bromination.[8,9] On the other hand, the (*Z,Z*)-allylic dibromides **11**, **15**, and **19** were prepared by partial hydrogenation of the corresponding alkadiyne diols with a Lindler catalyst.[8,9]

Electrochemical reduction of (*E,E*)- and (*Z,Z*)-allylic dibromides was carried out at a constant current in tetrahydrofuran (THF) containing 0.1 M† tetrabutylammonium perchlorate (*n*-Bu_4NClO_4) as a supporting electrolyte. Each allylic dibromide was gradually added to the cathodic solution with a microfeeder. The electricity passed was 2.2 Faradays per mole of the dibromide. The electrochemical reduction of (*E,E*)-1,14-dibromo-2,12-tetradecadiene (**1**) afforded three major products **2** (8%), **3** (5%), and **4** (19%) which could be separated by preparative GLC (Scheme 1). High resolution mass spectrometry indicated that **2** and **3** were isomeric and had the molecular formula $C_{14}H_{24}$. The ^1H NMR spectrum of **2** exhibited overlapped multiplets due to the four olefinic protons of the two unconjugated vinyl groups at δ 5.28. The geometry of the double bonds of **2** was deduced from the IR spectrum. (E)-Double bonds of the medium-sized cycloalkenes give rise to a medium to a strong band at 965—980 cm^{-1} while (Z)-double bonds at 700—710 cm^{-1}.[15,16] (E)-Double bonds of several 1,5-cycloalkadienes give a characteristic band at 960—970 cm^{-1} while (Z)-double bonds at 695—710 cm^{-1}.[8,9,16,17] A strong band at 980 cm^{-1} in the IR spectrum of cycloalkadiene **2** indicated that the configurations of the two double bonds are (E).

The ^1H NMR spectrum of **3** showed characteristic signals due to a vinyl group and its IR spectrum showed a characteristic band due to an (E) double bond at 970—980 cm^{-1}. On the basis of these results an (*E*)-4-vinylcyclododecene structure was assigned to **3**. The alkadiene **4** isolated was a mixture of two

† 1 M=1 mol dm^{-3}.

isomers and the structure of the major isomer was determined to be (*E,E*)-2,12-tetradecadiene (**4a**) as described in the experimental section.

Similar electrolysis of (*E,E*)-1,12-dibromo-2,10-dodecadiene (**5**) gave (*E,E*)-1,5-cyclododecadiene (**6**) (10%), (*E*)-4-vinylcyclodecene (**8**) (3%), (*E,Z*)-1,5-cyclododecadiene (**7**) (2%), and a mixture of isomeric dodecadienes (**9**) (21%) (Scheme 1). The structures of these products [including the geometries of their double bonds] were determined by MS, IR, and ^{1}H NMR spectra; the details are described in the experimental section. The structure of **7** was confirmed additionally by a direct comparison with an authentic specimen prepared by the selective reduction of (*E,E,Z*)-1,5,9-cyclododecatriene with hydrazine.[16]

Electrochemical reduction of (*E,E*)-1,10-dibromo-2,8-decadiene (**10**), however, gave a complex mixture of products that contained a large amount of isomeric decadienes.

We then turned our attention to the electrolysis of (*Z,Z*)-allylic bromides **11**, **15**, and **19**. Electrochemical reductions of (*Z,Z*)-1,14-dibromo-2,12-tetradecadiene (**11**), (*Z,Z*)-1,12-dibromo-2,10-dodecadiene (**15**), and (*Z,Z*)-1,10-dibromo-2,8-decadiene (**19**) afforded (*Z,Z*)-1,5-cycloalkadienes (**12**, **16**, and **20**) in 11—13% yields and (*Z*)-4-vinylcycloalkenes (**13**, **17**, and **21**) in 4—7% yields as outlined in Scheme 2. The structures of the above products [including their geometries] were deduced by MS, IR, and ^{1}H NMR spectroscopy. Thus, cycloalkadienes **12**, **16**, and **20** showed bands 715, 720, and 700 cm^{-1} respectively in their IR spectra, indicating (Z,Z)-geometries of their isolated double bonds. The ^{1}H NMR of **16** exhibited a double triplet at δ 5.26 and a multiplet at δ 5.60 that were due to the olefinic protons as well as two multiplets at δ 2.10 and δ 1.35. Irradiation at δ 2.10 collapsed the former two olefinic signals to two doublets each with J=10.7 Hz. Since the coupling constants of the olefinic protons of seven to ten-membered (*Z*)-cycloalkenes are in the range of 10.3—10.8 Hz,[18] we assigned Z-configurations to the geometry of the double bonds of **16**. Similar decoupling studies on the ^{1}H NMR spectra of **12** and **20** by 400 MHz NMR spectrometer indicated that the coupling constants of the four olefinic protons of **12** were 10.7 Hz in each case while those of two pairs of olefinic protons of **20** were 10.7 and 11.2 Hz. On the basis of these results, (Z)-configuration is assigned to all the double bonds of **12** and **20**. The IR showed that 4-vinylcycloalkenes **13**, **17**, and **21** have bands at 690—705 cm^{-1}; (Z)-configuration is therefore also assigned to their double bonds. The coupling constant of the olefinic protons of the internal double bond of **13** was found to be 10.0 Hz; this was consistent with its (Z)-geometry. In addition to these cyclic olefins, electrolysis of **15** gave (*E,Z*)-cyclic diene **7** in a 4% yield. It was identical with **7** obtained by the electrolysis of **5**. Electrolysis of **11** and **15** also gave a mixture of the isomeric alkadienes **14** and **18** in 18% and 16% yields. The major isomers of **14** and **18**, separated by preparative GLC, were shown to be (*Z,Z*)-2,12-tetradecadiene (**14c**) and (*Z,Z*)-2,10-dodecadiene (**18c**), respectively.

Cyclic voltammetry of the starting dibromides and the electrode potential during the electrolysis indicated that such an electrolysis as the one we have described involves a two-electron reduction of the carbon-bromine bond. Cyclic voltammetry has shown that the reduction peaks of **5**, **15**, and crotyl bromide in an *N,N*-dimethylformamide (DMF) solution are −2.00, −2.00, and −1.81 V vs. Ag/AgI and the reduction peak of crotyl bromide in a THF solution is −1.65 V vs. Ag/AgI. Although the present elec-

Scheme 2.

trochemical reduction was carried out at a constant current in a THF solution, the working electrode in the electrolysis of **15** was kept at the potential ranging from −1.6 V to −1.8 V, which nearly corresponded to the reduction potential of **15**. These results suggest that the electroreductive cyclization described above proceeds via an intramolecular nucleophilic attack at a bromine-bearing allylic carbon atom by the allylic carbanion which is generated by a two-electron reduction of the carbon-bromine bond.[19] In agreement with this mechanism the geometry of at least one of the double bonds in each of the starting dibromide was retained in all the cycloalkadienes obtained.

During such cyclizations as these, a partial interconversion between (E) and (Z) geometries may take place,[20] as the formation of (*E,Z*)-cycloalkadiene **7** from (*E,E*)-dibromide **5** and (*Z,Z*)-dibromide **15** indicates. Vinylcycloalkenes **3**, **8**, **13**, **17**, and **21** are likely to be formed via either an intramolecular nucleophilic attack on the bromine-carrying carbon atom by an allylic carbanion centered on the C-3 or by an intramolecular attack on the C-3 carbon by an allylic carbanion centered on the terminal carbon with allylic rearrangement.

Experimental

Tetrahydrofuran (THF) was dried over sodium benzophenone ketyl and distilled before use. The IR spectra were obtained with a Hitachi Model 285 spectrometer. The ^{1}H NMR spectra in $CDCl_3$ were measured with a JEOL FX 100 (100 MHz) and a JEOL FX 400 (400 MHz) (Faculty of Science of this University), using tetramethylsilane as an internal reference. Mass spectra were obtained with a JEOL JMS-D300 mass spectrometer (Faculty of Agriculture). Quantitative GLC analyses were carried out with a Hitachi 063 instrument by the internal standard method.

Preparation of Allylic Dibromides. (*E,E*)-Allylic dibromides **1**, **5**, and **10** were prepared according to an established procedure.[8,9] Since purification of these dibromides by distillation or column chromatography led to decomposition, the prepared dibromides were therefore immediately subjected to electrolysis without further purification. The spectral data of the (*E,E*)-allylic dibromides are recorded below.

(*E,E*)-1,14-Dibromo-2,12-tetradacadiene (1): n^{20} 1.5089; IR (neat) 3030, 1660, 965 cm^{-1}; ^{1}H NMR ($CDCl_3$)[9] δ=1.28 (bs, 12H), 2.02 (m, 4H), 3.94 (d, 4H, J=5.9 Hz), 5.71 (m, 4H); MS *m/z* (rel intensity) 273 (M^+ −Br, 1.0), 271 (M^+ −Br, 1.3), 109 (75), 97 (41), 95 (100), 83 (69), 81 (63), 69 (47), 67 (73), 55 (92).

(*E,E*)-1,12-Dibromo-2,10-dodecadiene (5): n^{20} 1.5237; IR (neat) 3030, 1660, 963 cm^{-1}; ^{1}H NMR ($CDCl_3$)[9] δ=1.32 (m, 8H), 2,06 (m, 4H), 3.95 (d, 4H, J=5.9 Hz), 5.72 (m, 4H); MS *m/z* (rel intensity) 326 (0.23), 324 (0.40), 322 (0.22), 163 (29), 109 (29), 95 (84), 81 (100), 69 (36), 67 (90), 55 (70). Found: *m/z* 323.9932. Calcd for $C_{12}H_{20}Br_2$: M, 323.9913.

(*E,E*)-1,10-Dibromo-2,8-decadiene (10): n^{20} 1.5291; IR (neat) 3030, 1660, 965 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.39 (m, 4H), 2.04 (m, 4H), 3.94 (d, 4H), 5.72 (m, 4H). MS *m/z* (rel intensity) 296 (0.17), 135 (56), 93 (40), 81 (79), 79 (38), 67 (100), 53 (48). Found: *m/z* 295.9621. Calcd for $C_{10}H_{16}Br_2$: M, 295.9599.

(*Z,Z*)-Allylic dibromides **11**, **15**, and **19** were prepared by bromination of (*Z,Z*)-alkadiene diols; these were obtained by hydrogenation of the corresponding 2, (*n*-2)-alkadiyn-1, *n*-diols by a Lindler catalyst.[8,9] The dibromides were subjected to electrolysis without any further purification.

(*Z,Z*)-1,14-Dibromo-2,12-tetradacadiene (11): n^{20} 1.5199; IR (neat) 3030, 1645, 720—750 (br) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.31 (bs, 12H), 2.13 (m, 4H), 4.00 (d, 4H), 5.66 (m, 4H); MS *m/z* (rel intensity) 273 (M^+ −Br, 0.9), 271 (M^+ −Br, 1.2), 109 (65), 97 (32), 95 (100), 83 (58), 81 (71), 69 (44), 67 (85).

(*Z,Z*)-1,12-Dibromo-2,10-dodecadiene (15): n^{20} 1.5310; IR (neat) 3030, 1645, 720—750 (br) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.33 (bs, 8H), 2.11 (m, 4H), 3.88 (d, 4H), 5.61 (m, 4H); MS *m/z* (rel intensity) 326 (0.20), 324 (0.38), 322 (0.21), 163 (26), 109 (32), 95 (80), 81 (100), 69 (41), 67 (91), 55 (70), 54 (35), 53 (41). Found: *m/z* 323.9890. Calcd for $C_{12}H_{20}Br_2$: M, 323.9913.

(*Z,Z*)-1,10-Dibromo-2,8-decadiene (19): n^{20} 1.5381; IR (neat) 3030, 1645, 720—750 (br) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.44 (m, 4H), 2.12 (m, 4H), 3.98 (d, 4H), 5.65 (m, 4H); MS *m/z* (rel intensity) 298 (0.15), 296 (0.29), 294 (0.17), 135 (54), 93 (34), 81 (63), 79 (30), 67 (100), 53 (40). Found: *m/z* 295.9576. Calcd for $C_{10}H_{16}Br_2$: M, 295.9599.

General Procedure for Electrolysis. For most of the electrolyses, we used a normal undivided cell (2.8 cm dia.) equipped with a magnetic stirrer, a reflux condenser, and a serun cap for the introduction of nitrogen gas. Electrolysis was carried out under a nitrogen atmosphere at a constant current (20 mA cm^{-2}) using two platinum electrodes (2×2 cm^2). Allylic dibromide (0.6—1.0 mmol) dissolved in 1 ml of THF was added to a 20 ml of THF solution containing 0.1 M Bu_4NClO_4 over a period of 3—4 h with a micro-feeder. The electricity passed was 2.2 Faradays per mole of the dibromide. After electrolysis, most of THF had been evaporated and the residue was dissolved in diethyl ether. The ethereal solution was washed with water and dried over magnesium sulfate. A column chromatography (silica gel; hexane) of the reaction mixture gave a mixture of cycloalkadienes and alkadienes which was subjected to a preparative GLC (Carbowax 20M 15%, 150—170 °C) to give pure products. Yields of the products were determined by GLC using an internal standard method and were based on the starting allylic dibromides employed. An amount of the unreacted allylic dibromides was not determined because of their instability in the GLC column.

Spectral data of the products obtained by electrolysis are recorded below.

(*E,E*)-1,5-Cyclotetradecadiene (2):[9] IR (neat) 3070, 980 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.29 (bs, 12H), 1.96 and 2.11 (bs and m, total 8H), 5.28 (m, 4H); MS *m/z* (rel intensity) 192 (M^+, 7), 95 (57), 82 (54), 81 (100), 80 (95), 68 (62), 67 (97), 55 (50), 54 (99). Found: *m/z* 192.1859. Calcd for $C_{14}H_{24}$: M, 192.1876. An attempt to determine the coupling constant between olefinic protons of **2** by decoupling technique was unsuccessful.

(*E*)-4-Vinylcyclododecene (3): IR (neat) 990, 978, 915 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.30 (s, 14H), 2.07 (m, 5H), 4.9—5.1 (m, 2H), 5.41 (m, 2H), 5.6—6.0 (m, 1H); MS *m/z* (rel intensity)

192 (M^+, 2), 95 (22), 82 (49), 81 (92), 80 (77), 68 (72), 67 (95), 55 (65), 54 (100). Found: *m/z* 192.1905. Calcd for $C_{14}H_{24}$: M, 192.1878.

A Mixture of Isomeric Tetradecadiene (4): IR (neat) 3020, 1640, 965, 910 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.27 (bs, CH_2), 1.64 (d, CH_3), 1.97 (bs, $=CHCH_2-$), 4.8—5.1 (m, $=CH_2$), 5.41 (m, $-CH=CH-$), 5.5—6.1 (m, $-CH=CH_2$); MS *m/z* (rel intensity) 194 (M^+, 4), 96 (26), 95 (25), 82 (39), 81 (37),69 (32), 68 (100), 67 (31), 55 (96). Found: *m/z* 194.2045. Calcd for $C_{14}H_{26}$: M, 194.2035. Tetradecadiene **4** was proved to be a 74:26 mixture of (*E,E*)-2, 12-tetradecadiene (**4a**) and (*E*)-1,12-tetradecadiene (**4b**).

n=6 **4a** **4b**
n=4 **9a** **9b** **9c**

(*E,E*)-1,5-Cyclododecadiene (6):[9] IR (neat) 3025, 973, 927 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.19 (m, 4H), 1.42 (bs, 4H), 2.03 and 2.12 (m and bs, total 8H), 5.10 (m, 4H); MS *m/z* (rel intensity) 164 (M^+, 4), 121 (65), 81 (81), 67 (100), 54 (99). Found: *m/z* 164.1569. Calcd for $C_{12}H_{20}$: M, 164.1564.

(*E,Z*)-1,5-Cyclododecadiene (7): IR (neat) 3030, 977, 970, 703 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.26 and 1.56 (m and bs, total 8H), 2.09 (m, 8H), 5.0—5.8 (m, 4H); MS *m/z* (rel intensity) 164 (M^+, 2), 121 (45), 81 (61), 80 (41), 68 (41), 67 (100), 54 (63). Found: *m/z* 164.1558. Cacld for $C_{12}H_{20}$: M, 164.1564. Various spectra of **7** were identical with those of (*E,Z*)-1,5-cyclododecadiene which was prepared by means of a selective reduction of (*E,E,Z*)-1,5,9-cyclododecatriene with hydrazine. Reduction of the triene (77 mmol scale) was carried out according to an established procedure[16] but in order to obtain a best yield of **7**, the reduction was discontinued after a shorter reaction time (20 min.). GLC analysis showed that the reaction mixture consisted of **7** (50%), a starting cyclododecatriene (30%), and (*Z*)-cyclododecene (20%). These three products were separated by a preparative GLC (Carbowax 20M 15% on Uniport B).

(*E*)-4-Vinylcyclodecene (8): IR (neat) 3030, 970, 913 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.38 and 1.57 (m and m, 10H), 2.12 and 2.25 (m and m, 5H), 4.8—5.2 (m, 2H), 5.48 (m, 2H), 5.6—6.1 (m, 1H); MS *m/z* (rel intensity) 164 (M^+, 3), 121 (66), 93 (26), 81 (94), 80 (46), 68 (30), 67 (100), 54 (59). Found: *m/z* 164.1560. Calcd for $C_{12}H_{20}$: M, 164.1562.

A Mixture of Isomeric Dodecadienes (9): IR (neat) 3020, 1640, 967, 910 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30 (bs, CH_2), 1.64 (d, $=CHCH_3$), 1.97 (bs, $=CHCH_2-$), 4.8—5.2 (m, $=CH_2$), 5.44 (m, $-CH=CH-$), 5.5—6.1 (m, $-CH=CH_2$); MS *m/z* (rel intensity) 166 (M^+, 2), 95 (31), 82 (50), 81 (51), 69 (44), 68 (100), 67 (67), 55 (88), 54 (40). Found: *m/z* 166.1736. Calcd for $C_{12}H_{22}$: M, 166.1721. GLC analysis and ^1H NMR spectrum of the mixture showed that it consisted of **9a** (90%), **9b** (8%), and **9c** (2%).

(*Z,Z*)-1,5-Cyclotetradecadiene (12): IR (neat) 3003, 1650, 945, 715 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (m, 12H), 2.05 (m, 8H), 5.43 (m, 4H, J=7.3 Hz, J=10.7 Hz); MS *m/z* (rel intensity) 192 (M^+, 10), 135 (35), 121 (31), 95 (67), 87 (100), 67 (96), 59 (70), 54 (71). Found: *m/z* 192.1883. Calcd for $C_{14}H_{24}$: M, 192.1878. Irradiation of the multiplet due to the allylic protons at δ 2.05 using a 400 MHz machine caused the multiplet of the olefinic protons at δ 5.43 to collapse into two doublets (each J=10.7 Hz).

(*Z*)-4-Vinylcyclododecene (13): IR (neat) 3060, 1650, 985, 945, 905, 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.34 and 1.57 (bs and s, 14H), 1.8—2.5 (m, 5H), 4.9—5.2 (m, 2H), 5.35 (m, 2H), 5.7—6.2 (m, 1H); MS *m/z* (rel intensity) 192 (M^+, 2), 135 (25), 121 (29), 95 (67), 81 (100), 67 (92), 54 (75). Found: *m/z* 192.1879. Calcd for $C_{14}H_{24}$: M, 192.1878. Irradiation of the multiplet due to the allylic protons at δ 2.2 caused the multiplet of the olefinic protons at δ 5.35 to collapse into two doublets (each J=10.0 Hz).

(*Z*)-1,12-Tetradecadiene (14a): IR (neat) 3030, 985, 910, 695 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.28 (s, 14H), 1.60 (d, 3H), 2.00 (m, 4H), 4.8—5.1 (m, 2H), 5.39 (m, 2H), 5.7—6.04 (m, 1H); MS *m/z* (rel intensity) 194 (M^+, 3), 96 (33), 95 (28), 82 (47), 81 (42), 68 (100), 55 (70). Found: *m/z* 194.2069. Calcd for $C_{14}H_{26}$: M, 194.2035. Tetradecadienes **14a** and **14c** were obtained in a ratio of 17:83.

(*Z,Z*)-2,12-Tetradecadiene (14c): IR (neat) 3003, 1655, (w), 965, 690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.28 (s, 12H), 1.60 (d, 6H), 2.03 (m, 4H), 5.39 (m, 4H); MS *m/z* (rel intensity) 194 (M^+, 2), 96 (34), 82 (65), 81 (45), 68 (100), 55 (63). Found: *m/z* 194.2051. Calcd for $C_{14}H_{26}$: M, 194.2035.

n=4 **18a** **18b** **18c**

(*Z,Z*)-1,5-Cyclododecadiene (16): IR (neat) 3005, 855, 805, 720 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 and 1.42 (bs and m, total 8H), 2.10 (m, 8H), 5.27 (m, 2H, J=10.7 Hz, J=8.2 Hz), 5.57 (m, 2H, J=10.7 Hz, J=8.2 Hz); MS *m/z* (rel intensity) 164 (M^+, 3), 81 (60), 67 (100), 54 (66). Found: *m/z* 164.1564. Calcd for $C_{12}H_{20}$: M, 164.1564. Irradiation of the multiplet due to the allylic protons at δ 2.10 caused the multiplets at δ 5.27 and δ 5.57 to collapse into the doublets (each J=10.7 Hz).

(*Z*)-4-Vinylcyclodecene (17): IR (neat) 3060, 1635, 990, 968, 915, 705 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.43 and 1.56 (m and s, total 10H), 2.11 and 2.25 (m and m, 5H), 4.8—5.2 (m, 2H), 5.44 (m, 2H), 5.7—6.2 (m, 1H); MS *m/z* (rel intensity) 164 (M^+, 3), 81 (86), 67 (100), 54 (88). Found: *m/z* 164.1563. Calcd for $C_{12}H_{20}$: M, 164.1563.

A Mixture of Isomeric Dodecadiene (18): IR (neat) 3020, 1650, 968, 910, 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (bs, 8.2H), 1.59 (d, 5.3H), 2.02 (m, 4.0H), 5.41 (m, 4.1H). GLC analysis of the mixture showed the presence of three isomers in a ratio of 14:36:50. Each of these isomers of nearly 80% purity was separated by a preparative GLC (Ucon oil 150 15% on Uniport HB 7000; 120 °C). The first peak was identified to be (*Z*)-1,10-dodecadiene (**18a**): IR (neat) 3030, 990, 910, 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30 (m, 10H), 1.59 (d, 3H), 1.93—2.05 (m, 4H), 4.9—6.0 (m, 5H); MS *m/z* (rel intensity) 166 (M^+, 4), 81 (40), 68 (100), 55 (56). Found: *m/z* 166.1713. Calcd for $C_{12}H_{22}$: M, 166.1719. The second peak was identified to be (*E,Z*)-2,10-dodecadiene (**18b**): ^1H NMR ($CDCl_3$) δ=1.31 (m, 8H), 1.60 (d, 6H), 1.93—2.05 (m, 4H), 5.42 (m, 4H), MS *m/z* (rel intensity) 166 (M^+, 4), 81 (43), 68 (100), 55 (78). Found: *m/z* 166.1731. Calcd for $C_{12}H_{22}$: M, 166.1721. The third peak was identified to be (*Z,Z*)-2,10-dodecadiene (**18c**): IR (neat) 3030, 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32 (m, 8H), 1.60 (d, 6H, J=5.0 Hz), 1.93—2.05 (m, 4H), 5.42 (m, 4H); MS *m/z* (rel intensity) 166 (M^+, 4), 81

(34), 68 (100), 55 (65). Found: *m/z* 166.1727. Calcd for $C_{12}H_{22}$: M, 166.1721.

(*Z,Z*)-1,5-Cyclodecadiene (20): IR (neat) 3005, 1650, 945, 700 cm^{-1}; ^1H NMR ($CDCl_3$; 400 MHz) δ=1.50 (m, 4H), 2.16 (m, 4H), 2.35 (m, 4H), 5.33 (m, 4H, J=11.2 Hz), 5.45 (dt, 4H, J=10.7 Hz, J=8.3 Hz); MS *m/z* (rel intensity) 136 (M^+, 38), 107 (34), 95 (64), 94(56), 93 (62), 81 (27), 80 (54), 79 (82), 67 (100), 54 (61). Found: *m/z* 136.1270. Calcd for $C_{10}H_{16}$: M, 136.1253. Irradiation of the multiplet due to the allylic protons at δ 2.35 caused the multiplet at δ 5.33 to collapse into a doublet (J=11.2 Hz). While irradiation of the multiplet at δ 2.16 caused the multiplet at δ 5.45 to collapse into a doublet (J=10.7 Hz).

(*Z*)-4-Vinylcyclooctene (21): IR (neat) 3060, 1660, 990, 910, 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.56 (m, 6H), 2.17 (m, 5H), 4.8—5.2 (m, 2H), 5.40 (m, 1H), 5.6—6.1 (m, 2H); MS *m/z* (rel intensity) 136 (M^+, 17), 121 (35), 107 (32), 95 (49), 94 (44), 93 (43), 82 (40), 81 (37), 80 (45), 79 (71), 67 (100), 54 (63). Found: *m/z* 136.1236. Calcd for $C_{10}H_{16}$: M, 136.1249.

Cyclic Voltammetry. Cyclic voltammetry was carried out with a Nichia potentiostat HP-E_{500H} in combination with a Nichia linear potential scanner. The sweep rate was 0.2 V s^{-1} and a platinum disc (1 mm dia.) was used as a working electrode. Reduction peaks of **5**, **15**, and crotyl bromide in DMF containing 0.1M *n*-Bu_4NClO_4 were observed at −2.00, −2.00, and −1.81 V vs. Ag/AgI. Another reduction peak was observed at −1.32 V only in the case of **15**. The reduction peak of crotyl bromide shifted to −1.65 V when a cyclic voltammetry was carried out in THF containing 0.1M *n*-Bu_4NClO_4.

The Synthesis of (15*R*)-Coleon C and (15*S*)-Coleon C

Takashi MATSUMOTO,* Sachihiko IMAI, and Takashi YOSHINARI
Department of Chemistry, Faculty of Science, Hiroshima University,
Higashisenda-machi, Naka-ku, Hiroshima 730
(Received January 21, 1987)

(15*R*)-11,16-Dihydroxy-12-methoxymethoxy-8,11,13-abietatrien-7-one and its (15*S*)-epimer prepared from a C-15 epimeric mixture of 12-methoxy-8,11,13-abietatrien-16-ol, were transformed into (15*R*)-6,11,12,14,16-pentahydroxy-5,8,11,13-abietatetraen-7-one and its (15*S*)-epimer; these were identical with natural (15*R*)-coleon C and (15*S*)-coleon C, respectively.

Coleon C was first isolated as a mixture of the C-15 epimers from the leaves of *Coleus aquaticus* Gürcke (Labiatae) by Eugster et al.;[1] they[2] later separated the mixture into (15*R*)-coleon C (**1a**) and (15*S*)-coleon C (**1b**). Recently, Burnell et al.[3] reported the synthesis of (15*R*)-coleon C tri-*O*-methyl ether (**2a**) via a (15*R*)-quinone intermediate (**3a**) which was prepared from 12,16-epoxy-8,11,13,15-abietatetraene (**4**) by the following series of reactions. Stereoselective catalytic hydrogenation of **4** gave a mixture of the C-15 epimeric 12,16-epoxy-8,11,13-abietatrienes (**5**) which was oxidized with chromium trioxide in acetic acid to give the epimeric 7-oxo compounds **6**. Further oxidation of **6** with hydrogen peroxide in acetic anhydride containing concentrated sulfuric acid produced two quinones, **3a** and its C-15 epimer **3b**, in a ratio of 5:2. Their stereochemical assignments of C-15 in **3a** and **3b** were based on the stereochemistries of C-15 in the catalytic hydrogenation products **5**, whose stereochemistries were assigned to be 15R for the major product and 15S for the minor product (from examinations of molecular models). However, it seemed to be necessary to confirm the stereochemistries of the hydrogenation products **5** by unambiguous methods. Very recently,[4] we also carried out the catalytic hydrogenation of **4** and assigned the stereochemistry of C-15 in the major product to have a S configuration in contrast to the assignment of Burnell et al. As an extension of our previous work,[4] we here describe the successful syntheses of (15*R*)-coleon C (**1a**) and (15*S*)-coleon C (**1b**) starting from a C-15 epimeric mixture of 12-methoxy-8,11,13-abietatrien-16-ol (**7**)[5] which was previously prepared from (+)-dehydroabietic acid.

6 R=O

Mixture **7** was demethylated with anhydrous aluminium chloride and ethanethiol in dichloromethane to give a mixture of the corresponding diols **8** (90.3%). To introduce an oxygen function at the C-11 position, mixture **8** was submitted to a series of reactions: oxidation with benzoyl peroxide in refluxing chloroform, reduction with lithium aluminium hydride in ether, and acetylation with acetic anhydride in pyridine. Purification of the crude product by column chromatography on silica gel afforded a mixture of the C-15 epimeric triacetates **9** (50.6%) along with a mixture of the C-15 epimeric diacetates **10** (24.8%) which gave back the starting **8** (95.1%) by reduction with lithium aluminium hydride. Oxidation of **9** with chromium trioxide in acetic acid yielded a mixture of the 7-oxo compounds **11a** and **11b** (61.4%). This mixture was then hydrolyzed with dilute hydrochloric acid in refluxing methanol and the crude product was immediately methoxymethylated with a mixture of chloromethyl methyl ether, anhydrous potassium carbonate, and dicyclohexano-18-crown-6 in tetrahydrofuran–dichloromethane (1:1) at room temperature to give 12-methoxymethyl ethers **12a** and **12b** (73.6%) and 12,16-bis(methoxymethyl) ethers **13** (14.3%). The C-15 epimeric mixture of 12-methoxymethyl ether was carefully separated by repeated column chromatography on silica gel and recrystalliza-

tion to afford the pure crystalline 11,16-dihydroxy-12-methoxymethoxy-8,11,13-abietatrien-7-one (**12a**), mp 135—136 °C, and its C-15 epimer **12b**, mp 140—142 °C. In order to assign the absolute configurations of C-15 in these epimers, the compound **12a** was hydrolyzed with dilute hydrochloric acid in refluxing tetrahydrofuran and the resulting triol was acetylated with acetic anhydride in pyridine to give a triacetate (88.5%) which was identical with authentic (15*R*)-11,12,16-triacetoxy-8,11,13-abietatrien-7-one (**11a**).[5] On the other hand, the authentic (15*S*)-triacetate **11b**[5] was hydrolyzed with dilute hydrochloric acid in refluxing methanol and then partially methoxymethylated as described above. Purification of the crude product yielded (15*S*)-11,16-dihydroxy-12-methoxymethoxy-8,11,13-abietatrien-7-one (70.7%) which was identical with **12b**. Thus, the absolute configurations of C-15 in **12a** and **12b** were assigned to be R and S respectively.

Subsequently, conversion of **12a** into (15*R*)-coleon C (**1a**) was carried out as follows. Hydrolysis of **12a** with dilute hydrochloric acid followed by methylation with diazomethane afforded 11,16-dihydroxy-12-methoxy-8,11,13-abietatrien-7-one (**14a**: 64.4%) together with small amounts of 11-hydroxy-12,16-methylenedioxy-8,11,13-abietatrien-7-one (**15a**: 19.8%) and 11-hydroxy-12,16-dimethoxy-8,11,13-abietatrien-7-one (**16a**: 13.9%). For the protection of the hydroxyl groups, **14a** was acetylated with acetic anhydride in pyridine to give a diacetate **17a** (93.9%). This was reduced with sodium borohydride in methanol and the resulting mixture of the epimeric 7-hydroxy compounds was immediately subjected to dehydration with *p*-toluenesulfonic acid in refluxing benzene to give 11,16-diacetoxy-12-methoxy-6,8,11,13-abietatetraene (**18a**: 86.8%). Epoxidation of **18a** with *m*-chloroperbenzoic acid in dichloromethane followed by treatment with *p*-toluenesulfonic acid in refluxing benzene afforded 11,16-diacetoxy-12-methoxy-8,11,13-abietatrien-6-one (**19a**: 79.6%). To introduce an oxygen function at the C-14 position, the 6-oxo compound **19a** was reduced with lithium aluminium hydride in ether and the resulting mixture of the epimeric 6-hydroxy compounds **20a** was immediately oxidized with *m*-chloroperbenzoic acid in methanol to give two *p*-quinones, **21a** (42.5%) and **22a** (6.6%). In the ^{1}H NMR spectrum of **21a**, the downfield shift of a signal (δ=1.69) due to the methyl group at C-10 relative to the corresponding signal (δ=1.36) for **22a** suggested a 1,3-diaxial-*cis*-relationship between the methyl group and the hydroxyl group at C-6. Thus, the structures of **21a** and **22a** were assigned to be 6β,16-dihydroxy-12-methoxy-8,12-abietadiene-11,14-dione and its 6α-hydroxy isomer respectively. Hydrolysis of **21a** with dilute hydrochloric acid in refluxing methanol afforded a trihydroxy quinone, which was partially acetylated with acetic anhydride in pyridine at 0—5 °C to give a 12,16-diacetoxy compound. This was further subjected to reductive acetylation with zinc powder and acetic anhydride in pyridine. The crude product

was then oxidized with Jones reagent at 0—5 °C to give 11,12,14,16-tetraacetoxy-8,11,13-abietatrien-6-one (**23a**: 21.9% from **21a**) and 11,12-diacetoxy-14,16-epoxy-8,11,13-abietatrien-6-one (**24a**: 23.5% from **21a**). The ^{1}H NMR spectrum of **23a** showed singlet (3H) signals at δ=2.00, 2.27, 2.29, and 2.32 due to four acetoxyl groups, while that of **24a** showed the corresponding signals at δ 2.25 and 2.27 ppm due to two acetoxyl groups and signals at δ=1.23 (3H, doublet), ca. 3.6 (1H, multiplet), 4.10 (1H, double doublet), and 4.69 (1H, triplet) due to a dihydrofuran moiety. The structure of **24a** was further supported from a similarity to its (15*S*)-epimer **24b** which is described later. To introduce a final oxygen function at the C-7 position, the tetraacetate **23a** was oxidized with Jones reagent at room temperature to afford 11,12,16-triacetoxy-14-hydroxy-8,11,13-abietatriene-6,7-dione [(15*R*)-coleon D triacetate] (**25a**: 27.4%). The presence of a hydroxyl group at C-14 in **25a** was supported by its ^{1}H NMR spectrum which showed a singlet signal due to a hydrogen-bonded hydroxyl group at δ 13.33. Compound **25a** was then hydrolyzed with dilute hydrochloric acid in refluxing methanol to give the desired 6,11,12,14,16-pentahydroxy-5,8,11,13-abietatetraen-7-one (**1a**: 98.9%) which was identical with natural (15*R*)-coleon C.

Similar conversion of (15*S*)-12-methoxymethyl ether **12b** into (15*S*)-coleon C (**1b**) was also carried out as follows. Hydrolysis of **12b** with dilute hydrochloric acid followed by methylation with diazomethane afforded 11,16-dihydroxy-12-methoxy-8,11,13-abietatrien-7-one (**14b**: 73.7%) along with small amounts of 12,16-methylenedioxy (**15b**: 13.9%) and 12,16-dimethoxy (**16b**: 12.1%) compounds. The 12-methoxy compound **14b** was acetylated and the resulting diacetate **17b** (90.2%) was transformed into 11,16-diacetoxy-12-methoxy-6,8,11,13-abietatetraene (**18b**: 83.0%) by sodium borohydride reduction and acid-catalyzed dehydration. Oxidation of **18b** with *m*-chloroperbenzoic acid followed by treatment with *p*-toluenesulfonic acid led to the corresponding 6-oxo compound **19b** (79.4%). This was converted into 6β,16-dihydroxy-12-methoxy-8,12-abietadiene-11,14-dione (**21b**: 38.7%) and its 6α-hydroxy isomer **22b** (9.1%) by reduction with lithium aluminium hydride and subsequent oxidation of the epimeric 6-hydroxy compounds **20b** with *m*-chloroperbenzoic acid. The *p*-quinone **21b** was then converted into tetraacetoxy ketone **23b** (66.1%) and diacetoxy ketone **24b** (31.8%) by a series of reactions; hydrolysis with dilute hydrochloric acid in methanol, acetylation with acetic anhydride in pyridine, reductive acetylation with zinc powder and acetic anhydride in pyridine, and oxidation with Jones reagent at 0—5 °C. The ^{1}H NMR spectrum of **24b** showed signals at δ 2.27 (6H, singlet) due to two acetoxyl groups and at δ 1.23 (3H, doublet), ca. 3.6 (1H, multiplet), 4.09 (1H, double doublet), and 4.69 (1H, triplet) due to a dihydrofuran moiety. For a structure determination of **24b**, the following conversion was carried out. Oxidation of the C-7 position in **24b** with Jones reagent afforded a mixture of the 6,7-dioxo compound **28b** and the diosphenol derivative **27b** which was hydrolyzed with dilute hydrochloric acid to give a phenolic compound **29b**. Since the ^{1}H NMR spectrum of **29b** showed no signal in the low field (δ=10—15) due to a hydrogen-bonded hydroxyl group at the C-14 position, the phenolic hydroxyl groups must be located at the C-11 and C-12 positions. Thus, the structure of **24b** was assigned to be 11,12-diacetoxy-14,16-epoxy-8,11,13-abietatrien-6-one. Further oxidation of **23b** with Jones reagent at room temperature produced 11,12,16-triacetoxy-14-hydroxy-8,11,13-abietatriene-6,7-dione [(15*S*)-coleon D triacetate] (**25b**: 54.4%). This was hydrolyzed with dilute hydrochloric acid in

refluxing methanol to give the desired 6,11,12,14,16-pentahydroxy-5,8,11,13-abietatetraen-7-one (**1b**: 99.7%) which gave the corresponding 6,11,12,16-tetraacetoxy compound **26b** with acetic anhydride in pyridine. The synthetic **1b** was also identical with natural (15*S*)-coleon C.

Finally, in order to confirm the absolute configuration of C-15 in the reported coleon C tri-*O*-methyl ether,[3] (15*S*)-12,16-epoxy-8,11,13-abietatriene[4] (**5b**) prepared by unambiguous methods in our laboratory was converted into the (15*S*)-*p*-quinone **3b**, mp 148—150 °C, via (15*S*)-12,16-epoxy-8,11,13-abietatrien-7-one (**6b**) by the method of Burnell et al.[3] As we would expect, the physical and spectral data of the synthetic **3b** are in good agreement with those of the reported (15*R*)-*p*-quinone (mp 143—145 °C),[3] but different from those of the reported (15*S*)-*p*-quinone (mp 119—120 °C).[3] Therefore, the reported 15R configuration for coleon C tri-*O*-methyl ether and all other compounds derived from the major *p*-quinone in the articles of Burnell et al.[3] must be corrected to the reverse configuration (15*S*).

Experimental

All melting points are uncorrected. The IR spectra and optical rotations were measured in chloroform, and the ^{1}H NMR spectra in deuteriochloroform at 60 MHz, with tetramethylsilane as an internal standard, unless otherwise stated; s: singlet bs: broad singlet, d: doublet, bd: broad doublet, dd: double doublet, t: triplet, m: multiplet. The column chromatography was performed using Merck silica gel (0.063 mm).

8,11,13-Abietatriene-12,16-diol (8). Anhydrous aluminium chloride (8.407 g) was added to a stirred solution of 12-methoxy-8,11,13-abietatrien-16-ol (**7**)[5] (6.651 g) and ethanethiol (9.4 ml) in dichloromethane (67 ml) at 4—10 °C with cooling in an ice-water bath over a 12-min period. After stirring at this temperature for 10 min and at room temperature for 2 h, the mixture was poured into ice-dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried over sodium sulfate, and evaporated in vacuo. The residue was chromatographed on silica gel (60 g), using ether–benzene (4:96) as eluent, to give a mixture of the C-15 epimeric diols **8** (5.739 g: 90.3%).

11,12,16-Triacetoxy-8,11,13-abietatriene (9). A solution of **8** (12.062 g) and benzoyl peroxide (15.078 g) in chloroform (240 ml) was refluxed for 5 h, cooled, and diluted with ether (250 ml). After the addition of acetic acid (60 ml) and aqueous potassium iodide (30%: 200 ml), the mixture was stirred at room temperature for 2 h and then washed successively with water, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo to give the crude product, which was used, without purification, in the next reaction.

A solution of the above crude product in dry ether (80 ml) was added dropwise to a stirred suspension of lithium aluminium hydride (2.876 g) in dry ether (100 ml) with cooling in an ice-water bath over a 20-min period. The mixture was refluxed for 80 min, cooled; the excess lithium aluminium hydride was decomposed with ethyl acetate (20 ml). The mixture was poured into ice-dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was acetylated with acetic anhydride (15 ml) in pyridine (15 ml) at 75—80 °C for 2 h. After the usual work-up, the crude product was chromatographed on silica gel (200 g), using ether–benzene (1:99) as eluent, to give 12,16-diacetoxy-8,11,13-abietatriene (**10**) (3.824 g: 24.8%). Further elution with ether–benzene (1:9) gave **9** (8.964 g: 50.6%). The IR and ^{1}H NMR spectra of **9** and **10** were identical with those of the corresponding (15*R*)-isomers or (15*S*)-isomers.[5]

A solution of **10** (3.782 g) in dry ether (25 ml) was added dropwise to a stirred suspension of lithium aluminium hydride (483 mg) in dry ether (25 ml) with cooling in an ice-water bath over a 10-min period. The mixture was refluxed for 1 h, poured into ice-dilute hydrochloric acid, and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give **8** (2.815 g: 95.1%).

11,12,16-Triacetoxy-8,11,13-abietatrien-7-one (11a,b). Chromium trioxide (4.177 g) was added to a stirred solution of **9** (9.771 g) in acetic acid (80 ml) with cooling in a water bath over a period of 1 h. The mixture was stirred at room temperature for 22 h, diluted with water, and extracted with ether. The ether extract was washed successively with water, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (250 g), using ether–benzene (4:96) as eluent, to give the recovered **9** (0.504 g: 5.2%) and a mixture of **11a** and **11b** (6.183 g: 61.4%).

11,16-Dihydroxy-12-methoxymethoxy-8,11,13-abietatrien-7-one (12a,b) and 11-Hydroxy-12,16-dimethoxymethoxy-8,11,13-abietatrien-7-one (13). A mixture of the triacetate (**11a,b**: 8.374 g) and dilute hydrochloric acid (15%: 15 ml) in methanol (80 ml) was refluxed for 2 h. After removal of the methanol in vacuo, the residue was extracted with ether. The ether extract was washed with water, dried, and evaporated in vacuo to give the crude triol (5.603 g).

A mixture of the crude triol (5.603 g), anhydrous potassium carbonate (3.028 g), and dicyclohexano-18-crown-6 (0.282 g) in tetrahydrofuran–dichloromethane (1:1, 100 ml) was stirred at room temperature for 30 min. After the addition of chloromethyl methyl ether (1.65 ml), the mixture was stirred at room temperature for 20 h and then diluted with ether. The ether solution was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (250 g), using ether–benzene (1:9) as eluent, to give **13** (1.095 g: 14.3%) and a mixture of **12a** and **12b** (5.060 g: 73.6%). ^{1}H NMR of **13**: δ=0.94 (3H, s) and 0.97 (3H, s) (-C(CH$_3$)$_2$), 1.19 (d, J=7 Hz) and 1.23 (d, J=7 Hz) (3H, C$_{15}$-CH$_3$), 1.40 (3H, s, C$_{10}$-CH$_3$), 3.26 (3H, s, C$_{16}$-OCH$_2$OCH$_3$), 3.62 (3H, s, C$_{12}$-OCH$_2$OCH$_3$), 4.56 (2H, s, C$_{16}$-OCH$_2$OCH$_3$), 5.03 (2H, s, C$_{12}$-OCH$_2$OCH$_3$), 7.56 (1H, s, C$_{14}$-H).

The mixture (**12a,b**) was separated into the pure **12a**, mp 135—136 °C (from acetone–hexane), $[\alpha]_D$ +44.1° (c 3.93), IR: 3620, 3480, and 1678 cm^{-1}, and **12b**, mp 140—142 °C (from acetone–hexane), $[\alpha]_D$ +5.7° (c 21.98), IR: 3620, 3480, and 1678 cm^{-1}, by repeated column chromatography on silica

gel and recrystallization. ^{1}H NMR of **12a**: δ=0.94 (3H, s) and 0.98 (3H, s) (-C(CH$_3$)$_2$), 1.22 (3H, d, J=6.5 Hz, C$_{15}$-CH$_3$), 1.42 (3H, s, C$_{10}$-CH$_3$), 3.62 (3H, s, -OCH$_3$), 5.02 (2H, s, -OCH$_2$O-), 7.28 (1H, s, C$_{11}$-OH), 7.52 (1H, s, C$_{14}$-H). ^{1}H NMR of **12b**: δ=0.97 (3H, s) and 0.99 (3H, s) (-C(CH$_3$)$_2$), 1.19 (3H, d, J=6.5 Hz, C$_{15}$-CH$_3$), 1.42 (3H, s, C$_{10}$-CH$_3$), 3.63 (3H, s, -OCH$_3$), 5.07 (2H, s, -OCH$_2$O-), 7.32 (1H, s, C$_{11}$-OH), 7.56 (1H, s, C$_{14}$-H). Anal. of **12a**; Found: C, 70.46; H, 8.66%. Calcd for $C_{22}H_{32}O_5$: C, 70.18; H, 8.57%. Anal. of **12b**; Found: C, 70.40; H, 8.82%. Calcd for $C_{22}H_{32}O_5$: C, 70.18; H, 8.57%.

Conversion of 12a into (15*R*)-11,12,16-Triacetoxy-8,11,13-abietatrien-7-one (11a). A mixture of **12a** (155.0 mg) and dilute hydrochloric acid (15%: 0.2 ml) in tetrahydrofuran (1.0 ml) was refluxed for 3 h. The mixture was cooled, diluted with ether, and then washed with brine. The dried solution was evaporated in vacuo to give (15*R*)-11,12,16-trihydroxy-8,11,13-abietatrien-7-one which was recrystallized from acetone-hexane, mp 250—252 °C. ^{1}H NMR (acetone-d_6) δ=0.95 (3H, s) and 0.99 (3H, s) (-C(CH$_3$)$_2$), 1.29 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.41 (3H, s, C$_{10}$-CH$_3$), 7.33 (1H, s, C$_{14}$-H).

The above trihydroxy ketone was acetylated with acetic anhydride (0.5 ml) in pyridine (0.5 ml) at 85—90 °C for 2 h. After the usual work-up, the crude product was chromatographed on silica gel (10 g), using ether-benzene (5:95) as eluent, to give **11a** (167.0 mg: 88.5%), $[\alpha]_D$ +65.0° (c 2.77). The IR and ^{1}H NMR spectra of **11a** were identical with those of authentic (15*R*)-11,12,16-triacetoxy-8,11,13-abietatrien-7-one.[5]

Conversion of (15*S*)-11,12,16-Triacetoxy-8,11,13-abietatrien-7-one (11b) into 12b. A mixture of **11b**[5] (3.251 g) and dilute hydrochloric acid (15%: 5.0 ml) in methanol (30 ml) was refluxed for 2 h. After removal of the methanol in vacuo, the residue was extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give (15*S*)-11,12,16-trihydroxy-8,11,13-abietatrien-7-one which was recrystallized from acetone-hexane, mp 228—230 °C, ^{1}H NMR (acetone-d_6) δ=0.97 (3H, s) and 1.01 (3H, s) (-C(CH$_3$)$_2$), 1.30 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.44 (3H, s, C$_{10}$-CH$_3$), 7.42 (1H, s, C$_{14}$-H).

A mixture of the above trihydroxy ketone (2.500 g), anhydrous potassium carbonate (1.274 g), and dicyclohexano-18-crown-6 (187 mg) in tetrahydrofuran-dichloromethane (1:1, 40 ml) was stirred at room temperature for 30 min. After the addition of chloromethyl methyl ether (0.69 ml), the mixture was stirred at room temperature for 18 h and then diluted with ether. The ether solution was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (100 g), using ether-benzene (2:8) as eluent, to give (15*S*)-11,16-dihydroxy-12-methoxymethoxy-8,11,13-abietatrien-7-one (1.886 g: 70.7%), mp 140—142 °C (from acetone-hexane), whose IR and ^{1}H NMR spectra were identical with those of **12b**.

Hydrolysis and Methylation of 12a. A mixture of **12a** (1.580 g) and dilute hydrochloric acid (15%: 1.0 ml) in tetrahydrofuran (10 ml) was refluxed for 1.5 h. After removal of the tetrahydrofuran in vacuo, the reidue was extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give the crude trihydroxy ketone.

A suspension of the above trihydroxy ketone in acetone-ether (1:4, 25 ml) was methylated with diazomethane in ether at room temperature for 3 h. After the usual work-up, the crude product was recrystallized from acetone-hexane to give (15*R*)-11,16-dihydroxy-12-methoxy-8,11,13-abietatrien-7-one (**14a**) (650 mg: 44.7%), mp 199—200.5 °C, $[\alpha]_D$ +41.2° (c 2.50), IR: 3490 and 1675 cm^{-1}; ^{1}H NMR δ=0.95 (3H, s) and 0.99 (3H, s) (-C(CH$_3$)$_2$), 1.26 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.42 (3H, s, C$_{10}$-CH$_3$), 3.73 (2H, bd, J=7 Hz, -CH$_2$OH), 3.84 (3H, s, -OCH$_3$), 6.29 (1H, s, C$_{11}$-OH), 7.58 (1H, s, C$_{14}$-H). Found: C, 72.71; H, 8.64%. Calcd for $C_{21}H_{30}O_4$: C, 72.80; H, 8.73%. The mother liquor of recrystallization was evaporated in vacuo and the residue was chromatographed on silica gel (50 g), using ether-benzene (1:9) as eluent, to give (15*R*)-11-hydroxy-12,16-methylenedioxy-8,11,13-abietatrien-7-one (**15a**) (286 mg: 19.8%) which was recrystallized from acetone-hexane, mp 182.5—183 °C, $[\alpha]_D$ +94.8° (c 1.54), IR: 3510 and 1675 cm^{-1}; ^{1}H NMR δ=0.95 (3H, s) and 0.99 (3H, s) (-C(CH$_3$)$_2$), 1.32 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.40 (3H, s, C$_{10}$-CH$_3$), 4.77 (1H, d, J=7 Hz) and 5.37 (1H, d, J=7 Hz) (-OCH$_2$O-), 6.24 (1H, s, C$_{11}$-OH), 7.49 (1H, s, C$_{14}$-H). MS (m/z): 344 (M$^+$). Found: C, 73.32; H, 8.28%. Calcd for $C_{21}H_{28}O_4$: C, 73.22; H, 8.19%.

Subsequent elution gave (15*R*)-11-hydroxy-12,16-dimethoxy-8,11,13-abietatrien-7-one (**16a**) (210 mg: 13.9%) which was recrystallized from hexane, mp 181—182.5 °C, $[\alpha]_D$ +20.0° (c 2.00), IR: 3505 and 1676 cm^{-1}, ^{1}H NMR δ=0.95 (3H, s) and 0.99 (3H, s) (-C(CH$_3$)$_2$), 1.23 (3H, d, J=6.5 Hz, C$_{15}$-CH$_3$), 1.41 (3H, s, C$_{10}$-CH$_3$), 3.31 (3H, s, C$_{16}$-OCH$_3$), 3.82 (3H, s, C$_{12}$-OCH$_3$), 6.11 (1H, s, C$_{11}$-OH), 7.59 (1H, s, C$_{14}$-H). Found: C, 73.17; H, 9.24%. Calcd for $C_{22}H_{32}O_4$: C, 73.30; H, 8.95%.

Further elution with ether-benzene (1:4) gave an additional **14a** (287 mg: 19.7%).

Hydrolysis and Methylation of 12b. The 12-methoxymethyl ether **12b** (690 mg) was hydrolyzed with dilute hydrochloric acid (15%: 0.5 ml) in refluxing tetrahydrofuran (5.0 ml) for 1.5 h. The crude trihydroxy ketone was then methylated with diazomethane in ether at room temperature for 4 h to give the following three compound **14b**, **15b**, and **16b**.

(15*S*)-11,16-Dihydroxy-12-methoxy-8,11,13-abietatrien-7-one (**14b**) (468 mg: 73.7%), mp 240—241 °C (from acetone-hexane), $[\alpha]_D$ −18.8° (c 0.59), ^{1}H NMR δ=0.94 (3H, s) and 0.98 (3H, s) (-C(CH$_3$)$_2$), 1.22 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.40 (3H, s, C$_{10}$-CH$_3$), 3.70 (2H, bd, J=7 Hz, -CH$_2$OH), 3.82 (3H, s, -OCH$_3$), 6.09 (1H, s, C$_{11}$-OH), 7.59 (1H, s, C$_{14}$-H). Found: C, 72.58; H, 8.67%. Calcd for $C_{21}H_{30}O_4$: C, 72.80; H, 8.73%.

(15*S*)-11-Hydroxy-12,16-methylenedioxy-8,11,13-abietatrien-7-one (**15b**) (88 mg: 13.9%), mp 210—211 °C (from acetone-hexane), $[\alpha]_D$ −41.0° (c 1.88), ^{1}H NMR: δ=0.97 (3H, s) and 1.00 (3H, s) (-C(CH$_3$)$_2$), 1.35 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.42 (3H, s, C$_{10}$-CH$_3$), 4.80 (1H, d, J=7 Hz) and 5.38 (1H, d, J=7 Hz) (-OCH$_2$O-), 6.35 (1H, s, C$_{11}$-OH), 7.53 (1H, s, C$_{14}$-H). Found: C, 73.24; H, 7.91%. Calcd for $C_{21}H_{28}O_4$: C, 73.22; H, 8.19%.

(15*S*)-11-Hydroxy-12,16-dimethoxy-8,11,13-abietatrien-7-one (**16b**) (80 mg: 12.1%), mp 169.5—171 °C (from hexane), $[\alpha]_D$ +9.2° (c 1.20), ^{1}H NMR δ=0.97 (3H, s) and 1.00 (3H, s)

(-C(CH$_3$)$_2$), 1.24 (3H, d, J=6.5 Hz, C$_{15}$-CH$_3$), 1.42 (3H, s, C$_{10}$-CH$_3$), 3.35 (3H, s, C$_{16}$-OCH$_3$), 3.84 (3H, s, C$_{12}$-OCH$_3$), 6.18 (1H, s, C$_{11}$-OH), 7.60 (1H, s, C$_{14}$-H). Found: C, 73.29; H, 8.93%. Calcd for $C_{22}H_{32}O_4$: C, 73.30; H, 8.95%.

(15*R*)-11,16-Diacetoxy-12-methoxy-8,11,13-abietatrien-7-one (17a) and Its (15*S*)-Epimer (17b). *a*): A mixture of **14a** (1.441 g) and acetic anhydride (3.0 ml) in pyridine (4.0 ml) was heated at 75—80 °C for 2 h. After the usual work-up, the crude product was chromatographed on silica gel (30 g), using ether-benzene (1:9) as eluent, to give **17a** (1.681 g: 93.9%), $[\alpha]_D$ +51.9° (*c* 10.01), IR: 1767, 1733, and 1680 cm^{-1}; ^{1}H NMR δ=0.98 (3H, s) and 1.00 (3H, s) (-C(CH$_3$)$_2$), 1.31 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.37 (3H, s, C$_{10}$-CH$_3$), 2.03 (3H, s, C$_{16}$-OCOCH$_3$), 2.38 (3H, s, C$_{11}$-OCOCH$_3$), 3.48 (1H, m, C$_{15}$-H), 3.79 (3H, s, C$_{12}$-OCH$_3$), 4.13 (2H, bd, J=7 Hz, -CH$_2$OAc), 7.98 (1H, s, C$_{14}$-H). Found: C, 69.86; H, 7.85%. Calcd for $C_{25}H_{34}O_6$: C, 69.74; H, 7.96%.

b): A mixture of **14b** (410.0 mg) and acetic anhydride (2.0 ml) in pyridine (3.0 ml) was heated at 75—80 °C for 2 h to give **17b** (459.6 mg: 90.2%), $[\alpha]_D$ +13.0° (*c* 2.77), IR: 1767, 1733, and 1680 cm^{-1}; ^{1}H NMR δ=0.98 (3H, s) and 1.00 (3H, s) (-C(CH$_3$)$_2$), 1.28 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.37 (3H, s, C$_{10}$-CH$_3$), 2.03 (3H, s, C$_{16}$-OCOCH$_3$), 2.38 (3H, s, C$_{11}$-OCOCH$_3$), 3.46 (1H, m, C$_{15}$-H), 3.78 (3H, s, C$_{12}$-OCH$_3$), 4.16 (2H, bd, J=7 Hz, -CH$_2$OAc), 7.97 (1H, s, C$_{14}$-H). Found: C, 69.54; H, 8.21%. Calcd for $C_{25}H_{34}O_6$: C, 69.74; H, 7.96%.

(15*R*)-11,16-Diacetoxy-12-methoxy-6,8,11,13-abietatetraene (18a) and Its (15*S*)-Epimer (18b). *a*): A mixture of **17a** (915.5 mg) and sodium borohydride (40.2 mg) in methanol (5.0 ml) was stirred at 0—5 °C for 30 min and at room temperature for 1 h. The mixture was diluted with ether, acidified with dilute hydrochloric acid, and then extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo. The residue was refluxed with *p*-toluenesulfonic acid (100 mg) in dry benzene (10 ml) for 1 h, cooled, and diluted with ether. The ether solution was washed with water, dried, and evaporated in vacuo. The crude product was chromatographed on silica gel (40 g), using ether-benzene (5:95) as eluent, to give **18a** (765.2 mg: 86.8%). This was recrystallized from hexane, mp 79.5—81 °C, $[\alpha]_D$ −76.9° (*c* 4.85), IR: 1745sh and 1730 cm^{-1}; ^{1}H NMR δ=0.98 (3H, s) and 1.02 (3H, s) (-C(CH$_3$)$_2$), 1.12 (3H, s, C$_{10}$-CH$_3$), 1.26 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.01 (3H, s, C$_{16}$-OCOCH$_3$), 2.31 (3H, s, C$_{11}$-OCOCH$_3$), 3.71 (3H, s, C$_{12}$-OCH$_3$), 4.08 (2H, d, J=7 Hz, -CH$_2$OAc), 5.89 (1H, dd, J=9.5 and 3 Hz, C$_6$-H), 6.43 (1H, dd, J=9.5 and 3 Hz, C$_7$-H), 6.78 (1H, s, C$_{14}$-H). Found: C, 72.20; H, 8.30%. Calcd for $C_{25}H_{34}O_5$: C, 72.43; H, 8.27%.

b): The ketone **17b** (437.0 mg) was treated as described in *a*) to give **18b** (349.4 mg: 83.0%), $[\alpha]_D$ −74.0° (*c* 2.65), IR: 1745sh and 1730 cm^{-1}, ^{1}H NMR δ=0.98 (3H, s) and 1.02 (3H, s) (-C(CH$_3$)$_2$), 1.12 (3H, s, C$_{10}$-CH$_3$), 1.22 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.03 (3H, s, C$_{16}$-OCOCH$_3$), 2.32 (3H, s, C$_{11}$-OCOCH$_3$), 3.72 (3H, s, C$_{12}$-OCH$_3$), 4.15 (2H, d, J=7 Hz, -CH$_2$OAc), 5.92 (1H, dd, J=9.5 and 3 Hz, C$_6$-H), 6.45 (1H, dd, J=9.5 and 3 Hz, C$_7$-H), 6.78 (1H, s, C$_{14}$-H). Found: C, 72.51; H, 8.18%. Calcd for $C_{25}H_{34}O_5$: C, 72.43; H, 8.27%.

(15*R*)-11,16-Diacetoxy-12-methoxy-8,11,13-abietatrien-6-one (19a) and Its (15*S*)-Epimer (19b). *a*): A mixture of **18a** (1.335 g) and *m*-chloroperbenzoic acid (80%: 1.042 g) in dichloromethane (10 ml) was stirred at 0—5 °C for 30 min and at room temperature for 2.5 h. The mixture was diluted with ether (30 ml) and washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residual oil was refluxed with *p*-toluenesulfonic acid (100 mg) in dry benzene (10 ml) for 1 h, cooled, and diluted with ether. The ether solution was washed successively with water, aqueous sodium hydrogencarbonate, and water. The dried solution was evaporated in vacuo. The crude product was chromatographed on silica gel (30 g), using ether-benzene (1:9) as eluent, to give an oily **19a** (1.104 g: 79.6%), $[\alpha]_D$ +92.1° (*c* 6.17), IR: 1767 and 1720 cm^{-1}, ^{1}H NMR δ=1.06 (3H, s), 1.23 (3H, s), and 1.33 (3H, s) (-C(CH$_3$)$_2$ and C$_{10}$-CH$_3$), 1.28 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.03 (3H, s, C$_{16}$-OCOCH$_3$), 2.36 (3H, s, C$_{11}$-OCOCH$_3$), 2.59 (1H, s, C$_5$-H), 3.72 (3H, s, C$_{12}$-OCH$_3$), 4.10 (2H, d, J=7 Hz, -CH$_2$OAc), 6.78 (1H, s, C$_{14}$-H). Found: C, 69.84; H, 7.91%. Calcd for $C_{25}H_{34}O_6$: C, 69.74; H, 7.96%.

b): The tetraene **18b** (1.019 g) was treated as described in *a*) to give an oily **19b** (840 mg: 79.4%), $[\alpha]_D$ +84.7° (*c* 2.36), IR: 1765 and 1720 cm^{-1}, ^{1}H NMR δ=1.06 (3H, s), 1.23 (3H, s), and 1.33 (3H, s) (-C(CH$_3$)$_2$ and C$_{10}$-CH$_3$), 1.23 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.03 (3H, s, C$_{16}$-OCOCH$_3$), 2.36 (3H, s, C$_{11}$-OCOCH$_3$), 2.58 (1H, s, C$_5$-H), 3.72 (3H, s, C$_{12}$-OCH$_3$), 4.14 (2H, d, J=7 Hz, -CH$_2$OAc), 6.79 (1H, s, C$_{14}$-H). Found: C, 69.59; H, 7.68%. Calcd for $C_{25}H_{34}O_6$: C, 69.74; H, 7.96%.

Conversion of 19a into (15*R*)-6β,16-Dihydroxy-12-methoxy-8,12-abietadiene-11,14-dione (21a) and Its 6α-Hydroxy Isomer (22a). A mixture of **19a** (1.074 g) and lithium aluminium hydride (142 mg) in dry ether (10 ml) was refluxed for 1.5 h. The mixture was poured into ice-dilute hydrochloric acid and extracted with ether. The ether extract was washed with brine, dried, and evaporated in vacuo to give a mixture of the C-6 epimeric triols **20a** (822 mg). This was recrystallized from acetone-hexane to give (15*R*)-12-methoxy-8,11,13-abietatriene-6β,11,16-triol, mp 201—203 °C, IR (KBr): 3515 and 3490—3350 cm^{-1}, ^{1}H NMR (acetone-d_6) δ=1.02 (3H, s) and 1.30 (3H, s) (-C(CH$_3$)$_2$), 1.20 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.72 (3H, s, C$_{10}$-CH$_3$), 3.69 (3H, s, C$_{12}$-OCH$_3$), 4.57 (1H, m, $W_{1/2}$=7 Hz, C$_6$-H), 6.35 (1H, s, C$_{14}$-H). Found: C, 72.47; H, 9.34%. Calcd for $C_{21}H_{32}O_4$: C, 72.38; H, 9.26%.

A mixture of **20a** (503 mg) and *m*-chloroperbenzoic acid (80%: 623 mg) in methanol (7.0 ml) was stirred at room temperature for 4 h and then diluted with ether (50 ml). The ether solution was washed successively with aqueous potassium iodide, aqueous sodium thiosulfate, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (30 g), using ether-chloroform (1:9) as eluent, to give **21a** (235 mg: 42.5%) which was recrystallized from acetone-hexane, mp 178—180 °C, $[\alpha]_D$ −73.8° (*c* 0.65). IR: 3600, 3450, 1658, and 1638 cm^{-1}; ^{1}H NMR δ=1.01 (3H, s) and 1.27 (3H, s) (-C(CH$_3$)$_2$), 1.18 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.69 (3H, s, C$_{10}$-CH$_3$), 3.72 (2H, bd, J=7 Hz, -CH$_2$OH), 3.91 (3H, s, C$_{12}$-OCH$_3$), 4.62 (1H, $W_{1/2}$=8 Hz, C$_6$-H). Found: C, 69.81; H, 8.37%. Calcd for $C_{21}H_{30}O_5$: C, 69.58; H, 8.34%. Further elution with ether-chloroform (1:4) gave **22a** as an

oil (37 mg: 6.6%), ^{1}H NMR δ=1.13 (3H, s) and 1.20 (3H, s) (-C(CH$_3$)$_2$), 1.16 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.36 (3H, s, C$_{10}$-CH$_3$), 3.87 (3H, s, C$_{12}$-OCH$_3$).

Conversion of 19b into (15*S*)-6β,16-Dihydroxy-12-methoxy-8,12-abietadiene-11,14-dione (21b) and Its 6α-Hydroxy Isomer (22b). A mixture of **19b** (725.0 mg) and lithium aluminium hydride (95.9 mg) in dry ether (8.0 ml) was refluxed for 1.5 h. The crude product **20b** (533.8 mg) was recrystallized from acetone-hexane to give (15*S*)-12-methoxy-8,11,13-abietatriene-6β,11,16-triol, mp 186—188 °C, IR (KBr): 3480 and 3370 cm^{-1}, ^{1}H NMR (acetone-d_6) δ=1.03 (3H, s) and 1.31 (3H, s) (-C(CH$_3$)$_2$), 1.19 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.73 (3H, s, C$_{10}$-CH$_3$), 3.71 (3H, s, C$_{12}$-OCH$_3$), 4.60 (1H, $W_{1/2}$=7 Hz, C$_6$-H), 6.38 (1H, s, C$_{14}$-H). Found: C, 72.25; H, 9.18%. Calcd for C$_{21}$H$_{32}$O$_4$: C, 72.38; H, 9.26%.

A mixture of **20b** (310.4 mg) and *m*-chloroperbenzoic acid (80%: 384.3 mg) in methanol (5.0 ml) was stirred at room temperature for 4 h. The crude product was chromatographed on silica gel (20 g), using ether-chloroform (1:4) as eluent, to give **21b** (137.3 mg: 38.7%) which was recrystallized from acetone-hexane, mp 183—185 °C, [α]$_D$ −63.6° (c 2.06), IR: 3615, 3450, 1660, 1642, and 1602 cm^{-1}; ^{1}H NMR δ=0.99 (3H, s) and 1.25 (3H, s) (-C(CH$_3$)$_2$), 1.14 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.67 (3H, s, C$_{10}$-CH$_3$), 3.72 (2H, bd, J=7 Hz, -CH$_2$OH), 3.91 (3H, s, C$_{12}$-OCH$_3$), 4.60 (1H, $W^1_{/2}$=8 Hz, C$_6$-H). Found: C, 69.31; H, 8.48%. Calcd for C$_{21}$H$_{30}$O$_5$: C, 69.58; H, 8.34%. Further elution gave **22b** as an oil (32.3 mg: 9.1%), IR: 3600, 3450, 1660, and 1640 cm^{-1}; ^{1}H NMR δ=1.12 (3H, s) and 1.20 (3H, s) (-C(CH$_3$)$_2$), 1.15 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.36 (3H, s, C$_{10}$-CH$_3$), 3.88 (3H, s, C$_{12}$-OCH$_3$).

(15*R*)-11,12,14,16-Tetraacetoxy-8,11,13-abietatrien-6-one (23a) and (15*R*)-11,12-Diacetoxy-14,16-epoxy-8,11,13-abietatrien-6-one (24a). A mixture of **21a** (341.5 mg) and dilute hydrochloric acid (5%: 0.3 ml) in methanol (3.0 ml) was refluxd for 30 min and then diluted with ethyl acetate. The solution was washed with water, dried, and evaporated in vacuo to give a crude triol, ^{1}H NMR δ=1.01 (3H, s) and 1.27 (3H, s) (-C(CH$_3$)$_2$), 1.63 (3H, s, C$_{10}$-CH$_3$), 4.60 (1H, $W_{1/2}$=7 Hz, C$_6$-H).

The crude triol was acetylated with acetic anhydride (1.0 ml) in pyridine (3.0 ml) at 0—5 °C for 1 h. The mixture was diluted with ethyl acetate and washed successively with dilute hydrochloric acid, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo to give a crude diacetate, ^{1}H NMR δ=1.01 (3H, s) and 1.27 (3H, s) (-C(CH$_3$)$_2$), 1.67 (3H, s, C$_{10}$-CH$_3$), 1.99 (3H, s, C$_{16}$-OCOCH$_3$), 2.31 (3H, s, C$_{12}$-OCOCH$_3$), 4.21 (2H, d, J=7 Hz, -CH$_2$OAc), 4.62 (1H, $W_{1/2}$=7 Hz, C$_6$-H).

A mixture of the crude diacetate, acetic anhydride (1.0 ml), and zinc powder (90 mg) in pyridine (3.0 ml) was stirred at 0—5 °C for 1 h. After the addition of ether, zinc powder was removed and the organic solution was washed successively with dilute hydrochloric acid, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo. The residue was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.57 ml) in acetone (2.0 ml) with cooling in an ice-water bath for 3 min. After the addition of ether, the mixture was washed with water, dried, and evaporated in vacuo. The crude product was chromatographed on silica gel (12 g), using ether-benzene (1:99) as eluent, to give **24a** (91.9 mg: 23.5%), [α]$_D$ +53.2° (c 1.32), IR: 1770 and 1719 cm^{-1}, ^{1}H NMR (90 MHz) δ=1.01 (3H, s), 1.22 (3H, s), and 1.33 (3H, s) (-C(CH$_3$)$_2$ and C$_{10}$-CH$_3$), 1.23 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.25 (3H, s) and 2.27 (3H, s) (C$_{11}$-OCOCH$_3$ and C$_{12}$-OCOCH$_3$), 2.60 (1H, s, C$_5$-H), 3.18 (1H, d, J=21 Hz) and 3.57 (1H, d, J=21 Hz) (-COCH$_2$-), 4.10 (1H, dd, J=7 and 8 Hz) and 4.69 (1H, t, J=9 Hz) (-OCH$_2$-). Found: C, 69.67; H, 7.43%. Calcd for C$_{24}$H$_{30}$O$_6$: C, 69.54; H, 7.30%. Further elution with ether-benzene (1:9) gave **23a** (106.6 mg: 21.9%) which was recrystallized from methanol, mp 214.5—217.5 °C, [α]$_D$ +37.4° (c 1.23), IR: 1776 and 1725 cm^{-1}, ^{1}H NMR (90 MHz) δ=1.01 (3H, s), 1.19 (3H, s), and 1.31 (3H, s) (-C(CH$_3$)$_2$ and C$_{10}$-CH$_3$), 1.18 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.00 (3H, s, C$_{16}$-OCOCH$_3$), 2.27 (3H, s), 2.29 (3H, s), and 2.32 (3H, s) (C$_{11}$-OCOCH$_3$, C$_{12}$-OCOCH$_3$, and C$_{14}$-OCOCH$_3$), 2.62 (1H, s, C$_5$-H), 3.16 (1H, d, J=21 Hz) and 3.42 (1H, d, J=21 Hz) (-COCH$_2$-), 4.03 (1H, dd, J=8 and 9.5 Hz) and 4.30 (1H, dd, J=8 and 9.5 Hz) (-CH$_2$OAc). Found: C, 65.38; H, 7.29%. Calcd for C$_{28}$H$_{36}$O$_9$: C, 65.10; H, 7.03%.

(15*S*)-11,12,14,16-Tetraacetoxy-8,11,13-abietatrien-6-one (23b) and (15*S*)-11,12-Diacetoxy-14,16-epoxy-8,11,13-abietatrien-6-one (24b). The quinone **21b** (19.0 mg) was hydrolyzed with dilute hydrochloric acid (5%: 0.1 ml) in refluxing methanol (1.0 ml) for 30 min to give a crude triol (19.0 mg), ^{1}H NMR δ=1.01 (3H, s) and 1.25 (3H, s) (-C(CH$_3$)$_2$), 1.28 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.61 (3H, s, C$_{10}$-CH$_3$), 4.60 (1H, $W_{1/2}$=7 Hz, C$_6$-H).

The crude triol (19.0 mg) was acetylated with acetic anhydride (0.5 ml) in pyridine (0.5 ml) at 0—5 °C for 1 h to give a crude diacetate (20.0 mg), ^{1}H NMR δ=1.00 (3H, s) and 1.25 (3H, s) (-C(CH$_3$)$_2$), 1.64 (3H, s, C$_{10}$-CH$_3$), 1.97 (3H, s, C$_{16}$-OCOCH$_3$), 2.30 (3H, s, C$_{12}$-OCOCH$_3$), 4.20 (2H, d, J=7 Hz, -CH$_2$OAc), 4.62 (1H, $W_{1/2}$=7 Hz, C$_6$-H).

A mixture of the crude diacetate (20.0 mg), acetic anhydride (0.5 ml), and zinc powder (50 mg) in pyridine (0.5 ml) was stirred at 0—5 °C for 1 h. After the addition of ether, zinc powder was removed and the ether solution was washed successively with dilute hydrochloric acid, aqueous sodium hydrogencarbonate, and brine. The dried solution was evaporated in vacuo to give an oil (26.0 mg).

The above oil (26.0 mg) in acetone (1.0 ml) was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.03 ml) at 0—5 °C for 3 min. After the addition of ether and water, the ether solution was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (5 g), using ether-benzene (5:95) as eluent, to give **24b** (6.9 mg: 31.8%) which was recrystallized from acetone-hexane, mp 186.5—188.5 °C, [α]$_D$ +107.2° (c 2.92), IR: 1769 and 1720 cm^{-1}, ^{1}H NMR (90 MHz) δ=1.02 (3H, s), 1.20 (3H, s), and 1.32 (3H, s) (-C(CH$_3$)$_2$ and C$_{10}$-CH$_3$), 1.23 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 2.27 (6H, s, C$_{11}$-OCOCH$_3$ and C$_{12}$-OCOCH$_3$), 2.63 (1H, s, C$_5$-H), 3.18 (1H, d, J=21 Hz) and 3.57 (1H, d, J=21 Hz) (-COCH$_2$-), 4.09 (1H, dd, J=7 and 8 Hz) and 4.69 (1H, t, J=9 Hz) (-OCH$_2$-). Found: C, 69.81; H, 7.59%. Calcd for C$_{24}$H$_{30}$O$_6$: C, 69.54; H, 7.30%. Further elution with ether-benzene (1:9) gave **23b** as an oil (17.9 mg: 66.1%), [α]$_D$ +77.4° (c 0.84), IR: 1771 and 1721 cm^{-1}, ^{1}H NMR (90 MHz) δ=1.01 (3H, s), 1.20 (3H, s), and 1.32 (3H, s) (-C(CH$_3$)$_2$ and C$_{10}$-CH$_3$), 1.18 (3H, d, J=7 Hz,

C_{15}-CH_3), 2.00 (3H, s, C_{16}-$OCOCH_3$), 2.27 (3H, s), 2.29 (3H, s), and 2.33 (3H, s) (C_{11}-$OCOCH_3$, C_{12}-$OCOCH_3$, and C_{14}-$OCOCH_3$), 2.63 (1H, s, C_5-H), 3.16 (1H, d, J=21 Hz) and 3.42 (1H, d, J=21 Hz) (-$COCH_2$-), 4.03 (1H, dd, J=8 and 9.5 Hz) and 4.30 (1H, dd, J=8 and 9.5 Hz) (-CH_2OAc). Found: C, 65.40; H, 6.81%. Calcd for $C_{28}H_{36}O_9$: C, 65.10; H, 7.03%.

(15*R*)-11,12,16-Triacetoxy-14-hydroxy-8,11,13-abietatriene-6,7-dione (25a) and Its (15*S*)-Isomer (25b). *a*): A solution of **23a** (103.6 mg) in acetone (2.0 ml) was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.40 ml) at 0—5 °C for 5 min and then at room temperature for 2.5 h. The mixture was diluted with ether and washed with water. The dried solution was evaporated in vacuo. The residue was chromatographed on silica gel (10 g), using ether-benzene (1:9) as eluent, to give (15*R*)-coleon D triacetate (**25a**) as an oil (26.9 mg: 27.4%), $[\alpha]_D$ +92.8° (*c* 0.83), IR: 1779, 1732, 1634, and 1606 cm^{-1}; ^1H NMR (90 MHz) δ=1.06 (3H, s), 1.36 (3H, s), and 1.38 (3H, s) (-$C(CH_3)_2$ and C_{10}-CH_3), 1.31 (3H, d, J=7 Hz, C_{15}-CH_3), 1.97 (3H, s, C_{16}-$OCOCH_3$), 2.28 (3H, s) and 2.30 (3H, s) (C_{11}-$OCOCH_3$ and C_{12}-$OCOCH_3$), 3.03 (1H, s, C_5-H), 4.37 (2H, d, J=7 Hz, -CH_2OAc), 13.33 (1H, s, C_{14}-OH). Found: C, 63.63; H, 6.71%. Calcd for $C_{26}H_{32}O_9$: C, 63.92; H, 6.60%.

b): A solution of **23b** (86.5 mg) in acetone (2.0 ml) was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.34 ml) at 0—5 °C for 5 min and then at room temperature for 2.5 h. The crude product was chromatographed on silica gel (7 g), using ether-benzene (1:9) as eluent, to give (15*S*)-coleon D triacetate (**25b**) as an oil (44.5 mg: 54.4%), $[\alpha]_D$ +100.0° (*c* 1.44), IR: 1777, 1733, 1636, and 1610sh cm^{-1}; ^1H NMR (90 MHz) δ=1.05 (3H, s), 1.37 (3H, s), and 1.39 (3H, s) (-$C(CH_3)_2$ and C_{10}-CH_3), 1.32 (3H, d, J=7 Hz, C_{15}-CH_3), 1.97 (3H, s, C_{16}-$OCOCH_3$), 2.28 (3H, s) and 2.30 (3H, s) (C_{11}-$OCOCH_3$ and C_{12}-$OCOCH_3$), 3.02 (1H, s, C_5-H), 4.37 (2H, d, J=7 Hz, -CH_2OAc), 13.31 (1H, s, C_{14}-OH). Found: C, 64.19; H, 6.88%. Calcd for $C_{26}H_{32}O_9$: C, 63.92; H, 6.60%.

(15*R*)-Coleon C (1a) and (15*S*)-Coleon C (1b). *b*): A mixture of **25a** (24.0 mg) and dilute hydrochloric acid (15%: 0.1 ml) in methanol (1.0 ml) was refluxed for 2 h. After the addition of ether, the mixture was washed with brine, dried, and evaporated in vacuo. The residue was chromatographed on silica gel (Mallinckrodt CC-4, 5 g), using hexane-chloroform (3:7) as eluent, to give **1a** (17.6 mg: 98.9%) which was recrystallized from methanol, mp 230—232.5 °C, $[\alpha]_D$ +39.0° (MeOH, *c* 0.21), IR (KBr): 3525, 3350sh, 1623, 1594, and 1576 cm^{-1}; ^1H NMR (90 MHz, acetone-d_6) δ=1.28 (3H, d, J=7 Hz, C_{15}-CH_3), 1.43 (3H, s) and 1.45 (3H, s) (-$C(CH_3)_2$), 1.68 (3H, s, C_{10}-CH_3), 3.89 (1H, dd, J=11 and 2 Hz) and 4.08 (1H, dd, J=11 and 4 Hz) (-CH_2OH), 13.12 (1H, s, C_{14}-OH). Found: C, 66.49; H, 7.15%. Calcd for $C_{20}H_{26}O_6$: C, 66.28; H, 7.23%. The synthetic **1a** was identical with natural (15*R*)-coleon C (mp 236—238 °C, $[\alpha]_D$ +46.8° (MeOH)).[2]

b): A mixture of **25b** (38.8 mg) and dilute hydrochloric acid (15%: 0.15 ml) in methanol (1.5 ml) was refluxed for 1 h. The crude product was chromatographed on silica gel (Mallinckrodt CC-4, 6 g), using hexane-chloroform (3:7) as eluent, to give **1b** (28.7 mg: 99.7%) which was recrystallized from methanol, mp 199.5—201.5 °C, $[\alpha]_D$ −41.0° (MeOH, *c* 0.39), IR (KBr): 3470, 3330sh, 1622, 1596, and 1574 cm^{-1}; ^1H NMR (90 MHz acetone-d_6) δ=1.31 (3H, d, J=7 Hz, C_{15}-CH_3), 1.43 (3H, s) and 1.45 (3H, s) (-$C(CH_3)_2$), 1.68 (3H, s, C_{10}-CH_3), 3.87 (1H, dd, J=11 and 2 Hz) and 4.08 (1H, dd, J=11 and 4 Hz) (-CH_2OH), 13.10 (1H, s, C_{14}-OH). Found: C, 66.53; H, 7.38%. Calcd for $C_{20}H_{26}O_6$: C, 66.28; H, 7.23%. The synthetic **1b** was identical with natural (15*S*)-coleon C (mp 202—204 °C, $[\alpha]_D$ −34.7° (MeOH)).[2]

(15*S*)-Coleon C Tetraacetate (26b). The synthetic **1b** (19.7 mg) was acetylated with acetic anhydride (0.5 ml) in pyridine (0.5 ml) at 75—80 °C for 2 h. The crude product was chromatographed on silica gel (5 g), using ether-benzene (1:9) as eluent, to give **26b** (22.2 mg: 77.1%) which was recrystallized from acetone-hexane, mp 222—224 °C, $[\alpha]_D$ +28.6° (*c* 0.63), IR: 1771, 1729, 1631sh, and 1611 cm^{-1}; ^1H NMR (90 MHz) δ=1.32 (3H, d, J=7 Hz, C_{15}-CH_3), 1.36 (6H, s, -$C(CH_3)_2$), 1.63 (3H, s, C_{10}-CH_3), 1.97 (3H, s, C_{16}-$OCOCH_3$), 2.28 (3H, s), 2.29 (3H, s), and 2.33 (3H, s) (C_6-$OCOCH_3$, C_{11}-$OCOCH_3$, and C_{12}-$OCOCH_3$), 3.37 (1H, m, C_{15}-H), 4.37 (2H, bd, J=7 Hz, -CH_2OAc), 13.51 (1H, s, C_{14}-OH). Found: C, 63.68; H, 6.51%. Calcd for $C_{28}H_{34}O_{10}$: C, 63.38; H, 6.46%.

(15*S*)-11,12-Diacetoxy-14,16-epoxy-6-hydroxy-5,8,11,13-abietatetraen-7-one (27b) and (15*S*)-11,12-Diacetoxy-14,16-epoxy-8,11,13-abietatriene-6,7-dione (28b). A solution of **24b** (86.0 mg) in acetone (3.0 ml) was oxidized with Jones reagent (2.5 mol dm^{-3}: 0.41 ml) at 0—5 °C for 5 min and then at room temperature for 2 h. The crude product was chromatographed on silica gel (10 g), using ether-benzene (1:9) as eluent, to give **27b** (21.9 mg: 24.6%) which was recrystallized from acetone-hexane, mp 248—250 °C, $[\alpha]_D$ +44.6° (*c* 0.56), IR: 3377, 1780, and 1631 cm^{-1}; ^1H NMR (90 MHz) δ=1.24 (3H, d J=7 Hz, C_{15}-CH_3), 1.42 (3H, s) and 1.44 (3H, s) (-$C(CH_3)_2$), 1.56 (3H, s, C_{10}-CH_3), 2.28 (3H, s) and 2.33 (3H, s) (C_{11}-$OCOCH_3$ and C_{12}-$OCOCH_3$), 4.32 (1H, dd, J=7 and 8 Hz) and 4.92 (1H, t, J=9 Hz) (-OCH_2-), 7.22 (1H, s, C_6-OH). Found: C, 67.53; H, 6.81%. Calcd for $C_{24}H_{28}O_7$: C, 67.27; H, 6.59%. Further elution gave a mixture of **27b** and **28b** (11.6 mg: 13.1%). Elution with ether-benzene (1:1) gave **28b** (13.0 mg: 14.6%) which was recrystallized from acetone-hexane, mp 220—223 °C decomp, $[\alpha]_D$ +177.5° (*c* 0.36), IR: 1779, 1747, and 1680 cm^{-1}; ^1H NMR (90 MHz) δ=1.07 (3H, s), 1.43 (3H, s), and 1.46 (3H, s) (-$C(CH_3)_2$ and C_{10}-CH_3), 1.25 (3H, d, J=7 Hz, C_{15}-CH_3), 2.28 (6H, s, C_{11}-$OCOCH_3$ and C_{12}-$OCOCH_3$), 2.54 (1H, bs, C_5-H), 4.32 (1H, dd, J=7 and 8 Hz) and 4.90 (1H, t, J=9 Hz) (-OCH_2-). Found: C, 67.48; H, 6.76%. Calcd for $C_{24}H_{28}O_7$: C, 67.27; H, 6.59%.

The diacetate **27b** (11.6 mg) was refluxed with dilute hydrochloric acid (15%: 0.1 ml) in ethanol (1.0 ml) for 3 h to give a triol **29b**, whose ^1H NMR spectrum showed no signal at δ=10—15 due to a hydrogen-bonded hydroxyl group at the C-14 position.

2-[4-[(*S*)-2-Acetoxy-1-methylethyl]-2,5-dioxo-1(6),3-cyclohexadienyl]-2,6,6-trimethylcyclohexaneacetic Acid (3b). A solution of (15*S*)-12,16-epoxy-8,11,13-abietatriene (**5b**)[4] (132 mg) in acetic acid (3.0 ml) was oxidized with chromium trioxide (69.6 mg) at room temperature for 1 h. The crude product was chromatographed on silica gel (10 g), using benene as eluent, to give (15*S*)-12,16-epoxy-8,11,13-abietatrien-7-one (**6b**) as an oil (87.2 mg: 63.0%), $[\alpha]_D$ +18.4° (*c* 2.99), IR: 1658 cm^{-1}; ^1H NMR δ=0.92 (3H, s) and 0.97 (3H, s)

(-C(CH$_3$)$_2$), 1.20 (3H, s, C$_{10}$-CH$_3$), 1.31 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 4.08 (1H, dd, J=7 and 9 Hz) and 4.71 (1H, t, J=9 Hz) (-OCH$_2$-), 6.71 (1H, s, C$_{11}$-H), 7.89 (1H, s, C$_{14}$-H). Found: C, 80.28; H, 8.94%. Calcd for $C_{20}H_{26}O_2$: C, 80.49; H, 8.78%.

According to the method of Burnell et al.,[3] the ketone **6b** (87.2 mg) in acetic anhydride (1.0 ml) was oxidized with peracetic acid prepared from hydrogen peroxide (30%: 0.5 ml), acetic anhydride (1.5 ml), and concentrated sulfuric acid (0.01 ml). The crude product was chromatographed on silica gel (10 g), using hexane-ethyl acetate (7:3 and then 1:1) as eluents, to give **3b** (74.4 mg: 65.2%) which was recrystallized from ethanol, mp 148—150 °C, $[\alpha]_D$ −52.4° (*c* 1.26), IR: 3200, 1726, and 1651 cm^{-1}; ^{1}H NMR δ=0.92 (3H, s) and 0.99 (3H, s) (-C(CH$_3$)$_2$), 1.21 (3H, d, J=7 Hz, C$_{15}$-CH$_3$), 1.29 (3H, s, C$_{10}$-CH$_3$), 2.09 (3H, s, -OCOCH$_3$), 3.76 (1H, dd, J=11 and 4 Hz) and 4.87 (1H, dd, J=11 and 3 Hz) (-CH$_2$OAc), 6.36 (1H, d, J=1.5 Hz, C$_{14}$-H), 6.58 (1H, s, C$_{11}$-H). The physical and spectral data of the synthetic (15*S*)-quinone **3b** were identical with those of the reported major quinone (mp 143—145 °C, $[\alpha]_D$ −50°), whose stereochemistry at the C-15 position was assigned to be R configuration by Burnell et al.[3]

(Received January 22, 1987)

In order to evaluate the influence of polar amino acid residues on peptide conformations, IR absorption spectroscopic analysis of peptide fragments of human hemoglobin α-chain (123-136) and Boc-Leu$_n$-OBzl (n=3—6, 9, and 12) was performed in the solid state. The polar amino acid residues involved in the peptide fragments are in the following: Asp(OBzl), Lys(Z), Ser(Bzl), and Thr(Bzl). Regardless of the amino acid composition, all of the peptides equal to or larger than a pentapeptide level exhibited a high potential for the formation of a β-sheet structure in the solid state. Conformational behaviors of peptides having polar amino acid residues are similar to those of Boc-Leu$_n$-OBzl, indicating that polar side chains can not cause disturbance of the formation of β-sheet structures. The fine relationship among the conformation, solubility, and $\langle P_c \rangle$ value of the peptide fragments strongly supports the propriety of the solubility prediction method for peptide intermediates. The influence of shear stress on peptide conformations in the solid state was also investigated precisely, and it was suggested that a heptapeptide size had the potential for the development of a helical structure in the solid state.

In previous papers,[2-6)] we have demonstrated that the insolubility of peptide intermediates in high-polar solvents is essentially caused by a β-sheet aggregation formed by peptides equal to or larger than an octapeptide sequence level and that their solubility is independent of their amino acid sequences and compositions. The insolubility of peptide intermediates is a serious problem in protein synthesis. The relationship between the conformation and the solubility of peptide having polar amino acid residues has received little attention,[5,6)] since their role in the conformational behavior of the peptides is complicated.

Fig. 1. The amino acid sequence of human hemoglobin α-chain (123-136) and peptides **1**—**16** used in this study.

This is in contrast to the fact that conformational analyses of homo- and sequential peptides have been widely carried out.[7-9]

On the other hand, in a study of the relationship between the conformation and solubility of human proinsulin C-peptide fragments,[5] we have shown that the average coil conformation $\langle P_c \rangle$ value of each peptide fragment was effective for estimating the potential for the formation of a β-sheet structure of peptide fragments below the critical size for the development of an α-helical structure in the solid state. The result also clearly showed that a synthetic route for peptides and proteins could be designed on the basis of the solubility prediction method which we previously proposed.[3] Human proinsulin C-peptide fragments previously investigated include the polar amino acids, Asp (OBzl), Gln, Glu (OBzl), and Ser (Bzl), and their conformational analysis was performed using IR absorption spectra in the solid state and in dichlormethane solution.

In this study, we performed IR absorption spectroscopic analysis of peptide fragments of human hemoglobin α-chain (123-136) in the solid state and investigated the influence of polar amino acid residues on peptide conformdtions. For the IR analysis, we also examined the influence of shear stress on peptide conformation. Human hemoglobin α-chain (123-136) shown in Fig. 1 corresponds to the partial sequence of the helical region H of the α-chain.[10,11] Figure 1 also illustrates the protected peptide fragments **1**—**10** and Boc-Leu$_n$-OBzl ($n=3$—6, 9, and 12) **11**—**16** used in this study.

Experimental

Materials. Samples of human hemoglobin α-chain (123-136) fragments **1**—**10** and Boc-Leu$_n$-OBzl **11**—**16** are those described in previous papers.[2,6] The solid samples of the peptides **1**—**4**, **6**—**8**, and **11**—**14** were obtained by repeated recrystallization from appropriate solvents.[2,6] Those of the peptides **5**, **9**, **10**, **15**, and **16** were obtained by repeated washing with hot methanol. The purity of the peptides was confirmed by elemental and amino acid analyses. The peptides soluble in *N,N*-dimethylformamide also gave a single peak on high-performance liquid chromatography.

IR Measurements. The IR absorption spectra of the solid samples were recorded with a JEOL Model JIR-100 FT-IR spectrometer in a Nujol mull. IR spectra (Figs. 2—4) of the peptides **1**—**16** under a slight shear stress were

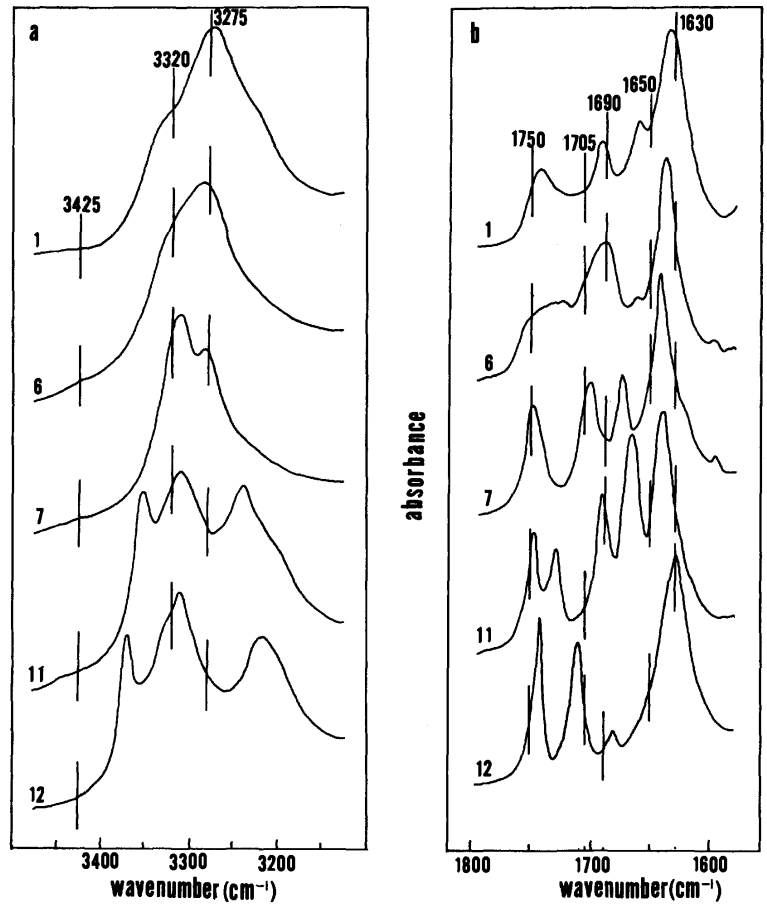

Fig. 2. IR absorption spectra of the tri- and tetrapeptides **1**, **6**, **7**, **11**, and **12** in the solid state. a: The amide A region; b: the amide I region.

obtained after the solid samples were pulverized with Nujol by weak shear stress. IR spectra (Figs. 5—7) of the peptides after application of shear stress were also obtained in a Nujol mull after the solid samples were pulverized without Nujol by strong shear stress.

Results

IR Absorption Spectra of the Tri- and Tetrapeptides 1, 6, 7, 11, and 12 in the Solid State. Figure 2 shows the IR absorption spectra of the peptides **1**, **6**, **7**, **11**, and **12** in the most significant spectral regions for the conformational assignments (3500—3100 cm^{-1}, amide A; 1800—1600 cm^{-1}, amide I). All of the peptides show a few of strong bands at 3371—3215 cm^{-1} and a negligibly small band around 3425 cm^{-1} in the amide A region, suggesting that the Boc- and Z-urethane N-H bonds and peptide N-H bonds are mostly subjected to hydrogen bonding in the solid state. The spectra in the amide A region further indicate that hydrogen bonding patterns of the peptides are different from those of helical and β-sheet structures.[7-9,12,13] However, the spectra of the tetrapeptides **1** and **6** still show the strong bands at 3284—3271 and 1641—1635 cm^{-1}, indicative of a large contribution of β-sheet-like structure.[8,9,13] The assignment of each band in the amide I region is as follows: The bands around 1750 cm^{-1} are assigned to the Pac- and Bzl-ester carbonyl groups, the bands at 1736—1705 cm^{-1} to the Boc- and Z-urethane-carbonyl groups and the bands at 1695—1630 cm^{-1} mainly to hydrogen-bonded amide-carbonyl groups. The Pac ketone carbonyl group is presumed to show the band around 1685 cm^{-1}, overlapped with the amide carbonyl group.[5]

IR Absorption Spectra of the Peptides 2—5, 8—10, and 13—16 Equal to or Larger than a Pentapeptide in the Solid State. Figure 3 shows the IR absorption spectra of the pentapeptides **2** and **13** through the heptapeptides **4** and **8**. Figure 4 also presents those of the octapeptide **5** through the tetradecapeptide **10**. All of the peptides have the strong bands at 3280—3265 cm^{-1} in the amide A region, at 1635—1625 cm^{-1} in the amide I region and the weak band at 1699—1689 cm^{-1} in the amide I region, being indicative of typical antiparallel β-sheet structures, although most of them are accompanied by weak shoulder bands around 1650 cm^{-1}, assigned to other conformations. The shoulder bands around 3320

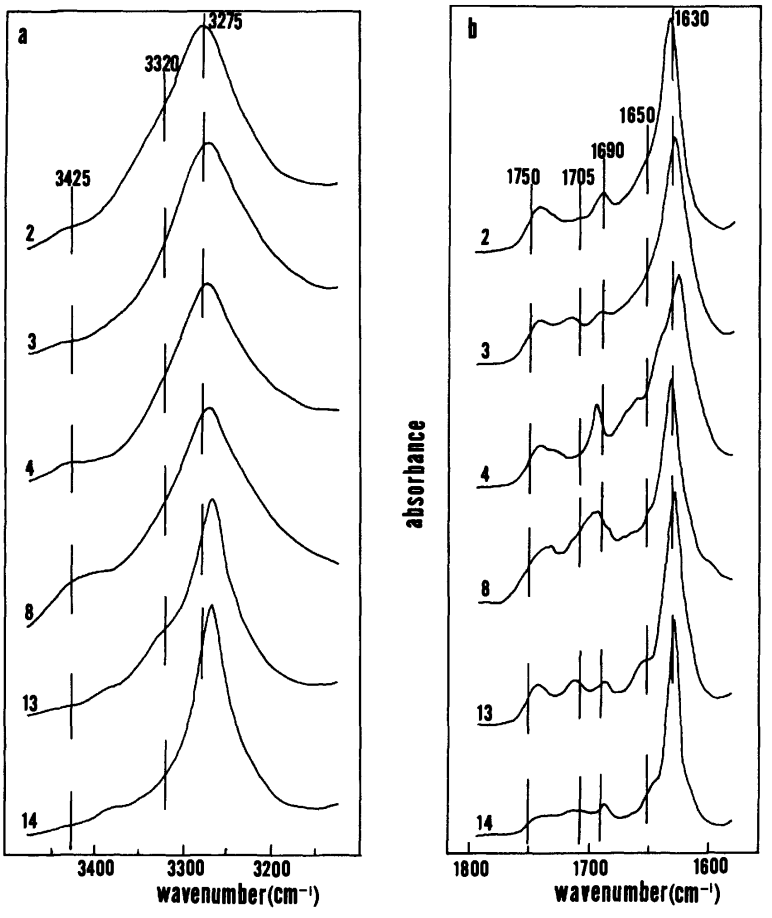

Fig. 3. IR absorption spectra of the pentapeptides **2** and **13** through the heptapeptides **4** and **8** in the solid state. a: The amide A region; b: the amide I region.

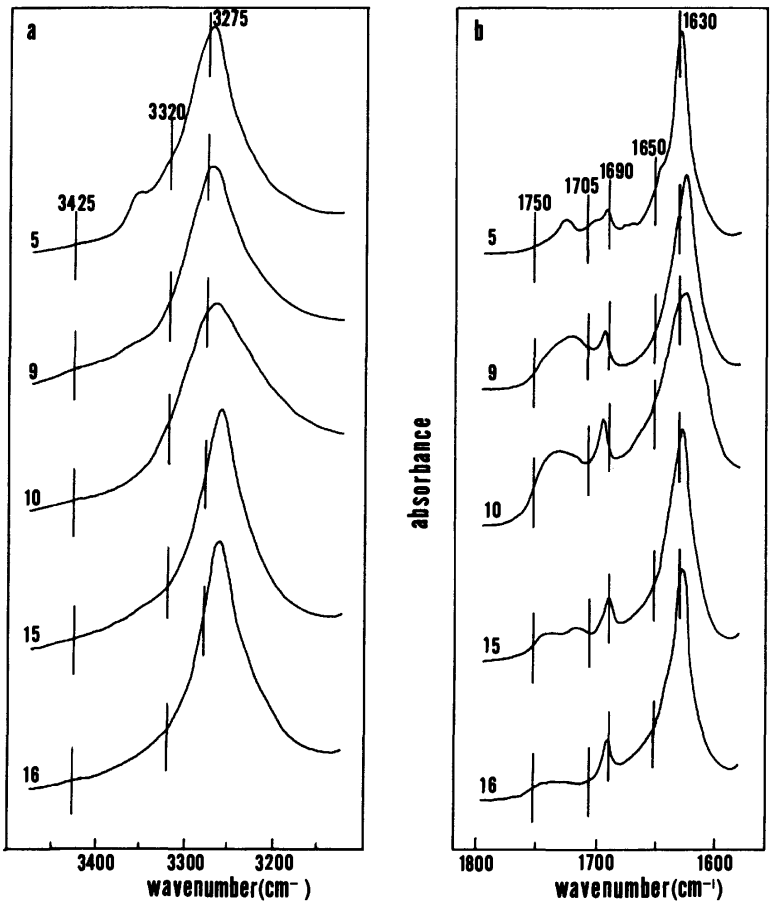

Fig. 4. IR absorption spectra of the octapeptide **5** through the tetradecapeptides **10** in the solid state. a: The amide A region; b: the amide I region.

cm^{-1} of peptides also indicate a small contribution of other conformations. The intensity of both shoulder bands increases with increasing shear stress when solid samples are pulverized with Nujol.

The Influence of Shear Stress on Peptide Conformations in the Solid State. It has been reported that β-sheet→α-helix conformational change occurs in the solid state on application of shear stress at the decapeptide level.[14] Figure 5 shows the IR absorption spectra of the tri- and tetrapeptides **1**, **6**, **7**, **11**, and **12** after application of strong shear stress and illustrates the influence of shear stress on peptide conformations in the solid state although it is difficult to estimate their specific conformational changes. For the peptides **1**—**16**, the influence of shear stress on their conformation is observed to a small or large extent. Conformational changes of the penta- and hexapeptides are relatively small although not negligible (not shown). Figures 6 and 7 exhibit the IR absorption spectra of the hepta- and octapeptides **4** and **5** and the peptides **8**—**10** after application of strong shear stress. The former spectra (Fig. 6) exhibit the influence of shear stress to a small extent, and the conformations of both peptides are essentially antiparallel β-sheet structures. On the other hand, the latter spectra (Fig. 7) are in contrast to the former. Especially, the conformational change of the heptapeptide **8** is quite drastic. The shoulder band at 3320 cm^{-1} in the amide A region and the band at 1657 cm^{-1} in the amide I region strongly suggest a β-sheet → α-helical transformation to a considerable extent. The onset of helical conformation, although to a small extent, is also evident in the undeca- and tetradecapeptides **9** and **10**.

Discussion

As pointed out, application of shear stress for solid peptides brings about a small or large extent of conformational transformation. IR spectra (Figs. 2—4) of the peptides **1**—**16** under a slight influence of shear stress are reproducibly obtained when solid samples are pulverized with Nujol by weak shear stress. Regardless of the amino acid composition, all of the peptides equal to or larger then a pentapeptide exhibit a high potential for the formation of β-sheet structures in the solid state. The conformational behavior of peptides having polar amino acid residues is essential-

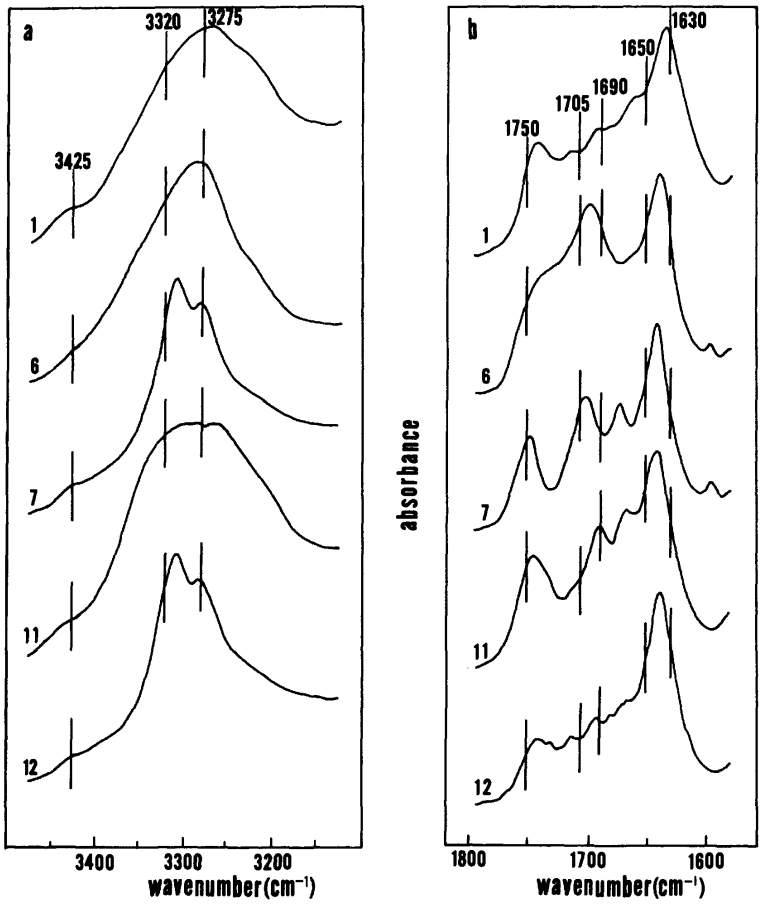

Fig. 5. IR absorption spectra of the tri- and tetra-peptides **1**, **6**, **7**, **11**, and **12** in the solid state after application of strong shear stress. a: The amide A region; b: the amide I region.

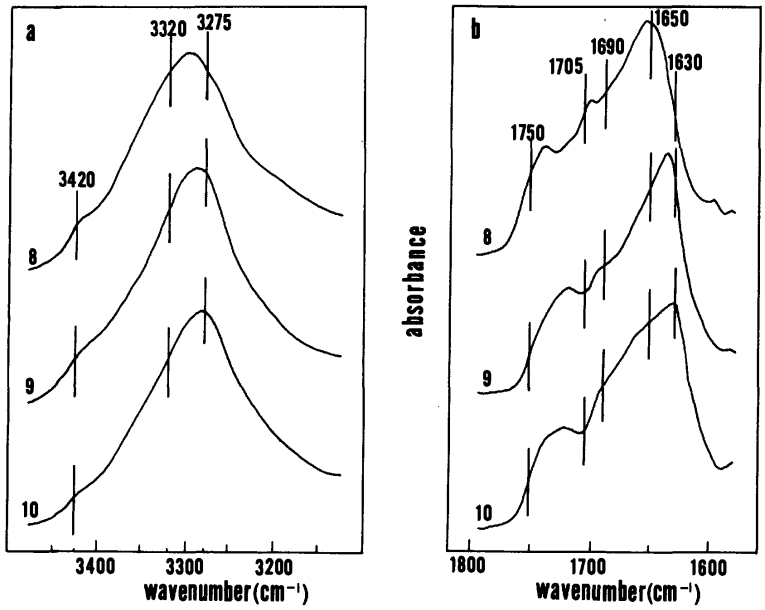

Fig. 7. IR absorption spectra of the peptides **8**—**10** in the solid state after application of strong shear stress. a: The amide A region; b: the amide I region.

ly similar to those of Boc-Leu$_n$-OBzl, indicating that polar side chains can not disturb the formation of β-sheet structures. Furthermore, as in the case of hydrophobic peptides and human proinsulin C-peptide fragments,[2-5] the peptides **5**, **9**, **10**, **15**, and **16** equal to or larger than an octapeptide are notably less soluble in high polar solvents.[2,6] These results strongly support our previous findings that the insolubility of peptide intermediates in highly polar solvents is principally caused by β-sheet aggregation formed by peptides equal to or larger than an octapeptide sequence level and that their insolubility is independent of their amino acid sequences and composition. However, apparently, this conclusion is not applicable to peptide intermediates including a Pro residue.[2,3,15]

In the Table 1, the average conformation $\langle P_c \rangle$, $\langle P_\alpha \rangle$, and $\langle P_\beta \rangle$ values of each peptide are summarized. The values of $\langle P_c \rangle$, $\langle P_\alpha \rangle$, and $\langle P_\beta \rangle$ were determined according to the literature.[3,16] The average coil conformation $\langle P_c \rangle$ values of the peptides **1**—**16** are below 0.9, suggseting that these peptides are highly structured. In fact, the peptides **2**—**5**, **8**—**10**, and **13**—**16** exhibit a high potential for the formation of β-sheet structures. This indicates that, even when the polar side chains of the Asp, Lys, Ser, and Thr residues are protected by suitable groups, the coil conformational parameters, P_c, obtained for intact amino acid residues[3] are useful for estimating the potential for the formation of a β-sheet structure of peptides smaller than critical size[14] for the development of an α-helical structure in the solid state. This result is also in good accord with our previous findings.[5] The fine relationship among the conformation, solubility,

Table 1. The Average Conformation $\langle P_c \rangle$, $\langle P_\alpha \rangle$, and $\langle P_\beta \rangle$ Values of Each Peptide

Compound	$\langle P_c \rangle$	$\langle P_\alpha \rangle$	$\langle P_\beta \rangle$
1	0.92	1.02	1.20
2	0.86	1.05	1.29
3	0.94	1.00	1.19
4	0.90	1.07	1.16
5	0.88	1.10	1.17
6	0.89	1.13	1.01
7	0.90	1.19	0.97
8	0.90	1.16	0.99
9	0.90	1.09	1.11
10	0.90	1.11	1.08
11—16	0.68	1.34	1.22

and $\langle P_c \rangle$ value of the peptide fragments **1**—**10** of human hemoglobin α-chain (123-136) also strongly supports the correctness of our solubility prediction method for peptide intermediates.[3]

IR spectra (Figs. 5—7) of peptides after application of shear stress are also reproducibly obtained when solid samples are pulverized without Nujol by strong shear stress. The effect of shaer stress on the conformational behavior of the peptides **4**, **5**, and **8**—**10** may directly reflect their potential for the formation of an α-helical structure, and the tendency of the β-sheet $\rightarrow\alpha$-helix transformation is clearly estimated using the average helix conformation $\langle P_\alpha \rangle$ values of each peptide. In fact, the heptapeptide **8** has the high $\langle P_\alpha \rangle$ value, 1.16, and the most significant transformation is observed. The minimum size for the development of

an α-helical structure in the solid state has hitherto been recognized to be not less than the decapeptide level,[14] but this result suggests that a helical structure can be held at a heptapeptide size level in the solid state as well as in dichloromethane solution.[17] On the other hand, the average $\langle P_\alpha \rangle$ and $\langle P_\beta \rangle$ values of the heptapeptide **4** are 1.07 and 1.16, and those of the octapeptide **5** are 1.10 and 1.17, respectively. This suggests that the peptides **4** and **5** have a high potential for the formation of a β-sheet structure. In fact, no tendency for the β-sheet→α-helix transformation is observed in the solid state as well as in dichloromethane solution.[17] Therefore, the partial β-sheet→α-helix transformanion of the peptides **9** and **10** probably takes place at their N-terminal portions, while their C-terminal portions remain β-sheet structures.

Synthesis of Some Five- and Six-Membered Oxasteroids of Cholestane Series by Ring Contraction and the Mass Spectrometric Fragmentations of Oxasteroids[1)]

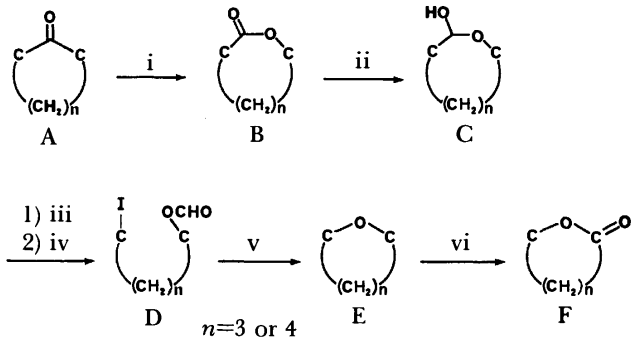
Hiroshi SUGINOME* and Shinji YAMADA
Organic Synthesis Division, Department of Chemical Process Engineering,
Faculty of Engineering, Hokkaido University, Sapporo 060
(Received January 30, 1987)

Synthesis of several new five- and six-membered oxasteroids of the cholestane series by the ring contraction of those oxasteroids whose oxygen-containing ring is larger by one member has been achieved. Ring contraction utilizes a series of reactions recently developed by us for the transformation of cyclic ketones into cyclic ethers; it involves a regioselective β-scission of the alkoxyl radical generated by irradiation of the lactol hypoiodite derived from the starting oxasteroid to give the iodoformate followed by its cyclization. The present work demonstrates the versatility of our new method for the synthesis of cyclic ethers and extends the scope of its application. The mass spectral fragmentation of some oxasteroids synthesized in the present and previous work is discussed.

We have recently reported a new, efficient and versatile method for transforming steroidal cyclic alcohols and ketones into cyclic ethers with the same ring size.[2-5)] The essential steps of the transformation of cyclic ketones into cyclic ethers are outlined as a sequence **A** to **E** in Scheme 1. The transformation involves four steps: a), the Baeyer-Villiger oxidation of cyclic ketones (**A**) to give the corresponding lactones (**B**); b), the reduction of these lactones with DIBAL (diisobutylaluminium hydride) to the corresponding lactols (**C**); c), a regioselective β-scission of the C-C bond of the corresponding hypoiodites generated in situ with mercury(II) oxide, iodine and pyridine, by irradiation to give an iodoformate (**D**); and d), the cyclization of the iodoformate to cyclic ether (**E**) with sodium borohydride or methyllithium.

By this method, a variety of steroidal ketones,[2,3)] camphor,[4)] and adamantanone[5)] have been transformed into the corresponding oxasteroids and cyclic ethers.

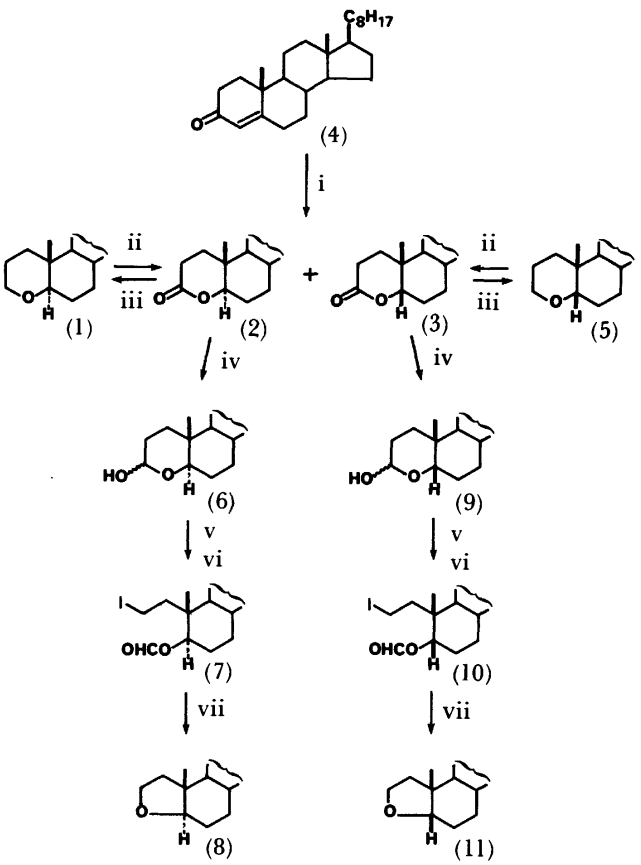
As will be apparent from Scheme 1, the oxasteroid (**E**) can be further transformed into oxasteroids with oxygen-containing rings smaller by one member if oxasteroid (**E**) can be oxidized to the corresponding lactone (**F**).



Scheme 1. Reagents: i, MCPBA: ii, DIBAL-toluene: iii, HgO-I_2-pyridine-benzene: iv, *hν*: v, MeLi-THF or $NaBH_4$-THF: vi, RuO_2-$NaIO_4$-CCl_4 or CrO_3-CH_3CO_2H-H_2O.

We therefore used this ring contraction sequence to undertake the synthesis of several more new five- and six-membered oxasteroids of the cholestane series in order to broaden the applicability of our method to include the synthesis of this group of chiral molecules of biological interest.

We chose three six-membered oxasteroids, 4-oxa-5α-cholestane (**1**),[3,6-9)] 4-oxa-5β-cholestane (**5**)[7)] and 4,4-



Scheme 2. Reagents: i, $K_2S_2O_8$-H_2SO_4-CH_3COOH: ii, RuO_2-$NaIO_4$-CCl_4: iii, $LiAlH_4$-BF_3-diethyl ether: iv, DIBAL-toluene: v, HgO-I_2-pyridine-benzene: vi, *hν*: vii, MeLi-THF.

dimethyl-3-oxa-5α-cholestane (**12**)[2] and a seven-membered oxasteroid, 6-oxa-*B*-homo-5β-cholestane (**17**).[12]

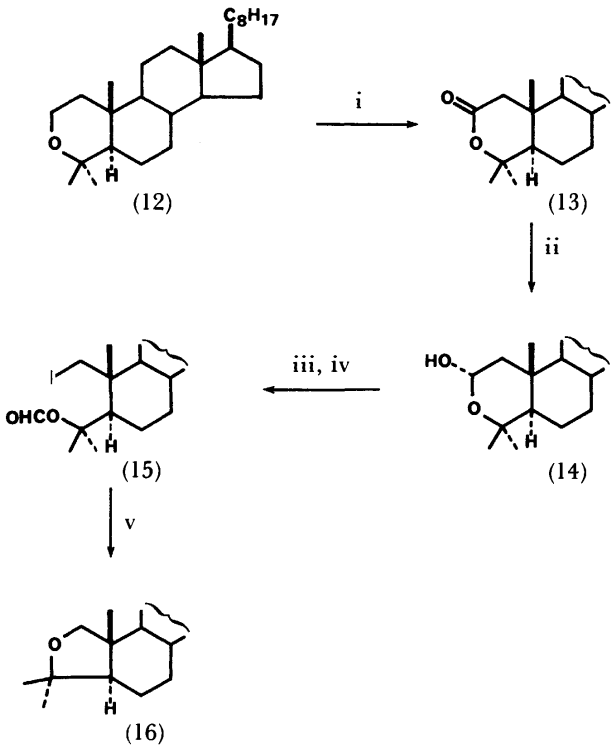
Oxidation of 4-oxa-5α-cholestane (**1**) with ruthenium tetraoxide[10] in THF gave 4-oxa-5α-cholestan-3-one (**2**)[7,9,11] in a good yield. Lactone **2** can be directly prepared by means of oxidation with peroxodisulfuric acid of cholest-4-en-3-one (**4**), as Pettit and Kasturi report.[9] Reduction of lactone **2** with DIBAL at $-78°C$ gave a mixture of the corresponding α- and β-lactols **6**.[9] Irradiation of the hypoiodites of the lactol mixture generated in situ with mercury(II) oxide-iodine and pyridine in benzene with a Pyrex-filtered light readily gave an iodoformate **7**. Its cyclization to *A*-nor-3-oxa-5α-cholestane (**8**) was achieved with methyllithium at $-78°C$ in an almost quantitative yield.

The isomeric 4-oxa-5β-chloestane (**5**), prepared after Edward and Morand,[7] was similarly oxidized to give 4-oxa-5β-cholestan-3-one (**3**)[7,11] with ruthenium tetraoxide (84%). Lactone **3** was then successively transformed into the lactols **9** (81%) and iodoformate **10** (59%). The cyclization of **10** with $NaBH_4$ gave *A*-nor-3-oxa-5β-cholestane (**11**). In the course of our study of the oxidation of cholest-4-en-3-one (**4**) with peroxodisulfuric acid after Pettit and Kasturi,[9] we found that lactone **3** can be obtained as a by-product (8% yield) along with the isomeric 5α-lactone **2**[7,9,11] (32% yield) reported by them. Although the yield is low, the formation of lactone **3** by one step from a readily available cholest-4-en-3-one may be useful in bringing about a quicker synthesis of lactone **3**.

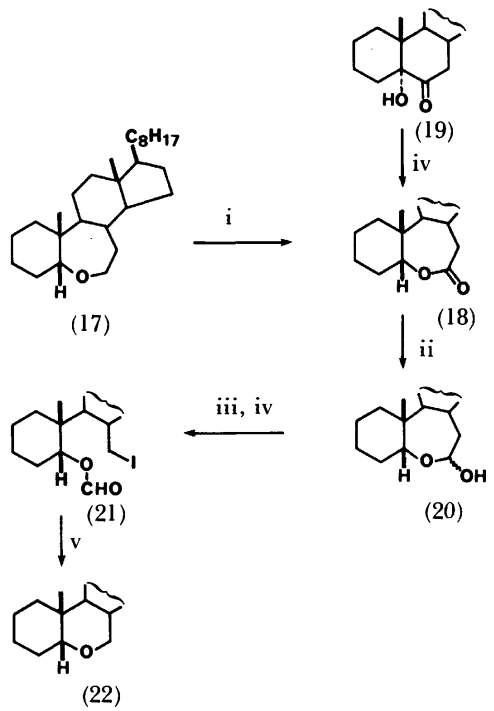
We were also able to transform 4,4-dimethyl-3-oxa-5α-cholestane (**12**)[2] into 3,3-dimethyl-*A*-nor-2-oxa-5α-cholestane (**16**) through a lactone **13**, an α-lactol **14**, and an iodoformate **15** in a good overall yield (Scheme 3).

We then turned our attention to the preparation of six-membered oxasteroids. Oxidation of *B*-homo-6-oxa-5β-cholestane (**17**)[12] with ruthenium tetraoxide in THF gave *B*-homo-6-oxa-5β-cholestan-6-one (**18**) in an 88% yield. This new lactone was also prepared by stereospecific photo-rearrangement of 5-hydroxy-5α-cholestan-6-one (**19**)[13] according to the method reported by Cookson et al.[14] Reduction of lactone (**18**) with DIBAL gave a mixture of *B*-homo-6-oxa-5β-cholestan-7α- and 7β-ols **20** in a 90% yield. Preparation of the corresponding hypoiodites with mercury(II) oxide, iodine and pyridine in benzene followed by the irradiation of the solution gave an iodoformate **21** in a 45% yield. Its cyclization with methyllithium gave a new oxasteroid, 6-oxa-5β-cholestane (**22**) in an 87% yield (Scheme 4).

The present results broaden the applicability of our method for the transformation of cyclic ketones into cyclic ethers and will extend its scope for application to synthetic problems. It should also be noted that since we have recently shown that the iodoformates in the sequence outlined in Scheme 1 can be transformed into thia- and azasteroids,[15] the present results imply



Scheme 3. Reagents i, CrO_3CO_2H-H_2O: ii, DINBAL-toluene: iii, HgO-I_2-pyridine-benzene: iv, *hν*: v, MeLi-THF.



Scheme 4. Reagents: i, RuO_2-$NaIO_4$-CCl_4: ii, DIBAL-toluene: iii, HgO-I_2-pyridine-benzene: iv, *hν*: v, MeLi-THF.

that the transformation of 6- or 7-membered oxasteroids into 5- or 6-membered cyclic sulfides as well as amines is now achievable.

The Mass Spectrometric Fragmentations of the Oxasteroids. The synthesis of a number of oxasteroids, steroidal lactones, and steroidal lactols reported in previous papers[2,3] as well as in the present ones has provided us with a good opportunity to examine the pattern of their mass spectral fragmentations.

In the following part, the structures and the probable genesis of the major fragment ions in the mass spectra of steroidal lactones, lactols, and cyclic ethers described in this and the previous papers,[2,3] are briefly discussed.

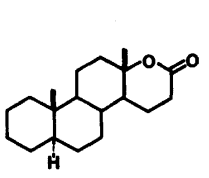
a) **Steroidal Lactones.** The mass spectral fragmentation of certain steroidal lactones has already been reported.[16] Our studies have revealed that the lactone-directed fragmentation and the general fragmentation of a complex hydrocarbon framework take place competitively after the electron impact of steroidal lactones.

We examined the mass spectra of four lactones **2**, **3**, **13**, and **18**, prepared in the present work, as well as the mass spectra of four lactones, 17*a*-oxa-*D*-homo-5*α*-androstan-17-one (**23**), 3*α*,5-cyclo-6-oxa-*B*-homo-5*α*-cholestan-7-one (**24**), 7*a*-oxa-*B*-homo-5*α*-cholestan-7-one (**25**), and 6-oxa-*B*-homo-5*α*-cholestan-7-one (**26**) reported in our previous paper.[3] We found that the mass spectra of these 8 lactones can be divided into two categories according to their mode of fragmentation. Thus, the mass spectra of lactones **2** and **3** are grouped in a category that exhibits a fragmentation pattern similar to that of the corresponding steroidal hydrocarbons. One of the distinct features of the mass spectra of the C-17 substituted steroidal hydrocarbons is the expulsion of the ring-D; this is of diagnostic importance. The genesis of this expulsion that involves both single and reciprocal electron transfers has been established by Djerassi and his colleagues.[16,17] The intensities of the molecular ions and fragment ions that arise from the ring-D cleavage of lactones **2** and **3** are listed in Table 1. Although no appreciable ions arising from the fragmentation of the oxygen-containing A-rings are present in the mass spectra of lactones **2** and **3**, the comparison of the mass spectra of the two isomeric lactones shows an interesting difference in the intensities of the fragment ions that arise from their ring-D cleavage. Thus, while the intensity of the fragment ions corresponding to the elimination of the ring-D involving both a single electron transfer and a reciprocal electron transfer were 100 and 70%, the intensity of the fragment ions corresponding to the elimination of the ring-D of the mass spectrum of the isomer was only 14 and 11%. It is thus apparent that the geometry of the remote ring can exert an appreciable effect on the elimination of the ring-D of these isomeric steroids during the electron impact.

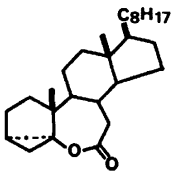
Table 1. Intensities of the Molecular Ions and the Fragment Ions Corresponding to the Elimination of the Ring-D of Isomeric Lactones **2** and **3**

Lactone	M^+ ion/%	M^+-155 ion/%	M^+-154 ion/%
 (2)	72	100	70
 (3)	100	14	11

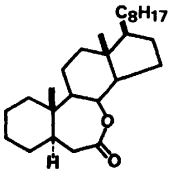
This seems to be a clear example of "conformational transmission"[18] in the mass spectrometric fragmentation. The mass spectra of the six other lactones revealed lactone-directed fragmentation. Thus, lactone **13** exhibited the fragment ion of m/z 316 that arose from the elimination of the ring-A as the base peak while the parent ion was very weak (2%). Accurate mass measurement indicated that the elemental composition of the ion at m/z 316 is $C_{23}H_{40}^+$ (316.31407). The probable structure of the ion



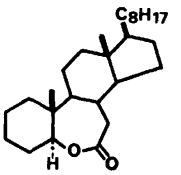
(23)



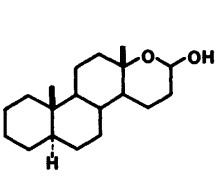
(24)



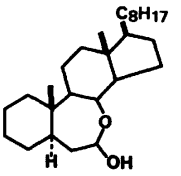
(25)



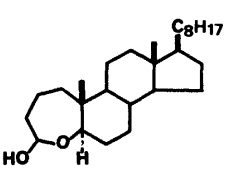
(26)



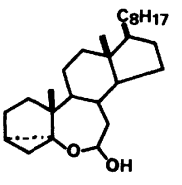
(27)



(28)



(29)



(30)

together with its genesis is outlined in Scheme 5.

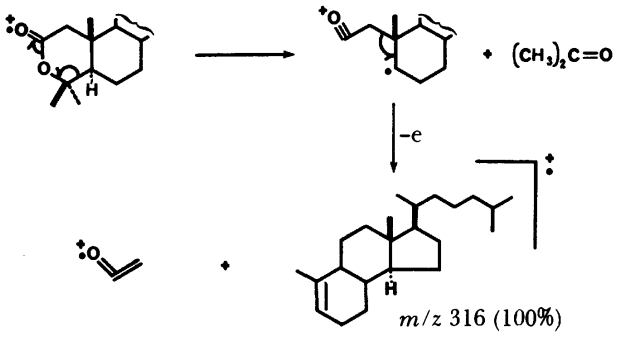
The mass spectrum of lactone **23**[3] exhibited a fragment ion at m/z 218 as the base peak and an oxonium ion at m/z 275 (32%) arising from the expulsion of 13β-Me from the molecular ion (Scheme 6). The intensity of the oxonium ion at m/z 275 was only 32% and this low intensity contrasts with the ion that arises from the expulsion of 13α-Me in the mass spectrum of a 17-oxasteroid,[19] which has been reported to be very prominent. Accurate mass measurement showed that the elemental composition of the base peak is $C_{16}H_{26}^+$ (218.20296). A probable structure of the ion at m/z 218 and its genesis involving the elimination of the ring-D is outlined in Schceme 7.

The mass spectra of isomeric seven-membered lactones **18** and **26** exhibited almost identical patterns of fragmentation, with a fragment ion at m/z 318 as their base peak. Accurate mass measurement of the ion that arises from lactone **18** indicated that the elemental composition of the ion is $C_{22}H_{38}O^+$ (318.29253). Scheme 8 illustrates a probable structure of the ion and its genesis.

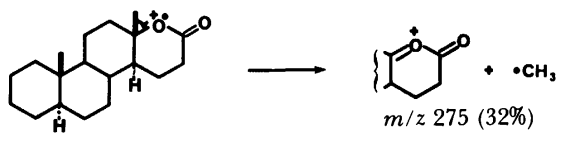
Although lactone **24** is structurally analogous to lactones **18** and **26**, its mass spectral fragmentation, nevertheless differed considerably from those of lactones **18** and **26**. It showed an ion at m/z 95 as the base peak and the intense ion at m/z 400 ($M^+ - CO$, 54.9%). A probable genesis of the ion at m/z 95, which was proved to have the elemental composition $C_7H_{11}^+$ by accurate mass measurement, is outlined in Scheme 9. An ion at m/z 95 was again the base peak in the mass spectrum of lactones **25**. A probable structure and the genesis of the ion is outlined in Scheme 10.

b) **Steroidal Lactols.** We examined the mass spectra of seven steroidal lactols, 17a-oxa-*D*-homo-5α-androstan-17α- and 17β-ols (**27**), 7a-oxa-*B*-homo-5α-cholestan-7α- and 7β-ols (**28**), 4a-oxa-*A*-homo-5α-cholestan-4α- and 4β-ols (**29**), 3α,5-cyclo-6-oxa-*B*-homo-5α-cholestan-7α- and 7β-ols (**30**), 4-oxa- 5α- and 5β-cholestan-3α- and 3β-ols (**6**) and (**9**), and 4,4-dimethyl-3-oxa-5α-cholestan-2α-ol (**14**). Most of these lactols showed that the decomposition of their oxygen-containing ring is predominant over the decomposition of their hydrocarbon framework. Thus, the mass spectrum of lactol **27** exhibited the base peak at m/z 218; this is equivalent to the ion from the corresponding lactone **23** (Scheme 7), which is attributable to the ion arising from the expulsion of the ring-D.

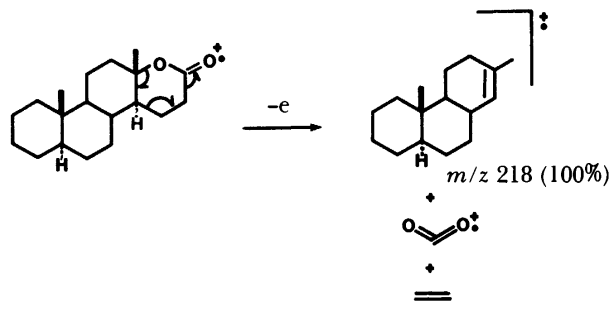
The mass spectrum of steroidal lactol **28** exhibited the base peak at m/z 95. Accurate mass measurement indicated that its elemental composition was $C_7H_{11}^+$ (95.0858). The ion probably arises from the breakdown of the oxygen-containing ring as outlined in



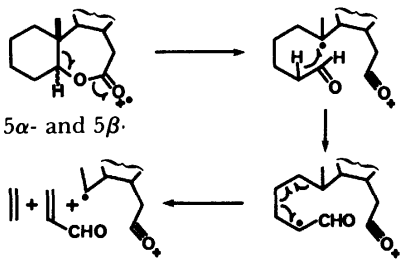
Scheme 5.



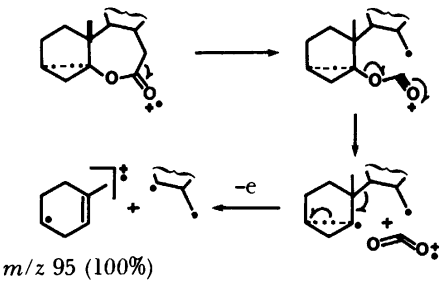
Scheme 6.



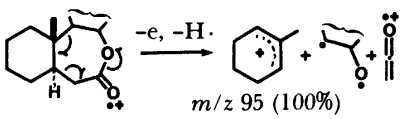
Scheme 7.



Scheme 8.



Scheme 9.

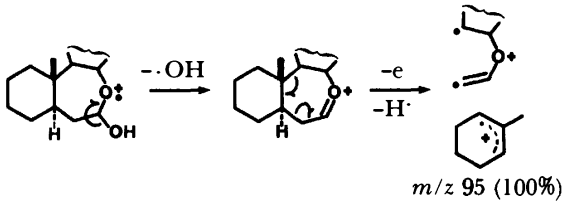


Scheme 10.

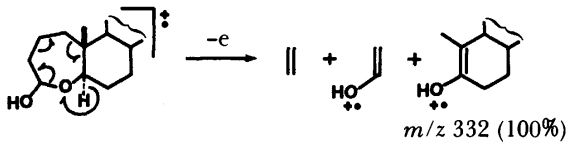
Scheme 11.

The base peak in the mass spectrum of steroidal lactol **29** appeared at m/z 332. Accurate mass measurement indicated that the elemental composition was $C_{23}H_{40}O^+$ (332.3092). The outline formation of this ion is rationalized in Scheme 12. It can be formed by the loss of the ring-A with a transfer of the angular hydrogen to the ethereal oxygen.

The mass spectrum of lactol **30** exhibited the base peak at m/z 111. Accurate mass measurement indicated that the elemental composition was $C_7H_{11}O^+$ (m/z 111.0826). The genesis of this ion, which involved a breakdown of its oxygen-containing ring, is outlined in Scheme 13.



Scheme 11.



Scheme 12.

Table 2. Intensities of the Molecular Ion and the Fragment Ions Corresponding to the Elimination of the Ring-D of Some Oxasteroids of Cholestane Series

Substrate	M+ ion/%	M+−155 ion/%	M+−154 ion/%
 (8)	75	100	74
 (11)	100	13	16
 (31)	79	100	76
 (1)	54	100	48
 (32)	37	100	28
 (22)	36	100	20
 (33)	7	100	6

The mass spectra of isomeric lactols **6** and **9** both exhibited their base peaks at m/z 372, owing to a loss of water.

Finally, the mass spectrum of 4,4-dimethyl-3-oxa-5α-cholestan-2-ol (**14**) exhibited the base peak at m/z 385; this is assignable to the loss of the element of water and the 4-methyl group.

c) **Steroidal Ethers.** We examined the mass spectra of 12 steroidal cyclic ethers prepared in our present and the previous work. As in the case of the steroidal lactones the mass spectra of these cyclic ethers can be divided into two categories according to their type of the fragmentation.

The mass spectra of seven steroidal cyclic ethers listed in Table 2 are grouped in the first category which shows fragmentation similar to that of the steroidal hydrocarbons. The mass spectra of these oxasteroids with an oxygen atom in their ring-A or B showed, with only one exception, normal fragmentation arising from the elimination of their ring-D. The mass spectrum of *A*-nor-3-oxa-5β-cholestane (**11**) showed the molecular ion as the base peak while the intensity of the fragment ions that corresponded to the elimination of the ring-D with a single electron transfer and a reciprocal electron transfer were only 13 and 16%. The 5α-isomer **8**, on the other hand, gave the mass 205 ion as the base peak and the ion at m/z 206 was very intense (74%). This is another example of what has been called the "conformational transmission" in the mass spectrometric fragmentation which we have already found in the mass spectra of the isomeric pair of lactones **2** and **3**. The geometry of the remote ring exerts a notable effect on the elimination of the ring-D of these oxasteroids during the electron impact.

The mass spectra of the five further oxasteroids listed in Table 3 exhibited fragmentation directed by their oxygen-containing ring. The mass spectrum of 16-oxa-5α-androstane (**34**) exhibited its base peak at m/z 231. The probable genesis, which is based on an

analogy with the loss of formaldehyde from tetrahydrofuran, [20] is outlined in Scheme 14.

The mass spectrum of 3,3-dimethyl-2-oxa-*A*-nor-5α-cholestane (**16**) exhibited the base peak at *m/z* 330 and an intense fragment ion at *m/z* 373 (85%). The base peak arises as the result of a similar loss of the element of acetone while the latter is generated by the expulsion of the 3-methyl-group as outlined in Scheme 15.

The mass spectra of 17-oxa-5α-androstane (**35**) and its 13-epimer (**36**) exhibited their base peak at *m/z* 247; this arises from the expulsion of 13α- and 13β-methyl group, as expected (Scheme 16).

The mass spectrum of 3α,5-cyclo-6-oxa-5α-cholestane (**37**) exhibited the molecular ion as the base peak and an intense fragment ion at *m/z* 111 (89%). Accurate mass measurement indicated that the molecular composition of the latter was $C_7H_{11}O^+$ (*m/z* 111.0828). Its formation is rationalized as outlined in Scheme 17.

Experimental

Mps were recorded with a Yanagimoto micro mp apparatus. IR spectra were determined for Nujol mulls with a Hitachi Model 285 infrared spectrophotometer. ^{1}H NMR spectra were determined with a JEOL PS 200 high-resolution FT-NMR spectrometer (200 MHz) (Solvent, $CDCl_3$: $SiMe_4$ as an internal standard) (Faculty of Pharmaceutical Sciences of this University). TLC was carried out on a Merck Kiesel gel 60 PF_{254}. All the high and low resolution mass spectra were recorded with a JEOL JMS-D 300 spectrometer (70 eV) (Faculty of Agriculture). Elemental analysis was performed by the staff of the Laboratory for Microanalysis of the Faculty of Pharmaceutical Sciences of this University.

4-Oxa-5α-cholestan-3-one (2). An aqueous $NaIO_4$ solution (300 mg $NaIO_4$ in water 1 ml) was added dropwise to carbon tetrachloride (4 ml) containing $RuO_2 \cdot X\,H_2O$ (15 mg) while stirring at about 0°C. 4-Oxa-5α-cholestane (**1**)[3,6-9] (65 mg) in carbon tetrachloride (4 ml) was added dropwise at room temperature to the solution containing RuO_2. The solution was stirred for 4 h and a further amount of aq $NaIO_4$ solution (100 mg $NaIO_4$ in water 0.3 ml) was added. The solution was stirred 20 h. After the addition of isopropyl alcohol to the solution, RuO_2 was removed by filtration. The solution was washed with water and dried over anhydrous Na_2SO_4. The work-up as usual gave crystals (60 mg) which were subjected to preparative TLC with

a 5 : 1 mixture of benzene and diethyl ether. Two fractions were obtained. The more mobile TLC fraction (13 mg) was the starting material. The less mobile fraction (35 mg, 65% based on the converted material) was lactone **2** which was recrystallized from pet. ether. Mp 111—118°C (lit,[7] mp 114—115°C; lit,[9] mp 118—119°C; lit,[11] mp 116—116.5°C). ^{1}H NMR (90 MHz) δ=0.67 (3H, s, 18-H), 0.93 (3H, s, 19-H), 3.95 (1H, dd, J=11.20 and 4.61 Hz, 5α-H), and 2.55—2.68 (2H, m, 2-H), MS m/z (rel intensities) 388 (M^+, 72%), 233 (100), 81 (48), 55 (60), and 43 (97).

4-Oxa-5α-cholestan-3-ols (6).[9] A solution of DIBAL (1.8 ml) was added dropwise to a solution of the lactone **2** (570 mg) in dry toluene (40 ml) at −78°C. The solution was stirred for 3 h at −78°C and poured into iced water. After the solution had been filtered, the filtrate was extracted with dichloromethane. The organic layer was washed with water and dried over anhydrous Na_2SO_4. The usual work-up gave a product (540 mg) which was recrystallized from acetone-dichloromethane to yield a 1 : 1 mixture of α- and β-lactols **6**, mp 185—187°C (lit,[9] β-lactol, 197—199°C). ^{1}H NMR δ=0.65 (3H, s, 18-H of α- and β-ols), 0.91 and 0.94 (each s, 19-H of α- and β-ols), 3.01 (dd, J=11.23 and 4.40 Hz, 5α-H of 3β-ol), 3.71 (J=10.74 and 5.37 Hz, 5α-H of 3α-ol), 4.73 (m, 3α-H of 3β-ol), and 5.25 (m, 3β-H of 3α-ol), MS, m/z (rel intensity) 390 (M^+, 0.5%), 372 [$(M-H_2O)^+$, 100], and 83 (83).

Irradiation of the Hypoiodite of 4-Oxa-5α-cholestan-3-ols in the Presence of Mercury(II) Oxide and Iodine. Lactols **6** (300 mg) were added to dry benzene (39 ml) containing pyridine (0.5 ml), mercury(II) oxide (332 mg), and iodine (391 mg). The solution in a Pyrex vessel was irradiated for 2 h in an atmosphere of nitrogen. The solution was filtered and the filtrate was worked up as usual to give an oily product (419 mg) which was subjected to preparative TLC with benzene. Three fractions were obtained. The most mobile TLC fraction (200 mg) was crystalline formate **7**. The next fraction (17 mg) was an intractable mixture. The least mobile fraction (120 mg) was lactone **2**. The formate **7** was recrystallized from methanol-acetone. Mp 99 — 100°C. (Found: C, 60.42; H, 8.76 %. Calcd for $C_{26}H_{45}IO_2$: C, 60.46; H, 8.78%). IR 1718 (CHO), 1210 and 1183 cm^{-1} (OCHO), ^{1}H NMR δ=0.65 (3H, s, 18-H), 0.92 (3H, s, 19-H), 2.95—3.19 (2H, m, 2-H), 4.86 (1H, dd, J = 11.23 and 4.89 Hz, 5α-H), 8.10 (1H, s, OCHO); MS m/z (rel intensity) 516 (M^+, 0.4%), 470 [$(M-OCH_2O)^+$, 8.2], 389 [$(M-I)^+$, 31], 343 (53), 315 (39), 287 (62), and 55 (100).

3-Oxa-A-nor-5α-cholestane (8). A solution of formate **7** (140 mg) in THF (30 ml) was cooled to −78°C by Dry Ice-methanol. Methyllithium (1.05 M† diethyl ether solution) (0.7 ml) was added to this stirred solution. The solution was stirred for 30 min at that temperature and then stirred for further 1 h at room temperature and then extracted with diethyl ether. The ethereal solution was worked up as usual. A crystalline product (98 mg) was recrystallized from methanol-acetone to yield a pure specimen (89 mg), mp 77—78°C. (Found: C, 83.11; H, 12.42%. Calcd for $C_{25}H_{44}O$: C, 83.27; H, 12.30%). IR 1124, 1010, and 975 cm^{-1}; ^{1}H NMR δ=0.67 (3H, s, 18-H), 0.81 (3H, s, 19-H), 3.04 (1H, dd, J=12.21 and 3.91 Hz, 5α-H), 3.85—3.93 (2H, m, 2-H); MS m/z (rel intensity) 360 (M^+, 75%), 345 [$(M-Me)^+$, 35], and 205 (100).

Oxidation of Cholest-4-en-3-one with Peroxodisulfuric Acid. Potassium peroxodisulfate (3 g) and concd sulfuric acid (3.3 g) were dissolved in glacial acetic acid (50 ml). The mixture was added to a solution of cholest-4-en-3-one (3 g) in glacial acetic acid (50 ml). The solution was stirred for two weeks at room temperature in the absence of light. The mixture was treated with aqueous 50% potassium hydroxide (14 ml). Precipitated salts were removed by filtration and the filtrates evaporated. The residue was extracted with diethyl ether. The ether solution was washed with water and dried over anhydrous Na_2SO_4. The solution was worked up as usual. The product (2.5 g) was subjected to column chromatography (Merck Kiesel gel 60; 70—230 mesh, 40 g). Elutions with benzene gave a major fraction (1.38 g) which was a crystalline mixture of lactones. Recrystallization with pet. ether gave 4-oxa-5α-cholestan-3-one (620 mg). The filtrate of the recrystallization was evaporated to yield a mixture of 5α- and 5β-lactones. An attempted separation of the mixture to its two components by preparative TLC with a variety of solvents was unsuccessful. The mixture was therefore subjected to fractional crystallization with methanol-pet. ether 6 times to give almost pure 5β-lactone **3**, (40 mg). This lactone was subjected to DIBAL reduction. A pure lactone melted at 106 — 107°C (pet. ether) (lit,[11] 109.5 — 110°C, lit,[7] 107 — 107.5°C). ^{1}H NMR δ=0.68 (3H, s, 18-H), 0.99 (3H, s, 19-H), 2.39—2.56 (2H, m, 2-H), and 4.14 (1H, dd, J=3.3 and 2.4 Hz), MS m/z (rel intensity) 388 (M^+, 100%), 315 (6), 233 (14), and 55 (19).

Reduction of 4-Oxa-5β-cholestan-3-one. Lactone **3** (38 mg) was dissolved in dry toluene (5 ml) and the solution was cooled to −78°C by Dry Ice-methanol. A DIBAL solution (0.13 ml) was added to this solution and the solution was stirred for 2 h at −78°C. The solution was poured into water and the inorganic precipitates were removed by filtration. The solution was washed with water and dried. The usual work-up gave 4-oxa-5β-cholestan-3-ols (40 mg) which were purified by preparative TLC with a 5 : 1 benzene-diethyl ether to yield an oily mixture of 4-oxa-5β-cholestan-3α- and 3β-ols. (Found: m/z 390.3533. Calcd for $C_{26}H_{46}O_2$: M, 390.3498). IR (neat) 3365 (OH) and 1015 cm^{-1}; ^{1}H NMR δ=0.65 (3H, s, 18-H of 3α- and 3β-ols), 0.88 and 0.92 (each 3H, each s, 19-H of 3α- and 3β-ols), 3.30 and 3.84 (each 1H, each, brs, 5β-H of 3α- and 3β-ols), and 4.72 and 5.32 (each 1H, each brs, 3α- and 3β-H of 3α- and 3β-ols); MS m/z (rel intensity) 390 (M^+, 7%), 372 [$(M-H_2O)^+$, 100], and 315 (14).

Irradiation of the Hypoiodite of 4-Oxa-5β-cholestan-3-ols in the Presence of Mercury(II) Oxide and Iodine. Lactols **9** (68 mg) were added to a dry benzene (9 ml) containing pyridine (0.1 ml), mercury(II) oxide (75 mg) and iodine (89 mg). The solution in a Pyrex vessel was irradiated for 2 h in an atmosphere of nitrogen. The solution was filtered and the filtrate was worked up as usual to give a crystalline product (98 mg) which was subjected to preparative TLC with benzene. Of the two fractions, the more mobile TLC fraction was a crystalline formate **10** (53 mg). After recrystallization from acetone-methanol, the formate melted at 112 — 117°C. (Found: m/z 516.2490. Calcd for $C_{26}H_{45}IO_2$: M, 516.2465). IR (Nujol) 1728 (CHO) and

† 1M=1 mol dm^{-3}.

1190 cm^{-1} (OCHO); ^1H NMR δ= 0.66 (3H, s, 18-H), 0.95 (3H, s, 19-H), 3.00—3.15 (2H, m, $-CH_2I$), 4.88 (1H, br. s, 5 β-H) and 8.11 (1H, s, CHO); MS *m/z* (rel intensity) 516 (M^+, 0.7%), 470 [$(M-OCH_2O)^+$, 14], 389 [$(M-I)^+$, 48], and 343 [$(M-OCH_2O-I)^+$, 100].

3-Oxa-*A*-nor-5β-cholestane (11). A solution of formate **10** (51 mg) in THF (10 ml) was cooled to −78°C. To this stirred solution, there was added methyllithium (1.05 M diethyl ether solution) (0.24 ml). The solution was stirred for 30 min and then the temperature of the solution was raised to room temperature. The solution was stirred for 1 h at room temperature and extracted with diethyl ether. The usual work-up of the solution gave a crude crystalline oxasteroid **11**. This was then recrystallized from methanol-acetone. Mp 91.5—92.5°C. (Found: C, 83.09; H, 12.31%. Calcd for $C_{25}H_{44}O$: C, 83.27; H, 12.30%). IR (Nujol) 1039 and 1017 cm^{-1} (C-O); ^1H NMR δ= 0.67 (3H, s, 18-H), 0.93 (3H, s, 19-H), 3.43 (1H, dd, J= 2.9 and 2.4 Hz, 5β-H), and 3.75—3.94 (2H, m, 2-H), MS *m/z* (rel intensity) 360 (M^+, 100%), 345 [$(M-Me)^+$, 3], 315 (6), 206 (16), and 43 (34).

4,4-Dimethyl-3-oxa-5α-cholestan-2-one (13). A solution of aqueous acetic acid (0.5 ml of water plus 5 ml of acetic acid) containing chromium trioxide (200 mg) was added dropwise to an acetic acid solution (10 ml) of 4,4-dimethyl-3-oxa-5α-cholestane (103 mg) at room temperature. The solution was stirred overnight and then heated at 40°C for 2 h. The solution was extracted with dichloromethane and the organic layer was neutralized with aqueous sodium hydrogencarbonate. The usual work-up of the solution gave an oily product which was subjected to preparative TLC to give a crystalline lactone **13** (35 mg). This was recrystallized from acetone-methanol to yield a pure material, mp 171—173°C. (Found: C, 80.62; H, 11.60%. Calcd for $C_{28}H_{48}O_2$: C, 80.71; H, 11.61%). IR 1720 (C=O), 1114, 1100, 989, and 950 cm^{-1}; ^1H NMR δ= 0.65 (3H, s, 18-H), 1.00 (3H, s, 19-H), 1.34 and 1.40 (each 3H, each s, *gem* dimethyl), and 1.92 and 2.65 (each 1H, each d, J= 16.8 Hz, 1-H), MS *m/z* (rel intensity) 416 (M^+, 2%), 401 [$(M-Me)^+$, 1.5], 358 (1.5), and 316 [(M−ring-A)$^+$, 100].

4,4-Dimethyl-3-oxa-5α-cholestan-2α-ol (14). A solution of DIBAL (0.1 ml) was added dropwise to a solution of lactone **13** (31 mg) in dry toluene (5 ml) at −78°C. The solution was stirred for 3 h and poured into iced water. After the solution was filtered, the solution was washed with water and dried over anhydrous Na_2SO_4. The work-up by the usual method gave a product (32 mg) which was recrystallized from acetone to yield 2α-lactol **14**. Mp 166—170°C. (Found: C, 80.07; H, 12.05%. Calcd for $C_{28}H_{50}O_2$: C, 80.32; H, 12.04%). IR 3375 (OH), 1130, and 1048 cm^{-1} (C-O); ^1H NMR δ= 0.63 (3H, s, 18-H), 1.01 (3H, s, 19-H,), 1.18 and 1.24 (each 3H, each s, *gem* dimethyl), 2.75 (1H, d, J= 7.3 Hz, OH), and 5.06 (1H, ddd, J= 9.0, 7.3, and 2.0 Hz, 2β-H); MS *m/z* (rel intensity) 400 [$(M-H_2O)^+$, 9%], 385 [$(M-H_2O-Me)^+$, 100], 316 (51), 95 (35), and 43 (94).

Irradiation of the Hypoiodite of 4,4-Dimethyl-3-oxa-5α-cholestan-2α-ol (14). The lactol (14 mg) was added to a dry benzene (3 ml) containing pyridine (0.05 ml), mercury(II) oxide (15 mg) and iodine (17 mg). The solution in a Pyrex vessel was irradiated for 2 h in an atmosphere of nitrogen. The solution was filtered and the filtrate was worked up as usual to give oily formate (20 mg). The product was subjected to preparative TLC with benzene. Of the two fractions, the more mobile TLC fraction was an oily formate **15** (11 mg). (Found: *m/z* 417.3760. Calcd for $C_{28}H_{49}IO_2-I$: M, 417.3732). IR (neat) 1720 (CHO), 1180 and 1143 cm^{-1} (OCHO); ^1H NMR δ= 0.63 (3H, s, 18-H), 1.13 (3H, s, 19-H), 1.56 and 1.63 (each 3H, each s, *gem* dimethyl), 3.35 and 3.94 (each 1H, each d, J= 10.25 Hz, CH_2I), and 8.12 (1H, s, CHO); MS *m/z* (rel intensity) 417 [$(M-I)^+$, 0.8%], 371 [$(M-I-OCH_2O)^+$, 81], 301 (18), and 95 (100).

3,3-Dimethyl-*A*-nor-2-oxa-5α-cholestane (16). A solution of formate **15** (10 mg) in THF (3 ml) was cooled to −78°C. To this stirred solution, there was added methyllithium (0.57 M diethyl ether solution) (0.08 ml). The solution was stirred for 1 h at that temperature and thereafter stirred for further 1 h at room temperature and extracted with diethyl ether. The usual work-up of the solution gave an almost pure crystalline oxasteroid **16** (7 mg). It was recrystallized from methanol. Mp 106—107°C. (Found: C, 83.21; H, 12.38%. Calcd for $C_{27}H_{48}O_2$: C, 83.43; H, 12.45%). IR 1019 and 1014 cm^{-1} (C-O); ^1H NMR δ= 0.66 (3H, s, 18-H), 1.01 (3H, s, 19-H), 1.13 and 1.19 (each 3H, each s, *gem* dimethyl), 3.27 and 3.58 (each 1H, each d, J= 7.33 Hz, 1H), MS *m/z* (rel intensity) 388 (M^+, 0.4%), 373 [$(M-Me)^+$, 85], 330 [$(M-(CH_3)_2CO)^+$, 100], 288 (39), 217 (38), 175 (34), 95 (38), and 43 (42).

***B*-Homo-6-oxa-5β-cholestan-7-one (18).** Aqueous $NaIO_4$ solution (200 mg $NaIO_4$ in water 1 ml) was added dropwise to carbon tetrachloride (3 ml) containing $RuO_2 \cdot X\,H_2O$ (20 mg) while stirring at about 0°C . The *B*-homo-6-oxacholestane (**17**) (23 mg) in carbon tetrachloride (3 ml) was added dropwise to the solution containing ruthenium tetraoxide at 0°C. The solution was stirred for 5 h at room temperature. After the addition of isopropyl alcohol to the solution, RuO_2 was removed by filtration. The solution was washed with water and dried over anhydrous Na_2SO_4. The usual work-up gave crystals (25 mg) which were recrystallized from methanol to yield a specimen for analysis, mp 119—121°C. (Found: C, 80.50; H, 11.61%. Calcd for $C_{27}H_{46}O_2$: C, 80.55; H, 11.51%). IR 1735 (C=O), 1310, 1253, 1144, 1106, and 1024 cm^{-1}; ^1H NMR δ= 0.65 (3H, s, 18-H), 0.95 (3H, s, 19-H), 2.44 (1H, br.d, J= 14.7 Hz, 7a-H), 2.97 (1H, m, 7a-H), and 4.17 (1H, br.s, 5β-H). MS *m/z* (rel intensity) 402 (M^+, 2%) and 318 (100).

Preparation of *B*-Homo-6-oxa-5β-cholestan-7-one (18) by the Photo-Rearrangement. 5-Hydroxy-5α-cholestan-6-one[10] (240 mg) in ethanol (50 ml) in a Pyrex vessel was irradiated with a 450-W high pressure Hg arc (Eikosha-PIH 450) in an atmosphere of nitrogen for 50 h. The solvent was removed under reduced pressure and the residue was recrystallized from methanol to yield *B*-homo-6-oxa-5β-cholestan-7-one (174 mg). This lactone was identical with the lactone obtained by the oxidation of *B*-homo-6-oxa-5β-cholestane with ruthenium tetraoxide.

***B*-Homo-6-oxa-5β-cholestan-7α- and 7β-ols (20).** A solution of DIBAL (0.25 ml) was added dropwise to a solution of lactone **18** (90 mg) in dry toluene (10 ml) at −78°C. The solution was stirred for 5 h at −78°C and poured into iced water. After the solution was filtered, the filtrate was washed with water and dried over anhydrous Na_2SO_4. The usual work-up gave an oily product. This was purified once by preparative TLC with a 10 : 1 benzene-diethyl ether to

yield a mixture of 7α- and 7β-ols **20**. (Found: m/z 404.3663. Calcd for $C_{27}H_{48}O_2$: M, 404.3655). IR 3260 (OH) and 1018 cm^{-1} (C-O); ^{1}H NMR δ= 0.65 and 0.66 (each 3H, each s, 18-H of 7α- and 7β-ols), 2.61 and 2.75 (each 1H, each d, J= 3.9 Hz, OH of 7α- and 7β-ols), 3.41 and 3.93 (each 1H, each t, J=6.6 and 4.2 Hz, 5β-H of 7α- and 7β-ols), 5.07 and 5.33 (each 1H, m, 7-H of 7α- and 7β-H); MS m/z (rel intensity) 404 (M^+, 2%), 386 [$(M-H_2O)^+$, 43], 249 (35), 140 (36), 112 (82), and 43 (100).

Irradiation of the Hypoiodite of *B*-Homo-6-oxa-5β-cholestan-7-ols in ths Presence of Mercury(II) Oxide and Iodine. Lactols **20** (24 mg) were dissolved in dry benzene (3 ml) containing pyridine (0.1 ml), mercury (II) oxide (26 mg) and iodine (31 mg). The solution in a Pyrex vessel was irradiated for 2 h in an atmosphere of nitrogen. After the removal of inorganic precipitates, the filtrate was worked up as usual to give an oily product (35 mg). This was subjected to preparative TLC with benzene to give two fractions. The less mobile fraction (10 mg) was lactone **18**. (Found: m/z 530.2614. Calcd for $C_{27}H_{47}IO_2$: M, 530.2619). IR (neat) 1714 (CHO) and 1177 cm^{-1} (OCHO); ^{1}H NMR δ=0.69 (3H, s, 18-H), 1.02 (3H, s, 19-H), 3.33 (1H, dd, J= 10.74 and 2.92 Hz, CH_2I), 3.51 (1H, dd, J= 10.74 and 1.95 Hz, CH_2I), 4.87 (1H, br.s, 5β-H), and 8.23 (1H, s, CHO); MS m/z (rel intensity) 530 (M^+, 0.2%), 403 (M^+-I, 0.7), 357 [$(M-I-OCH_2O)^+$, 48], 261 (18), 149 (36), 95 (96), and 83 (100).

6-Oxa-5β-cholestane (22). A solution of formate **21** (9 mg) in THF (3 ml) was cooled at −78°C. Methyllithium (0.57 M diethyl ether solution 0.08 ml) was added to this stirred solution. The solution was stirred for 2 h and the temperature of the solution was then raised to room temperature. The solution was then stirred for 1 h at room temperature and extracted with diethyl ether. The ethereal solution was worked up as usual to yield an oily product. This was purified by preparative TLC with benzene to yield a pure material (5.5 mg) (Found: m/z 374.3564. Calcd for $C_{26}H_{46}O$: M, 374.3549). IR 1102 and 1086 cm^{-1} (C-O); ^{1}H NMR δ= 0.67 (3H, s, 18-H), 1.07 (3H, s, 18-H), 3.34 (1H, dd, J= 12.2 and 4.40 Hz, 5β-H), 3.36 (1H, dd, J= 11.5 and 11.5 Hz, 7α-H), and 3.53 (1H, dd, J= 11.5 and 5.4 Hz, 7β-H); MS m/z (rel intensity) 374 (M^+, 36%), 219 (100), 201 (19), and 164 (16).

Synthesis of (Diethoxyphosphoryl)acetonitrile Oxide and Its Cycloaddition to Olefins. Synthetic Applications to 3,5-Disubstituted 2-Isoxazolines

Otohiko Tsuge,* Shuji Kanemasa, Hiroyuki Suga, and Norihiko Nakagawa
Institute of Advanced Material Study, and Department of Molecular Science and Technology, Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, Kasugakoen, Kasuga 816
(Received February 5, 1987)

(Diethoxyphosphoryl)acetonitrile oxide undergoes regioselective cycloaddition to olefins leading to 3-[(diethoxyphosphoryl)methyl]-2-isoxazolines or -isoxazole. The phosphorus-stabilized carbanions generated by deprotonation of the cycloadducts can be utilized for the condensation with carbonyl compounds, alkylation, and oxidation with oxygen to provide 3,5-disubstituted 2-isoxazolines as useful synthetic building blocks. Raney nickel hydrogenolysis of 3-[(diethoxyphosphoryl)methyl]-2-isoxazolines gives β-hydroxy-β′-phosphoryl ketones bearing a variety of functional groups, which can be further converted into α,β-unsaturated β′-phosphoryl ketones.

High synthetic versatility of isoxazoles and 2-isoxazolines is based on their potentiality as flexible synthetic equivalents of 1,3-diketones, β-hydroxy ketones, γ-amino alcohols, α,β-unsaturated ketones, and other related functions.[1] One of the most general preparation methods of these heterocycles is regioselective cycloaddition of nitrile oxides.[2] Use of monosubstituted acetylenes or olefins furnishes isoxazoles or 2-isoxazolines bearing a 5-substituent. As nitrile oxides undergo smooth cycloadditions to electron-poor to -rich dipolarophiles,[3] a wide variety of substituents may be introduced at the 5-position by the regioselective cycloaddition route. Accordingly it is soon realized that these cycloadducts will become synthetically versatile building blocks which involve masked complex functionalities.[4]

From this point of view, a functionalized nitrile oxide must be important because the cycloaddition reaction of this 1,3-dipole produces isoxazoles or 2-isoxazolines with this newly added functionality which can be then utilized to introduce these heterocycles as talent synthetic blocks into other molecules.[5] We recently started our project on the synthetic applications of a phosphorus-functionalized nitrile oxide, (diethoxyphosphoryl)acetonitrile oxide (**1**).

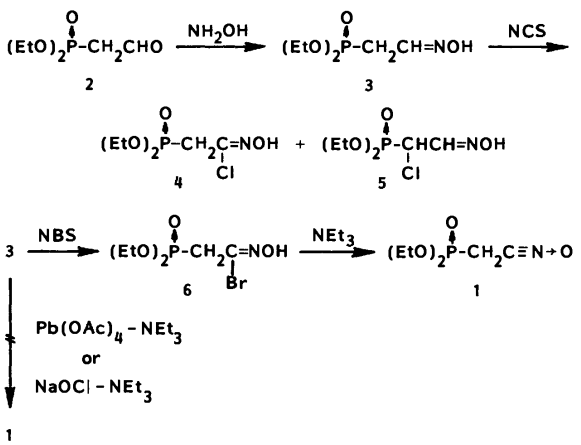
The present report describes the first preparation of **1** and some examples of its synthetic applications: Regioselective cycloaddition of **1** to monosubstituted olefins leading to 2-isoxazolines or isoxazole; reactions of the phosphorus-stabilized carbanions with electrophiles; reductive cleavage of the heterocycles on Raney Ni.[6]

Results and Discussion

Among several preparation methods of nitrile oxides,[7] the halogenation and dehydrohalogenation sequence of aldoximes as well as the direct oxidation method was applied to *N*-[2-(diethoxyphosphoryl)-ethylidene]hydroxylamine (**3**) because **3** is available in large quantities from bromoacetaldehyde diethyl acetal and triethyl phosphite. Thus, known (diethoxyphosphoryl)acetaldehyde (**2**)[8] was prepared by Arbuzov reaction of the acetal and further converted into oxime **3** in 95% yield (a 3 : 4 mixture of syn and anti forms).

The direct oxidative conversion of aldoxime **3** into nitrile oxide **1** was unsuccessful: Both the reaction of **3** with lead tetraacetate/triethylamine[7c] and the treatment of **3** with sodium hypochlorite/triethylamine,[7b] both in dichloromethane solution, failed in the generation of nitrile oxide **1**. Complex mixture of many products was only formed.

The chlorination and dehydrochlorination method[7d] was next applied. When **3** was treated with *N*-chlorosuccinimide (NCS) in DMF, chlorination took place not only at the oxime carbon but also at the adjacent methylene carbon to give a mixture of *N*-[1-chloro-2-(diethoxyphosphoryl)ethylidene]hydroxylamine (**4**) and its isomer **5** (Scheme 1). Both combined yield (**4** + **5**) and isomer ratio were found to depend upon the reaction temperature as shown in Table 1. Although the desired chloro oxime **4** could be separated from **5** through column chromatography over silica gel, the maximum yield of isolated **4** was only less than 50% even under the optimum conditions



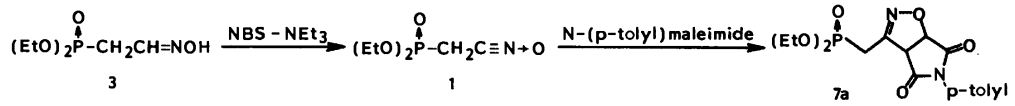
Scheme 1.

Table 1. Chlorination of Oxime **3** with NCS Leading to **4** and **5**[a]

Run	Reaction condition		Total yield/%[b]	Isomer ratio (**4**:**5**)[c]
	Addition of NCS	Reaction with NCS		
1	0 °C, 5 min	rt, 5 h	60	1:1
2	0 °C, 5 min	0 °C, 1 h	71	10:3
3	−15 °C, 5 min	−15 °C, 30 min	34	17:7
4	0 °C, 40 min	0 °C, 2 h	71	16:3

a) Carried out in DMF with 1 equiv amount of NCS. b) Yield of the isolated mixture of **4** and **5** based on **3**. c) Determined by ^{1}H NMR spectrum of the mixture of **4** and **5**.

Table 2. Generation of Nitrile Oxide **1** and Its Trapping with *N*-(*p*-Tolyl)maleimide[a]



3 1 7a

Run	Reaction with NBS		NEt_3 (equiv)[c]	Cycloaddition[b] time/h	Yield of **7a**/%[d]
	NBS (equiv)	Condition[e]			
1	1	0 °C, 30 min	1	15	54
2	1	−20 °C, 5 min then 0 °C, 30 min	1	12	63
3	1	−20 °C, 1 h then 0 °C, 30 min	1	12	67
4	2	−20 °C, 5 min then 0 °C, 30 min	1	21	71
5	2	0 °C, 30 min	2	21	41
6	2	−20 °C, 1 h then 0 °C, 30 min	1	18	80

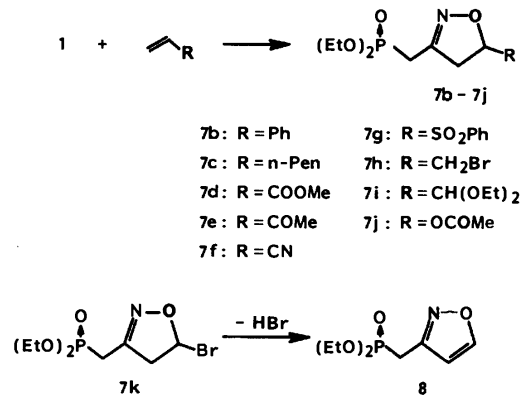
a) Carried out in DMF. b) Reaction temperature; room temperature. c) After the reaction with NBS was over, a mixture of *N*-(*p*-tolyl)maleimide and triethylamine was added. d) Yield of isolated **7a** based on **3**. e) NBS in DMF was added to **3** in a period of 5 min.

(Run 4, total yield: 71%; **4** : **5** = 16 : 3) to let us discard this chlorination route.

An alternative is bromination of oxime **3**. Thus, **3** was treated with *N*-bromosuccinimide (NBS) in DMF according to the Steven's method.[7d] As bromo oxime **6** was not isolable, **6** was in situ dehydrobrominated with triethylamine. The nitrile oxide **1** generated was trapped by *N*-(*p*-tolyl)maleimide as cycloadduct **7a** (Table 2). It should be noted that all procedures for the bromination of **3**, the dehydrobromination of **6**, and the cycloaddition trapping could be conveniently carried out in one flask.

When oxime **3** was treated with two equivalents of NBS at −20 °C in a period of 5 min and then one equivalent of triethylamine at room temperature (run 6 of Table 2), the desired nitrile oxide **1** was generated in an excellent yield and successfully captured by *N*-(*p*-tolyl)maleimide to give **7a** in 80% yield.

Cycloadditions of nitrile oxide **1** with a variety of olefins were next investigated. Under similar conditions, **1** underwent smooth cycloadditions to such a wide variety of olefins as electron-poor olefins (*N*-(*p*-tolyl)maleimide, methyl acrylate, 3-buten-2-one, acrylonitrile, phenyl vinyl sulfone), an electron-rich olefin



Scheme 2.

(vinyl acetate), and nonactivated olefins (styrene, 1-heptene, 3-bromopropene, 3,3-diethoxypropene) all in regioselective manners to give 5-substituted 3-[(diethoxyphosphoryl)methyl]-2-isoxazolines **7a—j** (Scheme 2 and Table 3). Better yields of **7** were generally obtained if more than 1 equivalent amount of dipolarophiles was employed. Accordingly some of low-boiling or volatile olefins were used as much as 5 equivalents. The reaction of **1** with bromoethene pro-

Table 3. Cycloaddition of Nitrile Oxide **1** to Olefins[a)]

Olefin (equiv)	Time/h[b)]	Product	Yield/%[c)]
N-(*p*-Tolyl)maleimide (1)	18	**7a**	80
Styrene (5)	18	**7b**	81

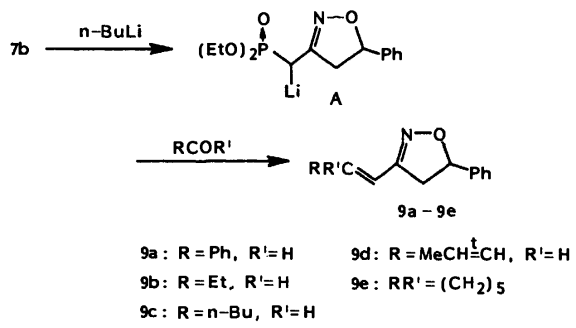
Vinyl acetate (5)	18	**7j**	73

a) Carried out in DMF. b) Bromo oxime **6** was first generated by treatment of oxime **3** with NBS (2 equiv) at −20 °C for 1 h and then 0 °C for 30 min. A mixture of olefin and triethylamine (1 equiv) was added. The mixture was stirred at room temperature for the reaction time listed in this table. c) Yield of isolated cycloadduct **7** based on **3**.

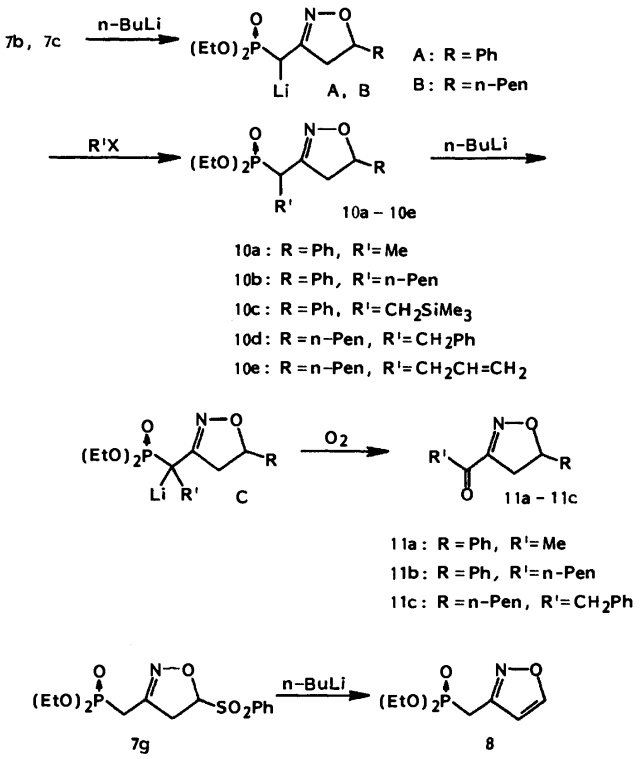
duced 3-[(diethoxyphosphoryl)methy]isoxazole (**8**) in 47% yield by the elimination of hydrogen bromide of the initial cycloadduct, 5-bromo-3-[(diethoxyphosphoryl)methyl]-2-isoxazoline (**7k**).

Regioselective deprotonation of 3-alkyl-2-isoxazolines is quite difficult. Thus, it is known that 3-methyl-5-phenyl-2-isoxazoline can be deprotonated, at a low temperature, with LDA both at the 3-methyl group (exo) and the 4-position (endo).[9] At an elevated temperature the endo carbanion causes a ring opening via a β-elimination leading to α,β-unsaturated ketone. The regioselectivity depends upon the substituents[10] as well as the polarity of reaction solvent.[11] Although a few successful cases of the trapping of exo carbanions have been recently reported,[12] the exclusive utilization of exo carbanion is still difficult. The phosphorus-functionalized 2-isoxazolines **7** are expected to generate stable phosphoryl-stabilized carbanions.

The 2-isoxazoline **7b** as a representative was first treated with butyllithium at −78 °C in THF. The resulting yellow carbanion **A** is so highly stabilized that it can servive even at room temperature. It was



Scheme 3.



Scheme 4.

then treated with carbonyl compounds at room temperature to succeed in reacting with aromatic, aliphatic, α,β-unsaturated aldehydes, and a ketone to give 3-(1-alkenyl)-2-isoxazolines **9a**—**e** (Scheme 3 and Table 4). The Horner-Emmons olefination products **9** were mostly E-isomers as expected. The carbanions derived from 2-isoxazolines **7d** and **7e** which carry a carbonyl group failed in reacting with aldehydes.[13]

Under similar conditions, the above carbanion **A** as well as **B** which was derived from 5-alkyl-2-isoxazoline **7c** by deprotonation reacted with alkyl halides to give 3-(1-phosphorylalkyl)-2-isoxazolines **10a**—**e** in good yields (Scheme 4 and Table 4). Alkyl iodides (methyl, pentyl, and trimethylsilylmethyl iodides) were sufficiently reactive toward **A** or **B**. Although activated bromides such as benzyl and 2-propenyl bromides are exceptions, less reactive alkyl bromides such as pentyl and 1-methylpropyl bromides were recovered intact.

The 3-(1-phosphorylalkyl)-2-isoxazolines **10** thus prepared could be again deprotonated with butyllithium at the same carbon to generate carbanions **C**. These anions **C** were oxidized with dry oxygen gas at −78 °C to furnish 3-(1-oxoalkyl)-2-isoxazolines **11a**—**c** (Scheme 4 and Table 4). The silylmethyl-substituted 2-isoxazoline **10c** led to desilylated ketone **11a** which was also accessible from **10a**.

When the cycloadduct **7g** obtained from the cycloaddition to phenyl vinyl sulfone was treated with butyllithium, deprotonation took place at the 4-position causing the elimination of benzenesulfinic acid

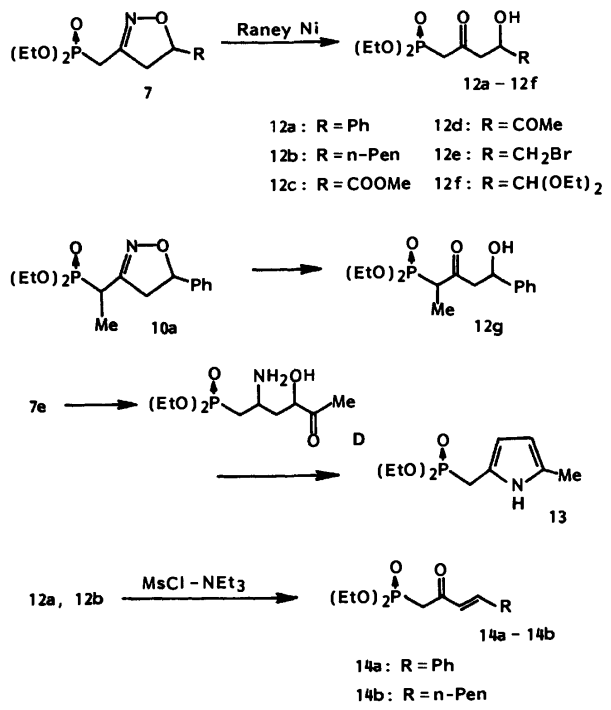
to give 3-phosphorylmethyl-2-isoxazole **8** whose formation was already mentioned above.

The phosphoryl moiety of **7** was found to servive on the reductive N-O bond fission and the subsequent hydrolysis. Thus, 3-phosphorylmethyl-2-isoxazolines **7** bearing a variety of substituents at the 5-position were hydrogenated on Raney-Ni (W-2) in aqueous ethanol in the presence of acetic acid or boric acid to give good yields of β-hydroxy ketones **12a** — **f** bearing phosphoryl and R moieties (Scheme 5). Such functional groups as ester, ketone, halogen, and acetal are also safe under the conditions of hydrogenolysis. Instability of **12d** may arise from its 1,4-dicarbonyl or α-hydroxy ketone structure.[14]

Although the Raney Ni reduction of **7e** in H_3BO_3-H_2O gave β-hydroxy ketone **12d** as described above, a similar reduction in AcOH-H_2O procuced 2-methyl-5-[(diethoxyphosphoryl)methyl]pyrrole (**13**) in a fair yield. The intermediary β-hydroxy imine, initially formed by the N-O bond reduction of 2-isoxazoline **7e**, was presumably overreduced to lead to 4-amino-2-hydroxy ketone intermediate **D** whose intramolecular dehydration gave **13**.

The alkylated derivative **10a** prepared above by methylation of the phosphorus-stabilized carbanion **A** was similarly converted into 1-phosphorylethyl 2-hydroxyalkyl ketone **12g** (Scheme 5).

The phosphorus-functionalized β-hydroxy ketones **12** could be further converted into phosphorus-functionalized α,β-unsaturated ketones **14a** and **14b**



Scheme 5.

in quantitative yields through the initial mesylation with methanesulfonyl chloride and triethylamine and the subsequent chromatography over silica gel (Scheme 5).

Synthetic utilization of the phosphoryl moiety of the compounds newly prepared herein is now under progress. The results will be soon published elsewhere.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 MHz) or a JEOL FX-100 instrument (100 MHz) and ^{13}C NMR on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. High resolution mass spectra were obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck). Visualization was made with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20 × 180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Preparative high performance liquid chromatography (HPLC) was performed on a Kusano KHLC-201 apparatus with a UV-detector Uvilog-III using a column (22 × 300 mm) packed with silica gel (Wakogel LC-50H). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3 × 2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25 × 5000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

***N*-[2-(Diethoxyphosphoryl)ethylidene]hydroxylamine (3).** To a solution of aldehyde **2**[8] (0.5 g, 2.78 mmol) in ethanol (5 ml) was added an aqueous hydroxylamine hydrochloride (0.386 g, 5.56 mmol in 2 ml of water). The mixture was stirred at room temperature for 11.5 h, poured into water (50 ml), and extracted with dichloromethane (25 ml × 2). The combined extracts were dried over magnesiun sulfate and evaporated in vacuo to give **3** (0.513 g, 95%) as a 3 : 4 mixture of syn and anti isomers, which was purified through a column chromatography (silica gel/ethyl acetate): Colorless liquid; IR (neat) 3200, 1600, and 1240 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ = 1.30 (6H, t, J = 7.0 Hz, OEt), 2.77 (3/7 × 1H, dd, J = 6.3 and 21.8 (HP) Hz, CH_2 (syn)), 3.04 (4/7 × 1H, dd, J = 6.0 and 22.0 (HP) Hz, CH_2 (anti)), 4.12 (4H, dq, J = 7.0 and 7.5 (HP) Hz, OEt), 6.75 (4/7 × 1H, dt, J = 6.0 and 5.0 (HP) Hz, CH=N (anti)), 7.35 (3/7 × 1H, dt, J = 6.3 and 5.0 (HP) Hz, CH=N (syn)), and 10.10 (1H, br, OH); ^{13}C NMR ($CDCl_3$) δ = 16.32 (qd, J_{cp} = 7.4 Hz, OEt), 23.56 (td, J_{cp} = 139.7 Hz, OEt (anti)), 28.18 (td, J_{cp} = 141.2 Hz, OEt (syn)), 62.62 (td, J_{cp} = 7.4 Hz, CH_2), 140.74 (dd, J_{cp} = 7.4 Hz, CH=N (anti)), and 142.27(dd, J_{cp} = 10.3 Hz, CH=N (syn)); MS (rel intensity, %) 195 (M^+, 13), 167 (17), 139 (39), 122 (49), 111 (25), 109 (56), 104 (19), 99 (64), 96 (23), 93 (32), 82 (27), 81 (base peak), and 65 (72). HRMS Found: m/z 195.0603. Calcd for $C_6H_{14}NO_4P$: M, 195.0660.

Reaction of Oxime 3 with NCS Leading to 4 and 5. A mixture of **3** (1 mmol) and NCS (1 mmol) in DMF (1 ml) was stirred under the conditions shown in Table 1. The mixture was poured into water (20 ml) and extracted with diethyl ether (20 ml × 2). The combined extracts were washed with water, dried over magnesium sulfate, and evaporated in vacuo. The residue was chromatographed over silica gel. The fraction eluted with hexane-ethyl acetate (1 : 2 v/v) gave *N*-[1-chloro-2-(diethoxyphosphoryl)-ethylidene]hydroxylamine (**4**) and with hexane-ethyl acetate (1 : 5 v/v) *N*-[2-chloro-2-(diethoxyphosphoryl)ethylidene]-hydroxylamine (**5**). Results obtained under several conditions are listed in Table 1. Both **4** and **5** are too labile to be highly purified as analytical samples.

4: Yellow liquid; IR (neat) 3200, 1625, 1220, 1020, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ = 1.31 (6H, t, J = 7.0 Hz, OEt), 3.06 (2H, d, J = 21.0 (HP) Hz, CH_2P), 4.10 (4H, qd, J = 7.0 and 7.5 (HP)Hz, OEt), and 10.66 (1H, br, OH); MS m/z (rel intensity, %) 229 (M^+, 4), 138 (11), 137 (16), 122 (21), 109 (51), 104 (19), 91 (21), 81 (86), 77 (18), 65 (42), and 43 (base peak).

5 (A 7 : 5 mixture of syn- and anti-isomers): Pale yellow liquid; IR (neat) 3200, 1625, 1240, and 1020 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ = 1.34 (6H, t, J = 7.0 Hz, OEt), 4.23 (4H, qd, J = 7.0 and 7.4 (HP) Hz, OEt), 4.61 (7/12 × 1H, dd, J = 8.5 and 13.0 (HP) Hz, CH (syn)), 5.42 (5/12 × 1H, dd, J = 8.0 and

13.0 (HP) Hz, CH (anti)), 6.77 (5/12×1H, dd, J=8.0 and 3.0 (HP) Hz, CH=N (anti)), and 7.38 (7/12×1H, dd, J=8.5 and 4.0 (HP) Hz, CH=N (syn)); ^{13}C NMR ($CDCl_3$) δ= 16.38 (qd, J_{cp}=6.1 Hz, OEt), 40.89 (dd, J_{cp}=159.9 Hz, OEt (anti)), 48.83 (dd, J_{cp} = 163.6 Hz, OEt (syn)), 64.74 (td, J_{cp}=7.3 Hz, CH), 142.26 (dd, J_{cp}=3.7 Hz, CH=N (anti)), and 143.89 (dd, J_{cp}=2.4 Hz, CH=N (syn)); MS m/z(rel intensity, %) 229 (M^+, 8), 130 (10), 127 (14), 109 (61), 99 (33), 91 (27), 81 (56), 73 (14), 65 (69), and 43 (base peak).

General Procedure for the Generation of Nitrile Oxide 1 and Its Cycloaddition to Olefins Leading to 7a—j. To a solution of oxime **3** (0.195 g, 1 mmol) in dry DMF (2 ml) was added NBS (0.356 g, 2 mmol in 2 ml of DMF) at −20 °C. The mixture was stirred at the same temperature for 1 h and then at 0 °C for 30 min. A mixture of triethylamine (0.101 g, 1 mmol) and an olefin (1 to 5 mmol) in dry diethyl ether (2 ml) was added. The mixture was stirred at room temperature, poured into water (20 ml), and extracted with dichloromethane (20 ml × 2) or diethyl ether (20 ml × 2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel to give cycloadduct **7**. The eluents used are as follows: **7a**, **7b**, **7d**, and **7j**: ethyl acetate; **7c**, **7e**, **7f**, **7g**, **7h**, and **7i**: hexane-ethyl acetate (1 : 5 v/v). The yields of **7**, the amounts of olefin used, and the reaction times are summarized in Table 3. The reaction with *N*-(*p*-tolyl)maleimide under various conditions is shown in Table 2.

7a: Colorless prisms (diethyl ether); mp 88—89 °C; IR (KBr) 1720, 1240, and 1020 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ= 1.32 (6H, t, J=7.0 Hz, OEt), 2.34 (3H, s, *p*-Me), 3.00 (1H, d, J = 15.5 (gem) and 22.5 (HP) Hz, one of CH_2P), 4.13 (1H, d, J = 15.5 (gem) and 21.0 (HP) Hz, the other of CH_2P), 4.14 (4H, qd, J=7.0 and 7.3 (HP) Hz, OEt), 4.75 (1H, dd, J=9.5 and 4.0 (HP) Hz, 3a-H), 5.43 (1H, d, J= 9.5 Hz, 6a-H), and 7.0—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=16.35 (qd, J_{cp}=5.9 Hz, OEt), 21.23 (q, *p*-Me), 24.35 (td, J_{cp} = 138.3 Hz, CH_2P), 52.82 (d, 3a-C), 63.18 (td, J_{cp} = 5.9 Hz, OEt), 79.77 (d, 6a-C), 126.24 (d), 128.54 (s), 130.07 (d), 139.48 (s), 148.54 (d, J_{cp} = 8.8 Hz, 3-C), 170.67, and 171.95 (each s, CON); MS m/z(rel intensity, %) 380 (M^+, 3), 353 (18), 352 (90), 246 (base peak), 218 (46), 190 (67), 133 (72), 132 (46), 109 (60), 107 (28), 105 (22), 104 (39), 91 (34), 81 (68), 78 (24), and 77 (26). Found: C, 53.86; H, 5.61; N, 7.46%. Calcd for $C_{17}H_{21}N_2O_6P$: C, 53.67; H, 5.57; N, 7.37%.

7b: Pale yellow liquid; IR (neat) 1620, 1250, 1020, and 825 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.2—1.4 (6H, m, OEt), 2.98 (2H, d, J=21.8 (HP) Hz, CH_2P), 3.07 (1H, ddd, J=17.5 (gem), 8.0, and 4.2 (HP) Hz, one of 4-H), 3.50 (1H, ddd, J= 17.5 (gem), 10.8, and 4.2(HP) Hz, the other of 4-H), 3.9—4.3 (4H, m, OEt), 5.56 (1H, dd, J = 10.8 and 8.0 Hz, 5-H), and 7.28 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=16.38 (qd, J_{cp}=6.1 Hz, OEt), 26.24 (td, J_{cp}=140.4 Hz, CH_2P), 45.26 (t, 4-C). 62.62 (td, J_{cp} = 6.1 Hz, OEt), 82.37 (d, 5-C), 126.02, 128.32, 128.51 (each d), 141.06 (s), and 151.27 (d, J_{cp}=9.8 Hz, 3-C); MS m/z (rel intensity, %) 297 (M^+, 2), 109 (16), 105 (11), 104 (13), 81 (15), 77 (19), and 43 (base peak). HRMS Found: m/z 297.1120. Calcd for $C_{14}H_{20}NO_4P$: M, 297.1128.

7c: Pale yellow liquid; IR (neat) 1630, 1260, 1025, and 825 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ= 0.88 (3H, t, J=7.0 Hz, *n*-Pen), 1.1—1.8 (8H, m, *n*-Pen), 1.33 (6H, t, J=7.0 Hz, OEt), 2.72 (1H, ddd, J=17.0 (gem), 8.2, and 4.2 (HP) Hz, one of 4-H), 2.93 (2H, d, J=21.5 (HP) Hz, CH_2P), 3.14 (1H, ddd, J = 17.0 (gem), 10.0, and 4.2 (HP) Hz, the other of 4-H), 4.12 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), and 4.52 (1H, m, 5-H); ^{13}C NMR ($CDCl_3$) δ= 14.00 (q), 16.41 (qd, J_{cp} = 5.8 Hz, OEt), 22.59, 25.06 (each t), 26.41 (td, J_{cp}=141.2 Hz, CH_2P), 31.71, 35.12 (each t), 42.36 (t, 4-C), 62.59 (td, J_{cp}= 5.8 Hz, OEt), 81.42 (d, 5-C), and 151.48 (d, J_{cp}=8.8 Hz, 3-C); MS m/z(rel intensity, %) 291 (M^+, 8), 220 (base peak), 192 (28), 164 (43), 146 (10), 109 (14), 81 (17), and 44 (29). HRMS Found: m/z 291.1587. Calcd for $C_{13}H_{26}NO_4P$: M, 291.1598.

7d: Pale yellow liquid; IR (neat) 1730, 1620, 1220, 1020, and 825 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, OEt), 2.98 (2H, d, J=21.5 (HP) Hz, CH_2P), 3.39 (2H, dd, J=9.0 and 4.0 (HP) Hz, 4-H), 3.76 (3H, s, COOMe), 4.13 (4H, qd, J= 7.0 and 7.4 (HP) Hz, OEt), and 5.04 (1H, t, J = 9.0 Hz, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.35 (qd, J_{cp}= 5.9Hz, OEt), 25.83 (td, J_{cp} = 141.2 Hz, CH_2P), 41.24 (t, 4-C), 52.77 (q, COOMe), 62.80 (td, J_{cp} = 7.4 Hz, OEt), 77.77 (d, 5-C), 151.48 (d, J_{cp} = 8.8 Hz, 3-C), and 170.77 (s, COOMe); MS m/z(rel intensity, %) 220 (M^+ −COOMe, 52), 192 (28), 164 (92), 146 (44), 109 (49), 91 (16), 83 (20), 82 (19), 81 (80), 65 (40), 59 (base peak), and 54 (89). Found: C, 43.25; H, 6.26; N, 4.74%. Calcd for $C_{10}H_{18}NO_6P$: C, 43.01; H, 6.50; N, 5.02%.

7e: Pale yellow liquid; IR (neat) 1725, 1625, 1250, 1025, and 800 cm^{-1} ^{1}H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, OEt), 2.27 (3H, s, COMe), 2.96 (2H, d, J=21.5 (HP) Hz, CH_2P), 3.1—3.5 (2H, m, 4-H), 4.13 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), and 4.90 (1H, dd, J=10.0 and 8.0 Hz, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.41 (qd, J_{cp}=5.9 Hz, OEt), 25.97 (td, J_{cp}=139.7 Hz, CH_2P), 26.12 (q, COMe), 39.71 (t, 4-C), 62.77 (td, J_{cp}=5.9 Hz, OEt), 84.18 (d, 5-C), 152.07 (d, J_{cp} = 8.8 Hz, 3-C), and 207.37 (s, COMe); MS m/z(rel intensity, %) 220 (M^+ −COMe, 54), 192 (25), 164 (base peak), 152 (18), 146 (30), 125 (15), and 42 (43). Satisfactory elemental analysis was not obtained because of its hygroscopic property.

7f: Pale yellow liquid; IR (neat) 2230, 1625, 1250, 1025, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.35 (6H, t, J=7.0 Hz, OEt), 3.01 (2H, d, J=22.0 (HP) Hz, CH_2P), 3.2—3.7 (2H, m, 4-H), 4.15 (4H, qd, J=7.0 and 7.6 (HP) Hz, OEt), and 5.27 (1H, dd, J = 9.0 and 7.2 Hz, 4-H); ^{13}C NMR ($CDCl_3$) δ= 16.35 (qd, J_{cp}=5.9 Hz, OEt), 25.71 (td, J_{cp}=141.2 Hz, CH_2P), 43.24 (t, 4-C), 63.03 (td, J_{cp}=7.3 Hz, OEt), 66.59 (d, 5-C), 117.30 (s, CN), and 152.33 (d, J_{cp}=10.3 Hz, 3-C); MS m/z(rel intensity, %) 246 (M^+, 62), 220 (17), 218 (35), 192 (17), 190 (58), 164 (40), 146 (40), 122 (47), 109 (67), 108 (21), 97 (19), 96 (45), 83 (88), 82 (23), 81 (base peak), 79 (20), 64 (45), and 54 (63). HRMS Found: m/z 246.0745. Calcd for $C_9H_{15}N_2O_4P$: M, 246.0768.

7g: Colorless prisms (benzene-hexane); mp 108—110 °C; IR (KBr) 1590, 1300, 1250, 1150, 1020, and 810 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.32 (6H, t, J=7.0 Hz, OEt), 2.71 (1H, dd, J = 17.5 (gem) and 21.5 (HP) Hz, one of CH_2P), 3.10 (1H, dd, J = 17.5 (gem) and 20.5 (HP) Hz, the other of CH_2P), 3.3—3.9 (2H, m, 4-H), 4.12 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), 5.42 (1H, dd, J=10.0 and 6.0 Hz, 5-H), and 7.4—8.0 (5H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=16.35 (qd, J_{cp}=5.9 Hz, OEt), 25.62 (td, J_{cp}=141.2 Hz, CH_2P), 39.00 (t,

4-C), 62.95 (td, J_{cp}=5.9 Hz, OEt), 93.18 (d, 5-C), 129.48, 129.83, 134.72 (each d), 135.60 (s), and 152.75 (d, J_{cp}=10.3 Hz, 3-C); MS *m/z* (rel intensity, %) 220 (M^+, 78), 192 (36), 164 (base peak), 146 (36), and 76 (32). Found: C, 46.42; H, 5.58; N, 3.89%. Calcd for $C_{14}H_{20}NO_6PS$: C, 46.54; H, 5.58; N, 3.88%.

7h: Pale yellow liquid; IR (neat) 1625, 1250, 1020, and 825 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, OEt), 2.93 (2H, d, J=21.8 (HP) Hz, CH_2P), 2.9—3.6 (4H, m, 4-H and CH_2Br), 4.13 (4H, qd, J=7.0 and 7.4 (HP) Hz, OEt), and 4.84 (1H, m, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.41 (qd, J_{cp}=5.9 Hz, OEt), 26.15 (td, J_{cp}=139.7 Hz, CH_2P), 33.24 (t, CH_2Br), 41.82 (t, 4-C), 62.74 (td, J_{cp}=5.9 Hz, OEt), 79.60 (d, 5-C), and 151.51 (d, J_{cp}=10.3 Hz, 3-C); MS *m/z* (rel intensity, %) 314 (M^+, 1), 220 (base peak), 192 (26), 164 (65), and 146 (17). HRMS Found: *m/z* 313.0055. Calcd for $C_9H_{17}NO_4BrP$: M, 313.0078.

7i: Pale yellow liquid; IR (neat) 1675, 1250, 1025, and 830 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1—1.3 (6H, m, OEt), 1.33 (6H, t, J=7.0 Hz, OEt), 2.93 (2H, d, J=22.0 (HP) Hz, CH_2P), 2.9—3.3 (2H, m, 4-H), 3.4—3.9 (4H, m, OEt), 4.14 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), and 4.3—4.7 (2H, m, 5-H and CH); ^{13}C NMR ($CDCl_3$) δ=14.65 (q, OEt), 15.71 (qd, J_{cp}=5.9 Hz, OEt), 25.41 (td, J_{cp}=141.2 Hz, CH_2P), 37.83 (t, 4-C), 61.83 (td, J_{cp}=5.9 Hz, OEt), 62.53, 63.48 (each t, OEt), 80.48 (d, 5-C), 101.65 (d, $CH(OEt)_2$), and 151.16 (d, J_{cp}=10.3 Hz, 3-C); MS *m/z* (rel intensity, %) 278 (M^+−OEt, 9), 103 (base peak), 75 (45), and 47 (27), Satisfactory elemental analysis was not available because of its hygroscopic property.

7j: Pale yellow liquid; IR (neat) 1750, 1230, 1020, and 825 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.34 (6H, t, J=7.0 Hz, OEt), 2.04 (3H, s, COMe), 2.9—3.6 (2H, m, 4-H), 3.05 (2H, d, J=22.0 (HP) Hz, CH_2P), 4.15 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), and 6.64 (1H, dd, J=6.2 and 2.0 Hz, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.41 (qd, J_{cp}=5.9 Hz, OEt), 21.00 (q, COMe), 25.83 (td, J_{cp}=141.2 Hz, CH_2P), 43.53 (t, 4-C), 62.83 (td, J_{cp}=5.9 Hz, OEt), 96.01 (d, 5-C), 152.89 (d, J_{cp}=8.8 Hz, 3-C), and 169.83 (s, OCOMe); MS *m/z* (rel intensity, %), 220 (M^+−OCOMe, base peak), 209 (39), 192 (40), 164 (78), 146 (24), 83 (21), 81 (28), 64 (20), 54 (23), and 44 (75). Found: C, 42.93; H, 6.57; N, 5.08%. Calcd for $C_{10}H_{18}NO_6P$: C, 43.01; H, 6.50; N, 5.02%.

Reaction of Nitrile Oxide 1 with Bromoethene Leading to 8. To a solution of oxime **3** (0.39 g, 2 mmol) in dry DMF (4 ml) was added at −20 °C NBS (0.712 g, 4 mmol in 4 ml of DMF) in a period of 5 min. The mixture was stirred at −20 °C for 1 h, at 0 °C for 30 min, and then again cooled to −20 °C. Dry diethyl ether (4 ml) and triethylamine (0.28 ml, 2 mmol in 4 ml of diethyl ether) were added. After bromoethene (5 ml, 71 mmol) was added, the resulting mixture was stirred at room temperature for 18 h, poured into ice water, and extracted with dichloromethane (100 ml × 2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane-ethyl acetate (3 : 1 v/v) to give **8** (0.205 g, 47%): Colorless liquid; IR (neat) 1650, 1565, 1250, 1020, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30 (6H, t, J=7.0 Hz, OEt), 3.27 (2H, d, J=20.8 (HP) Hz, CH_2P), 4.09 (4H, qd, J=7.0 and 7.4 (HP) Hz, OEt), 6.45 (1H, t, J=1.5 Hz, 4-H), and 8.36 (1H, dd, J=1.5 and 0.8 Hz, 5-H); ^{13}C NMR ($CDCl_3$) δ=16.35 (qd, J_{cp}=5.9 Hz, OEt), 24.47 (td, J_{cp}=141.2 Hz, CH_2P), 62.68 (td, J_{cp}=7.3 Hz, OEt), 105.36 (d, 4-C), 159.07 (d, 5-C), and 155.12 (d, J_{cp}=6.8 Hz, 3-C); MS *m/z* (rel intensity, %) 219 (M^+, 92), 192 (31), 176 (28), 174 (34), 164 (67), 163 (31), 149 (37), 148 (25), 146 (70), 112 (23), 111 (20), 110 (67), 83 (base peak), 82 (48), 81 (53), 65 (30), and 55 (35). HRMS Found: *m/z* 219.0658. Calcd for $C_8H_{14}NO_4P$: M, 219.0660.

General Procedure for the Horner Emmons Olefination of 7b Leading to 9a—e. To a solution of isoxazoline **7b** (1 mmol) in dry THF (3 ml) was added butyllithium (1.6 M† in hexane, 0.66 ml, 1.06 mmol) at −78 °C under nitrogen. After 1 h an aldehyde or a ketone (1 mmol) was added. The mixture was stirred under the conditions shown in Table 4, poured into ice water (30 ml), and extracted with dichloromethane (20 ml × 2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was crystallized or chromatographed over silica gel by using the following eluent: **9a**: crystallization; **9b** and **9d**: hexane-ethyl acetate (20 : 1 v/v); **9c** and **9e**: hexane-ethly acetate (30 : 1 v/v). All the results are summarized in Table 4.

9a: Colorless needles (diethyl ether-hexane); mp 109—111 °C; IR (KBr) 1600 and 950 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.10 (1H, ddd, J=16.5 (gem), 8.5, and 0.7 Hz, one of 4-H), 3.54 (1H, ddd, J=16.5 (gem), 10.8, and 0.7 Hz, the other of 4-H), 5.59 (1H, dd, J=10.8 and 8.5 Hz, 5-H), 6.64 (1H, d, J=16.0 Hz, CH=), 7.07 (1H, d, J=16.0 Hz, CHPh), and 7.2—7.4 (10H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=41.65 (t, 4-C), 82.76 (d, 5-C), 117.96 (d, CH=), 126.02, 127.14, 128.41, 128.91, 129.00, 135.88 (s), 136.81 (d), 141.02 (s), and 157.52 (s, 3-C); MS *m/z* (rel intensity, %) 249 (M^+, 10), 248 (18), 143 (20), 130 (23), 128 (20), 115 (81), 105 (23), 104 (43), 103 (42), 102 (25), 91 (55), 89 (30), 78 (45), 77 (base peak), 76 (19), and 65 (25). Found: C, 82.00; H, 6.21; N, 5.66%. Calcd for $C_{17}H_{15}NO$: C, 81.90; H, 6.21; N, 5.62%.

9b (A 75 : 25 mixture of E- and Z-isomers): Pale yellow liquid; IR (neat) 1640, 1610, and 970 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.01 (2/9×3H, t, J=7.5 Hz, Et (Z)), 1.03 (7/9×3H, t, J=7.0 Hz, Et (E)), 2.18 (2H, m, Et), 2.97 (7/9×1H, dd. J=16.5 (gem) and 8.5 Hz, one of 4-H (E)), 3.07 (2/9×1H, dd, J=16.5 (gem) and 8.5 Hz, one of 4-H (Z)), 3.46 (7/9×1H, dd, J=16.5 (gem) and 11.0 Hz, the other of 4-H (E)), 3.55 (2/9×1H, dd, J=16.5 (gem) and 11.0 Hz, the other of 4-H (Z)), 5.53 (1H, dd, J=11.0 and 8.5 Hz, 5-H), 5.7—6.5 (2H, m, CH=CH), and 7.26 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=12.84 (q, Et (E)), 14.06 (q, Et (Z)), 22.90 (t, Et (Z)), 25.92 (t, Et (E)), 42.09 (t, 4-C (E)), 45.36 (t, 4-C (Z)), 82.13 (d, 5-C (E)), 82.32 (d, 5-C (Z)), 117.19, 119.14, 125.97, 128.22, 128.80, 141.21, 142.04 (each d), 155.71 (s, 3-C (Z)), and 157.23 (s, 3-C (E)); MS *m/z* (rel intensity, %) 201 (M^+, 6), 129 (22), 128 (39), 127 (17), 115 (36), 105 (30), 104 (63), 91 (39), 78 (76), 77 (base peak), and 65 (30). Found: C, 77.65; H, 7.52; N, 6.93%. Calcd for $C_{13}H_{15}NO$: C, 77.58; H, 7.51; N, 6.96%.

9c (A 72 : 28 mixture of E- and Z-isomers): Colorless liquid; IR (neat) 1640, 1600, and 960 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (3H, m, *n*-Bu), 1.1—1.6 (4H, m, *n*-Bu), 2.0—2.4 (2H, m, *n*-Bu), 2.98 (7/10×1H, dd, J=16.5 (gem) and 8.5 Hz, one of 4-H (E)), 3.07 (3/10×1H, dd, J=16.5 and 8.5 Hz, one of 4-H (Z)), 3.46 (7/10×1H, dd, J=16.5 (gem) and

† 1M=1 mol dm^{-3}.

11.0 Hz, the other of 4-H (E)), 3.56 (3/10×1H, dd, J=16.5 (gem) and 11.0 Hz, the other of 4-H (Z)), 5.53 (1H, dd, J= 11.0 and 8.5 Hz, 5-H), 5.6−6.5 (2H, m, CH=CH), and 7.26 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=13.82 (q), 22.18, 29.29, 30.83, 31.71, 32.59, 42.12, 45.42 (each t), 82.12 (d, 5-C (E)), 82.36 (d, 5-C (Z)), 117.71, 120.07, 126.01, 128.25, 128.83, 139.83, 140.72 (each d), 141.30, 155.78 (s, 3-C (Z)), and 157.19 (s, 3-C (E)); MS m/z(rel intensity, %) 229 (M^+, 36), 212 (17), 200 (25), 168 (17), 129 (18), 128 (20), 115 (25), 105 (20), 104 (base peak), 103 (23), 91 (43), 78 (36), 77 (49), and 51 (30). Found: C, 78.28; H, 8.37; N, 6.12%. Calcd for $C_{15}H_{19}NO$: C, 78.56; H, 8.35; N, 6.11%.

9d: Colorless prisms (diethyl ether-hexane); mp 62—64 °C; IR (KBr) 1650, 1625, and 975 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.76 (3H, d, J=6.0 Hz, Me), 2.96 (1H, dd, J=16.5 (gem and 8.5 Hz, one of 4-H), 3.43 (1H, dd, J=16.5 (gem) and 11.0 Hz, the other of 4-H), 5.50 (1H, dd, J=11.0 and 8.5 Hz, 5-H), 5.6—6.6 (3H, m, CH=), and 7.24 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=18.41 (q, Me), 41.70 (t, 4-C), 82.42 (d, 5-C), 118.71, 126.01, 128.25, 128.83, 131.13, 134.48, 137.42 (each d), 141.13 (s), and 157.42 (s, 3-C); MS m/z (rel intensity, %) 213 (M^+, 30), 198 (base peak), 180 (25), 115 (19), 105 (18), 104 (46), 103 (26), 91 (36), 78 (39), 77 (68), and 65 (26). Found: C, 78.73; H, 7.05; N, 6.71%. Calcd for $C_{14}H_{15}NO$: C, 78.84; H, 7.09; N, 6.57%.

9e: Colorless needles (hexane); mp 82—84 °C; IR (KBr) 1640 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.54 (6H, m, c-Hex), 2.15, 2.41 (each 2H, m, c-Hex), 2.99 (1H, dd, J=16.5 (gem) and 8.5 Hz, one of 4-H), 3.50 (1H, dd, J=16.5 (gem) and 11.0 Hz, the other of 4-H), 5.47 (1H, dd, J=11.0 and 8.5 Hz, 5-H), 5.83 (1H, s, CH=), and 7.24 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=26.27, 27.78, 28.56, 30.81, 38.28, 45.90 (each t), 81.88 (d, 5-C), 111.18 (d, CH=), 125.93, 128.12, 128.76 (each d), 141.50, 151.56 (each s), and 155.71 (s, 3-C); MS m/z(rel intensity, %) 241 (M^+, 21), 224 (18), 135 (25), 134 (base peak), 128 (24), 107 (31), 106 (42), 105 (27), 104 (55), 103 (30), 91 (76), 79 (43), 78 (50), 77 (84), 67 (28), and 65 (41). Found: C, 79.52; H, 7.90; N, 5.94%. Calcd for $C_{16}H_{19}NO$: C, 79.63; H, 7.94; N, 5.80%.

Geneal Procedure for the Alkylation of 7b, 7c Leading to 10a—e. To a solution of isoxazoline **7b** or **7c** (1 mmol) in dry THF (3 ml) was added butyllithium (1.6M in hexane, 0.62 ml, 0.989 mmol) at −78 °C under nitrogen. After 1 h, an alkyl halide (2 mmol) was added. The mixture was stirred at −78 °C for 1 h, at 0 °C for 1 h, and then at room temperature for the time shown in Table 4. Ice water (30 ml) was added and the mixture was extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using the following eluent: **10a**: hexane-ethyl acetate (1 : 5 v/v); **10b**, **10c**, **10d**: hexane-ethyl acetate (1 : 1 v/v); **10e**: hexane-ethyl aceate (2 : 3 v/v). All alkylated isoxazolines **10** were mixtures of two diastereoisomers. The results are summarized in Table 4.

10a: Pale yellow liquid; IR (neat) 1600, 1250, 1020, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.2—1.6 (9H, m, OEt and Me), 2.8—3.7 (3H, m, CH and 4-H), 3.8—4.3 (4H, m, OEt), 5.55 (1H, dd, J=11.0 and 8.5 Hz, 5-H), and 7.27 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=12.35 (qd, J_{cp}=5.9 Hz, Me), 16.41 (qd, J_{cp}=5.9 Hz, OEt), 32.30, 32.47, (each dd, J_{cp}=141.2 Hz, CH), 43.71, 44.00 (each t), 62.69 (d, J_{cp}=7.4 Hz, 4-C), 82.24 (d, 5-C), 126.10, 128.30, 128.83 (each d), 141.13, 141.24 (each s), and 156.19 (d, J_{cp}=8.9 Hz, 3-C); MS m/z (rel intensity, %) 311 (M^+, 62), 310 (base peak), 248 (28), 234 (41), 220 (14), 206 (21), 178 (34), 156 (25), 129 (21), 128 (23), 109 (29), 105 (23), 104 (49), 103 (23), 91 (25), 81 (34), 78 (20), and 77 (31). HRMS Found: m/z 311.1268. Calcd for $C_{15}H_{22}NO_4P$: M, 311.1285.

10b: Pale yellow liquid; IR (neat) 1610, 1250, 1025, and 830 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.83, 0.89 (3H, each t, n-Pen), 1.1—2.1 (8H, m, n-Pen), 1.26 (6H, m, OEt), 2.7—3.7 (3H, m, 4-H and CH), 3.8—4.3 (4H, m, OEt), 5.56, 5.59 (1H, each dd, J=10.5 and 8.0 Hz, 5-H), and 7.27 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=13.87, 13.96 (each q, n-Pen), 16.38 (qd, J_{cp}=6.1 Hz, OEt), 22.31, 26.37, 26.56, 27.10, 27.29, 27.69, 27.88, 31.10, 31.25 (each t), 37.70 (dd, J_{cp}=139.2 Hz, CH), 43.21, 43.66 (each t), 62.35 (td, J_{cp}=4.7 Hz, 4-C), 62.57 (td, J_{cp}=6.1 Hz, 4-C), 81.98 (d, 5-C), 125.78, 126.02, 128.22, 128.80 (each d), 141.30 (s), and 155.13 (d, J_{cp}=7.3 Hz, 3-C); MS m/z (rel intensity, %) 367 (M^+, 53), 366 (66), 290 (19), 230 (24), 137 (31), 128 (21), 109 (base peak), 105 (33), 104 (43), 91 (35), 81 (68), 78 (20), and 77 (41). HRMS Found: m/z 367.1904. Calcd for $C_{19}H_{30}NO_4P$: M, 367. 1911.

10c: Pale yellow liquid; IR (neat) 1600, 1250, 1025, 850 and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.02, 0.07 (9H, each s, $SiMe_3$), 1.0—1.4 (8H, m, OEt and CH_2SiMe_3), 2.8—3.6 (3H, m, 4-H and CH), 3.9—4.3 (4H, m, OEt), 5.53 (1H, dd, J=11.0 and 8.0 Hz, 5-H), and 7.28 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=−1.37 (q, $SiMe_3$), 13.38 (t, CH_2SiMe_3), 16.38 (qd, J_{cp}=6.1 Hz, OEt), 33.50 (dd, J_{cp}=139.1 Hz, CH), 33.72 (dd, J_{cp}=137.9 Hz, CH), 43.41, 43.90 (each t), 62.50 (td, J_{cp}=7.3 Hz, 4-C), 62.60 (td, J_{cp}=7.3 Hz, 4-C), 82.22 (dd, J_{cp}=7.3 Hz, 5-C), 126.07, 128.22, 128.76 (each d), 140.72, 141.30 (each s), 155.95 (d, J_{cp}=9.8 Hz, 3-C), and 156.32 (d, J_{cp}=8.5 Hz, 3-C); MS m/z(rel intensity, %) 383 (M^+, base peak), 382 (72), 368 (29), 156 (19), and 73 (46). HRMS Found: m/z 383.1654. Calcd for $C_{18}H_{30}NO_4PSi$: M, 383.1680.

10d: Pale yellow liquid; IR (neat) 1600, 1250, 1025, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.85 (3H, t, n-Pen), 1.1—1.7 (8H, m, n-Pen), 1.30 (6H, t, J=7.0 Hz, OEt), 2.3—3.7 (5H, m, 4-H, CH, and CH_2Ph), 4.11 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), 4.40 (1H, m, 5-H), and 7.17 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=13.96 (q, n-Pen), 16.43 (qd, J_{cp}=6.2 Hz, OEt), 22.51, 24.91, 31.60, 32.76, 34.72, 34.91 (each t), 39.09 (dd, J_{cp}=137.9 Hz, CH), 39.38 (dd, J_{cp}=137.9 Hz, CH), 40.77, 41.02 (each t), 62.77 (td, J_{cp}=6.7 Hz, 4-C), 81.09 (d, 5-C), 126.96, 128.76 (each d), 137.74, 138.37 (each s), and 154.64 (d, J_{cp}=6.6 Hz, 3-C); MS m/z(rel intensity, %) 381 (M^+, 15), 311 (19), 310 (base peak), 254 (23), 91 (29), and 43 (45). HRMS Found: m/z 381.2062. Calcd for $C_{20}H_{32}NO_4P$: M, 381.2067.

10e: Colorless liquid; IR (neat) 1640, 1250, 1025, 980, and 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.89 (3H, t, n-Pen), 1.1—1.9 (8H, m, n-Pen), 1.33 (6H, t, J=7.0 Hz, OEt), 2.3—3.4 (5H, m, 4-H, CH, and $CH_2CH=CH_2$), 4.12 (4H, qd, J=7.0 and 7.4 (HP) Hz, OEt), 4.52 (1H, m, 5-H), 5.05 (1H, dd, J=10.0 and 1.7 Hz, one of $=CH_2$), 5.09 (1H, dd, J=17.5 and 1.7 Hz, the other of $=CH_2$), and 5.70 (1H, m, CH=); ^{13}C NMR ($CDCl_3$) δ=14.00 (q, n-Pen), 16.47 (qd, J_{cp}=5.9 Hz, OEt), 22.59, 25.07, 25.18, 30.88, 31.00, 31.71, 35.06 (each t), 37.56 (dd, J_{cp}=139.7 Hz, CH), 40.36 (t), 62.71 (td,

J_{cp}=5.9 Hz, 4-C), 81.12 (d, 5-C), 117.54 (t, =CH_2), 134.77 (dd, J_{cp}=17.6 Hz, CH=), and 154.98 (d, J_{cp}=7.3 Hz, 3-C); MS *m/z* (rel intensity, %) 331 (M^+, 6), 260 (34), 204 (20), 109 (21), 94 (29), 93 (21), 91 (24), 82 (23), 81 (52), 80 (24), 79 (25), and 43 (base peak). HRMS Found: *m/z* 311.1902. Calcd for $C_{16}H_{30}NO_4P$: M, 311.1911.

General Procedure for Oxidation of the Carbanions Derived from 10a—d Leading to 3-(1-Oxoalkyl)-2-isoxazolines 11a — c. Butyllithium (1.6 M in hexane, 0.63 ml, 1 mmol) was added, at −78 °C under nitrogen, to the solution of isoxazoline **10** (1 mmol) in dry THF (5 ml) and stirred for 1 h. Dry oxygen was slowly bubbled into this solution for 1 h at the same temperature. The mixture was poured into ice water (20 ml) and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesiun sulfate and evaporated in vacuo. The residue was chromatographed over silica gel with the following eluent: **11a**: hexane-ethyl acetate (10 : 1 v/v); **11b**, **11c**: hexane-ethyl acetate (20 : 1 v/v). Unreacted **10** was recovered from the fraction eluted with ethyl acetate. The results are listed in Table 4.

11a: Colorless liquid; IR (neat) 1680 and 1575 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.52 (3H, s, COMe), 3.09 (1H, dd, J= 17.7 (gem) and 9.0 Hz, one of 4-H), 3.53 (1H, dd, J=17.7 (gem) and 11.5 Hz, the other of 4-H), 5.73 (1H, dd, J=11.5 and 9.0 Hz, 5-H), and 7.31 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=26.71 (q, COMe), 39.77 (t, 4-C), 85.59 (d, 5-C), 126.01, 128.77, 129.01 (each d), 139.78 (s), 158.06 (s, 3-C), and 193.19 (s, COMe); MS *m/z* (rel intensity, %) 189 (M^+, 3), 115 (17), 105 (15), 104 (13), 78 (17), 77 (38), 51 (32), and 43 (base peak). Found: C, 69.90; H, 5.93; N, 7.37%. Calcd for $C_{11}H_{11}NO_2$: C, 69.83; H, 5.86; N, 7.40%.

11b: Colorless needles (hexane); mp 43—44 °C; IR (KBr) 1660 and 1560 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (3H, t, *n*-Pen), 1.1—1.9 (6H, m, *n*-Pen), 2.90 (2H, t, J=7.0 Hz, *n*-Pen), 3.07 (1H, dd, J=17.8 (gem) and 9.0 Hz, one of 4-H), 3.51 (1H, dd, J=17.8 (gem) and 11.2 Hz, the other of 4-H), 5.69 (1H, dd, J=11.2 and 9.0 Hz, 5-H), and 7.27 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=13.88 (q, *n*-Pen), 22.41, 23.71, 31.36, 39.30, 40.00 (each t), 85.24 (d, 5-C), 126.01, 128.71, 129.01 (each d), 139.89 (s), 157.59 (s, 3-C), and 196.02 (s, CO); MS *m/z* (rel intensity, %) 245 (M^+, base peak), 244 (24), 228 (43), 129 (21), 128 (16), 115 (20), 105 (19), 104 (83), 99 (49), 91 (20), 76 (26), and 71 (35). Found: C, 73.57; H, 7.85; N, 5.78%. Calcd for $C_{15}H_{19}NO_2$: C, 73.44; H, 7.81; N, 5.71%.

11c: Colorless prisms (hexane); mp 33—34 °C; IR (KBr) 1680 and 1580 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (3H, t, J=7.0 Hz, *n*-Pen), 1.2—1.8 (8H, m, *n*-Pen), 2.67 (1H, dd, J=17.5 (gem) and 9.0 Hz, one of 4-H), 3.10 (1H, dd, J= 17.5 (gem) and 10.5 Hz, the other of 4-H), 4.13 (2H, s, CH_2Ph), 4.67 (1H, m, 5-H), and 7.22 (5H, s, Ph); ^{13}C NMR ($CDCl_3$) δ=13.94 (q, *n*-Pen), 22.47, 24.88, 31.53, 35.18, 36.89, 45.65 (each t), 85.06 (d, 5-C), 127.19, 128.72, 129.89 (each d), 133.90 (s), 157.95 (s, 3-C), and 193.07 (s, CO); MS *m/z* (rel intensity, %) 259 (M^+, 71), 258 (base peak), 168 (38), 91 (89), and 65 (11). Found; C, 74.31; H, 8.26; N, 5.65%. Calcd for $C_{16}H_{21}NO_2$: C, 74.10; H, 8.16; N, 5.40%.

Reaction of 7k with Butyllithium Leading to 8. Butyllithium (1.6 M in hexane, 0.23 ml, 0.37 mmol) was slowly added, at −78 °C under nitrogen, to the solution of isoxazoline **7k** (0.133 g, 0.37 mmol) in dry THF (2 ml). After 1 h at −78 °C, pentyl iodide (0.146 g, 0.74 mmol) was added. The mixture was stirred at 0 °C for 1 h, at room temperature for 12 h, and then poured into ice water. The product was extracted with dichloromethane (30 ml × 2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using hexane-ethyl acetate (1 : 5 v/v) to give **8** (0.059 g, 73%) which was characterized above.

General Procedure for the Raney Ni Hydrogenolysis of 7 or 10a Leading to 12a—g. The following two procedures were applied: A mixture of **7** or **10a** (1 mmol), Raney Ni (W-2, suspension in ethanol, 1 ml), acetic acid (0.5 ml), and water (0.5 ml) in ethanol (5 ml) -Method A- or a mixture of **7** or **10a** (1 mmol), Raney Ni (1 ml), boric acid (0.13 g, 2 mmol), and water (1 ml) in ethanol (5 ml) -Method B- was stirred under an atmosphere of hydrogen (1 atm) at room temperature. The insoluble materials were removed off by filteration through celite 545 and the filtrate was evaporated in vacuo. The residue was dissolved in dichloromethane (20 ml). The solution was washed with water, dried over magnesium sulfate, and evaporated in vacuo to give **12**. The methods applied, the reaction times, the yields of **12**, and the purification methods are as follows: **12a**: B, 12 h, 80%, a silica-gel chromatography with ethyl acetate; **12b**: B, 13 h, 91%, a silica-gel chromatography with ethyl acetate; **12c**: B, 13 h, 63%, a silica-gel chromatography with ethyl acetate; **12d**: B, 13 h, 63%, decomposed in a silica-gel column; **12e**: A, 20 h, 77%, a silica-gel chromatography with hexane-ethyl acetate (5 : 1 v/v); **12f**: B, 13 h, 88%, a silica-gel chromatography with ethyl acetate. **12g**: B, 12 h, 73%, a silica-gel chromatography ethyl acetate.

12a: Colorless liquid: IR (neat) 3360, 1710, 1240, 1020, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.28 (6H, t, J=7.0 Hz, OEt), 2.7—3.2 (2H, m, $COCH_2$), 3.08 (2H, d, J=23.0 (HP) Hz, CH_2P), 3.8—4.3 (1H, br, OH), 4.08 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), 5.12 (1H, dd, J=8.0 and 4.5 Hz, CHPh), and 7.0−7.5 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ= 16.29 (qd, J_{cp}=5.9 Hz, OEt), 43.06 (td, J_{cp}=126.5 Hz, CH_2P), 53.06 (t, $COCH_2$), 62.83 (td, J_{cp}=5.9 Hz, OEt), 69.95 (d, CH), 125.95, 127.77, 128.65 (each d), 143.48 (s), and 202.02 (d, J_{cp}=5.9 Hz, CO); MS *m/z* (rel intensity, %) 300 (M^+, 1), 125 (14), 123 (20), 109 (37), 107 (33), 105 (29), 97 (20), 96 (22), 81 (48), 79 (84), 78 (33), and 77 (base peak). HRMS Found: *m/z* 300.1121. Calcd for $C_{14}H_{21}O_5P$: M, 300.1125.

12b: Colorless liquid IR (neat) 3400, 1710, 1240, 1025, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (3H, t, J=6.0 Hz, *n*-Pen), 1.33 (6H, t, J=7.0 Hz, OEt), 1.1—1.7 (8H, m, *n*-Pen), 2.72 (2H, d, J=6.0 Hz, $COCH_2$), 3.16 (2H, d, J=22.5 (HP) Hz, CH_2P), 3.82 (1H, br, OH), 4.04 (1H, m, CH), and 4.13 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt); ^{13}C NMR ($CDCl_3$) δ=14.06 (q, *n*-Pen), 16.29 (qd, J_{cp}=5.9 Hz, OEt), 22.65, 25.24, 31.83, 37.00 (each t), 43.00 (d, J_{cp}=126.5 Hz, CH_2P), 51.36 (t), 62.77 (td, J_{cp}=5.9 Hz, OEt), 67.77 (d, CH), and 202.89 (d, J_{cp}=5.9 Hz, CO); MS *m/z* (rel intensity, %) 294 (M^+, 3), 223 (base peak), 195 (33), 194 (42), 179 (19), 167 (17), 152 (18), 139 (19), 125 (20), 123 (25), and 97 (16). HRMS Found: *m/z* 294.1546. Calcd for $C_{13}H_{27}O_5P$: M, 294.1595.

12c: Colorless liquid; IR (neat) 3340, 1730, 1710, 1240,

1020, 970, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, d, J=7.0 Hz, OEt), 3.10 (2H, d, J=5.0 Hz, $COCH_2$), 3.15 (2H, d, J=22.5 (HP) Hz, CH_2P), 3.73 (3H, s, COOMe), 4.13 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), 4.51 (1H, t, J=5.0 Hz, CH), and 4.65 (1H, s, OH); ^{13}C NMR ($CDCl_3$) δ=16.30 (qd, J_{cp}=5.9 Hz, OEt), 42.80 (td, J_{cp}=128.0 Hz, CH_2P), 47.71 (t, $COCH_2$), 52.42 (q, COOMe), 62.89 (td, J_{cp}=5.9 Hz, OEt), 66.89 (d, CH), 174.19 (s, COOMe), and 199.89 (d, J_{cp}=5.9 Hz, CO); MS m/z (rel intensity, %) 282 (M^+, 2), 223 (base peak), 195 (16), 194 (22), 179 (29), 152 (21), 151 (23), 139 (21), 125 (34), and 123 (54). HRMS Found: m/z 282.0864. Calcd for $C_{10}H_{19}O_7P$: M, 282.0867.

12d: Labile colorless liquid; ^1H NMR ($CDCl_3$) δ=1.33 (6H, J=7.0 Hz, OEt), 2.25 (3H, s, COMe), 3.06 (2H, dd, J=6.2 and 4.2 Hz, $COCH_2$), 3.15 (2H, d, J=22.6 (HP) Hz, CH_2P), 4.13 (4H, qd, J=7.0 and 7.4 (HP) Hz, OEt), 4.37 (1H, dd, J=6.2 and 4.2 Hz, CH), and 4.34 (1H, br, OH); ^{13}C NMR ($CDCl_3$) δ=16.32 (qd, J_{cp}=7.4 Hz, CH_2P), 25.53 (q, COMe), 42.97 (td, J_{cp}=125.0 Hz, OEt), 47.12 (t, $COCH_2$), 62.98 (td, J_{cp}=8.3 Hz, OEt), 73.53 (d, CH), 200.37 (d, J_{cp}=5.9 Hz, CO), and 209.72 (s, COMe); MS m/z (rel intensity, %) 223 (M^+−COMe, 77), 195 (26), 179 (22), 167 (26), 152 (34), 151 (26), 139 (48), 125 (40), 123 (73), 121 (20), 109 (23), 97 (33), and 43 (base peak). This compound was too labile to be purified as an authentic sample.

12e: Colorless liquid; IR (neat) 3400, 1700, 1240, 1025, and 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (6H, t, J=7.0 Hz, OEt), 2.93 (2H, d, J=6.0 Hz, CH_2Br), 3.16 (2H, d, J=22.5 (HP) Hz, CH_2P), 3.46 (2H, d, J=5.0 Hz, $COCH_2$), 3.72 (1H, s, OH), 4.12 (4H, qd, J=7.0 and 7.3 (HP) Hz, OEt), and 4.24 (1H, tt, J=6.0 and 5.0 Hz, CH); ^{13}C NMR ($CDCl_3$) δ=16.30 (qd, J_{cp}=5.9 Hz, OEt), 37.82 (t, CH_2Br), 43.03 (td, J_{cp}=128.0 Hz, CH_2P), 48.94 (t, $COCH_2$), 62.95 (td, J_{cp}=5.9 Hz, OEt), 67.01 (d, CH), and 201.19 (d, J_{cp}=5.9 Hz, CO); MS m/z (rel intensity, %) 319, 317 (M^+, 17), 223 (base peak), 219 (47), 195 (23), 194 (60), 179 (40), 167 (22), 163 (19), 151 (33), 139 (34), 125 (36), 123 (59), 109 (32), 97 (26), and 80 (41). Found: C, 33.87; H, 5.65%. Calcd for $C_9H_{18}O_5BrP$: C, 34.09; H, 5.72%.

12f: Colorless liquid; IR (neat) 3370, 1710, 1245, 1025, and 965 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.1—1.4 (12H, m, OEt), 2.79 (2H, d, J=5.8 Hz, $COCH_2$), 3.12 (2H, d, J=21.6 (HP) Hz, CH_2P), 3.20 (1H, br, OH), 3.4—3.8 (4H, m, OEt), 3.9—4.2 (1H, m, CH), 4.07 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), and 4.30 (1H, d, J=5.8 Hz, $CH(OEt)_2$); ^{13}C NMR ($CDCl_3$) δ=15.35 (q, OEt), 16.29 (qd, J_{cp}=5.9 Hz, OEt), 43.15 (td, J_{cp}=128.0 Hz, CH_2P), 46.06 (t, $COCH_2$), 62.65 (td, J_{cp}=5.9 Hz, OEt), 63.36, 64.00 (each t, OEt), 68.77 (d, CHOH), 104.36 (d, $CH(OEt)_2$), and 201.60 (s, CO); MS m/z (rel intensity, %) 281 (M^+-OEt), 223 (16), 179 (7), 152 (6), 123 (9), 104 (6), 103 (base peak), 75 (31), and 47 (21). Found: C, 47.85; H, 8.24%. Calcd for $C_{13}H_{27}O_7P$: C, 47.85; H, 8.44%.

12g (A mixture of two diastereomers): Pale yellow liquid; IR (neat) 3360, 1710, 1240, 1020, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.26 (6H, t, J=7.0 Hz, OEt), 1.4—1.5 (3H, m, Me), 2.8—3.6 (3H, m, CH_2CO and CH), 4.04 (4H, qd, J=7.0 and 8.0 (HP) Hz, OEt), 5.12 (1H, dd, J=7.0 and 5.0 Hz, CHPh), and 7.1—7.5 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=10.24 (q, Me), 16.00 (qd, J_{cp}=5.9 Hz, OEt), 46.65, 47.12 (each td, J_{cp}=126.5 Hz, CH_2P), 52.12, 52.89 (each d), 62.30 (td, J_{cp}=5.9 Hz, OEt), 69.59, 69.89 (each d, CHPh), 125.60, 127.13, 128.13 (each d), 143.78 (s), 204.87, and 205.34 (each d, J_{cp}=4.4 Hz, CO); MS m/z (rel intensity, %) 314 (M^+, 4), 208 (16), 190 (23), 180 (32), 166 (28), 139 (21), 138 (29), 137 (26), 123 (30), 109 (79), 107 (47), 105 (52), 103 (24), 91 (26), 81 (68), 79 (86), 78 (30), 77 (base peak), 51 (24), and 43 (22). HRMS Found: m/z 314.1276. Calcd for $C_{15}H_{23}O_5P$: M, 314.1282.

2-[(Diethoxyphosphoryl)methyl]-5-methylpyrrole (13). The Raney Ni reduction of **7e** (0.270 g, 1.03 mmol) was carried out for 19 h according to the method A mentioned above and followed by the usual work-up and the column chromatography over silica gel (hexane-ethyl acetate (1 : 1 v/v)) to give **13** (0.056 g, 24%): Pale yellow liquid; IR (neat) 3220, 1590, 1225, 1020, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.24 (6H, t, J=7.0 Hz, OEt), 2.17 (3H, d, J=1.5 Hz, Me), 3.11 (2H, d, J=20.0 (HP) Hz, CH_2P), 4.00 (4H, qd, J=7.0 and 14.0 (HP) Hz, OEt), 5.6—5.9 (2H, m, 3- and 5-H), and 8.90 (1H, br, s, NH); ^{13}C NMR ($CDCl_3$) δ=13.00 (q, Me), 16.41 (qd, J_{cp}=5.3 Hz, OEt), 25.88 (td, J_{cp}=141.2 Hz, CH_2P), 62.50 (td, J_{cp}=7.4 Hz, OEt), 106.02 (d, 4-C), 108.33 (dd, J_{cp}=10.3 Hz, 3-C), 118.89 (d, J_{cp}=11.8 Hz, 2-C), and 128.33 (s, 5-C); MS m/z (rel intensity, %) 231 (M^+, 6), 95 (15), 94 (base peak), and 93 (12). HRMS Found: m/z 231.1019. Calcd for $C_{10}H_{18}NO_3P$: M, 231.1023.

General Procedure for the Dehydration of Hydroxy Ketones 12a, 12b Leading to 14a, 14b. To a solution of **12** (1 mmol) and triethylamine (0.3 g, 3 mmol) in dichloromethane (5 ml) was added dropwise methanesulfonyl chloride (0.14 g, 1.2 mmol) at −20 °C. The mixture was stirred at −20 °C for 0.5 h and at room temperature for 1 h. Ice water (20 ml) was added and the product was extracted with diethyl ether (20 ml × 2). The combined extracts were washed with 1 M hydrochloric acid (20 ml), aqueous sodium hydrogencarbonate (20 ml), and water (20 ml × 2). After dried over magnesium sulfate, the solvent was evaporated in vacuo. The residue was chromatographed over silica gel by using hexane-ethyl acetate (1 : 5 v/v).

14a: Yield 87%; pale yellow liquid; IR (neat) 1650, 1600, 1240, 1020, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30 (6H, t, J=7.0 Hz, OEt), 3.30 (2H, d, J=23.0 (HP) Hz, CH_2P), 4.14 (4H, qd, J=7.0 and 8.0 (HP) Hz, OEt), 6.84 (1H, d, J=16.0 Hz, CH=), 7.60 (1H, d, J=16.0 Hz, CH=), and 7.2—7.6 (5H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=16.29 (qd, J_{cp}=5.9 Hz, OEt), 40.97 (td, J_{cp}=128.0 Hz, CH_2P), 62.68 (td, J_{cp}=7.4 Hz, OEt), 125.95, 128.77, 129.13, 131.01 (each d), 134.06 (s), 144.89 (d), and 191.30 (d, J_{cp}=5.9 Hz,CO); MS m/z (rel intensity, %) 282 (M^+, 31), 253 (14), 224 (66), 197 (96), 180 (47), 179 (base peak), 169 (35), 152 (62), 151 (70), 144 (49), 131 (32), 125 (43), 123 (88), 109 (44), 97 (24), 88 (38), and 81 (38). HRMS Found: m/z 282.1019. Calcd for $C_{14}H_{19}O_4P$: M, 282.1020.

14b: Yield 93%; pale yellow liquid; IR (neat) 1690, 1660, 1250, 1025, 960, and 790 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (3H, t, J=6.0 Hz, *n*-Pen), 1.1—1.7 (6H, m, *n*-Pen), 1.32 (6H, t, J=7.0 Hz, OEt), 2.24 (2H, q, J=7.0 Hz, *n*-Pen), 3.20 (2H, d, J=22.0 (HP) Hz, CH_2P), 4.13 (4H, qd, J=7.0 and 7.5 (HP) Hz, OEt), 6.20 (1H, dt, J=15.0, 1.0, and 1.0 Hz, CH=), and 6.94 (1H, dt, J=15.0, 7.0, and 7.0 Hz, CH=); ^{13}C NMR ($CDCl_3$) δ=13.94 (q, *n*-Pen), 16.35 (qd, J_{cp}=5.9 Hz, OEt), 22.41, 27.71, 31.41, 32.59 (each t), 40.18 (tq, J_{cp}=129.4 Hz, CH_2P), 62.59 (td, J_{cp}=5.9 Hz, OEt),

130.25, 150.72 (each d), and 191.57 (d, $J_{cp} = 7.4$ Hz, CO); MS m/z (rel intensity, %) 276 (M^+, 6), 244 (73), 173 (40), 136 (24), 121 (base peak), 81 (23), 65 (70), and 55 (30). HRMS Found: m/z 276.1487. Calcd for $C_{13}H_{25}O_4P$: M, 276.1489.

Reinvestigation of Base-Catalyzed Condensation of Ethyl α,α-Dichloroacetoacetate with Aldehydes. A New Synthesis of (±)-Disparlure

Sadao Tsuboi,* Hiroyuki Furutani, Akira Takeda, Kayoko Kawazoe,† and Sadao Sato†

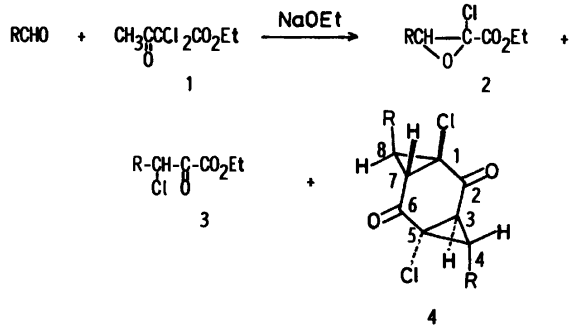
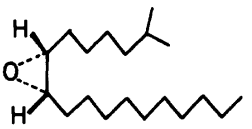
(Received February 5, 1987)

The titled reaction gave ethyl 2-chloro-2,3-epoxyalkanoates (**2**) and ethyl 3-chloro-2-oxoalkanoates in improved yields. The structure of the by-product was revised as 1,5-dichloro-4,8-dialkyltricyclo[5.1.0.0^{3,5}]octane-2,6-dione by means of the ^{13}C-^{1}H two-dimensional NMR spectrum and an X-ray crystallographic analysis. Compound **2** was applied to the synthesis of (±)-disparlure, the pheromone of the gypsy moth, in 49% overall yield via 6 steps.

As our continuing study on α-halo carbonyl compounds,[1] we have reported the reaction of ethyl α,α-dichloroacetoacetate (**1**) with aldehydes in the presence of sodium ethoxide.[2] This novel reaction involving a retro acetoacetate reaction[3] gave ethyl 2-chloro-2,3-epoxyalkanoate (**2**) or ethyl 3-chloro-2-oxoalkanoate (**3**) in low or moderate yields together with a small amount of crystalline by-products, one of which was identified as 2,5-bis(1-chloroalkylidene)-1,4-cyclohexanedione (**4′**).[2]



Recently, we reinvestigated this reaction in order to improve the yields of **2** and **3**; we also reexamined the structure of the by-product by means of the ^{13}C-^{1}H two-dimensional NMR spectrum and an X-ray crystallographic analysis. In the present paper we describe the results, which involve a revision of the previously assigned structure **4′** to 1,5-dichloro-4,8-dialkyltricyclo[5.1.0.0^{3,5}]octane-2,6-dione (**4**) as well as a highly stereoselective synthesis of the racemate of (+)-disparlure[(7*R*,8*S*)-7,8-epoxy-2-methyloctadecane] (**5**),[4] the pheromone of the gypsy moth.



(+)-Disparlure **5**

When we carried out the present reaction under an absolutely dry conditions,[5] the yields of the products **2** and **3** (R=C_6H_5) were dramatically improved, as shown in Table 1, although the crystalline by-product

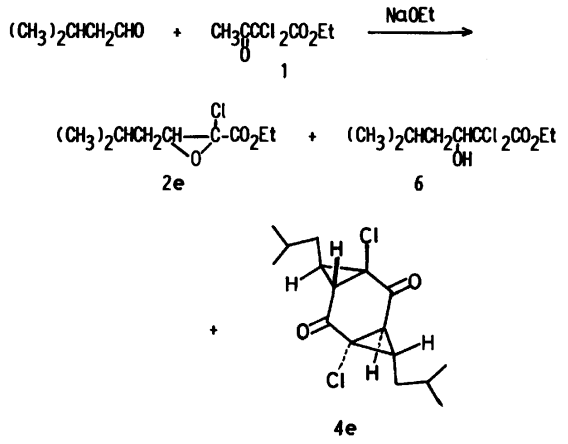
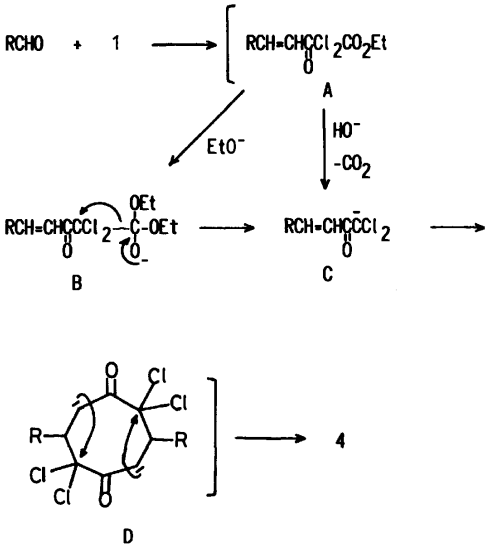
a) Previously reported values[3] are given in parenthesis. b) Isolated yields by distillation unless otherwise indicated. c) Bath temperature of bulb-to-bulb tube oven. d) Isolated yield by column chromatography.

4 produced before[2] was not isolated. All of the reactions gave the epoxide **2** in good yields. The epoxides **2a—e** (R=CH_3, C_2H_5, n-C_3H_7, $(CH_3)_2CH$, $(CH_3)_2CHCH_2$) bearing small alkyl groups were thermally stable, while the epoxides (**2f** and **2g**) (R=n-C_6H_{13}, C_6H_5) bearing larger groups were isomerized to keto esters (**3f** and **3g**) by distillation via halo-epoxy rearrangement.[1a,b] On the other hand, the reaction of **1** with 3-methylbutanal in the presence of commercial, old sodium ethoxide gave **4e** (R=$(CH_3)_2CHCH_2$) in 4.8% yield besides **2e** (R=$(CH_3)_2CHCH_2$) (18%) and ethyl 2,2-dichloro-3-hydroxy-5-methylhexanoate (**6**) (30%). Similarly, the reaction of **1** with undecanal under the same conditions gave **2j** (R=n-$C_{10}H_{21}$) in 73.6% yield and **4j** (R=n-$C_{10}H_{21}$) in 5.65% yield. Measurement of the ^{13}C NMR spectra of **4** coupled with that of the heteronuclear ^{13}C-^1H chemical shift correlated spectrum (HETCOR), led us to assign all the carbon signals (Table 2). The result indicated that the structure of **4'** was incorrect owing to the absence of signals due to olefinic carbons.



The structure of **4** was absolutely verified by a representative X-ray crystallographic analysis of **4b** (R=C_2H_5) to be 1,5-dichloro-4,8-diethyltricyclo[5.1.0.$0^{3,5}$]-octane-2,6-dione. ORTEP drawing in Fig. 1 illustrates the geometrical aspect of the molecule and explains the chemical structure reasonably. The molecule is located about a crystallographic center and the asymmetric unit contains half of the molecule.

Although the accurate mechanism is not clear, the formation of **4** can be explained by assuming intermediates **A**, **B**, C, and **D**. Aldol condensation product **A** between aldehydes and **1** would give an anion **C** via the intermediate **B**. Two molecules of the anion **C** would undergo a Michael addition each other to afford a cyclized product **D**. The subsequent double dehydrochlorinations of **D** would give the final product **4**.



Furthermore, compound **2j** was utilized for the synthesis of the racemate of (+)-disparlure **5**. Since (±)-**5** and (+)-**5** are effective as an attractant against the harmful forest pest like gypsy moth, their syntheses

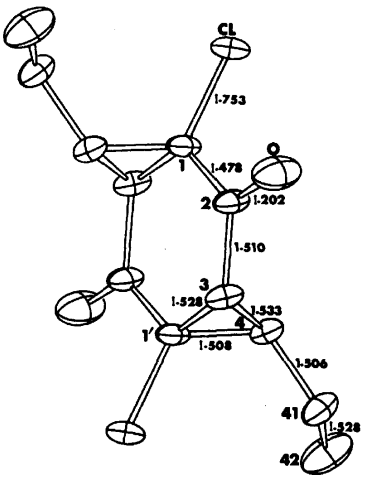


Fig. 1. ORTEP drawing of **4b**.

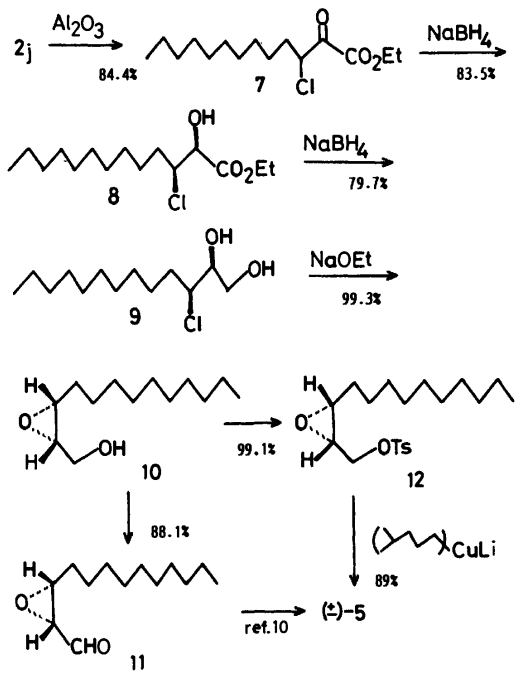
a) Prepared in the previous paper. See Ref. 2.



Scheme 1.

have been reported repeatedly to date.[6,7] Our synthetic sequence is shown in Scheme 1. A thermal treatment of **2j** with alumina in xylene induced a chlorocarbonyl rearrangement[1c] to give ethyl 3-chloro-2-oxotridecanoate (**7**) in 84.4% yield. Reduction of **7** with sodium borohydride in ethanol at 0°C afforded ethyl 3-chloro-2-hydroxytridecanoate (**8**) in 83.5% yield with high stereoselectivity (threo/erythro = 93/7). Purification of a stereoisomeric mixture with preparative HPLC afforded pure *threo*-**8**, which was reduced again with sodium borohydride at room temperature to give *threo*-3-chloro-1,2-tridecanediol (**9**) in 79.7% yield. Dehydrochlorination of **9** with sodium ethoxide in ethanol gave *cis*-2,3-epoxy-1-tridecanol (**10**)[8] in a quantitative yield. Reaction of **10** with tosyl chloride afforded tosylate **12** in 99.1% yield. Treatment of **12** with lithium bis(4-methylpentyl)cuprate(I) gave (±)-disparlure **5** in 89% yield. A total synthesis of (±)-**5** was established in 49% overall yield via 6 steps starting from **2j**. Furthermore, the oxidation of **10** with a Collins reagent afforded *cis*-2,3-epoxytridecanal (**11**) in 88.1% yield; this could be converted to (±)-**5** via a Wittig reaction and hydrogenation.[8]

Experimental

Melting and boiling points are uncorrected. Elemental analyses were carried out by Mr. Eiichiro Amano in our laboratory. Infrared (IR) spectra were obtained with a JASCO Model A-102 infrared spectrophotometer. ^{1}H NMR (100 MHz) and ^{13}C NMR spectra (25 MHz) were obtained with a JEOL JNM-FX100 apparatus, using $CDCl_3$ as a solvent. Two-dimensional NMR spectra were acquired on a Varian VXR 300 spectrometer operating at 300 and 75 MHz for ^{1}H and ^{13}C observation, respectively. Spectra were obtained for solutions in 5-mm NMR sample tubes in the ^{1}H-^{13}C switchable probe. Heteronuclear correlation spectra (HETCOR)[9] were run with the standard Varian 6.1-version software and obtained with sweep widths dictated by the appearance of the ^{13}C and ^{1}H spectra by using a 1024×512 data matrix and 128 increments in the first dimension.

Unless otherwise indicated, solvent (ether) was dried by distillation in the presence of sodium-benzophenone complex. Aldehydes were distilled prior to use.

Some representative examples of reactions of **1** with aldehydes are shown below.

Ethyl 2-Chloro-4-methyl-2,3-epoxypentanoate (2d) was prepared according to the procedure previously reported.[2] Sodium ethoxide was freshly prepared by dissolving sodium (250 mg, 11 mg-atom) in absolute ethanol (8 ml). After concentration of the solvent in vacuo, dry ether (50 ml) was added. To a stirred mixture was added dropwise ethyl α,α-dichloroacetoacetate (2.00 g, 10.1 mmol) at 0°C and then isobutyraldehyde (0.70 g, 0.9 ml, 9.5 mmol) was added dropwise. The mixture was stirred for 30 min at 0°C; it was then heated at the reflux temperature for 4 h, and poured into ice water. After the mixture was neutralized with 10% HCl, the organic materials were extracted with ethyl acetate. The combined extracts were washed with water and dried over $MgSO_4$. Removal of the solvent gave 2.01 g of an oil, which was distilled with bulb-to-bulb tube oven, giving 1.52 g (83.2%) of **2d**: Bp 130°C/2.5 Torr (1 Torr = 133.322 Pa). The IR and ^{1}H NMR data were consistent with those of an authentic sample.[2]

Reaction of 1 with 3-Methylbutanal. 1,5-Dichloro-4,8-diisobutyltricyclo[5.1.0.0^{3,5}]octane-2,6-dione (4e). Commercial sodium ethoxide (1.6 g, 24 mmol) in ether (50 ml) was added in several portions to a solution of **1** (4.0 g, 20.1 mmol) in dry ether (50 ml) with stirring at 0°C. The mixture was stirred for 10 min and then 3-methylbutanal (1.6 g, 2.0 ml, 19 mmol) was added dropwise. After being stirred for 30 min at 0°C and for 30 min at 25°C, the mixture was heated under reflux for 4 h and then poured into ice water. The mixture was neutralized with 10% HCl, and the organic materials were extracted with ethyl acetate. The combined extracts were washed with water, dried over $MgSO_4$, and concentrated. The residual oil containing crystals was filtered and washed with hexane to give 287 mg (4.8%) of **4e**: Mp 175—176°C (from hexane-ether); IR (KBr) 3050, 2960, 1699, 1285, 1100, and 875 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ = 0.98 (d, 12H, J = 6 Hz, 2(CH_3)$_2$CH), 1.4—2.1 (m, 8H, 2(CH_3)$_2$CHCH_2CH<), and 2.23 (d, 2H, J=5.5 Hz, 2COCH). Found: C, 60.62; H, 7.14%. Calcd for $C_{16}H_{22}Cl_2O_2$: C, 60.57; H, 6.99%.

Concentration of the filtrate gave an oil which was chromatographed on SiO_2 (hexane-acetone, 20 : 1—2 : 1) to afford 2.07 g of a mixture of **2e**[1c] (18%) and **6** (30%): 1 : 2 ratio by ^{1}H NMR analysis; TLC (hexane-acetone, 5 : 1), R_f = 0.34.

Compound **6** was prepared independently by the reaction of ethyl dichloroacetate with 3-methylbutanal in the presence of commercial sodium ethoxide: 35% yield; bp 100—108°C/2 Torr; IR (neat) 3500, 1745 cm^{-1}; ^{1}H NMR (CCl_4) δ = 0.95 (d, 3H, J = 6 Hz, (CH_3)$_2$CH), 0.98 (d, 3H, J = 6 Hz, (CH_3)$_2$CH), 1.35 (t, 3H, J = 6.5 Hz, $CO_2CH_2CH_3$), 1.3—2.2

(m, 3H, $(CH_3)_2CHCH_2$), 3.0 (br. s, 1H, OH), 4.12 (t, 1H, J = 5 Hz, CHOH), and 4.26 (q, 2H, J=6.5 Hz, $CO_2CH_2CH_3$). Found: C, 44.16; H, 6.69%. Calcd for $C_9H_{16}Cl_2O_3$: C, 44.45; H, 6.63%.

Ethyl 2-Chloro-2,3-epoxytridecanoate (2j) and 1,5-Dichloro-4,8-didecyltricyclo[5.1.0.0^{3,5}]octane-2,6-dione (4j). A mixture of undecanal (3.40 g, 4.12 ml, 20 mmol) and ethyl α,α-dichloroacetoacetate (4 g, 20.1 mmol) in the presence of commercial sodium ethoxide (1.6 g, 24 mmol) was heated under reflux for 17 h, and then worked up. The crude products containing crystals were filtered and washed with hexane to give 536 mg (5.50%) of **4j**: Mp 93.5—94.0°C, IR (KBr) 1700, 1458, 1298, 1280, 1140, and 875 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.90 (br. t, 6H, J=5Hz, CH_3), 1.28 (m, 36H, 2(CH_2)$_8$), and 1.50—2.30 (m, 4H, 4 >CH-). Found: C, 69.46; H, 9.39%. Calcd for $C_{28}H_{46}Cl_2O_2$: C, 69.26; H, 9.55%.

Concentration of the filtrate gave an oil which was chromatographed on SiO_2 (hexane-acetone, 20 : 1) to afford 4.30 g (73.6% yield) of **2j**: TLC (hexane-acetone, 5 : 1), R_f=0.32; IR (neat) 1750, 1465, 1255, 1020, and 715 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.90 (br. t, 3H, J=5 Hz, CH_3), 1.27 (m, 18H, (CH_2)$_9$), 1.30 (t, 3H, $CO_2CH_2CH_3$), 3.30 (m, 1H, >CH-O-CCl), and 4.25 (m, 2H, $CO_2CH_2CH_3$). Found: C, 61.90; H, 9.26%. Calcd for $C_{15}H_{27}ClO_3$: C, 61.95; H, 9.35%.

Compounds **2h** and **2i** were also obtained according to the same procedure as described above.

Ethyl 3-Chloro-2-oxoundecanoate (2h): IR (neat) 2950, 1750, 1470, 1255, 1030, and 870 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.90 (br, t, 3H, J=5 Hz, CH_3), 1.30 (q, 3H, J=7 Hz, $CO_2CH_2CH_3$), 1.20—2.40 (m, 14H, (CH_2)$_7$), 3.25 (t, 1H, J =3 Hz, >CH-O-), and 4.20 (m, 2H, $CO_2CH_2CH_3$). Found: C, 59.61; H, 8.75%. Calcd for $C_{13}H_{23}ClO_3$: C, 59.42; H, 8.82%.

Ethyl 2-Chloro-5,9-dimethyl-2,3-epoxy-8-decenoate (2i): IR (neat) 2950, 1750, 1450, 1380, 1270, and 1030 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.85—2.40 (m, 10H, (CH_2)$_2$-$CHCH_3CH_2$), 1.33 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 1.56 (s, 3H, $(CH_3)_2C$=CH), 1.65 (s, 3H, $(CH_3)_2C$=CH), 3.35 (t, 1H, J=7 Hz, >CHO-), 4.25 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), and 5.05 (m, 1H, $(CH_3)_2C$=CH). Found: C, 61.33; H, 8.26%. Calcd for $C_{14}H_{23}ClO_3$: C, 61.20; H, 8.44%.

Ethyl 3-Chloro-2-oxotridecanoate (7) was prepared by the procedure reported previously.[4c] A mixture of **2j** (9.71 g, 33.4 mmol), alumina (10 g), and xylene (25 ml) was heated under reflux with stirring for 2 h. After filtration, the solvent was evaporated to give an oil which was chromatographed on SiO_2 (hexane-acetone, 20 : 1), giving 8.20 g (84.4%) of **7**: IR (neat) 2950, 1735, 1470, 1300, 1070, and 790 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.90 (br. t, 3H, J=5.5 Hz, CH_3), 1.27 (m, 18H, (CH_2)$_9$), 1.38 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 4.21 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), and 4.82 (t, 1H, J=6 Hz, CHCl). Found: C, 61.94; H, 9.12%. Calcd for $C_{15}H_{27}ClO_3$: C, 61.95; H, 9.36%.

Ethyl *threo*-3-Chloro-2-hydroxytridecanoate (8). To a stirred mixture of $NaBH_4$ (52 mg, 1.37 mmol) and dry ethanol (3 ml) was added a solution of **7** (1.19 g, 4.10 mmol) in dry ethanol (2 ml) at 0°C. The mixture was stirred for 10 min at 0°C, then poured into ice water and neutralized with dilute HCl. The organic materials were extracted with dichloromethane, washed with water, and dried over $MgSO_4$. Concentration of the solvent gave a crude product (1.23 g) which was chromatographed on SiO_2 (hexane-acetone, 10 : 1) to give 1.00 g (84%) of **8**: threo/erythro (93 : 7) by HPLC analysis [column, SA-I (6 mmϕ × 250 mm); eluent, hexane-ethyl acetate (10 : 1), 1.25 ml min^{-1}]. Preparative HPLC gave 603 mg of *threo*-**8**: R_t=13.5 min; IR (neat) 3430, 1745, 1465, 1270, and 1135 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.86 (br. t, 3H, J=5 Hz, CH_3), 1.28 (br. s, 18H, (CH_2)$_9$), 1.30 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 4.16 (m, 2H, CHCl-CHOH-), and 4.25 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$). Found: C, 61.72; H, 9.92%. Calcd for $C_{15}H_{29}ClO_3$: C, 61.52; H, 9.98%. The component of R_t=21.6 min gave 64.4 mg of *erythro*-**8**: IR (neat) 3500, 1745, 1470, 1220, and 1130 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.86 (br. t, 3H, J=5 Hz, CH_3), 1.28 (br. s, 18H, (CH_2)$_9$), 1.30 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 4.16 (m, 2H, CHClCHOH), and 4.25 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$). Found: C, 61.70; 9.85%. Calcd for $C_{15}H_{29}ClO_3$: C, 61.52; H, 9.98%.

***threo*-3-Chloro-1,2-tridecanediol (9).** To a stirred mixture of $NaBH_4$ (266 mg, 7.0 mmol) and absolute ethanol (6 ml) was added a solution of **8** (1.64 g, 5.61 mmol) in absolute ethanol (4 ml) at 0°C. The mixture was stirred for 5 h at room temperature, then poured into ice water and neutralized with dilute HCl. The organic materials were extracted with dichloromethane. The combined extracts were washed with water, dried over $MgSO_4$, and the solvent was evaporated. The residual oil (1.40 g) was chromatographed on SiO_2 (hexane-acetone, 3 : 1) to give 1.12 g (79.7%) of **9**: TLC (hexane-acetone, 3 : 1), R_f = 0.37; mp 60 — 60.5°C (from pentane); IR (KBr) 3260, 2920, 1461, 1040, 1009, 882, and 690 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.90 (br. t, 3H, J=5.5 Hz, CH_3), 1.28 (br. s, 16H, (CH_2)$_8$), 1.5—2.7 (m, 4H, 2OH, CH_2CHCl), and 3.5—4.2 (m, 4H, $CHClCHOHCH_2OH$). Found: C, 62.36; H, 10.92%. Calcd for $C_{13}H_{27}ClO_2$: C, 62.26; H, 10.85%.

***cis*-2,3-Epoxy-1-tridecanol (10).**[8] Sodium (104 mg, 4.5 g-atom) was dissolved in 6 ml of absolute ethanol; a solution of **7** (1.01 g, 4.03 mmol) in absolute ethanol (4 ml) was added at 0°C. The mixture was stirred for 7 h at room temperature and then poured into ice water. After neutralization with dilute HCl, the organic materials were extracted with dichloromethane. The combined extracts were washed with water and dried over $MgSO_4$. The solvent was removed and the residual oil (1.12 g) was chromatographed on SiO_2 (hexane-acetone, 5 : 1), giving 856 mg (99.3%) of **10**: TLC (hexane-acetone, 3 : 1), R_f=0.30. Recrystallization from pentane gave 838 mg (97.2%) of **10**: mp 59.5—60.0°C (lit,[8b] 62.5—63.0°C for (−)-**10**; IR (KBr) 3500, 3400, 1461, 1103, 1027, 880, and 845 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.89 (br. t, 3H, J=5 Hz, CH_3), 1.05—1.95 (m, 19H, (CH_2)$_9$ and OH), 3.1 (m, 2H, -CH-CH-), and 3.73 (m, 2H, CH_2OH).

***cis*-2,3-Epoxytridecanal (11).**[8b] In a 50 ml two-necked flask was charged chromium trioxide (0.625 g, 6.25 mmol) and dried in vacuo under nitrogen. A solution of dry pyridine (1.97 g, 2 ml, 12.5 mmol) in dry CH_2Cl_2 (11 ml) was slowly added and the mixture was stirred for 30 min. After a solution of **10** (0.149 mg, 0.69 mmol) in dry CH_2Cl_2 (4 ml) was added dropwise, the mixture was stirred for 2.4 h and the organic materials were extracted with ether. The combined extracts were washed with 5% NaOH (10 ml), dilute HCl (10 ml), neutralized with aqueous $NaHCO_3$, washed with brine, and dried over $MgSO_4$. Evaporation of the sol-

vent gave 0.151 g of an oil which was chromatographed on SiO_2 (hexane-acetone, 15 : 1) to give 0.128 g (88.1 %) of **11**:[8b] IR (neat) 2950, 1730, 1470, and 840 cm^{-1}; ^1H NMR (CCl_4) $\delta = 0.86$ (br. t, 3H, $J = 5$ Hz, CH_3), 1.26 (m, 18H, $(CH_2)_9$), 3.15 (d, 2H, $J = 3.2$ Hz, >CH-O-CH<), and 9.30 (d, 1H, $J = 6.0$ Hz, CH=O).

2,3-Epoxytridecyl *p*-Toluenesulfonate (12). To 251 mg (1.32 mmol) of *p*-toluenesulfonyl chloride was added a solution of **10** (109 mg, 0.51 mmol) in pyridine (2 ml) at 0°C under an atmosphere of nitrogen. The mixture was stirred for 12 h and then poured into ice-water. The organic materials were extracted with ether. The combined extracts were washed with saturated $CuSO_4$, brine, and water successively, and dried over $MgSO_4$. Removal of the solvent gave 467 mg of an oil which was purified by preparative TLC (hexane-acetone, 3 : 1) to give 187 mg (99.1 %) of **12**: TLC (hexane-acetone, 3 : 1), $R_f = 0.33 - 0.46$: IR (neat) 2940, 1595, 1365, 1180, 1095, 970, 815, and 660 cm^{-1}; ^1H NMR (CCl_4) $\delta = 0.90$ (br. t, 3H, $J = 5$ Hz, CH_3), 1.30 (m, 18H, $(CH_2)_9$), 2.45 (s, 3H, $CH_3C_6H_4$), 2.70—3.15 (m, 2H, >CH-O-CH<), 4.03 (d, 2H, $J = 6$ Hz, CH_2OTs), 7.25 (d, 2H, $J = 8$ Hz, $CH_3C_6H_4$), and 7.73 (d, 2H, $J = 8$ Hz, $CH_3C_6H_4$). Found: C, 65.08; H, 8.76%. Calcd for $C_{20}H_{32}O_4S$: C, 65.18; H, 8.75%.

(±)-Disparlure (5). To a mixture of CuI (209 mg, 1.1 mmol) and dry ether (10 ml) was slowly added 2.3 ml (2.2 mmol) of 0.96 M 4-methylpentyllithium in ether at −22°C. After the mixture was stirred for 20 min at −20°C, a solution of **12** (76 mg, 0.21 mmol) in dry ether (4 ml) was added dropwise. The mixture was stirred for 20 min; then the ice bath was removed. After saturated NH_4Cl (15 ml) was added, the mixture was stirred for 30 min. The organic materials of the filtrate were extracted with ether three times and the combined extracts were washed with brine and dried over $MgSO_4$. Removal of the solvent gave 101 mg of an oil which was chromatographed on SiO_2 (hexane-acetone, 30 : 1) to afford 53 mg (89 %) of **5**: TLC (hexane-acetone, 3 : 1), $R_f = 0.81$. The IR and ^1H NMR data were identical with those of the literature.[7]

X-Ray Analysis of 4b. A crystal of dimensions 0.4×0.3×0.2 mm obtained from ethyl acetate-ether, was used for intensity measurement. Intensity data were obtained on a Rigaku AFC-5R diffractometer with graphite monochromatized Cu$K\alpha$ radiation, and using the $\theta - 2\theta$ scan technique ($2\theta \leqslant 128°$). The space group was approximated to be close to $P2_1/c$; however, a small number of very weak $0\,k\,0$ and $h\,0\,l$ reflections were observed for which $k \neq 2n$ and $1 \neq 2n$. The data were corrected for Lorentz and polarization effects but not for absorption. Among the 1014 unique reflection collected, 926 were considered to be observed at the 2.0 σ (F_o) level. Crystal data: $C_{12}H_{14}O_2Cl_2$, $Mr = 261.2$. Monoclinic, $P2_1/c$, $a = 6.858$ (1), $b = 9.630$ (3), $c = 9.307$ (4) Å, $\beta = 92.74$ (3)°, $U = 614.0$ Å^3, $Z = 2$, $Dx = 1.41$ g cm^{-3}. The structure was solved by direct method with MULTAN78 and refined by block-diagonal least-square methods. Positions of the hydrogen atoms were estimated from standard geometry. Final refinements with anisotropic temperature factors for the non-hydrogen atoms were reduced the R to 0.096.

The final atomic parameters, the full list of bond lengths and angles, and the F_o-F_c data have been deposited at the Chemical Sodiety of Japan (Document No. 8742).

We thank Mr. Shinichi Ninomiya for some experiments. We are grateful to Drs. Hajime Kato and Kazuhiko Kushida of Varian Instrument Ltd. for the measurement of two dimensional NMR spectra.

(Received February 17, 1987)

Several shorter analogues of heat-stable enterotoxin (ST) produced by *Yersinia enterocolitica* were synthesized by a conventional method and their toxicities were examined by using suckling mice. The full enterotoxigenic activity of ST of *Y. enterocolitica* was found to be carried on a peptide, which consists of 13 amino acid residues from the 18th Cys to the C-terminal Cys and has a similar amino acid sequence to those of ST's produced by enterotoxigenic *Escherichia coli* (S. Aimoto et al., *Eur. J. Biochem.*, **129**, 257 (1982)) and *Vibrio cholerae* non-01 (T. Takao et al., *FEBS Lett.*, **193**, 250 (1985)). The results imply that the structural elements for expression of the toxicity are present in the common amino acid sequences of ST's of *Y. enterocolitica*, *E. coli*, and *V. cholerae* non-01.

Some strains of *Yersinia enterocolitica* produce a heat-stable enterotoxin that is responsible for gastroenteritis in children.[1,2] Recently, we isolated six molecular species of the enterotoxin (named *Yersinia*-ST) from the culture supernatant of the bacteria,[3,4] purified them to homogeneity by high-performance liquid chromatography (HPLC) and determined their amino acid sequences, as shown in Fig. 1. These peptides had a common sequence from Asp at position 15 from the N-terminus to the C-terminal residue, although their N-terminal sequences differed in length. This finding suggested that peptides 2—6 in Fig. 1 were not synthesized individually in the cells, but derived from peptide **1** by proteolytic cleavage in the cells or after excretion from the cells. The amino acid sequence of *Yersinia*-ST from the 18th amino acid residue from the N-terminus to the C-terminal residue was very similar to those of STI's of enterotoxigenic *Escherichia coli*.[5,6] However, in *Yersinia*-ST the C-terminal residue is Cys without the additional Tyr residue present in STI's of *E. coli*. Moreover, the N-terminal portion of the sequence of *Yersinia*-ST from the 17th residue is quite different from those of STI's of *E. coli*. The homology and differences in the primary structures of STI's of *E. coli* and *Yersinia*-ST suggest common biological properties of the two but differences in their degrees of activity and physicochemical properties. These observations raised the question of whether most, or all

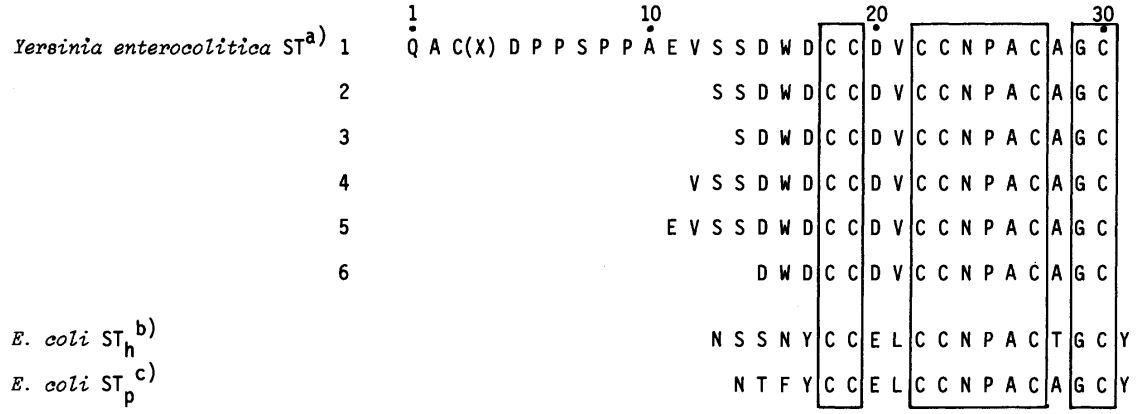

Fig. 1. Amino acid sequences of *Yersinia*-ST's and their comparison with those of ST_h and ST_p of enterotoxigenic *E. coli*. Amino acid residues in boxes are common to all sequences. a) Cited from Refs. 3 and 4. b) Cited from Ref. 5. c) Cited from Ref. 6. The single letter notations of amino acid residues are according to *J. Biol. Chem.*, **261**, 1 (1986).

† Part of this work was reported at the 21st Joint Conference on Cholera of the US-Japan Cooperative Medical Science Program at the National Institutes of Health, Oct. 21—23, 1985.

** Present address: National Children's Medical Research Center, Taishido, Setagaya-ku, Tokyo 154.

the toxicities of these ST's are due to the common sequence while the divergent sequences in the N-terminal and C-terminal regions merely represent the result of mutation, or whether these latter regions are responsible for the specific toxicities of the respective enterotoxins.

To elucidate the structure-activity relationship of *Yersinia*-ST, in this work we synthesized several shorter analogues of *Yersinia*-ST that had no N-terminal sequence or had an additional Tyr at the C-terminus, and examined their properties.

Experimental

The general and analytical methods used were as described previously.[7] All chemicals used for synthetic experiments were of reagent grade, while those used for analysis were of guaranteed grade and solvents were distilled before use. Carboxypeptidase B was obtained from Boehringer-Yamanouchi (Tokyo). A reversed-phase resin (YMC-ODS, S-5) was purchased from Yamamura Chemical Laboratories Co. (Kyoto) and packed in our laboratory into columns of 4×250 mm and 6×150 mm and 8×300 mm for analytical and preparative purposes. The abbreviations used in this paper are those recommended by the IUPAC-IUB [*J. Biol. Chem.*, **261**, 1 (1986)]. Additional abbreviations are: MBzl, *p*-methylbenzyl; TFA, trifluoroacetic acid; DMF, *N,N*-dimethylformamide; TEA, triethylamine; DMSO, dimethyl sulfoxide; HONSu, *N*-hydroxysuccinimide.

Peptide Synthesis. The protected linear peptides with the amino acid sequences of *Yersinia*-ST(16-30), *Yersinia*-ST(15-30), *Yersinia*-ST(14-30), Tyr^{31}-*Yersinia*-ST(18-30), and Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30) were synthesized according to the scheme shown in Fig. 2. Their experimental detail is described below.

Boc-Trp-Asp-Cys(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-OBzl (1). Boc-Asp(OBu')-Cys(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-OBzl[7] (0.42 g, 0.19 mmol) was dissolved in TFA (5 ml) and stirred at room temperature for 2 h. The solution was concentrated to a syrup, which was triturated in ether. The resulting powder was dissolved with Boc-Trp-ONSu (0.12 g, 0.28 mmol) in a mixture of DMF (1 ml) and 1-methyl-2-pyrrolidone (1 ml) and stirred at room temperature for 2 d. The solution was concentrated under reduced pressure to a solid, which was recrystallized from a mixture of EtOH and ether; 0.43 g (95.6%), mp 179—181 °C, $[\alpha]_D^{25}$ −38.0° (*c* 0.5, DMSO).

Found: C, 59.62; H, 6.41; N, 10.00; S, 8.00%. Calcd for $C_{119}H_{149}O_{23}N_{17}S_6 \cdot H_2O$: C, 59.66; H, 6.35; N, 9.94; S, 8.01%.

Z-Asp(OBu')-Trp-N_2H_3 (2). Z-Asp(OBu')-Trp-OMe[7] (2.62 g, 5.0 mmol) was dissolved in MeOH (100 ml) and mixed with 100% hydrazine hydrate (10 ml) in an ice-water bath. The mixture was stirred at room temperature for 2.5 h, concentrated under reduced pressure, and mixed with water. The resulting precipitate was recrystallized from a mixture of EtOH and ether; 1.8 g (68.7%), mp 195 °C (decomp), $[\alpha]_D^{20}$ −12.2° (*c* 1.0, DMF).

Found: C, 56.66; H, 6.73; N, 20.28%. Calcd for $C_{27}H_{33}O_6N_5 \cdot 3/2H_2O$: C, 56.72; H, 6.87; N, 19.60%.

Z-Asp(OBu')-Trp-Asp-Cys(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-

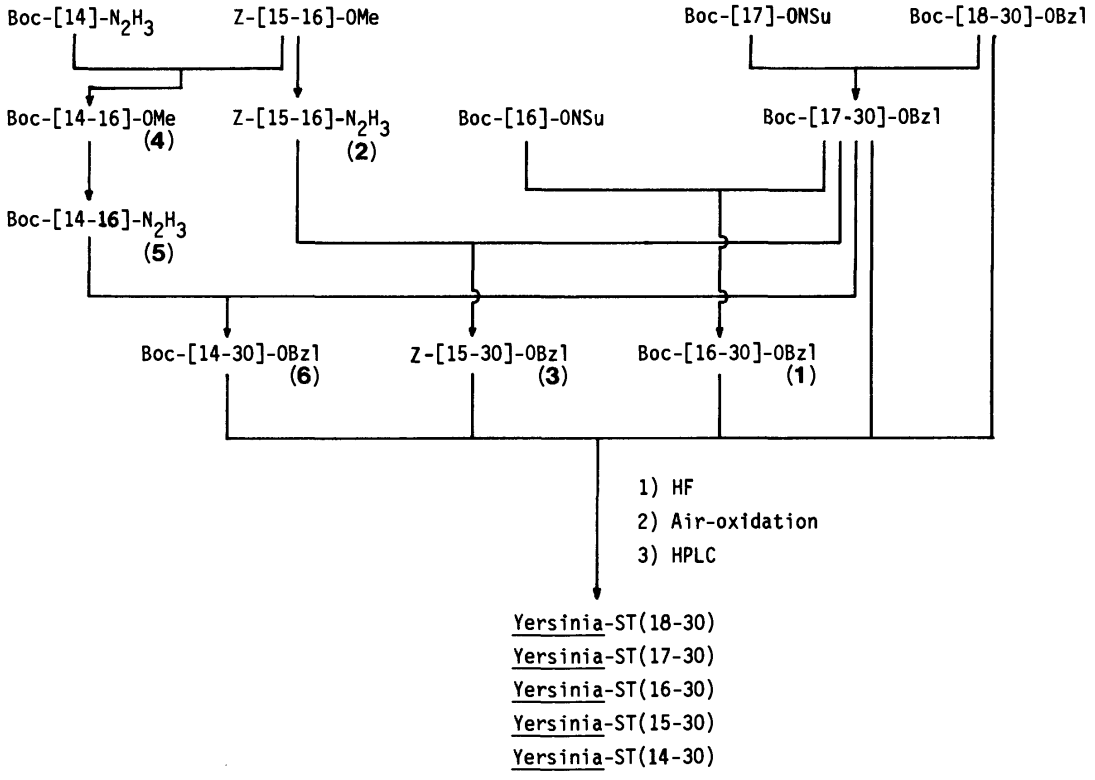

Fig. 2. Scheme for syntheses of shorter analogues of a heat-stable enterotoxin of *Y. enterocolitica*.

Ala-Gly-Cys(MBzl)-OBzl (3). Boc-Asp(OBu')-Cys-(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-OBzl[7] (1.12 g, 0.5 mmol) was dissolved in TFA (10 ml) and stirred at room temperature for 2.5 h. The residue was triturated in ether. Meanwhile, compound **2** (0.31 g, 0.6 mmol) was dissolved in DMF (4 ml), cooled below −20 °C, and treated with 6.72 M HCl (1 M≒1 mol dm^{-3}) in dioxane (0.7 ml) and isopentyl nitrite (0.1 ml, 0.7 mmol) at −20 °C for 30 min. The solution was then mixed with the above powder and TEA (0.87 ml) and stirred at 0 °C for 1 d. The solid isolated from the reaction mixture was recrystallized from a mixture of EtOH, DMF, and ether; 1.1 g (85.3%), mp 194 °C (decomp), $[\alpha]_D^{25}$ −69.4° (*c* 0.5, DMSO).

Found: C, 59.35; H, 6.15; N, 10.09; S, 7.40%. Calcd for $C_{130}H_{160}O_{26}N_{18}S_6 \cdot 2H_2O$: C, 59.62; H, 6.31; N, 9.63; S, 7.33%.

Boc-Ser-Asp(OBu')-Trp-OMe (4). Z-Asp(OBu')-Trp-OMe[7] (3.93 g, 7.5 mmol) was dissolved in MeOH (150 ml) and hydrogenated at room temperature for 40 min over 5% palladium-charcoal in the presence of a solution of 6.72 M HCl in dioxane (1.2 ml). The catalyst was filtered off and the filtrate was concentrated to a syrup under reduced pressure. Meanwhile, Boc-Ser-N_2H_3 (1.98 g, 9.0 mmol) was dissolved in DMF (20 ml) and cooled below −20 °C. The chilled solution was treated with 6.72 M HCl in dioxane (3.5 ml) and isopentyl nitrite (1.4 ml, 11 mmol) at the same temperature for 25 min. The solution was mixed with a solution of the above syrup in DMF (15 ml) and TEA (4.34 ml) and stirred at 0 °C for 1 d. The precipitate was filtered off and the filtrate was concentrated under reduced pressure to a syrup, which was dissolved in ethyl acetate and washed with 0.2 M HCl, 5% aq $NaHCO_3$, and water. The washed solution was dried over anhydrous Na_2SO_4 and then concentrated to dryness; 4.32 g (100%).

Boc-Ser-Asp(OBu')-Trp-N_2H_3 (5). Compound **4** (4.32 g, 7.5 mmol) was dissolved in MeOH (150 ml) and mixed with 100% hydrazine hydrate (15 ml) under cooling. The solution was stirred at room temperature for 2 h and concentrated under reduced pressure to a syrup, which was crystallized from EtOH and ether; 3.4 g (79.1%), mp 200 °C (decomp), $[\alpha]_D^{20}$ −13.7° (*c* 1.0, DMF).

Found: C,53.16; H,7.64; N,18.99%. Calcd for $C_{27}H_{40}O_8N_6 \cdot N_2H_4 \cdot H_2O$: C, 53.27; H, 7.28; N, 18.41%.

Boc-Ser-Asp(OBu')-Trp-Asp-Cys(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys-(MBzl)-Ala-Gly-Cys(MBzl)-OBzl (6). Boc-Asp(OBu')-Cys(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-OBzl[7] (0.99 g, 0.44 mmol) was dissolved in TFA (10 ml) and stirred at room temperature for 2 h. The solution was concentrated under reduced pressure to a syrup, which was triturated in ether. Meanwhile, compound **5** (0.32 g, 0.55 mmol) was dissolved in DMF (5 ml) and mixed with 6.72 M HCl in dioxane (0.87 ml) and isopentyl nitrite (0.78 ml, 0.6 mmol) below −20 °C. The mixture was stirred at the same temperature for 30 min, mixed with a solution of the above powder in DMF (10 ml), and stirred at 0 °C for 1 d. The mixture was concentrated to dryness under reduced pressure. The residue was washed with water and then recrystallized from EtOH and ether: 1.0 g (86.2%), mp 185 °C (decomp), $[\alpha]_D^{25}$ −55.4° (*c* 0.35, DMSO).

Found: C, 57.36; H, 6.11; N, 10.57; S, 7.28%. Calcd for $C_{130}H_{167}O_{28}N_{19}S_6 \cdot 4H_2O$: C, 57.63; H, 6.51; N, 9.83; S, 7.09%.

Boc-Cys(MBzl)-Cys(MBzl)-Asp(OBu')-Val-Cys-(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-Tyr-OBzl (7). Boc-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-Tyr-OBzl[8] (0.32 g, 0.2 mmol) was dissolved with anisole (0.07 ml) in TFA (2 ml) at 0 °C and stirred at room temperature for 50 min. The solution was concentrated under reduced pressure to a syrup, which was triturated in ether. Meanwhile, Boc-Cys(MBzl)-Cys(MBzl)-Asp(OBu')-Val-N_2H_3[7] (0.20 g, 0.25 mmol) was dissolved in DMF (2 ml) and cooled below −20 °C. The solution was treated with 6.72 M HCl in dioxane (0.14 ml) and isopentyl nitrite (0.04 ml) at −20 °C for 60 min. Then the mixture was mixed with *N*-methylmorpholine (0.2 ml) and a solution of the above powder in DMF (1 ml) and stirred at 0 °C for 6 d. The resulting precipitate was filtered off and the filtrate was concentrated under reduced pressure to a solid, which was washed with water and recrystallized from DMF and EtOH: 0.35 g (76.0%), mp 218—220 °C (decomp), $[\alpha]_D^{19}$ −55.6° (*c* 1.0, DMF).

Found: C, 61.03; H, 6.57; N, 9.27; S, 8.24%. Calcd for $C_{117}H_{151}O_{21}N_{15}S_6$: C, 61.20; H, 6.63; N, 9.15; S, 8.38%.

Boc-Cys(MBzl)-Cys(MBzl)-Asp(OBu')-Val-Cys-(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Thr-Gly-Cys(MBzl)-Tyr-OBzl (8). Boc-Cys(MBzl)-Cys-(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Thr-Gly-Cys(MBzl)-Tyr-OBzl[9] (1.64 g, 1.0 mmol) was treated with TFA (3.5 ml) and allowed to react with Boc-Cys(MBzl)-Cys(MBzl)-Asp-(OBu')-Val-N_3, which was prepared from Boc-Cys-(MBzl)-Cys(MBzl)-Asp(OBu')-Val-N_2H_3[7] (1.0 g, 1.2 mmol) according to the procedure described in **7**. The crude product was recrystallized from DMF and EtOH: 1.96 g (84.3%), mp 207.5—208.5 °C, $[\alpha]_D^{18}$ −46.5° (*c* 1.0, DMF).

Found: C, 60.76; H, 6.66; N, 8.89; S, 8.42%. Calcd for $C_{118}H_{153}O_{22}N_{15}S_6$: C, 60.93; H, 6.63; N, 9.03; S, 8.27%.

Removal of Protecting Groups and Air Oxidation. The protected peptides (Boc-Cys(MBzl)-Cys(MBzl)-Asp-(OBu')-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys-(MBzl)-Ala-Gly-Cys(MBzl)-OBzl,[7] Boc-Asp(OBu')-Cys-(MBzl)-Cys(MBzl)-Asp-Val-Cys(MBzl)-Cys(MBzl)-Asn-Pro-Ala-Cys(MBzl)-Ala-Gly-Cys(MBzl)-OBzl,[7] and compounds **1**, **3**, **6**, **7**, and **8**) (25 μmol) were each treated with anhydrous liquid hydrogen fluoride[10] and air-oxidized by the procedure described in Ref. 8. The solutions containing the deprotected and air-oxidized peptides were lyophilized and purified by HPLC, as described below.

High-Performance Liquid Chromatography (HPLC). The HPLC column was equilibrated with 10% CH_3CN in 0.05% TFA or 0.01 M ammonium acetate (pH 5.7) and after injection of the sample solution, was developed with a linear gradient of 10—40% CH_3CN with increase in CH_3CN concentration of 1% min^{-1} at a flow rate of 1 ml min^{-1}. Eluates were monitored for absorbance at 220 and 280 nm using a double-wavelength flow-through spectrophotometer.

Carboxypeptidase Digestion. The sample peptide (ca, 60 μg) was dissolved in 0.01 M pyridine acetate (pH 7.0) (50 μl) and mixed with carboxypeptidase B at a substrate; enzyme ratio (w/w) of 36 : 1. The solution was kept for 17 h at 37 °C and then the digested peptide was separated by HPLC.

Amino Acid Analysis and Fast Atom Bombardment

(FAB) Mass Spectrometry. The amino acid compositions and molecular weights of purified peptides were determined as described in a previous paper.[4]

Biological Assay. Toxicity was assayed in suckling mice of 2—4 d old as described previously.[11]

Heat Stability. The purified peptide was dissolved at a concentration of 200 μg ml^{-1} in 0.01 M phosphate buffered saline (pH 7.2), sealed in a capillary tube and heated for a given period at 100 or 120 °C. Then the solution was cooled in an ice bath and analyzed by HPLC, as described above.

Results and Discussion

Chemical Synthesis. To elucidate the structure-activity relationship of *Yersinia*-ST, in this work we tried to synthesize shorter analogues of *Yersinia*-ST with progressively fewer N-terminal amino acid residues or an additional Tyr residue at the C-terminus or with a replacement by Thr at position 28. In previous work,[7] we synthesized *Yersinia*-ST(13-30) (peptide **2** in Fig. 1), which has the sequence from the 13th residue from the N-terminus to the C-terminal residue, and found that the peptide had the same biological properties as those of the corresponding native peptide. This indicated that the procedure for synthesis of *Yersinia*-ST(13-30) is suitable for the syntheses of *Yersinia*-ST peptides. Therefore, we used this procedure for the syntheses of protected linear peptides **1**, **3**, and **6** which had 15, 16, and 17, respectively, of the amino acid residues in the C-terminal portion of *Yersinia*-ST as shown in Fig. 2. All the protecting groups in these protected peptides **1**, **3**, and **6** were removed by their treatment with anhydrous liquid hydrogen fluoride. Boc-[18-30]-OBzl and Boc-[17-30]-OBzl in Fig. 2, which were intermediates in the syntheses of **1**, **3**, and **6** and had 13 and 14 of the amino acid residues in the C-terminal region of *Yersinia*-ST, were also deprotected by treatment with hydrogen fluoride. The resulting free linear peptides were spontaneously oxidized by air in dilute solution (5×10^{-5} M) until no free mercapto groups were detectable.[12] All the *Yersinia*-ST peptides thus synthesized except *Yersinia*-ST(14-30) were obtained as main products by HPLC after deprotection and air-oxidation, suggesting that peptides with the same disulfide linkages as those

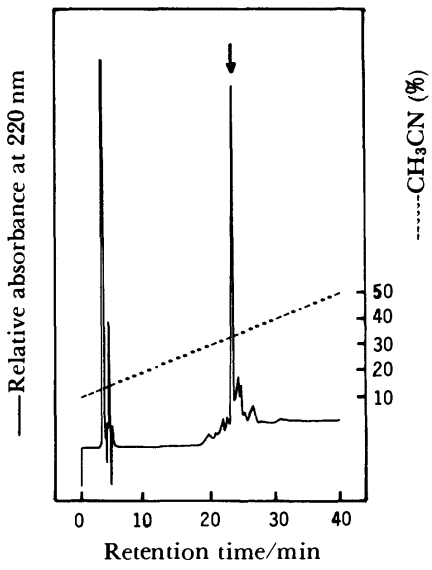

Fig. 3. HPLC profiles on a reversed-phase column (YMC-ODS S-5, 8×300 mm) of a deprotected and air-oxidized solution of compound **1**. The peak fraction marked by an arrow was separated as *Yersinia*-ST(16-30).

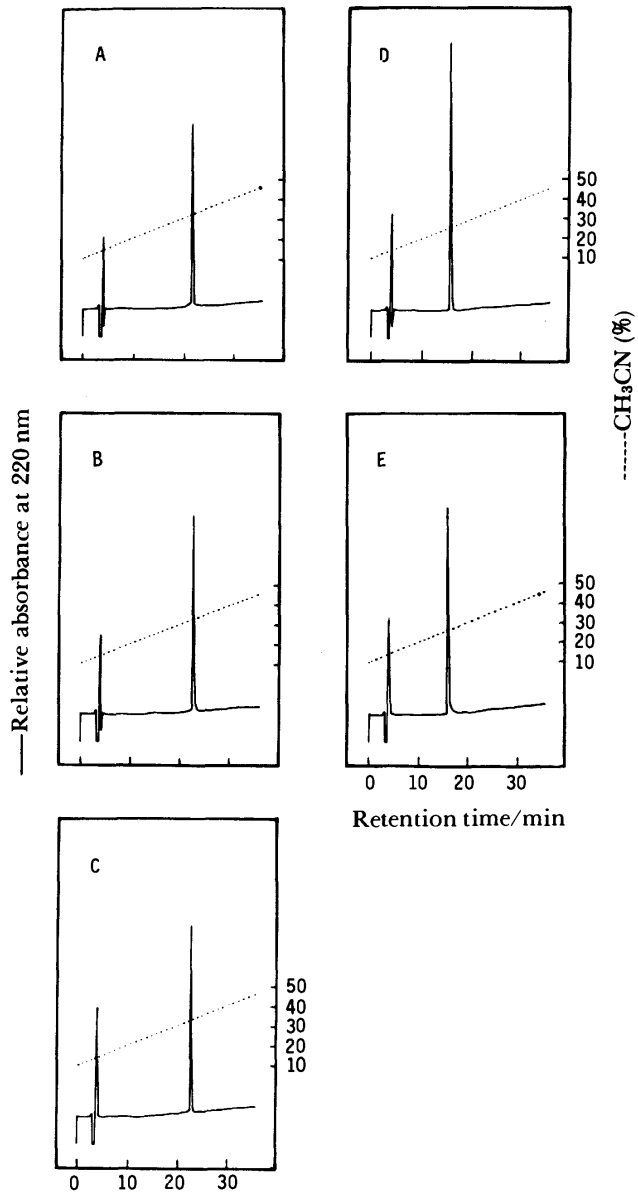

Fig. 4. HPLC profiles of purified synthetic *Yersinia*-ST peptides on a reversed-phase column (YMC-ODS S-5, 6×150 mm): A) *Yersinia*-ST(14-30); B) *Yersinia*-ST(15-30); C) *Yersinia*-ST(16-30); D) *Yersinia*-ST-(17-30); E) *Yersinia*-ST(18-30).

of native *Yersinia*-ST are thermodynamically most stable, as described below. Typical examples of the HPLC profiles of the air-oxidized products are shown in Fig. 3. *Yersinia*-ST(14-30) could be recovered by HPLC only as a minor peak, and it was very difficult to identify its peak on HPLC. Therefore, a deprotected and air-oxidized solution of synthetic *Yersinia*-ST(14-30) was coeluted with the corresponding native peptide (peptide **3** in Fig. 1), and in this way synthetic *Yersinia*-ST(14-30) was isolated. The low yield of *Yersinia*-ST(14-30) after deprotection and air-oxidation is probably due to various side-reactions in the deprotection, because the air-oxidized solution of *Yersinia*-ST(14-30) showed various unidentified peaks on an HPLC (not shown). The HPLC profiles of the purified synthetic peptides are depicted in Fig. 4.

The protected peptides with an additional Tyr residue at the C-terminal position (**7** and **8**) were also synthesized by the same way as that shown in Fig. 2. After treatment of **7** and **8** with hydrogen fluoride, the deprotected peptides were air-oxidized and purified by HPLC, to give Tyr^{31}-*Yersinia*-ST(18-30) and Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30), respectively (Fig. 5). Thr^{28}-*Yersinia*-ST(18-30) was prepared by digestion of Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30) with carboxypeptidase B. The amino acid compositions, mass values, and yields of the purified synthetic peptides are summarized in Table 1.

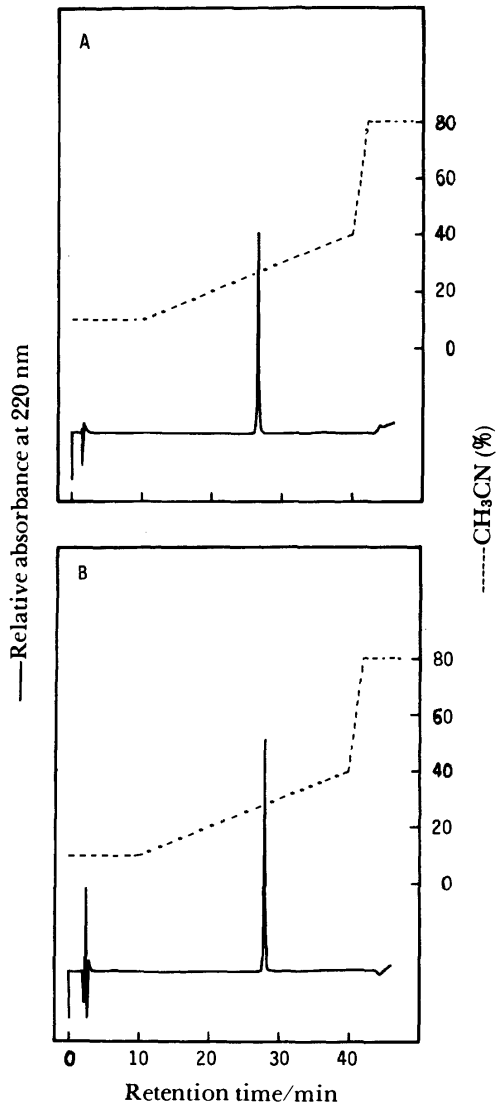

Fig. 5. HPLC profiles of A) purified Tyr^{31}-*Yersinia*-ST(18-30) and B) purified Thr^{28}, Tyr^{31}-*Yersinia*-ST-(18-30) on a reversed-phase column (YMC-ODS S-5, 4X250 mm).

Identification of Synthetic *Yersinia*-ST Peptides with Native Peptides. In a previous paper,[7] we presented evidence that synthetic *Yersinia*-ST(13-30) had the same structure as native peptide **2** in Fig. 1. To confirm that the *Yersinia*-ST peptides synthesized in this work had the same structure as native *Yersinia*-ST, we compared their retention times on HPLC with those of the corresponding native *Yersinia*-ST peptides. One-step Edman degradation of synthetic *Yersinia*-ST(13-30), which had the same structure as native *Yersinia*-ST(13-30),[7] gave a peptide with the same retention time on HPLC as synthetic *Yersinia*-ST(14-30). Synthetic *Yersinia*-ST(15-30) had the same retention time on HPLC as not only native peptide **3** in Fig. 1 but also *Yersinia*-ST(15-30), which was derived from synthetic *Yersinia*-ST(13-30) by digestion with aminopeptidase M. On HPLC synthetic *Yersinia*-ST(16-30) was eluted at the same position as preparations of *Yersinia*-ST(16-30) obtained both from synthetic *Yersinia*-ST(15-30) by the Edman reaction and from synthetic *Yersinia*-ST(17-30) by coupling with Boc-Trp-ONSu. Synthetic *Yersinia*-ST (18-30) was identical on HPLC with synthetic *Yersinia*-ST(17-30) degraded by the Edman reaction. Furthermore, digestions with carboxypeptidase B of synthetic Tyr^{31}-*Yersinia*-ST(18-30) and Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30), which were prepared from compounds **7** and **8**, gave *Yersinia*-ST(18-30) and Thr^{28}-*Yersinia*-ST(18-30), respectively. The former peptide was identical on HPLC with synthetic *Yersinia*-ST(18-30), which was obtained directly from Boc-[18-30]-OBzl, indicating that Tyr^{31}-*Yersinia*-ST(18-30) had the same structure as *Yersinia*-ST(18-30). A typical example of the correlation of the HPLC profiles of *Yersinia*-ST peptides with each other is shown in Fig. 6. These results demonstrate clearly that the synthetic *Yersinia*-ST peptides had the same structure as the native *Yersinia*-ST peptides. The correlations between these synthetic and native *Yersinia*-ST peptides are summarized in Fig. 7.

Biological Activity. The toxic activities of *Yersinia*-ST peptides synthesized in this paper were examined by the fluid accumulation test in suckling mice.[11] The minimum effective doses of *Yersinia*-ST(14-30), *Yersinia*-ST(15-30), *Yersinia*-ST(16-30), *Yersinia*-ST(17-30), and *Yersinia*-ST(18-30) were all be-

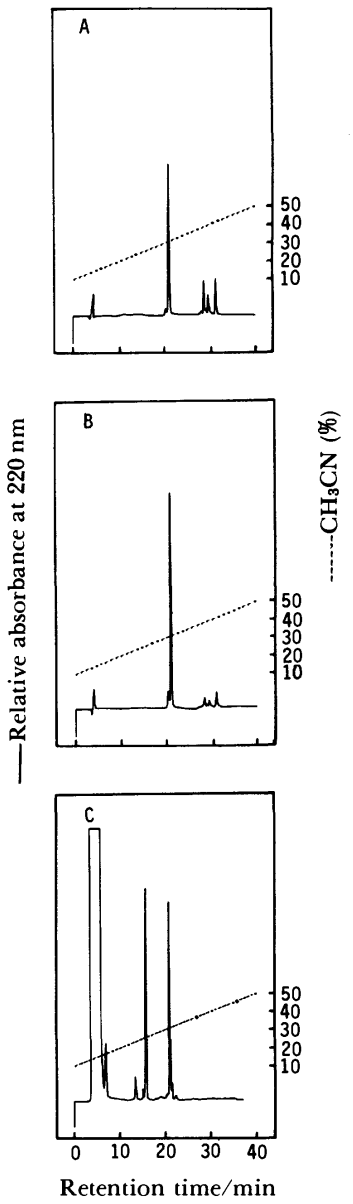

Fig. 6. HPLC profiles on a reversed-phase column (YMC-ODS S-5, 6×150 mm): A) synthetic *Yersinia*-ST(15-30) after one-step Edman degradation, B) a mixture of A) and synthetic *Yersinia*-ST(16-30), C) synthetic *Yersinia*-ST(17-30) after coupling with Boc-Trp-ONSu and removal of the Boc group.

tween 12.5 and 25 ng, as shown in Table 1, indicating that the N-terminal amino acid sequence from the 17th amino acid residue is not concerned in expression of the toxicities of *Yersinia*-ST. Namely, the enterotoxigenic activity of *Yersinia*-ST is carried on *Yersinia*-ST(18-30), which consists of 13 amino acid residues from the 18th Cys to the C-terminal Cys. This observation suggests that the divergency of the amino acid sequences in the N-terminal regions of ST's of *Y. enterocolitica* and *E. coli* is not related to their toxicities, but that the structural elements for expression of their toxicities are present in the commom amino acid sequences of ST's of *Y. enterocolitica* and *E. coli*.

Previously, we synthesized various analogues of ST's of enterotoxigenic *E. coli* and found that the minimum effective doses of their 13 amino acid peptides, which correspond to the sequence of *Yersinia*-ST from Cys at position 18 to the C-terminus, were 0.6 ng.[13] The activity of *Yersinia*-ST(18-30) was one-twentieth to one-thirtieth of those of *E. coli* peptides. The lower toxicity of *Yersinia*-ST(18-30) is considered to be due to the differences of amino acid residues in the common sequences of ST's of *Y. enterocolitica* and *E. coli*, that are at positions 20, 21, and 28 of *Yersinia*-ST(18-30).

The amino acid residue at position 28 is Ala in *Yersinia*-ST, but Thr in ST_h of *E. coli*, as shown in Fig. 1. To elucidate the effect of this amino acid residue on the biological activity of *Yersinia*-ST, we examined the activity of an analogue of *Yersinia*-ST(18-30), Thr^{28}-*Yersinia*-ST(18-30), in which Ala at position 28 is replaced by Thr. As shown in Table 1, Thr^{28}-*Yersinia*-ST(18-30) showed almost the same activity as *Yersinia*-ST(18-30). This result indicated that the toxicity of *Yersinia*-ST is not influenced by replacement of the amino acid residue at position 28 of *Yersinia*-ST by Thr.

The C-terminal amino acid residue, which is Tyr in ST's of *E. coli*, is not related to their toxicities.[13] Since this amino acid residue does not exist in *Yersinia*-ST, it was supposed that the addition of this residue to the C-terminus of *Yersinia*-ST would not effect the toxicity of *Yersinia*-ST. However, we synthesized two analogues of *Yersinia*-ST(18-30) with an additional Tyr at the C-terminus, Tyr^{31}-*Yersinia*-ST(18-30) and Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30), and found that these peptides had twice and four times the activity of *Yersinia*-ST(18-30), respectively. A monoclonal antibody (ST_h 8G7) raised against native ST_h of *E. coli* recognizes an epitope including the C-terminal Tyr residue of ST_h of *E. coli*, but does not react with synthetic analogues of ST_h lacking its C-terminal Tyr residue.[14,15] Synthetic *Yersinia*-ST peptides do not react with this monoclonal antibody over the range of their concentrations from 0.5 to 0.03 $\mu g\ ml^{-1}$ in an enzyme-linked immunosorbent assay system. However, Tyr^{31}-*Yersinia*-ST(18-30) and Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30) bind with this antibody. These results suggest that the addition of a Tyr residue to the C-terminus of *Yersinia*-ST(18-30) makes the tertiary structure around the Tyr residue in Tyr^{31}-*Yersinia*-ST(18-30) and Thr^{28}, Tyr^{31}-*Yersinia*-ST(18-30) somewhat similar to that of ST_h of *E. coli*, with resulting increase in toxicity.

The results discussed above imply that the lower toxicity of *Yersinia*-ST(18-30) than of ST_h(6-18) of *E. coli*, which consists of the sequence from position 6 to 18 in ST_h of *E. coli*, is mainly due to the difference in the amino acid residues at positions 20 and 21 of *Yersinia*-ST. In fact, a preliminary experiment showed

Table 1. Amino Acid Compositions[a], Mass Values[b], Yields, and Biological Activities[c] of Synthetic Peptides

a) Values were calculated as mol/mol of Ala; numbers in parentheses indicate theoretical values. b) $[M+H]^+$, mass value of quasi-molecular ion. c) MED, minimum effective dose.

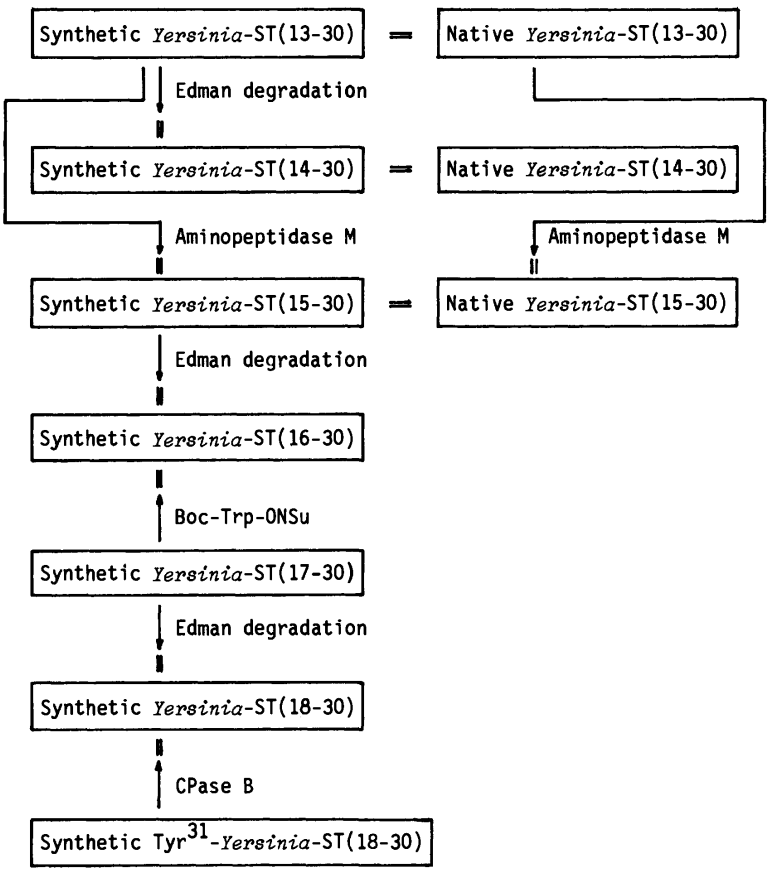

Fig. 7. Structural relationships of synthetic and native *Yersinia*-ST peptides.→=denotes that for example the reaction product of synthetic *Yersinia*-ST(13-30) obtained by Edman degradation is identical as judged by HPLC with synthetic *Yersinia*-ST(14-30).

that substitution of the amino acid residues at positions 20 and 21 in *Yersinia*-ST(18-30) by other amino acid residues influenced the toxicity, as will be reported elsewhere.

Heat Stability. Previously, a crude preparation of *Yersinia*-ST was found to be more heat-stable than a preparation of ST of *E. coli*.[6] In this work, to obtain detailed information about the heat-stability of *Yersinia*-ST peptides, we examined the heat-stabilities of synthetic shorter analogues. Figure 8 shows the HPLC profiles of synthetic *Yersinia*-ST(18-30) after its treatment at 100 and 120 °C for various times. After treatment at 100 °C for 30 min, the peak area of synthetic *Yersinia*-ST(18-30) on HPLC was reduced to about three-quarters of that of the untreated peptide. Under the same conditions the peak area of ST_h of *E. coli* is decreased drastically.[7] Furthermore, after heating at 100 °C for 60 min or at 120 °C for 10 min about two-thirds of the synthetic peptide remained unchanged, and on heating at 120 °C for 60 min the peptide was almost completely destroyed. This heat-stability of *Yersinia*-ST(18-30) was similar to that of synthetic *Yersinia*-ST(13-30) reported previously,[7] indicating that the N-terminal region from position 17 of *Yersinia*-ST does not affect its heat-stability.

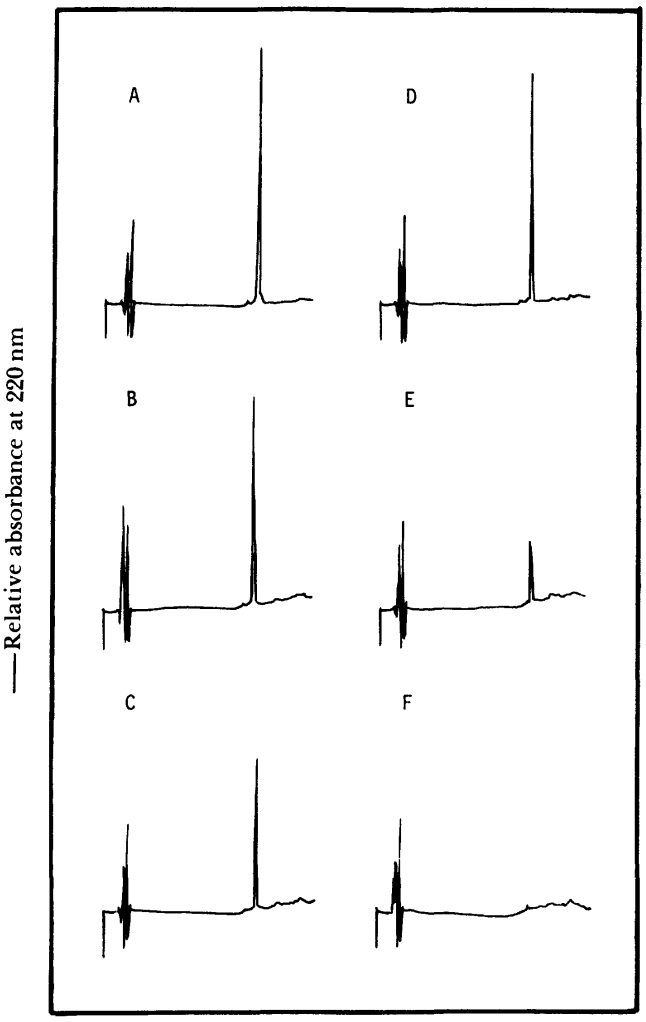

Fig. 8. HPLC profiles on a reversed-phase column (YMC-ODS S-5, 6×150 mm) of synthetic *Yersinia*-ST (18-30) treated under the following conditions: A) at 100 °C for 10 min, B) at 100 °C for 30 min, C) at 100 °C for 60 min, D) at 120 °C for 10 min, E) at 120 °C for 30 min, and F) at 120 °C for 60 min.

Recently, we reported that ST_h(6-19) of *E. coli*, which lacks the five N-terminal amino acid residues of ST_h of *E. coli*, has higher heat-stability than ST_h of *E. coli* with the whole amino acid sequences or ST_h(5-19) of *E. coli*, which lacks the four N-terminal amino acid residues of ST_h of *E. coli*.[7] These results imply that removal of the amino acid residues located at the N-terminal region from Tyr at position 5 results in increase of heat-stability of ST_h of *E. coli*. Moreover, the C-terminal Tyr residue is not related to the heat-stability of ST_h of *E. coli*, because ST_h(6-18) of *E. coli*, which lacks the C-terminal Tyr of ST_h(6-19) of *E. coli*, showed almost the same heat-stability as the latter.

The heat-stabilities of synthetic *Yersinia*-ST(13-30)[7] and *Yersinia*-ST(18-30) were higher than that of ST_h of *E. coli* and comparable with that of synthetic ST_h(6-19) of *E. coli*. Thus the degrees of heat-stability of heat-stable enterotoxins, in other words, the effects of heating in perturbation of their molecules, are due to differences in their N-terminal amino acid sequences.

This study was supported in part by a Grant-in-Aid for Scientific Research (No. 59340034 to Y. S.) from the Ministry of Education, Science and Culture. We are indebted to Mrs. Aiko Kobatake for elemental analysis and preparation of the manuscript.

Pyrolysis of Sulfoxide Bearing Electron-Withdrawing Substituents on β-Position in *S*-Ethyl Group of Ethyl Phenyl Sulfoxide

Toshiaki YOSHIMURA, Masaki YOSHIZAWA, and Eiichi TSUKURIMICHI*
Department of Industrial Chemistry, Faculty of Engineering, Toyama University, Gofuku, Toyama 930
(Received October 24, 1986)

In order to obtain information concerning the reaction mechanism of the pyrolysis of a sulfoxide bearing an electron-withdrawing substituent on the β-position in the *S*-ethyl group of ethyl phenyl sulfoxide, 2-(substituted phenyl)ethyl aryl sulfoxides(**1**) and 2-cyanoethyl (substituted phenyl) sulfoxides(**2**) were pyrolyzed. The rate-enhancing effect of the β-phenyl group of **1** was small. The activation enthalpy and entropy of **1** were found to be 110 kJ mol^{-1} and -45 JK^{-1} mol^{-1}, respectively. Hammett plots for **1** gave positive trends for the substituents, both on the β-phenyl group (ρ=0.76) and on the *S*-phenyl group (ρ=0.32), though the ρ-value of the latter was about half of the former. On the other hand, the Hammett plot for **2** did not give a straight line, but a concave curve in which a series of substituents from the *p*-OCH_3 to *p*-Cl groups gave a negative trend (ρ=$-$0.49), while the *p*-NO_2 group afforded a positive trend. The pyrolytic rate of **2** was found to be about 23-times faster than that of **1** at 100 °C. The kinetic isotope effect for β-position hydrogen in the β-phenylethyl group of **1** was considerably large (k_H/k_D=4.3). From the obtained results, it was suggested that the pyrolysis of **1** and **2** proceeds via a nearly carbanion-like mechanism in a five-membered cyclic transition state.

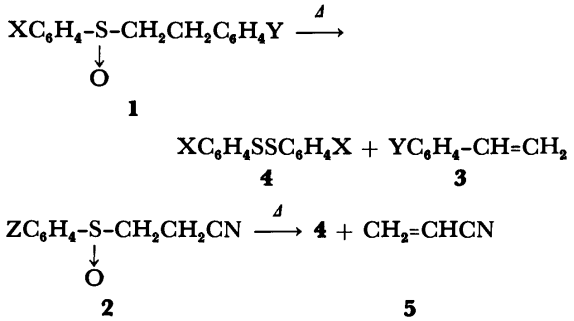
Sulfoxides having at least one hydrogen atom on the β-position carbon in the *S*-alkyl group are easily decomposed to give olefins, like *N*,*N*-dimethyl-2-phenylethylamine oxide,[1] at relatively lower temperatures than those in the pyrolysis of xanthates, i.e., a Chugaev elimination reaction.[2] From studies on the pyrolysis of various sulfoxides, it has been suggested that the reaction proceeds through a five-membered cyclic transition state:[6] That is, a concerted cis-elimination process, like a Cope reaction.[1,8] Three types of the Ei reaction mechanisms (an ideal cis-concerted[3] (i.e., the electron-delocarized state), an El-like[4,5] and a radical pair[6] process) have been observed in the pyrolysis of various sulfoxides of different molecular structures. For example, Emerson et al.[3] concluded that the pyrolysis of *s*-butyl propyl sulfoxide proceeds via an ideal concerted mechanism from observations of the product distribution. In contrast, phenyl propyl sulfoxide[4] and phenyl *t*-butyl sulfoxide[5] are considered to decompose thermally via an El-like process from observations of Hammett substituent effects.

On the other hand, Kingsbury and Cram[6] found that a stereospecific cis-elimination of 1,2-diphenylpropyl phenyl sulfoxides (**7**) is accompanied by a concomitant radical C-S bond cleavage. It is of interest to determine the mechanism regarding the pyrolysis of the sulfoxide bearing an electron-withdrawing group on the β-position in the *S*-ethyl group of ethyl phenyl sulfoxide; this has not yet been investigated kinetically.

Thus, 2-(substituted phenyl)ethyl phenyl sulfoxides (**1**) and 2-cyanoethyl (substituted phenyl) sulfoxides (**2**) were prepared and subjected to pyrolysis. In the present paper, we give a detailed account of a kinetic study of the pyrolysis of the reaction system as well as a possible mechanism.

Results and Discussion

Reaction Products. Pyrolysis was carried out by heating a solution of the sulfoxide in dioxane in a sealed tube in a thermostat adjusted to within the range ± 0.05 °C of the desired temperature. Though the reaction products were not actually isolated, the products were identified by comparing their HPLC and GLPC with those of authentic samples. Thus, under these reaction conditions, the resultant products were found to be both substituted styrene (**3**) and substituted diphenyl disulfide (**4**); **2** produced both **4** and acrylonitrile (**5**). The disulfide **4** is probably formed via an initial formation of arenesulfenic acid followed by a dimerization process.[14,15]



The NMR spectra of the product mixtures that resulted from the pyrolysis of sulfoxides **1** and **2** in CCl_4 in sealed tubes at 100 °C showed that the yields of **3** and **5** are nearly quantitative.

Kinetics. Kinetic measurements were carried out by following the intensity of the UV absorption (254 nm) by means of HPLC. In order to obtain pyrolytic information concerning the sulfoxide bearing a stronger electron-withdrawing group than the phenyl group

a) The rate constants were calculated by the least-squares method and the errors are standard diviations. b) The datum for *p*-nitro derivative is not included in calculation.

on the β-position, **2** was also subjected to pyrolysis. The reaction rates of the sulfoxides were all correlated in a fine manner with a first-order equation with respect to the concentration of the substrate.

The kinetic data obtained are summarized in Table 1.

An Arrhenius plot for 2-phenylethyl phenyl sulfoxide afforded a good straight line; the activation enthalpy (110 kJ mol^{-1}) and a considerably small activation entropy (−45 J K^{-1} mol^{-1}) were obtained. A comparison of the pyrolytic rate of **1** to that of other sulfoxides are listed in Table 2.

The pyrolytic rate of 2-cyanoethyl phenyl sulfoxide (**2**) was found to be 200-times faster than that of ethyl phenyl sulfoxide (**6**), while that of **1** was only 8-times faster than that of **6**. This finding reveals that the rate-enhancing effect of the β-phenyl group in the reaction system is rather small.

Kinetic Isotope Effect. The kinetic isotope effect using 2-phenylethyl-2,2-d_2 phenyl sulfoxide was measured and the effect was found to be $k_H/k_D=4.3$ (120 °C). The large kinetic isotope effect apparently reveals that the reaction process involves C-H bond breaking in a rate-determining step.

Table 2. The Relative Rates of Pyrolysis of Sulfoxides at 100 °C in Dioxane

Sulfoxide	Rate constant $k\times10^5$ s^{-1}	Relative rate
PhS(O)CH_2CH_3	0.165	1
PhS(O)$CHCH_3$ (threo)	43.5	264
Ph (erythro)	83.9	508
PhS(O)CH_2CH_2Ph	1.41	8.55
PhS(O)CH_2CH_2CN	33.0	200

The magnitude of the effect is larger than those for the pyrolysis of heptyl-2-*d* phenyl sulfoxide ($k_H/k_D=2.9$)[10] and *cis*- and *trans*-*N*,*N*-dimethylcyclooctyl-2-

Table 3. Solvent Effect on Pyrolysis of 2-Phenylethyl Phenyl Sulfoxide at 120 °C

Solvent	Dielectric constant	Rate constant $k\times10^5$ / s^{-1}	Relative rate
Dioxane	2.21	10.5 ±0.3	1
Benzene	2.27	9.00±0.34	0.86
DMSO	48.9	6.02±0.22	0.57
Acetonitrile	37.5	4.13±0.08	0.39
Ethanol	24.3	1.73±0.08	0.16

d-amine oxide ($k_H/k_D = 3.5$) in benzene,[7] which proceed via a five-membered cyclic transition state.[8]

Substituent Effect. The substituent effects for the pyrolysis of **1** and **2** were studied in dioxane. Figure 1 shows Hammett plots for **1** with both β-aryl and *S*-aryl substituents at 120 °C.

As is apparent from Fig. 1, log *k* nicely correlates with σ-values, showing a positive trend for both the X-side ($\gamma = 0.96$) and the Y-side ($\gamma = 0.99$). The ρ-value for the Y-side was +0.76, while that for the X-side ($\rho = +0.33$) was only about half of the Y-side. Thus, in the pyrolysis of **1**, electron-withdrawing substituents are apparently more favorable than electron-releasing types. On the other hand, the Hammett relation for **2** did not afford a straight line, but a concave curve in which a series of the substituents from the *p*-OCH_3 to *p*-Cl groups gave a negative trend ($\rho = -0.49$, $\gamma = 0.97$), while the *p*-NO_2 group, as a strong electron-withdrawing substituent, afforded a positive trend. The effect for **2** is shown in Fig. 2.

It appears at first sight that, due to the negative trend, that pyrolysis proceeds via another mechanism than that for **1**. However, since the effect corresponding to that of X-substituents in **1** is small, the pyrolysis mechanism should also be the same as that for **1**. The result of a Hammett relation for **2** together with the behavior of the *p*-NO_2 substituent will be discussed later.

Solvent Effects. Pyrolysis was carried out in five kinds of solvents; the obtained rate constants are summarized in Table 3. The pyrolysis was not much affected by solvent change. Though it seems that an increase in the solvent polarity tends to cause a retardation of pyrolysis, the rates of pyrolysis are not correlated to the dielectric constants and the effect is small. This indicates that the transition state of the reaction is not ionic. This observation is similar to those for the pyrolysis of sulfilimines[11] and sulfoxides **7**,[6] except for reactions in protic solvents. The small decrease in the rate for reactions in dipolar aprotic solvents is interpreted in view of the more solvation in the starting state by a dipole-dipole interaction than in the transition state. Meanwhile, a large rate retardation in the pyrolysis of sulfoxides and sulfilimines in protic solvents has been shown.[8] Kingsbury and Cram reported that the pyrolysis of sulfoxide **7** in methanol is 1000-times slower than that in dioxane.[6] Though the rate difference in both solvents is not so large, hydrogen-bonding to the sulfoxide oxygen in the starting state apparently prevents pyrolysis. Recently, we demonstrated the effect of hydrogen-bonding in the pyrolysis of aryl ethyl sulfilimines in protic solvents.[16]

From the above results the following conclusion can be obtained. In the first place, the considerably large β-hydrogen kinetic isotope effect rules out a radical pair mechanism, since the free radical mechanism involving the rate-determining C-S bond cleavage is not in accord with the large kinetic isotope effect.

Secondarily, an E1-like mechanism is also ruled out because of the positive ρ-value for Y-substituents and the small ρ-value for X-substituents. For example, recently it has been found that the pyrolysis of 1-phenylethyl phenyl sulfoxide, which has been revealed to proceed via an E1-like mechanism, gives relatively large positive ρ-values for *S*-phenyl substituents and negative ρ-values for electron-releasing substituents on 1-phenyl group.[9]

Oae et al.[11] proposed that the pyrolysis of *S*-(1- and 2-phenylethyl)-*S*-phenyl-*N*-tosylsulfilimines proceeds via an E1-like cis-concerted mechanism in view of the following results: A small kinetic isotope effect ($k_H/k_D=2.9$), a substituent effect of the opposite relation giving a positive ρ-value for *S*-aryl substituents against a negative one for 1-aryl substituents, a large rate acceleration by α-phenyl group and a small rate-enhancing effect of β-phenyl group [$k_{Ph}/k_H=2000$ for $PhS(NTs)CH(R)CH_3$, $k_{Ph}/k_H=1.5$ for $PhS(NTs)-CH_2CH_2R$ (R=H and Ph)].

However, in system **1**, the substituent effect on the β-phenyl group gave a positive Hammett correlation in both ρ_Y and ρ_X; also, the kinetic isotope effect for β-hydrogen gave a large value. Thus, the present data suggest that the pyrolysis of both **1** and **2** proceed via a nearly carbanion-like internal concerted cis-elimination.

The small rate-enhancing effect of the β-phenyl group might reveal that pyrolysis proceeds via an E1-like mechanism, since some E2 reactions[12] and Cope eliminations,[13] which are presumed to proceed via a nearly carbanion like mechanism, show large rate-enhancements by the β-phenyl group.[12,13] For the above reason, the small enhancement effect appears to be somewhat inconsistent with the nearly carbanion like mechanism; however, it may be explaind as follows. In general, the pyrolysis of the alkyl aryl sulfoxides tends to proceed, essentially, via an E1-like mechanism, which should give a positive Hammett ρ-value in the substituent effect on the *S*-phenyl group. On the other hand, in the nearly carbanion-like mechanism, the basicity of a sulfoxide-oxygen atom should affect the rate of the reaction giving a negative Hammett ρ-value for the substituent effect on the *S*-phenyl group. In the pyrolysis of **1** the ρ-value still shows a positive trend like other sulfoxides,[4] though the trend becomes considerably small. This small positive ρ-value is attributed to the substituent effect on the *S*-phenyl group being more susceptible to C-S bond cleavage than proton abstraction. In other words, the 2-phenyl group as a relatively weak electron-withdrawing substituent is insufficient to give a negative trend in the Hammett relation for *S*-phenyl substituents.

Therefore, the sulfoxide bearing a stronger electron-withdrawing group at the β-position can be expected to give a negative Hammett ρ-value. Thus, the

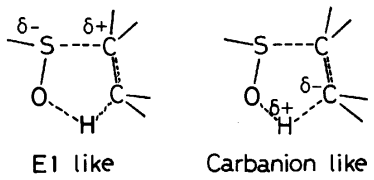

Fig. 3. El-like and Carbonion-like cyclic transition states.

Hammett relation on the pyrolysis of **2** indicated a negative trend. The result reveals that the transition state is apparently changed to a nearly carbanion-like type by the CN group as a stronger electron-withdrawing group than the phenyl type. Meanwhile, the positive trend for the *p*-Cl to the *p*-NO_2 group in the Hammett plot may be explained as follows. The substituent, the *p*-NO_2 group, is so strong in electron-withdrawing that the rate-enhancing effect by the CN group on the β-position might be weakened; thus, the reaction was conversely accelerated.

The Hammett relation for **2** apparently suggests that the transition state is gradually changed from a nearly carbanion-like to an E1-like type in going from *p*-CH_3 to *p*-NO_2 substituents (Fig. 2). Thus, it can be concluded that the pyrolysis of sulfoxides bearing electron-withdrawing substituents on the β-position carbon in the *S*-ethyl group proceeds via a nearly carbanion-like mechanism in a five-membered cyclic transition state (Fig. 3).

Experimental

Measurements. All the melting points are uncorrected. The IR spectra were determined on a JEOL-810 spectrometer. The ^1H NMR spectra were recorded with a Hitachi R-24B spectrometer in $CDCl_3$ or CCl_4 using TMS as an internal standard. The HPLC analysis were carried out with a JASCO FAMILIC-100N and UVIDEC-100 SYSTEM apparatus by using silica gel (SS-10) and styrene-divinylbenzene copolymer (HP-01) columns (CH_3CN/H_2O, hexane/THF as eluting solution). The peak area were mesured by a TAKEDA-RIKEN TR-2217 integrater. The MS spectra were taken with JEOL-JMS-D 300 mass spectrometer.

Procedures and Materials. All the reactions were monitored by TLC (MERCK, Kieselgel 60 GF), and the substrates were separated by column chromatography using Merck kieselgel 60 silica gel, Wako Activated Alumina (200 mesh). All the substrates obtained were identified by IR, ^1H NMR, GC, MS, and elemental analyses. The computations were performed on the NEC 9801-F computer. Elemental analyses were carried out by Chemical Analysis Center in Toyama Medical and Pharmaceutical University. All reagents were obtained from Wako Pure Chemical Industries Ltd., Tokyo Kasei Co. Ltd., or Aldrich Chemical Co. The reagents and solvents used were further purified by general methods.

Preparation of Sulfoxides. 2-(Substituted phenyl)-ethyl phenyl sulfoxides were prepared by treating methyl

phenyl sulfoxide with LDA and with substituted benzyl chlorides in dry ether at −78 °C, and were extracted with chloroform. The extracts were dried and evaporated. The residues were purified by column chromatography (a mixture of ether and hexane as eluent). Ethyl phenyl sulfoxide and 2-phenylethyl (substituted phenyl) sulfoxides were prepared by oxidizing the corresponding sulfides with hydrogen peroxide in acetic acid, and was isolated through SiO_2-column chromatography (chloroform as eluent), or was recrystallized from ether-methanol. 2-Cyanoethyl (substituted phenyl) sulfoxides (**2**) were prepared by oxidizing the corresponding sulfides obtained in the method described below with hydrogen peroxide, and was worked up as described above. The sulfides were prepared by treating acrylonitrile and substituted benzenethiol in benzene under the presence of a minute amount of triethylamine.

Preparation of 2-Phenylethyl-2,2-d_2 Phenyl Sulfoxide. 2-Phenylethyl-2,2-d_2 phenyl sulfoxide were prepared by treating methyl phenyl sulfoxide with LDA and with benzyl-α,α-d_2 chloride in dry ether at −78 °C.

Benzyl-α,α-d_2 Alcohol: Methyl benzoate was treating by lithium aluminium deuteride in the usual way; after the solution was extracted with ether and the solvent evaporated, the residue was distilled under reduced pressure. Yield 60%.

Benzyl-α,α-d_2 Chloride: The deuterated alcohol was converted into the corresponding chloro compound with thionyl chloride. Yield 60%.

Kinetics. A pre-cooled solution of desired amount of a sulfoxide (7.0×10^{-3} mol dm^{-3}) in an anhydrous solvent was prepared and devided into a number of 10 μl of sealed capillary tubes, which were immersed in a constant temperature silicone oil bath (±0.05°C), at appropriate time intervals, the tubes were taken out and frozen in ice bath to stop the reaction. The reaction rate was then calculated by following the decreasing peak area at UV 254 nm due to the recovered sulfoxide, which was separated from the reaction mixture by HPLC (column; HP-01, eluent; CH_3CN : H_2O=5 : 2) using diphenyl ether or diphenyl sulfide as an internal standard. The rate constants were calculated by a least-squares method using the 8—12 points accumulated during 70% completion of reaction. When the data were plotted as ln (V_0/V_0-V_t) vs. time (where V_0 is the initial volume of sulfoxide and V_t is the volume of sulfoxide at a particular time), a linear correlation was observed suggesting that the kinetics is of first order. Activation parameters were computer calculated by a least-squares method using ln k vs. $1/T$. The Hammett ρ-value was computed by the least-squares method using σ-values and the logarithmus of the rate constants.

The authors are grateful to Professor Shigeru Oae of Okayama University of Science, and Professor Naomichi Furukawa, the University of Tsukuba, for their helpful discussions.

Synthesis and Electrochemical Properties of 3-(3,6-Dioxo-1,4-cyclohexadienyl)methyl-*p*-tropoquinone. Analysis of a Four-Electron Redox System by Cyclic Voltammetry

Akira MORI, Yasutomo GOTO,† and Hitoshi TAKESHITA*

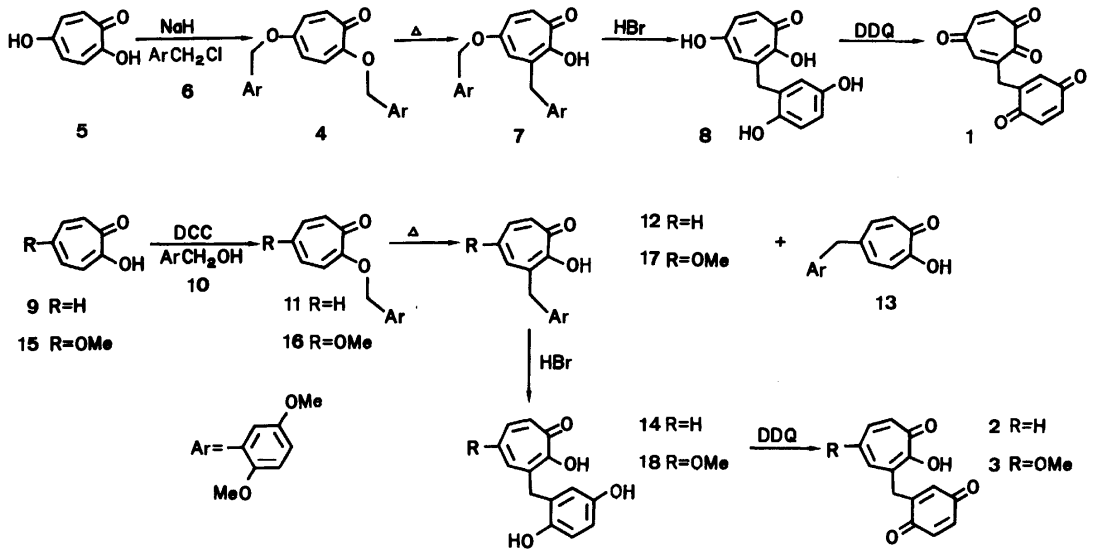
(Received January 26, 1987)

A methylene-linked bisquinone, 3-(3,6-dioxo-1,4-cyclohexadienyl)methyl-*p*-tropoquinone, was prepared from 2,5-bis(arylmethoxy)tropone by consecutive reaction, a homolytic rearrangement, subsequent debenzylation, and a DDQ-dehydrogenation. According to cyclic voltammetry, this four-electron redox system was operative, in sharp contrast to the case of the benzenoid bisquinones, via four successive one-electron transfer processes. Two other tropolone derivatives carrying *p*-benzoquinone segment were also prepared by a similar procedure. The first reduction potentials of these benzoquinones showed a slight enhancement by intramolecular hydrogen bonding.

Recently, we have measured an enhancement of the half-wave potentials due to an electron-attractive substituent of the *p*-tropoquinones;[1] in the case of 3-(*p*-hydroxybenzyl)-*p*-tropoquinone, the hydroxyl group considerably enhanced the redox potentials by an intermolecular hydrogen bonding.[2]

As one part of an electrochemical study of *p*-tropoquinones, we synthesized 3-(3,6-dioxo-1,4-cyclohexadienyl)methyl-*p*-tropoquinone (**1**), a methylene-linked bisquinone, together with 3-[(3,6-dioxo-1,4-cyclohexadienyl)methyl]tropolone and 5-methoxy-3-[(3,6-dioxo-1,4-cyclohexadienyl)methyl]tropolone (**2** and **3**). As described below, cyclic voltammetry (CV) of **1** indicated occurrence of four-times one-electron transfer processes.

When 2,5-bis(2,5-dimethoxybenzyloxy)tropone (**4**), prepared in 70% yield from 5-hydroxytropolone (**5**) and 2,5-dimethoxybenzyl chloride (**6**), was heated in decalin,[3] the thermally-transformed isomer, 3-(2,5-dimethoxybenzyl)-5-(2,5-dimethoxybenzyloxy)tropolone (**7**) was obtained in 55% yield. A debenzylation of **7** by 48% hydrobromic acid in acetic acid afforded 5-hydroxy-3-(2,5-dihydroxybenzyl)tropolone (**8**), and its DDQ (2,3-dichloro-5,6-dicyano-*p*-benzoquinone)-dehydrogenation gave desired **1**. The overall yield of **1** from **7** was 70%.



The condensation[4] of tropolone (**9**) with 2,5-dimethoxybenzyl alcohol (**10**) in the presence of dicyclohexylcarbodiimide (DCC) and copper(I) chloride gave 2-(2,5-dimethoxybenzyloxy)tropone (**11**), which was converted to 3-(2,5-dimethoxybenzyl)tropolone (**12**) and 5-(2,5-dimethoxybenzyl)tropolone (**13**) in refluxing decalin. Subsequent demethylation of **12** with concd hydrobromic acid in acetic acid afforded the hydroquinone derivative, 3-(2,5-dihydroxybenzyl)-tropolone (**14**), which was dehydrogenated with DDQ to **2**, a tropolonated *p*-benzoquinone.

Similarly, a condensation of 5-methoxytropolone

(**15**) and **10** gave the corresponding arylmethoxytropone (**16**) in 71% yield. Heating of **16** in refluxing decalin afforded 5-methoxy-3-(2,5-dimethoxybenzyl)-tropolone (**17**) in 93% yield. Hydrobromic acid-demethylation of **17** in acetic acid formed only a 5-methoxytropolone derivative, 3-(2,5-dihydroxybenzyl)-5-methoxytropolone (**18**). The dehydrogenation of **18** with DDQ gave **3**, another tropolonated *p*-benzoquinone.

The CV of **1** showed four waves. The first half-wave potential ($E_1 = -0.20$ V vs. Ag/AgCl) was just the same as the E_1 of *p*-tropoquinone (**19**),[4] indicating a negligible substituent effect due to a methylene-linked electronegative *p*-benzoquinone moiety; the second wave ($E_2 = -0.51$ V) was also similar to the $E_1 = -0.50$ V of methyl-*p*-benzoquinone (**20**).

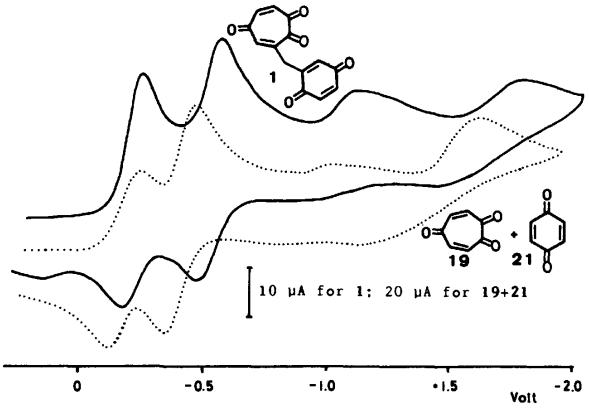


Fig. 1. The CV curve (working electrode, Pyrex-glass-sealed Pt wire; reference electrode, standard Ag/AgCl) of **1** (1.56×10^{-3} mol dm^{-3}, solid line) and a 1 : 1-mixture of **19** and **21** (1.49×10^{-3} mol dm^{-3}, dotted line) at 22—23 °C in anhydrous DMF with 0.1 M TBAF under N_2 with a scan rate of 100 mV s^{-1}.

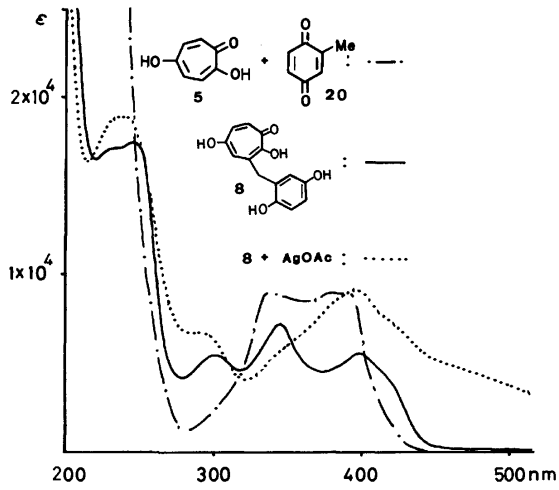

Fig. 2. Effect of AgOAc to the UV Spectrum of **8** in methanol: (——) without AgOAc; (------) in the presence of stoichiometric amount of AgOAc to produce the "Half-quinone" (**E**); (-·-·) equimolar amounts of **5** and **20**.

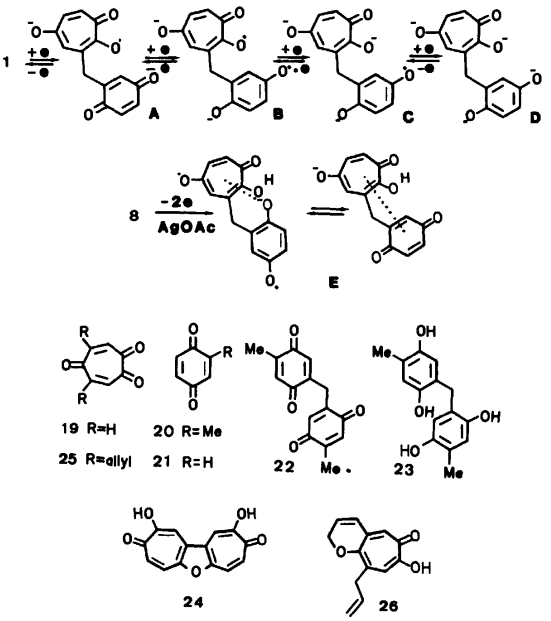
However, the intensities of the E_3 and E_4 peaks (−1.10 and −1.68 V) of **1** gradually decreased upon multiple-sweeping; finally, only the E_1 and E_2 remained at −0.21 and −0.52 V. This might be due to both or either the further chemical reaction and/or the instability of the intermediate species (**A** — **D**). On the other hand, a CV measurement of a 1 : 1-mixture of **19** and *p*-benzoquinone (**21**) showed four reproducible waves at $E_1 = -0.21$, $E_2 = -0.41$, $E_3 = -0.89$, and $E_4 = -1.46$ V. Consequently, **1** behaved as a combination of **19** and **21** in respect to CV.

The UV spectrum of **8** in the presence of silver acetate, whose amount was just equivalent to two-electron oxidation, showed a new absorption band around 430 nm. The UV spectrum of a 1 : 1-mixture of **5** and **20** showed no band around this region. Therefore, the occurrence of this absorption band indicated a charge-transfer character of the half quinone equivalent (**E**) formed in situ. Since the concentrations for the UV measurement were ca. 10^{-5} to 10^{-6} mol dm^{-3}, this must be an intramolecular charge-transfer absorption.[5] Should the two-electron reduced species (**B**) disproportionate to the deprotonated species of a half-quinone equivalent, **E**, the CV of **1** might reveal an irreversible intervention of subsequent processes due to an intramolecular side reaction. To date, there is no UV spectral evidence for the formation of either "quinhydrone" or charge-transfer complex in tropoquinones.



The peak potintials of **2** and **3** are shown in Table 1 together with those of **20** and **21**. Both show irreversible waves; particularly, their oxidation waves are hardly discernible. Nevertheless, their first reduction peaks move to a slightly more positive side than that

Table 1. The Peak Potentials/V of **2** and **3** together with Reference Quinones[a)]

Compds.	**2**	**3**	**20**	**21**
Ep1	−0.47	−0.46	−0.50	−0.44
Ep2	−1.23	−1.27	−1.58	−1.55

a) CV was measured in anhydrous DMF with 0.1 M TBAF using Pyrex glass-sealed Pt-wire as working electrode and standard Ag/AgCl as reference electrode at 22—23 °C under N_2 with a scan rate of 100 mv s^{-1}.

of **20**. This is attributable to an intramolecular hydrogen bonding.[2)]

Interestingly, bis(4-methyl-3,6-dioxo-1,4-cyclohexadienyl)methane, a bisquinone (**22**),[6)] is known to reveal two one-electron paths and one two-electron path in the formation of fully reduced bis[(2,5-dihydroxy-4-methyl)phenyl]methane (**23**); a marked difference in the reduction mode should be attributable to the structural difference of the two bisquinones.

In conclusion, this conversion of **1** to **8** via the four single-electron reduction processes constitutes a new redox system; its CV data suggested that the present bisquinone is as a strong oxidizing agent as **19**. At the same time, the appearance of a charge-transfer band in the UV spectrum might suggest a possible formation of a side product from the intermediate species, such as **B**.[7)] In fact, the electrolysis of **19** gave 2,10-dihydroxycyclohepta[*b*,*d*]furan-3,9-dione (**24**)[8)] in 44% yield under the same conditions as the CV measurement; moreover, we observed that 4,6-diallyl-*p*-tropoquinone (**25**) was electrolyzed to a cyclized derivative, 9-allyl-7-hydroxycyclohepta[*b*]pyran-6(2*H*)-one (**26**).[9)]

Experimental

The elemental analyses were performed by Miss S. Hirashima, of the Research Institute of Industrial Science, Kyushu University. The CV measurements were carried out in a standard three-electrode cell (working electrode; Pyrex glass-sealed Pt wire, reference electrode; standard Ag/AgCl) at 23°C in an anhydrous *N*,*N*-dimethylformamide (DMF) with 0.1 M tetrabutylammonium tetrafluoroborate (TBAF) under an N_2 stream with a scan rate of 100 mV s^{-1}; the values were corrected with an internal standard for the redox of a ferrocenium/ferrocene couple at +0.465 V vs. Ag/AgCl. The NMR spectra were measured by a JEOL FX 100 spectrometer in $CDCl_3$ solutions (unless otherwise specified) and the chemical shifts were expressed in δ units. The mass spectra were measured with a JEOL 01SG-2 spectrometer. The IR spectra were taken as KBr disks using a Jasco IR-A 102 spectrometer.

Preparation of 2,5-Bis(2,5-dimethoxybenzyloxy)-tropone (4). To an HMPA solution (4.5 cm^3) of **5** (300 mg), NaH (50%, 256 mg) was added under an N_2 atmosphere at 0—5°C. The mixture was then warmed to room temperature and stirred for a further 2 h at 60°C. After again cooling mixture to room temperature, an HMPA solution (2 cm^3) of **6** (853 mg) was added and stirring continued for 19 h; then, the mixture was diluted with water and the precipitates were collected by filtration and recrystallized from aqueous acetone to give **4** [yellow brown crystals, mp 123.5—125.5°C (decomp), 669 mg; 70%. Found: C, 68.20; H, 6.14%. Calcd for $C_{25}H_{26}O_7$: C, 68.48; H, 5.98%. ^{1}H NMR δ=3.72 (3H, s), 3.76 (3H, s), 3.79 (3H, s), 3.81 (3H, s), 4.97 (2H, s), 5.22 (2H, s), 6.35 (1H, d, J=11.5 Hz), 6.76 (1H, d, J=11.5 Hz), 6.7—7.0 (6H, m), 7.10 (1H, d, J=13 Hz), and 7.26 (1H, d, J=13 Hz). ^{13}C NMR δ=55.7 (2C), 55.9 (2C), 65.4, 65.8, 109.1, 111.3 (2C), 113.5, 113.8 (2C), 114.6, 116.5, 124.9, 125.3, 132.7, 137.6, 150.5, 150.8, 153.6, 153.8, 158.6, 158.9, and 179.5. IR ν: 1572, 1520, 1242, 1220, 1185, and 1042 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=37900), 251 (10100, sh), 308 (11300), 329 (12400), 361 (9100, sh), and 379 (5900, sh)].

Thermal Rearrangement of 4 to 3-(2,5-Dimethoxybenzyl)-5-(2,5-dimethoxybenzyloxy)tropolone (7). A decalin solution (40 cm^3) of **4** (800 mg) was refluxed for 2 h under an N_2 atmosphere. Silica-gel column chromatography of the mixture gave **7** [pale yellow crystals, mp 101—104°C, 482 mg; 55%. Found: C, 68.31; H, 5.96%. Calcd for $C_{25}H_{26}O_7$: C, 68.48; H, 5.98%. ^{1}H NMR δ=3.68 (3H, s), 3.70 (3H, s), 3.72 (3H, s), 3.74 (3H, s), 4.10 (2H, s), 4.93 (2H, s), 6.7—7.0 (6H, m), and 7.0—7.3 (3H, m). ^{13}C NMR δ=35.0, 55.7 (2C), 55.8 (2C), 65.8, 111.4 (2C), 112.1, 113.4, 114.5, 117.1, 120.5, 120.9, 124.2, 125.1, 128.3, 128.9, 140.2, 150.8, 151.8, 153.6, 157.7, 163.8, and 170.0. IR ν: 1605, 1502, 1400, 1230, 1218, 1200, and 1049 cm^{-1}. UV λ_{max}^{MeOH}: 229 nm (ε=35100), 251 (21100, sh), 298 (8900), 333 (10800), 370 (7400), and 387 (7100)].

Hydrobromic Acid Treatment of 7 to 3-(2,5-Dihydroxybenzyl)-5-hydroxytropolone (8). An AcOH solution (15 cm^3) of **7** (576 mg) and aq HBr (48%, 15 cm^3) was refluxed for 2 h. The mixture was then diluted with water and extracted with AcOEt. The organic extract was washed with an aqueous NaCl solution, dried on Na_2SO_4, and heated in vacuo to give a residue which, by recrystallization from $CHCl_3$, gave **8** [brown crystals, mp 167—170°C, 331 mg; 97%. Found: M.W., 260.0673. Calcd for $C_{14}H_{12}O_5$: 260.0683. ^{1}H NMR (CD_3OD) δ=4.00 (2H, s), 6.4—6.7 (3H, m), 6.92 (1H, dd, J=11.5, 3 Hz), 7.31 (1H, d, J=11.5 Hz), and 7.34 (1H, d, J=3 Hz). ^{13}C NMR (CD_3OD) δ= 36.7, 115.8, 118.0, 118.4, 122.6, 124.0, 127.8, 131.2, 145.6, 149.6, 151.7, 160.2, 163.9, and 171.9. IR ν: 3600—2400, 1375, and 1210 cm^{-1}. UV λ_{max}^{MeOH}: 231 nm (ε=17000), 244 (17200), 300 (5400), 344 (7100), 398 (5500), and 413 (4600, sh)].

DDQ-Oxidation of 8 to 3-[(3,6-Dioxo-1,4-cyclohexadienyl)methyl]-*p*-tropoquinone (1). To an acetone solution of **8** (25.4 mg) was added DDQ (48 mg) at room temperature. After stirring for 18 h, the mixture was evaporated in vacuo, and the residue was chromatographed on a silica-gel column; **1** [yellow crystals, mp 122—125°C (decomp), 17.9 mg; 72%. Found: M.W., 256.0368. Calcd for $C_{14}H_8O_5$: 256.0369. ^{1}H NMR δ=3.64 (2H, dd, J=1.5, 1 Hz), 6.65 (1H, tt, J=1.5, 1 Hz), 6.76 (2H, d, J=1 Hz), 6.82 (1H, quint, J=1 Hz), and 6.84 (2H, d, J=1 Hz). ^{13}C NMR δ=32.8, 134.2, 135.2, 136.8, 137.0, 138.5, 139.5, 144.0, 144.5, 186.6, 187.0, 187.5, 188.3, and 188.7. IR ν: 1655 cm^{-1}. UV λ_{max}^{MeOH}: 245 nm (ε= 21100)] was obtained from the elution with benzene: AcOEt (10 : 1).

AgOAc-Oxidation of 8 to 1. To an acetone solution (3 cm^3) of **8** (30 mg) was added AgOAc (79 mg) at room temperature. After 5 h, the insoluble materials were filtered off, and the filtrate was evaporated in vacuo and chromatographed on a silica-gel column to give **1** [10 mg; 34%].

Preparation of 2-(2,5-Dimethoxybenzyloxy)tropone (11). To an anhydrous benzene solution (0.5 cm^3) of **10** (895 mg) was added DCC (1.13 g) and CuCl (3 mg). After being stirred at 60°C for 11 h, an anhydrous benzene solution (0.5 cm^3) of **9** (436 mg) was added to the mixture and kept at 60°C for another 18 h. The resultant precipitates were filtered off and washed with AcOEt. The combined organic portion was evaporated in vacuo and the residue was chromatographed on a silica-gel column to give **11** [pale yellow crystals, mp 71—72.5°C, 806 mg; 83%. Found: C, 70.73; H, 6.06%. Calcd for $C_{16}H_{16}O_4$: C, 70.57; H, 5.92%. ^{1}H NMR δ=3.70 (3H, s), 3.80 (3H, s), 5.24 (2H, s), and 6.6—7.2 (8H, m). ^{13}C NMR δ=55.9, 56.1, 65.9, 111.7, 114.1, 114.3, 114.7, 124.8, 128.2, 133.0, 136.6, 137.4, 150.9, 154.2, 164.8, and 181.0 IR ν: 1594, 1580, 1515, 1498, and 1284 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=24900), 303 (7900), 318 (7200), 347 (5400), and 365 (3600)].

Thermal Rearrangement of 11 to 3-(2,5-Dimethoxybenzyl)tropolone (12) and 5-(2,5-Dimethoxybenzyl)-tropolone (13). A decalin solution (16 cm^3) of **11** (353 mg) was refluxed for 11.5 h under an N_2 atmosphere. The resultant mixture was chromatographed on a silica-gel column to give **12** [yellow brown crystals, mp 65—67°C, 270 mg; 93%. Found: C, 70.67; H, 5.92%. ^{1}H NMR δ=3.70 (3H, s), 3.72 (3H, s), 4.12 (2H, s), 6.7—7.0 (4H, m), and 7.2—7.4 (3H, m). ^{13}C NMR δ=34.6, 55.7, 56.1, 111.7, 112.1, 117.5, 121.0, 127.4, 128.7, 136.0, 139.6, 140.3, 152.1, 153.8, 168.2, and 173.0. IR ν: 1612, 1600, 1522, 1500, 1425, 1380, 1226, 1050, and 750 cm^{-1}. UV λ_{max}^{MeOH}: 231 nm (ε=26000), 243 (24700, sh), 304 (6900, sh), 322 (7600), 356 (5900), and 367 (5800)] and **13** [yellow crystals, mp 108.5—111°C, 8.8 mg; 3%. Found: C, 70.68; H, 6.01%. ^{1}H NMR δ=3.72 (6H, s), 3.88 (2H, s), 6.6—6.8 (3H, m), 7.18 (2H, d, J=12 Hz), and 7.30 (2H, d, J=12 Hz). ^{13}C NMR δ=40.1, 55.8, 56.0, 111.8, 112.1, 117.2, 124.1 (2C), 129.4, 138.8 (2C), 142.0, 151.8, 153.9, and 171.1 (2C). IR ν: 3200, 1560, 1495, 1460, 1420, 1270, 1238, and 1214 cm^{-1}. UV λ_{max}^{MeOH}: 228 nm (ε=26500), 325 (10300), and 372 (4800, sh)] together with **3** [61.7 mg; 17%].

Demethylation of 12. An AcOH solution (10 cm^3) of **12** (378 mg) and HBr (48%, 10 cm^3) was refluxed for 1.5 h. The mixture was then diluted with water and extracted with AcOEt. The organic extract was dried on $MgSO_4$ and heated in vacuo. The residue was purified by repeated recrystallizations from a mixture of AcOEt and hexane to give **14** [yellow crystals, mp 134—136°C, 267 mg; 79%. Found: C, 68.67; H, 5.24%. Calcd for $C_{14}H_{12}O_4$: C, 68.84; H, 4.95%. ^{1}H NMR (CD_3OD) δ=4.01 (2H, s), 6.47 (1H, dd, J=8.5, 2.5 Hz), 6.56 (1H, dd, J=2.5, 1 Hz), 6.63 (1H, dd, J=8.5, 1 Hz), and 6.8—7.7 (4H, m). ^{13}C NMR (CD_3OD) δ=36.8, 115.7, 117.8, 118.4, 122.7, 127.9, 129.4, 137.9, 141.5, 143.4, 149.6, 151.7, 169.5, and 175.0. IR ν: 3600—2500, 1542, 1510, 1482, 1476, 1380, and 1210 cm^{-1}. UV λ_{max}^{MeOH}: 237 nm (ε=20000), 331 (7700), 375 (5900), and 392 (4700, sh)].

The DDQ-Oxidation of 14. An acetone solution (10 cm^3) of **14** (99.1 mg) and DDQ (105 mg) was stirred at room temperature for 4 h. The solvent was then removed by evaporation and the residue was briefly chromatographed on a silica-gel column. Yellow crystals obtained by elution from hexane-AcOEt (10 : 1) and removal of the solvent were recrystallized from benzene to give **2** [mp 99.5—101.5°C, 65.2 mg; 66%. Found: C, 69.16; H, 4.11%. Calcd for $C_{14}H_{10}O_4$: C, 69.42; H, 4.16%. ^{1}H NMR δ=3.90 (2H, d, J=1.5 Hz), 6.53 (1H, dtd, J=2, 1.5, 1 Hz), 6.65 (1H, dd, J=10, 2 Hz), 6.77 (1H, dd, J=10, 1 Hz), 6.9—7.3 (3H, m), and 7.57 (1H, d, J=9.5 Hz). ^{13}C NMR δ=34.6, 120.7, 127.7, 128.7, 133.8, 136.7, 137.0, 137.3, 141.4, 146.4, 168.1, 173.6, 187.4, and 188.0. IR ν: 3600—3300, 3200, 1650, 1548, 1420, 1295, and 1236 cm^{-1}. UV λ_{max}^{MeOH}: 243 nm (ε=37600), 327 (8600), 333 (8700), 373 (6000), and 391 (4300, sh)].

Preparation of 2-(2,5-Dimethoxybenzyloxy)-5-methoxytropone (16). A benzene solution (0.3 cm^3) of **10** (357 mg), DCC (428 mg), and CuCl (5 mg) was stirred at 60°C for 16 h under an N_2 atmosphere, to which, a benzene solution (0.5 cm^3) of **15** (213 mg) was introduced and stirred further for 10 h. The precipitates formed were filtered off and washed with AcOEt, and the residue obtained by removing organic solvents in vacuo was recrystallized from AcOEt to give **16** [yellow crystals, mp 131—132°C, 300 mg; 71%. Found: C, 67.76; H, 6.05%. Calcd for $C_{17}H_{18}O_5$: C, 67.54; H, 6.00%. ^{1}H NMR δ=3.72 (6H, s), 3.81 (3H, s), 5.23 (2H, s), 6.21 (1H, dd, J=11, 2.5 Hz), 6.74 (1H, d, J=8 Hz), 6.77 (1H, d, J=11 Hz), 6.84 (1H, d, J=8 Hz), 7.02 (1H, dd, J=13, 2.5 Hz), 7.03 (1H, br s), and 7.21 (1H, d, J=13 Hz). ^{13}C NMR δ=55.5, 55.8, 56.0, 65.8, 107.3, 111.4, 113.8 (2C), 116.5, 125.3, 132.5, 137.6, 150.6, 153.8, 158.8, 159.5, and 179.7. IR ν: 1566, 1507, 1220, 1200, and 1102 cm^{-1}. UV λ_{max}^{MeOH}: 227 nm (ε=31600), 252 (7600, sh), 310 (9600, sh), 328 (11300), 347 (9900), 362 (3900, sh), and 378 (6300, sh)].

Thermolysis of 16. Formation of 3-(2,5-Dimethoxybenzyl)-5-methoxytropolone (17). A decalin solution (5 cm^3) of **16** (128 mg) was refluxed under an N_2 atmosphere for 3 h. A silica-gel column chromatography of the mixture afforded **17** [pale yellow crystals, mp 101—103°C, 96.3 mg; 93%. Found: C, 67.69; H, 6.01%. ^{1}H NMR δ=3.66 (3H, s), 3.69 (3H, s), 3.73 (3H, s), 4.11 (2H, s), 6.72 (1H, dd, J=11, 3 Hz), 6.7—6.9 (3H, m), 7.09 (1H, d, J=3 Hz), and 7.26 (1H, d, J=11 Hz). ^{13}C NMR δ=34.9, 55.6 (2C), 55.9, 111.4, 112.0, 117.2, 117.7, 120.3, 122.9, 124.2, 140.7, 151.8, 153.5, 158.5, 162.8, and 170.6. IR ν: 1610, 1540, 1498, 1451, 1226, 1205, and 1055 cm^{-1}. UV λ_{max}^{MeOH}: 230 nm (ε=21500), 250 (16200, sh), 300 (5200), 341 (7800), 388 (5200), and 416 (2300, sh)] and **16** [23.9 mg; 19%].

Demethylation of 17. An AcOH solution (7.5 cm^3) of **17** (328 mg) and HBr (48%, 7.5 cm^3) was refluxed for 2 h. The mixture was then diluted with water and extracted with AcOEt. After evaporation of the solvent, the residue was recrystallized from $CHCl_3$ to give **18** [yellow crystals, mp 162—165°C (decomp), 276 mg; 93%. Found: M.W., 274.0856. Calcd for $C_{15}H_{14}O_5$: 274.0841. ^{1}H NMR (CD_3OD) δ=3.73 (3H, s), 4.02 (2H, s), 6.45—6.7 (3H, m), 6.92 (1H, dd, J=11, 3 Hz), 7.33 (1H, d, J=11 Hz), and 7.34 (1H, d, J=3 Hz). ^{13}C NMR (CD_3OD) δ=36.4, 56.4, 115.7, 117.7, 118.4, 119.3, 122.7, 127.6, 130.6, 144.1, 149.4, 151.5, 160.7, 163.9, and 172.4. IR ν: 3300—3100, 1618, 1504, 1452, 1398, and 1208 cm^{-1}. UV λ_{max}^{MeOH}: 228 nm (ε=19600, sh), 249 (25400), 339 (11800), and 395 (9100)].

The DDQ-Oxidation of 18. To an acetone solution (9

cm^3) of **18** (93.2 mg), DDQ (85.6 mg) was added stirred at room temperature for 2 h. A brief silica-gel column chromatography of the mixture afforded **3** [deep yellow crystals, mp 105—107°C (decomp), 52 mg; 56%. Found: C, 65.78; H, 4.42%; M.W., 272.0682. Calcd for $C_{15}H_{12}O_5$: C, 66.17; H, 4.44%; M.W., 272.0682. ^{1}H NMR δ=3.79 (3H, s), 3.89 (2H, d, J=1.5 Hz), 6.52 (1H, dtd, J=2, 1.5, 1 Hz), 6.65 (1H, dd, J=10, 2 Hz), 6.77 (1H, dd, J=11, 3 Hz), 6.78 (1H, dd, J=10, 1 Hz), 7.46 (1H, d, J=11 Hz), and 7.47 (1H, d, J=3 Hz). ^{13}C NMR δ=34.9, 56.1, 118.4, 120.6, 130.7, 133.7, 136.6, 136.8, 137.2, 146.3, 158.8, 163.1, 171.0, 187.2, and 187.8. IR ν: 3600—3300, 1652, 1208, and 1200 cm^{-1}. UV λ_{max}^{MeOH}: 246 nm (ε=30800), 338 (11900), and 400 (7400)].

Electrolysis of 19 to 24. An anhydrous DMF solution (30 cm^3) of **19** (616 mg) was electrolyzed in the presence of TBAF (1 g) at −1.30 V for 22 h. After evaporation of the solvent in vacuo, the residue was diluted with AcOEt to precipitate **24** [258 mg; 44%], which was identical with the authentic sample.[9]

The Structure of Graucin A, a New Bitter Limonoid from *Evodia grauca* Miq. (Rutaceae)

Munehiro NAKATANI,* Hideki TAKAO, Takashi IWASHITA,† Hideo NAOKI,† and Tsunao HASE

Department of Chemistry, Faculty of Science, Kagoshima University, 1-21-35 Koorimoto, Kagoshima 890

(Received January 31, 1987)

Graucin A, a new bitter limonoid, has been isolated from the root bark of *Evodia grauca* Miq. as well as the known limonoids limonin, rutaevin and limonin diosphenol. Its structural and stereochemical assignments were made using NMR (COSY and NOESY), and CD spectroscopy, which indicated the uncommon 5β-H configuration of this new compound. Rutaevin was also recognized to be a 5β-H limonoid.

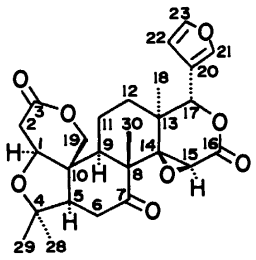
In the course of our studies on the biologically active limonoids,[1] we isolated a new limonoid graucin A (**1**) along with the known limonoid limonin (**2**),[2] rutaevin (**3**)[3] and limonin diosphenol (**4**)[3,4] as bitter components of the root bark of *Evodia grauca* Miq.(Rutaceae). The structure **1** was assigned on the basis of COSY and NOESY NMR spectra of **1** and the acetate **5**, and by the CD study on the benzoate **6**. Both graucin A and the structurally similar limonoid rutaevin (**3**) have been assigned the 5β-H configuration, which is opposite to that of many other known Rutaceae limonoids including limonin.

Some biological activities of the limonoids (**1**—**4**) were also examined.

Results and Discussion

The ether extract of the root bark contained a variety of limonoids which were detected by the characteristic color with Ehrlich's reagent on TLC. Fractionation by extensive silica-gel column chromatography followed by the final HPLC purification on a normal phase column using 0.4—1.0% methanol in dichloromethane as an eluant gave the new compound **1** named graucin A along with three known limonoids previously isolated from various Rutaceae plants: limonin (**2**), rutaevin (**3**) and limonin diosphenol (**4**).

Graucin A (**1**), $C_{26}H_{30}O_{10}$, mp > 310 °C (prisms from acetonitrile), exhibited the following spectral data. SI-MS: m/z 503 $(M+1)^+$; $[\alpha]_D^{15}$ −150° (c 0.0005, CH_3CN); UV (MeOH): 209 nm (ε 6300, π-π^* of furan). The IR spectrum showed the presence of hydroxyl (3450 cm^{-1}), γ-lactone (1765 cm^{-1}), δ-lactone (1740 cm^{-1}) and ketone groups (1700 cm^{-1}) and the CD spectrum also showed the presence of furan (228 nm, $\Delta\varepsilon$ −5.3; π-π^*) and ketone groups (297 nm, $\Delta\varepsilon$ −1.7; n-π^*). The ^{1}H NMR spectrum showed signals of four tertiary methyl groups at δ 0.61 (8-Me), 1.23 (4α-Me), 1.35 (13-Me), and 1.44 (4β-Me), a singlet at δ 4.15 (15-H), a AB quartet (J=12 Hz) at δ 4.10 (19-H_a) and 4.28 (19-H_b), and a signal at δ 5.51 (s, 17-H) weakly coupling with furan



limonin (**2**)

protons,[1,5] along with the usual limonoid furan signals at δ 7.29 (21-H), 6.46 (22-H), and 7.29 (23-H). The 19-H_b signal showed a W-type long-range coupling with a signal at δ 4.45 (br t, 1-H), which revealed the 1-H to be in α. Furthermore, the chemical shift of the deshielded 15-epoxide proton suggested the presence of a 7β-OH group.[6] The ^{1}H NMR spectrum of **1** also showed a signal for a carbinol methine proton at δ 4.34 (d, 7α-H), which collapsed to a singlet by addition of deuterium oxide (D_2O). Another carbinol methine signal was observed at δ 4.04 (12-H) as a multiplet, which also collapsed to a doublet by the addition of D_2O. The above ^{1}H NMR spectral feautures closely resembled to those of rutaevin (**3**) except for the presence of the signals due to an additional hydroxyl group (see experimental).

Because of the low solubility of the natural compound **1** in all common NMR solvents, the acetate **5**, obtained by treating with acetic anhydride/pyridine, was used for detailed NMR studies. The ^{1}H NMR spectrum of **5** also showed close similarity to that of rutaevin acetate (**7**) except for the additional acetyl signal at 1.83 (12α-OAc), which was heavily shielded by a paramagnetic anisotropy of the furan ring (Table 1). 2D-Homonuclear J-correlation (COSY) indicated the coupling protons on the linked carbons (C-1 and 2, and C-9, 11, and 12). No couplings were observed between 11α- and 9α-H and 11α- and 12β-H, showing their dihedral angles to be close to 90°. A skew boat conformation of the C ring was suggested by that the 11α-proton showed only geminal coupling (J=15 Hz).

The configuration of the 7- and 12-hydroxyl groups in **1** was also clarified from exciton-split CD curves arising from interaction between benzoate and furan chromophores.[7] The 7,12-dibenzoate **6** exhibited a positive split CD spectrum at 242 ($\Delta\varepsilon$+4.0) and 227 nm ($\Delta\varepsilon$−4.9) like rutaevin 7-benzoate (**8**), arised from the positively coupled oscillator of furan and 7-benzoate (Fig. 2). Since both interactions of 7-OBz/12-OBz (dihedral angle is *ca.* 180°) and 12-OBz/furan (dihedral angle is *ca.* 0°) are not appreciated, the configuration of the 12-hydroxyl group could be determined to be α.

In the ^{1}H NOE experiments of **5**, irradiation of the 8-Me protons at δ 0.78 induced 19.9, 10.0 and 2.9% peak enhancements on the 15α-H, 19-H_b and 5-H signals, respectively. The NOE on 5-H revealed its configuration to be in β opposite to that of limonin (**2**), in the spectrum of which irradiation of the 8-Me protons at δ 1.07 showed following NOEs: 5.5 (6β-H), 13.5 (15-H), 2.5 (19-H_a), and 6.7% (19-H_b). Therefore, graucin A should be the 7β,12α-dihydroxy-6-oxo-5β-*H* analog of limonin. The ^{1}H NMR spectrum of **5**

a) Distinguished couplings are listed and numerals in parenthesis denote small coupling. b) Numerals denote the proton exhibiting the NOE based on 2D-NOE.

(Table 1) well supports the structure **1** and the cross-relaxation correlated 2D-^{1}H NOE (NOESY) of **5** (4α-Me/1-H, 4β-Me/5-H, 8-Me/5-H, 19-H$_b$, 15-H, 13-Me/7-H, 9-H, 21-H, 22-H, 7-OAc/15-H, and 9-H/1-H, 7-H) revealed the gross conformation (Fig. 1).

The mutual similarities of the ^{1}H NMR spectra of graucin A (**1**) and rutaevin (**3**) and their acetates **5** and **7** suggested that rutaevin was also a 5β-H limonoid in contrast to the previously formulated structure. It had been determined by Dreyer as 6-oxoepilimonol possessing a 5α-H from the correlation with limonin (**2**) via limonin diosphenol (**4**), $\Delta^{5,6}$-6-hydroxylimonin, and analogy with other many Rutaceae limonoids.[3] The NOE different spectra of **3** and **7** showed 2.8% and 3.1% NOEs between 8-Me and 5-H, respectively, which assigned a 5β-H configuration to **3** as pointed out from the ^{13}C NMR study by Bennett and Hasegawa.[8] Further NOE data also supported the revised structure; NOEs between methyl and proton in **3**: 4α-Me/1-H (9.5%), 4β-Me/5-H (12.0%), 8-Me/15-H (18.4%), 19-H$_a$ (3.6%), 19-H$_b$ (11.3%), and 13-Me/7-H (5.8%), 9-H (6.1%), 21-H (4.2%), 22-H (6.1%); and Table 1 for **7**. The 5β-H configuration is apparently favored in **1** and **3** because a cis-fusion of the 5-membered A ring allows a less strained conformation.

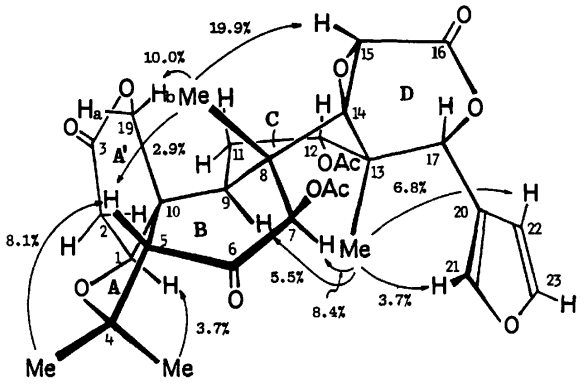

Fig. 1. Graucin A acetate (**5**), stereochemistry and NOEs between methyl and proton.

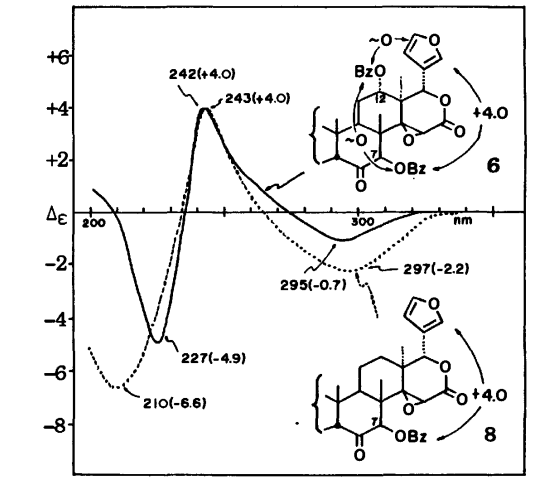

Fig. 2. CD spectra of 7,12-dibenzoylgraucin A (**6**) and 7-benzoylrutaevin (**8**).

Although there have been reported many Rutaceae limonoids, the 5β-H compounds are rare.[8] Among the compounds isolated in this work, limonin (**2**) and limonin diosphenol (**4**) were active as insect antifeedant against the larvae of *Spodoptera litura* Fab. with the leaf disk choice test. On the other hand, in antimicrobial tests against bacteria, yeasts and fungi rutaevin (**3**) showed weak antibacterial activity against *Bacillus subtilis*.

Experimental

Mps are uncorrected. UV spectra were measured in methanol (MeOH) and ^{1}H NMR spectra in chloroform-*d* with TMS as internal standard ($\delta = 0$ ppm) were measured at 360 MHz.

Plant Material. Roots of the plant were collected at Kagoshima University and identified by Dr. Sako, Kagoshima University.

Extraction and Isolation. Fresh root bark (1.0 kg) was extracted with MeOH (3×31). After concn to 200 ml, water (300 ml) was added to afford 5.2 g of a ppt which was applied onto a silica-gel column. The column was eluted with a dichloromethane (CH_2Cl_2)-MeOH gradient to yield a complex limonoid mixture and compound **1** (42 mg). The mixture was separated by repeated passage through a HPLC, semiprep silica-gel column, using 0.4—1% MeOH-CH_2Cl_2 as the solvent to give **2** (320 mg), **3** (26 mg) and **4** (21 mg).

Graucin A (1). Prisms from acetonitrile; mp >310 °C; $[\alpha]_D^{15}$ −150° (*c* 0.0005, CH_3CN); UV 209 nm (ε 6200); IR (Nujol) 3450, 1765, 1740, 1700, 1503, 1110, 1050, 1010, 875 cm^{-1}; CD(MeOH) 228 ($\Delta\varepsilon$ −5.3), 297 nm ($\Delta\varepsilon$ −1.7); SIMS *m/z*503 $(M+H)^+$, 645, 595, 553, 461, 277, 185, 93, 75, 57; ^{1}H NMR δ=0.61 (3H, s; 8-Me), 1.23 (3H, s; 4α-Me), 1.35 (3H, s; 13-Me), 1.44 (3H, s; 4β-Me), 2.63 (1H, dd, J= 15 and 3 Hz; 2-H$_a$), 2.91 (1H, dd, J=15 and 3 Hz; 2-H$_b$), 2.98 (1H, br d, J=12 Hz; 9-H), 3.13 (1H, s; 5-H), 3.87 (1H, d, J =3 Hz; -OH), 4.04 (1H, m; 12β-H), 4.10 (1H, d, J=12 Hz; 19-H$_a$), 4.15 (1H, s; 15-H), 4.28 (1H, d, J=12 Hz; 19-H$_b$), 4.34 (1H, m; 7-H), 4.37 (1H, d, J=7 Hz; -OH), 4.45 (1H, m; 1-H), 5.51 (1H, s; 17-H), 6.46 (1H, m; 22-H), 7.29 (2H, m; 21- and 23-H). Found: C, 62.12; H, 6.04%. Calcd for $C_{26}H_{30}O_{10}$: C, 62.14; H, 6.02%.

Limonin (2). Prisms from MeOH; mp 289 — 293 °C; $[\alpha]_D^{24}$ −136° (*c* 0.004, acetone); UV 208 nm (ε 7300); IR (Nujol) 1760, 1705, 1503, 878 cm^{-1}; CD (MeOH) 230 ($\Delta\varepsilon$ −4.9), 293 nm ($\Delta\varepsilon$ −2.3); EIMS *m/z*470 (M^+), 455, 426, 413, 347, 135, 108, 94; ^{1}H NMR δ=1.07 (3H, s; 8-Me), 1.18 (3H, s; 4β-Me), 1.18 (3H, s; 13-Me), 1.30 (3H, s; 4α-Me), 1.52 (1H, m; 12α-H), 1.78 (1H, m; 12β-H), 1.83 (1H, m; 11α-H), 1.90 (1H, m; 11β-H), 2.23 (1H, dd, J=16 and 3 Hz; 5-H), 2.47 (1H, dd, J=14.5 and 3.5 Hz; 6α-H), 2.55 (1H, dd, J=12 and 2.5 Hz; 9-H), 2.68 (1H, dd, J=17 and 2 Hz; 2-Ha), 2.86 (1H, dd, J=15.5 and 14.5 Hz; 6β-H), 2.98 (1H, dd, J=17 and 4 Hz; H-2$_b$), 4.03 (1H, m; 1-H), 4.03 (1H, s; 15-H), 4.47 (1H, d, J=13; 19-H$_a$), 4.77 (1H, br d, J

$=13$; 19-H_b), 5.47 (1H, br s; 17-H), 6.34 (1H, ddd, $J=2$, 1, and 1Hz; 22-H), 7.40 (1H, dd, $J=2$ and 1.5 Hz; 23-H), 7.42 (1H, dd, $J=1.5$ and 1 Hz; 21-H). NOEs (no indication in parentheses based on 2D-NOE): 9-H/1-H, 5-H, 13-Me, 13-Me/9-H (5.8%), 21-H (4.3%), 22-H (5%), 4α-Me/5-H (6.9%), 1-H (2.5%), 4β-Me/19-H_b, 8-Me/6β-H (5.5%), 15-H (13.5%), 19-H_a (2.5%), 19-H_b (6.7%).

Rutaevin (3). Needles from MeOH; mp >300 °C; $[\alpha]_D^{24}$ −146° (*c* 0.0005, MeOH); UV 208 nm (ε 9400); IR (Nujol) 3420, 1770, 1740, 1710, 1504, 880 cm^{-1}; CD (MeOH) 230 ($\Delta\varepsilon$−4.1), 295 nm ($\Delta\varepsilon$−1.0); FDMS *m/z* 487 (M^+), 410, 369, 327, 244, 190, 127, 85; ^1H NMR $\delta=0.65$ (3H, s; 8-Me), 1.21 (3H, s; 4α-Me), 1.36 (3H, s; 13-Me), 1.44 (3H, s; 4β-Me), 1.6 (1H, m; 12α-H), 1.73 (1H, br dd, $J=13$ and 8 Hz; 11α-H), 1.85 (1H, m; 11β-H), 1.95 (1H, m; 12β-H), 2.64 (1H, dd, $J=15$ and 3 Hz; 2-H_a), 2.79 (1H, br d, $J=12$ Hz; 9-H), 2.92 (1H, dd, $J=15$ and 3 Hz; 2-H_b), 3.12 (1H, s; 5-H), 3.89 (1H, d, $J=3$ Hz; -OH), 4.15 (1H, d, $J=12.5$ Hz; 19-H_a), 4.16 (1H, s; 15-H), 4.28 (1H, br d, $J=12.5$ Hz; 19-H_b), 4.35 (1H, br d, $J=3$ Hz; 7-H), 4.37 (1H, br t, $J=3$ Hz; 1-H), 5.48 (1H, br s; 17-H), 6.35 (1H, m; 22-H), 7.43 (1H, m; 23-H), 7.44 (1H, m; 21-H). NOEs: 13-Me/7-H (5.8%), 9-H (6.1%), 21-H (4.2%), 22-H (6.1%), 4α-Me/1-H (9.5%), 4β-Me/5-H (12.0%), 8-Me/15-H (18.4%), 19-H_a (3.6%), 19-H_b (11.3%).

Limonin Diosphenol (4). Needles from acetone; mp 273—278 °C; $[\alpha]_D^{24}$ −193° (*c* 0.002, acetone); UV 207 (ε 7900), 278 nm (ε 7900); IR (Nujol) 3450, 1740, 1690, 1660, 880 cm^{-1}; CD (MeOH) 208 ($\Delta\varepsilon$−4.2), 275 ($\Delta\varepsilon$+10.7), 320 nm ($\Delta\varepsilon$−8.5); ^1H NMR $\delta=1.04$ (3H, s; 8-Me), 1.16 (3H, s; 4β-Me), 1.49 (3H, s; 13-Me), 1.54 (3H, s; 4α-Me), 2.64 (1H, dd, $J=13$ and 3 Hz; 9-H), 2.84 (1H, dd, $J=17$ and 5 Hz; 2-H_a), 2.91 (1H, dd, $J=17$ and 3 Hz; 2-H_b), 4.07 (1H, br t, $J=3$ Hz; 1-H), 4.12 (1H, s; 15-H), 4.62 (1H, d, $J=13$ Hz; 19-H_a), 4.66 (1H, d, $J=13$ Hz; 19-H_b), 5.43 (1H, s; 17-H), 6.23 (1H, s; -OH), 6.38 (1H, m; 22-H), 7.40 (1H, m; 23-H), 7.41 (1H, m; 21-H).

7, 12-Diacetylgraucin A (5). Graucin A (**1**) (8 mg) was acetylated with Ac_2O-pyridine at room temperature and the product was purified by chromatography over SiO_2. Recrystallization from MeOH afforded diacetate **5** (6 mg) as needles, mp >300 °C. UV 213 nm (ε 8000); IR (CH_2CI_2) 1770—1740, 1720, 1700, 1225, 1060, 875 cm^{-1}; SIMS *m/z* 587 $(M+H)^+$, 609, 551, 527, 418, 207, 185, 115, 93, 61, 43.

7,12-Dibenzoylgraucin A (6). Graucin A (**1**) (3 mg) was benzoylated with benzoyl chloride in pyridine at 60 °C and the product was chromatographed over SiO_2 and purified by HPLC to give **6** (2 mg). 7,12-dibenzoylgraucin A (**6**): UV 207 (ε 9400), 232 nm (ε 18000); IR (CH_2Cl_2) 1770, 1750, 1720, 1600, 1245, 1180, 1100, 880 cm^{-1}; CD (MeOH) 227 ($\Delta\varepsilon$−4.9), 242 ($\Delta\varepsilon$+4.0), 295 nm ($\Delta\varepsilon$−0.7); SIMS *m/z* 711 $(M+H)^+$.

7-Acetylrutaevin (7). Rutaevin (**3**) (20 mg) was acetylated with Ac_2O-pyridine and the product was purified by chromatography. Recrystallization from MeOH afforded **7** (18 mg) as needles, mp 184—188 °C; $[\alpha]_D^{24}$ −101° (*c* 0.0005, MeOH); UV 209 nm (ε 9400); IR (CH_2Cl_2) 1770—1740, 1715, 1700, 1220, 1055, 875 cm^{-1}; CD (MeOH) 297 nm ($\Delta\varepsilon$−0.56), 227 nm ($\Delta\varepsilon$−2.29).

7-Benzoylrutaevin (8). Rutaevin (**3**) (15 mg) was benzoylated with benzoyl chloride in pyridine at 60 °C. Final purification of the product by HPLC afforded **8** (11 mg). Compound **8**, mp 285—288 °C; UV 209 (ε 9700), 234 nm (ε 14000); IR (CH_2Cl_2) 1780, 1750, 1730, 1605, 1503, 885 cm^{-1}; CD (MeOH) 210 ($\Delta\varepsilon$−6.6), 243 ($\Delta\varepsilon$+4.0), 297 nm $\Delta\varepsilon$−2.2); ^1H NMR $\delta=0.92$ (3H, s; 8-Me), 1.36 (3H, s; 4α-Me), 1.40 (3H, s; 13-Me), 1.42 (3H, s; 4β-H), 1.6 (1H, m; 12α-H), 1.8 (1H, m; 11α-H), 1.85 (1H, m; 11β-H), 1.95 (1H, m; 12β-H), 2.66 (1H, dd, $J=15$ and 3 Hz; 2-H_a), 2.93 (1H, dd, $J=15$ and 3 Hz; 2-H_b), 3.00 (1H, br d, $J=12$ Hz; 9-H), 3.12 (1H, s; 5-H), 3.79 (1H, s; 15-H), 4.20 (1H, d, $J=12$ Hz; 19-H_a), 4.36 (1H, br d, $J=12$ Hz; 19-H_b), 4.41 (1H, br t, $J=3$ Hz; 1-H), 5.47 (1H, s; 17-H), 5.90 (1H, s; 7-H), 6.35 (1H, m; 22-H), 7.40 (1H, m; 21-H), 7.42 (1H, m; 23-H), 7.52 (2H, t, $J=7$ Hz; 3′-and 5′-H), 7.65 (1H, tt, $J=7.5$ and 1.5 Hz; 4′-H), 8.06 (2H, dd, $J=7$ and 1.5 Hz; 2′-and 6′-H).

Limonin Diosphenol (4) from Limonin (2). Limonin (**2**) (100 mg) suspended in *t*-butyl alcoholic *N*-potassium *t*-butoxide (20 ml) was shaken with oxygen in a hydrogenetion apparatus for 2 h. After addition of water, the soln was acidified with 6M-hydrochloric acid (1 M=1 mol dm^{-3}) and extracted with chloroform ($CHCl_3$). The $CHCl_3$ soln was washed with aq sodium hydrogencarbonate and water, and then shaken with aq 4M-sodium hydroxide. Acidification of this extract with 6M-hydrochloric acid gave a ppt which was extracted with $CHCl_3$ again. The $CHCl_3$ soln was washed with water, and the solvent was removed. Recrystallization from acetone gave **4** (43 mg) as needles, mp 273—278 °C.[9]

Limonin Diosphenol (4) from Rutaevin (3). Pyridinium chlorochromate (80 mg) was added to a stirred soln of rutaevin (**3**) (44 mg) in CH_2Cl_2. After stirring over night at room temperature, MeOH was added and stirred for additional 1 h, and then the soln was evapolated in vacuo to yield a brown residue which was chromatographed over SiO_2 to give **4** (30 mg).

Biological Activities. Insect Antifeedant Activity. The limonoids **1**—**4** were tested against the larvae of the pest insect *Spodoptera litura* Fab. with the leaf disk method.[10] Limonin (**2**) and limonin diosphenol (**4**) showed the activity at 1000 ppm concn. **Antimicrobial Activity.** Effects of the compound **1**—**4** on growth of microorganisms were tested by the broth dilution method by Dr. M. Taniguchi (Osaka City University). Among the compounds rutaevin (**3**) was active against a bacterium *Bacillus subtilis* at 100 μg ml^{-1} concn. Test organisms; bacterium; *S. aureus, B. subtilis, E. coli* and *Ps. aeruginosa*: fungus; *Mucor mucedo, Rh. chinensis, Asp. niger* and *P. crustosum*: yiest; *S. cerevisiae, C. utilis, Schiz. pombe* and *H. anomala*.

We are grateful to Dr. Shizuo Sako (Kagoshima University) for the identification of the plant and to Mr. Mitsuo Tahara (Sankei Chemical Co. LTD.) for the supply of the insect. Our thanks are also due to Dr. Makoto Taniguchi (Osaka City University) for the antimicrobial test and Dr. Kozo Shibata (Osaka City University) for the elemental analysis.

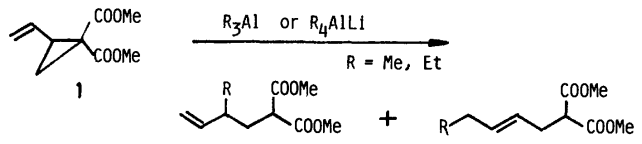
Preparation of 2-Alkenylsilanes and 2-Alkenylstannanes by the Reaction of 2-Alkenyl-1,1-cyclopropanedicarboxylate Esters with $PhMe_2SiAlEt_2$ and $(Ph_3Sn)_2Zn$. Generation of 2-Alkenyl-3-cyclopentene-1,1-dicarboxylates via Alkenyl-Substituted π-Allylpalladium Complexes Derived from Dienylsilanes and $[PdCl_2(CH_3CN)_2]$

Keigo FUGAMI, Koichiro OSHIMA,* Kiitiro UTIMOTO, and Hitosi NOZAKI
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Kyoto 606
(Received February 26, 1987)

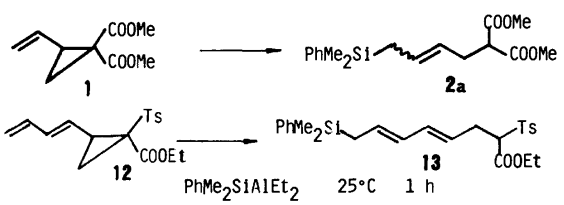
Reaction of 2-vinyl-1,1-cyclopropanedicarboxylate with $PhMe_2SiAlEt_2$, $PhMe_2SiZnEt_2Li$, or $(Ph_3Sn)_2Zn$ gave 1,7-homoconjugate addition products, 2-alkenylsilanes or 2-alkenylstannanes. In a similar fashion, 2-(1,3-butadienyl)-1,1-cyclopropanedicarboxylate provided the corresponding 1,9-homoconjugate adducts, dienylsilanes or dienylstannanes. The adducts were converted into π-allylpalladium complexes by means of $[PdCl_2(CH_3CN)_2]$. Treatment of the alkenyl-substituted π-allylpalladium complexes derived from dienylsilanes and $[PdCl_2(CH_3CN)_2]$ with bases such as PPh_3 or Na_2CO_3 gave 2-alkenyl-3-cyclopentene-1,1-dicarboxylates. In contrast, the reaction of the π-allylpalladiums generated from 2-alkenylsilanes and $[PdCl_2(CH_3CN)_2]$ with the bases resulted in the formation of original vinylcyclopropane derivatives.

Scheme 1 refers to the reaction of organoaluminum reagents with vinylcyclopropanes activated by two electron-withdrawing group. The regiochemistry in the homoconjugate addition of an alkyl group to 2-vinyl-1,1-cyclopropanedicarboxylic ester (**1**) is controlled by the nature of organoaluminum reagents.[1] Here we wish to report the reactions of Scheme 2, in which organometallic reagents such as $PhMe_2SiAlEt_2$,[3] $PhMe_2SiZnEt_2Li$,[3] and $(Ph_3Sn)_2Zn$[4] react with vinylcyclopropanes regioselectively to give 1,7-homoconjugate addition products, 2-alkenylsilanes and 2-alkenylstannanes. Similarly, 2-(1,3-butadienyl)cyclopropanes provide the corresponding dienylsilanes upon treatment with silylmetal reagents.

For example, the vinylcyclopropane **1** was allowed to react with 2.0 equivalents of $PhMe_2SiAlEt_2$ derived from $PhMe_2SiLi$ and Et_2AlCl in tetrahydrofuran. The reaction took place smoothly and was completed usually in 1 h at 0 °C. Dilution of the reaction mixture with dichloromethane, followed by workup (NaF and H_2O) and isolation by silica-gel column chromatography, gave a stereoisomeric mixture of (*E*)-2-alkenylsilane and the (Z)-isomer (**2a**, E : Z = 81 : 19, Run 1 in Table 1). Ate complexes such as $PhMe_2SiAlMe_3Li$,[3] $PhMe_2SiZnEt_2Li$,[3] $PhMe_2SiBEt_3Li$,[5] $(PhMe_2Si)_3MnMgMe$,[6] and $Ph_3SiAlMe_3Li$ are also effective for the regioselective formation of 1,7-homoconjugate adducts with an exception of the reaction of 2-styryl-1,1-cyclopropane dicarboxylate (**8**) (Run 10 in Table 1). The use of $(Ph_3Sn)_2Zn$ instead of silyl reagents produced 2-alkenylstannanes (Runs 6 and 7 in Table 1). In the same way, 2-(1,3-butadienyl)cyclopropanes gave the corresponding dienylsilanes upon treatment with these silylmetal reagents. The regiochemisty of the reaction heavily depends on the nature of the substrates. The 2-(1,3-butadienyl)-cyclopropane (**12**) gave 1,9-homoconjugate adduct mainly, whereas the 2-(4-phenyl-1,3-butadienyl)-cyclopropane (**14**) and 2-(3-methyl-1,3-butadienyl)-cyclopropane (**17**) afforded regioisomeric mixtures. The new method was successfully extended to the ring opening of vinylaziridines and dienylaziridines.



Scheme 1.



Scheme 2.

Two necessary factors for successful homoconjugate addition are as follows: (a) The presence of two activating groups and (b) a vinyl or dienyl group on the cyclopropane ring. Ethyl chrisanthemate did not undergo conjugate addition, and the attempted reaction of dimethyl 1,1-cyclopropanedicarboxylic ester resulted in the recovery of the starting material. Dimethyl 2-(2-methyl-1-propenyl)-1,1-cyclopropanedicarboxylate remained unchanged upon treatment with $PhMe_2SiAlEt_2$ (Run 11 in Table 1). Steric hindrance of geminal dimethyl groups explains the absence of the attack of $PhMe_2Si$ anion on the vinyl moiety.

Table 1. Homoconjugate Addition of Silylmetal Reagents to Vinylcyclopropanes and Dienylcyclopropanes

Run	Substrate	Reagent	Product	Y/% (E/Z)
1	 1	$PhMe_2SiAlEt_2$		100 (81/19)

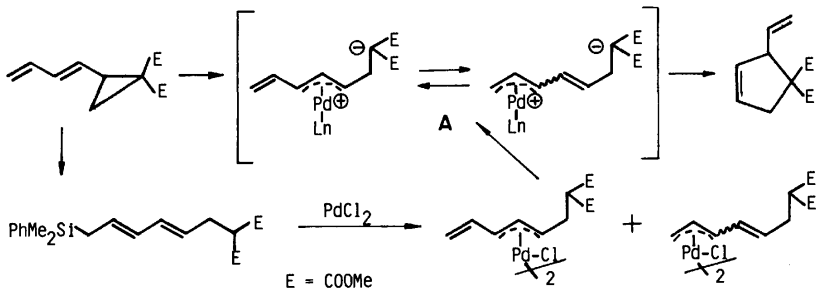


Scheme 3.

Previously, we reported[7,8] that 1,3-butadienylcyclopropanes in Scheme 3 activated by two electron-withdrawing groups smoothly rearranged to vinylcyclopentenes in the presence of a Pd(0) catalyst. 1-Tosyl-2-(1,3-butadienyl)aziridines reacted similarly to give pyrroline derivatives. A zwitterion **A** plays a critical role in the rearrangement. We next examined the synthesis of five-membered ring compounds via the π-allylpalladium complexes which were readily prepared from the above-mentioned alkenylsilanes and $[PdCl_2(CH_3CN)_2]$.

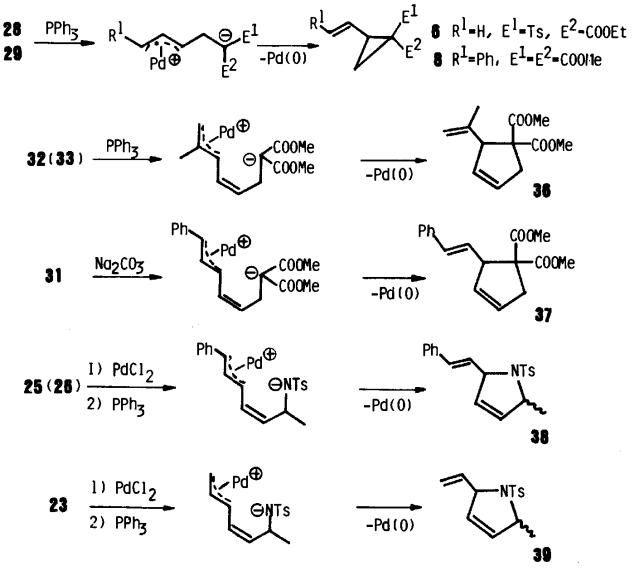
Treatment of the 2-alkenylsilanes **3**, **7**, **9(10)**, and

Table 2. Synthesis of π-Allylpalladium Complexes

Alkenylsilane (Alkenylstannane)	Product	Y/%
 **3**	 **27**	21
 **7**	 **28**	46
9, 10 (9/10 = 72/28)	 **29**	80
 **13**	 **30**	40
15, 16 (15/16 = 1/1)	 **31**	35
18, 19 (18/19 = 31/69)	 **32**	50
	 **33**	32/33 = 3/1
 **21**	 **34**	47
25, 26 (25/26 = 40/60)	 **35**	—

21 and 2,4-dienylsilanes **13**, **15(16)**, **18(19)**, and **25(26)** with one equivalent of $[PdCl_2(CH_3CN)_2]$ in tetrahydrofuran at 25 °C provided π-allylpalladium complexes[9] after purification by silica-gel column chromatography[10] (Table 2).

Exposure of the π-allylpalladiums **28** and **29** to PPh_3 resulted in the formation of the original alkenylcyclopropane derivatives **6** (40%) and **8** (46%) along with unidentified complex products containing isomeric methyl 2-methoxycarbonyl-6-phenylhexadienoate or ethyl 2-tosylhexadienoate. No trace of cyclopentene derivatives was observed. In contrast, treatment of a mixture of **32** and **33** in DMSO with PPh_3 or Na_2CO_3 gave the cyclopentene derivative **36** in 70% or 80% yield, respectively. Similarly, treatment of the crude π-allylpalladium **35** generated from a mixture of **25** and **26** with PPh_3 also produced the pyrroline derivative **38**. Naturally, the prerequisite to the cyclization into five-membered rings should be a U shaped configuration of the zwitterion **A** as shown in Scheme 4. The simple π-allylpalladium complexes such as **27**, **28**, and **29** can not take this form but give vinylcyclopropanes only. On the other hand, the conjugation of C=C bond to the π-allylpalladium moiety enables the aliphatic chain to assume the U shape and leads to the cyclization to five-membered rings. The observed behavior of the isolated π-allylpalladium complexes in the present work does support this idea.



Scheme 4.

Experimental

Distillation of the products was performed by use of Kugelrohr (Büchi), and boiling points are indicated by an airbath temperature without correction. All melting points were obtained on a Yanaco MP-50929 melting point apparatus and are uncorrected, too. ^{1}H NMR and ^{13}C NMR spectra were taken on a Varian XL-200 spectrometer, $CDCl_3$ was used as solvent unless otherwise noted, chemical shifts being given in δ with tetramethylsilane as an internal standard. IR spectra were determined on a JASCO IR-810 spectrometer. The analyses were carried out by the staff at the Elemental Analyses Center of Kyoto University. Tetrahydrofuran (THF) was freshly distilled from sodium benzophenone ketyl. Purification of 2-alkenylstannanes was performed by column chromatography on neutral alumina (Merck Art. 1077 (95 g), H_2O (5 g)), and other products were purified by silica-gel column chromatography.

Dimethyl 2-Vinyl-1,1-cyclopropanedicarboxylate (1). The compound was prepared by the reported procedure.[11]

Syntyesis of *cis*-1-Tosyl-3-methyl-2-vinylaziridine (20). This was synthesized in 40% overall yield from 1,3-pentadiene by oxyamination:[12] Mp 90—92 °C (crystallizes after distillation at 110 °C/0.2 Torr (1 Torr = 133.322 Pa)); ^{1}H NMR δ = 1.20 (d, J = 5.8 Hz, 3H), 2.44 (s, 3H), 3.03 (dq, J = 7.0, 5.8 Hz, 1H), 3.33 (d, J = 7.0, 6.9 Hz, 1H), 5.30 (dd, J = 9.9, 1.8 Hz, 1H), 5.39 (dd, J = 17.2, 1.8 Hz, 1H), 5.61 (ddd, J = 17.2, 9.9, 6.9 Hz, 1H); ^{13}C NMR δ = 12.2, 21.6, 40.8, 45.7, 121.3, 127.2, 127.6, 129.5, 129.6, 144.3; IR (nujol) 1596, 1323, 1161, 1091, 927, 841, 678 cm^{-1}; Found: C, 60.69; H, 6.35; N, 5.64%. Calcd for $C_{12}H_{15}NO_2S$: C, 60.73; H, 6.37; N, 5.90%.

General Procedure for the Preparation of Cyclopropanecarbaldehydes and Aziridinecarbaldehyde. These materials were prepared by means of oxidative cleavage of the corresponding olefinic compounds.[13] In a typical procedure a hexane solution of OsO_4 (0.06 mmol) was added to a solution of **20** (2.1 g, 9.0 mmol) in THF (55 ml) and water

(18 ml) at room temperature under argon atmosphere. The color of the solution turned dark brown after stirring for 5 min. Then powdered sodium periodate (5.2 g, 24.3 mmol) was added and the stirring was continued overnight. The mixture was diluted with hexane and the precipitate was filtered off. The filtrate was washed twice with aqueous sodium thiosulfate solution (1 M, 1 M = 1 mol dm^{-3}, 50 ml × 2), and aqueous layer was extracted with dichloromethane (30 ml). Combined organic layers were dried over anhydrous sodium sulfate and concentrated in vacuo. Purification by column chromatography (hexane-ethyl acetate, 3 : 1) afforded 1.7 g (80%) of *cis*-2-formyl-3-methyl-1-tosylaziridine: Mp 50 °C (crystallizes after distillation at 120 °C/0.2 Torr); ^{1}H NMR δ = 1.41 (d, J = 6.0 Hz, 3H), 2.48 (s, 3H), 3.0—3.4 (m, 1H), 3.20 (dq, J = 7.0, 6.0 Hz, 1H), 7.43 (d, J = 8.3 Hz, 2H), 7.89 (d, J = 8.3 Hz, 2H), 9.35 (d, J = 5.5 Hz, 1H); ^{13}C NMR δ = 12.9, 21.5, 40.8, 46.4, 127.8, 129.7, 129.8, 145.1, 195.3; IR (neat) 1727, 1595, 1326, 1162, 1090, 878, 714, 670 cm^{-1}.

Dimethyl 2-Formyl-1,1-cyclopropanedicarboxylate. Ozonolysis of **1** following the reported procedure[5] gave the title compound in 65% yield.

Ethyl 2-Formyl-1-tosyl-1-cyclopropanecarboxylate. This material was prepated in 87% yield from ethyl 1-tosyl-2-vinyl-1-cyclopropanecarboxylate[14] with $NaIO_4$ and OsO_4.

***cis*-3-Methyl-2-(4-phenyl-1,3-butadienyl)-1-tosylaziridine (24) (General Method for the Preparation of Dienylcyclopropanes[5] and Dienylaziridines).** To an ethereal suspension of cinnamyltriphenylphosphonium chloride (0.62 g, 1.5 mmol) was added potassium *t*-butoxide (0.12 g, 1.1 mmol) at 0 °C under argon atmosphere. The resulting red suspension was stirred for additional 10 min and then allowed to stand still. The supernatant was transferred using a hypodermic syringe into an ethereal solution of 1-tosyl-2-formyl-3-methylaziridine. After stirring for 30 min, the reaction mixture was poured into aqueous ammonium chloride (30 ml), extracted with hexane, and washed with water. The organic layer was dried over anhydrous sodium sulfate and evaporated in vacuo. Purification by column chromatography afforded **24** as a colorless oil (0.12 g, 54% yield): Bp 140 °C/760 Torr (decomp); ^{1}H NMR δ = 1.22 (d, J = 5.7, 3H), 2.37 (s, 3H), 3.14 (dq, J = 5.7, 7.2 Hz, 1H), 3.74 (ddd, J = 8.1, 7.2, 1.0 Hz, 1H), 5.21 (dd, J = 10.9, 8.1 Hz, 1H), 6.41 (dd, J = 11.1, 10.9 Hz, 1H), 6.61 (d, J = 15.5 Hz, 1H), 7.12 (ddd, J = 15.5, 11.1, 1.0 Hz, 1H), 7.2—7.5 (m, 7H), 7.85 (d, J = 8.3 Hz, 2H); ^{13}C NMR δ = 12.7, 21.5, 41.1, 41.9, 121.7, 123.1, 126.7, 127.6, 128.1, 128.6, 129.7, 135.4, 135.5, 135.7, 136.7, 144.3; IR (neat) 3026, 1591, 1493, 1450, 1396, 1323, 1156, 1091, 1046, 935, 875, 713, 693, 669 cm^{-1}; Found: C, 70.66; H, 6.48; N, 3.83%. Calcd for $C_{20}H_{21}NO_2S$: C, 70.77; H, 6.24; N, 4.13%.

***cis*-2-(1,3-Butadienyl)-3-methyl-1-tosylaziridine (22).** (E : Z = 22 : 78): Mp 78—80 °C (crystallizes after distillation at 150 °C/0.1 Torr); ^{1}H NMR δ = 1.19 (d, J = 5.9 Hz, 0.66H), 1.21 (d, J = 5.9 Hz, 2.34H), 2.43 (s, 3H), 3.0—3.2 (m, 1H), 3.37 (dd, J = 7.3, 7.3 Hz, 0.22H), 3.64 (ddd, J = 8.3, 7.1, 1.2 Hz, 0.78H), 5.1—5.7 (m, 3.22H), 6.2—6.5 (m, 0.22H), 6.25 (dd, J = 11.9, 10.1 Hz, 0.78H), 6.68 (dddd, J = 16.6, 11.2, 10.1, 1.1 Hz, 0.78H), 7.33 (d, J = 8.4 Hz, 2H), 7.82 (d, J = 8.4 Hz, 2H); ^{13}C NMR δ = 12.6, 21.5, 40.9, (41.2), 41.6, (45.2), (118.6), 120.7, 122.2, (124.6), (127.0), (127.2), 127.6, (129.5), 129.6, (131.1), 135.5, 135.6, (136.7), 144.3; IR (Nujol) 1596 (w), 1319, 1159, 1090, 910, 868, 677; Found: C, 63.61; H, 6.70; N, 5.58%. Calcd for $C_{14}H_{17}NO_2S$: C, 63.85; H, 6.51; N, 5.32%.

A Typical Procedure for Generation of Silylmetal Reagents. A THF solution of $PhMe_2SiLi$ (1.0 mmol) was added to a solution of Et_2AlCl (1.0 mmol) in THF (2 ml) at 0 °C under argon atmosphere and the resulting solution was stirred for 10 min. Other silylmetal reagents such as $PhMe_2SiBEt_3Li$,[6] $(PhMe_2Si)_3MnMgMe$,[7] and $PhMe_2SiAlEt_3Li$ were also prepared according to the procedures described before.

Reaction of Dimethyl 2-Vinyl-1,1-cyclopropanedicarboxylate (1) with $PhMe_2SiAlEt_2$. To a THF solution of $PhMe_2SiAlEt_2$ (0.94 mmol) was added a solution of **1** (80 mg, 0.43 mmol) in THF (2 ml) at 0 °C under argon atmosphere. After stirring for 1 h, the reaction mixture was diluted with dichloromethane (15 ml) and anhydrous sodium fluoride (0.42 g) was added. Then water (0.2 ml) was added dropwise and the resulting white suspension was vigorously stirred for 10 min. Filtration through a short column of anhydrous sodium sulfate and concentration followed by column chromatography gave 80 mg (100%) of dimethyl 5-(dimethylphenylsilyl)-3-pentene-1,1-dicarboxylate (**2a**) (E : Z = 81 : 19): Bp 125 °C/0.1 Torr; ^{1}H NMR δ = 0.21 (s, 4.9H), 0.28 (s, 1.1H), 1.66 (dd, J = 7.9, 0.8 Hz, 1.62H), 1.75 (dd, J = 8.7, 1.1 Hz, 0.38H), 2.53 (dd, J = 7.6, 7.6 Hz, 0.38H), 2.57 (dd, J = 7.6, 7.6 Hz, 1.62H), 3.25 (t, J = 7.6 Hz, 0.19H), 3.66 (t, J = 7.6 Hz, 0.81H), 3.70 (s, 4.9H), 3.71 (s, 1.1H), 5.1—5.3 (m, 1H), 5.4—5.6 (m, 1H), 7.3—7.6 (m, 5H); ^{13}C NMR δ = −3.6, (−3.4), (17.7), 21.8 (26.4), 32.0, (47.8), 51.6, (52.2), 52.3, (122.7), 124.2, 127.7, (127.8), (128.3), 128.9, (129.0), (129.1), 129.5, 133.5, 138.5, (143.0), 169.3, (169.5); IR (neat) 2952, 1752, 1737, 1437, 1249, 1156, 837, 731, 699 cm^{-1}; Found: C, 63.98; H, 7.71%. Calcd for $C_{17}H_{24}O_4Si$: C, 63.72; H, 7.55%.

Preparation of Dimethyl 5-(Triphenysilyl)-3-pentene-1,1-dicarboxylate (2b). (E : Z = 70 : 30). This compound was obtained (78 mg, 70%) by the reaction between vinylcyclopropane **1** (92 mg, 0.50 mmol) and $Ph_3SiAlMe_3Li$ (1.0 mmol) prepared from Ph_3SiLi[15] and Me_3Al: Bp 250 °C/0.1 Torr; ^{1}H NMR δ = 2.29 (d, J = 7.9 Hz, 1.4H), 2.37 (d, J = 7.4 Hz, 0.6H), 2.46 (dd, J = 7.3, 7.3 Hz, 0.6H), 2.50 (dd, J = 7.3, 7.3 Hz, 1.4H), 3.07 (t, J = 7.3 Hz, 0.3H), 3.23 (t, J = 7.3 Hz, 0.7H), 3.59 (s, 4.2H), 3.66 (s, 1.8H), 5.2—5.4 (m, 1H), 5.5—5.8 (m, 1H), 7.3—7.7 (m, 15H); ^{13}C NMR δ = (13.8), 19.4, (25.8), 32.1, 51.9, 52.3, 125.8, 127.8, 128.6, 129.5, 134.5, 135.7, 169.3; IR (neat) 3066, 3046, 3018, 2950, 1753, 1736, 1429, 1234, 1156, 1111, 967, 734, 700 cm^{-1}; Found: C, 73.09; H, 6.23%. Calcd for $C_{27}H_{28}O_4Si$: C, 72.94; H, 6.23%.

Preparation of Dimethyl 5-(Triphenylstannyl)-3-hexene-1,1-dicarboxylate (5). A hexane solution of diethylzinc (1.5 M, 0.24 ml, 0.35 mmol) was added to a THF solution of triphenylstannane (0.25 g, 0.70 mmol) at 0 °C under argon atmosphere. After stirring for 15 min, a solution of **4** (70 mg, 0.35 mmol) in THF (2 ml) was added. The reaction mixture was stirred for 30 min and poured into aqueous ammonium chloride (10 ml). Aqueous layer was extracted with dichloromethane. Organic layers were combined, washed with aqueous ammonium chloride and dried over anhydrous sodium sulfate. The solvent was removed and the residue was submitted to preparative TLC on silica

gel (hexane-ethyl acetate, 5 : 1) to give **5** (0.14 g, 74%, E : Z = 90 : 10) as a white solid: mp 63—66 °C (CH_2Cl_2); ^{1}H NMR δ=1.32 (dd, J=7.3, 1.5 Hz, 0.3H), 1.48 (d, J=7.3 Hz, 2.7H), 2.5—2.9 (m, 3H), 3.63 (s, 2.7H), 3.64 (s, 2.7H), 3.66 (s, 0.3H), 3.72 (s, 0.3H), 5.2—5.4 (m, 1H), 5.9—6.2 (m, 1H), 7.3—7.5 (m, 15H); ^{13}C NMR δ=16.9, 26.6, 32.1, 52.2, 52.3, 120.2, (128.0), 128.5, (128.8), 128.9, (136.9), 137.2, (137.4), 137.6, (137.8), 137.9, 138.1, 169.4; IR (neat) 2920, 2825, 1750, 1727, 1460, 1426, 1237, 1207, 1071, 971, 723, 697 cm^{-1}; Found: C, 61.29; H, 5.42%. Calcd for $C_{28}H_{30}O_4Sn$: C, 61.23; H, 5.51%.

Ethyl 6-(Dimethylphenylsilyl)-2-tosyl-4-hexenoate (7). (E : Z = 79 : 21): Bp 190 °C/0.1 Torr; ^{1}H NMR δ=0.21 (s, 4.74H), 0.27 (s, 1.26H), 1.12 (t, J=7.1 Hz, 2.37H), 1.13 (t, J=7.1 Hz, 0.63H), 1.63 (d, J=8.3 Hz, 1.58H), 1.73 (d, J=8.3 Hz, 0.42H), 2.44 (s, 3H), 2.5—2.8 (m, 2H), 3.75 (dd, J=8.6, 6.9 Hz, 0.21H), 3.88 (dd, J=11.2, 4.0 Hz, 0.79H), 4.0—4.2 (m, 2H), 5.0—5.2 (m, 1H), 5.4—5.6 (m, 1H), 7.1—7.6 (m, 9H); ^{13}C NMR δ=−3.6, 13.8, 21.6, 21.9, 30.1, 61.9, 70.8, 121.7, 127.7, 129.0, 129.3, 129.6, 131.1, 133.4, 134.1, 138.2, 145.3, 165.5; IR (neat) 2954, 1739, 1597, 1427, 1370, 1326, 1249, 1248, 1085, 837, 815, 731, 664, 572 cm^{-1}; Found: C, 64.33; H, 7.13%. Calcd for $C_{23}H_{30}O_4SSi$: C, 64.15; H, 7.02%.

A Mixture of Dimethyl (*E*)-3-(Dimethylphenylsilyl)-5-phenyl-4-pentene-1,1-dicarboxylate (9) and Dimethyl (*E*)-5-(Dimethylphenylsilyl)-5-phenyl-3-pentene-1,1-dicarboxylate (10) and (9 : 10= 72 : 28): Bp 190 °C/0.1 Torr; ^{1}H NMR δ=0.21 (s, 0.84H), 0.24 (s, 0.84H), 0.33 (s, 2.16H), 0.35 (s, 2.16H), 1.9—2.1 (m, 1.44H), 2.25 (dd, J=11.0, 10.0 Hz, 0.72H), 2.62 (dd, J=7.5, 7.3 Hz, 0.56H), 3.08 (d, J=10.0 Hz, 0.28H), 3.37 (t, J=7.3 Hz, 0.72H), 3.49 (dd, J=9.5, 4.5 Hz, 0.28H), 3.61 (s, 2.16H), 3.65 (s, 0.84H), 3.70 (s, 2.16H), 3.71 (s, 0.84H), 5.29 (dt, J=15.2, 7.5 Hz, 0.28H), 5.88 (dd, J=15.2, 10.0 Hz, 0.28H), 5.97 (dd, J=15.6, 9.0 Hz, 0.72H), 6.23 (d, J=15.6 Hz, 0.72H), 7.0—7.7 (m, 10H); ^{13}C NMR δ=−5.2, −4.5, (−4.41), (−4.36), 28.6, (32.05), 32.14, (42.5), 51.1, (52.0), 52.3, 52.4, (77.7), (124.2), (124.7), 125.7, 126.7, (127.3), 127.4, 127.8, 128.1, (128.4), 128.4, (129.1), 129.3, 129.6, 130.1, (132.9), 134.0, 134.2, (136.5), 137.7, 141.7, (169.3), (169.45), 169.54, 170.1; IR (neat) 2952, 1751, 1736, 1435, 1250, 1153, 832, 814, 700 cm^{-1}; Found: C, 69.78; H, 7.14%. Calcd for $C_{23}H_{28}O_4Si$: C, 69.66; H, 7.12%.

Ethyl 8-(Dimethylphenylsilyl)-2-tosyl-4,6-octadienoate (13): Bp 210 °C/0.1 Torr; ^{1}H NMR δ=0.2—0.3 (m, 6H), 1.1—1.2 (m, 3H), 1.6—1.9 (m, 2H), 2.46 (s, 3H), 2.5—2.9 (m, 2H), 3.8—4.3 (m 3H), 4.7—6.3 (m, 4H), 7.2—7.9 (m, 9H); ^{13}C NMR δ=−3.4, 13.9, 13.9, 21.7, 22.6, 30.1, 62.1, 70.4, 70.5, 73.0, 121.7, 127.0, 127.6, 127.7, 127.8, 128.6, 128.95, 129.04, 129.2, 129.3, 129.4, 129.5, 129.6, 131.2, 132.5, 133.9, 134.1, 134.9, 145.3, 165.5; IR (neat) 2956, 1738, 1598, 1428, 1327, 1148, 1085, 989, 835, 815, 700, 667 cm^{-1}; Found: C, 65.51; H, 7.10%. Calcd for $C_{25}H_{32}O_4SSi$: C, 65.75; H, 7.06%.

A Mixture of Dimethyl 5-(Dimethylphenylsilyl)-7-phenyl-3,6-heptadiene-1,1-dicarboxylate (15) and Dimethyl 3-(Dimethylphenylsilyl)-7-phenyl-4,6-heptadiene-1,1-dicarboxylate (16) (15 : 16 = 1 : 1): Bp 200 °C/0.2 Torr; ^{1}H NMR δ=0.30 (s, 1.5H), 0.31 (s, 1.5H), 0.31 (s, 1.5H), 0.33 (s, 1.5H), 1.8—2.0 (m, 1.0H), 2.20 (dd, J=11.4, 9.9 Hz, 0.5H), 2.62 (dd, J=7.3, 7.0 Hz, 1.0H), 2.76 (ddd, J=8.8, 4.4, 4.2 Hz, 0.5H), 3.38 (t, J=7.3 Hz, 0.5H), 3.4−3.5 (m, 0.5H), 3.64 (s, 1.5H), 3.68 (s, 3.0H), 3.70 (s, 1.5H), 5.21 (dt, J=16.2, 7.0 Hz, 0.5H), 5.5—5.6 (m, 0.5H), 5.63 (dd, J=16.2, 6.7 Hz, 0.5H), 6.04 (dd, J=15.2, 10.2 Hz, 0.5H), 6.1—6.2 (m, 1.0H), 6.39 (d, J=15.6 Hz, 0.5H), 6.73 (dd, J=15.6, 10.2 Hz, 0.5H), 7.0—7.6 (m, 10H); ^{13}C NMR δ=−5.2, −4.8, 28.6, 32.2, 39.6, 51.1, 52.1, 52.4, 52.5, 123.7, 125.7, 126.0, 126.5, 127.1, 127.6, 127.7, 127.8, 128.4, 128.6, 129.2, 129.48, 129.53, 130.6, 132.0, 134.05, 134.10, 134.7, 169.3, 169.5, 170.2; IR (neat) 3020, 2952, 1752, 1736, 1434, 1249, 1154, 1114, 832, 812, 735, 698 cm^{-1}; Found: C, 70.53; H, 7.22%. Calcd for $C_{25}H_{30}O_4Si$: C, 71.05; H, 7.16%.

Reaction of Dimethyl 2-(3-Methyl-1,3-butadienyl)-1,1-cyclopropanedicarboxylate (17) with $PhMe_2SiAlEt_3Li$. Treatment of **17** (0.13 g, 0.58 mmol) with $PhMe_2SiAlMe_3Li$ (1.5 mmol) afforded a mixture of dimethyl (3*E*)-5-(dimethylphenylsilyl)-6-methyl-3,6-heptadiene-1,1-dicarboxylate (**18**) and (4*E*)-3-(dimethylphenylsilyl)-6-methyl-4,6-heptadiene-1,1-dicarboxylate (**19**) (**18** : **19** = 31 : 69, 76 mg, 37%): bp 130 °C/0.1 Torr; ^{1}H NMR δ=0.28 (s, 0.93H), 0.28 (s, 0.93H), 0.29 (s, 2.07H), 0.30 (s, 2.07H), 1.58 (s, 0.93H), 1.78 (s, 2.07H), 1.80 (d, J=10.1 Hz, 0.31H), 1.8—2.0 (m, 0.69), 2.1—2.3 (m, 0.69H), 2.5—2.7 (m, 1.31H), 3.3—3.5 (m, 1H), 3.66 (s, 2.07H), 3.70 (s, 2.07H), 3.71 (s, 0.93H), 3.72 (s, 0.93H), 4.47 (bs, 0.31H), 4.66 (m, 0.31H), 4.81 (bs, 1.38H), 5.17 (dt, J=15.1, 7.1 Hz, 0.31H), 5.34 (dd, J=15.8, 9.3 Hz, 0.69H), 5.64 (dd, J=15.1, 10.1 Hz, 0.31H), 5.97 (d, J=15.8 Hz, 0.69H), 7.3—7.6 (m, 5H); ^{13}C NMR δ=−5.2, −4.5, (−4.3), 18.8, 28.5, 31.6, (32.1), (43.7), 52.0, (52.1), (52.3), 52.4 (108.5), 113.9, (123.4), 127.5, 127.7, (128.8), 128.95), (129.02), 129.2, 129.8, (129.9), (132.6), 132.7, (133.5), 134.0, 134.1, (136.6), 141.9, 169.4, (169.6), 170.2; IR (neat) 2954, 1754, 1737, 1435, 1250, 1155, 1115, 833, 816, 776, 735, 701 cm^{-1}; Found: C, 66.43; H, 7.87%. Calcd for $C_{20}H_{28}O_4Si$: C, 66.63; H, 7.83%.

(2*E*)-1-(Dimethylphenylsilyl)-4-tosylamino-2-pentene (21): Bp 170—180 °C/0.1 Torr; ^{1}H NMR δ=0.20 (s, 6H), 1.11 (d, J=6.7 Hz, 3H), 1.54 (d, J=7.9 Hz, 2H), 2.40 (s, 3H), 3.77 (ddq, J=7.0, 6.7, 6.7 Hz, 1H), 4.62 (d, J=7.0 Hz, 1H), 5.02 (ddt, J=15.2, 6.7, 1.2 Hz, 1H), 5.38 (ddt, J=15.2, 7.9, 1.0 Hz, 1H), 7.25 (d, J=8.1 Hz, 1H), 7.3—7.5 (m, 5H), 7.73 (d, J=8.1 Hz, 2H); ^{13}C NMR δ=−3.6, 21.4, 21.5, 22.3, 51.6, 127.1, 127.6, 127.7, 129.0, 129.4, 129.7, 133.5, 138.0, 138.2, 143.0; IR (neat) 3272, 2956, 1657, 1598, 1426, 1325, 1249, 1159, 1113, 1095, 1066, 965, 836, 813, 698, 663 cm^{-1}; Found: C, 64.11; H, 7.33; N, 3.68%. Calcd for $C_{20}H_{27}NO_2SSi$: C, 64.30; H, 7.28; N, 3.75%.

(2*E*,4*E*)-1-(Dimethylphenylsilyl)-6-tosylamino-2,4-heptadiene (23): Bp 220 °C/0.1 Torr (partially decomposed); ^{1}H NMR δ=0.26 (s, 6H), 1.18 (d, J=6.7 Hz, 3H), 1.74 (d, J=7.8 Hz, 2H), 2.40 (s, 3H), 3.94 (ddq, J=7.2, 6.5, 6.7 Hz, 1H), 4.28 (d, J=7.2 Hz, 1H), 5.20 (dd, J=15.1, 6.5 Hz, 1H), 5.59 (dt, J=15.0, 7.8 Hz, 1H), 5.74 (dd, J=15.0, 9.5 Hz, 1H), 5.92 (dd, J=15.1, 9.5 Hz, 1H), 7.28 (d, J=8.2 Hz, 2H), 7.3—7.6 (m, 5H), 7.75 (d, J=8.2 Hz, 2H); IR (neat) 3270, 2956, 1736, 1427, 1327, 1249, 1158, 1116, 1094, 833, 813, 700, 665 cm^{-1}; Found: C, 65.70; H, 7.38; N, 3.30%. Calcd for $C_{22}H_{29}NO_2SSi$: C, 66.12; H, 7.31; N, 3.50%.

Reaction of 2-(4-Phenyl-1,3-butadienyl)-3-methyl-1-tosylaziridine (24) with $PhMe_2SiAlEt_3tLi$. Reaction between **24** (89 mg, 0.26 mmol) and $PhMe_2SiAlEt_3Li$ (1.0 mmol)

afforded a mixture of 3-(dimethylphenylsilyl)-1-phenyl-6-tosylamino-1,4-heptadiene (**25**) and 5-(dimethylphenylsilyl)-1-phenyl-6-tosylamino-1,3-heptadiene (**26**) (**25** : **26** = 40 : 60, 63 mg, 46%): bp 250 °C/0.1 Torr; ^{1}H NMR δ = 0.24 (s, 2.4H), 0.26 (s, 1.8H), 0.27 (s, 1.8H), 1.11 (d, J = 6.7 Hz, 1.8H), 1.13 (d, J = 6.7 Hz, 1.2H), 2.2—2.4 (m, 0.4H), 2.32 (s, 1.8H), 2.43 (s, 1.2H), 2.61 (dd, J = 7.8, 6.7 Hz, 0.6H), 3.5—3.7 (m, 0.4H), 3.84 (ddq, J = 7.2, 6.7, 6.7 Hz, 0.6H), 4.30 (d, J = 7.2 Hz, 0.6H), 4.50 (d, J = 8.9 Hz, 0.4H), 4.93 (ddd, J = 15.4, 6.7, 1.0 Hz, 0.6H), 5.3—5.5 (m, 0.4H), 5.51 (ddd, J = 15.4, 8.9, 1.0 Hz, 0.6H), 5.9—6.2 (m, 1.2H), 6.2—6.6 (m, 1.2H), 7.1 — 7.8 (m, 9.0H); ^{13}C NMR δ = −5.2, −4.7, (−4.2), (−3.9), (19.7), 21.4, (21.5), 22.2, (36.5), 39.6, (50.4), 51.6, (123.9), 124.0, (125.6), 125.7, (126.5), 126.6, (127.0), 127.1, (127.5), 127.7, (127.9), 128.5, 128.8, 128.9, 129.4, 129.5, (129.59), (129.64), 130.1, (131.7), (133.0), (133.3), (133.8), 134.1, 136.4, (136.5), (137.3), 137.9, 138.1, (138.2), (139.1), 143.0, (143.1); IR (neat) 3446 (br, w), 3270, 2956, 1736, 1598, 1427, 1325, 1249, 1160, 1114, 1094, 1071, 969, 812, 698, 664; Found: C, 70.08; H, 7.08; N, 2.78%. Calcd for $C_{28}H_{33}NO_2SSi$: C, 70.69; H, 6.99; N, 2.94%.

General Method for the Preparation of π-Allylpalladium Complexes from 2-Alkenylsilanes and 2,4-Dienylsilanes with $[PdCl_2(CH_3CN)_2]$. The preparation of di-μ-chloro-bis{1,3-η-[5,5-bis(methoxycarbonyl)-2-pentenyl]-palladium(II)} (**27**) is representative. To a THF solution (2 ml) of dimethyl 5-(triphenylstannyl)-3-pentene-1,1-dicarboxylate (**3**) (0.20 g, 0.37 mmol) was added in one portion bis(acetonitrile)dichloropalladium(II) (0.10 g, 0.40 mmol) at room temperature under argon atmosphere. The resulting orange-yellow suspension was stirred for 1 h. The reaction mixture was subjected to column chromatography[15] (hexane-ethyl acetate, 1 : 1). Crude product was repurified by column chromatography to give 26 mg (0.07 mmol, 21% yield) of **27** as yellow crystals from CH_2Cl_2: mp 153.5—154 °C; ^{1}H NMR δ = 2.1—2.4 (m, 2H), 2.87 (d, J = 12.0 Hz, 1H), 3.6—3.8 (m, 2H), 3.73 (s, 3H), 3.75 (s, 3H), 3.94 (d, J = 6.7 Hz, 1H), 5.35 (ddd, J = 12.0, 6.9, 6.7 Hz, 1H); ^{13}C NMR δ = 31.2, 50.3, 52.6, 52.6, 59.8, 80.0, 111.2, 168.6, 168.8; IR (Nujol): 1731, 1294, 1212, 1154, 1025 cm^{-1}; Found: C, 33.35; H, 4.06%. Calcd for $C_{18}H_{26}Cl_2O_8Pd_2$: C, 33.05; H, 4.01%.

Di-μ-chloro-bis[1-3-η-(5-ethoxycarbonyl-5-tosyl-2-pentenyl)palladium(II)] (28) (Mixture of Diastereomers (6 : 4)): Mp 60 °C (CH_2Cl_2); ^{1}H NMR δ = 1.14 (t, J = 7.3 Hz, 1.2H), 1.18 (t, J = 7.2 Hz, 1.8H), 2.1—2.6 (m, 2H), 2.46 (s, 3H), 2.87 (d, J = 11.9 Hz, 0.6H), 2.92 (d, J = 11.9 Hz, 0.4H), 3.54 (dt, J = 11.1, 6.3 Hz, 0.6H), 3.83 (dt, J = 11.1, 6.3 Hz, 0.4H), 3.95 (d, J = 6.3 Hz, 0.6H), 3.98 (d, J = 6.3 Hz, 0.4H), 4.13 (q, J = 7.3 Hz, 0.8H), 4.15 (q, J = 7.2 Hz, 11.2H), 4.26 (dd, J = 7.3, 6.7 Hz, 0.4H), 4.36 (dd, J = 11.0, 3.9 Hz, 0.6H), 5.33 (ddd, J = 11.9, 11.1, 6.3 Hz, 0.6H), 5.36 (ddd, J = 11.9, 11.1, 6.3 Hz, 0.4H), 7.39 (d, J = 8.3 Hz, 2H), 7.78 (d, J = 8.3 Hz, 2H); ^{13}C NMR δ = (13.8), 13.9, 21.7, (29.2), 29.4, 60.3, (60.4), 62.4, 68.5, (69.0), 76.3, 77.8, (78.8), (111.0), 111.4, 129.2, (129.3), 129.8, (134.1), 145.6, 165.2; IR (neat) 2980, 2934, 1736, 1597, 1446, 1370, 1325, 1247, 1148, 1084, 1046, 814, 716, 668 cm^{-1}; Found: C, 41.16; H, 4.29%. Calcd for $C_{30}H_{38}Cl_2O_8S_2Pd_2$: C, 41.20; H, 4.38%.

Di-μ-chloro-bis{1-3-η-[5,5-bis(methoxycarbonyl)-1-phenyl-2-pentenyl]palladium(II)} (29, 80% from a mixture of **9** and **10**): Mp 195 °C (decomp) (CH_2Cl_2); ^{1}H NMR δ = 2.2—2.4 (m, 2H), 3.6—3.9 (m, 2H), 3.73 (s, 6H), 4.47 (d, J = 11.4 Hz, 1H), 5.70 (dd, J = 11.4, 10.8 Hz, 1H), 7.2—7.4 (m, 5H); ^{13}C NMR δ = 31.3, 50.5, 52.7, 52.7, 77.7, 78.8, 106.9, 128.0, 128.4, 129.0, 168.7, 168.9; IR (Nujol) 1750, 1733, 1282, 1222, 1147, 690 cm^{-1}; Found: C, 44.67; H, 4.31%. Calcd for $C_{30}H_{34}O_8Cl_2Pd_2$: C, 44.69; H, 4.25%.

Di-μ-chloro-bis[1-3-η-(7-ethoxycarbonyl-7-tosyl-2,4-heptadienyl)palladium(II)] (30) (1 : 1 Diastereomeric Mixture, Very Unstable): Mp 80 °C (decomp) (CH_2Cl_2); ^{1}H NMR δ = 1.14 (t, J = 7.0 Hz, 1.5H), 1.16 (t, J = 7.0 Hz, 1.5H), 2.46 (s, 3H), 2.5—2.7 (m, 2H), 2.89 (d, J = 11.7 Hz, 1H), 3.86 (d, J = 6.7 Hz, 1H), 3.98 (dd, J = 9.1, 6.0 Hz, 1H), 4.0—4.5 (m, 3H), 5.23 (ddd, J = 11.7, 10.2, 6.7 Hz, 1H), 5.73 (dd, J = 15.5, 9.5 Hz, 1H), 5.8—6.1 (m, 1H), 7.37 (d, J = 7.9 Hz, 2H), 7.75 (d, J = 7.9 Hz, 2H); IR (benzene) 1736, 1597, 1326, 1147, 1084 cm^{-1}.

Di-μ-chloro-bis{3-5-η-[7,7-bis(methoxycarbonyl)-1-phenyl-1,3-hephadienyl]palladium(II)} (31) (from a mixture of 15 and 16): Mp 80 °C (decomp) (CH_2Cl_2); ^{1}H NMR δ = 1.5—1.7 (m, 1H), 2.1—2.3 (m, 1H), 3.5—3.8 (m, 2H), 4.47 (dd, J = 15.6, 10.3 Hz, 1H), 5.31 (dd, J = 11.5, 10.3 Hz, 1H), 6.31 (dd, J = 15.6, 10.3 Hz, 1H), 6.99 (d, J = 15.6 Hz, 1H), 7.2—7.6 (m, 5H); IR (CH_2Cl_2) 2922, 2842, 1730, 1433, 1261 cm^{-1}.

A Mixtrure of Di-μ-chloro-bis{1-3-η-[7,7-bis(methoxycarbonyl)-2-methyl-2,4-heptadienyl] palladium(II)} (32) and Di-μ-chloro-bis{3-5-η-[7,7-bis(carbomethoxy)-2-methyl-1,3-heptadienyl]palladium(II)} (33) (32 : 33 = 3 : 1): Mp 80 °C (decomp) (CH_2Cl_2); ^{1}H NMR δ = 1.97 (s, 0.75H), 2.1—2.4 (m, 0.25H), 2.13 (s, 2.25H), 2.46 (dd, J = 7.3, 7.3 Hz, 0.25H), 2.53 (dd, J = 7.3, 7.1 Hz, 1.50H), 2.74 (s, 0.75H), 3.49 (t, J = 7.3 Hz, 0.75H), 3.5—3.6 (m, 0.25H), 3.7—3.8 (m, 0.25H), 3.74 (s, 0.75H), 3.75 (s, 4.50H), 3.77 (s, 0.75H), 3.80 (s, 0.75H), 4.19 (d, J = 10.3 Hz, 0.75H), 4.25 (d, J = 11.1 Hz, 0.25H), 5.26 (dd, J = 11.4, 11.1 Hz, 0.25H), 5.42 (s, 0.25H), 5.53 (s, 0.25H), 5.89 (dd, J = 15.4, 10.4 Hz, 0.75H), 6.12 (dt, J = 15.4, 7.1 Hz, 0.75H); ^{13}C NMR δ = 18.8, 32.8, 49.3, 50.5, 50.9, 52.58, 52.63, 52.7, 60.2, 67.2, 76.6, 83.8, 102.6, 120.1, 129.6, 135.0, 135.1, 169.0, 169.1; IR (neat) 2952, 2254, 2236, 1732, 1436, 1343, 1266, 1230, 1157, 1026, 969, 914, 731 cm^{-1}; Found: C, 39.15; H, 4.83%. Di-μ-chloro-bis[3-5-η-(1-phenyl-6-tosylamino-1,3-heptadienyl)palladium(II)] and Its Unidentified Isomers

(35): The compound is so unstable and the crude product was used directly for further transformation (see below).

4,4-Bis(methoxycarbonyl)-3-isopropenylcyclopentene (36). Treatment of **32** (36 mg, 0.08 mmol) with PPh_3 (87 mg, 0.3 mmol) in DMSO (2 ml) at 60 °C for 1 h gave **36** (15 mg, 70% yield) which was identical with a sample prepared by the Pd(0) promoted vinylcyclopropane-cyclopentene rearrangenent method.[5] The use of Na_2CO_3 (10 equiv) and anhydrous LiCl (10 equiv)[16] instead of PPh_3 also gave **36** in 80% yield.

4,4-Bis(methoxycarbonyl)-3-styrylcyclopentene (37). Na_2CO_3 (35 mg, 0.35 mmol) and LiCl (15 mg, 0.35 mmol) were added to a solution of **31** (15 mg, 0.035 mmol) in DMSO (1 ml) and the resulting mixture was heated at 60 °C for 3 h to give **37**[5] (11 mg, 95% yield).

General Procedure for the Transformation of Dienylsilanes into Pyrroline Derivatives via Alkenyl-substituted π-Allylpalladiums. The crude product **35** (^{1}H NMR δ=1.5—1.7 (m, 1H), 2.1—2.3 (m, 1H), 3.5—3.8 (m, 2H), 4.47 (dd, J=11.5, 10.3 Hz, 1H), 5.31 (dd, J=11.5, 10.3 Hz, 1H), 6.31 (dd, J=15.6, 10.3 Hz, 1H), 6.99 (d, J=15.6 Hz, 1H), 7.2—7.6 (m, 5H)) derived from a mixture of **25** and **26** (32 mg, 0.07 mmol) and $[PdCl_2(CH_3CN)_2]$ (20 mg, 0.08 mmol) was dissolved in 2 ml of dimethyl sulfoxide under argon atmosphere. To this yellow solution was added triphenylphosphine (15 mg, 0.057 mmol). The reaction mixtrure was heated at 63 °C overnight. Resulting dark brown suspension was poured into water and extracted with ether. Purification by preparative TLC on silica gel (hexane-ethyl acetate, 5 : 1) gave 1-tosyl-2-(*E*)-2-styryl-5-methyl-3-pyrroline (**38**, cis : trans = 85 : 15, 0.012 mmol, 18% overall yield from dienylsilane) as colorless crystals: mp 145 °C (CH_2Cl_2); ^{1}H NMR δ=1.42 (d, J=6.5 Hz, 2.55H), 1.55 (d, J=6.3 Hz, 0.45H), 2.33 (s, 0.45H), 2.37 (s, 2.55H), 4.58 (ddq, J=1.8, 0.9, 6.5 Hz, 0.85H), 4.6—4.8 (m, 0.15H), 5.05 (dm, J=7.1 Hz, 0.85H), 5.1—5.2 (m, 0.15H), 6.06 (dd, J=15.9, 7.1 Hz, 1H), 6.50 (d, J=15.9 Hz, 0.15H), 6.51 (d, J=15.9 Hz, 0.85H), 7.10 (d, J=8.0 Hz, 0.30H), 7.1—7.4 (m, 6.7H), 7.64 (d, J = 8.0 Hz, 0.30H), 7.74 (d, J = 8.4 Hz, 1.70H); ^{13}C NMR δ= 21.5, 23.8, 63.5, 68.9, 126.6, 127.4, 127.5, 127.7, 128.4, 129.6, 120.0, 131.0, 131.3, 135.8, 136.4, 143.3; IR (CCl_4) 2990, 1740, 1720, 1587, 1492, 1444, 1344, 1167, 1091 cm^{-1}; Found: C, 70.70; H, 6.29; N, 3.88%. Calcd for $C_{20}H_{21}NO_2S$: C, 70.77; H, 6.24; N, 4.13%.

2-Ethenyl-5-methyl-1-tosyl-3-pyrroline (39). (cis: trans = 84 : 16): Mp 63—64 °C (crystallizes after distillation at 150 °C/0.1 Torr); ^{1}H NMR δ=1.38 (d, J=6.5 Hz, 2.52H), 1.43 (d, J=6.3 Hz, 0.48H), 2.41 (s, 3H), 5.51 (ddq, J=1.9, 3.6, 4.5 Hz, 0.84H), 4.6—4.8 (m, 0.16H), 4.8—4.9 (m, 0.84H), 4.9—5.0 (m, 0.16H), 5.13 (dt, J=10.1, 1.1 Hz, 1H), 5.29 (dt, J=10.1, 1.1 Hz, 1H), 5.4—5.7 (m, 2H), 5.83 (ddd, J=17.1, 10.1, 6.7 Hz, 1H), 7.29 (d, J=8.0 Hz, 2H), 7.72 (d, J = 8.0 Hz, 2H); ^{13}C NMR δ= (20.1), 21.5, (21.7), 23.8, (63.0), 63.6, 69.2, (69.8), 115.8, (116.0), (116.7), (117.0), 127.3, 127.4, (127.6), (127.7), 129.2, 129.6, 131.0, (131.6), (135.4), 138.8, 143.3; IR (Nujol) 1343, 1182, 1163, 1126, 1091, 1044, 926, 806, 668, 656, 595 cm^{-1}; Found: C, 63.64; H, 6.60; N, 5.09%. Calcd for $C_{14}H_{17}NO_2S$: C, 63.85; H, 6.51; N, 5.32%.

Selective Formation of Formic Acid, Oxalic Acid, and Carbon Monoxide by Electrochemical Reduction of Carbon Dioxide

Shoichiro IKEDA,* Takehiko TAKAGI, and Kaname ITO
Department of Applied Chemistry, Nagoya Institute of Technology,
Gokiso-cho, Showa-ku, Nagoya 466
(Received October 8, 1986)

Selective formation of formic acid, oxalic acid, and carbon monoxide by electrochemical reduction of carbon dioxide (CO_2) is demonstrated using several metallic electrodes in aqueous and nonaqueous electrolytes. The electrode metals catalyze the electrochemical reduction of CO_2 and are classified to three groups according to their main products from CO_2. In and Pb electrodes as well as Hg electrodes are useful for the selective formation of formic acid by electrochemical reduction of CO_2 in aqueous electrolytes. In the case of nonaqueous electrolytes, Pb, Hg, and Tl are useful for oxalic acid, and In, Zn, Au, and Sn electrodes are useful for carbon monoxide. Also, reaction mechanisms of CO_2 electrochemical reduction are discussed.

We have studied the electrochemical reduction of carbon dioxide, CO_2, to organic compounds using solid-state metallic electrodes. Then, we have also indicated that the reduction product of CO_2 in aqueous electrolytes is only formic acid at all electrodes examined such as Zn, In, Sn and Pb,[1-3] as well as at Hg as previously reported by other authors.[4-6] In the previous papers,[7,8] we reported that oxalic acid and carbon monoxide were mainly produced by the electroreduction of CO_2 at some metallic electrodes in nonaqueous electrolytes.

In the present work, a gastight cell with a cyclic gas flow system was used for electrolytic experiments, and the gaseous products in the gas phase were then determined in a manner similar to that used for the products in the electrolytes. According to the results in this work and those reported in the previous papers, we will discuss on the electrochemical reduction of CO_2 in aqueous and nonaqueous electrolytes, and also we will summarize the selective formation of formic acid, oxalic acid, and carbon monoxide from CO_2 by the electrochemical method.

Experimental

The working electrodes were prepared from solid-state metals such as Ti (99.3%), Cr (99.2%), Fe (99.9%), Ni (99.3%), Cu (99.99%), Zn (99.9999%), Nb (99.2%), Mo (99.95%), Pd (99.9%), Ag (99.99%), Cd (99.9999%), In (99.999%), Sn (99.999%), Pt (99.99%), Au (99.99%), Tl (99.99%), and Pb (99.99%) which were as pure as possible. These have employed as plate electrodes described in the previous papers[1-3] except for Au having a string shape. Hg was also used in liquid-state after distillation. A silver-silver chloride electrode and a bright platinum plate served as a reference electrode and an anode, respectively.

An electolytic cell for electroreduction of CO_2 in this work was almost the same structure as that reported in a previous paper[9] except for lacking of a quartz window. Namely, the cell made of Teflon was designed to separate the cathode chamber from the anode one with a cation-exchange membrane, Nafion 315, and also to be able to operate with a small volume of electrolyte, that is, 10 ml, for easy determination of the products. The cell was gastight and CO_2 gas was supplied with the cyclic gas flow system,[9] which was assembled from a mini peristaltic pump, a manometer, a gas sampler, and glass tubes.

Carbon dioxide gas was at first supplied into the catholyte of the cell from a CO_2 gas cylinder and exhausted through the cyclic gas flow system for 30 min. After the electrolytes was sufficiently saturated with CO_2 gas and the system was filled with CO_2, the line was closed to make it gastight. Thereafter, the gas in the system was circulated by the mini peristaltic pump at a rate of 1 ml min^{-1}.

Aqueous electrolytes, namely 0.1 M TEAP/H_2O (1 M = 1 mol dm^{-3}), were prepared from the synthesized tetraethylammonium perchlorate, TEAP, which was prepared from tetraethylammonium bromide, TEABr, and perchloric acid, and twice distilled water.

In order to prepare the nonaqueous electrolytes, propylene carbonate, PC, acetonitrile, AN, and dimethyl sulfoxide, DMSO, were employed as an aprotic solvent. The nonaqueous electrolytes, namely 0.1 M TEAP/PC, were prepared from synthesized TEAP and PC purified by Jasinski and Kirkland's method.[10] AN and DMSO were dried with unhydrous sodium sulfate (1.5 g l^{-1}) and then with Molecular sieve-4A (40 g l^{-1}). They were used without the other purification, although a little amount of the reduction products of some impurities in AN was found by high performance liquid chromatography.

The electrolytic experiment for CO_2 reduction was potentiostatically performed using a potentiostat and an electronic coulometer, Hokuto Denko; PS-303 and HF-201, respectively. Mainly, 100 coulombs were passed through the working electrode for each experiment.

The products in the gas phase were quantitatively determined using a gas chromatograph, Shimadzu; GC-3AH, having a TC detector on a column of activated charcoal using He gas as the carrier gas. On the other hand, the products in the electrolytes were sampled after the line was exposed to the atmosphere and then were determined using a high performance liquid chromatograph, Mitsumi (Atto); HSLC-022, having a RI detector and an UV detector on a column of Shodex Ion-Exchanger HC-125S using 1% H_3PO_4 aqueous solution as an eluent solution. Also a steam chromatograph, Ohkura Riken; SSC-1, having a FID detector on a column of G-0 (Chlomosolb 101), was used for determination of alcohols and aldehydes, although they were not observed at all in the present work.

Results and Discussion

In Aqueous Electrolytes. Table 1 shows all products obtained by electroreduction of CO_2 at potentials of −2.0 and −2.4 V vs. Ag/AgCl/sat'd KCl, using Zn, In, Sn, and Pb electrodes in 0.1 M TEAP aqueous electrolytes. It is evident from this table that carbon monoxide is produced even in aqueous electrolytes. Also the sum of the current efficiencies for formic acid, carbon monoxide, and hydrogen as a by-product is approximately 100%, so that they must represent all of the products obtained in this experiment.

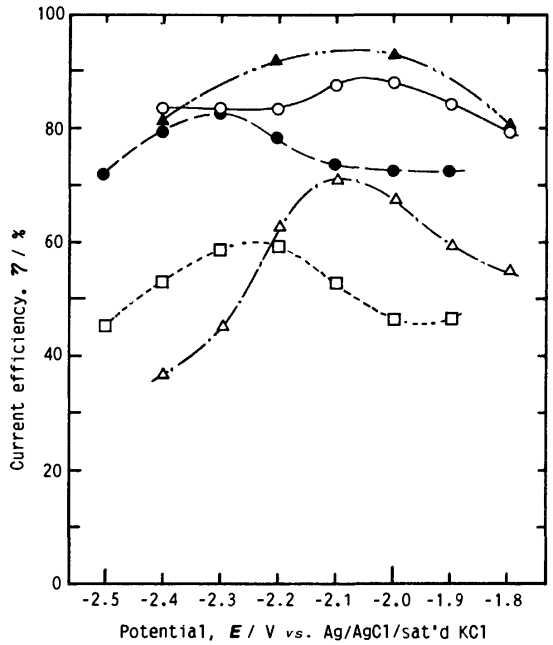

Fig. 1. Current efficiencies for formic acid formation at various metallic electrodes in 0.1 M TEAP/H_2O. Quantity of electricity passed: 100 C. ▲: Hg, ○: In, ●: Pb, △: Sn, □: Zn.

The current efficiencies for formic acid formation with respect to electrode potentials, when CO_2 has been reduced at various electrodes in 0.1 M TEAP aqueous electrolytes is shown in Fig. 1. In the case of In electrodes, the current efficiency went up to about 90% in the potential range of −2.0 to −2.1 V. Therefore, In electrode will be the most useful of the solid-state metallic electrodes for formic acid formation.

Figure 2 shows the current efficiencies for carbon monoxide formation under the same conditions as in Fig. 1. In the case of Zn electrodes, the current efficiency went up to about 36% in the potential range of −1.9 to −2.0 V even in the aqueous electrolyte.

In Nonaqueous Electrolytes. The brief results of electroreduction products of CO_2 obtained at In, Pb, Sn, and Zn electrodes in 0.1 M TEAP/PC electrolytes were already reported in the previous paper.[8] In the case of In electrodes, the efficiency for carbon

	4.2	0.0	0.0	63.6	20.0	83.6

Initial water content of 0.1 M TEAP/PC is 0.032%.

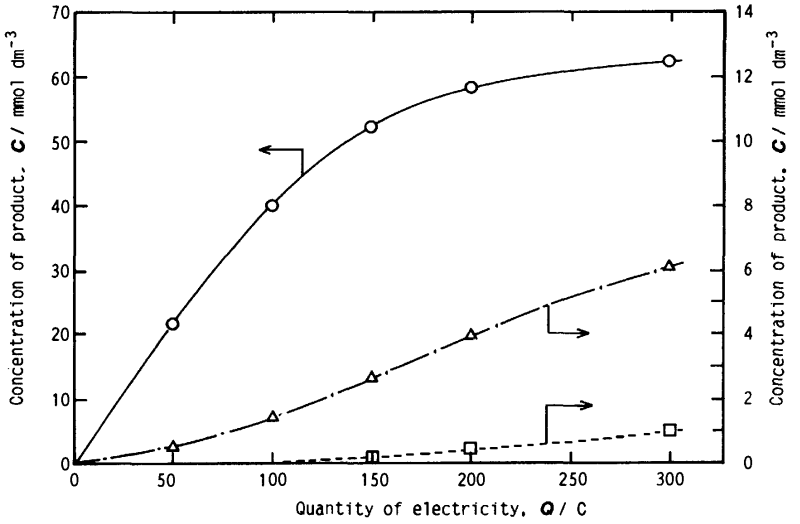

Fig. 3. Carboxylic acid formation at Pb electrode in 0.1 M TEAP/PC at −2.8 V vs. Ag/AgCl/(0.01 M LiCl+0.1 M TEAP)/PC. ○: Oxalic acid, △: glyoxylic acid, □: glycolic acid.

monoxide went up to 90% at −2.8 V, while the efficiency for formic acid and oxalic acid were very small. Therefore, an In electrode was suitable for selective production of carbon monoxide from CO_2 in nonaqueous electrolyte.

On the other hand, at a Pb electrode, the main product became oxalic acid, and the current efficiencies increased at more negative potentials and went up to 84% at −3.0 V. In this case, detectable amount of glyoxylic acid was produced and the efficiency went up to 7% at −3.0 V, while carbon monoxide increased at relatively noble potentials and the efficiency went up to 13% at −2.2 V. These results indicated that Pb electrodes were suitable for selective production of oxalic acid.

Figure 3 shows the concentration of oxalic acid, glyoxylic acid, and glycolic acid, with respect to the quantity of electricity passed, when electrolytic reduction of CO_2 has been performed at −2.8 V, using Pb electrodes in 0.1 M TEAP/PC nonaqueous electrolytes. The concentration of oxalic acid increased almost linearly up to 150 C and thereafter the rate of increase slowed. The concentration of glyoxylic acid then progressively increased, and after 150 C passed, glycolic acid also began to be produced.

These facts suggest that glyoxylic acid and glycolic acid are psoduced by the further reduction of oxalic acid obtined in the electrochemical reduction of CO_2.

Table 2 shows the relationship between the water content in nonaqueous electrolytes and the electroreduction products of CO_2. In the case of Pb electrodes, as mentioned above, oxalic acid was the main product in 0.1 M TEAP/PC electrolyte having an initial water content of 0.032%, while increasing the water content to 0.83 or 4.2% causes an extreme decrease in oxalic acid and an increase in formic acid.

In the case of In electrodes, increasing the water content causes a decrease in carbon monoxide and also an increase in formic acid. In both cases of 4.2% water content, formic acid becomes the main product in-

stead of oxalic acid or carbon monoxide.

The above mentioned results demonstrate that the main products of CO_2 electroreduction in nonaqueous electrolytes are oxalic acid at Pb electrodes and carbon monoxide at In electrodes. In order to clarify the function of these electrode metals, various electrodes were prepared from many kinds of metals and the current efficiencies for oxalic acid and carbon monoxide production were measured using these electrodes in 0.1 M TEAP/PC, 0.1 M TEAP/DMSO, and 0.1 M TEAP/AN nonaqueous electrolytes, respectively. The water content of each electrolyte determined by Karl Fischer's method was 294, 883, and 206 ppm, respectively.

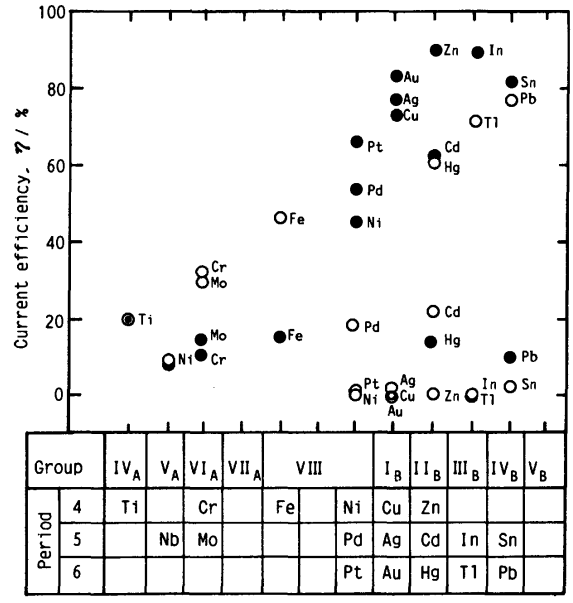

Fig. 4. Current efficiencies for oxalic acid or carbon monoxide formation from CO_2 at various electrodes in 0.1 M TEAP/PC at −2.8 V vs. Ag/AgCl/(0.01 M LiCl+0.1 M TEAP)/PC. Quantity of electricity passed: 100 C. O: Oxalic acid, ●: carbon monoxide.

Figures 4, 5, and 6 show the relationships between the position on the periodic table for the metals employed and the current efficiencies for oxalic acid and carbon monoxide formations in these electrolytes, respectively. These figures indicate that these metals are divided into three groups. The first group is the metals of Group A in the periodic table, such as Fe, Cr, Mo, and Ti; the electrodes prepared from such metals contribute to the production of substantial amounts of oxalic acid and carbon monoxide. The second group is VIII and B group metals except for Pb, Tl, and Hg; the electrodes of these metals contribute to the selective production of carbon monoxide, of which the current efficiencies at In and Zn electrodes go up to 90% and oxalic acid production is very small. The third group consists of Pb, Tl, and Hg, and such metal electrodes contribute to selective production of oxalic acid in spite of the B group metal. The current efficiency for oxalic acid production at the Pb electrode goes up to 80% and carbon monoxide production is very small. The Hg electrode belongs to this group, because it does not produce hydrogen at all similarly to the other IIB, IIIB, and IVB group metals as shown in Table 3, although its production rates of ox-

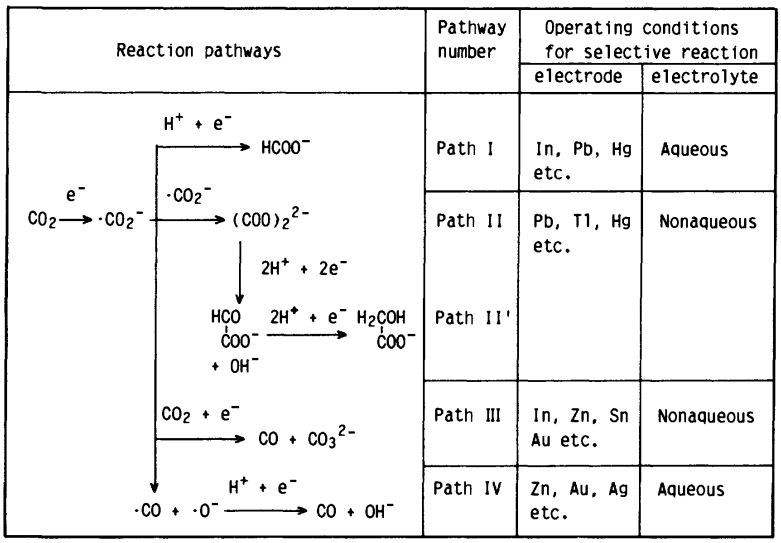

Fig. 7. Reaction pathways in electrochemical reduction of CO_2 under various conditions.

alic acid and carbon monoxide are like to those of the Fe electrode of which hydrogen production is in the order of 100 μmol for 100 C passed.

Such behavior of these metal electrodes has also been observed in the other nonaqueous electrolytes using AN and DMSO as aprotic solvents. Results were almost similar to that in the case of PC. Slight differences are thought to be due to the water content of them and electrode potentials.

Reaction Pathways. Figure 7 shows the reaction pathways in the electroreduction of CO_2 and the operating conditions for each pathway to proceed selectively. These reaction pathways may proceed competitively, but the reaction rate of each pathway is dependent upon the electrode metals and the electrolytes.

Namely, in Pass I, the reduced CO_2 anion radical reacts with proton or water molecule in aqueous electrolytes to produce formic acid. This reaction is competitive with the hydrogen evolution reaction (HER), so metals having higher overvoltages for HER, such as In, Pb, and Hg, are useful for the formic acid formation by Pass I.[1,2,11]

In nonaqueous electrolytes, if CO_2 anion radicals remained for a somewhat longer time at the surface of electrode metals such as Pb, Hg, and Tl, they would react together on the surface to produce an oxalate ion.[2,3,7,8] Thereafter the oxalate ion will be further reduced to produce glyoxalate, glycolate anions, etc. (Pass II′). These passes also observed at Pb electrodes in aqueous electlolytes.[3] If CO_2 anion radicals easily desorb from the surface of metals, such as Zn, Sn, and Au, they are attacked by CO_2 molecules near at the surface or in the bulk to disproportionate producing carbon monoxide and carbonate ion passing an intermediate anion radical (Pass III).[8,12] This mechanism also accounts for the production of carbon monoxide at some metals, such as Zn, in aqueous electrolytes.[13]

If metals are more attractive to CO_2 anion radicals, such as Zn, Au, and Ag, a dissociative adsorption mechanism of CO_2 anion radicals or molecules, Pass IV, may also be proposed to account for the carbon monoxide production in aqueous electrolytes.[9,13]

Novel Effect of Additives on the Quenching Mechanism of the Excited State of Copolymer-Pendant $[Ru(bpy)_3]^{2+}$ by Methylviologen in Methyl Alcohol

Masao KANEKO,* Xiao-Huai HOU, and Akira YAMADA
The Institute of Physical and Chemical Research, Wako-shi, Saitama 351-01
The Institute of Chemistry, Beijin, Chinese Academia Sinica, Beijin, China
(Received December 24, 1986)

The quenching of the excited state of acrylic acid copolymer-pendant $[Ru(bpy)_3]^{2+}$ by methylviologen (MV^{2+}) was studied in methyl alcohol. The Stern-Volmer plots for the quenching showed a line or a curve (downward or upward) depending on the additive such as acid, alkali, or neutral salt in methyl alcohol. This behavior in methyl alcohol is entirely different from that in water where only dynamic quenching occurs. The behaviors in alcohol were analyzed by assuming stepwise binding of MV^{2+} into the domains around the Ru complex formed by the dissociated carboxylates and by considering dynamic as well as static quenching models. The one kind of photochemical reaction system showed four different quenching mechanisms induced by the additives.

Photochemical reactions in polymer[1,2] and molecular assembly[3,4] systems are receiving intense interest as an approach to solar energy conversion.[5] Microenvironment of polymer systems very often affects remarkably photochemical reaction through electrostatic[6-8] or hydrophobic[9] interaction with quencher molecule. Tris(2,2′-bipyridine)ruthenium(II) complex ($[Ru(bpy)_3]^{2+}$) is attracting much attention as a sensitizer for visible light energy conversion.[2,4,5] Quenching of the excited state of $[Ru(bpy)_3]^{2+}$ by methylviologen (MV^{2+}) has been studied in the presence of anionic polymers[7,8] showing that an electrostatic interaction enhances the reaction rate. In such cases where polymer is present as a separate molecule in a sensitizer solution, the sensitizer should interact with the polymer in order that the polymer affects the sensitizing reaction. When a sensitizer is covalently attached to a polymer molecule, however, the microenvironmental effect of the polymer chain upon the photochemical reaction of the sensitizer can easily be studied independent of the interaction between sensitizer and polymer. The influencing factor is then only the interaction between polymer and quencher.

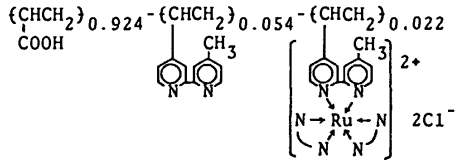
The present authors have prepared copolymer-pendant $[Ru(bpy)_3]^{2+}$, where copolymer is prepared from 4-methyl-4′-vinyl-2,2′-bipyridine and comonomer such as styrene, acrylic acid, etc.[10] These copolymer-pendant $[Ru(bpy)_3]^{2+}$ complexes have their characteristics in that the microenvironment around the Ru complex can drastically be changed by changing the comonomer compound. It means that the chemical as well as the physicochemical properties of the attached Ru complex can be changed with ease by choosing a proper comonomer. Taking solubility of a copolymer-pendant $[Ru(bpy)_3]^{2+}$, for example, a copolymer complex containing styrene comonomer is well soluble in many organic solvent such as benzene or chloroform, but entirely insoluble in water in contrast to the conventional low-molecular $[Ru(bpy)_3]^{2+}$ which is well soluble in water but insoluble in benzene or chloroform. This styrene-copolymer-pendant $[Ru(bpy)_3]^{2+}$ could be used as a stable membrane in water for fabricating photoresponsive graphite electrode[11,12] or stabilizing liquid-junction n-GaAs[13] and n-CdS[14].

When acrylic acid (AA) was used as a comonomer, the excited state of the water-soluble copolymer-pendant $[Ru(bpy)_3]^{2+}$ showed a remarkably pH-dependent activity toward MV^{2+} quencher due to the dissociation of the AA.[6] At neutral and alkaline regions in water, the quenching of the excited state of the AA-copolymer complex by MV^{2+} was remarkably enhanced due to the polyanionic domain formed around the Ru complex by the dissociation of the AA groups. It was concluded that electrostatic interaction brought about the enhancement of the quenching reaction, however, the linear relationship of the Stern-Volmer plots showed that the quenching is understood to occur via dynamic process in water.[6] Since the interaction is an electrostatic one, the reaction in a less polar solvent must present an aspect different from an aqueous system. It was found in the further study that static quenching occurs in methyl alcohol and that the mechanism is different depending on the additives such as base, acid, and neutral salt. This is the first example as far as the present authors know that one photochemical reaction system exhibits various quenching mechanisms as a function of additives. The mechanisms will be interpreted in terms of binding of MV^{2+} to polyanionic domain formed around Ru complex and of static quenching therein, and reported in this paper.

Experimental

Copolymer-pendant $[Ru(bpy)_3]^{2+}$ was prepared by reaction of a copolymer of 4-methyl-4′-vinyl-2,2′-bipyridine and acrylic acid (mol wt 4000) with *cis*-$[Ru(bpy)_2Cl_2]$ at the molar ratio of [bpy unit of the copolymer]/[Ru]=3.5 in n-BuOH under reflux for 2.5 h.[6] The polymer complex was

purified by dialysis in water. The composition of the copolymer-pendant complex **1** was as follows.



1 N⌒N=2,2′-bipyridine

Methylviologen (MV^{2+}) was purified by recrystallization in methyl alcohol–acetone mixture. The quenching of the excited state of the copolymer-pendant $[Ru(bpy)_3]^{2+}$ by methylviologen (MV^{2+}) was measured in methyl alcohol under the addition of various salts. Emission intensities were measured by the fluorimeter (Hitachi MPF-4). The emission decay was measured by a single-photon counting method with 1-ns pulsed light from a 12-atm hydrogen lamp.

Results and Discussion

The Stern–Volmer plots of the quenching of the excited state of the copolymer complex **1** by MV^{2+} in methyl alcohol were shown in Fig. 1. The plots without any additive show a downward curve. The plots of the quenching with the addition of HCl showed a linear relationship which almost coincides with those of conventional low molecular $[Ru(bpy)_3]^{2+}$. When neutral salt (Et_4NBr) is further added to this HCl-containing system, the quenching has become more efficient, and the slope of the plots is almost equal to the initial slope of the plots without additives. The solution in the presence of NaOH showed a very efficient quenching, and the plots gave a downward curve. The presence of thiourea in addition to HCl brought about an upward-curved plots.

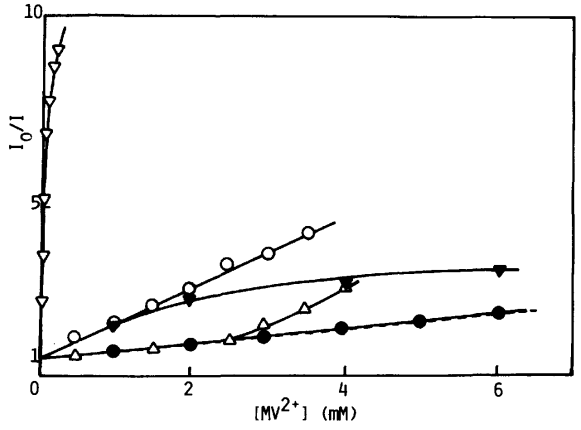


Fig. 1. Stern–Volmer plots for the quenching of excited **1** by MV^{2+} in methyl alcohol. Ru complex, 10^{-5} M (1 M=1 mol dm^{-3}). ▼, With no additive; ●, 0.5 mM HCl added; ○, 0.5 mM HCl and 0.1 M Et_4NBr added; ▽, 1 mM NaOH added; △, 0.5 mM HCl and 0.1 M H_2NCSNH_2 added; ------, $Ru(bpy)_3^{2+}$.

In the aqueous solution system reported before,[6] the quenching by MV^{2+} showed a remarkably pH-dependent behavior, indicating electrostatic interaction between carboxylate anions and MV^{2+}, but the linear Stern–Volmer plots showed a dynamic quenching. In the present system in methyl alcohol, the curved plots in Fig. 1 indicate the occurrence of static quenching. Since electrostatic interaction is enhanced in less polar medium as alcohol than in water, the behaviors of Fig. 1 are reasonable.

The polymer complex **1** contains both acid and base groups, i.e., carboxylic acid and free bpy pendant groups. These groups can interact and form hydrogen bonds as was reported.[6] Such interaction must be more enhanced in alcohol than in water and provide ionic environment around Ru complex. The much longer lifetime (843 ns) of the excited state of the polymer-pendant Ru complex in methyl alcohol than that of the monomeric complex (664 ns) supports a rigid and compact structure of the polymer complex which is possibly caused by such acid–base interactions between the pendant groups.

The plots of the emission quenching in the absence of any additive in Fig. 1 shows the occurrence of static quenching. The ionic microenvironment formed by acid–base interaction described above would attract the cationic substrate (MV^{2+}), and cause static quenching. Hydrogen chloride added to this solution destroys such interaction by protonating free bpy groups, thus making the plots linear. The quenching efficiency in the presence of HCl for the polymer system is almost the same as the monomeric complex. The cationic protonated bpy groups as well as the divalent Ru complex species attached to the polymer chain would bring about expanded macromolecular structure due to electrostatic repulsion, which would make the reactivity of the pendant Ru complex almost the same as an isolated monomeric complex. The quenching rate constants (k_q) for the polymer complex with HCl additive as well as for the monomeric complex were shown in Table 1. They have almost the same k_q values.

The addition of Et_4NBr to the HCl-added system enhanced the quenching efficiency, the Stern-Volmer plots still being linear. The neutral salt not only weakens the electrostatic repulsion between the pendant cationic groups, but also can enhance the reaction between the cationic Ru complex and MV^{2+} through shielding effect. The result of Fig. 1 shows that the latter effect prevails to make the quenching more efficient in the presence of Et_4NBr than in its absence for the HCl-added polymer system. The k_q value was also shown in Table 1 for the Et_4NBr-added system which is five times as high as that without Et_4NBr.

The addition of NaOH remarkably enhanced the quenching efficiency. This is understood as due to the

Ru; 10^{-5} M. a) Measured by a single photon counting method.

anionic domain formed around the Ru complex by the dissociation of the acrylic acid.[6] The Stern-Volmer plots in methyl alcohol show a downward curve different from the behavior in water for which the plots show a linear relationship. Static quenching must occur in methyl alcohol. The Stern-Volmer plots with the addition of thiourea shows an upward-curve, also indicating static quenching. The quenching of the excited state of the polymer complex **1** by MV^{2+} in methyl alcohol is therefore entirely depending on the additives. Both the dynamic and static quenching mechanisms have to be considered. The quenching mechanisms were analyzed as follows.

The occurrence of static quenching in the present system shows that we should consider some specific microenvironment (called "domain") around the pendant Ru complex to which the substrate (MV^{2+}) is bound and quenches the excited Ru complex statically. Such a domain which affects specifically catalytic reactions of polymeric compounds have often been studied.[15] The domain formed around pendant Ru complex is represented by [Ru]. Quencher molecule (MV^{2+}), Q is bound to this domain. Multistep reaction should be considered for such binding. It is assumed now that the rate constant of the forward binding reaction is equal for all the binding steps, but the backward rate constant of the binding is proportional to the number of Q bound to the domain. The stepwise bindings can then be expressed by Eqs. 1 to 3 where $[Ru\text{-}Q_i]$ represents the domain to which i molecules of Q are bound.

$$[Ru] + Q \underset{k_{-a}}{\overset{k_a}{\rightleftharpoons}} [Ru\text{-}Q_1] \qquad K_1 = k_a/k_{-a} \tag{1}$$

$$[Ru\text{-}Q_1] + Q \underset{2k_{-a}}{\overset{k_a}{\rightleftharpoons}} [Ru\cdot Q_2] \qquad K_2 = K_1/2 \tag{2}$$

$$\vdots \qquad\qquad \vdots$$

$$[Ru\text{-}Q_{i-1}] + Q \underset{ik_{-a}}{\overset{k_a}{\rightleftharpoons}} [Ru\text{-}Q_1] \qquad K_1 = K_1/i \tag{3}$$

According to this assumption, the number of Q molecule bound to the domain obeys the Poisson distribution. Such a Poisson distribution of quencher molecule to the microenvironment around sensitizer has often been considered for micellar[16,17] or polymeric[9] systems. The total concentration of the domain, $[Ru]_t$, is expressed by Eq. 4. The concentration of the Q bound to the domain, $[Q]_b$, is:

$$[Q]_b = \sum_{i=0}^{\infty} i[Ru\text{-}Q_i] = [Ru]K_1[Q]\exp(K_1[Q]) = [Ru]_tK_1[Q] \tag{5}$$

where [Q] is the concentration of the free Q and expressed by the following Eq.

$$[Q] = [Q]_t/(K_1[Ru]_t+1) \tag{6}$$

Under these situations the next four quenching models were considered where dynamic and static quenchings are concerned.

In model 1 are considered both the dynamic quenching of [Ru*] by the bulk Q and the static quenching in the domain, in the latter of which the quenching rate is independent of the number of the Q in the domain.

Model 1

$$[Ru] \xrightarrow{h\nu} [Ru^*] \begin{cases} \xrightarrow{k_{q,2}[Q]} [Ru] & (7) \\ \xrightarrow{k_d} [Ru] & (8) \\ \xrightarrow{k_f} [Ru] & (9) \end{cases}$$

$$[Ru\text{-}Q_i] \xrightarrow{h\nu} [Ru^*\text{-}Q_i] \begin{cases} \xrightarrow{k_{q,1}} [Ru\cdot Q_i] & (10) \\ \xrightarrow{k_d} [Ru\text{-}Q_i] & (11) \\ \xrightarrow{k_f} [Ru\cdot Q_i] & (12) \end{cases}$$

In these equations k_d and k_f are the rate constants of the nonluminescent and luminescent decays of the excited state of the Ru complex, respectively. It should be reasonable to assume that these photochemical processes of Eqs. 7 to 12 are much faster than the binding processes of Eqs. 1 to 3. It means that the equilibrium processes of Eqs. 1 to 3 etc. should be kept constant during the time period when the photochemical processes of Eqs. 7 to 12 occur. The total rate of light absorption at the excitation of the Ru complex, I_t is expressed by the following equation, when steady state is assmued for the Reactions 7 to 12.

$$I_t = [Ru^*](k_d+k_f+k_{q,2}[Q]) + \sum_{i=1}^{\infty}[Ru^*\cdot Q_i](k_d+k_f+k_{q,1}) \tag{13}$$

The rate of light absorption by [Ru] is,

$$I_t \times \frac{[Ru]}{[Ru]_t} = [Ru^*](k_d + k_f + k_{q,2}[Q]). \quad (14)$$

The relative emission intensity, I_0/I, from the excited state of the Ru complex in the absence and the presence of Q is,

$$I_0/I = (k_f/(k_d + k_f)) \div (k_f \sum_{i=0}^{\infty} [Ru^*\text{-}Q_i]/I_t). \quad (15)$$

From Eq. 13,

$$\sum_{i=0}^{\infty} [Ru^*\text{-}Q_i] = \frac{I_t + [Ru^*](k_{q,1} - k_{q,2}[Q])}{k_d + k_f + k_{q,1}}, \quad (16)$$

and from Eq. 14,

$$[Ru^*] = \frac{I_t}{k_d + k_f + k_{q,2}[Q]} \cdot \frac{[Ru]}{[Ru]_t}. \quad (17)$$

Therefore, from Eqs. 16 and 17,

$$\sum_{i=0}^{\infty} [Ru^*\text{-}Q_i] = I_t \cdot \frac{(k_1 + k_{q,2}[Q]) + (k_{q,1} - k_{q,2}[Q])[Ru]/[Ru]_t}{(k_1 + k_{q,2}[Q])(k_1 + k_{q,1})}, \quad (18)$$

where

$$k_d + k_f = k_1, \quad \text{Lifetime } \tau_0 = 1/k_1. \quad (19)$$

Since the lifetime in the absence of Q (τ_0) equals $1/k_1$, Eq. 15 becomes as Eq. 20.

$$I_0/I = \frac{\tau_0 I_t}{\sum_{i=0}^{\infty} [Ru^*\cdot Q_i]} = \frac{(1 + \tau_0 k_{q,1})(X + Y[Q]_t)}{X + Y[Q]_t + \tau_0 (X k_{q,1} - k_{q,2}[Q]_t) \exp(-K_1[Q]_t/X)} \quad (20)$$

$$X = K_1[Ru]_t + 1 \quad (21) \qquad Y = \tau_0 k_{q,2} \quad (22)$$

Although Eq. 20 contains too many parameters to be determined, it is shown by differentiation that the I_0/I vs. [Q] plots fall on a downward curve.

In model 2, no dynamic quenching by the bulk Q is considered, so that the reactions can be expressed by Eqs. 23 to 27.

Model 2

$$[Ru] \xrightarrow{h\nu} [Ru^*] \quad \begin{cases} \xrightarrow{k_d} [Ru] & (23) \\ \xrightarrow{k_f} [Ru] & (24) \end{cases}$$

$$[Ru\text{-}Q_i] \xrightarrow{h\nu} [Ru^*\cdot Q_i] \quad \begin{cases} \xrightarrow{k_{q,1}} [Ru\text{-}Q_i] & (25) \\ \xrightarrow{k_d} [Ru\cdot Q_i] & (26) \\ \xrightarrow{k_f} [Ru\text{-}Q_i] & (27) \end{cases}$$

In this model, $k_{q,2}=0$ and $Y=0$ in comparison to the model 1, so Eq. 28 can be derived from Eq. 20.

$$I_0/I = \frac{(1 + \tau_0 k_{q,1})}{1 + \tau_0 k_{q,1} \exp(-K_1[Q]_t/X)} \quad (28)$$

According to this model, the I_0/I vs. $[Q]_t$ plots show a downward curve as the model 1. The method to distinguish between the models 1 and 2 is described later.

In the next model 3 both the dynamic and the static quenchings were considered, but the rate of the static quenching in the domain is proportional to the number of the Q molecule bound to the domain. This is different from the model 1 where the rate of the static quenching is independent of the number of the Q molecule bound. The reactions are expressed by the Eqs. 29 to 34.

Model 3

$$[Ru] \xrightarrow{h\nu} [Ru^*] \quad \begin{cases} \xrightarrow{k_{q,2}[Q]} [Ru] & (29) \\ \xrightarrow{k_d} [Ru] & (30) \\ \xrightarrow{k_f} [Ru] & (31) \end{cases}$$

$$[Ru\text{-}Q_i] \xrightarrow{h\nu} [Ru^*\text{-}Q_i] \quad \begin{cases} \xrightarrow{ik_{q,1}} [Ru\text{-}Q_i] & (32) \\ \xrightarrow{k_d} [Ru\text{-}Q_i] & (33) \\ \xrightarrow{k_f} [Ru\text{-}Q_i] & (34) \end{cases}$$

In this model, the total rate of light absorption is expressed by Eq. 35 when steady state is assumed for the Reactions 29 to 34.

$$I_t = [Ru^*](k_1 + k_{q,2}[Q]) + \sum_{i=1}^{\infty} [Ru^*\cdot Q_i](k_1 + ik_{q,1}) = k_1 \sum_{i=0}^{\infty} [Ru^*\cdot Q_i] + k_{q,2}[Q][Ru^*] + k_{q,1} \sum_{i=0}^{\infty} i[Ru^*\text{-}Q_i] \quad (35)$$

The rate of light absorption by [Ru] is,

$$I_t \times \frac{[Ru]}{[Ru]_t} = [Ru^*](k_1 + k_{q,2}[Q]). \quad (36)$$

Therefore,

$$[Ru^*] = \frac{I_t[Ru]}{(k_1 + k_{q,2}[Q])[Ru]_t}. \quad (37)$$

The relative emission intensity, I_0/I, is,

$$I_0/I = (k_f/k_1) \div (k_f \sum_{i=0}^{\infty} [Ru^*\text{-}Q_i]/I_t) = \frac{\tau_0 I_t}{\sum_{i=0}^{\infty} [Ru^*\text{-}Q_i]}. \quad (38)$$

From Eq. 35,

$$\sum_{i=0}^{\infty} [Ru^*\text{-}Q_i] = \frac{I_t - k_{q,2}[Q][Ru^*] - k_{q,1} \sum_{i=0}^{\infty} i[Ru^*\text{-}Q_i]}{k_1} \quad (39)$$

From Eq. 5,

$$\sum_{i=0}^{\infty} i[Ru^*\text{-}Q_i] = [Ru^*]K_1[Q] \exp(K_1[Q]) \quad (40)$$

Therefore Eq. 39 becomes

$$\sum_{i=0}^{\infty}[Ru^*\text{-}Q_i] = \frac{1}{k_1}[I_t-(k_{q,2}[Q] + k_{q,1}K_1[Q]\exp(K_1[Q]))[Ru^*]]. \quad (41)$$

By using Eqs. 14 and 4, Eq. 41 becomes Eq. 42

$$\sum_{i=0}^{\infty}[Ru^*\cdot Q_i] = \frac{I_t}{k_1}\left[1-\frac{1}{k_1+k_{q,2}[Q]}\cdot\frac{[Ru]}{[Ru]_t} \times (k_{q,2}[Q]+k_{q,1}K_1[Q]\exp(K_1[Q]))\right] = \frac{I_t}{k_1}\cdot\frac{k_1+k_{q,2}[Q](1-\exp(-K_1[Q]))-k_{q,1}K_1[Q]}{k_1+k_{q,2}[Q]}. \quad (42)$$

Therefore, from Eqs. 15 and 42,

$$I_0/I = \frac{I_t\tau_0}{\sum_{i=0}^{\infty}[Ru^*\cdot Q_i]} = \frac{k_1+k_{q,2}[Q]}{k_1+k_{q,2}[Q](1-\exp(-K_1[Q]))-k_{q,1}K_1[Q]}. \quad (43)$$

Since

$$[Q] = [Q]_t/(K_1[Ru]_t+1) = [Q]_t/X, \quad (44)$$

Eq. 45 is concluded.

$$I_0/I = \frac{k_1+k_{q,2}[Q]_t/X}{k_1+k_{q,2}[Q]_t(1-\exp(-K_1[Q]_t/X)/X)-k_{q,1}K_1[Q]_t/X}. \quad (45)$$

The I_o/I vs. $[Q]_t$ plots of the model 3 thus show a downward curve.

In model 4, no dynamic quenching by the bulk Q is considered, and only the static quenching in the domain is assumed whose rate constant is proportional to the number of the bound Q (see Eqs. 46 to 50).

Model 4

$$[Ru] \xrightarrow{h\nu} [Ru^*] \begin{cases} \xrightarrow{k_d} [Ru] & (46) \\ \xrightarrow{k_f} [Ru] & (47) \end{cases}$$

$$[Ru\cdot Q_i] \xrightarrow{h\nu} [Ru^*\text{-}Q_i] \begin{cases} \xrightarrow{ik_{q,1}} [Ru\cdot Q_i] & (48) \\ \xrightarrow{k_d} [Ru\cdot Q_i] & (49) \\ \xrightarrow{k_f} [Ru\text{-}Q_i] & (50) \end{cases}$$

By substituting $k_{q,2}=0$ in the Eq. 45 (model 3), the next relation is obtained.

$$I_0/I = \frac{k_1}{k_1-k_{q,1}K_1[Q]_t/X} = \frac{1}{1-k_{q,1}\tau_0K_1[Q]_t/X} \quad (51)$$

The I_o/I vs. $[Q]_t$ plots should show an upward curve, and the I/I_o vs. $[Q]_t$ plots be linear.

The models 1 and 2 can be distinguished by emission decay profile. The patterns of the emission decay for the models 1 and 2 are illustrated as Fig. 2.

Since in the model 1 both dynamic and static quenching occur, the emission decay should be nonexponential, and both the shorter and the longer lifetime components should decay faster than the system without Q. In the model 2 only static quenching occurs, indicating that the emission decay is also nonexponential, but that the [Ru] which does not bind Q even in the presence of Q in the system emits just as the system without Q. It means that the longer lifetime components in the presence of Q decay at the same rate as the decay in the absence of Q. The decay profile of the model 2 can therefore be shown as Fig. 2.

In Fig. 1 the quenchings in the absence of additive as well as in the presence of NaOH showed downward curves, so that they should obey either the model 1 or 2. The emission decay in the absence of any additive was studied and shown in Fig. 3. The relative emission decays in the absence and the presence of MV^{2+} shown in Fig. 3 are corresponding to the decay profile of the model 1 shown in Fig. 2. The quenching with no additive should therefore obey the model 1. The emission decay in the presence of NaOH was shown in Fig. 4. This shows the same

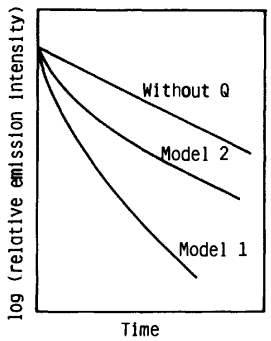

Fig. 2. Profiles of emission decay in the models 1 and 2.

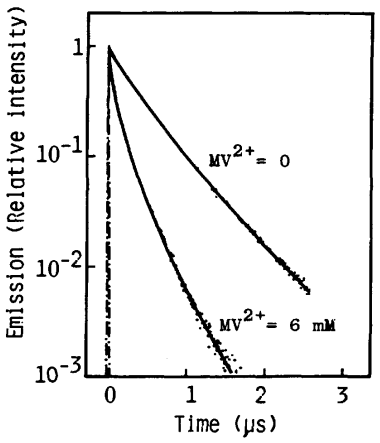

Fig. 3. Emission decay of excited **1** in MeOH with no additive under Ar at 25 °C.

Table 2. Quenching Mechanism of the Excited Copolymer-Pendent $[Ru(bpy)_3]^{2+}$ (**1**) by MV^{2+} in Methyl Alcohol

Model	Rates of quenching by		Stern-Volmer plot based on emission intensity	Additive
	Bulk Q	Bound Q		
1	$k_{q,2}[Q]$	$k_{q,1}$	Downward curve	None
2	—	$k_{q,1}$	Downward curve	NaOH
3	$k_{q,2}[Q]$	$ik_{q,1}$	Upward curve	$HCl+H_2NCSNH_2$
4	—	$ik_{q,1}$	Upward curve	
Conventional dynamic model	$k_{q,2}[Q]$	—	Linear relationship	HCl or $HCl+Et_4NBr$

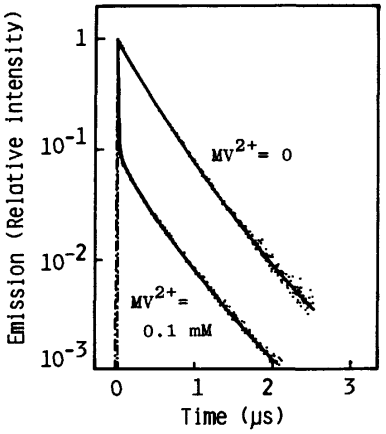

Fig. 4. Emission decay of excited **1** in MeOH containing 1 mM NaOH measured under Ar at 25 °C.

decay profile as the model 2 (see Fig. 2). The quenching in the presence of NaOH should therefore obey the model 2.

The quenching in the presence of HCl and H_2NCSNH_2 showed an upward curve (Fig. 1), indicating that it should obey either the model 3 or 4. Since the I/I_0 vs. $[Q]_t$ plots did not give a straight line, this should not obey the model 4, but the model 3.

The quenching mechanism of the systems shown in Fig. 1 can therefore be summarized as Table 2. It was already described that the quenching of the system containing HCl or both HCl and Et_4NBr is explained by a conventional dynamic model. In the system with no additive, both the dynamic quenching by the bulk Q and the static quenching in the domain occur, the rate of the latter being independent of the number of the bound Q.

In the presence of NaOH, no dynamic quenching occurs and only static quenching is involved whose rate is independent of the number of the bound Q. This situation is entirely different from the alkaline aqueous system[6] for which the Stern-Volmer plots showed a linear relationship indicating that the quenching in water can be explained by a dynamic model even in the presence of NaOH. In the present MeOH system, the quenching specificity of the NaOH-added system would be due to the less polarity of the medium than water. In MeOH the binding of MV^{2+} to the anionic domain composed by the dissociated carboxylato groups would be much stronger than in water, which would make the quenching static.

In the system containing HCl and H_2NCSNH_2, both the dynamic quenching by the bulk Q and the static quenching in the domain occur, the rate of the latter being proportional to the number of the bound Q. Some specific anionic domain formation might be suggested to occur due to acid-base interaction between carboxylic groups of the polymer chain and H_2NCSNH_2.

The quenching mechanism of the acrylic acid-copolymer pendant $[Ru(bpy)_3]^{2+}$ by MV^{2+} is thus strongly dependent on the conditions of the MeOH medium. This is the first example in which one photochemical reaction system exhibits different quenching mechanisms depending on the additives.

(Received January 20, 1987)

The X-ray photoelectron spectra and the ESR spectra of the (BEDT-TTF)$CuCl_2$ complex were taken. The analysis of the X-ray photoelectron spectra shows that the Cu atoms in (BEDT-TTF)$CuCl_2$ are in a mixed-valence state consisting of mono and bivalent cations and the concentration ratio of Cu(I) and Cu(II) is determined to be 2:1. The ESR signals show the presence of the BEDT-TTF cation radical and Cu(II)Cl_2. The temperature dependence of the magnetic susceptibility of these components were obtained from the ESR data.

A new family of organic conductors, based on 3,4;3′,4′-bis(ethylenedithio)-2,2′,5,5′-tetrathiafulvalene (BEDT-TTF), has been synthesized[1] and some of them are the first sulfur-based organic superconductors, (BEDT-TTF)$_2ReO_4$(T_c=2 K) at 0.4 GPa pressure[2] and (BEDT-TTF)$_2I_3$(T_c=1.5 K) at ambient pressure.[3] Following these complexes, a large number of BEDT-TTF salts have been synthesized in an attempt to obtain an organic superconductor with a high critical temperature. Many BEDT-TTF salts ever known have compositions (BEDT-TTF)$_2$X or (BEDT-TTF)$_3X_2$ where X is a monovalent anion such as PF_6^-,[4] AsF_6^-,[5] $InBr_4^-$,[6] ClO_4^-,[7] I_3^-,[8-10] or other polyhalide series. (BEDT-TTF)X(THF)$_{0.5}$ (X=ReO_4^- and IO_4^-) salts form 1:1 salts which consist of four independent complex units in the unit cell.[11] The new type of the 1:1 salt of (BEDT-TTF)$CuCl_2$ was recently found by us.[12] In this paper, we report the results of the measurement of the X-ray photoelectron and ESR spectra of the (BEDT-TTF)$CuCl_2$ complex.

Experimental

Black prism crystals were prepared by the diffusion method of BEDT-TTF and $CuCl_2 \cdot 2H_2O$ in 1,1,2-trichloroethane. The X-ray photoelectron spectra were recorded on a JEOL model JESCA-3A spectrometer. Aluminium $K_{\alpha 1,2}$ radiation (1486.6 eV) was used as the X-ray excitation source and the measurements were carried out at 5×10^{-8} Torr or below. The ESR spectra were taken by a Varian E112 at X-band with a continuous helium flow cryostat and a rectangular microwave cavity.

Results and Discussion

Figure 1 shows the X-ray photoelectron spectra (ESCA) of the (BEDT-TTF)$CuCl_2$ complex together with $CuCl_2 \cdot 2H_2O$ and CuCN. The cupric compound has intense satellites on the higher binding energy sides of the $2p_{1/2}$ and $2p_{3/2}$ peaks, however, the cuprous compound has no satellite associated with these bands.[13] Such a satellite pattern may be explained by the difference in the electronic structures of $3d^9$ for Cu(II) and $3d^{10}$ for Cu(I), respectively. The half-width (γ_ω) and intensity (γ_i) ratios of the satellite to the main $2p_{3/2}$ peak are estimated to be γ_ω=1.66 and γ_i=0.4 for $CuCl_2 \cdot 2H_2O$. However, these values are γ_ω=1.4 and γ_i=0.15 for the (BEDT-TTF)$CuCl_2$ complex. Accordingly, the ESCA spectrum of (BEDT-TTF)$CuCl_2$ is considered as the overlap of the signals of Cu(I) and Cu(II) in the 2p energy region. The dashed line of the $2p_{3/2}$ peak shows the contribution of Cu(II) to the ESCA line shape of the (BEDT-TTF)$CuCl_2$ complex and the ratio of area of the dashed line part and the remaining part of the $2p_{3/2}$ peak is estimated to be 1:2. That is, the Cu atoms in (BEDT-TTF)$CuCl_2$ are in a mixed-valence state consisting of mono and bivalent

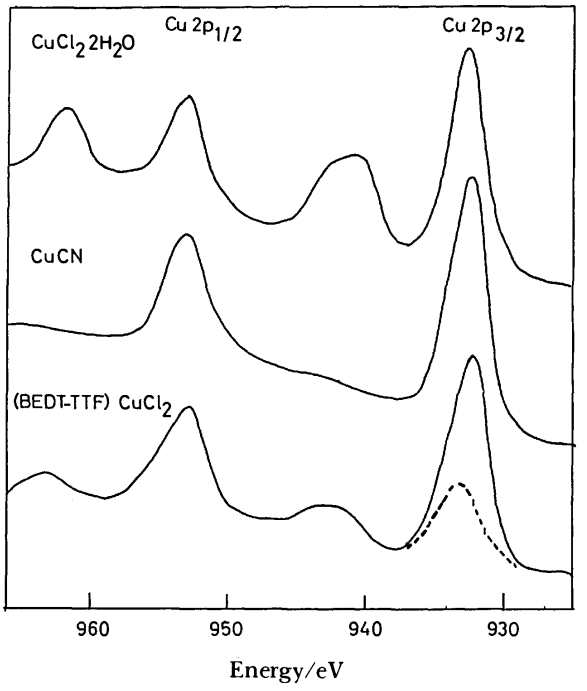

Fig. 1. X-Ray photoelectron spectra of $CuCl_2 \cdot 2H_2O$, CuCN, and (BEDT-TTF)$CuCl_2$.

cations and the concentration ratio of $[Cu(I)Cl_2]^-$: $[Cu(II)Cl_2]$ or $[BEDT\text{-}TTF\cdot]^+$:[BEDT-TTF] is determined to be 2:1.

The ESR spectra of (BEDT-TTF)$CuCl_2$ were measured over a temperature range of 4—300 K as is shown in Fig. 2. The numbers in parenthesis mean the relative intensity ((peak value/gain value)$\times 10^6$) of the maximum ESR peak. Bands I and II are the ESR signals of the impurity of $CuCl_2\cdot 2H_2O$.[14] The sharp band III with g=2.009 can be assigned to the unpaired π-electron of the BEDT-TTF cation radical[15] and the broad band IV with g=2.003 to the d electron of $Cu(II)Cl_2$.

The ESR spectra can be expressed by the following equation:

$$I = \sum_i \frac{2B_i A_i^2 (H_i - H)}{[1 + A_i^2 (H_i - H)^2]^2}. \quad (1)$$

The parameters A_i, B_i, and H_i are determined by the best fit of Eq. 1 to the observed ESR spectra and the magnetic susceptibility $X_i(T)$ of the i-th component at temperature T is given by the absolute intensity of $(\pi B_i/A_i)_T$ of the ESR signal,

$$X_i(T) = C\left(\frac{\pi B_i}{A_i}\right)_T. \quad (2)$$

The coefficient C is estimated with the observed static magnetic susceptibility at room temperature of $X(290\text{ K})=9\times 10^{-4}$ emu mol^{-1} by the following equation:

$$X(290\text{K}) = C\sum_i \left(\frac{\pi B_i}{A_i}\right)_{T=290\text{K}}. \quad (3)$$

The value of $X(290\text{ K})$ was corrected by considering the diamagnetic effect of the constituting atoms. The temperature dependences of the susceptibilities X_{III} and X_{IV} are shown in Figs. 3 and 4.

Band III is the ESR signal of the BEDT-TTF radicals with g=2.009 at room temperature and with the temperature-independent line-width of $\Delta H \approx 20$G. The susceptibility X_{III} seems to be independent of temperature above 240 K and decreases gradually from

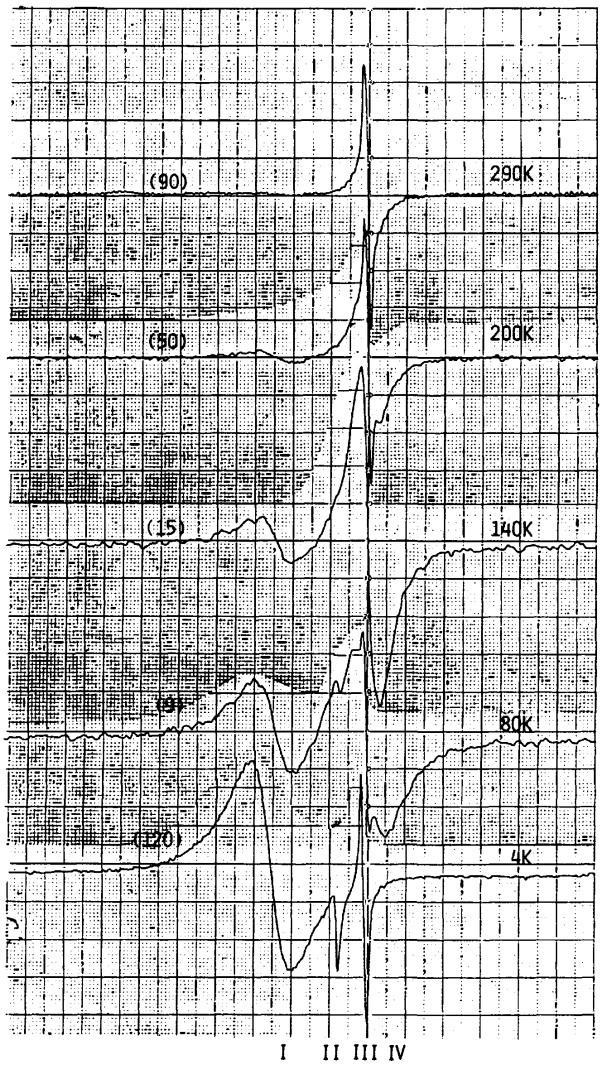

Fig. 2. ESR spectra of (BEDT-TTF)$CuCl_2$. The numbers in parenthesis mean the relative intensity.

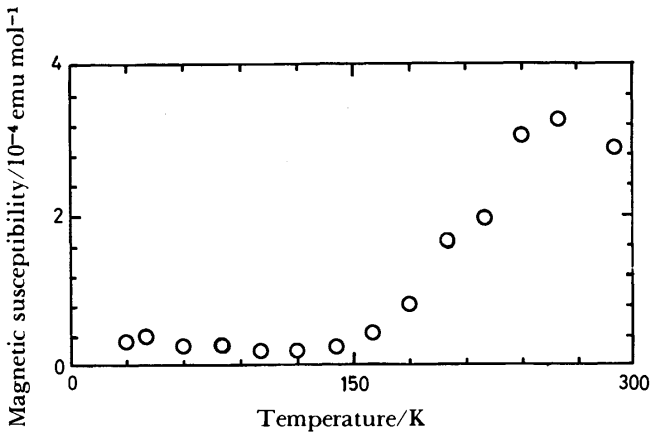

Fig. 3. Temperature dependence of the magnetic susceptibility X_{III} obtained by the analysis of the ESR signal of the band III.

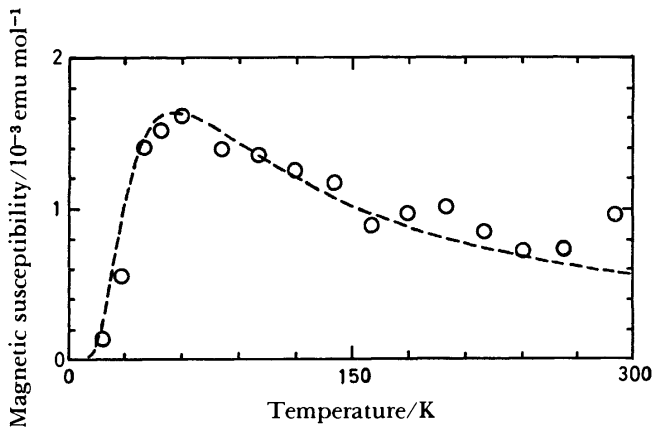

Fig. 4. Temperature dependence of the magnetic susceptibility X_{IV} obtained by the analysis of the ESR signal of the band IV. (°°°°: Obsd., ------: Calcd.)

240 to 140 K. After that, X_{III} remains constant down to 10 K. Then, the susceptibility below 240 K is described by the singlet-triplet model as follows:[16]

$$X(T) = \frac{0.750\,g^2}{T} n_{III} \exp(-J/kT), \quad (4)$$

where g=2 and J=850 K. n_{III}=0.78 is the mole number of the BEDT-TTF cation radical per one mole of (BEDT-TTF)$CuCl_2$. This value (≈3/4) is in agreement with the value (2/3) determined by the ESCA experiment. However, the calculated susceptibility above 240 K increases with the temperature and has no maximum peak below 300 K although the observed susceptibility does not change with temperature. Such temperature-independent susceptibility from 240 to 300 K may be described by the Pauli paramagnetism of the one-dimensional model. As BEDT-TTF molecules form the one-dimensional stacking column along the c axis (Fig. 5) and the overlap between the π- molecular orbitals along the stacking column forms the one-electron tight-binding band with a bandwidth 4t, the calculated X(T) is given by the simple Pauli susceptibility[17],

$$X = \frac{No\,\mu_B^2}{\pi t \sin(\rho\pi/2)}, \quad (5)$$

where N_o is Avogadro's number, μ_B is the Bohr magneton and ρ=4/3 is the number of carrier electrons per BEDT-TTF molecule. Accordingly, the observed susceptibility of ca. 3×10^{-4} emu mol^{-1} at room temperature gives t≈0.19 eV. Such large value of the transfer integral may be explained by the short interplanar distance of 3.39 A and the two-dimensional interaction of BEDT-TTF molecules.[12] The above-mentioned change of the magnetic susceptibility in the vicinity of 240 K may be explained by the metal-insulator transition due to the Peierls instability.

The temperature dependence of the susceptibility X_{IV} of band IV can be depicted by the following Bleaney-Bowers equation[16] for the dimerization of Cu(II)Cl_2,

$$X(T) = \frac{0.125\,g^2}{T} \frac{2\,n_{IV}}{1+\frac{1}{3}\exp(J/kT)}, \quad (6)$$

where g=2 and J=90 K. The magnitude of the g value obtained (g≈2.00) is almost similar to that of Cu(II).[18] n_{IV}=0.245 is the mole number of Cu(II)Cl_2 per one mole of (BEDT-TTF)$CuCl_2$. This value (≈1/4) is comparable with the value (1/3) determined by the ESCA experiment. The difference between these two values obtained by the ESCA and the magnetic susceptibility measurements may be due to the presence of the impurity of $CuCl_2\cdot2H_2O$. These facts mean that the crystal of the (BEDT-TTF)$CuCl_2$ complex consists of the columns of the stack of BEDT-TTF and the dimers of $[Cu(II)Cl_2]_2$ and $[Cu(I)Cl_2]^{2-}_2$. However, the crystal belongs to the space group of $P\bar{1}$ (Z=1) and the projection of the structure along the c axis is shown in Fig. 5.[12] Accordingly, all of BEDT-TTF molecules and $CuCl_2$ molecules are crystallographically equivalent and the charge carrier delocalizes along each column of BEDT-TTF and $CuCl_2$.

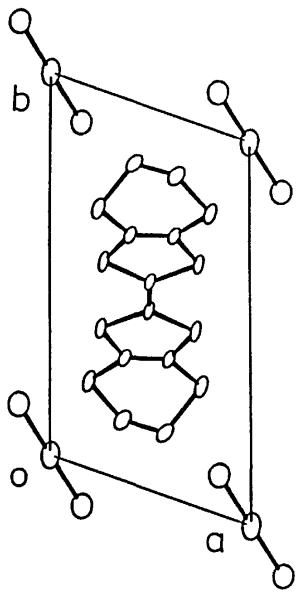

Fig. 5. Projection of the structure of (BEDT-TTF)-$CuCl_2$ along the c axis.[12]

The authors would like to thank Dr. Tetsuo Asaji of Nagoya university for the measurement of the static magnetic susceptibility.

(Received February 2, 1987)

^{13}C NMR spin-lattice relaxation time of carbon atom on methanol, ethanol, 1-propanol, and dimethyl sulfoxide molecules has been measured for solutions of $Ni(ClO_4)_2$ in these solvents and their mixtures with water. The comparison of the NMR data for solutions with aqueous mixtures and pure solvents gave the number of organic solvent molecules that locate in the first coordination sphere of Ni^{2+} ion. The result shows that Ni^{2+} ion is preferentially hydrated in water-alcohol systems, while in water-dimethyl sulfoxide system, the ion is solvated preferentially with dimethyl sulfoxide.

The preferential solvation of an ion in mixed solvents is an interesting subject in the electrolyte solution chemistry. The detailed information on the structure of solvated ion in a mixed solvent is expected to gain a better understanding of the behavior of ion. The NMR spectroscopy has provided a useful method for investigating local structure in the vicinity of ion. If the signal arising from the solvated solvent molecules is distinguished from that of bulk molecules, the solvation number can be determined directly from integration of the both signals.[1-3] The application of the direct NMR method is, however, confined to systems of high electrolyte concentration and of low rate of solvent exchange. On the other hand, the exchange rate of most ions with moderate number of charge is so high that the NMR spectrum gives a coalesced signal of both the coordinated and bulk molecules. In this case, chemical shift and relaxation rate are utilized to get information on the constitution of coordination sphere of ion.[4-7] This paper reports ^{13}C NMR paramagnetic relaxation rates for carbon atoms of organic solvent molecules caused by Ni^{2+} ion in Ni $(ClO_4)_2$ solution with water-solvent mixtures. The dependence of relaxation rate on concentration was analyzed to deduce the number of organic molecules that locate in the first coordination sphere of Ni^{2+} ion.

Experimental

Commercially available nickel perchlorate hexahydrate was recrystallized from water. The content of water was determined as six mole per formula from cation analysis using a cation-exchange column. The hydrated crystal was used to prepare solutions. Since the mole fraction of Ni(II) was less than 0.001 for solutions in pure organic solvents, a small amount of water accompanied with the crystal will give only a negligible effect on the ^{13}C NMR T_1 (spin-lattice relaxation time) of the solvent molecules. Methanol, ethanol, 1-propanol, and dimethyl sulfoxide (DMSO) were of reagent grade and used without further purification. ^{13}C NMR T_1 was measured by a JEOL FX90Q-FT NMR spectrometer at 35 °C with a standard inversion-recovery technique. The NMR frequency was 22.5 MHz. The error in measuring T_1 was leas than 5%.

Results and Discussion

If we denote the ^{13}C NMR relaxation rate of carbon atoms of solvent molecules located in the first coordination sphere of a paramagnetic ion as $1/T_{1M}$, and that of the bulk solvent as $1/T_{1B}$, then the observed relaxation rate $1/T_1$ is expressed by

$$\frac{1}{T_1} = \frac{X_M}{T_{1M}} + \frac{1-X_M}{T_{1B}}, \quad (1)$$

where X_M denotes the fraction of solvent molecule in the first coordination sphere. X_M is given by

$$X_M = n\frac{C_i}{C_s}, \quad (2)$$

where n is the number of coordinated solvent molecules to Ni^{2+} ion, C_i and C_s are the molar concentrations of ion and solvent molecule, respectively. If we assume that the rate $1/T_{1M}$ and coordination number of Ni^{2+} ion are unchanged in pure and mixed solvent, and that the relationship

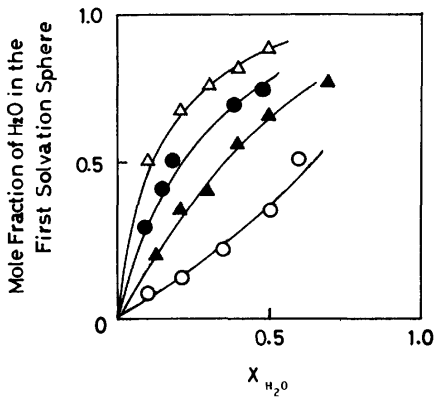

Fig. 2. Relationship between the mole fraction of H_2O in the first solvation sphere and H_2O mole fraction of the solvent at 35 °C. ○: DMSO-H_2O, ▲: MeOH-H_2O, ●: EtOH-H_2O, △: *n*-PrOH-H_2O.

between $1/T_1$ and $C_i/(C_sT_{1M})$ is linear at low concentration of Ni^{2+} ion, slope gives n directly. The coordination number, n, of Ni^{2+} ion in pure solvent was assumed to be six,[9-11] then $1/T_{1M}$ values were obtained from data for pure organic solvent solution. Figure 1 shows the plots for ethanol (Cl) carbon in water-ethanol systems, which appear to be linear. Tables 1—4 give the observed T_1 and the slopes for water-methanol, -ethanol (Cl), -1-propanol (Cl), and -DMSO, respectively. The variation of the composition of the first coordination sphere is shown in Fig. 2 as a function of the composition of bulk solvent. Figure 2 shows that Ni^{2+} ion is preferentially solvated with DMSO in water-DMSO system, while Ni^{2+} in water-alcohol mixture is preferentially hydrated. The magnitude of the preferential hydration increases with the increase in the chain length of alcohol molecules. The behavior of this preferential solvation in water-methanol system is consistent qualitatively with the result obtained by a kinetic study of solvated Ni^{2+} ion reacting with ammonia in water-methanol system.[12] The tendency of solvation in water-methanol mixture has been reported for other ions: Preferential solvation of Eu^{3+} was investigated by luminesence lifetime method[13] and those of Na^+ and Rb^+ were examined by ^{23}Na and ^{87}Rb spin-lattice relaxation rate.[5,6] A coordination ability of DMSO competing with water was demonstrated in $Al(ClO_4)_3$-DMSO-water system by direct ^1H NMR peak integration method.[1-3] ^{23}Na chemical shift and spin-lattice relaxation rate showed that Na^+ ion is solvated preferentially with DMSO in water-DMSO system.[5,7] Luminesence lifetime study of Eu^{3+} in water-DMSO system resulted in preferential solvation with DMSO.[13] ^{23}Na and ^1H NMR chemical shift studies also showed that Na^+ is solvated preferentially with DMSO in binary mixtures of DMSO with nitromethane, acetonitrile, pyridine, and 1-propanol.[7,8] It seems that solvation tendency is not expressed by the Gutmann donor number.[14,15] As for the solvation of Ni^{2+} ion, Munakata et al. have proposed the coordination power to express the solvent donor ability from electronic spectra of Ni^{2+} ion in various binary mixed solvents.[16] The present results agree qualitatively with the order proposed by them. The solvent used in our experiments is confined to solvent rich compositions because of the difficulty of ^{13}C NMR T_1 measurement in low contents of organic species. The measurement by a high field NMR spectrometer or the use of ^{13}C-enriched solvent will overcome the difficulty. The effect of perchlorate counter ion is completely ignored. Since the measurement was carried out in low electrolyte concentration, the effect of counter ion is considered to be small. The measurement with other counter ions will confirm the assumption.

^{1}H and ^{13}C NMR Studies of Formation and Molecular Dynamics of Methylated-Cyclodextrin Inclusion Complexes with Phenylalanine

Yoshio INOUE,* Fu-Hua KUAN, and Riichiro CHÛJÔ
Department of Polymer Chemistry, Tokyo Institute of Technology,
O-okayama 2-12-1, Meguro-ku, Tokyo 152
(Received February 10, 1987)

The formation and the molecular dynamics of the host-guest inclusion complexes in aqueous solution have been studied for hosts α- and permethylated α-cyclodextrin and permethylated β-cyclodextrin and guest phenylalanine by ^{1}H and ^{13}C NMR spectroscopy. The changes in ^{1}H chemical shift, ^{1}H spin-coupling constant, and ^{13}C spin-lattice relaxation time for the guest phenylalanine on addition of the host cyclodextrin show that they form the inclusion complexes in a similar manner, that is, by insertion of the guest's phenyl ring into the host's cavity. The strength of the host-guest dynamic coupling varies with the cavity size of cyclodextrins.

The cyclodextrins are a series of cyclic oligosaccharides composed of at least six(1→4)-linked α-D-glucosyl residues. Each cyclodextrin molecule has a toroidal, hollow, trancated cone with primary and secondary hydroxyl groups crowning the narrower and wider rims, respectively. The interior of the cavity of each cyclodextrin contains two bands of C-H groups and a band of glucosidic oxygens. Hence the interior of the cavity is relatively hydrophobic, whereas the exterior is relatively hydrophilic.

Cyclodextrins can admit various guest molecules into the cavity, without any covalent bonds being formed, and in some cases they catalyze reactions of included guest compounds.[1-4] Because of these properties, cyclodextrins serve as models for studying topochemical aspects and catalytic reactions of enzymes. In particular, cyclodextrins are good models for such hydrolytic enzymes as esterases and proteases in which the hydroxyl group of serine residue attacks the acyl group of a bound substrate.[5] It is well known that a typical serine protease, chymotrypsin, cleaves selectively at a significant rate the peptide bonds on the carboxyl side of residues with bulky side chain such as phenylalanine, tryptophan, and tyrosine. In these residues, the bulky side chains are assumed to be fitted neatly into a nonpolar pocket of chymotrypsin. Cyclodextrins also exhibit specificity for the guest inclusion.

The complexation and catalytic properties of chemically modified cyclodextrins have been extensively investigated.[2,3] Partially and fully methylated cyclodextrins can also form inclusion complexes in aqueous solution,[2,6] some of which are more stable than those of the parent cyclodextrins. Recently, these derivatives have become of great interest as their solubility in water as well as in organic solvents is very high and inclusion behaviors of them are not always the same as those of parent cyclodextrins.[7]

In order to characterize the inclusion behaviors, it is relevant to investigate the stoichiometry, the host-guest orientation, and the molecular dynamics of inclusion complex. In preceding papers,[8-11] the molecular dynamics of the inclusion complexes of α-, β-, and γ-cyclodextrin(α-, β-, and γ-CD, which are composed of **6**, **7**, and **8** glycosyl residues respectively) with some amino acids and dipeptides having aromatic side chain have been studied in aqueous solution by ^{13}C NMR. It was found that the strength of the host-guest dynamic coupling depends on the cavity size of the host cyclodextrin. We now report on the formation and molecular dynamics of inclusion complexes of methylated cyclodextrins with L-phenylalanine(Phe) in aqueous solution by the measurements of ^{1}H NMR parameters and ^{13}C spin-lattice relaxation times. The influence of the methylation of hydroxyl groups of cyclodextrins on the formation and the molecular dynamics of the complexes may be investigated by comparing the results with those obtained for unmodified cyclodextrin-Phe systems. As hosts we chose α-CD, hexakis(2, 3, 6-tri-*O*-methyl)-α-cyclodextrin(α-TMCD), and heptakis(2, 3, 6-tri-*O*-methyl)-β-cyclodextrin(β-TMCD). β-CD could not be studied because its solubility in neutral water is too poor to observe its natural abundance ^{13}C NMR spectrum with high quality.

Experimental

Materials α-CD, β-CD, and Phe were purchased from Nakarai Chemicals Ltd., Kyoto. α-TMCD and β-TMCD were synthesized by the procedure of Casu et al.[12] from α-CD and β-CD, respectively. They were recrystallized twice from hot water. Their structures and purities were confirmed by ^{1}H and ^{13}C NMR spectra as well as by thin-layer chromatography. Their ^{1}H NMR spectra were shown in Fig. 1, in which the previous assignments[13] were partly revised based on the ^{1}H-^{1}H and ^{1}H-^{13}C COSY spectra. The details of assignments will be published elsewhere.[14] $^{2}H_2O$ was purchased from Merck Sharp & Dohme, Canada, Ltd.

Methods. ^{1}H NMR spectra were recorded with a JEOL GX-500 spectrometer operated at 500 MHz. ^{13}C NMR spectra were recorded with a JEOL JNM PS-100 spectrometer operated at 25.1 MHz. The ^{13}C spin-lattice relaxation

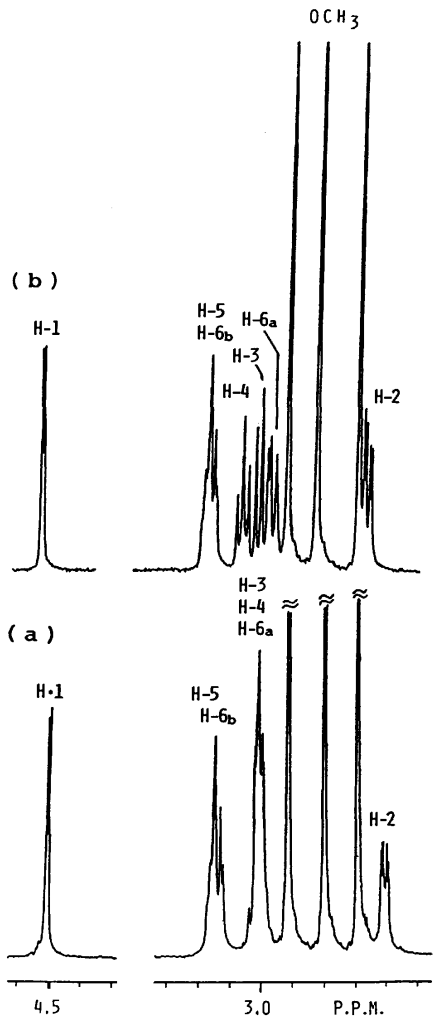

Fig. 1. 500 MHz ^{1}H NMR spectra of α-TMCD(a) and β-TMCD(b) in 0.01 M solution in ^2H_2O. The previous assignments[13] are partly revised[14] in this figure.

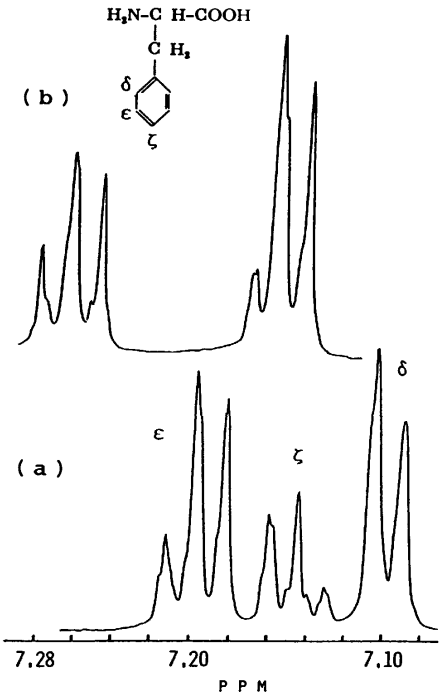

Fig. 2. 500 MHz ^{1}H NMR resonances of phenyl ring protons of phenylalanine(0.01 M) in the absence(a) and in the presence of α-TMCD(0.07 M)(b) in ^2H_2O.

time (T_1) was measured by the inversion-recovery method using a 180°-t-90° pulse sequence, where t is the time interval between the 180° and 90° pulses. The estimated error in the ^{13}C-T_1 values was approximately ±10%. The ^{1}H- and ^{13}C-chemical shifts were referenced to external tetramethylsilane. The digital resolution of ^{1}H shift was 0.0006 ppm. The macroscopic viscosity of solution was measured with a Cannon-Finske viscometer.[9] The temperature was kept at 30±2 °C for all measurements.

Results

Cyclodextrin-Induced ^{1}H-Chemical Shifts in Phe and Dissociation Constants. As found previously,[8-11] ^{1}H as well as ^{13}C NMR spectra of each cyclodextrin-Phe system consist of only one set of resonances, indicating that only one type of complexation occurs and/or the chemical exchange of the type

$$CD + S \rightleftarrows [CD, S] \quad (1)$$

is rapid process compared with the NMR time scale, where CD, S, and [CD, S] are host cyclodextrin, guest (substrate) Phe, and complex between them, respectively. The phenyl proton resonances of Phe in the 500 MHz ^{1}H NMR spectra were well resolved and were assigned easily as shown in Fig. 2. On addition of cyclodextrin, the phenyl proton resonances showed remarkably large changes, the example of which is also shown in Fig. 2. By plotting these cyclodextrin-induced ^{1}H chemical shift changes against the molar

ratio [CD]/[S], it is possible to determine the value of dissociation constant K_d (reciprocal of the association constant K_a) for CD-Phe complexation as shown in Fig. 3. In these experiments, the concentration of Phe was kept constant at 0.01 M and that of cyclodextrin was varied between 0 and ca. 0.07—0.10 M (1 M=1 mol dm^{-3}), depending on the solubility of cyclodextrins. The K_d value was estimated by fitting of the modified Hildebrand-Benesi equations[9,15,16] to the chemical shift change vs. [CD]/[S] curve. Here, it was assumed that a 1:1 complex between each CD and Phe was formed and that complexation was reversible as represented by Eq. 1. In Fig. 3 theoretically calculated shifts are also shown by the solid line, reproducing adequately the observed shift changes. Examination of the residuals obtained by subtraction observed shift changes from calculated ones revealed random but not systematic trends and the standard deviation was 0.003 ppm. The reversible dimerization has been suggested for α-TMCD in aqueous solution from its ^{13}C chemical shifts[17], but influence of dimerization was not found in the plot of ^1H shift change of guest Phe against [CD]/[S] molar ratio. That influence has also not been found for *p*-nitrophenol-α-TMCD system.[6]

The values of K_d and the cyclodextrin-induced ^1H chemical shift change $\Delta\delta$ were summerized in Table 1. Here, $\Delta\delta$ is defined as chemical shift difference between the shifts found in the fully complexed and in the uncomplexed states and was estimated from the chemical shifts at known concentrations of cyclodextrin and Phe, in conjunction with the predetermined K_d value.

The large chemical shift changes of phenyl proton resonances suggest that the Phe molecule forms the complex with each cyclodextrin by insertion of its phenyl ring into the cyclodextrin cavity.

The K_d values for three cyclodextrin-Phe systems are practically the same, although that for the α-CD-Phe system is the smallest and that for the β-TMCD one the largest.

Conformational Change of Phe by Complexation with Cyclodextrins. In order to investigate the steric host-guest interaction, a conformational change of the guest Phe on the occasion of complexation with cyclodextrin was analyzed by observing ^1H spin coupling constants.[18] The 500 MHz ^1H NMR resonances of the Phe α- and β-protons could be analyzed as an ABX three spin system. The ^1H coupling constants were observed at the host and guest concentrations of 0.07 and 0.01 M (in ^2H_2O solution), respectively. The coupling constants for Phe in the fully complexed states were estimated from the observed ones with the aid of K_d values. The results were given in Table 2, in which the rotamer populations for the side chain estimated with the use of the Feeney's approximation[19] were also included.

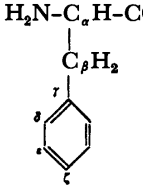
In the free as well as in the complexed states, the most stable rotamer is the gt one with the aromatic ring trans to the carboxyl group. These results are in agreement with the general observations that the aromatic side chain has a tendency to orient itself toward the amino group of the same residue.[20] Thus, the most stable rotamer, gt, in the free state is still the one in the complexed state.

The complexation with α-TMCD induces a small but a notable increase of gt rotamer population with a decrease of gg one. The influence of β-TMCD on the conformation is negligibly small. In the case of α-CD,

Table 1. Dissociation Constants K_d and Complexation-Induced ^1H Chemical-Shift Changes $\Delta\delta$ for Cyclodextrin-Phenylalanine System in Deuterium Oxide[a]

Compound	K_d/M[b]	$\Delta\delta$/ppm[c]		
		H_δ	H_ε	H_ζ
[Phe, α-CD]	3.0×10^{-2}	0.112	0.106	0.052
[Phe, α-TMCD]	3.3×10^{-2}	0.080	0.103	0.023
[Phe, β-TMCD]	3.5×10^{-2}	0.045	0.039	0.032

a) Assignments of carbon atoms of phenylalanine are as follows.

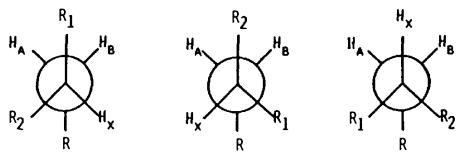


b) Estimated error is less than ±15%. c) $\Delta\delta$ is chemical shift difference between free and fully complexed states, and positive value indicates lowfield shift.

Table 2. ^1H Coupling Constants and Populations of Rotamers about C_α-C_β Bond of Phenylalanine in Free State and Complexed State with Cyclodextrin in Deuterium Oxide

Compound	Coupling constant/Hz			Rotamer population[a]		
	J_{AB}	J_{AX}	J_{BX}	gt	tg	gg
[Phe]	14.5	7.9	5.2	0.53	0.26	0.21
[Phe, α-CD]	14.5	7.5	5.5	0.49	0.28	0.23
[Phe, α-TMCD]	14.5	8.5	5.0	0.60	0.26	0.14
[Phe, β-TMCD]	14.5	8.0	5.1	0.54	0.25	0.21

a) Caluculated by Freeney's relation. Rotamer notations are as follows.



g t t g g g

where R=C_6H_5, R_1=COOH, and R_2=NH_2.

the complexation induces a small decrease of gt population. These results indicate that the steric perturbation of the host cyclodextrins on the conformation of the guest Phe is the largest in the α-TMCD system.

^{13}C Spin-Lattice Relaxation Times of Phe. The measurements of ^{13}C-T_1 values are particularly useful for the investigation of molecular dynamics of cyclodextrin inclusion complexes.[8-11] In Table 3 are given the values of ^{13}C-T_1 for Phe in the free state and in the cyclodextrin-Phe mixed systems in aqueous solution. In the limit of rapid exchange process of Eq. 1, one measures an average relaxation rate

$$\frac{1}{T_1} = p_f\frac{1}{T_{1f}} + p_c\frac{1}{T_{1c}} \tag{2}$$

where T_{1f} and T_{1c} are intramolecular spin-lattice relaxation times for a spin in the free and complexed states, and p_f and p_c ($=1-p_f$) are the probabilities that Phe is found in the free and complexed states, respectively.

For the complexation reaction of Eq. 1, the p_c value can be expressed by[8,9]

$$p_c = \frac{1}{2}(1+r)\left\{1-\left[1-\frac{4K_a}{K_a+1}\cdot\frac{r}{(1+r)^2}\right]^{1/2}\right\} \tag{3}$$

where r is the molar ratio of Phe to cyclodextrin and K_a is the association constant ($=1/K_d$).

The viscosity of the cyclodextrin solution varies widely, depending on the type and concentration of cyclodextrin.[9-11] In order to compare the ^{13}C-T_1 values of Phe in different solutions, a correction for the viscosity difference between the solutions is needed. For a molecule of medium size whose motion is rapid enough on the ^{13}C NMR time scale, it is likely that the ^{13}C-T_1 value of the carbon atom having at least one directly-bonded proton is governed by ^{13}C-^{1}H dipole-dipole relaxation brought about by a rotational motion.[21,22] In this case, if the overall molecular motion is isotropic, ^{13}C-T_1 is given by

$$\frac{1}{T_1} = \hbar^2\gamma_C^2\gamma_H^2 N r_{CH}^{-6}\tau_{eff} \tag{4}$$

where τ_{eff} is the effective correlation time for the overall molecular motion, r_{CH} is the carbon-hydrogen bond length, γ_H and γ_C are the gyromagnetic ratios of ^{1}H and ^{13}C nuclei, and N is the number of directly bonded proton. The τ_{eff} can be related to the viscosity of solution, η, by assuming the Brownian diffusion model.[21-23] As the result, ^{13}C-T_1 is given as follows

$$\frac{1}{NT_1} = \hbar^2\gamma_C^2\gamma_H^2 r_{CH}^{-6}\eta f_r V_m/kT. \tag{5}$$

where k is the Boltzman's constant, T is the absolute temperature, f_r is a microviscosity factor, and V_m is the molecular volume. We have shown in the previous paper[8] that the isotropic diffusion model expressed by Eq. 5 was applicable to the analysis of overall molecular motion of Phe in aqueous solution. According to Eq. 5, $NT_1\eta$ value for a given carbon nucleus must be constant, if all situations except the viscosity of solution remain unchanged. The expected

Table 3. Values of ^{13}C NT_1[a] for Free Phenylalanine and Its Inclusion Complexes with Cyclodextrins in Deuterium Oxide

Compound	Concn/10^{-1} M	^{13}C NT_1/s±10%				
		C_α	C_β	C_δ	C_ε	C_ζ

Compound	Viscosity η/cp	^{13}C NT_1 (^{13}C $NT_1\eta$)/s(s cp)				
		C_α	C_β	C_δ	C_ε	C_ζ
[Phe]	0.94	(1.50)	(1.71)	(1.74)	(1.75)	(1.25)
[Phe, α-CD]	1.27	0.42	0.54	0.52	0.54	0.35
		(0.53)	(0.69)	(0.66)	(0.69)	(0.44)
[Phe, α-TMCD]	1.43	0.71	0.77	0.68	0.67	0.37
		(1.02)	(1.10)	(0.97)	(0.96)	(0.53)
[Phe, β-TMCD]	1.70	0.75	0.80	0.78	0.79	0.54
		(1.28)	(1.36)	(1.33)	(1.34)	(0.92)

constancy of $NT_1\eta$ values has been certainly observed for aqueous solutions of Phe,[9] where the solution viscosity was controlled by adding various amounts of D-glucose. Thus, the ^{13}C-T_1 values of free Phe molecule in the cyclodextrin-Phe mixture can be estimated by multipling the ^{13}C-T_1 values observed in the solution containing only Phe by the value of viscosity ratio η(solution of cyclodextrin-Phe mixture)/η(solution of Phe). By using these T_1 values in Eq. 2 as T_{1f} values of Phe in the cyclodextrin-Phe solution, the T_{1c} values are calculated for each system. The results are shown in Table 4 with the values of solution viscosity.

The NT_{1c} values for phenyl ring C_ζ are always shorter than those of other ring protonated carbons. These results indicate the existence of rapid internal rotation of the Phe ring in addition to the overall molecular motion even in the complexed states. The rotational motion of Phe ring about the C_β–C_γ bond makes lengthen the NT_1 values of C_δ and C_ε. This motion, however, cannot affect that of C_ζ, since the C_ζ–H bond is on the extension line of rotational axis.[9]

To investigate strictly the influence of complexation on the molecular motion of the guest Phe, we used the $NT_1\eta$ values, which are shown also in Table 4 (in parenthesis). According to the theoretical prediction expressed by Eq. 5, a decrease in $NT_1\eta$ value corresponds to an increase in molecular volume Vm. For cyclodextrin-Phe inclusion systems, the greater the dynamic coupling between them, the greater is the increase in the apparent molecular volume of the Phe and hence the greater is the decrease in the $NT_1\eta$ value, as the molecular volume of cyclodextrins is about 6—9 times larger than that of Phe.[8] Thus, the extent of the decrease in the $NT_1\eta$ value may be used as a measure of the strength of dynamic coupling of Phe with cyclodextrins. As can be seen from the data in Table 4, all of the $NT_1\eta$ values show a decrease, to greater or lesser extents, on the addition of cyclodextrins. These results clearly indicate that the molecular motion of Phe is restricted by the cyclodextrins.

The degree of restriction can be clarified by estimating the ratios of $NT_1\eta$ values for the complexed and free states of Phe, which are shown in Table 5. It is noticeable that almost all phenyl-ring carbons in the three cyclodextrin-Phe systems show larger decreases in the $NT_1\eta$ values than those for other carbons in the same systems, indicating a larger slow-down of the internal rotation of the phenyl ring than that of the other part or of the overall molecular motion. The results clearly show that the Phe molecule forms truly the inclusion complexes with three cyclodextrins by insertion of its phenyl ring into the cyclodextrin cavities. This conclusion is supported by the large chemical shift changes of phenyl protons as shown in the preceding section.

Table 5. Values of ^{13}C $NT_1\eta$ Ratios for the Complexed and Free States of Phenylalanine[a]

Compound	$(NT_1\eta)_{complex}/(NT_1\eta)_{free}$				
	C_α	C_β	C_δ	C_ε	C_ζ
[Phe, α-CD]	0.35	0.40	0.38	0.39	0.36
[Phe, α-TMCD]	0.68	0.64	0.56	0.55	0.42
[Phe, β-TMCD]	0.85	0.80	0.76	0.77	0.74

a) The corresponding $NT_1\eta$ values are given in Table 4.

The $NT_1\eta$ values of the phenyl carbons suffer the largest reduction on complexing with α-CD. In this case, the values of C_α and C_β also suffer the largest reductions. On the other hand, the $NT_1\eta$ values of Phe show the intermediate and the smallest reductions by comlexation with α- and β-TMCD, respectively.

Discussion

The changes of chemical shifts and ^{13}C-T_1 of the guest Phe on addition of the hosts α-CD, α-TMCD, and β-TMCD show clearly that they form the inclusion complexes in a similar manner, namely, by insertion of the guest's phenyl ring into the host's cavity. The results that the NT_1 values of C_δ and C_ε in Phe phenyl ring agree well with each other and they are always larger than those of C_ζ indicate that all cyclodextrins investigated here favor the axial inclusion in which the internal rotation axis C_γ–C_ζ of the phenyl ring is parallel or nearly parallel to the axis of the cyclodextrin cavity. Thus, it is concluded that the permethylation of hydroxyl groups of cyclodextrin does not modify essentially the mode of Phe inclusion. It is generally accepted that many benzene derivatives form 1:1 complexes with α-CD by inserting their benzene rings into the α-CD's cavity from its secondary hydroxyl side, namely from the wider side of cavity. The same type inclusion has been also found for α-TMCD–*p*-nitrophenol system in aqueous solution.[6] The phenyl ring of Phe may be also inserted into the cavities of α- and β-TMCD as well as into that of α-CD[8–11] from the wider side with C_α as the head.

Several mechanisms have been proposed to interpret the formation of cyclodextrin inclusion complexes; such as van der Waals interactions between the guest and cyclodextrin, hydrogen bonding between the guest and the hydroxyl groups of cyclodextrins, release of strain energy in the macrocycle of cyclodextrin and so on.[1,2] But the driving force(s) for formation of cyclodextrin inclusion complexes is(are) still unclear and a matter of speculation.

In the general cases of the enzyme-substrate complex formation the binding force is supposed to be provided, at least partly, by hydrophobic interaction. The methylation of the hydroxyl groups of cyclodextrin is expected to increase the extent of the low

polar or apolar sphere of its cavity. In fact, heptakis (2,6-di-*O*-methyl)-β-cyclodextrin is found to be a hydrophobic solute in contrast with α-CD which is hydrophilic.[24,25] Thus, the permethylation may result an increasing the binding tendency of the Phe's apolar phenyl ring to the cyclodextrin cavity, if the hydrophobic interaction is the major mechanism for the formation of the inclusion complexes. The values of K_d and ^{13}C relaxation time do not support this expectation. Instead, the K_d values for both permethylated cyclodextrin-Phe systems are more or less larger than that for the α-CD-Phe system. The strength of dynamic coupling between the host and the guest estimated from the ^{13}C-T_1 is the largest also in the α-CD complex. Thus; only the hydrophobic interaction, although it may play some role, may not be the major driving force for the formation of inclusion complexes between Phe and permethylated cyclodextrins investigated here.

The X-ray crystallographic studies of the inclusion complexes of α-CD[26] and α-TMCD[27] with *p*-nitrophenol have shown that the size of the secondary hydroxyl side of the cyclodextrin cavity is widened by the methylation of all hydroxyl groups. In these cases, the intermolecular hydrogen-hydrogen distances indicate that the benzene ring of the guest *p*-nitrophenol has weaker van der Waals contacts with the inside of the α-TMCD cavity than with that of the α-CD cavity. Similar situations must hold for the cyclodextrin-Phe systems investigated here. The orders of stability of complex manifested in K_d values and the strength of host-guest dynamic coupling estimated from the ^{13}C relaxation times are related to that of cavity sizes of cyclodextrins. Namely, according to the CPK space-filling molecular models, the cavity size of α-CD is the smallest and that of β-TMCD is the largest. α-TMCD has the cavity of intermediate size. The steric contacts between the host and the guest molecules are expected to become the greatest and the smallest in the α-CD and β-TMCD systems, respectively. Therefore, the van der Waals interactions seem to play a significant role for the formation of cyclodextrin inclusion complexes with Phe in aqueous solution. This is also supported by the facts that the greatest and the smallest $\Delta\delta$ values were observed for the Phe aromatic proton resonances in the α-CD and β-TMCD systems, respectively, although it is not easy to interpret the signs and the magnitudes of the complexation-induced shifts.

The formation of hydrogen bond between the peripheral secondary hydroxyl groups of α-CD and the carboxyl group of Phe may also contribute, more or less, to the stabilization of complex, as the population of gt rotamer decreased and those of tg and gg rotamers increased slightly, on complexation with α-CD. In the α-CD inclusion complex, where the phenyl ring or Phe is inserted into the cyclodextrin cavity from its secondary hydroxyl side, the carbonyl group of Phe can form the hydrogen bond with the cyclodextrin's hydroxyl groups when the Phe side chain takes the tg and gg rotamers. The existence of this hydrogen bond is also suggested from the ^{13}C $NT_1\eta$ values for Phe C_α and C_β, which reveal significant decrease on complexation with α-CD (Table 5), indicating the reduction of mobility of these carbons in the complexed state. This reduction may be due to the anchoring effect of the hydrogen bond on the molecular motion.[28]

In the case of α-TMCD complex, the tg and gg rotamers may become unfavorable because of the repulsive interactions between the Phe's carbonyl and α-TMCD's methoxyl groups. Thus, the gt rotamer, in which the carbonyl group is far away from the methoxyl groups, becomes more probable. On complex formation with β-TMCD, which has the largest cavity size, the rotamer populations of Phe side chain remain unchanged. The cavity size of β-TMCD may be large enough to avoid severe contact between the Phe carboxyl and β-TMCD's rim even in the tg and gg rotamers. This conclusion is supported again by the ^{13}C $NT_1\eta$ values of C_α and C_β in the complexed state, which are comparable to those in the free state.

In conclusion, permethylated cyclodextrins form inclusion complexes with phenylalanine in a manner similar to parent cyclodextrins, but stability and strength of host-guest dynamic coupling change significantly by methylation. The NMR is useful method for studies of formation and molecular dynamics of cyclodextrin inclusion complexes.

The authors thank Dr. Yoshiyuki Nakamura of Research Laboratory of Resources Utilization, Tokyo Institute of Technology for the measurements of 500 MHz ^1H NMR spectra.

Study of One-Dimensional Metal Complexes: $K[Ni(mnt)_2]\cdot H_2O$ and $K[Pt(mnt)_2]\cdot H_2O$

Shoichi KUTSUMIZU,* Norimichi KOJIMA, Toshiro BAN, and Ikuji TSUJIKAWA
Department of Chemistry, Faculty of Science, Kyoto University,
Kitashirakawa-oiwake-cho, Sakyo-ku, Kyoto 606
(Received February 20, 1987)

The crystal structure, electrical conductivity and electronic and IR absorption spectra of two metal complexes, $K[Ni(mnt)_2]\cdot H_2O$ and $K[Pt(mnt)_2]\cdot H_2O$ (mnt=1,2-dicyano-1,2-ethylenedithiolato, $C_4N_2S_2^{2-}$) were investigated. These two metal complexes belong to orthorhombic system and the lattice constants are a=12.00 Å, b=28.85 Å, and c=3.90 Å for the Ni complex and a=12.11 Å, b=29.23 Å, and c=7.73 Å for the Pt complex. Despite the same stoichiometries and similar crystal structures, the conductivity of Pt complex is 10^3 times as high as that of the Ni complex. The difference in the conductivity between the Ni and Pt complexes may be explained from the density of the unpaired electron on the central metal. The effects of the central metal on the electrical conduction properties may not be negligible for this type of complexes.

In the last decade, many quasi-one-dimensinal (1-D) compounds have been synthesized and intensively studied[1] in order to look for new materials having novel properties. Furthermore, these 1-D systems have stimulated theoretical investigations.

Among these 1-D compounds, typical examples are the 1-D platinum complexes, such as $K_2Pt(CN)_4Br_{0.3}\cdot 3H_2O$ (KCP(Br)) and the selenium donor organic metals, such as $(TMTSF)_2ClO_4$ (TMTSF=tetramethyltetraselenafulvalene). In these complexes, the constituent planar molecules form columnar stack structures, which lead to highly directional intermolecular d_{z^2} or π orbital interaction and, consequently, 1-D electronic nature.

As mentioned above, the planarity of molecule is necessary to form a stack with large intermolecular interactions. For this reason, the metal dithiolate complex can be used as a constituent planar molecule and expected to form a 1-D electrical conductor. In addition, these metal dithiolate complexes have unusual redox properties,[2-5] whereas we have taken notice of following two characteristic features:

i) This system has the capacity for structural modifications through changes in the central metal, the ligand substituent, and the counter cation; these chemical modifications are expected to produce a rich variety of new compounds with interesting electrical properties.

ii) The planar molecules have both metal d_{z^2} and ligand p_z orbitals; from this reason, Little suggested that this system is one possible example of the model of excitonic superconductors.[6] Although the real system is not necessarily satisfied with his criterion, this possibility cannot be perfectly excluded.

In fact, Underhill and Ahmad[7] have succeeded in synthesizing a new type of 1-D metallic complex with the mnt ligand; $Li_{0.8}(H_3O)_{0.3}[Pt(mnt)_2]\cdot 1.7H_2O$ (mnt= 1,2-dicyano-1,2-ethylenedithiolato, $C_4N_2S_2^{2-}$). The crystal structure and physical properties[8-13] of this salt have indicated that it is similar to the sulfur donor organic metals rather than to the 1-D platinum complexes. This conduction pathway is attributed to the overlap of delocalized MO's within the whole anions in which S p_z orbitals in the ligands play a dominant role and the central metal Pt plays a minor role in its conduction. The contribution of the central metal to its physical properties are still uncertain and the partial oxidation state of this system is not fully described.

We intended to elucidate the role of the central metal in the electrical conduction of these metal dithiolate complexes. For this purpose, we chose the cyano-substituted complex (Fig. 1) from a following reason: In the metal dithiolate complexes the electron density is always larger on the ligand than on the metal, but in this cyano-substituted Ni complex the density on the metal is not so small compaired with that on the ligand; these results were suggested by Schläpfer and Nakamoto.[14] We synthesized two metal complexes, $K[Ni(mnt)_2]\cdot H_2O$ and $K[Pt(mnt)_2]\cdot H_2O$, which will be abbreviated as KNi(mnt) and KPt(mnt), respectively. Because the metal d orbitals of KPt(mnt) are more extended than those of KNi(mnt), it is expected that the differences of two central metal are reflected in those of electrical properties.

In this paper, we report the syntheses, crystal structures, electrical conductivity behaviors, optical absorption spectra, and IR spectra of KNi(mnt) and KPt(mnt). From these data, we have considered the central metal effects on the electrical conduction properties for this type of complexes.

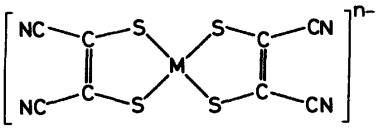

Fig. 1. $[M(mnt)_2]^{n-}$ complex.

Experimental

Preparation. The mnt^{2-} ligand was prepared following a procedure which is the combination of those described by Bray et al.[15] and Davison and Holm.[16] $[Et_4N]_2[Ni(mnt)_2]$ was prepared following a procedure described by Billig et al.[17] KNi(mnt) was prepared by use of a similar procedure of Ahmad and Underhill[8] described below. Slow O_2 oxidation of a solution of $K_2[Ni(mnt)_2]$ (ca. 10^{-3} mol dm^{-3}) in acetone-water (1:1) or (2:1) gave a black microcrystalline product. Oxidation by oxidant of H_2O_2 or slow evaporation on a steam bath gave the same results. KPt(mnt) may be prepared in a similar method described above, but we used a direct mixing at 50—70 °C of K_2PtCl_4 in aqueous solution and $Na_2(mnt)$ in EtOH-water (1:1). Obtained green-black precipitate was filtered off and washed with cold water.

The needle-like crystals of both KNi(mnt) and KPt(mnt) are dichroic with dark brown and green for polarized light parallel and perpendicular to the needle axis, respectively, under microscope. Both samples were stored in a moist (81% relative humidity) atmosphere to prevent dehydration.

Calcd for $KNiS_4C_8N_4H_2O$: C, 24.25; H, 0.51; N, 14.14; K, 9.9; Ni, 14.81; H_2O, 4.55%. Found: C, 24.32; H, 0.55; N, 14.05; K, 9.9; Ni, 13.8; H_2O, 4.35%. Calcd for $KPtS_4C_8N_4H_2O$: C, 18.04; H, 0.38; N, 10.52; K, 7.34; Pt, 36.63; H_2O, 3.49%. Found: C, 17.99; H, 0.38; N, 10.22; K, 7.0; Na, 0.08; Pt, 33; H_2O, 3.44%. Carbon, hydrogen, and nitrogen analyses were carried out by the Laboratory for Organic Elemental Microanalysis of Kyoto University.

Structure. The space group and lattice constants of KNi(mnt) were determined from X-ray oscillation photographs around the needle axis and X-ray Weissenberg photographs. The lattice constants were more accurately determined from X-ray powder diffraction patterns. The lattice constants of KPt(mnt) were determined from X-ray powder diffraction patterns by using those of KNi(mnt) as a guide.

Electrical Conductivity. The d.c. electrical conductivity measurements were performed on polycrystalline samples with two-probe method. Samples were prepared by pressing powders under pressure of (2.0—2.9)×10^8 GPa into cylindrical pellets, 10 mm in diameter and typically 0.5 mm in thickness. Electrical contacts to the disc planes by wetting gold wires with gold-paste (Tokuriki Chemical Research, No. 8560-1A). In order to prevent dehydration, samples were thinly covered with Apiezon N grease. For KPt(mnt), measurements parallel to the disc planes were also performed by cutting a pellet into a rectangular slice in order to evaluate the anisotropy in the conductivity. It is possible in such a case that microcrystalline needles are not oriented randomly but arranged nearly parallel to the disc planes in the compressed pellets. All samples gave ohmic behavior under the conditions of measurement.

IR and Electronic Spectra. The IR spectra were recorded on a Jasco Model IRA-1 (650—4000 cm^{-1}) in KBr pellets. Frequency reading was calibrated by recording the spectra of polystyrene film and the accuracy was about ±1 cm^{-1}.

The solid-state electronic spectra were recorded on a Cary 17D grating spectrometer (4000—33000 cm^{-1}) in KBr pellets.

DSC Measurement. The DSC measurements were performed with a Rigaku DSC-10A apparatus between 110K and 450K, scanning rate 3 or 5 °C min^{-1}.

Results and Discussion

Crystal Structure. Structural Analysis of KNi(mnt). Single crystals (typical size: 0.5×0.14×0.01 mm) coated with a thin layer of paraffin were used for the measurements. A careful inspection of the intensities of oscillation and Weissenberg photographs showed the Laue group *mmm*. The systematic absences $hk0$, $h=2n+1$ and $0kl$, $k+l=2n+1$ indicated two possible space groups: $Pn2_1a$ or *Pnma*. Unfortunately, because of the smallness in size of the crystals it has not been possible to obtain information on the space group for KPt(mnt).

Crystal Structure. The lattice constants of KNi(mnt) and KPt(mnt) are shown in Table 1 together with the values of $[NH_4][Ni(mnt)_2]\cdot H_2O$ reported by Isett et al.[18] They belong to orthorhombic system and have similar crystal structures. For KNi(mnt), there were no diffuse lines in oscillation photographs, which indicates that uniform spacing of the $[Ni(mnt)_2]^-$ anions along the c-axis. However, the $[Ni(mnt)_2]^-$ planes are probably tilted with respect to the c-axis as is often seen for other dithiolate complexes so that the plane-to-plane separation is decreased from 3.90 Å. On the other hand, the X-ray powder diffraction pattern and broadening of the C=C stretching modes on KPt(mnt) (see the section of IR Spectra) suggest a dimerization of the unit cell in the chain direction, the c-axis, which is similar to the fact that $Rb[Pt(mnt)_2]\cdot 2H_2O$[19] posesses a dimerized stack structure. In order to clarify this, the single crystal measurements are necessary and now in progress. Anyway, KPt(mnt) and KNi(mnt) have similar crystal structures, except the possibility of dimerization.

From Table 1, it is clear that there are significant similarities in the crystal structure between KNi(mnt) and $[NH_4][Ni(mnt)_2]\cdot H_2O$, which seems reasonable considering the comparable size of the cations (K^+, 1.33 Å; NH_4^+, 1.48 Å[20]). However, the conductivity for compressed pellets of NH_4 salt (5×10^{-3} S cm^{-1}) is 10^4 times as high as that of K salt (ca. 10^{-7} S cm^{-1}, vide infra). Although the space group of NH_4 salt is unknown, it is probable that the ability of NH_4^+ ions to form hydrogen-bonding networks causes some

subtle change in arrangement of the $[Ni(mnt)_2]^-$ monoanions, which causes large difference in the conductivity between NH_4 salt and K salt.

Electrical Conductivity. The experimental results of the electrical conductivity σ are shown in Fig. 2. In both complexes, thermally activated semiconducting behaviors were observed at all temperature. At room temperature, the value of KNi(mnt) is ca. 10^{-7} S cm^{-1}, whereas that of KPt(mnt) is 10^{-4} S cm^{-1}. The activation energy E_a was obtained by a least-squares fit to the usual equation, $\sigma=\sigma_0\exp(-E_a/k_BT)$, with E_a=0.33—0.37 eV (between 300—230 K) for KNi(mnt), whereas E_a=0.18 eV (between 300—200 K) for KPt(mnt). The value of KNi(mnt) is in agreement with that obtained by Underhill et al. ($\sigma_{r.t.}$=*ca.* 10^{-6} S cm^{-1}. E_a=0.346 eV)[21] on single crystals. In addition, observed anisotropy in the conductivity for KPt(mnt) was 10—20, which is considered as a lower limit (see Experimental section).

First, we will discuss the dependence of the conductivity on the central metal. Despite the same stoichiometries and similar crystal structures, the conductivity of KPt(mnt) differs significantly from that of KNi(mnt). However, caution must be paid in interpretation of these results because our measurements were made on compressed pellets; Rosseinsky and Malpas[22] have found that in some intervalence mixtures of more conductive $[Ni(mnt)_2]^-$ monoanion and less conductive $[Ni(mnt)_2]^{2-}$ dianion salts, the conductivities are enhanced; in the mixture with the best conduction, 10^3 times higher conductivity relative to the $[Ni(mnt)_2]^-$ monoanion salt was observed. In order to confirm this, we studied the IR spectra of KPt(mnt), which showed no evidence of the presence of $[Pt(mnt)_2]^{2-}$ dianions (see Fig. 4). Therefore, the sample of KPt(mnt) obtained was not such a mixture but was a genuine compound having the formula of $K[Pt(mnt)_2]\cdot H_2O$. Furthermore, very recently, similar results have been obtained for other metal complexes with the sulfur containing ligands, such as $Li_x[M(mnt)_2]\cdot nH_2O$ (M=Ni, Pd, Pt; for M=Pt, $Li_{0.8}(H_3O)_{0.3}[Pt(mnt)_2]\cdot 1.7H_2O$)[23] and TTF$[M(dmit)_2]_n$ (for M=Ni and Pd, n=2; for M=Pt, n=3; TTF=tetrathiafulvalene; H_2dmit=4,5-dimercapto-1,3-dithiol-2-thione),[24] which indicate that their central metals have considerable effects on conductivity. Our results show that it is inappropriate to ignore the role of the central metals of the metal mnt complexes with integral oxidation states as well as those with non-integral oxidation states.

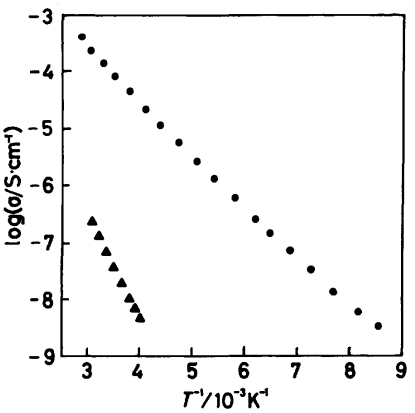

Fig. 2. Electrical conductivity of KNi(mnt) (▲) and KPt(mnt) (●).

Next, we will mention that effects of the ligand substituent R are important in the metal dithiolate complexes of the form $[M(S_2C_2R_2)_2]^-$. Table 2 shows the conductivity of alkali metal salts containing monoanions. Although for R=H and Ph (Ph=C_6H_5) the crystal structures are unknown and an exact comparison cannot be made, it is possible to point out that only the cyano-substituted complexes, namely the metal mnt complexes, show significant dependence of the conductivity on the central metals. This can be explained in terms of the difference of the electron distribution within the whole anion. From the IR spectra of $[Ni(S_2C_2R_2)_2]^z$ series (R=H, Ph, CF_3, and CN; z=0, 1− and 2−) and their normal coordinate analyses, Schläpfer and Nakamoto[14] have argued that in monoanion salts the density of the unpaired electron on the Ni atom increases in the order of R=H<Ph<CF_3<CN. Therefore, it can be interpreted that in R=CN the role of the central metal in the conductivity is significantly large compared with those in other complexes and the difference between Ni and Pt atom is directly reflected in the conductivity; on the other hand, in R=H and Ph the central metals have minor roles in determining the conductivity.

At this point, one question that arises is why the conductivity of the Pt complex, KPt(mnt), is higher than that of the Ni complex. We will discuss this problem in the section of General Discussion.

Electronic Spectra. The solid-state and solution electronic spectra of KNi(mnt) and KPt(mnt) are shown in Fig. 3. Our result of the solution spectra of KNi(mnt) is in agreement with that of [n-Bu_4N][Ni(mnt)$_2$] by Shupack et al.[27] For both Ni and Pt complexes, the spectra of a very dilute solution were

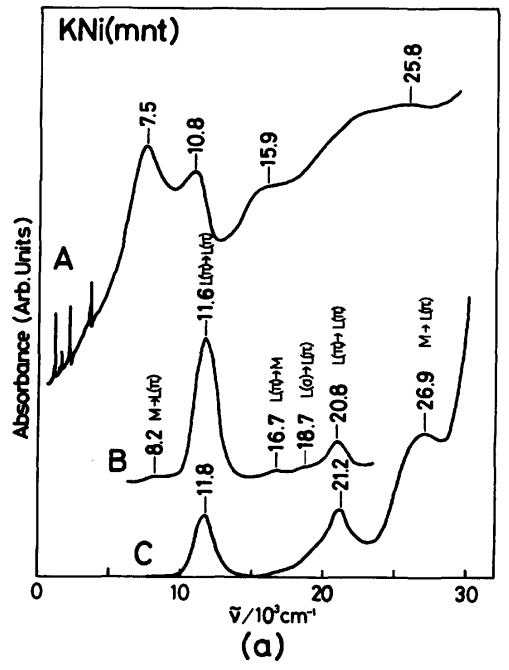
Compound	$\sigma_{r.t.}$/S cm^{-1} a)	
	M=Ni	M=Pt
$Cs[M(S_2C_2H_2)_2]$	1.4×10^{-7} [25]	8.3×10^{-7} [25]
$K[M(S_2C_2Ph_2)_2]$	1×10^{-7} [26]	$\sim10^{-6}$ [26]
$K[M(S_2C_2(CN)_2)_2]\cdot H_2O$	$\sim10^{-7}$	1×10^{-4}

a) All measurements were made on compressed pellets.



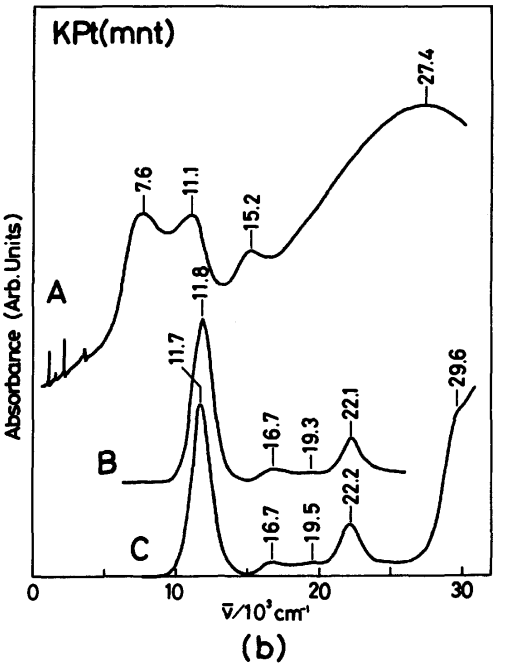


Fig. 3. Electronic spectra of (a) KNi(mnt) and (b) KPt(mnt): A, Solid-state spectra in KBr pellets; B, in acetonitrile solution; C, in acetone-water (1:1) solution. In the acetone-water (1:1) solution, very intense absorptions due to solvent made it impossible to measure below ca. 8000 cm^{-1}. In the case of the Ni complex, the assignments of solution spectra by Schrauzer and Mayweg[28] are also shown: L(π)=ligand π orbital dominant MO, L(σ)=ligand σ orbital dominant MO, M=metal d orbital dominant MO.

almost the same with Fig. 3, suggesting the presence of monomeric $[M(mnt)_2]^-$ species in solution. Moreover, the band positions are essentially the same in both acetone-water (1:1) and acetonitrile solutions. In the solution spectra of $[Ni(mnt)_2]^-$ monoanion, the assignments by Schrauzer and Mayweg[28] are also shown in Fig. 3 (a).

First, we will look at the results of the solid-state spectra of KNi(mnt) and KPt(mnt). In contrast with the significant differences in the conductivity, the solid-state spectra of both complexes are very similar. This is partly due to the intense absorptions involving the ligand-dominant orbitals, such as L(π)→L(π) transition. The differences of both Ni and Pt complexes which appear in solution spectra are smeared in the solid-state spectra. From the solid-state spectra, we could not find any marked differences in contrast to the conductivity.

Next, we compare the solid-state spectra of both complexes with their solution spectra. As the solid-state electronic bands are appreciably diffused and continuously overlap with each other, it is difficult to find the correspondence between the bands of the solid-state spectra and of solution spectra. However, in the solution spectra of both complexes there is no band observed corresponding to the lowest-energy bands around 7500 cm^{-1} in solid-state, except a very weak band at 8200 cm^{-1} in KNi(mnt). Therefore, these lowest-energy bands probably correspond to the intermolecular charge-transfer (CT) bands. Similar observations have been made on TCNQ anion radical salts[29] (TCNQ=tetracyanoquinodimethane); they have several electronic transitions from near-IR to visible region, among which the lowest-lying one or two peaks result from intermolecular CT transitions and higher-energy peaks correspond to the localized excitations within a single anion. In order to clarify the character of this band, the polarized optical measurements and photoconduction measurements are useful and now in progress.

IR Spectra. The frequencies of the bands observed in the IR spectra of KNi(mnt) and KPt(mnt) are given in Table 3, together with the assignments based on those of Schläpfer and Nakamoto.[14] A comparison of the IR spectra of both complexes indicates a surprising similarity.

As is well-known, IR spectra of the metal dithiolate complexes have following important features:

i) The frequencies of some modes, such as the C=C and C-S stretching modes, are dependent on the net charge of the $[M(S_2C_2R_2)_2]^z$ molecule; when the complex is oxidized and then the net charge is decreased, the frequencies of the C=C and C-S modes decreases and increases, respectively. In other words, the HOMO of the monoanion is bonding with respect to the C=C bond but antibonding with respect to the C-S bond.

ii) In the case of the isolated molecule in solid state,

such as in the dianion salts,[30] the dependence of the frequencies on the central metal M is very little, except for the M-S modes; the mass of the metal little affects the frequencies of modes arising principally from the ligand vibrations.

The most significant difference between KNi(mnt) and KPt(mnt) is that the band associated with the C=C modes in KPt(mnt) is much broad and energetically lower compared with the corresponding peak in KNi(mnt)(Fig. 4); the band of KPt(mnt) seems to comprise two C=C modes, whereas the band of KNi(mnt) is observed as a sharp single peak. In addition, the C-S mode of KPt(mnt) is seen at higher frequency than that of KNi(mnt)(see Table 3), which is consistent with the fact that the C=C modes of KPt(mnt) are observed at lower frequency than that of KNi(mnt).

These results can be interpreted as follows: Firstly,

Table 3. Observed IR Frequencies of KNi(mnt) and KPt(mnt) (cm^{-1})

KNi(mnt)	KPt(mnt)	Assignment
3628 m	3632 m	$\nu_3(H_2O)$
3552 vw	3558 vw	$\nu_1(H_2O)$

1155 vs	1154 vs	ν(C-C)+ν(C-S)
1142 sh	1138 sh	?
1112 w	1108 w	π(C-CN)
1064 vw	1063 vw	ν(C-C)+ν(C-S)
869 vw	876 vw	ν(C-S)

s: Strong, vs: very strong, m: medium w: weak, vw: very weak, b: broad, sh: shoulder.

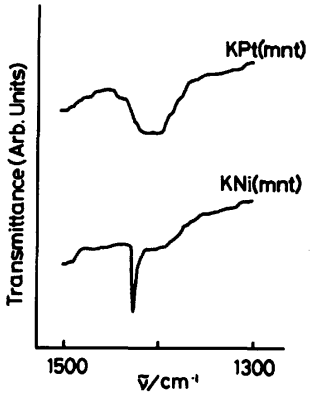

Fig. 4. The C=C stretching modes of KNi(mnt) (bottom curve) and KPt(mnt) (top curve). It can be pointed out that the C=C stretching modes around 1480 cm^{-1} which show the presence of the dianions are not observed for both complexes (see text).

the lower shift in frequency of the C=C bands in KPt(mnt) than in KNi(mnt) results from the differences in the electron distribution within the whole anion; the electron density on the ligand in KPt(mnt) is smaller than that in KNi(mnt). Secondly, the broadening or splitting of the C=C bands in KPt(mnt) reflects a lower symmetry around the anion than in KNi(mnt), which suggests the dimerization of the anion stack. Although the electron density and symmetry mentioned above are complicatedly related to each other, it is probable that both of these two factors more or less affect the C=C modes of both two metal complexes.

Thermal Properties and Crystal Water. No anomalies can be detected in thermal analyses by DSC for both complexes except irreversible heat anomalies corresponding to the loss of crystal water. The loss of crystal water occured slightly higher in temperature (80—160 °C) in both complexes compared with the cases of $Li_{0.8}(H_3O)_{0.3}[Pt(mnt)_2]\cdot 1.7H_2O$ (50—133 °C)[8] or KCP(Br) (30—110 °C).[31] However, close inspection of the stretching and bending motions of crystal water indicates that the ν_1 and ν_3 modes occur at rather high frequencies for a solid[32] and the ν_2 mode occurs at a low frequency, which suggests that there are only weak hydrogen bondings in both complexes, similar in KCP(Br)(ν_1 or ν_3=3490 cm^{-1}).[33]

General Discussion. The measured thermal activation energies from the conductivity for both complexes would indicate 'band gaps' which are ca. 0.7 eV for KNi(mnt) and 0.36 eV for KPt(mnt). The electronic spectra, on the other hand, shows that the lowest-energy bands have peaks at higher energies, 0.93 eV (7500 cm^{-1}) for KNi(mnt) and 0.94 eV (7600 cm^{-1}) for KPt(mnt). This discrepancy indicates that the simple band model is not appropriate for the conduction mechanism and a hopping mechanism must be taken into account, as proposed by Ahmad et al. in the cases of $Rb[Pt(mnt)_2]\cdot 2H_2O$[19] and other dithiolate complexes.[26] Moreover, similar behaviors have been reported for alkali TCNQ salts, such as K(TCNQ).[29]

At this point, we must consider the polycrystalline nature of the samples; in this case grain boundary effects are not negligible. However, although it cannot be a priori determined whether the observed activation energies from the conductivity measurements correspond to the true values for the single-crystal samples or activation energies for electron hopping through the grain boundary, the 'band gaps' estimated from the conductivity data are lower than those from the solid-state spectra. Hence, it is certain that true band gaps for conduction, if any, are lower than the electronic band gaps; we can conclude that a hopping model is appropriate for the conduction mechanism. In the case of the hopping mechanism, repulsive Coulomb interactions are important in

determining the conductivity behavior because the orbital for conduction is half-filled; the less Coulomb interactions lead to the higher conductivity.

On the basis of the hopping mechanism, we can understand the origin of the differences in the conductivity between KNi(mnt) and KPt(mnt). The IR spectra indicate a possibility that in KPt(mnt) the density of the unpaired electron on the ligand is lower than that of KNi(mnt). This possibility is also supported from the following consideration. In general, the metal d orbitals are raised in energy in the heavier transition metals, whereas the ligand-based orbitals are relatively unaffected. Although there is no detailed information about the mode of $[M(mnt)_2]^-$ stacking in both complexes, the structural similarities indicate that the ligand-dominant orbitals of both complexes are energetically equal. Following Schrauzer's MO scheme,[3,4,28] the HOMO of $[Ni(mnt)_2]^-$ monoanion salts is an antibonding combination of the ligand π and metal d_{xz} orbitals and the ligand π orbital associated with the HOMO lies energetically higher than the metal d orbital. The latter implies that the electron density is larger on the ligand (60%)[14] than on the metal. If one replaces Ni by a heavier atom Pt, the metal d orbitals rise in energy. As a result, one can expect larger mixing of the ligand π and metal d_{xz} orbitals compared with that in KNi(mnt), which leads lower density on the ligand in KPt(mnt). This lower density on the ligand of KPt(mnt) reduces the Coulomb interactions between anions, which facilitates higher conductivity. Although the differences in the electron distribution within the whole anion of both complexes may not be so large, this effect on the conduction arising from the hopping mechanism is possibly large.

In the above discussion, we have assumed that there is no contribution of structural difference between KNi(mnt) and KPt(mnt). In order to confirm whether or not above tentative explanation is true, further structural studies are necessary.

The authors wish to thank Professor Tsuyoshi Murao and Dr. Masako Tanaka of Kyoto University for their helpful discussions. Some measurements and calculations were carried out using the programs developed by Mr. Kazuya Suzuki and Mr. Naohilo Watanabe of Kyoto University.

We are indebted to Professor Tadamasa Shida and Dr. Tatsuhisa Kato of Kyoto University for the measurements of near-IR spectra; Dr. Eiichiro Nakayama of Research Center of Instrumental Analyses of Kyoto University offered an atomic absorption and flame emission spectrophotometer; Dr. Katsutoshi Tomita of Kyoto University offered a Weissenberg camera. We are grateful to Professor Allan E. Underhill for communicating their results on $M'[Ni(mnt)_2]\cdot H_2O$ (M'=Na, K, Rb, Cs, and NH_4) prior to publication.

Relations between Gas-Phase Stepwise and Bulk Solvation of Cl^- with Water and Aliphatic Alcohols

Kenzo HIRAOKA
Faculty of Engineering, Yamanashi University, Takeda-4, Kofu 400
(Received February 26, 1987)

Higher order clustering reactions of Cl^- with H_2O and ROH for ROH=CH_3OH, C_2H_5OH, and n-C_3H_7OH were measured in the gas phase with the pulsed electron-beam mass spectrometer. The general trend is found that the obtained $-\Delta H^\circ_{n-1,n}$ and $-\Delta S^\circ_{n-1,n}$ increase in the order $H_2O<CH_3OH<C_2H_5OH<n$-C_3H_7OH. This order is just the opposite to the free energies of solvation of Cl^-. This is due to the increasingly more unfavorable entropy changes for the solvation of Cl^- in the order $H_2O<CH_3OH<C_2H_5OH<n$-C_3H_7OH. This is clearly manifested on the increasing entropy changes $-\Delta S^\circ_{n-1,n}$ for the measured gas-phase clustering reactions for higher alcohols.

Cluster ions represent an aggregated state of matter, having properties midway between gaseous and condensed phase. Investigation into the formation and the properties of increasingly larger clusters offers a deep insight into the mode of the molecular interactions and a way of studying the molecular details of the course of change between gaseous and condensed phase.[1-4]

Equilibria for the ion-solvent molecule clustering reactions involving positive or negative ions can be measured in the gas phase. The van't Hoff plots of the equilibrium constants lead to the determination of thermochemical data $\Delta G°$, $\Delta H°$, and $\Delta S°$ for the stepwise addition of solvent molecules to the ion. In our laboratory, we have been making an effort to obtain some information which may bridge between gas and condensed phase by measuring the higher-order solvation reactions of ions in the gas phase. In our previous work,[5] we studied the stabilities and structures of cluster ions $X^-(M)_n$ for X^-=halide ions and M=protic solvents. In the present work, a study was made to extrapolate the thermochemical data obtained in the gas phase to those in the condensed phase. The obtained results give some insight for the elucidation of the ion solvation in the condensed phase.

Experimental

The measurements were made with a pulsed electron-beam mass spectrometer which has been described previously.[6,7] About 20—100 mTorr† of H_2O or aliphatic alcohols and 1 mTorr of electron capture agent CCl_4 were introduced into 2—3 Torr of CH_4 major (buffer) gas through stainless steel capillaries. The equilibrium constants were found to be independent on the change of solvent vapor pressure in the range 20—100 mTorr.

The equilibrium constants for the clustering reactions were obtained from the expression

$$K_{n-1,n} = \frac{I_n}{I_{n-1}} \cdot \frac{1}{P},$$

where I_n/I_{n-1} is the ratio of ion intensities of the clusters $Cl^-(ROH)_n$ and $Cl^-(ROH)_{n-1}$ in equilibrium and P is the sample pressure. The measurements of I_n/I_{n-1} were made using a mass spectrometer (ULVAC, MSQ-400) with a pulsed electron beam. Pulsing permits one to follow the kinetics of the approach to equilibrium. The enthalpy and entropy changes for each clustering reactions ($n-1$, n) are determined from van't Hoff plots based on the equation

$$\ln K_{n-1,n} = -\frac{\Delta H^\circ_{n-1,n}}{RT} + \frac{\Delta S^\circ_{n-1,n}}{R},$$

where the standard state is 1 atm.

Results

The enthalpy and entropy changes for the clustering reactions

$$Cl^-(H_2O)_{n-1} + H_2O = Cl^-(H_2O)_n, \quad (1)$$
$$Cl^-(CH_3OH)_{n-1} + CH_3OH = Cl^-(CH_3OH)_n, \quad (2)$$
$$Cl^-(C_2H_5OH)_{n-1} + C_2H_5OH = Cl^-(C_2H_5OH)_n, \quad (3)$$
$$Cl^-(n\text{-}C_3H_7OH)_{n-1} + n\text{-}C_3H_7OH = Cl^-(n\text{-}C_3H_7OH)_n. \quad (4)$$

obtained from the van't Hoff plots are summarized in Tables 1 and 2. The experimental errors for the $\Delta H^\circ_{n-1,n}$ and $\Delta S^\circ_{n-1,n}$ values are about ±0.5 kcal mol^{-1}†† and ±2 cal mol^{-1} K^{-1}, respectively. The obtained data are generally in good agreement with those obtained in other laboratories. The measurements for higher-order clustering reactions in the low temperature region were limited by the condensation of the sample vapor on the wall of the ion source. The values of $\Delta H^\circ_{n-1,n}$ and $\Delta S^\circ_{n-1,n}$ for Reactions 1—4 were measured down to temperatures just above the condensation of sample vapor.

Discussion

Referring to Table 1, the bond energies of $ROH\cdots Cl^-(-\Delta H^\circ_{0,1})$ increase in the order $H_2O<CH_3OH<C_2H_5OH<n$-C_3H_7OH. Interestingly, as shown in Table 3, the polarizabilities for H_2O, CH_3OH, C_2H_5OH, and n-C_3H_7OH follow the same order and the permanent dipole moments are just the opposite

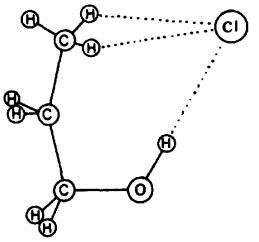
to the observed bond energies. Polarization must be one of the crucial factors in the determination of the bond energy of the cluster ROH···Cl$^-$. This may be due to the ability of the ligand to approach close to the ion, and thereby become more influenced by the ionic electric field with the attendant result of a larger induced dipole. Qualitatively, consideration of the polarizabilities partially explains the increased bonding strength of CH_3OH, C_2H_5OH, and n-C_3H_7OH over that of H_2O in clustering to the Cl^- ion.

It has been already pointed out that there is a good correlation between the gas-phase acidity and the bond energy ROH···Cl$^-$.[8,9] With increase of the

polarizability, the acidity of oxygen acid ROH increases, i.e., the decrease of the heterogeneous bond energy ROH→RO^-+H^+. The binding energy in ROH···Cl^- can be considered as a partial proton transfer, [RO···H···Cl]$^-$, in which the strength of the interaction increases with the acidity of ROH. This is an alternative explanation for the order of the bond strengths of ROH···Cl^-.

The bond energy of n-C_3H_7OH···Cl^- is larger than expected from its polarizability since it is appreciably larger than those of CH_3OH···Cl^- and C_2H_5OH···Cl^-. The strong bond may be explained by the head-and-tail interaction in n-C_3H_7OH···Cl^- as shown below.



Structure I

In such a configuration, acidic hydrogen atoms of -OH and $-CH_3$ can realize the most favorable interaction with Cl^- by adjusting the rotations around the C-O and two C-C bond axes. In the structure I, the C_3H_7OH ligand suffers a considerable restriction of internal rotations. This may explain the exceptionally large negative entropy change for Reaction 4 with n=1 (Table 2).

Castleman et al. measured the clustering reactions of Cl^- with H_2O and SO_2 in the gas phase. They found that the bond energy ($-\Delta H^\circ_{0,1}$) of Cl^-···SO_2 (21.8 kcal mol^{-1}) is much larger than that of Cl^-···H_2O (14.9 kcal mol^{-1}). However, the $-\Delta H^\circ_{n-1,n}$ values for SO_2 show a much a faster fall-off than those for H_2O with n and the cross-over of the values $-\Delta H^\circ_{n-1,n}$ was observed between n=3 and 4. A similar trend was also observed for the clustering reactions of alkali positive ions with H_2O and CH_3CN.[17] The bond energies $-\Delta H^\circ_{n-1,n}$ of $M^+(CH_3CN)_n$ for M=Na and Cs are considerably higher than those of $M^+(H_2O)_n$ for small n. However, much faster decrease of $\Delta H^\circ_{n-1,n}$ for the formers than those for the latters with n leads to the cross-over of $-\Delta H^\circ_{n-1,n}$ between n=4 and 5. Generally, the bond energies of the ionic clusters of aprotic solvents show faster decrease than those of protic solvents and the crossover of the bond energies are observed at relatively small n. Such a trend is not observed for the clusters $Cl^-(ROH)_n$ between ROH=H_2O and aliphatic alcohols (see Table 1). The ionic clusters of higher alcohols have increasingly stronger bonds compared to $Cl^-(H_2O)_n$ up to the largest n measured. This indicates that in the cluster $Cl^-(ROH)_n$, aliphatic alcohols in the inner shell maintain the stronger bonds with the core ion Cl^- at the expense of the more unfavorable entropy changes (see Table 2) than in the cluster $Cl^-(H_2O)_n$.

In Table 4, free energies (ΔG°_s), enthalpies (ΔH°_s), and entropies (ΔS°_s) of transfer of Cl^- from the gas phase into ROH solvents are summarized. These values are calculated from the free energies, enthalpies, and entropies of transfer of Cl^- from the gas phase into the aqueous solution[18] and those from the aqueous solution to CH_3OH, C_2H_5OH, and n-C_3H_7OH solvents.[19] The free energies of solution of Cl^- ($-\Delta G^\circ_s$) decrease in the order H_2O>CH_3OH>C_2H_5OH>n-C_3H_7OH, i.e., the solvating power of ROH solvents for Cl^- decreases in that order. Since the values of enthalpies of solution ($-\Delta H^\circ_s$) are more or less the same, the observed weaker solvating power for higher alcohols are mainly due to the increase of entropies of solution ($-\Delta S^\circ_s$). Interestingly, there is a similar trend in the gas phase clustering reactions as the case of entropies of solution, i.e., the greater $-\Delta S^\circ_{n-1,n}$ values for higher alcohols (see Table 2). It is evident that ligands of higher alcohols are highly immobilized in the inner shell of the clusters $Cl^-(ROH)_n$. The observed greater entropy changes $-\Delta S^\circ_{n-1,n}$ for the gas-phase clustering reactions may partly explain the more unfavorable entropies of solution for higher alcohols.

Recently Swain et al. have evaluated the anion and cation solvation components based on rate constants, product ratios, equilibrium constants, and electronic, IR, ESR, and NMR spectra.[25] They found that the solvating power for ion can be represented by the two factors, the acity (anion-solvating tendency) and the basity (cation-solvating tendency). It would be informative to compare the bond energy of single-molecule solvated Cl^-, D(ROH···Cl^-), with the acity which represents the solvating power of the bulk ROH solvent toward anions. Figure 1 shows the correlation between the bond energies D(ROH···Cl^-) and the solvent acity for H_2O, CH_3OH, C_2H_5OH, and n-C_3H_5OH. The solvent with larger value of acity is a better solvent for anion. As shown in Fig. 1, H_2O which is the best solvent for anion has the smallest bond energy D(HOH···Cl^-), and D(ROH···Cl^-) increases with decrease of solvent acity for higher

Table 4. Free Energies (ΔG°_s), Enthalpies (ΔH°_s), and Entropies (ΔS°_s) of Transfer of Cl^- from Gas Phase into Solvents

	$-\Delta G^\circ_s$ / kcal mol^{-1}	$-\Delta H^\circ_s$ / kcal mol^{-1}	$-\Delta S^\circ_s$ / cal mol^{-1} K^{-1}
H_2O	75.8	81.3	18.2

n-C_3H_7OH	69.6	79.2	32.1

alcohols. Since the enthalpies of solution of Cl^- are about the same for the four solvents (Table 4), the reverse order observed in Fig. 1 suggests that for solvents with larger acities, greater number of solvent molecules participate in the ion solvation and contribute to stabilize the anion in solution.

Some more detailed discussion on the stepwise solvation into the ultimate solvation may be given as follows.

In the interaction of ROH with Cl^-, the ROH molecule is polarized, $RO^{\delta-}$-$H^{\delta+}\cdots Cl^-$. For hard Brönsted acids, like H_2O and CH_3OH, the negative charge in the polarized ROH is mainly localized on the oxygen atom. The negatively polarized oxygen atom in ROH would enhance further hydrogen bonding with the ROH molecules in the outer solvation shell. This effect would extend from inner ligands to outer ligands in the shells surrounding the core ion and thus make the solvation energy ultimately large (enhancement effect).[4,20] When the size of alkyl group R gets larger, the ROH ligands in the inner shell of the cluster $Cl^-(ROH)_n$ bind more strongly due to their larger polarizabilities. However, the negative charge will be more delocalized in the rest parts of the acidic hydrogen atom, and the enhancement effect will become less effective than the case of harder ROH solvents. Such a cancellation may explain about the same enthalpies of solvation of Cl^- for H_2O, CH_3OH, C_2H_5OH, and n-C_3H_7OH.

In our previous paper,[3] gas-phase stepwise hydration and single-ion enthalpies and free energies of solution in water were studied. Here, the similar but some more detailed examination will be given. The stepwise solvation free energies $\Delta G^\circ_{n-1,n}$ and the free energies of solution ΔG°_s, or the stepwise solvation enthalpies $\Delta H^\circ_{n-1,n}$ and the enthalpies of solution ΔH°_s, or the stepwise solvation entropies $\Delta S^\circ_{n-1,n}$ and the entropies of solution ΔS°_s are related as[3,21,22]

$$\Delta G^\circ_s = \sum_{n=1}^{n=N} \Delta G^\circ_{n-1,n}(\text{ion(solvent)}_n) - \sum_{n=2}^{n=N} \Delta G^\circ_{n-1,n}(\text{solvent})_n \quad (5)$$

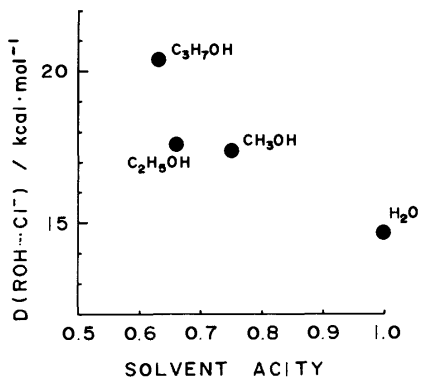

Fig. 1. Correlation between the bond energy D-(ROH···Cl^-) and the solvent acity.

$$\Delta H^\circ_s = \sum_{n=1}^{n=N} \Delta H^\circ_{n-1,n}(\text{ion(solvent)}_n) - \sum_{n=2}^{n=N} \Delta H^\circ_{n-1,n}(\text{solvent})_n, \quad (6)$$

$$\Delta S^\circ_s = \sum_{n=1}^{n=N} \Delta S^\circ_{n-1,n}(\text{ion(solvent)}_n) - \sum_{n=2}^{n=N} \Delta S^\circ_{n-1,n}(\text{solvent})_n. \quad (7)$$

The values of $\Delta G^\circ_{n-1,n}(\text{ion(solvent)}_n)$ and $\Delta G^\circ_{n-1,n}(\text{solvent})_n$, or $\Delta H^\circ_{n-1,n}(\text{ion(solvent)}_n)$ and $\Delta H^\circ_{n-1,n}(\text{solvent})_n$, or $\Delta S^\circ_{n-1,n}(\text{ion(solvent)}_n)$ and $\Delta S^\circ_{n-1,n}(\text{solvent})_n$ converge at $n=N$. In this section, relationships between $\Delta G^\circ_{0,n}$ and ΔG°_s, or $\Delta H^\circ_{0,n}$ and ΔH°_s, or $\Delta S^\circ_{0,n}$ and ΔS°_s are studied on the ground of Eqs. 5—7 with use of the presently available experimental $\Delta G^\circ_{n-1,n}$, $\Delta H^\circ_{n-1,n}$, and $\Delta S^\circ_{n-1,n}$ values.

Unfortunately not much thermochemical data are available for neutral solvent clusters. As a crude approximation, we assume that the enthalpy and entropy changes of stepwise Reaction 8

$$(H_2O)_{n-1} + H_2O = (H_2O)_n \quad (8)$$

are the same as that for $n=2$ for small n, $\Delta H^\circ_{1,2}(H_2O)_2$. In water, an H_2O molecule has four hydrogen bonds with neighboring H_2O molecules. Upon vaporization, each H_2O molecule dissociates these four hydrogen bonds. If one assumes that the strength of each hydrogen bond in water is the same as $-\Delta H^\circ_{1,2}(H_2O)_2$, the relation, $4\times\Delta H^\circ_{1,2}(H_2O)_2\times 1/2 = -\Delta H^\circ_{evap}$, holds. The factor 1/2 comes from the fact that two H_2O molecules participate in each hydrogen bond. Thus $\Delta H^\circ_{1,2}(H_2O)_2$ may be approximated to be $-1/2\Delta H^\circ_{evap}$. Similarly, the entropy change $\Delta S^\circ_{1,2}(H_2O)_2$ may also be approximated to be $-1/2\ \Delta S^\circ_{evap}$. The values of ΔH°_{evap}=10.5 kcal mol^{-1} and ΔS°_{evap}=35.2 cal mol^{-1} K^{-1} for water at the standard state lead to the approximated values $\Delta H^\circ_{1,2}(H_2O)_2$=−5.3 kcal mol^{-1} and $\Delta S^\circ_{1,2}(H_2O)_2$=−18 cal mol^{-1}K^{-1}.

For the clustering reactions of alcohols,

$$(ROH)_{n-1} + ROH = (ROH)_n, \quad (9)$$

$\Delta H^\circ_{n-1,n}(ROH)_n$ values are also assumed to be equal to $-1/2\Delta H_{evap}$. Since the standard state ΔS°_{evap} values are not available for alcohols, the $\Delta S^\circ_{n-1,n}(ROH)_n$ values are assumed to be the same as that of Reaction 8, i.e., −18 cal mol^{-1} K^{-1}.

Figures 2—5 show the n dependences of the right-hand side of Eqs. 5—7, $-[\Delta G^\circ_{0,n}(Cl^-(ROH)_n)-\Delta G^\circ_{0,n}(ROH)_n]$, (denoted as $-\Delta\Delta G^\circ_n$), $-[\Delta H^\circ_{0,n}(Cl^-(ROH)_n)-\Delta H^\circ_{0,n}(ROH)_n]$, (denoted as $-\Delta\Delta H^\circ_n$), and $-T[\Delta S^\circ_{0,n}(Cl^-(ROH)_n)-\Delta S^\circ_{0,n}(ROH)_n]$, (denoted as $-T\Delta\Delta S^\circ_{0,n}$) at T=298 K for ROH=H_2O, CH_3OH, C_2H_5OH, and n-C_3H_7OH. In these figures, the values of $-\Delta\Delta G^\circ_n$, $-\Delta\Delta H^\circ_n$, and $-T\Delta\Delta S^\circ_n$ with n=0 are taken as values of ΔG°_s, ΔH°_s, and $T\Delta S^\circ_s$, respectively. Since the values of the right-hand side of Eqs. 5—7 converge to ΔG°_s, ΔH°_s, and $T\Delta S^\circ_s$ with $n\to N$, all curves which start from the values ΔG°_s, ΔH°_s, and $T\Delta S^\circ_s$ at n=0

converge to the value 0 with an increase of n. Such a representation is useful because one can see how the stepwise solvation thermochemical data approach the ultimate values with an increase of n.

In Fig. 2, $-\Delta\Delta G_n^\circ$ and $-\Delta\Delta H_n^\circ$ converge to zero only very gradually. This suggests that a greater number of H_2O solvent molecules take part in the hydration of Cl^- in aqueous solution (enhancement effect). The small positive values of $-T\Delta\Delta S_n^\circ$ with n=1—7 suggest that H_2O ligands in the inner shell of $Cl^-(H_2O)_n$ are only slightly more immobilized than that of $(H_2O)_n$. The interaction of H_2O ligands with Cl^- does not

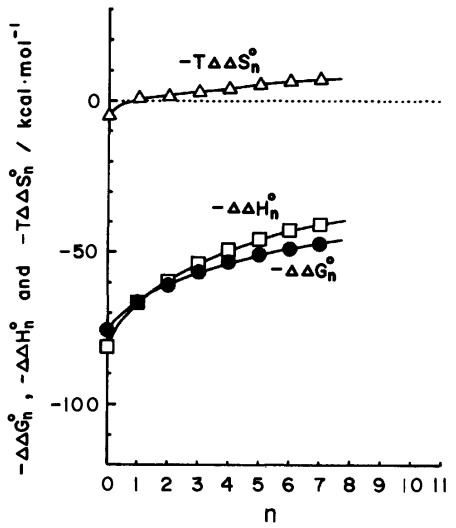

Fig. 2. The n dependence of the values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ (T=298 K) for reaction $Cl^-(H_2O)_{n-1}+H_2O=Cl^-(H_2O)_n$. The values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-\Delta\Delta S_n^\circ$, with n=0 are taken as those for the free energy of hydration, the enthalpy of hydration, and the entropy of hydration for Cl^-, respectively.

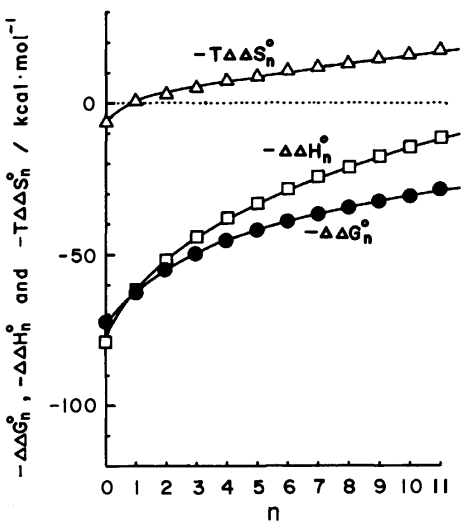

Fig. 3. The n dependence of the values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ (T=298 K) for reaction $Cl^-(CH_3OH)_{n-1}+CH_3OH=Cl^-(CH_3OH)_n$. The values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-\Delta\Delta S_n^\circ$ with n=0 are taken as those for the free energy of solution, the enthalpy of solution, and the entropy of solution for Cl^-, respectively.

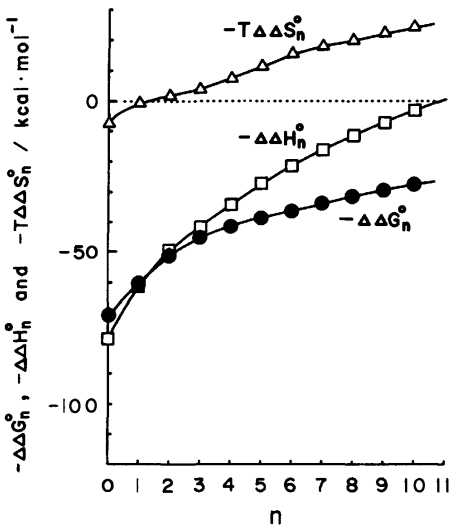

Fig. 4. The n dependence of the values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ (T=298 K) for reaction $Cl^-(C_2H_5OH)_{n-1}+C_2H_5OH=Cl^-(C_2H_5OH)_n$. The values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-\Delta\Delta S_n^\circ$ with n=0 are taken as those for the free energy of solution, the enthalpy of solution, and the entropy of solution for Cl^-, respectively.

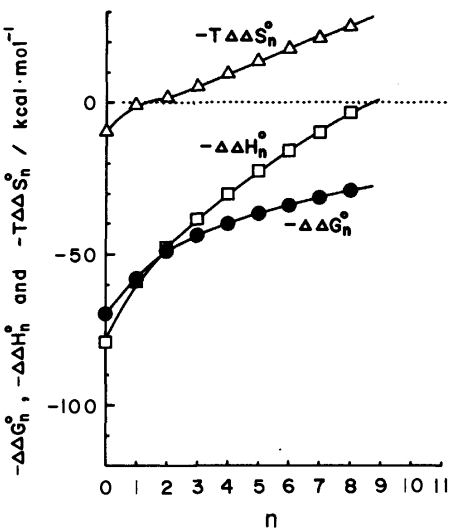

Fig. 5. The n dependence of the values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ (T=298 K) for reaction $Cl^-(C_3H_7OH)_{n-1}+C_3H_7OH=Cl^-(C_3H_7OH)_n$. The values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-\Delta\Delta S_n^\circ$ with n=0 are taken as those for the free energy of solution, the enthalpy of solution, and the entropy of solution for Cl^-, respectively.

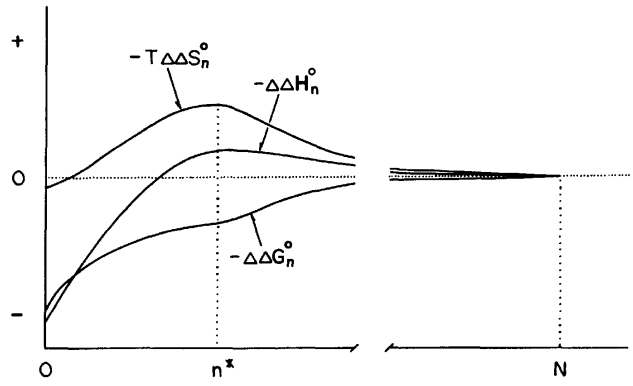

Fig. 6. Schematic representation of n-dependence of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ for n=0→N.

seem to induce a serious restriction of freedoms of motion. In fact, the libration motion of the H_2O molecule with a large amplitude in the cluster is suggested by a theoretical molecular orbital calculation.[23]

In Fig. 3, $-\Delta\Delta H_n^\circ$ and $-\Delta\Delta G_n^\circ$ deviate from each other progressively with an increase of n, and the deviation of $-T\Delta\Delta S_n^\circ$ from zero is larger than the case of H_2O. Such a tendency gets more prominent in the order $CH_3OH<C_2H_5OH<n$-C_3H_7OH as shown in Figs. 3—5. For n-C_3H_7OH, $-\Delta\Delta H_n^\circ$ seems to cross the ultimate value zero and become positive after n=8. The rapid increase of both of $-\Delta\Delta H_n^\circ$ and $-T\Delta\Delta S_n^\circ$ up to n=8 clearly indicates that strong bonds are formed between the Cl^- ion and the ligand molecules at the expense of the unfavorable entropy changes in the inner shell of the cluster ion $Cl^-(n\text{-}C_3H_7OH)_n$. Since all the values of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ converge to zero at n=N, the latter two must decrease at certain value of n=n^*. With this n^*, $\Delta H^\circ_{n-1,n}(\text{ion-(ROH)}_n)\approx\Delta H^\circ_{n-1,n}(\text{ROH})_n$ and $\Delta S^\circ_{n-1,n}(\text{ion(ROH)}_n)\approx\Delta S^\circ_{n-1,n}(\text{ROH})_n$. The decrease in $-\Delta\Delta H_n^\circ$ and $-T\Delta\Delta S_n^\circ$ may begin at the same time when the tight inner shells are completed and the loose outer shells start to be formed. Figure 6 shows the predicted conceptional idea of n-dependence of $-\Delta\Delta G_n^\circ$, $-\Delta\Delta H_n^\circ$, and $-T\Delta\Delta S_n^\circ$ for n=0→N. After the completion of the tight inner shells at n=n^*, the $-\Delta\Delta H_n^\circ$ and $-T\Delta\Delta S_n^\circ$ value start to decrease and the $-\Delta\Delta G_n^\circ$ value to increase more steeply at n^* where the outher shell formation begins. The values of n^* and N may increase in the order n-$C_3H_7OH<C_2H_5OH<CH_3OH<H_2O$ since the enhancement effect becomes more effective in that order. On the version of Frank and Wen,[24] the ligands with $n<n^*$ and $n>n^*$ may be regarded as those belonging to the structure making and structure breaking region, respectively.

Bis(dimethylsulfoxonium methylide)gold chloride, $[(CH_3)_2S(O)CH_2AuCH_2S(O)(CH_3)_2]Cl$, has been studied by X-ray photoelectron spectroscopy. The C 1s spectrum was separated into two peaks at E_B=284.0 and 285.1 eV in a ratio of 1:2. The peak at 285.1 eV corresponds to the methyl carbons, and that at 284.0 eV is assigned to the electron-rich methylene carbon (or carbanion). The E_B of Cl $2p_{3/2}$ agreed with that for chlorobis(triphenylphosphine)gold(I) and chlorobis(triphenylmethylenephosphorane)gold(I). The E_B of Au $4f_{7/2}$ was 84.4 eV, suggesting the oxidation number +1. These results indicate that the structure of the title complex is $(CH_3)_2S(O)CH_2Au(Cl)CH_2S(O)(CH_3)_2$, and different from that reported previously.

A previous paper[2] in this series reported an X-ray photoelectron spectroscopic study of methylenetriphenylphosphorane, $(C_6H_5)_3P{=}CH_2$, chlorobis(methylenetriphenylphosphorane)gold(I), $(C_6H_5)_3PCH_2Au(Cl)CH_2P(C_6H_5)_3$, and the corresponding copper(I) complex. However, the separation and assignment of the carbanion peak and the normal carbon peak for the bonded ylide in the complexes have been difficult, because the carbon ratio is 1:18. Only few XPS studies of ylide-metal complexes have been reported, and the separation and assignment of the carbanion and normal carbons remain uncertain. We surveyed ylides from the sulfonium, phosphonium, and arsonium ylides for XPS measurements, and found a dimethylsulfoxonium methylide to be suitable for the assignment, since the carbanion to the normal carbon ratio is 1:2. This paper deals with the XPS measurements and the structure of bis(dimethylsulfoxonium methylide)gold(I) chloride, $[(CH_3)_2S(O)CH_2AuCH_2S(O)(CH_3)_2]Cl$; the results are compared with those[2] from the chlorobis(methylenetriphenylphosphorane)gold(I) previously reported.

Experimental

Preparation of bis(dimethylsulfoxonium methylide)gold(I) chloride, $[(CH_3)_2S(O)CH_2]_2AuCl$ (**1**), was done as reported previously.[1] Sample handling was always carried out in a 99.9995% pure nitrogen atmosphere to prevent possible decomposition. The instrument was a VG ESCA 3 electron spectrometer.

For the XPS measurements, samples were placed on a nickel mesh holder and introduced into the spectrometer in a 99.9995% pure nitrogen atmosphere. After evacuating to a vacuum better than 2.7×10^{-5} Pa (2×10^{-7} Torr), the sample was cooled to 180—200 K, and irradiated with Mg $K\alpha$ X-ray (50—120 W). The analyzer energy was set to give a half width at half maximum [FWHM] of the Au $4f_{7/2}$ peak of 1.18 eV (high resolution) or 1.80 eV (low resolution) for vacuum evaporated gold on a smooth nickel plate. Peak separation of the spectra was made by the Gauss-Newton least-squares method, where a mixed Gaussian-Lorentzian curve shape was utilized. The electron binding energies, E_B, were calibrated by assigning 284.8 eV to the C 1s peak of the contamination from the spectrometer, 285.0 eV to the C 1s peak of the normal phenyl carbons, and 67.5 eV to the Br 3d peak of the bromide in $[(C_6H_5)_3PCH_3]Br$ and $[(C_6H_5)_3AsCH_3]Br$. This calibration is self-consistent (as shown in the results section).

Results and Discussion

We have reported[1] that dimethylsulfoxonium methylide, $(CH_3)_2S(O)CH_2$ (**L**),[3-5] in complex **1** was bonded to the metal atom through the carbanion donor atom[6-8] from the result of the ^1H NMR measurements. The elemental analysis of **1** and NMR results agreed with the proposed structure $(CH_3)_2S(O)CH_2Au(Cl)CH_2S(O)(CH_3)_2$ (**1a**) or $[(CH_3)_2S(O)CH_2{\cdot}AuCH_2S(O)(CH_3)_2]Cl$ (**1b**). Complex **1** has a free anion[1] judging from the molar conductance (Λ=100 S

Table 1. Binding Energies for Ylide Metal Complexes and Relative Compounds

	Compound	Binding energies of electrons, E_B/eV												
		C 1s			O	S	N	P	As	Cl	Br	Au	
		(a)	(b)	(c)	1s	2p	1s	2p	3d	$2p_{3/2}$	3d	$4f_{7/2}$	$4f_{5/2}$
1	$[(CH_3)_2S(O)CH_2]_2AuCl$	284.0 (±0.1)	285.1 (±0.2)	284.8[a]	531.5 (±0.6)	167.7 (±0.2)				197.7 (±0.5)		84.4 (±0.2)	88.1 (±0.1)
2	$[(CH_3)_3S{=}O]Br$		285.4 (±0.2)	284.8[a]	532.3 (±0.3)	168.4 (±0.4)					67.5[a]		
3	$[(C_6H_5)_3PCH_2]_2AuCl$	283.8	285.0[a]					132.4 (±0.4)		197.5 (±0.3)		84.9 (±0.3)	88.6 (±0.1)
	$[(C_6H_5)_3PCH_3]Br$		285.0[a]					132.6 (±0.4)			67.5[a]		
	$[(C_6H_5)_3AsCH_3]Br$		285.0[a]						44.4 (±0.3)		67.5[a]		
	$[(CH_3)_4N]Cl$		285.4[b]				402.3			197.1			

Uncertainties shown in parentheses are 90% confidence limits.
a) Reference peaks: E_B[Contamination C 1s]=284.8 eV, E_B[Phenyl C 1s]=285.0 eV, E_B[Br 3d]=67.5 eV. b) E_B of C 1s for methyl carbons was tentatively taken as 285.4 eV.

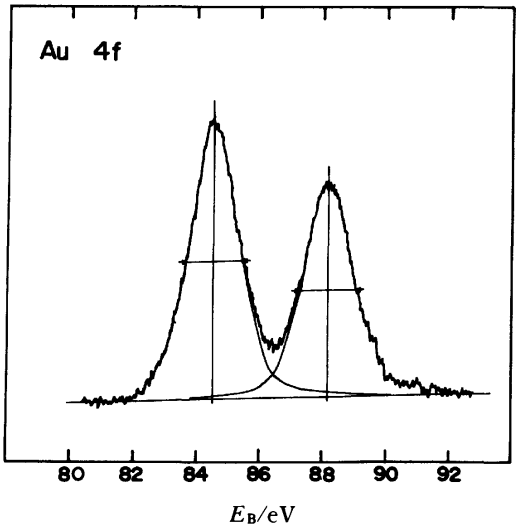

Fig. 2. The Au 4f spectrum of $(CH_3)_2S(O)CH_2Au(Cl)CH_2S(O)(CH_3)_2$ (this spectrum was measured together with the C 1s spectrum in Fig. 1).

$cm^2\ mol^{-1}$) in dry methanol. Thus, we suggested that the structure of **1** is $[(CH_3)_2S(O)CH_2AuCH_2S(O)(CH_3)_2]Cl$ (**1b**).[1]

With the XPS, the C 1s peak of **1** can be separated into three peaks having an intensity ratio of $1:x:2$ (Fig. 1). The peak separation was carried out under only two limiting conditions: One that the peak intensity ratio between methylene carbons, methyl carbons, and carbonaceous contamination from the spectrometer is $1:2:x$, and the other that the three peaks have the same FWHM. After the separation, the peak with an intensity x changed slightly in each measurement and could be assigned as a contamination carbon peak at 284.8±0.2 eV (with our instrument). The reproducibility of the E_B for carbonaceous contamination, when no other organic materials contaminate the sample surface, has been established by data accumulated over the 10-year operation of the instrument. The peak at 285.1 eV (C 1s (b) in Table 1) is assigned to methyl carbon and the peak at 284.0 eV to methylene carbon (C 1s (a)). The spectrum in Fig. 1 was taken in the high-resolution mode; the FWHM of the separated carbon peaks was 1.85 eV. The FWHM of the Au $4f_{7/2}$ peak for **1** taken under the same conditions was 1.81 eV (Fig. 2). Fig. 2 also indicates that there were no distortions of the spectra due to the charge-up effect. It should be noted that the symmetric peak shape for the contamination peak is a first approximation. Usually, the contamination peak shows a slight tailing at the higher E_B side: The degree of asymmetry is about 12:13 in a half width at half maximum. The asymmetric peak shape can be expressed by the superposition of a few symmetric peaks; but this introduces more parameters for the peak separation, leading to the arbitrary convergence in the calculation. The above approximation may not

Table 2. Relative Peak Intensities of XPS

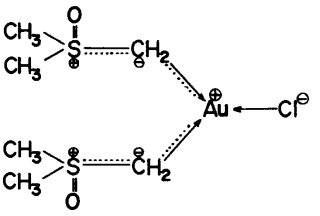
	Compound		Au 4f / S 2p	C 1s / S 2p (a)	C 1s / S 2p (b)	O 1s / S 2p	Cl 2p / S 2p	C 1s / Br 3d
1	$[(CH_3)_2S(O)CH_2]_2AuCl$	Atomic ratio	0.5	1	2	1	0.5	
		Intensity ratio	5.72 (±0.76)	0.78 (±0.03)	1.57 (±0.06)	2.25 (±0.20)	0.74 (±0.07)	
2	$[(CH_3)_3S{=}O]Br$	Atomic ratio			3	1		3
		Intensity ratio			2.23 (±0.28) [0.74]	2.24 (±0.62)		1.42 (±0.18) [0.47]
	$[(C_6H_5)_3PCH_3]Br$ / $[(C_6H_5)_3AsCH_3]Br$	Atomic ratio						19
		Intensity ratio						9.59[a] (±1.76) [0.50]

Uncertainties shown in parentheses are 90% confidence limits. Values in brackets are per one carbon atom.
a) The contributions from the contaminated carbons are not excluded.

lead to a serious error in the E_B values of the separated peaks. The validity of the peak separation is supported by the good reproducibility of the relative peak intensities, as shown in Table 2. Further, C 1s/S 2p and O 1s /S 2p relative intensities for **1** agree well with those for trimethylsulfoxonium bromide, $[(CH_3)_3S{=}O]Br$ (**2**), and C 1s/Br 3d relative intensity per carbon atom for **2** (0.47) agrees with the 0.50 for $[(C_6H_5)_3PCH_3]Br$ and $[(C_6H_5)_3AsCH_3]Br$ as well. In Table 2, the intensity due to the contaminated carbons is excluded by the peak separation, except for $[(C_6H_5)_3PCH_3]Br$ and $[(C_6H_5)_3AsCH_3]Br$. For these two compounds, the peak separation could not be performed precisely due to the large number of phenyl carbons. In this case, however, the contribution from the contaminated carbon is negligible compared with the intrinsic intensity. The results imply that the peak separation is correct and that the stability of **1** during the measurements was comparable to that of **2** and the others in Table 2. The E_B[S 2p] for **2** coincides with that for trimethylsulfoxonium iodide, $[(CH_3)_3S{=}O]I$, reported in Ref. 9.

The E_B value of the ylide methylene carbons for chlorobis(methylenetriphenylphosphorane)gold(I),[2] $(C_6H_5)_3PCH_2Au(Cl)CH_2P(C_6H_5)_3$ (**3**), was not very reliable (as mentioned in the introduction). The E_B value for the ylide methylene carbons in **3**, however, is very close to that of ylide methylene carbons in **1** (Table 1). The E_B of the ylide methylene carbon of **3** strongly suggests that the carbon is anionic (or possibly a carbanion).

The E_B[Au $4f_{7/2}$] for **1** is lower than that for **3** or chlorobis(triphenylphosphine)gold(I), $(C_6H_5)_3PAu(Cl)P(C_6H_5)_3$ (**4**),[2,10] but higher than that (E_B=84.2—84.4 eV) for tetraethylammonium dibromoaurate(I), $[(C_2H_5)_4N][Au(I)Br_2]$ (**5**),[10] which leads to the conclusion that the oxidation number of gold in **1** is +1. The E_B[Cl $2p_{3/2}$] for **1** agrees well with those for **3** and **4**,[2,10] and is higher than that for the unbound chloride ion in tetramethylammonium chloride, $[(CH_3)_4N]Cl$, and others.[11] The bond between the chlorine atom and gold atom in **4** has been established by X-ray diffraction.[12] Thus, the chlorine atom in **1** is bonding to the gold atom. Consequently, the structure of **1** must be similar to **3** and **4**, and the trigonal structure as shown in Scheme 1.



Scheme 1.

In the previous paper,[1] the structure of **1** was suggested to be bis(dimethylsulfoxonium methylide)-gold(I) chloride (**1b**) from the results of the electric conductivity (Λ=100 S cm^2 mol^{-1}) in dry methanol. Later, however, it was found that the compound **4** in which chlorine is bonding to gold[12] also shows the electric conductivity in dry methanol and it is 75 S cm^2 mol^{-1} (similar to the value for **1**). This indicates that the chlorine atom in **4** dissociates in the methanol, and so does the one in **1**.

Both E_B[O 1s] and E_B[S 2p] for **1** are lower than those for **2**, indicating that the density of electrons on the S=O group of **1** is higher than that for **2**. As E_B[Au $4f_{7/2}$] for **1** is lower than for **3**, the electrons on the ylide methylene carbons in **1** may be delocalizing over the molecular orbitals of O=S-C-Au-C-S=O as shown in Scheme 1.

Effect of Lattice Anions on the Ligand Substitution Reaction of Tris-(1,10-phenanthroline)metal(II) Complexes: $[M(phen)_3]SO_4$ and $[M(phen)_3]X_2$ (M: Fe(II), Co(II), Ni(II); X: Cl^-, Br^-, I^-)

(Received January 28, 1987)

The kinetics of the ligand substitution reaction of the title complexes in the solid state have been studied using thermogravimetry (TG) and differential scanning calorimeter (DSC) techniques. For these complex salts, an exothermic peak appears in the DSC curve which correlates with a ligand substitution in which anionatobis(1,10-phenanthroline)metal(II) complexes are formed. The heats of the exothermic reaction for ligand substitution of the sulfates decrease in the order Co(II)>Ni(II)>Fe(II). Isothermal and nonisothermal kinetic analyses were carried out using the exothermic peak. Activation energies of the ligand substitution for the same counterion generally increase with the metal in the order Co(II)<Ni(II)<Fe(II) and for the same metal, Ni(II) or Fe(II), increase with the counterion in the order Cl^-<Br^-<I^-<SO_4^{2-}. However, for the cobalt complex, the activation energies are almost identical for this series of counterions. From the trends in activation parameters for the ligand substitution, we propose a dissociative mechanism for the sulfates of all complexes studied and for the cobalt complex halides studied. For the halides of the iron(II) and nickel(II) complexes studied, a mechanism involving nucleophilic attack of the halide ions is important.

The ligand substitution reaction and the solvent exchange reaction of complex compounds in solution media have been studied by many workers.[1] However, only a few studies concerning such reactions in the solid phase have been done. One reason for this lack of effect is because it is difficult to estimate contributions from the lattice anions.

Counterions play an important role in reactions such as catalysis, due to their donicity. For example, the racemization of $[Ni(phen)_3]^{2+}$ is accelerated by the pairing of the complex ion with a counterion in water-*t*-BuOH. The rate increases in the order[2] ClO_4^-<I^-<Br^-<Cl^-. Moreover, we showed that since lattice anions in the solid state are in contact with the complex ion, the mechanism of the racemization could be determined by studying the effect of the donicity of lattice anions on the kinetic parameters.[3] We reported that such lattice anions affect the ligand substitution reaction in the solid state[4] as well as the racemization.

In this paper, the mechanism of the ligand substitution reaction of tris(1,10-phenanthroline) iron-(II), nickel(II), and cobalt(II) salts (chloride, bromide, iodide, and sulfate) is investigated from the point of view of the effect of lattice anions on the kinetic paramaters. By comparing kinetic information on the racemization mentioned above with that of ligand substitution, it was found that two types of mechanisms operate, depending on the donicity of the counterion, and M-N bond strengths.

Experimental

Materials. The complex salts, $[M(phen)_3]X_2 \cdot nH_2O$ (M: Fe(II), Co(II), Ni(II); X: Cl^-, Br^-, I^-; n=7 for chloride, 6 for bromide, and 2 for iodide) and $[M(phen)_3]SO_4 \cdot 10H_2O$, were prepared by the usual procedures.[4] The crude products were recrystallized three times from water, and dried in air. All the complexes were powdered by grinding with an agate mortar and pestle (200—270 mesh). Found: C, 53.26; H, 4.13; N, 10.36%. Calcd for $C_{36}H_{38}O_7N_6Cl_2Fe$: C, 54.49; H, 4.83; N, 10.59%. Kinetic Methods. Under linear heating conditions, the Reich-Stivala method[5] and the direct Arrhenius method were used. The Reich-Stivala method is based on the well-known expression involving mechanisms for homogeneous kinetics, i.e.

$$\ln [g(\alpha)T^{-2}] = -E_a R^{-1}T^{-1} + \ln[ARP(RH)^{-1}E_a^{-1}] \quad (1)$$

where, P=1−2X+6X^2−24X^3+120X^4−⋯; X=RT/E_a; (RH)= heating rate; α=fractional conversion; the symbols, T, R, A, E_a, have their usual meanings.[5] The following equation can readily be obtained from Eq. 1.

$$U(1) \ln [g(\alpha_1)g(\alpha_2)^{-1}T(1)] = E_a/R, \quad (2)$$

where $T(1)=(T_2/T_1)^2$; $U(1)=T_1T_2/(T_1-T_2)$. Data were fitted to Eq. 2 by interative calculations and the most probable function $g(\alpha)$ can be obtained when the minimum standard deviation of E_a/R is attained. The reaction rate $d\alpha/dt$ is given directly from differential scanning calorimeter (DSC) and thermogravimetric (TG) experiments.

Under isothermal conditions, the Arrhenius method was used. In this study, the conversion coefficient α corresponding to the concentration of the reactant in the liquid or gas phase, can be derived from the ratio of the area corresponding to heat evolved up to a certain heating time (t_1) to the integral area of the total reaction heat obtained by DSC (Fig. 1), or the mass lost up to a time (t_1), divided by the total mass loss, determined by TG analysis. More than 5 runs for each system were carried out, and the average and the standard deviation were calculated.

Measurements. DSC and TG measurements were performed using a Sinku-Riko Model ULBAC DSC-1500L and Sinku-Riko Model TGD-3000RHN instruments, respectively. The DSC instrument was calibrated[6] from the heat of fusion of indium (99.999%), mp 156 °C, ΔH(fusion)=3.26 kJ mol^{-1}. Dry nitrogen flowed through the system. The finely ground samples (200—270 mesh) were placed in an aluminium cell for the DSC measurement. The sample mass was varied until a linear relationship between mass and peak area or height was obtained. Table 1 presents the average activation energy obtained by more than 5 runs of the ligand substitution reaction at various heating rates. No significant change of the activation energy with different heating rates was appeared. In this study, a heating rate of less than 6 K min^{-1} was used throughout the experiment unless otherwise stated. Infrared spectra were obtained by the nujol method with a JASCO Model A-102 Infrared spectrometer.

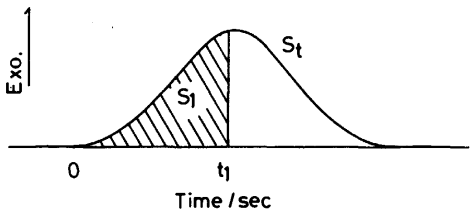

Fig. 1. Determination of reaction kinetics based on a part of the DSC curves. S_t: total area of this peak; S_1: the area evolved up to the heating time t_1. Conversion coefficient $\alpha_1=S_1/S_t$.

Results

Typical TG and DSC curves for $[M(phen)_3]SO_4 \cdot 10H_2O$ [M=Fe(II), Co(II), Ni(II)] are shown in Fig. 2. An exothermic peak is observed on the DSC curves and the TG curve shows that there is no loss of mass during this process. This is similar to the results already reported for the bromides of the iron and nickel complexes.[4] The heat of this exothermic reaction ($-\Delta H$) was determined from the area of the peak. The results obtained for the sulfates and the halides are given in Table 2, with the temperatures

a) T_p: The temperature at which the exothermal peak appears on the DSC curves.

(T_p) at which the exothermic peak appears. The $-\Delta H$ values for the sulfates decrease with the metal in the order Co(II)>Ni(II)>Fe(II), although the peak temperatures are almost equal for this series of metals. The amount of heat evolved at any time divided by the total heat corresponds to the degree of progress of the phen substitution for the complex salts except for the iodides of the iron and nickel complexes. The iodides undergo phen substitution at a temperature higher than 220 °C, which is the boiling point of 1,10-phenanthroline. 1,10-Phenanthroline molecules therefore evaporate rapidly out of the system as soon as they are released from the complexes.[4] The result is that the mass loss is related to the degree of progress of the phen substitution.

The sulfatobis(1,10-phenanthroline)metal(II) complexes, $[M(phen)_2SO_4]\cdot nH_2O$ [M=Fe(II), n=1; M=Co(II), n=0; M=Ni(II), n=0], were obtained as products of the ligand substitution by using the TG techniques for the sulfates. The Freeman-Carrol,[7] Coats-Redfern,[8] and Reich-Stivala[5] methods were applied to the data obtained from the ligand substitution observed here. Preliminary experiments showed that the Freeman-Carrol method involving the n order reaction gave unfavorable fits to the data curves. Analysis by the Coats-Redfern method or the Reich-Stivala method involving the function $g(\alpha)$ depending on processes controlling the reaction rates of solids, gave the best fits, using computer simulations. In this study, we employed the Reich-Stivala method as described above, due to its greater convenience. Avrami-Erofeyev functions based on the different nucleation and growth mechanisms[9] were selected to give the best possible fits of the substitution kinetic data for most of the complex salts, under linear heating conditions. However, the best fitting function could not be obtained only by the linear heating method because of a lack of significant differences in the relative errors obtained using the different functions (Table 3). Therefore the isothermal method was also applied and the best fitting function of a group of Avrami-Erofeyev functions was found. Figure 3 shows the degree of fitting for each function. A straight line is

expected to be obtained using the best function. The activation parameters obtained by the linear heating method and the isothermal method are in good agreement with each other, and the activation energy and enthalpy, E_a and ΔH^*, by the Reich-Stivala method are in good agreement with those by the Arrhenius method under linear heating conditions (Table 4). The kinetic parameters obtained are given in Table 5 with the functions which gave the best fits for the sulfates and halides of the complexes. The enthalpy and entropy of activation were calculated by the relationship: $E_a=\Delta H^*+2RT$, $\Delta S^*=R(\ln A-\ln(kT/h)-2)$ where the parameter, E_a and $\ln A$, were obtained by the Arrhenius equation and other parameters have their usual meanings.

The ΔH^* values for the same counterion increase with the metal in the order Co(II)<Ni(II)<Fe(II) for the bromides, iodides, and sulfates and for the chlorides, in the order Co(II)≃Ni(II)<Fe(II). For the same metal, the ΔH^* values increase with the counterion in the order $Cl^-<Br^-<I^-<SO_4^{2-}$ for the nickel and iron complexes while the values for the cobalt complexes are almost identical for this series of counterions.

Discussion

The ligand substitution reaction of $[M(II)(phen)_3]X_2$ in the solid state have been reported.[4] The scheme of the reaction is as follows.

$$[M(phen)_3]X_2(s) \longrightarrow [M(phen)_2X_2](s) + phen(g \text{ or } l),$$

where M is Fe or Ni, X^- is I^-, Br^-, or Cl^-, and s, l, and g indicate the solid, liquid, and gaseous states, respectively. A similar reaction occurs in the case of the sulfates of all the metal complexes studied and all the cobalt complex halides studied. The coordination of the SO_4^{2-} ion to the central metal ion was confirmed by IR measurements after heating under dynamic or constant temperature conditions. If the SO_4^{2-} ion is coordinated to a metal ion, the symmetry is lowered and splitting of degenerated vibrations occurs, together with the appearance of new bands in the IR spectrum, which correspond to Raman active

Fig. 4. Infrared spectra of sulfate ion for the complex salt, $[Fe(phen)_3]SO_4$. a: before heating; b: after dehydration; c: after exothermic reaction; d: product.

bands in the free ion.[11] These changes in SO stretching bands are observed when the sulfates are heated to the temperature where the exothermic DSC peak described above appears (Fig. 4).

It is interesting to note that the function based on nucleation and three- or one-dimensional growth, A_3 or F_1, respectively, gives best fits for the ligand substitution of most of the complex salts while for that of the nickel(II) or iron(II) complex iodides the D_2 or D_1 function based on two- or one-dimensional diffusion, respectively, is the best fitting function (Table 5). Many mathematical models have been advanced relating nucleation and nuclei growth rates to the kinetics of phase transformation and decomposition:[12] The solid-state reaction models have been based on the assumption that the nucleation of products at active sites and subsequent growth of the nuclei occurs. In the case where all the nuclei are initially present and the growth rate of the product phase is phase-boundary controlled, the three- and one-dimensional nuclei growth equations take the forms of A_3 and F_1, respectively. According to Laidler,[13] when a discontinuous product phase occurs, the rate-determining step may be the chemical process occurring at the phase boundary: The rate is controlled by the chemical reaction itself-that is, the breaking and re-forming of bonds at the interface. On the other hand, when material transport is the rate-controlling process (or the chemical reaction at the phase boundary is considerably faster than the transport process and thus the solid-state reaction is diffusion controlled), the functions, D_2 and D_1, ought to be applicable in two and one dimension(s), respectively.

The defect-diffusion mechanism proposed for solid-state reactions of coordination compounds by House[14] may be applicable to this diffusion process. If the reaction begins with the loss of a ligand from a complex ion in a lattice site, the ligand must be placed in an interstitial position in the lattice with the formation of a Frenkel type defect. Interstitial diffusion of Frenkel defects through the lattice is enhanced by a greater difference in size between cation and anion because the volume of free space is greater when the cations and anions are of greatly differing sizes. Thus, if the dissociation occurs, the diffusion of interstitial phenanthroline would be more difficult for the iodide owing to the smaller free volume: The expected difficulty should decrease in the order $SO_4^{2-}>I^->Br^->Cl^-$. On the other hand, Table 5 shows the same order of anion effects on activation energies for the phase-boundary controlled nuclei growth (A_3 and F_1: the chemical reaction itself), where the anion effects are attributed to the donicity of the lattice anions as discussed below. In the case of the iodides alone, the activation energy for the diffusion may be slightly larger than that for the chemical reaction and thus this leads to the ligand substitution through a diffusion controlling process for the iodides.

A dissociative mechanism has been proposed for ligand substitution of several transition metal complexes in solution.[15] If the dissociative mechanism is also operative in the solid state, the activation parameters, ΔH^* and ΔS^*, of ligand substitution should be independent of the donicity of lattice anions. This is demonstrated by the data on ΔH^* and ΔS^* for the cobalt complex salts (Table 5).

For the nickel and iron complexes, on the other hand, changes in the lattice anion were found to alter the activation parameters, indicating an interaction of the complex cations with the anions in the transition state. Moreover, the ΔH^* and ΔS^* values of ligand substitution for the iodide of the nickel complex, 197 ± 9 kJ mol^{-1} and 101 ± 12 J K^{-1} mol^{-1}, are almost equal to those of the solid-state racemization,[3] 203 ± 4 kJ mol^{-1} and 99 ± 8 J K^{-1} mol^{-1}, respectively (Table 5). This implies that the mechanism of ligand substitution should be the same as proposed in our previous paper for the solid-state racemization of the nickel complex.[3] The mechanism involves expansion of M-N bonds to a 7-coordinate transition state with one lattice anion. If so, the rate should be controlled by the donicity of the lattice anion in the same manner as the racemization rate. Table 5 shows that the ΔH^* values for the nickel and iron complexes decrease with the anion in the order $I^->Br^->Cl^-$. This sequence is the same as observed for the solid-state racemization of $[Ni(bpy)_3]X_2$[3] and $[Co(phen)_3]X_3$,[16] and lies in the order of increasing donicity of the anions.[17] Thus, the trend in ΔH^* is attributable to the ability of the anions to stabilize the transition state by donation. In such a mechanism, a metal-anion distance will shorten with lengthening of a M-N bond(s). The interaction of the anion with the metal leads to the stabilization of the transition state and thus to a lower energy of the activation for the ligand substitution. For the iron complex, we can note that the mechanism of ligand substitution discussed above is different from that of the solid-state racemization,[3] ΔH^* values for the racemization of all the iron complex halides are identical within experimental errors (174—178 kJ mol^{-1}), which can be explained by a twist mechanism.

Table 5 shows another interesting fact that the ΔH^* values for the sulfates of the nickel and iron complexes are larger than those for the corresponding iodides, respectively, despite the greater negative charge of the lattice anion, SO_4^{2-}, compared with the I^- ion. This indicates that the donicity of the SO_4^{2-} ion is lower than that of the I^- ion. Moreover, the ΔH^* and ΔS^* values of ligand substitution for the sulfate of the nickel complex, which are 219 ± 28 kJ mol^{-1} and 279 ± 33 J K^{-1} mol^{-1} ($\Delta H^*=254$ kJ mol^{-1} by Arrhenius method in Table 4), are comparable to those of the solid-state racemization for the corresponding per-

chlorate,[18] 268±36 kJ mol^{-1} and 240±20 J K^{-1}mol^{-1}, respectively (Table 5). It is reasonable to infer that the perchlorate racemizes in the solid state by a mechanism involving expansion of M-N bonds without donation of the ClO_4^- ion since the ion has negligible donor ability. The transition state for the phen substitution of the sulfate is assumed to be similar to that for the solid-state racemization of the perchlorate; thus a dissociative mechanism involving such an expansion of M-N bonds leading to bond breaking is most likely. Support for this is furnished by the relationship between E_a for ligand substitution in the solid state and the third stability constant, logK_3, for the following formation reaction in aqueous media:[19]

$$[M(phen)_2(H_2O)_2]^{2+}_{aq} + phen_{aq} \rightleftharpoons [M(phen)_3]^{2+}_{aq}$$

logK_3 can be taken as a measure of the strength of M-N bonds in the tris(1,10-phenanthroline)complexes.[20] If the rate determining step of the ligand substitution in the solid state is dominated by the ability to release a phen ligand, a linear relationship with a positive slope between E_a and log K_3 for these complexes would be expected. In fact, good linearity was obtained for the sulfates (Fig. 5). Furthermore, the logK_3 data show that the cobalt complex is less stable than the nickel and iron complexes and thus strength of the M-N bonds should be lower. This seems to be the reason for the change from an associative to a dissociative mechanism for the phen substitution of the cobalt complex salts.

The resultant exothermic heat of reaction for the ligand substitution of the complex salts in the solid state can be divided into two components. One is the release of one phen ligand molecule from the complex which is endothermic, and the other is the coordination of anions to the central metal which is exothermic. The heats of the exothermic reaction for the ligand substitution of the sulfates in the solid state also show a linear relationship with log K_3 (Fig. 5); the reaction heat decreases with increasing log K_3 (Table 5). This result implies that the release of phen is an important factor in lowering the reaction heat and the heat due to coordination of the SO_4^{2-} ion to all the metals is nearly identical, where there should be only an electrostatic effect. These results are consistent with the operation of a dissociative mechanism for the ligand substitution of the sulfates, suggesting negligible ability of the SO_4^{2-} ion to stabilize the transition state by donation.

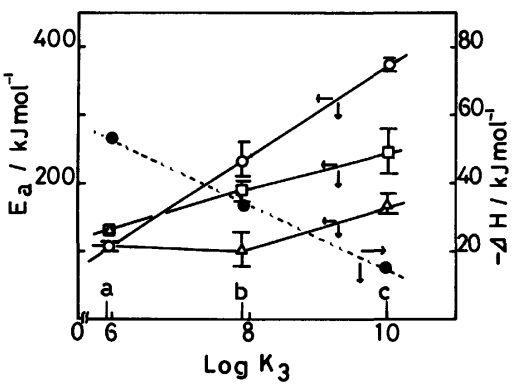

Fig. 5. Plots of activation energy (E_a: O, sulfate; Δ, chloride; □, bromide) and heat of reaction of ligand substitution ($-\Delta H$: ●, sulfate) vs. log of consecutive stability constant (log K_3) for the tris(1,10-phenanthroline)metal(II) complexes [a, cobalt(II); b, nickel(II); c, iron(II)].

In addition, the plots of E_a against logK_3 for the halides for the nickel and iron complexes show that the slopes for the chlorides and bromides are nearly half the slopes for the sulfates (Fig. 5). This result may suggest that expansion of two M-N bonds to the transition state is likely for the sulfates while for the bromides and chlorides, only one M-N bond expansion occurs, although the large, rigid, flat phenanthroline ligands seem to impose considerable steric constraints on one-ended phen dissociation.[3]

The heats of the exothermic reaction for the halides are smaller than those for the sulfate. This may be attributed to more difficulty of the migration of anions to the complex in the case of the halides compared to the sulfates since the process of substitution of one phenanthroline ligand in the solid state for the halides would require that two anions leave their lattice sites and enter the coordination sphere of the metal ion while for the sulfate only one lattice site is vacated. Although there is a good relationship between the activation energies for ligand substitution of the halides and the third stability constant, log K_3, no correlation of the reaction heats with log K_3 is observed for the halides. Factors such as covalency of M-X bonds in the products, crystal structures of the products, etc., other than strength of M-N bonds in the reactants, may be responsible for the differences in ΔH. Further research on other complexes and studies of crystal structures are required in order to understand this phenomenon. In addition, main differences in ΔS^* for the cobalt complex salts (Table 5) seem to arise from differences in the volume of free space in the lattice but at this time we have no clear explanation of the results and it is hoped that the studies of crystal structures will clarify the situation.

(Received January 29, 1987)

Three geometrical isomers (mer, u-fac, and s-fac) possible in each of $[Co(ida)(mdien)]^+$ and $[Co(mida)(mdien)]^+$ and u-fac isomer of $[Co(mida)(dien)]^+$ (ida=iminodiacetate, mida=*N*-methyliminodiacetate, mdien=3-methyl-3-azapentane-1,5-diamine, and dien=3-azapentane-1,5-diamine) were newly prepared, and the u-fac isomers were optically resolved. The geometrical structures of these isomers were assigned on the basis of their absorption and ^{13}C NMR spectral data. The crystal structure of $(+)^{CD}_{550}$-*u-fac*-$[Co(ida)(mdien)]\cdot(+)^{CD}_{575}$-$[Co(ox)_2(en)]\cdot 6H_2O$ was determined by X-ray diffraction method. The crystal is monoclinic, space group $P2_1$, a=15.793(6), b=12.855(3), c=7.070(2) Å, β=96.80(5)°, and Z=2. Both of the absolute configurations of the two complex ions take Λ configuration. The relationship between the absolute configurations and the CD spectral behaviors of the u-fac isomers is also discussed.

The mixed-ligand complexes of cobalt(III) with imino-diacetate (ida) or *N*-methyliminodiacetate (mida) and 3-azapentane-1,5-diamine (dien) or 3-methyl-3-azapentane-1,5-diamine (mdien) as the terdentate ligands can exist in three geometrical isomeric forms (mer, u-fac, and s-fac), as shown in Fig. 1. All of the three isomers have been first isolated for $[Co(ida)(dien)]^+$, while the mer and s-fac isomers except for u-fac have been isolated for $[Co(mida)(dien)]^+$.[1] The structures of these isomers were assigned based on their visible absorption and ^1H NMR spectra.[1] The u-fac isomer of $[Co(ida)(dien)]^+$, which has a chiral structure, was optically resolved by Yoshikawa et al., and the absolute configuration was assigned as ΛΔΛ for the $(-)_{589}$ isomer on the basis of the CD spectrum.[2] Koine et al. reported optical resolution of the mer isomer for $[Co(mida)(dien)]^+$.[3] Gailey et al.[4] and Kawamoto et al.[5] studied, respectively, the ^{13}C NMR spectra and the Raman spectra of the $[Co(ida)_n(dien)_{2-n}]$-type complexes.

Previously, we reported the methods to prepare all the geometrical isomers possible in $[Co(ida)_2]^-$,[6] $[Co(mida)_2]^-$,[7] $[Co(ida)(mida)]^-$,[6,8] $[Co(edma)_2]^+$,[9] $[Co(ida)(edma)]$,[10] and $[Co(mida)(edma)]$.[11] All the preparative reactions were performed under weakly acidic conditions.[6-11]

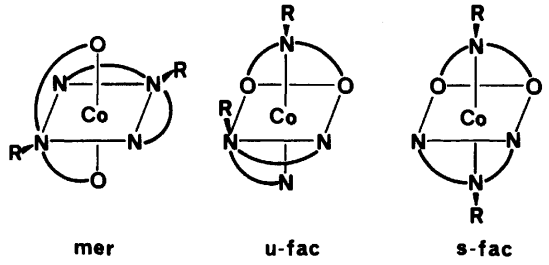

Fig. 1. Three geometrical isomers possible in $[Co(Rida)(Rdien)]^+$ (R=H or CH_3).

In the present paper, the preparations of the mixed-ligand type complexes, $[Co(ida)(mdien)]^+$ and $[Co(mida)(mdien)]^+$, will be described, and all the isomers isolated will be characterized on the basis of their absorption and ^{13}C NMR spectral data. In addition, we report the crystal structure of $(+)^{CD}_{550}$-*u-fac*-$[Co(ida)(mdien)]\cdot(+)^{CD}_{575}$-$[Co(ox)_2(en)]\cdot 6H_2O$ and will discuss on the relationship between the CD spectral behaviors of the u-fac isomers and the absolute configurations.

Experimental

Ligands. Iminodiacetic acid (H_2ida) and 3-azapentane-1,5-diamine (dien) were obtained commercially from Wako Pure Chemical Industries, Ltd. and used without further purification. *N*-Methyliminodiacetic acid[12] (H_2mida) and 3-methyl-3-azapentane-1,5-diamine trihydrochloride[13] (mdien·3HCl) were synthesized by the methods described in the literatures.

Preparation of Complexes. Three Isomers (mer, u-fac, and s-fac) of $[Co(mida)(mdien)]^+$: An aqueous solution containing 4.5 g (0.02 mol) of mdien·3HCl in 100 cm^3 of water was passed through a short Dowex 1×8 (OH^- form) column. The column was washed with ca. 100 cm^3 of water. Three grams (0.02 mol) of H_2mida and 4.8 g (0.02 mol) of $CoCl_2\cdot 6H_2O$ were added to the combined solution of eluate and washings, and the resulting solution was adjusted to pH 6 with 1 mol dm^{-3} NaOH solution. Lead dioxide (15 g, excess) was added into the solution with stirring. After stirring for 30 min at 50 °C, the solution was filtered to remove insoluble materials. The filtrate was poured onto an SP-Sephadex C-25 column (ϕ4.7 cm×50 cm, K^+ form). The adsorbed band, which was not eluted with water, was separated into two bands of purplish-red and orange colors by elution with 0.2 mol dm^{-3} KCl solution. The purplish-red band containing desired complexes was transferred into another SP-Sephadex C-25 column (ϕ4.7 cm×90 cm, K^+

form) and developed with the same eluent. The band separated into two bands of reddish-purple (first-eluted isomer: mer) and pinkish-red (a mixture of u-fac and s-fac isomers) colors. The reddish-purple band was eluted out. The pinkish-red band was transferred into another SP-Sephadex column (ϕ4.7 cm×90 cm, NH_4^+ form) and developed with 0.1 mol dm^{-3} $(NH_4)_2SO_4$ solution. The band easily separated into two bands of red (second-eluted isomer: s-fac) and purple (third-eluted isomer: u-fac) colors.

The reddish-purple eluate containing mer isomer was concentrated under reduced pressure and a large amount of methanol was added to the concentrated solution to eliminate potassium chloride. After methanolic solution was again concentrated, a crude complex was obtained by addition of methanol to the concentrated solution. The crude complex was recrystallized from a small amount of water by addition of a mixture (1:3) of methanol and ethanol. The crude crystals of the u-fac and s-fac isomers were also obtained as sulfate salts from the eluates of the red and purple bands, respectively, by the procedure similar to that described for the mer isomer above. By the use of a short QAE-Sephadex A-25 (Cl^- form) column, the sulfate salts of the u-fac and s-fac isomers were changed to the chloride salts, which were recrystallized from a small amount of water by addition of methanol. The formation molar ratio of the three isomers was mer:u-fac:s-fac=3:7:90. Found for the mer isomer: C, 30.44; H, 6.80; N, 14.31%. Calcd for [Co(mida)(mdien)]Cl·2H_2O=$C_{10}H_{26}N_4O_6ClCo$: C, 30.58; H, 6.67; N, 14.27%. Found for the u-fac isomer: C, 29.26; H, 6.84; N, 13.56%. Calcd for [Co(mida)(mdien)]Cl·3H_2O=$C_{10}H_{28}N_4O_7ClCo$: C, 29.24; H, 6.87; N, 13.64%. Found for the s-fac isomer: C, 31.30; H, 6.61; N, 14.75%. Calcd for [Co(mida)(mdien)]Cl·1.5H_2O=$C_{10}H_{25}N_4O_{5.5}ClCo$: C, 31.30; H, 6.57; N, 14.60%.

Three Isomers of [Co(ida)(mdien)]$^+$: The mer, u-fac, and s-fac isomers of this complex were obtained by the same method as that used for [Co(mida)(mdien)]Cl, except that the crystals of the u-fac isomer were obtained by converting the chloride salt to the bromide salt. The formation molar ratio was mer:u-fac:s-fac=4:42:54. Found for the mer isomer: C, 28.71; H, 6.33; N, 15.02%. Calcd for [Co(ida)(mdien)]Cl·2H_2O=$C_9H_{24}N_4O_6ClCo$: C, 28.54; H, 6.39; N, 14.79%. Found for the u-fac isomer: C, 26.52; H, 5.57; N, 13.78%. Calcd for [Co(ida)(mdien)]Br·H_2O=$C_9H_{22}N_4O_5BrCo$: C, 26.68; H, 5.47; N, 13.83%. Found for the s-fac isomer: C, 29.28; H, 6.28; N, 15.02%. Calcd for [Co(ida)(mdien)]Cl·1.5H_2O=$C_9H_{23}N_4O_{5.5}ClCo$: C, 29.24; H, 6.27; N, 15.16%.

Three Isomers of [Co(mida)(dien)]$^+$ and [Co(ida)(dien)]$^+$: Two isomers (mer and s-fac) of [Co(mida)(dien)]$^+$ and three isomers of [Co(ida)(dien)]$^+$ were already reported, but there is no report for the u-fac isomer of [Co(mida)(dien)]$^+$. In the present work all the three isomers of these complexes were obtained by the same method as that described above. The formation molar ratios were mer:u-fac:s-fac=23:18:59 for [Co(mida)(dien)]$^+$ and 24:46:30 for [Co(ida)(dien)]$^+$. Found for the newly prepared u-fac isomer: C, 29.34; H, 6.04; N, 15.03%. Calcd for [Co(mida)(dien)]Cl·1.5H_2O=$C_9H_{23}N_4O_{5.5}ClCo$: C, 29.24; H, 6.27; N, 15.16%. The chemical formulas of the other isomers were as follows: *mer*-[Co(mida)(dien)]Cl·1.5H_2O, *s-fac*-[Co(mida)(dien)]Cl, *mer*-[Co(ida)(dien)]Cl·H_2O, and *u-fac*- and *s-fac*-[Co(ida)(dien)]Cl·0.5H_2O.

Optical Resolution. The racemic u-fac isomers of the four complexes were optically resolved on an SP-Sephadex column using K_2Sb_2(*d*-tart)$_2$ aqueous solution as an eluent.

(+)$^{CD}_{564}$-*u-fac*-[Co(mida)(mdien)]Cl·3H_2O: A solution containing ca. 1.0 g of racemic *u-fac*-[Co(mida)(mdien)]Cl·3H_2O in a small amount of water was poured onto an SP-Sephadex C-25 column (ϕ4.7 cm×90 cm, K^+ form). The adsorbed band was developed with a 0.05 mol dm^{-3} K_2Sb_2(*d*-tart)$_2$ solution. After the band had been separated completely into two, each band was eluted out with a 0.1 mol dm^{-3} KCl solution. Each eluate was concentrated under reduced pressure and then ethanol was added to the concentrated solution. Potassium chloride which deposited out was removed by filtration and the filtrate was concentrated to a small volume. Ethanol was added to the concentrated solution and the ethanolic solution was kept in a refrigerator overnight. Violet crystals which deposited were collected by filtration and recrystallized from water by addition of ethanol. The (+)$^{CD}_{564}$ and (−)$^{CD}_{564}$ isomers were obtained from the front and rear eluates, respectively. Found for the (+)$^{CD}_{564}$ isomer: C, 29.37; H, 6.69; N, 13.64%. Calcd for [Co(mida)(mdien)]Cl·3H_2O=$C_{10}H_{28}N_4O_7ClCo$: C, 29.24; H, 6.87; N, 13.64%.

(+)$^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]Cl·1.5H_2O, (+)$^{CD}_{544}$-*u-fac*-[Co(mida)(dien)]Cl·0.5H_2O, and (+)$^{CD}_{538}$-*u-fac*-[Co(ida)(dien)]Cl·2H_2O: The racemates were also optically resolved in the same manner as that described for [Co(mida)(mdien)]$^+$. Found for the early eluted (+)$^{CD}_{550}$ isomer: C, 29.34; H, 6.25; N, 15.13%. Calcd for [Co(ida)(mdien)]Cl·1.5H_2O=$C_9H_{23}N_4O_{5.5}ClCo$: C, 29.24; H, 6.27; N, 15.16%. Found for the late eluted (+)$^{CD}_{544}$ isomer: C, 31.08; H, 6.05; N, 16.05%. Calcd for [Co(mida)(dien)]Cl·0.5H_2O=$C_9H_{21}N_4O_{4.5}ClCo$: C, 30.74; H, 6.02; N, 15.93%. Found for the late eluted (+)$^{CD}_{538}$ isomer: C, 26.59; H, 6.05; N, 15.49%. Calcd for [Co(ida)(dien)]Cl·2H_2O=$C_8H_{22}N_4O_6ClCo$: C, 26.35; H, 6.08; N, 15.36%. Previously, Okamoto et al. isolated this isomer as a monohydrate.[14]

X-Ray Analysis of (+)$^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]·(+)$^{CD}_{575}$-[Co(ox)$_2$(en)]·6H_2O. This diastereomer was prepared by adding methanol to the solution obtained by passing an aqueous solution of (+)$^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]Cl through a short QAE-Sephadex column of (+)$^{CD}_{575}$-[Co(ox)$_2$(en)]$^-$ form.

Unit cell parameters and intensity data for the single crystal (ca. 0.09×0.22×0.40 mm^3) were measured on a Rigakudenki four-circle diffractometer (AFC-5) with graphite-monochromatized Mo $K\alpha$ radiation. The unit cell parameters were determined by a least-squares refinement based on 25 reflections ($20<2\theta<30°$). Systematic absences led to the space group $P2_1$. Crystal Data: $Co_2C_{15}H_{40}N_6O_{18}$, M.W.=710.4, monoclinic, space group $P2_1$, a=15.793(6), b=12.855(3), c=7.070(2) Å, β=96.80(5)°, V=1425.3(8) Å^3, D_x=1.655 g cm^{-3}, D_m=1.66(1) g cm^{-3}, Z=2, and μ(Mo $K\alpha$)=1.303 mm^{-1}.

The intensity data were collected by the ω—2θ scan technique up to 2θ=60° with scan rate of 3° min^{-1}. The intensity data were converted to the Fo data in the usual manner. Absorption corrections were not applied. A total of 3864 independent reflections with $|F_o|>3\sigma(|F_o|)$ of the measured 4664 reflections were considered as 'observed' and used for the structure analysis.

The position of one cobalt atom was determined from a three-dimensional Patterson function. The difference-Fourier maps based on the cobalt position revealed the other cobalt position and then all non-hydrogen atoms. The structure was refined by a full-matrix least-squares refinement using the positional parameters, the anisotropic thermal parameters of the non-hydrogen atoms of the complex ions, and the isotropic thermal parameters of the non-hydrogen atoms of the water molecules (program RFINE by L. W. Finger[15] was used). The neutral atomic scattering factors for all the non-hydrogen atoms were taken from the literatures.[16,17] The final residual values were R=0.061 and R_w=0.066, respectively. We attempted to determine the absolute configurations of the complex ions by an anomalous-scattering technique. When the refinements were carried out by use of a set of the atomic parameters containing the Λ configuration of the complex ions (*Λ*- or *ΔΔΛ-u-fac*-[Co(ida)(mdien)]+ and *Λ*-[Co(ox)$_2$(en)]$^-$), the residual values converged to R=0.058 and R_w=0.059, respectively. On the contrary, the refinements in the enantiomeric atomic parameters (*Δ*- or *ΔΔΔ-u-fac*-[Co(ida)(mdien)]+ and *Δ*-[Co(ox)$_2$(en)]$^-$) resulted in the residual values of R=0.060 and R_w=0.062, respectively. These facts suggest that the former is probably the correct choice. This absolute configuration coincides with the result that $(+)^{CD}_{575}$-[Co(ox)$_2$(en)]$^-$, which was used as an internal reference, has been assigned to the Λ configuration based on the CD spectral behavior.[18]

The final positional parameters are listed in Table 1. A list of structure factors (Table A) and anisotropic thermal parameters of non-hydrogen atoms of the complex ions (Table B) are kept at the Chemical Society of Japan as Document No. 8745.

Measurements. The X-ray analysis calculations were carried out on a FACOM M-382 computer at the University of Tsukuba. The absorption and CD spectra were measured by a Hitachi 557-type spectrometer and a JASCO J-22 spectropolarimeter, respectively. The ^{13}C NMR spectra at 25 MHz were recorded on a JEOL JNM-FX 100 spectrometer. The peak positions were measured relative to internal dioxane (δ=67.40).

Results and Discussion

Formation Ratio of the Geometrical Isomers. In the previous studies concerning the reactivity of the [Co(ida)$_2$]$^-$ (and [Co(ida)(mida)]$^-$)[8] and [Co(mida)$_2$]$^-$[7] complexes, it was revealed that the mer isomer of the first complex easily isomerizes to u-fac and s-fac isomers in a basic aqueous solution and that the u-fac isomer of the third complex decomposes accompanying reduction of Co(III) to Co(II).

In the bis(terdentate) complexes, the formation ratio of the possible geometrical isomers varied largely with the stereochemistry of the chelate rings and reaction conditions (pH, temperature, etc.). The preparative reaction under basic conditions or using a catalyst such as activated carbon restricted the formation of less stable isomers.[1] As described in the Experimental section, however, the preparation of the present complexes under weakly acidic conditions provided all of the possible isomers. The formation ratios of the three isomers were mer:u-fac:s-fac=24:46:30 for [Co(ida)(dien)]+, 23:18:59 for [Co(mida)(dien)]+, 4:42:54 for [Co(ida)(mdien)]+, 3:7:90 for [Co(mida)-

a) $B_{eq}=8\pi^2(U_{12}+U_{22}+U_{33})/3$. b) Isotropic temperature factor.

(mdien)]+. When activated carbon was used as a catalyst,[1] the ratios for the first and second complexes (12:29:59 for [Co(ida)(dien)]+ and 20:0:80 for [Co(mida)(dien)]+) differ from the above ratios. These differences suggest that the formation ratios of the isomers depend not only on a thermodynamic factor but also largely on a kinetic factor. The small ratio of the u-fac isomer in [Co(mida)(mdien)]+ is surely attributed to a strong intramolecular repulsion between the coordinating mida and mdien ligands. However, the small ratios of the mer isomers in [Co(ida)(mdien)]+ and [Co(mida)(mdien)]+ can not be explained only by such the repulsion.

Geometrical Structure. Previously, the structures of three geometrical isomers of [Co(ida)(dien)]+ have been assigned on the basis of the visible absorption and ^{1}H NMR spectral data.[1] Figure 2 shows the absorption spectra of the mer, u-fac, and s-fac isomers of [Co(ida)(dien)]+ and the newly isolated isomers of [Co(mida)(mdien)]+, and their spectral data are summarized in Table 2, together with those of [Co(mida)(dien)]+ and [Co(ida)(mdien)]+.

For the four complexes, the geometrical isomers which were obtained in the same elution order on a column-chromatographic separation showed quite similar spectral behaviors to one another in the visible absorption region. Such spectral behaviors suggest that the isomers correspond to one another in geometry. All the first-eluted isomers exhibited the first bands with a shoulder (or broad band) in the shorter wavelength side (Fig. 2), which is generally observed for the *trans(O)*-[Co(N)$_4$(O)$_2$]-type complex.[19] This indicates that the structure of these isomers may be assigned to mer.

The structural assignments for the second- and third-eluted isomers of the new complexes can be made on the basis of their ^{13}C NMR data. Figure 3 shows a stick diagram of the ^{13}C resonance position for all the isomers. The most simple resonance patterns of the third-eluted isomers are due to two equivalent chelate rings in each of terdentate ligands and indicate that the third-eluted isomers take the s-fac structure having a mirror plane.

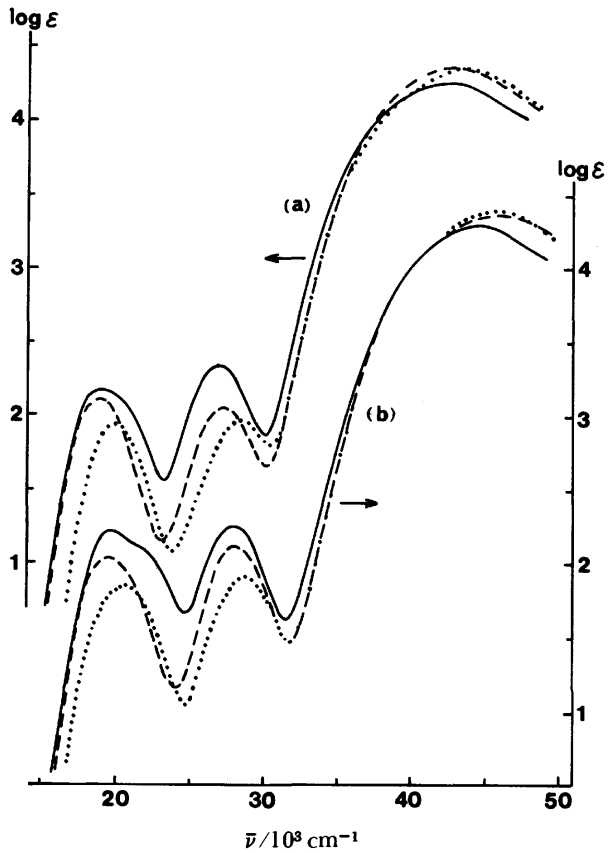

Fig. 2. Absorption spectra of the first-eluted (mer) ——, second-eluted (u-fac) ------, and third-eluted (s-fac) ····· isomers of (a) [Co(mida)(mdien)]+ and (b) [Co(ida)(dien)]+.

Table 2. Absorption Spectral Data of the [Co(L$_1$)(L$_2$)]+-Type Complexes

Complex	Structure	First band[a]	Second band[a]	CT band[a]
[Co(ida)(dien)]+	mer	19.65 (2.22)	27.93 (2.25)	44.25 (4.29)
		sh. 21.8 (2.08)

	u-fac	18.90 (2.11)	27.32 (2.06)	42.55 (4.35)
	s-fac	19.96 (1.95)	28.33 (1.98)	43.48 (4.34)

a) Wave numbers and log ε values (in parentheses) are given in 10^3 cm^{-1} and mol^{-1} dm^3 cm^{-1}, respectively. sh) Shoulder band.

The single peaks observed for the third-eluted isomers (s-fac), however, appear as doublet peaks in the second-eluted isomers except for the resonance peaks of methyl carbons. These doublet peaks for the second-eluted isomers indicate that the two chelate rings of each terdentate ligand are nonequivalent, as expected for the unsymmetrical (u-fac) structure. This structure was confirmed by X-ray crystal analysis (vide post).

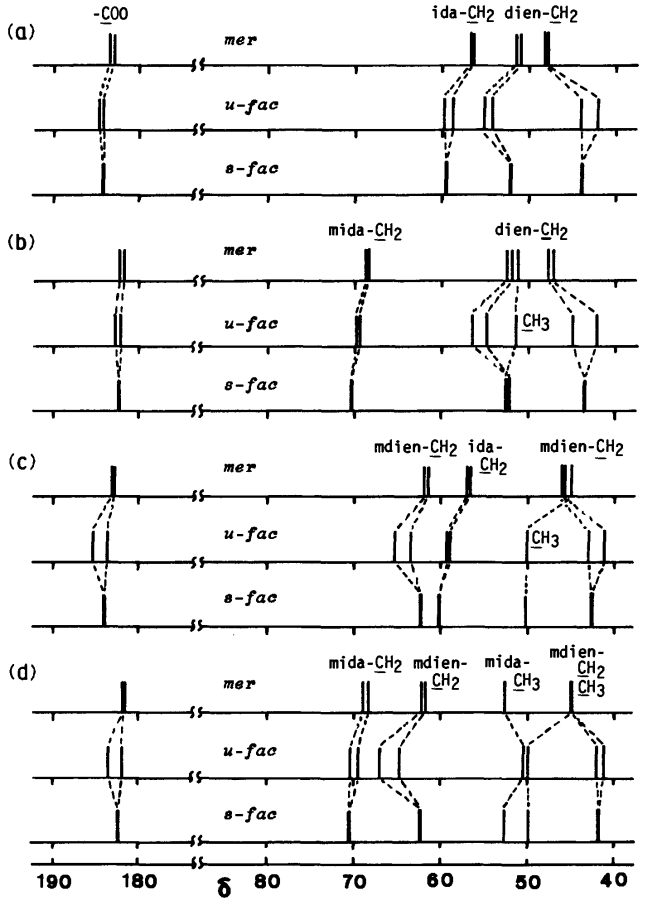

Fig. 3. ^{13}C NMR spectral patterns of the first-eluted (mer), second-eluted (u-fac), and third-eluted (s-fac) isomers of $[Co(L_1)(L_2)]^+$-type complexes: (a) [Co(ida)(dien)]+, (b) [Co(mida)(dien)]+, (c) [Co(ida)(mdien)]+, and (d) [Co(mida)(mdien)]+.

Crystal Structure of $(+)^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]·$(+)^{CD}_{575}$-[Co(ox)$_2$(en)]·6H$_2$O. Perspective drawings of the complex cation and anion obtained are given in Figs. 4 and 5 respectively, together with numbering scheme. The bond lengths and angles with their standard deviations are summarized in Table 3. In the complex cation (Fig. 4), the cobalt atom is surrounded octahedrally by two cis oxygen atoms and four nitrogen ones. Both of the ida and mdien ligands, which act as terdentate, take a facial form, and the tertiary amine, NA3, in the mdien ligand is located on the cis position of the nitrogen atom, NA1, in the ida one. As a result, the complex cation, [Co(ida)(mdien)]+, takes an unsymmetric facial configuration, u-fac. The absolute configuration of the complex anion, $(+)^{CD}_{575}$-[Co(ox)$_2$(en)]$^-$ (Fig. 5), was determined as Λ (see Experimental section) and this result confirms the suggestion made on the basis of the CD spectra.[18] Therefore, the absolute configuration of $(+)^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]+ can be assigned to ΛΔΛ (net Λ) configuration based on that of $(+)^{CD}_{575}$·*Λ*-[Co(ox)$_2$(en)]$^-$. This assignment for the $(+)^{CD}_{550}$ isomer coincides with that made by the ^1H NMR method using stereospecific deuteration.[20]

In the complex cation, the fused five-membered chelate rings in the ida and mdien ligands are not symmetrically equivalent. The ethylenediamine chelate ring in the mdien ligand, NA2-CA5-CA6-NA3, takes similar asymmetric gauche form with λ conformation (displacement from the NA2-CoA-NA3 plane: CA5=0.027 and CA6=0.640 Å) to those of *s-fac*- and *u-fac*-[Co(dien)$_2$]$^{3+}$.[21,22] The other chelate ring, NA3-CA8-CA9-NA4, takes the unusual form with λ conformation (displacement from the NA3-CoA-NA4

plane: CA8=−0.019 and CA9=0.599 Å) (Fig. 4). This conformation displacement seems to arise from the result that the NA3-NA4 chelate ring and the amine group, NA1, in the ida ligand repel each other. Similarly, the chelate ring, NA1-CA3-CA4-OA3, in the ida ligand takes an envelope form with λ conformation (displacement from the NA1-CoA-OA3 plane: CA3=−0.591 and CA4=−0.318 Å) similar to those of *u-fac*-$[Co(ida)_2]^-$.[23] While, the other chelate ring, OA1-CA1-CA2-NA1, takes nearly planar (displacement from the OA1-CoA-NA1 plane: CA1=−0.014 and CA2=0.097 Å). This planarity seems to depend on the steric repulsion between the OA1-NA1 chelate ring and the methyl group in the mdien ligand. In the complex anion, the ox ligands take similar conformation to those of $[Co(ox)_3]^{3-}$[24] and $[Co(ox)(en)_2]^+$.[25,26] The ethylenediamine takes a reasonable gauche form with δ(lel) conformation.[25-27]

The bond lengths and angles of the complex cation and anion are similar to those of the cobalt(III) complexes with the ida, dien, ox, and en ligands.[22-27] In the complex cation, the Co-N (tertiary) bond of 1.999(5) Å in the mdien ligand is considerably longer than the Co-N (terminal) bond of 1.943(6) Å, and this difference is more remarkable than those in the *u-fac*-$[Co(dien)_2]^{3+}$ [Co-N (secondary) 1.971 and Co-N (terminal) 1.961 Å].[22] The Co-N bond, 1.983(5) Å, in the ida ligand is longer than those of *u-fac*-$[Co(ida)_2]^-$ [1.946(4) and 1.936(4) Å].[23] These results seem to depend mainly on the arrangement of the terdentate ligands around the cobalt atom.

Absolute Configuration and CD Spectra of the u-fac Isomers. The CD spectral curves of the u-fac isomers in this work are shown in Fig. 6 and their CD data are summarized in Table 4. All the optically active u-fac isomers isolated from the later eluates on the column chromatographic resolution show similar CD patterns to one another in the first absorption band region. Since the absolute configuration of $(+)^{CD}_{550}$-*u-fac*-$[Co(ida)(mdien)]^+$ is ΛΔΛ (net Λ), we assign the remaining three u-fac isomers, which show the same

Table 4. CD Spectral Data of the $[Co(L_1)(L_2)]^+$-Type Complexes

CD pattern as that of $(+)^{CD}_{550}$-*u-fac*-[Co(ida)(mdien)]+, to be the ΛΔΛ configuration.

For the cobalt(III) complexes with bidentate ligands such as ethylenediamine, glycinate, oxalate, and so on, their CD spectral patterns in the first absorption band region have successfully been related with their absolute configurations.[28] However, the CD spectral behaviors of the cobalt(III) complexes with linear terdentate-*N,N,N*, -*N,N,O*, and -*O,N,O* ligands differ significantly from those of the cobalt(III) complexes with the bidentate one. In other words, the cobalt(III) complexes with the terdentate ligands, which take the same absolute configuration (for example, ΛΔΛ in this case), exhibit similar CD pattern in the first absorption band region, in spite of a difference in the type of chromophore. For example, $(+)_{589}$-*u-fac*-[Co(dien)$_2$]$^{3+}$ ([Co(N)$_6$]),[22] $(+)^{CD}_{514}$-*fac*(N_t)*cis*(N_c)- and $(+)^{CD}_{527}$-*mer*(N_t)*cis*(N_c)-[Co(edma)(dien)]$^{2+}$ ([Co(N)$_5$(O)]),[29] $(+)^{CD}_{543}$-*trans*(*O*)- and $(+)^{CD}_{534}$-*C*$_1$-*cis*(*O*)-[Co(edma)$_2$]$^+$ ([Co(N)$_4$(O)$_2$]),[9] $(+)^{CD}_{572}$-*mer*(*O*)*cis*(N_c)- and $(+)^{CD}_{565}$-*fac*(*O*)-[Co(ida)(edma)] ([Co(N)$_3$(O)$_3$]),[11] and $(-)_{546}$-*u-fac*-[Co(ida)$_2$]$^-$ ([Co(N)$_2$(O)$_4$]),[2,30] which have been determined to be the ΛΔΛ configuration, exhibited in common a positive and a negative CD bands from the lower energy in the first absorption band region, as in the case of the present ΛΔΛ-u-fac isomers. These facts suggest that the empirical treatment[28] applied favorably for the cobalt(III) complexes with the bidentate ligands can not be directly applied for those with the terdentate ones. In order to discuss these CD spectral behaviors, however, more data will be needed.

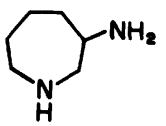
(Received February 9, 1987)

Orange-red copper(II) complexes of (*RS*)-3-aminohexahydroazepine (=*RS*-ahaz), Cu(*RS*-ahaz)$_2X_2\cdot nH_2O$ (X^-=ClO_4^-, BF_4^-, NO_3^-, Br^-, I^-) were prepared, and the molecular structures of complex **1** (X^-=ClO_4^-; n=0) and complex **2** (X^-=Br^-; n=2) were determined by the single-crystal X-ray diffraction method. The complex **1** has centrosymmetry, and the complex cation in **1** involves a pair of *R*- and *S*-ahaz (*R*- and *S*-ahaz refer to (*R*)- and (*S*)-3-aminohexahydroazepine) and takes a strict four-coordination geometry, so that **1** is formulated as [Cu(*R*-ahaz)(*S*-ahaz)]$(ClO_4)_2$. The complex cation in **2** resembles closely that of **1**, and **2** can be represented as [Cu(*R*-ahaz)(*S*-ahaz)]$Br_2\cdot 2H_2O$. The other orange-red complexes of *RS*-ahaz (X^-=BF_4^-, NO_3^-, I^-) were concluded to take similar strict four-coordinated structures. Blue-violet hetero-anion complexes Cu(*RS*-ahaz)$_2$X(ClO_4) were obtained from complex **1** and LiX (X^-=Cl^-, Br^-). The crystal structure determination of Cu(*RS*-ahaz)$_2$Br(ClO_4) (=complex **3**) revealed that **3** involves a pair of enantiomeric five-coordinated cations, $[CuBr(R\text{-ahaz})_2]^+$ and $[CuBr(S\text{-ahaz})_2]^+$, in the single crystal, whereby the ligand exchange which proceeds during the transformation from **1** to **3** is indicated.

3-Aminohexahydroazepine abbreviated as ahaz is a unique chiral 1,2-diamine having C- and N-substituents which are connected to form a seven-membered monoazaheterocycle. The R- and S-enantiomers and racemic form will be indicated hereafter by *R*-ahaz, *S*-ahaz, and *RS*-ahaz, respectively.



ahaz

In a previous paper we demonstrated through the X-ray crystallographic structure determination of a copper(II) complex of *S*-ahaz, [CuBr(*S*-ahaz)$_2$]ClO_4, that ahaz functions as a bidentate ligand, and that its ring carbon chain directs nearly perpendicular to the five-membered chelate ring as illustrated in Fig. 1 (I) (X^-=Br^-).[1] Evidently, the ring carbon chain of S-ahaz hangs over the central metal ion and blocks effectively the sixth coordination site from the access of a further ligand to maintain the square-pyramidal geometry of (I).

We noticed, further, that the copper(II) complex prepared from $Cu(ClO_4)_2$ and *RS*-ahaz was orange-red, while the corresponding complex with the single enantiomer (*S*-ahaz) was violet.[1] The latter was supposed to take a four-coordinated geometry such as

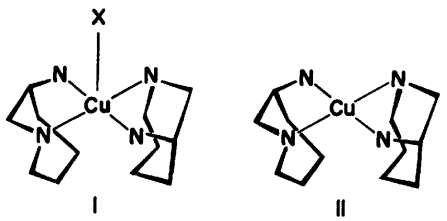


Fig. 1. Stereochemistries of copper(II) complexes of *S*-ahaz; five-coordinated $[CuX(S\text{-ahaz})_2]^+$ ion, (I) and four-coordinated $[Cu(S\text{-ahaz})_2]^{2+}$ ion, (II).

Fig. 1 (II),[1] but the structure of the former remained unsolved. To our surprise, the copper(II) complexes of *RS*-ahaz with certain anions other than perchlorate are thoroughly orange-red, which is rather exceptional color for bis(diamine)copper(II) complexes.[2] The coexistence of both *R*- and *S*-ahaz seems to be necessary to give these orange-red complexes, because no copper(II) complex of *S*-ahaz exhibits reddish color.[1] With a view to elucidate the common structural features of orange-red *RS*-ahaz copper(II) complexes, the crystal structures of Cu(*RS*-ahaz)$_2$-$(ClO_4)_2$[3] (**1**) and Cu(*RS*-ahaz)$_2Br_2\cdot 2H_2O$ (**2**) were determined by the X-ray diffraction method. This paper describes the structural characteristics of complexes **1** and **2** and other *RS*-ahaz complexes, Cu(*RS*-ahaz)$_2X_2$.

In addition we isolated the hetero-anion complexes[4] of *RS*-ahaz having the formula Cu(*RS*-ahaz)$_2$X(ClO$_4$)[3] (X$^-$=Cl$^-$, Br$^-$) from complex **1** and LiX. The crystal structure determination of Cu(*RS*-ahaz)$_2$Br(ClO$_4$) (complex **3**) revealed that a pair of enantiomeric five-coordinated cations, [CuBr(*R*-ahaz)$_2$]$^+$ and [CuBr(*S*-ahaz)$_2$]$^+$, are involved in the single crystal and suggested a possibility of interesting ligand exchange during the conversion of **1** into **3**. Besides the stereochmical features of complex **3**, the pathway for formation of five-coordinated **3** from four-coordinated **1** in solution will be discussed in the present paper.

Experimental

Measurements. Spectroscopic and electric conductivity data were obtained in the same way as in the previous paper.[1]

(*RS*)-3-Aminohexahydroazepine (*RS*-ahaz). This was obtained by the same procedure for preparing *S*-ahaz,[1] except the use of (*RS*)-3-aminohexahydro-2-azepinone hydrochloride in place of the *S*-enantiomer. The product was purified by distillation. Bp, 92—94 °C 27 mmHg (1 mmHg=133.322 Pa).

Preparation of Cu(*RS*-ahaz)$_2$X$_2$·*n*H$_2$O (*n*=0 for X$^-$=ClO$_4^-$, NO$_3^-$, BF$_4^-$, and I$^-$; *n*=2 for X$^-$=Br$^-$). The complexes (X$^-$=ClO$_4^-$, NO$_3^-$, or Br$^-$) were obtained from CuX$_2$·*n*H$_2$O and *RS*-ahaz in the same way for preparing the corresponding *S*-ahaz complexes.[1] Cu(*RS*-ahaz)$_2$(BF$_4$)$_2$ was prepared by using 45% aqueous solution of Cu(BF$_4$)$_2$ in a similar method of obtaining Cu(*S*-ahaz)$_2$(BF$_4$)$_2$.[1] Cu(*RS*-ahaz)$_2$I$_2$ was obtained by adding a methanol solution of LiI to an aqueous methanol solution of Cu(*RS*-ahaz)$_2$(ClO$_4$)$_2$. Found (complex **1**; X$^-$=ClO$_4^-$): C, 29.05; H, 5.60; N, 11.40. Calcd for $C_{12}H_{28}Cl_2CuN_4O_8$: C, 29.36; H, 5.75, N, 11.42%. Found (complex **2**; X$^-$=Br$^-$): C, 29.68; H, 6.56; N, 11.55. Calcd for $C_{12}H_{32}Br_2CuN_4O_2$: C, 29.54; H, 6.63; N, 11.49%. Found (X$^-$=NO$_3^-$): C, 34.59; H, 6.74; N, 20.16. Calcd for $C_{12}H_{28}CuN_6O_6$: C, 34.65; H, 6.78, N, 20.21%. Found (X$^-$=BF$_4^-$): C, 31.21; H, 6.04; N, 11.69. Calcd for $C_{12}H_{28}B_2CuF_8N_4$: C, 30.96; H, 6.06; N, 12.04%. Found (X$^-$=I$^-$): C, 26.22; H, 5.22; N, 10.47. Calcd for $C_{12}H_{28}CuI_2N_4$: C, 26.28; H, 5.14; N, 10.24%.

Table 1 summarizes the spectral and conductivity data of copper(II) complexes prepared in this study.

Preparation of Cu(*RS*-ahaz)$_2$X(ClO$_4$) (X$^-$=Cl$^-$, Br$^-$). Complex **1** (0.93 g, 2 mmol) was dissolved in hot aqueous methanol (methanol-water=4:1) and mixed with a methanol solution of LiX (3 mmol). The crystals which appeared were collected, washed with ethanol and diethyl ether, and air-dried. The crude product was recrystallized from aqueous methanol containing LiX. The bromo complex **3** (X$^-$=Br$^-$) was also obtained by adding a slight excess of LiClO$_4$ to a solution of complex **2**. Found (X$^-$=Cl$^-$): C, 33.44; H, 6.60; N, 12.77%. Calcd for $C_{12}H_{28}Cl_2CuN_4O_4$: C, 33.77; H, 6.61, N, 13.13%. Found (X$^-$=Br$^-$): C, 30.49; H, 5.85; N, 11.77%. Calcd for $C_{12}H_{28}BrClCuN_4O_4$: C, 30.58; H, 5.99; N, 11.89%.

X-Ray Diffraction. Diffraction data for the orange-red complexes **1** and **2** and blue-violet complex **3** were collected on a Rigaku AFC-5 four-circle diffractometer with graphite-monochromatized Mo *K*α radiation (λ=0.71073 Å) at 296 K. Details of crystal data and experimental conditions are listed in Table 2. Intensity data were collected by ω and ω—2θ (2θ>30°) scan mode and at scan rate, 4.0° min^{-1}. For each of the complexes, the intensities of three standard reflections

were measured after every 150 reflections, but they showed no appreciable changes. The intensities were corrected for Lorentz and polarization factors, but not for absorption.

Structure Analysis. Atomic scattering factors are taken from International Table for X-ray Crystallography.[5] All structures were refined by a block diagonal least-squares procedure based on $|F_o|$ including H atoms. Unit weight was used for all reflections. H atom coordinates were obtained by calculation. All non-hydrogen atoms are anisotropic and H atoms isotropic. The crystallographic calculations were performed on a FACOM M-380 computer of The Institute of Physical and Chemical Research using UNICS III program system.[6] The maximum heights in the final difference Fourier maps were 1.2, 1.5, and 0.9 e/Å^3 near

the heavy atoms for **1**, **2**, and **3**, respectively. The atomic coordinates for complexes **1**, **2**, and **3** are listed in Tables 3, 4, and 5.[7]

Complex **1**: Since Z is 2 in space group $P2_1/a$, Cu atom is at the origin. Thus, the structure was solved by the heavy atom method. The R index gave 0.054.

Complex **2**: Two space groups *Iba*2 and *Ibam* are possible from the systematic extinction. Independent structure analyses were attempted for both space groups using MULTAN 78 program.[8] The satisfactory solution was obtained only for *Iba*2. During the refinement, however, Br(2) was found to be disordered in two positions with equal population. Then, a half atomic multiplicity was given to these positions. The final R index gave 0.10.

Complex **3**: Two space groups $Pna2_1$ and *Pnam* are possible from the systematic extinction. Independent structure analyses were attempted for both space groups using MULTAN 78. It was found that all three heavy atoms, Cu, Br, and Cl, are happened to be on the ab plane, and the mirror symmetry appeared in both cases. However, the structure could not be refined for space group *Pnam*. After several trials, the structure was solved by assuming the space group $Pna2_1$ and carefully eliminating the ghost atoms due to the pseudo mirror operation.[6] The structure was refined to R=0.11. However, oxygen atoms of perchlorate and some of the carbon atoms in the ligands were disordered. Therefore, at the last stage the ligand was refined by using the molecular mechanical calculation (MM2 program described by Allinger[10]). The final R factor constrained by MM2 was 0.151.

Results

Preparation of Orange-Red Homo-Anion Copper(II) Complexes of *RS*-ahaz. The copper(II) complexes obtained by adding $CuX_2 \cdot nH_2O$ (X^-=ClO_4^-, NO_3^-, Br^-, BF_4^-) to twice the molar of *RS*-ahaz were found to be orange-red without exception. The diiodide prepared by mixing $[Cu(RS\text{-ahaz})_2](ClO_4)_2$ and LiI in methanol solution was also orange-red. It was found, however, that the product with $CuCl_2 \cdot 2H_2O$ was a mixture of red and blue complexes. We did not examine the dichloride further.

These orange-red homo-anion complexes had the general composition $Cu(C_6H_{14}N_2)_2X_2 \cdot nH_2O$ (n=0 for X^-=ClO_4^-, NO_3^-, BF_4^-, and I^-; n=2 for X^-=Br^-). Although the complex **2**, prepared from *RS*-ahaz and $CuBr_2$, was found to contain two water molecules per one complex molecule, it exhibited the visible reflectance spectrum closely similar to those of the others. The spectral data are summarized in Table 1.

As described in introduction, it is rather unusual[2] that a series of copper(II) complexes of bis(diamine) type is thoroughly orange-red and shows the reflectance spectral maximum around 21000 cm^{-1} regardless of the sort of counter ion. Hence, the crystal structures of complexes **1** and **2** were examined by the X-ray diffraction method.

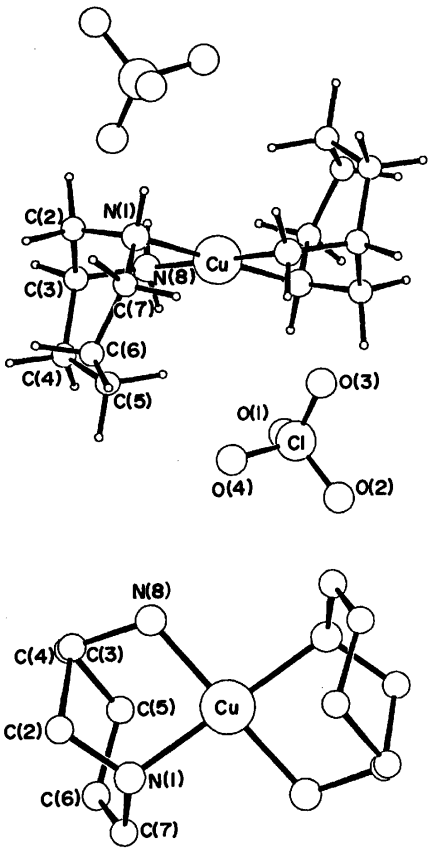

Fig. 2. Perspective views of complex **1**.

Molecular Structure of Complex 1. As is indicated by the crystal parameters, the molecular structure of the complex **1** has the strict C_i symmetry, where the Cu^{2+} ion occupies the center of inversion. The perspective views of **1** are shown in Fig. 2. The selected bond parameters are listed in Table 6. The bond distances and angles are in the normal range. It is noticed that one of two ahaz ligands has the R- and the other has the S-configuration.

Obviously the seven-membered rings of both ahaz stand perpendicular to the respective five-membered chelate rings. The primary and secondary amino groups of both diamines are located at the trans positions around the Cu^{2+} ion, and the seven-membered rings extend towards the opposite sides of the CuN_4 plane. Thus, the C(5) methylene group of *S*-ahaz and C(5)′ methylene of *R*-ahaz prevent completely the approach of the perchlorate, respectively, to the top and bottom apical sites of the central metal ion. The interatomic distance Cu-O(1), the shortest distance between Cu atom and the perchlorate group, is 3.77 Å and the Cu-O(1) vector intersects the CuN_4 plane at 62.8°, indicating no appreciable coordination of the anion to the Cu^{2+}. It is apparent, therefore, that the complex cation of **1** takes the strict four-coordination geometry with C_i symmetry, and that the cation can be expressed by the formula $[Cu(R\text{-ahaz})(S\text{-ahaz})]^{2+}$.

The five-membered chelate and the seven-membered ring of *S*-ahaz in **1** is depicted in Fig. 3 (i) and (ii). The chelate ring adopts a λ conformation, and the seven-membered ring takes a twist-chair conformation. The coordinating secondary N center has the S-configuration. The structural characteristics for *R*-ahaz are exactly antipodal to those for *S*-ahaz, reflecting the C_i symmetry of **1**.

The hydrogen bonding modes and intermolecular short contacts in complex **1** are summarized in Table 7. The nitrogen atoms of the ligands of **1** are hydrogen-bonded to the oxygen atoms of the perchlorate ions. Therefore, the shape of perchlorate is fairly normal in **1**.

Molecular Structure of Complex 2. The perspective views of complex **2** are shown in Fig. 4, and the selected bond parameters are given in Table 6. Each complex cation contains an *R*-ahaz and an *S*-ahaz as the ligands, in the same manner as **1**, but **2** no longer has the true centrosymmetry. The distances between Cu^{2+} and Br^- or O of water molecules, Cu-Br(1), Cu-Br(2)A, Cu-O(2)B, Cu-O(1), and Cu-O(2) are respectively, 4.6, 4.6, >7.0, 6.1, and 6.3 Å. Thus, neither the bromides nor the water molecules coordinate to

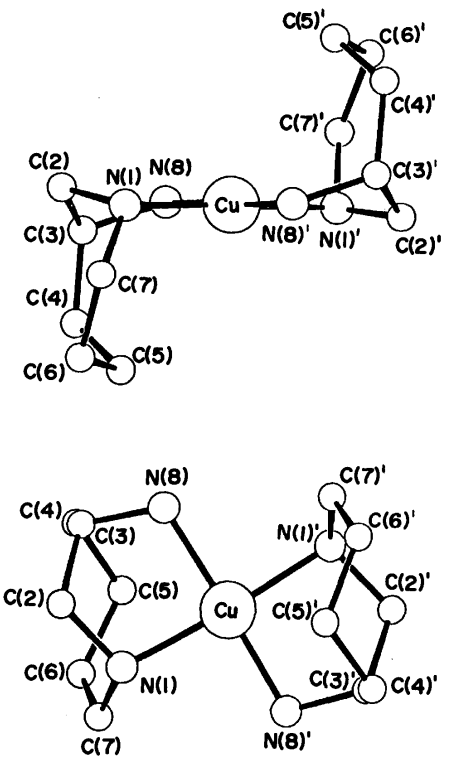

Fig. 4. Perspective views of complex **2**.

the central Cu^{2+} ion, showing that the complex cation also holds the strict four-coordination geometry as found in complex **1**, and that **2** can be represented with the formula $[Cu(R\text{-ahaz})(S\text{-ahaz})]Br_2 \cdot 2H_2O$.

The conformations of five-membered chelates and those of seven-membered rings of *S*-ahaz and *R*-ahaz in **2** are shown in Fig. 3 (iii)—(vi). The chelate rings of *S*-ahaz and *R*-ahaz take a λ and a δ gauche conformation respectively, and the seven-membered rings of these ligands adopt twist-chair conformations. Because of lacking the exact C_i symmetry, the conformation of *S*-ahaz is not the exact antipode of that of *R*-ahaz in **2** as indicated in Fig. 3, in contrast to the case of complex **1**. Despite of this fact, the conformation of *S*-ahaz (or *R*-ahaz) in **1** is quite similar to that of *S*-ahaz (or *R*-ahaz) in **2**, though slight deformations are recognized between them (Fig. 3).

The hydrogen bonding modes and intermolecular short contacts in **2** are also listed in Table 7. For complex **2**, the bromide ions are situated on the two fold axis and form rectangular parallelepiped with one-eighth of the unit cell as shown in Fig. 5. The Br(1) atom is near the center of bc plane of the parallelepiped. The complex cation is surrounded by Br^- ions. Although the Cu^{2+} ion is situated at a

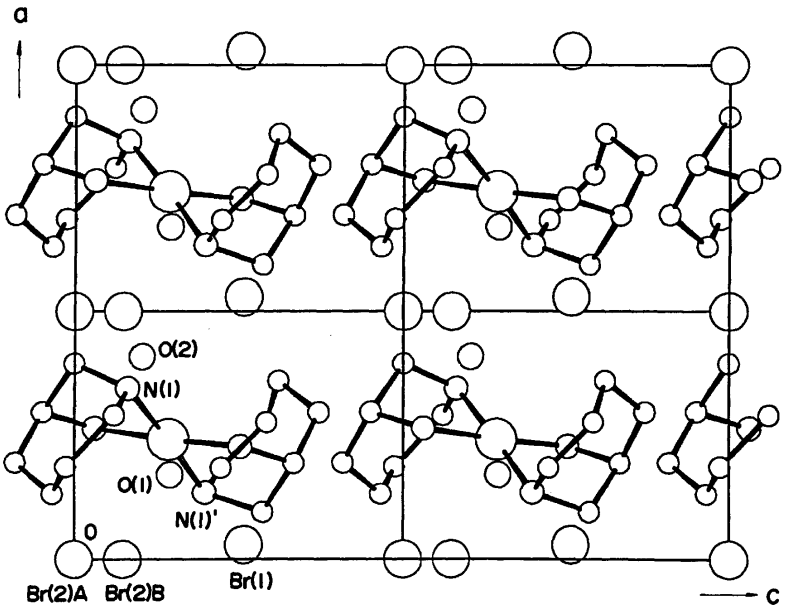

Fig. 5. Crystal packing of complex **2**.

general position, the complex has an approximate centrosymmetry similar to the complex **1**.

Preparation of Hetero-Anion Copper(II) Complexes of *RS*-ahaz. It was found that the orange-red complexes of *RS*-ahaz are classified into two categories based on their electric conductivity behaviors. The complexes with X^-=ClO_4^- and BF_4^- were bi-univalent electrolytes in nitromethane solution, while those of X^-=Br^-, I^-, and NO_3^- dissociated uni-univalently in the same solvent (Table 1). With regard to the latter family, the coordination of an X^- to the central Cu^{2+} seems to take place in the solution, generating new mono-positively charged five-coordinated Cu^{II} species. In spite of the clear difference in the conductivity behaviors, these two families showed no significant differences in their solution spectra (Table 1). Further, it was noticed that the visible absorption spectra of Cu(*RS*-ahaz)$_2$X$_2$ resemble closely those of Cu(*S*-ahaz)$_2$X$_2$ taken in the same solvent (Table 1). For example, the absorption curve of complex **2** is similar to that of Cu(*S*-ahaz)$_2$Br$_2$ and, further, to that of five-coordinated [CuBr(*S*-ahaz)$_2$]-ClO_4 (Fig. 6).

It was demonstrated previously[1] that a series of hetero-anion complexes of *S*-ahaz, Cu(*S*-ahaz)$_2$X-(ClO_4) were obtained by adding LiX or NaX to a solution of Cu(*S*-ahaz)$_2$(ClO_4)$_2$ or, alternatively, adding $LiClO_4$ to Cu(*S*-ahaz)$_2$X$_2$. Similarly the addition of $LiClO_4$ to a methanol solution of complex **2** resulted in the formation of blue-violet crystals having the composition Cu($C_6H_{14}N_4$)$_2$Br(ClO_4). The addition of LiX to a solution of Complex **1** afforded hetero-anion complexes more generally, but in a slightly limited manner compared with the case of *S*-ahaz complexes. The hetero-anion complexes

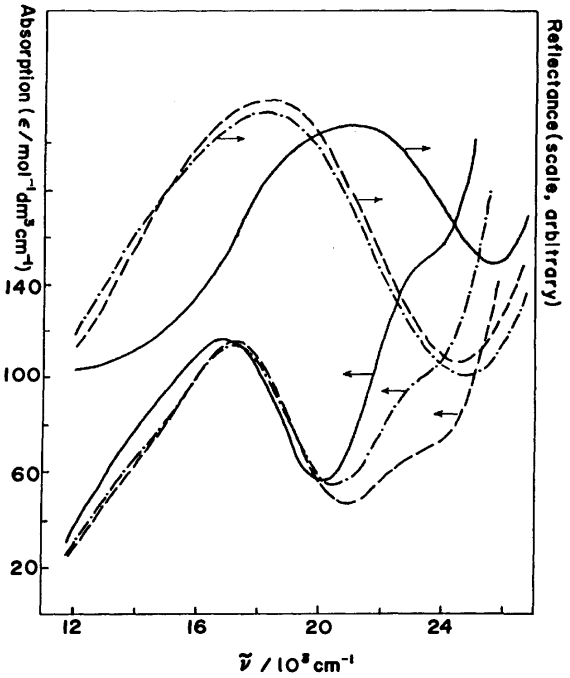

Fig. 6. Reflectance and absorption spectra in nitromethane solution for complexes **2**: (——), **3**: (------), and **4**; (-·-·-).

Cu(*RS*-ahaz)X(ClO_4) were obtained only for X^-=Cl^- and Br^-, while the addition of LiI resulted in the precipitation of orange-red [Cu(*R*-ahaz)(*S*-ahaz)]I_2 as described previously.

The reflectance and absorption spectral as well as electronic conductivity features of the hetero-anion complexes of *RS*-ahaz resembled indistinguishably those of the corresponding *S*-ahaz complexes (Table 1

and Fig. 6). This implies that both *RS*- and *S*-ahaz complexes of the hetero-anion type took stereochemistries closely similar to one another. Since the structure of $[CuBr(S\text{-ahaz})_2]ClO_4$, referred hereafter as to complex **4**, has already been clarified crystallographically,[1] the structure determination of the corresponding *RS*-ahaz complex **3** was performed by the X-ray diffraction method with a view to compare the stereochemical characteristics of **3** and **4** and to examine the ligand exchange mode for the formation of **3** from **1** or **2**.

Molecular and Crystal Structure of Complex 3. Although complex **3** has been represented as $Cu(RS\text{-ahaz})_2Br(ClO_4)$ for simplicity, the X-ray analysis result demonstrated that a racemic pair of five-coordinated complex ions, $[CuBr(R\text{-ahaz})_2]^+$ and $[CuBr(S\text{-ahaz})_2]^+$, exists in the single crystal, and so **3** is represented with the formula $[CuBr(R\text{-ahaz})_2]$-$[CuBr(S\text{-ahaz})_2](ClO_4)_2$. The perspective views shown in Fig. 7 are those for the complex cation comprised with *S*-ahaz, which is exactly antipodal to the counterpart involving *R*-ahaz. We will consider the stereochemical characteristics of the cation with *S*-ahaz as the representative, in relation to that of complex **4**. The selected bond parameters of **3** are listed in Table 6.

The $[CuBr(S\text{-ahaz})_2]^+$ ion in **3** (Fig. 7) is similar to that in **4**[1]. Both complex ions adopt typical square-pyramidal geometries, in which four amino nitrogens of ahaz ligands occupy the basal plane and a bromide at the apex, and the five-membered chelate rings take λ conformations. Seven-membered rings thoroughly assume preferable twist-chair conformations. A noticeable difference between **3** and **4** is found with regard to the cyclic sequences of dihedral angles of both seven-membered rings; i.e. those are nearly identical for **3**, but evidently different for **4**.[1] Thus, the complex ion of **3** appears to have a pseudo C_2 axis perpendicular to CuN_4 plane (Fig. 7), though that of **4** seems not to have such symmetry axis at all.[1]

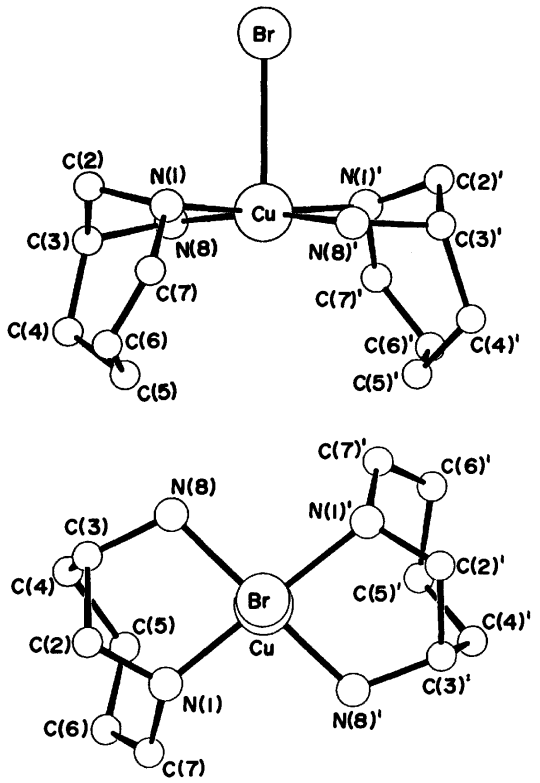

Fig. 7. Perspective views of complex **3**.

The crystal packings and lattice constants of complexes **3** and **4**, as well as their molecular structures, are fairly similar to each other, as shown in Fig. 8 and Table 2. Each complex forms zigzag chains consisting of the complex of the same chirality along c axis through two fold screw operation. Each chain is surrounded by four similar chains as in polyethylene packing.[11] For complex **3**, the neighboring chains, indicated by the broken line rectangles, have the chirality opposite to the chain shown with the solid line rectangle as indicated in Fig. 8 (a). On the other hand, all the chains for complex **4** in Fig. 8 (b) have the same chirality.

Discussion

Structural Characteristics of Reddish Bis(diamine)-copper(II) Complexes. The X-ray diffraction study revealed that $[Cu(R\text{-ahaz})(S\text{-ahaz})]^{2+}$ ion in **1** adopts the strictly rhombic-coplanar CuN_4 stereochemistry, and that the complex cation in **2** is intrinsically identical with that in **1**, though slight deformations from the centrosymmetric geometry take place. The fact that the reflectance spectra of other orange-red homo-anion complexes of *RS*-ahaz resemble those of **1** and **2** strongly suggests that these complexes also assume similar coplanar configurations represented as the structure (III) in Fig. 9 and can be formulated as $[Cu(R\text{-ahaz})(S\text{-ahaz})]X_2$ (X^-=BF_4^-, NO_3^-, I^-).

However, the existence of rhombic- or square-coplanar CuN_4 chromophore in copper(II) complexes has been considered to be unusual.[2] One of the rare examples of such chromophore has been established for $[Cu(deen)_2]^{2+}$ ion (deen=*N*,*N*-diethyl-1,2-ethanediamine) in the diperchlorate[12] or dinitrate.[2] In these deen complexes the coordination of the anions (ClO_4^- or NO_3^-) is disturbed by the *N*-ethyl groups, which orient axially with regard to the respective chelate rings as indicated by Fig. 9 (IV). It is noticeable that $[Cu(deen)_2]X_2$ (X^-=ClO_4^-, NO_3^-) are also reddish-colored and have centrosymmetric rhombic-coplanar structures in a similar manner as **1**.

In addition, it was demonstrated that the wine-red complexes $[Cu(1,3\text{-chxn})_2]X_2$ (1,3-chxn=*cis*-1,3-cyclohexanediamine; X^-=NO_3^-, Br^-) also took square-coplanar stereochemistries.[13,14] The established

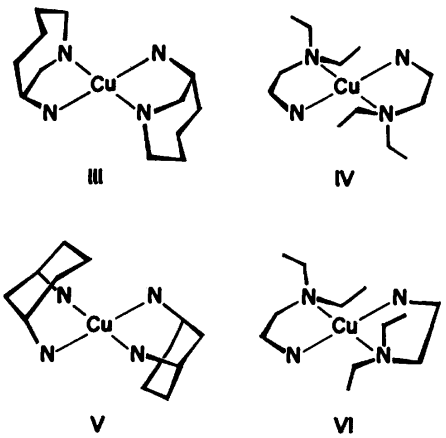

Fig. 9. Stereochemistries of copper(II) complexes having the CuN_4 chromophore. [Cu(*R*-ahaz)(*S*-ahaz)]$^{2+}$ ion, (III); [Cu(deen)$_2$]$^{2+}$ ion (red-form), (IV)[2,12]; [Cu(1,3-chxn)$_2$]$^{2+}$ ion, (V)[14]; [Cu(deen)$_2$]$^{2+}$ ion (blue-form), (VI).[12]

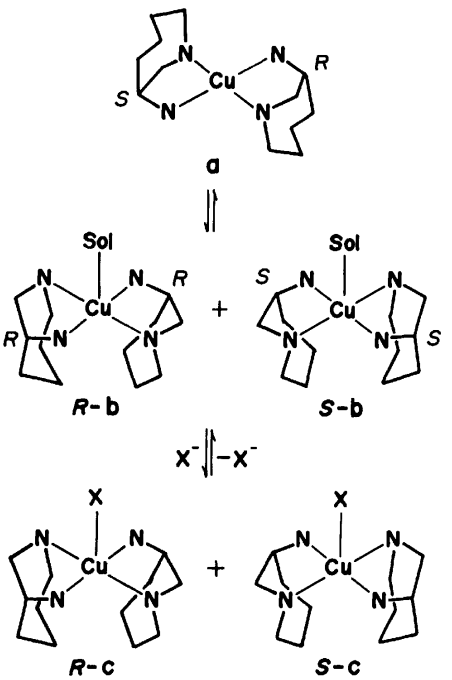
structure of [Cu(1,3-chxn)$_2$]$^{2+}$ ion in these wine-red complexes is illustrated in Fig. 9 (V), where the contact of anions to the apical coordination sites is completely prevented by the ring methylene chains of the ligands in quite a similar manner as that in (III). It can be concluded, therefore, that the common structural features of reddish-colored copper(II) complexes with diamine ligands are the strict four-coordination geometries with C_i or closely similar molecular symmetry and the absence of the coordination of anions to the central ion.

It is noteworthy that the production of reddish-colored bis(diamine)copper(II) complex with the square- or rhombic-coplanar stereochemistry is rather delicate phenomena, being influenced with some complicated factors. For example, Cu(1,3-chxn)$_2$Br$_2$ was found to form violet crystals from ethanol, in spite that it afforded wine-red crystals from methanol.[13] In the case of *RS*-ahaz complexes, the dibromide gave only orange-red crystals, but the dichloride was a mixture of orange-red and blue-violet forms. For deen complex, the dibromide was no longer reddish-colored, but blue-violet.[15] For the violet or blue-violet modifications of these diamine complexes, some intrinsic changes from the strictly four-coordinated centrosymmetric structure should be effected within the complex ion, though the details of such structural changes are uncertain.

Pathway for Formation of [CuBr(*R*-ahaz)$_2$]$^+$ and [CuBr(*S*-ahaz)$_2$]$^+$ Ions from [Cu(*R*-ahaz)(*S*-ahaz)]$^{2+}$ Ion. The X-ray diffraction study of complex **3** clarified the formation of the five-coordinated [CuBr(*S*-ahaz)$_2$]$^+$ and its antipode from [Cu(*R*-ahaz)(*S*-ahaz)]$^{2+}$ ion, indicating that not only the coordination of Br^- but certain ligand exchanges of ahaz take place during such transformation in solution. Moreover, the pair of **1** and **3** exemplifies two typical coordination modes possible for metal complexes containing the racemic modification of a chiral bidentate ligands; the first involves both of the R- and S-enantiomers in each complex ion, giving a meso type compound as **1**, while in the second case each complex ion comprises two molecules of the single enantiomer and becomes chiral as in **3**. The formation of **3** can therefore be regarded as a process of chiral discrimination; that is, the first *R*-ahaz (or *S*-ahaz) coordinated to Cu^{2+} ion chooses the same enantiomer as the second ligand to form the chiral five-coordinated complex.

The ligand exchange which occurs upon the dissolution of ahaz complexes is presumed by comparing the electronic spectral data of a series of copper(II) complexes of *RS*- and *S*-ahaz. Thus, the absorption spectrum of complex **1** obtained in nitromethane solution was found to be markedly different from its reflectance spectrum, while it closely resembles the solution spectrum of Cu(*S*-ahaz)$_2$(ClO$_4$)$_2$ (Table 1). Taking into consideration that these complexes dissociate uni-bivalently, it is supposed that such ligand exchanges as those shown in Scheme 1 occur in nitromethane solution, at least in part, to generate a racemic pair of [Cu(*R*-ahaz)$_2$(Sol)]$^{2+}$ and [Cu(*S*-ahaz)$_2$(Sol)]$^{2+}$ ((Sol) denotes the coordinating solvent molecule). When all the complexes take exclusively the square-pyramidal structures in solution, the spectra for the *RS*-ahaz complex should



Scheme 1. Equilibria for copper(II) complexes of *RS*-ahaz in the presence of X^-: **a**, [Cu(*R*-ahaz)(*S*-ahaz)]$^{2+}$; *R*-**b**, [Cu(*R*-ahaz)$_2$(Sol)]$^{2+}$; *S*-**b**, [Cu(*S*-ahaz)$_2$(Sol)]$^{2+}$; *R*-**c**, [Cu(*R*-ahaz)$_2$X]$^+$; *S*-**c**, [Cu(*S*-ahaz)$_2$X]$^+$.

coincide with that for the *S*-ahaz complex. In methanol, the absorption spectra of the above complexes of racemic and optically active ahaz actually become almost identical with each other, probably due to that most part of the racemic complex takes the solvent-coordinated square-pyramidal structures.

In the presence of anions such as Cl^-, Br^-, or I^-, the solvent-coordinated species tend to be converted into the five-coordinated $[CuX(S\text{-ahaz})_2]^+$ and its enantiomer as shown in Scheme 1. It is interesting to note that $[Cu(R\text{-ahaz})(S\text{-ahaz})]X_2$ (X^-=Br^-, I^-) dissociates uni-univalently in nitromethane, in contrast to that $[Cu(R\text{-ahaz})(S\text{-ahaz})]X_2$ (X^-=ClO_4^-, BF_4^-) behaves as uni-bivalent electrolytes in the same solvent. These facts suggest that the halide complexes transform almost completely into $[CuX(R\text{-ahaz})_2]^+$ and $[CuX(S\text{-ahaz})_2]^+$ in nitromethane.

Alternatively, when halides or pseudohalides (NCS^- or ONO^-) were added in excess to a solution of **1**, most part of the complex species would adopt the five-coordinated structures with a coordinating X^-. In the case where ClO_4^- and X^- coexist, the product that crystallized from an equilibrated mixture in Scheme 1 is likely to depend on the relative concentrations of ClO_4^- and X^- and the solubilities of individual species as the perchlorate or halide.

Thus, under the conditions where X^- is Cl^- or Br^- and sufficient amounts of both X^- and ClO_4^- coexist in aqueous methanol solution, the hetero-anion complex $Cu(RS\text{-ahaz})_2X(ClO_4)$ is the least soluble species and crystallizes out as the sole product. But in the case where X^- is I^-, $[Cu(R\text{-ahaz})(S\text{-ahaz})]I_2$ is the least soluble one in methanol, so that the addition of NaI to a solution of **1** results in the precipitation of $[Cu(R\text{-ahaz})(S\text{-ahaz})]I_2$. When X^- is ONO^-, a mixture of blue-violet crystals, probably the hetero-anion complex $Cu(RS\text{-ahaz})_2(ONO)(ClO_4)$, and orange-red **1** precipitated out of a solution of **1** containing $NaNO_2$. When X^- is NCS^-, the precipitation of blue-violet crystals no longer resulted, but complex **1** recovered.

It was found, further, that complex **1** crystallized out of an aqueous methanol solution of complex **3**. It was necessary for the recrystallization of the hetero-anion complex to add a small amount of LiBr to the solution. But the addition of a large excess of bromide to a solution of **3** resulted in the precipitation of complex **2**. We observed actually that the lattice constants of an orange-red crystal obtained from **3** by the treatment with excess KBr solution were the same as those of complex **2**. These facts demonstrate that the coordinating bromide is easily replaced with a solvent molecule in aqueous methanol solution, and that the equilibrium shown in Scheme 1 actually exists.

Stereochromism: Dichromism Due to Enantiomeric Composition of Chiral Ligand. Since the structural characteristics of orange-red homo-anion complexes of *RS*-ahaz has been clarified as mentioned above, it becomes possible to consider the interesting phenomenon caused by employing either the racemate or the pure single enantiomer of ahaz; i.e. $Cu(RS\text{-ahaz})_2X_2\cdot nH_2O$ are thoroughly orange-red, while the corresponding *S*-ahaz complexes $Cu(S\text{-ahaz})_2X_2$ are violet or blue-violet.[1] Although no exact structures of *S*-ahaz complexes have been established by the crystallographic method owing to poor quality of crystals, we have postulated them to be (I) or (II).[1] Whichever structures the *S*-ahaz complexes assume, they are intrinsically chiral, so that it is impossible for them to adopt any meso type structures such as centrosymmetric (III). Therefore, it is reasonable that no orange-red form was found for *S*-ahaz complexes, because it is concluded necessary for reddish bis(diamine)copper(II) complexes to adopt the centrosymmetric strict coplanar geometry.

Such color change depending on the enantiomeric composition of a chiral ligand, the racemate or the pure single enantiomer, may be termed "stereochromism" in analogy with thermochromism[16] or other dichromic phenomena. As far as bis(diamine)copper(II) complexes concern, the thermochromism exhibited by deen complexes is one of the most well known and thoroughly examined cases, i.e., $Cu(deen)_2X_2$ interconverts reversibly between the red lower temperature form and the blue higher temperature form, when X^- is of low coordinating ability as ClO_4^- or BF_4^-.[12,15,17-21] The structural change which may accompany with the color change has been studied from various aspects.[12,15,18-21] The hexagonal distortion involving the Cu-N bond lengthening and the synchronous access of anions to the apical sites of Cu^{2+} had been suggested to be responsible for the color change.[15,18-20] However, it was conclusively demonstrated for the diperchlorate[12] that in the course of the transformation from red to blue form no obvious Cu-N bond lengthening took place, and that the most apparent stereochemical change was the conformation inversion of one of the deen chelates. The structures of the red and blue forms thus determined[12] are illustrated in Fig. 9 (IV) and (VI), respectively. It should be pointed out that both chelate rings in (VI) adopt λ conformations (or δ conformations for the antipode of (VI)), so that the complex cation of the blue form (VI) is chiral, even though it has a C_2 axis perpendicular to the CuN_4 plane. As previously noted, (IV) in the red form is strictly centrosymmetric.[2,12] Thus, we can deduce common stereochemical features between the stereochromism of ahaz complexes and the thermochromism of deen complexes; the complex ions in the red forms has the C_i molecular symmetry and are strictly four-coordinated, and in the blue or violet forms they assume certain kind of chiral structures, irrespective of its coordination number being four or

five.

It is apparent that the interconversion between (II) and (III) requires the configurational inversion at the asymmetric carbon center of ahaz. Such conversion is difficult under ordinary condition, so that it is reasonable that orange-red Cu(*RS*-ahaz)$_2$X$_2$ does not show any sign of thermochromism. Alternatively, stereochromism can be realized by using *S*-ahaz in place of *RS*-ahaz as the ligand. More examples of stereochromism will probably be observed among copper(II) complexes by employing both racemic and optically pure forms of certain N-substituted diamines, an example of which will be presented in a following paper.[22]

(Received December 18, 1986)

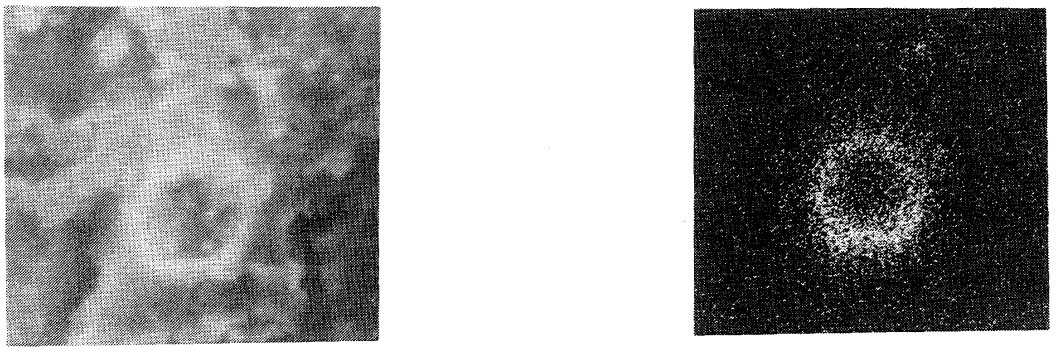
The thermal residual stresses during the fabrication of a Ni-coated carbon fiber composite are calculated by using two- and four-concentric-circular-cylinders models. The advantage of the CDL (chemical deposition in liquid phase) coating method at low temperature (200 °C), which is using organonickel compounds such as $Ni(cod)_2$ (cod=1,5-cyclooctadiene), over the conventional melted Ni-coating method (1453 °C) has been definitely confirmed from the crack prevention viewpoint.

There has been a growing interest in coated fiber composites such as electric composites or metal matrix composites. For such composites, the purpose of the coating on fiber is to develop a functionalized fiber or to serve as a chemical reaction barrier between the metal matrix and the fiber. We have recently reported that carbon materials were uniformly coated with metals such as Al,[2] Fe,[3] Co,[1] or Ni[1] at low temperature by the CDL method using organometallic compounds. Advantages of this CDL method have been investigated. This CDL method for an aluminum coating improved the wetting of carbon by aluminum metal and obviated the formation of aluminum carbide.[2] $Ni(cod)_2$ and $Co_2(CO)_8$, which do not have low boiling points, can be used by this CDL method for Co- and Ni-coating of carbon fibers, respectively, in sharp contrast to the CVD (chemical vapor deposition) method.

In order to evaluate the effect of the low coating temperature of the CDL method (ca. 200 °C) compared with the conventional nickel coating using melted nickel metal (1453 °C), we calculated the thermal residual stresses due to the mismatch of thermal expansion coefficients of its constituents. The thermal stresses in a coated short fiber composite[4] and in a coated continuous fiber composite[5] have been recently discussed by one of the authors. There have been a number of other works for a continuous fiber (not coated) composite,[6,7] and for a composite cylinder.[8,9] However, none of these works considered the thermal residual stresses of the coated continuous fiber composite during the fabrication process.

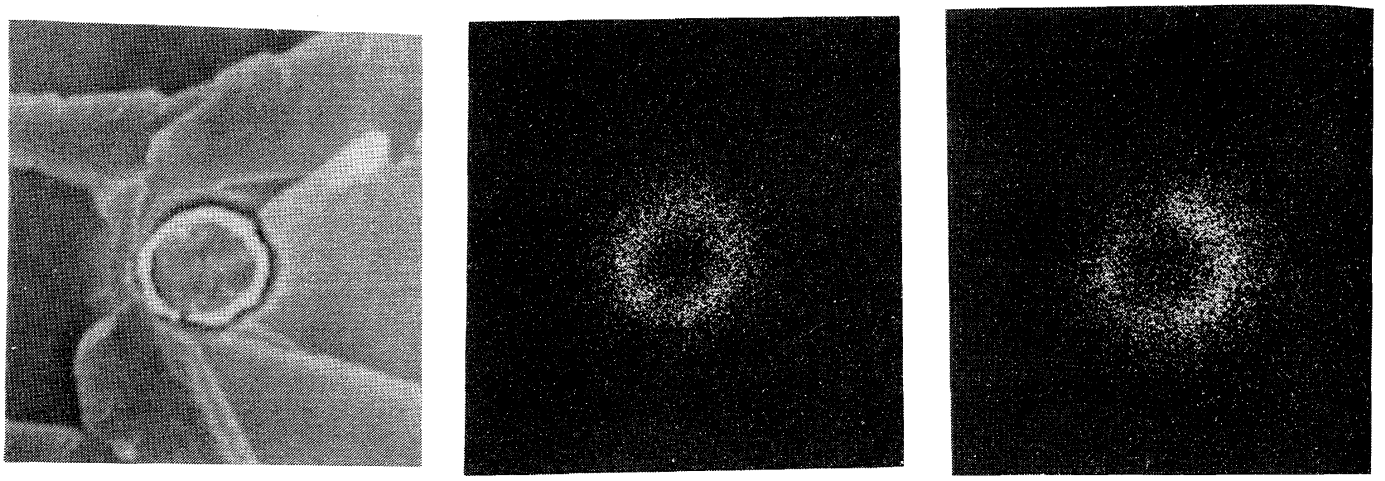
In this paper, specific emphasis will be given to the feasibility study of Ni-coated carbon fiber and its aluminum composite from the fabrication viewpoint. Two nickel coating methods were compared. One is the CDL method using organonickel compounds we recently reported.[1] The big advantage of this method is that the temperature at the time of coating is very low (about 200 °C) and to be controlled. The other is a conventional method in which nickel metal is heated up to its melting point (1453 °C) and coated on the carbon fiber. We will focus on the effect of the difference of these two temperatures on thermal residual stresses built up during the fabrication process.

Thermal Residual Stress. In the following analysis, we largely rely on the formulation presented in Ref. 4. For the sake of self containedness, however, we review some of the results reported before.[4]



(A) SEM picture (B) Characteristic X-ray picture

Fig. 1. Cross section of Ni coated carbon fiber.



(A) SEM picture (B) Ni characteristic X-ray picture (C) Al characteristic X-ray picture

Fig. 2. Cross section of Al/Ni coated carbon fiber.

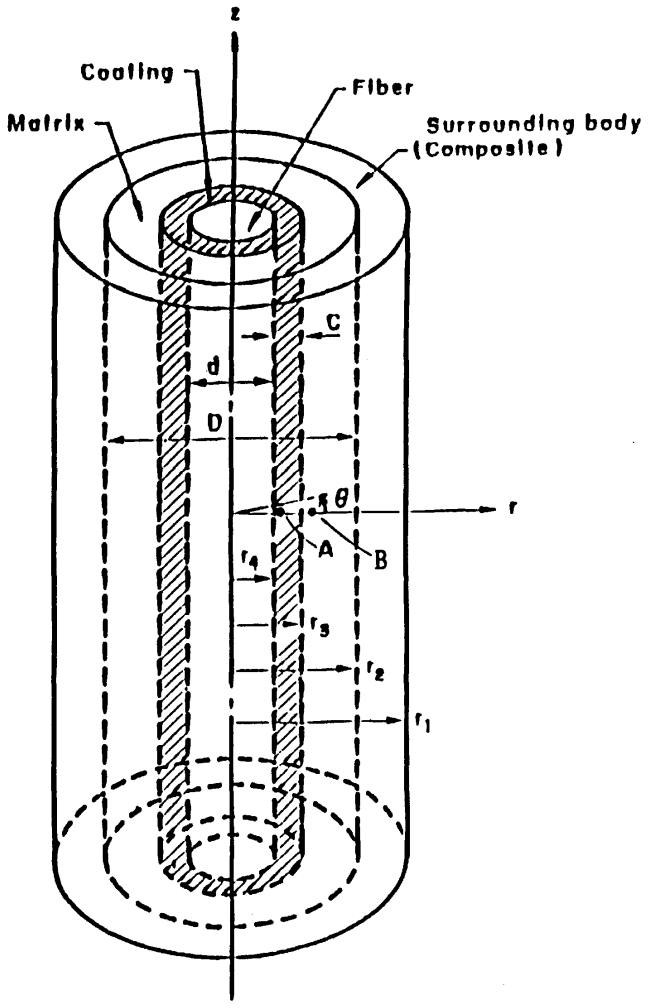


Fig. 3. Four phase model.

In order to evaluate the thermal residual stresses during the fabrication process, we need to consider two stages, stage-1: making the coated fiber, and stage-2: making the composite by combining the coated fiber and the matrix. At each stage, there are thermal residual stresses. The final thermal residual stresses are the sum of those stresses at stage 1 and 2.

Cross section of nickel-coated carbon fiber by the CDL method and that surrounded with aluminum are shown in Figs. 1 and 2. To simplify the calculations a coated continuous fiber composite is modeled as four concentric infinitely long circular cylinders (four phase model) as shown in Fig. 3. The surrounding body with the composite properties (outermost cylinder), matrix, coating and fiber (innermost cylinder) are denoted by domain 1, 2, 3, and 4, respectively, and their radii by r_1, r_2, r_3, and r_4, respectively. The diameters of fiber and matrix (including a coated fiber) are denoted by d and D, respectively, and the coating thickness by c. Since the surrounding body is infinite, r_1 will be made infinity at the end of the formulation.

To compute the thermal residual stresses at stage 1, we only need to consider two concentric circular cylinders, which consists of the fiber and the coating. Thermal residual stresses at stage 2 can be computed by using the four phase model described above.

Let us first obtain the thermal residual stresses at stage 1. The coating and the fiber are denoted as the domain 3 and 4, respectively, and the radii of the coating and the fiber as r_3 and r_4, respectively. Their surface of the coating is stress free at this stage. The constant temperature change is denoted as ΔT_1. The stress field is obtained in a similar manner as reported before[4] and given by

$$\sigma_{rr}^{(m),1} = C_{11}^{(m)}\left(A_m^1 - \frac{B_m^1}{r^2}\right) + C_{12}^{(m)}\left(A_m^1 + \frac{B_m^1}{r^2}\right) + C_{13}^{(m)}E^1 - \beta_1^{(m)}\Delta T_1$$
$$\sigma_{\theta\theta}^{(m),1} = C_{12}^{(m)}\left(A_m^1 - \frac{B_m^1}{r^2}\right) + C_{11}^{(m)}\left(A_m^1 + \frac{B_m^1}{r^2}\right) + C_{13}^{(m)}E^1 - \beta_1^{(m)}\Delta T_1 \quad (1)$$
$$\sigma_{zz}^{(m),1} = 2C_{13}^{(m)}A_m^1 + C_{33}^{(m)}E^1 - \beta_3^{(m)}\Delta T_1 \qquad m=3,4$$

with $B_4^1=0$, and where

$$\beta_1^{(m)} = (C_{11}^{(m)}+C_{12}^{(m)})\alpha_{mT} + C_{13}^{(m)}\alpha_{mL}$$
$$\beta_3^{(m)} = 2C_{13}^{(m)}\alpha_{mT} + C_{33}^{(m)}\alpha_{mL}, \qquad m=3,4 \quad (2)$$

$C_{ij}^{(m)}$ are elastic constants of the m-th material, and α_{mT} and α_{mL} are the thermal expansion coefficients of the m-th material along the transverse (r) and longitudinal (z) direction, respectively. The unknown coefficients A_3^1, A_4^1, B_3^1, E^1 are determined by solving the following simultaneous equations.

$$\begin{pmatrix} a_{11}^1 & a_{12}^1 & a_{13}^1 & 0 \\ a_{21}^1 & 0 & a_{23}^1 & a_{24}^1 \\ a_{31}^1 & a_{32}^1 & a_{33}^1 & a_{34}^1 \\ a_{41}^1 & a_{42}^1 & 0 & a_{44}^1 \end{pmatrix} \begin{pmatrix} A_3^1 \\ A_4^1 \\ B_3^1 \\ E^1 \end{pmatrix} = \begin{pmatrix} b_1^1 \\ b_2^1 \\ b_3^1 \\ b_4^1 \end{pmatrix} \quad (3)$$

where the explicit expressions of elements in the square matrix a_{ij}^1 and column vector b_i^1 are given in the Appendix A.

The thermal residual stresses in the stage 2 are obtained by using the four phase model.[4] Let us denote the constant temperature change as ΔT_2. Then we find the stress field as

$$\sigma_{rr}^{(n),2} = C_{11}^{(n)}\left(A_n^2 - \frac{B_n^2}{r^2}\right) + C_{12}^{(n)}\left(A_n^2 + \frac{B_n^2}{r^2}\right) + C_{13}^{(n)}E^2 - \beta_1^{(n)}\Delta T_2$$
$$\sigma_{\theta\theta}^{(n),2} = C_{12}^{(n)}\left(A_n^2 - \frac{B_n^2}{r^2}\right) + C_{11}^{(n)}\left(A_n^2 + \frac{B_n^2}{r^2}\right) + C_{13}^{(n)}E^2 - \beta_1^{(n)}\Delta T_2$$
$$\sigma_{zz}^{(n),2} = 2C_{13}^{(n)}A_n^2 + C_{33}^{(n)}E^2 - \beta_3^{(n)}\Delta T_2, \qquad n=1\text{—}4 \quad (4)$$

with $B_4^2=0$, and where

$$\beta_1^{(n)} = (C_{11}^{(n)}+C_{12}^{(n)})\alpha_{nT} + C_{13}^{(n)}\alpha_{nL}$$
$$\beta_3^{(n)} = 2C_{13}^{(n)}\alpha_{nT} + C_{33}^{(n)}\alpha_{nL}, \qquad n=1\text{—}4 \quad (5)$$

The simultaneous equations for the eight unknowns A_1^2, A_2^2, A_3^2, A_4^2, B_1^2, B_2^2, B_3^2, E^2 in (4) are given by

$$\begin{pmatrix} a_{11}^2 & a_{12}^2 & 0 & 0 & a_{15}^2 & a_{16}^2 & 0 & 0 \\ 0 & a_{22}^2 & a_{23}^2 & 0 & 0 & a_{26}^2 & a_{27}^2 & 0 \\ 0 & 0 & a_{33}^2 & a_{34}^2 & 0 & 0 & a_{37}^2 & 0 \\ a_{41}^2 & 0 & 0 & 0 & 0 & 0 & 0 & a_{48}^2 \\ a_{51}^2 & a_{52}^2 & 0 & 0 & a_{55}^2 & a_{56}^2 & 0 & a_{58}^2 \\ 0 & a_{62}^2 & a_{63}^2 & 0 & 0 & a_{66}^2 & a_{67}^2 & a_{68}^2 \\ 0 & 0 & a_{73}^2 & a_{74}^2 & 0 & 0 & a_{77}^2 & a_{78}^2 \\ a_{81}^2 & 0 & 0 & 0 & 0 & 0 & 0 & a_{88}^2 \end{pmatrix} \begin{pmatrix} A_1^2 \\ A_2^2 \\ A_3^2 \\ A_4^2 \\ B_1^2 \\ B_2^2 \\ B_3^2 \\ E^2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ b_4^2 \\ b_5^2 \\ b_6^2 \\ b_7^2 \\ b_8^2 \end{pmatrix} \quad (6)$$

where the explicit expressions of elements in the square matrix a_{ij}^2 and column vector b_i^2 are given in the Appendix B.

The final thermal residual stresses are computed as

$$\sigma_{ij}^{(l),f} = \sigma_{ij}^{(l),1} + \sigma_{ij}^{(l),2}, \qquad l=1\text{—}4 \quad (7)$$

where we have the following specifications.

$$\sigma_{ij}^{(1),1} = \sigma_{ij}^{(2),1} = 0 \quad (8)$$

Results and Discussion

Two Ni-coating methods are compared from 'mechanics viewpoint. Let us call the conventional melted nickel coating method at 1453 °C as the method I, and the CDL method at 200 °C as the method II.

The representative material properties of the Ni-coated graphite fiber/aluminum 6009 are given in Table 1,[10] where the tensile strength is denoted by σ_{ult}. It should be noted in Table 1 that the engineering elastic constants, E_T, E_L, ν_{12}, ν_{13}, G_L, are given instead of C_{ij}. The elastic constants C_{ij} are related to the engineering elastic constants.[11] Material properties of the surrounding body (composite) are obtained by using a rule of mixture,

$$C_{ij}^{(1)} = V_m C_{ij}^{(2)} + V_c C_{ij}^{(3)} + V_f C_{ij}^{(4)}$$
$$\alpha_{1T} = V_m\alpha_{2T} + V_c\alpha_{3T} + V_f\alpha_{4T} \quad (9)$$
$$\alpha_{1L} = V_m\alpha_{2L} + V_c\alpha_{3L} + V_f\alpha_{4L}$$

where V_m, V_c, V_f are the volume fraction of the matrix, coating and fiber, respectively, and they are given by

$$V_m = 1 - \left(\frac{r_3}{r_2}\right)^2, \quad V_c = \left(\frac{r_3}{r_2}\right)^2 - \left(\frac{r_4}{r_2}\right)^2,$$
$$V_f = \left(\frac{r_4}{r_2}\right)^2 = \left(\frac{d}{D}\right)^2 \quad (10)$$

In the following figures, the stresses in the surrounding body are omitted, because they are either 0 ($=\sigma_z$) or so small (σ_r, σ_θ) to draw in those scales.

Thermal residual stresses of the coated fiber along the radial direction (r-axis) which are caused by the method I and II are shown in the Figs. 4 and 5, respectively. It is assumed in both cases that the coated fiber is cooled down to room temperature (25 °C) after completing the Ni-coating. The ratio of coating thickness to fiber diameter c/d is set to be 0.2143. It is easily seen from Fig. 4 that σ_z in the coating (Ni) is far greater than the tensile strength of Ni (317 MPa). Thus it is very likely that the Ni-coating will be completely cracked, if we use the method I. Whereas, in the Fig. 5, it is seen that the maximum tensile stress (σ_z) in the Ni-coating is less than its tensile strength.

The final thermal residual stresses of the composite caused by the method II are shown in the Fig. 6. The

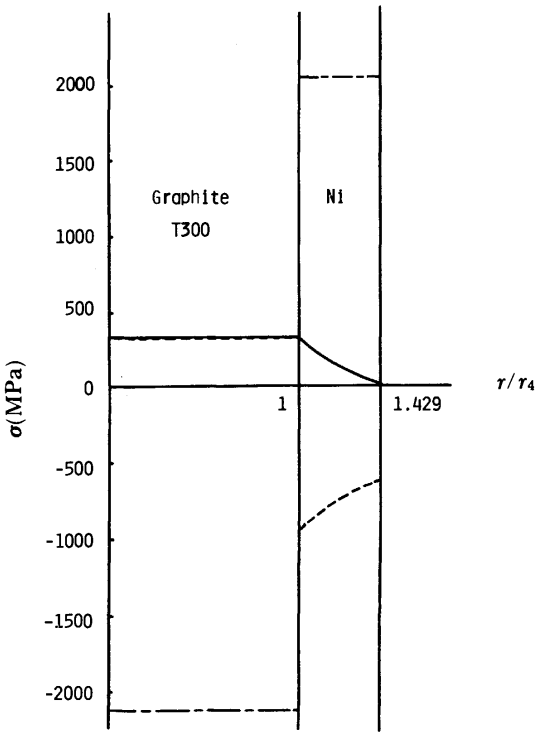

Fig. 4. Thermal residual stresses of the fiber caused by the method I (1453 °C—25 °C). $\Delta T \fallingdotseq -1428$ °C, $c/d \fallingdotseq 15/70$. ——σ_r, ------σ_θ, —·—σ_z.

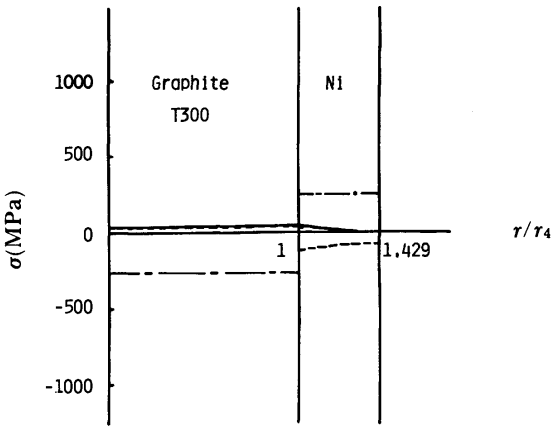

Fig. 5. Thermal residual stresses of the coated fiber caused by the method II. (200 °C—25 °C) $\Delta T \fallingdotseq -175$ °C, $c/d \fallingdotseq 15/70$, ——σ_r, ------σ_θ, —·—σ_z.

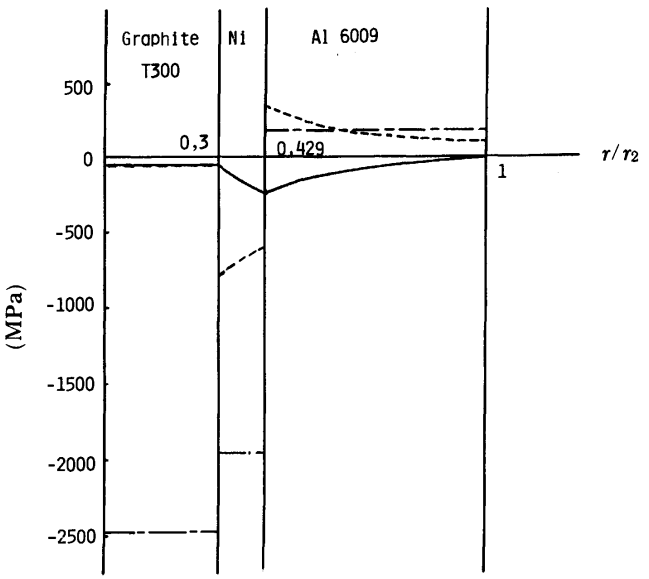

Fig. 6. Final thermal residual stresses of the composite by the method II. Coated fiber: 200 °C—(25 °C)—650 °C—25 °C, composite: 650 °C—25 °C. $V_f = 0.09$, $c/d \fallingdotseq 15/70$, ——σ_r, ------σ_θ, —·—σ_z.

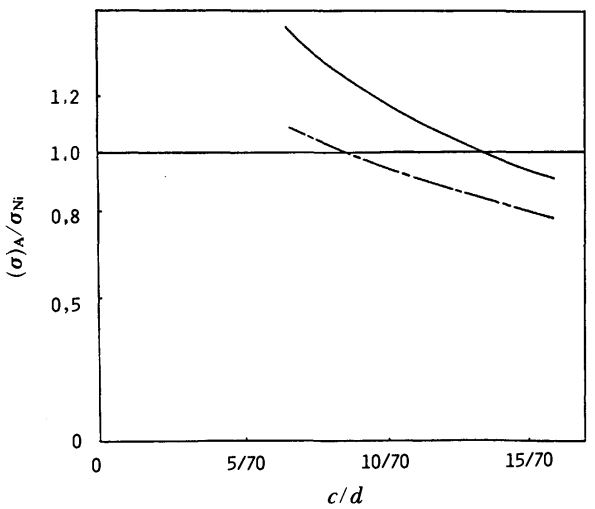

Fig. 7. Residual tensions of the coated fiber at a point A caused by the method II as a function of c/d. The stresses are normalized by the tensile strength of Ni. ——$(\sigma_\theta)_A/\sigma_{Ni}$, $\Delta T \fallingdotseq 450$ °C, 200 °C—(25 °C)—650 °C; —·—$(\sigma_z)_A/\sigma_{Ni}$, $\Delta T \fallingdotseq -175$ °C, 200 °C—25 °C; $\sigma_{Ni} \fallingdotseq 317$ MPa.

volume fraction of the fiber V_f and the ratio of coating thickness to fiber diameter c/d set to be 0.09 and 0.2143, respectively. These values have been determined so as to make the maximum tensile stress occurring in each phase of the composite less than its tensile strength. It is observed in the Fig. 6 that the highest tensile residual stress (σ_θ) is formed at a point B (see Fig. 3). Even though this stress ($(\sigma_\theta)_B$=341.69 MPa) is almost reaching the tensile strength (342 MPa) of Al 6009, it is expected that the stress is somewhat relaxed by a possible plastic deformation of Al 6009, which our elastic calculation cannot predict. It is generally true that our elasticity assumption of the model gives rise to a higher stress value than expected in reality.

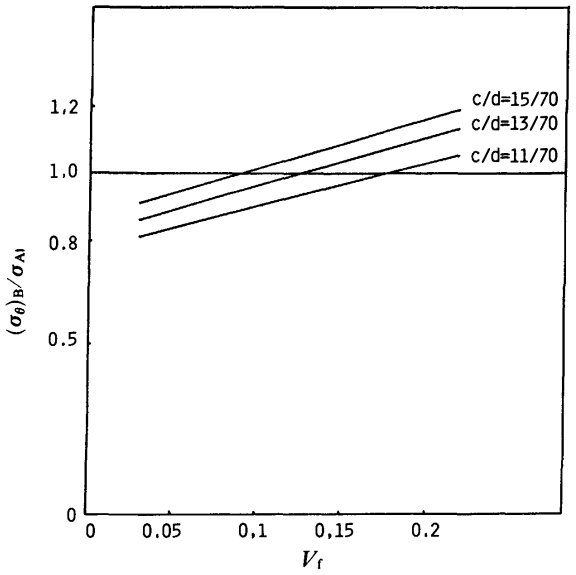

Fig. 8. Residual tension σ_θ of the composite at a point B caused by the method II as a function of V_f for various values of c/d. The stresses are normalized by the tensile strength of Al. ΔT=−625 °C, 650 °C—25 °C, σ_{Al}=342 MPa.

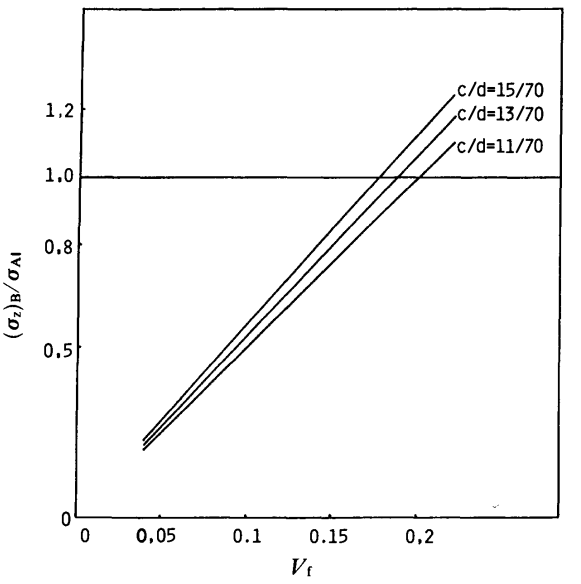

Fig. 9. Residual tension σ_z of the composite at a point B caused by the method II as a function of V_f for various values of c/d. The stresses are normalized by the tensile strength of Al. ΔT=−625 °C, 650 °C—25 °C, σ_{Al}=342 MPa.

A parametric study has been conducted by changing two parameters, i.e. V_f=0.04, 0.09, 0.16, and c/d= 11/70, 13/70, 15/70. Some of the highest tensile stresses occurring at each stage of the fabrication of the composite are drawn in the Figs. 7—9. In the Fig. 7, residual tensions of the coated fiber at a point A (see Fig. 3) caused by the method II are shown as a function of c/d. It is seen in this Figure that the residual tensions decrease as the ratio of coating thickness to fiber diameter c/d increases. In the Figs. 8 and 9, residual tensions σ_θ and σ_z of the composite at a point B caused by the method II are shown as a function of V_f for various values of c/d. It follows from Figs. 8 and 9 that the residual tensions increase as V_f and c/d increase.

Conclusion

(1) It was found that the melted Ni-coating method (method I) gives rise to a tremendous amount of tension (σ_z) in Ni phase, which presumably leads to cracking of Ni coating. Thus the method I is not desirable as a coating method of Ni on a carbon fiber.

(2) With suitable choices of geometrical parameters, it was found possible to make a Ni-coated graphite fiber/Al 6009 composite without cracking in any phase of the composite by the CDL method using organonickel compound (method II). It has been shown from this parametric study that, in general, the residual tension may be kept below the tensile strength of the material, if we design the composite so as to have sufficiently large c/d and sufficiently small V_f.

(3) Coupled with a possible applied stress field, however, the residual tension (σ_θ and σ_z) in Al phase may reach the tensile strength of Al rather easily. To reduce the residual tension, it would be desirable to lower the fabrication temperature of the composite by the CDL method using triisobutylaluminum for Al.[2]

(4) It should be also noted that since our calculation is based on the elasticity assumption of the model, it tends to give rise to a higher residual tension. Thus we may be able to fabricate a flawless composite even with a slightly smaller ratio of coating thickness to fiber diameter c/d, and with a slightly larger volume fraction of the fiber V_f than prescribed by our calculation.

Behavior of the Heat of Formation in the Bismuth-Antimony System

Walid Ahmad BADAWI
Department of Chemistry, Faculty of Science, Al-Fateh University, Tripoli, Libya
(Received December 2, 1985)

Calorimetric studies on the behavior of the heat of formation in the bismuth-antimony system have been carried out at eight different compositions (10—80 at-% Sb). Values of the enthalpy and excess enthalpy at those compositions have been determined and tabulated at even temperature intervals of 10 °C in the range 50 to 650 °C. The heat of formation at 200 °C is given through the equation:

$$H^F = 11.658x_2 - 14.436x_2^2 + 2.778x_2^3$$

The heat of formation is positive and takes a maximum value (2556±11) J mol^{-1} at 50 at-% Sb. The heat of formation is larger than the heat of mixing. The excess over the value of the heat of mixing is attributed to the larger excess volume in the solid state.

There has been considerable interest in the study of thermodynamic properties of binary systems of metals and metalloids. One such system, namely bismuth-antimony has been studied by some researchers e.g. phase diagram by Hansen and Anderko[1] and heat of mixing at 700 °C by Wittig and Gehring.[2]

The present study has been undertaken with the purpose of studying the behavior of the heat of formation in the bismuth-antimony system and of obtaining the ratio of the heats of formation to those of mixing. This would facilitate interpolation of the behavior of the heat of formation at positions having indefinite structures in other binary systems.

Experimental

Sample. The samples were prepared at eight different mole fractions of antimony between 0.1 and 0.8. The metals in the form of bars were procured from E. Merck Company. These were of chemically pure grade. The alloy samples were produced in a melting device operating as "Zintl funnel" system (Fig. 1). By this melting device, while the clean liquid metal flows down into the lower tube of quartz, the oxide layer remains apart in the first one. The mixture of metals was stirred mechanically with a stirrer made of ceramic for 30 min at 700 °C. In order to reduce the effect of oxidation, argon gas was used as a protector during the melting process.

The samples of 10—40 at-% Sb were tempered for 70 h at 200 °C, those of 50—80 at-% Sb at 280, 300, 320, and 380 °C for 70 h at each temperature. The homogeneity of all the compositions studied was established through testing the polished pictures prepared as described by Czochralsky and Przyjemski.[3]

Apparatus. The measurements of enthalpies were carried out using the calorimeter described and utilized by Wittig and co-workers.[4] Modifications on the calorimeter, alteration to the suitable dimensions, regulation of the furnace temperature by means of a p-regulator[5] and using a digital millivoltmeter for measurement of the potential of the thermocouples, revealed satisfactory result.

Procedure. The procedure used depended on the method of primary indirect provision of energy under adiabatic conditions. (see Ref. 6).

The heat of formation can be computed through the equations:

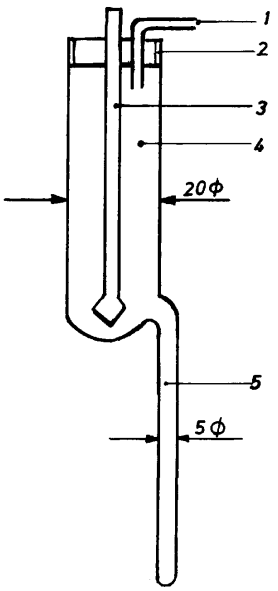

Fig. 1. Melting device.
1 : Gas supply, 2 : sealing, 3 : stirrer, 4 : quartz tube, 5 : quartz tube.

$$(1-x_2)\cdot Bi_{(l)} + x_2\cdot Sb_{(s)} \longrightarrow Bi_{1-x_2}Sb_{x_2(s)} - H^{F,M}$$
$$(1-x_2)\cdot Bi_{(s)} \longrightarrow (1-x_2)\cdot Bi_{(l)} - H_{Bi}^{s}$$

$$(1-x_2)\cdot Bi_{(s)} + x_2\cdot Sb_{(s)} \longrightarrow Bi_{1-x_2}Sb_{x_2(s)} - [H^{F,M} + (1-x_2)H_{Bi}^{s}]$$

$$H^F = H^{F,M} + (1-x_2)\cdot H_{Bi}^{s} \quad (1)$$

where H^F is the heat of formation of solid bismuth and antimony, $H^{F,M}$ the heat of formation at the temperature of mixing, H_{Bi}^{s} the heat of fusion of bismuth and x_2 the mole fraction of antimony. $H^{F,M}$ can be calculated with reference to the Helmholtz equation:

$$H^F(T_1) - H^F(T_0) = {}^eH(T_1) - {}^eH(T_0) \quad (2)$$

T_0 refers to the initial temperature, T_1 to any higher temperature and ${}^eH(T_1)-{}^eH(T_0)$ to the difference of the excess enthalpy which is given by

$${}^eH(T_1) - {}^eH(T_0) = [H_3(T_1)-H_3(T_0)] - (1-x_2)\cdot[H_1(T_1)-H_1(T_0)] - x_2\cdot[H_2(T_1)-H_2(T_0)] \quad (3)$$

The indices 1, 2, and 3 indicate bismuth, antimony, and the alloy, respectively. The enthalpies of the alloys were measured at even temperature intervals of 10 °C in the region 50 to 650 °C. The enthalpy differences between T_0 and T_1 for bismuth and antimony are reported and tabulated (see Ref. 7). The heat of mixing values are reported by Wittig and Gehring.[2)]

Results and Discussion

Results of the enthalpy measurements are presented in Table 1 at even temperature intervals of 10 °C in the range 50 to 650 °C. The values of the excess enthalpy are listed in Table 2 at even temperature intervals of 10 °C in the same region of temperature.

The data in Table 3 represent the integral and partial heat of formation at 200 °C. The error of the individual measurement was found to be about 1%. The experimental result is in good agreement with the calculated value. Table 3, also illustrate the ξ-values. For $\xi(T)$, the following equation was used:

$$\xi(T) = H^F(T)/x_2 \cdot (1-x_2) \quad (4)$$

The experimentally determined H^F-values were used to obtain a polynomial function for $H^F(T)$. The $H^F(T)$ function was employed together with Eq. 4 to derive the following relation for ξ:

$$\xi = 11.658 - 2.778x_2 \quad (5)$$

Using the ξ-function (Eq. 5) and Eq. 4, the heat of formation is given as a function of x_2 through the equation:

$$H^F(200\,°C) = 11.658x_2 - 14.436x_2^2 + 2.778x_2^3 \quad (6)$$

This equation represents the curve shown in Fig. 3. Table 3 illustrate the H^F-values, calculated with the aid of Eq. 6. These values are presented in brackets.

Table 3. Integral and Partial Molar Heats of Formation; ξ-Values in the Bi-Sb System at 200 °C

x_{Sb}	H^F / kJ mol^{-1} Found (Calcd)	$H_{Bi}{}^F$ / kJ mol^{-1}	$H_{Sb}{}^F$ / kJ mol^{-1}	ξ / kJ mol^{-1}
0.1	1.035 (1.024)	0.139	8.993	11.369
0.2	1.760 (1.770)	0.533	6.750	11.119
0.3	2.294 (2.273)	1.149	4.896	10.805
0.4	2.544 (2.531)	1.954	3.398	10.531
0.5	2.556 (2.567)	2.915	2.222	10.251
0.6	2.378 (2.398)	3.997	1.335	9.972
0.7	2.056 (2.398)	5.168	0.703	9.693
0.8	1.519 (1.501)	6.394	0.294	9.453

The partial molar heats of formation of bismuth and antimony are given by

$$H_{Bi}{}^F = H^F - x_2 \cdot (\partial H^F/\partial x_2)_{T,p} \quad (7)$$

$$H_{Sb}{}^F = H^F - (x_2-1) \cdot (\partial H^F/\partial x_2)_{T,p} \quad (8)$$

Using Eq. 6, we obtain

$$H_{Bi}{}^F = 14.436x_2^2 - 5.556x_2^3 \quad (9)$$

$$H_{Sb}{}^F = 11.658 - 28.872x_2 + 22.778x_2^2 - 5.556x_2^3 \quad (10)$$

The calculated partial molar heats of formation of bismuth and antimony are presented in Table 3.

The data in Table 3 clearly indicate that the heat of formation in the bismuth-antimony system is positive and larger than the heat of mixing. This leads to the

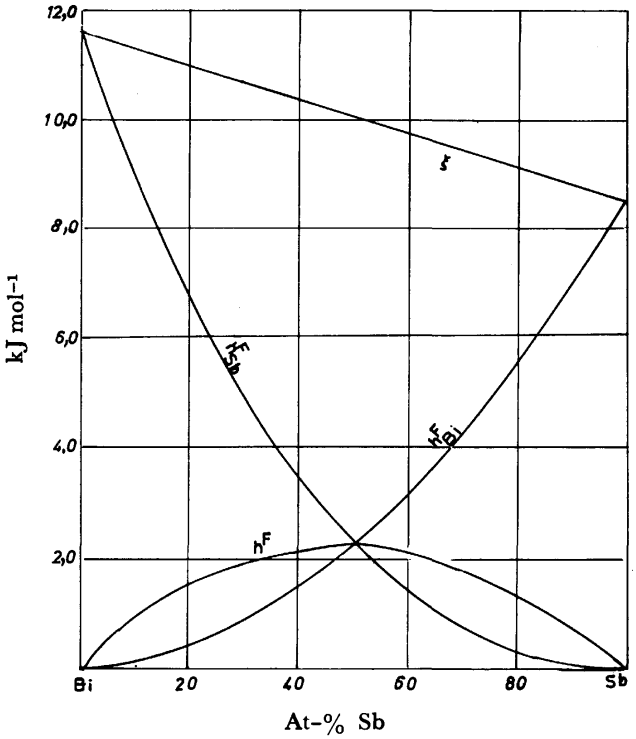

Fig. 2. The heat of formation, ξ-function and partial heats of formation of Bi and Sb in Sb–Bi system at 200 °C.

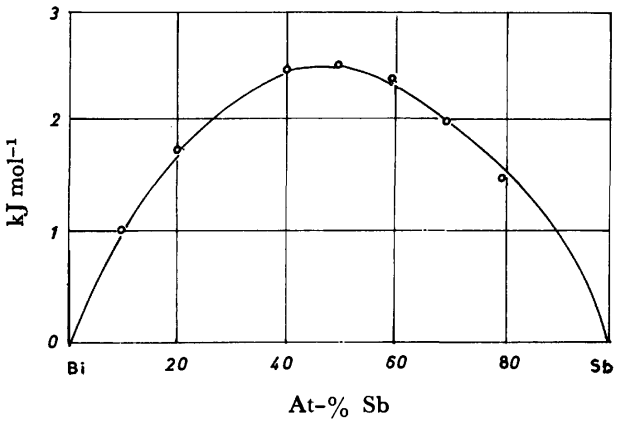

Fig. 3. Heat of formation in Bi–Sb system at 200 °C.

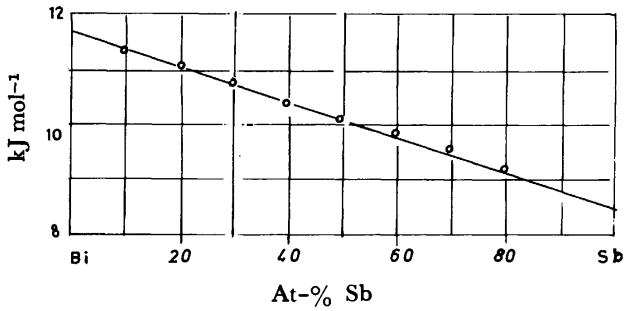

Fig. 4. ξ-Values in Bi-Sb system at 200 °C.

conclusion that there is a larger excess volume in the solid state. Bismuth expands more than antimony on solidification. As a result of this, the maximum of expansion lies at larger bismuth concentration.

Figure 2 shows the curves of the partial molar heats of formation of bismuth and antimony. These curves indicate that the partial heat of formation of bismuth is positive and increases with the increase of antimony mole fraction. The partial molar heat of formation of antimony is also positive but decreases with the increase of antimony mole fraction.

The heat of formation increases with the increase of the antimony mole fraction to reach a maximum at the point $x_{Sb}=0.5$ (Fig. 3); after that the heat of formation decreases with the increase of antimony mole fraction.

With reference to Eq. 5, ξ (200 °C) exhibits a linear function of x_2. Figure 4 represents the experimentally determined ξ-values at 200 °C.

Dissociation Constants of Some Amino Acid and Pyridinecarboxylic Acids in Ethanol-H_2O Mixtures

M. S. K. Niazi* and J. Mollin†
Department of Chemistry, Quaid-i-Azam University, Islamabad, Pakistan
(Received December 24, 1985)

The dissociation constants of nicotinic, picolinic, benzoic, and *o*-, *m*-, and *p*-aminobenzoic acids and those of glycine, *dl*-alanine, β-alanine, aniline, and pyridine were determined potentiometrically and spectrophotometrically in 0, 10, 30, 50, and 72% (w/w) ethanol-water mixtures at 25 °C at various ionic strengths (0.01—0.5 mol dm^{-3}). The pK's of benzoic, *o*-, *m*-, and *p*-aminobenzoic acids increased with increase of EtOH contents while those of nicotinic acid, picolinic acid, glycine, *dl*-alanine, and β-alanine passed through minimum (upto 30% w/w EtOH contents). The pK's of aniline and pyridine were almost the same as those found in literature. The variation in pK's with the solvent composition is discussed in terms of the free energy of transfer from H_2O to EtOH-H_2O mixtures. The zwitterion to neutral molecule ratio of these acids is also discussed in terms of variation of composition of mixtures.

There has been increasing interest during past few years in properties of mixed solvent systems such as water+organic solvent or mixtures of organic solvent themselves.[1] While there have been many physicochemical studies in these mixed solvents, relatively few data are available on the effect of these mixed solvent systems on the dissociation of weak acids or bases.[2-10,20]

Acid-base equilibria of pyridine monocarboxylic acid monoaminobenzoic acids and simple aliphatic amino acids like glycine, *dl*-alanine, β-alanine are well known in aqueous medium[11-13,15,21] as in the following;

$$\begin{array}{ccc} N^+H_3CHRCO_2^- & \underset{-H^+}{\overset{H^+}{\rightleftharpoons}} & N^+H_3CHRCO_2H \\ -H^+\downarrow\uparrow H^+ & \diagdown\!\!\diagup & -H^+\downarrow\uparrow H^+ \\ NH_2CHRCO_2^- & \underset{-H^+}{\overset{H^+}{\rightleftharpoons}} & NH_2CHRCO_2H \end{array} \quad (1)$$

Mostly these substances exist as dipolar zwitterions with varying percentage in aqueous medium. These acids while titrated with strong base and acid dissociate according to Eqs. 2 and 3.

$$K_1 = \frac{[H^+][(N^+H_3CHRCO_2^- + (NH_2CHRCO_2H)]}{[N^+H_3CHRCO_2H]} \quad (2)$$

and

$$K_2 = \frac{[H^+][(NH_2CHRCO_2^-)]}{[(NH_3^+CHRO_2^-) + (NH_2CHRCO_2H)]} \quad (3)$$

Generally, these dissociation constants (K_1 and K_2) have been determined potentiometrically and spectrophotometrically in the UV region.[21]

Protonation of aniline and pyridine and dissociation of acetic and benzoic acids are also known in aqueous medium as well as in some mixed solvents.[6,7]

Some measurement on dissociation, thermodynamic properties and viscosities of glycine, *dl*-alanine and β-alanine are also available in literature.[9,17] We have chosen ethanol (EtOH)-water mixtures of composition 0, 10, 30, 50, and 71.98% weight (w/w) of EtOH. We have determined dissociation constants of pyridine monocarboxylic, benzoic, and acetic acids, aniline, and pyridine in these mixtures titrimetrically and by emf measurements of cells (I) and (II) and spectrophotometrically using the known procedures.[2,14,15,19]

Pt, H_2(1 atm)/HA(m_1), NaA(m_2), NaCl(m_3)/AgCl-Ag (I)

Pt, H_2(1 atm)/B+H(m_1), B(m_2), NaCl(m_3)/AgCl-Ag (II)

From these pK values, the free energy of transfer $-\Delta G_{tr}$(dis) of these substances have been calculated and are discussed in terms of the effect of composition of solvent mixtures. Some attempts have been made for evaluation of the ratio of (dipolar) zwitterionic form to neutral molecular form of these amino acids in these EtOH-H_2O mixtures.

Experimental

All the substances under study were reagent grade product from Lachema BRNO. Ethanol was of a spectral grade purity from Lachema BRNO and was used without further purification. Doubly distilled conductivity water was used as aqueous medium as well as for preparation of EtOH-H_2O mixtures in a weight by weight composition.

For the determination of pK's, ethanolic and aqueous solutions of the substances under investigation were prepared. The ionic strengths (μ=0.1, 0.2, 0.3, and 0.5 mol dm^{-3}) were maintained with sodium perchlorate (reagent grade, Lachema, BRNO). Titrations were performed with 0.1 M†† sodium hydroxide or perchloric acid (both reagent grade, from Lachema BRNO and Jenapharm respectively) in the same solvent. The pH's were measured using a glass electrode with calomel electrode in aqueous medium and with 0.1 M silver-silver chloride electrode in EtOH-H_2O mixtures at 25 °C. A titration vessel was kept in a thermostat at 25±0.01 °C. The electrode assembly was

† Present address: Department of Inorganic and Physical Chemistry, Palacky University, Olomouc, Czechoslovakia 77000.

†† 1 M=1 mol dm^{-3}.

calibrated with buffer solutions prepared according to literature.[2,7,19] The UV spectra for 10^{-4}—5×10^{-5} mol dm^{-3} solutions in water or mixtures were obtained with a Pye Unicam SP 1800 spectrophotometer. For spectrophotometric determination of pK's, solutions of the substances were mixed with solutions of perchloric acid of various concentrations or with mixtures of 0.1 M perchloric acid and 0.1 M KH_2PO_4 (reagent grade Lachema, BRNO) in water or ethanolic mixtures. During these experiments pH was measured with a hydrogen electrode against references as mentioned above. The emf's of cells (I) and (II) were also measured with the same pH meter. Solutions of the substances were half neutralized with 0.1 NaOH or 0.1 M $HClO_4$ before putting in cell (I) and cell (II).

Calculations and Results

The pK's of weak acid (HA) and a base (BH^+) with the dissociation processes $HA \overset{K_1}{\rightleftharpoons} H^+ + A^-$ and $BH^+ \overset{K_2}{\rightleftharpoons} B + H^+$ were evaluated from the following equations:

$$pK_1 = pH - \log\frac{[A^-]}{[HA]} - \log\gamma_{A^-} = pK_1' - \log\gamma_{A^-} \quad (4)$$

$$pK_2 = pH - \log\frac{[B]}{[BH^+]} + \log\gamma_{BH^+} = pK_2' + \log\gamma_{BH^+} \quad (5)$$

Here, $\log\gamma_{A^-}$ and $\log\gamma_{BH^+}$ were calculated from the Debye-Hückel limiting law (DHLL).[14,15] The values of densities and dielectric constants of water and EtOH-H_2O mixtures at 25 °C were taken from literature.[2,7,19] The values of the radii of these substances used in DHLL were from 3—10 Å. The pK's measured at different μ were plotted against $\mu^{1/2}$ and extrapolated to μ=0, the values being listed in Table 1.

For the evaluation of pK's by the emf method, Eqs. 6 and 7 were used.[2,19,22]

$$E = E^\circ_{Ag\text{-}AgCl} + \frac{2.303}{F}RT\log[(m_{H^+}\cdot\gamma_{H^+})\cdot(m_{Cl^-}\cdot\gamma_{Cl^-})] \quad (6)$$

$$pK = p\overset{*}{a}_H = -\log m_{H^+}\cdot\gamma_{H^+} = \frac{E - E^\circ_{Ag\text{-}AgCl}}{0.0591} + \log\gamma_{Cl^-} + \log m_{Cl^-} \quad (7)$$

where values of $E^\circ_{Ag\text{-}AgCl}$ in these mixtures and water were taken from literature.[2,19] These pK'a calculated by Eq. 7 were plotted against $\mu^{1/2}$ and extrapolated to μ=0 and are given in Table 1. It was found that these pK's are in accord within ±0.02 pK units with those determined by the potentiometric titration method.

The spectrophotometric data were used in Eq. 8 for calculations of pK's.

$$pK = pH + \log\frac{(A - A_2)}{(A_1 - A)} \quad (8)$$

where A_1 and A_2 are absorbances of substance in acidic and basic media while A is absorbance at some other

pH of medium.[14,15,21] The pK's found by this method agree within ±0.03 units of pK with those obtained by the emf method. Therefore, Table 1 gives the average values of pK's of these substances obtained by three methods.

The free energy change in the transfer of these substances from H_2O(w) to EtOH-H_2O(s) mixtures was evaluated from Eq. 9 at 25 °C and are given in Table 2.

$$\left.\begin{aligned}\Delta G_{tr}(dis) &= 2.303\,RT(pK_a^s - pK_a^w)\\ &= 5.70(\Delta pK_a)\end{aligned}\right\} \quad (9)$$

Where pK_a^s and pK_a^w are dissociation constants in EtOH-H_2O mixtures and in H_2O respectively. The change in proton affinity ΔP_a of conjugate base ($\bar{A}$) of these acids on transfer from H_2O to H_2O+cosolvent were calculated by Eq. 10 at 25 °C and are given in Table 3.

$$\Delta P_a = 5.70\ (\Delta pK_a) + \Delta G_{tr}(H^+) - C \quad (10)$$

Here constant C=5.70 log (18.01 d_s/$M_s \cdot d_w$) in molar scale. The average mass M_s of EtOH-H_2O mixtures were calculated from Eq. 11.

$$M_s = 100/(\text{wt\% EtOH}/46.00) + (\text{wt\% } H_2O/18.016) \quad (11)$$

and $\Delta G_{tr}^{\circ}(H+)$ are free energies of transfer of proton from H_2O to EtOH-H_2O mixtures and were taken from literature.[23]

Discussion

The reproducibility of the measurements was ±0.01 both in the titrimetric as well as in the emf measurements and was ±0.03 in the spectrophotometric measurements. The pK values of all substances determined are in good agreement with earlier reported values in some EtOH-H_2O mixture.[2,7,9,19,24]

In Fig. 1, pK's of nicotinic and picolinic acids, glycine, *dl*-alanine, and *β*-alanine have been plotted against the reciprocal of dielectric constants (ε^{-1}) of EtOH-H_2O mixtures. These pK's decrease as the concentration of EtOH increases upto 30% (w/w) in the EtOH-H_2O mixtures and increase again in mixtures of higher EtOH contents. On the other hand pK's of *o*-, *m*-, and *p*-aminobenzoic acids (Table 1) and those of acetic acid[6] increase with increase in

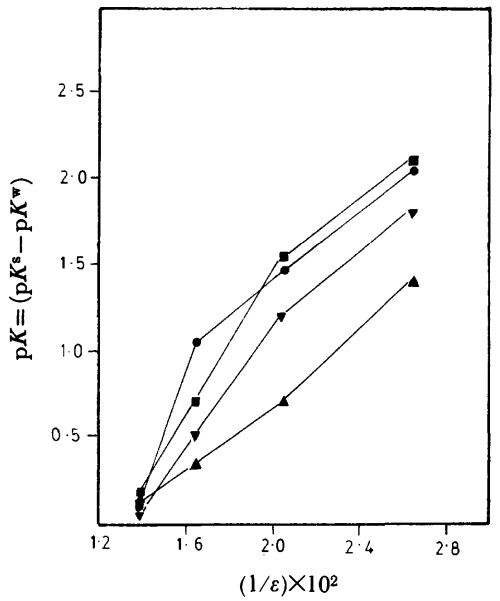

Fig. 2. Dependence of ΔpK of benzoic (●), *o*-(▲), *m*-(▼), and *p*-aminobenzoic acid (■) on inverse of permitivities (ε^{-1}) of EtOH-H_2O mixtures.

EtOH contents in EtOH-H_2O mixtures in a similar way as observed in case of benzoic acid (Fig. 2). It means that these aminobenzoic acids exist with stable structure as benzoic acid in EtOH-H_2O mixtures when ethanol contents are more than 10% (w/w). Further pK_1's of three aminobenzoic acids go on decreasing with increase of EtOH percentage in the same way as observed in case of aniline (Table 1). Therefore, one can postulate that *o*-, *m*-, and *p*-aminobenzoic acids exist as neutral molecules in EtOH-H_2O mixture rather than zwitterions as found in aqueous medium.

The anomalous dependence of pK_2's of glycine, *dl*-alanine, *β*-alanine, nicotinic, and picolinic acids on composition of EtOH-H_2O mixtures (Fig. 1) can be attributed to changes in structures of these acids when they transfer from H_2O to EtOH-H_2O media. Chattopadhyay et al.[9] have determined pK's of glycine, *dl*-alanine, *β*-alanine in some EtOH-H_2O mixtures and have evaluated K_Z (ratio of zwitterions to neutral molecules) of these acids with conclusion that this ratio (K_Z) decreases with increase of EtOH contents inferring preferential solvation of zwitterions with water and neutral molecules with alcohol. Wada et al.[20] have also determined the K_Z values of glycine in various water+organic solvent mixtures and have concluded that the K_Z value of glycine decreases with increase in the mole fraction of organic solvent. Khan et al.[3] have also postulated these results for nicotinic acid using ^{1}H NMR spectroscopy in DMSO-H_2O media and have pointed out that nicotinic acid exists in a neutral from in 80:20% DMSO-H_2O mixture.

In the present work, we have also chosen not only

nicotinic acid but its ethyl ester and trigonelline as model compounds. Table 1 shows that pK's of trigonelline almost did not change with change in composition of EtOH-H_2O mixtures. However, pK's of ethyl nicotinate and nicotinic acid decreased with increase of EtOH and become almost equal in 50 and 72% EtOH-H_2O mixtures. This decrease in pK values of nicotinic acid and its ethyl ester follows from the same course of decreasing as observed in case of pyridine with increase in EtOH (Table 1). As it has been assumed in literature[9,11,13] $K_Z=(K_1-K_E)/K_E$, one can verify that from the present values of K_1 and K_E of nicotinic acid and its ethyl ester, K_Z is equal to zero in 50% EtOH-H_2O mixtures. This procedure was also followed by Chattopadhyay et al.[9] in case of glycine and *dl*-alanine, etc.

Figure 3 (I—IV) are UV absorption curves of nicotinic acid, its ethyl ester and trigonelline at isoelectric points in 10, 30, 50, and 72% EtOH-H_2O mixtures at 25 °C. The UV spectra of these compounds show that nicotinic acid and its ethyl ester have similar absorption curves in 50 and 72% EtOH-H_2O mixtures but differ in H_2O and 10% EtOH-H_2O mixture. These spectra further assist in concluding that nicotinic acid exists as in a neutral form in EtOH-H_2O mixtures rather than zwitterions as found in aqueous medium.

Table 2 gives the values of free energy change ($-\Delta G_{tr}$(dis)) of dissociation on transfer of these acids from H_2O to EtOH-H_2O mixture. As shown in Fig. 2, the pK's of aminobenzoic acids and benzoic acid are not linear with variation of composition of EtOH-H_2O mixtures. Almost all compounds studied in the present work show remarkable deviation from $\Delta pK_a'$ calculated by using Born's equation.

$$pK_a = 122\left(\frac{1}{\varepsilon_r} - 0.0128\right)[(1/r_{H^+} + 1/r_{A^-})]$$

These deviations suggest that the effect of the EtOH-H_2O mixtures on the acidity of these amino

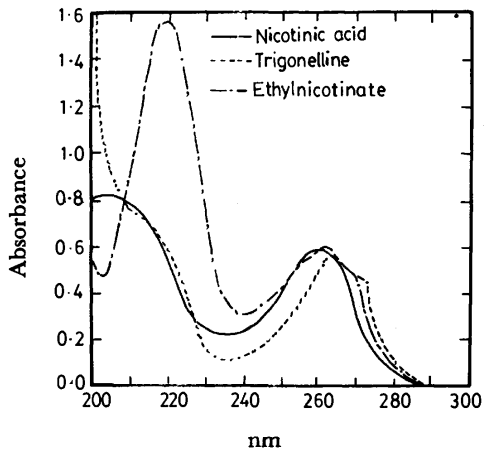

Fig. 3(I). UV spectra of nicotinic acid and its ethylester and trigonelline in 10% EtOH-H_2O mixture, at 25 °C, pH 3.43.

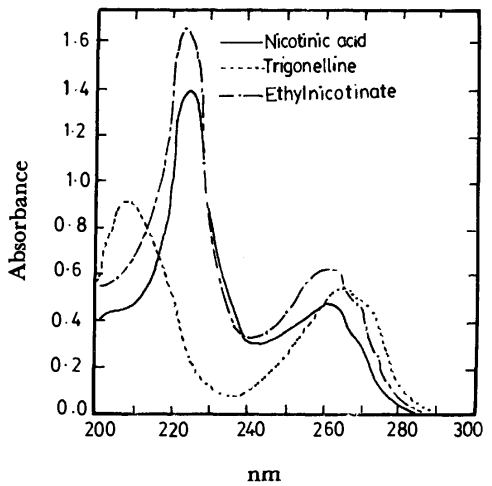

Fig. 3(IV). Same as above in 70% EtOH-H_2O mixture of pH 3.25, at 25 °C.

acids does not depend solely on electrostatic features, as predicated by Born's theory. It may also be caused by ignoring the variation in dielectric constant of the solvent molecules in the vicinity of an ion[25] and of specific change in $RH^{\mp} \rightleftharpoons RH$ i.e. from zwitterions to to neutral molecular form of these acid. If one divides G_{tr}(dis) into ΔG_{tr}(el) - electrostatic free energy and ΔG_{tr}(chem) - the non-electrostatic chemical free energy parts, of all these compounds, it is found that the contribution of the chemical free energy increases as the EtOH concentration is raised in case of aminobenzoic and benzoic acids but it passes through minimum in case of glycine, *dl*-alanine, *β*-alanine, and pyridine monocarboxylic acids. Again previous conclusion can be drawn.

The calculations of proton affinities ($-\Delta P_a$) of the corresponding conjugate bases of these amino acids are given in Table 3 in kJ mol^{-1}. These values show that again glycine, *dl*-alanine, *β*-alanine, and pyridinecarboxylic acids are grouped together giving similar trend in variation of ΔP_a with composition of EtOH–H_2O mixtures. While aminobenzoic acids are grouped together. Therefore, the present study fully supports the conclusion that these amino acids exist as in neutral molecular form in low polarity organic solvent mixtures with water rather than zwitterions as observed in aqueous medium.

Similar results are being found in some methanol-water mixtures and free enthalpy and entropy changes on dissociation of these amino acids are being measured in EtOH–H_2O mixture. These results will be published elsewhere in a near future.

Approximate Formulas for Hosoya's Topological Index

Ivan GUTMAN* and Zoran MARKOVIĆ
Faculty of Science, University of Kragujevac, P.O.Box 60,
YU-34000 Kragujevac, Yugoslavia
(Received June 30, 1986)

Approximate formulas for Hosoya's topological index (Z) are reported for the first time. These formulas reproduce ln Z with an error of some 1—2% and require the knowledge of only a few easily obtainable invariants of the molecular graph.

The topological index Z was introduced by Hosoya[1] in 1971. Since then numerous scientific results on this quantity have accumulated[1-11] revealing the importance of Z in various branches of theoretical chemistry and theoretical physics. In particular, the relations between Z and several physicochemical properties of alkanes are nowadays well established.[3,5,7,10] Hosoya also showed[2] that Z and the closely related nonadjacent numbers play a significant role in the molecular orbital theory of conjugated π-electron systems.

This later resulted in the introduction of the modified topological index,[12] topological bond order,[13,14] matching polynomial,[15-17] a novel theory of aromaticity,[18,19] novel approach to total π-electron energy,[12,20] π-electron charge distribution[21] etc.

A detailed account of various applications of the index Z and especially of its mathematical properties can be found in Chapter 11 of the book.[11]

In spite of such a great interest towards Hosoya's topological index, no attempts seem to have been made to find approximate methods for its calculation. This is even more surprising if one knows that the evaluation of Hosoya's index is a very hard combinatorial task, especially in the case of large polycyclic molecules. In the present paper we wish to fill this gap and to provide a class of reliable approximate formulas for Z, enabling its estimation from a number of easily obtainable invariants of the molecular graph.

Preliminaries

Hosoya's topological index is defined as[1]

$$Z = Z(G) = \sum_{k=0}^{h} m(G,k),$$

where $m(G,k)$ is the number of k-matchings of the molecular graph G. This means that one can select k independent edges in G in $m(G,k)$ distinct ways; therefore $m(G,k)$ is often called the k-th nonincident number of G.

In what follows the molecular graph considered will be assumed to possess n vertices and m edges, whereas h will denote the size of the maximal matching (i.e. $m(G,h)\neq 0$, $m(G,h+1)=0$). Note that $m(G,1)=m$ and $h\leqslant n/2$. Besides, by definition, $m(G,0)=1$ for all graphs G.

The Z-counting polynomial

$$Q(x) = \sum_{k=0}^{h} m(G,k)x^k$$

is an auxiliary quantity, introduced within the theory of Hosoya's index,[1] with the immediate property

$$Q(1) = Z.$$

A less obvious property of $Q(x)$ is that all its zeros are real and negative numbers.[17] Therefore we can write the Z-counting polynomial as

$$Q(x) = \prod_{i=1}^{h} (1+p_i x)$$

where $p_i>0$ and $-1/p_i$ is a root of $Q(x)=0$, $i=1,2,\cdots,h$. Consequently,

$$Z = \prod_{i=1}^{h} (1+p_i).$$

The Approximation

The basic idea of the present consideration is to approximate the Z-counting polynomial $Q(x)$ by means of another polynomial $Q^{\times}(x)$,

$$Q^{\times}(x) = (1+Ax)^t(1+Bx)^{h-t} \tag{1}$$

and to adjust the parameters A and B so that the first three coefficients of $Q^{\times}(x)$ and $Q(x)$ coincide:

$$Q^{\times}(x) = 1 + m(G,1)x + m(G,2)x^2 + \cdots . \tag{2}$$

$Q^{\times}(1)$ would then provide an approximate expression for Z.

Combining Eqs. 1 and 2 we arrive at

$$tA + (h-t)B = m(G,1) \tag{3a}$$

$$\binom{t}{2}A^2 + \binom{h-t}{2}B^2 + t(h-t)AB = m(G,2). \tag{3b}$$

It is easily seen that the approximation $Q(x)\approx Q^{\times}(x)$ is equivalent to the assumption that among the zeros of $Q(x)$, t of them are mutually equal and the remaining $h-t$ zeros are also mutually equal. The problems arising in connection with the choice of the third parameter in Eq. 1, namely t, will be discussed in the subsequent section.

Bearing in mind that

$$m(G, 1) = m,$$

and

$$m(G, 2) = (m^2+m-d)/2,$$

where d denotes the sum of the squares of the vertex degrees of the graph G, we can transform the Eqs. 3a and 3b into the form

$$tA + (h-t)B = m \tag{4a}$$

$$tA^2 + (h-t)B^2 = d-m. \tag{4b}$$

The solution of the system (4) in which we are interested in is

$$A = (m+RS)/h, \tag{5}$$

$$B = (m-R/S)/h, \tag{6}$$

where

$$R = \sqrt{hd-m^2-hm}, \tag{7}$$

$$S = \sqrt{(h-t)/t}.$$

We show now that R is necessarily a real quantity. In order to do this note that the right-hand sides of Eqs. 4a and 4b are equal to the sum of the numbers $p_1, p_2, \cdots, p_h$ and $p_1^2, p_2^2, \cdots, p_h^2$, respectively. Since the inequality

$$\left(\frac{1}{n}\sum_{i=1}^{n} x_i\right)^2 \leqslant \frac{1}{n}\sum_{i=1}^{n} x_i^2$$

holds for arbitrary numbers $x_1, x_2, \cdots, x_n$, we conclude that

$$\left(\frac{1}{h}\sum_{i=1}^{h} p_i\right)^2 \leqslant \frac{1}{h}\sum_{i=1}^{n} p_i^2$$

i.e.

$$\left(\frac{1}{h}m\right)^2 \leqslant \frac{1}{h}(d-m)$$

i.e.

$$hd - m^2 - hm \geqslant 0$$

which is a sufficient condition for the reality of R.

It is now immediate to conclude that A is positive for all $1 \leqslant t \leqslant h-1$ whereas B is positive for $1 \leqslant t \leqslant T$; where T stands for the integer part of $m^2/(d-m)$.

Substituting Eqs. 5 and 6 back into Eq. 1 and setting $x=1$, we arrive at

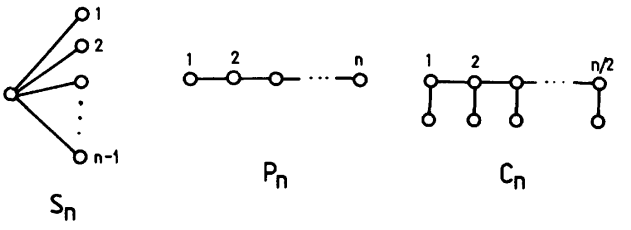
$$Z^x = Z^x(t) = [1+(m+RS)/h]^t[1+(m-R/S)/h]^{h-t} \tag{8}$$

which is the required algebraic expression for our approximate formulas for Hosoya's index Z.

As a matter of fact, it can be shown[23] that $Z^x(t)$ is a monotonously decreasing function of the parameter t and that for $t=1$, $Z^x(t)$ is an upper bound for Z.

The Function Z^x of Some Series of Graphs

In order to illustrate Eq. 8 we have examined the function Z^x for three classes of graphs, namely for the star S_n, the path P_n, and the comb C_n:



Both S_n, P_n, and C_n have n vertices and $n-1$ edges. Their topological indices are given as

$$Z(S_n) = n$$

$$Z(P_n) = \frac{1}{\sqrt{5}}\left[\left(\frac{1+\sqrt{5}}{2}\right)^{n+1} - \left(\frac{1-\sqrt{5}}{2}\right)^{n+1}\right]$$

$$Z(C_n) = \frac{1}{\sqrt{8}}[(1+\sqrt{2})^{n/2+1} - (1-\sqrt{2})^{n/2+1}].$$

For the star S_n we have $h=1$ and $d=(n-1)\cdot 1^2+1\cdot(n-1)^2=n(n-1)$ and therefore $R=0$. Consequently, $Z^x(S_n)=Z(S_n)$ for all values of n.

In the case of the path P_n, $h=n/2$ if n is even and $h=(n-1)/2$ if n is odd. Furthermore, $d=2\cdot 1^2+(n-2)\cdot 2^2=4n-6$. Substituting this back into Eqs. 7 and 8 we obtain an expression for $Z^x(P_n)$ whose form considerably differs from that of $Z(P_n)$. However, for large values of n,

$$Z^x(P_n) \approx t^{-t/2}(4n/9)^{t/2}(\sqrt{3})^n$$

whereas

$$Z(P_n) \approx \frac{1+\sqrt{5}}{2\sqrt{5}}\left(\frac{1+\sqrt{5}}{2}\right)^n.$$

This means that for large n, the logarithms of $Z(P_n)$ and $Z^x(P_n)$ are linearly proportional and, in particular,

$$\lim_{n\to\infty} \ln Z(P_n)/\ln Z^x(P_n) = [\ln(1+\sqrt{5})-\ln 2]/[(\ln 3)/2]$$

$$= 0.88$$

The above limit is independent of the parameter t and is not very different from the value 0.91, estimated for alkanes by least squares fitting (see later).

The case of the comb C_n is similar. Here $h=n/2$, $d=5n-10$ and for large values of n,

$$Z^x(C_n) \approx t^{-t/2}(5n/9)^{t/2}3^{n/2}$$

whereas

$$Z(C_n) \approx \frac{1+\sqrt{2}}{\sqrt{8}}(1+\sqrt{2})^{n/2}.$$

Therefore also the logarithms of $Z(C_n)$ and $Z^x(C_n)$ are linearly proportional and

$$\lim_{n\to\infty} \ln Z(C_n)/\ln Z^x(C_n) = \ln(1+\sqrt{2})/\ln 3 = 0.80.$$

The above examples can be generalized. Let G_1, G_2, $\cdots$, G_n, $\cdots$ be a series of graphs, such that G_{i+1} has

more vertices than G_i. Suppose that the parameter $d(G_n)$ is a linear function of n, say

$$d(G_n) = pn + q. \quad (9)$$

Suppose further that the limit L,

$$L = \lim_{n\to\infty} m(G_n)/h(G_n) \quad (10)$$

exists. Then for large values of n, the function $Z^x(G_n)$ behaves asymptotically as

$$Z^x(G_n) \approx t^{-t/2}\left(\frac{\sqrt{p}}{1+L}\right)^t (1+L)^{h(G_n)}.$$

Note that the conditions (9) and (10) are fulfilled for practically all molecular graphs. Furthermore, in almost all cases of chemical interest, the limit L equals to 2 and $h(G_n)\sim n(G_n)/2$.

Numerical Work

As already indicated in the previous section, a good linear correlation exists between ln Z and ln Z^x. We have examined this correlation on two samples of molecules—the hexanes, heptanes, octanes, and decanes from the book[24] (a total of 141 alkanes) and the benzenoid hydrocarbons from the paper[25] (a total of 116 benzenoid molecules). The results obtained are presented in Tables 1 and 2. Two approximate formulas have been investigated, viz.

$$\ln Z = a_0 \ln Z^x \quad (11)$$

$$\ln Z = a_1 \ln Z^x + b_1 \quad (12)$$

and the coefficients a_0, a_1, and b_1 calculated by least squares fitting.

The parameter t in Eq. 8 needs not be necessarily considered as an integer and we have examined the correlations of the type (11) and (12) for both integer and noninteger values of t, $0<t\leqq T$. Our calculations show, however, that the accuracy and the reliability of the approximations (11) and (12) are not very sensitive to the choice of t. If t is set to be a constant, then $t=1$ in the case of alkanes, and $t=2$ in the case of benzenoids gave the best results. For benzenoids a somewhat better correlation between Z and Z^x is found when t is adjusted to be equal to $T/2$.

The choice $t=T$ gave the worst correlation in both cases.

Table 1. Correlation between Hosoya's Index and $Z^x(t)$ in the Case of Alkanes with 6, 7, 8, 9, and 10 Carbon Atoms[24]

t	Formula	a_0 or a_1	b_1	Correlation coefficient	Mean error %	Max. error observed %
1	11	0.9707	—	0.995	1.4	3.0
1	12	0.9145	0.2224	0.995	1.1	3.0
$T/2$	11	0.9698	—	0.993	1.4	3.6
$T/2$	12	0.9507	0.0757	0.993	1.3	3.9
T	11	1.0200	—	0.984	2.0	6.1
T	12	1.0144	0.0212	0.984	2.0	6.2

Discussion

Our final conclusion is that in the case of alkanes

$$\ln Z = 0.914 \ln Z^x(t) + 0.222;\ t = 1,$$

whereas in the case of benzenoid hydrocarbons (as well as other polycyclic conjugated molecules)

$$\ln Z = 0.951 \ln Z^x(t) + 0.082;\ t = T/2$$

should be used for the approximate calculation of Hosoya's topological index. These formulas estimate ln Z with an error of some 1—2%, which is an acceptable accuracy for all practical applications of Hosoya's index.

The above formulas have been designed so to reproduce the topological indices of medium sized molecular graphs. However, in view of the three examples examined in a previous section, one may expect that formulas of the type (11) are capable to estimate the (logarithms of the) Hosoya indices of very large molecular graphs and infinite networks.

The right-hand sides of the above approximate expressions depend on the following invariants of the molecular graph: Number of edges (m), vertex degree sequence and size of the maximal matchings (h). The number of vertices and the number of maximal matchings play no (explicit) role in the present approach.

All the required invariants are easily obtained by inspection of the molecular graph. In particular, in the case of acyclic molecular graphs (i.e. molecular graphs of alkanes), $h=(n-n_0)/2$, where n is the number of vertices and n_0 is the number of isolated vertices which are obtained from the molecular graph by deleting from it a vertex of degree one and its first neighbor, and by repeating this deletion procedure

Table 2. Correlation between Hosoya's Index and $Z^x(t)$ in the Case of Benzenoid Hydrocarbons[25]

t	Formula	a_0 or a_1	b_1	Correlation coefficient	Mean error %	Max. error observed %
1	11	0.9166	—	0.9992	0.7	5.0
1	12	0.8917	0.3355	0.9992	0.6	4.0
2	11	0.9359	—	0.9995	0.8	10.2
2	12	0.9015	0.4554	0.9995	0.4	2.2
$T/2$	11	0.9574	—	0.9996	0.4	1.4
$T/2$	12	0.9511	0.0818	0.9996	0.4	1.4
T	11	1.0410	—	0.997	0.9	3.6
T	12	1.0282	0.1569	0.997	1.0	4.7

as long as it is possible. For practically all benzenoid hydrocarbons, $h=n/2$ if n is even and $h=(n-1)/2$ if n is odd.

Activation Parameters of Bromoacetate-Thiosulfate Reaction in Ethylene Glycol-Water Mixtures

Prasanta Kumar Biswas, Anwarul Maula, and Mihir Nath Das*
Department of Chemistry, Jadavpur University, Calcutta 700032, India
(Received July 3, 1986)

The activation parameters for the reaction between bromoacetate ($\bar{R}$) and $S_2O_3^{2-}$ ions in water and aqueous mixtures of ethylene glycol (5—50% by weight) have been evaluated from the rate constants, corresponding to zero ionic strength, at 15, 25, and 35 °C. The standard free energies of transfer (ΔG_{tr}°) of the reacting ions and hence of the transition state ($\Delta G_{tr}^{\neq}$) from water to the mixed media at 25 °C have been determined from the measured solubilities of AgR, TlCl, and $Tl_2S_2O_3$ in the different media, using the reported values of ΔG_{tr}° of Ag^+ and Cl^- ions. Attempts have been made to interpret the kinetic results in the light of solvent properties and free energies of transfer. Although both the reacting ions are destabilized, on adding glycol to the medium, the larger destabilization of the transition state, arising from decreased dielectric constant as well as solvating capacity of the medium, outweighs the combined effects on the reactants leading to reduced reaction rates.

The kinetics of the reaction between bromoacetate and thiosulfate ions

$$BrCH_2COO^- + S_2O_3^{2-} = S_2O_3CH_2COO^{2-} + Br^-$$

has been and is still being used as a probe for studying the effects of various factors influencing reaction rates. Medium effects on the kinetics of the reaction have been studied in different types of water-organic mixtures[1-7] as well as in anhydrous methanol and ethylene glycol.[8] Results of kinetic studies on the reaction in aqueous mixtures of ethylene glycol (5—50% by weight) at different temperatures were reported earlier.[7] The free energies of transfer (ΔG_{tr}°) of the two reacting ions and hence of the transition state from water to the water-glycolic media have now been evaluated from solubility measurements, using TlCl, $Tl_2S_2O_3$, and silver bromoacetate (AgR) in the different media at 25 °C. The medium effects on the rates and activation parameters have been discussed in the light of solvent properties and transfer free energies.

Experimental

Ethylene glycol was purified by a standard procedure.[9] Sodium bromoacetate was prepared by the method of Kappana and Patwardhan.[10] Silver bromoacetate (AgR) was prepared by precipitation on adding $AgNO_3$ to sodium bromoacetate solution followed by filtration and thorough washig with cold water. TlCl and $Tl_2S_2O_3$ were similarly prepared by precipitation on adding NaCl and $Na_2S_2O_3$ respectively to saturated solutions of $TlNO_3$.

The solubilities of the three salts in water and the water-glycolic media at 25 °C were determined by titrating measured volumes of the saturated solutions as described below:

For AgR: The titrant was 0.01 M(1 M≡1 mol dm^{-3}) KCNS, and the indicator iron(III) alum,

For TlCl: The titrant was 0.08 M $AgNO_3$, and the indicator K_2CrO_4.

For $Tl_2S_2O_3$: Measured volumes of the saturated solutions were added to measured excess of standard iodine solutions followed by back titration with 0.03 M $Na_2S_2O_3$ using starch as the indicator. The solubilities of TlCl and $Tl_2S_2O_3$ were reproducible within ±2%. For AgR, the solubilities being very low in the glycol-rich media, the errors are higher, but the order of the magnitude is definitely reproducible.

Results and Discussion

The values of the rate constants (k_o) in water and the mixed media[7] at 25 °C corresponding to zero ionic strength, as obtained by extrapolation, and the ratios k_s/k_w are recorded in Table 1, where k_w and k_s are the respective values of k_o in water and any water-glycolic medium. The activation parameters for 25 °C were evaluated from the rate constants (k_o) at 15, 25, and 35 °C, as reported earlier,[7] by the usual method, and recorded in Table 1.

The rate constant decreases with increase in the glycol content in the medium, i.e. with decrease in the dielectric constant, as expected for a reaction between two ions of like charge, $\Delta H^{\neq}$ for the reaction is found to increase with increasing glycol concentration, and so does the value of $\Delta S^{\neq}$ (which is negative for each medium, as expected). Thus, there occurs a reasonable degree of compensation between $\Delta H^{\neq}$ and $T\Delta S^{\neq}$, but the larger effect of $\Delta H^{\neq}$ predominates leading to a monotonic decrease in the reaction rate.

The medium effect on $\Delta H^{\neq}$ may be examined on the basis of the classification of solvents into typically

50	0.43	0.60	56.2	−29.1	85.3	1.3	11.1

aqueous (TA) and typically nonaqueous (TNA) groups.[11,12] The excess functions, G^E and H^E, for aqueous mixtures of ethylene glycol are negative.[12-14] However, ethylene glycol in its aqueous mixtures is considered to form a borderline between the two groups, but leaning more towards TA.[12] On the basis of the model of Caldin and Bennetto,[15,16] the process of the formation of an 'encounter complex' between the reacting ions involves the movement of solvent molecules from the second zone of solvation to the bulk. This second zone is more or less disordered, approximating to an ideal mixture. Hence the excess functions correspond to the changes in the respective thermodynamic quantities occurring in the process of the transfer of the solvent molecules from the second zone to the bulk. If G^E and H^E are negative as for water-glycolic mixtures, this step should tend to decrease $\Delta G^{\neq}$ and $\Delta H^{\neq}$. The experimental results (Table 1) are, however, just the reverse. Obviously other factors predominate. The electrostatic factor definitely operates, leading to increasing $\Delta H^{\neq}$ and $\Delta G^{\neq}$, for the reaction between similarly charged ions, with decreasing dielectric constant. Moreover, decreasing solvation of the transition state may also cause its destabilization. The decreasing magnitude of negative value of $\Delta S^{\neq}$ (Table 1) may be taken to indicate progressive desolvation of the transition state, in comparison with the reacting ions. The desolvation may arise from an overall reduction in the solvating capacity of the mixed medium, as glycol molecules are gradually substituted for water molecules, because of intramolecular hydrogen bond formation between the adjacent OH groups in the glycol molecule.[17,18]

For a better insight into the medium effect on the rates and activation parameters, the results should be examined in the light of the free energies of transfer of the reactants and the transition state.

The standard free energies of transfer (ΔG°_{tr}) of AgR, TlCl, and $Tl_2S_2O_3$ from water to the mixed media were evaluated from the solubility products (K_{sp}) of the salts (Tables 2 and 3) by Eq. 1.

$$\Delta G^\circ_{tr}(\text{salt}) = RT \ln \frac{K_{sp}(w)}{K_{sp}(s)} \quad (1)$$

where w and s refer to water and any mixed medium respectively. The results are recorded in Tables 2 and 3.

The standard free energies of transfer of the bromoacetate ($\bar{R}$) ion from water to the mixed media at 25 °C were calculated by subtracting from ΔG°_{tr} (AgR) the corresponding literature values[19] for the Ag^+ ion (Table 2).

The ΔG°_{tr} values for the $S_2O_3^{2-}$ ion were obtained as described below. The ΔG°_{tr} (Tl^+) values were first calculated by subtracting from the ΔG°_{tr}(TlCl) values (Table 3) the reported values[18] of ΔG°_{tr} for the Cl^- ion. The ΔG°_{tr} values for the $S_2O_3^{2-}$ ion were then evaluated by subtracting the free energies of transfer of two moles of Tl^+, i.e. $2\Delta G^\circ_{tr}$ (Tl^+) from the corresponding values of ΔG°_{tr} ($Tl_2S_2O_3$), as determined in the present work and recorded in Table 3.

The single ion free energies of transfer for Ag^+ and Cl^-, used above, are based on the familiar extrathermodynamic TATB assumption that ΔG°_{tr} for the tetraphenylarsonium (TA^+) ion is the same as that for the tetraphenylborate (TB^-) ion for any particular medium. Wells[17,20] has used a different extrathermodynamic assumption for evaluating single ion free energies of transfer, and his values are in general appreciably different. The TATB assumption is, however, considered to be more sound.[21] Although uncertainties are unavoidably involved in the ΔG°_{tr} values for the single ions because of the extrathermodynamic assumption, some conclusions of a semiquantitative nature can definitely be drawn

therefrom in respect of the medium effect.

The medium effect on the free energy of activation ($m\delta\Delta G^{\#}$) is given by Eq. 2.

$$m\delta\Delta G^{\#} = \Delta G^{\#}(s) - \Delta G^{\#}(w) \quad (2)$$

where w and s denote water and any mixed medium respectively. The standard free energy of transfer of the transition state ($\Delta G^{\#}_{tr}$) is given by Eq. 3.

$$\Delta G^{\#}_{tr} = m\delta\Delta G^{\#} + \Delta G^{\circ}_{tr}(\overline{R}) + \Delta G^{\circ}_{tr}(S_2O_3^{2-}) \quad (3)$$

The values of $m\delta\Delta G^{\#}$ and $\Delta G^{\#}_{tr}$ are shown in Table 1.

From Tables 1—3 it will be seen that for both the reacting ions as well as the transition state, ΔG°_{tr} values are positive, increasing with the proportion of glycol in the medium. The effect on the $\overline{R}$ ion (Table 2) is distinctly larger than that on the $S_2O_3^{2-}$ ion (Table 3). For the transition state (Table 1), however, the transfer free energy ($\Delta G^{\#}_{tr}$) is not only larger than the corresponding value of either of the reacting ions, but preponderates over the combined effect on the two reactants taken together, leading to a reduced rate. Thus, basically it is the large destabilization of the transition state which dictates the resultant medium effect on the reaction rate. The effect, however, is not as pronounced as it might have been, because of the simultaneous destabilization of the reacting, ions, although occurring to a smaller extent.

We thank the University Grants Commission, New Delhi, for the award of fellowships to P. K. B. and A. M. and the authorities of R. B. C. College, Naihati, West Bengal for granting P. K. B. leave of absence.

Zirconium-Bis(triethylamine): A New Class of Chelate Ion and Anion Exchanger

Jagdish Prasad RAWAT,* Masood ALAM,† Hasan M. Abdul AZIZ, and Balbir SINGH††
Department of Chemistry, Aligarh Muslim University, Aligarh-202001, India
(Received August 12, 1985)

A new inorganic ion exchanger, zirconium-bis(triethylamine) has been synthesized. The material has been studied for its anion exchange capacity, sorption capacity, K_d values, composition, infrared spectrum and thermodynamic behavior. Analytically important separation of anions have been achieved. Ion exchange equilibria of $Cr_2O_7^{2-}$, CrO_4^{2-}, SO_4^{2-}, $S_2O_3^{2-}$, and MnO_4^- systems have been studied at 30, 40, 45, and 60 °C. The exchange isotherms have been measured for both forward and backward reactions with solutions of ionic strength 0.10 by batch process. The isotherms showed S shaped curves. The overall thermodynamic data are also calculated.

In the continued effort to synthesize a new inorganic anion exchanger based on metal hydroxides with amino groups, some materials of this kind have been tried: Tin(IV)-bis(diethanolamine),[1] titanium-bis(diethanolamine),[2] aluminium triethanolamine,[3] and thorium triethanolamine.[4] The studies on these materials pave the way to develop some analytically important separations on the basis of their anion exchange behavior and for sorption of metal ions on the basis of their chelating action. Therefore the studies were extended to synthesize another material of this kind, zirconium-bis(triethylamine). The material has been studied for its anion exchange capacity, sorption capacity and distribution of different anions to measure selectivity. Composition and IR studies are made to characterize the exchanger. Thermodynamic study is actually the study of ion exchange equilibrium, which tells the possibility of an ion exchange process, it's spontaneity for different exchange systems can be compared by the free energy concept. Therefore, such a study was made on this exchanger, zirconium-bis(triethylamine).

Experimental

Apparatus. An electric temperature controlled SICO shaker, a Bausch and Lomb Spectronic 20 (USA) and an Elico pH-meter model Li-10 (India) were used for shaking, spectrophotometric determination and pH measurements, respectively.

Reagents. Zirconium dichloride oxide (BDH) and triethylamine (E. Merck) were used. The other chemicals were of analytical grade.

Synthesis. Zirconium-bis(triethylamine) was prepared by mixing 0.10 mol dm^{-3} zirconium dichloride oxide solution with 0.10 mol dm^{-3} solution of triethylamine in the ratio of 1:2 (Table 1). The precipitate thus obtained was kept standing for 24 h at room temperature (25±1 °C). The precipitate was then filtered and washed with deionized water. It was dried in an air oven at 40 °C and then kept in the air for 12 h. The dried material on immersion in water broke down in small pieces. The exchanger granules were converted into nitrate form by keeping in 1.0 mol dm^{-3}

Table 1. Conditions of Preparation and Properties of Zirconium-Bis(triethylamine) Exchanger

Sample	Conditions of synthesis		Mixing volume ratio	Nature of precipitate	Propertie	
	Molarity of reagent

sodium nitrate solution overnight intermittently replacing the supernatant liquid with fresh solution of sodium nitrate. It was finally washed and dried at 40 °C. The anion exchange capacity of zirconium-bis(triethylamine) was determined by column method. The anion exchanger weighing one gram was poured in a glass column measuring 20 cm in length and 0.60 cm diameter with a glass wool support. The capacity was calculated for different anions, namely chromate, dichromate, chloride, bromide, iodide, thiosulfate, sulfate, and thiocyanate by converting the exchanger in the required form with sodium or potassium salts of the required ions. The column was washed with deionized water. The eluent used was 1.0 mol dm^{-3} sodium nitrate. The elution rate was fixed at 0.5 cm^3 min^{-1}. Anion exchange capacities for Cl^-, Br^-, I^-, SO_4^{2-}, $S_2O_3^{2-}$, SCN^-, CrO_4^{2-}, and $Cr_2O_7^{2-}$ were 0.20, 0.16, 0.10, 1.00, 0.27, 0.15, 2.50, and 3.20 meq g^{-1}, respectively.

For sorption capacity 1.0 g of the exchanger was taken in the column, 10.0 cm^3 of 0.10 mol dm^{-3} copper(II) solution was poured over the column at a rate of 0.5 cm^3 min^{-1}. The effluent was then titrated and copper ions were determined. A fresh sample of 10.0 cm^3 of 0.01 mol dm^{-3} copper(II) nitrate was added over the column and the effluent was again titrated. The readings of EDTA consumed for total effluent was subtracted from the reading of EDTA consumed for total influent (0.01 mol dm^{-3} copper nitrate). The sorption capacity was then calculated from these readings. For the determination of copper(II) ions, the solution was titrated against 0.01 mol dm^{-3} EDTA solution using buffer of pH 3.6 and 1-(2-pyridylazo)-2-naphthol (PAN).

The composition of zirconium-bis(triethylamine) was determined by dissolving 1.0 g exchanger in 50.0 cm^3 aqua regia. Heating was avoided for preparing solution. It was then made upto the mark in a 100 cm^3 volumetric flask with deionized water. The amount of zirconium present in the sample was determined by chelometric titrations using copper PAN indicator while quantitative determination of triethylamine in another portion of the sample was done spectrophotometrically by ninhydrin.[5]

To check the chemical stability of the exchanger, zirconium-bis(triethylamine), 0.5 g of the exchanger was shaken with different solvents for 4 h. The amount of zirconium present in the supernatant liquid was determined by titrating a known volume of the solution against EDTA and the amount of triethylamine was determined spectrophotometrically in another sample by ninhydrin. The stability of the exchanger in different solvent systems reveal that the exchanger is stable in deionized water, methyl alcohol, ethyl alcohol, aqueous ammonia (10.0 mol dm^{-3}). However, the exchanger is less stable in concentrated solutions of acids.

Different samples of zirconium-bis(triethylamine) were heated in a muffle furnace for 4 h. The capacity of the exchanger at 60, 100, 150, 200, 300, and 400 °C were determined, respectively.

To characterize the exchanger infrared studies were performed. The spectrum of zirconium-bis(triethylamine) was observed by using KBr disc. The results are presented in Fig. 1.

IR spectrum of zirconium-bis-(triethylamine) exchanger shows the absorption peaks at different values of wave number as given below: (a) A broad peak ranging from 3300—3550 cm^{-1} is due to O-H stretching vibrations. (b) A strong peak at 1380 cm^{-1} is due to C-N vibrations and C-H bending vibrations. (c) A medium peak lies at 2930 cm^{-1} due to C-H stretching vibrations. (d) A strong C-C stretching vibration is observed in the frequency range of 1620—1660 cm^{-1}. (e) A medium C-N bending frequency lies in the frequency range 1070—1080 cm^{-1}, and (f) A medium peak in the frequency range of 800—840 cm^{-1} is observed due to metal oxygen bending vibrations.

pH Titrations of the exchanger were performed by shaking 0.50 g of the exchanger with solution of 0.01 mol dm^{-3} HCl and its salts of 0.01 mol dm^{-3} concentration by Topp and Pepper method.[6] The volume of the reaction mixture was kept 50.0 cm^3 in each case. The pH of the solution was noted after equilibrating the solution for 4 h. Results are plotted in Fig. 2.

K_d Values for anions were determined by batch process.

T.A. = Total adsorption.

1.0 cm^3 of anionic solution was taken in a 50.0 cm^3 volumetric flask. The remaining volume was filled up with NaOH solution in which its distribution studies were to be studied. This solution was then shaken for 4 h with the exchanger weighing 0.50 g in a shaker. The anions which remained in the solution after equilibration were then determined. Total amount of anions were also determined without equilibration. Results of the K_d values in deionized water and different concentrations of sodium hydroxide solutions are summarized in Table 2.

The anions having large differences in K_d values were tried for the separations. The column was prepared using 2.0 g of the exchanger (150—200 mesh size) in nitrate form in a glass column having a height of 30 cm and diameter 0.60 cm. A mixture of anionic solutions was poured on to the column. The solution was allowed to flow down very slowly through the column. These anions were adsorbed at the top of the exchanger bed forming initial zone. Column was washed with deionized water. The anions were then eluted by appropriate eluting reagent. The amount of anions were then determined by standard methods.

To study the thermodynamic behavior of the exchanger, the material (50—100 mesh) was converted to other anionic form by placing the material in a column and passing 1.0 mol dm^{-3} potassium or sodium salts of the respective anions until the concentration of anions in the eluent and eluate was identical. The sample was washed with deionized water until it was free from anions. After drying

the exchanger it was stored in the stoppered bottle.

The equilibrium experiments were performed by taking 20 cm^3 solution containing sodium or potassium nitrate solution and appropriate anion solution. The ionic strength of the total content was kept 0.10 mol dm^{-3} in the stoppered conical flasks. To this 0.20 g of the exchanger in nitrate form was added and flasks were shaken thoroughly in a temperature controlled shaker for 4 h at desired temperatures. Equilibrium was attained within this period and aliquots from supernatant solutions were analyzed for anions.

Experiments were also performed by equilibrating the exchanger in the particular anionic form with sodium nitrate solution at 30 °C.

Results and Discussion

The results of Table 1 show that for complete precipitation to occur, zirconium dichloride oxide to triethylamine ratio must be kept 1:2.

Anion Exchange Capacity. Anion exchange capacity of the exchanger is quite high. The capacity for dichromate, chromate, and sulfate is 3.20, 2.50, and 1.00 meq g^{-1}, respectively. A very high value of ion exchange capacity towards chromate ion (3.2 meq g^{-1}) is in accordance with the results of zirconia. The order for capacity for halides is $Cl^->Br^->I^-$. The capacity of the exchanger decreases as the ionic size of the halide increases and for some other ionic species the capacity decreases in the order $Cr_2O_7^{2-}>SO_4^{2-}>S_2O_3^{2-}$. Thus the exchanger behaves a chelating as well as an anion exchanger. On the basis of the above discussions it is concluded that zirconium-bis-(triethylamine) shows anion exchange capacity due to the presence of $-N^+-$ group and chelating properties due to the presence of $-\ddot{N}-$ group.

Sorption Capacity. The sorption capacity of copper(II) was found to be 0.42 meq g^{-1} of zirconium-bis(triethylamine). When zirconium-bis(triethylamine) in H^+ form was kept in contact with a solution of sodium nitrate, no release of H^+ was observed. When exchanger was kept in Cu(II) solution it turned blue in appearance. Copper(II) ions were so strongly attached to zirconium-bis(triethylamine) exchanger that even strong chelating group EDTA did not completely detach copper(II) from the exchanger. Hence sorption capacity was calculated by column method. Due to this great affection of exchanger for metal ions like copper(II), K_d values were not calculated for the metal ions.

Composition. The results of composition studies show that zirconium and triethylamine are present in the molar ratio of 1:2 in the exchanger. Results show that the exchanger is quite stable in aqueous and basic media. The use of acidic solutions of greater concentrations must be avoided.

Effect of Heating. The results of effect of temperature on the capacity of the exchanger, show that the capacity decreases with the increase in temperature. At higher temperatures the water molecules and amine molecules are lost from the exchanger thereby decreasing the capacity. As a result the capacity at higher temperatures is much low. Loss in weight per gram of the exchanger at different temperatures shows that at 100 °C the weight loss is because of loss in water molecules and amine molecules upto 300 °C. Above 300 °C there is no appreciable weight loss since all the amine is lost. These results are in accordance with the results of capacity at different temperatures.

Structural Studies. It is quite clear that the exchanger, zirconium-bis(triethylamine), contains amino group and the metal oxygen bond. It confirms that in the formation of this type of exchanger the amine is incorporated with the metal oxide forming the matrix.

Potentiometric Titrations. pH titrations of the exchanger, zirconium-bis(triethylamine) were performed by shaking 0.50 g of the exchanger with solution of 0.10 mol dm^{-3} HCl and its salts of 0.01 mol dm^{-3} concentration by Topp and Pepper method. The volume of reaction mixture was kept 50 cm^3 in each case. The pH of the solution was noted after equilibration of the solution for 4 h. Results plotted in Fig. 2 show that the exchanger behaves as monofunctional anion exchanger.

Table 3. Quantitative Separations of Anions on Zirconium-Bis(triethylamine)

Sample No.	Mixture	Eluent	Eluate ml	Amount loaded mg	Amount found mg	Percent recovery
1	Br^-	0.0001 mol dm^{-3} NaOH	90	2.640	2.480	93.93
	CrO_4^{2-}	0.1 mol dm^{-3} NaOH	120	11.078	10.846	97.90
2	I^-	0.001 mol dm^{-3} NaOH	90	2.667	2.603	97.60
	CrO_4^{2-}	0.1 mol dm^{-3} NaOH	100	11.078	10.904	98.42
3	Cl^-	0.001 mol dm^{-3} NaOH	120	2.023	1.917	94.76
	AsO_2^-	0.1 mol dm^{-3} NaOH	90	3.050	2.890	94.75
4	SCN^-	0.0001 mol dm^{-3} NaOH	120	3.509	3.422	97.52
	$Cr_2O_7^{2-}$	0.1 mol dm^{-3} NaOH	120	13.068	12.852	98.34

Distribution Studies. The distribution behavior of anions given in Table 2 indicates that the K_d values were high when deionized water was used as a medium. Distribution values were less when sodium hydroxide solution was used for studies. Distribution values decreased as the concentration of sodium hydroxide solution was increased. Being a weak anion exchanger, zirconium-bis(triethylamine) has a high affinity for hydroxide ions, hence anions other than hydroxide ion showed less uptake in the presence of hydroxide ions.

Separations. Separations of $Cr_2O_7^{2-}$ from Br^-, I^-; AsO_2^- from Cl^-; CrO_4^{2-} from I^-, Br^-; and $Cr_2O_7^{2-}$ from SCN^- were successfully achieved. The quantitative separations of anions on zirconium-bis-(triethylamine) exchanger given in Table 3, also show a high selectivity towards CrO_4^{2-} and $Cr_2O_7^{2-}$ as predicted by capacity.

The exchange isotherms for various anions at different temperatures are plotted in Figs. 3—7. From these results equivalent fractions of anions, selectivity coefficients and thermodynamic equilibrium constants can be evaluated.

The plot of $\ln K_c$ versus equivalent fraction of anion in exchanger phase are presented in Figs. 8—12.

change $\Delta G°$, and entropy change $\Delta S°$ were calculated and are reported in Table 4.

The ion exchange equilibria with certain ion exchangers, especially inorganic ion exchangers can be studied by the application of mass-action law modified in terms of activities. For the exchanger in nitrate form and solution having univalent counter ion A^- at equilibrium the exchange may be represented as:

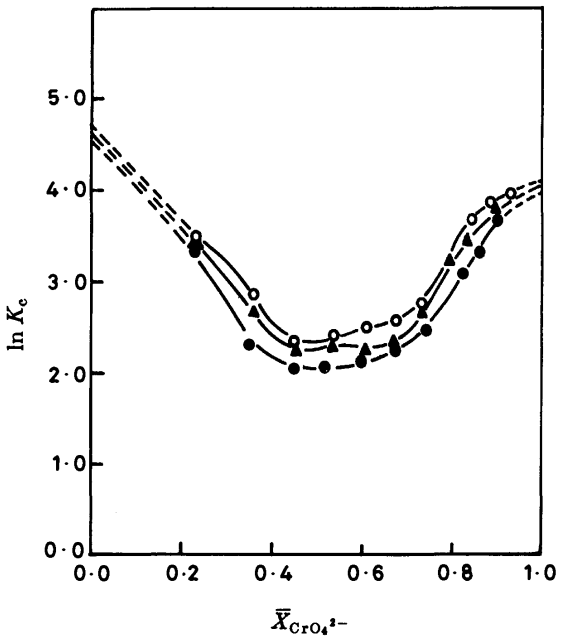

Fig. 9. Selectivity coefficients vs. equivalent fractions of CrO_4^{2-} in exchanger phase.

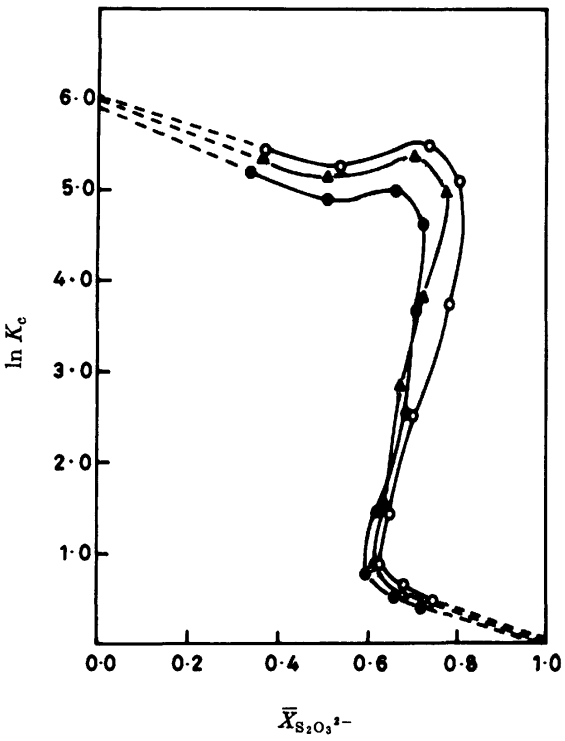

Fig. 10. Selectivity coefficients vs. equivalent fractions of $S_2O_3^{2-}$ in exchanger phase.

$$\overline{NO_3^-} + A^-_{(aq)} \rightleftharpoons \overline{A^-} + NO_3^-{}_{(aq)} \quad (1)$$

and for bivalent counter ion

$$\overline{2NO_3^-} + A^{2-}_{(aq)} \rightleftharpoons \overline{A^{2-}} + 2NO_3^-{}_{(aq)} \quad (2)$$

The thermodynamic equilibrium constant for the above reactions may be written for uni-univalent

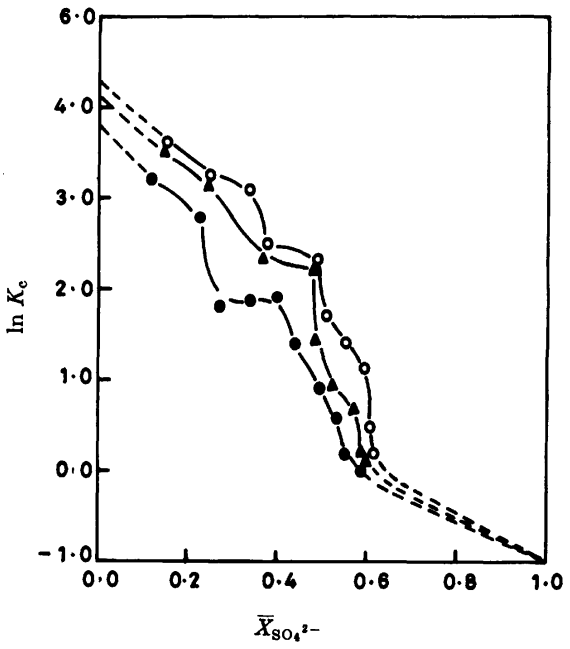

Fig. 11. Selectivity coefficients vs. equivalent fractions of SO_4^{2-} in exchanger phase.

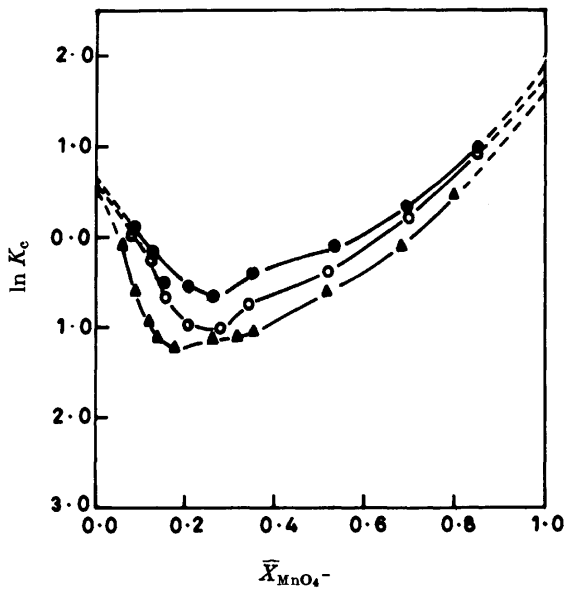

Fig. 12. Selectivity coefficients vs. equivalent fractions of MnO_4^- in exchanger phase.

exchange as:

$$K_a = \frac{\overline{a_{A^-}} a_{NO_3^-}}{\overline{a_{NO_3^-}} a_{A^-}} = \frac{[\overline{A^-}][NO_3^-]}{[\overline{NO_3^-}][A^-]} \times \frac{\gamma_{A^-} f_{NO_3^-}}{\gamma_{NO_3^-} f_{A^-}} \quad (3)$$

and uni-bivalent exchange as:

$$K_a = \frac{(\overline{a_{A^{2-}}})(a_{NO_3^-})^2}{(\overline{a_{NO_3^-}})^2 (a_{A^{2-}})} = \frac{[\overline{A^{2-}}][NO_3^-]^2}{[\overline{NO_3^-}]^2[A^{2-}]} \times \frac{\gamma_{A^{2-}} f^2_{NO_3^-}}{\gamma^2_{NO_3^-} f_{A^{2-}}} \quad (4)$$

where γ represents activity coefficients in the exchanger phase and f the activity coefficient in the aqueous phase.

An examination of the ion exchange isotherms, Figs. 3—7, show that the isotherms are above the diagonal except for MnO_4^- indicating that bivalent anions are strongly preferred in comparison to nitrate by the zirconium-bis(triethylamine) exchanger. The

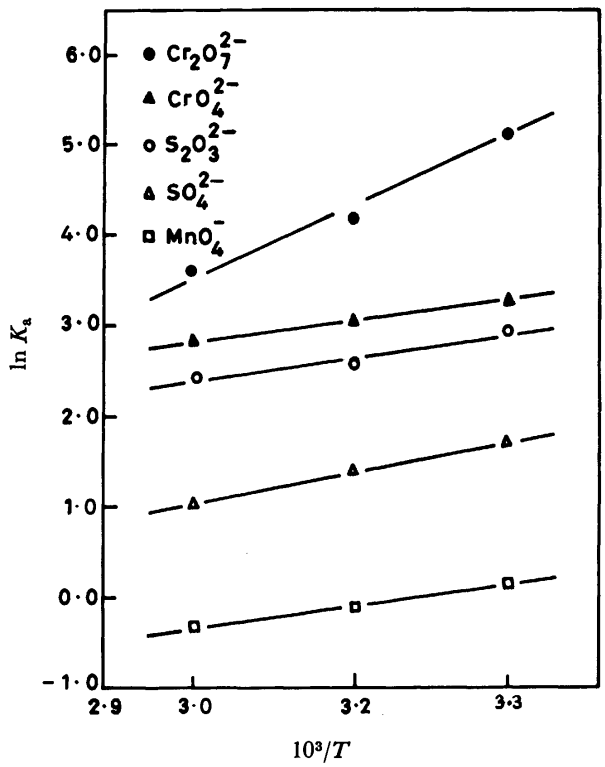

Fig. 13. Temperature dependece of the thermodynamic equilibrium constant.

Table 4. Thermodynamic Parameters on Zirconium-Bis(triethylamine) at Anionic Strength of 0.1 and Various Parameters

Anion	K_a			$\Delta G°$			$\Delta H°$/kJ equiv^{-1}	$\Delta S°$/J equiv^{-1} deg^{-1}
	30 °C	45 °C	60 °C	30 °C	45 °C	60 °C	30—60 °C	30—60 °C
$Cr_2O_7^{2-}$	170.28	64.08	39.25	−12.94	−10.99	−10.16	−4.80	20.80
CrO_4^{2-}	26.31	21.04	17.68	−8.21	−8.06	−7.94	−1.33	21.23
$S_2O_3^{2-}$	19.21	13.88	11.19	−7.43	−6.95	−6.67	−1.50	17.40
SO_4^{2-}	5.59	4.16	2.73	−4.33	−3.75	−2.77	−1.92	5.41
MnO_4^-	1.18	0.89	0.74	−0.40	0.32	0.83	−1.39	−5.09

affinity for the anions decreases as the temperature increases. Figures 3—7 show that all the studied isotherms were reversible whereas the selectivity sequence was

$$Cr_2O_7^{2-} > CrO_4^{2-} > S_2O_3^{2-} > SO_4^{2-} > MnO_4^-$$

If K_c is the selectivity coefficient, then for univalent exchange

$$K_c = \frac{\bar{X}_{A^-} X_{NO_3^-}}{\bar{X}_{NO_3^-} X_{A^-}} \times \frac{f_{NO_3^-}}{f_{A^-}} \quad (5)$$

and for uni-bivalent exchange

$$K_c = \frac{\bar{X}_{A^{2-}} X^2_{NO_3^-}}{\bar{X}^2_{NO_3^-} X_{A^{2-}}} \times \frac{f^2_{NO_3^-}}{f_{A^{2-}}} \quad (6)$$

where $\bar{X}_{NO_3^-}$ and $\bar{X}_{A^-}$ are equivalent fractions of competing anions in exchanger phase, $X_{NO_3^-}$ and X_{A^-} the equivalent fractions of the nitrate and competing anion in solution phase respectively. $f_{NO_3^-}$ and f_{A^-}, the activity coefficients of nitrate and the competing anion, respectively in solution. The activity coefficients of the anions in solution phase were calculated using Debye-Hückel equation:

$$-\log f_i = \frac{Az_i^2\sqrt{\mu}}{1+Ba_i\sqrt{\mu}} \quad (7)$$

where A and B are constants, a_i the ion size parameter, μ the ionic strength and z_i the charge of the ion i. The values of A and B at appropriate temperatures are taken from the table given earlier.

The results of the selectivity coefficients indicate that as the temperature increases the value of the selectivity coefficient decreases. The results plotted (Figs. 8—12) reveal that the selectivity coefficient K_c does not remain constant at all with the varying concentrations of anions in solution and therefore K_a should be calculated.

K_a, The thermodynamic equilibrium constant can be obtained according to Gaines and Thomas, from the equation:

$$\ln K_a = (Z_{X^-} - Z_{NO_3^-}) + \int_0^i \ln K_c \, d\bar{X}_{A^-} \quad (8)$$

The values of thermodynamic equilibrium constant are calculated by integration under the curves of Figs. 8—12 applying Eq. 8. Variation of $\ln K_c$ with loading, X, is given in Figs. 8—12. The values of the changes in thermodynamic quantities are calculated from the respective thermodynamic equilibrium constants as follows:

$$\Delta G^\circ = -RT \ln K_a \quad (9)$$

$$\Delta H^\circ = -R\frac{d(\ln K_a)}{d(1/T)} \quad (10)$$

and

$$\Delta S^\circ = (\Delta H^\circ - \Delta G^\circ)/T \quad (11)$$

ΔH° is obtained from Fig. 13 (expressing the variation of $\ln K_a$ with $1/T$). The results indicate that during the exchange of anions over zirconium-bis-(triethylamine) in nitrate form, the free energy change is negative in all cases except for MnO_4^- at higher temperatures. It reveals that for bivalent anions the exchange process is spontaneous and is in accordance with, mainly, on charge relations. However, for univalent anion exchange with MnO_4^- the charge being same it may depend on other factors.

The results (Table 4) giving enthalpy change in all the exchange reactions indicate that process is exothermic, i.e. the binding energy of one competing anion is lower than the two anions of nitrate. Thus nitrate ion is less tightly bound to the zirconium-bis-(triethylamine) matrix than any of the other anions studied except MnO_4^-.

The results of enthalpy changes given in Table 4 indicate that during the forward reaction the competing anionic species are more orderly arranged than that of nitrate form of zirconium-bis(triethylamine).

The authors are thankful to Professor M. S. Ahmad, Chairman, Department of Chemistry, Aligarh Muslim University, Aligarh for providing research facilities. Two of the authors (M.A. and B.S.) are thankful to C.S.I.R. and H.M.A.A. is grateful to Cultural Department, Ministry of Foreign Affairs, Govt. of India for financial assistance.

Synthesis and Characterization of New Three-Component Ion-Exchange Material: Zirconium(IV) Selenophosphate

Saidul Zafar QURESHI* and Nafisur RAHMAN
Department of Chemistry, Aligarh Muslim University, Aligarh-202001, India
(Received October 7, 1985)

Zirconium(IV) selenophosphate has been prepared by adding a mixture which is 0.05 M in sodium selenite and 0.05 M in orthophosphoric acid to a 0.05 M solution of zirconium(IV) bis(nitrate) oxide in different volume ratios at pH 1. Its ion-exchange capacity, thermal and chemical stability, pH titration curves, and chemical composition were studied. Adsorption of some of the metal ions in different solvent systems has been studied. The effect of particle size on the sorption behavior of metal ions has also been studied. The analytical importance of this material has been demonstrated by achieving the eleven quaternary separations of metal ions. A comparison of ion-exchange properties of this material has also been made with some other ion-exchangers.

The most intensively studied group of synthetic inorganic ion-exchangers are the acidic salts of multivalent metals (especially quadrivalent metals) prepared in combination with the anions of phosphate, arsenate etc. as two-component ion-exchangers.[1-3] Three-component inorganic ion-exchangers which consist of a combination of zirconium phosphate compound with other organic or inorganic salts such as zirconium arsenate, molybdate, tungstate, tellurate, oxalate, silicate etc. have been prepared. Attempts were made to increase the ion-exchange capacity by increasing degree of polymerization of the component materials.[4] However, a higher content of polyphosphate in the exchanger is considered to effect the kinetics of absorption[5] and therefore, the conditions are set within optimum limits.[6] A study of the literature shows the preparation of a large number of three-component ion-exchangers with increased ion-exchange capacity and selectivity of these materials.[7-16] In this manuscript, we describe the preparation and properties of zirconium(IV) selenophosphate. Some analytically important separation of metal ions of quaternary systems have been successfully achieved.

Experimental

Reagents. Zirconium(IV) bis(nitrate) oxide (B.D.H.), sodium selenite (B.D.H.), and orthophosphoric acid (B.D.H.) were used for the synthesis of ion-exchangers. All other chemicals were of analytical grade.

Apparatus. An Elico model Li-10 pH meter was used for pH measurement. A Bausch and Lomb Spectronic 20 colorimeter and a Perkin Elmer 137 spectrophotometer were used for spectrophotometric and IR studies respectively. An electric temperature-controlled shaker (SICO) was used for shaking.

Synthesis. Samples of zirconium(IV) selenophosphate ion-exchangers were synthesized by adding an aqueous solution which is 0.05 M (1 M=1 mol dm^{-3}) in sodium selenite and 0.05 M in orthophosphoric acid to an aqueous solution of zirconium(IV) bis(nitrate) oxide. The desired pH was adjusted by adding dilute HNO_3 or NaOH solution. The gel so formed was allowed to settle down for 24 h, washed several times with demineralized water to remove excess reagents and finally filtered under suction. It was

then dried at 40 °C for 7 d in an oven. The dried material was then treated with demineralized water, which resulted in cracking of the substance into smaller particles with slight evolution of heat. To convert the sample into H^+ form, the material was kept for 24 h in 1.0 M HNO_3 solution. It was then washed with demineralized water to remove excess acid.

Ion-Exchange Capacity. A half gram of the exchanger in H^+ form was taken into the column with the glass wool support. One molar solutions of different uni- and bivalent metal salts were passed through the column and the H^+ ion liberation capacity was determined as usual.[17] The ion-exchange capacities thus determined were therefore those at neutral pH conditions (pH ≈6.5).

Chemical Stability. A 0.50 gram exchanger material (ZSP_1, Table 1) was equilibrated with 50 ml of the solution or solvent of interest at room temperature and kept for 24 h with occasional shaking. Zirconium and selenium in the solution was determined spectrophotometrically using Alizarin Red-S[18] and 3,3′,4,4′-tetraaminobiphenyl tetrahydrochloride[19] as coloring reagents respectively. The phosphate was determined titrimetrically.[20]

pH-Titration. pH-Titrations for NaCl-NaOH and KCl-KOH systems, (using 0.1 M solution of NaCl and KCl each) of sample ZSP_1 were performed by the method of Topp and Pepper.[21]

Thermal Treatment. Thermogravimetric analysis of sample ZSP_1 in the H^+ form was performed at a heating rate of 10 °C min^{-1}. To examine the effect of drying temperature on the ion-exchange capacity the materials were heated at different temperatures in a muffle furnace for 1 h.

Chemical Composition. For the determination of chemical composition of zirconium(IV) selenophosphate sample ZSP_1, 0.10 g of exchanger was dissolved in hot concentrated sulfuric acid. Then the solution was diluted to 100 ml with water. Zirconium and selenium were determined gravimetrically[22,23] while phosphate was determined titrimeterically.[20] The mole ratio of Zr, Se, and P was found to be 5.06:2.0:4.05.

Infrared Spectrum. Infrared analysis of zirconium(IV) selenophosphate was performed using KBr technique.

Distribution Coefficient. The distribution coefficients of metal ions in various aqueous solutions were determined. A quarter gram of exchanger in H^+ form (30—50, 50—100, 100—150, 150—200 mesh sizes) was treated with 25.0 ml of 2.0×10^{-4} M metal salt solution in 250 ml Erlenmeyer flask. The mixture was then shaken for 6 h at 25±2 °C in a shaker incubator. The amount of metal species left in the solution was then determined by titrating against the standard solution of EDTA. The K_d values were calculated according to the formula.

$$K_d = \frac{\text{mmoles of metal species/gram of exchanger}}{\text{mmoles of metal species/ml of the total volume of the resultant solution.}}$$

Separation of Metal Ions. Quantitative separations of metal ions were achieved on a 0.6 cm diameter (i.d.) glass column using 2.0 g exchanger (50—100 mesh) in H^+ form. A metal ion mixture was poured on the top of the column. The flow rate of the effluent was maintained at 1 ml min^{-1} throughout the elution process.

Results and Discussion

Table 1 describes the preparations of samples of Zr(IV) selenophosphate. It is apparent from the table that the ion-exchange capacity of the mixed salt is greater when compared with other simple salts such as zirconium phosphate and zirconium selenite. The ion-exchange capacities for alkali and alkaline earth metals are shown in Table 2. It is clear from the table that the capacity increases with the decrease of hydrated ionic radii for both the alkali and alkaline earth metals.

The effect of heating on the ion-exchange capacities of Zr(IV) selenophosphate and other ion-exchange materials[5,13,15] at different temperatures has been shown in Fig. 1 and interpreted. A 300, 500, and 600 °C, the decreasing orders of the ion-exchange capacities are [Zr(IV) selenophosphate, Sn(IV) selenoarsenate, Sn(IV) selenite, Cr(III) arsenophosphate, Sn(IV) arsenophosphate], [Sn(IV) selenite, Sn(IV) selenoarsenate, Zr(IV) selenophosphate, Cr(III) arsenophosphate, Sn(IV) arsenophosphate], and [Sn(IV)

Table 2. Ion-Exchange Capacity (meq g^{-1}-dry exchanger) of Zirconium(IV) Selenophosphate Sample ZSP_1 for Various Cations at pH 6.5 and 25 °C

Sample No.	Cation	Hydrated ionic radius/Å	Ion exchange capacity (meq g^{-1}-dry exchanger)
1	Li^+	10	1.11
2	Na^+	7.9	1.23
3	K^+	5.3	1.51

8	Ba^{2+}	8.8	1.44

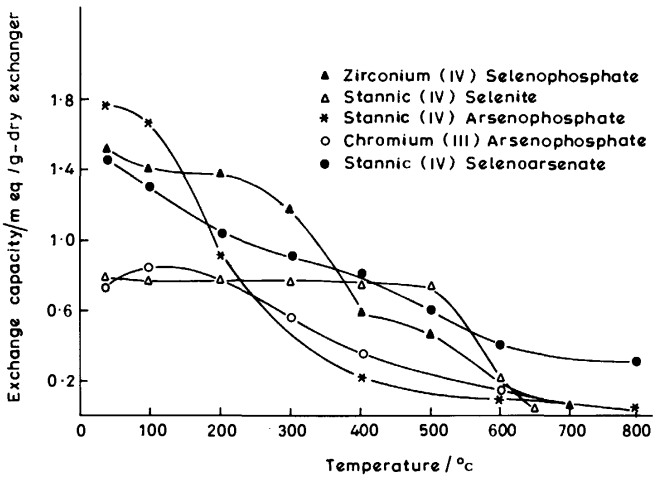

Fig. 1. Plot of exchange capacity vs. drying temperature.

selenoarsenate, Sn(IV) selenite, Zr(IV) selenophosphate, Cr(III) arsenophosphate, Sn(IV) arsenophosphate] respectively. The ion-exchange capacity of Zr(IV) selenophosphate for K^+ was found to be 1.51 meq g^{-1} when the sample was dried at 40 °C. However, a decreasing trend in ion-exchange capacities was observed when the drying temperature was elevated. The ion-exchange capacity became negligible i.e., 0.05 meq g^{-1} at 700 °C.

It is apparent from Table 3 that Zr(IV) selenophosphate is quite stable in water. It is fairly stable in dilute mineral acids such as hydrochloric acid, perchloric acid, nitric acid, and sulfuric acid. The material is also fairly stable in organic acids like formic acid, oxalic acid, acetic acid, citric acid, and tartaric acid and in organic solvents such as ethanol, 1-butanol, DMSO, and dioxane but is highly soluble in 2 M sodium hydroxide.

The titration curves with added salts have been shown in Fig. 2. The curve in the presence of added sodium salt showed a slight difference from that in the presence of potassium salt and the ion-exchange capacities calculated from these curves are 1.20 and 1.50 meq g^{-1} for sodium and potassium salts and those obtained from column operation are 1.23 and 1.51 meq g^{-1} respectively. Further the titration curves showed a monofunctional behavior of the exchanger.

Berardelli and coworkers[24] have synthesized a single crystalline phase, a layered mixed inorganic ion-exchanger, $Zr(HAsO_4)(HPO_4)\cdot H_2O$, containing two anions. The X-ray diffraction studies and differential thermal analysis of the crystalline product showed a great similarity with those of α-$Zr(HPO_4)_2\cdot H_2O$ and α-$Zr(HAsO_4)_2\cdot H_2O$ and possessed an interlayer spacing of 7.73Å intermediate between those of the last two compounds. It was, therefore, concluded that the mixed crystalline product possessed an α-type layered structure. Taking the example of this product we have tried to explain the increased ion-exchange capacity and tentatively extending this concept on synthesized material, zirconium(IV) selenophosphate (assuming that it possessed an α-type layered structure). Its ion-exchange capacity was reported to be 5.80 meq g^{-1}. In describing the structure of zirconium phosphate in terms of three-dimensional skeleton which composed of Zr, P, and O, Clearfield[25] suggested that each phosphate group is bonded to three different zirconium atoms through oxygen forming a sheet-like structure. The remaining phosphate oxygen atoms bear the hydrogen atoms. Half of these P-OH groups are believed to form hydrogen bonds with phosphate oxygen atoms in the adjacent layers (P-O-H·····O-P) and form a zigzag array of weak interlayers running parallel to the *b*-axis. The other half of the P-OH groups are thought to be hydrogen bonded to the water molecules to form interlayer bonds $\left(\text{P-OH}\cdots\text{O}\begin{matrix}\nearrow\text{H}\\ \searrow\text{H}\end{matrix}\right)$. These differences in hydrogen bonding give rise to different acidities or ion-exchange sites for the two hydrogen atoms. The ion-exchange capacity has been measured as the amount of the total H^+ ions available from the

two different interlayer bonds of P-OH groups. In case of three-component materials e.g., $Zr(HAsO_4)(HPO_4)\cdot H_2O$, X-ray diffraction studies revealed the existance of a mixed exchanger to give solid solutions because of the presence in the lattice layer of atoms (P and As) with analogous chemical characteristics but with different dimensions. Moreover, the substitution of P with As provided strength of their acidic sites when employed as acid catalysts.[24] On the basis of these studies, it can be suggested that in addition to the two different P-OH groups there should also be a third exchange site (in case of three-component materials) formed by mixed interlayer bonds (As-OH$\cdots\cdots$O-P), whose existance was supported by mixed ion-exchanger to give solid solution. The ion-exchange capacity is therefore a total contribution from all these different exchange sites. new let P-OH and As-OH represent dihydrogenphosphate ($-H_2PO_4$) and dihydrogenarsenate ($-H_2AsO_4$) groups corresponding to the second dissociation constant of the phosphoric and arsenic acid. The magnitude of the dissociation constants of these groups ($H_2PO_4^- \overset{K_2}{\rightleftharpoons} H^+ + HPO_4^{2-}$; $K_2=6.2\times10^{-8}$ and $H_2AsO_4^- \overset{K_2'}{\rightleftharpoons} H^+ + HAsO_4^{2-}$; $K_2'=8.3\times10^{-8}$) are almost of the same order and therefore the hydrogen ions released from these ion-exchange sites should be the sum from the above two groups. The total hydrogen ions released from all three different sources must be greater than the hydrogen ions released from the two ion-exchange sites.

The IR spectrum of Zr(IV) selenophosphate shows the presence of usual characteristic groups such as lattice water, free water and phosphates at corresponding frequencies. On the other hand, the separate identity of $-SeO_3$ group is indicated by a strong band at a frequency of 720 cm^{-1}.[26]

The combined studies of thermogram of Zr(IV) selenophosphate in H^+ form (Fig 3) and its exchange capacity at different temperatures compared with other exchange materials (Fig. 1) reveal some interesting results. At 200 °C about 8.6% of the total capacity is lost due to the loss of water molecules and start of the formation of pyrophosphate groups. The corresponding weight loss of exchanger is about 2.58%. At 560 °C, there is a complete conversion to pyrophosphate with a decrease in capacity equal to 72% of the starting value and the corresponding weight loss is about 4.6%. Further decrease in capacity may be attributed due to the condensation of $-HSeO_3$ group to $(Se_2O_5)H_2O$. After 800 °C the weight becomes constant and the capacity decreases, is 96% of the original value.

On the basis of the exchange capacity, pH titration curve, chemical composition and thermogravimetric analysis, the following formula for Zr(IV) seleno-

phosphate is tentatively suggested.

$$[(ZrO)_5(OH)_4(HSeO_3)_2(H_2PO_4)_4]_n \cdot 2nH_2O$$

If it is assumed that the weight loss (2.58%) up to 200 °C is due to the removal of water molecules, then the number of water molecules (n) per molecule of exchanger, calculated from the formula given by Alberti[27] is 2. If two hydrogen ions in the tentative formula above are exchanged at pH 6.5, the ion-exchange capacity calculated from the above formula is 1.55 meq g^{-1} which is in accordance with the experimental value (1.51 meq g^{-1}). The mole ratio of Zr, Se, and P, which is calculated from the above formula is found to be 5.04:2.00:4.01.

It is clear from Table 4 that the K_d values vary with

the composition and the nature of the contacting solution. The K_d value for Th^{4+} is very high showing a high affinity of Zr(IV) selenophosphate to Th^{4+}, whereas the rare earth metals are least strongly adsorbed in almost all the solution systems studied. An increase in the concentration of nitric acid has significant effect on the adsorption of Pb^{2+} and Fe^{3+} but has a little effect on the behavior of rare earth metals. Kd values are increasing as the mesh size of the exchanger increases (Table 5). The sorption studies on Zr(IV) selenophosphate for different metal ions reveal some important separations. As a result, eleven quaternary separations were performed by using small column (30 cm length and 0.6 cm internal diameter) of Zr(IV) selenophosphate. Results are summarized in Table 6. The elution profiles are shown in Fig. 4a—c.

Titanium Determination under High-Sensitivity Conditions with 2-(5-Chloro-2-pyridylazo)-5-dimethylaminophenol. II. Ternary Compounds of Ti(IV)-H_2O_2-5-ClDMPAP

Héctor José MARINI, Rosa Isabel ANTÓN, and Roberto Antonio OLSINA*
Departamento de Quimica Analitica "Dr. Carlos B. Marone," Universidad Nacional de San Luis, Argentina
(Received April 8, 1986)

Ti(IV) together with pyridylazo-type reagents and other molecular compounds form ternary complexes that may stand as the basis for analytical methods designed for the quantitative determination of the metal. This paper reports the results obtained by the use of the system Ti(IV)-H_2O_2-5-ClDMPAP in aqueous ethanolic solutions, and application to routine analyses of Ti(IV) in various types of samples. The spectral characteristics of the complexes formed, the pH ranges appropriate for their formation, ethanol influence, composition and stability have been studied. The complex selected for this analytical work is formed between pH 2.5 and 6.5 with a 1:2:2 Ti(IV)-H_2O_2-5-ClDMPAP molar ratio. The system fulfils Beer's law up to a Ti(IV) concentration of 0.7 ppm, working at λ_{max} 534 nm. The molar absorptivity and Sandell index are 4.59×10^4 dm^3 mol^{-1} cm^{-1} and 0.0010 μg cm^{-2} respectively.

Reactions involving ternary compounds are important in determination and separation methods, specially in absorptiometric analysis, liquid-liquid extraction and masking. Babko[1] describes four basic types of ternary compounds which form the following systems: a) Lewis' metallic ion-electronegative ligand-base; b) metallic ion-two different electronegative ligands; c) ternary heteropolyacids; d) two different metallic ions-one ligand. According to the general qualities of each of these types, our Ti(IV)-H_2O_2-2-(5-chloro-2-pyridylazo)-5-dimethylaminophenol, system, belongs to type b). Ternary compounds belonging to this type have been extensively studied and applied to absorptiometric determinations, as well as to complexometric titrations.[1] In the latter case, one of the complexing reagents helps in the process's kinetics for it destroys the existing hydroxopolynuclear complexes, and it usually activates the forming reaction of the ternary complex.

In the spectrometric determination of titanium, Ozawa[2] adds H_2O_2 together with 4-(2-pyridylazo)resorcinol, thus forming a ternary complex Ti(IV)-H_2O_2-PAR of 1:3:3 stoichiometry, and a molar absorptivity of 5.10×10^4 dm^3 mol^{-1} cm^{-1} at pH 7.9. When no H_2O_2 is addes, the complex formed at pH 3.2—3.8, Ti(IV)-PAR (1:2) has an absorptivity rate of 2.1×10^4 dm^3 mol^{-1} cm^{-1}. Nevertheless, no method to solve severe interferences caused by Cu(II), Fe(III), Co(II), Ni(II), Sn(II), Bi(III), V(V), and Zr(IV) is suggested.

Tsurumi and Furuya[3] have determined Ti(IV) by spectrometry, using 2-(2-thiazolylazo)-5-dimethylaminophenol (TAM) as a reagent of the azo group. This reagent together with Ti(IV) at a 1:2 (Ti(IV)-TAM) molar ratio, formed a complex capable of being quantitatively removed as an ionic association compound by means of 1,3-diphenylguanidine (DPG) in benzyl alcohol at pH 4.2—5.2. This proposed method becomes interesting due its relatively high molar absorptivity, but the interferences caused, in this case, by Fe(III), Co(II), Ta(V), and Zr(IV) are not solved. Cd(II), Co(II), Ni(II), Cr(VI), UO_2(II), Fe(III), Zr(IV), and Hf(IV) are severe interferers in most Ti(IV) spectrometric determination. These interferers could be drawn by means of an extraction technique with 8-quinolinol[4] and cupferron[5] when Ti(IV), under high sensitivity conditions, was determined by spectrometric with 5-ClDMPAP.[6] Although this method yields a relatively high molar absorptivity, its drawback is the complex's limited stability in solution. In order to solve this limitation, a method involving hydrogen peroxide was developed so as to greater stability to the system. The results attained by the use of ternary system Ti(IV)-H_2O_2-5-ClDMPAP in aqueous ethanolic solutions are shown in the present paper, as well as the studies on the spectral characteristics of the three species developed, proper pH ranges for forming them, the influence of the organic solvent used, stability and composition. An increase in both sensitivity and stability has been observed to occur when pyridylazo reagents are used and hydrogen peroxide is added to the reaction medium.

Experimental

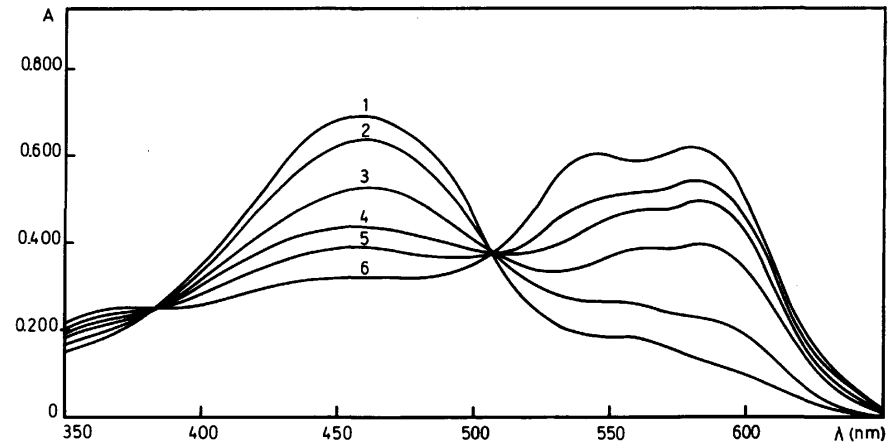
Reagents. A 5-ClDMPAP solution was prepared by coupling *m*-dimethylaminophenol with sodium 5-chloro-2-pyridinediazotate, according to the method described by Shibata et al.[7] Purification was carried out by means of repeated cycles of dissolution-reprecipitation starting from ethanol-water mixtures. A 0.25% (w/v) solution of the pure material was prepared. Lower concentration solutions of the above one, were prepared by dilution with ethanol. All solutions were kept away from light. A 5×10^{-4} mol dm^{-3} solution can be kept unaltered for at least 25 d. The Ti(IV) solution was prepared according to that described by Roseman and Thornton.[8] Its titer was determined by complexometric titration.[9] To obtain reproducible results, the solution must be prepared daily. The hydrogen peroxide solution was prepared by dilution from H_2O_2 of 200 vol. All the other chemicals were also of an analytical-

reagent grade.

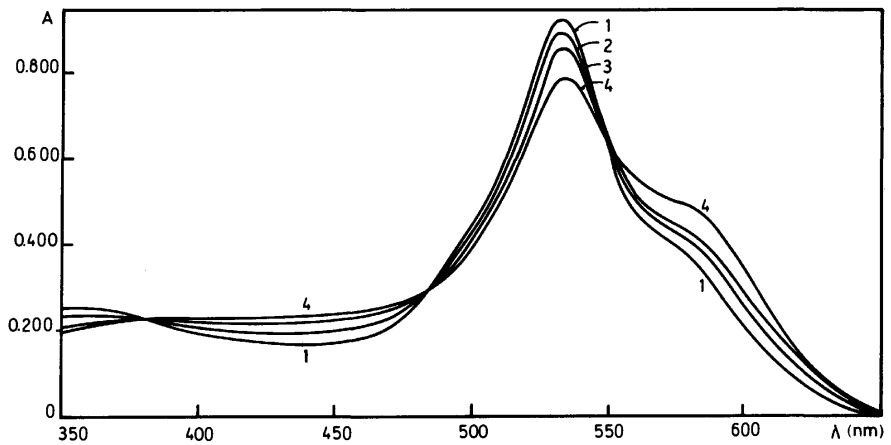
Apparatus. A Varian 634 UV-Vis. spectrophotometer with 10 mm optical path cell to obtain the absorption spectra an absorbance measures was used. An Orion 701-A pH meter for pH measurements was used. Volumes in Ti(IV) complexometric titrations were obtained by means of an automatic Metrohn Dosimat E412P buret.

Results and Discussion

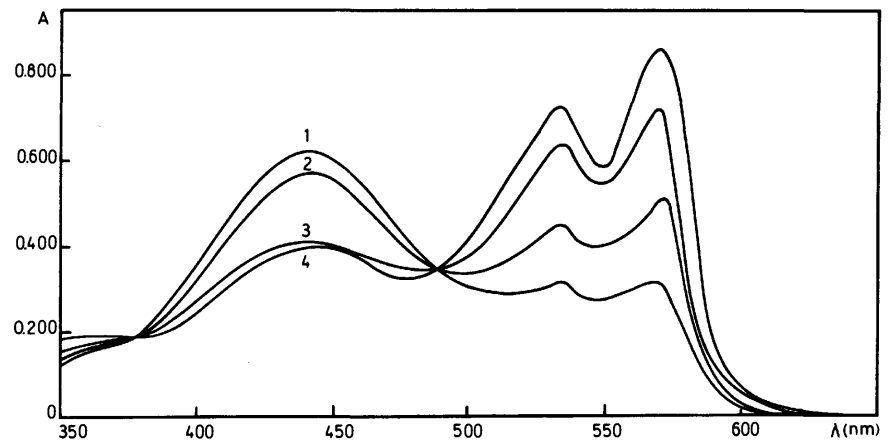
Study on Ti(IV)-H_2O_2-5-ClDMPAP. Influence of pH. In the presence of 5-ClDMPAP and H_2O_2, Ti(IV) forms three ternary complex species with compositions varying according to the pH value of the



1: pH=1, 2: pH=1.13, 3: pH=1.27, 4: pH=1.5, 5: pH=1.8, 6: pH=2



1: pH=4—5—6, 2: pH=3.5, 3: pH=3, 4: pH=2.5



1: pH=10, 2: pH=9, 3: pH=8.5, 4: pH=8

Fig. 1. Ternary complex's isosbestic point formed to different values of pH in presence of metal excess. $C_{Ti}=7.7\times10^{-5}$ M; $C_R=2.2\times10^{-4}$ M.

medium. For values ranging from 2.5 to 6.5 the prevailing species has λ_{max} at 534 nm; while the two other species are formed at pH values ranging from 1—2 to 7—9 with λ_{max} at 580 and 570 nm respectively.

The ternary species spectra formed show isosbestic points at different wavelengths, depending on the range (Figs. 1a, 1b, and 1c). For the analytical work, a ternary complex quantitatively formed between pH 2.5 and 6.5 was singled out bacause of its higher absorptivity values, stability and pH range of formation.

Stoichiometry of the Selected Ternary Species. Stoichiometry of the ternary complex was studied at pH 5.4. In order to determine Ti(IV)-5-ClDMPAP molar ratio, the method of continuous variations (Job)[10] was used, keeping H_2O_2 concentration constant at a rate of 0.3%. This methods proved to be uncapable of determining Ti(IV)-H_2O_2 molar ratio, so that the equilibrium shift methods[11] had to be employed (Fig. 2). Ti(IV)-H_2O_2-5-ClDMPAP molar ratio happened to be 1:2:2.

The order in which the reagents are added is very important. First, the reaction between Ti(IV) and H_2O_2 is caused at low pH values (<2), second a reaction between the Ti(IV)-H_2O_2 complex and 5-ClDMPAP is caused; and then a 5.4 pH buffer is added in order to select the wanted complex.

If it is accepted that the predominant Ti(IV) species at low pH values (2—3), is $[Ti(OH)_2]^{2+}$,[12,13] and that the reaction with H_2O_2 leads to the formulation of $[Ti(OH_2)_2]^{2+}$[15,16] the following equilibria can be written:

$$[Ti(HO)_2]^{2+} + 2H_2O_2 \rightleftharpoons [Ti(HO_2)_2]^{2+} + 2H_2O$$
$$[Ti(HO_2)_2]^{2+} + RH \rightleftharpoons [Ti(HO_2)_2R]^{+} + H^{+}$$
$$[Ti(HO_2)_2R]^{+} + RH \rightleftharpoons [Ti(HO_2)_2R_2] + H^{+}$$

The validity of the above formulation is guaranteed by the results obtained applying the equilibrium shift method[11] (Fig. 3). The equilibrium constant of the ternary compounds formation was studied by means of absorptiometric measurements,[14] the value obtained was 2.77×10^{13} at 25 °C.

Influence of the Solvent and the Hydrogen Peroxide Concentration. The influence of methanol, ethanol, dioxane, and acetone on the absorbance value was studied; whichever the solvent may be, the λ_{max} is the same. As the maximum absorptivity is attained when using methanol or ethanol, the latter was singled out for the present experiment. The best ethanol concentration is between 5 and 25% (v/v) (Fig. 4). The

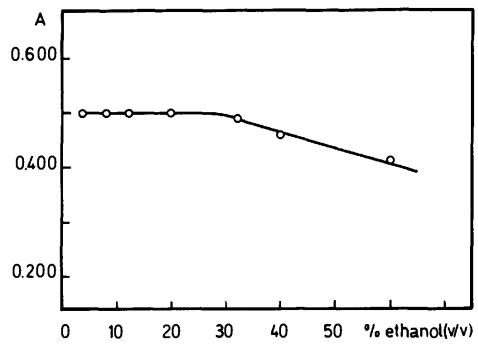

Fig. 4. Influence of the concentration of ethanol on the absorbance of ternary complex.
pH 5.4; $\lambda=534$ nm; $C_{Ti}=1.1\times10^{-5}$ M; $C_{H_2O_2}$= 0.3%(v/v); $C_R=2.2\times10^{-4}$ M.

minimum H_2O_2 concentration needed to get a maximum absorbance is 0.25%, and no transformations take place for concentration up to 1.2% (Fig. 5).

Reagent Concentration and Calibration Curve. The reagent concentration appropriate for the quantitative work was evaluated by plotting the saturation curve (Fig. 6) at pH 5.4. Ti(IV) concentration was kept constant (1.1×10^{-5} mol dm^{-3}), that one corresponding to 5-ClDMPAP was changed between 1×10^{-6} and 5.5×10^{-4} mol dm^{-3}, while H_2O_2 concentration remained constant (0.3% v/v). Absorbance was read at λ_{max} 534 nm and the ethanol concentration remained constant at 16% (v/v).

For a 1:10 Ti(IV):5-ClDMPAP molar ratio, the complete development of a complex is achieved, and this is kept unaltered for proportions up to 1:50. The ternary complex solutions at pH 5.4, keeping a 1:20:10000 metal-ligand-H_2O_2 ratio, change neither their absorption spectrum nor their absorptivity at λ_{max} 534 nm, during 1 h. Aqueous ethanolic solutions of the studied ternary species obey Beer's law up to a concentration of 0.7 ppm when they are made up in a medium with a pH 5.4 and are controlled by means of acetic acid-sodium acetate. The outstanding aspects referring to Ti(IV) absorptiometric determination are stated in Table 1.

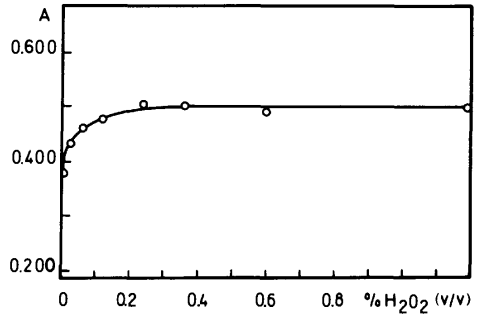

Fig. 5. Influence of the concentration of hydrogen peroxide on the absorbance of ternary complex. pH 5.4; λ=534 nm; ethanol-water 16% (v/v); $C_{Ti}=1.1\times10^{-5}$ M; $C_R=2.2\times10^{-4}$ M.

Effect of Foreign Ions. The reagent used reacts with ions different from Ti(IV) and produces various colors, depending upon the experimental complexation conditions. The interferences brought about by Fe(III), Cu(II), Ni(II), Co(II), W(VI), Nb(V), Ta(V),

and V(V) have severe effects on the systems and they cannot always be controlled by masking. Zn(II), Mn(II), Mo(VI), and Cr(VI) ions are tolerated in a 10:1 ratio (foreign ion:Ti(IV)). The tolerated ratio for Al(III) and Mg(II) is a 50:1 and for Na(I) and K(I) is 1000:1. Table 2 shows the tolerances for anions, coming from strong acids, used to dissolve samples, as well as for other anions or compound added as possible masking agents. In order to finish with the negative effects of the differents interferers the liquid-liquid extractions method was applied, using 8-quinolinol[4,6] as a removing reagent and chloroform as a solvent, and adjusting pH value in the presence of adequate complexing agents.

Methods and Applications. The method proposed by Cheng,[5] makes use of EDTA and cupferron. Adequately varying the concentration of both species, the selective and quantitative extraction of Ti(IV) present in complex samples as *cast iron* and *nickel bases Alloy* can be obtained. It is important to take into account that EDTA and cupferron concentration will be in agreement with the Ti(IV) concentration and to the other metal interferents concentration in the sample (Fe, Cu, Ni, Cr, and Mo).

Determination of Titanium in Standard Samples. The methodology developed was applied to two kinds of samples.

1. Nodular Cast Iron (NBS 342): A sample of 1 g was digested with 20 cm^3 of hydrochloric acid on a hot plate until action ceased. The insoluble matter was filtered while still hot and washed with 1% hydrochloric acid (Fl). After drying, the paper and residue were ignited in an uncovered platinum crucible. 1 cm^3 of 48% hydrofluoric acid and 1 cm^3 of to sulfuric acid were added and the solution was evaporated to dryness. The residue was fused with 1 to 2 g of sodium carbonate. The melt was dissolved in 50 cm^3 of water and digested for 15 min at 90 to 95 °C. The remaining residue was filtered and washed with water. The residue was ignited with 1 g of potassium disulfate for 10 min. The melt was cooled and dissolved with a minimum amount of 2 mol dm^{-3} sulfuric acid. This solution was added to the original (Fl) filtrate and diluted to approximately 250 cm^3. To a 25 cm^3 aliquot a slight excess of the disodium salt of EDTA (1 g) was added, followed by sufficient 6 M aqueous ammonia to adjust the solution to pH 5.4. The solution was boiled for 2 min and cooled. Then it was transferred to 125 cm^3 separatory funnel, and diluted to approximately 50 cm^3. 5 cm^3 of 0.4% freshly prepared cupferron were added dropwise with swirling. After standing for 5 min, the solution was extracted with 10 cm^3 of methylisobutylketone. Separate the organic phase, put it dry into a porcelain

crucible on sand bath and melt it with 0.4 g of potassium hydrogensulfate. Cool it take it with 3 cm^3 of 3% (v/v) hydrogen peroxide and pour it into a 25 cm^3 flask; then add 2 cm^3 of reagent, 2 cm^3 of ethanol, buffer acetic-acetate up to pH 5.4 and bring it to gauging. Read the solution absorbance at λ_{max} 534 nm against a reference prepared as usual. Results are shown in Table 3.

2. Synthetic Nickel Based Alloys Sample Corresponding to Metals Technology Center (BNF B. 7002 MONEL-ALLOY 400): To an aliquot of 25 cm^3 of synthetic sample, 0.5 g of the disodium salt of EDTA was added for masking purposes. The solution was made slightly acid and heated for a few minutes to hasten the reaction of EDTA and chromium. The solution was cooled and adjusted to pH 5.4. 5 cm^3 of 1.5% freshly-prepared cupferron were added and the solution was extracted with 25 cm^3 of the solvent. After the extraction, the method used for the *cast iron sample* is applied. Results and shown in Table 3.

The Reactions of Alkoxyl Radicals with O_2. IV. n-C_4H_9O Radicals†

Paul MORABITO and Julian HEICKLEN*
Department of Chemistry and Center for Air Environment Studies, The Pennsylvania State University, University Park, PA 16802, U.S.A.
(Received December 2, 1985)

n-C_4H_9ONO was photolyzed with 366 nm radiation at −8, 23, 55, 88, and 120 °C in the presence of NO, O_2, and N_2. The quantum yields of n-C_3H_7CHO, C_2H_5CHO, and CH_3CHO were measured as a function of reaction conditions. The primary photolytic act produces n-$C_4H_9O\cdot$ radicals which can react with NO by two routes

$$n\text{-}C_4H_9O\cdot + NO \longrightarrow n\text{-}C_4H_9ONO \quad (2a)$$
$$\longrightarrow n\text{-}C_3H_7CHO + HNO \quad (2b)$$

or isomerize via an internal H-atom abstraction

$$n\text{-}C_4H_9O\cdot \longrightarrow I\cdot \quad (4)$$

where I· is the $HOCH_2CH_2CH_2CH_2\cdot$ radical, and $\ln(k_4/k_2, \text{mol dm}^{-3})=1.93\pm1.60-(4014\pm509)/T$. If k_2 is taken as 2.6×10^{10} dm^3 mol^{-1} s^{-1}, then $\log(k_4, \text{s}^{-1})=11.25\pm0.69-(4014\pm509)/2.303T$. In the presence of O_2, n-$C_4H_9O\cdot$ radicals can also react with O_2

$$n\text{-}C_4H_9O\cdot + O_2 \longrightarrow n\text{-}C_3H_7CHO + HO_2 \quad (6)$$

with $\ln(k_6/k_2)=(-4.09\pm0.54)-(1178\pm176)/T$. If $k_2=2.6\times10^{-10}$ dm^3 mol^{-1} s^{-1}, then $k_6=4.5\times10^8 \exp\{(-1178\pm176)/T\}$ dm^3 mol^{-1} s^{-1}. The radical I· is removed via

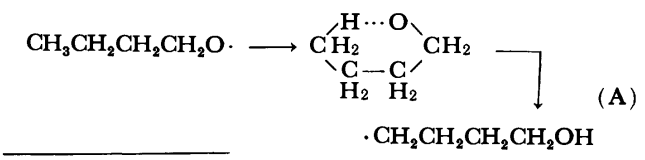
$$I\cdot \longrightarrow CH_3CHO + 2CH_2O + HO \quad (12a)$$
$$\longrightarrow \text{Undetected aldehydes} + HO \quad (12b)$$
$$I\cdot + O_2 \longrightarrow n\text{-}C_3H_7CHO + HO \quad (13a)$$
$$\longrightarrow C_2H_5CHO + HO \quad (13b)$$

where these reactions are composites of a series of steps. The ratio $k_{13a}/k_{13b}\simeq1.3\pm0.2$ nearly independent of temperature. The ratio k_{12}/k_{13} was not found very accurately, but is $\simeq3\times10^{-3}$ mol dm^{-3}. There was no evidence for the oxidation of I· leading to dioxygenated products.

Alkoxyl radicals are important intermediates in the atmospheric photooxidation of NO to NO_2. These radicals are produced in the atmosphere from the oxidation of hydrocarbons. Over the past few years studies have been undertaken to determine the rate coefficient for the alkoxyl radical oxidation reaction since these reactions have considerable importance in both photochemical smog and combustion.

Extensive rate coefficient studies have been made only for the $CH_3O\cdot$ radical oxidation.[1-9] Only three studies report rate coefficients for the $C_2H_5O\cdot+O_2$ reaction[9-11] while one report is given for higher homologs such as the n-$C_3H_7O\cdot+O_2$[12] and i-$C_4H_9O\cdot+O_2$[13] systems.

In this study, we investigate the reaction of n-$C_4H_9O\cdot+O_2$. Unlike the other radicals that have been studied, the n-$C_4H_9O\cdot$ radical can undergo a rapid intramolecular hydrogen abstraction to form a new radical:



(A)

Such isomerizations are well known in gas phase studies and occur when a δ-carbon atom is present which contains a hydrogen atom.[14] However very few measurements have been made on the isomerization reaction (A) because both reactant and product are free radicals.

The radical produced in step A could now decompose, or in the presence of O_2 and NO, form a new alkoxyl radical, $HO(CH_2)_4O\cdot$. This radical would have a variety of reaction paths available to it and has been subjected to speculation.[15] There are only three experimental studies which report processes involving the isomerization pathway.[16-18] Unfortunately these studies lack detailed qualitative and quantitative information concerning the isomerization pathway. The Arrhenius expressions for reaction A were estimated to be $k_A=10^{11.8}\exp(-8900/RT)$ and $k_A=10^{11.4}\exp(-7700/RT)$ s^{-1}, respectively, by Carter et al.[16] and Baldwin and Golden,[17] where the activation energies are in cal mol^{-1} (1 cal=4.184 J). Niki et al.[18] showed that at 298 K in 700 Torr (1 Torr=133.322 Pa) of air the ratio of reaction of n-$C_4H_9O\cdot$ with O_2 compared to isomerization was 0.23. In this study we not only report the rate coefficient for n-$C_4H_9O\cdot$ isomerization reaction but also report some of the

† CAES Report No. 744-85.

products that are formed from the isomerization pathway.

Experimental

Mixtures of n-C_4H_9ONO with NO, O_2, and N_2 were photolyzed with 366 nm radiation, and the products analyzed using gas chromatography and mass spectrometry. In the gas chromatography system, two reaction cells were used. A 765-cm^3 spherical Pyrex reaction vessel was used for the temperature range of 23 to 120 °C. The reaction vessel was enclosed in an aluminum furnace, resistively-heated in which temperature regulation was achieved by an Omega proportional temperature controller model type 1522. For low-temperature photolysis at −8 °C, a 413 cm^3 cylindrical Pyrex reaction vessel was used. The low temperature was obtained by circulating ethanol cooled by dry ice through a Pyrex jacket that surrounds the reaction vessel. This procedure has been previously described.[11]

After irradiation was terminated, n-C_3H_7CHO, C_2H_5CHO, and CH_3CHO were analyzed on a Varian 1520B gas chromatograph using a FID detector. The products were separated using a 9-foot by 1/4″-diameter stainless-steel column containing GP 20%, SP-2100/0.1% Carbowax 1500 on Supelcoport. All analyses were carried out at 23 °C with a helium flow rate of 25 $cm^3\ min^{-1}$. In experiments with added NO, N_2, or O_2 the excess reactants were removed by condensing a portion of the photolysis mixture in a gas sample loop at −196 °C and pumping off the non-condensable gases prior to analysis.

In the mass spectrometry system a 329-cm^3 cylindrical Pyrex reaction vessel was used for the temperature range of 23 to 120 °C. The heating and regulation of the cell temperature was the same as mentioned earlier. Photolyses at −8 °C were not performed using the mass spectrometer due to the difficulty involved in adapting the low temperature cell to the instrument. The performance and operating parameters of the mass spectrometer have been described in previous studies.[19-20]

In both systems a conventional Pyrex vacuum line was employed. The line was kept grease free by the use of Teflon stopcocks with Viton "O" rings. The source of radiation was a medium pressure mercury lamp (Hanovia type 30620), used in conjunction with a 0—52 and 7—54 Corning glass filters to isolate the 366 nm line.

Quantum yields were based on light intensities measured by the photolysis of azomethane which has also been previously described.[19] The azomethane was prepared as before.[19] Absorption cross-sections were determined by using the lamp/filter combination as a light source and an RCA 935 phototube to measure the radiation. The absorption cross-sections were found to be (to base 10) 5.94×10^{-20} cm^2 for n-C_4H_9ONO which was independent of temperature from −8 to 120 °C and 4.54×10^{-21} cm^2 for azomethane at 23 °C.

The butyl nitrite was prepared as before and stored over mercury and Drierite in the dark at −196 °C.[19] Ninety-nine percent acetaldehyde, propionaldehyde, and butyraldehyde were obtained from Aldrich and used without purification. Extra dry oxygen (>99.6%) was obtained from Airco and used without purification. Matheson NO and N_2 was used; only the NO was purified trap-to-trap from −186 to −196 °C prior to use. All compounds condensable at −196 °C were degassed at this temperature before use.

Results

n-C_4H_9ONO was photolyzed by 366-nm radiation in the presence of NO, N_2, and O_2. The photolysis products n-C_3H_7CHO, C_2H_5CHO, and CH_3CHO were measured. In experiments performed at 88 and 120 °C, product growth occurred even without irradiation. At these elevated temperatures the thermal decomposition of the nitrite starts to become significant thus explaining the dark growth. To obtain correct quantum yields at these temperatures each photolysis was performed along with an identical dark run in which the dark growth was subtracted from the photolytic run. The correction was usually small and always less than 15% of the total amount of each product produced.

Initially experiments were performed in the absence of O_2 with a constant pressure of NO and the total pressure was varied by the addition of N_2. The results are presented in Table 1. At 23 °C, the total density was varied from $\approx2.8\times10^{-4}$ n-C_4H_9ONO mol dm^{-3} (≈5.0 Torr) to 1.7×10^{-2} mol dm^{-3} (300 Torr) while the concentration of NO and n-C_4H_9ONO remained constant at $\approx1.6\times10^{-7}$ NO mol dm^{-3} (≈30 mTorr) and 2.8×10^{-4} n-C_4H_9ONO mol dm^{-3} (≈5.0 Torr) respectively. The quantum yield of C_3H_7CHO, $\Phi\{n$-$C_3H_7CHO\}$, essentially remained constant over the entire pressure range, and was equal to 0.012±0.001.

As the temperature increases from −8 to 120 °C, the value of $\Phi\{n$-$C_3H_7CHO\}$ at low NO pressures decreases. However if additional NO is added the value of $\Phi\{n$-$C_3H_7CHO\}$ increases to the same limiting value at high [NO] for every temperature. These results are presented in Table 2. Experiments were performed at constant total pressure of 400 Torr while the NO pressure was varied from ≈30 mTorr to ≈55 Torr.

We next introduced oxygen into our system. First mixtures of n-C_4H_9ONO, NO, and O_2 were photolyzed to illustrate the effect of irradiation time on $\Phi\{n$-

$C_3H_7CHO\}$. Photolyses were performed at 23 °C for mixtures containing $\approx2.8\times10^{-4}$ n-C_4H_9ONO mol dm^{-3} (≈5.0 Torr), $\approx1.6\times10^{-6}$ NO mol dm^{-3} (30 mTorr), and 5.5×10^{-3} O_2 mol dm^{-3} (100 Torr). These data are presented in Table 3 and show that the quantum yield drops slightly with irradiation time between 1.00 and 5.00 min. However it can be observed from a plot of n-C_3H_7CHO produced vs. irradiation time in Fig. 1 that a nearly linear plot is obtained up to ≈5.5 min of irradiation time. This corresponds to the production ≈14.0 mTorr of n-C_3H_7CHO. Thus as long as irradiations are short enough to produce $\leqslant14$ mTorr of n-C_3H_7CHO, accurate initial quantum yields will be obtained. In all subsequent runs, the amount of n-C_3H_7CHO produced was kept below this value.

Next a series of runs was performed at five temperatures (−8 °C to 120 °C) in which n-C_4H_9ONO and NO pressures were kept constant at ≈5.0 Torr and ≈30 mTorr respectively while the O_2 pressure varied from 25 to 200 Torr. In each experiment the total pressure was kept constant at 400 Torr by adding N_2 gas. The general trend at each temperature is that $\Phi\{n$-$C_3H_7CHO\}$ and $\Phi\{C_2H_5CHO\}$ increase while

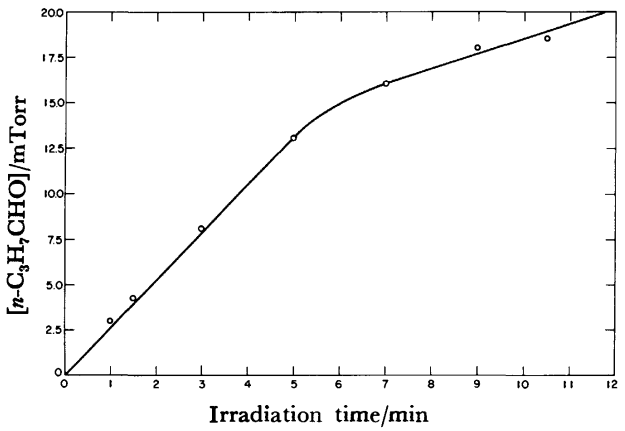

Fig. 1. Plot of $[n$-$C_3H_7CHO]$ vs. irradiation time at 23 °C for data in Table 3.

$\Phi\{CH_3CHO\}$ decreases with increasing O_2 pressure. The results are presented in Table 4.

Finally experiments were performed to check if any higher molecular weight products were being formed from the isomerization pathway. In these experiments n-C_4H_9ONO and NO were kept constant at ≈5.0 Torr and ≈30 mTorr, respectively, while the O_2 pressure was varied from 30 to 300 Torr. The total pressure in each experiment was kept constant at 400 Torr with N_2. Continuous recording of the mass spectra in the range of m/z 65—130 was obtained by allowing the contents of the cell to bleed through a small pinhole

into the mass spectrometer. Other techniques such as GC/CI mass spectrometry and high resolution mass spectrometry were also utilized to determine any higher molecular weight products. In all cases the only mass spectral peak that grew was the 76 m/z peak. Relative quantum yields were obtained by assuming a calibration factor since we could not determine the identity of the 76 m/z peak. The results are presented in Table 5 and indicate that $\Phi\{76\}$, the relative quantum yield of the product with m/z 76, remains nearly constant as the O_2 pressure increases at lower temperatures. However at 120 °C, $\Phi\{76\}$ drops as the O_2 pressure increases.

Discussion

O_2 Absent. The mechanism for the photolysis of n-C_4H_9ONO-NO mixtures is:

where I· is the $HOCH_2CH_2CH_2CH_2\cdot$ radical resulting from the internal abstraction of an H atom by the n-$C_4H_9O\cdot$ radical, and R· can be I· or any radical produced in Reaction 4b.

In addition, there is the possibility that vibrationally-excited n-$C_4H_9O\cdot$ radicals are being produced by photolysis. McMillan et al.[21] have shown that the production of these "hot" alkoxyl radicals is probably not very important in the photolysis of alkyl nitrites at 366 nm. If present, these hot radicals would be expected to rapidly decompose to yield the same products as in the decomposition of the thermally-equilibrated alkoxyl radicals, Reaction 4b.

The data in Table 1 indicate that at 23 °C there is no change in $\Phi\{n$-$C_3H_7CHO\}$ with an increase in total pressure. This leads to the conclusion that Reaction 2a is in its second-order regime at our working pressures (>5 Torr) and that "hot" alkoxyl radicals are not present to any significant extent in this sytem.

The Arrhenius expression for k_{4a} has been estimated to be $k_{4a}=10^{11.8}\exp\{-8900/RT\}$ s^{-1} by Carter et al.[16] and $k_{4a}=10^{11.4}\exp\{-7700/RT\}$ s^{-1} by Baldwin and Golden[17], where the activation energies are in cal mol^{-1}. As we will show our result is in good agreement with these estimates. No measurement exists for k_{4b}, but Baldwin and Golden[17] estimate a high-pressure value for $k_{4b}=10^{13.6}\exp\{-19100/RT\}$ s^{-1}. Furthermore Batt[22] has reported that for a series of alkoxyl radical decompositions log (A_∞ s^{-1}) is $\simeq$15 with high-pressure activation energies $\geqslant$13.8 kcal mol^{-1}. Thus Reaction 4b is very much slower than Reaction 4a at temperatures $\leqslant$120 °C and can be neglected.

The reaction mechanism then predicts that

$$\Phi\{n\text{-}C_3H_7CHO\}^{-1} = \frac{k_2}{\phi_1 k_{2b}}\left(1+\frac{k_2}{k_2[NO]}\right). \quad (a)$$

Plots of $\Phi\{n$-$C_3H_7CHO\}^{-1}$ vs. $[NO]^{-1}$ are given in

a) Uncertainties are one standard deviation. b) From Figs. 2—4.

Figs. 2—4 for the five temperatures studied. The plots are linear, and the intercepts and slopes are listed in Table 6. The slope increases with increasing temperature while the intercept remains essentially constant at 20.0±2.0. The data at 23 and 120 °C were taken to much higher values of [NO] than at the other temperatures and should give more reliable values for the intercept. However the uncertainty at 120 °C is quite large. Thus we adopt the value of 18.5 obtained at 23 °C for the intercept, independent of temperature. The intercept gives $k_2/k_{2b}\phi_1$. Previously we have shown that $k_{2b}/k_2=0.29\pm0.05$.[20] Thus $\phi_1=0.19\pm0.04$. The ratio of slope to intercept gives k_4/k_2 and these values are given in Table 6. An Arrhenius plot for k_4/k_2 is shown in Fig. 5. The data show some curvature, but the least-squares straight line gives $\ln(k_4/k_2,\ \text{mol dm}^{-3})=1.93\pm1.60-(4014\pm509)/T$. A value of k_2 has never been determined for butoxyl, but Batt[22] has shown that k_2 is essentially constant and independent of temperature for a series of alkoxyl radicals from methoxyl to *t*-pentoxyl. His value for k_2 for the ethoxyl radical is 2.6×10^{10} dm^3 mol^{-1} s^{-1}. With this value for k_2, $\log(k_4,\ \text{s}^{-1})=11.25\pm0.69-(4014\pm509)/2.303T$. Our activation energy of 8.0 kcal mol^{-1} is in good agreement with the estimates of 8.9[16] and 7.7[17] kcal mol^{-1}, while our pre-exponential factor of 11.25 is somewhat lower than the estimates of 11.8[16] and 11.4[17].

O_2 Present. In the presence of O_2, the following additional reactions occur.

$$n\text{-}C_4H_9O\cdot + O_2 \longrightarrow n\cdot C_3H_7CHO + HO_2\cdot \quad (6)$$

$$HO_2\cdot + NO \longrightarrow NO_2 + HO\cdot \quad (7)$$

$$HO\cdot + n\cdot C_4H_9ONO \longrightarrow H_2O + n\cdot C_3H_7CHO + NO \quad (8a)$$

$$\longrightarrow n\cdot C_4H_9O\cdot + HONO \quad (8b)$$

$$\longrightarrow \text{Termination } (+76) \quad (8c)$$

$$\longrightarrow \text{Termination } (-76) \quad (8d)$$

$$HO\cdot + NO + M \longrightarrow HONO + M \quad (9)$$

$$HO\cdot + NO_2 + M \longrightarrow HONO_2 + M \quad (10)$$

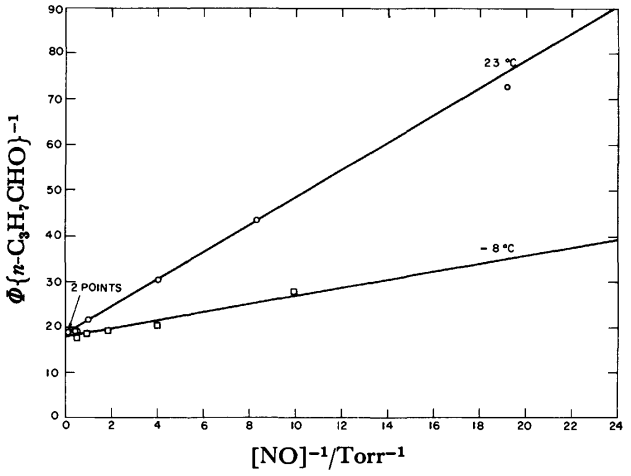

Fig. 2. Plots of $\Phi\{n\text{-}C_3H_7CHO\}^{-1}$ vs. $[NO]^{-1}$ at temperatures of −8 and 23 °C.

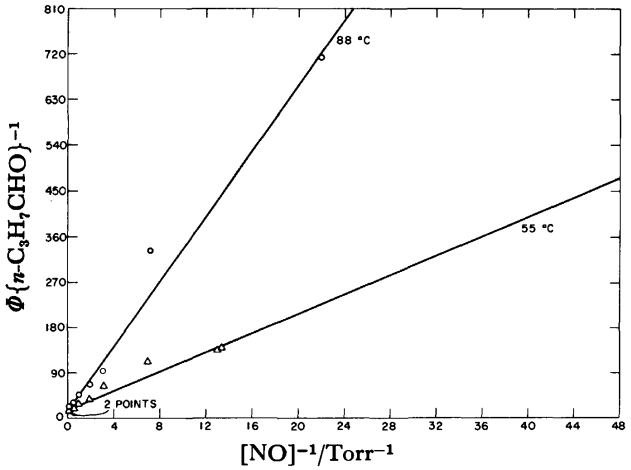

Fig. 3. Plots of $\Phi\{n\text{-}C_3H_7CHO\}^{-1}$ vs. $[NO]^{-1}$ at temperatures of 55 and 88 °C.

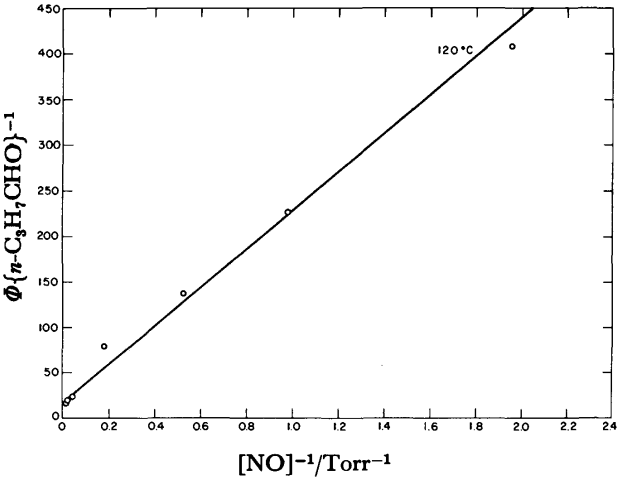

Fig. 4. Plot of $\Phi\{n\text{-}C_3H_7CHO\}^{-1}$ vs. $[NO]^{-1}$ at 120 °C.

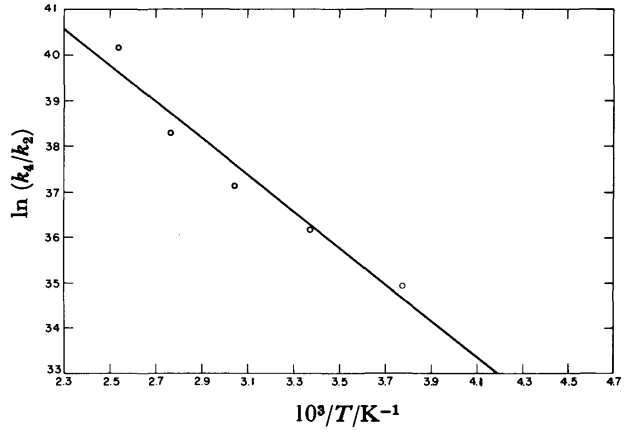

Fig. 5. Arrhenius plot for k_4/k_2.

$$n\text{-}C_4H_9O\cdot + NO_2 \longrightarrow n\text{-}C_4H_9ONO_2 \quad (11a)$$
$$\longrightarrow n\text{-}C_3H_7CHO + HONO, \quad (11b)$$

where Reactions 8c and 8d are some unspecified radical termination steps that either produce the high-molecular weight product with m/z 76 (Reaction 8c) or do not produce it (Reaction 8d). Some termination steps are required in Reaction 8 since other termination steps are too slow to account for the results. We believe that the unidentified product with m/z 76 may be formed in a termination step since its quantum yield is independent of O_2 pressure (except at 120 °C). In principle the reaction of $HO_2\cdot$ with NO_2 should be included, but it is very much slower than Reaction 7 under our reaction conditions so that it can be ignored.

The rate coefficients at 23 °C for k_9 and k_{10} are, respectively, 2.4×10^{11} dm^3 mol^{-1} s^{-1} and 9.4×10^{11} dm^3 mol^{-1} s^{-1}[23] for N_2 or O_2 as a chaperone. k_8 has been measured for butyl nitrite, and it is 2.9×10^9 dm^3 mol^{-1} s^{-1} at 295 K.[24] Furthermore k_8, k_9, and k_{10} are not very sensitive to temperature changes. Thus under all of our conditions 98% of the HO· radicals react with n-C_4H_9ONO, and Reactions 9 and 10 can be ignored. In principal Reaction 11 must be included in the reaction scheme, since NO is converted to NO_2, but Reaction 11 behaves just like Reaction 2, so that ignoring it does not affect the analysis.

The fate of the radical I· formed in Reaction 4b must be considered. It must lead to the aldehyde products which are observed. $\Phi\{CH_3CHO\}$ decreases but $\Phi\{C_2H_5CHO\}$ and $\Phi\{n\text{-}C_3H_7CHO\}$ increase with increasing O_2 pressure. Thus a competition exists to produce these aldehydes, and the implied reactions are

$$I\cdot \longrightarrow CH_3CHO + 2CH_2O + HO, \quad (12a)$$
$$\longrightarrow \text{Undetected aldehydes} + HO, \quad (12b)$$
$$I\cdot + O_2 \longrightarrow n\text{-}C_3H_7CHO + HO, \quad (13a)$$
$$\longrightarrow C_2H_5CHO + HO, \quad (13b)$$

where all the reactions are composite reactions. It is not clear how Reaction 12 proceeds. It may involve an internal rearrangement, a bond cleavage, or reaction with NO. Reaction 12b is included for generality, and appears to be needed. The undetected aldehydes may be $CH_2O\cdot$ or other carbonyl compounds. A corresponding reaction could be written for the I·+O_2 reaction, and it may occur to some extent. However for simplicity we shall ignore it.

Reaction 13a probably proceeds via

$$I\cdot + O_2 \longrightarrow HO_2\cdot + \cdot OCH_2CH_2CH_2CH_2\cdot$$

followed by Reaction 7 and rearrangement of the diradical to give n-C_3H_7CHO. The rearrangement may proceed through an excited cyclic tetrahydrofuran intermediate. Reaction 13b probably occurs by addition of O_2 to the radical site

$$I\cdot + O_2 \longrightarrow HOCH_2CH_2CH_2CH_2O_2\cdot$$

followed by

$$HOCH_2CH_2CH_2CH_2O_2\cdot + NO \longrightarrow HOCH_2CH_2CH_2CH_2O\cdot + NO_2$$
$$HOCH_2CH_2CH_2CH_2O\cdot \longrightarrow HOCH_2CH_2CH_2\cdot + CH_2O$$
$$HOCH_2CH_2CH_2\cdot + O_2 \longrightarrow HO_2\cdot + \cdot OCH_2CH_2CH_2\cdot$$

followed by Reaction 7 and rearrangement of the diradical to C_2H_5CHO.

At 120 °C, the ratio $\Phi\{n\text{-}C_3H_7CHO\}/\Phi\{C_2H_5CHO\}$ is constant at 1.40±0.07 independent of O_2 pressure. This indicates that all of the n-C_3H_7CHO is produced in reaction 13a, and that neither Reactions 6 nor 8a are important at 120 °C. Since Reactions 8a and 8b both have small and similar activation energies, then if Reaction 8a is unimportant at 120 °C, it will also be unimportant at all temperatures. This differs markedly from the situation with the lower alkyl nitrites, where it was found that Reactions 8a and 8b were of comparable importance at all temperatures.[11-13] Reaction 8a is really a two-step reaction; i.e. an H-atom abstraction followed by a decomposition of the resulting radical. Possibly with n-C_4H_9ONO, the radical formed from the abstraction isomerizes and undergoes further oxidation before decomposition. Thus Reaction 8a transforms into Reactions 8c and 8d.

The mechanism predicts that

$$\frac{\phi_1(k_{2b}[NO]+\varepsilon k_4+k_6[O_2])}{\sum\Phi\{ald\}(k_2[NO]+k_4+k_6[O_2])} = \frac{(k_{8c}+k_{8d}+\Gamma k_{8b})}{k_8} \quad (b)$$

where $\Gamma \equiv k_2[NO]/(k_2[NO]+k_4+k_6[O_2])$

$\varepsilon \equiv (k_{12a}+k_{13}[O_2])/(k_{12}+k_{13}[O_2])$

$\sum\Phi\{ald\} \equiv \Phi\{CH_3CHO\} + \Phi\{C_2H_5CHO\} + \Phi\{n\text{-}C_3H_7CHO\}$

At 120 °C, $\sum\Phi\{ald\}=0.27\pm0.01$ independent of O_2 pressure. This means that k_{12b} is unimportant so that $\varepsilon=1.0$, and that Reaction 2 is negligible compared to Reaction 4. Γ is essentially zero, and Eq. b simplifies to

$$\phi_1/\sum\Phi\{ald\} = (k_{8c}+k_{8d})/k_8. \quad (c)$$

Since $\phi_1=0.19$, $(k_{8c}+k_{8d})/k_8=0.70\pm0.03$ at 120 °C. At lower temperatures, the correction terms become more important, but they are still small at 88 °C. Here $\sum\Phi\{ald\}$ increases from 0.22 at low $[O_2]$ to 0.27 at high $[O_2]$ indicating that ε is not constant. However at high $[O_2]$, $\varepsilon\simeq1.0$, and Eq. c can be used. Thus at 88 °C, $(k_{8c}+k_{8d})/k_8$ also is $\simeq0.70$. This is in accord with the findings for lower alkyl nitrites that the branching ratios for k_8 are independent of temperature.[11-13] Thus we assume that $(k_{8c}+k_{8d})/k_8=0.70$ at

all temperatures and thus $k_{8b}/k_8=0.30$. This can be compared with the values of 0.57±0.13, 0.44±0.24, and 0.66±0.12 found, respectively, for $C_2H_5O\cdot$,[11] n-$C_3H_7O\cdot$,[12] and i-$C_4H_9O\cdot$.[13]

The mechanism gives a rate law for butyraldehyde production which can be cast into two forms:

$$(\Phi\{n\text{-}C_3H_7CHO\}_{corr}-\rho)^{-1}=\frac{k_{13}}{k_{13a}}+\frac{k_{12}}{k_{13a}[O_2]}, \quad (d)$$

$$\Phi\{n\text{-}C_3H_7CHO\}_{corr}-\frac{k_{2b}[NO]}{k_4}-\frac{k_{13a}[O_2]}{(k_{12}+k_{13}[O_2])}=\frac{k_6[O_2]}{k_4}, \quad (e)$$

where $\Phi\{n\text{-}C_3H_7CHO\}_{corr}\equiv\theta\Phi\{n\text{-}C_3H_7CHO\}/\phi_1\xi$

$\rho\equiv(k_{2b}[NO]+k_6[O_2])/k_4$

$\theta\equiv(\Gamma k_{8b}+k_{8c}+k_{8d})/k_8$

$\xi\equiv k_4/(k_2[NO]+k_4+k_6[O_2])$.

All of the rate coefficient ratios needed to compute the parameters in Eqs. d and e are known except for k_6/k_4, k_{12}/k_{13a}, and k_{13}/k_{13a}. Thus at each temperature we assume a value for k_6/k_2, compute the left-hand-side of Eq. d, and plot it vs. $[O_2]^{-1}$. From the slope and intercept of the plot, we obtain k_{12}/k_{13a} and k_{13}/k_{13a}, respectively. These values are then used to compute the left-hand-side of Eq. e, which is then plotted vs. $[O_2]^{-1}$ to get a new value for k_6/k_4. This value is then used for the next calculation of the parameters in Eq. d, and the process is repeated until consistent values of k_6/k_4, k_{13}/k_{13a}, and k_{12}/k_{13a} are obtained. This method works well at all temperatures except at −8 and 120 °C. At 120 °C, Eq. e fails because Reaction 6 makes a negligible contribution to $\Phi\{n\text{-}C_3H_7CHO\}$ under all conditions. At this temperature k_6/k_2 is obtained from an extrapolation of the Arrhenius plot of the values at lower temperatures. At −8 °C, Eq. d fails because the results suggest an excess production of n-C_3H_7CHO not accounted for in the mechanism. At this temperature k_{12}/k_{13a} and k_{13}/k_{13a} are obtained from an extrapolation of their Arrhenius plots of the values at higher temperatures.

The final plots based on Eqs. d and e are shown in Figs. 6 and 7, respectively, at each temperature. The values of the slopes and intercepts are listed in Table 7. The intercepts of Fig. 7 have been forced to zero as predicted. Regression analyses of the Arrhenius plots (not shown) give the Arrhenius expressions tabulated in Table 8. If k_2 is taken to be 4.4×10^{-11} cm^3 s^{-1},[22] then $k_6=4.5\times10^8\exp\{(-1178\pm176)/T\}$ dm^3 mol^{-1} s^{-1}. Both the pre-exponential factor and activation energy are slightly larger than those found for the lower alkoxyl radicals.[11-13] However, this difference probably just represents uncertainties since k_6 was determined over a small temperature range (23—88 °C) in this study.

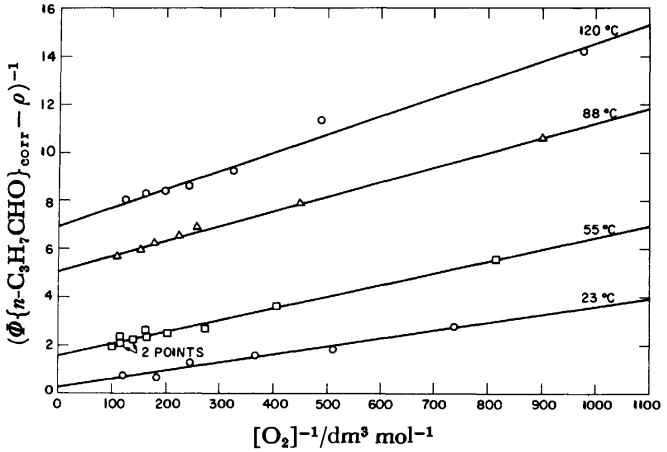

Fig. 6. Plots of $(\Phi\{n\text{-}C_3H_7CHO\}_{corr}-\rho)^{-1}$, computed using values of k_6/k_2 in Table 7, vs. $[O_2]^{-1}$. The plots are displaced upwards by 5, 3, −1, and −2 units, respectively, for 120, 88, 55, and 23 °C for clarity.

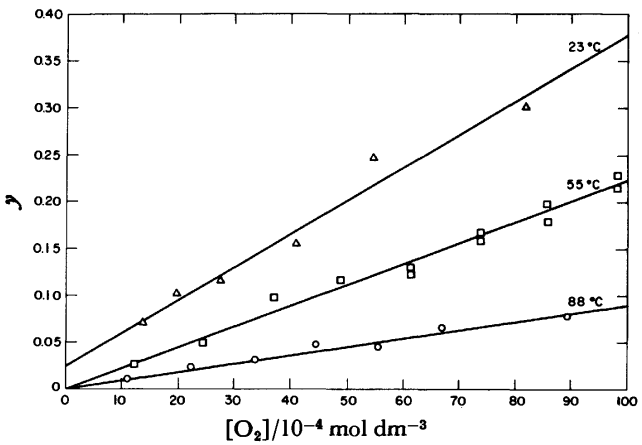

Fig. 7. Plots of y=left-hand side of Eq. e as computed using values of k_{13a}/k_{13} and k_{13a}/k_{12} in Table 7, vs. $[O_2]$. The plot at 23 °C is dispaced upward by 0.025 unit for clarity.

Table 7. Rate Coefficient Ratios from $\Phi\{n\text{-}C_3H_7CHO\}$ Analysis[a,b]

Temp/°C	$10^3\,k_{12}/k_{13a}$/mol dm^{-3}	k_{13a}/k_{13}	$10^3\,k_{12}/k_{13}$/mol dm^{-3}	k_6/k_2
−8	2.29[c]	0.38[c]	0.88[c]	1.97×10^{-4} [c]
23	3.37±0.30	0.444±0.016	1.49±0.22	$(3.05\pm0.20)\times10^{-4}$
55	4.90±0.17	0.394±0.080	1.93±0.30	$(4.92\pm0.17)\times10^{-4}$
88	6.19±0.15	0.489±0.050	3.02±0.18	$(6.21\pm0.40)\times10^{-4}$
120	7.57±0.45	0.508±0.052	3.85±0.23	$(8.35\pm0.55)\times10^{-4}$ [c]

a) Uncertainties are one standard deviation. b) Results tabulated using $k_{8b}/k_8=0.30$. c) Values were determined by extrapolation from Arrhenius plots.

A simpler analysis is obtained from examination of C_2H_5CHO production. The rate law for $\Phi\{C_2H_5CHO\}$ is

$$\Phi\{C_2H_5CHO\}_{corr}^{-1} = \frac{k_{13}}{k_{13b}} + \frac{k_{12}}{k_{13b}[O_2]}, \qquad (f)$$

where

$$\Phi\{C_2H_5CHO\}_{corr} \equiv \Phi\{C_2H_5CHO\}\theta/\phi_1\xi.$$

The left-hand-side of Eq. f is computed from the rate coefficient ratios already determined including those for k_6/k_2, though reaction 6 makes only a trivial correction. The left-hand side of Eq. f is plotted vs. $[O_2]^{-1}$ in Figs. 8 and 9. The values of k_{13b}/k_{13}, k_{12}/k_{13b}, and k_{12}/k_{13} obtained from the plots are listed in Table 9. Respective Arrhenius parameters are listed in Table 8.

The sum of $k_{13a}/k_{13}+k_{13b}/k_{13}$ should be 1.0 according to the mechanism. It is listed in Table 10 and varies from 0.74 to 0.90, indicating that another channel to Reaction 13, perhaps giving CH_2O, might also occur. The ratio k_{13a}/k_{13b} found from the individual values of k_{13a}/k_{13} and k_{13b}/k_{13} is also listed in Table 10. It is about 1.3 independent of temperature.

Another way to obtain k_{13a}/k_{13b} is directly from the following equation predicted by the mechanism:

$$(\Phi\{n\text{-}C_3H_7CHO\}_{corr}-\rho)/\Phi\{C_2H_5CHO\}_{corr} = k_{13a}/k_{13b} \qquad (g)$$

The values of the left-hand side of Eq. g are listed in

Table 8. Regression Equations[a)]

A) From $\Phi\{n\text{-}C_3H_7CHO\}$ analysis
$\ln(k_{13a}/k_{13}) = -0.17\pm0.49-(209\pm165)/T$
$\ln(k_{13a}/k_{12}) = -2.42\pm0.15+(963\pm49)/T$
$\ln(k_{12}/k_{13}) = -2.61\pm0.36-(1194\pm66)/T$
$\ln(k_6/k_2) = -4.09\pm0.54-(1178\pm176)/T$

B) From $\Phi\{C_2H_5CHO\}$ analysis
$\ln(k_{13b}/k_{13}) = -0.60\pm0.41-(139\pm131)/T$
$\ln(k_{12}/k_{13b}) = -6.35\pm1.77+(324\pm566)/T$
$\ln(k_{12}/k_{13}) = -7.12\pm1.87+(230\pm597)/T$

C) Others
$\ln(k_4/k_2) = 1.92\pm1.60-(4014\pm509)/T$[b)]
$\ln(k_{13a}/k_{13b}) = -2.03\pm0.68+(738\pm217)/T$[c)]

a) Uncertainties are 1 standard deviation. Units of rate coefficient ratios are in mol dm^{-3} to the appropriate power. b) From data in absence of O_2. c) From mean values listed in Table 10.

Table 9. Rate Coefficient Ratios from $\Phi\{C_2H_5CHO\}$ Analysis[a,b)]

Temp/°C	k_{13b}/k_{13}	$10^3\,k_{12}/k_{13b}$/ mol dm^{-3}	$10^3\,k_{12}/k_{13}$/ mol dm^{-3}
−8	0.361±0.074	7.01±1.99	2.52±0.17
23	0.295±0.079	6.22±2.17	1.96±0.12
55	0.334±0.010	2.16±0.23	7.31±0.10
88	0.413±0.022	3.82±0.30	1.39±0.12
120	0.385±0.016	6.33±0.25	2.42±0.12

a) Uncertainties are one standard deviation. b) Results tabulated using $k_{8b}/k_8 = 0.30$.

Table 10. Comparison of k_{13a}/k_{13} and k_{13b}/k_{13}

Temp/°C	$(k_{13a}+k_{13b})/k_{13}$[a)]	k_{13a}/k_{13b}[b)]	k_{13a}/k_{13b}[c)]
−8	0.74	1.06	2.32±0.81
23	0.74	1.51	1.65±0.25
55	0.73	1.18	0.97±0.11
88	0.90	1.18	0.90±0.10
120	0.89	1.32	1.07±0.10

a) Sum of values obtained individually from $\Phi\{n\text{-}C_3H_7CHO\}$ and $\Phi\{C_2H_5CHO\}$ as listed in Tables 7 and 9, respectively b) Ratio of values obtained individually from $\Phi\{n\text{-}C_3H_7CHO\}$ and $\Phi\{C_2H_5CHO\}$ as listed in Tables 7 and 9, respectively. c) Obtained from mean value of k_{13a}/k_{13b} obtained from $(\Phi\{n\text{-}C_3H_7CHO\}_{corr}-\rho)/\Phi\{C_2H_5CHO\}_{corr}$ from Table 4.

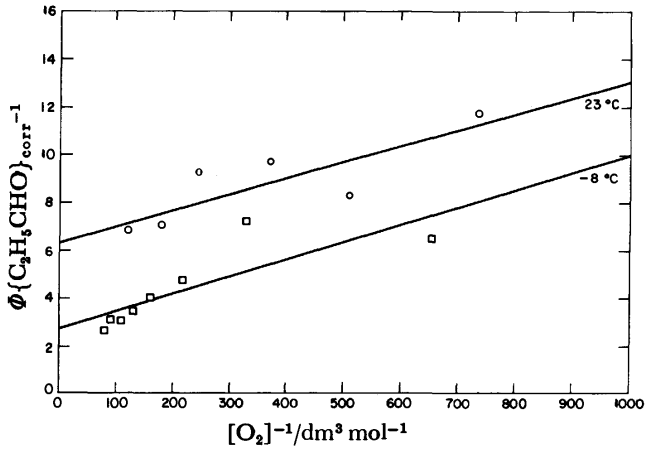

Fig. 8. Plots of $\Phi\{C_2H_5CHO\}_{corr}^{-1}$ computed using values of k_6/k_2 in Table 7, vs. $[O_2]^{-1}$ at −8 and 23 °C. The plot at 23 °C is displaced upward by 3 units for clarity.

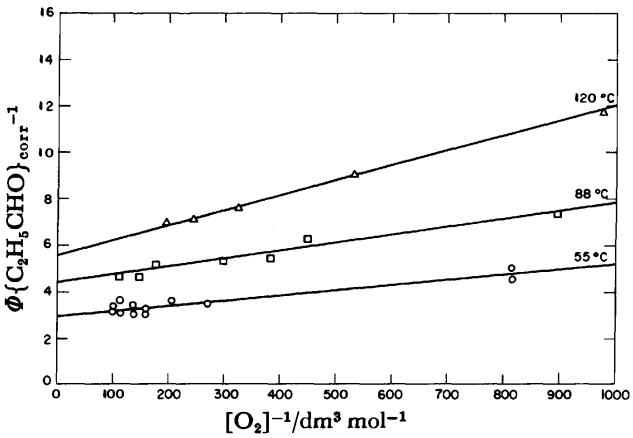

Fig. 9. Plots of $\Phi\{C_2H_5CHO\}_{corr}^{-1}$, computed using values of k_6/k_2 in Table 7, vs. $[O_2]^{-1}$ at 55, 88, and 120 °C. The plots at 88 and 120 °C are displaced upward by 2 and 3 units, respectively, for clarity.

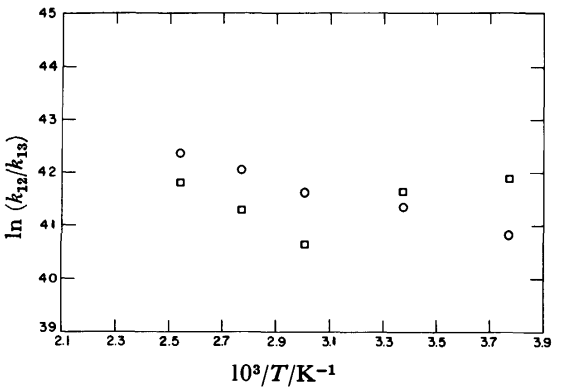

Fig. 10. Arrhenius plot for $\ln(k_{12}/k_{13})$ vs. reciprocal temperature.
○, from $\Phi\{n\text{-}C_3H_7CHO\}$; and □, from $\Phi\{C_2H_5CHO\}$.

Table 4 for every run. The values are nearly independent of O_2 pressure, as they should be, except at −8 °C, where they increase with $[O_2]$. It is not clear why this trend occurs at −8 °C, but an additional source of n-C_3H_7CHO, not given by the mechanism, is indicated. The mean values at any temperature are listed in Table 10, and they are consistent with the values obtained from analysis of the individual aldehyde quantum yields.

In principle additional information can be found from the rate law for CH_3CHO formation. However this is not feasible here since the details of the rate law are unknown. The values of k_{12}/k_{13} obtained from $\Phi\{n\text{-}C_3H_7CHO\}$ and $\Phi\{C_2H_5CHO\}$ are plotted in an Arrhenius plot in Fig. 10. The agreement between the values obtained from the two aldehydes is good only to within a factor of three. The values obtained from $\Phi\{n\text{-}C_3H_7CHO\}$ give a good linear Arrhenius plot, whereas those from $\Phi\{C_2H_5CHO\}$ do not. Thus we prefer the value of k_{12}/k_{13} obtained from $\Phi\{n\text{-}C_3H_7CHO\}$.

For the quantum yield of termination product of Reaction 8c, $\Phi\{76\}$, the mechanism predicts that

$$\Phi\{76\} = \phi_1(1-\Gamma)k_{8c}/(k_{8c}+k_{8d}+\Gamma k_{8b}) . \qquad (i)$$

Since $\Gamma \approx 0$, Eq. i simplifies to:

$$\Phi\{76\} = \phi_1 k_{8c}/(k_{8c}+k_{8d}) . \qquad (j)$$

Thus $\Phi\{76\}$ should be independent of O_2 pressure at any temperature, which it is, except at 120 °C. Perhaps at 120 °C, some secondary oxidation of this product occurs which reduces its primary quantum yield. However it decreases with increasing temperature indicating that both Reaction 8c and 8d must be playing a role in termination. Since only relative values are known for $\Phi\{76\}$, the relative importance of Reactions 8c and 8d cannot be found.

We appreciate helpful comments and suggestions by S. Zabarnick. This work was supported by the Environmental Protection Agency through Grant. No. R808528 for which we are grateful.

The syntheses of five optically active α-aryl-2-pyridylmethanols **1**—**5** are described. It is shown by means of chemical correlation with the known (−)-(α *R*,2*S*)-α-phenyl-2-piperidylmethanol **6** that all levo-rotatory isomers of **1**—**4** are of R configuration. It is also found via the relative integral intensities in the infrared spectra of the bands due to free and intramolecularly bonded hydroxyl groups in the compounds **1**—**4** and the free hydroxyl groups in the model compounds **7**—**10**, that the population of the conformers with an intramolecular OH···N bond in compounds **1**—**4** exceeds 80%.

In continuation of our investigations on the preparation, absolute stereochemistry and chiroptical properties of chiral 1,2-disubstituted 1,2-diarylethanes[1,2] were recently undertaken studies employing as models compounds containing two geminal aromatic carbo- or hetero-cyclic chromophores.

We presently wish to report the results from the preparation of a series of chiral α-aryl-2-pyridylmethanols **1**—**5** as well as data on their absolute configuration and preferred conformations obtained by means of chemical correlation and infrared spectroscopy. Our circular dichroism investigations require the stereochemical structure of the above mentioned compounds to be reliably known as the aim is the elucidation of some general relationships between molecular chirality and aromatic Cotton effects in compounds with geminal phenyl and pyridyl chromophores at the chiral center. It is known that such molecular moieties are present in important biologically active compounds with clearly observable biostereoselectivity.[3]

Results and Discussion

Synthesis of the Racemic Methanols 1—5. Various approaches exist in the literature regarding the preparation of the racemic methanols **1**—**5**.[4-10] Among the most convenient ones is the procedure developed by Gilman and Spatz[10a] based on the interaction of 2-pyridyllithium with the corresponding aromatic aldehyde. In the present case the reaction was conducted at −78 °C, a temperature considerably lower than the recommended, leading to the racemic methanols **1**—**5** in yields significantly better than those reported for analogous compounds (see Experimental).

Preparation of the Optically Active Methanols. Among all presently considered methanols **1**—**5** only compound **1** was found described in an optically active form.[11-13] This compound resolved by Davies with (+)-tartaric acid[11] and considered as the pure levo-rotatory isomer[12-14] was found in the present investigations to be optically impure (see below).

The racemic methanols **2** and **4** were successfully resolved by means of (+)-tartaric acid, while the racemic **3** was resolved by means of (−)-*O*,*O*′-dibenzoyltartaric acid.

The optically active methanol **1** was obtained by dehalogenating samples of (+)-**2**, (−)-**3**, and (+)-**4** of highest purity by treatment acc. ref.[15] with hydrazine hydrate in the presence of palladium over charcoal. In all three cases the obtained samples of **1** showed at λ=589 nm in chloroform practically the same absolute value of the specific rotation i.e. +162.9°, −161.5°, and +162.8°. It can be seen that these values agree very well among themselves while on the other hand they considerably exceed the reported ones for **1** by other authors i.e. $[\alpha]_{589}=-86.2°$ [11] and $[\alpha]_{589}=-108°$.[12]

It can thus be concluded that in the present investigations the racemates of **2**, **3**, and **4** were completely resolved, while the previously reported resolution of (±)-**1** with (+)-tartaric acid[11,12] indeed afforded a product of 50—70% optical purity.

The resolution of (±)-**5** offered considerable difficulties, the best result being obtained with (+)-camphor-10-sulfonic acid. Repeated recrystallization of the diastereoisomeric sulfonates afforded insufficiently pure free base **5** which had to be subjected to additional fractional recrystallization in order to remove the less soluble (±)-**5** finally leading to the desired optically pure **5**.

Absolute Configuration. The possibilities for the application of chemical correlation are rather restricted since only a few chiral compounds with geminal aryl and pyridyl groups with reliable absolute configuration have hitherto been reported.[3a,16]

Employing the chemical transformation approach and circular dichroism Pohl and Wollweber recently compared the absolute configuration of (−)-ephedrine and (−)-*erythro*-α-phenyl-2-piperidylmethanol **6**.[17] In this much more reliable way they corroborated the earlier assumption made by Fauley and LaPidus[18] that (−)-*erythro*-**6** is of (α*R*,2*S*) configuration. On the ground of this conclusion and the earlier results[12,14] regarding the conversion of (−)-α-phenyl-2-pyridylmethanol on catalytic hydrogenation into (−)-*erythro*-**6** it can be assumed that the chiral center in (−)-**1** is of R configuration.

In the conversion of (−)-**1** into (−)-**6** carried out by other researchers[12,14] samples of low optical purity have been used and the absence of *threo*-**6** in the products had not been experimentally determined. For this reason we subjected the presently obtained (−)-**1** with $[\alpha]_{578}=-169.5°$ (chloroform) to catalytic hydrogenation. The thin-layer chromatographic analysis of the crude reaction mixture revealed indeed the presence of the two expected diastereoisomers. From this mixture was successfully isolated in pure form only the predominating *erythro*-**6** isomer with $[\alpha]_{578}=-53.2°$(chloroform). The comparison of the data obtained in the present study for (−)-**1** and (−)-*erythro*-**6** with the reported ones[14] for (−)-**1** $[\alpha]_{578}=-113°$(chloroform) and for (−)-*erythro*-**6** $[\alpha]_{578}=-35.3°$(chloroform) shows that the two samples described earlier have been only of about 65% optical purity. The (α*R*, 2*S*) absolute configuration of the (−)-*erythro*-**6** is in agreement with data obtained recently in circular dichroism studies conducted on molybdenum and rhodium complexes of (−)-**6** formed in situ.[19]

On the other hand the chemical conversions conducted of (+)-**2** to (+)-**1**, of (−)-**3** to (−)-**1**, and of (+)-**4** to (+)-**1**, respectively, which obviously proceed without affecting the absolute configuration,[1b,15] allow the correlation of the absolute configurations also of the three presently obtained chlorine-containing methanols **2**—**4**. In this manner to all the levo-rotatory isomers of **1**—**4** should be assigned R configuration.

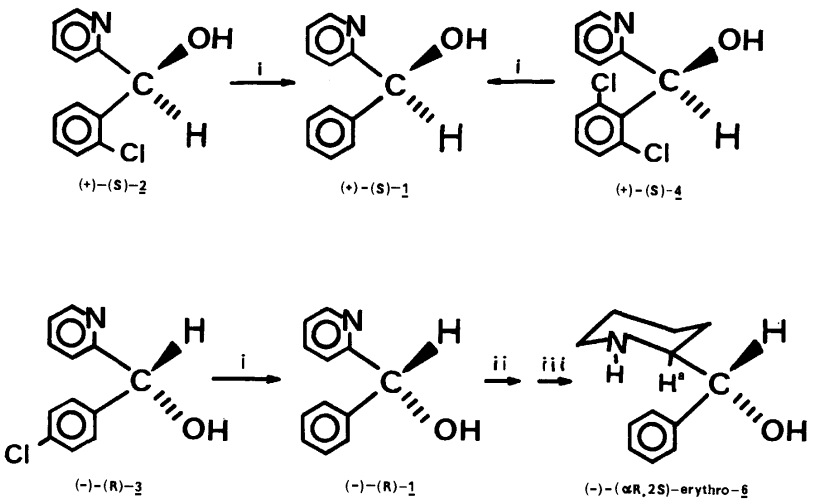
For the correlation of the absolute configuration of (−)-**5** CD method turned out to be the most convenient way. On the basis of the observed exciton coupling between the benzene and 2-pyridine chromophores of a series α-aryl-2-pyridylmethane derivatives we ascribed recently to the levo-rotatory isomer of **5** also the R configuration.[20]

Infrared Spectra. The infrared spectra of the compounds studied (**1**—**4**) give evidence for the existence of at least two conformations, one of them being intramolecularly hydrogen bonded. The task of this study consists in calculating statistical weights of these two conformations in order to give preference to one of them.

The relative populations of mobile conformational equilibria between conformers with bonded and nonbonded hydroxyl groups can be evaluated from the integral intensities (*B*) of the free OH band whose molar absorptivity has been taken from suitably chosen model compounds without intramolecular hydrogen bond.[21] Many reasons reject the use of the bonded OH band.[22] The mole percentage of the bonded conformation is simply derived by subtracting the mole percentage of the free one from 100%.

The IR spectral data are listed in Table 1. Besides the presently studied α-aryl-2-pyridylmethanols it also includes the corresponding 3- and 4-pyridyl-containing compounds used as models. The spectra were taken in 1×10^{-3} mol dm^{-3} carbon tetrachloride solutions in a 5 mm NaCl cell.

The relative error in the determination of the mole percentage of the free and bonded conformations mainly reflects the accuracy of the *B* values for the



Scheme 2. i $NH_2NH_2\cdot H_2O$, Pd/C; ii H_2, PtO_2; iii Separation of mixture erythro+threo, TLC analyse.

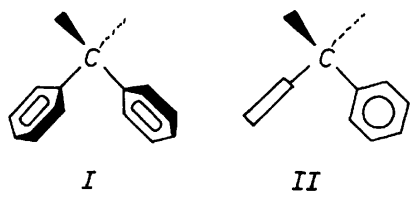
a) Bond OH···Cl. b) α-Phenyl-3-pyridylmethanol (**7**), α-Phenyl-4-pyridylmethanol (**8**), α-(2-Chlorophenyl)-3-pyridylmethanol (**9**), α-(4-Chlorophenyl)-3-pyridylmethanol (**10**), α-(2,6-Dichlorophenyl)-3-pyridylmethanol (**11**). c) The *B* value for OH···Cl band is 2570.

studied sample and the reference model compounds. The structural isomers containing 3- and 4-pyridyl groups **7**—**11** were chosen as standard compounds free of intramolecular OH···N bonding. The conformational distribution of compound **1** was determined employing **7** and **8** as models. The difference between the calculated B values of these two compounds was 4 units which renders the error in the evaluation of the conformational distribution below 1%. For this reason the conformational populations of the remaining compounds **2**—**4** were evaluated using one standard compound with free hydroxyl group — the corresponding α-aryl-3-pyridylmethanols.

The study of the mole percentage of the conformational populations of compounds **1**—**4** given in Table 1 leads to the conclusion that the greatest statistical weight (above 80%) should be ascribed to conformations with bonded hydroxyl functions. The introduction of a chlorine atom in an ortho position, compound **2**, increases the statistical weight of the intramolecularly bonded conformer by 13%. The effect of the chlorine atom in para position, compound **3**, in comparison with the ortho isomer appears to be less pronounced because of the lack of steric hindrance. The difference in the conformational populations of compound **1** and **3** is too small to seek for an explanation. They have been expected to give rise to nearly equal populations. The corresponding differences for **1** and **2** (respectively, 4) obviously reflect the presence of the voluminous chlorine atoms in the ortho positions. The helical (I) and the perpendicular (II) conformations are the two



I *II*

Scheme 3.

conformations that diarylmethanes may assume. The helical conformation is considered to be the preferred one in the solid state, while the data in solution are ambiguous.[23] Most probably the helical conformations are the preferred ones for compounds **1**—**4**, and the ortho substitution further diminishes the population of perpendicular and other forms.[24]

Compound **4** with two chlorine atoms in ortho positions deserves a special attention. Its IR spectrum shows weakening of the OH···N bonding and a presence of a second weak OH···Cl bond at 3579 cm^{-1},[27,28] thus indicating the existence of three conformations: A - without intramolecular hydrogen bonding, B - with an OH···N bonding and C - with an OH···Cl bonding. The contributions of these three conformations will be separately considered for the sake of clarity.

The IR spectrum of compound **11** used as a reference, however, contains two bands: A free OH band at 3618 cm^{-1} and a second one at 3579 cm^{-1} due to OH···Cl bonding. The correct use of these bands as standards requires an estimation of their relative populations. Firstly we calculated the mole percentage of the free OH population. This quantity could be determined employing the *B* value of compound **9** as a 100% free OH standard. A value of 39% free OH population for compound **11** was obtained in this way. Using this value and the *B* values of the free OH bands of compounds **4** and **11** we found 6% for the population of the conformation A of compound **4**. The remaining quantity of 94% is distributed among the conformations B and C. The contribution of the conformation C could be approximately estimated using the *B* value (2570) for the OH···Cl band of compound **11** taken as a standard. The relative population of this bonded conformation was found to be 61%. On this basis a value of ca. 3% is obtained for the conformation C in compound **4**. The remaining 91% should be ascribed to the OH···N bonded conformation B which appears to be the most populated one.

Experimental

The mp (on a Kofler apparatus) are uncorrected. Optical rotations were measured with a Perkin-Elmer 241 instrument. IR spectra were recorded on a Bruker IFS 113V instrument. TLC analyses of compound **1—5** were performed on plates coated with silica gel DG (Riedel de Haën, Hanover) using benzene: chloroform: methanol=6:4:1 as a solvent system.

Syntheses of the Racemic α-Aryl-2-pyridylmethanols (1—5) and Their Resolution. General Procedure. To a stirred ethereal solution of 2-pyridyllithium prepared by the halogen-interconversion method (see Refs. 9, 10) from 2-bromopyridine (38 g, 240 mmol) and butyllithium (4.25 g, 600 mmol Li and 41 g, 300 mmol butyl bromide) at −78 °C was added dropwise during 45 min (while the temperature was allowed to rise to −30 °C) the freshly-distilled aromatic aldehyde (120 mmol) dissolved in about 150 ml dry ether. The mixture was stirred for another 1.5 h at the same temperature, hydrolyzed carefully with 25 ml water and worked-up as usual. The isolated crude reaction product was purified as a base or after conversion into hydrochloride.

α-Phenyl-2-pyridylmethanol (1). (±)-**1**: Prepared according to the general procedure. Recrystallization from methanol of the crude base gave the pure (±)-**1** (16.4 g, 74%), mp 74—76 °C (lit,[4,5] mp 76—78 °C).

α-(2-Chlorophenyl)-2-pyridylmethanol (2). (±)-**2**: The crude hydrochloride was recrystallized from MeOH-Et_2O affording 25.4 g (83%) pure (±)-**2**·HCl, mp 170—174 °C (with decomposition) (lit,[4] mp 174—175 °C). Mp of free base 62—64.5 °C (lit,[5,8] mp 63—65 °C).

(+)-**2**: A hot solution of 10.98 g (±)-**2** and 7.50 g (+)-tartaric acid in 130 ml *i*-PrOH was allowed to cool slowly to room temp and then kept at this temp for another 24 h. The resulting crystalline product (10.10 g, mp 133—144 °C) was recrystallized three times with 8 ml *i*-PrOH for each gram of salt to give 5.11 g of crystals, mp 145—147 °C and $[\alpha]_D^{17}$ +28.2° (*c* 1.2, MeOH). After two additional recrystallizations the samples of the corresponding free base (oil) possess practically the same $[\alpha]_D^{17}$ values: +242.8° (*c* 0.5, $CHCl_3$). Yield of (+)-**2** was 2.20 g (40%).

α-(4-Chlorophenyl)-2-pyridylmethanol (3). (±)-**3**: After one recrystallization of the crude **3**·HCl from MeOH-Et_2O and one of the free base from EtOAc 20.2 g (77%) pure (±)-**3** was obtained with mp 82.5—84 °C (lit, mp 80—81 °C,[5] 83 °C[6]).

(−)-**3**: From a solution of 3.30 g (±)-**3** and 5.37 g (−)-*O,O'*-dibenzoyltartaric acid in 25 ml hot *i*-PrOH after slow cooling and standing for 24 h at room temp 3.14 g salt (mp 141—144 °C) was collected and subjected to two additional recrystallizations from 7 resp. 6 ml *i*-PrOH. Yield of the crystalline salt was 1.80 g, mp 145—148 °C, $[\alpha]_D^{17}$ −80.1° (*c* 0.6, MeOH). The corresponding free base mp 95—97 °C, $[\alpha]_D^{17}$ −123.2° (*c* 0.5, $CHCl_3$). After two further recrystallizations of the salt the optical rotation of the liberated base reached $[\alpha]_D^{13}$ −131.1° (*c* 0.5, $CHCl_3$), which value increased after two more recrystallizations of the salt to $[\alpha]_D^{16}$ −132.5° (*c* 0.7, $CHCl_3$).

α-(2,6-Dichlorophenyl)-2-pyridylmethanol (4). (±)-**4**: The pure **4**·HCl after recrystallization of the crude salt from MeOH-Et_2O (yield 28.7 g, 83%, Anal. ($C_{12}H_{10}Cl_3NO$) C, H, Cl) was converted into the free base (±)-**4**, mp 76—78 °C (lit,[7,8] mp 79.5—82 °C).

(+)-**4**: 5.08 g (±)-**4** and 3.00 g (+)-tartaric acid were dissolved in 75 ml of refluxing *i*-PrOH and then allowed to stand. After about 10 d by spontaneous crystallization at room temp 1.27 g crystals were collected. The further recrystallization of this crystalline product from *i*-PrOH (15 ml) afforded after 1 d at room temp 0.12 g of salt (3%), mp 105—108 °C and $[\alpha]_{546}^{19}$ +189.1° (*c* 0.4, MeOH). The corresponding free base (oil) with $[\alpha]_D^{19}$ +182.9° (*c* 1.0, $CHCl_3$) on hydrogenolysis to (+)-**1** found to be optically pure.

α-(4-Methoxyphenyl)-2-pyridylmethanol (5). (±)-**5**: After recrystallization of the crude base from EtOAc 12.94 g (50%) (±)-**5** with mp 131.5—133 °C (lit,[3] mp 133—134 °C) was obtained.

(−)-**5**: 4.30 g (±)-**5** and 4.00 g (+)-camphor-10-sulfonic acid were dissolved in 50 ml refluxing *i*-PrOH. After six recrystallizations from *i*-PrOH (salt(g): *i*-PrOH(ml)=1:6) the resulting crystalline salt with mp 144—147 °C and $[\alpha]_D^{16}$ −0.1° (*c* 0.5, MeOH) was found to be only partially resolved. The corresponding optically impure base with $[\alpha]_D^{16}$ −24.8° (*c* 0.7, $CHCl_3$) was recrystallized several times from EtOAc by which procedure only from the third mother liquor 90 mg (4%) of the levo-rotating isomer, mp 70.5—72 °C and $[\alpha]_D^{16}$ −139.2° (*c* 0.7, $CHCl_3$) was isolated.

Convesion of the Optically Active Chlorine-Containing Methanols 2—4 into α-Phenyl-2-pyridylmethanol 1. General Procedure. The chlorine containing methanol (1 mmol) dissolved in 10 ml dry EtOH was refluxed for 5 min in the presence of 2 ml of hydrazine hydrate (98%) and 70 mg of Pd/C (10%).[15] The catalyst was filtered off, washed with EtOH and the combined filtrates evaporated to dryness. The resulting oil was taken up in $CHCl_3$ and washed with water. The residue after removing the chloroform is the practically TLC pure methanol **1**. A recrystallization from light petroleum afforded **1** as colorless crystals.

Conversion of (+)-2 into (+)-1. From 450 mg (+)-**2** with $[\alpha]_D^{17}$ +242.8° (*c* 0.5, $CHCl_3$) according to the general procedure 266 mg (70%) of pure (+)-**1**, mp 63—67 °C and $[\alpha]_D^{17}$ +162.9° (*c* 0.4, $CHCl_3$), was obtained after recrystallization.

Conversion of (−)-3 into (−)-1. 220 mg (−)-**3** with $[\alpha]_D^{17}$ −132.5° (*c* 0.7, $CHCl_3$) in the same manner afforded 132 mg (71%) pure (−)-**1**, mp 64.5—66 °C and the following values for the optical rotation in chloroform: $[\alpha]_D^{16}$ −161.5° (lit, −86.2°,[11] −108°[12]), $[\alpha]_{578}^{16}$ −169.5° (lit,[14] −113°), $[\alpha]_{546}^{16}$ −197.0° (lit,[11] −104.7°).

Conversion of (+)-4 into (+)-1. From 221 mg of (+)-**4** with $[\alpha]_D^{23}$ +182.9° (*c* 0.5, $CHCl_3$) according to the general procedure after recrystallization pure (+)-**1** (62 mg, 39%), mp 64—67 °C and $[\alpha]_D^{17}$ +162.8° (*c* 0.4, $CHCl_3$), was obtained.

Catalytic Hydrogenation of (−)-1 to (−)-*erythro*-(*αR, 2S*)-α-Phenyl-2-piperidylmethanl (6). 2.44 g (11 mmol) of (−)-**1**·HCl ($[\alpha]_D^{17}$ −215.0° (*c* 0.4, MeOH), corresponding base: $[\alpha]_D^{17}$ −162.8° (*c* 0.4, $CHCl_3$)) dissolved in 100 ml dry EtOH in the presence of 70 mg of PtO_2 was hydrogenated according to Ref. 12a in a rotating laboratory autoclave at 5.5 atm and room temp. After the consumption of 36.3 mmol of H_2 (in about two hours and a half) the catalyst and the

solvent were removed. The resulting mixture containing the two optically active diastereoisomeric α-phenyl-2-piperidylmethanol hydrochlorides was subjected to separation by twofold recrystallization from abs EtOH–Et_2O[29] to give 1.24 g (51%) of (−)-*erythro*-**6**, mp 212—216 °C and $[\alpha]_D^{17}$ −32.2° (*c* 0.6, H_2O), $[\alpha]_D^{17}$ −12.4° (*c* 0.3, $CHCl_3$). TLC analysis of the corresponding free base: One spot (silica gel; Et_2O:MeOH=17:3) was found to be free from the threo isomer. At the same conditions TLC analysis of the crude reaction mixture gave two spots with $R_{f(erythro)}$=0.13 and $R_{f(threo)}$=0.21.

The free base of (−)-*erythro*-**6** had mp 127—130 °C and $[\alpha]_D^{17}$ −50.8°, $[\alpha]_{578}^{17}$ −53.2° (*c* 0.4, $CHCl_3$). Lit mp and optical rotation for (−)-*erythro*-**6**·HCl 213.5—215 °C, $[\alpha]_D$ −22.0° (H_2O),[18] $[\alpha]_D$ +7.0° ($CHCl_3$)[12] and for (−)-*erythro*-(α*R*,2*S*)-**6**-base −132—133°C, $[\alpha]_{578}$ −35.3° ($CHCl_3$).[14,17]

We thank the referees for thoroughly examining the paper and making critical comments which we feel have greatly contributed to its improvement. Thanks are also due to Dr. B. Jordanov for helpful discussions.

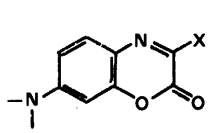
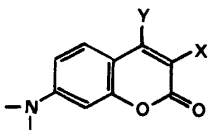
(Received December 19, 1985)

New benzoxazinone type dyes have been synthesized by the reaction of α-keto esters on 2-amino-5-(dialkylamino)phenols. The obtained 7-dialkylamino-2*H*-1,4-benzoxazin-2-ones show a strong fluorescence and a large Stokes shift, reaching 183 nm. An effect of 15 various substituents in position 3, together with a solvent effect have been characterized on their absorption and emission bands. Linear free energy relationships allow the tuning of their spectroscopic characteristics over a large spectral range.

The 2*H*-1,4-benzoxazin-2-ones, abusively called "azacoumarins," have been described by Wislicenus[1] in 1897, and more recently by Biekert[2] and Moffett.[3] They have synthesized many heterocyclic compounds of this kind by the reaction of an acid or a keto ester with an *o*-aminophenol. Actually, only a few derivatives of benzoxazinones with an amino group in the position 7 have been described in the literature.[4] These compounds (**A**) show a strong fluorescence which, due to the bathochromic effect of the heterocyclic nitrogen, is shifted towards the red when compared to the analogous 7-aminocoumarins (**B**). In order to better understand the spectroscopic properties of these highly fluorescent dyes (**A**), we have synthesized a large serie of 3-substituted 7-aminobenzoxazinones, and analyzed the substituent effect together with the solvent effect on their absorption and emission spectra.

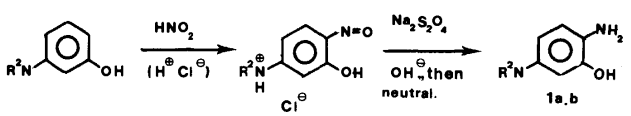


A

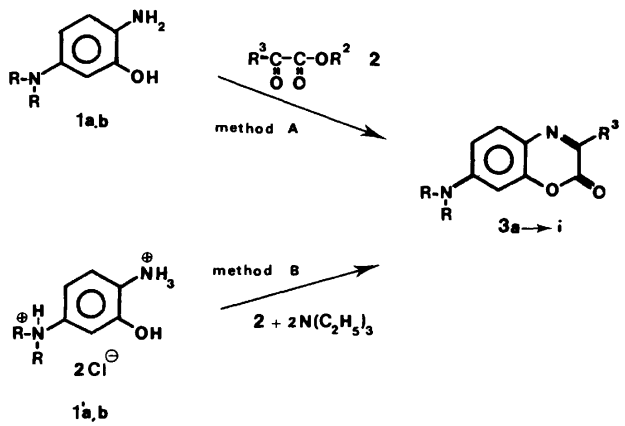


B

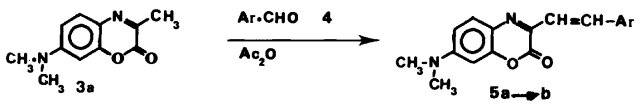
Synthesis of 2*H*-1,4-Benzoxazin-2-ones. The 7-amino derivatives of benzoxazinones are poorly described because of the difficulty to synthesize the starting 2,5-diaminophenols. These compounds are easily oxidized, and their fast degradation leads to highly-blue-colored products, whose structure is still unknown. Nevertheless, taking great care to avoid this oxidation, we isolated 2-amino-5-(dialkylamino)-phenols **1a,b** by reducing 5-dialkylamino-2-nitrosophenols with sodium dithionite in basic medium (**a**, R=Me; **b**, R=Et).



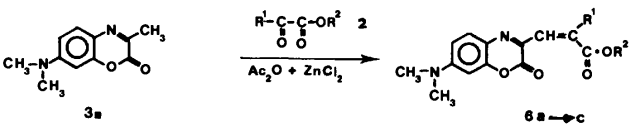
The 7-dialkylamino-2*H*-1,4-benzoxazin-2-ones, **3a,b** substituted in the position 3, have been obtained by the action of α-keto esters **2** on the 2-amino-5-(dialkylamino)phenols **1a,b**, or on the corresponding dihydrochloride **1a,b**, in the presence of a tertiary amine.



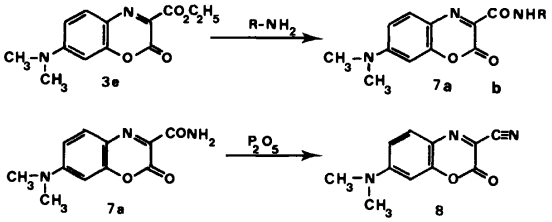
The reactivity of the methyl group on the position 3 in the 7-dimethylamino-3-methyl-2*H*-1,4-benzoxazin-2-ones **3a** allows the formation of 3-styrylbenzoxazinone **5**, by using the method described by Le Bris[4d] which involves the condensation of aromatic aldehydes.



Moreover, a Lewis acid such as anhydrous zinc chloride allows the condensation of a few α-keto esters **2** on the activated methyl group on the position 3.

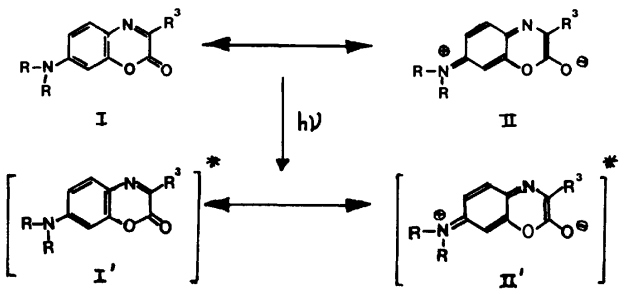


An ester function on the position 3 can also be easily substituted into an amide function, the unsubstituted amide leading to the corresponding nitrile by dehydration.



Spectral Properties of 3-Substituted Benzoxazinones. As shown on Table 1, 3-substituted benzoxazinones (**A**) thus obtained showed very interesting fluorescence properties, which can be explained on the basis of the following mesomeric forms (**I**) and (**II**).

In the ground state, the π-electron distribution in this essentially neutral molecule closely relates to the form (**I**), with a minor contribution of the dipolar form (**II**). On the other hand, the first excited singlet state S_1 can be described by a predominant dipolar



form (**II'**). Consequently, a large increase in the dipole moment of the molecule can be expected during the excitation $S_0 \rightarrow S_1$, which will result in a large rearrangement of the surrounding solvent molecule around the excited state. Thus the energy level of this excited state will be markedly lowered before the emission takes place, with regard to the energy level of its Franck-Condon excited state. These considerations explain the unusually large Stokes shift observed for these molecules (**A**), as compared to others dyes such as xanthenes or even the parent coumarins (**B**).

The dipolar moment variation will be controlled by

the extent of the contribution of the dipolar forms (**II, II'**) to the S_0 and S_1 states, and thus governed by external parameters which are able to modify the electronic distribution in the molecule. For instance substituent as well as solvent can be expected to affect on the position of the absorption and emission bands. For instance, if the small contribution of the polar form (**II**) in the ground state is increased by an electronic effect of the R^3 substituent, a shift of the main absorption band to longer wavelength will occur. A stabilization of (**II**) can also be achieved by the increase of the solvent polarity. The energy level of the S_1 excited state will also be affected by these effects, resulting in an even larger shift of the emission band towards longer wavelength.

In order to go into more details, we have analyzed the effects of the R^3 substituent and of the solvent on the spectral properties of this class of compounds (Tables 1 and 2). The R^3 substituent effect determined in three different solvents shows that shifts of the absorption band higher than 100 nm can be obtained by varying the electronic distribution in the molecule. Using the parameter σ_I which represents the polar nature of a substituent,[5] a satisfying correlation with absorption frequency is obtained for a few substituents for which σ_I is given (Fig. 1). The emission maximum is also shifted by the substituents but to a smaller extent, as could be expected for a state in which the dipolar form (**II'**) is predominant, even for unsubstituted molecule.

Solvents can also affect on the energy levels of the S_0 and S_1 states. As already shown in the literature, the spectroscopic properties of such type of molecules possessing two limit forms, a neutral and a dipolar one, are governed by the solvent polarity.[6] Solvent parameters have been proposed for representing this effect, as for instance E_T on the basis of the spectral behavior of the pyridinium derivative (**C**).[7] Ten solvents of varying polarity have been used to analyze the solvent effect on the absorption and emission bands of one representative molecule of (**A**), with

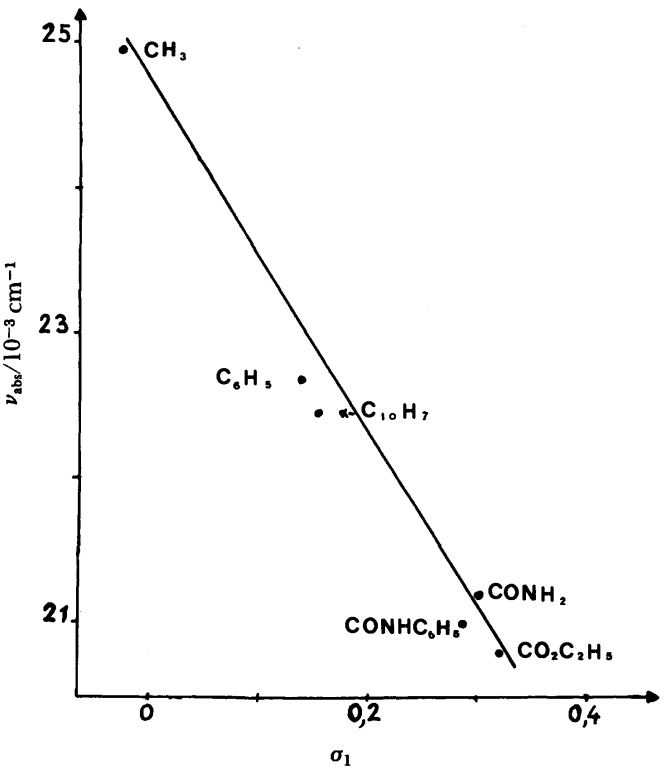

Fig. 1. Free energy relationship between absorption frequency ν_{abs} and substituent parameter σ_I. Solvent: $CHCl_3$.

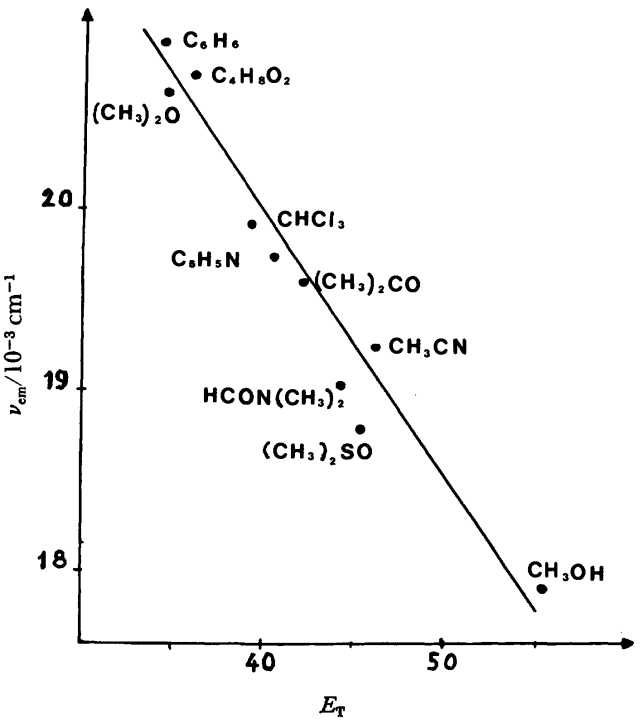

Fig. 2. Relationship between emission frequency (cm^{-1}) and the polarity parameter E_T in various solvents.

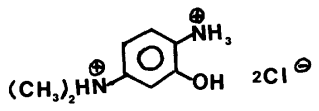
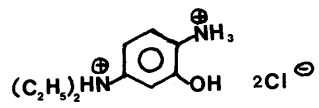
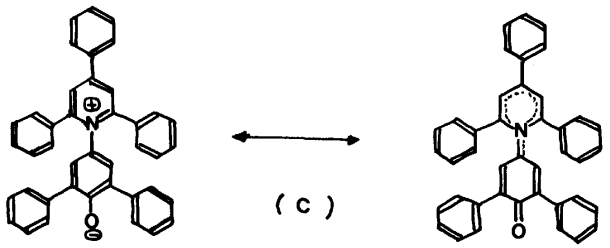
R=Me. The very large shift observed, which obey to a linear relationship with E_T (Fig. 2), emphasizes the significance of the dipolar form contribution to the





structure of these molecules. The observed Stokes shift reaches unusual value as high as 183 nm, compared with the 100 nm obtained with the parent coumarin dyes (**B**) when studied in the same range of solvent polarity. Furthermore, these benzoxazinone dyes possess a high fluorescence yield, as shown by the quantum yield η=0.93 obtained for R=CH_3 in chloroform, using Rhodamine 101 as standard.



In conclusion, the position of the absorption and emission bands of these news benzoxazinone dyes can be tuned over a very large spectral range by the use of a substituent and (or) a solvent effect. Taking also account for their strong fluorescence, this new class of material appears promising for a large field of applications and particularly as laser dyes.

Experimental

Melting points were not corrected and were determined on a Koffler apparatus. The IR spectra were recorded on a Pye Unicam SP 200 spectrophotometer, the ^{1}H NMR spectra on a JNM-FX 100 JEOL spectrometer (the chemical shifts were reported as δ values in parts per million employing tetramethylsilane as an internal standard). The absorption spectra were obtained on a Cary 219 spectrophotometer and the fluorescence spectra on a MPF-44R Perkin Elmer spectrophotometer. Elemental analyses were carried out by the CNRS Microanalysis Laboratory.

Preparation of 2-Amino-5-(dialkylamino)phenols (1a,b). The hydrochloride of 5-dialkylamino-2-nitrosophenols have been obtained in yields of 90% following Ref. 8, then reduced into 2-amino-5-(dialkylamino)phenols by sodium dithionite in basic medium.[9]

We have isolated the compounds **1a** and **1b** by operating under nitrogen atmosphere to avoid of oxidative degradation, and using them readily for subsequent cyclization into benzoxazinones **3**. Besides, the dihydrochlorides **1'a** and **1'b** are stable under solid state. **1'a**: Gray crystals; mp 230 °C (decomp). ^{1}H NMR (D_2O) δ=3.37 (s, 6H, $N(C\underline{H}_3)_2$), 7.20—7.37 (m, 2H, H_4+H_6), 7.63 (d, J=9 Hz, 1H, H_3). **1'b**: Slightly blue crystals; mp 220 °C (dec). ^{1}H NMR (D_2O) δ=1.10 (t, J=7 Hz, 6H, $N(CH_2C\underline{H}_3)_2$), 3.57 (q, J=7 Hz, 4H, $N\text{-}(C\underline{H}_2\text{-}CH_3)_2$), 6.80—7.10 (m, 3H, H_3+H_4+H_6).

Preparation of 3-Substituted 7-Dialkylamino-2*H*-1,4-benzoxazin-2-ones. Metod A. To a solution of 20 mmol of α-ketoester **2**† in 50 ml of dry toluene and under nitrogen atmosphere, 20 mmol of 2-amino-5-(dialkylamino)phenols (**1**) were added with stirring. This reaction mixture was refluxed for 1 h and the water produced during the cyclization was eliminated by azeotropic distillation. After cooling, the organic layer was separated and concentrated to dryness. The benzoxazinone **3** was purified by chromatography on deactivated alumina or on silica gel, then by recrystallization. **2d** p-$(CH_3)_2N$-C_6H_4-CO-$CO_2C_2H_5$: Yellow-green crystals, mp 95 °C (lit,[10] mp 95 °C), **2e** p-CH_3O-C_6H_4-CO-$CO_2C_2H_5$: Slightly yellow oil, bp 195 °C/2 mmHg,†† **2f** $C_{10}H_7$-CO-$CO_2C_2H_5$: Yellow oil, bp 155—160 °C/1 mmHg, (lit,[11] bp 213—215°/23 mmHg).

Method B. Under a nitrogen atmosphere and while stiring, a mixture of 20 mmol of dihydrochloride **1'** and 20 mmol of α-keto ester **2** in 50 ml of dry toluene was refluxed; then 40 mmol of triethylamine were gradually added. The reflux was continued for 1 h with elimination of water as azeotrope. The cooled solution was filtered, the solid triethylammonium chloride was washed two times by 15 ml of toluene. All the organic layers were then treated as above.

7-Dimethylamino-3-methyl-2*H*-1,4-benzoxazin-2-ones (3a). Orange yellow crystals mp 125—126 °C (benzene-ethanol), yield 60% (method A); 70% (method B). Found: C, 64.59; H, 5.97; N, 13.81%. Calcd for $C_{11}H_{12}N_2O_2$: C, 64.69; H, 5.92; N, 13.72%. ^{1}H NMR ($CDCl_3$) δ=2.47 (s, 3H, CH_3-3), 3.02 (s, 6H, $N(CH_3)_2$-7, 6.32 (d, J=2.5 Hz, 1H, H_8), 6.60 (dd, J=9 and 3 Hz, 1H, H_6), 7.42 (d, J=^{1}H, H_5). UV-visible: λ_{max} 400 ($CHCl_3$), 395 nm (DMF); fluorescence: 502 ($CHCl_3$), 525 nm (DMF). IR (KBr): 1725 (s), 1624 cm^{-1} (s) (s=strong).

7-Diethylamino-3-methyl-2*H*-1,4-benzoxazin-2-one (3b). Yellow crystals mp 63—64 °C (cyclohexane). Yield: 50% (Method A); 54% (Method B). Found: C, 67.35; H, 5.94; N, 12.18. Calcd for $C_{13}H_{16}N_2O_2$: C, 67.22; H, 6.94; N, 12.06. ^{1}H NMR ($CDCl_3$) δ=1.16 (t, J=7 Hz, 6H, $N(CH_2C\underline{H}_3)_2$-7), 2.37 (s, 3H, CH_3-3), 3.29 (q, J=7 Hz, 4H, $N(C\underline{H}_2CH_3)_2$-7), 6.16 (d, J=3 Hz, 1H, H_8), 6.39 (dd, J=9 and 3 Hz, 1H, H_6), 7.47 (d, J=9 Hz, 1H, H_5). UV-visible: λ_{max} 397 ($CHCl_3$), 402 nm (DMF); fluorescence: 500 ($CHCl_3$), 520 nm (DMF). IR (KBr): 1733 (s), 1633 cm^{-1} (s).

7-Dimethylamino-3-phenyl-2*H*-1,4-benzoxazin-2-one (3c). Orange crystals, mp 182 °C ($CHCl_3$-ethanol). Yield 40% (method A). Found: C, 72.14; H, 5.15; N, 10.51%. Calcd for $C_{16}H_{14}N_2O_2$: C, 72.16; H, 5.30; N, 10.52%. ^{1}H NMR ($CDCl_3$) δ=3.07 (s, 6H, $N(C\underline{H}_3)_2$-7), 6.33 (d, J=3 Hz, 1H, H_8), 6.68

† α-Ketoesters **2** used are commercial (methyl pyruvate **2a**, methyl benzoylformate **2b**, diethyl mesoxalate **2c**) or have been prepared by a Friedel-Crafts reaction between the ester chloride of oxalic acid ($ClCOCO_2C_2H_5$) and the appropriate aromatic derivative. The structure of these α-keto esters has been verified by ^{1}H NMR.

†† 1 mmHg=133.322 Pa.

(dd, J=9 and 3 Hz, 1H, H_6), 7.37—7.50 (m, 3H, $H_3'+H_4'+H_5'$), 7.62 (d, J=9 Hz, 1H, H_5), 8.17—8.33 (m, 2H, $H_2'+H_6'$). UV-visible: λ_{max} 440 ($CHCl_3$), 443 nm (DMF); fluorescence: 520 ($CHCl_3$), 551 nm (DMF). IR (KBr): 1728 (s), 1620 cm^{-1} (s).

7-Diethylamino-3-phenyl-2*H*-1,4-benzoxazin-2-one (3d). Yield: 60% (Method B). Yellow crystals, mp 101 °C (cyclohexane). Found: C, 73.22; H, 6.21; N, 9.48%. Calcd for $C_{18}H_{18}N_2O_2$: C, 73.45; H, 6.16; N, 9.52%. ^1H NMR ($CDCl_3$) δ=1.19 (t, J=7 Hz, 6H, $N(CH_2CH_3)_2$-7), 3.35 (q, J=7 Hz, 4H, $N(CH_2CH_3)_2$-7), 6.25 (d, J=3 Hz, 1H, H_8), 6.47 (dd, J=9 and 3 Hz, 1H, H_6), 7.15—7.37 (m, 5H, H aromatic phenyl-3), 7.40 (d, J=9 Hz, 1H, H_5). UV-visible: λ_{max} 450 ($CHCl_3$), 462 nm (DMF); fluorescence: 520 ($CHCl_3$), 550 nm (DMF). IR (KBr): 1730 (s), 1620 cm^{-1} (s).

7-Dimethylamino-3-ethoxycarbonyl-2*H*-1,4-benzoxazin-2-one (3e). Yield: 70% (Method A); red crystals, mp 153—154 °C (ethanol). Found: C, 59.77; H, 5.39; N, 10.65% Calcd for $C_{13}H_{14}N_2O_4$: C, 59.53; H, 5.38; N, 10.68%. ^1H NMR ($CDCl_3$) δ=1.43 (t, J=7 Hz, 3H, $CO_2CH_2CH_3$-3), 3.15 (s, 6H, $N(CH_3)_2$-7), 4.43 (q, J=7 Hz, 2H, $CO_2CH_2CH_3$), 6.35 (d, J=3 Hz, 1H, H_8), 6.72 (dd, J=9 and 3 Hz, 1H, H_6), 7.64 (d, J=9 Hz, 1H, H_5). Preparation of 7-dimethylamino-3-styryl-2*H*-1,4-benzoxazin-2-ones (5). A solution of 10 mmol of **3a** and 20 mmol of aromatic aldehyde **4** in 20 ml of acetic anhydride was refluxed for 7 h. In the case of *p*-nitrobenzaldehyde **4b**, the compound **5b** was obtained by filtration of the cooled mixture. In the case of the *p*-(dimethylamino)benzaldehyde **4a**, the compound **5a** was isolated after concentration and chromatography on silica gel using the chloroform as eluent.

7-Dimethylamino-3-(*p*-(dimethylamino)styryl)-2*H*-1,4-benzoxazin-2-one (5a). Yield: 6%; red crystals, mp 252 °C ($CHCl_3$-ethanol). Found: C, 71.53; H, 6.28; N, 12.58%. Calcd for $C_{20}H_{21}N_3O_2$: C, 71.62; H, 6.31; N, 12.53%. ^1H NMR ($CDCl_3$) δ=3.02 (s, 6H, $N(CH_3)_2$-4'), 3.07 (s, 6H, $N(CH_3)_2$-7), 6.43 (d, J=3 Hz, 1H, H_8), 6.67 (dd, J=9 and 3 Hz, 1H, H_6), 6.68 (d, J=9 Hz, 2H, $H_3'+H_5'$), 7.25 (d, J=16 Hz, 1H, H_β), 7.53 (d, J=9 Hz, 3H, $H_5+H_2'+H_6'$), 7.92 (d, J=16 Hz, 1H, H_α). UV-visible: λ_{max} 500 ($CHCl_3$), 495 nm (DMF); fluorescence: 616 ($CHCl_3$), 634 nm (DMF). IR (KBr): 1730 (s), 1632 (m), 1600 cm^{-1} (s).

7-Dimethylamino-3-(*p*-nitrostyryl)-2*H*-1,4-benzoxazin-2-one (5b). Yield: 64%; dark red crystals, mp 260 °C ($CHCl_3$). Found: C, 64.10; H, 4.54; N, 12.44%. Calcd for $C_{18}H_{15}N_3O_4$: C, 64.59; H, 4.48; N, 12.46%. This compound is nearly insoluble in NMR solvents and the spectrum cannot be registered. UV-visible: λ_{max} 496 ($CHCl_3$), 499 nm (DMF); fluorescence: 591 ($CHCl_3$), 682 nm (DMF). IR (KBr): 1737 (s), 1630 (s), 1615 (s), 1595 cm^{-1} (s).

Condensation of 3a with α-Ketoesters 2. A mixture of 5 mol of **3a**, 10 mmol of α-keto ester **2** and 5 mmol of anhydrous zinc chloride in 10 ml of acetic anhydride was refluxed for 1 h. After the removal of the solvent, the residue was washed with boiling methanol; the methanolic solution was evaporated and the residual oil was submitted to column chromatography on silica gel using the dichloromethane as eluent.

Methyl 3-(7-Dimethylamino-2-oxo-2*H*-1,4-benzoxazin-3-yl)-2-methylpropenoate (6a). Yield: 42%; red crystals, mp 174—175 °C ($CHCl_3$-methanol). Found: C, 62.27; H, 5.52; N, 9.22%. Calcd for $C_{15}H_{16}N_2O_4$: C, 62.49; H, 5.59; N, 9.72%. ^1H NMR ($CDCl_3$) δ=2.42 (d, J=1.6 Hz, 3H, C=C-CH_3): 3.08 (s, 6H, $N(CH_3)_2$-7), 3.82 (s, 3H, CO_2CH_3), 6.37 (d, J=3 Hz, 1H, H_8), 6.66 (dd, J=9 and 3 Hz, 1H, H_6), 7.52 (d, J=9 Hz, 1H, H_5), 7.88 (q, J=6 Hz, 1H, HC=C-CH_3). UV-visible: λ_{max} 469 ($CHCl_3$), 476 nm (DMF); fluorescence: 536 ($CHCl_3$), 572 nm (DMF). IR (KBr): 1730 (s), 1710 (s), 1630 cm^{-1} (s).

Methyl 3-(7-Dimethylamino-2-oxo-2*H*-1,4-benzoxazin-3-yl)-2-phenylpropenoate (6b). Yield: 21%; red crystals, mp 188 °C ($CHCl_3$-methanol). Found: C, 67.92; H, 5.17; N, 7.96%. Calcd for $C_{20}H_8N_2O_4$: C, 68.56; H, 5.18; N, 8.00%. ^1H NMR ($CDCl_3$) δ=3.08 (s, 6H, $N(CH_3)_2$-7), 3.95 (s, 3H, CO_2CH_3), 6.38 (d, J=3 Hz, 1H, H_8), 6.65 (dd, J=9 and 3 Hz, 1H, H_6), 7.20—7.70 (m, 7H, 5H aromatic+H_5+HC=C-3). UV-visible: λ_{max} 483 ($CHCl_3$), 488 nm (DMF); fluorescence: 551 ($CHCl_3$), 583 nm (DMF). IR (KBr): 1740 (s), 1730 (s), 1620 cm^{-1} (s).

Diethyl (7-Dimethylamino-2-oxo-2*H*-1,4-benzoxazin-3-yl)-methylenemalonate. Yield: 47%; red crystals, mp 175 °C ($CHCl_3$-methanol). Found: C, 60.00; H, 5.57; N, 7.61%.

Calcd for $C_{18}H_{20}N_2O_6$: C, 59.59; H, 5.59; N, 7.77%. ^{1}H NMR ($CDCl_3$) δ=1.35 (t, J=7 Hz, 6H, $C(CO_2CH_2C\underline{H}_3)_2$), 3.13 (s, 6H, $N(C\underline{H}_3)_2$-7), 4.38 (q, J=7 Hz, 4H, $C(CO_2C\underline{H}_2CH_3)_2$), 6.38 (d, J=3 Hz, 1H, H_8), 6.67 (dd, J=9 and 3 Hz, 1H, H_6), 7.33 (d, J=9 Hz, 1H, H_5), 7.96 (s, 1H, $\underline{H}$-C=C$(CO_2C_2H_5)_2$). UV-visible: λ_{max} 500 ($CHCl_3$), 510 nm (DMF); fluorescence: 557 ($CHCl_3$), 592 nm (DMF). IR (KBr): 1745 (s), 1700 (s), 1628 cm^{-1} (s).

Reactivity of the Ester Group on the 3 Position of the 1,4-Benzoxazin-2-one. 3-Carbamoyl-7-dimethylamino-2*H*-1,4-benzoxazin-2-one (7a). A solution of 10 mmol of **3e** in a mixture of 50 ml of methanol and 5 ml of concentrated aqueous ammonia was refluxed during 15 min.

The amide **7a** was obtained by filtration of the cooled mixture. Yield: 86%; red crystals, mp>280 °C. Found: C, 56.82; H, 4.73; N, 18.16%. Calcd for $C_{11}H_{11}N_3O_3$: C, 56.65; H, 4.75; N, 18.02%. This compound is nearly insoluble in NMR solvents and so the spectrum cannot be registered. UV-visible: λ_{max} 470 ($CHCl_3$), 445 nm (DMF); fluorescence: 530 ($CHCl_3$), 540 nm (DMF). IR (KBr): 3420 and 3285 (-NH), 1710, 1620, 1595 cm^{-1} (s).

7-Dimethylamino-3-phenylcarbamoyl-2*H*-1,4-benzoxazin-2-one (7b). To a refluxed solution of 5 mmol of **3e** in 10 ml of xylene, 10 mmol of aniline were slightly added while azeotrope ethanol-xylene issued from the reaction is eliminated. After cooling the compound **7b** is isolated by filtration. Yield: 50%; red crystals, mp 241 °C ($CHCl_3$-methanol). Found: C, 65.77; H, 4.68; N, 13.54%. Calcd for $C_{17}H_{15}N_3O_3$: C, 66.01; H, 4.89; N, 13.59%. ^{1}H NMR ($CDCl_3$) δ=3.18 (s, 6H, $N(C\underline{H}_3)_2$-7), 6.46 (d, J=3 Hz, 1H, H_8), 6.80 (dd, J=9 and 3 Hz, 1H, H_6), 7.0—7.6 (m, 3H, H_5+2H (o)N-aromatic group), 7.7—8.0 (m, 3H, 2H(m)+1H(p)N-aromatic group), 10.60 (s, large, 1H, $N\underline{H}C_6H_5$). UV-visible: λ_{max} 476 ($CHCl_3$), 474 nm (DMF): fluorescence: 524 ($CHCl_3$), 522 nm (DMF). IR (KBr): 3285 (s, -NH), 1710 (s), 1625 (s), and 1598 cm^{-1} (s).

3-Cyano-7-dimethylamino-2*H*-1,4-benzoxazin-2-one (8). A mixture of 10 mmol of amide **7a** and of 10 mmol of P_2O_5 was heated cautiously on the flame until near 100 °C. At this temperature the reaction starts violently and it can be slowed by rapid cooling. The residue was then extracted by boiling chloroform, the compound **8** then purified by submitting to column chromatography on silica gel, using the chloroform as eluent. Yield: 23%; red crystals, mp 260 °C. Found: C, 61.30; H, 4.31; N, 19.02%. Calcd for $C_{11}H_9N_3O_2$: C, 61.39; H, 4.22; N, 19.53%. ^{1}H NMR (DMSO-d_6) δ=3.22 (s, 6H, $N(C\underline{H}_3)_2$-7), 6.43 (d, J=3 Hz, 1H, H_8), 6.77 (dd, J=9 and 3 Hz, 1H, H_6), (7.68 (d, J=9 Hz, 1H, H_5). UV-visible: λ_{max} 476 ($CHCl_3$), 478 nm (DMF); fluorescence: 523 ($CHCl_3$), 548 nm (DMF). IR (KBr) 2212 (s, C=N), 1722 (s), 1625 cm^{-1} (s).

Support Effect of Zinc Oxide Catalyst on Synthesis of Methanol from CO_2 and H_2

Takashi INOUE, Tokio IIZUKA, and Kozo TANABE*
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received January 5, 1987)

Synopsis. The synthesis of methanol from CO_2+H_2 was carried out at 340—400 °C under total pressure of 10 atm over ZnO supported on MgO, Al_2O_3, SiO_2, TiO_2, ZrO_2, and Nb_2O_5. The ZnO/ZrO_2 catalyst showed high activity and selectivity for methanol formation. The hydrogenation of CO_2 was more selective for methanol synthesis than that of CO.

The hydrogenation of CO has been extensively studied for the synthesis of hydrocarbons and alcohols.[1] For the production of methanol from $CO+H_2$, several catalysts such as $ZnO-Cr_2O_3$, $CuO-ZnO-Al_2O_3$, $CuO-ZnO-Cr_2O_3$ are known to be efficient.[2] However, the study of CO_2 hydrogenation has been much less extensive than those of CO hydrogenation. Although, for the synthesis of methanol from CO_2+H_2, several catalysts such as CuO,[3] Pd,[4] Re,[5] or Pt[6] supported on metal oxides are reported, no study has been made of ZnO supported on metal oxides. Thus, the support effect of ZnO catalyst on CO_2 hydrogenation has been examined in the present work.

Experimental

Zinc oxides supported on various oxides were prepared by impregnating ZrO_2, TiO_2, SiO_2, Al_2O_3, or Nb_2O_5 with an aqueous solution of zinc nitrate followed by calcining at 500 °C for 3 h and reducing at 400 °C in a stream of hydrogen before use. In the case of ZnO/MgO, a methanol solution of zinc nitrate was used to avoid the partial dissolution of MgO in water. The content of ZnO was 10 wt % for all catalysts. Zinc oxide itself was prepared by hydrolyzing an aqueous solution of zinc nitrate with aqueous ammonia followed by treating similarly as above. Commercial catalysts of methanol synthesis from CO and H_2 used for comparison were Toyo CCI, KMA ($ZnO-Cr_2O_3$), and MDC-02 ($CuO-ZnO-Al_2O_3$) which were treated similarly as above.

The reaction was carried out at 340—400 °C under 10 atmospheric pressure by use of a conventional flow reactor. The molar ratio of CO_2/H_2 or CO/H_2 in the premixed gas obtained from Nippon Sanso Co. was 1/3. The flow rate of the gas was 12.5 mmol h^{-1} under standard condition, GHSV being 600—1200 h^{-1}. The reaction products were analyzed by gas chromatography.

Results and Discussion

Table 1 shows the results of the hydrogenation of CO_2 over supported ZnO catalysts. Main products were, besides CO, methanol and dimethyl ether. The ZnO and ZnO/MgO catalysts showed 100 % selectivity for methanol formation, but their activities (rate of methanol formation) were low. On the other hand, the activities of ZnO/Al_2O_3, ZnO/SiO_2, and ZnO/TiO_2 were higher, but their selectivities were lower. The ZnO/ZrO_2 catalyst exhibited not only high activ-

Table 1. Hydrogenation of CO_2 over Supported ZnO Catalysts
($CO_2/H_2=1/3$, Total Pressure = 10 atm)

Catalyst (weight)	Reaction temp / °C	Rate of MeOH+Me_2O formation / 10^{-4} mol h^{-1} g^{-1}	Selectivity/% MeOH	Selectivity/% Me_2O	Rate of CO formation / 10^{-4} mol h^{-1} g^{-1}
ZnO (3.0 g)	360	0.07	100.0	—	0.8
	400	0.08	100.0	—	2.5
ZnO/MgO (1.5 g)	360	0.02	100.0	—	0.1
	400	0.08	100.0	—	0.6
ZnO/Al_2O_3 (1.0 g)	360	0.18	40.8	59.2	1.3
	380	0.5	38.0	62.0	3.7
ZnO/SiO_2 (1.0 g)	360	0.13	97.8	2.2	0.3
	400	0.35	86.9	13.1	1.3
ZnO/TiO_2 (2.0 g)	340	0.3	86.9	13.1	0.6
	360	0.7	77.0	23.0	1.2
ZnO/ZrO_2 (2.0 g)	340	0.4	99.9	trace	0.4
	360	0.8	99.2	0.8	1.1
ZnO/Nb_2O_5 (2.0 g)	360	trace	—	—	1.5
KMA[a] (2.0 g)	360	0.8	99.8	0.2	10.6
MDC-2[a] (2.0 g)	340	0.5	89.7	(10.3)[b]	10.2

a) Commercial catalysts of Toyo CCI. The composition of KMA and MDC-2 are known to be $ZnO-Cr_2O_3$ and $CuO-ZnO-Al_2O_3$, respectively. b) No ether is formed, the selectivities of CH_4 and C_2^+ being 5.7 and 4.6%, respectively.

Table 2. Hydrogenation of CO over ZnO/TiO_2 ($CO/H_2=1/3$, Total Pressure = 10 atm)

Catalyst	Reaction temp °C	Rate of $MeOH+Me_2O$ formation 10^{-4} mol h^{-1} g^{-1}	Selectivity/%		Rate of CO_2 formation 10^{-4} mol h^{-1} g^{-1}
			MeOH	Me_2O	
ZnO/TiO_2	340	0.7	29.2	70.7	0.8
	360	2.2	9.9	90.0	1.0

ity, but also high selectivity. Little activity was found in the case of ZnO/Nb_2O_5.

These results can be interpreted in terms of acid-base properties of the catalyst supports. Dimethyl ether which is known to be formed by dehydration of methanol was formed over the acidic catalyst supports (Al_2O_3, TiO_2, and SiO_2). The stronger the acid strength of the oxides, the larger the amount of dimethyl ether. Thus, the high selectivity for formation of methanol was obtained over basic or less acidic catalyst or supports (ZnO, MgO, and ZrO_2). In the hydrogenation of CO over Rh supported on various metal oxides, Ichikawa[7] reported that the selectivity for methanol formation was high over Rh supported on basic oxides such as BeO, MgO, CaO, and ZnO. In the case of Pt supported on metal oxides, the selectivity for methanol formation was also high over Pt supported on a basic MgO in the hydrogenations of both CO and CO_2.[6] Hence, the use of basic supports seem to be advantageous for methanol synthesis regardless of the kinds of metals and the difference between CO and CO_2.

Commercial catalysts of methanol synthesis from $CO + H_2$ showed considerably high activities and KMA gave a high selectivity for methanol formation. However, the rate of CO formation was much higher over both KMA ($ZnO-Cr_2O_3$) and MDC-2 ($CuO-ZnO-Al_2O_3$) than over the other catalysts.

The rate of formation of methanol and dimethyl ether from CO_2+H_2 was low in the initial stage of the reaction, but gradually increased and reached steady states in 2—4 h over all the catalysts. The selectivity for methanol formation gradually increased as the reaction proceeded. This suggests the gradual change of surface active species to favor methanol formation. In fact, the activity and the selectivity of ZnO/TiO_2 for methanol formation in the initial stage of the reaction increased when treated with the mixture gas of H_2O+H_2. Therefore, water molecules are one of the factors to enhance the catalytic activity.

To clarify the difference in reactivity between CO_2 and CO, the reaction of CO_2+H_2 was compared with that of $CO+H_2$ over the ZnO/TiO_2 catalyst. As seen from the comparison of Table 2 with Table 1, the reactivity of CO was higher than that of CO_2, however the selectivity for methanol formation in the reaction of $CO+H_2$ was much lower than that in the reaction of CO_2+H_2. Denise and Sneeden[8] made a comparison of methanol synthesis from CO with that of CO_2 over CuO/ZnO and found that the hydrogenation of CO_2 is more reactive than that of CO at lower temperatures, though the latter is more reactive than the former at higher temperatures. These indicate that the superiority of CO_2 hydrogenation to CO hydrogenation for methanol synthesis depends on the kinds of catalysts and reaction conditions.

Electrochemical Preparation of Tetrakis(isocyanide)-dipalladium(I) Dichloride[1)]

Yasuhiro YAMAMOTO,* Katsuo TAKAHASHI,* and Hiroshi YAMAZAKI
RIKEN (The Institute of Physical and Chemical Research), Wako, Saitama 351-01
(Received January 8, 1987)

Synopsis. The electrochemical behavior of $PdCl_2(RNC)_2$ (1) has been investigated in acetonitrile at Pt and Hg electrodes. The cyclic voltammogram of **1** showed a reduction wave at ca. −1.2 V, corresponding to a two-electron transfer. Coulometric reduction of **1** at the Pt electrode gave a binuclear complex, $Pd_2Cl_2(RNC)_4$ (**2**). A similar reaction at the Hg electrode gave **2** in a relatively low yield. A Pt electrode was superior to a Hg one in the electrochemical synthesis of **2**. The polarogram of **1** at a Hg electrode suggested a CE mechanism of the electrode reaction.

Binuclear complexes having a metal-metal bond are of interest in areas of photo- and catalytic chemistry.[2)] Recently we described electrochemical preparation of $Pt_2Cl_2(RNC)_4$ from $PtCl_2(RNC)_2$.[3)] Analogous binuclear palladium(I) complexes of isocyanide have been prepared by the metathesis reactions between Pd(II) and Pd(0) complexes.[4)] We report here the electrochemical preparation of dichlorotetrakis(isocyanide)dipalladium(I).

The cyclic voltammogram (CVM) of $PdCl_2(2,6\text{-}Me_2C_6H_3NC)_2$ (**1a**) was measured in acetonitrile by means of a Pt electrode to determine the preparative condition of a macroscopic electroreduction (Fig. 1). The CVM showed reduction waves at ca. −1.1 V (current peak potential, E_{pc}) for aryl isocyanide complexes and at ca. −1.4 V for alkyl isocyanide complex. In comparison with the CVM of $PtCl_2(RNC)_2$,[5)] these waves were assigned to a two-electron reduction of the Pd(II) complexes.

When a charge-controlled electrolysis of **1a** consumed 1F (1F=96.5 kC) of charge per mole of the Pd(II) complex at −1.5 V, binuclear complex, $Pd_2Cl_2(2,6\text{-}Me_2C_6H_3NC)_4$ **2a** was obtained in a 73% yield. Similar binuclear complexes were obtained in a relatively high yield by the electroreduction of $PdCl_2(RNC)_2$ (R=2,6-Me_2-4-BrC_6H_2, 2,4-*t*-Bu_2-6-MeC_6H_2, 2,4,6-*t*-$Bu_3C_6H_2$, and *t*-Bu), as shown in Table 1.

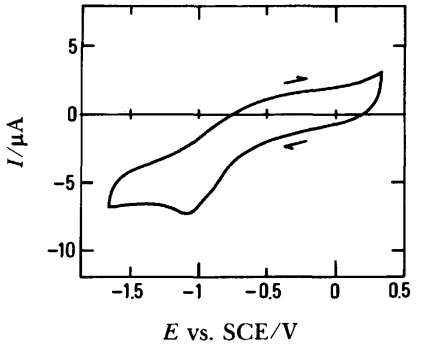

Fig. 1. Cyclic voltammogram of $PdCl_2(2,6\text{-}Me_2C_6H_3NC)_2$ (0.2 mM) on a Pt-tip electrode (surface area= 0.078 cm^2) in a 0.1 M *n*-Bu_4NClO_4-CH_3CN solution at 22 °C. Sweep rate=0.1 Vs^{-1}.

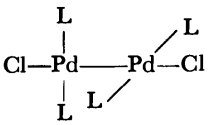

2
L=RNC

The charge-controlled electrolysis of **1a** consumed 1 F of charge per mole of complex at −1.4 V carried out at a mercury pool electrode and gave **2a** in a 23% yield. In this reaction, palladium metal was liberated as a precipitate, showing decomposition of a part of the palladium complexes. Yields of **2** at a mercury electrode were lower than those at a platinum one. In an attempt to reveal the origin of the low yields of **2** at a mercury electrode, a d.c. polarogram of **1a** was measured in a 0.1 M (mol dm^{-3}) *n*-Bu_4NClO_4-CH_3CN solution, using a dropping mercury electrode (Fig. 2). The polarogram showed a reduction wave at $E_{1/2}$ = 0.05 V where $E_{1/2}$ is an apparent halfwave potential. This was significantly different from that at the CVM. The shape of this wave and the reduction potential agreed resonably with those of the polarogram of $HgCl_2$ (Fig. 1).

These results suggest that the CE (chemical-electrochemical) reaction is operative at the Hg electrode surface, in which an initial chemical reaction of 1a with Hg proceeds to give $HgCl_2$ (Eq. 1), followed by an electrochemical reduction of $HgCl_2$ to Hg(0)

Table 1. Cathodic Current Peak Potential (E_{pc}) of $PdCl_2(RNC)_2$ (**1**) on the CVM and Yields of $Pd_2Cl_2(RNC)_4$ (**2**)[a)]

a) Reactions were carried out at −1.5 V except **1e** (−1.6 V) in a 0.1 M $NaClO_4$-CH_3CN solution (ca. 30 cm^3) containing ca. 0.25 mmol of a sample. Charge, ca. 1 F per mole of a sample, was passed. b) A Pt-tip electrode was used for the CVM measurement in a 0.1 M *n*-Bu_4NClO_4-CH_3CN solution. The potentials are shown against a saturated calomel electrode. Sample concentration: ca. 0.1—0.5 mM; scan rate: 0.2 Vs^{-1}.

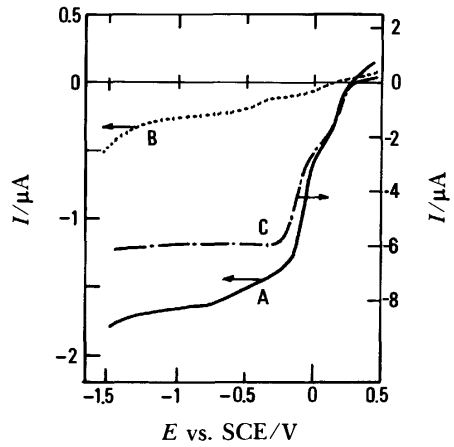

Fig. 2. d.c. Polarograms on a dropping mercury electrode (m=0.864 mg s^{-1}, drop time=4 s) in a 0.1 M n-Bu_4NClO_4-CH_3CN solution at 23 °C. A: $PdCl_2(2,6\text{-}Me_2C_6H_3NC)_2$ (0.2 mM). B: Blank (suppoting electrolyte solution). C: $HgCl_2$ (0.5 mM).

(Eq. 2).[6]

$$Hg(metal) + Pd(II) \longrightarrow Hg(II) + Pd(metal) \quad (1)$$

$$Hg(II) + 2e \longrightarrow Hg(metal) \quad (2)$$

Relatively high yields of complexes having bulky isocyanide ligands showed less interaction with mercury than that in the complex **1a**.

In conclusion, a Pt electrode was superior to a Hg electrode in the electrochemical synthesis of the Pd complex (Table 1).

The reaction path leading to the formation of $Pd_2Cl_2(RNC)_4$ was considered to be similar to that in a platinum complex.[5] The electrochemical reaction was initiated by a two-electron transfer to **1** to give a zerovalent species **3**. The chemical reaction of the zerovalent species (or a trinuclear complex, $Pd_3(RNC)_6$) and **1** led to a formation of **2**.

$$PdCl_2(RNC)_2 \xrightarrow{2e} \underset{\mathbf{3}}{\text{"}Pd(RNC)_2\text{"}} \text{ (or } Pd_3(RNC)_6\text{)}$$

$$\xrightarrow{PdCl_2(RNC)_2} \underset{\mathbf{2}}{Pd_2Cl_2(RNC)_4}$$

Experimental

The electrochemical apparatus has been already descrbed.[5] 2,6-Xylyl, 2,6-dimethyl-4-bromophenyl, 2,4,6-tri-t-butylphenyl, and t-butyl isocyanides were prepared according to the literature.[7] $PdCl_2(RNC)_2$ (R = 2,6-$Me_2C_6H_3$, 2,6-Me_2-4-BrC_6H_2) was prepared according to the literature.[3]

2,4-Di-t-methylphenyl isocyanide was prepared by a modification of the method described in the literature.[7b] IR (Nujol) 2109 cm^{-1},

^1H NMR($CDCl_3$) δ = 1.32 (s, 4-t-Bu), 1.52 (s, 2-t-Bu), 2.43 (s, 6-Me), ca. 7.2 (aromatic protons). Anal. ($C_{46}H_{23}N$) C, H, N.

(Received December 24, 1986)

Synopsis. The reaction of acetyl derivatives with double the molar quantity of benzyltrimethylammoniun tribromide in dichloromethane-methanol solution at room temperature gave dibromoacetyl derivatives in fairly good yields.

Organic ammonium tribromides are considered to be mild and selective brominating agents.[1] These reagents have a merit in that they can be quantitatively treated, compared with liquid bromine, because of their solid character. Previous work in this series[2] has shown that monobromoacetyl derivertives are readily obtained from reactions of acetyl derivatives with tetrabutylammonium tribromide (TBA Br_3) under mild conditions. In the present paper, we wish to report the syntheses of dibromoacetyl derivatives (**1**) by the use of a new reagent, benzyltrimethylammonium tribromide (BTMA Br_3).

Results and Discussion

The reaction of benzyltrimethylammonium chloride with bromine in dichloromethane gave BTMA Br_3. BTMA Br_3 was also prepared by the addition of hydrobromic acid to an aqueous solution of benzyltrimethylammonium chloride and sodium bromate in good yield.

The reaction of acetyl derivatives (**2**) with double the molar quantity of BTMA Br_3 in a dichloromethane-methanol solution for 2—7 h at room temperature gave **1** readily. The results are summarized in the Table 1.

$$\underset{\mathbf{2}}{RCOCH_3} \xrightarrow[\text{in } CH_2Cl_2\text{-}CH_3OH \text{ rt}]{2PhCH_2(CH_3)_3N^+Br_3^-} \underset{\mathbf{1}}{RCOCHBr_2}$$

a) Yield of isolated product.

When an equimolecular amount of BTMA Br_3 was used with **2**, monobromoacetyl derivatives **3** were obtained in the same manner as when using TBA Br_3.[2] However, the reaction of **2**, with double the molar quantity of TBA Br_3 gave **1** as a byproduct, together with the main product **3**.[12] Therefore, it turned out that the brominating effect of BTMA Br_3 is stronger than that of TBA Br_3. Nevertheless, BTAM Br_3 could not further brominate **1** to tribromoacetyl derivatives at room temperature.

Because the presence of methanol markedly facilitated the bromination of **2**, it can be presumed that active species which generate Br^+ is probably methyl hypobromite produced from the reaction of BTMA Br_3 with methanol. In fact, we confirmed the evolution of hydrogen bromide by the addition of methanol to BTMA Br_3 at room temperature.

$$PhCH_2(CH_3)_3N^+Br_3^- + CH_3OH \longrightarrow PhCH_2(CH_3)_3N^+Br^- + CH_3OBr + HBr$$

$$\mathbf{2} + 2CH_3OBr \longrightarrow \mathbf{1} + 2CH_3OH$$

In general, derivatives **1** such as phenacylidene dibromide (a material for mandelic acid), were prepared from acyl derivatives and bromine.[3] By our method, **1** was easily obtained under mild conditions.

Experimental

Benzyltrimethylammonium Tribromide (BTMA Br_3). To a solution of benzyltrimethylammonium chloride (11.1 g, 60 mmol) and sodium bromate (4.5 g, 30 mmol) in water (100 ml) was added hydrobromic acid (47%, 180 mmol) under stirring at room temperature. A precipitated solid was extracted with dichlormethane (50 ml×4). The organic layer was dried with magnesium sulfate and evaporated in vacuo to leave a residue which was recrystallized from dichloromethane-ether (10 : 1) to give BTMA Br_3 as orange crystals; yield 18.2 g (78%); mp 100—101 °C. Found: C, 30.69; H, 4.11; N, 3.76; Br, 61.44%. Calcd for $C_{10}H_{16}NBr_3$: C, 30.80; H, 4.14; N, 3.59; Br, 61.47%.

Phenacylidene Dibromide (1a): Typical procedure. To a solution of acetophenone (**2a**) (0.5 g, 4.16 mmol) in dichloromethane (50 ml)-methanol (20 ml) was added BTMA Br_3 (3.4 g, 8.74 mmol) at room temperature. The mixture was stirred for 2 hr until a decoloration of the orange solution took place. The solvent was distilled; the obtained precipitate was extracted with ether (40 ml × 4). The ether layer was then dried with magnesium sulfate and evaporated in vacuo to give a residue which was recrystallized from methanol-water (1 : 2) affording **1a** as colorless crystals; yield 1.0 g (86%); mp 33.5—34.5 °C (lit,[3] mp 36 °C).

2,2-Dibromo-3′-methoxyacetophenone (1d). Compound **1d** was obtained as colorless needles; mp 67—68 °C. ^1H NMR ($CDCl_3$) δ=3.82 (3H, s, OCH_3), 6.70 (1H, s, $CHBr_2$), and 6.9—7.75 (4H, m, H_{arom}). Found: C, 35.00; H, 2.78; Br, 51.80%. Calcd for $C_9H_8O_2Br_2$: C, 35.10; H, 2.62; Br, 51.89%.

Evaluation of the Hydrogen Shuttling Ability of Coal Liquefaction Solvents

Koji CHIBA,* Hideyuki TAGAYA,* Tohru SUZUKI, and Takashi SUZUKI
Department of Chemical Engineering, Faculty of Engineering, Yamagata University, Johnan, Yonezawa 992
(Received January 24, 1987)

Synopsis. The hydrogen-shuttling ability of coal liquefaction solvents were evaluated using benzophenone and dibenzyl ether as hydrogen acceptors. Hydrogen-transfer reactions from tetralin to acceptors were accelerated by shuttlers and the ranking of the shuttling ability was determined to be as follows:
anthracene > fluorene > pyrene≅triphenylmethane > phenanthrene > 1-methylnaphthalene

It is generally well-accepted that the hydrogen-donation of solvents plays an important role in the noncatalytic dissolution of coal.[1] Therefore, many researchers have attempted to evaluate the hydrogen donor ability of coal liquefaction solvents.[2] Hydroaromatic compounds, such as tetralin, are known as donors. On the other hand, polynuclear fused aromatics, such as pyrene, have been identified as being effective solvent components in spite of their low donor abilities. For example, when mixtures of pyrene and tetralin were used in the presence of hydrogen, coal conversions almost as high as that in pure tetralin were achieved at 30% tetralin.[3] Pyrene is not a donor; however, the ability of condensed aromatics to assist in liquefaction by physical solvation has been well recognized,[4] and an important role of pyrene as the hydrogen shuttler is suggested. In order to fully understand the function and importance of liquefaction solvents, an evaluation of the hydrogen-shuttling ability must be undertaken. We have developed a method by which the relative hydrogen-shuttling ability of liquefaction solvents can be evaluated using two different types of model hydrogen acceptors.

Experimental

Benzophenone and dibenzyl ether were used as hydrogen acceptors. An acceptor (1 g), tetralin (10 g) and a solvent (1 g) were placed in a magnet-driven autoclave and pressurized to 3 MPa with nitrogen. When benzophenone was used as an acceptor, the autoclave was heated to 430 °C and maintained at this temperature for 1 hour. The yields of diphenylmethane and benzhydrol were determined by gas chromatography (GC). Dibenzyl ether was unstable and decomposed completely at 430 °C. Therefore, the reaction was carried out at 375 °C for 1 h when dibenzyl ether was used as an acceptor. The yields of toluene, benzaldehyde and benzyl alcohol were determined by GC. Benzene was scarcely produced.

Results and Discussion

It has already been reported that benzophenone accepted hydrogen from tetralin as follows:[5]

$$2Ph_2CO \xrightarrow{\text{donor}} 2Ph_2CHOH \longrightarrow Ph_2CO + Ph_2CH_2 + H_2O. \quad (1)$$

Table 1. The Effect of Hydrogen Shuttlers on the Hydrogen Transfer Reaction[a] from Tetralin to Benzophenone (BZP)

Shuttler	Conv. of BZP/mol%	Yield of DPM[b]/mol%	Yield of BZH[b]/mol%
None	36.3	32.9	2.0
None	37.5	33.5	2.0
1-Methylnaphthalene	35.5	32.9	2.6
Anthracene	59.8	56.4	≈0
Phenanthrene	35.1	27.5	2.1
Pyrene	44.6	36.0	5.5
Fluorene	49.2	39.2	8.6
Triphenylmethane	40.2	33.1	5.0

a) Shuttler (1 g), tetralin (10 g) and benzophenone (1 g) were used. Reaction temperature 430 °C; initial nitrogen pressure 3MPa; reaction time 1 h. b) DPM=Diphenylmethane, BZH=benzhydrol.

In this work 36—38% of the benzophenone was hydrogenated by tetralin at 430 °C for 1 h (Table 1). Diphenylmethane is thermally stable, whereas benzhydrol is considered to be an unstable intermediate. When the mixture of benzhydrol and 1-methylnaphthalene was heated at 270 °C in a nitrogen atmosphere for 1 h, over 50% of the benzhydrol disproportionated to diphenylmethane and benzophenone. Actually, in the reaction of tetralin with benzophenone, the yield of benzhydrol was only 2%. Polyaromatic nondonor solvents such as 1-methylnaphthalene, anthracene, phenanthrene, pyrene, and fluorene were used to rank their shuttling ability. Triphenylmethane was also used because we had already confirmed that it accelerated the decomposition of bibenzyl in spite of a nondonor.[6] The ranking according to the degree of the reduction of benzophenone is as follows:

Anthracene > fluorene > pyrene > triphenylmethane > 1-methylnaphthalene≅phenanthrene.

We must pay attention to the fact that the two benzhydrol molecules disproportionate and produce one benzophenone molecule. Therefore, the total yield of products must be considered as the summation of the yield of diphenylmethane and one half of the yield of benzhydrol. The total yield of the products was 1.3 to 6.6% lower than the conversion of benzophenone. This indicates the presence of undetermined compounds. The high shuttling ability of anthracene is closely related to the fact that anthracene can be readily hydrogenated to dihydroanthracene. When anthracene was reacted with tetralin at 430 °C for 1 h,

Table 2. The Effect of Hydrogen Shuttlers on the Hydrogen Transfer Reaction[a] from Tetralin to Dibenzyl Ether (DBE)

Shuttler	Conv. of DBE /mol%	Yield of TOL[b] /mol%/2	Yield of BZA[b] /mol%/2	Yield of BYA[b] /mol%/2
None	21.4	8.7	7.5	3.5
None	21.8	7.2	5.8	5.1
1-Methylnaphthalene	21.3	8.8	6.9	5.6
Anthracene	60.4	21.6	22.4	7.1
Phenanthrene	33.4	14.5	12.0	5.9
Pyrene	36.9	8.5	8.7	3.5
Fluorene	41.4	17.4	15.8	8.2
Triphenylmethane	38.3	9.3	12.8	4.8

a) Shuttler (1 g), tetralin (10 g) and dibenzyl ether (1 g) were used. Reaction temperature 375 °C; initial nitrogen pressure 3MPa; reaction time 1 h. b) TOL= Toluene, BZA=benzaldehyde, BYA=benzyl alcohol.

26% of the anthracene was hydrogenated to dihydroanthracene. Dihydroanthracene is a hydrogen donor which was confirmed in a reaction with benzophenone. When dihydroanthracene (1 g) was heated with benzophenone (1 g) in 1-methylnaphthalene (10 g), 31.3% of the benzophenone was reduced. In blank tests (Table 1), 36—38% of the benzophenone was reduced by tetralin; however, the injection weight of tetralin was 10 times that of dihydroanthracene. The same mechanism, including the dihydroaromatic compound, may be applied to pyrene.

The high conversions noted for fluorene and triphenylmethane can possibly account for the high reactivity of their benzylic hydrogen.[7]

It is well-known that intermolecular (2) and intramolecular (3) reactions are involved in the dibenzyl ether thermolysis.[8]

$$PhCH_2OCH_2Ph \longrightarrow PhCH_2\cdot + \cdot OCH_2Ph \xrightarrow{\text{donor}} PhCH_3 + HOCH_2Ph \quad (2)$$

$$PhCH_2OCH_2Ph \longrightarrow PhCH_3 + OHCPh. \quad (3)$$

That two free radicals resulting from the fission of a C-O bond possess a higher dehydrogenation ability than benzophenone. Table 2 shows the effect of the hydrogen shuttler on the hydrogenation reaction of dibenzyl ether in tetralin. The yield of benzaldehyde is higher and the yield of toluene is lower than that expected from Reactions 2 and 3. This may be due to further reactions of benzyl alcohol and the benzyl radical to benzaldehyde and undetermined compounds.[9] The ranking for the dibenzyl ether conversion is

anthracene > fluorene > triphenylmethane > pyrene > phenanthrene > 1-methylnaphthalene.

This is almost similar to that of Table 1, except for triphenylmethane and phenanthrene. It is considered that triphenylmethane readily donates hydrogen and that the resulting triphenylmethyl radical initiates the bond fission of dibenzyl ether as a molecule-induced homolysis.[7] This indicates the possibility of an overestimation of the triphenylmethane shuttling ability if the ability is estimated only from the ranking for the dibenzyl ether conversion. Although the mixture of phenanthrene and tetralin was heated at 430 °C for 1 h, dihydrophenanthrene was scarcely produced. Furthermore, only 9.8% of the benzophenone was reduced when dihydrophenanthrene (1 g) was heated with benzophenone (1 g) in 1-methylnaphthalene (10 g). This indicates that the hydrogen-shuttling mechanism through dihydrophenanthrene is minor. Another mechanism, in which phenanthrene donates hydrogen to a free radical and the resulting phenanthryl radical abstracts hydrogen from tetralin, is possible.

From these results, using different types of hydrogen acceptors, the hydrogen-shuttling ability of the liquefaction solvent could be evaluated as follows:

anthracene > fluorene > pyrene ≅ triphenylmethane > phenanthrene > 1-methylnaphthalene.

It appears that the presence of the hydrogen shuttler constitutes a necessary and important component of coal conversion. A more effective solvent for coal liquefaction can be prepared by determining the capabilities of various solvents.

The Addition Reaction of Benzynes Generated Electrochemically from Dihalobenzenes with Tertiary Amines

Naoyoshi EGASHIRA,* Jun TAKENAGA, and Fumiaki HORI
Department of Environmental Chemistry and Engineering, Faculty of Engineering, Oita University, 700 Dannoharu, Oita 870-11
(Received January 8, 1987)

Synopsis. The electroreduction of dihalobenzenes was carried out in the presence of tertiary amines as benzyne acceptors in DMF-TBAP, giving the addition products in yields of more than 10%. For *o*-dibromobenzene, the yield of the addition product, *N*-phenylpiperidine, increased to 21% in the presence of *N*-ethylpiperidine.

Benzynes which undergo many types of addition reactions are uaually generated on the photolysis or pyrolysis of reactive reagents.[1] An electrolytic method can be expected to generate benzynes under mild conditions from reagents which are readily available. Wawzonek et al.[2] have reported on the generation of a benzyne in the electrolysis of *o*-dibromobenzene (**1**) in the presence of furan as a benzyne acceptor and have obtained the addition product derived from the benzyne in a 1% yield. This has been the sole report on the electrolytic generation of benzyne. We have previously reported that the yield of the addition product of the benzyne from **1** increased to 10% when *N*-ethylpiperidine (**2**) was used instead of furan.[3] In the present work, five dihalobenzenes are electrolyzed in a sufficiently dried electrolyte containing five tertiary amines; they are examined in detail for the addition products.

Compound **1** showed an irreversible cathodic peak at −3.00 V vs. Ag/Ag^+ in the presence of **2**. The electrolysis of **1** in the presence of a large excess of **2** was thus carried out at −3.20 V. The resulting products were bromobenzene, benzene, and an unknown compound. The unknown compound was isolated from the catholyte after electrolysis and confirmed to be *N*-phenylpiperidine (**3**) since it gave an IR spectrum identical with that of the authentic sample. The time-course of the products is shown in Fig. 1, which represents the simultaneous formation of each product. Three gaseous products containing ethylene were also detected by gas chromatography, and their amounts increased gradually. The electrolysis of bromobenzene at −3.20 V in the presence of **2** gave simply benzene; the consumption rate of bromobenzene was low, since the cathodic peak potential of bromobenzene (−3.30 V) was higher than the electrolysis potential of **1**. Furthermore, **3** was not detected in the electrolysis of **1** at −3.20 V when **2** was not added to the electrolyte. These results indicate that bromobenzene does not participate in the formation of **3** and that benzene is formed in part from **1** directly and in part through bromobenzene. It has been reported that **3** was produced through the reaction of benzyne generated in a homogeneous reaction with **2**.[1] Compound **3** is thus presumed to be produced through benzyne as depicted in Scheme 1.

The yield of **3** (14%) is larger than that of the product through benzyne reported by Wawzonek et al.[2] Table 1 shows the effects of the electrolyte temperature, the electrolysis potential, the benzyne acceptors, and the electrode materials on the electrolysis of **1**. An appropriate potential for the electrolysis is determined to be −3.20 V because of the higher yields obtained in three experiments (Runs 1—3). A decrease in the electrolyte temperature to 20 °C lowered the yield of **3** (Run 4). When SCE was used instead

a) Electrolysis was carried out in DMF solutions containing 5.0 cm^3 of the benzyne acceptor at 40 °C unless otherwise noted. b) The temperature was 20 °C. c) SCE was used as the reference electrode. d) 20 cm^3 of **2** was used. e) The retention time of each product, as determined by HPLC, agreed with that of an authentic sample. f) Ethylene was detected by means of gas chromatography.

of the Ag/Ag^+ reference electrode, the yield of **3** remarkably decreased (Run 5). This was due to a large increase in the water concentration of the electrolyte from the beginning of the electrolysis (0.010 M: 1 M = mol dm^{-3}) to the end (0.080 M); the use of an Ag/Ag^+ reference electrode hardly increased the water concentration at all. The further addition of **2** (20 cm^3) resulted in an increase in the yield of **3** to 21% (Run 6). Benzyne can exit in the vicinity of the electrode, as it has a short lifetime. The amount of benzyne available for the formation of the addition products may thus be smaller than that in a conventional homogeneous reaction. The disadvantage can be reduced by the use of a high concentration of a benzyne acceptor. The use of Hg and glassy carbon (GC) as working electrodes considerably decreases the yields of the products containing **3** (Runs 7 and 8). These products are perhaps attributable to the formation of mercury compounds and polymers respectively. The reaction of benzyne with several tertiary amines similarly gave the corresponding addition products, the yields of which were in the range of 11—14% (Runs 9—12). This fact suggests that the steric hindrance around nitrogen atoms of the tertiary amines against benzyne is of the same degree. Electrolysis in the presence of *N*-methylpiperidine and *N*-(hydroxyethyl)-piperidine produced methane and an unknown gaseous product respectively; the evolution mechanisms remain ambiguous. *o*-Dichlorobenzene and *o*-diiodobenzene gave the same addition product as **3** in moderate yields, while *o*-dichlorobenzene gave it in a very low yield (Runs 13 and 14). *o*-Dibromobenzene and *o*-diiodobenzene are thus thought to be suitable for the electrolytic generation of benzyne. The fact that *m*- and *p*-dibromobenzenes also give **3** is interesting, since it suggests the generation of *m*- and *p*-benzynes (Runs 15 and 16). Unfortunately, the yields of **3** for both the compounds were very low. Each electrolysis requires about 3 F mol^{-1} of electricity, except for Run 5, indicating that dihalobenzenes undergoes electroreduction with a good efficiency. The ratio of the total moles of the products containing the starting material to the original moles of the starting material, the material balance, gradually decreased (Fig. 1). This suggests that the generated intermediates, such as benzyne, radical anions, and free radicals, follow complex reactions.

Experimental

DMF was purified by a conventional method.[4)] Cyclic voltammetry was carried out in the same way as in a previous work.[5)] A DMF solution containing **1** (0.050 M), **2** (5.0 cm^3), and tetrabutylammonium perchlorate (TBAP, 0.10 M) was prepared. A large-scale electrolysis of the DMF solution was performed on a platinum electrode (25.5 cm^2) at 40 °C in a two-compartment cell after 6.4 g molecular sieve 4A (heated at 350 °C for 3 h) had been added to the catholyte in order to dry it. The counter and reference electrodes used were a platinum plate (1.0 cm^2) and an Ag/Ag^+ electrode. The outlet of nitrogen of the electrolytic cell was cooled with

water in order to collect any benzene produced in the cell. After the electrolysis has finished, the catholyte was concentrated under reduced pressure, and then the residue was extracted with diethyl ether. The product was separated with TLC (SiO_2, chloroform : benzene = 8 : 2) after the ethereal solution had been evaporated. Compound **3** as an authentic sample was synthesized in the way reported by Bunnett et al.:[6] ^1H NMR ($CDCl_3$) δ = 1.7—1.9 (6H, *m*, $-CH_2-$), 3.2—3.4 (4H, *m*, $N-CH_2-$), 6.9—7.5 (5H, *m*, Arom). The catholyte was analyzed by using HPLC (ODS, CH_3CN : H_2O = 55 : 45) in order to determine the concentrations of the products.

An Explanation of the Temperature Dependence of the Mössbauer Spectra of Mixed Valence Biferrocenium Derivatives with a (Valence-State) Order-Disorder Transition

Yuichi MASUDA* and Hirotoshi SANO
Deparment of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya-ku, Tokyo 158
(Received January 16, 1987)

Synopsis. The temperature dependence of the quadrupole splitting values in the Mössbauer spectra for monooxidized biferrocenium derivatives is well explained in term of an order-disorder transition with regard to the valence state of two iron atoms in the cations.

It has been reported that several kinds of triiodide salts of monooxidized 1′,1‴-dialkylbiferrocenium derivatives [Fe(II)·Fe(III)] ($R_2bfc \cdot I_3$) show a characteristic temperature dependence in their Mössbauer spectra,[1,3-5] where two well resolved doublets are observed at low temperatures. With an increase in the temperature, the quadrupole splitting (*Q.S.*) values of the outer and inner doublets decrease and increase respectively, until finally these two doublets are superimposed on each other, giving only one doublet, as is shown in Figs. 1 and 2. No line-broadening is observed in the process of the temperature dependence of *Q.S.*, although it might be expected for a relaxation process. There has thus far been no explanation for the characteristic temperature dependence of the quadrupole split lines commonly observed in the triiodide salts of ethyl, propyl, butyl, and benzyl derivatives.[5] In the present paper, this characteristic temperature dependence of the Mössbauer spectra is explained in terms of an order-disorder transition of the valence state of two iron atoms in the biferrocenium cations caused by a cooperative intermolecular interaction in a crystal.

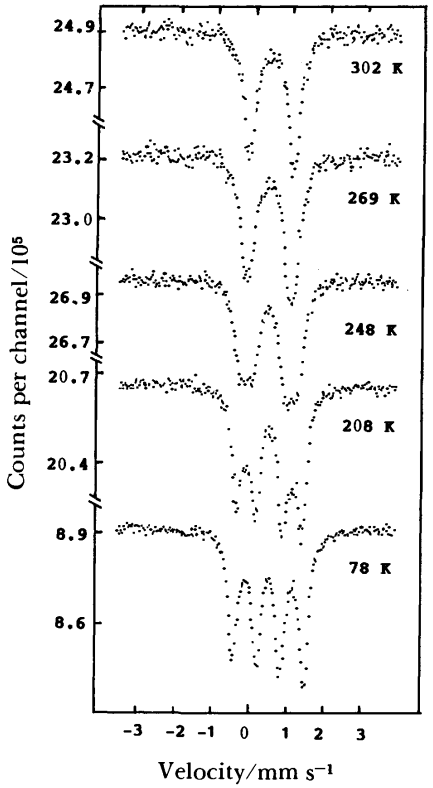

Fig. 1. Variable temperature ^{57}Fe Mössbauer spectra for 1′,1‴-dibutylbiferrocenium triiodide. The data are taken from Ref. 4.

I. Explanation of the Temperature Dependence of the Mössbauer Spectra. In order to explain the temperature dependence characteristic of the dialkylbiferrocenium triiodides, the following two hypotheses are assumed:

(i) The two iron atoms, Fe_A and Fe_B, in a cation are inequivalent in the crystal state, i.e., the potential energies between State I, [Fe_A(II)·Fe_B(III)], and State II, [Fe_A(III)·Fe_B(II)], differ from each other.

(ii) The electrontransfer rate between the two iron atoms becomes much faster than the Mössbauer time scale, $\approx 10^{-7}$ s, at higher temperatures, where the two ΔE_Q values start to change.

The (i) assumption is supported by the crystal structure of dipropylbiferrocenium triiodide.[2,3] The two iron atoms in the cation are found not to be

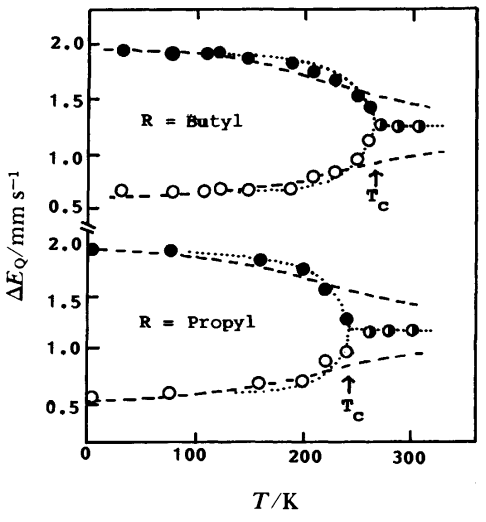

Fig. 2. Temperature dependence of quadrupole splitting for 1′.1‴-dialkylbiferrocenium triiodide ($R_2bfc \cdot I_3$). The open and closed circle corresponds to ferrocene and ferrocenium potion, respectively. The data were taken from Refs. 1 and 4 and the meanings of the dotted and broken lines in the figure are given in the text.

equivalent in the crystal packing. The (ii) assumption is important in explaining why no line-broadening is observed upon a change in the ΔE_Q values (see below). An intramolecular electron exchange rate faster than the Mössbauer time scale, as assumed above, has actually been found in, for example, 1′,1‴-dibromo and diiodobiferrocenium triiodides, even at 4.2 K, in the crystal state.[6,7]

At a sufficiently low temperature, if State I, [Fe_A(II)·Fe_B(III)], is assumed to be predominant, the two *Q. S.* values for iron A and B, atoms $\Delta E_{Q,A}$ and $\Delta E_{Q,B}$, will the approximately equal to those for the ferrocene and ferrocenium species corresponding to an outer doublet and an inner doublet in the Mössbauer spectrum respectively. At increased temperatures, the population of State II, [Fe_A(III)·Fe_B(II)], can be expected to increase. If the intramolecular valence exchange occurs sufficiently faster than the Mössbauer time scale, as assumed in the (ii) hypothesis, the observed $\Delta E_{Q,A}$ and $\Delta E_{Q,B}$ values can be represented by using the populations of State I, P_I, and State II, P_{II};

$$\Delta E_{Q,A} = P_I \cdot \Delta E_Q(\text{Fe(II)}) + P_{II} \cdot \Delta E_Q(\text{Fe(III)}) = P_I \cdot \Delta E_Q(\text{Fe(II)}) + (1-P_I) \cdot \Delta E_Q(\text{Fe(III)}) \quad (1)$$

because:

$$P_I + P_{II} = 1$$

and:

$$\Delta E_{Q,B} = P_I \cdot \Delta E_Q(\text{Fe(III)}) + (1-P_I) \cdot \Delta E_Q(\text{Fe(II)}) \quad (1)'$$

where ΔE_Q(Fe(II)) and ΔE_Q(Fe(III)) stand for the *Q. S.* values for the ferrocene-like and ferrocenium-like moieties in the R_2bfc·I_3 respectively; those values are determined by extrapolating the temperature dependences of the $\Delta E_{Q,A}$ and $\Delta E_{Q,B}$ values to 0 K. With an increase in the temperature, P_I decreases from unity, accompanied by both a decrease in the $\Delta E_{Q,A}$ value and an increase in the $\Delta E_{Q,B}$ value because $\Delta E_Q(\text{Fe(II)}) > \Delta E_Q(\text{Fe(III)})$. At sufficiently high temperatures, both the P_I and P_{II} populations both approach 0.5, and the values of $\Delta E_{Q,A}$ and $\Delta E_{Q,B}$ both also approach a mean value of ΔE_Q(Fe(II)) and ΔE_Q(Fe(III)), showing only one doublet just superimposed by the two doublets of the Fe_A and Fe_B absorbances in the Mössbauer spectrum. In this process, if the valence-exchange rate between the two iron atoms is sufficiently faster than the Mössbauer time scale, no line-broadening is observed in the Mössbauer absorptions. The observed Mössbauer spectra shown in Fig. 1 are qualitatively explained by the above consideration.

At 110 K and room temperature, the X-ray structure of the *n*-propyl derivative also supports this consideration. In the X-ray structure of Pr_2bfc·I_3 at 110 K, the cations have two kinds of inequivalent ferrocene and ferrocenium units, of which one corresponds to the Fe(II) unit, and the other, to the Fe(III) unit. These two units in the cations are aligned in the crystal in an orderly manner, as is schematically illustrated in Fig. 3(a). On the contrary, these two ferrocene and ferrocenium units become equivalent at room temperature; i.e., the configuration of the ferrocene or ferrocenium units in the cation is aligned in a disorderly manner at room temperature, as is demonstrated in Fig. 3(b).[3,7] If this disordering is dynamic, the time averaged population in the divalent and trivalent state for all the iron atoms will become nearly 0.5 in the crystal at room temperature.

II. Simple Model for the Order-Disorder Transition of the Valence State by Means of Cooperative Intermolecular Interaction. In the previous section, an energy difference between the states of [Fe_A(II)·Fe_B(III)] and [Fe_A(III)·Fe_B(II)] was assumed to explain the temperature dependence of the *Q.S.* values. If this energy difference remains constant over the temperature range where the Mössbauer spectra are observed, the population of State I or II, P_I or P_{II}, is related to the free-energy difference between State I and II, ΔG, as is expressed in the following equation:

$$P_I = (\exp(-\Delta G/RT) + 1)^{-1} \quad (2)$$

Table 1. Transition Temperatures and Interaction Energies

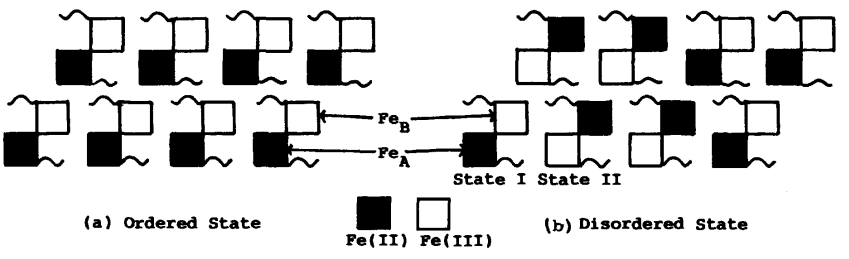

Fig. 3. Schematic representation of ordered (a) and disordered (b) state with regard to valence state of 1′,1‴-dialkylbiferrocenium triiodide.

The calculated temperature dependence of the ΔE_Q values for Fe_A and Fe_B, based on Eq. 1 and Eq. 2 with the ΔG values listed in Table 1, are shown in Fig. 2 by the broken lines. For all the cases, the calculated values do not fit well to the temperature dependence of the observed ΔE_Q values, especially the sudden change of ΔE_Q at 200—270 K.

This sudden change in the observed ΔE_Q values suggests an abrupt change in the population of the State I or II (see the previous section); i.e., an ordered state in which most cations remain in either one of the two states (I or II) changes to a disordered state, in which the populations of the two state of the cations are approximately equal, within a narrow temperature range, as is schematically illustrated in Fig. 3. This feature of the temperature dependence of the population in the valence states resembles the well-known order-disorder phase transitions, such as a ferro-to-para magnetic or electric transition. The small endothermic peak observed in the DSC measurements near the temperature showing a sudden change in the ΔE_Q value (e.g., several hundred J mol^{-1} for dipropylbiferrocenium triiodide) also indicates that change can be regarded as an order-disorder transition with regard to the valence state of the cations. In the crystal, the valence state of a cation may be affected by that of the neighboring cations, i.e., the energy difference between the two valence states, e.g., States I and II, of a cation are affected by those of the neighboring cations. This cooperative intermolecular interaction between cations is considered to cause an order-disorder transition. It seemed worthwhile to examine whether or not the Ising model could be applied to this system in order to explain such a cooperative intermolecular interaction. The states of I and II are represented by $\sigma_i=1$ and $=-1$ respectively, and an interaction Hamiltonian, H_{ij}, for the Ising model is geven with an intermolecular interaction energy, ε, that is:

$$H_{ij}=-(\varepsilon/2)\sum_{ij}\sigma_i\sigma_j \qquad (\sigma_i, \sigma_j=\pm 1) \tag{3}$$

where the intermolecular interaction, ε, is defined by considerig the interaction with the first neighboring cations, neglecting any anisotropic interaction. The values of P_I and P_{II} at various temperatures are obtained by using a molecular field approximation.[8] The ΔE_Q values for Fe_A and Fe_B can also be obtained by using the P_I and P_{II} values estimated based on Eq. (1). The results for butyl and propyl derivatives with ε values satisfactorily reproduce the observed ΔE_Q values at various temperature as is shown in Fig. 2 by dotted lines. The estimated interaction energies, ε, assuming a two- and three- dimensional interaction and the (second order) transition temperature, T_C, are listed in Table 1. Similarly good coincidences between the theoretical curves and the experimental data are also obtained for the ethyl and benzyl derivatives.

In this treatment, an isotropic interaction between neighboring cations placed on the square (for a two dimensional alignment) or the cubic (for a three dimensional alignment) lattice points is assumed, although the environment of a cation is not actually isotropic. For example, in the X-ray structure of $Pr_2bfc{\cdot}I_3$, the alignment of the cations shows a step-by-step slipping π-π stack between cycropentadienyl rings in one direction, while those same cations are aligned across one triiodide anion in two directions.[2] In spite of the different interaction in different direction in an actual crystal, the results show a fairly good coincidence between the experimental and theoretical results in which an isotropic interaction is assumed. This means that the valence state of the cations is determined by the alignment of the neighboring cations and by their interaction and that two- or three-dimensional[9] intermolecular interactions have a similar interaction energy value, ε, as is tabulated in Eq. 3.

We wish to thank Professor Hendrickson and Professor Kambara for their encouraging discussions. This work was partially supported by a Grant-in-Aid for Scientific Research (No. 60430014).

8) The calculation of P_I and P_{II} based on the molecular field approximation at various temperatures is equivalent to that of spontaneous magnetization for a 1/2 spin system. Regarding States I ($\sigma_i=1$) and II ($\sigma_i=-1$) as the +1/2 and −1/2 spin states respectively, the values (P_I-P_{II}) at various temperatures correspond to the values proportional to the spontaneous magnetization of the spin system. Such calculation of the magnetization based on the molecular-field approximation is carried out according to the procedure in such textbooks as "Introduction to Solid State Physics," ed by C. Kittel, Jhon Willey & Sons Inc., New York (1975), Chap. 15, and "The Structures and Properties of Solids. **6**, The Magnetic Properties of Solids," ed by J. Crangle, Edward Arnold, London (1976), Chap. 2.

9) It has been theoretically proved that one dimensional interaction in the Ising model shows no phase transition: in the exact solution for the one-dimensional Ising model, the population of the two states does not show any such steep temperature dependence as is shown in Fig. 2.

An Application of Factor Analysis to the Electronic Spectra of Iodine in Mixed Solvents

Koichiro NAKANISHI,* Kenkichi MAYA, and D. G. HOWERY†
Department of Industrial Chemistry, Kyoto University, Sakyo-ku, Kyoto 606
†Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U.S.A.
(Received January 20, 1987)

Synopsis. The electronic spectra of iodine diluted in three kinds of mixed solvents, ethanol-heptane, 1,4-dioxane-cyclohexane, and tetrahydrofuran-cyclohexane have been measured as a function of molar composition in mixed solvents and a factor analysis technique has been applied to interpret the results. The number of different iodine-solvent complexes in ethanol solutions is smaller than that in ether solutions.

It is well-known that iodine molecule can form charge-transfer complex with many organic molecules which act as an electron donor (e.g., benzene, alcohols, etc.) and its color becomes brown or red. In nonpolar solvents such as aliphatic hydrocarbons, however, the color of iodine remains purple just as in the vapor or solid phase. We may classify these solvents into complexing(C) and non-complexing(NC) solvents to iodine.

Now, what happen when we use mixed solvents? If we adopt a combination of C and NC solvents, there should be a preferential solvation of C solvent to iodine molecules because of stronger intermolecular interaction. The purpose of the present study is to investigate the behavior of iodine in some kinds of mixed solvents from the spectroscopic point of view.

When we adopt an associated liquid as the C solvent, we have again a preferential solvation because associated liquids are usually a strong C solvent and in addition, possible change in the state of the association of the solvent in mixed solvents may result anomalous behavior in some physical properties. We have already studied diffusion, solubility, and their temperature dependence of iodine in various kinds of mixed solvents.[1-3] In this paper, we will describe the results on the electronic spectra of iodine in the visible light region as a function of molar composition of some typical mixed solvents and an analysis of these spectra by a factor analysis technique developed by one of us.[4]

Spectral Measurements

Electronic spectra of iodine in three kinds of mixed solvents have been measured by using a Shimadzu multipurpose spectrophotometer. The mixed solvents used are ethanol-heptane, 1,4-dioxane-cyclohexane, and tetrahydrofuran-cyclohexane. Sample solutions were prepared by dissolving certain amounts of spectrograde iodine into mixed solvents which consist of two kinds of spectrograde reagents. The concentration of iodine which is near 1×10^{-3} M (1 M = 1 mol dm^{-3}) was determined by conventional iodometry and the molar composition of C solvent in mixed solvents is 0, 0.025, 0.05, 0.10, 0.15, 0.2, 0.4, 0.6, 0.8, or 1.0, respectively.

The wavelength range used is between 410 and 600 nm. Reproducibility of the spectra is ±0.003 for 100% absorbance and ±0.0005 for 0% absorbance and the effect of titration error on the absorbance is estimated to be ±0.0010. Total experimental error is thus as large as ±0.0025.

The spectra of iodine in the three mixed solvents obtained in the present study are shown in Fig. 1. Each absorbance value is corrected to that for a concentration of 1×10^{-3} M. Qualitative feature of the results is as follows: in the case of iodine in ethanol-heptane solutions, one can observe the presence of a rather clear isosbestic point, whereas there is no specific isosbestic point for 1,4-dioxane-cyclohexane and tetrahydrofuran-cyclohexane solutions. Note that the present measurement is different from that normally adopted when the charge-transfer complex between iodine and ethers is to be studied in dilute solution of inert solvents.[5] In this case, we would have a definite isosbestic point.

Factor Analysis

The Lambert-Beer law in the absorption spectra may be written as

$$A = \sum_{k=1}^{n_c} \varepsilon_k c_k \tag{1}$$

where A, ε, c, and n_c stand for the absorbance, molar extinction coefficient, the concentration of each component and the number of components, respectively. If we measure the absorbance in the wavelength between λ_1 and λ_r for some number(s) of solutions with different molar compositions, we obtain an absorbance matrix [A]

$$[A] = \begin{bmatrix} A_{11} \cdots\cdots A_{1s} \\ \vdots \qquad\quad \vdots \\ A_{r1} \cdots\cdots A_{rs} \end{bmatrix} \tag{2}$$

which has the elements A_{ij} given below.

$$A_{ij} = \sum_{k=1}^{n_c} \varepsilon_{ik} c_{kj} = \sum_{k=1}^{n_c} f_k \tag{3}$$

Here i and j refer to the number of wavelength used and of solutions with different molar composition, respectively.

The application of main component analysis in the factor analysis technique will permit us to determine the number of the factor n_c whenever the data matrix can be expressed by a linear summation of the factor f_k as in Eq. 3. This number n_c is equal to that of the component to be evaluated. Further details are referred to literature.[4]

We have prepared the data matrix which consist of the absorbance at each 10 nm for each finite molar composition

a) Case 1: $x_{EtOH} < 0.20$. Case 2: $1 > x_{EtOH} > 0$.

c. By using these data matrix, we have made factor analysis explained above. Necessary computer program has been written by one of us(D.G.H.).

The results of the main component analysis are given in Table 1. The value for RMS error is based on the following equation.

$$\mathrm{RMS} = [\sum_{i=1}^{r} \sum_{j=1}^{s} (d_{ij} - d^*_{ij})^2 / rs]^{1/2} \quad (4)$$

where r is the number of the wavelengths examined, s the number of solutions used, d^*_{ij} the raw data, and d_{ij} the reproduced data. Error 1 and Error 2 refer to the largest and second largest $(d_{ij} - d^*_{ij})$ values, respectively.

It is clear from the table that the RMS error becomes comparable with experimental uncertainty, ±0.0025, when the number of the factor is 3 for tetrahydrofuran-cyclohexane solution, 4 for 1,4-dioxane-cyclohexane solution, 2 or 3 for ethanol-heptane solution, respectively. More careful inspection of the table leads to the conclusion that the number of the factor for the first solution should be 4 rather than 3, because both Error 1 and Error 2 are as large as 0.01 for the factor number of 3.

We have made two analyses for ethanol-haptane solution with each different composition range. As shown in Table 1. the factor number is 3 for the whole composition range. This may be an effect of a small peak at 360 nm which is

ascribed to the presence of I_3^- in the solution. If we confine the composition range to the heptane-rich region, the factor number becomes 2, namely the presence of the only one isosbestic point. This suggests that there should be only the 1 : 1 complex in ethanol solutions.

The above analysis clearly shows that ether solutions are more complex environment for iodine than ethanol solution and that the present results coincide with the tendency in the magnitude of molar enthalpy of complex formation between iodine and electron donors.[6] There is thus essentially no difference between 1,4-dioxane and tetrahydrofuran as electron donor or a partner in complex formation, suggesting that the mode of complex formation with iodine is independent of the number of ether oxygens in the molecule.

Finally, we point out that the present results should be taken into account in the interpretation of the diffusion behavior in mixed solvents.

The authors thank the Data Processing Center of Kyoto University for the permission to use the facility.

Synopsis. The Raman spectra of a highly conductive molecular complex of the title were measured. The I_3^- symmetric stretching band and its well-known overtones were observed, indicating that the formula for this complex should be written as (TTM-TTF)$(I_3)_{0.823}$. A brief discussion is given comparing the spectra of the present complex with those of TMA-I-TCNQ and (BEDT-TTF)$_2I_3$ complexes.

Organic conductors containing trihalide ions have attracted the attention of many workers[1] since the discovery of the ambient pressure organic superconductor, β-(BEDT-TTF)$_2I_3$.[2] The intermolecular interactions through the sulfur atoms of BEDT-TTF(hereafter, ET) may, of course, be important in endowing this crystal with high conductivity. However, the role played by I_3^- ions should not be overlooked, since some similar ET complexes containing similar halide ions have been found to become superconducting.[3]

The structure and various properties of the iodine complex of TTM-TTF, tetrakis(methylthio)tetrathiafulvalene, were previously reported.[4] TTM-TTF has eight sulfur atoms, similarly to ET. The iodine complex, (TTM-TTF)$I_{2.47}$, is metal-like at room temperature, but becomes insulating at low temperatures below 100 K. The iodine atoms were found to make a fairly ordered sublattice which is incomensulate to the TTM-TTF lattice. However, the structure of the iodine sublattice has not yet been clarified.

In this note, we report on the Raman spectra of (TTM-TTF)$I_{2.47}$. The results comprise essentially the typical resonance Raman spectra of I_3^- ions.[5] Thus, the formula for the present complex should be written as (TTM-TTF)$(I_3)_{0.823}$. The frequencies and the band structures found for the I_3^- bands of the present complex are significantly different from those of the ET-complexes.[6] A brief discussion is given regarding the vibrational state of I_3^- ions.

Experimental

Black thin plate crystals of (TTM-TTF)$I_{2.47}$ were obtained by previously described methods.[4] These were apparently bundles of needle crystals. The crystal b axis is known to correspond to the needle axis.[4]

The Raman spectra were measured with a SPEX 1403 monochromater equipped with a Hamamatsu R-649 photomultiplier. Data were recorded with a convensional photoncounter in combination with a personal computer. An Oxford DN1704 cryostat was used between 89 K and room temperature. The samples were mounted in a nitrogen atmosphere. The 501.7 nm line from an NEC GLG-3201 Ar-ion laser was used as the excitation source with a grazing angle of about 20°. The Raman light was collected in the direction perpendicular to the incident light. To avoid any decomposition of the sample by the local heating, the incident light was attenuated to a power below 3 mW for measurements at low temperatures and below 1 mW at room temperature. The sample temperature was estimated with an alumel-chromel thermocouple which was placed near the sample surface.

Results and Discussion

Figure 1 shows the wide-scan spectrum at 89 K with the incident-light polarization parallel to the b axis and a spectral resolution of 1.8 cm^{-1}. A series of bands (No. 1—5) are seen with almost the same separations of about 108 cm^{-1}; the wavenumber of each band is listed in Table 1. For bands 1 and 2, solid curves were drawn for eyes guides. Some strong and sharp bands observed in addition to bands 1—5 are the plasma lines coming from the Ar-ion laser.

Bands 1—5 can obviously be assigned to the fundamental and overtone bands of the symmetric stretching mode of I_3^- ions.[5] The unusually strong intensities of the overtone bands, and the fact that

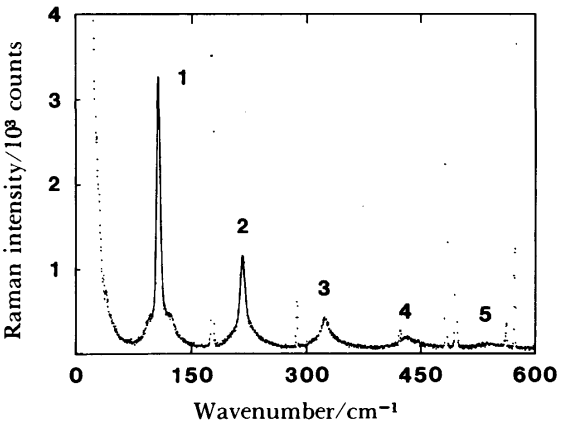

Fig. 1. Raman spectrum of (TTM-TTF)$I_{2.47}$ complex at 89 K.

Table 1. Raman Frequencies of the Fundamental and Overtone Bands (cm^{-1})

(TTM-TTF)$I_{2.47}$ (89K)	107.0 109.7	216.7	324	432	≈538
TMA-I-TCNQ (15K)[7]	110	218	327	435	544

only the I_3^- bands and no TTM-TTF band was observed, are attributed to the resonance Raman effect.[5] The fact that the spectra were observed with b-polarized incident light and not with the polarization perpendicular to this, indicates that the I_3^- ions exist with their molecular axis parallel to the b axis. This is because the intensity is enhanced by resonance with the electronic transition $\sigma_g \rightarrow \sigma_u^*$.[7] These results are in accordance with the result of the X-ray analysis.[4]

Details of band 1, measured with a spectral resolution of 0.6 cm^{-1}, is presented in Fig. 2. Band 1 apparently comprises two substructures. By assuming Lorentzian shapes, their frequencies were estimated to be 107.0 and 109.7 cm^{-1}, respectively, and the apparent width of either substructure to be 2.8 cm^{-1}. One possibility of the cause of this splitting is a factor-group splitting due to intermolecular interactions between I_3^- ions in the iodine sublattice. However, the polarization behaviors of the above substructures are almost the same, and we could not obtain any experimental evidence of this possibility. The fact that the structure of the iodine sublattice is inferred to be complicated, with 16 I_3^- ions in the unit cell and incommensurate to the TTM-TTF sublattice,[4] also excludes the above possibility of a simple factor-group splitting. Another possibility is that there exist roughly two kinds of I_3^- ions in the crystal, although a variety of environments of I_3^- ions must exist owing to the incommensuration. The relative ratio of the intensities of the substructures is about 2.5. This is not a ratio simply related to the structure of the iodine sublattice, and might manifest slightly different resonance effects for the different I_3^- ions.

The overtone frequencies are almost multiples of that of band 1. However, these frequencies are slightly larger than the multiples of the frequency of the main substructure of band 1. Bandrauk et al.[8] observed a regular sequence of overtone frequencies of I_3^- bands for TMA-I-TCNQ with a slight indication of anharmonicity (Table 1). In their case, the higher-order Raman processes could be assigned to multi-quantum excitations in the same vibrational mode. However, for explaining the frequencies of our overtones, we must assume that not the main substructure of band 1 but the smaller substructure gives the second-order band, or that the second-order process involves both the two modes which give these two substructures, respectively. Note that the peak frequency of band 2, 216.7 cm^{-1}, is comparable with the sum of 107.0 and 109.7 cm^{-1}, the frequencies of the substructures of band 1. An example, in which the peak of a second-order Raman band is located at a frequency higher than twice the most prominent fundamental band, is found for crystalline iodine.[9] In this case, the apparent shape of the second-order band is interpreted by a double phonon generation on the factor-group-splitted two phonon branches in the whole area of the Brillouin zone. In our case, the vibrations participating the higher-order Raman processes might not be those arising from the factor-group splitting. However, it is very likely that these processes involve the vibrations on different molecules or the vibrations delocalized over the molecules.

Figure 3 shows the temperature dependences of the frequencies of bands 1 and 2. As the temperature is raised, both bands decrease their frequecies almost monotonically within the experimental error. Such temperature shifts of low-frequency intramolecular vibrations are considered to occur by a coupling with the lattice vibrations and sometimes seen for molecular crystals. It has been inferred in connection with the metal-insulator transition around 100 K that the degree of the charge transfer would be slightly changed depending on the temperature.[4] The present Raman results do not answer this problem, but we can say that the vibrational states are not greatly affected by the temperature change.

The frequency of the fundamental band observed here is slightly smaller than of I_3^- in solution[5] or in TMA-I-TCNQ,[8] but it is not unusual as compared with other semicondutive iodine complexes.[7] Recently, the corresponding frequencies of the α and β forms of ET-iodine complexes were found to be 117 and 122 cm^{-1}, respectively at 80 K.[6] These are remarkably larger than those of other I_3^- complexes, and considered to manifest a tight crystal field around the I_3^- ions in these complexes.

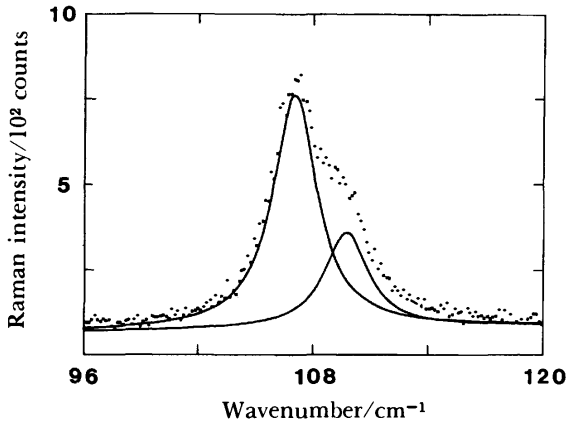

Fig. 2. Detail of band 1 with the resolution of 0.6 cm^{-1}. Solid lines are the assumed substructures.

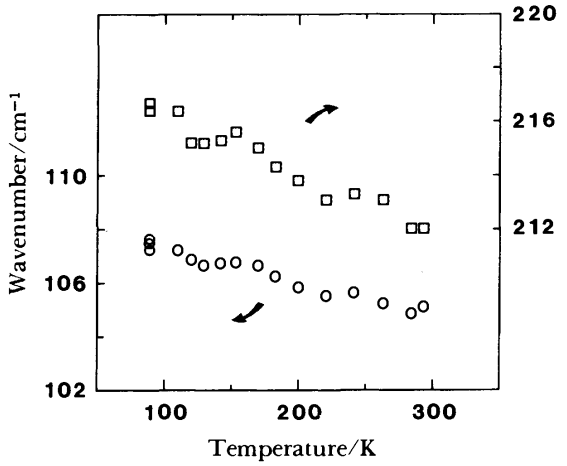

Fig. 3. Temperature dependences of the frequencies of bands 1 and 2.

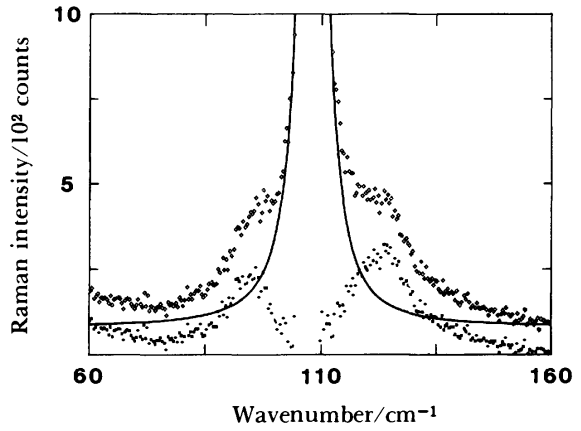

Fig. 4. Structure of the side bands accompanying band 1. Solid line is the assumed band shape of band 1, and closed squares are the difference spectrum giving the side bands.

Two side bands appear at the tail of band 1 (Fig. 1). This feature is very similar to that of TMA-I-TCNQ.[8] Similar side bands were also observed for the ET-complexes, and were attributed to the coupled excitations between the stretching and librational modes of I_3^- ions.[6] These assignments are plausible since the separations of the bands from the fundamental band are almost the same as the low-frequency bands appearing around 30 cm^{-1} in their spectra. In the cases of (TTM-TTF)$I_{2.47}$ and TMA-I-TCNQ, the separations of the side bands from the fundamental band are much smaller. Details of the side bands of our complex at 89 K are presented in Fig. 4, in which the spectrum is decomposed by assuming a Lorentzian shape for the fundamental band. The frequencies of these side bands were estimated to be 94 and 123 cm^{-1}, respectively. Then, the separations from the main substructure of band 1 are 13 and 16 cm^{-1}, respectively. No band appears in the 30 cm^{-1} region in both the (TTM-TTF)$I_{2.47}$ and TMA-I-TCNQ spectra. Thus, it is very likely that the librational frequencies of I_3^- ions in these complexes are as small as 15 cm^{-1}, much smaller than those in the ET-complexes. This indicates a large difference between the crystal fields in these two types of complexes.

The superconduction mechanism in the ET-complexes has not yet been clarified. However, it is likely that the Coulomb field produced by the halide ions or their large polarizability play important roles in the superconduction. Thus, it is worth noting that the frequencies of the optical phonons involving I_3^- ions in the ET-complexes are much larger than those in (TTM-TTF)$I_{2.47}$ or TMA-I-TCNQ, which are insulating at low temperatures.

Synopsis. The structure of optically active title compound was determined by X-ray diffraction. The absolute configuration is *trans*-δ-NH. A pair of two-fused six-membered rings is extended. The geometry of the octahedron is distorted by the presence of the six-membered chelate rings.

The linear triamine bis(3-aminopropyl)amine ($NH_2CH_2CH_2CH_2NHCH_2CH_2CH_2NH_2$, abbreviated as dpt) acts as a terdentate ligand and coordinates to the central metal ion in two topological modes. The cobalt complex, $[Co(dpt)_2]^{3+}$, which contains four six-membered chelate rings, can exist in three geometrical isomers, mer-, sym-fac-, and unsym-fac-isomers. As for the mer-isomers, an optical isomer due to the alternative disposition of N-H bond of the secondary nitrogen atom in dpt ligands is presumed (Fig. 1). The *mer*-$[Co(dpt)_2]^{3+}$ has been prepared and resolved by the present authors,[1] and the structure of optically nonactive complex, $[Co(dpt)_2](ClO_4)_3$, was determined by X-ray analysis by Hambley et al.[2] However, no report has been published on an optically active one. This paper reports the molecular structure of $(+)^{CD}_{490}$*mer*-$[Co(dpt)_2][Co(CN)_6]\cdot 2H_2O$.

Experimental

The $[Co(dpt)_2]^{3+}$ complex was prepared by the method described in a previous paper.[1] The product was dissolved in a small amount of water, and the solution was poured into a column of 2 cm diameter and 120 cm length containing SP-Sephadex C-25 resin (H^+ form). When the elution was carried out with a sodium bis[$(+)_{589}$tartrato]-diantimonate(III) solution of 0.20 mol dm^{-3} at pH≈2, adjusted with HCl,[2] and at a temperature below 7 °C, two reddish purple bands were separated as shown in Fig. 2. These bands were optically active.[3] The elute corresponding to the faster layer was collected and poured into a column (2×ca. 25 cm) of SP-Sephadex C-25 (H^+ form). After the column was washed with 1.0 dm^3 of 0.1 mol dm^{-3} hydrochloric acid, an elute with 1.0 mol dm^{-3} hydrochloric acid was obtained. Crystals were allowed to grow from the elute on addition of equivalent $K_3[Co(CN)_6]$.

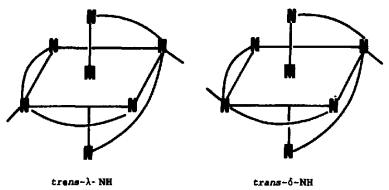

Fig. 1. Two optical isomers of *mer*-$[Co(dpt)_2]^{3+}$.

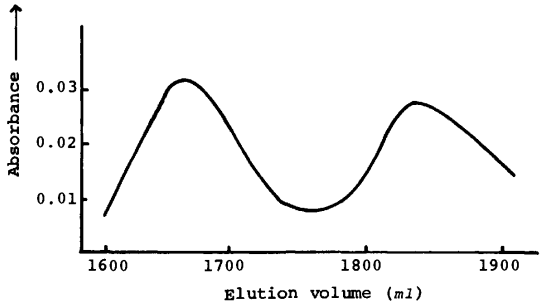

Fig. 2. Elution curve of *mer*-$[Co(dpt)_2]^{3+}$ (516 nm).

Crystal Structure Determination. The crystal is reddish purple, transparent hexagonal prism and of monoclinic structure. The absence of systematic ($0k0$) patterns for $k=2n+1$ indicated that the possible space group is $P2_1$ or $P2_1/m$. Since the crystal is optically active, the space group seems to be $P2_1$.

Crystal Data: $(+)^{CD}_{490}$*mer*-$[Co(dpt)_2][Co(CN)_6]\cdot 2H_2O$, $Co_2C_{18}H_{38}N_{12}O_2$ *F.W.* = 572.44, monoclinic, space group $P2_1$, $a=9.528(2)$, $b=16.464(2)$, $c=8.997(2)$ Å, $\beta=113.50(2)°$, $V=1294.3(5)$ Å^3, $Z=2$, $D_m=1.45$ Mg m^{-3}, $D_c=1.47$ Mg m^{-3}.

A crystal with dimensions of ca. 0.4 × 0.2 × 0.4 mm was used for X-ray diffraction intensity measurements. The intensity was determined by a Rigaku AFC-5 four-circle diffractometer with graphite-monochromated Mo $K\alpha$ radiation ($\lambda=0.7107$ Å) up to 2θ of 55°. Independent 3634 reflections containing Bijvoet pairs with $|F_o|>3\sigma(|F_o|)$ were used for the structure determination. The usual corrections were made for the Lorentz and polarization effects, but no correction was applied for absorption. The calculation was carried out on a FACOM M-360 computer at Rikkyo University. The structure was solved by the Patterson-Fourier method with UNICS III computation program system.[4] The positions of cobalt atoms were deduced from three-dimensional Patterson maps and those of other non-hydrogen atoms were derived from the Fourier map. The scattering factors were taken from Ref. 5). The refinements by the block diagonal least-squares with anisotropic thermal parameters gave R of 0.032. The absolute structure was de-

termined by the anomalous-scattering technique. The enantiomeric structure was refined in the same way at this stage and converged at residuals R of 0.042. As is shown in Table 1, the comparison of the observed and calculated differences between $|F(hkl)|$ and $|F(h\bar{k}l)|$ indicated that $(+)^{CD}_{490}$-isomer has the absolute configuration illustrated in Fig. 3.

The final refinement was carried out using the block diagonal least-squares with anisotropic thermal parameters for non-hydrogen atoms and isotropic ones for hydrogen atoms. The positions of twenty-nine hydrogen atoms among thirty-four, except those of water, were found from a difference synthesis. The final R and R_2 values were 0.022 and 0.028, respectively. The final atomic parameters and thermal parameters are given in Table 2.[6]

Results and Discussion

A perspective drawing of the complex cation is shown in Fig. 3. Two molecules of dpt ligands coordinate with six nitrogen atoms to form an octahedral complex. Each ligand occupies a meridional position as expected. The absolute structure shown in Fig. 3 was assigned to *trans*-δ-NH[7]($\vec{\Lambda}$).[8]

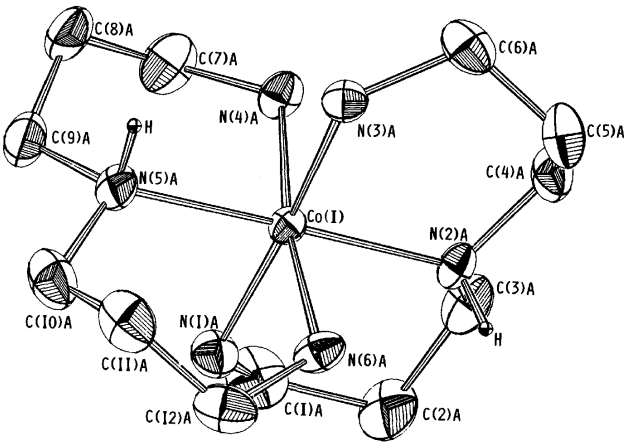

Fig. 3. Perspective drawing of the $[Co(dpt)_2]^{3+}$. The hydrogen atoms except for the secondary amine are not shown.

The bond lengths and angles in the complex cation are listed in Table 3. The Co-N bond lengths (the longest value is 2.053(3) Å for Co(1)-N(2) and the shortest is 1.979(4) Å for Co(1)-N(3)) agreed with the observations for the $[Co(diamine)_3]^{3+}$- and $[Co(triamine)_2]^{3+}$-type complexes containing six-membered chelate rings.[9] Co(1)-N(secondary) length is, however, longest in other values, in contrast to the cases of $(+)_{589}$*mer*-$[Co(dien)_2]Br_3\cdot 1.6H_2O$[6] and $(-)_{589}$*unsym*·*fac*-$[Co(dien)_2][Co(CN)_6]\cdot 2H_2O$.[10] All of the N(secondary)-Co-N(terminal) angles in the dpt chelates are larger than 90°. These results indicate that the six-membered chelate rings are considerably extended. As for the $[Co(triamine)_2]^{3+}$-type complexes containing six-membered chelate ring, such as $[Co(chta)_2]I_3$[11] and $(-)^{CD}_{474}$*mer*-$[Co(aepn)(dien)]I_3\cdot H_2O$[12] (chta: *r*-1,*c*-3,*c*-5-cyclohexanetriamine, aepn: *N*-(2-aminoethyl)-1,3-propanediamine), octahedrons of chromophores are not distorted, although these complexes have many six-membered chelate rings. In contrast to these complexes, a pair of two-fused six-membered chelates coordinate to form a distorted octahedral complex in $[Co(dpt)_2]^{3+}$. The reddish purple coloration of $[Co(dpt)_2]^{3+}$ is unusual as CoN_6 chromophores. The maxima of the absorption spectra (19400 and 27200 cm^{-1}) are at lower energy sides than other CoN_6 complexes, and imply that this octahedron is distorted. The structure described above is consistent with the speculations based on the absorption spectrum.

The Synthesis of Heteroaromatic Cations Containing Sulfur or Selenium Atoms

Isao SHIBUYA* and Hiroshi NAKANISHI
National Chemical Laboratory for Industry, Yatabe, Ibaraki 305
(Received December 26, 1986)

Synopsis. The dialkylamino-substituted heteroaromatic cations, such as 1,2,4-diselenazolium, 1,2-diselenolium, 1,3,5-selenadiazinium, and 1,3-selenazinium cations, were newly synthesized, and their *S*-analogs were also obtained through similar procedures.

Heteroaromatic cations containing sulfur atoms, **1, 3, 5,** and **7,** (Fig. 1), have been accessible; they are very reactive toward various nucleophiles to give many kinds of heterocyclic derivatives.[1-5] On the other hand, the synthetic routes of heteroaromatic cation compounds containing selenium atoms, such as **2, 4, 6,** and **8,** (Fig. 1), are so far unexplored.

Since it is of interest to examine the reactivities of these seleno-compounds and to compare them with the corresponding *S*- and *Se*-analogs regarding their chemical and physical properties, we attempted to synthesize these seleno-compounds, and have succeeded, as described below.

3,5-Bis(dimethylamino)-1,2,4-dithiazolium perchlorate (**1a**) and the corresponding *Se*-analog (**2a**) were prepared in the manner shown in Scheme 1.

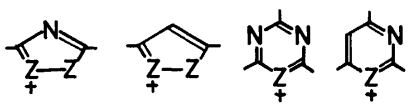

Fig. 1. Heteroaromatic cations containing *S*- or *Se*-atoms.

1,3-Bis(dimethylamino)-1,3-dichloro-2-azapropenylium chloride (**9**), obtained by treating (dichloromethylene)dimethylammonium chloride with dimethylcyanamide,[6] afforded tetramethyldithiobiuret by treating it with sodium hydrogensulfide. Then, without separating the biuret, a successive addition of perchloric acid and oxidation by hydrogen peroxide or *m*-chloroperbenzoic acid led to **1a** almost quantitatively. Similarly, the use of sodium hydrogen selenide, instead of sodium hydrogensulfide, gave **2a** as a stable white crystalline salt in 51 % yield. The results of their yields, mps, elemental analyses, and UV spectral data are summarized in Table 1.

3,5-Bis(dimethylamino)-1,2-dithiolium perchlorate (**3a**) and the 1,2-selenolium perchlorate (**4a**) were prepared when 1,3-bis(dimethylamino)-1,3-dichloropropenylium chloride[7] (**10**) was treated in a similar manner as **1a** and **2a**. Their characterization data are collected in Table 1.

As for the six-membered heteroaromatic cations, **5, 6, 7,** and **8** (Fig. 1), 2-substituted 4,6-bis(dimethylamino)-1,3,5-thiadiazinium perchlorates (**5a, b**) and the corresponding 1,3,5-selenadiazinium perchlorates (**6a—c**) were prepared by the reaction of **9** with thiocarbamoyl or selenocarbamoyl compounds, respectively (see Scheme 2). Similarly, the 1,3-thiazinium perchlorates (**7a, b**) and the 1,3-selenazinium perchlorates (**8a, b**) were also derived from **10** in good yields.

Z = S : 3a
Z = Se : 4a

The synthetic methods of heteroaromatic cations containing selenium atoms, as well as sulfur atoms, have thus been developed systematically, and their procedures could be performed at room temperature.

The results (summarized in Table 1) show that all *S*-analogs have better yields than the corresponding *Se*-analogs, and that, in many cases, they have a higher melting point. These facts suggested that the *S*-analogs are more stable than the corresponding *Se*-analogs.

Giving attention to the spectral data of dimethylamino-substituted cations, **1a**—**8a**, we found several interesting points to be noted. Namely, the IR spectra of **1a** and its *Se*-analog, **2a**, were almost the same, (Fig. 2); these phenomena were also observed between the other *S* and *Se*-analogs: (**3a**, **4a**), (**5a**, **6a**), and (**7a**, **8a**), respectively. In their UV spectra, the *Se*-analogs (**2a**, **4a**, **6a**, and **8a**), have their absorption maxima shifted to about 10 nm longer than that of the corresponding *S*-analogs. In the ^{1}H NMR spectra of **1a** and **2a**, the signals assignable to the dimethylamino group appear as two peaks in the range $\delta = 3.281 - 3.407$ at room temperature. This fact indicates that the rotation of their dimethylamino groups around the C(3)-N bond is restricted or stopped. Similar phenomena were also observed among **5a**—**8a**. A NMR study of these phenomena will be further discussed in our next report.

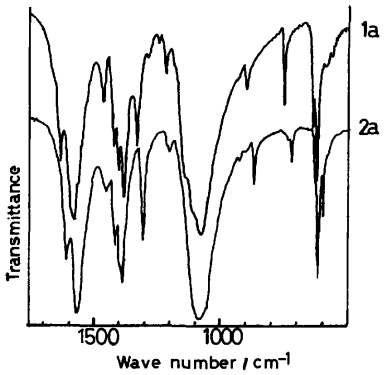

Fig. 2. IR spectra of **1a** and **2a**.

Experimental

All melting points are uncorrected. The IR spectra were recorded on a JASCO A-302 spectrometer using KBr disks. The UV spectra were taken in ethanol solutions using a Hitachi 200-10 spectrometer. The ^{1}H NMR spectra were measured on JEOL GX400 (399.65 MHz) spectrometer; solvent: DMSO-d_6, ca 7 mM (1 M = 1 mol dm^{-3}), δ: ppm from TMS.

3,5-Bis(dimethylamino)-1,2,4-dithiazolium Perchlorate (1a) and the 1,2,4-Diselenazolium Perchlorate (2a). A solution of 1,3-bis(dimethylamino)-1,3-dichloro-2-azapro-

penylium chloride (**9**) in dichloromethane (20 ml) was previously prepared by mixing dimethylcyanamide (0.70 g, 0.01 mol) and (dichloromethylene)dimethylammonium chloride (1.63 g, 0.01 mol).[6] Then, the solution of **9** was added to a solution of sodium hydrogensulfide (1.70 g, 0.03 mol) in ethanol (20 ml) drop by drop for 1 h with stirring; successively, 70% perchloric acid (2 ml) and 30% hydrogen peroxide (1 ml) or *m*-chloroperbenzoic acid (1.73 g, 0.01 mol) were added to it at room temperature. After the solvent was distilled away under reduced pressure, the residue was dissolved in hot acetonitrile (20 ml), and filtered in order to remove any insoluble substances. White crystals of **1a** were obtained from the mixed solution of the acetonitrile filtrate and the same volume of ethyl acetate after cooling overnight at 0—5 °C. Its *Se*-analog, **2a**, was obtained by a similar manner as follows. The solution of **9** was slowly added to a solution of sodium hydrogenselenide, which was obtained by the reaction of selenium powder (2.40 g, 0.03 mol) with sodium boron tetrahydride (1.15 g, 0.03 mol) in absolute ethanol (70 ml) under an argon atomosphere;[8] then, the reaction mixture was treated in the same procedure as described in **1a**. Their yields, mps, UV data, and elemental analyses results are listed in Table 1, and their IR spectra are shown in Fig. 2.

^{1}H NMR, **1a**: δ=3.281 and 3.395; **2a**: δ=3.286 and 3.407.[9]

3,5-Bis(dimethylamino)-1,2-dithiolium Perchlorate (3a) and the 1,2-Diselenolium Perchlorate (4a). The solution of 1,3-bis(dimethylamino)-1,3-dichloropropenylium chloride[7] (**10**) (2.32 g, 0.01 mol) in dichloromethane (20 ml) was treated with sodium hydrogensulfide or sodium hydrogenselenide using similar procedures as in the cases of **1a** and **2a**. Their characterization data are shown in Table 1.

3a IR: 3100, 1558, 1413, 1276, 1064, and 617 cm^{-1};
^{1}H NMR: δ=3.264 and 6.176.

4a IR: 3080, 1551, 1411, 1290, 1085, and 619 cm^{-1};
^{1}H NMR: δ=3.269 and 6.637.

2-Substituted 4,6-Bis(dimethylamino)-1,3,5-thiadiazinium Perchlorates (5a, b) and the 1,3,5-Selenadiazinium Perchlorates (6a—c). To the solution of **9** (0.01 mol) in dichloromethane (20 ml) was added 0.01 mol of thiocarbamoyl or selenocarbamoyl compounds with stirring at room temperature for 1 h; 70% perchloric acid (1 ml) was added to it. The resulting mixture was evaporated and recrystallized from ethanol to give **5a, b** and **6a—c**, respectively.

5a IR: 1603, 1577, 1551, 1413, 1176, 1091, and 619 cm^{-1};
^{1}H NMR: δ=3.279, 3.285, and 3.332.

6a, IR: 1621, 1580, 1545, 1411, 1197, 1091, and 619 cm^{-1};
^{1}H NMR: δ=3.332 and other very broad signals.

2-Substituted 4,6-Bis(dimethylamino)-1,3-thiazinium Perchlorates (7a, b) and the 1,3-Selenazinium Perchlorates (8a, b). The solution of **10** (0.01 mol) in dichloromethane (20 ml) was treated with 0.01 mol of thiocarbamoyl or selenocarbamoyl compounds and perchloric acid (as mentioned above). The resulting mixtures were recrystallized from ethanol to afford **7a, b**, and **8a, b**. Their characterization data are shown in Table 1.

7a, IR: 1613, 1577, 1545, 1414, 1317, 1089, and 617 cm^{-1};
^{1}H NMR: δ=3.285, 3.323, 3.352, and 3.368.

8a, IR: 1603, 1558, 1536, 1409, 1315, 1088, and 615 cm^{-1};
^{1}H NMR: δ=3.234, 3.285, and 3.338.

Clay Montmorillonite-Catalyzed Aldol Reactions of Silyl Ketene Acetals with Carbonyl Compounds

Makoto ONAKA,* Ryosuke OHNO, Motomitsu KAWAI, and Yusuke IZUMI
Department of Synthetic Chemistry, Faculty of Engineering, Nagoya University, Furo-cho, Chikusa-ku, Nagoya 464
(Received January 10, 1987)

Synopsis. Al^{3+} ion-exchanged montmorillonite efficiently catalyzes the aldol reactions of silyl ketene acetals with carbonyl compounds and acetals. The optimum preparation of the effective montmorillonite catalyst is described.

The use of silicon reagents in organic synthesis has been expanding rapidly in recent years.[1] During the course of our investigation on the application of solid acids as efficient catalysts to carbon-carbon bond formation reactions in a liquid phase, we discovered that the reactions of allylic silanes[2] and silyl enol ethers[3] with aldehydes and acetals are catalyzed by clay montmorillonite to afford the corresponding adducts in high yields. We describe herein catalytic efficiency of Al^{3+} ion-exchanged montmorillonite (Al-Mont) for aldol reactions of silyl ketene acetals (1-alkoxy-1-silyloxy-1-alkenes) with carbonyl compounds, and also the optimum preparation of the effective Al-Mont catalyst.

The cross-aldol reactions of silyl ketene acetals with aldehydes and acetals are generally conducted in the presence of a stoichiometric amount of various Lewis acids.[4,5] Recently the use of effective homogeneous catalysts such as Ph_3CClO_4,[6] Me_2AlCl,[7] and ZnX_2[8] was reported.

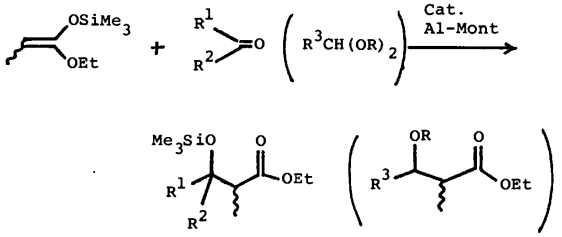

Table 1 summarizes reactions of 1-ethoxy-1-[(trimethylsilyl)oxy]propene with carbonyl compounds and acetals catalyzed by Al^{3+}-montmorillonite.

The Al-Mont-catalyzed aldol reaction of silyl ketene acetals is characterized as follows. 1) Aldehydes and ketones are more reactive than acetals. 2) The catalytic activities of Al-Mont are sensitive to reaction solvent; 1,2-dimethoxyethane (DME) is superior to

a) The reaction of the silyl ketene acetal (1 mmol) with an electrophile (0.8 mmol) was carried out in the presence of Al-Mont (0.05 g). b) Determined by GLC. c) E/Z=80 : 20. d) Al-Mont*(0.2 g) was used as a catalyst. e) Determined by NMR on the basis of the integral of the C-3 proton (δ=4.70, 4.98). f) Determined by NMR on the basis of the integral of methoxy protons (δ=3.18, 3.27).

dichloromethane and toluene. 3) Simple distillation, after removal of Al-Mont by filtration, is all that is required to furnish pure products. 4) Aldol products are obtained from aldehyde and ketone in the form of β-trimethylsiloxy esters owing to a non-aqueous work-up procedure, and no formation of α,β-unsaturated esters is observed. 5) In all cases mixtures of diastereomers are produced in good yields but with little or no apparent stereoselectivity.

The reactions of hexanal with silyl ketene acetals derived from acetate and isobutyrate were also catalyzed by Al-Mont catalyst (Runs 14 and 15). In each case the corresponding aldol adduct was readily obtained in the form of β-siloxy ester in high yield.

Clay montmorillonite is easily available and handled. The careful drying pretreatment of the clay is responsible for the attainment of high catalytic activity and good reproducibility in the present reactions because the clay structure changes irreversibly at high temperature.[9]

It should be noted that the present heterogeneous catalyst system of Al-Mont has several advantages and is an alternative to existing homogeneous catalyst systems in aldol reactions by use of silyl ketene acetals.

Experimental

Materials and Measurements. All reactions were performed under nitrogen atmosphere. Solvents were purified by distillation over an appropriate drying agent. Silyl ketene acetals were prepared according to procedures reported in the literature.[10] Aldehydes and ketone were purchased commercially. Acetals were prepared from aldehyde and trialkyl orthoformate by use of Amberlyst-15. Infrared spectra were obtained on a JASCO IRA-2 spectrometer. ^{1}H NMR spectra were recorded in $CDCl_3$ with a Hitachi R-600 spectrometer at 60 MHz. All chemical shifts were reported in relative to tetramethylsilane. GLC was performed with a Shimadzu GC-8A gas chromatograph with a capillary column (PEG-HT, 25 m).

Preparation of Al^{3+} Ion-Exchanged Montmorillonite (Al-Mont). Cation exchange was effected[11] by adding the powdered montmorillonite (100 g) (Purified Na^+ ion-exchanged montmorillonite "Kunipia-F" (cation exchange capacity = 1.19 meq./g) supplied by Kunimine Industries Co. Japan) to an aqueous solution (800 ml) of $Al(NO_3)_3 \cdot 9H_2O$ (150 g, 0.4 mol) with vigorous stirring at r.t. for 2 h. The resultant suspension was filtered on a Büchner funnel by suction. The clay was collected, suspended again in deionized water (500 ml) with stirring at r.t. for 1 h, filtered on a suction funnel, and washed with deionized water (200 ml). The clay collected was again suspended in a mixture of deionized water (200 ml) and methanol (200 ml) with stirring at r.t. for 1 h and filtered. This procedure was repeated twice. The washed clay was pre-dried at 20 °C/1 Torr (1 Torr = 133.322 Pa) for 6 h, and the agglomerated clay was then ground and passed through a 60 mesh screen. The resultant powdered clay was dried at 20 °C/0.5 Torr for 24 h, and stored in a desiccator over anhydrous silica gel until use.

Reaction Procedures. Al^{3+} ion-exchanged montmorillonite (0.05 — 0.2 g) was placed in a 30-ml round-bottomed flask equipped with a magnetic stirrer and dried at 120 °C/0.4 Torr for 3 h. To a suspended Al-Mont in a solvent (3 ml) at −78 °C were added an electrophile (0.8 mmol) in solvent (1 ml) and silyl ketene acetal (1 mmol) in solvent (1 ml) successively. The resulting mixture was stirred vigorously at the temperature shown in Table 1, and the reaction was monitored by TLC or GLC. As work-up, the suspended mixture was passed through a Celite pad and the organic filtrate was evaporated. Aldol products were purified by distillation on a Kugelrohr apparatus and diastereomer ratio of the products was determined by NMR, or by GLC after desilylation of the products.

Ethyl 2-Methyl-3-[(trimethylsilyl)oxy]octanoate. (A mixture of diastereomers): Distilled at 122 °C(bath temp)/0.5 Torr; IR (CCl_4) 1725 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ = 0.08 (s, CH_3Si), 0.86 (t, J=5.8 Hz, CH_3), 1.06 (d, J=6.8 Hz, $C\underline{H}_3CH$), 1.13 (d, J=6.8 Hz, $C\underline{H}_3CH$), 1.25 (t, J=7.0 Hz, $C\underline{H}_3CH_2O$), 1.00—1.60 (br, $(CH_2)_4$), 2.30—2.75 (m, $CH_3C\underline{H}$), 3.80—4.20 (br, CHOSi), 4.10 (q, J = 7.0 Hz, $CH_3C\underline{H}_2O$).

Ethyl 2-Methyl-3-phenyl-3-[(trimethylsilyl)oxy]propanoate. (A mixture of diastereomers): Distilled at 125 °C(bath temp)/0.3 Torr; IR (CCl_4) 1720 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ = −0.05 (s, CH_3Si), 0.02 (s, CH_3Si), 0.85 (d, J=7.0 Hz, CH_3), 1.15 (d, J=7.2 Hz, CH_3), 1.09 (t, J= 7.2 Hz, CH_3), 1.28 (t, J=7.2 Hz, CH_3), 2.40 — 3.00 (m, $C\underline{H}CH_3$), 3.98 (q, J=7.2 Hz, CH_2), 4.16 (q, J=7.2 Hz, CH_2), 4.70 (d, J=9.6 Hz, CHOSi), 4.98 (d, J = 7.0 Hz, CHOSi), 7.20—7.40 (br, Ph).

Ethyl 3-Cyclohexyl-2-methyl-3-[(trimethylsilyl)oxy]propanoate. (A mixture of diastereomers): Distilled at 128 °C(bath temp)/0.6 Torr; IR (CCl_4) 1725 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=0.00 (s, CH_3Si), 0.90—2.00 (br, cyclohexyl), 0.97 (d, J=7.8 Hz, $C\underline{H}_3CH$), 1.03 (d, J=6.4 Hz, $C\underline{H}_3CH$), 1.18 (t, J=7.4 Hz, CH_3), 2.30—2.85 (m, $C\underline{H}CH_3$), 3.50—3.85 (br, CHOSi), 4.07 (q, J=7.4 Hz, CH_2).

Ethyl 3-Ethyl-2-methyl-3-[(trimethylsilyl)oxy]pentanoate. Distilled at 130 °C(bath temp)/38 Torr; IR (CCl_4) 1730 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ = 0.02 (s, CH_3Si), 0.78 (t, J=6.8 Hz, CH_3), 1.03 (d, J=6.8 Hz, $C\underline{H}_3CH$), 1.18 (t, J=7.2 Hz, $C\underline{H}_3CH_2O$), 1.44 (q, J=6.8 Hz, CH_2), 2.55 (q, J=6.8 Hz, CH), 4.05 (q, J=7.2 Hz, $CH_3C\underline{H}_2O$).

Ethyl 3-Ethoxy-2-methyloctanoate. (A mixture of diastereomers): Distilled at 107 °C(bath temp)/0.3 Torr; IR (CCl_4) 1730 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=0.83 (t, J= 6.0 Hz, CH_3) 1.02 (d, J=7.2 Hz, $C\underline{H}_3CH$), 1.10 (d, J=7.2 Hz, $C\underline{H}_3CH$), 1.20 (t, J=6.8 Hz, $C\underline{H}_3CH_2O$, $C\underline{H}_3CH_2OCO$), 0.95—1.55 (br, $(CH_2)_4$), 2.35—2.95 (m, $CH_3C\underline{H}$), 3.47 (q, J =6.8 Hz, $CH_3C\underline{H}_2O$), 3.30−3.75 (br, CHOEt), 4.10 (q, J= 6.8 Hz, $CH_3C\underline{H}_2OCO$).

Ethyl 3-Methoxy-2-methyl-3-phenylpropanoate. (A mixture of diastereomers): Distilled at 130 °C(bath temp)/0.5 Torr; IR (CCl_4) 1720 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=0.88 (d, J = 6.6 Hz, $C\underline{H}_3CH$), 1.14 (d, J=6.4 Hz, $C\underline{H}_3CH$), 1.30 (t, J=7.0 Hz, CH_3), 2.45—2.95 (m, $C\underline{H}CH_3$), 3.18 (s, CH_3O), 3.27 (s, CH_3O), 4.02 (q, J=7.0 Hz, $CH_3C\underline{H}_2O$), 4.26 (d, J=6.8 Hz, $C\underline{H}OCH_3$), 4.45 (d, J=6.8 Hz, $C\underline{H}OCH_3$), 7.20—7.60 (br, Ph).

Methyl 3-[(*t*-Butyldimethylsilyl)oxy]octanoate. Distilled at 127 °C(bath temp)/0.6 Torr; IR (CCl_4) 1735 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ = −0.03 (s, CH_3Si), −0.01 (s, CH_3Si), 0.80 (s, $(CH_3)_3C$), 0.70—1.00 (br, CH_3), 1.00—1.70 (br, $(CH_2)_4$), 2.39 (d, J=6.6 Hz, CH_2CO_2), 3.61 (s, CH_3O), 3.80—4.25 (br, CHOSi).

Methyl 2,2-Dimethyl-3-[(trimethylsilyl)oxy]octanoate. Distilled at 120 °C(bath temp)/0.4 Torr; IR (CCl_4) 1730 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ = 0.04 (s, CH_3Si), 0.75—0.95 (br, CH_3), 1.02 (s, CH_3), 1.09 (s, CH_3), 1.10—1.55 (br, $(CH_2)_4$), 3.62 (s, CH_3O), 3.70—4.05 (br, CHOSi).

Substitution Reaction of Organic Halide by Trimethylsilyl Isothiocyanate: Formation of Thiocyanate and Its Rearrangement to Isothiocyanate†

Kozaburo NISHIYAMA* and Makoto OBA
Department of Chemistry, Tokyo Metropolitan University,
2-1-1, Fukasawa, Setagaya, Tokyo 158
(Received January 31, 1987)

Synopsis. The reaction of organic halide with trimethylsilyl isothiocyanate (TMSTC) gave thiocyanate **1** and its isomerized isothiocyanate **2**. Details of the substituion and the isomerization reactions were examined.

Recently, the application of silicon reagents has increased regarding organic synthesis. For example, a variety of silyl cyanides and silyl azides have been widely employed as synthetic tools.[1] Although trimethylsilyl isothiocyanate (TMSTC) is one of these silyl pseudo-halides, there have been only a few reports on its reactivity: Our previous report[2] concerning the formation of symmetrically and unsymmetrically isothiocyanato-substituted ethers is one of them. As the substitution reaction by TMSTC, Sasaki et al. explored the reaction of adamantyl chloride in the presence of $TiCl_4$.[3] For introducing NCS group into an organic molecule, the use of metal thiocyanate has been generalized,[4] but no detailed discussion has been given. As one part of our studies on silicon chemistry, we report here on the substitution reaction of organic halide by TMSTC and the rearrangement of thiocyanate into isothiocyanate.

Results and Discussion

When a solution of benzyl bromide and TMSTC in hexamethylphosphoric triamide (HMPA) was stirred at 60 °C for 24 h, a mixture of benzyl thiocyanate **1** and benzyl isothiocyanate **2** was obtained in a ratio of 32 : 68. On the other hand, only *S*-benzylation product **1** was yielded from a reaction which was carried out at room temperature. The effects of the solvent, leaving group, and substituent were examined and the results are summarized in Table 1. The results using sodium thiocyanate are also shown in the parentheses of Table 1. Both isomer ratios of **1** and **2** were very similar. The reaction occured favorably in HMPA or DMF. With benzyl chroride (harder alkylating agent than the bromide), compound **1** resulted as the sole product when the reaction was performed at 60 °C. This result could not be accounted for by "the principle of hard and soft acids and bases" which was often applied to the alkylation of ambident nucleophile.[5] The reactions of other *p*-substituted benzyl bromides, similarly, gave a mixture of **1** and **2**. The *N*-benzylation product was relatively increased by an electron-donating group. Coupled with the result of benzyl chloride, this indicates that *N*-benzylation can be rationalized by the consideration that the carbon-halogen bond breaking is more important than the carbon-nitrogen bond making in a transition state, i.e. the stability of the corresponding benzyl cation.

Furthermore, we investigated the substitutent effects on the *S*-benzylation. Plotting the $\log(k_X/k_H)$ values vs. the Hammett's σ constant gave a nonlinear relationship (Fig. 1). Both the electron-attracting and electron-donating substituents accelerated the rate of substitution, suggesting that a gradual change in mechanism occurs. This has been discussed by Swain and Langsdorf[6] in terms of the relative importance of bond-making and bond-breaking in the transition state. This behavior is commonly characteristic for a benzyl-type S_N2 reaction.

For a mechanistic study, the time dependency of the

† Dedicated to Professor Yoichiro Nagai on the Occasion of his 60th birthday.

product distributions was examined at 60 °C. Compound **1** was predominant during the early stages of the reaction and the molar ratios were gradually changed. After 120 h, the mixture consisted of **1** (9%), **2** (87%), and benzyl bromide (4%). *S*-Benzylation product **1** is the kinetically controlled product and **1** is isomerized to the *N*-benzylation product **2** which is thermodynamically more stable. A treatment of **1** with bromotrimethylsilane gave a mixture of isomerized **2** (55%) and benzyl bromide (16%), and chlorotrimethylsilane converted **1** into only benzyl chloride (51%). In the absence of bromosilane, no isomerization occurred. From these experiments, it is likely that the coexistent bromide ion catalyzes the isomerization of **1** to **2** and *S*-benzylation should be reversible. As shown in the equation, isothiocyanate **2** may be explained as being produced by the competitive *N*-attack of TMSTC on benzyl bromide, not by the direct isomerization of **1** to **2**

$$ArCH_2Br + Me_3SiNCS \rightleftharpoons ArCH_2SCN + Me_3SiBr$$
$$\searrow^{slow} \qquad \mathbf{1}$$
$$ArCH_2NCS + Me_3SiBr$$
$$\mathbf{2}$$

Allyl halide, 1-bromo-3-methyl-2-butene, was also reactive toward TMSTC, giving a mixture of three products. This reaction pathway is supported by the time dependency of the product distribution (Table 2). The intramolecular rearrangement between (A) and (B) was known,[7] and the rearrangement was postulated to take place via a cyclic mechanism:

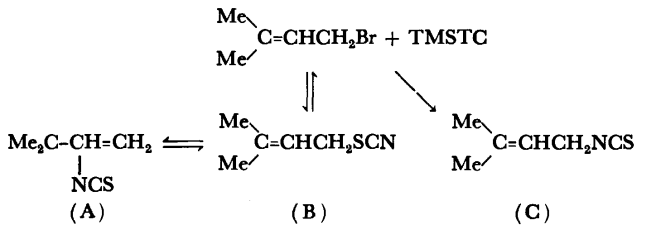

Table 2. Reaction of 1-Bromo-3-methyl-2-butene with TMSTC[a]

Time/h	Product/%		
	(A)	(B)	(C)
24	37	34	29
48	27	25	48
72	23	23	54
120	15	22	63

a) The reaction was carried out in HMPA at room temperature.

These results led us to examine the reactions of vinyl, aryl, and aliphatic halides. As expected, alkyl halide was converted to thiocyanate or isothiocyanate but vinyl and aryl halides were unreactive.

$$PhCH_2CH_2Br + TMSTC \longrightarrow PhCH_2CH_2SCN \quad (56\%)$$
$$Me_2CHCH_2Br + TMSTC \longrightarrow Me_2CHCH_2SCN \quad (12\%)$$
$$EtOCOCH_2Br + TMSTC \longrightarrow EtOCOCH_2NCS \quad (68\%)$$
$$NCCH_2Cl + TMSTC \longrightarrow NCCH_2SCN \quad (39\%)$$

From these results, it has become clear that TMSTC may be a useful reagent for introducing an NCS group under homogeneous and neutral conditions in nonaqueous solvent. Moreover, details concerning *S*- and *N*-benzylation were distinctly observed.

Experimental

Infrared spectra were measured on a Hitachi 260-10 infrared spectrometer. ^{1}H NMR spectra were determined with a Hitachi R-600 or a Varian XL-300 spectrometer using tetramethylsilane as an internal standard. Mass spectra were obtained using a JEOL DX-300 spectrometer. Trimethylsilyl isothiocyanate (TMSTC) was prepared by the reaction of sodium thiocyanate with chlorotrimethylsilane, bp 144 °C (lit,[8] bp 141.8—142 °C). Organic halides were commercial products and were purified if necessary. Some benzyl bromides were obtained from the corresponding toluenes and *N*-bromosuccinimide in the presence of benzoyl peroxide in CCl_4.

Reaction of Organic Halides with TMSTC. A solution of benzyl bromide (1.71 g, 10 mmol) and TMSTC (1.31 g, 10 mmol) in HMPA (6.7 cm^3) was heated at 60 °C for 24 h. The reaction mixture was poured into water and extracted with dichloromethane. The organic layer was washed five times with water and dried over $MgSO_4$. After the removal of solvent, fast elution with hexane on silica gel contained benzyl isothiocyanate (0.45 g, 30%), IR (neat) ν 2100 cm^{-1} (NCS); ^{1}H NMR ($CDCl_3$) δ=4.70 (s, 2H) and 7.35 (s, 5H) and benzene eluted benzyl thiocyanate (0.44 g, 30%), mp 42—43 °C, IR (KBr) ν 2150 cm^{-1} (SCN); ^{1}H NMR ($CDCl_3$) δ=4.17 (s, 2H) and 7.38 (s, 5H). The conversion and the ratio were determined by ^{1}H NMR spectra before the chromatographic separation. All the products were identified by a comparison with the authentic samples by at least two of the following methods: Mixed melting point, IR, NMR, and retention time of HPLC.

Kinetic Measurement. A competitive reaction was carried out at −20 °C for 6 min. For example, a solution of benzyl bromide (0.513 g, 3 mmol) and *p*-methoxybenzyl bromide (0.603 g, 3 mmol) in HMPA (4 cm^3) was cooled at −20 °C, and then TMSTC (0.79 g, 6 mmol) was added. The mixture was stirred for 6 min at the temperature. Work-up was similar to that described above. The relative rate of the substitution reaction was determined by ^{1}H NMR spectrum (at 300 MHz) of the products. All competitive reactions were carried out at least twice and the results were obtained from the averaged values.

Rearrangement of Benzyl Thiocyanate to Benzyl Isothiocyanate. An HMPA solution of benzyl thiocyanate (0.22 g, 1.5 mmol) and bromotrimethylsilane (0.31 g, 2 mmol) was stirred at 60 °C for 24 h. Similar work-up gave a mixture of benzyl isothiocyanate (55%), benzyl bromide (16%), and the starting material (29%). The product distribution was determined by ^{1}H NMR spectrum.

Reaction of 1-Bromo-3-methyl-2-butene with TMSTC. A mixture of 1-bromo-3-methyl-2-butene (1.49 g, 10 mmol), TMSTC (1.31 g, 10 mmol), and HMPA was treated at room temperature for 24 h. A similar work-up gave a mixture of 3-isothiocyanato-3-methyl-1-butene (A), 1-thiocyanato- (B), and 1-isothiocyanato-3-methyl-2-butene (C) in a ratio of 37 : 34 : 29, determined by ^{1}H NMR spectrum. An attempt to separate a mixture failed because of the intramolecular rearrangement during the separation on silica gel. Each structure was confirmed by ^{1}H NMR and IR spectra. ^{1}H NMR signals were assigned by their intensities. The time de-

pendency of the product distribution is given in Table 2. 3-Isothiocyanato-3-methyl-1-butene (A), IR (neat) ν 2080 cm^{-1} (NCS); ^1H NMR ($CDCl_3$) δ=1.49 (s, 6H) and 4.99—6.09 (m, 3H). 1-Thiocyanato-3-methyl-2-butene (B), IR (neat) ν 2150 cm^{-1} (SCN); ^1H NMR ($CDCl_3$) δ=1.79 (d, 6H), 3.61 (d, 2H), and 5.32 (t, 1H). 1-Isothiocyanato-3-methyl-2-butene (C), IR (neat) ν 2060 cm^{-1} (NCS); ^1H NMR ($CDCl_3$) δ=1.74 (d, 6H), 4.05 (d, 2H), and 5.30 (t, 1H).

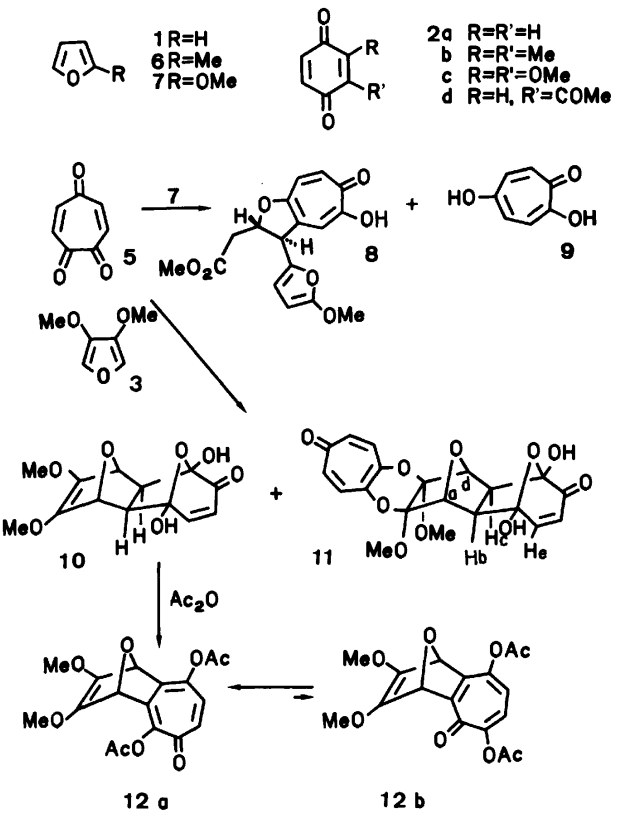
†Research Institute of Industrial Science, 86, Kyushu University,
Kasuga-koen, Kasuga, Fukuoka 816
(Received February 10, 1987)

Synopsis. The Diels-Alder reactions of *p*-tropoquinone with furans were investigated under normal- and high-pressure conditions. With furan or 2-methylfuran, no cycloadduct was obtained at all, but with 2-methoxyfuran, a double Michael adduct was isolated from the reaction under the atmospheric pressure, and its structure was elucidated mainly by ^{1}H NMR analysis. With 3,4-dimethoxyfuran, an exo-1 : 1-adduct and its further reacted 2 : 1-adduct were isolated.

Because of the poor reactivity of furan (**1**) towards dienophiles,[1] there is no successful example of a reaction with simple *p*-benzoquinone (**2a**) and its derivatives (such as **2b** and **2c**) under atmospheric pressure. However, furans became accessible to the reaction under the high-pressure conditions; with 3,4-dimethoxyfuran (**3**), formations of the endo- and exo-adducts were exemplified in the reaction with various dienophiles.[2-4] Recently, we have succeeded in obtaining the Diels-Alder adducts of tropone (**4**) with **1** under high-pressure conditions,[5] and with a continuing interest to the chemistry of tropoquinones as well as high-pressure cycloaddition reactions in troponoids, we have carried out the reaction with *p*-tropoquinone (**5**), and the results obtained therefrom are described briefly as illustrated in Scheme 1.

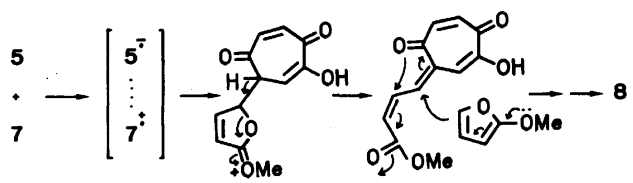


Scheme 1.

When the reaction of **5** with **1** or 2-methylfuran (**6**) was performed under 2800 bar at 40 °C, no identifiable product was formed. The reaction of **5** with 2-methoxyfuran (**7**) at room temperature gave a single adduct (**8**) in 24% yield with some amounts of 5-hydroxytropolone (**9**), which was inevitably formed by reduction of **5**. The molecular ion peak of **8** at m/z= 332, in the mass spectrum was indicated as being a 2 : 1-adduct of **7** with **5**. The IR spectrum of **8** still disclosed the presence of a tropone ring system and a newly-formed ester carbonyl function. The ^{1}H NMR spectrum revealed the signals ascribable to the ester methyl, at δ = 3.80, ethereal methyl on the furan ring, 3.69, and two furan ring protons, at 5.08 and 6.17, as well as four aliphatic proton signals, at 2.83 (2H), 4.41, and 5.11. In addition to these, there were three troponoid proton signals; at 7.12, which only spin-coupled to a proton on a sp^3-carbon, and an *AB*-pair at 6.94 and 7.24 (J=11 Hz). Analyses of these observations led to the assignment of the structure, 3-(5-methoxy-2-furyl)-5-hydroxy-2-methoxycarbonylmethyl-2,3-dihydro-1-oxaazulen-6-one. Presumably, the formation of **8** could be explained by a Michael-type addition of **7** to **5**, a furan-ring-cleavage, and a further Michael addition of **7** (as illustrated in Scheme 2).

This preferential occurrence of a Michael addition over a Diels-Alder reaction is of interest; since a distinct coloration occurred immediately after mixing **7** and **5** a charge-transfer complex should have been formed. Also, the recombination of the cation radical and the anion radical initiated a series of the subsequent C-C bond formations.[6] In this case, 5-hydroxytropolone was isolated in 33% from the reaction mixture. In this respect, a Michael addition of furans and thiophenes had a precedence in a benzenoid quinone, acetyl-*p*-benzoquinone (**2d**).[7]

On the other hand, the reaction of **5** with **3** under ordinary pressures afforded a 1 : 1-adduct (**10**) in 49% yield. Under 3000 bar at room temperature, the reac-



Scheme 2.

tion afforded an additional product (**11**) in 17% yield together with **10** in 59% yield. However, the yield of **11** under 2900 bar at 40 °C improved to 58% and that of **10** decreased to 18%. Hence, **10** is a precursor of **11**. The ^{1}H NMR spectrum of **10** immediately identified its structure to be an exo-Diels-Alder product on the basis of a lack of the vinyl protons on the furan ring: The proton signals ascribable to the ethereal carbons were doublets (J=1 Hz) at δ=4.90 and 4.99 which indicated the exo-orientation, and two mutually-coupled (J=9.5 Hz) olefinic proton signals at 5.97 and 7.33 were appropriate for the α,β-unsaturated keto group. These NMR data closely resembled those of 8-oxabicyclo[3.2.1]oct-3-en-2-one derivatives,[8] and suggested the formation of the same framework via an intramolecular hemiacetalization.[9] This was verified when **10** was treated with acetic anhydride in pyridine, a diacetate **12** was obtained and it possessed a 2,5-diacetoxytropone structure. The proton signals on the ethereal carbons caused a down-field shift, δ=5.31 and 5.49, and the observed magnitude of the coupling constant for the vicinal protons on the troponoid ring was J=13 Hz, from which, the α-acetoxy keto function could be expressed as depicted (**12a**).[10] It is interesting to point out that **12** showed no tendency of an "acetotropy" which is common in the 2-acetoxytropones.[11] Probably, a bond strain from the fused oxanorbornene framework might disfavor the contribution of the isomeric form, **12b**. Indeed, the ^{13}C NMR of **12** has not revealed any appreciable broadening of the signals at room temperature.

The structure of **11** was also elucidated by the NMR spectral data: Its ^{1}H NMR spectrum resembled that of **10**, other than the additional signals at 6.94 (2H) and 7.40 (2H), ascribable to the overlapped tropone ring protons. Furthermore, the methoxyl signal moved to an up-field region. Therefore, **11** was assumed to be a secondary adduct of **5** with the dimethoxyethylene moiety of **10**. In this case, the α-dioxo group of **5** worked as the 4π component in the Diels-Alder reactions; as a cyclic α-diketone, this also has a precedence.[12] The stereochemistry of the methoxyl groups was assigned to be anti to two ether bridges on the basis of the positive nuclear Overhauser effect (NOE)[13] between the methoxyl and the methine proton signals (H_b and H_c), and between the β-proton (H_e) of the enone part and the H_b, respectively. This stereopreferential formation was parallel to other examples of the 7-oxabicyclo[2.2.1]heptene system.[14]

Consequently, the Diels-Alder reaction of **5** with **3** under normal- and high-pressure conditions gave a single exo-[4+2]π adduct, which was a thermodynamically controlled product. In the case of **2a** with **3**, the endo-[4+2]π adduct was the sole product under the ordinary pressure, but under the high-pressure conditions, e.g., 7000 to 19000 bar, the exo-[4+2]π adduct gradually increased.[4] This contrast in the stereoselectivity is noteworthy.

Experimental

Reaction of 5 with 7 under Ordinary Pressure. A benzene solution (1 cm^3) of **5** (68 mg) and **7** (213 mg) was kept at room temperature for 1 h. The resultant precipitate was filtered to collect **9** [22.8 mg; 33%], whose identity with the authentic sample was confirmed by direct comparisons. Silica-gel column chromatography of the filtrate afforded **8** [yellow crystals, mp 138—139 °C, 26.1 mg; 24%. Found: C, 61.62; H, 4.92%; M.W., 332.0938. Calcd for $C_{17}H_{16}O_7$: C, 61.44; H, 4.85%; M.W., 332.0895. ^{1}H NMR δ[15]=2.83 (2H, d, J=6 Hz), 3.69 (3H, s), 3.80 (3H, s), 4.41 (1H, dd, J=9, 1.5 Hz), 5.08 (1H, d, J=3.5 Hz), 5.11 (1H, dt, J=9, 6 Hz), 6.17 (1H, d, J=3.5 Hz), 6.94 (1H, d, J=11 Hz), 7.12 (1H, d, J=1.5 Hz), and 7.24 (1H, d, J=11 Hz). ^{13}C NMR δ=38.7, 50.6, 52.1, 57.8, 80.2, 81.9, 110.9, 118.4, 123.0 (2C), 139.0, 139.8, 158.6, 162.4, 166.5, and 170.2 (2C). IR ν 1740, 1585, 1460, and 1260 cm^{-1}. UV λ_{max}^{MeOH} 232 nm (ε=26600), 238 (27100), 342 (10700), 386 (7000), 400 (7600), and 425 (3700)].

Reaction of 5 with 3 under Ordinary Pressure. A benzene solution (1.5 cm^3) of **5** (30 mg) and **3** (70.4 mg) was kept at room temperature for 5 h. Silica-gel column chromatography of the mixture afforded **10** [colorless crystals, mp 129 — 131 °C (decomp), 30.5 mg; 49%. Found: C, 55.24; H, 5.11%. Calcd for $C_{13}H_{14}O_7$: C, 55.31; H, 5.01%. ^{1}H NMR (CD_3OD) δ=2.44 (1H, d, J=6.5 Hz), 2.70 (1H, d, J=6.5 Hz), 3.66 (3H, s), 3.68 (3H, s), 4.90 (1H, d, J=1 Hz), 4.99 (1H, d, J=1 Hz), 5.97 (1H, d, J=9.5 Hz), and 7.33 (1H, d, J=9.5 Hz). ^{13}C NMR (CD_3OD) δ=52.2, 57.2, 59.5 (2C), 78.4, 79.1, 101.4, 102.6, 127.4, 141.6, 142.3, 159.4, and 197.6. IR ν 3370, 3170, 1690, 1175, 1160, 1015, and 1005 cm^{-1}. UV λ_{max}^{MeOH} 218 nm (ε=8350)].

Reaction of 5 with 3 under High-Pressure. a) An isopropylbenzene (IB) solution (2.5 cm^3) of **5** (55.2 mg) and **3** (53.7 mg) was kept at room temperature under 3000 bar for 5 h. The silica-gel column chromatography of the mixture afforded **10** [67.4 mg; 59%] and **11** [colorless crystals, mp 223 °C (decomp), 14.2 mg; 17%. Found: C, 57.47; H, 4.58%. Calcd for $C_{20}H_{18}O_{10}$: C, 57.41; H, 4.35%. ^{1}H NMR (CD_3OD) δ=2.58 (1H, d, J=7 Hz), 2.86 (1H, d, J=7 Hz), 3.39 (3H, s), 3.43 (3H, s), 5.02 (1H, d, J=1 Hz), 5.07 (1H, d, J=1 Hz), 6.09 (1H, d, J=10 Hz), 6.94 (2H, d, J=12.5 Hz), 7.36 (1H, d, J=10 Hz), and 7.40 (2H, d, J=12.5 Hz). ^{13}C NMR (CD_3OD) δ=48.5, 49.4, 51.4, 52.9, 83.2, 84.4, 101.9, 103.3, 108.4 (2C), 128.3, 135.1 (2C), 137.6 (2C), 148.2, 148.5, 159.3, 187.8, and 197.0. IR ν 3020, 1705, 1550, 1510, 1212, 1180, 1110, and 1015 cm^{-1}. UV λ_{max}^{MeOH} 232 nm (ε=19500) and 337 (12000)].

b) An IB solution (3 cm^3) of **5** (54 mg) and **3** (62 mg) was kept at 40 °C under 2900 bar for 5 h. The silica-gel column chromatography of the mixture afforded **10** [19.9 mg; 18%] and **11** [48.2 mg; 58%].

Acetic Anhydride Treatment of 10. An Ac_2O solution (2.5 cm^3) of **10** (100.4 mg) and pyridine (2.5 cm^3) was kept at room temperature for 1 d. Evaporation of the solvent in vacuo revealed the formation of **12** [pale yellow crystals, 134 — 136 °C, 84.4 mg; 68%. Found: C, 58.45; H, 4.68%. Calcd for $C_{17}H_{16}O_8$: C, 58.62; H, 4.63%. ^{1}H NMR δ=2.29 (3H, s), 2.34 (3H, s), 3.71 (3H, s), 3.73 (3H, s), 5.31 (1H, d, J=2 Hz), 5.49 (1H, d, J=2 Hz), 6.77 (1H, d, J=13 Hz), and 6.94 (1H, d, J=13 Hz). ^{13}C NMR δ=20.4, 20.5, 59.2 (2C), 80.0, 80.5, 135.2, 136.3, 138.7, 142.1, 142.9, 143.7, 144.2, 147.2, 167.8, 168.8, and 177.9. IR ν 1770, 1675, 1600, 1230, 1185, 1165, 1115, and 1085 cm^{-1}. UV λ_{max}^{MeOH} 216 nm (ε=23650) and 302 (13800)].

Attempted Reaction of 5 with 1. A mixture of **5** (62 mg) and **1** (332 mg) was kept at 40 °C under 2800 bar for 12 h, no appreciable change occurred, and 21.8 mg (35%) of **5** was recovered.

Attempted Reaction of 5 with 6. A mixture of **5** (62 mg) and **6** (391 mg) was similarly kept at 40 °C under 2800 bar for 12 h. TLC of the mixture indicated no formation of

the adduct, and silica-gel column chromatography furnished no isolable material.

We thank The Ministry of Education, Science, and Culture for a financial support by a Grant-in-Aid for Scientific Research to S. S. (No. 61740294).

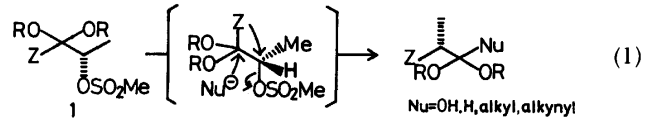
Substitution-Type Thermal 1,2-Rearrangement. Synthesis of Chiral β-Aryl(or Alkenyl) α-Oxo Nitrile Acetal

Yutaka HONDA* and Gen-ichi TSUCHIHASHI*
Department of Chemistry, Faculty of Science and Technology, Keio University,
3-14-1 Hiyoshi, Kohoku-ku, Yokohama 223
(Received March 13, 1987)

Synopsis. Title compound was synthesized via a substitution-type thermal 1,2-rearrangement accompanied by introduction of a cyano group, and derived into the corresponding aldehyde, alkanoic acid, and amide.

In the last five years, we have studied on 1.2-rearrangement accompanied by introduction of hydroxide,[1-3] hydride,[4] alkanide, and alkynide anion[5] to give chiral α-substituted alkanoic ester, aldehyde acetal, and ketone acetal, respectively. They were promoted by elimination of sulfonyloxy group caused by heating or activation with Lewis acids (Eq. 1).

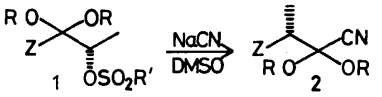


(1)

Now, we report a new thermal rearrangement accompanied by introduction of a cyano group.

Results and Discussion

Since cyanide anion is a strong nucleophile compared with hydroxide anion, cyano group was expected to be introduced even when chiral α-sulfonyloxy ketone acetal (**1**) is treated with sodium cyanide in aqueous solution. In practice, however, the corresponding alkanoic ester (**3**, Fig. 1) was formed quantitatively instead of the desired β-substituted α-oxo nitrile acetal (**2**). Under reflux conditions in anhydrous methanol, **2** was yielded in 11%, but the main product was also **3**. It is concluded that the attack of a large excess of methanol has occurred predominantly. As the results, **1** was treated with two equivalents of sodium cyanide in anhydrous dimethyl sulfoxide to yield chiral α-oxo nitrile acetal (**2**) in a good yield (Eq, 2, Table 1).



(2)

Obtained **2** was sensitive to light. Many by-products were generated in Entries 1—3, because the rate of migration of a phenyl group was extremely low. Taking into consideration of the reaction temperature and time, the migratory aptitudes are enhanced by the migrating groups in the order alkenyl≧*p*-methoxyphenyl>phenyl and by the acetal groups in the order dimethyl>trimethylene>2,2-dimethyltrimethylene.

α-Oxo nitrile acetal (**2**) can be transformed into the variety of the corresponding derivatives. At first **2** was treated with DIBAL (*i*-Bu_2AlH) to give an imino derivative quantitatively,[6] and then with oxalic acid dihydrate to give α,α-dialkoxy aldehyde (**4**) (Eq. 3,

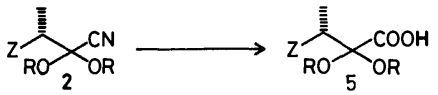
a) $KMnO_4$-10% KOH. b) CrO_3-H_2SO_4-Acetone.

Table 2), which would be capable to be a useful building block for acyclic stereoselective synthesis of chiral compounds.

Aldehyde (**4**) was easily oxidized by treatment with $KMnO_4$-KOH[7] or Jones reagent in acetone to yield α,α-dialkoxy carboxylic acid (**5**) (Eq. 4, Table 3).



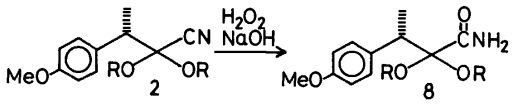
(4)

The absolute configuration of **2** was determined to be *S* from the sign of the specific rotation of the corresponding dithioacetal (**6**); $[\alpha]_D^{21} = -20.7°$ (c 0.34, $CHCl_3$), prepared from **5** in 88% yield by treatment with 1,3-propanedithiol in the presence of catalytic amount of $BF_3 \cdot OEt_2$ in dichloromethane at rt. An authentic **6**; $[\alpha]_D^{21} = -21.3°$ (c 0.35, $CHCl_3$), was prepared from (*S*)-aldehyde acetal (**7**)[4] by dithioacetalization, followed by lithiation and carboxylation with CO_2 (Fig. 2).

Table 4. Synthesis of α,α-Dialkoxy Amide (**8**)

R	Yield/%	$[\alpha]_D$/° (t/°C, c, in $CHCl_3$)
	95	−54.9 (22, 0.81)
Me	62	+ 8.8 (23, 0.64)

The enantiomeric excess was determined to be over 98% by HPLC analysis[8] of α,α-dimethoxy amide (**8**), which was prepared from **2** (R = $CH_2CMe_2CH_2$, Z = $MeOC_6H_4$) in 95% yield by treatment with 30% H_2O_2-NaOH in ethanol[9] (Eq. 5, Table 4).



(5)

Consequently, it was concluded that the optical purity of the starting material, ethyl (*S*)-lactate,[10] was remained through the rearrangenent and the follwing derivation.

Experimental

General Synthetic Procedure of α-Oxo Nitrile Acetal (2). Under an argon atmosphere, **1** (1.00 mmol) was dissolved in anhydrous dimethyl sulfoxide (10 ml) containing sodium cyanide (2.00 mmol) in a sealed tube. The mixture was heated in dark, and allowed to cool to rt. It was poured into a vigorously stirred ice-water, and extracted with ethyl acetate (30 ml×2). The residual syrup was purified by using silica-gel column chromatography (hexane-ethyl acetate-pyridine) to give **2** as a colorless oil.

(*S*)-3-(*p*-Methoxyphenyl)-2-oxobutanenitrile 2,2-Dimethyltrimethylene Acetal: IR (film) $\nu = 2230\ cm^{-1}$; ^1H NMR (CCl_4) $\delta = 0.78$ (s, 3H), 0.99 (s, 3H), 1.42 (d, $J = 7.2$ Hz, 3H), 3.05 (q, $J = 7.2$ Hz, 1H), 3.46 (d, $J = 11.4$ Hz, 2H), 3.72 (d, $J = 11.4$ Hz, 2H), 3.73 (s, 3H), 6.69 (d, $J = 9.0$ Hz, 2H), 7.58 (d, $J = 9.0$ Hz, 2H) ppm. HRMS; Found: m/z 275.1539. Calcd for $C_{16}H_{21}NO_3$: M^+, m/z 275.1522.

(3*S*,4*Z*)-3-Methyl-2-oxo-8-phenyl-4-heptenenitrile 2,2-Dimethyltrimethylene Acetal: IR (film) $\nu = 2230\ cm^{-1}$; ^1H NMR (CCl_4) $\delta = 0.83$ (s, 3H), 1.10 (d, $J = 6.3$ Hz, 3H), 1.17 (s, 3H), 1.5—2.2 (m, 4H), 2.58 (t, $J = 7.5$ Hz, 2H), 2.83 (dq, $J = 8.3$ Hz, $J = 6.3$ Hz, 1H), 3.48 (d, $J = 10.8$ Hz, 2H), 3.76 (d, $J = 10.8$ Hz, 2H), 5.1—5.7 (m, 2H), 6.9—7.3 (m, 5H) ppm. HRMS; Found: m/z 313.2018. Calcd for $C_{20}H_{27}O_2N$: M^+, m/z 313.2043.

General Synthetic Procedure of α,α-Dialkoxy Aldehyde (4). Into a solution of α-oxo nitrile acetal (**2**, 1.00 mmol) in toluene (10 ml), DIBAL (1.20 mmol, in hexane) was added at −78 °C. After 30 min, THF (10 ml) and oxalic acid dihydrate (5 mmol) were added at 0 °C. The mixture was extracted with ethyl acetate (30 ml×2). Obtained residue was purified by using silica-gel column chromatography to give **4** as a colorless oil.

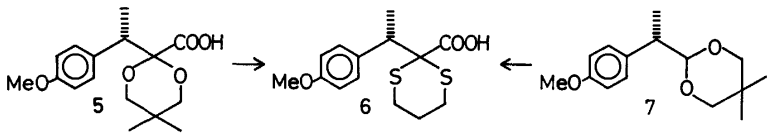


Fig. 2. Determination of the absolute configuration of **2**.

(*S*)-5,5-Dimethyl-2-formyl-2-[2-(*p*-methoxyphenyl)-propyl]-1,3-dioxane: IR (film) ν=1740 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.65 (s, 3H), 1.04 (s, 3H), 1.32 (d, J=7.2 Hz, 3H), 2.89 (q, J=7.2 Hz, 1H), 3.43 (m, 4H), 3.73 (s, 3H), 6.65 (d, J=9.0 Hz, 2H), 7.08 (d, J=9.0 Hz, 2H), 9.20 (s, 1H) ppm. HRMS; Found: m/z 278.1515. Calcd for $C_{16}H_{22}O_4$, M^+: m/z 278.1519.

(*S*)-5,5-Dimethyl-2-formyl-2-[(*Z*)-1-methyl-6-phenyl-2-hexenyl]-1,3-dioxane: IR (film) ν=1735 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.68 (s, 3H), 1.00 (d, J=7.2 Hz, 3H), 1.17 (s, 3H), 1.4—2.2 (m, 4H), 2.59 (t, J=7.5 Hz, 2H), 2.66 (dq, J=9.5 Hz, J=7.2 Hz, 1H), 3.2—3.5 (m, 4H), 5.1—5.5 (m, 2H), 6.9—7.3 (m, 5H), 9.36 (s, 1H) ppm. HRMS; Found: m/z 316.2026. Calcd for $C_{20}H_{28}O_3$, M^+: m/z 316.2036.

(*S*)-2-Carboxy-5,5-dimethyl-2-[2-(*p*-methoxyphenyl)-propyl]-1,3-dioxane (5): Colorless oil: IR (film) ν=1729 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.67 (s, 3H), 0.96 (s, 3H), 1.32 (d, J=7.2 Hz, 3H), 3.43 (br m, 4H), 3.73 (s, 3H), 6.65 (d, J=8.4 Hz, 2H), 7.12 (d, J=8.4 Hz, 2H), 10.17 (br s, 1H) ppm. HRMS; Found: m/z 249.1502. Calcd for $C_{15}H_{21}O_3$, M^+-COOH: m/z 249.1491.

(*S*)-2-Carboxy-5,5-dimethyl-2-[(*Z*)-1-methyl-6-phenyl-2-hexenyl]-1,3-dioxane (5): Colorless oil: IR (film) ν=3070, 1715 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.70 (s, 3H), 1.04 (d, J=6.9 Hz, 3H), 1.19 (s, 3H), 1.4—2.2 (m, 4H), 2.55 (t, J=7.5 Hz, 2H), 2.86 (dq, J=9.0 Hz, J=6.9 Hz, 1H), 3.2—3.7 (m, 4H), 5.1—5.5 (m, 2H), 6.9—7.3 (m, 5H), 10.92 (br s, 1H) ppm. HRMS; Found: m/z 287.1998. Calcd for $C_{19}H_{27}O_2$, M^+-COOH: m/z 287.2009.

(*S*)-2-Carboxy-2-[2-(*p*-methoxyphenyl)propyl]-1,3-dithiane (6): Colorless oil: IR (film) ν=1720 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.57 (d, J=7.2 Hz, 3H), 1.8—2.2 (m, 2H), 2.5—2.9 (m, 2H), 2.9—3.3 (m, 2H), 3.53 (q, J=7.2 Hz, 1H) 3.79 (s, 3H), 6.83 (d, J=9.0 Hz, 2H), 7.33 (d, J=9.0 Hz, 2H), 10.23 (br s, 1H) ppm. HRMS; Found: m/z 253.0715. Calcd for $C_{13}H_{17}OS_2$, M^+-COOH: m/z 253.0722.

(*S*)-2-Carbamoyl-5,5-dimethyl-2-[2-(*p*-methoxyphenyl)propyl]-1,3-dioxane (8): Colorless oil: IR (film) ν=1685 cm^{-1}, ^{1}H NMR ($CDCl_3$) δ=0.68 (s, 3H), 1.01 (s, 3H), 1.40 (d, J=6.9 Hz, 3H), 3.00 (q, J=6.9 Hz, 1H), 3.77 (s, 3H), 5.86 (br s, 1H), 6.02 (s, 1H), 6.76 (d, J=8.4 Hz, 2H), 7.21 (d, J=8.4 Hz, 2H) ppm. HRMS; Found: m/z 249.1517. Calcd for $C_{15}H_{21}O_3$, M^+-CONH_2: m/z 249.1491.

Some Unusual Phase Transitions of Nickel(II) Diamine Complexes

Sukumar Roy, Goutam De, and Nirmalendu Ray Chaudhuri*
Department of Inorganic Chemistry, Indian Association for the Cultivation of Science, Calcutta 700 032, India
(Received December 26, 1985)

Synopsis. $[NiX_2(tn)_2]$, (tn=1,3-propanediamine; X_2=Br_2, SO_4, or SeO_4) undergoes phase transitions upon heating and reverts to their original structure upon cooling. These transitions have been investigated by differential scanning calorimetry and infrared spectroscopy.

Earlier, we reported the thermally induced phase transitions of nickel(II) diamine complexes.[1-5] Most of these phase transitions are time dependent reversible type and the extent of reversibility are found to be catalyzed by humid atmosphere. $[Ni(tn)_3]X_2$[6] and $[NiX_2(tn)_2]\cdot H_2O$[7,8] (X_2=Cl_2, Br_2, SO_4 etc.) were found to decompose through bis and monodiamine steps. We isolated and characterized all the possible intermediates. But we did not carry out thermal studies of these intermediates from the room temperature. This communication reports some new and interesting reversible phase transitions of $[NiX_2(tn)_2]$ (X_2=Br_2, SO_4, or SeO_4).

Experimental

Preparation of the Complexes: The complexes $[NiBr_2(tn)_2]$ (**1**) and $[Ni(SO_4)(tn)_2(H_2O)]$ (**3**) were prepared following the method reported earlier.[6,7]

The complex $[Ni(SeO_4)(tn)_2(H_2O)]$ (**8**) was prepared by mixing $NiSeO_4$ and the diamine in 1:2 molar ratio in water and subsequent precipitation by adding ethanol. This complex was recrystallized from water–ethanol (2:1) mixture.

Elemental analyses of these samples are in good conformity with their compositions. Infrared spectra were recorded in KBr matrices (pellets) on a Perkin Elmer 783 IR spectrophotometer. Temperatures of the samples were varied using a variable temperature cell with a temperature controller. C, H, and N were analyzed using a Perkin-Elmer 240C elemental analyzer. Electronic spectra were recorded in a Pye Unicam SP8-150 and Hitachi 330 spectrophotometer. Thermal measurements were carried out with a Perkin-Elmer DSC-2 differential scanning calorimeter. The enthalpy of melting of indium was used for the calculation of enthalpy changes associated with the phase transition.

Results and Discussion

Earlier, we reported the synthesis of $[NiBr_2(tn)_2)]$ from $[Ni(tn)_3]Br_2\cdot H_2O$ in solid state and its spectral properties.[6] This complex is slightly hygroscopic. It is very difficult to distinguish the cis or trans form of the nickel(II) octahedral complexes by usual spectral data. We have taken the electronic spectra (Table 1) of *trans*-$[Ni(NCS)_2(tn)_2]$,[1] $[NiBr_2(tn)_2]$, $[Ni(SO_4)(tn)_2(H_2O)]$,[7] and found hardly any difference. But the IR spectra of these three are quite different. Splitting of $\rho(CH_2)$ and $\delta(NH_2)$ of the latter two complexes suggest probably cis-structure (C_2 symmetry) of $[NiBr_2(tn)_2]$ (**1**).[9,10] Figure 1 and Table 2 show the thermal behavior of $[NiBr_2(tn)_2]$ (**1**) which shows one phase transition upon heating accompanied by no color change. The species **2**, after phase transition reverts to **1** upon cooling. IR spectra of **1** and **2** are taken at 380 K (room temperature IR spectrum of this complex is faulty owing to its hygroscopic nature) and 450 K, respectively (Table 3). It is found that **2** shows a simpler spectrum than **1**. Splitting of $\delta(NH_2)$, ν(C–N), ν(C–C), and $\rho_r(CH_2)$ bands occurs in **1**. This is absent or reduced in **2** (Table 3). This suggests **2** exists in more symmetrical form than **1**.

Earlier, we reported[7] thermal behavior of $[Ni(SO_4)(tn)_2(H_2O)]$ (**3**) where we presumed that water molecule in **3** was not coordinated to nickel as we were unable to record the IR spectrum of the dehydrated complex due to its hygroscopic nature. With the new technique of IR measurements, it was found that water molecule is coordinated in **3** as it shows $\rho_r(H_2O)$ at 731 cm^{-1} and $\rho_w(H_2O)$ at 700 cm^{-1}. These bands are found to be absent in the anhydrous species. With the help of IR the prediction about the mode of coordination of SO_4 in $[Ni(SO_4)(tn)_2(H_2O)]$ (**3**) and its dehydrated form **4** is not possible due to the serious overlapping of diamine and SO_4 bands.

But SO_4 appears to be unidentate in **3**, which exists in octahedral geometry as is evident from its electronic spectral data (Table 1) and magnetic moment reported by us.[7] However, on comparison of the geometry attained by the analogous species $[Ni(SeO_4)(tn)_2]$,[7] bidentacy of SO_4 may be predicted indirectly in **4**. It is interesting to note that the dehydrated complex $[Ni(SO_4)(tn)_2]$ (**4**) undergoes three successive reversible phase transitions (Table 2; Fig. 2). Earlier,[7] we could not notice these phase transitions in DTA curve because the first two peaks were hidden in the endothermic peak associated with the elimination of water and the third peak was weak in nature which was not possible to detect by DTA. Differential scanning calorimetry traces of the phase transitions (both heating and cooling curve) are shown in Fig. 2. These phase transitions are not associated with any color change. On comparison the IR spectra of **3**,

Table 2. Thermal Data

a) (**3**) shows $\delta(HOH)$, $\rho_r(H_2O)$, and $\rho_w(H_2O)$ bands at 1628 s, 731 s, and 700 s cm^{-1}. b) Spectra complicated due to overlapping of diamine vibration with ν_3 of SO_4. Some diamine vibrations are masked by SO_4 vibration.

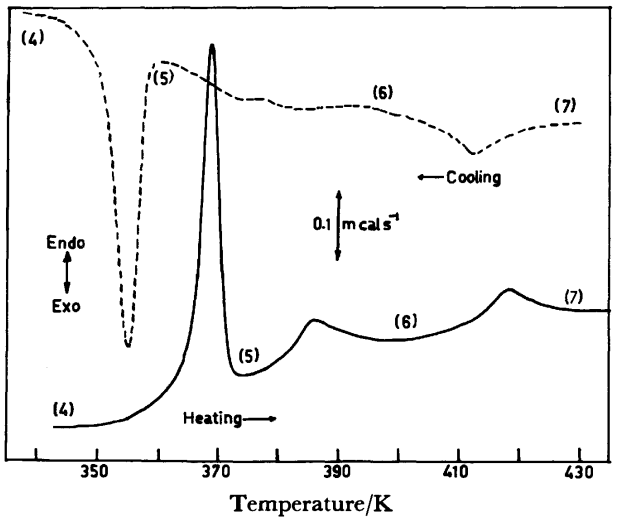

Fig. 2. DSC curves showing the transformations of: complex **4** (wt taken=16.08 mg) into **5**, **6**, and **7**, heating curve (——), **7**, into **6**, **5**, and **4**, cooling curve (----).

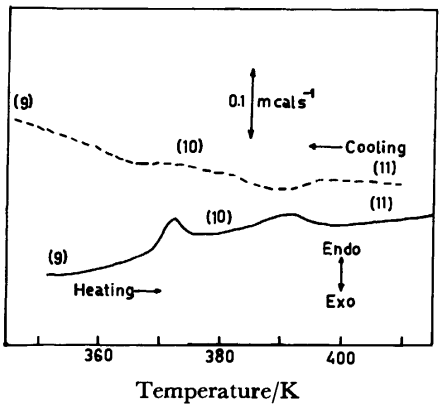

Fig. 3. DSC curves showing the transformations of: complex **9** (wt taken=11.85 mg) into **10** and **11**, heating curve (——), **11** into **10** and **9**, cooling curve (----).

4, and **7** taken at 303, 340, and 435 K respectively (Table 2), it is noticed that complex **3** possesses more infrared active bands than **4** and **7**. IR spectra of **4** and **7** differ in the $\delta(NH_2)$, $\delta(CH_2)$, $\rho_w(CH_2)$, ν(C-N), ν(C-C), and $\rho_r(CH_2)$ regions (Table 3). These data indicate that the six-membered chelate conformations in **4** and **7** are different.

$[Ni(SeO_4)(tn)_2(H_2O)]$ (**8**) shows similar IR and electronic spectra to its corresponding sulfato complex **3**. Its dehydration and phase transition phenomena are tabulated in Table 2. Figure 3 shows the differential scanning calorimetry traces of the phase transitions of $[Ni(SeO_4)(tn)_2]$ (**9**). It shows two overlapping endothermic peaks during heating and transforms to **11** via **10**. Here, the enthalpy changes for the transformation of **9**→**11** is low in comparison to the bromo and sulfato complexes. This is probably due to the presence of large anion SeO_4^{2-} (ionic size of which is larger than SO_4^{2-} and Br^-). Regarding IR spectra of **9** and **11**, we observe only a little difference.

The occurrence of phase changes in $[NiX_2(tn)_2]$ (X_2=Br_2, SO_4, or SeO_4) but not in $[NiCl_2(tn)_2]$ is probably due to the intramolecular interaction of the large anion with hydrogen atoms of the six-membered chelate owing to its unfavorable entropy effect.[11] Experiments have been carried out with large anion like halogenoacetates. But any phase transition phenomena were not noticed due to the decomposition of halogenoacetates at appreciably low temperatures.

The Brillouin Scattering of Highly Viscous Mixtures

Ryuki HASHITANI, Shinobu KODA, and Hiroyasu NOMURA*
Department of Chemical Engineering, School of Engineering, Nagoya University, Chikusa-ku, Nagoya 464
(Received November 28, 1986)

The sound velocities of mixtures of tri-*o*-tolyl phosphate and diisobutyl phthalate were measured by means of the Brillouin scattering method in the temperature range from 214 to 333 K. The velocity dispersion was observed in the mixtures at temperatures from 273 to 323 K in the gigahertz region. The velocity dispersion was attributed to the structural relaxation, as in the case of pure highly viscous liquids. The reduced variable method proposed by Lamb et al. could not be applied to the storage moduli over wide frequency and temperature ranges. The relaxation curves of the reduced storage modulus obtained at room temperature, where the viscosity obeyed the Arrhenius equation, were well expressed by a single relaxation equation. The structural relaxation mechanism of the highly viscous liquids investigated here is related to the weak cooperative motions of molecules in the liquid state. The activation energy, ΔE_τ, obtained from the temperature dependences of the relaxation times was about a third of those estimated from the Arrhenius plots of the shear viscosities of the mixtures.

Generally, liquids cannot support shear stress, no matter how small it may be. They yield or flow in response to the applied shear stress. However, on a short time scale, liquids can show elastic properties. Therefore, in the liquid state relaxations exist which are related to the collective motion of molecules. Such relaxations are called viscoelastic and/or structural relaxations. In order to study the dynamical aspects of the local structure in liquids and solutions, information on the mechanism of structural relaxation is highly desirable. Highly viscous liquids, such as glycerol and 1,3-butanediol, are suitable for the investigation of these relaxations, since they have long relaxation times as a result of their high viscosities at low temperatures and their relaxation times can be easily determined by experiments.

Such highly viscous liquids, which have no definite freezing point, are called "supercooled liquids." The viscoelastic and/or structural relaxations of supercooled liquids have been extensively investigated by means of ultrasonic methods, and the studies have been summarized.[1] In the studies by Lamb's school, the relaxation curves were obtained by superimposing the data at different temperatures on the basis of a reduced variable method. i.e., the frequency-temperature superposition method, applied to the elastic modulus, since measurable ultrasonic frequencies were limited to a narrow range. Besides, in the experiments on ultrasonic methods, measurements were made only at low temperatures, since, at room temperature, the relaxation times are too short to be measured in the megahertz region. In view of this situation, direct measurements of relaxation behavior in higher temperature ranges are indispensable to elucidate the structural relaxation mechanism of highly viscous liquids in detail.

The Brillouin scattering method is also very useful for investigating the structural relaxation of highly viscous liquids. The Brillouin spectra which arise from the local thermal density fluctuation provide information about the dynamic properties of liquids in the GHz region.

Previously, we investigated the relaxation behavior of two pure highly viscous liquids, tri-*o*-tolyl phosphate[2] and diisobutyl phthalate,[3] by means of Brillouin scattering method. Assuming that the reduced variable method can be applied to the data obtained from Brillouin scattering, as well as those from the ultrasonic method, the master curves obtained were analyzed by means of the generalized B.E.L. (Barlow, Erginsav, and Lamb) model.[1] The values of the parameter K in the generalized B.E.L. equation were found to be around 0.3—0.5, within the limits of experimental error, although, in ultrasonic studies, the K's of these materials have been found to be nearly unity.[1] Besides, the data on the master curves deviated systematically from the curves calculated by the B.E.L. model, even if experimental errors were taken into account. These results suggested that a reduced variable method might be invalid for the superposition of elastic moduli over such wide frequencies as from MHz to GHz regions. However, the differences in K values obtained by the two methods were not so large that we could not conclude clearly whether or not the reduced variable method was useful.

In order to ascertain the validity of the reduced variable method for analyzing the data in the GHz region, and in order to discuss the relaxation mechanism in detail, careful experiments are required.

Large deviations in the parameter K from unity were observed by Barlow et al.[4] for several binary mixtures of supercooled liquids in their ultrasonic studies. The values of the parameter K have varied widely, from about 0.2 to about 2.0, depending on the mole fraction of the components of the binary mixtures. Besides, these composition dependences of the parameter K have been expressed by a universal curve, independent of the species of the supercooled liquids.

In this paper, the structural relaxation of binary mixtures of diisobutyl phthalate and tri-*o*-tolyl phosphate are investigated by means of the Brillouin scattering method. The compositions of the binary mixtures were chosen as 0.20 mole fraction and 0.78 mole fraction of diisobutyl phthalate. In these composi-

tions, the parameter K takes the minimum and maximum values. The spectra were observed over wide frequency ranges at various temperatures, especially in the relaxation regions. The dependences of the relaxation behavior on the temperature and/or the frequency are discussed by comparing the data in the GHz region with those in the MHz region. The structural relaxation mechanism of highly viscous liquids in the higher-temperature range is also discussed.

Experimental

The diisobutyl phthalate (DIBP), which was of a guaranteed grade, was obtained from the Nakarai Chemicals Co., Ltd., while a practical grade of tri-*o*-tolyl phosphate(TOTP) was obtained from Eastman Organic Chemicals. They were distilled under reduced pressure. Mixtures with composition of 0.78 and 0.20 mole fraction of DIBP were prepared. For pure DIBP, some measurements were carried out in addition to those previously reported.,[3] The sample liquids were poured into the scattering cells through a millipore filter with a pore size of 1.0 μm.

The Rayleigh-Brillouin spectra were obtained by the use of a pressure-scanning Fabry-Perot interferometer, using a He-Ne laser (NEC, GLG 5800, output 50 mW). Measurements were done over the temperature range from 214 to 331 K (0.78 DIBP mole fraction) and from 223 to 333 K (0.20 DIBP mole fraction). At 263, 273, 298, and 323 K, spectra were obtained over scattering angles from 40 to 145°. The experimental procedures were described in detail previously.[2,5]

The sound velocity and density were measured by means of an ultrasonic interferometer operating at 5 MHz and by means of the buoyancy balance method respectively. The viscosity measurements were carried out using a rotational viscometer, which was calibrated using standard sample liquids with known viscosities. The refractive indexes were measured by the use of an Abbe refractometer, manufactured by the Erma Optical Co., Ltd. All measurements were carried out within the temperature range from about 260 to 340 K. The values needed for the data analysis at the lower temperature were estimated by means of the extrapolation method.

Results

Typical Rayleigh-Brillouin scattering spectra of the 0.78 DIBP mole fraction mixture are shown in Fig. 1 at a constant scattering angle (θ=90°) as a function of the temperature. The sound velocity, V, can be calculated from the Brillouin shift, Δf, and the scattering angle, θ, by the use of the following relation;

$$V = \frac{\lambda_i \, \Delta f}{2n \sin(\theta/2)} \tag{1}$$

where λ_i is the wavelength of the incident light, and n, the refractive index of the sample.

Figure 2 shows the frequency dependence of the sound velocities of the samples obtained. The data measured at 273, 298, and 323 K all show clear sound velocity dispersions. These velocity dispersions can be attributed to the structural relaxation, much as in the

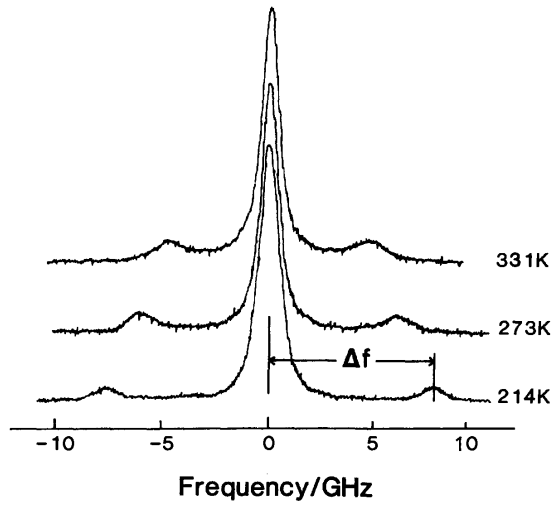

Fig. 1. Representative Rayleigh-Brillouin spectra of 0.78 mole fraction mixture at the scattering angle at 90°.

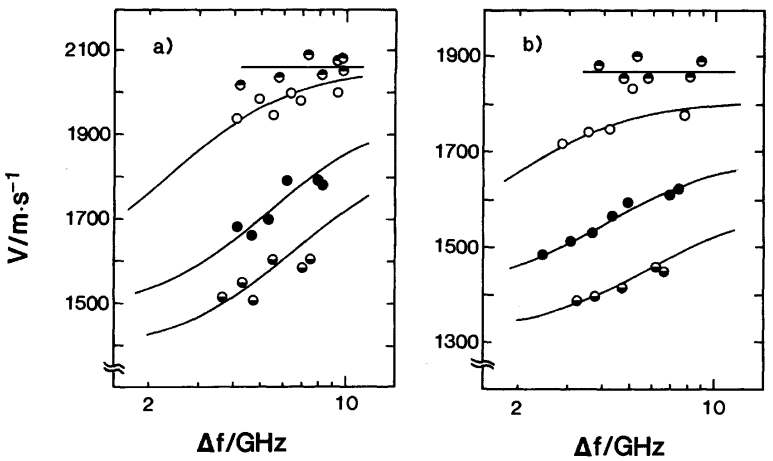

Fig. 2. Frequency dependence of sound velocities. a) 0.2 DIBP mole fraction, b) 0.78 DIBP mole fraction. ◓: −10°C, ○: 0°C, ●: 25°C, ◒: 50°C.

cases of pure DIBP[3] and TOTP.[2] The temperature dependences of the sound velocity obtained from the Brillouin scattering spectra at the scattering angle of 90° are shown in Figs. 3 and 4. In those figures, the temperature dependences of the sound velocities are different in the lower and higher temperature ranges. The sound velocities in the higher temperature region belong to those in the relaxation range, as is shown in Fig. 2. Besides, the sound velocities for the 0.20 DIBP mole fraction and 0.78 DIBP mole fraction mixtures below 260 K were almost independent of the frequencies investigated, as is shown in Fig. 2. Therefore, we can consider that the sound velocities below 260 K shown in Figs. 3 and 4 correspond to the velocities of the high-frequency limit. These limiting values were fitted to the following Doolittle type equation;

$$V_\infty = \frac{a}{T} + b \tag{2}$$

where T is the absolute temperature. The following values were obtained for the fitting parameters: a=4.00×10^5 (m s^{-1} K^{-1}), b=339 (m s^{-1}) for the 0.78 DIBP mole fraction and a=3.59×10^5 (m s^{-1} K^{-1}), b=739 (m s^{-1}) for the 0.20 DIBP mole fraction.

The sound velocities measured at 5 MHz by means of an ultrasonic interferometer were used as the low-frequency limiting sound velocities, as is usually done. The temperature dependences of these data were reproduced by the following linear relations;

V_0=−3.410×T+2420 for the 0.20 DIBP mole fraction (3)

and;

V_0=−3.573×T+2538 for the 0.78 DIBP mole fraction. (4)

In order to discuss the viscoelastic behavior of highly viscous liquids, the storage modulus, M', which is the real part of the complex longitudinal modulus, M^* ($=M'+iM''$), was calculated by the use of $M'=\rho V^2$ assuming that $(\alpha V/\omega)^2 \ll 1$, where ρ is the density and α is the absorption coefficient of the sound wave in a sample.

Discussion

The Validity of the Reduced Variable Method. First, we will discuss the value of making a composed relaxation curve, a master curve, by means of the reduced variable method for structural relaxation, as was proposed by Lamb's school. According to the reduced variable method, proposed by Lamb, a reduced elastic modulus, $(M'-M_0)/(M_\infty-M_0)$, should be plotted against $\omega\eta_s/G_\infty$, where ω is the angular frequency ($\omega=2\pi f$) and where G_∞ is the shear modulus at the high frequency limit. In our mixed systems, no values of G_∞ were found at any temperature in any literature. For this reason, we used the parameter $\omega\eta_s/M_2$ ($M_2=M_\infty-M_0$) instead of $\omega\eta_s/G_\infty$. According to Litovitz and Davis,[6] the relation $(1/M_2)(\partial M_2/\partial T)=(1/G_\infty)(\partial G_\infty/\partial T)$ holds over a wide temperature range and the quantity G_∞/M_2 is independent of the temperature.

Therefore, a reduced plot of $(M'-M_0)/(M_\infty-M_0)$ against $\omega\eta_s/M_2$ should provide the same distribution of relaxation times as those obtained by plotting the reduced modulus against $\omega\eta_s/G_\infty$. The master curves obtained are shown in Figs. 5 and 6 for the 0.20 DIBP mole fraction mixture and 0.78 DIBP mole fraction mixture, respectively.

Assuming the generalized B.E.L. equation for complex shear and bulk moduli,[1,4] the expression for complex longitudinal modulus can be given as follows;

$$\frac{M^*-M_0}{M_\infty-M_0} = C\left[1+\left(\frac{1}{i\zeta\omega\tau_s}\right)+2K\left(\frac{1}{i\zeta\omega\tau_s}\right)^{1/2}\right]^{-1} + (1-C)\left[1+\left(\frac{1}{i\omega\tau_s}\right)+2K\left(\frac{1}{i\omega\tau_s}\right)^{1/2}\right]^{-1} \tag{5}$$

and

$$C=\frac{K_\infty-K_0}{M_\infty-M_0}=1-\frac{4}{3}\frac{G_\infty}{M_\infty-M_0},\quad \tau_s=\frac{\eta_s}{G_\infty}$$

$$\zeta=\frac{\tau_v}{\tau_s}=\frac{\eta_v}{\eta_s}\frac{G_\infty}{K_\infty-K_0}=\frac{3}{4}\frac{\eta_v}{\eta_s}\frac{1-C}{C}$$

where η_s and η_v are the shear and bulk viscosities and where K is an adjustable parameter which represents a measure of the distribution of the relaxation times. As has been mentioned previously, the estimation of the parameters, C and ζ, of our experimental systems is impossible, since the data on G_∞ are lacking. However, the values of C and ζ exert little effect on the shape of the relaxation curve calculated from Eq. 5. The broken lines in Figs. 5 and 6 are those calculated using Eq. 5 with the same values of C=0.35, and ζ=2.64 as were used for pure DIBP. The values of K

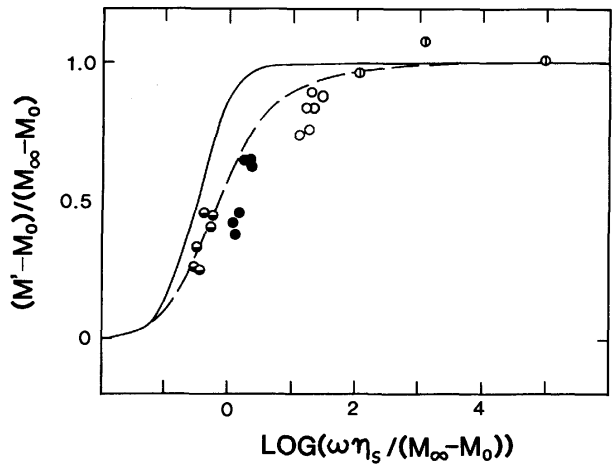

Fig. 5. Plots of $(M'-M_0)/(M_\infty-M_0)$ against log $(\omega\eta_s/(M_\infty-M_0))$ for 0.2 DIBP mole fraction. The solid and broken lines were drawn by the generalized B.E.L. Eq. 5 with $K=0$ and $K=0.28$, respectively. O: 0°C, ●: 25°C, ◒: 50°C, Φ: others.

used in Figs. 5 and 6 were 0.28 and 1.8 respectively; they were determined by experiments in the ultrasonic region.[4] The solid lines in Figs. 5 and 6 correspond to the Maxwell equation with $K=0$ in Eq. 5.

As is shown clearly in Figs. 5 and 6, the data obtained in the GHz region do not agree with the broken lines in either case. This indicates that the reduced variable method fails in the superposition of elastic moduli over such a wide frequency range as from the MHz to the GHz region. Besides, the data in the GHz region deviate systematically from the curve calculated using Eq. 5. Consequently, we can not draw a master relaxation curve for both systems. Moreover, the data at each constant temperature form a group which seems to be parallel to a Maxwellian relaxation curve.

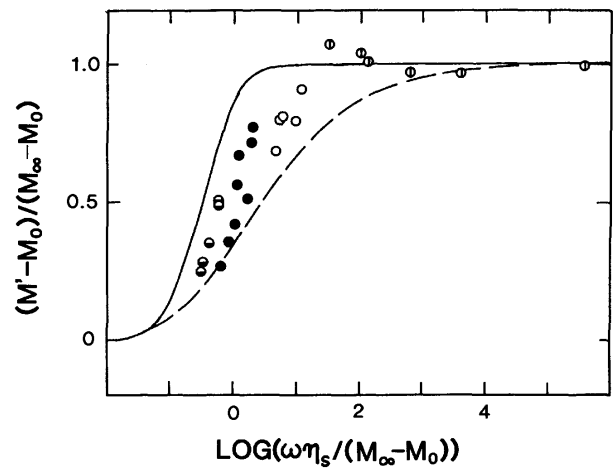

Fig. 6. Plots of $(M'-M_0)/(M_\infty-M_0)$ against log $(\omega\eta_s/(M_\infty-M_0))$ for 0.78 DIBP mole fraction. The solid and broken lines were drawn by the generalized B.E.L. Eq. 5 with $K=0$ and $K=1.8$, respectively. O: 0°C, ●: 25°C, ◒: 50°C, Φ: others.

As is shown in Fig. 6, the data corresponding to $(M'-M_0)/(M_\infty-M_0)=0.5$, can be measured at 298 K with an angular frequency, $\omega=2.5\times10^{10}$ (rad s^{-1}), that is, $f=\omega/2\pi=3.99$ (GHz). In order to obtain the same plot based on the ultrasonic method working at $f=50$ (MHz), and considering the temperature dependence of V_0, V_∞, η_s, and ρ, the temperature must be controlled at about 242 K. Brillouin scattering provides information about the relaxation behavior at room temperature, while the ultrasonic methods provide information in the low temperature region.

Therefore, we can clearly conclude that the reduced variable method for the relation between $(M'-M_0)/(M_\infty-M_0)$ and $\omega\eta_s/M_2$ may hold for the behavior at low temperatures, but that it breaks down at room temperature.

Relaxation Spectrum Obtained by Brillouin Scattering. Apart from the generalized B.E.L. model and the reduced variable method, we would like to examine Figs 5 and 6 carefully. As has been mentioned previously, we can recognize in Figs. 5 and 6 that the data at the same temperature are located on the line parallel to the Maxwellian curve in both cases. If the reduced elastic modulus, $(M'-M_0)/(M_\infty-M_0)$, in the GHz region could be expressed by the following single relaxation equation;

$$\frac{M'-M_0}{M_\infty-M_0}=\frac{\omega^2\tau^2}{1+\omega^2\tau^2} \tag{6}$$

where τ is the relaxation time, the plot of $((M'-M_0)/(M_\infty-M_0))^{-1}$ against $1/\omega^2$ should be linear and its slope should show the square of the reciprocal relaxation time, $1/\tau^2$. As an example, Fig. 7 shows this relationship between $((M'-M_0)/(M_\infty-M_0))^{-1}$ and $1/\omega^2$ for the case of 0.78 DIBP mole fraction at each temperature. As may be seen in Fig. 7, linear relationships are obtained within the limits of experimental error. Sim-

ilar linear relationships are also obtained for the case of the 0.2 mole fraction at each temperature. Using the relaxation times thus obtained, the reduced elastic moduli, $(M'-M_0)/(M_\infty-M_0)$, in the GHz region can be well expressed by a single relaxation equation (Eq. 6) within the measured frequency and temperature ranges, as is shown in Fig. 8.

Previously, we also analyzed the Brillouin scattering data of pure DIBP[3] and TOTP[2] by the use of the generalized B.E.L. equation, on the basis of the reduced variable method. However, as has been mentioned above, the elastic moduli measured over a wide frequency range and at several constant temperatures suggested that the reduced variable method might be invalid for analyzing the Brillouin scattering data. Therefore, the previous experimental data for the pure systems of DIBP and TOTP were re-analyzed using a single relaxation equation by means of the method described above. Figure 9 shows plots of $(M'-M_0)/(M_\infty-M_0)$ against the observed Brillouin frequency. A single relaxation process can reproduce very well the experimental results at any temperature of our experiments. Thus, it is confirmed that the viscoelastic behavior of highly viscous liquids at higher temperatures, (that is, around room temperature) can be expressed well by a single relaxation process.

Similar single relaxation behavior in viscoelastic and/or structural relaxations have previously been reported. Tauke, Litovitz, and Macedo[7] reported that the B_2O_3 in the liquid state behaves as a simple Maxwellian liquid in the temperature ranges where its viscosity obeys the Arrhenius viscosity equation, while the liquid of B_2O_3 showed relaxation processes with a wide distribution of relaxation times in the temperature ranges where its viscosity is expressed in terms of the free volume type, namely, the Doolittle-type equation. For the molten zinc chloride, a single relaxation time was also observed for the absorption of the longitudinal wave in the frequency range from 5 to 95 MHz at temperature ranges from 582 to 673 °C.[8] Madigosky and Warfield,[9] who carried out ultrasonic relaxation

Solid lines were drawn by single relaxation Eq. 6.

measurements in the frequency range from 5.5 to 200 MHz, concluded that the mixture of water and dimethyl sulfoxide (DMSO) shows structural relaxation behavior at temperatures below −55 °C. This relaxation behavior can also be expressed by a single relaxation equation, while the viscosities of these mixtures can be fitted well by Arrhenius equation in the temperature ranges investigated. In these papers, it was suggested that single relaxation behavior is observed if the viscosity obeys the Arrhenius viscosity equation.

Figure 10 shows the temperature dependence of the viscosities of the 0.20 and 0.78 DIBP mole fraction mixtures. As may be seen in Fig. 10, in the high temperature region the relationship between ln η and $1/RT$ is almost linear for the liquid mixtures involved here. This also indicates that, in the temperature range where the temperature dependence of the viscosity is expressed by the Arrhenius equation, the relaxation spectrum of the elastic modulus of liquids shows a single relaxation.

Litovitz and McDuffie[10] considered that, in a liquid

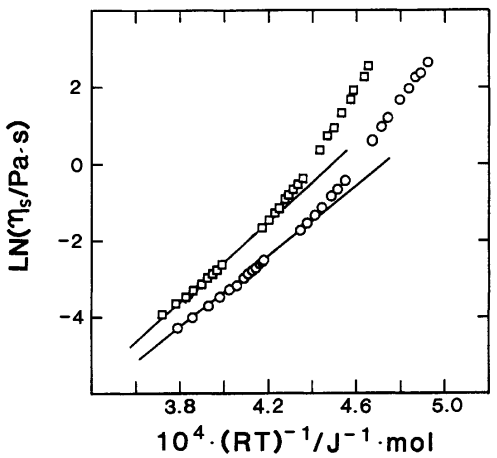

Fig. 10. Plots of ln η_s against $1/RT$. □: 0.2 DIBP mole fraction, ○: 0.78 DIBP mole fraction. The lines were drawn by fitting the data in the higher temperature region to linear relation between ln η_s against $1/RT$.

obeying a free volume type equation for viscosity, a molecule moves in a manner cooperative with the surrounding ones, while in a liquid obeying Arrhenius viscosity equation, the motions of molecules have a non-cooperative character. They proposed that the distribution of the relaxation time arises from the cooperative motions of molecules. From this point of view, the relaxation behavior of the reduced elastic moduli of highly viscous liquids obtained from Brillouin scattering are considered to be related to the weak cooperative motions of molecules.

The relaxation times of pure TOTP, the 0.20 DIBP mole fraction, the 0.78 DIBP mole fraction, and pure DIBP at various temperatures, and the activation energies obtained from the linear plot of ln τ against $1/RT$, are summarized in Table 1. In view of the experimental errors, it is difficult to discuss the concentration dependence of ΔE_τ. The activation energy for viscosity, ΔE_η, obtained from the slope in Fig. 10 is also listed in Table 1. The values of ΔE_τ are about a third those of ΔE_η. Also, the concentration dependence of ΔE_η can not be found clearly.

The composition of a mixture should affect the cooperative motions of molecules very much because of the large differences in their molecular size and in their intermolecular interaction. As for the low-temperature behavior which corresponds to that of the free volume type liquids, the relaxation curves (broken lines in Figs. 5 and 6) depend largely on the composition of the mixture. The values of the parameter K in the generalized B.E.L. equation vary largely, from 1.8 for the 0.78 DIBP mole fraction to 0.28 for the 0.2 DIBP mole fraction.[4] On the contrary, in the case of high-temperature behavior obtained from the Brillouin scattering investigated here, all the relaxation curves can be reproduced well by the use of the single relaxation equation. This fact also confirms that the cooperative character involved is weak in this relaxation mechanism.

Very recently, Oh et al.[11] have reported the experimental results on the Rayleigh-Brillouin spectra of bis(2-ethylhexyl)sebacate (hereafter abbreviated as DOS) and tetracosane at temperatures higher than their

Table 1. Relaxation Times at Various Temperatures and Activation Energies

ΔE_η (kJ mol^{-1})	50.2[a]	46.6	48.3	60.3[b]

a) Ref. 13. b) Ref. 14.

melting points. They analyzed the temperature dependences of the Brillouin spectra, using the generalized hydrodynamic theory proposed by Lin and Wang,[12] and concluded that these spectra were attributable to the single relaxation of the longitudinal stress modulus. The relaxation times estimated by them are 49 and 67 ps at 325 K, while the activation energies are 16.1 and 12.7 kJ mol^{-1} for DOS and tetracosane respectively. Their experimental results are in close agreement with ours. They have pointed out that this relaxation is related to the structural relaxation of liquids, but they did not present any detailed relaxation picture.

Conclusion

According to the experimental results obtained in this investigation, the following conclusions can be drawn. 1) The reduced variable method proposed by Lamb et al. does not hold over the wide temperature and frequency ranges. 2) The relaxation spectra of the elastic moduli of highly viscous liquids and mixtures at higher temperature and in the GHz region can be well expressed by a single relaxation equation. 3) In the temperature range where the single relaxation spectrum is obtained, the viscosity of liquids and mixtures can be expressed by the Arrhenius equation. 4) The activation energies obtained by the relation between ln τ and $1/RT$ were a third of those obtained from the Arrhenius plot of viscosity. These facts indicate that this structural relaxation mechanism is related to the weak cooperative motions and the elementary dynamic properties of liquids.

Homogeneous and Electrochemical Electron-Transfer Reaction of Nitrobenzene Anion Radical Dissolved in Nitrobenzene

Kosaku SUGA* and Shigeru AOYAGUI
Department of Chemical Engineering, Tokyo Institute of Technology, Ohokayama, Meguro-ku, Tokyo 152
(Received November 28, 1986)

Nitrobenzene anion radical was stably prepared by the electrolytic reduction of nitrobenzene solution containing various kinds and amounts of tetraalkylammonium perchlorates. The rate constants of homogeneous electron-transfer reactions of these nitrobenzene anion radicals with nitrobenzene molecules as a solvent were determined by ESR method at various temperatures. These rate constants at 25 °C were about 10^7 dm^3 mol^{-1} s^{-1} and comparable with the rate constant of electron-transfer reation between nitrobenzene and its anion radial in *N,N*-dimethylformamide. The quasi-first order rate constants evaluated from these rate constants were about 10^8 s^{-1} and were larger than the rate constants of the intramolecular electron-transfer reactions of the anion radical of bis(*p*-nitrophenyl) compounds except for bis(*p*-nitrophenyl)methane. The absorption spectrum of the solution of nitrobenzene anion radical in nitrobenzene containing 0.1 M tetrabutylammonium perchlorate or 0.1 M tetraethylammonium perchlorate showed an additional weak peak at about 800 or 900 nm as well as the ordinary peak. The light energies of these additional peaks were in good agreement with the energy values of the optical electron-transfer reactions evaluated according to the theory of Hush from the activation energies of corresponding thermal electron-transfer reactions. The rate constants of electrochemical electron-transfer reactions and the diffusion coefficients of nitrobenzene anion radical in nitrobenzene were also measured.

Nitrobenzene (NB) is well-known to be reduced to a stable anion radical in an aprotic solvent as *N,N*-dimethylformamide (DMF),[1] and also can be used as a solvent at room temperature. An anion radical molecule dissolved in a solvent composed of its parent molecules such as NB^- in NB, can exchange its electron with contiguous parent molecules. Such an electron-exchange reaction is different from usual electron-exchange reactions in the following points: Anion radical and its parent molecules are always in contact with one another, and therefore do not require their encounter prior to the electron transfer between them. This would be expected to cause the following unique behavior of such a system. According to Hush,[2] electron-transfer reactions can be caused not only by thermal energy but also by optical energy when two reactants are in the immediate neighbourhood of each other. He discussed the relation between the activation energy of a thermal electron-transfer reaction and the light energy of the corresponding optical electron-transfer reaction. In the electron-transfer systems examined by them, however, only one of the values of the electron-transfer rate and the absorption maximum was determined. Therefore, the theory about the relation between them has not yet been proved experimentally. Since NB^- molecules are always in the immediate neighbourhood of NB molecules in the considering NB^-/NB system, the possibility of the occurrence of the optical electron-transfer reaction between them may be very high. Furthermore, the rate constant of thermal electron-transfer reaction between them can be easily determined by ESR.

On the other hand, as suggested by Levich,[3] Dahms,[4] and Ruff and Friedrich,[5] the large increase of the apparent diffusion coefficient of anion radicals due to an electron-hopping mechanism may be expected to occur in these systems.

In this paper, we report the rate constants and the activation energies of homogeneous electron-transfer reactions, the absorption spectra, the rate constants of electrochemical electron-transfer reactions, and the diffusion coefficients of NB^- prepared by electrolytic reduction of NB containing various tetraalkylammonium perchlorates. Furthermore, we will examine the possibility of the occurrence of an optical electron-transfer reaction and the increase of the diffusion coefficients of NB^- in this system by making use of these results.

Experimental

Reagents. Nitrobenzene commercially obtained was purified by passing through a column packed with activated alumina from ICN Pharmaceuticals GmbH & Co. Tetrabutylammonium perchlorate (TBAP) and tetraethylammonium perchlorate (TEAP) used as supporting electrolytes were prepared and purified as described in the previous paper.[6]

Cell and Electrodes. Electrolytic cell used for electrochemical measurements was an air-tight Pyrex glass cell composed of three compartments. For voltammetric measurements, a platinum gauze and a platinum sphere were used as the counter and working elctrodes respectively. The reference electrode used for the measurements of cyclic voltammogram (CV) for a NB solution without NB^- was composed of a silver wire dipped in the NB solution which was saturated with $AgNO_3$ and contained the same supporting elctrolyte as the test solution. The reference and the counter electrode used for the measurements of CV for a NB solution containing NB^- was the platinum gauze electrode in the test solution. For bulk electrolysis, the platinum gauze electrode was used as the working electrode, and a platinum spiral wire was used as the counter electrode. Bulk electrolysis was carried out while stirring the solution with a magnetic stirrer.

Electrochemical Measurements. The anion radical of NB

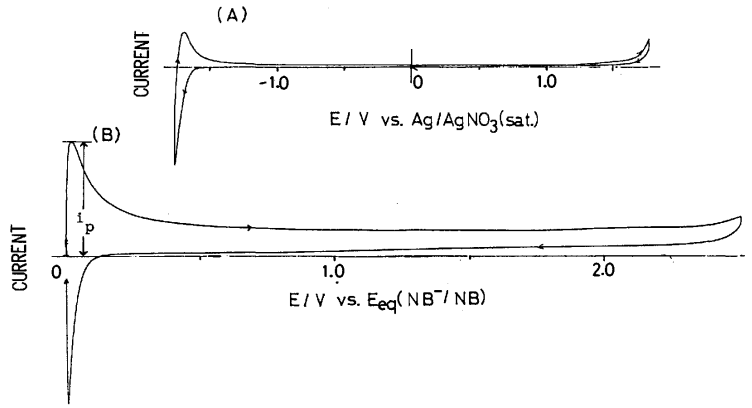

Fig. 1. Cyclic voltammograms of NB containing 0.1 M TEAP; (A) without NB^-, (B) with 0.8 mM NB^-. Scan rate: 0.1 V s^{-1}.

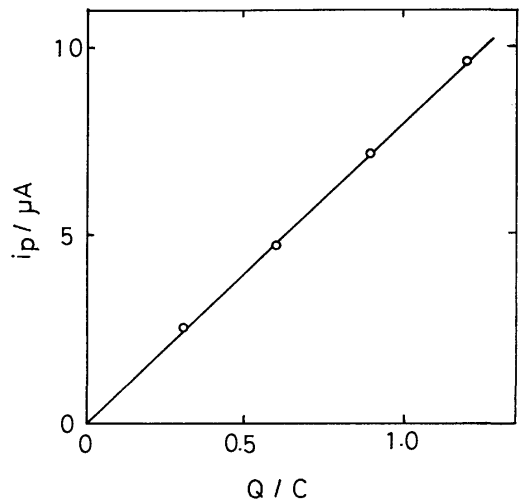

Fig. 2. Dependence of peak current, i_p, on the quantity of electricity, Q, consumed during the electrolytic reduction of NB containing 0.1 M TEAP.

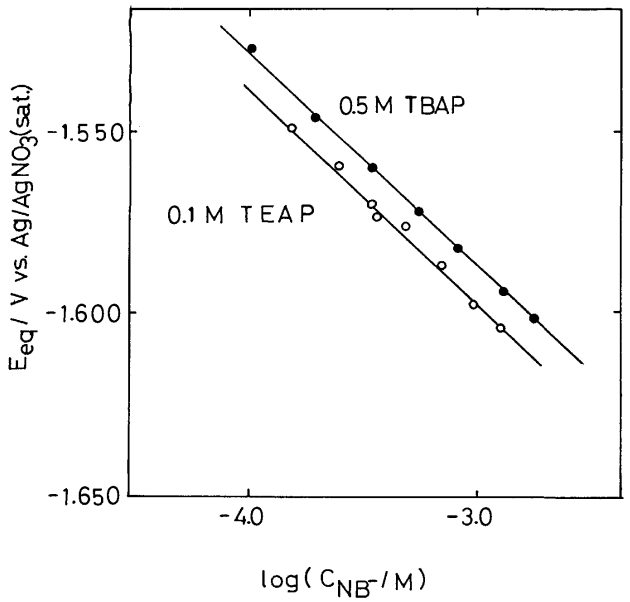

Fig. 3. Nernst plots for the NB^-/NB systems in NB containing 0.1 M TEAP and 0.5 M TBAP.

was prepared by electrochemical reduction. The concentration of NB^- was determined by the quantity of electricity passed during the electrolysis. Diffusion coefficients were determined by potential step chronoamperometry. Standard rate constants of the electrochemical electron transfer reactions were determined by the galvanostatic double pulse (gdp) method. A conventional potentiostat and function generators assembled from operational amplifiers were used for linear sweep voltammetry. Galvanostatic double pulse measurements were performed on an apparatus devised in this laboratory.[7]

ESR Measurements. ESR spectra were measured with a JEOL JES3BSX ESR spectrometer equipped with a variable temperature adapter.

Results and Discussion

Electrochemical Preparation of NB^- in NB. Figure 1 (a) shows the CV of a solution of NB containing 0.1 M TEAP (1 M=1 mol dm^{-3}). This CV showed a sharp cathodic current rise corresponding to the reduction of NB to NB^-, and an anodic peak corresponding to the oxidation of NB^- at about −1.6 V. During the bulk electrolysis with constant current, the solution gradually became brown coloured. Figure 1 (b) shows the CV of a solution of NB^- in NB containing 0.1 M TEAP prepared by the eletrolytic reduction as described above. This CV was obtained by scanning from the equilibrium potential of NB^-/NB. It shows an anodic peak current (illustrated as i_p in Fig. 1 (b)) corresponding to the oxidation of NB^- existing in the test solution, at the potential about 25 mV positive from the equilibrium potential.

Figure 2 shows the dependence of i_p for such solution on the quantity of electricity (Q) consumed during the electrolytic preparation of the solution. Good linearity was attained between i_p and Q. Moreover, the values of i_p, which are proportional to the concentration of NB^- in NB containing various tetraalkylammonium perchlorates, decreased only 10—20% after a period of one night from the end of the preparation. These results show that NB^- in NB prepared electrolytically is fairly stable.

Table 1. Standard Redox Potentials, $E°$, of NB^-/NB Systems in NB Containing Various Kinds and Amounts of Tetraalkylammonium Perchlorates

Supporting electrolyte	$E°(NB^-/NB)$/V vs. $Ag/AgNO_3$(sat.)	
	Potentiometry	Potential sweep method
0.1 M TEAP	−1.782	−1.782
0.17 M TEAP	−1.778	−1.757
0.1 M TBAP	−1.775	−1.757
0.5 M TBAP	−1.764	−1.783

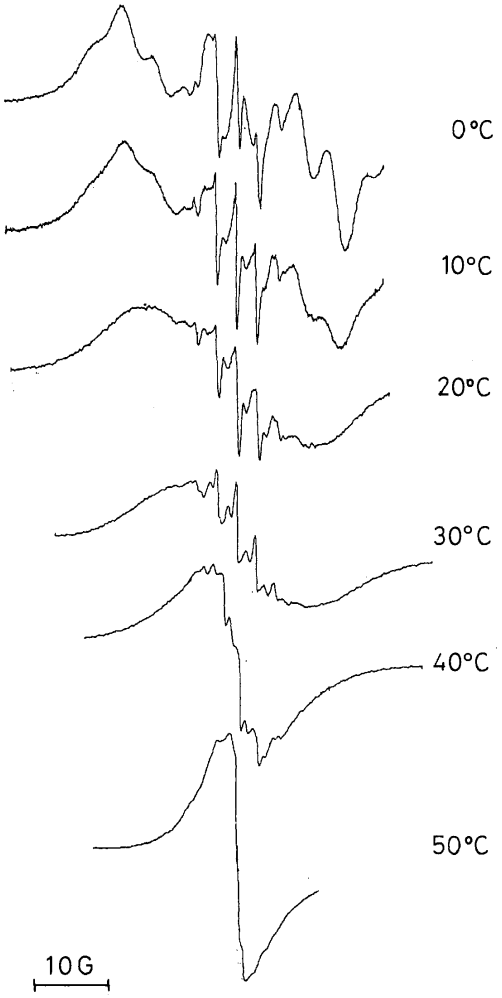

Fig. 4. ESR spectra of NB^- prepared by the electrolytic reduction of NB containing 0.5 M TBAP at various temperatures. Concentration of NB^- is about 1 mM.

In Fig. 3, we show the Nernstian plots between equilibrium potentials and the logarithm of the concentrations of NB^- determined from Q for the solution of NB^- in NB containing 0.1 M TEAP or 0.5 M TBAP. These plots showed good linearity. The solutions of NB^- in NB containing other supporting electrolyte also showed linear Nernstian plots. All of the slopes of these Nernstian plots were close to 60 mV per decade of concentration. This result shows that the electrode reactions of NB^- in NB containing several tetraalkylammonium perchlorates are the reversible ones accompanying the transfer of one electron. Table 1 shows the value of the standard redox potentials for NB^-/NB couples determined from these Nernstian plots in NB containing several kinds and amounts of tetraalkylammonium perchlorates, together with those determined by the potential sweep method according to the literatures.[8] The values determined by both methods agreed well with each other.

Homogeneous Electron-Transfer Reaction of NB^- in NB. Figure 4 shows the ESR spectra of the solutions of NB containing about 1 mM of NB^- and 0.5 M TBAP at various temperatures. Each spectrum was composed of one group of intense broad lines corresponding to NB^- superposed by another group of weak and sharp lines corresponding to a small amount of paramagnetic impurity probably formed by the decomposition of NB^-. The ESR signal due to NB^- at low temperature has a hyperfine structure, but this hyperfine structure disappeared and the ESR lines changed to a single broad one at higher temperature. ESR spectra of the solutions of NB containing NB^- and other tetraalkylammonium perchlorates are similar to these spectra.

These ESR signals due to NB^- can be well reproduced by computer simulation by the use of a modified Bloch equation. By these simualations we can determine the rate constant (k) of the homogeneous electron-exchange reactions between NB^- and NB. In these simulations we have used the values of hyperfine coupling constants for NB^- produced electrolytically in *N,N*-dimethylformamide (DMF) containing TEAP.[1] Figure 5 shows the Arrhenius plots for the rate constants of homogeneous electron-exchange reactions between NB^- and NB in the solutions containing 0.1 M TEAP or 0.5 M TBAP determined as described above. The respective rate constants at the same temperature are different from each other, and their activation energies are equal to 31 and 35 kJ mol^{-1} for the solutions containing 0.1 M TEAP or 0.5 M TBAP, respectively. This difference may be due to the ion pairing of NB^- with the different tetraalkylammonium ions as well as in the case of anthracene anion radical.[6]

Table 2 shows the homogeneous rate constants for the electron-exchange reactions at 25 °C between NB^- and NB determined in this experiment together with the value determined in DMF by Malachesky et al.[9] It is noteworthy that the values in this experiment are nearly equal to that in DMF. In this experiment, the

molecule of NB^- is always in contact with NB molecules, but such a situation did not affect the rate of the electron-exchange reaction. The reason for this result may be based on the fact that these reactions are slow and not diffusion limited.

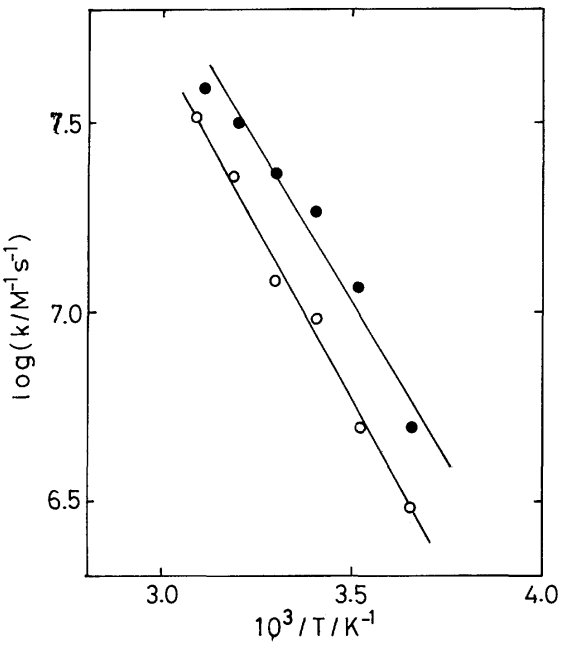

Fig. 5. Arrhenius plots for homogeneous electron-transfer reactions of NB^-/NB systems in NB containing (—○—) 0.5 M TBAP or (—●—) 0.1 M TEAP.

Table 2. Rate Constants of Homogeneous Electron-Transfer Reactions between NB^- and NB at 25 °C

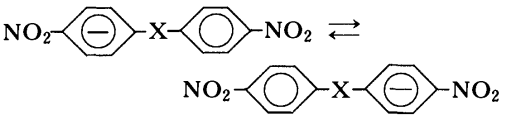
NB	0.5 M TBAP	1.5×10^{7} a)
DMF	0.01 M TEAP	3.0×10^{7} b)

a) This experiments. b) Ref. 9.

However, such a situation is interesting from another view point. Since the NB^- molecule are always in contact with NB molecules, the quasi-first order rate constant, $k_1=k[NB]$, may be closely related to the rate constants of the following intramolecular electron-transfer reactions,



(1)

where X represents some bifunctional groups. Table 3 shows the quasi-first order rate constant, k_1, determined in this experiment and the rate constants of intramolecular electron-transfer reactions of such compounds measured by Harriman and Maki.[10] The fact that the quasi-first order rate constant is larger than the rate constants of intramolecular electron-transfer reactions except bis(*p*-nitrophenyl)methane is based on the follwing points: (a) A molecule of NB^- in this experiment is surrounded by several NB molecules, (b) the overlap of the orbitals of NB^- and NB in which the transfering electrons exist or will exist, is larger than those for the intramolecular electron-transfer reactions.

Examination of the Optical Electron-Transfer Reaction of NB^- in NB. Hush discussed the intervalence-transfer absorption of mixed valent compounds.[2] In his papers, he derived the relations between the light energy of such optical electron-transfer reaction, E_{op}, and the activation energy of the corresponding thermal electron-transfer reaction, E_{th} and between the wavenumber of the intervalence-transfer absorption maximum, $\bar{\nu}_{max}$, and the half width of the absorption band, $\Delta\bar{\nu}_{1/2}$, according to the theory of Kubo and Toyozawa.[11] When the Gibbs energy of the thermal

electron-transfer reaction, $\Delta G°$, is zero as in the NB^-/NB system, these relations are represented by the following equations.

$$E_{op}=4E_{th} \quad (2)$$

$$\bar{\nu}_{max}=(\bar{\nu}_{1/2})^2/2310 \ (\bar{\nu} \text{ in } cm^{-1}) \quad (3)$$

Figure 6 shows the absorption spectra of NB^- prepared by the electrolytic reduction of NB containing 0.1 M TBAP (A) and 0.1 M TEAP (B), together with that of NB^- in DMF containing 0.1 M TEAP (C). The absorption spectrum (A) has a large peak at about 460 nm and an additional small peak at about 790 nm. The spectrum (B) has a large peak at about 580 nm and an additional small peak at about 930 nm. The spectrum (C), however, has only one peak at about 460 nm in the visible range. Chambers and Adams reported that the absorption spectrum of NB^- in DMF containing 0.1 M TEAP has a single peak at 465 nm.[12] Lyons and Mackie reported that the absorption spectrum of NB^- in DMF containing 0.2 M $NaNO_3$ has two adjacent peaks at 435 and 465 nm.[13] However, Ishitani et al. reported that the absorption spectrum of NB^- prepared by potassium reduction in 1,2-dimethoxyethane has a peak at 560 nm.[14] Therfore, the absorption peak of the spectra (A) and (C) at 460 nm can be attributed to the NB^-. Although the reason of the shift of the peak is not clear, the peak of the spectrum (B) at 580 nm may also be attributed to NB^-. If the additional small peak of (A) at 790 nm and that of (B) at 930 nm, which do not exist in the spectrum (C), were the peak due to an optical electron-transfer reaction, there must be a relation represented by Eq. 3. From the values of the activation energies of homogeneous thermal electron-transfer reactions between NB^- and NB described above, we can estimate the values of E_{op} as 140 and 125 kJ mol^{-1} for 0.5 M TBAP and 0.1 M TEAP solutions, respectively. The values of these energies correspond to wavelengths of 850 and 960 nm, respectively. These values are in good agreement with the experimental wavelengths of the additional small peaks of the spectra (A) and (B). This result suggests that these absorption peaks may be attributable to the optical electron-transfer reactions between NB^- molecules and adjacent NB molecules.

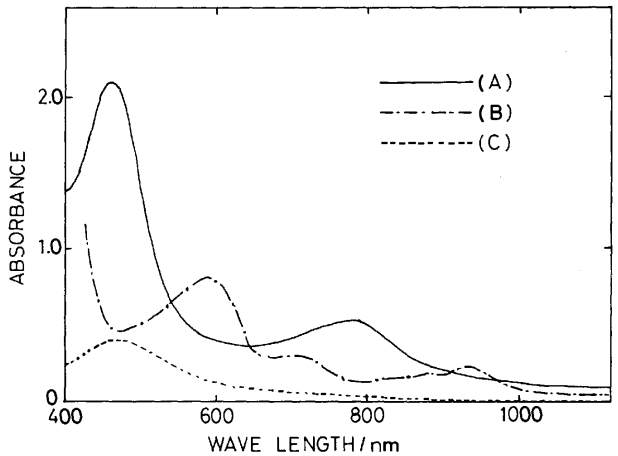

Fig. 6. Absorption spectra of solutions containing NB^- prepared by the electrolytic reduction of (A) NB containing 0.1 M TBAP; (B) NB containing 0.1 M TEAP; (C) DMF solution of NB containing 0.1 M TEAP.

On the other hand, the half width of these additional peaks were smaller than the half values of those predicted by the Eq. 3. This discrepancy may be attributed to the limitation of the applicability of Eq. 3 to this system, or the disturbance of the exact determination of $\Delta\bar{\nu}_{1/2}$ by the impurity formed by the decomposition of NB^-. Therefore, a more carefull experimental and theoretical examination is required for the complete confirmation of the occurence of optical electron-transfer reaction in this system.

Electrochemical Electron-Transfer Reaction Rates of NB^- in NB. Figure 7 shows the plots of log (I_o/Fc_O/cm s^{-1}) vs. log (c_R/c_O) for NB^-/NB couples in NB containing various kinds and amounts of tetraalkylammonium perchlorates determined by the gdp method, where I_o, F, c_O, and c_R are the exchange current density, the Faraday constant, the concentration of oxidant, and the concentration of reductant, respectively. I_o/Fc_O corresponds to the rate constant of electrochemical electron-transfer reaction at various reductant/oxidant ratios. The standard rate constants were determined by the extrapolation of these plots to the zero value of the abscissa. These rate constants in various solutions are different from each other, but even the largest value in 0.17 M TEAP, 7×10^{-3} cm s^{-1}, is smaller by about two orders than that in a DMF solu-

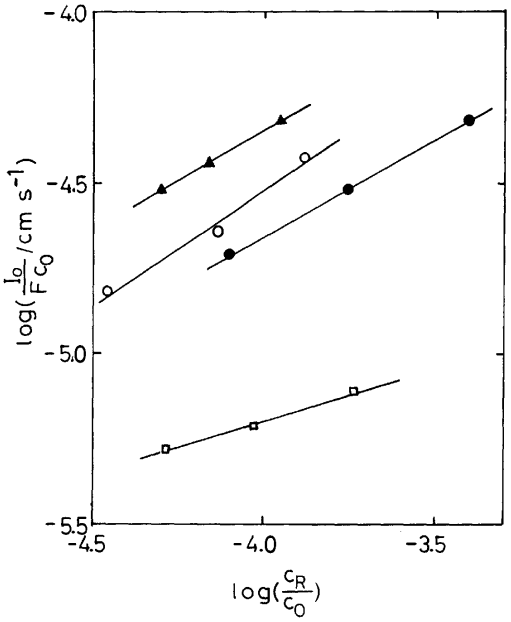

Fig. 7. Plots of log(I_o/Fc_O/cm s^{-1}) vs. log(c_R/c_O) for NB^-/NB systems in NB containing various kinds and amounts of tetraalkylammonium perchlorates determined by gdp method at 25 °C. (—▲—) 0.17 M TEAP; (—○—) 0.1 M TBAP; (—●—) 0.5 M TBAP; (—□—) 0.1 M TAAP.

a) Ref. 15.

tion.[15] NB molecules which have formed compact double layer in contact with the electrode surface may act as oxidants for this electrode reaction. These molecules are considered to be specifically adsorbed oxidants in a sense. The reason for the retardation of the electron-transfer reaction in these system is not clear, but such unique structure of the electrical double layer of these systems as described above may be attributed to these phenomena.

Diffusion Coefficients of NB^- in NB. Dahms,[4] and Ruff and Friedrich[5] derived an expression for the contribution of an exchange reaction to the diffusion coefficient of species which participate in the exchange reaction. When the rate constant of the electron-exchange reaction between NB^- and NB is expressed by k, the apparent diffusion coefficient of NB^- in NB, D_{NB^-}, is represented by the following equation.[5]

$$D_{NB^-}=D^{\circ}_{NB^-}+(\pi\delta^2k/4)c_{NB} \quad (4)$$

where $D^{\circ}_{NB^-}$ is the intrinsic diffusion coefficient of NB^- in NB when the value of k is assumed to be zero, δ is the jumping distance of an electron from NB^- to NB, and c_{NB} is the concentration of NB. The second term represents the contribution of the electron-exchange reaction.

Table 4 shows the diffusion coefficients of NB^- in NB containing various kinds of tetraalkylammonium perchlorates determined by the potential step method, together with that in DMF. If the contribution of the electron-transfer reaction between NB^- and NB to an apparent diffusion coefficient of NB^- predicted by the Eq. 4 would be larger than the intrinsic diffusion coefficient of NB^-, $D^{\circ}_{NB^-}$, a large apparent diffusion coefficient might be observed. However, this result shows that the diffusion coefficients of NB^- in NB is smaller than the value in DMF, even if we corrected the value considering the difference of the viscosities of these solvents. These results can probably be attributed to the small rate constant of the homogeneous electron-transfer reaction of these systems and ion pairing of NB^- with tetraalkylammonium ions. In fact, although the rate constant of the electron-transfer reaction between anthracene (An) and its anion radical (An^-) is larger by about two orders than these system, its contribution to the electric conductivity of anthracene anion radical is only a few percent.[16] Even when we consider the large concentration of NB in these system compared with that of An, the contribution of the electron-transfer reaction between NB and NB^- may be not so large as to be detectable by this experiment. Moreover, it is considered that NB^- in this system will usually be ion paired with tetraalkylammonium ions, because the odd electrons in free NB^- molecules tend to transfer to NB molecules in the vicinity of tetraalkylammonium ions. In a separate paper, we will report the electrical conductivity of solid NB containing NB^- and tetraalkylammonium salts in order to detect only the contribution of electron hopping to the electric conductivity.

A Light-Scattering Study of Temperature Effect on Micelle Formation of *N*-Alkanoyl-*N*-methylglucamines in Aqueous Solution

Makoto Ōkawauchi, Mayumi Hagio, Yoshitomi Ikawa,† Gohsuke Sugihara,*
Yoshio Murata, and Mitsuru Tanaka

†San-Ei Chemical Industries, Ltd., 1-1-11 Sanwa-cho, Toyonaka 561
(Received December 10, 1986)

The physicochemical properties of *N*-alkanoyl-*N*-methylglucamine in aqueous solution have been studied by applying a Debye plot and small-system thermodynamics to an analysis of static light scattering data in the temperature range from 25 to 55 °C. A small minimum was found in a plot of the critical micelle concentration vs. temperature, instead of the monotonously decreasing tendency, as in the case of poly(oxyethylene) alkyl ether. The temperature dependence of the aggregation number of the micelle and the spread of the aggregation number distribution of micelle are both very small. The standard enthalpy change associated with micelle formation varies from positive to negative as the temperature is raised. The micellization of *N*-alkanoyl-*N*-methylglucamine surfactants is discussed separately in terms of the respective contributions from the hydrophilic and hydrophobic groups.

N-Alkanoyl-*N*-methylglucamines (MEGA-n; the chemical structure is shown in Fig. 1), nonionic surfactants, have been utilized to solubilize membrane proteins[1-3] since the time it was synthesized by Hildreth[4] in 1982. However, the physicochemical properties, such as the critical micelle concentration (cmc) and the aggregation number of micelle, at various temperatures have not yet been accurately determined. In the present study, we investigated the physicochemical properties of *N*-octanoyl-, *N*-nonanoyl-, and *N*-decanoyl-*N*-methylglucamine (MEGA-8, MEGA-9, MEGA-10) in aqueous solution at temperatures ranging from 25 to 55 °C by using a static light-scattering technique.

Ikeda et al.[5-13] have extensively studied various ionic surfactants by means of a light-scattering technique and have clearly revealed the interesting behaviors of the size and shape of surfactant aggregates. Some light-scattering studies have been made for poly(oxyethylene)-type nonionic surfactants.[14-20] For other nonionic surfactants, especially for the present MEGA-n, however, few light-scattering studies have been made in spite of the usefulness of MEGA-n in the special field of biochemistry. Thus, we have investigated the light-scattering behavior of aqueous solutions of the homologues series, MEGA-n. To analyze light-scattering data, not only Debye plots, but also small-system thermodynamics[21] have been applied. As partly described elsewhere,[20,25,26] the treatment of micelle formation by small-system thermodynamics constitutes a general theory which partly includes treatments of both mass-action and phase-separation models and can be used to clarify the thermodynamical meaning of the application of both models.

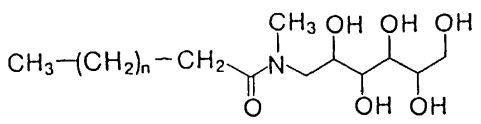

Fig. 1. The structures of *N*-octanoyl- (n=7), *N*-nonanoyl- (n=8), and *N*-decanoyl-*N*-methylglucamine (n=9).

Experimental

Materials. MEGA-8, MEGA-9, and MEGA-10 were purchased from Dojindo Laboratories and recrystallized several times from a methanol–dimethyl ether mixture and acetone. The purities of the surfactants were examined by the surface tension method. No minimum around cmc was observed for the surface tension vs. concentration curve of their aqueous solutions. Solvent water was redistilled from alkaline $KMnO_4$ after being passed through a column of an ion-exchange resin.

Methods. The light-scattering measurement was carried out using a JASCO Light Scattering Photometer LSP-1 with the unpolarized light of a mercury lamp at 436 nm. The intensities of light scattered at scattering angles, 45, 90, and 135° were measured for sample solutions in a semioctagonal cell. The semioctagonal cell was placed in a cell housing whose temperature was controlled within ±0.1 °C by circulating water around it. The reduced intensity of scattered light at 90° was calculated by

$$R_{90} = \frac{I_{90}}{I_0} \phi_{90}^{B} \frac{n_0}{n_B}, \quad (1)$$

where I_0 and I_{90} are, respectively, the intensities of the incident and scattered light at 90°; n_0 and n_B are the refractive indices of the solvent and benzene, respectively. The calibration constant, ϕ_{90}^{B}, was determined by using purified benzene at 25 °C.[22] We assumed in this study that the ϕ_{90}^{B} was independent of the temperature. The angular dissymmetry Z_{45} of light scattering was determined by

$$Z_{45} = \frac{I_{45}}{I_{135}}, \quad (2)$$

where I_{45} and I_{135} are the intensities of scattered light at 45 and 135°, respectively. A surfactant solution was directly filtered into the semioctagonal cell by using the cell-filling apparatus shown in Fig. 2. All parts of the cell-filling apparatus were cleaned in a sonicater. A membrane filter (Advan-

50	63.2	20.5	6.7
55	63.7	20.8	6.9

tec) having a pore size of 0.1 μm was washed with boiling redistilled water; these parts were then arranged as shown in the figure. Firstly, the cell was filled with a sample solution or solvent which came from S through paths 1, 2, 3, F, and 4; after that, the solution or solvent was drained through paths 5, 2, 3, and 6. By repeating this procedure several times, the cell and other parts of the apparatus could be completely washed. Finally, the cell was again filled with a sample solution by the same procedure as described above and the sample solution in the cell was repeatedly circulated through path 5 to 4. A concentration change of the sample solution before and after filteration was not detected in the refractive index.

The specific refractive index increment at temperatures ranging from 25 to 55 °C was measured by means of an Otsuka Electronics Differential Refractometer R102 at 436 nm of a tungsten-halogen lamp. The calibration of the apparatus was carried out with an aqueous solution of KCl at 25 °C;[23] we assumed in this study that the calibration constant of the apparatus was independent of the temperature. The specific refractive index increment was constant over the whole concentration range measured and was almost constant at temperatures ranging from 25 to 55 °C.

Results and Discussion

The angular dissymmetry, Z_{45}, was found to be very close to unity for all the MEGA-n solutions over the whole range of the temperatures and concentrations investigated. Figure 3 shows a plot of the reduced intensity, R_{90} vs. total surfactant concentration in molality of MEGA-9 at 30 and 55 °C. Each curve has a break point indicating the beginning of micelle formation. Thus, the cmc is determined as the concentration at the break point. The values of the cmc's of MEGA-8, MEGA-9, and MEGA-10 are listed in Table 1 and the temperature dependence of the cmc's are shown in Fig. 4. It is noteworthy that a minimum appears in the cmc vs. temperature curve for MEGA-n, since the

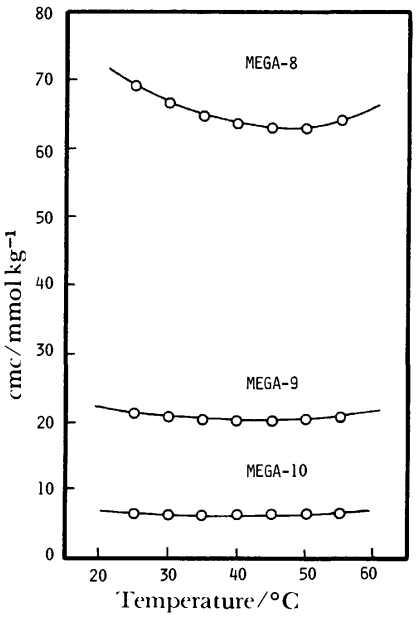

Fig. 4. Temperature dependence of cmc of MEGA-n.

existence of such a minimum has been considered to be characteristic of ionic surfactants. The cmc of poly (oxyethylene) alkyl ethers had been found to decrease monotonously with increasing temperature.[24]

From the data of R_{90} and cmc a Debye plot of MEGA-n could be made. In the absence of angular dissymmetry, the scattered light intensity at 90° from a dilute micellar solution irradiated by unpolarized light can be represented by Debye's equation:

$$\frac{K_D(C-\mathrm{cmc})}{R_{90}-R_{90,\mathrm{cmc}}} = \frac{1}{\bar{N}_w M_n} + 2B(C-\mathrm{cmc}), \quad (3)$$

where K_D, the optical constant, is

$$K_D = \frac{2\pi^2 n^2}{N_A \lambda^4}(\partial n/\partial C)^2. \quad (4)$$

Further, C is the total surfactant concentration (g ml^{-1}), $R_{90,\mathrm{cmc}}$ the reduced intensity of the solution at cmc, $\bar{N}_w$ the weight-average aggregation number of micelle, M_n the molecular weight of MEGA-n and B the second virial coefficient. n_0 and n are, respectively, the refractive indices of solvent and solution, λ the wavelength of the incident radiation and N_A Avogadro's number. Debye plots of MEGA-9 at various temperatures are shown in Fig. 5. If we draw an approximate straight line which threads through the plotted points by a least-square method, we can obtain the weight-average aggregation number of micelle as well as the second virial coefficient from the intercept and slope of this straight line, respectively. It can be seen from Fig. 5 that the respective second virial coefficients have small and negative values (2×10^{-3} mol ml g^{-2}) with a small temperature dependence. The same trends were also found for MEGA-8 and MEGA-10. It should be noted that the second virial coefficients of poly(oxyethylene) alkyl ethers change from positive to negative[16,17] in the same temperature range as the present case.

The application of small-system thermodynamics to the analysis of light-scattering data[24-27] allowed us to determine the monomeric concentration, C_1, micellar concentration, C_m, number-average and mean-square aggregation number of micelle $\bar{N}_1$, $\bar{N}_1^2$ and spread of the aggregation number distribution of micelle of MEGA-n.

In the absence of angular dissymmetry, the R_{90} of a micellar solution is given by

$$R_{90}-R_{90,0} = K_s(C_1+\bar{N}_1^2 C_m), \quad (5)$$

where

$$K_s = \frac{2\pi^2 n^2}{N_0 \lambda^4}(\partial n/\partial C_1^t)^2. \quad (6)$$

Here, $R_{90,0}$ is the reduced scattered intensity at 90° from solvent water, C_1^t the total surfactant concentration and N_0 the number of solvent molecules per unit volume. Equation 5 can be easily derived from Eq. 3 when B=0 in Eq. 3.

C_1 and C_m can be determined from the following equations:

$$\ln C_1 = \int_{\mathrm{cmc}}^{C_1^t} K_s/(R_{90}-R_{90,0})\mathrm{d}C_1^t + \ln \mathrm{cmc} \quad (7)$$

and

$$C_m = \int_{\mathrm{cmc}}^{C_1^t} K_s C_1^t/(R_{90}-R_{90,0})\mathrm{d}C_1^t - C_1 + \mathrm{cmc}. \quad (8)$$

From C_1 and C_m, thus obtained, $\bar{N}_1$, and $\bar{N}_1^2$ can be determined using

$$\bar{N}_1 = (C_1^t - C_1)/C_m \quad (9)$$

and

$$\bar{N}_1^2 = [(R_{90}-R_{90,0})/K_s - C_1]/C_m. \quad (10)$$

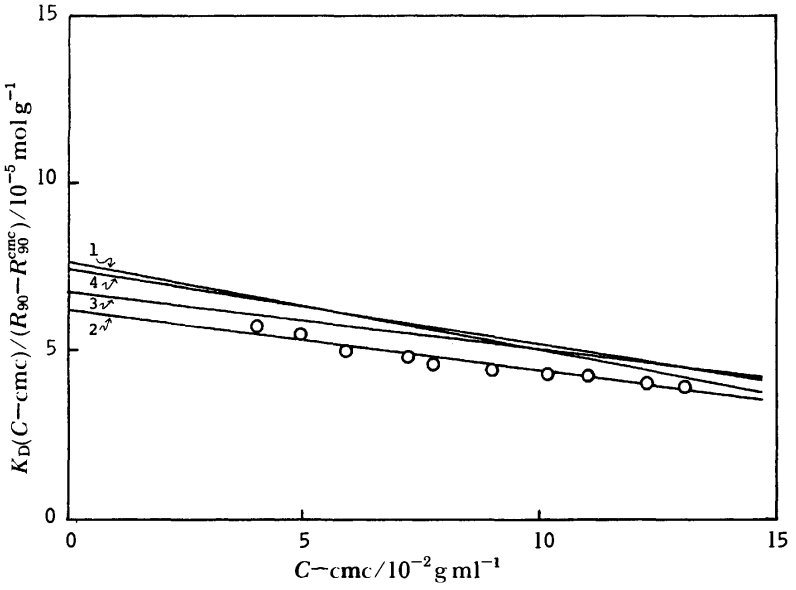

Fig. 5. The Debye plots of MEGA-9 at various temperatures; 1: 25 °C, 2: 35 °C, 3: 45 °C, 4: 55 °C.

In these calculations, the concentration (C_1^t, C_1, and C_m) units are the solute molecular number per solvent molecular number (in figures, concentrations are represented by molality).

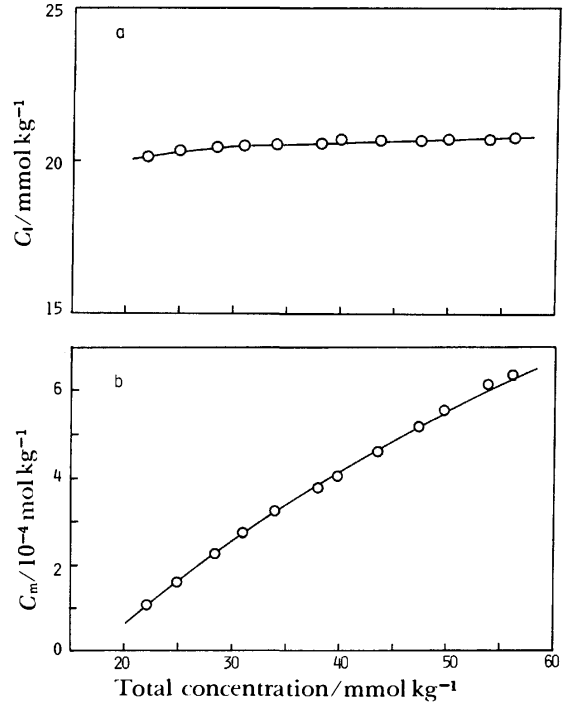

Fig. 6. Monomer concentration, C_1 and micellar concentration, C_m of MEGA-9 as a function of total concentration at 45°C.

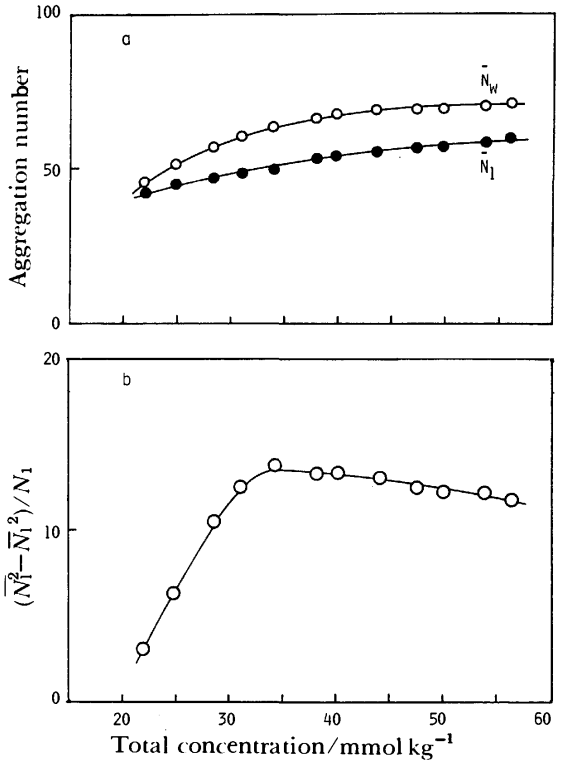

Fig. 7. Number-average and mean square aggregation number of MEGA-9 micelle (a) and the spread of aggregation number of micelle of MEGA-9 (b) at 45°C.

Figure 6 shows the dependence of C_1 and C_m on C_1^t in the case of MEGA-9 at 45 °C. C_1 increases only slightly from cmc with increasing C_1^t, and is regarded approximately as equal to the cmc. The same trend can be seen in the cases of MEGA-8 and MEGA-10 at various temperatures. This shows that the micellization of these nonionic surfactants can be approximately treated by the phase separation model. C_m increases with an increase of C_1^t and has a value of the order of 0.01 C_1^t in the total concentration range.

Figure 7-a shows the dependence of $\bar{N}_1$ and the weight-averaged aggregation number $\bar{N}_w$ ($=\bar{N}_1^2/\bar{N}_1$) of the micelle of MEGA-9 on C_1^t at 45 °C. Both $\bar{N}_1$ and $\bar{N}_w$ increase with an increase in C_1^t. The same trend can be seen in the cases of MEGA-8 and MEGA-10 at various temperatures. The increasing tendency of $\bar{N}_1$ with C_1^t is consistent with the Eq. 11, which has been derived using a treatment based on small-system thermodynamics:[26]

$$(\partial\bar{N}_1/\partial C_1^t)=(\bar{N}_1^2-\bar{N}_1^{\,2})/(C_1+\bar{N}_1^2C_m)\geqq 0. \quad (11)$$

Corkill et al.[28] have also derived a similar equation from the multiequilibrium model. They found that $\bar{N}_1$ of the 3-(dimethyloctylammonio)-1-propanesulfonate micelle increases with C_1^t. We also found that $\bar{N}_1$ of penta- and hexa(oxyethylene) dodecyl ether micelles increase with C_1^t under various pressures[20] at 25 °C.

The spread of the aggregation number of MEGA-9 micelle, $(\bar{N}_1^2-\bar{N}_1^{\,2})/\bar{N}_1$, obtained from the difference between $\bar{N}_w$ and $\bar{N}_1$, is shown in Fig. 7-b, where $(\bar{N}_1^2-\bar{N}_1^{\,2})/\bar{N}_1$, increases initially with C_1^t and then reaches an almost constant value. The same trend was observed for MEGA-8 and MEGA-10 at various temperatures. The spread of the aggregation number of the micelle of MEGA-n is much smaller than that of polyoxyethylene alkyl ether, and its C_1^t dependence is also smaller.[20]

In order to analyze the results based on small-system thermodynamics, we assumed an ideal condition for

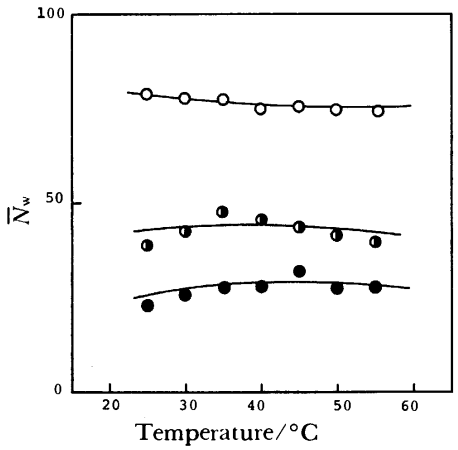

Fig. 8. Temperature dependence of weight averaged aggregation numbers of micelle of MEGA-8 (●), MEGA-9 (◑), and MEGA-10 (○).

very dilute micellar solutions of MEGA-n. This assumption can be regarded as reasonable owing to the very small value of the second virial coefficient obtained from the Debye plot.

The value of $\overline{N}_w$ extrapolated to cmc in Fig. 7 agrees well with the weight-average aggregation number obtained from the Debye plot. Figure 8 shows the temperature dependence of $\overline{N}_w$. The extrapolated $\overline{N}_w$ of MEGA-8, MEGA-9, and MEGA-10 may be regarded as being almost constant, irrespective of the temperature change, which differs remarkably from the strikingly increasing trend of $\overline{N}_w$ of poly(oxyethylene) alkyl ethers.[15] The temperature dependence of C_m and the $(\overline{N_1^2}-\overline{N}_1^2)/\overline{N}_1$ of MEGA-8, MEGA-9, and MEGA-10 are also very small.

From the temperature dependence of C_1, C_m, and $\overline{N}_1$, the standard Gibbs free energy, enthalpy and entropy change on micelle formation, ΔG_m°, ΔH_m°, and ΔS_m° can be estimated by the use of the following equations from small-system thermodynamics:[27]

$$\Delta G_m^\circ \simeq RT \ln C_1 - RT/\overline{N}_1 \ln C_m, \quad (12)$$

$$\Delta H_m^\circ \simeq -RT^2 (\partial \ln C_1/\partial T)_p - RT^2/\overline{N}_1 (\partial \ln C_m/\partial T)_p, \quad (13)$$

and

$$\Delta S_m^\circ \simeq -RT (\partial \ln C_1/\partial T)_p + RT/\overline{N}_1 (\partial \ln C_m/\partial T)_p - R \ln C_1 + R/\overline{N}_1 \ln C_m. \quad (14)$$

These equations are (formally) the same equations as derived from the mass-action model. However, the second terms of Eqs. 12—14 and the 4 th term of Eq. 14 are much smaller than the other terms in the respective equations because of the factor $1/\overline{N}_1$; also, the smaller temperature dependence of ln C_m than that of ln C_1. C_1 is nearly equal to the cmc (as described above). The equations obtained from the elimination of the terms on the respective equations described above are consistent with the equations derived from the phase-separation model. We have taken the standard states of monomer and micelle as the states of an infinite dilute solution; therefore, their standard free energies consist of self free energies as well as their interaction with water. Then, ΔG_m° represents the change of the interaction (hydrophobic and hydrophilic) of the monomer and water accompanied by the transfer of a mole of the monomer from the solution bulk into the micelle.

The temperature dependence of ΔG_m°, ΔH_m°, and ΔS_m° thus obtained, are shown in Fig. 9. The ΔG_m°, ΔH_m°, and ΔS_m° of MEGA-n decreases monotonously with the temperature. ΔG_m° is always negative and ΔS_m° positive. On the other hand, ΔH_m° changes sign from positive to negative at a lower temperature, since the hydrocarbon chain is longer. However, ΔH_m° is always positive and decreases to zero with temperature in the case of poly(oxyethylene) alkyl ether.[29-32]

In order to investigate these features of MEGA-n in detail, let us try to separate these thermodynamic parameters into contributions from the hydrophilic and hydrophobic parts of a MEGA-n molecule, assuming the additivity. ΔG_m° can be divided into three parts:

$$\Delta G_m^\circ \simeq \Delta G_m^\circ(w) + (N_c - 1)\Delta G_m^\circ(CH_2) + \Delta G_m^\circ(CH_3), \quad (15)$$

where $\Delta G_m^\circ(w)$ is the contribution of the hydrophilic part, $\Delta G_m^\circ(CH_2)$ the methylene group, and $\Delta G_m^\circ(CH_3)$ the terminal methyl group; N_c should be taken as 7, 8, and 9, respectively, for MEGA-8, MEGA-9, and MEGA-10. Similar equations are valid for ΔS_m° and ΔH_m°.

From the linear plots of ΔG_m°, ΔH_m°, and ΔS_m° vs. the number of carbon atoms in alkyl chain of MEGA-n at various temperatures, $\Delta G_m^\circ(CH_2)$, $\Delta H_m^\circ(CH_2)$, and $\Delta S_m^\circ(CH_2)$, can be determined (as listed in Table 2). These are the same values as those of poly(oxyethylene) alkyl ethers.[33]

$\Delta G_m^\circ(w)$ can be obtained by substituting the values of $\Delta G_m^\circ(CH_2)$ and $\Delta G_m^\circ(CH_3)$ (=2100 cal mol^{-1} (1 cal= 4.184 J))[24] into Eq. 15. The $\Delta H_m^\circ(w)$ and $\Delta S_m^\circ(w)$ can be determined from Eqs. 16 and 17 (see Table 3):

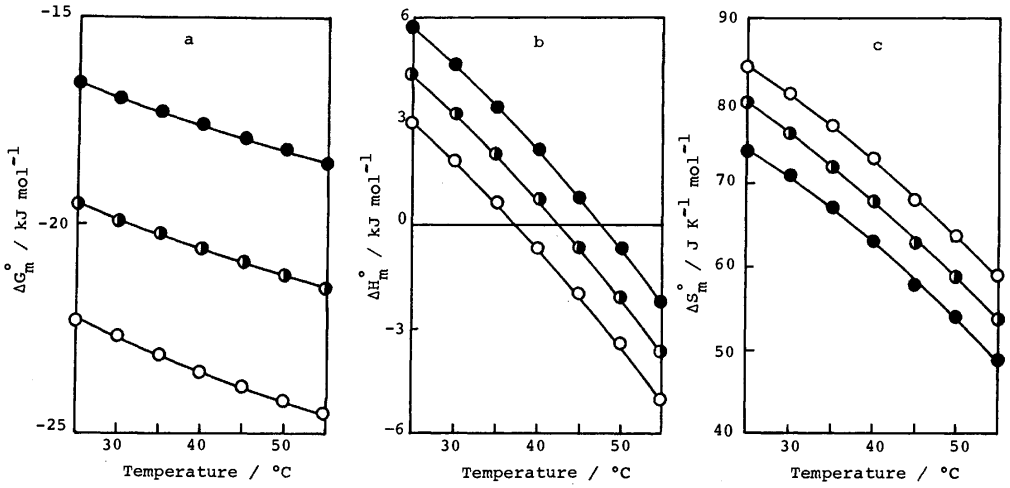

Fig. 9. Thermodynamic parameter changes on micelle formation of MEGA-8 (●), MEGA-9 (◑), and MEGA-10 (○) as a function of temperature.

Table 2. The Thermodynamic Parameters per Methylene Group of MEGA-n on Micelle Formation at Various Temperatures

55	8.48	14.6	18.7

$$\Delta H_m^\circ(w) = \partial(\Delta G_m^\circ(w)/T)/\partial(1/T) \quad (16)$$

and

$$T\Delta S_m^\circ(w) = \Delta H_m^\circ(w) - \Delta G_m^\circ(w). \quad (17)$$

Let us compare the contribution of $\Delta H_m^\circ(w)$ to $\Delta G_m^\circ(w)$ between poly(oxyethylene) alkyl ether and MEGA-n. In the case of MEGA-n, the enthalpy term, $\Delta H_m^\circ(w)$, is superior to the entropy term, $T\Delta S_m^\circ(w)$, while in the case of poly(oxyethylene) alkyl ether both terms are comparable.[33] This difference can be interpreted in terms of the interaction between water and the respective hydrophilic parts. The relatively large contribution of $T\Delta S_m^\circ(w)$ to $\Delta G_m^\circ(w)$ in the poly (oxyethylene) group compared to the case of the hydrophilic part of MEGA-n seems to be caused by a relatively large degree of weakening of the hydration of poly(oxyethylene) group on micellization.

The experimental results are summarized as follows. The cmc vs. temperature curve has a small minimum in the temperature range from 25 to 55 °C; also, the temperature dependence of micellar aggregation numbers, the spread of its distribution and the micellar concentration of MEGA-n are very small. The standard enthalpy change on micelle formation, ΔH_m°, changes sign from positive to negative with increasing temperature. Further, a cloud point was not observed for MEGA-8, MEGA-9, or MEGA-10, even if their solutions were heated to the boiling point and a large amount of NaCl was added into the solutions of MEGA-n (on the basis of the fact that addition of NaCl depress the cloud point of poly(oxyethylene) alkyl ethers).[34]

A suggestion concerning the solution properties of MEGA-n resulted through a comparison with those of poly(oxyethylene) alkyl ethers. The hydrophilicity of poly(oxyethylene) alkyl ether arises from the formation of two hydrogen bonds per oxyethylene group with water.[35] On the other hand, a hydroxyl group of the hydrophilic part of MEGA-n can possibly make three hydrogen bonds with water. However, by taking into account the fact that a cloud point was not observed for MEGA-n and that cmc has a shallow minimum at a certain temperature (instead of monotonous decreasing with temperature like the cmc of poly (oxyethylene) alkyl ether), it may be concluded that there is a considerable difference between the interaction of hydroxyl groups of MEGA-n with water and that of the oxyethylene groups of poly(oxyethylene) alkyl ether with water. The minimum in the temperature dependence of the cmc, as observed in ionic surfactants with ion-water dipole interaction, may result from the predominant role of the electrostatic dipole-dipole interaction of the hydrophilic part of MEGA-n with water. Further, the amide group may also play an important role in the hydrophilicity of MEGA-n. The hydrogen bond formation between hydroxyl groups in the micellar state cannot be considered as an important factor of micelle formation, since it should cause the micelle size to be much larger than the observed values.

It seems, however, that it is not always reasonable to regard the character of hydrophilic group of MEGA-n as attributable to each separate hydroxyl group. It has been well-known that for such a molecule (having several hydroxyl groups) that the steric configuration of the hydroxyl groups plays a more important role than the nature of each hydroxyl group itself. For instance, galactaric acid and D-glucaric acid are only different in the stereochemical configuration of a certain hydroxyl group; however, the former is very soluble in water and the latter is insoluble.

Finally, one should pay attention to the fact that the micellization behavior of poly(oxyethylene)-type nonionic surfactants is not common to all other types of nonionic surfactants.[31,36,37]

Ion/Molecule Reactions in Gaseous Isopropyl Alcohol

Kenzo HIRAOKA,* Hajime TAKIMOTO, and Shinichi YAMABE†,*
Faculty of Engineering, Yamanashi University, Takeda-4, Kofu 400
†Department of Chemistry, Nara University of Education, Takabatake-cho, Nara 630
(Received December 25, 1986)

The ion/molecule reactions observed in 4 Torr CH_4 containing known small amounts of i-C_3H_7OH or i-C_3H_7OH/H_2O mixture were studied over the temperature range 40—400 °C. The experiments were carried out using a pulsed electron beam mass spectrometer. At low temperatures (<150 °C), the major ions are i-$C_3H_7OH_2^+(i\text{-}C_3H_7OH)_n$. By increasing the temperature, the slow growth of ions with m/z=59, 85, and 101 is observed. These ions are assigned to $(CH_3)_2COH^+$, $(CH_3)_2CHC^+(CH_3)_2$, and $C_6H_{13}O^+$, respectively. They are probably produced from reactions of i-$C_3H_7^+$ with isopropyl alcohol. The $(CH_3)_2COH^+$ ion may be produced from the electrophilic attack of i-$C_3H_7^+$ onto the secondary carbon atom of i-C_3H_7OH. At high temperatures (≈400 °C), the $(CH_3)_2COH^+$ ion becomes dominant. Acid-catalyzed dehydration of isopropyl alcohol, i-$C_3H_7OH_2^+ + H_2O \rightarrow H_3O^+(H_2O) + C_3H_6$, is also observed. Ion/molecule reactions involved in the present experiment are discussed according to the frontier-orbital theory.

The kinetics of the gas-phase ion/molecule reactions of aliphatic alcohols have been studied in various respects. The condensation reactions of protonated alcohols ROH_2^+ leading to the formation of protonated ethers R_2OH^+have been observed.[1-7]

$$ROH_2^+ + ROH \rightarrow R_2OH^+ + H_2O \quad (1)$$

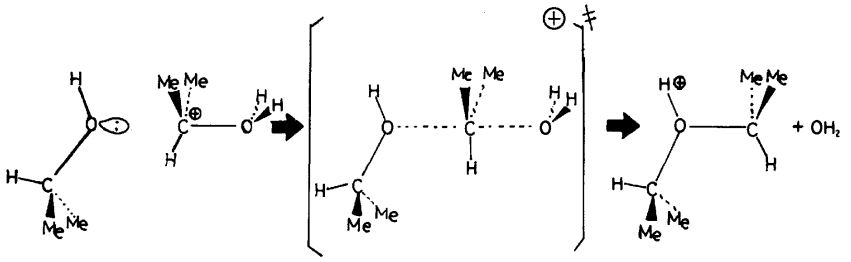
The γ-radiation-sensitized pyrolysis of isopropyl alcohol vapor has been studied by Freeman and coworkers.[7-9] At temperatures about 250 °C, chain reactions were found to be important in isopropyl alcohol vapor. Four modes of radiation-induced chain decomposition were found.[9] The stoichiometric representation of the modes, with G values at 380 °C are $2i$-$C_3H_7OH \rightarrow H_2O + (i\text{-}C_3H_7)_2O$, 300; i-$C_3H_7OH \rightarrow H_2O + C_3H_6$, 1200; i-$C_3H_7OH \rightarrow CH_4 + CH_3CHO$, 43; i-$C_3H_7OH \rightarrow H_2 + (CH_3)_2CO$, 600. For the formation of diisopropyl ether, radiation-induced cationic chain reactions 2—4 have been proposed.[8]

$$i\text{-}C_3H_7OH_2^+ + i\text{-}C_3H_7OH \rightarrow (i\text{-}C_3H_7)_2OH^+ + H_2O \quad (2)$$

$$(i\text{-}C_3H_7)_2OH^+ + i\text{-}C_3H_7OH \rightarrow (i\text{-}C_3H_7)_2OH^+(i\text{-}C_3H_7OH) \quad (3)$$

$$(i\text{-}C_3H_7)_2OH^+(i\text{-}C_3H_7OH) + i\text{-}C_3H_7OH \rightarrow i\text{-}C_3H_7OH_2^+(i\text{-}C_3H_7OH) + (i\text{-}C_3H_7)_2O \quad (4)$$

Reaction 2 has the mechanism of the bimolecular nucleophilic substitution (S_N2).



Back side attack of i-PrOH to cation S_N2

Reaction 3 is the standard clustering, and reaction 4 is the displacement reaction.

Van der Linde and Freeman[9] suggested the radical chain reactions 5—8 for the formation of H_2, $(CH_3)_2CO$, and C_3H_6.

$$H + i\text{-}C_3H_7OH \longrightarrow H_2 + (CH_3)_2\dot{C}OH \quad (5)$$

$$(CH_3)_2\dot{C}OH \longrightarrow (CH_3)_2CO + H \quad (6)$$

$$OH + i\text{-}C_3H_7OH \longrightarrow H_2O + \dot{C}H_2(CH_3)CHOH \quad (7)$$

$$CH_2(CH_3)CHOH \longrightarrow C_3H_6 + OH \quad (8)$$

Hiraoka and Kebarle found the acid-catalyzed dehydration reaction 9 of t-butyl alcohol in the gas phase.[10] It is a unimolecular elimination (E1).

$$t\text{-}C_4H_9OH_2^+ + H_2O \rightarrow H_3O^+(H_2O) + i\text{-}C_4H_8 \quad (9)$$

So far the gas-phase ion/molecule reactions in isopropyl alcohol have not been studied before. In the present work, some detailed examination of the same reactions were done using a pulsed electron beam mass spectrometer. It was found that several unique ions were produced from the ion/molecule reactions in isopropyl alcohol such as i-$C_3H_7^+$, $(CH_3)_2COH^+$, $C_6H_{13}^+$, $C_6H_{11}O^+$, $C_6H_{13}O^+$, $(i\text{-}C_3H_7)_2OH^+$, and $C_6H_{13}O_2^+$ in addition to the proton-bound cluster ions i-$C_3H_7OH_2^+$ $(i\text{-}C_3H_7OH)_n$. The mechanisms for the

formation of these ions were proposed on the grounds of the thermochemical data and the frontier-orbital theory. The evidence for the occurrence of the acid-catalysed dehydration reaction analogous to reaction 9 was obtained for isopropyl alcohol.

Experimental

The measurements were made with the pulsed electron beam mass spectrometer which has been described previously.[11-13] A small amount of isopropyl alcohol or isopropyl alcohol/water vapor mixture was introduced into 4 Torr[14] CH_4 carrier gas through stainless steel capillaries.

Two keV electron beam was pulsed on for 100 μs and off for 3 ms. The electron beam entered the ion source through the electron entrance slit made of stainless steel razor blades. The width and the length of the slit were 15 μm and 1 mm, respectively. The incident electron current at non-pulsed mode was about 5×10^{-9} A. The ions produced were sampled through an ion exit slit made of razor blades. The width and the length of the slit were the same as those of the electron entrance slit. Under the present experimental conditions, the mean free paths of ions and molecules are greater than the slit width. Thus the ions pass through the slit by molecular flow and the adiabatic cooling of the escaping gas is negligible. The lifetime of ions due to the diffusive loss to the wall was more than a few ms under the present experimental conditions. They were dependent on the ion source temperature and the gas pressure. The loss of ions due to the electron-positive ion recombination reaction is negligible under the present experimental conditions. About 2 ms after the electron pulse, a short positive pulse (+25 V) was applied to the ion repeller electrode in order to annihilate all ions produced in the ion source. The ions escaping from the field-free ion source into an evacuated region were mass analysed by a quadrupole mass spectrometer (ULVAC MSQ-400) and collected in a multichannel analyser as a function of their arrival time after the electron pulse. The intensities of all ions are normalized on the measurements so that they correspond to their relative concentrations in the ion source. The ion counts collected in a multichannel analyser were transferred to the microcomputer and the time profiles of the calculated per cent of the total ionization of observed ions were recorded on the x-y plotter.

Structural data were obtained by the ab initio MO calculation with the 3-21G and STO-3G basis sets. The GAUSSIAN 80 program was used.[15]

Results

When the ion source temperature is low (<150 °C), the observed major ions are $i\text{-}C_3H_7OH_2^+(i\text{-}C_3H_7OH)_n$. That is, the standard clustering reaction takes place. When the ion source temperature is raised, several new ions are formed. Figure 1 shows the temporal profile of ions observed in 4.05 Torr of CH_4 containing 2.3 mTorr of $i\text{-}C_3H_7OH$ and 0.116 Torr of H_2O at 302.0 °C. The primary ion H_3O^+ is produced from reactions of the added H_2O with CH_5^+ and $C_2H_5^+$. These major ions are produced from the methane ion/molecule reactions. The rapid increase of $H_3O^+(H_2O)$ (mass 37) and $i\text{-}C_3H_7^+$ (mass 43) is observed at the expense of the H_3O^+ ion. The onsets of appearance of ions with m/z=59 and higher masses are slower than those of $H_3O^+(H_2O)$ and $i\text{-}C_3H_7^+$ ions. This indicates that the ions with m/z=59 and higher masses are the

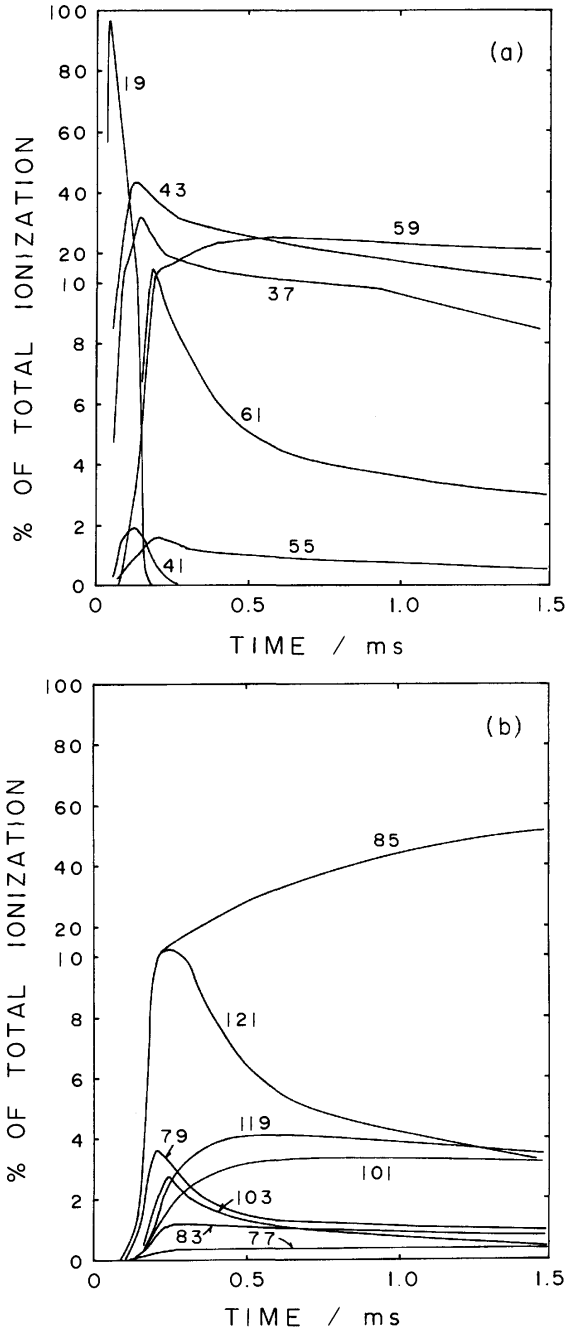


Fig. 1. Positive ions observed after electron pulse ionization in a gas mixture containing 4.05 Torr of CH_4, 0.116 Torr of H_2O, and 2.3 mTorr of $i\text{-}C_3H_7OH$ at 302.0 °C.
(a) Mass 19: H_3O^+, mass 37: $H_3O^+(H_2O)$, mass 41: $C_3H_5^+$, mass 43: $i\text{-}C_3H_7^+$, mass 55: $H_3O^+(H_2O)_2$, mass 59: $(CH_3)_2COH^+$, mass 61: $i\text{-}C_3H_7OH_2^+$.
(b) Mass 77: $(CH_3)_2COH^+(H_2O)$, mass 79: $i\text{-}C_3H_7OH_2^+(H_2O)$, mass 83: $C_6H_{11}^+$, mass 85: $C_6H_{13}^+$, mass 101: $C_6H_{13}O^+$, mass 103: $(i\text{-}C_3H_7)_2OH^+$, mas 119: $(CH_3)_2COH^+(i\text{-}C_3H_7OH)$, mass 121: $i\text{-}C_3H_7OH_2^+(i\text{-}C_3H_7OH)$.

secondary ions mainly produced from $H_3O^+(H_2O)_n$ or i-$C_3H_7^+$ as precursor ions.

Figure 2 shows the temporal profiles of ions observed in 4.08 Torr of CH_4 and 2.0 mTorr of i-C_3H_7OH at 307.3 °C. The CH_5^+ (mass 17) and $C_2H_5^+$ (mass 29) ions which are the primary ions produced from the ion/molecule reactions in methane are quickly converted to ions with m/z=41, 43, and 61. The slower onsets of appearance of ions with m/z=83 and higher masses suggest that these ions are secon-

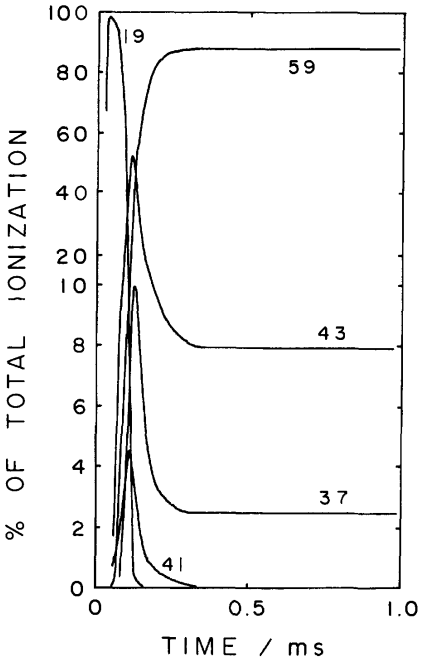

Fig. 3. Positive ions observed after electron pulse ionization in a gas mixture containing 4.06 Torr of CH_4, 0.12 Torr of H_2O, and 2.4 mTorr of i-C_3H_7OH at 413.0 °C.
Mass 19: H_3O^+, mass 37: $H_3O^+(H_2O)$, mass 41: $C_3H_5^+$, mass 43: i-$C_3H_7^+$, mass 59: $(CH_3)_2COH^+$.

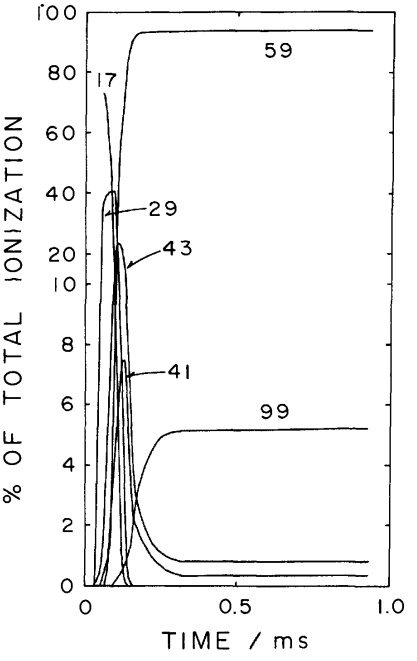

Fig. 4. Positive ions observed after electron pulse ionization in a gas mixture containing 4.1 Torr of CH_4 and 2.0 mTorr of i-C_3H_7OH at 403.0 °C.
Mass 17: CH_5^+, mass 29: $C_2H_5^+$, mass 41: $C_3H_5^+$, mass 43: i-$C_3H_7^+$, mass 59: $(CH_3)_2COH^+$, mass 99: $C_6H_{11}O^+$.

dary product ions in gaseous i-PrOH. The ions with m/z=99 and 117 are formed which are not detected in Fig. 1. The H_2O vapor seems to suppress the formation of these ions.

Figure 3 shows the temporal profiles of ions observed in 4.06 Torr of CH_4, 0.12 Torr of H_2O, and 2.4 mTorr of i-PrOH at 413 °C. The strong growth of the ion with m/z=59 is observed.

In Fig. 4 are shown the temporal profiles of ions observed in 4.1 Torr of CH_4 and 2.0 mTorr of i-PrOH at 403.0 °C. In this case, the ion with m/z=99 as well as that with m/z=59 are observed as major product ions.

Discussion

$C_3H_7^+$ Ion m/z=43. In Fig. 1, the rapid increase of the i-$C_3H_7^+$ ion, at the expense of the H_3O^+ ion is observed. This indicates that the i-$C_3H_7^+$ ion is produced by reaction 10.

$$H_3O^+ + i\text{-}C_3H_7OH \rightarrow i\text{-}C_3H_7^+ + 2H_2O \qquad \Delta H^\circ = -0.9 \text{ kcal mol}^{-1} \quad (10)$$

(1 cal=4.184 J)

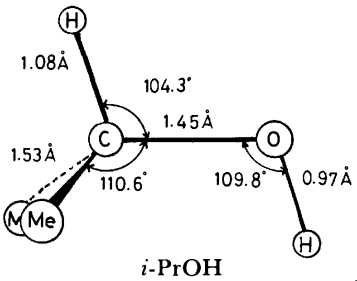
The thermochemically estimated bond energy of the species i-$C_3H_7^+ \cdots OH_2$ is 23.8 kcal mol^{-1}. Since the proton transfer reaction 11

$$H_3O^+ + i\text{-}C_3H_7OH \rightarrow i\text{-}C_3H_7OH_2^+ + H_2O \qquad \Delta H^\circ = -24.7 \text{ kcal mol}^{-1} \quad (11)$$

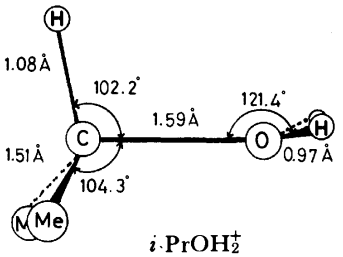
is exothermic by −24.7 kcal mol^{-1}, the protonated isopropyl alcohol produced from reaction 11 has more than enough energy to dissociate toward i-$C_3H_7^+$ and OH_2.

As is shown later in reactions 13, 16, 17, and 23, i-$C_3H_7^+$ reacts with i-PrOH in various patterns. It is of interest to examine its electronic structure with the theoretically optimized geometry. i-PrOH and i-$PrOH_2^+$ are also investigated. Three carbon atoms and H_α are in the common plane. As an electrophile, i-$C_3H_7^+$ has two reactive sites. The reactivity is demonstrated by the shape of the lowest unoccupied MO (LUMO) and the next lowest unoccupied one (LU+1)MO. Anions or bases attack $C_3H_7^+$ potentially from two directions. These are indicated by bold arrows in the figure above.

Geometries of i-PrOH and i-$PrOH_2^+$ are shown below.

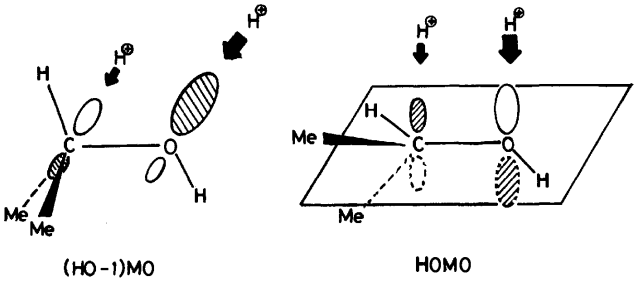


i-PrOH

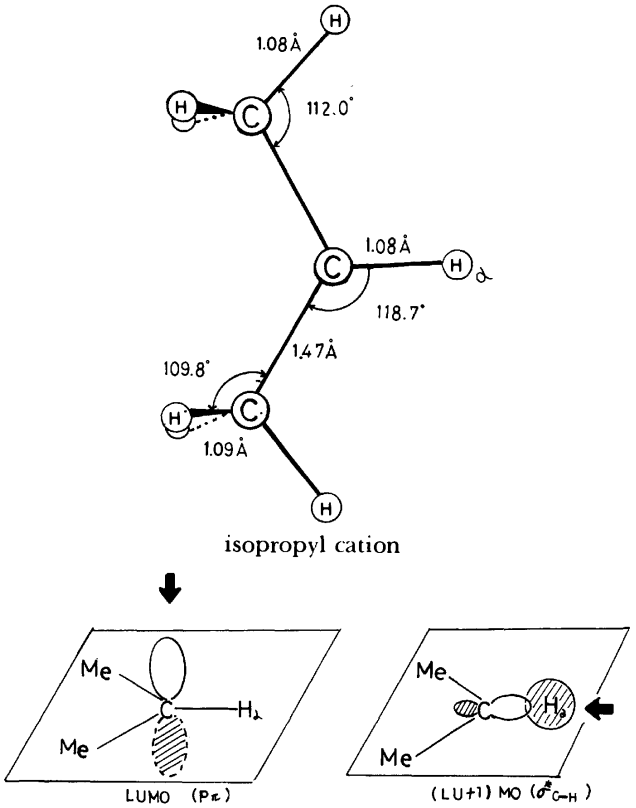


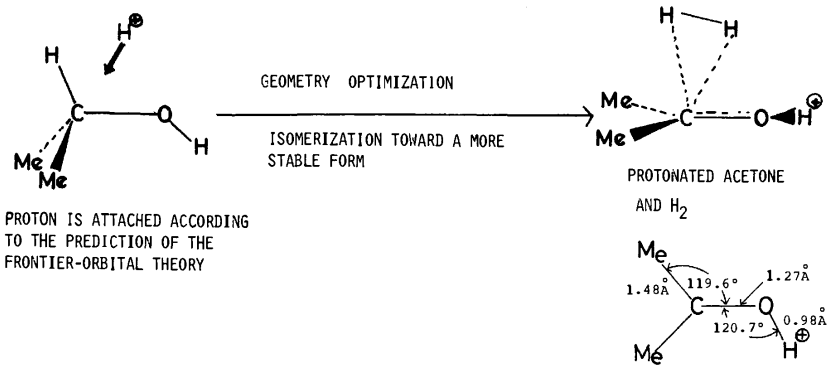
i-$PrOH_2^+$

By protonation of i-PrOH, the C-O bond is elongated, 1.45 Å→1.59 Å. The decrease of the C-O bond population, 0.24→0.05, is remarkable. This bond weakening suggests that the thermal decomposition of i-$PrOH_2^+$ to i-$C_3H_7^+$ and H_2O in reaction 15 shown later is likely as well as the proton transfer in reaction 11. It is natural that the proton should attack the oxygen atom of i-PrOH. However, it is a question whether the attacking pattern is exclusive or not. To examine this, the shape of the highest occupied MO, HOMO, and the next highest occupied MO, (HO−1)-MO of i-PrOH is drawn. The shape indicates that



the oxygen lone-pair electron is the best target for an electrophile (e.g., proton) and the next favorable site is the secondary carbon atom. The carbon may be





attacked by a proton. In the next sub-section, this reactivity is described.

$(CH_3)_2COH^+$ Ion m/z=59. The production of the ion m/z=59 from the ion/molecule reaction of i-PrOH is stated. As the case of i-$C_3H_7^+$, the initial rapid increase of this ion is due to the proton transfer reaction. What kind of species is formed by the protonation on the secondary carbon of i-PrOH? To answer this question, the geometry of the species is optimized with the MO of the 3-21G basis set. A following isomerization reaction is found during the optimization. That is, two C-H bonds begin to be cleaved to give a hydrogen molecule. This geometric change occurs without the energy barrier. The secondary carbon gets the electronic density from two methyl groups through the hyperconjugation and pushes out H_2 by the exchange repulsion. Thus, the ion m/z=59 is the protonated acetone. Three reactions, 12—14, are possible to form the protonated acetone. Their difference lies in the source of the proton.

$$H_3O^+ + i\text{-}C_3H_7OH \rightarrow (CH_3)_2COH^+ + H_2 + H_2O \qquad \Delta H^\circ = -17 \text{ kcal mol}^{-1} \quad (12)$$

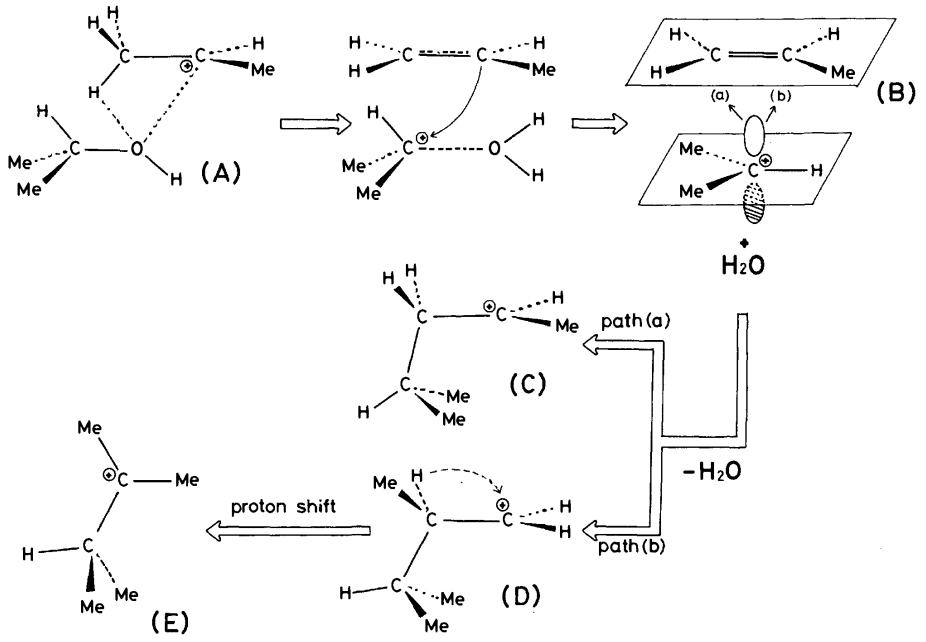
$$i\text{-}C_3H_7^+ + i\text{-}C_3H_7OH \rightarrow (CH_3)_2COH^+ + H_2 + C_3H_6 \qquad \Delta H^\circ = -3.9 \text{ kcal mol}^{-1} \quad (13)$$

$$i\text{-}C_3H_7OH_2^+ + i\text{-}C_3H_7OH \rightarrow (CH_3)_2COH^+ + H_2 + i\text{-}C_3H_7OH \qquad \Delta H^\circ = 7.3 \text{ kcal mol}^{-1} \quad (14)$$

Reaction 12 is more exothermic than reaction 10, however, the frontier orbital [(HO−1)MO or HOMO] of i-PrOH suggests that reaction 10 is more favorable than reaction 12. The ion-permanent dipole interaction between H_3O^+ and i-PrOH also favors reaction 10. This explains the greater initial increase of i-$C_3H_7^+$ than $(CH_3)_2COH^+$ (Fig. 1,a). Since reaction 14 is endothermic by 7.3 kcal mol^{-1}, the contribution of the reaction for the formation of protonated acetone is negligible under the present experimental conditions.

The gradual increase of the m/z=59 ion following the initial rapid growth is also observed (Fig. 1,a). Since the reactive ion which survives after 0.2 ms is i-$C_3H_7^+$, this ion is a possible precursor for the gradual formation of the m/z=59 ion in reaction 13.

The gradual decrease of i-$C_3H_7OH_2^+$ (mass 61) and i-$C_3H_7OH_2^+$ (i-C_3H_7OH) (mass 121) may be due to the consumption of these ions by the unimolecular decomposition reaction 15 of i-$C_3H_7OH_2^+$ at high temperatures.



Scheme 1.

$$i\text{-}C_3H_7OH_2^+ \rightarrow i\text{-}C_3H_7^+ + OH_2$$
$$\Delta H^\circ = 23.8 \text{ kcal mol}^{-1} \quad (15)$$

$C_6H_{13}^+$Ion m/z=85. The gradual growth of the m/z=85 ion, probably $C_6H_{13}^+$, is also observed as shown in Fig. 1,b. As in the case of the m/z=59 ion, no other probable candidates are conceivable for the precursor ions except for the i-$C_3H_7^+$ ion. It seems likely that the reaction of i-$C_3H_7^+$ with i-C_3H_7OH produces the $C_6H_{13}^+$ ion.

$$i\text{-}C_3H_7^+ + i\text{-}C_3H_7OH \rightarrow C_6H_{13}^+ + H_2O$$
$$\Delta H^\circ = -27 \text{ kcal mol}^{-1} \quad (16)$$

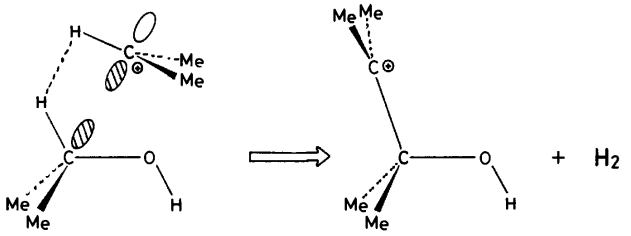
The mechanism for the $C_6H_{13}^+$ formation by reaction 16 may be described in Scheme 1. In the process of the elimination of H_2O in the associated complex **A**, the intermediate complex may have the structrure **B** in which i-$C_3H_7^+$ is interacting with propylene. According to the Markownikov rule, the less substituted sp^2 carbon in propylene may be attacked by the cation, i.e., the path (a). This leads to the formation of the secondary carbonium ion C. The enthalpy change of reaction 16 leading to the formation of C is calculated to be -9.7 kcal mol^{-1}. Here, the heat of formation of C is estimated to be 174 kcal mol^{-1} by the method proposed by Nakata and Kobayashi.[16] The species C has the structure of protonated 4-methyl-1-pentene, CH_2=CH-CH_2-$CH(CH_3)_2$. The proton affinity of this compound is expected to be much lower than that of i-PrOH.[17] Thus the rate constant of the proton transfer reaction $C_6H_{13}^+ + i\text{-PrOH} = i\text{-PrOH}_2^+ + C_6H_{12}$ may be of the order of 10^{-9} cm^3/molecule·s. From this value, the lifetime of the decay of the $C_6H_{13}^+$ ion due to the proton transfer reaction can be calculated to be $\approx$20 μs under the present experimental conditions. Since the condensation reactions such as reaction 16 are usually much slower than the collision rate ($\approx 10^{-9}$ cm^3/molecule·s), the steady state concentration of the ion C would become very low under the present experimental conditions. However, as shown in Fig. 1,b, $C_6H_{13}^+$ shows a gradual increase. This indicates that $C_6H_{13}^+$ has a much more stable structure than **C**. If the central sp^2 carbon of propylene is attacked by i-$C_3H_7^+$ and the hydrogen atom on it migrates to the terminal sp^2 carbon of propylene (path b), the tertiary carbonium ion **E** would be formed. From the calculated heat of formation of **E**, 156.7 kcal mol^{-1},[16] the enthalpy change of reaction 16 can be estimated to be -27 kcal mol^{-1}. E is about 17 kcal mol^{-1} more stable than C. **E** has the structure of protonated 2,3-dimethyl-1-butene, CH_2=$C(CH_3)CH(CH_3)_2$. Since the proton transfer reaction of $C_6H_{13}^+$(**E**) with i-PrOH is endothermic by about 7 kcal mol^{-1}, the long lifetime of $C_6H_{13}^+$(**E**) can be expected under the present experimental conditions. This explains the time profile of $C_6H_{13}^+$ shown in Fig. 1,b. Thus we would like to conclude that $C_6H_{13}^+$ has the structure E. It would be worthwhile noting that the nominal Markownikov rule may not be applied to the reactions of propylene (or terminal olefins) with the secondary carbonium ions. The rule is concerned usually with the orientation of the proton (electrophilic) addition to the double bond. However, when the electrophile is a large species with the secondary carbon, the rule would become exceptionally invalid. The present reaction seems to favor the formation of thermochemically more stable tertiary carbonium ions (by the anti-Markownikov rule) through the hydrogen migration in the intermediate complex.

The $C_6H_{13}^+$ ion starts to be observed at $\approx$180 °C and becomes a dominant ion at $\approx$300 °C. At higher temperature, its intensity decreases and becomes nil at $\approx$400 °C. Some finite lifetime for the intermediate complex of (i-$C_3H_7^+ \cdots i$-C_3H_7OH)* seems indispensable for the formation of $C_6H_{13}^+$ in the condensation reaction 16.

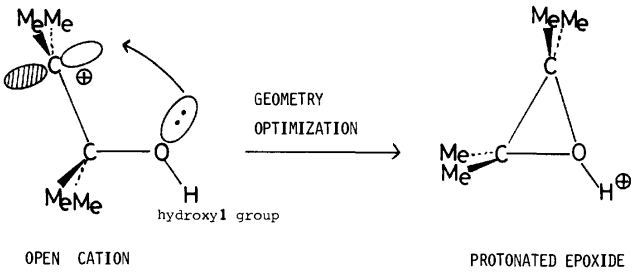
$C_6H_{13}O^+$ Ion m/z=101. The slow production of the m/z=101 ion in Figs. 1 and 2 may be explained by reaction 17.

$$i\text{-}C_3H_7^+ + i\text{-}C_3H_7OH \rightarrow C_6H_{13}O^+ + H_2 \quad (17)$$

Reaction 17 would consist of two steps. One is the H_2 elimination leading to the formation of the tertiary carbonium ion, $(CH_3)_2C^+$-$C(CH_3)_2OH$. The other is



the closure of the epoxide ring. During the optimization, the open cation is found to be converted smoothly to the protonated epoxide. The hydroxyl group cannot stay alone due to the intramolecular charge transfer.



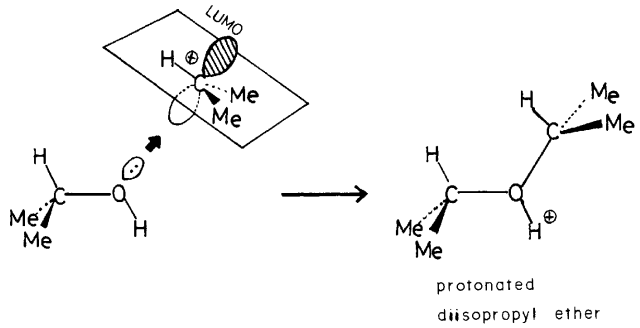
The minor product ion with m/z=83 may be produced from the dehydration of $C_6H_{13}O^+$.

$$C_6H_{13}O^+ \rightarrow C_6H_{11}^+ + H_2O \quad (18)$$

$(i\text{-}C_3H_7)_2OH^+$ Ion m/z=103. The $(i$-$C_3H_7)_2OH^+$ ion (mass 103) shows the initial rapid increase which is followed by the slow decrease (Fig. 1,b). Freeman[8] proposed the cationic chain reactions 2—4 for the formation of diisopropyl ether. The obtained experi-

mental results can be interpreted by the Freeman's proposal. The initial rapid increase of the $(i\text{-}C_3H_7)_2OH^+$ ion may be mainly due to reaction 2 and partly to reaction 19.

$$i\text{-}C_3H_7^+ + i\text{-}C_3H_7OH \xrightarrow{M} (i\text{-}C_3H_7)_2OH^+ \quad (19)$$

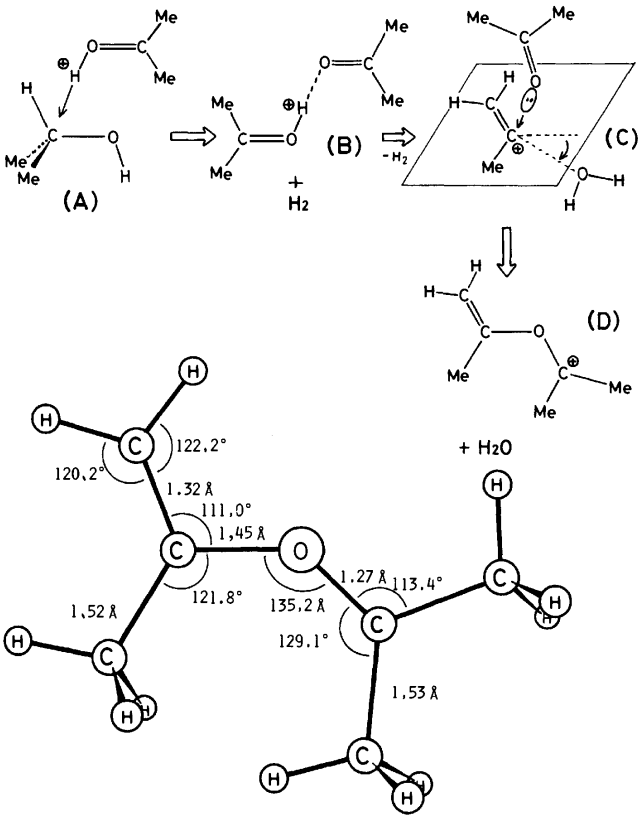


The slow decrease of $(i\text{-}C_3H_7)_2OH^+$ may be due to reactions 3 and 4. The contribution of the direct proton transfer reaction 20 may be negligible, because the reaction is highly endothermic.

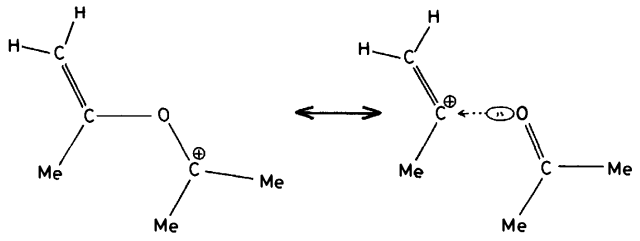
$$(i\text{-}C_3H_7)_2OH^+ + i\text{-}C_3H_7OH \rightarrow i\text{-}C_3H_7OH_2^+ + (i\text{-}C_3H_7)_2O$$
$$\Delta H^\circ = 15.2 \text{ kcal mol}^{-1} \quad (20)$$

$C_6H_{13}O_2^+$ and $C_6H_{11}O^+$ Ions m/z=117 and 99. Strong growths of m/z=117 and 99 ions are observed in Fig. 2,b. The $(CH_3)_2COH^+$ ion as a precursor may explain the formation of these ions.

$$(CH_3)_2COH^+ + i\text{-}C_3H_7OH \rightarrow C_6H_{13}O_2^+ + H_2 \quad (21)$$
$$(CH_3)_2COH^+ + i\text{-}C_3H_7OH \rightarrow C_6H_{11}O^+ + H_2 + H_2O \quad (22)$$



The attack of the secondary carbon of i-PrOH by the protonated acetone yields the proton-held acetone dimer cation (m/z=117) (**A**→**B**). This reaction may be followed by the dehydration to give the m/z=99 ion. The dehydration involves two mechanisms. One is the keto-enol isomerization of the protonated acetone. The other is the subsequent attack of acetone onto the unsaturated carbon of the enol form in C. The latter reaction is similar to the nucleophilic displacement on the carbonyl carbon. It is well known that the $C_6H_{11}O^+$ ion with m/z=99 is formed from the ion/molecule reactions in gaseous acetone.[18-20] We think that this ion D is produced by the same mechanism as shown above. It is noteworthy that the length of the C$^+$-O bond is 1.27 Å in the optimized geometry of D. The double bond makes the cationic nature small, leading to the stability of the species. The geometry of the m/z=99 ion is described by the resonance structure.



Freeman[8,9] found that the isopropyl alcohol vapor starts to suffer the thermal decomposition on the wall of the reaction vessel above ≈300 °C. It would be possible that $(CH_3)_2COH^+$ (mass 59) and $(CH_3)_2COH^+ \cdots OC(CH_3)_2$ (mass 117) ions observed in Fig. 2 originate from the acetone produced from the thermal decomposition of i-PrOH in the reaction chamber. If this was the case, acetone should exist in the system regardless of the presence or absence of the H_2O vapor. However, the m/z=117 ion could not be detected in Fig. 1 where the H_2O vapor is present in the system. This clearly indicates that the m/z=59 and 117 ions in Fig. 2 are produced from the ion/molecule reactions in gaseous i-PrOH. In Figs. 3 and 4, the situation is more serious since the ion source temperature is high (≈400 °C). If an appreciable amount of acetone were produced, all the protonated species should be quickly converted to the protonated acetone due to the high proton affinity of acetone. However, the steady concentrations of ions such as $H_3O^+(H_2O)$ and i-$C_3H_7^+$ are established in Fig. 3. It is likely that the thermal decomposition of i-PrOH toward acetone is negligible under the present experimental conditions.

It is of interest to note that the $C_6H_{11}O^+$ ion (mass 99) is observed in Fig. 4, but not in Fig. 3. The presence of H_2O vapor seems to suppress the formation of this ion. It is described that the $C_6H_{11}O^+$ ion is produced through the formation of several intermediate complexes such as **A**—**C**. When such intermediate complexes are formed in the atmosphere of highly polar H_2O vapor, the neutral species in the

complex may suffer the displacement reaction with an H_2O molecule. For example, the loose complex of $(CH_3)_2COH^+ \cdots i\text{-}C_3H_7OH$ (A) may be converted to $(CH_3)_2COH^+ \cdots OH_2$ by the displacement reaction, $(CH_3)_2COH^+ \cdots i\text{-}C_3H_7OH + H_2O \rightarrow (CH_3)_2COH^+ \cdots OH_2 + i\text{-}C_3H_7OH$. Such reactions of intermediate complexes may interrupt the formation of the $C_6H_{11}O^+$ ion. This also explains the absence of the m/z=99 and 117 ions in Fig. 1. This kind of reactions may become important when the lifetimes of the intermediate complexes are long enough that the complexes suffer multiple collisions with third-body gas molecules. The destruction of the complex, A, B, or C by a water molecule may be regarded as a solvent effect in the gas-phase ion/molecule reactions.

$C_3H_7^+$ Ion Re-Visited. After the rapid decrease, the intensity of $i\text{-}C_3H_7^+$ becomes time-independent as shown in Figs. 1—4. The rapid consumption of the ion is mainly due to reaction 23, proton transfer.

$$i\text{-}C_3H_7^+ + i\text{-}C_3H_7OH \rightarrow i\text{-}C_3H_7OH_2^+ + C_3H_6 \qquad \Delta H^\circ = -11.7 \text{ kcal mol}^{-1} \quad (23)$$

The contribution of reactions 13, 16, 17, and 19 may be relatively minor compared to that of reaction 23. The lifetime of $i\text{-}C_3H_7^+$ due to reaction 23 is estimated to be less than 20 μs under the present experimental conditions. Since the steady-state concentration is established for $i\text{-}C_3H_7^+$, the rate of the regeneration of $i\text{-}C_3H_7^+$ by reaction 15 must be comparable to that of the consumption by reaction 23.

Van der Linde and Freeman[9] proposed the radical chain reactions 5—8 for the formation of H_2, $(CH_3)_2CO$, and C_3H_6 in the γ-radiation-sensitized pyrolysis of gaseous i-PrOH. In the present experiments, the strong growth of $(CH_3)_2COH^+$ is observed at high temperatures in ion/molecule reactions in gaseous i-PrOH. Alternative cationic chain reactions 13, 24, and 15 may be possible for the formation of $(CH_3)_2CO$ and H_2 in the γ-radiation-sensitized pyrolysis of gaseous i-PrOH.

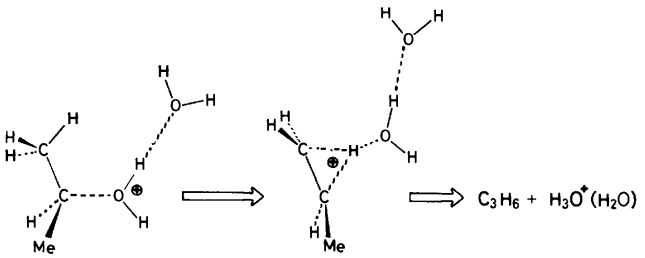
$$(CH_3)_2COH^+ + i\text{-}C_3H_7OH \rightarrow i\text{-}C_3H_7OH_2^+ + (CH_3)_2CO \qquad \Delta H^\circ = 5.5 \text{ kcal mol}^{-1} \quad (24)$$

Besides, the rapid chain reactions 23 and 15 for the formation of C_3H_6 are established at high temperatures in gaseous i-PrOH. The formation of C_3H_6 in the γ-radiation-sensitized pyrolysis of i-PrOH could also be accounted for by the cationic chain reactions 23 and 15.

It would be of great interest to measure the temperature dependences of the rate constants of reactions 13, 16, etc., and determine the energy barriers for the corresponding reactions. However, the measurements of the rate constants for these reactions are difficult due to the regeneration of the $i\text{-}C_3H_7^+$ ion by reaction 15. Besides, the product ions such as $(CH_3)_2COH^+$ and $C_6H_{13}^+$ are slowly consumed by the proton transfer reactions with i-PrOH. This also makes the kinetic measurements difficult. Thus we are discouraged to perform the detailed measurements of rate constants to obtain the meaningful information on the reaction kinetics.

Acid-Catalyzed Dehydration Reaction of $i\text{-}C_3H_7OH$. It should be noted that the steady-state concentration of $H_3O^+(H_2O)$ (m/z=37) is established in Fig. 3. If the $H_3O^+(H_2O)$ ion establishes the equilibrium with H_3O^+, the concentration ratio of $H_3O^+(H_2O)/H_3O^+$ can be estimated to be about 3 to 1 under the present experimental conditions. Thus, the $H_3O^+(H_2O)_n$ ions should be rapidly converted to $i\text{-}C_3H_7OH_2^+$ by the proton transfer reaction 11. The expected lifetime of $H_3O^+(H_2O)_n$ is less than 100 μs under the present experimental conditions. The steady appearance of $H_3O^+(H_2O)$ indicates that the $H_3O^+(H_2O)$ ion is quickly reproduced from some ion/molecule reactions. The regeneration of $H_3O^+(H_2O)$ may be due to reaction 25.

$$i\text{-}C_3H_7OH_2^+ + H_2O \rightarrow H_3O^+(H_2O) + C_3H_6 \qquad \Delta H^\circ = 2 \text{ kcal mol}^{-1} \quad (25)$$

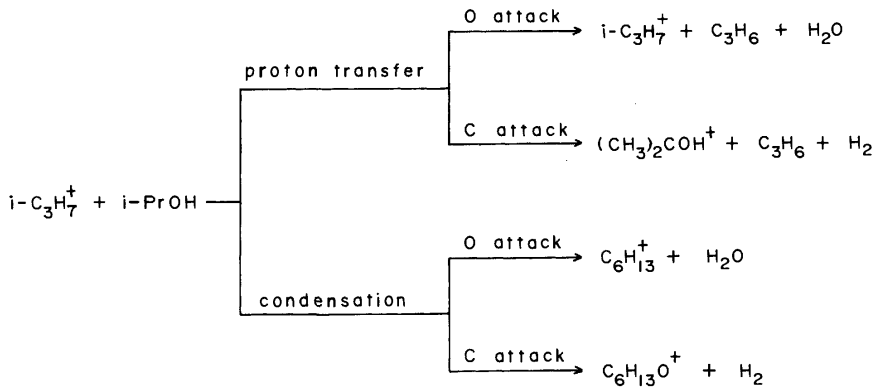


The $i\text{-}C_3H_7OH_2^+$ ion produced from reaction 23 decomposes unimolecularly to produce $i\text{-}C_3H_7^+$. When the $i\text{-}C_3H_7OH_2^+$ ion collides with an H_2O molecule within its lifetime, the dehydration of $i\text{-}C_3H_7OH_2^+$ may take place. Since the product ion $H_3O^+(H_2O)$ from reaction 25 reproduces the $i\text{-}C_3H_7OH_2^+$ ion by reaction 11, H_2O acts as a catalyst for the formation of propylene. Reaction 25 is analogous to acid-catalyzed dehydration of alcohols in solution. A similar reaction is also found for t-butyl alcohol in the gas phase.[10]

Summary and Conclusion

The positive ion/molecule reactions in gaseous isopropyl alcohol were studied in detail. The new information obtained in the present work may be summarized as follows.

1) The isopropyl alcohol has two reactive sites for the nucleophilic reactions, i.e., the oxygen atom and the secondary carbon atom. The protonations onto the O and s-C atom yield $i\text{-}C_3H_7^+$ and $(CH_3)_2COH^+$ ion, respectively. The condensation reactions of $i\text{-}C_3H_7^+$ with i-PrOH leads to the formation of $C_6H_{13}^+$ and $C_{16}H_{13}O^+$ ion. The reactions of $i\text{-}C_3H_7^+$ with i-PrOH may be summarized as the Scheme 1.



2) The condensation reactions of the secondary product ion $(CH_3)_2COH^+$ with *i*-PrOH produce $C_6H_{13}O_2^+$ and $C_6H_{11}O^+$ ion. The $C_6H_{13}O_2^+$ ion may have the structure of the proton-bound acetone dimer cations. The dehydration of $C_6H_{13}O_2^+$ yields $C_6H_{11}O^+$ through the keto-enol isomerization of the protonated acetone molecule in the complex $C_6H_{13}O_2^+$. The $C_6H_{11}O^+$ ion (m/z=99) is known to be one of the major product ions from the gas-phase ion/molecule reactions in acetone.[18-21] We think that this ion has the same structure as the one produced in the present system. It was found that the presence of H_2O in the system greatly suppresses the formation of $C_6H_{13}O_2^+$ and $C_6H_{11}O^+$ ion. This may be due to the displacement reactions of the intermediate ions with the H_2O molecule. This may be regarded as the solvent effect in the gas-phase ion/molecule reactions.

3) The acid-catalyzed dehydration reaction, $i\text{-}C_3H_7OH_2^+ + H_2O \rightarrow H_3O^+(H_2O) + C_3H_6$, was observed. The similar reaction has also been observed for *t*-C_4H_9OH but at much lower temperature.[10]

4) Acetone and propylene are produced with high *G* values from the γ-radiation-sensitized pyrolysis of *i*-PrOH vapor.[7-9] The formation of these compounds may be explained by the cationic chain reactions 13, 24, 23, and 15. The radical chain reactions 5—8 suggested by van der Linde and Freeman[9] for the formation of these compounds are not unique because the rate constants of hydrogen abstraction reactions such as reactions 5 and 7 are relatively small.[22]

5) The Markownikov rule may not be applied to the reactions of terminal olefins with the secondary carbonium ions. When the electrophile is a large secondary carbonium ion, the reaction seems to favor the formation of thermochemically more stable tertiary carbonium ion through the hydrogen migration in the intermediate complex.

One of the authors (KH) thanks Mr. Yukio Chino of the Yamanashi University for making the ion source used in this experiment. The financial supports of the Grant-in-Aid from the Ministry of Education and of the 1st Morino Trust for Molecular Science are gratefully acknowledged.

MO calculations were carried out on the FACOM M-382 computer at the Data Processing Center of Kyoto University and on the HITAC M-200H computer at the Institute for Molecular Science.

(Received December 25, 1986)

The structures of the Langmuir-Blodgett (LB) films of the ordinary mixed monolayer (LPF) and the supermonomolecular layer (HPF) of a surface active squarylium dye-icosanoic acid binary mixed system were examined by absorption spectroscopy. The absorption spectra of one unit layer of LPF with a molar mixing ratio ranging from 1/10 to 1/1 were almost the same, strongly suggesting that each component exists separately in the films. The LB films of two unit layers of LPF showed two peaks at 590 and 560 nm ascribed to intralayer and interlayer aggregates, respectively, besides the monomeric peak at 640 nm. The absorption spectra of one unit layer of HPF indicated a critical value of the mixing ratio 1/3.5 above which the 700-nm peak is observed. This peak is an indication of a multilayer consisting of pure **1** due to the interlayer interaction. The 560-nm peak observed for LPF is caused by a hindered interlayer interaction of the chromophores between the mixed monolayers.

Recently, the vacuum-deposited films of squarylium dyes have been investigated from the viewpoint of photovoltaic properties, whose quantum yields are high and depend not only upon the structure of the chromophore itself but also upon the packing of molecules involving intermolecular interaction and aggregate formation.[1-4] Two polymorphs are observed for a squarylium dye.[5,6] A change in the crystal form is considered to be the reason for the quick deterioration of the high solar energy conversion efficiency.[1] It is therefore important to develop a technique to obtain the desired aggregate structure.

In order to construct a system with the desired structure, i.e., suitable arrangement of molecules and aggregate formation, the Langmuir-Blodgett (LB) technique is one of the most powerful tools.[7] This technique contains a process in which a condensed phase at the air-water interface is deposited onto a substrate. Consequently, it is quite important to obtain a condensed phase with the desired structure. The desired structure is not necessarily limited to the typical condensed monolayer. In a previous paper,[8] we pointed out the technical importance of the supermonomolecular layer defined as an ordered multilayer at the gas-liquid interface.

Indeed, many studies have been categorized as concerning the supermonomolecular layer. For instance, the formation of ordered multilayers of some polypeptides at the air-water interface was observed when compressed under appropriate surface pressures.[9-11] As for 1-octadecanol, octadecanoic acid, and substituted phthalocyanine, the use of different spreading solvents leads to various structures of the condensed phases at an air-water interface.[12-15] A stable multilayer is obtained when a class of water-soluble azobenzene amphiphiles form complexes with polyanion.[16] Even more interesting are the cases where surface active azo dyes were squeezed out of the fatty acid matrices.[17,18] Selective squeezing-out of dye molecules from the mixed layer was, however, estimated mainly from *F-A* isotherms and molecular models, and the structure of the subsequent supermonomolecular layer has not yet been fully understood.

We have found, for surface active squarylium dye-fatty acid binary mixed system, that an ordinary mixed monolayer is formed under lower surface pressures (ca. 25 $mN\,m^{-1}$), and that higher surface pressures (ca. 40 $mN\,m^{-1}$) result in the supermonomolecular structure.[8,19] The structure of the supermonomolecular layer with the mixing ratio of 1/5 is characterized as a bilayer stack of a cadmium icosanoate monolayer and monolayer islands of the dye molecules squeezed out under the icosanoate monolayer. The dye molecules exist in such a manner that they are attached to the icosanoate matrix with their hydrophobic carbon chains and that the long axis of the chromophore is parallel to the film surface.

In this report, LB films with various mixing ratios were examined by absorption spectroscopy in order to clarify the supermonomolecular structure.

Experimental

The surface active squarylium dye, 2,4-bis[3,3-dimethyl-1-octadecyl-2(3*H*)-indolylidenemethyl]-1,3-cyclobutadienediylium-1,3-diolate, (**1**) was synthesized as previously described.[20] Icosanoic acid was purchased from Eastman Kodak Co. and used without further purification. Experimental conditions where LB films were prepared were the same as those in the previous reports.[8,19] Icosanoic acid was converted to cadmium icosanoate (**2**) upon the subphase containing 4.0×10^{-4} mol dm^{-3} of $CdCl_2$ and 5.0×10^{-5} mol dm^{-3} of $KHCO_3$. Mixed LB films deposited at 25 $mN\,m^{-1}$ and at 40 $mN\,m^{-1}$ are hereafter referred to as LPF and HPF, respectively. The molar mixing ratio r of mixed LB films of **1** and **2** was in the range of 1/10 to 1/1. Absorption spectra of the deposited films were taken by differential spectroscopy,

using the method of Kuhn et al.[21] Polarized absorption spectra were measured under four conditions described previously;[22] an incident angle of 45 or 90° to the film surface, and the electric field of the incident light parallel or normal to the dipping direction. The polarized spectra showed that all the transition moments discussed below were alomst parallel to the film surface. Absorption spectra of the solutions were measured by use of the Cary 17 DX spectrometer.

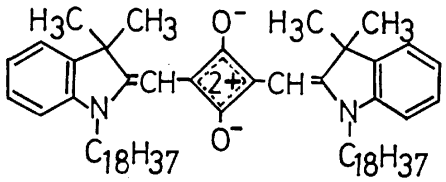
Results and Discussion

Two Condensed Phases at Air-Water Interface. Figure 1 shows *F-A* isotherms of **1** (curve g), **2** (curve a), and mixed layers of **1** and **2** with the mixing ratio r ranging from 1/10 to 1/1 (curves b—f). A common feature is observed for mixed layers: the first condensed phase at ca. 20—30 mN m^{-1}, the plateau region at ca. 30 mN m^{-1}, the second condensed phase at ca. 30—60 mN m^{-1}, and finally the collapse point at ca. 60 mN m^{-1}. The observed plateau region can be attributed to a transition from a monolayer in the first condensed phase to a multilayer in the second condensed phase.[9]

The mean area per molecule, s, is expressed as

$$s=(rs_1+s_2)/(r+1), \quad (1)$$

where s_1 and s_2 are the areas per molecule of **1** and **2**, respectively. On the plausible assumption of s_2 as 0.020 nm^2, even in the mixed layers,[8,19] the values of s_1 obtained were independent of the mixing ratio: 0.70 and nearly 0 nm^2 at 25 and 40 mN m^{-1}, respectively.



1

The former value is consistent with the molecular model when the chromophore is oriented with the long axis parallel and the short axis perpendicular to the surface. This fact indicates that an ordinary mixed monolayer is formed in the first condensed phase. In other words, the occupied area is governed by both **1** and **2**.

On the other hand, the value of s_1 (0 nm^2) under higher surface pressures indicates that the occupied area is governed by **2** alone. This strongly suggests the presence of a monolayer of **2**, which is supported by the same collapse pressure of the mixed layers with that of the monolayer of **2** (curve a). Absorption spectra of HPF with r=1/5 gave the model for the supermonomolecular structure.[19] This model for the squeezing-out is supported by the fact that the *F-A* isotherm of pure **1** (curve g) also shows a plateau region at ca. 30 mN m^{-1} which is almost identical with that for the onset of the plateau region for the mixed layers. The large plateau region for pure **1** (curve g) suggests that the molecules **1** tend to form a multilayer at air-water interface without any detectable rise in surface pressure.

The area occupied by HPF is ns_2' where n is the number of the molecule **2** in the mixed films and s_2' is the area per molecule of **2** at 25 mN m^{-1} (0.20 nm^2). If the squeezed-out molecules of **1** in the above film form a monolayer under the monolayer of **2**, the area occupied by **1** will be nrs_1' where s_1' is the area per molecule of **1** at 25 mN m^{-1} (0.70 nm^2). The fact that the area is governed by ns_2' suggests that the layer of the squeezed-out molecules of **1** becomes a multilayer when $nrs_1'>ns_2'$ ($r>s_2'/s_1'$=1/3.5).

Four Types of LB Films. In order to examine the supermonomolecular structure more precisely, four types of mixed LB films were prepared for each mixing ratio. Figure 2 shows a schematic view of one or two unit layers of LPF in the first condensed phase or HPF

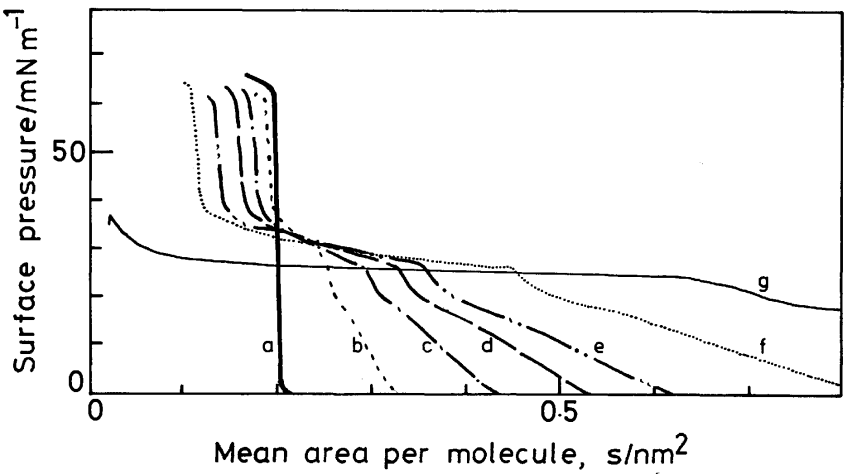


Fig. 1. Surface pressure-area isotherms of **1**, **2**, and mixed layers of **1** and **2**. a: r=0 (pure **2**), b: r=1/10, c: r=1/5, d: r=1/3, e: r=1/2, f: r=1/1, g: pure **1**. The data of a—f were reproduced from Ref. 19 by permission of Elsevier Sequoia, Lausanne.

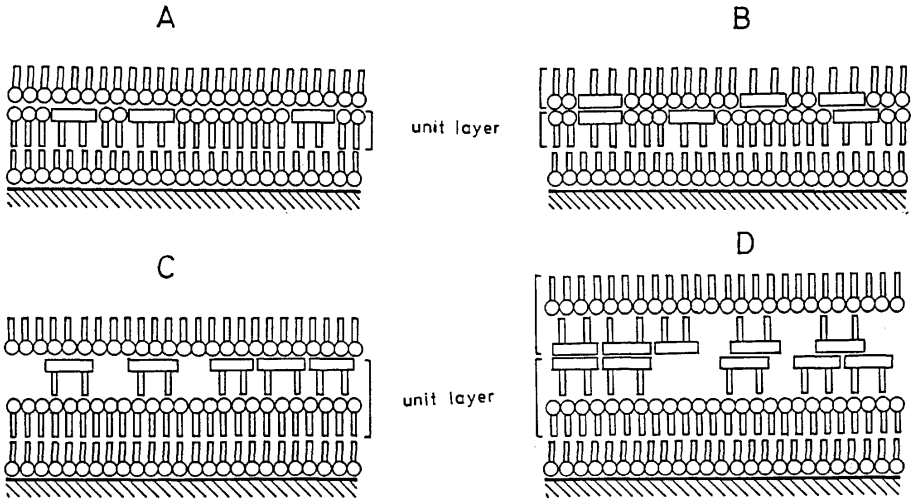

Fig. 2. Schematic view of the LB films of LPF and HPF with the mixing ratio of 1/5 deposited on a glass slide precoated with five monolayers of **2**. Only one monolayer of **2** is drawn in each case for simplicity. A: One unit layer of LPF followed by deposition of one monolayer of **2**, B: two unit layers of LPF, C: one unit layer of HPF followed by deposition of one monolayer of **2**, D: two unit layers of HPF.

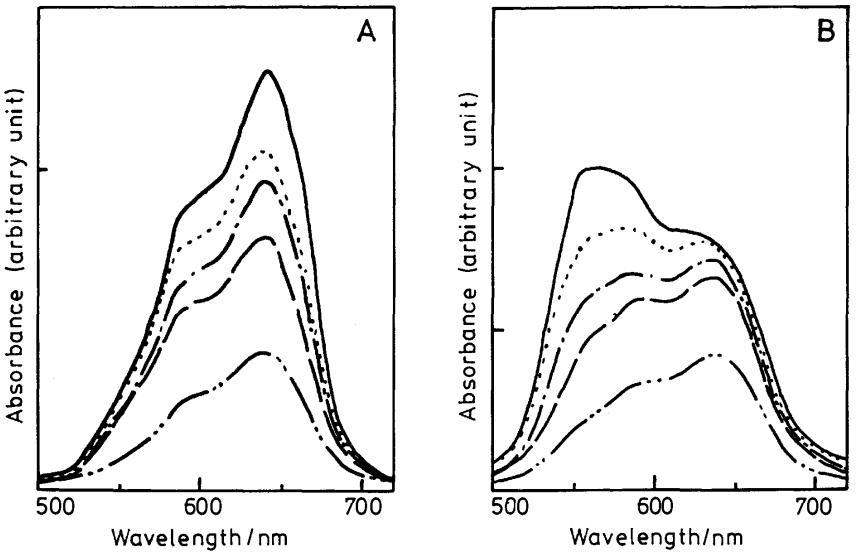

Fig. 3. Absorption spectra of one unit layer (A) and two unit layers (B) of LPF with various mixing ratios.
——: r=1/1, ·····: r=1/2, -·-·-: r=1/3, ----: r=1/5, -·····-: r=1/10.

in the second condensed phase with the mixing ratio of 1/5 deposited on a glass slide precoated with five monolayers of **2**. Only one monolayer of **2** is drawn in each case in Fig. 2 for simplicity.

In case A, where one unit layer of LPF is deposited on a substrate followed by deposition of one monolayer of **2**, the formation of chromophore aggregates is restricted within the same plane. Therefore, isolated molecules and intralayer aggregates with their characteristic spectra may be detected. In the case B, where two unit layers of LPF are deposited, there is a possibility of interlayer chromophore aggregation. Consequently, interlayer aggregates may be observed in addition to isolated molecules and intralayer aggregates. As is seen in this figure, LPF is an ordinary mixed monolayer whose occupied area is governed by both **1** and **2**.

In the cases C and D where one and two unit layers of HPF are deposited, respectively, the structures are quite different from those in the above two. HPF consists of dye and cadmium icosanoate segregated from each other into different layers. This gives rise to aggregates different from those in the cases A and B. The occupied area of HPF is, as is seen, governed by **2** alone.

One Unit Layer of LPF (Case A). Figure 3A shows the absorption spectra of one unit layer of LPF. Almost the same spectral patterns were observed for

LPF with r ranging from 1/10 to 1/1. This fact strongly suggests that the molecules **1** are immiscible with the molecules **2** and that each component exists separately in the form of domains.

Each peak value of absorbance,I, was proportional to the area fraction of **1** in the film plane (Fig. 4). This is expressed by

$$I=I_0 rs_1'/(rs_1'+s_2'), \quad (2)$$

where I_0 is the limiting value of I when the area fraction approaches unity. This proportional relationship indicates that **1** was not dissolved into the subphase and supports the structure of the ordinary mixed monolayer.

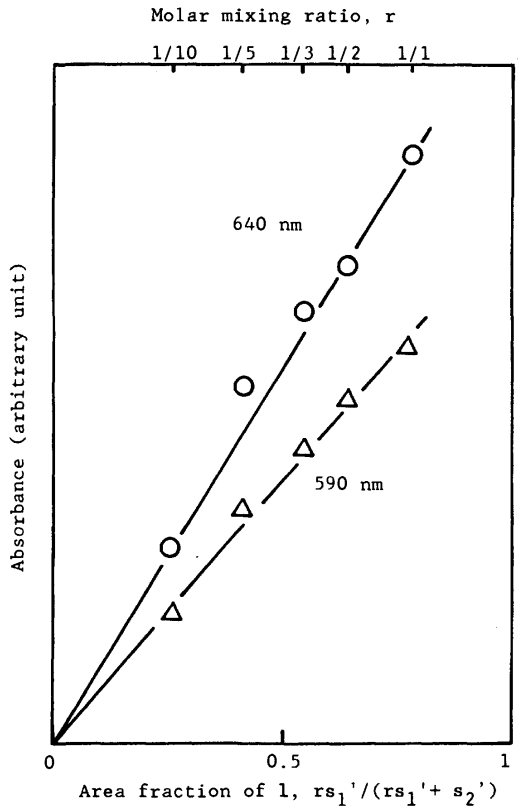

Fig. 4. Absorbance of one unit layer of LPF at each peak position as a function of area fraction of **1**. The molar mixing ratio is also shown.
○: 640 nm, △: 590 nm.

The absorption spectra of **1** in $CHCl_3$ solution ranging in concentration from 4.5×10^{-8} to 1.0×10^{-3} mol dm^{-3} show a main peak at ca. 640 nm (The full width at half maximum is ca. 20 nm.) and a shoulder at ca. 590 nm. The 640-nm peak and the 590-nm peak as well are attributed to isolated molecules. The absorbance ratio of the latter to the former is ca. 0.2 irrespective of concentration. This indicates that these two peaks are a vibronic progression.[23,24]

In contrast to the case of chloroform solutions, the 590-nm peak observed for LB films will be ascribed to an aggregate by the following reasons, although we cannot deny the contribution from the vibronic state. Firstly, the 590-nm peak is also observed even when the monomeric peak at 640 nm is hardly found (shown later in Fig. 5B). Secondly. the absorbance ratio of the 590-nm peak to the 640-nm peak is ca. 0.7, which is much larger than the value observed in solution. Therefore, we assume that the 590-nm peak mainly originates from the side-by-side structure of the aggregate[25] formed through intralayer interaction, since the origin of the 590-nm peak does not change the context significantly.

Studies with polarized light indicated that the transition moments for both 590-nm and 640-nm peaks lie statistically in the layer plane.

Two Unit Layers of LPF (Case B). The absorption spectra of two unit layers of LPF are depicted in Fig.

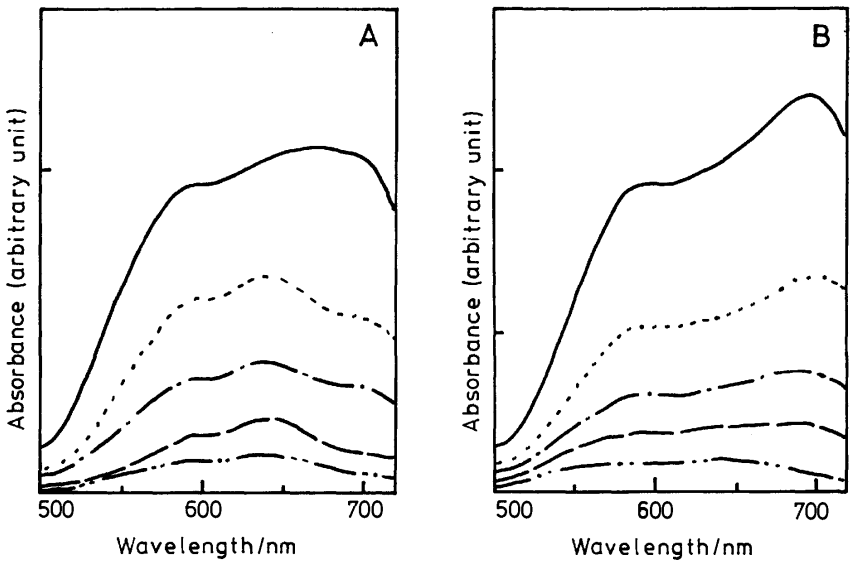

Fig. 5. Absorption spectra of one unit layer (A) and two unit layers (B) of HPF with various mixing ratios.
——: r=1/1, ·····: r=1/2, -·-·-: r=1/3, – – –: r=1/5, -·····-: r=1/10.

3B. In this case, both intralayer and interlayer aggregates have the possibility of being formed. Actually, evidence for an interlayer aggregate is clearly shown in the spectra. The 560-nm peak becomes prominent with an increase in the r value, which is presumably caused by the increasing occurrence of the interlayer interaction between two chromophores located in adjacent unit layers. Therefore, this peak is ascribed to the side-by-side structure of the aggregate through interlayer interaction.[26]

Polarized spectra indicated that the transition moments for the 590-nm and the 640-nm peaks lie statistically in the film plane, whereas that of the interlayer aggregate prefers the arrangement parallel to the dipping direction (absorbance ratio of 1.2—1.3). This suggests that the chromophores are slightly rearranged during or after the deposition process when the interlayer interaction of the chromophores occurs.

One Unit Layer of HPF (Case C). Figure 5A shows the absorption spectra of one unit layer of HPF. In the case of $r>s_2'/s_1'=1/3.5$, the excessive **1** should be squeezed out of the monolayer of **1** to form a complicated multilayer, since otherwise the area must be governed by nrs_1'. This structural change with r value is schematically shown in Fig. 6.

This change is clearly detected in the absorption spectra, which is strong evidence for the validity of the supermonomolecular structure. With an increase in the r value, the monomeric peak at 640 nm is relatively suppressed and the 700-nm peak emerges instead of the 560-nm peak observed for LPF. The 700-nm peak is observed only when r is higher than the critical value of 1/3.5. This peak is an indication of a multilayer consisting of pure **1**. The 700-nm peak indicates the aggregate involving end-to-end interaction[25] or J-aggregate[27] induced by interlayer interaction within the multilayer region consisting of pure **1**.

Studies with polarized light showed that the transition moment of the above aggregate also has the tendency to be oriented parallel to the dipping direction (absorbance ratio of 1.3—1.4). This again suggests a slight rearrangement of the chromophores during or after the deposition process. The transition moments for the other peaks lie statistically in the film plane.

Two Unit Layers of HPF (Case D). The absorption spectra of two unit layers of HPF are shown in Fig. 5B. The feature of the similar spectral patterns for samples with r ranging from 1/5 to 1/1 should be noted. Two peaks are observed at 590 and 700 nm, whereas the monomeric peak at 640 nm and the 560-nm peak are hardly to be seen.

The supermonomolecular structure is supported by the absorbances at peak positions for samples with r ranging from 1/5 to 1/1. If the structures shown in Fig. 6 are valid, the absorbances should be proportional to the number of the molecule **1** per unit area because the spectral patterns are similar for these samples. The number of the molecule **1** per unit area is nr/ns_2'. Therefore, the absorbances I' should obey the following equation:

$$I'=rI_0', \tag{3}$$

where I_0' is the absorbance when r equals unity. This relationship is clearly seen in Fig. 7. This figure includes the points for the sample with r=1/10. It is noted that the point for the 700-nm peak is signifi-

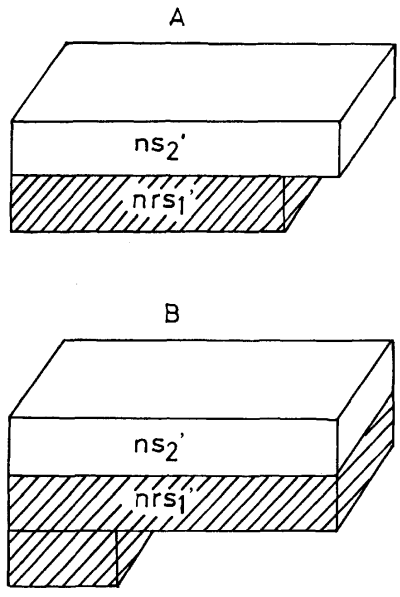

Fig. 6. Schematic view of the structural change of one unit layer of HPF with r value. The portions with and without hatches represent the layers composed of pure dye **1** and pure **2**, respectively. A: $nrs_1' \leqq ns_2'$ ($r \leqq 0.20/0.70$), B: $nrs_1' > ns_2'$ ($r > 0.20/0.70$). When r is small, the supermonomolecular structure is a bilayer as shown in A, while the excessive **1** and the bilayer should form a complicated multilayer in the case of $r>1/3.5$.

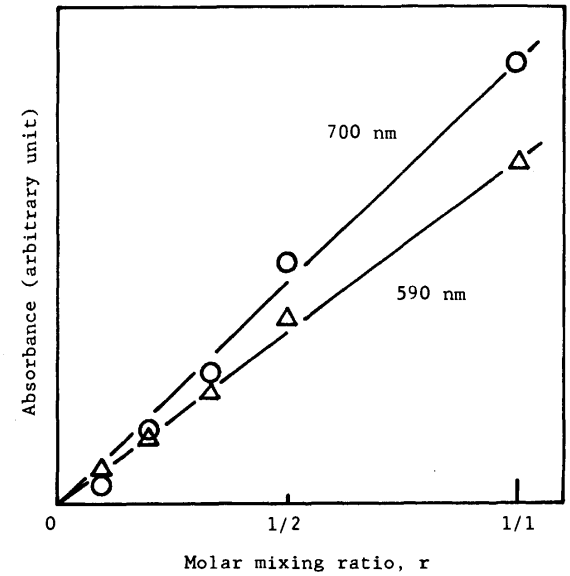

Fig. 7. Absorbance of two unit layers of HPF at each peak position as a function of the mixing ratio r. O: 700 nm, Δ: 590 nm.

cantly deviated under the straight line. Equation 3 also indicates that **1** was not dissolved into the subphase even when compressed under higher surface pressures.

The two observed peaks are attributed to two different aggregates, as opposed to the single herringbone structure whose unit cell contains two chromophores and which possesses two allowed transitions.[24,28] This is concluded by the fact that the 590-nm peak is also observed for the case of intralayer interaction in LPF, while the 700-nm peak is found only when the multilayer consisting of pure **1** is formed. Furthermore, the transition moment for the 590-nm peak lies statistically in the film plane, while that for the 700-nm peak has a preference of being oriented to the dipping direction (absorbance ratio of 1.3—1.4). This is quite contradictory to a herringbone structure, where two allowed transitions are governed by one and the same distribution of the aggregate. In other words, if a random distribution in a plane is the case with one transition moment, this applies also to the other.

The relationship of Eq. 3 suggests that the relative ratio of occurrence of the two aggregates remains invariant for HPF with higher mixing ratios (1/5—1/1), i.e., the equilibrium between the two aggregates is held in the multilayer region consisting of pure **1**. As for HPF with r=1/10, the 700-nm peak is almost extinguished and the broad band covering from 550 to 650 nm remains. This suggests that the 700-nm peak is attributable to a larger aggregate than the 590-nm peak since HPF with r=/10 would have a considerable fraction of area which is not occupied by **1** in the mutilayer region of pure **1**.

The aggregates in HPF containing multilayers of pure **1** (case C with $r \geqq 1/3$ and case D with $r \geqq 1/5$) are not the same as those in LPF consisting of multilayers diluted by **2** (case B with all values of r studied). This is reflected in the fact that the 700-nm peak emerges only for the former films and that the 560-nm peak is observed only for the latter films. The chromophores of the dyes are subjected to interlayer interaction for both cases. In contrast to the former films, however, this is more or less hindered by the molecules **2** for the latter films.

In conclusion, the desired aggregates can be obtained by the control of mixing ratio and surface pressure, which is useful in constructing molecular organizates. The method employed in this work will serve as means for clarifying other supermonomolecular structures involving interlayer interaction between chromophores.

We would like to thank Professor Kiyoshige Fukuda and Dr. Hiroo Nakahara of Saitama University for helpful comments. We also acknowledge Dr. Shinichi Kuroda, Dr. Keiichi Ikegami, and Dr. Koichi Honda for stimulating discussions.

Time-Resolved Unimolecular Fragmentations of $C_3H_7O^+$ Ions

Ryuichi ARAKAWA* and Yozaburo YOSHIKAWA
Institute of Chemistry, College of General Education, Osaka University, Osaka 560
(Received December 26, 1986)

The unimolecular dissociations of the $C_3H_7O^+$ ions produced by the dissociative ionization of *t*-butyl and *s*-butyl alcohols have been studied by means of trapped ion mass spectrometry(TIMS). The metastable peak intensities for two competing formations of $C_3H_5^+$ and CH_3O^+ have been measured for the ion lifetimes of 0—50 μs. Also, the shifts of the electron-ionization-efficiency(EIE) curves for these ions have been observed between the ion-storage times of 2 and 800 μs. These data have then been fitted by means of QET model calculations. The dissociation paths of $C_3H_7O^+$ can be interpreted without any assumption of a rate-determining isomerization process.

The potential energy profiles have been of much interest in understanding the reaction mechanism. One of the problems is the experimental uncertainty concerning a rate-determining isomerization process or its barrier height on the potential surface. In a $C_3H_7O^+$ system, most of the studies have employed electron-impact(EI) ionization,[1-5] isotope labeling techniques,[6,7] and chemical ionization(CI)[8,9] for metastable fragmentations. Collision-induced dissociation(CID) spectra of ions have been used for the identification of ion structures.[10] The molecular orbital calculations[11] have provided accurate knowledge about the relative energies of the various $C_3H_7O^+$ ions involved on the potential energy surface. In the reaction paths for water and ethylene elimination (Scheme 1), several structures of $C_3H_7O^+$ ions have been postulated to lie on the same potential energy surface. Detailed potential energy surfaces for the fragmentations of $(CH_3)_2C{=}OH^+$ [**I**] and $CH_3CH_2CH{=}OH^+$ [**II**] have been studied by Williams and his co-workers.[2,3] Their results for the ratios of the metastable peak intensity or kinetic energy releases showed that the fragmentation of **I** by either reaction, 1 or 2, involves a rate-determining isomerization to **II** prior to fragmentation. Harrison et al.[9] have obtained the same conclusion from the fact that the ratios of metastable peak intensities for **I** are essentially insensitive to activation modes, such as the EI, CI, and CID methods. However, measurements of the metastable appearance energies for $C_3H_5^+$ and CH_3O^+ with energy-selected electrons have shown that the fragmentations of the **I** and **II** isomers, which were formed from *t*-butyl and *s*-butyl alcohols respectively, take place at the thermochemical threshold.[4]

There is no consistent explanation for the rate-determining isomerization of **I**→**II**. Therefore, our present study examines in more detail the fragmentations of the **I** and **II** ions by means of time-resolved measurements of the metastable peak intensities and the EIE curves. In particular, an experiment for long-lifetime ions can study the lower internal energy fragmentation than have previous studies. A wide variation in ion lifetimes permits a close comparison of the metastable peak intensity with the calculated intensity by assuming the rate models. The TIMS experiment can change the ion residence time up to several milliseconds, so that the unimolecular reaction of 10^3—10^6 s^{-1} can be sampled.

$$\underset{\mathbf{I}}{(CH_3)_2C{=}OH^+} \longrightarrow \underset{\mathbf{II}}{CH_3CH_2CH{=}OH^+}$$

$$CH_2{=}CHCH_2OH_2^+ \longrightarrow C_3H_5^+ + H_2O \quad (1)$$

$$\longrightarrow CH_3\overset{+}{C}HCH_2OH \longrightarrow {}^+CH_2CH_2CH_2OH \longrightarrow CH_3O^+ + C_2H_4 \quad (2)$$

Scheme 1.

Experimental

The ion-trapping technique has been described in detail elsewhere.[12] The space charge formed by a continuous 5-eV electron beam was used to trap ions produced when a negative pulse was applied to a filament. At a known delay time after the ionizing pulse, a positive pulse 5 μs in duration and 4 eV high was applied to a repeller electrode in order to remove ions for mass analysis. Argon ions were stored far up to several milliseconds without any serious decrease in the trapped ion concentration, as is shown in Fig. 1. An ionizing pulse 2 μs in duration was applied to the filament at 1ms-intervals. The nominal electron energy was varied by changing the pulse height applied to the filament.

A home-built tandem-type mass spectrometer was used to measure the EIE curves and the metastable fragmentation. The parent ions, which are selected by the first magnet,

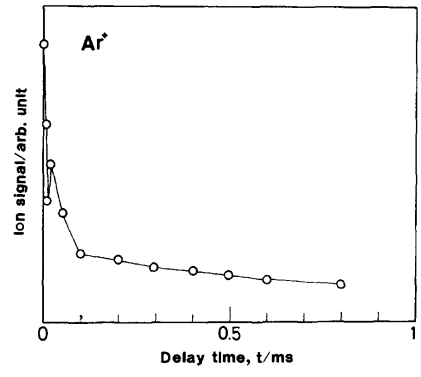

Fig. 1. Argon ion signals as a function of the delay time, *t*.

decompose in the second field free region between two magnets. The product ions are analyzed by the second magnet. A data accumulation of about an hour was statistically needed for both the EIE and metastable peak measurements. The temperature of the ion source was 423 K. The ion-accelerating voltage was 1.5 kV. The ion-source pressure was kept at 2×10^{-6} Torr (1 Torr=133.32 Pa). The collision-induced reactions were negligible, because the pressure in the field free region was always less than 1×10^{-6} Torr. Samples were commercially obtained.

Results and Discussion

Figure 2 shows the time-resolved EIE curves for the $C_3H_5^+$ and CH_3O^+ fragments produced from *t*-butyl and *s*-butyl alcohols. The argon EIE curve was used for the EIE curve normalization between different ion storage times, because the ion trapping efficiency decreases with the delay time, as is shown in Fig. 1. The EIE shifts observed at V=13.5 eV are about 0.4 eV for $C_3H_5^+$ and zero for CH_3O^+. These shifts are due to the so-called "kinetic shift," the excess energy required to produce a detectable dissociation (usually 10^5 s^{-1}) of a polyatomic ion. The molecular ions for both samples were very low in intensity in the present energy range, while the $C_3H_7O^+$ fragment is very abundant on both mass spectra. The EIE shifts with the delay times are, therefore, believed to be caused by the slow dissociation, not for the molecular ions, but for the $C_3H_7O^+$ precursor ions.

The time-dependent EIE for the *i*-th daughter ion at a nominal electron energy V can be written in this form:[13]

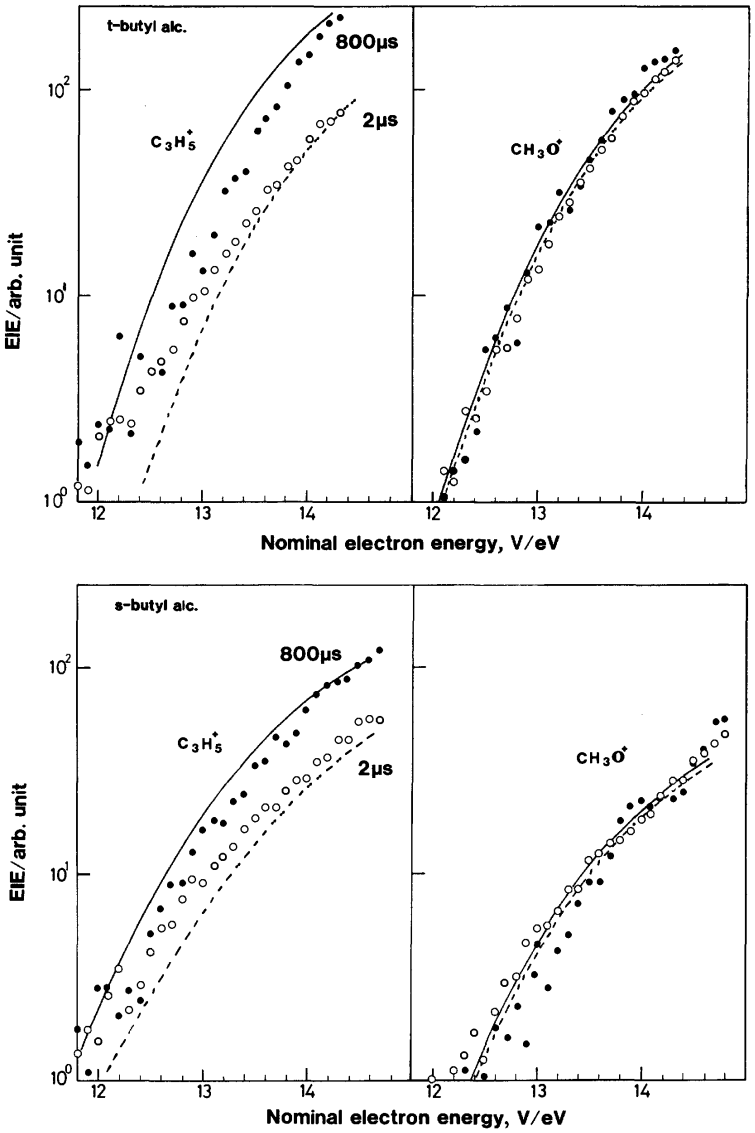

Fig. 2. Time-resolved electron-ionization-efficiency(EIE) curves for $C_3H_5^+$ and CH_3O^+ daughter ions vs. nominal electron energy V: (a) *t*-butyl alcohol, (b) *s*-butyl alcohol. ● (——) and ○ (----) indicate the experimental (calculated) EIEs of t=800 and 2 μs, respectively.

$$\mathrm{EIE}_i(V,t) \propto \int_0^\infty m(E'-V)\left[\int_{AE_0}^{E'} f(E',E)\times (k_i(E)/\sum k_j(E))w(E)\mathrm{d}E\right]\mathrm{d}E' \quad (3),$$

where t is the ion-source-residence time, $m(E'-V)$ is the instrumental electron-energy distribution, E' is the total electron energy, $f(E',E)$ is the internal energy distribution of $C_3H_7O^+$, AE_0 is the 0 K appearance energy for the daughter ion, $k_i(E)$ is the unimolecular rate constant for the i-th path, and $w(E)$ is the fraction of dissociation given by $1-\exp(-t\sum k_j(E))$. The $m(E'-V)$ distribution was obtained from the second derivatives of a helium experimental EIE curve on the basis of Morrison's method[14]; its half-width was 0.8 eV. The $f(E',E)$ distribution for the ionized $C_3H_7O^+$ was assumed to be equal to that for the molecular ions. From the ionization-threshold law,[15] the energy distribution for molecular ions can be given by $p(E)(E'-E)$, where $p(E)$ is the energy-deposition function. The photoelectron spectra of t-butyl and s-butyl alcohols were assumed to represent $p(E)$.[16]

The decay rates were obtained from a simple form[17] of $k(E)=v(1-E_0/E)^s$, where v is the frequency factor, E_0 is the activation energy, and s is the effective number of oscillators. In the same reaction system, Tsang and Harrison[1] have investigated, by means of model calculation, the effect of change in the internal energy distribution on the metastable peak ratio of $C_3H_5^+/CH_3O^+$. Their adjusted parameters of the frequency factor were $v_a=10^{8-9}$ and $v_b=10^{11}-10^{12}$ for reactions 1 and 2 respectively. In the present calculation, we employed similar parameters of the frequency factor, as are summarized in Table 1. Moreover, for the sake of simplicity, the frequency factors for **I** and **II** were assumed to be the same. The s value was taken to be 9, corresponding to a third of the number of vibrational degrees of freedom of $C_3H_7O^+$. The activation energies were obtained from the potential energy diagram illustrated in Ref. 9, assuming that the dissociations occur at their thermochemical onsets. The calculated EIE curves are in fair agreement with the experimental curves. The amount of the EIE shift between different delay times depends principally on the rising steepness of the $k(E)$ vs. E curves. As may be seen in Fig. 2, the EIE shift is greater for $C_3H_5^+$ formation than for CH_3O^+. This is because the $k(E)$ curve of $C_3H_5^+$, having the smaller frequency factor, rises more slowly with the energy.

The metastable peak intensities relative to the parent ions, $m^*/C_3H_7O^+$, for the **I** and **II** ions are shown in Fig. 3 for the range of t=0—50 μs. Our ratios of the peak intensities, $C_3H_5^+/CH_3O^+$, at t=0 μs agree with those of the literature.[9] The experimental errors estimated were, at most, 20%. After a careful consideration of the reproducibility and error limits, we obtained the significant result for **I** that the peak intensities between $C_3H_5^+$ and CH_3O^+ are reversed at a long delay time. This result is inconsistent with the previous results[3,9] indicating that the metastable peak ratios are insensitive to ion formation and to ion lifetime of several microseconds. Its lifetime was varied by change in an accelerating voltage. The ratios of $C_3H_5^+/CH_3O^+$ are not affected by the ion lifetime if there is the rate-determining isomerization of **I**→**II**. The metastable peak intensities were calculated assuming the direct fragmentation of **I** and **II** to products. For the calculation, Eq. 3 was modified in such a way that $w(E)$ was replaced by $\exp(-t_1\sum k_j(E))-\exp(-t_2\sum k_j(E))$. Therefore, $w(E)$ means the fraction of dissociation occurring in the second field-free region. t_1 and t_2 are the entrance and exit times relative to the time of ion formation (t_1=5.8+t and t_2=10.1+t μs).

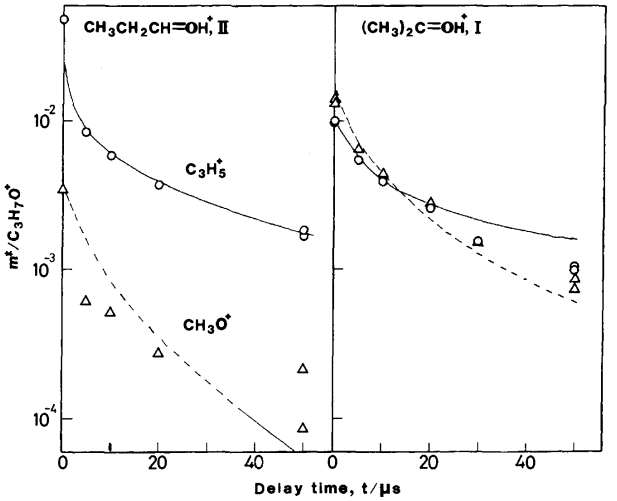

Fig. 3. A plot of metastable peak intensities relative to the parent ion, $m^*/C_3H_7O^+$, against delay time when V=40 eV. Experimental (calculated) data; $C_3H_5^+$, ○ (——) and CH_3O^+, △ (----). The ions **I** and **II** were produced by dissociative ionization from t-butyl and s-butyl alcohols, respectively.

The smooth lines in Fig. 3 are the fragmentation curves calculated by the use of the same rate models as in Table 1. The overall agreement with the experimental curves is fairly satisfactory. The rate-determining isomerization of **I**→**II** was supported by the experimental evidence that the metastable-peak ratios for **I** were independent of the activation modes. In other words, the relative rates were essentially constant over the internal-energy range generated. Accordingly, the rate-determining isomerization mechanism may be ruled out by the presence of curve crossing for **I**.

Table 1. Activation Energies and Frequency Factors Used in the Rate Model of the $C_3H_7O^+$ Dissociation

Ion	$C_3H_5^+$		CH_3O^+	
	E_0	v_a	E_0	v_b
	eV	s^{-1}	eV	s^{-1}
I	2.08	$10^{8.5}$	2.66	10^{11}
II	1.56	$10^{8.5}$	2.14	10^{11}

A collisional deactivation and an infrared radiative decay are nondissociative processes particularly important for long-lived ions. However, these processes proved to have no effect on the EIE curves or the metastable fragmentations at the present pressure of the sample. This has previously been discussed in detail in the case of pyridine dissociation.[13]

The time-resolved measurements of EIEs and metastable fragmentations lead to the conclusion that the dissociations of **I** and **II** require no hypothesis of the rate-determining isomerization or the barrier on their paths. This conclusion is exclusively valid for the dissociation of ions whose internal energy is close to the threshold. In the case of t=50 μs, for example, the rate of $k(E)=1.7\times10^4$ s^{-1} corresponding to a peak of $w(E)$ contributes principally to metastable fragmentation.

(Received January 12, 1987)

The binding behavior of metal ions to the monolayers of a crown ether compound has been studied by the surface potential measurements. The obtained data are analyzed from the viewpoint of interfacial electrochemistry, i.e., the electrical double layer theory at the interfaces. The analysis reveals that the generated double layer at a membrane-solution interface after the complexing of metal ions with crown ethers is well described by the Stern model for the electrical double layer; it shows that there exists a possibility to evaluate the binding constants of metal ions with crown ethers under interfacial circumstances.

The transport behavior across biological membranes or oil liquid film is one of the attractive problems in colloid and surface chemistry. A lot of compounds which mediate ion transport through membranes have been found in biological systems (e.g. antibiotics) and have been manufactured artificially.[1-3] These compounds are called "ionophores" and are classified approximately into two categories from their functional characteristics, (carrier type and channel type). Crown ethers are the most attractive synthetic ionophores, which can complex with various metal ions with a characteristic selectivity.[2,3] Since these complexes are lipophilic, arising from crown's hydrophobic rings, they can dissolve in nonaqueous media. Thus, the crown ether can transport metal ions through oil liquid films or lipid bilayer membranes. Despite the fact that a lot of studies have been performed on this subject, details concerning the transport mechanisms, whether carrier type or channel type, have been incompletely revealed. For the purpose of understanding the transport mechanism, it is desirable to clarify fundamental factors of the transport process, e.g. the binding characteristics of metal ions with crown ethers, the adsorption and desorption equilibrium between oily phase and aqueous phases, etc.[4,5] In the case of amphiphilic crown ethers, binding with metal ions can occur both in the bulk aqueous phase and at the interface of the membrane-aqueous phase. On the other hand, some lipophilic crown ethers hardly dissolve in the aqueous phase; therefore, they make complexes with metal ions only at the interface of the oil-aqueous phase or the membrane-aqueous phase. At such interfaces, the binding behavior of metal ions with crown ether are influenced by various interfacial properties, especially an electrical double layer at the interface.

In this work, the binding behavior of metal ions with a crown ether under interfacial circumstances has been studied from the viewpoint of interfacial electrochemistry. To find the fundamental feature of binding at the interface, simple systems have been employed, i.e., monolayers of a water-insoluble crown compound and the change in the surface potential of the monolayers caused by ion-binding to them has been studied.[6]

Experimental

Materials. To make a monolayer on a water surface, a crown ether which had a long hydrocarbon chain was prepared. The compound was octadecyloxymethyl 18-crown-6 (see Fig. 1) and is hereafter abbreviated as C18-18-crown-6.

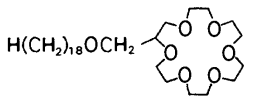

Fig. 1. Molecular structure of octadecyloxymethyl 18-crown-6.

C18-18-crown-6 was synthesized from octadecyl glycidyl ether and pentaethylene glycol by the same method as that reported in the literature.[7,8] The product was purified by column chromatography on silica gel or repeated Kugelrohr distillation (bp 230—235 °C/0.002 Torr (1 Torr=133.322 Pa)) and then recrystallized from methanol (mp 46—47 °C). The purity (>99%) was confirmed by GLC, TLC, NMR, IR, and elemental analyses. To make mixed monolayers with C18-18-crown-6, stearyl alcohol (Tokyo Kasei Kogyo Co.) was employed.

Surface Potential Measurement. A monolayer of C18-18-crown-6 was spread from a hexane solution on pure water. The packing density of the membrane was about 1/100 (molecule/Å^2). This value is comparable to the density of this compound in a close-packed state of a two-dimensional array. After the addition of a concentrated metal chloride aqueous solution to the subphase solution in a 80-ml Teflon trough, the solution was stirred for more than 30 min; the change in the surface potential ($\Delta\Delta V$) caused by a binding of the metal ions was measured by the vibrating-electrode method[9] at 23 °C. The 1:1 mixed monolayer of C18-18-crown-6 with stearyl alcohol was also employed and the experiment was carried out according to the same procedure as that for the pure monolayer, except for the packing density (in this case: ca. 1/100 molecular pair/Å^2).

Results and Discussion

The monolayer of C18-18-crown-6 has no electrical charges when it is spread on distilled water. The addition of metal ions to the subphase solution causes the formation of an electrical double layer at the membrane-water interface by binding to the crown

rings, leaving counter ions (Cl^-) in the aqueous phase. The generation of the electrical double layer can be observed by measuring the surface potential of the monolayer. Strictly speaking, the surface potential of the monolayer is described as a combination of the potential arising from the oriented dipoles of polar head groups of crown ether molecules and the ionic double-layer potential. In the present analysis, the change in the surface potential is assumed to be caused by a structural change in the ionic double layer; this has no serious disadvantage judging from the following fact. The change in the molecular orientation of this type crown ether, caused by a variation in the molecular packing density in the monolayer, shows a rather drastic potential change (Details will be published elsewhere). In Fig. 2, the change in the surface potential is plotted against the concentration of several kinds of metal ions. As can be seen, the contribution of these ions to $\Delta\Delta V$ is of the order of $K^+ > Na^+$ for alkali ions and $Ba^{2+} > Ca^{2+}$ for alkaline earth ions. These orders are the same as those of the complexing stability constant of these ions with 18-crown-6 in water or methanol.[10] For a mixed monolayer of C18-18-crown-6 with steary alcohol (1 : 1 molar ratio), plots of $\Delta\Delta V$ vs. the concentrations of various metal ions are shown in Fig. 3. A similar tendency to those in Fig. 2 is observed regarding $\Delta\Delta V$; however, the apparent ion-selectivity is lower than that for the pure membrane. All these facts suggest that there exists the same ion-selectivity of crown ethers at the membrane-solution

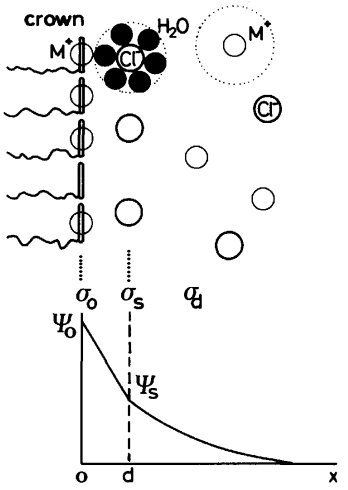

Fig. 4. Schematic representation of the distribution of ions and the profile of electrostatic potential across the double layer at the interface of crown ether monolayer and aqueous solution.

interface to that in the bulk phase.

To know further details regarding the binding behavior, the obtained data are analyzed using the concepts of interfacial electrochemistry.[11] Figure 4 shows a schematic representation of an electrical double layer at the interface between the monolayer of a crown ether and aqueous salt solution. In this system, the charges on the membrane-surface arise from the binding of metal ions with crown rings after dehydration, while the hydrated chloride ions remaining in the solution become counter ions. Therefore, the Gouy-Chapman-Stern model may be adequate for describing this elctrical double layer. However, a slight modification is required to describe the feature of surface charges. That is, the charges are localized at each of the crown rings; then the number of binding sites for metal ions is limited. This corresponds to the number of crown ether molecules in the monolayer. Therefore, the Langmuir adsorption isotherm is adopted to represent the binding behavior of metal ions to the membrane. The relations between the potential and the charges are described in the following way.

(1) The electroneutrality requires the following relation:

$$\sigma_0 + \sigma_s + \sigma_d = 0, \tag{1}$$

where σ_0 is the charge density on the membrane surface, σ_s the charge density on the Stern plane, and σ_d the charge density in the diffuse double layer.

(2) σ_0 is represented by a Langmuir-type equation:

$$\sigma_0 = z|e| \frac{KC_0[M^+]_b \exp(-z|e|\Phi/kT)}{1 + K[M^+]_b \exp(-z|e|\Phi/kT)} \tag{2}$$

where K is the binding constant, C_0 the density of crown ether on the monolayer (in the present experiment, $C_0 = 1/100$ number/Å^2), $[M^+]_b$ the concentration of metal ion in the bulk solution, z the valency of

metal ions, and Φ the micropotential which influences the binding of metal ions.[12] Φ is represented by the following simple formula:

$$\Phi = \alpha \cdot \psi_0, \tag{3}$$

where ψ_0 is the surface potential of the membrane and α is a constant ($0<\alpha<1$).

(3) σ_s is also represented by a Langmuir-type equation:

$$\sigma_s = -|e| \frac{K^*C_0^*[Cl^-]_b \exp(|e|\psi_s/kT)}{1+K^*C_0^*[Cl^-]_b \exp(|e|\psi_s/kT)}, \tag{4}$$

where K^* is the binding constant of Cl^- to the Stern plane, C_0^* the maximum binding density of Cl^- ions, $[Cl^-]_b$ the concentration of Cl^- ion in the bulk, and ψ_s the electrostatic potential at the Stern plane.

(4) The electrical charge density in a diffuse double layer is expressed by the Gouy-Chapman theory, as follows:

$$\sigma_d = -\left(\frac{2N[Cl^-]_b \varepsilon kT}{\pi}\right) \sinh\left(\frac{\psi_s|e|}{2kT}\right), \tag{5}$$

where N is Avogadoro's number and ε is the dielectric constant of bulk water (ε=80).

(5) The potential at the Stern plane is related to the surface potential as

$$\psi_0 - \psi_s = \frac{4\pi d\sigma_0}{\varepsilon^*}, \tag{6}$$

where d is the distance between the membrane surface and the Stern plane and ε^* is the dielectric constant in the Stern layer.

When the counter ions are completely distributed in the diffuse double layer, i.e., when the existence of the Stern plane can be ignored, the relation $\sigma_0+\sigma_d=0$ can hold by replacing ψ_s in Eq. 5 by ψ_0. On the other hand, when the counter ions are completely localized on the Stern plane, the relation $\sigma_o+\sigma_s=0$ holds. For the intermediate states, K^* and C_0^* in Eq. 4 can be expressed by the following equations:

$$K^* = AK\exp(-z|e|(\Phi+\psi_s)/kT) \tag{7a}$$

$$C_0^* = C_0, \tag{7b}$$

where A is a parameter representing the mixed ratio of Stern model and Gouy-Chapman model ($0<A<1$). For monovalent ions, the potential change ($\Delta\Delta V=\psi_0$) is calculated using the above equations; the results are drawn against the concentration of metal ions in Fig. 5. In these calculations, several parameters are assumed to be consistent with the physical meaning. That is, ε^*=32, which corresponds to a partially immobilized water layer and d=7 Å, which is calculated from $d=r_M+\phi_w+r_{Cl}$, where r_M is the radius of metal ions (for K^+ $r_M\simeq$1.3, for Ba^{2+} $r_M\simeq$1.4 Å), ϕ_w is the diameter of a water molecule (ϕ_w=3—4 Å), and r_{Cl} is the radius of a chloride ion (r_{Cl}=1.8 Å). In Fig. 5, the experimental data of $\Delta\Delta V$ for K^+ are also plotted. As can be seen from the figure, the data are fit the Stern model better than the Gouy-Chapman model. That is, a condenser-type double layer is adequate for describing the present double layer. Next, the same analysis is carried out for divalent ions. In Fig. 6, analytical curves are presented together with experimental data for Ba^{2+}. As can be seen, the Stern model is more suitable for describing the double layer on the membrane of crown ethers than the Gouy-Chapman model. Further, in Figs. 7 and 8, the experimental data for K^+ and Ba^{2+} are plotted along with the analytical curves from the Stern model calculated using "α" as a parameter. In these calculations, we assumed that α is a parameter which correlates the micropotential (Φ) with macropotential ($\Delta\Delta V=\psi_0$) and takes a value between 0 and 1, where α=0 indicates that the adsorbing ions are not influenced by electrostatic potential generated by the already adsorbed ions, while α=1 indicates that the electrostatic potential influences the adsorption of next adsorbing ions completely. As can

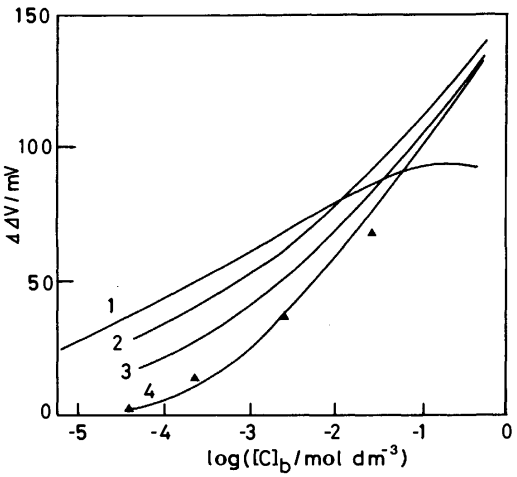

Fig. 5. Calculated curves from Eqs. 1—6 for the change of surface potential caused by mono-valent metal ions in various cases: (1) Gouy-Chapman model, (2) A=0.5, (3) A=0.8, and (4) Stern model; $\log K$=2.3, α=1. Experimental data (▲) of KCl are also plotted as to fit to one of these curves.

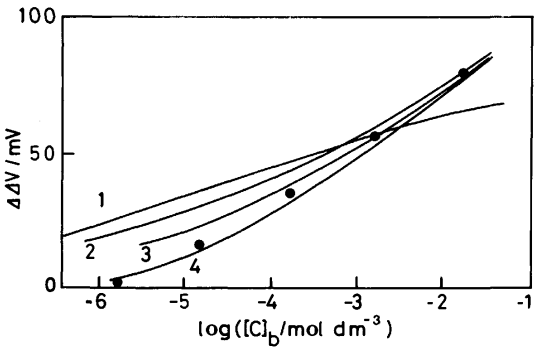

Fig. 6. Calculated curves from Eqs. 1—6 for the change of surface potential caused by di-valent metal ions in various cases: (1) Gouy-Chapman model, (2) A=0.5, (3) A=0.8, and (4) Stern model; $\log K$=3.6, α=1. Experimental data (●) of $BaCl_2$ are also plotted as to fit to one of these curves.

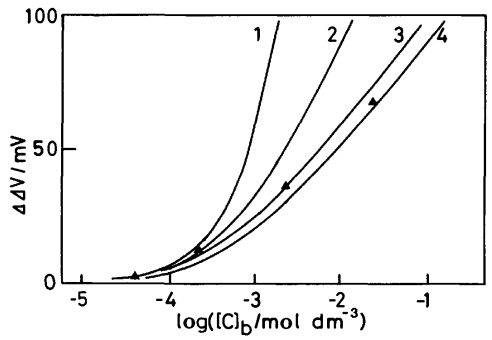

Fig. 7. Calculated curves of the change of surface potential for mono-valent ions from the Stern model with various values of parameters: (1) α=0, (2) α=0.5, (3) α=1, (d=7 Å); and (4) α=1, (d=5 Å). Experimental data (▲) of KCl are also plotted as to fit to one of the curves.

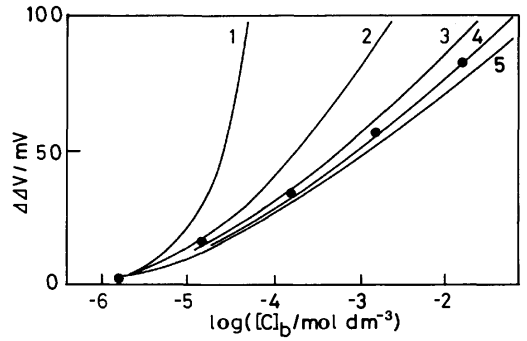

Fig. 8. Calculated curves of the change of surface potential for di-valent ions from the Stern model with various values of parameters: (1) α=0, (2) α=0.5, (3) α=0.8, (4) α=0.9, and (5) α=1. Experimental data (●) of $BaCl_2$ are also plotted as to fit to one of the curves.

be seen in Fig. 7, the experimental data for K^+ are well fitted to the analytical curve of α=1, in the range of low salt concentration. However, in the range of high salt concentration, $\Delta\Delta V$ changes more slowly than the analytical curve against the salt concentration. This phenomenon may arise from the fact that either the thickness of the Stern layer is smaller than that of this model (7 Å); in Fig. 7 the analytical curve of $\Delta\Delta V$ (assuming d=5 Å) is also drawn; or the diffuse double layer may be combined with the Stern layer to some extent in the high salt concentration range, i.e., an incomplete condenser type-double layer is formed and some counter ions are distributed over the diffuse double layer. The experimental data for Ba^{2+}, on the contrary, are well fitted to the theoretical curve for α=0.9—1. These results indicate that the mutual electrostatic repulsion among adsorbed metal ions is stronger for K^+ than for Ba^{2+}. This difference may arise from a difference in the discreteness of the charge distribution on the membrane surface. That is, the charges on di-valent metal ions are more localized than those on mono-valent ions on the membrane surface. In the case of di-valent ions, the one site for adsorption on the membrane can carry two electrical charges, while the site for mono-valent ions can carry only one charge.

Also, it is possible to obtain the value of the binding constant (K) in Eq. 2 by fitting the data to analytical curves. The estimated values for K^+ and Ba^{2+} are log $K\simeq$2 and log $K\simeq$4, respectively. These values are compared with the ones of 18-crown-6 appearing in the literatures, which were obtained by various kinds of experiments in the bulk liquid phase. Some typical examples are as follows: for K^+, log K=2.03—2.15 in H_2O and log K=5.93—6.20 in MeOH, while for Ba^{2+}, log K=3.87 in H_2O and log K=7.04 in MeOH.[10] As can be seen from these data, the estimated values of K in the present study are not so different from the values determined experimentally in bulk water.

In the present study, we can indicate that the electrical double layer generated by the complex-formation of a crown ether membrane with metal ions is of the type of the Stern model and that the binding constants of metal ions with the crown ethers under the interfacial circumstances can be evaluated by a simple electrical double layer theory.

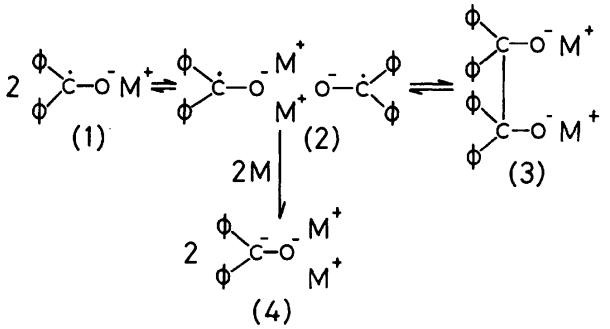
Fluorenone Monomer Dianion Studied by ^1H and ^{13}C NMR and Charge Density Distribution

Masatoshi HIRAYAMA* and Hiroshi OHHATA
Department of Chemistry, Faculty of Science, Ibaraki University, 2-1-1 Bunkyo, Mito 310
(Received January 17, 1987)

The diamagnetic monomer dianion of fluorenone was prepared from 1,2-dimethoxyethane solution of neutral molecule in contact with excess sodium metal at −5 °C for 5 days and its ^1H and ^{13}C NMR spectra were measured. The possibility that a pinacolate-type dimer dianion occurs in an equilibrium system was ruled out from reactivity with oxygen, water, deuterium oxide, and reducible aromatics in addition to the analysis of NMR spectra. The charge density distribution of neutral and dianion molecules was estimated by MO calculations. Comparison between experimental and theoretical ^{13}C shifts suggested a strong interaction of sodium ions with carbonyl group. It is presumed that an anormalous diamagnetic ring current in 14π-peripheral structure is responsible for poor correlation between theoretical and observed ^1H shifts.

It was demonstrated by Hirota et al.[1] from ESR and optical measurements that when aromatic ketones (fluorenone, benzophenone, and xanthone) were in contact with alkali metal in a dilute solution, a ketyl monomer (**1**) and a paramagnetic ketyl dimer (**2**) mainly coexisted in equilibrium in an etherial solvent, while in a nonpolar solvent there mainly existed an equilibrium between **2** and a diamagnetic ketyl dimer (**3**). These authors further studied in detail ion-pair structures of **1** and **2** and the equilibrium between **1** and **2**.[2] On the other hand, Herold et al. discussed in



detail the substituent effect on the spin density distribution (or hfs patterns) of free anion radical and sodium ketyl of fluorenone by means of ENDOR technique and ESR.[3] Hirota et al. further proposed from optical spectra that when fluorenone of approximately 10^{-2} mol dm^{-3} was in contact with excess sodium in 2-methyltetrahydrofuran (2MTHF) **2** was further reduced into diamagnetic monomer dianion (**4**)[1a] and the concentration of **3** was extremely small.

A direct evidence for the occurrence of **3** and **4** has been required, because their existence was proposed only indirectly by optical measurements. Although the best method to identify a diamagnetic species in solution will be NMR analysis, it seems that NMR measurement of these systems at high-resolution is difficult due to line broadening by fast spin exchange between diamagnetic species and paramagnetic ketyl monomer or dimer. Moreover, it is difficult to discuss the same equilibrium state as that for optical measurements by NMR method, which requires a much higher concentration of species than that in optical measurements.

The present paper demonstrates that a diamagnetic green species formed from fluorenone and excess sodium metal in 0.15 mol dm^{-3} 1,2-dimethoxyethane (DME) solution is ascribed to its monomer dianion (**4**) on the basis of ^1H and ^{13}C NMR spectra and calculated electron density distribution.[4]

Experimental

Fluorenone was contacted with sodium metal in DME-d_{10} in high vacuum by standard technique for preparing hydrocarbon anion radicals. Fluorenone (Tokyo Kasei Co. Ltd.) was used without further purification. DME-d_{10} (Canada MSD Co. Ltd.) was dried, degassed, and stored over sodium/potassium alloy in vacuo. 0.6 ml of DME-d_{10} was transferred into an NMR tube containing 10 mg of fluorenone at its bottom and connecting with a high-vacuum line. Sodium mirror was previously made in the upper part of the sample tube, so that the solution could be in contact with metal even after the sample tube was cut off from the vacuum line. The solution was contacted with sodium mirror by turning upside down the sealed tube. ^1H and ^{13}C NMR spectra were measured on Varian VXR-300 at 300 MHz on the FT mode. ESR spectra were measured on JEOL JES-FE1XG, in order to confirm the disappearance of anion radical. The MO calculation of charge density was performed on HITAC M-240H at Ibaraki University, the program used for the CNDO calculation being Y4CB04[5] in library programs of the University of Tokyo.

Results and Discussion

The color of fluorenone solution in DME-d_{10} changed to reddish-yellow immediately after contact with sodium at −5 °C. The resulting solution gave a well-resolved ESR spectrum of sodium fluorenide after dilution. The ESR signal gradually disappeared upon continued contact, and the color of the solution turned to green. Several new lines gradually grew up in ^1H NMR spectrum. This green species was stable even at room temperature for several days. ^1H and ^{13}C NMR spectra observed after 5 days of contact are shown in

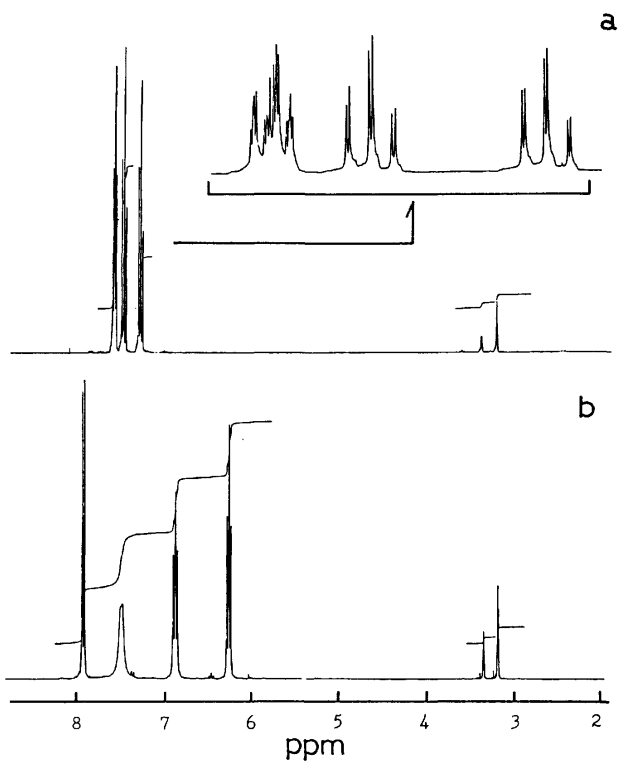


Fig. 1. ^{1}H NMR spectra (300 MHz) of fluorenone in DME-d_{10} (a) and of the diamagnetic green species formed by sodium reduction in DME-d_{10} (b). In (b), the high-field one of two doublets is considerably broadened by the spin exchange with a slight amount of the fluorenone ketyl.

Figs. 1 and 2, respectively, together with that of the precursor. The ^{1}H spectrum consisted of two triplets and two doublets which were separated well. Its center of gravity shifted toward higher field by 0.39 ppm than that of neutral molecule. The pattern of ^{13}C spectrum of this species was identical with that of neutral molecule, suggesting that the spectrum arises from four carbons bonded to a hydrogen and three quaternary carbons, one of which has particularly long T_1. The high-field shift of center of gravity in ^{13}C spectrum was 20.9 ppm relative to that in neutral molecule.

The assignment of ^{1}H and ^{13}C spectra of neutral molecule was made by literature,[7] which was confirmed here by the H-C shift correlation 2D NMR (Fig. 3). For the green species, the smallest ^{13}C line was assigned to C_9 by its very large T_1. This is consistent with the intramolecular distribution of calculated excess charge density of a monomer dianion mentioned later. The residual two carbon lines with weak intensity were assigned to C_{10} and C_{11} due to their long T_1 values, the higher-field one being tentatively assigned to C_{10} by the comparison of observed shifts with excess charge density of the dianion. In the ^{1}H spectrum, the line at a higher field of two doublets became much broader than the other in the existence of a small amount of ketyl radical. This is considered to be due to an electron spin exchange between diamagnetic green species and paramagnetic ketyl. From the fact that the hfs constant a_1^H is much larger than a_4^H,[3] the higher-field doublet could be assigned to H_1, and the lower-field one to H_4. The lower-field triplet was assigned to H_2 using the same technique. The assignment of four ring carbons was made by combining the above ^{1}H assignment with the 2D correlation NMR between ^{1}H and ^{13}C shifts (Fig. 4). The results are listed in Table 1.

By introducing oxygen into this green solution fluorenone was regenerated. Contacting this solution with a reducible aromatics, methyl *m*-nitrobenzoate, in vacuo, gave ESR of sodium salt of anion radical of this compound. From these experimental results, it may be reasonable to determine that a pinacolate-type compound (diamagnetic ketyl dimer, **3**) is not formed by bonding between ketyl monomers. It was further confirmed by analysing ^{1}H and ^{13}C NMR that addition of water to this species in oxygen-free conditions gave 9-fluorenol and that deuterium oxide treatment gave the corresponding deuterated 9-fluorenol. This result supports the assumption that dimer dianion is not formed. This is also consistent with the fact that C_9 appeared at much lower field than that of pinacol. It can thus be said that an adequate evidence for the formation of diamagnetic monomer dianion (**4**) was obtained. As seen from Figs. 1 and 2, no other diamagnetic species were observed from this green solution and line broadening completely disappeared during contact with sodium metal. Monomer dianion (**4**) is the final product at a high concentration (1.5×10^{-1} mol dm^{-3}) by complete reduction with excess sodium in etherial solvent, similarly as the reduction at a low concentration (4×10^{-2}—5×10^{-3} mol dm^{-3}) in 2MTHF discussed by Hirota et al.[1a] A direct formation of **4** from **1** may be expected in the present system in DME in addition to the process through **2**, from larger dissociation constant in $\mathbf{2} \rightleftarrows 2\cdot\mathbf{1}$ in DME than that in 2MTHF.[1a] One may expect that monomer dianion observed here is of an ion pair form $A^{=}2M^{+}$ or solvated ion pair $A^{=}2M^{+}(S)_n$, where A and S are fluorenone and solvent, respectively, but not of a solvent-separated ion pair $A^{=}(S)_n2M^{+}$,[8] from analogy with the ion pair structures of monomer ketyl proposed by Hirota et al.[2a]

Reduction of fluorenone with excess sodium or potassium metal in THF also gave the green species, which was insoluble in THF and precipitated. On the reduction with potassium in DME, paramagnetic reddish-yellow solution initially formed did not change to green even after a long time. These results are consistent with the order of solvation power of solvents for alkali metals, DME>THF. It may be considered that the ionic interaction between ion pairs, $A^{=}2Na^{+}$, is so strong as to overcome solvation of THF to $A^{=}2Na^{+}$, while the ionic interaction between ion pairs $A^{\cdot-}Na^{+}$ is relatively weaker than solvation power of THF to $A^{\cdot-}Na^{+}$. The ionic bonding of potassium

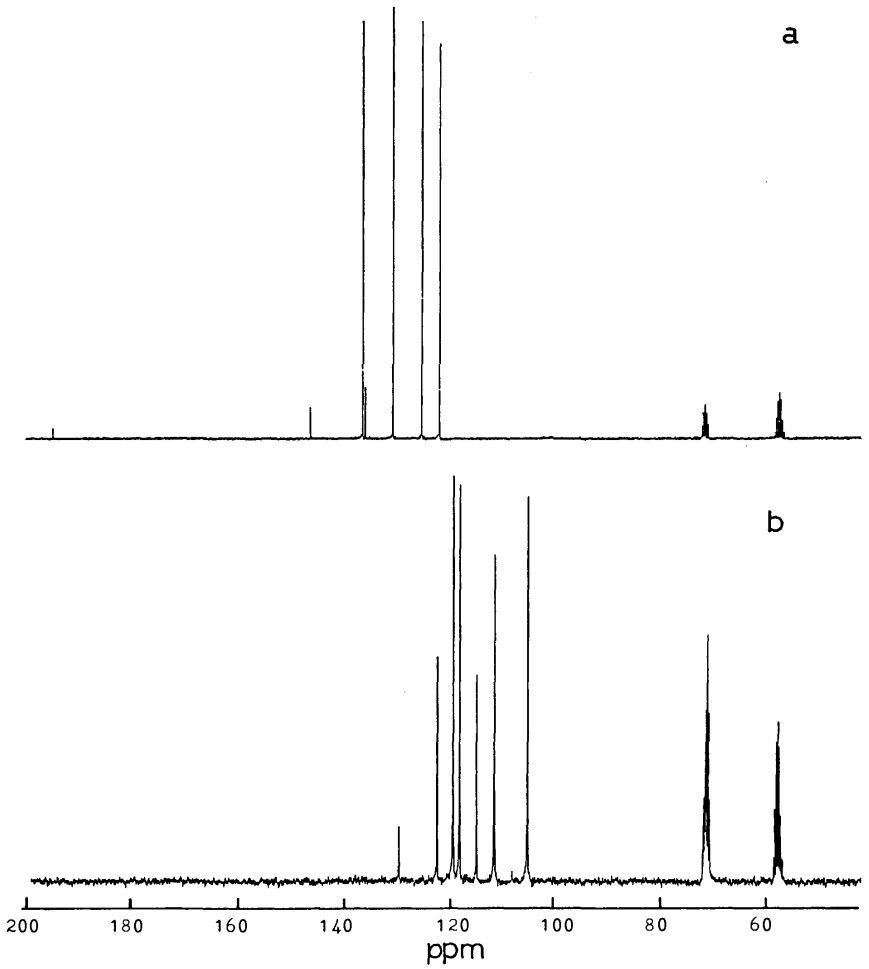

Fig. 2. ^{13}C NMR spectra (75 MHz) of fluorenone in DME-d_{10} (a) and of the diamagnetic green species formed by sodium reduction in DME-d_{10} (b).

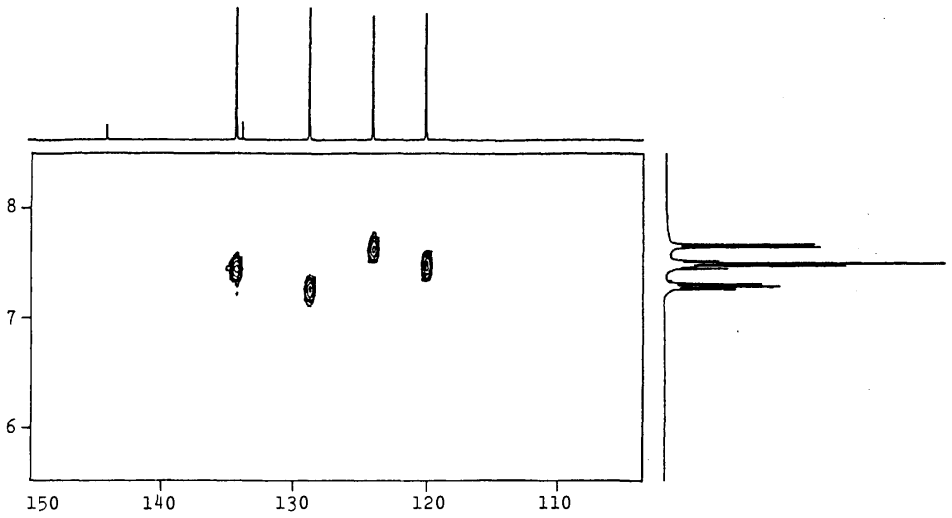

Fig. 3. ^{1}H-^{13}C shift correlation 2D NMR spectrum of fluorenone in $CDCl_3$.

ion to the carbonyl group (perhaps a carbonyl oxygen) is generally considered to be weaker than that of sodium ion owing to the difference in ionic radius. This may explain the experimental result that an ion pair structure $A^{=}2K^{+}$ doesn't exist as a stable species in DME, but exists in THF of which solvation power is weaker than that of DME.

Several workers have previously noted a linear relationship between proton chemical shift $\Delta\delta_H$ and excess local π-charge density at a carbon bonded to proton, Δq_C^{π}, according to the formula,[9] $\Delta\delta_H = k_H \cdot \Delta q_C^{\pi}$. The gradient k_H amounts to 10.7 ppm per unit charge. A

a) In ppm relative to TMS. All chemical shifts were determined relative to the high-field multiplet of DME. (3.22 ppm from TMS for ^{1}H and 57.8 ppm from TMS for ^{13}C.) b) Shifts of dianion relative to those of neutral molecule. (Positive signs denote high-field shifts. $\Delta\delta_{obsd}=-(\delta_D-\delta_N)$.)

similar correlation, $\Delta\delta_C=k_C\cdot\Delta q_{\pi}$, was later found for ^{13}C chemical shifts with $k_C\approx160$ ppm per electron.[10] Although one should be aware that such empirical dependence of δ_H and δ_C on charge density has no firm theoretical foundation, such relations are applicable to the closely related compounds, provided that one accounts for ion pairing, ring current effect, and magnetic anisotropy of neighboring atoms or substituent groups. The neutral precursor was used as a reference of shift (Table 1)[11] for estimating charge-induced shifts ($\Delta\delta_{obsed}$), and these three effects were considered as follows. It has been predicted from theoretical consideration that two excess electrons in the lowest vacant π-orbital of dianion doesn't contribute to the ring current.[12] The ^{13}C chemical shift is particularly insensitive to ring-current effect as long as carbons are within a π-periphery. No correction of the observed shifts for ring current effect was, therefore, applied for comparing the observed shifts with calculated ones. Although the anisotropy of carbonyl bond in dianion is different from that of neutral molecule, the difference may be ignored as a small correction of charge-induced shifts for all the protons and carbons except for C_9. The ^{1}H and ^{13}C chemical shifts of π-dianion may be affected by ion pairing effect of counter ions, as will be mentioned later.

The charge density on carbon 2pz orbitals, q_{2p_z}, was calculated by both the CNDO[6] and semi-empirical SCF π-MO (PPP) methods. The averaged crystallographic data[13] were used for geometric parameters. The changes of π-charge Δq_{2p_z} and calculated shift $\Delta\delta$ on going from the neutral molecule to dianion are listed in Table 2 together with the corresponding observed changes of δ_H and δ_C. It is found that the $\Delta\delta$(obsd) pattern of ^{13}C correlates, though roughly, with those of $\Delta\delta$(calcd) estimated by both the CNDO and PPP methods. However, the comparison between observed and theoretical shifts at each position showed very poor agreement: At C_9 $\Delta\delta$(obsd) is extraordinarily larger than $\Delta\delta$(calcd), at C_1 larger, at C_3 slightly smaller, at C_2 very smaller, and at C_4 the comparison was vague, because the theoretical values obtained from CNDO and PPP are widely different. For fluorenone ketyl, the ion-pair effect on electron-spin-density distribution has successfully been explained by INDO calculations.[14] Also for the present dianion, the ionic bonding of sodium ions to carbonyl group may affect largely the shift pattern. Then, in order to make a rough estimate of the change of $\Delta\delta$(calcd) pattern caused by ion pairing, the dependence of Δq_{2p_z} on the Coulomb integral parameter of carbonyl oxygen, h_O, was calculated by the Hückel approximation.[15] With

Table 2. Comparisons of Observed and Calculated Differences of ^1H and ^{13}C Shifts of Dianion from Those of Neutral Molecule[a)]

	CNDO				PPP		$\Delta\delta_{obsd}$

C_{11}	0.1797	28.75			0.1371	21.94	22.64

a) In ppm. See Table 1 for the numbering system. b) Excess charge density at carbon 2pz orbitals in dianion relative to those in neutral molecule. c) Estimated using 10.7 ppm/electron as k_H and 160 ppm/electron as k_C. d) Excess charge density at proton 1s orbitals in dianion relative to those in neutral molecule. e) Estimated using 16.7 ppm/electron as k'_H.

increasing h_O from 1.45, Δq_{2pz} at C_9 considerably increased, at C_1 next largely increased, at C_4 and C_3 slightly increased, at C_2 largely decreased, and at C_{10} and C_{11} almost unchanged. It appears that the result implies the calculated ^{13}C shift pattern changing toward the experimental one and that it suggests formation of strong ionic interaction of sodium ions with carbonyl group. However, the extraordinarily large high-field shift at C_9 will be ascribed to a possible difference of bond anisotropy of carbonyl group in dianion from neutral molecule, in addition to the ion-pair effect. The experimental fact that the shift value of C_9, 129.7 ppm, is much smaller than those of pinacolate-type compounds supports the conclusion that no diamagnetic dimer dianion is formed in the present system. It is generally said that the PPP method explains better the observed ^{13}C shift pattern rather than the CNDO method for hydrocarbon dianions having no hetero atoms or substituents. Since several factors other than charge-induced effect may affect the ^{13}C shift pattern in the present case, it is indefinite which method is more favorable.

As shown in Table 2, ^1H $\Delta\delta$(obsd) of dianion is fairly smaller on the overall ring than $\Delta\delta$(calcd) predicted by both methods and its pattern doesn't correlate well with that of ^{13}C $\Delta\delta$(obsd). This allows us to consider that the observed ring proton shifts may contain another effect in addition to the counter ion effect. It may be prossible for polycyclic systems that an anormalous peripheral ring current affects ring proton shifts,[16)] although it doesn't affect the shifts of carbons which are members of the ring itself. One of the most probable structures of fluorenone dianion is that at which one of two excess π-electrons is occupied by C_9. Since this structure has a 14π-periphery, an induced-diamagnetic ring current may be found in the fluorenone dianion. Thus, one may consider that the anormalous ring current is responsible for the decrease in ring proton shifts.

An attempt was made further to calculate $\Delta\delta$ of protons directly from excess charges at proton 1s-orbitals, Δq_{1s}. A value of 16.7 ppm per electron obtained simply from the character of a hydrogen 1s-orbital was used as the proportionality constant k'_H in the relation, $\Delta\delta_H = k_H' \cdot \Delta q_{1s}$. The resulting values of $\Delta\delta_H$ were on the whole larger than $\Delta\delta$(obsd) values as well as those obtained from $\Delta\delta_{2p_z}$ and were more uniform through all protons. One must, therefore, depend on the peripheral ring current model.

11) Although the use of benzene as a reference for the estimation of charge-induced shifts has generally been made, the correction of ring current and anisotropy of substituents must be precisely made. On the other hand, if the corresponding neutral precursor is used as a reference, it may be considered that such corrections need not be made as mentioned in the text, when one doesn't take into account an anormalous ring current effect and a possible change of anisotropy of substituents induced by excess charges.

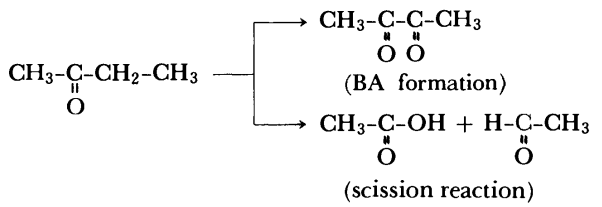
Oxidation of Ketones over Metal Oxide Catalysts. II. Biacetyl Synthesis over Co_3O_4-Lanthanoid Oxide Catalysts

Yusaku TAKITA,* Fumiaki HORI, Noboru YAMAZOE,† and Tetsuro SEIYAMA†
Department of Environmental Chemistry and Engineering, Faculty of Engineering, Oita University, Dannoharu, Oita 870-11
†Department of Materials Science and Technology, Graduate School of Engineering Science, Kyushu University, Kasuga, Fukuoka 816
(Received January 29, 1987)

The effects of the addition (10 atomic%) of lanthanoid oxides into Co_3O_4 on the oxidation of methyl ethyl ketone (MEK) were studied. The addition of La_2O_3 brought about marked enhancement of the rate of biacetyl (BA) formation. MEK conversion increased by a factor of 2.8 and the BA selectivity was improved at 450—500K owing to the suppression of deep oxidation. The addition of CeO_2 much improved the MEK conversion but BA selectivity decreased to less than 50% and the scission reaction leading to acetaldehyde and acetic acid was enhanced. The addition of Pr_6O_{11} improved MEK conversion but the addition of Nd_2O_3, Gd_2O_3, or Er_2O_3 showed little effect on MEK conversion. The reduction of both scission reaction and deep oxidation and the compensative increase in BA selectivities were observed. An approximately linear relationship was found between the specific rate of BA formation of the catalysts and logarithmic solubitity product constants of hydroxides of tervalent lanthanoid elements added, suggesting that the basicity of the catalysts is one of major factors for BA formation. The maximum efficiency (23.4%) of BA formation was attained at a La content of ca. 10 at.%.

In the previous papers,[1,2] we have been studied the gas phase oxidation of methyl ethyl ketone over the various metal oxides. In part I of this series,[2] the following findings were reported. Two types of competitive partial oxidation, i.e., biacetyl formation and oxidative scission reaction leading to acetaldehyde and acetic acid took place on every oxide studied at 400—500K.



The former reaction was accelerated on the basic or amphoteric oxides such as Co_3O_4, NiO, ZnO, and CuO, while the latter reaction became predominant on the acidic oxides such as MoO_3, V_2O_5, WO_3, and Cr_2O_3. The addition of Li_2O or Na_2O into Co_3O_4, the most effective biacetyl former of the single component oxides, improved BA selectivity by depressing the scission reaction and deep oxidation. The addition of K_2O or Rb_2O brought about negative effects on BA formation, however, it was somewhat effective to depress the scission reaction and successive complete oxidation at higher temperatures. These results suggest that basic oxides added diminish acidic sites of the catalysts on which scission reaction proceeds.

Lanthanoid oxides are known to belong to a group of basic oxides. Basisity of La_2O_3, Pr_2O_3, and Gd_2O_3 are comparable to that of CaO.[3] So that provided that the oxides of lanthanoid elements are added into Co_3O_4, the lanthanoid oxides added can be expected to induce the desirable effects for BA formation.

In the present paper, we describe the effects of lanthanoid oxide addition into Co_3O_4 on the methyl ethyl ketone oxidation.

Experimental

Catalysts. Binary oxide cataltysts used in this work were prepared by the following procedure. Aqueous solutions of $Co(NO_3)_2 \cdot 6H_2O$ and either of lanthanoid nitrates, phosphoric acid, telluric acid, or selenous acid were mixed and evaporated to dryness on a hot plate with stirring. The powder obtained was submitted to calcination at 673 K for 3 h followed by pressing at 500 kg cm^{-2}. 24—32 mesh granules of the oxides were finally calcined at 823 K for 4 h in the air.

Apparatus and Method. Experimental procedures and analyses of reactants and products were the same as described in the previous paper.[2]

The oxidation reaction was carried out in a conventional flow type reaction system using a 17-mm-i.d. Pyrex glass tubular reactor with a fixed catalyst bed inside. An aqueous solution of MEK was introduced by means of a microliquid feeder to a glass wool bed which was located at the entrance of the reactor and heated at 473 K, where the solution was evaporated and mixed with oxygen and nitrogen. Before every experimental run, prereaction was carried out for 10 h at the temperature where MEK conversion reached about 10% for the stabilization of activity of catalyst.

The effluent gas was led into a cold trap kept at ca. 290 K, to condense the products having high boiling points along with water vapor. Both trapped products and the gas that passed through the trap were analyzed by gas chromatography. The column packings used were PEG No. 1000 (3 m, 313 K) for aldehydes, ketones, and alcohols, silica gel (1.5 m, r.t.) for carbon dioxide, molecular sieves 5A (1.5 m, r.t.) for oxygen, nitrogen, and carbon monoxide, and DOS (dioctyl sebacate, 2 m, 363 K) for carboxylic acids. The selectivity of a product A is defined as

$$\frac{\text{Moles of MEK converted to A}}{\text{Total moles of MEK consumed}} \times 100\ (\%).$$

a) Ten atomic% Lanthanoid oxide. b) Normalized to MEK; $W/F=2.00$ sg-cat. cm^{-3}; feed gas composition: 1.5 mol% MEK, 8.5 mol% O_2, 30.0 mol% H_2O, 60.0 mol% N_2.

Results and Discussion

The Oxidation of MEK over Binary Oxides of Cobalt-Lanthanoid Elements. Modification of Co_3O_4 by the addition of lanthanoid oxides was examined to develop more effective catalysts for BA synthesis. The results of the MEK oxidation are shown in Fig. 1 and Table 1. The results of Co_3O_4 containing no lanthanoid oxide are also shown in Fig. 2 for comparison although the reaction conditions are somewhat different.

The addition of lanthanoid oxides into Co_3O_4 more or less affected the activities of the catalysts and the product distributions, however, gave rise to the formation of no new compound other than formed in the oxidation over Co_3O_4.

The addition of La_2O_3 into Co_3O_4 brought about the increase of MEK conversion by a factor of 2.5—2.8 (Table 1(a)). It can be seen from the comparison of Fig. 1 with Fig. 2 that the addition of La_2O_3 into Co_3O_4 gave no significant influence on the selectivity of scission reaction but depressed the deep oxidation over the whole temperature range examined, especially at below 500 K. Consequently the selectivity of BA was improved at 450—500 K. In the previous paper we noted the maximum efficiency of 13% in BA formation over Co_3O_4-Li_2O (Co/Li=93/7) catalyst.[2] The much higher BA yield (17.7 and 23.4% at 472 and 493 K, respectively) was attained over Co_3O_4-La_2O_3 (Co/La=90/10) catalyst.

The activity of Co_3O_4-CeO_2 was 4—5 times as high as that of Co_3O_4 (Table 1(b)). Almost equimolar BA and acetic acid were formed at 425—450K as the major products and the selectivities of both products decreased monotonously with increasing the reaction temperature. Acetaldehyde and acetone were also formed, the selectivity of the both products remained less than 10% at all temperatures examined.

Co_3O_4-Pr_6O_{11} also showed higher activity for MEK oxidation (Table 1(c)). The selectivity of acetic acid

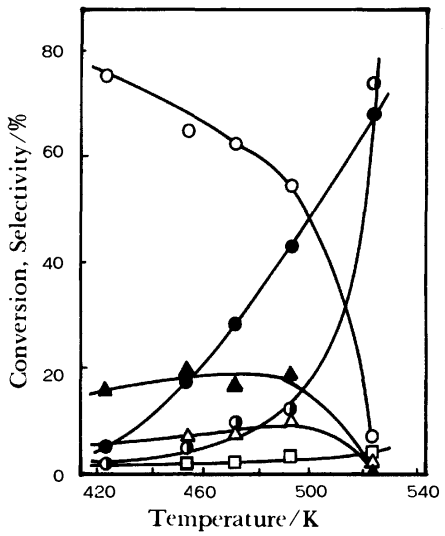

Fig. 1. The oxidation of MEK over Co_3O_4-La_2O_3 catalyst. Catalyst: 10 at.% La_2O_3, 2.48 g. W/F=2.00 (s.g-cat.cm^{-3}). Feed gas composition is the same as in Table 1. Symbols: ●, MEK conversion; ○, BA; △, acetaldehyde; ▲, acetic acid; ◑, carbon oxides; □, acetone.

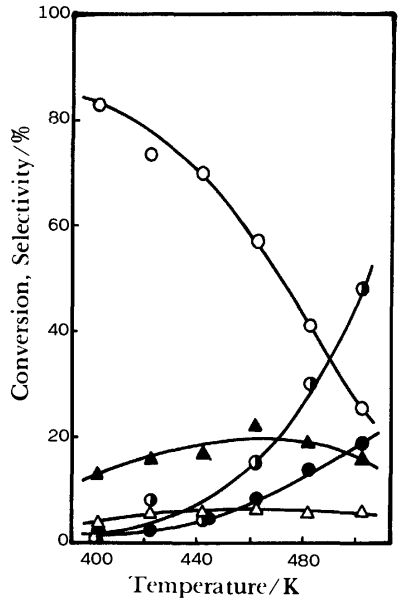

Fig. 2. The oxidation of MEK over Co_3O_4 catalyst. W/F=2.65 (s.g-cat.cm^{-3}). Feed gas composition: 1.62 mol% MEK, 32.8 mol% each of N_2, O_2, and H_2O. Symbols are the same as in Fig. 1.

was reduced at >460 K and the selectivity of deep oxidation was also suppressed at 470—490 K and compensatory increase in BA selectivity was observed at 460—490 K.

The activities of the catalysts containing Nd_2O_3, Gd_2O_3, and Er_2O_3 were comparable to that of Co_3O_4. Comparing the results of Table 1(d)—(f) with Fig. 2, it emerges that the addition of these oxides brought about the inhibition of scission reaction and deep oxidation at relatively high reaction temperatures. Therefore, BA selectivities were improved compensatively at above 440 K.

The addition of Yb_2O_3 gave negative effects on BA formation as shown in Table 1 (g). In this catalyst, since scission reaction was much promoted the BA selectivity remained low value even at low conversion level although the deep oxidation was much suppressed over the whole temperature range examined. A very small amount of acetone was formed over the Co_3O_4 catalyst whereas the Co_3O_4 catalysts containing lanthanoid oxides gave no neglectable extent of acetone and the catalysts containing Nd, Gd, and Er were somewhat peculiar in its ability to form acetone.

It is well-known that the decomposition of metal acetate gives acetone. Alternatively, lanthanoid oxides have been reported to be effective catalysts for vapor phase synthesis of ketones from C_2-C_4 alcohols and carboxylic acids.[4-7] According to mechanistic investigations for 1-butanol, at first 1-butanol was dehydrogenated to corresponding aldehyde which was rapidly succeively converted to aldol and then final ketone.[4,8] In latter case, feed gas contained no molecular oxygen. In the previous work,[2] a large amount of acetone formation (20—55% selectivity) from MEK was observed on the Co_3O_4 catalysts supported on MgO and CaO and it was presumed that acetone plausibly originates from acetate ions adsorbed on the basic supports. Although acetaldehyde was actually formed during the oxidation over every lanthanoid oxide containing catalyst, its selectivities were less than those of acetic acid. It appears that there is no correlation between the selectivities of acetaldehyde and those of acetone.

In addition, in this study feed gas contained 8.5 mol% O_2 which was larger than the stoichiometric concentration of complete oxidation of MEK. It is

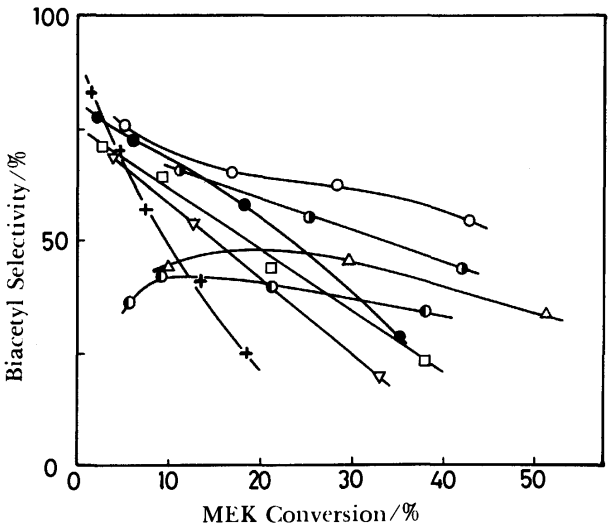

Fig. 3. Improvement in BA selectivity of Co_3O_4 catalyst by the addtion of lanthanoid oxide.
○: La_2O_3, ●: Nd_2O_3, ◑: Pr_6O_{11}, ◐: Yb_2O_3, △: CeO_2, ▽: Er_2O_3, □: Gd_2O_3, +: none (Co_3O_4 only).

confirmed by IR that only the bands arising from surface acetate and carbonate appeared when acetaldehyde was introduced on a wafer of Co_3O_4 at 373 K. So that it is believed that acetone was formed through the carboxylate intermediate on the surface. The activity-selectivity profiles of the catalysts are shown in Fig. 3. In case of Co_3O_4, BA selectivity decreased steeply with increase in conversion. This figure explicitly shows the improvement in the BA selectivity at higher MEK conversion by the addition of lanthanoid oxides especially by the addition of La_2O_3. Specific surface area of the Co_3O_4 catalyst was determined to be 8.4 m^2g^{-1} by BET method and those of the catalysts containing lanthanoid oxides are listed in Table 1. The values were distributed 8.4—20.3 m^2g^{-1} and the active catalysts in general had relatively large specific surface area, however, there is no simple correlation between the catalytic activities per unit weight and the specific surface areas of the catalysts. Specific activities of the catalysts for the MEK consumption (rate per unit surface area at 443—483 K) decreased in the order of

$$Ce > La > Pr > none > Gd > Er > Nd, Yb.$$

While the specific activities of BA formation decreased in the order of

$$La > Ce, Pr, Gd > none > Nd, Er, Yb.$$

It can be roughly said from these orders that the addition of lighter lanthanoid oxides into Co_3O_4 are favorable to BA formation.

The specific rates of BA formation of the catalysts were plotted in Fig. 4 against logarithmic solubility product constants (log K) of hydroxides of tervalent lanthanoid elements[9] as a measure of basicity of the catalysts. The figure shows an approximately linear relationship, suggesting that the basicity of the catalysts in one of the major factors for BA formation.

The Effects of Composition in Co_3O_4-La_2O_3 System. In foregoing section, it has become apparent that the Co_3O_4-La_2O_3 catalyst exceeds the Co_3O_4-Li_2O catalyst in the activity of BA formation. So that the effects of La content of the catalysts on the activity and BA selectivity were examined. At first, the oxidation of MEK was examined over La_2O_3 catalyst (9.0 m^2g^{-1}) under the same reaction conditions as those in Table 1. Oxidation took place with measurable rate at above 500 K, MEK conversion, however, reached only 1.5% even at 558 K. BA selectivity was less than 15% and acetaldehyde, acetone and methyl vinyl ketone were formed as major products. The MEK oxidation was examined over four Co_3O_4-La_2O_3 catalysts with different compositions at 423—493 K. No new kind of products appeared in the reactions over these catalysts.

Figure 5 shows specific surface areas and specific rates of BA formation of the catalysts. The catalysts showed almost similar surface areas except the catalyst of 10% La content (5.8 m^2g^{-1}). While BA formation rates have taken sharp peaks at 10% La content in the different reaction temperatures. Since it has been well known the compounds $LnCoO_3$ (Ln: lanthanoid elements) with perovskite structure[10,11] in Co_3O_4-Ln_2O_3 systems, the catalyst powder with 10% La content was examined by X-ray diffractmeter. However only the diffractions characteristic of Co_3O_4 crystallites of spinel structure were observed. The absence of the perovskite type compounds may be due to the relatively low calcination temperature in the catalyst preparation process. The thickness of La_2O_3 layer is calculated to be about 4.9 nm from its density (6.51 gcm^{-3}) assuming that the whole amount of La_2O_3 covered the surface of Co_3O_4 in the Co_3O_4-La_2O_3 (Co/La=9/1) catalyst. This thickness is sufficient to be detected by XRD. Absence of diffraction arising from La_2O_3 in the XRD measurement suggests that the catalyst composed of no simple mixture of the component oxides.

In summary, it has become apparent that the addition of ca. 10 atomic% of La oxide into Co_3O_4 is much preferable to BA formation.

a) Ten atomic% P_2O_5, TeO_2, SeO_2, Li_2O. b) Normalized to MEK; $W/F=4.27$ s g-cat. cm^{-3}; feed gas composition: 1.16 mol% MEK, 32.9 mol% each of N_2, O_2, and H_2O.

has been examined the effects of basic additives on MEK oxidation. The effects of some acidic additives were studied in this section.

The addition of P_2O_5 brought about exceeding acceleration of scission reaction as it is expected (Table 2). The selectivity of scission reaction went up over 55% and BA selectivity remained very low value at the all temperatures examined. MEK conversion of the catalyst was presumed to be higher than that of the Co_3O_4-La_2O_3 catalyst even if the difference of W/F is taking into account.

Scission reaction was also enhanced over Co_3O_4-TeO_2 catalyst and the product distribution was closely similar to that of Co_3O_4-P_2O_5.

In case of Co_3O_4-SeO_2 catalyst, activity of the catalyst was somewhat lower than the P_2O_5 or TeO_2 containing catalyst and both BA formation and acetaldehyde formation proceeded with comparable rates and substantially the selectivities did not vary at between 423—463K.

According to Sanderson,[3] SeO_2 do not act as a base since the partial negative charge of the oxide ions in SeO_2 is very low (0.07), on one hand, TeO_2 possessing relatively high partial charge (0.13) is rather amphoteric. So that Co_3O_4-TeO_2 catalyst is expected to be more efficient in BA formation than Co_3O_4-SeO_2 catalyst. The specific activity of Co_3O_4-SeO_2 catalyst, however, was far beyond that of Co_3O_4-TeO_2 catalyst both for MEK conversion and for BA formation. Selective inhibition of scission reaction was attempted by the addition of Li_2O into the Co_3O_4-SeO_2 catalyst (Table 2). MEK conversion was significantly reduced by the addition of Li_2O, and the oxidative dehydrogenation to methyl vinyl ketone was completely inhibited. Although the scission reaction was somewhat depressed at higher reaction temperatures, the improvement in BA selectivity was rather small.

When scission reaction takes place, a part of acetaldehyde molecules formed can be successively oxidized to acetic acid and a part of acetic acid molecules formed can likewise be oxidized to carbon oxides. Then the selectivity of acetaldehyde (normalized to reactant) never surpasses the sum of the selectivities of acetic acid and carbon oxides. In practice, that is the case in all catalysts except for the catalysts containing SeO_2. In case of Co_3O_4-SeO_2 catalyst the selectivity of acetaldehyde was greater than that of acetic acid but also corresponding to the sum of selectivities of acetic acid and carbon oxides. This may suggests that there is another path of acetaldehyde formation expressed by

$$MEK + 1/2\ O_2 = 2\ CH_3CHO.$$

The reason of the complicated behavior of Co_3O_4-SeO_2 catalyst in MEK oxidation is obscure at the present stage. Measurement of the concentrations of surface acidic and basic sites, observation of surface structure, and detailed study on the reaction mechanism will be required for understanding the result of Co_3O_4-SeO_2.

It can be said from the results in this section that the addition of acidic oxides into Co_3O_4 generally enhance the activity of the Co_3O_4 catalyst for scission reaction.

The Structure of the Cyclodextrin Complex. XX. Crystal Structure of Uncomplexed Hydrated γ-Cyclodextrin

Kazuaki HARATA
Research Institute for Polymers and Textiles, 1-1-4 Yatabe-Higashi, Tsukuba, Ibaraki 305
(Received February 9, 1987)

Crystal structure of uncomplexed γ-cyclodextrin, $C_{48}H_{80}O_{40}\cdot 14.1H_2O$, was determined by the X-ray method. The crystal is monoclinic and the space group is $P2_1$ with cell dimensions; $a=16.847(2)$, $b=11.098(2)$, $c=20.271(2)$ Å, and $\beta=104.97(1)°$. The structure was solved by the inspection of a Patterson map and the R-map method combined with the rigid-body least-squares technique and refined by the block-diagonal least-squares method to the R-value of 0.061 for 5099 reflections ($\sin\theta/\lambda\geqq 0.57$). γ-Cyclodextrin is in a round shape and somewhat distorted from the regular octagonal symmetry. Intramolecular hydrogen bonds are formed between adjacent glucose residues and maintain the round structure of γ-cyclodextrin. γ-Cyclodextrin molecules are arranged in a cage-type packing, and 7.1 water molecules, occupying 14 sites, are located within the host cavity.

Cyclodextrins are cyclic oligosaccharides consisting of six or more D-glucose residues, which are connected to form a macrocycle by the α-1,4-linkage. Because of the cylindrically-shaped intramolecular cavity, cyclodextrins form inclusion complexes with a wide variety of molecules and ions,[1] which can be fitted into the cavity, even if only partially. X-Ray studies of a number of crystalline complexes of α-cyclodextrin and β-cyclodextrin have revealed the geometrical feature of the host-guest interaction as well as the conformation of the macrocyclic ring,[2] and chemical and physical properties of the inclusion complexes have been interpreted on that basis. On the other hand, only a few crystal structures have been reported for γ-cyclodextrin[3] and its complexes.[4,5] Maclennan and Stezowski have reported the crystal structure of uncomplexed γ-cyclodextrin at 120 K,[3] and suggested that one glucose residue is statistically disordered. The low accuracy of their structure analysis, however, has prevented them from discussing the detailed bonding geometry and the conformation of the macrocycle in comparison with other cyclodextrins. We have been investigating the crystal structure of uncomplexed γ-cyclodextrin at room temperature, and have elucidated the structure with the accuracy comparable to that of other cyclodextrins. The preliminary report of this study[6] has shown the round structure of γ-cyclodextrin having no disordered glucose residue. We here report details of the crystal structure of γ-cyclodextrin in comparison with the structure of α-cyclodextrin and β-cyclodextrin.

Experimental

Materials and Measurements. γ-Cyclodextrin was purchased from Nihon Shokuhin Kako Co., Ltd., and recrystallized three times from water. Crystals were obtained at room temperature by the slow evaporation of an aqueous solution containing γ-cyclodextrin and D-xylose in ca. 1:1 molar ratio. Lattice parameters and diffraction intensities were measured at 22 °C on a Nicolet P3/F diffractometer with graphite-monochromated Cu $K\alpha$ radiation. The crystal was sealed in a thin glass capillary with a drop of mother solution. By using θ—2θ scan mode, 5099 independent reflections with $|F_o|\geqq 3\sigma(F)$ were obtained up to 118° in 2θ. No corrections were made for absorption or extinction effects.

Crystal Data: $C_{48}H_{80}O_{40}\cdot 14.1H_2O$, F.W.=1551.2, monoclinic, space group $P2_1$, $Z=2$, $a=16.847$ (2), $b=11.098$ (2), $c=20.271$ (2) Å, $\beta=104.97$ (1)°, $V=3661.4$ Å^3, $D_x=1.415$ g·cm^{-3}.

Determination and Refinement of the Structure. The orientation of the pseudo octagonal axis of γ-cyclodextrin was deduced from a Patterson map. The rotation around the molecular axis and the position in the unit cell were determined by the R-map method by using the model structure with the regular octagonal symmetry. After the correction of the positional and orientational parameters of each glucose residue, the structure was refined by the usual least-squares method. Water molecules were found on a difference-Fourier map. The final block-diagonal least-squares refinement of the structure, including 87 hydrogen atoms, achieved the R-value of 0.061. The quantity minimized was $\sum w(|F_o|-|F_c|)^2$, with $w=1.0$ for all the reflections. Atomic coordinates and B_{eq} values of non-hydrogen atoms are given in Table 1. Tables of observed and calculated structure factors, anisotropic temperature factors of non-hydrogen atoms, and atomic parameters of hydrogen atoms, are deposited to the Chemical Society of Japan (Document No. 8749). The computation was carried out on a FACOM M380 computer at the Center of Research Information Processing System (RIPS), Agency of Industrial Science and Technology, Tsukuba.

Description of the Structure

γ-Cyclodextrin is in the shape of a nearly regular octagon as shown in Fig. 1. Each glucose unit has the $^4C_1$ chair conformation and is connected to the next residue by the α-1,4-linkage. Average bond distances and angles are shown in Fig. 2. These values are in good agreement with the corresponding values of α-cyclodextrin[7] and β-cyclodextrin.[8] The C(6)-O(6) bonds show two types of orientations; gauche-gauche (to the C(5)-O(5) bond and to the C(4)-C(5) bond, respectively) in the G2, G3, G4, and G7 residues and gauche-trans in the G1, G5, and G8 residues. The C(6)-O(6) bond in the G6 residue is disordered and the occupancy factor of the O(6,G6) atom is 0.76 for the

a) $B_{eq}=8\pi^2(u_1^2+u_2^2+u_3^2)/3$, where u_i is the root-mean-square deviation in the i-th principal axis of the thermal ellipsoid.
b) *OC* indicates the occupancy factor.

former and 0.24 for the latter. Some geometrical parameters describing the macrocyclic conformation are summarized in Table 2. Eight glycosidic oxygen atoms (O(4)) form a nearly regular octagon with the radius of 5.81—5.94 Å and the side length of 4.43—4.59 Å. These O(4) atoms are coplanar within the maximum deviation of 0.192 Å. The torsion-angle index of 97.0—120.4° is somewhat larger than those of other two cyclodextrins. Since the O(4)···O(4′) distance is in rather narrow region, the correlation

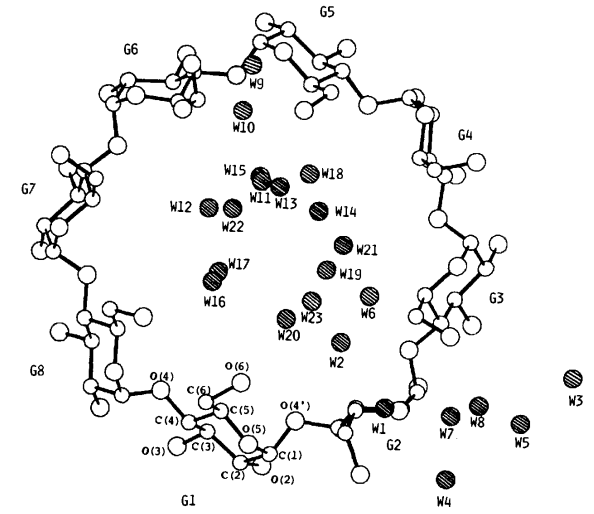

Fig. 1. The Structure and numbering scheme of γ-cyclodextrin hydrate. Water molecules are shaded.

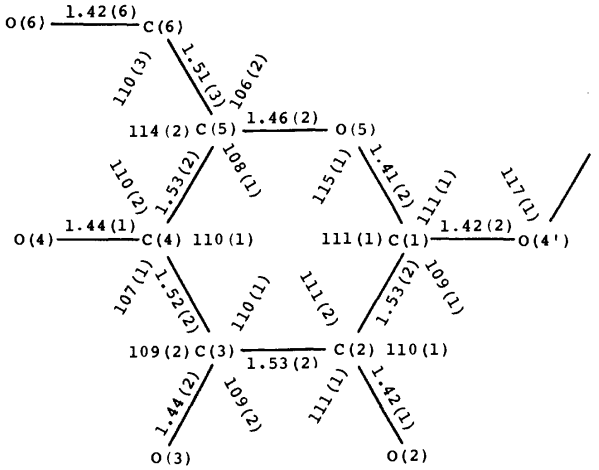

Fig. 2. Average bond distances and angles for the eight glucose residues. Standard deviations in parentheses were estimated according to the equation: $\sigma=[\sum_{i=1}^{8}(x_i-\bar{x})^2/7]^{1/2}$ where x_i refers to the bond distance or angle of the i-th residue and $\bar{x}$ is the average value.

between the O(4)···O(4′) distance and the torsion-angle index is less obvious than the correlation found in α-cyclodextrin,[9] β-cyclodextrin,[10] or in mono- and disaccharides.[11] The tilt-angle is distributed in the range form −2.5° to 23.8°. The G2 and G4 residues are almost normal to the plane through the eight O(4) atoms, while the other residues incline with their O(6) side turning to the inside of the macrocycle. The average value of 13.9° is similar to that of β-cyclodextrin (12.5°), but smaller than that of α-cyclodextrin (19.2°). The O(2)···O(3′) distances of 2.76—2.91 Å between adjacent residues indicate that adjacent two residues are linked by the O(2)···O(3′) hydrogen bond. Although no hydrogen bond is observed between O(2,G7)H and O(3,G8)H hydroxyl groups, four O(2)-H···O(3) and three O(3)-H···O(2) hydrogen

Table 2. Geometrical Parameters Describing the Macrocyclic Conformation of γ-Cyclodextrin

I. Distance from the Center of Gravity of Eight O(4) Atoms to Each O(4) Atom[a)]

Residue	Distance (l/Å)	Residue	Distance (l/Å)
G1	5.84	G5	5.88
G2	5.88	G6	5.81
G3	5.90	G7	5.94
G4	5.84	G8	5.94

a) The estimated standard deviation is 0.01 Å.

II. O(4)···O(4′) Distance between Adjacent Glucose Residues[a)]

Distance (l/Å)		Distance (l/Å)	
O(4,G1)···O(4,G8)	4.54	O(4,G4)···O(4,G5)	4.48
O(4,G1)···O(4,G2)	4.59	O(4,G5)···O(4,G6)	4.48
O(4,G2)···O(4,G3)	4.46	O(4,G6)···O(4,G7)	4.58
O(4,G3)···O(4,G4)	4.46	O(4,G7)···O(4,G8)	4.43

a) The estimated standard deviation is 0.01 Å.

III. O(2)···O(3′) Distances between Adjacent Glucose Residues[a)]

Distance (l/Å)		Distance (l/Å)	
O(2,G1)···O(3,G2)	2.91	O(2,G4)···O(3,G5)	2.83
O(3,G1)···O(2,G8)	2.88	O(2,G5)···O(3,G6)	2.81
O(2,G2)···O(3,G3)	2.77	O(2,G6)···O(3,G7)	2.84
O(2,G3)···O(3,G4)	2.76	O(2,G7)···O(3,G8)	2.77

a) The estimated standard deviation is 0.01 Å.

IV. Torsion Angle Index[a)]

Residue	Index (ϕ/°)	Residue	Index (ϕ/°)
G1	99.8	G5	112.0
G2	107.0	G6	97.0
G3	113.1	G7	120.4
G4	119.9	G8	116.5

a) The torsion angle index is defined as follows: $\phi=|\phi(C(1)\text{-}C(2))|+|\phi(C(2)\text{-}C(3))|+|\phi(C(5)\text{-}O(5))|+|\phi(O(5)\text{-}C(1))|-|\phi(C(3)\text{-}C(4))|-|\phi(C(4)\text{-}C(5))|$, where the conformation angle, C(1)-C(2)-C(3)-C(4), is expressed as ϕ(C(2)-C(3)).

V. Tilt Angle[a)]

Residue	Tilt angle (ϕ/°)	Residue	Tilt angle (ϕ/°)
G1	16.6	G5	18.4
G2	−2.5	G6	13.4
G3	23.8	G7	12.7
G4	4.8	G8	23.6

a) The tilt angle is defined as the angle made by the plane through the eight O(4) atom and the plane through C(1), C(4), O(4), and O(4′) of each residue.

VI. Deviation of O(4) Atoms from Their Least-Squares Plane

Atom	Deviation (d/Å)	Atom	Deviation (d/Å)
O(4,G1)	0.054	O(4,G5)	−0.077
O(4,G2)	−0.173	O(4,G6)	−0.046
O(4,G3)	−0.005	O(4,G7)	−0.056
O(4,G4)	0.192	O(4,G8)	0.126

bonds are found. These hydrogen bonds may maintain the round structure of γ-cyclodextrin.

The crystal structure is shown in Figs. 3 and 4. γ-Cyclodextrin molecules are stacked along the crystallographic b axis, showing a packing feature similar to the cate-type packing found in the crystal of uncomplexed β-cyclodextrin.[10] The plane through eight O(4) atoms makes an angle of 46.5° with the b axis. As the result, adjacent two molecules along the b axis are laterally shifted each other by about half a molecule.

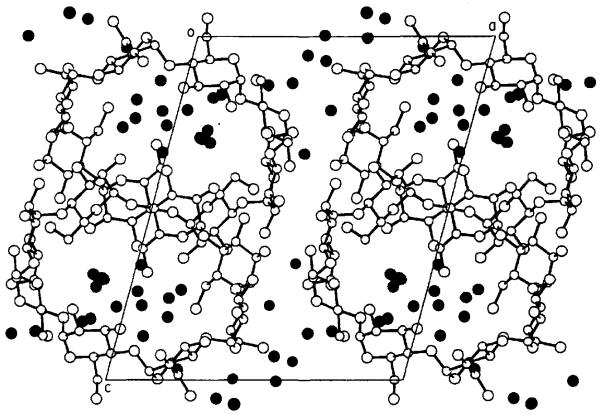

Fig. 3. The crystal structure viewed along the b axis. Water molecules are shown by full circles.

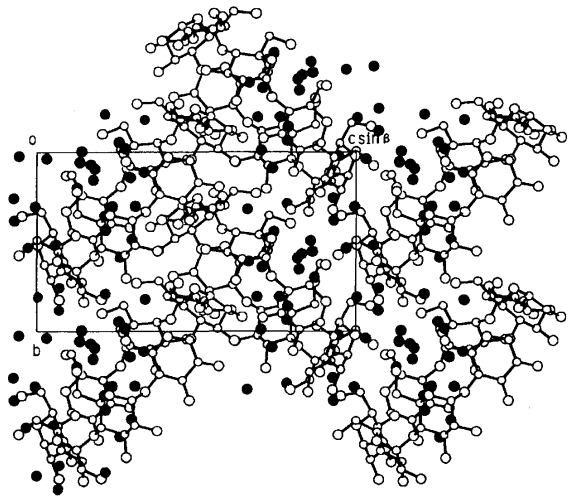

Fig. 4. The crystal structure viewed along the a axis. Water molecules are shown by full circles.

Both ends of the γ-cyclodextrin cavity are blocked by adjacent molecules. Owing to the incomplete blockade, however, the cavity is not closed. A narrow channel runs through the inside of the macrocycle stacked along the b axis. This channel is filled with water molecules as shown in Fig. 4. The G7 and G8 residues are partially inserted into the adjacent γ-cyclodextrin ring from the O(2), O(3) side, and form hydrogen bonds with included W6, W15, W18, and W23 water molecules.

The asymmetric unit of the crystal contains 14.1 water molecules, which are distributed over 23 sites. γ-Cyclodextrin includes 7.1 water molecules which occupy 14 sites. It is obvious that water molecules within the cavity can not fully form hydrogen bonds. These water molecules are arranged in the limited accommodation space so that they can form no ideal geometry of hydrogen bonding. Although it is not possible to discuss the details of hydrogen-bonding scheme because most of hydrogen atoms of water molecules were not located on the difference-Fourier map, most of hydroxyl groups of γ-cyclodextrin are hydrogen-bonded to water molecules located outside the cavity and form hydrogen-bond network in the crystal.

Discussion

The present X-ray analysis has shown that the γ-cyclodextrin molecule is round and rather symmetrical. When compared this structure with the structure reported by Maclennan and Stezowski,[3] a major difference is that one glucose residue is disordered in the structure at 120 K. In the structure at room temperature, however, all glucose residues are well ordered although the average temperature factor of the G8 residue is ca. twice greater than the average value of the other residues. This difference may be ascribed to the different conditions of data measurements and/or crystallization.

Table 3 gives some geometrical parameters to compare the macrocyclic conformation among three cyclodextrins. The glycosidic oxygen angle does not significantly change among these cyclodextrins, and is in good agreement with the O(4) angle found in maltosides.[12-14] This indicates that the effect of cyclization on the O(4) angle is small. A difference is found in the

Table 3. Comparison of Average Values of Some Geometrical Parameters Describing the Macrocyclic Conformation[b]

	α-Cyclodextrin	β-Cyclodextrin	γ-Cyclodextrin
O(2)···O(3′) distance (l/Å)	3.3(0.6)	2.9(0.1)	2.8(0.1)
O(4)···O(4′) distance (l/Å)	4.3(0.1)	4.4(0.1)	4.5(0.1)
O(4) angle (ϕ/°)	118(1)	118(1)	117(1)
Planarity of the O(4) polygon (d/Å)[a]	0.084	0.178	0.110
Torsion-angle index (ϕ/°)	127(9)	120(7)	111(9)
Tilt-angle (ϕ/°)	19(12)	12(10)	14(9)

a) The root-mean-square deviation from the least-squares plane through the O(4) polygon. b) Standard deviations are given in parentheses.

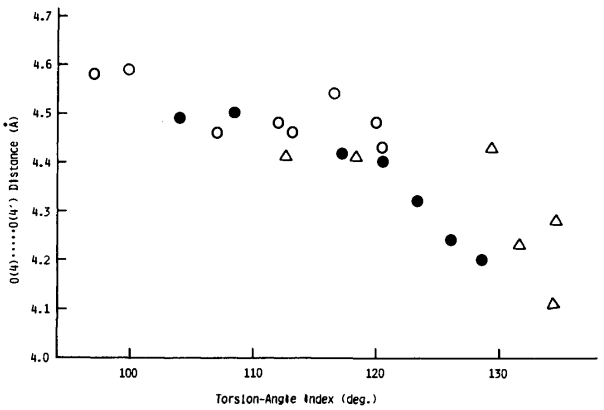

Fig. 5. Plot of the O(4)···O(4′) distance between adjacent glucose residues against the torsion angle index: α-cyclodextrin (△), β-cyclodextrin (●), and γ-cyclodextrin (○).

O(4)··· O(4′) distance and the torsion-angle index. The average O(4)··· O(4′) distance increases with the increasing number of the glucose residues, while the average torsion-angle index decreases. Figure 5 shows that the O(4)··· O(4′) distance and the torsion angle index are in the limited region depending on the size of the macrocycle. Since the O(4) atoms of γ-cyclodextrin are aligned on a circle with the radius larger than the radius of the other cyclodextrins, the greater O(4)··· O(4′) distance is necessary to avoid the unfavorable distortion of the glycosidic linkage. The change of the O(4)··· O(4′) distance can be easily derived by the small change of the endocyclic conformation angle of the pyranose ring, as indicated by the correlation between the O(4)··· O(4′) distance and the torsion-angle index.

The O(2)··· O(3′) distance indicates that the intramolecular hydrogen bond becomes stronger in order of α-, β-, and γ-cyclodextrin. The α-cyclodextrin ring is remarkably distorted and two intramolecular hydrogen bonds are disrupted because of the sharp inclination of glucose residues. Chako and Saenger[15] have also reported that the uncomplexed α-cyclodextrin, crystallized in the presence of $BaCl_2$, is more symmetrical with the six O(2)··· O(3′) hydrogen bonds. In that case, however, the average O(4)··· O(4′) distance is decreased to 4.234 Å and the glycosidic oxygen angle is somewhat increased (118.4°), suggesting that the strain is imposed on the macrocycle although such strain energy may be compensated by the formation of additional two hydrogen bonds. In β-cyclodextrin and γ-cyclodextrin, the radius of the macrocycle is so large that the macrocyclic ring can be symmetrical and also in the relaxed state.

The G7 and G8 residues are found to be partially inserted into the cavity of the adjacent γ-cyclodextrin, which is related by the two-fold screw axis. Such close contact between host molecules has not been observed in other cyclodextrin crystals since the diameter of the cavity is too small to allow the penetration of the glucose moiety. The effective space of the γ-cyclodextrin cavity to accommodate water molecules becomes considerably smaller than the expected space from the radius of the macrocycle. The interesting fact is that the temperature factor of the G8 residue is significantly larger than the temperature factor of the other residues. This may be ascribed to the limited hydrogen-bonding contacts of the G8 residue in the hydrophobic environment. The O(2,G8)H and O(3,G8)H hydroxyl groups form hydrogen bonds with W15 and W18, respectively, which have relatively low occupation factor (0.25 and 0.55, respectively). Moreover, no intramolecular hydrogen bond is observed between O(2,G7)H and O(3,G8)H hydroxyl groups. This indicates that hydrogen bonds, especially intramolecular hydrogen bonds, play an important role to maintain the rigid structure of cyclodextrins.

(Received February 16, 1987)

An assignment of the normal vibrations of 2-aminopyrimidine was made through the vibrational analyses of the polarized Raman and infrared spectra and also through the normal coordinate calculation. The assignment was confirmed by the same study made on 2-amino-d_2-pyrimidine.

Lafaix and Lebas studied the infrared and Raman spectra of various amino-substituted pyrimidines and gave tentative assignments for some normal vibrations of these molecules.[1] Kydd studied the amino inversion vibration of 2-aminopyrimidine through observation of the infrared spectrum in vapor and showed that the molecule is planar in the vibrational ground state.[2] Scheinbeim and Schempp[3] and Furberg et al.[4] determined the crystal structure of 2-aminopyrimidine and pointed out that the molecules form hydrogen-bonded dimer-like pairs in crystal.

Since the orientation of the 2-aminopyrimidine molecule in crystal has been known, the vibrational analyses of the polarized Raman and infrared spectra in single crystals became possible. In this paper, the assignment of the normal vibrations of 2-aminopyrimidine is discussed based on polarization behavior of the Raman and infrared bands observed in single crystals and also the normal coordinate calculation. The same study is made on 2-amino-d_2-pyrimidine and the assignment is confirmed.

Experimental

Material. 2-Amino-d_2-pyrimidine was synthesized by the exchange reaction of 2-aminopyrimidine obtained from Tokyo Kasei Chemical Company with D_2O. Isotopic purity of the product was determined by the nuclear magnetic resonance measurement. The samples were purified by zone-refining of about 100 passages.

Optical Measurements. Polarization measurement of the Raman spectrum was made in molten and single crystal phases with a JEOL 400 T Laser Raman Spectrophotometer. The sample was excited with the 514.5 nm line from an Ar^+ ion laser. A well grown single crystal of 2-aminopyrimidine obtained by the Bridgman method was cut along the cleavage bc plane and then cut along the ab and ac planes. Samples with cubic shape of about 5 mm^3 were prepared. The crystal axes were determined by observing the birefringence under the polarization microscope. The crystal growth direction was found to be the c axis. 2-Amino-d_2-pyrimidine changes quite rapidly into 2-amino- and 2-amino-d_1-pyrimidines by the exchange reaction with moisture in atmosphere, and thus the polarized Raman spectrum of the 2-amino-d_2-pyrimidine crystal was observed for a single crystal grown in a capillary glass tube of about 50 mm in length and 3 mm in diameter. The method of measurement of the polarized Raman spectrum was exactly the same as that described previously.[5,6]

The infrared spectrum of 2-aminopyrimidine was observed in vapor and single crystal phases with a Hitachi Infrared Spectrophotometer Model 345. The single crystal sample was grown between two KRS-5 plates in the same way as that described previously.[7] A well grown single crystal portion of the crystal sample was selected under polarized light and other portion was covered with aluminum foil. The polarized infrared spectrum was measured with an AgBr wire-grid polarizer. The incident infrared light was polarized by the polarizer in such a way that the electric vector pointed in the direction of 45° from both the vertical and horizontal directions. The polarizer is rotatable by 90°. Although the spectrophotometer had some preferential sensitivity to vertically polarized light, the two components of the diagonally polarized light beam behaved equally concerning the intensity. The sample crystal sandwiched between two KRS-5 plates was held in a cell holder adjusting the orientation of the crystal, so that the spectrum showed the most remarkable polarization behavior by rotating the polarizer by 90°. The spectrum observed with polarized light which gives the maximum intensity for the strong and narrow band at 1210 cm^{-1} is referred to as the $\perp$ spectrum and that giving the minimum intensity is to as the // spectrum. In this orientation of the sample crystal, the crystal growth direction (c axis) was found to point roughly in the vertical direction. The infrared spectrum of the 2-amino-d_2-pyrimidine single crystal could not be observed because the deuterium atoms were replaced by the hydrogen atoms with moisture in atmosphere.

Normal Coordinate Calculation

A normal coordinate calculation was performed through the standard GF matrix methods with a FACOM M-200 computer at the Computer Center of Fukuoka University. The geometric parameters of the 2-aminopyrimidine molecule were taken from the data determined by Scheinbeim and Schempp.[3] The F matrix elements for the in-plane vibrations were evaluated with the potential field of an improved modification of the Urey-Bradley force field described previously.[5-7] For the out-of-plane vibrations the valence force field and ϕ type torsional coordinates were used. Values of the force constants used for the calculation of the in-plane and out-of-plane normal vibrations of 2-amino- and 2-amino-d_2-pyrimidines are listed in Table 1. The notation of the force constants are exactly the same as those used previously[5-7] and the symbols given for atoms and internal coordinates are shown in Fig. 1. The calculated frequencies and modes of the normal vibrations are given in Table 4.

Calculation of Relative Intensities of the Raman and Infrared Bands in Single Crystals

2-Aminopyrimidine crystallizes in orthorhombic space group D^{15}_{2h} with eight molecules in the unit cell, where the structure contains centrosymmetrically related hydrogen-bonded dimer-like pairs separated by hydrophobic regions and the dihedral angle between the planes of the amino group and pyrimidine ring is about 22°.[3,4)] The projection of the crystal structure on the bc plane is shown in Fig. 2. No factor group splitting was observed for the Raman bands due to molecular vibrations in crystal and thus the relationship between the Raman tensors for the free molecule and the crystal was derived based on the simple oriented gas model. Evaluation of the matrix elements of the Raman tensor of 2-aminopyrimidine was made in the same way as that made for maleic anhydride[5)] and tetramethylpyrazine.[6)] The direction cosines between the crystal and molecular axes were calculated using the crystal data given by Scheinbeim and Schempp.[3)] The squares of relative values of the elements of the Raman tensor, which are proportional to the relative intensities of the Raman bands, are given in Table 2, where the molecular structure of 2-aminopyrimidine is assumed to belong to point group C_{2v}.

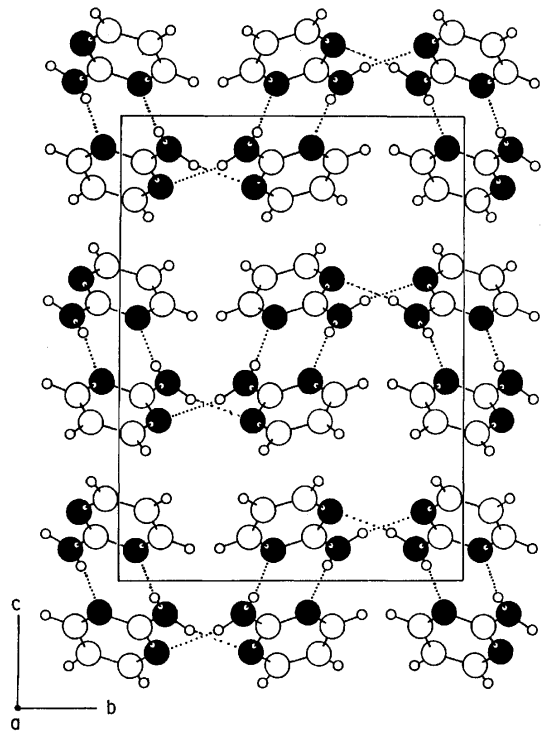

Fig. 2. Projection of the 2-aminopyrimidine crystal on the bc plane.

In order to carry out the vibrational analysis of the polarized infrared spectrum, the crystal axes in the sample crystal sandwiched between two KRS-5 plates have to be determined. Since the crystal growth direction (c axis) was found in a plane of the sample crystal,

	⊥	0.00	0.65	0.35

a) θ is the angle between the c axis and the vertical line. The plane of the sample crystal was assumed to be the cleavage bc plane. b) For the definition of the // and ⊥ polarized spectra, see text.

the plane would be the cleavage bc or ac plane. Proportionality factors of the intensity of the infrared bands in the // and ⊥ spectra were calculated for the bands assigned to the vibrations belonging to symmetry species a_1, b_2, and b_1 assuming that the sample crystal plane is the bc or ac plane, in the same way as calculated for pyrazine.[9] The calculation was made varying the angle between the c axis and the vertical line and the values obtained for the angles of 0, 10, and 20° for the bc plane are listed in Table 3.

Results and Discussion

2-Aminopyrimidine. The polarized Raman spectrum of 2-aminopyrimidine observed in single crystal is shown in Fig. 3. The polarized spectrum was denoted by two characters such as ab in the same manner as described previously.[5,6] The first letter refers to the direction of polarization of the excitation light and the latter to that of the scattering light. It is expected from Table 2 that the relative intensity of the b_2 vibrations is strongest in the bb polarized spectrum, the b_1 vibrations in the aa spectrum and the a_2 vibrations in the cc spectrum.

The polarized infrared spectrum of 2-aminopyrimidine in single crystal is shown in Fig. 4, where the // and ⊥ spectra are drawn with the solid and dotted lines, respectively. As can be seen in the figure, polarization behavior of the infrared bands in crystal can be classified into three types. The bands showing the first type polarization are almost missing in the ⊥ spectrum, while the second type bands are observed much strongly in the ⊥ spectrum. The intensity of the third type bands observed in the // spectrum is about 1.5

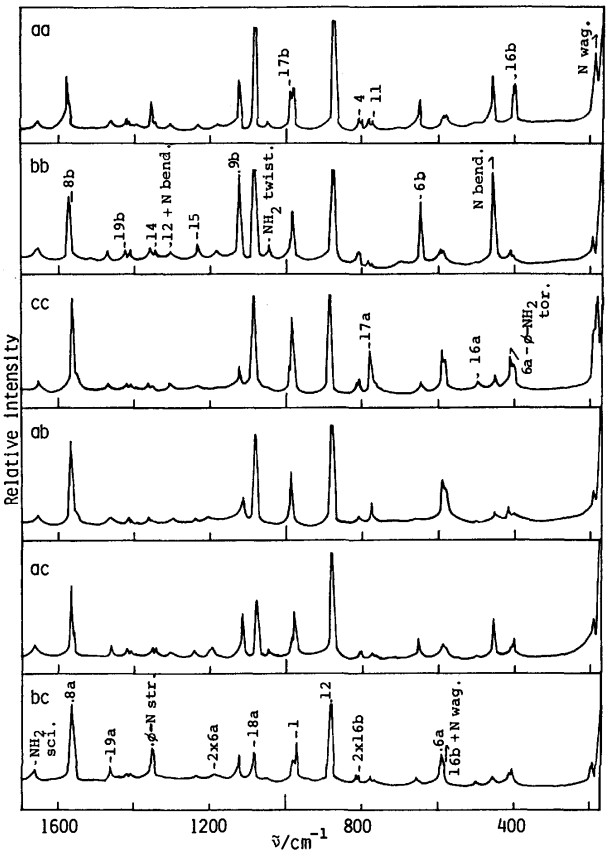

Fig. 3. Polarized Raman spectra of the 2-aminopyrimidine crystal. For the definition of the symbols of the spectra such as aa, see text.

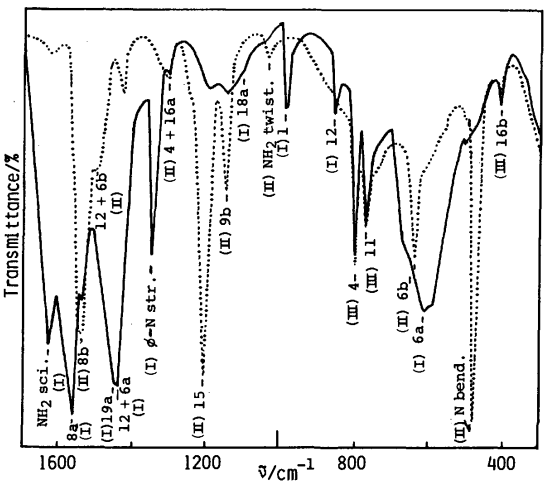

Fig. 4. Polarized infrared spectrum of the 2-aminopyrimidine crystal.

times strong as that in the ⊥ spectrum. These three types of polarization behavior are referred to as the types I, II, and III, respectively. The proportionality factors of the intensity of the bands calculated for the bc plane, which is given in Table 3, indicate that the spectra can be well explained by the values calculated for the crystal orientation with the c axis pointing in the direction of 10° from the vertical line. This means

that the propagation direction of the incident light was along the a axis and the direction of the electric vector deviated from the c axis by 35° in our polarization measurement. The calculation was also made for the ac plane, but the result was not consistent with the observed polarization behavior even if the sample crystal assumes to be in any orientation. Thus the infrared bands showing the type I, II, and III polarization behavior could be assigned to the vibrations belonging to the symmetry species a_1, b_2, and b_1, respectively.

The vibrational modes were determined through the normal coordinate calculation. Since the 2-aminopyrimidine molecule forms hydrogen-bonded dimer-like pairs in crystal, the infrared bands whose frequencies largely shift in crystal from those in vapor could be assigned to the vibration involving the NH_2 group.

Species a_1: The strongly polarized Raman bands observed at 3330, 3025, 1580, 1448, 1360, 1080, 990, and 870 cm^{-1} in molten phase were directly ascribed to the a_1 vibrations and assigned to the N-H stretching, ν_2, ν_{8a}, ν_{19a}, ϕ-N stretching, ν_{18a}, ν_1, and ν_{12} vibrations, respectively. Where ϕ refers to the pyrimidine ring. The corresponding infrared bands showed the type I polarization as predicted. The Raman band observed at 1650 cm^{-1}, whose corresponding infrared band was observed strongly in crystal but was not in vapor and showed the type I polarization, was ascribed to the NH_2 scissoring vibration of the hydrogen-bonded molecule. The strong infrared band observed at 1597 cm^{-1} in vapor was assigned to the NH_2 scissoring vibration of the free molecule. The band at 605 cm^{-1} showing the type I polarization was assigned to the ν_{6a} vibrations, although the corresponding Raman band showed low depolarization factor in molten phase.

Species b_2: The relative intensities of the Raman bands observed at 1558, 1425, 1355, 1230, 1130, 1040, 642, and 457 cm^{-1} were strongest in the bb spectrum and decreased in the aa and ac spectra in order. This polarization behavior is consistent with the assignment to the b_2 vibrations and thus these bands were assigned to the ν_{8b}, ν_{19b}, ν_{14}, ν_{15}, ν_{9b}, NH_2 twisting, ν_{6b}, and N bending vibrations, respectively. The corresponding infrared bands showed the type II polarization.

Species b_1: The relative intensities of the Raman bands observed at 997, 802, 765, 410, and 187 cm^{-1} were strongest in the aa spectrum and medium in the bc and cc spectra. Thus these bands were assigned to the ν_{17b}, ν_4, ν_{11}, ν_{16b}, and N wagging vibrations belonging to the species b_1, respectively. The corresponding infrared bands showed the type III polarization. The NH_2 wagging vibration could not be resolved.

Species a_2: The relative intensities of the Raman bands observed at 782, 516, and 417 cm^{-1} were strongest in the cc spectrum and decreased in the ab, bc, aa, and bb spectra in order. Thus these bands were assigned to the ν_{17a}, ν_{16a}, ν_{6a}—ϕ-NH_2 torsional vibrations of the species a_2, respectively. The very weak infrared band observed at 514 cm^{-1} in crystal was assigned to the ν_{16a} vibration of the species a_2. An appearance of the infrared inactive a_2 band may be due to the distortion of the molecular structure in crystal.

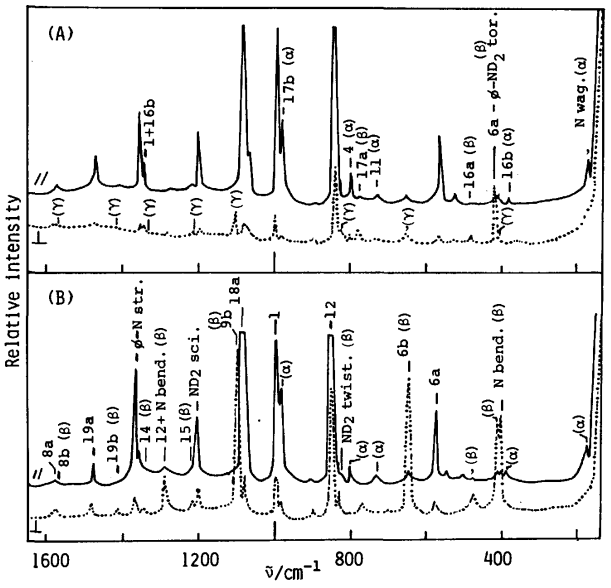

Fig. 5. Polarized Raman spectrum of the 2-amino-d_2-pyrimidine crystal. For the definition of the spectra of (A) and (B), see text.

2-Amino-d_2-pyrimidine. The polarized Raman spectrum of 2-amino-d_2-pyrimidine is given in Fig. 5. A single crystal of 2-amino-d_2-pyrimidine grown in a capillary tube was held in a cell holder in such a way that the crystal growth direction was along the polarization direction of the excitation light and the scattering light was observed at the direction perpendicular to the excitation light beam. The polarized Raman spectra were observed in two crystal orientations, in which the spectra showed drastically different polarization behaviors with each other. These crystal orientations are referred to as the orientations A and B. The narrow band at 648 cm^{-1} gave the minimum intensity in the orientation A and the maximum intensity in the orientation B.

The Raman spectra observed for the scattering lights polarized parallel and perpendicular to the crystal growth direction are referred to as the // and ⊥ spectra, respectively. The polarized Raman bands can be classified into three types α, β, and γ as indicated in Fig. 5. The type α refers to the band whose intensity is stronger in the // spectrum than in the ⊥ spectrum, the type β to the band whose intensity is stronger in the ⊥ spectrum than in the // spectrum, and the type γ to the band whose intensity is nearly equal in the // and ⊥ spectra. Polarization behavior of the Raman band is represented by two symbols such as $\gamma\beta$, where the first and second letters refer to the types of polarization behavior observed in the crystal orientations A and B, respectively. Observed polarization behavior of the non-totally symmetric Raman bands can be classi-

a) See Ref. 1. b) H is replaced by D in 2-amino-d_2-pyrimidine. Vibrational modes for the NH_2 group are determined on referring to Ref. 8. c) Lafaix and Lebas presented the modes of H bending and H wagging vibrations instead of individual modes such as ν_{18a} and ν_{11} vibrations for these frequencies. d) Frequency obtained from difference band.

fied into three types $\gamma\beta$, $\alpha\alpha$, and $\beta\beta$ through which each Raman band can be experimentally assigned to the certain symmetry species.

Species a_1: The strongly polarized Raman bands observed at 3027, 2410, 1578, 1475, 1363, 1078, 983, and 848 cm^{-1} in molten phase were assigned to the ν_2, N-D stretching, ν_{8a}, ν_{19a}, ϕ-N stretching, ν_{18a}, ν_1, and ν_{12} vibrations, respectively. The Raman band observed at 578 cm^{-1} in molten with low depolarization factor and the band clearly observed at 1205 cm^{-1} in crystal were assigned to the ν_{6a} and ND_2 scissoring vibrations, respectively, because these bands showed no $\gamma\beta$, no $\alpha\alpha$, and no $\beta\beta$ polarization behavior in crystal.

Species b_2: The depolarized Raman bands observed at 3053, 2520, 1557, 1420, 1350, 1220, 1102, 823, 648, and 407 cm^{-1} in molten phase showed the type $\gamma\beta$ polarization in crystal and were assigned to the ν_{7b}, N-D stretching, ν_{8b}, ν_{19b}, ν_{14}, ν_{15}, ν_{9b}, ND_2 twisting, ν_{6b}, and N bending vibrations, respectively, because the frequencies of the out-of-plane vibrations are lower than 1000 cm^{-1} in pyrimidine derivatives.

Species b_1: The depolarized Raman bands observed at 975, 798, 745, 390, and 173 cm^{-1} in molten phase showed the type $\alpha\alpha$ polarization in crystal and were assigned to the ν_{17b}, ν_4, ν_{11}, ν_{16b}, and N wagging vibrations, respectively.

Species a_2: The depolarized Raman bands observed at 780, 480, and 415 cm^{-1} in molten phase showed the type $\beta\beta$ polarization in crystal and thus were assigned to the ν_{17a}, ν_{16a}, and ν_{6a}—ϕ-ND_2 torsional vibrations, respectively.

The normal vibrations thus assigned are summarized in Table 4. The table shows that the assignment of the normal vibrations given for 2-amino-d_2-pyrimidine is consistent with the assignment given for 2-aminopyrimidine, and this fact confirms the reasonability of the assignments.

The normal coordinate calculation indicates that the ν_{19a},ν_{12}, and ν_{6a} vibrations mix largely with the ϕ-N stretching vibration. This mixing is supported by the experimental fact that the ν_{19a} vibration increases in frequency and the ν_{12} and ν_{6a} vibrations decrease com-

pared with the corresponding vibrations of pyrimidine (1402, 1068, and 677 cm^{-1}).[10] The normal coordinate calculation shows that the ν_{16b} and ν_{16a} vibrations mix with the N wagging and ϕ-NH_2 torsional vibrations, respectively. The fact that the ν_{16b} and ν_{16a} vibrations increase in frequency compared with the corresponding vibrations of pyrimidine (344 and 394 cm^{-1}) justifies the mixing. The ν_{17a} vibration decreases in frequency compared with the ν_{17a} vibration of pyrimidine (1004 cm^{-1}). This fact may be caused by the mixing of the ν_{17a} and NH_2 twisting vibrations as indicated by the normal coordinate calculation. The out-of-phase displacements of the H atoms of the NH_2 group from the plane of the pyrimidine ring are calculated to be fairly large in the NH_2 twisting vibration because of the nonplanality of the planes of the amino group and the ring. The same frequency shifts due to vibrational mixing were also found in the normal vibrations of 2-amino-d_2-pyrimidine. The vibrational analysis of the polarized sublevel phosphorescence spectra of 2-aminopyrimidine, which will be reported soon, also confirms the validity of the assignments made in this work.[11]

Radiolysis of Methanol Adsorbed on Zeolite

Chiyoko NAKAZATO,* Ryoji MURAYAMA, Masayoshi AOKI, and Takahiro MASUDA
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukasawa, Setagaya-ku, Tokyo 158
(Received February 26, 1987)

Radiolysis of methanol adsorbed on synthesized zeolite was investigated by means of product analysis. Molecular hydrogen, formaldehyde, and ethylene glycol are produced as major products. The *G*-value for the formation of H_2 increases with increasing amount of methanol adsorbed on zeolite and approaches ca. 2.1 at about 10^{-2} mol of methanol per g of zeolite, where the coverage of methanol is approximately unity and *G*-values of ca. 1.0 are observed for formaldehyde and ethylene glycol. Addition of an electron scavenger causes decrease in $G(H_2)$. However, the hydrogen formation is not completely suppressed by N_2O, SF_6, or CCl_4. Kinetics in solution is useful for the interpretation of results and allows the estimation of the *G*-value for the generation of electron in zeolite and of its relative reactivity toward methanol and some electron scavengers.

Radiolysis of compounds adsorbed on the surface of solid has been extensively investigated because of much interest in the mechanism of energy transfer from adsorbent to adsorbate and in reaction specificity possibly observed in the adsorbed state.[1-6] In an irradiated solid such as silica gel or zeolite, formation of electron and positive hole has been confirmed by experiments using electron or hole scavenger.[7-12] Recently, we found that a part of electrons generated in an irradiated zeolite (Molecular Sieve 13X; abbreviated to MS) are very similar to quasi-free electrons produced in irradiated liquid 2,2-dimethylpropane with respect to reactivity toward some electron scavengers.[13,14] The result suggests that rate constants for reactions of electrons produced in irradiated MS with a substrate adsorbed on the solid may be estimated by competition kinetics using electron scavengers. The synthetic zeolite, MS, is characterized by the possession of many cages and channels. Especially, the supercavity of MS is known to allow passage of molecules below 1 nm in effective diameter. A variety of compounds, therefore, can be used as substrates or scavengers to clarify the detailed profile of radiolysis in heterogeneous systems.

This paper deals with a kinetic study on reactions of methanol adsorbed on MS with electrons or positive holes generated in irradiated MS. Yields of radiolytic products, molecular hydrogen, formaldehyde, and ethylene glycol, were discussed in terms of a mechanism which resembles one operative in solution.

Experimental

Zeolite (MS) was obtained from Nippon Kuromatokogyo K. K. The specific surface area is 1030 $m^2 g^{-1}$. Dinitrogen monoxide and sulfur hexafluoride were purchased from Takachiho Kagakukogyo K. K. Methanol (Uvasol) and carbon tetrachloride were obtained from Merck.

Samples were evacuated at 600 °C for 24 h prior to introduction of adsorbate(s). The experimental procedures were described in detail elsewhere.[13,14] Irradiation was carried out by ^{60}Co with a total dose of 1.34×10^4 Gy at room temperature. The amounts of molecular hydrogen and nitrogen were determined by gas chromatography according to the method employed in previous works.[11-14] Formaldehyde was determined colorimetrically by using chromotropic acid. Ethylene glycol was oxidized with periodic acid to formaldehyde after being extracted from the irradiated sample with methanol and subjected to the colorimetry.

Results

As shown in Fig. 1, the *G*-value for the formation of molecular hydrogen increases with increasing amount of methanol adsorbed on MS, but the increase rate is gradually reduced in the range of adsorbed amount above 5×10^{-3} mol of methanol per g of MS (the adsorbed amount on MS will be expressed in mol g^{-1} hereafter). $G(H_2)$ was observed to be ca. 2.1 at 1×10^{-2} mol g^{-1} where the coverage of methanol is unity approximately. On the other hand, the formation of H_2 was hardly observed in the region below 1×10^{-3} mol g^{-1}. This suggests that a limited amount of H_2 or H atom produced by irradiation is chemisorbed on MS or otherwise that some active sites of MS may consume a limited amount of methanol without irradiation, since chemisorption of ethanol was reported to proceed on high-surface silica (Cabosil) by Abrams and Allen.[3]

In the presence of an electron scavenger such as N_2O, $G(H_2)$ decreases with increasing amount of the scavenger. Figures 2 and 3 show the dependence of $G(H_2)$ on amounts of N_2O and CCl_4, respectively. The adsorbed amount of methanol is 9×10^{-3} mol g^{-1}. In

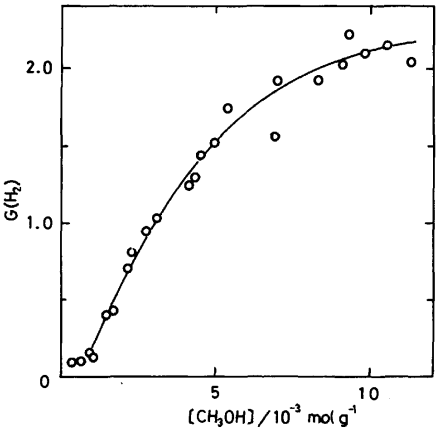

Fig. 1. $G(H_2)$ vs. $[CH_3OH]$.

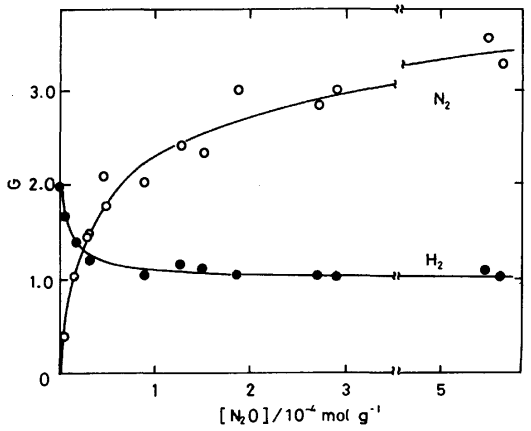

Fig. 2. $G(H_2)$ and $G(N_2)$ vs. $[N_2O]$. $[CH_3OH]=9\times10^{-3}$ mol g^{-1}.

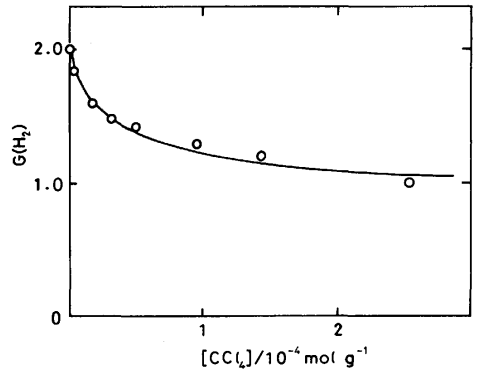

Fig. 3. $G(H_2)$ vs. $[CCl_4]$. $[CH_3OH]=9\times10^{-3}$ mol g^{-1}.

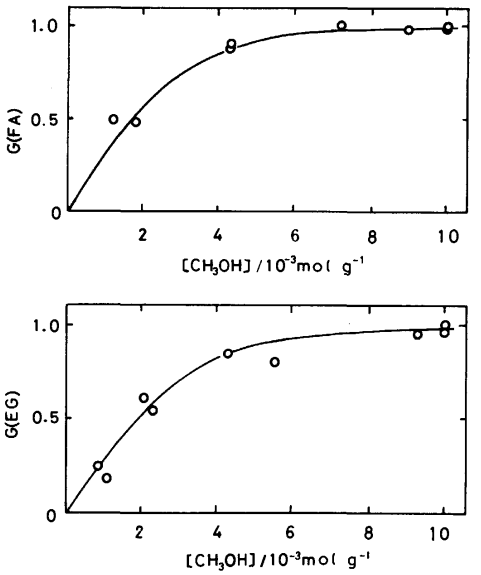

Fig. 4. $G(FA)$ and $G(EG)$ vs. $[CH_3OH]$.

both cases, $G(H_2)$ approaches to 1 and appears to be fixed over the region above 1×10^{-4} mol g^{-1} for N_2O and 2×10^{-4} mol g^{-1} for CCl_4. In the MS-CH_3OH-N_2O system, N_2 is produced from N_2O as expected. $G(N_2)$ increases also with increasing amount of N_2O and a small increase continues even in the region where $G(H_2)$ appears to be constant. At 5.5×10^{-4} mol g^{-1}

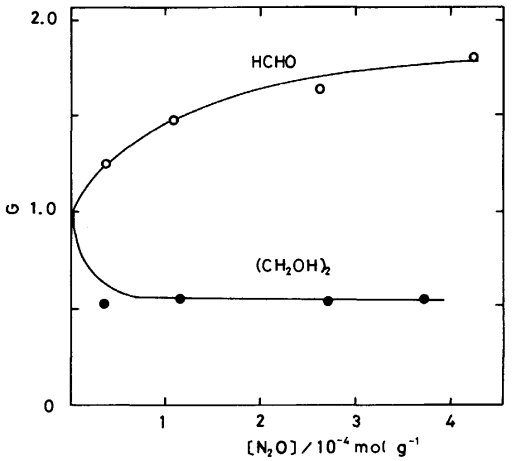

Fig. 5. $G(FA)$ and $G(EG)$ vs. $[N_2O]$. $[CH_3OH]=9\times10^{-3}$ mol g^{-1}.

N_2O, $G(N_2)$ amounts to 3.4. On the contrary, in the MS—N_2O system $G(N_2)$ is constant, 2.8, at amounts above 1×10^{-4} mol g^{-1} N_2O, as already reported.[14] With SF_6, the behavior of $G(H_2)$ is similar to that in the case of CCl_4, but not suitable for quantitative treatment because of a deviation of experimental points.

As in liquid methanol, a considerable amount of formaldehyde or ethylene glycol has been detected and their G-values increase with increasing amount of methanol similarly to the case of $G(H_2)$ (Fig. 4). At 9×10^{-3} mol g^{-1}, the G-values for formaldehyde, $G(FA)$, and ethylene glycol, $G(EG)$, are ca. 1.0, as seen in Fig. 4. In the presence of N_2O, $G(EG)$ is reduced to 0.57 and $G(FA)$ increases with increasing amount of N_2O as seen in Fig. 5. At 4.2×10^{-4} mol g^{-1} of N_2O, $G(FA)$ was observed to be 1.87.

Discussion

In this study, G-values are calculated on the basis of the total energy absorbed by adsorbent and adsorbate, because the energy absorbed by adsorbate cannot be neglected for such a large amount of methanol as 1×10^{-2} mol g^{-1}. In the range of adsorbed amount of methanol below 1×10^{-2} mol g^{-1}, the coverage is kept within unity and an adsorbed methanol molecule is allowed barely to have a limited number of neighbors. In consideration of the highly developed network structure of MS, the situation can be approximated to a dilute solution where solvent is immovable. Therefore, an attempt was made to use a kinetic treatment usually applied to dilute solution so as to interpret the experimental results obtained in the present heterogeneous systems. The formation of molecular hydrogen will be explained by the following reactions:

$$MS \wedge\!\!\vee MS^+ + e^-, \quad (1)$$

$$e^- + MS^+ \longrightarrow MS^*, \quad (2)$$

$$e^- + CH_3OH_{ad} \longrightarrow CH_3O^- + H, \quad (3)$$

$$H + CH_3OH_{ad} \longrightarrow H_2 + CH_2OH, \quad (4)$$

where CH_3OH_{ad} represents an adsorbed methanol molecule and MS^+ designates a positive hole. In this system, electrons produced in Reaction 1 will be consumed by Reactions 2 and 3. Thus the following equation is derived:

$$1/G(H_2)=1/G_e(1+k_2[MS^+]/k_3[CH_3OH_{ad}]). \quad (I)$$

As shown in Fig. 6, plots of $1/G(H_2)$ vs. $1/[CH_3OH_{ad}]$ give a straight line with a slope of 1.56×10^{-3}, an intercept of 0.371, and a correlation coefficient of 0.9683, if correction is made for the adsorbed amount of CH_3OH ineffective in the formation of H_2 by shifting the origin of Fig. 1 to (1×10^{-3}, 0.13). From the intercept, G_e is obtained to be 2.7, which is close to the $G(N_2)$ of 2.8 obtained in the MS-N_2O system. This indicates that methanol reacts with N_2O-scavengeable electrons to produce H_2. The slope gives the ratio, $k_2[MS^+]/k_3$, of 4.2×10^{-3} mol g^{-1}.

In the presence of N_2O, the following reaction occurs:

$$e^- + N_2O \longrightarrow N_2O + O^-. \quad (5)$$

For the MS-CH_3OH-N_2O system, therefore, $G(H_2)$ will be expressed by

$$1/G(H_2)=1/G_e(1+k_2[MS^+]/k_3[CH_3OH_{ad}] + k_5[N_2O]/k_3[CH_3OH_{ad}]). \quad (II)$$

Plots of $1/G(H_2)$ vs. $[N_2O]$ with data shown in Fig. 2 should give a straight line. As shown in Fig. 7, however, they give a curve dependent on the amount of N_2O. In a limited region below 1.5×10^{-5} mol g^{-1} N_2O where the formation of hydrogen is effectively suppressed by N_2O, a straight line with a slope of 1.03×10^4, an intercept of 0.556, and a correlation coefficient of 0.9954 is obtained. At amounts above 1.5×10^{-5} mol g^{-1}, the decrease in $G(H_2)$ is slowed down and $G(H_2)$ becomes constant. The partial depression will be interpreted in terms of either a precursor of hydrogen other than electron or decrease in effective amount of N_2O on MS due to the coexistence of methanol. In the MS-N_2O system, $G(N_2)$ was observed to be 2.8 at amounts of N_2O above 2×10^{-4} mol g^{-1} and a partial depression of $G(N_2)$ by SF_6 or CCl_4 was observed similarly with the present case of $G(H_2)$. If a precursor of hydrogen other than electron exists and N_2O does not react with it, a good agreement between the saturated $G(N_2)$, 2.8, and the G_e estimated by extrapolation of plots of $1/G(H_2)$ vs. $1/[CH_3OH_{ad}]$, cannot be interpreted. Furthermore, CCl_4 was observed to behave similarly to N_2O with respect to the partial depression of the hydrogen formed from methanol, in spite of the fact that it lowers only a part of $G(N_2)$ in the MS-N_2O system. These results suggest that the partial depression of hydrogen formation is caused by decrease in effective amount of scavenger due to competition with methanol for limited adsorption sites. From the linear relation between $1/G(H_2)$ and $[N_2O]$ obtained in the region of small amount of N_2O, G_e can be estimated. Since the intercept is equal to $1/G_e(1+k_2[MS^+]/k_3[CH_3OH_{ad}])$ and $k_2[MS^+]/k_3$ is 4.2×10^{-3} mol g^{-1} as described above, 2.6 is obtained as G_e, which is consistent with that obtained in the MS-CH_3OH and MS-N_2O systems. Thus, the ratio of rate constants, k_5/k_3, is estimated to be 2.5×10^2 from the slope, which is equal to $1/G_e(k_5/k_3 \cdot [CH_3OH_{ad}])$.

In the MS-MeOH-CCl_4 system, the same kinetic treatment is also applicable if the following reaction is considered:

$$e^- + CCl_4 \longrightarrow \text{product}. \quad (6)$$

Plots of $1/G(H_2)$ vs. $[CCl_4]$ give the curve as shown in Fig. 8. From the experimental data in the limited amount region, G_e is obtained as 2.9 and the ratio of rate constants, k_6/k_3, as 2.0×10^2. It should be noticed

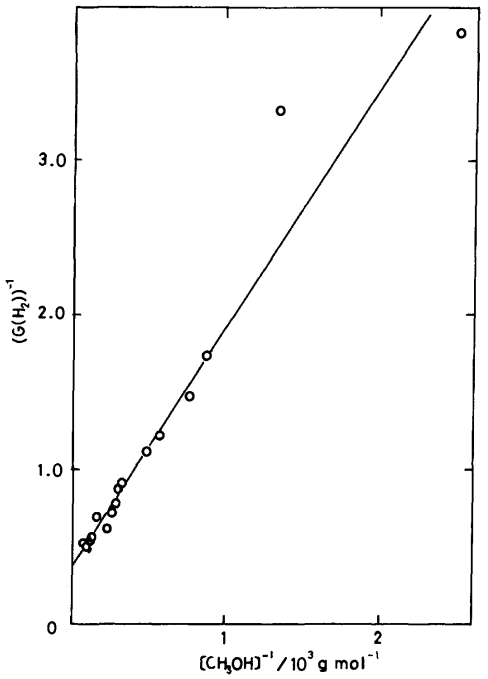

Fig. 6. $1/G(H_2)$ vs. $1/[CH_3OH]$. $[CH_3OH]$ and $G(H_2)$ are corrected by moving the origin of Fig. 1 to (1×10^{-3}, 0.13), respectively.

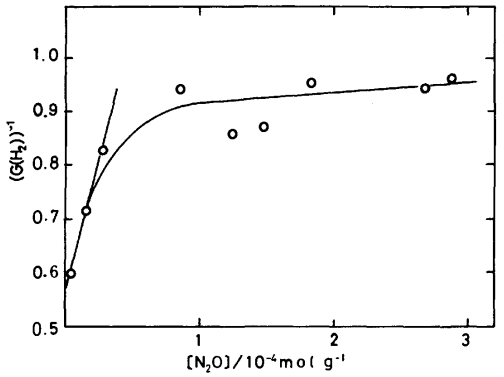

Fig. 7. $1/G(H_2)$ vs. $[N_2O]$. Calculated from the data shown in Fig. 2.

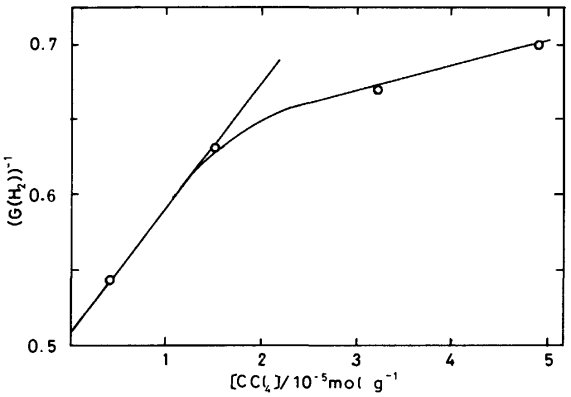

Fig. 8. $1/G(H_2)$ vs. $[CCl_4]$. Calculated from the data shown in Fig. 3.

that the ratio of k_6/k_5, 0.8, is quite different from that obtained in the MS-N_2O-CCl_4 system, 12.8.[14] The ratio obtained in the present system is close to that obtained for electrons generated in nonpolar liquid such as hexane or cyclohexane rather than in 2,2-dimethylpropane. This suggests that an energy state of excess electrons in MS, probably the conduction band of MS, may be affected by the adsorption of methanol. If the rate constant of electron for its reaction with N_2O in hexane, 1.09×10^{12} dm^3 mol^{-1} s^{-1}, or in cyclohexane, 2.4×10^{12} dm^3 mol^{-1} s^{-1},[15] is applied to k_5, 4.4×10^9 or 9.6×10^9 dm^3 mol^{-1} s^{-1} is obtained, respectively, as the rate constant of methanol for its reaction with the electron produced in MS.

The formation of formaldehyde and ethylene glycol may be explained by a mechanism which has been composed of Reactions 1, 4, 7, 8, and 9 by assuming processes similar to those of the radiolysis of liquid methanol:

$$MS^+ + CH_3OH_{ad} \longrightarrow MS + CH_3OH^+, \quad (7)$$

$$CH_3OH^+ + CH_3OH \longrightarrow CH_3OH_2^+ + \cdot CH_2OH, \quad (8)$$

$$2\cdot CH_2OH \longrightarrow HCHO + CH_3OH \quad (9a)$$

$$\longrightarrow (CH_2OH)_2. \quad (9b)$$

From these reactions we obtain

$$2\{G(FA) + G(EG)\} = G_e + G(MS^+), \quad (III)$$

where $G(FA)$ and $G(EG)$ designate the G-values for the formation of formaldehyde and ethylene glycol, respectively. Since electrons and positive holes which have escaped from Reaction 2 produce these products and the G-value for such electrons or positive holes can be taken as $G(H_2)$, the relation expressed by Eq. III holds. The above mechanism appears to be very simple despite the complexity of adsorbed state. However, the formation of methane was observed to be negligible (G-value below 0.1) and no other products including carbon have been found. Furthermore, the yield of ethylene glycol decreases in the presence of N_2O, whereas formaldehyde increases as shown in Fig. 5. The result may be explained by addition of Reaction 10 to the above reactions:

$$O^- + \cdot CH_2OH \longrightarrow HCHO + OH^-. \quad (10)$$

At 4.2×10^{-4} mol g^{-1} N_2O, $G(FA)$ of 1.87 and $G(EG)$ of 0.57 were obtained. If the ratio of Reactions 9a to 9b is not affected by N_2O, the formaldehyde produced through Reaction 9a is 0.57 and hence 1.3 is estimated as the G-value for the formaldehyde through Reaction 10. Therefore, the G-value for $\cdot CH_2OH$, which is a precursor radical of formaldehyde and ethylene glycol, is calculated to be 3.58. On the other hand, $\cdot CH_2OH$ is produced through Reactions 4 and 8. Thus $G(\cdot CH_2OH)$ is equal to the sum of $G(H_2)$ in Reaction 4 and $G(MS^+)$ in Reaction 7. In the presence of ca. 10^{-2} mol g^{-1} methanol and 4.2×10^{-4} mol g^{-1} N_2O, Reaction 2 may be neglected. Therefore, the total $G(\cdot CH_2OH)$ is calculated to be 3.8. This is considerably close to the value calculated on the basis of $G(FA)$ and $G(EG)$. The above mechanism, therefore, seems to be reliable.

The formation of N_2 is hard to understand in the presence of methanol. $G(N_2)$ increases with increasing amount of N_2O even in the region where $G(H_2)$ reaches a plateau value. It amounts to 3.4 at ca. 5×10^{-4} mol g^{-1} N_2O in spite of the incomplete suppression of H_2 formation. Although these results suggest that a short chain mechanism works, it needs another study to find a consistent mechanism.

Effects of Some Additives on Proton-Transfer Reaction Studied by Ultrasonic Methods

Yukio YOSHIDA and Sadakatsu NISHIKAWA*
Department of Chemistry, Faculty of Science and Engineering, Saga University, Saga 840
(Received March 5, 1987)

Ultrasonic absorption and velocity were measured in aqueous solutions of propylamine at 25 °C both in the absence and in the presence of 2 g dm^{-3} PVA(poly(vinyl alcohol)), 5 mol dm^{-3} urea and 1 mol dm^{-3} NaCl. No excess absorption was observed in these solutions without propylamine. A single relaxational absorption was observed in the concentration range from 0.0196 to 0.719 mol dm^{-3} of propylamine both in the presence and absence of the additives. The ultrasonic parameters have been found to be quite dependent on the concentration of propylamine and also on the structure of additives. This relaxational absorption has been attributed to the perturbation of an equilibrium associated with a proton-transfer reaction. The rate constants and the standard volume change of the reaction have been determined from the concentration dependences of the relaxation frequency and the maximum excess absorption per wavelength. As a result, it was discovered that the forward rate in a solution with PVA increased and those with urea and NaCl, on the other hand, decreased; also, the standard volume change associated with the reaction increased in a series of the solutions with urea, no additive, NaCl, and PVA. The data have been interpreted by means of the structural changes of the solvent water.

Any mechanism by which protons get carried along particularly quickly has important implications for a large area of molecular biology. The proton-transfer reaction is directly followed by the ultrasonic absorption technique.[1] So far, investigations for the proton-transfer in aqueous solutions of various amines have been performed;[1,2] the present authors[3] have also reported some results of the rate constants with a revised analysis of the reaction mechanism. Recently, Yamashita et al.[4] have examined the effect of an additive on this reaction in the presence of the surfactant micelle; also, the decreasing effect on the proton-transfer rates has been reported. They have interpreted the effect as restricted reaction fields owing to the charged surface of the micelles. On the other hand, it is expected that the proton-transfer reaction in an aqueous solution of amine may be closely related to the water structure since the reaction is hydrolysis. From this view, the present study was undertaken in order to clarify this speculation by adding nonelectrolyte and electrolyte using ultrasonic methods. Propylamine was chosen as the solute since another type relaxation which is observed in the solutions of some amines with larger hydrophobic groups[5] was not expected to be observed. The phenomenon that the reaction rate is accelerated or decelerated by additives is also interesting from a pharmacological point of view.

Experimental

All reagents, i.e. propylamine, urea, PVA(poly(vinyl alcohol)), and NaCl, were purchased from Wako Pure Chemical Industries Ltd. Propylamine was distilled once; however, the other reagents which were of the purest grade obtainable were used without further purification. Solutions were prepared by weight with doubly distilled water. The additive concentrations were fixed to be 2 g dm^{-3}, 1 mol dm^{-3}, and 5 mol dm^{-3} for PVA (number-average molecular weight; 22000), NaCl and urea, respectively.

A semiautomatic pulse method was used for ultrasonic absorption measurements over a frequency range from 15 to 220 MHz. Two cells with fundamental crystals of 5 and 20 MHz were utilized at their odd harmonic frequencies. Details of the apparatus are described elsewhere.[6] The sound velocity was determined using an interferometer at 2.5 MHz. The ultrasonic cells were immersed in a water bath which was controlled within ±0.002 °C. The density of the solutions was measured by using a standard pycnometer, the volume of which was about 4 cm^3. The measurement of pH was performed using a HITACHI-HORIBA pH meter with a glass electrode. The standard buffer solutions at 9.18 and 11.88 were used as the standard references of the electrode. All pH and ultrasonic measurements were carried out under a dry nitrogen atmosphere because of the high basicity of the solution. They were all measured at 25 °C.

Results

No excess absorption was observed in any aqueous solutions of urea, PVA, or NaCl at the concentrations used in this work. However, the value of the absorption coefficient, α, divided by the square of the frequency, f, has been found to be frequency dependent in all of aqueous solutions of propylamine both in the presence and in the absence of the additives. If an observed spectrum is due to a single relaxational process, it may be generally well expressed by[7]

$$\alpha/f^2 = A/(1+(f/f_r)^2)+B, \quad (1)$$

where A is the excess absorption amplitude, f_r the relaxation frequency and B the back ground absorption. Figure 1 shows some representative absorption spectra in an aqueous solution of propylamine. The ultrasonic parameters have been determined in terms of a nonlinear least mean square method by microcomputer, and the solid curves in the figure represent the theoretical values. The fact that the agreements between experimental and theoretical values are excellent indicates that the relaxation phenomenon observed in the measured frequency range can be associated with a clear single relaxation process.

Another relation, which is a modification of Eq. 1, is the plot of the chemical absorption per wavelength, $(\alpha\lambda)_{chem}$ against the frequency:

$$(\alpha\lambda)_{chem} = Afc/(1+(f/f_r)^2). \quad (2)$$

Here, $(\alpha\lambda)_{chem}$ is calculated from the relation $(\alpha\lambda)_{chem} = (\alpha/f^2 - B)fc$, where c is the sound velocity. Figure 2 shows the spectra observed in the aqueous solutions in the absence and in the presence of additives at 0.236 mol dm^{-3} of propylamine. The spectra can also be well expressed by a single relaxational equation. It can clearly be seen that the absorption amplitude and the relaxation frequency strongly depend on the additives. The obtained excess absorption amplitude, A, and the background absorption, B, are shown in Fig. 3 as a function of propylamine concentration. In Table 1, they are also tabulated along with other values obtained in this study. The background absorptions are close to those of solvent water, though they decrease slightly when NaCl and urea are added. On the other hand, the excess absorption amplitudes differ from each other, depending upon the additives. They increase at a low-concentration range and tend to show a plateau. These concentration dependences are very similar to the result for the ultrasonic absorption due to proton-transfer reaction reported previously.[3,5] Figure 4 shows the analytical concentration dependence of the relaxation frequency, f_r for the solutions in the absence and the in presence of additives. Obviously, f_r shifts to higher or lower values, and its degree depends upon the additives. These results imply that the additives affect the dynamic properties

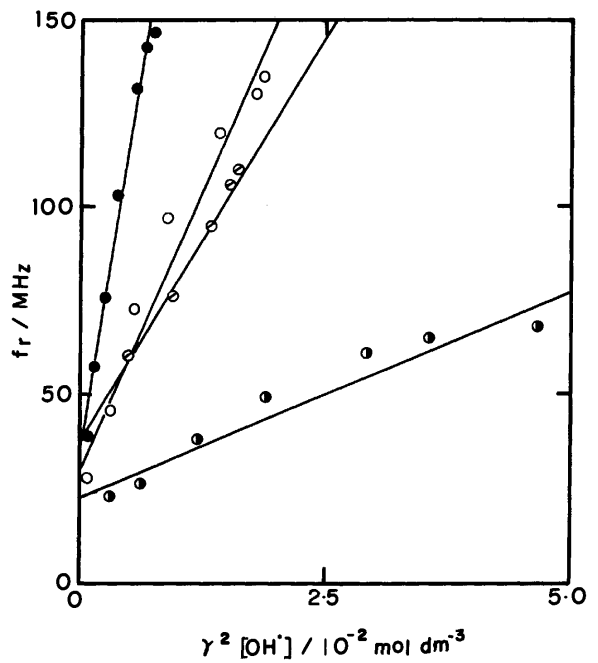

Fig. 5. The plots of f_r vs. $\gamma^2[OH^-]$ for aqueous solutions of propylamine at 25 °C. O: No additive, ●: PVA, ∅: NaCl, ◑: urea.

of the aqueous solutions. However, these similar concentration dependences of the ultrasonic parameters, that is, the plateau of the excess absorption amplitude and the monotonical increase of the relaxation frequency, have let us to predict that the cause of the relaxation in all of the solutions is the same and that it may be associated with the hydrolysis of amine. A detailed reaction mechanism has been proposed origi-

nally by Eigen,[1] and is expressed by

$$\text{R-NH}_3^+ + \text{OH}^- \underset{k_{21}}{\overset{k_{12}}{\rightleftharpoons}} \text{R-NH}_3^+ \cdots \text{OH}^- \underset{k_{32}}{\overset{k_{23}}{\rightleftharpoons}} \text{R-NH}_2 + \text{H}_2\text{O}, \quad (3)$$

where k_{ij} is the rate constant at each step. Usually, the relation between the relaxation frequency and the reactant concentrations is derived on the bases of the coupled reactions;[8] that is, the faster process influences the slower one. However, as has been reported in a previous paper,[3] the analysis based on the assumption that the only first step is associated with the observed relaxation process gives us a reasonable result. This means that the second step in Eq. 3 may not so affects on the observed process even if the relaxation associated with the second step may exist in other time region. Then, the relation between the relaxation frequency and the reactant concentrations is simply represented by

$$\tau^{-1} = 2\pi f_r = \gamma^2 k_{12}([\text{R-NH}_3^+] + [\text{OH}^-]) + k_{21}, \quad (4)$$

where τ is the relaxation time and γ a mean activity coefficient which is calculated using Davies equation.[9] Figure 5 shows plots of f_r vs. $\gamma^2[\text{OH}^-]$. The linearity of these plots confirms that the cause of the relaxational sound absorption is due to the hydrolysis of propylamine. The rate constants, k_{12} and k_{21}, were determined from the slope and intercept of the straight lines, respectively. The obtained results are listed in Table 2. These results enable us to determine the dissociation constant, K_b.[3] The relation between K_b and the analytical concentration, C_o, is derived as

$$K_b = [(\tau^{-1})^2 + k_{21}^2 - 2\tau^{-1} k_{21}] / [k_{12}(4\gamma^2 C_o k_{12} + 2k_{21} - 2\tau^{-1})]. \quad (5)$$

The calculated K_b values for each solution are listed in Table 2.

The dissociation constants for these solutions have been estimated from the results of pH measurements using the relation $K_b = \gamma^2[\text{OH}^-]/(C_o - \gamma[\text{OH}^-])$, which are also listed in Table 2. The value for a solution without any additives is very close to that in the literature.[10] The smaller K_b value in the solution with PVA indicates the smaller concentrations of the ionic species in Eq. 4. The larger value in the solution with urea, on the other hand, shows the opposite condition. It should be noticed that the relaxation frequency in the PVA solution is higher than that in the urea solution.

Another parameter obtained from ultrasonic absorption measurement along with the sound velocity is the maximum excess absorption per wavelength, μ_{max}. It is related to the thermodynamic parameters as

$$\mu_{max} = Af_r c/2 = \pi\rho c^2 \Gamma \Delta V^2/2RT. \quad (6)$$

where ρ is the density, ΔV the standard volume change of the reaction, and Γ the concentration term which is expressed for the reaction under consideration as

$$\Gamma = (1/[\text{R-NH}_3^+] + 1/[\text{OH}^-] + 1/[\text{R-NH}_3^+ \cdots \text{OH}^-])^{-1} \quad (7)$$

With the help of Eqs. 6 and 7, standard volume changes could be calculated at each concentration (listed in Table 2).

Discussion

As has been described previously, it is certain that the cause of the relaxation process observed by the ultrasonic absorption measurement in the aqueous solutions of propylamine with some additives is due to the hydrolysis of the amine. The additives have been found to considerably affect the rate processes. The micellar effect on the hydrolysis seems to be associated with the restricted reaction field by micelles.[4] However, the present additive effects are not associated with such a microscopic heterogenious reaction field. They seem to be associated with structural changes of the solvent water.

First, the effect of PVA on the hydrolysis is considered. When PVA is added, the relaxation frequency shifts to a higher frequency range and the reactant concentration, i.e. $[\text{OH}^-]$ decreases, even if the analytical concentration of propylamine is identical (Table 1). Therefore, as a result, the forward rate constant, k_{12} has been found to increase considerably when PVA is added. This may be considered as follows. Adding a small amount of the polymer with the hydroxyl groups to the solution, the water structure may be changed by an extension of the hydrogen-bond network. Consequently, it can be expected that hydrogen or hydroxide ion mobility increases. It is said that the

proton-transfer rate in a more hydrogen-bonded network is faster than that in less hydrogen-bonded types.[11] The above experimental evidence is consistent with the proton-transfer proposed reaction mechanism so far. The obtained standard volume change for the reaction also reflects the solvent structural change by an addition of PVA. That is, it is larger than that in only water (Table 2). The considerably large volume change may be caused by a breaking of the constructed water hydrogen-bonds by PVA.

Second, the additive effect of urea on the hydrolysis is now considered. Urea is a so-called water structure-breaker.[12] When it is added to water, it breaks the water hydrogen bonds; then, the sound velocity increases, the absorption decreases and the solution density increases. These trends are also observed in aqueous solutions of propylamine (Table 1). This means that the solvent water may be in a less structured state. Then, the diffusion-controlled reaction rate may decrease. This expectation has been supported by the concentration dependence of the relaxation frequency. That is, the relaxation frequency shifts to a lower range when it is compared wiht that in the absence of additive. The smaller volume change for the reaction has also reflected this situation. The reaction may proceed through breaking hydrogen bonds just around the reaction site.

Third, in a solution with NaCl, it has been observed that the relaxation frequency is lower than that without additives (Fig. 4). The recent investigation[13] for the proton-transfer reaction by a fluorimetry has shown that the effect of NaCl on the decreasing rate is due to the structure breaking for solvent water. This seems to be sonsistent with the result obtained in our study. However, it is not so reasonable to compare the rate constants with those obtained in the solutions with urea and PVA because they are at quite different ionic strengths each other. In order to obtain more information concerning the effect of electrolytes on the proton-transfer reaction, it should be necessary to clarify the concentration dependence of the salts on the rate.

In conclusion, the additive effects on the proton-transfer reaction have been well interpreted on the bases of the structural changes of solvent water. This is, when the water structure is promoted by the addition of PVA, the rate for the proton transfer is accelerated. On the other hand, when water hydrogen-bonds are partly broken by the addition of urea, the proton-transfer rate is diminished. It may be expected that the fast proton-transfer reactions are now utilized in order to investigate the structural properties of liquids and solutions. The concentration dependences of the additives on the hydrolysis of various amines are now under investigation and the results will be reported in due course.

Effect of an Ionic Surfactant on the Kinetic Properties of an Aqueous Nonelectrolyte Solution Studied by Ultrasonic Methods

Sadakatsu NISHIKAWA
Department of Chemistry, Faculty of Science and Engineering, Saga University, Saga 840
(Received March 12, 1987)

In order to investigate the effect of ionic surfactant on the dynamic properties of nonelectrolyte aqueous solutions, the ultrasonic absorption, velocity and the conductivity have been measured for aqueous solutions of triethylene glycol monobutyl ether (TGBE) in the presence of sodium dodecyl sulfate (SDS) at 25 °C. In aqueous solution of TGBE, a clear single relaxational ultrasonic absorption is observed in the MHz frequency range. When SDS is added the relaxation process is observed in the more dilute solutions, the relaxation frequency shifts to lower frequency and the amplitude of the excess absorption increases in the TGBE concentration range of less than 1.0 mol dm^{-3}. Further, for TGBE concentration greater than 1.0 mol dm^{-3}, the relaxation frequency is found to be almost independent of SDS concentration and the amplitude of the excess absorption decreases with increasing SDS concentration. The observed relaxation is well accounted for by a kinetic scheme involving the interaction between the nonelectrolyte and water. From the concentration dependence of TGBE, the rate and thermodynamic parameters have been determined as a function of SDS concentration. The obtained data have been interpreted in terms of the structural changes of the solvent water by SDS molecules. As the results, it has been proposed that the hydrophobic parts of SDS have a considerable effect on water structure.

It has been proposed that the MHz frequency ultrasonic absorptions in aqueous solutions of nonelectrolytes containing hydroxyl groups are well accounted for the two relaxations by mechanisms involving an interaction between the solute and solvent and a molecular aggregation of the solutes.[1-4] The former process is observed in most of the solutions studied, whereas the latter is limited to solutions of solutes containing large hydrophobic groups.

On the other hand, it is generally accepted that micellar surfactant solutions solubilize sparingly water-soluble compounds. Many nonelectrolytes are not soluble enough to allow examination of their dynamic properties by ultrasonic methods. The ability of the surfactant to solubilize the nonelectrolyte provides an apparent homogeneous aqueous nonelectrolyte system and also allows studies of the phenomena associated with cosurfactants, which are very important in understanding microemulsions.

Zana et al.[5,6] have measured ultrasonic absorptions in aqueous solutions of butanol and hexanol in the presence of surfactants. They have interpreted the observed relaxation by a model involving an exchange reaction of the nonelectrolyte between the micellar and bulk phase in these solutions. Hall et al.[7-9] have also analyzed the relaxation process observed in aqueous alcohol solutions of other surfactants using a similar kinetic model and also a phenomenological treatment. In addition, an ultrasonic study concerning the effect of surfactant on the relaxation properties of aqueous solutions of 2-butoxyethanol (ethylene glycol monobutyl ether) was also performed by Verrel et al.[10] and they also accounted for the observations by the same analysis as Zana's. A very recent study by Verrall's[11] group showed that there exist a clathrate aggregate of alcohol with water in aqueous solution of 2-butoxyethanol and a surfactant. However, it is evident that the excess absorption or relaxational absorption of the ultrasound in the MHz frequency range exists in aqueous solutions of highly soluble alcohols. In the solution of 2-butoxyethanol, for example, a clear excess absorption is observed even at 0.7 mol dm^{-3}.[12] It is very important to prove if the observed relaxation corresponds to the interconversion of such nonelectrolytes between micelles and the bulk phase. For this purpose, we have chosen triethylene glycol monobutyl ether (TGBE) and sodium dodecyl sulfate (SDS) as solutes. In aqueous solutions of TGBE,[4] a clear single relaxational absorption is observed in the frequency range of 6.5 to 220 MHz, while in aqueous SDS solution, no excess absorption is found in the same frequency range up to 0.1 mol dm^{-3} concentration.[13] Therefore, such a ternary system may be very suitable for studying the effect of surfactant on the ultrasonic properties. Though too much time has been required to accumulate such desirable ultrasonic data by a pulse method, our recent semiautomatic equipment[2] has made it possible to perform such experiments much faster.

Experimental

Triethylene glycol monobutylether (TGBE) was purchased from TOKYO Kasei Co. Ltd. and was distilled once. Sodium dodecyl sulfate (SDS) was from BDH Chemicals Ltd. and was used without further purification. Doubly distilled water was used as a solvent. The concentrations of TGBE were determined by weighing. A stock solution of SDS was prepared and it was added to TGBE solutions in order to obtain the desired concentrations of SDS.

Ultrasonic absorption measurements were performed by the computerized pulse method in the frequency range from 6.5 to 220 MHz using three cells with 0.5, 5, and 20 MHz fundamental x-cut transducers. The detailed description of the apparatus was reported elsewhere.[2] Sound velocity was measured by means of an interferometer at 2.5 MHz and by a sing around method at 1.92 MHz. By both methods, the absolute values of the sound velocity were obtainable with a

precision of ±1 m s^{-1} and the relative values by the sing around method were reproducible to within ±5 cm s^{-1}. All ultrasonic measurement cells were immersed in a water bath which was controlled to within ±0.002 °C. Conductivity measurements were carried out on a conductivity meter (Yanagimoto Model MY-7). All measurements were made at 25 °C.

Results and Interpretation

Figure 1 shows a representative ultrasonic absorption spectrum in aqueous solutions of TGBE with SDS present at 25 °C. In the concentration range of TGBE from 0.2 to 1.7 mol dm^{-3} and that of SDS from 1 to 100 mmol dm^{-3}, the observed spectra are all satisfactorily fitted to an equation which is characteristic of a single relaxation process:

$$\alpha/f^2 = A/[1+(f/f_r)^2]+B, \quad (1)$$

where α is the absorption coefficient, f the frequency, A the amplitude of the excess absorption, f_r the relaxation frequency and B the background absorption including the classical absorption.[14] These parameters, f_r, A, and B, have been determined by a least mean square method described in detail elsewhere.[4] Figure 2 shows the TGBE concentration dependence of the relaxation frequency at various concentrations of SDS. At low concentrations of SDS (less than 5 mmol dm^{-3}), the plot indicates a minimum, while it seems to increase monotonically when SDS is present at a concentration greater than 20 mmol dm^{-3}. Another interesting feature is that the relaxation frequency at more than 1.0 mol dm^{-3} of TGBE falls on almost a same line even if the concentration of SDS is changed.

The excess absorption amplitudes as a function of TGBE are shown in Fig. 3 at various concentrations of SDS and it is seen that they indicate maxima, i.e. the peak sound absorption concentrations. Without SDS, the excess absorption is only observed in the TGBE concentration range of more than 0.60 mol dm^{-3}. However, when SDS is added the excess absorption is found in more dilute solutions of TGBE. For example when the SDS concentration is 100 mmol dm^{-3}, the

The calculated values at 20 and 100 mmol dm^{-3} SDS solutions are almost same. ◑; 0 mmol dm^{-3}, ◒; 1.5 mmol dm^{-3}, ◐; 5 mmol dm^{-3}, ⊙; 20 and 100 mmol dm^{-3}.

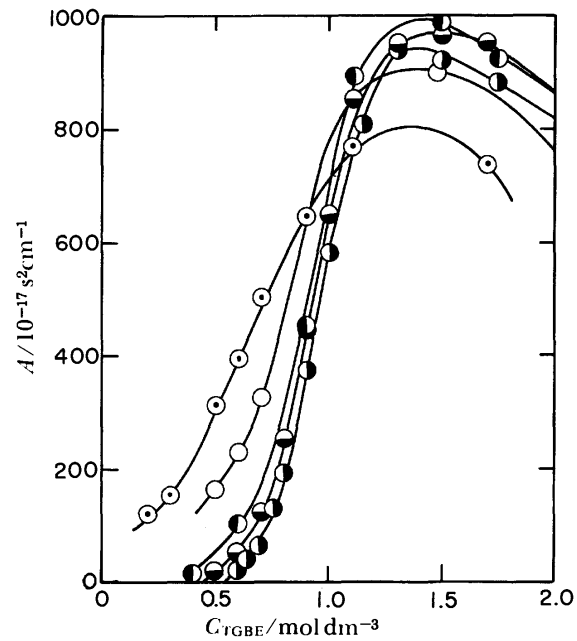

Fig. 3. TGBE concentration dependence of the amplitude of the excess absorption at different SDS concentrations. ◑; 0 mmol dm^{-3}, ◒; 1.5 mmol dm^{-3}, ◐; 5 mmol dm^{-3}, ○; 20 mmol dm^{-3}, ⊙; 100 mmol dm^{-3}.

excess absorption is clearly observed even at 0.20 mol dm^{-3} of TGBE. The amplitude of the excess absorption depends on the concentrations of both SDS and TGBE.

In order to see if micelles are formed in the solutions, sound velocity and conductivity measurements have been carried out. The former results are shown in Fig. 4 and the latter in Fig. 5. In 0.60 mol dm^{-3} solution of TGBE, a break point has been found in the sound velocity at 6.2 mmol dm^{-3} SDS concentration and in the conductivity at about 7 mmol dm^{-3}. These results indicate that the addition of TGBE decreases the critical micelle concentration (cmc) because the cmc for SDS solution is 8.3 mmol dm^{-3}.[15]

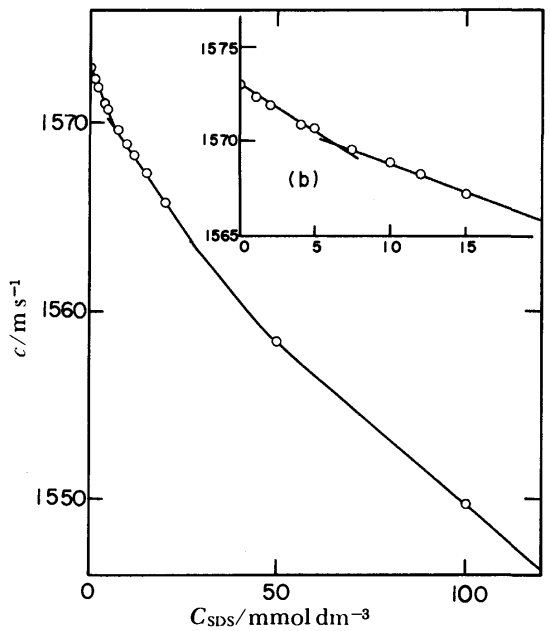

Fig. 4. SDS concentration dependence of the sound velocity at 0.60 mol dm^{-3} TGBE. The break point has been seen at about 6.2 mmol dm^{-3}. In (b), the scale of the concentration is expanded.

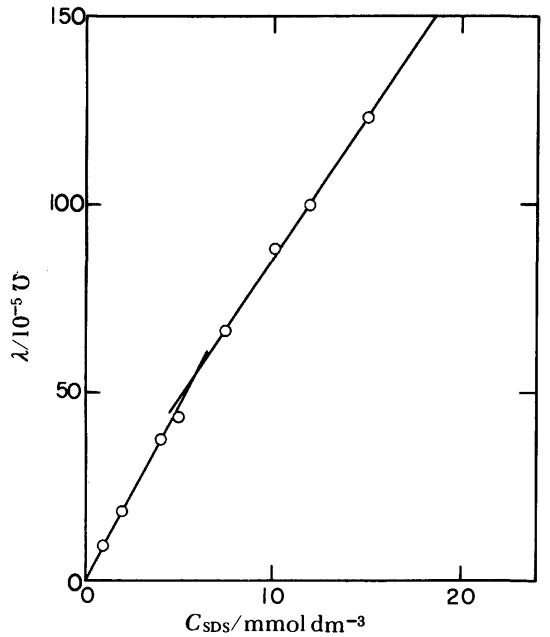

Fig. 5. SDS concentration dependence of the conductivity at 0.60 mol dm^{-3} at 25°C. At 7 mmol dm^{-3} SDS, the two straight lines intercect.

In aqueous solution of SDS it has been reported that the ultrasonic relaxational absorption is observed far below the MHz frequency range.[13] Even if the surfactant is added to the aqueous solutions of TGBE, the ultrasonic spectra can be well expressed by a single relaxational equation and the ultrasonic relaxation parameters change gradually with the concentration of SDS. Therefore, it may be considered that the cause of the excess absorption in the TGBE solutions with SDS present is associated with the same mechanism as that observed in the absence of SDS. Therefore, we may interpret the relaxation phenomena in terms of a similar reaction mechanism. It is represented as follows:[3]

$$AB \underset{k_f}{\overset{k_r}{\rightleftharpoons}} A+B \qquad (2)$$

where k_f and k_b are the forward and reverse rate constants, A the solute and B the solvent, and AB the complex formed between the solute and the solvent. In order to analyze the relaxation process, it is a reasonable assumption that water exists in hydrogen honded and nonhydrogen bonded states. Only the latter molecules may participate in the reaction. The relationship between the relaxation frequency and the analytical concentrations is derived to be[3]

$$2\pi f_r = k_b[(C_{TGBE} - \beta C_w + K_{12})^2 + 4\beta C_w K_{12}]^{1/2}, \qquad (3)$$

where C_{TGBE} and C_w are the analytical concentrations of TGBE and water, β the fraction of nonhydrogen bonded water and K_{12} is defined as $K_{12}=k_f/k_b$. Under the assumption that the rate and thermodynamic parameters in Eq. 3 are independent of TGBE concentration, a nonlinear least mean square computer program has been used in order to determine the three parameters, β, k_b, and K_{12} at the various concentrations of SDS. In Table 1, the experimental results are shown and the solid lines in Fig. 2 represent f_r's which are calculated according to Eq. 3 and using these values.

The excess absorption amplitude is related to the reaction parameters as follows:[16]

$$A = (\rho c/f_r)(\Gamma/RT)(\Delta V - \alpha_p \Delta H/\rho C_p)^2(C_P^\infty/C_p), \qquad (4)$$

Table 1. Rate and Thermodynamic Constants for Aqueous Solutions of Triethylene Glycol Monobutyl Ether with Sodium Dodecyl Sulfate at 25°C

SDS	k_f	k_b	β
mmol dm^{-3}	10^7 s^{-1}	10^8 mol^{-1}dm^3 s^{-1}	
0	4.6±0.3	3.5±0.2	0.0285±0.0006
1.5	5.3±0.4	3.1±0.2	0.0225±0.0004
5.0	5.1±0.4	2.9±0.2	0.0216±0.0011
20	4.9±1.5	2.2±0.7	0.0051±0.0019
100	5.0±2.0	2.2±0.7	0.0046±0.0011

where ρ is the solution density, c the sound velocity, ΔV the standard reaction volume change, α_P the thermal expansion coefficient in the high frequency limit, C_P^∞ the specific heat in the high frequency limit, ΔH the standard enthalpy change of the reaction, C_p the specific heat in the low frequency limit, and Γ the concentration term expressed by,

$$\Gamma=(1/[A]+1/[B]+1/[AB]-1/([A]+[B]+[AB]))^{-1}. \quad (5)$$

The relaxational specific heat and the relaxational thermal expansion coefficient are very small compared with those values in the low frequency limit, and the concentration dependences of these two values are not expected to contribute so much to the dependence of the amplitude of the excess absorption, A. Therefore, the most important term that controls the dependence of the excess absorption amplitude may be $\rho c\Gamma/f_r$. In order to see how they depend on the analytical concentration, the terms have been calculated as a function of TGBE concentrations at various concentrations of SDS and they are shown in Fig. 6. These calculations indicate that the amplitude of the excess absorption should increase in the low concentration range of TGBE when SDS is added, and the calculated results are consistent with the experimental data shown in Fig. 3. However, we are reluctant to make the quantitative analysis for the amplitude of excess absorption because of the lack of the definitive thermodynamic constants, e.g. the specific heat and the thermal expansion coefficient.

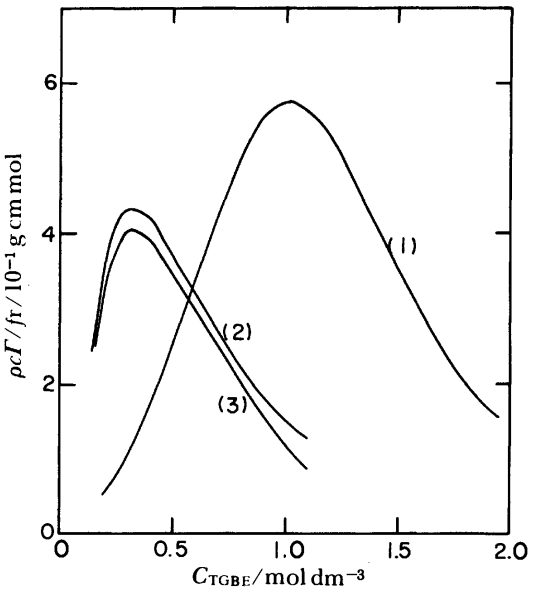

Fig. 6. The calculated $\rho c\Gamma/f_r$ values as a function of TGBE concentration. Those at 0, 1.5, and 5 mmol dm^{-3} SDS are almost identical. When SDS increases, the position of the maximum decreases. (1): 0, 1.5, and 5 mmol dm^{-3} SDS, (2): 20 mmol dm^{-3} SDS, (3): 100 mmol dm^{-3} SDS.

Discussion

Previous investigations[5-9] by ultrasonic relaxation methods for aqueous solution containing both surfactants and alcohols as solutes seem to have been focussed on the findings that no relaxation was observed for either pure surfactant solutions or for alcohol solutions, and that a relaxational absorption appears when the surfactant and alcohol are mixed. Those experiments were carried out above cmc of the surfactants because the solubilities of the solutes were limited. The relaxation time depends on the concentrations of both surfactant and alcohol. From these results the source of the relaxation was attributed to the perturbation of the equilibrium involving the exchange process of the alcohols between micelles and bulk solvent.[5-8,11] However, our ultrasonic studies[1,4] for aqueous solutions of various nonelectrolytes bearing a hydroxyl group have indicated that the water structure may be changed when a certain amount of nonelectrolyte is added, and then the relaxational absorption appears suddenly and the cause of the relaxation is due to the interaction between the solute and solvent. Under these circumstances, the present experimental study indicates that when SDS is added to the aqueous solution of TGBE the ultrasonic parameters are affected considerably by the surfactant as is seen in Figs. 2 and 3. However, the observed ultrasonic spectra are all characterized by a single relaxation process in the concentration range employed of both TGBE and SDS, and the ultrasonic parameters seem to change gradually with concentration. These experimental results lead us to believe that the cause of the excess absorption in aqueous solution of TGBE in the presence of SDS is the same as that observed when SDS is absent. That is, the equilibrium associated with the solute-solvent (TGBE-water) interaction is perturbed. The exchange reaction of the nonelectrolyte between the micellar and bulk phase may be ruled out as the cause of the observed excess absorption, though such process does exist in an other frequency range. It is worth noting that when the SDS concentration is greater than 10 mmol dm^{-3} the dependence of the relaxation frequency on TGBE concentration is quite similar to those reported so far for aqueous solutions of some alcohols in the presence of some surfactants. That is, the relaxation frequency increases approximately linearly with TGBE concentration. However, it might be expected that the exchange reaction may be observed in the pulse frequency range if the appropriate system had been chosen. That is, we do not deny the analysis for other systems studied so far.

It is easily seen that the concentration dependences of the relaxation frequency and the amplitude of the relaxational absorption are controled by the reactant concentration according to Eqs. 3—5. The reason why the relaxation frequency look to increase

monotonically with TGBE concentration when SDS is more than 10 mmol dm^{-3} may be speculated as follows. The concentration of water participating in the reaction may decrease when SDS is added, and then the dominant variable for the relaxation frequency becomes the concentration of TGBE. This situation is reflected in the change of β value. The β representing the fraction of nonhydrogen bonded water or less structured water decreases with increasing concentration of SDS. This means that the SDS may also act as a water structure promoter. It should be noted that the difference in the value of parameter, β above and below cmc is remarkable.

Next, it is examined the kinetic results obtained by this investigation in light of the reaction kinetics of solute-solvent interaction. The rate constant for the dissociation of the solute-solvent complex seems to be SDS concentration independent, while the association rate constant decreases with increasing SDS concentration. This result may imply that some of the nonelectrolytes are bound to the SDS micelles and the electrorepulsive force may hinder the interaction between the water and nonelectrolyte, or that the mobility of the cosurfactants may decrease because of the existence of the micelles.

A similar micelle effect has also been observed in the kinetics of a proton-transfer reaction: the rate constant diminished when the ionic surfactants formed micelles.[17] In order to interpret the observations more quantitatively, other surfactants should be selected and such studies are now under investigation.

A Linear Response Polarizability Theory for an Extended Fano-DeVoe Model with Comments on the Joint Use of Both Short- and Long-Range Inter(sub)molecular Interaction Approximations

Hirotoshi Ito and Yasumasa J. I'haya*
Department of Materials Science, The University of Electro-Communications, Chofu, Tokyo 182
(Received March 5, 1987)

An approach to extend the Fano-DeVoe model is presented for copolymer systems by making use of the Green's operator method within the dipole-dipole approximation. We derive a model Hamiltonian for a system by expanding its primitive Hamiltonian in terms of a bare complete basis set consisting of zero-order one-site and two-site excitation states in the first-order perturbation theory. A generalized extension of the Fano-DeVoe theory can be given by the polarizability tensor derived for this model Hamiltonian. As a more refined way, we derive another model Hamiltonian by expanding the primitive Hamiltonian of the system in terms of the corrected complete basis set consisting of the first-order excitation states. With such model Hamiltonians, we can fabricate polarizability theories on the same footing with the exciton wave function approaches based on the usual perturbation theory. Simplified schemes for the latter model Hamiltonians are applied to the copolymer system consisting of such chromophores that have permanent dipole moments in their ground states. Even if the constituent chromophores do not have permanent moments, extension of the Fano-DeVoe model is made by allowing for the total polymer ground state wave function corrected in terms of two-site excitation states. To circumvent the deficiency of the dipole approximation in the region of short separations of submolecules, we show a recipe as to how to make use of the monopole approximation together with the dipole approximation in conformity with the compromized idea of Moffitt.

When predicting the UV absorption as well as the CD and ORD spectra for free molecules[1] and molecular aggregates,[2] polarizability tensors afford their bandshape functions. In the previous paper,[2] we presented such a polarizability tensor theory for the real DNA molecules, which have the highly repeating sequences of base pairs. This formulation for copolymer systems is essentially the same as the decorrelation approximation[3] for homogeneous systems and the polarizability theory for homopolymer systems sketched by Herzenberg and Modinos[4] as a Fano-DeVoe model.[5-7] Also, DeVoe's coupled oscillator theory[8] which was semiclassically derived for copolymers and has been applied successfully to various biomolecules[9,10] falls under the cetegory of this model. We showed that the polarizability tensor equation[2] is of the same form as the matrix equation for the scalar polarizability in DeVoe's theory. However, if the kth submolecule for a copolymer (N-mer) has k_f oscillators, the size of the latter matrix equation is $(\sum_{k=1}^{N} k_f)\times(\sum_{k=1}^{N} k_f)$, whereas the size of our tensor matrix is always limited to be $3N\times3N$. This means that for the large N-mer with large number of k_f transitions, the oscillator formalism comes to require extremely longer computing time than the tensor formalism needs. Furthermore, we can use in our formalism the Green's operator methos which offers a convenient tool capable of expanding the polarizability theory in different ways by use of model Hamiltonians designed on the same footing with the usual exciton wave function approaches.

Herzenberg and Modinos[4] first used the terminology of the Fano-DeVoe model for the polarizability theory of homopolymers. However, in this paper, both DeVoe's scalar polarizability theory[8] and our polarizability theory[2] for copolymers are referred to as the original Fano-DeVoe model. The theories on the optical properties of molecular aggregates have often been developed by the usual perturbation theory on the basis of the exciton-state wave function approaches, in which we can find analogous treatments useful for the present purpose. For instance, some of the wave function approaches[13,14,19] can refine the polymer-state wave functions by taking into account the static field effect of permanent moment $\boldsymbol{\mu}_{00}^{(\mathrm{site})}$ of a certain chromophore onto the rest of constituent chromophores for the polymer system. We hope to develop polarizability theories in parallel with the works made by such perturbational approaches; we extend our previous polarizability tensor theory for the UV absorption and CD spectra by designing a model Hamiltonian on the same footing with the exciton theory given in Tinoco's review[19] on optical activity. Also, it is another concern to consider how the interactions between transition and permanent dipole moments are involved in the present theory.

Most of polarizability theories were not able to involve the effect of permanent dipole moments of submolecules. However, by making use of the so-called transition matrix method[14,15] based on a Green's operator approach, Rebenold has presented the linear response theory which contains the static effect,[16,17] i.e., the static interaction terms of the inner excited f→g transitions of a certain submolecule with the ground states of the rest of submolecules such as $|fm\rangle\{\sum_{g\neq f}\sum_{k\neq m}\boldsymbol{\mu}_{fg}^{(m)}\cdot\boldsymbol{U}_{mk}\cdot\boldsymbol{\mu}_{00}^{(k)}\langle gm|$. Having a glance at the original Fano-DeVoe model Hamiltonian,[2] one may perhaps be apt to judge it impossible to bring the static effect in the polarizability tensor theory in a usual way rather than in an artificial way. This is

because, in the expansion[20] of inter(sub)molecular interaction in terms of Legndre's polynomials, the terms including the point charge defined as the sum of net charges on nuclei vanish for neutral submolecules with permanent moments. However, we must note that even if there are no such point charges in permanent-polarized submolecules, each atom of these submolecules has nonzero net charge which exerts the static field effect to other submolecules. In this paper, we will derive such a model Hamiltonian that can involve the static effect in a natural fashion.

We build the polarizability theory within the dipole-dipole approximation. However, the dipole approximation is valid only for large separations between charge clouds, so that it is better to introduce the monopole-monopole approximation[18-20] at least for the nearest neighbors of monomer units and the dipole-dipole approximation for the remaining neighbors, following Moffitt.[18] In this joint use of the two approximations for the Fano-DeVoe type of polarizability tensor theory, it is impossible to use the monopole approximation without changing its present form,[2] as will be shown in the following section. In order to make use of the monopole approximation, it is of course necessary to obtain the transition and permanent monopole densities at each atom in the monomers. For the case where the sizes of chromophores in a copolymer are larger than or nearly equal to the separations of adjacent monomers, it is expected that the monopole approximation between the near neighbors becomes operative to remedy the dipole approximation. DNA and protein molecules are certainly the cases.[18,24-26]

In the next section, we first present a new scheme to extend the Fano-DeVoe model. Then, we simplify this scheme and apply it to the copolymer system of such constituent chromophores that have permanent dipole moments. Finally, we show a recipe as to how to make use of the short-range-oriented monopole approximation together with the long-range-oriented dipole approximation.

An Extended Fano-DeVoe Model Hamiltonian and the Polarizability

We will develop a polarizability tensor theory for describing the UV absorption and CD bandshapes of nucleic acids, in which the subunits of the purine and pryrimidine bases have the permanent dipole moments that are as large as the transition moments in magnitude.[24-25]

To begin with, let us assume that for the electronic Hamiltonian of the mth monomer H_m°, we know the eigenfunctions of the fth excitation states $\xi_f^{(m)}$ with the eigenvalues $E_f^{(m)}$ (f=0; ground state). Let V_{mn} be an interaction operator between the two submolecules located at sites m and n. The total Hamiltonian of the copolymer(N-mer) is then given by

$$H=\sum_{m=1}^{N} H_m^\circ+\sum_{n=1}^{N-1}\sum_{m>n}^{N} V_{mn}=H^\circ+V, \tag{1}$$

in which V_{mn} involves all the Coulomb interactions among electrons and nuclei of both submolecules separated by the distance R_{mn}. Neglecting higher-order terms in the expansion of V_{mn}, we approximate it for the two neutral submolecules by the dipole-dipole term:

$$V_{mn}=\boldsymbol{\mu}_m\cdot(R_{mn}^2\mathbf{1}-3\,\boldsymbol{R}_{mn}\boldsymbol{R}_{mn})R_{mn}^{-5}\cdot\boldsymbol{\mu}_n=\boldsymbol{\mu}_m\cdot\boldsymbol{U}_{mn}\cdot\boldsymbol{\mu}_n, \tag{2}$$

where $\boldsymbol{U}_{mn}$ defines the unit dipole interaction tensor, and $\boldsymbol{\mu}_m$ is the electric dipole moment operator centered at site m:

$$\boldsymbol{\mu}=\sum_{\mathrm{A}}^{\mathrm{Nuc}} Z_{\mathrm{A}}\,e\,\boldsymbol{r}_{m\mathrm{A}}-\sum_{i}^{\mathrm{Elec}} e\,\boldsymbol{r}_{mi}. \tag{3}$$

Z_{A} is the effective nuclear charge on nucleus A. In relation with Eq. 2, we dropped lower-order interaction terms involving point charges which vanish for neutral submolecules. Here, we define the point charges of a certain submolecule by the quantity which is equal to the summation of net charges on atoms in the submolecule. However, even if the total point charges are zero, permanent-polarlized subunits have nonzero net charges on nuclei. Such submolecules can exert the electrostatic effect to the ground as well as excited states of other submolecules. In the following section, we wish to show that the static field effect can be brought in the usual polarizability theories by deriving a model Hamiltonian.

For the polymer ground state $|0\rangle$ of the assembly of hypothetically non-interacting chromophores, we may take the product of the ground state wavefunctions of N submolecules, $\xi_0^{(m)}$, such that

$$|0\rangle=|\prod_{m=1}^{N}\xi_0^{(m)}\rangle. \tag{4}$$

The composite excited state $|fm\rangle$ considering only the fth local excitation at site m, $\xi_f^{(m)}$, is then given by

$$|fm\rangle=|\xi_f^{(m)}\prod_{n\neq m}\xi_0^{(n)}\rangle, \tag{5}$$

which may be referred to as one-site excitation state. For simplicity, we shall ignore the additional effect due to the antisymmetrization of those composite states with respect to the exchange of all the electrons between any pair of (sub)molecules. Furthermore, we define a two-site excitation state such as

$$|smtn\rangle=|\xi_s^{(m)}\xi_t^{(n)}\prod_{k\neq m,n}\xi_0^{(k)}\rangle. \tag{6}$$

(A) Polarizability for the Bare Basis Set-Dependent Model Hamiltonian. Let us denote a set of these states defined above as $\{|\psi\rangle\}$, $|0\rangle$ being the polymer ground state. We confine ourselves to weak and intermediate coupling cases, where no reorganization of electrons may occur in the polymer system retaining the identity of submolecules. Even if there exist such interaction terms as $\langle\psi|V|0\rangle$ and $\langle 0|V|\psi\rangle$ that are large but not huge in magnitude, it is convenient not

to take into account the direct mixing of $|0>$ with the rest of $\{|\psi>\}$ in the total wavefunctions of a polymer, $|\text{polymer}(L)>$, but to correct $|0>$ by using the first-order perturbation theory.

We can expand the polymer-state wave function in term of $\{|\psi>\}$ as follows:

$$|\text{polymer}(L)>=\sum_{\psi\neq 0}^{\text{All}}|\psi><\psi|\,\text{polymer}(L)>, \quad L=1,2,3,\cdots \tag{7}$$

with the assumption

$$1=\sum_{\psi\neq 0}^{\text{All}}|\psi><\psi|, \tag{8}$$

where we exclude the ground state $|0>$ for the reason mentioned above.

Now, we expand the primitive Hamiltonian H of Eq. 1 in terms of $\{|\psi>\}$ and put a model Hamiltonian as

$$\begin{aligned}\bar{H}&=\sum_{\psi,\psi'\neq 0}\sum|\psi><\psi|H|\psi'><\psi'|-<0|H|0>\\&=\sum_{\psi,\psi'\neq 0}\sum|\psi>\{<\psi|H|\psi'>-\delta_{\psi,\psi'}<0|H|0>\}<\psi'|\\&=\sum_{\psi'\neq 0}\varepsilon_{\psi,0}|\psi><\psi|+\{\sum_{\psi\neq\psi'}^{\text{intrasite}}\sum|\psi><\psi|V|\psi'><\psi'|\\&\quad+\sum_{\psi'\neq\psi'}^{\text{intersite}}\sum|\psi><\psi|V|\psi'><\psi'|\}\\&=\bar{H}_0+\bar{V}\end{aligned} \tag{9}$$

with

$$\varepsilon_{\psi,0}=<\psi|H|\psi>-<0|H|0>. \tag{10}$$

This model Hamiltonian formally gives the generalized extension of the Fano-DeVoe model. The $\varepsilon_{\psi,0}$ represents the modified excitation energy of a monomer embedded in the hypothetical polymer. By putting solely $|\psi>=|fm>$ in Eq. 9 and neglecting not only the level-shift in the $\varepsilon_{\psi,0}$ of the following Eq. 18 but also the mth intrasite $f\rightarrow$g transition terms such as

$$\begin{aligned}&\sum_{f}\sum_{g}\sum_{m}|fm><fm|V|gm><gm|=\\&\quad\sum_{f}\sum_{g}\sum_{m}\sum_{k}|fm>\mu_{fg}^{(m)}\cdot U_{mk}\cdot\mu_{00}^{(k)}<gm|,\quad (f,g\neq 0)\end{aligned} \tag{11}$$

one can obtain the polarizability tensor for the original Fano-DeVoe model Hamiltonian which was first derived by the present authors.[2)]

For a hypothetically non-interacting copolymer molecule, the crude Green's operator is defined as

$$\begin{aligned}G^{\circ}(E)&=(E-\bar{H}_0+i\eta)^{-1}\\&=(1/E)\{1+[(\bar{H}_0-i\eta)/E]+[(\bar{H}_0-i\eta)/E]^2+\cdots\}\\&=(1/E)\{\sum_{\psi\neq 0}|\psi><\psi|+\sum_{\psi\neq 0}[(\varepsilon_{\psi,0}-i\eta_{\psi})/E]|\psi><\psi|\\&\quad+\sum_{\psi,\psi'\neq 0}\sum[(\varepsilon_{\psi,0}-i\eta_{\psi})/E][(\varepsilon_{\psi',0}-i\eta'_{\psi'})/E]\\&\quad\times|\psi><\psi|\psi'><\psi'|+\cdots\}\\&=\sum_{\psi\neq 0}\frac{|\psi><\psi|}{E-\varepsilon_{\psi,0}+i\eta_{\psi}}.\end{aligned} \tag{12}$$

For a weak coupling case where $\{|\psi>\}$ do not strongly mix with the ground state $|0>$, we define the monomer polarizability tensor $\alpha(E)$ as

$$\alpha(E)=-<0|\mu G^{\circ}(E)\mu|0>=\sum_{\psi\neq 0}\frac{-<0|\mu|\psi><\psi|\mu|0>}{E-\varepsilon_{\psi,0}+i\eta_{\psi}}, \tag{13}$$

with

$$\mu=\sum_{m=1}^{N}\mu_m. \tag{14}$$

For a complete basis set which spans the one- and two-site excitation states, we note that the diagonal Hamiltonian $\bar{H}_0$ and the interaction part $\bar{V}$ in Eq. 9 are written down as

$$\bar{H}_0=\sum_{f}\sum_{m}\varepsilon_{fm,0}|fm><fm|+\sum_{s}\sum_{m}\sum_{t}\sum_{n}\varepsilon_{smtn,0}|smtn><smtn|, \tag{15}$$

$$\begin{aligned}\bar{V}&=\sum_{m>m}\sum\sum_{f}\sum_{g}|fm>\mu_{f0}^{(m)}\cdot U_{mn}\cdot\mu_{0g}^{(m)}<gn|\\&\quad+\sum_{m}\sum_{f}\sum_{g\,(g\neq f)}|fm>\{\sum_{k\neq m}\mu_{fg}^{(m)}\cdot U_{mk}\cdot\mu_{00}^{(k)}\}<gm|\\&\quad+\sum_{m>n}\sum_{s}\sum_{t}\sum\{\sum_{f}[|fm>\mu_{fs}^{(m)}\cdot U_{mn}\cdot\mu_{0t}^{(n)}<smtn|\\&\quad+|fn>\mu_{0s}^{(m)}\cdot U_{mn}\cdot\mu_{ft}^{(n)}<smtn|]\\&\quad+\sum_{g}[|smtn>\mu_{s0}^{(m)}\cdot U_{mn}\cdot\mu_{tg}^{(n)}<gn|\\&\quad+|smtn>\mu_{sg}^{(m)}\cdot U_{mn}\cdot\mu_{t0}^{(n)}<gm|]\}\\&\quad+\sum_{m>n}\sum_{f}\sum_{g}\sum_{s}\sum_{t\,(f,g\neq s,t)}|fmgn>\mu_{fs}^{(m)}\cdot U_{mn}\cdot\mu_{gt}^{(n)}<smtn|.\end{aligned} \tag{16}$$

Here, the first term is the original Fano-DeVoe type of operator. The terms after the first one in Eq. 16 show the interaction operators of the inner excited transition moments $\mu_{fg}^{(\text{site})}$ (involving $0\rightarrow 0$), which are classfied into three types of electric moments such as $\mu_{00}^{(\text{site})}$, $\mu_{0f}^{(\text{site})}$, and $\mu_{fg}^{(\text{site})}$. In particular, the second term is a special version of the transition matrix theory[14,15)] for the static field effect of permanent dipole moments $\mu_{00}^{(\text{site})}$ on all the transition moments $\mu_{fg}^{(\text{site})}$ for a specific site and similar effect for the rest of all the sites.

Thus, the matrix element of the monomer polarizability tensor with respect to sites m and n is given by

$$\begin{aligned}\alpha_{mn}(E)&=-\sum_{f}\sum_{g}<0|\mu|fm><fm|G^{\circ}(E)|gn><gn|\mu|0>\\&\quad-\sum_{s}\sum_{t}\sum_{f}\sum_{g}\sum_{k}\sum_{l}<0|\mu|smtk>\\&\quad\times<smtk|G^{\circ}(E)|flgn><flgn|\mu|0>\\&=\sum_{f}\delta_{mn}\frac{-<0|\mu|fm><fm|\mu|0>}{E-\varepsilon_{fm,0}+i\eta_{fm}}\\&\quad+\sum_{s}\sum_{t}\frac{-<0|\mu|smtn><smtn|\mu|0>}{E-\varepsilon_{smtn,0}+i(\eta_{sm}+\eta_{tn})},\end{aligned} \tag{17}$$

in which $<0|\mu|fm>$ is nothing but $\mu_{0f}^{(m)}$ and where $\varepsilon_{fm,0}$ and $\varepsilon_{smtn,0}$ are calculated to be as follows:

$$\varepsilon_{fm,0}=E_{f0}^{(m)}+\sum_{k\neq m}\mu_{ff}^{(m)}\cdot U_{mk}\cdot\mu_{00}^{(k)}-\sum_{k\neq m}\mu_{00}^{(m)}\cdot U_{mk}\cdot\mu_{00}^{(k)}, \tag{18}$$

$$\varepsilon_{smtn,0}=E_{s0}^{(m)}+E_{t0}^{(n)}+\mu_{ss}^{(m)}\cdot U_{mn}\cdot\mu_{tt}^{(n)}-\mu_{00}^{(m)}\cdot U_{mn}\cdot\mu_{00}^{(n)}. \tag{19}$$

The $E_{f0}^{(m)}=(E_f^{(m)}-E_0^{(m)})$ is the excitation energy of the mth free monomer. The tensor $\alpha_{mn}(E)$ is diagonal, since the second term in Eq. 17 vanishes due to $<0|\mu|smtn>=0$. However, this electric moment comes

to be nonvanishing if we replace the bare ground state $|0\rangle$ with the more exact ground state $|\tilde{0}\rangle$. Actually, we assume the corrected ground state as follows:

$$|\tilde{0}\rangle=|0\rangle-\sum_{k\neq m}\varepsilon_{\psi,0}^{-1}\langle\psi|V|0\rangle|\psi\rangle\equiv|0\rangle-\sum_{\psi\neq m}C_{\psi,0}|\psi\rangle, \tag{20}$$

where $C_{\psi,0}=C_{0,\psi}$. It should be noted that $|0\rangle$ does not mix with one-site excitation states but mix only with two-site excitation states, unless submolecules have permanent dipole moments.

For the true Green's operator

$$\begin{aligned}G(E)&=(E-\bar{H}+i\eta)^{-1}\\&=G^{\circ}(E)+G^{\circ}(E)\bar{V}G^{\circ}(E)+G^{\circ}(E)\bar{V}G^{\circ}(E)\bar{V}G^{\circ}(E)+\cdots,\end{aligned} \tag{21}$$

we can derive the polymer polarizability tensor ${}^{p}\alpha_{mn}(E)$ as follows:

$$\begin{aligned}{}^{p}\alpha_{mn}(E)=&-\sum_{f,g\neq0}\sum\langle0|\mu|fm\rangle\langle fm|G(E)|gn\rangle\langle gn|\mu|0\rangle\\&-\sum_{s,t,f,g\neq0}\sum\sum_{k}\sum_{l}\langle0|\mu|smtk\rangle\\&\times\langle smtk|G(E)|flgn\rangle\langle flgn|\mu|0\rangle.\end{aligned} \tag{22}$$

The second term of Eq. 22 vanishes due to $\langle0|\mu|smtk\rangle=0$ and $\langle flgn|\mu|0\rangle=0$. For the first term of Eq. 22, we only point out that in addition to the original Fano-DeVoe type of matrix elements, various types of matrix elements of one-site part of $G^{\circ}(E)$,

$$\Sigma_f\Sigma_m|fm\rangle\langle fm|G^{\circ}(E)|fm\rangle\langle fm|,$$

mixing with two-site part of $G^{\circ}(E)$,

$$\Sigma_s\Sigma_m\Sigma_t\Sigma_n|smtn\rangle\langle smtn|G^{\circ}(E)|smtn\rangle\langle smtn|,$$

are produced by matching of the bra- and ket-operators for the various types of combinations of the seven interaction operators of Eq. 16. Because of the complexity, we will mention about the matrix elements of Eq. 22 any more. However, it is here interesting to observe that the second term of Eq. 16 leads to the first-order polarizability tensor:

$$\begin{aligned}&-\sum\sum_{f,g\neq0(g\neq f)}\langle0|\mu|fm\rangle\langle fm|G^{\circ}(E)\\&\quad\times[\text{2nd term of }\bar{V}]G^{\circ}(E)|gm\rangle\langle gm|\mu|0\rangle\delta_{mn}\\&=\sum\sum_{f,g\neq0(f\neq g)}\frac{-\mu_{0f}^{(m)}\{\sum_{k\neq m}\mu_{fg}^{(m)}\cdot U_{mk}\cdot\mu_{00}^{(k)}\}\mu_{g0}^{(m)}}{(E-\varepsilon_{fm,0}+i\eta_{fm})(E-\varepsilon_{gm,0}+i\eta_{gm})}\delta_{mn},\end{aligned} \tag{23}$$

which indicates that the static field effect involved is quite large, when $\varepsilon_{fm,0}$ and $\varepsilon_{gm,0}$ are nearly degenerate.

For the intermediate coupling case where there exists a strong mixing of $\{|fm\rangle\}$ with $|0\rangle$, we must evaluate the average value of the correlated ground state $|\tilde{0}\rangle$ instead of the bare ground state $|0\rangle$. Namely, we have a more refined polymer polarizability tensor:

$$\begin{aligned}{}^{rp}\alpha(E)=&-\langle\tilde{0}|\mu G(E)\mu|\tilde{0}\rangle\\=&{}^{p}\alpha(E)+\sum_{\psi\neq0}\langle0|\mu G(E)\mu|\psi\rangle C_{\psi,0}\\&+\sum_{\psi\neq0}C_{0,\psi}\langle\psi|\mu G(E)\mu|0\rangle\\&-\sum_{\psi,\psi'\neq0}\sum C_{0,\psi}\langle\psi|\mu G(E)\mu|\psi'\rangle C_{\psi',0}.\end{aligned} \tag{24}$$

The treatment of Eq. 24 is thus quite analogous to that of the renormalized random-phase approximation for a free molecule. The theoretical procedure outlined above will be more generalized in (B) which contains the calculations of Eqs. 22 and 24.

(B) Polarizability for the Corrected Basis Set-Dependent Model Hamiltonian. Instead of the bare basis set $\{|\psi\rangle\}$ of the excited states, let us make use of a basis set corrected by the first-order perturbation theory, that is,

$$\begin{aligned}|\tilde{\psi}\rangle=&|\psi\rangle+\varepsilon_{\psi,0}^{-1}\langle0|V|\psi\rangle|0\rangle+\sum_{\psi'\neq\psi}\varepsilon_{\psi,\psi'}^{-1}\langle\psi'|V|\psi\rangle|\psi'\rangle\\\equiv&|\psi\rangle+C_{0,\psi}|0\rangle+\sum_{\psi'\neq\psi}C_{\psi',\psi}|\psi'\rangle\\=&|\psi\rangle+C_{\psi,0}|0\rangle+\sum_{\psi'\neq\psi}C_{\psi,\psi'}|\psi'\rangle,\end{aligned} \tag{25}$$

where $\varepsilon_{\psi,\psi'}$ denotes an energy difference $\langle\psi|H|\psi\rangle-\langle\psi'|H|\psi'\rangle$. Again, we must note that the two-site excitation states for ψ always mix with the ground state, while the one-site excitation states can mix with the ground state only if the constituent chromophores have permanent dipole moments $\mu_{00}^{(\text{site})}$. Then, similar to Eq. 7, the wave function for the copolymer system is expanded in terms of the corrected basis set as[19]

$$|\text{polymer}(L)\rangle=\sum_{\psi\neq0}|\tilde{\psi}\rangle\langle\tilde{\psi}|\,\text{polymer}(L)\rangle,\qquad L=1,2,3,\cdots \tag{26}$$

where we assume the completeness for the $\{|\tilde{\psi}\rangle\}$.

The model Hamiltonian is now set to be

$$\begin{aligned}\tilde{H}=&\sum_{\psi,\psi'\neq0}\sum|\tilde{\psi}\rangle\langle\tilde{\psi}|H|\tilde{\psi}'\rangle\langle\tilde{\psi}'|-\langle\tilde{0}|H|\tilde{0}\rangle\\=&\sum_{\psi\neq0}\tilde{\varepsilon}_{\psi,0}|\tilde{\psi}\rangle\langle\tilde{\psi}|+\sum_{\psi\neq\psi}\sum|\tilde{\psi}\rangle\langle\tilde{\psi}|V|\tilde{\psi}'\rangle\langle\tilde{\psi}'|\\=&\sum_{\psi\neq0}\tilde{\varepsilon}_{\psi,0}|\tilde{\psi}\rangle\langle\tilde{\psi}|+\{\overset{\text{intrasite}}{\sum_{\psi\neq\psi'}\sum}|\tilde{\psi}\rangle\langle\tilde{\psi}|V|\tilde{\psi}'\rangle\langle\tilde{\psi}'|\\&+\overset{\text{intersite}}{\sum_{\psi\neq\psi'}\sum}|\tilde{\psi}\rangle\langle\tilde{\psi}|V|\tilde{\psi}'\rangle\langle\tilde{\psi}'|\}\\=&\tilde{H}_0+\tilde{V},\end{aligned} \tag{27}$$

with

$$\tilde{\varepsilon}_{\psi,0}=\langle\tilde{\psi}|H|\tilde{\psi}\rangle-\langle\tilde{0}|H|\tilde{0}\rangle. \tag{28}$$

Equation 27 gives the more generalized Fano-DeVoe model Hamiltonian than that defined by Eq. 9. The modified excitation energy $\tilde{\varepsilon}_{\psi,0}$ is formally corrected up to the order of V^2 by the usual perturbation theory. Also, we define the crude and true Green's operators for $\tilde{H}_0$ and $\tilde{H}$, respectively, as follows:

$$\tilde{G}^{\circ}(E)=(E-\tilde{H}_0+i\tilde{\eta})^{-1}=\sum_{\psi\neq0}\frac{|\tilde{\psi}\rangle\langle\tilde{\psi}|}{E-\tilde{\varepsilon}_{\psi,0}+i\tilde{\eta}_{\psi}}, \tag{29}$$

$$\tilde{G}(E)=(E-\tilde{H}+i\tilde{\eta})^{-1}=\tilde{G}^{\circ}(E)+\tilde{G}^{\circ}(E)\tilde{V}\tilde{G}(E), \tag{30}$$

which may be called a dressed or effective and/or renormalized Green's operator, if we follow the terminology of Mattuck.[23]

The monomer and polymer polarizability tensors for Eqs. 29 and 30 are defined by the average values over the bare ground state $|0>$ as follows:

$$\tilde{\alpha}(E)=-<0|\mu\tilde{G}^{\circ}(E)\mu|0>=\sum_{\psi\neq 0}\frac{-<0|\mu|\tilde{\psi}><\tilde{\psi}|\mu|0>}{E-\tilde{\varepsilon}_{\psi,0}+i\tilde{\eta}_{\psi}}, \tag{31}$$

$$^{p}\tilde{\alpha}(E)=-<0|\mu\tilde{G}(E)\mu|0>$$
$$=-<0|\mu(\tilde{G}^{\circ}(E)+\tilde{G}^{\circ}(E)\tilde{V}\tilde{G}(E)+\cdots)\mu|0>. \tag{32}$$

Unfortunately, it becomes more complicated to calculate the matrix elements for the dressed $^{p}\tilde{\alpha}(E)$ than to do so for the bare $^{p}\alpha(E)$, so that it may be hopeless to linearlize $^{p}\tilde{\alpha}(E)$ by intuitively finding and summing up kinds of modules comprising simple types of polarizabilities and unit interaction factors just like the derivation of the original Fano-DeVoe polarizability.[2]

The most generalized tensor $^{rp}\tilde{\alpha}(E)$ for a copolymer is formally obtained by taking the average over the correlated ground state as follows:

$$^{rp}\tilde{\alpha}(E)=-<\tilde{0}|\mu\tilde{G}(E)\mu|\tilde{0}>$$
$$=^{p}\tilde{\alpha}(E)+\sum_{\psi\neq 0}<0|\mu\tilde{G}(E)\mu|0>C_{\psi,0}$$
$$+\sum_{\psi\neq 0}C_{0,\psi}<\psi|\mu\tilde{G}(E)\mu|0>$$
$$-\sum_{\psi,\psi'\neq 0}\sum C_{0,\psi}<\psi|\mu\tilde{G}(E)\mu|\psi'>C_{\psi',0}, \tag{33}$$

which may be referred to as a self-consistent renormalized RPA, while Eq. 32 is called simply a renormalized RPA.

In what follows, we will mention the procedures described in (A) and (B) in more detail for comparatively simple cases.

(C) Polarizability for the Model Hamiltonian of the bare $\{|fm>\}$. The choice of the bare basis set consisting of one-site excitation states for the total Hamiltonian $\bar{H}(=\bar{H}_{o}+\bar{V})$ leads to the following operators

$$\bar{H}_{0}=\sum_{f}\sum_{m}\varepsilon_{fm,0}|fm><fm|, \tag{34}$$

$$\bar{V}=\sum_{f}\sum_{m}\overset{\text{intersite}}{\sum_{g}\sum_{n}}|fm>\mu_{f0}^{(m)}\cdot U_{mn}\cdot\mu_{0g}^{(n)}<gn|$$
$$+\overset{\text{intrasite}}{\sum_{f}\sum_{m}\sum_{g\neq f}}|fm><fm|V|gm><gm|$$
$$=\bar{V}_{FD}+\bar{V}_{S} \tag{35}$$

where $\bar{V}_{FD}$ denotes the original Fano-DeVoe type of interaction operator. $\bar{V}_{S}$ given by $\sum_{k}\mu_{fg}^{(m)}\cdot U_{mk}\cdot\mu_{00}^{(k)}$ signifies the operator for the Bayley, Nielsen, Schellman type of static field effect[15] to the mth intrasite f→g transitions: i.e., the operator for the intrasite f→g excitation state of the mth subunit which interacts with the ground states of the rest of the kth permanent-polarized subunits. For the off-diagonal static interaction term $<fm|V|gm>$, $\varepsilon_{fm,0}$ contains the diagonal element $<fm|V|fm>$ which is given by the second term of Eq. 18. It may be convenient for the calculations of $^{p}\alpha(E)$ to specify that for example the element $<fm|V|gn>$ represented by $\mu_{0f}^{(m)}\cdot U_{mn}\cdot\mu_{0g}^{(n)}$ implies such a scalar quantity that the operation of $\mu\cdot U\cdot\mu$ has already been performed.

From the calculation of $-<0|\mu G(E)\mu|0>$ with $G(E)=[E-(\bar{H}_{o}+\bar{V})+i\eta]^{-1}$, we can obtain $^{p}\alpha_{mn}(E)$. However, inclusion of $\bar{V}_{S}$ brings about too much complexity, so that we shall collect only several important terms to be linearlized as shown in the following; for the convenience of this purpose, we put

$$^{p}\bar{V}_{FD}(E)=\bar{V}_{FD}+\bar{V}_{FD}G^{\circ}(E)\bar{V}_{FD}+\bar{V}_{FD}G^{\circ}(E)\bar{V}_{FD}G^{\circ}(E)\bar{V}_{FD}+\cdots, \tag{36}$$

$$^{p}\bar{V}_{S}(E)=\bar{V}_{S}+\bar{V}_{S}G^{\circ}(E)\bar{V}_{S}+\bar{V}_{S}G^{\circ}(E)\bar{V}_{S}G^{\circ}(E)\bar{V}_{S}+\cdots. \tag{37}$$

Thus, we have

$$^{p}\alpha_{mn}(E)=-\sum_{f,g\neq 0}\sum<0|\mu|fm><fm|G(E)|gn><gn|\mu|0> \tag{38a}$$

$$\simeq-\sum_{f,g\neq 0}\sum\{\mu_{0f}^{(m)}<fm|G^{\circ}(E)+G^{\circ}(E)^{p}\bar{V}_{FD}(E)G^{\circ}(E)|gn>\mu_{g0}^{(n)}$$
$$+\mu_{0f}^{(m)}<fm|G^{\circ}(E)^{p}\bar{V}_{S}(E)G^{\circ}(E)|gn>\mu_{g0}^{(n)}$$
$$+\mu_{0f}^{(m)}<fm|G^{\circ}(E)^{p}\bar{V}_{S}(E)G^{\circ}(E)^{p}\bar{V}_{FD}(E)G^{\circ}(E)|gn>\mu_{g0}^{(n)}$$
$$+\mu_{0f}^{(m)}<fm|G^{\circ}(E)^{p}\bar{V}_{FD}(E)G^{\circ}(E)^{p}\bar{V}_{S}(E)G^{\circ}(E)|gn>\mu_{g0}^{(n)}$$
$$+\mu_{0f}^{(m)}<fm|G^{\circ}(E)^{p}\bar{V}_{FD}(E)G^{\circ}(E)^{p}\bar{V}_{S}(E)G^{\circ}(E)\times{}^{p}\bar{V}_{FD}(E)G^{\circ}(E)|gn>\mu_{g0}^{(n)}$$
$$+\mu_{0f}^{(m)}<fm|G^{\circ}(E)^{p}\bar{V}_{S}(E)G^{\circ}(E)^{p}\bar{V}_{FD}(E)G^{\circ}(E)\times{}^{p}\bar{V}_{S}(E)G^{\circ}(E)|gn>\mu_{g0}^{(n)}\}$$
$$=\{\mathbf{1}+\alpha(E)\cdot U\}_{mn}^{-1}\cdot\alpha_{nn}(E)-\sum_{f\neq g}\sum\mu_{0f}^{(m)}K_{mm}^{fg}(E)\mu_{g0}^{(m)}\delta_{mn}$$
$$+\sum_{f\neq t}\sum_{k}\sum\mu_{0f}^{(m)}K_{mm}^{ft}(E)\mu_{t0}^{(m)}\cdot\{\mathbf{1}+U\cdot\alpha(E)\}_{mk}^{-1}\cdot U_{kn}\cdot\alpha_{nn}(E)$$
$$+\sum_{k}\sum_{t\neq g}\sum\alpha_{mm}(E)\cdot U_{mk}\cdot\{\mathbf{1}+\alpha(E)\cdot U\}_{kn}^{-1}\cdot\mu_{0t}^{(n)}K_{nn}^{tg}(E)\mu_{g0}^{(n)}$$
$$-\sum_{k}\sum_{l}\sum_{j}\sum_{t\neq g}\sum\alpha_{mm}(E)\cdot U_{mk}\cdot\{\mathbf{1}+\alpha(E)\cdot U\}_{kl}^{-1}\cdot\mu_{0t}^{(l)}K_{ll}^{tg}(E)\mu_{g0}^{(l)}\times\{\mathbf{1}+U\cdot\alpha(E)\}_{lj}^{-1}U_{jn}\cdot\alpha_{nn}(E)$$
$$-\sum_{k}\sum_{f\neq t}\sum_{s\neq g}\sum\mu_{0f}^{(m)}K_{mm}^{ft}(E)\mu_{t0}^{(m)}\cdot\{\mathbf{1}+U\cdot\alpha(E)\}_{mk}^{-1}\cdot U_{kn}\times\mu_{0s}^{(n)}K_{nn}^{sg}(E)\mu_{g0}^{(n)},\ m,\ n=1,2,3,\cdots,\ N \tag{38b}$$

with the relationships

$$\{\mathbf{1}+\alpha(E)\cdot U\}_{mn}^{-1}=\delta_{mn}-\alpha_{mm}(E)\cdot U_{mn}+\sum_{k}\alpha_{mm}(E)\cdot U_{mk}\cdot\alpha_{kk}(E)\cdot U_{kn}-\cdots, \tag{39}$$

$$\{\mathbf{1}+U\cdot\alpha(E)\}_{mn}^{-1}=\delta_{mn}-U_{mn}\cdot\alpha_{nn}(E)+\sum_{k}U_{mk}\cdot\alpha_{kk}(E)\cdot U_{kn}\cdot\alpha_{nn}(E)-\cdots, \tag{40}$$

where we put

$$K_{mm}^{fg}(E)=\left\{\frac{<fm|V|gm>}{E-\varepsilon_{fm,0}+i\eta_{fm}}+\sum_{t\neq f,g}\frac{<fm|V|tm><tm|V|gm>}{(E-\varepsilon_{fm,0}+i\eta_{fm})(E-\varepsilon_{tm,0}+i\eta_{tm})}+\cdots\right\}\Big/(E-\varepsilon_{gm,0}+i\eta_{gm}) \tag{41}$$

In Eq. 38b, the first term gives the pure Fano-DeVoe type of polarizability tensor components,[2] and the second term corresponds to the tensor components involving the static field effect appeared in the transition matrix theory.[15] The remaining four terms show only the simple geometric progressive parts of the tensor components produced from all the crossed terms of $\overline{V}_{FD}$ and $\overline{V}_S$. From the fact that by inspection of Eq. 38b the corrections to the ordinary Fano-DeVoe polarizability tensor are at least the first order in $\langle\psi|V|\psi'\rangle$ for the permanent-polarized system, it is indicated that Eq. 38b gives a significant extension of the Fano-DeVoe model, when the magnitudes of $\boldsymbol{\mu}_{fg}^{(\mathrm{site})}$ and $\boldsymbol{\mu}_{00}^{(\mathrm{site})}$ are large.

Furthermore, for the intermediate coupling case, a higher approximation than that of ${}^{p}\alpha_{mn}(E)$ can be made as follows:

$$
\begin{aligned}
{}^{rp}\alpha_{mn}(E)={}&{}^{p}\alpha_{mn}(E)+\sum_{f}\sum_{g}\langle 0|\boldsymbol{\mu}|fm\rangle\langle fm|G(E)\boldsymbol{\mu}|gn\rangle C_{gn,0}\\
&+\sum_{f}\sum_{s}\sum_{k}\sum_{t}\langle 0|\boldsymbol{\mu}|fm\rangle\langle fm|G(E)\boldsymbol{\mu}|sktn\rangle C_{sktn,0}\\
&+\sum_{f}\sum_{g}C_{0,fm}\langle fm|\boldsymbol{\mu}G(E)|gn\rangle\langle gn|\boldsymbol{\mu}|0\rangle\\
&+\sum_{s}\sum_{t}\sum_{k}\sum_{g}C_{0,smtk}\langle smtk|\boldsymbol{\mu}G(E)|gn\rangle\langle gn|\boldsymbol{\mu}|0\rangle\\
&-\sum_{f}\sum_{g}C_{0,fm}\langle fm|\boldsymbol{\mu}G(E)\boldsymbol{\mu}|gn\rangle C_{gn,0}\\
&-\sum_{f}\sum_{s}\sum_{k}\sum_{t}C_{0,fm}\langle fm|\boldsymbol{\mu}G(E)\boldsymbol{\mu}|sktn\rangle C_{sktn,0}\\
&-\sum_{s}\sum_{t}\sum_{j}\sum_{g}C_{0,smtj}\langle smtj|\boldsymbol{\mu}G(E)\boldsymbol{\mu}|gn\rangle C_{gn,0}\\
&-\sum_{s}\sum_{t}\sum_{j}\sum_{f}\sum_{k}\sum_{g}C_{0,smtj}\langle smtj|\boldsymbol{\mu}G(E)\boldsymbol{\mu}|fkgn\rangle C_{fkgn,0},
\end{aligned}
\tag{42}
$$

which gives the renormalized RPA. The final result of Eq. 42 is not specified for saving space. Actually, the correction terms after the first term in Eq. 42 may be unnecessary to calculate, since the static interactions in Eq. 38b are sufficiently taken into account through $\overline{V}_S$ given by Eqs. 11 and 35. However, for the case where the permanent moments are all zero, the correction terms related with two-site excitations become operative, so that Eq. 42 becomes

$$
\begin{aligned}
{}^{rp}\alpha_{mn}(E)={}&{}^{p}\alpha_{mn}(E)\\
&+\sum_{s}\sum_{k}\sum_{t}\{[\mathbf{1}+\boldsymbol{\alpha}(E)\cdot\boldsymbol{U}]^{-1}_{mk}\cdot\boldsymbol{\mu}_{0s}^{(k)}C_{sktn,0}\boldsymbol{\mu}_{0t}^{(n)}/(E-\varepsilon_{sk,0}+i\eta_{sk})\\
&+[\mathbf{1}+\boldsymbol{\alpha}(E)\cdot\boldsymbol{U}]^{-1}_{mn}\cdot\boldsymbol{\mu}_{0t}^{(n)}C_{sktn,0}\boldsymbol{\mu}_{0s}^{(k)}/(E-\varepsilon_{tn,0}+i\eta_{tn})\\
&+\boldsymbol{\mu}_{t0}^{(k)}C_{0,smtk}\boldsymbol{\mu}_{0s}^{(m)}/(E-\varepsilon_{sm,0}+i\eta_{sm})\cdot[\mathbf{1}+\boldsymbol{U}\cdot\boldsymbol{\alpha}(E)]^{-1}_{mn}\\
&+\boldsymbol{\mu}_{s0}^{(m)}C_{0,smtk}\boldsymbol{\mu}_{0t}^{(k)}/(E-\varepsilon_{tk,0}+i\eta_{tk})\cdot[\mathbf{1}+\boldsymbol{U}\cdot\boldsymbol{\alpha}(E)]^{-1}_{kn}\}\\
&+O(C_{0,smtj}C_{fktn,0}),
\end{aligned}
\tag{43}
$$

which means that in this case the correction of the polymer ground state produced only by the two-site excitations gives the extension of the pure Fano-DeVoe model.

Thus, we can obtain the UV absorption and the CD and ORD bandshape functions either from the calculations[1,2] of $3^{-1}\,Tr\,{}^{p}\alpha_{mn}(E)$ and $12^{-1}\boldsymbol{R}_{mn}\cdot({}^{p}\alpha_{mn}(E):\boldsymbol{\varepsilon})$ for Eq. 38b, or from the calculations of $3^{-1}\,Tr\,{}^{rp}\alpha_{mn}(E)$ and $12^{-1}\boldsymbol{R}_{mn}\cdot({}^{rp}\alpha_{mn}(E):\boldsymbol{\varepsilon})$ for Eq. 42 and/or Eq. 43.

(D) Polarizability for the model Hamiltonian of the Corrected $\{|\tilde{fm}\rangle\}$. The expansion of the primitive Hamiltonian of Eq. 1 in terms of the corrected basis set of the one-site excitation states $\{|\tilde{fm}\rangle\}$ leads to

$$
\begin{aligned}
\tilde{H}=&\sum_{f}\sum_{m}\tilde{\varepsilon}_{fm,0}|\tilde{fm}\rangle\langle\tilde{fm}|\\
&+\{\sum_{g\neq f}\sum_{m}\sum^{\text{intrasite}}|\tilde{fm}\rangle\langle\tilde{fm}|V|\tilde{gm}\rangle\langle\tilde{gm}|\\
&+\sum_{f}\sum_{m}\sum_{g}\sum_{n}\sum^{\text{intersite}}|\tilde{fm}\rangle\langle\tilde{fm}|V|\tilde{gn}\rangle\langle\tilde{gn}|\}\\
=&\tilde{H}_0+\tilde{V}=\tilde{H}_0+\{\tilde{V}_S+\tilde{V}_{FD}\},
\end{aligned}
\tag{44}
$$

with

$$
|\tilde{fm}\rangle=|fm\rangle+C_{0,fm}|0\rangle, \tag{45a}
$$

The corrected ground state is written down as

$$
|\tilde{0}\rangle=|0\rangle-\sum_{g}\sum_{n}C_{gn,0}|gn\rangle-\sum_{s}\sum_{m}\sum_{t}\sum_{n}C_{smtn}|smtn\rangle. \tag{46a}
$$

Since $|0\rangle$ of Eq. 4 can be defined in N different ways by $|0k\rangle$ for $k=1,2,\cdots,N$ and since we wish to represent explicitly the site-dependence of $C_{0,fm}$, $C_{gn,0}$, and $C_{smtn,0}$ so as to show to what extent the transition moments are intermolecularly mixed with which site of the permanent dipole moment in the $|0\rangle$, we write Eqs. 45a and 46a as in the following:

$$
\begin{aligned}
|\tilde{fm}\rangle=&|fm\rangle+\sum_{k}\varepsilon^{-1}_{fm,0}\boldsymbol{\mu}_{00}^{(k)}\cdot\boldsymbol{U}_{km}\cdot\boldsymbol{\mu}_{0f}^{(m)}|0k\rangle\\
=&|fm\rangle+\sum_{k}C_{0,fm}^{(k)}|0k\rangle,
\end{aligned}
\tag{45b}
$$

$$
\begin{aligned}
|\tilde{0j}\rangle=&|0j\rangle-\sum_{g}\sum_{n}C_{gn,0}^{(j)}|gn\rangle\\
&-\sum_{s}\sum_{t}\sum_{n}C_{sjtn,0}^{(jn)}|sjtn\rangle,\quad j=1,2,\cdots,N
\end{aligned}
\tag{46b}
$$

where the two-site excitation coefficients are expressed in terms of $\varepsilon^{-1}_{sjtn,0}\,\boldsymbol{\mu}_{s0}^{(j)}\cdot\boldsymbol{U}_{jn}\cdot\boldsymbol{\mu}_{0t}^{(n)}$. The fth excitation energy of the mth submolecule is obtained as

$$
\begin{aligned}
\tilde{\varepsilon}_{fm,0}=&\langle\tilde{fm}|H|\tilde{fm}\rangle-\langle\tilde{0}|H|\tilde{0}\rangle\\
\simeq&\{1+\sum_{k}2|C_{fm,0}^{(k)}|^2\}\varepsilon_{fm,0}+\sum_{g}\sum_{n}2|C_{gn,0}^{(m)}|^2\varepsilon_{fn,0}\\
&+\sum_{s}\sum_{t}\sum_{n}2|C_{smtn,0}^{(mn)}|^2\varepsilon_{smtn,0}.
\end{aligned}
\tag{47}
$$

Similarly, the transfer integrals over modified interactions come to be of the forms

$$
\begin{aligned}
\langle\tilde{fm}|V|\tilde{gm}\rangle=&\sum_{k}\boldsymbol{\mu}_{fg}^{(m)}\cdot\boldsymbol{U}_{mk}\cdot\boldsymbol{\mu}_{00}^{(k)}+\sum_{l}\boldsymbol{\mu}_{f0}^{(m)}\cdot\boldsymbol{U}_{ml}\cdot\boldsymbol{\mu}_{00}^{(l)}C_{gm,0}^{(l)}\\
&+\sum_{k}C_{0,fm}^{(k)}\boldsymbol{\mu}_{00}^{(k)}\cdot\boldsymbol{U}_{km}\cdot\boldsymbol{\mu}_{g0}^{(m)}+\sum_{k}\sum_{l}C_{0,fm}^{(k)}\boldsymbol{\mu}_{00}^{(k)}\cdot\boldsymbol{U}_{kl}\cdot\boldsymbol{\mu}_{00}^{(l)}C_{gm,0}^{(l)},
\end{aligned}
\tag{48}
$$

$$
\begin{aligned}
\langle\tilde{fm}|V|\tilde{gn}\rangle=&\boldsymbol{\mu}_{f0}^{(m)}\cdot\boldsymbol{U}_{mn}\cdot\boldsymbol{\mu}_{0g}^{(n)}+\sum_{l}\boldsymbol{\mu}_{f0}^{(m)}\cdot\boldsymbol{U}_{ml}\cdot\boldsymbol{\mu}_{00}^{(l)}C_{gn,0}^{(l)}\\
&+\sum_{k}C_{0,fm}^{(k)}\boldsymbol{\mu}_{00}^{(k)}\cdot\boldsymbol{U}_{kn}\cdot\boldsymbol{\mu}_{g0}^{(n)}+\sum_{k}\sum_{l}C_{0,fm}^{(k)}\boldsymbol{\mu}_{00}^{(k)}\cdot\boldsymbol{U}_{kl}\cdot\boldsymbol{\mu}_{00}^{(l)}C_{gn,0}^{(l)}.
\end{aligned}
\tag{49}
$$

In (C), it has been shown that the intrasite interaction $\langle fm|V|gm\rangle$ as well as the renormalization such as $-\langle\tilde{0}|\boldsymbol{\mu}G(E)\boldsymbol{\mu}|\tilde{0}\rangle$ can introduce the static effect in the polarizability theory, while Fano-DeVoe's intersite

interaction term $\langle fm|V|gn\rangle$ does not contain the static effect. However, in (D) we have noted that the Fano-DeVoe type of interaction term $\langle\tilde{f}\tilde{m}|V|\tilde{g}\tilde{n}\rangle$ can involve the electrostatic modification against the bare interaction term $\langle fm|V|gm\rangle$ by using the one-site excitation states mixed with the ground state.

For later convenience, let us define the f,g-matrix elements of the monomer polarizability tensor $\tilde{\alpha}_{mn}(E)$ by

$$\tilde{\alpha}_{fm,gm}(E)=-\langle 0|\mu|\tilde{f}\tilde{m}\rangle\langle\tilde{g}\tilde{n}|\mu|0\rangle/(E-\tilde{\varepsilon}_{gn,0}+i\tilde{\eta}_{gn}), \tag{50}$$

in relation with the diagonal elements

$$\begin{aligned}\tilde{\alpha}_{mm}(E)&=-\sum_f\sum_g\langle 0|\mu|\tilde{f}\tilde{m}\rangle\langle\tilde{f}\tilde{m}|\tilde{G}^{\circ}(E)|\tilde{g}\tilde{n}\rangle\langle\tilde{g}\tilde{n}|\mu|0\rangle\\&=\sum_f\sum_g\tilde{\alpha}_{fm,gn}(E)\delta_{mn}\delta_{fg},\end{aligned} \tag{51}$$

Calculation of the modified transition moment yields

$$\langle 0|\mu|\tilde{f}\tilde{m}\rangle\equiv\tilde{\mu}_{0f}^{(m)}=\mu_{0f}^{(m)}+\sum_k C_{0,fm}^{(k)}\mu_{00}^{(k)}. \tag{52}$$

Then, we introduce the following definitions for the components of $\tilde{\alpha}_{mm}(E)$

$$\tilde{\alpha}_{mm}^{oo}(E)=\sum_{f\neq 0}-\mu_{0f}^{(m)}\mu_{f0}^{(m)}/(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}), \tag{53a}$$

$$\tilde{\alpha}_{mm}^{lo}(E)=\sum_{f\neq 0}-\tilde{\mu}_{0f}^{(m)}\mu_{f0}^{(m)}/(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}), \tag{53b}$$

$$\tilde{\alpha}_{mm}^{ol}(E)=\sum_{f\neq 0}-\mu_{0f}^{(m)}\tilde{\mu}_{f0}^{(m)}/(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}), \tag{53c}$$

While original Fano-DeVoe's polymer polarizability can be linearlized in terms of the monomer polarizability components, the polymer polarizability tensor ${}^p\tilde{\alpha}_{mn}(E)$ cannot be expressed simply in terms of the monomer polarizability tensors $\tilde{\alpha}_{mm}(E)$ and interaction tensors U. We therefore derive ${}^p\tilde{\alpha}_{mn}(E)$ in the following by use of the polarizability components $\tilde{\alpha}_{fm,gn}(E)$ newly defined by Eq. 50. The calculations are performed in the same way as Eq. 38a:

$$\begin{aligned}{}^p\tilde{\alpha}_{mn}(E)&=-\sum_{f,g\neq 0}\sum\langle 0|\mu|\tilde{f}\tilde{m}\rangle\langle\tilde{f}\tilde{m}|\tilde{G}(E)|\tilde{g}\tilde{n}\rangle\langle\tilde{g}\tilde{n}|\mu|0\rangle\\&\simeq-\sum_f\sum_g\tilde{\mu}_{0f}^{(m)}\langle\tilde{f}\tilde{m}|\tilde{G}^{\circ}(E)+\tilde{G}^{\circ}(E)\tilde{V}_{FD}\tilde{G}^{\circ}(E)\\&\qquad+\tilde{G}^{\circ}(E)\tilde{V}_{FD}\tilde{G}^{\circ}(E)\tilde{V}_{FD}\tilde{G}^{\circ}(E)+\cdots|\tilde{g}\tilde{n}\rangle\tilde{\mu}_{g0}^{(n)}\\&\quad-\sum_f\sum_g\tilde{\mu}_{0f}^{(m)}\langle\tilde{f}\tilde{m}|\tilde{G}^{\circ}(E)\tilde{V}_S\tilde{G}(E)\\&\qquad+\tilde{G}^{\circ}(E)\tilde{V}_S\tilde{G}^{\circ}(E)\tilde{V}_S\tilde{G}^{\circ}(E)+\cdots|\tilde{g}\tilde{n}\rangle\tilde{\mu}_{g0}^{(n)}\\&\quad-\sum\sum\{\tilde{\mu}_{0f}^{(m)}\langle fm|\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_S(E)\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_S(E)\tilde{G}_{FD}^{\circ}(E)|gn\rangle\tilde{\mu}_{g0}^{(n)}\\&\quad+\tilde{\mu}_{0f}^{(m)g}\langle fm|\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_{FD}(E)\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_S(E)\tilde{G}_{FD}^{\circ}(E)|gn\rangle\tilde{\mu}_{g0}^{(n)}+\\&\quad\tilde{\mu}_{0f}^{(m)}\langle fm|\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_{FD}(E)\tilde{G}_{FD}^{\circ}(E)\\&\qquad\times\ {}^p\tilde{V}_S(E)\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_{FD}(E)\tilde{G}_{FD}^{\circ}(E)|gn\rangle\tilde{\mu}_{g0}^{(n)}\\&\quad+\tilde{\mu}_{0f}^{(m)}\langle fm|\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_S(E)\tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_{FD}(E)\\&\qquad\times\ \tilde{G}_{FD}^{\circ}(E){}^p\tilde{V}_S(E)\tilde{G}_{FD}^{\circ}(E)|gn\rangle\tilde{\mu}_{g0}^{(n)}\},\end{aligned} \tag{54}$$

except for the third term in which we put merely the pure Fano-DeVoe part as $\tilde{G}_{FD}^{\circ}(E)=\sum_{\psi}(E-\tilde{\varepsilon}_{\psi,0}+i\tilde{\eta}_{\psi})^{-1}|\psi\rangle\langle\psi|$ in the $\tilde{G}^{\circ}(E)$. Also, we make use of the $\langle fm|$ and $|gn\rangle$ instead of the $\langle\tilde{f}\tilde{m}|$ and $|\tilde{g}\tilde{n}\rangle$, and employ only the bare interaction operator $\bar{V}$ instead of the dressed interaction operator $\tilde{V}$. The reason for this last treatment is that the components of the third terms are clearly at least second order in the bare interaction $\langle\psi|V|\psi'\rangle$ and therefore the corrections produced by such truncation of the third term become third order in $\langle\psi|V|\psi'\rangle$.

The working formula for the polymer polarizability tensor is obtained from Eq. 54:

$$\begin{aligned}{}^p\tilde{\alpha}_{mn}(E)&\simeq{}^p\tilde{\alpha}_{mm}^{FD}(E)+{}^p\tilde{\alpha}_{mm}^{S}(E)\delta_{mm}\\&\quad+\sum_{f\neq t}\sum_k\sum\tilde{\mu}_{0f}^{(m)}\tilde{K}_{mm}^{ft}(E)\mu_{t0}^{(m)}\cdot\{\mathbf{1}+\boldsymbol{U}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)\}_{mk}^{-1}\cdot\boldsymbol{U}_{kn}\cdot\tilde{\boldsymbol{\alpha}}_{nn}^{ol}(E)\\&\quad+\sum_k\sum_{t\neq g}\sum\tilde{\boldsymbol{\alpha}}_{mm}^{lo}(E)\cdot\boldsymbol{U}_{mk}\cdot\{\mathbf{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}\}_{kn}^{-1}\cdot\boldsymbol{\mu}_{0f}^{(n)}\tilde{K}_{nn}^{tg}(E)\tilde{\boldsymbol{\mu}}_{g0}^{(n)}\\&\quad-\sum_k\sum_l\sum_{t\neq g}\sum\tilde{\boldsymbol{\alpha}}_{mm}^{lo}(E)\cdot\boldsymbol{U}_{mk}\cdot\{\mathbf{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}\}_{kl}^{-1}\cdot\boldsymbol{\mu}_{0f}^{(l)}\tilde{K}_{ll}^{tg}(E)\tilde{\boldsymbol{\mu}}_{g0}^{(l)}\\&\quad\times\{\mathbf{1}+\boldsymbol{U}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)\}_{lj}^{-1}\cdot\boldsymbol{U}_{jn}\cdot\tilde{\boldsymbol{\alpha}}_{nn}^{ol}(E)-\sum_{f\neq t}\sum_k\sum_{s\neq g}\sum\tilde{\boldsymbol{\mu}}_{0f}^{(m)}\tilde{K}_{mm}^{ft}(E)\boldsymbol{\mu}_{t0}^{(m)}\\&\quad\times\{\mathbf{1}+\boldsymbol{U}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)\}_{mk}^{-1}\cdot\boldsymbol{U}_{kn}\cdot\boldsymbol{\mu}_{0s}^{(n)}\tilde{K}_{ll}^{sg}(E)\tilde{\boldsymbol{\mu}}_{g0}^{(n)}\quad m,n=1,2,3,\cdots,N\end{aligned} \tag{55}$$

with

$$\begin{aligned}K_{mm}^{fg}(E)=\Big\{&\frac{\langle\tilde{f}\tilde{m}|V|\tilde{g}\tilde{m}\rangle}{E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}_{fm}}+\sum_{t\neq f,g}\\&\times\frac{\langle\tilde{f}\tilde{m}|V|\tilde{t}\tilde{m}\rangle\langle\tilde{t}\tilde{m}|V|\tilde{g}\tilde{m}\rangle}{(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}_{fm})(E-\tilde{\varepsilon}_{tm,0}+i\tilde{\eta}_{tm})}+\cdots\Big\}/\\&(E-\tilde{\varepsilon}_{gm,0}+i\tilde{\eta}_{gm})\end{aligned} \tag{56}$$

where $\{\mathbf{1}+\boldsymbol{U}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)\}_{kn}^{-1}$ and $\{\mathbf{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}\}_{mk}^{-1}$ have similar expressions as Eqs. 39 and 40. Equatition 55 is a renormalized RPA. The first and second terms are put into a single equation:

$$\begin{aligned}{}^p\tilde{\alpha}_{mn}^{FD}(E)+{}^p\tilde{\alpha}_{mn}^{S}(E)\delta_{mm}&=\sum_{f,g\neq 0}\sum\tilde{\alpha}_{fm,gn}(E)\{\delta_{mn}\delta_{fg}\\&+\frac{\langle\tilde{f}\tilde{m}|V|\tilde{f}\tilde{n}\rangle}{E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}_{fm}}+\sum_{s\neq f,g}\sum_k\frac{\langle\tilde{f}\tilde{m}|V|\tilde{s}\tilde{k}\rangle\langle\tilde{s}\tilde{k}|V|\tilde{g}\tilde{n}\rangle}{(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}_{fm})(E-\tilde{\varepsilon}_{sk,0}+i\tilde{\eta}_{sk})}\\&+\sum_k\sum_l\sum_{s\neq t,f,g,t\neq g,f,s}\sum\\&\qquad\frac{\langle\tilde{f}\tilde{m}|V|\tilde{s}\tilde{k}\rangle\langle\tilde{s}\tilde{k}|V|\tilde{l}\tilde{l}\rangle\langle\tilde{l}\tilde{l}|V|\tilde{g}\tilde{n}\rangle}{(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}_{fm})(E-\tilde{\varepsilon}_{sk,0}+i\tilde{\eta}_{sk})(E-\tilde{\varepsilon}_{ll,0}+i\tilde{\eta}_{ll})}\\&\equiv\sum_{f,g\neq 0}\sum\tilde{\alpha}_{fm,gn}(E)\,{}^pB_{mn}^{fg}(E),\end{aligned} \tag{57}$$

where we must note that the $n=m$ case corresponds to the Bayley, Nielsen, and Schellman type of polarizability tensor ${}^p\tilde{\alpha}^s(E)$.

The scalar quantity ${}^pB_{mn}^{fg}(E)$ defines the coefficient for the $\tilde{\alpha}_{fm,gn}(E)$. ${}^pB_{mn}^{fg}(E)$ involves the interaction elements $\{\langle\tilde{f}\tilde{m}|V|\tilde{g}\tilde{n}\rangle\}$ up to infinite orders. It goes without saying that ${}^p\tilde{\alpha}(E)$ involves the usual Fano-DeVoe type of term $\{\mathbf{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}\}^{-1}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)$. If we resolve all the interaction matrices into the form $\boldsymbol{\mu}\cdot\boldsymbol{U}\cdot\boldsymbol{\mu}$, by use of which if we try to express ${}^p\tilde{\alpha}(E)$ in terms of the average of dyadic products $\boldsymbol{\mu}G^{\circ}(E)\boldsymbol{\mu}$ over the polymer ground state and unit dipole interaction

tensors $\boldsymbol{U}$, we must face with a tremendous variety of complicated matrix elements of ${}^{p}\tilde{\alpha}(E)$, so that it becomes difficult to outline the total image of the theory. However, as shown in Eqs. 55 and 57, it is not difficult to compute ${}^{p}\tilde{\alpha}(E)$ up to higher orders of V without resolving matrix elements into small pieces such as $\boldsymbol{\mu}\cdot\boldsymbol{U}\cdot\boldsymbol{\mu}$. Namely, Eq. 55 gives a simple expression for ${}^{p}\tilde{\alpha}(E)$, in which Eq. 57 is represented in terms of scalar modules such as $\langle\tilde{fm}|V|\tilde{gn}\rangle$. In addition to this merit, ${}^{p}B(E)$ defined by Eq. 57 can easily be linearlized in terms of simple matrix elements such as

$$B^{fg}_{mn}(E)=\langle\tilde{fm}|V|\tilde{gn}\rangle/(E-\tilde{\varepsilon}_{fm,0}+i\tilde{\eta}_{fm}). \tag{58}$$

In the following, we show that ${}^{p}B(E)$ can formally be calculated up to infinite orders of V without resort to such reckless term-by-term calculations as that of Eq. 57.

In relation with Eq. 57, we can put

$$\begin{aligned}{}^{p}B^{fg}_{mn}(E)&=\delta_{mn}\delta_{fg}+B^{fg}_{mn}(E)+\sum_{s}\sum_{k}B^{fs}_{mk}(E)B^{sg}_{kn}(E)\\&\quad+\sum_{s}\sum_{k}\sum_{t}\sum_{l}B^{fs}_{mk}(E)B^{st}_{kl}(E)B^{tg}_{ln}(E)+\cdots\\&=\delta_{mn}\delta_{fg}+\sum_{s}\sum_{k}B^{fs}_{mk}(E)\{\delta_{kn}\delta_{sg}\\&\quad+\sum_{t}\sum_{l}B^{st}_{kl}(E){}^{p}B^{tg}_{ln}(E)\}\\&=\delta_{mn}\delta_{fg}+\sum_{s}\sum_{k}B^{fs}_{mk}(E){}^{p}B^{sg}_{kn}(E)=\{[1-B(E)]^{-1}\}^{fg}_{mn},\end{aligned} \tag{59a}$$

where $B(E)$ is a $(\sum_{m=1}^{N}f_m)\times(\sum_{k=1}^{N}S_k)$ matrix, f_m being the number of the fth oscillators of the mth site. In more detail, if we define the block matrices ${}^{p}B_{mn}(E)$ and $B_{mk}(E)$ with the elements ${}^{p}B^{fg}_{mn}(E)$ and $B^{fs}_{mk}(E)$. Equation 59a yields the relationship of an unknown matrix ${}^{p}B(E)$ with the known matrix $B(E)$ as follows:

$${}^{p}B(E)=1+B(E)\,{}^{p}B(E),\ \text{i.e.,}\ {}^{p}B(E)=\{1-B(E)\}^{-1}, \tag{59b}$$

which gives the involvement of infinite orders of the interaction $\tilde{V}$ in Eq. 57. Actually, it may be sufficient to carry out the calculations of several higher terms in the braces of Eq. 57 without use of Eqs. 59a and 59b.

If we follow the scheme of Eq. 42 which corresponds to the intermediate coupling case, we have

$$\begin{aligned}{}^{rp}\tilde{\alpha}_{mn}(E)&={}^{p}\tilde{\alpha}_{mn}(E)\\&\quad+\sum_{k}\sum_{f}\sum_{g}C^{(k)}_{0,fm}\langle fm|\boldsymbol{\mu}\tilde{G}^{\circ}(E)|\tilde{gn}\rangle\langle\tilde{gn}|\boldsymbol{\mu}|0\rangle\\&\quad+\sum_{k}\sum_{f}\sum_{g}\langle 0|\boldsymbol{\mu}|\tilde{fm}\rangle\langle\tilde{fm}|\tilde{G}^{\circ}(E)\boldsymbol{\mu}|gn\rangle C^{(k)}_{gn,0}\\&\quad+\sum_{k}\sum_{s}\sum_{t}\sum_{g}C^{(m,k)}_{0,smtk}\langle smtk|\boldsymbol{\mu}\tilde{G}^{\circ}(E)|\tilde{gn}\rangle\langle\tilde{gn}|\boldsymbol{\mu}|0\rangle\\&\quad+\sum_{k}\sum_{f}\sum_{s}\sum_{t}\langle 0|\boldsymbol{\mu}|\tilde{fm}\rangle\langle\tilde{fm}|\tilde{G}^{\circ}(E)\boldsymbol{\mu}|sktn\rangle C^{(k,n)}_{sktn,0}\\&\quad+O(|C_{mix}|^{2}),\end{aligned} \tag{60}$$

which is the self-consistent renormalized RPA. The transition moments necessary for the calculations of Eq. 60 are reduced to

$$\langle fm|\boldsymbol{\mu}|\tilde{gn}\rangle=\boldsymbol{\mu}^{(m)}_{fg}\delta_{mn}+\sum_{k}C^{(k)}_{0,gn}\boldsymbol{\mu}^{(m)}_{f0}\delta_{mk}, \tag{61}$$

$$\langle\tilde{fm}|\boldsymbol{\mu}|gn\rangle=\boldsymbol{\mu}^{(m)}_{fg}\delta_{mn}+\sum_{k}C^{(k)}_{0,gn}\boldsymbol{\mu}^{(m)}_{g0}\delta_{nk}, \tag{62}$$

$$\langle smtk|\boldsymbol{\mu}|\tilde{gn}\rangle=\delta_{mn}\delta_{sg}\boldsymbol{\mu}^{(k)}_{t0}+\delta_{kn}\delta_{tg}\boldsymbol{\mu}^{(m)}_{s0}, \tag{63}$$

$$\langle\tilde{fm}|\boldsymbol{\mu}|sktn\rangle=\delta_{mk}\delta_{sf}\boldsymbol{\mu}^{(n)}_{0t}+\delta_{mn}\delta_{ft}\boldsymbol{\mu}^{(k)}_{0s}, \tag{64}$$

As mentioned before regarding to Eq. 43, it may be not necessary to carry out the calculations of the correction terms for Eq. 60. However, for a polymer system of the constituent monomers having no permanent dipole moment, we need to calculate Eq. 60 as follows:

$$\begin{aligned}{}^{rp}\tilde{\boldsymbol{\alpha}}_{mn}(E)&=[\boldsymbol{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}]^{-1}_{mn}\cdot\tilde{\boldsymbol{\alpha}}^{oo}_{nn}(E)\\&\quad+\sum_{s}\sum_{k}\sum_{t}\{[\boldsymbol{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}]^{-1}_{mk}\cdot\boldsymbol{\mu}^{(k)}_{0s}C_{sktn,0}\boldsymbol{\mu}^{(n)}_{0t}/\\&\quad(E-\tilde{\varepsilon}_{sk,0}+i\tilde{\eta}_{sk})\\&\quad+[\boldsymbol{1}+\tilde{\boldsymbol{\alpha}}^{oo}(E)\cdot\boldsymbol{U}]^{-1}_{mn}\cdot\boldsymbol{\mu}^{(n)}_{0t}C_{sktn,0}\boldsymbol{\mu}^{(k)}_{0s}/(E-\tilde{\varepsilon}_{tn,0}+i\tilde{\eta}_{tn})\\&\quad+\boldsymbol{\mu}^{(k)}_{t0}C_{0,smtk}\boldsymbol{\mu}^{(m)}_{0s}/(E-\tilde{\varepsilon}_{sm,0}+i\tilde{\eta}_{sm})\cdot[\boldsymbol{1}+\boldsymbol{U}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)]^{-1}_{mn}\\&\quad+\boldsymbol{\mu}^{(m)}_{s0}C_{0,smtk}\boldsymbol{\mu}^{(k)}_{0t}/(E-\tilde{\varepsilon}_{tk,0}+i\tilde{\eta}_{tk})\cdot[\boldsymbol{1}+\boldsymbol{U}\cdot\tilde{\boldsymbol{\alpha}}^{oo}(E)]^{-1}_{kn}\}\\&\quad+O(C_{0,smtj}C_{fkgn,0}),\end{aligned} \tag{65}$$

which is the same as Eq. 43 except for the excitation energies replaced by Eq. 47, where the mixing coefficients of one-site excitation states vanish.

For the dressed polarizability tensors derived above, we can obtain the bandshape functions of the UV absorption, CD, and ORD spectra for the DNA molecules, either from the calculations[1,2] of $3^{-1}\,Tr\,{}^{p}\tilde{\boldsymbol{\alpha}}_{mn}(E)$ and $12^{-1}\,\boldsymbol{R}_{mn}\cdot({}^{p}\tilde{\boldsymbol{\alpha}}_{mn}(E)\colon\boldsymbol{\varepsilon})$ by making use of Eq. 55, or from the calculations of $3^{-1}\,Tr\,{}^{rp}\tilde{\boldsymbol{\alpha}}_{mn}(E)$ and $12^{-1}\,\boldsymbol{R}_{mn}\cdot({}^{rp}\tilde{\boldsymbol{\alpha}}_{mn}(E)\colon\boldsymbol{\varepsilon})$ by making use of Eq. 60 and/or Eq. 65.

Joint Use of Short-Range Monopole and Long-Range Dipole Approximations in All the Interaction Integrals $\langle\psi|V|\psi'\rangle$

The use of the dipole approximation makes it easy to calculate the polarizability tensors, since the transition moments are easily obtainable from the experimental data. However, in order to circumvent the deficiency of the dipole approximation in short distances, it is recommendable to make use of the monopole approximation for the near or nearest neighbors, and to make use of the dipole approximation for the distant monomers, when the data for the monopole densities are easily available. Especially, in very long-chain polymers, such joint use of different approximations will clearly have a lot of practical merits. Consequently, let us show how to introduce the monopole approximation in the present polarizability theory. All the interaction integrals $\langle\psi|V|\psi'\rangle$ as well as the mixing coefficients $C_{0,\psi}$ and $C_{\psi,0}$ are reduced to the forms such as $\boldsymbol{\mu}^{(m)}_{sf}\cdot\boldsymbol{U}_{mn}\cdot\boldsymbol{\mu}^{(n)}_{gt}\equiv V^{(sf,gt)}_{mn}$.

The scalar potential $V^{(sf,gt)}_{mn}$ is expressed by

$$\begin{aligned}V^{(sf,gt)}_{mn}&=\boldsymbol{\mu}^{(m)}_{sf}\cdot\boldsymbol{U}_{mn}\cdot\boldsymbol{\mu}^{(n)}_{gt}\\&=[\boldsymbol{\mu}^{(mx)}_{sf}\ \boldsymbol{\mu}^{(my)}_{sf}\ \boldsymbol{\mu}^{(mz)}_{sf}]\begin{bmatrix}U^{(xx)}_{mn}&U^{(xy)}_{mn}&U^{(xz)}_{mn}\\U^{(yx)}_{mn}&U^{(yy)}_{mn}&U^{(yz)}_{mn}\\U^{(zx)}_{mn}&U^{(zy)}_{mn}&U^{(zz)}_{mn}\end{bmatrix}\begin{bmatrix}\boldsymbol{\mu}^{(nx)}_{gt}\\\boldsymbol{\mu}^{(ny)}_{gt}\\\boldsymbol{\mu}^{(nz)}_{gt}\end{bmatrix}\\&\simeq\sum_{A}^{\text{atoms}}\sum_{B}q^{(m)}_{sf,A}q^{(n)}_{gt,B}/R_{mA,nB},\end{aligned} \tag{66}$$

where the final replacement from the dipole approximation is the so-called transition monopole approximation[9-14,21,22] with the monopole densities separated by the distance $R_{mA,nB}$. Particularly, $q^{(m)}_{0f,A}$ denotes the usual 0→f transition monopole density at atom A in the mth submolecule, and $q^{(m)}_{00,A}$ specifies the permanent monopole density. The knowledge of the transition and permanent monopole densities of a monomer may be obtained by some molecular orbital calculations[9] or by the semiempirical estimates.[10-14,21,22]

The ${}^{p}\alpha(E)$ appeared in Eq. 38b takes the following various forms:

$$\begin{aligned}{}^{p}\alpha(E) &= \{\mathbf{1}+\alpha(E)\cdot U\}^{-1}\cdot\alpha(E)\\ &= \{\alpha^{-1}(E)+U\}^{-1}\\ &= \alpha(E)\cdot\{\alpha(E)+\alpha(E)\cdot U\cdot\alpha(E)\}^{-1}\cdot\alpha(E)\end{aligned} \tag{67}$$

where the second line indicates the equivalence to DeVoe's coupled oscillator theory.[8] The third line is found to be convenient to introduce the transition and permanent monopole approximations for the near neighbor interactions.

It is also convenient for the monopole approximation to rewrite Eqs. 39 and 40 as follows:

$$\{\mathbf{1}+\alpha(E)\cdot U\}^{-1}=\alpha(E)\cdot\{\alpha(E)+\alpha(E)\cdot U\cdot\alpha(E)\}^{-1}, \tag{68}$$

$$\{\mathbf{1}+U\cdot\alpha(E)\}^{-1}=\{\alpha(E)+\alpha(E)\cdot U\cdot\alpha(E)\}^{-1}\cdot\alpha(E). \tag{69}$$

In order to introduce the monopole approximation for the near neighbor submolecules, the matrix elements for $\alpha(E)\cdot U\cdot\alpha(E)$ are calculated as

$$\begin{aligned}&\alpha_{mm}(E)\cdot U_{mn}\cdot\alpha_{nn}(E)\\ &=\sum_f\sum_g (E-\varepsilon_{fm,0}+i\eta_{fm})^{-1}(E-\varepsilon_{gn,0}+i\eta_{gm})^{-1}V^{(f0,0g)}_{mn}\mu^{(m)}_{0f}\mu^{(n)}_{g0},\end{aligned} \tag{70}$$

where the dyadic product $\mu^{(m)}_{0f}\mu^{(n)}_{g0}$ is expressed in terms of the multiplication of the column matrix $\mu^{(m)}_{0f}$ by the row matrix $\mu^{(n)}_{g0}$ and the Coulomb energy $V^{(f0,0g)}_{mn}$ is calculated by Eq. 66.

For non-near neighbors, we can also make use of the monopole approximation, but it is suffcient to make use of the dipole approximation. For the latter case, it may be convenient to calculate the corresponding matrix elements in a way different from Eq. 70 in algolithm as follows:

$$\begin{aligned}&\alpha_{mm}(E)\cdot U_{mn}\cdot\alpha_{mn}(E)\\ &=\sum_f\sum_g (E-\varepsilon_{fm,0}+i\eta_{fm})^{-1}(E-\varepsilon_{gn,0}+i\eta_{gn})^{-1}\times\\ &\quad\{\mu^{(m)}_{0f}\mu^{(m)}_{f0}\}\cdot U_{mn}\cdot\{\mu^{(n)}_{0f}\mu^{(n)}_{f0}\},\end{aligned} \tag{71}$$

where $\mu^{(m)}_{0f}\mu^{(m)}_{f0}$ is a 3×3 matrix.

It is practically important to note that the inverse of the matrix $\{\alpha(E)+\alpha(E)\cdot U\cdot\alpha(E)\}$ concerned should be obtained in units of 10^{-24} cm^3 according to the numerical treatment of the previous paper,[2] whereas the inverse of $\{\mathbf{1}+\alpha(E)\cdot U\}$ can always be calculated to be at most in the vicinity of unity or with much smaller values in its matrix elements.

Summary and Discussion

We have presented a new approach capable of extending the Fano-DeVoe model. Such an approach is inherently based upon the dipole-dipole approximation, which has however a deficiency in the near neighbors of submolecules. In the previous section, we have shown how to bring in the monopole approximation by changing the present forms of polymer polarizability tensors derived. Thus, following Moffitt's idea, it becomes possible to use jointly the short-range-oriented monopole and long-range-oriented dipole approximations in the present theory.

We can first point out that this approach makes it possible to calculate the polarizability tensors by involving the static effect of permanent dipole moments for some DNA molecules and polypeptides,[13-15,17] whereas the ordinary Fano-DeVoe model cannot involve the static field effect in calculations. It should be noted that inclusion of the static effect in the theory is made in the three ways: (i) We can observe the static effect in the level-shift energy of the excitation energy $\varepsilon_{\psi,0}$ given by Eqs. 18 and 19; (ii) The static effect is clearly found to be involved, if we see that the second terms of Eqs. 16 and 35 are expressed by Eq. 11, which corresponds to the static field effect appeared in the transition matrix theory;[15] (iii) The static effect is taken into account by use of the exact basis set $\{|\tilde{\psi}>\}$ as well as by the renormalization of $-<\tilde{0}|\mu G(E)\mu|\tilde{0}>$ of Eqs. 24, 42, and 43 and/or $-<\tilde{0}|\mu\tilde{G}(E)\mu|\tilde{0}>$ of Eqs. 33, 60, and 65. If there is no static effect due to $\mu^{(\text{site})}_{00}=0$, Eq. 38b embodies the original Fano-DeVoe model. Even for this case, as shown in Eq. 43 and also Eq. 65, we can extend the pure Fano-DeVoe model by the renormalization of the polymer ground state through two-site excitation states.

In relation with (ii), we must note that Eq. 38a without truncation is identical to Rabenold's linear response theory.[16,17] His derivation is based upon the transition matrix theory[15] with the use of Green's operator method. Let us take a look at his formulation in terms of our notations. The polymer polarizability tensor is expressed by

$$\begin{aligned}{}^{p}\alpha(E) &= -\sum_{\psi,\psi'\neq 0}\sum <0|\mu|\psi><\psi|(E-\bar{H}+i\eta)^{-1}|\psi'><\psi'|\mu|0>\\ &= -\sum_f\sum_g\sum_m\sum_n \mu^{(m)}_{0f}\{\{[(E\mathbf{1}-\varepsilon+i\eta)\bar{V}_S]-\bar{V}_{FD}\}^{-1}\}^{fg}_{mn}\mu^{(n)}_{g0},\end{aligned} \tag{72}$$

whose matrix elements are

$$\{\bar{V}_S\}^{fg}_{mn}=\delta_{mn}<fm|V|gm>=\delta_{mn}\sum_{k\neq m(f\neq g)}\mu^{(m)}_{fg}\cdot U_{mk}\cdot\mu^{(k)}_{00}, \tag{73}$$

$$\{\bar{V}_{FD}\}^{fg}_{mn}=<fm|V|gm>=\mu^{(m)}_{f0}\cdot U_{mk}\cdot\mu^{(n)}_{g0}, \tag{74}$$

$$\{E\mathbf{1}-\varepsilon+i\eta\}^{fg}_{mn}=(E-\varepsilon_{fm,0}+i\eta_{fm})\delta_{mn}\delta_{fg}. \tag{75}$$

The $[(E\mathbf{1}-\varepsilon+i\eta)-\bar{V}_s]$ in Eq. 72 is an m,m-block diagonal matrix with the off-diagonal f,g,-elements, while

the Fano-DeVoe type interaction $\overline{V}_{FD}$ is an m,n-block off-diagonal matrix. The f,f-diagonal elements $<fm|V|fm>$ of $\overline{V}_S$ for the static field effect are included in the excitation energy $\varepsilon_{fm,0}$. If we follow Rabenold, the equivalence of the two theories can be shown by diagonalizing each m,m-block diagonal matrix of Eq. 72 as follows:

$$\boldsymbol{X}^{+}[(E\mathbf{1}-\varepsilon+i\eta)-\overline{V}_S]\boldsymbol{X}=E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta}, \tag{76}$$

with the eigenvector:

$$\boldsymbol{X}=\mathrm{diag}\{\boldsymbol{X}_1, \boldsymbol{X}_2, \ldots\ldots, \boldsymbol{X}_N\}, \tag{77}$$

by use of which we newly define the dressed interaction matrix for the polymer system

$$\{{}^{px}\overline{V}_{FD}\}_{mn}=\sum_f\sum_j\sum_g\sum_k X^{+}_{m,fj}\{\overline{V}_{FD}\}^{fg}_{jk}X_{gk,n}. \tag{78}$$

In Eq. 72, we can express the secular matrix in terms of the block diagonal matrix of Eq. 77, X, as follows:

$$\boldsymbol{X}^{+}\{[(E\mathbf{1}-\varepsilon+i\eta)-\overline{V}_S]-\overline{V}_{FD}\}X=(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})-\boldsymbol{X}^{+}\overline{V}_{FD}\boldsymbol{X}$$
$$\equiv(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})-{}^{px}\overline{V}_{FD} \tag{79}$$

where the first term is given by Eq. 76. Equation 79 gives rise to

$$\{[(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})-\overline{V}_S]-\overline{V}_{FD}\}^{-1}=\boldsymbol{X}\{(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})-{}^{px}\overline{V}_{FD}\}^{-1}\boldsymbol{X}^{+}. \tag{80}$$

Thus, if we make an allowance for

$$\{{}^{px}\overline{V}_{FD}\}^{fg}_{jk}=\sum_m\sum_n X^{+}_{j,fm}<fm|V|gn>X_{gn,k}$$
$$=<\bar{f}\bar{j}|V|\bar{g}\bar{k}>=\bar{\boldsymbol{\mu}}^{(j)}_{f0}\cdot\boldsymbol{U}_{jk}\cdot\bar{\boldsymbol{\mu}}^{(k)}_{0g}, \tag{81}$$

with the relationships

$$|\bar{g}\bar{k}>=\sum_n|gn>X_{gn,k}, \tag{82}$$

$$\{[(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})-{}^{px}\overline{V}_{FD}]^{-1}\}^{fg}_{jk}=(E-\bar{\varepsilon}_{fj,0}+\mathrm{i}\,\bar{\eta}_{fj})^{-1}\delta_{jk}\delta_{fg}$$
$$+(E-\bar{\varepsilon}_{fj,0}+i\bar{\eta}_{fj})^{-1}\{{}^{px}\overline{V}_{FD}\}^{fg}_{jk}(E-\bar{\varepsilon}_{gk,0}+i\bar{\eta}_{gk})^{-1}+\ldots, \tag{83}$$

we note that Eq. 72 can be reduced to

$${}^{p}\boldsymbol{\alpha}(E)=-\sum_f\sum_m\sum_g\sum_n\sum_j\sum_k\boldsymbol{\mu}^{(m)}_{0f}X_{fm,j}\{[(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})$$
$$-{}^{px}\overline{V}_{FD}]^{-1}\}^{fg}_{jk}X^{+}_{k,gn}\boldsymbol{\mu}^{(n)}_{g0},$$
$$=-\sum_f\sum_j\sum_g\sum_k\bar{\boldsymbol{\mu}}^{(j)}_{0f}\{[(E\mathbf{1}-\bar{\varepsilon}+i\bar{\eta})-{}^{px}\overline{V}_{FD}]^{-1}\}^{fg}_{jk}\bar{\boldsymbol{\mu}}^{(k)}_{g0}$$
$$=-\sum_f\sum_k\{\mathbf{1}+\bar{\boldsymbol{\alpha}}(E)\cdot\boldsymbol{U}\}^{-1}_{jk}\cdot\bar{\boldsymbol{\alpha}}_{kk}(E), \tag{84}$$

where we put

$$\bar{\boldsymbol{\mu}}^{(j)}_{0f}=\sum_m\boldsymbol{\mu}^{(m)}_{0f}X_{fm,j}, \tag{85}$$

$$\bar{\boldsymbol{\alpha}}_{kk}(E)=-\sum_f\bar{\boldsymbol{\mu}}^{(k)}_{0f}\bar{\boldsymbol{\mu}}^{(k)}_{g0}/(E-\bar{\varepsilon}_{fk,0}+i\bar{\eta}_{fk}). \tag{86}$$

Equation 86 defines the kth monomer polarizability tensor corrected by the permanent moments in the rest of monomers. Equation 84 is rather more beautifully linearlized than Eq. 38b. However, Eq. 84 together with Eq. 85 needs the process of the diagonalization for the $\{(E\mathbf{1}-\varepsilon+i\eta)-\overline{V}_s\}$ of each submolecule to obtain X, whereas Eq. 38b requires only to solve the inverse matrix.

In the opening section, we have insisted upon that the theories should be built up so as to be capable of comparing the works made by the ordinary perturbational wavefunction approaches.[19] By doing so, we might find their similarities and clarify the relationships of the present theory with the well-known literature. By applying the present theory to the calculations of quantities such as $<0|\boldsymbol{\mu}G(E)\cdot\boldsymbol{m}|0>$ and $<0|\boldsymbol{\mu}\tilde{G}(E)\cdot\boldsymbol{m}|0>$, $\boldsymbol{m}$ being the magnetic moment operator, we can construct a new polarizability theory capable of discussing the UV absorption, CD, and ORD spectra on the same footing with as that mentioned in Tinoco's review,[19] in which a corrected basis set $\{|\tilde{\psi}>\}$ was introduced. If we confine ourselves to lower-orders approximation in $\overline{V}$ and/or $\tilde{V}$, it will be not so difficult to directly apply the schemes of (A) and (B) for the CD and ORD bandshape calculations without resort to the simplifications of (C) and (D). Such a lower-orders truncation may bring about the theoretical similarity with the results for the ordinary perturbational approaches. However, it is extremely hard to calculate ${}^{p}\boldsymbol{\alpha}(E)$, ${}^{rp}\boldsymbol{\alpha}(E)$, ${}^{p}\tilde{\boldsymbol{\alpha}}(E)$, and ${}^{rp}\tilde{\boldsymbol{\alpha}}(E)$ up to higher orders as mentioned in (A) and (B), so that the simplification is introduced in (C) and (D). Even in the simplified schemes, if we wish to apply the working formula of Eq. 55 to large polymer systems, we must face with the difficulty of solving the inverse matrix extremely larger than the $3N\times3N$ matrix of the working formula of Eq. 38b in (C). The deficiency of DeVoe's coupled oscillator theory also is this case. However, if we wish to allow for the static effect in terms of only the data of $\boldsymbol{\mu}^{(\mathrm{site})}_{00}$ and $\boldsymbol{\mu}^{(\mathrm{site})}_{0f}$ by dropping $\boldsymbol{\mu}^{(\mathrm{site})}_{fg}$ which is not easily available, Eq. 55 is clearly preferred to Eq. 38b. It is again to be pointed out that the renormalized RPA's given by Eqs. 43 and 65 are kind of extensions of the Fano-DeVoe model for the polymer of the constituent chromophores without permanent dipole moments. Applying the theory to the real DNA molecules, the bandshape calculations of UV absorption and CD spectra are now in progress involving the permanent dipole moments.[24-26]

^{63}Cu High Resolution NMR of Cu(I) Halides in Aqueous Solution and Suspension

Kazunaka ENDO,* Kyonosuke YAMAMOTO, Kenzo DEGUCHI,† and Kazuhiro MATSUSHITA†
R & D Laboratories for Photo Materials, Mitsubishi Paper Mills, Ltd., Nagaokakyo, Kyoto 617
†NMR Application Laboratory, Scientific Instrument Division, JEOL Ltd., Akishima, Tokyo 196
(Received March 11, 1987)

In an aqueous solution, ^{63}Cu chemical shielding order ($[CuCl_4]^{3-} \simeq [CuBr_4]^{3-} < [CuI_4]^{3-}$) and line widths (10 to 30 kHz) for CuX-KX systems(where X=Cl, Br, I) have been obtained. The chemical shift(−694 ppm) between $[CuCl_4]^{3-}$ and $[Cu(CN)_4]^{3-}$ is interpreted by the paramagnetic term which depends mainly upon a 3d-hole on a Cu(I) atom by using perturbation theory with an average excitation energy approximation. The line-broadening of Cu(I) halide complexes in aqueous solution is explained dominantly by a Cu(I) nuclear quadrupole interaction with the electric field gradient which arises from a 3d-hole on a Cu atom. For the abnormal increasing metal shielding order of $[MX_4]^{(4-i)-}$($[MCl_4]^{(4-i)-} \leqslant [MBr_4]^{(4-i)-} < [MI_4]^{(4-i)-}$), a possibility of the heavy-atom effect in the metal shielding of $[CuI_4]^{3-}$(649 ppm, using the lowest excitation energy of the diatomic molecule) and $[CdI_4]^{3-}$(1941 ppm using the lowest excitation energy of the diatomic molecule), is evaluated.

It is known that copper(I) halides are photosensitive and semiconductive materials. We think that it is a useful step for determing new materials to study the electronic structure of metal complexes as well as the nature of the chemical bond between metal and ligand. Magnetic properties have long been powerful tools for studies of the electronic structures of transitionmetal complexes. Recently, there have been published a number of papers[1-4] on experimental NMR studies of metal complexes in solid and liquid solution. These studies can be approached from both experimental and theoretical points of view. As one part of a continuing investigation, we have reported ^{109}Ag NMR and MO theoretical studies.[5,6] We now describe a ^{63}Cu high-resolution NMR investigation of nuclear relaxation and chemical shifts for Cu(I) halides in aqueous solution, elucidating correlations with electronic structure in these complexes.

To our knowledge, there were several ^{63}Cu and ^{65}Cu NMR investigations[4a,4b,7,8] dealing with copper(I) halides. Of these studies, Guenther et al.[7] performed a detailed investigation on ^{63}Cu spin-lattice relaxation for solid-state CuX. Lutz et al.[4b] observed that the Cu chemical shift in solid CuX indicates a remarkable increasing shielding order (CuCl≤CuI< CuBr) which does not show a linear dependence on the atomic number of the halide ligand. There have, until now however, been no theoretical study reported for the Cu chemical shift in solid CuX of a repetitive zinc-blende structure. This is because immense time and funds are needed for computer calculations using the ab initio SCFMO method. Thus, first it is necessary to investigate the Cu chemical shift in gaseous and solution-state Cu(I) halides.

Nakatsuji et al.[6] studied the metal chemical shielding constants in Cu, Zn, Ag, and Cd complexes by the ab initio finite perturbation SCF method. For the metal complexes, whose electronic configurations are primarily $d^{10}s^{1-2}p^0$, the metal chemical shifts are due mainly to the paramagnetic term, which depends upon the electrons in the valence np orbital and the holes in the valence (n-1) d orbital. For the Cu complexes(CuCl, $[CuCl_4]^{3-}$, $[Cu(CN)_4]^{3-}$, $[Cu(NH_3)_2]^+$), the d orbital mechanism is predominant. To obtain a physical picture of the Cu shielding of Cu(I) complexes($[CuCl_4]^{3-}$, $[Cu(CN)_4]^{3-}$), a simplified calculation was performed using perturbation theory,[5,9] with an average excitation energy approximation.

This paper presents representative ^{63}Cu NMR spectra obtained from aqueous solutions and suspensions of Cu(I) halides, and provides a theoretical interpretation of the Cu chemical shift and linewidth. We suggest from a qualitative perturbation theory that the Cu chemical shielding is governed by a paramagnetic term, which depends upon a 3d-hole of the Cu(I) atom. For the increasing metal shielding order of $[MX_4]^{(4-i)-}$, we propose the possibility of an effect due to the heavy atom on the metal shielding of $[CuI_4]^{3-}$ and $[CdI_4]^{2-}$. The line-broadening in aqueous solution can be interpreted dominantly by a Cu(I) nuclear quadrupole interaction with the electric field gradient which arises from a 3d-hole in the Cu(I) atom. Lastly, the Cu chemical-shielding difference($[CuCl_4]^{3-} < CuCl \leqslant CuI < [CuI_4]^{3-}$) between a suspension CuX and solution $[CuX_4]^{3-}$ is discussed qualitatively from the standpoint of structure.

Experimental

Materials. $[Cu(CH_3CN)_4]BF_4$ was prepared by a method described in the literature.[10] The compound was checked by elementary analysis and an optical absorption method with the aid of the absorbance at 440 nm of a derived bis(2,2′-bipyridine)copper(I) in acetone(ε_{max}=4800 $M^{-1}cm^{-1}$ (1 M=1 mol dm^{-3})). All chemicals except an NMR reference sample used here were commercially available.

NMR Measurements. All ^{63}Cu spectra were measured at 71.50 MHz with a FX-270 spectrometer. Between 1000 and 10000 transients were accumulated using a 17.5 μs (90°) pulse; 16 K data points were collected over a band width of 50 kHz. These measurements were made at temperature of 30 °C.

Before we measured solutions and suspensions, the samples were bubbled with nitrogen gas for three minutes. The molar ratio of CuX to water for the CuX suspension was 1/28. All ^{63}Cu spectra were externally referenced to liquid

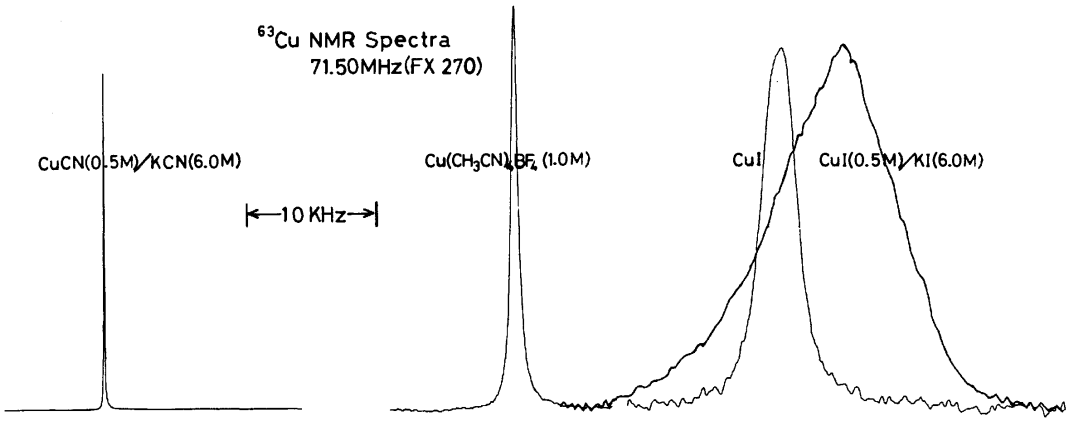

Fig. 1. ^{63}Cu NMR spectra for Cu(I) compounds in aqueous solution and suspension at 71.50 MHz.

Table 1. Chemical Shifts and Linewidths for ^{63}Cu Resonance and Mole Fraction of Cu(I) Complexes for Cu(I) Halides in Aqueous Solution and Suspension at 30°C

Cu(I) salt	Chemical shift[a] (ppm)	linewidth (Hz)	Mole fraction(%) CuX(s)	Cu^+	$[CuX_2]^-$	$[CuX_3]^{2-}$	$[CuX_4]^{3-}$	X^- (M)
CuCl(suspension)	−331	3500	100		0	0	0	
CuCl(0.5M)/KCl(4.0M) (aqueous solution)	−200	28000	0	0	3.4	22.3	74.3	2.7
CuBr(suspension)	−388	3800	100	0	0	0	0	
CuBr(0.5M)/KBr(4.0M) (aqueous solution)	−200	21000	0	0	0	2.0	98.0	2.5
CuI(suspension)	−330	2700	100	0	0	0	0	
CuI(0.5M)/KI(6.0M) (aqueous solution)	−434	12500	0	0	0.3	13.6	86.1	4.6
$[Cu(CH_3CN)_4]BF_4$	0	600						
CuCN(0.5M)/KCN(6.0M) (aqueous solution)	494	70	0	0	0	0.4	99.6	4.5

a) More positive values refer to lower shielding. The reference sample is a 1.0 molar solution of $[Cu(CH_3CN)_4]BF_4$ in CH_3CN.

1.0 M $[Cu(CH_3CN)_4]BF_4$ in CH_3CN. All chemical shifts for ^{63}Cu are defined by

$$\Delta\delta_{sam} = (\nu_{sam} - \nu_{ref})/\nu_{ref},$$

where ν_{sam} is the resonance frequency of a sample and ν_{ref} is the reference frequency. Shifts defined in this manner are positive for lower shielding. The linewidth was evaluated from the widths at half-height. The line shape of the Cu spectra in a suspension and liquid solution is assumed to be Gaussian and Lorentzian, respectively.

Table 2. Solubility Products and Formation Constants of Cu(I) Complexes (30°C)

Cu(I) salt	$-\log K_{sp}$	$\log\beta_1$	$\log\beta_2$	$\log\beta_3$	$\log\beta_4$
CuCl	6.73	*	5.4	5.8	5.9
CuBr[a]	8.28	*	5.16	6.65	7.95
CuI	12.03	*	8.20	9.26	9.40
CuCN	19.5	*	24.0	28.6	30.3

The formation constant has not been obtained. a) The formation constant of $[CuBr_4]^{3-}$ has been obtained by the potential E_{Cu} measurement.[12]

Results and Discussion

Spectra of Solution Cu(I) Complexes. Figure 1 shows a typical ^{63}Cu spectra for Cu(I) complexes in an aqueous solution and suspension; Table 1 gives chemical shift and linewidth data. The total range of chemical shifts is in excess of 900 ppm. Such large variations in shielding are due to a domination of the shielding constant by local paramagnetic contributions.[5,6,9] Note that the shifts and linewidths given in the figure and table represent weighted averages of the shifts and linewidths for various species in equilibrium in the solution. In order to determine the mole fraction of the Cu(I) species in each NMR sample in Table 1, we utilized the solubility products and stability constants[11,12] for Cu(I) salts in Table 2, and performed numerical calculations.

Cu Chemical Shift of Cu(I) Complexes. Table 3

Table 3. The Change in AO Populations of Copper(I) Complexes

Orbital	$[CuCl_4]^{3-}$	$[Cu(CN)_4]^{3-}$

4s	0.217	0.292
$4p_x$	0.302	0.357
$4p_y$	0.302	0.357
$4p_z$	0.302	0.357
Ligand		
	Cl^-	CN^-
	(Cl−n=3)	(C−n=2 : N−n=2)
ns	−0.020	−0.494 0.000
np_x	−0.040	−0.119 0.256
np_y	−0.040	−0.119 0.256
np_z	−0.040	−0.119 0.256

In our MO calculation, the AO population of copper(I) ion is given as: AO population of 4s, $4p_x$, $4p_y$, and $4p_z$ was 0.000, that of $2p_x$, $2p_y$, and $2p_z$ in C and N of CN^- was 1.000 (because of $(p\pi)_x$, $(p\pi)_y$, and $(p\pi)_z$ of CN^-) and that of others is 2.000, respectively.

summarizes the change in valence atomic orbital population of the Cu(I) ion and the Cl^- and CN^- ligands due to ligand addition by the ab initio SCF MO method.[5,6] In the table the population increases in the 4s and 4p AOs of Cu(I) atoms and the population decreases in the s and p AOs of ligands indicate an electron transfer from the ligand to copper. Also, a back donation to a ligand produces a hole in the 3d orbitals, coincident with the bonding axes of Cu(I) complexes.

As reported earlier for ^{109}Ag, the chemical shifts of metal complexes for a ligand-metal(Ib and IIb) interaction system can be governed by the paramagnetic term. This will also be explained by the following Eq. 1 for Cu chemical shieldings:

$$\sigma_{para}(Cu(I)) \simeq \frac{-2\alpha^2}{3}\left(\frac{<1/r^3>_p}{E_p}\cdot P_T^e + \frac{<1/r^3>_d}{E_d}\cdot 3D_T^h\right), \quad (1)$$

where P_T^e and D_T^h are the total populations of the p electrons and d holes, respectively.

The paramagnetic term for Cu shielding can be estimated from $E_{p,d}$ and $<1/r^3>_{4p,3d}$ as parameters in the equation. We assume that $E_p=E_d=E$, $<1/r^3>_{4p}=$ 0.59 a.u. and $<1/r^3>_{3d}=5.0$ a.u. (The latter two terms are obtained from the SCF functions by Clementi et al.[13]) The results in Table 4 agree qualitatively with the observed value (Table 1, CuCl/KCl vs. CuCN/KCN). We can also see that the d-orbital contribution is much larger than the p-orbital contribution. This tendency corresponds well to the theoretical result using an ab initio finite-perturbation SCF method.[6]

Possibility of an Effect of a Heavy Atom on Cu Shieldings. In an aqueous solution, we observed an

Table 4. Calculated ^{63}Cu Chemical Shielding Constants of Cu(I) Complexes

a) The densities were obtained from Ref. 6. b) The values were estimated from the diatomic molecule.[16] c) These values were calculated from the corrected hyperfine splitting constants given by Knight.[17]

anomalous shielding order $[CuI_4]^{3-}$ (for (CuI 0.50M/KI 6.0M))>$[CuBr_4]^{3-}$ (for(CuBr 0.50M/KBr 4.0M))≃ $[CuCl_4]^{3-}$ (CuCl 0.50M/KCl 4.0M)). For other metal(Ag(I), Zn(II), Cd(II)) four coordinate halide complexes, the ^{109}Ag shielding order may be $[AgCl_4]^{3-}$> $[Ag\text{-}Br_4]^{3-}$>$[AgI_4]^{3-}$ (The ^{109}Ag signal for $[AgCl_4]^{3-}$ has not been observed),[5] while the ^{67}Zn and ^{113}Cd shielding order $[ZnI_4]^{2-}$>$[ZnBr_4]^{2-}$>$[ZnCl_4]^{2-}$ and $[CdI_4]^{2-}$ >$[CdBr_4]^{2-}$>$[CdCl_4]^{2-}$ were shown[1a,2] The same shielding order in $[ZnX_4]^{2-}$ and $[CdX_4]^{2-}$ has been observed for ^{13}C in CX_4.[14] Thus, the shielding in $[CuX_4]^{3-}$, $[ZnX_4]^{2-}$, and $[CdX_4]^{2-}$ can be explained in terms of the heavy atom effect (σ_{LS}).[15] On the other hand, the ^{109}Ag shielding may be unaffected by the term but due mainly to the paramagnetic term.

The heavy atom effect has been related to a spin-orbit coupling parameter ζ which is especially large for Br and I in Table 6. The simplified equation for the metal four-coordinate halide complex is

$$\sigma_{LS}^{xx} \simeq -4\pi\zeta\alpha^2|\phi_s(0)|^2\frac{1}{E^2}[\,2P_{yBsA}P_{yBzB}P_{zBsA} - P_{yBsA}^2(P_{zBzB}-1) - P_{zBsA}^2(P_{yByB}-1)], \quad (2)$$

where $P_{\mu\nu}$ is the orbital density: P_{yBsA} denotes the density of the p_y orbital on the B (halogen) atom and an s orbital on the A (metal) atom. Other notations correspond to reference.[15]

In order to estimate the LS shift, σ_{LS}, for $[CuX_4]^{3-}$, $[AgX_4]^{3-}$, and $[CdX_4]^{2-}$, we used the quantities shown in Table 5. There, the densities of the metal four-coordinate halide complexes were approximated by tetrachloride complexes instead of tetrabromide and tetraiodide, which we have not calculated by the ab initio SCFMO method.[6] An inspection of Table 6 shows that the LS shift (using both the 1st ionization potential of the metal atom and the lowest excitation energy of the diatomic molecule) is $[CdX_4]^{2-} > [CuX_4]^{3-} \geqslant [AgX_4]^{3-}$. This tendency corresponds to the observed one. For $[AgX_4]^{3-}$, the observed shift shows the opposite shielding order. This indicates that the Ag paramagnetic term is much larger than the LS term.

Line-Broadening for Cu(I) Halide Complexes. In Table 1, we can see remarkably different line widths for Cu(I) complex species of Cu(I) halides in aqueous solution. The linewidths[18] can be approximated by

$$\Delta\nu_{1/2} \simeq \frac{1}{10}\left(1+\frac{\eta^2}{3}\right)(e^2Qq/\hbar)^2\tau_c\,, \qquad (3)$$

where we can assume the asymmetry parameter, η, is nearly 0 for CuX; the correlation time, τ_c, of the complex $[CuX_4]^{3-}$ is estimated as $2\pi\times10^{-11}$ s in nonviscous water from the Einstein-Stokes relationship, the quadrupole moment of ^{63}Cu, Q, is given as -0.16×10^{-24} cm^2 and the electric field gradient around the Cu nucleus, q, is affected by any change of the p- and d- electron densities. These densities are considered to result from the lone-pair electrons of the ligand. The field gradient will, thus, be the dominant factor for ^{63}Cu linewidths.

An estimation of e^2Qq by Eq. 3 gives 40 and 4 MHz for the different linewidths of 10 and 0.1 kHz in Table 1, respectively. The term e^2Qq can be rewritten as

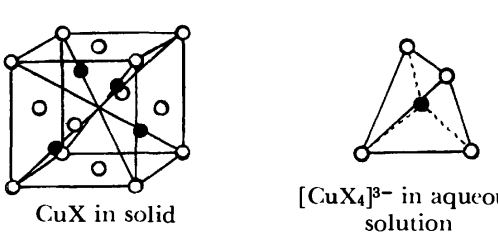
$$e^2Qq/\hbar = \frac{e^2}{\hbar}\frac{2L(L+1)}{(2L-1)(2L+3)}\langle 1/r^3\rangle Q\,. \qquad (4)$$

We can evaluate e^2Qq for the maximum case where the contribution arises from a single hole or electron on a 3d- or 4p-orbital. The value was estimated to be 110 or 12 MHz for a single 3d-hole or 4p-electron, respectively. It can, therefore, also be seen for the ^{63}Cu observed linewidths (10 to 30 kHz) that the d-contribution (76 kHz) is larger than the p-contribution (0.9 kHz).

When we consider ^{63}Cu linewidths from the sysmmetry of Cu(I) complexes in aqueous solution, the complex with a higher symmetry gives a sharper signal. The sharper signals of $[Cu(CN)_4]^{3-}$ and $[Cu(CH_3CN)_4]BF_4$ in solution are due to their tetrahedral symmetry. However, we observed broader signals for aqueous CuX-KX solution systems. This broadening may be partially attributed to a lower symmetry of $[CuX_3]^{2-}$ and a distortion of $[CuX_4]^{3-}$.

The Difference between ^{63}Cu Chemical Shieldings of Cu(I) Halides in Suspension and in Solution. An inspection of Table 1 indicates that the Cu shift of CuX in suspension is in good accordance with a remarkable increasing shielding order ($CuCl \leqslant CuI < CuBr$) in solid, as reported by Lutz et al.[4b] The ^{63}Cu of $[CuCl_4]^{3-}$ in solution is more deshielded than that of solid CuCl in suspension (the shift between $[CuCl_4]^{3-}$ and CuCl is about 130 ppm), while the $[CuI_4]^{3-}$ in solution is more shielded than the solid CuI in suspension (the shift between $[CuI_4]^{3-}$ and CuI ($\geqslant$CuCl) is about −100 ppm). We can, thus, explain these anomalous shielding orders seen in the Cu(I) halides.

Cu(I) halides, solid CuX in suspension and $[CuX_4]^{3-}$ in solution, have the same tetrahedral four-coordinate symmetry. Their ^{63}Cu nuclei, however, reflect the different chemical shieldings (as mentioned above). The reason can be explained by considering the difference between the lattice repetitive zincblende structure in a solid and a single tetrahedral structure in an aqueous solution (Fig. 2). For a solid, each Cu atom bonds to four halogens, while each halogen atom bonds to four Cu ones for the sake of the repetitive structure of zincblende. On the other hand, in a solution, a copper ion



CuX in solid

$[CuX_4]^{3-}$ in aqueous solution

Fig. 2. Zincblende structure of CuX in solid and a tetrahedral structure of $[CuX_4]^{3-}$ in aqueous solution.

has four halogens in a single tetrahedral complex. Then, in a solid, the electron donation from the halogen p orbital to the Cu(I) 4s and 4p orbitals and the back donation from the Cu(I) 3d orbital to the ligand may be much smaller than those in solution.

Here, in order to explain the observed ^{63}Cu shielding order in $[CuX_4]^{3-}$ and CuX, we consider the paramagnetic, σ_{para} (Cu(I)), and LS-shielding, σ_{LS}, terms. For Cu(I) chloride complexes, the shift between $[CuCl_4]^{3-}$ and CuCl is interpreted mainly by the diffrences between the paramagnetic terms in Eq. 1, because the contribution of the LS-shielding is ignored for the chloride complex (Table 6). Now, we assume that ($E_{p,d}$ solution)$\simeq$($E_{p,d}$ in solid) and ($\langle 1/r^3\rangle_{3d,4p}$ in solution) $\simeq$($\langle 1/r^3\rangle_{3d,4p}$ in solid) in Eq. 1. We can also take into account the population orders, P_T ($[CuCl_4]^{3-}$)>P_T (CuCl) and D_T ($[CuCl_4]^{3-}$)>D_T(CuCl), as discussed above. Then, the observed deshielding order, σ($[CuCl_4]^{3-}$)>σ (CuCl), is shown from the paramagnetic shielding order, σ_{para} ($[CuCl_4]^{3-}$)>σ_{para} (CuCl).

In the case of Cu(I) iodide complexes, both σ_{para} (Cu(I)) and σ_{LS} terms must be considered. For the σ_{para} term, we may show the deshielding order, σ_{para} ($[CuI_4]^{3-}$)> σ_{para} (CuI) as well as σ_{para} ($[CuCl_4]^{3-}$)>σ_{para} (CuCl). For σ_{LS}, the difference between σ_{LS} ($[CuI_4]^{3-}$ and σ_{LS} (CuI) depends mainly upon the populations, p_{zBzB} and p_{yAyA} in Eq. 2. The populations in solid CuI are also assumed to be smaller than those in solution, for the sake of the repeat structure in solid. Thus, if ($\sigma_{LS}([CuI_4]^{3-})-\sigma_{LS}(CuI)$)>($\sigma_{para}(CuI)-\sigma_{para}([CuI_4]^{3-})$) is pointed out, we can explain the observed shift between CuI and $[CuI_4]^{3-}$.

Conclusion

In this paper, we presented representative ^{63}Cu NMR spectra obtained from an aqueous solution and a pure solid of Cu(I) halides. Especially, a few tens of kHz of broader ^{63}Cu spectra for CuX-KX systems (where X=Cl, Br, I) were shown. We provided a theoretical interpretation of the ^{63}Cu line width and the chemical shielding. The line width and shielding were found to be due mainly to a 3d-hole in the Cu atom: The broadening is due to a Cu(I) nuclear quadrupole interaction with the electric field gradient, which arises from the 3d-hole. The shielding could be explained by the paramagnetic term which depends dominantly on the 3d-hole. Furthermore, for increasing metal shieldings of $[MX_4]^{(4-i)-}$, we evaluated the possibility of the heavy atom effect on the shielding of $[CuX_4]^{3-}$ and $[CdX_4]^{2-}$.

In a forthcoming paper, we hope to clarify the shielding order of $[CuX_4]^{3-}$ with the ab initio SCF MO method.

We express our appreciation to Prof. G. C. Levy of the N. I. H. Biotechnology Research Resource, Syracuse University who read the manuscript and corrected the English. We wish to thank Dr. Hiroshi Nakatsuji of Kyoto University for his helpful discussion.

12) To determine the formation constant β_4 of $[CuBr_4]^{3-}$, an electrode potential (E_{Cu}) measurement has been performed. A homemade solid-state copper electrode was used with a double junction silver chloride reference electrode HS-305DS (TOA Electronics Ltd.). These electrodes were standardized with solubility products of purified CuCl and CuI in 1.0M KNO_3. The measurement cell was bubbled with nitrogen gas during E_{Cu} measurement to prevent oxidation of Cu^+. The potential E_{Cu} value was determined as $E_{Cu}=0.318+0.0261 1n[Cu^+]$, where $[Cu^+]$ denotes molarity. The E_{Cu} value was measured as a function of the free ligand concentration, to obtain the formation constants. The measurements were performed in thermostated vessels at 30±0.1 °C and at an ionic strength of 1.0M KNO_3.

Preparation and Time-Resolved in Situ Reflection Spectra of Bilayer Electrodes with Polythiophene Outer Layers

Kenji MURAO* and Kazuhiro SUZUKI
Advanced Research Laboratory, Hitachi, Ltd., Kokubunji, Tokyo 185
(Received March 12, 1987)

Bilayer electrodes, Pt/poly-**1**/polythiophene [**1**: tris(4-vinyl-4′-methyl-2,2′-bipyridine)ruthenium(II) perchlorate], where polythiophene is derived from poly(3-methylthiophene) [poly(3-methyl-2,5-thienylene), abbreviated as PMeT] and poly(2,2′-bithiophene) [poly(2,2′-dithienyl-5,5′-ene), abbreviated as PBT], have been prepared. Electropolymerizations of MeT and BT at Pt/poly-**1** occur at the platinum electrode surface, followed by phase separation of the polymer components which results in the bilayer structure. Significant imbalance, observed between charge densities involved in the cathodic and anodic waves of the cyclic voltammogram for Pt/poly-**1**/PBT, is explained as being due to the positive charge leakage from the PBT layer to the platinum substrate through the 2+/3+ redox level of the intervening poly-**1** during the potential sweep in the negative direction. This charge leakage is ascribed to the consequence of the closely located oxidation potential of PBT to that of the 2+/3+ of poly-**1** ($E^{\circ\prime}$=+0.875 V vs. Ag/Ag^+). Time-resolved in situ reflection spectra taken at Pt/poly-**1**/PMeT immersed in electrolytic solutions give evidence for the mediated redox reactions of PMeT by the poly-**1** layer. The spectral changes strongly suggest the transient occurrence of polarons during the doping process.

Electrically conducting polyheterocycles, e.g., polypyrrole [poly(2,5-pyrrolylene), hereafter abbreviated as PP] and polythiophene [poly(2,5-thienylene), hereafter abbreviated as PT] have attracted increasing interest in the past decade. One of the reasons for this stems from their important situation as examples for non-degenerate ground-state systems. It has been shown that bipolarons are evolved in those polymer chains upon electrochemical dopings (oxidations) as the most stable charged states (Fig. 1).[1-3] Polarons have also been detected in PP.[4,5] Although there has been some controversy,[2] Kaneto et al. and Hattori et al. first obtained the spectroscopic evidence for polarons in very dilutely doped PTs.[6-8] Basically consistent results were subsequently reported for poly(3-methylthiophene) [poly(3-methyl-2,5-thienylene), hereafter abbreviated as PMeT].[9] Thus, the studies of the electrochemically induced changes in PP and PT have provided understanding of the charged states in PP and PT.

It has been recognized that several tens of minutes are required to achieve quasi equilibria in PP[4] and PT[2,8] upon charge injections. The relaxations possibly involve manifold processes in the polymer chains, which apparently has confined the former studies basically to static conditions, except for a transient ESR study of PP.[5] Another aspect of the preceding studies is that they have been based exclusively on the configuration in which the positive and negative charge injections (i.e., doping-undoping reactions) into the conducting polymers are performed at the conducting substrates, simply as a consequence of the electropolymerization of conducting polymers at metallic or semiconducting substrates. In this configuration, the electronic states of the conducting polymers are totally governed by the Fermi level of the substrates, even in the course of relaxations within them. This becomes disadvantageous for studying the relaxation processes taking place in conducting polymers upon charge injections.

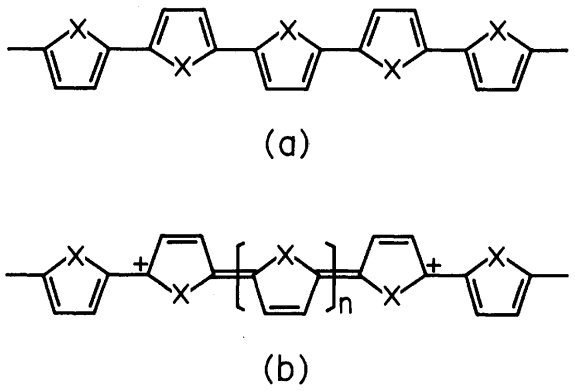

Fig. 1. Structures of polypyrrole (X=NH) and polythiophene (X=S) in neutral (a) and bipolaron (b) states.

In the above context, it would be interesting to realize a configuration in which charge injections into the bulk of conducting polymers are performed via discrete electronic levels of the adjacent layer which is electrochemically active but electrically insulating. In a previous communication,[10] we reported on the first example of PP deposited on the electrically insulating film, poly[tris(4-vinyl-4′-methyl-2,2′-bipyridine)ruthenium(II) perchlorate] (hereafter abbreviated as poly-**1**), to give a bilayer electrode, Pt/poly-**1**/PP. Deposition of PP at the Pt/poly-**1** electrode is initiated at the platinum electrode. The PP film growth occurs within the existing poly-**1** layer and proceeds further outside it. Phase separation of the both polymer components, poly-**1** and PP, is subsequently caused by repeated electrochemical potential sweeps in 0.1 M† TBAP (tetrabutylammonium perchlorate)-acetonitrile, and the above

† 1 M=1 mol dm^{-3}.

bilayer structure is eventually obtained. In this bilayer electrode, oxidation (doping) and reduction (undoping) reactions of the PP layer are mediated by the 2+/1+ and 2+/3+ redox levels of the $[Ru(bpy)_3]^{2+}$ centers (bpy: 2,2′-bipyridine moiety) in the inner layer. Recently,[11] we preliminarily reported on the successful applications of this procedure to PMeT and poly(2,2′-bithiophene) [poly(2,2′-dithienyl-5,5′-ene), hereafter abbreviated as PBT] in preparations of the bilayer electrodes, Pt/poly-**1**/PMeT and Pt/poly-**1**/PBT. Figure 2 depicts the energy diagram for the Pt/poly-**1**/PMeT bilayer electrode. The locations of

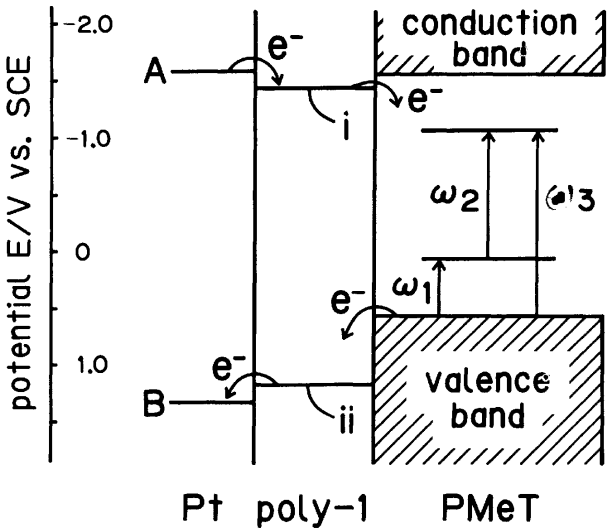

Fig. 2. Energy diagram for the Pt/poly-**1**/PMeT bilayer electrode. i and ii denote 2+/1+ and 2+/3+ redox levels of poly-**1**, respectively. ω_1, ω_2, and ω_3 are the possible optical transitions involving the mid-gap states of PMeT. PMeT: poly(3-methylthiophene). For poly-**1** see text.

the conduction and valence bands are estimated based on optical (band gap energy: 2.1 eV)[6] and electrochemical data,[11] and are consistent to the reported values.[12] The redox potentials of poly-**1** are determined according to the published data.[10,13] The reductive and oxidative charge transfers to the PMeT layer are performed through the electrochemical mediation by 2+/1+ and 2+/3+ redox levels of poly-**1**, respectively. Mid-gap states are evolved upon oxidation of PMeT. In these bilayer systems, it has been found that the quasi equilibria in PMeT and PBT are established within anomalously short periods of time upon electrochemical charge injections. This remarkable feature enabled us to detect transiently occurring polarons in PMeT in the course of achieving equilibria.[14] The above electrochemical procedures might be an important step towards the establishment of molecular technolgy to construct microstructures involving conducting polymers,[15] in view of the generally untractable nature of conducting polymers. This paper describes the preparations, electrochemistry and time-resolved in situ reflection spectra of the bilayer electrodes of PMeT and PBT.

Experimental

Materials. The monomer precursor of poly-**1**, tris(4-vinyl-4′-methyl-2,2′-bipyridine)ruthenium(II) perchlorate (**1**), was synthesized according to a modified method of the reported procedures.[16] Pt/poly-**1** electrodes were prepared using the reported method.[10,13] Commercially obtained TBAP was purified by thermal recrystallization from an EtOH-H_2O 2:3 mixed solvent and was dried in vacuo at 80 °C for 32 h. Commercial acetonitrile was refluxed over P_2O_5 and distilled before use.

Electrochemical Experiments. Platinum disks (4 mm diameter) embedded in glass, and evaporated films of plati-

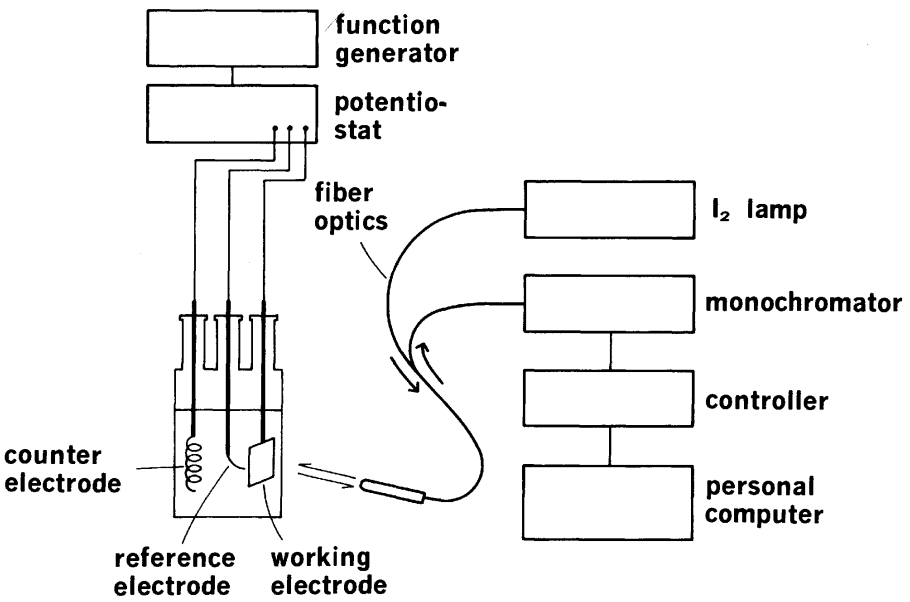

Fig. 3. Schematic representation of the experimental setup for time-resolved in situ reflection spectroscopy during the electrochemical reactions.

num (280 nm thick; active area: 4 mm diameter) on glass substrates (Corning # 7059, 1.2 mm thick) were used as the working substrates. The surfaces of the platinum disks were polished using 1 μm diamond paste. A platinum wire (1 mm diameter) was used as the counter electrode. An Ag/Ag^+ quasi reference electrode was used which showed 290 mV vs. SCE (saturated calomel electrode) in 0.1 M TBAP-acetonitrile. Potentials indicated in the following are all vs. Ag/Ag^+ unless otherwise noted. Preparations and electrochemical measurements were performed by immersing electrodes in electrolytic solutions in one compartment cells. All of the electrochemical experiments were carried out under Argon-purged conditions. The preparations of Pt/poly-**1**/PMeT and Pt/poly-1/PBT electrodes have been outlined in a previous communication.[11] Electrochemical polymerizations of MeT and BT were carried out by both potential sweeps and galvanostatic anodizations. Typically, the galvanostatic polymerizations of MeT and BT were performed at a current density of 275 $\mu A\,cm^{-2}$ at Pt/poly-1 electrodes immersed in anhydrous acetonitrile containing 120 mM monomers and 0.1 M TBAP.

In situ reflection spectra at electrode surfaces were measured with a normally incident light beam led by fiber optics using an MCPD-100 Multi-Channel Photo Detector (Ohtsuka Denshi Co.), as shown in Fig. 3. Each spectrum is based on the accumulated signal obtained by eight repeated wavelength sweeps with a gate time of 12 ms each.

Results and Discussion

Preparations of Pt/Poly-1/PMeT and Pt/Poly-1/PBT. The cyclic voltammograms (CVs) monitored during the electropolymerizations of MeT and BT at Pt/poly-**1** electrodes by potential sweeps are depicted in Fig. 4. The expansion of the waveforms at every cyclic sweep, as indicated by the arrows in Fig. 4(a), is a result of the deposition and the film growth of PMeT at the electrode. When the positive sweeps were limited to potentials lower than +1.1 V, the expansion of the CV waves was not observed and only the redox waves for poly-**1** were repeatedly observed. This means that the electropolymerization of MeT occurs at potentials higher than +1.1 V. This is consistent with the fact that the applied potential upon galvanostatic electropolymerization of MeT (Fig. 5) reached a steady value of +1.17 V. The fact that MeT has a substantially higher oxidation potential than that of 2+/3+ of poly-**1** ($E^{\circ\prime}$=+0.875 V) rules out the possibility of the mediated oxidation of MeT by poly-**1**. The observed potential for MeT oxidation during the galvanostatic anodization is initially lower than the ultimately achieved steady value, +1.17 V. This is understood as being due to the initially predominant oxidation of the poly-**1** layer. The subsequently occurring peak in the V vs. t curve would be representing a crossover from poly-**1** oxidation to MeT oxidation. These observations indicate that the electropolymerization of MeT occurs at the surface of the platinum substrate as a result of the permeation of the monomer molecules through the poly-**1** layer. In fact, the PMeT-as-deposited Pt/poly-**1** electrode showed the CV waves for

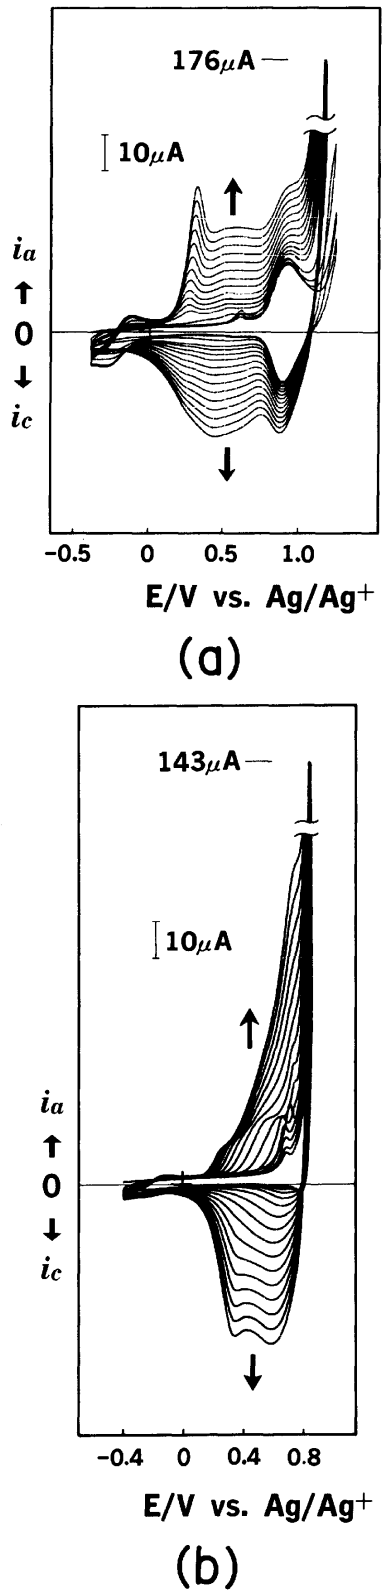

Fig. 4. Cyclic voltammograms monitored on electropolymerizations of 3-methylthiophene (a) and 2,2′-bithiophene (b) at Pt/poly-**1** electrodes immersed in 0.1 M tetrabutylammonium perchlorate-acetonitrile including 30 mM 3-methylthiophene (a) and 2,2′-bithiophene (b), respectively. The employed coverages of poly-**1** layers for (a) and (b) are 1.85×10^{-9} and 3.60×10^{-9} mol cm^{-2}, respectively. Sweep rate: 0.1 $V\,s^{-1}$. For poly-**1** see text.

PMeT and 2+/3+ of poly-**1** independently, essentially as a superimposition of the CV waves for both origins in 0.1 M TBAP-acetonitrile, which means that PMeT was electrochemically accessed directly from the platinum substrate. On the other hand, in the negative potential region, where PMeT is electrochemically inert, the 2+/1+ waves of poly-**1** are totally absent except for a spiky current peak centered at −1.33 V, indicating that PMeT present at the platinum electrode surface is blocking the reduction of the $[Ru(bpy)_3]^{2+}$ centers. The subsequent cyclic potential sweeps between the 2+/1+ and 2+/3+ potentials of poly-**1** caused the CV changes (depicted in Fig. 1 of Ref. 11) as follows; 1) anodic peak shifts of PMeT in the positive direction followed by peak growths as a prewave of the 2+/3+ wave of poly-**1**, 2) gradual loss of the cathodic wave of PMeT, 3) growths of the spiky peak at −1.33 V with a slight shift at every cycle in the negative direction, 4) evolution of the 2+/1+ waves of poly-**1** in the negative potential region. These concurrent changes eventually lead to the final waveform as shown in Fig. 6(a). In Fig. 6(a), the large spiky current peaks (i and iii) are observed only for virgin scans in negative and positive directions after allowing the spiky current peaks of the opposite signs, respectively. When potential sweeps are repeated in the same direction, the second sweeps produce small waves only (ii and iv), which reproduce the CV waves for Pt/poly-**1** before the deposition of PMeT, except for a residual small peak in iv. The CV waves in Fig. 6(a) represent the mediated redox reactions of PMeT by poly-**1**, and are essentially consistent with the electrochemistry of bilayer electrodes.[10,13,17-19]

The electropolymerization of BT at Pt/poly-**1** by potential cyclings occurs at potentials near $E^{\circ\prime}$ of poly-**1** as evidenced by the onsets of large current peaks (Fig. 4(b)). The galvanostatic electropolymerization of BT proceeds at potentials lower than +0.83 V (Fig. 5) which is slightly lower than the $E^{\circ\prime}$ of poly-**1**. This means that oxidation of BT (and hence the deposition of PBT) can be mediated by the poly-**1** layer, which should directly lead to the bilayer structure. However, for both modes of BT oxidations (i.e., by potential cyclings and by galvanostatic anodization) the occurrence of PBT at the platinum substrates was evidenced by the fact that the initial potential sweeps of the PBT-as-deposited electrodes in 0.1 M TBAP-acetonitrile showed the CV waves for PBT that was electrochemically accessed directly from the platinum substrates, in the same way as for the PMeT-deposited poly-**1** electrode described above. These observations, however, do not exclude the possibility that the anodization of BT is partly mediated by $[Ru(bpy)_3]^{2+}$ centers in poly-**1**. The bilayer electrode, Pt/poly-**1**/PBT, was subsequently brought by repeated potential sweeps in 0.1 M

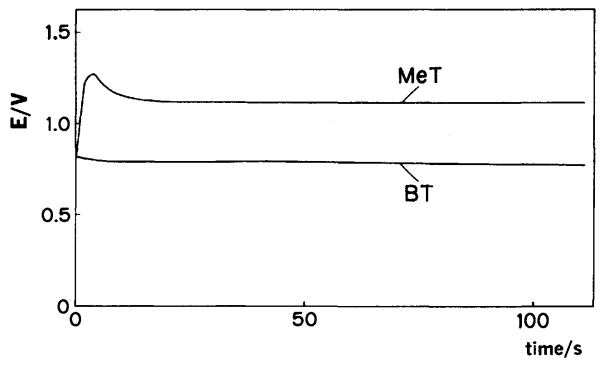

Fig. 5. Potential vs. t curves monitored on galvanostatic polymerizations of 3-methylthiophene (MeT) and 2,2′-bithiophene (BT) at Pt/poly-**1** electrodes immersed in 0.1 M tetrabutylammonium perchlorate-acetonitrile including 120 mM MeT (a) and 120 mM BT (b). Current densities are 275 $\mu A\,cm^{-2}$ for both runs. The employed coverages of poly-**1** layers for (a) and (b) are 1.98×10^{-9} and 2.90×10^{-9} mol cm^{-2}, respectively. For poly-**1** see text.

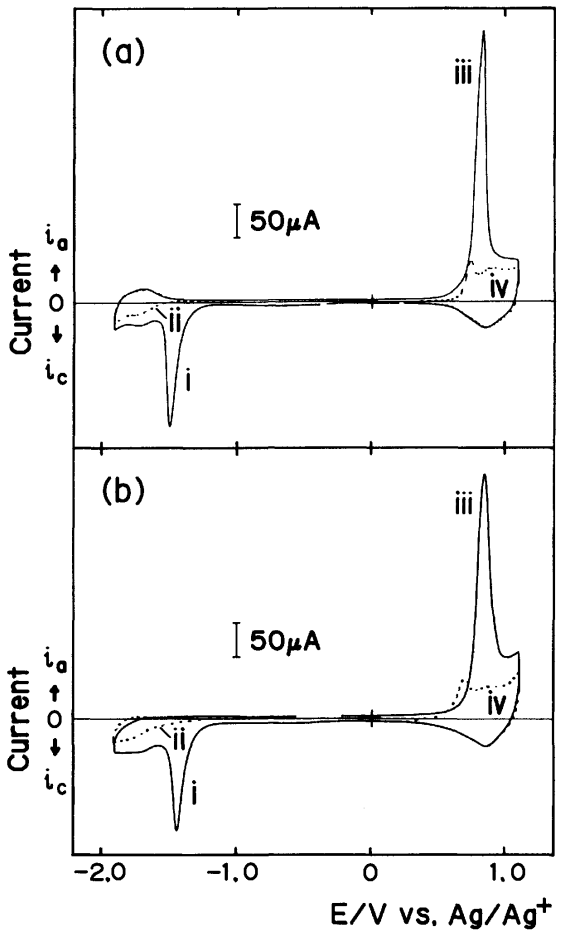

Fig. 6. Cyclic voltammograms for Pt/poly-**1**/poly(3-methylthiophene) (a) and Pt/poly-**1**/poly(2,2′-bithiophene) (b) bilayer electrodes in 0.1 M tetrabutylammonium perchlorate-acetonitrile. Coverages of the inner layer are 2.62×10^{-9} (a) and 2.58×10^{-9} (b) mol cm^{-2}, respectively. Outer layers were deposited by galvanostatic polymerizations at current densities of 275 $\mu A\,cm^{-2}$ and charge densities passed during the depositions of 32.4 mC cm^{-2} for both (a) and (b). For poly-**1** see text.

TBAP-acetonitrile, accompanying CV changes in the same way as for PMeT-deposited poly-**1** electrodes. The above electrochemical scheme in preparing bilayer electrodes — i) permeation of monomeric precursors of the outer layer through the first layer, ii) electropolymerization of the monomer at the surface of the substrate, iii) repeated potential sweeps in 'innocent' electrolytic solutions — is basically the same as that employed for the preparation of the bilayer electrodes with PP as the outer layer,[10] suggesting the extensive applicability of this scheme to other material systems. The above scheme, i—iii), contrasts with other processes employed in obtaining bilayer electrodes,[13,17-19] where the outer layer is deposited directly at the surface of the first layer, i.e., by mediated electropolymerizations of the monomer precursors by the first layer, or droplet evaporation of polymer solutions of the outer layer at the surface of the first layer. In step iii) phase separation occurs between poly-**1** and PMeT or PBT. This phase separation is consistently understood with that of the PP-based bilayer electrode and will be discussed in a separate paper.

Significant imbalance was found to exist between involved charges for anodic (>+0.60 V) and cathodic (<−1.25 V) peaks in the CVs of Pt/poly-**1**/PBT (Fig. 6(b)). The amount of charge involved in the cathodic peak is only 60—70% that of the anodic counterpart. Although precise quantitative arguments regarding the amount of charges are not possible due to the complexities arising from background currents and capacitive components of PBT, such an apparently large imbalance in charges has not been observed for Pt/poly-**1**/PP.[10] It was found from Q (charge densities) vs. V plot that the amount of the negative and positive charges were balanced by adding an amount of cathodic charges collected during the sweeps in the negative direction in the potential region more negative than +0.25 V. This can be reasonably explained by assuming a leakage of positive charges of the outer layer to the platinum substrate through the poly-**1** layer during the sweep in the negative direction. The significant overlapping of the distributions of the electrochemical density of states for PBT oxidation and 2+/3+ oxidation of poly-**1** is likely due to the nearness of their oxidation potentials each other (PBT: E_{pa}=+1.00 V vs. SSCE,[20] 2+/3+ of poly-**1**: $E^{\circ\prime}$=+0.875 V vs. Ag/Ag^+). Actually, substantial optical changes have been detected corresponding to the reduction of the PBT layer, when the applied potential is fixed at 0 V for 20 s after oxidizing the PBT layer by sweeping the potential of the platinum substrate, 0 V → +1.15 V → 0 V,[21] which is indicative of a positive charge leakage from PBT layer to the platinum substrate. Similar leakage behavior has also been observed, though less significantly, for PMeT. In contrast, the corresponding negative charge leakage has not been detected for both PBT and PMeT. This is also consistent with the above explanation. The charge leakage in a polymeric Fe(II) complex bilayer electrode has been similarly explained by Denisevich et al.[17] and Leidner et al.[19]

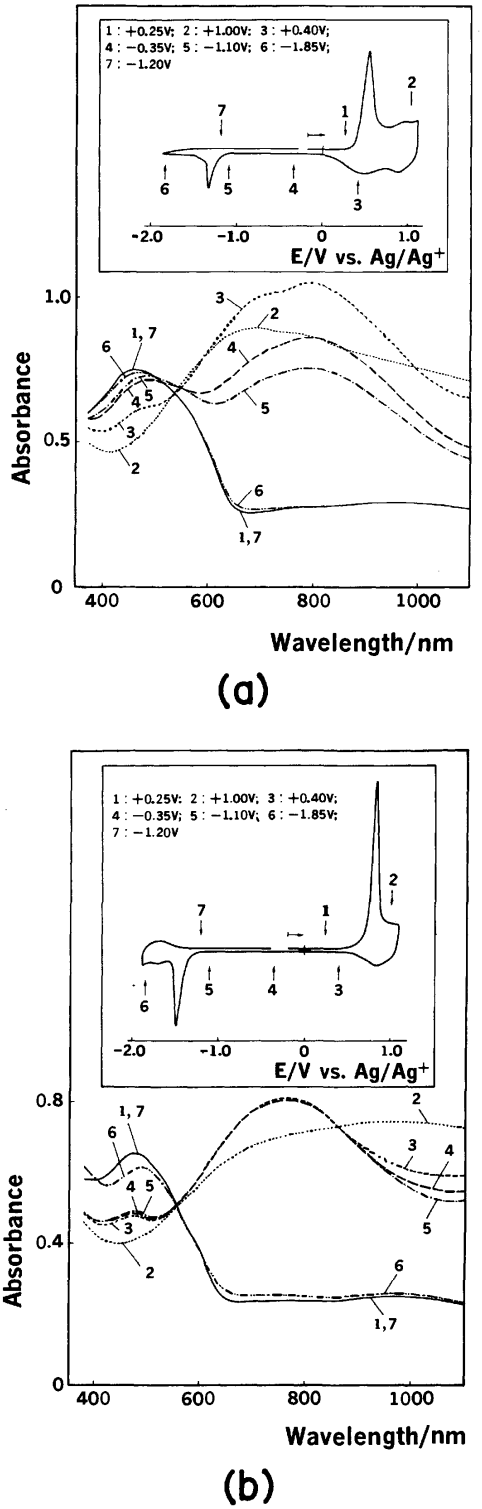

Fig. 7. In situ reflection spectra at Pt/poly-**1**/poly(3-methylthiophene) immersed in 0.1 M tetrabutylammonium perchlorate-acetonitrile during potential sweeps (scan rate: 50 mV s^{-1}, inset), before (a) and after (b) the repeated potential sweeps causing phase separation. The employed coverage of poly-**1** is 2.70×10^{-9} mol cm^{-2}. PMeT was deposited by passing 31.7 mC cm^{-2}. For poly-**1** see text.

Time-Resolved in Situ Reflection Spectra of Pt/Poly-1/PMeT and Pt/Poly-1/PBT. In situ reflection spectra of Pt/poly-**1**/PMeT during the potential sweeps at 50 mV s^{-1} before and after the phase separation are shown in Figs. 7(a) and (b), respectively. Each spectrum is taken within ca. 100 ms. During this period, the potential is swept ca. 5 mV. The absorption band centered at ca. 480 nm in **1** of Fig. 7(a) has been ascribed to the interband transition of PMeT.[2,6] Optical switching occurs on the potential sweep across the sharp oxidation peak of PMeT (**1**→**2**), i.e., loss of the interband absorption and the evolution of bands for 560 nm<λ. However, the sweep **2**→**5** is seen to regenerate the interband absorption with paralleled decrease of the absorption for 560 nm<λ. The subsequent sweep **5**→**6** nearly completes the backward changes. These optical changes imply that a major portion of the PMeT layer is electrochemically accessible directly from the platinum substrate, and that only a small portion of PMeT is electrochemically mediated by poly-**1** before the phase separation. These features are consistent with the concurrent CV (inset).

On the other hand, from the spectra of Fig. 7(b) it is evident that reversible optical switchings occur when the potential is swept across the sharp anodic and cathodic CV waves i.e., **1**→**2** and **5**→**6**. This means that the spectra of Fig. 7(b) give further evidence for the mediated electrochemical doping and undoping reactions of PMeT. The forward (doping) optical change (**1**→**2**) consists of the disappearance of the absorption band for interband transition and the evolution of bands for 560 nm<λ. Small backward increase in absorption below 560 nm is observed for **2**→**3**, while the absorption also increases for 560 nm<λ<870 nm. During the sweep **3**→**5**, absorption below 560 nm changes only slightly, while the absorption intensity decreases for 870 nm<λ. Throughout these changes, the isosbestic point is maintained, which is indicative of quasi-equilibria established in the present system in the time scale of the CV sweep (50 mV s^{-1}); this is surprising, since much longer durations of time have been required for the achievement of the quasi-equilibria in PTs deposited at metallic or other conducting substrates.[2,8]

It should be noted that the essentially consistent optical changes were observed with various modes of positive charge injections, i.e., linear sweep, or potential step with and without subsequent open-circuiting. Figure 8 shows the reflection spectra at Pt/poly-**1**/PMeT taken as follows: Positive charges were first injected by stepping the applied potential of the platinum substrate from 0 to +0.90 V. After the potential was held at +0.90 V for 1 s, the electrode was then opencircuited. The optical change **1**→**2** is due to the doping (oxidation) reaction upon the positive potential step, and the subsequent changes **2**→**3**—**6** occurred during 70 s after the open-circuiting. The observed spectral changes are similar to those for

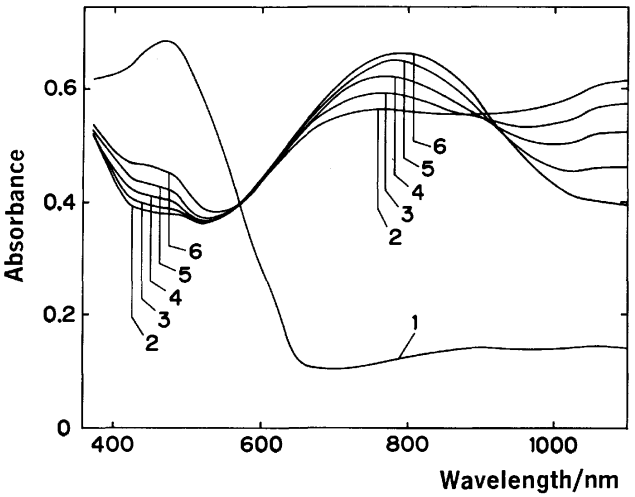

Fig. 8. In situ reflection spectra at a Pt/poly-**1**/poly(3-methylthiophene) bilayer electrode immersed in 0.1 M tetrabutylammonium perchlorate–acetonitrile. Potential was first stepped from 0 V (initial neutral state, spectrum **1**) to +0.90 V vs. Ag/Ag^+. After the potential was held there for 1 s, the electrode was open-circuited. Spectra, 2—6, were taken 1, 5, 13, 33, and 73 s after the open-circuiting, respectively. The coverage of poly-**1** is 2.60×10^{-9} mol cm^{-2}. 27.0 mC cm^{-2} was passed for deposition of PMeT. For poly-**1** see text.

1→**2**→**3** in Fig. 7(b), where the backward increase of the absorption in the interband region is observed here again together with the 'unparalleled' forward increase for 560 nm<λ<870 nm. The optical spectra of a Pt/poly-**1** electrode were measured upon the electrochemical cycle to assess the electrochromic contribution of the inner layer to the observed changes in Figs. 7 and 8, since the potential cycling involves the redox reactions of the inner layer. Figure 9 shows the reflection spectra at Pt/poly-**1** obtained upon potential sweeps. The absorption band centered at 465 nm in Fig. 9(a) is due to the MLCT (metal-to-ligand charge transfer) which is lost upon the positive sweep causing the reaction,

$$[Ru(bpy)_3]^{2+} \xrightarrow{-e^-} [Ru(bpy)_3]^{3+}. \quad (1)$$

The spectral changes indicate that at least for 560 nm<λ, the absorption change caused by the inner layer upon the doping (positive) sweep is negligible, while the Reaction 1 can contribute to the spectral changes in the interband region of PMeT. Therefore, the spectral changes for λ<560 nm in Figs. 7(b) and 8 are the results of i) the Reaction 1, ii) the doping reaction of PMeT driven by $[Ru(bpy)_3]^{3+}$, and iii) the reactions between charged states in PMeT.

Well-defined band maxima centered at 670—680 nm and near 1000 nm are often observed in spectrum **2** in Fig. 7(b) among a number of tested electrodes. The transient occurrence of the bands is also seen in difference spectra upon positive charge injections by a potential step.[14] These characteristic changes are

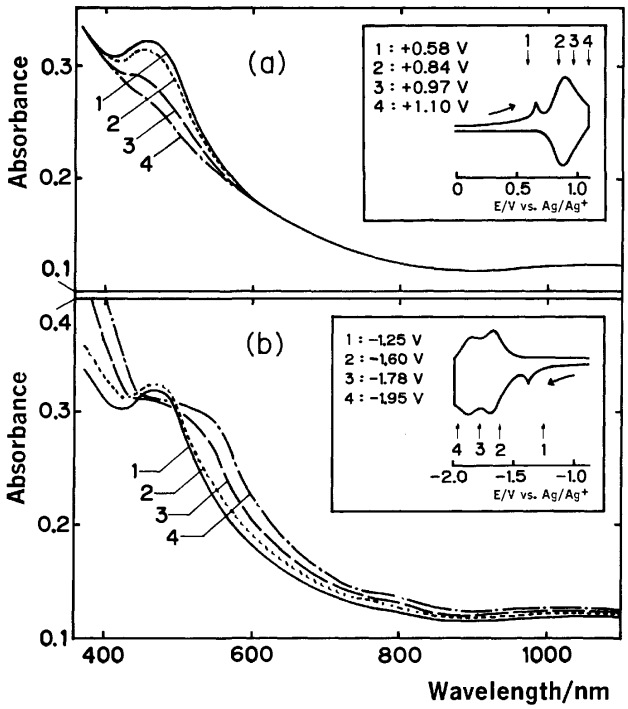

Fig. 9. In situ reflection spectra at Pt/poly-**1** (coverage: 2.90×10^{-9} mol cm^{-2}), immersed in 0.1 M tetrabutylammonium perchlorate–acetonitrile, taken during the potential sweeps (inset). For poly-**1** see text.

strikingly consistent with those reported by Kaneto et al. on very dilutely doped PT under static conditions[8] where the former two bands and the latter band are assigned to polaronic (ω_2 in Fig. 2) and bipolaronic (ω_3 in Fig. 2) transitions, respectively. Harbeke et al.[9] also reported on the similar spectral changes for PMeT at very low doping levels in equilibria, while they did not detect a band corresponding to the band at 670 nm in the present study. Hence, we conclude that the spectral changes of **2**→**3** in Fig. 7(b) and **2**→**3** of Fig. 8 are understood as follows; the polaron states are initially predominant upon doping, but are subsequently transformed to bipolarons due to the self-quenching reaction,

$$P^+ + P^+ \longrightarrow BP^{2+} \quad (2)$$

where P^+ and BP^{2+} represent a polaron and a bipolaron, respectively. Although further experiments are needed to find the origin of the band centered at 670—680 nm, which is higher in energy than the bipolaronic transition, we assume that the band is due to the excitonic transitions which become prominent in the presence of polarons, as a result of strong interactions between excitons and polarons.

In a separate run, backward spectral changes are observed for $\lambda<560$ nm similar to Figs. 7(b) and 8 described above, even when the PMeT in the bilayer configuration is doped by applying a pulse potential, 0 V→+0.90 V for 1 s →0 V vs. Ag/Ag$^+$.[22] The backward spectral relaxations subsequently take place in the time scale similar to Fig. 8. In this mode of potential application, the residual $[Ru(bpy)_3]^{3+}$ centers in the inner layer, after the mediated doping Reaction 3,

$$[Ru(bpy)_3]^{3+} + PMeT^\circ \longrightarrow [Ru(bpy)_3]^{2+} + P^+ \quad (3)$$

where PMeT° denotes a neutral portion in a PMeT chain, are reduced back to the 2+ state at the electrode. Hence, the contribution of $[Ru(bpy)_3]^{3+}$ to the spectral changes for $\lambda<560$ nm is substantially negligible. This means that the mediated doping Reaction 3 is rapid compared to the Reaction 2, and that the backward spectral changes in $\lambda<560$ nm in Fig. 8 should be attributed principally to the Reaction 2. We assume that the backward increase in absorption for $\lambda<560$ nm in Fig. 8, and possibly in Fig. 7(b), is due to the increase in the neutral portion in the PMeT chains as a result of the Reaction 2 and the subsequent reduction of the bipolaron size. The latter effect would occur in the last stage of a series of relaxation processes upon charge injections.

Most of the spectral studies on PTs reported so far have been performed under static conditions based on relatively thick films ($\approx\mu$m). In contrast, the spectral changes for 560 nm$<\lambda$ of Figs. 7(b) and 8 represent dynamic processes in the course of achieving equilibrium within the PMeT layer. This scheme is enabled by the configuration in which a relatively thinner PMeT layer (<100 nm) is isolated from the substrate by the intervention of an electrically insulating but electrochemically active inner layer. Without the intervening layer, i.e., for Pt/PMeT electrodes, no isosbestic behavior was observed even at very low sweep rates (<5 mV s^{-1}) with similar PMeT thickness (<100 nm). Detection of the transient P^+ at Pt/PMeT was not successful with varying doping conditions because the spectral changes under the dynamic conditions were ambiguous and much less systematic, probably reflecting the manifold relaxation processes occurring within the PMeT layer. The charge injections via discrete electronic levels into the conducting polymers would generate charged states which are energetically more confined. These charged states should be able to relax more rapidly through less diversified relaxation pathways, giving rise to the isosbestic behavior in Fig. 7(b). This characteristic feature has allowed the detection of the transiently occurring polarons. Studies of electrochemically induced changes in conducting polymers based on the structure of the present study, i.e., substrate/electrochemically active film/conducting polymer film, would yield further insight into the charged states of the conducting polymers.

Use of Propagators in the Hückel Model. VIII. Intermolecular Interaction

Toshiharu KANO, Kiyoshi NISHIKAWA, and Shigeyuki AONO*
Department of Chemistry, Faculty of Science, University of Kanazawa, Marunouchi, Kanazawa, Ishikawa 920
(Received March 18, 1987)

Intermolecular interactions are analyzed by the propagator method, under the tight-binding approximation. The stabilization energy or the change of charge density due to the intermolecular interaction are expressed in terms of propagators, so that the mechanism resulting above effects is satisfactorily realized. As an interesting example, the intermolecular interaction between guanine and benzo[*a*]pyrene (a famous chemical carcinogen) is investigated.

There are various types of intermolecular interactions. If interacting molecules are charged, or have permanent dipoles, the interaction between them is purely classical, due to the static coulomb potentials. If they are neutral, the induced dipole moments are responsible for their combination.[1] The hydrogen-bond is classified as one of the intermolecular interaction, but this would be a rather weak chemical bond. Another one is the charge-transfer complex proposed by Mulliken:[2] Even if the composite molecules are neutral themselves, the charge-transfer state which is energetically higher than the neutral state mixes with the latter to yield the more stable ground state.

Recently a high ability of the computer may enable us to calculate the intermolecular interaction energies on the same footing dealing with simple molecules. If this be done satisfactorily, the effects involving the above mentioned treatments would be wholly taken into account, but the concepts introduced by the respective methods will be lost. In addition, one cannot expect the computer ability to reproduce the experimental details which the common chemists are interested in.

The present analysis which is facilitated by the propagator technique is at most semiquantitaive. The interaction terms responsible for the molecular combination are assumed to have a single-particle character, i.e., are written by the so-called transfer integrals. This mechanism should be interpreted as a mutual charge transfer in Mulliken's sense.[2]

In the followings, we begin with writting the stabilization energy due to the intermolecular interaction in terms of the Green's function up to the second order of the interaction. In the first half of this paper, the first order term plays a central role in searching for the preferable conformations of the composite molecules. In the second half, adopting the unperturbed system of separated molecules, we express the stabilization energy as a second order effect due to the perturbation. This is very easily carried out by the propagator method. Then we advance one more step of approximation procedure called the closure approximation, so that the mechanism yielding the interaction effect is made very much clear. Finally the interaction between guanine and benzo[*a*]pyrene is investigated as a suggestive example for chemical carcinogenesis.

General

As has been shown,[3] in the tight-binding approximation (Hückel approximation in the π-conjugated molecules) the bond order and the total energy are expressed, respectively, in terms of propagators as

$$q_{rs} = \frac{1}{2\pi i}\int_c dz G_{rs}(z), \tag{1}$$

$$E = Tr\frac{1}{2\pi i}\int_c dz z G(z), \tag{2}$$

where r and s are site indices. In the above the propagator G is

$$G(z) = \frac{1}{z-H} \tag{3}$$

with

$$H = \begin{bmatrix} 0 & \beta_{12} & \beta_{13} & \cdot & \cdot \\ \beta_{21} & 0 & \beta_{23} & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \end{bmatrix}, \tag{4}$$

where β_{rs} is a transfer integral, which is usually taken into account for the adjacent neighbors. The integration with respect to z is carried out along the Coulson contour, which goes along the circuit enclosing poles referring to the occupied levels. We assume that the integration involves the spin sum. Tr(trace) means the diagonal sum, ensurering the independent character from representations.

If the Hamiltonian is separated as

$$H = H^0 + v, \tag{5}$$

where v is the perturbation, then Eq. 3 is rewritten as

$$\begin{aligned} G(z) &= \frac{1}{z-H} \\ &= \frac{1}{z-H^0} + \frac{1}{z-H^0} v \frac{1}{z-H} \\ &= G^0(z) + G^0(z) v G(z). \end{aligned} \tag{6}$$

In the above, we defined $G^0(z)$ for the unperturbed Hamiltonian.

Expanding $G(z)$ as in Eq. 6 and keeping up to the second order term of v, we can obtain changes of energy and bond order. The energy change due to v is

$$\Delta E = \mathrm{Tr}\frac{1}{2\pi i}\int_c dz z(G-G^0)$$
$$\fallingdotseq \mathrm{Tr}\frac{1}{2\pi i}\int_c dz z(G^0vG^0+G^0vG^0vG^0)$$
$$= \mathrm{Tr}\frac{1}{2\pi i}\int_c dz(G^0v+\frac{1}{2}G^0vG^0v). \quad (7)$$

The last result is obtained by partial integration in the second line. If the perturbation v is independent of z, the first term of Eq 7 is evaluated as

$$\Delta E^{(1)} = 2\sum_{rs} q_{rs}v_{sr} \quad (8)$$

by the use of Eq. 1. The numerical factor 2 is due to the spin sum. If we use the representation diagonalizing the Hamiltonian H^0, $G^0(z)$ is written as

$$G^0(z) = \sum_i \frac{|i><i|}{z-\varepsilon_i}, \quad (H^0|i> = \varepsilon_i|i>). \quad (9)$$

We can evaluate the second term of Eq. 7 as follows:

$$\Delta E^{(2)} = \frac{1}{2\pi i}\int_c dz \frac{1}{2}\sum_{rstu}\sum_{ij}\frac{<r|i><i|s>}{z-\varepsilon_i}v_{st}\frac{<t|j><j|u>}{z-\varepsilon_j}v_{ur}$$
$$= 2\sum_{rstu}\sum_{i}^{occ}\sum_{j}^{un}<r|i><i|s>v_{st}<t|j><j|u>v_{ur}/(\varepsilon_i-\varepsilon_j). \quad (10)$$

This result is also rewritten in terms of polarizabilities.[4]

The similar expression for the bond order is also obtained as well. The above expressions are useful for the case of the interaction v being intramolecular, and in the intermolecular case are replaced by a little more complicated expressions.

Now we advance the approximation procedure (so-called the closure approximation) one more step in Eq. 10. If the denominators are replaced by their average,

$$\Delta\varepsilon \simeq <\varepsilon_j-\varepsilon_i>_{av} (>0), \quad (11)$$

we can carried out the summation with respect to i and j to obtain

$$\Delta E^{(2)} = -\frac{1}{2}\frac{1}{\Delta\varepsilon}\sum_{rstu} q_{rs}v_{st}\hat{q}_{tu}v_{ur}, \quad (12)$$

where

$$q_{rs} = 2\sum_{i}^{occ}<r|i><i|s> \quad (13)$$

is the so-called the bond order, and

$$\hat{q}_{tu} = 2\sum_{i}^{un}<t|i><i|u>$$
$$= 2\delta_{tu} - q_{tu}. \quad (14)$$

The last line is obtained from the completeness relation.

We can understand from Eq. 12 that the additional energy arises from going round a circuit as $r\to s\to t\to u\to r$, which are constructed of bond orders and interaction matrix elements.

As an illustrative example, we ask which is energetically more stable, anthracene or phenanthrene. First we note that the energy difference between them occurs from the second order terms. Observing Fig. 1, we can immediately obtain (noticing that $\Delta\varepsilon>0$), for anthracene

$$\Delta E^{(2)} = -\frac{1}{\Delta\varepsilon}q_{79}v_{9,14}\hat{q}_{14,2}v_{27} = 0, \quad (15)$$

since $q_{79}=\hat{q}_{14,2}=0$, and for phenanthrene

$$\Delta E^{(2)} = -\frac{1}{\Delta\varepsilon}\hat{q}_{69}v_{9,14}q_{14,1}v_{16} < 0, \quad (16)$$

since $q_{14,1}>0$, and $\hat{q}_{69}>0$. Therefore phenanthrene is more stable than anthracene.

Mutual Orientation of Interacting Molecules

Let us imagine that two conjugated ring molecules, A and B approach with each other, and a bond indicated by a solid line in Fig. 2 takes place between them. If molecular planes are mutually parallel, this bond is a σ-type between π-orbitals of A and B molecules. The mutual phases of π atomic orbitals of both molecules are put so that all resonance integrals are attractive. This situation seems appropriate for the beginning of intermolecular reaction. Problem is: Where is the next bond formed (not necessarily restricted only one) to get a firmer combination between? The answer will be provided by Eq. 8. Since we can consider the above molecular compound, A—B as a whole system because

of the bond described by the solid line, it is expected that the next bond (indicated by the dotted line in Fig. 2) will arise between r and s sites where $\Delta E^{(1)}$ of Eq. 8 is negative and as large as possible in its absolute value. In other words, v_{rs} being negative, q_{rs} should be positive and as large as possible.

We give two examples: Benzene-anthracene pair and benzene-phenanthrene pair. As is shown in Fig. 3(a), benzene and anthracene approach with each other keeping their molecular plane parallel, and make a bond between the *1*-site of benzene and the *7*-site of anthracene. The calculated results of which absolute values are considerably large are shown in Table 1a. Observing the data we can expect new bonds between sites *2* and *14*, or between sites *4* and *8*. If we consider that the new bond is likely under the condition that the original *1-7* bond does not shift so much, it should be concluded that the pair under consideration is stable at the conformation, I or III in Fig. 4.

From the symmetry consideration it is enough to select the anthracene sites *7-10* to make similar treatments. From Table 1b which refers to the *1-8* original bond, we expect again the conformation III. Table 1c corresponding to the *1-9* original bond suggests con-

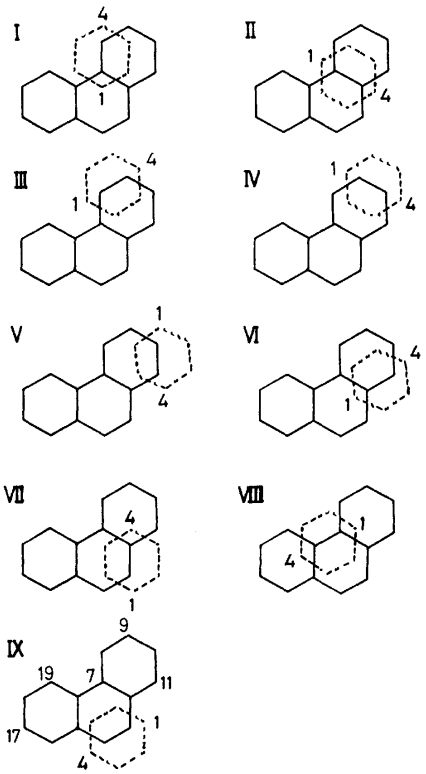

Fig. 5. Various conformations of benzene–phenanthrene pair.

formations II and IV. Finally from Table 1d referring to the original *1-10* bond we can expect the conformation V. Unexpectedly we can not find the conformation VI from Table 1d.

From the preceding considerations we find that, in every compound, benzene rings avoid the face-to-face structure as if the steric effect be satisfactorily taken into account. This fact is already pointed out by one of the present authors.[5]

The entirely same investigation is also applied to the benzene-phenanthrene pair. From the symmetry consideration the phenanthrene sites combining with the benzene *1*-site are selected to be *7—13* in Fig. 3(b). As an example we evaluate bond orders in the case of the pair with the *1-7* original bond. The results are shown in Table 2. From this it is easy to presume that conformations I and II in Fig. 5 are likely. Similar considerations for cases involving sites *8—13* in phenanthrene lead to various conformations III—VII in Fig.5.

Intermolecular Interaction

If we take the separated molecules, A and B as the unperturbed system, the additional energy is of the second order to the perturbation v. We find a little more complicated expression than that of Eq. 7, as

$$\Delta E^{(2)} = Tr \frac{1}{2\pi i}\int_c dz G_A^0 v_{AB} G_B^0 u_{BA} , \tag{17}$$

where the factor 1/2 in the first line of Eq. 7 cancels out with the factor arising in interchanging A and B in the above. Then the straightforward calculation yields:

$$\Delta E^{(2)} = 2\sum_{rs}^{A}\sum_{tu}^{B} \left\{ \sum_{iA}^{occ}\sum_{\mu B}^{un} \frac{1}{\varepsilon_{iA}-\varepsilon_{\mu B}} [<r|i><i|s>]^A v_{st}^{AB} [<t|\mu><\mu|u>]^B v_{ur}^{BA} + \sum_{\mu A}^{un}\sum_{iB}^{occ} \frac{1}{\varepsilon_{iB}-\varepsilon_{\mu A}} [<r|\mu><\mu|s>]^A v_{st}^{AB} [<t|i><i|u>]^B v_{ur}^{BA} \right\} \tag{18}$$

where the numerical factor 2 is due to the spin sum.

Now we want to take the closure approximation. Replacing the energy denominators in the above by suitable averages, for example

$$\Delta\varepsilon_{BA} \simeq <\varepsilon_{\mu B}-\varepsilon_{iA}>_{av},\ \Delta\varepsilon_{AB} \simeq <\varepsilon_{\mu A}-\varepsilon_{iB}>_{av}, \tag{19}$$

we obtain

$$\Delta E^{(2)} = \frac{-1}{2}\sum_{rs}^{A}\sum_{tu}^{B} \left\{ \frac{1}{\Delta\varepsilon_{BA}} q_{rs}^A v_{st}^{AB} q_{tu}^B v_{ur}^{BA} + \frac{1}{\Delta\varepsilon_{AB}} q_{rs}^A v_{st}^{AB} q_{tu}^B v_{ur}^{BA} \right\} \tag{20}$$

where q_{rs}^B is the bond order and (see Eq. 14)

$$\hat{q}_{tu}^B = 2\delta_{tu} - q_{tu}^B . \tag{21}$$

Next we evaluate the change of bond order due to v. To this end we begin with the expansion

$$G_B = G_B^0 + G_B^0 v^{BA} G_A^0 v^{AB} G_B^0 + \cdots \tag{22}$$

and obtain

$$\Delta q_{rs}^B = \frac{1}{2\pi i}\int_c dz (G_B - G_B^0) = \sum_{s's''t't''} \frac{1}{2\pi i}\int_c dz G_{B,rs'}^0 v_{s's''}^{BA} G_{A,s''t'}^0 v_{t't''}^{AB} G_{B,t''s}^0 . \tag{23}$$

Substituting Eq. 9 in the above, and integrating along the Coulson contour, we obtain the result:

$$\begin{aligned}\Delta q_{rs}^B = 2\sum_{s't''}^{A}\sum_{s''t'}^{B} \Bigg\{ & \sum_{iB}^{occ}\sum_{jA}^{occ}\sum_{kB}^{un} \frac{-2}{(\varepsilon_{kB}-\varepsilon_{iB})(\varepsilon_{kB}-\varepsilon_{jA})} \\ & + \sum_{iB}^{coo}\sum_{jA}^{un}\sum_{kB}^{occ} \frac{-1}{(\varepsilon_{jA}-\varepsilon_{iB})(\varepsilon_{jA}-\varepsilon_{kB})} \\ & + \sum_{iB}^{occ}\sum_{jA}^{un}\sum_{kB}^{un} \frac{2}{(\varepsilon_{jA}-\varepsilon_{iB})(\varepsilon_{kB}-\varepsilon_{iB})} \\ & + \sum_{iB}^{un}\sum_{jA}^{occ}\sum_{kB}^{un} \frac{1}{(\varepsilon_{iB}-\varepsilon_{jA})(\varepsilon_{kB}-\varepsilon_{jA})} \Bigg\} \\ & \times <r|i><i|s'>^B v_{s's''}^{BA} <s''|j><j|t'>^A v_{t't''}^{AB} <t''|k><k|s>^B .\end{aligned} \tag{24}$$

Now we employ the closure approximation in the above and obtain

$$\begin{aligned}\Delta q_{rs}^B = \frac{1}{4}\sum_{s't''}^{B}\sum_{s''t'}^{A} \Bigg\{ & \frac{-2}{\Delta\varepsilon_{BB}\Delta\varepsilon_{BA}} q_{rs'}^B v_{s's''}^{BA} q_{s''t'}^A v_{t't''}^{AB} \hat{q}_{t''s}^B \\ & + \frac{-1}{\Delta\varepsilon_{AB}\Delta\varepsilon_{AB}} q_{rs'}^B v_{s's''}^{BA} \hat{q}_{s''t'}^A v_{t't''}^{AB} q_{t''s}^B \\ & + \frac{2}{\Delta\varepsilon_{AB}\Delta\varepsilon_{BB}} q_{rs'}^B v_{s's''}^{BA} \hat{q}_{s''t'}^A v_{t't''}^{AB} \hat{q}_{t''s}^B \\ & + \frac{1}{\Delta\varepsilon_{BA}\Delta\varepsilon_{BA}} \hat{q}_{rs'}^B v_{s's''}^{BA} q_{s''t'}^A v_{t't''}^{AB} \hat{q}_{t''s}^B \Bigg\} .\end{aligned} \tag{25}$$

Here we again stress that the change of bond order does arise from additional contributions of some reaction pathes which are constructed of bond orders and interaction matrix elements. We can get, with a little sacrifice of accuracy in Eq. 24, a very transparent physical insight of the phenomena under consideration.

We present numerical results in the followings. The parameters used here are:

1. The distance of molecular planes (e.g. between benzene and anthrathene planes) is assumed to be 2 in the unit of the benzene bond distance (1.39 Å).

2. The values of v_{rs} are estimated to be reciprocally proportional to the cube of the r-s distance, and are assumed to be zero for cases with distances larger than 8. Then a multicative factor *2* is applied because of the σ-bond character of v_{rs}.

In Table 3, we have shown the calculated results of various conformations of benzene-anthracene pair. The first column presents the types of pairs as displayed in Fig. 4. The energy changes of the second column are given in the unit of $|\beta|$. The minus sign indicates the system to be stable. The values of the first line is obtained by the closure approximarion, Eq. 20, while the second line by the relation without approximation, Eq. 18. Agreements between them are remarkable, though the values themselves are rather qualitative. The following columns present the changes of charge densities at various benzene sites. As to these, the agreements between the first and second lines are not so satisfactory as in the case of energy. This is a

well-known trend in quantum chemistry. We can say, the values of the second lines are more reliable.

We have carried out calculations for the type VI, not acceptable in the previous treatment, and find that this is not so stable, as is type V.

The calculations for the various types of the benzene-phenathrene pair are given in Table 4. The results are almost satisfactory as was seen in the case of benzene-anthracene pair. If we regard phenanthrene as a prototype of benz[*a*]pyrene (a famous chemical carcinogen), we can find stable structures in which the benzene molecule sits on areas extending over the so-called Bay, K, and L regions.

Benzo[*a*]pyrene-Guanine Pair

Benzo[*a*]pyrene is a famous chemical carcinogen, of which activity has been widely discussed connecting with its structure or its derivatives produced by the metabolic reactions.[6] Though recent studies rather stress the metabolic effect, we come back to an old-fashioned view of chemical carcinogenesis, based on the direct combination of carcinogen with nucleotide.

Replacing benzene and phenanthrene in the previous section by guanine and benzo[*a*]pyrene, respectively, we carry out the same treatment as before. However, in this time we have not tried to optimize the mutual orientation of these molecules, but begin with assuming several conformations as described in Fig. 6, which are presumed from the investigation of the benzene-phenanthrene pair. Empirical parameter added to previous ones are

$$\alpha(\ddot{\mathrm{O}})=2.0\beta,\quad \alpha(\ddot{\mathrm{N}})=1.5\beta,\quad \alpha(\dot{\mathrm{N}})=0.5\beta \tag{26}$$

where the dotts represent the number of π electrons given by these atoms.

Strictly speaking, it is inadequate to disregard cytosine bonded with guanine by hydrogen bonds (see Fig. 7). We have to imagine cytosines at the appropriate positions in conformations I—V of Fig. 6. Calculated results are in Table 5. In each row, the numerals of the first line are obtained by the closure approximation (Eqs. 20 and 25), and those of the second line are without this approximation. Therefore the latter is a little

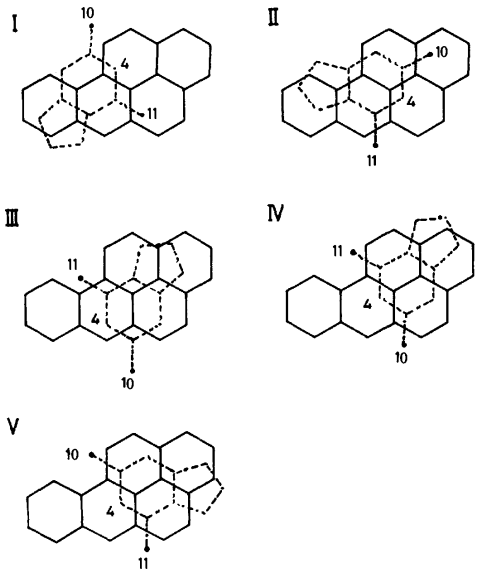

Fig. 6. Various conformations of guanine-benzo[*a*]pyrene pair.

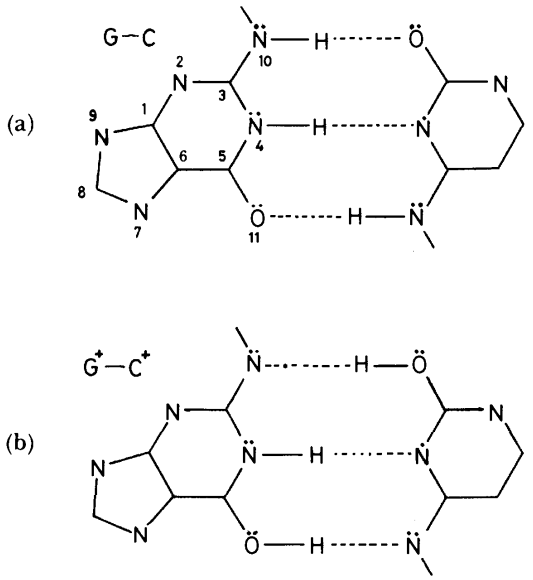

Fig. 7. Conformations of guanine-cytosine pair.

more reliable, even though it is quite crude from the quantitative viewpoints. However we may insist that if we pass from column to column, or from row to row, the trends observed there tell us something true. The types I and II are not energetically stable. The conformation adopted in a current investigation,[7] is an almost face-to-face structure, because of the maximum overlap between π orbitals of the composite molecules being achieved. As mentioned before, this is not necessarily favorable for molecular compounds.

The conformations III—V are stable, where the mutual arrangement of guanine and cytosine is opposite in the direction to that of I and II. In these stable structure we estimated the changes of charge densities at the positions relating to the hydrogen bonds. We proceed discussions based upon the data of the second

lines in Table 5. In Fig. 7(a), we present the normal guanine-cytosine pair in which three hydrogen bonds are there. We can see that, in Table 5, a considerably large increase of charge arises at the *10*-N̈ (the upper most N̈ in Fig. 7(a)). This shifts the proton of NH group in guanine toward the oxygen of cytosine, and results in shitfing the proton of the NH group in cytosine toward the oxygene of guanine. As a result, we have a new pair denoted G*-C* in Fig. 7(b). It is understood that, in the new pair, the original two hydrogen bonds are lost, and only a weak hydrogen bond remains, and this conformation might be a source of mutation.

One may say the above consideration is old, and seems almost denied. The O- or OH- substituted benzo[*a*]pyrene produced by the metabolic reaction strongly binds the nucleotide, so that the order of nucleotide is confused to arise the mutation. However we may argue the present investigation especially of the mutual orientation between composite molecules is still suggestive in the further investigation to chemical carcinogen.

Concluding Remarks

In the present work, the intermolecular interaction is treated as a perturbation of the sigle-particle character between molecules. We have assumed that the intermolecular distance and other geometrical factors are almost predetermined by other mechanical sources, e.g., the van der Waals interaction and so on. In other words, we consider that two molecules come near to an appropriate position and the charge exchange begins to work between them.

In the usual treatments, the local interactions are taken into account for predominantly determining geometrical structure of the molecular complex, i.e., the maximum overlap between atomic orbitals of composite molecules being achieved. This consideration inevitably leads to the face-to-face structure for the present systems, and then an undesirable feature is avoided by introducing a steric effect of it. Really the structure experimentally observed is not of a face-to-

face type, but is that the benzene ring of one molecule shifts by about a half of width relatively to that of the other moledule. What we have claimed here is follows: This preferable structure is explained energetically, that is to say, the additional energy producing a stable structure is arisen by the product of the transfer integral between sites under consideration and the coresponding long-range bond order. The latter that is hiden before introducing the perturbation is a decisively important factor to determin geometrical structure.

Next, supposing that the geometrical structure of a couple of molecules is given by the previous analysis, we treat the intermolecular interaction as a second order perturbation problem with respect to transfer matrix elements. The propagator technique enable us to obtain the complicated results very easily. The resultant expression is reinterpreted by introducing the closure approximation: The stabilization aises as an effect from a closed path constructed of bond orders and interaction matrix elements. We should like to stress a deep understanding of the bond order of a quantum mechanical and wave-functional character.

As a final example, interaction between guanine and benzo[*a*]pyrene is investigated. This is rather old-fashioned, but might be helpfull in remembering a conformational investigation apt to be missed in the recent studies.

A Study of Inorganic Ion Exchangers. XI. The Hydrothermal Reactions of $ZrOCl_2$ and $M(H_2PO_4)_2$ (M=Mg, Ca, Sr, Ba)

Kiyomi OKABE* and Etsuro KOBAYASHI
National Chemical Laboratory for Industry, Yatabe, Tsukuba, Ibaraki 305
(Received October 22, 1986)

The possibility of the hydrothermal synthesis of layered zirconium phosphates containing various alkaline earth metals (abbreviated as ZrMP; M=Mg, Ca, Sr, Ba) has been studied from $ZrOCl_2$ and $M(HPO_4)_2$, and their characteristics have been investigated. The optimum conditions for the synthesis of a highly crystalline product were as follows; the molar ratio of the starting materials of $Ca(H_2PO_4)_2$ and $ZrOCl_2$ was Ca/Zr=3, and the temperature of the hydrothermal reaction was in the range of 200—270 °C. By the hydrothermal reaction of $ZrOCl_2$ and $Mg(H_2PO_4)_2$, a new compound of $ZrMg_{0.5}H(PO_4)_2 \cdot H_2O$ with a layer-spacing of 11.94 Å was obtained. Layered phosphate (ZrMP) was not obtained by the hydrothermal reaction of $ZrOCl_2$ and $Ba(H_2PO_4)_2$. The temperature range of the inter-layer dehydration of the layered phosphates (ZrMgP, ZrCaP, and ZrSrP) was similar to that of α-zirconium(IV) bis(hydrogenphosphate) (α-ZrP); i.e. the water in the interlayer was lost at 130—240 °C, and dehydro-condensation took place at a higher temperature above 340 °C. Zirconium phosphate containing Mg^{2+} or Ba^{2+} was not obtained by the ion exchange of the protons in α-ZrP with the alkaline earth metal cations (M^{2+}) in MCl_2, while Ca^{2+} and Sr^{2+} were exchanged with the protons. These alkaline earth metal ions except for Ba^{2+} were easily exchanged with H^+ in α-ZrP, when NaOH was added. The layer-spacing of the Mg^{2+}-exchanged zirconium phosphate was 9.6 Å, which was different from that of the hydrothermal product. The layer distances of Ca^{2+}- or Sr^{2+}-exchanged products were similar to those of the hydrothermal products.

Layered tetravalent metal phosphates are widely used as inorganic ion-exchangers of great importance. Much attention has been paid recently for the layered compounds with different molecules and ions as catalysts for various reactions.[1)]

As reported previously,[2)] α-zirconium phosphates containing tertiary amines or aluminum ions between the layers have been synthesized hydrothermally, and used as catalysts for methanol conversion. However, a thermally stable layered phosphate having a wide inter-layer distance was not obtained.

This paper reports whether layered zirconium phosphates containing alkaline earth metal ions (abbreviated as ZrMP; M^{2+}=Mg^{2+}, Ca^{2+}, Sr^{2+}, Ba^{2+}) may be hydrothermally synthesized, and discusses the difference between the hydrothermal products and the layered compounds obtained by ion-exchange of H^+ in α-zirconium(IV) bis(hydrogenphosphate) (abbreviated as α-ZrP) with alkaline earth metal ions.

Experimental

Hydrothermal Reactions of $ZrOCl_2$ and $M(H_2PO_4)_2$ (M=Mg, Ca, Sr, Ba). A glass tube (20 cm^3) was filled with the appropriate amount of $ZrOCl_2 \cdot 8H_2O$, $M(H_2PO_4)_2$, H_2O, and NaCl or $Ca(OH)_2$ as listed in Table 1. After stirring the mixture thoroughly, the tube was sealed, and autoclaved (200—270 °C; 93—106 h). The hydrothermal products were separated from the mother liquor by centrifugation, and were washed with distilled water. The products were dried in a desiccator at 75% relative humidity.

Ion Exchange of H^+ in $Zr(HPO_4)_2$ with M^{2+} in MCl_2 (M=Mg, Ca, Sr, Ba). 100 cm^3 of an aqueous solution of MCl_2 (0.1 mol dm^{-3}) was added to 1.00 g of $\alpha\text{-}Zr(HPO_4)_2 \cdot H_2O$ (α-ZrP) and stirred overnight at room temperature. The precipitate was washed and separated by centrifugation. 50 cm^3 of an aqueous solution of MCl_2 (0.2 mol dm^{-3}) was added to 1.00 g of α-ZrP and stirred. Thirty cm^3 of an aqueous solution of NaOH (0.1 mol dm^{-3}) was slowly added to the mixture with vigorous stirring. The precipitate was washed and separated as described above.

Chemical Analysis. The composition of the products was determined as follows.[3)] The amount of H_2O was determined on the basis of the weight loss of the samples heated up to 800 °C.

The heated product was fused with 2.0 g of flux (Na_2CO_3:K_2CO_3=1:1) at 1000 °C. After cooling, the fused product was dissolved in distilled water at 100 °C, and 6 mol dm^{-3} HCl was added in order to dissolve the solid completely. Zirconium hydroxide was precipitated by adding 6 mol dm^{-3} NH_3 aq to the solution, and separated by filtration. After igniting the precipitate, a gravimetric method was employed for the determination as ZrO_2.

The phosphate ion in the filtrate was determined absorptiometrically, by the JIS K-0102 method.

The alkaline earth metals in the products were determined by atomic absorption after dissolving it.

Instrumental Analysis. The X-ray diffraction (XRD) was performed with Cu $K\alpha$ radiation (30 kV, 20 mA), by using an X-ray diffractometer (Rigaku, Geigerflex RAD). A scanning electron microscope (Shimadzu, ASM-SX) was employed for observation of the surfaces of the hydrothermal products. Surface areas of the products were determined by adsorption of argon at liquid nitrogen temperature using a fully-automatic surface area analyzer (Shimadzu, Micromeritics 2200). A micro-thermal analyzer, with 100 μV of DTA sensitivity and ±20 mg of TG sensitivity was used for the thermal analysis.

Results and Discussion

Hydrothermal Reaction of $ZrOCl_2$ and $Ca(H_2PO_4)_2$. The conditions of the hydrothermal reaction of zirconium(IV) oxychloride and various alkaline earth metal salts of bis(dihydrogenorthophosphate), as well as the analytical data of the products, are listed in Table 1.

Effects of Reaction Temperature. By varying the

a) M=Ca for No. 1—7; M=Mg (4 mol dm^{-3} $Mg(H_2PO_4)_2$) for Nos. 8 and 9; M=Sr for Nos. 10 and 11; M=Ba for Nos. 12 and 13. b) NaCl for Nos. 6, 9, 11, and 13; $Ca(OH)_2$ for No. 7.

reaction temperature, it was found that the products were amorphous below 150 °C, but that highly crystalline products were obtained above 200 °C. The X-ray diffraction intensity of the products increased in the order of No. 1 (200 °C)<No. 2 (250 °C)<No. 3 (270 °C) in Table 1.

The average content of P_2O_5 in these products was about 42% and was almost the same as that of α-zirconium(IV) bis(hydrogenphosphate) (42.09%). About 40% of the ZrO_2 content in the product was a little higher than that of α-zirconium(IV) bis(hydrogenphosphate) (α-Zrp). The CaO content was in the range of 1.1—2.7%, corresponding to about 0.1 mol of P_2O_5. The average H_2O content was 13.7%, which was slightly higher than that (10.68%) of α-ZrP.

Effects of $Ca(H_2PO_4)_2/ZrOCl_2$ Molar Ratio (Ca/Zr). The Ca/Zr molar ratios in the hydrothermal products of Nos. 4, 2, and 5 are listed in Table 1, and the XRD patterns of these samples are shown in Fig. 1. The XRD patterns of the products were almost the same as those of α-ZrP, except for a new peak at 2θ=8.7—8.9°. The new peak suggests the partial expansion of the layer distance of the products by the intercalation of Ca^{2+} between the layers. The crystallinity of the pro-

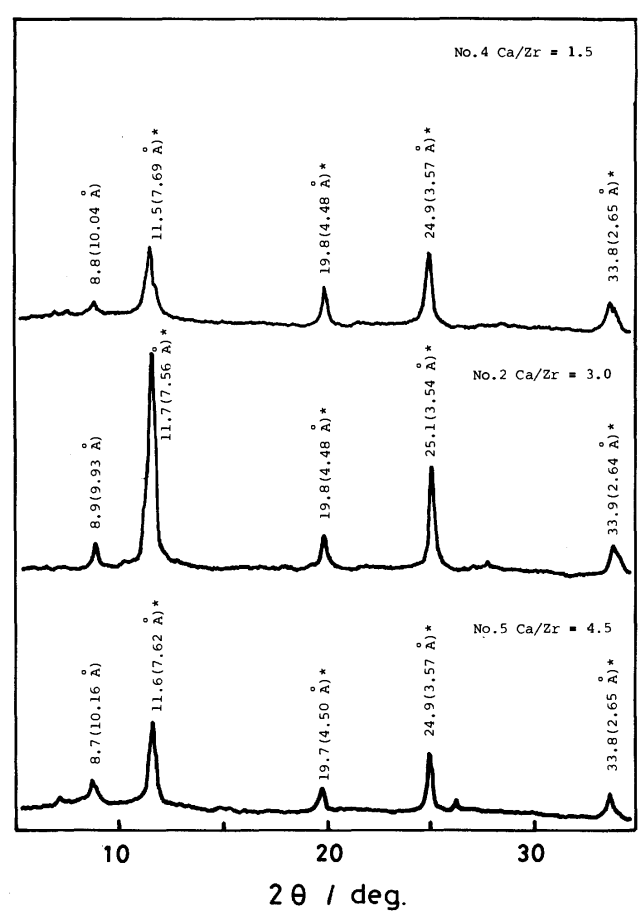

Fig. 1. X-Ray diffraction patterns of reaction products of $ZrOCl_2$ with $Ca(H_2PO_4)_2$ (Influence of molar ratio of $Ca(H_2PO_4)_2/ZrOCl_2$ (Ca/Zr)). Numerals on peaks indicate 2θ/degrees and lattice distances. *: The diffraction peaks of α-ZrP.

duct No. 4 (Ca/Zr=1.5) was low, suggesting an insufficient amount of phosphate in the starting materials. When the Ca/Zr ratio was 4.5 (No. 5), the XRD intensity was low. The crystallization of the product was assumed to be prevented by the excess amount of Ca in the starting materials. Therefore, the molar ratio of Ca/Zr=3.0 (No. 2) was optimal for the crystallization of the hydrothermal product (ZrCaP).

Effects of Additives. On the hydrothermal reaction of $ZrOCl_2$ and $Ca(H_2PO_4)_2$, appropriate amount of NaCl and $Ca(OH)_2$ were added. The XRD patterns of the products are shown in Fig. 2.

It is known that the layer distance is expanded up to 11.8 Å by the ion exchange of H^+ in α-ZrP with Na^+, and then Mg^{2+} is easily introduced between the layers after the expansion.[4,5] Expecting a similur effect, addition of NaCl was carried out in this investigation. The first d-value of the product No. 6 (NaCl addition) was 9.93 Å. The XRD pattern was not changed remarkably by the addition. Additional weak peaks in the XRD pattern were observed at 13.9, 19.5, 23.9, 28.1, and 31.1° by the NaCl addition. These new peaks did not belong to those of α-ZrP in the Na^+ form.

In order to obtain a product having a high content of Ca^{2+}, $Ca(OH)_2$ was added (No. 7). As shown in Table 1, the pH of the mother liquor was a little higher (pH=3.3) than the solution without $Ca(OH)_2$ (pH=2.5—2.7). The reaction product contained higher amounts of ZrO_2 and CaO than the others (Nos. 1—3). It was suspected from this result that the product was a mixture of zirconium(IV) hydroxide, calcium hydrogenphosphate ($CaHPO_4$) and zirconium phosphates.

Hydrothermal Reaction of $ZrOCl_2$ and $Mg(H_2PO_4)_2$. The hydrothermal synthesis of Mg-salts was examined under the optimal conditions similar to the case of Ca (Nos. 2, 6, and 7). The XRD patterns of the products (Nos. 8 and 9 in Table 1) were shown in Fig. 3. The chemical analysis of the samples suggests that the composition of the products corresponded to $ZrMg_{0.5}H(PO_4)_2 \cdot H_2O + 1/2[Zr(OH)_4 \cdot H_2O]$. When NaCl was added (No. 9), the product contained only a slight amount of Na. The XRD pattern was similar to that of No. 8. These results showed that the addition of NaCl had no effect on the crystal form of the product. The first d-value was 11.94 Å, and was larger than that of α-ZrP (7.56 Å). As mentioned below, the XRD pattern showed many additional peaks, suggesting that the product was a mixture of zirconium(IV) hydroxide, magnesium phosphates and layered zirconium(IV)

phosphate containing Mg^{2+} (ZrMgP).

Hydrothermal Reaction of $ZrOCl_2$ and $Sr(H_2PO_4)_2$. The Sr-containing products are listed in Table 1, and the XRD patterns are shown in Fig. 4. The chemical analysis showed that the ZrO_2 content was lower than α-ZrP by about 10%, and that the SrO content was up to about 20%. The first d-value was 10.39 Å in the XRD pattern, suggesting that the product was a mixture of strontium hydrogenphosphate ($SrHPO_4$) and layered zirconium(IV) phosphate containing Sr^{2+} between the layers (d=10.2 Å).[7] This is supported by the fact that a part of the product was dissolved by treatment with HCl to leave zirconium(IV) bis(hydrogenphosphate). The reaction product No. 11 (NaCl addition) contained larger amount of ZrO_2 than No. 10. The first d-value was 9.02 Å, suggesting a wide layer spacing, but the product was easily dissolved in 1 mol dm^{-3} HCl solution. Therefore, it cannot be layered zirconium phosphate, since zirconium phosphate should be stable in acidic conditions in general.

Hydrothermal Reaction of $ZrOCl_2$ and $Ba(H_2PO_4)_2$. The Ba-salts are listed in Table 1 (Nos. 12 and 13), and the XRD patterns are shown in Fig. 4. The BaO contents of the salts were as high as 25%. The peaks corresponding to α-ZrP were not found in the XRD patterns. The salts were easily dissolved in HCl solution. These results suggest that layered zirconium phosphate did not form in this reaction.

Treatment of Hydrothermal Products with Hydrochloric Acid. As mentioned above, when 1.00 g of the hydrothermal products were treated with 1 mol dm^{-3} HCl solution (100 cm^3), the products containing Mg, Ca, or Sr were partially dissolved and the weight was reduced to 0.76, 0.82, and 0.50 g, respectively. The Ba-salt was completely dissolved by this treatment. The XRD pattern of the Mg-salt treated with HCl is shown in Fig. 5. The XRD pattern of α-ZrP is also shown as the reference. The Mg-salt was turned into α-ZrP by this treatment. The by-products were dissolved in HCl solution, and the alkaline earth cations between the layers of the main products were exchanged with protons by this treatment.

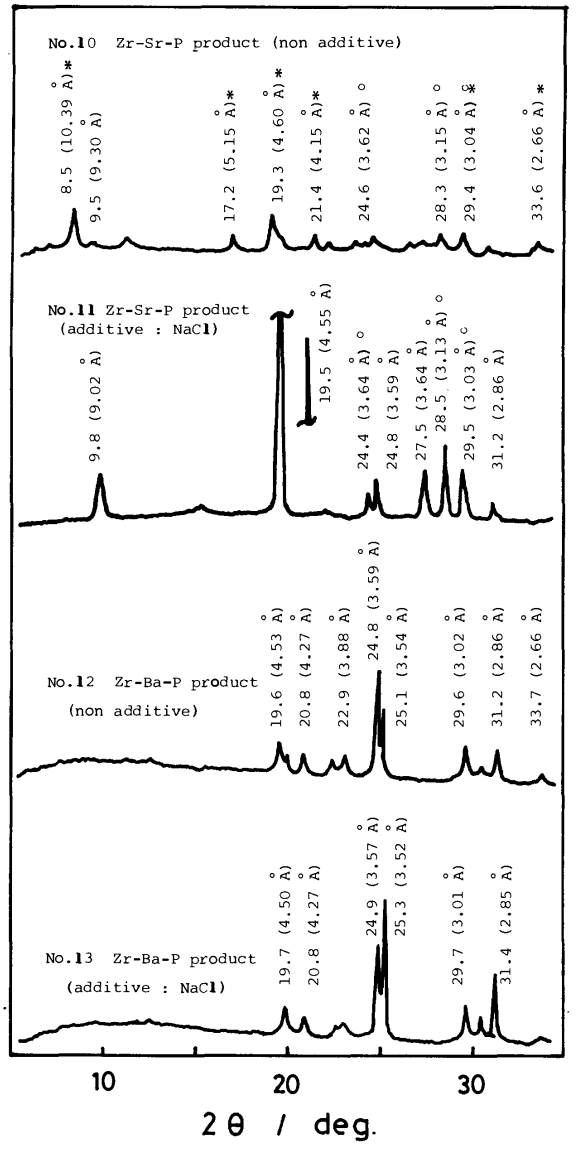

Fig. 4. X-Ray diffraction patterns of reaction products of $ZrOCl_2$ with $Sr(H_2PO_4)_2$ and $ZrOCl_2$ with $Ba(H_2PO_4)_2$. Numerals on peaks indicate 2θ/degrees and lattice distances. *: The diffraction peaks of α-ZrP containing Sr^{2+} between the layers, O: the diffraction peaks of $SrHPO_4$.

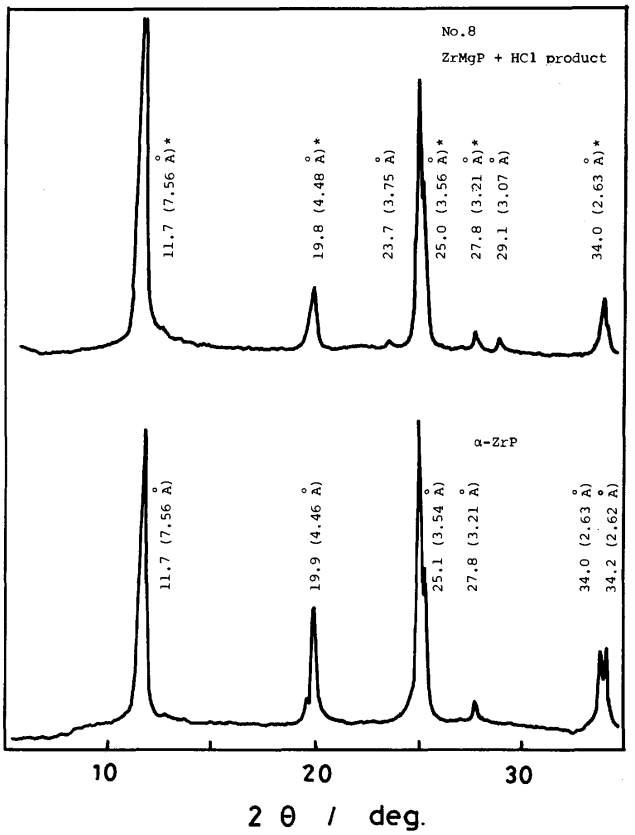

Fig. 5. X-Ray diffraction patterns of HCl-treated products of ZrMgP (No. 8) and α-$Zr(HPO_4)_2 \cdot H_2O$ (α-ZrP). Numerals on peaks indicate 2θ/degrees and lattice distances. *: The diffraction peaks of α-ZrP.

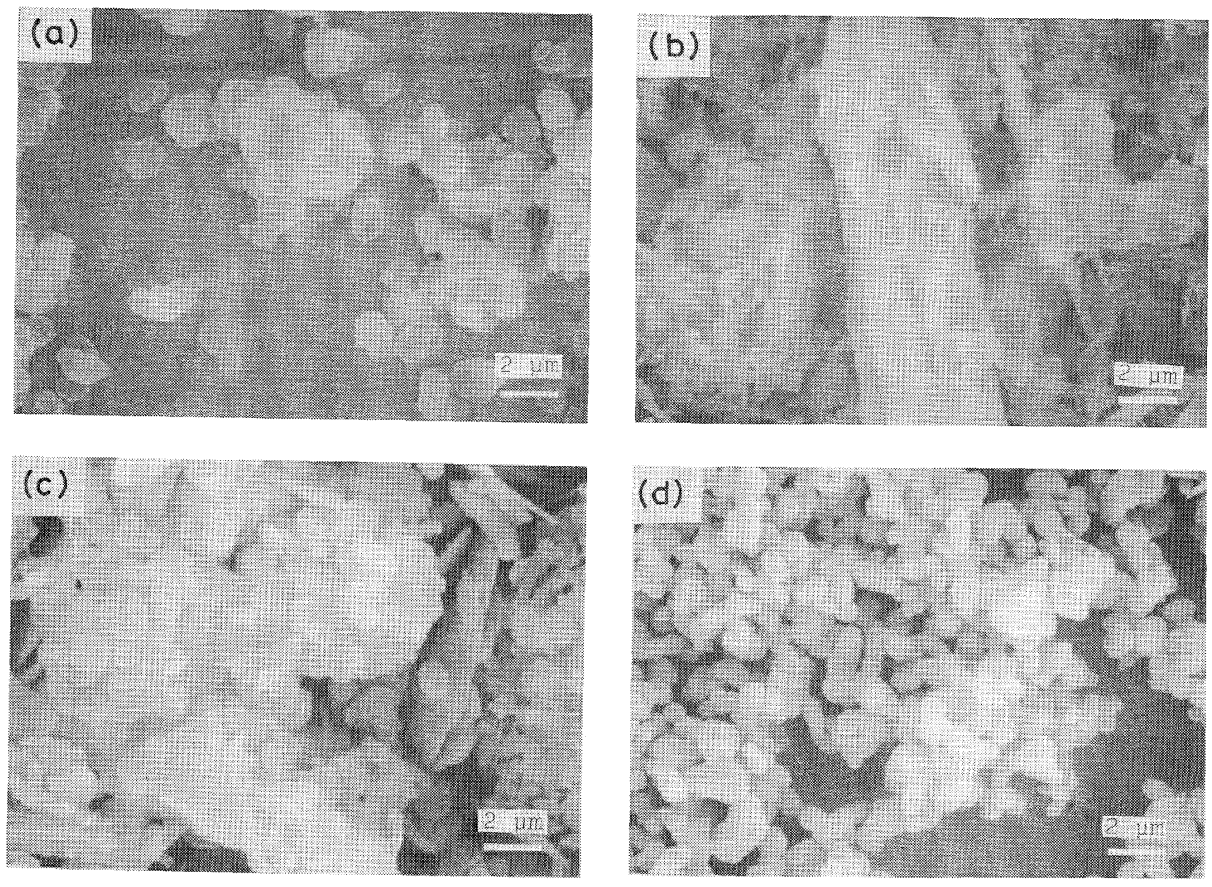

Fig. 6. Scanning electron micrographs of (a) reaction product No. 2, (b) reaction product No. 8, (c) reaction product No. 8 treated with HCl, and (d) α-$Zr(HPO_4)_2 \cdot H_2O$ (α-ZrP).

SEM Results. A few products were observed by a scanning electron microscope (SEM), and are shown in Fig. 6. The scale below right of each picture denotes 2 μm.

The product No. 2 containing Ca (a) had a hexagonal plate shape, with a diameter of about 1 μm. The surface area was estimated by BET method at 9.4 $m^2 g^{-1}$, which was smaller than that of α-ZrP (14 $m^2 g^{-1}$) or γ-ZrP (22 $m^2 g^{-1}$).

The shape of the product No. 8 containing Mg (b) was hexagonal plate. But the crystals seemed to be columns because they were associated and the large crystals were surrounded by small needles. The surface area of the product was estimated at 11 $m^2 g^{-1}$.

After the HCl treatment, the product No. 8 changed into large hexagonal plate crystals (c). The shape resembled that of α-ZrP (d). The crystallinity of the HCl-treated product was high, but the crystals were associated.

Thermal Analyses. The DTA and TG curves of the products are shown in Fig. 7 with those of α-ZrP. The endothermic peaks at 130—245 °C in DTA of the products containing Ca (No. 2) or Mg (No. 8), as well as α-ZrP, corresponded to the desorption of water from the interlayers. The endothermic peak of the Sr-containing product (No. 10) at 100 °C was not due to the dehydration between the layers of zirconium(IV) phosphate containing Sr, but to dehydration of other compounds. The dehydro-condensation between the layers of the phosphates gradually occurred above 340 °C, and the TG curves were similar to that of α-ZrP.

Ion Exchange of H^+ in α-ZrP with M^{2+} ($M=Mg^{2+}$, Ca^{2+}, Sr^{2+}, Ba^{2+}). All of the hydrothermal products obtained by the reaction of $ZrOCl_2$ and $M(H_2PO_4)_2$, except for the case of M=Ba, were turned into α-ZrP by the HCl treatment. Thus, it was investigated whether the same compounds as the hydrothermal products could be obtained by the ion exchange of H^+ in α-ZrP with M^{2+} or not. The ion exchange has already been investigated by Alberti et al.[6] and Clearfield et al.[7] They reported that Na^+ acts as a catalyst for the reactions.[4,5] In this paper, ion exchange of the proton in α-ZrP with M^{2+} was compared (1) in the absence and (2) presence of NaOH. The ion exchange conditions and the analytical data are listed in Table 2. The pH of the reaction solution was acidic in each case. The pH decreased in spite of the addition of NaOH, indicating that the ion exchange was accelerated by the addition. The XRD patterns of the ion-exchanged products are shown in Fig. 8. The XRD profile of (a) was almost the same as that of α-ZrP, indicating that ion exchange did not occur. In the case of (b), the peak corresponding to the basal spacing of α-ZrP at

a) α-$Zr(HPO_4)_2 \cdot H_2O$. b) $MgCl_2 \cdot 6H_2O$ for Nos. 1 and 2; $CaCl_2 \cdot 2H_2O$ for Nos. 3 and 4; $SrCl_2 \cdot 6H_2O$ for Nos. 5 and 6; $BaCl_2 \cdot 2H_2O$ for Nos. 7 and 8. c) 0.1 mol dm^{-3}.

2θ=11.7° (7.5 Å) decreased, and a new peak appeared at 2θ=9.2° (9.60 Å). In this reaction, it was considered that the proton in α-ZrP was first exchanged with Na^+ and then with Mg^{2+}. However, the chemical analysis showed that the Na content of the product was negligible. The product was a mixture of α-ZrP and a Mg^{2+}-exchanged compound having the same layer-spacing as $ZrMg_{0.75-1}H_{0.5-0}(PO_4)_2 \cdot H_2O$ (9.64 Å).[7] The layer-spacing was a little smaller than that of reported compounds $ZrMg_{0.5}H(PO_4)_2 \cdot 3H_2O$ (9.9 Å)[8] and $ZrMg_{0.72}H_{0.56}(PO_4)_2 \cdot 4H_2O$ (9.85 Å).[4] The Mg^{2+}-exchanged compound had a different layer-spacing from the hydrothermal product (11.94 Å), as mentioned above.

In the XRD profiles of (c) and (d), the peak intensity corresponding to the basal spacing of α-ZrP (7.56 Å) decreased, and a new peak appeared at 2θ=8.9° (9.93 Å). The intensity of the new peak increased on

(a): α-ZrP+$MgCl_2$, (b): α-ZrP+$MgCl_2$+NaOH, (c): α-ZrP+$CaCl_2$, (d): α-ZrP+$CaCl_2$+NaOH, (e): α-ZrP+$SrCl_2$, (f): α-ZrP+$SrCl_2$+NaOH, (g): α-ZrP+$BaCl_2$, (h): α-ZrP+$BaCl_2$+NaOH.

the addition of NaOH (d). This fact clearly implies that the layer distance (9.93 Å) of the ion-exchanged product with Ca^{2+} was similar to that of the corresponding reported compounds, $ZrCa_{0.5\text{-}0.65}H_{1\text{-}1.7}(PO_4)_2 \cdot 3H_2O$ (9.4 Å)[7] or $ZrCa_{0.8\text{-}1.0}H_{0.3\text{-}0}(PO_4)_2 \cdot 4H_2O$ (9.64 Å),[7] and the distance was in accord with that of $ZrCa_{0.63}H_{0.74}(PO_4)_2 \cdot H_2O$ (9.98 Å)[6] within the experimental error, and perfectly agreed with that of the hydrothermal product. The composition of (d) compound (NaOH addition) was determined to be $ZrCa_{0.75}H_{0.5}(PO_4)_2 \cdot 3H_2O$.

The XRD pattern of (e) showed that the proton in α-ZrP was exchaned with Sr^{2+} only slightly. By the addition of NaOH (f), the peak corresponding to the basal spacing of α-ZrP disappeared in the XRD profile, and changed into the peak of the ion-exchanged product (10.27 Å). The value was in good accord with those of the hydrothermal product (10.39 Å) mentioned above and the reported compound $ZrSrH(PO_4)_2 \cdot 3.6H_2O$ (10.2 Å)[8] within the experimental error.

The XRD profile of the reaction product of α-ZrP and $BaCl_2$ (g) was almost the same as that of α-ZrP, suggesting that ion exchange did not occur. In the XRD pattern of (h), the peak intensity decreased and new peaks appeared at 2θ=17.4, 21.4, 23.9, and 30.5°. The peak corresponding to the basal spacing was not clear. As for such a compound, $ZrBa_{0.8\text{-}1}H_{0.4\text{-}1}(PO_4)_2 \cdot 2H_2O$ has been reported.[7]

Vapor Phase Fluorination of Silica Surface with Chlorofluoromethanes and CF_4

Susumu OKAZAKI* and Akito KUROSAKI
Department of Industrial Chemistry, Faculty of Engineering, Ibaraki University, Nakanarusawa, Hitachi, Ibaraki 316
(Received November 22, 1986)

For a surface modification, fluorinations of silica samples including a quartz fiber and a commercial glass fiber, were carried out at around 500 °C in a conventional flow reactor. The surface compositions before and after the fluorination were determined by XPS analyses. Among chlorofluoromethanes and CF_4, CCl_3F was the most effective for fluorination. Surface OH groups were completely removed or replaced by the fluorination. Adsorptions of water vapor, hexane, hexafluoropropene, and octafluorocyclobutane showed that the silica surface became more hydro- and lipophobic after the fluorination. On the contrary, the chlorofluoro·methane-treated surface exhibited a higher affinity to the perfluorocarbons compared to the untreated surface.

In general, a SiO_2 surface has been fluorinated in the liquid phase with an aqueous solution of HF,[1] NH_4F,[2] or NH_4HF_2.[3] Recently, it was found that a SiO_2 surface may be more conveniently fluorinated by a vapor phase treatment at high temperatures (e.g., 1500 °C) with volatile fluorine compounds such as CF_4,[4] SF_4,[5] NF_3,[6] and CCl_2F_2.[7] The vapor phase treatment was reported to be especially effective for the removal of surface OH groups which cause a loss of photoactivity when SiO_2 is used as an optical fiber.[8] The treatment process, however, is still undesirable since the fluorine compounds cited above are expensive and/or unstable in moist air except for CCl_2F_2; also, the treatment temperature is too high. Thus, it is preferable to perform a vapor phase treatment or fluorination by using less expensive and more stable fluorides such as chlorofluorocarbons (flon) at lower temperatures.

It was previously found that some chlorofluoromethanes are effective for the vapor-phase fluorination of Al_2O_3 at temperatures lower than 500 °C.[9] In addition, a certain flon, $CClF_3$, was also effective for the surface fluorination of mordenite (SiO_2/Al_2O_3 molar ratio=19) at about 450 °C.[10] Hence, it is possible that some flons are available for the vapor phase fluorination of a SiO_2 surface. However, the reaction conditions must be carefully selected because of the large possibility of SiF_4 formation in such a fluorination of SiO_2.

Thus, in this study the most suitable flon and the optimal treatment conditions to promote the surface fluorination of SiO_2 with flon were sought first. Then, changes in the surface composition and property were examined, since they have only been slightly clarified in previous studies.[4-7] As for surface properties changes in the adsorptive activity for water vapor and hexane are examined to determine the effect of the fluorination on the affinity of a SiO_2 surface to a polar or nonpolar compound. In addition, such perfluoro·compounds as hexafluoropropene and octafluorocyclobutane were selected as adsorbents since they are known to be inert, in general, in interactions with other molecules.

During this study, an emphasis was placed on comparing the effects of a flon-treatment with that of the most widely adopted HF acid-treatment in order to increase the effectiveness of the vapor-phase treatment using flon.

Experimental

Materials. A commercial fine silica powder, Aerosil 200 (Nippon Aerosil Co.) was used as the main silica sample (SA) after heat treatments at temperatures higher than 1000 °C. In addition, a quartz fiber supplied by Gaschro Kogyo Co., and a commercial glass fiber supplied by Nittobo Co. (E Glass, SiO_2 52—56%; Al_2O_3 12—16%; CaO 15—25%; MgO 0—6%; B_2O_3 8—13%; Na_2O+K_2O 0—1%) were used for comparisons of the reactivity with that of SA.

Various chlorofluoromethanes, CF_4, hexafluoropropene, and octafluorocyclobutane, all of which were of purities higher than 99%, supplied by Mitsui-Dupont Fluorochemical Co., were directly used without further purification.

Fluorination Procedure. Fluorinations were carried out in a closed system by circulating gaseous chlorofluoromethane through a sample bed at 450—550 °C. The replacement of OH groups with fluoride ions was also carried out by soaking SA in dilute hydrofluoric acid (0.1 or 1.0 wt%) at room temperature for 30 min.

Structure and Surface Composition. The structure of silica before and after fluorination with flon or diluted hydrofluoric acid was determined from the powder diffraction patterns obtained with a Rigaku Geigerflex X-ray diffractometer by using Cu $K\alpha$ radiation. The structural change was also examined using a scanning electron microanalyzer (SEM).

The compositions in the surface layer were determined by IR and XPS. The XPS was measured with Mg $K\alpha$ radiation. The base pressure of the spectrometer was usually below 10^{-7} Torr (1 Torr=133.322 Pa) during the experiments. The compositions were calculated from the areas of the spectral peaks (i.e., the maximum in the counting rate) on the basis of the photo ionization cross section at 1245 eV in units of the Cls cross section of 22200 barns.[11] The behavior of the surface OH groups was examined by IR spectroscopy using a self-supporting disc.

Determination of Surface Properties. Surface areas were determined by applying the BET equation for the adsorption isotherm of N_2 at −196 °C. The effect of the flon-treatment on the surface properties of silica was examined by the adsorptions of water vapor, hexane, hexafluoropropene, and octafluorocyclobutane at 50 °C.

Table 1. Surface Fluorination of SiO_2

Sample	Treatment condition[a]		Content/atom%		Fls peak position[b]/eV
	Pressure/Toor	Time/min	F	Cl	
SiO_2(1000)-CCl_4	54	30	0	1.2	—
SiO_2(1000)-CCl_3F	54	30	4.2	0	688.7

a) The treatment temperature was kept constant at 550°C. b) The binding energy values were measured by refering to the Cls value of the contaminant carbon (285 eV).

Results and Discussion

Reactivities of Various Flons and Diluted HF Acid Toward Silica Surface. As shown in Table 1, CCl_3F exhibited the highest fluorination activity among various flons. The order of the fluorination activities of these flons the opposite to that of the C-Cl[12] or C-F[13] bond strength of the flon molecules. Thus, the ease of the C-Cl[12] or C-F[13] bond splitting seems to determine the surface fluorination activities of flon.

Since the CCl_3F having the weakest C-Cl or C-F bond was found to the most active as a fluorinating reagent, it was used for the surface fluorination of SiO_2 in the succeeding study.

Comparison of Reactivities of Various SiO_2 Materials. As shown in Table 2, a quartz fiber sample was fluorinated more readily than SA. A commercial glass fiber sample was fluorinated much more markedly. In this case, however, the Fls peak position (686.9 eV) for the fluorinated sample was remarkably different from that for a simple or pure silica sample, such as the quartz and SA. It rather coincided to that for the CCl_3F-treated Al_2O_3 (686.8 eV). Therefore, the F component introduced by the CCl_3F-treatment was presumed to be bound not to Si, but the Al atom on the treated glass fiber. Evidence suggested that heat treated SiO_2 is less active than Al_2O_3 in the reaction toward the flon. Nevertheless, it is noteworthy that SA was considerably fluorinated with a relatively stable compound CCl_3F, even after heat-treatment at a high temperature, such as 1150°C.

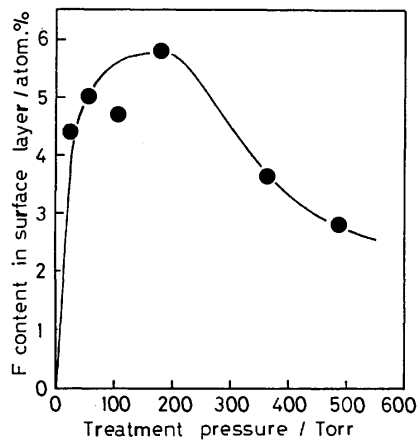

Fig. 1. Effect of the CCl_3F-treatment pressure on the F content in surface layer. Treatment temperature: 550°C; Treatment time: 2 h.

Effect of CCl_3F-Treatment Conditions. As Fig. 1 shows, there was an optimal CCl_3F pressure to increase the F content of the treated silica. The infrared spectra, which were taken for the gaseous components obtained by 54, 200, and 500 Torr treatment, indicated a peak at 1010—1022 cm^{-1} assignable to a Si-F bond[12] only for the product obtained at 500 Torr. This finding suggested that excessive fluorination, or formation of SiF_4, may be avoided when fluorination is gently carried out by using a flon of lower pressure or concentration.

The treatment temperature was more effective on the surface fluorination than the treatment gas pressure. Thus, the F content in the surface layer increased linearly with temperature up to 550 °C (Fig. 2).

Changes of Surface Area and Structure. The specific surface area somewhat decreased with an increase in the F content of the CCl_3F-treated SA. The decrease in the surface area, however, was not so remarkable as in the case of the diluted HF acid treatment (shown in Fig. 3).

The XRD and SEM analyses revealed that SA was still amorphous, even after treatment with the CCl_3F or the diluted HF acid.

Surface Constitution Examined by IR Spectra. The IR spectrum of SA exhibited a sharp and slightly asymmetric peak at 3734 cm^{-1} (Fig. 4). This peak, assignable to the isolated OH groups,[14] was still observed even after heat-treatment at high temperatures, such as 1000 °C. This was also observed for a sample treated with dilute HF acid. On the other hand, this peak due to the isolated OH groups was not found in all for the SA samples which were treated with CCl_3F at 500 °C. The complete removal of surface OH groups is considered to be due to the replacements of the OH groups with F atoms. In fact, a shoulder due to a Si-F bond appeared at 940 cm^{-1},[15] in accordance with the disappearance of the peak due to the OH groups.

Unlike the Si-F bond in SiF_4 molecule, the bond formed on the silica sample was fairly stable towards moisture. Thus, the band due to the Si-F bond of the treated SiO_2 did not disappear after contact with water vapor (10 Torr) at room temperature for 1 h, and even after further contact with that (15 Torr) at 120 °C (Fig. 5). The band attributable to the free silanol groups at 3734 cm^{-1} [15] reformed with difficulty after contact with water vapor (15 Torr) for a long time, such as 15 h.

Changes in Adsorptive Activities for Various Gases. For Water Vapor. As is exhibited in Fig. 6(A), the adsorptive activity of silica for water vapor was remarkably enhanced by a treatment with dilute HF acid. On the other hand, the activity was somewhat decreased by the CCl_3F-treatment at 450 °C. Furthermore, the activity was a entirely removed by a treatment at 500 °C.

Water vapor is considered to be adsorbed on the silica surface through hydrogen bonding,[15] and the amount of physically adsorbed water should be related to the number of the surface OH groups. During a treatment with dilute HF acid, the surface siloxane may be hydrolyzed. The hydrolysis should increase the amount of surface OH groups on silica surface, although a part of the OH groups may be replaced by

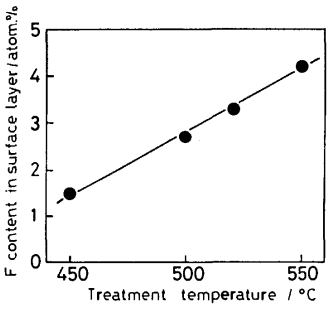

Fig. 2. Effect of the CCl_3F-treatment temperature on the F content in surface layer. Treatment pressure: 54 Torr; treatment time: 0.5 h.

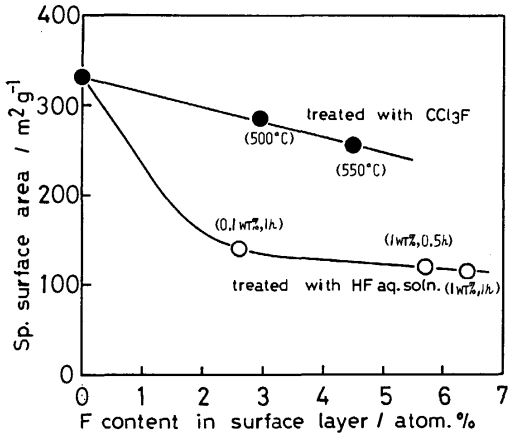

Fig. 3. The variation of specific surface area with F content in surface area. The CCl_3F-treatment was carried out at 54 Torr and 500 or 550 °C. The acid treatment was carried out at room temperature for 0.5 or 1 h with the diluted HF.

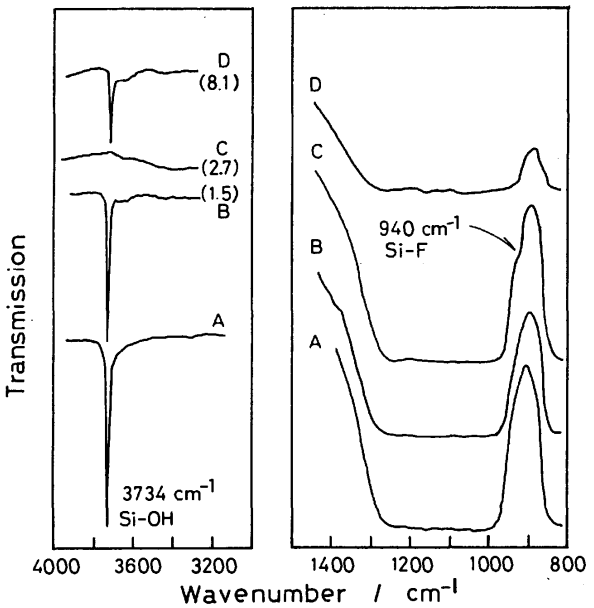

Fig. 4. IR spectra of SiO_2 treated with CCl_3F or diluted HF. A: Background or the untreated sample after evacuation at 500 °C for 2 h; B, C: for the samples treated with CCl_3F (54 Torr) at 450 and 550 °C for 0.5 h, respectively; D: for the sample treated with 0.1 wt% HF solution at room temperature for 0.5 h, and then dried at 120 °C, followed by evacuation at 500 °C for 1 h. The numbers in parentheses indicate the F content of respective samples.

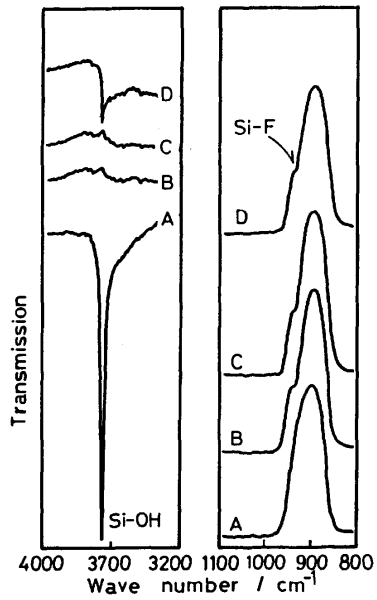

Fig. 5. Effect of contact with water vapor on IR spectra. A: Background or the untreated SiO_2 sample after evacuation at 550 °C for 2 h; B: for the sample treated with CCl_3F (200 Torr) at 550 °C for 0.5 h; C: further contact of B with water vapor (15 Torr) at 120 °C for 1 h; D: further contact of C with water vapor (15 Torr) at room temperature for 15 h.

F^- ion in the acid solution. The net increase in the amount of the surface OH groups should contribute to the enhancement of the adsorptive activity for water vapor.

While, in the case of the CCl_3F-treatment, the amount of the surface OH groups may be reduced in accordance with the progress of the surface fluorination, especially the surface OH group may be fully replaced by a F atom in a treatment at higher temperatures as has been revealed by the IR study for the treated silica (Fig. 4). A silica surface which is sufficiently covered by F atoms may be hydrophobic owing to the low surface energy ascribable to the F atoms. In fact, an SA sample treated with CCl_3F at 550 °C remained floating on water for about 1 week at room temperature; nevertheless, the untreated or the diluted HF acid-treated SA sank into water as soon as it was placed on the water surface.

For Hexane Vapor. As shown in Fig. 6(B), the adsorptive activity of silica for gaseous hexane decreased slightly with a CCl_3F-treatment at 500 °C. It was further decreased by a treatment at a higher temperature, 550 °C. A decrease in the adsorptive activity for hexane was also observed for the dilute HF acid-treated sample in the adsorption at a pressure higher than 20 Torr.

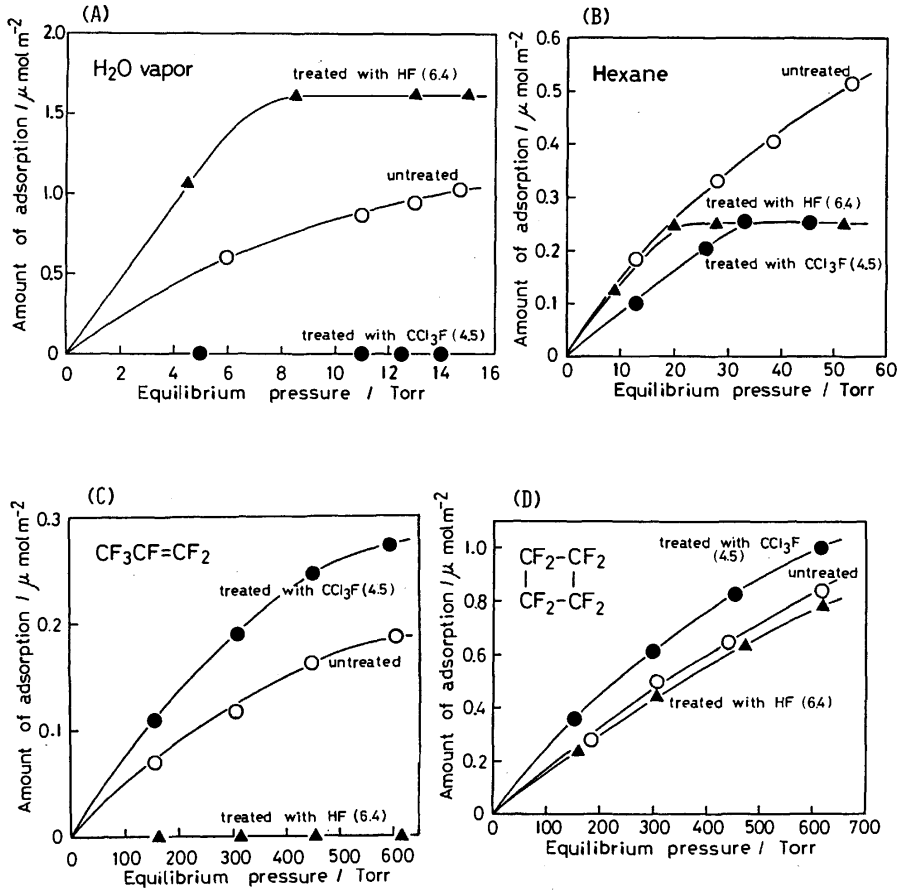

Fig. 6. Effect of the surface fluorination on the adsorptive activities for various compounds. All the adsorptions were carried out at 50 °C, and the numbers in parentheses indicate the F content of respective samples.

The results for the CCl_3F-treated silica seem to be in conflict with the current view that hydrophobic solids should exhibit an affinity for nonpolar or lipophilic compounds. The evidence that the CCl_3F-treated silica is concurrently hydrophobic and lipophobic is considered to be a result of the extremely low surface energy of the solid surface which is well-covered by F atoms. Similar characteristics are also revealed in the oil- and water-repellency of some polyfluoro or perfluoro compounds used as a special fiber treatment agent.[16]

For Perfluorocompounds. Finally, the results of the adsorptions of hexafluoropropene and octafluorocyclobutane are displayed in Figs. 6(C) and (D). In contrast to the adsorptive activities for water and for hexane, those for the perfluorocarbons were fairly increaed by the CCl_3F-treatment. These increases in the adsorptive activities may have resulted from an affinity of the F atoms in the perfluoro-compounds to the atoms of the same kind on the well-fluorinated silica surface. However, the essence and the details of the interaction between the adsorbent and the adsorbates are not clear at the present stage of this study.

In contrast with the CCl_3F-treated surface, a silica surface treated with dilute HF acid was entirely inactive for the adsorption of hexafluoropropene, possibly due to the highly polar character of the acid-treated surface. The decrease in the adsorptive activity of silica was also observed for the adsorption of octafluorocyclobutane (bp −5 °C), which is more condensable than hexafluoropropene (bp −29.4 °C), although the decrease was not so remarkable as that observed for the hexafluoropropene adsorption.

Conclusion

The results of this study are as follows:

(1) Flon-treatments are available for the vapor phase fluorination of a SiO_2 surface at around 500 °C.

(2) Among various chlorofluoromethanes and CF_4, CCl_3F having the weakest C-Cl and/or C-F bonds is especially suitable for the surface fluorination.

(3) Complete removal of surface OH groups on SiO_2 by the CCl_3F-treatment is accomplished at 500 °C. This temperature is much lower than that of another treatment (e.g. 1500 °C) with volatile fluorides (such as Cf_4, SF_4, and NF_3), which was reported to be carried out in order to remove surface OH groups.

(4) The formation of SiF_4 can be suppressed by decreasing the pressure or concentration of CCl_3F in a reactor.

(5) A silica surface becomes more hydro- and lipophobic with the CCl_3F-treatment. On the other hand, the a affinity of a SiO_2 surface to perfluorocompounds is increased by a CCl_3F-treatment.

Preparation and Metal-Adsorption Properties of the Polymer-Coated Silica Gel Having Iminodiacetate Functional Group

Toshishige M. SUZUKI,* Osamu ITABASHI, Tomio GOTO,
Toshiro YOKOYAMA, and Tetsuo KIMURA
Government Industrial Research Institute, Tohoku, 4-2-1 Nigatake, Sendai 983
(Received December 22, 1986)

A new adsorbent containing an iminodiacetate group has been prepared by the surface modification of a polymer-coated silica gel. The obtained beads (SG-IDA) are porous and have a high specific surface area ($\approx 350\,m^2\,g^{-1}$). The adsorption properties of SG-IDA, including the adsorption capacities, equilibrium distribution coefficients (K_d) and adsorption rates, have been examined for divalent metal ions. The selectivity order of SG-IDA is Cu(II) > Pb(II) > Ni(II) > Zn(II) ≫ Ca(II) > Mg(II). The SG-IDA shows appreciably high K_d values and rapid kinetics toward the adsorption of heavy metal ions. The concentration of 10 ppb level of metal ions [Cu(II), Zn(II), and Cd(II)] has been demonstrated using the SG-IDA column.

The application of solid adsorbents for the separation and concentration of trace metal ions has received recent attention owing to their operational conveniences.[1-3] Silica gel is one of the most widely used inorganic supports for a metal adsorbent because of its porous and hydrophilic nature. The nominal shrinking and swelling property is also of great advantage for use in the column stationary phase.[4] So far, numerous kinds of chelating reagents have been immobilized (adsorbed or chemically bound) onto silica-gel surface.[5,6] The use of sililation reagent is one of the most popular approaches for the modification of a silica-gel surface through chemical bonding.[6-11] However, commercially available sililation reagents having a chelating functional group are limited. Furthermore, the cleavage of a Si-O-Si bond formed by a coupling reaction tends to take place upon repeated use, leading to a lowering of the adsorption activity.[6]

We have proposed a convenient procedure for a surface modification which involves the adsorption of vinyl monomers over the surface of porous supports followed by the polymerization of the monomers.[12] The polymer network which covers a silica-gel surface can, subsequently, be functionalized with the desired reagents by the usual synthetic procedures. Preliminary results have been briefly reported.[13] This is a detailed paper in which we describe the preparation of the new adsorbent based on a polystyrene-coated silica gel having iminodiacetic acid (IDA) as the functional group. The adsorption properties of the adsorbent and its application to the column concentration of trace metal ions are reported.

Experimental

Reagents. Silica-gel beads for chromatography shieved to 60—100 mesh were obtained from Nakarai Chemical Co., washed with water and then dried in vacuo. (Chloromethyl)styrene was purified by distillation prior to use. Diethyl iminodiacetate was prepared according to the usual procedure. The commercial chelating resin Dowex A-1 (60—100 mesh) was treated with 2 M (M=mol dm^{-3}) hydrochloric acid, washed thoroughly with water and then dried in vacuo. Other chemicals were reagent grade and used without further purification.

Polymer-Coating of Silica-Gel Beads. Silica-gel beads (100 g) were immersed in a DMF solution (60 cm^3) containing (chloromethyl)styrene (66 g), divinylbenzene (0.7 g) and α,α'-azobisisobutyronitrile (1 g) under cooling below 0 °C and then filtered. The beads were transferred to a glass autoclave and then heated at 80 °C for 5 h under a N_2 atmosphere. The product was washed with benzene in a Soxhlet extractor and dried. The polymer-coated silica-gel beads, thus formed, were functionalized with iminodiacetic acid through a reaction of the surface chloromethyl group with diethyl iminodiacetate in refluxed dioxane (48 h), followed by the hydrolysis of the ester moiety with 6 M hydrochloric acid. The hydrolysis of the ester moiety was monitored by the decrease in the IR intensity of the 1740 cm^{-1} band. The IDA bound silica gel was washed successively with water, ethanol and diethyl ether and then dried in vacuo.

Adsorption Capacity. A batchwise technique was employed to determine the equilibrium adsorption capacity (amount of metal ion adsorbed on one gram of dry beads) with metal ions always being in excess over the ligand capacity.[14]

A 1 g portion of SG-IDA was added to ca. 80 cm^3 of a metal ion solution (0.02 M) of a certain pH; the suspension was stirred at room temperature overnight. Then, the mixture was transferred to a volumetric flask (100 cm^3) and finally diluted to the mark with water. The amount of metal ion that remained in the supernatant solution was determined using an atomic absorption spectrometer. The capacities of the adsorbent were calculated from the change in the observed metal concentration. The beads were then placed into a glass column and thoroughly washed with water. The adsorbed metal ions were liberated from the beads by elution with 2 M hydrochloric acid, and the metal ions in the eluent were analyzed. In most cases, a satisfactory material balance could be observed between the metal ions liberated from the beads and those remaining in the solution.

Distribution Coefficient. The equilibrium distribution coefficients of the metal ions were determined by a batchwise procedure.[14] Typically, dry SG-IDA beads (1 g) were immersed in 100 cm^3 of a 1 mM metal ion solution (I=0.05, $NaClO_4$). The pH from 3.0 to 5.0 was adjusted with an acetate buffer while that below 3.0 was adjusted with hydrochloric acid. After shaking for 3 d, the equilibrium pH was measured and the amount of metal ion remaining in

the supernatant solution were determined. The results are expressed as the distribution coefficient, K_d=(amount of metal adsorbed on 1 g of the beads)/(amount of metal remained in 1 cm^3 of the solution).

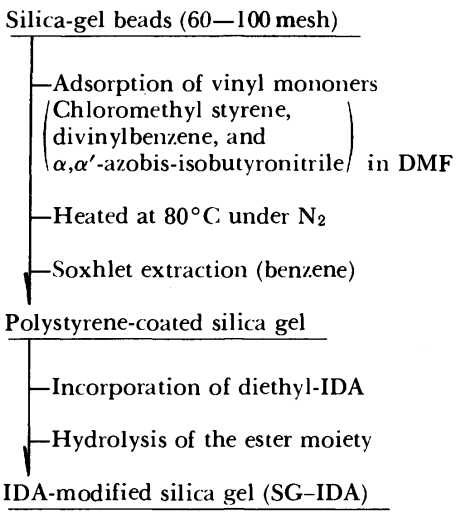
Adsorption Rate. The following batchwise procedure was employed: To a buffered metal ion solution (1 mM, 500 cm^3) at pH 4.5 was added 3 g of the SG-IDA beads (H^+ form). Small portions of the metal solution were withdrawn under stirring at appropriate intervals and analyzed with an atomic absorption spectrometer. Similar experiments were carried out by using Dowex A-1 (H^+ form), in which the IDA group is immobilized onto cross-linked polystyrene beads.

Concentration of Metal Ions by the Column of SG-IDA. A 5 dm^3 solution containing 10 ppb each of metal ions [Cu(II), Zn(II), and Cd(II)] at pH 4.5 was continuously passed through a column containing SG-IDA (ϕ 1.2×4 cm, 5 cm^3) at a constant flow rate that could be adjusted with a microtube-type pump. After the whole solution was fed to the column, the bed beads were washed with water in order to eliminate any free metal ions. Then, the adsorbed metal ions were eluted with 20 cm^3 of 2 M hydrochloric acid. The eluate was collected in a volumetric flask (50 cm^3) and finally diluted to the mark with water. The percentage recovery was calculated in terms of the ratio of the amount of metal ion recovered and that in the feed solution.

Measurements. The metal ion concentration was determined with a Shimadzu atomic absorption/flame photometer Model AA-610S. The IR spectra were measured using a KBr method with a Perkin-Elmer Model 599 spectrophotometer. A specific surface area was determined with an Yuasa Ionic MONOSORB; samples were treated for 30 min at 110 °C in the stream of a mixture gas consisting of 32% N_2 and 68% He prior to measurements. The polymer contents of the chemically modified silica gel were determined by a thermal gravimetric analysis using a Rigaku Thermoflex.

Results and Discussion

Preparation and Characterization of SG-IDA. The silica-gel surface was coated with a (chloromethyl)-styrene-divinylbenzene copolymer through the adsorption and subsequent polymerization of the vinyl monomers. Polystyrene chains were partially cross-linked with divinylbenzene in order to avoid leaking of the polymer moiety upon contact with organic solvents. Unreacted monomers and oligomers were eliminated by Soxhlet extraction with benzene. The polymer-coated silica gel, thus formed, could successively be modified with a wide variety of functional groups. In the present study, diethyl iminodiacetate was introduced onto the polymer surface through a reaction of the ligand with the chloromethyl group (Scheme 1). This was confirmed by the characteristic IR bands at



Scheme 1. Procedures for polymer-coating of silica gel beads and subsequent functionalization with iminodiacetic acid.

around 1740 and 1640 cm^{-1} due to (C=O) stretching vibrations of the carboxylic ester group. The band intensity at 1740 cm^{-1} decreases upon the hydrolysis of the ester moiety, whereas that of 1640 cm^{-1} increases. The obtained SG-IDA beads have a sufficient mechanical strength for use in the usual experimental procedures. Different from typical polymer chelating resins, the SG-IDA beads revealed minor volume changes upon adsorption and regeneration cycles. For example, the change in the volume of SG-IDA on interconversion between H^+ and Na^+ forms was only within 10%. However, the Dowex A-1, whose matrix is a gel-type polystyrene, showed an increase in volume by more than 60% with the change in ion forms from H^+ to Na^+. A large volume change must be unfavorable for uniform packing in a column system.

Table 1 shows the analytical data as well as the specific surface area of the functionalized silica gel along with the non-functionalized ones. A nitrogen analysis indicated that SG-IDA contains approximately 0.8 mmol of IDA per gram of the beads. Although SG-IDA is coated with a polymer, the specific surface area remains considerably high, i.e., 350 $m^2 g^{-1}$. This indicates that most of the pores with large diameters are not clogged with polymer, presumably because the inner surfaces of the pores are uniformly covered with a polymer network. The SG-IDA beads form colored complexes with Cu(II), Co(II), and Cr(VI) ions. The colors appeared to be homogeneously distributed over the beads when observed under an optical microscope.

Table 1. Numerical Data of the Chemically Modified Silica Gel

Type of the modified silica	N/%	Polymer content/%[a)]	Specific surface area[b)]/$m^2 g^{-1}$
Silica gel	—	—	440
Coated with poly[(chloromethyl)styrene]	0.1	12.0	357
Functionalized with IDA	1.1	14.0	348

a) Weight percent of polymer determined by thermal gravimetric analysis. b) Obtained by B. E. T. method.

It has been pointed out that the specific surface area is closely related to the amount of polymer coated on silica gel.[15] When the polymer content exceeds about 15%, the specific surface area sharply decreases; in some cases, an aggregation of beads takes place.

The titration curve of SG-IDA with 0.1 M potassium hydroxide gave apparent inflection points at ca. pH 3.8 and 7.7 regions; this can be assigned to a dissociation of protons on the introduced IDA and surface silanol group, respectively, since non-functionalized silica-gel beads gave an inflection point at about pH 7.6.

Equilibrium Adsorption Capacity. The SG-IDA beads adsorb various kind of metal ions in a similar manner to that observed for polymer chelating resins having the IDA groups.[16,17] Profiles of the adsorption capacities vs. pH for several metal ions are given in Fig. 1. The maximum capacity of the SG-IDA lies in the range 0.3—0.4 mmol g^{-1}. The pH dependence of the curves is closely related to the stability of the metal complexes formed with the IDA group. Thus, a metal ion which forms a very stable complex with a functional group is retained to the beads at a much lower pH region. The adsorbed metal ions were released from SG-IDA upon a treatment of the beads with 2 M hydrochloric acid. The adsorption capacities for most of the metal ions examined were reproducible over several adsorption and regeneration cycles, with the exception of Fe(III). The capacity for Cu(II) was reproducible within a ±3% deviation for more than ten repeated cycles of use. Since Fe(III) is strongly retained to the beads, a quantitative recovery is difficult, even by treating with concd hydrochloric acid. In this case, a reduction of Fe(III) to Fe(II) with a 1 M $Na_2S_2O_4$ solution prior to acid leaching gave satisfactory results.

The SG-IDA beads are sufficiently durable in an acidic solution. For example, no obvious change in the Cu(II) capacity has been observed upon treating the beads in refluxed 3 M hydrochloric acid for 3 h. In a strongly alkaline media, on the contrary, a gradual dissolution of silica gel inevitably took place.

Distribution Coefficient. The distribution coefficient (K_d) for several metal ions was examined as a function of the pH; the results are given in Fig. 2. The slopes in the linear plots at a pH lower than 3.0 are approximately 2.0 for the adsorption of Cu(II), Pb(II), Ni(II), and Zn(II). This result indicates that the adsorption of these divalent metal ions at this pH region is accompanied by the release of two protons as given in the following formula, where RH_2 denotes the protonated form of SG-IDA:

$$RH_2 + M^{2+}(aq) \rightleftarrows RM + 2H^+$$

The log K_d vs. pH profile clearly implies that the order of selectivity for SG-IDA is Cu(II)>Pb(II)>Ni(II) >Zn(II)>Cd(II)≫Ca(II)>Mg(II). The behavior of Pb(II) and Ni(II) is somewhat unusual in view of its stability constants of the IDA chelates where log K_{ML} of the Ni(II) chelate is larger than that of the Pb(II) chelate. The shift in the position of the two ions is most likely to be due to the difference in the steric environment between the free and immobilized ligand. A similar change in the selectivity series has also been observed in IDA-type chelating resins with different types of polymer matrix.[16]

Appreciably high K_d values ($\log K_d > 4.0$) were observed for the adsorption of Cu(II), Pb(II), Ni(II), Zn(II), and Cd(II), whereas those for alkaline earth metal ions are relatively low. The K_d values for Mg(II) and Ca(II) are three to four orders of magnitude lower than those for other metal ions. Thus, interference from these alkaline earth metal ions by competed complexation must be less significant.

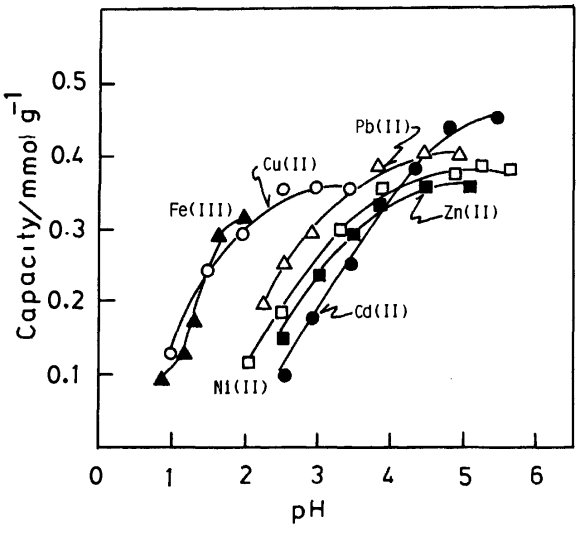


Fig. 1. Equilibrium adsorption capacity of the SG-IDA for Fe(III) (▲), Cu(II) (○), Pb(II) (△), Ni(II) (□), Zn(II) (■), Cd(II) (●).

Table 2. Column Concentration of Trace Amount of Metal Ions[a)]

Run	Foreign ion	% Recovered			Flow rate SV/h^{-1}
		Cu(II)	Zn(II)	Cd(II)	
1	—	100	110	102	36
2	—	100	95	70	48
3[b)]	—	107	108	105	50
4	Ca(II), 1000 ppb	100	108	100	36
5	Mg(II), 1000 ppb	100	110	98	36

a) Column bed: 5 cm^3 of SG-IDA feed metal: 10 ppb each (5000 cm^3), pH 4.5. b) The pH of feed solution was 5.5.

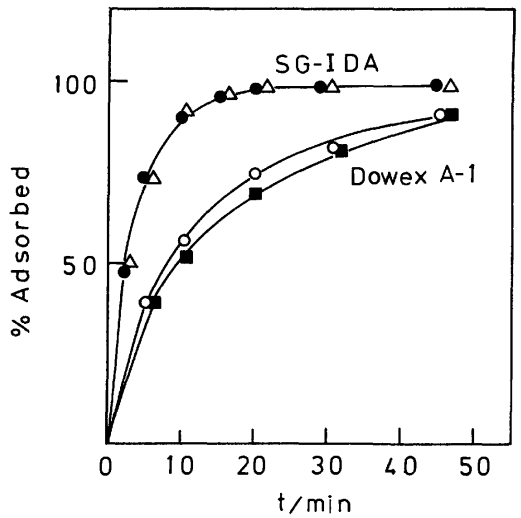

Fig. 3. Time-courses for the adsorption of metal ions with the SG-IDA and Dowex A-1. SG-IDA: Cu(II) (●); Ni(II) (△), Dowex A-1: Cu(II) (○); Ni(II) (■). Conditions: Adsorbent=3 g, $[M]_{feed}$= 1×10^{-3} M (500 cm^3), pH of the feed solution=4.5.

Adsorption Rate. A rapid attainment of adsorption equilibrium is of fundamental importance for the concentration of metal ions from a practical point of view, particularly for the treatment of a large volume of a dilute solution. The time-courses for the adsorption of Cu(II) and Ni(II) were examined by monitoring the change in the metal concentration in the batch systems. Figure 3 shows the rate profiles using the SG-IDA along with those by Dowex A-1 (60—100 mesh). The SG-IDA adsorbed more than 95% of the metal ions within 15 min while the adsorption rate of the Dowex A-1 was relatively slow. The rapid kinetics of SG-IDA can be attributed to the porous structure of the beads which allows a facile diffusion of the metal ions inside the matrix. The hydrophilic nature of the surface due to the unshielded silanol groups may also contribute to the rapid adsorption.

Column Concentration of Metal Ions. Rapid kinetics and sufficiently high K_d values of SG-IDA for the adsorption of heavy metal ions suggest the possibility of a fast concentration of trace metal ions in a column system.

A 5 dm^3 solution containing a 10 ppb level of Cu(II), Zn(II), and Cd(II) was continuously supplied onto the SG-IDA column; finally, the adsorbed metal ions were released from the column by elution with 2 M HCl. The percent recovery was then determined by the metal ratio in the eluate and in the feed solution. Typical results are given in Table 2. When the flow rate was controlled under 3 $cm^3 min^{-1}$, which corresponds to the space velocity (SV) of 36 h^{-1} at the given experimental conditions, all the metal ions of interest were quantitatively recovered in a concentrated form. Copper(II) was quantitatively recovered, even at a higher flow (SV=48 h^{-1}), whereas the recovery of Zn(II) and Cd(II), which form less stable complexes with SG-IDA than Cu(II), decreased at this flow rate. At a much higher pH (=5.5), however, an improved result could be attained.

Interference from alkali and alkaline earth metal ions was not significant when they were present in concentrations of about hundred times that of the metal ions of interest.

Cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica) intercalation complexes were prepared by titrating cobalt(II) nitrate solutions in the presence of mica with sodium hydroxide under oxygen-free conditions. These complexes were characterized by chemical analysis, XRD, DTA-TGA, IR, and surface area measurements. These confirmed that the brucite-like cobalt(II) hydroxide sheet developed within the interlayer of the silicate. Cobalt atoms reduced at 400—700 °C by H_2 migrated from the interlayer of the silicate to the external surface of these where highly dispersed cobalt particles were formed. Ultra-fine cobalt metals (50—200 Å) with a hexagonal close-packed form were prepared at 400 °C by H_2. The degree of reduction and the grain diameter of cobalt increased with an increase of the reducing temperature and/or the reducing time.

The preparation and properties of metal hydroxide-expansible layer silicates (montmorillonite, vermiculite, etc.) intercalation complexes are important subjects concerning the research of clay minerals. Much work has been done on this topic: especially, on aluminium hydroxide-,[1] magnesium hydroxide-,[1] and nickel(II) hydroxide-[2,3] expansible layer silicate intercalation complexes in relation to the formation and alternation of clay minerals.

On the other hand, only a few studies have been carried out on the reduction behavior of metal hydroxide interlayers of these complexes.[3,4] We found that highly dispersed nickel particles can be formed on the external surface, not in the interlayer space of the silicates, by the reduction of the nickel hydroxide interlayer of the complex.[3] Therefore, metal (especially transition elements) hydroxide-layer silicate complexes appear to be unique materials as catalysts and magnetic materials etc, since the reduction of these complexes may provide isolated metal atoms on the external surface of the silicates.

Cobalt is a typical transition element that is widely used in catalysts and magnetic materials etc. However, no attempt has been made to study the preparation of cobalt(II) hydroxide-layer silicate complexes. In this work, the preparation of cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica) intercalation complexes, the thermal stability of these complexes, and the reduction behavior with H_2 were investigated. Sodium fluoride tetrasilicic mica, $NaMg_{2.5}Si_4O_{10}F_2$, has very important characteristics: first, it has no acidity at all; second, it has a high thermal stability; and third, it has a sheet-forming capability owing to its flake-like particles.

Experimental

Materials. A 10 wt% sol of sodium fluoride tetrasilicic mica, synthesized silicate material, (supplied by Topy Ind. Co., under the name of Na-TSM) was used. Since this mica sol contains a little α-cristobalite and magnesium fluoride richiterite, $Na_2Mg_6F_2(Si_4O_{11})_2$, as impurities, the sol was diluted with distilled water and most of the impurities were separated by centrifugation. Sodium fluoride tetrasilicic mica was finally dried in air at 100 °C. The characteristics of this mica were described in detail in our previous work.[3] Na^+ ions are located within the interlayer of the silicate and balance the negative layer charge of −1 derived from vacancies in the octahedral sheets. These Na^+ ions are exchangeable in water and the theoretical cation-exchange capacity is 254 meq/100 g · mica.

Preparation and Examination of Intercalation Complexes. Cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica) complexes were prepared by titrating cobalt(II) nitrate solutions in the presence of the mica with sodium hydroxide under oxygen-free conditions. In general, the addition of alkali metal hydroxide to a solution of cobalt(II) salts results in the precipitation of cobalt(II) hydroxide. However, suspensions of cobalt(II) hydroxide are gradually oxidized by air to cobalt(III) oxide hydrate and/or cobalt(III) oxide hydroxide.[5] Therefore, the preparation procedures were operated under a N_2 gas atmosphere. All solutions were prepared using distilled water free of O_2; dissolved oxygen was expelled by keeping N_2 gas bubbling through the boiling water for 2 h.

The preparation procedures were as follows: 1.5 g samples of the mica were dispersed in 150 ml of 0.1 M (1 M=1 mol dm^{-3}) cobalt(II) nitrate solutions to give a 1 mol Co/100 g · mica. After stirring for 1 d, these suspensions were titrated with an appropriate volume of 0.1 M sodium hydroxide solutions to yield OH/Co molar ratios of 0, 0.2, 0.5, 0.8, and 1.0, respectively, at a rate of 5 ml h^{-1} under vigorous stirring, and kept stirring for 3 d. Following these treatment, samples were repeatedly washed in order to remove any electrolyte with the distilled water free of O_2 and dried at 50 °C in a vacuum oven. These samples were stored under nitrogen in a tightly closed desiccator.

Cobalt(II) hydroxide were also prepared by titrating a 2 M cobalt(II) nitrate solution with an equivalent volume of a 2 M sodium hydroxide solution under similar conditions.

† Present address: Tohoku Institute of Technology, Sendai 982.

Table 1. Conditions of Preparation and Chemical Analyses of Sodium Fluoride Tetrasilicic Mica and Cobalt(II) Hydroxide-(Sodium Fluoride Tetrasilicic Mica)

No.	Condition of preparation	Chemical analysis/wt%			Molar ratio (SiO_2=4)		
	OH/Co (1 mol Co/100 g·mica)	SiO_2	Na	Co	SiO_2	Na	Co
a)		57.34	4.36	—	4.00	0.80	—
1	0.0	50.89	0.65	3.37	4.00	0.13	0.27

a) Initial sodium fluoride tetrasilicic mica ($NaMg_{2.5}Si_4O_{10}F_2$). Interlayer charge is +1; interlayer cations are Na^+ and H^+ that replaced the part of Na^+ cations in distilled water.

Table 2. Basal Spacings (Å) of Cobalt(II) Hydroxide-(Sodium Fluoride Tetrasilicic Mica) after Heat Treatment

No.	OH/Co	Heat treatment/°C[a]				
		105	200	250	300	350
Initial mica[b]		9.6	9.6	9.6	9.6	9.6
1	0.0	15.0[c]	9.6	9.6	9.6	9.6
2	0.2	14.5	9.6	9.6	9.6	9.6
3	0.5	14.5	9.6	9.6	9.6	9.6
4	0.8	14.5	14.5	14.5	ML[d]	9.6
5	1.0	14.6	14.5	14.5	ML	9.6

a) Heat treatment for 2 h. b) Basal spacing of sodium fluoride tetrasilicic mica is 9.6 Å (anhydrous form); 12.3 Å (single water layer hydrated form); 15.2 Å (double water layer hydrated form). c) Rehydrated form on exposure to air at room temperature. d) ML=mixed layer (mixtures of 14.5 and 9.6 Å layers).

The resulting precipitate was cobalt(II) hydroxide in pink form (β-$Co(OH)_2$) determined by XRD analysis. The pink cobalt(II) hydroxide has a brucite ($Mg(OH)_2$) structure.

The chemical analyses of the complexes were performed by atomic absorption analyses. Surface areas were measured by the nitrogen-adsorption method with a Carlo Elba Sorptomatic Series 1800. All samples were examined by XRD as thin, oriented films on glass slides. IR spectra were obtained from KBr disks. The thermal stability of the complexes in air and the reduction behavior with H_2 were investigated at 100—700 °C (the mica is stable below 800 °C); the heating rate was 10 °C min^{-1} and slowly cooled after holding for a set time.

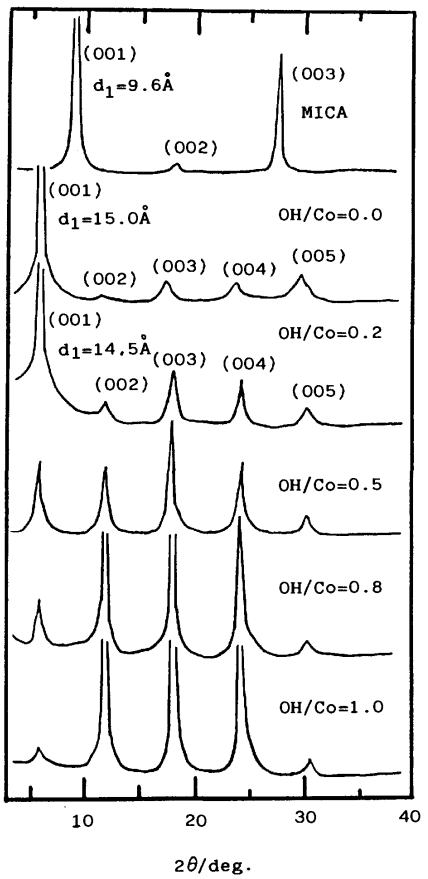

Fig. 1. X-Ray powder diffraction patterns (Cu $K\alpha$ radiation) of cobalt (II) hydroxide-(sodium fluoride tetrasilicic mica). MICA: Anhydrous form.

Results and Discussion

Chemical Analysis and XRD Measurements. Chemical analyses of the mica and its intercalation complexes are listed in Table 1. The amount of Co taken into the mica increased with an increase of the OH/Co ratio. The highest Co yield of about 2.3 mol Co per formula unit of the mica was obtained with a OH/Co ratio of 1.0. As the ion-exchange rate is 87%, this value corresponds to 2.6 mol Co per formula unit of the mica being 100% ion exchanged. In the case a complete cobalt(II) hydroxide developed between the silicate layers, as a nickel(II) hydroxide interlayer,[3] for instance, the limiting composition would be $[Co_3(OH)_5(H_2O)](Mg_{2.5}Si_4O_{10}F_2)$. This composition corresponds to 3 mol Co per formula unit of the mica 100% ion exchanged. Therefore, at a OH/Co ratio of 1.0, the cobalt(II) hydroxide interlayer would be well developed, but not completely.

The basal spacings of these complexes are expanded by about 14.5 Å from the 9.6 Å basal spacing of the mica; these basal spacings are almost constant and independent of the amount of cobalt taken into the mica (Table 2). Moreover, X-ray diffraction analyses did not show any free cobalt(II) hydroxide in these

complexes or cobalt oxide in the heat-treated sample. Therefore, a brucite-like cobalt(II) interlayer must have developed between the silicate layers without free cobalt(II) hydroxide. The X-ray powder diffraction patterns of these complexes are shown in Fig. 1. With an increase in the OH/Co ratio, the (001) first-order reflection decreased in intensity; on the contrary, the (002)—(004) higher-order reflections increased in intensities. These changes of the relative intensities also indicate that a cobalt(II) hydroxide-forming reaction took place in the interlayer of the silicate.[6]

Changes of the basal spacings after heat treatments are shown in Table 2. Basal spacings of the samples with OH/Co=0.8, 1.0 retained 14.5 Å up to 250 °C and reduced to about 9.6 Å with further heating. The XRD patterns of these collapsed samples are almost similar to that of the original mica; the (001) reflection of these collapsed samples increased in intensity. β-Cobalt(II) hydroxide changed to cobalt (II, III) oxide after a heat treatment at 150 °C for 2 h; therefore, well-developed cobalt(II) hydroxide within the interlayer of the silicate has a higher thermal stability than β-cobalt(II) hydroxide.

Thermal Analysis. Figure 2 shows the DTA and TGA curves for the complexes; the heating rate was 10 °C min^{-1}. Sample No. 1 (prepared at OH/Co=0.0) showed a single endothermic peak at about 164 °C with a corresponding weight loss. This dehydration is due to the water of hydration associated with the exchanged cobalt(II) ions within the interlayer of the silicate; this water is much more dissociated than water in the bulk state.[7] Therefore, the composition of these interlayer cobalt(II) ions is $[Co(OH)_\delta(H_2O)_{6-\delta}]^{2-\delta}$.

On the other hand, samples prepared with the addition of sodium hydroxide, OH/Co=0.2—1.0, showed a first endothermic peak at about 140—160 °C and a second one at about 380—400 °C, with corresponding weight losses. With an increase in the OH/Co ratio, the endothermic peak area at about 380—400 °C increased; on the contrary, the endothermic peak area at about 140—160 °C decreased. These correspond to the fact that cobalt(II) hydroxide, to be exact, hydroxocobalt(II) complex $[Co_x(OH)_y(H_2O)_m]^{2x-y}$ developed within the interlayer of the silicate with the progressive hydrolysis and olation of cobalt(II) cations by addition of alkali. Therefore, the first endothermic peak (140—160 °C) corresponds to the loss of absorbed water and coordinated water and the second one (380—400 °C) to the loss of hydroxo. The mechanism of formation of cobalt(II) hydroxide interlayers must be the same as that discussed in the study of the formation of a nickel(II) hydroxide interlayer.[2] The endothermic peaks at about 820 and 884 °C are due to the reactions between cobalt oxide and the mica; cobalt silicate (Co_2SiO_4) was detected by XRD after the measurement of DTA-TGA.

The DTA-TGA curves for β-cobalt(II) hydroxide showed an endothermic peak corresponding to the dehydration of hydroxyl at about 295 °C; this temperature is considerably lower than the dehydration temperature (380—400 °C) of the hydroxo of cobalt(II) hydroxide interlayer. These correspond to the fact that a well developed cobalt(II) hydroxide interlayer has a higher thermal stability than β-cobalt(II) hydroxide; that cobalt(II) hydroxide interlayer is strongly fixed by electrostatic force and hydrogen bond to the silicate layer like as brucite interlayer in chlorite.[8]

Specific Surface Areas. The specific surface areas of the complexes are shown in Fig. 3. With an increase

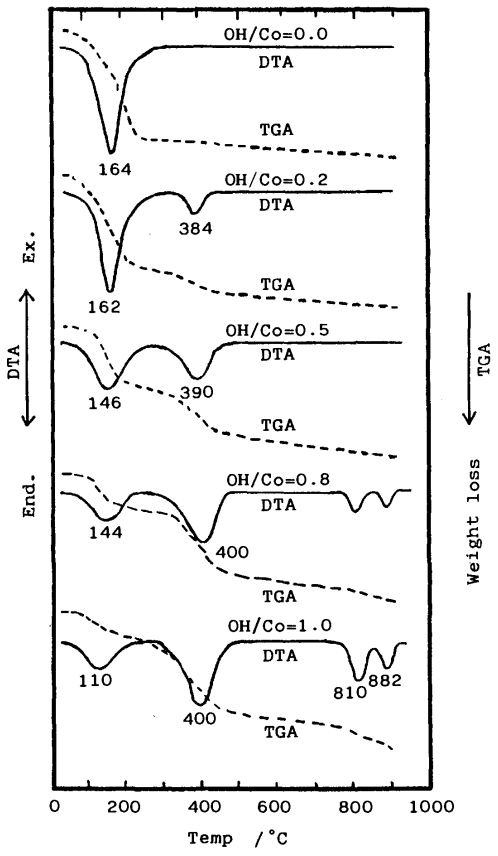

Fig. 2. DTA and TGA curves for cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica).

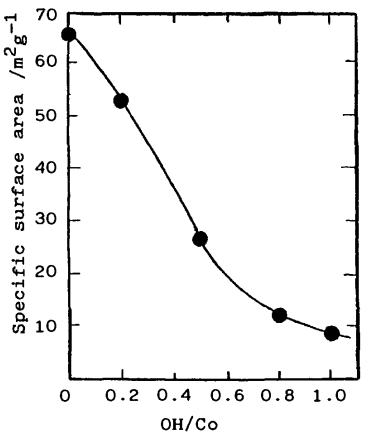

Fig. 3. Specific surface areas of cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica).

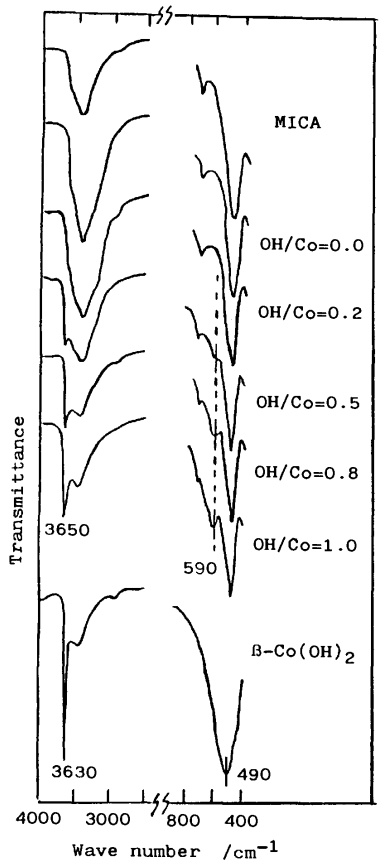

Fig. 4. IR absorption spectra of β-cobalt(II) hydroxide and cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica).

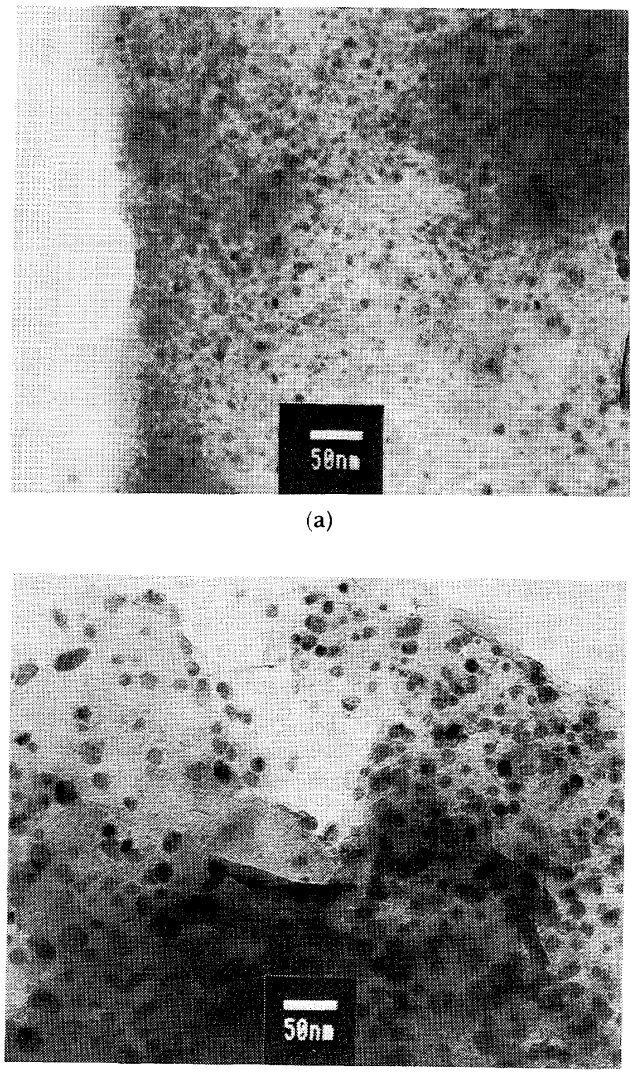

Fig. 5. Transmission electron micrographs of cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica) (OH/Co=1.0) heat treated at 400°C for 24 h (a) and 48h (b) in H_2 flow.

in the OH/Co ratio, the specific surface areas decreased since the interlayer space becomes smaller with the development of a cobalt(II) hydroxide interlayer; finally, the internal surfaces become completely covered.

IR Analysis. The IR absorption spectra of the complexes and β-cobalt(II) hydroxide are shown in Fig. 4. Characteristic absorption bands appeared at about 3650 and 590 cm^{-1} in the complexes with an increase of the OH/Co ratio. The 3650 cm^{-1} band is due to the OH stretching vibration of cobalt(II) hydroxide interlayer. The 590 cm^{-1} band is also from the cobalt(II) hydroxide interlayer and appears to be shifted from 490 cm^{-1} band shown in absorption spectrum of β-cobalt(II) hydroxide.

Reduction Behavior with H_2. Complexes with OH/Co=1.0 were heat treated in flowing H_2 at 400, 500, 600, and 700 °C for 2 h. All samples collapsed to a basal spacing of 9.6 Å and metallic cobalt was detected by XRD above 500 °C. These metallic cobalt structures were mixtures of the face centered cubic and hexagonal close-packing phases. In general, cobalt exists as a h.c.p phase (α-Co) at ordinary temperatures; above 417 °C, it has a f.c.c phase (β-Co). However, mixtures normally coexist because of the very low free energy change associated with the α–β transformation.[9] On the other hand, those complexes with OH/Co=1.0 were also heat treated in flowing H_2 at 400 °C for 2, 4, 6, 24, and 48 h and cobalt with h.c.p form was identified by XRD after over a 4 h heat treatment.

With an increase in the reducing temperature and/or the reducing time, the reflection intensity of cobalt increased and the (001) mica basal reflection peak became sharper. These results indicate that reduced cobalt atoms gradually migrate from the interlayer of the silicates to its external surface. Patel[10] reported that finely divided metal particles (15—100 Å) can be formed in interlayer spaces of clay minerals with an H_2 reduction of transition metal (Ni^{2+}, Cu^{2+}) interlayer cations. However, our results have shown that reduced cobalt metals exist mainly not in the interlayer of the silicates but on the external surface of the silicate, owing to the fact that the basal spacings of the silicate are always 9.6 Å after H_2 reduction. TEM

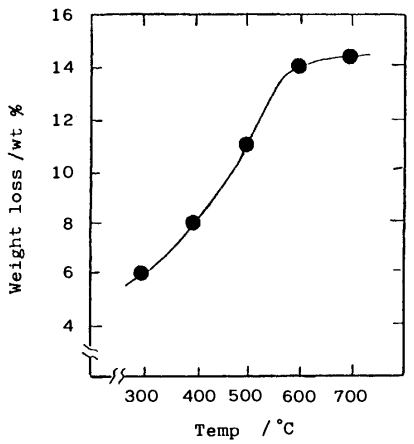

Fig. 6. Weight loss for cobalt(II) hydroxide-(sodium fluoride tetrasilicic mica) after various temperatures of reduction for 2 h.

photographs (heat treated complexes at 400 °C for 24 and 48 h in H_2 flow) show that ultra-fine metallic cobalt particles (50—200 Å) are distributed on the whole surface of the mica and that the grain diameter of this cobalt increases with an increase of the reducing time (Fig. 5). Furthermore, particles with a crystal habit of hexagonal plates can be observed.

Only a few studies have hitherto been made on the reduction behavior of transition metal cations and/or transition metal (=nickel) hydroxide within the interlayer of the expansible layer silicate. However, many studies have been performed on the reduction behavior of metal cations in zeolite. It is generally accepted that the metal ions in a zeolite are reduced to zero valent metal particles by H_2 as follows:[11]

$$Me^{x+}(ZO^-)_x + x/2H_2 \rightarrow M\overset{0}{e} + x(ZOH).$$

Here, $(ZO^-)_x$ represents the zeolite lattice and ZOH represents surface hydroxyl groups. Moreover, a similar reaction mechanism was proposed in the case of metal ions in montmorillonite.[10]

The following reduction mechanism is likely in the case of metal hydroxide-layer silicate complexes as well:

$$[Me_x(OH)_y(H_2O)_m]^{1+} + (O\text{-}MICA)^- + H_2 \rightarrow H^+(O\text{-}MICA)^- + x\overset{0}{Me} + (m+y)\,H_2O, \quad (1)$$

where $[Me_x(OH)_y(H_2O)_m]^{1+}$ represents the metal hydroxide interlayer and $(O\text{-}MICA)^-$ represents a mica layer sheet. The weight loss during H_2 reduction was determined on sample No. 5 (OH/Co=1.0); it was first heat treated at 100 °C for 2 h and then heated in flowing H_2 (i) at 300, 400, 500, 600, and 700 °C for 2 h (Fig. 6), and (ii) at 400 °C for 2, 4, 6, 24, and 48 h. From chemical analyses of sample No. 5, the chemical composition of the complex were evaluated to be

$$\{[Co_{2.64}(OH)_{4.28}(H_2O)]^{+1}\}_{0.87}\,Na_{0.13}\,(Mg_{2.5}Si_4O_{10}F_2) = \{Co_{2.3}(OH)_{3.72}(H_2O)_{0.87}\}Na_{0.13}\,(Mg_{2.5}Si_4O_{10}F_2),$$

assuming that the cobalt(II) hydroxide interlayer has a composition of $[Co_x(OH)_y(H_2O)_m]^{+1}$, $(y+m)/x=2$ with a charge of +1.0 to balance the negative layer charge. The theoretical weight loss of the sample after a complete reduction was calculated to be 13.3 wt% (according to the Eq. 1). As shown in Fig. 6, the cobalt(II) hydroxide interlayer was almost reduced to cobalt metal upon being heat treated at about 600 °C for 2 h; the theoretical and experimental values agreed well. On the other hand, the weight losses after heat treatments at 400 °C for 2, 4, 6, 24, and 48 h were 8.0, 8.8, 9.3, and 10.5 wt%, respectively. Therefore, the reduction reaction was not completed, even after a 48 h treatment.

(Received January 13, 1987)

Dimeric copper(II) trichloroacetate adducts with 3-substituted pyridines, $[Cu(Cl_3CCOO)_2(3\text{-Xpy})]_2$ where X=Cl, Br, H, CN, and CH_3, have been prepared. Magnetic susceptibility and ESR data show that both the singlet-triplet separation ($-2J$) and the zero field splitting (D) decrease in the order: 3-Clpy adduct (193 and 0.397 cm^{-1})≈3-Brpy adduct (191 and 0.399 cm^{-1})>py adduct (188 and 0.385 cm^{-1})>3-CNpy adduct (138 and 0.216 cm^{-1})>3-CH_3py adduct (83 and 0.182 cm^{-1}). Electronic spectra indicate that the adducts with X=Cl, Br, and H have a distorted square-pyramidal copper(II) geometry and that those X=CN and CH_3 have a distorted trigonal-bipyramidal geometry. Form these results, it is concluded that the strength of antiferromagnetic interaction in $[Cu(Cl_3CCOO)_2(3\text{-Xpy})]_2$ complexes decreases as the distortion of copper(II) geometry increases from square-pyramid toward trigonal-bipyramid.

Recent structural studies on dimeric copper(II) carboxylate adducts, $[Cu(RCOO)_2 \cdot L]_2$, have demonstrated that the metal-metal distance becomes longer as either the acidity of the parent carboxylic acid RCOOH[1] or the basicity of the axial ligand L[2] becomes stronger. Then, a longer Cu-Cu distance is usually associated with a greater displacement of the metal ion from the equatorial plane composed of four oxygen atoms. Consequently, the variation of both the group R and the ligand L affects the strength of the Cu-O bonds in the CuO_4 basal plane accompanying a deformation of the bridging framework. For 13 dimeric copper(II) acetate adducts reported up to date, Cu-Cu distances span a narrow range of 2.581—2.671 Å with a variation of 0.09 Å.[2] On the other hand, Cu-Cu distances found for dimeric copper(II) trichloroacetate adducts, $[Cu(Cl_3CCOO)_2 \cdot L]_2$, span a considerably wide range: 2.731 Å for L=benzonitrile (PhCN),[3] 2.776 Å for L=2-chloropyridine (2-Clpy),[1] 2.852 Å for L=caffeine,[4] 3.197 Å for L=2,2,5,5-tetramethyl-1-pyrrolidinyloxyl,[5] and 3.256 Å for L=2,2,6,6-tetramethyl-1-piperidinyloxyl.[5] The coordination environment around each copper(II) ion in the first three adducts is square-pyramidal, whereas that in the last two adducts is trigonal-bipyramidal. These structural data indicate that, for the variation of L, the bridging trichloroacetato ligand coordinates more flexibly than the bridging acetato ligand does. Dimeric copper(II) trichloroacetate adducts may therefore be a suitable choice for the study of structural factors which affect the magnetic properties of copper(II) carboxylate dimers.

This paper reports results of synthetic, magnetic, and spectroscopic studies on five copper(II) trichloroacetate adducts with 3-substituted pyridines, $Cu(Cl_3CCOO)_2(3\text{-Xpy})$, where X=Cl, Br, H, CN, and CH_3.

Table 1. Analytical Data of $Cu(Cl_3CCOO)_2(3\text{-Xpy})$

X	Found (Calcd)/%			
	C	H	N	Cu
Cl	21.85 (21.53)	0.87 (0.87)	2.68 (2.79)	12.58 (12.66)
Br	19.83 (19.78)	0.81 (0.73)	2.35 (2.56)	11.78 (11.63)
H	22.88 (23.13)	1.17 (1.08)	2.87 (3.00)	13.62 (13.60)
CN	24.33 (24.39)	0.82 (0.82)	5.81 (5.69)	12.98 (12.90)
CH_3	24.70 (24.95)	1.53 (1.46)	2.80 (2.91)	13.19 (13.19)

Experimental

Syntheses. $Cu(Cl_3CCOO)_2(3\text{-Xpy})$ (X=Cl, Br, H, CN, and CH_3): $Cu(Cl_3CCOO)_2 \cdot 3H_2O$ (1 mmol) and 3-Xpy (1 mmol) were suspended in a mixture of a solvent (benzene for X=Cl, Br, and CH_3; chloroform for X=H and CN) (30 ml) and 2,2-dimethoxypropane (1 ml). The mixture was warmed gently with stirring and then filtered. After the solution had been concentrated to one-third of its original volume, it was allowed to stand overnight at ca. 5 °C in a refrigerator. The separated green crystals were collected, washed with petroleum ether, and dried in vacuo at room temperature.

The results of the elemental analyses are given in Table 1.

Physical Measurements. The magnetic susceptibility in the temperature range of 80—300 K was determined by the Faraday method. The correction for diamagnetic contribution was made by use of Pascal's constants.[6] The cryomagnetic data were applied to the modified Bleaney-Bowers equation

$$\chi_A = \frac{Ng^2\beta^2}{3kT}\left[1+\frac{1}{3}\exp\left(\frac{-2J}{kT}\right)\right]^{-1}\cdot(1-P) + \frac{Ng_i^2\beta^2}{4kT}\cdot P + N\alpha, \quad (1)$$

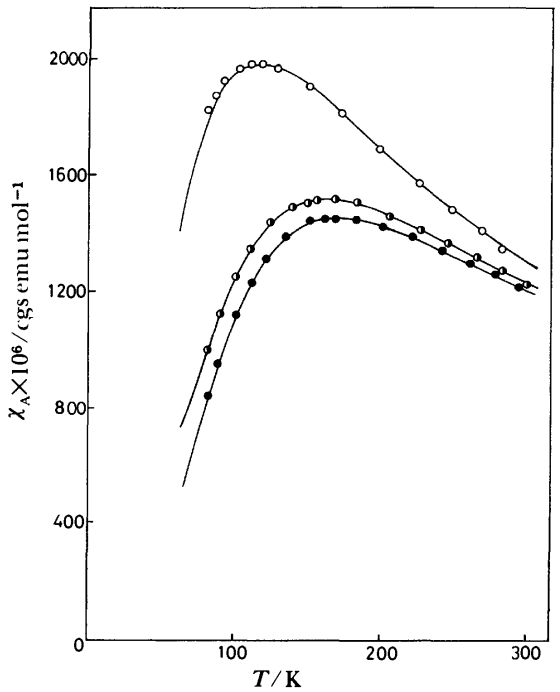

Fig. 1. Variation of magnetic susceptibilities with temperature. (●): $Cu(Cl_3CCOO)_2(3\text{-Brpy})$, (○): $Cu(Cl_3CCOO)_2(py)$, (○): $Cu(Cl_3CCOO)_2(3\text{-CNpy})$. The solid curves were obtained as described in the text.

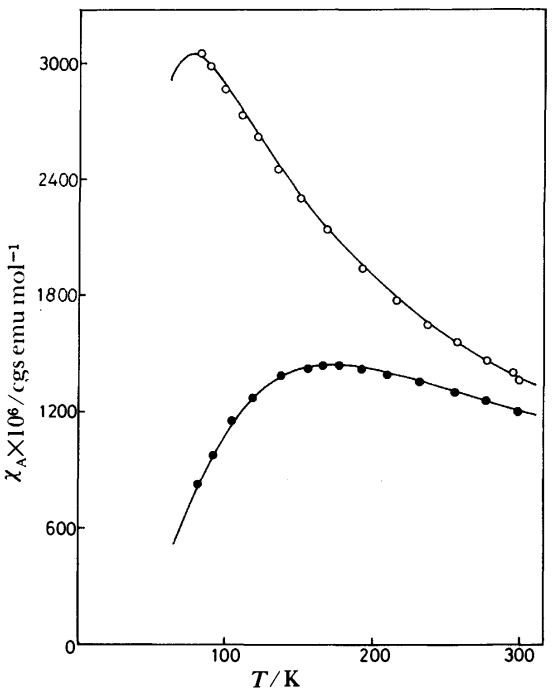

Fig. 2. Variation of magnetic susceptibilities with temperature. (●): $Cu(Cl_3CCOO)_2(3\text{-Clpy})$, (○): $Cu(Cl_3CCOO)_2(3\text{-CH}_3\text{py})$. The solid curves were obtained as described in the text.

where P is the mole fraction of the noncoupled copper(II) impurity and g_i is the average g factor for the impurity. The values of g_i of 2.2 and $N\alpha$ of 60×10^{-6} cgs emu (1 cgs emu=$4\pi\times10^{-6}$ m^3) were used throughout the present study.

Table 2. Magnetic Parameters for $Cu(Cl_3CCOO)_2(3\text{-Xpy})$

X	$-2J$/cm^{-1}	g	$P\times10^2$	$\sigma_{dis}\times10^3$
Cl	193	2.25	1.45	3.28
Br	191	2.24	1.25	3.99
H	188	2.25	4.06	3.72
CN	138	2.20	4.74	5.19
CH_3	83	2.17	0.87	5.45

The best-fit parameters of $-2J$, g, and P were obtained by the non-linear least-squares fitting procedure. The quantity of fit was estimated by means of a discrepancy index

$$\sigma_{dis} = \left[\frac{\sum(\chi_{obsd}-\chi_{calcd})^2}{\sum\chi_{obsd}^2}\right]^{1/2} \quad (2)$$

The thermal magnetic data are shown in Figs. 1 and 2 as plots of χ_A vs. T. The values of $-2J$, g, p, and σ_{dis} are summarized in Table 2.

The IR spectrum of $Cu(Cl_3CCOO)_2(3\text{-CNpy})$ was recorded on a Hitachi 260-10 IR Spectrophotometer with Nujol mulls.

Reflectance spectra were recorded on a Hitachi Recording Spectrophotometer 323. The wave numbers of the ligand-field band maxima in the range 5000—20000 cm^{-1} (so-called Band I) are collected in Table 3 and the spectral curves are shown in Fig. 3. For comparison, the reflectance spectral curve of $[Cu(Cl_3CCOO)_2(2\text{-Clpy})]_2$ is also given in Fig. 3.

Polycrystalline powder ESR X-band spectra were recorded with a Jeolco JES-ME 2 Spectrometer at room temperature. The spectra are shown in Fig. 4 and the ESR parameters are given in Table 4.

Results and Discussion

The magnetic susceptibility data of the complexes, $Cu(Cl_3CCOO)_2(3\text{-Xpy})$, are well represented by Eq. 1, which indicates that these complexes have a carboxylato bridged dimeric structure.[1-3] As shown in Table 2, the $-2J$ values of the 3-substituted pyridine adducts with X=Cl, Br, and H are comparable to those of $[Cu(Cl_3CCOO)_2(2\text{-Clpy})]_2$ (217 cm^{-1})[1] and $[Cu(Cl_3CCOO)_2(PhCN)]_2$ (224 cm^{-1}),[3] whereas those of the adducts with X=CN and CH_3 are considerably small. Such a substituent effect of 3-CN and 3-CH_3 groups will be discussed later. For the 3-cyanopyridine adduct, the CN stretching vibration (2240 cm^{-1}) appears in almost the same region as the free 3-cyanopyridine ligand (2232 cm^{-1}),[7] which suggests that in this adduct the CN group does not coordinate to the metal ion.

The electronic spectra of the adducts with X=Cl, Br, and H are similar to one another and closely resemble that of $[Cu(Cl_3CCOO)_2(2\text{-Clpy})]_2$ (Fig. 3), giving a band maximum at ca. 12500 cm^{-1} and a low-energy shoulder at ca. 8000 cm^{-1}. The separation between these two peaks, $\Delta\tilde{\nu}_{max}$=3890—4930 cm^{-1}, is comparable to those observed for $[Cu(CH_3COO)_2(py)]_2$ (5000 cm^{-1})[8] and $[Cu(Cl_3CCOO)_2(2\text{-Clpy})]_2$ (4900 cm^{-1}). These facts indicate that these three adducts have a

distorted square-pyramidal copper(II) geometry similarly to $[Cu(Cl_3CCOO)_2(2\text{-}Clpy)]_2$.[1] On the other hand, the spectral feature of the adducts with X=CN and CH_3 is quite similar to those of distorted trigonal-bipyramidal copper(II) complexes such as $Cu_4OCl_6(Ph_3PO)_4$ ($\Delta\tilde{\nu}_{max}$=1300 cm^{-1}),[9] $[Cu(bpy)_2Cl]NO_3\cdot 3H_2O$ ($\Delta\tilde{\nu}_{max}$=2000 cm^{-1}),[10] $[Cu(bpy)_2CN]NO_3\cdot 2H_2O$ ($\Delta\tilde{\nu}_{max}$= 2100 cm^{-1}),[11] and $[Cu(Ph_3CCOO)_2(py)]_2\cdot$benzene ($\Delta\tilde{\nu}_{max}$=2510 cm^{-1}).[12] The spectra of the latter two adducts show two peaks of about equal intensity with a separation of ca. 1800—1900 cm^{-1} in the range 10000—15000 cm^{-1} (Fig. 3 and Table 3). These $\Delta\tilde{\nu}_{max}$ values are comparable to those of the distorted trigonal-bipyramidal copper(II) complexes described above. The spectral similarity suggests that these two adducts have a distorted trigonal-bipyramidal copper(II) geometry, which may be produced rather by steric effects of the large CN and CH_3 substituents than by their electronic effects. Such a large size of substituents probably hinders smooth packing of molecules in crystal lattices, resulting in a steric strain in the coordination environment around the metal ion. Harrison et al.[10] demonstrated, in their study of $[Cu(bpy)_2Cl]X$ where X=ClO_4, $NO_3\cdot 3H_2O$, $1/2[(S_5O_6)\cdot 6H_2O]$, Cu^ICl_2, and $Cl\cdot 6H_2O$, that copper(II) complexes with a metal geometry close to the regular trigonal-bipyramid show a single broad peak in their electronic spectra at 12500 cm^{-1} (the $^2E' \leftarrow {}^2A_1'$ transition in the D_{3h} symmetry), whereas those with the square-pyramidally distorted trigonal-bipyramidal CuN_4Cl chromophore show a twin-peaked band in the region of 10000—14500 cm^{-1} with a maximum splitting of 4060 cm^{-1} for the complex whose metal geometry is closest to the regular square-pyramid. This fact suggests that, for five-coordinated copper(II) complexes, the $\Delta\tilde{\nu}_{max}$ value can be taken as a measure of the degree of distortion in metal geometry from square-pyramid to trigonal-bipyramid. As can be seen from Table 3, the $\Delta\tilde{\nu}_{max}$ value observed for the present complexes decreases in the order: 3-Clpy and 3-Brpy adducts>py adduct>3-CNpy adduct>3-CH_3py adduct. This order is just the same as that of the decrease in the $-2J$ values of these complexes (Table 2); there exists a parallel relation between $-2J$ and $\Delta\tilde{\nu}_{max}$ values (smaller $-2J$ with smaller $\Delta\tilde{\nu}_{max}$). This parallelism indicates that the strength of antiferromagnetic interaction in the present complexes decreases as the distortion of copper(II) geometry increases from square-pyramid toward trigonal-bipyramid.

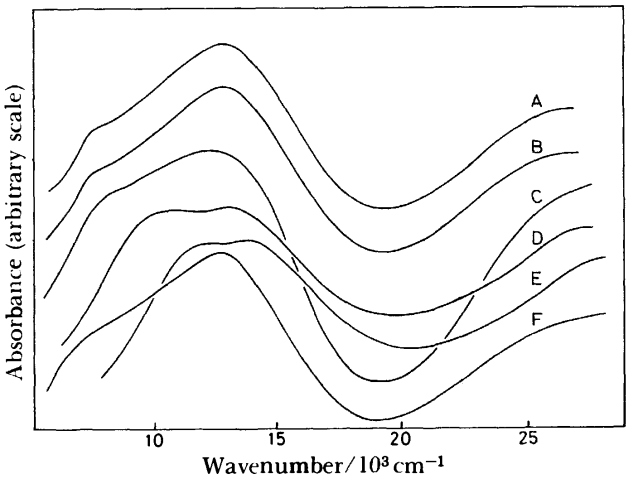

Fig. 3. Reflectance spectra of $Cu(Cl_3CCOO)_2\cdot L$. (A): L=3-Clpy, (B): L=3-Brpy, (C): L=py, (D): L=3-CNpy, (E): L=3-CH_3py, (F): L=2-Clpy.

Table 3. Reflectance Spectral Data of $Cu(Cl_3CCOO)_2(3\text{-}Xpy)$

X	$\tilde{\nu}_{max}\times 10^{-3}$/$cm^{-1}$	$\Delta\tilde{\nu}\times 10^{-3}$/$cm^{-1}$	
Cl	12.50	7.57	4.93
Br	12.50	7.57	4.93
H	12.27	8.40	3.89
CN	12.82	10.86	1.96
CH_3	14.28	12.50	1.78

The ESR spectra of the present complexes show absorption bands arising from the triplet state. The parameters listed in Table 4 were evaluated by a general method for the analysis of powder ESR spectra of dimeric copper(II) complexes.[13] The ESR spectral feature of the adducts with X=Cl, Br, and H is the same as that usually observed for dimeric copper(II) carboxylate adducts, which have a square-pyramidal metal geometry.[13] For these three adducts, the common relation between zero field splitting (D) and resonance magnetic field (H_o), $D>H_o$,[13,14] was observed. On the other hand, the ESR spectra of the adducts with X=CN and CH_3 are quite different from those of the above three adducts (Fig. 4) and fundamentally the same as that of $[Cu(Ph_3CCOO)_2(py)]_2\cdot$benzene ($D$=0.204 cm^{-1}).[12] For the latter two adducts, an uncommon relation, $D<H_o$, was observed; this relation has recently been detected for $[Cu(Ph_3CCOO)_2(py)]_2\cdot$benzene, whose $-2J$ (184 cm^{-1}) is quite small as compared with those of common dimeric copper(II) carboxylates.[12] The order of decrease in the D values of the present complexes is the same as that in the $-2J$ values. Thus, it is concluded that the zero field splitting of $[Cu(Cl_3CCOO)_2(3\text{-}Xpy)]_2$ decreases as the distortion of the metal geometry increases from square-pyramid toward trigonal-bipyramid, just in the same way as the singlet-triplet separation does.

It is noted here that the values of g_{av} obtained from

Table 4. ESR Parameters for $Cu(Cl_3CCOO)_2(3\text{-}Xpy)$

X	D/cm^{-1}	$g_{//}$	$g_\perp$	g_{av}[a]
Cl	0.397	2.536	2.143	2.282
Br	0.399	2.575	2.154	2.304
H	0.385	2.562	2.159	2.301
CN	0.216	2.425	2.155	2.248
CH_3	0.182	2.396	2.183	2.256

a) $g_{av}=[1/3(g_{//}^2+2g_\perp^2)]^{1/2}$.

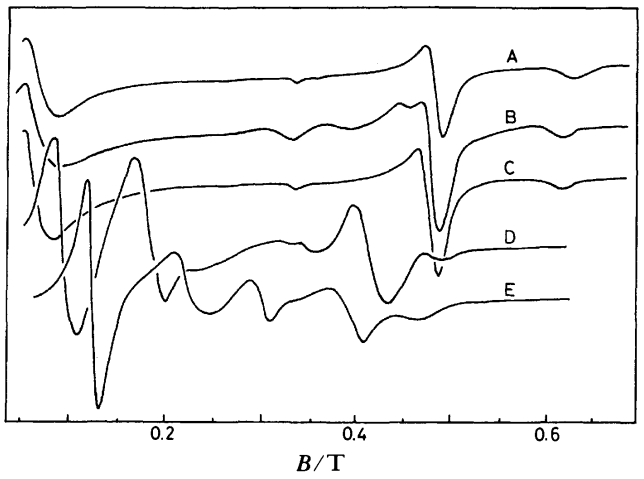

Fig. 4. Room-temperature polycrystalline powder ESR spectra of $Cu(Cl_3CCOO)_2(3\text{-}Xpy)$ at X-band frequency. (A): X=Cl, (B): X=Br, (C): X=H, (D): X=CN, (E): $X=CH_3$.

the present ESR study are smaller than those estimated from the magnetic susceptibility measurements (Tables 2 and 4); this is often observed for dimeric copper(II) carboxylates. The reason for this fact, however, is not clear at present.

A New Detection Method of Electromigrating Ions through a Cation-Exchange Membrane

Akihiro KAWAGUCHI,* Shin-ichi MAGAINO, Takashi SUZUKI,† and Yasushi TAKEUCHI††
Industrial Research Institute of Kanagawa Prefecture, 3173 Shouwa, Kanazawa-ku, Yokohama 236
†Department of Applied Chemistry, Yamanashi University, 4 Takeda, Koufu 400
††Department of Industrial Chemistry, Meiji University, 1-1-1 Higashi-mita, Tama-ku, Kawasaki 214
(Received January 20, 1987)

An isotachophoretic analysis and electromigration of ions through a cation-exchange membrane have been investigated. K, Li, Na, and Cu ions were migrated at a constant current. The potential difference between fibrous ion exchanger and cathode reservoir was measured during migration of ion zone. The relative ionic mobility of K^+, Na^+, Li^+, and Cu^{2+} calculated by potential difference was 1, 0.667, 0.420, and 0.218, respectively. The concentration of mobile cations in unit volume of the membrane was calculated by the amount of migration and the migration time of each ion. The concentration of mobile Li^+ in the Li zone was about 10% lower than that of mobile K^+ in the K zone. This difference in concentration is similar to the result by the usual isotachophoresis using a capillary tube. The migration time of each ion zone through detection part was proportional to the amount of migration. K^+ and Li^+ in the concentration range from 0.6×10^{-3} to 0.2 mol dm^{-3} were quantitatively determined by the migration time with reproducible errors less than ±5 %.

The ion-exchange membrane is one of the useful electromigration media for separating ions in isotachophoresis. The ionic mobility in the membrane is different from that in aqueous solution, because ionic mobility is influenced by affinity of the membrane and hydration of the ions. Electromigration using an ion-exchange membrane was reported by Kakihana et al. for separating lithium isotope,[1,2] alkalis,[3] and alkaline earth metals.[4] They described the relationship between electromigration time and electromigration distance at a constant current. For the measurement of migration amount of ions, they used thin membranes and determined ions by means of flame spectrophotometry and mass spectrometry. In a previous paper,[5] the authors have reported a rapid detection method for migrating ions by measuring the potential gradient in the membrane without any sensing electrode on the membrane surface. A more sensitive method, however, is required for the analysis of migrating ions.

In capillary-tube isotachophoresis, platinum electrodes are usually used for potential gradient detectors. Everaerts and Verheggen,[6] and Akiyama and Mizuno[7] reported that bubbles are generated from platinum surface and that the potential gradient fluctuated at high current densities. To prevent these phenomena, they made the electrode surface smooth, and added Triton X-100 or Na_2AsO_4 to electrolyte in the capillary tube.

A redox reaction occurs on platinum surface because of high electronic conductivity. The reaction will be prevented by use of an ionic conductor electrode instead of platinum. The ionic conductivity of ion exchanger has been studied by several workers.[8,9] Although ion exchanger is widely used for electrodialysis,[10,11] fuel cells using solid polymer electrolytes,[12,13] electrolysis,[14] etc., it has not been used for potential gradient measurement in isotachophoresis.

In this study, the authors examined fibrous ion exchanger as a potential gradient detector at high current densities. The fibrous anion exchanger was contacted with cation-exchange membrane as a sensing electrode and the electromigration of K^+, Na^+, Li^+, and Cu^{2+} through membrane was examined. Firstly, the relative ionic mobility was determined in order to detect mobile cation by measuring the potential difference between fibrous anion exchanger and cathode reservoir at a constant current. Secondly, the concentration of mobile cation per unit volume of the membrane was obtained by measuring the amount of migrating ions and the migration time of each ion zone. The relationship between migration time and concentration of sample solution was discussed.

Theoretical

Qualitative Analysis of the Migration Ion. When an ion i migrates in ion-exchange membrane, migration velocity v_{mi}(cm s^{-1}) is the product of potential gradient E_{mi}(V cm^{-1}) and ionic mobility u_{mi} (cm^2 V^{-1} s^{-1}) as

$$v_{mi} = u_{mi}E_{mi}. \quad (1)$$

In isotachophoresis, v_{mi} is a constant. For example, when K^+ and Li^+ are electrically displaced by Cu^{2+} as a terminating ion, we get a formula

$$u_{mK}E_{mK} = u_{mLi}E_{mLi} = u_{mCu}E_{mCu}. \quad (2)$$

When u_{mK} and E_{mK} are defined to be unity, the relative ionic mobility of Li^+ and Cu^{2+} is obtained by the potential gradient

$$u_{mLi} = 1/E_{mLi} \text{ and } u_{mCu} = 1/E_{mCu}. \quad (3)$$

Migration Amount in the Membrane. When ion i migrates from aqueous solution to membrane, the amount of migration A_{mi}(mol) passing through a unit area of interfaces in a unit time is expressed by

$$A_{mi} = v_i c_i/1000, \quad (4)$$

where v_i and c_i are migration velocity in cm s^{-1} and solution concentration in mol dm^{-3}, respectively.

When v_i is proportional to mobility u_i ($cm^2\ V^{-1}\ s^{-1}$) in the solution, the ratio between amounts of migration for Li^+ and K^+ A_{mLi}/A_{mK} is obtained as follows:

$$A_{mLi}/A_{mK} = (u_{Li}/u_K)(c_{Li}/c_K). \quad (5)$$

Concentration of Mobile Cation. From thickness t (cm) and width w (cm) at the detection part of membrane, the concentration of mobile cation c_{mi} (mol dm^{-3}) per unit volume is defined by using migration amount A_{mi} and migration velocity v_m ($cm\ s^{-1}$) by

$$c_{mi} = 1000\,A_{mi}/s_i v_m t w, \quad (6)$$

where s_i (s) is the migration time of i ion zone passed through the center of detection part. The ratio of migration time of K^+ to that of Li^+ is obtained by Eq. 6 as

$$s_{Li}/s_K = (A_{mLi}/A_{mK})/(c_{mLi}/c_{mK}). \quad (7)$$

If A_{mLi}/A_{mK} is unchanged during the migration, s_{Li}/s_K will be constant, because c_{mLi}/c_{mK} is constant in isotachophoresis. Substituting Eq. 5 by Eq. 7, we obtain

$$c_{Li}/c_K = (s_{Li}/s_K)(c_{mLi}/c_{mK})(u_K/u_{Li}). \quad (8)$$

If c_{mLi}/c_{mK} and u_K/u_{Li} remain constant, c_{Li}/c_K will be estimated by measuring s_{Li}/s_K.

Experimental

Electromigration Cell. The symbol c in Fig. 1 indicates the narrowed part of cation-exchange membrane (Selemion CMV). When potential gradient is measured at the narrowed part of membrane, a small amount of migrating ions will be detected. The membrane was washed with 1 mol dm^{-3} NaOH, 1 mol dm^{-3} HCl, and distilled water. The H^+-form membrane was stored in distilled water. Before each run, the membrane was taken out and wiped with filter paper to remove surface water. The membrane was placed on a clean glass plate coated with a small amount of grease. Both ends of the membrane were connected to the bottom edge of each anode and cathode reservoir. A fibrous anion exchanger (Selemion AMV, OH^--form) of 0.02 mm in diameter and 10 mm in length was placed on the membrane at a distance of 1 mm from the cathode reservoir. The membrane was tightly covered with a glass plate coated with grease. The apparatus is shown in Fig. 1.

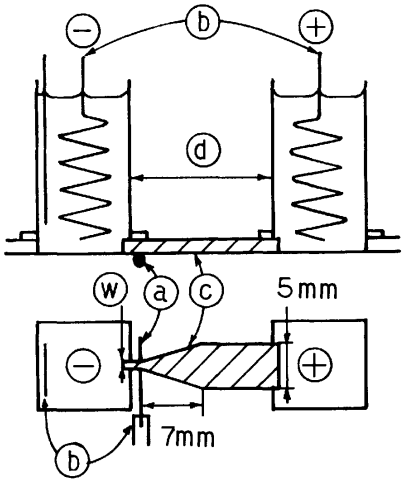

Fig. 1. Cell assemblies.
a; Anion exchange fiber, b; Pt electrode, c; cation-exchange membrane, d; distance of electromigration, w; outlet width (0.60 mm).

Isotachophoretic Separation. Ionic migration was generated by a constant current power source (Toyo PS-1510), which connects to platinum electrodes in cathode and anode reservoirs. The cathode reservoir was filled with 0.5 mol dm^{-3} H_2SO_4 and the anode reservoir with a mixture of KOH and LiOH in the range from 0.6×10^{-3} to 0.2 mol dm^{-3}. In the experiment for separating K^+ and Li^+, the anode reservoir was filled with KOH-LiOH mixture and a constant current of 0.8 mA was applied for 3 min. Then the reservoir solution was replaced by 0.5 mol dm^{-3} $CuSO_4$ to continue the experiment under the same current at room temperature.

Migration Time and Amount of Ion. The fibrous ion exchanger was contacted in series with thin platinum foil and the potential difference between fibrous ion exchanger and cathode reservoir was measured by a high impedance potentiometer (Nichia NP-PM-1). The migration time and potential difference between the fibrous ion exchanger and cathode reservoir were measured. K^+ and Li^+ were allowed to migrate for 3 min under the same current. The membrane was then taken out of the apparatus and K^+ and Li^+ were eluted with 2 mol dm^{-3} HCl. Concentrations of K^+ and Li^+ in HCl were measured by means of flame spectrophotometry.

Results and Discussion

Sensing Electrode. First, a platinum wire of 0.05

mm in diameter was used as sensing electrode instead of fibrous anion exchanger. When the potential difference between platinum wire and cathode reservoir was measured, fluctuations were observed in potential curve. Bubbles were simultaneously generated from platinum wire. Moreover, Cu^{2+} passing through the membrane was reduced to black metallic copper on platinum, and black portion grew toward the anode reservoir. This phenomenon shows that a redox reaction occurred on the surface of platinum wire.

On the other hand, when the fibrous anion exchanger was used as a sensing electrode, no redox reaction was observed in the migration. Figure 2 shows typical electropherograms for K^+, Li^+, and Cu^{2+} using fibrous anion exchanger. The first moving boundary between the first zone of H^+ and the second zone of alkali metal ions, the second moving boundary between the second zone of alkali metal ions, and the third zone of Cu^{2+} are sharply recognized during the migration. As shown in Fig. 2, the potential difference between fibrous ion exchanger and cathode reservoir is approximately constant in each zone. When each boundary passed through the detection part, an increase in potential difference was clearly observed. These results are similar to the case of capillary-tube isotachophoresis. It seems that fibrous ion exchanger is a useful medium for detecting potential gradient at high current densities.

Qualitative Analysis. When K^+, Li^+, and Cu^{2+} zones pass through the detection part, the potential difference between fibrous ion exchanger and cathode reservoir is 0.97, 2.31, and 4.44 V, respectively, as shown in① of Fig. 2. The relative value of the potential difference for Na^+, Li^+, and Cu^{2+} to that for K^+ was calculated to be 1.50, 2.38, and 4.58, respectively. Equation 3 indicates that the relative mobility for an ion is the reciprocal of potential value. The calculated relative mobility is given in Table 1. The relative mobility of alkali metals was reported by Hosoe et al.[3)] using a sulfonated cation-exchange membrane. Their values agreed with those obtained in this study within ±3%.

The mobility of Cu^{2+} is considerably lower than that in aqueous solution. It has been mentioned[3,4)] that the ionic mobility in membrane is different from that in aqueous solution, because the mobility is influenced by the affinity of ions with membrane and the hydration of ions. The affinity of membrane with ions increases with the increase in valency of ions.[15)] The relative mobility of Cu^{2+} is, therefore, smaller

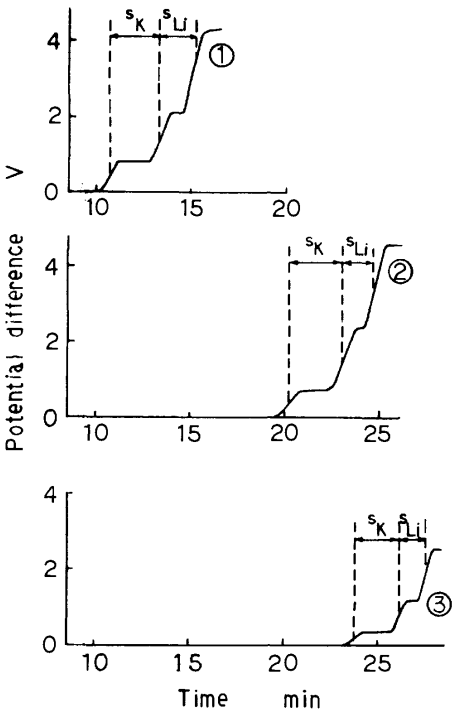

Fig. 3. Effect of the migration distance for the isotachophoretic separation. Sample: 0.2 mol dm^{-3} KOH+0.2 mol dm^{-3} LiOH; 0.8 mA for 3 min. Terminal solution: 0.5 mol dm^{-3} $CuSO_4$; 0.8 mA.

③	15

than that of alkali metal ions. It is plausible that migrating ion is identified by the measurement of potential difference in membrane.

Concentration of Mobile Cation. A mixture of each 0.2 mol dm^{-3} KOH and LiOH was put into anode reservoir and a constant current of 0.8 mA was applied, then the solution in reservoir was replaced with 0.5 mol dm^{-3} $CuSO_4$ and migration continued. Figure 3 shows the effect of migration distance for isotachophoretic separation using membranes of 10, 13, and 15 mm in length. The ratio of migration time s_{Li}/s_K was determined to be 0.75, 0.61, and 0.61, respectively. The result indicates that K^+ and Li^+ migrate at a same speed by using membrane longer than 13 mm.

Table 2 gives amounts of migration A_{mK} and A_{mLi} obtained by spectrophotometry when migration current of 0.8 mA was applied for 3 min. The concentration of mobile K^+ and mobile Li^+ in unit volume of membrane was calculated using Eq. 6 and given by c_{mK}

Table 2. A_{mi}, s_i, and c_{mi} for Different Concentration of K^+ and Li^+ at $v_m=6.94\times10^{-3}$ cm s^{-1}, $t=0.0126$ cm, and $w=0.060$ cm

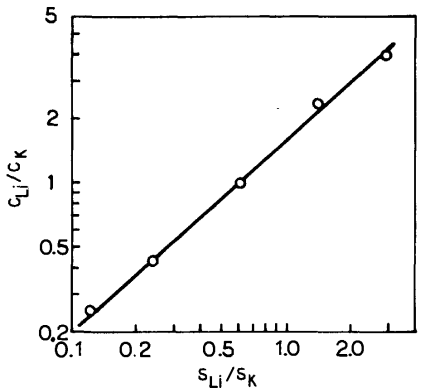

Fig. 4. Relation between c_{Li}/c_K and s_{Li}/s_K. Sample: KOH and LiOH; 0.8 mA for 3 min. Terminal solution; 0.5 mol dm^{-3} $CuSO_4$; 0.8 mA.

and c_{mLi} in Table 2. The mean values of c_{mK} and c_{mLi} were 1.03 and 0.92 mol dm^{-3}, respectively. These values were approximately constant in the range of migration current from 0.3 to 1.0 mA. The concentration of mobile Li^+ in Li^+ zone was about 10% lower than that of mobile K^+ in K^+ zone. This concentration difference is similar to the result in the usual isotachophoresis using a capillary tube.

Quantitative Analysis. Table 3 gives the ratios of A_{mi}, u_i, c_{mi}, and s_i to each value for K^+ for different ratios of concentration c_{Li}/c_K at the same conditions described in Table 2. Using Eq. 5, u_{Li}/u_K was obtained as an approximately constant value of 0.561, independent of A_{mLi}/A_{mK} and c_{Li}/c_K, and it was close to the value of relative ionic mobility in aqueous solution (0.526 at 25 °C). The product of c_{mK}/c_{mLi} multiplied by u_{Li}/u_K is nearly 0.61, then c_{Li}/c_K was obtained from Eq.

Table 3. Relative Values of A_{mi}, u_i, c_{mi}, and s_i for Different c_{Li}/c_K

c_{Li}/c_K	A_{mLi}/A_{mK}	u_{Li}/u_K	c_{mLi}/c_{mK}	s_{Li}/s_K
2.333	1.296	0.556	0.927	1.400
1.000	0.533	0.533	0.880	0.607

mean		0.561	0.897	

8 as follows:

$$c_{Li}/c_K=(s_{Li}/s_K)/0.61. \quad (9)$$

Figure 4 shows this relation. The value of c_{Li}/c_K was estimated by use of s_{Li}/s_K in a reproducibility of ±5%. To determine the measurable concentration region of K^+ or Li^+, the migration was investigated in the concentration range of 0.6×10^{-3} to 0.2 mol dm^{-3} KOH and LiOH. In this region, it was confirmed that the concentration of K^+ or Li^+ is estimated by Eq. 9 using s_{Li}/s_K and known concentration of Li^+ or K^+. The limit of detection for K^+ was 0.11 μmol from the electropherogram in this study. The proposed method is more sensitive than the method reported previously.[5]

Alkaline Hydrolysis of Inorganic *cyclo*-Polyphosphates

Genichiro KURA
Department of Chemistry, Fukuoka University of Education, Akama, Munakata, Fukuoka 811-41
(Received February 2, 1987)

The hydrolysis rates of inorganic *cyclo*-polyphosphates in alkaline solutions were determined. The rates in a NaOH solution were significantly faster than those in a $(CH_3)_4NOH$ solution. Ion-pair formation between PO^- and Na^+ renders the P atom more positive by reducing the electron density around the atom and more susceptible to the nucleophilic attack by OH^-. In a $(CH_3)_4NOH$ solution, higher-membered *cyclo*-polyphosphates with a larger ring structure became rather stable. Arrhenius' activation energy for each phosphate decreases in the order $HCl>NaOH>(CH_3)_4NOH$.

As the major compounds of the condensed phosphates produced by the dehydration of the oxoacid of phosphorus oxidation number 5, linear phosphates with linear chain structure and *cyclo*-polyphosphates with cyclic structure consisting of middle P-O-P bond have been well-known.[1] In these condensed phosphates, the chemical properties of linear phosphates with shorter chain length, especially those of di- and triphosphate have been extensively investigated in connection with ADP and ATP, both of which are biochemically important.

In the *cyclo*-polyphosphate series, *cyclo*-tri- and *cyclo*-tetraphosphates have been prepared since earlier time, and the chemical properties have extensively been studied.[1] As in the case of linear phosphates with a polymerization degree larger than four, the investigation about *cyclo*-polyphosphates above pentamer with a ten-membered ring structure has been hindered by the difficulty involved in their preparation or isolation. Since the preparation of *cyclo*-hexa- and *cyclo*-octaphosphate were reported by Griffith and Buxton,[2] and by Schülke,[3] respectively, we have investigated various properties of these higher-memberted *cyclo*-polyphosphates.[4-13]

cyclo-Polyphosphates of the general formula $M^I_n(PO_3)_n$ have a high negative charge on their relatively compact molecule and hence they can be utilized as important electrolytes in aqueous solutions since the anion is very weak as a Brønsted base. These *cyclo*-polyphosphates are very stable in a neutral aqueous solution even if they are boiled up to one hour.

However, in strong acidic or basic solutions, they are easily hydrolyzed and their hydrolysis rate is accelerated, especially by hydrogen ions.[13] Their hydrolysis rate in the alkaline solutions has not been elucidated as systematically as in acidic solutions. We predicted that *cyclo*-polyphosphates in alkaline solution would be hydrolyzed more slowly than in strong acidic conditions. Alkaline hydrolysis of *cyclo*-tetraphosphate was employed for the preparation of linear tetraphosphate.[14-17] In this regard, it is important to clarify the alkaline hydrolysis of *cyclo*-hexa- and *cyclo*-octaphosphate. Hydrolysis data on *cyclo*-penta- and *cyclo*-heptaphosphate could not be obtained since the isolation of both phosphates in sufficient quantity is difficult.[4,8]

Experimental

Materials. Sodium salts of *cyclo*-polyphosphates were prepared by the methods described in the literature.[2,3,18,19] Their purities were checked by an analytical system applied to the analysis of the hydrolysis products.[13]

A tetramethylammonium hydroxide solution was prepared by treating the chloride with an anion-exchange resin of the OH^- form.

All other chemicals used were reagent grade and commercially available.

Analytical System. The separation of *cyclo*-polyphosphates to be hydrolyzed from linear phosphates as hydrolysis products was achieved by an anion-exchange chromatography. As an anion exchanger, TSK Gel SAX 10 μm was used; column dimensions were 4 mm in diameter and 250 mm in height. As an eluting agent, 0.4 mol dm^{-3} KCl of pH 10.2 (plus 0.1% EDTA) was used. The phosphates in the effluent were automatically determined by spectrophotometry with the use of a Mo(V)-Mo(VI) reagent.[11]

Futher details on the analytical system are described in the references.[11-13]

Procedure. The initial concentration of each *cyclo*-polyphosphate to be hydrolyzed was adjusted to 1.25×10^{-3} mol dm^{-3} and the hydrolysis reaction was performed in a water bath, the temperature of which was maintained within ±0.1 °C. At measured time intervals, samples were withdrawn and neutralized with the same equivalents of hydrochloric acid, and stored in a refrigerator until taken out for analysis.

Results and Discussion

Hydrolysis rates of four *cyclo*-polyphosphates in 0.25, 0.5, 0.75, and 1 mol dm^{-3} NaOH solutions at 50 °C were determined by the liquid chromatography. If $[P]_0$ and $[P]_t$ denote the concentration of the phosphate at time zero and t, respectively, log $([P]_t/[P]_0)$ versus t plots for *cyclo*-octaphosphate hydrolysis are shown in Fig. 1 and in each case the rates are first order for the phosphate as

$$-\frac{dc}{dt} = k_{obsd}c, \quad (1)$$

where c is the total concentration of the phosphate. Since the hydrolysis rate is also a function of the OH^-

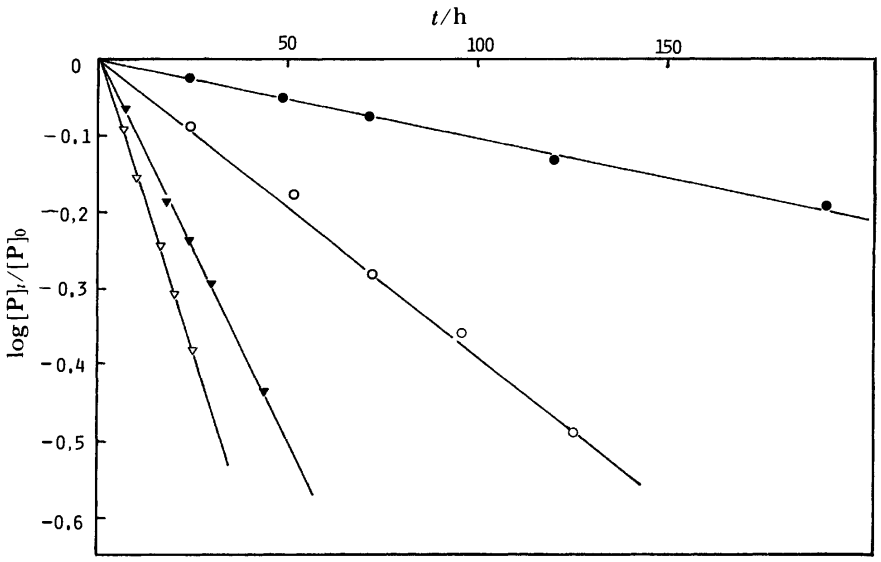

Fig. 1. Hydrolysis rates of *cyclo*-octaphosphate at different NaOH concentrations at 50°C. ●; 0.25 mol dm^{-3}, ○; 0.5 mol dm^{-3}, ▼; 0.75 mol dm^{-3}, ▽; 1 mol dm^{-3}.

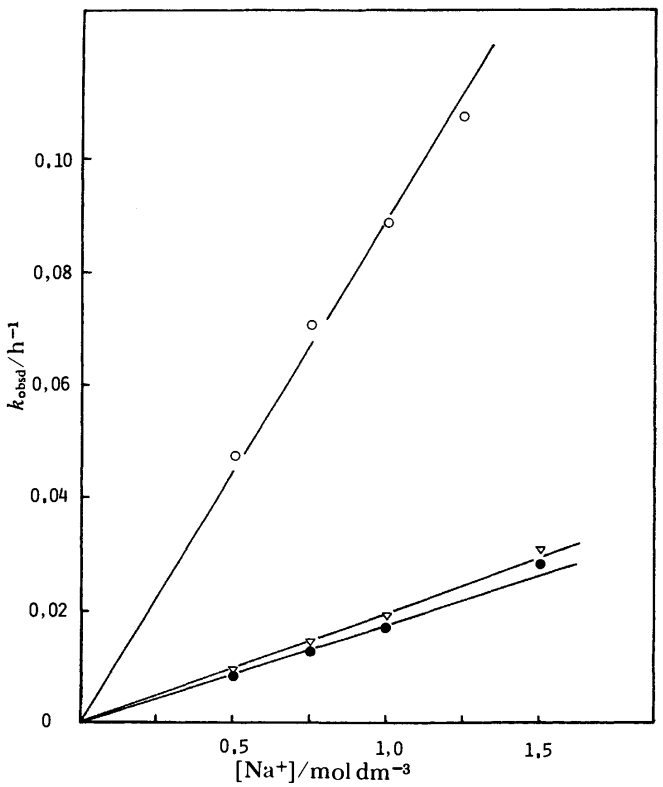

Fig. 2. Plots of the rate constants of *cyclo*-polyphosphates at 50°C against sodium ion concentration ([OH$^-$]≒0.5 mol dm^{-3}). ○; P_{4m}, ●; P_{6m}, ▽; P_{8m}.

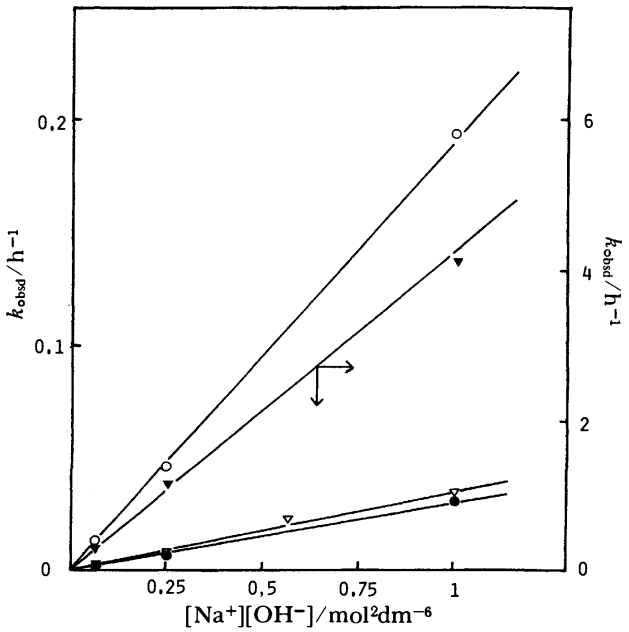

Fig. 3. Plots of the rate constants of *cyclo*-polyphosphates at 50°C against the product of sodium ion and hydroxide ion concentration. ▼; P_{3m}, ○; P_{4m}, ●; P_{6m}, ▽; P_{8m}.

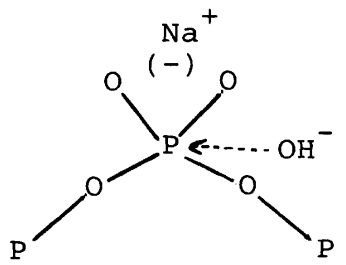
ion concentration, k_{obsd} can be written as $k[OH^-]^n$.

The hydrolysis rate was also measured at a constant hydroxide ion concentration ([OH$^-$]=0.5 mol dm^{-3}) by changing the sodium ion concentration by adding sodium chloride. As shown in Fig. 2, k_{obsd} changed in proportion to [Na$^+$]. From the above fact and the results of the hydrolysis rates at various sodium hydroxide concentration shown in Fig.3, the hydrolysis rate in NaOH solutions can be presented as Eq. 2. Sodium ions directly affect the hydrolysis rate in NaOH solutions.

$$-\frac{dc}{dt} = k[Na^+][OH^-]c \qquad (2)$$

It has been shown[3-5,8] that *cyclo*-polyphosphate anions having such high negative charge form complexes (or ion-pairs) with various cations. The ion-pair formation of PO$^-$ and Na$^+$ renders the phospho-

rus atom more positive by reducing the electron density around the P atom and more susceptible to the nucleophilic attack by OH^- in a similar manner at the acidic conditions.[13]



For a comparison with acidic conditions, the activation energy of *cyclo*-octaphosphate hydrolysis in a 0.5 mol dm^{-3} NaOH solution was determined. An Arrhenius' plot is shown in Fig. 4. The activation energy of 82.8±0.3 kJ mol^{-1} is slightly lower than the value of 96.7±0.3 kJ mol^{-1} in a 0.1 mol dm^{-3} HCl solution.[13]

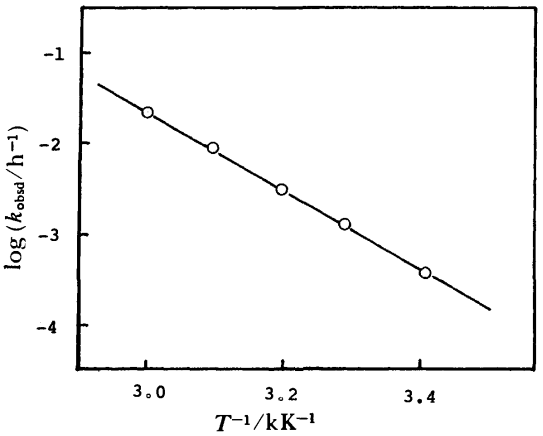


Fig. 4. Arrhenius' plots for *cyclo*-octaphosphate hydrolysis in 0.5 mol dm^{-3} NaOH solution.

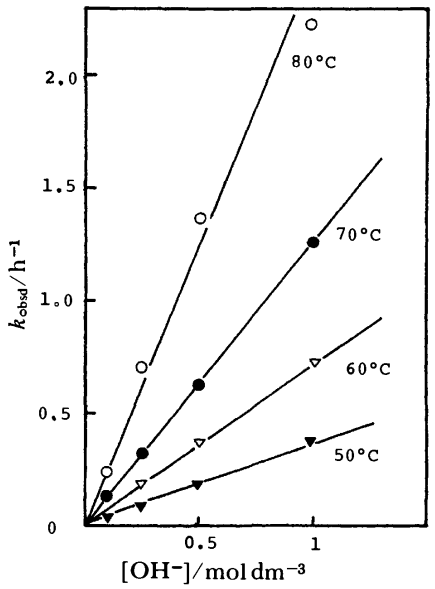

Fig. 5. Plots of the rate constant of *cyclo*-triphosphate at different temperatures and at different tetramethylammonium hydroxide concentrations.

The hydrolysis rates in tetramethylammonium hydroxide solutions were also determined. The hydroxide dose not contain a cation which interacts with *cyclo*-polyphosphate anions. Hydrolysis rates were also first-order for *cyclo*-polyphosphates. Reaction rates of *cyclo*-triphosphate at various hydroxide concentrations and various temperatures are shown in Fig. 5. At each temperature, k_{obsd} varied proportionally with [OH^-]. This suggests that the hydrolysis reaction in alkaline solutions in the absence of any cations which might interact with *cyclo*-polyphosphate anions is caused by the nucleophilic attack of OH^- on P atom in the phosphate tetrahedra. Similar results were obtained for *cyclo*-tetraphosphate hydrolysis. The rate constants in 0.5 and 1.0 mol dm^{-3} $(CH_3)_4NOH$ solutions at various temperatures are shown in Fig. 6. At each temperature, k_{obsd} in a 1.0 mol dm^{-3} $(CH_3)_4NOH$ solution was twice that in a 0.5 mol dm^{-3} $(CH_3)_4NOH$ solution. The activation energy of *cyclo*-tetraphosphate was 75.3±1.8 kJ mol^{-1} regardless of $(CH_3)_4NOH$ concentration. Analogously, that of *cyclo*-triphosphate was 62.8±0.8 kJ mol^{-1}. These values were lower than those in NaOH solutions and a 0.1 mol dm^{-3} HCl solution. However, a large discrepancy between them was not observed.

Since higher-membered *cyclo*-hexa- and *cyclo*-octaphosphates with a larger ring structure were not hydrolyzed very much, even if at higher $(CH_3)_4NOH$ concentrations and at higher temperatures, detailed data on their hydrolysis rate at various conditions were not obtained on the contrary to the case of *cyclo*-tri- and *cyclo*-tetraphosphate hydrolysis.

In Fig. 7, the rate constants of each *cyclo*-polyphosphate in 0.5 mol dm^{-3} $(CH_3)_4NOH$, 0.5 mol dm^{-3} NaOH and 0.1 mol dm^{-3} HCl solutions are shown for comparison. Each *cyclo*-polyphosphate is most rapid-

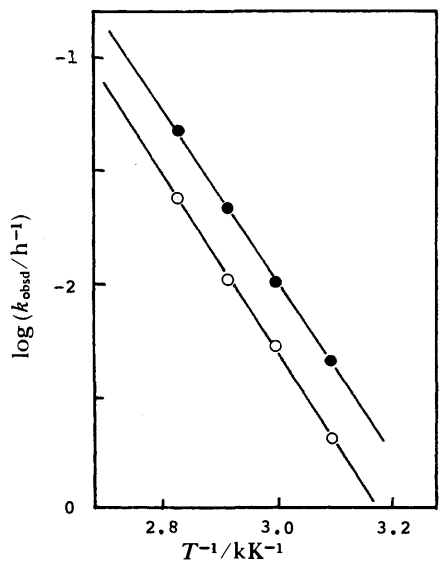

Fig. 6. Arrhenius' plots for *cyclo*-tetraphosphate hydrolysis in 0.5 and 1 mol dm^{-3} $(CH_3)_4NOH$ solution. ●; 1 mol dm^{-3}, ○; 0.5 mol dm^{-3}.

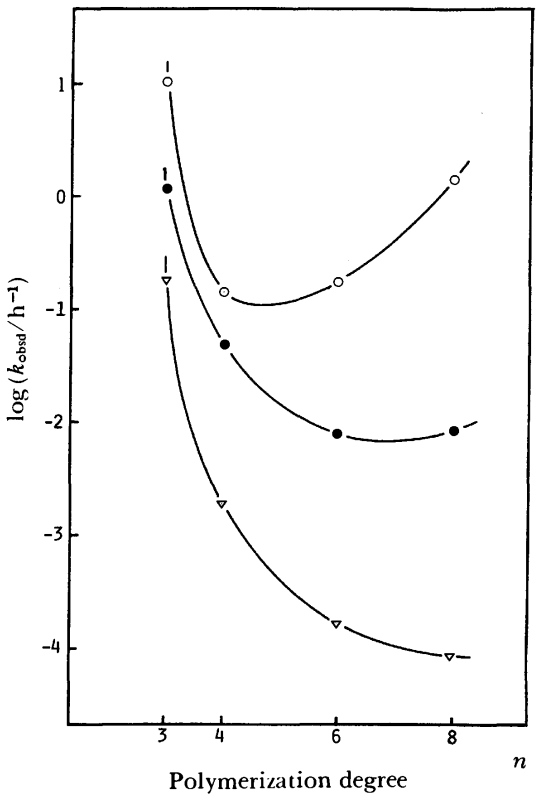

Fig. 7. Variation of the rate constants with the polymerization degree for the *cyclo*-polyphosphates hydrolysis at 50°C. O; 0.1 mol dm^{-3} HCl, ●; 0.5 mol dm^{-3} NaOH, ▽; 0.5 mol dm^{-3} $(CH_3)_4NOH$.

ly hydrolyzed in a 0.1 mol dm^{-3} HCl solution. In a $(CH_3)_4NOH$ solution where there are no cations which might interact with *cyclo*-polyphosphate anions, higher-membered *cyclo*-polyphosphates become extremely stable even at higher OH^- ion concentrations and temperatures.

In NaOH solutions, the interaction of sodium ions with the phosphate anions accelerates the hydrolysis rate. This tendency is more pronounced for *cyclo*-octaphosphate which has the highest flexibility.

The obtained results can be summarized as follows. The hydrolysis rate in alkaline solutions is affected not only by the hydroxide ion concentration but also, more strongly, by the presence of cations. The hydrolysis rates in NaOH solutions were significantly faster than those in $(CH_3)_4NOH$ solutions. This tendency is stronger in the case of higher-membered *cyclo*-polyphosphates. The acceleration of the rate is considered to be due to ion-pair formations between sodium ions and *cyclo*-polyphosphate anions. The activation energy decreases in the order of HCl (0.1 mol dm^{-3})> NaOH>$(CH_3)_4NOH$, but great discrepancies were not observed.

The properties of alkali-free lead phosphate glasses containing silver oxide as an anion selective electrode were examined, and their application to a potentiometric detector for an ion chromatographic technique were developed. The series of these glasses are characterized by their low softening temperature and are only responsive to anionic substances. The featureless potential response of almost anions tested becomes a rather useful property as a detector for an ion chromatographic analysis of anions. The response characteristics and selectivity coefficients revealed that the glass composition of $10Ag_2O:55P_2O_5:25PbO:10Al_2O_3$ is the most suitable electrode materisl for anion chromatography. With this glass electrode, nonsuppressed anion chromatographic parameters were studied, including a comparison of an eluent composition, the flow rate and the retention time. This detector could be used in a high pH eluent without any interference of the large blank value. In paticular, the detector was highly sensitive to iodide ions. This may be due to the interaction of iodide ions with silver ions which are involved in membrane materials.

Ion-selective electrodes are versatile devices for the continuous monitoring of a wide range of processes and reactions such as titrations, industrial processes, enzyme reaction, flow injection analyses, and high-performance liquid chromatography.

It is well-known that various types of the ion-selective glass electrodes such as alkali silicate glasses,[1] chalcogenide glasses[2] and phosphate glasses[3,4] are available. All alkali-silicate and chalcogenide glasses have been utilized for measurements of cationic substances. On the other hand, it has been suggested that the replacement of aluminium in the sodium alminosilicate glasses by phosphorus can be expected to lead to anion-exchanger properties.[5] Since we had already investigated some phosphate glass membrane as materials of the nitrate ion selective electrode,[6] their alkali-free phosphate glass electrodes were characterized by their anion responsive properties.

Ion chromatography is a very effective method for the analysis of many common anions using an electrochemical detector[7,8] or a UV absorbance detector.[9] Electrochemical detection of inorganic anions by potentiometry, amperometry, or coulometry is generally applied to a restricted number of cases, but can exhibit a greater sensitivity than a conductivity detector. Nonsuppressed ion chromatographic techniques with TSK Gel IC Anion SW as an anion-exchanger column have been successful in a variety of applications.[10]

In this investigation, the physical and chemical characteristics of alkali-free lead phosphate glasses were measured, and a systematic check of the potential response and selectivity coefficients on the glass composition were performed; also, their applicability for an anion selective glass electrodes were examined. Moreover, the potentiometric detector based on the alkali-free lead phosphate glass electrode was constructed and utilized in order to determine various anions by the ion chromstographic technique.

Experimental

Preparation of the Glass Membrane. In order to obtain electrode glasses, the following analytical reagent grades were used: orthophosphoric acid (85%), silver carbonate, lead carbonate, and aluminium hydroxide. The preparation procedures of the phosphate glasses and the glass membranes have been described previously.[11] The chemical compositions of some of the tested glasses are listed in Table 1.

Measurements of physical and chemical properties and membrane potentials have been described previously.[6] The physical and chemical properties of some of the lead phosphate glasses containing Ag_2O and Al_2O_3 are summarized in Table 2.

Reagents and Solutions. Stock solutions were prepared by dissolving the reagent of KF, NaCl, $NaNO_3$, $NaNO_2$, Na_2SO_4, KBr, KI, $Na_2S_2O_3$, Na_2SO_3, $NaClO_4$, $NaBrO_3$, and $NaClO_3$ in twice-distilled water. Sodium tartrate eluents were prepared from the reagent grade tartaric acid in concentration ranging from 2×10^{-4} to 5×10^{-3} mol dm^{-3}; in general the eluents were buffered with sodium hydroxide. Citrate eluents with a pH range of 4.3 to 8.0 were prepared from sodium salt.

Chromatographic Procedure. Figure 1 shows a cross-sectional view of the flow-through type potentiometric detector, which consists of a combination of ion-selective

glass electrodes and an Ag/AgCl reference electrode, both with a direct internal contact.

The ion-selective electrode used consists of a lead phosphate glass working electrode of disks 8.0 mm in diameter and 0.4—0.6 mm thick tightened between a plastic detector body and an Ag/AgCl reference electrode with a silicone rubber O-ring on both sides. The detector cell, which has been developed for flow injection analyses by DKK Co., was used for this purpose with some improvements: a flow path diameter was thinned down by filling in the path way with ID 0.25 mm SUS pipe.

The chromatographic system employed comprised a Toyo Soda Co. HLC-803D pump, a 2 μm pore sintered ceramic filter, a TSK IC-A guard column, a TSK Gel IC Anion PW or SW anion-separator column, a DKK Co. ion-selective flow cell, a DKK COM-20 pH meter, and a Sekonic model SS-250F recorder. Unless otherwise specified, the injector sample loop volume was 100 mm^3, and samples of 1.0 cm^3 were introduced with a Hamilton syringe. The eluent flow rate was 1.0 cm^3 min^{-1}. A 0.1 mol dm^{-3} sodium citrate solution was used for column regeneration before the injection of a sample. The measurement temperature was maintained at 25±1 °C.

Results and Discussion

Physical and Chemical Properties of Glasses. As shown in Table 2, the values of T_g and T_s of the tested glasses were considerably lower than those of the other phosphate glasses.[6] This may be due to the addition of lead oxide instead of magnesium oxide in the glass compositions. Although the membrane resistance increased only slightly, the chemical durability of the tested glasses were better than the magnesium phosphate glasses.

Potential Response of the Lead Phosphate Glasses. The potential response curves of some of the alkali-free lead phosphate glass membranes (No. 7) for various anions are shown in Fig. 2. All the glasses investigated were sensitive to anions, except for sulfate, sulfide and thiosulfate ions. It is apparent that the potential response of the common anions examined were featureless to each others and gave calibration slopes of 45—50 mV per decade, except for iodide ions. It is a rather useful property for the potentiometric detector of ion chromatograph. However, iodide ions show a sensitive electrode response; the slope was at about 58 mV in the concentration range of 5×10^{-2} to 10^{-5} mol dm^{-3} of iodide ion and the analytical range was 10^{-1} to 10^{-6} mol dm^{-3}.

The potential response of several anions for all tested lead phosphate glass electrodes are listed in Table 3.

The response characteristics of the tested glass membranes depended upon its glass composition. In particular, glasses that do not contain Ag_2O show a small electrode response and an unsatisfactory poten-

Table 3. Electrode Function of Several Anions

Glass No.	NO_3^-	Cl^-	I^-	ClO_4^-	SO_4^{2-}
1	30.1	21.8	35.2	28.2	5.5

8	41.5	40.7	48.2	43.5	6.0
9	47.0	43.5	48.9	42.8	7.8

The numerical value shows a potential response of mV per decade.

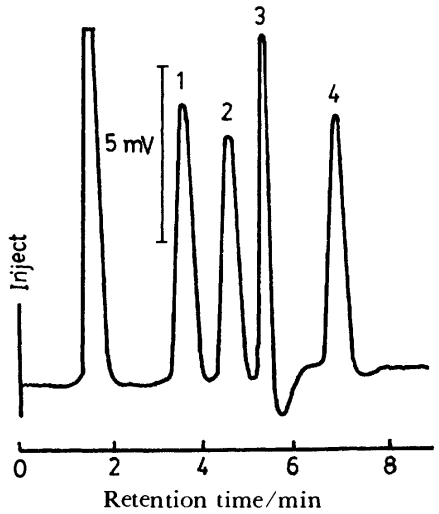

Fig. 3. Ion chromatogram of 4 anions with TSK Gel IC Anion SW column. Eluent: 0.5 mmol dm^{-3} sodium tartrate (pH 6.34), 1: 15 μg mm^{-3} Cl^-; 2: 20 μg mm^{-3} NO_3^-; 3: 2 μg mm^{-3} I^-; 4: 30 μg mm^{-3} ClO_4^-.

tial reproducibility. Moreover, it was observed that the response rate of the glasses with a lower P_2O_5 content (48 mol%) was rather worse than that of the higher P_2O_5 content glasses (55 mol%). This fact suggests that the ultraphosphate glasses corresponding to the branched structure seem to be more structurally useful than the polyphosphate glasses corresponding to the chain structure.

As the results of the potential response of various lead phosphate glass electrodes, the 10 Ag_2O:55 P_2O_5:25 PbO:10 Al_2O_3 glass membrane was concluded to be best in terms of the response speed, reproducibility of potential, and sensitivity of the electrode response for the determination of various anions.

Application of Lead Phosphate Glass Membrane Eectrode for the Potentiometric Detector of Ion Chromatography. The separation of 4 anions with TSK Gel IC Anion SW column using 0.5 mmol dm^{-3} sodium tartrate eluent is shown in Fig. 3.

Peaks of chloride, nitrate, iodide, and perchlorate ion appeared with very good separation. Sulfate, sulfide, and thiosulfate ion produce a small peak, and are unsuitable. The sensitivity of iodide ion is much

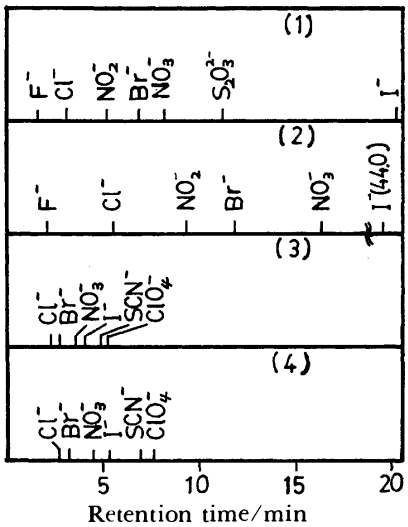

Fig. 4. Comparison of separation column. 1,2: TSK Gel IC Anion PW column; 3,4: TSK Gel IC Anion SW column; 1,3: 0.5 mmol dm^{-3} sodium citrate eluent (pH 6.80); 2,4: 0.5 mmol dm^{-3} sodium tartrate eluent (pH 6.34).

higher than the other anions.

As shown in Fig. 3, a negative dip was observed at the end of the iodide ion peak. It increases with a decrease in the pH of the eluent, and with an increase in the iodide concentration. A negative dip peak signal similar to the present case has been reported when using an iodide selective electrode as the potentiometric detector of ion chromatography.[12] In the present experiment, even if the recorder was operated at much faster chart speed, the elution curve of iodide ion was not splited into its positive and negative parts.

Comparison of the Anion-Exchanger Column. Figure 4 lists the retention times of selected anions using both the TSK Gel IC Anion PW and SW as the separation column, and sodium citrate and sodium tartrate as the eluents. Anions such as chloride, nitrate, nitrite, and bromide show rather small changes in the order of the retention time from one eluent to another. However, iodide shows considerable variations between two columns, changing from a retention time of 5.16 min for SW to 44.0 min for PW wi 0.5 mmol dm^{-3} sodium tartrate eluent. It was considered that a large lag of the retention time of iodide ion with PW column is caused by a characteristics of hydrophobic group anions such as iodide, perchlorate, and thiocyanate.[10]

Effect of Retention Time on the pH and the Concentration of Eluent. The equilibrium reaction for anions exchanging on a strong base anion exchanger is expressed as

$$xA^{-y} + yB\text{-}R_x \rightleftarrows yB^{-x} + xA\text{-}R_y, \quad (1)$$

where R represents the anion exchanger, A and B are competing anions, and y and x are the charge of the anion in the sample solution and the eluent, respectively.

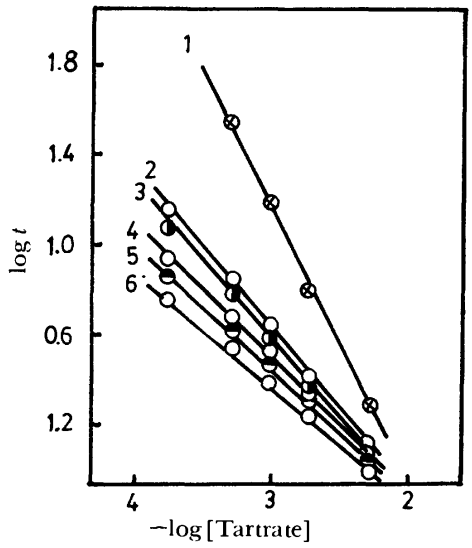

Fig. 5. Effect of eluent concentration on the retention time. TSK Gel IC Anion SW column, sodium tartrate eluent (pH 6.0—6.5), 1: $S_2O_3^{2-}$, 2: ClO_4^-, 3: SCN^-, 4: I^-, 5: NO_3^-, 6: Cl^-.

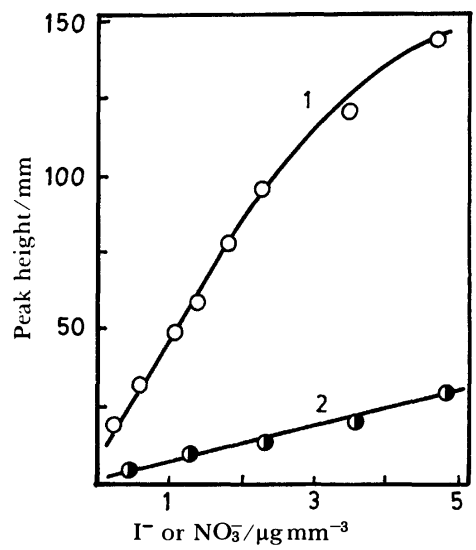

Fig. 6. Calibration curves of nitrate and iodide ion. TSK Gel IC Anion SW column, 0.5 mmol dm^{-3} sodium tartrate eluent (pH 6.34), 1: iodide ion; 2: nitrate ion.

From a consideration of the retention time, t, and the eluent concentration, [eluent], Eq. 2 can be obtained:[13]

$$\log t = \frac{-y}{x} \log [\text{eluent}] - \text{constant.} \quad (2)$$

This shows that a change in the logarithm of the eluent concentration versus the logarithm of the retention time will have the straight line relationship with the slope of $-y/x$, which varies with the charge of the anions involved.

Figure 5 show the relation of the retention time and the concentration of sodium tartrate eluent for the TSK Gel IC Anion SW column. All anions show a straight line. The slopes of the perchlorate and thiocyanate ions are close to the theoretical value of -1, but the slopes of most of the monovalent anions are lower than the predicted values. Sulfate, sulfite, and thiosulfate have a slope of approximately -1.6.

The effect of the pH of the eluent on the retention time, using 0.5 mmol dm^{-3} sodium citrate as the eluent, was examined and revealed that the lower pH of the eluent below about 6.5 caused the larger difference of the retention time. However, the retention time remained almost constant for an eluent with a pH above 6.5.

Sensitivity of Various Anions and the Determination of Iodide Ion. As is shown in Fig. 4, the retention time of anions remains fixed in terms of the species of eluent, the pH of the eluent and the characteristics of anion-exchanger column.

By using the lead phosphate glass membrane as a potentiometric detector and the TSK Gel IC Anion SW as an anion-exchanger column, calibration curves of nitrate and iodide ion were examined; the results are shown in Fig. 6.

With a 100 mm^3 injection loop and 0.5 mmol dm^{-3} sodium tartrate at pH 6.34 as an eluent, calibration curves of the peak hight as a function of these concentration are almost linear at concentrations from 0.5 to 30 μg cm^{-3} for nitrate ion and from 0.1 to 5 μg cm^{-3} for iodide ion. The detection limit for nitrate and iodide are 0.2 and 0.05 μg cm^{-3}, respectively. The detection limit of iodide ions reported here is approximately several times lower than those reported with the use of the conductivity detector.[10]

A Calorimetric Study of Ternary Zinc(II) Complexes with Chloride Ions and 2,2′-Bipyridyl in *N,N*-Dimethylformamide

Shin-ichi Ishiguro,* László Nagy,§ and Hitoshi Ohtaki†
Coordination Chemistry Laboratories, Institute for Molecular Science, Myodaiji, Okazaki 444
†Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta, Nagatsuta, Midori-ku, Yokohama 227
(Received March 5, 1987)

Formation equilibria of ternary zinc(II) complexes with chloride ions and 2,2′-bipyridyl (bpy) have been calorimetrically studied in *N,N*-dimethylformamide (DMF) containing 0.4 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a constant ionic medium at 25 °C. Formation of binary (2,2′-bipyridyl)zinc(II) complexes has also been explored. The calorimetric data were satisfactorily explained in terms of formation of the ternary $[ZnCl(bpy)]^+$ and $[ZnCl_2(bpy)]$ complexes together with the binary $[Zn(bpy)_n]^{2+}$ (n=1—3) ones, and their formation constants and enthalpies were determined. The formation of the ternary $[ZnCl(bpy)]^+$ and $[ZnCl_2(bpy)]$ complexes is not so favorable in DMF. It is suggested that both $[ZnCl(bpy)]^+$ and $[ZnCl_2(bpy)]$ complexes have the four-coordinate tetrahedral structure in DMF.

Complexation of zinc(II) ion with 2,2′-bipyridyl (bpy) has so far been studied in aqueous solution and the formation of mononuclear $[Zn(bpy)_n]^{2+}$ (n=1—3) complexes has been established.[1-6] However, the complexation equilibria in nonaqueous solvents have not been well investigated yet. In fact, the only formation of $[Zn(bpy)]^+$ was kinetically investigated in dimethyl sulfoxide.[7]

Ternary (2,2′-bipyridyl)zinc(II) complexes with various carboxylic acids, amino acids (peptides), and amines have been extensively studied in aqueous solution.[1,8] On the other hand, as to the (2,2′-bipyridyl)zinc(II) complexes with halide ions, their formation equilibria have not been reported in any solvent, although the $[ZnCl_2(bpy)]$ complex was isolated from acetonitrile solution and its crystal structure was determined.[9]

In a previous paper,[10] we reported the formation equilibria of the ternary copper(II) complexes with bromide ions and 2,2′-bipyridyl in DMF. In the present work, in order to shed more light on the formation equilibria of ternary metal(II) complexes with 2,2′-bipyridyl and halide ions in solution, we calorimetrically investigated the formation of the ternary (2,2′-bipyridyl)chlorozinc(II) complexes in DMF. As to the related binary zinc(II)-chloride system, the formation equilibria having been previously explored,[11] the thermodynamic quantities of formation of the $[ZnCl_n]^{(2-n)+}$ (n=1—4) complexes were used as known values in the course of the analysis of calorimetric data obtained in the present study.

Experimental

Reagent. All chemicals used were of reagent grade. *2,2′-Bipyridyl* was used without further purification and dried in vacuum over P_2O_5 in a desiccator. Other chemicals were prepared or purified as described elsewhere.[11]

Measurements. Calorimetric measurements were carried out in a room thermostated at (25.0±0.2) °C. All solutions prepared contained 0.4 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a constant ionic medium. A Dewar vessel was immersed in a thermostated water-bath at (25.0±0.007) °C. 100 cm^3 of a DMF solution with varying concentrations of $Zn(ClO_4)_2$ and $(C_2H_5)_4NCl$ was placed in a Dewar vessel which was filled with dry nitrogen gas and isolated from moisture with a P_2O_5 drying-tube, and then it was titrated with 0.1 mol dm^{-3} 2,2′-bipyridyl DMF solution. The concentration of zinc(II) ion in the initial test solution was varied over the range 3—21 mmol dm^{-3}. Heats of complexation observed at each titration point were ranged 0.3—3 J with a certainty ±0.05 J. The measured heats of complexation were corrected for heats of dilution. Heats of dilution were determined in advance by separate experiments by titrating a 0.4 mol dm^{-3} $(C_2H_5)_4NClO_4$ DMF solution with the 2,2′-bipyridyl solution containing 0.4 mol dm^{-3} $(C_2H_5)_4NClO_4$. The observed heats of dilution were found to be very small. All of the measurements were carried out by using a fully automatic on-line system for calorimetry developed in our laboratory.[12,13] The method of the data treatment was similar to that used in a previous work.[10]

Results and Discussion

Calorimetric titration curves obtained for the binary zinc(II)-2,2′-bipyridyl system are depicted in Fig. 1. In the figure, enthalpies $\Delta H^\circ = -q/(\delta v C_{L,tit})$ are plotted against C_L/C_M, where q, δv, C_L and C_M stand for the heat evolved, the volume of an aliquot of the titrant added and the total concentrations of chloride and zinc(II) ions in solution, respectively, at each titration point, and $C_{L,tit}$ denotes the concentration of 2,2′-bipyridyl in the titrant solution. The observed ΔH° values were all negative, indicating an exothermic formation of zinc(II) 2,2′-bipyridyl complexes. As well as in water,[1] the formation of a series of mononuclear $[Zn(bpy)_n]^{2+}$ (n=1—3) complexes was expected in DMF. The calorimetric data were thus analyzed by assuming the formation of the complexes and their formation constants and enthalpies were optimized, the result being summarized in the column of "Binary" in Table 1. The solid lines in Fig. 1 show the

§Present address: Department of Inorganic and Analytical Chemistry, A. József University, Szeged, Hungary.

titration curves calculated by using the constants in Table 1, which satisfactorily reproduce the experimental points over the whole range of C_L/C_M examined. Therefore, the formation of the $[Zn(bpy)_n]^{2+}$ (n=1—3) complexes was concluded in DMF.

Calorimetric titration curves for the ternary zinc(II)-Cl⁻-2,2′-bipyridyl system are depicted in Fig. 2. In the figure, the titration curves remarkably shift to lower C_L/C_M region as the molar ratio of chloride to metal ions in solution is increased. The titration curves calculated with the only known formation constants and enthalpies of $[ZnCl_n]^{(2-n)+}$ (n=1—4) and those of $[Zn(bpy)_n]^{2+}$ (n=1—3) determined above hardly reproduced the experimental points, and thus the formation of ternary $[ZnCl_p(bpy)_q]^{(2-p)+}$ (denoted as ($1pq$)) complexes must be taken into account. At the first step of approach, a plausible set of the ternary complexes such as (111), (121), and (112) were assumed. Their formation constants and enthalpies were obtained with a satisfactorily small Hamilton R-factor of 0.0437. However, the formation constant of the (112) complex thus obtained was rather small with a relatively large uncertainty, and thus the formation of the complex was ambiguous. The least-squares analysis was then carried out by eliminating the (112) complex from the first set of complexes, the R-factor in this case being 0.0439. In both cases with and without the (112) complex, the R-factor remained practically unchanged, and thus the formation of $[ZnCl(bpy)_2]^+$ may be insignificant in DMF. Subsequent least-squares analyses were performed by assuming the only formation of either (111) or (121) complex, together with the binary chloro and 2,2′-bipyridyl complexes. The Hamilton R-factors in both cases were relatively large, indicating that the formation of both complexes must be taken

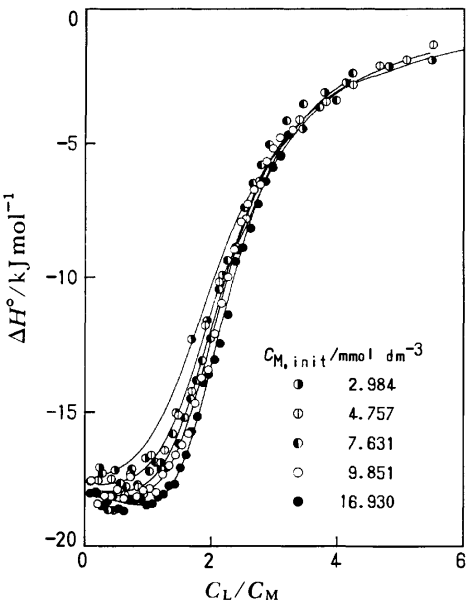

Fig. 1. Calorimetric titration curves of zinc(II) 2,2′-bipyridyl DMF solutions containing 0.4 mol dm^{-3} $(C_2H_5)_4NClO_4$ at 25 °C. Concentrations of zinc(II) ions, $C_{M,init}$/mol dm^{-3}, in the initial test solutions are given in the figure. The solid lines show the curves calculated by using the constants in the column of "Combined" in Table 1.

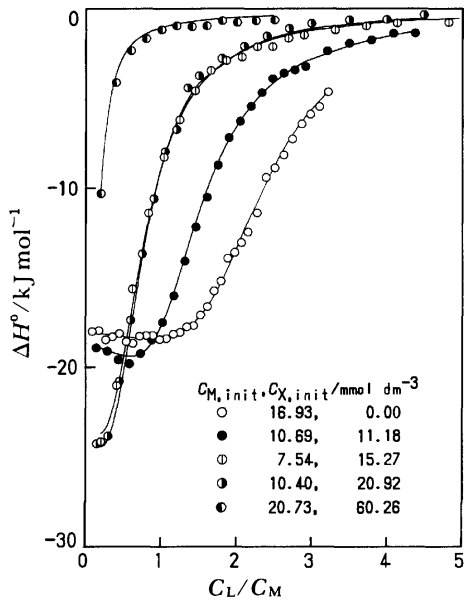

Fig. 2. Calorimetric titration curves of the ternary zinc(II) system obtained by titrating zinc(II) chloride DMF solutions with a 2,2′-bipyridyl DMF solution, each containing 0.4 mol dm^{-3} $(C_2H_5)_4NClO_4$ at 25 °C. Concentrations of zinc(II) and chloride ions, $C_{M,init}$/mol dm^{-3} and $C_{X,init}$/mol dm^{-3}, in the initial test solutions are given in the figure. The solid lines show the curves calculated by using the constants in the column of "Combined" in Table 1.

into account in DMF. The thermodynamic quantities of the (111) and (121) complexes are summarized in the column of "Ternary" in Table 1. Finally the whole calorimetric data obtained for the binary and ternary systems were analyzed altogether to simultaneously optimize the thermodynamic quantities of the binary $[Zn(bpy)_n]^{2+}$ (n=1—3) and ternary $[ZnCl(bpy)]^+$ and $[ZnCl_2(bpy)]$ complexes with the fixed values of the $[ZnCl_n]^{(2-n)+}$ (n=1—4) complexes, the result being listed in the column of "Combined" in Table 1. The values are in satisfactory agreement with the corresponding ones in the columns of "Binary" and "Ternary". As seen in Fig. 2, the solid lines, calculated by using the constants of the binary and ternary zinc(II) complexes in the column of "Combined" in Table 1 and with those of $[ZnCl_n]^{(2-n)+}$ (n=1—4),[11] well reproduce the experimental points over the whole range of C_L/C_M examined.

Distribution of Species. In Fig. 3 the distribution of species in solutions with varying R_c ($=C_X/C_M$) values is shown as a function of $-\log([bpy]/mol\ dm^{-3})$, which was calculated by using the formation constants given in the column of "Combined" in Table 1, together with those of the zinc(II) chloro complexes.[11] In solutions involving chloride ions ($R_c>0$), the ternary (111) and (121) complsxes are formed, the formation of these complexes being strongly suppressed, however. It is indicated that the formation of the ternary complexes is very much unfavorable in solution of $R_c>3$ in which the tri- and tetrachlorozincate(II) complexes are predominated. In Fig. 4 the distribution of species in solutions with varying R_c' ($=C_L/C_M$) values is shown as a function of $-\log([Cl^-]/mol\ dm^{-3})$ for comparison. It is seen in Fig. 4 that the ternary complexes are only formed in a range $-\log([Cl^-]/mol\ dm^{-3})$=3—6 and they disappear in solution of a higher chloride concentration where the $[ZnCl_3]^-$ and $[ZnCl_4]^{2-}$ complexes are mainly yielded.

Binary (2,2'-Bipyridyl)zinc(II) Complexes. The thermodynamic quantities of stepwise formation of the $[Zn(bpy)_n]^{2+}$ (n=1—3) complexes obtained in DMF are listed in Table 2 together with those in water.

The stepwise formation constants of each $[Zn(bpy)_n]^{2+}$ complex in DMF are smaller than those in water, and the smaller values in DMF are mainly due

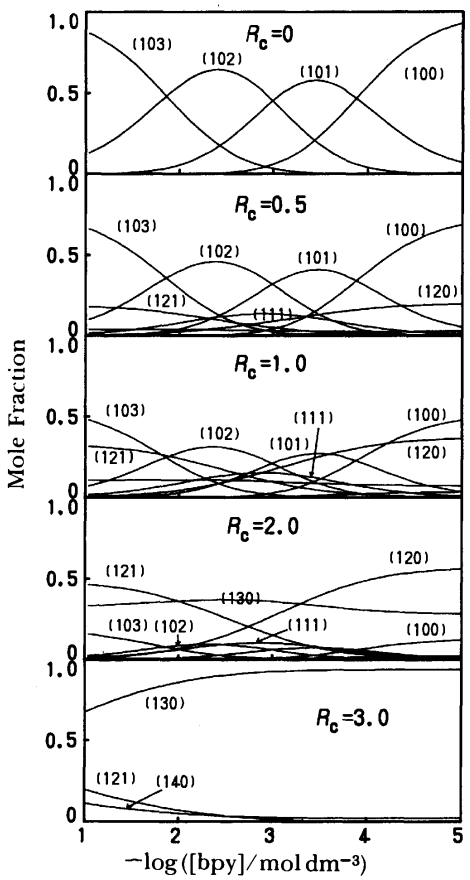

Fig. 3. Distribution of the $[ZnCl_p(bpy)_q]^{(2-p)+}$ (denoted as (l*pq*)) complexes as a function of $-\log([bpy]/mol\ dm^{-3})$ at the total zinc(II) ion concentration of 0.01 mol dm^{-3} in DMF. The R_c value stands for the molar ratio of chloride to zinc(II) ions in solution.

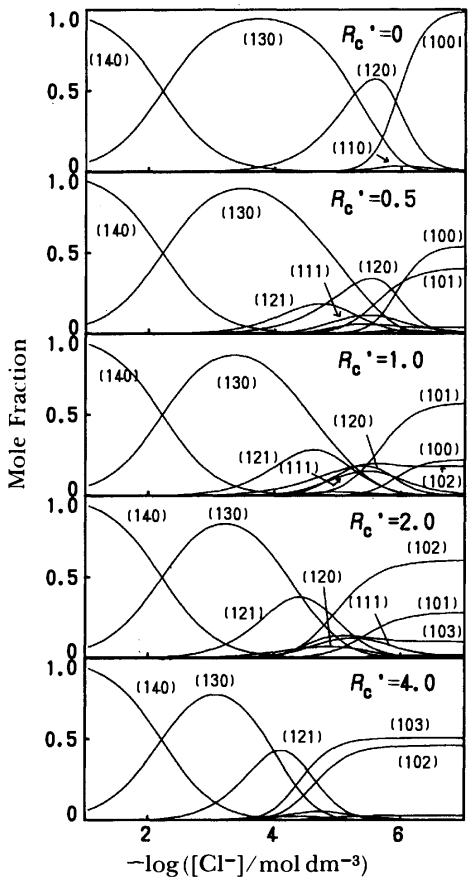

Fig. 4. Distribution of the $[ZnCl_p(bpy)_q]^{(2-p)+}$ (denoted as (l*pq*)) complexes as a function of $-\log([Cl^-]/mol\ dm^{-3})$ at the total zinc(II) ion concentration of 0.01 mol dm^{-3} in DMF. The R_c' value stands for the molar ratio of 2,2'-bipyridyl to zinc(II) ion in solution.

to the less negative enthalpy values in the solvent than those in water. Since the donicity of DMF (the donor number D_N=26.6) is stronger than that (D_N=14.8) of water,[14] the less negative enthalpy values of the zinc(II) 2,2′-bipyridyl complexes in DMF than those in water may be mainly ascribed to a stronger solvation of the metal ion in the former solvent than in the latter.

We note that the ΔS_n° ($n=1$—3) values of the zinc(II) 2,2′-bipyridyl complexes are practically the same as those of the nickel(II)-2,2′-bipyridyl ones with octahedral structure in DMF.[15] The stepwise ΔH_n° ($n=1$—3) values are practically kept constant and the corresponding entropy values stepwise decreased by ca. 20 $\text{J K}^{-1}\,\text{mol}^{-1}$ in the zinc(II)-2,2′-bipyridyl system in DMF. Such changes in the stepwise enthalpy and entropy values may hardly be expected provided that the $[\text{Zn(bpy)}_2]^{2+}$ complex has the four-coordinate tetrahedral structure, because the formation of $[\text{Zn(bpy)}_3]^{2+}$ may be very much unfavorable owing to the change from tetrahedral to octahedral structure. Therefore, we suggest an octahedral structure for the bis(2,2′-bipyridyl)zinc(II) complex. It is also suggested that the bis(2,2′-bipyridyl)zinc(II) complex may have the cis-configulation as expressed by $[\text{Zn(bpy)}_2(\text{dmf})_{eq}(\text{dmf})_{ax}]^{2+}$ because the trans-configulation is sterically unfavorable.[16]

Ternary (2,2′-Bipyridyl)chlorozinc(II) Complexes. The thermodynamic quantities of the stepwise formation of the $[\text{ZnCl}_n(\text{bpy})]^{(2-n)+}$ ($n=0$—2) in DMF are summarized in Table 3, which can be calculated from the values in Table 1. The thermodynamic quantities of the stepwise formation of the zinc(II) chloro complexes[11] are also listed in Table 3 for comparison. Comparing the enthalpy and entropy values for the reactions:

$$Zn^{2+} + bpy = [Zn(bpy)]^{2+}, \quad (1)$$

$$[ZnCl]^+ + bpy = [ZnCl(bpy)]^+, \quad (2)$$

$$[ZnCl_2] + bpy = [ZnCl_2(bpy)], \quad (3)$$

in Table 3, we see that the ΔH° and ΔS° values for Reaction 3 are significantly negative compared with those for Reactions 1 and 2, the result suggesting that solvation of the $[ZnCl_2]$ complex is weaker than that of Zn^{2+}, as well as $[ZnCl]^+$ in DMF. As noted in a previous paper,[11] the dichlorozinc(II) complex may have the four-coordinate $[ZnCl_2(dmf)_2]$ structure with weak metal-dmf bonds in DMF, and thus it is plausible that the DMF molecules within the $[ZnCl_2(dmf)_2]$ complex are replaced to 2,2′-bipyridyl and the four-coordinate $[ZnCl_2(bpy)]$ complex is formed in DMF. It has in fact been revealed that the $[ZnCl_2(bpy)]$ complex has the four-coordinate tetrahedral structure in crystal.[9] Similarly, the $[ZnCl_2(phen)]$ (phen=1,10-phenanthroline)[17] and $(ZnX_2(py)_2]$ (X=Cl, Br, and I, and py=pyridine)[18,19] complexes have the tetrahedral

structure in crystal.

We subsequently compare the enthalpy and entropy values for the reactions:

$$[Zn(bpy)]^{2+} + Cl^- \rightleftharpoons [ZnCl(bpy)]^+, \quad (4)$$

$$[ZnCl(bpy)]^+ + Cl^- \rightleftharpoons [ZnCl_2(bpy)]. \quad (5)$$

The $[Zn(bpy)]^{2+}$ complex may have the octahedral structure with four DMF molecules coordinating to the metal ion, and the DMF molecules are stepwise liberated in the course of Reactions 4 and 5. As seen in Table 3, the ΔH° value for Reaction 4 is positive, while that for Reaction 5 is negative. The ΔS° value for Reaction 4 is much more positive than that of Reaction 5. The result suggests that liberation of DMF molecules from the central metal ion takes place relatively extensively in Reaction 4. Therefore, it is plausible that the $[ZnCl(bpy)]^+$ complex has the four-coordinate structure with one DMF molecule within the first coordination sphere of the metal ion.

The present work has been financially supported by the Grant-in-Aid for Special Project Research No. 61134043 from the Ministry of Education, Science and Culture.

Cis-to-Trans Isomerization of Bis(diamine)bis(isothiocyanato)chromium(III) Thiocyanate in the Solid State

Goutam De, Masatatsu Suzuki, and Akira Uehara*
Department of Chemistry, Faculty of Science, Kanazawa University, Kanazawa 920
(Received March 9, 1987)

Solid-state thermal reactions of *trans*- and *cis*-$[Cr(NCS)_2(AA)_2]SCN$ where AA is 1,2-ethanediamine (en) or 1,3-propanediamine (tn) were studied. Upon heating, both the cis- and trans-complexes lost half mole of diamine to convert into the double complex *trans*-$[Cr(NCS)_2(AA)_2][Cr(NCS)_4(AA)]$. The anion moiety $[Cr(NCS)_4(AA)]^-$ was isolated from the double complex. The thermal reactions are thus useful for easy preparation of $[Cr(NCS)_4(AA)]^-$complex, which has previously been obtained with difficulty from solution reactions.

In 1904, Pfeiffer et al. reported the solid state deamination of the tris(1,2-ethanediamine) complex $[Cr(en)_3]X_3$ ($X=Cl^-$ or NCS^-).[1] The complex, when heated, deaminated to form *cis*-$[CrCl_2(en)_2]Cl$ or *trans*-$[Cr(NCS)_2(en)_2]SCN$. Until recently, the above deamination has been used as the standard procedures for synthesizing a series of *cis*- and *trans*-bis(diamine) complexes.[2] We recently investigated in detail the deamination of a complete series of tris(diamine) complexes: $[Cr(AA)_3]X_3$, $[Cr(AA)_2(BB)]X_3$, and $[Cr(AA)(BB)(CC)]X_3$ where AA, BB, and CC denote different diamines, and X is a halide ion.[3] We noticed that the bis(diamine)complexes obtained by the deamination sometimes undergo subsequent isomerization. Then, we studied the effect of various diamines and anions on the isomerization.[4,5] The solid-state thermal reaction of bis(diamine)bis(isothiocyanato)chromium(III) thiocyanates has never been approached. In this paper, we describe the behavior of the solid *cis*- and *trans*-$[Cr(NCS)_2(AA)_2]SCN$ when heated non-isothermally in open dynamic condition, where AA is 1,2-ethanediamine or 1,3-propanediamine; the former can form a five-membered chelate ring and the latter, a six-membered chelate ring with chromium(III) ion.

Experimental

Preparation of Complexes. *trans*-$[Cr(NCS)_2(en)_2]SCN$ (**1**) was prepared according to the known method.[3] *cis*-$[Cr(NCS)_2(en)_2]SCN$ (**2**), *trans*-$[Cr(NCS)_2(tn)_2]SCN$ (**3**), and *cis*-$[Cr(NCS)_2(tn)_2]SCN\cdot H_2O$ (**4**) were obtained by the metatheses from the corresponding chloro-chloride[6,7] and KSCN as reported previously.[3]

Non-Isothermal Measurements. Thermal reactions of the samples were recorded on SEIKO SSC/580 TG/DTA-30 and SSC/580 DSC/10 thermal analysers in a nitrogen atmosphere (flow rate: 200 $cm^3\ min^{-1}$). All the measurements were carried out at the heating rate of 2 °C min^{-1}. About 15 mg of the samples was used for TG/DTA and about 10 mg, for DSC.

Spectral Measurements. Visible spectra of the samples were measured with a JASCO UVIDEC 505 spectrophotometer. IR spectra were obtained by a KBr method with a JASCO A-3 infrared spectrophotometer.

TLC. The presence of a single species in the deaminated products was confirmed by TLC. The plates used were those of silica gel 60F-254 made by Merck Ltd.

Molar Conductivities. Molar conductivities were measured in acetone at 25 °C to determine the charges of the samples using a Yokogawa Universal Bridge TYPE BU-Z-13A.

Purification of Products Obtained by Deamination. *trans*-$[Cr(NCS)_2(en)_2][Cr(NCS)_4(en)]$(**5**). One gram of finely powdered complex [**1** or **2**] was spread in a thin layer on a watch glass and heated in an air oven [heating conditions: 200—205 °C (2 h) for **1** and 195—200 °C (5 h) for **2**]. The product thus obtained was throughly washed with boiling water (250 cm^3), cold water, ethanol, and ether, and recrystallized from a mixture of acetone-water (4 : 1). Pink flaky crystals thus obtained were collected by filtration and air dried. Yield 80%.

trans-$[Cr(NCS)_2(tn)_2][Cr(NCS)_4(tn)]$ (**6**). The complex was prepared by the same method as that described for **5**. In this case, either the complex **3** or **4** was taken as the starting material [heating conditions: 195—200 °C (5 h) for **3** and 195—200 °C (3 h) for **4**]. This complex appears as red-pink crystals. Yield 80%.

Results

Thermal Reactions under Non-Isothermal Conditions. Figure 1 shows the TGA and DSC curves for the complexes **1** and **2**. As seen from the TG curve of the complex *trans*-$[Cr(NCS)_2(en)_2]SCN\cdot H_2O$ (**1**), it is dehydrated at 38 °C followed by the evolution of half mole of en at 181—254.5 °C and then a clear plateau is obtained. The complex changed in color from yellowish orange to pink due to the formation of the double complex *trans*-$[Cr(NCS)_2(en)_2][Cr(NCS)_4(en)]$. The corresponding DSC curve shows two endothermic peaks for the elimination of diamine. The complex *cis*-$[Cr(NCS)_2(en)_2]SCN$ (**2**) deaminates at 183.5 °C and is transformed to the double complex *trans*-$[Cr(NCS)_2(en)_2][Cr(NCS)_4(en)]$ quantitatively at 250 °C. For this reaction, the DSC curve shows a series of endo- and exothermic peaks (Fig. 1). It is interesting to note that during deamination, the complex undergoes cis-to-trans isomerization. Similar results were observed in case of the 1,3-propanediamine complexes. The complex *trans*-$[Cr(NCS)_2(tn)_2]SCN$ (**3**) undergoes deamination at 170—243 °C and a clear plateau is obtained in the TG curve (Fig. 2). The weight loss corresponds

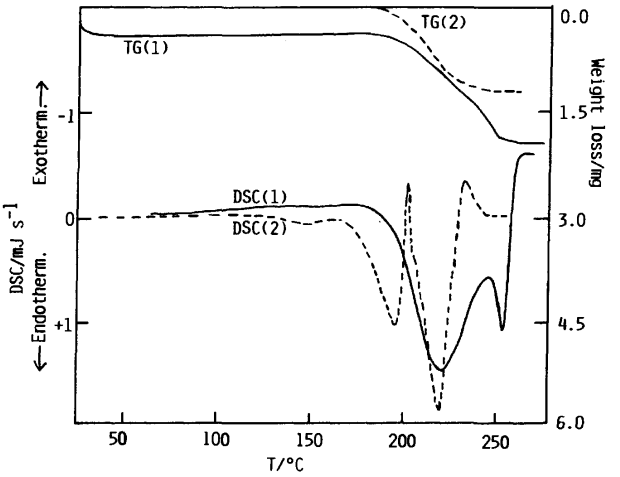

Fig. 1. TG and DSC curves of *trans*-[Cr(NCS)$_2$(en)$_2$]SCN·H$_2$O (**1**) (——) and *cis*-[Cr(NCS)$_2$(en)$_2$]SCN (**2**) (----). Sample weights: for TG, **1**, 18.45 mg, **2**, 13.90 mg; for DSC, **1**, 8.40 mg, **2**, 9.80 mg. (Endothermic DSC peak for the dehydration of **1** is not shown because the compound started dehydration during grinding at ambient temperature).

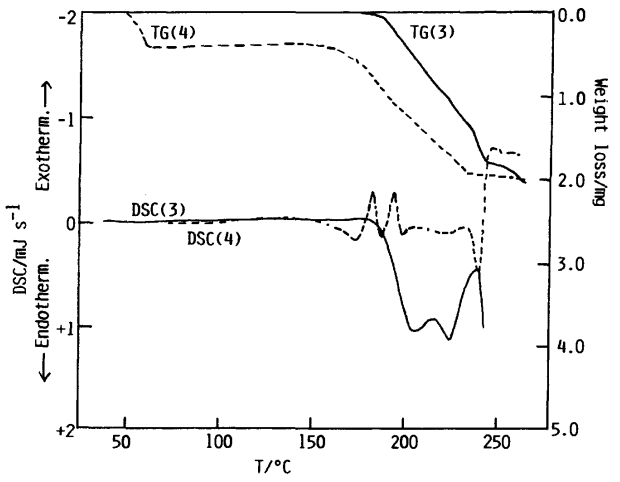

Fig. 2. TG and DSC curves of *trans*-[Cr(NCS)$_2$(tn)$_2$]SCN (**3**) (——) and *cis*-[Cr(NCS)$_2$(tn)$_2$]SCN·H$_2$O (**4**) (----). Sample weights: for TG, **3**, 17.50 mg, **4**, 18.80 mg; for DSC, **3**, 9.70 mg, **4**, 9.58 mg. (Endothermic DSC peak for the dehydration of **4** is not shown because the compound started dehydration during grinding at ambient temperature).

to 0.5 mol of the diamine. The corresponding DSC curve shows two endothermic peaks. In case of *cis*-[Cr(NCS)$_2$(tn)$_2$]SCN·H$_2$O (**4**) (Fig. 2), dehydration starts at 42 °C and anhydrous weight level is attained at 64 °C. As the temperature is raised further, it begins to lose the diamine (146—234 °C) showing a series of endo- and exothermic DSC peaks leaving a stable double complex *trans*-[Cr(NCS)$_2$(tn)$_2$][Cr(NCS)$_4$(tn)]. Like the 1,2-ethanediamine complex, cis-to-trans isomerization also takes place along with deamination. The following schemes summarize the solid state reactions:

$$2\ trans\text{-}[Cr(NCS)_2(AA)_2]SCN \xrightarrow[\Delta]{-(AA)} trans\text{-}[Cr(NCS)_2(AA)_2][Cr(SCN)_4(AA)]$$

$$2\ cis\text{-}[Cr(NCS)_2(AA)_2]SCN \xrightarrow[\Delta]{-(AA)} trans\text{-}[Cr(NCS)_2(AA)_2][Cr(SCN)_4(AA)]$$

Characterization of Complexes 5 and 6. The presence of complex cation and anion in the double complexes **5** and **6** was convincingly demonstrated by the following ion exchange experiments: A concentrated solution of **5** or **6** in acetone-water(3 : 2) mixture [addition of more water causes precipitation of the complex] was passed through a Dowex 1·X8 anion exchanger in Cl$^-$ form (20×1.5 cm) and the cations were eluted with one column volume of acetone-water (3 : 2) mixture. The effluents were orange in color and the upper part of the resins turned red-violet due to the retention of the complex anion. The effluents were quickly concentrated in a rotoevaporator at room temperature and thereto excess NH$_4$SCN was added. Yellowish orange [in case of **5**] and reddish orange [in case of **6**] crystals of *trans*-[Cr(NCS)$_2$(AA)$_2$]SCN separated out on standing. The IR and electronic spectra (350—700 nm) of these products were identical with those of *trans*-[Cr(NCS)$_2$(en)$_2$]SCN·H$_2$O (**1**) and *trans*-[Cr(NCS)$_2$(tn)$_2$]SCN (**3**) respectively. For the isolation of complex anions, similar exchange experiments were performed utilizing the cation exchanger Amberlite IR-120B (Na$^+$ form). In these cases, red-violet effluents were obtained and the resins were turned orange due to the retention of the complex cation. From these effluents the anionic complexes were precipitated out by adding tetraethylammonium bromide (Et$_4$NBr). These products were recrystallized from acetone-water (1 : 1) mixture. [Et$_4$N][Cr(NCS)$_4$·(en)] and [Et$_4$N][Cr(NCS)$_4$(tn)] were obtained as red-violet and red-purple crystals, respectively. All the compounds were characterized by analytical data (Table 1), DSC and TG measurements, electronic and IR data (Table 2), molar conductivities and TLC data (Table 3). Although *cis*- and *trans*-[Cr(NCS)$_2$(AA)$_2$]SCN exhibit similar absorption maxima in their visible electronic spectra, they can be easily distinguished from thier molar absorbances (Table 2). As the trans-complexes are much more symmetrical (D_{4h}) than the cis-complexes (C_{2v}), the former shows much lower molar absorbances than the latter in their visible absorption spectra.

The double complexes obtained from *cis*- and *trans*-[Cr(NCS)$_2$(AA)$_2$]SCN possess exactly similar IR, electronic spectra (350—700 nm), molar conductivities and TLC data. We also separated the cationic and anionic parts by ion exchange chromatography from both the double complexes synthesized from *cis*- and *trans*-[Cr(NCS)$_2$(AA)$_2$]SCN. In both the cases identical prod-

a) Assignment of ν(CS) and δ(NCS) are difficult due to the presence of ligand bands. b) Due to ionic SCN group. c) The complexes prepared from **1** and **2** showed the same spectral data. d) The complexes prepared from **3** and **4** showed the same spectral data. e) In H_2O. f) In acetone.

ucts were obtained. The molar conductivities of **5** and **6** are slightly lower than that usually found for 1 : 1 electrolyte probably due to the ion pair formation (Table 3).

Discussion

The experimental studies indicate the presence of complex cation (*trans*-$[Cr(NCS)_2(AA)_2]^+$) and anion ($[Cr(NCS)_4(AA)]^-$) in the double complexes which were synthesized pyrolytically from *cis*- and *trans*-$[Cr(NCS)_2(AA)_2]SCN$ according to the following sequence of reactions:

(i) $[Cr(NCS)_2(AA)_2][Cr(NCS)_4(AA)]$ **5** or **6** $\xrightarrow[Cl^- \text{ form}]{\text{Dowex 1-X8}}$

- $[Cr(NCS)_4(AA)]^-$ (retained in column)
- $[Cr(NCS)_2(AA)_2]^+ \xrightarrow{NH_4SCN}$ *trans*-$[Cr(NCS)_2(AA)_2]SCN$ (orange effluent) orange crystal

(ii) $[Cr(NCS)_2(AA)_2][Cr(NCS)_4(AA)]$ **5** or **6** $\xrightarrow[Na^+ \text{ form}]{\text{Amberlite 1R-120B}}$

- $[Cr(NCS)_2(AA)_2]^+$ (retained in column)
- $[Cr(NCS)_4(AA)]^- \xrightarrow{Et_4NBr} [Et_4N][Cr(NCS)_4(AA)]$ (red-violet effluent) red-violet crystal

The interesting feature of these thermal reactions are that the double complexes formed after the deamination of both *cis*- and *trans*-$[Cr(NCS)_2(AA)_2]SCN$ contain *trans*-$[Cr(NCS)_2(AA)_2]^+$ cation. Therefore during the deamination of the cis-complexes, cis-to-trans isomerization occured. In the course of our earlier studies,[4,8,9] we observed trans-to-cis isomerization in the bis(diamine)dihalogeno complexes containing diamine which is capable of forming five-membered chelate ring with chromium(III) ion, whereas cis-to-trans isomerization was found in the complexes containing six-membered diamine chelate ring. However, in this study, only cis-to-trans isomerization is observed irrespective of the ring size of the diamines. From this and previous results,[4,5] we tentatively assume that the anion size also plays a substantial role on the direction of the isomerization. The details are now under investigation.

It is interesting to note that only endothermic DSC peaks are observed for the deamination of trans-complexes (Fig. 2), whereas both endo- and exothermic peaks appeared in case of the cis-complexes. The exothermic peaks appeared during deamination of the cis-complexes is probably responsible for the isomerization because the isomerization of the *cis*-(diamine)-chromium(III) has been found to proceed exothermically.[5]

By utilizing these thermal reactions, the anionic

Preparation, Stereochemistry, and CD Spectra of Cobalt(III) Complexes with 1,3-Propanedithiolate and 1,3-Propanedisulfinate. Crystal Structure and Absolute Configuration of $(-)^{CD}_{460}$-(1,3-Propanedisulfinato)(3,6-diazaoctane-1,8-diamine)-cobalt(III) Perchlorate Monohydrate

Ken-ichi Okamoto,* Hideki Umehara, and Jinsai Hidaka
Department of Chemistry, University of Tsukuba, Sakura, Ibaraki 305
(Received March 18, 1987)

The cis-α isomers of the 3,6-diazaoctane-1,8-diamine (trien) cobalt(III) complexes with 1,3-propanedithiolate (pdt) and 1,3-propanedisulfinate (pdsi) were selectively prepared and optically resolved. Of these isomers, the crystal structure and the absolute configuration of $(-)^{CD}_{460}$-[Co(pdsi)(trien)]$ClO_4 \cdot H_2O$ have been determined by X-ray diffraction method. The complex cation takes a Δ-cis-α configuration. The 1,3-propanedisulfinate coordinates to cobalt atom through two sulfur atoms and its chelate ring takes a skew boat form with the λ conformation. The CD spectral behaviors in the d-d transition and the sulfur-to-metal (Co(σ*) ← S(σ)) charge-transfer band regions are discussed in relation to the absolute configurations of the cobalt(III) complexes with sulfinate type sulfur donor atoms and the corresponding thiolate ones.

Cobalt(III) complexes with the 3,6-diazaoctane-1,8-diamine (trien) and its derivatives have been extensively investigated for the relation between their CD spectra in the d-d transition region and the absolute configuration, which arises from the chirality due to the skew pair of the chelate rings.[1-6] Recently, it has been reported that the absolute configuration of the cobalt(III) complexes with two or three thiolate type sulfur donor atoms and the corresponding sulfinate ones can be estimated on the basis of the two CD bands with the opposite signs in the sulfur-to-metal (Co(σ*)←S(σ)) charge-transfer band region, taking the CD spectral pattern in the d-d transition band region into consideration.[7] For the trien cobalt(III) complexes with 1,3-propanedithiolate (pdt; $S(CH_2)_3S^{2-}$) and 1,3-propanedisulfinate (pdsi; $O_2S(CH_2)_3SO_2^{2-}$), which were employed in the present work, however, this empirical estimation based on the CD spectral behaviors in the sulfur-to-metal charge-transfer band region is inconsistent with that in the d-d transition band region.

This paper deals with the preparation and resolution of the trien cobalt(III) complexes with the pdt and pdsi, and with the X-ray crystal structure analysis of $(-)^{CD}_{460}$-[Co(pdsi)(trien)]$ClO_4 \cdot H_2O$. The CD spectra of the pdt and pdsi isomers obtained are discussed in relation to the absolute cofiguration of $(-)^{CD}_{460}$ pdsi isomer, which is determined by the X-ray crystal structure analysis.

Experimental

1) Preparation of Complexes. a) *cis*-α-(1,3-Propanedithiolato)(3,6-diazaoctane-1,8-diamine)cobalt(III) Perchlorate. *cis*-α-[Co(pdt)(trien)]ClO_4. To an ice-cold solution containing 3.1 g (0.01 mol) of *cis*-α-[$Co(Cl)_2$(trien)]Cl in 60 cm^3 of water was added an ice-cold solution containing 1.08 g (0.01 mol) of 1,3-propanedithiol in 40 cm^3 of an 1 mol dm^{-3} NaOH solution of an H_2O-methanol (1 : 1) mixture. The mixture was stirred for 1 h in an ice bath. After removing the precipitate by filtration, about 20 cm^3 of a saturated $NaClO_4$ solution was added to the filtrate and it was kept in a refrigerator for 5 h. The precipitate which appeared was filtered off. The filtrate was concentrated to a half volume and kept in a refrigerator overnight. After this procedure was repeated twice, the desired black complex was collected by filtration. The crude complex was recrystallized from a small amount of water, washed with ethanol and ether, and then dried in a vacuum desiccator. It was found from the absorption and ^{13}C NMR spectral measurements that the complex contained only *cis*-α-[Co(pdt)(trien)]$^+$. Yield: 21%. Found: C, 26.09; H, 5.94; N, 13.52%. Calcd for $C_9H_{24}N_4O_4S_2ClCo \cdot 0.25H_2O$: C, 26.03; H, 5.94; N, 13.49%.

b) *cis*-α-(1,3-Propanedisulfinato)(3,6-diazaoctane-1,8-diamine)cobalt(III) Perchlorate. *cis*-α-[Co(pdsi)(trien)]ClO_4. An excess amount of 8 cm^3 of a 5% H_2O_2 solution was added to a solution containing 0.5 g of *cis*-α-[Co(pdt)(trien)]$ClO_4 \cdot 0.25H_2O$ in 20 cm^3 of water, followed by the addition of 1 cm^3 of a 30% $HClO_4$ solution. The mixture was stirred for 1 h in an ice bath and then kept in a refrigerator overnight. The thiolato complex reacts almost quantitatively with hydrogen peroxide to form the sulfinato complex. The orange crystals which appeared were collected by filtration, washed with ethanol and ether, and then dried in a vacuum desiccator. Orange crystals were obtained more by concentrating the filtrate. Yield: 48%. Found: C, 22.76; H, 5.11; N, 11.82%. Calcd for $C_9H_{24}N_4O_8S_2ClCo$: C, 22.76; H, 5.10; N, 11.80%.

2) Resolution of Complexes. a) *cis*-α-[Co(pdt)(trien)]$^+$. An excess amount (0.5 g) of $Na_2[Sb_2(d\text{-}tart)_2] \cdot 5H_2O$ was added with stirring to a solution containing 0.1 g of *cis*-α-[Co(pdt)(trien)]$ClO_4 \cdot 0.25H_2O$ in 10 cm^3 of water. After the solution was stirred for 3 min, 3 cm^3 of ethanol was added to it and cooled in an ice bath. The precipitate which appeared was filtered. The aqueous solution of the precipitate showed an enantiomeric CD spectrum in the region of 260—650 nm for the filtrate, which contained $(+)^{CD}_{530}$-*cis*-α-[Co(pdt)(trien)]$^+$. This fact seems to indicate that the present complex was partially resolved, because of the small Δε values. However, the complete resolution of this complex was unsuccessful, since the optically active isomer was unstable in the aqueous

solution without the resolving agent.

The partially resolved $(+)^{CD}_{530}$-*cis*-α-[Co(pdt)(trien)]$^+$ isomer could be oxidized by a procedure similar to that used in (1b). This oxidation product showed the identical absorption and CD spectral patterns with $(+)^{CD}_{460}$-*cis*-α-[Co(pdsi)(trien)]$^+$ as in (2b) (vide infra).

b) *cis*-α-[Co(pdsi)(trien)]ClO$_4$. The solution containing 0.4 g of *cis*-α-[Co(pdsi)(trien)]ClO$_4$ in 30 cm^3 of water was poured onto a Dowex 50W-X8 column (Na^+ form, 200—400 mesh, 3.0 cm×20 cm). After sweeping the column with water, the adsorbed band was eluted with a 0.075 mol dm^{-3} aqueous solution of $K_2[Sb_2(d\text{-tart})_2]\cdot H_2O$. Two deep yellow bands were separated completely and then fractionated. It was found from the CD spectral measurements for each of the fractions that the earlier moving band contained $(-)^{CD}_{460}$-*cis*-α-[Co(pdsi)(trien)]$^+$ and the later one contained the $(+)^{CD}_{460}$ isomer. The fractions were combined to two portions and they were concentrated to a small volume with a rotary evaporator below 25 °C. The deposited $K_2[Sb_2(d\text{-tart})_2]$ was filtered off. The filtrate was converted into the perchlorate salt using a QAE-Sephadex A-25 column (ClO_4^- form, 2.5 cm×20 cm) by eluting with water. The eluate was concentrated to a small volume again and kept in a refrigerator overnight. The resulting crystals were collected by filtration. Found: C, 21.82; H, 5.27; N, 11.24%. Calcd for $(-)^{CD}_{460}$-*cis*-α-[Co(pdsi)(trien)]ClO$_4\cdot H_2O$: C, 21.93; H, 5.31; N, 11.36%. A piece of the crystals of the $(-)^{CD}_{460}$ isomer was used for the X-ray crystal structure analysis.

3) General Data. The electronic absorption spectra were recorded on a JASCO UVIDEC-1 or UVIDEC-610 spectrophotometer and the CD spectra on a JASCO J-20 spectropolarimeter. All measurements were carried out in aqueous solution at room temperature. The ^{13}C NMR spectra were recorded in deuterium oxide on a JEOL JNM-FX-100 or-FX-90Q NMR spectrometer at the probe temperature. Sodium 2,2-dimethyl-2-silapentane-5-sulfonate was used as an internal reference. The X-ray analysis calculations were carried out on a Facom M-382 computer in the Science Information Processing Center of the University of Tsukuba.

4) X-Ray Data Collection. Unit cell parameters and intensity data for the single crystal (ca. 0.16×0.20×0.35 mm^3) were measured on a Rigaku-denki four-circle diffractometer (AFC-5) with graphite-monochromatized Mo $K\alpha$ radiation. The unit cell parameters were determined by a least-squares refinement based on 25 reflections. Systematic absences led to the space group $P3_1$ or $P3_2$. The final space group was determined to $P3_1$ by the anomalous scattering technique (vide infra). Crystal Data: $C_9H_{26}N_4O_9S_2ClCo$, M.W.=492.8, trigonal, space group $P3_1$, a=12.350(2), c=10.407(5) Å, V=1374.7(7) Å^3, d_m=1.77 g cm^{-3}, d_x=1.786 g cm^{-3}, Z=3, and μ(Mo $K\alpha$)=1.391 mm^{-1}.

The intensity data were collected by the ω—2θ scan technique up to 2θ=60° with scan rate of 3° min^{-1}. The intensity data were converted to the F_o data in the usual manner. Absorption corrections were not applied. A total of 2453 independent reflections with $|F_o|>3\sigma(|F_o|)$ of the measured 3056 reflections were considered as 'observed' and used for the structure analysis.

5) Determination of the Crystal Structure. The positions of the cobalt atom and the coordinated two sulfur and four nitrogen atoms were determined by the direct method (program MULTAN was used).[8] The difference-Fourier maps based on these atomic positions revealed the other non-hydrogen atoms. The structure was refined by a full-matrix least-squares refinement using the positional parameters, the anisotropic thermal parameters of the non-hydrogen atoms for the complex cation and chloride, and the isotropic thermal parameters for the oxygen atoms of the perchlorate and water molecule (program RFINE[9] was used). Since the positions of the hydrogen atoms of the complex cation were not determined exactly on the difference-Fourier map, we did not add their parameters to the calculation. The neutral atomic scattering factors for all the non-hydrogen atoms were taken from the literatures.[10] The final residual values were R=0.066 and R_w=0.082, respectively.

The absolute configuration was determined by the anomalous scattering technique. When the refinements were carried out by use of a set of the atomic parameters containing the Δ configuration of the complex cation, the residual values converged to R=0.064 and R_w=0.080, respectively. On the contrary, the refinements in the enantiomeric atomic parameters (the Λ configuration) resulted in the residual values of R=0.074 and R_w=0.088, respectively. These facts indicate that the former is probably the correct choice, namely, the complex cation has the Δ configuration (Fig. 1). A similar relationship between the residual values and the absolute configuration was observed for the determination of the crystal structure of cobalt(III) complexes with 2-aminoethaneseleninate.[11,12] The final positional parameters for the Δ-cis-α isomer are listed in Table 1. A list of

Results and Discussion

Description of the Structure. A perspective drawing of the complex cation, $(-)^{CD}_{460}$-[Co(pdsi)(trien)]$^+$, is given in Fig. 1,[13] together with a numbering scheme. The bond lengths and angles (with their standard deviations) in the complex cation are summarized in Table 2. The coordination geometry around cobalt atom is approximately octahedral. The trien, which coordinates as a quadridentate ligand, takes the cis-α configuration by coordination.[14] The pdsi ligand coordinates to the cobalt atom through two sulfur atoms to form the six-membered chelate ring. This indicates that the treatment of the thiolato complex with hydrogen peroxide proceeds without the linkage isomerization as in the case of the cobalt(III) complexes with the sulfinate ligands,[15] although the linkage isomerization was observed for the sulfinato complex[16] obtained by the photochemical preparation and the seleninato complex.[11]

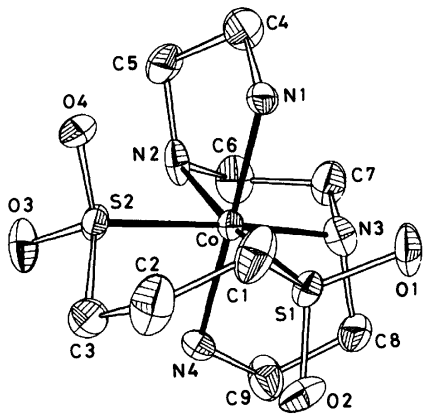

Fig. 1. Perspective view of $(-)^{CD}_{460}$-Δ-*cis*-α-[Co(pdsi)(trien)]$^+$ ion with the numbering scheme.

For *cis*-α-[Co(pdsi)(trien)]$^+$, the optical isomers, Δ and Λ, are possible.[17] The result of the X-ray crystal structure analysis indicates that the absolute configuration of the $(-)^{CD}_{460}$ isomer takes the Δ configuration and the two asymmetric nitrogen atoms in the trien have the absolute configuration S. In the trien ligand, the two outer chelate rings take the unsymmetrical skew form with the λ conformation. The central chelate ring takes nearly symmetrical skew form with the δ conformation. Similar conformational relationship of the chelate rings was also observed for the L-3,8-dimetrien (δλδ conformation) in $(-)_{589}$-*Λ-cis*-α-[$Co(NO_2)_2$(L-3,8-dimetrien)]$^+$,[4,5] where L-3,8-dimetrien denotes (2*S*,7*S*)-2,7-dimethyl-3,6-diazaoctane-1,8-diamine. The pdsi has the symmetrical skew boat form with the λ conformation. Thus, the complex cation of the $(-)^{CD}_{460}$-Δ-cis-α isomer has an approximately two-fold axis.

In $(-)^{CD}_{460}$-*Δ-cis*-α-[Co(pdsi)(trien)]$^+$, the bond lengths and angles around the sulfinato group are almost equal to those in [Co(aesi-*N*,*S*)$(en)_2$]$^{2+}$,[15] except for the angles of Co-S-C (111.2(5) and 110.1(5)° for the pdsi complex and 100.1(2)° for the aesi one) which seem to depend on the difference between the pdsi and aesi chelate rings, where aesi denotes 2-aminoethanesulfinate. The bond lengths and angles for the trien are similar to those for $(-)_{589}$-*cis*-α-[$Co(NO_2)_2$(L-3,8-dimetrien)]ClO_4,[4] except for the Co-N distances. The mean value of the Co-N distance in the pdsi complex, 1.987(9) Å, is significantly longer than the corresponding distance (1.952(7)) Å in $(-)_{589}$-*cis*-α-[$Co(NO_2)_2$(L-3,8-dimetrien)]ClO_4[4] and those (1.95(2) and 1.955(9) Å) in *cis*-β-[Co(*S*-pro)(trien)]$^+$.[18] Lange et al. reported the structural trans effect that the Co-N distance for the group trans to the sulfur atom in the sulfinato group

was longer than the other Co-N distances in [Co(aesi-*N*,*S*)(en)$_2$]$^{2+}$.[15] Therefore, the lengthening of the Co-N distances in the present pdsi complex seems to depend on the trans effect for the two sulfinato groups.

^{13}C NMR Spectra. The ^{13}C NMR spectrum of $(-)^{CD}_{460}$-*Δ-cis-α*-[Co(pdsi)(trien)]$^+$ exhibits five resonance lines (20.37, 46.21, 55.20, 58.08, and 58.35 ppm) due to the nine methylene carbon atoms. This indicates that the $(-)^{CD}_{460}$-Δ-cis-α isomer has C_2 symmetry in an aqueous solution as well as in the crystalline state. The spectrum of [Co(pdt)(trien)]$^+$ exhibits also five resonance lines (24.05, 35.11, 46.43, 57.05, and 57.43 ppm) due to the nine methylene carbon atoms, indicating the C_2 symmetry. Further, [Co(pdt)(trien)]$^+$ reacts with hydrogen peroxide to give selectively *cis-α*-[Co(pdsi)(trien)]$^+$. Similar oxidation reaction has proceeded with retention of the geometrical configuration in the reaction of the thiolato cobalt(III) complexes with hydrogen peroxide.[11,19] These facts indicate that [Co(pdt)-(trien)]$^+$ takes the cis-α configuration.

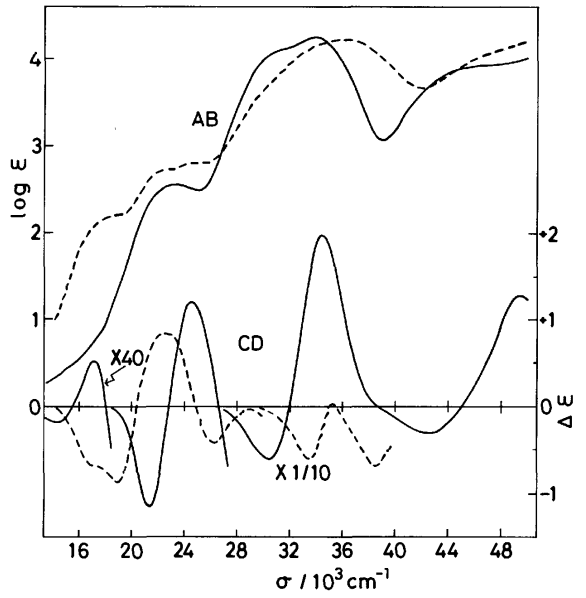

Fig. 2. Absorption and CD spectra of $(-)^{CD}_{460}$-Δ-*cis*-α-[Co(pdsi)(trien)]$^+$ (——) and $(-)^{CD}_{530}$-*cis*-α-[Co(pdt)(trien)]$^+$ (----).

Electronic Absorption and CD Spectra. The electronic absorption and CD spectra of $(-)^{CD}_{460}$-*Δ-cis-α*-[Co(pdsi)(trien)]$^+$ are shown in Fig. 2, together with the corresponding thiolato complex, $(-)^{CD}_{530}$-*cis-α*-[Co(pdt)(trien)]$^+$, and their data are summarized in Table 3. The absorption spectrum of $(-)^{CD}_{460}$-Δ-*cis-α*-[Co(pdsi)(trien)]$^+$ exhibits a broad band at 23.26×10^3 cm^{-1}, similar to those of the cobalt(III) complexes including the sulfinate group.[11] The CD bands of the $(-)^{CD}_{460}$-Δ-cis-α pdsi isomer in this region exhibit a negative and a positive signs from the lower energy (Fig. 2). This CD spectral behavior of the Δ-sulfinato complex is consistent with those of the trien type cobalt(III) complexes.[1-6] which have been successfully assigned to the Δ configuration.

For $(-)^{CD}_{460}$-*Δ-cis-α*-[Co(pdsi)(trien)]$^+$, the intense and broad absorption band in the region of 27—37×10^3 cm^{-1}, which is assigned to the sulfur-to-metal charge-transfer transition,[7,19-21] is composed of two components at ca. 31.50 and 33.94×10^3 cm^{-1} (Fig. 2). This absorption spectral behavior is characteristically observed for the cis(S) geometry of the cobalt(III) complexes with the thiolate and sulfinate ligands.[7,20,21] In this absorption band region, $(-)^{CD}_{460}$-*Δ-cis-α*-[Co(pdsi)-(trien)]$^+$ exhibits the two CD bands with the opposite signs ((−) and (+) from the lower energy). According to the empirical estimation,[7] which a negative and a positive CD bands from the lower energy are favorable

Table 3. Absorption and CD Spectral Data of $(-)^{CD}_{460}$-*cis-α*-[Co(pdsi)(trien)]$^+$ and $(-)^{CD}_{530}$-*cis-α*-[Co(pdt)(trien)]$^+$

Complex	Absorption maxima σ/10^3 cm^{-1}	CD extrema σ/10^3 cm^{-1}
	log ε/mol^{-1} dm^3 cm^{-1}	Δε/mol^{-1} dm^3 cm^{-1}
$(-)^{CD}_{460}$-*cis-α*-[Co(pdsi)(trien)]$^+$	23.26 (2.55)	14.43 (−0.005)
	31.50 (4.12 sh)	17.12 (+0.013)
	33.94 (4.25)	21.36 (−1.154)
	46.51 (3.93 sh)	24.51 (+1.206)
		30.40 (−6.076)
		34.36 (+19.982)
		42.37 (−2.953)
		49.26 (+12.830)
$(-)^{CD}_{530}$-*cis-α*-[Co(pdt)(trien)]$^+$	18.69 (2.19 sh)	17.15 (− sh)
	22.42 (2.72 sh)	18.80 (−)
	25.00 (2.80)	22.47 (+)
	33.33 (4.11 sh)	26.32 (−)

sh denotes a shoulder.

for the Λ configuration, the present $(-)^{CD}_{460}$-Δ-cis-α pdsi isomer may be assigned to the Λ configuration.

The absorption spectrum of $(-)^{CD}_{530}$-*cis*-α-[Co(pdt)-(trien)]$^+$ coincides with the cis(S) cobalt(III) complexes with L-penicillaminate[20] and the [Co(amine)$_4$-(thiolato)$_2$]-type complexes.[7,21] In the first absorption and sulfur-to-metal charge-transfer band regions, the $(-)^{CD}_{530}$-*cis*-α pdt isomer exhibits a similar CD spectral pattern to $(-)^{CD}_{460}$-*Λ*-*cis*-α-[Co(pdsi)(trien)]$^+$, although the intensities are shown by an arbitrary scale (Fig. 2). Further, the absorption and CD spectra of the oxidation product, which was obtained by the reaction of $(+)^{CD}_{530}$-*cis*-α-[Co(pdt)(trien)]$^+$ with hydrogen peroxide, exhibit the identical patterns with those of the $(+)^{CD}_{460}$-*Λ*-*cis*-α-[Co(pdsi)(trien)]$^+$ (Fig. 2). Accordingly, these facts suggest that $(-)^{CD}_{530}$-*cis*-α-[Co(pdt)(trien)]$^+$ takes the Δ configuration.

The authors wish to express thanks to Miss Yuko Hanada and Mrs. Yoko Koizumi for their aids in the experiment. This work was supported by a Grant-in-Aid for Scientific Research No. 60470043 from the Ministry of Education, Science and Culture.

Control of the Impregnation Profile of Co in an Al_2O_3 Sphere

Masashi Otsuka, Takeshi Fujiyama, Yoshikazu Tsukamoto,
Hideyasu Tsuiki, and Akifumi Ueno*
Department of Materials Science, Toyohashi University of Technology, Tempakucho, Toyohashi, Aichi 440
(Received February 16, 1987)

A radial distribution of cobalt metal particles in an alumina sphere was controlled by impregnation of the spheres with a solution composed of cobalt nitrate dissolved in ethylene glycol, ethyl silicate, and a small amount of nitric acid. The radial position of cobalt narrow band in the sphere was varied with the impregnation time and the cobalt loading was controlled by the concentration of cobalt nitrate in the impregnation solution. It was also found that porous SiO_2 film resulted from the gelling of ethyl silicate covered whole external surface of the sphere.

From the viewpoints of catalyst durability and poison, a control of the impregnation profile of an active component in a support sphere has been desired for catalysts of practical use; especially for steam reforming and automotive catalysts.[1,2] Four kinds of profiles are well-known, designated as uniform, egg shell, egg white, and egg yolk,[3] respectively. The uniform and egg shell types of catalysts are considered to be applied for reactions whose rate determining steps are in the reactions between surface species or in the diffusions of reactant molecules.[4] These profiles are easily achieved by control of the impregnation time[5] or by alteration of the starting materials of the catalyst constituents.[6] While the egg white and egg yolk types of catalysts are often employed to minimize the catalysts poison or the loss of active components during operations.[4] The preparation of catalysts with these profiles requires proper additions to the impregnating solutions. As additives to control the impregnation profiles, citric acid,[7] oxalic acid,[8] urea,[9] and nitric acid[10] have often been employed. These additives are volatile and decomposed when the catalysts are calcined at high temperature.

Besides the technical developments, theoretical approaches to the control of impregnation profiles have been studied by Vincent and Merril[11] with an assumption of one dimensional diffusion of metal ions in micropores of a catalyst support. Komiyama et al.[12] developed the assumption to three-dimensional diffusion of metal ions and showed that this model was consistent with an actual impregnation profile of Ni in an alumina sphere. Despite these advanced techniques and theories, impregnation profiles are not always reproducible, probably because of the heterogeneity of solid surfaces and the lack of knowledge about micropore structure.[13]

In conventional impregnation, free metal ions are formed in the impregnating solution and are ready to penetrate in micropores of support spheres when the spheres are immersed. The size of free metal ions is generally considered to be smaller than those of the micropores in the support spheres. What will happen in the impregnation profile and the metal loading, if macromolecules, larger than the micropores in size, containing metal ions are in the impregnating solution? The present work was done to answer this question using the impregnating solution composed of cobalt nitrate dissolved in ethylene glycol and ethyl silicate. In our earlier paper,[14] the solution consisting of a metal nitrate dissolved in ethylene glycol and ethyl silicate was proved to form macromolecules containing $(-M-O-Si-)_n$ structures, where M represents the metal ion.

Experimental

Impregnation Procedure. $Co(NO_3)_2 \cdot 6H_2O$ (8.9 g) was dissolved in 153 ml of ethylene glycol (EG) at 80 °C and then pored into 30 ml of ethyl silicate at the same temperature with 3 ml of nitric acid. The solution (pH=1) was transparent and colored pale violet. Alumina spheres (5 g) with 3 mm of diameter and 298 m^2g^{-1} of BET surface area were immersed with the solution at room temperature. The impregnation time was varied from 1 min to 30 h. After the impregnation, the spheres were dried at 110 °C in an oven for

24 h and then calcined at 300 °C for 4 h in air, followed by reduction at 900 °C in flowing hydrogen. The impregnation conditions were settled above unless specified. The amount of $Co(NO_3)_2 \cdot 6H_2O$ in EG could be varied, if necessary.

The impregnation procedure employed in this work is summarized in Table 1.

EPMA Measurement. The shperes thus impregnated were mounted in a polyester support and the support was polished with fine alumina powder until the cross section of a sphere appeared. The alumina powder adhered to the support was removed by ultrasonication. In order to avoid charge-up phenomenon, Pt was evaporated over the support surface. The radial distributions of Co and Si in the sphere was measured by electron probed X-ray microanalyser (EPMA, Hitachi model X-650), operated at an accelerating voltage of 20 kV with an energy dispersion detector.

Measurement of Co Loading. The impregnated spheres calcined at 300 °C were ground and then mixed with the appropriate amount of $Na_2B_4O_7$ to be fired at 1000 °C in platinum crucible. In a B_2O_3 disk thus prepared, the catalyst constituents were well dispersed and the disk was subjected to X-ray fluorescence spectrometer (Rigaku Denki, Model 3080), operated at 50 kV with a filament current of 50 mA to generate Rh $K\alpha$ radiation.

Pore Size Measurements. The micropore size distributions of bare alumina spheres and the impregnated spheres reduced at 900 °C were measured with a porosimeter (Carlo Erva, Sorptmatic 1800) using nitrogen as a sorption gas at the liquid nitrogen temperature.

Results

Radial Distribution of Cobalt. Typical photographs of the cross sections of reduced catalysts and the associated EPMA profiles are given in Fig. 1. The position of the narrow cobalt band in the catalyst sphere was proved to shift into the center of sphere with increasing the impregnation time, as shown in Fig. 2. The bars given in Fig. 2 represent the width of the Co metal bands in the impregnated catalysts. The loading of cobalt in the reduced catalyst was found not

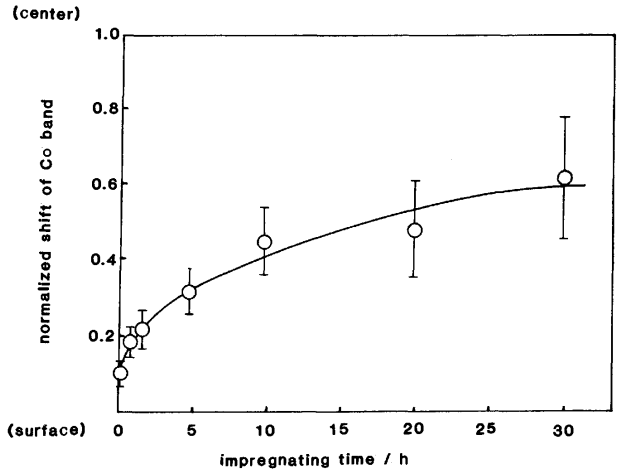

Fig. 2. Shift of the narrow cobalt band in the alumina sphere with the impregnation time; the distance from the center of the sphere was normalized in this Figure.

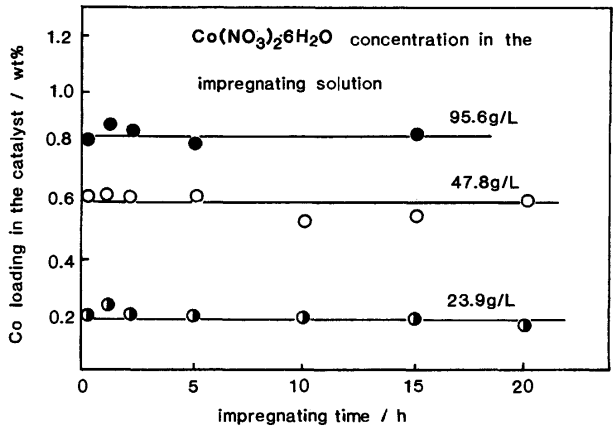

Fig. 3. Change in Co loading with the impregnation time; the concentrations of cobalt nitrate in the impregnation solutions were 23.9, 47.8, and 95.6 g L^{-1}, respectively.

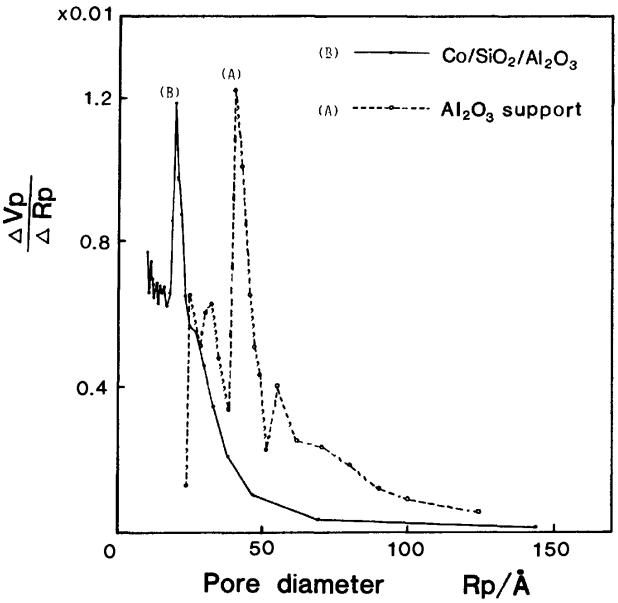

Fig. 4. Pore size distributions of the alumina sphere (A) and the impregnated catalyst (B).

to depend upon the impregnation time but to depend upon the concentration of cobalt nitrate in the impregnating solution (see Fig. 3).

Distribution of Si. On the contrary, Si was observed on the external surface of spheres, forming thin SiO_2 film, revealed by EPMA profiles shown in Fig. 1. The apparent thickness of this SiO_2 film was estimated less than 50 μm from an EPMA result shown in Fig. 4.

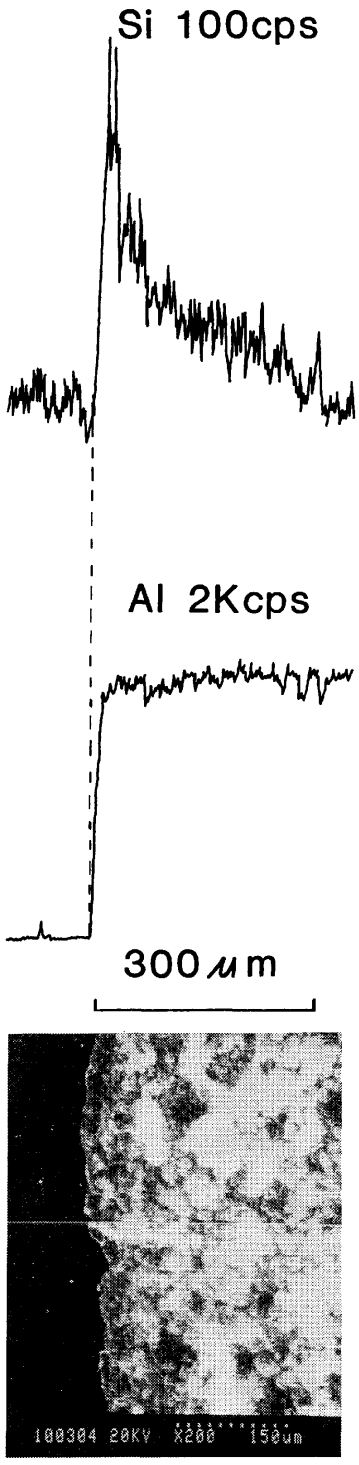

Fig. 5. EPMA profile of the impregnated catalyst at its fringe.

Pore Size Distribution. Pore size distributions of bare alumina spheres and the reduced catalyst are depicted in Fig. 5. The pore size of the bare alumina was sharply distributed at about 45 Å, while that of the reduced catalyst was observed at 20 Å. Thus, the mean pore size of alumina spheres was found to shift to the smaller one when they were immersed with the impregnation solution employed. The pore volume of the reduced catalyst was 0.36 ml g^{-1}, almost the same as that of the bare alumina spheres, 0.33 ml g^{-1}, nevertheless the specific surface area of the reduced catalyst decreased to 256 m^2g^{-1}.

Discussion

As was mentioned previously,[14] metal nitrate dissolved in ethylene glycol forms the metal glycolate as follows;

$$\begin{matrix} H_2C\text{-}OH \\ | \\ H_2C\text{-}OH \end{matrix} + Co(NO_3)_2 \longrightarrow \begin{matrix} H_2C\text{-}O \\ | \quad \diagdown \\ \quad\quad Co \\ | \quad \diagup \\ H_2C\text{-}O \end{matrix} + 2H^+ + 2NO_3^- \qquad (1)$$

The metal glycolate thus produced reacts with tetraethyl silicate to form the species containing -M-O-Si-structure according to the following reaction;

$$\begin{matrix} H_2C\text{-}O \\ | \quad \diagdown \\ \quad\quad Co \\ | \quad \diagup \\ H_2C\text{-}O \end{matrix} + 2Si(OEt)_4 \longrightarrow (EtO)_3Si\text{-}O\text{-}Co\text{-}O\text{-}Si(OEt)_3 + (EtO)\text{-}CH_2\text{-}CH_2\text{-}(OEt). \qquad (2)$$

The reaction between the species containing -M-O-Si- structure results in the three-dimensional expansion of -M-O-Si- structure producing Et-O-Et, diethyl ether. Thus, macromolecules possessing cobalt ions are produced in the impregnating solution employed in this work. If the size of these macromolecules is smaller than that of the micropores on the alumina spheres, the macromolecules may penetrate into the spheres. The EPMA profiles given in Fig. 1 showed that Si ions in the macromolecules are deposited over the external surface of the sphere forming SiO_2 thin film but not inside the sphere. This indicates that the size of the macromolecule is larger than 50 Å, since the micropore size of the alumina spheres is sharply distributed at 50 Å (see Fig. 5). When alumina spheres with micropores sized around 100 Å were immersed with the solution, Si ions were clearly observed inside the spheres by EPMA, suggesting that the macromolecules are sized smaller than 100 Å. Once an appropriate amount of macromolecules adhered over the surface of sphere, no more molecules seem to adsorb on the sphere. This resulted in the constant loading of cobalt ions in the catalyst even when the impregnation time was prolonged (see Fig. 3). By changing the concentration of cobalt nitrate in the impregnating solution, the cobalt concentration in the macromolecules may change, hence the cobalt loading in the catalyst can be controlled by the concentration of cobalt ions in the solution, as also could be seen in Fig. 3.

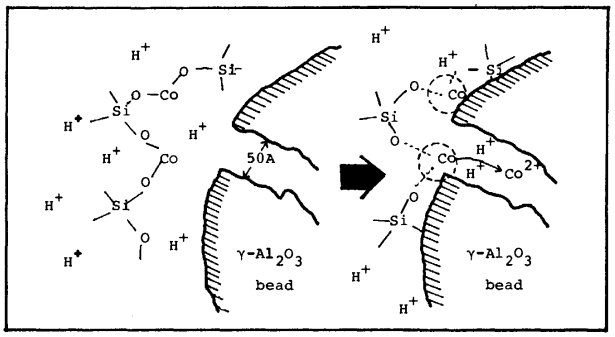

Fig. 6. Model of the mechanism for controlled impregnation profile and formation of SiO_2 thin film.

The impregnation mechanism was imagined as shown in Fig. 6. The $(\text{-M-O-Si-})_n$ structures in adsorbed macromolecules may decompose somehow on the alumina surface and the cobalt ions eliminated diffuse into the spheres,competing with H^+ ions[15] produced by the Reaction 1 and originating from nitric acid added. H^+ ions may adsorb more strongly on alumina than cobalt ions, resulting that the position of cobalt ions adsorbed moved to the center of the sphere with increasing the impregnation time. Thus, the cobalt narrow band is achieved as shown in Fig. 1. The SiO_2 film was not deposited inside the micropores of the reduced catalyst but just over their external surface, since the pore volumes of the bare alumina spheres and the reduced catalyst are almost the same with each other.

It must be mentioned that when the alumina spheres with the pore size of 50 Å were immersed with mere tetraethyl silicate, i.e., monomeric tetraethyl silicate, Si ions were observed not only on the surface but inside the spheres of the reduced catalyst.

Conclusion

The impregnation profile of cobalt in alumina spheres was controlled by the impregnation time of alumina shperes with the micropore sized around 50 Å, the impregnating solution consisting of cobalt nitrate dissolved in ethylene glycol, tetraethyl silicate, and a small amount of nitric acid. The cobalt loading in the catalyst was adjusted by the concentration of cobalt nitrate in the impregnating solution. Thus, by employing an appropriate solution both the impregnation profile and the loading of cobalt in the alumina sphere can be simultaneously controlled. On the external surface of the reduced catalyst thus produced was found to be covered with thin and porous SiO_2 film, the pore size on this SiO_2 film being sharply distributed at 20 Å.

The mechanism and the driving force of the decomposition of macromolecules containing $(-M-O-Si-)_n$ structures over the alumina surface are still unrevealed in the present work.

The authors express their thanks to Dr. Goro Satoh at Shokubai Kasei Company for supplying alumina spheres and to Dr. Akio Furuta at Nikki (JGC) company for measurements of micropore sizes of various catalysts and alumina spheres.

Mössbauer and DTA Studies on the Structure of Semiconducting Sodium Vanadate Glasses

Tetsuaki NISHIDA,* Michiko OGATA, and Yoshimasa TAKASHIMA
Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashiku, Fukuoka 812
(Received March 6, 1987)

Distinct decreases in the quadrupole splitting of the tetrahedral Fe^{3+} ions and the T_g suggest a gradual change from the layer structure composed of the VO_5 tetragonal pyramids to the chain structure composed of the VO_4 tetrahedra. It is also concluded that nonbridging oxygen atoms are present in the VO_4 tetrahedra.

Structural study of the crystalline V_2O_5 has been performed by Byström et al.[1] and Jansen and Sperlich.[2] They revealed that each V^{5+} ion is surrounded by five oxygen atoms making a distorted tetragonal pyramid, which can also be viewed as a distorted trigonal bipyramid, sharing edges and corners to form a layer structure. An IR study of several vanadate glasses performed by Dimitriev et al.[3] revealed that the introduction of alkali or alkaline earth oxides into the V_2O_5 matrix results in a destruction of the layer structure followed by a formation of tetrahedral VO_4 units. Dimitriev et al.[3] also elucidated that only the VO_4 units are present in the skeleton of metavanadate glasses. The same conclusion has been obtained in an NMR study of KVO_3 glass.[4] The crystal structure of the alkali metavanadate crystals including the KVO_3 is known to be composed of chains of VO_4 tetrahedra.[5] Dimitriev et al.[3] also revealed that the introduction of other kind of oxides which play a role of a network former, such as SiO_2, B_2O_3, GeO_2, and TiO_2, affects little structural change on the skeleton of the V_2O_5-based glass originally made of only VO_5 units.[1,2] On the other hand, a neutron diffraction study performed by Wright et al.[6] revealed that the coordination number of the vanadium is always 5 in P_2O_5-V_2O_5, BaO-V_2O_5, and PbO-V_2O_5 glasses irrespective of the glass composition, and that the skeleton of the vanadate glasses is composed of the interconnected and distorted VO_5 tetragonal pyramid. It should be noted that the neutron diffraction study by Wright et al.[6] has not been performed for alkali vanadate glasses. Similar conclusion has been obtained in a simultaneous EXAFS and XANES study of P_2O_5-V_2O_5 glass.[7] Besides the VO_4 and the VO_5 units described above, the presence of octahedral VO_6 units has been proposed based on the ESR measurements of the V^{4+} (VO^{2+}) ions.[8,9] Mössbauer spectroscopy has been utilized for the structural study of potassium vanadate glasses,[10] where the present authors revealed that all the Fe^{3+} ions are tetrahedrally coordinated by oxygen atoms at the substitutional sites of the V^{5+} or V^{4+} ions constituting the VO_4 tetrahedra.

The present Mössbauer study was carried out in order to elucidate the structure of the sodium vanadate glasses. DTA measurements were performed in order to know the structural change through the glass transition temperature (T_g), because the T_g is known to reflect a change in the coordination number of the network-forming atoms and a formation of nonbridging oxygen atoms.[10]

Experimental

Sodium vanadate glasses were prepared by fusing the individual mixtures (1 g) of commercially available Na_2CO_3, V_2O_5, and Fe_2O_3, of guaranteed reagent grade, at 950 °C for 1 h in an electric muffle furnace. After the fusion in the ambient atmosphere, each melt in a platinum crucible was quenched with ice-cold water. The vanadate glasses were tried to prepare in the compositional ranges of 0 mol%$\leqslant$ $Na_2O\leqslant$40 mol%, 50 mol%$\leqslant V_2O_5\leqslant$90 mol%, and 0 mol%$\leqslant$ $Fe_2O_3\leqslant$30 mol%. All the glass samples prepared in the present study are almost black in color. Mössbauer and DTA measurements were performed for the pulverized glasses similarly to the case of the potassium vanadate glasses.[10]

Results and Discussion

The glass-forming region for the ternary Na_2O-V_2O_5-Fe_2O_3 glass system is shown in Fig. 1, where open and closed circles indicate the formations of glass and non-glassy (devitrified) samples, respectively. A Mössbauer spectrum of the sodium vanadate glasses measured at room temperature is shown in Fig. 2, which indicates the presence of paramagnetic Fe^{3+} ions of high spin state.[11,12] The isomer shift and the linewidth of the absorption peaks are located in the ranges of 0.39—0.35 and 0.53—0.47 mm s^{-1}, respectively. As to the coordination number of the iron in glasses, earlier results are reviewed by Kurkjian[13] and Coey.[14] Recent Mössbauer results on the structure of

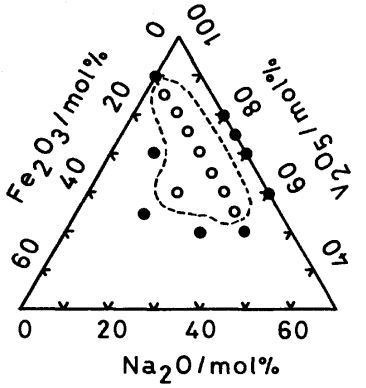

Fig. 1. Glass-forming region of the Na_2O-V_2O_5-Fe_2O_3 system.

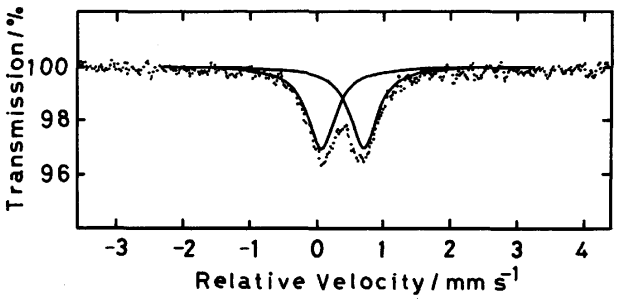

Fig. 2. Mössbauer spectrum of the $25Na_2O \cdot 65V_2O_5 \cdot 10Fe_2O_3$ glass measured at room temperature.

glasses are reviewed by Müller-Warmuth and Eckert.[15] According to Coey, Fe^{3+} ions are reported to be present at the tetrahedral sites in borate and silicate glasses.[14] This is well consistent with the Mössbauer results of borate[16-18] and borosilicate[19-20] glasses, performed by the present authors, where the isomer shift ranges from 0.38 to 0.22 mm s^{-1} with respect to metallic iron. (The experimental error for the isomer shift is usually estimated to be ± 0.01 mm s^{-1}.) Judging from the experimental results shown in those reviews[13-15] and papers,[16-20] the Fe^{3+} ions are concluded to be present at the tetrahedral environments in the sodium vanadate glasses. This conclusion indicates the presence of the tetrahedral VO_4 units, because the Fe^{3+} ions should be present either at the substitutional sites of the V^{5+} or V^{4+} ions constituting the glass matrix or at the interstitial sites of the glass matrix. These results are well consistent with the IR results obtained by Dimitriev et al.[3] and with the Mössbauer results of the potassium vanadate glasses.[10]

The composition dependency of the isomer shift is shown in Fig. 3, which shows a distinct decrease with increasing Na_2O content. Similar composition dependency has been observed in the case of the potassium vanadate glasses,[10] where the decrease in the isomer shift was ascribed to the formation of nonbridging oxygen atoms in the VO_4 tetrahedra. The composition dependency of the isomer shift is well consistent with that of the quadrupole splitting shown in Fig. 4, where the quadrupole splitting shows a distinct decrease with increasing Na_2O content. (The experimental error for the quadrupole splitting is usually estimated to be ± 0.02 mm s^{-1}.) The decrease in the quadrupole splitting of the Fe^{3+} ions is ascribed to the increased symmetry around the Fe^{3+} ions, because the high-spin Fe^{3+} ions have a symmetric electron configuration of $3d^5$ in the outermost orbital. The present results of the isomer shift (Fig. 3) and the quadrupole splitting (Fig. 4) therefore indicate the formation of nonbridging oxygen atoms in the VO_4 tetrahedra constituting the skeleton of the sodium vanadate glasses. The decrease in the quadrupole splitting may be correlated with the decrease in the coordination number of the V^{5+} and V^{4+} ions from 5 to 4, because the electric field gradient (e^2qQ) is considered to be smaller in the

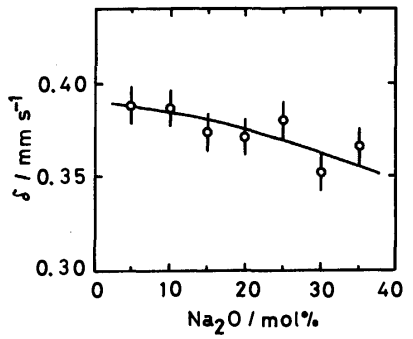

Fig. 3. Composition dependency of the isomer shift (δ) of the Fe^{3+} ions in the Na_2O-V_2O_5 glasses containing 10 mol% Fe_2O_3.

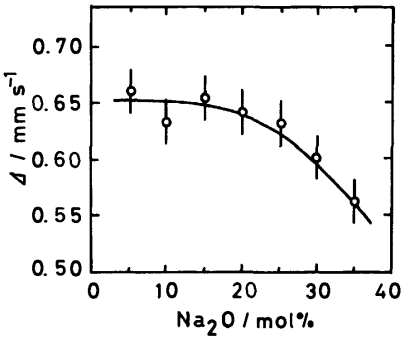

Fig. 4. Composition dependency of the quadrupole splitting (Δ) of the Fe^{3+} ions in the Na_2O-V_2O_5 glasses containing 10 mol% Fe_2O_3.

case of the tetrahedral configuration.

Each DTA curve of the sodium vanadate glasses containing 10 mol% Fe_2O_3 consists of an endothermic peak due to glass transition and one or a few exothermic peak(s) due to crytallization. All the glass transition temperatures (T_g) are plotted in Fig. 5, where the T_g values are plotted against the Na_2O content. A Mössbauer and DTA study of potassium vanadate glasses[10] revealed that the T_g shows a distinct decrease when the coordination number of the V^{5+} or V^{4+} ions decreases from 5 to 4 and when the nonbridging oxygen atoms are formed in the VO_4 tetrahedra. The distinct decrease in the T_g from 237 to 195 °C (Fig. 5) is therefore ascribed to the gradual decrease in the coor-

Table 1. Glass Transition and Crystallization Temperatures of the Na_2O–V_2O_5 Glasses Containing 10 mol% Fe_2O_3

Composition	T_g[a)]/°C	T_c[b)]/°C
$5Na_2O \cdot 85V_2O_5 \cdot 10Fe_2O_3$	237	254
$10Na_2O \cdot 80V_2O_5 \cdot 10Fe_2O_3$	232	253
$15Na_2O \cdot 75V_2O_5 \cdot 10Fe_2O_3$	228	247
$20Na_2O \cdot 70V_2O_5 \cdot 10Fe_2O_3$	222	238
$25Na_2O \cdot 65V_2O_5 \cdot 10Fe_2O_3$	223	250
$30Na_2O \cdot 60V_2O_5 \cdot 10Fe_2O_3$	210	239
$35Na_2O \cdot 55V_2O_5 \cdot 10Fe_2O_3$	195	213

a) Glass transition temperature. b) Crystallization temperature.

dination number of the V^{5+} and V^{4+} ions from 5 to 4 and to the formation of the nonbridging oxygen atoms in the VO_4 (and FeO_4) tetrahedra. All the T_g values obtained in the present study are summarized in Table 1, together with the individual crystallization temperatures (T_c). In Table 1, only one crystallization temperature corresponding to the main peak is given for each glass sample.

It is concluded that Fe^{3+} ions are present at the substitutional sites of the V^{5+} or V^{4+} ions constituting the VO_4 tetrahedra. It is also concluded that the introduction of Na_2O into the V_2O_5 matrix results in a gradual change from the layer structure composed of the VO_5 tetragonal pyramids (or trigonal bipyramids) to the chain structure composed of the VO_4 tetrahedra having nonbridging oxygen atoms.

The authors are grateful to Dr. Koji Yamada of Hiroshima University for his useful discussion on the structure of the vanadate glasses. One of the authors (TN) is grateful to the Itoh Science Foundation, Corning Research Grant, and a Grant-in-Aid for Scientific Research No. 61740350 from the Ministry of Education, Science and Culture.

Photochemical Reactions of Ethoxycarbonyl-Substituted Quinolines

Isao ONO* and Norisuke HATA
Department of Chemistry, College of Science and Engineering, Aoyama Gakuin University, Chitosedai, Setagaya-ku, Tokyo 157
(Received December 20, 1986)

The photochemical reactions of the quinoline derivatives substituted by an ethoxycarbonyl group at the 2-, 3-, and 4-positions of a quinoline nucleus have been investigated in several alcohols and cyclohexane. Irradiation of ethyl 4-quinolinecarboxylate (**1**) yielded ethyl 2-hydroxyalkyl-4-quinolinecarboxylates (**4a—c**) in alcohols and ethyl 2-cyclohexyl-4-quinolinecarboxylate (**4d**) in cyclohexane in a good yield, respectively. The photochemical reactions of ethyl 3-quinolinecarboxylate (**2**) showed remarkable solvent dependency. Irradiation in methanol and cyclohexane afforded a solvent·additive product, ethyl 4-hydroxymethyl-1,4-dihydro-3-quinolinecarboxylate (**5a**) and ethyl 4-cyclohexyl-1,4-dihydro-3-quinolinecarboxylate (**5b**), while such photo-addition of the solvent did not proceed in ethanol and 2-propanol but instead ethyl 1,4-dihydro-3-quinolinecarboxylate (**6**) and dimeric compounds were formed, both of which were unstable and finally reverted to **2** at room temperature in air. In the case of ethyl 2-quinolinecarboxylate two types of the products, ethyl 4-hydroxyalkyl-1,4-dihydro-2-quinolinecarboxylate (**7**) and ethyl 1,4-dihydro-2-quinolinecarboxylate (**8**) were obtained in ethanol and 2-propanol but the yields of those products were poor. On the basis of triplet quenching experiments, the photochemical reactions of those ethyl quinolinecarboxylates are suggested to occur through hydrogen abstraction from the solvents by the ring nitrogen in the S_1 state.

The photochemical reactions of cyano-substituted quinolines have been the subject of a number of investigations.[1] Especially, we have mechanistically investigated in detail the photosubstitution of 2-quinolinecarbonitriles in ethanol and proved that the replacement of a cyano group by a 1-hydroxyethyl one occurred via a hydrogen-bonded radical-pair intermediate formed by hydrogen abstraction by a ring nitrogen from the solvents in the S_1 state.[1b,c] Next, we reported the photochemical reactions of 2-(dimethylcarbamoyl)quinolines, where the ring nitrogen brought about hydrogen abstraction from the dimethylcarbamoyl substituent via the T_1 state to give 2-(methylaminoacetyl)quinolines and cyclized products.[2] In this paper, we report the photochemistry of ethoxycarbonyl quinolines bearing also an electron-withdrawing group such as ethyl 4-quinolinecarboxylate (**1**), ethyl 3-quinolinecarboxylate (**2**), and ethyl 2-quinolinecarboxylate (**3**) in several alcohols and in cyclohexane. Sugimori et al. reported that methyl 2-pyridinecarboxylate underwent methylation at the 5-position in methanol through hydrogen abstraction by the excited carbonyl group from the solvent.[3] In the case of the ethoxycarbonyl quinolines two types of reactions were observed, both of which were initiated by hydrogen abstraction by the ring nitrogen from the solvent. One is a recombination of a radical pair in a solvent cage and another is probably further hydrogen abstraction by a semi-reduced radical from the solvent. We describe the excited state involved in those reactions and reaction mechanism.

Photochemistry of Ethyl 4-Quinolinecarboxylate (1). Irradiation of **1** in several alcohols and cyclohexane under an oxygen atmosphere gave one major photoproduct **4** in good yield as shown in Table 1. Although we attempted irradiation in nitrogen, the yield of **4** decreased about to 20 percent because of an increase in the amount of decomposition products. The NMR spectra of **4** indicated that the ethoxycarbonyl substituent at the 4-position of a quinoline remained and the proton at the 2-position was replaced by a corresponding hydroxyalkyl group derived from the alcohol used as a solvent or a cyclohexyl group when irradiation was carried out in cyclohexane. From the data of MS, IR, or elemental analysis, **4** was assigned to be ethyl 2-hydroxyalkyl-4-quinolinecarboxylate (**4a—c**) or ethyl 2-cyclohexyl-4-quinolinecarboxylate (**4d**), respectively.

Photochemistry of Ethyl 3-Quinolinecarboxylate (2). Irradiation of **2** was carried out in nitrogen atmosphere, because no reaction occurred in oxygen. Any photoproduct obtained in each solvent (MeOH, EtOH, 2-PrOH, or cyclohexane) has a UV spectrum showing its maximum at a wavelength longer than

Table 1. Photochemical Reactions of **1** in Several Solvents

Solvent	Irradiation time/h	Atm	Conversion %		Product yield %
Ethanol	4	O_2	80	**4a**	67
	2.5	N_2	84	**4a**	22

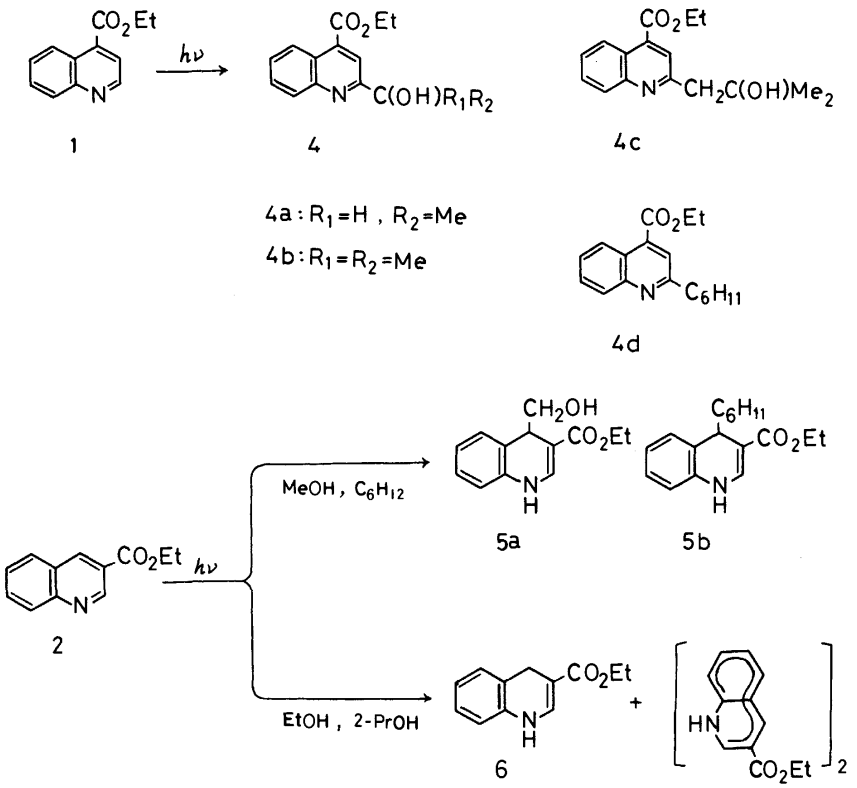
Cyclohexane	4	O_2	64	**4d**	56



320 nm which remarkably shifts from that of **2** (UV-(MeOH)λ_{max} 286 nm). The types of those products were, however, different depending on the nature of the solvent used. That is, irradiation in methanol and cyclohexane gave the solvent addition products, ethyl 4-hydroxymethyl-1,4-dihydro-3-quinolinecarboxylate (**5a**) and ethyl 4-cyclohexyl-1,4-dihydro-3-quinolinecarboxylate (**5b**) as only one major product, respectively. The structures were determined on the basis of NMR, IR, and MS spectra. NMR proved that the addition of the solvent occurred at the 4-position but not the 2-position. IR showed absorption by NH stretching at about 3340 cm^{-1} and a strong peak due to a CO group at 1650 cm^{-1}. On the other hand, irradiation in both ethanol and 2-propanol did not afford any solvent addition product, but instead lead to two unstable products which finally reverted to the starting material **2**. Both were especially labile in solution, for example, if the solutions after irradiation were allowed to stand 12 h at room temperature in dark, their UV spectra completely reverted to that of **2**. Therefore, the reaction solvent was evaporated under 30 °C immediately after irradiation, and the residue was subjected to separation on plate layer chromatography at 10 °C. As a result, two colorless solid products of mass 203 and 404 were isolated. Although both were unstable at room temperature, especially, the latter more rapidly changed to **2**, they were stable in a sealed tube, indicating that their lability was due to oxygen. The IR spectrum of the former showed absorption by NH stretching at 3340 cm^{-1} and a strong peak due to a CO group at 1640 cm^{-1}. In the NMR spectra taken in

	15	82	—	50	38

protons at the 4-position of the quinoline were observed. Thus, it was determined to be ethyl 1,4-dihydro-3-quinolinecarboxylate (**6**). The treatment of this product with $FeCl_3$ caused quantitative conversion to **2**, giving further proof for this structure. The latter product, which is insoluble in alcohols and chloroform, seems to have the structure akin to the dimeric compound of **6**, considering that its molecular weight was 404 and the IR spectrum was similar to that of **6**. Although the NMR spectrum (in DMSO-d_6) was complicated as shown in Fig. 1a, it seems similar to that of **6** in DMSO (Fig. 1b). Two broad peaks observed at δ 8.65 and 8.79 were confirmed to be due to the protons on the ring nitrogen by decoupling the protons at the 2-position which appeared as two doublets at δ 7.15 and 7.19, respectively. The relative intensity of the signals at δ 8.65 and 8.79 was 0.7 : 1, indicating that this consisted of a mixture of two dimers (0.7 : 1 ratio). The multiplet around δ 1.35 may show the overlap of two triplet signals arising from the methyl groups. A number of peaks around δ 3.9—4.15 corresponding to those of methylene protons are complicated by overlap by the signals of some impurities. At present, the assignment of these dimers was unsuccessful. Separation and purification could not be achieved. On irradiation in *t*-butyl alcohol an unidentified oily product of mass 275 was obtained, but formation of **6** and the dimers was not observed. Table 2 shows the product yields.

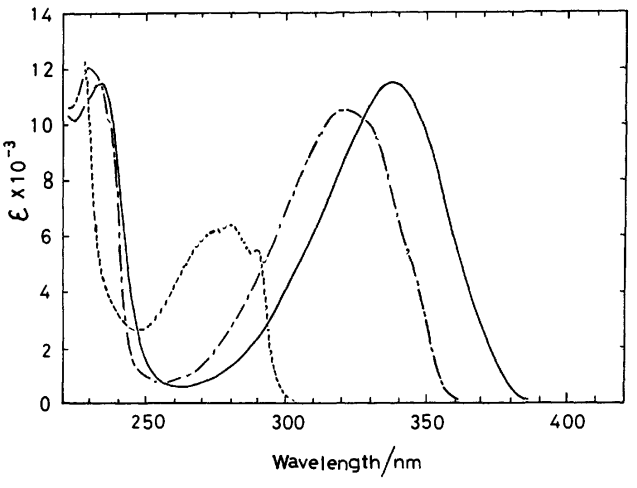

Fig. 2. UV spectra of **6** and **8** in methanol or cyclohexane. (——) **6** in methanol, (-·-·-) **6** in cyclohexane, and (----) **8** in methanol.

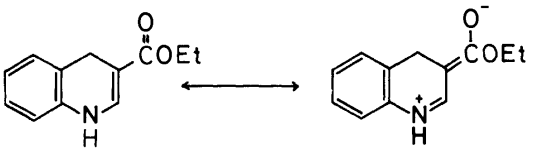
It is noteworthy that the UV spectra of the photoproducts arising from the ethyl 3-quinolinecarboxylate shifted to much longer wavelength than that expected from their structures. Figure 2 displayed the absorption spectra of **6** in methanol and cyclohexane together with that of ethyl 1,4-dihydro-2-quinolinecarboxylate (**8**) in methanol. Such a large bathochromic shift can be explained by a resonance contribution from a zwitterion structure. It is supported by the fact that the UV spectrum of **6** shifted to shorter wavelength in cyclohexane. That the IR absorption of the CO group appeared at a considerably lower frequency of 1650 cm^{-1} also supports the possibility of a contribution from an ionic structure.



Photochemistry of Ethyl 2-Quinolinecarboxylate (3). The irradiation of **3** in nitrogen lead to two low yield products ethyl 4-hydroxyalkyl-1,4-dihydro-2-quinolinecarboxylate (**7**) and ethyl 1,4-dihydro-2-quinolinecarboxylate (**8**) in ethanol and 2-propanol (Table 3), but the major product in *t*-butyl alcohol or cyclohexane was an intractable tar. The structures of **7** and **8** were determined in a similar manner with to **5** and **6**. The experiments in an atmosphere of oxygen were discontinued, because the reaction in oxygen was hard to achieve.

Triplet Quenching Experiment. In order to identify the reactive excited state of the photochemical reactions of those ethoxycarbonyl quinolines the triplet quenching experiment was carried out for **1** and **2**. The experiment for **3** was excluded because of too low yield of the products. From the phosphorescence spectra measured in ethanol and methylcyclohexane at 77 K the triplet excitation energy (E_T) of **1** was estimated to be 244.1 kJ mol^{-1} in both solutions. E_T for **2** were

a) Nitrogen gas was passed through an aqueous basic solution of pyrogallol.

259.4 kJ mol^{-1} in ethanol and 258.1 kJ mol^{-1} in methylcyclohexane, respectively. As a triplet quencher 1,3-cyclohexadiene (E_T=219 kJ mol^{-1}) could be used for **1** and 1,3-pentadiene (E_T=240.6 kJ mol^{-1}) for **2**. The relatively long phosphorescence lifetimes of 0.9 s for **1** and 0.46 s for **2** in ethanol indicated that the lowest triplet excited states were of π,π^* configuration. The lifetimes could not be estimated in methylcyclohexane because of the very weak phosphorescence intensity. The fluorescence was observed in ethanol for both quinolines but was not clear in methylcyclohexane, suggesting that the singlet n,π^* and π,π^* states lies closely to each other as in the case of 2-quinolinecarbonitrile.[1b)]

Table 4 shows the quantum yields of the disappearance of **1** (Φ_d) and the formation of **4** (Φ_f) on irradiation in 2-propanol or cyclohexane under various conditions. Both the quantum yields Φ_d and Φ_f were independent of the concentration of 1,3-cyclohexadiene, indicating that the S_1 state was responsible for the reaction of **1**. It is noted that Φ_f under an oxygen atmosphere was greater than the value in nitrogen. This means that oxygen plays an important part in the formation of **4b**. In practice, Φ_f was only less than 0.004 in the 2-propanol purged by nitrogen gas from which oxygen was removed more completely through a potassium hydroxide solution of pyrogallol. The quantum yields for the photochemical reaction of **2** were carried out in methanol and cyclohexane using 1,3-pentadiene as a triplet quencher. As shown in Fig. 3, the triplet quencher had no influence on the reaction. We could not take the measurement of the quantum yields in ethanol and 2-propanol because **6** and the dimers obtained in those solution easily changed to the starting material **2** during the isolation procedure.

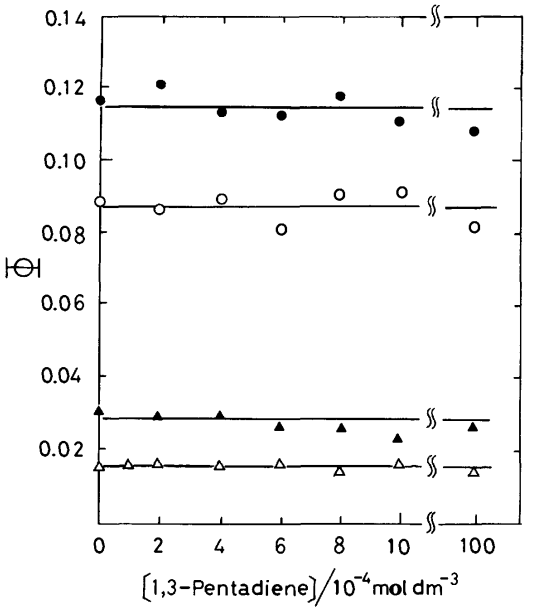

Fig. 3. Effect of triplet quencher on quantum yields of photochemical reactions of **2**. [**2**]=0.002 mol dm^{-3}. —○—: Formation of **5a**, —●—: disappearance of **2** in methanol, —△—: formation of **5b**, —▲—: disappearance of **2** in cyclohexane.

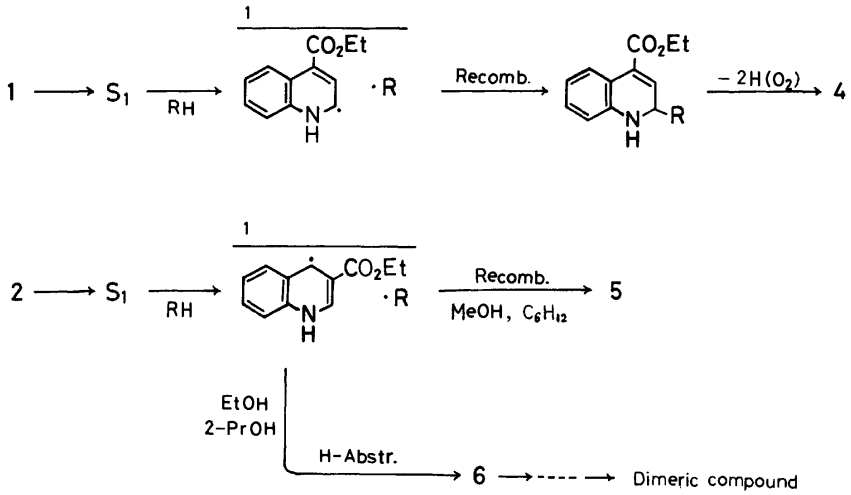
Reaction Mechanism. The photochemistry of **1** could be explained in terms of the mechanism as shown in Scheme 1. Hydrogen abstraction from the solvent by the ring nitrogen in the S_1 state forms a radical pair which combines to give 1,2-dihydroquinoline derivatives expected as a precursor of **4**. Its conversion to **4** may be caused by oxidation but not via disproportionation, considering that Φ_f of **4b** become extremely low in the nitrogen gas including almost no oxygen (Table 4). Although we tried to isolate the precursor from the reaction mixture obtained on irradiation in nitrogen, the attempt failed because of its



Scheme 1.

lability. Such 1,2-dihydroquinolines are known to be unstable.[4] The initial step of the photochemical reaction of **2** may also be hydrogen abstraction by the ring nitrogen from the solvent in the S_1 state. Considering that this reaction was not affected by 1,3-pentadiene in both high polar methanol and less polar cyclohexane, the photochemical reaction of **2** in ethanol and 2-propanol leading to the formation of **6** is thought to occur also in the S_1 state. Apparently, the solvent dependency of the photoproducts of **2** could be ascribed to the hydrogen-donating efficiency of the solvent used. The reaction mechanism is summarized in Scheme 1. In methanol or cyclohexane the formed radical pair recombines as the case of **1** to give **5**, while in ethanol or 2-propanol being a good hydrogen-donor solvent the semi-reduced radical of **2** may carry out further hydrogen abstraction from the solvent to afford **6** before undertaking recombination. The formation of the dimer types would be expected as follows, considering the results that the yields of **6** and the dimers varied remarkably depending on irradiation time as shown in Table 2, and also that the latter products were not formed in methanol, cyclohexane and *t*-butyl alcohol; **6** (QH_2) excited by light absorption donates a hydrogen atom to **2** (Q) to generate two semi-reduced radicals (2·QH), whose recombination yields the dimeric compounds Q_2H_2.

$$QH_2 \xrightarrow{h\nu} QH_2^*$$

$$QH_2^* + Q \longrightarrow 2\cdot QH$$

$$2\cdot QH \longrightarrow Q_2H_2$$

We tried the irradiation of QH_2 in the ethanol solution in the presence of Q under a nitrogen atmosphere with 366 nm light which could be absorbed only by the former. As a result, QH_2 disappeared rapidly, but the product found in the reaction solution after irradiation was only Q. Perhaps, the formed Q_2H_2 is thought to have reverted to Q by reabsorbing 366 nm light. Actually, the irradiation of Q_2H_2 by 366 nm light in the absence of Q induced its rapid conversion to Q, although the mechanism of the conversion was now ambiguous. Anyway, the photochemical reaction of **2** in ethanol or 2-propanol may shuttle between the starting material **2** and the products.

The photochemical reaction of **3** may be thought to be essentially similar to that of **2**. The simultaneous formation of **7** and **8** shows that the recombination of the radical pair and the hydrogen abstraction by the semi-reduced radical of **3** from the solvent occurs competitively.

Experimental

The NMR spectra were measured on a JEOL GX-270 with TMS as an internal standard. The mass spectra were obtained by a Hitachi RMU-6M, a JEOL JMS-DX303, or a Shimadzu GCMS-9020DF machines. The IR spectra were taken on a JASCO-302. For the measurement of fluorescence and phosphorescence spectra a Hitachi MPF-2A was used, and UV spectra were recorded with a Shimadzu UV-220.

Materials. The solvents used in the irradiation experiments were reagent grade obtained from Wako Pure Chemical Industry. Methanol, ethanol, and *t*-butyl alcohol were used without purification but 2-propanol and cyclohexane were purified by distillation and silica-gel chromatography, respectively. 1,3-Cyclohexadiene and 1,3-pentadiene (Tokyo Kasei Kogyo) were used after distillation. Ethoxycarbonyl quinolines **1**, **2**, and **3** were synthesized by adding trimethylamine and ethanol to the chloroform solution including the corresponding quinolinecarboxylic acids treated with $SOCl_2$.[5] Those carboxylic acids were obtained from the basic hydrolysis of quinolinecarbonitriles. 2-Quinolinecarbonitrile of those was synthesized by a Reisert reaction of quinoline *N*-oxide,[6] but 3-and 4-quinolinecarbonitriles were prepared by heating the corresponding bromoquinoline with copper (I) cyanide.[7] 3-Bromoquinoline was reagent grade from Tokyo Kasei Kogyo and 4-bromoquinoline was synthesized by treatment with phosphorus trichloride of 4-bromoquinoline *N*-oxide obtained by refluxing 4-nitroquinoline *N*-oxide in hydrobromic acid.[8]

Colorless liquid, bp 120 °C/1 mmHg (1 mmHg=133.32 Pa); IR (neat) 3050, 2990, 2910, 1725 (CO), 1585, 1250, 1150 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.49 (3H, t, J=7.25 Hz, $CH_2C\underline{H}_3$), 4.53 (2H, q, J=7.25 Hz, $C\underline{H}_2CH_3$), 7.63—7.81 (2H, m, H-6 and 7), 7.90 (1H, d, J=4.43 Hz, H-3), 8.18 (1H, d, J=8.46 Hz), 8.77 (1H, d, J=8.46 Hz), 9.02 (1H, d, J=4.43 Hz, H-2); MS m/z 201 (M^+).

Ethyl 3-Quinolinecarboxylate (2). Mp 68 °C (from hexane-ethanol); IR (KBr) 3050, 2990, 2930, 1710 (CO), 1570, 1240, 1130 cm^{-1}; ^1H NMR($CDCl_3$) δ=1.47 (3H, t, J=7.25 Hz, $CH_2C\underline{H}_3$), 4.49 (2H, q, J=7.25 Hz, $C\underline{H}_2CH_3$), 7.63—7.81 (2H, m, H-6 and 7), 7.94 (1H, d, J=8.24 Hz), 8.17 (1H, d, J=8.25 Hz), 8.85 (1H, s, H-4), 9.46 (1H, s, H-2); MS m/z 201 (M^+).

Ethyl 2-Quinolinecarboxylate (3). Colorless liquid, bp 140 °C/1 mmHg; IR (KBr) 3050, 2980, 2930, 1705 (CO), 1590, 1245, 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.50 (3H, t, J=7.25 Hz, $CH_2C\underline{H}_3$), 4.57 (2H, q, J=7.25 Hz, $C\underline{H}_2CH_3$), 7.64—7.79 (2H, m, H-6 and 7), 7.88 (1H, d, J=8.25 Hz), 8.19, 8.30 (2H, AB, q, J=8.58 Hz, H-3 and 4), 8.32 (1H, d, J=8.24 Hz); MS m/z 201 (M^+).

Photochemical Reactions of 1 and 3. **1** or **3** (100 mg) dissolved in 70 cm^3 of alcohol (EtOH, 2-propanol, or *t*-BuOH) or cyclohexane was irradiated in a Pyrex vessel with a 100 W high pressure immersion mercury lamp (Riko Kagaku Sangyo Co.) under nitrogen or oxygen. After the evaporation of the reaction solvent, the residue was developed on thin-layer chromatography of Kieselgel (PF_{254}, Merck) with a mixture of chloroform and diethyl ether to isolate the starting material and the products.

Photochemical Reaction of 2. A solution of **2** (50 mg) in 70 cm^3 of alcohol or cyclohexane was irradiated in nitrogen with the same setup. The isolation of the reaction mixture on irradiation in methanol and cyclohexane was carried out by a method similar to the former two cases. However, the photoproducts **6** and dimeric compounds in ethanol and 2-propanol were labile, the latter especially was easily decomposed to the starting material **2**. Therefore, the evaporation of the reaction solvent was done below 30 °C and the development on thin-layerchromatography was undertaken at 10 °C, using chloroform and ethanol (20 : 1 V/V). Still, the dimeric compounds are thought partly to have reverted to **2** during the isolation procedure.

Ethyl 2-(1-Hydroxyethyl)-4-quinolinecarboxylate (4a). Colorless liquid (it gradually decomposed at room temperature); IR (neat) 3400 (OH), 3070, 2990, 2940, 1715 (CO), 1600, 1510, 1240, 1150 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.51 (3H, t, J=7.25 Hz, $CH_2C\underline{H}_3$), 1.64 (3H, d, J=6.43 Hz, CH (OH)$C\underline{H}_3$), 4.55 (2H, q, J=7.25 Hz, $C\underline{H}_2CH_3$), 4.75 (1H, s, OH), 5.12 (1H, q, J=6.43 Hz, $C\underline{H}$(OH)CH_3), 7.67—7.80 (2H, m, H-6 and 7), 7.88 (1H, s, H-3), 8.16 (1H, d, J=8.91 Hz), 8.75 (1H, d, J=8.91 Hz); Found: m/z 245.1049. Calcd for $C_{14}H_{15}NO_3$: M, 245.1052.

Ethyl 2-(1-Hydroxy-1-methylethyl)-4-quinolinecarboxylate (4b). Mp 72 °C (from hexane); IR (KBr) 3250 (OH), 3050, 2980, 2920, 1720 (CO), 1590, 1505, 1240, 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.50 (3H, t, J=7.10 Hz, $CH_2C\underline{H}_3$), 1.65 (6H, d, J=5.28 Hz, $(CH_3)_2$), 4.54 (2H, q, J=7.10 Hz, $C\underline{H}_2CH_3$), 5.53 (1H, s, OH), 7.64—7.77 (2H, m, H-6 and 7), 7.95 (1H, s, H-3), 8.14 (2H, d, J=8.57 Hz), 8.70 (1H, d, J=8.24 Hz); MS m/z 259 (M^+); Found: C, 69.41; H, 6.60; N, 5.35%. Calcd for $C_{15}H_{17}NO_3$: C, 69.49; H, 6.61; N, 5.40%.

Ethyl 2-(2-Hydroxy-2-methylpropyl)-4-quinolinecarboxylate (4c). Colorless liquid, picrate 172 °C (decomp); IR (neat) 3380 (OH), 3050, 2990, 2920, 1720 (CO), 1590, 1510, 1240, 1145 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.31 (6H, s, C(OH)($C\underline{H}_3$)$_2$), 1.48 (3H, t, J=7.23 Hz, $CH_2C\underline{H}_3$), 3.16 (2H, s, C(OH)$C\underline{H}_2$), 4.52 (2H, q, J=7.23 Hz, $C\underline{H}_2CH_3$), 5.71 (1H, s, OH), 7.73—7.79 (3H, m, H-3, 6, and 7), 8.09 (1H, d, J=8.14 Hz), 8.70 (1H, d, J=8.58 Hz); MS m/z 273 (M^+); Found (for picrate): C, 52.51; H, 4.37; N, 11.10%. Calcd for $C_{22}H_{22}N_4O_{10}$: C, 52.59; H, 4.41; N, 11.15%.

Ethyl 2-Cyclohexyl-4-quinolinecarboxylate (4d). Colorless liquid, picrate 156—158 °C; IR (neat) 3070, 2990, 2930, 1720 (CO), 1595, 1240, 1150 cm^{-1}; ^1H NMR δ=1.37—2.07 (10H, m, cyclohexyl), 1.49 (3H, t, J=7.09 Hz, $CH_2C\underline{H}_3$), 2.96 (1H, tt, J=11.9 , 3.5 Hz, H'-1), 4.52 (2H, q, J=7.09 Hz, $C\underline{H}_2CH_3$), 7.54—7.75 (2H, m, H-6 and 7), 7.81 (1H, s, H-3), 8.10 (1H, d, J=8.57 Hz), 8.66 (1H, d, J=8.57 Hz); MS m/z 283 (M^+); Found (for picrate): C, 56.20; H, 4.72; N, 10.87%. Calcd for $C_{24}H_{24}N_4O_9$: C, 56.25; H, 4.72; N, 10.93%.

Ethyl 4-Hydroxymethyl-1,4-dihydro-3-quinolinecarboxylate (5a). Unstable colorless liquid (it easily released H_2O); UV (CH_3OH) λ_{max} 330 nm (ε 11600); IR (neat) 3400 (br, OH and NH), 3110, 2960, 2930, 1680 (CO), 1585, 1490, 1235, 1190 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30 (3H, t, J=7.25 Hz, $CH_2C\underline{H}_3$), 3.67 (2H, d, J=5.28 Hz, $C\underline{H}_2OH$), 4.10 (1H, t, J=5.28 Hz, H-4), 4.25 (2H, q, J=7.25 Hz, $C\underline{H}_2CH_3$), 6.32 (1H, s, NH), 6.71—7.21 (4H, m, ArH), 7.55 (1H, d, J=6.72 Hz, H-2); MS m/z 233 (M^+); Found after loss of H_2O(M^+−18): m/z 215.0931. Calcd for $C_{13}H_{11}NO_2$: M, 215.0946.

Ethyl 4-Cyclohexyl-1,4-dihydro-3-quinolinecarboxylate (5b). Mp 149—150 °C (from hexane-ethanol); UV (CH_3OH) λ_{max} 327 nm (ε 11500); IR (KBr) 3290 (NH), 3100, 3030, 2990, 2920, 1650 (CO), 1635, 1585, 1490, 1238, 1160 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.60—1.60 (11H, m, cyclohexyl), 1.30 (3H, t, J=7.26 Hz, $CH_2C\underline{H}_3$), 3.82 (1H, d, J=4.19 Hz, H-4), 4.15—4.25 (2H, m, $C\underline{H}_2CH_3$), 6.15 (1H, s, NH), 6.68—7.14 (4H, m, ArH), 7.55 (1H, d, J=5.94 Hz, H-2); MS m/z 285 (M^+); Found: C, 75.72; H, 8.13; N, 4.82%. Calcd for $C_{18}H_{23}NO_2$: C, 75.76; H, 8.12; N, 4.91%

Ethyl 1,4-Dihydro-3-quinolinecarboxylate (6). Mp 139 °C (it changed gradually to **2** at room temperature); UV (CH_3OH) λ_{max} 338 nm (ε 11500); IR (KBr) 3280 (NH), 3100, 2980, 2930, 1640 (CO), 1590, 1495, 1250, 1120 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.29 (3H, t, J=7.04 Hz, $CH_2C\underline{H}_3$), 3.76 (2H, s, H-4), 4.20 (2H, q, J=7.04 Hz, $C\underline{H}_2CH_3$), 6.00 (1H, s, NH), 6.57—7.04 (4H, m, ArH), 7.32 (1H, d, J=5.61 Hz, H-2); Found: m/z 203.0931. Calcd for $C_{13}H_{13}NO_2$: M, 203.0947.

Dimeric Compound. From inspection of the NMR spectrum of Fig. 1a it consisted of two dimers (1 : 0.7 ratio) which melted ranging from 176 to 182 °C, and finally to reverted to **2**. UV (CH_3OH) λ_{max} 336 nm; IR (KBr) 3300 (NH), 3100, 3040, 2990, 2910, 1660 (CO), 1630, 1590, 1495, 1240, 1120 cm^{-1}; MS m/z 404 (M^+).

Ethyl 4-(1-Hydroxyethyl)-1,4-dihydro-2-quinolinecarboxylate (7a). Mp 88.5 °C (from hexane-benzene); IR (KBr) 3450 (NH), 3220 (OH), 3050, 2970, 2920, 1708 (CO), 1620, 1450, 1225, 1165 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.23 (3H, t, J=7.20 Hz, $CH_2C\underline{H}_3$), 1.55 (3H, d, J=6.92 Hz, CH(OH)$C\underline{H}_3$), 3.80 (1H, s, H-4), 4.16 (2H, q, J=7.20 Hz, $C\underline{H}_2CH_3$), 5.20 (1H, q, J=6.92 Hz, $C\underline{H}$(OH)CH_3), 7.11—7.80 (5H, m, ArH and H-3), 8.79 (1H, s, NH); MS m/z 247 (M^+); Found: C, 67.87; H, 6.89; N, 5.66%. Calcd for $C_{14}H_{17}NO_3$: C, 67.99; H, 6.93, N, 5.66%.

Ethyl 4-(1-Hydroxy-1-methylethyl)-1,4-dihydro-2-quinolinecarboxylate (7b). Colorless liquid, bp 130 °C/1 mmHg; IR (neat) 3500 (br, NH and OH), 3070, 2990, 2940, 1730 (CO),

1610, 1495, 1250, 1160 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.24 (3H, t, J=7.10 Hz, $CH_2C\underline{H}_3$), 1.29 (6H, d, J=6.26 Hz, $(CH_3)_2$), 3.71 (1H, s, H-4), 4.13 (2H, q, J=7.10 Hz, $C\underline{H}_2CH_3$), 7.07—7.56 (5H, m, ArH and H-3), 8.45 (1H, s, NH); Found: m/z 261.1330. Calcd for $C_{15}H_{19}NO_3$: M, 261.1365.

Ethyl 1,4-Dihydro-2-quinolinecarboxylate (8). Colorless liquid, bp 130 °C/1 mmHg; IR (neat) 3500 (NH), 3070, 2990, 2940, 1730 (CO), 1610, 1495, 1250, 1160 cm^{-1}; ^1H NMR($CDCl_3$) δ=1.26 (3H, q, J=7.12 Hz, $CH_2C\underline{H}_3$), 3.80 (2H, s, H-4), 4.17 (2H, q, J=7.12 Hz, $C\underline{H}_2CH_3$), 7.11—7.25 (3H, m, H-3, 6, and 7), 7.36 (1H, d, J=8.24 Hz), 7.63 (1H, d, J=7.19 Hz), 8.10 (1H, s, NH); Found: m/z 203.0948. Calcd for $C_{12}H_{13}NO_2$: M, 203.0947.

Quantum yields were determined by irradiating a sample solution (2×10^{-3} mol dm^{-3}) in a quartz cylindrical cell (5-cm in diameter and 1-cm in length) with 313 nm-light from a USH-500D lamp. The 313-nm line was isolated by a combination of a $NiSO_4$ solution with a UV-31 filter. The light intensity was determined by means of a potassium trioxalatoferrate(III) actinometer. The amounts of the products and consumed starting material **1** and **2** were spectrometrically measured after the separation on a silica-gel chromatograph using the mixture of chloroform and diethyl ether.

The Photocycloaddition of *N*-Vinylcarbazole with 3-Cyanostyrene

Akira TSUCHIDA, Masahide YAMAMOTO,* and Yasunori NISHIJIMA
Department of Polymer Chemistry, Faculty of Engineering, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606
(Received January 21, 1987)

The photocycloaddition reaction of *N*-vinylcarbazole (VCZ) as an electron donor, with 3-cyanostyrene as an electron acceptor, was studied. In nonpolar solvents, two cyclobutanes of *cis*-1-(9-carbazolyl)-2-(3-cyanophenyl)-cyclobutane and *trans*-1-(9-carbazolyl)-2-(3-cyanophenyl)cyclobutane (in a ratio of 3 : 1) were obtained from an exciplex intermediate. The structure of cis cyclobutane seemed to originate from a sandwich conformation of the exciplex. In polar solvents, a photodissociation to free ion radicals was observed and *trans*-1,2-di(9-carbazolyl)cyclobutane was produced efficiently by means of a chain mechanism via a cation radical of VCZ. Transient intermediates were measured by means of nanosecond laser photolysis; the results supported the reaction scheme.

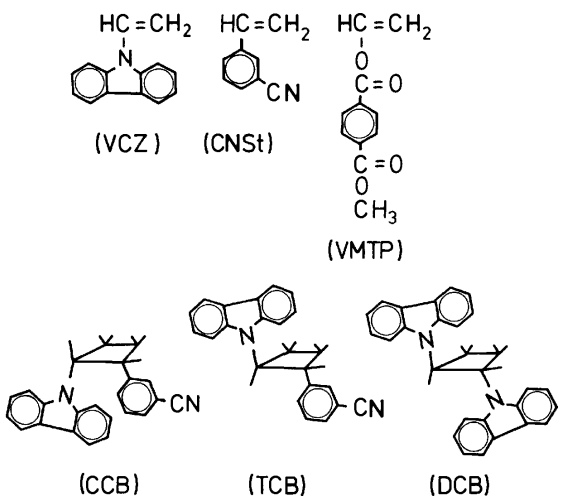
Previously, we reported on the photocycloaddition of 4-dimethylaminostyrene (DMASt) with 1-vinylpyrene (VP) and that with styrene (St).[1] In both systems, cyclobutanes were obtained as the main photoproducts in nonpolar solvents, and the stereochemistry of the cyclobutanes produced was explained by the reactivity of the exciplex intermediates. The long lifetime of the exciplex of DMASt with VP or the large pi system of VP allows a wide variety of conformations and leads to a trans-type cyclobutane, whereas in the reaction of DMASt with St, the short lifetime or the overlap of small pi rings limits the conformations of the exciplex and leads to a cis-type cyclobutane.

Here, we will report on the photocycloaddition reactions of *N*-vinylcarbazole (VCZ) with 3-cyanostyrene (CNSt). The photoirradiation of this system in nonpolar solvents gave mainly the cis-type cyclobutane, although an appreciable amount of trans-type cyclobutane formation was found simultaneously. From the results of the solvent effect on the photocycloaddition reaction and from the spectroscopic data, the reaction type of this VCZ-CNSt system is considered to be situated between those of the DMASt-VP and DMASt-St systems.

Experimental

Materials. *N*-Vinylcarbazole (VCZ, Tokyo Kasei Kogyo Co., Ltd.) was purified by recrystallization from ethanol and hexane. 3-Cyanostyrene (CNSt) was prepared from 3-cyanotoluene (Tokyo Kasei Kogyo Co., Ltd.),[2,3] and was purified by distillation under reduced pressure three times. Vinyl methyl terephthalate (VMTP) was synthesized by the ester-exchange reaction of vinyl acetate with the terephthalic acid monomethyl ester.

Benzene, diethyl ether, tetrahydrofuran (THF), methyl ethyl ketone (MEK), and acetone were dried and purified by distillation. *N*,*N*-Dimethylformamide (DMF) was dried and purified by distillation under reduced pressure. 2-Chlorobutane and 2-methyltetrahydrofuran (MTHF) for gamma-ray irradiation were dried by the use of molecular sieves and then distilled prior to use.



Photoreaction. A solution of VCZ (0.052 mol dm^{-3}) with CNSt (0.19 mol dm^{-3}) in benzene (2 ml) was degassed by repeated freeze-pump-thaw cycles in a Pyrex ampoule. The photoirradiation of the degassed ampoule was done by means of a 300-W high-pressure mercury lamp (Toshiba) fitted with a UV-33 filter (Toshiba) at 298 K: VCZ was selectively photoexcited in this system at 334 nm. After the evaporation of the benzene solvent, the photoproducts were analyzed by means of a gel-permeation chromatograph (Toyo Soda HLC-802UR) fitted with analytical columns eluting with THF. The quantity of products was determined by the use of a refractive index detector, where the refractive index for each compound was calibrated. The effect of thermal side reactions, which produced a small amount of a VCZ dimer or polymer in polar solvents, was corrected by the blank experiment in all cases.

The reaction quantum yield of cycloadducts was determined by using a degassed 1-cm quartz cell where the light intensity at 335 nm was found to be 1.77×10^{-9} E s^{-1} by actinometry.[4,5]

Identification of Cycloadducts. A degassed solution of VCZ (0.4 g) with CNSt (1.0 g) in benzene (40 ml) was photoirradiated for 14 h by means of a 300-W high-pressure mercury lamp fitted with a Pyrex glass filter at 298 K.[1,6] Products were injected into a recycle gel-permeation chromatograph (Toyo Soda HLC-802R) fitted with TSK-GEL-G2000HG6 and TSK-GEL-G2000HG8 columns, with chloroform as the eluent. Recycling for four times gave enough separation of cycloadducts: The cis cycloadduct (CCB) had a larger retention time than the trans cycloadduct (TCB). Recrystallization from hexane gave 79 mg of CCB and 25 mg of TCB. The configuration of the two cycloadducts was determined by NMR (JOEL JNM-FX90Q) on the basis of the chemical shifts.[1,6,7] The positions of the pro-

tons were determined by means of ^1H homonuclear decoupling or selective proton decoupling ^{13}C NMR measurements.

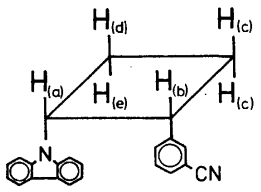
Spectroscopic Measurements. All measurements of the absorption and emission spectra and of the lifetime were made on the samples in a degassed 1-cm quartz cell at 298 K. The absorption spectra were measured by means of a UV-200S (Shimadzu) spectrophotometer. The emission spectra were obtained by the use of an RF-501 (Shimadzu) spectrofluorophotometer. The emission quantum yield was determined relative to that of quinine sulfate in sulfuric acid.[8] The lifetime of the emission was measured by the single-photon counting method (PRA, Inc.).

The transient absorption was obtained by the use of a nanosecond ruby laser photolysis apparatus which has been described elsewhere.[9] The exciting 347-nm light pulse had a pulse energy of 10 mJ and a pulse duration of 14 ns.

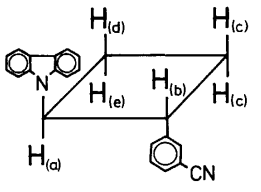
The reference spectra of VCZ^+ and $CNSt^-$ were measured by means of gamma-ray irradiation at 77 K in 2-chlorobutane and MTHF respectively.[10]

Results and Discussion

Emission Analysis. The fluorescence of VCZ (emission lifetime=10.4 ns in a benzene solvent) was quenched by the addition of CNSt in the degassed solvents. The rate constants of fluorescence quenching (k_q) were determined, by means of the Stern-Volmer plots at 298 K, to be 3.1×10^8 and 2.9×10^9 $M^{-1}s^{-1}$ in nonpolar benzene and polar *N,N*-dimethylformamide (DMF) solvents respectively; the value of k_q in benzene is rather small when it is compared with a diffusion-controlled rate constant (ca. 1×10^{10} $M^{-1}s^{-1}$ in benzene). This fluorescence quenching is considered to occur via an electron-transfer reaction from $^1VCZ^*$ to CNSt; energy-transfer quenching can be excluded by considering their energy levels. In this case, the free energy change of electron-transfer quenching is estimated by Weller's equation[11] to be ca. 5 kcal mol^{-1} exothermic.



(CCB)



(TCB)

A weak and structureless emission was observed at around 470 nm in a nonpolar benzene solvent when the VCZ fluorescence was quenched by CNSt; the quantum yield of this new emission was ca. 0.01, and the lifetime was 10.7 ns, under these experimental conditions. This new emission is ascribed to the exciplex emission as it disappears in polar solvents, where photodissociation to free-ion radicals competes with exciplex formation from a transient ionic complex.[12]

Photoproduct Formation. The selective photoexcitation (Hg lamp, UV-33 filter) of VCZ (0.052 mol dm^{-3}) in the presence of CNSt (0.19 mol dm^{-3}) in a degassed benzene solvent produced two cyclobutanes: *cis*-1-(9-carbazolyl)-2-(3-cyanophenyl)cyclobutane (CCB) and *trans*-1-(9-carbazolyl)-2-(3-cyanophenyl)cyclobutane (TCB). The quantum yields of the cyclobutane formation were determined by actinometry to be 0.28 and 0.10 for CCB and TCB respectively under the complete quenching of $^1VCZ^*$ by CNSt. In this system, the yield of the cis-type cyclobutane formation was three times larger than that of the trans-type, and the other side reactions gave only a small yield of the by-products. A small amount of a polymer was also produced by photoirradiation, but the initiating species of the polymer was negligible, judging from the estimate based on the molecular weight of the polymer (ca. 10^4). As a control, the following experiments were carried out: the photoirradiation of VCZ (0.052 mol dm^{-3}) in the absence of CNSt in benzene produced the polymer and a very small amount of *trans*-1,2-di(9-carbazolyl)cyclobutane (DCB), while the photoirradiation of CNSt (0.19 mol dm^{-3}), which has no light absorption at 334 nm, in the absence of VCZ produced no photoproduct. The thermal reaction produced only a small amount of a copolymer, the contribution of which was corrected for in all experiments.

Figure 1 shows the time-conversion plots of the photoproducts. Here, the yield of the photoproducts was calculated on the basis of the total amount of VCZ. The formation of CCB and TCB is proportional to the

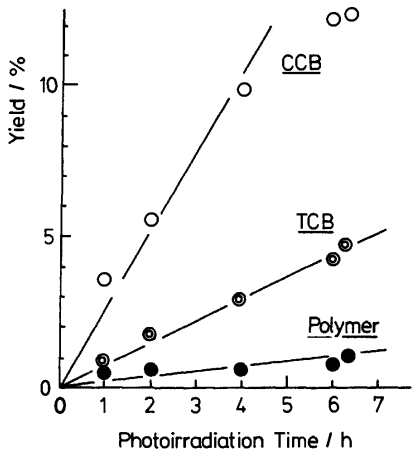


Fig. 1. Time-conversion plots of photoproducts. VCZ (0.052 mol dm^{-3}) was photoirradiated in the presence of CNSt (0.19 mol dm^{-3}) in benzene at 298 K.

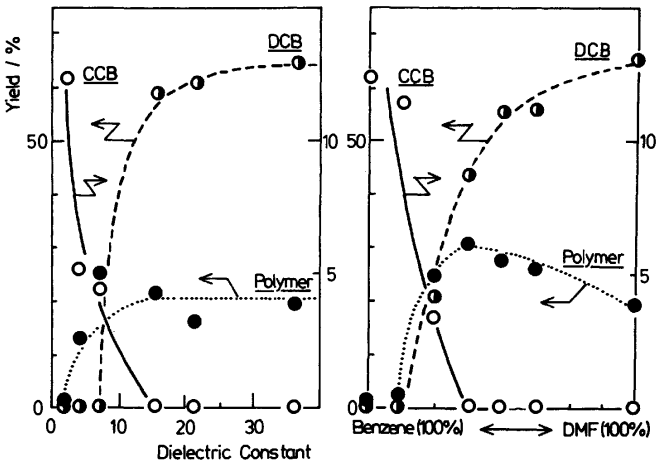

Fig. 2. Effects of solvent polarity on the distribution of photoproducts. Solvents used in the left figure were benzene, diethyl ether, tetrahydrofuran, methyl ethyl ketone, acetone, and *N*,*N*-dimethylformamide. A mixed solvent of benzene and *N*,*N*-dimethylformamide was used in the right figure. VCZ (0.052 mol dm^{-3}) was photoirradiated in the presence of CNSt (0.19 mol dm^{-3}) at 298 K for 320 min. The yield of TCB, which was not plotted in this figure, was ca. 1/3 of CCB in every solvent.

irradiation time, though the yield of CCB reaches the saturation point after a long irradiation time (>4 h). The effect of cis-trans isomerization on the photoproduct distribution is neglected, since the photoisomerization rates from CCB to TCB and from TCB to CCB were slow enough under these experimental conditions.

Solvent Effects. This photocycloaddition reaction of VCZ with CNSt was found to be greatly affected by the solvent polarity. In a polar DMF solvent, no CCB and TCB could be found; a large amount of the VCZ cyclobutane dimer (DCB) was produced instead of these cycloadducts. The photodimerization of VCZ in polar solvents was extensively studied by Ledwith,[13] who found that the dimerization proceeds by means of a chain mechanism via the cation radical of VCZ. In DMF, the participation of the chain mechanism is obvious, as the quantum yield of DCB formation was much larger than unity. The effect of solvent polarity on the photoreaction of VCZ with CNSt is demonstrated in Fig. 2. The left half of Fig. 2 shows the effect of the solvent polarity on the photoreaction in six different solvents, while the right half shows the results in mixed solvents of benzene and DMF. The results of these two experiments are in fairly good agreement. In nonpolar solvents, the cycloadditions are the main reactions, and the dimerization and polymerization are negligible. However, with an increase in the solvent polarity, the yield of the DCB by means of a chain mechanism increases greatly, and the cycloadduct formation is suppressed. This tendency is the same as that we reported previously.[1] In nonpolar solvents, photocycloaddition via an exciplex is dominant, while in polar solvents, the photodissociation of the exciplex to free-ion radicals becomes predominant, and the free-ion radicals so produced lead to product formation. In the photoreaction system of VCZ with CNSt in polar solvents, the dimerization occurs via an ion-radical intermediate, and the reaction is amplified by a chain mechanism.

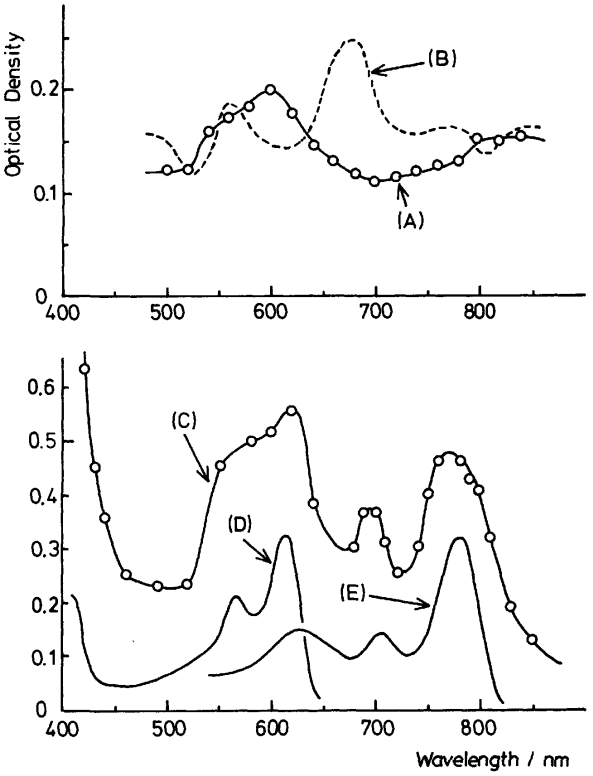

Fig. 3. Transient absorption spectra of VCZ (OD_{347}=1.2) with CNSt (1.1 mol dm^{-3}) measured by ns laser photolysis. Spectra were obtained in benzene at 20 ns (A) or in *N*,*N*-dimethylformamide at 50 ns (C) after excitation. Transient absorption spectrum of VCZ (B) without CNSt was obtained in benzene at 20 ns after excitation as a reference of the spectrum (A). Reference absorption spectra of ion radicals $CNSt^-$ (D) and VCZ^+ (E) were obtained by gamma-ray irradiation in rigid matrices at 77 K.

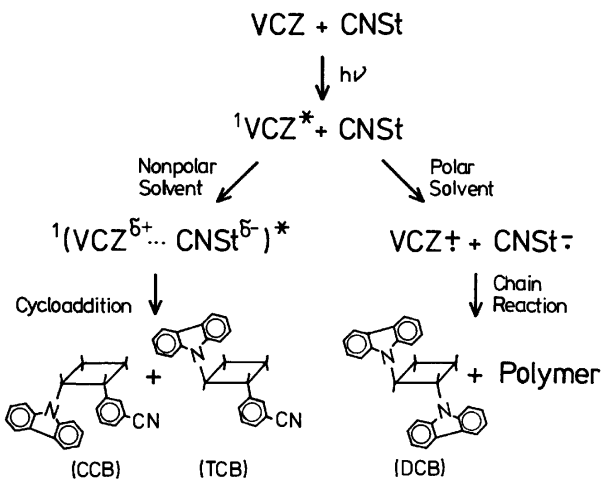
Transient Spectra. The transient species in this photoreaction were studied by means of ns ruby-laser-photolysis measurements. The upper half of Fig. 3 shows the transient absorption spectra obtained in benzene 20 ns after excitation at 298 K. The photoexcitation of VCZ in the presence of CNSt (1.1 mol dm^{-3}) by means of a laser pulse (347 nm, 14 ns) gave Spectrum (A). This absorption spectrum is different from the S-S absorption of VCZ which was obtained by the reference sample without CNSt and which is shown by Spectrum (B). The lifetime of the transient species of Spectrum (A) agreed well with that of the exciplex emission, and the absorption bands are broad. Therefore, this transient absorption is considered to originate from the exciplex of VCZ with CNSt. No transient absorption which has a longer lifetime could be found except that of ^{3}VCZ*. On the other hand, in DMF, the formation of free-ion radicals was observed, as is shown in the lower half of Fig. 3. Spectrum (C) was obtained by the photoexcitation of VCZ with CNSt in DMF. The transient species found in this spectrum are ascribed to $CNSt^{\cdot-}$ and $VCZ^{\cdot+}$ by reference to the (D) and (E) absorption spectra. The lifetimes of these ion radicals were longer than a micro second, and these ion radicals are considered to be solvated free-ion radicals. The free $VCZ^{\cdot+}$ leads to DCB formation by means of a chain reaction.

The Reaction Mechanism. The scheme summarizes the photochemical reaction mechanism. In nonpolar solvents, two cycloadducts, CCB and TCB, are produced by the photoirradiation of VCZ with CNSt. Three times as much of the cis-type cyclobutane (CCB) is obtained as the trans-type cyclobutane (TCB). In a previous report,[1] we discussed the relationship between the reactivity of the exciplex intermediates and the stereochemistry of the cycloadduct products. The pair of 4-dimethylaminostyrene (DMASt) and 1-vinylpyrene (VP) gave an emissive exciplex whose lifetime was 55 ns in benzene. The long lifetime or the large pi ring of VP allows for a wide variety of exciplex conformations, which in turn leads to a trans-type cyclobutane formation. On the other hand, the photoreaction of DMASt with styrene (St) produces cis-type cyclobutane by means of the short lifetime or the small overlap of pi rings in the exciplex intermediate. Hence, the conformational distribution of the exciplex intermediate was concluded to allow the formation of trans-type cyclobutane. In the present study of the VCZ-CNSt system, the cis-type cyclobutane, which reflects the sandwich structure of the exciplex intermediate, was the main product, but an appreciable amount of the trans-type cyclobutane was also obtained simultaneously. The exciplex lifetime of this system is rather short (10.7 ns), and the pi ring of carbazole is not as large as that of pyrene. The reactivity of this exciplex is considered to be situated between those of the DMASt-VP and DMASt-St systems. On the other hand, in polar solvents, the photodissociation of the exciplex to $VCZ^{\cdot+}$ and $CNSt^{\cdot-}$ becomes a dominant reaction process, and DCB is mainly produced by a chain mechanism of VCZ via $VCZ^{\cdot+}$ as the intermediate; the chain reaction via $VCZ^{\cdot+}$ amplifies the reaction yield. The anion radical of CNSt is considered to be neutralized by the recombination with $VCZ^{\cdot+}$ or $DCB^{\cdot+}$. Hence, the reactivities of the ion radical and exciplex can be clearly distinguished.[14-21]



Scheme

To understand the reactivity of the cycloaddition reactions via the exciplex, the VCZ-VMTP system was also examined. The diffusion-controlled quenching of ^{1}VCZ* by VMTP in benzene produced an emissive exciplex (lifetime=49 ns). The free-energy change of the electron transfer from VCZ to VMTP is estimated to be 14-kcal mol^{-1} exothermic by the use of Weller's equation.[11] The photoirradiation of this system, however, produced only a polymer with a very small amount of DCB; no cyclobutane formation between VCZ and VMTP could be detected. It seems that the cyclobutane formation between two vinyl groups of aromatic vinyl monomers requires the pi conjugation of the vinyl group to the aromatic ring in the exciplex state.

Conclusion

The photoexcitation of VCZ with CNSt in nonpolar solvents produced two cycloadducts of CCB and TCB via an exciplex intermediate. In this system, the yield of cis cyclobutane CCB was three times higher than that of the trans-type TCB. The structure of CCB originated from the sandwich conformation of the exciplex. The formation of trans cyclobutane TCB is considered to be due to the looseness of the exciplex conformation. In polar solvents, the photodissociation of the exciplex to free $VCZ^{\cdot+}$ and $CNSt^{\cdot-}$ occurred. The $VCZ^{\cdot+}$ thus produced gave DCB efficiently by means of a chain mechanism, and the products of the exciplex reaction and the ion radical reaction were clearly differentiated.

We wish to thank Professor Hitoshi Yamaoka of the

Research Reactor Institute, Kyoto University, for his help in determining the reference absorption spectra of the ion radicals. This work was partially supported by a Grant-in-Aid for Energy Research (No. 60045061) from the Ministry of Education, Science and Culture.

Liquid Crystalline Compounds Bearing Pyridine Ring: Azoxy Compounds with Alkyl Substituents

Hiroyoshi KAMOGAWA,* Tsuneharu KASAI, Toshio ANDOH, and Tomoyuki NAKAMURA
Department of Applied Chemistry, Yamanashi University, Kofu 400
(Received February 9, 1987)

Azoxy compounds bearing a 2,5-disubstituted pyridine ring as a principal constituent and at least one alkyl group at a molecular end were synthesized and their mesomorphic (nematic) ranges were examined. As for azoxy compounds containing an alkyl and an alkoxy group at both ends, respectively, mesomorphic ranges appeared with lower alkyl groups than those for azo compounds, their precursors. The ranges were also lower than those with both alkoxy ends. As regards an azoxy compound containing alkyl groups at both ends, no mesomorphic phenomenon appeared within the scope of this study.

Relatively few studies have been reported on liquid crystalline compounds bearing a pyridine ring as a principal constituent. A couple of studies on liquid crystalline Schiff bases[1,2] and phenylpyridines[3] can be found in the literature and we have reported 3-(4-alkoxyphenylazoxy)-6-alkoxypyridines as a novel liquid crystal series.[4] The replacement of the benzene ring by the pyridine, which exerts a sideward dipole moment, appears to profoundly affect the mesomorphic property of a compound.

In this study, we wish to report on the synthesis and the liquid-crystalline properties of azoxypyridines containing at least one terminal alkyl group in comparison with the known compounds containing only benzene rings, as well as the results of the previous study.[4]

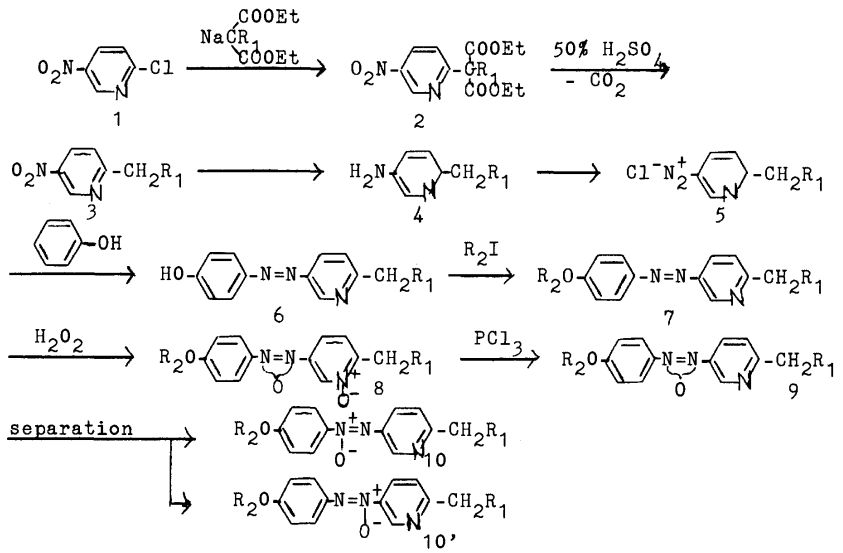
Two synthetic sequences (indicated in Schemes 1 and 2) were adopted.

Where R_1=CH_3, C_2H_5; R_2=CH_3, C_2H_5, n-C_6H_{13}; R_3=CH_3, n-C_4H_9.

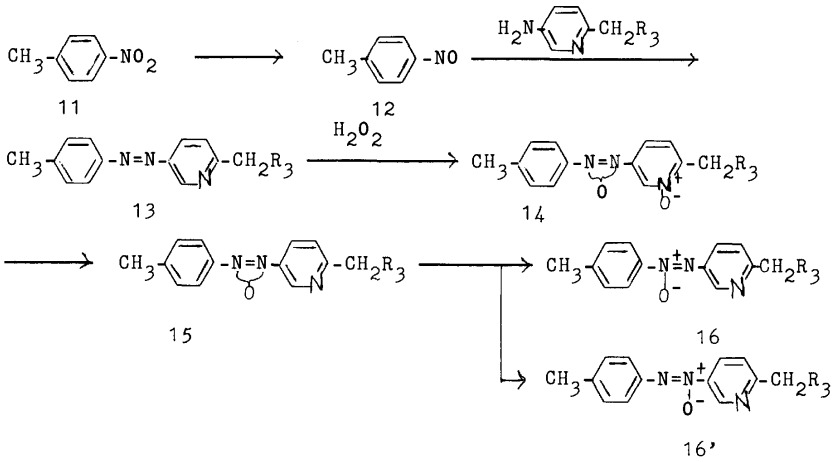
The mesomorphic behaviors of azoxy compounds **9**, **10**, **10′** and **15**, **16**, **16′** as well as those of azo compounds **7** and **13** were investigated.

Results and Discussion

2-[1,1-Bis(ethoxycarbonyl)alkyl]-5-nitropyridines (**2**) were prepared in a conventional manner by replacing the activated chlorine atom of 2-chloro-5-nitropyridine (**1**) with the carbanion from diethyl alkylmalonate prepared with sodium metal in xylene in 45—70% yields. The hydrolysis and subsequent decarboxylation of **2** with sulfuric acid were carried out according to Champa[2] to give 2-alkyl-5-nitropyridine (**3**) in 40—73% yield. A reduction of nitro to amino groups with cyclohexene in the presence of Pd-C (5%) proceeded quantitatively to afford 2-alkyl-5-amino-pyridines (**4**). A diazotization of **4** followed by coupling with phenol in the conventional manner provided azo compound **6** in high yield (83—91%). Etherification of the phenolic hydroxyl group via phenoxide ion with R_2I in DMF at 20 °C for 48 h afforded crude 3-(*p*-alkoxyphenylazo)-6-alkylpyridine (**7**), which was purified by silica-gel (Wakogel C-300) column chromatography using benzene as the eluting solvent. The oxidative conversion of **7** to azoxy derivatives **8** with hydrogen peroxide in acetic acid took 4 h, until the orange color of the



Scheme 1.



Scheme 2.

solution faded to some extent. IR (1250 cm^{-1}) and mass spectrometry clearly showed that the product was azoxypyridine *N*-oxide (**8**). This took a longer time than in the case of a previous report.[4] *N*-Oxides **8** were converted to the aimed 3-(*p*-alkoxyphenylazoxy)-6-alkylpyridines (**9**) by refluxing in PCl_3-$CHCl_3$ (1 : 4 v/v) followed by the usual work-up and recrystallization from ethanol in reasonable yields. The results of IR, MS, and ^1H NMR studies indicated that **9** was obtained. Since azoxy compounds **9** included two isomers by TLC, silica-gel column chromatography using ether-hexane (1 : 5 v/v) as the eluting solvent was employed in order to separate these isomer mixtures (**10** and **10'**). Identifications of azoxy compounds, thus separated, were satisfactorily made by ^1H NMR signals (δ 9.1—9.2 for **10**; δ 9.4—9.5 for **10'**). The ratioes of **10**/**10'** in **9** (Table 1) were determined from ^1H NMR signals. A remarkable feature is that **10'** is produced exclusively in samples **9b**, **9d**, and **9e**, indicating that the electron-donating effect of R_2O makes the azoxy N-atom more distant from the benzene ring more electrophilic as a result of resonance.

In the 2nd series, *p*-nitrotoluene (**11**) was converted to *p*-nitrosotoluene (**12**) via *p*-tolylhydroxylamine in usual manner.[5] The yield of *p*-nitrosotoluene was 40% on the basis on the starting *p*-nitrotoluene. **12** was reacted with **4** in acetic acid to give the corresponding azo compound **13** in low yield. The oxidation of **13** with hydrogen peroxide took 6 h (this time), and refluxing with PCl_3 afforded crude 3-(*p*-tolylazoxy)-6-alkylpyridine (**15**). A purification of the crude product with column chromatography eluted (hexane-benzene 5 : 1 v/v) the purified product in 21% yield (**15b**; R_3=C_4H_9). The ratio of two isomers in **15**(**16**/**16'**) was also determined from ^1H NMR signals (δ 9.1—9.2 for **16**; δ 9.5—9.6 for **16'**). For **15a**, the separation of two isomers was carried out by centrifugal liquid chromatography using hexane-ether (5 : 1 v/v) as the eluting solvent to afford isomers **16** and **16'**. These azoxy compounds indicated no mesomorphic range, presumably due to the presence of a very short methyl group at the one end.

Tables 1—3 summarize the transition temperatures of **9**, **10**, **10'**, and their precursors **7**, together with the values of the molar absorptivity (ε) in ethanol at the absorption maxima.

It can be recognized from Tables 1 and 2 that the azoxy compounds with relatively short R_2 chains such as Nos. **9a**, **9b**, **10a**, **10'a**, and **10'b** indicate no mesomorphic ranges when R_1=Me; however, the conventional azoxy compounds containing only benzene rings exhibit mesomorphic phases, even in the case of a compound corresponding to **9a**(C37N71I).[6] Therefore, it appears that the introduction of 2,5-

disubstituted pyridine in place of the usual benzene ring in the alkyl-substituted azoxy compounds gives rise to a sideward polar effect on a molecule due to the unshared electron pair present on the 2,5-disubstituted pyridine ring; longer alkyl chains are required than the conventional azoxy compounds[5,7] to exhibit mesomorphism.

The mesomorphic ranges shown in Tables 1 and 2 were comparatively low, even with longer R_2, such as **9e** and **10′e**, as compared with those of the corresponding azoxy compounds with alkoxy groups at both ends.[4] This difference appears to be caused by the fact that alkyl group did not produce any polar effects on the arrays of molecules, as compared with polar alkoxy type. It can also be recognized from Table 3 that azo compounds **7** are inferior to azoxy types in the mesomorphic range formation, since even **7c** with long alkoxy chain does not afford any mesomorphic range. This may be caused by the fact that the polar character of azoxy at the central portion of the molecule would play a role in the appearance of mesomorphism. Generally, ONN isomers had higher CN and CI temperatures than NNO ones, presumably due to the more balanced polarities of the formers (Table 2), where ONN and NNO mean that the nitrogen atom on the benzene ring side and that on the pyridine side were oxidized, respectively. These azo-azoxy series are, more or less, colored; therefore, the values of molar absorptivity (ε) at absorption maxima are shown in Tables 1—3. However, the differences of ε and the absorption maxima are generally small, although visual colors are considerably different due to the difference in the expansion of absorption spectrum.

Experimental

IR, ^{1}H NMR, and mass spectra were recorded on a Hitachi 215 spectrophotometer, a JNM-PMX60 spectrometer, and a Hitachi RMU-6 spectrometer, respectively, under standard conditions. Elemental analyses and centrifugal liquid chromatography were carried out with Perkin-Elmer 250 and Hitachi CLC-5 instruments.

The transition temperatures were determined by means of either a Yamato MP-21 melting-point apparatus or an optical microscope, both equipped with crossed polarizers.

2-[1,1-Bis(ethoxycarbonyl)alkyl]-5-nitropyridine (2). Diethyl alkylmalonate (30 mmol) was stirred with a sand-like suspension of sodium metal(0.7 g, 30 mmol) in xylene (50 ml) at 50 °C until sodium metal completely disappeared (0.5—1 h). The resulting mixture was heated under reflux with 2-chloro-5-nitropyridine (**1**; 4.8 g, 30 mmol) for 4 h. Xylene was distilled off from the reaction mixture and the residue was extracted with ether-water. The organic layer was washed with water, dried over anhydrous sodium sulfate, and concentrated on a rotary evaporator, followed by distillation under reduced pressure (152—210 °C, 0.1 mmHg[†]) to give a fluid. Yield: 68% for R_1=Me, 50% for Et, 45% for C_4H_9. IR ($CHCl_3$) 1740 (C=O), 1350 (NO_2) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=0.9—2.4 (m, alkyl), 4.3 (q, 4H, $2CH_2O$), 8.0 (d, 1H, pyridine), 8.5 (q, 1H, pyridine), 9.4 (d, 1H, pyridine).

2-Alkyl-5-nitropyridine (3). These compounds were prepared according to a known method.[2] A solution of **2** (30

[†]1 mmHg=133.322 Pa.

mmol) in 50% H_2SO_4 was stirred at 110 °C until the generation of carbon dioxide gas was no longer discernible (2 h). The usual work-up and distillation under reduced pressure (100 °C/0.1 mmHg) gave a pure product. Yield: 61% for R_1=Me, 73% for Et, 40% for C_4H_9.

The results of IR and NMR were satisfactory.

2-Alkyl-5-aminopyridine (4). A solution of **3** (10 mmol) and cyclohexene (5 ml) in absolute ethanol (70 ml) was heated under reflux with the addition of 5% Pd-C (1 g) for 2 h with stirring. The reaction mixture was filtered and the filtrate was concentrated on a rotary evaporator to leave a fluid.

^{1}H NMR ($CDCl_3$) δ=0.9—3.0 (m, alkyl), 3.7 (b, 2H, amine), 6.9 (d, 2H, pyridine), 8.0 (b, 1H, pyridine).

3-(*p*-Hydroxyphenylazo)-6-alkylpyridine (6). To a solution of **4** (10 mmol) in a mixture of hydrochloric acid (4.5 ml) and water (10 ml) was added under ice cooling a solution of sodium nitrite (0.7 g) in water (10 ml), followed by stirring for a while. A solution of phenol (10 mmol) and sodium hydroxide (1.0 g) in water (20 ml) was dropped at 0—5 °C under ice-water cooling. Stirring was continued for one hour; then the solution was neutralized with sodium hydrogencarbonate, and the resulting precipitate was picked up by filtration. Recrystallization was carried out from chloroform-hexane. Yield; 91% for R_1=Me, 83% for Et. Mp 182—183 °C for R_1=Me, 151—151 °C for Et.

R_1	C%	H%	N%	MS(m/z)
CH_3	68.53(68.72)	5.86(5.73)	18.60(18.50)	227(M^+)
C_2H_5	69.57(69.71)	6.25(6.22)	17.28(17.43)	241(M^+)

Figures in parentheses indicate the calcd values.

IR($CHCl_3$) 3600—3150 (OH) cm^{-1}. ^{1}H NMR ($CDCl_3$) δ= 0.9—2.0 (m, alkyl), 2.9 (q, or t, 2H, $ArCH_2$), 6.9—8.1 (m, 6H, ArH+pyridine), 8.9 (d, 1H, pyridine), 10.0 (b, 1H, OH).

3-(4-Alkoxyphenylazo)-6-alkylpyridine (7). **6** (10 mmol) was dissolved in a solution of potassium hydoxide (12 mmol) in methanol (20 ml). Methanol was then removed on a rotary evaporator and the residue was dissolved in anhydrous DMF (20 ml). Alkyl iodide (12 mmol) was dropped and the mixture was stirred at 20 °C for 48 h. A 1 M[††] sodium hydroxide solution was then added and the mixture was extracted with chloroform. The organic layer was first washed with an aqueous sodium hydroxide solution and then with water. It was next dried over anhydrous sodium sulfate and evaporated on a rotary evaporator. Column (SiO_2, Wakogel C-300) chromatography using benzene as the eluting solvent was employed for purification.

3-[(4-Alkoxyphenyl)-NON-azoxy]-6-alkylpyridine *N*-Oxide (8). A solution of **7** (5 mmol) and 30% hydrogen peroxide (17 ml) in glacial acetic acid (100 ml) were heated at 65 °C until the color of the solution faded to some extent (4 h). The solution was poured onto ice and the resulting precipitate was picked up by filtration. The precipitate was recrystallized from ethanol-water.

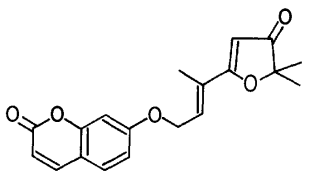
Synthesis of 5-[(*E*)-1-Alkenyl]-3(2*H*)-furanones by the Stereoselective Dehydration with Me_3SiCl

Takashi SAKAI,* Kazuhiko KOHDA, Sadao TSUBOI, Masanori UTAKA, and Akira TAKEDA
Department of Synthetic Chemistry, School of Engineering, Okayama University, Tsushima, Okayama 700
(Received February 20, 1987)

The stereoselective dehydration of 5-(2-hydroxyalkyl)-3(2*H*)-furanones is accomplished conveniently by the treatment with Me_3SiCl in acetonitrile to give 5-[(*E*)-1-alkenyl]-3(2*H*)-furanones.

5-(1-Alkenyl)-3(2*H*)-furanone is one of the important skeletons observed in natural products, e. g. geiparvarin (**1**)[1] and eremantholide A,[2] and hence much attention has been paid on their stereoselective synthesis. We previously reported a short step synthesis of **1**,[3] in which the (*E*)-olefinic side chain was introduced



1

by the utilization of tiglic acid. Smith et al.[4] elaborated the olefinic moiety of **1** and the related 3(2*H*)-furanone **4** in a manner as shown in Scheme 1, which involves the aldol reaction of lithium enolate of 5-ethyl-2,2-dimethyl-3(2*H*)-furanone (**2**) with an appropriate aldehyde followed by the DCC-CuCl-catalyzed dehydration of the resulting diastereomeric mixture of 5-(2-hydroxyalkyl)-3(2*H*)-furanone (**3**) in refluxing benzene. However, the E/Z-stereoselectivity of the side chain of **4** is not satisfactory as cited in Table 1 and seems to be still open to further improvement. Recently, Tsuge et al.[5] have reported that the Horner-Emmons olefination of 5-[1-(diethoxyphosphoryl)-ethyl]-3(2*H*)-furanone with aldehydes gives **4a—e** with a considerable E selectivity. In the preceding paper of our laboratory concerning the stereoselective synthesis of polyenoic acids,[6] the Me_3SiCl-NaI reagent was successfully employed for the dehydration of acyclic allylic alcohol to produce a conjugated (E)-olefinic double bond. The fact stimulated us to examine the suitability of the reagent for the dehydration of **3**, and Me_3SiCl itself was found to be remarkably effective on the improvement of the stereoselectivity.

The present reaction merely involves stirring of a mixture of **3a—e** and 2.5 equiv of Me_3SiCl in acetonitrile at room temperature to give the desired product with sufficient purity after washing with aqueous sodium hydrogencarbonate. Addition of NaI to the reaction had no effect on the yield. The reaction time of 10—14 h is required, while the reaction for allylic alcohol **3e** was finished within 1 h. These results are summarized in Table 1. The olefinic side chains of **3a—e** thus obtained have only the E geometry, which was confirmed by the comparison of the ^1H NMR spectral data with those reported.[4b] Furthermore, their ^{13}C NMR spectral data summarized in Table 2 indicate the absence of (Z)-isomer definitely. The yields of the dehydration were also improved generally. The method seems to be more practical as compared with the reported one,[4] because the reagent is inexpensively available and the procedure is quite simple.

A possible mechanism for the present reaction is depicted in Scheme 2, which involves the formation of bis(trimethylsilyl)oxonium chloride intermediate **5**.[7] Subsequent elimination of hexamethyldisiloxane (**6**) from **5** would occur accompanying the abstraction of the reactive allylic proton by a chloride anion. Formation of **6** was confirmed by GLPC analysis.[8] The alcohols **3a—e** used were a diastereomeric mixture. Smith et al.[4] did not describe the detail of the isomeric
