where subscripts "A" and "R" represent the optically active and racemic modifications, respectively, *R* is the gas constant, ΔC_P is the difference in heat capacity between the liquid and solid states in the vicinity of melting point, and ΔC^{s} is that in solid state between racemic and optically active modifications; $\Delta\Delta H^{f} = \Delta H^{f}_{R} - \Delta H^{f}_{A}$ (ΔH^{f}, enthalpy of fusion), $\Delta\Delta S^{f} = \Delta S^{f}_{R} - \Delta S^{f}_{A}$ (ΔS^{f}, entropy of fusion), and $\Delta T^{f} = T^{f}_{R} - T^{f}_{A}$ (T^{f}, melting point); T^{f} represents T^{f}_{A} when $T^{f}_{R} > T^{f}_{A}$ and T^{f}_{R} when $T^{f}_{R} < T^{f}_{A}$. The term containing ΔC_p is ignored for the calculation of ΔG^{F}_{mp} at melting point, because the contribution is obviously smaller than that of the sum of the other terms in the right-hand side of Eq. 1.[5] The ΔG^{F}_{mp} of the salts of DL-FrTyr having melting points were calculated by Eq. 1 using ΔH^{f} and T^{f}.[5-7] Thermodynamic data of *N*-formyltyrosine salts are listed in Table 1. The values of ΔG^{F}_{mp} are negative, and further, these salts have eutectic points; the mole fractions of L-salt at eutectic point are 0.70—0.77 as listed in Table 2, and the binary melting point diagram of DCH salt is illustrated in Fig. 1. The above results indicate that these DL-salts form racemic compounds at melting point.

Table 2. Data at Eutectic Point for Organic Ammonium Salts of *N*-Formyltyrosine

Salt[a]	Mole fraction of L-salt[b]	Temperature/K	
		Found	Calcd[b]
PTA	0.77	398	399
TMB	0.70	424	425
DBA	0.70	411	410
DCH	0.75	494	493
DBZ	0.75	433	432
4-MP	0.71	425	426

a) See notes in Table 1. b) These values were calculated from Schröder-Van Laar and Prigogine-Defay equations.

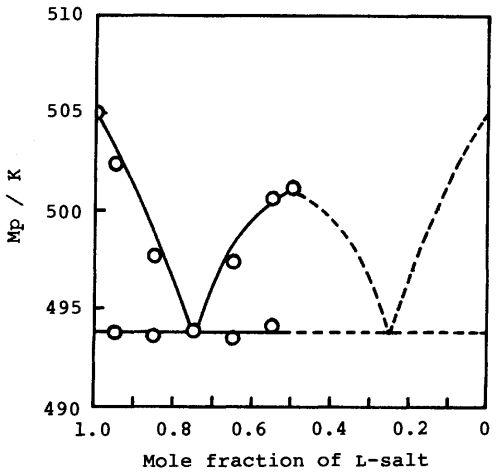

Fig. 1. Binary melting point diagram of dicyclohexylammonium salt of *N*-formyltyrosine.

Racemic Structure at Room Temperature: The ΔG^{F}_{283} at 283 K was also calculated by Eq. 1; in the calculation, ΔC_p was taken as 105 J mol^{-1} K^{-1} and ΔC^{s} as 31.4 J mol^{-1} K^{-1}.[5-7] Only the DL-DCH salt gives a positive ΔG^{F}_{283} value (+5.39 kJ mol^{-1}). This value suggests that the DL-salt does not form a racemic compound at 283 K. DL-DCH salt shows infrared spectrum identical with that of the L-salt and is more soluble than the L-salt as described in the experimental section.

Table 4. Successive Preferential Crystallization of Dicyclohexylammonium Salt of *N*-Formyl-DL-tyrosine[a)]

Run	Added amount of DL-salt	Operation amount[b)]/g		Resolution time	Salt obtained			
					Yield	Optical purity	YOPM	Degree of resolution
	g	D-Salt	L-Salt	min	g	%	g	%
1	2.154	1.077	1.077	130	0.172	L 92.2	0.109	60.9
2	0.122	1.131	1.022	60	0.219	D 94.0	0.156	67.0
3	0.169	1.053	1.100	60	0.195	L 93.7	0.133	65.8
4	0.145	1.120	1.034	100	0.202	D 94.6	0.141	63.5

a) Solvent: 25 cm³ of methanol. Degree of supersaturation of initial solution: 120%. Seed crystals: 0.050 g of D- or L-salt. Temperature: 10°C. b) Operation amounts of D- and L-salts in solution were calculated from analyses of the salts obtained in Runs 1—3.

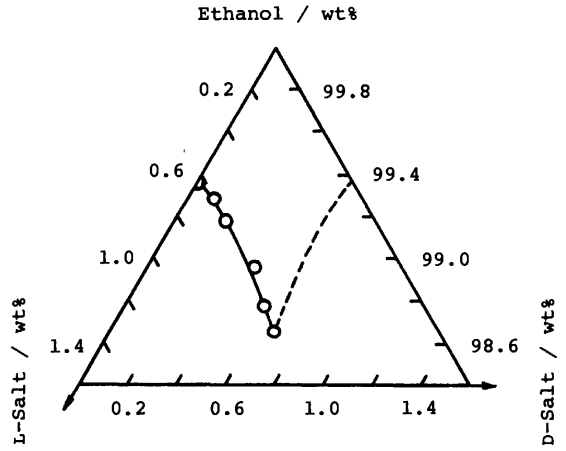

Fig. 2. Ternary solubility diagram of dicyclohexylammonium salt of *N*-formyltyrosine. Solvent: Ethanol. Temperature: 10°C.

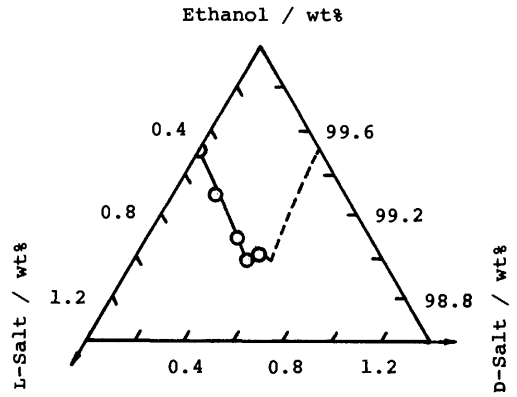

Fig. 3. Ternary solubility diagram of *t*-butylammonium salt of *N*-formyltyrosine. Solvent: Ethanol. Temperature: 10°C.

The ternary solubility diagram shows what is expected for a conglomerate as shown in Fig. 2.[2)]

For other DL-salts, the values of ΔG^{F}_{283} are negative, and the infrared spectra are different from those of the corresponding L-salts. These results indicate that DL-DCH salt exists in a conglomerate at room temperature, whereas other DL-salts form racemic compounds.

In the salts that decompose on heating, DL-*t*-butylammonium salt (DL-TBA salt) shows infrared spectrum excellently identical with that of L-salt, whereas the spectra of other DL-salts are different from those of the corresponding L-salts. DL-TBA salt is more soluble than the L-salt; DL-TBA salt 0.764 g/(100 cm³ ethanol), L-TBA salt 0.423 g/(100 cm³ ethanol) at 10°C. The ternary solubility diagram, however, suggests that DL-TBA salt is an unstable racemic com-

pound at room temperature as shown in Fig. 3,[2] because the mole fraction of L-salt at eutectic point is 0.55. This instability of DL-TBA salt may give infrared spectrum excellently identical with that of L-salt.

The above results lead to the conclusion that only the DL-DCH salt exists in a conglomerate at room temperature though the salt forms a racemic compound at melting point.

Optical Resolution of DL-Dicyclohexylammonium Salt. Preferential crystallization of DL-DCH salt is listed in Table 3; L-DCH salt was used as seed crystals.

It was possible to obtain L-DCH salt with optical purity of over 90%. Since the yield in methanol was nearly equal to that in ethanol, it is expected that the optical resolution from methanol solution in the same scale as that from ethanol solution gives L-DCH salt in about 4 times higher yield from ethanol. The optical resolution by a successive preferential crystallization for methanol solution was found to give D- and L-DCH salts with optical purity of 92—95% in degree of resolution of 60—67% as shown in Table 4. Optically pure D- and L-Tyr's were obtained from purified D- and L-DCH salts, respectively.

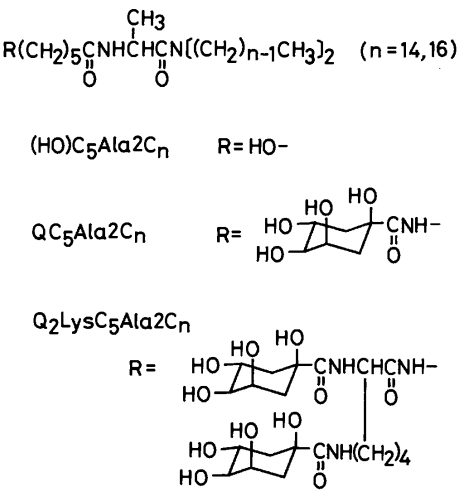
Aggregate Morphology of Peptide Lipids Having Hydroxyl Groups: Molecular Basis for Formation of Inverted Hexagonal, Inverted Cubic, Bilayer, and Micellar Phases

Yukito MURAKAMI,* Jun-ichi KIKUCHI, Toshihiko TAKAKI, and Katsuya UCHIMURA
Department of Organic Synthesis, Faculty of Engineering, Kyushu University, Hakozaki, Higashi-ku, Fukuoka 812
(Received October 24, 1986)

Three types of peptide lipids having different numbers of hydroxyl groups in their head moieties, $(HO)C_5Ala2C_n$, QC_5Ala2C_n, and $Q_2LysC_5Ala2C_n$ (n=14, 16), were prepared, and their morphological behavior was investigated by various physical techniques: negative staining and freeze-fracture electron microscopy, low-angle X-ray diffraction, selected area electron diffraction, fluorescence polarization spectroscopy, and differential scanning calorimetry. QC_5Ala2C_n, having four hydroxyl groups in the head moiety, underwent aggregation in the aqueous dispersion state to afford the nonbilayer phase, which was constituted with highly developed globular domains with face-centered cubic (C_{II}) lattice, above the phase transition temperature (T_m). This C_{II} phase was transformed into the bilayer one below T_m. On the other hand, $Q_2LysC_5Ala2C_n$, having eight hydroxyl groups in the head moiety, formed bilayer aggregates in a whole temperature range, above and below T_m. Deprotonation of the hydroxyl groups of QC_5Ala2C_n and $Q_2LysC_5Ala2C_n$ resulted in morphological changes to afford the bilayer and micellar phases, respectively. Two-component lipid systems composed of $(HO)C_5Ala2C_{14}$ and $Q_2LysC_5Ala2C_{14}$ at appropriate molar ratios afforded the inverted hexagonal (H_{II}) phase in the aqueous dispersion state; the first example of the H_{II} phase formed with artificial double-chain amphiphiles. The aggregate morphology was discussed on the basis of the critical packing mode of lipid molecules.

Extensive studies on structures and functions of biomembranes gave an impetus to rapid growth of *membrane mimetic chemistry*.[1] While synthetic lipids having a wide variety of molecular structures have been demonstrated to afford bilayer aggregates, structural limitations of such lipids in morphological behavior have not been unveiled up to the present time. Nonbilayer structures, such as inverted hexagonal and inverted cubic ones, have often been observed with natural lipid systems,[2] and some useful concepts have been proposed to explain the molecular basis for the formation of such aggregates.[3,4] However, feedback of these concepts to the development of artificial lipids requires the guidepost for molecular design of lipids, which adopt desired aggregate structures, and such attempts have encountered some difficulties.[5] In other words, appropriate structural modifications must be systematically exercised in designing artificial lipids, so that changes in their morphological behavior are significantly amplified. The *peptide lipids* are suitable candidates for such purposes, since amino acid residues involved in aggregates of these lipids form the tight hydrogen-belt domain which acts to separate two intramembrane domains, the surface domain composed of polar head moieties and the hydrophobic interior domain formed with double-chain segments, so that direct structural interactions between the latter two domains tend to be minimized.[6] Thus, only the size of double-chain segments of the lipid molecules primarily controls the phase transition behavior.[6c,7] On these grounds, we can exactly evaluate the effects of structural modifications of lipid molecules on aggregate morphology. In the present work, we investigated the aggregate morphology of individual and mixed lipid systems of the following three types of peptide lipids having different numbers of hydroxyl groups in their head moieties; $(HO)C_5Ala2C_n$, QC_5Ala2C_n, and $Q_2LysC_5Ala2C_n$ (n=14, 16). Four different types of aggregate morphology, inverted hexagonal, inverted cubic, bilayer, and micellar phases, were systematically created for the first time with these artificial lipids by controlling the packing mode of lipid molecules in the aggregate state.



Experimental

Materials. 1,6-Diphenyl-1,3,5-hexatriene (DPH) was obtained from Nakarai Chemicals as a guaranteed reagent and used without further purification. Trisodium 8-hydroxy-1,3,6-pyrenetrisulfonate (pyranine) was purchased from Tokyo Kasei Kogyo Co. and purified after the method reported by Kano and Fendler.[8] Hexadecyltrimethylammonium bromide (CTAB) from Nakarai Chemicals was recrystallized from ethanol, mp 237—239 °C (decomp). Preparation of nonionic peptide lipids having the 1,3,4,5-tetrahydroxy-[1*R*-(1α,3α,4α,5β)]cyclohexylcarbonyl (quinoyl) moiety has been reported previously: *N*,*N*-dihexadecyl-N^{α}-[6-(quinoylamino)hexanoyl]-L-alaninamide (QC_5Ala2C_{16})[7] and *N*,*N*-ditetradecyl-N^{α}-[6-(quinoylamino)hexanoyl]-L-alaninamide

(QC_5Ala2C_{14}).[9]

***N,N*-Dihexadecyl-N^{α}-(6-hydroxyhexanoyl)-L-alaninamide [(HO)C_5Ala2C_{16}].** A mixture of *N,N*-dihexadecyl-N^{α}-(6-bromohexanoyl)-L-alaninamide[7] (1.0 g, 1.6 mmol), formamide (2.5 g, 86 mmol), and water (60 mg, 3.2 mmol) was stirred for 3 h at 140—150 °C and cooled to room temperature. Water (4 mL) was added to the mixture, which was subsequently extracted with dichloromethane (3×10 mL). The solvent was removed in vacuo, and the residue was dissolved in ethanol (20 mL). Aqueous NaOH (2 mol dm^{-3}, 3 mL) was added to the ethanol solution, and the resulting solution was refluxed for 3 h. After addition of water (10 mL), the mixture was acidified with hydrochloric acid and extracted with chloroform (3×15 mL). The extract was washed with water, dried over sodium sulfate, and evaporated to dryness in vacuo. The residue was purified by gel-filtration chromatography on a column of Sephadex LH-20 with methanol as an eluant: a colorless solid, yield 110 mg (11%); mp 44.8—45.2 °C; IR (KBr) 3440 (OH), 3280 (NH), 2920 and 2845 (CH), and 1635 cm^{-1} (C=O); ^1H NMR ($CDCl_3$, Me_4Si) δ=0.87 [6H, t, $(CH_2)_{15}C\underline{H}_3$], 1.25 [65H, m, $CH_2(C\underline{H}_2)_{14}CH_3$, $CH(C\underline{H}_3)$, and $HOCH_2(C\underline{H}_2)_3CH_2$], 2.20 [2H, t, $HO(CH_2)_4C\underline{H}_2$], 3.2 [4H, m, $C\underline{H}_2(CH_2)_{14}CH_3$], 3.60 [2H, t, $HOC\underline{H}_2$], 4.83 [1H, m, $C\underline{H}(CH_3)$], and 6.60 [1H, d, CONH].

Found: C, 74.55; H, 12.50; N, 4.33%. Calcd for $C_{41}H_{82}N_2O_3 \cdot 1/2\ H_2O$: C, 74.60; H, 12.67; N, 4.24%.

***N,N*-Ditetradecyl-N^{α}-(6-hydroxyhexanoyl)-L-alaninamide [(HO)C_5Ala2C_{14}].** This was prepared from *N,N*-ditetradecyl-N^{α}-(6-bromohexanoyl)-L-alaninamide[7] in a manner similar to that stated above: a colorless solid, yield 18%; mp 48.5—49.0 °C; IR (KBr) 3440 (OH), 3280 (NH), 2920 and 2845 (CH), and 1635 cm^{-1} (C=O); ^1H NMR ($CDCl_3$, Me_4Si) δ=0.88 [6H, t, $(CH_2)_{13}C\underline{H}_3$], 1.25 [57H, m, $CH_2(C\underline{H}_2)_{12}CH_3$, $CH(C\underline{H}_3)$, and $HOCH_2(C\underline{H}_2)_3CH_2$], 2.20 [2H, t, $HO(CH_2)_4C\underline{H}_2$], 3.2 [4H, m, $C\underline{H}_2(CH_2)_{12}CH_3$], 3.59 [2H, t, $HOC\underline{H}_2$], 4.84 [1H, m, $C\underline{H}(CH_3)$], and 6.60 [1H, d, CONH].

Found: C, 74.34; H, 12.39; N, 4.75%. Calcd for $C_{37}H_{74}N_2O_3$: C, 74.69; H, 12.54; N, 4.71%.

***N,N*-Dihexadecyl-N^{α}-[6-[[N^{α},N^{ε}-bis(*t*-butoxycarbonyl)-L-lysyl]amino]hexanoyl]-L-alaninamide [(Boc)$_2$LysC_5Ala2C_{16}].** Trifluoroacetic acid (25 g, 220 mmol) was added to a dry dichloromethane solution (20 mL) of *N,N*-dihexadecyl-N^{α}-[6-(*t*-butoxycarbonylamino)hexanoyl]-L-alaninamide[7] (5.0 g, 6.7 mmol), and the mixture was stirred for 4.5 h at room temperature. An excess amount of trifluoroacetic acid and the solvent were evaporated off in vacuo. The residue was dissolved in chloroform (50 mL) and then washed with 5% aqueous sodium hydrogencarbonate (3×30 mL). After being dried over sodium sulfate, the solution was evaporated to dryness in vacuo to give a pale yellow solid (3.0 g). Elimination of the *t*-butoxycarbonyl group was confirmed by IR and ^1H NMR spectroscopy. Dicyclohexylcarbodiimide (0.93 g, 4.5 mmol) was added to a dry dichloromethane solution (20 mL) of the N^{α},N^{ε}-bis(*t*-butoxycarbonyl)-L-lysine dicyclohexylamine salt (2.3 g, 4.5 mmol) and *p*-toluenesulfonic acid (0.77 g, 4.5 mmol) at 0 °C. After the mixture being stirred for 15 min at 0 °C, a dry dichloromethane solution (10 mL) of the amine was added to it at the same temperature. The mixture was stirred for 3 h at 0 °C and overnight at room temperature. The resulting precipitate (*N,N'*-dicyclohexylurea) was removed by filtration, the filtrate was evaporated to dryness in vacuo, and the residue was dissolved in ethyl acetate (100 mL). The ethyl acetate solution was then washed with 10% aqueous citric acid (2×50 mL), water (50 mL), 4% aqueous sodium hydrogencarbonate (2×50 mL), and water (50 mL) in this sequence. After being dried over sodium sulfate, the solution was evaporated to dryness in vacuo. The residue was chromatographed on a column of silica gel (Wako Gel C-100) with chloroform as an eluant: a pale yellow solid, yield 1.7 g (22%); IR (KBr) 3320 (NH), 2920 and 2850 (CH), and 1770 and 1660 cm^{-1} (C=O); ^1H NMR ($CDCl_3$, Me_4Si) δ=0.87 [6H, t, $(CH_2)_{15}C\underline{H}_3$], 1.25 [71H, m, $CH_2(C\underline{H}_2)_{14}CH_3$, $CH(C\underline{H}_3)$, $CONHCH_2(C\underline{H}_2)_3CH$, and $CONHCH_2(C\underline{H}_2)_3CH_2$], 1.42 [18H, s, $OC(CH_3)_3$], 2.3 [2H, m, $CONH(CH_2)_4C\underline{H}_2$], 3.14 [8H, m, $CONHC\underline{H}_2$ and $C\underline{H}_2(CH_2)_{14}CH_3$], 4.27 [3H, m, $C\underline{H}(CH_2)_3$ and $CONHC\underline{H}_2$], 4.80 [1H, m, $C\underline{H}(CH_3)$], 5.12 [1H, d, $OCONH\underline{C}H$], and 7.60 [1H, d, $CONH\underline{C}H$].

***N,N*-Dihexadecyl-N^{α}-[6-[[N^{α},N^{ε}-bis(tetraacetylquinoyl)-L-lysyl]amino]hexanoyl]-L-alaninamide [(AcQ)$_2$LysC_5Ala2C_{16}].** Trifluoroacetic acid (25 g, 220 mmol) was added to a dry dichloromethane solution (20 mL) of (Boc)$_2$LysC_5Ala2C_{16} (1.1 g, 1.1 mmol), and the mixture was stirred for 2 h at room temperature. Evaporation of an excess amount of trifluoroacetic acid and the solvent gave a pale yellow oil (1.2 g). Elimination of the *t*-butoxycarbonyl group was confirmed by ^1H NMR spectroscopy. The amine was dissolved in dry dichloromethane (20 mL), and the solution was cooled to 0 °C. Triethylamine (2.3 g, 22 mmol) was added to the solution, and then (−)-tetraacetylquinoyl chloride[10] (1.7 g, 4.5 mmol) dissolved in dry dichloromethane (20 mL) was added dropwise to the mixture at 0 °C with stirring. The resulting mixture was stirred for 1 h at 0 °C and for 2 h at room temperature, and then dichloromethane (100 mL) was added to it. The mixture was washed with saturated aqueous sodium chloride (2×50 mL), 5% aqueous citric acid (2×50 mL), saturated aqueous sodium chloride (2×50 mL), 5% aqueous sodium hydrogencarbonate (2×50 mL), and saturated aqueous sodium chloride (2×50 mL) in this sequence. After being dried over sodium sulfate, the solution was evaporated to dryness in vacuo. The residue was chromatographed on a column of silica gel (Wako Gel C-100) with ethyl acetate as an eluant. The product was further purified by gel-filtration chromatography on a column of Sephadex LH-20 with methanol as an eluant: a colorless solid, yield 0.32 g (20%); mp 75.0—76.5 °C; IR (KBr) 2920 and 2850 (CH), and 1740 and 1650 cm^{-1} (C=O).

***N,N*-Dihexadecyl-N^{α}-[6-[(N^{α},N^{ε}-diquinoyl-L-lysyl)amino]-hexanoyl]-L-alaninamide [Q_2LysC_5Ala2C_{16}].** After addition of hydrazine monohydrate (700 mg, 14 mmol) to a solution of (AcQ)$_2$LysC_5Ala2C_{16} (270 mg, 0.19 mmol) in 85% aqueous ethanol (3 mL), the mixture was refluxed for 1 h, cooled to room temperature, and poured into cold water (20 mL). Chloroform (30 mL) was added to the mixture, and the organic layer was separated by centrifugation. After being dried over sodium sulfate, the organic layer was evaporated to dryness in vacuo. The residue was purified by gel-filtration chromatography on a column of Sephadex LH-20 with methanol as an eluant: a colorless solid, yield 120 mg (59%); final mp 227 °C; IR (KBr) 3350 (OH), 2920 and 2850 (CH), and 1640 cm^{-1} (C=O).

Found: C, 64.07; H, 10.26; N, 6.20%. Calcd for $C_{61}H_{115}N_5O_{13} \cdot H_2O$: C, 64.01; H, 10.30, N, 6.12%.

***N,N*-Ditetradecyl-N^{α}-[6-[(N^{α},N^{ε}-diquinoyl-L-lysyl)amino]-hexanoyl]-L-alaninamide [Q_2LysC_5Ala2C_{14}].** This was prepared from *N,N*-ditetradecyl-N^{α}-[6-(*t*-butoxycarbonyl-

amino)hexanoyl]-L-alaninamide[7] in a manner similar to that stated above: a colorless solid; final mp 173 °C; IR (KBr) 3350 (OH), 2920 and 2850 (CH), and 1640 cm^{-1} (C=O).

Found: C, 62.93; H, 10.32; N, 6.45%. Calcd for $C_{57}H_{107}N_5O_{13}\cdot H_2O$: C, 62.89; H, 10.09; N, 6.43%.

Analyses and Measurements. Elemental analyses were performed at the Microanalysis Center of Kyushu University. Melting points were measured with a Yanagimoto MP-S1 apparatus (hot-plate type). ^1H NMR spectra were taken on a Hitachi R-24B spectrometer. IR spectra were recorded on a JASCO IR-810 spectrophotometer. pH Measurements were carried out with a Beckman Φ71 pH meter equipped with a Beckman 39505 combined electrode after calibration with a combination of appropriate standard aqueous buffers. A JASCO UVIDEC-100 UV spectrophotometer was used as a detector for gel-filtration chromatography. Fluorescence spectra were recorded on a Hitachi 650-60 spectrofluorometer. A Daini Seikosha SSC-560U calorimeter was used for differential scanning calorimetry (DSC). The phase-transition temperature (T_m, temperature at a peak maximum of DSC thermogram) and the enthalpy change for phase transition (ΔH) were determined in a manner as reported previously.[7]

Electron micrographs were taken on a JEOL JEM-2000FX electron microscope installed at the Research Laboratory for High Voltage Electron Microscopy of Kyushu University. Negatively stained and freeze-fractured samples for the measurements were prepared in a manner as described previously.[7] Selected area electron diffraction measurements were carried out by using the same electron microscope, electron wavelength being adjusted at 100 kV (λ=0.037 Å). The camera length (2870 mm) was calibrated on the basis of diffractions from (111) and (200) planes of the face-centered cubic lattice of single crystalline gold.

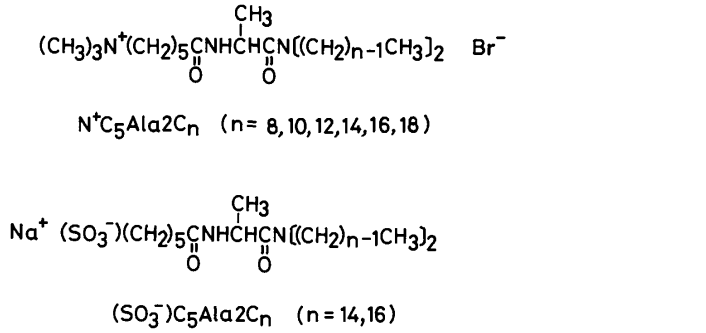
The fluorescence polarization measurements were carried out on a Union Giken FS-501A fluorescence polarization spectrophotometer equipped with a Sord microcomputer M200 Mark II; emission at 450 nm originated from DPH was monitored upon excitation at 358 nm with a slit width of 3.5 nm for both excitation and emission sides. The steady-state fluorescence anisotropy (r_S) was calculated by Eq. 1, where I is the fluorescence intensity, and the subscripts v and h refer to the orientations, vertical and horizontal, respectively, for the excitation and analyzer polarizers in this sequence. C_f is the grating correction factor, given by I_{hv}/I_{hh}.

$$r_S = (I_{vv} - C_f I_{vh})/(I_{vv} + 2C_f I_{vh}), \quad (1)$$

The nickel-filtered Cu $K\alpha$ radiation (λ=1.542 Å) from a Rigaku Rotaflex RU-200 X-ray generator was used for X-ray diffraction measurements. Each sample was sealed up in a specimen holder equipped with mica windows, and a low-angle diffraction pattern was recorded on a Fuji X-ray film 150; a sample-film distance being set at 200 mm.

Results and Discussion

Molecular Design of Nonionic Peptide Lipids. Ionic peptide lipids having an α-amino acid residue interposed between a polar head moiety and a hydrophobic double-chain segment generally form bilayer aggregates in an aqueous dispersion state.[6] On the other hand, we have recently found that nonlamellar aggregates appear in the aqueous dispersions of cationic and anionic lipids, *N,N*-dialkyl-N^{α}-[6-(trimethylammonio)hexanoyl]-L-alaninamide bromide [N^+C_5Ala2C_n] and sodium *N,N*-dialkyl-N^{α}-(6-sulfonatohexanoyl)-L-alaninamide [$(SO_3^-)C_5$Ala2C_n], respectively, mixed at the 1:1 molar ratio above the phase-transition temperature (T_m).[11] This nonlamellar phase is



referred to the inverted cubic (C_{II}) one composed of three-dimensional network of globular aggregates with small internal aqueous compartments.[12] The following two effects control the packing mode of lipid molecules to adopt the C_{II} phase in aqueous media: (i) intramembrane electrostatic interactions between cationic and anionic head moieties to form highly developed ion-pair clusters in the membrane surface, and (ii) recovery of the rotational and bending motions of hydrophobic double-chain segments above T_m. As a result, these lipid molecules are allowed to retain the *inverted truncated cone* shape[4a] in their aggregates above T_m, and the critical packing mode under such conditions favors the formation of inverted micellar aggregates. We have also found that the nonlamellar phase was formed with nonionic peptide lipids having the quinoyl moiety, QC_5Ala2C_n, through the hydrogen-bonding interaction among the polar head moieties. These observations imply that the peptide lipids tend to construct various aggregate structures, which have been demonstrated so far with naturally occurring lipid systems, in aqueous media by manipulating steric bulkiness of their polar head moieties so that specific packing modes are attained in their aggregates.

A useful concept has been proposed on the self-assembling behavior of lipid molecules in dilute aqueous solutions, based on the critical packing parameter, v/a_0l_c, where v, a_0, and l_c are the hydrocarbon volume, the optimal surface area, and the critical chain length of lipid molecules, respectively.[4] The following guidepost for the formation of specific aggregate structures has been postulated on the basis of the dynamic packing mode: $v/a_0l_c < 1/3$ for spherical micelles, $1/3 < v/a_0l_c < 1/2$ for cylindrical micelles, $1/2 < v/a_0l_c < 1$ for bilayers, and $v/a_0l_c > 1$ for inverted micelles.[4] However, there are few successful explanations to distinguish between structural factors for the formation of the two kinds of nonlamellar phases; a hexagonally

packed array of inverted cylindrical micelles (H_{II} phase), and a closely packed cubic array of inverted spherical micelles (C_{II} phase).[13] Recently, Verkleij mentioned in his review article that lipidic particles are found in a variety of lipid mixtures and in total lipid extracts under physiological conditions in excess water, and that lipidic particles are only found in mixed systems of natural lipids, in which one component or more of the lipids prefer to adopt the H_{II} phase in their individual states.[2a] Since the C_{II} phase is considered to be the principal morphology pertaining to lipidic particles, the C_{II} aggregate is granted to be the intermediary form lying between bilayer and H_{II} ones. Thus, the critical packing parameter for the H_{II} forming lipid seems to be larger than that for the C_{II} forming lipid.

As for the peptide lipids, the critical packing parameter is primarily controlled by the a_0 value if only the polar head moiety undergoes structural variation and the rest of the molecule remains the same. As one of such purposive series of lipid molecules, we prepared three types of nonionic peptide lipids having various numbers of hydroxyl groups in their head moieties; (HO)C_5Ala2C_n, QC_5Ala2C_n, and Q_2LysC_5-Ala2C_n (n=14, 16). The CPK molecular models of these lipids are shown in Fig. 1. Since the four hydroxyl groups of the quinoyl moiety are located on one side of the cyclohexane ring with chair-type conformation, the head moieties of QC_5Ala2C_n and Q_2LysC_5Ala2C_n seem to hold configurations paralled to the membrane surface. In addition, the extent of solvation of the head moieties of the present lipids mainly depends on a number of the hydroxyl groups in the presence of excess water. Thus, the a_0 value for the present peptide lipids decreases in the following order: Q_2LysC_5Ala2C_n > QC_5Ala2C_n > (HO)C_5Ala2C_n. Now, correlations between aggregate morphology and lipid structure are described below on the basis of the critical packing concept.

Inverted Cubic Phase. Recently, we have found that QC_5Ala2C_n having four hydroxyl groups in the head moiety form nonlamellar aggregates in the aqueous dispersion state by means of negative staining electron microscopy.[9] The low-angle X-ray diffraction technique was applied to these aggregates in this work. Four diffractions with the spacing ratio, $1:\sqrt{3}/2:\sqrt{3}/\sqrt{8}:1/2$, were observed for QC_5Ala2C_n (n=14, 16) at pH 7 above T_m (Table 1). This spacing ratio is in conformity with diffractions from (111), (200), (220), and (222) planes of the face-centered cubic (fcc) lattice with lattice constant a (Fig. 2). We have obtained similar diffraction patterns for aggregates formed with equimolar mixtures of cationic and anionic lipids.[12] It has been claimed that an apparent cubic phase observed in the 1-oleoylglycerol-water system actually consists of a lipid bilayer forming a tetrahedral periodic minimal surface which separates two water channel networks.[14] The existence of such continuous

water channels in our peptide lipid systems, however, can be ruled out in the light of the electron microscopic measurements.[9,11,12] The (111) plane of the fcc lattice is the closest packed one, and the distance between the nearest neighbors in the plane ($a/\sqrt{2}$) is referred to the repeating distance of internal aqueous compartments. When the weight fraction of QC_5-Ala2C_{14} in water was increased from 0.22 to 0.28, the $a/\sqrt{2}$ value was reduced by 9 Å. In addition, the $a/\sqrt{2}$ value as observed by negative staining electron microscopy, for which water was completely removed during the sample preparation, was 70 Å.[9] Such large dependence of the $a/\sqrt{2}$ value on the lipid concentration seems to be originated from the fact that the hydrogen-bonding interaction among polar head moieties of the lipid molecules predominantly controls the critical packing mode to give thermodynamically stable aggregates and water molecules solvated onto the head moieties also take part in the hydrogen-bonding interaction. In dilute aqueous solutions, on the other hand, the $a/\sqrt{2}$ value seems to approach to a limiting value (ca. 110 Å) in a manner as observed for an equimolar mixture of N^+C_5Ala2C_{14} and (SO_3^-)-C_5Ala2C_{14} by means of freeze-fracture electron micros-

copy.[11] It is noteworthy, however, that the $a/\sqrt{2}$ value is not so sensitively dependent on the lipid concentration for the cationic and anionic lipid system as observed for the QC_5Ala2C_{14} system in the light of observations by negative staining and freeze-fracture electron microscopy[11] and low-angle X-ray diffraction measurements.[12] The tight ion-pair cluster formed with cationic and anionic head moieties of the mixed lipid system seems to minimize hydration in the surface domain, while such an effect is not operative for QC_5Ala2C_n. These hydration effects must be reflected on the correlations between $a/\sqrt{2}$ and lipid concentration, and the $a/\sqrt{2}$ value is more strongly dependent on the lipid concentration in the case of the latter lipid system. The $a/\sqrt{2}$ value for the QC_5Ala2C_{16} aggregate (94 Å) is slightly larger than that for the QC_5Ala2C_{14} aggregate (91 Å) at a comparable concentration; mole fraction, 0.009.

Bilayer Phase. We have previously reported that the C_{II} phase formed with QC_5Ala2C_{14} was transformed into the bilayer phase upon deprotonation of the polar head moiety as confirmed by freeze-fracture electron microscopy, differential scanning calorimetry (DSC), and turbidity measurements.[7] This behavior was further evidenced by low-angle X-ray diffraction measurements in this work. As listed in Table 1, the diffractions from the C_{II} lattice at pH 7 completely disappeared at pH 14 to give a single diffraction with a spacing of 59 Å, which corresponds to the bilayer thickness evaluated by the CPK molecular model (Fig. 1B).

The diffraction patterns originating from the C_{II} phase formed with QC_5Ala2C_{16} disappeared below T_m even at pH 7 and were replaced with two diffractions (Table 1). The stronger diffraction with a spacing of 55 Å and the relatively weak one with a spacing of 77 Å presumably correspond to the thickness of the lipid bilayer and that of the bilayer plus water layer, respectively. Formation of the bilayer phase below T_m was also confirmed by negative staining electron microscopy applied to the specimen prepared at 5 °C. We have previously suspected that QC_5Ala2C_{16} would form the nonlamellar phase even below T_m on the basis of its smaller phase transition enthalpy and a lower value of steady-state fluorescence anisotropy for DPH embedded in the aggregate below T_m as compared with the corresponding values for bilayer-forming lipids having an analogous molecular structure.[7] Now, it is concluded that the C_{II} phase formed with QC_5Ala2C_{16} above T_m is transformed through phase transition into the bilayer phase accompanied with relatively loose packing of the hydrocarbon chains in comparison with those of bilayer-forming

ionic peptide lipids.

The phase transition parameters (T_m; enthalpy change, ΔH) for the aggegates of $Q_2LysC_5Ala2C_n$ having two quinoyl moieties are 1.7 °C and 17.1 kJ mol^{-1} for n=14 and 24.9 °C and 28.0 kJ mol^{-1} for n=16, respectively, at pH 7 as evaluated by DSC. These values are comparable to those observed for other bilayer aggregates having the same double-chain segments.[6c,7] The bilayer aggregates were formed both above and below T_m as observed by electron microscopy. As shown in Figs. 3A and 3B, multiwalled bilayer aggregates are observed in the specimens of $Q_2LysC_5Ala2C_{16}$ and $Q_2LysC_5Ala2C_{14}$, respectively, which were negatively stained at 20 °C in the aqueous dispersion state. Upon sonication of these dispersions with a probe-type sonicator, single-walled bilayer vesicles in the diameter range of 200—500 Å were obtained, as confirmed by negative staining and freeze-fracture electron microscopy (Figs. 3C and 3D). The steady-state fluorescence anisotropy (r_S) of DPH embedded in the $Q_2LysC_5Ala2C_{16}$ membrane is shown in Fig. 4 (curve A) as a function of temperature. The T_m value obtained from the inflection range (24.5 °C) is in good agreement with that evaluated by DSC. When homogeneous mixtures of QC_5Ala2C_n and $Q_2LysC_5Ala2C_n$ (n=14, 16) at the 1:1 and 2:1 molar ratios were dispersed in water, formation of multiwalled bilayer aggregates was detected by negative staining electron microscopy. Thus, it became apparent that transformation of the C_{II} phase formed with QC_5Ala2C_n above T_m into the bilayer phase can be achieved by the following perturbations to reduce the v/a_0l_c value: (i)

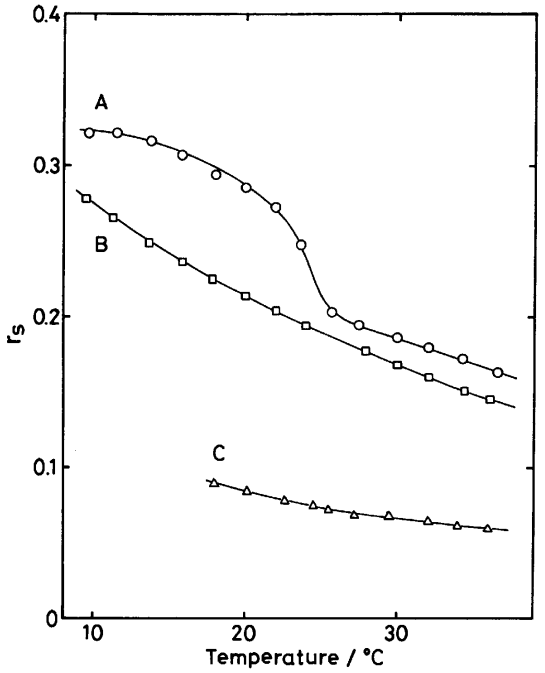

Fig. 4. Correlations of steady-state fluorescence anisotropy (r_S) with temperature for DPH (1.0×10^{-7} mol dm^{-3}) embedded in the following aggregates: A, 0.10 mmol dm^{-3} $Q_2LysC_5Ala2C_{16}$ at pH 7; B, 0.10 mmol dm^{-3} $Q_2LysC_5Ala2C_{16}$ at pH 14; C, 3.0 mmol dm^{-3} CTAB at pH 7.

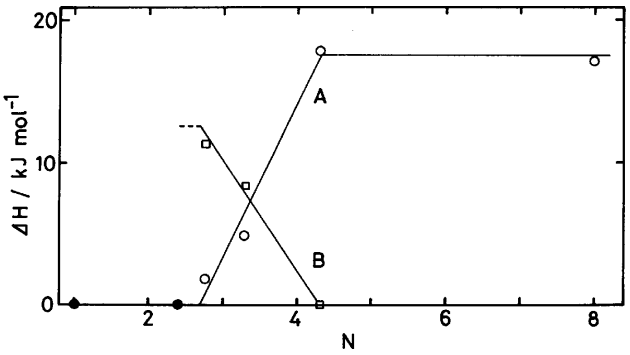

Fig. 5. Correlations of phase transition enthalpy (ΔH) with a number of hydroxyl groups per lipid molecule (N) for the aggregates formed with $(HO)C_5Ala2C_{14}$ and $Q_2LysC_5Ala2C_{14}$; total lipid concentration, 5.0 mmol dm^{-3}: A, for the phase transition peak at 1.8 °C; B, for the phase transition peak at 4.6 °C; closed circles for lipid mixtures which were not dispersed in water. The ΔH value is given for unit mol of the total lipid, regardless of morphology.

freezing of the rotational motion of the hydrophobic double-chain segment by a phase transition from the liquid-crystalline state to the gel state (decrease in v); (ii) a volume increase in the hydration shell around the polar head moiety of the lipid molecule upon deprotonation of the four hydroxyl groups (increase in a_0); and (iii) an increase in average bulkiness of the polar head moiety by incorporation of another bilayer-forming lipid (increase in a_0). In addition, it may be predicted that an increase in l_c, e.g. introduction of a longer hydrocarbon connector in between the quinoyl moiety and an amino acid residue, also causes a morphological change from C_{II} to bilayer.

Inverted Hexagonal Phase. As mentioned above, the H_{II} forming lipids may have v/a_0l_c values greater than those for the C_{II} forming lipids. We examined this criterion in this work by using the three types of nonionic peptide lipids. Since QC_5Ala2C_n forms the C_{II} phase above T_m, the individual or mixed lipid systems having a_0 values smaller than that of QC_5Ala2C_n are the candidates to form the H_{II} phase. Although accurate evaluation of the a_0 values for these peptide lipids is much difficult due to hydration of the polar head moieties, the effective bulkiness of these head moieties can be reasonably correlated with the average number of hydroxyl groups per lipid molecule (N): the N values for $(HO)C_5Ala2C_n$, QC_5Ala2C_n, and $Q_2LysC_5Ala2C_n$ are apparently 1, 4, and 8, respectively. $(HO)C_5Ala2C_n$ was not dispersed in water without coexisting lipid(s). When $(HO)C_5Ala2C_n$ and QC_5Ala2C_n were mixed at the 1 : 1, 1 : 2, and 1 : 4 molar ratios (N values are 2.5, 3.0, and 3.4, respectively), stable aqueous dispersions were not obtained even by prolonged vortex mixing.

Mixtures of $(HO)C_5Ala2C_{14}$ and $Q_2LysC_5Ala2C_{14}$ at the 1 : 1, 2 : 1, and 3 : 1 molar ratios (N values are 4.5, 3.3, and 2.8, respectively) were readily dispersed in water by vortex mixing, and turbidity of the aqueous dispersions remained unchanged at least over a week. The aggregates formed with $(HO)C_5Ala2C_{14}$ and $Q_2LysC_5Ala2C_{14}$ at the equimolar ratio showed a single phase transition at 1.8 °C, and the ΔH value was comparable to that observed for the bilayer aggregates formed with $Q_2LysC_5Ala2C_{14}$ alone (Fig. 5). The negatively stained electron micrograph showed the formation of multiwalled bilayer membranes. On the other hand, the DSC thermograms for the aggregates formed with $(HO)C_5Ala2C_{14}$ and $Q_2LysC_5Ala2C_{14}$ at the 2 : 1 and 3 : 1 molar ratios showed two phase transition peaks at 1.8 and 4.6 °C. The ΔH value for the latter peak increased as the N value was reduced, and the ΔH value for the former peak decreased concomitantly (Fig. 5). In the light of the correlations given in Fig. 5, the aggregate having T_m at 4.6 °C is referred to the H_{II} phase (above T_m) while that having T_m at 1.8 °C to the bilayer phase. In the negatively stained electron micrographs for these aggregates, three types of images, which are typical of the H_{II} phase, were observed: two kinds of striped patterns with different layer thickness and a network array of small internal aqueous compartments were observed in different areas of the specimen (Fig. 6). We evaluated these repeating distances by means of electron diffraction measurements applied to selected areas of the electron micrographs;[15] 52 and 31 Å of the repeating distances of layers (ratio, $\sqrt{3}$: 1) and 62 Å of the repeating dis-

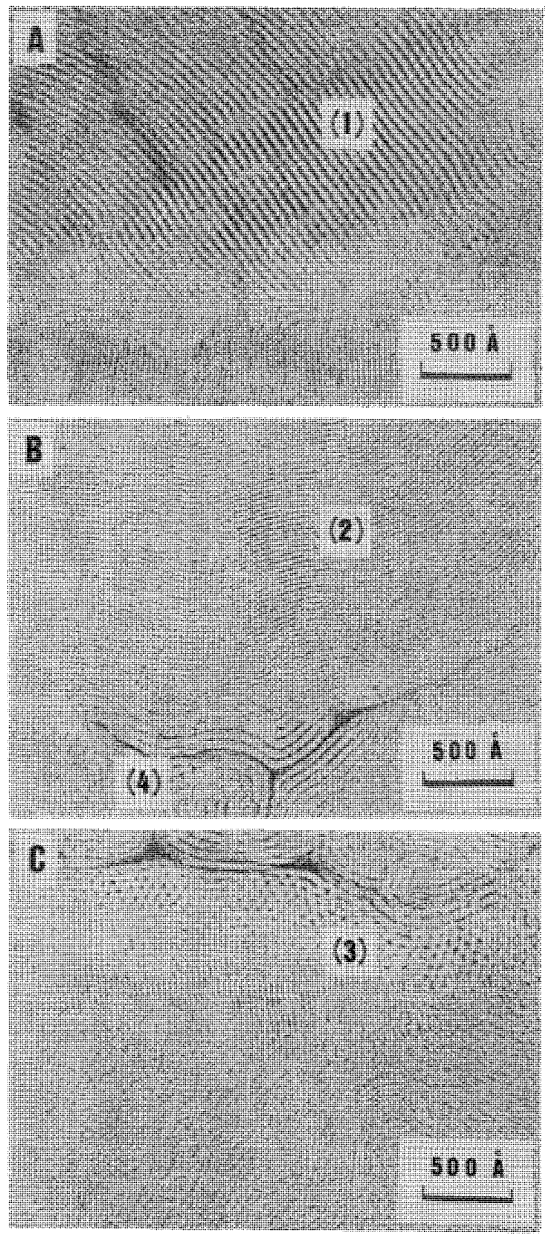

Fig. 6. Electron micrographs for a mixture of $(HO)C_5Ala2C_{14}$ (3.33 mmol dm^{-3}) and $Q_2LysC_5Ala2C_{14}$ (1.67 mmol dm^{-3}) in the aqueous dispersion state at room temperature, negatively stained with uranyl acetate. The images shown in A, B, and C were observed in different areas of the specimen. Numerals **1**, **2**, and **3** refer to three different cross sectional views of the H_{II} tubes, and **4** is attributed to the bilayer phase.

tance of aqueous compartments.[16] On these grounds, the aggregation status, which is referred to the H_{II} phase, is schematically illustrated in Fig. 7. The electron micrographic pattern, which presumably corresponds to the bilayer aggregate, was also observed in a limited area of the electron micrographs. However, it is rather difficult to distinguish between the image due to bilayer aggregates and that due to thicker layers of the H_{II} phase, since these show comparable layer thicknesses. The distinction between these aggregation states became possible by tilting the specimen in the electron microscope, as mentioned in our preliminary communication.[16] That is, the image and the corresponding electron diffraction pattern originating from one of the layers of the H_{II} phase were converted into those from the other type of layers by 30° rotation of the specimen (Fig. 8). The electron micrographic pattern showing a network array of internal aqueous compartments for the H_{II} phase resembles that for the C_{II} phase. However, the domain for the former phase is rather limited relative to that for the latter phase and surrounded by domains of the two types of layers attributable to the H_{II} phase. Fractions of the H_{II} phase in the overall aggregates were evaluated from the phase transition enthalpy; 0.7 and 0.9 for the $(HO)C_5Ala2C_{14}$-$Q_2LysC_5Ala2C_{14}$ system at the molar ratios of 2 : 1 and 3 : 1, respectively. These lipid mixtures were not dispersed in water at the N value smaller than 2.4. However, the H_{II} phase seems to be exclusively obtained at the N value below 2.7 in the light of the correlations given in Fig. 5. The mixed lipid system composed of $(HO)C_5Ala2C_{16}$ and $Q_2LysC_5Ala2C_{16}$ did not give stable aqueous dispersions at the N value smaller than 4, so that the aggregate morphology was not critically characterized.

Micellar Phase. Multiple ionization of the polar head moiety of $Q_2LysC_5Ala2C_n$ tends to expand the hydration shell around the quinoyl moieties to give an increase in a_0. As a result, the bilayer phase may be converted into the micellar one. The multiwalled bilayer aggregates formed with $Q_2LysC_5Ala2C_n$ exhibited relatively large turbidity in aqueous media, presumably due to extended aggregation of the membranes, in comparison with those formed with cationic or anionic peptide lipids. Deprotonation of the hydroxyl groups of the lipids caused turbidity decrease above pH 13. We characterized the aggregates formed at pH 14 by means of DSC, gel-filtration treatments, and fluorescence polarization measurements. The phase transition peak observed for $Q_2LysC_5Ala2C_n$ (n=14, 16) at pH 7 disappeared completely at pH 14 in the temperature range of 0—60 °C. Both dispersed and sonicated (with a probe-type sonicator at 30 W for 3 min) samples of $Q_2LysC_5Ala2C_{16}$ at pH 14 were completely eluted at the void volume on a column of Sephadex G-50 with aqueous 1 mol dm^{-3} KOH as an eluant, as monitored by a UV detector at 254 nm. Then, we adopted experiments entrapping fluorescent probes into the aggregates. When DPH (1.0×10^{-5} mol dm^{-3}) was added to the aqueous dispersion of $Q_2LysC_5Ala2C_{16}$ (1.0 mmol dm^{-3}), this hydrophobic probe was quantitatively incorporated into and remained in the aggregates even by gel-filtration treatments as confirmed by fluorescence spectroscopy. On the other hand, pyranine (1.0 mmol dm^{-3}) as a hydrophilic probe[8,17] was not incorporated at all into the aggregates of $Q_2LysC_5Ala2C_{16}$ (1.0 mmol dm^{-3}) as confirmed by gel-filtration treatments at pH 14,

regardless of the sample conditions, sonicated or dispersed. The results apparently indicate that these aggregates do not hold inner aqueous compartments.

A correlation of the r_S value due to DPH embedded in the aggregates with temperature at pH 14 is shown in Fig. 4 (curve B). Apparently, any inflection region is

Table 2. Aggregate Morphology for Synthetic Peptide Lipids in Aqueous Media

not observed. This is consistent with the formation of micelles and in good agreement with the result obtained from DSC. The critical aggregate concentration was evaluated from a correlation of the r_S value due to DPH embedded in the aggregate with the lipid concentration; 3.0×10^{-5} mol dm^{-3} for $Q_2LysC_5Ala2C_{16}$ at pH 14. It should be noted that the r_S values for the aggregates formed with $Q_2LysC_5Ala2C_{16}$ at pH 14 are much larger than those for the normal micelles composed of CTAB at various temperatures (Fig. 4, curve C) and comparable to those for the bilayer aggregates of the same lipid in the liquid crystalline state. Thus, this lipid undoubtedly forms rigid micelles in its polyanionic form. We have previously clarified that monocationic peptide amphiphiles having a hydrophobic single-chain segment form rigid cylindrical micelles by means of negative staining electron microscopy, ESR, and low-angle light scattering measurements.[18] We have also observed similar cylindrical micelles in the aqueous dispersion of $N^+C_5Ala2C_8$, having a double-chain segment shorter than those of the corresponding bilayer-forming lipids, $N^+C_5Ala2C_n$ (n=10—18).[6c] In the latter case, the aggregate morphology is controlled by modifying the v and l_c values but not the a_0 value. The aggregate structures of these various peptide amphiphiles seem to be tightened due to the intermolecular hydrogen-bonding interactions among the amino acid moieties within each aggregate.

Concluding Remarks. It became apparent that a series of synthetic peptide lipids having various numbers of hydroxyl groups in their head moieties, $(HO)C_5Ala2C_n$, QC_5Ala2C_n, and $Q_2LysC_5Ala2C_n$, adopt four kinds of aggregate morphology in aqueous media; H_{II}, C_{II}, bilayer, and micellar phases (Table 2). The difference in aggregate morphology can be well correlated with the critical packing parameter, v/a_0l_c, and the a_0 value is cited as a primary factor for controlling the morphology in the present case. The v/a_0l_c value increases in the order: micelle, bilayer, C_{II}, and H_{II} forming lipids. The a_0 value is reasonably correlated with the average number of hydroxyl groups per lipid molecule involved in the head moieties of the individual or mixed nonionic lipids. Although the polar head moieties of these nonionic lipids in the aggregated state are hydrated to a certain extent, the hydration shells of these moieties become much expanded upon deprotonation of the hydroxyl groups. The a_0 value becomes significantly larger under such conditions, and the aggregate morphology undergoes relevant transformations as a consequence. Recent rapid growth of the membrane mimetic chemistry has yielded a large number of bilayer-forming synthetic lipids. On the other hand, relevant nonbilayer-forming lipids have not been explored up to the present time, even though important aspects of such morphological status in the biomembrane fusion have been emphasized.[2] We believe that the present study provides useful molecular criteria for designing nonbilayer-forming lipids.

We are grateful to Professor Tisato Kajiyama and Dr. Kenji Yamada of Kyushu University for the X-ray diffraction measurements and Professor Toyoki Kunitake of Kyushu University for the use of a freeze-fracture device. We also thank Dr. Yoshitsugu Tomokiyo, Mr. Takeshi Manabe, and Mr. Eiji Tanaka of Kyushu University for their comments and expert technical assistance in the electron diffraction measurements. The present work was supported in part by a Grant-in-Aid for Scientific Research No. 58430016 from the Ministry of Education, Science, and Culture.

(Received October 28, 1986)

The title compounds **29** and **19** have been prepared from mycaminosyl tylonolide 9,20-bis(ethylene acetal) via 9 (for **19**) and 13 steps (for **29**). The key step in the synthesis of **19** is Baeyer-Villiger reaction applied to 2′,4′-di-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-23-deoxy-23-oxomycaminosyl tylonolide 9,20-bis(ethylene acetal), and the desired 14-*O*-formyl derivative is obtained with other products including 12,13-epoxy and 14-*C*-carboxylic acid. The key step in the synthesis of **29** is Mitsunobu reaction applied to (14*S*)-2′,4′-di-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-14-de(hydroxymethyl)-14-hydroxymycaminosyl tylonolide 9,20-bis(ethylene acetal), and the desired (14*R*)-acyloxy product is obtained by inversion at C-14, with other compounds including 10(11), 12(22),13(14)-triene and 12-acyloxy-10(11),13(14)-diene.

Several derivatives substituted at C-23 of mycaminosyl tylonolide (MT), a macrolide antibiotic, had been prepared in our laboratory; these include 23-*O*-acyl,[1] 23-deoxy-23-halo,[1] 23-dialkylamino-23-deoxy,[2,3] and 23-acylamido-23-deoxy[4] derivatives. Recently we also prepared 23-C-alkyl[3] and 23-C-alkylidene-23-deoxy derivatives[6] from a 14-C-aldehyde,[5] a key synthetic intermediate, by the reaction using Grignard and Wittig reagents. Some of these synthesized compounds showed marked antibacterial activities against Gram-negative bacteria, to which usual macrolide antibiotics have almost no activity.

Since the above derivatives were all concerned with the substitutions at C-23, we changed our attention to attach functional groups directly at C-14 with cleavage of the C(14)–C(23) bond. One reason for this transformation is that the replacement of the projecting hydroxymethyl group at C-14 with a small functional group will result in a fundamental change in antibacterial activity. In this paper we describe the syntheses of two 14-de(hydroxymethyl)-14-hydroxy derivatives (**19**, **29**) of mycaminosyl tylonolide.

Results and Discussion

Treatment of mycaminosyl tylonolide diethyl acetal[7] (**1**) with ethylene glycol in the conditions described in the Experimental section gave the 9,20-bis(ethylene acetal) **2**. Presence of a ethylene acetal fragment at C-9 was confirmed indirectly by the shift values of H-10 (δ 5.75) and H-11 (δ 6.36), which differ, respectively, from those of usual 9-keto derivatives (δ ≈6.3 and ≈7.3). Acetylation of **2** with acetic anhydride in acetonitrile[8] gave the 2′,4′-di-*O*-acetyl derivative (**3**). Treatment of **3** with *t*-butylchlorodimethylsilane in the conditions reported[5,9] gave the 3,23-bis(*O*-*t*-butyldimethylsilyl) derivative (**4**). The 23-*O*-silyl group was then selectively removed with use of limited amount of tetrabutylammonium fluoride in oxolane to afford the 3-*O*-silyl derivative (**5**). Oxidation of **5** with dimethyl sulfoxide in the presence of pyridinium trifluoroacetate and dicyclohexylcarbodiimide in a manner as reported[5,9] gave the 14-C-aldehyde (**6**).

In order to introduce an oxygen atom at C-14 with splitting of the 14-C-aldehyde group, Baeyer-Villiger reaction was examined for **6** after several kinds of unsuccessful reactions were tested. In **6**, the two carbonyl groups at C-9 and C-20 are protected and the carbonyl at C-23 remains free. For such a C-aldehyde fragment, however, successful application of Baeyer-Villiger reaction has not been described yet to our knowledge. When **6** was treated with 3 molar equivalents of *m*-chloroperbenzoic acid in chloroform, an unstable compound supposed the *N*-oxide (**7**) of **6** was first produced, then four products [**8**, **9**(trace), **10**(trace), and **11**; in the order of mobility] followed. Presence of the 3′-dimethylamino *N*-oxide group in **7** (for the isolation: see the Experimental section for **12**)

was supported by the shift value of the methyl protons of dimethylamino group (δ 3.23[10]) in the ^{1}H NMR spectrum. The minor product **8**, was presumed, according to its ^{1}H NMR spectrum, the desired product having a formyl ester at C-14 and 3′-dimethylamino *N*-oxide group. As these products were all unstable and considered to have the *N*-oxide structure, de(*N*-oxid)ation was immediately carried out. When, however, triphenylphosphine was used in the presence of acetic acid, a typical procedure for de(*N*-oxid)ation, 9-acetal group was simultaneously hydrolyzed. Thus triphenyl phosphite [$(PhO)_3P$] was attempted as the reducing agent in an inert solvent to successfully give a reaction mixture. Column chromatography of the mixture gave the desired protected 14-formyloxy derivative (**12**) in 24% yield from **5** through **6** and **8**, together with **13** (from **9**), **14** (from **10**), and **15** (from **11**). The structure of **14** is thought to be, from the nature of the reagent, the 14-C-carboxylic acid derivative formed by oxidation of **7**, but the structure remains to be studied.

The structure of **12** was determined by the ^{1}H NMR spectrum; signals for a *t*-butyldimethylsilyl, two acetyls, and two ethylene acetal groups (estimated by the signal integration between δ 3.8—4.0) were observed. The low shift value of H-14 (δ 5.49), and the accordance of $J_{13,14}$(=10 Hz) and $J_{14,15}$(=10 Hz) values with those of other MT derivatives[9,11] including **6** indicate that the aldehyde group at C-14 of **6** was replaced by a formyloxy group with retention of the configuration at C-14. Presence of the formyl group was also supported by appearance of a singlet at low field (δ 8.03).

The structure of **13** was concluded to be the 12,13-epoxy analog of **12**. In its ^{1}H NMR spectrum, H-11, H-14, Me-22, and especially H-13 (δ 3.15) showed marked upfield shifts, in comparison with those of **12**, indicating the disappearance of the double bond between C(12)-C(13). Other proton resonances showed approximate accordance with those of **12** in shift and *J* value. Considering from the reaction reagent, it is clear that the double bond was oxidized to the epoxide, with the C(10)-C(11) double bond remained intact. The structure of **13** was also supported by the UV spectrum[12] and TLC detection [**13** was inert under UV lamp (2536 Å)]. The absolute configurations around the epoxide ring could not be decided, but if the reagent approaches from the less-hindered side, 12*S*,13*S* structure is expected. This assumption was sustained by similarity of the ^{1}H NMR spectra (δ and *J* values,

especially $J_{13,14}$) between **13** and rosaramicin, a 16-membered macrolide antibiotic, which contains (12*S*, 13*S*)-12,13-epoxy structure.[13,14]

The structure of another product **15** was determined to be 12,13-epoxy-14-C-carboxylic acid by methylation with diazomethane to give the corresponding methyl ester (**16**), and the similarity of the ^{1}H NMR spectrum with that of **13** with only lacking the formyl proton signal ($\delta \approx 8$). In conclusion, on oxidation with *m*-chloroperbenzoic acid, the 14-C-aldehyde (**6**) was majorly converted to the 12,13-epoxy-14-C-carboxylic acid (**15**), but Baeyer-Villiger reaction also did occur to give the desired 14-*O*-formyl product **12**.

Treatment of **12** in hot methanol removed the acetyl and formyl groups to give **17**, which, on acetylation with acetic anhydride in acetonitrile, gave the 2′,4′-di-*O*-acetyl derivative (**18**). The configuration at C-14 of **18** was determined by the NOE experiment, in that 10% enhancement of H-14 was observed[11] on irradiation of Me-22. This result also supported the structure of **12**.

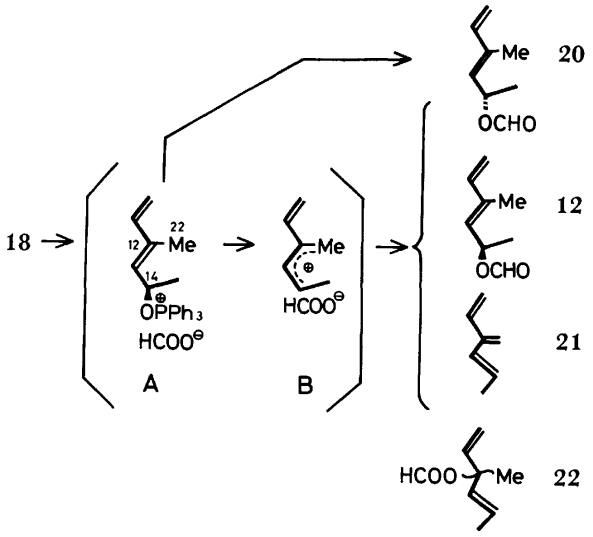
Removal of the silyl and acetal groups of **17** with tetrabutylammonium fluoride in oxolane, and acidic treatment followed gave the desired (14*S*)-14-hydroxy compound (**19**). It is noteworthy that **19** was stably obtained under acidic conditions but the corresponding (14*R*)-14-hydroxy compound (**29**) later mentioned was unstable and converted into several products by the same treatment.

Next, inversion of configuration of the hydroxyl group at C-14 of **19** was attempted to obtain the 14*R* isomer **29**. At first, several substitution reactions were tried for the 14-*O*-sulfonyl derivatives of **18**, but only fruitless results were obtained. Attempt to oxidize **18** to the 14-carbonyl derivative, followed by reduction with sodium borohydride to obtain the 14*R* alcohol, also failed only giving **21** (see later). When, however, Mitsunobu reaction[15] was appled to **18** in benzene in the presence of formic acid, the (14*R*)-formyloxy derivative (**20**) was obtained in a moderate yield (≈50%) with other products (**21** and **22**). Comparison of the ^{1}H NMR spectra of **20** and **12** (14*S* isomer of **20**) showed that there were marked differences in the shift and *J* values between them in relation to H-14 (**20**: δ 5.82, $J_{13,14}$=6, $J_{14,15}$=2.5 Hz; **12**: δ 5.49, $J_{13,14}$=$J_{14,15}$=10 Hz). The lower shift of H-14 of **20** indicates that the H-14 is pseudoequatorial for the average macrolactone plane, and this is in accord with the small *J* values showing the gauche relationships between H-14 and H-13, and H-14 and H-15.

In the ^{1}H NMR spectrum of the by-product **21**, the signal of Me-22 (δ 1.73) of **18** disappeared, and, instead, a pair of small doublet (H-22a,b), typical for a terminal methylene, appeared at low field (δ 5.00 and 5.07). The proton of H-14 also resonated at low field (δ 5.57) and coupled with H-13 (δ 6.34, $J_{13,14}$=15.5 Hz) and H-15 ($J_{14,15}$=7.5 Hz). These results indicate that **21** has a *trans, trans*-10,11 : 13,14-dieno-12-C-methylene struc-

ture. The structure of **21** was also confirmed by the ^{1}H NMR spectrum (and the ^{1}H shift-correlated 2D spectrum) of the deacetyl derivative (**24**).

The second by-product **22** in Mitsunobu reaction seems to have a similar structure with that of **21**, because both compounds had almost the same J values relating to $J_{10,11}$, $J_{13,14}$, and $J_{14,15}$. However, in **22**, Me-22 appeared as a singlet at δ 1.62 (**21** has a 22-methylene), the shift being different from the usual value ($\delta \approx 1.8$), and a formyl proton (δ 8.05) was observed. These results indicate that compound **22** is 12-formyloxy-10,11 : 13,14-diene. The reaction mechanism will be that the 14-*O*-phosphonic intermediate[15] (A) of **18** born during Mitsunobu reaction detaches the phosphoniooxy portion to give the intermediate (B) and it



was converted to **20** (and **12**), **21**, and **22** by the action of the formate anion attacked at C-14, H-22, and C-12, respectively. Direct pathway from A to **20** is also considered. The absolute configuration at C-12 of **22**, however, remained undetermined. Disappointingly treatment of **22** and **24** with methanol or 0.1 mol dm^{-3} hydrochloric acid in water-acetonitrile (10 : 1) gave, respectively, a complex mixture indicating there is no hope to obtain the corresponding deblocked derivatives. Deacylation of **20** with methanol (to give **23**) followed by 2′,4′-di-*O*-acetylation gave **25**. In the ^{1}H NMR experiment, no NOE between H-14 and Me-22 was observed supporting indirectly the strucure of **25** and therefore **20**. Unexpectedly deblocking of **23** in an acidic medium to obtain **29** gave a complex mixture. This suggests that the presence of the (14*R*)-hydroxyl group of **23**, unlike the (14*S*)-hydroxyl, make the compound labile against acid. Therefore we intended to change the unstable 14-*O*-formyl group of **20** into an acid-stable *O*-acetyl group. Thus Mitsunobu reaction was carried out on **18** in the presence of acetic acid, whereupon the (14*R*)-acetoxy derivative (**26**) was obtained with **21** and the acetyl congener (**27**) of **22**. Successive treatment of **26** with methanol (to give the 2′,4′-diol derivative), tetrabutylammonium fluoride in oxolane (to remove the silyl group), and hydrochloric acid in aqueous acetonitrile (to remove acetal groups) gave the 14-*O*-acetyl derivative (**28**), all other protecting groups being removed. Finally, basic treatment (NH_3 in aq acetonitrile) of **28** gave the desired product (**29**).

The compound **19** exhibited almost the same or slightly better antibacterial activity in comparison with that of MT, whereas **29** had much weaker activity (see Experimental). Although these two compounds showed no characteristic antibacterial activity, some of the derivatives prepared from them showed remarkable antibacterial activity, which will be reported in another paper.[16] Therefore **19** and **29** will serve as useful compounds, instead of MT, for preparation of new types of macrolides.

Experimental

General. Optical rotations were measured with a Perkin-Elmer 241 polarimeter. Thin-layer chromatography (TLC) was carried out on Kieselgel 60 F-254 (E. Merck) silica gel with detection by spraying with sulfuric acid, followed by slight heating. Column chromatography was performed on Wakogel C-200 or Kieselgel 60, 230—400 mesh (E. Merck). ^{1}H NMR spectra were recorded at 250 MHz with a Bruker WM 250 spectometer.

Mycaminosyl Tylonolide 9,20-Bis(ethylene acetal) (2). A flask containing **1**[11] (38.5 g), ethylene glycol (37 ml), pyridinium *p*-toluenesulfonate (18 g), *p*-toluenesulfonic acid (5.7 g of monohydrate was dried at 100 °C in vacuo for 1 h), sulfolane (200 ml), and benzene (800 ml) was connected to a Soxhlet-type extractor[17] filled with molecular sieves 4A (250 ml, activated at 220 °C under a stream of nitrogen) with a reflux condenser, and the mixture was refluxed for 48 h. On TLC with chloroform-methanol-28% aqueous ammonia (10 : 1 : 0.1), the solution showed spots at R_f 0.3 (**2**, major) and R_f 0.25 (trace; cf. **1**: R_f 0.3). The mixture was poured into an ice-cold, half-saturated aqueous sodium hydrogencarbonate solution (1 L), and extracted with chloroform (1 L×3). The organic solution was washed with aqueous sodium sulfate (saturated, 1 L), dried (Na_2SO_4), and concentrated. The residue was again extracted with benzene (2 L) and the organic solution was washed with aqueous sodium sulfate (saturated, 0.7 L×3), dried (Na_2SO_4), and concentrated. The residue was chromatographed on a silica-gel column with chloroform-methanol-28% aqueous ammonia (25 : 1 : 0.1) to give a solid of **2**, 24.4 g (62%), $[\alpha]_D^{20}$ +13° (*c* 1, chloroform); ^{1}H NMR ($CDCl_3$) δ=2.50 (6H, s, NMe_2), 4.31 (1H, d, $J_{1',2'}$=7.5 Hz, H-1′), 5.30 (1H, d, H-13), 5.75 (1H, d, H-10), 6.36 (1H, d, H-11).

Found: C, 60.48; H, 8.46; N, 1.88%. Calcd for $C_{35}H_{59}NO_{12} \cdot 1/2H_2O$: C, 60.52; H, 8.65; N, 2.02%.

2′,4′-Di-*O*-acetylmycaminosyl Tylonolide 9,20-Bis(ethylene acetal) (3). A solution of **2** (17.2 g) and acetic anhydride (5.6 g) in acetonitrile (172 ml) was kept at room temperature overnight. Evaporation with several additions of toluene gave a residue, that was extracted with benzene, and the organic solution was washed with aqueous sodium hydrogencarbonate (saturated), dried (Na_2SO_4), and concentrated to give a solid of **3**, 17.4 g (90%), $[\alpha]_D^{20}$ -17° (*c* 1, chloroform);

^{1}H NMR ($CDCl_3$) δ=2.01 and 2.05 (each 3H, s, Ac ×2), 2.34 (6H, s, NMe_2), 2.77 (1H, t, $J_{2',3'}=J_{3',4'}$=10 Hz, H-3'), 4.65 (1H, d, $J_{1',2'}$=7.5 Hz, H-1'), 4.76 (1H, t, H-4'), 4.95 (1H, dd, H-2'), 5.34 (1H, d, $J_{13,14}$=10 Hz, H-13), 5.70 (1H, d, $J_{10,11}$=16 Hz, H-10), 6.39 (1H, d, H-11).

Found: C, 60.69; H, 8.02; N, 1.94%. Calcd for $C_{39}H_{63}NO_{14}$: C, 60.86; H, 8.19; N, 1.82%.

2',4'-Di-*O*-acetyl-3,23-bis(*O*-*t*-butyldimethylsilyl)mycaminosyl Tylonolide 9,20-Bis(ethylene acetal) (4). A mixture of **3** (17.4 g), imidazole (9.2 g), and *t*-butylchlorodimethylsilane (17 g) in *N*,*N*-dimethylformamide (140 ml) was heated at 80 °C for 9 h. Evaporation with several additions of xylene gave a residue, that was extracted with benzene. The solution was washed with aqueous sodium hydrogencarbonate (saturated), aqueous sodium sulfate (saturated), dried (Na_2SO_4), and concentrated to give a solid of **4**, 22 g (97%). An analytical sample was obtained by column chromatography with toluene-ethyl acetate (4:1), $[\alpha]_D^{20}$ −58° (*c* 1, chloroform); ^{1}H NMR ($CDCl_3$) δ=0.01, 0.02, 0.03, and 0.13 (each 3H, s, $SiMe_2$×2), 0.87 and 0.89 (each 9H, s, Si-Bu^t ×2), 1.71 (3H, s, Me-22), 2.05 and 2.06 (each 3H, s, Ac ×2), 2.35 (6H, s, NMe_2), 2.72 (1H, t, H-3'), 4.45 (1H, d, H-1'), 4.76 (1H, t, H-4'), 4.90 (2H, H-2',15), 5.37 (1H, d, H-13), 5.55 (1H, d, H-10), 6.34 (1H, d, H-11).

Found: C, 61.55; H, 8.88; N, 1.66%. Calcd for $C_{51}H_{91}NO_{14}Si_2$: C, 61.38; H, 9.13; N, 1.40%.

2',4'-Di-*O*-acetyl-3-*O*-(*t*-butyldimethylsilyl)mycaminosyl Tylonolide 9,20-Bis(ethylene acetal) (5). To an ice-cold solution of **4** (22 g) in oxolane (220 ml) was added a 1 mol dm^{-3} solution (20 ml) of tetrabutylammonium fluoride (1 molar equivalent for **4**) in oxolane, and the solution was kept at room temperature for 2 h. On checking by TLC with toluene-ethyl acetate (2:1), the solution showed a major spot at R_f 0.27. Evaporation gave a residue, that was extracted with benzene. The organic solution was then treated in a manner as described for **4**, to give, after column chromatography with toluene-ethyl acetate (1:1→1:2, gradually changed), a solid of **5**, 16 g (82%), $[\alpha]_D^{20}$ −54° (*c* 1, chloroform); ^{1}H NMR ($CDCl_3$): δ=0.02 and 0.15 (each 3H, s, $SiMe_2$), 0.89 (9H, s, Si-Bu^t), 0.94 (3H, t, Me-17), 1.75 (3H, s, Me-22), 2.05 and 2.06 (each 3H, s, Ac ×2), 2.34 (6H, s, NMe_2), 2.74 (1H, t, H-3'), 2.79 (1H, m, H-14), 4.44 (1H, d, H-1'), 4.76 (1H, t, H-4'), 4.87 (1H, dt, $J_{14,15}=J_{15,16a}$=10, $J_{15,16b}$=3 Hz, H-15), 4.90 (1H, dd, H-2'), 5.36 (1H, d, $J_{13,14}$=10 Hz, H-13), 5.60 (1H, d, H-10), 6.39 (1H, d, H-11).

Found: C, 60.76; H, 8.58; N, 1.57%. Calcd for $C_{45}H_{77}NO_{14}Si$: C, 61.15; H, 8.72; N, 1.58%.

(14*S*)-2',4'-Di-*O*-acetyl-3-*O*-(*t*-butyldimethylsilyl)-14-de(hydroxymethyl)-14-(formyloxy)mycaminosyl Tylonolide 9,20-Bis(ethylene acetal) (12). A solution of **5** (5.02 g), pyridinium trifluoroacetate (1.67 g), and dicyclohexylcarbodiimide (2.37 g) in dry DMSO-benzene (1:1, 50 ml) was stirred at room temperature overnight, then poured into 1,4-dioxane (20 ml) containing oxalic acid dihydrate (1 g). Precipitates occured were filtered off with aid of benzene. The filtered solutions were concentrated, and the residue was extracted with benzene. The extracts were washed as described for **4**, and concentrated. The residual syrup, that showed on TLC with toluene-ethyl acetate (2:1) a single spot at R_f 0.42, was passed through a short column with toluene-ethyl acetate (3:1) to give an unstable solid of **6**, 4.7g. ^{1}H NMR ($CDCl_3$ at 90 MHz) δ=0.90 (9H, s, Si-Bu^t), 1.80 (3H, s, Me-22), 2.07 (6H, s, Ac ×2), 2.38 (6H, s, NMe_2), 3.65 (1H, dt, $J_{13,14}=J_{14,15}$=10 Hz, H-14), 4.47 (1H, d, H-1'), 5.40 (1H, d, H-13), 5.72 (1H, d, H-10), 6.43 (1H, d, H-11), 9.67 (1H, d, $J_{14,23}$=2.8 Hz, H-23).

To a solution of the solid in chloroform (90 ml) were added powdered sodium hydrogencarbonate (1.4 g) and *m*-chloroperbenzoic acid (3.01 g), and the mixture was stirred at room temperature for 3 h. On checking by TLC with chloroform-methanol (5:1), the solution just after the reaction started showed a single spot at R_f 0.46 (**7**; cf. **6**: R_f 0.91; **7** could be isolated by stopping the reaction within 5 min and succeeding prompt purification), and after 3 h, four spots at R_f 0.2 (major, non-sensitive to UV light, **11**), 0.35 (trace, **10**), 0.45 (trace, non-sensitive to UV light, **9**), and 0.53 (minor, **8**). After addition of chloroform (500 ml), the organic solution was washed with aqueous sodium sulfate (saturated), dried (Na_2SO_4), and concentrated to give an unstable mixture of products (≈4.6 g). In a run, **8** was isolated, though in a poor yield, by column chromatography with chloroform-methanol (9:1); ^{1}H NMR ($CDCl_3$) δ=0.04 and 0.12 (each 3H, s, $SiMe_2$), 0.86 (9H, s, Si-Bu^t), 1.87 (3H, s, Me-22), 2.09 and 2.12 (each 3H, s, Ac ×2), 3.23 (6H, s, N(O)Me_2), ≈5.02 (H-15), 5.37 (1H, d, $J_{13,14}$=10 Hz, H-13), ≈5.48 (1H, t, $J_{14,15}$=10 Hz, H-14), ≈5.69 (1H, d, $J_{10,11}$=16 Hz, H-10), 6.27 (1H, d, H-11), 8.04 (1H, s, OCHO).

To an ice-cold solution of the product mixture in toluene (46 ml) was added triphenyl phosphite (4.2 ml) and the solution kept at room temperature overnight. On checking by TLC with previous developing system, all the spots of the starting products disappeared with appearance of spots with larger R_f values, respectively, and with toluene-ethyl acetate (1:1), well-separated four spots of R_f 0.05 (major, **15**), 0.13 (trace, **14**), 0.55 (trace, **13**), and 0.68 (minor, **12**) appeared. Concentration of the reaction mixture gave a product mixture, that was separated by column chromatography with toluene-ethyl acetate (3:1→2:1) to give solids of **12**, 1.22 g (24%) and **13**, 0.28 g (5%). On subsequent change of the developing systems to chloroform-acetone (3:1) and then chloroform-methanol (5:1), solids of **14**, 0.28 g (5.5%) and **15**, 2.15 g (41%) were obtained, respectively.

(14*S*)-14-De(hydroxymethyl)-14-hydroxymycaminosyl Tylonolide (19). To a solution of **17** (57.8 mg) in oxolane (1 ml) was added a 1 mol dm^{-3} oxolane solution (0.22 ml) of tetrabutylammonium fluoride, and the solution was kept at room temperature overnight. Concentration gave a residue, that was extracted with chloroform. The organic solution was washed with aqueous sodium sulfate (saturated), dried (Na_2SO_4), and concentrated. To the residual syrup in acetonitrile (0.3 ml) was added 0.1 mol dm^{-3} aqueous hydrochloric acid (2.9 ml) and the solution was kept at room temperature overnight. TLC of the solution with chloroform-methanol-28% aqueous ammonia (10:1:0.1) showed a single spot at R_f 0.25 (**19**). After neutralization with excess sodium hydrogencarbonate, the reaction mixture was extracted with chloroform. The obtained product was purified by a short column with chloroform-methanol-28% aqueous ammonia (15:1:0.1) to give a solid of **19**, 35.7 mg (83%), $[\alpha]_D^{20}$ −24° (*c* 1, chloroform); ^1H NMR ($CDCl_3$) δ=0.97 (3H, t, Me-17), 1.02 (3H, d, Me-18), 1.22 (3H, d, Me-21), 1.27 (3H, d, Me-6′), 1.83 (3H, s, Me-22), 2.36 (1H, t, $J_{2',3'}$=$J_{3',4'}$=10 Hz, H-3′), 2.50 (6H, s, NMe_2), 3.06 (1H, t, H-4′), 3.48 (1H, dd, H-2′), 4.25 (1H, d, H-1′), 4.45 (1H, t, $J_{13,14}$=$J_{14,15}$=9 Hz, H-14), 4.84 (1H, dt, $J_{15,16a}$=9, $J_{15,16b}$=3 Hz, H-15), 5.83 (1H, d, H-13), 6.34 (1H, d, H-10), 7.30 (1H, d, H-11), 9.70 (1l, s, H-20).

(14*R*)-14-Acetoxy-2',4'-di-*O*-acetyl-3-*O*-*t*-butyldimethylsilyl-14-de(hydroxymethyl)mycaminosyl Tylonolide 9,20-Bis(ethylene acetal) (26). To a cold (5 °C) solution of **18** (100 mg) and triphenylphosphine (70 mg) in benzene (1 ml) were added diethyl azodicarboxylate (41 μl) and acetic acid (16 μl) and the solution was stirred at room temperature for 1 h. TLC of the resulting solution with toluene–ethyl acetate (2 : 1) showed three spots at R_f 0.52 (**21**), 0.44 (**26**), and 0.34 (**27**). Work-up as described for **20** gave **26**, 72 mg (65%), $[\alpha]_D^{23}$ −38° (*c* 1, chloroform); ^{1}H NMR ($CDCl_3$) δ=0.96 (9H, s, Si-Bu^t), 1.83 (3H, s, Me-22), 2.05 and 2.06 (each 3H, s, Ac ×2), 2.15 (3H, s, AcO-14), 2.35 (6H, s, NMe_2), 4.50 (1H, d, H-1'), 4.80 (1H, t, H-4'), 4.93 (1H, dd, H-2'), 5.23 (1H, d, $J_{13,14}$=6 Hz, H-13), 5.26 (1H, dq, $J_{14,15}$=2.5, $J_{15,16a}$=6, $J_{15,16b}$=9 Hz, H-15), 5.48 (1H, d, H-10), 5.75 (1H, dd, H-14), 6.26 (1H, d, H-11).

Found: C, 60.84; H, 8.36; N, 1.33%. Calcd for $C_{46}H_{77}NO_{15}Si$: C, 60.59; H, 8.45; N, 1.54%.

(14*R*)-14-Acetoxy-14-de(hydroxymethyl)mycaminosyl Tylonolide (28). A solution of **26** (61 mg) in methanol (1 ml) was heated at 37 °C overnight. Evaporation gave a residue, that was chromatographed on a column with chloroform–methanol–28% aqueous ammonia (30 : 1 : 0.1) to give a solid. A solution of the solid and a 1 mol dm^{-3} oxolane solution (0.2 ml) of tetrabutylammonium fluoride in oxolane (1 ml) was kept at room temperature for 3 h. Usual work-up gave a syrup, that was dissolved in acetonitrile (0.25 ml). After addition of 0.1 mol dm^{-3} hydrochloric acid (1 ml), the solution was kept at room temperature for 6 h. After usual work-up, the syrup obtained was chromatographed on a column with chloroform–methanol–28% aqueous ammonia (25 : 1 : 0.1) to give a solid of **28**, 23 mg (41%). $[\alpha]_D^{20}$ −64° (*c* 1, chloroform); ^{1}H NMR ($CDCl_3$) δ=0.92 (3H, t, Me-17), 1.05 (3H, d, Me-18), 1.21 (3H, d, Me-21), 1.26 (3H, d, Me-6'), 1.93 (3H, s, Me-22), 2.16 (3H, s, AcO-14), 2.35 (1H, t, H-3'), 2.50 (6H, s, NMe_2), 3.06 (1H, t, H-4'), 3.51 (1H, dd, H-2'), 4.26 (1H, d, H-1'), 5.21 (1H, dq, $J_{14,15}$=2.5, $J_{15,16a}$=6, $J_{15,16b}$=9 Hz, H-15), 5.67 (1H, dd, $J_{13,14}$=6.5 Hz, H-14), 5.75 (1H, d, H-13), 6.34 (1H, d, $J_{10,11}$=16 Hz, H-10), 7.16 (1H, d, H-11), 9.71 (1H, s, H-20).

Cycloaddition of Pyridinium Methylides with Electron-Deficient Olefins and Silica-Gel Mediated Elimination of Pyridines from the Cycloadducts: A New Method of Alkylation or Hydroalkylidenation of Olefins

Otohiko TSUGE,* Shuji KANEMASA, and Shigeori TAKENAKA
Research Institute of Industrial Science, and Department of Molecular Science and Technology, Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, Kasugakoen, Kasuga 816
(Received October 28, 1986)

Pyridinium methylides bearing an anion-stabilizing substituent at the ylide carbon react with a variety of olefins carrying two electron-withdrawing groups at the both carbons such as *N*-substituted maleimides, a citraconimide, dimethyl maleate, dimethyl fumarate, and 1,2-dibenzoylethene. The cycloadducts thus formed undergo a ready elimination of pyridines when treated with silica gel. This sequence is a new method for alkylation or hydroalkylidenation of olefins.

Heteroaromatic nitrogen ylides are readily accessible by the general procedure of *N*-alkylation of nitrogen-containing aromatic heterocycles and subsequent deprotonation with a base.[1] These ylides show high reactivity to a wide variety of olefins which are activated by electron-withdrawing substituents.[2] As a result, a fused pyrrolidine ring is added to the heterocycles and this cycloaddition reaction takes place in a highly stereo-, regioselective, and stereospecific manner.[2]

In the cycloaddition step, heteroaromatic ring of the ylides loses its aromaticity. Accordingly, the cycloadducts produced are often rather labile so as to undergo either a thermal retro cycloaddition going back to the ylides and olefins or a carbon-carbon bond cleavage into betaines.[2a,b] These reversible processes become visible only when they are accompanied by some further conversions leading to thermodynamically more stable compounds. A novel fragmentation reaction of the cycloadducts of pyridinium methylides via such betaine intermediates has been recently demonstrated.[3,4]

The present paper describes silica-gel mediated elimination reaction of pyridines from the olefin cycloadducts of pyridinium methylides. Part of the present results was previously reported as a preliminary communication.[4]

Results and Discussion

Pyridinium methylides bearing an anion-stabilizing group W such as benzoyl, 2-furoyl, acetyl, methoxy- and ethoxycarbonyl, cyano, or *p*-nitrophenyl moiety are easily generated in situ by treatment of the corresponding 1-alkylpyridinium halides with such a weak base as triethylamine. If a maleimide as a reactive olefinic dipolarophile is present, the pyridinium methylides are captured by the maleimide as soon as they are generated to give stereoselective cycloadducts **1**—**9** all in quantitative yields (Scheme 1).[2a]

These cycloadducts have quite different stability in an aprotic and a protic solvent. At room temperature in dry aprotic solvents such as benzene, toluene, dichloromethane, chloroform, tetrahydrofuran, and dimethyl sulfoxide, they stay stable. When warmed at 50—60 °C, they started to decompose slowly and changed into a mixture of complex and unidentified products after a long heating.[5] On the other hand, when heated under reflux in ethanol or treated with a catalytic amount of acetic acid in chloroform at room temperature, **1** underwent a clean decomposition leading to **10**. Use of strong acids such as hydrogen chloride, *p*-toluenesulfonic acid, trifluoroacetic acid, and titanium(IV) chloride, however, led to complex mixture of products. The most effective method of all employed so far is to treat the crude cycloadduct of **1** with silica gel in a glass column.

The procedure is very simple as shown below: A mixture of 1-phenacylpyridinium bromide and *N*-methylmaleimide in chloroform was treated with triethylamine (each 1 equivalent). After 10 min at room temperature, the mixture was poured into ice water and extracted in dichloromethane. The crude cycloadduct **1** thus obtained was charged in a silica-gel

a) These cycloadducts were isolated when crude mixture from the cycloaddition was washed with water and then the dried solvent was evaporated in vacuo. b) These products were obtained when the crude cycloaddition product was subjected to a silica-gel chromatography or treated with acetic acid. The yields are all based on maleimides. c) CF: chloroform; DCM: dichloromethane; DMSO: dimethyl sulfoxide. d) S: silica-gel chromatography; A: treatment with acetic acid.

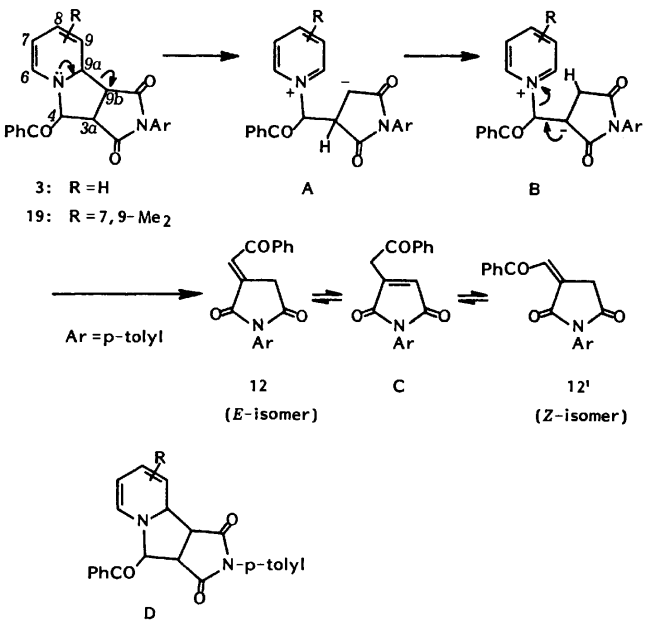
column and then eluted with chloroform to give a single product **10** in 86% yield.

The product **10** was assigned as (*E*)-3-benzoylmethylene-1-methyl-2,5-pyrrolidinedione on the basis of spectral data as well as elemental analysis. The E-geometry of olefin part of **10** was based on low chemical shifts of both the 4-methylene hydrogens (3.76 ppm) and the olefinic hydrogen (7.94 ppm), compared with those (4-H: 3.47 ppm; $=CH_2$: 5.70 and 6.43 ppm) of 3-methylene-1-(*p*-tolyl)-2,5-pyrrolidinedione (*N*-(*p*-tolyl)itaconimide).[3a]

The other cycloadducts **2—9** underwent similar silica gel-mediated elimination of pyridine to afford derivatives of itaconimides **11—18** (Scheme 1 and Table 1).

Scheme 2 illustrates a possible mechanism: The cycloadduct **3** as an example undergoes a reversible cleavage at the 9a,9b-bond into betaine intermediate **A**. This transformation is driven by the recovery of aromaticity. A 1,2-proton migration into **B** is followed by the β-elimination of pyridine to give itaconimide **12**.

The exclusive formation of (*E*)-itaconimide **12** was previously explained by a stereoselective elimination route from the sterically defined cycloadduct **3**.[4] However, this mechanism should be now renewed on the basis of the following observations: 1) 3-Methylene-1-(*p*-tolyl)pyrrolidine-2,5-dione (*N*-(*p*-tolyl)-itaconimide) readily isomerizes into 3-methyl-1-(*p*-tolyl)-3-pyrroline-2,5-dione (*N*-(*p*-tolyl)citraconimide) on treatment with triethylamine;[3a] 2) 4-Methyl derivative of **12** (or **12'**) is so unstable that it is isolated in a structure of 3,4-disubstituted 3-pyrroline-2,5-dione (see compound **39** in Scheme 5); 3) No isomerization occurs on treatment of **12** with butyllithium in THF.[6] Thus, the selective formation of (*E*)-itaconimide **12** has presumably resulted from the thermodynamic stability of



Scheme 2.

12 over either of its *Z*-isomer **12'** or citraconimide **C** (Scheme 2).[7]

Electron-donating substituents on the pyridine nucleus of cycloadducts were found to facilitate the elimination reaction of pyridines. For example, cycloadduct **19** bearing two methyls at the 7- and 9-positions underwent a quick elimination leading to **12** when chromatographed over silica gel.[8] However, cycloadducts **D** bearing an electron-withdrawing substituent (R is 8-CN, 7- or 9-CF_3, and 7- or 9-COOMe) were recovered unchanged under similar conditions. Presumably, the reversible 9a,9b-bond cleavage into betaine **A** was facilitated by the electron-donating substituents (Scheme 2).

Table 2. Reaction of Pyridinium Methylides with Acyclic Olefinic Dipolarophiles Leading to **20**—**23**[a)]

Pyridinium methylide $Py^{+}-\bar{C}H_2-W$ W	Olefin	Reaction conditions	Product	Yield/%[b)]

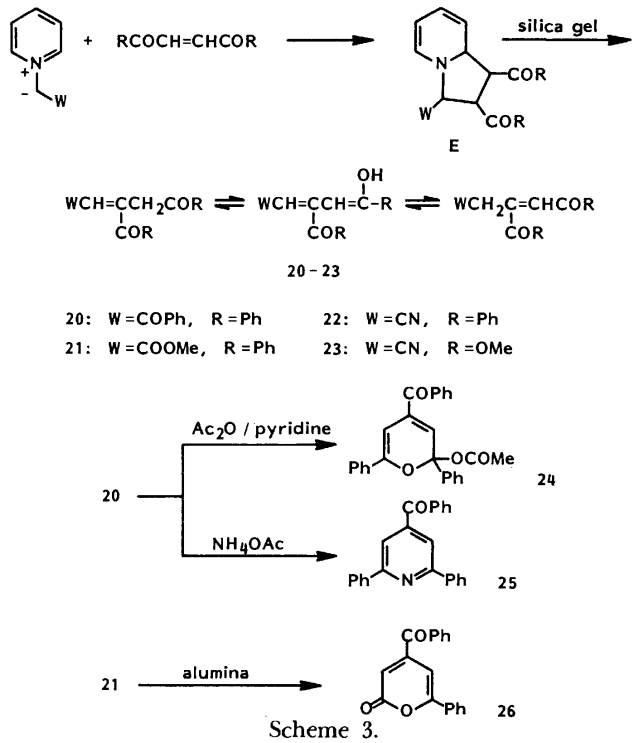
a) After the cycloaddition was over, the crude reaction mixture was chromatographed over silica gel by using chloroform or benzene as an eluent. b) All isolated yields based on the olefin.

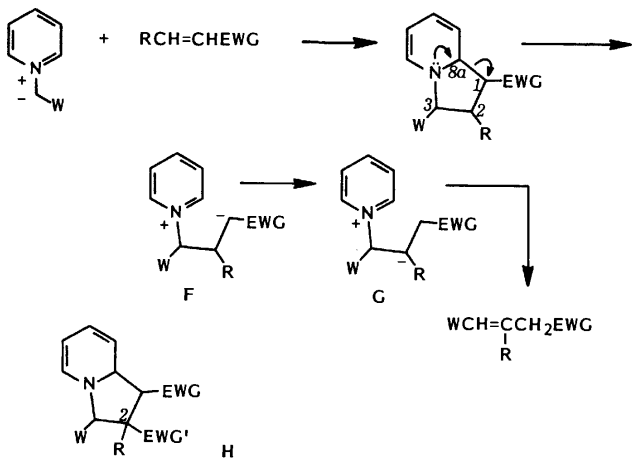
Reactions of pyridinium methylides with acyclic olefins such as (*E*)- and (*Z*)-1,2-dibenzoylethene and dimethyl fumarate and maleate formed unstable cycloadducts **E** which could not be isolated in pure forms. During the usual work-up or chromatographic operation on silica gel, the cycloadducts **E** eliminated pyridine to give olefins **20**—**23** (Scheme 3 and Table 2).

These products **20**—**22** were not single isomers but mixtures of several isomers and/or tautomers. As **20**—**22** belong to allyl systems bearing strongly electron-withdrawing substituents at every carbon, the stable structure of **20**—**22** depends upon the polarity of solvent in which they are dissolved. For example, **20** mainly takes propene structures (mixture of *E*- and *Z*-isomers) in chloroform, while 1,3-butadien-1-ol structure as an enol form is a major contributor in dimethyl sulfoxide. When electron-withdrawing property of the substituents is decreased, isomeric purity is increased as seen in the case of **23** which exclusively exists in one isomer form of propene structure, dimethyl 3-cyanopropene-1,2-dicarboxylate, in its chloroform solution.



Scheme 3.

Treatment of **20** with acetic anhydride in the presence of a catalytic amount of pyridine gave 2-acetoxy-4-benzoyl-2,6-diphenyl-2*H*-pyran (**24**) (Scheme 3). With ammonium acetate at room temperature, 4-benzoyl-2,6-diphenylpyridine (**25**) was obtained. The latter pyridine formation foregone by the ylide cycloaddition and the pyridine elimination presumably corresponds to a sequence of reactions which are involved in the pyridine synthesis discovered by Kröhnke.[9] The ester group of **21** participated in a lactonization leading to 4-benzoyl-6-phenyl-2*H*-pyran-2-one (**26**) on its chromatography on alumina.



Scheme 4.

Since only olefins activated by electron-withdrawing moiety (EWG) can be successfully employed in the cycloaddition with pyridinium methylides, the cycloadducts carry an EWG at the 1-position (Scheme 4). Accordingly, every cycloadduct has a chance to undergo the 1,9a-bond cleavage leading to betaine **F**. When R is an anion-stabilizing moiety, 1,2-proton migration of **F** occurs to form another betaine **G** which is an inevitable intermediate in the pyridine elimination reaction. This means that the cycloaddition and pyridine elimination sequence can be performed only by use of the olefins in which the both olefinic carbons are attached by electron-withdrawing substituents. If

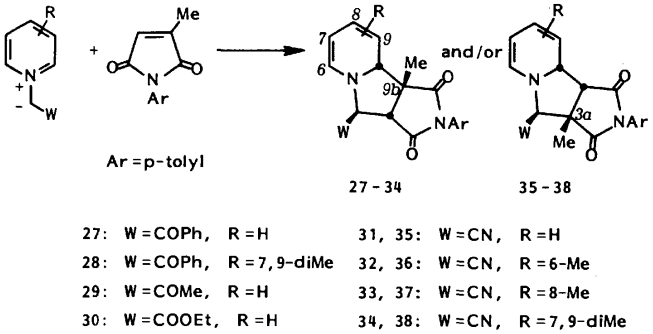
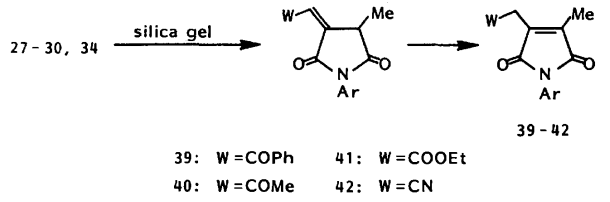
the 2-position of cycloadduct is occupied by two substituents EWG′ and R as shown in **H**, such elimination should become impossible.





Scheme 5.

N-(*p*-Tolyl)citraconimide was allowed to react with a variety of pyridinium methylides (Scheme 5). When W is a bulky electron-withdrawing substituent such as benzoyl, acetyl, or methoxycarbonyl, single isomers of cycloadducts **27—30** were only produced. They were assigned as endo cycloadducts to the anti form of ylides with the methyl moiety at the 9b-position.[2b] On the other hand, when W is sterically small in size (W is CN), mixtures of two regioisomeric cycloadducts **31—34**+**35—38** were formed. Major regioisomers **35—38** carry the methyl moiety at the 3a-exo position.

The regioisomers with 9b-methyl were found to undergo a similar pyridine elimination when treated with silica gel. Thus, **27—30** and **34** were passed through a silica-gel column to give 3-methyl-4-(substituted methyl)-1-(*p*-tolyl)-3-pyrroline-2,5-diones **34—42**, respectively (Scheme 5 and Table 3). Exclusive isolation of **39—42** was presumably due to the ready isomerization of the intermediary 3-alkylidenepyrrolidine-2,5-diones under the reaction or work-up conditions.

As expected, such pyridine elimination reaction did not occur on the other regioisomers **35—38** bearing 3a-methyl. Instead, they decomposed into complex mixture of unidentified products when treated with silica gel. This instability was surprising. It is probable that cycloadducts **35—38** have taken an unassigned decomposition route via the corresponding betaine intermediates.

Experimental

General. Melting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40 (90 MHz) or a JEOL FX-100 instrument (100 MHz) and ^{13}C NMR on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. GC-Mass spectra as well as high-resolution mass spectra were also obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck) or of aluminum oxide 60 F-254 type-E (Merck). Visualization was made with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20×180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Preparative high-performance liquid chromatography (HPLC) was performed on a Kusano KHLC-201 apparatus with a UV-detector Uvilog-III using a column (22×300 mm)

packed with silica gel (Wakogel LC-50H). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×5000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

General Procedure for the Silica-Gel Mediated Pyridine Elimination from the Cycloadducts 1—9 and 19 Leading to 10—18. The reactions of pyridinium methylides with maleimides were carried out under the conditions previously reported[2a] giving quantitative yields of 1 : 1 cycloadducts **1**—**9** and **19**. The pyridine elimination was performed according to the following two methods: 1) The crude cycloadducts **1**—**9** were chromatographed over silica gel (Wako C-300) by using chloroform as an eluent to furnish the pyridine-eliminated products **10**—**18**. 2) The crude cycloadduct **9** was stirred in chloroform (20 ml/1 mmol) at room temperature for 24 h in the presence of a catalytic amount of acetic acid. The mixture was washed with water several times and then dried over anhydrous magnesium sulfate. The chloroform was evaporated in vacuo to give solid which was washed with a small amount of diethyl ether to afford **18** (52%). The results are summarized in Table 1.

10: Colorless needles (diethyl ether-petr. ether); mp 144 °C; IR (KBr) 1760, 1690, and 1650 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.13 (3H, s, NMe), 3.76 (2H, d, J=3.0 Hz, 4-H), 7.3—7.7 (3H, m, Ph), 7.83 (1H, t, J=3.0 Hz, =CH-), and 7.9—8.1 (2H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=24.95 (q, NMe), 34.65 (t, 4-C), 122.75 (d, =CH-), 128.45, 128.89, 133.86 (each d), 136.17, 139.76 (s, 3-C), 169.72, 174.01 (each s, 2- and 5-C), and 189.41 (s, CO); MS m/z (rel intensity, %) 229 (M^+, 45), 144 (18), 105 (base peak), 77 (69), and 51 (25). Found: C, 67.92; H, 4.80; N, 6.14%. Calcd for $C_{13}H_{11}NO_3$: C, 68.11; H, 4.84; N, 6.11%.

11: Pale yellow needles (cyclohexane); mp 176 °C; IR (KBr) 1770, 1700, and 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.93 (2H, d, J=3.0 Hz, 4-H), 7.2—7.6 (6H, m, ph), 7.37 (1H, t, J=3.0 Hz, =CH-), and 7.9—8.1 (4H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=34.94 (t, 4-C), 124.13 (d, =CH-), 126.48, 128.54, 128.77, 129.01, 129.19, 129.36, 134.25 (each d), 137.42, 139.60 (each s), 172.07, 173.25 (each s, 2- and 5-C), and 189.83 (s, CO); MS m/z (rel intensity, %) 291 (M^+, 5), 105 (74), 91 (15), 77 (base peak), 67 (20), and 51 (41). Found: C, 74.04; H, 4.58; N, 4.97%. Calcd for $C_{18}H_{13}NO_3$: C, 74.21; H, 4.50; N, 4.81%.

12: Pale yellow prisms (cyclohexane); mp 180—181 °C; IR (KBr) 1770, 1700, 1660, and 1620 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.38 (3H, s, p-Me), 3.92 (2H, d, J=2.8 Hz, 4-H), 7.0—7.4 (4H, m, Ar), 7.4—7.7 (3H, m, Ph), 7.8—8.1 (2H, m, Ph), and 7.94 (1H, t, J=2.8 Hz, =CH-); ^{13}C NMR ($CDCl_3$) δ=21.19 (q, p-Me), 34.87 (t, 4-C), 123.70 (d, =CH-), 125.99, 128.51, 128.93, 129.75, 133.98 (each d), 137.20, 138.85, 139.50 (each s), 168.79, 173.08 (each s, 2-and 5-C), and 189.52 (s, CO); MS m/z (rel intensity, %) 305 (M^+, 58), 199 (31), 105 (base peak), and 76 (43). Found: C, 74.55; H, 5.05; N, 4.77%. Calcd for $C_{19}H_{15}NO_3$: C, 74.74; H, 4.95; N, 4.59%.

13: Colorless needles (diethyl ether-petr. ether); mp 172 °C; IR (KBr) 1780, 1710, and 1670 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.37 (3H, s, p-Me), 3.93 (2H, d, J=3.0 Hz, 4-H), 6.58 (1H, dd, J=4.0 and 1.8 Hz, 4-H of furyl), 7.20 (4H, br s, Ar), 7.34 (1H, dd, J=4.0 and 1.0 Hz, 5-H of furyl), 7.62 (1H, dd, J=1.8 and 1.0 Hz, 3-H of furyl), and 7.72 (1H, t, J=3.0 Hz, =CH-); MS m/z (rel intensity, %) 295 (M^+, 43), 189 (17), and 89 (base peak). Found: C, 69.14; H, 4.45; N, 4.81%. Calcd for $C_{17}H_{13}NO_4$: C, 69.14; H, 4.44; N, 4.74%.

14: Colorless needles (diethyl ether-petr. ether); mp 128 °C; IR (KBr) 1780, 1710, and 1698 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.37 (3H, s, p-Me), 2.40 (3H, s, COMe), 3.78 (2H, d, J=2.8 Hz, 4-H), 7.1—7.4 (4H, m, Ar), and 7.14 (1H, t, J=2.8 Hz, =CH-); MS m/z (rel intensity, %) 243 (M^+, base peak), 201 (29), 173 (20), 172 (14), 143 (23), 101 (16), 99 (38), 67 (15), and 43 (74). Found: C, 69.11; H, 5.42; N, 5.75%. Calcd for $C_{14}H_{13}NO_3$: C 69.12; H, 5.39; N, 5.76%.

15: Colorless needles (chloroform-diethyl ether); mp 146—147 °C; IR (KBr) 1776, 1720, and 1710 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.37 (3H, s, p-Me), 3.80 (3H, s, COOMe), 3.80 (2H, d, J=3.0 Hz, 4-H), 6.86 (1H, t, J=3.0 Hz, =CH-), and 7.1—7.3 (4H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=21.24 (q, p-Me), 34.52 (t, 4-C), 52.34 (q, COOMe), 122.46 (d, =CH-), 126.22, 129.10 (each d), 139.11, 140.67 (each s), 165.48, 168.26 (each s, 2- and 5-C), and 172.80 (s, COOMe); MS m/z (rel intensity, %) 259 (M^+, 91), 228 (19), 227 (72), 167 (33), 149 (base peak), 129 (38), 114 (25), 72 (25), 71 (28), 67 (22), and 57 (60). Found: C, 64.87; H, 5.08; N, 5.57%. Calcd for $C_{14}H_{13}NO_4$: C, 64.86; H, 5.05; N, 5.40%.

16: Colorless needles (diethyl ether); mp 121—122 °C; IR (KBr) 1777, 1700, and 1690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.34 (3H, t, J=7.0 Hz, Me of Et), 2.37 (3H, s, p-Me), 3.81 (2H, d, J=3.0 Hz, 4-H), 4.26 (2H, q, J=7.0 Hz, CH_2 of Et), 6.85 (1H, t, J=3.0 Hz, =CH-), and 7.2—7.4 (4H, m, Ar); MS m/z (rel intensity, %) 273 (M^+, base peak), 228 (26), 227 (85), and 67 (25). Found: C, 66.04; H, 5.56; N, 5.01%. Calcd for $C_{15}H_{15}NO_4$: C, 65.92; H, 5.53; N, 5.13%.

17: Colorless needles (chloroform-diethyl ether); mp 147 °C; IR (KBr) 2202, 1780, 1705, and 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.37 (3H, s, p-Me), 3.66 (2H, d, J=3.0 Hz, 4-H), 6.43 (1H, t, J=3.0 Hz, =CH-), and 7.1—7.4 (4H, m, Ar); MS m/z (rel intensity, %) 226 (M^+, base peak), 198 (19), 87 (33), and 65 (40). Found: C, 68.97; H, 4.55; N, 12.38%. Calcd for $C_{13}H_{10}N_2O_2$: C, 69.01; H, 4.46; N, 12.38%.

18: Pale yellow leaflets (chloroform-diethyl ether); mp 220—221 °C; IR (KBr) 1770, 1694; 1649, and 1598 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.38 (3H, s, p-Me), 3.72 (2H, d, J=2.6 Hz, 4-H), 7.1—7.8 (2H, m, ArH), 7.61 (1H, t, J=2.6 Hz, =CH-), 7.76 (2H, d, ArH), and 8.23 (2H, d, ArH); ^{13}C NMR ($CDCl_3$) δ=21.29 (p-Me), 34.13 (4-C), 125.41 (=CH-), 126.32, 127.73, 129.24, 130.12, 130.86, 132.52, 139.21, 140.33, 148.38, and 172.51 (2- and 5-C); MS m/z (rel intensity, %) 322 (M^+, base peak), 161 (85), 115 (32), and 76 (14). Found: C, 66.82; H, 4.38; N, 9.02%. Calcd for $C_{18}H_{14}N_2O_4$: C, 67.07; H, 4.38; N, 8.69%.

General Procedure for the Reaction of Pyridinium Methylides with Acyclic Olefins Leading to 20—23. To the mixture of a 1-alkylpyridinium bromide (1 mmol) and an olefin (1 mmol) in dichloromethane or chloroform was added triethylamine (1 mmol) at room temperature. The mixture was allowed to react under the conditions listed in Table 2, and then poured in ice water. The organic layer separated was dried over anhydrous magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel (Wako C-300) to give **20**—**23** (eluent for the chromatography: **20**: chloroform; **21**, **22**, and **23**: benzene). Only **23** could be purified by vacuum distilation. The results are summarized in Table 2.

20: (Mixture of several tautomers in solution): Orange

needles (acetone); mp 125—127 °C (lit,[10] mp 121—123 °C); IR (KBr) 3200, 1630, 1600, 1530, and 1530 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.22 (4/11H, d, J=0.8 Hz, CH_2 of minor isomer), 4.88 (18/11H, d, J=1.4 Hz, CH_2 of major isomer), and 7.1—8.1 (16H, m, Ph); ^1H NMR (DMSO-d_6) δ=4.45, 4.65 (2/9H, each br s, CH_2 of two minor isomers), 6.56 (8/9H, br s, exchanged with D_2O, =CH- of major isomer), 7.2—8.0 (16H, m, Ph and =CH-), and 8.50 (8/9H, br s, exchanged with D_2O, OH of major isomer); ^{13}C NMR (DMSO-d_6) δ=99.86, 108.91 (each d), 110.85 (s), 124.94, 126.81, 127.46, 128.46, 128.75, 129.18 (each d), 131.75, 132.22, 138.91, 140.61 (each s), 164.15, 169.73, and 188.17 (each s); MS m/z (rel intensity, %) 354 (M^+, 14), 105 (base peak), 82 (26), 79 (32), and 78 (52). Found: C, 81.13; H, 5.13%. Calcd for $C_{24}H_{18}O_3$: C, 81.34; H, 5.12%.

This compound **20** was also available in 75% yield from a similar procedure using 3,5-dimethyl-1-phenacylpyridinium bromide (306 mg, 1 mmol), (*E*)-1,2-dibenzoylethene (236 mg, 1 mmol), and triethylamine (0.14 ml, 1 mmol) in dichloromethane (20 ml) at room temperature for 5 min.

21: (Mixture of several tautomers in solution): Yellow liquid; IR (neat) 1720, 1680, and 1600 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.60, 3.65, 3.70 (each s, COOMe, integration area 18 (1 : 3 : 2)), 3.37 (s, area 1.2), 4.00 (br s, area 5.4), 4.15 (br s, area 0.7), 4.89 (br s, area 3.2), 6.35 (br s, area 1.7), 7.22 (br s, area 4.8), and 7.3—8.0 (area 72); ^{13}C NMR ($CDCl_3$) δ=50.73, 51.78 (each q, COOMe), 98.46, 104.91 (each d), 109.85 (s), 124.82, 126.58, 128.31, 128.63, 128.87, 128.98 (each d), 140.84 (s), 163.69, 166.50, 166.97 (each s). MS m/z (rel intensity, %) 308 (M^+, 33), 249 (18), 105 (base peak), and 77 (77). When chromatographed over alumina, this compound **21** changed into **26** which provided satisfactory elemental analysis as described below.

22: (Mixture of several tautomers in solution): Pale yellow liquid; IR (neat) 2250, 2200, 1740, 1680, 1660, 1600, and 1580 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.32 (br s, integration area 5), 4.54 (br s, area 14), 5.80 (br s, area 7), and 7.0—8.2 (m, area 150); ^{13}C NMR ($CDCl_3$) δ=32.47, 41.98 (each t), 108.97 (d), 114.96 (s), 128.05, 128.22, 128.52, 128.69, 130.04 (each d), 133.33, 133.74, 135.27, 135.56 (each s), 155.17 (s), 189.34, 194.04, and 194.62 (each s); MS m/z (rel intensity, %) 167 (M^+ −108, 36), 127 (51), 105 (88), 79 (base peak), 78 (89), 92 (29), 51 (55), and 50 (37). This compound **22** was too labile to be purified as an authentic sample for elemental analysis.

23: Pale yellow liquid; IR (neat) 2220, 1750, 1740, 1720, and 1630 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.66 (2H, d, J=0.8 Hz, CH_2), 3.72, 3.83 (each 3H, s, COOMe), and 6.48 (1H, d, J=0.8 Hz, =CH-); ^{13}C NMR ($CDCl_3$) δ=35.92 (t, CH_2), 52.48, 53.16 (each q, COOMe), 110.76 (d, =CH-), 114.81 (s, CN), 146.04 (s), 164.17, and 168.61 (each s, COOMe); MS m/z (rel intensity, %) 183 (M^+, 12), 152 (79), 139 (33), 124 (29), 113 (base peak), 82 (29), 81 (60), 59 (93), and 39 (22). Found: C, 52.33; H, 4.90; N, 7.57%. Calcd for $C_8H_9NO_4$: C, 52.46; H, 4.95; N, 7.65%.

2-Acetoxy-4-benzoyl-2,6-diphenyl-2*H*-pyran (24): A solution of **20** (100 mg, 0.3 mmol) in acetic anhydride (6 ml) was heated at 50—60 °C under stirring for 1 h in the presence of a catalytic amount of pyridine. The mixture was poured into ice water (200 ml) and sodium hydrogencarbonate was added. After allowed to stand for 2 h, the mixture was extracted with chloroform (30 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo. The residue was chromatographed over silica gel by using chloroform as an eluent to give **24** (78 mg, 66%): Pale yellow prisms (diethyl ether-petr. ether); mp 153—155 °C; IR (KBr) 1760, 1670, 1640, and 1040 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.76 (3H, s, COMe), 6.70 (1H, s, 5-H), 7.2—7.7 (10H, m, 3-H and Ph), and 7.8—8.2 (6H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=19.83 (COMe), 115.78 (5-C), 125.28, 129.96, 133.03, 134.11, 136.10, 137.17, 151.11, 153.06, 167.88 (COMe), and 187.96 (COPh); MS m/z (rel intensity, %) 396 (M^+, 9), 337 (22), 250 (18), 249 (93), 105 (base peak), and 77 (78). Found: C, 78.77; H, 5.47%. Calcd for $C_{26}H_{20}O_4$: C, 78.77; H, 5.09%.

4-Benzoyl-2,6-diphenylpyridine (25). A mixture of **20** (187 mg, 0.5 mmol) and ammonium acetate (0.5 g, 0.5 mmol) in ethanol (20 ml) was allowed to stand at room temperature for a week. The precipitate was collected on a filter and washed with hexane to give **25** (141 mg, 84%): Beige leaflets (ethanol); mp 127—129 °C (lit,[9] mp125 °C); IR (KBr) 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.2—7.7 (9H, m, Ar), 7.8—8.0 (2H, m, Ar), 7.90 (2H, br s, 3- and 5-H), and 8.0—8.3 (4H, m, Ar); MS m/z (rel intensity, %) 336 (M^+ +1, 25), 335 (M^+, base peak), 334 (27), 306 (41), 127 (25), 105 (37), and 77 (49).

4-Benzoyl-6-phenyl-2*H*-pyran-2-one (26): The benzene solution of ester **21** (308 mg, 1 mmol in 0.5 ml) was charged in a column packed with activated alumina (Wako, 300 mesh) and eluted with benzene to give **26** (143 mg, 52%): Yellow prisms (diethyl ether); mp 135—137 °C; IR (KBr) 1720 and 1660 cm^{-1}; ^1H NMR ($CDCl_3$) δ=6.40 (1H, d, J=1.0 Hz, 5-H), 6.90 (1H, d, J=1.0 Hz, 3-H), and 7.3—8.1 (10H, m, Ph); ^{13}C NMR ($CDCl_3$) δ=99.75 (5-C), 114.72 (3-C), 125.70, 128.81, 128.93, 129.87, 131.22, 134.10, 134.62, 150.92 (6-C), 161.34 (2-C), and 192.92 (COPh); MS m/z (rel intensity, %), 276 (M^+, 19), 248 (19), 238 (17), 105 (base peak), and 77 (55). Found: C, 78.21; H, 4.43%. Calcd for $C_{18}H_{12}O_3$: C, 78.25; H, 4.38%.

General Procedure for the Cycloaddition of Pyridinium Methylides with *N*-(*p*-Tolyl)citraconimide Leading to 27—38. To a mixture of pyridinium halide and *N*-(*p*-tolyl)-citraconimide (each 1 mmol) in dry dichloromethane or chloroform (20—30 ml) was added triethylamine (1.1 mmol) at room temperature. The mixture was stirred at room temperature, poured into ice water, and extracted with dichloromethane (20 ml×2). The combined extracts were dried over magnesium sulfate and evaporated in vacuo below room temperature to give **27—38** as unstable products. As cycloadducts **27—29**, **31+35**, and **34+38** are all known, they were prepared under the reported reaction conditions.[2b] The results are summarized in Table 3. Purification of these cycloadducts was unsuccessful because of their lability. The ^1H NMR spectra of regioisomeric mixture are separatedly assigned to each isomer as shown below.

32+36 (Inseparable mixture in a ratio of 1 : 3): Colorless solid; IR (KBr) 2220, 1780, 1720, 1705 and 1510 cm^{-1}; ^1H NMR ($CDCl_3$) **32**: δ=1.60 (3H, s, 9b-Me), 1.93 (3H, s, 6-Me), 2.37 (3H, s, *p*-Me), 3.20 (1H, d, J=0.6 Hz, 3a-H), 4.43 (t, J=2.0 Hz, 9a-H), 4.7—4.9 (1H, m, 7-H), 5.08 (d, 1H, J=0.6 Hz, 4-H), 5.52 (1H, br d, 9-H), 5.88 (1H, m, 8-H), and 6.9—7.3 (4H, m, Ar). **36**: δ=1.69 (3H, s, 3a-Me), 1.93 (3H, s, 6-Me), 2.37 (3H, s, *p*-Me), 3.10 (1H, d, J=8.2 Hz, 9b-H), 4.7—4.9 (2H, m, 7- and 9a-H), 5.00 (1H, s, 4-H), 5.52 (1H, br d, 9-H), 5.88 (1H, m, 8-H), and 6.9—7.3 (4H, m, Ar).

33+37 (Inseparable mixture in a ratio of 1 : 3): Colorless solid; IR (KBr) 2250, 2200, 1780, 1720, 1705, and 1515 cm^{-1}; ^1H NMR ($CDCl_3$) **33**: δ=1.59 (3H, s, 1.72 (3H, br s, 8-Me), 2.34 (3H, s, *p*-Me), 3.23 (1H, s, 3a-H), 4.38 (1H, m, 9a-H), 4.6—5.0 (1H, m, 7-H), 5.30 (1H, m, 9-H), 6.28 (1H, br d,

6-H), and 6.9—7.3 (4H, m, Ar). **37**: δ=1.67 (3H, s, 3a-Me), 1.72 (3H, br s, 8-Me), 2.34 (3H, s, *p*-Me), 3.06 (1H, d, J=8.2 Hz, 9b-H), 4.76 (1H, s, 4-H), 4.6—5.0 (2H, m, 7- and 9a-H), 5.30 (1H, br s, 9-H), 5.94 (1H, br d, 6-H), and 6.9—7.3 (4H, m, Ar).

General Procedure for the Silica-Gel Mediated Elimination of Pyridines from the Citraconimide Cycloadducts 27—30 and 34 Leading to 39—42. The solution of cycloadducts **27—30** and **34** in chloroform (1 mmol in 0.5 ml) was charged in a column packed with silica gel (Wako C-300) and eluted with another portion of chloroform to give pyridine-eliminated products **39—42**. The results are summarized in Table 3.

39: Beige prisms (diethyl ether-petr. ether); mp 99—101 °C; IR (KBr) 1780, 1710, and 1690 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.02 (3H, s, 4-Me), 2.34 (3H, s, *p*-Me), 4.13 (2H, s, CH_2), and 7.0—8.1 (9H, m, Ar); ^{13}C NMR ($CDCl_3$) δ=9.22 (q, 4-Me), 20.96 (q, *p*-Me), 33.17 (t, CH_2), 125.52, 128.22, 128.65 (each d), 129.28 (s), 129.40, 133.63 (each d), 134.27, 135.80, 137.15, 140.91 (each s), 170.03, 170.32 (each s, 2- and 5-C), and 193.81 (s, COPh); MS *m/z* (rel intensity, %) 319 (M^+, 36), 105 (base peak), 77 (33), 74 (19), and 59 (37). Found: C, 75.06; H, 5.38; N, 4.46%. Calcd for $C_{20}H_{17}NO_3$: C, 75.22; H, 5.37; N, 4.39%.

40: Pale yellow needles (diethyl ether-petr. ether); mp 68 °C; IR (KBr) 1720, 1700, 1520, and 1390 cm^{-1}. ^1H NMR ($CDCl_3$) δ=2.00 (3H, s, 4-Me), 2.25 (3H, s, COMe), 2.34 (3H, s, *p*-Me), 3.56 (2H, s, CH_2), and 7.18 (4H, br s, Ar); ^{13}C NMR ($CDCl_3$) δ=9.28 (q, 4-Me), 21.08 (q, *p*-Me), 30.12 (q, COMe), 37.81 (t, CH_2), 125.64 (d), 129.05 (s), 129.52 (d), 133.68, 137.44, 140.73 (each s), 170.03, 170.32 (each s, 2- and 5-C), and 201.90 (s, COMe); MS *m/z* (rel intensity, %) 257 (M^+, 63), 216 (15), 215 (base peak), 53 (24), and 43 (55). Found: C, 69.84; H, 5.75; N, 5.35%. Calcd for $C_{15}H_{15}NO_3$: C, 70.02; H, 5.88; N, 5.44%.

41: Colorless liquid; IR (neat) 1770, 1740, 1710, 1510, and 1400 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.33 (3H, t, J=7.0 Hz, Me of Et), 2.12 (3H, s, 4-Me), 2.40 (3H, s, *p*-Me), 3.52 (2H, s, CH_2), 4.20 (2H, q, J=7.0 Hz, CH_2 of Et), and 7.19 (4H, br s, Ar); MS *m/z* (rel intensity, %) 287 (M^+, 37), 202 (14), 201 (base peak), 157 (10), 132 (10), 117 (11), and 68 (12). HRMS Found: *m/z* 287.1130. Calcd for $C_{16}H_{17}NO_4$: M, 287.1156.

42: Pale yellow needles (diethyl ether-petr. ether); mp 106—107 °C; IR (KBr) 2250, 1710, 1520, and 1400 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.20 (3H, s, 4-Me), 2.35 (3H, s, p-Me), 3.51 (2H, s, CH_2), and 7.19 (4H, br s, Ar); MS *m/z* (rel intensity, %) 240 (M^+, base peak), 213 (11), 169 (11), 156 (20), 132 (17), 104 (13), 91 (13), 79 (12), 78 (17), 77 (15), and 52 (28). Found: C, 69.25; H, 5.09; N, 11.43%. Calcd for $C_{14}H_{12}N_2O_2$: C, 69.99; H, 5.03; N, 11.66%.

Reactions of 1,4-Bis(trimethylsilyl)-1,4-dihydropyridines with Carbonyl Compounds: A New Method for Regioselective Synthesis of 3-Alkylpyridines

Otohiko Tsuge,* Shuji Kanemasa, Toshio Naritomi, and Junji Tanaka
Research Institute of Industrial Science, and Department of Molecular Science and Technology, Interdisciplinary Graduate School of Engineering Sciences, Kyushu University, Kasugakoen, Kasuga 816
(Received October 31, 1986)

A new method for the alkyl group introduction at the 3-position of pyridienes is described: Reductive disilylation of pyridine, its 2-methyl, 3-methyl, and 4-methyl derivatives affords the corresponding 1,4-disilyl-1,4-dihydropyridines. In the presence of a catalytic amount of tetrabutylammonium fluoride, these dihydropyridines smoothly react with a variety of aldehydes and ketones to give 3-alkylpyridines.

Although direct substitution at the carbon atom of pyridine has been an attracting theme for a long time, no effective method was reported until a recent year. Compared with benzene as an isoelectronic hydrocarbon counterpart, electrophilic substitution at the ring of pyridine is awfully sluggish.[1] Especially so if a carbon electrophile is used. Quaterization occurs at the ring nitrogen, under the reaction conditions, so that the nucleophilicity of pyridine ring is lowered. Substituted pyridines have been mostly synthesized according to the conventional methods such as a ring synthesis[1,2] and a chain elongation at the preexisting functional groups.[3]

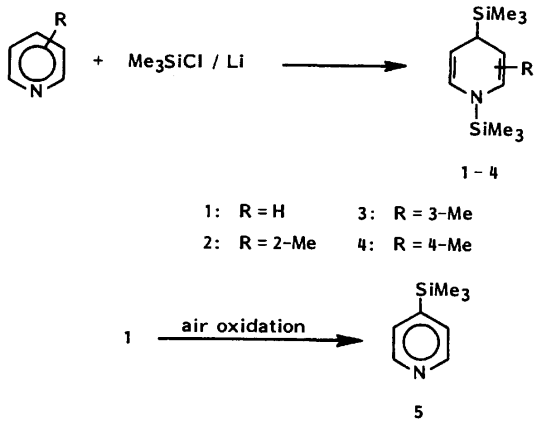
Two new methods have merged recently: One is the reaction of lithiopyridines with an electrophile, which can be generated in a regioselective manner by the aid of a directing group.[4] The other is the nucleophilic addition of organometallics with pyridines in the presence or absence of a pyridine-activating agent.[5] These reactions are performed on the aromatic ring of pyridines, and the pyridines substituted only at the 3-position are hardly accessible.

When the aromatic ring of pyridine is formally reduced by a metal hydride or its equivalent, *N*-metalated dihydropyridines are formed.[6] 1,4-Bis(trimethylsilyl)-1,4-dihydropyridine (**1**), which is available by a reductive disilylation of pyridine and is not so unstable as to exclude its isolation,[7] belongs to this family. So far no synthetic application of **1** has been reported. Since **1** carries an *N*-silylated cyclic enamine moiety,[8] its reaction with electrophiles is expected to occur regioselectively at the 3-position of pyridine.

The present article describes a new synthetic method of 3-alkylpyridines from pyridines.[9] Fluoride-catalyzed reactions of 1,4-bis(trimethylsilyl)-1,4-dihydropyridine (**1**) with a variety of carbonyl compounds produce 3-alkylpyridine derivatives. This method can be extended to several alkyl-substituted pyridines.

Results and Discussion

1,4-Disilyl-1,4-dihydropyridine **1** was synthesized by the known method starting with pyridine, chlorotrimethylsilane, and lithium powder in dry THF.[7] Though isolable by distillation under vacuum, **1** was found extremely air-sensitive. Oxidation starts once **1** is exposed to air, and it becomes contaminated by 4-trimethylsilylpyridine (**5**). The purification by distillation caused its partial oxidation, and the purity of **1** was only slightly higher than 90%. For its safety use, **1** may be stored in a bottle which is capped with a rubber septum and filled with dry nitrogen. A syringe is used to take **1** out of the bottle.



Scheme 1.

This preparation method was successfully applied to 2-methyl-, 3-methyl-, and 4-methylpyridines to give the corresponding 1,4-bis(trimethylsilyl)-1,4-dihydropyridines **2**—**4** in fair yields (Scheme 1). Again they are all air-sensitive.

An equimolar mixture of **1** and benzaldehyde in dry THF was treated, at room temperature and under an inert atmosphere, with a catalytic amount (10 mol%) of tetrabutylammonium fluoride (TBAF). After usual hydrolytic work-up and column chromatography over silica gel, 3-benzylpyridine (**6**) was obtained in 72% yield (Scheme 2). The fluoride catalyst could not be replaced by a Lewis acid, titanium(IV) chloride, most of the benzaldehyde being recovered (1 h at room temperature in dry dichloromethane).

The Friedel-Crafts acylation of benzene with 3-pyridinecarbonyl chloride followed by the carbonyl reduction is the major route for preparing **6**.[10] However, the Friedel-Crafts reaction can not be an effective preparation method for 3-benzylpyridines bearing an *o*- or *m*-substituent. Accordingly, benzaldehydes hav-

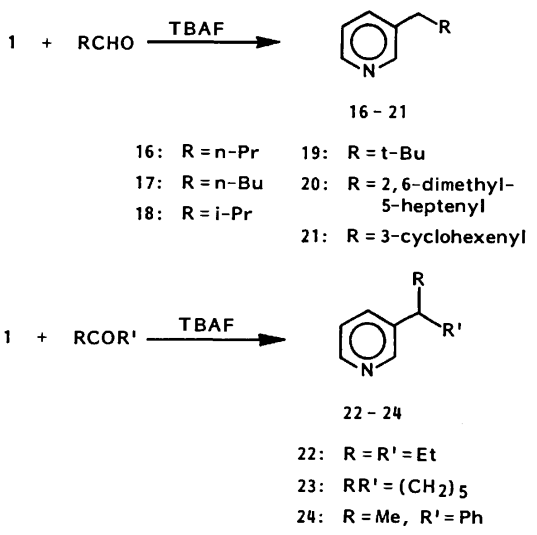

Scheme 3.

ing a variety of substitution patterns were employed to the reaction, and 3-(substituted benzyl)pyridines **7—11** were obtained in good yields (Scheme 2 and Table 1). Heteroaromatic aldehydes such as 2-furan- and 2-thiophenecarbaldehydes also reacted with **1** as well to produce **12** and **13**.

In most cases, 3-alkylpyridines **6—13** were the sole products. However in the reactions with *p*-methylbenzaldehyde and 2-thiophenecarbaldehyde, the major products **7** and **13** were accompanied by minor products **14** and **15**, respectively. They were assigned to be 2,5-disubstituted pyridine structures in which two molelules of the aldehydes had been incorporated at the 2- and 5-positions. Their formation indicates that not only the *N*-silyl group but also the 4-silyl moiety has participated in the reaction. This will be discussed later.

Similar reactions of **1** with aliphatic aldehydes required an elevated reaction temperature. Thus, **1** reacted with aldehydes carrying a primary, secondary, and tertiary alkyl group, under reflux in dry THF, to afford 3-alkylpyridines **16—19** (Scheme 3 and Table 2). Aldehydes bearing a carbon-carbon double bond could be employed without any trouble. The corresponding 3-alkylpyridines **20** and **21** were obtained. Further applications to the reactions with ketones were also successful to giving **22—24**.

The site of substitution was clearly determined to be the 3-position on the basis of spectral data. As an example, **18** shows an unsymmetrical substitution pattern with two vacant α-positions in the ^1H NMR spectrum: δ 7.06 (1H, dd, 5-H), 7.31 (1H, dt, 4-H), and

8.2—8.4 (2H, m, 2- and 6-H). Its ^{13}CNMR spectrum confirmed the 3-substitution, in which a singlet signal appeared at δ 136.64 (3-C) and two doublets at 147.11 and 150.38 (2- and 6-C).[11)]

The most practical route to 3-alkylpyridines available so far is a chain elongation of 3-methyl- or 3-ethylpyridines via α-metalated intermediates.[12)] Our present method implies even more important synthetic values since 3-alkylpyridines substituted by a variety of alkyl groups are readily accessible, in a simple procedure under mild conditions, by the employment of appropriate carbonyl compounds.

Figure 1 illustrates a possible mechanism for the reaction of **1** with *p*-methylbenzaldehyde. The silyl moiety on the nitrogen is selectively eliminated by an attack of fluoride anion to form 3-azapentadienyl anion intermediate **A**. This anion adds to the aldehyde at the 3-position to form adduct **B**. The other addition onto the nitrogen might occur as well. Even if so, the resulting adduct would not find any stabilization path, undergoing a reversible retro addition going back to the starting **A**. The elimination of silanol from **B** leads to **C**. Subsequent fluoride-induced desilylation of **C** forms the methanide **D** stabilized by two aryls. **D** is then quenched with water to give 3-(*p*-methylbenzyl)-pyridine (**7**). If the desilylation of **C** is immediately followed by attack of the second molecule of the aldehyde, the 2,5-disubstituted pyridine **14** is produced as a side-product.

Similar reactions of other 1,4-disilyl-1,4-dihydropyridines **2—4** were next examined. In these cases,

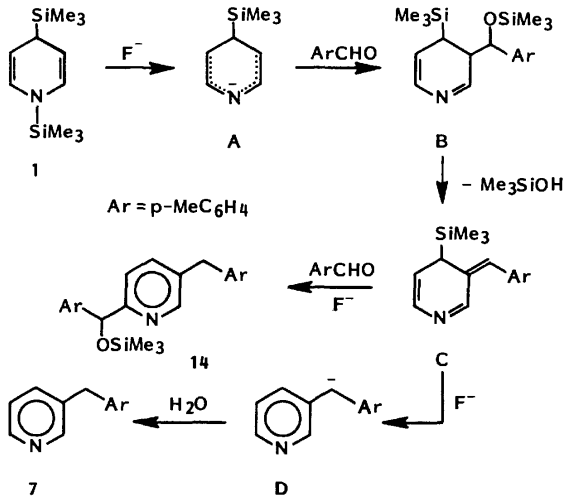

Fig. 1. A mechanism for the reaction of **1** with *p*-methylbenzaldehyde.

benzaldehyde and 2-methylpropanal were employed as representatives of aromatic and aliphatic aldehydes, respectively. The results are summarized in Table 3.

2-Methyl-1,4-disilylpyridine **2** furnished mixtures of 2,5-and 2,3-disubstituted pyridines **25—26** and **25′—26′**, respectively (Scheme 4 and Table 3). Although the 2,5-disubstituted regioisomers **25—26** were major products, their preference over the others was not so big as expected (**25** : **25′**=**6** : 4; **26** : **26′**=6 : 4 (by ^{1}H and/or ^{13}CNMR)). No persuasive explanation for the comparable regioisomeric ratio is available. It is readily understood on the basis of steric demand that only the

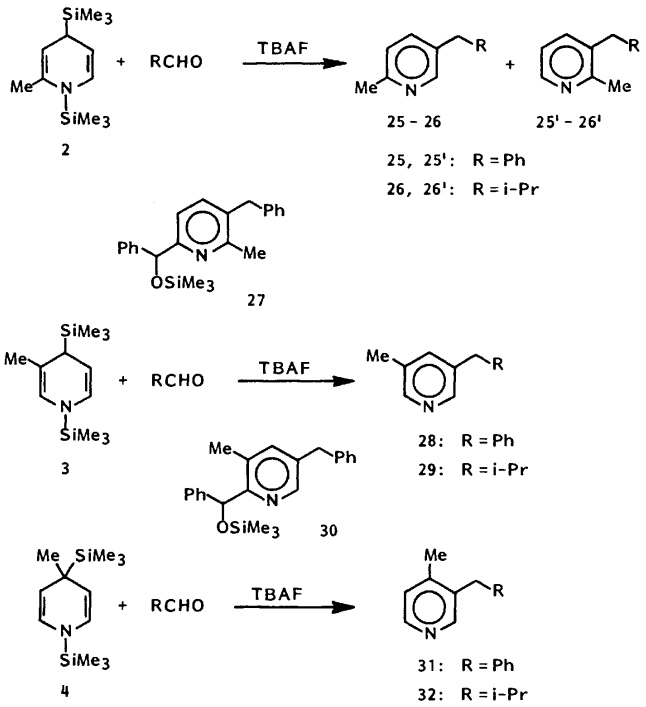
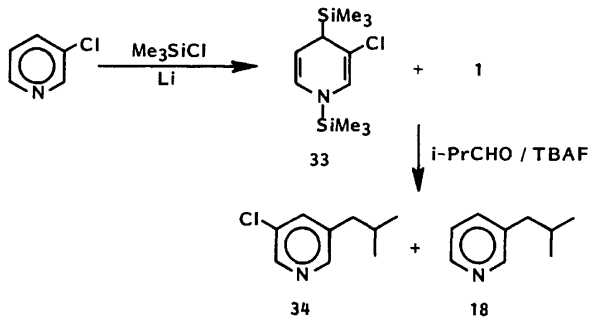


Scheme 4.



Scheme 5.

intermediate leading to **25'** could further react with the second molecule of benzaldehyde to give **27**.

In the reactions of 3-methyl-1,4-disilylpyridine (**3**), the 5-position is the only place where the nucleophilic addition can occur. For example, 3,5-disubstituted pyridines **28** and **29** were obtained as single isomers in excellent yields. As anticipated, the second addition took place at the place adjacent to the sterically less bulky 3-methyl moiety to give **30**.

4-Methyl-1,4-disilylpyridine (**4**) also demonstrated the 3-substitution providing **31** and **32**, but the yields were relatively diminished (Scheme 4 and Table 3).

Thus, these facile methods of alkyl group introduction could be successfully applied to methylpyridines with all possible substitution patterns. Pyridines with other alkyl group(s) will be utilized as well if the corresponding 1,4-dihydropyridines are obtainable.

Reductive disilylation of 3-chloropyridine was carried out under similar conditions (Scheme 5). The product isolated by vacuum distillation was found to be a mixture of 3-chloro-1,4-bis(trimethylsilyl)-1,4-dihydropyridine (**33**) and **1** (by ^{1}H NMR). As their separation was rather difficult, this mixture was subjected to the reaction with 2-methylpropanal in the presence of TBAF. A mixture of 3-chloro-5-(2-methylpropyl)pyridine (**34**) and 3-(2-methylpropyl)pyridine (**18**) was obtained, indicating that the alkyl group introduction via the disilylation method seems not so fruitful for halogen-substituted pyridines.

Experimental

General. Meting points were determined on a Yanagimoto melting point apparatus and are uncorrected. IR spectra were taken with a JASCO IRA-1 or a JASCO A-702 spectrometer. ^{1}H NMR spectra were recorded on a Hitachi R-40

(90 MHz) or a JEOL FX-100 instrument (100 MHz) and ^{13}C NMR on a JEOL FX-100 spectrometer at 25.05 MHz. Chemical shifts are expressed in parts per million downfield from tetramethylsilane as an internal standard. Mass spectra were measured with a JEOL-01SG-2 spectrometer at 70 eV of ionization energy. GC-Mass spectra as well as high resolution mass spectra were also obtained on the same instrument. Elemental analyses were performed on a Hitachi 026 CHN analyzer. Thin-layer chromatography (TLC) was accomplished on 0.2 mm precoated plates of silica gel 60 F-254 (Merck) or of aluminum oxide 60 F-254 type-E (Merck). Visualization was made with ultraviolet light (254 and 365 nm), iodine, molybdophosphoric acid (5% in ethanol), or *p*-anisaldehyde (5% in ethanol containing 5% of sulfuric acid). For preparative column chromatography, Wakogel C-200, C-300 (Wako), and Silicagel 60 (Merck) were employed. Flash chromatography was carried out on an EYELA EF-10 apparatus using a column (20×180 mm) packed with Silicagel 60 (Merck, size: 0.04—0.063 mm). Preparative high-performance liquid chromatography(HPLC) was performed on a Kusano KHLC-201 apparatus with a UV-detector Uvilog-III using a column (22×300 mm) packed with silica gel (Wakogel LC-50H). Gas liquid chromatography (GLC) was accomplished on a Yanaco G-2800 gas chromatograph (Yanagimoto) with an ionization flame detector using a glass column (SE-30, 3×2000 mm) or a glass capillary column (Silicone GE, SE-30, 0.25×50000 mm). Micro vacuum distillation was carried out on a Sibata GTO-250R Kugelrohr distilling apparatus. Solvents were evaporated with a Tokyo Rikakikai rotary evaporator type-V at about 50 °C unless otherwise stated.

General Procedure for Reductive Disilylation of Pyridines Leading to 1,4-Bis(trimethylsilyl)-1,4-dihydropyridines 1—4. The Sulzbach's method[7] was applied with a minor modification. All the procedure has to be carried out in an inert atmosphere, or air-sensitive dihydropyridines **1—4** are readily oxidized into 4-trimethylsilylpyridines. Detail of the reductive disilylation of pyridine is described below as a typical procedure: To a suspension of lithium powder (2.08 g, 300 mmol) in freshly distilled dry THF (30 ml) was added chlorotrimethylsilane (38.1 ml, 300 mmol) at −10 °C. Pyridine (100 mmol) in dry THF (25 ml) was added dropwise by use of a syringe in a period 30 min. After the completion of addition, the mixture was allowed to stir at 0 °C for 1 h. The precipitate was filtered off by the aid of the pressure of dry nitrogen. The filtrate was condensed in vacuo and then distilled under a reduced pressure to give **1** (7.64 g, 34%) which was contaminated by a small amount of **5** (purity 90%). The receiver flask containing distilled **1** was filled with dry nitrogen and capped with a rubber septum. To the septum was attached a needle which was connected to a balloon filled with dry nitrogen. In this way, **1** can be safely stored at room temperature at least for a week. A syringe may be used in order to take **1** out of the flask.

Similar procedures were applied to 2-methyl-, 3-methyl-, and 4-methylpyridine to give the corresponding dihydropyridines **2—4**. When **1** was exposed to dry air and chromatographed over silica gel with hexane-diethyl ether (10 : 1 vol/vol), 4-trimethylsilyl-pyridine (**5**) was obtained.

1,4-Bis(trimethylsilyl)-1,4-dihydropyridine (1): Yield 34%; colorless air-sensitive liquid; bp 45—50 °C/33 Pa; ^1H NMR ($CDCl_3$) δ=−0.11 (9H, s, 4-Me_3Si), 0.11 (9H, s, 1-Me_3Si), 2.25 (1H, t, J=6.9 Hz, 4-H), 4.35 (2H, dd, J=9.0 and 6.9 Hz, 3- and 5-H), and 5.70 (2H, d, J=9.0 Hz, 2- and 6-H).

2-Methyl-1,4-bis(trimethylsilyl)-1,4-dihydropyridine (2): Yield 27%; colorless air-sensitive liquid; bp 70—75 °C/320 Pa; ^1H NMR ($CDCl_3$) δ=− 0.11 (9H, s, 4-Me_3Si), 0.08 (9H, s, 1-Me_3Si), 1.62 (3H, s, 2-Me), 1.89 (1H, t, J=6.9 Hz, 4-H), 4.0—4.3 (2H, m, 3- and 5-H), and 5.61 (1H, d, J=9.0 Hz, 6-H).

3-Methyl-1,4-bis(trimethylsilyl)-1,4-dihydropyridine (3): Yield 37%; colorless air-sensitive liquid; bp 74—77 °C/200 Pa; ^1H NMR ($CDCl_3$) δ=0.08 (9H, s, 4-Me_3Si), 0.17 (9H, s, 1-Me_3Si), 1.53 (3H, s, 3-Me), 2.07 (1H, d, J=6.9 Hz, 4-H), 4.30 (1H, dd, J=9.0 and 6.9 Hz, 5-H), 5.52 (1H, s, 2-H), and 5.72 (1H, d, J=9.0 Hz, 6-H).

4-Methyl-1,4-bis(trimethylsilyl)-1,4-dihydropyridine (4): Yield 25%; colorless air-sensitive liquid; bp 70—75 °C/333 Pa; ^1H NMR ($CDCl_3$) δ=−0.12 (9H, s, 4-Me_3Si), 0.06 (9H, s, 1-Me_3Si), 1.86 (3H, s, 4-Me), 3.87 (2H, d, J=9.0 Hz, 3- and 5-H), and 5.53 (2H, d, J=9.0 Hz, 2- and 6-H).

4-Trimethylsilylpyridine (5): Pale yellow liquid; IR (neat) 1250 and 840 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.07 (9H, s, Me_3Si), 7.05 (2H, d, J=6.5 Hz, 3- and 5-H), and 8.55 (2H, d, J=6.5 Hz, 2- and 6-H); ^{13}C NMR ($CDCl_3$) δ=1.82 (q, Me_3Si), 128.05 (d, 3- and, 5-C), 148.54 (d, 2- and 6-C), and 150.18 (s, 4-C); MS *m/z* (rel intensity, %) 151, (M^+, 36), 137 (13), 136 (base peak), 83 (11), and 73 (10). HRMS Found: *m/z* 151.0796. Calcd for $C_8H_{13}NSi$: M, 151.0817.

General Procedure for Fluoride-Catalyzed Reaction of 1 with Aromatic Aldehydes Leading to 6—13. The reaction of **1** with benzaldehyde is described below as a typical procedure: Under an argon atmosphere, **1** (purity 90%, 0.287 g, 1.15 mmol) was added, by use of a syringe, to the solution of benzaldehyde (0.117 g, 1.1 mmol) in dry THF (5 ml). A solution of TBAF in THF (1M solution, 0.1 ml, 0.1 mmol) was slowly added also by the aid of a syringe. The mixture was stirred at room temperature under argon for 15 h and poured into saturated sodium hydrogencarbonate solution. The product was extracted with diethyl ether (20 ml), the ether washed with brine, dried over magnesium sulfate, and then evaporated in vacuo. The residue was chromatographed over silica gel (10 g) by using hexane-diethyl ether (5 : 1 vol/vol) to give **6** (0.134 g, 72%) as a pale yellow liquid.

Other seven aromatic aldehydes were treated in a similar way. The reaction times and the yields of 3-alkylpyridines **6—13** are listed in Table 1.

3-Benzylpyridine (6): Pale yellow liquid; mp (picrate) 100—101 °C; IR (neat) 1600, 1575, 1495, 1480, 1450, 1420, and 1025 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.92 (2H, s, CH_2), 7.0—7.5 (7H, m, ArH), and 8.3—8.5 (2H, m, 2- and 6-H); ^{13}C NMR ($CDCl_3$) δ=28.65 (t, CH_2), 123.34, 126.41, 127.53, 128.35, 128.59, 128.74, 136.25 (d), 139.66, 147.46 (d, 6-C), and 149.99 (d, 2-C); MS *m/z* (rel intensity, %) 169 (M^+, base peak), 168 (77), 167 (20), 91 (20), 83 (11), and 65 (16). Found (picrate): C, 54.44; H, 3.62; N, 14.27%. Calcd for $C_{18}H_{14}N_4O_7$: C, 54.28; H, 3.54; N, 14.07%.

3-(*p*-Methylbenzyl)pyridine (7): Yellow liquid; mp (picrate) 111—114 °C; ^1H NMR ($CDCl_3$) δ=2.26 (3H, s, *p*-Me), 3.86 (2H, s, CH_2), 6.9—7.2 (5H, m, ArH), 7.35 (1H, m, ArH), and 8.3—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 183 (M^+, base peak), 182 (46), 168 (34), 167 (13), 105 (15), 91 (12), and 77 (14). Found (picrate): C, 55.40; H, 3.84; N, 13.77%. Calcd for $C_{19}H_{16}N_4O_7$: C, 55.34; H, 3.91; N, 13.59%.

After the first fraction affording **7** was eluted with hexa-

ne-diethyl ether (10:1 vol/vol), the second fraction was followed (5:1 vol/vol) giving **14** in 34% yield. **14**: Pale yellow liquid; IR (neat) 1245, 1080, 880, and 840 cm^{-1}. ^1H NMR ($CDCl_3$) δ=0.16 (9H, s, Me_3Si), 2.34 (6H, s, *p*-Me), 3.89 (2H, s, CH_2), 5.89 (1H, s, CH), 7.0—7.6 (10H, m, ArH), and 8.37 (1H, s, 2-H), MS *m/z* (rel intensity, %) 375 (M^+, base peak), 360 (30), 286 (12), 254 (14), 193 (44), 147 (14), 142 (18), 75 (17), and 73 (43). HRMS Found: *m/z* 375.2008. Calcd for $C_{24}H_{29}NOSi$: M, 375.2017.

3-(*p*-Chlorobenzyl)pyridine (8): Pale yellow liquid; mp (picrate) 107—110 °C; IR (neat) 1570, 1515, 1480, 1420, and 1025 cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.83 (2H, s, CH_2), 6.8—7.5 (6H, m, ArH), and 8.2—8.4 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 205, 208 (M^+, 26 and 78), 168 (base peak), 153 (21), and 80 (13). Found (picrate): C, 49.66; H, 3.21; N, 12.83%. Calcd for $C_{18}H_{13}N_4O_7$: C, 49.96; H, 3.03; N, 12.95%.

3-(*m*-Methylbenzyl)pyridine (9): Yellow liquid; mp (picrate) 142—144 °C; IR (neat) 1610, 1575, 1480, 1420, and 1030 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.26 (3H, s, *m*-Me), 3.85 (2H, s, CH_2), 6.8—7.5 (6H, m, ArH), and 8.3—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 183 (M^+, base peak), 182 (55), 169 (13), 168 (94), 167 (44), 128 (11), 115 (17), 105 (14), 91 (16), 80 (16), 77 (19), and 65 (25). Found (picrate): C, 54.95, H, 3.95; N, 13.67%. Calcd for $C_{19}H_{16}N_4O_7$: C, 55.34; H, 3.91; N, 13.59%.

3-(*o*-Methylbenzyl)pyridine (10): Yellow liquid; mp (picrate) 130—132 °C; IR (neat) 1575, 1480, 1455, 1420, and 1025 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.17 (3H, s, *o*-Me), 3.88 (2H, s, CH_2), 6.9—7.4 (6H, m, ArH), and 8.2—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 183 (M^+, base peak), 182 (38), 169 (11), 168 (77), 167 (25), and 104 (14). Found (picrate): C, 55.40; H, 4.00; N, 13.61%. Calcd for $C_{19}H_{16}N_4O_7$: C, 55.34, H, 3.91; N, 13.59%.

3-(*o*-Fluorobenzyl)pyridine (11): Yellow liquid; mp (picrate) 97—98 °C; IR (neat) 1590, 1495, 1480, 1450, 1420, 1230, and 1025 cm^{-1}. ^1H NMR ($CDCl_3$) δ=3.92 (2H, s, CH_2), 6.8—7.5 (6H, m, ArH), and 8.2—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 187 (M^+, base peak), 186 (54), 185 (16), 168 (17), 167 (12), 133 (12), and 109 (18). Found (picrate): C, 52.07; H, 3.23; N, 13.66%. Calcd for $C_{18}H_{13}N_4O_7F$: C, 51.93; H, 3.15; N, 13.46%.

3-(2-Furylmethyl)pyridine (12): Yellow liquid; mp (picrate) 123—125 °C; IR (neat) 1600, 1580, 1500, 1480, 1425, 1250, 1150, 1070, and 1010 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.90 (2H, s, CH_2), 5.97, 6.23 (each 1H, each m, 3- and 4-H of furyl), 7.1—7.5 (3H, m, ArH), and 8.4—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 159 (M^+, base peak), 158 (16), 131, (11), 130 (76), 81 (20), and 51 (11). Found (picrate): C, 49.56; H, 3.27; N, 14.44%. Calcd for $C_{16}H_{12}N_4O_8$: C, 49.49; H, 3.11; N, 14.43%.

3-(2-Thienylmethyl)pyridine (13): Yellow liquid; mp (picrate) 104—105 °C; IR (neat) 1570, 1480, 1420, 1030, and 700 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.09 (2H, s, CH_2), 6.83, 6.98 (each 1H, each m, 3- and 4-H of thienyl), 7.1—7.6 (3H, m, ArH), and 8.3—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 175 (M^+, base peak), 174 (49), 130 (12), and 97 (46). Found (picrate): C, 47.65; H, 3.24; N, 13.77%. Calcd for $C_{16}H_{12}N_4O_7S$: C, 47.53; H, 2.99; N, 13.86%.

After the first fraction giving **13** was eluted with hexane-diethyl ether (2:1 vol/vol), the second fraction was followed with the same eluent. This fraction afforded **15** (0.127 g, 28%) after treatment with methanol and crystallization from diethyl ether. **15**: Colorless prisms (diethyl ether); mp 98—100 °C; IR (KBr) 3080, 1470, 1430, 1145, 1050, 1030, and 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=4.10 (2H, s, CH_2), 4.85 (1H, br, OH), 5.94 (1H, s, CH), 6.6—7.3 (7H, m, ArH), 7.45 (1H, m, ArH), and 8.38 (1H, br s, 2-H); MS *m/z* (rel intensity, %) 287 (M^+, 85), 204 (10), 203 (11), 176 (21), 175 (base peak), 174 (22), 173 (11), 149 (28), 147 (11), 113 (19), 111 (11), 97 (71), 85 (33), and 57 (16). Found: C, 52.45; H, 4.61; N, 5.09%. Calcd for $C_{15}H_{13}NOS_2$: C, 62.69; H, 4.56; N, 4.87%.

General Procedure for Fluoride-Catalyzed Reaction of 1 with Aliphatic Aldehydes or Ketones Leading to 16—24. As a typical procedure, the reaction of **1** with 2-methylpropanal is described below: Under argon, **1** (purity 90%, 0.817 g, 3.26 mmol) was added to a solution of 2-methylpropanal (0.35 ml, 3.8 mmol) in dry THF (8 ml). After TBAF (1 M solution in THF, 0.38 ml, 0.38 mmol) was added, the mixture was heated under reflux for 7 h and then poured into saturated sodium hydrogencarbonate. The product was extracted with diethyl ether (30 ml), the ether washed with brine, dried over magnesium sulfate, and finally evaporated in vacuo. The residue was chromatographed over silica gel (20 g) with hexane-diethyl ether (10:1 vol/vol) to give **18** (0.34 g, 77%). Other aliphatic aldehydes and ketones were similarly treated. The results are summarized in Table 2.

3-Butylpyridine (16): Pale yellow liquid; IR (neat) 2800—3000, 1470, 1420, 1360, and 1020 cm^{-1}, ^1H NMR ($CDCl_3$) δ=0.8—2.6 (9H, m, butyl), 7.14 (1H, dd, *J*=8.1 and 5.0 Hz, 5-H), 7.43 (1H, dt, *J*=8.1, 2.1, and 2.1 Hz, 4-H), and 8.3—8.5 (2H, m, 2- and 6-H).

3-Pentylpyridine (17): Pale yellow liquid; IR (neat) 2800—3000, 1570, 1455, 1420, 1370, and 1020^{-1} cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.7—2.6 (11H, m, pentyl), 7.10 (1H, dd, *J*=8.1 and 5.0 Hz, 5-H), 7.38 (1H, dt, *J*=8.1, 2.1, and 2.1 Hz, 4-H), and 8.2—8.4 (2H, m, 2- and 6-H).

3-(2-Methylpropyl)pyridine (18): Pale yellow liquid; mp (picrate) 111—113 °C; IR (neat) 2800—3000, 1570, 1470, 1420, 1030, and 730 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.82 (6H, d, *J*=7.2 Hz,Me), 1.81 (1H, m, CH), 2.39 (2H, d, *J*=7.2 Hz, CH_2), 7.06 (1H, dd, *J*=8.1 and 4.5 Hz, 5-H), 7.31 (1H, dt, *J*=8.1, 2.1, and 2.1 Hz, 4-H), and 8.2—8.4 (2H, m, 2- and 6-H); ^{13}C NMR ($CDCl_3$) δ=22.17 (q, Me), 29.97 (d, CH), 42.30 (t, CH_2), 123.04 (d, 5-C), 136.34 (d, 4-C), 136.64 (s, 3-C), 147.11 (d, 6-C), and 150.38 (d, 2-C). Found (picrate) C, 49.44; H, 4.46; N, 15.35%. Calcd for $C_{15}H_{16}N_4O_7$: C, 49.45; H, 4.43; N, 15.38%.

3-(2,2-Dimethylpropyl)pyridine (19): Pale yellow liquid; mp (picrate) 125—127 °C; ^1H NMR ($CDCl_3$) δ=0.89 (9H, s, *t*-Bu), 2.46 (2H, s, CH_2), 7.16 (1H, dd, *J*=8.1 and 5.0 Hz, 5-H), 7.38 (1H, dt, *J*=8.1, 2.0, and 2.0 Hz, 4-H), and 8.3—8.5 (2H, m, 2- and 6-H); ^{13}C NMR ($CDCl_3$) δ=29.06 (q, *t*-Bu), 31.59 (s, *t*-Bu), 47.09 (t, CH_2), 122.59 (d, 5-C), 137.44 (d, 4-C), 137.74 (s, 3-C), 147.13 (d, 6-C), and 151.18 (d, 2-C). Found (picrate) C, 50.64; H, 4.91; N, 14.65%. Calcd for $C_{16}H_{18}N_4O_7$: C, 50.79; H, 4.80; N, 14.81%.

3-(3,7-Dimethyl-6-octenyl)pyridine (20): Yellow liquid; IR (neat) 2850—3000, 1580, 1490, 1460, 1430, 1380, 1020, and 720 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.8—2.7 (12H, m, Me, CH_2, and CH), 1.60, 1.68 (each 3H, s, $=C(Me)_2$), 5.02 (1H, br t, olefinic), 7.08 (1H, dd, *J*=8.0 and 5.0 Hz, 5-H), 7.37 (1H, dt, *J*=8.0, 2.0, and 2.0 Hz, 4-H), and 8.3—8.5 (2H, m, 2- and 6-H); MS *m/z* (rel intensity, %) 217 (M^+, 17), 149 (13), 134 (12), 107 (19), 106 (base peak), 93 (48), 92 (45), 69 (26), and 66 (27).

3-(3-Cyclohexenylmethyl)pyridine (21): Pale yellow liquid; mp (picrate) 101—103 °C; IR (neat) 2850—3030, 1580, 1480, 1425, 1030, 730, and 715 cm^{-1}; ^1H NMR ($CDCl_3$)

δ=0.8—2.1 (7H, m, cyclohexenyl), 2.51 (2H, d, J=7.0 Hz, CH_2), 5.53 (2H, br s, olefinic), 7.08 (1H, dd, J=8.1 and 4.5 Hz, 5-H), 7.35 (1H, dt, J=8.1, 2.0, and 2.0 Hz, 4-H), and 8.2—8.5 (2H, m, 2- and 5-H); MS m/z (rel intensity, %) 173 (M^+, 55), 130 (19), 118 (25), 117 (16), 94 (20), 93 (base peak), 92 (33), 91 (16), 81 (97), 80 (13), 79 (49), 78 (11), 77 (25), and 66 (54). Found (picrate): 53.97; H, 4.60; N, 14.07%. Calcd for $C_{18}H_{18}N_4O_7$: C, 53.73; H, 4.51; N, 13.91%.

3-(1-Ethylpropyl)pyridine (22): Pale yellow liquid; mp (picrate) 112—113 °C; ^{1}H NMR ($CDCl_3$) δ=0.83 (6H, t, Me), 1.57 (4H, m, CH_2), 2.32 (1H, m, CH), 7.13 (1H, dd, J=8.1 and 4.5 Hz, 5-H), 7.32 (1H, dt, J=8.1, 2.1, and 2.1 Hz, 4-H), and 8.3—8.6 (2H, m, 2- and 6-H). Found (picrate) C, 50.63; H, 4.80; N, 14.81%. Calcd for $C_{16}H_{18}N_4O_7$: C, 50.79; H, 4.80; N, 14.81%.

3-Cyclohexylpyridine (23): Pale yellow liquid; mp (picrate) 130—131 °C; IR (neat) 2950, 2850, 1580, 1480, 1450, 1425, 1025, 810 and 720 cm^{-1}. ^{1}H NMR ($CDCl_3$) δ=1.0—2.6 (11H, m, cyclohexyl), 7.09 (1H, dd, J=8.1 and 4.5 Hz, 5-H), 7.41 (1H, dt, J=8.1, 2.0, and 2.0 Hz, 4-H), and 8.3—8.5 (2H, m, 2- and 6-H); MS m/z (rel intensity, %) 161 (M^+, base peak), 160 (18), 133 (41), 132 (24), 130 (10), 119 (13), 118 (59), 117 (25), 107 (12), 106 (40), 105 (96), 104 (20), 93 (26), 92 (38), 91 (13), 80 (15), 78 (15), 77 (13), and 65 (20). Found (picrate): C, 52.31; H, 4.65; N, 14.35%. Calcd for $C_{17}H_{18}N_4O_7$: C, 52.31; H, 4.65; N, 14.35%.

3-(1-Phenylethyl)pyridine (24): Pale yellow liquid; mp (picrate) 138—141 °C; IR (neat) 2900—3100, 1570, 1495, 1480, 1445, 1420, 1020, 710, and 700 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.63 (3H, d, J=6.3 Hz, Me), 4.12 (1H, q, J=6.3 Hz, CH), 7.0—7.5 (7H, m, ArH), and 8.3—8.5 (2H, m, 2- and 6-H); MS m/z (rel intensity, %) 183 (M^+, 47), 169 (14), 168 (base peak), 167 (33), 115 (10), 77 (11), and 51 (12). Found (picrate): C, 54.88; H, 4.01; N, 13.43%. Calcd for $C_{19}H_{16}N_4O_7$: C, 55.34; H, 3.91; H, 13.59%.

Reactions of 2—4 with Benzaldehyde or 2-Methylpropanal Leading to 25—32. The procedures are essentially the same to those described above: The reactions with benzaldehyde was carried out at room temperature and with 2-methylpropanal under reflux. All the results are listed in Table 3.

2-Methyl-5-benzylpyridine (25) + 2-Methyl-3-benzylpyridine (25′): Inseparable mixture (6:4 by ^{1}H NMR and ^{13}C NMR); Pale yellow liquid; ^{1}H NMR ($CDCl_3$) δ=2.43 (3H, s, 2-Me), 3.80, 3.85 (2H, 4:6, each s, CH_2), 6.8—7.4 (7H, m, ArH), and 8.2—8.3 (1H, m, 6-H); ^{13}C NMR ($CDCl_3$) δ=22.08, 23.48 (each q, 6:4, 2-Me), 38.34 (t, CH_2), 120.93 (d), 122.70 (s), 125.99, 128.22, 128.34, 136.32, 136.85 (each d), 146.48, 148.77 (each d, 6-C), 155.58, 156.70 (each s, 2-C); MS m/z 183 (M^+). Found (picrate, mp 143—146 °C): C, 55.22; H, 4.02; N, 13.77%. Calcd for $C_{19}H_{16}N_4O_7$: C, 55.34; H, 3.91; N, 13.59%.

The first fraction affording **25+25′** (hexane-diethyl ether (5:1 vol/vol)) was followed by the second fraction which gave **27** (0.145 g, 22%): Colorless liquid; IR (neat) 2900—3100, 1570, 1490, 1445, 1400, 1245, 1090, 1060, 890, and 840 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.06 (9H, s, Me_3Si), 2.30 (3H, s, 2-Me), 3.83 (2H, s, CH_2), 5.77 (1H, s, CH), 6.9—7.4 (12H, m, ArH); MS m/z (rel intensity, %) 361 (M^+, 36), 281 (10), 179 (29), 91 (12), 77 (15), 75 (24), 73 (38), and 43 (base peak).

2-Methyl-5-(2-methylpropyl)pyridine (26) + 2-Methyl-3-(2-methylpropyl)pyridine (26′): Inseparable mixture (6:4 by ^{13}C NMR); Pale yellow liquid; ^{1}H NMR ($CDCl_3$) δ=0.88 (6H, d, Me), 1.82 (1H, m, CH), 2.3—2.5 (5H, m, 2-Me and CH_2), 6.9, 7.2, and 8.2 (each 1H, m, ArH); ^{13}C NMR ($CDCl_3$) δ=21.72, 22.02 (each q, 2-Me and Me), 28.42, 29.59 (d, 6:4, CH), 41.57 (t, CH_2), 120.41, 122.11 (each d), 124.21 (s), 136.27, 136.73 (each d), 146.07, 149.18 (each d, 6-C), 155.05, and 156.23 (each s, 2-C). Found (picrate, mp 114—116 °C): C, 50.74, H, 4.75; N, 15.25%. Calcd for $C_{16}H_{18}N_4O_7$: C, 50.79; H, 4.80; N, 14.81%.

3-Benzyl-5-methylpyridine (28): Pale yellow liquid; mp (picrate) mp 149—151 °C; IR (neat) 2950—3100, 1605, 1580, 1505, 1460, 1450, 1040, 730, and 710 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.15 (3H, s, 5-Me), 3.79 (2H, s, CH_2), 6.9—7.3 (6H, m, ArH), and 8.13 (2H, br s, 2- and 6-H); MS m/z (rel intensity, %) 183 (M^+, 57), 182 (48), 168 (20), 167 (16), 128 (21), 115 (49), 91 (51), 89 (27), 78 (22), 77 (45), 65 (73), and 39 (base peak). Found (picrate): C, 55.22; H, 3.94; N, 13.66%. Calcd for $C_{19}H_{16}N_4O_7$: C, 55.34; H; 3.91; N, 13.59%.

The first farction containing **28** was followed by the second fraction (both eluted with hexane-diethyl ether (5:1 vol/vol)) which gave **30** (0.074 g, 17%): Pale yellow liquid; IR (neat) 2900—3100, 1600, 1500, 1450, 1410, 1255, 1090, 1060, 890, 840, and 730 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.06 (9H, s, Me_3Si), 2.19 (3H, s, 3-Me), 3.83 (2H, s, CH_2), 5.98 (1H, s, CH), 6.9—7.4 (11H, m, ArH), and 8.17 (1H, br s, 6-H); MS m/z (rel intensity, %) 361 (M^+, 41), 346 (15), 272 (14), 270 (14), 181 (15), 180 (18), 179 (43), 115 (15), 91 (36), and 73 (base peak).

3-Methyl-5-(2-methylpropyl)pyridine (29): Pale yellow liquid; mp (picrate) 140—142 °C; IR (neat) 2900—3050, 1580, 1470, 1440, 1390, 1370, 740, and 720 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.85 (6H, d, J=8.0 Hz, Me), 1.81 (1H, m, CH), 2.23 (3H, s, 5-Me), 2.37 (2H, d, J=8.0 Hz, CH_2), 7.11 (1H, br s, 4-H), and 8.09 (2H, br s, 2- and 6-H); ^{13}C NMR ($CDCl_3$) δ=18.27 (q, 5-Me), 22.22 (q, Me), 30.02 (d, CH), 42.20 (t, CH_2), 132.30 (s, 3-C), 136.00 (s, 5-C), 136.93 (d, 4-C), and 147.60 (d, 2- and 6-C); MS m/z (rel intensity, %) 149 (M^+, 31), 107 (base peak), 106 (70), 92 (11), 86 (11), 84 (17), 79 (29), 78 (26), and 77 (59). Found (picrate): C, 50.57; H, 4.77; N, 15.03%. Calcd for $C_{16}H_{18}N_{N4}O_7$: C, 50.57; H, 4.80; N, 14.81%.

3-Benzyl-4-methylpyridine (31): Yellow liquid; ^{1}H NMR ($CDCl_3$) δ=2.15 (3H, s, 4-Me), 3.91 (2H, s, CH_2), 6.9—7.3 (6H, m, ArH), and 8.2—8.4 (2H, m, 2- and 6-H); MS m/z (rel intensity, %) 183 (M^+, base peak), 182 (81), 168 (40), 167 (27), 128 (17), 115 (31), 105 (45), 91 (37), 78 (22), and 77 (35). HRMS Found: m/z 183.1055. Calcd for $C_{13}H_{13}N$: M, 183.1047.

4-Methyl-3-(2-methylpropyl)pyridine (32): Yellow liquid; mp (picrate) 106—108 °C; IR (neat) 2900—3000, 1600, 1460, and 1410 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.75 (6H, d, J=8.0 Hz, Me), 1.64 (1H, m, CH), 2.06 (3H, s, 4-Me), 2.24 (2H, d, J=8.0 Hz, CH_2), 6.75 (1H, d, J=5.0 Hz, 5-H), and 7.96 (2H, m, 2- and 6-H); MS m/z (rel intensity, %) 149 (M^+, 30), 135 (35), 107 (base peak), 106 (72), 79 (32), 78 (21), 77 (54), and 53 (25). Found (picrate): C, 50.66; H, 4.77; N, 14.99%. Calcd for $C_{16}H_{18}N_4O_7$: C, 50.79; H, 4.80; N, 14.81%.

3-Chloro-1,4-bis(trimethylsilyl)-1,4-dihydropyridine (33) and 3-Chloro-5-(2-methylpropyl)pyridine (34). A similar procedure as mentioned above was performed by employing 3-chloropyridine (3.0 ml, 31 mmol) in dry THF (6 ml), chlorotrimethylsilane (19 ml, 150 mmol), and lithium powder (1.04 g, 150 mmol) in dry THF (40 ml) to give a mixture of **33** and **1** (1.52 g, bp 65—70 °C/146 Pa, yellow liquid): ^{1}H NMR ($CDCl_3$, the signals of **1** were excluded) δ=—0.08 (9H, s, 4-Me_3Si), 0.10 (9H, s, 1-Me_3Si), 2.26 (1H, d, J=7.5 Hz, 4-H), 4.38 (1H, dd, J=10.5 and 7.5 Hz, 5-H), 5.66 (1H, d, J=10.5 Hz, 6-H), and 5.87 (1H, s, 2-H).

To a solution of thus prepared **33** (0.63 g) and 2-methylpropanal (0.22 ml, 2.43 mmol) in dry THF (5 ml) was added slowly TBAF (1M in THF, 0.22 ml, 0.22 mmol). The mixture was refluxed for 10 h under argon. A similar hydrolytic work-up was followed by a column chromatography over silica gel with hexane-diethyl ether (5 : 1 vol/vol) to give **18** (0.112 g, 34% base on the aldehyde) and then **34** (0.086 g, 21% based on the aldehyde). **34**: Pale yellow liquid; ^{1}H NMR ($CDCl_3$) δ=0.88 (6H, d, J=7.5 Hz, Me), 1.77 (1H, m, CH), 2.35 (2H, d, J=7.5 Hz, CH_2), 7.38 (1H, br s, 4-H), 8.19 (1H, br s, 6-H), and 8.32 (1H, br s, 2-H).

Thermoelectric Conversion by Thin-Layer Thermogalvanic Cells with Soluble Redox Couples

Tamio IKESHOJI
Government Industrial Research Institute, Tohoku, Nigatake 4-2-1, Sendai 983
(Received September 26, 1986)

Thermogalvanic cells containing a redox couple of $[Fe(CN)_6]^{4-/3-}$ or $Fe^{2+/3+}$ as an electroactive species were built for thermoelectric conversion from low-grade heat with a temperature less than 100 °C. The distance between high- and low-temperature electrodes was set to 1 mm in order to produce a high power density. Thermoelectric powers, inner resistances, and heat fluxes of the cells, which were placed horizontally (i.e. in which the temperature gradient was vertical) were measured under steady state conditions. Natural convection, which was induced by a temperature difference and current flowing in appropriate directions, produced lower inner resistances than those with no convection by several times. It had only a small effect on thermoelectric powers and heat-transfer coefficients. Thus, both the power densities and the thermal efficiencies increased by nearly one order of magnitude due to the convection. A power density of 2.6 W m^{-2} was obtained during steady state using a cell containing an aqueous solution of 0.13 mol dm^{-3} $K_4[Fe(CN)_6]$ and 0.85 mol dm^{-3} $K_3[Fe(CN)_6]$ at a temperature difference of 72 K and a thermal efficiency of 6.7×10^{-5}; the upper electrode was kept at a lower temperature.

The direct energy conversion of heat to electricity is a very attractive technique. Although a successful effort using an electrochemical system has not been presented yet, it has a higher thermoelectric power than that of metal thermocouples by nearly two orders of magnitude. It is of the order of 1 mV K^{-1}, which is as large as that of semiconductor thermocouples.

Several electrochemical systems for thermoelectric conversion appeared in the 1950s—60s and some of them were patented.[1,2] The systems of this period were mainly designed for high-temperature heat from the nuclear reactors in space crafts. In recent years two new systems have been proposed. One is called AMTEC (alkali metal thermoelectric converter), which is for high-temperature heat.[3] The other is a thermogalvanic cell using an aqueous electrolyte solution in order to convert low-grade heat (for instance, waste heat, geothermal heat, ocean thermal energy, etc).[4-6] Such thermoelectric conversions by electrochemical systems, sometimes called "thermally regenerative electrochemical system," have been reviewed in recent papers.[1,2,7] This paper is concerned with the aqueous thermogalvanic cells for energy conversion from heat sources of less than 100 °C.

A basic electrochemical cell for thermoelectric conversion is a thermogalvanic cell in which two electrodes of an identical type are maintained at a high temperature (T_H) and a low temperature (T_L) as

where "electrolyte" means an electrolyte solution such as molten salt, solid solution, or any other ionic conductors. A big difference in the thermoelectric conversion system using a thermogalvanic cell from that using a semiconductor or metal thermocouple concerns the type of charged species that move in the respective closed circuit. Only electrons move in the latter case, while ions and electrons move in the former thermogalvanic cell. A compound is, thus, accumulated at one of the two electrodes, where a charge-transfer reaction between ions and electrons takes place during operation. At the other electrode this same compound is consumed. These accumulated species must be returned to the latter electrode from the former one in order to continuously produce electricity from the cells. In many cases pumps are used to transfer the accumulated species through an outer circuit of the cells. This method, however, results in the losing of a major merit in that there are no moving parts in the direct thermoelectric conversion system. Another way for continuous operation is to periodically reverse the temperatures of the electrodes.[8]

It was suggested by Burrows that it is possible to return the accumulated species without using a pump if a soluble redox couple is used as the electroactive species with innert electrodes.[5,6] The electroactive species, i.e. the redox couple, are transferred by diffusion or convection in the electrolyte solution. As shown in a schematic diagram of the thermogalvanic cell with a soluble redox couple, $M^{m+/n+}$, in Fig. 1, M^{m+} is reduced to M^{n+} at the electrode of T_H, and the opposite reaction takes place at the electrode of T_L, as

$$M^{m+} + (m-n)e^- \longrightarrow M^{n+} \quad (T_H),$$

and

$$M^{n+} \longrightarrow M^{m+} + (m-n)e^- \quad (T_L),$$

where the thermoelectric power of this cell is assumed to be positive, i.e. the potential of the higher temperature electrode is positive against the lower temperature one. The counter ion, X^-, migrates from the higher-temperature electrode to the lower-temperature one in order to maintain the electroneutrality of the solution. At the T_H electrode, MX_m is consumed and MX_n is accumulated. At the T_L electrode, the opposite species are consumed and accumulated. A concentration polarization, then, arises in the thermogalvanic cell. If MX_n and MX_m are not transferred from one electrode

to the other, the potential difference due to this concentration polarization will increase until it becomes equal to the potential difference produced by the thermoelectric power; eventually, current will cease to flow.[8]

Since there is neither a diaphragm nor a membrane in the cell, the accumulated species can diffuse to the opposite electrode. A current corresponding to the amount of the species returned to the electrodes by the diffusion will continue to flow. The amount, however, is usually very small. In Burrows' cell rotating electrodes were used to obtain a higher current than that by diffusion only.[5] In this cell the consumed species is supplied by forced convection. Having a moter to rotate the electrode, the cell unfortunately again loses the big advantage of the direct thermoelectric conversion sysytem. Consequently, a short distance electrode cell, i.e. a thin-layer cell,[9] has been investigated in this study in order to obtain a high power density. Since the thermal efficiency of thermoelectric converters in which heat and electricity pass through the same part in the same direction is not fundamentally changed by their structures,[10] the thin-layer cell is expected to have a high power density without lowering the thermal efficiency.

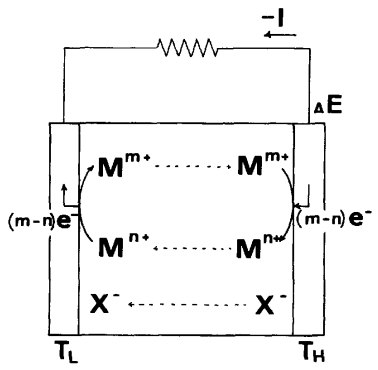

Fig. 1. A schematic diagram of a thermogalvanic cell with a soluble redox couple, $M^{m+/n+}$. T_H And T_L: Temperatures of electrodes ($T_H > T_L$), E: potential at T_H against that at T_L, I: current.

The current at a steady state in a thin-layer cell is, primarily, proportional to the speed of the diffusion determined by the concentration gradient induced by the flowing current. This means that the observed inner resistance of this cell increases from the solution resistance measured by the normal method. If the concentration gradient of the redox species can be diminished by homogenizing, the inner resistance will decrease. This would be possible by a natural convection induced by a temperature and/or concentration gradient in the cell without a motor. However, the convection in the cell has a possibility of enhancing the heat transfer through the cells, which may cause a low thermal efficiency. In this paper some effects to homoginize the redox couple on power densities, thermal efficiencies, etc. in the thin-layer thermogalvanic cells are described. The redox couple of $[Fe(CN)_6]^{4-/3-}$ was used in dilute and saturated solutions. Since a more concentrated solution results in a higher power density,[6] a redox couple of $Fe^{2+/3+}$ was used in a more concentrated solution than the saturated solution of $[Fe(CN)_6]^{4-/3-}$.

Experimental

The thin-layer thermogalvanic cell used in this study is illustrated in Fig. 2. The distance between two platinum plates (ca. 120×120×0.05 in mm) was kept at 1 mm with a byton rubber spacer, which had many holes of ca. 9 mm in diameter. The platinum electrodes were in contact with two heat transfer-plates of copper, of which temperature was kept constant by flowing water from thermostats. The two heat transfer-plates were tightened by electrically insulated bolts. Each hole of a spacer was filled with an aqueous electrolyte solution containing a redox couple ($[Fe(CN_6]^{4-/3-}$ or $Fe^{2+/3+}$). This thermogalvanic cell was horizontally placed and covered with a thermal insulator of polystyrene and polyurethane foams. Since the inner resistance of the cell was very small (<1Ω), a potentiostat or a power supply was used as an electrical load instead of a resistance. The cell voltage was measured through two leads independent of current leads, i.e. 4-probe method.

Three types of aqueous electrolyte solutions were used: a: a dilute solution of mixture of 0.010 mol dm^{-3} $K_4[Fe(CN)_6]$

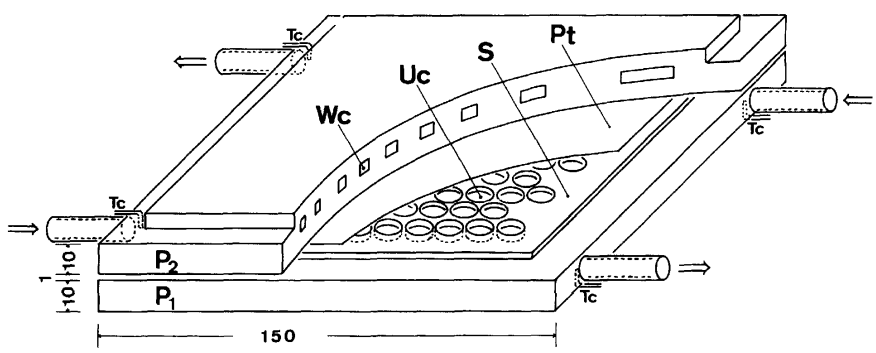

Fig. 2. Thin layer thermogalvanic cell. (Numbers in the illustration is in a unit of mm.) P_1 And P_2: Heat transfer plates, Pt: platinum plate, S: spacer, Tc: thermocouple, Uc: a unit cell, Wc: water channel, ⇨⇦: water inlet and outlet.

and 0.010 mol dm^{-3} $K_3[Fe(CN)_6]$, b: a concentrated solution of mixture of 0.13 mol dm^{-3} $K_4[Fe(CN)_6]$ and 0.85 mol dm^{-3} $K_3[Fe(CN)_6]$, which was made as a saturated solution at 0 °C of their mixture solution, c: a solution of 1.0 mol dm^{-3} $FeCl_2$ and 1.0 mol dm^{-3} $FeCl_3$ in pH 0.6 adjusted by hydrochloric acid. Every chemical used was guaranteed grade.

Notations and Definitions: The potential difference (ΔE) between two electrodes of a cell is defined here as the potential measured for the upper side electrode (temperature T_2) of two horizontal electrodes against the lower one (temperature T_1). The direction of the positive current (I) is defined here from the upper electrode to the lower one through the cell. The temperature difference (ΔT) is defined as T_2-T_1. The thermoelectric power (ε) of the cell is calculated from $\varepsilon=\Delta E/\Delta T$. T_1 and T_2 are the mean values of the temperatures measured by thermocouples placed at the water inlet and outlet in the respective heat-transfer plates, P_1 and P_2. The temperature differences between the inlet and outlet were less than 3 K. Heat transferred through the cell was calculated from a temperature decrease or increase of the flowing water (rates of ca. 15 ml s^{-1}). Heat transfer to the surroundings from the cell was so small that it could be neglected. The current density (i), resistance (R), power density (w), heat flux through the cell (q), and heat transfer coefficient (h) were calculated on a basis of the surface area (A=68.1 cm^2) of the platinum electrodes in contact with the solution as follows (units are shown in parentheses):

i = current through the cell/A (A m^{-2}),

R = cell resistance × A (Ω m^2),

$w = i \times \Delta E$ (W m^{-2}),

q = (heat transferred through the platinum electrode in contact with the solution)/A (W m^{-2}), and

$h = q/\Delta T$ (W K m^{-2}).

Results and Discussion

Thermoelectric Powers. When the temperature of one electrode was increased by changing the water source from a thermostat at ca. 5 °C to another at ca. 40 °C, the potential differences of the cells increased with time (t) as shown in Figs. 3-a, b, and c. In Fig. 3-d, a typical change in the temperature difference with time is shown. It is well known that species in the cell move to the higher or lower temperature electrodes due to Soret diffusion.[11,12] During steady state the Soret diffusion is in equilibrium with the diffusion due to a concentration difference built up by the Soret diffusion. The observed thermoelectric power is, therefore, changed by the potential difference due to this concentration polarization.[11,12] Then, there are two kinds of thermoelectric powers: an initial type (ε_i) defined as the thermoelectric power under the condition of uniform concentration in the cell, i.e. just after the temperature is changed, and a final type (ε_f) at a steady state under no convection, i.e. at time=∞.[11,12] The decreases in $|\Delta E|$ after maximum peaks in case of the cells with the $[Fe(CN)_6]^{4-/3-}$ redox couple (Fig. 3-a(−) and b(−)) are, thus, considered to be due to the Soret diffusion. The first increase in $|\Delta E|$ is toward

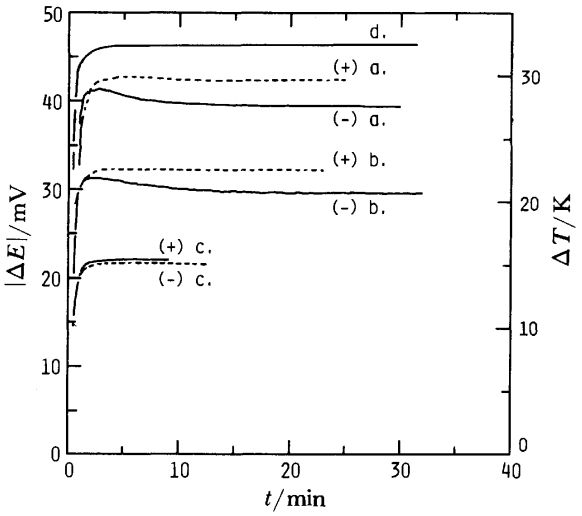

Fig. 3. Variations of potential (a, b, and c) and temperature (d) differences with time. (+): $\Delta E>0$, (−): $\Delta E<0$, min(T_1, T_2)=6.5—6.9 °C, a: cell with dilute $[Fe(CN)_6]^{4-/3-}$ solution, b: cell with concentrated $[Fe(CN)_6]^{4-/3-}$ solution, c: cell with concentrated $Fe^{2+/3+}$ solution, d: a typical temperature difference during the measurement of curve (−)a, ——: changes at $\Delta T>0$, ----: changes at $\Delta T<0$.

$\varepsilon_i\Delta T$, and the decrease of $|\Delta E|$ is toward $\varepsilon_f\Delta T$. The fact that there was no decrease of $|\Delta E|$ in Figs. 3-a(+), b(+), and c will be explained later.

In many measurements of the thermoelectric power reported so far, only initial thermoelectric powers have been presented,[13] since it generally takes a long time to attain Soret equilibrium. It is not surprising that Soret equilibrium was attained within a few minutes in the cells used here. This was because of the short distance between the two electrodes. The speed of the Soret diffusion can be evaluated by a characteristic time, τ, calculated from

$$\tau = \frac{d^2}{\pi^2 D},$$

where d is the distance between the electrodes, and D is the diffusion coefficient of the species in the cell.[13] For instance, from $D(K_4[Fe(CN)_6])=1.183\times10^{-9}$ m^2 s^{-1} (0.01 mol dm^{-3}, 25 °C)[15] and d=1 mm τ is about 1.5 min, which is corresponding to the observed speed.

In Fig. 4 thermoelectric powers under steady state conditions in these cells are shown as a function of the temperature differences with initial thermoelectric powers measured using an anti U-shaped cell shown in Ref. 16. Since the steady state thermoelectric powers were larger than $|\varepsilon_i|$ in cells with $[Fe(CN)_6]^{4-/3-}$, $[Fe(CN)_6]^{3-}$ migrates to the higher-temperature electrode and/or $[Fe(CN)_6]^{4-}$ to the lower-temperature one. In the cell with $Fe^{2+/3+}$, Fe^{2+} migrates to the higher-temperature electrode and/or Fe^{3+} to the lower-temperature one.

There is some evidence for natural convection arising in the cell with $[Fe(CN)_6]^{4-/3-}$, which could make

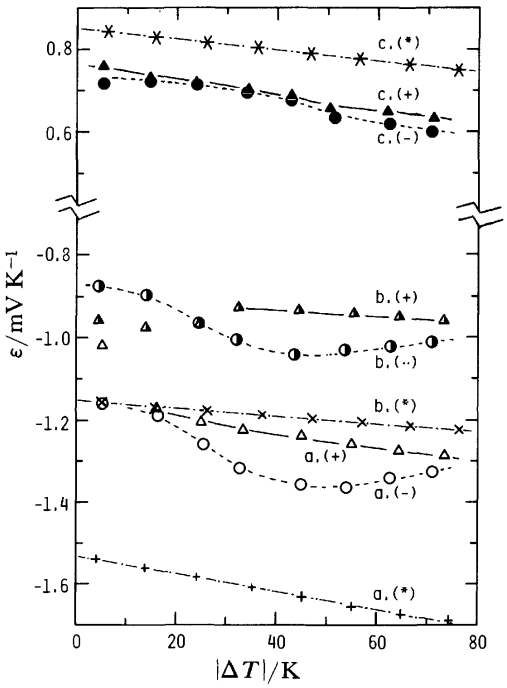

Fig. 4. Initial and steady state thermoelectric powers as a function of temperature difference. Min(T_1, T_2)=4.0—8.0 °C, (+): steady state ε at $\Delta T>0$, (−): steady state ε at $\Delta T<0$, (*): ε_i, a, b, and c: see Fig. 3.

the concentration uniform. They were observations that the steady state thermoelectric powers at $\Delta T<0$ shifted toward ε_i from ε_f (as can be seen in Figs. 4-a and b) and that the potential difference at $\Delta T<0$ achieved a steady state with no maximum (Fig. 3). The cause of the convection is considered to be explained as follows.

Natural convection in a pure solvent occurs when the temperature difference in a vertical direction exceeds a point (ΔT_{cr}) calculated from the critical Rayleigh number (Ra_{cr}) as[17]

$$Ra_{cr} = \frac{g\alpha|\Delta T_{cr}|d^4}{a\nu} = 1708,$$

where g, α, a, and ν are the accelation of gravity, the coefficient of volume expansion, the thermal diffusivity, and the kinematic viscosity of the solvent, respectively, and d is the distance of two plates of different temperature, i.e. the distance between the two electrodes. If $|\Delta T|<|\Delta T_{cr}|$, no convection occurs, even when the lower electrode is hotter. The critical temperature difference calculated is ca. −120 K at d=1 mm for pure water. Since the physical constants in this equation do not change much, even for the electrolyte solutions, ΔT_{cr} will not be so different from −120 K in the thermogalvanic cells. However, convection took place from $\Delta T\approx$−20 K in the cell with $[Fe(CN)_6]^{4-/3-}$ (as can be seen in Figs. 4-a and b, in which ε at $\Delta T<0$ was observed to shift toward ε_i, even at ΔT=−20 K. This suggests that the main cause of the convection is not due to a thermal expansion of the solution but, rather, it comes from the electrolyte, since the critical temperature difference may move close to 0 or convection takes place even at $\Delta T>0$ in two-component fluids.[18] The observed small critical temperature difference would, thus, be due to this special convection in the electrolyte solution.

In the case of $Fe^{2+/3+}$, at ε at $\Delta T>0$ is observed to shift toward ε_i as can be seen in Fig. 4-c. As pointed out in the above, convection could abnormally take place at this temperature difference, in which the lower electrode is hotter. Changes of the potential difference with time by increasing of the temperature (see Fig. 3-c), however, didn't show a distinguishable difference between the $\Delta E-t$ curves at $\Delta T>0$ and $\Delta T<0$. Clearer experimental evidence concerning the convection at $\Delta T>0$ will be given in the next section.

Inner Resistances. Resistances at $T_1=T_2$: When a small potential difference (=10 mV) was applied to cells at $T_1=T_2$, the current densities (i) through the cells decreased with time in different ways depending on the direction of the currents as shown in Fig. 5. The positive i for the cells with $[Fe(CN)_6]^{4-/3-}$ and the negative i for the cells with $Fe^{2+/3+}$ decreased like an exponential curve to steady state currents. Currents in the opposite direction decreased with oscillation to bigger steady state currents. In the latter case $K_4[Fe(CN)_6]$ and $FeCl_3$ were generated at the electrode of the upper side. The density of the solutions containing these compounds was higher than that of $K_3[Fe(CN)_6]$ or $FeCl_2$ solutions in the same molar concentration, respectively. A natural convection, then, could take place in the cells. It produces a smaller inner resistance during steady state than that of the former case in which the currents were controlled by the diffusion. The convection in the cell with a dilute solution seems to be weak (Fig. 5-a); it took a longer time for the oscillation of the current to start and its steady state current was not so large as that by diffusion. The reason is that the concentration difference induced in the dilute solution by the same applied voltage, which corresponds to the ratio of the concentrations of the oxidized and reduced species of the redox couple, is smaller than that in the cell with a concentrated solution.

Relations between the applied potential difference (ΔE) and the steady state current are shown in Fig. 6, wherein the measurements were performed from +500 mV to −500 mV in ΔE for Fig. 6-a and b and from +500 mV to −500 mV for Fig. 6-c, i.e. from the diffusion state to the convection one. The currents approached limiting values at a large potential difference, in which the concentration of one species of the redox couple was almost zero at one electrode. The currents will not increase beyond the limiting currents, unless another charge-transfer reaction or the stronger convection takes place. At a small potential difference (about less than 50 mV) currents were linearly proportional to ΔE in each side of $\Delta E>0$ and $\Delta E<0$ with different proportional ratios, i.e. different resistances, except at ΔE very close to 0, in which the concentra-

tion difference is so small that no convection arises. Detailed features of $i-\Delta E$ curves and resistances at $T_1=T_2$ are shown in Appendix 1.

Resistances at $T_1 \neq T_2$: In case of $T_1 \neq T_2$ i-ΔE relations can be divided into four regions, due to the signs of ΔT and i, i.e. due to how the convection arises. The results are shown in Fig. 7, wherein the measurements were performed in the same direction for applying ΔE (as in Fig. 6). It is noted here that an observation of the greater current at $\Delta T>0$ than at $\Delta T<0$ in the cell with $Fe^{2+/3+}$ (Fig. 7-c) confirms the previous argument that the convection is induced by $\Delta T>0$.

As already described, it is obvious that there are two causes (the temperature difference and the current) for the onset of convection. Those condisions are summarized as follows.

solutions	ΔT	i
$[Fe(CN)_6]^{4-/3-}$	−	−
$Fe^{2+/3+}$	+	+

When these two causes for the convection were superimposed positively, the biggest currents flowed (i.e. in cases of $\Delta T<0$ and $i<0$ for the cells with $[Fe(CN)_6]^{4-/3-}$ and in case of $\Delta T>0$ and $i>0$ for the cell with $Fe^{2+/3+}$). Under the conditions of the opposite

signs in ΔT and i, the smallest currents controlled by the diffusion were observed (i.e. in cases of $\Delta T>0$ and $i>0$ for the cells with $[Fe(CN)_6]^{4-/3-}$ and in case of $\Delta T<0$ and $i<0$ for the cell with $Fe^{2+/3+}$. When the two causes for convection are competitive, the following three states are possible: convection arises, it is diminished, or no convection arises. In cells with $[Fe(CN)_6]^{4-/3-}$, convection became completely diminished at $i\gg 0$, even at $\Delta T<0$. The limiting currents under these conditions were observed to be equal to those controlled by the diffusion. In the same cells at $\Delta T>0$, convection arose at $i\gg 0$. From these relations it is concluded that the condition $i<0$ is more predominant for convection to arise than that of $\Delta T<0$ in these cells. This is especially evident in a cell with a dilute solution as the almost equal negative limiting currents under the convection were observed at both $\Delta T<0$ and $\Delta T>0$. In cells with $Fe^{2+/3+}$ the condition $\Delta T>0$ was more predominant than that of $i>0$. This can be seen in curves at $\Delta T>0$, in which the currents of either $i\gg 0$ or $i\ll 0$ are bigger than those at $\Delta T<0$. More detailed descriptions for $i-\Delta E$ relations are given in Appendix 1.

The resistance during the generation of the electric power, where $i\Delta E<0$, is dependent on which region the $i-\Delta E$ relation belongs to during this condition. In cells with $[Fe(CN)_6]^{4-/3-}$ a negative current flows when a negative temperature difference is applied, i.e. $\Delta T<0$ and $i<0$. These two conditions are positive for convection to arise (as already described). Therefore, in this case the resistance was much smaller than that obtained under the opposite conditions ($\Delta T>$, $i>0$). In the cell with $Fe^{2+/3+}$ a negative current flowed when a positive temperature difference was applied, i.e. $\Delta T>0$ and $i<0$. Since only one of these two conditions ($\Delta T>0$) is positive for the convection, the resistances were not so small in comparison with that obtained under the opposite conditions ($\Delta T<0$, $i>0$).

The resistances measured by applying half of $\varepsilon\Delta T$, at which maximum power densities were obtained, are shown as a function of ΔT in Fig. 8. A typical change in the resistances with ΔT was observed in the cell with a dilute $[Fe(CN)_6]^{4-/3-}$ solution, in which the difference between the resistances at $\Delta T<0$ and $\Delta T>0$ increased with increasing $|\Delta T|$. This would be a reflection of a stronger convection at a bigger $|\Delta T|$.

Power Densities. Effects of Convection: In the region of $i\Delta E<0$ (Fig. 7) where the cells have electrical works to the surroundings, currents changed linearly with ΔE, i.e. the resistances were constant. Since the maximum power density (w) is obtained when the electrical load is equal to the inner resistance (R), it can be expressed as

$$w=\frac{\varepsilon^2\Delta T^2}{4R}, \qquad (1)$$

where R is assumed to be independent on the potential differences. The power densities obtained by applying $\varepsilon\Delta T/2$, which corresponds to the electrical load=R, are shown in Fig. 9. Those of the convection cells were larger than those of the diffusion cells at equal temperature differences due mainly to $1/R$ rather than ε. The differences between convection and diffusion cells are within 10% in ε, but is 4-times

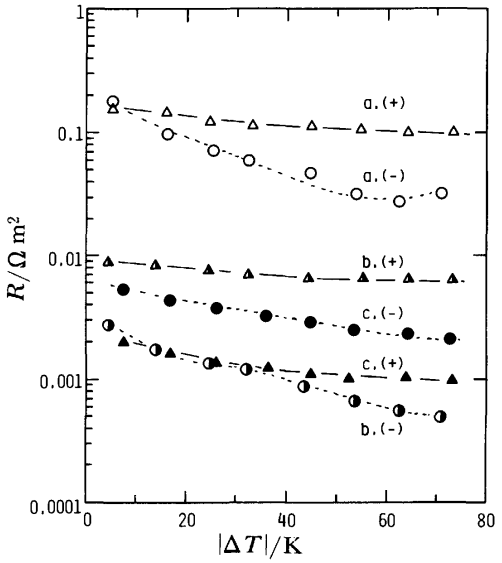

Fig. 8. Steady state resistances as a function of temperature difference. (+) And (−): see Fig. 7, a, b, and c: see Fig. 3.

greater in $1/R$ for convection cells. The biggest power density obtained in these measurements was 2.6 W m^{-2} by a cell with a concentrated $[Fe(CN)_6]^{4-/3-}$ solution at ΔT=−72 K. A greater power density might be possible at greater temperature differences; however, it would become difficult to apply a temperature differences of nearly 100 °C or more than 100 °C. The biggest power density obtained in these measurements by a cell with $Fe^{2+/3+}$ was 0.56 W m^{-2} (at ΔT=71 K), less than the above cell because of a smaller $|\varepsilon|$, though the concentration was higher than the former cell and the inner resistance was of the same order.

It is possible to imagine an ideal state in which the inner resistnace is equal to the AC resistance (R_{AC}). This state can be achieved by a strong convection, which would also make the thermoelectric power close to ε_i. The ideal power density (w_{id}) is, then, calculated by inserting ε_i and R_{AC} instead of ε and R, respectively, into Eq. 1. At this ideal state, where the current does not decrease from the initial current, the power density in cells with $[Fe(CN)_6]^{4-/3-}$ can increase up to 40 W m^{-2}, which is higher than the observed power density (by 20 times). These estimations are summarized in Table 1. It is necessary to consider the size of ε_f and ε_i to conclude that convection always makes the power density bigger. In all the cells measured here $|\varepsilon_f|$ was smaller than $|\varepsilon_i|$; however, this relation can not be extended to all kinds of thermogalvanic cells. Some cases of $|\varepsilon_f|>|\varepsilon_i|$ were reported, but the difference between them was negligibly small: usually ca. 0.1—0.5 mV/K.[11] Therefore, it can be stated in a practical sense that convection can produce a higher power density in any type of thermogalvanic cell.

ΔT Dependence: If ε and R were not dependent on ΔT, the power densities should increase by a power of two from Eq. 1. However, the observed power densities fit lines with slopes of 2—3 in log-log plots of w and $|\Delta T|$ (Fig. 9). In the whole region of ΔT used here, $1/R$ increased by ca. 3—4 times in convection cells but only by ca. twice in diffusion cells. In the same region of ΔT the changes of ε were as small as ca. 20% in convection cells and ca. 10% in diffusion cells. The increase of $1/R$ with $|\Delta T|$, therefore, has greater affects on the power densities than on the changes of ε with $|\Delta T|$.

Heat Transfer. In thermoelectric converters the heat supplied to the high-temperature electrode is different from that taken away from the low-temperature electrode. The difference between two thermal energies is converted into electrical work. In the case of thermogalvanic cells, the heat flux supplied to the electrode at T_H is the sum of a heat flux (q_c) transferred by conduction and convection through the cell and that ($q_{e,H}$) transported by electrolyte and electrochemical reactions. The two heat fluxes can be expressed as[10]

$$q_c = h\Delta T, \tag{2}$$

and

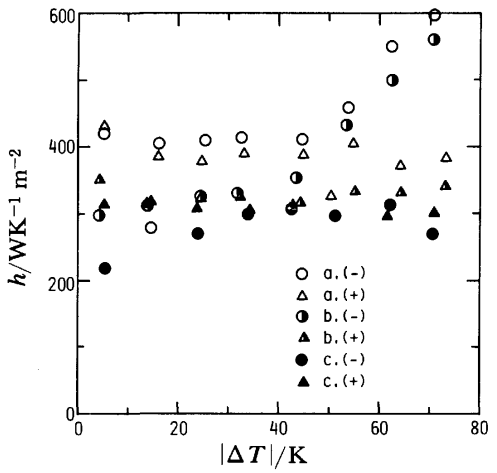

Fig. 10. Heat transfer coefficients as a function of temperature difference at no current. (+) and (−): see Fig. 9, a, b, and c: see Fig. 3.

$$q_{e,H} = -T_H i, \tag{3}$$

where h is the heat-transfer coefficient through the cell. The heat taken away from the cell at the low-temperature electrode is also the sum of q_c and the heat flux ($q_{e,L}=-T_L i$) transported by electrochemical processes. The difference between two heat fluxes, $q_{e,H}$ and $q_{e,L}$, is equal to the electrical work of this cell, $-\varepsilon\Delta T i$. A part of this work is converted into Joule heat in the cell.

Heat fluxes q_c and $q_{e,H}$ passing through a distance of 1 mm are estimated as q_c=609 W m^{-2} and $q_{e,H}$=0.3 W m^{-2} from $h=k$(the thermal conductivity of pure water)=0.609 W K^{-1} m, ε=1 mV K^{-1} the solution resistivity=1 Ωm, ΔT=1 K, and T_H=300 K. From $q_{e,H} \ll q_c$, the heat flux, q, transferred from the high-temperature electrode to the low one will be

$$q \approx q_c = h\Delta T.$$

Heat transfer coefficients obtained from $h=q/\Delta T$ in case of no current are shown as a function of the temperature difference in Fig. 10. In the cells with $[Fe(CN)_6]^{4-/3-}$, the heat-transfer coefficient started to increase at $\Delta T \approx -50$ K owing to the convection due to the temperature difference. In cells with $Fe^{2+/3+}$ it did not increase at both regions of $\Delta T>0$ and $\Delta T<0$. Although there was a possibility for the heat flux to increase by convection due to the current, no increase was observed within the experimental error (less than 40 W m^{-2} in q corresponding to 0.5—20 W K m^{-2} in h) during the measurement of Fig. 7.

Thermal Efficiencies. The thermal efficiency (η) at the maximum power of this cell can be calculated from Eqs. 1, 2, and 3 as

$$\eta = \frac{w}{q_c + q_{e,H}} = \frac{T_H - T_L}{T_H}\frac{1}{2}\left(\frac{1}{1+2/ZT_H}\right),$$

and

$$Z = \varepsilon^2/hR,$$

where the term, $(T_H-T_L)/T_H$, is the thermal efficiency of the Carnot cycle, and Z is called a figure of merit.[10] Under the condition $q=q_c$, η will be

$$\eta = \frac{w}{q} = \frac{T_H - T_L}{T_H}\frac{ZT_H}{4}. \quad (4)$$

The highest thermal efficiency obtained in these measurements was 6.7×10^{-5} by the cell with the concentrated $[Fe(CN)_6]^{4-/3-}$ solution at $\Delta T=-72$ K (i.e. under the convection) with the biggest figure of merit, 3.7×10^{-6} K^{-1} (Table 1). In any cell a higher η and a bigger Z were obtained by convection cells than those by the diffusion cells. Though the heat-transfer coefficient increased with $|\Delta T|$ in the range of $\Delta T<-50$ K, the thermal efficiencies did not decrease except at one point, since increase in the electric work compensates for the heat leak across the cells. This can be proved generally, as described in Appendix 2.

The thermal efficiencies calculated from the measured power densities and heat fluxes are shown in Fig. 11 as a function of the temperature difference. From Eq. 4, they should increase linearly in the first order with the temperature difference, if the three constants, h, R, and ε, were not dependent on the temperature difference of the cell. The observed thermal efficiencies are on straight lines of slope greater than 1 in $\log(\eta)$-$\log(|\Delta T|)$ plots. This means that the higher thermal efficiencies (than those expected from the small temperature difference) were obtained at a greater temperature difference. This is mainly because of the lower resistance among the three factors (h, R, and ε) at large temperature differences.

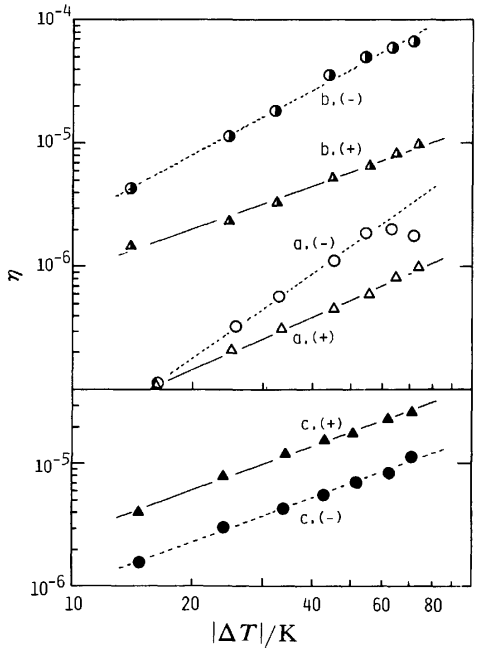

Fig. 11. Thermal efficiencies measured for the cell operating at temperature difference ΔT. (+) And (−): see Fig. 9, a, b, and c: see Fig. 3.

Conclusion

It was confirmed that in thin-layer thermogalvanic cells with soluble redox couples a natural convection induced by a temperature difference and by a concentration change due to current produces a small inner resistance under steady state conditions without sacrificing the thermal efficiency. An $[Fe(CN)_6]^{4-/3-}$ couple with K^+ is more suitable than an $Fe^{2+/3+}$ couple with Cl^-, since the convection induced by two causes is superimposed positively in the former case but it is reciprocal in the latter case. In addition, the former cell exhibits a bigger thermoelectric power than the latter. Minimizing the inner resistance during steady state conditions close to the AC resistance as possible is important for obtaining a high performance thermogalvanic cell. It is also necessary to find a redox couple with a higher thermoelectric power.

Appendix 1

$i-\Delta E$ Relations at Small $|\Delta E|$ and Isothermal Resistances. The $i-\Delta E$ curves measured by small potenital differences at $T_1=T_2$ are shown in Fig. 12, in which the transition points from the diffusion states to the convection states can be clearly seen as inflection points (ΔE_{in}) in those curves; $\Delta E_{in}=-6$ mV for the cell with the dilute $[Fe(CN)_6]^{4-/3-}$ solu-

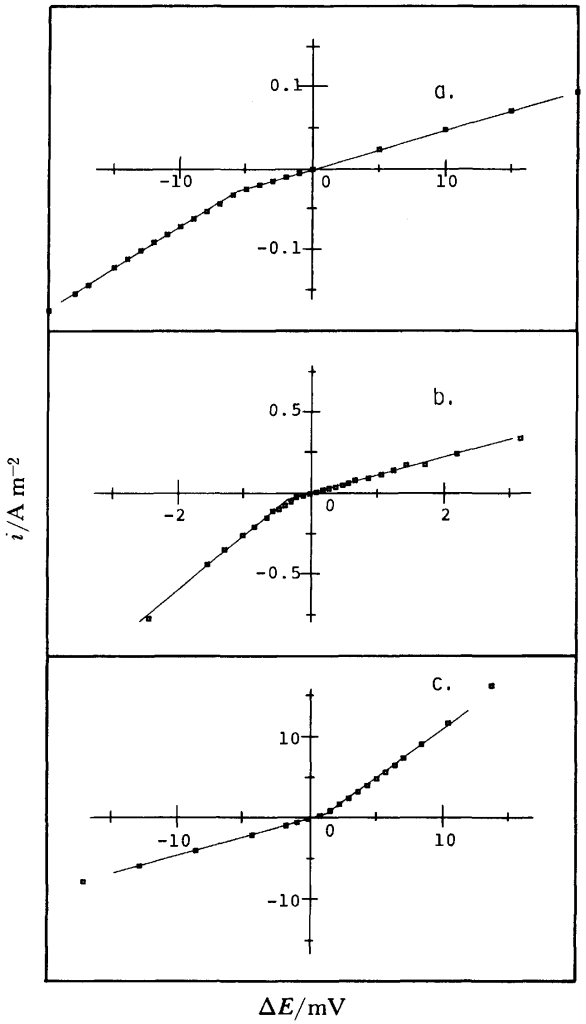

Fig. 12. Relations between steady state current and small potential difference applied at $T_1=T_2$. See Fig.6.

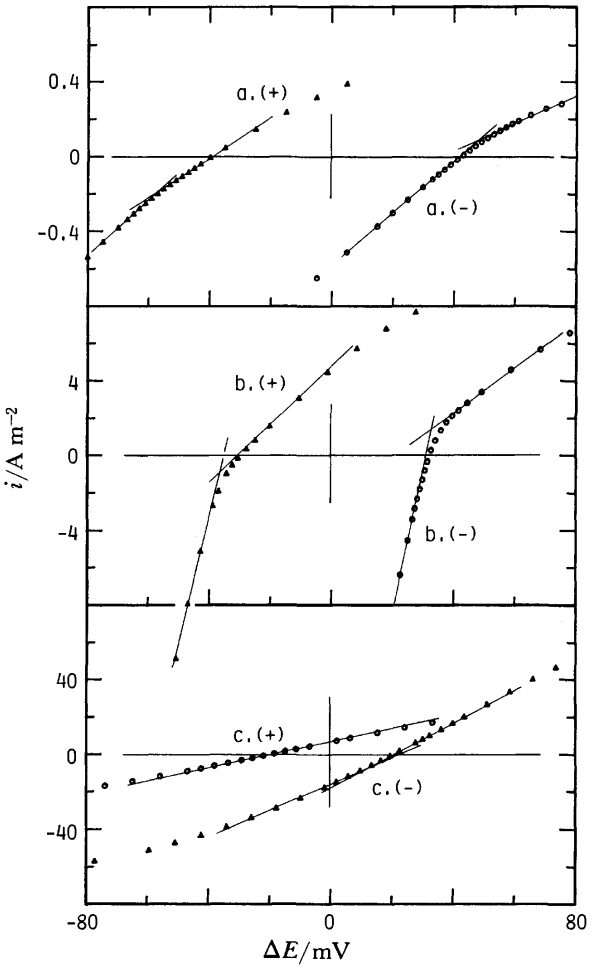

Fig. 13. Relations between steady state current and small potential difference applied at $T_1 \neq T_2$. See Fig. 7.

tion, ΔE_{in}=−0.3 mV for the concentrated $[Fe(CN)_6]^{4-/3-}$ one, and ΔE_{in}=2 mV for the concentrated $Fe^{2+/3+}$ one. In case of low concentration, this inflection point was farther from ΔE=0 than that of the concentrated solutilon, for the same reason as described for weak convection in a cell with a dilute solution.

The $i-\Delta E$ curves measured by small potential differences at $T_1 \neq T_2$ are shown in Fig. 13. The inflection points near i=0 in the $i-\Delta E$ curves (Fig. 13-c) of the cell with $Fe^{2+/3+}$ were not observed clearly. The reason for this may be due to the fact that a change of ΔE from − to + produces a small change in the state of this cell, such as from diffusion to weak convection or from weak convection to strong convection. In cells with $[Fe(CN)_6]^{4-/3-}$ a change of ΔE from + to makes it from diffusion to convection at the both directions of the temperature difference. Therefore, the clearer inflection points were observed in the latter cells. They moved to a somewhat more positive or negative potential difference than $\varepsilon_f \Delta T + \Delta E_{in}$, which is an expected inflection point by assuming no convection due to the temperature difference.

In Fig. 14 three kinds of resistances at $T(=T_1=T_2)$, the steady state resistances under diffusion with no convection (R_d), those under the convection (R_c), and AC resistances measured at 1 or 5 kHz (R_{AC}), are shown. The steady state resistances were calculated from changes in the steady state currents at $|\Delta E|$=5→10 mV. The AC resistances had a small frequency dispersion. Since both resistances (R_d and R_{AC}) are related to the diffusion coefficients, they decreased with an increase in the temperature with almost the same slope in log(R) vs. $1/T$ curves; 0.66±0.04, 0.72±0.09, and 1.1±0.1 $\times 10^3$ K for Fig. 14-a(+, *), b(+, *), and c(−, *), respectively. Since the resistances under convection (R_c) are related not only to R_d and R_{AC}, but also to the convection speeds, there is a possibility of having different features in log(R) vs. $1/T$ curves. However, they exhibited similar slopes in log(R) vs. $1/T$ curves; 0.55, 0.58, and 1.0×10^3 K for Fig. 14-a(−), b(−), and c(+), respectively.

Appendix 2

Thermal Efficiency in the Convection Cells. It is first assumed that a volume, V, of the solution in contact with the electrode at T_H is moved to the electrode at T_L within time Δt; heat flux under this condition can increase by

$$\Delta q_{convection} = V\rho c(T_H - T_L)/\Delta t,$$

where ρ and c are the density and the heat content of the solution, respectively. If all electroactive species transferred

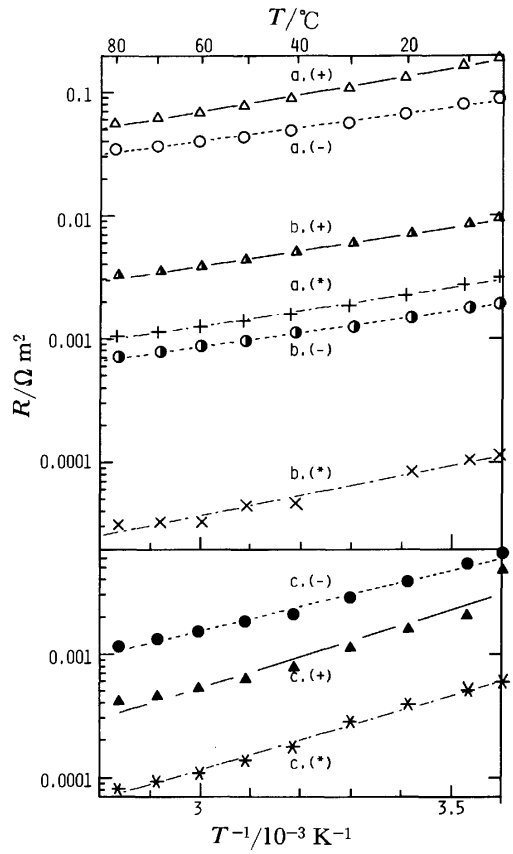

Fig. 14. Steady state and AC resistances as a function of temperature. (T_1=T_2) (+): Steady state R at $\Delta E>0$, (−): steady state R at $\Delta E<0$, (*): R_{AC} at 1 kHz (a and b) or 5 kHz (c), a, b, and c: see Fig. 3.

by this movement have a one-electron charge-transfer reaction with the electrodes, it can result in a current increase

$$\Delta i = FCV/\Delta t \quad (F\text{: Faraday constant}),$$

where C is the concentration of the electroactive species. The efficiency of increased work against the increased heat flux due to the convection is

$$\eta_{convection} = \frac{\varepsilon \Delta T \Delta i}{\Delta q_{convection}} = \frac{F\varepsilon C}{\rho c}.$$

If the efficiency of cells without convection (η_d), which can be roughly estimated as

$$\eta_d = \frac{(\varepsilon \Delta T)(FDC/d)}{k\Delta T/d} = \frac{F\varepsilon DC}{k} \quad (k\text{: thermal conductivity of the solution}),$$

assuming that the current is equal to the limiting current, FDC/d, is larger than $\eta_{convection}$, i.e. if

$$\frac{\eta_{convection}}{\eta_d} = \frac{a}{D} > 1,$$

where $a=k/\rho c$ (thermal diffusivity), the convection will make the thermal efficiency higher than that by the diffusion cell. Since the thermal diffusivity of the pure water is 1.45×10^{-7} $m^2 s^{-1}$ and the diffusion coefficients of many ions in water are in range of 10^{-10}—10^{-8} $m^2 s^{-1}$,[15] it is concluded that the convection always improves the thermal efficiency. If the convection is very strong, however, improvement may be impaired, since the current is limited by $\varepsilon_i \Delta T/R_{AC}$ under this condition. It is necessary to more rigorously determine how convection effects the heat transfer and the electrical resistance. This might be a new type of Benard problem[18] having not only the temperature difference but also the concentration difference induced by the current.

The author wishes to thank Dr. Shigeo Kimura of our Research Institute for his critical reading of the manuscript.

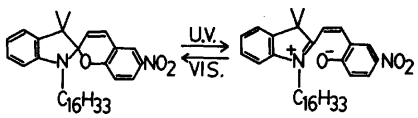
Photo-Excitable Membranes. Effects of Nonactin as a Membrane Additive on the Photoresponse of Poly(vinyl chloride)/ Spirobenzopyran Membrane

Jun-ichi ANZAI, Yasushi HASEBE, Akihiko UENO, and Tetsuo OSA*
Pharmaceutical Institute, Tohoku University, Aobayama, Sendai 980
(Received September 11, 1986)

Synopsis. The magnitude of the photoinduced membrane potential across the poly(vinyl chloride)/spirobenzopyran/nonactin composite membrane depends considerably on the concentration of ammonium ion in the aqueous solution. The results are explained in terms of the charge density on the membrane surface.

Several groups have reported that the membrane potential across the polymer membranes doped with spirobenzopyran derivatives changes reversibly upon photoirradiation.[1-7] We have found that the photoinduced potential changes of more than 100 mV can be attained with rapid response time by the use of plasticized poly(vinyl chloride) (PVC) as a membrane matrix.[5-7] The low density of the fixed charge in the membrane and/or on the membrane surface may be favorable for the enhanced photoresponse. To verify the effects of the charge density on the photoresponse, a macrocyclic ionophore, nonactin, is immobilized in the membrane together with spirobenzopyran derivative (**1**). Since nonactin is an ionophore selective for NH_4^+ ion, it is possible to regulate the charge density on the membrane surface by varying the NH_4Cl concentration in the solution. This paper describes the effects of nonactin as a membrane additive on the photoresponse of the PVC/**1** membrane.



Closed-(1) Open-(1)

Experimental

Materials. PVC (molecular weight of ca. 70000) was obtained from Wako Co. Ltd. and used without further purification. Dibutyl phthalate (DBP), tetrahydrofuran (THF), and ammonium chloride (NH_4Cl) are of extra pure reagent grade. Nonactin was purchased from Fluka Co. The synthetic procedure and analytical data of **1** were reported previously.[7]

Membrane preparation. PVC/**1**/nonactin membrane of ca. 0.15 mm thickness was prepared by pouring the mixture of 250 mg of PVC, 0.5 ml of DBP, 20 mg (0.038 mmol) of **1**, 5 mg (0.007 mmol) of nonactin, and 20 ml of THF onto a flat Petri dish (8.5 cm diameter), and allowing the solvent to evaporate at room temperature. The membrane was conditioned by soaking it in 0.1 mM (M=mol dm^{-3}) NH_4Cl solution before use.

Membrane Potential Measurement. All measurements were conducted at 25 °C using a U-shaped glass cell. The composition of the electrochemical cell for the membrane potential measurements was as follows; Ag/AgCl| 0.1 M $(CH_3)_4NCl$| buffer solution (C_1)| PVC/**1**/nonactin membrane| NH_4Cl solution (C_2)| 0.1 M $(CH_3)_4NCl$| Ag/AgCl. The electrode in the C_1 compartment was earthed. All solutions were prepared using 5 mM Britton-Robinson buffer (pH 5.1). Photoirradiation was carried out from the C_2 side with a 500 W xenon lamp using cut-off filters to isolate UV (320 nm$<\lambda<$400 nm) and visible ($\lambda>$490 nm) light. Noise level in the potential was within 1 mV under the present experimental conditions.

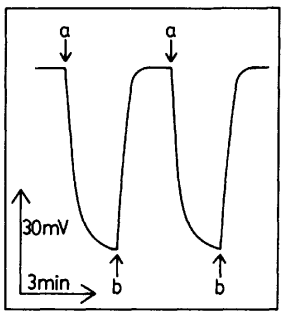


Fig. 1. Photoresponse of the membrane potential across the PVC/**1**/nonactin membrane. The C_2 side solution contained 10^{-5} M NH_4Cl. (a); UV light irradiation and (b); visible light irradiation.

Results and Discussion

A typical photoresponse of the membrane potential across the PVC/**1**/nonactin membrane is depicted in Fig. 1. When the membrane was exposed to UV light, the membrane potential shifted in the negative direction rapidly and, then, the original value of the potential was recovered by the subsequent visible light irradiation. The photoresponse of the membrane potential stems from the photochemical reaction of **1** accompanied with the generation of the fixed charge in the membrane, as was discussed for the PVC/**1** membrane previously.[5-7]

Figure 2 illustrates the membrane potential ($\Delta\phi$) across the PVC/**1**/nonactin membrane in the presence 1×10^{-7}—1×10^{-2} M of NH_4Cl in the C_2 side solution. In the dark, the $\Delta\phi$ values depend linearly on the concentration of NH_4^+ ion in the solution over the range of 1×10^{-5}—1×10^{-2}M, showing that NH_4^+ ions are adsorbed on the membrane surface by forming complexes with nonactin. In other words, the charge density on the membrane surface is determined by the concentration of NH_4^+ ion in the aqueous solution adjacent to the membrane surface. The $\Delta\phi$ values measured under UV light irradiation are also affected by the concentration of NH_4^+ ion in the range of 1×10^{-4}—1×10^{-2} M.

The photoinduced membrane potential ($\Delta(\Delta\phi)$), the difference between the $\Delta\phi$ value under UV light irra-

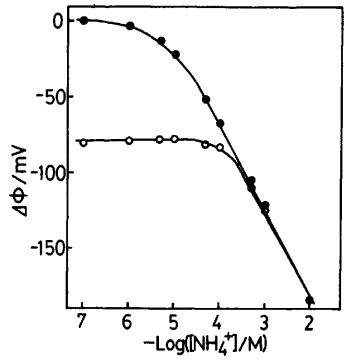

Fig. 2. The membrane potential across the PVC/1/nonactin membrane in the presence of NH_4Cl under UV light irradaition (—○—) and in the dark (—●—). The concentration of NH_4Cl in the C_1 side solution is zero.

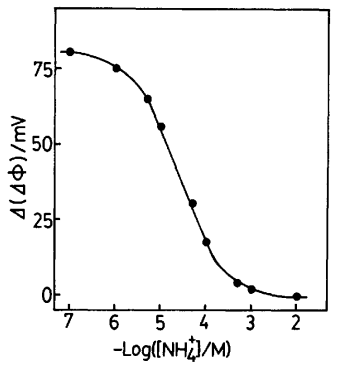

Fig. 3. The effects of the NH_4Cl concentration on the $\Delta(\Delta\phi)$ value.

diation and the one in the dark, is shown in Fig. 3. An approximately linear relationship exists between the $\Delta(\Delta\phi)$ values and the concentration of NH_4^+ ion over the range of 5×10^{-6}—1×10^{-4} M. It is clear that the photoresponse is enhanced in the lower concentration region of NH_4^+ ion. In the case of NH_4^+ ion concentration over 5×10^{-4} M, the photoresponse of the membrane potential is severely suppressed, being only 5 mV or less. This implys that the higher charge density on the membrane surface is not favorable for the enhanced photoresponse.

It is worth noting that these membranes can be applied to the sensitive layer of a novel class of ion sensors which change the $\Delta(\Delta\phi)$ value in response to the concentration of NH_4^+ ion. Furthermore, the membrane may be used for constructing the biosensors by coupling it with microorganisms and enzyme reactions that consume or produce NH_4^+ ion. The development of such biosensors is now in progress in this laboratory.

Liquid Crystal Formation in Binary Systems. XI.[1] Effects of Branching of Ester Alkyl Group on the Induction of Liquid Crystals in the *N,N,N',N'*-Tetramethylbenzidine-Alkyl 4-(4-Nitrobenzylideneamino)benzoate Systems

Yoshio MATSUNAGA* and Yurie NIKI
Department of Chemistry, Faculty of Science, Hokkaido University, Sapporo 060
(Received September 22, 1986)

Synopsis. Smectic A liquid crystals are induced in binary mixtures with normal alkyl esters as well as with esters of branched alkyl groups.

In our previous work,[2] the effects of branching of terminal alkyl groups on the liquid crystal induction in electron-donor-acceptor systems were studied employing nonmesogenic alkyl 4-[4-(dimethylamino)benzylideneamino]benzoates and 4,4'-dinitroazoxybenzene. Smectic A liquid crystals were found not only in the systems with the normal alkyl esters but also with the esters of branched alkyl groups such as *t*-butyl, 1,2-dimethylpropyl, and 1-ethylpropyl. These observations are in contrast with what are known for single mesogenic compounds. According to our study on alkyl 4-(4-phenylbenzylideneamino)benzoates, the *t*-butyl and 1-ethylpropyl esters are nonmesogenic.[3] While the thermally stable nematic and smectic A phases in the propyl ester are eliminated by the introduction of methyl groups to the 1- and 2-carbons, the monotropic smectic B phase is stabilized by 4 °C by the substitution. In order to confirm that methyl branching of the alkyl chains of acceptor molecules does result in the same behavioral trends in binary mixtures, a further study was made on the systems composed of nonmesogenic *N,N,N',N'*-tetramethylbenzidine (TMB) and alkyl 4-(4-nitrobenzylideneamino)-benzoates. TMB is known to produce liquid crystals when it is mixed with 4-alkoxy-4-nitro derivatives of *N*-benzylideneaniline.[4]

Experimental

Materials. *N,N,N',N'*-Tetramethylbenzidine was obtained from Aldrich Chemical Co. and was recrystallized from benzene. The acceptor compounds were prepared by the condensation reaction between *p*-nitrobenzaldehyde and appropriate alkyl *p*-aminobenzoate and purified by repeated recrystallization from ethanol.

Measurements. The calorimetric measurements and visual examinations were carried out as described in our earlier papers.[2,4]

Results and Discussion

The combination of TMB and the ethyl ester gives a phase diagram of the simple eutectic type. The smectic A phase induced in the composition range from 45 to 65 mol% of TMB is stable in a small area as the smectic-isotropic (S-I) transition point curve meets both the freezing point curves of the component compounds near the eutectic point, which is located at 53 mol% and 147 °C. The maximum lies at 152 °C and around 55 mol%. The isopropyl ester forms a 1:1 complex melting incongruently at 144 °C. Metastable smectic A phase appears in the range from 30 to 60 mol%, the maximum temperature being about 148 °C. The *t*-butyl ester complex also produces a peritectic at 151 °C. The maximum of the metastable S-I transition point curve is located at 147 °C. Thus, the branching methyl groups in these two cases enhance the thermal stability of the solid complex but diminish slightly that of the induced smectic A phase.

Figure 1a presents the phase diagram of the propyl ester-TMB system. Unlike the ethyl ester, this ester gives a 1:1 solid complex which decomposes to its component compounds at 104 °C. The induced smectic A phase is stable in the range from 25 to 50 mol%; however, it is metastable at the maximum located at about 138 °C and 55 mol%. No solid complex is produced by the *s*-butyl ester (see Fig. 1b). The smectic A phase is formed entirely beneath the freezing point curve of TMB. Although the maximum of the clearing point curve is not well defined, it is certain that the effect of the branching methyl group on the thermal stability of the mesophase is small.

The phase behavior of the isobutyl ester-TMB system shown in Fig. 1c bears a close similarity to that of the propy ester-TMB system. The peritectic is located at 102 °C and the maximum temperature of the induced mesophase is 133 °C. The latter temperature is lower by 5 °C than the corresponding one found for the *s*-butyl ester. Contrary to these findings, it is generally known for single mesogenic compounds that 1-methylation produces the largest decrease in the thermal stability of the smectic A phase and that as the methyl group is moved to the end of the chain, the effect becomes less marked.[5,6] The stabilization of the solid complex by the methyl groups at both the 1- and 2-carbons is significant (see Fig. 1d). The striking feature is nearly the same maximum S-I transition temperature observed for the 1,2-dimethylpropyl ester- and isobutyl ester-TMB systems.

We examined the effect of a branching methyl group introduced to the 1-, 2-, and 3-carbons respectively on the mesophase induced in the butyl ester-TMB system. The butyl and 1-methylbutyl esters yield diagrams of the peritectic type. The smectic A phase is enantiotropic in the former system and is monotropic in the latter. The whole S-I transition point curve is below the freezing point curve of TMB in the diagrams of the simple eutectic type given by the other two esters. Although the clearing point curve is traceable up to 55 mol% of TMB, the maximum appears to be located at a composition a little higher than this. The highest observable temperature is 149 °C for the liquid crystal

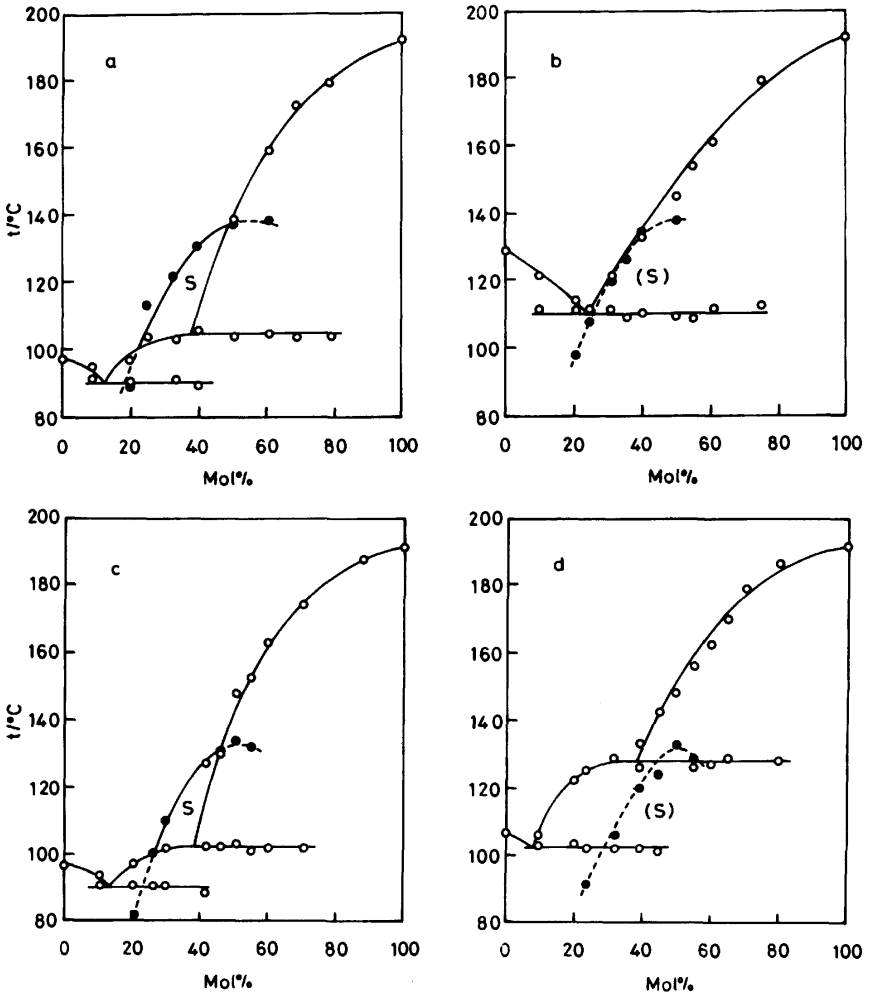

Fig. 1. Phase diagrams of the systems of TMB with (a) the propyl ester, (b) the *s*-butyl ester, (c) the isobutyl ester, and (d) the 1,2-dimethylpropyl ester. The open and shaded circles are transitions observed in the processes of heating and cooling respectively.

given by the butyl ester. It is depressed to 140 °C by 1-methylation, to 134 °C by 2-methylation, and to 138 °C by 3-methylation. The degree of depression by 1- and 2-methyl groups is consistent not only with the tendency found with the propyl ester but also with that reported for the alkyl 4-[4-(dimethylamino)benzylideneamino]benzoate-4,4′-dinitroazoxybenzene system.[2] Thus, the anomalously small effects of 1-methylation of terminal alkyl groups appear to be common to binary liquid crystals and the arguments proposed in the previous paper may also be advanced for them. The 1-methyl group may be accommodated readily within room made available by shorter molecules and cause no serious steric effects when molecules of different lengths are aligned side by side.

Electrocrystallization of Phenothiazine

Kyuya YAKUSHI,* Michiko YOSHITAKE, and Haruo KURODA
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo 113
(Received October 1, 1986)

Synopsis. New cation radical salts of phenothiazine with (1:1), (3:2), and (2:1) compositions were prepared by the method of electrochemical oxidation. The electrical resistivities measured on the compaction of crystalline powder were 10^3—10^5 Ω cm at room temperature in the case of the complex salts. The powder absorption spectra in IR and Visible regions were also studied.

Phenothiazine (PTZ) is an electron donor with relatively low oxidation potentials, 0.58 volt vs. SCE, in acetonitrile solution.[1] The electron donor-acceptor compounds and the cation radical salts of PTZ have been studied by several groups,[2-9] but little is known about the behaviors of the complex salts: Only the bromine and iodine complexes prepared by the solid state reaction[10-13] are the complex salts of PTZ which have been studied so far. In addition to the property as an electron donor, PTZ is expected to behave as a proton donor as well as proton acceptor. This could provide a possibility to prepare a new type electronic conductor in which the coupling between the conduction electrons and proton plays an important role. From this point of view, we synthesized several complex salts of PTZ by means of the electrochemical method.

Experimental

The PTZ were recrystallized twice from its benzene solution. As the solvent of elctrochemical reaction, we used 1,2-dichloroethane which were purified by distillation with CaH_2 in nitrogen atmosphere. The materials for the counter anions, $(n\text{-Bu})_4NX$, (X=BF_4, ClO_4, ReO_4, $FeCl_4$, PF_6, AsF_6) were recrystallized for 2 or 3 times from methanol or ethanol. The electrochemical preparation of PTZ salts were carried out by using a U-shape electrochemical cell, in which the anode and the cathod compartments are separated by glass filters. Platinum plates were used as the electrodes. The concentrations of PTZ and supporting electrolyte were 2×10^{-2} mol dm^{-3} and 3×10^{-2} mol dm^{-3}, respectively. The electrochemical preparation were conducted in the galvanostatic mode with a current of 100 μA for 2 d. Since the solubility of PTZ salt is very high, the electrochemical cell were cooled down to −35 °C. The salt crystals deposited on the anode were washed by cooled 1,2-dichloroethane. The results of the chemical analysis are as follows; $(PTZ)FeCl_4$, Found/Calcd: C, 36.50/36.31; H, 2.75/2.29; N, 3.65/3.53; S, 7.80/8.08; Cl, 32.78/35.73.[14] $(PTZ)_2BF_4$, Found/Calcd: C, 57.87/59.39; H, 3.79/3.74; N, 5.62/5.77; S, 12.92/13.21. $(PTZ)_2ClO_4$, Found/Calcd: C, 57.76/57.88; H, 3.65/3.64; N, 5.70/5.63; S, 13.21/12.88; Cl, 7.39/7.12. $(PTZ)_2PF_6$,[15] C, 52.07/53.04; H, 3.30/3.34; N, 5.08/5.15. $(PTZ)_2AsF_6$, C, 48.91/49.07; H, 3.06/3.09; N, 4.79/4.77; S, 11.37/10.91. $(PTZ)_3(ReO_4)_2$, C, 39.42/39.37; H, 2.70/2.48; N, 3.76/3.83; S, 8.56/8.76.

The powder absorption spectra of PTZ salts were measured with HITACHI 260-30 for the infrared region and HITACHI 340 for the Near IR and visible region by use of the KBr disk method.

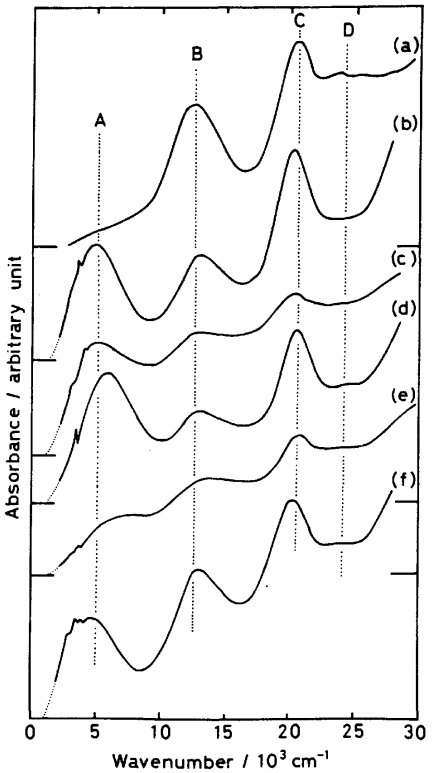

Fig. 1. Absorption spectra of phenothiazine (PTZ) radical salts. (a) $(PTZ)FeCl_4$, (b) $(PTZ)_2BF_4$, (c) $(PTZ)_2ClO_4$, (d) $(PTZ)_2PF_6$, (e) $(PTZ)_2AsF_6$. (f) $(PTZ)_3(ReO_4)_2$.

Results and Discussion

All PTZ complexes were obtained as black crystalline powders. Hexagonal prism were sometimes obtained in the case of $(PTZ)_2ClO_4$ when acetonitrile was used as a solvent, but they were found to be not a single crystal but polycrystalline by X-ray diffraction. PTZ is known to have many oxidation stages in solution including the transfer of hydrogen atom.[16] In this electrochemical cell, the solution always had an orange color at low temperature, which is the typical color of a PTZ radical cation. However, the color of the solution rapidly changed to deep green on mixing of the solutions in the anode and the cathod compartments. The UV-Visible absorption spectrum of the 1,2-dichloroethane solution of each PTZ salt exhibited the spectrum characteristic of PTZ cation radical, which has a weak absorption band around 13.5×10^3 cm^{-1} accompanied by several vibrational structures, a strong band at 19.3×10^3 cm^{-1} with vibrational progressions and a band at 22.5×10^3 cm^{-1}.[7] The absorption bands, B, C, and D of the solid PTZ complexes shown in Fig. 1 correspond to each of these character-

istic absorption bands of PTZ cation radical, providing an evidence for the formation of the PTZ cation radical salt.

The absorption spectrum of solid (PTZ)$FeCl_4$ is quite similar to the polarized absorption spectrum of the single crystal of the PTZ simple salt, (PTZ)$SbCl_6$,[8] in which the PTZ cation is isolated without charge-transfer interaction. Therefore, solid (PTZ)$FeCl_4$ is likely to be composed of an isolated PTZ cation radical. The spectra of $(PTZ)_2BF_4$, $(PTZ)_2ClO_4$, $(PTZ)_2PF_6$, and $(PTZ)_2AsF_6$ are quite similar to each other. They exhibit an absorption band, A, around 5×10^3 cm^{-1}, in addition to bands associated with the intramolecular transitions of PTZ cation radical, B, C, and D. These salts involve formally PTZ^+ and PTZ^0 according to their chemical composition. We can assign the new absorption band, A, to the charge-transfer(CT) transition from PTZ^0 to PTZ^+, since this type of CT band usually appears in the near infrared or infrared region in the case of the organic charge-transfer salts with a mixed valence molecular column. The CT transition of the same type were observed at about 4×10^3 cm^{-1} in TCNQ complex salt[17] and around 2×10^3 cm^{-1} in (2:1) TMTTF salt.[18] Very similar spectra were observed by Doi and Matsunaga in $(PTZ)_2Br$, which were synthesized by the solid state reaction between (PTZ)Br and PTZ.[10] The absorption band corresponding to A was also observed in (PTZ)Br by Iida who attributed it $(PTZ^0)(PTZ^+)(Br_3^-)$ contained by a small amount in the sample of (PTZ)Br.[7] Matsunaga and Shono found that the intensity of the above-mentioned band significantly increased by the addition of iodine to (PTZ)Br,[11] and suggested the formation of a complex cation salt, $(PTZ^0)(PTZ^+)(IBr_2^-)$. All these PTZ complex salts hitherto investigated were prepared by means of the solid state reaction, and are not stoichiometric compounds. In contrast, the PTZ complex salts obtained in the present study were prepared by the electrochemical oxidation and have a definite composition. To the best of our knowledge, these are the first stoichiometric complex salts of PTZ ever made. Among the complex salts prepared here, $(PTZ)_3(ReO_4)_2$ has a stoichiometry different from other salts, but the absorption spectrum of this material was almost the same as the (2:1) complex salts except that the CT band is slightly shifted to the low-wavenumber side.

Finally we listed in Table 1 the electrical resistivities measured on the compaction of powder sample. Unfortunately, none of them exhibits a metallic low resistivity, although the resistivities of the complex salts are found to be smaller by a factor of 10^2—10^3 than that of the simple salt, (PTZ)$FeCl_4$.

Table 1. Electrical Resistivity and the Position of the CT Band of PTZ Cation Radical Salts

Salts	ρ/Ωcm	$\nu_{max}/10^3$ cm^{-1}
(PTZ)$FeCl_4$	2×10^7	—
$(PTZ)_2BF_4$	4×10^4	4.8
$(PTZ)_2ClO_4$	1×10^5	5.0
$(PTZ)_2PF_6$	7×10^5	5.9
$(PTZ)_2AsF_6$	2×10^5	7.6
$(PTZ)_3(ReO_4)_2$	4×10^3	4.5

Partition Parameters for Three Redox Forms of Viologen in a Nonionic Micellar Solution

Katsuyoshi HOSHINO, Hiroaki SASAKI, Kosaku SUGA, and Tetsuo SAJI*
Department of Chemical Engineering, Tokyo Institute of Technology, Ohokayama, Meguro-ku, Tokyo 152
(Received October 24, 1986)

Synopsis. The partition parameters of 1,1′-dimethyl-4,4′-bipyridinium (**1**), 1-decyl-1′-methyl-4,4′-bipyridinium (**2**), and 1-dodecyl-1′-methyl-4,4′-bipyridinium (**3**) between the micellar and water phases were determined by electrochemical methods. It was shown that $\mathbf{1}^0$, $\mathbf{2}^{+}$, $\mathbf{2}^0$, and $\mathbf{3}^{2+}$ are almost completely solubilized in the micellar phase and that $\mathbf{1}^{2+}$, $\mathbf{1}^{+}$ and $\mathbf{2}^{2+}$ are partitioned into two phases.

In relation to photochemical splitting of water, the reduction of 1,1′-dimethyl-4,4′-bipyridinium (methyl violigen) and its surfactant derivatives with photoexcited sensitizers has been investigated in micellar systems.[1] In order to interpret quantitatively the efficiency and kinetics of this process, we must know partition parameters (K) of the viologens between micellar and water phases, because the reaction rate of micelle-solubilized substance is a function of K for both the reactants and the products.[2,3]

No report, however, has dealt with the change in partition of viologens in redox states of bipyridinium group. The purpose of this paper is to estimate the values of K for divalent, mono-reduced, and fully reduced viologens in a nonionic micellar system by means of electrochemical methods.

The viologen derivatives studied are 1,1′-dimethyl-4,4′-bipyridinium dichloride (**1**), 1-decyl-1′-methyl-4,4′-bipyridinium dibromide (**2**), and 1-dodecyl-1′-methyl-4,4′-bipyridinium dibromide (**3**).

Experimental

3 was prepared by the method described in the literature[4] and identified by elemental analysis and melting point. The synthesis of **2** was similar to that of **3**: Mp 266—267 °C; Found: C, 52.85; H, 6.84; N, 5.73%. Calcd for $C_{21}H_{32}N_2Br_2$: C, 53.52; H, 6.63; N, 5.94%. **1** was used as supplied by Tokyo Kasei Co.

Electrochemical measurements were carried out at 25 °C under a nitrogen atmosphere for test solutions containing 0.1 M (1 M=1 mol dm^{-3}) NaCl as a supporting electrolyte. A glassy-carbon disk electrode and a saturated calomel electrode (SCE) were used respectively as working and reference electrodes in cyclic voltammetry and potential-step chronoamperometry. Controlled potential bulk electrolysis was performed with a Hg working electrode.

The host surfactant used is α-[*p*-(1,1,3,3-tetramethylbutyl)-phenyl]-ω-hydroxypoly(oxyethylene), Triton X-100, (TX-100, Wako Pure Chemicals Co.) and used as supplied. The concentration of TX-100 was kept constant at 0.1 M throughout the experiments. The concentration of **1**, **2**, and **3** in 0.1 M TX-100 micellar solution was ajusted to the condition that one micelle contains not more than one molecule of **1**, **2**, and **3** on average. All of the solutions were prepared with twice-distilled water.

Results and Discussion

Figure 1 shows cyclic voltammograms for solutions of 0.62 mM $\mathbf{1}^{n+}$ (n=2, 1, and 0) containining 0.1 M TX-100 and 0.1 M NaCl. The solutions of $\mathbf{1}^{+}$ and $\mathbf{1}^0$ were prepared by controlled-potential bulk reduction of $\mathbf{1}^{2+}$ at −0.84 and −1.3 V vs. SCE, respectively. The color of the solution of $\mathbf{1}^{+}$ was intense blue, while that of $\mathbf{1}^0$ was brownish yellow.

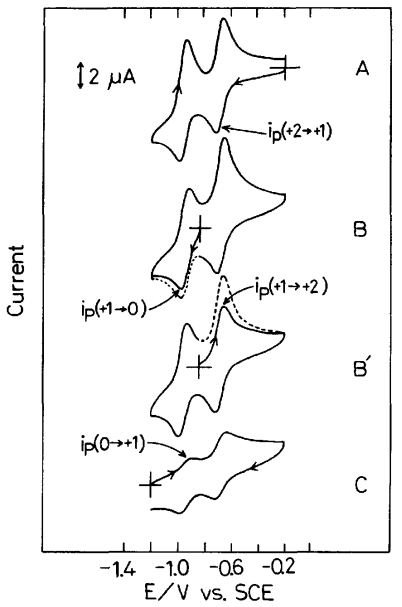

Fig. 1. Cyclic voltammograms for (A) a solution of 0.62 mM $\mathbf{1}^{2+}$, (B) and (B′) a solution of 0.62 mM $\mathbf{1}^{+}$, and (C) a solution of 0.62 mM $\mathbf{1}^0$ containing 0.1 M TX-100 and 0.1 M NaCl at 25 °C. Sweep rate: 12 mV s^{-1}. Working electrode area: 0.071 cm^2.

The first and the second reduction steps seem to be reversible one-electron processes judging from the value of peak separation, i.e., the difference between cathodic and anodic peak potentials.[5] The half-wave potentials were −0.69 and −0.96 V vs. SCE for the first and the second reduction steps, respectively. These values agreed well with those described in the literature.[6] The peak current for the first reduction step of $\mathbf{1}^{2+}$, $i_p(+2\rightarrow+1)$, in Fig. 1A is nearly equal to that for the first reduction step of $\mathbf{1}^{+}$, $i_p(+1\rightarrow0)$, in Fig. 1B and that for the first oxidation step of $\mathbf{1}^{+}$, $i_p(+1\rightarrow+2)$, in Fig. 1B′. On the other hand, the peak current for the first oxidation step of $\mathbf{1}^0$, $i_p(0\rightarrow+1)$, in Fig. 1C is much smaller than $i_p(+2\rightarrow+1)$, $i_p(+1\rightarrow0)$, and $i_p(+1\rightarrow+2)$.

Table 1 shows the apparent diffusion coefficients (D_{app}) for $\mathbf{1}^{2+}$, $\mathbf{1}^{+}$, and $\mathbf{1}^0$ in a solution containing 0.1 M TX-100 and 0.1 M NaCl. D_{app} was determined from inclination of the current vs. (time)$^{-1/2}$ plot in potential-step chrono-amperometry.[5]

According to the electrochemistry of micelle-solubilized substances,[3,7] D_{app} for the solubilizate (S) partitioning into micellar and aqueous phases gives the partition parameter (K) defined as the ratio of concentration of S in aqueous phase, [S]$_w$, to that in

Table 1. Apparent Diffusion Coefficient (D_{app}), Partition Parameter (K), and Mole Fraction in the Micellar Phase (x) of **1**, **2**, and **3** in 0.1 M NaCl with and without 0.1 M TX-100 at 25 °C

Solubilizate	Surfactant	$D_{app}\times10^6$ / $cm^2\,s^{-1}$	K	x
$\mathbf{1}^{2+}$	—	14	—	—
$\mathbf{1}^{2+}$	0.1 M TX-100	7.4	1.0	0.50
$\mathbf{1}^{+}$	0.1 M TX-100	7.4	1.0	0.50
$\mathbf{1}^{0}$	0.1 M TX-100	0.73	0.01	0.99
$\mathbf{2}^{2+}$	—	8.0	—	—
$\mathbf{2}^{2+}$	0.1 M TX-100	3.1	0.50	0.67
$\mathbf{2}^{+}$	0.1 M TX-100	1.4	0.11	0.90
$\mathbf{2}^{0}$	0.1 M TX-100	0.71	0.01	0.99
$\mathbf{3}^{2+}$	—	8.0	—	—
$\mathbf{3}^{2+}$	0.1 M TX-100	0.87	0.03	0.97

micellar phase, $[S]_M$:

$$D_{app} = ([S]_W D_W + [S]_M D_M)/([S]_W + [S]_M), \quad (1)$$

$$K = [S]_W/[S]_M = (D_{app} - D_M)/(D_W - D_{app}), \quad (2)$$

where D_M is the diffusion coefficient of micelles and D_W, the diffusion coefficient of the monomeric S measured in an aqueous solution without micelle. These equations are based on the assumption that the solubilization equilibrium of S is established in the diffusion process of S toward the electrode.

$$S + \text{micelle} \rightleftarrows S(\text{in micelles}), \quad (3)$$

This assumption is valid for $\mathbf{1}^{n+}$ (n=2, 1, and 0), $\mathbf{2}^{n+}$ (n=2, 1, and 0), and $\mathbf{3}^{2+}$ because the electrode reactions were diffusion-controlled, i.e., the current vs. $(\text{time})^{-1/2}$ plots in potential-step chronoamperometry gave straight lines.[8] D_M for TX-100 micelle in the presence of 0.1 M NaCl was 6.5×10^{-7} $cm^2\,s^{-1}$ determined by the method described in the literature.[3] D_W for $\mathbf{1}^{2+}$ in 0.1 M NaCl aqueous solution was 1.4×10^{-5} $cm^2\,s^{-1}$. The values of K for $\mathbf{1}^{2+}$, $\mathbf{1}^{+}$, and $\mathbf{1}^{0}$ were determined by Eq. 2 on the assumption that the values of D_W for $\mathbf{1}^{+}$ and $\mathbf{1}^{0}$ are equal to D_W for $\mathbf{1}^{2+}$ (Table 1). Table 1 also lists the mole fraction (x) of $\mathbf{1}^{n+}$ (n=2, 1, and 0) solubilized in the micellar phase, which can be derived from the respective K value.

$$x = [\mathbf{1}^{n+}]_M/([\mathbf{1}^{n+}]_M + [\mathbf{1}^{n+}]_W),$$

$\mathbf{1}^{2+}$ and $\mathbf{1}^{+}$ are partitioned equally into two phases, and $\mathbf{1}^{0}$ is almost completely solubilized in the micellar phase.

Figure 2 shows cyclic voltammograms for solutions of 0.62 mM $\mathbf{2}^{n+}$ (n=2, 1, and 0) containing 0.1 M TX-100 and 0.1 M NaCl. At a relatively slow sweep rate, both the first and the second reduction steps were electrochemically reversible one-electron steps. The half-wave potentials were −0.56 and −0.84 V vs. SCE for the first and the second reduction steps, respectively.

The peak current is in order of $i_p(+2\rightarrow+1)>i_p(+1\rightarrow0)=i_p(+1\rightarrow+2)>i_p(0\rightarrow+1)$, suggesting that the value of D_{app} is in order of $\mathbf{2}^{2+}>\mathbf{2}^{+}>\mathbf{2}^{0}$. The values of D_{app}, K, and x for $\mathbf{2}^{2+}$, $\mathbf{2}^{+}$, and $\mathbf{2}^{0}$ determined by potential-step chronoamperometry are listed in Table 1. K and x show that the proportion of the solutes in the micellar phase is in order of $\mathbf{2}^{2+}<\mathbf{2}^{+}<\mathbf{2}^{0}$, and that $\mathbf{2}^{+}$ is more hydrophobic than $\mathbf{2}^{2+}$. This result is different from the case of methyl viologen.

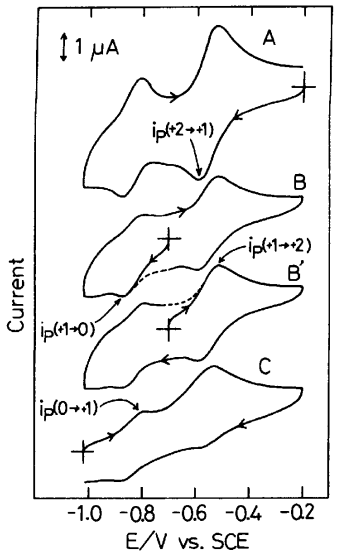

Fig. 2. Cyclic voltammograms for (A) a solution of 0.62 mM $\mathbf{2}^{2+}$, (B) and (B') a solution of 0.62 mM $\mathbf{2}^{+}$, and (C) a solution of 0.62 mM $\mathbf{2}^{0}$ containing 0.1 M TX-100 and 0.1 M NaCl at 25 °C. Sweep rate: 12 mV s^{-1}. Working electrode area: 0.071 cm^2.

D_{app}, K, and x for $\mathbf{3}^{2+}$ are also shown in Table 1. The values of x mean that $\mathbf{3}^{2+}$ is completely solubilized in the micellar phase irrespective of its highly hydrophilic character of bipyridinium group. D_{app} values for $\mathbf{3}^{+}$ and $\mathbf{3}^{0}$ were not obtained, because their electrochemical behavior was complicated due to the adsorption on electrode surface.

The results described in this paper and particularly the suggestion of hydrophobic nature of viologen derivatives with different redox states will be useful for designing a redox system with viologen and for predicting reaction mechanism of chemical conversion of light energy.

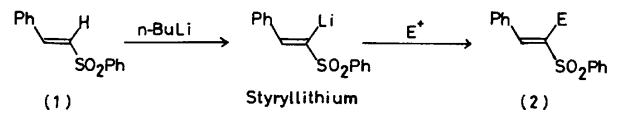
Lithio Styryl Sulfone as an Acyl Anion Synthon

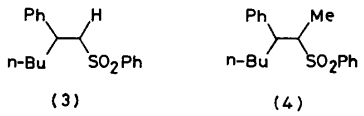
Makoto YAMAMOTO,* Kazuya SUZUKI, Seiji TANAKA, and Kazutoshi YAMADA
Department of Industrial Chemistry, Faculty of Engineering, Chiba University, 1-33 Yayoi-cho, Chiba 260
(Received October 11, 1986)

Synopsis. Lithio styryl sulfone, which was shown to be an acyl anion synthon, reacted with various electrophiles; the products were rearranged by treatments with *m*-chloroperbenzoic acid to give acyl benzyl sulfones in good yields.

Recents reports concerning reactions of vinyl anions (especially α-vinyl anions activated with such heteroatoms as oxygen,[1] sulfur,[2] nitrogen,[3] silicon,[4] halogen,[5] or selenium[6]) showed that these anions serve as useful synthons for organic syntheses.

Here, we wish to report on a method for the formation and the reaction of lithio styryl sulfone and alkylated products (after epoxidation with *m*-chloroperbenzoic acid (*m*-CPBA)) rearranged to acyl benzyl sulfones in good yields.





Scheme 1.

(*E*)-Phenyl styryl sulfone (**1**) was lithiated at the β-styryl position regioselectively with butyllithium in tetrahydrofuran (THF) at −78 °C under nitrogen. Styryllithium is stable below −50 °C for several hours, but above −15 °C it gradually decomposes. Styryllithium reacted smoothly with methyl iodide between −78 and −50 °C to give (*E*)-1-phenyl-2-phenylsulfonyl-1-propene (**2a**), mp 91—92 °C (lit,[7] mp 90—93.5 °C) in 92% yield. The reaction was highly regioselective and only the β-methylated product **2a** was obtained. Although this styryl sulfone system has the property that it tends to serve as a Michael acceptor for bases[8] and organometallics,[9] none of **3** or **4** could be detected in a reaction of styryllithium with methyl iodide.[2b]

Styryllithium was allowed to react with various electrophiles to give the corresponding products in good yields (Table 1).

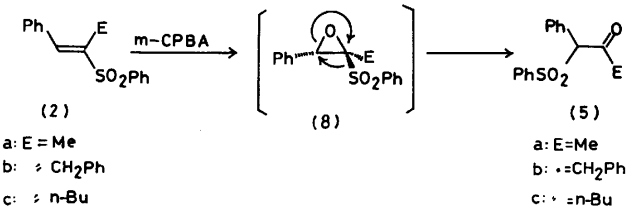
Alkylated styryl sulfone (**2a**) was treated with 3 equivalents of *m*-CPBA in refluxing carbon tetrachloride for 48 h to give 1-phenyl-1-phenylsulfonyl-2-propanone (**5a**), mp 120—122 °C (lit,[10] mp 122—123 °C) in 82% yield. In this reaction none of the Baeyer-Villiger oxidation product (**6** or **7**) was detected.

In the mechanism for the formation of **5a** from **2a**, it is considered that upon a treatment of **2a** with *m*-CPBA, epoxy sulfone (**8**) is initially formed as an unstable intermediate and then rearranged to an acyl compound **5a**, as illustrated in Scheme 2.[11,12]

Table 1. The reaction of Styryllithium with Various Electrophiles

Entry	Electrophile	Yield/%
a	MeI	92
b	$PhCH_2Br$	90[a]
c	*n*-BuI	88[a]
d	PhCOCl	89[a]
e	$(n\text{-Bu})_3SnCl$	85[b]

a) Same reaction condition as general procedure A. b) In addition to the reaction condition of general procedure A, 10 mmol of tetramethylethylenediamine (TMEDA) was used as a stabilizer of styryllithium.



Scheme 2.

Scheme 3.

Styryl sulfones **2b** and **2c** were also allowed to become oxidatively rearranged to the corresponding products: **5b** (75%) and **5c** (72%).

By combining this regioselective alkylation and oxidative rearrangement, it is obvious that lithio phenyl styryl sulfone is a masked acyl anion synthon (Scheme 3). Furthermore, the sulfonyl group can be easily removed from the sulfone (**5**) to obtain an olefin; it can also be reductively removed to form a saturated acyl compound, indicating that this method is useful in organic syntheses.

Experimental

(*E*)-Phenyl Styryl Sulfone (1): Compound **1** was synthesized from methyl phenyl sulfone with benzaldehyde in the presence of a base and a phase-transfer catalyst.[13]

Formation and Reaction of Lithio Styryl Sulfone: General Procedure A: To a stirred solution of **1** (2.44 g, 10 mmol) in 60 ml of dry THF, 6.3 ml (10 mmol) of *n*-BuLi (1.6 mol solution in hexane) was added dropwise within 5 min at −78 °C under a nitrogen atmosphere. After 30 min styryllithium was formed as a red solution.

To this red solution 1.42 g (10 mmol) of methyl iodide in dry THF (5 ml) was added dropwise, continuously stirred at −78—−50 °C for 1 h and then warmed to room temperature within 30 min. The reaction mixture was quenched with water and neutralized with diluted hydrochloric acid. The organic layer was separated and the aqueous layer was extracted with ethyl acetate. The combined organic layer was dried over anhydrous magnesium sulfate and concentrated. The crude product was purified by silica-gel column chromatography with benzene to give a crystalline product **2a** (2.37 g, 92%), mp 91—92 °C (lit,[7] mp 90—93.5 °C). ^{1}H NMR (CCl_4) δ=2.04 (d, 3H), 7.30 (s, 5H), 7.50 (m, 3H), 7.8—8.0 (m, 3H). MS *m/z* 258 (M^+).

Test of the Stability of Styryllithium: The lithio compound was formed by the general procedure A; then, the solution was warmed to −15 °C in an ice-salt bath. After 15 min stirring at −15 °C an equimolar amount of methyl iodide was added dropwise and the reaction mixture was treated by general procedure A. Only 24% of **2a** was detected.

Compound **2b—e** was synthesized by general procedure A.

2b: Mp 143.5—145.5 °C (from EtOH). ^{1}H NMR ($CDCl_3$) δ=4.05 (s, 2H), 7.06 (s, 5H), 7.38 (m, 8H), 7.74 (m, 2H), 8.13 (s, 1H). Found: C; 75.43, H; 5.46% Calcd for $C_{21}H_{18}O_2S$; C; 75.42, H; 5.42%.

2c: Oil ^{1}H NMR (CCl_4) δ=0.68—1.60 (m, 7H), 2.32 (m, 2H), 6.90—7.90 (m, 11H).

2d: Mp 136—137 °C (from EtOH) (Lit,[14] mp 137—138 °C). IR (neat) 1670 (C=O), 1310 and 1150 cm^{-1} (SO_2).

2e: Oil NMR (CCl_4) 0.62—1.60 (m, 27H), 7.28 (s, 5H), 7.51 (m, 3H), 7.85 (m, 2H), 7.83 (s, 1H).

1-Phenyl-1-phenylsulfonyl-2-propanone (5a): General Procedure B: The mixture of **2a** (318 mg, 1.16 mmol) and *m*-CPBA (600 mg, 3.48 mmol) in CCl_4 (10 ml) was refluxed for 48 h under nitrogen. The reaction mixture was then washed with a diluted sodium hydrogencarbonate solution three times and with a diluted sodium hydrogensulfite solution. The organic layer was separated and the aqueous layer was extracted with chloroform. The combined organic layer was worked up as usual and the obtained residue was purified by silica gel column chromatography with benzene-ethyl acetate (19:1) to give crystalline product **5a** in 82% (260 mg) yield. Mp 120—122 °C (lit,[10] mp 122—123 °C). ^{1}H NMR ($CDCl_3$) δ=2.30 (s, 3H), 5.29 (s, 1H), 7.19 (s, 5H), 7.3—7.7 (m, 5H). IR ($CHCl_3$) 1730 (C=O), 1310 and 1150 cm^{-1} (SO_2). MS *m/z* 274 (M^+, 25), 232 (M^+-CH_2CO, 100).

According to general procedure B, compound **5b** and **5c** were synthesized.

5b: Mp 145—145.5 °C (from benzene). ^{1}H NMR ($CDCl_3$) δ=4.00 (s, 1H), 7.00 (s, 5H), 7.1—7.5 (m, 8H), 7.70 (m, 2H), 8.10 (s, 1H). MS *m/z* 192 ($M-PhSO_3H$, 100), 91 ($PhCH_2^+$, 72). Found: C; 71.86, H; 5.15%. Calcd for $C_{21}H_{18}O_3S$: C; 71.98, H; 5.18%.

5c: Oil ^{1}H NMR ($CDCl_3$) δ=0.85 (m, 3H), 1.00—1.60 (m, 4H), 2.65 (t, 2H), 5.24 (s, 1H), 7.3—8.2 (M, 10H). IR ($CHCl_3$) 1730 cm^{-1} (C=O)

Oxidation of 2d: Compound (**2d**) (500 mg, 1.44 mmol) and *m*-CPBA (496 mg, 2.88 mmol) in 15 ml of CCl_4 were refluxed for 24 h. The reaction mixture was then treated as general procedure B. Benzoic acid (81 mg), mp 120—122 °C (lit,[15] mp 122.4 °C) was obtained and the starting material **2d** (308 mg, 62%) was recovered. Both compounds could be identified by their NMR spectra, compared with those of known samples.

Oxidation of 2e: Compound **2e** (250 mg, 0.47 mmol) and *m*-CPBA (162 mg, 0.94 mmol) in 7 ml of CCl_4 were refluxed for 24 h. The reaction mixture was treated by general procedure B. Phenyl styryl sulfone (**1**) (61 mg, 53%) and an unknown product (92 mg) (NMR spectrum of this product in CCl_4 showed at 0.7—1.8 ppm.) were obtained. In this reaction the starting material (**2e**) was not recovered.

Hexacarbonylmolybdenum(0)-Catalyzed Reaction of Allylic Carbonates with Arylsulfonyl-Stabilized Carbanions

Yoshiro MASUYAMA,* Hidenori HIRAI, Yasuhiko KURUSU, and Koh-ichi SEGAWA
Department of Chemistry, Faculty of Science and Technology, Sophia University, 7-1, Kioicho, Chiyoda-ku, Tokyo 102
(Received October 23, 1986)

Synopsis. *p*-Tolylsulfonylacetonitrile reacted with allylic carbonates in the presence of a catalytic amount of hexacarbonylmolybdenum(0) to give monoallylated derivatives. Using sodium hydride as a base, methyl *p*-tolylsulfonylacetate reacted with those to give mixtures of mono- and di-allylated derivatives. No nucleophilic attack of bulky bis-(phenylsulfonyl)methane occurred, whether sodium hydride was present or absent.

Hexacarbonylmolybdenum(0), which is available and stable to oxygen and moisture, is a convenient catalyst for allylic alkylation of carbon nucleophiles with allylic acetates and carbonates.[1] However, sulfones, which stabilize an adjacent carbanion and are easily transformed into other functional groups,[2,3] can not be applied as a carbon nucleophile in this catalytic allylic alkylation yet. If sulfones could be used, the molybdenum-catalyzed allylic alkylation would increase significance as a synthetic tool for the formation of carbon framework in organic synthesis.[4] Here, we wish to report that sulfones, especially *p*-tolylsulfonylacetonitrile reacts with allylic carbonates in the presence of a catalytic amount of $Mo(CO)_6$ to give monoallylated products.

Using methyl *p*-tolylsulfonylacetate (**1**),[5] *p*-tolylsulfonylacetonitrile (**2**),[6] and bis(phenylsulfonyl)methane (**3**)[7] as carbon nucleophile, reactivity of allyl acetate and allyl carbonate for $Mo(CO)_6$-catalyzed reaction was investigated under various conditions. In the case of allyl acetate, neither of carbanions, derived from **1** and **2** with sodium hydride, reacted under the conditions similar to those in the reaction of dimethyl malonate.[1] In refluxing dioxane containing 2,2′-bipyridyl (bpy), a trace of likely product could be detected by thin-layer chromatography. Consequently, investigation of allyl carbonate was attempted using bpy in dioxane, as summarized in Table. **1** did not react under neutral conditions, namely without a base (Entry 1).[8] The use of sodium hydride for the abstraction of proton from **1** caused allylation. However, no selectivity of monoallylation was exhibited, and a mixture of mono- (**4**, 36%) and di-allylated product (40%) was found (Entry 2). On the other hand, the reaction of **2** under neutral conditions provided only monoallylated product in 64% yield (Entry 4). In refluxing THF, the yield was lowered to 16% (Entry 5). Unfortunately, even allyl carbonate did not react with **3**. It seems that steric hindrance of two bulky phenylsulfonyl groups disturbs nucleophilic attack of **3** to π-allylmolybdenum complex.[9] Addition of PPh_3 and *N,N,N′,N′*-tetramethylethylenediamine instead of bpy did not promote the reaction.

The reactions of several allylic carbonates were carried out under the same conditions as Entries 2 and 4 in Table. The results are also summarized in the Table. In the case of crotyl carbonate as well as allyl carbonate, selectivity of **1** to monoallylation was low, while **2** showed high selectivity (Entries 6—8). The reactivity of **2** to α,γ-disubstituted allyl carbonate (2-cyclohexenyl carbonate) was low (Entry 11). Further, geranyl carbonate did not react with **2**. This reaction should be limited by steric demand of both the α-sulfonyl carbanion and the allylic carbonate. At all events, it became possible to employ available *p*-tolylsulfonylacetonitrile (**2**) as the α-sulfonyl carbanion source in the chemistry of π-allylmolybdenum complex.

Experimental

Reaction of Allylic Carbonates with Carbon Nucleophiles. 5: To a solution of **2** (0.20 g, 1.0 mmol), allyl methyl carbonate (0.12 g, 1.0 mmol), and bpy (31 mg, 0.20 mmol) in dioxane (10 ml) was added $Mo(CO)_6$ (53 mg, 0.20 mmol) under argon atmosphere. The mixture was refluxed for 48 h. The reaction mixture was diluted with ether (50 ml), washed

Table. Reaction of Allylic Carbonates with **1** and **2**

with 10% aq HCl soln (20 ml) followed by water (2×20 ml), and dried over $MgSO_4$. Evaporation of ether and column chromatography on silica gel using hexane/EtOAc (2/1) as eluent gave monoallylated product **5** as a colorless oil in 64% yield (0.15 g). IR (neat) 2240 (C≡N) and 1320, 1140 cm^{-1} (SO_2); ^1H NMR ($CDCl_3$) δ=2.48 (s, 3H), 2.41—3.03 (m, 2H), 3.82 (dd, J=11, 4 Hz, 1H), 5.20 (d, J=10 Hz, 1H), 5.26 (d, J=16 Hz, 1H), 5.51—6.05 (m, 1H), 7.38 (d, J=8 Hz, 2H), and 7.83 (d, J=8 Hz, 2H); MS (70 eV) m/z (rel intensity) 235 (M^+, 8), 155 (71), and 91 (100). Found: m/z 235.0668. Calcd for $C_{12}H_{13}NO_2S$: 235.0666.

4: The structure was confirmed by comparison with ^1H NMR of the reported one.[10]

6: An oil; IR(neat) 1735 (C=O) and 1320, 1140 cm^{-1} (SO_2); ^1H NMR ($CDCl_3$) δ=1.10 (d, J=6.8 Hz, 0.9H), 1.35 (d, J=6.8 Hz, 1.2H), 1.61 (d, J=6.4 Hz, 0.9H), 2.45 (s, 3H), 2.50—2.88 (m, 0.6H), 2.92—3.15 (m, 0.7 H), 3.51 (s, 1.2H), 3.64 (s, 0.9H), 3.67 (s, 0.9H), 3.98 (d, J=9.1 Hz, 0.4H), 3.94 (d, J=8.4 Hz, 0.3H), 3.90—3.99 (m, 0.3H), 4.93—5.17 (m, 1.4H), 5.17—5.33 (m, 0.3H), 5.43—5.58 (m, 0.3H), 5.58—5.93 (m, 0.7H), 7.28—7.42 (m, 2H), and 7.69—7.83 (m, 2H); MS (70 eV) m/z (rel intensity) 282 (M^+, 0.3), 155 (12), 127 (100), 95 (41), and 91 (44). Found: m/z 282.0930. Calcd for $C_{14}H_{18}O_4S$: 282.0925.

7: An oil; IR (neat) 2240 (C≡N) and 1320, 1140 cm^{-1} (SO_2); ^1H NMR ($CDCl_3$) δ=1.29 (d, J=6.8 Hz, 1H), 1.38 (d, J=6.8 Hz, 1.4H), 1.68 (d, J=6.1 Hz, 0.6H), 2.47 (s, 3H), 2.76—2.92 (m, 0.4H), 3.13—3.33 (m, 0.8H), 3.91—4.02 (m, 1H), 5.13—5.32 (m, 1.6H), 5.32—5.47 (m, 0.2H), 5.60—6.00 (m, 1H), 7.36—7.48 (m, 2 H), and 7.82—7.93 (m, 2H); MS (70 eV) m/z (rel intensity) 249 (M^+, 8), 155 (75), 94 (34), and 91 (100). Found: m/z 249.0824. Calcd for $C_{13}H_{15}NO_2S$: 249.0823.

8: An oil; IR (neat) 2240 (C≡N) and 1340, 1140 cm^{-1} (SO_2); ^1H NMR ($CDCl_3$) δ=2.42 (s, 0.85H), 2.46 (s, 1.7H), 2.47 (s, 0.45H), 2.70—2.86 (m, 0.15 H), 3.00—3.16 (m, 0.15H), 4.01 (dd, J=10.4, 4.5 Hz,0.15H), 4.14 (d, J=3.2 Hz, 0.57H), 4.22 (br. t, J=6.6 Hz, 0.28H), 4.33 (d, J=6.6 Hz, 0.28H), 4.38 (dd, J=8.1, 3.2 Hz, 0.57H), 5.14—5.36 (m, 1.7H), 6.00—6.33 (m, 1H), 6.57 (d, J=15.4 Hz, 0.15H), 7.30 (s, 5 H), 7.24—7.46 (m, 2H), 7.70 (d, J=8.3 Hz, 0.57H), 7.85 (d, J=8.3 Hz, 1.14H), and 7.89 (d, J=8.3 Hz, 0.3 H); MS (70 eV) m/z (rel intensity) 311 (M^+, 0.1), 155 (100), 154 (67), 128 (57), 127 (40), and 115 (54). Found: m/z 311.0985. Calcd for $C_{18}H_{17}NO_2S$: 311.0979.

9: An oil; IR (neat) 2240 (C≡N) and 1320, 1140 cm^{-1} (SO_2) ^1H NMR ($CDCl_3$) δ=0.87 (m, 3H), 1.25 (br, 10.8H), 1.92—2.08 (m, 1.2H), 2.48 (s, 3H), 2.40—2.58 (m, 0.6H), 2.76—2.93 (m, 0.6H), 2.93—3.07 (m, 0.4H), 3.91 (dd, J=11.1, 4.3 Hz, 0.6H), 3.84—3.95 (m, 0.4H), 5.15—5.43 (m, 1.4 H), 5.56—5.78 (m, 1H), 7.42 (d, J=8.2 Hz, 2H), and 7.86 (d, J=8.2 Hz, 2H); MS (70 eV) m/z (rel intensity) 333 (M^+, 4), 178 (91), 155 (81), and 91 (100). Found: m/z 333.1760. Calcd for $C_{19}H_{27}NO_2S$: 333.1761.

10: mp 92—94 °C; IR (KBr) 2240 (C≡N) and 1320, 1140 cm^{-1} (SO_2); ^1H NMR ($CDCl_3$) δ=1.41—2.24 (m, 6H), 2.47 (s, 3H), 2.91—3.22 (m, 1H), 3.67 (d, J=4.5 Hz, 0.5 H), 3.76 (d, J=5.0 Hz, 0.5 H), 5.27—6.02 (m, 2 H), 7.37 (d, J=8 Hz, 2H), and 7.81 (d, J=8 Hz, 2 H); MS (70 eV) m/z (rel intensity) 275 (M^+, 0.5), 157 (44), 120 (100), and 91 (100). Found: C, 65.92; H, 6.31; N, 4.92%. Calcd for $C_{15}H_{17}NO_2S$: C, 65.42; H, 6.22; N, 5.08%.

Hexacarbonylmolybdenum(0)-Catalyzed Reductive Coupling of Allylic Acetates

Yoshiro MASUYAMA,* Kiyotaka OTAKE, and Yasuhiko KURUSU

(Received November 20, 1986)

Synopsis. The reaction of allylic acetates with zinc in the presence of a catalytic amount of hexacarbonylmolybdenum(0) led to reductive coupling for the formation of a 1,5-diene framework. Reductive coupling of nerolidyl acetate provided squalene and its isomers in high yield.

Allylic halides have been generally employed in reductive coupling for the formation of 1,5-diene frameworks.[1] Recently, instead of the unstable allylic halides, allylic acetates which are easier to prepare and store than the halides have been applied in the palladium-catalyzed reductive coupling via π-allylpalladium complex with zinc.[2] On the other hand, hexacarbonylmolybdenum(0), which is relatively inexpensive and is stable against oxygen and moisture, reacts with allylic acetates to form π-allylmolybdenum complexes.[3] Hexacarbonylmolybdenum(0) is likely to become a convenient catalyst for the reductive coupling of allylic acetates with zinc.

The molybdenum-catalyzed reductive coupling of cinnamyl acetate was carried out under various reaction conditions, as summarized in Table 1. The coupling reaction did not occur in refluxing toluene, which had been effective in hexacarbonylmolybdenum (0)-catalyzed reactions of the allylic acetates with carbon nucleophiles, and did not also occur in refluxing dioxane or in DMF at 110 °C (Entries 1—3). Next, the effect of ligands was investigated. The addition of 10 mol% of 2,2′-bipyridyl (bpy) accelerated the reaction in refluxing dioxane and THF (Entries 4 and 5). Ligands such as *N,N,N′,N′*-tetramethyl-1,2-ethanediamine, *N,N,N′,N′*-tetramethyl-1,3-propanediamine, and triphenylphosphine were not effective under the same conditions. Accordingly, the reductive coupling of various allylic acetates was carried out in refluxing dioxane containing 10 mol% of bpy. The reaction of 3-acetoxy-1-octene produced 6,10-hexadecadiene (48%)[4] and 9-vinyl-6-tetradecene (52%)[4] in 54% yield. The reaction of (*E*)-3-acetoxy-1-phenyl-1-butene also provided (1*E*,5*E*)-3,4-dimethyl-1,6-diphenyl-1,5-hexadiene (42%), 4,5-diphenyl-2,6-octadiene (8%),[4] and 1,4-diphenyl-3-methyl-1,5-heptadiene (50%)[4] in 37% yield. However, 3-acetoxy-1-cyclohexene did not cause the reductive coupling.

Reactivity and regio- and stereoselectivity were investigated in the reductive coupling of terpenoid allylic acetates such as linalyl, neryl, geranyl, nerolidyl, and farnesyl acetate. The results are summarized in Table 2. Zn-Cu couple as a reducing agent, compared with zinc powder, accelerated the reaction of linalyl acetate (Entries 1 and 2). The difference in the reactivity between linalyl acetate and neryl and geranyl acetate may be due to the difference in the rate of the formation of π-allylmolybdenum complexes (Entries 2—4).[3] In every case (Entries 1—4), the ratios of regioisomers (**I**/**II**) are similar, about 25/75. Being distinct from palladium-catalyzed reductive coupling,[2] stereoselectivities did not depend on the substrates (**a** : **b**=ca. 30 : 70, **c** : **d** : **e**=ca. 10 : 50 : 40). It is presumed from the results that the reductive couplings proceed after syn/anti isomerization of the π-allylmolybdenum complexes occurs to reach the equilibrium,[3] in contrast with the π-allylpalladium complexes which do not cause the syn/anti isomerization.[5] Using this method, nerolidyl acetate, which was more reactive than farnesyl acetate, was reduced to give squalene and its isomers as coupling products (Entries 5 and 6).

As mentioned above, hexacarbonylmolybdenum(0) proved to be a good catalyst for the reductive coupling of allylic acetates.

Experimental

General Procedure of Hexacarbonylmolybdenum(0)-Catalyzed Reductive Coupling of Allylic Acetates. To a solution of allylic acetate (2 mmol), zinc powder (0.39 g, 6

5		Zn	72	75	25 : 75 (31:69) (14:47:39)
6		Zn–Cu	115	20	20 : 80 (30:70) (10:48:42)

a) Isolated yields. b) The isomer ratios were determined by GLPC [5% OV-17/Chromosorb W (AW-DMCS), 60—80 mesh, 2 m, He, 160 °C (Entries 1—4), 200 °C (Entries 5 and 6).

mmol), and bpy (31 mg, 0.2 mmol) in dioxane (2 ml) was added hexacarbonylmolybdenum(0) (26 mg, 0.1 mmol). The mixture was refluxed for 8—115 h under a nitrogen atmosphere. The reaction mixture was diluted with ether (50 ml), washed with 10% HCl soln (20 ml) followed by water (2×20 ml), and dried over $MgSO_4$. Evaporation of ether and column chromatography on silica gel (Wakogel C-200) using hexane or hexane/EtOAc as the eluent gave coupling products. The structures and isomer ratios were determined by comparison with GLPC and ^1H NMR results of the samples prepared by the alternative method.[2]

Synthesis on 1,4-Diaminocyclitol Antibiotics. III. Synthesis of 4-Hydroxypurpurosamine B Derivatives

Kazuaki KANAI, Itsuki SAKAMOTO, Seiichiro OGAWA,* and Tetsuo SUAMI†
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Yokohama 223
(Received September 13, 1986)

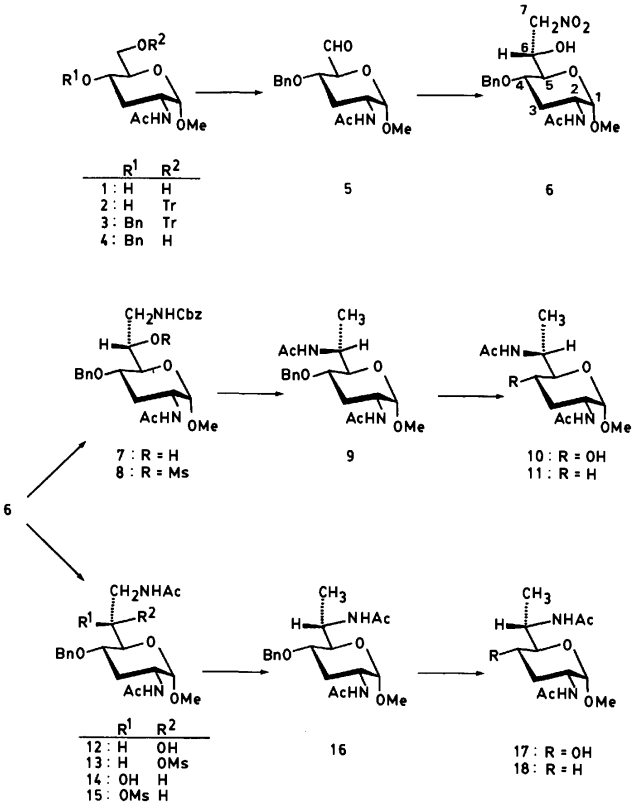
Synopsis. Methyl 2,6-di-*N*-acetyl-4-hydroxy-6-epi-α-purpurosaminide B and -4-hydroxy-α-purpurosaminide B have been prepared from D-glucosamine by sequence of reactions including stereoselective nitro aldol reaction.

In connection with synthetic studies on 4′-hydroxyfortimicins,[1] synthesis of 4-hydroxy-6-epipurpurosamine B has been carried out.

One of the authors reported that nitro aldol reaction of methyl 2-acetamido-2,3,4-trideoxy-α-*erythro*-hexodialdo-1,5-pyranoside with nitromethane gave the heptose derivative with D-ribo configuration in 52% yield.[2] In contrast the present work has shown that similar reaction of the corresponding 4-*O*-benzyl compound **5** gives selectively single condensate **6** with L-talo configuration in good yield. The C-4 benzyloxy group seems to control the direction of nucleophilic attack of aci-nitronium salt. We now describe syntheses of 4-hydroxypurpurosamine derivatives (**10**) and (**17**) starting from **6**.

Methyl 2-acetamido-2,3-dideoxy-α-D-*ribo*-hexopyranoside (**1**)[3] was converted into the 4-*O*-benzyl derivative (**4**) (84% in three steps). Oxidation of **4** with dimethyl sulfoxide and dicyclohexylcarbodiimide in the presence of pyridinium phosphate gave aldehyde **5**, which reacted with nitromethane in the presence of sodium methoxide to give the nitro compound **6** (84% based on **4**). The stereochemistry of **6** was determined finally by converting it to the known α-purpurosamine B derivative (**11**).[4] Catalytic hydrogenation of **6** in the presence of Raney nickel, followed by *N*-benzyloxycarbonylation, gave **7** in 86% yield. Treatment of **7** with methanesulfonyl chloride in pyridine afforded **8** in 95% yield. Treatment of **8** with sodium isopropoxide in 1,4-dioxane gave an epimino intermediate, which was hydrogenated in the presence of Raney nickel, followed by *N*-acetylation, to give 60% yield of **9**. The ^{1}H NMR spectrum of **9** revealed the presence of a terminal methyl group. Catalytic hydrogenation of **9** in the presence of 10% palladium on charcoal gave **10** in a quantitative yield. Deoxygenation at C-4 was carried out by Barton's method[5] to give **11** identical to an authentic sample[4] in all respects.

Inversion of the 6-hydroxyl group of **6** was attempted in order to obtain the 4-hydroxy-6-epipurpurosamine B derivative. Catalytic hydrogenation of **6** in the presence of Raney nickel, followed by *N*-acetylation, gave the 2,7-di-*N*-acetyl derivative (**12**) in 83% yield. Compound **12** was converted to the mesylate (**13**, 96%), which was then treated with sodium acetate in water, followed by *N*-acetylation, to give 83% yield of the D-allo derivative (**14**). This compound was similarly transformed into **17**. The proposed structure of **17** was determined by converting it to the 6-epipurpurosamine B derivative (**18**)[2,4] as described for the preparation of **11**.



Experimental[6]

Methyl 2-Acetamido-2,3-dideoxy-6-*O*-trityl-α-D-*ribo*-hexopyranoside (2). Compound **1**[3] (6.0 g) was treated with trityl chloride (19.1 g) and 4-dimethylaminopyridine (1.10 g) in pyridine (120 ml) at 60 °C overnight. The mixture was concentrated after addition of triethylamine (1.2 ml). The residue was chromatographed on silica gel with toluene-ethanol (10 : 1) to give **2** (12.6 g, quant.): mp 162—163.5 °C; $[\alpha]_D^{24}$ +35.1° (*c* 1.06, $CHCl_3$).

Found: C, 72.61; H, 6.99; N, 2.88%. Calcd for $C_{28}H_{31}NO_5$: C, 72.86; H, 6.77; N, 3.03%.

Methyl 2-Acetamido-4-*O*-benzyl-2,3-dideoxy-6-*O*-trityl-α-D-*ribo*-hexopyranoside (3). Compound **2** (12.1 g) in *N*,*N*-dimethylformamide (200 ml) was treated with 60% sodium hydride (1.32 g), benzyl bromide (6.44 ml) and tetrabutylammonium iodide (0.11 g) for 1.5 h at room temperature. The product was purified by chromatography on silica gel with toluene-ethanol (20 : 1) to give **3** (14.0 g, 99%): mp 70—76 °C; $[\alpha]_D^{24}$ +39.4° (*c* 0.64, $CHCl_3$).

Found: C, 76.03; H, 6.79; N, 2.46%. Calcd for $C_{35}H_{37}NO_5$: C, 76.20; H, 6.76; N, 2.54%.

Methyl 2-Acetamido-4-*O*-benzyl-2,3-dideoxy-α-D-*ribo*-

†Present address: Department of Chemistry, Faculty of Science and Technology, Meisei University, Hodokubo, Hino, Tokyo 191.

hexopyranoside (4). Compound **3** (14.0 g) was treated with *p*-toluenesulfonic acid monohydrate (9.97 g) in methanol (300 ml). After stirring for 1 h, the mixture was neutralized with $NaHCO_3$ and concentrated. The residue was chromatographed on silica gel with toluene–ethanol (8 : 1) to give **4** (6.90 g, 85%): mp 167—168 °C; $[\alpha]_D^{24}$ +111° (*c* 0.92, MeOH).

Found: C, 62.35; H, 7.38; N, 4.30%. Calcd for $C_{16}H_{23}NO_5$: C, 62.12; H, 7.49; N, 4.53%.

Methyl 2-Acetamido-4-*O*-benzyl-7-nitro-2,3,7-trideoxy-β-L-*talo*-hexopyranoside (6). To a stirred solution of **4** (1.84 g) in dimethyl sulfoxide (8 ml) and benzene (3.4 ml), pyridine (0.47 ml), phosphoric acid (0.16 ml) and dicyclohexylcarbodiimide (3.67 g) were added successively under ice cooling. The stirring was continued for 2 h at room temperature and then oxalic acid (2.20 g) in methanol (20 ml) was added. Dicyclohexylurea precipitated was removed by filtration and the filtrate was extracted with ethyl acetate (200 ml). The extract was successively washed with saturated aqueous $NaHCO_3$ and water, dried, and evaporated to give aldehyde **5**. It was dissolved in methanol (7.4 ml), and nitromethane (6.0 ml) and methanolic 1M sodium methoxide (7.4 ml) were then added under ice cooling. After stirring overnight in a refregirator, the mixture was acidified with Amberlite IR-120 (H^+) resin and concentrated. The product was purified by chromatography on silica gel with toluene–ethanol (14 : 1), and recrystallized from ethanol to give **6** (1.54 g, 84%): mp 150—151 °C; $[\alpha]_D^{26}$ +87.8° (*c* 1.19, MeOH); IR (KBr) 1550, 1370 (NO_2) cm^{-1}.

Found: C, 63.54; H, 6.83; N, 5.93%. Calcd for $C_{25}H_{32}N_2O_7$: C, 63.27; H, 6.72; N, 5.74%.

Methyl 2-Acetamido-4-*O*-benzyl-7-benzyloxycarbonylamino-2,3,7-trideoxy-β-L-*talo*-heptopyranoside (7). Compound **6** (288 mg) was hydrogenated in methanol (3 ml) in the presence of Raney nickel in an initial hydrogen pressure of 3.4 kg cm^{-2} overnight to give the corresponding 7-amino derivative (351 mg). To a solution of the amino-derivative in methanol (6 ml) and water (2 ml), *N*-(benzyloxycarbonyloxy)succinimide (195 mg) and triethylamine (0.06 ml) were added. After stirring for 0.5 h, the mixture was extracted, dried, and concentrated. The residue was chromatographed on silica gel with toluene–ethanol (15 : 1) to give **7** (318 mg, 86%): mp 156—157 °C; $[\alpha]_D^{22}$ +70.9° (*c* 0.17, $CHCl_3$).

Found: C, 63.54; H, 6.83; N, 5.93%. Calcd for $C_{25}H_{32}N_2O_7$: C, 63.27; H, 6.72; N, 5.74%.

Methyl 2-Acetamido-4-*O*-benzyl-7-benzyloxycarbonylamino-2,3,7-trideoxy-6-*O*-mesyl-β-L-*talo*-heptopyranoside (8). Compound **7** (33 mg) was treated with methanesulfonyl chloride (0.01 ml) in pyridine (1 ml) at 0 °C for 1.5 h. The product was purified by chromatography on silica gel with toluene–ethanol (10 : 1) to give **8** as a solid (37 mg, 95%): $[\alpha]_D^{23}$ +29.8° (*c* 1.79, $CHCl_3$).

Found: C, 56.44; H, 6.19; N, 4.90%. Calcd for $C_{26}H_{34}N_2O_9S$: C, 56.72; H, 6.22; N, 5.09%.

Methyl 2,6-Diacetamido-4-*O*-benzyl-2,3,6,7-tetradeoxy-α-D-*allo*-heptopyranoside (9). To a solution of **8** (331 mg) in dioxane (3 ml), a solution of sodium (35 mg) in isopropyl alcohol (6 ml) was added at 95 °C. After stirring for 1 h, an insoluble material was filtered and the filtrate was concentrated to give the epimino derivative, which was hydrogenated as described for the preparation of **7** and then *N*-acetylated with acetic anhydride (0.5 ml) in methanol (5 ml). The product was purified by chromatography on silica gel with toluene–ethanol (10 : 1) to give **9** (132 mg, 60%): mp 196—197 °C; $[\alpha]_D^{22}$ +118° (*c* 1.3, $CHCl_3$); ^1H NMR ($CDCl_3$), δ=0.94 (3H, d, *J*=8 Hz, H-7), 1.89, 1.95 (each 3H, s, NAc), 3.37 (3H, s, OMe), 4.27—4.70 (3H, m, H-1 and benzyl), 7.29 (5H, s, phenyl).

Found: C, 62.35; H, 7.60; N, 7.43%. Calcd for $C_{19}H_{28}N_2O_5$: C, 62.62; H, 7.74; N, 7.69%.

Methyl 2,6-Di-*N*-acetyl-4-hydroxy-α-purpurosaminide B (10). Compound **9** (105 mg) was hydrogenated in ethanol (10 ml) containing 1M hydrochloric acid (0.5 ml) (1 M=1 mol dm^{-3}) in the presence of 10% palladium on charcoal (50 mg) in an initial hydrogen pressure of 3.4 kg cm^{-2} overnight. The product was purified by chromatography on silica gel with toluene–ethanol (3 : 1) to give **10** (90 mg, quant.): mp gradually melt over than 135 °C; $[\alpha]_D^{26}$ +159° (*c* 1.0, MeOH); ^1H NMR (CD_3OD) δ=1.14 (3H, d, *J*=7 Hz, H-7), 1.95 (6H, s, NAcX2), 3.40 (3H, s, OMe), 4.60 (1H, d, *J*=3.8 Hz, H-1).

Found: *m/z*, 275.1622. Calcd for $C_{12}H_{23}N_2O_5$: M+1, 275.1606.

Methyl 2,6-Di-*N*-acetyl-α-purpurosaminide B (11). Compound **10** (50 mg) was converted into the xanthate derivative (44 mg), which was treated with *n*-Bu_3SnH (0.1 ml) and α,α′-azobisisobutyronitrile in toluene (4 ml) to give **11** (17 mg, 56%) by the method described in the preceding paper:[1] mp 256—257 °C; $[\alpha]_D^{19}$ +178° (*c* 0.48, MeOH). Lit,[4] mp 261—262 °C, $[\alpha]_D^{20}$ +185.7° (*c* 0.7, MeOH). ^1H NMR and IR spectra were superimposable on those of an authentic sample.[4]

Methyl 2,7-Diacetamido-4-*O*-benzyl-2,3,7-trideoxy-β-L-*talo*-heptopyranoside (12). Compound **6** (1.54 g) in methanol (10 ml) was hydrogenated as described for the preparation of **7**. The amine was *N*-acetylated and the product was crystallized from ethanol to give **12** (1.37 g, 83%): mp 233—234 °C; $[\alpha]_D^{17}$ +62.4° (*c* 1.0, MeOH).

Found: C, 59.76; H, 7.38; N, 7.31%. Calcd for $C_{19}H_{28}N_2O_6$: C, 59.99; H, 7.41; N, 7.36%.

Methyl 2,7-Diacetamido-4-*O*-benzyl-2,3,7-trideoxy-6-*O*-mesyl-β-L-*talo*-heptopyranoside (13). Compound **12** (916 mg) was treated with methanesulfonyl chloride in pyridine, and the product was purified as described for the preparation of **8** to give **13** (1.01 g, 96%): $[\alpha]_D^{26}$ +25.8° (*c* 0.95, $CHCl_3$); IR (KBr) 1370, 1195 (SO_2) cm^{-1}.

Methyl 2,7-Diacetamido-4-*O*-benzyl-2,3,7-trideoxy-α-D-*allo*-heptopyranoside (14). A suspension of **13** (6.5 g) and sodium acetate (1.2 g) in water (200 mg) was refluxed for 15 h, and then concentrated. The residue was treated with acetic anhydride (1.0 ml) in methanol (10 ml) for 1 h. The product was purified by chromatography on silica gel with toluene–ethanol (5 : 1) and crystallized from methanol–ethyl acetate to give **14** (4.47 g, 83%): mp 173—174 °C; $[\alpha]_D^{20}$ +119° (*c* 1.0, MeOH).

Found: C, 60.25; H, 7.51; N, 7.20%.

Methyl 2,7-Diacetamido-4-*O*-benzyl-2,3,7-trideoxy-6-*O*-mesyl-α-D-*allo*-heptopyranoside (15). Compound **14** (3.92 g) was treated with methanesulfonyl chloride in pyridine, and the product was purified as described for the preparation of **8** to give **15** (4.26 g, 90%): $[\alpha]_D^{26}$ +104° (*c* 0.88, $CHCl_3$); IR (KBr) 1370, 1195 (SO_2) cm^{-1}.

Methyl 2,6-Diacetamido-4-*O*-benzyl-2,3,6,7-tetradeoxy-β-L-*talo*-heptopyranoside (16). Compound **15** (1.60 g) was converted into the epimino derivative, which was hydrogenated, and then acetylated as described for the preparation of **9** to give **16** (698 mg, 55%): mp 144—145 °C; $[\alpha]_D^{18}$ +83.3° (*c* 0.78, $CHCl_3$); ^1H NMR ($CDCl_3$) δ=1.18 (3H, d, *J*=6 Hz, H-7), 1.95, 1.99 (each 3H, s, NAc), 3.38 (3H, s, OMe), 4.59 (1H, d, *J*=3 Hz, H-1), 5.81 (2H, d, *J*=9 Hz, NH-2,6), 7.34 (5H, s, phenyl).

Found: C, 62.76; H, 7.70; N, 7.80%.

Methyl 2,6-Di-*N*-acetyl-4-hydroxy-6-epi-α-purpurosaminide B (17). Compound **16** (50 mg) was hydrogenated as described for the preparation of **10** to give **17** (37 mg, 99%): mp 221—222 °C; $[\alpha]_D^{19}$ +42.3° (*c* 0.70, MeOH); ^1H NMR δ=1.26 (3H, d, *J*=6.5 Hz, H-7), 1.99, 2.11 (each 3H, s, NAc), 3.34 (3H, s, OMe), 4.57 (1H, d, *J*=3 Hz, H-1).

Found: C, 52.44; H, 7.95; N, 10.02%. Calcd for $C_{12}H_{22}N_2O_5$: C, 52.54; H, 8.08; N, 10.21%.

Methyl 2,6-Di-*N*-acetyl-6-epi-α-purpurosaminide B (18).

Compound **17** (75 mg) was converted into the xanthate derivative (97 mg, 97%), which was treated *n*-Bu_3SnH (0.2 ml) and α,α'-azobisisobutyronitrile as described for the preparation of **11** to give **18** (24 mg, 34%): mp 208—209 °C; $[\alpha]_D^{19}$ +70.3° (*c* 0.45, MeOH). Lit,[2] mp 212—213 °C, $[\alpha]_D^{20}$ +63.3° (*c* 1.0, MeOH). ^1H NMR and IR spectra were superimposable on those of an authentic sample.[2]

The authors wish to thank Mr. Saburo Nakada for elemental analyses.

Synthesis on 1,4-Diaminocyclitol Antibiotics. V. Synthesis of 3′-Enofortimicin D

Kazuaki KANAI, Shigeki YOKOI, Seiichiro OGAWA,* and Tetsuo SUAMI†
Department of Applied Chemistry, Faculty of Science and Technology, Keio University, Hiyoshi, Yokohama 223
(Received October 7, 1986)

Synopsis. 3′-Enofortimicin D has been prepared by condensation of 1-*O*-acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,4,6-tetradeoxy-D-*erythro*-hex-3-enopyranose with 2,5-di-*O*-benzoyl-1,4-bis-*N*-(methoxycarbonyl)fortamine B, followed by deprotection.

In the preceding paper,[1] we have reported the synthesis and antibacterial assay of 4′-hydroxyfortimicin D. In continuation of our study on modification of the amino sugar moiety of antibiotic fortimicins, introduction of a double bond into the diamino sugar moiety of fortimicins would be of interest in connection with elucidation of a role of its conformation. We now describe the synthesis and biological activity of 3′-enofortimicin D.

Methyl 2,6-diamino-2,3,4,6-tetradeoxy-α-D-*erythro*-hex-3-enopyranoside sulfate (**1**),[2] was first converted to the bis[*N*-(2,4-dinitrophenyl)] derivative (**2**) in 79% yield. Hydrolysis of **2** with acetic acid containing 2M hydrochloric acid (1 M=1 mol dm^{-3}), followed by acetylation, gave the acetate (**3**) in 64% yield.

Condensation of **3** with 2,5-di-*O*-benzoyl-1,4-bis[*N*-(methoxycarbonyl)] fortamine B (**4**)[3] was carried out in 1,2-dichloroethane in the presence of trimethylsilyl trifluoromethanesulfonate under argon to give sole condensate **5** in 36% yield.

Deprotection of **5** with barium hydroxide in boiling aqueous dioxane in the usual way resulted in further hydrolysis of the glycosidic bond to give mainly fortamine B (**7**) (71%), together with a small amount (11%) of desired 3′-enofortamine KE (**6**). The ^{1}H NMR spectrum of **6** revealed a doublet (δ 5.26, $J_{1',2'}$=3 Hz) due to C-1′ α-anomeric proton. The ready cleavage of the α-glycosidic bond might be attributable to the presence of a double bond between C-3′ and C-4′. Similar results have been observed by Fukatsu[5] in the case of 3′-enokanamycin derivative. Several attempts to increase the yield of **6** failed.

Compound **6** was treated with 2-(*t*-butoxycarbonyloxyimino)-2-phenylacetonitrile (BocON)[6] in aqueous dioxane to give 1,2′,6′-tris[*N*-(*t*-butoxycarbonyl)] derivative (**8**) in 65% yield. The 4-[*N*-(*N*-*t*-butoxycarbonyl)glycyl] derivative (**9**) was obtained in 66% yield by treatment of **8** with activated ester of *N*-(*t*-butoxycarbonyl)glycine[7] in tetrahydrofuran. Finally, treatment of **9** with trifluoroacetic acid in chloroform gave 3′-enofortimicin D (**10**) as the trifluoroacetate.

The minimum inhibitory concentration of **10** is listed together with those of fortimicin A (Table 1). 3′-Enofortimicin D (**10**) exhibited weak activity compared to that of fortimicin A against many organisms.

Table 1. Antimicrobial Activity of **10** and Fortimicin A[a]

Test Organisms	**10**	FM A
Streptococcus faecalis KY4280	100	6.3
Pseudomonas aeruginosa KY4276	50	6.3

Experimental[8]

Methyl 2,6-Bis(2,4-dinitrophenylamino)-2,3,4,6-tetradeoxy-α-D-*erythro*-3-enopyranoside (2). A solution of methyl 2,6-diamino-2,3,4,6-tetradeoxy-α-D-*erythro*-hex-3-enopyranoside sulfate (**1**)[2] (500 mg) in 85% aqueous methanol (10 ml) containing 1-fluoro-2,4-dinitrobenzene (0.51 ml) and triethylamine (1.1 ml) was stirred at 0 °C for 1 h, and stirring was continued at room temperature overnight. The product was purified by chromatography on silica gel with toluene–acetone (20 : 1) and crystallization from acetone–petroleum ether gave **2** (754 mg, 79%): mp 150—152 °C; $[\alpha]_D^{23}$ −143° (*c* 1.08, $CHCl_3$).

†Present address: Department of Chemistry, Faculty of Science and Technology, Meisei University, Hodokubo, Hino, Tokyo 191.

Found: C, 46.48; H, 3.76; N, 17.04%. Calcd for $C_{19}H_{18}N_6O_{10}$: C, 46.54; H, 3.70; N, 17.14%.

1-*O*-Acetyl-2,6-bis(2,4-dinitrophenylamino)-2,3,4,6-tetradeoxy-D-*erythro*-hex-3-enopyranose (3). A solution of **2** (400 mg) in acetic acid (20 ml) containing 2M hydrochloric acid (2 ml) was stirred at 80 °C for 7 h. The mixture was extracted with chloroform (50 ml) and the extract was dried. After concentration, the residue was treated with acetic anhydride (4 ml) in pyridine (10 ml) for 12 h. The product was purified by chromatography on silica gel and crystallization from acetone-2-propanol gave **3** (273 mg, 64%): mp 92—102 °C; $[\alpha]_D^{24}$ −226° (*c* 1.07, $CHCl_3$).

Found: C, 46.28; H, 3.58; N, 16.34%. Calcd for $C_{20}H_{18}N_6O_{11}$: C, 46.34; H, 3.50; N, 16.21%.

2,5-Di-*O*-benzoyl-2′,6′-bis[*N*-(2,4-dinitrophenyl)]-1,4-bis[*N*-(methoxycarbonyl)]-3′-enofortimicin KE (5). To a solution of **3** (249 mg) and **4**[3] (271 mg) in 1,2-dichloroethane (5 ml) in the presence of powdered molecular sieve 4A (230 mg) was added trimethylsilyl trifluoromethanesulfonate (0.07 ml), and the mixture was stirred for 3.5 h under argon at room temperature. The product was purified by chromatography on silica gel with toluene-2-butanone (30 : 1) and crystallization from acetone-2-propanol gave **5** (166 mg, 36%): mp 134—140 °C; $[\alpha]_D^{20}$ −97.5° (*c* 1.02, $CHCl_3$).

Found: C, 53.22; H, 4.46; N, 11.27%. Calcd for $C_{44}H_{44}N_8O_{19}$: C, 53.44; H, 4.48; N, 11.33%.

3′-Enofortimicin KE (6). A solution of **5** (135 mg) in aqueous dioxane (2 : 1, 9 ml) in the presence of barium hydroxide octahydrate (3.0 g) was refluxed for 12 h. After cooling, carbon dioxide was introduced to the mixture, and an insoluble material was filtered. After concentration, the residue was eluted from a column of Amberlite CG-50 (NH_4^+) resin with aqueous ammonia (0—0.20 M) to give, first, fortamine B (**7**) (20 mg, 71%), the ^1H NMR spectrum of which was superimposable on that of an authentic sample.[4] The fraction eluted second contained compound **6** as a solid (5 mg, 11%): $[\alpha]_D^{25}$ −47.2° (*c* 0.23, MeOH); ^1H NMR (CD_3OD) δ=2.40 (3H, s, NMe), 3.45 (3H, s, OMe), 5.26 (1H, d, *J*=3 Hz, H-1′), 5.71 (2H, bs, H-3′, 4′); MS (SIMS) Found: *m/z*, 333. Calcd for $C_{14}H_{29}N_4O_5$: M+1, 333.

1,2′,6′-Tris[*N*-(*t*-butoxycarbonyl)]-3′-enofortimicin KE (8). To a solution of **7** (7.9 mg) in 50% aqueous dioxane (0.5 ml) was added Boc-ON (29.3 mg), and the mixture was stirred for 6 h. Triethylamine (0.03 ml) was added to it and stirring was continued overnight. The product was purified by chromatography on silica gel with chloroform-methanol (30 : 1) to give **8** as a solid (8.7 mg, 65%): $[\alpha]_D^{23}$ −32.9° (*c* 1.02 . $CHCl_3$); ^1H NMR ($CDCl_3$) δ=1.43 (27H, bs, Boc×3), 2.40 (3H, s, NMe), 3.46 (3H, s, OMe).

1,2′,6′-Tris[*N*-(*t*-butoxycarbonyl)]-4-[*N*-[*N*-(*t*-butoxycarbonyl)-glycyl]]-3′-enofortimicin KE (9). To a mixture of *N*-(*t*-butoxycarbonyl)glycine (3 mg), 1-hydroxybenzotriazole (2.4 mg) and dicyclohexylcarbodiimide (4.3 mg) in tetrahydrofuran (0.5 ml) was added a solution of **8** (8.7 mg) in tetrahydrofuran (0.5 ml), and the mixture was stirred for 3 d. The product was purified by chromatography on silica gel with chloroform-methanol (97 : 3) to give **9** as a solid (7.2 mg, 66%): $[\alpha]_D^{27}$ −6.0° (*c* 0.55, $CHCl_3$); ^1H NMR ($CDCl_3$) δ=1.41, 1.43 (36H in total, each s, Boc×4), 3.14 (3H, s, NMe), 3.46 (3H, s, OMe); MS (SIMS) Found: *m/z*, 790. Calcd for $C_{36}H_{64}N_5O_{14}$: M+1, 790.

3′-Enofortimicin D (10). To a solution of **9** (7.2 mg) in chloroform (0.5 ml) was added trifluoroacetic acid (0.1 ml), and the mixture was stirred for 1.5 h. After concentration, the residue was washed with ether to give a solid of **10** (7.2 mg) as the trifluoroacetate: $[\alpha]_D^{26}$ −5.5° (*c* 0.44, water); ^1H NMR (200 MHz, D_2O) δ=3.12 (1H, s, NMe), 3.22 (1H, dd, *J*=6 Hz, 14 Hz, H-6′a), 3.36 (1H, dd, *J*=3.5 Hz, 14 Hz, H-6′b), 3.46 (3H, s, OMe), 5.46 (1H, d, *J*=4 Hz, H-1′), 5.92 and 6.18 (each 1H, bd, *J*=11 Hz, H-3′ and 4′); MS (SIMS) Found: *m/z*, 390. Calcd for $C_{16}H_{32}N_5O_6$: M+1, 390.

The authors wish to thank Drs. Kunikatsu Shirahata and Hiroshi Sano of Kyowa Hakko Co. for antibacterial assay. We also thank Mr. Akio Takahashi of the University for elemental analyses.

Determination of the Intrinsic Reaction Coordinate in the 2H+O(^{1}D) System Near the Equilibrium H_2O

Seikichi CHO
Department of Chemistry, Faculty of Education, Gunma University, Aramakicho 4-2, Maebashi, Gunma 371
(Received July 23, 1986)

Synopsis. A normal coordinate analysis was applied to the 2H+O(^{1}D) three atomic system, using the Schinke-Lester analytic expression for the adiabatic potential energy. Defining the reaction coordinates as the "infinitely slow motion trajectories," the reaction coordinate of the heavy oxygen atom was calculated easily, while that of the light hydrogen atom was obtained with some difficulty. Several repeated corrections were needed to converge the reaction coordinates to the "intrinsic" reaction coordinate. The intrinsic reaction coordinate of a hydogen atom to the uphill side of H_2O was found to be very difficult to follow. This fact might help to explain the low frequency factor of the decomposition reaction of H_2O.

A chemical reaction arises from a relative motion of nuclei in a system composed of atoms. When the adiabatic potential energy surface of the system is extensively calculated by quantum mechanics, determination of the reaction coordinates turn into a problem of classical mechanics. In a preceding paper,[1] we have defined the reaction coordinates as the infinitely slow motion trajectory,[2] and proved the reaction coordinates to coincide with the normal coordinates.[3] The HNC-to-HCN isomerization reaction was treated by normal coordinate analysis using the STO-3G potential surface, and the intrinsic reaction coordinate[4] was easily calculated. As might be expected, the extension of this work to the reaction of H_2CO was not so easy as the case of HNC. In this paper we treat the 2H+O(^{1}D) three atomic system. For this system contour maps of the potential energy surface could be drawn and the reaction coordinates could be shown explicitly. Schinke and Lester[5] fitted the extensive first-order configuration interaction energies of Howard et al.[6] with an analytic expression, and carried out trajectory calculations.

At first we briefly review the normal coordinate analysis of reaction coordinates. The potential energy V of a system can be expanded in a Taylor series in terms of the normal coordinates Q_i,

$$V = V_0 + \sum_i g_i Q_i + \frac{1}{2}\sum_i \lambda_i Q_i^2, \quad (1)$$

where the expansion is truncated to the second-order. The Lagrange equations of motion are set up and solved by assuming the infinitely slow motions of nuclei. The solutions are given by

$$Q_i = -\tau^2 g_i/(1+\tau^2\lambda_i), \quad (i = 1, 2, \cdots, f) \quad (2)$$

where τ^2 is a constant. Equations 2 imply that the nuclei move along Q_i infinitely slowly, vibrating simple-harmonically along the same Q_i. The magnitude of Q_i is greater the greater the absolute value of g_i and the smaller the absolute value of λ_i. In an equilibrium state the first-order gradients g_i and the reaction coordinates Q_i are all vanishing. The first-order gradients are, however, not always vanishing in any non-equilibrium states and a few or several reaction coordinates are possible. If one of the non-zero reaction coordinates is chosen to be the "intrinsic," the other reaction coordinates should be corrected to zero. The corrections can be easily calculated to

$$d_i = -g_i/\lambda_i, \quad (i = 1, 2, \cdots, f) \quad (3)$$

Equations 3 are consequences of Eq. 1. Once the corrections are made by Eqs. 3, the intrinsic reaction coordinate can be followed step by step uphill or downhill by taking care of the sign of the gradient along the intrinsic reaction coordinate.

If O(^{1}D) aproaches the H_2 molecule colinearly, a small barrier of about 1 kcal mol^{-1} (1 cal=4.184 J) is found at O-H distance about 1.8 Å, as described by Schinke and Lester.[5] Passing through the barrier, the H-H distance increases rapidly and an equilibrium state is attained. In the equilibrium state, the geometry of R(OH)=0.99 Å and R(HH)=2.86 Å is calculated. The Van der Waals complex has three vibrational modes. ν_1=206 cm^{-1} (doubly degenerate), ν_2=396 cm^{-1}, and ν_3=3737 cm^{-1} (the vibrational modes are numbered in an increasing order of wavenumber for convenience sake.) We decided to set up this state as a starting point.

The ν_3 mode is the OH stretching, and the ν_2 mode is an H ··· HO vibration. The motion along Q_2 leads to a further separation of H ··· H or backwards to the H_2+O state. The lowest wavenumber mode is a bending one, along which one is led to a saddle point and further to the equilibrium state of H_2O. The normal coordinate Q_1 is then chosen as the "intrinsic" reaction coordinate of this system. To ascend the potential energy valley to the saddle point, a constant step width (0.05 Å) was used in spite of Eqs. 2. Corrections expressed by Eqs. 3 were made at each step. These movements are illustrated graphically in Fig. 1 and Fig. 2. Figure 1 shows the motion of the oxygen nucleus along the "intrinsic" reaction coordinate, which is plotted in a potential energy contour map. One of the hydrogen atoms is fixed at the origin and the other is floating on the left side of the abscissa. The oxygen atom goes round the hydrogen atom at the origin and no irregularities occur. The saddle point is located at R(OH)=0.99 Å, R(OH′)=3.22 Å, and ∠HOH′=50.0°, and the energy is 1.8 kcal mol^{-1} above the H ··· HO or 112.0 kcal mol^{-1} above the H_2O states. The valley of the potential energy surface is well-defined in Fig. 1.

On the other hand, Fig. 2 shows the motion of one hydrogen nucleus plotted in a contour map, in which the oxygen atom is fixed at the origin and the second hydrogen atom is slightly floating on the right side of

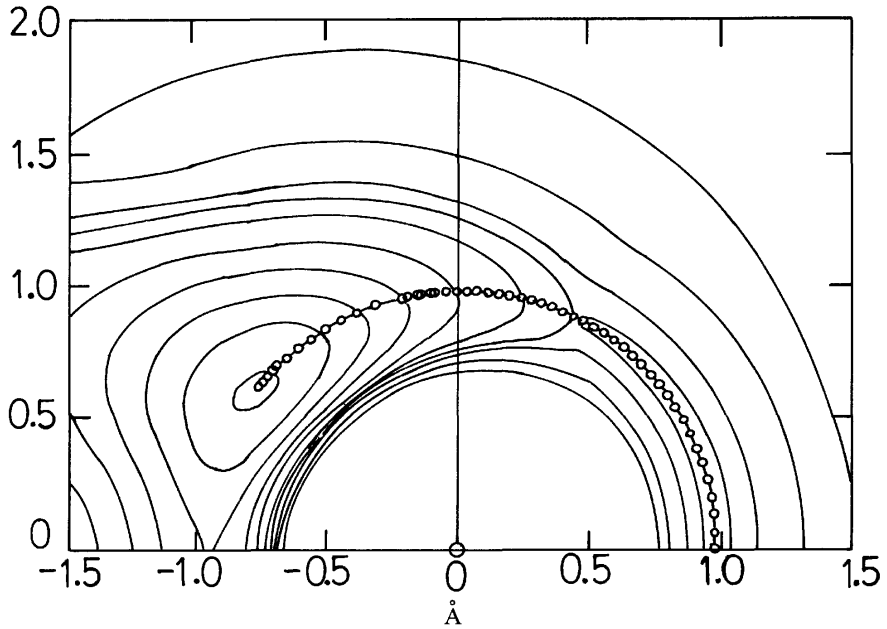

Fig. 1. Contour map of O-motion in the 2H+O(^{1}D) system near the equilibrium H_2O, using the Schinke-Lester analytical expression of energy. One hydrogen atom is located at the origin and the other is floating on the left side of the abscissa. The energies are 2, 20, 40, 60, 80, 100, 112, 120, 140, and 160 kcal mol^{-1} above the equilibrium H_2O. The points denoted by —O— are the calculated intrinsic reaction trajectories of the oxygen atom.

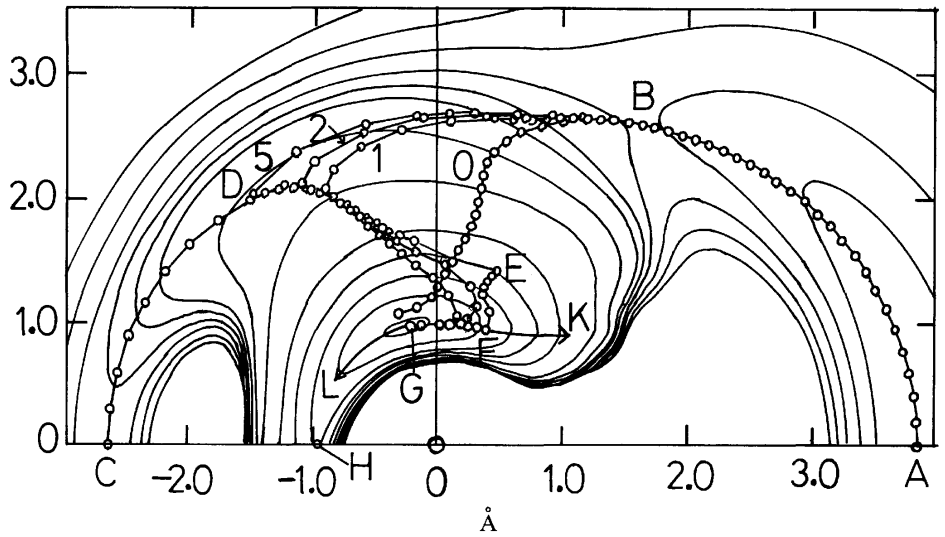

Fig. 2. Contour map of H-motion in the 2H+O(^{1}D) system near the equilibrium H_2O, using the Schinke-Lester analytical expression of energy. The oxygen atom is fixed at the origin and the second hydrogen atom is slightly floating on the right side of the abscissa. The energies are 2, 20, 40, 60, 80, 100, 107, 110, 111, 112, 113, 114, and 115 kcal mol^{-1} above the equilibrium H_2O. The points denoted by —O— are the calculated reaction trajectories of the hydrogen atom.

the abscissa. The intrinsic reaction trajectory of the hydrogen atom is well-defined from the H···HO equilibrium state (denoted by A in the figure) to the saddle point (denoted by B). Passing through the saddle point, the points become scattered. This results from the fact that the corrections given by Eqs. 3 become large and several repeated applications of Eqs. 3 are required. A few of these calculations are also plotted in Fig. 2. The points denoted by 0 describe the calculations with no correction, the points denoted by 1 the calculations with up to one correction at each cycle, and so on. The curve 0 means a "least-motion"

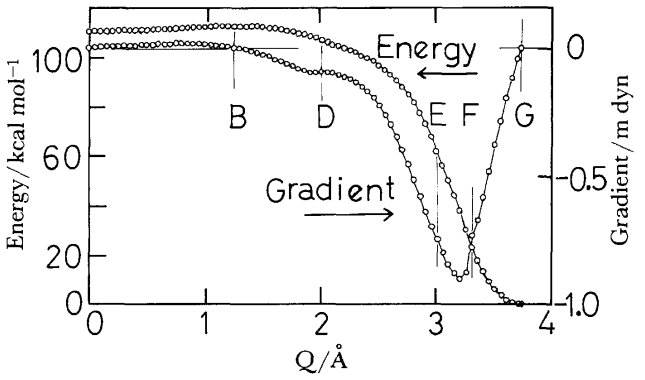

Fig. 3. Variations of the potential energy and the gradient along the intrinsic reaction coordinate of the 2H+O(¹D) system near the equilibrium H_2O. The point where the gradient is vanishing corresponds to the saddle point.

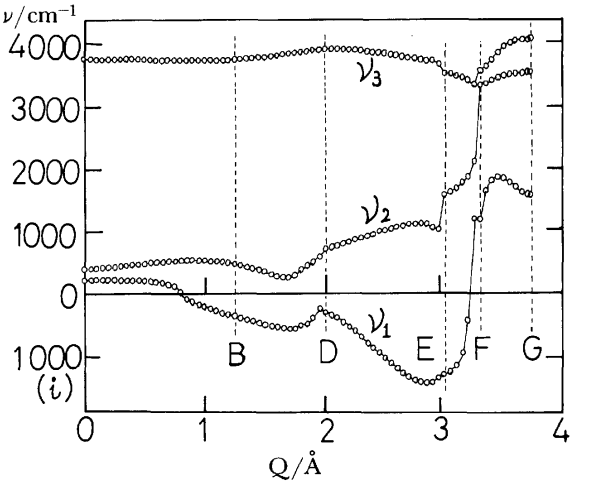

Fig. 4. Variations of the vibrational wavenumber along the intrinsic reaction coordinate of the 2H+O(¹D) system near the equilibrium H_2O. The points were calculated on the Schinke-Lester analytical expression of the potential energy surface.

reaction coordinate. It closely resembles to the "steepest-descent" reaction coordinate, as can be seen from the figure. Once corrections are made, the curves are remote from the "least-motion" reaction coordinate. With up to fivefold correction iteration, the curves converge to the "intrinsic" reaction coordinate. The points C to D denote the descending pathway from a saddle point expressed as H··· O-H (the point C in Fig. 2). The intrinsic reaction coordinate merges in the descending pathway at the point D. Descending the potential energy valley, the curve turns at E and F. The curve F-G is along the bending mode of the vibrations of the equilibrium H_2O.

The reason for this complicated behavior of the hydrogen atom is not yet clear. It is difficult to reverse the intrinsic reaction coordinate from the equilibrium H_2O to the H··· H-O state. The equilibrium H_2O state is calculated to have three vibrational modes, a doubly degenerate bending (ν_1=1568 cm^{-1}), a symmetrical stretching (ν_2=3527 cm^{-1}),and an antisymmetric stretching (ν_3=4037 cm^{-1}) vibrations. If one follows the lowest wavenumber mode Q_1, it leads to the direction of K or L in Fig. 2, which results in the inversion of H_2O. The C_{2v} symmetry of equilibrium H_2O is retained in the inversion pathway. To ascend the "intrinsic" reaction coordinate, one should move along Q_3 (the antisymmetric stretching mode) at the point F. Then the path turns at the point E, and at the point D. Although the intrinsic reaction coordinate does not correspond to any actual trajectory, it is considered to give a path along which many actual trajectories, especially those of low energy, are likely to travel.[4] These facts might be helpful to explain the low frequency factor of the decomposition reaction of H_2O.

Despite the complexity of the H-motion, energies and gradients along the intrinsic reaction coordinate vary smoothly, as is seen in Fig. 3. Variations of the vibratinal wavenumber along the pathway were, however, remarkable as is shown in Fig. 4. The saddle point was of little significance in this case. Discontinuous changes of wavenumber occur at points D,E, and F, where the hydrogen atom comes in another valley on the potential surface. Again, the wavenumbers along the reaction coordinate were imaginary over a wide range of the reaction process.

In conclusion, the determination of an intrinsic reaction coordinate was difficult, especially for the light hydrogen atom. Nevertheless it provides an insight into the detailed mechanism of the chemical reactions.

The whole calculations, including the contour mapping, were carried out with a NEC PC-9801 personal computer in our laboratory.

(Received October 2, 1986)

Synopsis. The catalytic activity of ruthenium(III) chloride in a chemiluminescence reaction with 1,10-phenanthroline-hydrogen peroxide has been found to decrease in the presence of protein. On the basis of this phenomenon, bovine serum albumin as a model protein was determined within the concentration range of 5×10^{-5}—1×10^{-1} g dm^{-3} and a detection limit of about 1 ng.

Several new methods for the determination of protein by the use of a chemiluminescence(CL) reaction between 5-amino-2,3-dihydro-1,4-phthalazinedione or 1,10-phenanthroline(phen) and hydrogen peroxide(H_2O_2) have been reported by the present authors in previous papers.[1-4] The methods are based on the measurement of the decreasing catalytic activity of copper(II), the iron(III) complex, or the cobalt(III) complex for a CL reaction in the presence of protein. According to Suzuki et al.,[5,6] CL emission from phen in the presence of H_2O_2 was markedly enhanced by a copper(II) catalyst, but not another catalyst, such as Cd(II), Co(II), Hg(II), Zn(II), Pb(II), or Ni(II). They used this phenomenon in determining a small amount of copper(II). It has now been found by the present authors that the ruthenium(III) chloride acts as a catalyst for a CL reaction between phen and H_2O_2 and that, moreover, its catalytic activity decreases in the presence of protein. As bovine serum albumin(BSA), human serum albumin(HSA), bovine serum α-globulin, and human serum γ-globulin show similar CL responses, BSA was selected as the model protein for their determination. A new procedure for the determination of protein has been established on the basis of the above-mentioned phenomenon. The present method is 10^2—10^3 times as sensitive as the conventional method[7] for the determination of protein and is no less sensitive than the most sensitive other method[4] in the present series of reports by the present authors.

Experimental

All the reagents were of a commercially available special grade. The ion-exchange water was distilled for use. A phen solution, a H_2O_2 solution, and a buffer solution were prepared as in the previous paper.[8] A 1.0×10^{-3} mol dm^{-3} ruthenium(III) catalyst solution was prepared as a stock solution by dissolving ruthenium(III) chloride hydrate(NAKARAI CHEMICAL, LTD.) in 0.36 N HCl; it was then diluted to the desired concentration with a buffer solution. BSA and HSA from NAKARAI CHEMICAL, LTD., bovine serum α-globulin from ICN Pharmaceuticals, Inc., and human serum γ-globulin from the SIGMA CHEMICAL COMPANY were prepared by diluting them with the above-mentioned buffer solution.

The experiment was carried out using the apparatus described in a previous paper.[8] The optimum flow rates and the optimum distance between the point where a phen-H_2O_2 mixture solution and a buffer solution were mixed and a certain cell were decided by the experiment. A definite volume of the ruthenium(III) solution was added to a sample solution containing protein, and the resulting solution was heated for a definite period. After the solution had then cooled to room temperature, an aliquot of the solution (50 mm^3) was injected into the flow-through system and the CL intensity was measured.

Results and Discussion

The CL intensity of the 1.0×10^{-6} mol dm^{-3} ruthenium(III) catalyst solution was measured by the use of 3-, 90-, 180-, and 270-cm portions of the tube, portions which corresponded to the distance between the point where a phen-H_2O_2 mixture solution and a buffer solution were mixed and a certain cell. The maximum CL intensity was observed by the use of a 90-cm tube. Both the flow rate of a phen solution and that of a H_2O_2 solution were chosen simultaneously at the following rates: 0.5, 0.7, 1.0, and 1.3 ml min^{-1}; the CL intensity of a 1.0×10^{-6} mol dm^{-3} ruthenium(III) catalyst solution was also measured. The maximum CL intensity was observed at 0.7 ml min^{-1}. The flow rate of a buffer solution was always set at 2.3 ml min^{-1}, the maximum capacity of the pump, so as to deal with as many samples as possible in a definite time. On the basis of the experimental results, the optimum conditions were established as follows: tube length: 90 cm; flow rates of a phen, a H_2O_2, and a buffer solution: 0.7, 0.7, and 2.3 ml min^{-1} respectively.

The calibration curve for the ruthenium(III) catalyst solution is shown in Fig. 1; it was almost linear for 1.0×10^{-7}—1.0×10^{-5} mol dm^{-3} ruthenium(III).

The relationships between the CL intensity and the reaction time at 20, 60, and 95 °C are shown in Fig. 2. On the basis of the results pertaining to the decrease in the CL intensity and the reaction time, the CL intensity of a protein sample solution was examined after it had been treated for 45 min at 95 °C in all the following experiments.

The CL responses of a sample solution containing 3×10^{-3} g dm^{-3} each of BSA, HSA, bovine serum α-globulin, and human serum γ-globulin were examined (Table 1). As they showed similar responses, BSA was selected as the model protein in the following experiment.

Figure 3 shows the calibration curve for BSA. As

Table 1. The CL Responses of Various Proteins

Protein	Experimental CL intensity/kcps	Relative CL intensity
(Protein-free)	3.44	1.00
BSA	1.68	0.49
HSA	1.80	0.52
Bovine serum α-globulin	1.84	0.53
Human serum γ-globulin	1.74	0.51

a) Conditions: 1.2×10^{-4} mol dm^{-3} phen, 5.0 wt% H_2O_2, 3.0×10^{-6} mol dm^{-3} Ru(III), and 3.0×10^{-3} g dm^{-3} protein.

Table 2. The Apparent Coupling Ratio and Coupling Constant When a Ru(III) or Cu(II) Catalyst is Used

Catalyst	Detection limit of BSA/ng	Catalyst concn used for BSA determination/mol dm^{-3}	Coupling ratio (Metal:Protein)	Coupling constant
Ru(III)	1	3.0×10^{-6}	6.0 : 1	3.5×10^{35} (mol^{-1} dm^3)$^{6.0}$
Cu(II)	5[a)]	5.0×10^{-8}	2.3 : 1	1.9×10^{18} (mol^{-1} dm^3)$^{2.3}$

Conditions: 6.1×10^{-7} mol dm^{-3} BSA against 2.0×10^{-6}—5.0×10^{-6} mol dm^{-3} Ru(III), 6.1×10^{-8} mol dm^{-3} BSA against 7.5×10^{-8}—1.5×10^{-7} mol dm^{-3} Cu(II), ionic strength $\fallingdotseq$0.1 mol dm^{-3}, and reaction temperature=95 °C. The molecular weight of BSA was regarded as being 66000 for purposes of calculation. a) Estimated using the apparatus described in a previous paper.[8)]

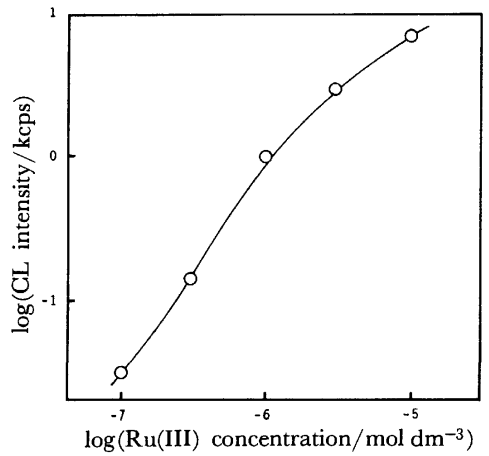

Fig. 1. Calibration curve of Ru(III) catalyst solution. Conditions: 1.2×10^{-4} mol dm^{-3} phen and 5.0 wt% H_2O_2.

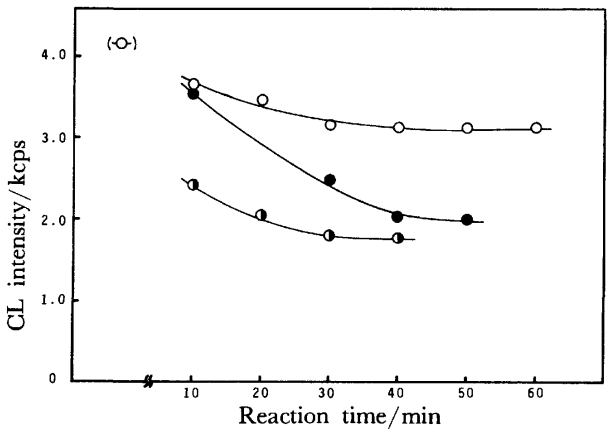

Fig. 2. Relationship between CL intensity and reaction time. Reaction temperature O: 20 °C, ●: 60 °C, and ◑: 95 °C. (-O-): BSA free. Conditions: 1.2×10^{-4} mol dm^{-3} phen, 5.0 wt% H_2O_2, 3.0×10^{-6} mol dm^{-3} Ru(III), and 5.0×10^{-3} mol dm^{-3} BSA.

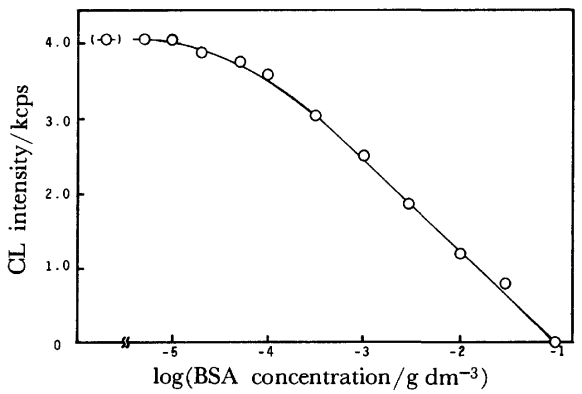

Fig. 3. Calibration curve of BSA. (-O-): BSA free. Conditions: 1.2×10^{-4} mol dm^{-3} phen, 5.0 wt% H_2O_2, and 3.0×10^{-6} mol dm^{-3} Ru(III).

can be seen from Fig. 3, BSA in the concentration range of 5×10^{-5}—1×10^{-1} g dm^{-3} could be determined within a detection limit of about 1 ng. The coefficients of variation for 10 analyses of 1×10^{-3} g dm^{-3} BSA and protein-free sample solutions by the present method were 1.27 and 2.03% respectively. The lowering of the CL activity of the ruthenium(III) catalyst solution in the presence of 5.0×10^{-3} g dm^{-3} glycylglycine and 5.0×10^{-3} g dm^{-3} glycylglycylglycine was examined; their relative CL intensities were 0.88 and 0.79 respectively. The lowering of the CL activity of the ruthenium(III) catalyst solution in the presence of protein seems to be caused by the formation of a ruthenium-polypeptide linkage. The results suggest that the present method can be applied to the determination of biological constituents containing a peptide linkage, such as albumin and globulin as well as an enzyme.

The apparent ratios of ruthenium(III) to a protein and the coupling constant of a ruthenium(III)-protein complex were estimated in a way similar to that de-

scribed in a previous paper.[8] These value were then compared with those of a copper(II)-protein complex in the previous paper;[8] they are shown in Table 2, together with the detection limit of BSA. The apparent coupling ratio and coupling constant of a ruthenium(III) complex were larger than those of a copper(II) complex. It was difficult to compare these values exactly because they were obtained under quite different conditions. However, the data suggest that BSA can be estimated with a detection limit of about 1 ng even though a ruthenium(III) catalyst with a concentration 60 times as high as that of a copper(II) catalyst is used. The reaction mechanism between the metal and the protein still remains unknown.

(Received October 7, 1986)

Synopsis. Stratospheric and tropospheric air samples were collected by means of a balloon-borne grab-sampler launched from Sanriku (39°N, 142°E) in the late summers of 1981, 1983, and 1984. The mixing ratios of CCl_3F and CCl_2F_2 were determined precisely by using gas chromatography with ECD, and that of CH_4, by gas chromatography with FID. The vertical profiles of these compounds are presented and compared with the model calculations.

Large amounts of chemical species have been released into the atmosphere from human activities; their atmospheric concentrations increase depending on the released amounts and tropospheric lifetimes. Among them, entirely man-made chlorofluoromethanes, CCl_3F and CCl_2F_2, both with extremely long lifetimes, are believed to have a severe impact on the Earth's environment; the stratospheric ozone is depleted by chlorine atoms released from these compounds in the stratosphere.[1-3] In this connection, we have been measuring the background concentrations of several halocarbons in the atmosphere in Hokkaido since 1979 and have observed that the CCl_3F and CCl_2F_2 concentrations increase by 4—6% a year.[4]

We have also observed that the atmospheric concentration of methane increases gradually as well (about 1% a year); in the troposphere, it will cause an elevation of the surface temperature (i.e., a "greenhouse effect"),[5] and a depletion of the tropospheric OH radical concentration leading to prolonged lifetimes of many air pollutants susceptible to OH attack.[6]

In this paper we report the vertical profiles of CCl_3F, CCl_2F_2, and CH_4 over Japan obtained by the analysis of air samples collected by means of a balloon-borne large-volume grab-sampler. While the vertical distributions of these compounds have often been observed in the USA[7,8] and southern France,[9] no systematic measurements have been attempted to date in Asia.

Experimental

Stratospheric Air Sampling. A balloon-borne grab-sampling system for collecting stratospheric whole air samples was developed; the details have been described elsewhere.[10]

Six 30-l sample cylinders were installed in a sealed large aluminum container called a "scientific gondola" (0.9 m in diameter, 1.3 m in height, and weighing 150 kg), together with a sampling manifold, a monitor circuit, and a valve-controller. A motor-driven stainless-steel bellows valve was installed between each sample cylinder and the sampling manifold; it was operated at the desired altitude by command signal from the ground station. The sampling manifold was connected to an outside air-intake tube (4-m-long flexible tubing equipped with a glass-sealed end for ensuring a high vacuum and extremely clean conditions).

In order to avoid contamination by halocarbons from the components (cylinder, valve, manifold, etc.), all parts were cleaned thoroughly before they were assembled. The inside of the electropolished sample-cylinder was further passivated by silanization with hexamethyldisilazane, and then evacuated for several hours at 150 °C.

After launching, the scientific gondola was reeled down to 100 m below the control gondola/15000 m^3 balloon in order to avoid contamination from these systems and from the helium gas to be released from the balloon. Then, the end glass-seal was cut off and the 4-m intake tubing was extended downward. Sampling was performed when the balloon system was descending, and the inlet port was continuously flushed with ambient air. The sampling system was launched in the early morning on September 2nd, 1981, on August 28th, 1983, and on September 7th, 1984, from the Sanriku Balloon Center on the Pacific coast (39.16°N, 141.83°E). In the beginning, it flew east over the Pacific Ocean while ascending (at 300 m min^{-1}) on the west wind in the troposphere; it then returned to the west at an altitude of about 28 km on the weak east wind in the stratosphere. After 2—4 h flight for degassing and returning to over Sanriku, it was made to descend at 50—100 m min^{-1}; five stratospheric samples were collected in the meantime. Then the balloon was cut off, and one tropospheric sample was collected during descent by parachute. The scientific gondola alighted on the sea near Sanriku and was recovered within an hour.

Analysis. The sample cylinders were returned to the laboratory, and an aliquot of the atmospheric sample was introduced into an extremely clean, evacuated sample loop for precise and accurate analysis with the gas chromatographic system we had developed.[11,12] The halocarbons were determined with an ECD (electron capture detector), while methane was determined with an FID (flame ionization detector).

Results and Discussion

Since the atmospheric pressure decreases with the altitude, the concentration is expressed in terms of the volume mixing ratio (molar ratio of each component to dry air, in units of pptv=10^{-12} v/v or ppmv=10^{-6} v/v).

The observed mixing ratios of CCl_3F and CCl_2F_2 (1981, 1983, and 1984), and CH_4 (1983 and 1984) are shown in Fig. 1, together with the observed concentrations on the surface (background concentrations observed in Hokkaido in August).[4]

While these compounds were distributed uniformly in the troposphere, the mixing ratios of halocarbons decreased rapidly in the stratosphere because of the slow transport into the stratosphere and the photodissociation by intense solar radiation with short wave-

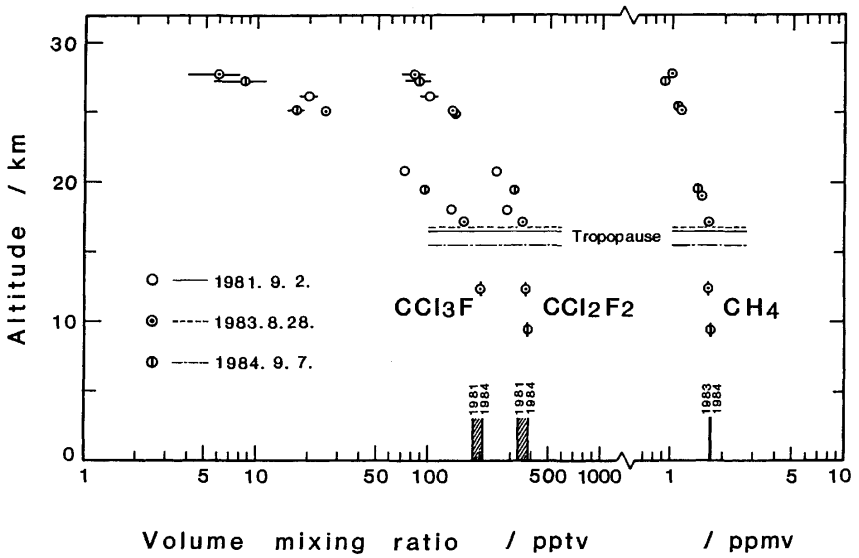

Fig. 1. Observed vertical distribution of halocarbons and methane in the stratosphere and troposphere over Sanriku (39°N, 142°E) in summers of 1981, 1983, and 1984.

lengths (190—220 nm). As compared with CCl_2F_2, CCl_3F, with a larger photodissociation cross-section, indicated a quicker decrease in the mixing ratio.

Since no removal process (sink) for CCl_3F and CCl_2F_2 has been found in the troposphere (i.e., no photodissociation with sunlight (>280 nm), no reaction with OH, no dissolution into rain or sea water, etc.), their tropospheric lifetimes have been confirmed to be extremely long, more than several hundred years.[13] In the stratosphere, however, ultraviolet solar radiation not absorbed by stratospheric ozone can decompose CCl_3F (at about <230 nm) and CCl_2F_2 (at about <220 nm) effectively, with maximum dissociation at altitudes of about 25 and 30 km respectively. The photodissociation of CCl_3F and CCl_2F_2 ($CCl_3F+h\nu\rightarrow Cl+CCl_2F$, and $CCl_2F_2+h\nu\rightarrow Cl+CClF_2$) is followed by the release of all the Cl atoms in the molecule, and the released Cl joins the ClO_x-catalyzed decomposition of ozone ($Cl+O_3\rightarrow ClO+O_2$, and $ClO+O\rightarrow Cl+O_2$), leading to the depletion of the stratospheric ozone.[1-3]

By contrast, methane is decomposed mainly in the troposphere by the reaction with the OH radical ($CH_4+OH\rightarrow H_2O+CH_3$), with a tropospheric lifetime of about 10 years.[6] In the lower stratosphere, the observed mixing ratio of CH_4 decreases only slowly due to the low OH and $O(^1D)$ concentrations, the small photodissociation cross-section with UV, and the upward diffusion to the upper stratosphere. As compared with the CH_4 profile, it is obvious that CCl_3F and CCl_2F_2 are decomposed effectively in the lower and mid stratospheres.

The vertical profiles of the stratospheric mixing ratios observed in this work (Fig. 1) agree reasonably well with those calculated on the basis of recent atmospheric models.[14-17] A two-dimensional (2-D) atmospheric model calculation[14] suggests, for summer at latitude 38°N, that the CCl_3F mixing ratio will drop to 1/10 and 1/100 (of the tropospheric value) at altitudes of about 25 and 28 km respectively, while the CCl_2F_2 mixing ratio will fall to 1/10 at about 31 km. Our measurements at 39°N in summer indicate that the CCl_3F mixing ratio fell to 1/10 and 1/100 at altitudes of 25—26 km and 28—29 km, while that of CCl_2F_2 fell to 1/10 at 30—31 km. The 2-D model calculation[14] similarly suggests that the CH_4 mixing ratio decreases to 1/2 (of the tropospheric value) at about 30 km; this is also in agreement with the value of 29—30 km in the observed profile (Fig. 1).

Meteorological conditions should be taken into consideration for a closer examination of the vertical distribution of these compounds in the stratosphere. The heights of the tropopause were about 16.5, 16.8, and 15.5 km respectively at the time of the flights in 1981, 1983, and 1984. The flights were made in more or less similar seasons and under similar weather conditions, because these factors were chosen to ensure the recovery of the sampler on the sea off Sanriku; the stable combination of a tropospheric west wind and a stratospheric east wind is possible only in early and late summer.

Since the tropopause moves upward or downward with the air, the observed mixing ratios were plotted against the height above the tropopause in Fig. 2; the tropopause height was normalized to 16.5 km. With such normalization, less scattered and more reasonable plots were obtained. The atmospheric pressure-temperature curves on the sampling day were very similar in 1981 and 1983, and a clear turning point corresponding to the tropopause was observed, whereas there was a gradual change in the temperature around the tropopause in 1984, indicating that the profile around the tropopause was affected by air mass motions. Our data are less scattered and indicate a slower fall-off in the lower stratosphere than those reported over the USA (41°N)[7] or southern France (44°N).[9] Such a discrepancy of vertical profiles may be attributed to the difference in the dynamic processes in this altitude region (lower stratosphere) depending on

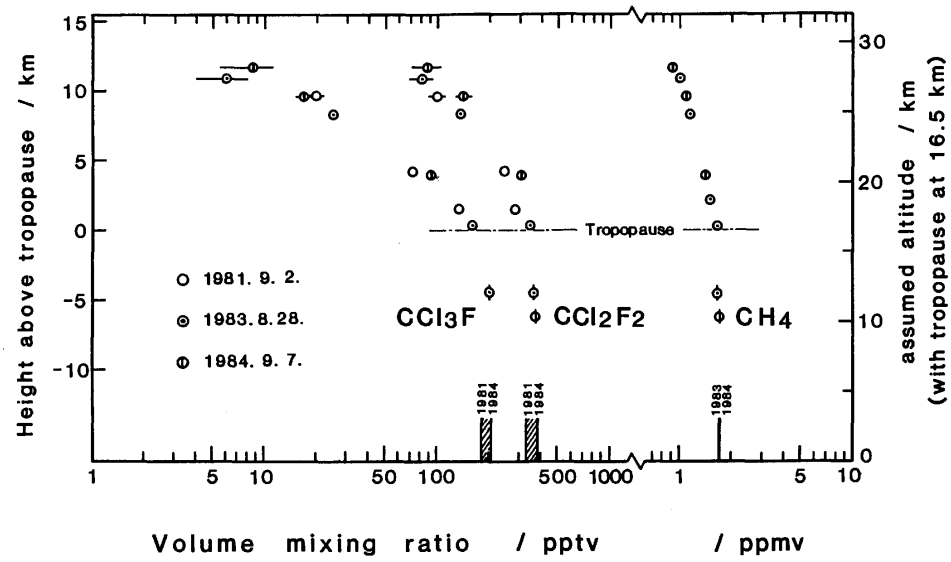

Fig. 2. Vertical distribution of halocarbons and methane vs. height above tropopause.

the latitude, season, and meteorological conditions.

The observed atmospheric concentrations of CCl_3F and CCl_2F_2 on the surface increased by about 12 and 15% respectively in these 3 years (1981—1984).[4] While the mixing ratios of these halocarbons in the stratosphere may also tend to increase slightly (Fig. 2), it is still difficult, in view of variable meteorological conditions, to indicate the trend in the stratosphere quantitatively on the basis of 3 years' data. A long-term monitoring is needed to determine unequivocally the trend of their stratospheric concentrations. Since stratospheric air samples from higher altitudes should be analyzed for a more detailed comparison with models, a balloon-borne liquid-helium-cooled cryogenic-sampler has been developed to collect sufficient amounts of samples at lower-pressure altitudes.[18]

Conclusion

The vertical profiles of CCl_3F, CCl_2F_2, and CH_4 were determined by the analysis of the air samples collected by means of a balloon-borne grab-sampler. The mixing ratios of halocarbons decreased sharply in the stratosphere, indicating the emission of large amounts of Cl atoms, which in turn cause the depletion of stratospheric ozone: this situation will persist for several tens to hundreds of years in view of the increasing tropospheric concentrations of halocarbons with extremely long lifetimes.

Synopsis. The light lanthanoid(III) (La or Nd) 1-hydroxy-2-naphthoate crystals indicated in the title were obtained and their structures were determined by the X-ray diffraction method using their single crystals. They are orthorhombic with the space group $P2_12_12_1$, Z=4. The unit-cell axis lengths of the lanthanum(III) complex are: a=11.985(4), b=40.21(5), and c=7.017(1) Å. The central metal atom is ennea-coordinated and is in a tricapped trigonal-prism geometry, where two carboxylate ions act as the unidentates, and the other coordinating positions are occupied by water oxygen atoms. The non-coordinated carboxylate ion is hydrogen-bonded to two ligated water oxygen atoms with its respective carboxylato oxygen atoms. The complex molecules are not directly bridged by the carboxylate ions, but the complexes are linked by hydrogen-bondings in the a- and c-axis directions. Such hydrophilic and the hydrophobic layers of the naphthalene rings, both of them being parallel to the ac-plane, are laid alternately in the crystal.

It has been already reported that many lanthanoid carboxylates have high coordination-number metal atoms and are almost always in dimeric or polymeric structures in their crystals.[1-6] We previously reported two types of neodymium(III) 1-hydroxy-2-naphthoates: one in a dimer form including water and ethanol, $[NdL_3(H_2O)(C_2H_5OH)]_2\cdot 2H_2O\cdot 2C_2H_5OH$ (**1**),[7] and the other is a monomeric type one, $[NdL_2(H_2O)_5]L\cdot 2H_2O$ (**2**) (HL=1-hydroxy-2-naphthoic acid).[8] The metal atoms of both complexes are ennea-coordinated and are in a tricapped trigonal-prism geometry. This time we could obtain other types of the salts (isomorphous lanthanum(III) and neodymium(III) salts), which include eight molecules of water per one metal atom. It is interesting to compare their structures with those of **1** and **2**; we examined their crystal and molecular structure by the single-crystal X-ray diffraction method.

Experimental

Synthesis of [Heptaaquabis(1-hydroxy-2-naphthoato)-lanthanum(III)] (1-hydroxy-2-naphthoate) Hydrate. The lanthanum hydroxide was obtained by mixing aqueous solutions of lanthanum(III) chloride heptahydrate (0.38 g, 1.0 mmol) and an excess sodium hydroxide. The precipitate was separated, washed with water, and dissolved into 30 cm^3 of a warmed 2-propanol-water mixed solvent (2:1=v/v), including 1-hydroxy-2-naphthoic acid (0.56 g, 3.0 mmol). The solution was filtered and the filtrate was left standing for several days at room temperature; and the crystals of the title complex were precipitated. Yield: 0.37 g (43%). Anal ($LaC_{33}H_{37}O_{17}$), La, C, H. A pure lanthanum complex was thus obtained; however, when the same process was applied to the neodymium salt, the product also contained some crystals of **2**. Therefore, from the mixture we picked up the title complex crystals, which were spatula-like thin-plate types that could be clearly distinguished from those of **2**.

Single-Crystal X-Ray Analysis. Crystallographic data and various experimental conditions for collecting intensity data are summarized in Table 1. Reflections were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer with graphite-monochromated Mo $K\alpha$ radiation, by means of a ω-scan technique (scan speed=4° min^{-1} (θ)). Reflections with $|F_o|>3\sigma(|F_o|)$ were used for a structure determination. All calculations were carried out on a HITAC M-680H computer at the Computer Center of the

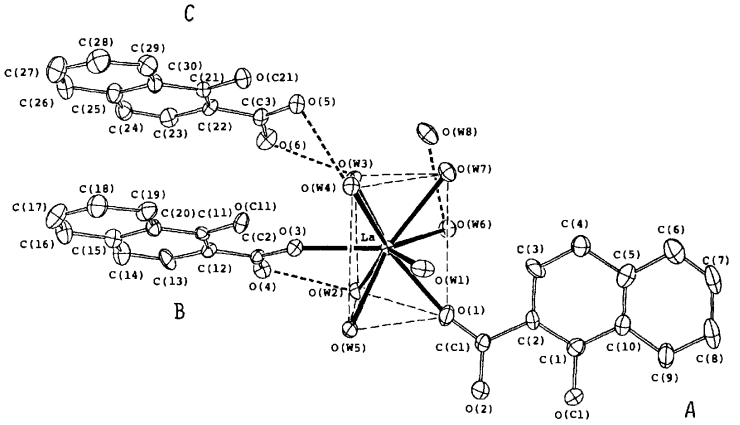

Fig. 1. A perspective drawing around the metal atom with the numbering scheme of the atoms and the notation of the naphthalene rings.

University of Tokyo, using the local version of UNICS.[10] The scattering factors were taken from Ref. 11.

The structure of the lanthanum(III) complex was solved by common heavy-atom method. Refinements of the parameters of the neodymium(III) complex were started from the final parameters of the isomorphous lanthanum(III) salt, and was refined as usual. Their final R values are shown in Table 1, together with those of the reversed structures. As the R value of the reversed structure was larger in the case of the lanthanum complex, it was rejected; however, that of the neodymium complex was a little smaller and should be adopted for the salt.

Results and Discussion

The selected bond lengths and bond angles are shown in Table 2.[12] A perspective drawing of the complex together with a carboxylate ion and a water molecule near it is shown in Fig. 1; the numbering scheme of the atoms as well as the notation of the naphthalene rings are also given. A projection of the unit cell is shown in Fig. 2.

No carboxylato bridgings were found between the metal atoms, although some hydrogen bondings link those complexes in a- and c-axis directions.

The metal atom is ennea-coordinated and is in a tricapped trigonal-prism geometry. Two carboxylate ions are coordinated as unidentates with each carboxyl oxygen atom at one apex of the prism and one cap position; the other seven positions are occupied by the water oxygen atoms. Compared with **2**, where both of

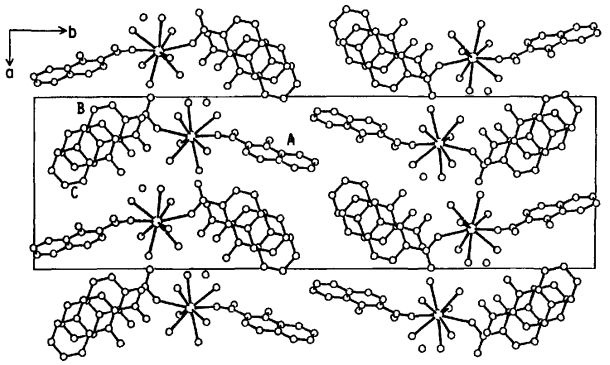

Fig. 2. Crystal packing diagram.

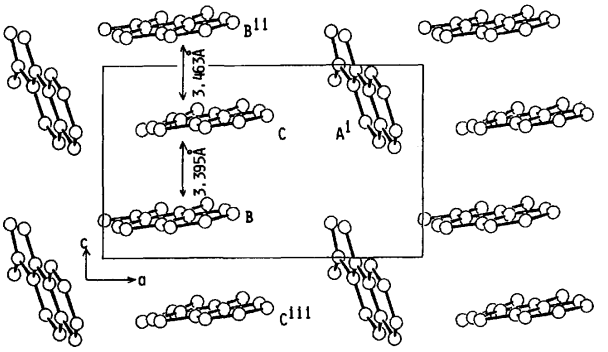

Fig. 3. A projection of the naphthalene rings to the ac-plane. Key to the symmetry operations; i, 0.5+x, 0.5−y, 1−z; ii, x, y, 1+z; iii, x, y, −1+z.

the carboxylate ions form four-membered chelate rings, this compound is regarded as being one in which each carboxyl oxygen atom of the ligands of the former complex is substituted by a water oxygen atom.

The non-coordinated carboxylato oxygen atoms of the coordinated ligands, O(4) and O(2), are hydrogen-bonded with O(W2) and O(W7^{iii}) (Key to the symmetry operation: iii, x, y, −1+z). The carboxylato oxygen atoms of the non-coordinated carboxylate ion, O(5) and O(6), atoms are hydrogen bonded with O(W4) and O(W3) atoms, respectively. These water oxygen atoms, O(W2,) O(W7^{iii}), O(W4), and O(W3) atoms are all ligated to respective metal atoms. The crystalline water oxygen, O(W8), and the hydroxyl oxygen atoms of the carboxylate ions also join the hydrogen-bonding network formation, which is spread approximately parallel to the ac-plane.

In this type complex, the M-O(carboxylate) lengths are shorter than those of M-O(water), though in **2**, on the contrary, the average of the former bond lengths is slightly longer than that of the latter ones. Probably the chelate-ring formation in **2** gives some steric effect to lengthen the former bond lengths.

The lanthanum and neodymium complexes are isomorphous with each other, and the respective La-O bond lengths are longer than the corresponding Nd-O ones, except M-O(W5), which are about the same in length in both complexes. Except for these discrepancies, there are no fundamental differences between the corresponding bond lengths and angles of both complexes, respectively.

The arrangement of naphthalene rings of the ligands and the metal core parts resembles that of **2**. The naphthalene ring parts are intercalated between the hydrophilic sheets of the hydrogen bonded metal core layers. As shown in Fig. 3, **B** and **C** naphthalene rings are almost parallel (dihedral angle=0.8°) and, as written in the figure, the inter-layer distances are approximately the thickness of an aromatic ring. The overlapping area[13] of **B** and **C**, and **C** and **B**^{ii} rings are about 26 and 58%, respectively. The respective dihedral angles between **B** and **A**^{i}, and **C** and **A**^{i} rings are 81.7° and 81.0°.

The hydroxyl groups of the parallel **B** and **C** naphthalene rings direct themselves to the same side in these complexes, while those of **2** to opposite sides from each other.

The authors wish to thank the Shin-Etsu Chemical Ind. Co., Ltd., for the highly pure neodymium(III) oxide.

Template Synthesis of Binuclear Lanthanoid Complexes with Macrocyclic Schiff Base Constituted of 2,6-Diacetylpyridine and 1,3-Diamino-2-propanol

Masatomi SAKAMOTO
Department of Industrial Chemistry, Faculty of Engineering, Ehime University, Bunkyo-cho, Matsuyama 790
(Received November 29, 1986)

Synopsis. Reaction of 2,6-diacetylpyridine with 1,3-diamino-2-propanol in the presence of lanthanoid(III) ions gave complexes of (2+2) macrocyclic tetraimine ligand, H_2apdapy. Complexes synthesized have the composition of $Ln_2(apdapy)(NO_3)_4(H_2O)_5$ (Ln=La or Pr) or $Ln_2(apdapy)(NCS)_4(H_2O)_4$ (Ln=La, Pr, Nd, Sm, or Eu). It is suggested that the complexes are considerably stable and maintain the binuclear structure in dimethylsulfoxide solution.

It is well known that some metal ions function as effective templating agents in the syntheses of macrocyclic Schiff bases constituted of 2,6-diacetylpyridine or 2,6-diformylpyridine and a primary diamine.[1-5] The success in such template syntheses depends upon the conformity in shape and size between the templating ions and the macrocycles thus formed. In this point of view lanthanoid ions have been used for the systematic investigations on template syntheses of macrocyclic complexes.[6-10] The lanthanoid complexes so far characterized, however, are almost limited to those of mononucleating macrocycles, and lanthanoid complexes of binucleating macrocycles have been only reported by Kahwa et al.,[11] in spite of much interest in physicochemical properties[12] and quantum efficiency of luminescence in the condensed systems of f-block elements.[13]

Recently, Bailey et al. have reported that a template reaction of 2,6-diacetylpyridine and 1,3-diamino-2-propanol in the presence of barium perchlorate forms a macrocyclic complex, $Ba(H_2apdapy)(ClO_4)_2 \cdot 2H_2O$ (see Fig. 1).[14,15] This complex was then used for the synthesis of a binuclear copper(II) complex, $Cu_2(Hapdapy)(ClO_4)_3 \cdot 2H_2O$, by the transmetallation.[14,15] X-ray crystal analysis[15] for the dicopper(II) complex demonstrates a relatively large internal cavity size of H_2apdapy and significant flexibility of propanol site, suggesting that the macrocycle, H_2apdapy, can also function as a binucleating ligand toward lanthanoid(III)ions. Therefore, it was attempted in this study to synthesize binuclear lanthanoid complexes of H_2apdapy by template reaction. This paper deals with the synthesis and characterization of $Ln_2(apdapy)(NO_3)_4(H_2O)_5$ and $Ln_2(apdapy)(NCS)_4(H_2O)_4$.

Experimental

Preparations of Complexes. Nitrate complexes were synthesized as follows: Lanthanum(III) nitrate or praseodymium(III) nitrate hydrate (1.2 mmol) and 2,6-diacetylpyridine (1.2 mmol) were dissolved in methanol (20 cm^3). To this solution was added a methanolic solution (10 cm^3) of 1,3-diamino-2-propanol (1.2 mmol) with stirring. After the mixture was refluxed for 2—3 h with stirring, the precipitate thus formed was filtered, washed with methanol, then with diethyl ether, and dried in the open air.

Thiocyanate complexes were prepared as follows: Potassium thiocyanate(33 mmol) was added with stirring to a methanolic solution(50 cm^3) of lanthanoid chloride hydrate (10 mmol) (Ln=La, Pr, Nd, Sm, or Eu). Potassium chloride precipitated was removed by filtration and washed with methanol (50 cm^3). The filtrate and the washings were combined, and to this solution was added 2,6-diacetylpyridine(10 mmol) and then a methanolic solution (25 cm^3) of 1,3-diamino-2-propanol (10 mmol) with stirring. After the mixture was refluxed with stirring for 2—3 h, the precipitate thus obtained was filtered, washed with methanol, then with diethyl ether, and dried in the open air.

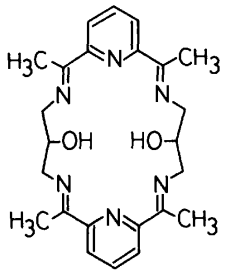

Fig. 1. Chemical structure of H_2 apdapy.

Results of elemental analyses for the complexes are given in Table 1.

Measurements. Infrared spectra were measured with a JASCO IR-G Spectrometer on KBr disks. Magnetic measurements were carried out by the Gouy method at room temperature. The apparatus was calibrated by the use of $HgCo(NCS)_4$. ^{13}CNMR spectra were recorded on a JEOL FX-100 Spectrometer in dimethylsulfoxide-d_6 (DMSO-d_6) at 30 °C.

Results and Discussion

Analytical results summarized in Table 1 demonstrate the composition of the complexes obtained to be $Ln_2(apdapy)(NO_3)_4(H_2O)_5$(Ln=La or Pr) for the nitrate complexes and $Ln_2(apdapy)(NCS)_4(H_2O)_4$ (Ln=La, Pr, Nd, Sm, or Eu) for the thiocyanate complexes, respectively, where the hydroxyl groups of the ligand are presumed to be deprotonated. Infrared spectra of both the nitrate and thiocyanate complexes are essentially similar to each other, except for the IR bands associated with the anions (NO_3^-, NCS^-). For both types of the complexes, the in-plane ring deformation band due to the coordination of pyridine nitrogen is observed at 630—640 cm^{-1}.[1,17] Absorption in the region of 1630—1645 cm^{-1} is attributable to the C=N stretching mode. As described in a previous paper,[17] azomethine nitrogen is probably coordinated to the metal, since Schiff bases of the present type are thermally stabilized only when the azomethine nitrogen is coordinated to a metal ion.[18] In fact, it was impossible to isolate H_2apdapy in the metal free state, as was the case of 1,3-bis(2-pyridylmethyleneamino)-2-prop-

anol.[17]

For the nitrate complexes, the bands assignable to bidentate nitrate ion appear at 1450, 1300, 1030—1035, and 815 cm^{-1}.[19] The frequencies of the nitrate bands are very similar to those of hexaazamacrocyclic lanthanum(III) complex, in which all the nitrate ions are revealed to be bidentate.[6] Based on this fact, it may be concluded that all of the nitrate ions of $Ln_2(apdapy)(NO_3)_4(H_2O)_5$ function as bidentate ligands. This is also supported by the splitting of the combination bands in the 1700—1800 cm^{-1} region;[20] the separation for the La and Pr complexes is 25 and 29 cm^{-1}, respectively.

For the thiocyanate complexes, a sharp singlet band appears at 2050 cm^{-1}, suggesting that the thiocyanate ions are coordinated to the metal at the nitrogen.[21]

Magnetic moments of the complexes at room temperature are common for the tervalent lanthanoid ions and no significant magnetic interaction was inferred between a pair of metal ions, for the reason that 4f-electrons are shielded by outer-shell electrons.

It seems that the binuclear structure of the macrocycle is maintained even in solutions because each complex gave no precipitate when treated with KOH in DMSO or DMSO-H_2O.[6]

The ^{13}CNMR spectral data of $La_2(apdapy)(NO_3)_4(H_2O)_5$ and $La_2(apdapy)(NCS)_4(H_2O)_4$ in DMSO-d_6 are summarized in Table 2. These complexes give no signal at about 200 ppm, whereas the signal due to carbonyl carbon is observed at 198.68 or 200.09 ppm for the DMSO-d_6 solution of 2,6-diacetylpyridine or of lanthanum(III) nitrate and 2,6-diacetylpyridine, respectively, suggesting that apdapy does not dissociate into its components in DMSO. Signals due to the methine carbon atoms of the La complex shift downfield compared with those of complex reported by Fenton et al.,[14] implying that the hydroxyl groups are deprotonated and coordinated to the metal. Furthermore, it is seen that each signal for the La complexes is composed of two or more components. This fact suggests that (1) the symmetry of the binuclear structure is low or (2) the complex is a mixture of some geometrical isomers. All efforts to obtain single crystals of the lanthanoid complexes suitable for X-ray analysis are in vain at this moment.

Though the detailed structure of the complexes is

still unknown, it is evident from the above discussion that the lanthanoid ions function as the template for the 2:2 condensation of 2,6-diacetylpyridine and 1,3-diamino-2-propanol to form binucleating macrocycle H_2apdapy.

The author is greatly thankful to Prof. Tomitaro Ishimori of Ehime University for his helpful discussion and encouragement throughout this work.

Asymmetric Hydrogenation Catalyzed by Bis(disubstituted glyoximato)-cobalt(II)(L)-Chiral Cocatalyst System. Effect of Structural Variation of Ligands and Hydrogen Pressure[1)]

Yoshiaki OHGO,* Yasuhisa TASHIRO,† and Seiji TAKEUCHI

(Received August 25, 1986)

Synopsis. The reaction rate was extremely enhanced by increasing the basicity of the axial ligand of [Co(dmgH)$_2$(L)] and by increasing the hydrogen pressure without decreasing the enantioselectivity. Substituting one and two methyl groups of the dimethylglyoxime ligand in [Co(dmgH)$_2$(L)] with a phenyl group enhanced and retarded the reaction rate, respectively. The chirality at the cobalt did not affect the enantioselectivity.

The authors have reported asymmetric hydrogenations of diketones, α-ketocarboxylates and olefinic compounds[2-6)] catalyzed by bis(dimethylglyoximato)-cobalt(axial ligand)-chiral cocatalyst systems and have proposed a mechanism for the catalysis of the asymmetric hydrogenations.[4,5)] The proposed mechanism involves an electron-donating site and an enantiodifferentiating site that are separated in these systems (Fig. 1).

We examined the effects of a structural variation of inplane and axial ligands as well as hydrogen pressure in order to determine a guideline for finding a better catalyst and to provide further support regarding the mechanism.

Results and Discussion

Effect of Structural Variation of Inplane and Axial Ligands. In Table 1 are summarized the results for asymmetric hydrogenations of benzil that were catalyzed by several catalyst systems in which inplane and axial ligands were varied (Eq. 1 and Fig. 2).

$$\mathrm{PhCOCOPh} \xrightarrow[\mathrm{Co(PL)_2L\text{-}B^*}]{\mathrm{H_2}} \mathrm{Ph\overset{*}{C}HCOPh} \quad (1)$$
$$\qquad\qquad\qquad\qquad\qquad\qquad\quad \mathrm{OH}$$

The chemical yields were almost quantitative. An increase in the sigma-donor character of an axial ligand accelerates the reaction rate (as already reported in part);[5)] an increase in the steric bulkiness decreases it. A steric hinderance of the inplane ligand is considered to decrease the rate, but the electronic effect of an inplane substituent is somewhat complicated. Since the plane of a phenyl group is oriented almost perpendicular to the glyoxime plane,[7)] the electronic influence of the phenyl group is considered to be inductive rather than resonance; thus, the phenyl group will act as an electron-withdrawing group, which can bring about a decrease in the electron density of cobalt atoms. In fact, the Co-CH_3 proton signal in the series of complexes shifts to a lower field (^{1}H NMR spectrum) with an increase in the phenyl substituent (Table 1). The fact that the substitution of one of the two methyl groups of the dimethylglyoxime ligand in Co(dmgH)$_2$L with a phenyl group causes some rate enhancement seems to be incompatible with the fact that the sigma-donor character of the axial ligand enhances the reaction rate. The reason has not yet been clarified.

We have shown that chiral amine coordinates preferentially to one of the two prochiral faces of bis[(*E,E*)-1-phenyl-1,2-propanedione dioximato]cobalt-(I).[8)] If a cobalt complex is involved in the enantiodifferentiating transition state, the enantioselectivities should vary by changing an achiral axial ligand to a chiral one. The results showed that a chiral axial ligand did not alter the enantioselectivity. This provides further support for the proposed mechanism regarding the enantioselection described in previous papers.[4,5)]

Effect of Pressure. Asymmetric hydrogenation catalyzed by chiral rhodium complexes are sensitive to the hydrogen pressure: a high hydrogen pressure decreases the enantioselectivity remarkably.[9,10)] The hydrogen

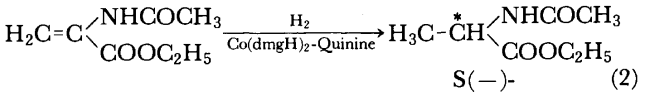
In every experiment, equimolar amounts of quinine (Q*) and its HCl salt were used (Q*/Co=Q*HCl/Co=1) as the chiral cocatalyst. b) S/Co: molar ratio of substrate to cobalt. c) Enantioselectivity (% enantiomeric excess) in every experiment was calculated from the specific rotation of the product based on that of the optically pure (*S*)-(−)-ethyl *N*-acetylalaninate, $[\alpha]_{578}^{20}=-66.4°$ (*c* 6, ethanol).[11] d) RT: Room temperature.

pressure effect was ascribed to a difference in the reactivity of the two diastereomeric complexes (leading to the two enantiomeric products) toward hydrogen.[10] However, our catalyst systems are completely different from the chiral ligand-coordinated rhodium complexes. Mechanistic studies on our systems revealed that the electron-donating site and the enantiodifferentiating site are separated:[4,5] this suggested that a higher hydrogen pressure should accelerate the reaction rate without any decrease in the enantioselectivity. When an easily ligating amine, $PhCH_2NH_2$, was used, the reaction rate was too rapid for a measurement, even at a 20 kg/cm^2 pressure of hydrogen. Consequently, experiments on pressure effect were examined in the asymmetric hydrogenation of ethyl 2-(acetylamino)propenoate by using bis(dimethylglyoximato)cobalt(II)-quinine without the addition of a simple axial base (Eq. 2).



S(−)- (2)

As expected, the reaction rate was extremely enhanced with increasing hydrogen pressure, while the enantioselectivities were almost constant within the experi-

mental error (Table 2). The reaction rate under a 60 $kg\,cm^{-2}$ initial pressure of hydrogen became roughly 100 times that under an atmospheric pressure of hydrogen.

Experimental

Effect of Inplane and Axial Ligands on the Catalytic Asymmetric Hydrogenation of Benzil. Catalytic asymmetric hydrogenation of benzil was carried out in benzene under an atmospheric pressure of hydrogen according to the procedure described in previous papers,[5,6] except for using the inplane and axial ligands specified in Table 1. The reaction temperature was maintained at 30±0.2 °C.

Pressure Effect. The catalyst solution was prepared according to the procedure described in previous papers[5,6] under a nitrogen atmosphere. Methanol was evaporated in vacuo to give a wet paste which was dissolved in 25 ml of a degassed benzene solution of 2-(acetylamino)propenoate. The solution was transferred under a nitrogen atmosphere to a 100-ml autoclave. The nitrogen atmosphere was replaced with hydrogen. Asymmetric hydrogenation was performed in the initial pressure of hydrogen specified in Table 2. The time required to complete the reaction was determined by a pressure gauge. After carrying out the usual workup,[6] an oily product was obtained which was purified on silica gel (Kiesel gel-60) column chromatography using benzene/acetone (3/1) as an eluent. The eluate was concentrated under a reduced pressure to give a syrup whose optical rotation was measured. The enantioselectivities were calculated from the specific rotations. The results are shown in Table 2.

Carbonate Formation from Oxiranes and Carbon Dioxide Catalyzed by Organotin Halide-Tetraalkylphosphonium Halide Complexes

Akio BABA,* Takashi NOZAKI, and Haruo MATSUDA
Department of Applied Chemistry, Faculty of Engineering, Osaka University, 2-1, Yamadaoka, Suita, Osaka 565
(Received September 11, 1986)

Synopsis. Cycloaddition of carbon dioxide to oxiranes was excellently promoted by the complexes of organotin halides and tetraalkylonium halides, while either components of the complexes had no catalytic activity individually. Particularly, the complex composed of Bu_3SnI-Bu_4PI was the most favorable catalyst, yielding a variety of five-membered cyclic carbonates under neutral and mild conditions.

Among many studies on carbon dioxide (CO_2) fixation, the reaction of oxiranes with CO_2 has received attention, yielding poly- or cyclic carbonates in the presence of many kinds of catalysts.[1] In particular, the synthesis of five-membered cyclic carbonates has been ardently investigated, and for example, a devised catalytic reactions using γ-butyrolactones and oxiranes was recently reported.[2] However, some inactive or acid sensitive oxiranes were hardly converted to the corresponding cyclic carbonates by these methods. We recently reported that the complexes composed of organotin halides and Lewis bases showed a catalytic activity toward the addition of CO_2 to oxiranes.[3] In this system, it was proposed that the coordinated Lewis bases activated the tin-halogen bond. It is well known that onium haides also readily complexate with organotin halides in a different mode to form a salt complex.[4] Its synthetic use, however, has been scarcely reported.

We wish to report herein a method using a 1 : 1 complex of Bu_3SnI and Bu_4PI as a catalyst(**3**),[5] which permitted inactive or acid sensitive oxiranes to react with CO_2 to produce the corresponding carbonates in good yields. This is probably due to the neutrality and high activity of the catalyst **3**.

The effects of combinations of organotin halides with onium halides on the product yield of the addition of CO_2 to 2-ethyloxirane were shown in Table 1, which shows the following notable features. (1) Tetrabutylphosphonium iodide was more suitable than Bu_4NI (Entries 1, 12). (2) The activity order of Bu_4PX (X=halogen) is X=I>Br>Cl (Entries 1—3). (3) The activities of organotin halides decrease as the following orders; Bu_3SnI, Me_3SnI, Ph_3SnI (Entries 1, 4, 5), Bu_3SnI, Bu_3SnBr, Bu_3SnCl (Entries 1, 6, 7), and Me_3SnI, Me_2SnI_2 (Entries 4, 8). All these orders were reverse to the order of acidity of organotin halides.[6] Thus, the lowest acidic complex **3** was the most efficient catalyst among the complexes examined. This was an interesting result, since even acid sensitive oxiranes were hoped to be beautifully converted to the corresponding carbonates by this almost neutral catalyst.[7] (4) The formation of 1 : 1 complex was strongly suggested by the comparison of the results of Entries 1, 10, and 11. In addition, the complex formation was also confirmed by ^{119}Sn NMR. The upfield shift values by complexations suggest that a five coordinated tin complex is formed,[8] although a six coordinated one, [Me_3SnBr-Et_4NBr], is proposed by Seyferth et al.[4b]

The above tendencies (1)—(4) were distinctly different from the case of ZnX_2-Bu_4NI systems reported quite recently by Kisch et al.,[9] in which $ZnCl_2$ being a stronger acid is more active than ZnI_2, and an ammonium halide is preferred to a phosphonium halide. Furthermore, use of excess amounts of Bu_4NI (4 equiv) is required for the formation of carbonates in high yields.

In the complex Bu_3SnI-Bu_4PI, the iodide anion in Bu_4PI is thought to be transfered on the tin atom,[4] and this iodide anion may play an effective role for a nucleophilic cleavage of oxirane rings, although a detailed mechanism can not be proposed because of the indefinite configuration of the complex.

various carbonates **2** in the presence of the catalyst **3**. The complexation was essential, since neither Bu_3SnI nor Bu_4PI individually showed any catalytic activity, giving **2b** less than 2% yields under similar conditions. This catalyst was very effective for the reaction of monosubstituted oxiranes. For example, 2-methyloxirane gave propylene carbonate quantitatively at 40 °C for 1 h. Moreover, even in the reaction of acid sensitive monosubstituted oxiranes such as allyl glycidyl ether and glycidyl methacrylate, the corresponding carbonates could be isolated in high yields without polymerization or decomposition (Entries vi, vii). Although the reactivity of oxiranes bearing electron-withdrawing substituents was somewhat lower, satisfactory yields of **2** were effected by the prolonged reaction times. Some vigorous conditions, 100 °C, 5h, were required for the addition of CO_2 to 2,2-dimethyloxirane (85% yield, Entry ix).

An additional advantage of the complex **3** was its high solubility in organic solvents, thus carbonate **2b** was easily obtained from the reaction using benzene as a solvent as well as without solvent (Entry ii). On the contrary, the SnI_2-Bu_4PI system was inefficient probably due to a poor solubility of SnI_2, giving **2b** in only 16% yield (Entry iii).

The complex catalyst, Bu_3SnI-Bu_4PI, provides a method for carboxylation of unreative or acid sensitive oxiranes, extending the scope of a carbonate synthesis under mild conditions.

Experimental

The following instruments were used: Melting points, Yanagimoto micro melting point apparatus; IR spectra, Hitachi 260-10; Mass spectra, Hitachi RMU-6E; GC, Shimadzu 8A (FID, 5% FFAP or 2% OV-17 on Chromosorb WAW); ^{1}H NMR and ^{13}C NMR spectra, Hitachi R-90H.

Tin compounds[10)] and onium halides[11)] were prepared according to the known methods. All oxiranes were available commercially, and were used after distillation on CaH_2.

Values of the boiling points of the compounds are given as °C/mmHg (1 mmHg=133.322Pa).

Reaction of 2-Ethyloxirane and CO_2 under Atmospheric Pressure (Table 1). In a typical procedure, a mixture of organotin compound (1 mmol) and onium halide (1 mmol) and 2-ethyloxirane (50 mmol) was placed in a 30 cm^3 three necked flask, and was heated at 60 °C under the slow stream of CO_2 gas. The amounts of 4-ethyl-1,3-dioxolan-2-one (**2b**) were monitored by GC.

Reaction of Oxiranes and CO_2 under Pressurized Conditions (Table 2). An oxirane (50 mmol), Bu_3SnI (1 mmol), Bu_4PI (1 mmol) and a magnetic bar were placed in a 50 cm^3 stainless steel autoclave, then CO_2 gas was pressurized up to 50 kg cm^{-2}. The vessel was heated with stirring at an appropriate temperature. After cooling, the yields of carbonates were determined by GC. All carbonates were isolated by distillation or recrystalization, and **2a**, **2b**, **2c**, **2d**, and **2g** were characterized by spectral data and bps.[2)]

4-Allyoxymethyl-1,3-dioxolan-2-one (2e): Bp 108 °C/2 mmHg (lit,[2)] 92—94 °C/0.1 mmHg); IR (neat) 1800 (C=O), 1645 cm^{-1} (C=C); MS m/z 158 (M^+); ^{1}H NMR ($CDCl_3$) δ=3.4—4.1 (4H, m), 4.1—4.6 (2H, m), 4.7—5.0 (1H, m), 5.1—5.4 (2H, m), 5.7—6.1 (1H, m).

4-Methacryloyloxymethyl-1,3-dioxolan-2-one (2f): Bp 123 °C/2 mmHg (lit,[2)] 72—73 °C/0.1 mmHg); IR (neat) 1800 (C=O), 1735 (C=O), 1640 cm^{-1} (C=C); MS m/z 186 (M^+); ^{1}H NMR ($CDCl_3$) δ=2.0—2.2 (3H, s), 4.3—4.9 (4H, m), 4.9—5.4 (1H, m), 5.7 (1H, s), 6.2 (1H, s); ^{13}C NMR ($CDCl_3$) δ=17.6, 63.2, 65.9, 73.8, 126.3, 134.9, 154.4, 166.0.

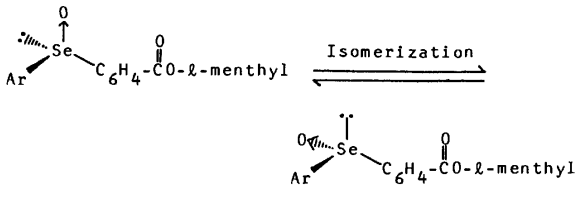
An Estimation of the Configurational Stability of Diaryl Selenoxides by Means of ^{77}Se NMR Spectroscopy

Toshio SHIMIZU, Masato YOSHIDA, and Michio KOBAYASHI*
Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya-ku, Tokyo 158
(Received September 25, 1986)

Synopsis. The activation energies for the racemization of the optically active diaryl selenoxides were estimated by the use of the ^{77}Se NMR spectra of the diastereomeric diaryl selenoxides.

Many optically active sulfoxides have been prepared. On the contrary, though, despite repeated attempts,[1] there has been no example of the isolation of the enantiomerically pure selenoxide until recently. The difficulty of the optical resolution of selenoxide has been attributed to its facile racemization through an achiral hydrate ($RSe(OH)_2R'$) formed by the addition of water to seleninyl group.[2] A few years ago, the synthesis of the partly optically active alkyl aryl selenoxides was reported by Davis et al.[3,4] In these alkyl aryl selenoxides, bulky ortho substituents were found to be effective for retarding the racemization via an achiral hydrate.[3] We succeeded previously in preparing the optically active diaryl selenoxides, which had bulky ortho substituents by using asymmetric oxidation[5] or optical resolution.[6] The attempt to resolve optically the diaryl selenoxides which did not possess bulky ortho substituents was unsuccessful as well as in the case of the alkyl aryl selenoxides. Therefore, it seemed that it would be very interesting to study the configurational stabilities of the diaryl selenoxides which have ortho substituents with different bulkiness. The activation energies for the racemization of the optically active diaryl selenoxides have not been studied. When we measured the selenium-77 NMR spectra of diastereomeric mixture of the diaryl selenoxides with the *p*-(*l*-menthoxycarbonyl) group, we noticed the existence of two signals of ^{77}Se assignable to each isomers.



This finding suggested that the measurement of selenium-77 resonance at various temperatures may make it possible to estimate Gibbs' free energies of activation for the racemization of optically active diaryl selenoxides. We will report here the results of one study of the racemization of diastereomeric diaryl selenoxides obtained from selenium-77 NMR.

Results and Discussion

Firstly, the ^{77}Se NMR spectrum of 2,4,6-tri-*t*-butylphenyl 4′-(*l*-menthoxycarbonyl)phenyl selenoxide (**5**) was observed in $CDCl_3$; Compound **5** is a mixture of the diastereomers of d,l- and l,l-form. The chemical shifts of ^{77}Se NMR for organic selenium compounds spread over a range of the order of 3000 ppm, and the half widths of the signals are usually narrow ($\Delta\nu_{1/2} \lesssim 1$ Hz).[7] These features of ^{77}Se resonance allow us to expect that a small difference between two diastereomers may give two well-resolved signals. In fact, the two selenium atoms of the diastereomers of **5** resonated at different frequencies in ^{77}Se NMR; $\Delta\nu_{ab}$=8.79 Hz (Fig. 1). In the ^{1}H NMR (60 MHz) and ^{13}C NMR (22.5 MHz) spectra of **5**, the assignment of signals to each diastereomer was difficult because of their complexity. Similarly, other diastereomeric selenoxides (**1**—**4**), which had less bulky ortho substituents than the *t*-butyl group, were subjected to ^{77}Se NMR measurements. The results are summarized in Table 1. Two signals for the diastereomeric selenoxides were observed for **2**, **3**, and **4**. In the case of **1**, which had no ortho substituent, only one signal was observed at 20 °C; at −40 °C, however, the signals were separated.

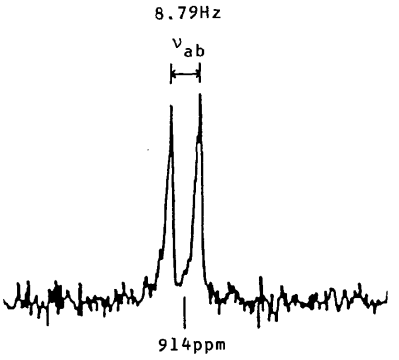


Fig. 1. Resolution of ^{77}Se signals for diastereomeric selenoxide (**5**) in $CDCl_3$ at room temperature.

Table 1. ^{77}Se NMR Chemical Shifts and Separations of Signals for Diastereomeric Selenoxides (**1**—**5**)[a]

	R	Chemical shift[b] ppm	ν_{ab} Hz
1	H	873	—[c]
2	Me	888	7.08
3	Et	886, 891 d)	6.10, 13.67 d)
4	*i*-Pr	881	4.15
5	*t*-Bu	914	8.79

a) The spectra were measured in $CDCl_3$ at 20 °C. b) The chemical shifts from MeSeMe were calculated based on PhSeSePh[8] as the external standard. c) The signals for this selenoxide could not be separated at 20 °C. d) In C_6D_6.

Table 2. Coalescence Temperatures (T_c) and Gibbs' Free Energies of Activation (ΔG^*) for Isomerization of Diastereomeric Selenoxides (**1**—**5**)

Selenoxide	Solvent	Chemical shift[a]	νab[a]	T_c	ΔG^*
		ppm	Hz	K	(kJ mol^{-1})
1	$CDCl_3$	873	11.35[b]	283	61.6
2	$CHCl_2CHCl_2$	892	5.86	333	74.8
3	$CHCl_2CHCl_2$	929	5.62	343	77.2
4	$CHCl_2CHCl_2$	886	3.42[c]	>373	>85.8
5	$CHCl_2CHCl_2$	919	12.70	>353[d]	>77.1

a) At 20 °C. b) At −40 °C. c) At 70 °C. d) This selenoxide decomposed slowly during the measurement at 80 °C to give di-[4-(*l*-menthoxycarbonyl)phenyl] diselenide as the major decomposition product.

This observation suggested that the isomerization between two diastereomers of **1** is too fast compared to the ^{77}Se NMR time scale at 20 °C. The signals of selenoxide (**1**) coalesced at 10 °C. Gibbs' free energy of the activation for the isomerization of diastereomeric **1** was estimated to be 61.6 kJ mol^{-1} in chloroform-*d* from the following equation[9]:

$$\pi\nu_{ab}/\sqrt{2} = (kT/h)\exp(-\Delta G^{\ddagger}/RT).$$

The two signals for **2**—**5** showed little indication to coalesce at 40 °C in the same solvent. Therefore, in the cases of **2**—**5**, the ^{77}Se NMR were examined in high-boiling solvents such as *p*-xylene (in the case of **5**), chlorobenzene (in the cases of **2** and **5**), or 1,1,2,2-tetrachloroethane. Interestingly, the isomers of **2**—**5** resonated at the same frequencies in the aromatic solvents, even at 20 °C (in the case of chlorobenzene) or at 20—60 °C (in the case of *p*-xylene). The lack of the separation of the ^{77}Se signals may be attributed to the specific aromatic solvent-induced shifts, not to the rapid racemization. The measurement of the coalescence temperature was successful in 1,1,2,2-tetrachloroethane. The coalescence temperatures and the free energies of activation for the isomerization are summarized in Table 2. These results indicate that the rate of the isomerization of the selenoxides is strongly dependent on the bulkiness of the ortho substituents. The free energy of the activation for the isomerization obtained from the coalescence temperature of ^{77}Se signals is, because of the inversion of the configuration around selenium atom in the optically active selenoxides, considered to correspond to the free energy of activation for the racemization. The above results suggest that the optical resolution of the diaryl selenoxides which possess no ortho substituent may be difficult at room temperature because of the facile racemization. For the racemization of the optically active selenoxide, there are two plausible mechanisms. One is the racemization through the formation of the achiral hydrate, and the other is the pyramidal inversion of the configuration around the selenium atom. The values of Gibbs' free energies of activation for the racemization obtained in the present study can reasonably be explained by the pyramidal inversion.

Experimental

All the melting points were determined on a Yamato MP-21 apparatus. The IR spectra were recorded on a Hitachi 260-10 Spectrometer, the ^{1}H NMR spectra, with TMS as an internal standard, on a JEOL-JNM-PMX 60SI apparatus, and the mass spectra, on a JEOL JMS-DX300 Mass Spectrometer. The optical rotations were measured on a JASCO DIP-140 digital polarimeter.

Measurement of ^{77}Se NMR spectra. The ^{77}Se NMR spectra were recorded at 17.03 MHz on a JEOL FX90Q NMR instrument. About 0.2 mol dm^{-3} solutions of the selenoxides were prepared in solvents well-dried with molecular sieves. The external rocks with DMSO-d_6 were used except in the cases using $CDCl_3$ and C_6D_6 as solvents. The chemical shifts were measured with complete proton decoupling at room temperature. The separations of the two signals were observed with 0.24 Hz per data point (data points: 8192, sampling time: 4.09s, pulse-flipping angle: 45°).

Materials. The diastereomeric 2,4,6-trisubstituted-phenyl 4′-(*l*-menthoxycarbonyl)phenyl selenoxides (**1**—**5**) were synthesized by means of the oxidation[5] of the corresponding selenides, which themselves been prepared by the esterification of 2,4,6-trisubstituted phenyl 4′-carboxyphenyl selenides.[6] For the preparation of latter, two synthetic routes were possible. The phenyl and triisopropylphenyl derivatives were prepared by means of reactions of potassium areneselenolates with 4-iodobenzoic acid in the presence of copper powder.[10] For the preparation of mesityl, triethylphenyl, and tri-*t*-butylphenyl derivatives, the reactions[11] of aryllithiums with *p*-ethoxycarbonylphenyl selenocyanate,[12] followed by hydrolysis, were applied. The physical properties of the selenoxides (**1**—**5**) were measured as a mixture of the diastereomeric isomers. The preparation of **4** was previously reported.[6]

Phenyl 4-(*l*-Menthoxycarbonyl)phenyl Selenoxide (1): Mp 164—170 °C; $[\alpha]_D^{24}$−41.1°(*c* 1.12, $CHCl_3$); IR (KBr) ν=825 (Se=O) and 1700 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.6—2.3 (18H, m, *l*-menthyl except O-methine H), 4.91 (1H, dt, *J*=5.6, 9.8 Hz, O-methine), 7.3—7.9 (5H, m, aromatic protons of phenyl), 7.73 and 8.09 (4H, ABq, *J*=8.0 Hz, aromatic protons of *p*-substituted phenyl); Exact Mass. Found: *m/z* 432.1146 (^{80}Se), Calcd for $C_{23}H_{28}O_3Se$: 432.1204.

Mesityl 4-(*l*-Menthoxycarbonyl)phenyl Selenoxide (2): Mp 49.5—53 °C; $[\alpha]_D^{24}$−36.9° (*c* 1.03, $CHCl_3$); IR (KBr) ν=825 (Se=O) and 1710 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.6—2.2 (18 H, m, *l*-menthyl except O-methine H), 2.24 (3H, s, para methyl), 2.43 (6H, s, ortho methyl), 4.91 (1H, dt, *J*=4.4, 10.0 Hz, O-methine), 6.79 (2H, s, aromatic protons of mesityl), 7.59 and 8.04 (4H, ABq, *J*=8.0 Hz, aromatic protons of *p*-substituted phenyl); Exact Mass. Found: *m/z* 474.1638 (^{80}Se), Calcd for $C_{26}H_{34}O_3Se$: 474.1673.

2,4,6-Triethylphenyl 4′-(*l*-Menthoxycarbonyl)phenyl Selenoxide (3): Viscous oil; $[\alpha]_D^{24}$−32.0° (*c* 1.06, $CHCl_3$); IR (liquid film) ν=820 (Se=O) and 1705 (C=O) cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.6—2.3 (27H, m, methyl of triethylphenyl and *l*-menthyl except O-methine H), 2.4—3.2 (6H, m, methylene of triethylphenyl), 4.93 (1H, dt, *J*=4.2, 9.9 Hz, O-methine),

6.93 (2H, s, aromatic protons of triethylphenyl), 7.63 and 8.07 (4H, ABq, J=8.6 Hz, aromatic protons of *p*-substituted phenyl); Mass: 516 (^{80}Se) (M^+). Exact Mass. Found: m/z 500.2228 (^{80}Se) (lack of one oxygen), Calcd for $C_{29}H_{40}O_2Se$: 500.2193.

2,4,6-Tri-*t*-butylphenyl 4′-(*l*-Menthoxycarbonyl)phenyl Selenoxide (5): Mp 145—146 °C; $[\alpha]_D^{21}$−23.2° (*c* 1.25, $CHCl_3$); IR (KBr) ν=830 (Se=O) and 1710 (C=O) cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.6—2.4 (18H, m, *l*-menthyl except O-methine H), 1.37 (9H, s, methyl of para *t*-butyl), 1.48 (18H, s, methyl of ortho *t*-butyl), 4.89 (1H, dt, J=5.6, 10.0 Hz, O-methine), 7.52 (2H, s, aromatic protons of tri-*t*-butylphenyl), 7.01 and 7.91 (4H, ABq, J=8.0 Hz, aromatic protons of *p*-substituted phenyl); Mass: 600 (^{80}Se) (M^+); Exact Mass. Found: m/z 584.3182 (^{80}Se) (lack of one oxygen), Calcd for $C_{35}H_{52}O_2Se$: 584.3133.

Generation and Reactions of Phosphorin 1-Sulfides

Hideyuki TANAKA and Shinichi MOTOKI*
Department of Chemistry, Faculty of Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received September 26, 1986)

Synopsis. Phosphorin 1-sulfides generated by the thermolysis of 1-phospha-2-thiabicyclo[4.4.0]deca-3,7,9-triene 1-sulfides reacted with triphenylphosphine, dienophiles, or nucleophiles to give the corresponding phosphorins, 1-phosphabicyclo[2.2.0]octa-2,5-diene 1-sulfide, or 1,2-dihydrophosphorin 1-sulfide derivatives, respectively.

Previously, we reported that 2,9-dithia-1-phosphabicyclo-[4.3.0]nona-3,7-diene 1-sulfides (**2**)[1] derived from α,β-unsaturated ketones **1** reacted with phenylacetylene to afford 1-phospha-2-thiabicyclo[4.4.0]deca-3,7,9-triene 1-sulfides (**3**).[2] From the mass spectral fragments, it is expected that thermolysis of **3** generates phosphorin 1-sulfides (**4**) along with α,β-unsaturated thiones (**5**)[3] in the manner of the retro-Diels-Alder reaction.

Recently, Mathey et al. reported that 4,5-dimethyl-2-phenylphosphorin 1-sulfide formed by the treatment of the corresponding phosphorin with sulfur in boiling xylene was trapped by 2,3-dimethylbutadiene or dimethyl acetylenedicarboxylate.[4] However, no other papers on the synthesis or reactions of phosphorin 1-sulfides have been presented.

In this paper, we wish to describe some reactions of phosphorin 1-sulfides **4** generated by the thermolysis of the precursors **3**.

Results and Discussion

Treatment of **3** with triphenylphosphine in refluxing toluene produced phosphorins **6** and triphenylphosphine sulfide (Table 1). Another component, thiones **5** were decomposed by triphenylphosphine. The phosphorins **6** were easily identified by comparison of the ^{1}H NMR spectral data with those of **6a** in the literature.[5] The ^{13}C NMR spectra of **6** were assigned as shown in Table 2.[6]

Phosphorins were synthesized by Märkl et al. by the

a) These signals were not confirmed.

reaction of the corresponding pyrylium salts with $P(CH_2OH)_3$ or $P(SiMe_3)_3$.[7] By our method, **6** can be readily obtained from α,β-unsaturated ketones **1** by three step reactions.

Phosphorin sulfides **4** reacted as heterodienes at their 1, 4 positions with some dienophiles to give the corresponding cycloadducts.[1,4] When the reaction of **3** with butyl vinyl ether was carried out in refluxing toluene, the cycloadducts **7** were obtained along with **8** (Table 1). The cycloadducts **8** were easily identified by comparison with the authentic compounds reported previously.[3] In the ^{13}C NMR spectra of the cycloadducts **7**, the signals for the methine carbons [δ=77.6 (J_{CP}=8.5 Hz)] and the methylene carbons [δ=37.5 (J_{CP}=47.6 Hz)] indicated that butoxyl groups were linked to C(β) carbons,[1] but the cofiguration of the C(β) carbons could not be determined. The signals for the C(2)-(6) carbons in **7** were assigned as shown in Table 2.[2,4]

The reaction of **3** with norbornene gave the cycloadducts **9**, **10**, and **11** in high yields (Table 1). The thione(**5**)-norbornene cycloadducts (**11**) were identified by comparing the spectral data with those for the authentic compounds.[3] The elemental analyses and mass spectra indicated that both **9** and **10** were 1 : 1 adducts of **4** with norbornene. In the ^{13}C NMR spectra of these adducts, seven signals due to the norbornane ring system were observed and the C(α), C(β) methine carbons showed C-P coupling [C(α), δ=52.2—53.2 (J_{CP}=46.4 Hz); C(β), δ=51.1—53.7 ($^2J_{CP}$=8.5—9.8 Hz)]. The signals for the C(2)-C(6) carbons in 1,4-dihydrophosphorin 1-sulfide ring system were assigned by comparison with those for phosphabarrelene derivatives[2,4] (Table 2). The chemical shifts for the C(2), C(3), and C(5) carbons gave the information on the configuration of **9** and **10**. The cycloadducts **10** showed the resonance for C(2) and C(3) carbons shifted upfield by 1.1 and 3.4 ppm, respectively, compared with those for **9**, whereas **9** showed that the resonance for C(5) carbon shifted upfield by 2.7 ppm compared with that for **10**. On the basis of these shifts, the norbornyl skeleton is considered to be situated on the side of the C(5) and C(6) carbons in **9** and on the side of the C(2) and C(3) carbons in **10**.[1,8] The signals for the bridged methylene carbons (C*) in **9** and **10** shifted upfield by 4.8—4.6 ppm compared with that in unsubstituted norbornane and appeared at δ=33.9 and 34.1, respectively. This suggested that the configuration of these isomers would be *exo* with respect to the norbornyl ring.[1,8]

The reactions of **3** with styrene or acrylonitrile were unsuccessful.

Finally, we examined the reaction of **3** with nucleophiles.[9] Treatment of **3** with benzyl alcohol in boiling toluene gave **12** in high yields. The products showed strong IR absorptions due to the P-O bonding at about 1000 cm^{-1}. In the ^1H NMR spectra, the multiplets of two protons at δ=3.33—3.67 were assigned to the H(6) AB protons. The signals for the C(6) methylene carbon showed large C-P coupling constant (Table 2).

Similarly, the reaction of **3** with benzenethiol gave the expected adducts **13**. The structure of **13** was confirmed by comparison of the spectral data with those for **12**.

In these reactions, addition of the hydrogen of the nucleophiles Nu-H to the C(6) carbons took place preferentially. These adducts **12** and **13** seem to be more stable than their isomeric 1,2- or 1,4-dihydrophosphorin 1-sulfides due to the effective conjugation of the double bond in dihydrophosphorin ring with three aryl groups at the 2-, 4-, and 5-positions. In both cases thiones **5** did not react with the nucleophiles, and were recovered as their dimers **14**.[3]

Reaction of **3** with amines was complicated and no identified product was isolated.

Experimental

All melting points are uncorrected. IR spectra were recorded on a Hitachi Model 260-10 spectrometer. ^1H and ^{13}C NMR spectra were measured in $CDCl_3$ solution using Me_4Si as an internal standard [spectrometer: ^1H; JEOL JNM-PMX60SI (60 MHz), ^{13}C; JEOL JNM-FX 100 (25.05 MHz)]. Mass spectra were recorded on a Hitachi M-80 spectrometer or a JEOL JMS-D300 spectrometer, operating at an ionizing potential of 70 eV. Elemental analyses were performed using a Yanaco Model MT-3 CHN corder. 1-Phospha-2-thiabicyclo[4.4.0]deca-3,7,9-triene 1-sulfides

(**3**) were prepared according to the method previously described.[1)]

General Procedure for the Reaction of 3 with Triphenylphosphine: A solution of **3** (1.0 mmol) and triphenylphosphine (1.2 mmol) in dry toluene (5.0 cm^3) was refluxed under a nitrogen atmosphere for 3 h. The toluene was removed, and the residue was chromatographed on Wakogel C-200 with benzene-hexane (1 : 3) as an eluent. The solvent was evaporated, and the residue was recrystallized from hexane to give **6**.

2,4,5-Triphenylphosphorin (6a): ^{1}H NMR δ=6.93—7.87 (m, 15H, Ar-H), 8.08 [d, 1H, J_{HP}=6.0 Hz, H(3)], and 8.73 [d, 1H, J_{HP}=38.0 Hz, H(6)]; MS *m/z* 324 (M^+, 100). Found: C, 84.99; H, 5.23%. Calcd for $C_{23}H_{17}P$: C, 85.17; H, 5.28%. The ^{1}H NMR spectrum is identical with that reported by Märkl et al.[5)]

4,5-Diphenyl-2-*p*-tolylphosphorin (6b): ^{1}H NMR δ=2.43 (s, 3H, CH_3), 6.97—7.90 (m, 14H, Ar-H), 8.08 [d, 1H, J_{HP}=6.0 Hz, H(3)], and 8.73 [d, 1H, J_{HP}=38.0 Hz, H(6)]; MS *m/z* 338 (M^+, 100). Found: C, 85.14; H, 5.62%. Calcd for $C_{24}H_{19}P$: C, 85.19; H, 5.66%.

General Procedure for the Reaction of 3 with Dienophiles or Nucleophiles: A solution of **3** (1.0 mmol) and large excess of dienophile or nucleophile (10.0 mmol) in dry toluene (2.5 cm^3) was refluxed under a nitrogen atmosphere until **3** was consumed, as indicated by TLC. After evaporation of the solvent, the residue was chromatographed on Wakogel C-200 with benzene-hexane (2 : 1—3 : 1) as an eluent. The products were recrystallized from ethanol or ligroine.

8-Butoxy-2,4,5-triphenyl-1-phosphabicyclo[2.2.2]octa-2,5-diene 1-Sulfide (7a): IR(KBr) 1085 cm^{-1} (C-O); ^{1}H NMR δ=0.67—2.67 (m, 9H), 3.33—4.83 (m, 3H), 6.53 [d, 1H, J_{HP}=20.0 Hz, H(3)], and 6.83—7.67 (m, 16H); MS *m/z* 456 (M^+, 1), 356 (**4a**, 72), 324 (**6a**, 50), 254 (**4a**-PhC≡CH, 100), and 100(CH_2=CHOBu^n, 75). Found: C, 76.37; H, 6.45%. Calcd for $C_{29}H_{29}OPS$: C,76.29; H, 6.40%.

8-Butoxy-4,5-diphenyl-2-*p*-tolyl-1-phosphabicyclo[2.2.2]-octa-2,5-diene 1-Sulfide (7b): IR(KBr) 1085 cm^{-1}(C-O); ^{1}H NMR δ=0.67—2.27 (m, 9H), 2.33 (s, 3H, *p*-Tol-CH_3), 3.33—4.00(m, 3H), 6.52 [d, 1H, J_{HP}=20.0 Hz, H(3)], and 6.93—7.67 (m, 15H); MS *m/z* 470 (M^+, 1), 370 (**4b**, 94), 338 (**6b**, 100), 268 (**4b**-PhC≡CH, 82), and 100 (CH_2=CHOBu^n, 76). Found: C, 76.50; H, 6.66%. Calcd for $C_{30}H_{31}OPS$: C, 76.57; H, 6.64%.

8,10,12-Triphenyl-1-phosphatetracyclo[6.2.2.1^{3,6}.0^{2,7}]trideca-9,11-diene 1-Sulfide (9a): ^{1}H NMR δ=0.75—3.17 (m, 9H), 3.67—3.83 (m, 1H), 6.45 [d, 1H, J_{HP}=20.0 Hz, H(3)], and 6.67—7.75 (m, 16H); MS *m/z* 450 (M^+, 3), 356 (**4a**, 100), 324 (**6a**, 65), 254 (**4a**-PhC≡CH, 68), 121 (39), 94 (13), and 66 (81). Found: C, 79.99; H,5.92%. Calcd for $C_{30}H_{27}PS$: C, 79.97; H, 6.04%.

10a: ^{1}H NMR δ=0.67—3.17 (m, 10H), 6.37 [d, 1H, J_{HP}=19.0 Hz, H(3)], and 6.50—7.67 (m, 16H); MS *m/z* 450 (M^+, 2), 356 (**4a**, 100), 324 (**6a**, 42), 254 (**4a**-PhC≡CH, 69), 121 (22), 94 (4), and 66 (31). Found: C, 79.74; H, 6.04%. Calcd for $C_{30}H_{27}PS$: C, 79.97; H, 6.04%.

8,12-Diphenyl-10-*p*-tolyl-1-phosphatetracyclo[6.2.2.1^{3,6}.0^{2,7}]-trideca-9,11-diene 1-Sulfide (9b): ^{1}H NMR δ=0.75—3.17 (m, 9H), 2.35 (s, 3H, CH_3), 3.67—3.83 (m, 1H), 6.45 [d, 1H, J_{HP}=18.0 Hz, H(3)], 6.67—7.50 (m, 13H), and 7.50 (d, 2H, J_{HH}=8.0 Hz, *p*-Tol-H); MS *m/z* 464(M^+, 1), 370 (**4b**, 100), 338 (**6b**, 36), 268 (**4b**-PhC≡CH, 80), 135 (38), 94 (10), and 66 (69). Found: C, 79.81; H, 5.99%. Calcd for $C_{31}H_{29}PS$: C, 80.14; H, 6.29%.

10b: ^{1}H NMR δ=0.67—3.17 (m, 10H), 2.40 (s, 3H, CH_3), 6.35 [d, 1H, J_{HP}=20.0 Hz, H(3)], 6.50—7.50 (m, 13H), and 7.62 (d, 2H, J_{HH}=8.0 Hz, *p*-Tol-H); MS *m/z* 464 (M^+, 2), 370 (**4b**, 100), 338 (**6b**, 63), 268 (**4b**-PhC≡CH, 80), 135 (28), 94 (7), and 66 (47). Found: C, 80.28; H, 6.17; S, 6.96%. Calcd for $C_{31}H_{29}PS$: C, 80.14; H, 6.29; S, 6.90%.

1-Benzyloxy-3,4,6-triphenyl-1,2-dihydrophosphorin 1-Sulfide (12a): IR(KBr) 1000, 970 cm^{-1} (P-O); ^{1}H NMR δ=3.33—3.67 [m, 2H, H(6)], 4.75—5.50 (m, 2H, $PhCH_2O$), 6.82 [d, 1H, J_{HP}=22.0 Hz, H(3)], and 6.67—7.83 (m, 20H, Ar-H); MS *m/z* 464 (M^+, 72), 356 (**4a**, 22), 340 (75), 324 (**6a**, 10), 293 (66), 254 (**4a**-PhC≡CH, 23), 215 (44), and 91 (100). Found: C, 77.58; H, 5.44%. Calcd for $C_{30}H_{25}PS$: 77.56; H, 5.42%.

1-Benzyloxy-3,4-diphenyl-6-*p*-tolyl-1,2-dihydrophosphorin 1-Sulfide (12b): IR(KBr) 980, 960 cm^{-1} (P-O); ^{1}H NMR δ=2.38 (s, 3H, CH_3), 3.33—3.67 [m, 2H, H(6)], 4.75—5.50(m, 2H, $PhCH_2O$), 6.77 [d, 1H, J_{HP}=20.0 Hz, H(3)], 6.60—7.57 (m, 17H, Ar-H), and 7.57 (d, 2H, J_{HH}=8.0 Hz, *p*-Tol-H); MS *m/z* 478 (M^+, 67), 370 (**4b**, 11), 354 (59), 338 (**6b**, 22), 307 (100), 268 (**4b**-PhC≡CH, 15), 215 (33), and 91 (74). Found: C, 77.54; H, 5.57; S, 6.66%. Calcd for $C_{31}H_{27}OPS$: C, 77.80; H, 5.69; S, 6.70%.

1-(Phenylthio)-3,4,6-triphenyl-1,2-dihydrophosphorin 1-Sulfide (13a): ^{1}H NMR δ=3.50—4.00 [m, 2H, H(6)], 6.68 [d, 1H, J_{HP}=18.0 Hz, H(3)], and 6.68—7.83 (m, 20H, Ar-H); MS *m/z* 466 (M^+, 10), 356 (**4a**, 100), 324 (**6a**, 69), 254 (**4a**-PhC≡CH, 87), 121 (36), and 110 (46). Found: C, 74.40; H, 4.88%. Calcd for $C_{29}H_{23}S_2P$: C, 74.65; H, 4.97%.

3,4-Diphenyl-1-(phenylthio)-6-*p*-tolyl-1,2-dihydrophosphorin 1-Sulfide (13b): ^{1}H NMR δ=2.37 (s, 3H, CH_3), 3.50—4.00 [m, 2H, H(6)], 6.68 [d, 1H, J_{HP}=19.0 Hz, H(3)], 6.67—7.50 (m, 17H, Ar-H), and 7.65 (d, 2H, J_{HH}=8.0 Hz, *p*-Tol-H); MS *m/z* 480 (M^+, 3), 370 (**4b**, 87), 338 (**6b**, 100), 268 (**4b**-PhC≡CH, 80), 135 (40), 110 (78), and 66 (17). Found: C, 75.03; H, 5.21%. Calcd for $C_{30}H_{25}S_2P$: C, 74.97; H, 5.24%.

Syntheses and Biological Activities of Neurokinin B Analogs Modified at Positions 2, 3, and 6

Yoshiki UCHIDA, Keiko OKIMURA, Katsuro KUROSAWA, Naoki SAKURA, Kyoko HIROSE, and Tadashi HASHIMOTO*

School of Pharmacy, Hokuriku University, Ho-3, Kanagawa-machi, Kanazawa 920-11

(Received October 28, 1986)

Synopsis. Nine neurokinin B [NKB] related octa- and nona-peptides containing Arg and *N*-methylglycine, D-Ala, D-Phe, D-Trp, D-α-aminophenylacetic acid, D-Arg, D-Pro, D-homoglutamine, or D-homoglutamic acid instead of Met[2] or His[3], and Phe[6], respectively, in the original sequences were synthesized by standard solid phase method. The biological activities of the analogs were assayed on isolated guinea-pig ileum. [Arg[3], D-Ala[6]]-NKB (3—10) was found to act as an antagonist of NKB.

Neurokinin B[1,2] (NKB) is a novel neuropeptide isolated from porcine spinal cord and sequenced as decapeptide amide (Fig. 1). NKB has close structural homology, particularly in the C-terminal sequence, with tachykinin such as substance P (SP).

The relationship study[3] between chain length and activity indicated that the contractile potency of NKB on guinea-pig ileum, rat vas deferens and rat duodenum remained nearly complete after removal of N-terminal tripeptide portion from the native peptide.

Our recent study[4] on the structure activity relationship of NKB revealed that the replacement of Phe[6] or Val[7] residue with Gly moiety brings drastic decrease of the contractile activities on isolated guinea-pig ileum and rat vas deferens, while the substitution of Gly for Phe[5] enhances their activities. Octapeptide analogs, [Gly[6]]-NKB (3—10) **1** and [Gly[7]]-NKB (3—10) **2**, have no agonistic activity on both assays.

Since our synthetic study on the structure activity relationship of NKB aimed the development of a specific and potent antagonist, the analogs **1** and **2** were examined for their antagonistic effects against NKB. The analog **1** was found to exert potent antagonistic effect, but analog **2** was not an antagonist. Based on this observation, a new series of octa-and nona-peptide analogs containing unusual amino acid at position 6 (Fig. 1) was designed in order to obtain more potent antagonist. *N*-methylglycine (sarcosine, Sar), D-Ala, D-Phe, D-Trp, D-α-aminophenylacetic acid (D-α-phenylglycine, Phg), D-Arg, D-Pro, D-homoglutamine (Hgn),[5] or D-homoglutamic acid (Hgu) residue was substituted for Phe[6]. It has been observed that the replacement of natural residue with unusual amino acid in SP[6,7] changes the pharmacological spectrum of SP from that of an agonist to that of an antagonist. Arg moiety was incorporated into peptide chain to improve the solubility of the peptides in water according to SP antagonists.[7]

This paper describes the first application of a new amino acid D-Hgu to the synthetic study of bioactive peptide analogs. D-Hgu residue was incorporated into a peptide chain by the usual solid phase technique using Boc-D-Hgu(OBzl)-OH,[5] which was derived from the N^{α},N^{ca}-(Boc)$_2$-D-Hgn-OH[5,6] by the reaction with anhydrous sodium benzylate in benzyl alcohol.

The new NKB analogs were synthesized in the same way with the preparation of NKB analogs[4] on an automated peptide synthesizer by standard solid phase method[8] starting from *t*-butoxycarbonyl(Boc)-Met-benzhydrylamine-resin. Boc protection was used for α-amino function. The side-chain protective groups used were cyclohexyl for Asp, benzyl for D-Hgu, *p*-tolylsulfonyl for Arg and His, and Boc for the amide nitrogen (N^{ca}) of D-Hgn. After the completion of the chain elongation, the peptide resin was treated with liquid hydrogen fluoride[9] in the presence of anisole to cleave the peptide from the resin with simultaneous removal of the protecting groups and formation of the carboxyl terminal amide. The synthetic products were purified by preparative reverse-phase high-performance liquid chromatography (HPLC) using 0.1% trifluoroacetic acid in acetonitrile as eluent. Highly purified peptides (Table 1) were obtained after gel filtration on Sephadex LH-20 column. Homogeneity of the peptides was demonstrated by analytical HPLC

a) Condition of analytical HPLC: column, Chemcosorb ODS; flow rate, 1 ml min^{-1}; Detection, 210 nm; eluent system, linear gradient from 14% to 35% CH_3CN (15 min) in 20 mM phosphate buffer (pH 3.0).

and thin-layer chromatography (TLC). When single peak and single spot were observed for a peptide in all chromatographic systems, the peptide was considered appropriately pure for bioassay. The chromatographic data were reinforced by the amino acid analytical data.

Biological properties of the synthetic peptides were examined on contractile activities of isolated guinea-pig ileum. The agonistic effects of analogs **3**—**11** were compared with that of our synthetic NKB. Analogs **1**—**11** were tested for their antagonistic effects against NKB. The antagonistic activities of the analogs were evaluated in terms of pA_2 (negative concentration of antagonist that reduces the contractile response to a double dose of agonist in the presence of antagonist to that of a single dose without it), according to Schild.[10] The results are presented in Table 2.

Analogs **3**, **4**, **5**, **7**, **8**, **9**, and **11**, in which Phe[6] was replaced by Sar, D-Ala, D-Phe, D-Phg, D-Arg, D-Pro, or D-Hgu, had no agonistic activity on the ileum assay, and [Arg[3], D-Trp[6]]-NKB (3—10) **6** and [Arg[2], D-Hgn[6]]-NKB (2—10) **10** possessed a little contractile activity. It was observed that the replacement of Phe[6] with Gly or D-Ala changed the pharmacological spectrum of NKB from that of an agonist to that of an antagonist and the substitution by the unusual amino acide except D-Ala was unfavorable for antagonism to NKB. Analogs **1** and **4** exerted antagonistic effects against NKB showing similar pA_2 values. The results reveal that **1** and **4** are the first NKB analogs to act as fairly potent antagonists against NKB.

a) **3**, **5**, **7**, **8**, **9**, and **11** showed no agonistic and antagonistic activity. b) Relative contractile activity to NKB=1. c) Data from Ref. 4. d) —, no antagonistic activity.

Experimental

Amino acid derivatives were purchased from Peptide Institute, Inc., Osaka, Japan and benzhydrylamine (BHA) resin (available amine of the resin: 0.6 mmol g^{-1} of support) from Beckman Inc., Palo Alto, Calif. Optical rotations were measured in a 1 dm tube using a Nipponbunkoh DIP-4 Polarimeter. Amino acid analyses on samples previously hydrolyzed with 6 M HCl (1 M=1 mol dm^{-3}) (110 °C, 24 h) or on analog **6** with 4 M methanesulfonic acid containing 0.2% 3-(2-aminoethyl)indole (115 °C, 24 h) were performed on a Beckman System 7300 Amino Acid Analyzer. TLC were carried out on silica-gel plates (Merck). The following solvent systems were used and allowed to ascend for 10 cm: R_f^1, *n*-BuOH: AcOH: H_2O (4:1:5, upper phase); R_f^2, *n*-BuOH: pyridine: AcOH: H_2O (30:20:6:24). Analytical HPLC were effected on the following systems: column, Chemcosorb ODS (Chemco, 3.9×300 mm); flow rate, 1 ml min^{-1}; detection, 210 nm; eluent system, linear gradient for 15 min from 14% to 35% CH_3CN in 20 mM phosphate buffer (pH 3.0).

General Procedure for the Preparation of Analogs. The solid phase synthesis was carried out using a Beckman System 990C Peptide Synthesizer as described previously.[4] Half gram of BHA-resin hydrochloride for each analog served as the solid support. A 2.5 fold excess of the amino acid derivative was used for all coupling. The coupling was affected with dicyclohexylcarbodiimide/1-hydroxybenzotriazole. The protected peptide resin was treated with anhydrous liquid HF containing 10% anisole. After evaporation of HF in vacuo under ice-cooling, the residue was washed with AcOEt and the peptide was extracted with 50% AcOH.

Purification of the Peptides. The crude peptide was subjected to HPLC as reported previously.[4] The apparatus was composed of a model 590 pump and a U6K injector (Waters) connecting with a column of Chemcosorb ODS (Chemco, 20×300 mm) or μ-Bondasphere C_{18} (Waters, 19×150 mm). The eluates were monitored with a UV detector S-310A model-II (Soma) at 210 nm wavelength. CH_3CN-0.1% TFA solvent system was used as eluent at flow rate 10 or 7 ml min^{-1}. Each peptide was emerged at 40-60 min by isocratical elution with 15—26% CH_3CN contents of the solvent system. The desired fraction was passed through a Sephadex LH-20 column (16×500 mm) eluted with aqueous DMF (90%) containing 0.02% 1,2-ethanedithiol. Homogeneity of the peptides was analyzed by analytical HPLC and TLC. Amino acid compositions of the acid hydrolysates of the synthetic peptides were consistent with the calculated values.

Bioassay. The agonistic activity of the synthetic analog was measured on ileum taken from guinea-pig, as described before.[4] The contraction was recorded by means of an isotonic transducer (Nippon Kohden, TD-111T) with load of 2 g on a Servocorder (Watanabe Instruments, SR6204). Concentration-response curves were obtained using a

cumulative dose-assay, and the time between two consecutive dose-response curves was longer than 10 min. Though NKB at concentration 10^{-7} M induced maximal response, all of analogs were applied up to 10^{-6} M. In the tests for antagonistic activity on guinea-pig ileum, analog was added 10 min before NKB was added. The cumulative dose-response curve of NKB in the presence or the absence of the analog was obtained. In the presence of analogs at concentration 2×10^{-6} M, the maximal response induced by NKB was almost the same response without analogs.

Insertion of Ketene and Diphenylketene to the Pnictogen-Heteroatom Bonds

Fumio ANDO,* Yoshihiko KOHMURA, and Jugo KOKETSU
Department of Industrial Chemistry, College of Engineering, Chubu University, Matsumoto-cho, Kasugai, Aichi 487
(Received November 12, 1986)

Synopsis. Ketene and diphenylketene insert across the heteroatom-metal bond of amino-, alkoxy-, and alkylthiopnictogens, $R_{3-n}MX_n$, to give the corresponding α-metallated acetamides, esters, and thioesters, $R_{3-n}M(CH_2COX)_n$ and $R_{3-n}M(CPh_2COX)_n$ (M=As, Sb, Bi; X=NR_2, OR, SR; n=1,3), respectively.

Ketene has been known to react with various organometallic compounds, especially with the compounds containing the group 3B and 4B elements.[1] However, the reactions of ketene with analogous arsenic, antimony, and bismuth compounds have been received scarce attention so for. Lustenko et al.[2] reported that alkoxyarsines and -stibines react with ketene to give alkoxycarbonylmethylarsines and -stibines. However, there is no report dealing with the reaction of ketene with group 5B metal amides and thiolates. As a part of our continuing work[3] on the reaction of group 5B metal compounds with multiply bonded reagents, the reactions of ketene and diphenylketene with amides, alkoxides, and alkanethiolates of arsenic, antimony, or bismuth have been investigated.

Ketene, generated by the pyrolysis of diketene, reacted with dialkylaminodialkylarsines in ether at about −20 °C to give *N,N*-dialkyl(dialkylarsino)-acetamides. The reaction of dialkylaminodimethylstibines with ketene proceeded more readily to yield *N,N*-dialkyl(dimethylstibino)acetamides (Table 1).

$$R_2M\text{-}NR'_2 + CH_2{=}C{=}O \longrightarrow R_2MCH_2CONR'_2$$
(M = As, Sb; R = Me, Ph; R' = Me, Et)

These insertion products were obtained as thermally stable (up to ca. 200 °C) and distillable liquids. The structure of the products was determined on the basis of IR, NMR, and mass spectra and elemental analyses. The IR spectra of the arsinoacetamides show a strong C=O stretching vibration at 1630—1622 cm^{-1}. The corresponding C=O stretching band of antimony analogues is located at a lower frequency (1620—1613 cm^{-1}). This may be explained by increased electron density on the α-methylene carbon and intramolecular coordination of carbonyl oxygen to antimony. The ^1H NMR spectra of these adducts contain a singlet peak of the methylene protons attached directly to the metal atoms at δ=2.5—3.1 and also characteristic peaks due to magnetically nonequivalent two alkyl groups on the nitrogen atom of amide groups, namely, two singlets at δ=2.7—3.1 for the dimethylamides and two quartets at δ=3.0—3.5 and two triplets at δ=0.9—1.2 for the diethylamides.

Tris(dialkylamino)bismuthines readily reacted with ketene at −50 °C with liberation of heat, and three moleclues of ketene inserted into the Bi-N bonds to give tris(dialkylcarbamoylmethyl)bismuthines. On the treatments of ketene with tris(dialkylamino)arsines at 0 °C or with tris(dialkylamino)stibines at −20 °C, the corresponding addition products containing arsenic or antimony were obtained.

$$M(NR_2)_3 + 3CH_2{=}C{=}O \longrightarrow M(CH_2CONR_2)_3$$
(M = As, Sb, Bi; R = Me, Et)

These adducts are reddish brown viscous liquids or waxy solid which, on attempted vacuum (ca. 10^{-2} Pa) distillation by heating up to 250 °C, decomposed to *N,N*-dialkylacetamides (70—80%) and unidentified black residues containing metals. Nevertheless, the formation of adducts was confirmed by ^1H NMR, ^{13}C NMR and IR spectra. In the ^1H and ^{13}C NMR spectra of the adducts, the methylene groups attached to the metals, in general, appeared at somewhat lower

a) Masses refer to ^{121}Sb for the antimony compounds.

field compared with those of the corresponding *N,N*-dialkyl(dialkylmetal)acetamides, probably due to additional two electron-withdrawing $NCOCH_3$ groups. The α-methylene groups shift towards higher field with the central metal going from As to Sb and Bi, due to increasing electron density of the neighboring methylene groups in this order.

Diphenylketene, in which the methylene carbon is more sterically crowded than ketene, reacted slowly with aminoarsines and aminostibines, leading to the corresponding insertion products.

$$R_2M\text{-}NR'_2 + Ph_2C{=}C{=}O \longrightarrow R_2MCPh_2CONR'_2$$
$$M(NR'_2)_3 + 3Ph_2C{=}C{=}O \longrightarrow M(CPh_2CONR'_2)_3$$
$$(M = As, Sb;\ R = Me, Ph;\ R' = Me, Et)$$

Reaction of trimethoxyarsine with ketene proceeded very slowly in boiling benzene to give mono-insertion product, dimethoxy(methoxycarbonylmethyl)arsine, in quite low yield (24%), but ethoxy and higher alkoxyarsines did not react under the same conditions. On the other hand, tris(alkoxycarbonylmethyl)stibines were easily obtained in high yield by the reaction of ketene with trialkoxystibines in ether at room temperature, as reported by Lutsenko et al.[2a,b] Tris(ethylthio)stibine also reacted slowly with ketene to afford tris[(ethylthio)-carbonylmethyl)]stibine in 50% yield under refluxing benzene, whereas tris(ethylthio)arsine did not react under the analogous reaction conditions.

$$As(OMe)_3 + CH_2{=}C{=}O \longrightarrow (MeO)_2AsCH_2COOMe$$
$$Sb(OR)_3 + 3CH_2{=}C{=}O \longrightarrow Sb(CH_2COOR)_3$$
$$Sb(SEt)_3 + 3CH_2{=}C{=}O \longrightarrow Sb(CH_2COSEt)_3$$

Thus, the reactivity of tervalent group 5B compounds, =M-X, toward ketene increases in the order As<Sb<Bi for the metal (M), and SR<OR<NR_2 for the functional group(X). The highest reactivity of $Bi(NR_2)_3$ may be attributed to the enhanced nucleophilicity of the nitrogen caused by the weak and highly polar Bi-N bonds.

Experimental

Materials and General Procedures. The compounds Me_2AsNEt_2,[4] Ph_2AsNMe_2,[4] Ph_2AsNEt_2,[4] Me_2SbNMe_2,[5] Me_2SbNEt_2,[5] $As(NMe_2)_3$,[4] $As(NEt_2)_3$,[4] $Sb(NMe_2)_3$,[6] $Sb(NEt_2)_3$,[6] $Bi(NMe_2)_3$,[3c] $Bi(NEt_2)_3$,[3c] $As(OMe)_3$,[7] $Sb(OR)_3$ (R=Et, *n*-Pr, *i*-Pr, *n*-Bu),[7] and $Sb(SEt)_3$[7] were synthesized according to the published procedures. Ketene[8] was generated by the pyrolysis of diketene at 550 °C, and was purified through two traps cooled to −20 °C. Diphenylketene[9] was prepared by dehydrochlorination of diphenylacetyl chloride with triethylamine. All reactions were performed under an atmosphere of nitrogen or argon. ^1H (60 MHz) and ^{13}C (15.04 MHz) NMR spectra were measured in $CDCl_3$ with JEOL C-60 HL and JNM FX-60 FT instruments, respectively. IR spectra were recorded on a Shimadzu IR-430 spectrometer. Mass spectra (70 eV) were measured with a Hitachi RMU-6L spectrometer.

Reaction of Dialkylaminodialkylarsines or -stibines with Ketene. An excess of ketene was passed through a stirred solution of diethylaminodimethylarsine (6.52 g, 36.8 mmol) in 20 ml of ether at about −20 °C during 10 min. Solvent removal under vacuum left a yellow liquid residue. From the residue, *N,N*-diethyl(dimethylarsino)acetamide (6.49 g, 81%) was obtained by fractional distillation as a yellowish liquid. In a similar way, reactions of ketene with dimethylaminodiphenylarsine at room temperature, with dimethyl aminodimethylstibine at −50 °C, and with diethylamino dimethylstibine at −50 °C gave the corresponding insertion products. Bp, yield, analytical, and mass spectral data of these products are shown in Table 1. The NMR and IR spectra of these metallated acetamides are summarized in Table 2.

Reaction of Tris(dialkylamino)arsines, -stibines, and -bismuthines with Ketene. Ketene was passed into an ethereal (20 ml) solution of tris(dimethylamino)arsine (3.89 g, 18.8 mmol) at room temperature. After removal of the solvent, the residue was dried under reduced pressure (ca. 10^{-2} Pa) for 4 h, leaving a reddish brown liquid (5.61 g), and whose ^1H and ^{13}C NMR and IR spectra were measured without further purification because of difficulties encountered during distillation or recrystallization: ^1H NMR δ=2.84 (s, 2H), 2.95 (s, 3H), and 3.11 (s, 3H); ^{13}C NMR δ=29.82, 35.22, 38.27, and 171.20; IR (neat) 1627 cm^{-1}. These spectra proved the product to be tris(dimethylcarbamoylmethyl)arsine (90%). A similar treatment of ketene with tris(diethylamino)-arsine at 0 °C, tris(dimethylamino)stibine at −20 °C, tris(diethylamino)stibine at −20 °C, tris(dimethylamino)bismuthine at −50 °C, or tris(diethylamino)bismuthine at −50 °C gave the corresponding insertion products. $As(CH_2CONEt_2)_3$: Red oil (84%); ^1H NMR δ=1.13, 1.19 (each t, 3H),

Reaction of Diphenylketene with Aminoarsines or Aminostibines. Diphenylketene (1.88 g, 9.68 mmol) was added dropwise to a solution of diethylaminodimethylarsine (1.71 g, 9.66 mmol) in 20 ml of ether at room temperature. The mixture was heated under reflux for 30 min. After removal of the solvent, the residue was distilled under vacuum to afford *N,N*-diethyl(dimethylarsino)diphenylacetamide (1.62 g, 45%) as an orange liquid, bp 180—187 °C/1.3×10^{-2} Pa: ^1H NMR δ=0.91 (s, 3H, CH_3As), 1.11, 1.12 (each t, 3H), 3.26, 3.38 (each q, 2H), and 7.22 (m, 5H); ^{13}CNMR δ=6.04 (CH_3As), 12.86, 14.62 (NCC), 40.67, 42.17 (NC), 54.58 (q-C), 126.89 (p), 128.45 (m), 129.04 (o), 140.02 (i), and 170.68 (CO); IR (neat) 1658 cm^{-1} (C=O); MS *m/z* (rel intensity) 371 (M^+; 8), 105 (100), 100 (82), 77 (88). Similarly, the following diphenylketene insertion products were obtained by the reaction of 3 molar equivalent of diphenylketene with dimethylaminodiphenylarsine, diethylaminodiphenylarsine, dimethylaminodimethylstibine, diethylaminodimethylstibine, tris(dimethylamino)arsine, tris(diethylamino)arsine, tris(dimethylamino)stibine, and tris(diethylamino)stibine. *N,N*-Dimethyl(diphenylarsino)diphenylacetamide: Yield 41%; bp 146—151 °C/5.3×10^{-3} Pa; ^1H NMR δ=2.94 (s, 3H), 2.98 (s, 3H), and 7.30 (m, 20H); ^{13}CNMR δ=36.13, 37.55, 54.90 126.96, 128.52, 129.04, 129.17, 131.05, 133.78, 139.63, 146.32, and 179.30; IR ($CHCl_3$) 1645 cm^{-1} (C=O). *N,N*-Diethyl(diphenylarsino)diphenylacetamide: Yield 68%, bp 140—150 °C/5.3×10^{-3} Pa; ^1H NMR δ=1.09, 1.10 (each t, 3H), 3.28, 3.39 (each q, 2H), and 7.27 (m, 10H); ^{13}CNMR δ=12.80, 14.62, 40.61, 42.10, 54.51, 126.83, 128.45, 128.97, 129.17, 130.99, 134.37, 139.95, 146.19, and 173.02; IR ($CHCl_3$) 1640 cm^{-1}. *N,N*-Dimethyl(dimethylstibino)diphenylacetamide: Yield 23%; bp 137—144 °C/1.3×10^{-2} Pa; ^1H NMR δ=0.97 (s, 6H), 2.94 (s, 3H), 2.97 (s, 3H), and 7.32 (m, 10H); ^{13}CNMR δ=4.09, 36.06, 37.55, 54.77, 126.89, 128.52, 129.04, 139.70, and 175.75; IR ($CHCl_3$) 1640 cm^{-1} (C=O). *N,N*-Diethyl(dimethylstibino)diphenylacetamide: Yield 25%; bp 110—111 °C/1.3×10^{-2} Pa; ^1H NMR δ=1.03 (s, 3H), 1.09 (t, 3H), 3.27, 3.39 (each q, 2H), and 7.28 (m, 5H); ^{13}CNMR δ=3.96, 12.86, 14.62, 40.67, 43.17, 54.51, 126.89, 128.26, 128.97, 138.85, and 172.49; IR (neat) 1656 cm^{-1} (C=O). Tris(dimethylcarbamoyldiphenylmethyl)arsine: Yield 41%; bp 114—126 °C/1.3×10^{-2} Pa; ^1H NMR δ=2.92 (s, 3H), 2.95 (s, 3H), and 7.26 (m, 10H); ^{13}CNMR δ=36.00, 37.49, 54.77, 126.89, 128.45, 128.97, 139.63, and 171.72; IR ($CHCl_3$) 1643 cm^{-1} (C=O). Tris(diethylcarbamoyldiphenylmethyl)arsine: Yield 56%; bp 136—141 °C/1.3×10^{-2} Pa; ^1H NMR δ=1.13 (t, 3H), 3.32, 3.44 (each q, 2H), and 7.33 (m, 5H); ^{13}CNMR δ=12.80, 14.62, 40.61, 42.17, 54.51, 126.89, 128.45, 128.97, 139.95, and 170.68; IR ($CHCl_3$) 1630 cm^{-1}. Tris(dimethylcarbamoyldiphenylmethyl)stibine: Yield 23%; bp 158—160 °C/1.3×10^{-2} Pa; ^1H NMR δ=2.98 (s, 3H), 3.00 (s, 3H), and 7.28 (m, 10H); ^{13}CNMR δ=36.06, 37.55, 54.84, 126.96, 128.52, 129.04, 139.63, and 171.72; IR ($CHCl_3$) 1639 cm^{-1} (C=O). Tris(diethylcarbamoyldiphenylmethyl)stibine: Yield 23%; bp 111—112 °C/1.3×10^{-2} Pa; ^1H NMR δ=1.07, 1.10 (each t, 3H), 3.28, 3.40 (each q, 2H), and 7.30 (m, 5H); ^{13}CNMR δ=12.80, 14.55, 40.61, 42.10, 54.44, 126.83, 128.38, 128.97, 139.95, and 170.68; IR ($CHCl_3$) 1625 cm^{-1} (C=O).

Reaction of Trimethoxyarsine and Trialkoxystibines with Ketene. A large excess ketene was bublled into a solution of trimethoxyarsine (4.66 g, 27.7 mmol) in boiling benzene (10 ml). After removal of the solvent, dimethoxy(methoxycarbonylmethyl)arsine (1.37 g, 24%) was obtained by distillation: Bp 58—59 °C/5.3 Pa; ^1H NMR δ=3.13 (s, 2H), 3.55 (s, 6H), and 3.74 (s, 3H); ^{13}CNMR δ=37.88 (AsC), 48.93 (MeOAs), 52.63 (COOMe), and 168.41; IR (neat) 1718 cm^{-1}. Reaction of trialkoxystibines with ketene was carried out in ether at room temperature. The following tris(alkoxycarbonylmethyl)stibines were obtained. $Sb(CH_2COOR)_3$: R=Et (yield 77%): Bp 134—138 °C/0.47 Pa; ^1H NMR δ=1.26 (t, 3H), 2.53 (s, 2H), 4.08 (q, 2H); ^{13}CNMR δ=14.42, 21.77 (SbC), 60.49, and 172.24; IR (neat) 1710 cm^{-1} (C=O). R=*n*-Pr (85%): Bp 150—151 °C/1.3×10^{-2} Pa; ^1H NMR δ=0.95 (t, 3H), 1.66 (m, 2H), 2.52 (s, 2H), and 3.98 (t, 2H); ^{13}C NMR δ=10.46, 21.83 (SbC), 22.16, 66.14 and 172.24; IR (neat) 1709 cm^{-1} (C=O). R=*i*-Pr (85%): Bp 122—123 °C/6.7×10^{-2} Pa; ^1H NMR δ=1.23 (d, 6H), 2.50 (s, 2H), and 4.91 (m, 1H); ^{13}CNMR δ=21.50 (SbC), 22.03, 67.12, and 171.72; IR (neat) 1708 cm^{-1} (C=O). R=*n*-Bu (74%): Bp 161—162 °C/1.2×10^{-2} Pa; ^1H NMR δ=0.95 (t, 3H), 1.13—1.78 (m, 4H), 2.50 (s, 2H), and 4.05 (t, 2H); ^{13}CNMR δ=13.71, 19.17, 21.83 (SbC), 30.86, 64.58, and 172.37; IR (neat) 1700 cm^{-1} (C=O).

Reaction of Tris(ethylthio)stibine with Ketene. Ketene was bubbled through a boiling benzene (20 ml) solution of tris(ethylthio)stibine (3.70 g, 12.2 mmol). Distillation afforded tris[(ethylthio)carbonylmethyl]stibine (2.80 g, 53%) as a yellow liquid: Bp 150—154 °C/1.3×10^{-1} Pa; ^1H NMR δ=1.26 (t, 3H), 2.90 (q, 2H), and 3.06 (s, 2H); ^{13}CNMR δ=19.17, 21.05 (SbC), 24.69, and 178.29; IR (neat) 1662 cm^{-1} (C=O).

The Oxidation of $PbSO_4$ to PbO_2 in Sulfuric Acid Solution

Zen-ichiro TAKEHARA* and Kiyoshi KANAMURA
Department of Industrial Chemistry, Faculty of Engineering, Kyoto University, Yoshida-honmachi, Sakyoku, Kyoto 606
(Received December 24, 1985)

The interface between PbO_2 and $PbSO_4$ was considered to be the reaction site of the oxidation of $PbSO_4$ to PbO_2. The area of this site depended on the changing crystal size of $PbSO_4$ with the discharge conditions. The oxidation rate of $PbSO_4$ to PbO_2 increased with a decrease in the crystal size of $PbSO_4$ since the reaction site area per unit volume increased with a decrease in the crystal size of $PbSO_4$. The oxidation of $PbSO_4$ to PbO_2 depended on the discharge current, the sulfuric acid concentration and the rest time after a discharge.

$PbSO_4$ is deposited on the electrode surface during discharging of the positive active material of a lead-acid battery. The charge reaction of the positive active material is a conversion from $PbSO_4$ by anodic oxidation at the electrode surface. This reaction has been studied by many workers.[1-8] They potentiostatically investigated the oxidation of $PbSO_4$ formed by the anodic polarization of lead in the $PbSO_4$ potential region and suggested that the formation process of PbO_2 involved the nucleation and three-dimensional crystal growth. Casson et al. used an electrodeposited PbO_2 electrode to show that there is no evidence for nucleation and crystal growth.[9] Pohl measured different current-time curves at a lead electrode in a sulfuric acid solution during anodic polarization. He used an anodic current preimpulse before potentiostatic oxidation. The current-time curves measured after an anodic current preimpulse did not have any peaks. From this result, he suggested that the charge reaction did not proceed through nucleation and crystal growth.[2]

$PbSO_4$ is a nonconducting ionic crystal that becomes depodited on an electrode surface as a thin dense film.[9] Its solubility is very small in a sulfuric acid solution.[11] Therefore, only a special site can sustain a sufficient reaction rate to oxidize $PbSO_4$ to PbO_2. In this study, the effect of the size of $PbSO_4$ on the oxidation of $PbSO_4$ to PbO_2 was investigated.

Experimental

A lead rod mounted in a teflon tube was used as the working electrode (purity:99.9%). This electrode was polished with emery paper and etched with dilute nitric acid. The lead electrode surface was oxidized to PbO_2 in 0.5 M† H_2SO_4 at 1 mA cm^{-2} for about 24 h, and then galvanostatically discharged at 1 mA cm^{-2} in 0.5 M H_2SO_4. The discharge-charge cycle was continued until the capacity of the PbO_2 electrode increased to 40 mA min.

Figure 1 shows the experimental cell used in this study. The PbO_2 electrode placed in it and discharged at a constant current. $PbSO_4$ crystals became deposited on its surface during the discharge. The surface $PbSO_4$ was oxidized to PbO_2 by utilizing the potential sweep method. Anodic sweeps from the rest potential after discharging toward the anodic direction at various sweep rates were carried out using a potentiostat (HOKUTO HA-301) and a function-generator (HOKUTO HB-104). The anodic currents were recorded with an X-Y recorder (WATANABE). A Hg/Hg_2SO_4 electrode was used as a reference electrode and a Pt wire was used as a counter electrode. All experiments were performed at 30 °C.

Results and Discussion

Figure 2 shows a potentiodynamic current-voltage curve for the oxidation of $PbSO_4$ to PbO_2 by the potential sweep method in 5.0 M H_2SO_4. $PbSO_4$ was formed by a potentiostatic discharge at 0.8 V vs. Hg/Hg_2SO_4 in 5.0 M H_2SO_4 until the cathodic current decreased to 0 mA. Two anodic peaks were observed at 1.0 and 1.43 V. The peak at 1.0 V corresponded to the oxidation of PbO to PbO_2.[12] The recovered electrode potential after the potentiostatic discharge was more cathodic than the redox potential of the $PbO_2/PbSO_4$ couple. The PbO_2/PbO redox potential was more cathodic than the $PbO_2/PbSO_4$ redox potential. The recovered redox potential may have been due to the mixed potential of the $PbO_2/PbSO_4$ and PbO_2/PbO

† 1 M=1 mol dm^{-3}.

couples. PbO is not thermodynamically stable in an acidic media. The local pH at the interior of the film formed by the potentiostatic discharge increased, since PbO is thermodynamically stable in the film. The PbO_2/PbO electrode potential at pH=9.34 was about 0.5 V vs. Hg/Hg_2SO_4. The electrode potential of the $PbO_2/PbSO_4$ couple was about 1.0 V vs. Hg/Hg_2SO_4 at pH=0.48.[13] Therefore, the recovered electrode potential was due to a mixed potential of the $PbO_2/PbSO_4$ and PbO_2/PbO couples. The peak at 1.43 V corresponded to the oxidation of $PbSO_4$ to PbO_2. The formation of PbO depended on the discharge conditions. PbO was formed by a deep discharge at a slow rate. In order to avoid the formation of PbO at the interior of $PbSO_4$, the electrode was discharged at a high rate, but not deeply. The potential after such a discharge recovered to the redox potential of the $PbO_2/PbSO_4$ couple. This fact indicates that PbO was not formed at the interior of the film. The oxygen evolution current was observed at 1.5 V and superimposed to the anodic current for the oxidation of $PbSO_4$ to PbO_2. In order to achieve clear curves for the oxidation of $PbSO_4$ to PbO_2, the current for the oxygen evolution was subtracted from the whole anodic current. The oxygen evolution current was determined from the potentiodynamic current-voltage curve by use of a fully charged electrode. Figure 3 shows potentiodynamic current-voltage curves which were obtained after the subtraction of the oxygen evolution current from the

whole anodic current. Symmetric current-potential curves were observed. Such curves are similar to those for a surface reaction rather than a diffusion-controlled electrode reaction.[14] Figure 4 shows the dependence of the peak potential on the sweep rate obtained from Fig. 3. The peak potential shifted to a more anodic potential upon increasing the sweep rate. Figure 5 shows the dependence of the half-wave width on the sweep rate (obtained from Fig. 3). The width became larger with increasing sweep rate. These results indicate that the charge-transfer process of the oxidation of $PbSO_4$ to PbO_2 is very slow. These dependences are very similar to those obtained for the irreversible electrode reaction of an adsorbed species on the electrode surface. Figure 6 shows the dependence of the peak current on the sweep rate (obtained from Fig. 3). The peak current was proportional to $v^{0.73}$. Such behavior regarding the oxidation of $PbSO_4$ to PbO_2 may be understood in terms of the electrochemistry of the adsorbed species on the electrode surface, if the $PbSO_4$ deposited on the electrode surface is a monolayer. $PbSO_4$ was deposited on the electrode surface as small ionic crystals. Therefore, it is very difficult to treat the oxidation of $PbSO_4$ to PbO_2 quantitatively in terms of the electrochemistry of adsorbed species, though the results shown in Figures 4, 5, and 6 were very similar to the irreversible electrode reaction of an adsorbed species on the electrode surface. In this study the electrode reaction of the conversion of $PbSO_4$ to PbO_2 was determined by an assumption regarding the reaction site (discussed below).

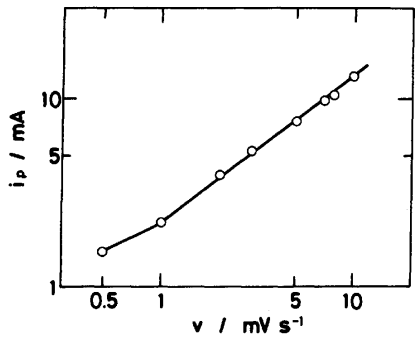

Fig. 6. Dependence of peak current on sweep rate obtained from Fig. 3.

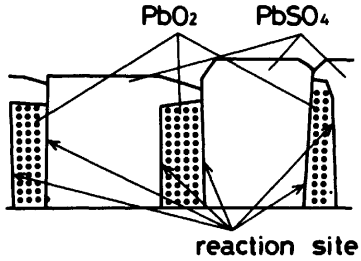

Fig. 7. Schematic representation of reaction site for charging reaction of $PbO_2/PbSO_4$ electrode.

A large ionic crystal without electronic and ionic conductivities would not be able to oxidize in the same way as soluble species. In the case of the oxidation of $PbSO_4$, the soluble species would be Pb^{2+} ions. The dissolving Pb^{2+} ions from a $PbSO_4$ crystal are oxidized to Pb^{4+} ions and react with H_2O to precipitate on the electrode surface as PbO_2:

$$Pb^{2+} + 2H_2O \longrightarrow PbO_2 + 2e^- + 4H^+. \quad (1)$$

Conditions for the oxidation of $PbSO_4$ are not equal over the electrode surface, causing the distribution of the oxidation rate of $PbSO_4$ to PbO_2. The high oxidation rate is sustained by the high concentration of Pb^{2+} ions on the PbO_2 surface. In this study, it is assumed that the interface between PbO_2 and $PbSO_4$ is the reaction site (Fig. 7). At such an interface, Pb^{2+} ions can be adequately supplied from the $PbSO_4$ crystal; also, a charge-transfer reaction can occur on PbO_2. The peak current was larger than that estimated from the solubility of Pb^{2+} ions and the diffusion coefficient in the electrodeposition layer of PbO_2 on a planar electrode in a sulfuric acid solution. If the oxidation of $PbSO_4$ occurs at the interface between $PbSO_4$ and PbO_2, the diffusion path is so short that the mass-transport process hardly influences the oxidation of $PbSO_4$. The potentiodynamic current-voltage curve in Fig. 3 can be explained as follows. As the electrode potential becomes more positive, the charge-transfer reaction rate increases, while the reaction site area decreases. The reaction rate depends on both the charge-transfer reaction rate and the reaction site area. If the oxidation of $PbSO_4$ proceeds with an increase and a decrease of the interface area between PbO_2 and $PbSO_4$, which corresponds to the reaction site area,[15] such a simple anodic peak could not be obtained. The reaction site area seems to decrease monotonously. Therefore, the maximum rate is obtained at the peak. The reaction-site area depends on the size of the $PbSO_4$ crystal since the interface area between PbO_2 and $PbSO_4$ per unit volume of $PbSO_4$ changes with this value. If the discharge capacity is the same, the surface area of $PbSO_4$ increases upon decreasing of the crystal size. As a result, the interface area between PbO_2 and $PbSO_4$ also increases upon decreasing the crystal size of $PbSO_4$.

Figure 8 shows electronmicrographs of $PbSO_4$ precipitated by galvanostatic discharges in 5.0 M H_2SO_4 at 0.5, 1.0, 5.0 and 10.0 mA cm^{-2}. The discharge was continued until it reached 600 mC cm^{-2}. The size of $PbSO_4$ decreased with increasing discharge current. The surface concentration of Pb^{2+} ions during the galvanostatic discharge depended on the discharge current. A large discharge current resulted

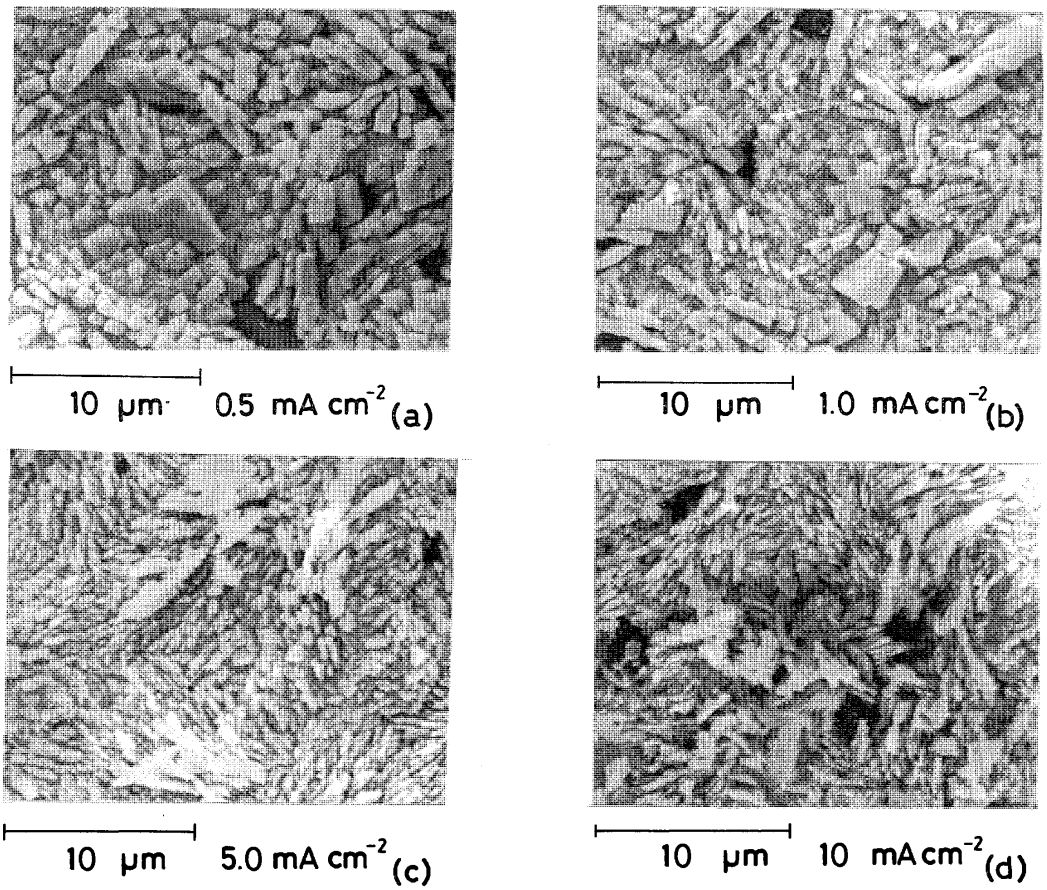

Fig. 8. Electronmicrographs of $PbSO_4$ precipitated by galvanostatic discharge at (a): 0.5 mA cm^{-2}, (b): 1.0 mA cm^{-2}, (c): 5.0 mA cm^{-2}, (d): 10.00 mA cm^{-2} in 5.0 M H_2SO_4, sweep rate 1 mV s^{-1}.

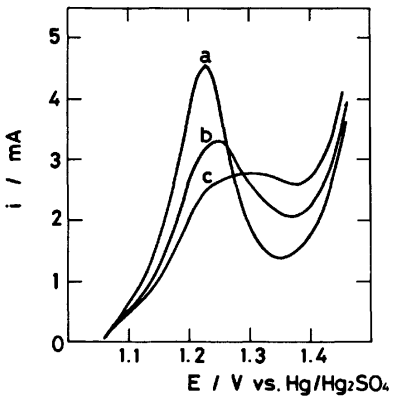

Fig. 9. Potentiodynamic current-voltage curves for the oxidation of $PbSO_4$ formed by galvanostatic discharge at 0.5, 1.0, and 10.0 mA cm^{-2} in 5.0 M H_2SO_4, sweep rate 1 mV s^{-1}.

in a large supersaturation of Pb^{2+} ions on the electrode surface and caused the formation of a lot of $PbSO_4$ nuclei. On the other hand, the large supersaturation of Pb^{2+} ions could not be caused by a small current discharge. Therefore, the crystal size of $PbSO_4$ increases with a decreasing discharge current.

Figure 9 shows potentiodynamic current-voltage curves for the oxidation of $PbSO_4$ formed by galvanostatic discharges at 0.5, 1.0 and 10.0 mA cm^{-2} in 5.0 M H_2SO_4. These discharges were continued until the current reached 1200 mC cm^{-2}. The anodic peak potential shifted to a more positive value upon decreasing the discharge current. This result indicates that the oxidation of $PbSO_4$ formed under a low discharge current is more difficult than that formed at a high discharge current. The size of $PbSO_4$ formed at a low discharge current was very large (Fig. 8). Increasing the size of $PbSO_4$ resulted in a decrease in the reaction-site area (as discussed above). Therefore, increasing the $PbSO_4$ crystal size caused difficulty regarding the oxidation of $PbSO_4$; also, the anodic peak potential shifted to more positive potentials. The shape of the anodic current peak obtained at a low current discharge was broad and nonsymmetrical. $PbSO_4$ may be oxidized with an increase and a decrease in the reaction-site area.[15] The oxidation of the very large $PbSO_4$ formed at a low discharge rate seems to be different from that of a small $PbSO_4$ crystal under high discharge rate.

Figure 10 shows electronmicrograhs of $PbSO_4$ crystals which were immersed in 5.0 M H_2SO_4 for a

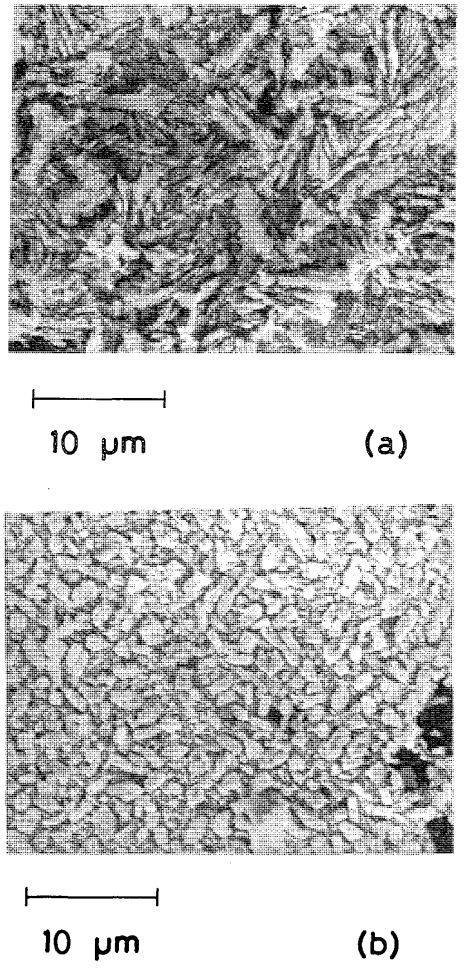

Fig. 10. Electronmicrographs of $PbSO_4$ precipitated by galvanostatic discharge at 1.0 mA cm^{-2} in 5.0 M H_2SO_4, immersion time (a): a few minutes (b): 60 min.

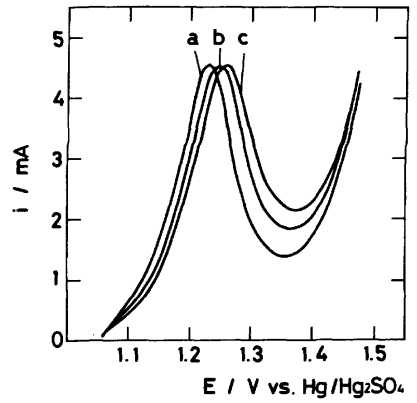

Fig. 11. Potentiodynamic current-voltage curves for the oxidation of $PbSO_4$ formed by galvanostatic discharge at 1.0 mA cm^{-2} in H_2SO_4 after immersion in 5.0 M H_2SO_4 for (a): a few minutes (b): 30 minutes (c): 60 minutes.

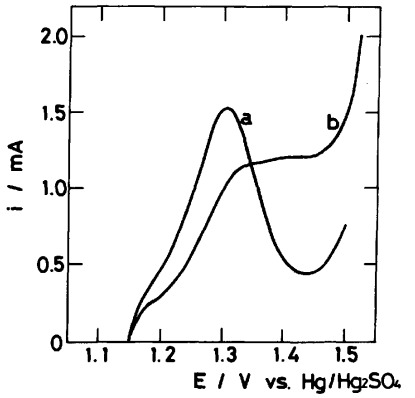

Fig. 12. Potentiodynamic current-voltage curves for the oxidation of $PbSO_4$ formed by galvanostatic discharge at 1.0 mA cm^{-2} for 60 s in 5.0 M and 0.5 M H_2SO_4, in 5.0 M H_2SO_4 at 1 mV s^{-1}.

few minutes or one hour after a discharge at 10 mA cm^{-2} in 5.0 M H_2SO_4. The electronmicrographs show that immersion after a discharge results in an increased size of a $PbSO_4$ crystal as the result of an aging process which involves a mass transfer from small crystals to large crystals by way of the solution. A high stability and a reduction of the surface area and energy were obtained by this aging process. The difference in crystal size between (a) and (b) was smaller than that shown in Fig. 8.

Figure 11 shows potentiodynamic current-voltage curves for the oxidation of $PbSO_4$ in Fig. 10. The anodic current peak for the oxidation of $PbSO_4$ after a one-hour immersion appeared at a more positive potential than that after a few minutes. The amount of $PbSO_4$ increased as the result of immersion in a sulfuric acid solution (Fig. 10). Increasing the crystal size resulted in a shift of the current peak shown in Fig. 11, since the reaction site per unit volume of the $PbSO_4$ crystal decreased.

Figure 12 shows potentiodynamic current-voltage curves for the oxidation of the $PbSO_4$ precipitated during a galvanostatic discharge at 10 mA cm^{-2} in 5.0 M and 0.5 M H_2SO_4 for 60 s. Both electrodes were oxidized in 5.0 M H_2SO_4 by a potential sweep method. The oxidation rate of $PbSO_4$ formed in 5.0 M H_2SO_4 was larger than that in 0.5 M H_2SO_4. The size of $PbSO_4$ depends on the concentration of the sulfuric acid solution (as discussed in previous paper [11]). In this case, the size of $PbSO_4$ formed in 5.0 M H_2SO_4 was less than that in 0.5 M H_2SO_4.

Thus, the reaction rate of the oxidation of $PbSO_4$ depends on the crystal size of $PbSO_4$ precipitated on the electrode surface during a discharge. The crystal size of $PbSO_4$ is very important for the oxidation of $PbSO_4$ to PbO_2. This fact indicates that the reaction site is the interface between $PbSO_4$ and PbO_2, at which a high reaction rate is sustained while allowing the oxidation of $PbSO_4$ to PbO_2.

The Mechanism of Electron Transfer Reaction for Xanthene Dye-Sensitized Formation of Methyl Viologen Radical

Yoshiharu Usui,* Hiroaki Misawa,† Hirochika Sakuragi,† and Katsumi Tokumaru†
*Department of Chemistry, Faculty of Science, Ibaraki University, Mito 310
†Department of Chemistry, University of Tsukuba, Sakura-mura, Ibaraki 305
(Received June 5, 1986)

Sensitized reduction of methyl viologen, MV^{2+}, occurs efficiently through electron transfer from triplet xanthene dyes to MV^{2+} followed by electron transfer to the resulting semioxidized dyes from a reductant like triethanolamine. Unreactive ion pair complexes between these dyes and MV^{2+} are formed (formation constant: $1.2\times10^3\ M^{-1}$ for Eosine Y and MV^{2+} in 50% aqueous ethanol solution). The quantum yield for the reduced methyl viologen radical depends on the concentrations of MV^{2+} and the amine and on the ionic strength of solution. The efficiency of the electron transfer from triplet dyes to MV^{2+} is increased by addition of alcohol, and solvent effects on the reaction mechanism are discussed.

Active efforts have recently been devoted to the hydrogen liberation from water through visible light irradiation on an appropriate sensitizer in a suitable electron transferring system comprising an electron donor like amine, a mediator like methyl viologen, and a redox catalyst like colloidal platinum or hydrogenase.[1-5]

Although various sensitizers of ruthenium complexes have been well studied, only a few reports have appeared on utilization of organic dyes, and mechanistic studies on such reaction systems are required to increase the reaction yield.[6-16]

We reported that a photosensitized reaction of Eosine Y (EY^{2-}) induced hydrogen evolution from water under the irradiation of visible light on a mixed solution of methyl viologen (MV^{2+}), triethanolamine (TEOA), and colloidal platinum. The maximum quantum yield for the formation of semireduced radical ($MV^{+}\cdot$) was measured to be ca. 0.3.[17] For the three-component system, the yield of $MV^{+}\cdot$ is dependent on such a mechanism as may be switched over from an initial process of electron transfer from $^3EY^{2-}$ to MV^{2+} to that from TEOA to $^3EY^{2-}$. Further it has been observed that an ion pair complex is formed between xanthene dye and MV^{2+}, and that the complex formation is sensitive to the composition of solution.

In the present paper, attention is focused on determination of the efficiency of electron transfer processes from triplet dye to MV^{2+} and on the solvent effect in aqueous alcohol solution, in order to increase the yield of $MV^{+}\cdot$. To elucidate the reaction mechanism, we have mainly investigated effects of the concentrations of TEOA and MV^{2+} and the ionic strength and solvent composition of alcohol–water mixtures on the yield of $MV^{+}\cdot$ by kinetic analysis.

Experimental

Materials. Fluorescein, Eosine Y (2′,4′,5′,7′-tetrabromofluorescein), and Erythrosine (2′,4′,5′,7′-tetraiodofluorescein) were recrystallized three times from ethanol. Methyl viologen (1,1′-dimethyl-4,4′-bipyridinium dichloride, Nakarai, G. R.) and triethanolamine (Tokyo Kasei, G. R.) were used as received. Methanol, ethanol, and 2-propanol (Kanto, G. R.) were used without further purification. Phosphate and borate buffer solutions were prepared by dissolving the respective salts (Kanto, G. R.) in redistilled water. Sodium perchlorate (Kanto, G. R.) was used to control the ionic strength of sample solutions. Each sample was deaerated by bublling argon gas (99.9%) for at least 30 min or by repeating freezing and evacuation 5—7 times under vacuum before irradiation.

Procedures. A degassed sample in a cell (1 cm×1 cm×4 cm) was irradiated at 25 °C in a steady-light illumination apparatus with a 300 W tungsten lamp. The experimental procedure used to determine the quantum yield of $MV^{+}\cdot$ formation was similar to that previously described.[18,19] Laser flash photolysis was carried out by using a pulsed dye laser (Phase R, 2100B; dye, G4; excitation, 500 nm; FWHM of pulse, 500 ns) and a usual monitoring system composed of a light source, a monochromator, and a transient recorder. For the ns-laser excitation, pulsed nitrogen laser was used (excitation; 337 nm FWHM of pulse, 7 ns). The yield of $MV^{+}\cdot$ for the dye-laser flash excitation was determined by the conventional actinometry using Reinecke's salt.

Results and Discussion

Formation of Ionic Complex between EY^{2-} and MV^{2+} in the Ground State. It was observed that the absorption spectrum of EY^{2-} changed with an isosbestic point at 537 nm by addition of MV^{2+} in 50 v/v% aqueous ethanol solution, in such a manner that the maximum wavelength (λ_{max}) of EY^{2-} was shifted from 526 to 528 nm with the maximum extinction coefficient at λ_{max} decreased to 7.6×10^4 from 9.4×10^4 $M^{-1}\,cm^{-1}$ (1 M=1 mol dm^{-3}).[17] Also, the fluorescence of EY^{2-} was remarkably quenched by addition of 1.0×10^{-3} M MV^{2+}, but the fluorescence lifetime in solution was not affected at all. Increasing the alcohol content (95%) in the mixture made the fluorescence from EY^{2-} hardly observable. The degree of the change in absorption spectra and fluorescence intensities depended on the ionic strength, (μ) of solution and the solvent composition of alcohol–

Table 1. Formation Constants of the Ion-Pair Complex, $EY^{2-}\cdots MV^{2+}$ in 50 v/v% Ethanol

μ	K/M^{-1}
0.005	1.5×10^3
0.020	1.0×10^3
0.050	6.0×10^2
0.090	2.1×10^2

water mixture. In a mixed solvent with a molar fraction of ethanol (χ_{EtOH}) of 0.80, the maximum absorption and fluorescence intensities of EY^{2-} with 0.05 mM MV^{2+} were increased by the factors of 1.5 and 50, respectively, with increase in μ from 0 to 0.05. These phenomena mean that EY^{2-} forms a non fluorescent ionic complex with MV^{2+} and that the equilibrium, Eq. 1 is shifted to the right by increase in the molar fraction of ethanol or decrease in the ionic strength:

$$EY^{2-} + MV^{2+} \rightleftharpoons EY^{2-}\cdots MV^{2+} \quad (1)$$

From an analysis of the results of absorption and fluorescence spectra, values of the formation constant (K) for the complex were estimated at several values of ionic strength, as shown in Table 1.

Effects of MV^{2+} Concentration and Ionic Strength on the Quantum Yield of $MV^{+}\cdot$ Formation. For the three-component system of $EY^{2-}/MV^{2+}/TEOA$, either the initial electron transfer from triplet eosine Y ($^3EY^{2-}$) to MV^{2+} or that from TEOA to $^3EY^{2-}$ needs to be considered. The competitive reactions can be switched over between each other depending on the rate constants and the concentrations of TEOA and MV^{2+}.[20] The rate constant of the $^3EY^{2-}$ quenching with MV^{2+} or with TEOA was obtained as 3.2×10^9 (k_Q) or $3.0\times10^6\ M^{-1}\ s^{-1}$ in a laser-flash experiment, respectively ([EY^{2-}]=10 μM, μ=0.05, 50 v/v% ethanol-water mixture). The rate constant of the $MV^{+}\cdot$ formation was also obtained as $3\times10^9\ M^{-1}\ s^{-1}$ (k'_Q) in the $^3EY^{2-}$ reaction with MV^{2+} and was approximately the same as the quenching rate constant. Thus, at an MV^{2+} concentration of about 1 mM and a TEOA concentration of 10 mM, the photosensitized reduction of MV^{2+} is to be initiated by the efficient electron transfer from $^3EY^{2-}$ to MV^{2+}, which leads to formation of $EY^{-}\cdot$ followed by the electron transfer from TEOA.

In the laser flash experiment with an aerated solution of EY^{2-} and MV^{2+} where $MV^{+}\cdot$ was scavenged by oxygen, only transient absorption of $EY^{-}\cdot$ was observed after about 30 μs. The decay rate of free radical $EY^{-}\cdot$ (λ_{max}=462 nm) was increased by the addition of TEOA, and the rate constant (k) of the electron transfer from TEOA to $EY^{-}\cdot$ was obtained as $k=1.5\times10^7\ M^{-1}\ s^{-1}$.

For a steady light irradiation, the dependence of the quantum yield for $MV^{+}\cdot$ radical formation (Φ_{mv}) on the MV^{2+} concentration showed a maximum of 0.2 at an MV^{2+} concentration of ca. 1 mM in aqueous ethanol with a constant ionic strength and a fixed concentration of TEOA (Fig. 1). The concentration of the EY^{2-} complexed with MV^{2+} noted on the upper abscissa in Fig. 1 was calculated from the K values in Table 1. It can be considered that the decreasing tendency of Φ_{mv} values at higher concentrations of MV^{2+} (> ca. 3 mM) is due to the fact that EY^{2-} forms an ion-pair complex with MV^{2+} and that this complex is unreactive. Actually, the transient absorption of $MV^{+}\cdot$ was scarcely observed by the μs-laser flash excitation of the complex.

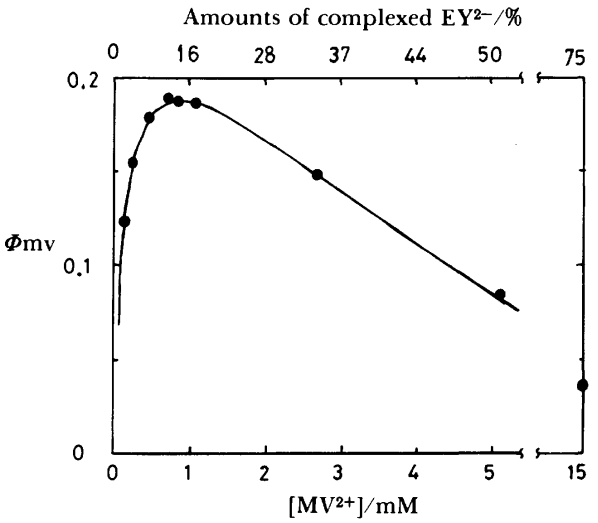

Fig. 1. Effect of MV^{2+} concentration on the quantum yield of $MV^{+}\cdot$ formation. [EY^{2-}]=17 μM, [TEOA]= 10 mM, μ=0.08, pH=11.7, in 40% Ethanol-water mixture.

In an air saturated solution of EY^{2-} and MV^{2+} ([EY^{2-}]=4.85 μM, [MV^{2+}]=0—5 mM, [O_2]=220 μM, pH=5, μ=0.004, 50 v/v% ethanol-water mixture), the photobleaching of EY^{2-} was accelerated by the addition of MV^{2+}. Considering that the $MV^{+}\cdot$ radical produced by the electron transfer from $^3EY^{2-}$ is fairly reactive to the dissolved oxygen ($MV^{+}\cdot + O_2 \rightarrow MV^{2+} + O_2^{-}\cdot$; $k'=6\times10^8\ M^{-1}\ s^{-1}$),[21] the reverse electron transfer to the resulting $EY^{-}\cdot$ from $MV^{+}\cdot$ can be taken to be prohibited. Thus, it is supposed that the acceleration of EY^{2-} bleaching is attributed to the irreversible decomposition of semioxidized radical, $EY^{-}\cdot$.[20] The dependence of the bleaching yield on the MV^{2+} concentration was the same as that shown in Fig. 1, and the contribution of the unreactive ionic pair complex is supposed similar. Figure 2 shows the pH effect on Φ_{mv} which is enhanced in alkaline solution. The production yield of $^3EY^{2-}$ does not seem to undergo a significant change in the pH region.[20] We also confirmed that the equilibrium of

the ionic complex of Eq. 1 was not affected by the change in pH because similar K values were obtained in the pH region from 5.4 to 11.4 (μ=0.05, 50 v/v% ethanol-water mixture). Judging from the property of TEOA that electron donation is effective in its basic form (pK_a (protonated TEOA)=7.76), the curve in Fig. 2 seems to match the result on the dissociation of protonated TEOA.

Figure 3 shows the effect of ionic strength, μ, on Φ_{mv} at two MV^{2+} concentrations. In the case where EY^{2-} and MV^{2+} exist free at the lower concentration of MV^{2+} (0.2 mM), the decrease in Φ_{mv} in Fig. 3 is due to a neutral salt effect on the competetive reactions between $^3EY^{2-}$ and MV^{2+} since the rate constant decreases with increasing μ.[22] At the higher concentration of MV_2^+ (5.7 mM) where 50% of EY^{2-} forms the ion-pair complex, it was suspected that the Φ_{mv} value increased as a result of the dissociation of the unreactive complex to the free EY^{2-} and MV^{2+} caused by increase in μ as shown in Table 1. Considering both of the opposite effects, i.e., the neutral salt effect and the dissociation of the ion-pair complex, the small effect observed at the MV^{2+} concentration of 5.7 mM can be interpreted in terms of the mutual compensation of these effects.

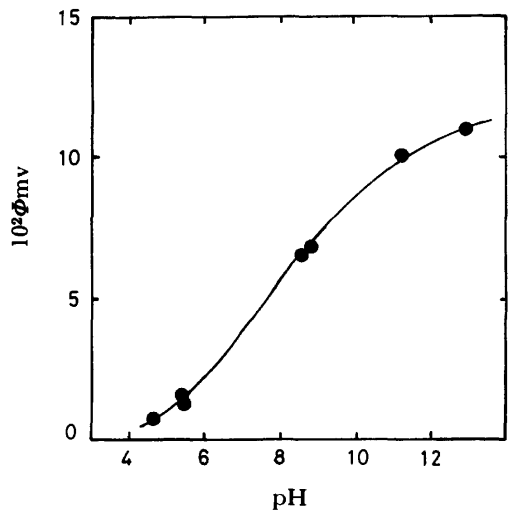

Fig. 2. Effect of pH on the quantum yield of $MV^{+}\cdot$ formation. [EY^{2-}]=17 μM, [MV^{2+}]=5.7 mM, [TEOA]= 10 mM, in 40% Ethanol-water mixture.

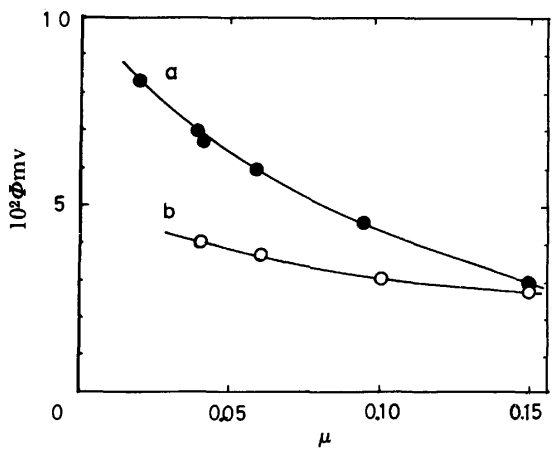

Fig. 3. Effect of ionic strength on the quantum yield of $MV^{+}\cdot$ formation. (a) [MV^{2+}]=0.2 mM, (b) [MV^{2+}]=5.7 mM. [EY^{2-}]=17 μM, [TEOA]=10 mM, in 40% Ethanol-water mixture.

Efficiency of Electron Transfer from Triplet Eosine Y to Methyl Viologen. Kinetic investigations for the efficiency of the initial electron transfer from $^3EY^{2-}$ to MV^{2+} existing in the free form were carried out to increase the sensitization yield. Scheme 1 shows the electron-transfer mechanism proposed as applicable to the present system by reference to the investigations reported by Harriman et al.[12,22-25]

$$^3EY^{2-} + MV^{2+} \underset{k_{DS}}{\overset{k_{DF}}{\rightleftharpoons}} (^3EY^{2-}\ MV^{2+})$$

$$\downarrow k_A$$

$$EY^{-}\cdot + MV^{+}\cdot \underset{k_C}{\overset{k_{-C}}{\rightleftharpoons}} {}^{1,3}(EY^{-}\cdot\ MV^{+}\cdot) \xrightarrow{k_B} EY^{2-} + MV^{2+}$$

$$k_Q{}^r = \frac{k_{DF}k_A}{k_A + k_{DS}} \quad (2)$$

$$k_b = \frac{k_{-C}k_B}{k_B + k_C} \quad (3)$$

Scheme 1.

The formation of an encounter complex ($^3EY^{2-}$ MV^{2+}) is to be a diffusion controlled process (k_{DF}), which is reversible (k_{DS}). The complex undergoes an electron transfer to form a geminate radical pair of $^{1,3}(EY^{-}\cdot\ MV^{+}\cdot)$, which can be regarded as an exciplex with a radical-pair-like electronic structure.[24,25] This complex may collapse either to give the radical ions through a separation (k_C) followed by a recombination (k_{-C}), or to reform the ground states of EY^{2-} and MV^{2+} (k_B). The yield of free radical $MV^{+}\cdot$ or $EY^{-}\cdot$ (ϕ_{mv}) is given by[23,24]

$$\phi_{mv} = \phi_{st}\phi_Q\phi_S \quad (4)$$

where ϕ_{st}, ϕ_Q, and ϕ_s refer to the probabilities of the intersystem crossing to $^3EY^{2-}$ (0.64),[26,27] the quenching of $^3EY^{2-}$ by MV^{2+} to give the geminate radical pair with $\phi_Q = k_Q^r[MV^{2+}]/(k_Q[MV^{2+}]+\tau_T^{-1})$, and the formation of the free radicals from $^{1,3}(EY^{-}\cdot MV^{+}\cdot)$ with $\phi_s = k_C/(k_C+k_B)$, respectively. The lifetime of $^3EY^{2-}$(τ_T) is equal to 220 μs at [EY^{2-}]=10 μM. On the assumption that the rate constant $k_Q{}^r$ ($=k_{DF}k_A/(k_A+k_{DS})=3.0\times10^9\ M^{-1}\ s^{-1}$) as obtained from the ns laser experiment corresponds to the process of $^{1,3}(EY^{-}\cdot MV^{+}\cdot)$ formation, ϕ_Q can be estimated to be 0.94 for the present condition ([MV^{2+}]=0.05 mM) from the observed values of k_Q^r, k_Q, and τ_T, where k_Q^r and k_Q

are the rate constants for the genuine and total reactions between $^3EY^{2-}$ and MV^{2+}, respectively. These rate constants are numerically almost equal to each other as described in a previous section (i.e., $k_Q^r \approx k_Q$). The absorption by $MV^{+}\cdot$ observed in the μs and ms time regions will arise from the free species of $MV^{+}\cdot$ dissociated from $^{1,3}(EY^{-}\cdot\ MV^{+}\cdot)$. Since $EY^{-}\cdot$ is completely reduced by the addition of 10 mM TEOA and $MV^{+}\cdot$ does not decrease, ϕ_{mv} can be obtained from the concentration of $MV^{+}\cdot$ produced per laser pulse. Thus, we can estimate the value of ϕ_s (=0.53) from Eq. 4 and the ratio of k_C/k_B(=1.1) by using the value of the maximum yield of the sensitized $MV^{+}\cdot$ formation (0.32) in 50 v/v% ethanol and water mixture. On the other hand, assuming the diffusion controlled process with k_{-C}(=1.2×10^{10} M^{-1} s^{-1}) and substituting the rate constant k_b (=2.9×10^9 M^{-1} s^{-1}) from the recombination kinetics of the free $EY^{-}\cdot$ and $MV^{+}\cdot$ radicals into the equation of $k_b=k_{-C}/(1+(k_C/k_B))$ we obtain a similar value for the ratio of k_C/k_B(=1—3). These results mean that $^{1,3}(EY^{-}\cdot\ MV^{+}\cdot)$ complex dissociates to the free radicals or to the molecules of ground state to a comparable extent.

The decay processes through the recombination of the free radical ions $EY^{-}\cdot$ (λ_{max}=462 nm, $\varepsilon_{max}=5.5\times10^4$ M^{-1} cm^{-1})[28] and $MV^{+}\cdot$ (λ_{max}=395 nm, $\varepsilon_{max}=4.2\times10^4$ M^{-1} cm^{-1})[29] followed by the dissociation of $^{1,3}(EY^{-}\cdot\ MV^{+}\cdot)$ complex, were monitored under various reaction conditions in a laser flash experiment in the μs region and analyzed in terms of the second-order reaction kinetics to evaluate k_b for the $EY^{-}\cdot$ decay as 4.7×10^9 M^{-1} s^{-1} and that for the $MV^{+}\cdot$ decay as 5.1×10^9 M^{-1} s^{-1} (in 60 v/v% CH_3OH-H_2O, μ=0.02). There was no permanent production of $MV^{+}\cdot$ or $EY^{-}\cdot$ radical in the EY^{2-}/MV^{2+} system by irradiation. Incidentally, it was ascertained that the observed decay process did not correspond to the recombination to the geminate radical pair $^3(EY^{-}\cdot\ MV^{+}\cdot)$, because the decay data hardly satisfy the root equation for the kinetical treatment on the geminate pair in the μs-region.[30]

Values of k_b depend on the solvent composition of binary mixtures of methanol-water, ethanol-water, 2-propanol-water, and ethylene glycol-water, in such a manner that the k_b values decrease initially in regard to the molar fraction of alcohol and then increase gradually. As shown in Fig. 4, the plot of k_b against the reciprocal of solvent viscosity (η) satisfies a linear relationship. Even if the processes designated the rate constants of k_B and k_C result from the local diffusion of each paired radical in a cage to the bulky phase, this viscosity effect will be cancelled out in the expression of Eq. 3 so as to be negligible for the k_b value itself. On the other hand, the polarity effect of solvent is supposed to be in corporated in the k_B value, which will be discussed in a later section. It is known that there is no considerable change in the solvent polarity

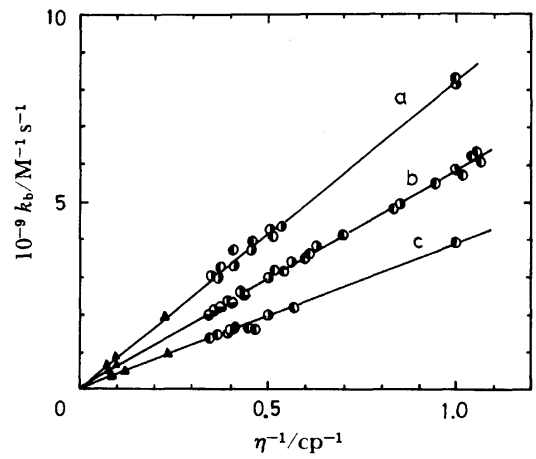

Fig. 4. Solvent viscosity effect on k_b values. (a): Erythrosine/MV^{2+} system, (b): Eosine Y/MV^{2+} system, (c): Fluorescein/MV^{2+} system([NaOH]=0.5 mM). of dielectric constant or in the empirical solvent parameters such as Kosowar's Z-value for such a mixture of methanol and ethylene glycol. However, since the linear relationship between k_b and η^{-1} in the methanol and ethylene glycol mixture is the same as that for the alcohol and water mixture, and since the polarity change in the latter mixture is not so large in the region $\chi_{alc}<0.7$, it is considered that the diffusional recombination process between $EY^{-}\cdot$ and $MV^{+}\cdot$ with k_{-C} (=$8RT/3000\eta$) will reflect the viscosity effect on k_b values in the expression of $k_b=k_{-C}/(1+(k_C/k_B))$. Such linear relationships were observed with the Eosine Y-MV^{2+}, Erythrosine-MV^{2+}, and fluorescein-MV^{2+} systems. This result seems to confirm that the observed decay processes correspond to the diffusional recombinations between the free radical ions.

Solvent Effect on ϕ_{mv} Values. Since the quantum yield of hydrogen evolution for the three-component system with a catalyst was increased by the addition of methanol or ethanol, the dependence of ϕ_{mv} after the laser excitation (about 30 μs) on the concentration of methanol, ethanol, or 2-propanol was investigated. ϕ_{mv} values are increased by the addition of each alcohol as shown in Figs. 5a and 5b. The yield for $EY^{-}\cdot$ increased in a similar manner.

The results shown in Figs. 5a—c refer to the solvent effect on ϕ_{mv} and the second shows the difference in ϕ_{mv} among the dye sensitizers. On the basis of the fact that the effect of alcohol addition on ϕ_{st} is negligible[20,26,27] and on the assumption that the effect on ϕ_Q is negligible, the first effect could result from the ϕ_s in Eq. 4. From the view point that the free radicals are produced by the separation of the

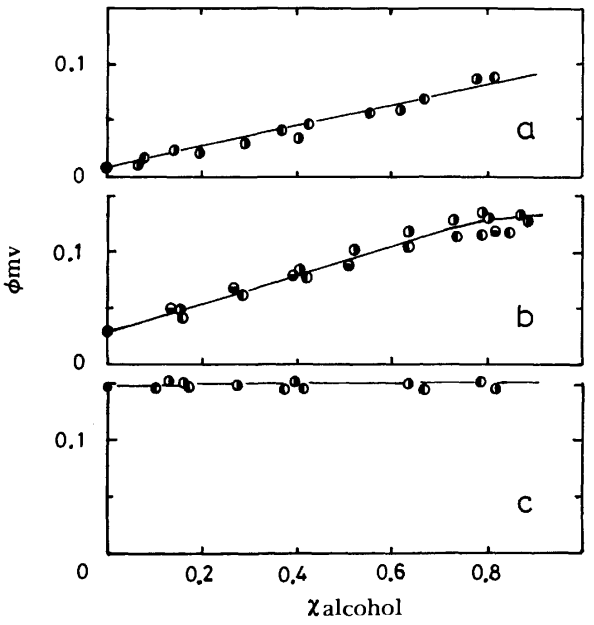

Fig. 5. Effect of molar fraction (χ) of alcohol on the yield of $MV^{+}\cdot$, ϕ_{mv}. (a) Erythrosine/MV^{2+} system, (b) Eosine Y/MV^{2+} system, (c) Fluorescein/MV^{2+} system([NaOH]=0.5 mM). geminate radical pair in competition with the decay process as discussed in respect of Scheme 1, a similar explanation as reported by Winter and Steiner can be applied in terms of the solvent polarity dependence of the energy gap between the exciplex and the corresponding Franck-Condon ground state.[32] Thus, the observed effect on ϕ_{mv} is determined by two decay constants for the exciplex as

$$\phi_{mv} = \phi_{st}\phi_Q \frac{k_C}{k_B + k_C} \quad (5)$$

$$= \phi_{st}\phi_Q \left(1 + \frac{F_{el}F_{FC}}{k_C}\right)^{-1} \quad (6)$$

where k_b is a product of a factor F_{el} (the electronic coupling strength) and a factor F_{FC} which is determined mainly by the Franck-Condon weighted density of vibrationally excited ground state levels isoenergitic with the exciplex; $k_B = F_{el}F_{FC}$. If the analysis for ϕ_{mv} discloses no significant influence of solvent on k_C, the radical yield ϕ_{mv} may be concluded to be determined mostly by the factor F_{FC}.

Since the explanation for the polarity dependence in the presence of alcohol added calls for F_{FC} or k_B to be small, it may be expected that ϕ_{mv} becomes large because of the lesser polarity of alcohol. As shown in Fig. 5, such solvent effects are found in the systems of EY^{2-} and MV^{2+} and of Erythrosine and MV^{2+}. In the system of fluoresceine and MV^{2+} shown in Fig. 5c, the solvent effect is little observed and ϕ_{mv} value are larger than those in the other systems.

In the systems of EY^{2-}/MV^{2+} and Ery^{2-}/MV^{2+}, the correlations of ϕ_{mv} with the solvent parameter of Kosowar's Z are similar to each other in both the methanol-water and ethanol-water mixtures. In relation to the solvent dependence on the ionic photodissociation yield in the singlet exciplex state (for example, pyrene and *N,N*-dimethylaniline), the radical yield increased with the solvent dielectric constant (ε) and a quantitative analysis for the mechanism was carried out.[33] In the present case, ϕ_{mv} decreases with ε values of alcohol-water mixtures and the mechanism differs from the case involving the singlet excited state. From a variation of solvent viscosity in the range 1—3 cp effected by mixing methanol, ethanol, or 2-propanol with water, the viscosity dependence may be expected to appear on k_C and accordingly on ϕ_{mv}. However, the effect of viscosity was observed as a decrease in ϕ_{mv} beyond ca. 4 cp.

A second effect on ϕ_{mv} values in Fig. 5 may be derived by making a comparison between the heavy-atom-substituted sensitizers (Br, I). A similar heavy atom effect was reported with thiopyronine reduction by substituted electron donors (Br, I).[32] In the present case, ϕ_{mv} values are 0.12 for fluorescein, 0.090 for Eosine Y, and 0.055 for Erythrosine ([MV^{2+}]=0.05 mM, μ=0.02, χ_{MeOH}=0.5). It is known that ϕ_{st} values of dyes increase in the order: $\phi_{st}(Ery^{2-}) > \phi_{st}(EY^{2-}) > \phi_{st}(Fl^{2-})$.[20] To interpret the order: ϕ_{mv} (Ery^{2-})< $\phi_{mv}(EY^{2-}) < \phi_{mv}(Fl^{2-})$ as obtained from Figs.5a—c at a given molar fraction of alcohol on the basis of Eq. 2, ϕ_s values of dyes must taken to be in the same order with more decrease than the change in the respective ϕ_{st} values: $\phi_S(Ery^{2-}) < \phi_s(EY^{2-}) < \phi_s(Fl^{2-})$. Since the k_b values for the Ery^{2-}/MV^{2+}, EY^{2-}/MV^{2+}, and Fl^{2-}/MV^{2+} systems decrease in the order listed, k_C/k_B and then ϕ_{mv} values should increase in the same order, in conformity with the above results on ϕ_{mv} values. However, further investigations for the effects of solvent viscosity and polarity and the heavy atom associated with spin conversion on the dissociation of $^{1,3}(Dye^{-}\cdot\ MV^{+}\cdot)$ are required for quantitative interpretation.

Electron Donation to Semioxidized Eosine. In an alkaline deaerated aqueous solution of EY^{2-} and MV^{2+} without TEOA, sensitized production of $MV^{+}\cdot$ was observed by means of stationary illumination, although the yield was very low as shown in Table 2. The electron donative reaction from OH^{-} ion to $EY^{-}\cdot$ may be possible to produce an adduct $EYOH^{2-}\cdot$ from $OH\cdot$ and EY^{2-}, since $EY^{-}\cdot$ is a strong oxidant ($E^0(EY^{-}\cdot/EY^{2-}) = 1.1$ V NHE).[34-37] The possibility of the above process is experimentally suggested from: (i) the decay rate of $EY^{-}\cdot$ is enhanced by the addition of OH^{-} ion and the rate constant is about 10^5 M^{-1} s^{-1}; (ii)

Table 2. Quantum Yield of $MV^{+}\cdot$ Formation in Alkaline Solution[a)]

[NaOH]/mM	χ_{CH_3OH}	Φ_{mv}

a transient spectrum (λ_{max}=600 nm, $\tau_{1/2}$=4.4 ms) is observed which is similar to that of $EYOH^{2-}\cdot$ reported by Grossweiner et al. as a result of pulse radiolysis experiment;[38] (iii) the spectrum of $EYOH^{2-}\cdot$ disappeared after reaction with methanol, with simultaneous increase in the permanent yield of $MV^{+}\cdot$, Φ_{mv}. The above phenomenon (iii) suggests that the competetive recombination between $EYOH^{2-}\cdot$ and $MV^{+}\cdot$ is prohibited by the addition of methanol, and thus that the reaction process of $EYOH^{2-}\cdot$ with methanol causes the yield to increase as shown in Table 2.

The authors wish to express their thanks to Mr. Yoshio Takada for his contribution to the work. This work was supported by a Grant-in-Aid for Special Project Research (No. 61123001) from the Ministry of Education, Science and Culture.

Liquid-Phase Hydration of Acrylonitrile to Acrylamide over the Copper-Nickel Alloy Catalysts

Kazuo SUGIYAMA,* Hiroshi MIURA, Yoshichika WATANABE, Yasunori UKAI, and Tsuneo MATSUDA
Department of Applied Chemistry, Faculty of Engineering, Saitama University, Shimo-okubo, Urawa 338
(Received September 6, 1986)

The liquid-phase hydration of acrylonitrile to acrylamide has been examined over various metal catalysts at 75 °C. Five metal elements-Cu, Ag, Fe, Co, and Ni-showed the catalytic conversion of acrylonitrile. The Cu and Ag catalysts gave the acrylamide with a 100% selectivity, while the other metals, Fe, Co, and Ni, yielded three products: acrylamide, ethylene cyanohydrin, and bis(2-cyanoethyl) ether. The alloying of Cu and Ni led to an increase in the formation of acrylamide with keeping the high selectivity to acrylamide. Especially, Cu-Ni alloys, with a range of 20—70% Cu in their bulk composition, were much more active catalysts than Cu. The maximum yield of acrylamide was obtained on the Cu-Ni alloy catalysts was observed, although such a retardation occurred on the Cu catalyst surface. The maximum synergistic effect was observed over the alloy with the surface component ratio of Cu to Ni of 4; this effect was discussed.

In relation to the liquid-phase hydration of acrylonitrile(AN) over various metal oxides or metals, it has been found that acrylamide(AA), ethylene cyanohydrin(ECH), and bis(2-cyanoethyl) ether(BCE) are chiefly produced.[1] Commercially available AA, which is used as paper-strengthening agents and flocculants etc., can be obtained by the selective hydration of the cyano group in an AN molecule. This hydration is effectively catalyzed by a metallic Cu such as the Cu prepared by reduction with H_2, Raney and Ullmann Cu.[2-4]

It is known that the catalytic hydration processes using metallic Cu catalysts have a number of excellent characteristics, such as simplicity of outline, easy handling, and the absence of any by-product formation.[5] A modification of the catalysts is rather effective if one aims to study the improvement of the hydration process. In the investigation of the basic design of highly active catalysts on AA production, as has been reported in a previous paper,[6] we recently found out that Ni-enriched Cu-Ni alloys had more ability for the AA formation than did the Cu catalysts in the liquid-phase hydration of AN. In this paper, the synergistic effect of Cu and Ni on the AA formation will be reported.

Experimental

Catalyst Preparation: The Cu-Ni alloys employed in this work were prepared by the reduction of the oxides obtained by the thermal decomposition, in air, of the Cu-Ni carbonates coprecipitated from their nitrates in aqueous solutions; this was done in the manner described by a number of workers.[7-11] In a typical preparation of the present investigation, a 5 wt% Na_2CO_3 aqueous solution was slowly added to a 0.5 M solution of mixed nitrates (Kanto Chemicals), keeping it at 32 °C, until the pH value of 9.5 was reached; and the suspension was then stirred for 1 h and left to stand overnight. After the resulting slurry has been filtered, the precipitate was washed with a large amount of ion-exchanged water until the pH value of the filtrate attained 8.0. The mixed carbonate was dried overnight at 120 °C and then calcined in air for 3 h at 300 °C. The resulting oxide powder was sieved from 20 to 60 mesh. The oxide was then reduced in a Pyrex tube with deoxygenated hydrogen-first at a flow rate of 10 ml min^{-1} for 1 h at 150 °C and then at 100 ml min^{-1} for 1.5 h at 300 °C. The reduced metal catalyst was kept in a deoxygenated nitrogen atmosphere.

Pure Cu, Ni, and other metals were prepared by similar procedures. Five wt% Rh, Pd, and Pt, supported on silica, were prepared by the manner described by Benesi et al.[12]

Activity Measurements: The hydration of AN was carried out in a conventional batch reactor equipped with a reflux condenser. After the air in the reactor had been replaced with deoxygenated nitrogen, pure water (100 ml) and purified AN (8.5 ml) were introduced into the reactor, and the mixture was kept at 75 °C. A prereduced catalyst (2.5 g) was transferred from the tube to the reactor in a stream of nitrogen for further reduction. The reaction products were analyzed by the use of a FID gas chromatograph. The detailed procedure was described in a previous paper.[13]

Adsorption Measurements: The chemisorption measurements were carried out in a pulse system with the apparatus described in detail elsewhere.[14] The absorption measurements were done as follows: the samples in the adsorption-tube, connected with a vacuum line, were reduced in the same manner as in the catalyst reduction described above, and then evacuated to 1×10^{-5} Torr (1 Torr=133.322 Pa). The amount of hydrogen chemisorbed on the Ni surface of the catalyst was measured by the pulse chemisorption method. The total surface area of the catalysts was determined by the BET method using N_2 physisorption.

TPD and XRD Analysis: In order to examine the materials, such as AN and AA, adsorbed on the metal-catalyst surface, the TPD experiments were performed. Desorbed molecules were analyzed by means of a quadrupole gas analyzer(ANERVA: NAG-110). The temperature was increased from room temperature to 400 °C at a rate of 5 °C min^{-1}. The crystal structures of the metal

catalysts used were identified by X-ray-diffraction measurements.

Results and Discussion

Activity and Selectivity of Metal Catalysts: As shown in Table 1, the selectivity of the catalysts differed entirely between the Group IB and Group VIII metals. AA was selectively formed on the metallic Cu and Ag catalysts, while AA, ECH, and BCE were produced on the Fe, Co, and Ni catalysts. The other metals, such as Rh, Pd, and Pt supported on silica were inactive.

In order to improve the catalytic activity of metallic Cu, various Cu-based binary metals, such as Cu-Ni, -Co, and -Fe, were prepared. As shown in Table 1, it has been found that the combination of Cu and Ni leads to an increase in the AA formation while keeping a high selectivity to AA. Even in the case of a comparison of the catalytic activity per specific surface area, the amount of AA obtained on the Cu-Ni binary metal was greater than that of the Cu catalyst. Binary metal catalysts combined with Cu and Fe or Co exhibited a low selectivity to AA. When the crystal structures of the binary metals were identified by means of the X-ray-diffraction method, it was observed that a single-phase alloy of Cu and Ni was formed, but in the case of Cu-Fe and -Co no such phase could be detected.

Catalytic Properties of Cu-Ni Alloys: Figure 1 shows the catalytic activity and AA selectivity as a function of the bulk composition of Cu in the Cu-Ni alloys. The catalytic activity of Cu-Ni alloys was greater than that of Cu over a wide range of Cu bulk compositions. Especially, Cu-Ni alloys, having 20—70% Cu in their bulk composition, were much more active catalysts than was neat Cu. The maximum conversion of AN was obtained on the Cu-Ni alloy catalyst containing 35% of Cu in the bulk phase.

It is known that Cu is concentrated on the surface of the alloy; [15] this finding is in agreement with the results of this study, as shown in Table 2. By alloying Ni with a small amount of Cu (e.g., only 3% of Cu), the Cu was concentrated on the surface of the alloy to a value of more than 10 times. Especially, when the content of Cu increased over 20% in the bulk composition, the concentration of Cu on the surface attained 70 to 90%, which agreed with the results reported in the literature.[9-11,16] It seems reasonable that the Cu atom on the alloy surface is the active site for the hydration of AN to AA, because Ni shows a poor catalytic activity.

Figure 2 illustrates the change in turnover frequency (TOF) at the initial stage, i.e., the number of reacted molecules of AN per minute per number of surface Cu or Ni atoms of the alloys. The TOF based on the Cu atom of the alloys increased with an increase in the surface concentration of Cu and attained its maximum at 80% Cu. The TOF based on the Ni atoms was negligibly small in comparison with

Table 1. Catalytic Activity and Selectivity over Various Metals on Liquid-Phase Hydration of Acrylonitrile at 75 °C

Catalyst	Reduction temperature/°C	Conversion of AN/%	Selectivity to AA/%	Yield of AA/%

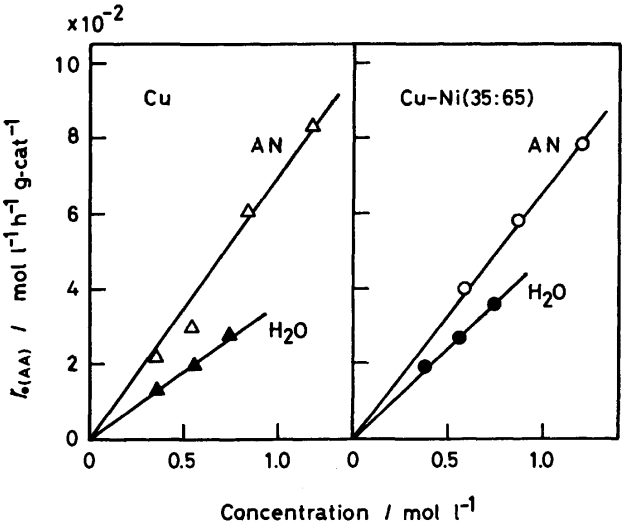

Fig. 3. Reaction order of Cu and Cu-Ni (35:65) catalysts.

that of Cu.

Kinetic Parameters at the Initial Stage of the Reaction: The initial rate of AA formation on Cu-Ni and Cu catalysts was examined in various concentrations of AN and water. On the Cu-Ni (35:65) and Cu catalysts, a first-order concentration dependency of both AN and water was obtained, as shown in Fig. 3. In addition, the values of the apparent activation energy of the Cu-Ni (35:65) and Cu catalysts were 10.9 and 12.1 kcal mol^{-1} (1 cal=4.184 J) respectively. These results indicate that the hydration on the Cu-Ni (35:65) and Cu catalysts proceeds according to the same mechanism at the initial state of the reaction.

Effect of Product Retardation: Differences in the catalytic activity between the Cu and Cu-Ni (35:65) catalysts were observed a few hours after the start of the reaction. Deviations from the first-order plots were observed on the Cu catalyst at a higher

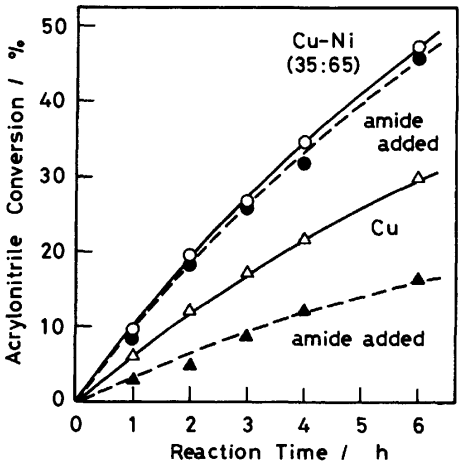

Fig. 4. Addition effect of acrylamide; amount of AA added is 1 g.

conversion of AN, while in the case of the Cu-Ni (35:65) alloy catalyst no deviation was observed.

Hayashi et al.[17] have proved that the catalytic activity of Cu supported on $MgO-SiO_2$ is depressed by the accumulation of AA on the catalyst surface. It is predictable that the retardation on the support-free Cu catalyst in this study is also caused by AA. Therefore, the effect of the addition of AA on the reaction was investigated.

Figure 4 shows the plots of the time course of the hydration in the existence and in the absence of AA. In the case of the Cu catalyst, the activity dropped to 55% of its original value upon the addition of AA. On the other hand, the catalytic activity of the Cu-Ni (35:65) alloy was not affected at all by the AA addition. It can be thought that AA is not liable to adsorb on the Cu-Ni catalyst surface.

In order to further ascertain the effect of AA on the Cu and Cu-Ni catalysts, the solution in the reactor, after the reaction had finished, was removed by means of a syringe equipped with a long needle in a N_2 atmosphere, leaving the catalyst in the reactor. After the catalyst had then been washed with pure water a few times, the reaction was started again by charging AN and water into the reactor. The relations of AN conversion to the reaction time were shown by exactly the same dotted lines as those shown in Fig. 4. Thus, the retardation was observed on Cu, and not on Cu-Ni, catalysts. Therefore, it is necessary also to examine the absorption behavior of AA and AN on the Cu and Cu-Ni catalysts.

By assuming the pseudo-first-order kinetics from the reaction conditions being rich in water, the hydration rate of AN may be expressed as:

$$r_{AN} = k\theta_{AN} \quad (1)$$

where k represents the rate constant and where θ is the surface coverage of AN.

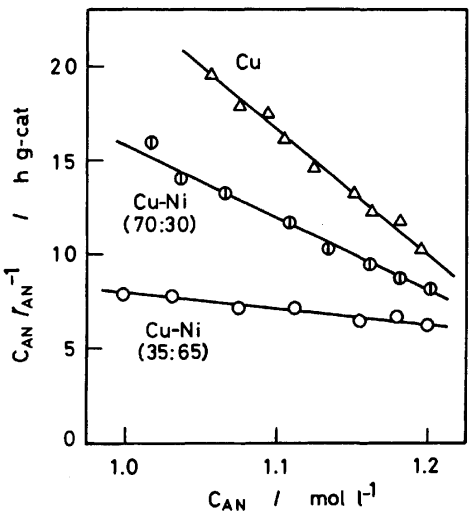

Fig. 5. Verification of Eq. 4.

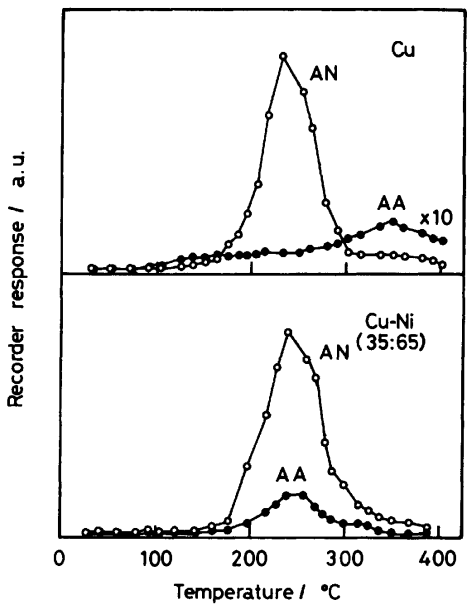

Fig. 6. TPD profiles of Cu and Cu-Ni (35:65) alloy.

Table 3. Adsorption Equilibrium Constants of Acrylonitrile and Acrylamide on Cu and Cu-Ni Alloy Surface

Catalyst	Cu atomic fraction		K_{AN} / l mol^{-1}	K_{AA} / l mol^{-1}
	Bulk	Surface		
Cu	1.0	1.0	1.6	20.5
Cu-Ni	0.70	0.92	0.7	11.4
Cu-Ni	0.35	0.79	0.3	2.1

In the case of the competitive adsorption of AN and AA, the surface coverage of AN can be expressed as:

$$\theta_{AN} = \frac{K_{AN}C_{AN}}{1+K_{AN}C_{AN}+K_{AA}C_{AA}} \quad (2)$$

where K_{AN} and K_{AA} represent the adsorption equilibrium constants of AN and AA respectively. In Eq. 2, the adsorption term of water is neglected, for scarcely water is absorbed on the Cu catalysts.[18-20]

As the hydration product is AA alone:

$$C_{AA} = C_{AN_0} - C_{AN} \quad (3)$$

By substituting Eqs. 2 and 3 into Eq. 1, we obtain:

$$\frac{C_{AN}}{r_{AN}} = \frac{1+K_{AA}C_{AN_0}}{kK_{AN}} + \left(\frac{K_{AN}-K_{AA}}{kK_{AN}}\right)C_{AN} \quad (4)$$

Figure 5 shows excellent fits of the data with Eq. 4. The negative slopes indicate that K_{AA} is greater than K_{AN}. The adsorption constants in Eq. 4 were calculated to be as shown in Table 3. These results indicate that AA is rather more strongly adsorbed on the Cu surface than is AN. The values of K_{AA} decreased with the increase in the concentration of Ni atoms on the Cu-Ni alloy surface. This suggests that the coexistence of Cu and Ni on the alloy surface leads to the smooth desorption of AA from that surface.

TPD Profiles: The TPD profiles of Cu and Cu-Ni (35:65) catalysts after a 6-h reaction are shown in Fig. 6. On the Cu surface, a small amount of AA desorption at a higher temperature (ca. 350 °C) and a large amount of the desorption of AN at a lower temperature (ca. 250 °C) were observed. On the other hand, on the Cu-Ni alloy catalyst the desorption peak of AA shifted to a lower temperature. Thus, it seems clear that AA can easily desorb from the catalyst surface as a result of the functioning of Ni in Cu-Ni alloy. Consequently, it can be concluded that the deactivation of the Cu catalyst by product retardation can be prevented by alloying Cu and Ni, thus leading to the improvement of the hydration catalyst to a more active one.

Conclusion

The results of the liquid-phase hydration of AN to AA over the metal catalysts can be summarized as follows:

1) Cu and Ag in Group IB selectively produced AA, while Fe, Co, and Ni in Group VIII yielded AA, ECH, and BCE.

2) The Cu-Ni alloy with the surface concentration of 80% Cu was the best catalyst for the AA formation.

3) The Ni in the Cu-Ni alloy contributes to the smooth desorption of AA from the catalyst surface, preventing the retardation of AA; a high activity can thus be preserved.

Hydrates of Organic Compounds. XII. Intercalation of Methyl and Ethyl Alcohols within the Clathrate-Like Hydrates of Tetrabutylammonium Fluoride and of Tetrabutylammonium Propionate

Haruo NAKAYAMA,* Kiyoshi TSUNAKAWA, Mizue KANŌ, and Hiroshi MATSUI†
Department of Chemistry, Faculty of Engineering, Yokohama National University, Tokiwadai, Hodogaya-ku, Yokohama 240
†The Radio Isotope Center, Yokohama National University, Tokiwadai, Hodogaya-ku, Yokohama 240
(Received October 2, 1986)

The amount of either methyl or ethyl alcohol intercalated within clathrate-like hydrates of tetrabutylammonium fluoride and of tetrabutylammonium propionate has been determined using ^{14}C-labeled alcohols. It was found that (1) methyl alcohol could be intercalated within the tetrabutylammonium fluoride hydrate but not within the tetrabutylammonium propionate hydrate; (2) ethyl alcohol could be intercalated within both the tetrabutylammonium fluoride and tetrabutylammonium propionate hydrates; and (3) the amount of the alcohol intercalated increased with increasing concentration of alcohol in the initial solutions. These results were interpreted by taking into consideration the states of vacant pentagonal dodecahedra formed by hydrogen-bonded water networks.

As a way of examining the ability of an organic substance to form a clathrate-like hydrate, we have proposed a new method.[1,2] It is based upon the examination of the formation of either double or mixed hydrates in a ternary system consisting of the substance under consideration, water, and a third component which is clearly known to form a clathrate-like hydrate by itself. In an earlier experiment[2] for ternary systems of methyl (or ethyl) alcohol–water–tetrahydrofuran(THF), it was found that (1) both methyl and ethyl alcohols were intercalated within the THF clathrate hydrate, (2) ethyl alcohol could form a mixed hydrate with THF, and (3) the amount of methyl alcohol intercalated within the THF hydrate increased with increasing the concentration of methyl alcohol, indicating that methyl alcohol formed a double hydrate with THF, presumably by being intercalated in a vacant pentagonal dodecahedron. These results suggest that the state of vacant polyhedra, especially of vacant pentagonal dodecahedra, plays an important role for the intercalation of such alcohols into a clathrate-like hydrate.

On the other hand, according to the single-crystal X-ray examination for a clathrate-like hydrate of tetrabutylammonium fluoride, $(n\text{-}C_4H_9)_4NF$, by Jeffrey et al.,[3] vacant pentagonal dodecahedra coexist with large polyhedra (such as tetrakaidecahedra and pentakaidecahedra) which accommodate one of the butyl groups of a tetrabutylammonium cation, and five pentagonal dodecahedra face-share with each other and form a part of anionic host structure together with the fluoride ions. It is of interest to examine the capability of these pentagonal dodecahedra to intercalate such small organic molecules as methyl and ethyl alcohols.

Furthermore, it has recently been known that various tetrabutylammonium carboxylates, $(n\text{-}C_4H_9)_4NOOCC_2H_5$ for example, can also form a clathrate-like hydrate having the same hydration numbers as that of the tetrabutylammonium fluoride hydrate (around 30).[4–6] It has been presumed that (1) these carboxylate hydrates are iso-structural with the $(n\text{-}C_4H_9)_4NF$ hydrate and (2) an alkyl group of the carboxylate anion occupies one pentagonal dodecahedron which is located in the nearest position to the tetrabutylammonium cation. If this speculation is correct, there may be some difference in the states of the pentagonal dodecahedra between the $(n\text{-}C_4H_9)_4NF$ hydrate and the tetrabutylammonium carboxylate hydrates, i.e., all the pentagonal dodecahedra are vacant in the former, whereas some of them are already occupied by the alkyl group of the carboxylate anion in the latter.

In this investigation, the enclathration of methyl and ethyl alcohols within the clathrate-like hydrates of $(n\text{-}C_4H_9)_4NF$ and $(n\text{-}C_4H_9)_4NOOCC_2H_5$ has been investigated in order to see if (1) such alcohols can actually be intercalated in vacant pentagonal dodecahedra existing in these tetrabutylammonium salt hydrates and (2) there exists some difference in the intercalation abilities between the two hydrates.

Experimental

Materials and Procedure. An aqueous solution of tetrabutylammonium fluoride was prepared by neutralization of an aqueous solution of tetrabutylammonium hydroxide with hydrofluoric acid. The hydroxide solution was prepared by reacting tetrabutylammonium iodide, which was prepared and purified by the same procedure as in earlier papers,[4,5] with freshly prepared silver hydroxide in water, followed by filtration of the silver iodide precipitate. An aqueous solution of tetrabutylammonium propionate was prepared by reacting the tetrabutylammonium iodide with silver propionate in water, followed by filtration of the silver iodide precipitate. The silver

propionate was prepared by reacting sodium propionate with silver nitrate in water, followed by repeated washing with water to remove sodium nitrate. The concentration of the mother solutions of the tetrabutylammonium salts was determined by titration with tetraphenylborate aqueous solution standardized by pure tetrabutylammonium iodide. Radioactive methyl and ethyl alcohols were purchased from The Japan Radioisotope Association. Sample solutions were prepared by dissolving a known amount (0.2—1.0 g) of the sample containing 0.1—0.3 μCi in 4—5 cm^3 of scintillator, Insta-gel (Packard Instrument Co., Inc.). The radioactivity was measured using the TRI-CARB 460C Automatic Liquid Scintillation System (Packard Instrument Co., Inc.).

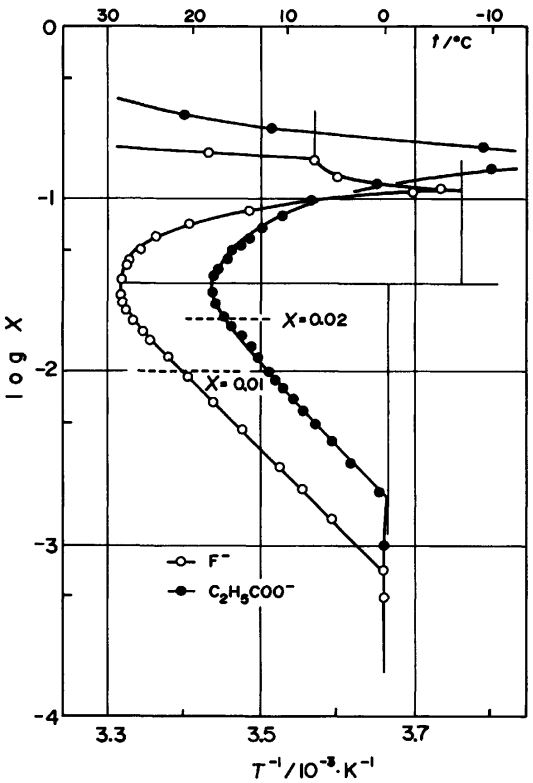

Fig. 1. The solid-liquid phase diagrams for the binary systems of $(n\text{-}C_4H_9)_4NF+H_2O$(○) and $(n\text{-}C_4H_9)_4NOOCC_2H_5+H_2O$(●). The mole fraction ($X$) which is kept constant throughout this study is shown for each salt.

Determination of the Experimental Conditions. In Fig. 1, the solid-liquid phase diagrams for the binary systems of $(n\text{-}C_4H_9)_4NF\text{-}H_2O$[7] and of $(n\text{-}C_4H_9)_4NOOCC_2H_5\text{-}H_2O$[4] are shown, in which the ordinate represents the logarithm of the concentration expressed by the mole fraction (X) of each salt and abscissa represents the reciprocal of the absolute temperature. These phase diagrams clearly indicate the formation of hydrates for both salts. The congruent composition of the hydrate is around X=0.032 for both hydrates and the congruent melting point is 28.3 °C[7] for the fluoride hydrate and 18.0 °C[4] for the propionate hydrate, respectively. As is obvious from this figure, the experimental temperature range is inevitably limited between the eutectic point (around 0 °C for both hydrates) and the congruent melting point of the hydrate, and is highly dependent upon the concentration of each tetrabutylammonium salt. Therefore, the concentration of the tetrabutylammonium salt, which is kept constant throughout this experiment, is determined to be X=0.01 for the systems containing the $(n\text{-}C_4H_9)_4NF$ and X=0.02 for those containing the $(n\text{-}C_4H_9)_4NOOCC_2H_5$, respectively. This situation is also depicted in Fig. 1.

In Fig. 2 the melting points of the two hydrates are plotted against the concentration of the alcohol added. These data were obtained by the usual ampoule method used in

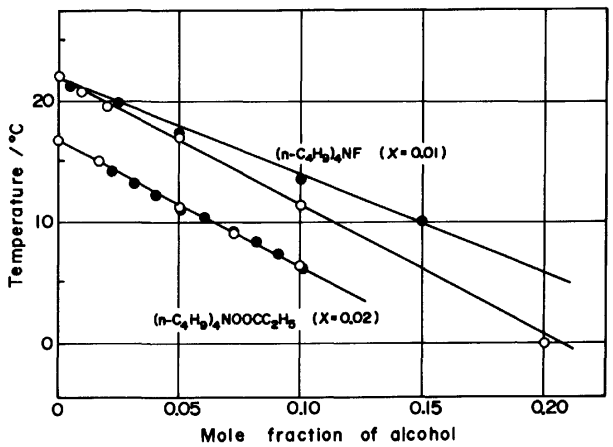

Fig. 2. The effect of added alcohols on the melting points of the clathrate-like hydrates of $(n\text{-}C_4H_9)_4NF$ and of $(n\text{-}C_4H_9)_4NOOCC_2H_5$. The mole fraction of each salt is kept constant at the value given in parenthesis. ○: CH_3OH; ●: C_2H_5OH.

Table 1. List of the Experimental Conditions

No.	Tetrabutylammonium salt	Alcohol	X_{TBA}	X_{alc}	Experimental temperature/°C
1	$(n\text{-}C_4H_9)_4NF$	CH_3OH	0.01	0.01	15.0
2	$(n\text{-}C_4H_9)_4NF$	CH_3OH	0.01	0.10	5.0
3	$(n\text{-}C_4H_9)_4NF$	C_2H_5OH	0.01	0.01	17.5
4	$(n\text{-}C_4H_9)_4NF$	C_2H_5OH	0.01	0.10	9.5
5	$(n\text{-}C_4H_9)_4NOOCC_2H_5$	CH_3OH	0.02	0.02	12.0
6	$(n\text{-}C_4H_9)_4NOOCC_2H_5$	CH_3OH	0.02	0.10	3.1
7	$(n\text{-}C_4H_9)_4NOOCC_2H_5$	C_2H_5OH	0.02	0.02	12.5
8	$(n\text{-}C_4H_9)_4NOOCC_2H_5$	C_2H_5OH	0.02	0.10	3.2

previous papers.[4,5,7] The concentration of the tetrabutylammonium salts are kept constant as mentioned above. This figure indicates that the melting point of each hydrate is lowered almost linearly with increasing concentration of the alcohol. At temperatures above each line only a single liquid phase is present and at temperatures several degrees below the line the mixture apparently looks like a single solid phase in which the coexisting liquid phase is absorbed in the interstice between the hydrate crystal. Therefore, the experimental temperature at which both liquid and solid phases are present in nearly equal proportion is limited to a temperature of a few degrees below each line.

From these standpoints all the experimental conditions are determined. They are summarized in Table 1. The X_{TBA} and X_{alc} represent the mole fraction of tetrabutylammonium salt and of alcohol added, respectively.

Results and Discussion

(1) Estimation of the Amount of the Liquid Phase Adhering to the Solid Phase. Prior to the main experiment, the weight fraction, P, of the liquid phase adhering to the wet solid phase must be estimated. The process for estimating the P is divided into the following processes: (1) a ternary mixture (about 5 cm^3) containing a given amount of tetrabutylammonium salt, of nonradioactive alcohol, and of water was cooled down to about −20 °C in order to deposit a solid phase, then a large portion of the solid was dissolved by gradual warming to a temperature about one degree above the experimental temperature; (2) a well-formed crystalline phase is slowly developed by cooling again to the experimental temperature listed in Table 1; (3) a small amount of radioactive alcohol (0.1—0.3 μCi) is added into the solid-liquid mixture which is kept at the experimental temperature and well mixed with the liquid phase by shaking; and (4) the liquid phase is separated from the solid phase by decantation, followed by suction through a long thin syringe needle. The radioactivity per unit weight is then measured for the liquid phase and for the solid phase, respectively.

If we represent the radioactivity (dpm) and the weight (g) of the sample by r and m, and the liquid phase by a suffix 1 and the wet solid phase by s, P can be calculated by the following equation:

$$P = \frac{r_s/m_s}{r_l/m_l}, \quad (1)$$

since the amount of the liquid phase contained in the m_s g wet solid is equal to the quantity $(m_l/r_l)r_s$. In this procedure, it is assumed that radioactive alcohol is not present in the solid phase since additional solid phase deposition owing to the addition of alcohol is impossible: i.e., the addition of alcohol never causes the rise in the melting point as shown in Fig. 2 and the temperature is always kept constant. The P values of all the systems determined by this procedure are summarized in Table 2. The number of the system is the same as that listed in Table 1. These values are averages of 5—10 measurements and the limits of error attached to each value simply represent the deviation from the mean value from experiment to experiment. In general, a long and well-shaped, parallelepiped crystal was formed in the systems 1 to 4, especially in the systems containing ethyl alcohol, leading to small values of P. However, in the systems containing $(n\text{-}C_4H_9)_4NOOCC_2H_5$ (systems 5—8), many thin and wedge-shaped crystals were developed almost simultaneously over the whole part of the solution, resulting in relatively large and less accurate values of P.

Table 2. Summary of P Values for All the Systems Examined

System[a)]	P	System[a)]	P
1	0.097±0.006	5	0.09±0.04
2	0.097±0.005	6	0.29±0.06
3	0.017±0.010	7	0.24±0.03
4	0.040±0.009	8	0.12±0.03

a) The number of the system stands for the same one listed in Table 1.

(2) Enclathration of Alcohols within the Clathrate-Like Hydrates of Tetrabutylammonium Fluoride and of Tetrabutylammonium Propionate. Through the measurements of radioactivity of ^{14}C-labeled alcohols, the amount of either methyl or ethyl alcohol included in the hydrate solid which is formed in ternary mixtures of tetrabutylammonium fluoride (or propionate)–radioactive methyl (or ethyl) alcohol–water has been determined. The solid phase was carefully developed by the same procedure as the processes (1) and (2) described in the preceding section.

Since water networks which have the possibility to enclathrate alcohol molecules are vacant pentagonal dodecahedra, the molar ratio of the tetrabutylammonium salt to water in the hydrate solid remains unchanged, i.e., 1:30, irrespective of the presence of alcohol within the hydrate solid. Therefore, the molecular formula of the solid phase may be expressed as (Tetrabutylammonium salt)$(Alcohol)_x30H_2O$. The maximal value of x is equal to 2 according to the crystal structure examination by Jeffrey et al.[3] Thus, the following relation can be obtained with respect to the amount of alcohol existing in the solid phase:

$$\frac{M_{alc}x}{M_{TBA}+M_{alc}x+30M_{H_2O}} = \frac{w_s-Pw_l}{1-P}, \quad (2)$$

in which M_{TBA}, M_{alc}, and M_{H_2O} are the molecular weights of tetrabutylammonium salt, alcohol, and water, and w_s and w_l, are the weight fractions of the alcohol in the wet solid phase and in the liquid phase, respectively. These two weight fractions were

Table 3. The x Values Determined for All the Systems Examined

System[a)]	x	System[a)]	x
1	0.12±0.03	5	0.03±0.03
2	0.71±0.10	6	0.21±0.25
3	0.10±0.01	7	0.12±0.05
4	0.75±0.10	8	0.79±0.10

a) The number of systems is the same as listed in Table 1.

determined by the radioactivity measurements for both phases separated from each other by the same procedure as the process (4) in the previous section. From Eq. 2 we can get the following relation:

$$x = \frac{w_s - Pw_l}{1 - P - (w_s - Pw_l)} \cdot A, \quad (3)$$

where A is a constant calculated from the molecular weight of each component in ternary mixtures: A is equal to 25.03 for systems 1 and 2; 17.41 for systems 3 and 4; 26.72 for systems 5 and 6; and 18.58 for systems 7 and 8.

The values of x determined for all the systems are summarized in Table 3. These values are averages of 5—10 measurements. The limit of error attached to each x is estimated by taking into consideration the uncertainty of the P values (Table 2) and the error arising from the radioactivity measurements. In system 6 the deviation from the mean value is exceptionally large because of the difficulty to obtain a well-formed crystal in this system as partly exemplified by large P value for this system (Table 2).

From these results the following conclusions can be drawn:

(1) In the systems containing tetrabutylammonium fluoride (systems 1—4), both methyl and ethyl alcohols are intercalated within the hydrate solid.

(2) In the systems 1—4, the amounts of alcohol intercalated increase with increasing concentration of alcohol in the initial solutions, showing a feature characteristic of a nonstoichiometric inclusion compound. The increment of x is 5.9 times for methyl alcohol and 7.5 times for ethyl alcohol for the 10 times increment of the mole fraction of each alcohol, i.e., from X=0.01 to 0.10.

(3) For the systems 5 and 6, taking into account the relatively small values of x and the deviations from the mean values, it may be concluded that methyl alcohol is not intercalated within the tetrabutylammonium propionate hydrate.

(4) On the other hand, the values of x for the systems 7 and 8 clearly indicate that ethyl alcohol is intercalated within the tetrabutylammonium propionate hydrate. The values of x for the systems 7 and 8 are similar to those of the systems 3 and 4, respectively.

As mentioned in the introduction section, in the structure of the tetrabutylammonium fluoride hydrate[3] there exists a vacant space which is made of five pentagonal dodecahedra face-sharing with each other. However, this space must be appreciably deformed by the arrangement of other large polyhedra like tetrakaidecahedra and pentakaidecahedra which accommodate butyl groups of a tetrabutylammonium cation. The experimental above listed facts may be explained if we assume the presence of at least two types of pentagonal dodecahedra, i.e., geometrically highly deformed pentagonal dodecahedra which exist near the tetrabutylammonium cation (denoted by S-type hereafter) and geometrically less deformed ones which exist somewhat apart from the tetrabutylammonium cation (denoted by L-type hereafter).

Taking into account the fact that free diameter of a nondeformed pentagonal dodecahedron is about 5.2 Å[8] and the molecular diameter of methyl alcohol is about 5.2 Å and that of ethyl alcohol is about 6.3 Å, it will be reasonable to assume that methyl alcohol is enclathrated in the S-type pentagonal dodecahedra and ethyl alcohol in the L-type ones. This assumption means that the free diameter of the L-type pentagonal dodecahedron is elongated enough to accommodate an ethyl alcohol molecule. These assumptions lead to a conclusion compatible with the experimental facts: (1) since in the $(n\text{-}C_4H_9)_4NF$ hydrate the S-type pentagonal dodecahedron is vacant, it can enclathrate methyl alcohol; (2) however, the S-type pentagonal dodecahedron in the $(n\text{-}C_4H_9)_4NOOCC_2H_5$ hydrate must accommodate the C_2H_5 group of the $C_2H_5COO^-$ ion, it can enclathrate methyl alcohol no longer; and (3) since the L-type pentagonal dodecahedra are considered to be in a similar situation in both hydrates, their ability to enclathrate ethyl alcohol is expected to be similar in both hydrates.

Homogeneous Isomerization of 1-Butene Catalyzed by $[MX_2(PR_3)_2]$-$NaBH_4$ Systems (M=Co, Ni, X=Halides, SCN, $PR_3=PPh_nEt_{3-n}$)— Acceleration by Phosphine Addition and Stereoselectivity

Hiroyoshi KANAI,* Shigeyoshi SAKAKI,† and Takenobu SAKATANI††
Department of Hydrocarbon Chemistry, Faculty of Engineering, Kyoto University, Sakyo-ku, Kyoto 606
(Received October 2, 1986)

The stoichiometric or a little excess amount of $NaBH_4$ was treated with $[MX_2(PR_3)_2]$ (M=Co, Ni, X= halides, SCN, $PR_3=PPh_nEt_{3-n}$) in THF-1,2-dimethoxyethane to form monohydride species which were active for isomerization of 1-butene. The reaction was accelerated by excess PPh_3 in $[CoX_2(PPh_3)_2]$-$NaBH_4$ systems. Other catalytic systems have optimum ratios of excess phosphine to metal for getting maximum activities. Thiocyanate-metal complexes are the most active in each Co- and Ni-catalyst system. Cis-selectivity depends on the cone angle of PR_3, the size of anion ligands, and the congested structure of complexes.

Double bond migration of linear terminal olefins is homogeneously catalyzed by many transition metal catalysts.[1] Cocatalysts are frequently required: hydrogen,[2] acids,[3] and oxygenated compounds[4] have been used for heavy transition metal complexes to give metal hydrides. Alkylaluminum, Grignard reagents, and alkali metal alkyls and hydrides are effective cocatalysts for complexes of the first row transition metal complexes.[5]

We have found the isomerization of 1-butene catalyzed by $[MX_2(PR_3)_2]$ (M=Co, Ni, X=halogen, SCN, NO_3, CN, $PR_3=PPh_nEt_{3-n}$) with sodium tetrahydroborate as a cocatalyst. One of characteristic features in these systems is that *cis*-2-butene is preferentially formed to the trans-isomer. Another is that the more PPh_3 is added, the more the rates of isomerization increase in the cobalt system. Since rates and stereoselectivity are dependent on halogen ligands, active species are cobalt or nickel hydrides containing Co-X or Ni-X bonding.

Experimental

Materials. The 1-butene which was purchased from Takachiho Chemicals had a purity of 99.8%. Tetrahydrofuran (THF) and 1,2-dimethoxyethane (glyme) were refluxed over sodium and distilled before use. Cobalt and nickel halides were obtained from Nakarai Chemicals and used without purification. PPh_3 was recrystallized from methanol. Phosphines containing ethyl group were prepared by standard Grignard synthesis. $[CoX_2(PR_3)_2]$ (X=halides, SCN, $PR_3=PPh_nEt_{3-n}$, n=0—3) were prepared from cobalt halides and PR_3 in ethanol or acetone by the methods described in the literatures.[6] $[NiX_2(PR_3)_2]$ (X=halides, SCN, NO_3, CN) were similarly prepared from NiX_2 and phosphines in 1-butanol or ethanol according to the literatures.[7] Elemental analytical data of complexes agree with those of calculated values.

Procedure and Analysis. Three ml of THF solution of a cobalt or a nickel complex (0.1 or 0.15 mmol) and 2 ml of glyme solution of $NaBH_4$ (0.025—0.1 mmol) were placed in each 10-ml ampule connected with each other. 1-Butene (4.2 mmol) was added to the ampules which were degassed and chilled in liquid nitrogen. After they were sealed and stored at 0 °C, two solutions were mixed and allowed to stand at 0 °C for a given interval. The reaction was stopped by freezing the solution in liguid nitrogen and the reaction mixture was distilled rapidly in vacuo. The distillate was analyzed by a Shimadzu-6A gas chromatograph on a column packed with 30% dimethylsulfolane on Celite 545 (5.6 m) at r.t. The concentration of $NaBH_4$ in glyme was determined by the titration with 1/100 N HCl using Methyl Red as an indicator.

Results

Formation of Metal Hydrides and Their Catalysis. Anhydrous cobalt chloride dissolved in THF was reacted with $NaBH_4$ at 0 °C to yield black precipitates. They had very little activity for isomerization of 1-butene. The presence of hydrogen caused isomerization but less rapidly compared to hydrogenation.[8]

Cobalt halide complexes containing phosphine ligands such as $[CoCl_2(PPh_3)_2]$, were found to react with $NaBH_4$ to give green homogeneous solution, which effectively catalyzed isomerization of 1-butene. The rate of isomerization gradually decreased due to the decomposition of active species where cobalt metal began to be deposited. The decomposition was prevented by adding excess phosphine. A hydrogenated product, butane, was formed at the beginning of the rection, but the amount did not increase with the elapse of time. The ratios of *cis*-2-butene to the trans-isomer (abbreviated as c/t) remain constant until 1-butene has almost been consumed. Scrambling of 2-butenes was much slower compared to double-bond migration.

Effects of the Concentration of $NaBH_4$ on the Isomerization of 1-Butene Catalyzed by $[CoX_2(PPh_3)_2]$ (X=Halides, SCN). Sodium tetrahydroborate is nec-

essary for the formation of metal hydrides as active species. The effects of the ratio of $NaBH_4$ to cobalt complexes on the isomerization are shown in Fig. 1. In the case of $[CoCl_2(PPh_3)_2]$, the apparent rate, which is expressed as the conversion of 1-butene, increases proportionally with the increase of $NaBH_4$. The reaction at $H^-/Co=4$ proceeded in suspension from the beginning. The initial state of the reaction mixture was homogeneous at $H^-/Co \leqq 2$, and metal deposited at the end of the reaction at $H^-/Co \geqq 1$. The c/t ratio was almost independent of H^-/Co ratios. The rates reach maxima at nearly stoichiometric concentration of $NaBH_4$ to produce monohydride in cases of $[CoX_2(PPh_3)_2]$ (X=Br, I, SCN). The c/t ratios remain constant when H^-/Co is less than 2, but decrease at $H^-/Co>2$.

The amounts of butane produced are nearly proportional to the concentration of $NaBH_4$ for any complexes. They decrease in the order Cl>Br>I>SCN at the same ratio of $NaBH_4$ to the cobalt complex.

Similar effect of the $NaBH_4$ concentration was observed for $[CoX_2(PPh_nEt_{3-n})_2]$ (n=0—2) and $[NiX_2(PPh_nEt_{3-n})_2]$ (n=0—3) whereas H^-/M values giving maximum rates shift to somewhat higher ones than stoichiometry.

Effect of Addition of Excess Phosphine. The reaction mixture of Co-PPh_3 complexes at $H^-/Co \leqq 2$ was kept homogeneous for several hours after which metallic precipitates began to be formed. The addition of excess PPh_3 kept homogeneity throughout the reaction and accelerated the isomerization (Fig. 1). The low values of c/t in Fig. 1 (the dotted lines) indicate the completion of double-bond migration of 1-butene followed by the scrambling of 2-butenes. The dependence of the rate on H^-/Co is the same with and without excess PPh_3.

Rate Constants and Stereoselectivity in the Isomerization of 1-Butene Catalyzed by Co- and Ni-Phosphine Complexes. The isomerization was first order in 1-butene and the rates were proportional to the metal concentrations. The second-order rate constants, k', are expressed as follows:

$$\frac{-d[1\text{-}C_4H_8]}{dt} = k[1\text{-}C_4H_8] \quad (1)$$

$$k=k'[M] \quad (2)$$

where [M] stands for the concentration of metal complexes.

Cobalt catalysts, on the whole, are more active than nickel ones for the same ligands (Table 1, Fig. 2). $[Co(SCN)_2(PPh_3)_2]$-$NaBH_4$ system is by far the most

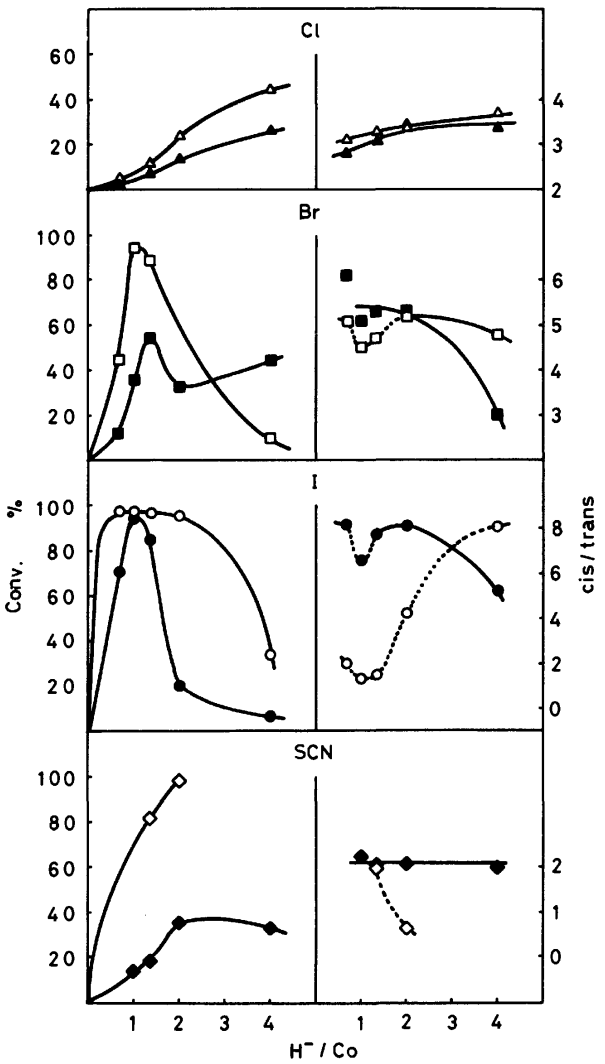

Fig. 1. The apparent rates and cis-selectivity of the isomerization of 1-butene by $[CoX_2(PPh_3)_2]$-$NaBH_4$ depend on the concentration of $NaBH_4$. [Co]=3×10^{-2} mol dm^{-3} (X=halogen), 8×10^{-3} mol dm^{-3} (X=SCN), [1-C_4H_8]=0.83 mol dm^{-3}. ▲■●◆: Without free PPh_3; △□○◇: free PPh_3/Co=2 (X=Cl, Br, SCN), 1.2 (X=I).

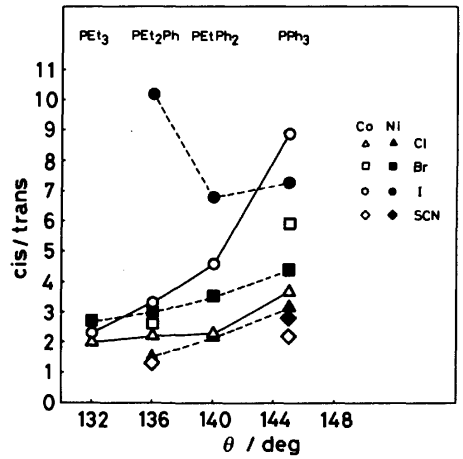

Fig. 3. Cis-selectivity depends on the cone angle of PR_3.

active among them, where a very small amount of excess PPh_3 increases the rate. The same tendency is observed for $[CoI_2(PPh_3)_2]$ system. A large excess of PPh_3 never retards the ismerization for all Co-PPh_3 complexes. However, a small excess of PPh_3 increases the rate, but a large excess retards the isomerization for Ni-PPh_3 complexes. The rates decrease in the order SCN>I>Br>Cl for cobalt catalysts, and SCN>Br>I>Cl>NO_3 for nickel catalysts. The substituents of ethyl group in PR_3 lower the rates and much more in nickel catalyst systems.

The c/t ratios which give a measure for stereoselectivity are dependent on both halogen and PR_3 ligands (Table 2, Fig. 3). The c/t ratio decreases in the order I>Br>Cl>SCN for Co-PPh_3 catalysts, and

I>Br>Cl>NO_3>SCN>CN for Ni-PPh_3 catalysts. Cis-selectivity increases with cone angle of PR_3 (Fig. 3). An exception is observed with $[NiI_2(PPhEt_2)_2]$-$NaBH_4$ system where the less stoichiometric ratio of H^-/Ni gives high cis-selectivity. The increase of H^-/Ni decreases the c/t ratio from 10.5 at H^-/Ni=0.6 to 3.3 at H^-/Ni=1. The effect of the change from Cl to Br and I on the cis-selectivity becomes less pronounced with the substituents of ethyl group of PR_3 for cobalt catalysts, but is magnified for nickel catalysts (numbers in parentheses in Table 2).

Discussion

Active Species. The stoichiometric amount of $NaBH_4$ to form cobalt monohydride species gives maximum rates for the isomerization of 1-butene catalyzed by $[CoX_2(PPh_3)_2]$-$NaBH_4$ systems (X=Br, I) (Fig. 1). Active species should be metal hydrides containing halogen ligands since cis-selectivity of 2-butene is dependent on halogen ligands.

$$[MX_2(PR_3)_2] + NaBH_4 \longrightarrow [MHX(PR_3)_2] \quad (3)$$
$$M = Co, Ni,\ X = \text{halogen, SCN},\ PR_3 = PPh_nEt_{3-n}$$

Metal hydrides are stabilized by phosphines which act as σ-donors and π-acceptors.[9] More basic phosphines strengthen M-H bonds[10] to give less active catalysts. The coordination number of PR_3 is mostly two, but exceptionally three (vide post).

The isomerization has occurred through a metal-hydride addition and elimination mechanism. A small amount of butane was formed in the beginning of reactions. The amount of butane decreases in the order, Cl(33)>Br(22)>I(22)>SCN(10) for $[CoX_2(PPh_3)_2]$, PPh_3(33)>PPh_2Et(16)>$PPhEt_2$(6)>PEt_3(8) for $[CoCl_2(PR_3)_2]$ and does not change regularly with anion or PR_3 ligands (17—33) for $[NiX_2(PR_3)_2]$ (the number in parentheses is the percentage of H^- (from $NaBH_4$) consumed into butane). No increase of butane during kinetic runs shows that butane was produced via Eq. 4 rather than Eq. 5.

$$M\text{-}R + H^-(\text{from } NaBH_4) \longrightarrow M(+M\text{-}H) + RH \quad (4)$$
$$M\text{-}R + M\text{-}H \longrightarrow 2M + RH \quad (5)$$

Rate Enhancement and Retardation by Excess PR_3. Phosphines are very convenient and efficient ligands for many homogeneous catalytic reactions.[11] The disadvantages are susceptibility of orthometallation[12] and the inhibition of reactions by excess phosphines.[13,14] Some reactions which need drastic conditions such as high temperatures contain excess phosphines to maintain catalytic species irrespective of lowering of rates.[14] Many catalytic reactions by transition metal phosphine complexes are retarded by a small amount of phosphines.[14,15] Here are presented two cases where (1) the more PR_3 is added, the more the reaction is accelerated, and (2) an optimum addition of excess PR_3 gives a maximum rate as is often observed.

Acceleration of reactions by excess phosphines has been rarely observed.[16] Cobalt(II) hydrides are too unstable to be isolated and identified due to thermal unstability and lability.[17] $[CoX_2(PPh_3)_2]$ are originally tetrahedral.[6] The stoichiometric amount of $NaBH_4$ reacts with $[CoX_2(PPh_3)_2]$ to give monohydrido-substituted complexes.[18] Since hydride is a strong σ-donor but halides are weak ones,[19] monohydridocobalt complexes may change their structure into square planar one.[20] The active species should be bis(triphenylphosphine)cobalt complexes which holds the same stereoselectivity with and without free PPh_3. Excess PPh_3 can stabilize unstable cobalt hydrides which are easily decomposed by dissociation of PPh_3,[6a,b] and prevent coupling of alkyl- and hydrido-metal complexes (Eq. 5). Accelerating effect per unit PPh_3 addition decreases in the order SCN>I>Br>Cl parallel to their soft character.[21]

Large excess of $NaBH_4$ gives $[CoH_3(PPh_3)_3]$ in Ar,[22] $[CoH(N_2)(PPh_3)_3]$ in N_2,[23] and $[Co(BH_4)(PPh_3)_2]$ and $[Co(BH_4)(PPh_3)_3]$.[17] These are assigned to be tri- and monovalent. $[CoX(PPh_3)_3]$ forms on standing of $[CoHX(PPh_3)_2]$ with PPh_3 in THF. A less bulky phosphine such as PMe_3 coordinates to Co(II) to give a five-coordinate complex, $[CoMe_2(PMe_3)_3]$.[24] The reason why the third molecule of PPh_3 does not coordinate to halogenohydridocobalt(II) complexes is not obvious, but steric bulkiness of ligands may prevent further coordination.[25] In fact, excess of less bulky phosphine, PPh_2Et, hinders the isomerization catalyzed by cobalt chloride system.

A small amount of PPh_3 accelerates but large excess inhibits the reaction in $[NiX_2(PPh_3)_2]$-$NaBH_4$ systems. The c/t ratio of nickel iodide system drops at H^-/Ni>1.3 due to the partial dissociation of PPh_3. The addition of 2 mol of PPh_3 maintains the c/t ratio of 7.3. However, large excess inhibits the reaction with the coordination site for 1-butene blocked by PPh_3.[26] Less reactivity of nickel systems may come from the strength of coordinated 1-butene onto the metal.[27] More basic phosphines retard the reaction and the tendency is pronounced for nickel catalyst systems. This is caused by the stability of hydrido and alkyl metal complexes as intermediates. Many σ-alkylnickel(II) complexes including PPh_3 were isolated and characterized,[28] but only a few alkylcobalt complexes with basic phosphines were identified.[20]

Cobalt catalysts are more active than nickel ones for the complexes with the same ligands. On the contray, $[(\eta^6\text{-toluene})Ni(C_6F_5)_2]$ is a very active catalyst for 1-butene isomerization, but the analogous cobalt complex is not.[29] The electronic state of metals reflects the strength of metal-ligand bonds[30] leading to different reactivity. It is interesting that a metal

complex is active but another is not where they are isostructural. It is very hard to expect which metal complex is active or not.

Stereoselectivity. Bulky phosphines and large-sized anions lead high cis-selectivity in the cobalt catalyst systems similar to $[NiX(PPh_3)_3]$.[15] Such tendency is not necessarily observed in the nickel catalyst systems. Nickel iodide complex with less bulky $PPhEt_2$ in the range of $H^-/Ni \leqq 0.6$ gives the highest cis-selectivity among Ni-catalyst systems. This is due to congested $[NiHI(PR_3)_3]$[26,31] which is formed from $[NiHI(PR_3)_2]$ and dissociated PR_3. A similar congested complex, $[CoH(N_2)(PPh_3)_3]$, gives high cis-selectivity (c/t=14) in the isomerization of 1-pentene.[32]

The atomic radius of cobalt is almost the same as that of nickel. The dependency of cis-selectivity on the metal (Table 3) is not due to the metal size. The strong σ-donor (the weak π-acceptor) character of phosphines and the soft character of anions lead the ratios, $(c/t)_{Co}/(c/t)_{Ni}$, less than unity. The electronic factor of these ligands may control stereoselectivity similar to the isomerization of 1-pentene with $[PdX_2(RCN)_2]$.[33]

Some nickel(I) complexes might be formed analogously to cobalt complexes.[34] Nickel(I) complexes effectively catalyze isomerization of olefins,[15] though cobalt(I) complexes do not. The c/t ratios in the isomerization of 1-butene catalyzed by $[NiX(PPh_3)_3]$ are 3.0, 3.7, and 8.1 for X=Cl, Br, I, respectively. The cis-selectivity is somewhat diffecrent from that by $[NiX_2(PPh_3)_2]$-$NaBH_4$ systems suggesting that Ni(I) species are rarely responsible for the reaction.

(Received October 8, 1986)

Raman spectra of alkaline metal doped polyacetylene were studied at various levels of doping for $(CHM_y)_x$, and $(CDM_y)_x$, M=Na and K, with y=0—0.18. Several steps in the doping process can be recognized in changes of the Raman spectra; the initial Raman lines remain for y=0—0.06 but change completely into a new pattern at y=0.13. Raman and ESR spectra of alkaline metal doped β-carotene were measured as a model study of the alkaline metal doping of polyacetylene. The correlation of these spectra together with the ab initio SCF MO calculation on model compounds show that a heavily alkaline metal doped polyacetylene chain does not have a uniform bond length structure but is composed of a charged soliton structure connected by a uniform chain. The new Raman bands were assigned based on this structure, implying that a bond alternation still exists in the metallic state of alkaline doped polyacetylene.

Raman spectra of neat and doped polyacetylene (PA) provide characterizing insight regarding the molecular structure of the polymer.[1] The change in the Raman spectra upon doping the polymer has been extensively investigated; however, only a relatively few studies have appeared which discuss the quantitative aspect of alkaline metal doping of PA.[2,3] Recently, Heeger et al.[4,5] discussed the structural change from a spinless soliton lattice to a metallic polaron lattice in alkaline metal doping of PA by an ESR measurement. In this paper we present Raman spectral evidence of a structural change occurring at a definite level of Na and K doping of $(CH)_x$ and $(CD)_x$. The Raman and ESR spectra of Na-doped β-carotene were measured; here, the structure of the anion radical is discussed in terms of an analysis of the hyperfine structure and chemical information. The structure of alkaline metal doped PA is considered from an ab initio SCF MO calculation of the model compound[6] and a close similarity of the Raman spectra between the Na doped PA and Na doped β-carotene. The present study gives information regarding the structural aspect of a heavily doped PA lattice and the nature of the structural change occurring in the doping of PA.

Experimental

Materials. Thin films of PA were synthesized by Shirakawa's method[7] on the inner surface of a quartz cell for UV, visible, near IR and Raman spectral measurements. Doping was carried out by the use of naphthalene anions in a dried THF solution. The film was immersed into the solution under a completely sealed condition and washed with THF for five to ten times until the solution became colorless. β-Carotene was recrystallized from benzene and stored under a nitrogen atmosphere.

Spectrometers. Visible and near IR spectra were measured by a Hitachi model 330 spectrophotometer (40000—4000 cm^{-1}). In situ doping and combined visible, near IR and Raman spectral measurements were carried out using a JEOL Model JRS 400T spectrometer with Ar-ion (Spectra Physics 164-05) and He-Ne lasers (Spectra Physics 125A) and a Varian Model 2300 spectrophotometer at the Instrument Center of Institute for Molecular Science (IMS). ESR spectra were obtained by a Varian E112 at X-band in IMS. IR spectra were measured with a Hitachi 230-50 spectrophotometer.

Analysis. The dopant content was analyzed by a flame analysis using an Evans Model 100 flame photometer. A radiation chemical analysis was performed with some films by Dr. Tohru Kishi of National Police Science Institute.

Conductivity. All conductivity measurements were carried out by a four-probe technique, and the mechanical pressed contacts were applied between the film and the Pt leads. The measurement was carried out down to 80 K in cold N_2 gas.

Results and Discussion

(1) Doping and Electronic Spectra. The visible and near IR spectra of PA are largely dependent on the concentration of the dopant in PA.[8-10] In order to estimate the doping level of the polymer, the visible and near IR absorption of Na-doped PA were measured at several concentrations of the dopant. The spectra were taken on different films of approximately the same thickness; the absorbance was recorded by normalizing the absorption peak of *cis*-PA at 18500 cm^{-1} to unity. The change in the spectra upon doping in the near IR region was recorded with reference to the peak intensity of an undoped *cis*-rich film. The dopant content was analyzed on each thin film; the thickness of the film was estimated before doping by the absorption intensity[11] and the total amount of PA was determined from the area and the thickness of the film. Then, the composition was determined on each film. The optical densities of the doped film were found to change with the dopant concentration.[10] It appears that the 6000 cm^{-1} band increases almost linearly, while the 18500 cm^{-1} band

also decreases linearly with the dopant concentration. A change in the spectra might be recognized as being due to a transition from the undoped *cis*-$(CH)_x$ to the doped state of PA. A doped film has a characteristic electronic absorption band at about the 6000 cm^{-1} region.[8] Another broad peak was recognized around the 38000 cm^{-1} region, which may indicate that the electronic structure of the polyene chain is completely changed. By the use of a linear relation[10] between the dopant concentration and the absorption intensities, the dopant level was estimated for each doped film in the following measurements. The ratio of the optical densities in the near IR region to the maximum in the visible region before the doping was used to estimate the dopant concentration at each stage of doping.

The change in the electronic spectra after compensation of the dopant by H_2O in the air is shown in Fig. 1. The spectrum of the cis-rich film before Na doping is shown by curve 0 and curve 1 is that of a heavily doped film. The vacuum system was leaked to 0.1 Torr (1 Torr=133.322 Pa) and the spectral change was recorded. The intensity of the 6000 cm^{-1} peak decreased and the 16000 cm^{-1} band increased by a reaction of the Na doped film with H_2O. After three hours the intensity at 6000 cm^{-1} almost disappeared and a new peak of the trans form was found at 16000 cm^{-1}; the cis-form band was not found. The result indicated that the cis-trans isomerization occurred completely by Na doping and that the trans film was obtained by a reaction of Na with H_2O. A side reaction, such as bond cleavage, was not involved since the spectral curve 7 (Fig. 1) was coincident with that of native trans film.

The origin of the 6000 cm^{-1} band is not unique; at the initial stage of doping, the so-called mid gap absorption was found in this region.[8] However, a heavily doped film may show broad absorption due to free carriers, as was observed in the case of an I_2 doped PA film.[12] A distinction between the two origins is not easy; however, the predominance of the mid gap band in the initial stage and the free carrier in the final stage was confirmed by reflectivity measurements as well.[9]

(2) Near IR and Raman Spectra of Doped *trans*-$(CH)_x$. Measurements of near IR absorption and Raman spectra of doped PA films were carried out systematically with in situ doping and monitoring of

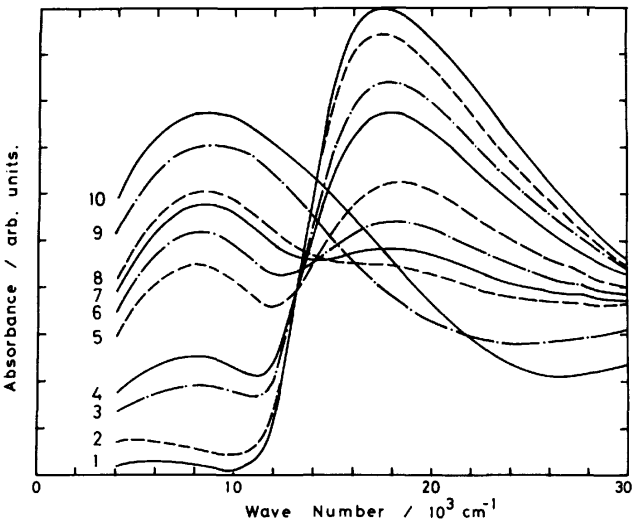

Fig. 2. Absorption spectra of the same thin *trans*-PA film doped with Na. The numbers of the curves correspond to the doping level y in $(CHNa_y)_x$; (1) y=0, (2) y=0.015, (3) y=0.036, (4) y=0.047, (5) y=0.085, (6) y=0.095, (7) y=0.108, (8) y=0.114, (9) y=0.133, and (101) y=0.146.

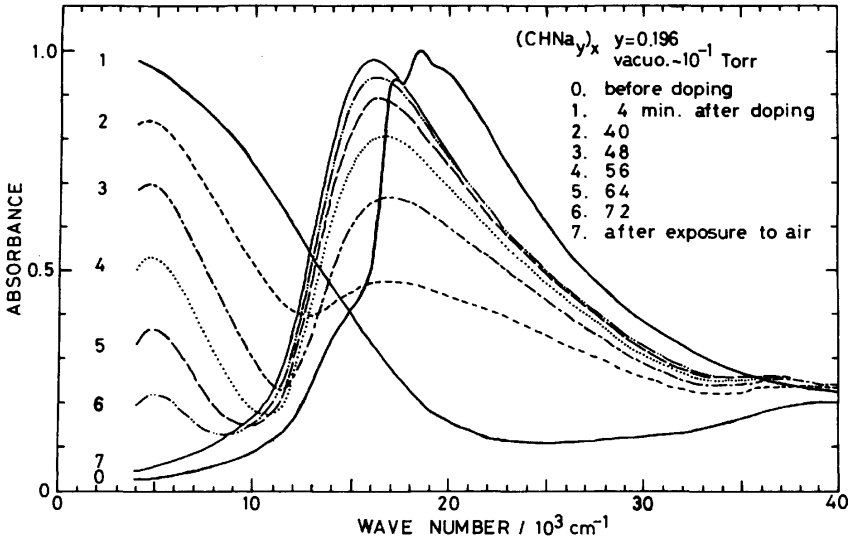

Fig. 1. Absorption spectral change of Na doped as grown $(CH)_x$ film after exposing to the keak of air. (0) undoped film, (1) doped film, after 4 min, (2) 40 min, (3) 48 min, (4) 56 min, (5) 64 min, (6) 72 min, (7) 3 h. exposing to the air.

the dopant level. Figure 2 illustrates changes in the near IR spectra of *trans*-$(CH)_x$ film upon Na doping at each stage; cruve 1 is for undoped *trans*-PA and 10 is for heavily doped film. Two isosbestic points were found in the series of spectra; the first one appears at 13200 cm^{-1} in the initial stage (y=0—0.05; y refers to atomic composition in $(CHNa_y)_x$) and the second one was observed at 14000 cm^{-1} in the intermediate stage (y=0.08—0.11). The same PA film was used for all measurements. These isosbestic points could be clearly found for initially isomerized trans-film; if we use a cis-rich film, the cis-trans isomerization process is involved which shows another spectral change. The appearance of two distinct isosbestic points may imply that the doping proceeds through several steps, and that it is consistent with electrochemical doping results,[13] where several reduction potentials were observed for the doping process of y=0—0.18.

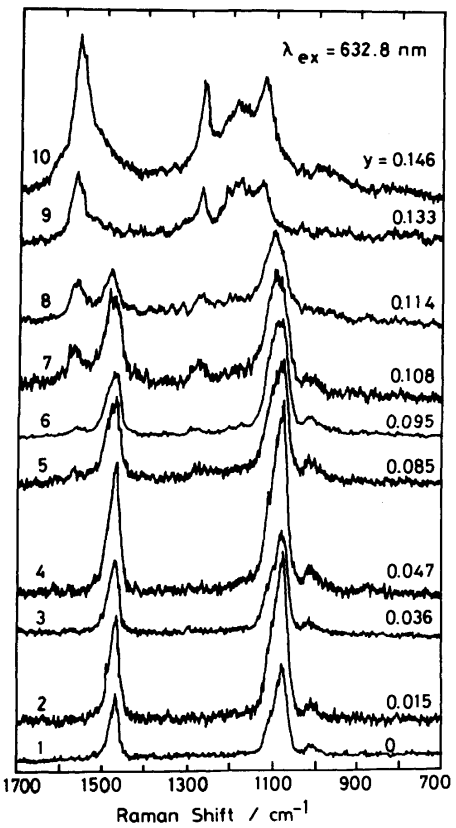

Fig. 3. Raman spectra of thin *trans*-$(CH)_x$ film doped with Na; the composition is shown by the value of y in $(CHNa_y)_x$.

The Raman spectra measured at 632.8 nm (15803 cm^{-1}) excitation are shown in Fig. 3, where the excitation wavelength is selected so as to obtain optimum efficiencies to both the undoped and doped part of PA. The undoped part showed an absorption peak at 18500 cm^{-1}. On the other hand, the doped part displayed an absorption peak at 6000 cm^{-1}, only a post resonance condition is realized by 15803 cm^{-1} excitation. In spite of this, the excitation at 632.8 nm is the best means to find any structural change during the doping process by the Raman spectra. This is because short-wavelength excitation shows little efficiency to the Raman bands of the doped part of PA.

Figure 3 shows that the characteristic Raman bands of *trans*-PA at 1470 and 1080 cm^{-1} did not change at all during the initial stage of doping (curves 1—4). In contrast with this, the characteristic absorption band in the near IR region increased linearly with the dopant; therefore, it is suggested that the skeletal conformation of PA is not significantly changed from the initial structure during the first stage of doping except for the local region where Na is coordinated. The structure of the metal coordinated chain is found by a theoretical calculation[6] (Fig. 4); this particular structure may be called a charged soliton structure in the following discussion. For a light doping level, charged soliton structures are formed in pairs, since no spin susceptibility has been found and such a structure has been called bipolaron.[8,14] The singlet state is obtained by putting two charged soliton structures at distant positions of the conjugated chain with an inversion symmetry; such a chain may give Raman spectra that are almost the same as that of undoped PA.

In the spectra of an intermediate stage of doping (Fig. 3, curves 5—8), new Raman lines appear at 1560, 1275 cm^{-1} etc.; however, a reminiscence of the initial lines suggests that the lightly doped bipolaron structure coexists with the new structure at this stage ($0.08<y<0.11$). The intensities of the new and initial

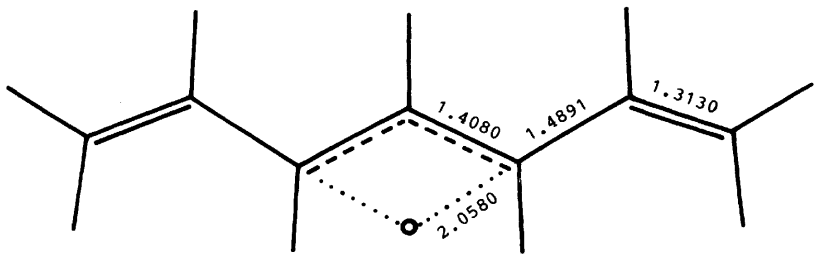

Fig. 4. A model of charged soliton structure, C_7H_9LI, estimated by ab initio SCF MO calculation.

bands are almost equal at y=0.114; the spectra changed completely to a new form above y=0.133. The new structure shows strong peaks at 1570, 1275, 1180, and 1125 cm^{-1} and weak ones at 1040 and 900 cm^{-1}. The transition to the new form may be completed at y≈0.13; the critical point to the new form may be at y=0.12—0.13.

The changes in the visible, near IR and Raman spectra with K doping were almost the same as that of Na doping. The Raman spectrum of a heavily K-doped $(CH)_x$ film showed a peak at 1560 cm^{-1}, about 10 cm^{-1} lower compared to the Na doped film. This result indicates that the 1560 cm^{-1} band is closely connected with the charged soliton structure, since the position is affected by the kind of coordinated metal atom.

(3) Doping and Spectral Changes of *trans*-$(CD)_x$. Changes in the visible and near IR spectra of Na doped *trans*-$(CD)_x$ were measured (Fig. 5). The 18500 cm^{-1} band decreased and the 6000 cm^{-1} band increased as the doping proceeded. Isosbestic points were found at 12500 and 14000 cm^{-1}, as detected in $(CH)_x$ film. The dopant level in $(CD)_x$ was similarly estimated as for $(CH)_x$ film using a calibration curve.[10] The change in the Raman spectra with increasing dopant concentration is illustrated in Fig. 6. The critical point of the Raman-spectral change is much clearer for $(CD)_x$ than $(CH)_x$; the Raman band did not change for y=0—0.09 (curves 1—4) and the transition state appeared at y=0.113 and then changed drastically at y=0.13. The transition from the initial state to the new form occurred rather suddenly and the critical concentration was almost same as $(CH)_x$ at y=0.12.

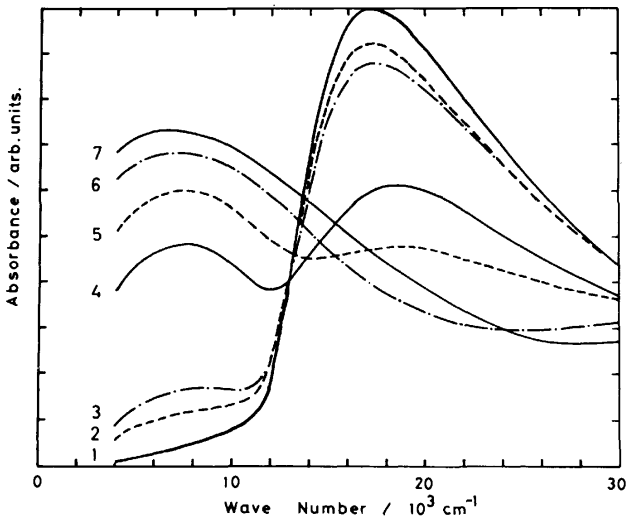

Fig. 5. Absorption spectra of *trans*-$(CD)_x$ film doped with Na. The numbers of absorpiton curves correspond to the content of Na in $(CDNa_y)_x$; (1) y=0, (2) y=0.023, (3) y=0.031, (4) y=0.090, (5) y=0.113, (6) y=0.129, and (7) y=0.140.

The Raman bands of a heavily K-doped $(CD)_x$ film were found at 1500 and 900 cm^{-1}, which were 20 cm^{-1} lower and 10 cm^{-1} higher than the bands of $(CDNa_y)_x$. This result is consistent with the previous argument that these bands are associated with the metal coordinated charged soliton region.

(4) Change of Electronic and Raman Spectra in Na Doping of as Grown $(CH)_x$ and $(CD)_x$ Films. An as-grown $(CH)_x$ film by Shirakawa's method is obtained as a cis-rich form but the isomerization to the trans form occurs to some extent at ambient temperature. The Na doping of a cis-rich film accelerates isomerization to the trans form. The Raman spectra may show the process of a cis-trans isomerization and a transformation to the new form. The change in the visible and near IR spectra of a cis-rich film were measured during Na doping; apparent isosbestic points were found at 14300 cm^{-1} for y=0—0.05 and at 14800 cm^{-1} for y=0.08—0.13. The Raman spectra of the doped cis-rich film were measured and the characteristic cis peaks disappeared almost completely at y=0.10; a new peak appeared at y=0.13 and a transition to the new form occurred at y=0.15 and completed at y=0.17. The critical concentration for this transition was relatively higher than the case starting from a pure trans film.

The changes in the Raman spectra of an as-grown $(CD)_x$ film by Na doping were also measured with the

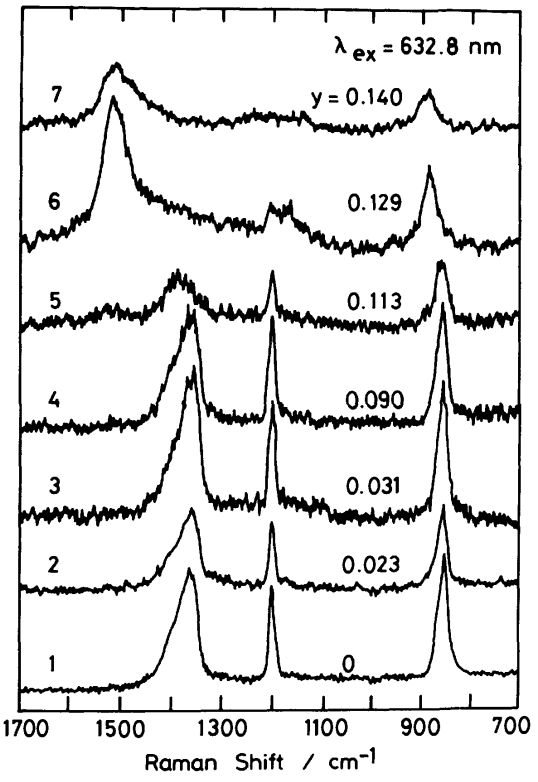

Fig. 6. Raman spectra of *trans*-$(CD)_x$ film doped with Na. The content of Na is shown by y value in the figure.

same film at various stages of doping from $y=0$ to $y=0.18$. The cis-trans isomerization was completed at $y=0.11$ and the new lines were found at $y=0.14$; the transition to the new form was complete at $y=0.18$.

(5) Dispersion of Raman Lines by Changing Excitation Wavelength. The dispersion of the Raman spectra upon changing the excitation wavelength has been found for a *trans*-PA film[1,15-17]; however, it has been explained by an inhomogenous distribution of the chain length of the polymer.[1] Dispersion effects were also found for Na-doped ($y=0.11$ and 0.13) and K-doped ($y=0.15$) *trans*-$(CH)_x$ film. The presence of two forms at $y=0.11$ and 0.13 was clearly indicated by changing the excitation wavelength. The film with $y=0.11$ showed only initial PA lines upon 488.0 and 514.5 nm excitations since the content of the new form was too small. The film with $y=0.13$ showed a new band by 632.8 nm excitation and the initial band which was at 1520 cm^{-1} (514.5 nm) and 1525 cm^{-1} (488.0 nm excitation), considerably higher than the initial PA band. The completely transformed film with $y=0.15$ showed no initial lines, even upon short wavelength excitation. A slight dispersion of the 1555 cm^{-1} line was found at 1585 cm^{-1} (514.5 nm) and 1590 cm^{-1} (488.0 nm).

The dispersion effect was also measured for the film with $y=0.13$ of *trans*-$(CDNa_y)_x$ and $y=0.18$ of initially cis film. Upon short wavelength excitation of $y=0.13$ film, the 1450 cm^{-1} band of a relatively short conjugated double bond was found to be rather strong; however, under 632.8 nm excitation the same film exhibited only Raman lines of the new form. In contrast, the heaviest doped film showed only the new lines under excitation at any wavelength, implying that the PA chain was completely trans formed into the new form. The Raman lines showed a dispersion effect upon changing the excitation wavelength: 1555 cm^{-1} (457.9 nm), 1541 cm^{-1} (514.5 nm), and 1515 cm^{-1} (632.8 nm), respectively.

The dispersion relation upon changing the excitation wavelength for $y=0.11$ as-grown film was almost the same as that of the undoped trans film. However, those for the $y=0.17$ as-grown film showed almost a new form; but a small fraction of the trans form was observed under 457.9 nm excitation. The completely transformed as-grown $(CDNa_y)_x$ film ($y=0.18$) showed a small dispersion effect upon changing the excitation wavelength.

(6) DC Conductivity Measurement of Na Doped as Grown $(CH)_x$. The room-temperature d.c. conductivity of a Na doped as-grown PA film was measured as a function of y. The conductivity increased rapidly from $y=0$ to 0.03 and saturated at about $y=0.10$. The maximum conductivity was 72 S cm^{-1} at 295 K for a film with $y=0.18$ The temperature dependence of the conductivity was measured and plotted for $1/T$ (Fig.

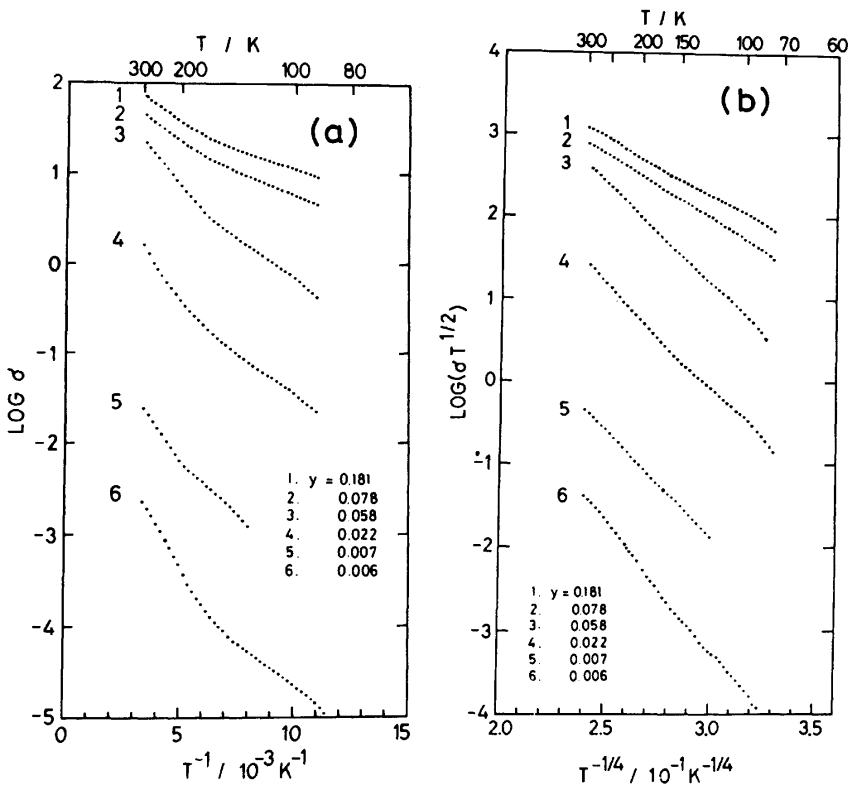

Fig. 7. Temperature dependence of conductivity of Na doped $(CH)_x$; (a) log σ plot for $1/T$, (b) log σ $T^{1/2}$ plot for $T^{-1/4}$; the doping levels are shown in the figure.

7(a)). Also, the activation energies were estimated from the initial slopes; the values were about 0.1 eV for lightly doped films and 0.03 eV for $y=0.18$. A plot of log $(\sigma T^{1/2})$ against $T^{-1/4}$ gave a straight line (Fig. 7(b)). Mott's variable range hopping model[18] could be applied for an analysis of the conduction mechanism. The parameters by this analysis are shown in Table 1, where $T_0=16\,\alpha^3/k_B N(E_F)$ and α^{-1} is the decay length of a localized state. These values are comparable to the values reported for I_2 and $FeCl_3$ doped $(CH)_x$.[19,20]

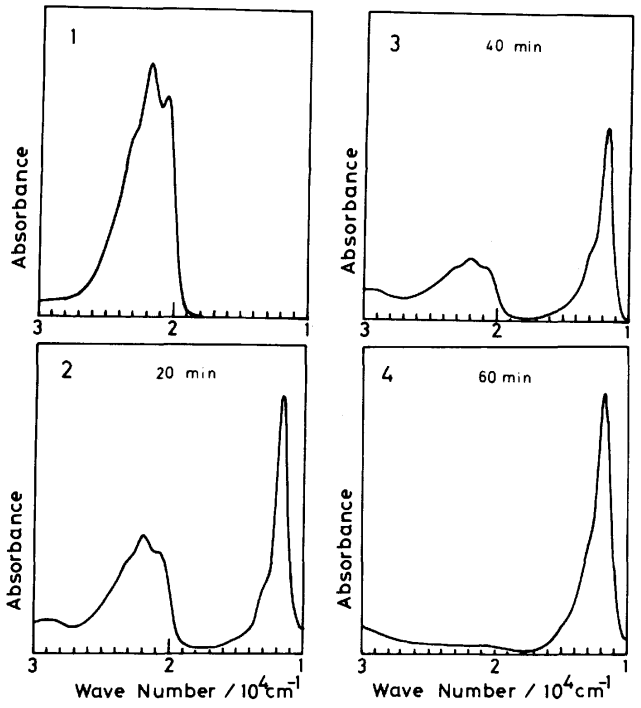

Fig. 8. Absorption spectral changes of β-carotene with Na doping. (1) undoped β-carotene, (2) 20 min, (3) 40 min, (4) 60 min, after doping. (Absorbances are given in arbitrary unit).

(7) Electronic, ESR and Raman Spectra of Na Doped β-Carotene. The characteristic absorption spectra of β-carotene in the visible region was changed upon Na doping (Fig. 8). As the doping proceeded the absorption band around 20000 cm^{-1} decreased and

Table 1. Parameters for Mott's Variable Range Hopping Model

y	σ(300 °K)/S·cm^{-1}	$T_0/10^6$ K°	A/10^7 S·cm^{-1}·K$^{1/2}$
0.181	72	1.2	0.34
0.076	44	1.5	0.38
0.056	22	12	62
0.022	1.7	15	7.5

The conductivity σ is given by a formula $\sigma(T)=AT^{-1/2}\exp(-(T_0/T)^{1/4})$, and $A=0.39(N(E_F)/\alpha k_B)^{1/2}\nu_0 e^2$ where ν_0 is optical phonon frequency.

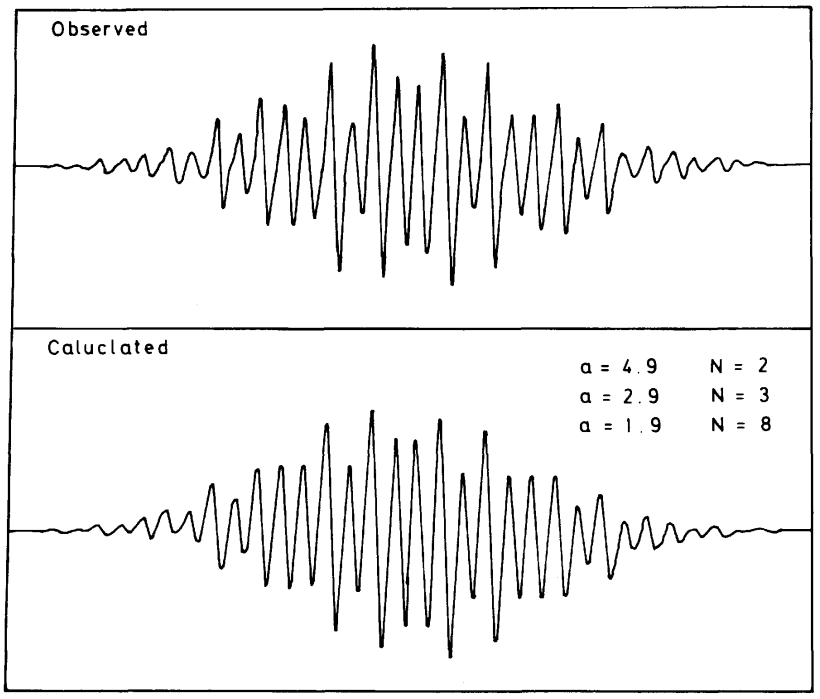

Fig. 9. ESR spectra of Na doped β-carotene in THF solution. Upper curve is the observed ESR spectra by low resolution and the lower one is simulated ESR spectra.

new bands were found at around 12000 cm^{-1} as well as another broad one at a higher energy region. The tail of the higher energy band was found around 30000 cm^{-1}. The ESR spectra of Na-doped β-carotene in a THF solution at low and high resolution were measured (Fig. 9(a)) and the low-resolution spectra were simulated (Fig. 9(b)) by the following coupling parameters: two protons with a_H=4.9 Gauss, three protons with a_H=2.9 Gauss and eight protons with a_H=1.9 Gauss. The agreement between the calculated and the observed spectra are quite satisfactory. In these simulations, the ESR hyperfine structures could be explained by assuming the coupling of an unpaired electron with thirteen hydrogen atoms; this result is important when considering the structure of Na-doped β-carotene.

In order to determine the structure of doped β-carotene, the reaction product of β-carotene with Na was decomposed with H_2O; also, a mass spectral analysis was performed on the product. It showed that eight hydrogen atoms reacted and that the positions of the coordinated alkaline atoms were guessed (Fig. 10(a)) since the mass spectra indicated a fragmentation of the hydrogenerated compound at these positions. This part of the experiment was carried out by Mr. H. Ozeki under the guidance of Dr. M. Kitamura of Prof. Noyori's laboratory. The electrochemical reduction potentials of β-carotene in the THF solution also indicated that the reaction took place to the level of a four-electron reduction.[21] Then, the structure of the radical, which was found in THF solution, is considered as shown in Fig. 10 (b); the localization of the unpaired electron over the chain of nine carbon atoms can be naturally understood by this structure.

The Raman spectra of Na doped β-carotene in a THF solution were significantly changed by the wavelength of excitation (Fig. 11). This result implies that the solution includes both forms shown in Fig. 10 (a) and (b) and that a doped molecule has several chromophoric groups. The Raman spectrum at 457.9 nm excitation was compared with that of the

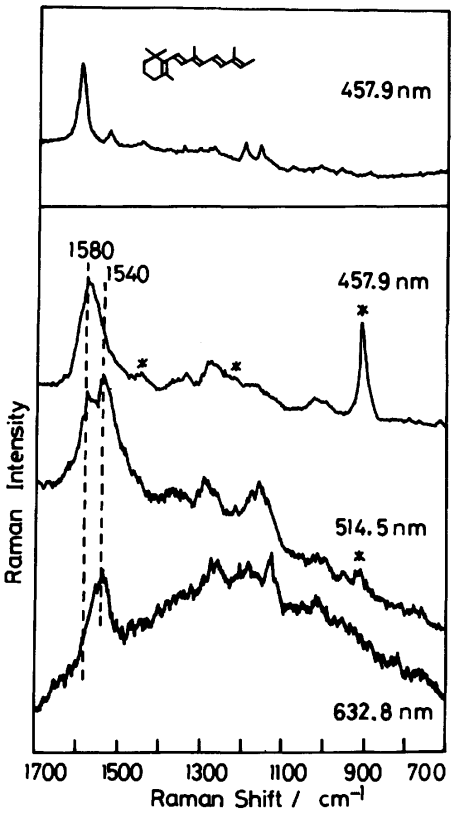

Fig. 11. Raman spectra of Na doped β-carotene and axerophten. The top curve is that of axerophten and the upper one is that of Na doped β-carotene, which are excited by 457.9 nm. The middle curve and the bottom one are Raman spectra of Na doped β-carotene excited by 514.5 and 632.8 nm, respectively.

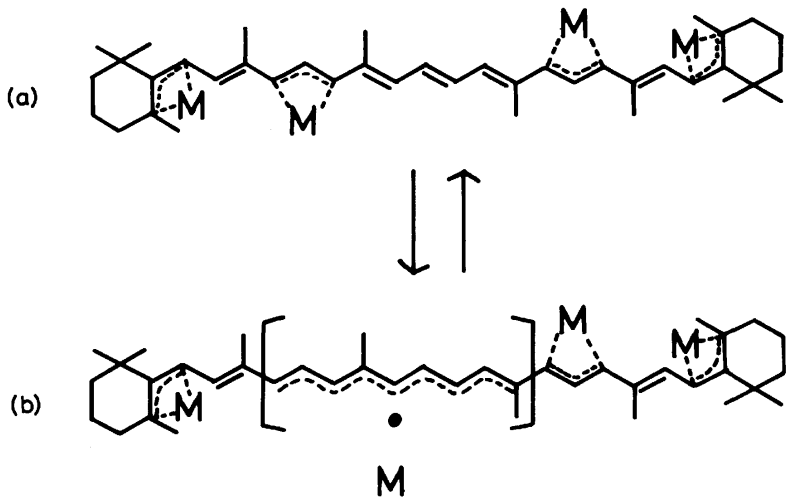

Fig. 10. Equilibrium structures of alkaline metal doped β-carotene.

model compound, axerophten[22], which was kindly prepared by Prof. K. Yamada and Mr. H. Kigoshi of this Department (Fig. 11). The similarity between the two spectra strongly suggests that the doped β-carotene has a partial structure of a short conjugated chain. Regarding SO_2 doping of β-carotene, Harada et al.[1] proposed that the molecule has a shortened double bond system, which is consistent with the present result. By considering these experimental results, the molecular structure of Na-doped β-carotene could be guessed by a formula (a) (Fig. 10).

(8) Structure of Alkaline Metal Doped Polyacetylene. Although a PA film comprises many fibrils and a lightly doped film is never homogeneous, alkaline metal doping proceeds through several stages, implying that a definite conformation exists for each doping step. From the present result and electrochemical studies,[13] three stages are conceivable for the doping process. When the dopant concentration is dilute ($y<0.06$), the doped PA chain can have a charged soliton structure (Fig. 12(a)) in which a bipolaron with about twenty carbon atoms between metal atoms can be formed at first. At a higher dopant level, the PA chain has one Na atom for about six carbon atoms ($y=0.16$) and the chain has unpaired electrons. (Fig. 12(b)) In the intermediate regime ($y=0.06$—0.12) both forms can coexist.

The result of an ab initio SCF MO calculation on the model compound, dilitiopolyenes,[6] is useful for determining the structures of a bipolaron and a heavily doped PA chain. The structure of the singlet state of dilithiopolyene represents a model of the bipolaron structure (Fig. 12 (a)). The triplet state has a unique structure in which a charged soliton structure and a chain without bond alternation are sequentially connected (Fig. 12(b)). Such a structural characteristic was already envisaged in the proposed model of β-carotene anion radical, in which the radical chain is conjugated with a charged soliton structure.

A structural feature of the charged soliton calculated by ab initio SCF MO is represented in Fig. 4; one Li atom coordinates to the end two carbon atoms in a three-carbon chain, the bond alternation being lost in the central coordination region which has an intermediate bond length with weak adjacent bonds. Then, the next adjoining bonds are strong (bond lengths are long and short). The planarity of the conjugated chain including the CH bond is lost ; the effect of coordination is rather limited within the region shown in Fig. 4. The coordinated Li atom forms a domain wall separating the conjugated chain into regions of different phases. Such a characteristic structure of a charged soliton is always found in both the singlet and triplet states of dilithiopolyene and the doublet state of lithiopolyene. In the singlet state such structures are connected by the normal conjugated double bond with an inversion symmetry in the center of the chain and the conjugation between the soliton structure is extended for long range (Fig. 12(a)). This reduces the Raman frequencies to the value of the extended long chain. In the triplet state the charged soliton structures are connected by a uniform bond length chain and the conjugation between the double-bond units are lost (Fig. 12(b)). This difference in conjugation mode is the origin of a drastic change in the Raman spectra from the initial to the final doped level and in magnetic properties during doping. In the intermediate stage of doping, both structural characteristics can coexist, rather than another structure being involved. This is because the Raman spectra exhibit only the mixed bands of the initial and the final structures (Figs. 3 and 6).

(9) Assignment of Vibrational Bands. The neat *trans*-PA has an alternating double bond structure; the double and single bond lengths are estimated as 1.36

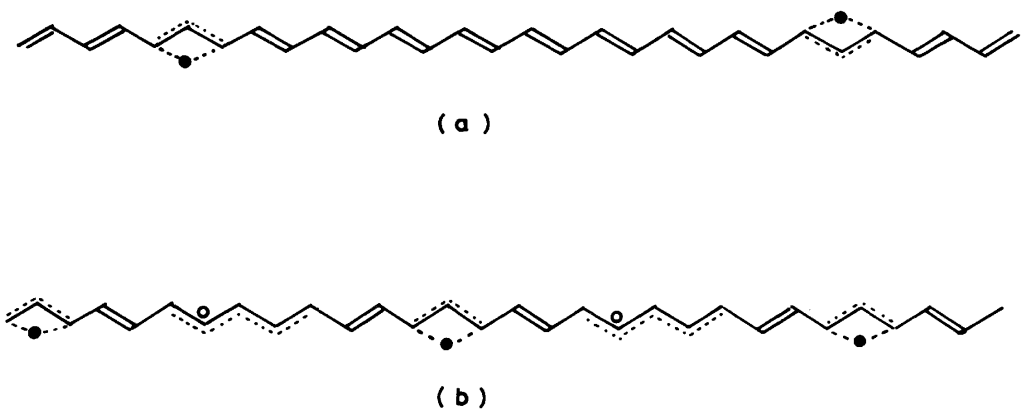

Fig. 12. Proposed model structures of (a) the lightly doped chain (charged soliton pair (bipolaron)) and (b) the heavily doped *trans*-PA chain. The filled circle (●) represents the coordinated alkaline metal ion, and the open circle (○) implies the coordinated alkaline metal atom.

and 1.44 A, respectively.[23] A normal coordinate analysis on Raman bands of *trans*-PA was recently presented by Takeuchi et al.;[24] the 1470 cm^{-1} band and 1079 cm^{-1} band of $(CH)_x$ were assigned to the coupled modes of the -(C=C)- stretching and the C-H in plane bending and the weak band at 1295 cm^{-1} was assigned to the stretching of the -(C-C)- single bond.

In the lightly doped *trans*-PA chain, a pair of soliton structures (bipolaron) were formed (Fig. 12(a)); this particular structure may have characteristic IR and Raman bands. In the IR spectra of Na-doped PA reported by Francois et al.[25] an intense band was observed at 1410 cm^{-1}, weak bands at 1250 cm^{-1}, and broad strong bands below 1100 cm^{-1}. In the IR spectra of Li-doped PA measured by us (Fig. 13), strong peaks were found at 1420 cm^{-1}, a weak one at 1250—1280 cm^{-1}, another weak one at 1160 cm^{-1}, and fairly strong bands below 1060 cm^{-1} at 1060, 950, 830, and 650 cm^{-1}. These band characteristics are common to the n- and p-doped PA;[8] therefore, they may be regarded as the charged soliton characteristic band.

The IR absorption bands associated with the charged soliton are not a simple atomic vibration in the usual sense; this is because the atomic vibration is strongly coupled with the charge flow along the chain and the intensities are extraordinaly large compared to usual infrared absorption of the polymer. In the theoretical treatment of the IR absorption of charged soliton by Horovitz[26], Wada and Terai et al,[27] and Mele and Hicks[28] several in-plane vibrational modes were considered to couple with electron. We suppose that the CH bending and several C-C stretching vibrations around the metal coordinated center are coupled. The prominent IR band at 1400 cm^{-1} is assigned to the C-H in plane bending of the charged soliton structure, because it is largely shifted by deuteration[29,30] and the peak position is dependent on the metal species. The weak 1250—1280 cm^{-1} IR band may be the coupled mode of several C-C stretchings around the charged soliton and the strong band around 1050 cm^{-1} region may be another coupled mode of C-C stretchings.

The Raman spectra of the lightly or medium doped $(CH)_x$ and $(CD)_x$ did not show any characteristic band of the charged soliton. This is because the electronic absorption band of the charged soliton lies in the near IR region and the resonance condition is not satisfied even under 632.8 nm excitation. Also, the short double bonds in the charged soliton structure are coujugated with the chain of a double-bond system in the bipolaron structure; it may give the vibrational mode of the long chain. In the heavily doped regime, the charged soliton structure is rather isolated (Fig. 12(b)) and the Raman bands of the charged soliton may be found at 1570 and 1125 cm^{-1} in addition to the 1270 and 1180 cm^{-1} bands.

Zannoni and Zerbi[31] discussed the vibrational modes of doped PA from a symmetry consideration regarding defect structure and a selection rule. They argued that a C_{2v} local symmetry of the charged soliton is rather unlikely compared to the centro-symmetrical defect structure of C_{2h} symmetry. In our analysis, the charged soliton structures might have appeared in pairs by forming a bipolaron during the

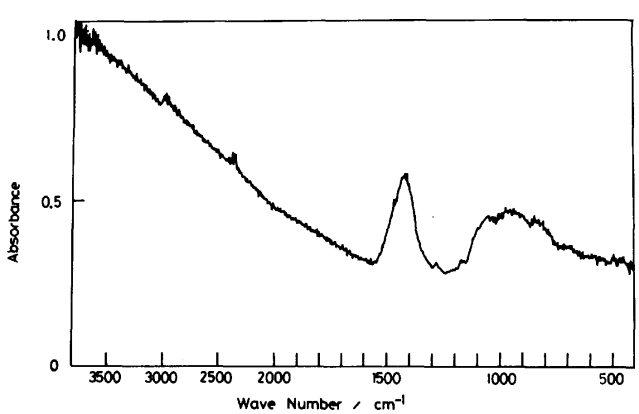

Fig. 13. Infrared spectrum of Li doped thin $(CH)_x$ film.

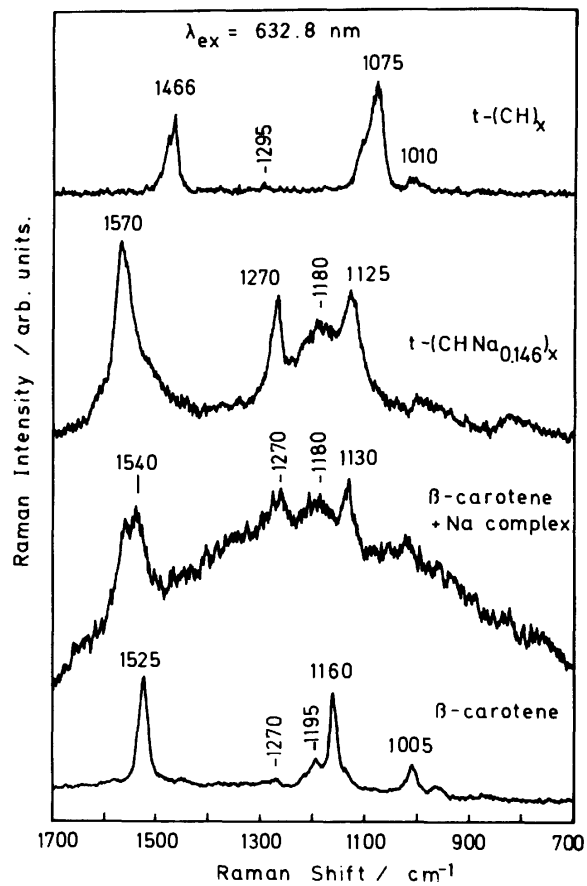

Fig. 14. Comparison of Raman spectra of *trans*-$(CH)_x$, the Na doped film and doped and undoped β-carotene.

early stage of doping; therefore, a center of symmetry is expected in the middle of the conjugated chain and the mutual exclusion of IR and Raman bands may be reasonably understood.

The Raman spectra of a heavily doped $(CH)_x$ film showed a drastically different behavior: -(C=C)- double bond stretching appeared at a higher frequency (1570 cm^{-1}) and CH bending also shifted to the higher side (1125 cm^{-1}). Also, strong Raman bands could be observed at 1270 and 1180 cm^{-1}; the former may be associated with -(C-C-C)- stretching in the center of the charged soliton structure and the broad 1180 cm^{-1} band may be the stretching of the -(C-C-C)- bond in the uniform bond chain. Both bands could be weakly observed in the IR spectra of Li doped PA (Fig. 13). This result is consistent with the selection rule, since an inversion symmetry is lost in the triplet chain model shown in Fig. 12(b) and a local symmetry of C_{2v} may be valid. The observed high-frequency shift can be reasonably explained by the model structure of triplet dilithiopolyene (Fig. 12(b)), where the short double bonds are connected with a uniform chain. In this conformation the cojugation with another double-bond system is interrupted. Takeuchi et al.[24] discussed the relationship between the $-(C=C)_n-$ stretching frequency and the number of double bond units n in a neutral trans-polyene chain. Following their calculation, the observed Raman band at 1540 cm^{-1} in heavily doped PA corresponds reasonably to the ethylenic double bond (Fig. 12(b)).

The similarity of Raman spectra for heavily Na doped *trans*-PA and Na doped β-carotene excited by 632.8 nm is very remarkable when compared it in the same chart (Fig. 14). Skeletal vibrations of -(C=C)- bonds and CH bending modes were found at almost the same position in both spectra; also, the positions of new -(C-C-C)- modes were also the same. Such a close agreement might be explained only when similar backbone structures are involved. The structures of Na doped β-carotene shown in Fig. 11 have an isolated butadiene or ethylene-type skeletons and the uniform radical type chain, and these characteristics are also apparent in the model structure of Fig. 12(b). Following the calculation of Takeuchi et al.[24] the 1580 cm^{-1} band in doped β-carotene might be related to the butadiene or hexatriene skeletons. The observed band positions by 457.9 and 632.8 nm excitation may correspond to butadiene and ethylene type bonds; the observed values are in good agreement with their calculation.

The Raman and IR spectra of Na, K, and Li doped PA at various levels of doping showed that a characteristic structural change from the charged soliton lattice to the new structure occurred in the heavily doped regime. The new structure comprised both charged soliton and the uniform chain units. The structural transformation observed by Raman spectra is in accordance with electrochemical results[13] and ESR experiments.[4,5]

A transition to the new structure started at about $y \approx 0.08$, and was completed at about $y \approx 0.13$ level in $(CH)_x$; this is in partial agreement with ESR results.[4,5] It occurred rather sharply at $y=0.11$ in $(CD)_x$. A simple model of a one-dimensional metal of uniform bond was not substantiated in the present analysis since the Raman spectra of a heavily doped film showed a pattern of isolated short double bonds. In the Raman spectra of the polymethine cyanine dye[32] studied in this laboratory, the skeletal stretching mode of the uniform -(C-C-C)- bond was found at the 1300 cm^{-1} region; this may correspond to the 1280 cm^{-1} band in heavily doped PA. A theory of a polaron metal was presented by Kivelson and Heeger,[33] however, a structural view regarding the polaron lattice was not clearly described. The present structure may afford a model of the regular polaron lattice which was considered in their treatment.

The most important consequence of the present result is that the heavily doped chain is composed of a twill unit comprising a charged soliton structure and a uniform chain unit in an alternating sequential way. Further investigation concerning other aspects of the structure may be required in order to clarify details of the physicochemical properties of doped PA.

All Raman measurements were carried out at the Instrument Center of the Institute for Molecular Science. A part of this study was a joint research program at IMS. We are grateful to the Director General Professor Saburo Nagakura and Professor Iwao Yamazaki for the joint program. A part of this work was supported by a grant in aid of the Ministry of Education (No. 61103003) for organic thin films for information conversion. We also thank Professors Ryoji Noyori and Kiyoyuki Yamada and Dr. Masato Kitamura, Messrs. Hideo Kigoshi and Hiroyuki Ozeki for their help during the experiment and to Dr. Tohru Kishi of the Institute of National Police Science for the radiation chemical analysis.

Epitaxial Growth and Its Growth Mechanism in Physical Vapor Deposited Films of Alkyl Octadecanoates

Michiko TAKAMOTO, Seiji OGIHARA, Kiyoshi YASE,* and Masakazu OKADA
Faculty of Applied Biological Science, Hiroshima University,
2-17 Midori-cho, Fukuyama, Hiroshima 720
(Received October 28, 1986)

Esters of octadecanoic acid and three primary alcohols such as methanol, ethanol, and propanol were deposited on substrates of potassium chloride (KCl), mica and amorphous carbon film under vacuum. The surface morphology of their films was observed by transmission electron microscope. They grew epitaxially to form the rectangular crystals with lateral molecular orientations on KCl substrate. On the other hand, ester molecules tend to arrange normal to the surface of mica and amorphous carbon film and construct the molecular layers like to Langmuir-Blodgett films. The crystal axis relationship between esters and KCl(001) surface was followed; c-axis$_{ester}$ is parallel to $\langle 110\rangle_{KCl}$ direction and $\langle 110\rangle_{ester}$ direction inclines with an angle of about ±16° corresponding to $\langle 110\rangle_{KCl}$. These molecules had resemble crystal structures with trans configuration in the ester moiety. The optimum temperatures of substrates in the former epitaxial growth exist and the temperature decreases in proportion to the chain length of alcohol group with the discrepancy of about 10 to 30 °C.

Organic thin-solid-film was studied for the new devices for electronic, magnetic and optical thin films[1]. The thin-solid-films of octadecanoic acid (stearic acid; $C_{17}H_{35}$ COOH) have been used as the lubricated films,[2] photo-resist and insulators.[3] The preparing of such organic films was carried out by the Langmuir-Blodgett (LB) methods, which were used the air–water interface.[4] Their films, however, had only molecular arrangements normal to the surface and the molecular packing in the first monolayer was not perfect from the results of transmission electron microscopic observation.[5] On the other hand, physical-vapor-deposition (PVD) method could give the alternative molecular orientations.[6] The molecules in the films laid along or stood normal to the surface. The crystal morphology on the substrate had the own habits and molecular orientations in the crystal could be identified by the granularity of the germanium decoration.[6] If the deposition conditions of PVD were controlled, the alternativity in the molecular orientations revealed. Therefore, uniform and well-defined crystal films could be obtained. Furthermore, the lengths of linear chain molecules such as fatty acids of hexadecanoic (palmitic), octadecanoic (stearic), eicosanoic (arachidic) and docosanoic (behenic) acids became clear to relate with the molecular orientations in given deposition conditions of PVD.[7] The longer molecules gave the tendency of normal orientations at same deposition condition than shorter ones.

Fatty acids such as octadecanoic acid form esters with primary alcohols. T. Malkin[8] firstly studied the crystal structures of them by powder X-ray diffractometry. Then single crystal X-ray analysis was carried out for methyl octadecanoate (18-1) by S. Aleby and E. von Sydow[9] and for ethyl octadecanoate (18-2) by S. Aleby[10,11] and A. McL. Mathieson and H. K. Welsh.[12] These crystals belong to monoclinic. The cell dimensions of 18-1[9] are a=5.61, b=7.33, c=106.6 Å, β=116.78° with space group of $A2/a$. Those of 18-2, however, are a=5.59, b=7.40, c=57.1 Å, β=118° with Aa[10] and a=5.59, b=7.40, c=55.0 Å, β=113.5° with Ia[11]. The difference between two cell parameters of 18-2 exists in the configuration of ester group (C_1–O_1–C_{01}–C_{02}). The former has trans configuration, while the latter has cis form as same as that of 18-1 (C_1–O_1–C_{01}). The molecules in the crystal arrange to construct the layer normal to the c-axis. From these cell dimensions the angle of c-axis with $\langle 110\rangle$ direction in the crystal is 105.9° for 18-1 and 106.4° and 103.9° for 18-2, respectively. The crystal structure of 18-3, however, was not revealed yet.

The ester molecules were not good at forming the LB films in order that their ester groups had low hydrophilic properties.[13] The PVD of methyl triacontanoate (30-1; $C_{29}H_{59}COOCH_3$) was carried out by Y. Ueda.[14] He evaporated it on KCl in vacuo. The crystal structure and the growth mechanism were studied by using electron microscope and electron diffraction. The film was composed of V-shape crystals. The 30-1 molecules grew epitaxially with the defined axial relations. The c-axis which is alkyl chain direction of molecule had the angles of ±16° with $\langle 110\rangle$ direction on KCl (001) plane.

This paper describes the preparing of well-defined thin solid films of three esters of fatty acids such as methyl octadecanoate (18-1; $C_{17}H_{35}COOCH_3$), ethyl octadecanoate (18-2; $C_{17}H_{35}COOC_2H_5$) and propyl octadecanoate (18-3; $C_{17}H_{35}COOC_3H_7$) and the film morphology of them.

Experimental

Methyl octadecanoate (18-1), ethyl octadecanoate (18-2), and propyl octadecanoate (18-3) were provided from Sigma Co. Ltd. with the purity of about 99%. These materials have melting points (mp) at the inversely proportional to the alkyl chain lengths of ester groups, as shown in Fig. 1.

The sample was set in the vacuum system and deposited

on three substrates. These substrates were three types; air-cleaved KCl and mica, amorphous carbon film (amorphous film) forming on mica before. The vacuum was kept at 6.7×10^{-4} Pa (5×10^{-6} Torr). After the substrates were baked at the temperature of greater than 100 °C for 1 h, the substrates were cooled down to 30 °C or less temperatures by using a cold trap and then the sample was evaporated. The temperature dependence of substrate with molecular orientations was found from the thin crystal morphology.

As the sample has low mp, it is difficult to evaporate in vacuo. So that the indirectional heating system was performed. The heater of tungsten wire and the sample holder of quartz plate were separated to differ from each other at the distances corresponding with specimen. When the temperature around the heater was kept at 500 to 800 °C, the specimen melted to sublimate.

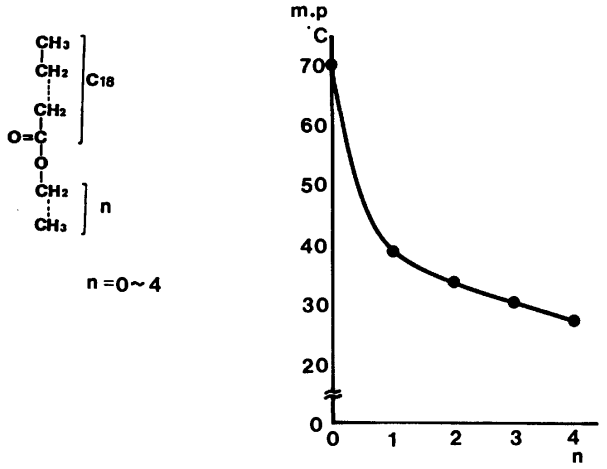

Fig. 1. Molecular shape and its melting point of alkyl octadecanoates (18-*n*; *n*=0, 1, 2, 3, and 4).

After the specimen was deposited on the substrates with the thickness of about 10 nm, germanium and carbon were successively evaporated in same vacuum system. The deposited germanium is surface decoration of organic crystals. When the surface was methyl-end like to (001) plane of octadecanoic acid, germanium grew discrete grains with star-like shapes. While, on the other plane it revealed the continuous layers. So that germanium decoration becomes indirect method for the determination of molecular orientation in thin-solid-films[6].

The three layers of sample, germanium and carbon were stripped off from the substrates on the surface of distilled water. Electron microscope used here was Hitachi HU-11DS with the accelerating voltage of 75 kV. The direct magnification was 5000 and 16000.

Results and Discussion

The typical electron micrographs are represented in Fig. 2(a), (b), and (c). These are thin-solid-films of 18-2 formed at substrate temperature of 10 °C on KCl, 0 °C on mica and −10 °C on amorphous film, respectively. On KCl, 18-2 molecules laid on the substrate surface. The molecular orientation was determined by the appearance of germanium decoration. The axis relation between thin crystal and substrate surface was decided by the shadowing direction of germanium along ⟨110⟩ direction of KCl (001) surface. Molecules formed the rectangular crystals and revealed the epitaxy. The bisectional direction of twinned crystals

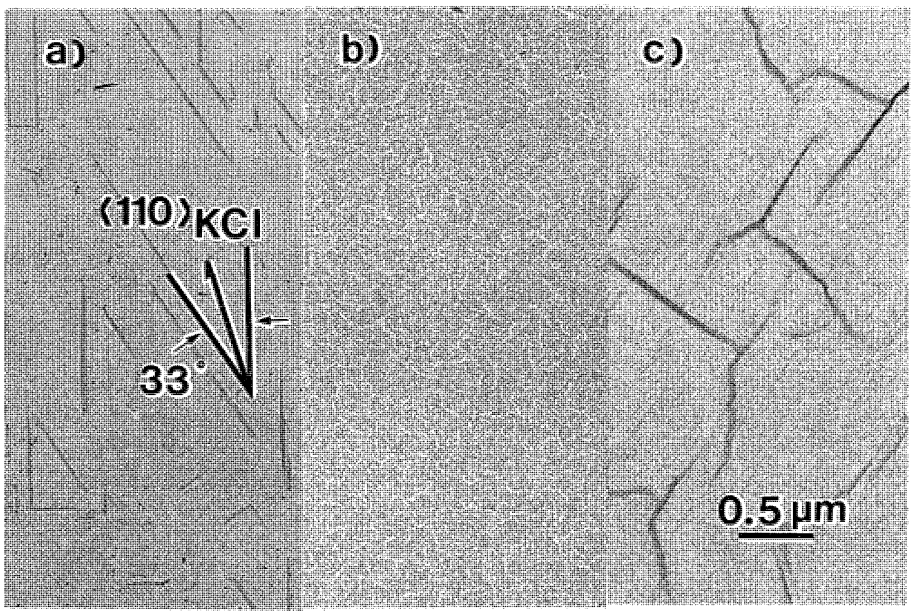

Fig. 2. Electron micrographs of deposited ethyl octadecanoate (18-2) on KCl at sustrate temperature of 10 °C (a), on mica at 0 °C (b) and on amorphous carbon film at −10 °C (c). On KCl (001) surface, 18-2 molecules grew epitaxially along two directions. Each direction indinate an angle of ±16.5° corresponding to KCl ⟨110⟩ direction.

was ⟨110⟩ direction of KCl (001) plane. The longitudinal direction of rectangular crystals crosses with an angle of 33°(±16.5°). This value can be led by the angle relationship between c-axis and ⟨110⟩ direction which is 106.4° (90°+16.4°). The fact shows that deposited films take the cell dimensions of reference [10] and the ester group of 18-2 would have trans configuration. The latitudinal direction is corresponding to c-axis. This result coincides with that for 30-1 by Ueda.[14] On the other hand, the regions covered with granular germanium on mica revealed, as shown in Fig. 2(b). Molecules in the film stood normal to the substrate surface and had no crystal habit. The same result was obtained in the deposition film formed on amorphous carbon film, as shown in Fig. 2(c).

The temperature dependency of substrate with molecular orientations was carried out at −20, −10, 0, and 10 °C for 18-1 and 18-2; from −60 to 10 °C with a step of 10 °C for 18-3 on KCl, mica and amorphous

carbon film. These results only on KCl substrate are shown in Figs. 3, 4, and 5 for 18-1, 18-2, and 18-3, respectively.

There were the discrepancies of crystal morphology at each substrate temperature on KCl. On the other hand, molecules grew normal to the substrate surface on mica and amorphous carbon film without differency of substrates and substrate temperatures. When the substrate temperature of KCl increases, the thin crystals with parallel molecular orientations to the substrate surface grow greater and reveal more epitaxially. There are the optimum temperatures of substrates for epitaxial growth; 0 °C for 18-1, −10 °C for 18-2 and −40 °C for 18-3, as shown in Fig. 6. The cross angles of rectangular crystals were 58° for 18-1, 33° for 18-2 and 33° for 18-3, in which an angle of 58° is a supplement of 32°. The results represent as followed; three crystals were monoclinic, the angle

between the rectangular crystals could be led from the relation between c-axis with ⟨110⟩ direction, these esters had resemble cell shapes and one of crystal parameters for 18-3 which had not determined by other methods was an angle of 106°. Above the optimun temperature of substrate, molecules stood normal to the substrate as same as on mica or amorphous film.

The formation mechanism of thin-solid-films will be explained as followed. The alkyl chain of molecules tends to lay along the substrate surface with the good contact on cations or anions of KCl ⟨110⟩ direction, as described above. If the substrate temperature increased, molecules get the surface migration energy and crystallization energy from the substrate to let the crystal more epitaxial and larger. When the excess energy was supplied, molecules could not contact the substrate surface to stand normal to the surface. The normal crystal has the ability of surface migration and self-aggregation more than lateral one. The tendency revealed the thin crystals on mica and amorphous film. The surface of them had no tetragonal symmetry. The interaction between molecules and substrate surface was lower than ionic crystal surface of KCl. The long chain molecules did not lay on the surface but tended to stand normal to the substrate.

The morphology of deposited thin films on KCl was summarized in Fig. 7. The "L" and "N" are represented the dominant crystals of the film surface with lateral and normal orientations of molecules, respectively. The temperature effect is inversely proportional to the alkyl chain length. The facts are coincided with the resemble study,[7] which was performed on several fatty acids with different chain length.

Additivity Law for the Activity of a Counter Ion in Ion-Exchange Resin

Hideo KIMIZUKA,* Hirohiko WAKI, Akira MATSUBARA, and Yōichi ARIMOTO
Department of Chemistry, Faculty of Science, Kyushu University,
Hakozaki, Higashi-ku, Fukuoka 812
(Received November 8, 1986)

The ion-exchange resin–electrolyte solution equilibria were studied on the basis of thermodynamics. The experimental results showed that the external salt activity divided by the co-ion concentration in the ion-exchange resins was linear against the co-ion concentration in the resin. The equilibria were consistently explained by a partition coefficient of salt distribution with the additivity law for the counter ions in the ion-exchange resin. A thermodynamic expression for the ion-exchange reaction was also discussed.

It is of importance to elucidate the behavior of ions in the ion-exchange resin in order to understand the ion transport through the charged membrane and the ion-exchange reaction.

Teorell[1] and Meyer and Sievers[2] explained the membrane potential across a charged membrane by applying the Donnan relation[3] to the membrane surface-electrolyte solution equilibria. Later, the ion concentration in the Donnan relation was replaced by the ionic activity.[4] However, the problem of the change in the activity coefficients of the ions in the ion-exchange resin with the external electrolyte solution has remained unsolved.[5]

On the other hand, it is well-known that the counter-ion activity in a polyelectrolyte solution with an added electrolyte obeys the additivity law;[6] that is, the total activity of counter ions is best expressed as a sum of the independent contributions of counter-ion activities from the polyelectrolyte and the added salt.

Toyoshima et al.[7] treated the membrane properties on the assumption of the additivity law for counter ions in the membrane, disregarding the partition factor. Unfortunately, however, they did not verify the additivity law experimentally.

Since the ion-exchange resin may be regarded as a polyelectrolyte, it is possible to elucidate the salt partition between an ion-exchange resin and an external electrolyte solution on the basis of thermodynamics by taking the additivity law into account.

This paper will describe the theory and the experimental evidence.

Theory

The thermodynamic treatment of the ion-exchange resin-single electrolyte solution equilibria leads to:

$$\bar{a}_{\pm}/a_{\pm} = K \tag{1}$$

and:

$$-RT\ln K = \bar{\mu}^{0}_{\pm} - \mu^{0}_{\pm} + \pi\bar{V}_{\pm} \tag{2}$$

where the overbars refer to the membrane phase; $a_{\pm}$ denotes the mean electrolyte activity; K, the partition coefficient; R, the gas constant; T, the absolute temperature; $\mu^{0}_{\pm}$, the standard chemical potential; π, the swelling pressure, and $\bar{V}_{\pm}$, the mean partial molar volumes of electrolytes, which are assumed identical in both the resin and external-solution phases.

By applying the additivity law[6] to the counter ion α in the membrane with a fixed charge concentration of $\bar{X}$, the activity of the counter ion, $\bar{a}_{\alpha}$, is expressed by;

$$\bar{a}_{\alpha} = (\bar{\gamma}_{f}|Z_{f}|\bar{X} + \bar{\gamma}_{\alpha}|Z_{\beta}|\bar{C}_{\beta})/|Z_{\alpha}| \tag{3}$$

where $\bar{\gamma}_{f}$ denotes the activity coefficirent of ion α referred to the fixed charge; Z_{f}, the valency of the fixed site; $\bar{\gamma}_{\alpha}$, the activity coefficient of the ion α referred to the Donnan salt present in the interstitial space; Z_{β}, the valency of the co-ion; $\bar{C}_{\beta}$, the co-ion concentration, and Z_{α}, the valency of the ion α. The activity of the co-ion β, $\bar{a}_{\beta}$, is given by a usual expression;

$$\bar{a}_{\beta} = \bar{\gamma}_{\beta}\bar{C}_{\beta} \tag{4}$$

where $\bar{\gamma}_{\beta}$ denotes the activity coefficient of the co-ion. By combining Eq. 1 with Eqs. 3 and 4, we obtain;

$$(a_{\pm})^{(\nu_{\alpha}+\nu_{\beta})}/(\bar{C}_{\beta})^{\nu_{\beta}} = (\bar{\gamma}_{\pm}/K)^{(\nu_{\alpha}+\nu_{\beta})}[(\bar{\gamma}_{f}|Z_{f}|\bar{X}/\bar{\gamma}_{\alpha} + |Z_{\beta}|\bar{C}_{\beta})/|Z_{\alpha}|]^{\nu_{\alpha}} \tag{5}$$

where ν_{α} and ν_{β} are the stoichiometric coefficints of the counter ion and the co-ion respectively and $\bar{\gamma}_{\pm}$, the mean activity coefficient of the Donnan salt.

For the system composed of a symmetric electrolyte and a resin having ion-exchange sites with $|Z_{f}|=1$, Eq. 5 is reduced to:

$$(a_{\pm})^{2}/\bar{C}_{\beta} = (\bar{\gamma}_{\pm}/K)^{2}(\bar{\gamma}_{f}\bar{X}/|Z_{\alpha}|\bar{\gamma}_{\alpha} + \bar{C}_{\beta}) \tag{6}$$

Thus, for a symmetric electrolyte, $(a_{\pm})^{2}/\bar{C}_{\beta}$ is linear against $\bar{C}_{\beta}$, providing that $\bar{\gamma}_{\pm}/K$ and $\bar{\gamma}_{f}/\bar{\gamma}_{\alpha}$ are constant.

Experimental

Materials. The anion-exchange membrane used in the present study was a styrene–divinylbenzene copolymer with a quarternary ammonio group developed by the Asahi Chemical Co., Ltd., and coded as CA-1, 0.2 t. The ion-exchange capacity was 1.70 meq. (g dry membrane)$^{-1}$; the water content, 0.37 g H_2O (g dry membrane)$^{-1}$, and the thickness, 0.225 mm. This membrane was prepared without

any other supporting polymer and was of a homogeneous distribution of functional groups within the membrane. The cation-exchange resins were commercial ones, coded as Dowex 50W−X2, −X8, and −X12, whose water contents were 0.75, 0.59, and 0.53 g H_2O (g dry resin)$^{-1}$ respectively and whose ion-exchange capacities were 1.8, 3.2, and 3.8 meq. (g dry resin)$^{-1}$ respectively. The degrees of cross linkage and the water contents of these cation-exchange resins are also different from each other. Pure inorganic salts and twice-distilled water were used for preparing the salt solutions. The concentrations of the electrolyte solutions varied from 0.5 to 3 mol dm^{-3}.

Procedure of Experiments. A membrane of 2×2 cm^2 preconditioned with a test solution was dipped into a 100-ml test solution for 5 days. After equilibration, the solution which had adhered to the membrane was removed by the filter paper; then the Donnan salt was extracted 5 times with 10 ml of distilled water, each extraction being carried out for 1 day. All the extracts were then gathered, and the concentration was determined by measuring the electric conductance of the solution. The Donnan-salt concentration was calculated from the concentration of the extract and the geometry of the membrane determined after equilibration with the test solution. The procedure for determining the ion concentrations in the cation-exchange resin has been described elsewhere.[8] The experiments were carried out at 25±1 °C.

Results and Discussion

The experimental results are shown in Figs. 1 and 2 where the activity data of the external electrolyte solutions were taken from the text book.[9] It is shown in these figures that $(a_\pm)^2/\bar{C}_\beta$ is linear against $\bar{C}_\beta$. This indicates that $\bar{\gamma}_\pm/K$ and $\bar{\gamma}_f/\bar{\gamma}_\alpha$ may be regarded as constants. These values, as estimated from Figs. 1 and 2, are cited in Table 1, together with the ratio of $\bar{\gamma}_f/\bar{\gamma}_\alpha$ to $K/\bar{\gamma}_\pm$, $(\bar{\gamma}_f/K)(\bar{\gamma}_\beta/\bar{\gamma}_\alpha)^{1/2}$.

Table 1 shows that the values of $K/\bar{\gamma}_\pm$ and $\bar{\gamma}_f/\bar{\gamma}_\alpha$ are smaller than unity except for those of $MgSO_4$, while their ratios are of the same order of magnitude. This table also indicates that co-ions in the anion-exchange membrane, Na^+ and K^+, exert different effects on the thermodynamic parameters and that the variation in the cation-exchange resin gives rise to a change in the thermodynamic parameters.

Since $\bar{\gamma}_\pm$ and $\bar{\gamma}_\alpha$ may be regarded as less than unity, both K and $\bar{\gamma}_f$ values for all electrolytes may be deduced to be less than unity. The small values of $\bar{\gamma}_f$ for the uni-univalent electrolyte, a measure of the counter-ion condensation caused by an array of charged sites as a polyelectrolyte, may also be considered to indicate a strong trapping of counter ions by charged sites. The low K values may be ascribed to the co-ion repulsion by charged sites in addition to the exclusion effect due to the resin matrix with a hydrophobic nature. The anomalous values of $K/\bar{\gamma}_\pm$ and $\bar{\gamma}_f/\bar{\gamma}_\alpha$ for $MgSO_4$ may be due to a stronger interaction of magnesium ions with sulfate ions than with charged sites as deduced from the extremely low activity coefficient of $MgSO_4$ in an aqueous solution, an order of 10^{-2}. In fact, the ratio of $\bar{\gamma}_f/\bar{\gamma}_\alpha$ to $K/\bar{\gamma}_\pm$ for $MgSO_4$ was comparable to those for the other

Table 1. Thermodynamic Parameters in the Ion-Exchange Resin-Electrolyte Solution Equilibria

electrolytes as is shown in Table 1. This may indicate that the interactions of Mg^{2+} and $MgSO_4$ with the ion-exchange resin are not anomalous. Assuming $\bar{\gamma}_\alpha=\bar{\gamma}_\beta=\bar{\gamma}_\pm$, the ratio is reduced to $\bar{\gamma}_f/K$, which expresses the ratio of the counter ion-charged site interaction to the electrolyte-resin interaction.

So far, the difference in the standard chemical potential of an ion between the resin and the external solution has been ignored in thermodynamic treatments of the equilibria.[5] This may, in general, not be valid, since the resin-electrolyte solution equilibria are heterogeneous.

It is likely that $\bar{\gamma}_\pm$ as well as $\bar{\gamma}_\alpha$ varies with the concentration of Donnan salt. Thus, the constant values of $K/\bar{\gamma}_\pm$ and $\bar{\gamma}_f/\bar{\gamma}_\alpha$ observed in the present study may be regarded as apparent ones. A constant value of $K/\bar{\gamma}_\pm$ will be realized if the swelling pressure term is cancelled by $\bar{\gamma}_\pm$. On the other hand, a constant value of $\bar{\gamma}_f/\bar{\gamma}_\alpha$ can not thus be explained, since $\bar{\gamma}_f$ is regarded constant in terms of the additivity law.[6] The apparent constancy of $\bar{\gamma}_f/\bar{\gamma}_\alpha$ is probably related to the fact that the total counter ion concentration did not change so remarkably as the concentration of Donnan salt.

For the ion-exchange reaction:

$$M^+ + NR \rightleftharpoons N^+ + MR$$

where R is the ion-exchange site, we obtain, from Eqs. 1 and 2:

$$\bar{a}_M a_N/\bar{a}_N a_M = K_N^M \quad (7)$$

The equilibrium constant, K_M^N, is given by:

$$-RT \ln K_N^M = (\bar{\mu}_M^\circ-\mu_M^\circ) - (\bar{\mu}_N^\circ-\mu_N^\circ) + \pi(\bar{V}_M-\bar{V}_N) \quad (8)$$

where the subscripts M and N refer to the M and N ions respectively. Since the difference in the ionic molar volume is small, the contribution of the swelling pressure term may be ignored unless the swelling pressure is extremely high.

It is well-known that the selectivity coefficinet for an ion-exchange reaction varies with the composition of the ions involved in the reaction.[5] This indicates the changes in the activity coefficients of ions with the composition. Even in this case, the additivity law may also provide a way of elucidating the behavior of counter ions in the ion-exchange reaction. A more detailed study will be required to establish thermodynamic treatments concerning the ion-exchange resin-electrolyte solution equilibria.

ESR and Mass Spectrometric Studies of Methanol Combustion. II. Correlation between Labile and Stable Chemical Species in Methanol-Oxygen-Argon Flame at Low Pressure

Masayuki TANIGUCHI, Toshiharu YOSHIOKA,† and Hiroshi YOSHIDA*
Faculty of Engineering, Hokkaido University, Kita-ku, Sapporo 060
(Received November 11, 1986)

In order to experimentally elucidate the chemical reactions of methanol combustion, the concentration profiles of ten chemical species were determined in stoichiometric CH_3OH-O_2-Ar flat flame at low pressure, 1.11×10^4 Pa. The concentrations of three labile intermediates (H, O, and OH) as well as that of stable O_2 molecules, were measured by means of the probe-sampling-ESR method. The concentrations of six stable species (CH_3OH, CH_2O, CO, CO_2, H_2, and H_2O) were measured using a quadrupole mass spectrometer. The rates of the net chemical formation (or decay) of these species were determined by subtracting the effect of diffusion from their observed concentration profiles, and were examined on the basis of the reaction mechanisms previously proposed for methanol combustion. The experimental results were found to be consistent with the oxidation pathway $CH_3OH\rightarrow CH_2OH\rightarrow CH_2O\rightarrow CHO\rightarrow CO\rightarrow CO_2$. The results also showed that the reaction $CH_2OH+O_2\rightarrow CH_2O+HO_2$ is an important pathway for O_2 consumption.

In order to elucidate complex combustion reactions in flames, it is indispensable to determine the concentration profiles of as many chemical species, both labile and stable, as possible in the flames. However, it is a difficult task to determine the concentration profiles, especially, of the labile intermediates in high temperature flames. We have been using the probe-sampling-electron spin resonance (ESR) technique to detect the labile intermediates (H, O, and OH; the principal carriers of chain reactions of combustion), in free-burning methane and methanol flames.[1,2] Recently, we carried out a combined ESR-mass spectrometric study in order to examine the concentration profiles of nine (labile and stable) chemical species in free-burning methanol-air flames at atmospheric pressure (in the previous study of this series).[3] The study was extended in our work to the CH_3OH-O_2-Ar flames at a low pressure; this allowed us to control more strictly the physical conditions of combustion and to change more freely the equivalence ratio of the premixed gas.

The reaction mechanism of methanol combustion has theoretically been studied over ten years;[4-7] several numerical models concerning combustion reactions, including more than twenty species, have been proposed.[6-8] However, most of the experimental data so far reported[4,5,9-11] have only partially shown chemical features of the combustion, and have not been sufficiently comprehensive for a comparison with theoretical predictions and to substantiate the proposed models. Akrich et al. first determined the concentration profiles of stable chemical species in methanol-air flames at low pressures by means of the gas chromatographic method.[9] Pauwels et al.[10] later studied the concentration profiles of H, O, and OH by means of the ESR method under the same flame conditions as those in the above gas chromatographic study; these gave general support to the numerical model proposed by Westbrook and Dryer.[6] Very recently, Vandooren and Van Tiggelen,[11] and Andersson et al.[4] performed mass spectrometric studies and obtained a comprehensive set of the profiles of stable species and labile intermediates in methanol flames at low pressures. Based on these results, Dove and Warnatz[7] developed a simplified model of methanol combustion. The present ESR-mass spectrometric study complements these previous studies and serves as an experimental basis for obtaining a further insight into chemical reactions during methanol combustion.

Experimental

The burner and sampling system used in the present study is schematically shown in Fig. 1. The burner comprised two concentric stainless-steel tubes: The inner tube was attached with a porous stainless-steel disk (27-mm diameter) at the end which acted as the burner mouth, and the outer tube (58-mm diameter) enclosed the flame at a low pressure and supported a quartz sampling probe. The sampling probe was pretreated with an aqueous HF solution and cleaned with aqueous NaOH and HNO_3 solutions in order to reduce the surface destruction of labile intermediates.[2,10] Sampling of burning gas was made at several positions on the center axis of the flame by sliding the inner tube with respect to the outer one. The burner was cooled by circulating water.

Oxygen, and argon of purity higher than 99.9% were supplied from cylinders through regulated rotermeters. Methanol of reagent grade was continuously injected into preheated gas flow with a microfeeder. The flames of premixed gas, CH_3OH-O_2-Ar, were stabilized in the burner at a low pressure (1.11×10^4 Pa); this was controlled by adjusting the pumping rate.

The ESR and mass spectrometric measurements of burning gas were made with an X-band ESR spectrometer

† Present address: Nihon Furnace Kogyo, Ltd., Tsurumi-ku, Yokohama 230.

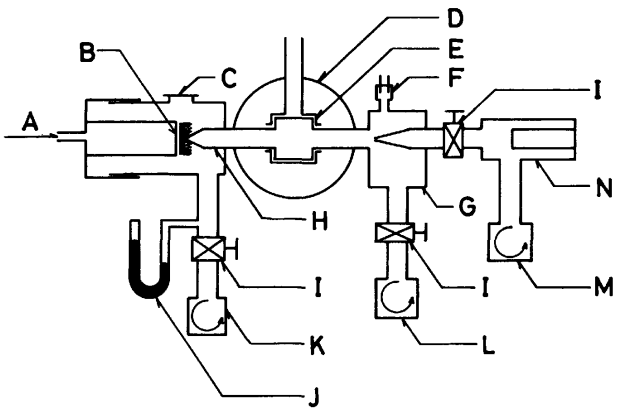

Fig. 1. Schematic drawing of the burner and the sampling system. and a quadrupole mass spectrometer (as previously described).[3] About one-tenth of the burning gas was continuously sampled through a tiny hole (about 0.1 mm in diameter) at the tip of the sampling probe; it was subjected to ESR measurements at 13.3 Pa and mass spectroscopic measurements at a total pressure of 10^{-3} Pa. The residence time of the sampled gas in the sampling probe before reaching the ESR cavity was estimated to be about 2 ms. The flame temperature was measured with a SiO_2-coated Pt/Pt-Rh thermocouple.

Analysis of Data

From the apparent local concentration obtained by ESR or mass spectrometric measurements of the i-th species at each position in the flame, the mass flux was calculated as

$$G_i = \frac{X_i M_i}{\bar{M}}\left(1+\frac{V_i}{v}\right), \tag{1}$$

where $\bar{M}$ is the average molecular weight, v the velocity of the flame gas, and X_i, M_i, and V_i the mole fraction, the molecular weight, and the diffusion velocity of the i-th species in the flame gas. By taking the z-axis along the gas flow, the diffusion velocity was calculated as

$$V_i = -\frac{D_{ij}}{X_i}\cdot\frac{dX_i}{dz}, \tag{2}$$

using the binary diffusion coefficients D_{ij} given by

$$D_{ij} = \frac{1.66\times10^{-3}(1/M_i+1/M_j)^{1/2}T^{1.67}}{P\sigma_{ij}^2(\varepsilon_{ij}/\kappa)^{0.17}} \tag{3}$$

as well as the Lennard-Jones potential parameters (σ_{ij} and ε_{ij}/κ) derived by Westenberg and Fristrom,[12] and Warnatz.[13] In actual calculations, argon was always taken as the j-th species.

The net reaction rate was then calculated as

$$K_i = \frac{\rho v}{M_i}\cdot\frac{dG_i}{dz}, \tag{4}$$

where ρ is the density of the flame gas. This quantity gives the rate of net formation (or consumption) at a particular position in the flame solely due to chemical reactions involving the i-th species, i.e., the net formation rate derived by subtracting the effect of diffusion from the concentration profile observed by ESR or mass spectrometric measurements.

Results and Discussion

Concentration Profiles. ESR spectra due to H, O, OH, and O_2 were observed in the present CH_3OH-O_2-Ar flame. The spectral features were essentially the same as those previously observed for methane-air and methanol-air flames.[1-3] The intensity of the spectra of H and O was calibrated with reference to the spectrum of O_2 with a known concentration in order to determine their absolute concentrations in the ESR cavity; while the spectral intensity of OH was calibrated with reference to the NO spectrum.[14,15] A correction for the first-order destruction of H and O on the wall of the sampling probe before reaching the ESR cavity was made by changing the residence time in the sampling probe, as described previously.[3]

A correction for the destruction of OH during sampling was rather difficult, since it did not follow a simple first-order process and was thought to be largely due to unknown reactions occurring at or close to the hole of the sampling probe.[3] The correction factor was, therefore, determined from the observed ESR intensities of H, O, OH, and O_2 in the post flame region and the assumed partial equilibrium of the reaction,

$$H + O_2 \longrightarrow O+OH, \tag{R1}$$

by using the equilibrium constant, $K=300\cdot T^{-0.372}\exp(-8565/T)$ reported previously.[16]

Stable intermediates (H_2, CH_2O, and CO) were detected together with the fuel CH_3OH and the final products (CO_2 and H_2O) by the mass spectrometric method. The concentrations of the stable species were determined from the observed intensities of their mass patterns with reference to those of the mixtures of known compositions. No correction was made for the reactions in the sampling probe for these stable species.

Figure 2 shows the concentration profiles (all in the mole fraction unit) of stable and unstable species in the flame of stoichiometric composition (CH_3OH: 11.7%, O_2: 17.7%, Ar: 70.6%) with the cold gas velocity

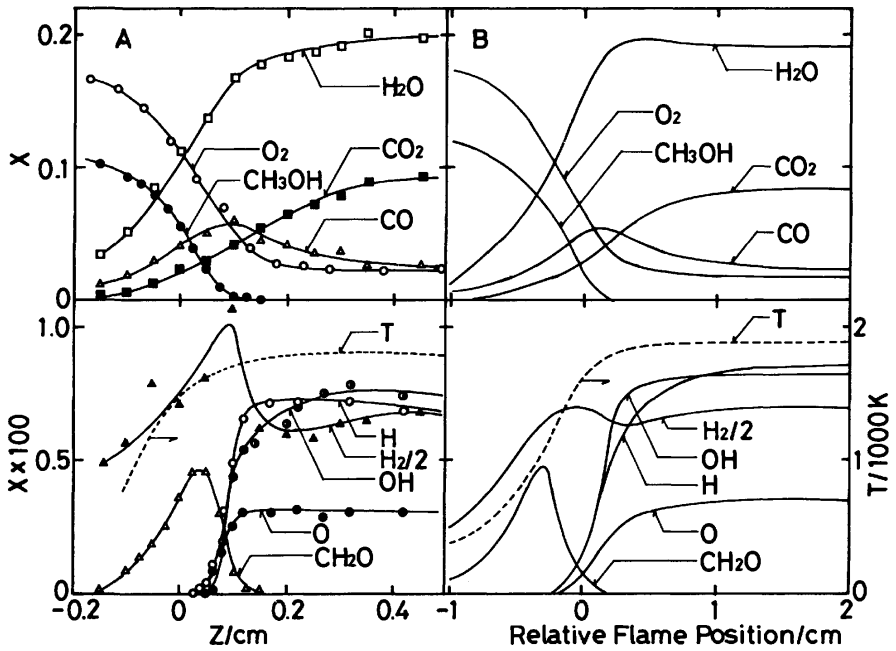

Fig. 2. The profiles of mole fractions (X) of labile and stable species and temperature (A) experimentally observed in stoichiometric methanol-oxygen-argon flame at 1.11×10^4 Pa, and (B) calculated in stoichiometric methanol-air flame at 1.01×10^4 Pa by Westbrook and Dryer (Ref. 6). The scale of abscissa is different between the observed and calculated profiles.

of 41.6 cm s^{-1} (mass flow rate of 6.36×10^{-3} g $cm^{-2}s^{-1}$). The origin of the z-axis corresponds to the beginning of the luminous zone of the flame. The observed profiles resemble those for the low-pressure methanol-air flames of the equivalence ratio (ϕ, $([fuel]/[O_2])_{actual}/([fuel]/[O_2])_{stoichiometric}$) of 1.0 observed by Andersson et al. by means of the mass spectrometric method.[4] There is a slight difference from the previous data regarding the absolute values at the concentration maximum of the profiles. This is probably due to a difference in the flame temperature. The general trend of the present concentration profiles is also very similar to that of low-pressure methanol-air flames of $\phi=1.08$.[9,10]

Westbrook and Dryer[6] have reported on the concentration profiles of chemical species in the stoichiometric methanol-air flame at 1.01×10^4 Pa which have been calculated on the basis of the numerical model of the methanol combustion including 26 species and 84 reactions. The concentration profiles observed in the present study agree with the calculated profiles (as demonstrated in Fig. 2), except that the transient change in the observed concentrations is generally steeper than that expected from model calculations. The same agreement between the observed and calculated profiles has been found for methanol-air flames at atmospheric pressure in the previous study of this series.[3] Thus, it is concluded that the numerical model proposed by Westbrook and Dryer[7] reproduces fairly well the effect of the pressure on the chemical reactions of methanol combustion. A similar conclusion has also been obtained from previous mass spectrometric studies.[4,5]

Formation and Consumption Rates of Chemical Species. In order to examine the chemical aspects of the flame more carefully, the net reaction rate, K, of each species was derived from the concentration profile and Eq. 4, and is shown in Fig. 3. The positive K value indicates net formation, while the negative value indicates net consumption.

The consumption rates of CH_3OH and O_2 and the formation rates of H_2O, H_2, and CO show maxima at almost the same positions. In contrast, the formation rate of CO_2 shows a very broad maximum at the downstream region. It is slowly formed in an extended region of the flame.

For all the labile intermediates (H, O, and OH), the K value first grows in the negative side and then changes to the positive. The features of local K values of the labile intermediates in flame indicates that the labile intermediates are supplied by backward diffusion to the upstream, preheated region, where they are effectively consumed by reactions with CH_3OH.

Reaction Mechanism. The comprehensive reaction mechanism for methanol combustion was first developed by Westbrook and Dryer[6] and was later modified.[5,8] The calculated concentration profiles for one-dimensional flames based on this reaction

mechanism have generally agreed with experimental results.[3,4,9,10] An agreement can also be seen in the present experimental results (already shown in Fig. 2).

Recently, however, Dove and Warnatz proposed a different reaction mechanism, which is simpler (14 species and 40 reactions) than the previous one and explicitly regards the pathway of methanol oxidation to be $CH_3OH \rightarrow CH_2OH \rightarrow CH_2O \rightarrow CHO \rightarrow CO \rightarrow CO_2$.[7] They have argued that the new model predicts well the experimentally observed burning velocity. The formation (or consumption) rates determined in the present experimental study will be examined with reference to the reaction mechanism proposed by Dove and Warnatz. According to the proposed mechanism,[7] CH_3OH reacts mainly with the labile intermediates (H, O, and OH) as follows:

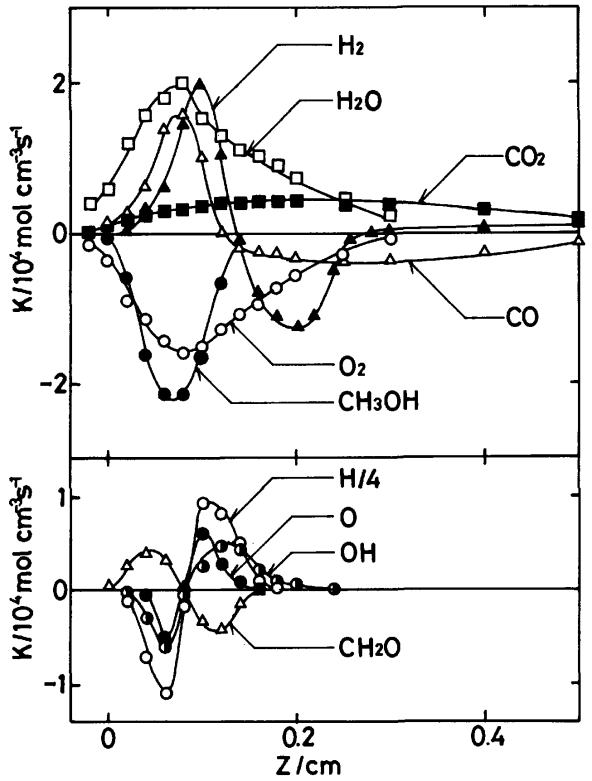

Fig. 3. Net formation (or consumption) rates of labile and stable species in the stoichiometric methanol-oxygen-argon flame at 1.11×10^4 Pa, directly derived from the observed concentration profiles in Fig. 2.

$$CH_3OH + OH \longrightarrow CH_2OH + H_2O, \quad (R2)$$
$$CH_3OH + H \longrightarrow CH_2OH + H_2, \quad (R3)$$

and

$$CH_3OH + O \longrightarrow CH_2OH + OH. \quad (R4)$$

The reactions of CH_2O, CHO, and CO are

$$CH_2O + H \longrightarrow CHO + H_2, \quad (R5)$$
$$CH_2O + O \longrightarrow CHO + OH, \quad (R6)$$
$$CH_2O + OH \longrightarrow CHO + H_2O, \quad (R7)$$
$$CHO + M \longrightarrow CO + H + M, \quad (R8)$$
$$CHO + H \longrightarrow CO + H_2, \quad (R9)$$
$$CHO + OH \longrightarrow CO + H_2O, \quad (R10)$$

and

$$CHO + O_2 \longrightarrow CO + HO_2. \quad (R11)$$

CO_2 is then formed mainly by the reaction,

$$CO + OH \longrightarrow CO_2 + H. \quad (R12)$$

Though CH_3OH can be oxidized also by HO_2 as

$$CH_3OH + HO_2 \longrightarrow CH_2OH + H_2O_2 \quad (R13)$$

and

$$CH_2O + HO_2 \longrightarrow CHO + H_2O_2, \quad (R14)$$

Table 1. Elementary Reactions of Methanol Combustion and Their Rate Parameters Used in the Discussion of the Present Experimental Results

Reaction		A	n	T_0
$H + O_2 \longrightarrow O + OH$	(R1)	2.4×10^{16}	−0.91	8310
$CH_3OH + OH \longrightarrow CH_2OH + H_2O$	(R2)	1.0×10^{13}	0	850
$CH_3OH + H \longrightarrow CH_2OH + H_2$	(R3)	4.0×10^{13}	0	3070
$CH_3OH + O \longrightarrow CH_2OH + OH$	(R4)	1.0×10^{13}	0	2370
$CH_2O + H \longrightarrow CHO + H_2$	(R5)	2.5×10^{13}	0	2010
$CH_2O + O \longrightarrow CHO + OH$	(R6)	3.5×10^{13}	0	1770
$CH_2O + OH \longrightarrow CHO + H_2O$	(R7)	3.0×10^{13}	0	600
$CO + OH \longrightarrow CO_2 + H$	(R12)	4.6×10^{6}	1.5	−370
$CO_2 + H \longrightarrow CO + OH$	(−R12)	1.6×10^{14}	0	13200
$CH_2OH + O_2 \longrightarrow CH_2O + HO_2$	(R16)	1.0×10^{13}	0	3620
$CH_2OH + M \longrightarrow CH_2O + H + M$	(R17)	1.0×10^{14}	0	12600
$CH_2OH + H \longrightarrow CH_2O + H_2$	(R18)	2.0×10^{13}	0	0

The reactions were taken from the reaction mechanism proposed by Dove and Warnatz (Ref. 7). The rate parameters are those in the expression of the reaction rate constant $k = AT^n \exp(-T_0/T)$ in cm^3 mol^{-1} s^{-1} unit.

these oxidation paths are unimportant compared with reactions R2—4 and R5—7 under the present high-temperature conditions. The rate constants of some of these reactions[7] are cited in Table 1.

The above oxidation pathway gives the formation (or consumption) rates, K, as a function of the concentrations of reacting species as following:

$$K(CH_3OH) = -\{k_{R2}[OH]+k_{R3}[H]+k_{R4}[O]\}[CH_3OH] \quad (5)$$

and

$$K(CO_2) = k_{R12}[CO][OH] - k_{-R12}[CO_2][H]. \quad (6)$$

Assuming a quasi-stationary state for CHO,

$$K(CO) + K(CO_2) = \{k_{R5}[H]+k_{R6}[O]+k_{R7}[OH]\}[CH_2O] \quad (7)$$

is also obtained. The K values can be calculated from the observed concentration profiles of the reacting species and the rate constants cited in Table 1. On the other hand, the K values have been directly observed experimentally as shown in Fig. 3 (strictly speaking, directly derived from the concentration profile of the species itself). A comparison between the observed and calculated K's will verify the relevance of the reaction mechanism on which the calculation has been made.

The calculated K is compared with the observed K for the consumption of CH_3OH (Fig. 4). Both K values agree fairly well, except that the calculated K is lower in the very upstream region. The disagreement in the upstream region is attributable to a perturbation due to the inserted sampling probe: The sampling of burning gas acts as a sink for the labile intermediates, and violates their concentration profiles determined by the balance of chemical reactions and diffusion. This effect becomes important when sampling is made at positions close to the burner mouth, since a backward diffusion of the labile intermediates (only source of the labile intermediates existing at the sampling position) is seriously hindered by the sampling probe. Such a perturbation due to the sampling probe has been experimentally shown by observing the OH concentration in the preheated zone of a propane-oxygen flame by mass spectrometric (with sampling) and UV spectroscopic (without sampling) methods.[17]

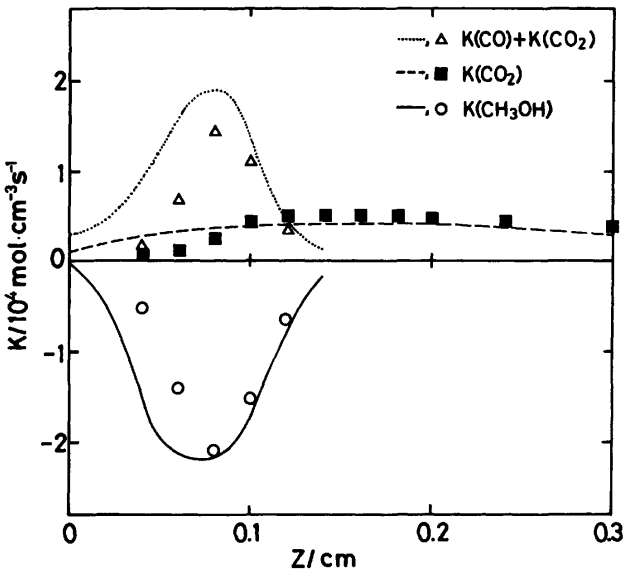

Fig. 4. Comparison between the observed (lines) and the calculated (plots) net formation (or consumption) rates of CH_3OH, CO_2, and sum of CO and CO_2. The lines showing the observed rates were taken from Fig. 3. The plots were obtained by calculating rates based on the rate constants in Table 1 and the concentration profiles of reacting species in Fig. 2. See text also for detail.

Figure 4 shows an agreement between the observation and calculation, also for $K(CO_2)$ and $K(CO)+K(CO_2)$ in the region $z>0.1$ cm, where the concentrations of the labile intermediates reach a plateau value and the perturbation due to the sampling probe is expected to be insignificant. Because the CH_2O consumption appears to balance the formation of CO and CO_2, CHO is very probably short-lived and is converted quickly to CO. Although CH_2O can react with O_2 as

$$CH_2O + O_2 \longrightarrow CHO + HO_2, \quad (R15)$$

numerical examinations based on the observed concentration profiles and the reported rate constants show that the rate of reaction R15 is much smaller than the rates of the reactions of CH_2O with H, O, and OH (reactions R5—7) throughout the flame.

The general agreement between the observed and calculated K values indicates a consistency between the observed concentration profiles of labile and stable chemical species in the flame, and gives experimental support to the simpler mechanism of methanol oxidation.

According to the Dove and Warnatz's mechanism,[7] the consumption of O_2 is mostly due to the following reactions:

$$H + O_2 \longrightarrow O + OH \quad (R1)$$

and

$$CH_2OH + O_2 \longrightarrow CH_2O + HO_2. \quad (R16)$$

The rate of O_2 consumption is, therefore, given as

$$-K(O_2) = \{k_{R1}[H] + k_{R16}[CH_2OH]\}[O_2] - k_{-R1}[O][OH]. \quad (8)$$

However, the consumption rate cannot be calculated in a straight-forwatd manner from the observed concentration profiles, since no experimental data is available for the CH_2OH concentration. If one

assumes that the decay of CH_2OH is exclusively due to its oxidation into CH_2O by

$$CH_2OH + O_2 \longrightarrow CH_2O + HO_2, \quad (R16)$$

$$CH_2OH + M \longrightarrow CH_2O + H + M, \quad (R17)$$

and

$$CH_2OH + H \longrightarrow CH_2O + H_2, \quad (R18)$$

reactions of CH_2OH will determine the sum of the formation rates:

$$K(CH_2O) + K(CO) + K(CO_2) = \{k_{R16}[O_2] + k_{R17}[M] + k_{R18}[H]\}[CH_2OH]. \quad (9)$$

Substituting $[CH_2OH]$ of equation 9 into equation 8,

$$-K(O_2) = k_{R1}[H][O_2] - k_{-R1}[O][OH] + k_{R16}[O_2]\frac{K(CH_2O)+K(CO)+K(CO_2)}{k_{R16}[O_2]+k_{R17}[M]+k_{R18}[H]}. \quad (10)$$

Thus, the O_2 consumption rate can be calculated from the observed $K(CH_2O)$, $K(CO)$, $K(CO_2)$, $[O_2]$, [M], and [H] and from the rate constants cited in Table 1 (the rate constant k_{-R1} can be obtained from the k_{R1} value and the equilibrium constant for reaction R1).

The calculated $-K(O_2)$, by using the rate constants in Table 1, is shown in Fig. 5 (curve B). Thus, calculated $-K(O_2)$ differs from the $-K(O_2)$ determined directly from the observed concentration profile of O_2 (curve A), especially in the downstream region. The agreement between the calculated and observed $-K(O_2)$ is much improved in the downstream region (curve C in Fig. 5), if one uses the rate constant, $k_{R1}=1.2\times10^{17}T^{-0.91}\exp(-8310/T)$, recently recommended by Warnatz.[18] This is five times as large as the previous rate constant (cited in Table 1) at the present flame temperature.

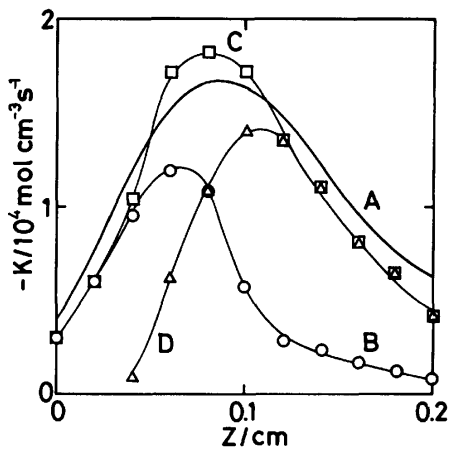

Fig. 5. Comparison of the consumption rates of O_2 obtained in different ways. (A): The observed rate taken from Fig. 3. (B): The rate calculated based on equation 10 and by using the rate constants in Table 1. (C): The rate calculated by using the newly-recommended rate constant for reaction R1. (D): The rate calculated with the newly-recommended rate constant and by excluding reaction R16. See also the text for detail.

$K(O_2)$ calculated with the new K_{R1} and neglecting reaction R16 is also shown in Fig. 5 (curve D). It is evident that reaction R16 is an important process for O_2 consumption in the upstream region of the flame. The observed $-K(O_2)$ appears to agree well with the calculation including reaction R16 rather than the calculation excluding it. We do not, however, dare to stress this agreement in the upstream region, since there is some ambiguities related to perturbation due to the inserted sampling probe in this region (as mentioned before).

Concluding Remarks. Together with seven stable species, three labile intermediates were observed in the CH_3OH-Ar-O_2 stoichiomeric flame at a low pressure by the combined ESR-mass spectrometric method. Their concentration profiles and the local distribution of their net formation (or consumption) rates in the flame were examined to elucidate the chemical reactions of methanol combustion.

The experimental results agree with the concentration profiles predicted by numerical calculations based on the model for methanol combustion consisting of very many elementary reactions previously reported by Westbrook and Dryer.[6] However, the results are also shown to be consistent even with the simplified model for the methanol combustion recently proposed by Dove and Warnatz.[7] As far as the authors are aware, the present study provides some of the most comprehensive experimental data on the distribution of the chemical species in a methanol flame. There is still no need to make the reaction mechanism complex in order to interpret the present experimental results. This does not necessarily means that the reaction mechanism of methanol combustion is really simple. Further progress in combustion chemical experiments is desirable for unambiguous comparisons with the proposed models and to totally elucidate the chemical aspect of combustion.

^{129}I Mössbauer Spectroscopic Study of 2:3 Molecular Complexes of Triphenylphosphine Sulfide-Iodine and Acridine-Iodine

Hiroshi SAKAI* and Yutaka MAEDA
Research Reactor Institute, Kyoto University,
Kumatori-cho, Sennan-gun, Osaka 590-04
(Received November 12, 1986)

The ^{129}I Mössbauer effect has been applied to investigate 2:3 molecular complexes of triphenylphosphine sulfide–iodine and acridine–iodine. The Mössbauer spectra indicate the presence of three unequivalent iodine sites (I_A, I_B, and I_C), as expected from the crystallographic data of these complexes. The iodine atom (I_A) coordinating to the sulfur or nitrogen atom of each donor molecule is more positively charged than that of the 1:1 molecular complex containing the same donor atom. This result can be interpreted in terms of the covalency of the S···I_A or N···I_A bond. The degrees of charge transfer in the 2:3 complexes are close to those in the 1:1 complexes, and the transferred charges are mainly localized on the terminal iodine atoms (I_B). The iodine molecule (I_C) cross-linked to two I_B atoms has a slightly negative charge, consistent with the bond distance of the molecule. The iodine moieties of these complexes are very similar to the structure of I_8^{2-} in Cs_2I_8.

The iodine molecule is known to be a typical electron acceptor and to form molecular or charge-transfer complexes with various electron-donor molecules such as amines, ethers, and thioethers. Many of these complexes usually have a 1:1 stoichiometry in the solid phase, consisting of a linear orientation of the iodine molecule with the donor atom. However, triphenylphosphine sulfide (TPPS)[1] and acridine (AC)[2] form 2:3 molecular complexes with the iodine molecule in the solid state, although these donors form 1:1 complexes with iodine monobromide. The crystallographic data of the triphenylphosphine sulfide–iodine (2TPPS–3I_2) complex suggest that two iodine molecules are bonded to each sulfur atom of two TPPS molecules, resulting in a nearly linear S···I_A–I_B arrangement; another iodine molecule is cross-linked to two terminal iodine atoms (I_B) with a Z-shaped structure (Fig. 1).[3] The six iodine atoms of the complex lie in one plane. The intermolecular S···I_A bond distance (2.69 Å) is considerably shorter than the sum of the respective van der Waals radii, whereas the intramolecular I_A–I_B bond disance (2.86 Å) is longer than that of the free iodine molecule. The corresponding bond distances for the usual 1,4-dithiane-iodine complex having a similar S···I_A–I_B configuration have been reported as 2.867 Å for the S···I_A bond and 2.787 Å for the I_A–I_B bond.[4] This comparison of the bond distances for both complexes suggests that the charge-transfer interaction of the unusual 2:3 iodine complex is stronger than that of usual 1:1 iodine complex containing the same donor atom.

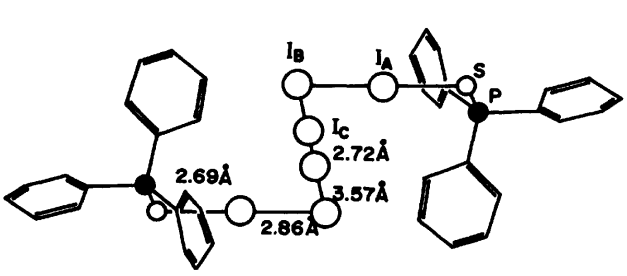

Fig. 1. The structure of the 2TPPS–3I_2 complex (taken from Ref. 3).

Recently, Uchida[5] has revealed the crystal structure of the acridine–iodine (2AC–3I_2) complex, in which the configuration of the iodine atoms is very similar to that of 2TPPS-3I_2. This 2:3 complex is apparently not the ionic compound formulated as $[(AC)_2I]^+I_5^-$, predicted from the low-frequency vibrational spectra.[2] Ichiba et al.[6] previously measured the ^{129}I Mössbauer spectrum of the acridine–iodine complex at 85 K. The analysis of the spectrum with two unequivalent iodine atoms (1:1 type complex) did not give a completely satisfactory result, suggesting the existence of three unequivalent iodine atoms in the complex.

It is of interest to estimate the charge densities on the iodine atoms in the unusual 2:3 iodine complexes of TPPS and AC, in comparison with those in the usual 1:1 iodine complexs of thioethers and amines. The Mössbauer spectroscopy of ^{129}I is favorable for this purpose, since the charge density and the charge distribution on the iodine atom can be directly derived from the such Mössbauer parameters as the quadrupole coupling constant (e^2Qq) and its sign, the asymmetry parameter (η), and the isomer shift (δ). In the present work, the ^{129}I Mössbauer spectra of the 2TPPS–3I_2 and 2AC–3I_2 complexes were measured and the electronic structure on each iodine atom could be determined. The nature of the charge-transfer bond for these 2:3 complexes is discussed in comparison with that for 1:1 complexes of thioether–iodine and amine–iodine.

Experimental

The complexes were prepared on a small scale using radioactive ^{129}I (99% enriched) obtained from the New

England Nuclear Co. as Na ^{129}I in a Na_2SO_3 solution. Molecular iodine, prepared by H_2O_2 oxidation of an acidified solution of NaI, was extracted with carbon tetrachloride or chloroform. Each iodine solution was thoroughly washed with water and passed through a Teflon filter to eliminate any slight amount of water. The 2TPPS-$3I_2$ complex was prepared by adding a solution of a stoichiometric amount of TPPS in carbon tetrachloride to the iodine solution of the same solvent. A purple-red crystalline product was collected by filtration and air-dried. The mole ratio was determined for a complex prepared with nonradioactive (natural) iodine by elemental analysis. Found: C, 31.7; H, 2.5; I, 56.7%. Calcuild for $2(C_6H_5)_3PS$-$3I_2$: C, 32.0, H, 2.2; I, 56.4%. A brown crystalline complex of 2AC-$3I_2$ was prepared in chloroform using a procedure similar to that for the 2TPPS-$3I_2$ complex. The iodine content was determined to be 67.4% by means of iodometry. Calcuild for $2(C_{13}H_9N)$-$3I_2$: I, 68.0%. The thicknesses of the absorber samples, mounted in Teflon sample holders, were in the range of 20 to 30 mg ^{129}I cm^{-2}.

The $^{66}Zn^{129}Te$ Mössbauer source was prepared by irradiation of 150 mg ^{66}Zn ^{128}Te compound at a thermal neutron fluence rate of 2×10^{13} n cm^{-2} s^{-1} for 1 h in the Kyoto University Reactor (KUR). The source, about 10 mCi in radioactivity initially, was immediately used for the measurement since the half life of ^{129}Te is very short (70 min). The Mössbauer measurement was carried out in the transmission geometry by cooling the source and the absorber to 16 K with a closed-cycle helium refrigerator. For the 2AC-$3I_2$ complex the spectra were measured at 78 K in addition to 16 K in order to make a comparison with the previous spectrum.[6] The Mössbauer spectrometer was calibrated using an iron foil spectrum.

Results and Discussion

The Mössbauer spectra of the 2TPPS-$3I_2$ and 2AC-$3I_2$ complexes are shown in Figs. 2 and 3. The top (a)

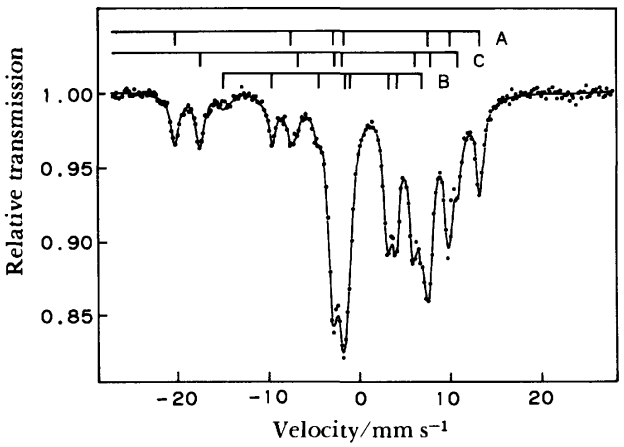

Fig. 2. ^{129}I Mössbauer spectrum of the 2TPPS-$3I_2$ complex at 16 K.

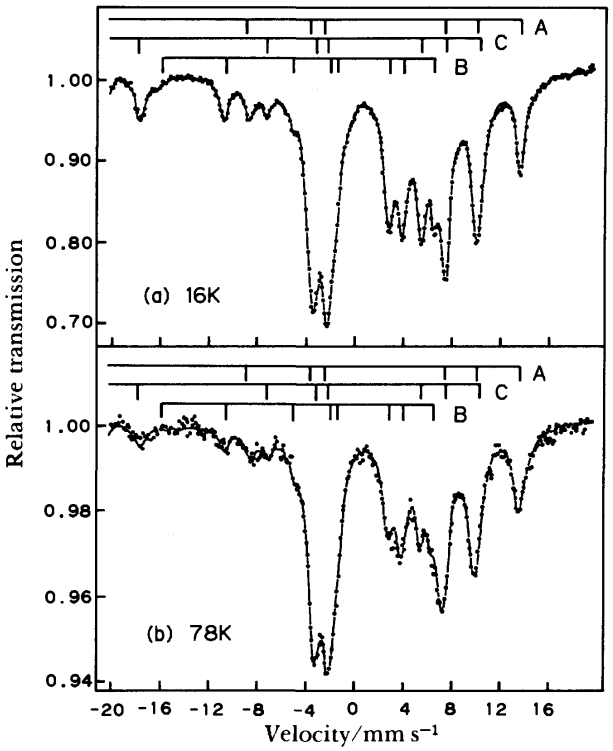

Fig. 3. ^{129}I Mössbauer spectra of the 2AC-$3I_2$ complex at (a) 16 K and (b) 78 K.

a) The e^2Qq values are converted to the ^{127}I nucleus. b) The δ values are relative to the ZnTe source. c) $U_p = -e^2Qq_{obsd}/e^2Qq_{atom}$, $e^2Qq_{atom} = 2292.7$ MHz. d) $\delta = 1.5h_p - 0.54$ (mm s^{-1}).

and bottom (b) spectra of 2AC–3I_2 in Fig. 3 were measured at 16 and 78 K, respectively. These spectra comprise three kinds of quadrupole octets (A, B, and C), as is expected from the crystal structures of 2TPPS–3I_2[3] and 2AC–3I_2[5]. The spectra were fitted with Lorentzian curves of an equal linewidth by a least-squares method using a triple set of the Mössbauer parameters, e^2Qq, η, and δ. The solid curves and the stick diagrams in the figures indicate the best-fitted superimposed Lorentzian curves and the peak positions, respectively. The Mössbauer parameters obtained are summarized in Table 1, together with the results for the usual 1:1 complexes of 1,4-dithiane-iodine[7] and pyridine–iodine.[8] The values of e^2Qq were converted to those for the ^{127}I nucleus.

The Mössbauer spectra of the 2TPPS–3I_2 and 2AC–3I_2 complexes, showing the existence of three unequivalent iodine atoms (I_A, I_B, and I_C), are similar to each other. This observation is in accord with the results of structural analyses for these complexes, in which the iodine groups have a similar configuration. It is established for usual 1:1 molecular complexes that the iodine atom coordinating to the donor atom indicates larger values of e^2Qq and δ than the terminal iodine atom. Therefore, it is appropriate to assign the iodine with the largest quadrupole splting (A) to the iodine atom (I_A) coordinating to the sulfur or nitrogen atom of each donor molecule, whereas the iodine with the smallest quadrupole splitting (B) should be assigned to the terminal iodine atom (I_B). The intermediate quadrupole splitting (C) corresponds to the iodine molecule (I_C) cross-linked to the two terminal iodine atoms, since the values of e^2Qq and δ are close to those for the solid iodine.[9] The Mössbauer spectrum of 2AC–3I_2 at 78 K is very similar to that previously measured at 85 K by Ichiba et al.[6] It was found from the comparison with the spectrum at 16 K that the absorption peaks corresponding to the intermediate quadrupole splitting (C) decrease more rapidly at 78 K than the other absorption peaks. This result implies that the iodine molecule cross-linked to two I_B atoms has a lower Debye temperature than the other iodine atoms.

The values of e^2Qq, η, and δ are closely related to the charge distribution and the charge density localized on the iodine atom as follows:[10,11]

$$U_p = -e^2Qq_{obsd}/e^2Qq_{atom} = -N_z + (N_x+N_y)/2, \quad (1)$$

$$\eta = 3(N_x-N_y)/2U_p, \quad (2)$$

$$\delta = -9.2h_s + 1.5h_p - 0.54, \quad \text{(mm/s, for ZnTe source)}, \quad (3)$$

and

$$h_p = 6-(N_x+N_y+N_z). \quad (4)$$

Here, U_p is the number of unbalanced p-electrons and e^2Qq_{atom}, the atomic iodine quadrupole coupling constant, is equal to 2292.7 MHz for ^{127}I. N_x,N_y, and N_z are the populations of 5p-electrons in the x, y, and z orbitals, respectively. The sign of e^2Qq, obtained directly from the unsymmetrical Mössbauer spectrum, shows whether the main bond of the iodine atom is σ-bonding (z-direction) or π-bonding (x or y direction). The e^2Qq values for all iodine atoms of the present molecular complexes are negative in sign, suggesting that the bonding of each iodine atom is predominantly of the σ-type. The asymmetry parameter (η), the deviation of the electric field from the cylindrical symmetry, is attributed to an additonal π-bonding or an intermolecular bonding in the x or y direction. The large η values for the terminal iodine atoms (I_B) in these complexes are due to the weak intermolecular $I_B\cdots I_C$ bonds, since the bond distances are 3.57 Å and 3.51 Å for 2TPPS–3I_2[3] and 2AC–3I_2[5], respectively (shorter than the sum of the van der Waals radius (4.30 Å)). The isomer shift (δ) is directly related to the s-electron density at the nucleus $|\psi_s(0)|^2$. Since the 5s-electron density is shielded by outer 5p-electrons, the δ value is also dependent on the 5p-electron density. This effect is expressed quantitatively as Eq. 3 by using Slater's shielding coefficients, where h_s and h_p are the numbers of 5s- and 5p-electrons removed from the $5s^25p^6$ (I^-) configuration, respectively. When the bonding of iodine is formed by only $5p_\sigma$-electrons, one expects the relationship $U_p=h_p=1\pm i$ to be valid, where i is the ionic character. If $5p_\pi$-electrons take part in bond formation (π-bonding), in addition to $5p_\sigma$-electrons, the relationship $U_p<h_p$ and non-zero η value are generally observed. On the other hand, the contribution of 5s-electrons (sp hybridization) leads to the relationship that $U_p>h_p$ because of the decrease in the s-electron density at the nucleus. The U_p and h_p values obtained for each iodine atom are presented in Table 1 (assuming that there is no contribution of 5s-electrons to the bonding of iodine).

It can be seen for the I_A atom coordinating to the S or N atom of each donor molecule that the h_p value is larger than the U_p value. The same tendency was found in the I_A atoms of the usual 1:1 complexes, such as thioether–iodine[7] and amine–iodine.[6,8] This relation has generally been explained in terms of the presence of double or intermolecular bonding in the x or y direction. However, it is quite difficult for the I_A atom to consider the presence of the double bond or the intermolecular bond from the crystallographic data of 2TPPS–3I_2[3] or 2AC–3I_2.[5] Furthermore, the η value was observed to be zero for the I_A atom in each complex. This phenomenon has been successfully interpreted in terms of the slight contribution of core $4d_\sigma$-electrons (dp hybridization) to the charge-transfer bond formation, in addition to the delocalized three-center four-electron bonding.[7,8] The promotion energy of the $4d_\sigma$-electron is probably compensated for

by the stabilization of the charge-transfer bond formation. The contribution of the $4d_\sigma$ hybridization remarkably increases the δ value but hardly increases the e^2Qq value. Therefore, the net charge density is close to that obtained from the e^2Qq value. Consequently, the charge densities localized on the I_A atoms of the 2TPPS-$3I_2$ and 2AC-$3I_2$ complexes were evaluated to be approximately +0.12 e and +0.27 e, respectively, by using Eqs. 4 and 5 in Ref. 8. The same calculations lead to charge densities of +0.07 e and +0.11 e for the I_A atoms in dithiane-iodine[7] and pyridine-iodine[8], respectively.

On the other hand, the relationship $U_p<h_p$ and the non-zero η value for the terminal I_B atom are attributable to the additional intermolecular $I_B\cdots I_C$ bond as previously described. Both I_B atoms of the present complexes were estimated to be negatively charged by about 0.39 e from the h_p values (close to the charge densities on the I_B atoms of the 1 : 1 complexes). From the η values for the I_B atoms, very little charge (ca. 0.06 e for 2TPPS-$3I_2$ and ca. 0.04 e for 2AC-$3I_2$) was found to be transferred to the iodine molecule (I_C) cross-linked to the two I_B atoms along the weak $I_B\cdots I_C$ bond. The charge transfer leads to an increase in the charge densities on the I_C atoms of these complexes. The U_p and h_p values for the I_C atoms are in agreement with each other, indicating that the bonding is mainly due to $5p_\sigma$-electrons. The charge densities localized on the I_C atoms are estimated to be −0.04 e and −0.01 e for the 2TPPS-$3I_2$ and 2AC-$3I_2$ complexes, respectively (from the mean values of U_p and h_p). The charge densities obtained for the I_C atoms agree with those transferred from the I_B atoms within the experimental error. Therefore, the slightly negative charge densities on the I_C atoms are apparently due to the charge transfer from the I_B atoms. This result is consistent with the increase in the bond distance (2.73 Å) between the I_C atoms, compared with the gaseous iodine molecule (2.67 Å), since the transferred charges occupy the antibonding molecular orbital (σ_u^*) of the iodine molecule. The charge densities obtained for the I_A, I_B, and I_C atoms of the investigated complexes from the Mössbauer parameters are presented in Fig. 4, together with those for the 1,4-dithiane-iodine[7] and pyridine-iodine[8] complexes.

As shown in Fig. 4, the I_A atoms in the unusual 2:3 molecular complexes are more positively charged than those in the usual 1 : 1 complexes containing the same donor atoms. This result can be qualitatively interpreted on the basis of the strength of a covalent bond between the donor and the I_A atoms. The positive charge on the donor atom, arising from the charge transfer to the iodine molecule, is delocalized on the I_A atom by back donating along the covalent $S\cdots I_A$ or $N\cdots I_A$ bond. The degree of the back donation increases with an increase in the covalency of the intermolecular bond. It is clear from a comparison of the bond distances that the covalency of the $S\cdots I_A$ bond is stronger in the 2TPPS-$3I_2$ complex than in the 1,4-dithiane-$2I_2$ complex. Therefore, it is concluded that the positive charge density on the I_A atom is dependent on the covalency of the intermolecular

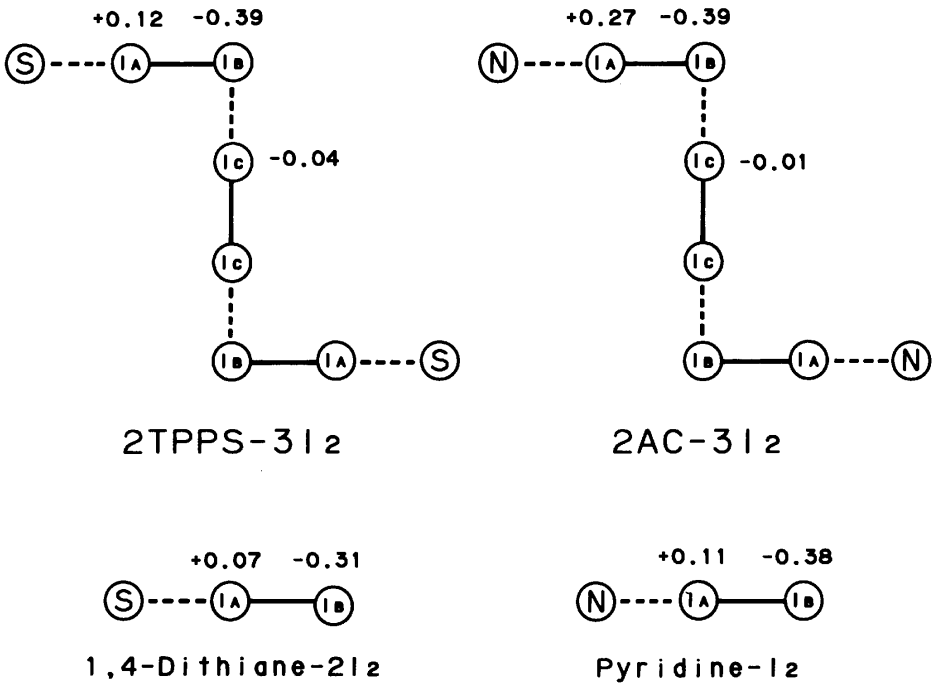

Fig. 4. Charge densities localized on the iodine atoms for the 2TPPS-$3I_2$, 2AC-$3I_2$, 1,4-dithiane-$2I_2$, and pyridine-I_2 complexes.

bond between the donor and the iodine molecules, but not on the degree of the charge transfer from the donor molecule to the iodine molecule. The I_A atoms in the amine complexes are also found to be more positively charged than those in the sulfur-containing donor complexes. As pointed out in our previous paper,[7] this fact is because the amine cations (N^+), produced by a charge transfer, have a larger electron affinity than the sulfur cations (S^+) in the sulfur-containing donor molecules and, therefore, attract more electrons from the I_A atom than do S^+. The charge densities localized on the I_B atoms in the 2:3 complexes are close to those in the 1:1 complexes, suggesting that the degree of the charge transfer is comparable to each other.

The linear S···I_A–I_B or N···I_A–I_B bond can be essentially described in terms of a delocalized three-center four-electron bonding in the electronic ground state, and resembles the linear triiodide anion (I_3^-) very closely in chemical bonding. The similarity seems to explain the formation of the unusual 2:3 complex: the I_3^- anions combine with the I_2 molecules to form polyiodides such as a pentaiodide anion (I_5^-), a heptaiodide anion (I_7^-), and an octaiodide dianion (I_8^{2-}). The structure of the iodine moieties in the 2TPPS-3I_2 and 2AC-3I_2 complexes is very similar to that of Cs_2I_8, in which the iodine atoms consist of two I_3^- units and one I_2 unit with a flat Z-shaped structure.[12] Furthermore, the distances of the intra- and intermolecular bonds in the iodine moiety are close to each other.

The authors wish to thank Prof. Takenobu Higashimura (Research Reactor Institute, Kyoto University) for his useful discussion and encouragement. The authors are also grateful to Prof. Tokiko Uchida (Faculty of Science and Technology, Science University of Tokyo) for her suggestions and advice concerning unpublished crystallographic data of the 2AC-3I_2 complex.

(Received December 1, 1986)

Solid-state ^{2}H NMR spectra were measured as a function of relative humidity for nonoriented DNA films and oriented DNA fibers deuterated at C8 carbons of the purine bases. The line-shape analyses of the quadrupole echo spectra from oriented DNA fibers demonstrated that the purine base planes of the A form of DNA were tilted by about 70° relative to the helix axis, and that base planes of the B form varied significantly, although they were, on average, perpendicular to the helix axis. These results were generally consistent with the X-ray fiber diffraction studies and the single crystal structures of oligonucleotides. Analyses of ^{2}H relaxation times, T_1 and T_2, showed at 79% RH that the orientation of the base planes fluctuated about an axis normal to the helix axis with a correlation time, $\tau_c=3.6\times10^{-8}$ s and amplitude of 8.5°. The correlation time of the base plane fluctuation was 1.5×10^{-8} s and the amplitude was 13.5° at 92% RH. In addition, at 92% RH, but not at 79% RH, the base planes reoriented slowly, $\tau_c \approx 10^{-6}$ s, about the helix axis, through an rms angle of ca. 30°.

We have recently reported ^{31}P nuclear magnetic resonance (NMR) studies of the structure and dynamics of DNA in the fibers as a function of relative humidity.[1,2] The results were in general agreement with the structure inferred from the X-ray diffraction studies of the fibers at relatively low humidities, but differed from the X-ray results, in some respects, at high humidities. The most interesting conclusion derived from the NMR studies is the finding of heterogeneity in the structure and dynamics in the backbone of the B form of DNA at high relative humidities. It seems likely that local heterogeneity in dynamics and structure also occurs in base domains as well.

However, some lines of evidence indicate that the base domains are less mobile than the DNA backbone in the fiber;[3] in crystals,[4] and in solution.[5,6] Since ^{31}P NMR only provides information about the phosphodiester groups of DNA, a question arises as to whether the conclusions derived from ^{31}P NMR studies correctly represent the nature of the base domains as well. It is therefore important to examine the base domains of DNA using the same conditions as employed in ^{31}P NMR studies. ^{2}H NMR is the most suitable probe if nonexchangeable protons of the bases of DNA are selectively substituted by deuterium nuclei. DiVerdi and Opella[3] and later Bendel et al.[7] have reported the solid state ^{2}H NMR studies of DNA with the deuterium-labeled purine bases at C8 position. The former group has attributed the different behavior of ^{2}H and ^{31}P NMR line-shapes, observed when humidity or temperature was changed, to differences in flexibility in the backbone and base domains in hydrated DNA. We have pointed out, however, that differences in the ^{2}H and ^{31}P NMR time scales must be taken into account in the line-shape analysis, and we also suggested that more clear-cut conclusions could be obtained if oriented DNA samples were used for NMR measurements.[2] Recently Vold et al.[8] reported a ^{2}H NMR study of oriented Na- and Li-DNA samples at relatively low humidities.

In the present study, we prepared highly oriented Na-DNA fibers by the traditional method, rather than the wet-spinning technique[9] employed by Vold et al.[8] that produces a block of oriented sample. Humidity control is easier for the fibers than for the DNA block because of the size of sample. We report measurements of ^{2}H NMR spectra and relaxation times of two typical forms of DNA, i.e., the A and B forms of oriented DNA fibers with deuterated purine bases, and discuss the structure and dynamics of DNA fibers. We also show that ^{2}H and ^{31}P NMR results are consistent and discuss the relative merits of ^{2}H and ^{31}P NMR spectroscopy for studying DNA.

Experimental

Deuterium Labeled Nucleosides and DNA. Lyophilized salmon sperm DNA was purchased from P. L. Biochemicals and purine nucleosides were from Sigma Chemical company U.S.A. Nucleosides were dissolved in D_2O, heated at 90 °C for 6 h, dried in vacuo. They were redissolved in H_2O and dried, and this procedure was repeated several times to remove the residual D_2O. The degree of deuteration at C8 position was checked by ^{1}H NMR. Deuterium exchange of C8 position of purine bases of DNA was carried out following the method of tritium exchange of DNA by Doppler-Bernardi and Felsenfeld.[10] Lyophilized DNA was dissolved overnight into D_2O (10 mM††† Tris-HCl, 1 mM EDTA, pH 7.5) and then the solution was mixed with 4.0 M NaCl and 10 mM Tris in D_2O to a final concentration of 2.0 M NaCl and 10 mM Tris (pH 7.5). The solution was held at 83 °C in a thermostat for 10 h and then cooled in an ice bath. Two volumes of cold ethanol were added, yielding a fibrous precipitate. The precipitate was dried in the atmosphere and redissolved in H_2O, 10 mM Tris, at 4 °C overnight. The solution was exaustively dialyzed against H_2O, 10 mM NaCl, for 2 d.

††† 1 M=1 mol dm^{-3}

DNA Films and Fibers. The solution of DNA (1—2% w/v) prepared above was centrifuged at 50000 rpm for 16 h, yielding viscous pellets. The viscous pellets were dried on a plastic sheet in the atmosphere to make films, and many pieces of films were collected for NMR measurements. To make an oriented fiber a drop of the pellet was placed between the ends of tooth picks and left to dry in the atmosphere. Optically homogeneous fibers of 3—5 mm length and 0.1—0.3 mm diameter were usually obtained. The fibers gave excellent X-ray fiber diffraction images of the A type of DNA at 79% RH.

NMR Measurements. About 40 fibers were aligned in parallel on a sample holder and held overnight for equilibration in the atmosphere of a given humidity. The DNA films prepared above were also equilibrated at an appropriate humidity before NMR measurements. Relative humidity was controlled by saturated solutions of various salts.[11] The sample holder was inserted into a sample tube (6 mm o.d.), capped tightly and mounted on a goniometer. ^{2}H NMR spectra were obtained at 38.45 MHz with a quadrupole echo pulse sequence, 90°-τ-90°-τ-FID, on a home-built spectrometer with a NIC-1280 computer (for details, see Sarkar et al.[12]). Some ^{2}H NMR spectra were observed at 76.77 MHz on a NIC-500 spectrometer (Nicolet Inc.). The 90° pulse was 2.5 μs at 38.45 MHz and 3.0 μs at 76.77 MHz. A time interval of 50 μs was used between the two pulses of the echo sequence, unless otherwise stated, to eliminate the base line distortion caused by probe ringing after the pulse.

Relaxation times T_1 and T_2 were measured by a progressive saturation method with variable repetition time, and a quadrupole echo with variable pulse interval, respectively. All measurements were performed at 22 °C.

Analysis of ^{2}H NMR Spectra

In the case of the ^{2}H nucleus the solid-state NMR spectrum is dominated by the electric quadrupole interaction whose coupling constant for ^{2}H in C-^{2}H bonds e^2qQ/h=180 kHz can lead to spectra up to 250 kHz wide. As a result, the quadrupole echo spectrum may be distorted depending on the ^{2}H relaxation time and the instrumental performance. A general rewiew of ^{2}H NMR spectroscopy[13] has appeared recently and spectral distortions have been analyzed in detail, taking into account the effect of relaxation (Spiess and Sillescu[14]) and finite pulse power (Bloom et al.[15]).

Analysis of the ^{2}H NMR spectrum from an axially oriented specimen is straightforward. By the analogy with the analysis of the ^{31}P NMR from oriented DNA fibers,[1,16] the frequencies of the observed quadrupolar split lines, $\nu^{obsd}(\phi,\alpha)$, are give by

$$\nu^{obsd}(\phi,\alpha) = \pm\sqrt{\frac{3}{2}}\frac{eQ}{2\hbar}\rho_{20}^{lab}$$

$$\rho_{20}^{lab}(\phi,\alpha) = \sum_{m,n,p=-2}^{2} D_{p0}^{(2)}(0,\phi,0)D_{np}^{(2)}(\psi,\theta,0)D_{nm}^{(2)}(\alpha,\beta,\gamma)\rho_{2n} \quad (1)$$

for ^{2}H with I=1. Here $D_{nm}^{(2)}(\alpha,\beta,\gamma)$ is the Wigner rotation matrix of the second rank, ρ_{2n} is the irreducible EFG tensor in the principal axis system[17] and the Euler angle notations are given in Figs. 1A and B. The principal axis system of the tensor is defined by Euler angles α, β, and γ with respect to the molecular fixed axis system (a, b, c). The fiber axis system is taken to be identical to the goniometer axis system (Fig. 1B). The goniometer angle ϕ between the fiber axis and the magnetic field direction can be varied. The spectrum in which ϕ=0° corresponds to the spectrum of the fibers oriented parallel to the magnetic field, and the spectrum at ϕ=90° is that of fibers oriented perpendicular to the field. The angle θ is the angle made by the molecular fixed axis, c, and the fiber axis. As described previously,[1] the spectrum at a given ϕ can be calculated by the superposition of the spectral lines with appropriate weights over all the possible angles for α, β, γ, θ, and ψ. Gaussian distributions were also assumed for β and θ with standard deviations, $\langle\Delta\beta\rangle$ and $\langle\Delta\theta\rangle$, respectively.

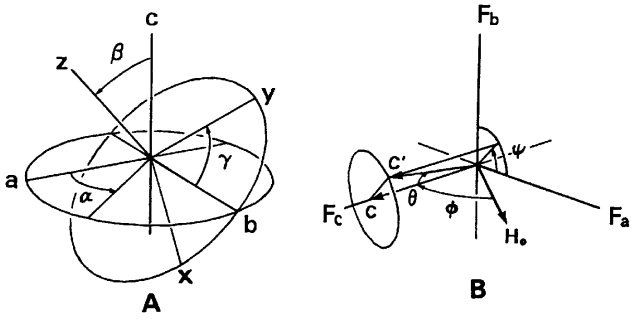

Fig. 1. Coordinate systems. (A) System (a, b, c) represents the molecular fixed system and axis c coincides with the helix axis of DNA. The principal axis system (x, y, z) of the quadrupolar coupling tensor is described by Euler angles α, β, and γ with respect to the molecular axis system as a reference frame. (B) Vector c lies along the fiber axis and vector c′ represents the helix axis of misaligned DNA which makes an angle θ with respect to the fiber axis. H_0 is the magnetlc fieid and ϕ is the goniometer angle.

Results

The degree of deuteration at the C8 positions of guanosine and adenosine was estimated to be about 70 and 75%, respectively, from the signal intensity in the ^{1}H NMR spectrum of each molecule in $CDCl_3$. According to the tritium-exchange reaction[10] of DNA in D_2O solution at 83 °C for 10 h, 30% of the total number of guanosine and adenosine residues, about 20% of the adenosine and 40% of the guanosine residues, were assumed to be deuterated. No appreciable degradation was expected under our experimental conditions.

^{2}H Powder Pattern Spectra. The spectra from polycrystalline guanosine and adenosine exhibited a typical static powder pattern with a quadrupolar splitting of 126±2 kHz as shown in Fig. 2. The long relaxation time T_1 of these samples at 22 °C, 30±10 s, indicated that the molecules were virtually immobile. It is interesting to note that the sugar ring of deoxyguanosine is found to be mobile.[18] The best visual fit with the observed spectrum of adenosine, shown in the bottom of Fig. 2, yielded values of principal frequencies of the quadrupolar coupling tensor, ν_1, ν_2, and ν_3, of −72±1, −63±1, and 135±3 kHz, respectively. The resulting nuclear quadrupole coupling constant and asymmetry parameter were 180±3 kHz and 0.06—0.07(±0.01), respectively. On the other hand, the parameter η of guanosine was a little larger than that of adenosine but it was in the above error range. The non-zero asymmetry parameter observed for the C8-^{2}H bonds in guanosine and adenosine is not surprising because a value of η=0.07—0.08 have been reported for the C2-^{2}H bonds in imidazole and benzimidazole at 77 K by Hiyama et al.[19]

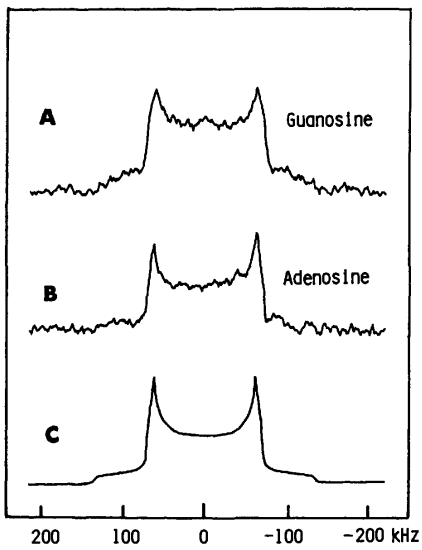

Fig. 2. Quadrupole echo ^{2}H NMR spectra (38.5 MHz) of polycrystalline guanosine (A), adenosine (B), and simulated powder pattern (C) at 22 °C. Measurement conditions: Spectral window 1 MHz; data points 4096 with zero filling; pulse width 2.2 μs; pulse interval 50 μs; delay time 40 s; exponential line broadening 2 kHz; scan number 1600. The simulated spectrum (C) was calculated using line broadening of 2 kHz and the principal values, 132, −64, and −70 kHz for ν_3, ν_2, and ν_1, respectively.

Figure 3 shows the ^{2}H powder patterns of DNA films, labeled at C8 position of guanosine and adenosine, at 79 and 92% RH. Note that a spike at the center of each spectrum arises from the natural abundance of deuterium water in the sample. At each relative humidity, two spectra were obtained by the quadrupole echo method with different pulse intervals (the time between $\pi/2$ pulses). The top spectrum was obtained with a 50 μs pulse interval and the bottom was with a 100 μs interval.

The reduction of signal intensity observed at 79% RH with the larger interval is a consequence of the finite T_2 value (200 μs) of the sample. The anisotropy in T_2 is evidently quite small, since the line-shapes observed using both pulse intervals are virtually identical to those of guanosine and adenosine (Fig. 2). The quadrupolar splitting (123±2 kHz) is slightly smaller than that observed for adenosine (126±1 kHz). The large splitting observed in the DNA sample shows that the amplitudes of molecular motions are small, and the small intensity losses (due to finite T_2) show that the amplitudes of motion on the time scale of ω_Q^{-1} (10^{-4}—10^{-6} s) are insignificant.

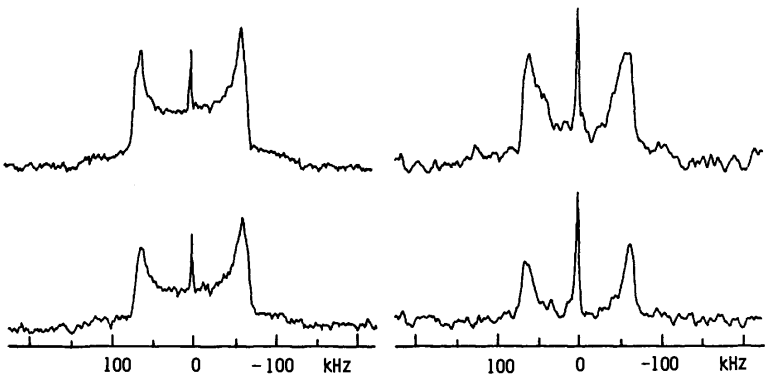

Fig. 3. Quadrupole echo spectra (38.5 MHz) of ^{2}H NMR of nonoriented DNA films at 79% RH (left) and 92% RH (right). Top and bottom spectra were taken with different pulse intervals, 50 and 100 μs, which may be used for examining the anisotropy effect of the relaxation time T_2. The measurement conditions were almost the same for all the samples as in Fig. 2, with delay time 0.6 s and scan number 32000.

Although the line-shape and T_2 data at 79% RH are similar to those observed in the model compounds, the measured T_1 is much smaller in DNA than in the model bases (Table 1). This implies that a small amplitude motion is taking place on the time scale of ω_0^{-1} (10^{-7}—10^{-10} s) in the 79% RH sample.

We can obtain an estimate of the amplitude of this motion by comparing the observed quadrupole splitting in DNA with the splitting observed in the model compounds. $2|\nu_1|$ and $2|\nu_2|$ (the quadrupole splittings) in DNA were smaller by 5.0 (±1) and 4.0 (±1) kHz, respectively, than in the model compounds. Because the reduction in splittings is much less than $2|\nu_1|-2|\nu_2|$ for either guanosine or adenosine, 16 kHz, there is little likelihood of the principal axis interchange between the nucleoside and DNA. Therefore, we make the reasonable assumption that the orientation of the nonaveraged ^{2}H EFG tensor is the same in the nucleoside and in the DNA molecule.

Table 1. Relaxation Times T_1 and T_2 of ^{2}H NMR at 38.5 MHz of Unoriented DNA Films and Oriented DNA Fibers at 22 °C

Relative Humidity/%	T_1/ms[a]		T_2/μs[a]	
	DNA Film	Fiber[b]	DNA Film	Fiber[b]
75	177±20	—	164±15	—
79	167±13 (480±80)[c]	158±25	183±20	—
87	75±9	—	134±14	—
92	30±6 (71±14)[c]	25±7	96±9	100±20
98	16±3	—	101±8	—

a) Relaxation times measured for the perpendicular component of the tensor in the powder pattern spectrum of DNA films. b) Relaxation times measured for the parallel spectrum of DNA fibers. c) T_1 values measured at 76.8 MHz.

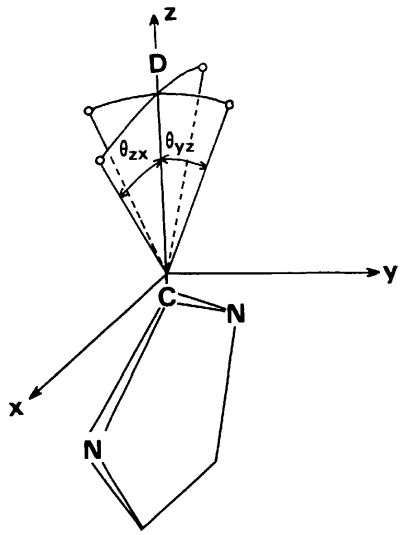

Fig. 4. Principal axis system (x, y, z) of the EFG tensor relative to the atomic coordinates of a purine base, and two sets of two jump sites for the C8-^{2}H bond whose fluctuation amplitude are represented by θ_{zx} and θ_{yz}.

The reduced splittings were analyzed using the four-site jump model illustrated in Fig. 4. If the jump rate is much larger than ω_Q, the motionally averaged principal frequencies, $\bar{\nu}_1$ and $\bar{\nu}_2$, are related to the motional amplitudes, θ_{zx} and θ_{yz}, by following equations

$$\bar{\nu}_1 = \frac{1}{2}(\nu_1+\nu_1\cos^2\theta_{zx}+\nu_3\sin^2\theta_{zx}), \quad (2)$$

$$\bar{\nu}_2 = \frac{1}{2}(\nu_2+\nu_2\cos^2\theta_{yz}+\nu_3\sin^2\theta_{yz}). \quad (3)$$

Using these equations together with two sets of the observed values of ν_i and $\bar{\nu}_i$ (i=1, 2), θ_{yz} and θ_{zx} were calculated to be 8.1° and 8.9°, respectively. Since these angles are nearly equal, the motion does not appear to have a preferential axis.

As mentioned earlier, the spin-lattice relaxation time, T_1 at 79% RH, 167 ms, is substantially shorter than that found in the nucleosides. The possible minimum T_1 resulting from dipole-dipole interactions with the nearest neighbor protons is about 10 s. Therefore, T_1 is determined by quadrupolar relaxation.

Since in the line-shape we assumed that the rotation about a single axis is not likely at 79% RH, we analyse the measured T_1 values at 38.5 and 76.8 MHz using the diffusion-in-a-cone model. In this model we assume that the C–^{2}H bond diffuses uniformly over the surface of a cone having semiangle θ_0. In this case the rms fluctuation in θ is $\sqrt{\theta_0^2/2}$, and θ_{rms} is taken to be the average of θ_{zx} and θ_{yz}, 8.5°, calculated from the line-shape analysis. Using the general formalism of Torchia and Szabo[17] together with the condition that $\theta_{rms}^2 \ll 1$, we find that

$$\left\langle \frac{1}{T_1} \right\rangle = (\omega_Q^2/10)\sin^2 2\theta_{rms}[g(\tau,\omega_0) + 4g(\tau,2\omega_0)], \quad (4)$$

where $\langle\cdots\rangle$ indicates the average overall orientations of the field relative to a crystal fixed axis system, and $g(\tau,\omega)$ equals $\tau(1+\omega^2\tau^2)^{-1}$. In writing Eq. 4 we have made the approximation that η equals zero and $\omega_Q/2\pi$ is taken to be the average of $2|\nu_1|$ and $2|\nu_2|$ of the nucleoside. Inserting the measured values of $\langle 1/T_1\rangle$, ω_Q, θ_{rms}, and $\omega_0/2\pi$ (38.5 MHz) into Eq. 4 we obtain two solutions τ_c=2.5×10^{-10} and 3.6×10^{-8} s. Only the larger value is consistent with the observation of a strong frequency dependence of T_1 (Table 1). The ratio of T_1 at 76.8 MHz to T_1 at 38.5 MHz was 2.9±0.5 which was a little smaller than the theoretical value of 4.0.

In contrast with the 79% RH DNA spectra (left, Fig. 3) the 92% RH DNA powder patterns (right, Fig. 3) are distinctly different from the static powder patterns of the model compounds, Fig. 2. Only the perpendicular components of the pattern have significant intensity. This observation suggests that the DNA molecule reorients about the helix axis with a correlation time in the 10^{-4}—10^{-7} s range. Such a motion would cause T_2 to be very short for all orientations of the field relative to the helix axis, except for the field parallel to the rotation (helix) axis.

In order to estimate the rate and amplitude of the axial motion, the observed spectra were simulated using an N-site jump model, in which jumps were restricted to nearest neighbors (Fig. 5). The computer program includes correction for the relaxation effect on the line-shape of quadrupole echo spectrum as reported by Speiss and Sillescu.[14] Six sites are sufficient to approximate rotational diffusion, and limit computational costs. Figure 6 shows spectral shape as a function of maximum rotation amplitude (i.e., 5 ω). Each jump rate, k, shown in the figure legend was estimated so as to give a reasonable fit to the observed spectra (right, Fig. 3). It was found that a maximum rotation amplitude of 150°, i.e., root mean square fluctuation for each jump Φ_{rms}, of at least 30°, was required to simulate the observed 92% RH DNA spectrum. As expected, the jump rate required to fit the spectrum, $(2\pm1)\times10^6$ s^{-1}, was approximately equal to $\omega_Q/2\pi$. Motions on the time scale of ω_Q result in anisotropic T_2 values which cause intensity losses and line-shape distortions in ^{2}H spectra. Although satisfactory spectral simulations were also obtained with values of Φ_{rms} greater than 30°, again with the jump rate approximately equal to ω_Q, these solutions were ruled out by the ^{31}P spectra of 92% RH DNA. These spectra showed that the ^{31}P chemical shift anisotropy, $\sigma_{33}-\sigma_{11}$, observed in the spectra of 92% RH at 24 MHz (Shindo et al.[20]) and 40 MHz (not shown) were only 12% smaller than that in the spectra of the 79% RH DNA. Futhermore, by applying a restricted rotation model with a rectangular potential well to the ^{31}P NMR data of DNA fibers at 92% RH, the average rotation amplitude about the helix axis was estimated to be about 130° (Fujiwara and Shindo[2]). This amplitude is close to the maximum rotation angle of 150° as estimated above. Therefore only the motions of restricted six-site jump model having a root mean square fluctuation less than 35° are consistent with the ^{31}P data.

Although the restricted, slow azimuthal reorientation of the DNA molecule accounts for the line-shape observed at 92% RH, this motion does not explain

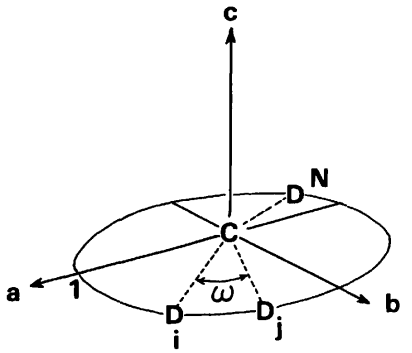

Fig. 5. N site jump model for rotational motion about the helix axis. Jumping is allowed only between nearest neighbors with jump rate k and jumping matrix $R_{i,i+1}=k$. For free jump, site N+1 equals site 1, allowing $R_{1N}=R_{N1}=k$. For restricted jump, $R_{1N}=R_{N1}=0$.

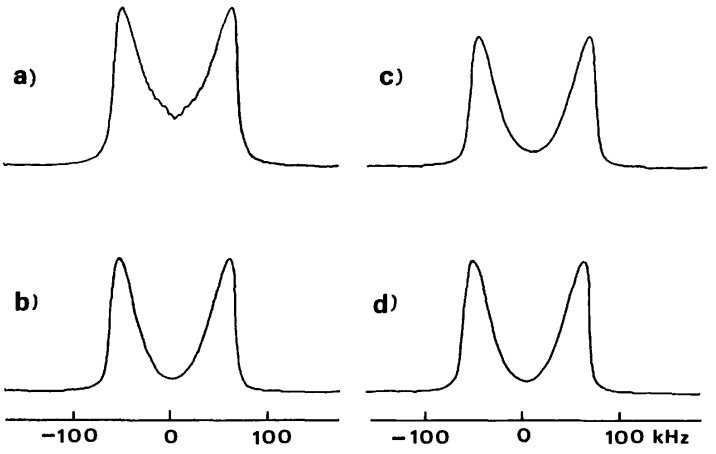

Fig. 6. Calculated ^{2}H NMR powder patterns based on the six-site jump model, (a) $5\omega=100°$, $k=2.5\times10^6$ rad s^{-1}, (b) $5\omega=150°$, $k=3\times10^6$ rad s^{-1}, (c) $5\omega=200°$, 1.5×10^6 rad s^{-1}, (d) $5\omega=250°$, $k=10^6$ rad s^{-1}. Angle ω represents the azimuthal angle between nearest neighbor sites as in Fig. 5.

either the small average T_1 value, Table 1, measured at 92% RH or the 5 kHz reduction in $2|\nu_1|$ observed when RH is increased from 79 to 92%. The rotational motion is too slow, i.e., the correlation time is too far from the T_1 minimum, to account for the small T_1 value, and the motion about the helix axis does not affect the value of $2|\nu_1|$ regardless of time scale. The reduction of $2|\nu_1|$ with increasing RH can be explained by assuming that the amplitude of the C-^{2}H bond fluctuation in the cone, θ_{rms}, increases from 8.5 to 13.5° upon increasing RH from 79 to 92%. Using this value in Eq. 5 together with the measured values of $\langle 1/T_1 \rangle$, ω_0, and ω_Q, we calculate $\tau_c = 1.5 \times 10^{-8}$ s, ca. one-half as large as found at 79% RH.

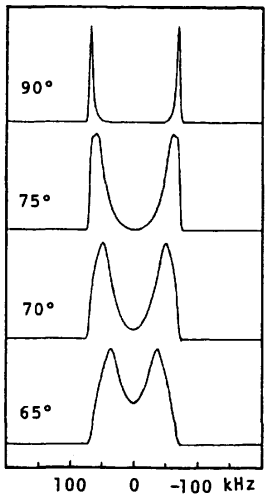

Fig. 7. Effect of Euler angle, β, and the distribution of $\langle \Delta\beta \rangle$ and $\langle \Delta\theta \rangle$ on the spectrum of DNA fibers oriented parallel to the magnetic field direction. A series of spectra show the dependence of spectral pattern on Euler angle β with fixed parameters, $\langle \Delta\beta \rangle = 3°$, $\gamma = 0°$, $\langle \Delta\theta \rangle = 8°$

^{2}H Spectra of Oriented DNA Fibers. Before presenting the experimental spectra of axially aligned DNA fibers we first present theoretical spectra which demonstrate how Euler angle β and standard deviations of β and θ affect the line-shape. The standard deviations $\langle \Delta\theta \rangle$ and $\langle \Delta\beta \rangle$ represent the imperfect alignment of molecules along the fiber axis and heterogeneity of the local structure, respectively. In calculating the theoretical spectra, the orientation of the ^{2}H EFG tensor was assumed to be as shown in Fig. 4, and effects of molecular motion on the line-shape were included with use of motionally averaged principal frequencies.

Figure 7 shows a series of the theoretical spectra calculated for DNA fibers oriented parallel to the magnetic field. The spectra in Fig. 7 demonstrate how the line-shape changes as a function of Euler angle β. The values of the other parameters were goniometer angle $\phi = 0°$, standard deviations $\langle \Delta\beta \rangle = 3°$ and $\langle \Delta\theta \rangle = 8°$, $\gamma = 0°$ and line-width=2 kHz. As expected, the dependence of the peak separation on β is weak around ca. 90°, and becomes stronger as β decreases. It is important to note that at $\phi = 90°$ the spectrum (top, Fig. 7) is hardly affected by either $\langle \Delta\beta \rangle$ or $\langle \Delta\theta \rangle$.

We now turn to an analysis of the experimental spectra. Figure 8 shows the observed and simulated spectra for the fibers at 79% RH oriented parallel, at 45°, and perpendicular to the magnetic field. The fibers at this humidity gave a typical A form of DNA as judged from the X-ray fiber diffraction patterns. Simulated spectra, which reproduced the observed spectra, were calculated using the parameters, $\beta = 70°$, $\langle \Delta\beta \rangle = 3°$, $\gamma = 0°$, and $\langle \Delta\theta \rangle = 8°$. Simulated spectra include 10% of the B form in the A form of DNA,

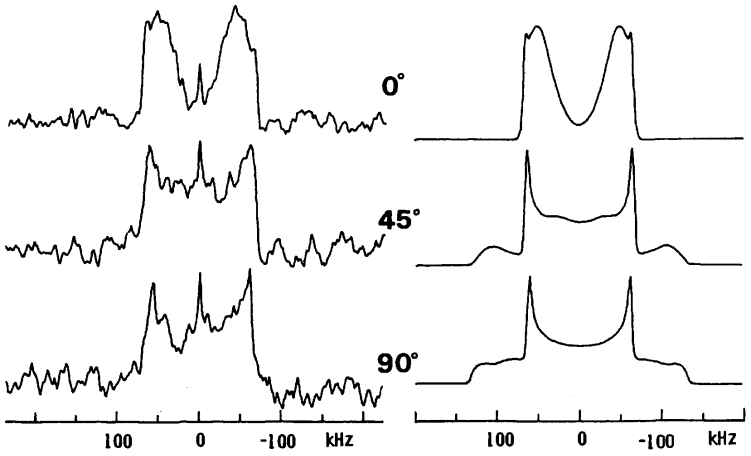

Fig. 8. Quadrupole echo spectra (left) of ^{2}H NMR (38.5 MHz) of oriented DNA fibers at 79% RH at different orientations of fiber axis to the magnetic field as indicated, and simulated spectra (right). Measurement conditions are the same as in Fig. 2, except for pulse width 2.5 μs, delay time 0.3 s, line broadening 2 kHz, scan number 120000—160000.

which gives small peaks at the edges of both sides in the parallel spectrum. The signal components beyond ca. 100 kHz from the carrier were attenuated, because of the finite pulse power of the instrument ($\pi/2$ pulse with 2.5 μs) and were not detectable above the noise level. The standard deviation in θ, $\langle\Delta\theta\rangle=8°$, was estimated from the ^{31}P NMR of the same sample (data not shown), and was close to the value of 10° reported previously (Shindo et al.[1]). The value obtained for β, 70°, has an experimental error of less than three degrees, because the peak separation is very sensitive to the value of β, where β is in the range 65°—75°, Fig. 7. The narrow distribution of β is consistent with the fact that the A form of DNA has a very narrow conformational distribution,[1,16] i.e., the structure is independent of the base composition and sequence.

Although we were able to simulate the 79% RH fiber spectra using the static quadrupole coupling obtained for the model compounds, the splittings in the calculated fiber spectra were always larger than the measured splitting. The best simulations of those measured DNA fiber spectra at 79% RH were obtained using a quadrupole splitting that was 4 kHz smaller than that measured in the model compounds. This result confirms the conclusion, obtained from the analysis of the spectra of DNA films, that a small amplitude motion $\theta_{rms}=8.5°$ takes place in DNA at 79% RH. Further support for this conclusion is provided by the small T_1 value observed in the fiber sample, Table 1, which agreed (within experimental error) with the measurement of T_1 at the perpendicular component in the spectrum of DNA films at 79% RH. Finally we note that because the small amplitude motion takes place on a rapid time scale, $\omega_Q\tau_c\ll1$, T_2 is large for all orientations relative to the external magnetic field H_0. For this reason, the same relative intensity was observed in the spectra of all three orientations shown in Fig. 8.

Figure 9 shows the observed and simulated spectra of the fibers at 92% RH oriented parallel, at 45°, and perpendicular to the magnetic field. All the spectra were measured under the same conditions and were recorded in the absolute intensity mode. The simulated spectra are normalized to have a constant spectral area. The fibers gave an X-ray pattern of the B form of DNA, and therefore we used the X-ray structure of the B form of DNA (Arnott et al.[21]), together with the results of ^{31}P NMR (Shindo et al.[1]) to set initial parameters for simulating the spectra in Fig. 9: The base plane was nearly normal to the helix axis, i.e., $\beta=90°$ and $\gamma=0°$ with standard deviations $\langle\Delta\beta\rangle=10°$ and $\langle\Delta\theta\rangle=8°$. The peak separation measured for the parallel spectrum was 132±2 kHz, corresponding to the peaks at ±66 kHz. The value of 66 kHz is closer to the principal value $|\nu_1|$ than $|\nu_2|$. Considering that the base plane is nearly perpendicular to the helix axis, the axis of ν_1 must be approximately parallel to the helical axis, i.e., $\beta=90°$ and $\gamma=0°$ or 180°. In agreement with the results obtained at 79% RH the best simulation of the observed splittings at 92% RH was obtained by assuming principal values of the EFG tensor were reduced from their static values by small amplitude motion, $\theta_{rms}=13.5°$. The T_1 value observed for the oriented fibers (parallel orientation) is listed in Table 1 where it is seen that the T_1 values measued for the fibers and films at 92% RH are in agreement within experimental error. This result confirms that a small amplitude motion occurs in the fibers. The parallel spectrum is quite sharp (natural line-width ca. 6 kHz)

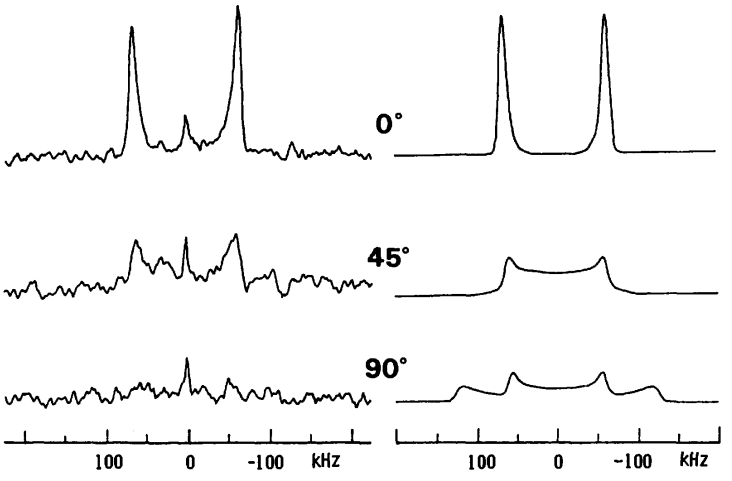

Fig. 9. Quadrupole echo spectra (left) of the ^2H NMR of oriented DNA fibers at 92% RH and at different orientations of the fiber axis, and simulated spectra (right). All the spectra were obtained under the same conditions as in Fig. 6, with delay time 0.3 s and scan number 112000.

in spite of the presence of fairly wide distributions of β and θ. This observation is caused for the fact that the peak positions are very insensitive to changes in β and θ when $\beta=90°$, as mentioned above (Fig. 7). In contrast with the results obtained at 79% RH, large intensity losses were observed when the sample was oriented at 45 and 90° with respect to the field, Fig. 9. In fact, at 90° orientation, the signal intensity was not above the noise level, and at 45°, the signal was observed in the neighborhood of the perpendicular components of the spectrum ($\nu\approx\pm65$ kHz). These observations are explained by the slow reorientation of the DNA about the fiber axis (rms fluctuation 30°, $\tau_c\approx10^{-6}$ s) discussed in conjunction with the analysis of the line-shape of the DNA films at 92% RH. This motion will make the ^{2}H T_2 value very short for all orientations of the fiber axis relative to the field, except for the parallel orientation only where the axis of motion (the fiber axis) is parallel to the field. Therefore spectral intensity at this orientation (where $\nu\approx\pm65$ kHz) only remains unattenuated in the quadrupole echo experiment.

The spectra of oriented DNA fibers at 98% RH (not shown) were similar to those observed at 92% RH. However, the T_1 measured at 98% RH, Table 1, was about one-half as large as measured at 92% RH. Since the splitting observed in the parallel spectra at 92 and 98% RH was the same, the value of θ_{rms} was the same at these RH. Therefore the samller T_1 value observed at 98% RH was due to a shorter correlation time, i.e., $\tau_c=6\times10^{-9}$ s.

Discussion

Powder Pattern Spectra of Purine Bases. According to recent communication from Vold and coworkers,[22] they observed two types of deuterons in polycrystalline guanosine deuterated at the C8 position and they attributed this to two different conformations of guanosine in the unit cell. As shown in Fig. 2, however, the powder pattern of guanosine is rather normal, although the peak is a little broad compared with that of adenosine. The difference between the spectra of Tsang et al.[22] and ours is probably accounted for by the different cystal forms of guanosine. For many other purine bases, including those of 5′-AMP and 5′-GMP, the static quadrupolar coupling constant, $e^2qQ/h=179\pm2$ kHz and asymmetry factor $\eta=0.06$—0.07 (±0.01), appeared to be characteristic of the 8-position in all the purine derivatives. These parameters are in good agreement with those determined by us.

Structure of the Base Domain. Previously reported ^{31}P NMR studies of DNA fibers,[1,5,20,23] have shown that the backbone conformation of the B form of DNA is very heterogeneous, i.e., Euler angles β and γ (structural parameters of the phosphodiester) had a wide distribution of values with standard deviation 5—15° at 92% RH, whereas the backbone of the A form had nearly a single conformation. As for the base domain, according to the structural models inferred from X-ray fiber diffraction studies,[21] the base planes of the A form of DNA tilt by ca. 70° and roll by several degrees with respect to the axis normal to the helix axis, while the base planes of the B form of DNA are almost perpendicular to the helix axis. Assuming that the C8–H bond axis of the purine bases lies on the bisector of the angle made by the base atoms, N7–C8–N9, Euler angles β and γ were calculated using the atomic coordinates of the DNA structure. Because of the small asymmetry factor, $\eta=0.06$, the ^{2}H spectrum was only slightly affected by changes in γ. The angle made by the C8–H bond axis and the helix axis was calculated to be 67.8° (or 112.2°) and 96.1° (or 83.9°) for the A and B forms of DNA, respectively. The values in the parenthesis represent the angles for the antiparallel chain in the duplex. (Both chains give the same spectrum because of the diad symmetry of the DNA model.) On the other hand, the observed value was 70° (at most 73°) and 90°±10 for the A and B forms, respectively. The observed and calculated values agreed with each other within the experimental error. This was also the case for Fuller's B-DNA model[24] as seen in Table 2. Levitt's model[25] gave a value (73.2°) close to the averaged value (75.2°) for the 10 independent purine bases of the single crystal structure[26] of r(GCG)d(AATTCGC). The values of β calculated for two oligonucleotides in the A family of DNA are within the range from 70 to 80°, and their averaged values are slightly higher than the observed value. Several possible reasons for this discrepancy are as follows, 1) the principal axis z of the quadrupolar tensor is not exactly along the C8–^{2}H bond, 2) the C8–^{2}H bond does not lie on the bisector of the atoms, N7–C8–N9, and 3) the average structures of DNA in the fiber and oligonucleotides are not identical. As for the first item, although the orientation of the z

principal axis is not known for the purine ring, all of the single crystal ^{2}H NMR studies[27-30] have shown that the major principal axis of the ^{2}H bonds is along the C–H bond axis within a couple of degrees. As for the second item, the neutron diffraction study[31] of 1-methylthymine:9-methyladenine crystal has shown that the C8 proton is not on the bisector of the atoms, N7–C8–N9, although the purine base is planar. That is, the C8–H bond axis inclines by about 1.7° from the bisector towards atom N9. Using this result, the Euler angle β was recalculated for the decamer, r(GCG)d-(AATTCGC), and its averaged value changed by only 0.1°. With regard to item three, it is often difficult to determine the helix axis of small oligonucleotides such as those mentioned above. Furthermore, the helix axis often bends, probably due to molecular packing forces.[4] We believe that this factor is the major reason for the discrepancy between the value of β calculated for oligonucleotides and that observed for the fibers.

It is interesting to note the conformational variation in the base planes in the single crystals of oligonucleotides, such as a decamer in the A family of crystalline form of DNA,[26] and two dodecamers, d(CGCGAATTCGCG) and d(CGCGAATTBr5CGCG) in the B family of the crystalline form of DNA.[32] The β values of the decamer are in a very narrow range of a few degrees (±3°), whereas those of the dodecamers are significantly varied over the range of ±15° from the average value. These results indicate that the bases of the A form of DNA are restricted to nearly a single conformation, while those of the B form of DNA have a wide distribution of conformations. The results derived from line-shape analysis of the quadrupole spectra of the A and B DNA fibers are consistent with the above mentioned.

In conclusion, the ^{2}H NMR spectra of DNA fibers studied here demonstrated that the orientations of the bases in the A form of DNA were constant within a few degrees in Euler angle β, whereas value of β in the B form of DNA varied over a range of ±10°. These results are consistent with the distribution of the Euler angles β and γ, calculated on the basis of the structure of oligonucleotides (see Table 2), and they are also consistent with structural features of DNA deduced from ^{31}P NMR studies. It should be noted that the structural information that can be obtained from the spectra of the C8–^{2}H label is limited. Accurate values of γ are not attainable because η is very small, and the values of β and $\langle\Delta\beta\rangle$ have large uncertainties (±7°) in the case of B-DNA because β is ca. 90°, a value in the range where the line-shape and peak splitting are least sensitive to changes in β. More comprehensive and accurate information would be obtained by using synthetic DNA molecules ^{2}H labeled at another position.[18]

Dynamics of the Base Domain. As described earlier in this paper, the relatively small ^{2}H T_1 values observed at 75—79% RH, Table 1, are a consequence of rapid ($\tau_c=3.8\times10^{-8}$ s) motions of the C8–^{2}H bond axis. The line-shape and T_1 data are both well fit using a model in which the orientation of C8–^{2}H bond axis fluctuates in a cone (normal to the helix axis) throughout a rms angle of 8.5°. The reductions in T_1 value and peak splitting observed at higher relative humidity (92% RH) can be accounted for by a large fluctuation of the C8–^{2}H bond axis, rms angle of 13.5°, and smaller correlation time, $\tau_c=1.5\times10^{-8}$ s. It is interesting to note that the amplitude of the base fluctuation, 13.5°, estimated here for Na-DNA at 92 and 98% RH is almost identical to the value 10—13° estimated for Li-DNA at 66% RH by Vold et al.[8] These results suggest that the fluctuation amplitude of the base in the B form of DNA has only a weak humidity dependence over the range from 66 to 98% RH, although its correlation time has an appreciable dependence. The rapid, small amplitude fluctuation of the C8–^{2}H bond axis explains the humidity dependence of quadrupole splittings and T_1, but it does not fully explain the frequency dependence of T_2. Brandes et al.[33] therefore, suggested that a distribution of correlation times must be taken into account for this frequency dependence. We demonstrated that the large distortions and intensity losses in the quadrupole echo spectra of the oriented and unoriented DNA at 92% RH are explained by a slower ($\tau\approx10^{-6}$ s), larger root mean square amplitude (ca. 30°), reorientational motion of the C8–^{2}H bond axis about the helix axis. The six-site model employed here leads to a conclusion consistent with the rotational diffusion about the helix axis as discussed in the ^{31}P NMR study of DNA fibers.[1]

In the course of the present study, we learned that Dr. R. R. Vold in UC San Diego was studying oriented DNA samples by solid-state ^{2}H NMR. We greatly appreciate her kindness for sending us preprints in advance of publication. We thank Robert G. Griffin of MIT for the computer program to calculate spectra of the six-site jump model, and also thank Dr. L. Lerner of NIH for her reading of this manuscript and valuable discussions.

The bimolecular rate constants for the reactions of ground state atomic nitrogen with hydrogen halides and deuterium iodide were measured by employing a pulse radiolysis-resonance absorption technique. As for the reactions of hydrogen iodide and deuterium iodide, the temperature dependence was also measured; it was found that the rate constants were well expressed by the following Arrhenius expressions: $k(N+HI)=(3.6\pm0.6)\times10^5 \exp[-(1530\pm50)/T]$; $k(N+DI)=(1.0\pm0.4)\times10^5 \exp[-(1460\pm130)/T]$, in units of $m^3 mol^{-1} s^{-1}$. The preexponential factors for these reactions are much smaller than the semiempirically calculated ones. These small preexponential factors suggest that these reactions proceed non-adiabatically. The rate constants for hydrogen bromide and hydrogen chloride were found to be very small.

Recently, we have reported the Arrhenius parameters for the reactions of ground-state atomic nitrogen with halogen molecules.[1] The preexponential factors for these reactions were found to be much smaller than those for the analogous reactions of atomic hydrogen and oxygen or those predicted by the semiempirical calculations. It was also found that the preexponential factor increases with the increase in the molecular weight. In order to explain these experimental results, we proposed that the potential barrier for the adiabatic route on the quartet surface is very high and that the major route of the reaction is a non-adiabatic one via a doublet surface. If this hypothesis is true, the preexponential factors for the $N(^4S)+HI$ and DI reactions should also be small, although the production of NH (or ND) and I is spin-allowed and exothermic. In order to check this hypothesis, we have performed experiments with HI and DI. As for the reaction of $N(^4S)+HBr$, Milton and Dunford have reported the bimolecular rate constant to be 2×10^4 $m^3 mol^{-1} s^{-1}$ at 313 K.[2] They considered that the formation of NH and Br is almost thermoneutral, but recent measurement of the heat of the formation of NH suggests that the reaction is 55 kJ mol^{-1} endothermic,[3] and the rate constant they obtained seems to be too large. Although the formation of NH and Cl is unquestionably endothermic in the reaction of $N(^4S)+HCl$, it is not certain if the production of NCl and H is also endothermic, since the NCl bond energy is not known precisely.[4] In the present work, we have measured the rate constants for the reactions of $N(^4S)$ with hydrogen halides and deuterium iodide at various temperatures.

Experimental

The experimental apparatus and the procedures were the same as those reported in a previous paper.[1]

The HI and DI were synthesized from H_2 or D_2 (both Takachiho Kako) and I_2 (Koso Chemical Co.) in the presence of platinized asbestos and were used after repeated trap-to-trap distillations. In order to estimate the isotopic purity of DI, it was photolyzed by the light from a high-pressure mercury lamp; the ratio of D_2 to HD was measured mass-spectrometrically. Since the absorption coefficient of HI is a little larger than that for DI,[5] the HI content must have been overestimated. The initial content of HI was 7%; it increased gradually during the storage, until it was 13% when the experiments were over. Then, all the data for DI were corrected by assuming that it contained 10% of HI. The HBr was separated from its aqueous solution (Wako Pure Chemical Industries) and used after repeated trap-to-trap distillations. The HCl was the product of the Takachiho Kako Co. and was used without further purification.

Results

The decay rate of $N(^4S)$ increased linearly with the increase in the pressure of HI or DI; it also increased with the temperature of the system, while it was independent of the total pressure at a given pressure of HI. On the other hand, in the cases of HBr and HCl, the decay rate did not show any marked dependence on the partial pressures of these gases. In other words, the rate constants for the reactions of $N(^4S)$ with HBr and HCl are too small to be measured by the present technique. From the least-squares slopes of the linear relationships between the decay rates and the pressures of HI and DI, the bimolecular rate constants can be determined. As has been discussed in the previous paper, the apparent rate constants determined from these slopes are considered to be twice the rate constants for the reactions of $N(^4S)$ with HI and DI.[1] This is because one of the products of the reaction, NH or ND, is considered to react with $N(^4S)$ once again very rapidly. The rate constant for the reaction of N and NH (ND) should be of the same order as those for the N+OH, N+CN, and $N+NH_2$ reactions.[6] It should be noted that the formation of NI and H (D) is highly endothermic. Table 1 summarizes the rate

constants determined in this way at various temperatures. The rate constants for HI and DI are well expressed by the Arrhenius expressions. This is shown in Fig. 1, while the Arrhenius parameters are listed in Table 2.

The semiempirical LEPS and BEBO calculations were performed to evaluate the preexponential factors for the reactions of N(^{4}S) with HI and DI. The procedure for the LEPS calculation was the same as that described in the previous paper.[1] The Sato parameter was adjusted to give the activation energy experimentally obtained for the N+HI reaction. As

for the BEBO calculation, in the previous work the factor of the anti-Morse function, C_1, according to the notation by Singleton and Cvetanović,[7] was parametrized and adjusted to give the experimental activation energy. In the present work, not only this factor, but also the Pauling constant, C_2, were parametrized. A similar procedure has been employed by Brown and Smith in the calculation of the rate constant for the O+DCl and DBr reactions.[8] When C_1 was adjusted, C_2 was fixed at 0.28, the recommended value by Gilliom, while, when C_2 was adjusted, C_1 was fixed at 3 considering that atomic nitrogen is a quartet. The rest of the calculational procedure was the same as that reported previously.[1] The results are shown in Tables 2 and 3. The calculations for the N+DI reaction were performed by using the same parameters as those for the N+HI reaction.

Discussion

As has been discussed in the previous paper, the reactions of N(^{4}S) with halogen molecules are considered to proceed non-adiabatically via doublet surfaces.[1] In the present cases, the experimentally obtained preexponential factors for the N+HI and DI reactions were also found to be much smaller than those for the analogous reactions of H and O atoms[7,9] or than the results of the semiempirical LEPS and BEBO calculations, as is shown in Table 2. In general, the agreement between the experimentally obtained Arrhenius parameters and the semiempirically calculated ones is not very good, even in the simple systems, such as H+HX and O+HX, where

HX stands for hydrogen halides.[7,8,10,11] Three-dimensional trajectory calculations are necessary for a quantitative discussion.[12] However, the present disagreement between the experimental and the calculated preexponential factors is outstanding. This discrepancy suggests that these reactions involve transitions between potential surfaces of different multiplicities. Correlation diagrams similar to that presented in the previous paper for the N+halogens systems may also be drawn in the present cases.[1] The preexponential factor for the N+HI reaction was found to be around one-third of that for the $N+I_2$ reaction. This is also consistent with the above consideration that the reactions are not adiabatic, because in the $N+I_2$ system, a stronger spin-orbit coupling is expected and the spin-conservation rule is considered to hold less rigorously. The isotope effect observed in the preexponential factors for HI and DI may be attributed to the difference in the probabilities of crossing from a quartet surface to a doublet surface, since the semiempirical calculations predict no large isotope effect.

The extremely slow reaction rates for HBr and HCl are consistent with the thermodynamical predictions. The formation of NH and halogen atoms from these molecules is endothermic. The production of NCl and H from N(⁴S) and HCl may also be endothermic. The rate constant reported by Milton and Dunford for the N+HBr reaction seems to be erroneous.[2] Their method, a diffusion-flame technique, is too indirect for quantitative measurements. Moreover, their reported value for the $N+C_2H_4$ reaction has not been confirmed in a recent work.[13]

From the present results, together with those of our recent work,[1,13] it can be concluded that N(⁴S) atoms are very inert to stable molecules with even-numbered electrons. This inertness can be attributed to the conservation of the spin-angular momentum. In most practical systems at moderate temperatures, such as discharge-flow systems, the decay of N(⁴S) is governed by the reactions with the molecules with odd-numbered electrons, such as free radicals. In the absence of such active species, the only decay process is the termolecular or heterogeneous recombination reaction between atomic species.

Conductance Matrix of Amphoteric Ion-Exchange Membrane in Three Ion System

Akira YAMAUCHI,* Hitoshi SHINOHARA, Makoto SHINODA, Masashi DATE, Yutaka HIRATA, and Hideo KIMIZUKA
Department of Chemistry, Faculty of Science, Kyushu University 33, Hakozaki, Higashi-ku, Fukuoka 812
(Received December 8, 1986)

A conductance matrix describing the ion-transport phenomena in the membrane-three ion system has been determined. It was indicated there that six independent experiments were required in order to determine six independent elements of the conductance matrix. The NaCl-$CaCl_2$-amphoteric membrane system was chosen as the three ion system, and three kinds of fluxes, two kinds of transport numbers, and the membrane conductance were measured. Nine elements were experimentally determined on the assumption of Onsager's reciprocal relation. The results showed that the order of elements in conductance matrix was $g_{CaCa}>g_{ClCl}>g_{NaNa}>g_{CaCl}>g_{NaCl}>g_{CaNa}$. In addition, it was pointed out that the interactions among ions can never be ignored when the ion-transport phenomena across membrane are studied.

The transport phenomena of ions through an ion-exchange membrane have been still important subject in spite of many reported papers with respect to the transport properties. The subject appears in processes concentrating the saline water or obtaining the pure water from the saline water.[1] Probably the practical process would be a complicated one because of involving a number of ions. On the other hand, it is also interesting to understand the transport properties of ions through the membrane physicochemically. Generally, according to nonequilibrium thermodynamics, the fluxes transported across the membrane in the electrolyte solution–ion-exchange membrane system can be expressed by a linear combination of the forces generated in the system such as concentration gradient, potential difference and etc. In the previous studies, we have investigated the relationships among the fluxes and the forces in the system consisting of only a single electrolyte.[2-5] If the number of ions in the system increase, the relationships among the fluxes and the forces would become more complex. However, the thermodynamic examination concerning multi-ionic system simulating the realistic subject should be done. We have therefore chosen to study the three ion system which consisted of the mixed electrolytes having common anion, as representing a typical and simple example of multi-ionic system. Moreover, in order to observe simultaneously the detectable ion fluxes due to both cation and anion, use of the ion-exchange membrane having cation- and anion-exchange sites may be preferable from experimental standpoint. Thus, an amphoteric ion-exchange membrane was employed instead of homogeneous ion-exchange membrane.

The purpose of the present study is to clarify the correlation among behaviors of three ions within membrane.

Theory

We consider three ion system which consists of the amphoteric ion-exchange membrane and the mixed electrolyte solution having the common anion. According to the nonequilibrium thermodynamics,[3-5] the relationship between the current densities, i's and the transmembrane potential, V can be given as the following equation,

$$\begin{pmatrix} i_1 \\ i_2 \\ i_3 \end{pmatrix} = - \begin{pmatrix} g_{11} & g_{12} & g_{13} \\ g_{21} & g_{22} & g_{23} \\ g_{31} & g_{32} & g_{33} \end{pmatrix} \begin{pmatrix} V-V_1 \\ V-V_2 \\ V-V_3 \end{pmatrix}, \quad (1)$$

where subscripts 1—3 refer to the ionic species in the system, V_1—V_3 denote the pseudoequilibrium potentials due to each ionic species, and g_{11}—g_{33}, nine elements of the conductance matrix. In the present system, we assume that Onsager's reciprocal relations are well held among the elements, i.e.,

$$g_{ij} = g_{ji}. \quad (2)$$

With help of Eq. 2, the numbers of elements to be determined are reduced to six from nine. At this point, introducing the contribution due to water, the elements to be determined increase to ten even using Eq. 2. Fortunately, it was pointed out in the previous papers[3-5] that the effect of water on the conductance matrix was negligible when the interaction between ions mainly contribute to the transport phenomena. Therefore, six independent experiments are needed to understand the ion transport phenomena in this system.

The conductance for ions, g_1—g_3 and the membrane conductance, G_m are given as[3]

$$g_k = g_{k1} + g_{k2} + g_{k3} \quad (k=1, 2, 3), \quad (3)$$

$$G_m = g_1 + g_2 + g_3, \quad (4)$$

where subscript k refers to ionic species.

Taking account of Eqs. 3 and 4, one can obtain the alternative expression of Eq. 1 as follows,

$$\begin{pmatrix} i_1 \\ i_2 \\ I \end{pmatrix} = - \begin{pmatrix} g_{11} & g_{12} & g_1 \\ g_{21} & g_{22} & g_2 \\ g_1 & g_2 & G_m \end{pmatrix} \begin{pmatrix} V_3-V_1 \\ V_3-V_2 \\ V-V_3 \end{pmatrix}. \quad (5)$$

On the other hand, when the supplied current is absent, the membrane current, I and the membrane potential, V_0 are written by

$$I = i_1 + i_2 + i_3, \quad (6)$$

$$V_0 = t_1V_1 + t_2V_2 + t_3V_3, \quad (7)$$

$$t_k = g_k/G_m \quad (k=1, 2, 3), \quad (8)$$

$$t_1 + t_2 + t_3 = 1, \quad (9)$$

where the subscript o refers to the absence of the supplied membrane current and t_k's are the transport numbers.

Considering the ionic currents in the presence and absence of the membrane currents, we have from Eq. 1,

$$i_k - i_k^0 = g_k(V-V_0) \quad (k=1, 2, 3), \quad (10)$$

where i_k^0 denotes the ionic current at zero membrane current.

When I=0, we obtain from Eq. 5,

$$i_1^0 = - G_{11}^0(V_3-V_1) - G_{12}^0(V_3-V_2),$$
$$i_2^0 = - G_{21}^0(V_3-V_1) - G_{22}^0(V_3-V_2), \quad (11)$$

where

$$G_{11}^0 = g_{11} - G_m t_1^2,$$
$$G_{12}^0 = G_{21}^0 = g_{12} - G_m t_1 t_2, \quad (12)$$
$$G_{22}^0 = g_{22} - G_m t_2^2.$$

If the measurements of i_1^0 and i_2^0 are performed under the condition, either (V_3-V_1) or (V_3-V_2) is zero, Eq. 11 reduces to

$$i_1^0 = - G_{12}^0(V_3-V_2),$$
$$i_2^0 = - G_{22}^0(V_3-V_2), \quad (13)$$

or

$$i_1^0 = - G_{11}^0(V_3-V_1),$$
$$i_2^0 = - G_{21}^0(V_3-V_1), \quad (14)$$

respectively, Equations 13 and 14 serve to determine G_{11}^0, G_{12}^0, and G_{22}^0.

Combining Eq. 12 with Eqs. 3, 4 and 9, we obtain

$$g_{11} = G_{11}^0 + G_m t_1^2, \; g_{13} = G_m t_1(1-t_1-t_2) - G_{11}^0 - G_{12}^0,$$
$$g_{12} = G_{12}^0 + G_m t_1 t_2, \; g_{23} = G_m t_2(1-t_1-t_2) - G_{12}^0 - G_{22}^0, \quad (15)$$
$$g_{22} = G_{22}^0 + G_m t_2^2, \; g_{33} = G_m(1-t_1-t_2)^2 + G_{11}^0 + G_{22}^0 + 2G_{12}^0.$$

Eq. 15 indicates that all the elements of conductance matrix can be determined when G_{11}^0, G_{12}^0, G_{22}^0, G_m, t_1, and t_2 are experimentally measured.

Experimental

In this study, Na, Ca, and Cl ions were chosen as three ions and six independent experiments were performed in order to determine the six independent conductance elements for the system consisting of membrane and mixed electrolyte solutions having the same concentrations of electrolytes in phases I and II.

Materials. An amphoteric ion-exchange membrane used in this work was supplied by Tokuyama Soda Co. Ltd.,[6,7] and the characteristics of the membrane and the conditioning before use were already described elsewhere.[8-10]

Procedure of Experiments. As outlined in theoretical section, six independent experiments such as the membrane conductance, G_m transport numbers, t_1 and t_2 and the ion fluxes, i_1^0 vs. V_3-V_1 and i_1^0 vs. V_3-V_2 under the condition of $V_3-V_1=0$ and i_2^0 vs. V_3-V_1 under the condition of $V_3-V_2=0$ were measured, respectively. Of these, the procedure of the experiments for G_m, t_1, and t_2 were the same as those described in the preceding papers.[8-10] As to ion fluxes, the concentration change of Na and Ca in mixed electrolyte solutions in chambers I and II across the membrane were measured against a lapse of time by an atomic absorption spectroscopy (Hitachi Co. Ltd., Model 180-50). All the experiments were carried out at 25 °C, and the electrolyte solutions in both chambers were sufficiently stirred by magnetic stirrer throughout the experiment.

Preparation of Mixed Electrolyte Solutions. On the preparation of mixed electrolyte solution, two kinds of electrolytes were suitably mixed so as to eliminate either of two driving forces in Eq. 11. That is, as NaCl and $CaCl_2$ are used in the present system and the subscripts 1, 2, and 3 correspond to Na, Ca, and Cl ion, respectively, the driving forces, V_3-V_1 and V_3-V_2 are written as

$$V_{Cl} - V_{Na} = \frac{RT}{F} \ln \frac{a_{Cl}^{II} a_{Na}^{II}}{a_{Cl}^{I} a_{Na}^{I}}, \quad (16)$$

$$V_{Cl} - V_{Ca} = \frac{RT}{F} \ln \frac{a_{Cl}^{II} (a_{Ca}^{II})^{1/2}}{a_{Cl}^{I} (a_{Ca}^{I})^{1/2}}, \quad (17)$$

where a denotes activity and the superscripts I and II refer to phases I and II, respectively. The prepared electrolyte solutions were summarized in Table 1(a), in which the concentrations of mixed electrolytes in phase II was kept constant while those in phase I were changed so as to make the values of Eq. 16 always zero. Table 1 (b) also shows the prepared electrolyte solutions in which the values of Eq. 17 are zero. For the membrane conductance and transport

Table 1. Concentration of Prepared Electrolyte Solutions

number measurements, the mixed electrolyte solutions of identical composition and concentration were placed in chambers I and II across membrane. The single ion activities in Table 1 were calculated according to Debye-Hückel equation for activity coefficient.[11]

Results and Discussion

The concentration changes of ions in phases I and II in the absence of applied current were examined as a function of time for all the systems in Tables 1(a) and (b), which have the concentration difference of ions between phases I and II. Figure 1 shows a typical example about the system made of first two columns in Table 1(a) in which moles of Ca ions transported across membrane were plotted against times. It can be recognized that Ca ion concentration in phase I increase and that of phase II decrease with a lapse of time, and the concentration changes are linear against time within experimental error. This fact suggests that the transport of Ca ion is in a steady state. The mean absolute values of concentration changes in phases I and II were plotted against time in Figs. 2(a), 2(b), and 2(c). Figures 2(a) and 2(b) indicate Δn_{Na} vs. time plot and Δn_{Ca} vs. time plot under the condition, $V_{Cl}-V_{Na}=0$. The ion flux, J_i^0 was evaluated from the slopes in Fig . 2 as follows,

$$J_i^0 = \frac{\Delta n_i}{tS}, \tag{18}$$

where t and S denote time interval in second and the membrane area in cm^2, respectively. Taking account of the electricity on the ion fluxes, one can obtain the

ion current density, $i_i^0=z_iFJ_i^0$ in the absence of the supplied currents. The obtained i_1^0's were divided by $V_{Cl}-V_{Na}$ or $V_{Cl}-V_{Ca}$ and plotted against $V_{Cl}-V_{Na}$ or $V_{Cl}-V_{Ca}$ in Fig. 3. According to Eq. 12, the quantities in Fig. 3 contain important informations concerning the elements in conductance matrix given by Eqs. 1 or 5. As mentioned in experimental section, the membrane conductance and transport numbers were obtained under the experimental conditions that ionic concentration difference between the mixed electrolyte solutions in phases I and II are all zero. This corresponds to the case in which $V_{Cl}-V_{Na}$ or $V_{Cl}-V_{Ca}$ in Fig. 3 is extrapolated to zero. The values of G^0_{NaNa}, G^0_{NaCa} and G^0_{CaCa}, at $V_{Cl}-V_{Na}=V_{Cl}-V_{Ca}=0$ were estimated from Fig. 3 by interpolation.

On the other hand, the electrodialysis[8] and the membrane resistance were measured to obtain the transport numbers, t_{Na} and t_{Ca} and the membrane conductance, G_m for the membrane-electrolyte solution system in which the electrolyte solutions in phases I and II are identical. The results are shown in Table 2 together with the values of conductance elements estimated according to Eq. 15.

It can be seen in Table 2 that $g_{CaCa}>g_{ClCl}>g_{NaNa}>g_{CaCl}>g_{NaCl}>g_{CaNa}$. It is impressive that the tendency is partly in accord with $g_{CaCa}\simeq g_{ClCl}>-g_{CaCl}$ in the other amphoteric membrane system[3] in contrast to the result in the cation-exchange membrane, $g_{CaCa}>g_{CaCl}>g_{ClCl}$ in the previous paper.[12] As to the first three elements, the order in the present work also corresponds to that of the transport numbers in Table 2 ($t_{Cl}=1-t_{Na}-t_{Ca}=0.29$). This means that the g factors partly reflect the ionic composition within membrane. As seen in comparison with t in a single electrolyte system that $t_{Na}=0.90$ and $t_{Cl}=0.10$ in NaCl system and $t_{Ca}=0.62$ and $t_{Cl}=0.38$ in $CaCl_2$ system, respectively, the situation in mixed electrolyte system is largely different from the single electrolyte system, however. The reason for the inversion of g_{NaNa} and g_{ClCl} in mixed system is not clear in the present, but a possible explanation is that Cl ion within membrane may be relatively concentrated. That is, for the sake of high selectivity of Ca ion over Na ion to the sites in the case of mixed solutions,[8] Na ion may be excluded from the membrane. On the contrary, Cl ion may sufficiently be retained around the anion-exchange sites. The smaller value of g_{NaNa} compared with g_{ClCl} may be attributed to the different behaviors in mixed electrolyte.

The remained three elements, which express the interactions between the different ionic species, can not be ignored. The small but finite values mean that the respective ion fluxes are subject to the coupled forces and the coupling plays an important role in ion-transport phenomena.

Thus, it may be concluded that the transport phenomena can not be predicted by a simple combination of the single electrolyte systems, but the interaction among ions should be taken into account.

The present work was partially supported by Grant-in-Aid for Scientific Research No. 58470007 from the Ministry of Education, Science and Culture.

Synthesis and Properties of 5,10,15,20-Tetrakis(3,5-di-*t*-butyl-2-nitrophenyl)porphyrin: Conformational Stabilities of the Respective Atropisomers and Oxygenation Capabilities of the Iron(III) and Manganese(III) Complexes

(Received July 11, 1986)

The synthesis and properties of new, bulky atropisomeric porphyrins are described. Four atropisomers of 5,10,15,20-tetrakis(3,5-di-*t*-butyl-2-nitrophenyl)porphyrins has been easily separated and purified by column chromatography. The isomers all have different thermal stabilities toward atropisomerization. Below 60 °C, however, they have rather high conformational stabilities, and an iron(III) or manganese(III) ion has been incorporated into each isomer, with a retention of the ligand conformation. By the use of these metal complexes, the catalytic oxygenation reactions, i.e., the epoxidation of olefins (styrene, α-methylstyrene, cyclohexene, and cyclooctene) and the hydroxylation of alkanes (cyclohexane and heptane), have been done in the presence of hypochlorite or iodosylbenzene as an oxidant. Products analyses by GLC show that these new complexes effectively catalyze the oxygenations in higher yields or in more selective ways, than the corresponding TPP complexes.

The cytochrome P-450 family of monooxygenase enzymes have increasingly attracted the attention of chemists because of the versatility of its catalyses, i.e., aliphatic hydroxylation, alkene epoxidation, and heteroatom dealkylation.[1] Most of all, an inestimable blessing to inorganic chemists is the fact that iron(II—IV) porphyrin IX serves as an active center throughout enzymatic reactions.[2]

So far many efforts have been made to exploit P-450 models which include the metalloporphyrin–iodosylbenzene,[3–6] the metalloporphyrin–hypochlorite,[7–9] or the metalloporphyrin–O_2-reducing reagent system.[10,11] In these model systems, a variety of protected porphyrins have been used as catalysts. As far as atropisomeric porphyrins are concerned, however, limited numbers of the isomers have been employed, and they are not in extensive use at present.[12] This is surprising in view of the possible unsymmetrical steric protection afforded on both faces of the porphyrin plane by the use of atropisomerism. One factor in explaining this insufficient use is the lack of easily prepared atropisomeric porphyrin that either have a high conformational stability to heating or show no serious deterioration during catalysis. Two types of new atropisomers, i.e., 5,10,15,20-tetrakis(2-methoxy-1-naphthyl)porphyrin (**2**)[13] and 5,10,15,20-tetrakis(2-cyanophenyl)porphyrin (**3**),[14] have been reported. Although the four possible isomers of **2** were cleanly isolated, the instabilities of the 2-methoxy-1-naphthyl groups toward such oxidants as iodosylbenzene or hypochlorite hamper the practical use of their metal complexes as catalysts. Inversely, metal complexes of **3** may not be decomposed by the oxidant, but the separation conditions to the respective atropisomers are very severe. Thus, it is of great interest to develop new synthetic entries into atropisomeric porphyrin chemistry that either have new types of polar bulky groups around the porphyrin plane or lead to recoverable, reusable catalysts for P-450 models.

Recently, we described the synthesis of 5,10,15,20-tetrakis(3,5-di-*t*-butyl-2-nitrophenyl)porphyrin (**1**) and the separation of the four possible isomers (Fig. 2).[15] Each isomer has a relatively high conformational stability to prolonged heating, and the conversion into the iron complex (**1**-FeX) was done with a retention of the ligand conformation. The thermally stable *hydroxy iron(III) complexes* (**1**-FeOH) were also isolated by the treatment of the corresponding halo iron(III) species (**1**-FeBr or **1**-FeCl) with aqueous sodium hydroxide or with basic alumina. The stability of these complexes was explained as a steric

effect attributable due to *t*-butyl and/or nitro groups.

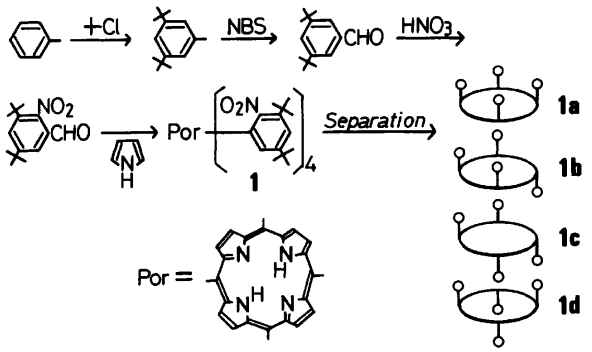
Herein we wish to report details of the syntheses of **1** and their manganese(III) and iron(III) complexes (**1**-MnX or **1**-FeX) and of GLC analyses of the oxygenation products of the styrene, α-methylstyrene, cyclohexene, cyclooctene, cyclohexane, or heptane catalyzed by these complexes in the presence of hypochlorite or iodosylbenzene (Fig. 3 or 4). A preliminary account of the synthetic and spectral work has appeared.[15-17]

Experimental

The synthetic procedure to **1** is shown in Scheme 1.[15]

3,5-Di-*t*-butyl-2-nitrobenzaldehyde. In a 2 dm^3, three-necked, round-bottomed flask, powder of 3,5-di-*t*-butylbenzaldehyde (214 g, 0.98 mol) was dissolved, with mechanical stirring, in 0.9 dm^3 of sulfuric acid. After the mixture had then cooled to 5 °C, 88 cm^3 of nitric acid (Sp. Gr. about 1.38) was added, drop by drop, at such a rate that the temperature did not rise above 10 °C. After the addition was complete, the mixture was stirred for a further 30 minutes and then poured into 6 dm^3 of water containing chipped ice. The solid product was separated by filtration with a G3 sintered glass filter and washed with three 1-dm^3 portions of water. The solid thus obtained was dissolved in the minimum ammount of the 1:9 chloroform–hexane (about 600 cm^3). The solution was then submitted to 3.5×40 cm of 70—230 mesh Merck alumina 90, and the product was eluted from the column with 1:9 chloroform–hexane. The solution was evaporated to dryness, and the residue was purified by vacuum distillation (bp 150—155 °C/1.3 Pa) to give 214 g (83% based on 3,5-di-*t*-butylbenzaldehyde; mp 90—91 °C) as yellow crystals. Found: C, 68.54; H, 8.07; N, 5.37. Calcd for $C_{15}H_{21}NO_3$: C, 68.41; H, 8.04; N, 5.32. ^{1}H NMR ($CDCl_3$) δ=1.3 (9H, s, 3-*t*-butyl H), 1.4 (9H, s, 5-*t*-butyl H), 7.7 (2H, m, phenyl H), 9.7 (1H, s, CHO). Mass spectrum, *m/z* 263.3.

5,10,15,20-Tetrakis(3,5-di-*t*-butyl-2-nitrophenyl)porphyrin (1). The porphyrin was prepared by a modification of the method of Sorrell's.[18] Two hundred and eighty grams of 3,5-di-*t*-butyl-2-nitrobenzaldehyde were dissolved in 1.3 dm^3 of glacial acetic acid in a 3-dm^3, three-necked, round-bottomed flask fitted with Allihn condensers and a dropping funnel. The solution was heated and stirred with a magnetic bar. To the boiling solution, 74.5 g of pyrrole (1.1 mol) was added, drop by drop. The resulting black mixture was allowed to reflux for 60 min and then left to stand over-night. The purple brown crystals thus precipitated were filtered by suction and washed with



Scheme 1. The synthetic procedure to porphyrin **1**.

methyl alcohol (ca. 500 cm³). Yield: 36.0 g (11%). **1** is very easily soluble in chloroform; very soluble in benzene or toluene; soluble in hexane, dioxane, *N*,*N*-dimethylformamide, or carbon tetrachloride, and sparingly soluble in methyl or ethyl alcohol. **1**: Found: C, 73.28; H, 7.46; N, 8.88. Calcd for $C_{76}H_{90}N_8O_8$: C, 73.40; H, 7.29; N, 9.01. UV-vis. ($CHCl_3$) λ/nm at 25 °C (ε/M^{-1} cm^{-1}),[19] 421 (3.5×10^5), 474 (3.1×10^3), 512 (2.2×10^4), 542 (3.1×10^3), 586 (6.9×10^3), 640 (5.6×10^2). The nitro groups show characteristic infrared absorptions: 760, 840, 1530 cm^{-1}. **1** is a mixture of four atropisomers. TLC on silica (toluene) show four spots; R_f values: **1a**, 0.28; **1b**, 0.65; **1c**, 0.74; **1d**, 0.88.

Separation of Four Isomers. The most polar isomer, the **1a** isomer, could be separated from the other three isomers by means of a skillful column-chromatographic technique. Before the isomer separation, the preferential isomerization was carried out by the utilization of adsorption.[20,21] Ten grams of the porphyrin **1** were dissolved in 2 dm³ of toluene. The solution was then refluxed under Ar, and a 30-g portion of Merck alumina 90 was added nine times every three hours. After refluxing for 30 h, the solution was cooled to the ambient temperature. The isomerized product was then extracted from the alumina with a 1:1 chloroform–acetone mixed solvent. The solvent was removed by the use of a rotary evaporator, and the residue was redissolved in a minimum amount of chloroform (about 300 cm³). The chloroform solution was poured onto a 5.5×60 cm column of Merck alumina 90 prepared as a slurry in chloroform. After all the material had been loaded, chloroform (about 2 dm³) was passed through the column until the eluate became very pale. The **1a** isomer was then removed by the use of a 1:1 chloroform–acetone mixture, and the solvent was removed at a temperature lower than 40 °C. Five grams of the crude **1a** isomer obtained as has been described above was dissolved in 100 cm³ of chloroform and again loaded onto a 3×60 cm column of Merck alumina 90 prepared as a slurry in chloroform. After the loading, the column was eluted with chloroform, and the eluate of the second brown band was collected. The solution was subsequently taken to dryness at room temperature. The residue was redissolved in 300 cm³ of toluene. After it had then been placed in a 3×40 cm column of silicagel (Wako gel C-200) prepared as a slurry in toluene, toluene (about 2 dm³) was passed through the column. The desired pure **1a** isomer was then removed by elution. The solution was concentrated to 40 cm³ at the ambient temperature. The resulting purple brown crystals were filtered, washed with methyl alcohol, and dried in vacuo. Percentage yield: ca. 15%.

The other three isomers were separated in the usual way. Ten grams of **1**, the **1a** isomer of which had been removed in the above procedure, were dissolved in a minimum amount of toluene (about 600 cm³). After the sample had then been placed in a 5.5×60 cm column of alumina (Woelm N-Super 1) prepared as a slurry in toluene, the column was eluted with toluene. The separation was followed by the TLC analysis of the eluate. The fractions of the three bands were separately collected and condensed for crystallization using a rotary evaporator at room temperature. The purple brown crystals were filtered, washed with methyl alcohol, and dried in vacuo. Yields: **1b**, 5.7 g, **1d**, 1.2 g. The **1c** isomer still contained a minor amount of the **1d** isomer at this stage of the separation. Several subsequent recrystallizations from toluene gave 0.9 g of the desired pure **1c** isomer.[22]

Measurement of Atropisomerism. The change in the isomer distribution was measured by the method of the literature[14] with the following modification. A 0.4-g portion of the porphyrin was dissolved in 300 cm³ of toluene or chloroform. Under Ar, the solution was refluxed in a oil bath or photoirradiated with a high pressure mercury lamp (400 W, Riko. UVL-400HA) at the ambient temperature. A few cm³ of the solution was sampled with a pipet at appropriate intervals and spotted on a 20×20 cm TLC plate (Merck silica gel 60). The four isomers were separated with toluene on the TLC plate. The quantity was measured by spectrometry after the extraction of each isomer from the TLC plate with chloroform. The relative abundance of the isomers was photometrically determined using the Soret-band.

Iron Insertion. A 0.4-g portion (0.32 mmol) of **1** was dissolved in a 100-cm³ portion of a mixed solvent of 1:3 chloroform–acetic acid, after which the solution was purged with Ar to remove the O_2. Then, anhydrous $FeBr_2$ (0.34 g, 1.6 mmol), anhydrous sodium acetate (0.4 g, 4.9 mmol), and 2,6-lutidine (0.18 cm³) were added to this solution of **1**. The resulting solution was stirred for 5 h at 50 °C. When **1a** was used, the solution was stirred for 1 h at 50 °C. After a 100-cm³ portion of water was added to the resulting solution, the organic layer was separated and subsequently washed, first with water and then with a dilute sodium hydroxide solution. The crude iron complex of **1** was purified by silica-gel chromatography. The chloroform solution of the product was placed in a silica-gel column (Wako gel C-200) prepared as a slurry in chloroform. Afrer loading, the column was eluted with chloroform. The remaining porphyrin free base was first eluted, and then the desired iron complex of **1** was eluted. The second eluate was collected and then stirred together with 47% hydrobromic acid. The red-brown solution turned dark brown during stirring. After the organic layer had been separated, the solvent was removed by means of a evaporator. The iron complex **1**–FeBr was recrystallized from a benzene–heptane mixed solvent, and the resulting dark blue-purple crystals were dried in vacuo. Percentage yields: **1a**–FeBr, 64%; **1b**–FeBr, 59%; **1c**–FeBr, 65%; **1d**–FeBr, 74%. Found: C, 66.06; H, 6.57; N, 7.99; Br, 5.99. Calcd for $C_{76}H_{88}N_8O_8FeBr$: C, 66.28; H, 6.41; N, 8.14; Br, 5.80. UV-vis. (toluene) λ/nm: 360, 392, 422, 512, 588, 650.

In order to estimate the relative ease of iron insertion in

relation to atropisomeric porphyrins, controlled metal-insertion experiments were carried out. In a typical experiment,[21] a porphyrin free base (0.08 mmol), 2,6-lutidine (0.4 mmol), and anhydrous $FeBr_2$ (0.4 mmol) were dissolved in 20 cm^3 of THF, and the reaction was carried out under Ar for 3 h at 30 °C. The products were separated by the use of a silica-gel column (Wako gel C-200) prepared as a slurry in chloroform. The silica-gel column was eluted by chloroform, and the second band was collected. The second eluate was stirred with 47% of hydrobromic acid. After the solvent had been removed, a bromo iron(III) complex was dried in vacuo and weighed. The insertion ratios were calculated relative to the total amount of porphyrin ligands.

Manganese Insertion. The porphyrin **1** (1.0 g), $MnBr_2 \cdot 4H_2O$ (1.0 g), anhydrous CH_3COONa (0.5 g), and pyridine (10 cm^3) were dissolved in 300 cm^3 of a mixed solvent of 1:3 chloroform–acetic acid under oxygen-free conditions. The resulting solution was stirred for 5 h at 50 °C. When the porphyrin **1a** was used, the manganese insertion was carried out for 5 h at room temperature. The solution was then brought to dryness, and the residue was redissolved in a minimum amount of chloroform. The chloroform solution was poured into the alumina column (Merck alumina 90) prepared as a slurry in chloroform. After loading, the column was eluted by chloroform. The porphyrin free base was eluted, and the desired manganese complex was adsorbed on alumina. Chloroform was passed through the column until the eluate was very pale. Then, a 2:1 chloroform–methanol mixed solvent was added, the desired manganese complex of **1** was removed. The eluate was stirred with 20% hydrobromic acid. After the solvent had been removed by the use of a rotary evaporator, the manganese porphyrin was recrystallized from dichloromethane–hexane; the dark green crystals thus obtained were dried in vacuo. Percentage yields: **1a**–MnBr, 40%; **1c**–MnBr, 18%; **1d**–MnBr, 20%. Found: C, 65.19; H, 6.23; N, 7.97; Br, 5.89. Calcd for $C_{76}H_{88}N_8O_8MnBr \cdot H_2O$: C, 65.46; H, 6.51; N, 8.04; Br, 5.73. UV-vis. (toluene) λ/nm: 376, 490, 588.

Measurement of the Stabilities of the Hydroxy Iron(III) Complexes. The hydroxy iron(III) porphyrins **1a—d**–FeOH were prepared from the corresponding bromo iron(III) complexes. The bromo iron(III) porphyrins **1a—d**–FeBr were treated with aqueous sodium hydroxide. The products (the hydroxy iron complex and the μ-oxo dimer) were purified by the use of an alumina column (Merck alumina 90), using toluene as an eluate, and were identified by spectroscopic methods. The thermal stabilities of the hydroxy iron(III) complexes were measured as follows. Chloroform solutions of **1a—d**–FeOH were refluxed for 8 h, and then the resulting material was analyzed by means of UV-vis. and ^1H NMR spectroscopy.[23] Other porphyrins, $TBPPH_2$ and $TMPPH_2$,[24] were used for comparison.

Oxygenation Reaction. In controlled experiments using iodosylbenzene as an oxidant, the reaction conditions were as follows. In a typical experiment of olefin epoxidation, **1**–FeBr or **1**–MnBr (0.010 mmol) and olefin (1.7 mmol) were dissolved in 5 cm^3 of dichloromethane. Iodosylbenzene (0.3 mmol) was added to this solution, and the resulting mixture was stirred for 3 h in an ice bath. All these operations were carried out under Ar. In the experiments on the hydroxylation of alkane,[25] **1**–FeBr (0.002 mmol), cyclohexane (2 mmol), and iodosylbenzene (0.060 mmol) were employed. The reaction was continued for 3 h at 15—17 °C. In both olefin epoxidation and alkane hydroxylation, the products were analyzed by means of GLC.

When hypochlorite was used as an oxidant, the reaction rates and the yields were also measured for comparison with those of the authentic catalyst, MnTPPBr.[4] All kinetic experiments in the metalloporphyrin–hypochlorite system were controlled, as will be described below.[17] The complex, **1**–FeBr or **1**–MnBr (0.0082 mmol), olefin (7.8 mmol, styrene, α-methylstyrene, cyclohexene, or cyclooctene), the internal standard reagent (*p*-dichlorobenzene or 1,3,5-trichlorobenzene), and the phase-transfer reagent (benzyldimethyltetradecylammonium chloride) were dissolved in 20 cm^3 of dichloromethane. When manganese complexes were used, 1-triphenylmethylimidazole (0.46 mmol) was added to the solution as the N-base ligand. Then, 15 cm^3 of the sodium hypochlorite solution (8.7 mmol) was layered over the organic phase. The epoxidation reaction was initiated by vigorous stirring, and the reaction temperature was maintained at 22 °C during olefin epoxidation. The products were periodically monitored by means of GLC.

Results

In contrast with 5,10,15,20-tetrakis(2-nitrophenyl)-porphyrin, which has hardly shown solubility to any organic solvent,[18] the pophyrin **1** is soluble in common organic solvents. Their iron and manganese complexes of **1** are also well soluble in organic solvents, such as chloroform, benzene, toluene, acetone, alcohol, and *N,N*-dimethylformamide. All the isomers of **1** show identical electronic absorption spectra, but their proton NMR patterns are substantially different from each other (See Table 1).

Atropisomerization. The results of atropisomerization are listed in Table 2. Each isomer is rather stable in refluxing chloroform (61 °C), but is gradually converted to other isomers in refluxing toluene (111 °C). Strong UV irradiation with a mercury lamp for 11 h gives no appreciable amount of other isomers. The time-dependency of the distribution of the isomer which was isomerized from the **1a** isomer to others in refluxing toluene or chloroform is shown in Fig. 5 or 6. The change in the isomer distribution in refluxing toluene has not been observed over 60 h refluxing. The results of this experiment are listed in Table 3.

The Stabilities of Hydroxy Iron(III) Complexes. The treatment of the bromo iron(III) complex of $TMPPH_2$ with sodium hydroxide quantitatively gave the μ-oxo dimer, while that of $TBPPH_2$ afforded a mixture of the hydroxy and μ-oxo compounds, the two species was separated by alumina column chromatography (relative weight of products; hydroxy/μ-oxo=5:1), as is shown in Scheme 2 and Table 4.

The purified hydroxy complex of $TBPPH_2$ was stable in organic solvents at room temperature (ca. 23 °C) for at least 6 d. At higher temperatures, however, the hydroxy complex of $TBPPH_2$ was

gradually converted to the μ-oxo dimer. After 8 h heating in toluene (60 °C), the hydroxy complex of $TBPPH_2$ was completely turned into the μ-oxo dimer.

The treatment of bromo iron(III) complexes of **1a**—**d** quantitatively converted them into hydroxy iron(III) complexes. These four hydroxy iron complexes are stable at 60 °C for at least 8 h.

Oxygenation Reaction. The yields of oxygenation reaction using iodosylbenzene are listed in Table 5.

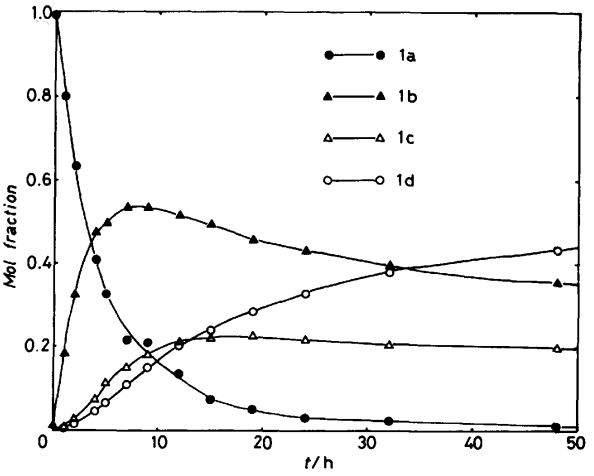

Fig. 5. Time course of isomerization reaction starting from **1a** in refluxing toluene (111 °C).

All the percentage yields are based on the iodosylbenzene consumed. These results show that manganese and iron complexes of the porphyrin **1** are efficient catalyst for both epoxidation and hydroxylation in iodosylbenzene systems.

For obtaining a further understanding of the catalytic activity of **1**–FeBr and **1**–MnBr, we developed olefin epoxidation in hypochlorite systems.

In the estimation of the oxygenation capabilities of the porphyrin catalyst, the oxygenation reaction with hypochlorite was continued until the porphyrins were decomposed by bleaching. The yields in these experiments are represented as "maximum yield in turnovers" in Table 6.[26)]

The kinetic results (the reaction rates and the yields) of controlled experiments in hypochlorite systems are listed in Table 7. The reaction rates are represented by

turnovers/sec, while the yields are represented by turnover numbers. The kinetic results of the epoxidation of olefin using MnTPPBr are also listed in Table 7.

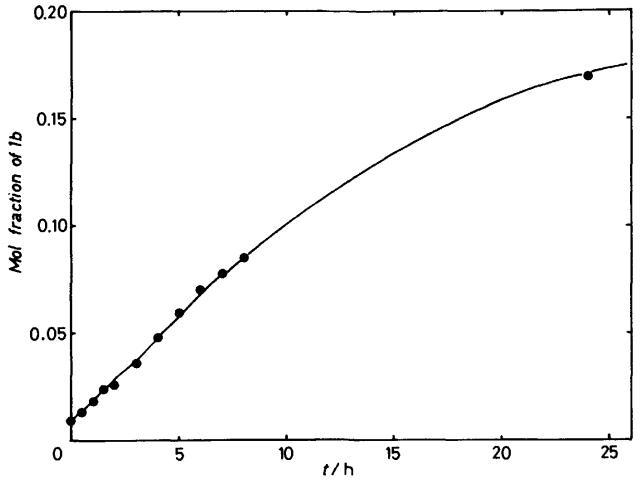

Fig. 6. Time course of isomerization reaction from **1a** to **1b** in refluxing chloroform (61 °C). Other isomers, **1c** and **1d**, were not detected in this experiment.

The epoxides are the main product in all the olefin oxygenation reactions except for the measurements of the "maximum yield in turnovers" using FeTPPCl. When MnTPPBr is used for a control experiment of styrene oxygenation, a notable amount of phenylacetaldehyde (15%) and a small amount of benzaldehyde are also detected. By the use of all the

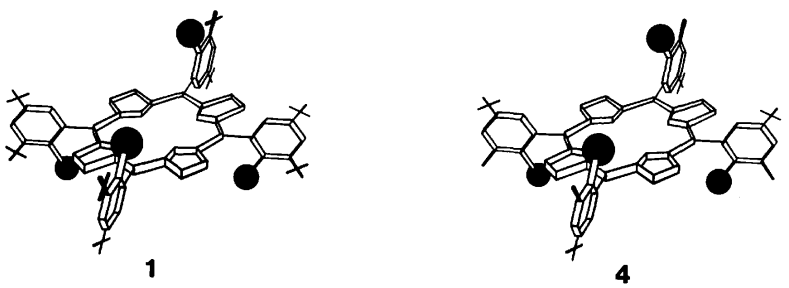
Discussion

Atropisomerization. The atropisomerization of various ortho-substituted tetraphenylporphyrins has been the subject of several recent studies.[13,14,27,28] For example, when the methanol solution of the $\alpha\alpha\alpha\beta$ isomer of 5,10,15,20-tetrakis(2-hydroxyphenyl)porphyrin was allowed to stand for an hour at 23 °C, the other three isomers began to reappear.[27] On the contrary, each isomer of **1a—d** is stable in refluxing chloroform (61 °C, See Fig. 6 and Table 3). When toluene solution is refluxed for 11 h (111 °C), each isomer of **1a—d** is gradually converted to other isomers. In this experiment, the total conversion ratio from the **1a** isomer is the largest, while that from **1d** is the smallest, among the four isomers (see Table 2). The conversion ratio from **1a** achieves ca. 50% after 3 h refluxing in toluene (111 °C). Hatano et al. investigated the gradual transition of one isomer to the other isomers using 5,10,15-20-tatrakis(2-cyanophenyl)porphyrin **3** at 40—60 °C.[14a] The $\alpha\alpha\alpha\alpha$ isomer of the porphyrin **3** decreased to 50% when the chloroform solution was allowed to stand for 1.5 h at 50 °C[14a] These results clearly show that the porphyrin **1** has a higher conformational stability than 5,10,15,20-tetrakis(2-hydroxyphenyl)porphyrin or the porphyrin **3**.

As a further comparative study, an analogous porphyrin, 5,10,15,20-tetrakis(5-*t*-butyl-3-methyl-2-nitrophenyl)porphyrin **4** (See Fig. 1 and 7), has been prepared by a method similar to that shown in Scheme 1,[15] and its $\alpha\beta\alpha\beta$ isomer has been separated (Fig. 7). Heating in chloroform (61 °C) or photoirradiation in a toluene solution for 11 h results in an easy isomerization of the $\alpha\beta\alpha\beta$ isomer of **4**, with the conversion percentages of 50 and 20 respectively. In the case of the **1d** isomer, the conversion percentage is negligible upon heating in chloroform for 11 h or upon photoirradiation (see Table 2). Although both **1** and **4** are ortho-substituted by nitro groups, the conformational stability of **1** is considerably higher than that of **4**. The conformational stability toward the atropisomerization of the ortho-substituted tetraphenylporphyrins depend on the rotational barrier around the phenyl-porphyrin single bond—in other words, the activation energy to the atropisomerization. The four isomers of **1** apparently have higher activation energies than those of **4**. Judging from the CPK model of the porphyrin **1**, the plane of the nitro group is forced to be almost perpendicular to the phenyl ring by the steric bulk of neighboring *t*-butyl moiety. This steric interaction of *t*-butyl is what is called "the buttressing effect." In contrast, the CPK model of the porphyrin **4** suggests that the steric interaction between the nitro group and the neighboring methyl group is small. Therefore, the nitro group may be supposed to be conjugated with the phenyl ring π system. The planar structure of the



1 **4**

Fig. 7. The porphyrins **1** and **4**.

nitrophenyl group in **4** may cause easy isomerization. The high conformational stability of the porphyrin **1** is given by the strong buttressing effect of the adjacent *t*-butyl group, i.e., by the absence of the conjugation of the nitro group with the phenyl π system.

It has been reported that the four isomers of 5,10,15,20-tetrakis-(2-hydroxyphenyl)porphyrin,[27] 5,-10,15,20-tetrakis(4-*t*-butyl-2-aminophenyl)porphyrin,[21] 5,10,15,20-tetrakis(2-aminophenyl)porphyrin,[14b] and "picket fence" porphyrin[14b] have been equilibrated in a statistical abundance ($\alpha\alpha\alpha\alpha:\alpha\alpha\alpha\beta:\alpha\alpha\beta\beta:\alpha\beta\alpha\beta$= 12.5:50:25:12.5). The isomer distribution of **1a—d** in the equilibrium state ($\alpha\alpha\alpha\alpha:\alpha\alpha\alpha\beta:\alpha\alpha\beta\beta:\alpha\beta\alpha\beta$=1.6: 33.8:17.2:47.5), however, is quite different from that of the statistical abundance. In the equilibrium state, **1d** is the dominant isomer. The amount of the **1a** isomer is much smaller, while the corresponding ratio of **1d** is considerably larger than that of the statistical abundance. In kinetic studies of isomerization, the $\alpha\alpha\alpha\beta$ isomer has been the key compound for the analyses of atropisomerization. Hence, the relative ratios are represented by the amounts of **1a**, **1c**, and **1d** in relation to that of **1b**; the results are listed in Table 8. For the sake of comparison, the relative ratios ($\alpha\alpha\alpha\alpha/\alpha\alpha\alpha\beta$, $\alpha\alpha\beta\beta/\alpha\alpha\alpha\beta$, $\alpha\beta\alpha\beta/\alpha\alpha\alpha\beta$) of the porphyrin **3** and the statistical abundance are also listed in Table 8. These results clearly show that the relative ratios toward **1b** ($\alpha\alpha\alpha\beta$) of the porphyrin **1** or **3** are rather different from those of the statistical abundance and that **1** and **3** porphyrins have similar tendencies. These findings on the isomer distribution in the porphyrin **1** indicate that the thermal stability of the porphyrin **1d** is higher than that of **1b**, while that of **1a** is lower than that of **1b**. In the course of the isomerization, the **1a** isomer is immediately changed into the other three isomers. After 3 h refluxing in toluene (111 °C), the conversion ratio from **1a** is achieved at ca. 50%. The relative ratio of **1d** has been constantly growing during refluxing (see Fig. 5). These results of the time-course experiment also show that the thermal stability of **1d** is higher than those of the other isomers, while that of **1a** is extremely low among the four isomers. The variation in the stabilities of **1a—d** is explained by an electrostatic repulsive model. In the porphyrin **1a—d**, the interactions between the two nitro groups projecting from the diagonal phenyl rings are supposed to be negligible. On the contrary, the two nitro groups projecting to the same side of the porphyrin plane from the adjacent phenyl rings may have large repulsive interactions. The **1a**, **1b**, **1c**, and **1d** isomers have four, two two, and no pairs of such large repulsive interactions respectively. Because of these repulsive interactions, the **1a** isomer has the lowest conformational stability. On the other hand, the **1d** isomer has the highest conformational stability because of the absence of the repulsion between nitro groups.

As has been mentioned above, ortho-substitution by nitro groups with the *t*-butyl moiety at the adjacent position seems to have a great influence on the comformational stability or on the isomer distribution of atropisomerization. At any rate, the extremely high conformational stability toward the isomerization of the porphyrin **1** pushed us to further investigations of the relationship between the shape of the porphyrin and its capability as oxygenation catalyst.

Iron Insertion and Stabilities of Hydroxy Iron(III) Complexes. The insertion ratio of each isomer of **1** in controlled experiments is listed in Table 9. In controlled experiments at 30 °C, the yield of **1a** is rather higher than that of the other three isomers. Therefore, the metal incorporation of **1a** need not maintain a high temperature for a long time. Although the yields of the other three isomers **1b—d** are very low at 30 °C, the metal insertion of these isomers can be carried out at high temperatures. After all, each isomer of the porphyrin **1a—d** is converted to the corresponding iron(III) complex, with a retention of the ligand conformation.

In recent years, several research groups have reported the formation of stable hydroxy iron(III) complexes by the use of such protected porphyrins as 5,10,15,20-tetrakis(2,4,6-trimethoxyphenyl)porphyrin or 5,10,15,20-tetramesitylporphyrin.[23,27,31] Iron(III) complexes of our protected porphyrins **1a—d** have also formed stable hydroxy iron(III) complexes. By contrast, simple unprotected porphyrins, e.g., 5,10,15,20-tetraphenylporphyrin or 2,3,7,8,12,13,17,18-octaethylporphyrin, from the hydroxy iron species in

solution; however, these are serious difficulties with the isolation of the species as stable compounds.[32]

The thermal stability of the hydroxy iron(III) complex against transformation into the μ-oxo dimer is supposed to be influenced by the protection of the porphyrin plane. Our results show that the steric bulk of $TBPPH_2$ is just enough for the stabilization of the hydroxy iron(III) species at room temperature, while that of $TMPPH_2$ is insufficient. Furthermore it is certain that ortho substituted nitro groups of **1a—d**, which give rise to great restrictions on the rotation about porphyrin-phenyl single bonds, afford additional thermal stability to the hydroxy iron(III) complexes of **1a—d**.

Oxygenation Reaction. In cyclohexene epoxidation by iodosylbenzene, **1**-FeBr, and **1**-MnBr, but not **1d**-FeBr and **1d**-MnBr, completely consumed the iodosylbenzene (see Table 5). The **1**-FeBr complex sufficiently catalyzed the hydroxylation of alkanes in comparison with FeTPPCl, which generated only a trace amount of the oxygenation products (see Table 5). Groves et al. investigated the influence of the ortho-position substitution of phenyl groups using FeTPPCl and FeTTPCl (TTP=5,10,15,20-tetrakis(2-tolyl)porphyrin)iodosylbenzene system.[33,34] In cyclohexene epoxidation, the total yield and the selectivity for epoxide production of the FeTTPCl catalyst (cyclohexene oxide 67%; 2-cyclohexen-1-ol 15%) were slightly higher than those of the FeTPPCl catalyst (cyclohexene oxide 55%, 2-cyclohexen-1-ol 15%).[33] In the experiment on cyclohexane hydroxylation, the total yields of the FeTTPCl system (cyclohexanol 22%, cyclohexanone 2.4%) were considerably higher than those of the FeTPPCl system (cyclohexanol 7.6%, cyclohexanone 0.5%).[34] These results show that ortho-substitution by the methyl group give rise to high yields in both epoxidation and hydroxylation reactions. The selectivity for epoxide production in cyclohexene oxygenation was also enhanced in the FeTTPCl system. In our **1**-FeBr system, these tendencies are extremely remarkable (see Table 9). Our results indicate that the ortho-substitution of the phenyl moiety by the nitro group is effective and better than the ortho-substitution by the methyl group. Although the yields based on the porphyrin catalyst in these experiments are very small (within 30 turnovers), these results clearly show that the iron and manganese complexes of **1** have quite high catalytic activities compared with FeTPP or MnTPP in metalloporphyrin-iodosylbenzene systems.

The hypochlorite is a cheap, convenient oxygen source for olefin-epoxidation reactions; hence, the manganese porphyrin-hypochlorite systems have been well established for olefin-epoxidation reactions.[7-9] We recently reported a successful olefin epoxidation in iron porphyrin-hypochlorite systems.[17] In order to gain a better understanding of catalysis by our protected metalloporphyrin **1**, the maximum yields in turnovers, the reaction retes, and the yields of the olefin-epoxidation reactions were measured by the use of hypochlorite as an oxidant. The maximum yields in tunovers of manganese complexes of **1a—d** are considerably larger than those of MnTPP, while those of the iron complexes **1**-FeBr are comparable to those of MnTPP (see Table 6). In styrene are α-methylstyrene epoxidation, the reaction rates and the yields of **1**-FeBr or **1**-MnBr are almost the same as those of MnTPP (see Table 7). In cyclohexene and cyclooctene epoxidation, however, the reaction rates and the yields by the use of **1**-FeBr are higher than those of MnTPP and the respective manganese complexes of **1a** and **1d**. These results clearly show that the manganese and iron complexes of the protected porphyrin **1** are useful catalysts for the epoxidation using hypochlorine. In all cases of styrene epoxidation catalyzed by **1**-FeBr or **1**-MnBr except for that catalyzed by **1a**-MnBr, a phenylacetaldehyde is not produced. Thus, the catalytic system of the protected porphyrin **1** has a high selectivity for the epoxide production in styrene oxygenation reactions.

The reaction rates are slightly different among the three isomers (see Table 7). When manganese complexes are used for olefin epoxidation, the orders of the reaction rates in controlled measurements are **1a**>**1d**>**1c** (in styrene epoxidation), **1a**>**1c**>**1d** (in α-methylstyrene epoxidation), and **1a**>**1d** (in cyclohexene and cyclooctene epoxidation). In each reaction, the reaction rates of the **1a** isomer (**1a**-MnBr) are the highest among the isomers. As for the controlled experiments using iron complexes, the orders of the reaction rates are **1c**>**1d**>**1a** (in styrene, α-methylstyrene, and cyclohexene epoxidation) and **1d**>**1a**>**1c** (in cyclooctene epoxidation). When manganese complexes are used, the reaction rates of **1a** are always higher than those of **1d**. When iron complexes are used, however, the reaction rates of **1a** are always lower than those of **1d**. These results indicate that the shape of the porphyrin catalyst might influence the reaction rates in olefin epoxidation, and that the mechanism of olefin epoxidation may be different between manganese and iron complexes.

These kinetic results can be explained by our speculative mechanisms as follows. The isomer **1d** is symmetrical and has two topological identical faces ("half-crowded sites" in Fig. 8). On the contrary, the steric environments of the upper and lower sides of the isomer **1a** are quite different. The porphyrin **1a** has a steric bulk on one side of the porphyrin plane formed by four nitro groups ("crowded site" in Fig. 8), yet leaves the other side comparatively unemcumbered ("open site" in Fig. 8). In the MnBr or FeBr complexes of **1a**, Br is expected to ligate on the "open site" (see Scheme 3-(1)).[35] Employing a N-base such

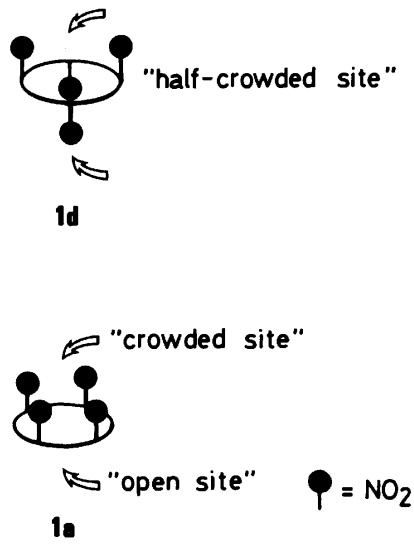

Fig. 8. The reaction site of **1a** and **1d**.

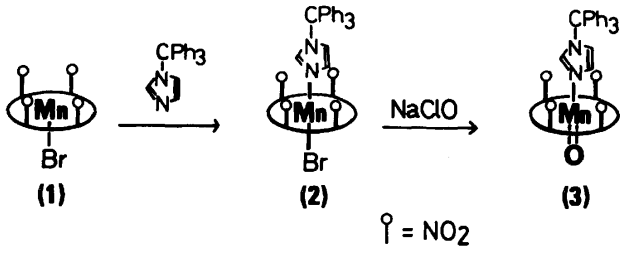

Scheme 3. The speculative oxygenation mechanism of **1a**-MnBr system.

as 1-triphenylmethylimidazole with **1a**-MnBr probably allows the coordination of the N-base on the "crowded site" (see Scheme 3-(2)). The high-valent manganese oxo complex which is illustrated in Scheme 3-(3) may be produced by hypochlorite, and it seems that the oxygenation reaction is carried out on the "open site" in **1a**-MnBr with the N-base system. The oxygenation reaction of **1d**-MnBr and the N-base, however, is done on the "half-crowded site." The analysis of products in styrene oxygenation provides similar information about the reaction site of **1a**-MnBr with the N-base. The ratios of the products in styrene oxygenation are shown in Table 10. In the experiments using **1c**-MnBr and **1d**-MnBr, which oxygenated the olefin on the "half-crowded site," a phenylacetaldehyde cannot be detected. A notable amount of phenylacetaldehyde was, however, produced in the MnTPPBr (15%), MnTBPPBr (11%), and **1a**-MnBr (11%) systems. These results indicated that the reaction site of **1a**-MnBr with the N-base may be the "open site," which is a steric environment similar to that of the reaction site of MnTBPPBr with the N-base. The electronic factors do not influence the rates of oxygenation. In fact, the manganese complexes of **1a**—**d** have similar electronic structures, judging from their identical UV-vis spectra. The reaction rates of the oxygenation reaction using **1**-MnBr and the N-base are only influenced by the steric environments of the reaction site. The epoxidation reaction on an "oprn site" seems to be more reactive than the reaction on a "crowded site" or on a "half-crowded site." Therefore, the reaction rates of **1a**-MnBr with N-base are always higher than those of **1d**-MnBr with the N-base.

When iron complexes of **1a** are used in the absence of the N-base,[36] the reaction mechanism of epoxidation is different from that of the manganese complex of **1a**. In the **1a**-MnBr and N-base system, the axial ligand Br is ligated on the same side ("open site") in the resting state because the "crowded site" is occupied by the N-base. On the contrary, the axial ligand displacement by X (Br^- or other anion in a water solution) may occur on both sides of the porphyrin plane during the oxygenation-reaction cycles in the **1a**-FeBr system.[37] Because of the easy dissociation and scrumbling of the axial ligand, the oxygenation reaction of **1a**-FeBr may take place on both an "open site" and a "crowded site," the average reaction rate of **1a**-FeBr is deduced comparison with the case in which the oxygenation is performed only on an "open site." Accordingly, the reaction rates of **1a**-FeBr are lower than those of **1d**-FeBr whose reaction site is "half-crowded site."

When iron complexes of **1** are used in styrene oxygenation, no phenylacetaldehyde could be detected in any isomer system (see Table 10). In the absence of the N-base, styrene oxygenation catalyzed by **1a**-MnBr or MnTBPPBr afforded no phenylacetaldehyde. These results indicated that phenylacetaldehyde production is affected not only by the reaction site ("open site" or "crowded site"),[38] but also by the N-base. Taking all these findings together, we proposed the speculative mechanism shown in Scheme 3.

At the present stage, we cannot explain completely

Table 10. The Ratios of Products in the Styrene Oxygenation

the relationship between the reaction rates of oxygenation and the shape of the porphyrin catalysts. Spectroscopic measurements were not useful for the specification of the chemical species in each step; further efforts to get kinetic information still continue in our laboratory. However, it has been proved that our protected porphyrins, **1**–FeBr and **1**–MnBr, show sufficient catalytic activity against olefin epoxidation and alkane hydroxylation.

(Received April 16, 1986)

The catalytic electroreduction of an oxygen molecule on a glassy carbon electrode covalently modified with [5,10,15,20-tetrakis(4-carboxyphenyl)porphinato]iron(III) (abbreviated as GC-O-Fe(III)TCPP) was investigated in an aqueous solution. The reduction of oxygen on the GC-O-Fe(III)TCPP electrode occurs at a more anodic potential than on the glassy carbon electrode adsorbing Fe(III)TCPP. This anodic shift of the oxygen reduction potential may be closely related to the number of bonds between a metalloporphyrin molecule and the electrode material. The oxygen molecule is reduced via the one-step reduction accompanying four-electron and four-proton transfer at pH 7—11 and via two successive reductions accompanying two-electron transfer and subsequently two-electron and four-proton transfer at pH>11.5. At pH<6, the number of transferred electron could not be reproducibly determined because of the cleavage of several ester linkages.

A number of studies of the application of transition metal complexes with such macrocyclic compounds as porphyrins and phthalocyanines to the electrocatalytic reduction of molecular oxygen have been reported.[1,2] Recently, Kobayashi and Osa reported a study of the catalytic electroreduction of molecular oxygen using 5,10,15,20-tetrakis(4-carboxyphenyl)porphinato iron in aqueous solutions.[3] In their study, molecular oxygen was reduced on either a polished solid electrode in a metalloporphyrin complex solution or a metalloporphyrin-adsorbed electrode in a supporting electrolyte solution. They suggested the mechanism of the catalytic reduction to be an electrochemical (EC) catalytic regeneration.

We have been interested in preparing covalently modified electrodes with iron porphyrin complexes and studying the electrochemical behavior of the modified electrodes.[4] Although solid electrodes have previously been modified by fixing porphyrins through amide[5-9] or ester[4,10] linkage, the reduction of oxygen using these modified electrodes has been rarely studied.[11]

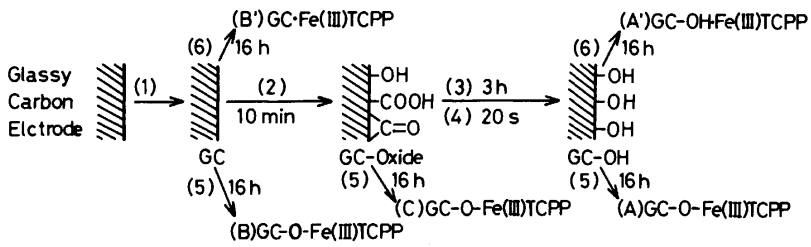
In the present paper, we will report on an electrochemical study of catalytic oxygen reduction on glassy carbon electrodes covalently modified with [5,10,15,20-tetrakis(4-carboxyphenyl)porphinato]iron(III) (represented by Fe(III)TCPP) and will report our finding that the oxygen reduction proceeds with an EC mechanism which changes with the pH-range.

Experimental

Materials. The Fe(III)TCPP was prepared by the metal insertion of 5,10,15,20-tetrakis(4-carboxyphenyl)porphine (Porphyrin Products Inc.) with $FeCl_2$.[12] The purification of Fe(III)TCPP was carried out several times by adding an HCl solution to the crude Fe(III)TCPP alkaline solution until the pH became ca. 5. The precipitated product was dried over phosphorus pentoxide at a reduced pressure for 20 h and identified by means of elemental analysis. Found: C, 65.88; H, 3.46; N, 6.55%. Calcd for Fe(III)TCPP(H_2O)-(OH): C, 65.54; H, 3.55; N, 6.37%.

The water-soluble carbodiimide hydrochloride (WSCD·HCl, 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide hydrochloride) used for dehydration was obtained from the Peptide Institute, Inc. (Osaka). All the other chemicals of a guaranteed reagent grade (Wako Pure Chemical Industries) were used without further purification.

Modification of Glassy Carbon Electrodes. A glassy carbon rod (GC-30, 5.4 mmϕ, Tokai Carbon, Ltd.) was inserted into a Teflon tube to give an exposed disc of area of ca. 0.23 cm^2; this rod then served as a working electrode. The mechanical and chemical treatments in the preparation procedure of each modified electrode are shown in Scheme 1. The numbers, (1) to (6), in Scheme 1 represent the following treatment steps, (1) *Mechanical polishing*: The exposed disc surface of the GC-30 electrode was polished with abrasive paper, followed by suspensions of alumina powders (Marumoto, Ltd.) of decreasing size, down to 0.06 μm, until a mirror-like finish was obtained. (2) *Oxidation*: The polished electrodes were immersed in a 0.4 mol dm^{-3}



Scheme 1. Modification procedures of GC electrode.

$Na_2Cr_2O_7$ acidic (H_2SO_4) solution and then refluxed at ca. 100 °C. (3) *Reduction*: The oxidized electrodes were immersed in a refluxed 0.1 mol dm^{-3} $LiAlH_4$ diethyl ether solution. (4) *Cleaning*: The $Al(OH)_3$ precipitated on the surface during the (3) treatment was removed by ultrasonic cleaning in a 0.05 mol dm^{-3} H_2SO_4 solution. (5) *Dehydration condensation*: Fe(III)TCPP was linked to the electrode surface covered with a hydroxyl group by dehydration condensation in dichloromethane saturated with Fe(III)TCPP and WSCD·HCl. (6) *Adsorption*: Fe(III)TCPP was adsorbed on the electrodes by immersing the elerctrodes for 16 h in dichloromethane saturated with Fe(III)TCPP.

Each time of treatment is also presented in Scheme 1. The electrodes prepared are identified by abbreviations, such as GC-OH or (A)GC-O-Fe(III)TCPP.

Electrochemical Measurements. The cyclic voltammetric measurement was performed using a Nikko Keisoku NPGFZ-2501-A potentiogalvanostat. For rotating disc voltammetry, a Nikko Keisoku DPGS-1 potentiogalvanostat, an NPS-2 potential sweeper, an RRDE-1 rotator, and an SC-5 speed controller were also used.

In the oxygen-free experiment, the solutions were deaerated by passing nitrogen gas through them for 20 min prior to the electrochemical measurement and by then keeping them blanketed during the measurement, though the reduction experiments of oxygen were carried out in air-saturated solutions. The potentials were referred to a saturated calomel electrode (SCE).

The buffer solutions, which also served as supporting electrolytes, were prepared from acetate, phosphate, borate, and carbonate. The adjustment of the pH was done using H_2SO_4 and/or NaOH, and the ionic strength was adjusted at 0.1 mol dm^{-3} with Na_2SO_4. The pH values were measured with a Toa-5B pH meter. All the measurements were performed at 25 °C.

Results and Discussion

The cyclic voltammetric current-potential (I-E) curves obtained on the (A)GC-O-Fe(III)TCPP and (B)GC-O-Fe(III)TCPP electrodes in oxygen-free electrolytic solutions at pH 7 are shown in Fig. 1. The hatched area for each curve corresponds to the charges consumed during the reduction of modified Fe(III)-TCPP to Fe(II)TCPP. The close potentials of the cathodic and anodic peaks indicate that the corresponding redox process is a surface one.[13,14] The peak current values were so small that we can not examine the dependence of the peak current on the potential sweep rate. In spite of the large difference in residual currents observed on the (A) and (B) electrodes, the same amount of attached Fe(III)TCPP was determined by integrating the cathodic peak current of the wave. The details of these results will be discussed below (see Table 1).

Figure 2 shows the reduction waves of oxygen

Electrode	E_p/V	10^6[Quantity of electricity]/C	10^{11}[Surface concentration]/mol cm^{-2}
A	−0.207	1.30	5.9
B	−0.286	1.60	7.2
C	−0.270	0.60	2.7
A′	−0.300	—	—
B′	−0.350	—	—

Scan rate: 0.05 V s^{-1}.

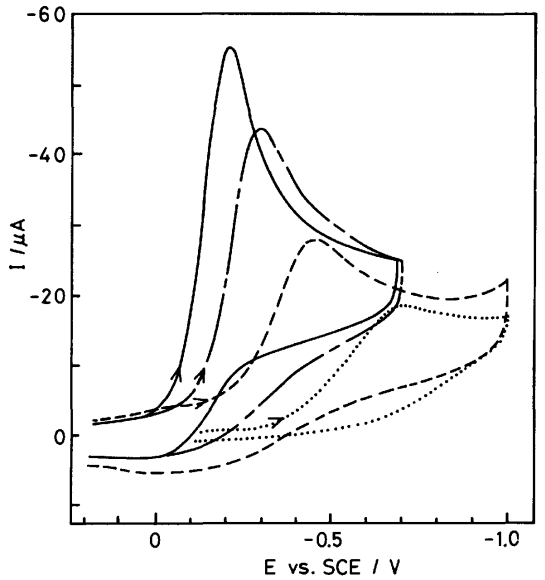

Fig. 2. Cyclic voltammograms for the reduction of O_2 on a glassy carbon and the chemically modified glassy carbon electrodes in the air saturated electrolyte solutions of pH 7. —— (A)GC-O-Fe(III)TCPP, —·— (A′)GC-OH·Fe(III)TCPP, ------ GC-OH, and ····· GC. Scan rates: 0.05 V s^{-1}.

observed on the four kinds of electrodes in air-saturated electrolytic solutions at pH 7. The anodic shift of the peak potential attributable to the Fe(III)TCPP modification is considerably greater on the (A)GC-O-Fe(III)TCPP electrode than on the (A')GC-OH·Fe(III)TCPP-adsorbed electrode (see also Fig. 3).

The peak potentials of oxygen reduction in aqueous solutions of pH 7 and the quantities of Fe(III)TCPP molecules on the modified electrodes (A, B, and C), obtained from the quantity of the charge in the reduction of Fe(III)TCPP, are listed in Table 1, together with the values on the Fe(III)TCPP-adsorbed electrodes. In order to exclude the reduction current attributable to the residual oxygen in the solution, the peak potentials were measured after consecutive scans, in which no variation in the current had been observed. The amounts of Fe(III)TCPP covalently attached to the (A) and (B) electrodes were almost the same, while the amount attached on the (C) electrode was about a half of that value. On the lst scan in the cyclic voltammogram, the (C) electrode gave almost the same area of the reduction peak as those of the (A) and (B) electrodes. In the case of the (C) electrode, however, the consecutive scans caused an abrupt decrease in the area of the reduction peak with a slight decrease in the residual current. This observation suggests that the Fe(III)TCPP attached on the GC-Oxide partially peeled off during the consecutive potential scans.

The amounts of the hydroxyl group on the (A) and (B) electrodes, which was calculated from the quantity of the charge in the reduction of the 3,5-dinitrobenzoyl chloride covalently attached to the OH group of the GC and GC-OH electrodes,[4,15,16] were 1.9×10^{14} and 0.53×10^{14} molecules respectively. In spite of the large difference (ca. 4 times) in the amount of hydroxyl group on the surfaces, the amount of Fe(III)TCPP on the (A) electrode was nearly equal to that on the (B) electrode. This indicates that a large portion of the hydroxyl groups introduced on the (A) electrode is covered with the attached large molecule of Fe(III)-TCPP and is not utilized effectively for the modification. This interpretation is supported by the fact that the redox peak couple at −0.05 V, probably attributable to groups introduced by the oxidation, observed on the (A) electrode was not noticeable on the (B) electrode, as is shown in Fig. 1.[4]

Table 1 shows that the reduction of oxygen on the covalently attached (A)GC-O-Fe(III)TCPP electrode occurs at the most anodic potential among the series of Fe(III)TCPP modified GC electrodes: The peak potential of oxygen reduction on the (A) electrode shifted ca. 80, 90, and 140 mV toward the positive direction compared to those on the (B), (A'), and (B') electrodes respectively.

Figure 3 shows the peak potential of oxygen reduction on the (A)GC-O-Fe(III)TCPP electrode as a function of the condensation time with WSCD·HCl. The complete potential shift, ca. 100 mV, is obtained within 10 min of the condensation. Because of the previously mentioned existence of the excess hydroxyl group on the (A)GC-O-Fe(III)TCPP electrode, all the four carboxyl groups of Fe(III)TCPP may link with the electrode. A preliminary experiment on the modified GC electrode with hemin, which has two carboxyl groups, showed an anodic potential shift of ca. 30—40 mV for oxygen reduction. A similar anodic shift upon the oxygen reduction was reported by Kobayashi et at.[11] on the electrode modified with the metalloporphyrin through amide linkages. Consequently, it can be speculated that this anodic shift of

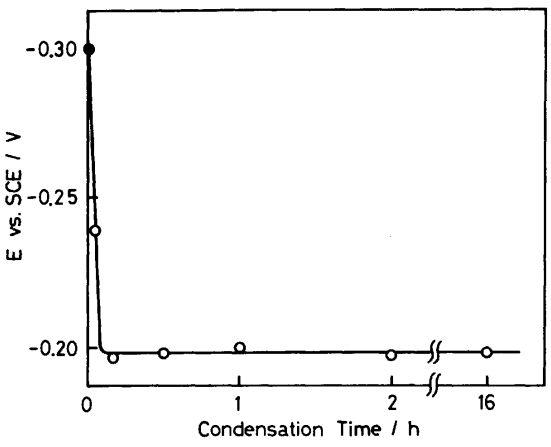

Fig. 3. Plots of the peak potential of oxygen reduction vs. condensation time. ○: (A)GC-O-Fe(III)TCPP, ●: (A')GC-OH·Fe(III)TCPP.

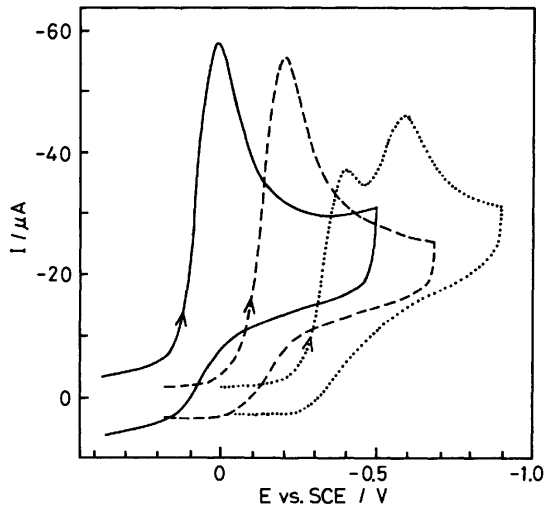

Fig. 4. Cyclic voltammograms for oxygen reduction on the (A)GC-O-Fe(III)TCPP electrode in the air saturated electrolyte solution of pH 1.3 (——), 7.0 (-----), and 12.4 (·····).

the oxygen-reduction potential on the covalently modified electrodes is closely related to the number of bonds between a metalloporphyrin and an electrode material. The more cathodic potential of oxygen reduction on the (B) electrode compared to that on the (A) electrode is probably attributable to the smaller number of covalent bonds per metalloporphyrin molecule on the electrode.

Figure 4 shows some typical cyclic voltammograms obtained on the (A)GC-O-Fe(III)TCPP electrode in air-saturated aqueous solutions of various pHs. The peak potential of oxygen reduction is shifted cathodically with an increase in the pH of the solution. In a high-pH solution, a discrete and successive two-step reduction was observed. The dependence of the peak potential on the pH of the solutions is represented in Fig. 5. Three different potential shifts per unit of pH were observed according as the pH range was pH<5, pH 6—11, or pH>11. The peak-potential shifts with slopes of ca. −55 mV/pH at pH 6—11; that is, the reduction of the oxygen molecule is accompanied by the addition of one electron per one-proton addtition. At pH>11, two successive reduction waves are observed. They shift with slopes of 0 mV/pH and ca. −110 mV/pH; that is, one oxygen molecule is reduced by the electron addition followed by a one-electron addition per two-proton addition. At pH<5, on the other hand, the slope of the peak potential shift is reduced with a decrease in the pH.

In Fig. 5, the dashed line represents the data for oxygen reduction on the GC-20 electrode in Fe(III)-TCPP aqueous solutions, while the open triangle is the peak potential on the Fe(III)TCPP-adsorbed GC-20 electrode in the porphyrin-free solution, as reported by Kobayashi and Osa.[3] Though the peak potential on the adsorbed electrode is almost the same as on the naked electrode in the porphyrin solution, the oxygen reduction potential on our covalently modified electrode shifts anodically by ca. 175 mV in the range of pH 6—11.

In order to estimate the number of transferred electrons in the oxygen reduction, current-potential curves were obtained using an (A)GC-O-Fe(III)TCPP rotating electrode. Figure 6 shows some typical current-potential curves obtained in air-saturated solutions at the pHs corresponding to the ranges in Fig. 5. Because of the lower stability of the modified electrodes at low pHs, the current increased slowly with an increase in the potential, and the reproducibility of the values of limiting current was poor. This behavior suggests the presence of complicating electrode processes, including the cleavage of some ester linkages and the release of Fe(III)TCPP molecules from the surface. Except for the acidic solution, the Levich plots (the limiting current vs. (the rotating rate)$^{1/2}$)[8] showed good straight lines through the point of origin. The number of transferred electrons in the oxygen reduction was calculated by the use of the Levich equation from the limiting current at each rotation rate (250, 500, 750, 1000, and 1250 rpm). In the calculation, the following values were used for the variables in the equation: 2.1×10^{-5} cm^2 s^{-1} and 2.4×10^{-4} mol dm^{-3} [1] for the diffusion coefficient and the concentration of oxygen in air-saturated solutions respectively, 8.9×10^{-3} cm^2 s^{-1} for the kinetic viscosity of aqueous solutins, and 0.23 cm^2 for the surface area of modified electrodes.

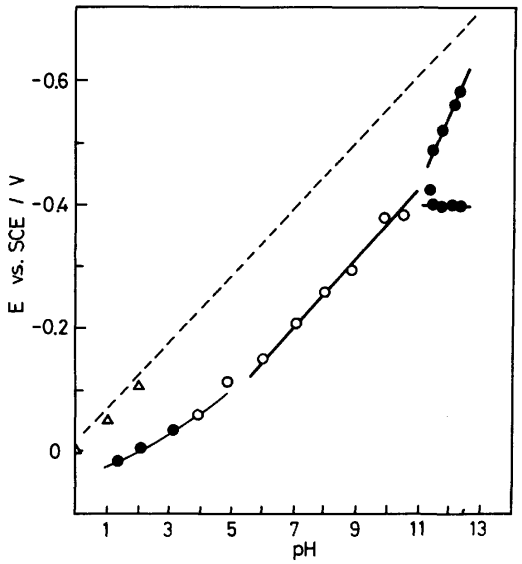

Fig. 5. The peak potentials of oxygen reduction on the (A)GC-O-Fe(III)TCPP electrodes as a function of the pH. ○: in buffered solutions, ●: in non-buffered solutions, △ and dashed line: replotted from Ref. 3.

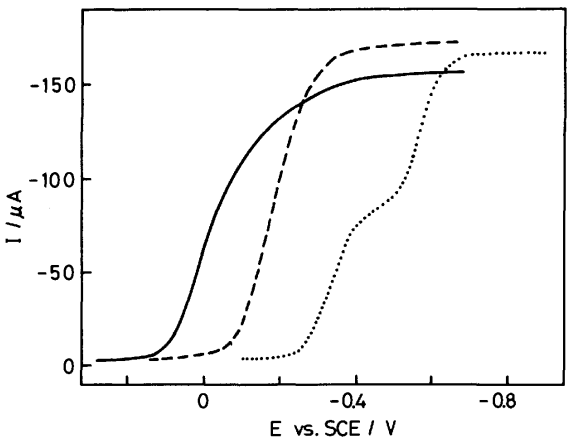

Fig. 6. Current-potential curves of the reduction of oxygen at the rotating disc modified (A) Electrodes. The electrode was rotated at 500 rpm. The potential was scanned at 50 mV s^{-1}. —— pH 3.1, ----- pH 7.1, ·····pH 12.0

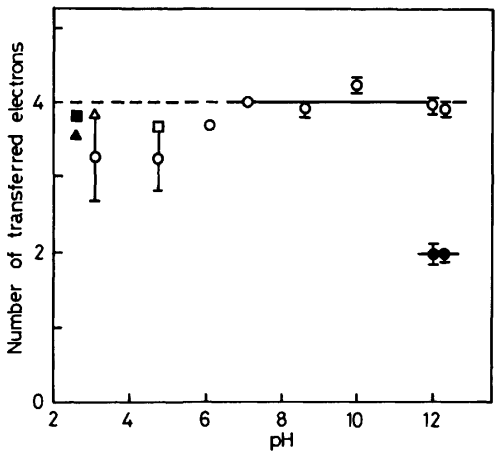

Fig. 7. Number of transferred electrons for the oxygen reduction at the rotating disc modified (A) electrodes as a function of the pH. ○: average overall number of transferred electrons. ●: average number of transferred electrons at the first wave at pH>11.5. Rotation rate (rpm): △250, ▲500, □1000, and ■1250.

Figure 7 shows the relationship between the number of transferred electrons measured on the (A) GC-O-Fe(III)TCPP rotating electrode and the pH of the solutions. At pH>11.5, the solid circle and the open circle indicate the number of transferred electrons in the lst reduction wave and in the overall reduction respectively. Figure 7 indicates that the oxygen molecule is reduced via a one-step reaction with four-electron transfer at pH 7—11 and via two successive reactions, each with a two-electron transfer, at pH>11.5.

The numbers of transferred electrons and protons in the oxygen reduction suggest that the reduction of the oxygen molecules in the solutions on the (A)GC-O-Fe(III)TCPP electrode proceeds via the following EC catalytic regeneration mechanisms. At pH 7—11, the linked Fe(III)TCPP molecules are reduced to Fe(II)-TCPP by Eq. 1 (E step) and reproduced by Eq. 2 (C step), reducing an oxygen molecule to H_2O:

$$\text{Fe(III)TCPP} + e^- \longrightarrow \text{Fe(II)TCPP} \quad (1)$$

$$4\text{Fe(II)TCPP} + O_2 + 4H^+ \longrightarrow 4\text{Fe(III)TCPP} + 2H_2O \quad (2)$$

At pH>11.5, however, the Fe(II)TCPP molecules, which are produced by Eq. 1 (E step), reduce an oxygen molecule to the O_2^{2-} ion by Eq. 3 (C step) at the first peak potential; then they reduce O_2^{2-} by Eq. 4 (C step) at the more cathodic potential:

$$2\text{Fe(II)TCPP} + O_2 \longrightarrow 2\text{Fe(III)TCPP} + O_2^{2-} \quad (3)$$

$$2\text{Fe(II)TCPP} + O_2^{2-} + 2H_2O \longrightarrow 2\text{Fe(III)TCPP} + 4OH^- \quad (4)$$

In the solution at pH<6, there was some scatter in the limiting current of oxygen reduction. However, the largest number of transferred electron determined was nearly equal to four. Therefore, the reduction of oxygen in the solution at pH<6 probably proceed via essentially the same mechanism as that observed in the solution at pH 7—11.

Though the transient formation of an intermediate such as hydrogen peroxide during the reduction of oxygen could be considered, we did not detect the formation of any intermediates by the use of the RDE apparatus.

The authors are grateful to Dr. Kentaro Okuma, Fukuoka University, for the elemental analysis of Fe(III)TCPP and for his helpful suggestions. The present work was partially supported by a Grant-in-Aid for Scientific Research (No. 61740358) from the Ministry of Education, Science and Culture, and a grant from the Central Research Institute of Fukuoka University.

Electrochemical and Spectroelectrochemical Speciation of [5-phenyl-10,15,20-tris(4-sulfonatophenyl)porphinato]iron in Aqueous Solution

Fumihiro ARIFUKU,* Rika NISHINO, Kikujiro UJIMOTO, and Hirondo KURIHARA
Department of Chemistry, Faculty of Science, Fukuoka University,
Nanakuma, Jonan-ku, Fukuoka 814-01
(Received August 30, 1986)

The equilibria among the species of [5-phenyl-10,15,20-tris(4-sulfonatophenyl)porphinato]iron (Fe-$TPPS_3$) ion in aqueous solution and the redox reactions of the central metal were investigated by electrochemical and spectro-electrochemical methods. In the range of pH 3—12.5, the species formed by the reduction of Fe(III)-$TPPS_3$ in solution was identified as the monomeric Fe(II)-$TPPS_3$, while Fe(III)-$TPPS_3$ exists in both monomeric and dimeric species in equilibrium. The monomeric Fe(III)-$TPPS_3$ was demetallated at pH below 3 in the course of reduction of the Fe(III)-$TPPS_3$ solution. The μ-oxo-dimer of Fe(III)-$TPPS_3$ in highly basic solution was reversibly reduced to Fe(II)-$TPPS_3$ and subsequently the monomeric Fe(I)-$TPPS_3$. The formation of the stacking-type dimer of Fe(III)-$TPPS_3$, significantly depending on the concentration of Fe(III)-$TPPS_3$, was presumed to have a pH below 6.

Metalloporphyrin complexes are well-known to play important roles in various biological systems.[1,2] These complexes are essential for the carriers and storage of oxygen and as enzymatic cofactors. Recently, noteworthy reports on an electrocatalytic reduction of molecular oxygen by metalloporphyrins, together with metallophthalocyanines, have been reported.[3,4]

Some of these functions of metalloporphyrins must depend on the addition or replacement of axial ligands of the central metals.[5] In order to elucidate the specificity of such macrocyclic compounds, it is important to clarify their solute species and redox properties. Therefore, we have been interested in studying the properties of some water-soluble iron-porphyrin complexes.[6-8]

The characteristics of a monomer and a μ-oxo-dimer of [tetrakis(*p*-sulfonatophenyl)porphinato]iron-(III) (abbreviated as Fe(III)-$TPPS_4$) in aqueous solution was investigated in detail.[9,10] We found, by spectrophotometric and magnetochemical methods, that the solute species in a 1.00×10^{-5} mol dm^{-3} [5-phenyl-10,15,20-tris(4-sulfonatophenyl)porphinato]iron-(III) (abbreviated as Fe(III)-$TPPS_3$) solution were similar to that in a Fe(III)-$TPPS_4$ solution.[11] However, the solute species of the reduced form has not been established. The purpose of the present study is to determine the redox characteristics of Fe(III)-$TPPS_3$ in aqueous solution on the glassy carbon electrode and to identify the solute species of the reduced complex using electrochemical and spectro-electrochemical methods.

Experimental

Materials and Sample Solutions. Fe(III)-$TPPS_3$ was prepared by metal insertion of tetraphenylporphinetrisulfonic acid (Dojindo Laboratories, abbreviated as $TPPS_3$) with $FeSO_4\cdot7H_2O$ according to the method of Fleischer et al.[9] All other chemicals of guaranteed reagent grade (Wako Pure Chemical Industries) were used without further purification. The pH of the sample solution was adjusted with a sulfuric acid and/or sodium hydroxide solution. The ionic strength was adjusted to 0.1 mol dm^{-3} with a sodium sulfate solution except for solutions of pH below 1 or above 13. Where buffered solutions were required, the following buffers were used: acetate buffer at pH 4—6, phosphate-borate buffer at pH 6—9, and carbonate buffer at pH 9—11. Measurements of the pH were made on a Toa HM-5B pH meter.

Spectrophotometric, Electrochemical, and Spectroelectrochemical Measurements. A Hitachi 228A spectrophotometer was used for the spectrophotometric investigation.

The cyclic voltammograms of Fe(III)-$TPPS_3$ in solutions of various pH were obtained by means of Dual Potentiogalvanostat DPGS-1, Potential Sweeper NPS-2 (Nikko Keisoku) and X-Y recorder WX4403 (Watanabe, Inc.) equipped with a conventional three-electrode system. A glassy carbon rod (GC-30, Tokai Carbon) plugged into a Teflon tube was used as the working electrode. The carbon surface exposed to a solution was a circle 0.196 cm^2 in area. The exposed disc surface of a GC-30 electrode was polished with an abrasive paper followed with suspensions of alumina powders (Marumoto, Inc.) of decreasing size, down to 0.06 μm in diameter, until a mirror-like finish was obtained. To completely remove the alumina particles adhering on the polished electrode surfaces,[12,13] the electrodes were thoroughly washed by ultrasonication for 20 s in 0.05 mol dm^{-3} sulfuric acid.[14]

The spectroelectrochemical experiments were achieved with an optically transparent thin-layer electrode (OTTLE)[6,15] constructed with a gold minigrid (500 wires per inch, Backbee Mears) which was sandwiched between two microslide glasses. The distance between the two plates was controlled with Teflon spacers (Delectrix DF-1200). While the Soret and Q band spectra of Fe(III)-$TPPS_3$ and its reduced-form complexes were measured with a Hitachi 228A spectrophotometer, the potential at the gold minigrid as the working electrode was controlled by a Potentiostat NPOT-2501 (Nikko Keisoku).

Prior to both the electrochemical and spectro-electrochemical measurements, the sample solution was deoxygenated by bubbling nitrogen gas through the solution for about 20 min, and the measurements were carried out under

an atmosphere of nitrogen. A saturated calomel electrode (SCE) was employed as a reference electrode. All the measurements were performed at 25 °C.

Results and Discussion

Electrochemistry. Figures 1 and 2 illustrate typical cyclic voltammograms of 5.00×10^{-4} mol dm^{-3} Fe(III)-$TPPS_3$ aqueous solutions at different pH values. The dashed line in Fig. 1 shows the 1st cyclic voltammetric curve observed in Fe(III)-$TPPS_3$ solution of pH 2.04. The catalytic reduction of oxygen, which was not removed from the solution, via the reduction of Fe(III)-$TPPS_3$ was observed at ca. −0.1 V. In addition to this reduction peak, two redox peak couples were clearly observed at the more cathodic potential. The solid line in Fig. 1 shows the stationary cyclic voltammogram (9th cycle) and indicates that the reduction wave at ca. −0.1 V virtually disappeared and the two redox peak couples remained. This disappearance of the 1st current peak must be attributed to a demetallation of Fe(III)-$TPPS_3$ in addition to a consumption of oxygen in an electrical double layer. The 1st current peak at ca. −0.1 V corresponds to the peaks at ca. −0.1 V in Fig. 3 and at ca. −0.07 V in Fig. 4. The redox couple at ca. −0.3 V was observed only in solutions of pH<6 (cf. Fig. 4); the peak current of this redox couple decreased with a decrease in the concentration of the porphyrin complex and the peak couple was then no longer detectable in the solution of 1.00×10^{-5} mol dm^{-3} Fe(III)-$TPPS_3$.

Figure 2 shows the stationary cyclic voltammograms observed in the Fe(III)-$TPPS_3$ solution at pH 7.16 and 12.81. At these pH, the 1st peak attributable to the reduction of Fe(III)-$TPPS_3$ remained intact even after multicycles. The value of

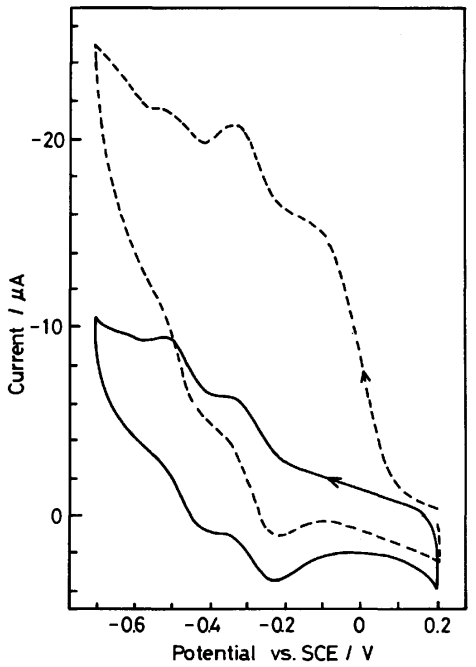

Fig. 1. Cyclic voltammograms of 5.00×10^{-4} mol dm^{-3} Fe(III)-$TPPS_3$ aqueous solution (pH 2.04). ------: 1st cycle, ——: 9th cycle. Scan rate: 0.05 V s^{-1}.

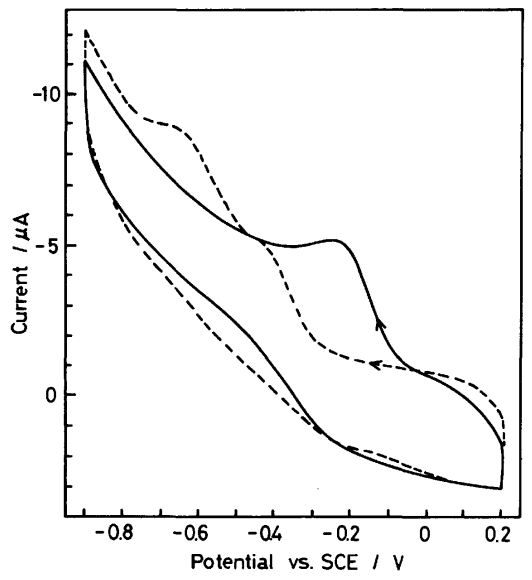

Fig. 2. Cyclic voltammograms of 5.00×10^{-4} mol dm^{-3} Fe(III)-$TPPS_3$ aqueous solutions. ——: pH 7.16, ------: pH 12.81. Scan rate: 0.05 V s^{-1}.

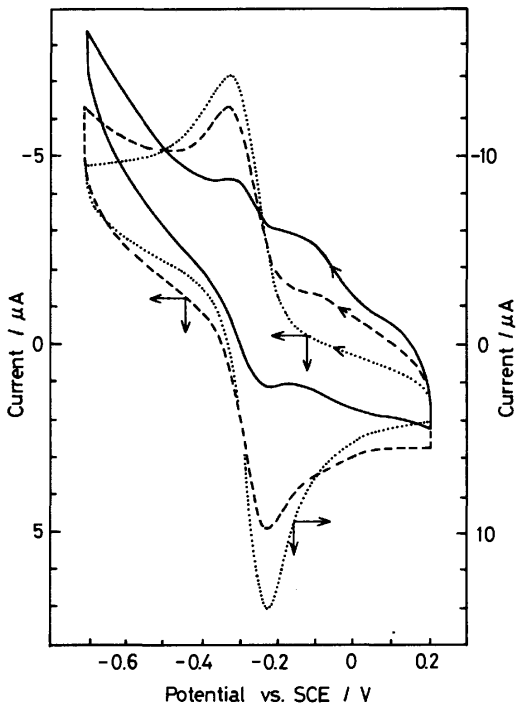

Fig. 3. Cyclic voltammograms of Fe(III)-$TPPS_3$ aqueous solutions (pH 4.21). ——: 1.00×10^{-4} mol dm^{-3}, ------: 3.00×10^{-4} mol dm^{-3}, ·····: 9.00×10^{-4} mol dm^{-3}. Scan rate: 0.05 V s^{-1}.

the reduction current of Fe(III)-TPPS$_3$ at pH 7.16 is almost the same as that of each of two reduction peaks at pH 12.81, respectively. That is to say, the total quantity of electron transfered to Fe(III)-TPPS$_3$ in the two-step reduction at pH 12.81 is twice that at pH 7.16 in the potential range from −0.2 to −0.9 V.

Figure 3 shows the stationary cyclic voltammograms obtained in the Fe(III)-TPPS$_3$ solutions of three different concentrations at pH 4.21, where a well defined redox peak couple appeared around −0.3 V. The reduction wave at ca. −0.1 V, which was observed clearly in 1.00×10^{-4} mol dm^{-3} Fe(III)-TPPS$_3$ solution, diminished with increase in the concentration of Fe(III)-TPPS$_3$ and was scarcely observed in the solution of 9.00×10^{-4} mol dm^{-3}. On the other hand, the reversible redox peak couple around −0.3 V became sharp and well-behaved with increasing concentration of Fe(III)-TPPS$_3$. This phenomenon suggests that a certain species, transformed from Fe(III)-TPPS$_3$ monomer, accumulated in the electrical double layer. However, no significant difference in near-UV and visible absorption spectra obtained in 1.00×10^{-5} and 1.00×10^{-3} mol dm^{-3} Fe(III)-TPPS$_3$ solutions was observed. Furthermore, the excellent linearity between the absorbance at the Soret band peak and the concentration of the solutions at pH 3.9 was obtained over a wide range of concentration.[11]

Figure 4 shows the plot of the reduction peak potential $(E_p)_R$ of the lst cyclic voltammograms obtained in 1.00×10^{-3} mol dm^{-3} Fe(III)-TPPS$_3$ against pH of the solutions. The potential of the lst reduction peak at pH<6 was measured by observing the catalytic peak of dissolved oxygen. The peak potential of the lst and 2nd reduction peaks in the low pH range were −0.07 V (pH<4) and −0.32 V (pH<5), respectively, and no potential shift was observed except for the point at pH 0.6. The 2nd reduction peak was observed at pH<6 and was shifted by ca. −60 mV/pH in the pH range of 5—6. The peak potential ca. −0.5 V of the 3rd reduction peak at low pH is approximately in agreement with that of metal-free TPPS$_3$. The $(E_p)_R$ of the lst reduction peak shifted by ca. −60 mV/pH in the pH range 4—11. At pH>11, a pH-independent reduction peak was observed at −0.47 V followed by a pH-dependent reduction peak by ca. −60 mV/pH.

Spectroelectrochemistry. Figures 5—7 show the typical absorption spectra of the reduced sample solutions, which are prepared by reducing 1.00×10^{-4} mol dm^{-3} Fe(III)-TPPS$_3$ solutions potentiostatically

in the OTTLE cell at various pH. At pH 1.54 (Fig. 5), the Soret band shifted from 394 to 488 nm, leaving a weak absorption band at 424 nm in the course of the reduction of Fe(III)-TPPS$_3$. The Soret band at 488 nm was also observed in the solutions containing metal-free TPPS$_3$ in contact with an Au-minigrid electrode. Therefore, the appearance of the Soret band at 488 nm suggests the occurrence of a demetallation[16] from the reduced species of Fe(III)-TPPS$_3$ in highly acidic solution of pH<2.5. This phenomena is supported also by the electrochemical results described in the preceding section.

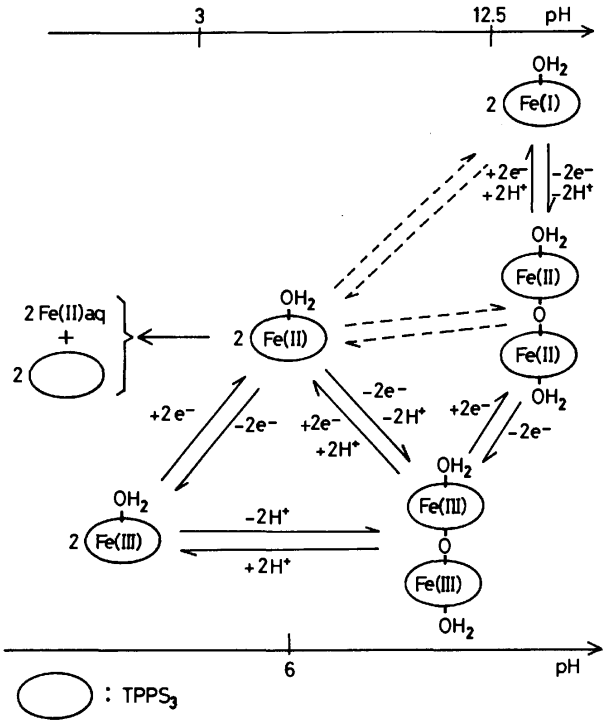
The Soret band and visible absorption spectra in the pH range of 3—12 are represented in Fig. 6. The Soret band shifted from 394 (pH<5.5) or 406 nm (pH>7) to 427 nm by the reduction of Fe(III)-TPPS$_3$ (see Fig. 8 also). The visible absorption of the reduced species changes from a four-band toward a two-band spectrum with an increase of pH. Such a change in the visible absorption spectrum suggests that the unsymmetric structure of the complex species changes with pH toward the more symmetric one in highly basic solutions.

Figure 7 shows the change of the absorption spectrum in the course of reduction at pH>12.5. The Soret band shifted from 406 to 439 nm via 427 nm transiently at pH>12.5. The change in the shape of the visible spectra suggests that a symmetric structure of Fe(III)-TPPS$_3$ with a six-coordination was transformed to an unsymmetric structure of the reduced species with five-coordination. When the reduction potential was put off, the reduced species of Fe(III)-TPPS$_3$ in the solution of pH>3 was rapidly reoxidized to give the initial Fe(III)-species without degradation of the porphyrin ring system.

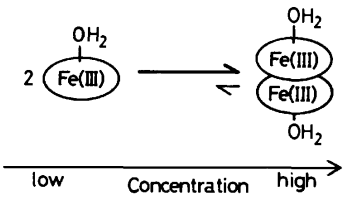
The relationship between the pH of the sample solution and the wavelength of the Soret band maximum of Fe(III)-TPPS$_3$ or its reduced species is summarized in Fig. 8. No change in the structure of the reduced species was observed at 4<pH<11, while the structure of the Fe(III)-species transformed clearly at around pH 7.

Electrochemical Characteristic and Speciation of Fe(III)-TPPS$_3$ and Its Reduced Fe-TPPS$_3$. The solute species of Fe(III)-TPPS$_3$ and its reduced form in the aqueous solution at the concentration of 1.00×10^{-5} mol dm^{-3} are assigned to those in Scheme 1 from the results of the spectrophotometric experiment[11] and the electrochemical and spectro-electrochemical experiments presented above. Scheme 1 also presents the numbers of protons and electrons transferred in each redox reaction, which were observed from the data in Fings. 2 and 4.

The results of the spectro-electrochemical experiment indicate the reduced complex in aqueous solutions to be a single ionic species over the pH range of 3—12.5. The pattern of the visible absorption spectrum in Fig. 6 together with the numbers of proton and electron added to the Fe(III)-TPPS$_3$ suggest that the species is in the low symmetric structure similar to the five-coordinated Fe(III)-TPPS$_3$(H_2O). In the solution of pH<3, the release of iron ion easily occur in the course of reduction of Fe(III)-TPPS$_3$ because of the enlargement of the electron cloud of the central ion. In the solution of pH>12.5, the data in Fig. 4 suggest that the μ-oxo-dimer of Fe(III)-TPPS$_3$ is first reduced to that of Fe(II)-TPPS$_3$ by the two-electron transfer per dimer, and then the second reduction rapidly follows to give



Scheme 1.



Scheme 2.

Table 1. pH Values of the Inflection Point on the Spectroscopic pH Titration Curves of Fe(III)-TPPS$_3$ Aqueous Solutions

Concentration	Monitoring Wavelength	Inflection Point
mol dm^{-3}	nm	pH
5.60×10^{-6}	394	6.7
8.20×10^{-5}	529	6.3
1.00×10^{-3}	394	5.6
1.00×10^{-3}	529	5.6

two Fe(I)-TPPS$_3$ monomers by the two-proton and two-electron transfer per dimer. The iron(I) monomer is suggested to be a species of low symmetry, such as Fe(I)-TPPS$_3$ (H_2O), by the shape of visible spectrum in Fig. 7 (dashed line).

In accordance with the inference from Fig. 3, it may be presumed that the Fe(III)-TPPS$_3$(H_2O) monomer, in the acidic and relatively concentrated solution (more than 10^{-4} mol dm^{-3}), could make a stacking-type dimer, as suggested for the metal-free TPPS$_4$.[17] The stacking -type dimer, as is shown in Scheme 2, is made up possibly of the two five-coordinated porphyrin complexes, which have an unoccupied axial site and stack each other with the dispersion force such as van der Waals force. The formation of the stacking-type dimer is supported by the data of the pH titration in Table 1. If the stacking-type dimer is formed, the π-electron energy level of the dimer is lowered comparing to the monomer and hence the donation of electron from the axial ligand to the central Fe^{3+} will be increased. The lowering the electron density of the axial ligand will facilitate the deprotonation from the axial ligand of the complex; consequently, the formation of μ-oxo-dimer occur more easily from the two stacking-type dimers compared to the formation from two monomeric species. That is to say, the pH value of the inflection point of the spectrophotometric pH titration curves decreases with the increase in the amount of stacking-type dimer in the solution, as is shown in Table 1.

No difference in near-UV and visible absorption spectra between the monomer and the stacking-type dimer was observed because of the limitation of the resolution of the spectrophotometer used, since the magnitude of the dispersion force corresponded to the order of 10^2 cm^{-1}.

The authors wish to thank Misses Yukari Yonemura and Setsuko Nakamura for their technical collaboration and Professor Hiroko Shimada, Fukuoka University, for her valuable comments.

Mössbauer and ESR Spectroscopic Studies on the Mixed-Valence States of 1′,1‴-Dialkyl- and 1′,1‴-Bis(methylbenzyl)biferrocenium Triiodides in Crystalline and Dispersed State

Satoru NAKASHIMA, Yuichi MASUDA, Izumi MOTOYAMA,† and Hirotoshi SANO*

†Department of Chemistry, Faculty of Engineering, Kanagawa University, Rokkakubashi, Kanagawa-ku, Yokohama 221
(Received October 24, 1986)

Iron atoms in the two different crystal forms of 1′,1‴-dibutylbiferrocenium triiodide showed different temperature-depending mixed-valence states; i.e., an averaged-valence state at higher temperatures and a trapped-valence state at lower temperatures in one crystal form but only a trapped-valence state from 78 K to room temperature in the other crystal form. The temperature-depending mixed-valence states were observed in 1′,1‴-diisobutylbiferrocenium triiodide, whereas only a trapped-valence state was found in 1′,1‴-dipentylbiferrocenium triiodide. Both the 1′,1‴-dibutyl- and 1′,1‴-diisobutylbiferrocenium triiodide showed Mössbauer spectra that were different from those of their crystalline states in a dispersed state. A good correlation of the anisotropy of *g*-values with the mixed-valence states was observed in the ESR spectra for a series of 1′,1‴-dialkyl- and 1′,1‴-bis(methylbenzyl)biferrocenium triiodides. The difference in the ESR parameters between these compounds in the crystalline state was reduced in the dispersed state.

It has been known that biferrocene derivatives are easily mono-oxidized to give mixed-valence cations. Those mixed-valence biferrocene compounds can be classified into two types of valence states of iron atoms; a trapped-valence type and an averaged-valence type, by means of Mössbauer spectroscopy.[1] Different states of iron atoms corresponding to ferrocene-like bivalent and ferricenium-like tervalent iron atoms are found in the former, while only an equivalent state of iron atoms is found over the Mössbauer time scale (ca. 10^{-7} s) in the latter.

In studies of bridged biferrocene derivatives it was concluded that the presence of conjugated π-systems between the two ferrocene moieties was necessary to have an interaction between the two metal atoms in well-separated mixed-valence compounds.[2-4] Recently, it has been found that an introduction of a substituent to biferrocenium cations influences the mixed-valence states; e.g., a monocationic salt of 1′,1‴-dichlorobiferrocene[5] shows a trapped-valence state from 4.2 K to room temperature, while monocationic salts of 1′,1‴-diiodo-[6] and 1′,1‴-dibromobiferrocene[5] show an averaged-valence state over the Mössbauer time scale in the same temperature range. Studies by XANES and XPS show that the electron-transfer rate between the two iron atoms in dibromo derivative is lower than ca. 10^{16} s^{-1}.[7] A trapped-valene state of iron atoms in 1′,1‴-diethyl- and 1′,1‴-dipropylbiferrocenium triiodide are known to change into an averaged-valence state at high temperatures.[8]

Similar temperature dependences of the valence state were recently reported for the triiodide salts of monocationic 1′,1‴-dibutyl-,[9] 1′,1‴-dibenzyl-,[9] 1′,1‴-bis(*o*-methylbenzyl)-,[10] and 1′,1‴-bis(*p*-methylbenzyl)-biferrocene.[10] It has been found that a trapped-valence state and an averaged-valence state coexist in 1′,1‴-dibutyl-,[9] 1′,1‴-dibenzyl-,[9] and 1′,1‴-bis(*p*-methylbenzyl)biferrocenium triiodide.[10] In these studies, it has been suggested that the environment surrounding each cation in the solid state should determine the mixed-valence state. The studies on the effects of counter anions were carried out to elucidate the mechanism of the intramolecular electron transfer.[11-15]

It has been suggested that the anisotropy of the *g*-value, $\Delta g = g_{\parallel} - g_{\perp}$, has a close connection with those mixed-valence states obtained from Mössbauer spectra in the studies of mixed-valence biferrocene derivatives.[16] In the present study, the mixed-valence states of 1′,1‴-diisobutyl- and 1′,1‴-dipentylbiferrocenium triiodide and two crystal forms of the 1′,1‴-dibutyl derivative were investigated in a crystalline state and in a state dispersed in poly(methyl methacrylate) by using Mössbauer spectroscopy. The mixed-valence states for a series of 1′,1‴- dialkyl- and 1′,1‴-bis(methylbenzyl)biferrocenium triiodides are also investigated in a crystalline and in a dispersed state by using ESR spectroscopy.

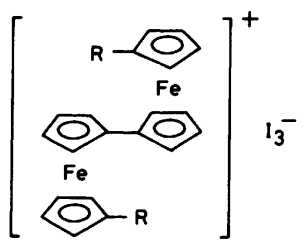

Fig. 1. 1′,1‴-Disubstituted biferrocenium triiodides used in the present studies (R=ethyl, propyl, butyl, isobutyl, pentyl, benzyl, *o*-methylbenzyl, *m*-methylbenzyl, and *p*-methylbenzyl).

Experimental

Materials. 1′,1‴-Dialkyl- and 1′,1‴-bis(methylbenzyl)-biferrocenes were prepared by the Ullmann coupling of 1-bromo-1′-alkylferrocenes and 1-bromo-1′-(methylbenzyl)ferrocenes at 100—110 °C for 18 h, respectively. The products were identified by using ^{1}H NMR and elemental analysis. Data of the elemental analysis and melting points for the new compounds, 1′,1‴-diisobutyl- and 1′,1‴-dipentylbiferrocene, are shown below, respectively: Found: C, 68.69; H, 7.66%. Calcd for $C_{28}H_{34}Fe_2$: C, 69.73; H, 7.11%. mp: 62 °C. Found: C, 69.67; H, 8.27%. Calcd for $C_{30}H_{38}Fe_2$: C, 70.61; H, 7.51%. mp: 36 °C.

The triiodide salts were prepared by a partial oxidation of the corresponding 1′,1‴-dialkyl- and 1′,1‴-bis(methylbenzyl)biferrocenes in benzene with a stoichiometric amount of I_2. The products were recrystallized from CH_2Cl_2 and identified by using elemental analysis. Data of the elemental analysis for the new mixed-valence compounds, 1′,1‴-diisobutyl- and 1′,1‴-dipentylbiferrocenium triiodide, are shown below, respectively: Found: C, 36.86; H, 4.31%. Calcd for $C_{28}H_{34}Fe_2I_3$: C, 38.97; H, 3.97%. Found: C, 40.56; H, 4.99%. Calcd for $C_{30}H_{38}Fe_2I_3$: C, 40.44; H, 4.30%.

1′,1‴-Dibutylbiferrocenium triiodide recrystallized from CH_2Cl_2 gave two kinds of crystal forms. One is needle-like crystals (crystals A), and the other is plate-like crystals (crystals B). Data of elemental analysis for these two crystal forms are shown below. Found for crystals A: C, 39.31; H, 4.14%. Found for crystals B: C, 39.20; H, 4.20%. Calcd for $C_{28}H_{34}Fe_2I_3$: C, 38.97; H, 3.97%.

The samples dispersed in polymer were obtained by evaporating a CH_2Cl_2 solution of poly(methyl methacrylate) containing 1—4% of each triiodide salt.

Mössbauer Spectroscopic Measurements. A ^{57}Co(Rh) source moving in a constant-acceleration mode was used for Mössbauer spectroscopic measurements. Mössbauer spectra were obtained by using an ELSCINT Mössbauer spectrometer and a proportional counter. Isomer shifts were referred to metallic iron foil. Mössbauer parameters were obtained by least-squares fitting to Lorentzian peaks.

ESR Measurements. X-band ESR spectra for powdered crystalline samples and dispersed samples were determined at 78 K using a JEOL JES-PE-3X ESR spectrometer.

Results and Discussion

Mössbauer Spectra. The biferrocene derivatives used in the present studies are shown in Fig. 1. Mössbauer spectrum for crystals obtained by the diffusion of hexane into a CH_2Cl_2 solution of 1′,1‴-dibutylbiferrocenium triiodide at room temperature shows only a single doublet which corresponds to a valence state averaged over ferrocene-like bivalent and ferricenium-like tervalent state. On the other hand,

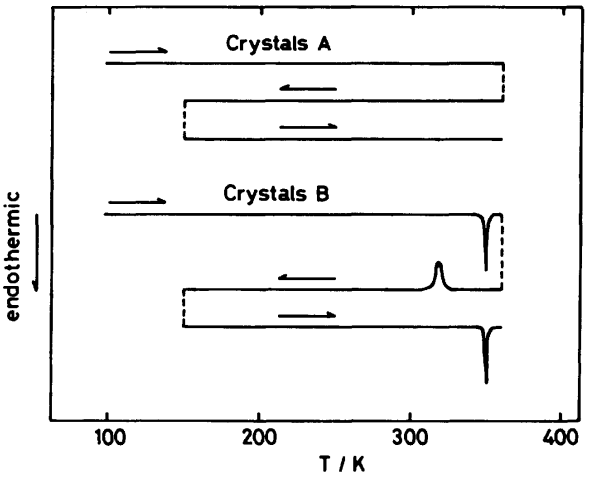

Fig. 3. Differential scanning calorimetric curves for two crystal forms of 1′,1‴-dibutylbiferrocenium triiodide at scanning rate, 5 K min^{-1}.

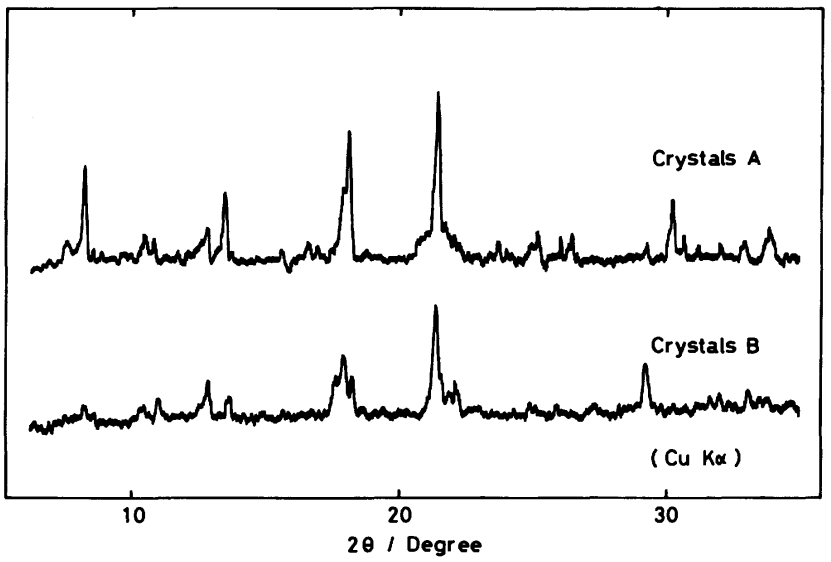

Fig. 2. X-Ray powder patterns for two crystal forms of 1′,1‴-dibutylbiferrocenium triiodide at room temperature.

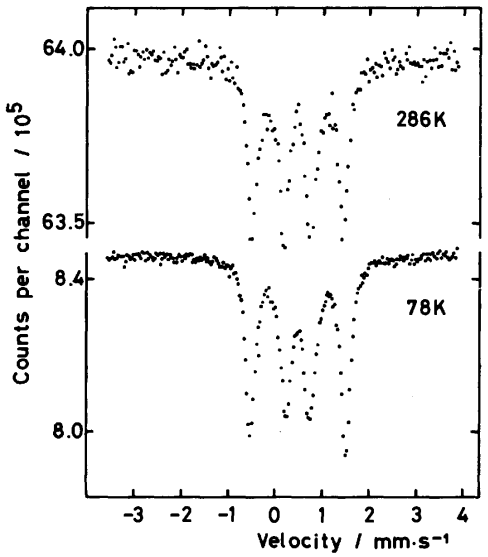

Fig. 4. Mössbauer spectra for crystals A of 1′,1‴-dibutylbiferrocenium triiodide at 78 and 286 K.

the microcrystals obtained by adding a benzene solution of I_2 to a benzene solution of 1′,1‴-dibutylbiferrocene give three doublets in the Mössbauer spectrum, which consist of two doublets corresponding to ferrocene-like bivalent and ferricenium-like tervalent iron atoms and of one doublet of a valence state averaged over the two valence states.[9]

Crystals A and crystals B of 1′,1‴-dibutylbiferrocenium triiodide give different X-ray powder patterns (Fig. 2) and different DSC (differential scanning calorimetry) curves (Fig. 3). An endothermic peak can be observed at 349 K in crystals B under a heating rate of 5 K min^{-1} but not observed in crystals A under the same heating rate. These results suggest that both crystals A and B have crystal structures different from each other.

The Mössbauer spectra in the two crystal forms are shown in Figs. 4 and 5. The Mössbauer spectroscopic data are summarized in Table 1. In crystals A, the spectra at 78 and 286 K consist of an inner- and an outer-doublet with a nearly 1:1 ratio in the areal intensity; these are ascribable to a ferricenium-like tervalent and ferrocene-like bivalent iron, respectively.

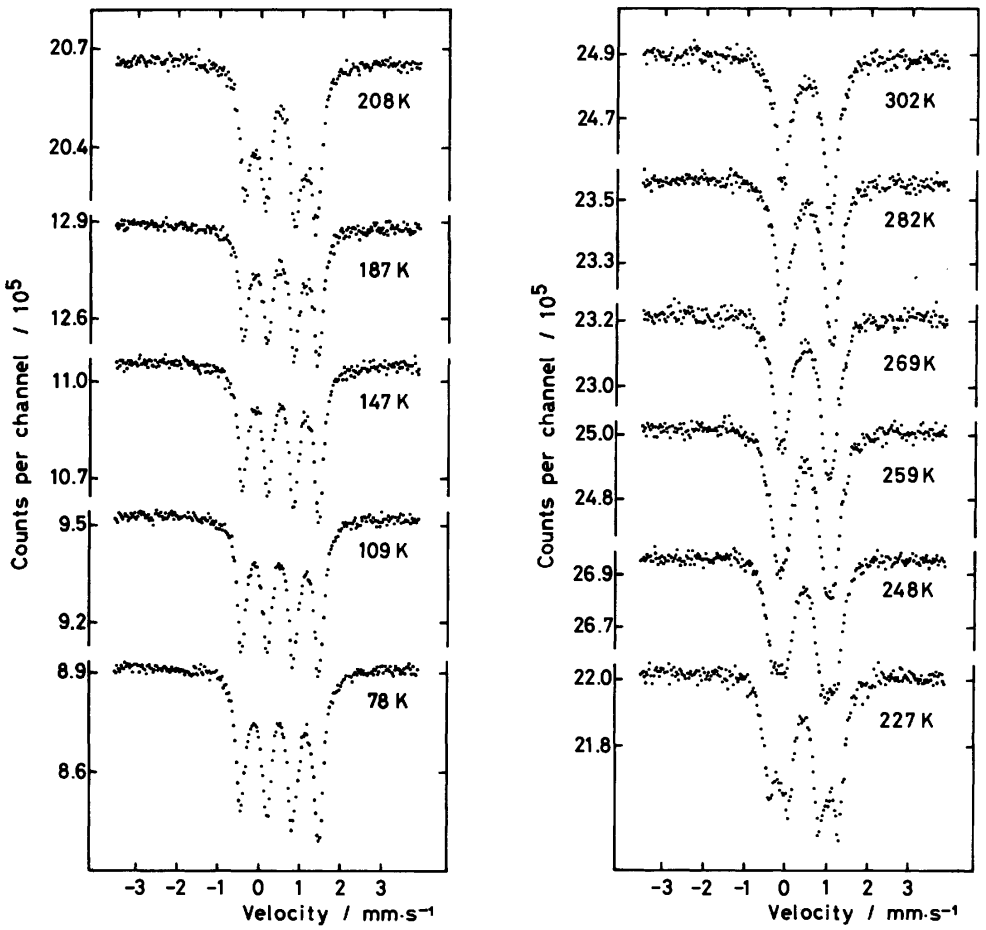

Fig. 5. Mössbauer spectra for crystals B of 1′,1‴-dibutylbiferrocenium triiodide from 78 K to room temperature.

It is clearly concluded that crystals A are of the trapped-valence type from 78 K to room temperature. On the contrary, the spectra of crystals B consist of one doublet ascribed to a state averaged over ferrocene-like and ferricenium-like states near room temperature, but of two doublets below ca. 250 K; i.e., crystals B show temperature-dependent mixed-valence states. The results indicate that the electron-transfer rate between the two iron atoms is dependent on the crystal structure.

The quadrupole splitting, ΔE_q, for the outer doublet ascribed to ferrocene-like iron atoms found in crystals B is a little smaller than that found in crystals A, while the ΔE_q value of the inner-doublet corresponding to ferricenium-like iron atoms is a little larger in crystals B than in crystals A (both at 78 K). This suggests that the interaction between Fe(II) and Fe(III) in crystals B is a little stronger than that in crystals A (even at 78 K).

Figures 6 and 7 show the Mössbauer spectra of 1′,1‴-diisobutyl- and 1′,1‴-dipentylbiferrocenium triiodide. The Mössbauer spectroscopic data are summarized in Table 2. A spectral change from two doublets (trapped-valence state) to one doublet (averaged-valence state) with increased temperatures is observed in 1′,1‴-diisobutylbiferrocenium triiodide, as in the case of crystals B of 1′,1‴-dibutylbiferrocenium triiodide. However, the transition tem-

perature, where the valence state changes from a trapped- to an averaged-valence state, is found to be lower in the isobutyl derivative than in crystals B of the butyl derivative. On the other hand, the Mössbauer spectra of the pentyl derivative show only a trapped-valence state from 78 K to room temperature.

It has already been reported that 1′,1‴-dibutylbiferrocenium cations take a trans conformation with respect to a planar fulvalene ligand in structual studies of their needle form triiodide salt (crystals A).[9,17] There are two structural features that also indicate that the structure of the cation is unsymmetric; the carbon-atom framework of one of the butyl groups lies essentially parallel to the Cp ring to which the butyl group is attached; whereas a part of the carbon-atom framework of the other butyl group is folded perpendicular to the Cp ring, and the I_3^- ion has an unsymmetric structure being disposed unequally to the two iron atoms in the cation, putting more negative charge on one terminal iodine atom than the other terminal iodine atom. It is interesting to note that the more negative iodine atom is situated closer to the Fe(III) atom than the other iron atom, Fe(II). It may be concluded that the conformation of the butyl substituents influences the positioning of the I_3^- ion.

a) Isomer-shift data are reported with respect to metallic iron foil.

Figure 8 shows the Mössbauer spectra of 1′,1‴-dibutylbiferrocenium triiodide dispersed in poly(methyl methacrylate). The Mössbauer spectroscopic data are summarized in Table 3. The Mössbauer spectra in the dispersed state show two doublets; i. e., a definite trapped-valence state below 196 K and an insufficiently averaged state at 300 K. The collapse of the two doublets of the Mössbauer spectra begins at a higher temperature in the dispersed state than in crystals B, while that is not observed in the temperature range from 78 K to room temperature in crystals A. The Mössbauer spectra and those parameters of 1′,1‴-diisobutylbiferrocenium triiodide dispersed in poly(methyl methacrylate) are shown in Fig. 9 and in Table 3, respectively. Two doublets are found in the Mössbauer spectra for the dispersed state in the temperature range of 78—302 K, whereas an averaged-valence state is observed above ca. 210 K in the crystalline state.

Table 3. Mössbauer Parameters for 1′,1‴-Dibutyl- and 1′,1‴-Diisobutylbiferrocenium Triiodide Dispersed in Poly(methyl methacrylate)

Compound	Temperature / K	δ[a] / mm s^{-1}	ΔE_q / mm s^{-1}
1′,1‴-Dibutylbiferrocenium triiodide dispersed in poly(methyl methacrylate)[b]	300	0.49	1.04
	196	0.50	1.94
		0.51	0.61
	78	0.54	2.06
		0.55	0.60
1′,1‴-Diisobutylbiferrocenium triiodide dispersed in poly(methyl methacrylate)	302	0.47	2.08
		0.44	0.45
	216	0.50	2.13
		0.43	0.41
	78	0.53	2.15
		0.44	0.36

a) Isomer-shift data are reported with respect to metallic iron foil. b) The mixture of the crystals A and B was used for the Mössbauer spectroscopic measurement in the dispersed system, because the observed ESR parameters were close to each other in the crystals A and B dispersed in poly(methyl methacrylate).

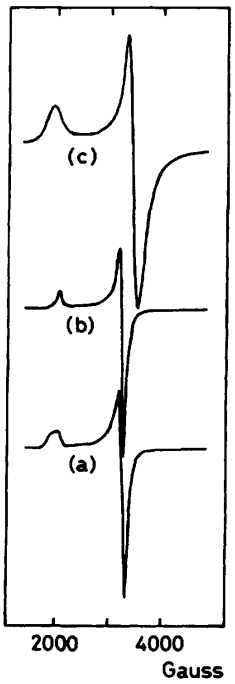

Fig. 10. ESR spectra for (a) crystals A, (b) crystals B, and (c) dispersed state of 1′,1‴-dibutylbiferrocenium triiodide at 78 K.

The difference in the valence state between the dispersed and the crystalline state is also reflected on the quadrupole splittings, ΔE_q, of the 1′,1‴-dibutyl and 1′,1‴-diisobutyl derivatives. For example, the values of ΔE_q for the outer and inner doublet for 1′,1‴-diisobutylbiferrocenium triiodide in the dispersed state are a little larger and smaller than those crystalline state, respectively. This suggests that the interaction between Fe(II) and Fe(III) atoms in dispersed state is a little weaker than that in crystalline state in 1′,1‴-diisobutylbiferrocenium triiodide even at 78 K and that the trapped-valence state remains at higher temperatures in the dispersed state. The same relationship between the valence state and the ΔE_q value is also observed in the dispersed and crystalline (A and B) states in the dibutyl derivative. The results of the valence state reflected on the quadrupole splittings in the dispersed and the crystalline state also indicate that the interaction between the triiodide anions and the biferrocenium monocations plays an important role in the intramolecular electron exchange between the two iron atoms.

ESR Spectra. It has been known that g-tensor anisotropy has a close connection with the mixed-valence states of biferrocene derivatives observed by the method of Mössbauer spectroscopy.[16] Figure 10 shows the ESR spectra of 1′,1‴-dibutylbiferrocenium triiodide (crystals A, crystals B, and a dispersed sample) at 78 K. The $g_{\parallel}$ and $g_{\perp}$ values were found in crystals B to be 3.00 and 1.91, respectively. These g-values are in a good agreement with those previously reported ($g_{\parallel}$=2.98 and $g_{\perp}$=1.92 at 4.2 K);[11] they were obtained by diffusing hexane into a CH_2Cl_2 solution of the triiodide salt. As mentioned above, the Mössbauer spectra of the present crystals B and the crystals obtained by the diffusion method satisfactorily coincide with each other from 78 K to room temperature. These two kinds of crystals obtained by the different methods are considered to have the same crystal structure. The spectral features of the ESR for crystals A are different from those for crystals B. The difference is remarkable in the signal corresponding to $g_{\parallel}$ component; i.e., the sharp signal ($g_{\parallel}$=3.00) was observed for crystals B, while the signal corresponding to $g_{\parallel}$ was observed as a superposition of two kinds of $g_{\parallel}$ values ($g_{\parallel}$=3.04 and 3.26) in crystals A. These differences in the ESR spectra between crystals A and B are in accordance with the results of the Mössbauer spectra.

An intermediate $g_{\parallel}$ value (3.17) in the crystals (3.26 and 3.04) is observed for butyl derivative dispersed in poly(methyl methacrylate).

The ESR parameters of the other dialkylbiferrocenium derivatives in crystalline and dispersed states at 78 K are also shown in Fig. 11 and in Table 4. ESR parameters for 1′,1‴-diethylbiferrocenium triiodide observed in the present experiment ($g_{\parallel}$=3.13 and $g_{\perp}$=2.00 and 1.88) are consistent with those previously reported ($g_{\parallel}$=3.02 and $g_{\perp}$=2.01 and 1.89 at 3.3 K).[11] As discussed above, the Mössbauer spectra of 1′,1‴-diethyl-, 1′,1‴-dipropyl-, 1′,1‴dibutyl-(crystals B), and 1′,1‴-diisobutylbiferrocenium triiodide show an av-

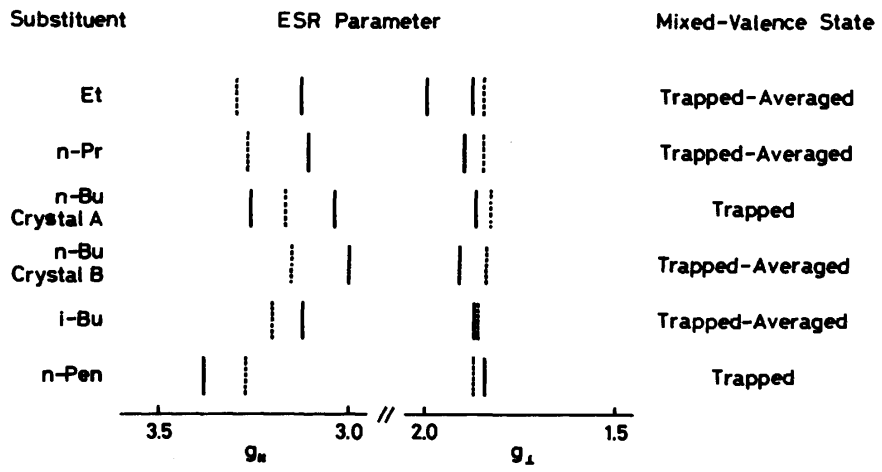

Fig. 11. Summary of ESR parameters in crystalline state (——) and dispersed state (------) at 78 K with those mixed-valence states in crystalline state for 1′,1‴-dialkylbiferrocenium triiodides. "Trapped-Averaged" shows a trapped-valence state at low temperatures and an averaged-valence state near room temperature. "Trapped" shows only the trapped-valence state from low temperature to room temperature.

Table 4. ESR Parameters for 1′,1‴-Dialkylbiferrocenium Triiodide at 78 K

Substituent	State	$g_{\parallel}$	$g_{\perp}$	$\Delta g^{a)}$
Ethyl-	Crystalline	3.13	2.00	1.19
			1.88	
	Glassy	3.30	1.85	1.45

	Glassy	3.27	1.85	1.42
Butyl-	Crystalline	3.26	1.87	1.39
(Crystals A)		3.04		1.17
	Glassy[b)]	3.17	1.83	1.34
Butyl-	Crystalline	3.00	1.91	1.09
(Crystals B)	Glassy[c)]	3.15	1.84	1.31
Isobutyl-	Crystalline	3.12	1.87	1.25
	Glassy	3.20	1.86	1.34
Pentyl-	Crystalline	3.38	1.84	1.54
	Glassy	3.27	1.87	1.40

a) This is the g-tensor anisotropy defined as $\Delta g = g_{\parallel} - g_{\perp}$. When a rhombic signal is seen, an average of two $g_{\perp}$ values is used for $g_{\perp}$. b) Crystals A were dispersed in poly(methyl methacrylate). c) Crystals B were dispersed in poly(methyl methacrylate).

eraged-valence state near room temperature; they change into those for a trapped-valence state with decreasing temperature while only trapped-valence states are observed for 1′,1‴-dibutyl- (crystals A) and 1′,1‴-dipentylbiferrocenium triiodide from 78 K to room temperature. For the above two groups (classified based on the difference of the temperature dependence of the valence states), the Δg value for each group shows a characteristic feature; i.e., the Δg values (Δg=1.09—1.25) for the former group, whose valence state changes from 78 K to room temperature, are smaller than those (Δg=1.39—1.54) for the latter group, whose valence state shows only a trapped-valence state.

As mentioned in the Introduction, 1′,1‴-dibenzyl-, 1′,1‴-bis(*o*-methylbenzyl)- and 1′,1‴-bis(*p*-methylbenzyl)biferrocenium triiodide show temperature-dependences of the mixed-valence state similar to those observed in 1′,1‴-dipropylbiferrocenium triiodide. On the other hand, 1′,1‴-bis(*m*-methylbenzyl)biferrocenium triiodide shows a trapped-valence state from low temperature to room temperature.

Figure 12 and Table 5 summarize the results of ESR spectra for the compounds in crystalline and dispersed states. ESR parameters for 1′,1‴-dibenzylbiferrocenium triiodide observed in the present experiment ($g_{\parallel}$=3.33 and $g_{\perp}$=1.81) are consistent with those previously reported ($g_{\parallel}$=3.42 and $_{\perp}$=1.80 at 4.2 K).[11] In 1′,1‴-bis(methylbenzyl)biferrocenium triiodides, the Δg values also show a characteristic feature; i.e., Δg=1.33—1.52 for the samples whose valence state changes from 78 K to room temperature. The Δg values are much smaller than the value (Δg=2.13) for the sample which shows only a trapped-valence state.

These results indicate that the decrease in the Δg values has a relationship with the nature of the electron exchange between the bivalent and tervalent iron atoms in the biferrocenium derivatives. This consideration is reasonable for explaining the appreciably small Δg values of the 1′,1‴-diiodo- and 1′,1‴-dibromobiferrocenium triiodide whose Mössbauer spectra show an averaged-valence state (only one

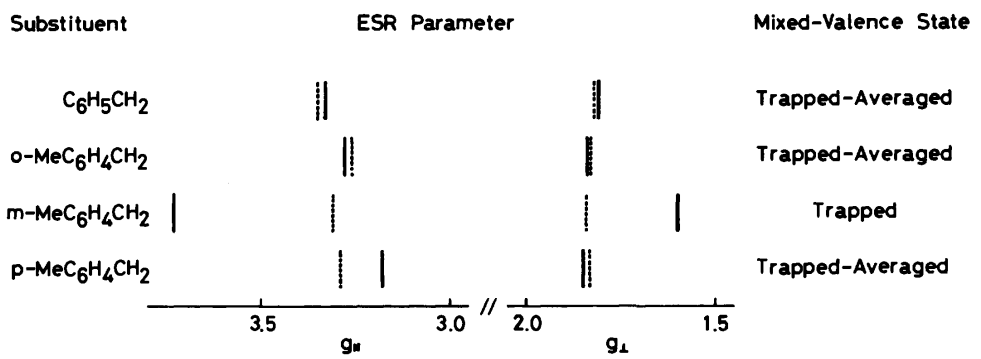

Fig. 12 Summary of ESR parameters in crystalline state (——) and dispersed state (------) at 78 K with those mixed-valence states in crystalline state for 1′,1‴-bis(methylbenzyl)biferrocenium triiodides. "Trapped-Averaged" shows a trapped-valence state at low temperatures and an averaged-valence state near room temperature. "Trapped" shows only the trapped-valence state from low temperature to room temperature.

a) This is the g-tensor anisotropy defined as $\Delta g = g_{\parallel} - g_{\perp}$.

doublet), even at 4.2 K.[11]

The difference of the ESR parameters ($g_{\parallel}$, $g_{\perp}$, and Δg) among the various kinds of 1′,1‴-dialkyl and 1′,1‴-bis(methylbenzyl) derivatives in their crystalline state is reduced in the dispersed state. These differences in the ESR parameters between the crystalline and dispersed state also correspond to the differences in the valence state between both the states observed in the Mössbauer spectra for the derivatives (see the previous section). The difference in ESR parameters in crystalline samples should be attributed not only to intramolecular effects of the alkyl or methylbenzyl substituent but also to intermolecular effects. The results obtained in the present studies indicate that the packing effect of the biferrocenium cations and their counter anions influences the electronic structures and the intramolecular electron transfer rates between the two iron atoms.

(Received November 11, 1986)

The crystal structures of four binuclear copper(II) complexes of *N,N',N'',N'''*-tetrakis(2-aminoethyl)-1,4,8,11-tetraazacyclotetradecane (taec), $[Cu_2(taec)I](ClO_4)_3$ (**1**), $[Cu_2(taec)F](ClO_4)_3 \cdot H_2O$ (**2**), $[Cu_2(taec)(NO_2)](ClO_4)_3$ (**3**), and $[Cu_2(taec)(CH_3COO)](ClO_4)_3 \cdot 2H_2O$ (**4**), were determined by single-crystal X-ray analysis. In all the complexes, each copper is coordinated by two ring- and two pendant-nitrogen atoms. All the complexes except for **4** adopt similar structures, where I^-, F^-, or NO_2^- is incorporated into the "cavity" of $[Cu_2(taec)]^{4+}$ as a bridging group. The structure of **4** is different from those of **1**, **2**, and **3**. In **4**, one of the oxygen atoms of acetate ion coordinates to one of the copper ions at the apical site and the other oxygen occupies an in-plane coordination site of the other copper ion. The structural effect of incorporation of an anion, X, into $[Cu_2(taec)]^{4+}$ was discussed on the basis of the crystal structures.

Recently we have prepared an octadentate ligand, *N,N',N'',N'''*-tetrakis(2-aminoethyl)-1,4,8,11-tetraazacyclotetradecane (abbreviated as taec) and its metal complexes.[1-5] So far, all the complexes isolated are 2:1 (metal:taec) binuclear complexes where each metal ion is coordinated by two cyclam-ring nitrogens and two pendant amino nitrogens. Two types of binuclear structures are known for these complexes. One is the chair form (Fig. 1(A)) where the cyclam ring adopts the trans III form [6] as found for $[M_2(taec)](ClO_4)_4$ (M=Cu, Ni).[1,2] The other is the boat form (Fig. 1(B)) where the cyclam ring adopts the trans I form,[6] as found for $[Cu_2(taec)X](ClO_4)_3$ (X=Br, N_3, NCO).[2,5] In the latter case, the two coordination planes face to each other forming a space or cavity in the molecule to accommodate an anion which bridges the two copper ions. Owing to this property, we obtained a series of $[Cu_2(taec)X](ClO_4)_3$ complexes (X=F, Br, I, N_3, NCO, NO_2, CH_3COO) as single crystals.[3] Further ligation of X^- to $[Cu_2(taec)]^{4+}$ was investigated by potentiometric and spectrophotometric methods.[3,7] The stabilities of halogeno-copper linkage in aqueous solution are greatly enhanced compared to those of ordinary halogeno copper complexes. Such a high stability should be ascribed not only to the binding to both copper ions but rather to the incorporation of X^- into the "cavity" of $[Cu_2(taec)]^{4+}$. It is expected that the size and shape of the anion, X^-, may affect the structure of $[Cu_2(taec)]^{4+}$, i.e., the size of the "cavity" and the coordination mode of taec. Therefore, we have carried out the X-ray structure analyses of the title complexes and compared their structures with the previous data of the bromo, azido, and cyanato complexes in order to examine the relationship between the anion, X, and the structure of taec in the $[Cu_2(taec)X](ClO_4)_3$ complexes.

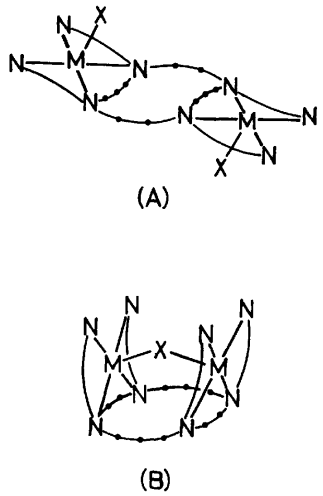

Fig. 1 Coordination modes of taec.

Experimental

The preparative methods for all the complexes were reported in the preceding paper.[3]

A Rigaku AFC-5 automated four-circle diffractometer was used for all measurements at 21±1 °C. Crystal data and details of the data collection are given in Table. 1. Lattice constants were determined by least-squares refinement based on 40 reflections with $20<2\theta<30°$. The intensity data were corrected for Lorentz-polarization effects, but not for absorption. The structures were solved by the direct methods. Refinements were carried out by the block-diagonal least-squares methods. In the course of the refinement it became apparent that the carbon atom, C(3), is

a) Superscript i refers to the equivalent position $(-x, y, z)$.

subjected to disorder in $[Cu_2(taec)X](ClO_4)_3$ (X=F and NO_2). The carbon atom was divided into two positions with an occupancy factor 0.5 on the basis of a difference Fourier map. Hydrogen atoms were inserted in their calculated positions and fixed at their positions. The final discrepancy factors, $R=\Sigma||F_o|-|F_c||/\Sigma|F_o|$ and $R'=[\Sigma w(|F_o|-|F_c|)^2/\Sigma w|F_o|^2]^{1/2}$, are listed in Table 1. The weighting scheme, $w=[\sigma_{count}^2+(0.015|F_o|)^2]^{-1}$, was employed.

The atomic scattering factors for all the atoms and the anomalous dispersion corrections, $\Delta f'$ and $\Delta f''$, for all the non-hydrogen atoms were taken from Ref. 8. All the calculations were carried out on the HITAC M-680 H computer at the Computer Center of the Institute for Molecular Science using a local version of the MULTAN 78,[9] UNICS-III,[10] and ORTEP[11] programs. Atomic coordinates and thermal parameters of non-hydrogen atoms are listed in Table 2. The anisotropic thermal parameters of non-hydrogen atoms, the atomic coordinates and thermal parameters of hydrogen atoms, and the F_o—F_c tables have been deposited as a Document No. 8737 at the Office of the Editor.

Description of the Structures

$[Cu_2(taec)I](ClO_4)_3$. The crystal and molecular structure of $[Cu_2(taec)I](ClO_4)_3$ is similar to that of $[Cu_2(taec)Br](ClO_4)_3$[2]; they are isomorphous. A perspective drawing of the complex cation, $[Cu_2(taec)I]^{3+}$, and the numbering system are illustrated in Fig. 2. The cyclam ring assumes the trans I form. The taec ligand forms two 5-5-5 fused chelate ring systems with two copper ions. The coordination geometry of each copper ion is an elongated square pyramid. The basal plane is formed by two nitrogens of the cyclam ring and two pendant amino nitrogens. The deviations of the basal atoms from the mean plane are within ±0.15 Å, and Cu(1) and Cu(2) are displaced by 0.48 and 0.38 Å, respectively, from the mean planes toward the iodide ion. The iodide ion coordinates to both copper ions at the apical positions with Cu–I distances of 2.919(3) and 2.901(3) Å in the "cavity" of

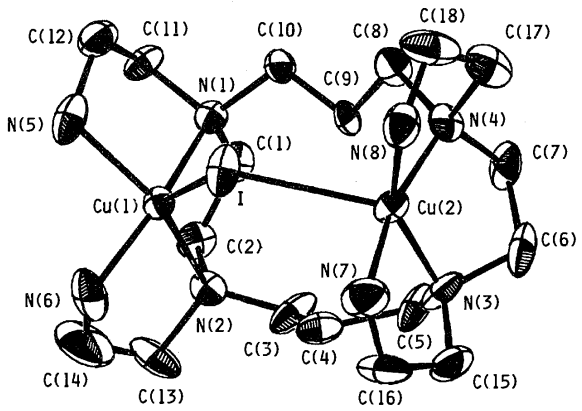

Fig. 2. ORTEP diagram of $[Cu_2(taec)I](ClO_4)_3$.

$[Cu_2(taec)]^{4+}$. The sixth coordination is not feasible because the other axial site of the copper ion is blocked by the CH_2 chains of taec. The pendant amino groups form hydrogen bonds with the iodide ion i.e., I···N(5) 3.593(19), I···N(6) 3.696(19), I···N(7) 3.507(22), I···N(8) 3.582(21) Å. These hydrogen bonds may contribute to the stabilization of the Cu–I bonds. The perchlorate ions are hydrogen-bonded to the pendant amino groups, e.g., O(4)···N(5) 3.262(27) Å.

$[Cu_2(taec)F](ClO_4)_3 \cdot H_2O$. A perspective drawing of the complex cation of $[Cu_2(taec)F](ClO_4)_3 \cdot H_2O$ is shown in Fig. 3. The complex cation has a mirror plane containing Cu(1), Cu(2), and F as required from the crystallographic symmetry. The coordination mode of taec is similar to that of $[Cu_2(taec)I](ClO_4)_3$. The coordination geometry of each copper ion is an elongated square pyramid. The basal planes are perfectly planar as required from the symmetry (the mirror plane) of the complex cation and the copper ions, Cu(1) and Cu(2), are displaced by 0.41 and 0.47 Å, respectively, from the planes toward the fluoride ion. The fluoride ion bridges the two copper

ions at the apical positions with Cu–F distances of 2.234(10) and 2.106(10) Å. The Cu(1)–Cu(2) separation (4.229(2) Å) is the shortest and the Cu(1)–F–Cu(2) angle (154.0 (2)°) is the largest among the $[Cu_2(taec)X](ClO_4)_3$ complexes. The oxygen atom of the water molecule, OW, (whose occupancy factor is 0.5) is located in a vicinity of the "cavity" of $[Cu_2(taec)]^{4+}$ forming a hydrogen bond with the fluoride ion (F···OW 2.587(10) Å).[12] The pendant amino groups form hydrogen bonds to the fluoride ion and perchlorate ions, e.g., F···N(3) 3.203(11), F···N(4) 3.129(11). O(2)···N(4) 3.240(13) Å.

$[Cu_2(taec)(NO_2)](ClO_4)_3$. The crystals of $[Cu_2(taec)(NO_2)](ClO_4)_3$ and $[Cu_2(taec)F](ClO_4)_3 \cdot H_2O$ are isomorphous. The complex cation, $[Cu_2(taec)(NO_2)]^{3+}$, has a mirror plane containing Cu(1), Cu(2), O(11), N(5), O(12A), and O(12B) (Fig. 4). The nitrite ion bridges the two copper ions with one of its oxygen atoms. The other oxygen atom of the nitrite ion is disordered in the ratio 1:1 (O(12A):O(12B)). Such disorder is a common feature of crystal structure of nitrito complexes.[13]

$[Cu_2(taec)(CH_3COO)](ClO_4)_3 \cdot 2H_2O$. A perspective drawing of the complex cation, $[Cu_2(taec)(CH_3COO)]^{3+}$, is illustrated in Fig. 5. The two copper ions are bridged by the acetate ion. There is, however, a significant difference between the coordination geometries about the two copper ions. As found in other $[Cu_2(taec)X](ClO_4)_3$ complexes, the coordination geometry of Cu(1) is a distorted square pyramid with two nitrogens of the cyclam ring and two nitrogens of the pendant amino groups in the basal plane and an oxygen atom of the acetate ion, O(1), in the apical position. The geometry of Cu(2) is also described as a square-pyramid, but in this case the apical position is occupied by the pendant amino nitrogen, N(8), and the basal plane is formed by one of the bridging-acetate oxygens, O(2), the pendant-amino nitrogen, N(7), and two nitrogens of the cyclam ring, N(3) and N(4). Thus, the coordination mode of taec is different from those of other $[Cu_2(taec)X](ClO_4)_3$ complexes (X=F, Br, I, N_3, NCO, NO_2). The Cu(1)–Cu(2) distance is 4.758(2) Å shorter than that of $[Cu_2(taec)I](ClO_4)_3$. One of two water molecules is hydrogen-bonded to the bridging acetate oxygen atom, O(2), and a pendant amino nitrogen, i.e., O(2)···OW(2) 2.831 (12), N(7)···OW(2) $(1-x, -y, 2-z)$ 2.983(12) Å. Another water molecule is hydrogen-bonded to the perchlorate oxygen, O(10), and the pendant-amino nitrogen, N(5), i.e., O(10)···OW(1) $(1/2+x, 1/2-y, 1/2+z)$ 2.780(15), N(5)···OW(1) $(1/2-x, 1/2+y, 3/2-z)$ 2.959 (12) Å.

Discussion

The structures of all the present complexes except for $[Cu_2(taec)(CH_3COO)](ClO_4)_3 \cdot 2H_2O$ are essentially the same as those of previously reported $[Cu_2(taec)X](ClO_4)_3$ (X=Br, N_3, NCO),[2,5] where the coordination

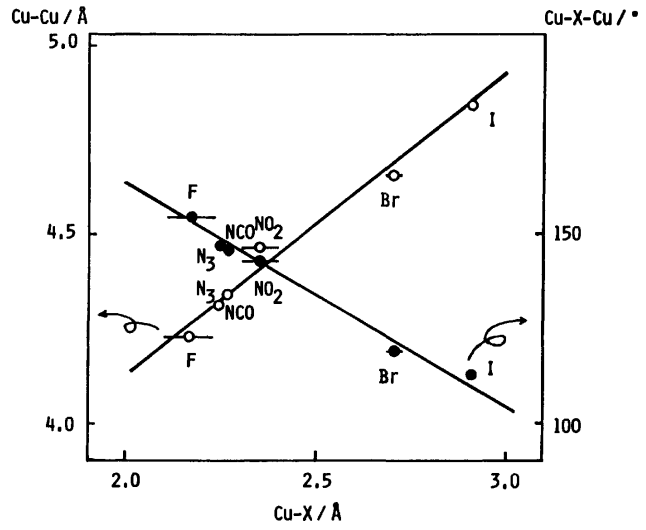

Fig. 6. Correlations of Cu-Cu distance (O) and Cu-X-Cu angle (●) with Cu-X distance.

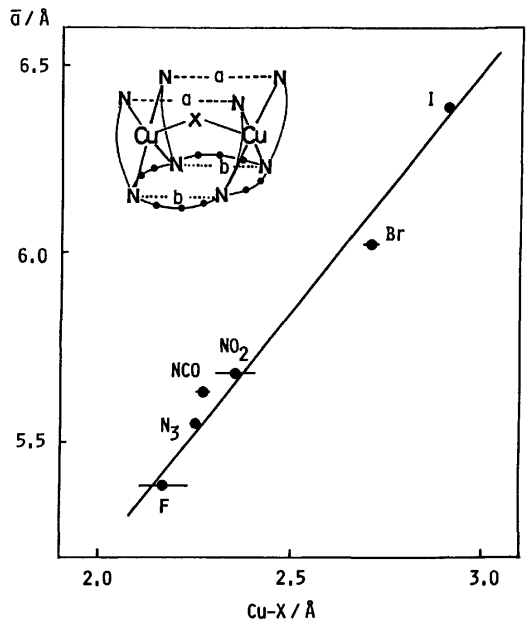

Fig. 7. Correlation between Cu-X and average value of a in $[Cu_2(taec)X](ClO_4)_3$. Parameters a and b represent the N-N distances indicated by ------ and ·····, respectively.

mode of taec is the boat form as shown in Fig. 1(B), and an anion, X, is incorporated into the "cavity" of $[Cu_2(taec)]^{4+}$. Coordination geometry of each copper ion can be described as an elongated square-pyramid. The in-plane Cu-N distances are in the range of 1.988—2.111 Å. The displacement of the copper ion from the basal plane is in the range of 0.38—0.48 Å. The Cu-X and Cu-Cu distances increase and the Cu-X-Cu angle decreases in the increasing order of bridging atom size, $F<N_3<NCO<NO_2<Br<I$ (Fig. 6). The decrease of the Cu-X-Cu angle implies that the anion is pushed out in some degree from the center of the complex cation. It is interesting to see the "cavity" size as a function of the size of X^-. The size may be expressed by two parameters a and b defined in Fig. 7. The a value increases from 5.382 Å to 6.393 Å with increasing the size of bridging atom of X or Cu-X distance, whereas b varies little (4.800—4.912 Å). In other words, the $[Cu_2(taec)]^{4+}$ slightly varies its configuration to accommodate the anion though the expansion of the "cavity" size is limited so that the larger anion tends to be somewhat pushed out from the center of the complex cation as already stated. However, in the case of $X=CH_3COO$, the acetate ion can not take a bridging mode similar to that of NO_2^- in $[Cu_2(taec)(NO_2)](ClO_4)_3$ because of steric hindrance between its methyl group and the pendant amino groups. Thus, one of the pendant amino group (N(8)) is pushed out from the equatorial coordination position of the copper ion and located at the axial position. Instead, the equatorial coordination position is occupied by another oxygen of the acetate ion.

(Received November 17, 1986)

Complexation of copper(II) with Br^- ions has been studied by calorimetry and spectrophotometry in *N,N*-dimethylformamide (DMF) containing 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 as constant ionic media at 25 °C. Calorimetric titration curves obtained in each solution were well explained in terms of formation of $[CuBr_n]^{(2-n)+}$ (n=1—4) and their formation constants, enthalpies and entropies were determined. Electronic spectra of individual copper(II) bromo complexes were also determined in the $(C_2H_5)_4NClO_4$, $LiClO_4$, and NH_4ClO_4 DMF solutions over the range 260—500 nm, the spectra of each complex being kept practically unchanged in these solutions. The complexation of copper(II) with Br^- ions is considerably weaker in the $LiClO_4$ solution than in the $(C_2H_5)_4NClO_4$ one and is even more weakened in the NH_4ClO_4 solution due to the formation of LiBr and NH_4Br ion pairs in the relevant solutions. The variation of the stepwise enthalpy and entropy values suggests that the coordination structure around copper(II) ion changes from octahedral to tetrahedral at the formation of $[CuBr_3]^-$. The result for the complexation between copper(II) and bromide ions thus obtained was compared with that for the complexation between the metal and chloride ions.

Complexation of copper(II) with chloride ions has so far been studied in aqueous and nonaqueous solutions, and the formation constants and enthalpies of the mononuclear $[CuCl_n]^{(2-n)+}$ (n=1—4) complexes have been determined.[1-6]

On the other hand, as to the copper(II) bromo complexes, the formation constants and enthalpies have been obtained only for the mono- and dibromocopper(II) complexes,[7] although the formation of $[CuBr_4]^{2-}$ was indicated by spectrophotometry in some aprotic solvents.[8-12] The $[CuBr_4]^{2-}$ complex has the flattened tetrahedral D_{2d} structure in the $Cs_2[CuBr_4]$ crystal.[13] By judging from similar electronic spectra of $[CuBr_4]^{2-}$ in solution and in the $Cs_2[CuBr_4]$ crystal,[14-15] the flattened tetrahedral D_{2d} structure of $[CuBr_4]^{2-}$ is also expected in solution, as well as in the case of $[CuCl_4]^{2-}$.[16] In fact, the tetrahedral $[CuBr_4]^{2-}$ complex was revealed in water by the X-ray diffraction method.[17] Although the structure of the tetrahalogenocuprate(II) complex is thus well established both in crystal and in solution, the knowledge of the structure of the mono-, di-, and trihalogeno complexes of copper(II) ion in solution is limited because these complexes have hardly been isolatd as single crystals. We recently elucidated by the X-ray diffraction method that the mono- and trichloro complexes have the distorted octahedral $[CuCl(dmf)_5]^+$ and the distorted tetrahedral $[CuCl_3(dmf)]^-$ structures, respectively, in *N, N*-dimethylformamide (DMF).[18] The formation of the distorted octahedral $[CuBr(H_2O)_5]^+$ complex has been also indicated.[17] Barnes and Hume[10] suggested the formation of the five-coordinate $[CuBr_3(solvent)_2]^-$ complex having a distorted trigonal-bipyramidal structure from measurements of electronic spectra in various aprotic solvents.

In order to throw more light on the formation and the structure of copper(II) bromo complexes in solution, we investigated the complexation between copper(II) and bromide ions in DMF containing 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 as constant ionic media at 25 °C by using similar calorimetric and spectrophotometric procedures to those employed previously for the copper(II) chloride system in some aprotic solvents.[1,2]

Experimental

Reagent. All chemicals used were of reagent grade. *Lithium bromide* was once recrystallized from methanol. *Ammonium perchlorate, tetraethylammonium bromide,* and *ammonium bromide* were used without further purification. LiBr and $(C_2H_5)_4NBr$ were dried at 150 and 100 °C, respectively, in vacuum and NH_4ClO_4 and NH_4Br at 150 °C under an atmospheric pressure.

Other chemicals were prepared or purified as described elsewhere.[1]

Measurements. Calorimetric and spectrophotometric measurements were carried out in a room thermostated at (25±0.2) °C. Test solutions contained 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$ or 1 mol dm^{-3} NH_4ClO_4 as a constant ionic medium.

Calorimetric titrations were performed using a Dewar vessel in a water-bath thermostated at (25±0.007) °C. 100 cm^3 of a $Cu(ClO_4)_2$ DMF solution containing 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, or 1 mol dm^{-3} NH_4ClO_4 was placed in a Dewar vessel which was filled with dry nitrogen gas and isolated from moisture with a P_2O_5 drying-tube, and then it was titrated with the relevant titrant solution of 0.16 mol dm^{-3} $(C_2H_5)_4NBr$, 1 mol dm^{-3} LiBr, or 1 mol dm^{-3} NH_4Br. The concentration of metal

† Present address: Department of Inorganic and Analytical Chemistry, A. József University, Szeged, Hungary.

ions in the initial test solution was varied over the range 5—20 mmol dm^{-3} in the $(C_2H_5)_4NClO_4$ DMF solution and 20—50 mmol dm^{-3} in the $LiClO_4$ and NH_4ClO_4 DMF solutions. Heats of complexation observed at each titration point were ranged 1—7 J in the $(C_2H_5)_4NClO_4$ and NH_4ClO_4 solutions and 1—12 J in the $LiClO_4$ solution with a certainty ±0.05 J and were corrected for heats of dilution of the titrant. Heats of dilution were measured in advance by separate experiments. All of the measurements were carried out by using a fully automatic on-line system for calorimetry developed in our laboratory.[19] Details of the data treatment have been described elsewhere.[1]

Electronic spectra were measured with a HITACHI 340 spectrophotometer (HITACHI) equipped with a PC-9801 computer (NEC) which recorded data every 2 nm over the wavelength range 260—500 nm. A flow cell with a light-path length of 0.5 cm was connected with a titration vessel through Teflon and glass tubes. 20 cm^3 of a $Cu(ClO_4)_2$ solution was placed in a vessel under a dry nitrogen atmosphere and then titrated with the relevant titrant solution.

Results and Discussion

Calorimetric Results. Calorimetric titration curves for complexation between copper(II) and bromide ions obtained in 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 DMF solutions are depicted in Figs. 1, 2, and 3, respectively. In each figure, enthalpies $\Delta H^\circ = -q/(\delta v C_{X,tit})$ were plotted against C_X/C_M, where q, δv, C_X, and C_M stand for the heat evolved, the volume of an aliquot of the titrant added and the total concentrations of bromide

and copper(II) ions in solution, respectively, at each titration point, and $C_{X,tit}$ denotes the concentration of bromide ion in the titrant solution.

The calorimetric data obtained in each solution were analyzed by assuming the formation of plausible copper(II) bromo complexes and by simultaneously optimizing their formation constants and enthalpies by the least-squares method, the typical results obtained in the $(C_2H_5)_4NClO_4$ DMF solution being listed in Table 1. As seen in Table 1, among various sets examined the set (1—4) assuming the formation of $[CuBr_n]^{(2-n)+}$ (n=1—4) shows the minimal error-square sum U. The calorimetric data obtained in the $LiClO_4$ and NH_4ClO_4 DMF solutions were also

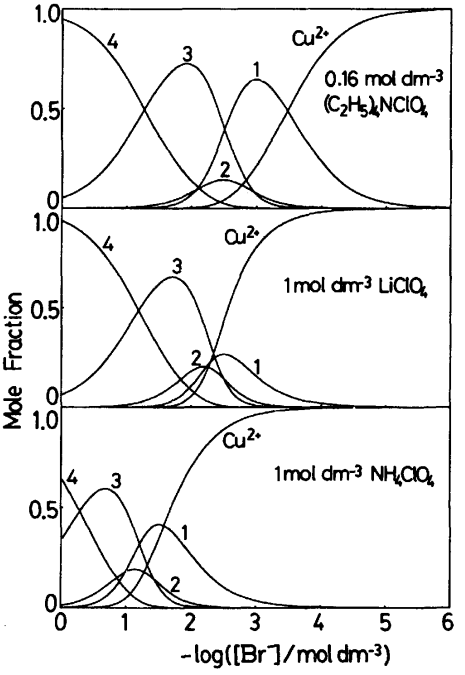

Fig. 4. Distribution of the copper(II) bromo complexes in 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 DMF solutions. The numbers represent n within $[CuBr_n]^{(2-n)+}$.

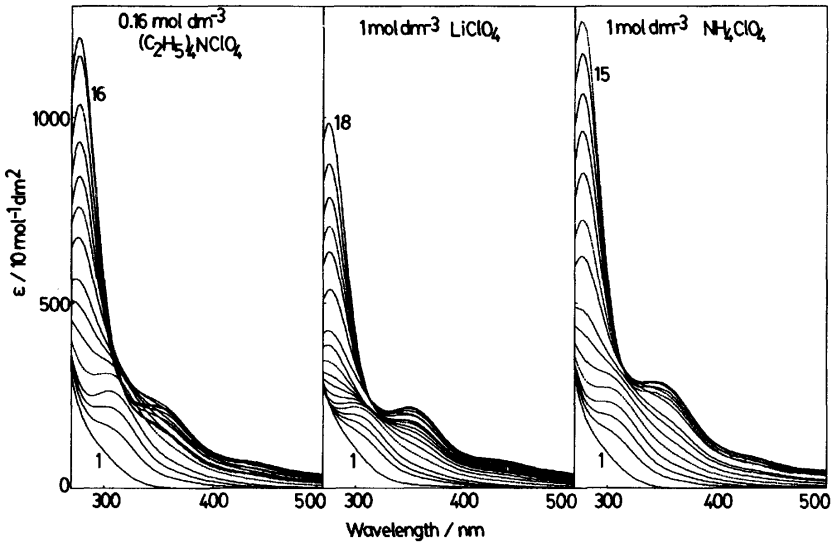

Fig. 5. Electronic spectra of copper(II) bromide DMF solutions in the range 260—500 nm. Intensities are normalized with the unit concentration of the metal ion in solution. Electronic spectra were obtained at various C_X/C_M, the value being varied from 0 (the solution No. 1) to 413 (No. 16), 318 (No. 18) and 2051 (No. 15) in the $(C_2H_5)_4NClO_4$, $LiClO_4$ and NH_4ClO_4 DMF solutions, respectively.

satisfactorily explained by the set (1—4). The overall formation constants and enthalpies of the $[CuBr_n]^{(2-n)+}$ (n=1—4) complexes thus obtained in the DMF solutions are summarized in Table 2. As seen in Figs. 1—3 the solid lines, the titration curves calculated using the constants in Table 2, well reproduce the experimental points over the whole range of C_X/C_M examined in each solution, and thus we conclude the formation of a series of four mononuclear copper(II) bromo complexes in all the solutions examined.

The complexation is weaker in the $LiClO_4$ solution than in the $(C_2H_5)_4NClO_4$ one and is even more weakened in the NH_4ClO_4 solution, as seen in the distribution of the copper(II) bromo complexes in Fig. 4. It is noted that the formation of $[CuBr_2]$ is strongly suppressed in any DMF solution examined. It is also noted that the formation of $[CuBr]^+$ is extensive in the $(C_2H_5)_4NClO_4$ DMF solution but is strongly suppressed in the $LiClO_4$ and NH_4ClO_4 DMF solutions.

Spectrophotometric Results. Electronic spectra of copper(II) bromide DMF solutions in the 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 DMF solutions are depicted in Fig. 5 over the wavelength range 260—500 nm, absorbance being normalized with the metal concentration in solution. Absorption bands observed are not simply assignable to each coppar(II) bromo complex, because absorbance monotonously increases with increasing concentration of bromide ion in the solutions over the wavelength range measured. Since each measured spectrum should be represented as the sum of electronic spectra of individual copper(II) bromo complexes by taking into account the distribution of species in solution, absorbance data obtained at selected 28 wavelengths in the range 260—500 nm were analyzed by assuming the formation of a series of mononuclear copper(II) bromo complexes, and their formation constants and molar extinction coefficients of each complex at relevant wavelengths were optimized by the least-squares method. The formation constants thus obtained are summarized in Table 3, the values, as a whole, being in satisfactory agreement with those calorimetrically determined.

In the $LiClO_4$ DMF solution, the variation in the measured electronic spectra with C_X/C_M is well explained in terms of the formation of $[CuBr_n]^{(2-n)+}$ (n=1—4). On the other hand, in the $(C_2H_5)_4NClO_4$ and NH_4ClO_4 DMF solutions the corresponding

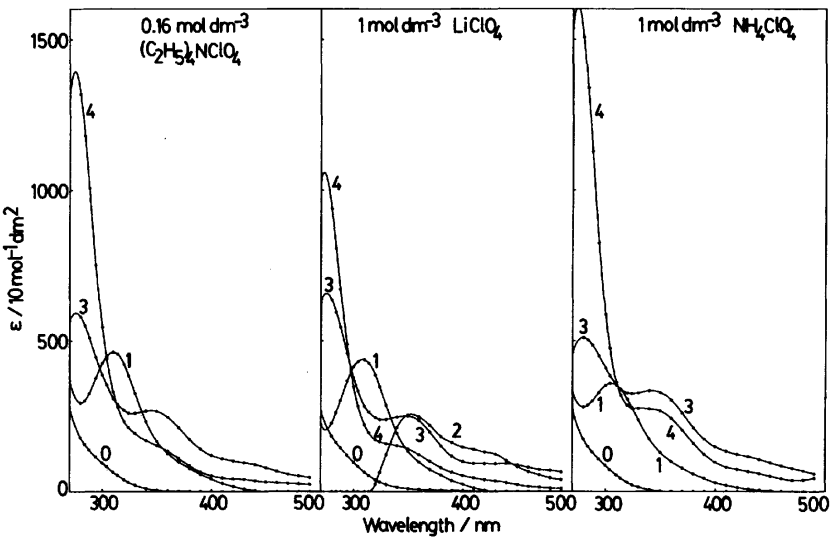

Fig. 6. Electronic spectra of individual copper(II) bromo complexes in the range 260—500 nm obtained in 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 DMF solutions. The numbers represent n within $[CuBr_n]^{(2-n)+}$.

spectral changes can be explained even without taking the formation of $[CuBr_2]$ into account. The degree of the formation of $[CuBr_2]$ might be too small to extract its characteristic electronic spectrum from the measured spectra in the DMF solutions.

The electronic spectra of individual copper(II) bromo complexes are shown in Fig. 6. In the $LiClO_4$ DMF solution, the electronic spectrum of $[CuBr]^+$ shows a single peak at 310 nm, and the spectrum of $[CuBr_2]$ shows a peak at 350 nm and a weak absorption at ca. 430 nm, over the range measured. On the other hand, the $[CuBr_3]^-$ complex has two peaks at 275 and 350 nm and a weak absorption at ca. 450 nm. It is noted that the absorption band of the $[CuBr_2]$ complex overlaps that of $[CuBr_3]^-$, and thus it is difficult to extract the individual spectrum of the former complex at the coexistence of the $[CuBr_2]$ and $[CuBr_3]^-$ complexes in solution. The $[CuBr_4]^{2-}$ complex shows a peak at 275 nm and a broad peak at ca. 350 nm. The peak positions thus determined for each copper(II) bromo complex are in accordance with those of the ligand to metal charge transfer bands reported by Howard and Keeton.[11] Similar electronic spectra were obtained for each $[CuBr_n]^{(2-n)+}$ (n=1,3, or 4) complex in the $(C_2H_5)_4NClO_4$, $LiClO_4$, and NH_4ClO_4 DMF solutions as seen in Fig. 6, so that the coordination structure of each $[CuBr_n]^{(2-n)+}$ (n=1, 3, or 4) complex may be essentially the same in these ionic medium solutions.

Ion-Pair Formation of Bromide Ions. As noted in a preceding section, the complexation of copper(II) with bromide ions is considerably weaker in the 1 mol dm^{-3} $LiClO_4$ solution than in the 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$ one, and is even more weakened in the 1 mol dm^{-3} NH_4ClO_4 solution. A similar trend has been observed for the comlexation of copper(II) with chloride ions in the 0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ and 1 mol dm^{-3} $LiClO_4$ DMF solutions.[1] The ion-pair formation of chloride ion with medium cations

a) Ref. 1. b) For the overall formation of $[CuBr_4]^{2-}$.

is practically negligible in a 0.1—0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ DMF solution, and thus the weaker complexation between copper(II) and chloride ions in the $LiClO_4$ solution than that in the $(C_2H_5)_4NClO_4$ one is ascribed to the formation of LiCl ion pairs in the former solution.[1] It is expected that the ion-pair formation of bromide ion with medium cations is also negligible in the $(C_2H_5)_4NClO_4$ DMF solution but is appreciably enhanced in the $LiClO_4$ and NH_4ClO_4 solutions. Therefore, the formation of LiBr and NH_4Br ion pairs may be responsible for the weaker complexation of copper(II) with Br^- ions in the $LiClO_4$ and NH_4ClO_4 DMF solutions, respectively. It is noted that, since the complexation between copper(II) and bromide ions in the NH_4ClO_4 solution is weaker than that in the $LiClO_4$ solution, the ion-pair formation of bromide ion should occur more extensively in the former solution than in the latter.

In Fig. 7, the formation functions $\bar{n}$ calculated for the copper(II) chloride and bromide systems in the $LiClO_4$ solution are compared with those in the $(C_2H_5)_4NClO_4$ solution, the shift is larger for the chloride system than for the bromide one, the result suggesting that the LiCl ion pairs are more extensively formed than the LiBr ones in DMF. This is reasonable because hard Li^+ ion prefers hard and small Cl^- to Br^- ion.

As seen in Table 4, the $\Delta H^\circ_{\beta 4}$ and $\Delta S^\circ_{\beta 4}$ values for the overall formation of the $[CuBr_4]^{2-}$ complex in the $LiClO_4$ solution are smaller than those in the $(C_2H_5)_4NClO_4$ one, the values in the NH_4ClO_4 solution being even smaller than those in the $LiClO_4$ one. The result suggests that both enthalpy and entropy values associated with the formation of LiBr and NH_4Br ion pairs are positive. Since the formation of ion pairs may be accompanied by an extensive desolvation of both cation and anion, a positive enthalpy entropy change may be ascribed to the rupture of the M^+–dmf (M^+=Li^+ and NH_4^+) and Br^-–dmf bonds and a positive entropy change to the liberation of DMF molecules from the coordination shells of M^+ and Br^- ions. The entropy increase of the ion-pair formation may be especially large in DMF because DMF molecules are randomly distributed in the bulk,[20] and thus the increased entropy due to the liberation of DMF molecules coordinating to the ions may not be compensated with the entropy decrease due to the intermolecular interactions in the bulk solution. A similar result has also been observed for the complexation of cadmium(II) with bromide ions in dimethyl sulfoxide containing various ionic media.[21]

Stepwise Thermodynamic Quantities. Stepwise formation constants, Gibbs energies, enthalpies and entropies of formation of the $[CuBr_n]^{(2-n)+}$ (n=1—4) complexes in the 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$, 1 mol dm^{-3} $LiClO_4$, and 1 mol dm^{-3} NH_4ClO_4 DMF solutions are summarized in Table 4, together with those of the $[CuCl_n]^{(2-n)+}$ (n=1—4) complexes in the 0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ DMF solution.[1]

Copper(II) ion is coordinated with six DMF molecules and the $[Cu(dmf)_6]^{2+}$ solvate species has the distorted octahedral structure in DMF[18] as well as in water.[22] On the other hand, the flattened tetrahedral $[CuBr_4]^{2-}$ complex is formed in a solution of a high concentration of Br^- ion in DMF. Thus, the coordination structure around copper(II) ion changes from the six- to four-coordinate in the course of the complexation with bromide ions. In any ionic medium examined, a relatively large and positive stepwise entropy value is observed at the third step, indicating an extensive liberation of DMF molecules from the primary solvation shell of the metal ion. It is thus suggested that the coordination structure about copper(II) ion changes at the third consecutive step and the $[CuBr_3(dmf)]^-$ complex with the tetrahedral structure is yielded. Relatively large endothermicities are also observed at the third step in the 1 mol dm^{-3} $LiClO_4$ and NH_4ClO_4 DMF solutions, and the result may be reasonably explained in terms of the breaking of more than two metal-solvent bonds accompanying the structure change from the five- or six-coordinate $[CuBr_2]$ complex to the four-coordinate $[CuBr_3]^-$ complex at this step.

In 0.1—0.2 mol dm^{-3} $(C_2H_5)_4NClO_4$ DMF solutions where the fomation of $(C_2H_5)_4NX$ (X^-=Cl^- or Br^-) ion pairs is practically negligible, the formation constants of the copper(II) bromo complexes are significantly smaller than those of the copper(II) chloro complexes,[1] due mainly to more positive ΔH°_n values for the bromide system than those for the chloride one. The result evidently indicates the weaker Cu–Br bond than the Cu–Cl bond as expected from the larger size of Br^- ion.[23]

The present work has been financially supported by the Grant-in-Aid for Special Project Research No. 61134043 from the Ministry of Education, Science and Culture.

(Received November 20, 1986)

Nine new cobalt(III) complexes containing 3,6-diphenyl-3,6-diphosphaoctane-1,8-diamine (NPPN), *trans*-[$CoCl_2$(*rac*(*P*)-NPPN)]$^+$, *cis*α-[Co(L)(*rac*(*P*)-NPPN)]$^{n+}$ (L=en, *n*=3; L=acac, *n*=2) and *Δ*- and *Λ*-*cis*α-[Co(L′)(*rac*(*P*)-NPPN)]$^{n+}$ (L′=*R*-pn, *n*=3; L′=*S*-ala or *S*-pro, *n*=2), and five new cobalt(III) complexes containing (2*S*,9*S*)-4,7-diphenyl-4,7-diphosphadecane-2,9-diamine (*SS*(*C*)-NPPN), *Δ*- and *Λ*-*cis*α-[Co(L)(*rac*(*P*),*SS*(*C*)-NPPN)]$^{n+}$ (L=en, *n*=3; *L*=acac, *n*=2) and *Δ*-*cis*β-[Co(acac)(*meso*(*P*),*SS*(*C*)-NPPN)]$^{2+}$, were prepared, where en, *R*-pn, acac, *S*-ala and *S*-pro denote ethylenediamine, (*R*)-1,2-propanediamine, 2,4-pentanedionate, (*S*)-alaninate and (*S*)-prolinate ions, respectively. Stereochemistries of the complexes and the chiral phosphorus donor atoms were studied on the basis of the absorption, ^{1}H and ^{13}C NMR, and CD spectra. The *rac*(*P*)-NPPN and *rac*(*P*),*SS*(*C*)-NPPN ligands formed selectively either the trans or cisα isomer, while no stable complex was obtained with the meso(P) isomers of NPPN and *SS*(*C*)-NPPN except *cis*β-[Co(acac)(*meso*(*P*),*SS*(*C*)-NPPN)]$^{2+}$ which slowly decomposes in water.

Studies on stereochemistry of optically active octahedral metal complexes containing chiral phosphorus or arsenic donor atoms have little been reported,[1–5] except a systematic study on cobalt(III) complexes containing a quadridentate arsine ligand $(CH_3)_2As(CH_2)_3As(C_6H_5)(CH_2)_3As(C_6H_5)(CH_2)_3As(CH_3)_2$ reported by Bosnich and his co-workers.[6] Since a chiral phosphorus or arsenic atom is stable to racemization,[7] a multidentate ligand containing such chiral donor atoms is expected to exhibit different stereoselectivity in complex formation from that of the corresponding amine ligand which has been studied extensively.[8]

In this paper, we report the preparation and stereochemistry of two quadridentate ligands having two chiral phosphorus donor atoms, $NH_2CH_2CH_2P(C_6H_5)CH_2CH_2P(C_6H_5)CH_2CH_2NH_2$ (NPPN) and (2*S*,9*S*)-$NH_2CH(CH_3)CH_2P(C_6H_5)CH_2CH_2P(C_6H_5)CH_2CH(CH_3)NH_2$ (*SS*(*C*)-NPPN), and their cobalt(III) complexes.

Experimental

The phosphine ligands were prepared and handled under an atmosphere of nitrogen until they formed cobalt(III) complexes. All solvents for the preparation were made oxygen-free by bubbling nitrogen for 20 min immediately before use. Absorption, circular dichroism (CD), and ^{1}H and ^{13}C NMR spectra were recorded on a Hitachi 323 spectrophotometer, a JASCO J-40CS spectropolarimeter, and Jeol PMX-60, FX-100 and GX-400 spectrometers, respectively.

Preparation of Ligands. 3,6-Diphenyl-3,6-diphosphaoctane-1,8-diamine (NPPN). Method 1. This method is a modified one of Issleib and Oehme.[9] To (2-aminoethyl)-phenylphoshine[9] (4.95 g) in dry tetrahydrofuran (THF) (500 cm^3) was added dropwise a 15% hexane solution (14 g) of butyllithium over a period of 1 h with stirring. After further stirring for 1 h, 1,2-dichloroethane (1.6 g) was added dropwise, the solution was refluxed for 3 h, and then cooled. Water (2 cm^3) was added dropwise, the solvent THF was evaporated, and to the residue water (200 cm^3) and then diethyl ether (200 cm^3) were added with stirring. The ethereal layer was separated, dried over $MgSO_4$ (ca. 5 g) overnight, filtered, and evaporated to give an oily product. It was heated at ca. 100 °C under highly reduced pressure (<ca. 135 pa) to remove by-products and starting materials since the NPPN ligand is not distillable under ordinary conditions. Yield: ca. 60%. The crude product was used for preparing cobalt(III) complexes without further purification.

Method 2. A 15% hexane solution (30 g) of butyllithium was added dropwise to a dry THF solution (200 cm^3) of 1,2-bis(phenylphosphino)ethane[10] (7.34 g) over a period of 2 h with stirring. Stirring was continued for 3 h. Aziridine (3.7 g) was added dropwise at 40 °C, and the solution was refluxed for 10 h. After cooling water (1.5 cm^3) was added, and the soluiton was dried over $MgSO_4$ (ca. 10 g) overnight, filtered and evaporated to yield an oily product. It was treated by the same way as described in Method 1. Yield: ca. 60%.

(2*S*,9*S*)-4,7-Diphenyl-4,7-diphosphadecane-2,9-diamine (*SS*-(*C*)-NPPN). This ligand was prepared by the same method as Method 2 for NPPN, using (*S*)-2-methylaziridine[11] instead of aziridine. Yield: 50—60%.

Preparation of Cobalt(III) Complexes. *trans*-[$CoCl_2$(*rac*-(*P*)-NPPN)]$ClO_4 \cdot H_2O$. A methanol solution (30 cm^3) of NPPN (2.89 g, 8.02 mmol) was added dropwise to [CoCl-$(NH_3)_5]Cl_2$[12] (2.21 g) in a mixture (700 cm^3) of methanol and water (1 : 1) with stirring. After the color of the solution had been changed from violet to green (15 min), concd HCl (5 cm^3) was added and the solution was stirred for 15 min. The solvent methanol was removed under reduced pressure, and the unreacted NPPN ligand and by-products were extracted with diethyl ether (100 cm^3×2). The aqueous solution was concentrated to a small volume under reduced

pressure to yield a green precipitate (*trans*-[$CoCl_2$ (*rac*(*P*)-NPPN)]Cl). The precipitate was recrystallized from water by adding $NaClO_4 \cdot H_2O$. Yield: 1.5 g (32%). Found: C, 37.17; H, 5.27; N, 4.63%. Calcd for $C_{18}H_{28}N_2Cl_3CoO_5P_2$: C, 37.30; H, 4.78; N, 4.83%. Perchlorate salts of cobalt(III)-phosphine complexes are potentially explosive, and should be handled carefully.

***cis*α-[Co(en)(*rac*(*P*)-NPPN)]$(ClO_4)_3 \cdot 0.5H_2O$.** A methanol solution (100 cm^3) containing *trans*-[$CoCl_2$(*rac*(*P*)-NPPN)]Cl (300 mg, 0.578 mmol) and en (100 mg, 1.66 mmol) was stirred overnight. The resulting yellow solution was diluted with water (1 dm^3) and applied on a column (ϕ3 cm×60 cm) of SP-Sephadex C-25. The adsorbed product was eluted with 0.15 mol dm^{-3} Na_2SO_4. The yellow eluate (major product) was collected, diluted with water, and applied again on a column (ϕ1 cm×10 cm) of SP-Sephadex C-25. The adsorbed yellow product was eluted with 0.5 mol dm^{-3} $NaClO_4$, and the eluate was concentrated slowly in a desiccator, yielding yellow crystals. Yield: 350 mg (89%). Found: C, 31.69; H, 4.65; N, 7.33%. Calcd for $C_{20}H_{35}N_4CoCl_3O_{12.5}P_2$: C, 31.66; H, 4.65; N, 7.38%.

***cis*α-[Co(acac)(*rac*(*P*)-NPPN)]$(ClO_4)_2$.** The complex was prepared by the same method as for the en complex, using lithium 2,4-pentanedionate (Li(acac)) instead of en. Yield: 65%. Found: C, 39.90; H, 4.86; N, 3.83%. Calcd for $C_{23}H_{33}N_2CoCl_2O_{10}P_2$: C, 40.08; H, 4.83; N, 4.06%.

***Δ-cis*α-[Co(en)(*RR*(*P*),*SS*(*C*)-NPPN)]$(ClO_4)_3 \cdot 0.5H_2O$ and *Λ-cis*α-[Co(en)(*SS*(*P*),*SS*(*C*)-NPPN)]$Cl_2 \cdot ClO_4 \cdot 0.5H_2O$.** To [Co(en)$_3$]$(ClO_4)_3$[13] (1 g) in a mixture (100 cm^3) of water and methanol (5:3) were added a methanol solution (100 cm^3) of *SS*(*C*)-NPPN (700 mg, 1.94 mmol) and active charcoal (ca. 50 mg). The mixture was stirred overnight, filtered, diluted with water (3 dm^3) added concd HNO_3 (2 cm^3), and applied on a column (ϕ3 cm×60 cm) of SP-Sephadex C-25. By elution with 0.3 mol dm^{-3} Na_2[Sb_2(*d*-tartrate)$_2$], the column gave two large yellow bands (F1 (faster) and F2 (slower)) with a large orange-yellow ([Co(en)$_3$]$^{3+}$) and a few small bands. Each eluate of F1 and F2 was diluted ten times with water, poured again on a column (ϕ2 cm×15 cm) of SP-Sephadex C-25, and the complex was eluted with 2 mol dm^{-3} NaCl. The eluate was concentrated to a small volume under reduced pressure. On addition of excess $NaClO_4 \cdot H_2O$ the concentrate gave crystals of the complex. Yields, F1 (Δ-*cis*α): 80 mg (5%) and F2 (Λ-*cis*α): 200 mg (15%). Found for F1: C, 33.71; H, 4.77; N, 6.61%. Calcd for $C_{22}H_{39}N_4CoCl_3O_{12.5}P_2$: C, 33.58, H, 5.00; N, 7.12%. Found for F2: C, 39.13; H, 6.29; N, 8.16%. Calcd for $C_{22}H_{41}N_4CoCl_3O_{5.5}P_2$: C, 39.04; H, 6.11; N, 8.28%.

***Δ-cis*α-[Co(acac)(*RR*(*P*),*SS*(*C*)-NPPN)]$(ClO_4)_2 \cdot H_2O$, *Λ-cis*α-[Co(acac)(*SS*(P),*SS*(*C*)-NPPN)]$(ClO_4)_2$, and *Δ-cis*β-[Co(acac)(*RS*(P),*SS*(*C*)-NPPN)][$B(C_6H_5)_4$]$_2 \cdot 3H_2O$.** To [Co(acac)$_3$][14] (400 mg, 1.12 mmol) in methanol (200 cm^3) were added a methanol solution (50 cm^3) of *SS*(*C*)-NPPN (550 mg, 1.53 mmol) and active charcoal (ca. 50 mg). The mixture was stirred overnight, filtered, diluted with water (3 dm^3) added concd HNO_3 (2 cm^3), and applied on a column (ϕ3 cm×150 cm) of SP-Sephadex C-25. The adsorbed product was eluted with 0.15 mol dm^{-3} Na_2[Sb_2(*d*-tartrate)$_2$], yielding three large bands (orange F1 (fast), orange F2 (middle), and orange-red F3 (slow)). Each eluate of F1, F2, and F3 was diluted ten times with water acidified with HCl (pH ca. 3.0), and applied again on a column (ϕ2 cm×15 cm) of SP-Sephadex C-25. The adsorbed complex was eluted with 1 mol dm^{-3} Na_2SO_4. Either eluate obtained from F1 and F2 was evaporated to dryness under reduced pressure, and the complex was extracted with methanol. The extract gave orange crystals on addition of excess $NaClO_4 \cdot H_2O$. The complex contained in eluate F3 was isolated by adding sodium tetraphenylborate and purified by column (ϕ2.5 cm×60 cm) chromatography using Toyopearl TSK-GEL and methanol. Yields, F1 (Δ-*cis*α): 95 mg (9%), F2 (Λ-*cis*α): 70 mg (6%) and F3 (Δ-*cis*β): 195 mg (11%). Found for F1 : C, 40.51; H, 5.09; N, 4.07%. Calcd for $C_{25}H_{39}N_2CoCl_2O_{11}P_2$: C, 40.83; H, 5.35; N, 3.81%. Found for F2: C, 41.53; H, 5.29; N, 4.36%. Calcd for $C_{25}H_{37}N_2CoCl_2O_{10}P_2$: C, 41.86; H, 5.20; N, 3.91%. Found for F3: C, 72.15; H, 6.65; N, 2.28%. Calcd for $C_{73}H_{83}N_2B_2CoO_5P_2$: C, 72.41; H, 6.91; N, 2.31%. Complex F3 decomposes slowly in neutral water, so that it should be treated always in slightly acidic conditions.

Derivation of the en Complexes of *SS*(*C*)-NPPN from the acac Complexes. To isomer F1 (10 mg) of the acac complex in a small amount of methanol was added concd HCl (2 cm^3) and the solution was allowed to stand overnight, the color changing gradually from orange to red. The red solution was diluted ten times with water and applied on a column (ϕ1 cm×15 cm) of SP-Sephadex C-25. The adsorbed red complex was eluted with 0.3 mol dm^{-3} HCl. To the red eluate was added a methanol solution of excess en, the color being changed instantly from red to yellow. The yellow eluate was diluted ten times with water and applied on a column (ϕ1 cm×15 cm) of SP-Sephadex C-25. The adsorbed yellow complex was eluted with 0.4 mol dm^{-3} NaCl. The absorption and CD spectra of the yellow eluate coincide with those of isomer F1 of the en complex prepared from

$[Co(en)_3]^{3+}$ and *SS(C)*-NPPN. By the same method, isomer F2 of the en complex was derived from isomer F2 of the acac complex. However, any en complex of *SS(C)*-NPPN could not be obtained from isomer F3 of the acac complex. A methanol solution of F3 turned red by adding concd HCl, but the product gradually decomposed to Co(II) species on addition of excess en.

Optical Resolution of the NPPN Complexes. Partial resolutions of *cisα*-[Co(en)(*rac(P)*-NPPN)]$^{3+}$ and *cisα*-[Co(acac)(*rac(P)*-NPPN)]$^{2+}$ were achieved by an SP-Sephadex C-25 column-chromatographic method using a column (ϕ3 cm×120 cm), and 0.2 mol dm^{-3} and 0.1 mol dm^{-3} $Na_2[Sb_2(d\text{-tartrate})_2]$ as an eluent, respectively. In each resolution the first and last several fractions of the band showed a constant $\Delta\varepsilon/\varepsilon$ value. The fractions with a constant $\Delta\varepsilon/\varepsilon$ value were collected, diluted five times with water and applied on a column (ϕ1 cm×10 cm) of SP-Sephadex C-25. The column was washed with water and the complex was eluted with 0.3 mol dm^{-3} NaCl. The effluent was used for CD measurements, and the concentration of the complex was determined by reference to the ε values of the racemate.

Results and Discussion

NPPN Complexes. We have prepared the NPPN ligand from $(C_6H_5)HPCH_2CH_2PH(C_6H_5)$ and aziridine (Method 2) and also from $NH_2CH_2CH_2PH(C_6H_5)$ and $ClCH_2CH_2Cl$ by Method 1 which is a modified method of Issleib and Oehme.[9] Both methods gave similar yields. The ligand could not be purified by vacuum distillation because it had a high boiling point and decomposed at a high temperature.[9] Thus, the crude product was used without purification for preparing the cobalt(III) complexes.

By reaction of NPPN with $[CoCl(NH_3)_5]Cl_2$, only one isomer of $[CoCl_2(NPPN)]^+$ was isolated, no dichloro complex being formed by oxidizing $[Co(NPPN)]^{2+}$ with Cl_2[15] or O_2.[16] The absorption spectrum of $[CoCl_2(NPPN)]^+$ is similar in pattern to that of *trans(Cl,Cl)*, *cis(P,P)*-$[CoCl_2(ebpp)_2]^+$ (ebpp= $NH_2CH_2CH_2P(C_4H_9)(C_6H_5)$) whose structure has been determined by X-ray analysis (Fig. 1).[2] Although the NPPN complex exhibits strong Co–Cl and Co–P charge-transfer bands[2,15,17] at fairly lower energies, the spectrum indicates that the complex has a trans(Cl,Cl) configuration. For *trans(Cl,Cl)*-$[CoCl_2(NPPN)]^+$, there are two possible diastereomers arising from the combination of chiral phosphorus atoms of the ligand; racemic(RR,SS) and meso(RS)[18] (Fig. 2). The isolated *trans(Cl,Cl)*-$[CoCl_2(NPPN)]^+$ complex can be assigned to have the racemic NPPN ligand, since the complex affords only *cisα*-$[Co(L)(NPPN)]^{n+}$ (L=en, acac) by reaction with L. The meso NPPN ligand can not coordinate to a metal ion in the cisα form, but only in the cisβ form. The filtrate obtained after *trans(Cl,Cl)*-$[CoCl_2(rac(P)\text{-NPPN})]^+$ had been removed contained another green complex which seemed to be *trans(Cl,Cl)*-$[CoCl_2(meso(P)\text{-NPPN})]^+$. However, the complex was rather unstable and decomposed during the course of isolation to give cobalt(II) species and an oily material. The instability of this complex may be attributable to its strained structure, in which the central five-membered P–Co–P chelate ring is forced

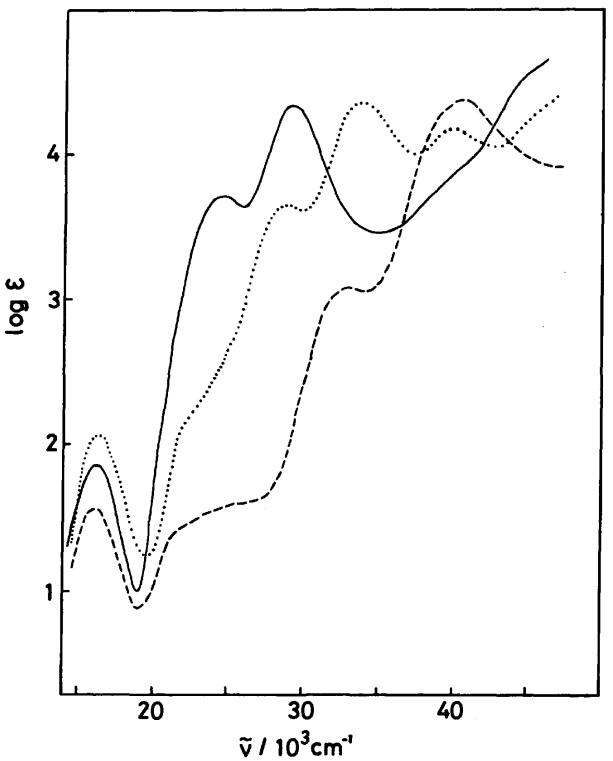

Fig. 1. Absorption spectra of *trans*-$[CoCl_2(rac(P)\text{-NPPN})]^+$ (——), *trans*-$[CoCl_2(en)_2]^+$ (------), and *trans*-$[CoCl_2(ebpp)_2]^+$ (·····).[2]

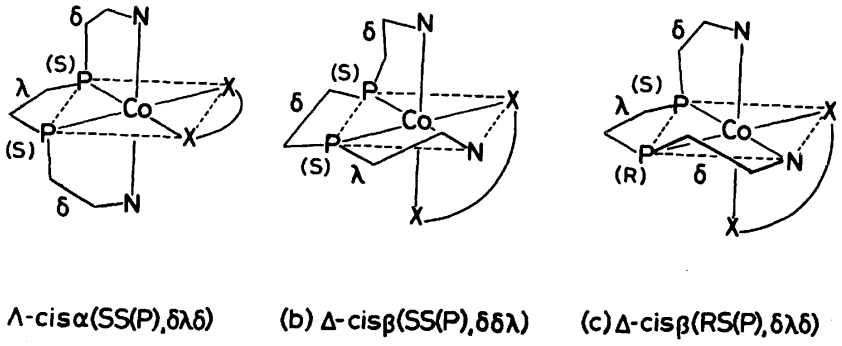

Fig. 3. Three possible isomers of $[Co(L)(NPPN)]^{n+}$.

to take an envelope conformation (Fig. 2), although such an envelope conformation was found in *trans*-$[Co(NH_3)_2(trien)]^{3+}$ (trien=$NH_2CH_2CH_2NHCH_2CH_2NHCH_2CH_2NH_2$).[20] The *trans*(*Cl,Cl*)-$[CoCl_2$ (*rac*(*P*)-NPPN)$]^+$ complex is very stable and does not change in water over several days. Thus only the *rac*(*P*)-NPPN ligand can form stable *trans*(*Cl,Cl*)-$[CoCl_2$-(NPPN)$]^+$.

As stated previously, either reaction of *trans*(*Cl,Cl*)-$[CoCl_2(NPPN)]^+$ with L (L=en, acac) afforded one geometrical isomer of $[Co(L)(NPPN)]^{n+}$. In each reaction product, a very small band (yellow for en and orange for acac) was observed on column chromatography, but they were not characterized because of a very small amount. For [Co(chelate)(NPPN)]$^{n+}$, three geometrical isomers are possible and each isomer has its antipode (Fig. 3). The [Co(chelate)(*meso*(*P*)-NPPN)]$^{n+}$ complex can not form the cisα isomer, since two terminal P–N chelate arms point to the same apical site with respect to the P–Co–P plane. The ^{13}C NMR spectra of the en and acac complexes exhibit eight and ten carbon signals, respectively. Thus these complexes can be assigned to the cisα isomer which has C_2 symmetry. The reason for preferential formation of the cisα isomer in [Co(L)(*rac*(*P*)-NPPN)]$^{n+}$ is not clear at the moment. Molecular models show that the cisβ isomer of the *rac*(*P*)-NPPN complex involves fairly large steric interactions between the phenyl group on the central phosphorus atom of three meridionally coordinated atoms N–P–P and all of three chelate rings formed by NPPN. The instability of the cisβ isomer of the *rac*(*P*)-NPPN complex seems to come from such a steric factor.

The chirality of phosphorus atoms (RR or SS) of *rac*(*P*)-NPPN has a mutual relation with the chirality of [Co(chelate)(*rac*(*P*)-NPPN)]$^{n+}$ (Δ or Λ); *SS*(*P*)-NPPN can form Λ-cisα and Δ-cisβ isomers, while *RR*(*P*)-NPPN Δ-cisα and Λ-cisβ isomers (Fig. 3). Figure 4 shows absorption and circular dichroism spectra of the faster-moving *cis*α-[Co(en)(*rac*(*P*)-NPPN)]$^{3+}$ isomer in column chromatography. The CD spectrum of this isomer is quite similar to that of *Λ-cis*α-[Co(en)(*SS*(*P*),*SS*(*C*)-NPPN)]$^{3+}$ (vide post) whose

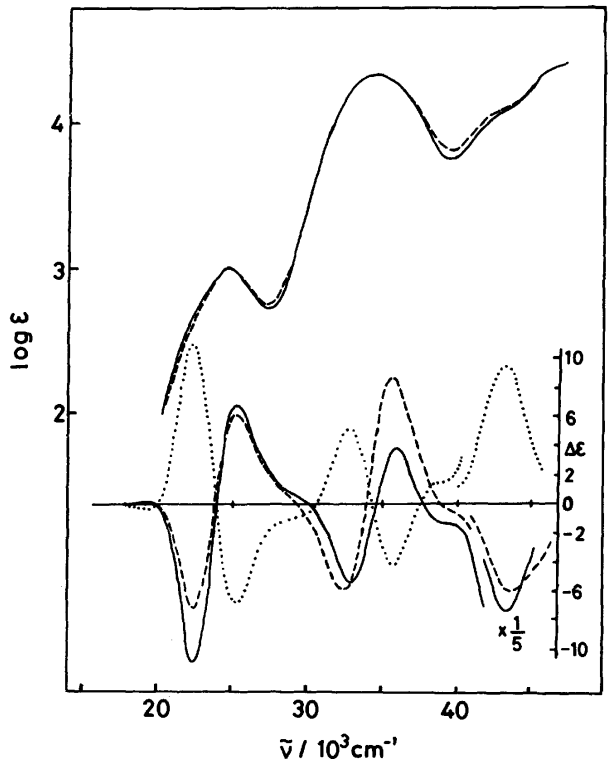

Fig. 4. Absorption and CD spectra of *cis*α-[Co(L)(NPPN)]$^{3+}$: *cis*α-[Co(en)(NPPN)]$^{3+}$ (——) (faster-eluting fractions (see Experimental)), *cis*α-[Co(*R*-pn)(NPPN)]$^{3+}$ (F1) (·····), *cis*α-[Co(*R*-pn)(NPPN)]$^{3+}$ (F2) (------).

absolute configuration has been determined by X-ray analysis.[21] Thus the isomer is assigned to the Λ-cisα isomer and the phosphorus atoms to the S configuration. By reaction of *trans*-$[CoCl_2$(*rac*(*P*)-NPPN)$]^+$ with *R*-pn, two isomers of [Co(*R*-pn)(*rac*(*P*)-NPPN)]$^{3+}$ (F1 and F2) were obtained in similar yields. The isomers were completely separated by SP-Sephadex column chromatography. Both isomers show identical absorption spectrum and the spectrum is nearly the same as that of *cis*α-[Co(en)(*rac*(*P*)-NPPN)]$^{3+}$. The CD spectra of isomers F1 and F2 are also very similar to those of the faster- and slower-

moving isomers of the en complex, *Δ-cisα*-[Co(en)(*RR*(*P*)-NPPN)]$^{3+}$ and *Δ-cisα*-[Co(en)(*SS*(*P*)-NPPN)]$^{3+}$ respectively (Fig. 4). Thus isomers F1 and F2 of the *R*-pn complex can be assigned to *Δ-cisα*-[Co(*R*-pn)(*RR*(*P*)-NPPN)]$^{3+}$ and *Δ-cisα*-[Co(*R*-pn)(*SS*(*P*)-NPPN)]$^{3+}$, respectively. It is noted that the Λ-isomer of these diamine complexes of *rac*(*P*)-NPPN shows a negative main CD band in the first d-d band region. The result is in contrast to the CD pattern for usual chelate complexes of Co(III), although the CD spectra of the present NPPN complexes involve the vicinal effect of chiral phosphorus atoms that can not be evaluated.

Similarly two isomers (F1 and F2) were obtained for each amino acidato complex [Co(L)(*rac*(*P*)-NPPN)]$^{2+}$ (L=*S*-ala, *S*-pro). From comparisons of the absorption and CD spectra with those of the above diamine complexes (Fig. 5), isomer F1 can be assigned to *Δ-cisα*-[Co(L)(*RR*(*P*)-NPPN)]$^{2+}$ and isomer F2 to *Δ-cisα*-[Co(L)(*SS*(*P*)-NPPN)]$^{2+}$. Spectral data for the NPPN complexes are listed in Table 1.

***SS*(*C*)-NPPN Complexes.** The *SS*(*C*)-NPPN ligand was prepared from $(C_6H_5)HPCH_2CH_2PH(C_6H_5)$ and (*S*)-2-methylaziridine by a method similar to Method 2 for NPPN. The *trans*-[$CoCl_2$(*SS*(*C*)-NPPN)]$^+$ complex was yielded from *SS*(*C*)-NPPN and [CoCl$(NH_3)_5$]Cl_2 by the same method as for the NPPN complex, but the yield was very poor. The N-P chelate ring of *SS*(*C*)-NPPN in a complex will be stabilized in a δ-gauche conformation because of the equatorial preference of the methyl group on the (*S*)-carbon atom. Molecular models indicate that when the N-P chelate ring takes a λ-conformation, the methyl group becomes axial and has steric interactions with the phenyl group disposed nearly axially and also with the chloride ion at the apical position of the complex. Of these possible isomers of the *trans*-dichloro complex shown in Fig. 2, only the

a) CD data are observed for faster eluting fraction.

trans(RR(P),$\delta\lambda\delta$) isomer[22] has no axial methyl group. The poor yield of *trans*-[$CoCl_2$(*SS*(*C*)-NPPN)]$^+$ will be attributable to such a stereochemical requirement of the complex, neither SS(P)- nor RS(P)-isomer of *SS*(*C*)-NPPN forming the stable *trans*-dichloro complex.

Two isomers (F1 and F2) of [Co(en)(*SS*(*C*)-NPPN)]$^{3+}$ were obtained by the reaction of *SS*(*C*)-NPPN with $[Co(en)_3]^{3+}$. As stated previously, the structure of isomer F2 was determined by X-ray analysis to *Λ-cisα*-[Co(en)(*SS*(*P*),*SS*(*C*)-NPPN)]$^{3+}$ where three chelate rings of *SS*(*C*)-NPPN take $\delta\lambda\delta$ conformations (Fig. 3(a)), and the two methyl groups have an equatorial disposition with respect to the N–P chelate ring. The other isomer F1 can be assigned to Δ-cisα, since the isomer exhibits nine carbon signals in the ^{13}C NMR spectrum, and shows absorption spectrum very similar to that of isomer F2, but the CD spectrum is nearly enantiomeric to that of isomer F2 (Fig. 6). In the Δ-cisα structure, both phosphorus atoms have necessarily the R configuration, and the stable conformation of *RR*(*P*),*SS*(*C*)-NPPN would be λδλ enantiomeric to those of the Λ-cisα isomer (F2). When the P–N chelate ring takes a λ-gauche conformation, the methyl group is disposed axially and approaches very close to one of the methylene groups of the central P–P chelate ring. However, the terminal P–N chelate ring in the cisα configuration is rather flexible and can take other conformation than λ-gauche such as an envelope-type to release the crowding. Such an envelope conformation of a similar P–N chelate ring has been found in *Λ-cisβ*-[Co(acac){(*S*,*S*)-$(CH_3)_2PCH_2$-$CH(CH_3)NHCH_2CH_2NHCH(CH_3)CH_2P(CH_3)_2$}]$^{2+}$.[23] Thus we have assigned isomer F1 to *Λ-cisα*-[Co(en)(*RR*(*P*),*SS*(*C*)-NPPN)]$^{3+}$.

No indication of formation of [Co(en)(*RS*(*P*),*SS*(*C*)-NPPN)]$^{3+}$ was observed in column chromatography. The *RS*(*P*),*SS*(*C*)-NPPN ligand can form only the cisβ isomer as stated previously. However, molecular models indicate that the puckered chelate ring of en has steric interactions with two phenyl groups of *RS*(*P*),*SS*(*C*)-NPPN arranged in the cisβ configuration. Thus the en complex with *RS*(*P*),*SS*(*C*)-NPPN will be unstable by such a steric factor.

The reaction of *SS*(*C*)-NPPN with [Co(acac)$_3$] afforded three isomers of [Co(acac)(*SS*(*C*)-NPPN)]$^{2+}$ (F1, F2, and F3). The ^{13}C NMR spectra suggest the cisα configuration for isomers F1 and F2, and the cisβ configuration for F3. Table 2 lists the NMR data. The assignments were made on the basis of the previous work on analogous complexes.[1,24] The absorption spectra of isomers F1 and F2 are similar, while the CD spectra are nearly enantiomeric to each other (Fig. 7). Isomers F1 and F2 of the acac complex

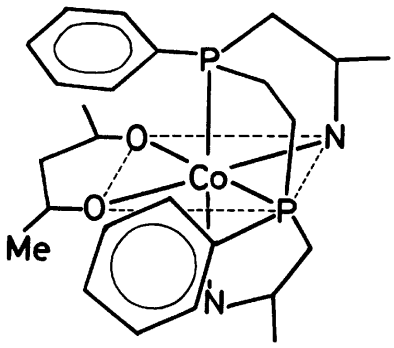
a) Not obsd. Internal reference: dioxane.



Δ-cisß(RS(P))

Fig. 8. A schematic structure of *Δ-cisβ*-[Co(acac)-(*RS(P),SS(C)*-NPPN)]$^{2+}$ (F3).

afford isomers F1 (Δ-*cisα*) and F2 (Λ-*cisα*) of the en complex, respectively (see Experimental). Thus isomer F1 of the acac complex is assigned to *Δ-cisα*-[Co(acac)(*RR(P),SS(C)*-NPPN)]$^{2+}$ and isomer F2 to *Λ-cisα*-[Co(acac)(*SS(P),SS(C)*-NPPN)]$^{2+}$.

Isomer F3 of the acac complex, which was suggested to be the cis*β* isomer from the ^{13}C NMR spectrum, does not afford any en complex by reaction with en (see Experimental). The result suggests that isomer F3 is the complex containig *RS(P),SS(C)*-NPPN, since the en complex of *RS(P),SS(C)*-NPPN was not formed by the reaction of *SS(C)*-NPPN with $[Co(en)_3]^{3+}$ as described above. A schematic structure of *cisβ*-[Co(acac)(*RS(P),SS(C)*-NPPN)]$^{2+}$ is given in Fig. 8. The assignment of this structure for isomer F3 is supported by the ^1H NMR spectrum. The isomer shows the methine proton signal of acac at a higher field (δ=5.17) than those of isomers F1 (δ=5.93) and F2 (δ=5.80), and also exhibits one of the two methyl proton signals of acac at a remarkably higher field (1.23 and 2.15 ppm) than those of isomers F1 (δ=2.23) and F2 (δ=2.21). The high field shifts of the methine and methyl proton signals of isomer F3 are attributable to the shielding effect of the phenyl groups approached very closely to those protons, as seen in Fig. 8. Such a high field shift of methyl signal is not expected for *cisβ*-[Co(acac)(*RR(P),SS(C)*- or *SS(P),SS(C)*-NPPN)]$^{2+}$ complex. For *cisβ*-[Co(acac)(*RS(P),SS(C)*-NPPN)]$^{2+}$, the Δ isomer will be much more stable than the Λ isomer, since two methyl groups of *RS(P),SS(C)*-NPPN are equatorial in the former, while axial in the latter (Fig. 8). The CD spectrum of isomer F3 suggests a Δ configuration. The isomer shows a similar CD pattern to that of isomer F1 (Δ-cis*α*) in the first d–d band region; both isomers give a negative and a positive CD band from the lower energy side in this region (Figs. 7 and 9). Thus isomer F3 can be assigned to *Δ-cisβ*-[Co(acac)

Table 3. Absorption (AB) and CD Spectral Data for *SS(C)*-NPPN Complexes

Complexe	AB ($\bar{\nu}/10^3$ cm^{-1} (log ε))	CD ($\bar{\nu}/10^3$ cm^{-1} ($\Delta\varepsilon$))

Λ-cisα-[Co(en)(*SS(C)*-NPPN)]$^{3+}$	24.5(3.02), 34.5(4.33)	19.8(+0.45), 22.5(−14.0), 25.4(+6.78), 33.2(−3.34), 35.5(+3.97), 43.0(−17.8)

a) Shoulder absorption.

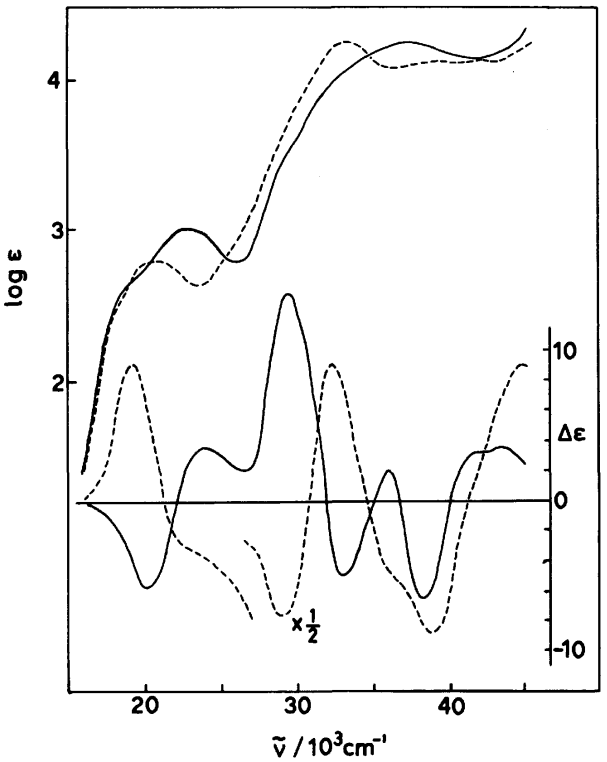

Fig. 9. Absorption and CD spectra of *Δ-cisβ*-[Co(acac)(*RS(P)*,*SS(C)*-NPPN)]$^{2+}$ (F3) (——) and *Λ-cisβ*-[Co(acac){*SR(P)*,*SS(C)*-$(CH_3)(C_6H_5)PCH_2CH(CH_3)NHCH_2CH_2NHCH(CH_3)CH_2P(CH_3)(C_6H_5)$}]$^{2+}$ (------).[4]

(*RS(P)*,*SS(C)*-NPPN)]$^{2+}$. As stated above, this structure is very crowded and will involve steric interactions between the acac ligand and the phenyl groups of *RS(P)*,*SS(C)*-NPPN. In fact, the isomer in aqueous solution changes slowly from orange to red in color, although the red complex could not be isolated.

The first d–d band of isomer F3 (cisβ) splits into two components (Fig. 9), while those of isomers F1 and F2 (cisα) do not (Fig. 7). If it is assumed that the ligand field strengths of donor atoms are P>N>O, a large band-splitting is expected for the cisβ isomer than for

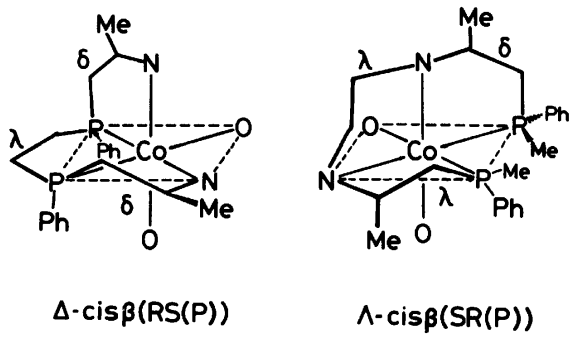

Fig. 10. Molecular models of *Δ-cisβ*-[Co(acac)(*RS(P)*,*SS(C)*-NPPN)]$^{2+}$ (F3) and *Λ-cisβ*-[Co(acac){*SR(P)*,*SS(C)*-$(CH_3)(C_6H_5)PCH_2CH(CH_3)NHCH_2CH_2NHCH(CH_3)CH_2P(CH_3)(C_6H_5)$}]$^{2+}$.

the cisα isomer from Yamatera's rule.[25] Figure 9 compares the CD spectrum of isomer F3 with that of *Λ-cisβ*-[Co(acac){*RS(P)*,*SS(C)*-$(CH_3)(C_6H_5)PCH_2CH(CH_3)NHCH_2CH_2NHCH(CH_3)CH_2P(CH_3)(C_6H_5)$}]$^{2+}$,[4] which has a chelate ring between the two N atoms in place of the P–P chelate ring in isomer F3. Both complexes have the same geometrical arrangement for the coordinating donor atoms, cis(P,P)cis(N,N)cis(O,O), but are antipodal to each other with respect to the arrangement of donor atoms and of chelate rings as seen in Fig. 10. These two complexes show CD spectra nearly enantiomeric to each other except those in the higher energy region.

The absorption and CD spectral data of the *SS(C)*-NPPN complexes are listed in Table 3.

The authors wish to thank the Ministry of Education for Scientific Research Grant-in-Aid No. 60470046 and 61430013.

(Received December 6, 1986)

Of three possible isomers for the (L-cysteinato)(diethylenetriamine)cobalt(III) complex, [Co(L-cys)(dien)]$^+$, two isomers are selectively prepared. Of the two isomers, the crystal structure of the dominantly formed isomer has been determined by the X-ray diffraction method. The greenish brown needle crystal was orthorhombic, space group $P2_12_12_1$, a=16.589(4), b=20.510(9), c=12.479(4) Å, and Z=4. The structure has been refined to R=0.068 on 5913 observed reflections. There are three crystallographically independent complex cations in an asymmetric unit. All the complex cations have trans(N_iS) configuration and the L-cysteinate coordinates facially to the cobalt atoms as terdentate-N,O,S ligand. The isomers of the (*S*-methyl-L-cysteinato)(diethylenetriamine)cobalt(III) complex were derived from [Co(L-cys)(dien)]$^+$ by the reaction with dimethyl sulfate. The electronic absorption, CD, and ^{1}H and ^{13}C NMR spectral behaviors for these complexes are discussed in relation to their geometrical configurations.

Cobalt(III) complexes with the thiolato or thioether type terdentate-N,O,S ligand such as *S*-methyl-L-cysteinate (L-smc), L-penicillaminate (L-pen), and *S*-methyl-L-penicillaminate (L-smp) have been investigated for the stereochemical and spectrochemical interests.[1-10] However, L-cysteinate (L-cys) usually coordinates to cobalt(III) as a bidentate-N,S ligand[11-16] or tends to form the stable *S*-bridged complexes.[17] So we attempted to prepare the (diethylenetriamine)-cobalt(III) complex with L-cysteinate functioning as a terdentate-N,O,S, [Co(L-cys)(dien)]$^+$, and the result is able to compare with the stereochemistry of the corresponding L-penicillaminato complex.[5,7]

In the present paper, the (diethylenetriamine)cobalt(III) complex with L-cysteinate, which could not be prepared by a procedure similar to that used for [Co(L-pen)(dien)]$^+$,[5,7] was successfully obtained for the first time. Two isomers were selectively formed and the crystal structure of the dominantly formed isomer, [Co(L-cys)(dien)]$_3$(ClO_4)$_3$·0.82H_2O, was determined by X-ray diffraction method. The *S*-methyl-L-cysteinato complex, [Co(L-smc)(dien)]$^{2+}$, was prepared by the reaction of [Co(L-cys)(dien)]$^+$ with dimethyl sulfate. The absorption, CD, and ^{1}H and ^{13}C NMR spectra, and the stereochemical properties of [Co(L-cys or L-smc)(dien)]$^{+\text{ or }2+}$ are discussed in comparison with those of the corresponding [Co(L-pen or L-smp)-(dien)]$^{+\text{ or }2+}$ complexes.[5,7]

Experimental

1) Preparation of Complexes. a) [Co(L-cys)(dien)]ClO_4. To a deoxygenated solution containing 4.8 g of $CoCl_2$·6H_2O in 25 cm^3 of water were successively added with stirring a deoxygenated solution containing 2.1 g of diethylenetriamine in 25 cm^3 of water and 2.4 g of L-cystine powder. The mixture was continuously stirred under nitrogen atmosphere at room temperature for 1 h. The greenish brown solution was filtered and the filtrate was poured onto a column of SP-Sephadex C-25 (Na^+ form, 5 cm×45 cm). After the column had been swept with water, the adsorbed band was eluted with a 0.15 mol dm^{-3} aqueous solution of $NaClO_4$. Only a greenish brown band (E-1) was eluted and the eluate was immediately concentrated to a small volume with a rotary evaporator below 25 °C. To the solution was added a small amount of ethanol and then the solution was kept in a refrigerator overnight. A small amount of crystals (A-1) appeared and was collected by filtration. The filtrate was concentrated and kept in a refrigerator again. The greenish brown crystals (A-2) which appeared were collected by filtration. When the A-1 isomer was recrystallized from as little water as possible by adding ethanol, the crystals contained a mixture of the A-1 and A-2 isomers as evidenced from the ^{1}H and ^{13}C NMR spectral measurements. This suggests that the A-1 isomer isomerized to the A-2 one. The A-2 isomer was obtained as pure crystals, collected by filtration, washed with ethanol, and dried in a desiccator. A piece of the crystals of the A-2 isomer was used for the X-ray crystal analysis. The A-1 and A-2 isomers could not be separated using a column chromatographic method because these isomers, especially A-1 isomer, were unstable in the column. Yield for A-2: 39%. Found for A-2: C, 21.94; H, 4.84; N, 14.61%. Calcd for [Co(L-cys)(dien)]ClO_4·0.27H_2O=$C_7H_{18}N_4O_6ClSCo$·0.27H_2O: C, 21.81; H, 4.85; N, 14.53%.

b) [Co(L-smc)(dien)](ClO_4)$_2$. Method 1. To a solution containing 0.3 g of the A-2 isomer, [Co(L-cys)(dien)]-ClO_4·0.27H_2O, in 12 cm^3 of water was added 6 cm^3 of dimethyl sulfate. When the mixture was allowed to stand in a refrigerator overnight, it was separated into two layers. The upper red layer was taken out and poured onto a column of QAE-Sephadex A-25 (ClO_4^- form, 2.5 cm×20 cm) in order to obtain the perchlorate salt. The eluate was concentrated to a small volume with a rotary evaporator and to this was added a small amount of ethanol. After the solution was kept in a refrigerator overnight, the needle

crystals which appeared were collected by filtration, washed with ethanol, and dried in a desiccator. Found: C, 19.38; H, 4.26; N, 11.32%. Calcd for $[Co(L\text{-}smc)(dien)](ClO_4)_2 = C_8H_{21}N_4O_{10}Cl_2SCo$: C, 19.40; H, 4.27; N, 11.32%.

Method 2. The eluate containing $[Co(L\text{-}cys)(dien)]^+$ (E-1) eluted from the SP-Sephadex column in Ia) was methylated by a similar procedure to that used in Method 1. The upper red layer was poured onto a column of Dowex 50W-X8 (200—400 mesh, Na^+ form, 4.5 cm×40 cm). After the column had been swept with water, the adsorbed band was eluted with a 0.5 mol dm^{-3} aqueous solution of NaCl. Two red bands, B-1 and B-2, were eluted in this order. The eluate B-2 showed the identical absorption and CD spectra with the isomer obtained in Method 1. The formation ratio of the isomers, B-1 and B-2, was about 1:3. Then the eluate B-1 was concentrated to a small volume with a rotary evaporator below 25 °C and the deposited NaCl was filtered off. The filtrate was passed through a column of Sephadex G-10 (3 cm×53 cm) in order to eliminate NaCl. The eluate was concentrated to a small volume and poured onto a column of QAE-Sephadex A-25 (ClO_4^- form, 2.5 cm×20 cm). The eluate converted to the perchlorate salt was concentrated to a small volume and to this was added a small amount of ethanol. The solution was kept in a refrigerator for several days. The crystals which appeared were collected by filtration, washed with ethanol, and dried in a desiccator. Found for B-1: C, 19.10; H, 4.43; N, 11.13%. Calcd for $[Co(L\text{-}smc)(dien)](ClO_4)_2 \cdot 0.5H_2O$: C, 19.06; H, 4.40; N, 11.11%.

2) General Data. The electronic absorption spectra were recorded on JASCO UVIDEC-1 and UVIDEC-610 spectrophotometers and the CD spectra on a JASCO J-20 spectropolarimeter. All measurements were carried out in aqueous solution at room temperature. The ^1H and ^{13}C NMR spectra were recorded in deuterium oxide on a JEOL JNM-FX-100 or -FX-90Q NMR spectrometer at the probe temperature. Sodium 2,2-dimethyl-2-silapentane-5-sulfonate was used as an internal reference. The X-ray analysis calculations were carried out on a FACOM M-382 computer at the University of Tsukuba.

3) X-Ray Data Collection. Unit cell parameters and intensity data for the single crystal (A-2) (ca. 0.18×0.20×0.80 mm^3) were measured on a Rigaku-denki four-circle diffractometer (AFC-5) with graphite-monochromatized Mo $K\alpha$ radiation. The unit cell parameters were determined by a least-squares refinement based on 25 reflections.

a) $B_{eq} = 8\pi^2(U_{12}+U_{22}+U_{33})/3$. b) Isotropic temperature factor.

Systematic absences led to the space group $P2_12_12_1$. Crystal Data: $C_{21}H_{55.64}N_{12}O_{18.82}Cl_3S_3Co_3$, $M.W.$=1156.84, orthorhombic, space group $P2_12_12_1$, a=16.589(4), b=20.510(9), c=12.479(4) Å, V=4246(3) Å^3, D_x=1.810 g cm^{-3}, D_m=1.79 g cm^{-3} (by the flotation), Z=12, and μ(Mo Kα)=1.623 mm^{-1}.

The intensity data were collected by the ω-2θ scan technique up to 2θ=60° with scan rate of 3° min^{-1}. The intensity data were converted to the F_o data in the usual manner. Absorption corrections were not applied. A total of 5913 independent reflections with $|F_o|>3\sigma(|F_o|)$ of the measured 6881 reflections were considered as 'observed' and used for the structure analysis.

4) Determination of the Crystal Structure. The positions of three cobalt atoms and the coordinated sulfur, oxygen, and nitrogen atoms were determined by the direct method (program MULTAN[18]) was used). The difference-Fourier maps based on these atomic positions revealed the other nonhydrogen atoms. The structure was refined by a full-matrix least-squares refinement using the positional parameters, the anisotropic thermal parameters of the nonhydrogen atoms of the complex ions, and the isotropic thermal parameters of the oxygen atoms in the perchlorate ions and the water molecule (program RFINE[19]) was used). The occupancy for the oxygen atom of the water molecule was also refined and converged to 0.82(3), since the analytical result of the water molecule indicates the small value. The neutral atomic scattering factors for all the nonhydrogen atoms were taken from the literatures.[20,21]) The final residual values were R=0.068 and R_w=0.076, respectively. The configuration was determined on the basis of the known configuration of L-cysteinate.[22]) The final positional parameters are listed in Table 1. A list of structure factors (Table A) and anisotropic thermal parameters (Table B) are kept at the Chemical Society of Japan as Document No. 8738.

Results and Discussion

Description of the Structure. A perspective drawing of the typical complex cation (CoA species) is shown in Fig. 1, together with the numbering scheme.

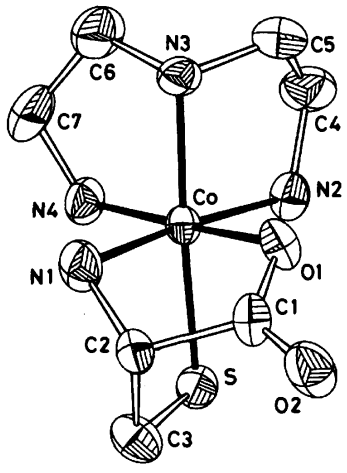

Fig. 1. A. perspective drawing of *trans*(N_iS)-[Co(L-cys)(dien)]$^+$ (CoA species) with the numbering scheme of atoms.

The packing mode is illustrated in Fig. 2. There are three crystallographically independent complex cations in an asymmetric unit, though their shapes and sizes remarkably resemble one another. The cobalt atom was octahedrally surrounded by the oxygen, sulfur, and four nitrogen atoms. The L-cysteinate and diethylenetriamine coordinate facially to the cobalt atom as terdentate ligands. The sulfur atom of the L-cys occupies the trans position to the imino nitrogen atom of the dien. Accordingly, all of these complex cations are determined to take a trans(N_iS) configuration (Figs. 1 and 2).[23])

The bond lengths and angles in the three crystallographically independent complex cations are similar to those for the cobalt(III) complexes with diethylenetriamine and/or sulfur-containing amino carboxylates (Table 2).[1-3,5]) The average Co–N3 distance bonded trans to the sulfur atom is 2.005(8) Å and the average cis Co–N distance is 1.952(8) Å. A difference between the trans and cis Co–N distances, 0.053 Å, indicates the trans effect due to the coordinated sulfur atom, as in the case of the cobalt(III) complexes with the thiolato ligands such as L-penicillaminate[5]) and 2-aminoethanethiolate.[24]) Especially, the CoA and CoB complex cations exhibit the large trans effect, 2.013 Å.

cations resemble one another and the average displacements of the relevant atoms from the Co-O1-N1 or Co-S-N1 plane are somewhat different from those of *trans*(N_iN)-[Co(L-pen)(dien)]$^+$ (Cl and C2 for the L-cys (L-pen) complex, 0.599(0.371) and 0.942(0.838) Å, λ form; C2 and C3, 1.101(1.154) and 0.590(0.780) Å, δ form).[5] The conformation of the dien in the CoD complex cation are quite similar to those in *trans*(N_iN)-[Co(L-pen)(dien)]$^+$ (the displacement of the CoD-ND2-ND3 or CoD-ND3-ND4 plane: CD4 and CD5 for the L-cys (L-pen) complex, −0.237(−0.239) and 0.366(0.362) Å, δ form; CD6 and CD7, 0.437(0.431) and −0.093(−0.097) Å, λ form). On the contrary, the conformations of the dien in the CoA and CoB complex cations are significantly different from those of the CoD and L-pen ones; namely, both of the diamine chelate rings in the former take an asymmetric skew with λ form (the average displacement of the Co-N2-N3 or Co-N3-N4 plane: C4 and C5, −0.070 and 0.568 Å; C6 and C7, 0.130 and 0.681 Å).

Preparation and Characterization. Three geometrical isomers, trans(N_iN), trans(N_iS), and trans-(N_iO),[23] are possible for [Co(L-cys)(dien)]$^+$, as in the case of [Co(L-pen)(dien)]$^+$.[5,7] The L-cys complex was prepared for the first time by the reaction of cobalt(II) chloride with L-cystine under a nitrogen atmosphere. In this preparative reaction, two isomers, A-1 and A-2 (trans(N_iS) based on the X-ray crystal structure analysis) were selectively formed. The absorption and CD spectra of the A-1 isomer, which were shown by the arbitrary scale in Fig. 3, exhibit quite similar spectral patterns to those of *trans*(N_iN)-[Co(L-pen)(dien)]$^+$ whose structure was determined by the X-ray crystal structure analysis.[7] Therefore, the A-1 isomer can be assigned to the trans(N_iN) configuration.

The absorption, CD, and ^1H and ^{13}C NMR spectra of *trans*(N_iN)-[Co(L-cys)(dien)]$^+$ (A-1) changes with time and these spectral behaviors suggest that the trans(N_iN) isomer isomerizes to the trans(N_iS) one, though *trans*(N_iN)-[Co(L-pen)(dien)]$^+$ did not isomerize in an aqueous solution.[5,7] *trans*(N_iS)-[Co(L-cys)(dien)]$^+$ (A-2) did not isomerize in an aqueous solution and gave only one isomer of [Co(L-smc)(dien)]$^{2+}$ by the reaction with dimethyl sulfate. This fact suggests that the methylation for the A-2 isomer proceeded with retention of the trans(N_iS)

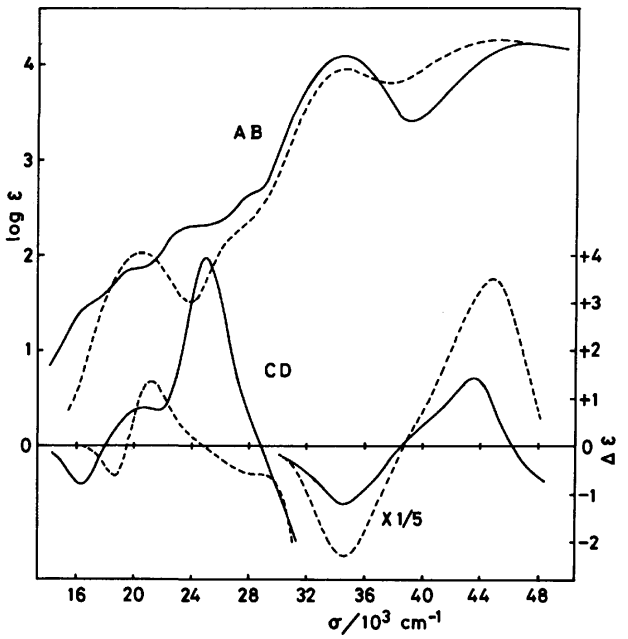

Fig. 3. Absorption and CD spectra of *trans*(N_iN)-[Co(L-cys or L-smc)(dien)]$^{+ \text{ or } 2+}$: L-cys (—) and L-smc (------).

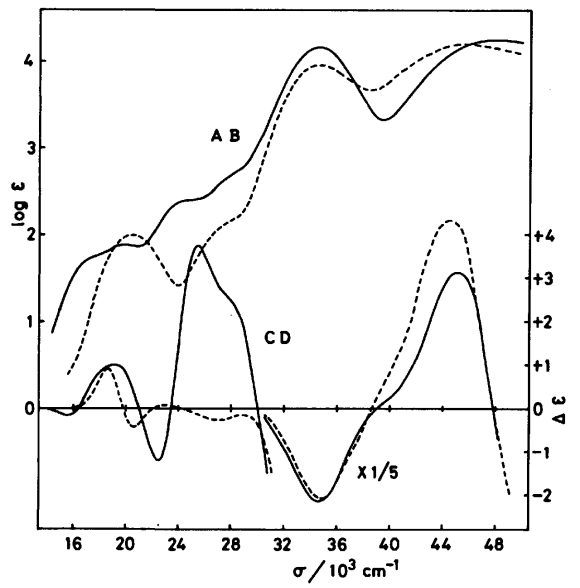

Fig. 4. Absorption and CD spectra of *trans*(N_iS)-[Co(L-cys or L-smc)(dien)]$^{+ \text{ or } 2+}$: L-cys (——) and L-smc (------).

configuration, as in the case of [Co(L-pen)(dien)]$^+$.[7] When the reaction mixture containing [Co(L-cys)(dien)]$^+$ reacted with dimethyl sulfate, two isomers, B-1 and B-2, of [Co(L-smc)(dien)]$^{2+}$ were obtained after the column chromatographic separation. The B-2 isomer showed the identical absorption and CD spectra with *trans*(N_iS)-[Co(L-smc)(dien)]$^{2+}$ (Fig. 4 and Table 3) and the B-1 isomer exhibits quite similar absorption and CD spectra to *trans*(N_iN)-[Co(L-smp)(dien)]$^{2+}$ (Fig. 3 and Table 3), in which the L-smp has a similar framework to the L-smc. This fact seems to indicate that the B-1 isomer has the trans(N_iN) configuration. The formation ratio of the trans(N_iN) and trans(N_iS) isomers was about 1:3 and the two isomers were stable in an aqueous solution. The trans(N_iO) isomer could not be detected. The difference in formation seems to depend on the nitrogen donor atoms, imino and terminal amino nitrogens, in the dien occupying the trans position of the sulfur one in the L-cys.

sh denotes a shoulder.

In the former paper,[7] we assigned the trans(N_iS) and trans(N_iO) configurations for [Co(L-pen)(dien)]$^+$ and [Co(L-smp)(dien)]$^{2+}$ on the basis of the CD spectral patterns of the (diethylenetriamine)cobalt(III) complexes with iminodiacetate, *N*-(carboxylatomethyl)-L-alaninate, and D- or L-aspartate. However, the present assignment for *trans*(N_iS)-[Co(L-cys)(dien)]$^+$ based on the X-ray crystal analysis and the spectral behaviors of the isomers of the derivative, [Co(L-smc)(dien)]$^{2+}$ (Fig. 4), point out that the assignments in the former paper should be reversed.[7]

The ^{1}H NMR spectrum of *trans*(N_iS)-[Co(L-smc)(dien)]$^{2+}$ exhibits two resonance lines at σ=2.18 and 2.35 (intensity ratio; 9.3:1) in the *S*-methyl protons

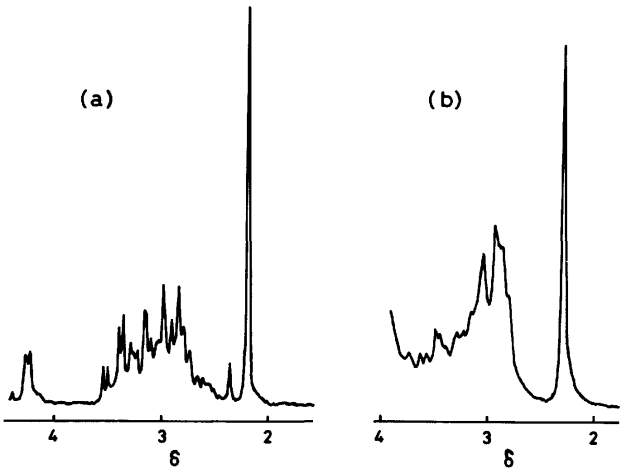

Fig. 5. ^{1}H NMR spectra of $[Co(L\text{-}smc)(dien)]^{2+}$: (a) trans($N_iS$) and (b) trans($N_iN$).

region (Fig. 5). The corresponding resonance lines were also observed for the ^{13}C NMR spectrum at σ=19.8 and 21.8, respectively. For the asymmetric sulfur donor atom, R or S, in the trans(N_iS) isomer, the interligand interaction, which exists between an *S*-methyl group and the amino group of the dien, of the S configuration can be expected to be weaker than that of the R one. The *S*-methyl protons of the S configuration in the trans(N_iS) isomer lies above the carboxyl group, while there is no such steric relation for the *S*-methyl group of the R configuration. Taking account of the model inspections mentioned above and the up field shift due to the methyl group lying above the carboxyl group,[25,26] it is suggested that the major species (2.18 ppm) in the *trans*(N_iS)-$[Co(L\text{-}smc)(dien)]^{2+}$ has the S configuration and the minor one (2.35 ppm) has the R configuration. On the other hand, *trans*(N_iN)-$[Co(L\text{-}smc)(dien)]^{2+}$ exhibits only one resonance line at 2.29 ppm (for ^{1}H NMR) or at 20.69 ppm (for ^{13}C NMR) in the *S*-methyl region (Fig. 5). The model inspection concerning the interligand interaction between the *S*-methyl group and an ethylenediamine moiety in the dien also suggests that the coordinated sulfur atom has only S configuration. These results are in line with the fact that *trans*(N_iN)- and *trans*(N_iS)-$[Co(L\text{-}smp)(dien)]^{2+}$, which exhibit only resonance line in the *S*-methyl protons region, take the S configuration.[7]

The authors wish to express their thanks to Miss Mikako Adachi and Mrs. Yoko Koizumi for their aids in the experiment.

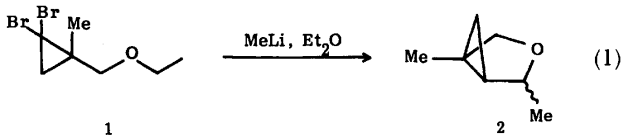
Regio- and Stereoselectivity of the Intramolecular C-H Insertion by Cyclopropylidenes Bearing a Remote Oxido Substituent

Toshiro HARADA, Yasunari YAMAURA, and Akira OKU*
Department of Chemistry, Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto 606
(Received August 14, 1986)

(ω-Oxidoalkyl)cyclopropylidenes generated from (2,2-dibromo-1-methylcyclopropyl)-CH_2-X-$(CH_2)_n$-OH (X=CH_2 or O, n=1, 2) by the reaction with methyllithium underwent a regioselective intramolecular insertion into the C-H bond at the δ position to the carbenic carbon. The activation effect of the oxido substituent on the reactivity of C-H bonds is discussed on the basis of (1) the ratio of the insertion products to the rearrangement product allenyl alcohol, and (2) the endo stereoselectivity of the present insertion reactions.

The intramolecular C-H insertion by carbenes has been utilized as a powerful tool for the construction of highly strained molecules or cage structures which would be otherwise difficult to synthesize.[1] However, due to the lack of regioselectivity, the utilization of carbenic insertion reactions in organic synthesis has been limited only to the cases where the molecular geometry puts a potential insertion site close to the carbenic centers.[2] One of the most promising approaches to the regio-controlled intramolecular insertion in a less stereo-defined system is to activate a specific C-H bond by an adjacent heteroatom, such as oxygen, nitrogen, and sulfur.[3] Recently, we disclosed a novel oxyanionic substituent effect that facilitates the intermolecular insertion by carbenes into the α C-H bond of alkoxides.[4-8] We also showed in the study of ω-oxidoalkyl(phenylthio)carbenes that a regio-controlled intramolecular insertion is made possible by the utilization of the oxyanionic effect.[9,10]

Baird reported a number of substituent effects of oxygen-containing groups on the intramolecular cyclopropylidene insertion reaction.[11] He observed that the treatment of dibromocyclopropane (**1**) with methyllithium gave the regioselective insertion product **2** to the almost complete exclusion of the expected allene derivative 4-ethoxy-3-methyl-1,2-butadiene (Eq. 1).[12] Paquette and Taylor noted,



1 2 (1)

however, that alkoxyl substituents in the norcaranylidene system can either activate or deactivate the adjoining C-H bond toward carbene insertion and that the reactvity depends on the site of the alkoxyl group.[13] In contrast to a number of studies on the effect of neutral oxygen-containing substituents in intramolecular insertion reactions,[3] little is known on the effect of oxyanion. Skattebøl reported an activation effect of oxyanion in his study of the cyclopropylidene bearing an oxido substituent at the β position to the carbenic carbon.[14] The similar effect was also noted recently by Baird et al.[15] In order to investigate the effect of oxido substituents located at more remote positions, we examined the reaction of dibromocyclopropyl alcohols (**6**, **7**, and **8**) with methyllithium.[16]

Results

Preparations of Dibromocyclopropyl Alcohols. Dibromocyclopropyl alcohols (**6**, **7**, and **8**) were prepared by the reaction of the tetrahydropyranyl ethers (**3**, **4**, and **5**) of the corresponding alkenols with dibromocarbene generated under the phase-transfer conditions (Eq. 2). We also attempted a direct cyclopropanation of 2-(2-methyl-2-propenyloxy)ethanol under similar reaction conditions, but the desired dibromocyclopropyl alcohol **7** was obtained only in 7% yield.

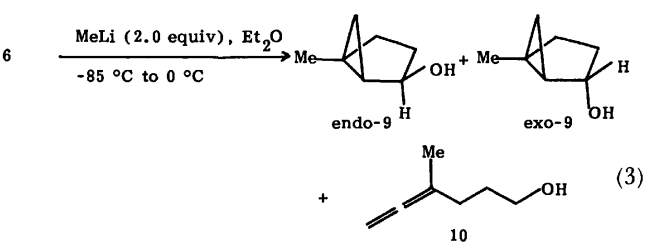
Reaction of Dibromocyclopropyl Alcohols with Methyllithium. The reaction of dibromocyclopropyl alcohol **6** was carried out in ether utilizing 2.0 equiv of methyllithium to give the insertion products (two stereoisomers *endo*-**9** and *exo*-**9**) together with allenyl alcohol **10**[16] in 49% total yield (*endo*-**9**:*exo*-**9**:**10**=44:6:50)(Eq. 3). In order to evaluate the effect of oxido substitution relatively to the effect of alkoxyl substitution, we also performed the reaction of the



(3)

tetrahydropyranyl ether of alcohol **6** under similar reaction conditions. *endo*-**9**, *exo*-**9**, and **10** were obtained in the ratio of 22:18:60 (73% total yield) after the treatment of the reaction mixture with pyridinium *p*-toluenesulfonate (PTS) in ethanol.

In the previous study of ω-oxidoalkyl(phenylthio)-carbenes,[9] we showed that the five- and six-membered ring formation can be achieved by the substitution of an oxido group at the δ and ε position to the carbenic carbon, respectively. We examined the possibility of six-membered ring formation in the reaction of dibromocyclopropyl alcohols **7** and **8** (Eqs. 4 and 5). The reaction of **7** with methyllithium (2.0 equiv) gave exclusively the endo isomer of δ insertion product *endo*-**11** in 54% yield without forming the allene alcohol. On the other hand, the reaction of **8** with methyllithium followed by quenching the reaction mixture with benzoyl chloride gave the endo and exo isomers of insertion product **12** with a low endo selectivity together with the rearrangement product allenyl benzoate **13** (*endo*-**12**:*exo*-**12**:**13**=24:11:65; 59% total yield). Owing to the difficulty in separating the product alcohols, they were isolated and analyzed as benzoate esters in this reaction. In both reactions, the intramolecular insertion proceeded exclusively at the δ position to the carbenic carbon, and six-membered ring formation was not observed.

(5)

Determination of the Structure of Insertion Products. The ^{1}H NMR spectrum of the insertion product obtained in the reaction of **7** (Eq. 4) is consistent with either primary alcohol *endo*-**11** (δ insertion product) or secondary alcohol **14** (ε insertion product). The structure, however, was established unambiguously to be *endo*-5-methyl-3-oxabicyclo-[3.1.0]hexane-2-methanol (*endo*-**11**) by the ^{1}H NMR analysis of acetyl derivative **15**: The number of

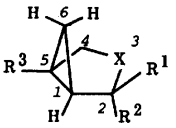

Fig. 1.

Table 1. ^{1}H NMR Coupling Constants between Protons Attached to C(1) and C(2) of Bicyclo[3.1.0]hex-2-yl Derivatives

Compound	endo-Isomer J_{12}/Hz	exo-Isomer J_{12}/Hz
9	4.2	<1
11	2.8	—
12	4.6	<1
16	3.0	<1

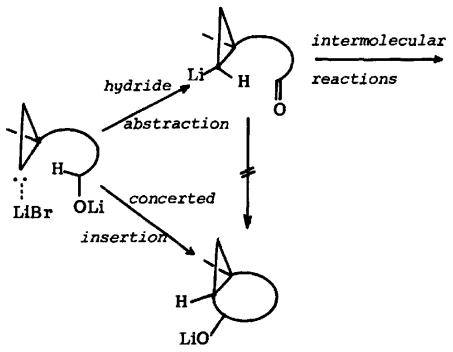
proton(s) whose chemical shift was shifted by acetylation to a lower field (δ 3.95 and 4.2) than the corresponding protons of *endo*-**11** was two.

^{1}H NMR spectrum of the major insertion product *endo*-**9** obtained in the reaction of dibromocyclopropyl alcohol **6** was identical with that reported previously.[17] In other cases endo and exo stereochemistry of the insertion products was determined by the comparison of ^{1}H NMR vicinal coupling constants between protons attached to C(1) and C(2) (Fig. 1); J_{12} values for endo isomers range from 2.8 to 4.6 Hz whereas those for the exo isomers are very small (<1 Hz).[17] In Table 1, these coupling constants are summarized together with those reported for the endo and exo isomers of 3-oxabicyclo[3.1.0]hexane-2-methanol (**16**).[18]

Discussion

In a previous study, we clarified that the mechanism of the intermolecular insertion by norcaranylidene into the α C–H bond of alkoxides is different from the concerted insertion which takes place at the C–H bond adjoining to an alkoxyl group,[8] and we proposed the hydride abstraction-recombination mechanism in the reaction of carbenes with alkoxides.[7,8,10] As shown in Scheme 1, if the intramolecular hydride abstraction by the cyclopropylidene proceeds, the intramolecular recombination step becomes unfavorable due to the anti configuration between the generated cyclopropanide anion and the carbonyl-containing side chain: the anion may be consumed by intermolecular reactions. Since the inversion of cyclopropanide anion under the present reaction conditions is unlikely,[19] we conclude that the intramolecular insertion proceeds via a concerted mechanism.

In the reactions of both dibromocyclopropyl



Scheme 1.

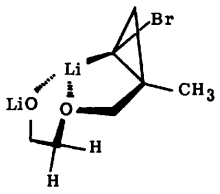


Fig. 2.

alcohol **6** and its tetrahydropyranyl ether with methyllithium, similar ratios of the insertion products to the rearrangement product were observed (Eq. 3). Since the rate of rearrangement to form allenes will not be affected by the oxido group or alkoxyl group located three carbons apart from the cyclopropane ring,[20] these results suggest that the activations by the oxyanion substituent and alkoxyl group are similar in magnitude in the intramolecular insertion by cyclopropylidenes.

It has been known that cyclopropylidenes bearing simple alkyl substituents preferentially undergo the rearrangement to allenes, and when the intramolecular insertion competes with the rearrangement, the insertion generally takes place at the C-H bond β to the carbenoid carbon.[21] Contrastingly, in the present study, the formation of a considerable amount of δ insertion product **12** in the reaction of **8** (Eq. 5) suggests the presence of an activation effect of the adjacent vicinal oxido group which surpasses the other reactions.[22]

It is well-documented in the literature that the cyclopropylidene lithium carbenoids bearing an oxygen-containing substituent at an appropriate position are stabilized by the intramolecular coordination of the oxygen atom with lithium.[23] It has been suggested that the coordination which holds the δ C-H bond in a closer proximity to the carbenic carbon is responsible, at least partly, for the observed efficient insertion of dibromocyclopropyl ether **1** (Eq. 1). As shown in the present study, the reaction of **7** with methyllithium (Eq. 4) which proceeds through the carbenoid intermediate possessing the additional oxido group at the ε position also proceeded efficiently to give *endo*-**11** without forming the allene alcohol. The exclusive formation of the endo isomer can be rationalized by the coordination of two oxygen atoms with lithium on the carbenoid carbon as depicted in Fig. 2. Moreover, the endo selectivity observed in the reaction of dibromocyclopropyl alcohol **6** with methyllithium (product ratio; *endo*-**9**: *exo*-**9**=44:6, Eq. 3) can also be rationalized in terms of the participation of a similar folded conformation of the intermediate carbenoid.

Experimental

Infrared spectra were measured on a JASCO IRA-1 grating spectrophotometer, ^{1}H NMR spectra were recorded on a Varian XL-200 (200 MHz) or a Varian T-60A (60 MHz) spectrometer. Mass spectra were measured on a Hitachi M-80 or a Shimazu QP-1000 mass spectrometer. Silica gel (Wakogel C-300) was used as an adsorbent in flash chromatography. GLC analyses were performed utilizing a capillary column (OV-101, 25 m). Analytically pure products were obtained by preparative GLC (5% OV-17 on Chromosorb W, 0.3×200 cm). Ether and dichloromethane were dried over sodium benzophenone ketyl and CaH_2, respectively, and distilled prior to use. An ethereal solution of methyllithium complexed with lithium bromide (ca. 1.4 mol dm^{-3}) was purchased from Aldrich Chemical Co., and used after titration.

2-(4-Methyl-4-pentenyloxy)tetrahydropyran (3). To a stirred suspension of $LiAlH_4$ (30 mmol) in ether (100 ml) was slowly added ethyl 4-methyl-4-pentenoate (1.66 g, 11.7 mmol) at 0 °C, and the mixture was stirred overnight at a room temperature. Ather the addition of 10% aq HCl followed by the extraction with ethyl acetate, the organic layer was washed with aq $NaHCO_3$, dried over sodium sulfate, and concentrated in vacuo to give the crude alcohol. This was dissolved in CH_2Cl_2 (50 ml), and then 3,4-dihydro-2*H*-pyran (2.52 g, 30.0 mmol) and pyridinium *p*-toluenesulfonate (50 mg) were added at a room temperature. After stirring for 14 h, the reaction mixture was concentrated in vacuo, and the residue was purified by flash chromatography (2% ethyl acetate/petroleum ether) to give 1.82 g (9.91 mmol, 85% yield) of **3**: An oil, IR (neat) 1660, 1150, 1130, 1040, and 890 cm^{-1}.

2-[2-(2-Methyl-2-propenyloxy)ethoxy]tetrahydropyran (4). To a stirred solution of 6.6 g of KOH in ethylene glycol (28 ml) was added 9.76 ml (100 mmol) of 3-chloro-2-methylpropene and the mixture was heated at 100 °C for 7 h. After the addition of water followed by the extraction with ether, the organic layer was dried over sodium sulfate and concentrated in vacuo. The crude material was purified by flash chromatography (30% ethyl acetate/petroleum ether) to give 3.96 g (34 mmol, 34% yield) of 2-(2-methyl-2-propenyloxy)ethanol; an oil, ^{1}H NMR (60 MHz, $CDCl_3$) δ=1.77 (3H, br s, CH_3), 2.57 (1H, br s, OH), 3.53 (2H, m, -C$\underset{\downarrow}{H}_2$O-), 3.73 (2H, m, -$CH_2$O-), 3.97 (2H, br s, =C-$CH_2$-O), and 4.97 (2H, m, CH_2=).

2-(2-Methyl-2-propenyloxy)ethanol (1.00 g 8.61 mmol) was treated with 3,4-dihydro-2*H*-pyran (1.80 g, 21.5 mmol) and

pyridinium *p*-toluenesulfonate (10 mg) in CH_2Cl_2 as described above. A purification by flash chromatography (5% ethyl acetate/petroleum ether) gave **4**: an oil; ^1H NMR (60 MHz, $CDCl_3$) δ=1.2—2.0 (9H, m), 3.4—3.9 (6H, m), 4.65 (1H, m, -OCHO-), and 4.97 (2H, m, CH_2=).

2-(5-Methyl-5-hexenyloxy)tetrahydropyran (5). To the Grignard reagent prepared by the reaction of 2-(4-chlorobutyloxy)tetrahydropyran (10.4 mmol) and Mg (18 mmol) in THF (10 ml) was slowly added a THF solution (10 ml) of acetaldehyde (440 mg, 10 mmol) at 0 °C, and the mixture was stirred at the same temperature for 1 h. After the addition of aq NH_4Cl followed by the extraction with ethyl acetate, the organic layer was washed with aq $NaHCO_3$, dried over sodium sulfate, and concentrated in vacuo to give the crude alcohol, which was dissolved in 5 ml of CH_2Cl_2. To a stirred suspension of pyridinium chlorochromate (3.23 g, 15 mmol) and sodium acetate (205 mg, 2.5 mmol) in CH_2Cl_2 (20 ml) was added the above solution, and the mixture was stirred at a room temperature for 3 h. After the dilution with ether (200 ml) followed by filtration through a short silica-gel column, the reaction mixture was concentrated to give 1.64 g of the crude ketone, which was used without further purification in the next reaction. To a suspension of methyltriphenylphosphonium bromide (3.93 g, 11.0 mmol) in THF (60 ml) was added *t*-BuOK (1.12 g, 10.0 mmol) at a room temperature. After stirring for 1 h, a THF (2 ml) solution of the crude ketone was added to the resulting orange suspension, and the mixture was stirred for 1 h. After the addition of brine followed by the extraction with ether, the organic layer was dried over sodium sulfate and concentrated in vacuo. The crude material was purified by flash chromatography (5% ethyl acetate/petroleum ether) to give 947 mg (4.78 mmol, 46%) of **5**: an oil; ^1H NMR (60 MHz, $CDCl_3$) δ=0.8—2.4 (15H, m), 3.1—4.2 (4H, m), and 4.59 (1H, m, -OCHO-); IR (neat) 1660, 1130, 1085, 1040, and 890 cm^{-1}.

General Procedure for the Preparation of Dibromocyclopropyl Alcohols 6, 7, and 8. A mixture of a THP ether (**3**, **4**, or **5**)(2 mmol), bromoform (2.5 mmol), benzyltriethylammonium chloride (20 mg), and 2 ml of 50% aq NaOH was stirred vigorously at a room temperature for 2 d. After the addition of water followed by extraction with CH_2Cl_2, the organic layer was washed with brine, dried over sodium sulfate, and concentrated in vacuo. The resulting mixture was dissolved in 25 ml of ethanol containing 20 mg of pyridinium *p*-toluenesulfonate, and the solution was heated at 60 °C for several hours. After removing ethanol in vacuo at a room temperature, the residue was subjected to flash chromatography (10—20% ethyl acetate/petroleum ether) to give the dibromocyclopropyl alcohol (**6**, **7**, or **8**).

3-(2,2-Dibromo-1-methylcyclopropyl)-1-propanol (6): An oil; ^1H NMR (60 MHz, $CDCl_3$) δ=1.40 (3H, s, CH_3), 1.55 (3H, m), 1.80 (4H, m), and 3.70 (2H, m, CH_2-OH); IR (neat) 3360, 1060, and 695 cm^{-1}.

2-[(2,2-Dibromo-1-methylcyclopropyl)methoxy]ethanol (7): An oil; ^1H NMR (60 MHz, $CDCl_3$) δ=1.50 (3H, s, CH_3), 1.6 (2H, m), 2.13 (1H, br s, OH), and 3.4—3.9 (6H, m); IR (neat) 3400, 1130, 1070, and 695 cm^{-1}.

4-(2,2-Dibromo-1-methylcyclopropyl)-1-butanol (8): An oil; ^1H NMR (60 MHz, $CDCl_3$) δ=1.37 (3H, s, CH), 1.43 (2H, m), 1.6 (6H, m), 2.25 (1H, m, OH), and 3.65 (2H, m, CH_2OH); IR (neat) 1660, 1130, 1085, 1040, and 890 cm^{-1}.

General Procedure for the Intramolecular Reaction of Dibromocyclopropyl Alcohols 6, 7, and 8. To a solution of a dibromocyclopropyl alcohol (**6**, **7**, or **8**)(1.0 mmol) in dry ether (5 ml) was slowly added methyllithium (ether solution, 2.0 mmol) at −85 °C under a nitrogen atmophere. The reaction mixture was gradually warmed up to 0 °C over a period of 5 h, and quenched by the addition of water. After the extraction with ether, the organic layer was dried over sodium sulfate, and concentrated in vacuo. After a capillary GLC analysis, the residual oil was subjected to flash chromatography (ethyl acetate/petroleum ether) to give a mixture of intramolecular insertion products and the allenyl alcohol. Analytically pure products were obtained after purification by preparative GLC. In the reaction of **8**, the reaction mixture was quenched by addition of benzoyl chloride (1.2 mmol) at 0 °C, and then stirred further for 14 h at a room temperature. By the similar workup procedure, a mixture of the benzoate ester of the insertion product *endo*-**12** and *exo*-**12**, and allenyl alcohol **13** was obtained.

(Received August 20, 1986)

The chemo-selectivity of group-VIII metal catalysts has been examined in the hydrogenation of nonconjugated enones at ambient temperature under an atmospheric pressure of hydrogen. A cobalt catalyst gave high yields of unsaturated alcohols from trialkylated olefinic ketones. Osmium showed the highest selectivity among platinum metal catalysts for the reduction of the carbonyl bond in the hydrogenation of trialkylated olefinic ketones. The hydrogenation of mono- and dialkylated olefinic ketone ordinarily proceeded with a preferential saturation of the olefinic function, regardless of the catalyst. The hydrogenation of 4-methylene- and 4-ethylidenecyclohexanone was accompanied by the formation of diethyl acetals over ruthenium, rhodium, and palladium black catalysts in an ethanol solvent. The acetals were not detected in the hydrogenation of the other enones and over the other catalysts. In addition, the chemoselectivity on the hydrogenation of acyclic enones was examined over nickel and cobalt catalysts treated with small amounts of alkali and carbon monoxide. The amount of unsaturated alcohols increased when the catalyst was treated with alkali in the case of di- and trialkylated olefinic ketones, whereas the characteristics of cobalt, which selectively reduces the ketonic function in trialkylated olefinic ketones, were completely missing when cobalt was treated with carbon monoxide.

Selective catalytic hydrogenation of nonconjugated enones to the corresponding saturated ketones is achieved easily;[2] however, a selective reduction to afford unsaturated alcohols is a formidable task. This type of compound is usually prepared from a nonconjugated enone by a non-catalytic route. However, it has also been reported that in some structural features the catalyst may have a marked effect on chemo-selectivity.[3] The ketonic function in hexahydronaphthalenedione system was reduced over Ru-on-carbon in preference to the double bond.[4] France et al. reported the preferential reduction of carbonyls in an octahydronaphthalenedione system over platinum oxide in ethanol and the preferential saturation of the double bonds over Pd-on-carbon.[5] Nishimura et al. have reported that 17-oxo group is extensively reduced in preference to Δ^5 unsaturation over unsupported osmium and ruthenium blacks in the hydrogenation of 3-hydroxyandrost-5-en-17-one (dehydroepiandrosterone).[6]

Those available data are, however, insufficient for applications to the selective reduction of the ketonic or olefinic group in unsaturated ketones; little is known about the consistent study concerning the selectivity of group-VIII metal catalysts in the hydrogenation of nonconjugated enones. Recently, we examined the catalytic hydrogenation of 7-methylenebicyclo[3.3.1]nonan-3-one (**1**) and 7-methylbicyclo[3.3.1]non-6-en-3-one (**2**) over group-VIII metals.[7,8] The olefinic bond was selectively reduced to afford 7-endo-methylbicyclo[3.3.1]nonan-3-one (**2A**) over ruthenium, rhodium, and platinum catalysts, whereas the olefinic one remained intact during the reduction of the ketone to give 6-methylbicyclo[3.3.1]-non-6-en-3-endo-ol (**2B**) exclusively in the hydrogenation of **2** over a cobalt catalyst. Hydrogenation over nickel, osmium, and iridium catalysts gave mixtures of **2A** and **2B**.

Therefore, it seems of interest to more precisely study the differences for chemo-selectivity of group-VIII transition metal catalysts by an examination of the hydrogenation of simple nonconjugated aliphatic enones in comparison with their behavior under the same experimental conditions as that of **1** and **2**. The substrates which were chosen comprised the acyclic (5-hexen-2-one: **3**, 5-methyl-5-hexen-2-one: **4**, (*E*) or (*Z*)-5-hepten-2-one: **5**, 6-methyl-5-hepten-2-one: **6**) and alicyclic (4-methylenecyclohexanone: **7**, 4-ethylidenecyclohexanone: **8**) nonconjugated enones. In addition, the chemo-selectivities of the hydrogenation of **3**, **5**, and **6** were also examined using nickel and cobalt catalysts treated with small amounts of alkali and carbon monoxide.

Results and Discussion

Since the reaction of a substrate with a solvent over metal catalysts occurs because of the reactivity of the carbonyl and hydroxy functions when methanol or ethanol is used as a solvent for ketone hydrogenation,[9] the chemo-selectivity of group-VIII metal catalysts in the hydrogenation of nonconjugated enones was examined in a cyclohexane solvent at ambient temperature and approximately atmospheric pressure. Cobalt and nickel catalysts were prepared from Raney alloys using a W-4 method[10] or by reducing the corresponding metal oxides, and platinum metal catalysts by reducing the corresponding metal oxides or hydroxides.[11] The products are saturated ketone (**A**), unsaturated alcohol (**B**), and

saturated alcohol (**C**).

Although the hydrogenation of all substrates used here showed chemo-selectively the saturated ketones over ruthenium, rhodium, palladium,[12] platinum, and iridium[13] catalysts, osmium catalyst showed different chemo-selectivities from that of other platinum metals. Osmium gave unsaturated alcohols together with saturated ketones and saturated alcohols in the hydrogenation of trialkylated ones (**2**, **6**, and **8**). A nickel catalyst showed a similar chemo-selectivity to osmium. The initial chemo-selectivity for unsaturated alcohols of osmium and nickel catalysts are listed in Table 1. Since hydrogenation products increased linearly until 50% of reaction conversion of the substrates, the values shown in Tables give the initial chemo-selectivity of catalysts at 50% conversion. Cobalt catalysts gave high yields of unsaturated alcohols from trialkylated olefinic ketones, and **2B**, 6-methyl-5-hepten-2-ol (**6B**), and 4-ethylidenecyclohexanol (**8B**) were exclusively produced (Table 2).

Table 1. Initial Selectivity for Unsaturated Alcohol(**B**) of Osmium and Nickel Catalysts[a]

1, **3**, **4**, **5**, **7**	0	0
2	0.24	(0.26)[e]
6	0.15	0.05
8	0.24	0.45

a) Substrate, 0.5 mmol; solvent(cyclohexane), 5 ml. Enones were hydrogenated at ambient temperature under atomospheric pressure. Values are the ratio when 50% of substrate was consumed. b) **A**=Saturated ketone, **B**=unsaturated alcohol, **C**=saturated alcohol. Selectivity for the formation of unsaturated alcohol to all products. c) A 5 mg of catalyst was used. d) A weighed sample of catalyst (500 mg for Raney Ni under wet conditions; 200 mg as NiO for Ni-black) was used. e) Value in parentheses indicates the product ratio over Ni-black catalyst.

Table 2. Hydrogenation of Enones over Cobalt Catalyst[a]

Enone	Product[b]/mol%		
	A	**B**	**C**
1	(64)[c]	(0)	(4)
2	(0)	(100)	(0)
3	100	0	0
4	50	8	42
5	34	12	54
6	0	100	0
7	56(56)	22(44)	22(0)
8	0(0)	100(100)	t[d] (0)

a) See footnote a in Table 1 except for the weight of catalyst. A weighed sample of catalyst (500 mg for Raney Co under wet conditions; 1000 mg as CoO for Co-black) was used. Values in parentheses indicate the product ratios over Co-black catalyst. b) See footnote b in Table 1. c) 1-Adamantanol (26%) and 1-methyl-2-oxa-adamantane (6%) were also detected. d) Trace.

The hydrogenation of **1** and **2** was examined over a variety of group-VIII transition metals in order to evaluate how an intramolecular orbital interaction operates regarding the selectivity of an addition reaction.[7,8,14] Different selectivities were observed depending on the catalysts used in the hydrogenation of **1** and **2**. A novel reductive cyclization occurred to give 1-adamantanol (**2E**) over cobalt, nickel, rhodium, and palladium catalysis in the hydrogenation of **1**,[7] and to give selectively **2E** over palladium in the hydrogenation of **2**.[8] However, reductive cyclization could not be observed in the hydrogenation of acyclic nonconjugated enones (**5** and **6**). We envisage that the proximity between two π-orbitals is closely associated with the formation of reductive cyclization products.[15]

Figure 1 shows the product ratios of unsaturated alcohols (**2B**, **6B**, **7B**, and **8B**) when 50% of the enones were consumed over cobalt, nickel, and osmium catalysts. The high-selectivity to the unsaturated alcohol formation was observed when a carbonyl moiety was associated with a relative hindered olefinic bond. In the case of trialkylated olefinic ketones (**2**, **6**, and **8**), the unsaturated alcohols (**2B**, **6B**, and **8B**) were exclusively produced over cobalt catalyst; however, the formation of **7B** decreased to 22% yield in the case of dialkylated olefinic ketone (**7**). These results show that the reactivity of the carbonyl moiety over cobalt is a little lower than the dialkyl-substituted olefins but is much higher than the trialkyl-substituted ones in nonconjugated enones. This trend was also observed over nickel and osmium catalysts. The hydrogenation

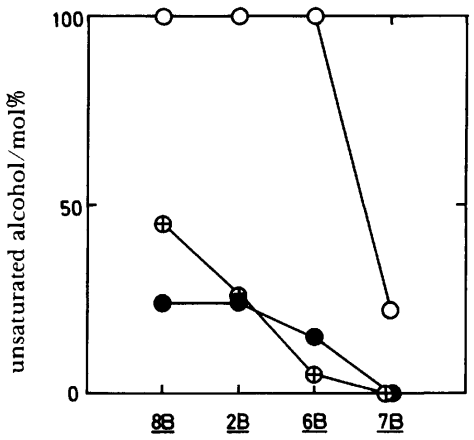

Fig. 1. Product ratios of unsaturated alcohols (**2B**, **6B**, **7B**, **and 8B**) when 50% of substrates were consumed over Co, Ni, and Os catalysts. ○: Co, ⊕: Ni, ●: Os.

of **2**, **6**, and **8** gave 5—45% of **B** over those catalysts, while **7B** was rarely formed in that of **7**. An osmium catalyst showed the highest selectivity for the reduction of the carbonyl bond in platinum metals. Osmium might be expected to be the most suited for reducing the carbonyl function of nonconjugated enones among the platinum metats in this sense.

The selectivity of the reduction of trialkylated olefinic ketones to unsaturated alcohols declined in the series Co≫Ni, Os≫Ir, Ru, Rh, Pd, Pt. This tendency may be attributed to the fact that nickel, osmium, and especially cobalt catalysts have a stronger affinity for the carbonyl moiety than the other catalysts.[16] It is important in organic syntheses that the unsaturated alochol is selectively obtained from trialkylated olefinic ketones during hydrogenation over a cobalt catalyst. The hydrogenation of **2**, **6**, and **8** over cobalt gave those corresponding unsaturated alcohols in 98% yield after absorption of one equivalent of hydrogen. A Raney cobalt catalyst was also remarkably chemoselective in the competitive hydrogenation of a mixture of 6-methyl-2-heptanone (**6A**) and 6-methyl-5-hepten-2-ol (**6B**). The carbonyl moiety of **6A** was completely reduced before the double bond of **6B** was saturated, whereas **6A** and **6B** were converted with a comparable rate over a Raney nickel catalyst (Fig. 2).

Hydrogenations were also carried out in an ethanol solvent. Although the proportion of saturated alcohols decreased according to the catalysts used, the chemo-selectivity of metal catalysts in ethanol showed a similar trend of that in cyclohexane as a whole. Diethyl acetals were rapidly formed in addition to the hydrogenated products by the use of **7** and **8** as nonconjugated enones over ruthenium, rhodium, and palladium catalysts in ethanol. The acetals were a mixture of 4-alkylidenecyclohexanone diethyl acetal (**F**), 4-alkyl-3-cyclohexenone diethyl acetal (**G**), 4-alkylcyclohexanone diethyl acetal (**H**) (Fig. 3). The acetal formation relative to the hydrogenation increased in the order Rh<Ru<Pd. Those were not detected at all during the hydrogenation of the other enones, and were not observed over the other catalysts.

Since **7** and **8**, which have olefinic and carbonyl functions at 1 and 4 positions on a cyclohexane ring, take a rigid and flat chair conformation compared with the other simple nonconjugated enones, it is suggested that the neighborhood of the carbonyl moieties of **7** and **8** is hindered less sterically than that of the other enones. The effect of such steric factors is associated with the formation of diethyl acetals. 4-Ethylidenecyclohexanone diethyl acetal (**8F**) is found to be the most abundant among acetals in the hydrogenation of **8**; it is contemplated that acetal formation occurs faster than a reduction of the olefin. The varying composition of the reaction mixture at the initial stage of the hydrogenation over a Pd catalyst in ethanol is shown in Fig. 4 as an example. Palladium, rhodium, and ruthenium catalysts are the ones which efficiently hydrogenate olefins. It is,

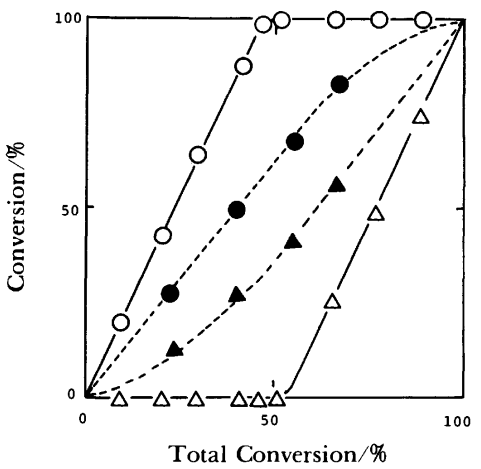

Fig. 2. Conversion of 6-methyl-2-heptanone (**6A**: ○, ●) and 6-methyl-5-hepten-2-ol (**6B**: △, ▲) versus total conversion. Raney Co (○, △: ——), Raney Ni (●, ▲: ------).

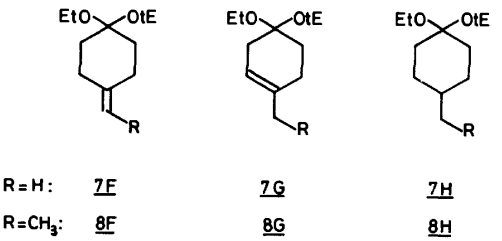

Fig. 3

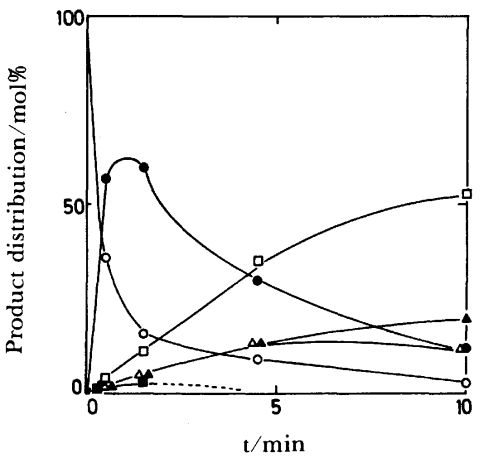

Fig. 4. Product distribution in hydrogenation of 4-ethylidenecyclohexanone (**8**) over Pd catalyst in ethanol. ○: **8**, ▲: 4-ethylcyclohexanone (**8B**), ■: 4-ethyl-3-cyclohexenone (**8D**), ●: 4-ethylidenecyclohexanone diethyl acetal (**8F**), △: 4-ethyl-3-cyclohexenone diethyl acetal (**8G**), □: 4-ethylcyclohexanone diethyl acetal (**8H**).

nevertheless, interesting that the formation of the acetal occurs faster than the hydrogenation of the olefin. Acetal formation is an acid-catalyzed reaction; therefore it may be considered that palladium, rhodium, and ruthenium black catalysts tend to have ionized hydrogens on the surfaces of these metals.[9]

In anticipation of a more preferential reduction of the ketone group of the nonconjugated enones, we also examined the hydrogenation of **5** and **6** over Raney nickel, cobalt, and cobalt black catalysts treated with alkali and carbon monoxide (Table 3). Selectivity to the unsaturated alcohols varied greatly with the additives over cobalt and nickel catalysts. When the catalysts were treated with alkali, the amount of **5B** over Raney cobalt and of **6B** over Raney nickel increased compared with that over the untreated catalysts, respectively. However, the treatment of carbon monoxide for catalysts indicated an opposite and marked effect to that of alkali. The double bond of **6** was selectively reduced to give **6A** over Raney nickel treated with carbon monoxide. When cobalt was treated with carbon monoxide in the hydrogenation of **6**, the characteristics of cobalt, which proceed with the preferential reduction of the ketone group, was completely missing.

Since alkali has a promoting effect on the ketone reduction, the hydrogenation of **3** was examined over Raney cobalt and nickel catalysts which were treated with sodium and potassium hydroxides. However, the chemo-selectivity for **3** was not altered by the treatment of alkali. Gradeff and Formica achieved a preferential reduction of the ketone group in trialkylated olefinic ketones. They have obtained the corresponding unsaturated alcohol using a chromium-promoted Raney nickel catalyst in the presence of a strong inorganic base, triethylamine, and small amounts of water in methanol solvents.[17] The amounts of **5B** and **6B** increased similarly to the results of Gradeff and Formica when the catalysts were treated with alkali (Table 3). The function of alkali in the promotion on the ketone reduction is not always obvious. It may increase the enol content, or change the product-determining step by altering the adsorbability of the substrate.[18]

Table 3. Effect of Modification of Cobalt and Nickel Catalysts in Hydrogenation of Enones **5** and **6**[a]

Enone	Catalyst	Modification (mmol)	Product[b]/mol%		
			A	**B**	**C**
5	Co	——	61	22	17
	Co	NaOH (1)[c]	59	30	11
	Co	KOH (1)	42	42	16
	Ni	——	100	0	0
6	Co	——	(2)[d]	(96)	(2)
	Co	NaOH (0.1)[e]	(0)	(100)	(0)
	Co	CO (0.001)	(100)	(0)	(0)
	Ni	——	61	10	29
	Ni	NaOH (0.1)	34	37	29
	Ni	NaOH (1)	6	88	6
	Ni	NaOH (2)	5	74	21
	Ni	Reflux (CO)[f]	94	2	4

a) Substrate, 0.5 mmol; Raney Ni and Co, 500 mg; Co-black, 1000 mg; Solvent(ethanol), 5 ml. Values are the composition (mol.%) 50% of substrate was consumed. Enones were hydrogenated in ethanol in terms of modification of catalyst. b) See footnote b in Table 1. c) Added ca. 60% solution of NaOH or KOH in water then stirred for 0.5 h at ambient temperature under hydrogen atmosphere. d) Values in parentheses indicate the product ratios over Co-black catalyst. e) Introduced CO, then stirred under the same conditions as alkali. f) Refluxed in ethanol for 2 h under nitrogen atmosphere; when Ni is refluxed in ethanol, CO is adsorbed over catalyst.

Carbon monoxide has no promoting effect on ketone reduction, and the apparent rate of the hydrogenation over a catalyst treated with carbon monoxide decreases compared to an unmodified catalyst. When Raney nickel refluxed in ethanol was used in the hydrogenation of **6**, **6A** increased in a similar manner as a cobalt catalyst treated with carbon monoxide. Ethanol is decomposed to carbon monoxide and methane by refluxing over Raney nickel.[19] It has been known that the amount of the adsorbed hydrogen on nickel pretreated with carbon monoxide is larger than that on an unpoisoned catalyst.[20] Similarly, the adsorption of pyridine on nickel-silica can be promoted if nickel is pretreated with carbon monoxide.[21] Sheets and Hansen considered that if a strong electron withdrawing species like carbon monoxide is already present on the surface of a catalyst, the formation of a coordinated pyridine can be promoted owing to the electron defficiency of the catalyst surface.[22] This suggests that the absorbed state on cobalt and nickel catalysts treated with carbon monoxide is different from that on untreated ones; it may be responsible for the disappearance of the characteristics proceeding with the preferential reduction of the ketone group.

Experimental

All boiling points are uncorrected. ^{1}H and ^{13}C NMR spectra were obtained with either a JEOL JNM-MH100 or a JEOL-JNM-FX100 spectrometer. The frequency was 100 MHz for ^{1}H NMR and 25 MHz for ^{13}C NMR spectra. All IR spectra were obtained with a JASCO A-3 spectrometer as neat samples. Mass spectra were taken at 70 eV on a JEOL JMS-D300 GC/MS spectrometer.

Materials. 5-Hexen-2-one (**3**) and 6-methyl-5-hepten-2-one (**6**) were commercially available: **3** and **6** were obtained from Tokyo Kasei Kogyo and used after distillation: **3**, bp 126 °C/755 mmHg (1 mmHg=133.322 Pa); **6**, bp 73 °C/18 mmHg. The preparation of 5-methyl-5-hexen-2-one (**4**) is described hereinafter. By use of the method of Jones and Sondheimer,[23] 25 g of 2,5-hexanediol, 164 ml of dry

pyridine, 84 g of benzoyl chloride, and 400 ml of dry chloroform gave a 48% yield of 2,5-hexanediol monobenzoate: bp 143—147 °C/1.8 mmHg. The monobenzoate (44.4 g) was oxygenized by pyridinium chlorochromate (PCC) in dichloromethane,[24] affording a 79% yield of 5-benzoyloxy-2-hexanone: bp 130 °C/0.65 mmHg; IR (neat) 1720 (s), 1605 (w), 1590 (w), 1495 (w), 1455 (w), 1320 (m), 1280 (s), 1030 (m), 715 (s). 5-Benzoyloxy-2-methyl-1-hexene was prepared by the Wittig reaction of 5-benzoyloxy-2-hexanone using methylsulfinylmethanide (yield: 70%),[25] a following hydrolysis gave a 50% yield of 5-methyl-5-hexen-2-ol (**4B**). 5-Benzoyloxy-2-methyl-1-hexene: bp 150—155 °C/20 mmHg; IR (neat) 1720 (s), 1650 (w), 1600 (w), 1585 (w), 1450 (m), 1315 (m), 1275 (s), 1115 (m), 1030 (m), 890 (m), 710 (s). **4B**: bp 68—69 °C/20 mmHg; IR (neat) 3350 (s, br), 1650 (m), 1378 (m), 890 (m). A 70% yield of **4** was obtained by the oxidation of **4B** using PCC. **4**: bp 60—62 °C/20 mmHg; IR (neat) 1720 (s), 1660 (m), 1360 (m), 1162 (m), 895 (m); ^{1}H NMR ($CDCl_3$) δ=1.72 (3H, s), 2.15 (3H, s), 2.40 (4H, m), 4.69 (2H, dd); ^{13}C NMR ($CDCl_3$) δ=22.57, 29.77, 31.59, 41.86, 110.17, 144.34, 207.92; MS *m/z* 112 (M^+, 13), 97 (42), 69 (81), 55 (28), 43 (100), 41 (98) 39 (35), 28 (25). Found: C, 74.90; H, 10.81. Calcd for $C_7H_{12}O$: C, 74.95; H, 10.78.

5-Hepten-2-one (**5**) was prepared by the method of Schechter, Green, and LaForge.[26] **5** was a mixture of cis and trans isomers (cis:trans=14:86). **5**: bp 140—150 °C/755 mmHg (yield: 54%); IR (neat) 1720 (s), 1360 (m), 1165 (m), 980 (m); ^{13}C NMR ($CDCl_3$, trans isomer) δ=17.85, 26.89, 29.88, 43.50, 125.81, 129.51, 208.18; MS *m/z* 112 (M^+, 50), 97 (43), 69 (46), 58 (36), 55 (68), 43 (100), 41 (98), 39 (44), 28 (36).

4-Methylenecyclohexanone (**7**) and 4-ethylidenecyclohexanone (**8**) were prepared by a modification of the synthetic method of **4**.[23-25] **7**: bp 65 °C/27 mmHg; IR (neat) 1720 (s), 1650 (w), 1440 (m), 1142 (m), 900 (m), 792 (w); ^{1}H NMR ($CDCl_3$) δ=2.48 (8H, bs), 4.89 (2H, s); ^{13}C NMR ($CDCl_3$) δ=33.14, 41.57, 110.73, 144.34, 210.65; MS *m/z* 110 (M^+, 100), 82 (85), 81 (71), 68 (51), 55 (38), 54 (98), 53 (61), 41 (48), 40 (31), 39 (82), 28 (62). Found: C, 76.53; H, 9.21. Calcd for $C_7H_{10}O$: C, 76.32; H, 9.15. **7B**: bp 78 °C/16 mmHg; IR (neat) 3350 (s. br), 1650 (m), 1070 (m), 895 (m); ^{13}C NMR ($CDCl_3$) δ=31.88, 35.87, 68.98, 107.70, 147.74. **8**: bp 78 °C/20 mmHg; IR (neat) 1720 (s), 1442 (m), 1150 (m), 950 (w), 825 (w), 780 (w), 700 (w); ^{1}H NMR ($CDCl_3$) δ=1.65 (3H, d), 2.43 (8H, bs), 5.41 (1H, q); ^{13}C NMR ($CDCl_3$) δ=13.12, 25.77, 34.14, 40.69, 41.77, 119.36, 134.50, 211.73; MS *m/z* 124 (M^+, 87), 82 (39), 81 (35), 68 (27), 67 (100), 54 (37), 41 (32), 39 (38), 28 (26). Found: C, 77.41; H, 9.74. Calcd for $C_8H_{12}O$: C, 77.37; H, 9.74. **8B**: bp 83—87 °C/14 mmHg: ^{13}C NMR ($CDCl_3$) δ=12.83, 24.57, 33.47, 35.40, 36.40, 69.89, 116.33, 137.70; MS *m/z* 126 (M^+, 7), 108 (50), 93 (79), 79 (100), 67 (38), 41 (32), 39 (26).

Catalysts. Unsupported metal catalysts were prepared by reducing the corresponding metal hydroxides (Ru, Rh, Pd, Ir) or oxides (Pt, Os) with hydrogen in water at atmospheric or elevated pressure using a method which is similar to that described by Nishimura[27] and Tanaka.[11] Care was taken to removal alkaline or acidic impurities with reductions and washings. W-4 Raney Ni and Co were prepared as described earlier.[10] Reduced Ni and Co were prepared by the reduction of NiO and CoO which were obtained from $Ni(NO_3)_2$ and $Co(NO_3)_2$ in hydrogen atmosphere at 350 °C.

Hydrogenation. All hydrogenations were carried out in a 50 ml round glass bottle with a silicone rubber stopper at room temperature (20—25 °C) and approximately atmospheric pressure (1—1.05 atm). A high purity hydrogen gas was used without further purification. In the reaction vessel a weighed sample of catalyst (5 mg for noble metals; 500 mg for Raney Ni and Co under wet conditions; 200 mg as NiO for Ni-black; 1000 mg as CoO for Co-black) was placed along with 5 ml of purified cyclohexane or 99% ethanol, and then the vessel was flushed with hydrogen. The catalyst was stirred magnetically with hydrogen in a solvent for 0.5—1 h; the substrate (0.5 mmol) to be hydrogenated was then added with a microsyringe through a silicone rubber stopper.

Product Analysis. The reaction was followed volumetrically by measuring the hyrogen consumption and also followed gas-chromatographically by analyzing aliquots of the reaction mixture at appropriate time intervals. The reaction mixture was taken into a microsyringe through the silicone rubber stopper during the course of hydrogenation. The gas chromatography was performed on Hitachi F-6 and 164 instruments equipped with a flame ionization detector using nitrogen as the carrier gas. The products were analyzed on a 45 m×0.25 mm Goley column of PEG 400 at 60 °C for **3**, and on a 45 m×0.25 mm Goley column of PEG 4000 at 80—90 °C for **4**, **5**, and **6** or at 120—140 °C for **7** and **8**. The peaks were identified by a comparison of their retention times with those of authentic samples.

(Received August 27, 1986)

A versatile chiral compound, (1*R*,6*R*,8*R*,9*R*)-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]non-4-en-3-one (**6**), was efficiently synthesized from D-glucose. The synthesis featured an intramolecular aldol cyclization of 3-*C*-acetylmethyl-3-deoxy-1,2-*O*-isopropylidene-α-D-*ribo*-pentodialdo-1,4-furanose, which was readily derivatized from the known Wittig adducts of 1,2:5,6-di-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose. The utility of this highly functionalized chiral synthon **6** was embodied by conversion to four optically active pseudo-sugars, these are pentaacetyl derivatives of pseudo-α-L-altropyranose, pseudo-β-D-glucopyranose, pseudo-2-amino-2-deoxy-β-L-altropyranose, and pseudo-2-amino-2-deoxy-α-D-glucopyranose (a derivative of pseudo-glucosamine). The transformation of **6** to the pseudo sugars involved 1) a stereospecific epoxidation of the double bond in **6** providing (1*R*,4*S*,5*S*,6*S*,8*R*,9*R*)-4,5-epoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]-nonan-3-one (**8**), and 2) an exclusive diaxial ring opening of the β-epoxy alcohols, which were derived from **8**, providing (1*R*,3*R*,4*S*,5*S*,6*S*,8*R*,9*R*)-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane-3,4,5-triol (**11**) or (1*R*,3*S*,4*S*,5*R*,6*S*,8*R*,9*R*)-4-azido-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane-3,5-diol. Treatment of (1*R*,2*S*,3*S*,4*S*,5*R*)-3,4,5-tris(benzyloxy)-2-hydroxycyclohexanecarbaldehyde, which was derived from **11**, with methanesulfonyl chloride, and successive sodium borohydride reduction provided (3*S*,4*S*,5*R*)-3,4,5-tris(benzyloxy)-1-cyclohexene-1-methanol (**19**). Hydroboration of **19** proceeded from the less hindered side stereoselectively.

1-Hydroxymethyl-2,3,4,5-cyclohexanetetrols, known as "pseudo-sugars," may be regarded as carbocyclic analogues of carbohydrates (mainly, hexopyranoses). They are of current interest in the field of biological chemistry. The pseudo-sugars are found in partial components of antibiotics (validamycins) and enzyme inhibitors (adiposins).[1] In addition to the biological studies, the synthesis of pseudo-sugars is also of current interest. Several approaches directed toward optically active pseudo-sugars synthesis have appeared in the literatures. Ogawa and Suami demonstrated the preparation of the optically active *endo*-7-oxabicyclo[2.2.1]hept-5-ene-2-carboxylic acid, a common intermediate for the synthesis of pseudo-sugars, by optical resolution of the Diels-Alder adduct of furan and acrylic acid.[2] Paulsen and Heiker reported the synthesis of chiral valienamine, a component of validamycin type antibiotics, from quebrachitol (2-*O*-methyl-L-chiroinositol).[3] Paulsen and co-workers also successfully transformed the L-chiroinositol, which was derived from quebrachitol, to pseudo-α-D-galactopyranose and pseudo-β-D-mannopyranose.[4] In connection with the synthesis of prostaglandins employing carbohydrates as chiral starting materials, Ferrier and co-workers extensively pursued chiral cyclopentanoids and cyclohexanoids syntheses. The remarkable strategy developed by their group was the mercury(II)-promoted intramolecular cyclization of the 5,6-unsaturated hexopyranose derivative to the optically active polyhydroxylated cyclohexanone.[5] Applying Ferrier's strategy, Kuzuhara and Sugawara achieved the synthesis of aminocyclitol-containing pseudo-disaccharides by the partial conversion of maltose into cyclohexane derivatives.[6] Recently, Wilcox and co-workers realized an elegant approach towards an optically active carbocycle synthesis. This featured "the radical cyclization" of unsaturated halo sugars.[7] Carbocyclic analogues of D-fructofuranose (pseudo-D-fructofuranose) and D-fructofuranose 6-phosphate were synthesized by this radical cyclization strategy.[8]

In our continuing research on the synthesis of optically active carbocyclic compounds and pseudo-sugars from carbohydrates,[9] we wish to describe herein a novel and utilizable approach directed toward synthesis of pseudo-hexopyranoses.[10] The new approach features an efficient access to the versatile chiral synthon **6** from the readily available **5** by an intramolecular aldol cyclization, and a stereoselective introduction of a triol or an azido diol system on the 2-cyclohexenone moiety of **6** providing the compounds **11** and **22**. From compounds **11** and **22**, four pseudo-hexopyranoses were synthesized in acceptable overall yields.

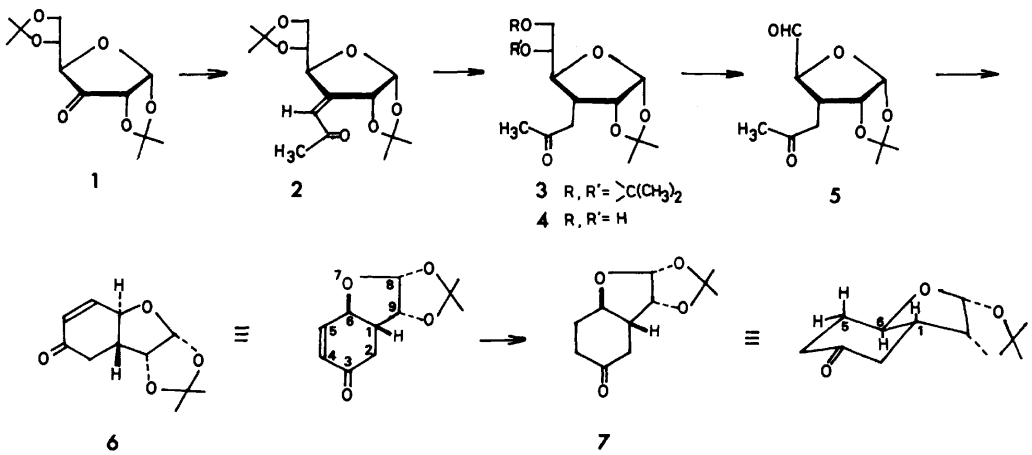
Results and Discussion

Synthesis of the Chiral Synthon 6 from D-Glucose (Scheme 1). 1,2:5,6-Di-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose (**1**) was subjected to Wittig olefination with (acetylmethylene)triphenylphosphorane in refluxing benzene according to the literature.[11] This provided an approximately 3 to 1 [(*Z*) to (*E*)] geometrical mixture of the adduct **2** in 96% yield.

Hydrogenation of the mixture **2** in the presence of Raney nickel furnished a diastereomeric mixture of the 3-*C*-(2-hydroxypropyl) derivative. This was directly oxidized with pyridinium chlorochromate (PCC) to provide 3-*C*-acetylmethyl-3-deoxy-1,2:5,6-di-*O*-isopropylidene-α-D-allofuranose (**3**) as crystals in 88% yield. As expected, based on the result of the hydrogenation of the corresponding 3-*C*-methylene derivative,[12] the hydrogenation of **2** proceeded from the β-side to give the α-D-allo derivative **3** exclusively. In the initial stage of the hydrogenation, the presence of **3** was detected in the reaction mixture. However, the compound **3** was rapidly converted to over-hydrogenated products. Selective hydrolysis of the 5,6-*O*-isopropylidene group in **3** with 60% aqueous acetic acid afforded compound **4** in 98% yield. The glycol cleavage of **4** by an aqueous sodium periodate solution gave a 5-aldehyde **5** quantitatively, which was subjected to the next aldol cyclization without purification. The crucial aldol cyclization of **5** to the synthon **6** was examined under the following conditions; 1) with sodium methoxide in methanol; 2) in 1 mol dm^{-3} aqueous NaOH; 3) with triethylamine in refluxing benzene; 4) lithium diisopropylamide (LDA) in THF from −78 to 0 °C; 5) with sodium hydride in refluxing benzene; 6) with BF_3–Et_2O in CH_2Cl_2. None of these reactions gave compound **6** in a practical yield. However, we found finally that 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) was an effective base for the cyclization. By refluxing **5** in benzene in the presence of 0.05 molar equivalent of DBU for 35 h followed by an acetic anhydride–pyridine treatment of the cyclization products, compound **5** was converted to compound **6** in 45% yield after chromatographic purification on silica gel. For the complete β-elimination of the cyclization products (α,β-enone formation), the acetic anhydride–pyridine treatment was necessary. The β-elimination was presumably proceeded via the β-acetate, which could not be isolated from the reaction mixture. For the Dieckmann cyclization of methyl 3-*C*-(methoxycarbonylmethyl)-1,2-*O*-isopropylidene-3,5,6-trideoxy-α-D-*ribo*-heptofuranuronate (a structurally similar model to the compound **5**), Fraser-Reid and co-workers found potassium *t*-butoxide to be an effective base.[13] We were able to find optimal conditions for the aldol cyclization, but an occurrence of epimerization at C-4 in **5** (an α-position of the aldehyde) under the basic conditions could not be excluded. Accordingly it was necessary to confirm the structure of **6**. Hydrogenation of **6** in the presence of Raney nickel and successive PCC oxidation of a cyclohexanols mixture afforded 7-oxabicyclo[4.3.0]nonan-3-one **7** in 82% yield. In the ^1H NMR spectrum of **7**, a doublet of triplets, which was attributable to H-6, appeared at δ 4.10 with $J_{1,6}=J_{5ax,6}=10.5$ Hz and $J_{5eq,6}=4.5$ Hz. This fact indicated that H-1 and H-6 of **6** (those are H-3 and H-4 of **5**) were in a trans diaxial relationship and no epimerization had occurred under the cyclization conditions. Consequently, the structure of the compound **6** was established.

The Transformation of Compound 6 to Pseudo-α-L-altropyranose Pentaacetate (17) (Scheme 2). Compound **6** possesses the proper functional groups for an introduction of hydroxyl groups (for instance, the carbonyl group or the double bond in the cyclohexenone moiety are convertible to the hydroxyl groups by reduction or oxidation). In addition, a portion of C-1 to C-8 via C-9 is convertible to a hydroxymethyl pseudo-sugar side chain by one-carbon degradation.

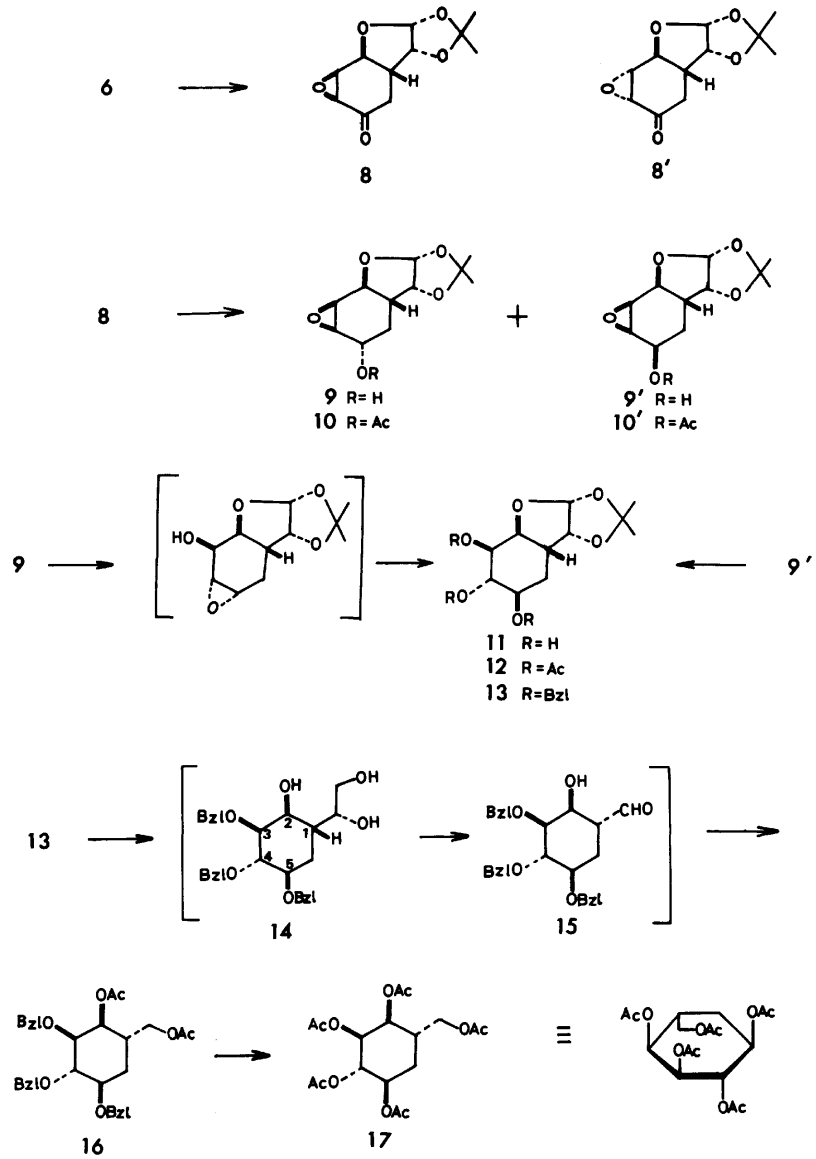
Epoxidation of **6** with 35% aqueous hydrogen peroxide in slightly alkaline methanol solution gave a β-epoxy ketone **8** stereospecifically in 96% yield. An α-epoxy ketone **8′** was isoltated in 3% yield. Although the structure of the β-epoxy ketone **8** [(4*S*,5*S*)-configuration] could not be determined unambiguously from the ^1H NMR spectrum, it was confirmed at a later stage. Sodium borohydride reduction of the carbonyl group in **8** gave a 5 to 1 mixture of the epoxy alcohols **9** and **9′**, which were cleanly separated by



Scheme 1.

silica-gel chromatograpy, in 84% combined yield. The compounds **9** and **9′** were acetylated to afford **10** and **10′**. The ^{1}H NMR spectra of **10** and **10′** revealed a quartet with $J_{2,3}=J_{2',3}=J_{3,4}=4$ Hz for H-3 of **10′** and a triplet with $J_{2,3}=J_{2',3}=8.5$ Hz, $J_{3,4}=0$ Hz for H-3 of **10**. Unfortunately, from these results, we were not able to establish the configurations of the newly introduced acetoxyl groups of **10** and **10′** (therefore hydroxyl groups of **9** and **9′**) unambiguously, since the conformation of the cyclohexane moiety of **10** and **10′** (pseudo-boat form or pseudo-chair form) remained unclear. We tentatively assigned it to a (*S*)-configuration for the major 3-hydroxyl derivative **9** as depicted,[14] and this was confirmed on azidolysis of **9** and **9′** and successive conversion to pseudo-amino sugars (vide infra).

The epoxide-ring opening of **9** and **9′** by solvolysis in refluxing aqueous 2-methoxyethanol in the presence of sodium acetate provided the same triol **11** as a single product in 73 and 81% yield, respectively. Acetylation of **11** afforded the triacetate **12** in 80% yield. In the ^{1}H NMR spectrum of **12**, the protons on carbons bearing acetoxyl groups, (at H-3, 4, and 5), appeared as a quartet at δ 5.00 for H-3 ($J_{2,3}=J_{2',3}=J_{3,4}=3$ Hz) and two triplets at δ 5.12 and 5.37 for H-4 and 5 (or H-5 and 4) ($J_{3,4}=J_{4,5}=J_{5,6}=3$ Hz). This fact supported the view that three acetoxyl groups were in a trans diaxial relationship to one another. Accordingly the structure of **11** [(3*R*,4*S*,5*S*)-configuration] was established. The formation of **11** from **9** is explainable as follows. A neighboring group participation of the α-hydroxyl group in **9** on the



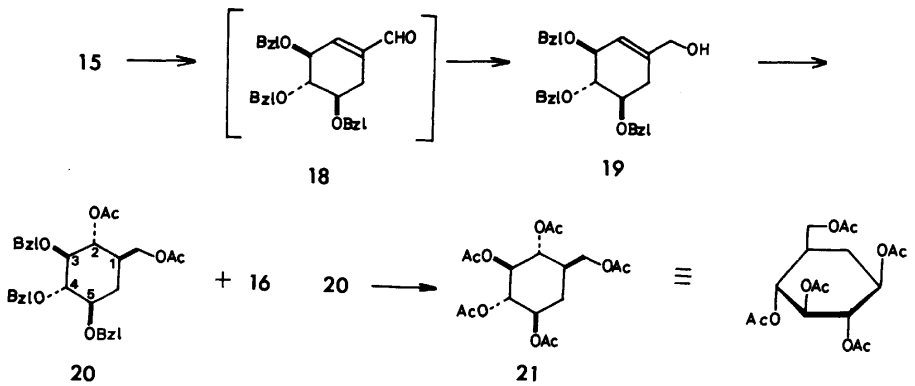
Scheme 2.

occasion of the epoxy-ring opening resulted in the formation of 3,4-α-epoxy-5-β-hydroxyl derivative as an intermediate, which could not be isolated. The intermediate was then attacked by hydroxide anion in a diaxial opening manner providing the compound **11**. The formation of **11** from **9'** was a result of direct diaxial opening of the epoxy ring. Therefore, we could introduce three hydroxyl groups into the cyclohexane moiety of **11** stereospecifically from both compounds **9** and **9'**.

The transformation of compound **11** to pseudo-α-L-altropyranose pentaacetate (**17**) was achieved as follows. Benzylation of **11** furnished a tri-*O*-benzyl derivative **13** in 93% yield. By acid hydrolysis and successive sodium borohydride reduction, the compound **13** was converted to a branched cyclohexane tetrol **14** (a derivative of pseudo-heptopyranose). The glycol cleavage of **14** by periodate gave (1*R*,2*S*,3*S*,4*S*,5*R*)-3,4,5-tris(benzyloxy)-2-hydroxycyclohexanecarbaldehyde (**15**), which was reduced with sodium borohydride, then acetylated providing a fully protected pseudo-α-L-altropyranose **16** in 52% overall yield from **13**. *O*-Debenzylation of **16** with sodium in liquid ammonia and successive acetylation furnished (1*S*,2*S*,3*S*,4*S*,5*R*)-2,3,4,5-tetraacetoxy-1-(acetoxymethyl)cyclohexane, pseudo-α-L-altropyranose pentaacetate (**17**) in 33% yield. The ^{1}H NMR spectrum of **17** was superimposable on that of the known DL-**17**,[15] therefore, the structure of **17** was confirmed.

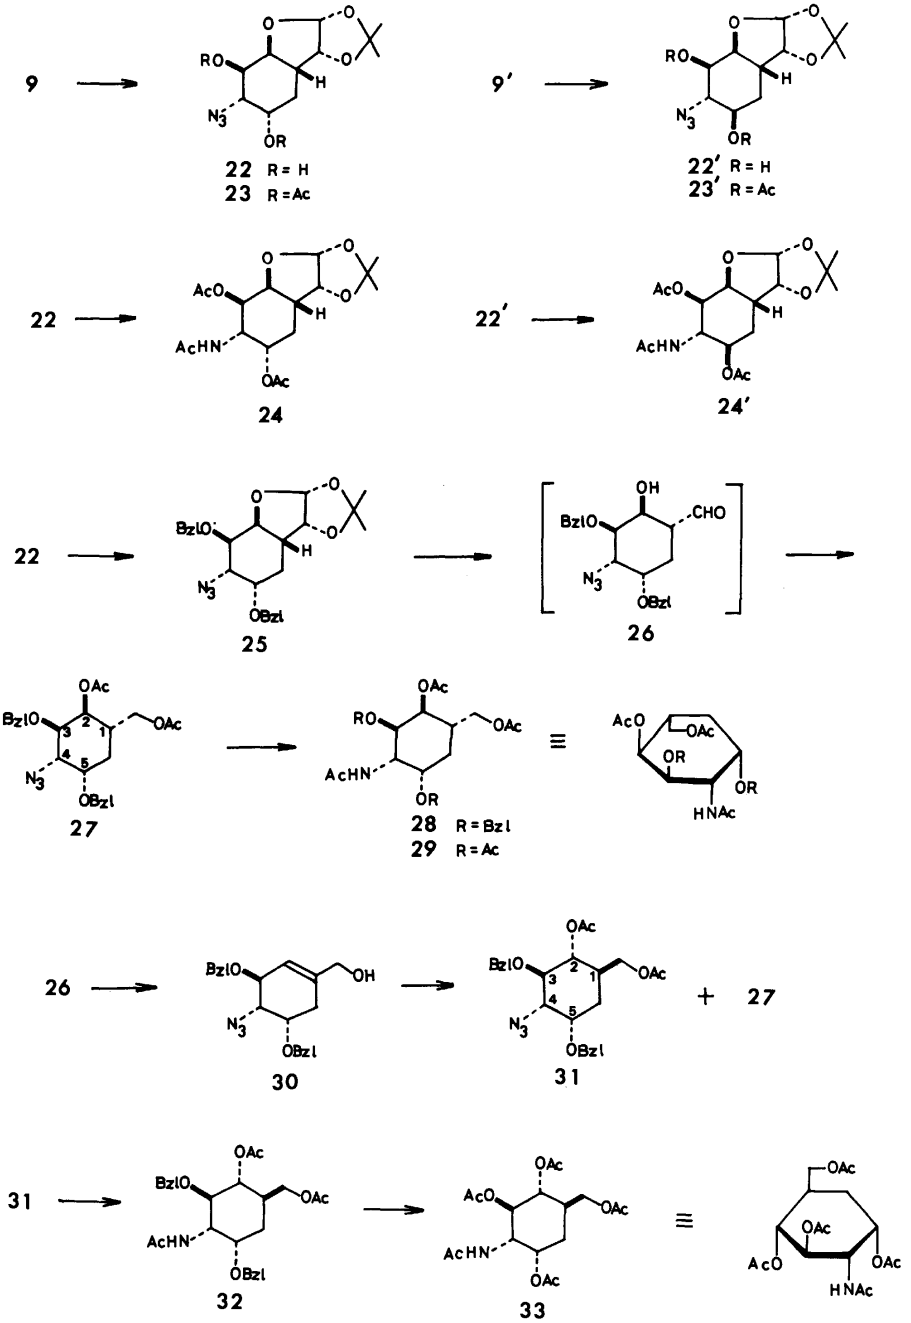
Synthesis of Pseudo-β-D-glucopyranose Pentaacetate 21 from Compound 15 (Scheme 3). The inversion of the configurations of C-1 and C-2 in compound **17** was next investigated. Treatment of compound **15** with excess methanesulfonyl chloride in pyridine at ambient temperature afforded the α,β-unsaturated aldehyde **18**, which was subjected to the next step without purification. Although we could not detect an intermediate of the reaction, we assumed the β-elimination proceeded via a β-methanesulfonate. Sodium borohydride reduction of compound **18** gave (3*S*,4*S*,5*R*)-3,4,5-tris(benzyloxy)-1-cyclohexene-1-methanol (**19**) in 22% overall yield from **13**. Hydroboration of **19** with borane–THF complex at 0 °C, oxidative work-up with 35% hydrogen peroxide in an alkaline solution, and successive acetylation afforded a pseudo-β-D-glucopyranose derivative **20** accompanied by compound **16**. These were separated on a silica-gel chromatography in 63 and 11% yield, respectively. This result indicates that the hydroboration of **19** proceeded from the α-side preferentially. In this case, a stereocontrolling factor for the attack of borane was probably the configuration of the benzyloxy group at C-3. Consequently, we could establish a methodology for the configurational inversion at the branched carbon. *O*-Debenzylation of compound **20** by hydrogenolysis in the presence of palladium on charcoal and successive acetylation gave the known (**21**), (1*R*,2*R*,3*S*,4*S*,5*R*)-2,3,4,5-tetraacetoxy-1-(acetoxymethyl)cyclohexane, pseudo-β-D-glucopyranose pentaacetate, in 98% yield. The ^{1}H NMR spectrum of **21** was superimposable on that of an authentic sample.[2,16]

Syntheses of Pentaacetyl Derivatives, 29 and 33, of Pseudo-2-amino-2-deoxy-β-L-altropyranose and of Pseudo-2-amino-2-deoxy-α-D-glucopyranose (Scheme 4). Our interest next turned to an access to pseudo-amino sugars from compound **9**. In order to introduce an amino group at an appropriate position in the cyclohexane moiety, azidolysis of **9** was investigated. By refluxing **9** in aqueous 2-methoxyethanol with excess sodium azide in the presence of ammonium chloride, the epoxy ring was cleaved by the azide anion in a diaxial-opening manner providing compound **22** in 84% yield as crystals. No other azido-containing compounds were detected. The structure of **22** was estimated as depicted from the ^{1}H NMR spectrum of the di-*O*-acetyl derivative **23**, in which the H-5 signal revealed at δ 5.38 as a triplet with $J_{4,5}=J_{5,6}=3$ Hz and the H-4 (H–C–N_3) signal revealed at δ 4.02 as a triplet with $J_{3,4}=J_{4,5}=3$ Hz. Azidolysis of the other epoxy alcohol **9'** under the same reaction conditions described above gave another azido containing compound **22'** in 87% yield. The structure of **22'** was determined from the ^{1}H NMR spectrum of the



Scheme 3.

di-*O*-acetyl derivative **23′**, in which the H-5 signal appeared at δ 5.32 as a triplet with $J_{4,5}=J_{5,6}=3$ Hz and the H-4 (H–C–N_3) signal appeared at δ 4.09 as a triplet with $J_{3,4}=J_{4,5}=3$ Hz. The structures of **22** and **22′** were confirmed by the ^{1}H NMR spectra (400 MHz) of compounds **24** and **24′**, which were prepared from **22** and **22′** by hydrogenation in the presence of 10% palladium on charcoal and successive acetylation (**24** from **22**, 71%, and **24′** from **22′**, 80%). In the ^{1}H NMR spectrum of **24**, the H-4 signal (H–C–NHAc) appeared at δ 4.47 with $J_{3,4}=J_{4,5}=2.9$ Hz and $J_{NH,4}=7.8$ Hz, which changed to a triplet ($J=2.9$ Hz) on adding D_2O. The H-3 signal appeared at δ 5.20 as a double triplet with $J_{2ax,3}=12.2$ Hz and $J_{2eq,3}=J_{3,4}=2.9$ Hz and H-5 signal appeared at δ 5.59 as a triplet with $J_{4,5}=J_{5,6}=2.9$ Hz. This fact indicated that the acetamido group located at C-4 axially and the acetoxyl groups at C-3 and C-5 were equatorial- and axial-orientation. Therefore, two possibilities that 1) azidolysis of **9** proceeded via a neighboring group participation of the hydroxyl group in the epoxide ring opening, and 2) attack of the azide anion at C-3 in a diaxial opening manner of



Scheme 4.

the formed 3,4-epoxide were excluded. The azidolysis of **9** proceeded in a diaxial ring opening manner without migration of the epoxide providing **22** exclusively. The ^{1}H NMR spectrum of **24'** was also consistent with the assigned structure. The H-4 signal appeared at δ 4.43 as a broad doublet with $J_{NH,4}$= 8.3 Hz, which changed to a broad singlet (less than 3 Hz for $J_{3,4}$ and $J_{4,5}$). The H-3 appeared at δ 5.00 with less than 3 Hz coupling constants for $J_{2ax,3}$, $J_{2eq,3}$, and $J_{3,4}$. Consequently, compound **22'** was a diaxial ring opening product of **9'**. The compounds **22** and **22'** were considered to be promising precursors for pseudo-2-amino-2-deoxy sugars. The conversion of **22** to two pseudo-amino sugars proceeded as follows. *O*-Benzylation of the compound **22** gave a di-*O*-benzyl derivative **25** in 82% yield. By the reaction sequence described for transformation of **13** to **16**, [1) refluxing in 1 mol dm^{-3} aqueous HCl, 2) sodium borohydride reduction, 3) periodate glycol cleavage, 4) sodium borohydride reduction, and 5) acetylation], the compound **25** was converted to (1*S*,2*S*,3*R*,4*S*,5*S*)-2-acetoxy-1-acetoxymethyl-4-azido-3,5-bis(benzyloxy)cyclohexane (**27**) in 56% overall yield via compound **26**. Hydrogenation of **27** in the presence of Raney nickel and successive acetylation gave an acetamido derivative **28** in 80% yield. *O*-Debenzylation of **28** by hydrogenolysis followed by acetylation afforded pentaacetyl derivative of pseudo-2-amino-2-deoxy-β-L-altropyranose **29** in 96% yield.

Treatment of compound **26**, which was prepared from **25**, with excess methanesulfonyl chloride for formation of an α,β-unsaturated aldehyde and successive diisobutylaluminium hydride reduction afforded (3*S*,4*S*,5*S*)-4-azido-3,5-bis(benzyloxy)-1-cyclohexene-1-methanol (**30**) in 27% yield from **25**. Hydroboration of **30** with borane–THF complex at 0 °C, oxidative work-up with 35% aqueous hydrogen peroxide in an alkaline solution, and successive acetylation provided a pseudo-α-D-glucopyranose derivative **31** and **27** in 21 and 49% yield, respectively. The hydroboration of **30** proceeded from the less hindered side providing **27** as a major product. In this case, the configuration of the 5-*O*-benzyl group was presumably a stereocontrolling factor. Hydrogenation of **31** followed by acetylation afforded compound **32** in 66% yield. *O*-Debenzylation of **32** and successive acetylation provided the pentaacetyl derivative **33** of pseudo-2-amino-2-deoxy-α-D-glucopyranose in 92% yield. Compound **33** is a derivative of pseudo-glucosamine.[17]

Experimental

General. Evaporations were performed under diminished pressure below 40 °C (bath). Melting points were determined with a Mitamura Riken micro mp apparatus and are uncorrected. Specific rotations were measured in a 10 mm cell with a Jasco DIP-4 polarimeter. Column chromatography was performed on Kieselgel 60 (Merck), and thin-layer chromatography (TLC) was performed on a glass plate coated with Kieselgel 60 GF_{254} (Merck) followed by detection by UV light and charring with sulfuric acid. Preparative TLC (PTLC) was performed on a glass plate (20×20 cm) coated with Kieselgel PF_{254} (Merck) and the compounds were extracted with $CHCl_3$. IR spectra were recorded with a Hitachi Model 225 (KBr) or with a Jasco Model A-202 ($CHCl_3$) spectrometer. ^{1}H NMR spectra were recorded with a Varian EM-390 (90 MHz) or with a JEOL JNM-GX FT NMR for compounds **24** and **24'** (400 MHz) spectrometer for solutions in $CDCl_3$ (internal standard Me_4Si). High resolution mass spectra were obtained using a Hitachi Model M-80 spectrometer. Elemental analyses were performed by Messrs. Saburo Nakada and Akio Takahashi of the university to whom our thanks are due.

Dichloromethane and benzene were dried over CaH_2, then distilled. Pyridine was distilled from NaOH. Tetrahydrofuran (THF) was distilled from $LiAlH_4$.

Mixture of (*E*)- and (*Z*)-3-*C*-Acetylmethylene-3-deoxy-1,2:5,6-di-*O*-isopropylidene-α-D-*ribo*-hexofuranose (2). An approximately 3 to 1 [(*Z*) to (*E*)] mixture, **2**, was prepared according to the reported procedure.[11] A mixture of 1,2:5,6-di-*O*-isopropylidene-α-D-*ribo*-hexofuranos-3-ulose (**1**) (8.93 g, 34.6 mmol) and (acetylmethylene)triphenylphosphorane (22.0 g, 69.2 mmol) in benzene (150 ml) was refluxed for 2 h and evaporated. The residue was partitioned between ethyl acetate (500 ml) and water (250 ml). The aqueous layer was extracted with ethyl acetate (500 ml×2). The organic layers were dried (Na_2SO_4) and evaporated. The residue was triturated with petroleum ether (450 ml) at 40 °C and cooled at 5 °C overnight. The precipitated triphenylphosphine oxide was removed by filtration, and the filtrate was evaporated. The residue was chromatographed on silica gel (220 g, ethyl acetate–toluene=1:20). Fractions corresponding to R_f 0.55 to 0.60 (ethanol–toluene=1:10) were evaporated to afford the mixture **2** (9.88 g, 96%) as a colorless syrup.

3-*C*-Acetylmethyl-3-deoxy-1,2:5,6-di-*O*-isopropylidene-α-D-allofuranose (3). A solution of the mixture **2** (9.88 g, 33.1 mmol) in methanol (50 ml) was hydrogenated in the presence of Raney nickel T-4 (ca. 6 g) under atmospheric hydrogen pressure at ambient temperature for 20 h. The catalyst was removed by filtration through a Celite-pad and washed with methanol. The combined filtrate and washing were evaporated to afford a diastereomeric mixture of 3-deoxy-3-*C*-(2-hydroxypropyl)-1,2:5,6-di-*O*-isopropylidene-α-D-allofuranose (TLC R_f 0.24 and 0.29, ethyl acetate–hexane=1:2, 10.3 g) as a colorless syrup. To a solution of the mixture in dichloromethane (150 ml) were added PCC (17.8 g, 82.8 mmol) and molecular sieves (3A, powder, 15.0 g). After stirring at the ambient temperature for 18 h, the mixture was diluted with ether (150 ml), then stirred for 1 h. The mixture was applied to a silica-gel column (200 g), and the column was eluted with ether (3 l). The eluate was evaporated and the residue was chromatographed on silica gel (200 g, ethyl acetate–toluene=1:15). Fractions corresponding to R_f 0.47 (ethyl acetate–toluene=1:2) were evaporated to afford **3** as a colorless syrup which was crystallized gradually upon standing at 5 °C, 8.77 g (88%). Mp 36.5—37 °C; $[\alpha]_D^{20}$ +82.1° (*c* 1.35, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3000, 2950, 2890, 1720, 1455, 1410, 1380, 1250, 1215, 1165, 1100, 1065 cm^{-1};

^{1}H NMR ($CDCl_3$) δ=1.27, 1.30, 1.40, 1.47 (3H×4, each s, 2×C(CH_3)$_2$), 2.17 (3H, s, $COCH_3$), 2.25—2.60 (1H, m, H-3), 2.67—2.93 (2H, m, CH_2COCH_3), 3.40—4.23 (4H, m, H-4,5,6,6'), 4.77 (1H, t, J=4.5 Hz, H-2), 5.75 (1H, d, J=4.5 Hz, H-1). Found: C, 59.77; H 8.02%. Calcd for $C_{15}H_{24}O_6$: C, 59.98; H, 8.05%.

3-*C*-Acetylmethyl-3-deoxy-1,2-*O*-isopropylidene-α-D-allofuranose (4). A solution of **3** (8.26 g, 28.0 mmol) in 60% aqueous acetic acid (120 ml) was stirred at the ambient temperature for 17 h and evaporated. The residue was chromatographed on silica gel (230 g, ethanol-toluene=1:12). Fractions corresponding to R_f 0.11 (ethyl acetate-toluene=1:2) were evaporated to afford **4** (7.00 g, 98%) as crystals, mp 69—69.5 °C; $[\alpha]_D^{24}$ +79.7° (*c* 1.82, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3450, 2980, 2930, 1715, 1405, 1370, 1245, 1215, 1165 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.23, 1.43 (3H×2, each s, C(CH_3)$_2$), 2.13 (3H, s, $COCH_3$), 2.20—2.60 (1H, m, H-3), 2.81 (2H, d, J=6 Hz, CH_2COCH_3), 2.93—3.90 (6H, m, H-4,5,6,6',2×OH), 4.70 (1H, t, J=4.5 Hz, H-2), 5.73 (1H, d, J=4.5 Hz, H-1). Found: C, 55.47; H, 7.52%. Calcd for $C_{12}H_{20}O_6$: C, 55.37; H, 7.75%.

(1*R*,6*R*,8*R*,9*R*)-8,9-Isopropylidenedioxy-7-oxabicyclo[4.3.0]-non-4-en-3-one (6). To a stirred solution of **4** (11.1 g, 42.6 mmol) in methanol (200 ml), an aqueous (50 ml) solution of sodium periodate (10.0 g, 46.9 mmol) was added. After stirring at the ambient temperature for 30 min, the solution was evaporated to ca.50 ml, then diluted with water (300 ml). The aqueous solution was extracted with dichloromethane (500 ml×3). The aqueous layer was saturated with NaCl and extracted with dichloromethane (400 ml×2). The combined organic layers were dried (Na_2SO_4) and evaporated to afford a TLC homogeneous **5** (10.2 g, quantitatively) as a colorless syrup, which was subjected to the next step without purification. **5**: TLC, R_f 0.52, ethanol-toluene=1:5; ^{1}H NMR ($CDCl_3$) δ=1.30, 1.48 (3H×2, each s, C(CH_3)$_2$), 2.17 (3H, s, $COCH_3$), 2.25—2.67 (1H, m, H-3), 2.67—3.00 (2H, m, CH_2COCH_3), 3.33—4.15 (1H, m, H-4), 4.47—4.93 (1H, m, H-2), 5.67—6.03 (1H, m, H-1), 9.67 (1H, d, J=3 Hz, CHO).

A solution of **5** (10.2 g, 42.6 mmol) in benzene (200 ml) containing DBU (0.33 ml, 2.24 mmol) was refluxed for 35 h and evaporated. The residue was dissolved in pyridine (50 ml) and acetic anhydride (50 ml) was added. The mixture was stirred for 19 h and evaporated. The residue was dissolved in water (300 ml) and extracted with dichloromethane (600 ml×3). The extracts were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (500 g, ethyl acetate-hexane=1:6). Fractions corresponding to R_f 0.50 (ethanol-toluene=1:10) were evaporated to afford **6** (4.01 g, 45%) as crystals, mp 61—62 °C (from hexane); $[\alpha]_D^{17}$ −45.3° (*c* 0.92, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3050, 2980, 2850, 1675, 1600, 1450, 1380, 1335, 1295, 1255, 1210, 1160, 1140 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.35, 1.53 (3H×2, each s, C(CH_3)$_2$), 1.90—2.35 (1H, m, H-1), 2.35—3.00 (2H, m, H-2,2'), 4.47—4.80 (2H, m, H-6,9), 5.73—6.10 (2H, m, H-4,8), 7.28 (1H, d, J=9 Hz, H-5). Found: C, 62.96, H, 6.80%. Calcd for $C_{11}H_{14}O_4$:C, 62.85; H, 6.71%.

(1*R*,6*R*,8*R*,9*R*)-8,9-Isopropylidenedioxy-7-oxabicyclo[4.3.0]-nonan-3-one (7). A solution of **6** (40.0 mg, 0.19 mmol) in ethanol (2 ml) was hydrogenated in the presence of Raney nickel T-4 under hydrogen at atmospheric pressure for 2 h. After removal of the catalyst through a Celite-pad, the filtrate was evaporated to afford a syrupy diastereomeric mixture of (1*R*,6*R*,8*R*,9*R*)-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonan-3-ol, which was oxidized without purification. To a stirred solution of the mixture in dichloromethane (2 ml) was added PCC (102 mg, 0.48 mmol). After stirring at ambient temperature for 15 h, the mixture was evaporated. The residue was applied to a silica-gel column (3 g), and the column was eluted with ether to afford **7** (33.2 mg, 82%), TLC R_f=0.66 (ethanol-toluene=1:5); mp 98—98.5 °C; $[\alpha]_D^{21.5}$ −33.7° (*c* 1.66, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2980, 2875, 1710, 1450, 1415, 1375, 1325, 1305, 1270, 1245, 1210, 1165, 1150, 1120, 1095 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.35, 1.57 (3H×2, each s, C(CH_3)$_2$), 1.59—2.05 (2H, m, 5,5'), 2.10—2.73 (5H, m, H-1,2,2',4,4'), 4.10 (1H, dt, $J_{1,6}$=$J_{5ax,6}$= 10.5Hz, $J_{5eq,6}$=4.5 Hz, H-6), 4.60 (1H, t, $J_{1,9}$=$J_{8,9}$=4 Hz, H-9), 5.93 (1H, d, $J_{8,9}$=4 Hz, H-8). Found: C, 62.01; H, 7.42%. Calcd for $C_{11}H_{16}O_4$: C, 62.25; H, 7.60%.

(1*R*,4*S*,5*S*,6*S*,8*R*,9*R*)-4,5-Epoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonan-3-one (8) and the (1*R*,4*R*,5*R*,6*S*,8*R*, 9*R*) stereomer (8'). To a stirred solution of **6** (450 mg, 2.14 mmol) in methanol (3 ml), hydrogen peroxide (35 wt% aqueous solution, 0.56 ml, 6.42 mmol) and an aqueous NaOH solution (1 mol dm^{-3}, 0.07 ml) (pH 9) were added. After stirring at the ambient temperature for 3 h, the mixture was diluted with water (10 ml) and extracted with ethyl acetate (30 ml×5). The extracts were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (35 g, ethyl acetate-hexane=1:12). Fractions corresponding to R_f 0.62 (ethanol-toluene=1:10) were evaporated to afford **8** (467 mg, 96%) as a colorless syrup, and fractions corresponding to R_f 0.52 were evaporated to afford **8'** (16 mg, 3%) as a colorless syrup. **8**:$[\alpha]_D^{18.5}$ −108.8° (*c* 1.77, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2980, 2940, 2870, 1715, 1450, 1410, 1375, 1320, 1300, 1260, 1210, 1160, 1085 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.32, 1.50 (3H×2, each s, C(CH_3)$_2$), 2.28—2.76 (3H, m, H-1,2,2'), 3.37 (1H, d, J=5 Hz, H-5), 3.90 (1H, d, J=5 Hz, H-4), 4.30 (1H, d, J=10.5 Hz, H-6), 4.57 (1H, t, J=3.5 Hz, H-9), 5.94 (1H, d, J=3.5 Hz, H-8). High-resolution mass spectrum, calcd for $C_{11}H_{15}O_5$: *m/z* 227.0918, found: M+H, 227.0917. **8'**: $[\alpha]_D^{17}$ −11.0° (*c* 0.82, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2990, 2940, 2870, 1715, 1450, 1415, 1375, 1300, 1260, 1240, 1210, 1160, 1115 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.31, 1.52 (3H×2, each s, C(CH_3)$_2$), 1.73—2.18 (1H, m, H-1), 2.42—2.73 (2H, m, H-2,2'), 3.19 (1H, d, J=4 Hz, H-5), 3.79 (1H, d, J=4 Hz, H-4), 4.05 (1H, d, J=10.5 Hz, H-6), 4.57 (1H, t, J=3.5 Hz, H-9), 5.91 (1H, d, J=3.5 Hz, H-8).

(1*R*,3*S*,4*R*,5*S*,6*S*,8*R*,9*R*)- (9) and (1*R*,3*R*,4*R*,5*S*,6*S*,8*R*,9*R*)-(9') 4,5-Epoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonan-3-ol. The compound **6** (991 mg, 4.72 mmol) was converted to **8** containing a trace of **8'** as described above. The syrupy crude **8** was dissolved in ethanol (10 ml) and sodium borohydride (176 mg, 4.65 mmol) was added. After stirring at 0 °C for 40 min, the mixture was neutralized by addition of 1 mol dm^{-3} HCl, then evaporated. The residue was triturated with chloroform (20 ml) and an insoluble solid was removed by filtration. The filtrate was evaporated and the residue was chromatographed on silica gel (110 g, ethyl acetate-hexane=1:3). Fractions corresponding to R_f 0.29 (ethyl acetate-hexane=1:1) were evaporated to afford **9** (758 mg, 70%) as a colorless syrup, and fractions corresponding to R_f 0.16 were evaporated to afford **9'** (153 mg, 14%) as crystals. **9**: $[\alpha]_D^{27}$ +26.1° (*c* 1.05, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3600, 2990, 2930, 2880, 1450, 1390, 1370, 1300, 1240, 1170,

1130, 1070, 1050 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.36, 1.55 (3H×2, each s, $C(CH_3)_2$), 1.47—2.47 (3H, m, H-1,2,2′), 2.62 (1H, br s, OH), 3.25 (1H, d, $J_{4,5}$=4 Hz, $J_{3,4}$=0 Hz, H-4), 3.67 (1H, d, $J_{4,5}$=4 Hz, $J_{5,6}$=0 Hz, H-5), 4.21 (1H, $J_{1,6}$=10.5 Hz, $J_{5,6}$=0 Hz, H-6), 4.05—4.40 (1H, m, H-3; changed to triplet with $J_{2,3}$=$J_{2',3}$=8 Hz, $J_{3,4}$=0 Hz centered at δ 4.15 by addition of D_2O), 4.57 (1H, t, J=4 Hz, H-9), 5.87 (1H, d, J=4 Hz, H-8). High-resolution mass spectrum, calcd for $C_{11}H_{17}O_5$: m/z 229.1075, found: M+H, 229.1078. **9′**: mp 141—144 °C; $[\alpha]_D^{27}$ +63.2° (c 0.89, $CHCl_3$); IR ν_{max}^{KBr} 3490, 2980, 2930, 2860, 1460, 1440, 1410, 1390, 1380, 1280, 1250, 1210, 1170, 1150, 1130, 1085, 1015 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.30, 1.48 (3H×2, each s, $C(CH_3)_2$), 1.60—2.21 (3H, m, H-1,2,2′), 2.67 (1H, br s, OH), 3.44 (1H, t, $J_{3,4}$=$J_{4,5}$=4 Hz, H-4), 3.72 (1H, d, $J_{4,5}$=4 Hz, $J_{5,6}$=0 Hz, H-5), 4.04 (1H, d, $J_{1,6}$=10 Hz, $J_{5,6}$=0 Hz, H-6), 4.13—4.37 (1H, m, H-3; changed to triplet with J=4 Hz centered at δ 4.24 by addition of D_2O), 4.53 (1H, t, J=4 Hz, H-9), 5.84 (1H, d, J=4 Hz, H-8). Found: C,57.62; H, 7.09%. Calcd for $C_{11}H_{16}O_5$: C, 57.88; H, 7.06%.

(1*R*,3*S*,4*R*,5*S*,6*S*,8*R*,9*R*)-3-Acetoxy-4,5-epoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (10). The compound **9** (33 mg, 0.14 mmol) was acetylated with acetic anhydride (1 ml) and pyridine (1 ml) for 3 h. After removal of the reagents, the residue was chromatographed on silica gel (2 g, ethyl acetate–hexane=1:8) to give **10** (TLC R_f=0.32, ethanol–toluene=1:10) (19 mg, 50%) as a colorless syrup, $[\alpha]_D^{27}$ +50.1° (c0.77, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2980, 2930, 1740, 1455, 1370, 1220, 1165, 1130, 1110, 1055 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.30, 1.50 (3H×2, each s, $C(CH_3)_2$), 1.58—2.58 (3H, m, H-1,2,2′), 2.09 (3H, s, $OCOCH_3$), 3.15 (1H, d, $J_{4,5}$=4 Hz, $J_{3,4}$=0 Hz, H-4) 3.61 (1H, d, $J_{4,5}$=4 Hz, $J_{5,6}$=0 Hz, H-5), 4.15 (1H, d, $J_{1,6}$=10 Hz, $J_{5,6}$=0 Hz, H-6), 4.52 (1H, t, J=4 Hz, H-9), 5.11 (1H, t, $J_{2,3}$=$J_{2',3}$=8.5 Hz, $J_{3,4}$=0 Hz, H-3), 5.83 (1H, d, J=4 Hz, H-8). High-resolution mass spectrum, calcd for $C_{13}H_{19}O_6$: m/z 271.1180, found: M+H, 271.1209.

(1*R*,3*R*,4*R*,5*S*,6*S*,8*R*,9*R*)-3-Acetoxy-4,5-epoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (10′). The compound **9′** (29 mg, 0.13 mmol) was acetylated with acetic anhydride (1 ml) and pyridine (1 ml) for 3 h. After removal of the reagents, the residue was chromatographed on silica gel (2 g, ethyl acetate–hexane=1:8) to give **10′** (R_f=0.32, ethanol–toluene=1:10) (25 mg, 73%), mp 136—138 °C; $[\alpha]_D^{27}$ +84.6° (c 1.04 $CHCl_3$); IR ν_{max}^{KBr} 2990, 1725, 1375, 1320, 1280, 1245, 1210, 1165, 1150, 1125, 1100, 1075, 1050 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.30, 1.50 (3H×2, each s, $C(CH_3)_2$), 1.66—2.32 (3H, m, H-1,2,2′), 2.11 (3H, s, $OCOCH_3$), 3.52 (1H, t, $J_{3,4}$=$J_{4,5}$=4 Hz, H-4), 3.60 (1H, d, $J_{4,5}$=4 Hz, $J_{5,6}$=0 Hz, H-5), 4.06 (1H, d, $J_{1,6}$=10.5 Hz, $J_{5,6}$=0 Hz, H-6), 4.53 (1H, t, J=4 Hz, H-9), 5.25 (1H, q, $J_{2,3}$=$J_{2',3}$=$J_{3,4}$=4 Hz, H-3), 5.83 (1H, d, J=4 Hz, H-8). (1*R*,3*R*,4*S*,5*S*,6*S*,8*R*,9*R*)-8,9-Isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane-3,4,5-triol (11). From **9**. A solution of **9** (153 mg, 0.67 mmol) in a mixture of 2-methoxyethanol and water (10:3, v/v, 7.5 ml) containing sodium acetate (110 mg, 1.34 mmol) was refluxed for 9 h and evaporated. The residue was chromatographed on silica gel (20 g, ethanol–hexane=1:9), and fractions corresponding to R_f 0.26 (ethanol–toluene=1:5) were evaporated to afford **11** (120 mg, 73%), mp 160—162 °C; $[\alpha]_D^{25}$ −6.6° (c 1.00, MeOH); IR ν_{max}^{KBr} 3420, 3250, 2990, 2940, 2910, 1450, 1380, 1370, 1265, 1210, 1170, 1140, 1105, 1075, 1025 cm^{-1}; ^{1}H NMR (CD_3OD) δ=1.32, 1.47 (3H×2, each s, $C(CH_3)_2$), 1.71—2.41 (3H, m, H-1,2,2′), 3.81—4.80 (8H, m, H-3,4,5,6,9, 3×OH), 5.79 (1H, d, J=4 Hz, H-8). Found: C, 49.66; H, 7.51%. Calcd for $C_{11}H_{18}O_6 \cdot H_2O$: C, 49.99; H, 7.63%.

From **9′**. A solution of **9′** (63 mg, 0.67 mmol) in a mixture of 2-methoxyethanol and water (10:3, 4 ml) containing sodium acetate (45 mg) was refluxed for 9 h and evaporated. After chromatographic purification as described above, **11** was obtained (55 mg, 81%).

(1*R*,3*R*,4*S*,5*S*,6*S*,8*R*,9*R*)-3,4,5-Triacetoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (12). A solution of **9** (85 mg, 0.37 mmol) in a mixture of 2-methoxyethanol and water (10:3, 5 ml) containing sodium acetate (61 mg) was refluxed for 8 h and evaporated. The residue was acetylated with acetic anhydride (5 ml) and pyridine (5 ml) for 12 h and evaporated. The residue was partitioned between dichloromethane (40 ml) and water (40 ml). The aqueous layer was extracted with dichloromethane (40 ml×2). The combined organic layers were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (15 g, ethyl acetate–hexane=1:5), and fractions corresponding to R_f 0.77 (ethanol–toluene=1:5) were evaporated to afford **12** (112 mg, 80%), mp 56—58 °C; $[\alpha]_D^{26}$−7.8° (c 1.26, $CHCl_3$); IR ν_{max}^{KBr} 2985, 2940, 1755, 1745, 1440, 1375, 1250, 1170, 1125, 1115, 1085, 1030 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.32, 1.51 (3H×2, each s, $C(CH_3)_2$), 2.05 (3H, s, $OCOCH_3$), 2.08 (6H, s, 2×$OCOCH_3$), 1.84—2.48 (3H, m, H-1,2,2′), 4.00 (1H, dd, $J_{1,6}$=11 Hz, $J_{5,6}$=3 Hz, H-6), 4.60 (1H, t, J=4 Hz, H-9), 5.00 (1H, q, $J_{2,3}$=$J_{2',3}$=$J_{3,4}$=3 Hz, H-3), 5.12 (1H, t, $J_{4,5}$=$J_{5,6}$=3 Hz, H-5), 5.37 (1H, t, $J_{3,4}$=$J_{4,5}$=3 Hz, H-4), 5.83 (1H, d, J=4 Hz H-8). Found: C, 54.71; H, 6.39%. Calcd for $C_{17}H_{24}O_9$: C, 54.83; H, 6.50%.

(1*R*,3*R*,4*S*,5*S*,6*S*,8*R*,9*R*)-3,4,5-Tris(benzyloxy)-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (13). A stirred suspension of sodium hydride (60% in mineral oil, 431 mg, 10.8 mmol, washed with hexane 10 ml×3 then dried) in dry DMF (5 ml) was added a DMF (10 ml) solution of **11** (442 mg, 1.79 mmol). After stirring for 15 min, benzyl bromide (1.28 ml, 10.8 mmol) was added. The mixture was stirred at ambient temperature for 16 h. The mixture was evaporated and the residue was partitioned between dichloromethane (60 ml) and water (60 ml). The aqueous layer was extracted with dichloromethane (60 ml×2). The organic layers were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (50 g, ethyl acetate–hexane=1:12), and fractions corresponding to R_f 0.40 (ethyl acetate–hexane=1:5) were evaporated to afford **13** (858 mg, 93%) as a colorless syrup, $[\alpha]_D^{27}$ −0.8° (c 1.22, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3050, 3025, 2995, 2930, 2870, 1600, 1495, 1450, 1380, 1370, 1265, 1240, 1210, 1165, 1120, 1065 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.31, 1.48 (3H×2, each s, $C(CH_3)_2$), 1.79—2.67 (3H, m, H-1,2,2′), 3.69 (1H, q, $J_{2,3}$=$J_{2',3}$=$J_{3,4}$=3 Hz, H-3), 3.84 (1H, t, $J_{3,4}$=$J_{4,5}$=3 Hz or $J_{4,5}$=$J_{5,6}$=3 Hz, H-4 or H-5), 4.08 (1H, dd, $J_{1,6}$=11.5 Hz, $J_{5,6}$=3 Hz, H-6), 4.17 (1H, t, $J_{3,4}$=$J_{4,5}$=3 Hz or $J_{4,5}$=$J_{5,6}$=3 Hz, H-4 or H-5), 4.44—4.69 (6H, m, 3×$OCH_2C_6H_5$), 4.56 (1H, t, J=4 Hz, H-9), 5.84 (1H, d, J=4 Hz, H-8), 7.28 (15H, s, 3×$OCH_2C_6H_5$). High-resolution mass spectrum, calcd for $C_{32}H_{36}O_6$: m/z 516.2509, found: M, 516.2505.

(1*S*,2*S*,3*S*,4*S*,5*R*)-2-Acetoxy-1-acetoxymethyl-3,4,5-tris(benzyloxy)cyclohexane (16). A solution of **13** (648 mg, 1.26 mmol) in a mixture of 80% aqueous acetic acid (20 ml) and

1,4-dioxane (7 ml) was refluxed for 2 h and evaporated. The resulting crude *O*-deisopropylidene derivative (TLC, R_f= 0.41, ethanol-toluene=1:8) was used in the next step directly. To a stirred solution of the residue in methanol (30 ml) was added sodium borohydride (143 mg, 3.78 mmol) at 0 °C. After stirring at the same temperature for 3 h, 35% aqueous hydrogen peroxide (5 ml) was added. After stirring at 0 °C for 1 h, the solution was diluted with saturated aqueous sodium sulfite (25 ml), then acidified (pH 5) with 1 mol dm^{-3} HCl solution. The resulting white precipitate was removed by filtration and washed with ethanol (100 ml). The combined filtrate and washing were evaporated to ca. 20 ml and extracted with dichloromethane (50 ml×5). The extracts were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (30 g, ethyl acetate-hexane=1:3, 1:2, 1:1, then ethyl acetate-ethanol=1:1). Fractions corresponding to R_f 0.35 (ethanol-toluene=1:8) were evaporated afford (1*R*)-1-[(1*S*,2*S*,3*S*,4*S*,5*R*)-3,4,5-tris-(benzyloxy)-2-hydroxycyclohexyl]-1,2-ethanediol (**14**) (419 mg) as a colorless syrup. To a stirred solution of **14** in methanol (9 ml), an aqueous (1.9 ml) solution of sodium periodate (207 mg, 0.97 mmol) was added. After stirring at the ambient temperature for 1 h, the precipitated solid was removed and the filtrate was evaporated. The residue was dissolved in water (10 ml) and extracted with dichloromethane (10 ml×4). The extracts were dried (Na_2SO_4) and evaporated to afford curde (1*R*,2*S*,3*S*,4*S*,5*R*)-3,4,5-tris(benzyloxy)-2-hydroxycyclohexanecarbaldehyde (**15**) as a colorless syrup, which was reduced directly. To a solution of **15** in ethanol (10 ml), sodium borohydride (73 mg, 1.93 mmol) was added. After stirring at the ambient temperature for 5 h, 35% aqueous hydrogen peroxide (3 ml) was added. After stirring for 1 h, saturated sodium sulfite (15 ml) and 1 mol dm^{-3} HCl (pH 7) were added. The solution was diluted with water (5 ml) and extracted with dichloromethane (100 ml×3, 80 ml×3). The combined extracts were dried (Na_2SO_4) and evaporated. The residue was acetylated with acetic anhydride (3 ml) in pyridine (3 ml) for 5 h. After evaporation of the mixture, the residue was chromatographed on silica gel (20 g, ethyl acetate-hexane=1:10). Fractions corresponding to R_f 0.67 (ethyl acetate-hexane=1:2) were evaporated to afford **16** (350 mg, 52%) as a colorless syrup, $[\alpha]_D^{26}$ −25.7° (*c* 0.74, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3060, 2900, 1735, 1495, 1450, 1365, 1230, 1110, 1085, 1070 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.87 (2H, dd, *J*=5 and 6.5 Hz, H-6,6′), 2.00, 2.06 (3H×2, each s, 2×OCOCH_3), 2.42 (1H, q, *J*=6 Hz, H-1), 3.47—3.82 (3H, m, H-3,4,5), 4.00 (2H, dd, *J*=2.5 and 6.5 Hz, CH_2OAc), 4.59 (4H, s, 2×OCH_2C$_6$H$_5$), 4.72 (2H, s, OCH_2C$_6$H$_5$), 5.28 (1H, dd, *J*=2.5 and 6 Hz, H-2), 7.30 (15H, s, 3×OCH$_2$C$_6$H$_5$). High-resolution mass spectrum, calcd for $C_{32}H_{36}O_7$: *m/z* 532.2466, fornd: M, 532.2459.

(1*S*,2*S*,3*S*,4*S*,5*R*)-2,3,4,5-Tetraacetoxy-1-(acetoxymethyl)-cyclohexane, Pentaacetate of Pseudo-α-L-altropyranose (17). Sodium (180 mg, 7.88 mmol) was added to a liquid ammonia (30 ml) at −78 °C. To the resulting blue solution, a THF (3 ml) solution of **16** (350 mg, 0.66 mmol) was added. After stirring at the same temperature for 25 min, 180 mg of sodium was added. The mixture was stirred for 3 h at −78 °C. Ammonium chloride (200 mg) was added to this, and the mixture was allowed to warm to the ambient temperature. The resulting solid was dried, then acetylated with acetic anhydride (7 ml) in pyridine (7 ml) for 5 h. The mixture was evaporated, and the residue was partitioned between ethyl acetate (50 ml) and water (10 ml). The aqueous layer was extracted with ethyl acetate (50 ml×3). The combined organic layers were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (12 g, ethyl acetate-hexane=1:4) and fractions corresponding to R_f 0.49 (ethyl acetate-hexane=1:2) were evaporated to afford **17** (85 mg, 33%), mp 84—85 °C, $[\alpha]_D^{26.5}$ −13.7° (*c* 1.36, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2930, 2855, 1740, 1435, 1370, 1220, 1040 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.96 (2H, dd, *J*=5 and 6 Hz, H-6,6′), 2.00, 2.01, 2.04, 2.06, 2.08 (3H×5, each s, 5×OCOCH_3), 2.40 (1H, q, *J*=6 Hz, H-1), 4.15 (2H, d, *J*=6.5 Hz, CH_2OAc), 4.88—5.40 (4H, m, H-2,3,4,5). High-resolution mass spectrum, calcd for $C_{17}H_{25}O_{10}$: *m/z* 389.1446, found: M+H, 389.1463.

(3*S*,4*S*,5*R*)-3,4,5-Tris(benzyloxy)-1-cyclohexene-1-methanol (19). The compound **13** (945 mg, 1.83 mmol) was converted to the crude **15** (326 mg) as described in the preparation of **16**. To a stirred solution of the crude **15** in pyridine (7 ml) was added methanesulfonyl chloride (0.34 ml, 4.40 mmol). After stirring at ambient temperature for 24 h, the mixture was evaporated. The residue was diluted with water (25 ml) and extracted with dichloromethane (40 ml×3). The extracts were dried (Na_2SO_4) and evaporated to give crude α,β-unsaturated aldehyde (**18**) (TLC R_f=0.62, ethyl acetate-hexane=1:2), which was reduced without purification. To a stirred solution of the crude **18** (syrup) in ethanol (7 ml) was added sodium borohydride (51 mg, 1.35 mmol). After stirring at ambient temperature for 3.5 h, the mixture was evaporated. The residue was partitioned between dichloromethane (40 ml) and water (40 ml), and the aqueous layer was extracted with dichloromethane (40 ml×2). The organic layers were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (30 g, ethyl acetate-hexane=1:10, 1:8, then 1:5). Fractions corresponding to R_f 0.34 (ethyl acetate-hexane=1:2) were evaporated to afford **19** (173 mg, 22% overall yield from **13**) as a colorless syrup, $[\alpha]_D^{26}$ +12.3° (*c* 1.11, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3590, 3000, 2910, 2870, 1590, 1490, 1450, 1360, 1080 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ 1.54—1.80 (1H, m, OH), 1.90—2.64 (2H, m, H-6,6′), 3.63—4.26 (5H, m, H-3,4,5,CH_2OH), 4.50—5.00 (6H, m, 3×OCH_2C$_6$H$_5$), 5.52—5.80 (1H, m, H-2), 7.33 (15H, s, 3×OCH$_2$C$_6$H$_5$). High-resolution mass spectrum, calcd for $C_{28}H_{30}O_4$: *m/z* 430.2142, found: M, 430.2134.

(1*R*,2*R*,3*S*,4*S*,5*R*)-2-Acetoxy-1-acetoxymethyl-3,4,5-tris(benzyloxy)cyclohexane (20) and the (1*S*,2*S*,3*S*,4*S*,5*R*)-Stereoisomer 16. To a stirred solution of **19** (163 mg, 0.38 mmol) in THF (5 ml), borane-THF complex (1 mol dm^{-3} in THF, 1.33 ml, 1.33 mmol) at 0 °C was added under argon atmosphere. After stirring at 0 °C for 20 min, then at ambient temperature for 90 min, 0.20 ml (0.20 mmol) of the reducing reagent was added and stirred for another 1 h. After addition of water (0.8 ml), aqueous NaOH (3 mol dm^{-3}, 1.26 ml) and aqueous hydrogen peroxide (35%, 1.44 ml) were added successively. The mixture was stirred for 3 h, neutralized with 1 mol dm^{-3} HCl, and evaporated. The mixture was diluted with water (30 ml) and extracted with dichloromethane (40 ml×3). The extracts were dried (Na_2SO_4) and evaporated. The residue was acetylated with acetic anhydride (3 ml) in pyridine (3 ml) for 12 h, then evaporated. The residue was chromatographed on silica gel (20 g, ethyl acetate-hexane=1:6). Fractions corresponding

to R_f 0.74 (ethyl acetate-hexane=1:2) were evaporated to afford **16** (17 mg), and fractions corresponding to R_f 0.72 were evaporated to afford **20** (111 mg). In addition, a mixture of **16** and **20** (27 mg) was obtained, from which pure **16** (5 mg) and **20** (17 mg) were separated by repeated PTLC (ethyl acetate-hexane=1:5) [**16** (22 mg, 11%) and **20** (128 mg, 63%)]. **20**: Mp 56—57 °C; $[\alpha]_D^{24}$ +1.9° (*c* 1.03, $CHCl_3$); IR ν_{max}^{KBr} 3080, 2850, 1740, 1490, 1450, 1360, 1240 cm^{-1}; ^1H NMR ($CDCl_3$) δ 1.71—2.26 (3H, m, H-1,6,6'), 1.89, 2.01 (3H×2, each s, 2×$OCOCH_3$), 3.31—3.70 (3H, m, H-3,4,5), 3.86—4.17 (2H, m, CH_2OAc), 4.52—5.19 (7H, m, H-2, 3×$OCH_2C_6H_5$), 7.29, 7.32, 7.37 (15H, each s, 3×$OCH_2C_6H_5$). Found: C, 71.91; H, 6.77%. Calcd for $C_{32}H_{36}O_7$: C, 72.16; H, 6.81%.

(1*R*,2*R*,3*S*,4*S*,5*R*)-2,3,4,5-Tetraacetoxy-1-(acetoxymethyl)cyclohexane, Pentaacetate of Pseudo-β-D-glucopyranose (21). A solution of **20** (80 mg, 0.15 mmol) in methanol (2 ml) was hydrogenolyzed in the presence of 10% palladium on charcoal using a Parr apparatus for 14 h. The catalyst was removed by filtration, washed with methanol, and the filtrate and washing were combined, then evaporated. The residue was acetylated with acetic anhydride (1 ml) in pyridine (1 ml) for 7 h and evaporated. The residue was chromatographed on silica gel (6 g, ethyl acetate-hexane=1:4), and fractions corresponding to R_f 0.58 (ethyl acetate-hexane=1:1) were evaporated to afford **21** (57 mg, 98%), mp 114—116 °C, lit,[2] mp 115—116 °C; $[\alpha]_D^{23}$ +4.4° (*c* 1.23, $CHCl_3$), lit.,[2] $[\alpha]_D^{20}$ +13.8° (*c* 1.0, $CHCl_3$); IR ν_{max}^{KBr} 2860, 1740, 1430, 1370, 1230, 1030 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.23—2.60 (3H, m, H-1,6,6'), 1.97, 1.99, 2.02, 2.03 (3H, 3H, 6H, 3H, each s, 5×$OCOCH_3$), 3.84—4.26 (2H, m, CH_2OAc), 4.76—5.54 (4H, m, H-2,3,4,5). Found: C, 52.41; H, 6.08%. Calcd for $C_{17}H_{24}O_{10}$: C, 52.57; H, 6.23%.

(1*R*,3*S*,4*S*,5*R*,6*S*,8*R*,9*R*)-4-Azido-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane-3,5-diol (22). A solution of **9** (1.24 g, 5.43 mmol) in a mixture of 2-methoxyethanol and water (4:1, v/v, 20 ml) containing sodium azide (1.412 g, 21.7 mmol) and ammonium chloride (581 mg, 10.9 mmol) was refluxed for 4 h, and evaporated. To the residue, ethyl acetate (150 ml) was added and the mixture was stirred for 30 min. Insoluble material was removed by filtration through a Celite-pad, and the filtrate was evaporated to afford a crystalline **22**. Recrystallization from ethyl acetate and hexane gave 1.24 g (84%) of **22**, mp 172—173 °C; TLC R_f 0.18 (ethyl acetate-hexane=1:2); $[\alpha]_D^{27}$ +66.2° (*c* 1.00, MeOH); IR ν_{max}^{KBr} 3460, 3350, 3000, 2910, 2110, 1390, 1380, 1270, 1240, 1210, 1120 cm^{-1}. Found: C, 48.94; H, 6.34; N, 15.23%. Calcd for $C_{11}H_{17}N_3O_5$: C, 48.70; H, 6.32; N, 15.49%.

(1*R*,3*S*,4*S*,5*R*,6*S*,8*R*,9*R*)-3,5-Diacetoxy-4-azido-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (23). The compound **22** (17 mg, 0.06 mmol) was acetylated with acetic anhydride (1 ml) in pyridine (1 ml) for 4 h. After removal of the reagents, the residue was chromatographed on silica gel (2 g, ethyl acetate-hexane=1:6). Fractions corresponding to R_f 0.48 (ethyl acetate-hexane=1:2) were evaporated to afford **23** (21 mg, 96%) as a colorless syrup, $[\alpha]_D^{28}$ +39.6° (*c* 0.89, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2990, 2930, 2110, 1750, 1390, 1380, 1250, 1210, 1130, 1120 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.31, 1.50 (3H×2, each s, $C(CH_3)_2$), 1.78—2.20 (3H, m, H-1,2,2'), 2.09 (6H, s, 2×$OCOCH_3$), 3.95 (1H, dd, *J*=10.5 and 3 Hz, H-6), 4.02 (1H, t, $J_{3,4}=J_{4,5}$=3 Hz, H-4), 4.54 (1H, t, *J*=4 Hz, H-9), 4.96—5.26 (1H, m, H-3), 5.38 (1H, t, $J_{4,5}=J_{5,6}$=3 Hz, H-5), 5.80 (1H, d, *J*=4 Hz, H-8).

(1R,3*R*,4*S*,5*R*,6*S*,8*R*,9*R*)-4-Azido-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane-3,5-diol (22'). A solution of **9'** (220 mg, 0.96 mmol) in a mixture of 2-methoxyethanol and water (4:1, v/v, 5 ml) containing sodium azide (251 mg, 3.86 mmol) and ammonium chloride (103 mg, 1.93 mmol) was refluxed for 6 h, and evaporated. To the residue, ethyl acetate (40 ml) was added and the mixture was stirred for 30 min. Insoluble material was removed by filtration through a Celite-pad, and the filtrate was evaporated to afford crystalline **22'**. Recrystallization from ethyl acetate gave 228 mg (87%) of **22'**, mp 157—159 °C; TLC R_f=0.61 (ethanol-toluene=1:4); $[\alpha]_D^{24}$ −22.0° (*c* 1.00, MeOH); IR ν_{max}^{KBr} 3420, 3260, 2990, 2900, 2110, 1440, 1390, 1380, 1310, 1250, 1220 cm^{-1}.

(1*R*,3*R*,4*S*,5*R*,6*S*,8*R*,9*R*)-3,5-Diacetoxy-4-azido-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (23'). The compound **22'** (22 mg, 0.08 mmol) was acetylated with acetic anhydride (0.5 ml) in pyridine (1 ml) for 10 h. After removal of the reagents, the residue was chromatographed on silica gel (1.5 g, ethyl acetate-hexane=1:6). Fractions corresponding to R_f 0.40 (ethyl acetate-hexane=1:2) were evaporated to afford **23'** (27 mg, 94%) as crystals, mp 95—96 °C; $[\alpha]_D^{22}$ −17.2° (*c* 1.35, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2980, 2960, 2930, 2120, 1740, 1380, 1300, 1250, 1220, 1200 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.32, 1.51 (3H×2, each s, $C(CH_3)_2$), 1.80—2.44 (3H, m, H-1,2,2'), 2.05, 2.07 (3H×2, each s, 2×$OCOCH_3$), 3.95 (1H, dd, $J_{1,6}$=11.5 Hz and $J_{5,6}$=3 Hz), 4.09 (1H, t, $J_{3,4}=J_{4,5}$=3 Hz, H-4), 4.58 (1H, t, *J*=4 Hz, H-9), 5.04 (1H, q, $J_{2ax,3}=J_{2eq,3}=J_{3,4}$=3 Hz, H-3), 5.32 (1H, t, $J_{4,5}=J_{5,6}$=3 Hz, H-5), 5.81 (1H, d, *J*=4 Hz, H-8).

(1*R*,3*S*,4*S*,5*R*,6*S*,8*R*,9*R*)-4-Acetamido-3,5-diacetoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (24). A solution of **22** (87 mg, 0.32 mmol) in methanol (6 ml) was hydrogenated in the presence of 10% palladium on charcoal (40 mg) under atmospheric hydrogen pressure for 3 h. After removal of the catalyst, the filtrate was evaporated. The residue was acetylated with acetic anhydride (1 ml) in pyridine (3 ml) for 10 h. The solution was evaporated, and the residue was chromatographed on silica gel (3 g, ethanol-toluene=1:30). Fractions corresponding to R_f 0.41 (ethanol-toluene=1:5) were evaporated to afford **24** (84 mg, 71%), mp 110—112 °C; $[\alpha]_D^{24}$ +9.5° (*c* 0.84, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2980, 2930, 1740, 1670, 1490, 1460, 1370, 1300, 1240 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ 1.33, 1.53 (3H×2, each s, $(CH_3)_2$), 1.68 (1H, q, *J*=12.2 Hz, H-2ax), 2.03, 2.05, 2.09 (3H×3, each s, 2×$OCOCH_3$ and $NCOCH_3$), 1.99—2.18 (2H, m, H-1 and 2eq), 3.83 (1H, dd, $J_{1,6}$=11.2 Hz, $J_{5,6}$=2.9 Hz, H-6), 4.47 (1H, dt, $J_{3,4}=J_{4,5}$=2.9 Hz, $J_{NH,4}$=7.8 Hz, H-4, changed to t with *J*=2.9 Hz by D_2O), 4.58 (1H, t, $J_{1,9}=J_{8,9}$=3.4 Hz, H-9), 5.20 (1H, dt, $J_{2ax,3}$=12.2 Hz, $J_{2eq,3}=J_{3,4}$=2.9 Hz, H-3), 5.43 (1H, d, $J_{NH,3}$=7.8 Hz, NH), 5.59 (1H, t, $J_{4,5}=J_{5,6}$=2.9 Hz, H-5), 5.83 (1H, d, $J_{8,9}$=3.4 Hz, H-8). High-resolution mass spectrum, calcd for $C_{17}H_{25}NO_8$: *m/z* 371.1579, found: M, 371.1595.

(1*R*,3*R*,4*S*,5*R*,6*S*,8*R*,9*R*)-4-Acetamido-3,5-diacetoxy-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (24'). The compound **22'** (100 mg, 0.37 mmol) was converted to **24'** (110 mg, 80%) as described in preparation of **24**. **24'** as a colorless syrup; TLC R_f 0.41 (ethanol-toluene=1:5); $[\alpha]_D^{25}$ −15.1° (*c* 1.32, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2990, 2940, 1740, 1680, 1490,

1440, 1370, 1300, 1240, 1200 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ=1.34, 1.52 (3H×2, each, s, $(CH_3)_2$), 2.01, 2.07, 2.08 (3H×3, each s, 2×$OCOCH_3$ and $NCOCH_3$), 1.80—2.36 (3H, m, H-1 and H-2ax, 2-eq), 3.79 (1H, dd, $J_{1,6}$=11.2 Hz, $J_{5,6}$=2.9 Hz, H-6), 4.43 (1H, broad d, $J_{NH,4}$=8.3 Hz, changed to broad singlet with less than 3 Hz of $J_{3,4}$, $J_{4,5}$ by D_2O, H-4), 4.60 (1H, t, $J_{1,9}$=$J_{8,9}$=3.9 Hz, H-9), 5.00 (1H, q, $J_{2ax,3}$, $J_{2eq,3}$, $J_{3,4}$ less than 3 Hz, H-3), 5.37 (1H, broad singlet, $J_{4,5}$ less than 3 Hz, $J_{5,6}$=2.9 Hz, H-5), 5.47 (1H, d, $J_{NH,3}$=8.3 Hz, NH), 5.83 (1H, d, $J_{8,9}$=3.9 Hz, H-8). High-resolution mass spectrum, calcd for $C_{17}H_{25}NO_8$: m/z 371.1577, found: M, 371.1558.

(1*R*,3*S*,4*S*,5*R*,6*S*,8*R*,9*R*)-4-Azido-3,5-bis(benzyloxy)-8,9-isopropylidenedioxy-7-oxabicyclo[4.3.0]nonane (25). To a stirred suspension of sodium hydride (60%, 416 mg, 10.4 mmol, washed with hexane, then dried) in DMF (10 ml), a DMF (10 ml) solution of **22** (564 mg, 2.08 mmol) was added. After stirring for 20 min, benzylbromide (1.24 ml, 10.4 mmol) was added to the mixture. The mixture was stirred for 5 h at ambient temperature, then ethanol (10 ml) was added. After evaporation of the mixture, the residue was partitioned between dichloromethane (60 ml) and water (60 ml). The aqueous layer was extracted with dichloromethane (60 ml×2). The organic layers were dried (Na_2SO_4) and evaporated. The residue was chromatographed on silica gel (20 g, ethyl acetate–hexane=1:20), and fractions corresponding to R_f 0.40 (ethyl acetate–hexane=1:6) were evaporated to afford **25** (772 mg, 82%) as a colorless syrup, $[\alpha]_D^{27}$ +48.2° (*c* 1.02, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3000, 2930, 2880, 2110, 1450, 1390, 1380, 1270, 1170, 1140 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.30, 1.51 (3H×2, each s, $C(CH_3)_2$), 1.66—2.14 (3H, m, H-1,2,2′), 3.80—4.10 (4H, m, H-3,4,5,6), 4.43—4.88 (5H, m, H-9,2×$OCH_2C_6H_5$), 5.81 (1H, d, *J*=4 Hz, H-8), 7.32, 7.34 (10H, each s, 2×$OCH_2C_6H_5$). High-resolution mass spectrum, calcd for $C_{24}H_{26}N_3O_5$: m/z 436.1860, found: M−CH_3, 436.1870.

(1*S*,2*S*,3*R*,4*S*,5*S*)-2-Acetoxy-1-acetoxymethyl-4-azido-3,5-bis(benzyloxy)cyclohexane (27). A solution of **25** (600 mg, 1.33 mmol) in a mixture of 1 mol dm^{-3} HCl (2 ml) and 1,4-dioxane (8 ml) was refluxed for 30 min, neutralized with saturated aqueous $NaHCO_3$, then evaporated. To the residue, ethyl acetate (80 ml) was added and insoluble solids were removed by filtration through a Celite-pad. The filtrate was evaporated to afford crude *O*-deisopropylidene derivative. To a stirred solution of the residue in ethanol (10 ml), sodium borohydride (101 mg, 2.66 mmol) was added. The mixture was stirred at 0 °C for 1 h, diluted with water (2 ml), neutralized with 1 mol dm^{-3} HCl, and evaporated. To the residue, ethyl acetate (80 ml) was added, and insoluble solids were removed by filtration through a Celite-pad. The filtrate was evaporated to afford a foam. The foam was dissolved in methanol (10 ml), and an aqueous (2 ml) solution of sodium periodate (568 mg, 2.66 mmol) was added. The mixture was stirred at the ambient temperature for 1 h and evaporated. To the residue, ethyl acetate (60 ml) was added, and insoluble materials were removed. The filtrate was evaporated to afford crude (1*R*,2*S*,3*R*,4*S*,5*S*)-4-azido-3,5-bis(benzyloxy)-2-hydroxycyclohexanecarbaldehyde (**26**) (TLC R_f 0.70, ethanol–toluene=1:5). To a solution of the crude **26** in ethanol (10 ml), sodium borohydride (101 mg, 2.66 mmol) was added, and the mixture was stirred for 2 h. The mixture was diluted with water (2 ml), neutralized with 1 mol dm^{-3} HCl, and evaporated. To the residue, ethyl acetate (60 ml) was added, and insoluble solids were removed. The filtrate was evaporated. The residue was chromatographed on silica gel (20 g, toluene, then ethanol–toluene=1:5). Fractions corresponding to R_f 0.56 (ethanol–toluene=1:5) were evaporated to afford (1*S*,2*S*,3*R*,4*S*,5*S*)-4-azido-3,5-bis(benzyloxy)-2-hydroxycyclohexanemethanol as a colorless syrup, which was acetylated with acetic anhydride (4 ml) in pyridine (8 ml) for 10 h. The mixture was evaporated, and the residue was chromatographed on silica gel (35 g, ethyl acetate–hexane=1:8). Fractions corresponding to R_f 0.45 (ethyl acetate–hexane=1:3) were evaporated to afford **27** (348 mg, 56% from **25**) as a colorless syrup, $[\alpha]_D^{27}$ −29.1° (*c* 0.70, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2920, 2110, 1730, 1450, 1370, 1320, 1250, 1210 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.47—2.52 (3H, m, H-1,6,6′), 1.97, 2.02 (3H×2, each s, 2×$OCOCH_3$), 3.78—4.13 (5H, m, H-3,4,5, OH_2OAc), 4.34—4.72 (4H, m, 2×$OCH_2C_6H_5$), 4.92 (1H, dd, *J*=12 and 3 Hz, H-2), 7.30, 7.33 (10H, each s, 2×$OCH_2C_6H_5$).

(1*S*,2*S*,3*R*,4*S*,5*S*)-4-Acetamido-2-acetoxy-1-acetoxymethyl-3,5-bis(benzyloxy)cyclohexane (28). A solution of **27** (198 mg, 0.42 mmol) in ethanol (10 ml) was hydrogenated in the presence of Raney nickel T-4 under hydrogen at atmospheric pressure for 2 h. The catalyst was removed by filtration through a Celite-pad, and the filtrate was evaporated. The residue was acetylated with acetic anhydride (3 ml) in pyridine (6 ml) for 2 h. The mixture was evaporated, and the residue was chromatographed on silica gel (14 g, ethanol–toluene=1:20), and fractions corresponding to R_f 0.35 (ethanol–toluene=1:10) were evaporated to afford **28** (164 mg, 80%) as a colorless syrup, $[\alpha]_D^{24}$ −3.6° (*c* 1.10, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 3000, 2930, 2870, 1730, 1670, 1490, 1450, 1370, 1250 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.44—2.58 (3H, m, H-1,6,6′), 1.91 (3H, s, $NCOCH_3$), 1.97, 2.02 (3H×2, each s, 2×$OCOCH_3$), 3.80—4.26 (4H, m, H-3,5, CH_2OAc), 4.34—4.74 (1H, m, H-4), 4.43, 4.62 (4H, each s, 2×$OCH_2C_6H_5$), 5.06 (1H, dd, *J*=9 and 3 Hz, H-2), 5.69 (1H, d, *J*=7 Hz, NH), 7.30, 7.33 (10H, each s, 2×$OCH_2C_6H_5$). High-resolution mass spectrum, calcd for $C_{27}H_{34}NO_7$: m/z 484.2333, found: M+H, 484.2317.

(1*S*,2*S*,3*R*,4*S*,5*S*)-4-Acetamido-2,3,5-triacetoxy-1-(acetoxymethyl)cyclohexane, Pentaacetate of Pseudo-2-amino-2-deoxy-β-L-altropyranose (29). A solution of **28** (140 mg, 0.29 mmol) in ethanol (10 ml) was hydrogenolyzed in the presence of palladium black in a Parr apparatus for 15 h. The catalyst was removed by filtration through a Celite-pad, and the filtrate was evaporated. The residue was acetylated with acetic anhydride (3 ml) in pyridine (8 ml) for 15 h. The mixture was evaporated, and the residue was chromatographed on silica gel (10 g, ethanol–toluene=1:20). Fractions corresponding to R_f 0.43 (ethanol–toluene=1:4) were evaporated to afford **29** (108 mg, 96%) as a colorless syrup, $[\alpha]_D^{18}$ +37.7° (*c* 0.87, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 1760, 1670, 1500, 1370, 1230 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.57—2.52 (3H, m, H-1,6,6′), 1.94 (3H, s, $NCOCH_3$), 2.06 (12H, s, 4×$OCOCH_3$), 3.98—4.23 (2H, m, CH_2OAc), 4.40—4.70 (1H, m, H-4), 5.10—5.37 (3H, m, H-2,3.5), 5.95 (1H, d, *J*=9 Hz, NH). High-resolution mass spectrum, calcd for $C_{17}H_{25}NO_9$: m/z 387.1528, found: M, 387.1533.

(3*S*,4*S*,5*S*)-4-Azido-3,5-bis(benzyloxy)-1-cyclohexene-1-methanol (30). The compound **25** (802 mg, 1.78 mmol) was converted to the crude **26** as described in preparation of **27**. To the solution of the crude **26** in pyridine (20 ml) was

added methanesulfonyl chloride (0.57 ml, 7.11 mmol). The mixture was stirred at the ambient temperature for 8 h and evaporated. The residue was partitioned between dichloromethane (60 ml) and water (60 ml), and the aqueous layer was extracted with dichloromethane (60 ml×2). The organic layers were dried (Na_2SO_4) and evaporated to afford a brown syrup [main product, R_f 0.63 (ethyl acetate-hexane=1:3)]. To a solution of the syrup in dichloromethane (10 ml) was added diisobutylaluminium hydride (1.5 mol dm^{-3} in toluene, 9.47 ml, 14.2 mmol) at −15 °C. The resulting insoluble materials were removed through a Celite-pad and washed with ethyl acetate. The combined filtrate and washings were evaporated. The residue was chromatographed on silica gel (30 g, ethyl acetate-hexane=1:4), and fractions corresponding to R_f 0.31 (ethyl acetate-hexane=1:2) were evaporated to afford **30** (176 mg, 27% from **25**) as a colorless syrup, $[\alpha]_D^{22}$ +68.1° (*c* 1.39, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2920, 2860, 2110, 1350, 1260 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.57—1.84 (1H, m, OH), 2.20—2.39 (2H, m, H-6,6′), 3.68—4.25 (5H, m, H-3,4,5,C*H*$_2$OH), 4.62 (4H, s, 2×OC*H*$_2$C$_6$H$_5$), 5.66—5.80 (1H, m, H-2), 7.34 (10H, s, 2×OCH$_2$C$_6$*H*$_5$).

(1*R*,2*R*,3*R*,4*S*,5*S*)-2-Acetoxy-1-acetoxymethyl-4-azido-3,5-bis(benzyloxy)cyclohexane (31) and the (1*S*,2*S*,3*R*,4*S*,5*S*)-stereoisomer 27. To a solution of **30** (170 mg, 0.47 mmol) in THF (2 ml) was added borane-THF complex (1.0 mol dm^{-3} in THF, 1.86 ml, 1.86 mmol) at 0 °C under argon atmosphere. The mixture was stirred for 3 h, then hydrogen peroxide (35% aqueous solution, 4 ml) and 3 mol dm^{-3} NaOH (1 ml) were added. After stirring for 6 h, the solution was neutralized with 1 mol dm^{-3} HCl and diluted with water (20 ml). The aqueous solution was extracted with dichloromethane (30 ml×3). The extracts were dried (Na_2SO_4) and evaporated. The residue was acetylated with acetic anhydride (2 ml) in pyridine (4 ml) for 14 h and evaporated. The residue was chromatographed on silica gel (20 g, ethyl acetate-hexane=1:20). Fractions corresponding to R_f 0.61 (ethyl acetate-hexane=1:2) were evaporated to afford **27** (106 mg, 49%), and fractions corresponding to R_f 0.54 were evaporated to afford **31** (46 mg, 21%) as a colorless syrup. **31**: $[\alpha]_D^{18}$ +20.0° (*c* 0.75, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 2920, 2100, 1730, 1450, 1360, 1250, 1200 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.16—2.57 (3H, m, H-1,6,6′), 1.92, 2.01 (3H×2, each s, 2×OCOC*H*$_3$), 3.23—3.47 (1H, m, H-5), 3.70—4.23 (4H, m, H-3,4, C*H*$_2$OAc), 4.46—5.30 (4H, m, 2×OC*H*$_2$C$_6$H$_5$), 5.01 (1H, t, *J*=9 Hz, H-2), 7.32, 7.37 (10H, each s, 2×OCH$_2$C$_6$*H*$_5$).

(1*R*,2*R*,3*R*,4*S*,5*S*)-4-Acetamido-2-acetoxy-1-acetoxymethyl-3,5-bis(benzyloxy)cyclohexane (32). A solution of **31** (43 mg, 0.09 mmol) in ethanol (4 ml) was hydrogenated in the presence of Raney nickel T-4 under hydrogen at atmospheric pressure for 1.5 h. After removal of the catalyst, the filtrate was evaporated. The residue was acetylated with acetic anhydride (1 ml) in pyridine (3 ml) for 2 h. The mixture was evaporated, and the residue was chromatographed on silica gel (3 g, ethanol-toluene=1:20). Fractions corresponding to R_f 0.56 (ethanol-toluene=1:6) were evaporated to afford **32** (29 mg, 66%), mp 154—156 °C (recrystallized from ethyl acetate); $[\alpha]_D^{18}$ +65.6° (*c* 0.90, $CHCl_3$); IR ν_{max}^{KBr} 1730, 1640, 1380, 1370, 1280, 1240 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.27—2.57 (3H, m, H-1,6,6′), 1.72 (3H, s, NCOC*H*$_3$), 2.00, 2.04 (3H×2, each s, 2×OCOC*H*$_3$), 3.55—4.74 (9H, m, H-3,4,5, C*H*$_2$OAc, 2×OC*H*$_2$C$_6$H$_5$), 5.08 (1H, dd, *J*=11 and 9 Hz, H-2), 5.46 (1H, d, *J*=8 Hz, NH), 7.30, 7.33 (10H, s, 2×OCH$_2$C$_6$*H*$_5$). High-resolution mass spectrum, calcd for $C_{27}H_{34}NO_7$: *m/z* 484.2333, found: M+H, 484.2345.

(1*R*,2*R*,3*R*,4*S*,5*S*)-4-Acetamido-2,3,5-triacetoxy-1-(acetoxymethyl)cyclohexane, Pentaacetate of Pseudo-2-amino-2-deoxy-α-D-glucopyranose (33). A solution of **32** (22 mg, 0.05 mmol) in ethanol (4 ml) was hydrogenolyzed in the presence of palladium-black in a Parr apparatus for 12 h. The catalyst was removed through a Celite-pad, and the filtrate was evaporated. The residue was acetylated with acetic anhydride (2 ml) in pyridine (4 ml) for 10 h. After evaporation of the mixture, the residue was chromatographed on silica gel (2 g, ethanol-toluene=1:15). Fractions corresponding to R_f 0.43 (ethanol-toluene=1:4) were evaporated to afford **33** (17 mg, 92%) as a colorless syrup, $[\alpha]_D^{23}$ +75.6° (*c* 0.81, $CHCl_3$); IR $\nu_{max}^{CHCl_3}$ 1740, 1670, 1510, 1380, 1370, 1240 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.14—2.66 (3H, m, H-1,6,6′), 1.90 (3H, s, NCOC*H*$_3$) 2.03, 2.05, 2.13 (6H, 3H, 3H, each s, 4×OCOC*H*$_3$), 3.72—4.38 (3H, m, H-4, C*H*$_2$OAc), 4.94—5.34 (3H, m, H-2,3,5), 5.83 (1H, d, *J*=10 Hz, NH). (Received September 11, 1986)

The reactions of an aryliminodimagnesium reagent ($ArN(MgBr)_2$) with four oxidizing agents ((i): I_2, OsO_4, $C_6H_5IO_2$, I_2O_5) and four push-pull substituted α-benzylideneacetophenones(ii) were examined. In the reactions with (i), the maximum yield of *sym*-azobenzene was 50%. In the reactions with (ii), in addition to products formed via condensation and the typical radical processes, unexpected products formed via cleavages of C=C and C_β–H bonds were observed. Summarizing these results, a pathway involving the formation of aryl-nitrene-like species via disproportionation of arylaminyl radicals ($Ar\dot{N}MgBr$) has been proposed.

Biaryl is frequently formed as a by-product in the reaction of Grignard reagent(ArMgBr) with a substrate via an electron transfer to the substrate and a subsequent radical dimerization. Similarly, symmetrical(*sym*-) azoarene(ArN=NAr) is formed as a by-product in the reaction of aryliminodimagnesium reagent($ArN(MgBr)_2$, aryl-IDMg), especially with nitrobenzenes[1] and *ortho*-quinones.[2] The formation of *sym*-azoarene is initiated by electron transfer from the reagent, in spite of its weak electron-donating ability(EDA),[3] to produce arylaminyl radical($Ar\dot{N}MgBr$).[4] However, a further removal of electrons is needed for azoarene formation; the pathway has not been studied. The previously reported yield of *sym*-azoarenes, based on the half molar amount of substrate used,[1,2] must be reexamined for elucidating the reaction pathway.

The present authors first studied *sym*-azoarene formation in a reaction of IDMg with four oxidizing agents: iodine(**A**), osmium tetraoxide(**B**), iodylbenzene(**C**), and iodine pentaoxide(**D**). The latter three agents have functional groups($-\overset{+}{X}\!\!\begin{array}{l}/\!/O\\ \backslash O^-\end{array}$: X=Os and I) that are structurally similar to the nitro group(X=N). Agents **A**—**C** proved to be more effective than nitrobenzenes for *sym*-azoarene formation, but the yield never exceeded 50%. On the other hand in the IDMg reaction with some α-benzylideneacetophenones, the formation of an abnormal product via the cleavage of C=C and C_β–H bonds was observed. Summarizing these results, the pathway for the oxidation of IDMg molecules will be discussed.

Results and Discussion

***sym*-Azoarene Formation in IDMg Reactions with Oxidizing Agents.** Oxidants **A**, **C**, and **D** are difficultly soluble in tetrahydrofuran (THF), and reactions with IDMg were carried out by adding a solution of the reagent in THF to the oxidant suspended in the same solvent at room temperature. The resulting mixture was stirred at the same temperature(or at 55 °C) for a certain number of hours. In order to avoid the oxidation of THF, oxidant **B** was dissolved in benzene. Because of the dimeric structure of *sym*-azoarenes, their yields were calculated based on the half molar amount of **A**—**D** used(summarized in Table 1(Runs 1—21)).

In the reaction with **A**(Runs 1—8), the *p*-MeO-substituted reagent is oxidized more easily than *p*-Me- and *p*-Cl-substituted ones(Runs 1, 3, and 6); prolonged heating is also effective for improving the yields (Runs 2 and 7). When two molar equivalents of **A** is used(Runs 4, 5, and 8), the yields given in the table(20 and 25%) correspond to those of 40 and 50%(based on the molar amount of IDMg used). It is thus concluded that the yield does not exceed 50%. The yield was unaffected by the addition of anhydrous $CoCl_2$, which is effective for the formation of biaryl from ArMgBr.[5]

In the reaction of **B** with *p*-$MeOC_6H_4$–IDMg(Runs 9—12), heating the mixture for half an hour is more effective than the use of two molar equivalents of the reagent. Oxidant **B** is more effective than **A** for *sym*-azoarene formation, but the yield does not exceed 50%(again).

In the reaction with **C**(Runs 13—19), the use of two molar equivalents of IDMg and prolonged heating were needed for improving the yields (Runs 17 and 18), but the use of two molar equivalents of the oxidant is not effective(Run 19). The deoxygenation of **C**, affording iodobenzene in yields of 35—70%, was confirmed by GLC analyses, but the yield of *sym*-azoarene did not exceed 50%(again). An attempt to estimate the electron-accepting ability(EAA) of **C** in THF by measuring the reduction potential with cyclic voltammetry[6] was unsuccessful due to the insolubility of **C** in the solvent. The low yield in the reaction with **D**(Runs 20 and 21) is due to its insolubility in THF.

Unusual C=C and C_β–H Cleavage of Some α-Benzylideneacetophenones in IDMg Reactions. The

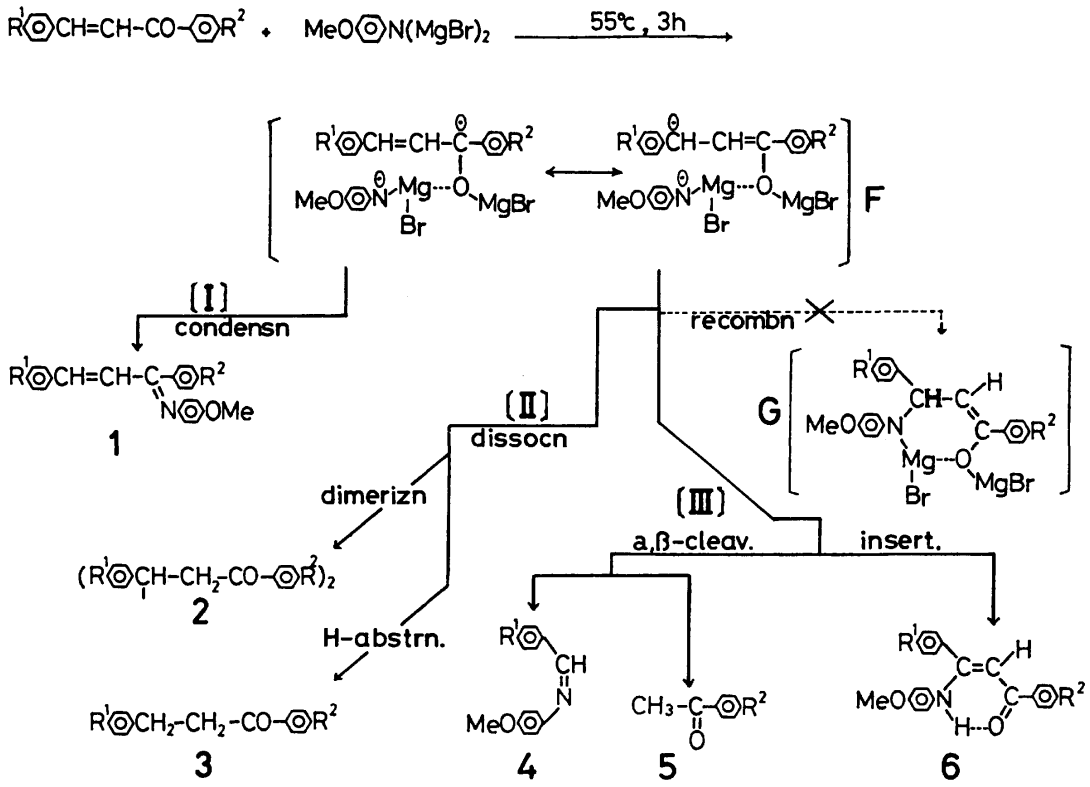
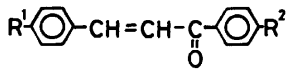


Scheme 1.

IDMg reactions with α-benzylideneacetophenones were independent of those with the oxidants **A**—**C**, and afford no *sym*-azoarene. The results of the reactions with the enones, however, are described in this paper because the formation of some unusual products is explainable(shown below) by a pathway involving two electron oxidation of IDMg molecules. The initial plan was to examine the electronic effect of substituents of the enones on the formation of the 1,4-addition product. This product was obtained in low yield in a preliminary study[2] using an enone having substituents in the weakly pull-push manner, namely, *p*-Cl and *p*-Me substituents on the benzylidene and benzoyl moieties, respectively.

In the present study, enones having substituents in the strongly pull-push(**Ea** and **Ec**) and push-pull(**Eb** and **Ed**) manners were sumbitted to the reaction with 1.2 molar equivalents of *p*-$MeOC_6H_4$-IDMg. The molar ratio of the reagent to enone was the same as that used in the previous study.[2] Six products(**1**—**6**)



Ea: R^1=Cl, R^2=MeO; **Eb**: R^1=MeO, R^2=Cl;
Ec: R^1=CN, R^2=Me_2N; **Ed**: R^1=Me_2N, R^2=CN.

obtained are shown in Scheme 1 and the yields as well as the amount of recovery are summarized in Table 2. The overall amount of recovery and conversion were sufficiently high with respect to the substrate. In the reaction with **Ea**, *p*-$MeOC_6H_4$-IDMg (oxidation peak potential: 0.941 V[3]) and *p*-MeC_6H_4-IDMg(0.921 V[3]) gave **1**—**6** in almost the same yields.

The relative amounts of recovery(**Ed**>**Eb**>**Ea**>**Ec**) suggest that the σ-complex formation via coordination of an enone carbonyl oxygen to a Mg atom of the reagent governs the reactivity of enone. A similar enhancement of the reactivity by an electron-repelling substituent of the substrate was observed in IDMg reactions with benzophenones.[4] The lowest reactivity of **Ed** may be related to its resonance stabilized structure, indicated by the λ_{max} appearing at much longer wavelnegths (Table 2).

The six products are classified into three types(I—III). Each type of product and its combined yields are given in brackets in the scheme and table. Types-I(**1**) and -II(**2** and **3**) products are those expected from the previous results,[2] the former being formed via condensation and the latter being formed via typical radical pathways: dimerization and hydrogen abstraction. For elucidating the yields of Types-I and -II products, the EAA of enone is an estimate for the rapidness in generating the radical intermediate **F**(Scheme 1). The reduction potentials(redox) of **Ec**(−1.491 V) and **Ed**(−1.527 V) are consistent with the relative reactivities given above and also with the high and low yields of II. The quantumn mechanical calculations were carried out by assuming a planar geometry for estimating the spin density on the carbonyl and β-carbon of anion radicals of **Ec** and **Ed**(Fig. 1). The actual intermediate must be magnesium ketyl(**F**), but not the anion radical; the actual geometry is equivocal. However, the spin density on β-carbon is positive in the case of the

Table 2. Product Distribution in the Reaction of *p*-MeC_6H_4-IDMg with Pull-Push and Push-Pull α-Benzylideneacetophenones **Ea**, **Eb**, **Ec**, and **Ed**

p-$R^1C_6H_4CH$=$CHCOC_6H_4R^2$-*p*			Product yield/% [Type]/No.						
		λ_{max}/nm	Recovd.	[I]	[II]		[III]		Overall
R^1	R^2			**1**	**2**	**3**	**4**	**5**[a] **6**	
Ea Cl	MeO	318	18	[0] 0	[38] 33	5	9	[24] (10) 15	80
Eb MeO	Cl	340	31	[23] 23	[14] 0	14	3	[29] (2) 26	97
Ec CN	Me_2N	352	2	[9] 9	[48] 48	0	19	[27] (?) 8	86
Ed Me_2N	CN	424	50	[12] 12	[20] 5	15	Trace	[Trace][b] (0) Trace	82

a) The yield of **5** should be the same with that of **4**, and is given in parentheses. The reason for the unsuccessful detection of **5c** is obscure. b) The trace amounts of **4d** and **6d** were identified by ^1H NMR on the basis of the singlets at δ 8.9(-CH=N-) and 13.18(⟩NH···O=C⟨), respectively.

most reactive **Ec**, while it is negative in the case of the least reactive **Ed**. The positive spin density on the β-carbon of **Ec** ketyl, which is effectively generated, is thus responsible for the high yield of II. The yield of **2** is remarkably higher than that of **3** in cases of more reactive **Ea** and **Ec**, while the yields of **3** is slightly higher than that of **2** in cases of the less reactive **Eb** and **Ed**. The relative yield of the dimeric(**2**) and monomeric(**3**) products indicates the relative rapidness in generating **F** from the former and the latter enones, and is explained similarly.

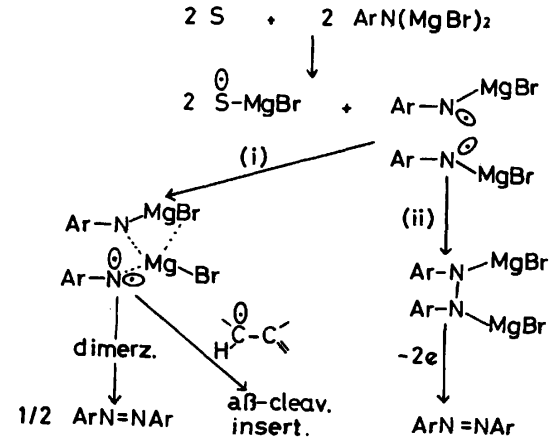
The relative yields of Type-I products(**Eb**>**Ed**>**Ec**>**Ea**) indicate that their formation is favored by the small but positive spin density on the carbonyl carbon of the enone ketyl; the effect, however, is modified by EAA.

Type III products(**4**—**6**) are those formed via an attack of a species generated from IDMg on the β-position of the enone, causing the cleavage of C=C and C_β–H bonds. No evidence for the initially expected attack of the arylaminyl radical on the β-carbon of ketyl leading to 1,4-addition product(**G**, Scheme 1) was obtained. An unusual bond cleavage was observed for the first time in reactions of the enones with Grignard and IDMg reagents;[2] the attacking species will be discussed separately in the following section.

Two-Electron Oxidation of IDMg Molecules. The seemingly poor, but significant, results suggesting the possibility of the formation of an arylnitrene-like species from IDMg molecules were obtained in the following experiments. When reactions of *p*-MeC_6H_4–IDMg with **C** was carried out in the presence of an equimolar amount of bicyclo[2.2.1]hept-2-ene(norbornene), the main product was the *sym*-azoarene and a trace amount of the corresponding 1-azirine was detected. When IDMg derived from 2-aminobiphenyl in THF was electrolyzed using Bu_4NClO_4 as a supporting electrolyte, a trace amount of carbazole was detected. No formation of carbazole was observed in reactions of 2-biphenylyl–IDMg with 2,4,6-Me_3-, 2-Cl-, and 4-Cl-nitrobenzenes.

In contrast to the good yields of 1-azirine and carbazole obtained in photolyses of the corresponding azides[7] and in the thermal deoxygenation of 2-nitrobiphenyl by phosphorus(III) compounds,[8] the results of the above experiments are quite poor. However, the poor yields are reasonable since the arylnitrene-like species is not free from Mg ions and is not effectively trapped by norbornene and/or by the phenyl group (vide infra). The identification of arylnitrene by the electronic absorption spectra[9] was unsuccessful because the reaction mixture was deeply colored.

The most possible pathway for generating arylnitrene-like species from an arylaminyl radical is its disproportionation shown in Scheme 2(i), which is compatible with the maximum yield of *sym*-azoarenes(vide supra). Another pathway involving the dimerization of arylaminyl radicals (Scheme 2(ii)) is suggested from the formation of a product having an *o*-(*N*,*N*′-diarylhydrazino) group in the IDMg reaction with *o*-MeO-nitrobenzene;[11] the latter scheme, however, is incompatible with the maximum yield of *sym*-azoarenes.



Scheme 2.

In reactions with enones, the correlation of yields of **4** and **6** with those of **2** and **3**, respectively, supports the proposal of a pathway involving the attack of arylnitrene-like species on the β-position of enone ketyl. The poor yields of **4** and **6** in the reaction with **Ed** is consistent with its weak EAA and the lowest reactivity(vide supra). As the enone varies from **Ec** via **Ea** to **Eb**, the yields of **4** and **2** increase while those of **6** and **3** decrease. The yield of **4** is always less than half of that of **2** while the yield of **6** is always higher than that of **3**.

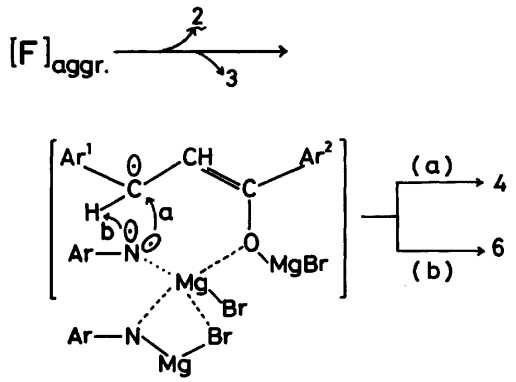
The enone **Ec** having strong EAA generates **F** rapidly, leading to aggregate formation. Inside an aggregate of **F**, a remarkable part of the ketyl dimerizes to afford **2** in high yields, leaving arylaminyl radical behind. The interaction of two arylaminyl radicals leads to generation of an arylnitrene-like species which attacks the ketyl at its β-carbon having positive spin density to give **4**(Scheme 3a). In the case of the less reactive **Eb**, the aggregate of **F** is not greatly accumulated. A part of the ketyl detached from **F** abstracts hydrogen from the solvent, affording the lower yield of **3**. Due to the interaction of **F** with the arylaminyl radicals left behind, an arylnirene-like species is generated; it attacks the ketyl at its β-hydrogen (which has a low spin density) instead of the β-carbon (which has a negative spin density (Scheme 3b)).

The fact that only 36% molar amount of IDMg is available for affording **1**, **4**, and **6** even in the reaction with **Ec** is also compatible with the pathways of Scheme 3. Whether the other ArN-moiety regenerates IDMg or not remains to be determined. The multiplicity of arylnitrene-like species has not yet been determined because of poor direct evidences. However, a triplet state is possible since a cleavage of the C=C bond of α-benzylideneacetophenone in the manner proposed above resembles formally an effective cleavage of the same enone anion radical via an attack of triplet oxygen.[10]

General Discussion. Most probably, *sym*-azoarenes are formed via the dimerization of an arylnitrene-like species,[9] which is generated according to Scheme 2(i). The substrates having strong EAA generate arylaminyl radicals effectively, and are favorable for *sym*-azoarene formation. Another essential factor assisting its formation is the structure of the substrate. An oxidative dimerization leading to *sym*-azoarenes was observed in IDMg reactions with nitrobenzenes,[1] *ortho*-quinones,[2] and the oxidants **B** and **C**, but was not observed in a reaction with 1,4-naphthoquinones, in spite of its strong EAA.[2] The neighboring oxygen atoms of substrates as well as the iodine atoms of **A** assist the arylaminyl radicals in being generated in proximity to each other, effectively leading to *sym*-azoarenes.

α-Benzylideneacetophenones have weaker EAA's than that of nitrobenzenes and quinones, and are less favorable for the rapid generation of an arylaminyl radical. As shown, however, by the formation of **4** and **6** in the reaction of weakly electron-donating IDMg[3] with weakly electron-accepting enones, the aggregation of **F** (vide supra) participates in generating arylnitrene-like species. In the IDMg reaction with benzophenones,[4] only the condensation and typical radical products are formed, probably because the phenyl groups are more resistant than the -CH=CH- group to the attack of arylnitrene-like species. Also, the poor yield of carbazole in the electrolysis of 2-biphenylyl-IDMg is not unexpected.

In accordance with the disproportionation mechanism, the previously reported yields of *sym*-azoarenes calculated based on half molar amount of substrates need not to be revised.



Scheme 3.

Experimental

Melting points are uncorrected.

Materials and Procedures. The oxidizing agents (**A**, **B**, and **D**) were commercially avilable; **C** was prepared from iodobenzene according to a reported method.[12] The enones **Ea—Ed** were prepared according to the usual procedure from the corresponding benzaldehydes and acetophenones. The IDMg reagents in THF were prepared by a reported procedure.[2]

In reactions of IDMg with the oxidants, the reagents(3—5 mmol) in THF(25—40 ml) was added to the suspension of **A—D** in THF or benzene(30 ml). The molar ratio of the reagent to the oxidant and the reaction conditions are given in Table 1. In reactions of IDMg with the enones, the substrates(2.6 mmol) dissolved in THF(20 ml) was added at

0 °C to a solution of *p*-$MeOC_6H_4$-IDMg (3.1 mmol) in THF(25 ml), and the resulting mixture was stirred at 55 °C for 2 h.

All the reaction mixtures were quenched with aqueous NH_4Cl and the products were isolated by column chromatography on silica gel(Wako Gel C-200 and C-300).

The reaction of IDMg with **C** in the presence of norbornene was carried out as follows: *p*-MeC_6H_4-IDMg(4.0 mmol) in THF(45 ml) was added to the suspension of equimolar amounts of **C** and the hydrocarbon in THF(20 ml), and the resulting mixture was stirred under the same conditions as those of Run 15 (Table 1).

The electrolysis of 2-biphenylyl-IDMg was carried out as follows: In a flask equipped with two Pt-wire electrodes, the reagent(6.0 mmol) in THF(40 ml) containing Bu_4NClO_4 (0.1 M 1 M=21 mol dm^{-3}) was electrolyzed under the conditions of 15.0 V–0.012 A and/or 20.0 V–0.062 A for 8—10 h. Reactions of the same reagent with 2,4,6-Me_3-, 2-Cl-, and 4-Cl-nitrobenzenes were carried out using a molar ratio of 2.5 at 55 °C for 2 h; the reaction mixtures were worked up according to the manner described above.

The reduction potentials(redox) of the enones **Ec** and **Ed** were measured in THF according to the reported method.[6]

The calculation of spin density was carried out within the framework of ab initio spin-unrestricted Hartree-Fock-(UHF) theory, using the STO-3G set[13] and standard geometry.[14]

Products. The results of elemental analyses and ^1H NMR data of the products **1**, **2**, **3**, and **6** are satisfactory. The melting points and ^1H NMR data are summarized in Table 3. Products **4** and **5** were identified by comparing their ^1H NMR spectra with those of commercially available and/or easily prepared authentic samples.

A trace amount of 1-azirine derived from norbornene was detected on the basis of the characteristic doublets appearing at δ 1.5—4.5.[7] A trace amount of carbazole was identified by a comparison with the characteristic doublet appearing at δ 8.2.

The authors are grateful to the Ministery of Education, Science, and Culture for a financial support by a Grant-in-Aid for Scientific Research (No. 60740026). Ab initio calculations were carried out at the Computor Center of the Institute for Molecular Science.

Thermal Rearrangement of 2,5-Bis(allyloxy)tropone, Revisited. Formation of Four Thermolysates under the Claisen Rearrangement Conditions and Structure Revision of the Major Thermolysate

Hitoshi TAKESHITA,* Akira MORI, Yasutomo GOTO,† and Tomohiro NAGAO†

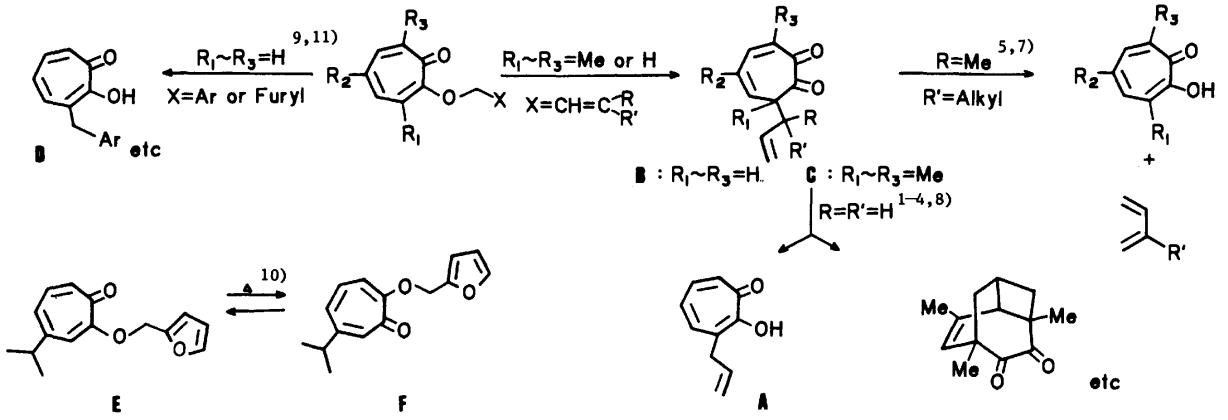
(Received September 12, 1986)

A reinvestigation of the Claisen rearrangement of 2,5-bis(allyloxy)tropone led to the isolation of three diallyl-5-hydroxytropolones along with an intermediary thermolysate, 3-allyl-5-allyloxytropolone. The structure of the formerly identified product was revised from 3,6-diallyl-5-hydroxytropolone to 4,6-diallyl-5-hydroxytropolone. The involvement of no cleavage-recombination process was established by cross-over deuterium labelling experiments. These derivatives were respectively converted to *p*-tropoquinones, one of which was further converted to a cyclohepta[*b*]pyranone derivative by an electrochemical reaction.

The Claisen-type [3,3] sigmatropy of a troponoid derivatives has revealed anomalous features; unsubstituted allyl and propargyl ethers of tropolones gave rearrangement products (**A**) in excellent yields.[1-4] However, allyl groups having a hydrogen-carrying substituent at C-3, e.g., 3-methyl-2-butenyl (prenyl) ethers of tropolones, gave rearrangement products in low yields[2,5] due to a consecutive occurrence of a Woodward-Hoffmann rule-allowed[6] [$_{\pi}6+_{\sigma}2+_{\sigma}2$] process from the proto-Claisen products (**B**).[7] The intramolecular Diels-Alder reaction of Claisen products from 2-allyloxy- and 2-propynyloxy-3,5,7-trimethyltropones constitutes a trapping of unaromatizable protoproducts (**C**).[8] The arylmethoxy- and heteroarylmethoxytropones, which are superficially capable of concerted sigmatropic reactions, yielded homolytic rearrangement products, 3- or/and 5-arylmethyl- and heteroarylmethyltropolones (**D**).[9-11] A sort of degenerated [1,9] sigmatropy[12] was conceived to occur prior to the rearrangement; the heating of two isomeric 2-furylmethyl ethers (**E** and **F**) prepared from hinokitiol (4-isopropyltropolone) gave thermolysates in the same yields.[10] Furthermore, thermolysis in dimethylsulfoxide caused an oxidative fragmentation to carbonyl compounds.[13] These chemical properties of tropolonyl ethers made their thermal reactions very complicated.

A decade ago, we investigated the Claisen rearrangement of 2,5-bis(allyloxy)tropone (**1**) and its various derivatives in order to construct several heterocyclic troponoids, e.g., cycloheptadifurans.[14] From parent **1**, we isolated yellow crystalline thermolysate (**2**) in 39% yield, and assigned it to 3,6-diallyl-5-hydroxytropolone from a mechanistic view point. Although the ^{1}H NMR spectrum of **2** or its acetate (**3**) revealed overlapped signals, indicating the presence of a symmetry element in the molecule, we simply thought that this phenomenon was accidental. During our recent studies regarding the preparation of various *p*-tropoquinone derivatives[15] and their cyclic voltammetry (CV) analysis,[16,17] we have reinvestigated the Claisen rearrangement of **1**, and have found the occurrence of four rearrangement products, suggesting the complicated pathways involved.



Scheme 1.

In this paper, we describe the structural determination of these thermolysates; this eventually leads to a revision of the structure of former thermolysate, **2**, from 3,6-diallyl-5-hydroxytropolone to 4,6-diallyl-5-hydroxytropolone, and the deuterium-labelling experiments to prove the intramolecular nature of this rearrangement.

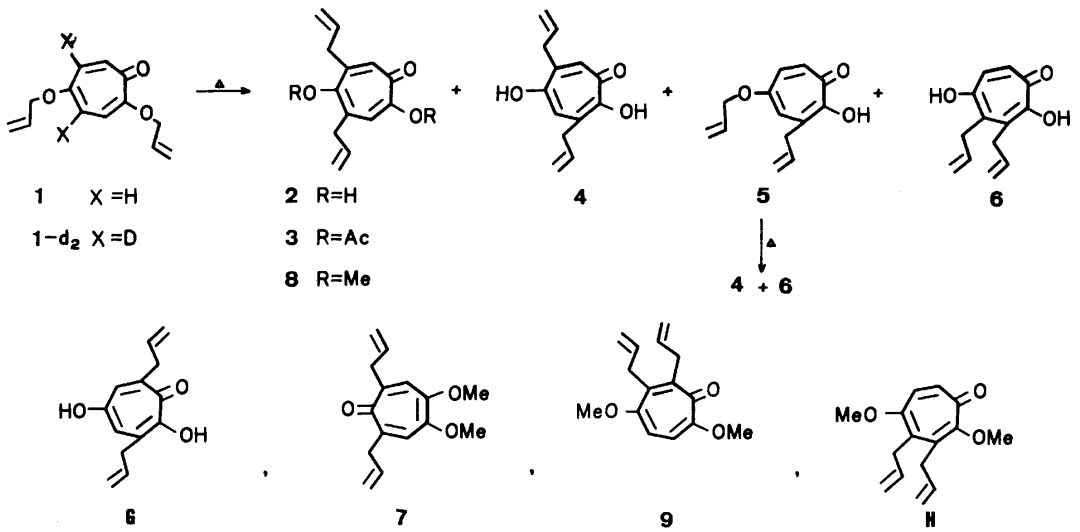
Results and Discussion

When **1** was refluxed in xylene for 2 h,[14] four products (**2**, **4**, **5**, and **6**) were formed; however, only three of them (**2**, **4**, and **5**) were detectable on the thin-layer chromatogram (TLC). The major products (**2** and **5**) were isolated by a silica-gel column chromatography and were identical with the previous samples.[14] Repeated silica-gel column chromatography of the intermediary fractions gave another product, **4**. Its ^{13}C and ^{1}H NMR spectra revealed no element of symmetry and no spin-spin coupling between the protons on the seven-membered ring. Consequently, it must be 3,6-diallyl-5-hydroxytropolone; thus, the previously assigned structure of **2** should be revised. These facts suggest that the structure of **2** is either 3,7-diallyl-5-hydroxytropolone (**G**) or 4,6-diallyl-5-hydroxytropolone. To differentiate the point, **2** was converted to two methyl ethers (**7** and **8**) by a treatment with diazomethane. The mixture could be fractionated by silica-gel column chromatography; the ^{1}H NMR spectrum of **8** revealed two aromatic proton signals at different fields (δ=6.59 and 7.15); however, that of **7** showed an overlapped signal for two protons at 7.32. In parallel, the ^{13}C NMR spectrum of **7** showed only eight signals but that of **8** showed fifteen well-resolved lines. If **2** were **G**, **8** should be formulated as 3,7-diallyl-2,5-dimethoxytropone, and its ^{1}H NMR spectrum must exhibit mutually spin-coupled C-4 and C-6 protons (as in the cases of **1**, **10**, and **5**) whose spin-spin coupling constants fall in a range of ca. J=3 Hz.[14] As mentioned, the aromatic proton signals of **8** appeared as two singlet lines. Moreover, the chemical shift of the aromatic protons of **7**, at 7.32, closely resembled the C-3 proton of 4,5-dimethoxytropone. Therefore, **2** must be 4,6-diallyl-5-hydroxytropolone.

From the later fractions of chromatography the third methyl ether (**9**) was isolated, which should be derived from the remaining thermolysate, **6**. Although the isolation of **6** from the thermolysis mixture failed, it was independently prepared in 12% yield together with **4**, in 72% yield, by a further thermolysis of **5**. The samples of methyl ether, **9**, prepared from both sources were mutually identical. The ^{1}H NMR of **6** revealed a pair of AB-signals (J=12 Hz) ascribable to vicinal protons on the seven-membered ring, indicating **6** to be 3,4-diallyl-5-hydroxytropolone and, hence, **9**, 2,3-diallyl-4,7-dimethoxytropone. The undetectability of the isomer, 3,4-diallyl-2,5-dimethoxytropone (**H**) in the methylation product of **6** must be explained in terms of a steric effect.

The product, **5**, was 3-allyl-5-allyloxytropolone. Among the thermolysates, **4** was the expected Claisen rearrangement product, while the major product, **2**, was an abnormal thermolysate, whose formation should involve complicated rearrangement processes.

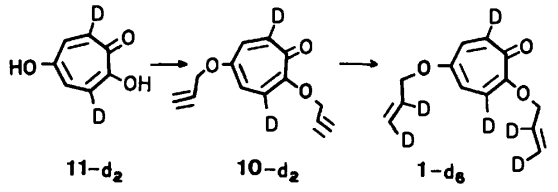
In order to elucidate the mechanism, we analyzed the isotope distributions of the thermolysates of the deuterio derivatives of **1**, 2,5-bis(allyloxy)tropone-4,6-d_2 (**1**-d_2) and 2,5-bis(allyl-2,3-d_2-oxy)tropone-3,7-d_2 (**1**-d_6). The **1**-d_2 was prepared by a condensation of 3-bromo-1-propene with 5-hydroxytropolone-4,6-d_2 (**11**-4,6-d_2).[18] The **1**-d_6 was prepared by catalytic deuteration with Lindlar's catalyst of 2,5-bis(2-propynyloxy)-tropone-3,7-d_2 (**10**-d_2), prepared by a condensation of 5-hydroxytropolone-3,7-d_2 (**11**-3,7-d_2) with 3-bromo-1-propyne.



Scheme 2.

The thermolysis of **1**-d_2 determined the location of the allyl groups; the major thermolysate, **2**-*d*, caused a loss of two deuterium atoms, while **4**-*d* retained half of the deuterium atoms and **5**-*d* lost only a fractional amount of deuterium atoms. Table 1 shows a mass-spectral analysis of these thermolysates.

When a 1:2-mixture of **1**-d_6 and **1**-d_0 was heated under similar conditions, again the mass spectrometry of the products isolated after silica-gel column chromatography eliminated the radical dissociation-recombination mechanism; the major product, **2**-*d*, revealed identical deuterium distributions with that of the starting material within the experimental error; i.e., its mass spectrometry deduced to be **2**-d_6 and **2**-d_0 (1:2), and there was no **2**-d_2 or **2**-d_4. Therefore, **2** had been formed by the intramolecular process throughout. Table 2 demonstrates the deuterium distributions of **2**-*d* and other thermolysates to confirm the conclusion. In the cases of **4**-*d* and **5**-*d*, an approximate 1:2:1-distribution of d_4-, d_5-, and d_6-components did not contradict the suggested mechanism, since there were substantial amounts of **1**-d_7 in the starting material. Probably, a partial deuterium exchange of the acidic hydrogen on the sp-carbon might have taken place prior to catalytic deuteration.



Scheme 3.

Table 1. The Mass-Spectral Determinations of Deuterium Contents of Thermolysates from **1**-d_2

Compound	*m/z* 218(d_0)	219(d_1)	220(d_2)	221(d_3)	222(d_4)
1-d_2	3.2	4.4	53.2	23.2	16.0
2-*d*	55.7	17.6	18.5	8.3	
4-*d*	27.6	50.4	20.7	1.4	
5-*d*	2.0	10.5	49.8	34.5	3.2

Interestingly, the thermolysis of **5** gave only **4** and **6**, whose formation must be straightforward. Hence, **2** might be derived from an undetected intermediary protoproduct (**J**). If it occurred via thermally-allowed concerted processes, either a), two-fold [3,3] sigmatropies, or b), consecutive [3,7] and [3,3] sigmatropies, should be considered, but the deuterium distributions can not distinguish these two routes. In this particular system, the [3,7] process, however, requires a relatively long-distance flight of the allyl group from C-2 oxygen to the C-5 oxygen; in such a case, the [3,7] process should be the rate-determining step of the rearrangement. The absence of the intermediate thermolysates from **J** to **2** may suggest that the possibility is unfavorable.[19]

In addition, the DDQ (2,3-dichloro-5,6-dicyano-*p*-benzoquinone)-oxidation of **4**, similar to that of **2**,[15] afforded 3,6-diallyl-*p*-tropoquinone (**12**) in good yield. The NMR spectra were consistent to the structure assigned in the present study.

Finally, we wish to record the results of an electrolytic reduction of **13**, 4,6-diallyl-*p*-tropoquinone, obtained from the major thermolysate, **2**. As described in the preliminary paper, the CV of several *p*-tropoquinones exhibited an extra oxidation wave after returned at the second oxidation wave.[20] For this extra wave, we assumed the occurrence of a side reaction from the quinones. When **13**, of which the wave was indeed the most pronounced one, was electrolyzed in an *N*,*N*-dimethylformamide (DMF) solution in the presence of a supporting electrolyte, tetrabutylammonium tetrafluoroborate (TBAT) at −0.4 V for 25 h,[21] the formation of a product (**14**) was detected by a TLC analysis. The NMR evidence showed the structure of **14** to be 9-allyl-7-hydroxycyclohepta[*b*]pyran-6(2*H*)-one; particularly, a related model compound, 2-methylfuro[3′,2′:3,4]cyclohepta-[1,2-*b*]pyran-4(8*H*)-one (**K**), identified previously among the Claisen rearrangement products of **10**, provided a closely resembled ^{1}H NMR spectral feature.[14]

Consequently, at least in the case of **13**, the irreversible extra oxidation wave was explainable in terms of the chemical reaction. However, the wave has appeared in the alkyl-*p*-tropoquinones, which should

Table 2. The Deuterium Distributions of the Starting Material and the Thermolysates Obtained from a 1:2-Mixture of **1**-d_6 and **1**-d_0

Compound	*m/z*	218(d_0)	219(d_1)	220(d_2)	221(d_3)	222(d_4)	223(d_5)	224(d_6)	225(d_7)
1-d_6		14.8	4.6	2.1	4.2	8.3	23.1	25.8	17.6[a]

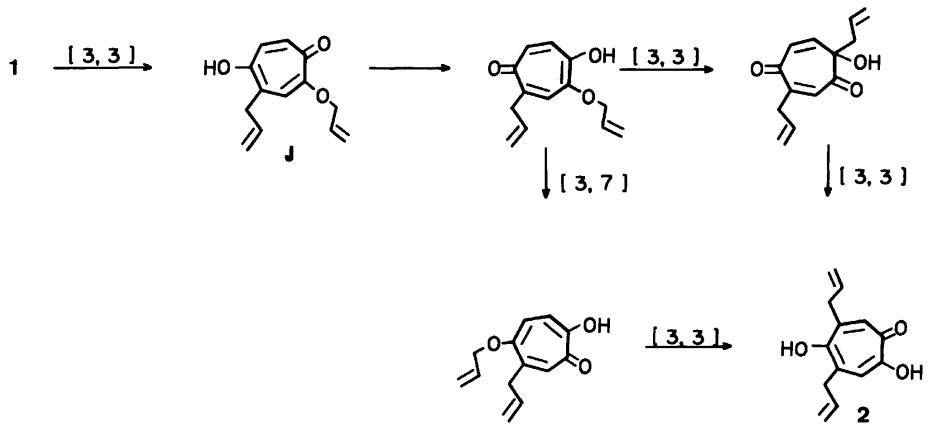
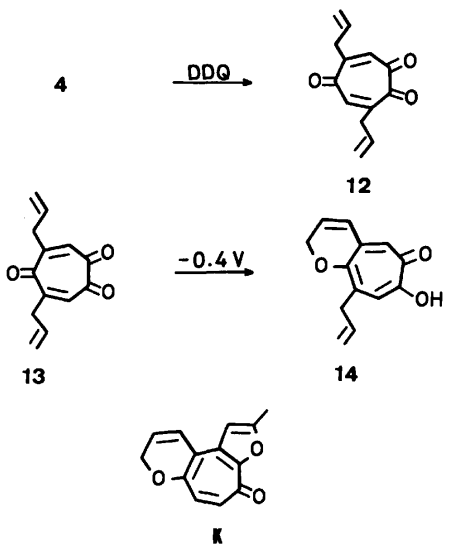
4-*d*		64.6	2.0	3.4	3.1	7.9	11.7	5.5	1.8
5-*d*		70.6	1.9	1.2	1.8	6.8	12.8	4.0	0.8

a) These figures show that the sample of **1**-d_6 contains nearly equal amount of **1**-d_5, together with some amounts of **1**-d_7.



Scheme 4.



Scheme 5.

not be capable of such a cyclization; thus, more extensive studies are needed.

Experimental

The elemental analyses were carried out by Miss S. Hirashima, of the Research Institute of Industrial Science, Kyushu University. The NMR spectra were measured by a JEOL FX 100 Spectrometer in $CDCl_3$ solution, unless otherwise specified, and the chemical shifts expressed were in δ unit. The mass spectra were measured with a JEOL OISG-2 Spectrometer. The IR spectra were taken as either KBr disks or an inserted liquid film between NaCl plates using a Jasco IR-A 102 Spectrometer.

Preparation of 2,5-Bis(allyloxy)tropone (1). To a mixture of an anhydrous hexamethylphosphoric triamide (HMPA, 100 cm³), **11** (2.0 g), and NaH (55%, 1.3 g), 3-bromo-1-propene (3 cm³) was added under an N_2 atmosphere at 70 °C. After stirring for 4 h, the mixture was acidified with dil HCl and extracted with ether. A silica-gel column chromatography of the extract afforded 5-allyloxytropolone [colorless needles, mp 137—138 °C (lit,[14] 137—138 °C), 485 mg; 19%], and **1** [a colorless oil, 1.65 g; 52%].[14]

Thermal Reaction of 2,5-Bis(allyloxy)tropone (1). Formation of 2, 4, and 5. A xylene solution (50 cm³) of **1** (1.17 g) was refluxed for 5 h under an N_2 atmosphere. The mixture was then heated in vacuo to remove the solvent, and the residue was chromatographed on a silica-gel column to give **5** [colorless needles, mp 72—73 °C (lit,[14] mp 72—73 °C), 316 mg; 27%], **4** [pale yellow crystals, mp 142.5—144.5 °C, 113 mg; 9.7%. Found: C, 71.53; H, 6.48%. Calcd for $C_{13}H_{14}O_3$: C, 71.54; H, 6.47%. ^{1}H NMR δ=3.37 (2H, d, J=5.5 Hz), 3.53 (2H, d, J=5.5 Hz), 4.9—5.3 (4H, m), 5.7—6.2 (2H, m), 7.30 (1H, br s), 7.43 (1H, s), and 8.1 (2H, br s). ^{13}C NMR δ=38.9, 39.2, 117.8, 118.0, 126.7, 128.2, 134.7, 134.9, 136.4, 138.5, 155.1, 164.5, and 167.2. IR ν: 3200—2600, 1395, 1290, 1240, and 925 cm^{-1}. UV λ_{max}^{MeOH}: 246.5 nm (ε=28400), 337.2 (7600), and 390 (11300)], and **2** [colorless needles, mp 126—127 °C (lit, [14] 126—127 °C), 304 mg; 26%].

Acetylation of 2 to 3. A pyridine solution (0.3 cm³) of **2** (15 mg) was treated with Ac_2O (20 mg) at room temperature for 24 h. The mixture was evaporated in vacuo, washed with dil $NaHCO_3$, and chromatographed on a silica-gel column to give **3** [colorless needles, mp 64.5—65.5 °C (lit, [14] 64.5—65.5 °C), 14 mg; 85%. Found: C, 67.41; H, 6.07%. Calcd for $C_{17}H_{18}O_5$: C, 67.54; H, 6.00%. ^{1}H NMR δ=2.28 (6H, s), 3.40 (4H, dd, J=7, 1 Hz), 5.1—5.2 (4H, m), 5.84 (2H, m), and 7.02 (2H, t, J=1 Hz). IR ν: 2980, 1765, and 1635 cm^{-1}].

Methylation of 2. Formation of 7 and 8. A 1:1-mixture of ether and acetone (50 cm³) containing **2** (129 mg) was treated with an excess of ethereal CH_2N_2 at 5—10 °C, and chromatographed on a silica-gel column to give **7** [a colorless oil, 76.4 mg; 53%. Found: M. W., 246.1214. Calcd for $C_{15}H_{18}O_3$: 246.1256. ^{1}H NMR δ=3.46 (4H, dm, J=7 Hz), 3.86 (6H, s), 5.0—5.2 (4H, m), 5.7—6.1 (2H, m), and 7.32 (2H, s). ^{13}C NMR δ=39.9 (2C), 58.9 (2C), 117.5 (2C), 129.5 (2C), 135.9 (2C), 145.8 (2C), 150.5 (2C), and 182.0. IR ν: 3500, 3080, 2990, 2950, 2850, 1735, 1710, 1635, 1560, 1490, 1390, 1255, 1130, 1090, 995, and 915 cm^{-1} UV λ_{max}^{MeOH}: 229 nm (ε=12200), 245 (14300), and 355 (9700)], and **8** [a colorless oil, 56.6 mg; 40%. Found: M. W., 246.1255. ^{1}H NMR δ=3.38 (2H, dm. J=7 Hz), 3.45 (2H, dm, J=7 Hz), 3.64 (3H, s), 3.85 (3H, s), 5.0—5.2 (4H, m), 5.7—6.1 (2H, m), 6.59 (1H, m), and 7.15 (1H, m). ^{13}C NMR δ=38.5, 39.4, 56.1, 61.7, 115.5, 117.7, 117.9, 134.8, 135.6, 136.4, 136.7, 147.6, 155.9, 161.2, and 178.9. IR ν: 3490, 3080, 2980, 2940, 2850, 1590, 1560, 1480, 1390, 1280, 1220, 1170, 1130, 1100, 1010, 990, and 920 cm^{-1}. UV λ_{max}^{MeOH}: 247 nm (ε=24900), 308 (5300, sh), 324 (7100, sh),

351 (7900), and 371 (5300)]. From the intermediary fractions, **9** [a colorless oil, a trace amount. Found: M. W., 246.1308. ^{1}H NMR δ=3.54 (2H, dt, J=6, 1.5 Hz), 3.64 (2H, dt, J=6, 1.5 Hz), 3.76 (3H, d, J=0.5 Hz), 3.81 (3H, d, J=0.5 Hz), 4.8—5.1 (4H, m), 5.7—6.1 (2H, m), 6.26 (1H, dq, J=11, 0.5 Hz), and 6.60 (1H, dq, J=11, 0.5 Hz). IR ν: 3600, 3090, 3000, 2950, 2850, 1600, 1560, 1505, 1460, 1410, 1390, 1240, 1210, 1175, 1125, and 1045 cm^{-1}. UV λ_{max}^{MeOH}: 245 nm (ε=19400), 332 (6900), 362 (7100), and 379 (5400, sh)], were isolated.

Further Thermal Reaction of 5. A xylene solution (4 cm^3) of **5** (70.5 mg) was heated in a sealed tube for 12 h. Silica-gel column chromatography of the mixture afforded **4** [50.8 mg; 72%] and **6** [yellow prisms, mp 172—174 °C, 8.5 mg; 12%. Found: C, 71.66; H, 6.52%. ^{1}H NMR (CD_3OD) δ=3.63 (2H, dt, J=6, 2 Hz), 3.73 (2H, dt, J=6, 2 Hz), 4.95—5.1 (4H, m), 5.75—6.2 (2H, m), 7.08 (1H, d, J=12 Hz), and 7.20 (1H, d, J=12 Hz). ^{13}C NMR (CD_3OD) δ=35.8, 36.3, 116.0 (2C), 123.3, 123.5, 136.5 (2C), 141.0, 141.7, 158.8, 166.0, and 169.7. IR ν: 3080—2330, 1630, 1610, 1520, 1350, and 1260 cm^{-1}. λ_{max}^{MeOH}: 246 nm (ε=25400), 339 (7400), 380 (9000), and 394.5 (9800)].

Methylation of 6. Similarly, **6** (21.4 mg) was methylated with ethereal CH_2N_2 to give **9** [15.3 mg; 63%], which was identical with the sample obtained from the above methylation mixture.

Methylation of 5-Hydroxytropolone. An acetone suspension (7 cm^3) of **11** (20 mg) was treated with ethereal CH_2N_2 (30 cm^3) and kept at 5 °C for 16 h. The resultant homogeneous solution was evaporated in vacuo and chromatographed on an alumina column to give 2,5-dimethoxytropone [17.5 mg; 71%] and 4,5-dimethoxytropone [colorless needles, mp 52—53 °C, 4.2 mg; 17%. Found: C, 65.11; H, 5.98%. Calcd for $C_9H_{10}O_3$: C, 65.05; H, 6.07%. ^{1}H NMR δ=3.91 (6H, s), 6.92 (2H, d, J=12 Hz), and 7.23 (2H, d, J=12Hz). ^{13}C NMR δ=58.6 (2C), 130.8 (2C), 136.3 (2C), 152.3 (2C), and 184.6].

Preparation of 5-Hydroxytropolone-3,7-d_2 (11-3,7-d_2). 2-Methoxytropone-3,5,7-d_3 (1.07 g) was dissolved in a mixed solution (260 cm^3) of MeOH:CS_2:ether (1:9:3) and irradiated by a 400-W tungsten lamp in the presence of tetraphenylporphyrin (42 mg) under the O_2 atmosphere at −30 °C for 10 h. The mixture was then treated with thiourea (5 g) at −5 °C for 4 d to give **11**-3,7-d_2 [665 mg; 62%].

Preparation of 2,5-Bis(2-propynyloxy)tropone-3,7-d_2 (10-d_2). An HMPA solution (5 cm^3) of **11**-3,7-d_2 (100 mg) was treated with NaH (50%, 103 mg) at room temperature, and 3-bromo-1-propyne (270 mg) was added drop by drop at room temperature. After being kept at 60 °C with stirring for 4 h, the mixture was worked up as usual to give **10**-d_2 [36 mg; 24%. ^{1}H NMR δ=2.51 (1H, t, J=2.5 Hz), 2.57 (1H, t, J=2.5 Hz), 4.65[22] (2H, d, J=2.5 Hz), 4.83 (2H. d, J=2.5 Hz), 6.43 (0.86H, br s), and 7.06 (1.14H, br s). m/z, 216:217:218:219=6.9:30.6:60.0:2.5].

Catalytic Deuteration of 10-d_2 with Lindlar's Catalyst to 1-d_6. An AcOEt solution (1.5 cm^3) with quinoline (0.25 cm^3) of **10**-d_2 (47.8 mg) was reduced by Lindlar's catalyst (Pd/$CaCO_3$-Pb, 25 mg) with D_2 gas. After take up of 13.4 cm^3 of D_2 (1.35 mol equiv), the mixture was chromatographed on a silica-gel column to give **1**-d_6 [a colorless oil, 23 mg; 46%. ^{1}H NMR δ=4.44 (2H, br s), 4.59 (2H, br s), 5.25—5.4 (1.82H, m), 6.2—6.4 (0.73H, m), 6.28 (0.24H, d, J=12 Hz), 6.76 (0.24H, d, J=12 Hz), and 6.9—7.2 (1.21H, m). m/z=220:221:222:223:224:225:226:227=14.8:4.6:2.1:4.2:8.3:23.1:25.8:17.0].

Thermal Reaction of 1-4,6-d_2. A xylene solution (6 cm^3) of **1**-4,6-d_2 [93 mg. ^{1}H NMR δ=4.44 (2H, dt, J=5, 1.5 Hz), 4.60 (2H, dt, J=5, 1.5 Hz), 5.2—5.5 (4H, m), 5.8—6.2(2H, m), 6.74 (0.38H, s), and 7.15 (0.38H, s)] was similarly thermolyzed. Silica-gel column chromatographic fractionation gave **5**-d_2 [12.5 mg. ^{1}H NMR (CD_3OD) δ=3.52 (2H,dt, J=6.5, 1.5 Hz), 4.52 (2H, dt, J=5, 1.5 Hz), 5.0—5.5 (4H. m), 5.7—6.2 (2H, m), and 7.26 (0.38H, s)] and **4**-d_1 [11.2 mg. ^{1}H NMR (CD_3OD) δ=3.35—3.65 (4H, m), 4.9—5.3 (4H, m), 5.7—6.2 (2H, m), and 7.35 (0.29H, s)], and **2**-d_0 [20 mg. ^{1}H NMR (CD_3OD) δ=3.35—3.55 (4H, m), 4.9—5.5 (4H, m), 5.7—6.2 (2H, m), and 7.35 (0.68H, s)].

Thermal Reaction of a 1:2-Mixture of 1-d_6 and 1-d_0. A xylene solution (5 cm^3) of 1:2-mixture of **1**-d_6 and **1**-d_0 (69 mg) was similarly refluxed for 3 h. The mixture was fractionated on a silica-gel column to give **2**-d [17.3 mg. ^{1}H NMR (CD_3OD) δ=3.43 (4.3H br d, J=7 Hz), 5.0—5.2 (4.5H, m), 5.7—6.2 (2H, m), and 7.35 (1.9H, s). ^{13}C NMR (CD_3OD) δ=39.6, 116.0, 128.7, 135.5, 141.3, and 156.9 (3C)], **4**-d [10 mg. ^{1}H NMR (CD_3OD) δ=3.35—3.6 (3.8H, m), 5.0—5.2 (5H, m), 5.7—6.2 (2H, m), 7.20 (0.7H, s), and 7.36 (1.3H, s). ^{13}C NMR (CD_3OD) δ=39.7, 40.1, 117.5 (2C), 127.7, 128.8, 136.8, 137.1, 139.4 (2C), 157.5, 166.8, and 167.8], and **5**-d [15.6 mg. ^{1}H NMR (CD_3OD) δ=3.50 (2H, br d, J=7 Hz). 3.82 (2.3H, dt, J=5, 1.5 Hz), 5.0—5.5 (5H, m), 5.7—6.2 (2H, m), 6.94 (1H, dd J=11.5, 3 Hz), and 7.24 (d, J=3 Hz) +7.27 (d, J=11 Hz) for 2.2H. ^{13}C NMR (CD_3OD) δ=39.3, 69.8, 117.7, 118.7, 120.3, 129.8, 132.4, 135.1, 140.4, 157.9, 163.1, and 171.2], respectively.

DDQ-dehydrogenation of 4 to 3,6-Diallyl-*p*-tropoquinone (12). An acetone solution (5 cm^3) of **4** (129 mg) was treated with DDQ (160 mg) at room temperature for 15 h. The mixture was then filtered off to remove the resultant hydroquinone; the filtrate was chromatographed on a silica-gel column to give **12** [a yellow oil, 117 mg; 92%. Found: M. W., 216.0817. Calcd for $C_{13}H_{12}O_3$: 216.0787. ^{1}H NMR δ=3.25 (4H, dm, J=6.5 Hz), 5.0—5.3 (4H, m), 5.68 (2H, ddt, J=16, 10.5, 6.5 Hz), 6.71 (1H, t, J=1 Hz), and 6.78 (1H, t, J=1 Hz). ^{13}C NMR δ=36.4, 37.2, 119.2, 120.0, 132.1, 132.5, 133.0, 138.1, 145.2, 151.2, 188.4, 189.6, and 189.8. IR ν: 1665, 1250, 1235, 995, and 920 cm^{-1}].

Electrolytic Conversion of 13 to 9-Allyl-7-hydroxycyclohepta[*b*]pyran-6(2*H*)-one (14). An anhydrous DMF solution (30 cm^3) of **13** (172.2 mg) was electrolyzed in the presence of TBAT (1 g) at -0.4 V for 25 h. After evaporation of the mixture in vacuo, the residue was chromatographed on a silica-gel column to give **14** [colorless crystats,mp 104—106 °C, 23 mg; 13%. Found: M. W., 216.0786. Calcd for $C_{13}H_{12}O_3$: 216.0787. ^{1}H NMR δ=3.38 (2H, dt, J=6.5, 1.5 Hz), 4.75 (2H, dd, J=3.5, 2 Hz), 5.08 (1H, dq, J=9.5, 1.5 Hz), 5.09 (1H, dq, J=17.5, 1.5 Hz), 5.92 (1H, ddt, J=17.5, 9.5, 6.5 Hz), 6.11 (1H, dt, J=9.5, 3.5 Hz), 6.37 (1H, dt, J=9.5, 2 Hz), 6.96 (1H, s), and 7.24 (1H, s). IR ν: 3450, 3200, 1595, 1582, 1512, 1445, 1230, and 1195 cm^{-1}. UV λ_{max}^{MeOH}: 264 nm (ε=8900, sh), 272 (9700), 284 (6600), 318 (2200), 359 (1800), 407 (2100), and 424 (1900)].

We are grateful to the Ministry of Education, Science, and Culture for a financial assistance through

a Grant-in-Aid for Scientific Research to A. M. (No. 60470025).

Reaction of Olefins with α-Cyanoacetamide in the Presence of Manganese(III) Acetate

Hidehiko SATO, Hiroshi NISHINO,* and Kazu KUROSAWA
Department of Chemistry, Faculty of Science, Kumamoto University, Kurokami 2-39-1, Kumamoto 860
(Received October 3, 1986)

2-Butenamides and 2-buten-4-olides are formed by the reaction of phenyl or 4-chlorophenyl-substituted olefins with α-cyanoacetamide in the presence of manganese(III) acetate. On the other hand, aryl substituted olefins having electron-donating groups are oxidized under similar reaction conditions to give 1,5-dihydro-2*H*-pyrrol-2-ones and 3-ethenyl-2-pyrrolidones. All these reactions also produce glycols or ketones which are given by the direct oxidation of these olefins with manganese(III) acetate. The question whether an intermediate carbocation in the oxidation process cyclized on an oxygen or a nitrogen atom can be explained by the hard and soft acids and bases (HSAB) concept. A possible mechanism for the formation of 2-butenamides and 2-buten-4-olides is proposed.

Recently, some useful annulation reactions using manganese(III) salts have been reported. Manganese(III) acetate oxidation of alkenes in acetic acid gave γ-lactones,[1] and similar oxidation in the presence of malonic acid or substituted acetic acid yielded spirodi-γ-lactones[2] or α-substituted γ-lactones.[3] On the other hand, alkenes were oxidized with tris(2,4-pentanedionato)manganese(III) to produce dihydrofurans in good yields.[4] One of the authors tried spirodilactamization by the manganese(III) oxidation of malonamide in the presence of alkenes. However, this oxidation did not give spiroannulated products, but α,β-unsaturated γ-lactones and γ-lactams along with other products.[5] This prompted us to investigate the synthesis of γ-lactam analogs, which might be bioactive new compounds or precursors of naturally occurring compounds, by the use of α-cyanoacetamide instead of malonamide. It was found that the reaction gave γ-lactams and γ-lactones together with some other products. We will describe these results and discuss the factors which may govern the mode of the cyclization either on a nitrogen atom or an oxygen atom in the acetamide group.

Results and Discussion

When a mixture of 1,1-diphenylethene (**1a**) and α-cyanoacetamide was oxidized with manganese(III) acetate, products **2a** and **3a** were obtained together with small amounts of **4a**, **5a**, **8a**, **9a**, and benzophenone (**10a**) (Table 1, Entry 1). The ^{1}H NMR spectrum of **2a** showed a singlet due to a vinylic proton at δ 8.51 and the ^{13}C NMR spectrum exhibited three singlets assigned to two carbonyl carbons and a cyano carbon. The IR spectrum of **2a** revealed a characteristic absorption band due to α,β-unsaturated nitrile. These spectral data indicated that the structure of **2a** was 4-acetoxy-2-cyano-4,4-diphenyl-2-butenamide. However, the configuration of the C=C double bond in **2a** could not be determined. The structures of **3a**, **4a**, **5a**, **8a**, and **9a** were determined to be 2-cyano-4,4-diphenyl-2-buten-4-olide, 2-carbamoyl-4,4-diphenyl-2-buten-4-olide, 2-cyano-2-(2,2-diphenylethenyl)-4,4-diphenyl-4-butanolide, 3-cyano-3-(2,2-diphenylethenyl)-5,5-diphenyl-2-pyrrolidone, and 4-acetoxy-2-cyano-4,4-diphenylbutanamide, respectively, on the basis of their spectral data. When a similar reaction was carried out under anhydrous conditions, the carbamoylbutenolide (**4a**) was not formed (Entry

a) **1a** : $CH_2(CN)CONH_2$: manganese(III) acetate. b) The yields are based on the amount of the **1a** used. c) Acetic anhydride (10 equivalents) was added.

3). On the other hand, the oxidation in a molar ratio of **1a**:α-cyanoacetamide:manganese(III) acetate=1:1:6 gave **4a** as the main product and the yield of **2a** decreased, although the reaction time has become longer (Entry 5). It suggests that the **2a** could be hydrolyzed under the reaction conditions to yield **4a**. In fact, the **2a** gave **4a** (27%) on treatment with six molar equivalents of manganese(II) acetate tetrahydrate, $[Mn(OAc)_2]\cdot 4H_2O$, in boiling acetic acid for 2 h. The cyanobutenolide (**3a**) was also hydrolyzed in the presence of manganese(II) acetate tetrahydrates to yield **4a** (21%). However, this route (**3a**→**4a**) would not be important because the **3a** was constantly produced irrespective of the molar ratio.

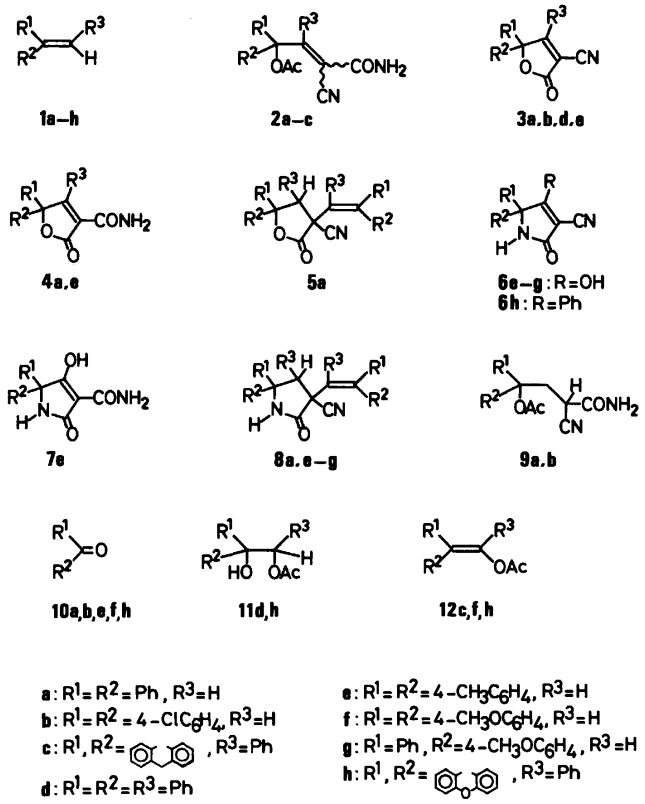

Fig. 1.

The similar oxidations of 1,1-bis(4-chlorophenyl)-ethene (**1b**), 9-benzylidene-9,10-dihydroanthracene (**1c**), and 1,1,2-triphenylethene (**1d**) mainly produced butenamides (**2b** an **2c**) and butenolides (**3b** and **3d**) (Table 2, Entries 2-4).

On the other hand, 1,1-bis(4-methoxyphenyl)ethene (**1f**) was oxidized under similar reaction conditions to yield 3-cyano-4-hydroxy-5,5-bis(4-methoxyphenyl)-1,5-dihydro-2*H*-pyrrol-2-one (**6f**) and 3-cyano-3-[2,2-bis(4-methoxyphenyl)ethenyl]-5,5-bis(4-methoxyphenyl)-2-pyrrolidone (**8f**) along with small amounts of 4,4′-dimethoxybenzophenone (**10f**) and 1-acetoxy-2,2-bis(4-methoxyphenyl)ethene (**12f**) (Table 2, Entry 6).

It has already been discussed that the reaction of aryl-substituted olefins having electron-donating groups with malonamide tends to give such *N*-cyclized products as 1,5-dihydro-2*H*-pyrrol-2-ones.[5] Reactions of 1-(4-methoxyphenyl)-1-phenylethene (**1g**) and 9-benzylidene-9*H*-xanthene (**1h**) with α-cyanoacetamide also yielded 1,5-dihydro-2*H*-pyrrol-2-ones (**6g** and **6h**) and 3-ethenyl-2-pyrrolidone (**8g**). However, the oxidation of **1h** mainly gave 9-xanthenone (**10h**), 9-(α-acetoxybenzyl)-9-xanthenol (**11h**), 9-(α-acetoxybenzylidene)-9*H*-xanthene (**12h**), and α,α-diacetoxytoluene (**14**), which would be formed via an electron-transfer mechanism. This mechanism is well-known in manganese(III) acetate oxidation.[1d,6]

The structure of manganese(III) acetate has been erroneously described in organic chemistry to be a simple acetate, $[Mn(OAc)_3]\cdot 2H_2O$, until a recent date.[5,7,8] However, Fristad et al. explained the radical mechanism for the manganese(III)-mediated γ-lactone annulation by use of the correct structure of manganese(III) acetate: oxygen-centered triangle, $[Mn_3O(OAc)_6(OAc)(HOAc)]\cdot 5H_2O$.[1c,9] In the manganese(III)-α-cyanoacetamide system, a similar mechanism can be considered (Scheme 1), and compound **3** or **6** would be formed via path A. On path A, it was assumed that butanolide(**I**) might be a precursor of **3** and **5**. When 2-cyano-4,4-diphenyl-4-butanolide

a) **1** : $CH_2(CN)CONH_2$: manganese(III) acetate=1 : 2 : 4. b) The reactions were terminated within 1 min. c) The yields are based on the amount of the substrate used.

(**I**, $R^1=R^2=Ph$), which was prepared by an alternative method,[3c,3d,10] was oxidized with manganese(III) acetate, **3a** was not formed, while the oxidation of **I** ($R^1=R^2=Ph$) in the presence of **1a** gave rise to **5a**. Therefore, one can consider another pathway (path B) for the formation of **3** or **6** via 2-cyano-3-butenamide (**III**) as a reaction intermediate. The intermediate **III** was not isolated from the reaction products, probably because **III** was more liable to be oxidized than the parent olefin under the reaction conditions. However, the involvement of **III** is suggested by the fact that 2,2-diphenylethenylmalonate (**15**) was actually isolated together with 2-ethoxycarbonyl-4,4-diphenyl-2-buten-4-olide (**16**) in the manganese(III)-mediated reaction of **1a** with diethyl malonate and that the **15** was subsequently converted to **16** under the reaction conditions (Table 3).

The cyclization of carbocation (**II** or **IV**) depends on whether **II** or **IV** is "hard" or "soft" on the basis of the hard and soft acids and bases (HSAB) concept.[12] That is to say, when the cation is relatively hard (as in the cases of **1a—d**), it cyclizes on an oxygen atom to give butenolide (**3**), while the reaction of **1f—h** yields 1,5-dihydro-2*H*-pyrrol-2-one (**6**) since the carbocation derived from **1f—h** is relatively soft. This tendency is also the case for the reaction with malonamide.[5] Both *O*-cyclized (**3e** and **4e**) and *N*-cyclized products (**6—8e**) were obtained by the reaction of **1e**, indicating that the corresponding carbocation (**IV**) has an intermediate

nature of "hard and soft acids." It seems that the formation of **2** depends on the configuration of **IV**. When the configuration of the cyano group and the $-\overset{+}{C}R^1R^2$ group on **IV** is cis, the **IV** could not cyclize on a nitrogen atom of nitrile, but was probably attacked by an acetate ion to give **2**.

In conclusion, the reaction of olefins with α-cyanoacetamide gave 2-butenamides, 2-buten-4-olides, 1,5-dihydro-2*H*-pyrrol-2-ones, and 3-ethenyl-2-pyrrolidones; these are more complex than the products in the reaction with malonamide.[5] Although the cyano group on α-cyanoacetamide is favorable to the formation of the $\cdot CH(CN)CONH_2$ radical, the cyano group itself is not so reactive in these reactions: the cyclization involving the cyano group did not occur. The reason for the absence of spiroannulation products in the reaction with α-cyanoacetamide or diethyl malonate could be ascribed to the preferential formation of **III** via path B and to the difficulty of the spiroannulation of **5** and **8** involving the cyano group. Moreover, the formation of **3** and **6** could be explained by the HSAB concept.

Experimental

Measurements. Melting points were determined with an Electrothermal apparatus and are uncorrected. The IR spectra were taken on a JASCO A-102 infrared spectrometer. The ^1H and ^{13}C NMR spectra were recorded on a Hitachi Perkin-Elmer R-24 (60 MHz) and a JEOL FX-100 instrument at room temperature. The mass spectra were obtained with a JEOL JMS-DX-300 mass spectrometer using a direct-insertion probe at an ionizing voltage of 70 eV.

Materials. The olefin (**1a—h**) and manganese(III) acetate used were prepared according to methods described in the literature.[5] α-Cyanoacetamide, diethyl malonate, and manganese(II) acetate tetrahydrate were obtained from commercial samples from the Wako Pure Chemical Industries, Ltd.

Reaction of Olefins with α-Cyanoacetamide. The typical procedure for the reaction of olefins with α-cyanoacetamide in the presence of manganese(III) acetate was as follows. To a heated solution of olefin (1 mmol) and α-cyanoacetamide (2 mmol) in acetic acid (25 cm^3), manganese(III) acetate (4 mmol) which was calculated based on the formula weight of $[Mn(OAc)_3 \cdot 2H_2O]$[5] was added. The mixture was heated under reflux until the color of Mn(III) ion changed from brown to transparent. The solvent was removed in vacuo and the residue was triturated with 2 M (1 M=1 mol dm^{-3}) hydrochloric acid (25 cm^3), followed by extraction with chloroform. The products were separated on TLC (Wakogel B-10 or Kieselgel 60G) with chloroform or diethyl ether as the developing solvent. The characteristic data of the new compounds are summarized in Table 4. All spectral data and the melting points of known compounds were identical with those reported in the literatures.

Oxidation Products. 1a: 2a, 3a, 4a,[5] **5a, 8a, 9a,** and **10a.**[5] **1b**: 4-Acetoxy-4,4-bis(4-chlorophenyl)-2-cyano-2-butenamide (**2b**), 4,4-bis(4-chlorophenyl)-2-cyano-2-buten-4-olide (**3b**), 4-acetoxy-4,4-bis(4-chlorophenyl)-2-cyanobutanamide (**9b**), and 4,4'-dichlorobenzophenone (**10b**).[11]

1c: 3-(9-Acetoxy-9,10-dihydro-9-anthryl)-2-cyano-3-phenylpropenamide (**2c**), 9-(α-acetoxybenzylidene)-9,10-dihydroanthracene (**12c**),[5] and 9-acetoxy-9-benzoyl-9,10-dihydroanthracene (**13**).[5]

1d: 2-Cyano-3,4,4-triphenyl-2-buten-4-olide (**3d**), **10a**, 2-acetoxy-1,1,2-triphenylethanol (**11d**).[5]

1e: 2-Cyano-4,4-bis(4-methylphenyl)-2-buten-4-olide (**3e**), 2-carbamoyl-4,4-bis(4-methylphenyl)-2-buten-4-olide (**4e**), 3-cyano-4-hydroxy-5,5-bis(4-methylphenyl)-1,5-dihydro-2*H*-pyrrol-2-one (**6e**), 3-carbamoyl-4-hydroxy-5,5-bis(4-methylphenyl)-1,5-dihydro-2*H*-pyrrol-2-one (**7e**), 3-cyano-3-[2,2-bis(4-methylphenyl)ethenyl]-5,5-bis(4-methylphenyl)-2-pyrrolidone (**8e**), and 4,4'-dimethylbenzophenone (**10e**).[12]

1f: **6f, 8f, 10f,**[13] and **12f.**[14]

1g: 3-Cyano-4-hydroxy-5-(4-methoxyphenyl)-5-phenyl-1,5-dihydro-2*H*-pyrrol-2-one (**6g**) and 3-cyano-3-[2-(4-methoxyphenyl)-2-phenylethenyl]-5-(4-methoxyphenyl)-5-phenyl-2-pyrrolidone (**8g**). The stereochemistry of **6g** and **8g** was not determined.

1h: 4-Cyano-3-phenyl-1,5-dihydrospiro[2*H*-pyrrole-2,9'-xanthen]-5-one (**6h**), **10h,**[15] **11h,**[5] **12h,**[4] and **14.**[16]

Hydrolyses of 2a and 3a. When **2a** (174.0 mg) was treated with manganese(II) acetate tetrahydrate (803.5 mg) in acetic acid (25 cm^3) for 2 h at reflux temperature, **4a** (41.8 mg, 27%) and **2a** (52.0 mg, 30% recovered) were obtained. On the other hand, **3a** (168.9 mg) and manganese(II) acetate tetrahydrate (636.9 mg) were heated under reflux in acetic acid (25 cm^3) for 80 min, giving **4a** (38.0 mg, 21%) and **3a** (90.4 mg, 53% recovered).

Synthesis of 2-Cyano-4,4-diphenyl-4-butanolide (I). A mixture of **1a** (903.5 mg), cyanoacetic acid (3.401 g), and manganese(III) acetate (2.746 g) was heated in acetic acid (50 cm^3) at 70 °C for 15 min according to Fristad method.[3b] On cooling, water (200 cm^3) was added to it and the aqueous solution was extracted with ether. The ethereal extract was washed with aqueous sodium hydrogencarbonate solution and then water. The reaction products were purified on TLC, giving colorless liquid **I** (650.2 mg, 49%). All spectral data were identical with those of the literature.[3b]

Oxidation of 2-Cyano-4,4-diphenyl-4-butanolide (I) with Manganese(III) Acetate. The butanolide **I** (183.6 mg) was oxidized with manganese(III) acetate (373.9 mg) in acetic acid (25 cm^3). The mixture was heated under reflux for 3 min and gave a tarry material, but the butenolide (**3a**) was not detected.

The Reactions of 1,1-Diphenylethene (1a) and 2-Cyano-4,4-diphenyl-4-butanolide (I). A mixture of **1a** (154.5 mg), **I** (223.0 mg), and manganese(III) acetate (457.2 mg) was heated under reflux in acetic acid (25 cm^3) for 1 min. After treatment by the procedure described above, a mixture of **5a** and 3-cyano-1,1,5,5-tetraphenyl-4-penten-1-ol (115.7 mg, 31% yield as **5a**) was obtained and **1a** was recovered (29%).

3-Cyano-1,1,5,5-tetraphenyl-4-penten-1-ol: Colorless prisms (from light petroleum), mp 105.0—105.5 °C; IR ($CHCl_3$) 2236 (CN) and 3200—3600 (OH); ^1H NMR ($CDCl_3$) δ=2.28 (1H, s, OH), 2.6—2.9 (2H, m, CH_2), 3.2—3.7 (1H, m, >CH–), 5.92 (1H, d, J=9.6 Hz, =CH–), and 6.7—7.6 (20H, m, 4×Ph). Found: C, 86.44; H, 6.00; N, 3.32%. Calcd for $C_{30}H_{25}ON$: C, 86.71; H, 6.06; N, 3.37%.

Reaction of 1,1-Diphenylethene (1a) with Diethyl Malonate in the Presence of Manganese(III) Acetate. To a heated solution of **1a** (1 mmol), diethyl malonate (1 mmol), and

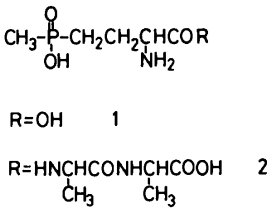
Asymmetric Synthesis of (+)-Phosphinothricin and Related Compounds by the Michael Addition of Glycine Schiff Bases to Vinyl Compounds

Nobuto MINOWA,* Masao HIRAYAMA, and Shunzo FUKATSU
Central Research Laboratories, Meiji Seika Kaisha Ltd., Morooka, Kohoku-ku, Yokohama 222
(Received October 3, 1986)

(*S*)-(+)-Phosphinothricin was prepared in good optical yield by the Michael addition of chiral glycine Schiff base derived from (*S*)-2-hydroxy-3-pinanone to vinyl phosphorus compound. (*R*)-(−)-Phosphinothricin, an enantiomeric isomer, can also be prepared from the same chiral glycine Schiff base by choosing suitable reaction temperature.

The stereochemistry of an amino carbon is a biologically important factor in naturally occurring phosphorus analogues of glutamic acid, such as phosphinothricin ((*S*)-(+)-(**1**)),[1] its alanylalanine derivative **2**,[1] and (+)-2-amino-4-phosphonobutyric acid ((*S*)-(+)-(**3**)),[2] which have been paid a special attention for their herbicidal[3] and antiviral activities.

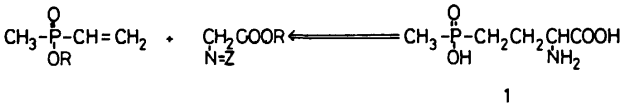


Scheme 1.

Although several methods for the racemic synthesis were already known[4], there have been reported a few example for the asymmetric synthesis.[5] In our preliminary communications,[4g,5] we reported a practical synthesis of (±)-**1** and an effective asymmetric synthesis of (*S*)-(+)-**1**, (*S*)-(+)-**3**, and their enantiomers by the Michael addition of glycine Schiff base to vinyl phosphorus compounds. In the latter, the S- and R-configuration were induced from two glycine Schiff bases bearing different chiral auxiliaries derived from (*S*)-2-hydroxy-3-pinanone ((−)-(**9**)) and its (**R**)-isomer (+)-**9**, respectively. In the course of our study on the asymmetric Michael addition, it has been found that the stereochemistry of the Michael adducts is reversed depending on reaction temperature to yield the *S*-enantiomer at −78 °C and *R*-enantiomer at an elevated temperature. Thus, both enantiomers can be easily prepared from a single chiral glycine Schiff base (−)-**10** by choosing suitable reaction temperature. In this paper, we would like to report the features of the Michael addition of glycine Schiff bases to several kinds of vinyl compounds in detail.

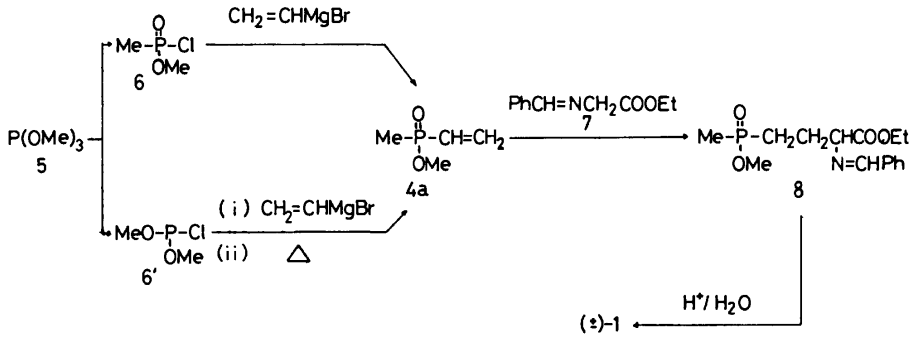
Results and Dicussion

Our basic strategy for the synthesis of glutamic acid analogues involves the Michael addition of glycine Schiff base to appropriate vinyl compounds; The retrosynthetic analysis of **1** is illustrated in Scheme 2.



Scheme 2.

Racemic Synthesis of Phosphinothricin 1. Racemic (±)-**1** was synthesized according to the procedures shown in Scheme 3. Methyl vinylmethylphosphinate (**4a**), a Michael acceptor, was conveniently prepared by the following two methods: Trimethyl phosphite (**5**) was converted to methylphosphonochloridate **6** by the Arbusov rearrangement followed by chlorination. Coupling of a vinyl group with phosphorus atom was

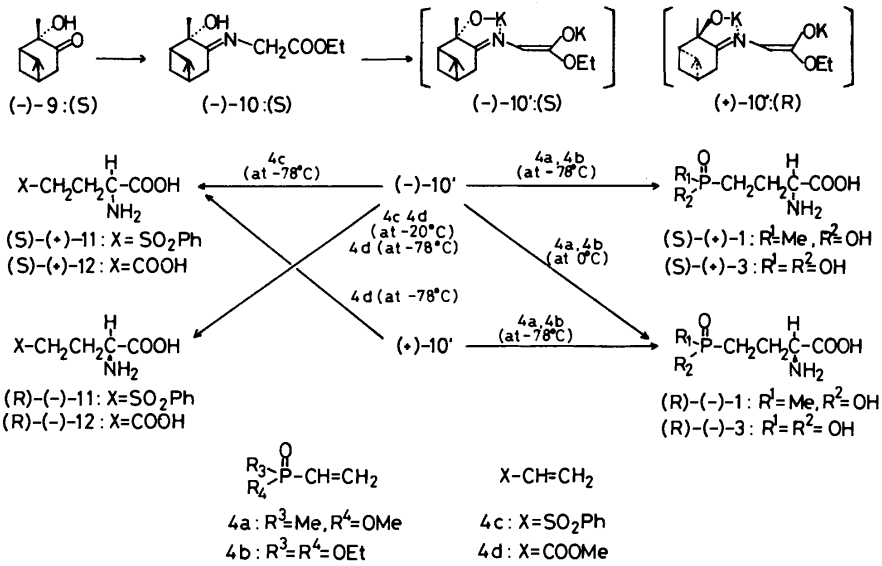


Scheme 3.

accomplished by the addition of vinylmagnesium bromide to **6** in tetrahydrofuran (THF) to give the desired phosphinate **4a** in 61% yield. As a vinyl group could be directly introduced into various phosphonochoridate, this procedure provides a general and facile method for the preparation of vinylalkylphosphinates. According to an alternative method, phosphorochloridite **6'**, prepared by treating **5** with phosphorous trichloride, was subjected to alkylative coupling with vinylmagnesium bromide in THF and the resulting vinylphosphonite was heated to afford **4a**. The α-amino acid part could be successfully introduced into the vinyl group of **4a** by utilizing Schiff base **7** of glycine ethyl ester as a Michael donor. Treatment of the Schiff base with **4a** in the presence of 0.2 equiv of base afforded the adduct **8**, which was successively refluxed with 6M-hydrochloric acid (1 M=1 mol dm^{-3}) for 24 h to give racemic phosphinothricin (±)-**1** as shown in Table 1 after purification (Dowex 50×2). Although the use of either sodium ethoxide or potassium hydroxide in ethanol gave the (±)-**1** in good yield, the latter base was preferable in practice because the reaction is carried out at room temperature (Entries 1—4). The use of the other bases, DBN and Triton B, could not improve the yield of (±)-**1**. (Entries 6, 7).

Asymmetric Synthesis of (*S*)-(+)-1 and (*R*)-(−)-1. A successful Michael addition of the achiral glycine Schiff base **7** suggested that the desired S-configuration of **1** would be prepared by a similar procedure utilizing a chiral Schiff base **7**. Attempted experiment to perform the asymmetric addition of **7** to **4a** in the presence of a chiral base, quinine, was unsuccessful, while the addition of a chiral Schiff base to **4a** provided optically active adduct **1**. Although a number of asymmetric reactions with chiral acceptors has been known,[6] there have been reported a few examples of using chiral Michael donors.[7]

The asymmetric Michael addition was shown in Scheme 4. Chiral Schiff bases (−)-**10** and (+)-**10** having chiral auxiliaries were readily prepared by the condensation of glycine ethyl ester with (*S*)-2-hydroxy-3-pinanone (−)-(**9**) and its (R)-isomer (+)-(**9**) obtained by oxidation of natural (+)-α-pinene and (−)-α-pinene, respectively.[8] The results of the Michael addition of these chiral Schiff base to



Scheme 4.

Table 1. The Michael Addition of **7** to **4a**

Entry	Base	Ratio[a]	Solvent	Temperature/°C (Time/h)	Yield/% (±)-**1**
1	EtONa	1 : 1.5 : 0.25	EtOH	−10 (5)	64
2	EtONa	1 : 1 : 0.25	EtOH	−10 (4)	50
3	EtONa	1 : 1 : 0.25	EtOH	5 (7)	36
4	KOH	1 : 1.5 : 0.2	EtOH	r.t. (2)	65
5	KOH	1 : 1.5 : 0.2	PhH	r.t. (4)	30
6	DBN	1 : 1.5 : 0.2	$PhCH_3$	r.t. (6)	11
7	Triton B	1 : 1.5 : 0.2	EtOH	r.t. (2)	26

a) Molar ratio of **4a** : **7** : base.

vinylphosphinate **4a** investigated under various conditions at −78 °C are summarized in Table 2. (Entries 1—10) Metalation of the chiral Schiff base (−)-**10** with two equivalents of potassium *t*-butoxide (*t*-BuOK) in THF followed by conjugate addition of the dianion **10′** to an equimolar amount of vinylphosphinate **4a** at −78 °C gave the Michael adduct, which was further converted into the desired phosphinothricin (S)-(+)-**1** with 79% optical purity in 66% yield (Entry 1). The results of the effects of concentration and molar ratio of the reactants, reverse addition of the reactants, and solvent are summarized in Entries 2—9. Particularly, reverse addition of the reactants reduced enantiomeric excess extremely from 79 to 2%. In addition, similar treatment after metalation of (−)-**10** with other base, sodium hydride or lithium diisopropylamide, gave no desired product. Judging from extreme decrease of the optical purities shown in the effects of the reverse addition and change of the molar ratio, a proceeding metalation of (−)-**10** with *t*-BuOK seemed to be important for this asymmetric synthesis. Similar asymmetric addition of the other glycine Schiff base (+)-**10** to **4a** gave unnatural phosphinothricin (*R*)-(−)-(**1**) with 73% optical purity in a similar yield as (*S*)-(+)-**1**. (Entry 10).

The stereoselectivity is not influenced by the kind of the solvents, such as toluene, Et_2O, and THF. (Entries 1, 8, and 9) However, addition of hexamethylphosphoric triamide (HMPA) or dicyclohexano-18-

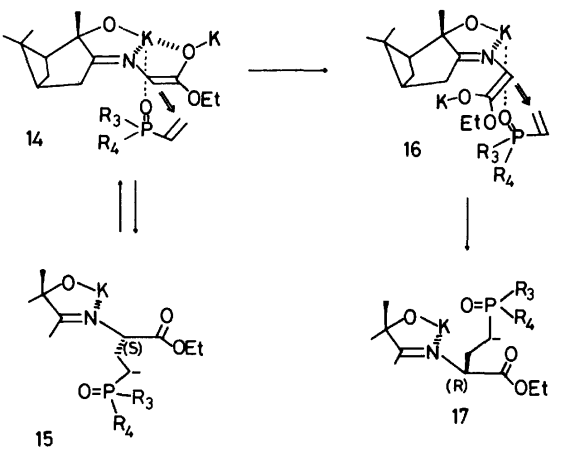
crown-6 (18-crown-6) which has strong ability to solvate cations,[9] at −78 °C, reduced optical purity of the product (Entries 24 and 25). It is assumed that the chelate structure existed in transition state plays an important role in controlling the stereochemistry and a strong coordination of solvent depressed stereoselectivity by interfering the chelation.[10]

Thus, the metalation of (−)-**10** with base resulted in the formation of five-membered rigid chelate structure and next phosphorus oxygen of vinyl phosphorus compound would coordinate to the potassium cation of potassium alkoxide. Consequently, the Michael addition would take place preferentially from the botton face as shown in **14**.

The Asymmetric Michael Addition of 10 to Other Vinyl Compounds. Similar additioin of **10** at −78 °C to three vinyl acceptors, diethyl vinylphosphonate (**4b**), phenyl vinyl sulfone (**4c**), and methyl acrylate (**4d**), was further investigated as shown in Scheme 4. Asymmetric addition of (−)-**10** and (+)-**10** to **4b** smoothly proceeded in a similar way to afford biologically interesting phosphonic acid (*S*)-(+)-**3**,[2] and its isomer (*R*)-(−)-**3** in good optical yields, respectively (Entries 11 and 12). Although addition of (−)-**10** to **4c** also took place smoothly, the data of the optical rotation and high-performance liquid chromatography (HPLC) analysis suggested that the expected chiral sulfone (+)-**11** had less enantiomeric excess than those of phosphorus compound (*S*)-(+)-**1** and (*S*)-(+)-**3** (Entry 31). Interestingly, addition of (−)-**10** and (+)-**10** to **4d** gave (−)-glutamic acid (*S*)-(−)-**12** and and its isomer (*R*)-(+)-**12** in fairly good yields, respectively (Entries 13 and 14). That is, the result of these reactions at −78 °C indicated that the stereochemical course of the addition of (−)-**10** and (+)-**10** to methyl acrylate **4d** was the same as that of alkylation and opposite to that of addition to vinyl phosphorus compounds **4a** and **4b**. However, study of the effect of reaction temperature in these reaction revealed another information about the stereochemistry as described in the following.

Effect of Reaction Temperature. It was found that the reaction temperature is strongly influential on the diastereoface selectivity of the addition as summarized in Table 2 (Entries 15—32). For example, addition product **1** prepared from (−)-**10** with **4a** at 0 °C had negative optical rotation (Entry 20). When the reaction temperature is elevated from −78 up to 20 °C, increase of enantiomeric excess of (*R*)-(−)-**1** was observed. Furthermore, treatment of (−)-**10** with **4a** at −78 °C for 1 h and then at 0 °C for 0.5 h before quenching also afforded (*R*)-(−)-**1** (Entry 23), which was assumed to be produced by isomerization of (*S*)-(+)-**1** formed at −78 °C. These results suggested that (*R*)-(−)-**1** obtained from (−)-**10** with **4a** at 0 °C appeared to be a thermodynamic product.[11] It is assumed that, at low temperature, the reaction



Scheme 5.

proceeds via a double chelated intermediate and the addition takes place from the α face to produce **15** as shown in **14**, **15**, whereas at elevated temperature, the potassium enolate adopts the cisoid conformation shown as the increased molecular mobility leads to the potassium-oxygen interaction being broken. The addition then occurs from the α face as for **14** to produce, this time, **17** as shown in **16**, **17**.

Almost the same results were observed in addition of (−)-**10** to phosphonate **4b** (Entries 11 and 26—29). In the reaction of phenyl vinyl sulfone **4c**, similar change of the stereochemistry was observed by changing reaction temperature from −78 to −20 °C (Entries 31 and 32). Although the change of the configuration was not observed in the reaction of (−)-**10** with **4d**, enantiomeric excess of addition product (*R*)-(−)-**12** at elevated temperature was increased compared with that at −78 °C (Entries 13 and 30). Therefore, in this Michael addition of (−)-**10** to four vinyl acceptors, increase of the product with R-configuration was observed by an elevation of the reaction temperature. From these results, it is assumed that the geometry of the imine and potassium enolate in **10'** at the reaction temperature play an important role in this asymmetric Michael addition. Addition of intermediate **14** or **16** to the acceptor always takes place from the face opposite to the β-methyl in pinanone, resulting in **15** or **17**, respectively.

As the addition products of (−)-**10** to **4a** and **4b** were obtained in good optical yields either −78 or 0 °C, this asymmetric Michael addition was useful for preparation of S- and R-enantiomers of **1** and **3** from (−)-**10** and vinyl phosphorus compounds by just changing reaction temperature.

The herbicidal activity of synthesized (*S*)-(+)-**1** was nearly equal to natural (*S*)-(+)-**1** in foliage treatment. However, synthesized (*R*)-(−)-**1**, unnatural form, had almost no herbicidal activity.

Experimental

The IR spectra were recorded on a JASCO IR-G spectrometer and mass spectra on a JEOL-OISG spectrometer. The ^1H and ^{13}C NMR spectra were taken on a Varian FT-80A spectrometer using TMS or DSS as an internal standared.

Methyl Methylphosphonochloridate (6): The chloride **6** was prepared from trimethyl phosphite and phosphorus pentachloride according to the procedure in Ref. 12; bp 59—61 °C (11 mmHg) (1 mmHg=133.322 Pa) (lit,[12] 64 °C (15 mmHg)).

Dimethyl Phosphorochloridite (6'): The chloride 6' was prepared from trimethyl phosphite and phosphorus trichloride by the procedure in Ref. 13; bp 40 °C (40 mmHg).

Methyl Methylvinylphosphinate (4a): Method A: A solution of 1.00 M vinylmagnesium bromide in THF (18.7 ml, 18.7 mmol) was added dropwise to a solution of methyl methylphosphonochloridate (2.00 g, 15.6 mmol) in THF (5 ml) under argon at −20 °C, and the mixture was stirred at the same temperature for 1 h, 2M ammonium chloride (10 ml) was added to the reaction mixture. The solution was extracted with chloroform (15 ml×3) and dried over magnesium sulfate. The solvent was removed in vacuo, and the residue was distilled to give **4a** (1.14 g, 61%) as a colorless oil; bp 74—76 °C (14 mmHg); IR (neat) 1610 (C=C), 1300 (P=O), 1210 (P=O), and 1030 (P-O-CH_3) cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.51 (3H, d, J=15 Hz), 3.65 (3H, d, J=11 Hz), 5.80—6.50 (3H, m).

Method (B); To a stirred solution of the chloride **6'** (2.00 g, 15.6 mmol) in THF (10 ml) was added 1.00 M vinylmagnesium bromide (1.72 ml, 1.72 mmol) in THF dropwise with cooling to maintain the reaction temperature at −10 °C. The mixture was stirred for 3 h at 0 to 25 °C. After distillation (bp 40—45 °C (30 mmHg)), the colorless oil was heated at 60 °C for 9 h. The solution was distilled to give **4a** (1.42 g, 76%) as a colorless oil; bp, IR, and NMR data were identical with those of **4a** in Method (A).

(±)-Phosphinothricin (±)-(1): Entry 4 in Table 1; To a stirred solution of the Schiff base **7** (1.19 g, 6.24 mmol) and 95% KOH (47 mg, 0.838 mmol) in EtOH (5 ml) was added a solution of vinylphosphinate **4a** (500 mg, 4.16 mmol) in EtOH (5 ml) at room temperature. After the reaction mixture was stirred for 2 h at room temperature, the solvent was removed. To the residue was added 6M HCl (20 ml) and the solution was refluxed for 24 h. After concentration of the resulting solution followed by washing with benzene, the residue was dissolved in EtOH-H_2O (1:1, 12 ml) and a large excess amount of propylene oxide was added. The resulting solution was concentrated and purified by ion-exchange resin (Dowex 50×2). Elution with water and subsequent removal of water gave (±)-**1** as a colorless crystals (490 mg, 69%); mp 211—213 °C (lit, [14] (mp 214 °C); ^1H NMR (D_2O) δ=1.45 (3H, d, J=14 Hz), 1.5—2.6 (4H, m), 4.04 (1H, t, J=6 Hz); ^{13}C NMR (D_2O) δ=14.81 (d, J=92.8), 23.96 (d, J=2.4 Hz), 26.58 (d, J=92.2 Hz), 54.43 (d, J=16.2 Hz), 172.9 (s).

Entry 1 in Table 1; to a stirred solution of sodium (19.2 mg, 0.833 mmol) in EtOH (5 ml) was added a solution of the Schiff base **7** (956 mg, 5.00 mmol) in EtOH (1 ml) at −10°C, followed by addition of a vinylphosphinate **4a** (400 mg, 3.33 mmol) in EtOH (1 ml) at −10 °C. After the same workup and purification, (±)-**1** was obtained as a colorless crystals, (387 mg, 64%); mp 212—214 °C.

(−)- and (+)-2-Hydroxy-3-pinanone (−)-9 and (+)-(9): The ketol (−)-**9** was prepared from (1*R*,5*R*)-(+)-α-pinene ($[\alpha]_D^{22}$ +47.1° (neat)) by the procedure in Ref. 8; bp 115—117 °C (15 mmHg) (lit,[8] 118—119 °C (15 mmHg); $[\alpha]_D^{25}$ −37.0° (*c* 2.60, $CHCl_3$) (lit,[8] $[\alpha]_D^{25}$ −38.9° (*c* 2.64, $CHCl_3$)); IR (neat) 3450 (OH) and 1720 (C=O) cm^{-1}; NMR ($CDCl_3$) δ=0.89 (3H, s), 1.37 (3H, s), 1.38 (3H, s), 1.6—2.6 (6H, m); the optical purity of the ketol (−)-**9** may be estimated to be at least 92.5%.

According to the same procedure, (+)-**9** was prepared from (1*S*,5*S*)-(+)-α-pinene ($[\alpha]_D^{22}$ −42.0° (neat)); $[\alpha]_D^{25}$ +33.0° (*c* 2.60, $CHCl_3$).

The Chiral Schiff Base (−)-(10) and (+)-(10): A solution of glycine ethyl ester hydrochloride (2.99 g, 21.4 mmol), the ketol (−)-**9** (3.00 g, 17.8 mmol), and triethylamine (2.17 g, 21.4 mmol) in benzene (50 ml) containing boron trifluoride etherate (0.1 g) was refluxed for 6 h using a Dean-Stark apparatus under nitrogen. After filtration followed by evaporation, the reasidue was distilled to give (−)-**10** (3.52 g, 78%) as a slight yellow oil; bp 106—108 °C (0.3 mmHg); $[\alpha]_D^{25}$ −7.6° (*c* 3.00, $CHCl_3$); IR (neat) 3250 (OH), 1760 (COOEt), and 1660 (C=N) cm^{-1}; NMR ($CDCl_3$) δ=0.88 (3H, s), 1.29 (3H, t, J=7 Hz), 1.34 (3H, s), 1.52 (3H, s), 1.6—2.6 (6H, m), 2.60 (1H, s), 4.15 (2H, s), 4.20 (2H, q, J=7 Hz); FD MS *m/z* 254 (M+1). According to the same procedure, (+)-**10** was prepared from (+)-**9**; $[\alpha]_D^{25}$ +6.8° (*c* 3.00, $CHCl_3$).

General Procedure for Reaction of the Chiral Schiff Base (10) with Michael Acceptors:. To a stirred solution of potassium *t*-butoxide (1.58 mmol) in THF (3 ml) was added a solution of the chiral Schiff base **10** (0.789 mmol) in THF (1 ml) at −78°C, followed by addition of a solution of vinyl compound (0.789 mmol) in THF (1 ml) at −78 °C under argon. After stirred for 1 h at −78 °C, 1M HCl (3 ml) was added to the resulting yellow solution and the solvent was removed. To the residue was added 6M HCl (4 ml) and the solution was refluxed for 24 h. After concentration of the resulting solution followed by washing with benzene, the residue was dissolved in EtOH-H_2O (4 ml) and a large excess amount of propylene oxide was added. The resulting solution was concentrated and purified by ion-exchange resin (Dowex 50×2). Elution with water and subsequent removal of water gave the amino acid.

(−)-and (+)-Phosphinothricin (−)- and (+)-(1): Entry 1 in Table 2; (S)-(+)-**1** was obtained from vinylphosphinate **4a** as a colorless crystals according to the general procedure; mp 214—216 °C (decomp); ^1H NMR (D_2O) δ=1.45 (3H, d, J=14 Hz), 1.5—2.6 (4H, m), 4.04 (1H, t, J=6 Hz); FD MS *m/z* 182 (M+1).

Entry 23 in Table 2; After the addition reaction according to the general procedure, the reaction mixture was stirred for 1 h at −78 °C and then warmed at 0 °C for 0.5 h.

Entries 24 and 25 in Table 2; To a stirred solution of *t*-BuOK (1.58 mmol) and additive (3.95 mmol) in THF (4 ml) was added a solution of the chiral Schiff base (−)-**10** (0.789 mmol) in THF (1 ml) at −78 °C, followed by addition of a solution of vinylphosphinate **4a** (0.789 mmol) in THF (1 ml) at −78 °C under argon. The reaction mixture was stirred for 1 h at −78 °C.

Entry 18 in Table 2; to a stirred solution of *t*-BuOK

(1.58 mmol) in THF (3 ml) was added a solution of the chiral Schiff base (−)-**10** (0.789 mmol) in THF (1 ml) at −20 °C, followed by addition of a solution of vinylphosphinate **4a** (0.789 mmol) in THF (1 ml) at −20 °C under argon. The reaction mixure was stirred for 1 h at −20 °C.

Recovery of the Ketol (−)-(9): After the reaction according to the general procedure, the workup and purification was carried out as follows. To the reaction mixture was added satd. aq NH_4Cl (3 ml) and the solution was extracted with ethyl acetate (8 ml×2). After the extract was washed with satd. aq NaCl, the solvent was removed in vacuo. The residue was added 1 M aq HCl (2 ml) and the solution was heated at 45 °C for 24 h. The reaction mixture was extracted with benzene (2 ml×2). After the solvent was removed in vacuo, the residue was purified by column chromatography (silica gel, benzene) to give (−)-**9** (95 mg, 72%) as a colorless oil; $[\alpha]_D^{25}$ −34.7° (*c* 2.50, $CHCl_3$).

2-Amino-4-phosphonobutyric acid (3): Entry 28 in Table 2; (R)-(−)-**3** was obtained from the chiral Schiff base (−)-**10** and vinylphosphonate **4b** as colorless crystals according to the procedure in Entry 18 as described above; FD MS *m/z* 184 (M+1); mp 226 °C (decomp); NMR (D_2O) δ=1.5—2.6 (4H, m), 4.03 (1H, t, *J*= 6Hz).

2-Amino-4-phenylsulfonylbutyric Acid (11): Entry 32 in Table 2; (R)-(−)-**11** was obtained from the chiral Schiff base (−)-**10** and phenyl sulfone **4c** as a colorless crystals according to the procedure in Entry 18 as described above; FD MS *m/z* 244 (M+1); mp 216 °C (decomp); ^1H NMR (D_2O) δ=2.1—2.6 (2H, m), 3.5—3.8 (2H, m), 3.92 (1H, t, *J*=6Hz), 7.7—8.2 (5H, m). For elemental analysis, methyl 2-acethylamino-4-phenylsulfonylbutyrate was derived from **11**. Found: C, 51.87; H, 5.95; N, 4.72; S, 10.61%. Calcd for $C_{13}H_{17}NO_5S$: C, 52.16; H, 5.72; N, 4.68; S, 10.71%.

Glutamic Acid (12): Entry 30 in Table 2; (R)-(−)-**12** was obtained from the chiral Schiff base (−)-**10** and methyl acrylate **4c** as colorless crystals according to the procedure in Entry 18 as described above; FD MS *m/z* 148 (M+1); mp 198 °C (decomp).

We are grateful to Professor Teruaki Mukaiyama, The University of Tokyo, and Professor Kikumasa Sato, Yokohama National University, and Mr. Masao Takada, Nippon Chemical Industrial Co., for their valuable advice throughout this work.

(Received October 11, 1986)

1- or 2-*p*-Tolylsulfonyl(=tosyl)-1-alkenes, vinylic sulfones, were regioselectively prepared from 1-alkenes via iodosulfonization or sulfonylmercuration and also from 1-haloalkanes by the homologation or unhomologation methods. The vinylic sulfones thus prepared were further converted to the corresponding allylic sulfones under basic conditions. The stereochemistry of this conversion was discussed. One-carbon homologated allylic sulfones were directly obtained from aldehydes in good yields by the reaction with diethyl phenylsulfonylmethylphosphonate and 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) under mild conditions.

The useful synthetic procedure using vinylic and allylic sulfones as synthons have been recently developed. The importance of vinylic sulfones in synthesis is now well-established.[1-4] Allylic sulfones have been proven to be particularly useful synthetic intermediates,[1] because of the ability of the sulfonyl group to generate an adjacent carbanion[5] and to act as a leaving group in substitution reactions[6] and elimination reactions.[7]

In connection with our continued interest to extend the synthetic utility of sulfones,[8a-e] we have so far investigated the syntheses[9a-c] and reactions[10a-e] of allylic sulfones. Some of them were successfully employed for the synthesis of naturally occurring substances such as recifeiolide,[10b] squalene[10c] and coenzyme Q_{10}.[10e] We herein report facile methods for the preparation of vinylic sulfones from alkenes[11] and haloalkanes and their conversion to the corresponding allylic sulfones under mild basic conditions. On the basis of these facts, a direct preparation of one-carbon homologated allylic sulfones from aldehydes was also achieved.

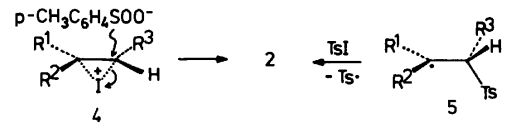
Results and Discussion

Preparation of Vinylic and Allylic Sulfones from Alkenes. Recently Kao Liu and his coworkers reported a convenient synthesis of various β-iodo sulfones,[12] which involves additions of alkane- and arenesulfonyl iodide to alkenes under the catalytic action of copper(II) chloride in aprotic solvents. Though they and others[13] established from the various evidences that tosyl iodide adds homolytically to alkenes, we thought it was possible to prepare β-iodo sulfones in an ionic fashion from iodine and sulfinate just like iodolactonization. Therefore, we tried the iodosulfonization and the subsequent elimination of hydrogen iodide with a base to yield the corresponding vinylic sulfones (**3**). It was consequently found that the iodosulfonization proceeds readily in methanol or in a two-phase system using ethyl acetate and water. The latter is favorable to avoid the formation of methyl *p*-toluenesulfinate as a by-product when an alkene is sparingly soluble in methanol (See the cases of **1d** in Table 1). The subsequent elimination was accomplished by the treatment with triethylamine in dry acetonitrile at room temperature for 15 min. The results are summarized in Table 1.

We could not exclude the possibility of the initial formation of tosyl iodide as an intermediate in the above iodosulfonization, since the reaction was retarded in the dark as in the case of the reaction of tosyl iodide with alkenes (the yield of **3a** was 75% in the reaction carried out in the dark under similar conditions).[9b] However, it was found that the addition of sodium iodide and sodium *p*-toluenesulfinate was effective to improve the yields of the addition products even for the reaction of tosyl iodide carried out in methanol.[14] These results seem to suggest that the reaction proceeds through the competitive two pathways, ionic one through the iodonium intermediate **4** and radical one for tosyl iodide produced in situ. The advantage of the present method for the preparation of vinylic sulfones from alkenes is obvious, namely it does not require the preparation of unstable tosyl iodide and the use of metal catalyst such as copper(II) chloride.

The results in Table 1 show that the iodosulfonization proceeds regiospecifically. This is considered as follows: If the reaction proceeds in an ionic fashion, *p*-toluenesulfinate ion attacks a less hindered carbon atom of the iodonium intermediate **4**, and if in a radical fashion, the more stable radical intermediate **5** is preferentially formed as shown in Scheme 1.

In contrast to the iodosulfonization, it was found that sulfonyl group is introduced on the C-2 position in sulfonylmercuration of 1-alkenes using mercury(II) chloride and sodium *p*-toluenesulfinate. The treatment of the addition product of sulfonylmercuration



Scheme 1.

with a base afforded exclusively 2-tosyl-1-alkenes (**7a—e**) as shown in Table 2.

This fact seems to suggest that Hg(II) ion of the intermediate **8** does not exist on the central position of olefinic bond, being different from the ionic

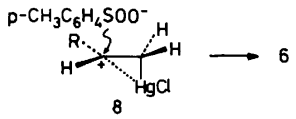

Scheme 2.

intermediate **4** of the iodosulfonization mentioned above, but lies on the less hindered carbon atom. Therefore, the tosylate ion attacks the C-2 position as shown in Scheme 2.

O'Connor and Lyness have reported that the equilibrium between 1-methylsulfonyl-1-hexene (**9**) and 1-methylsulfonyl-2-hexene (**10**) under basic conditions (*t*-BuOK in *t*-BuOH at room temperature) almost completely shifts to **10**.[15] We therefore tried the conversion of **3b—d** to the corresponding allylic sulfones (**11b—d**) with DBU as a base in acetonitrile as shown in Scheme 3. In each case, the proton rearrangement products (**11b—d**) were obtained in excellent yields.

On the other hand, it was found that the 2-tosyl-1-alkenes (**7b—d**), prepared above from 1-alkenes via sulfonylmercuration, were also converted to the corresponding allylic sulfones (**11b—d**) by the treatment with *p*-toluenesulfinic acid and DBU in refluxing dioxane (Table 3). This reaction appears to proceed through the addition of *p*-toluenesulfinate anion to give **12**, elimination (**12** to **3**) reaction of *p*-toluenesulfinic acid and the subsequent isomerization as shown in the scheme of Table 3. The intermediate **12** was actually isolated by decreasing the amount of DBU from 4 to 1.5 equiv.

Consequently, the present reactions provide a convenient method for the preparation of allylic sulfones from alkenes via vinylic sulfones.

Preparation of Vinylic and Allylic Sulfones from 1-Haloalkanes. In the previous papers,[9c,10d] we have reported the convenient methods for the preparation of two- or three-carbons homologated allylic sulfones from 1-haloalkanes using 2-(1-pyrrolidinyl)ethyl sulfone[9c] or allyl *p*-tolyl sulfone[10d] as a starting material, respectively. We herein report facile and new methods for the preparation of two- or one-carbon(s) homologated and unhomologated vinylic and allylic sulfones from 1-haloalkanes.

It was previously found that the anions of β-keto sulfones react with formaldehyde to give the corresponding vinylic sulfones via deacylation.[8b] The application of this reaction enabled the preparation of two-carbons homologated vinylic (**15**) and allylic (**16**) sulfones starting from 1-haloalkanes as shown in Scheme 4.

$$R'CH_2CH=CHTs \xrightarrow[\text{in } CH_3CN,\ \text{r.t., overnight}]{\text{DBU (2 equiv)}} R'CH=CHCH_2Ts$$

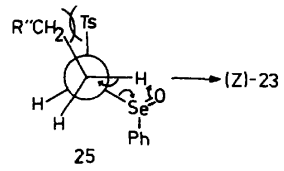
Scheme 6. Preparation of unhomologated vinylic and allylic sulfones from 1-haloalkanes.

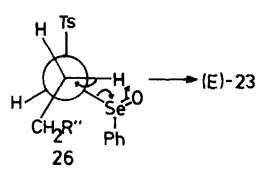
The synthesis of one-carbon homologated vinylic (**19**) and allylic (**20**) sulfones from 1-haloalkanes was accomplished according to Scheme 5. Haloalkanes were initially transformed to the corresponding *p*-tolyl sulfones (**17**) by a general method using sodium *p*-toluenesulfinate.[8e]

Unhomologated vinylic (**23**) and allylic (**24**) sulfones were prepared from 1-haloalkanes in a similar manner used in the preparation of 1-cyano-1-alkenes[16] according to Scheme 6.

In contrast to the case of cyanoalkane,[16] this reaction was found to afford only (E)-isomer of **23** from the observation of its 400 MHz ^{1}H NMR spectrum. This may be due to the bulkiness of tosyl group, namely cis-elimination of benzeneselenenic acid might proceed preferentially via the conformation illustrated in the structure **26** in which the unfavorable steric interaction between alkyl and tosyl groups, represented in the structure **25**, does not exist.



25



26

The final transformation of (*E*)-vinylic sulfones (**23**) to the corresponding allylic sulfones (**24**) was performed with DBU in acetonitrile at room temperature. It is noteworthy that Z-isomers of **24** were predominantly formed in contrast to the results of similar reaction using E/Z-mixture of vinylic sulfones (**3b—d** to **11b—d** in Scheme 3).

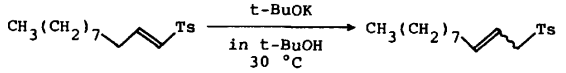
a) 2 equiv of DBU (0.26 mmol) was used toward **23d** (0.13 mmol) in each solvent (1 ml). b) Determined by 400 MHz ^{1}H NMR spectra.

Stereochemistry of the Conversion of Vinylic Sulfones to the Corresponding Allylic Sulfones. In order to rationalize the above peculiar phenomenon, the conversion of (*E*)-vinylic sulfone (**23d**) to the corresponding allylic sulfone (**24d**) was investigated using DBU as a base under various conditions as shown in Table 4. The polar solvent such as

acetonitrile (Entry 1) or *N,N*-dimethylformamide (DMF, Entry 2) seemed to be preferable to the less polar ones (Entries 3—7) for the conversion. It is noteworthy that (Z)-isomer of **24d** was preferentially formed at room temperature or at lower temperature in any solvent examined (Entries 1—10), while (E)-isomer was predominant in the reaction carried out at higher temperature (Entries 11 and 12). These results suggest that (Z)-isomer of **24d** is the kinetically-controlled product and the more stable (E)-isomer is the thermodynamically-controlled one.

The results of the similar reaction of **23d** with *t*-BuOK in *t*-BuOH made this point clearer, though the selectivity was not so high as that in the case of DBU. (Z)-Isomer of **24d** was initially formed predominantly and it gradually changed to the (E)-isomer (Table 5).

Table 5. Conversion of (*E*)-Vinylic Sulfone (**23d**) to Allylic Sulfone (**24d**) with *t*-BuOK[a)]

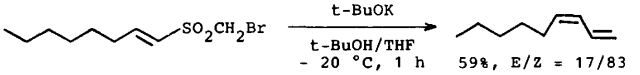


23d **24d**

Reaction time/h	Product ratio[b)]	
	23d :	**24d** (E/Z)
0.5	5	95 (41/59)
1	5	95 (51/49)
2	3	97 (63/37)
4	2	98 (75/25)
15	<1	>99 (86/14)

a) 2 equiv of *t*-BuOK (0.26 mmol) was used toward **23d** (0.13 mmol) in *t*-BuOH (6 ml). b) Determined by 400 MHz ^{1}H NMR spectra.

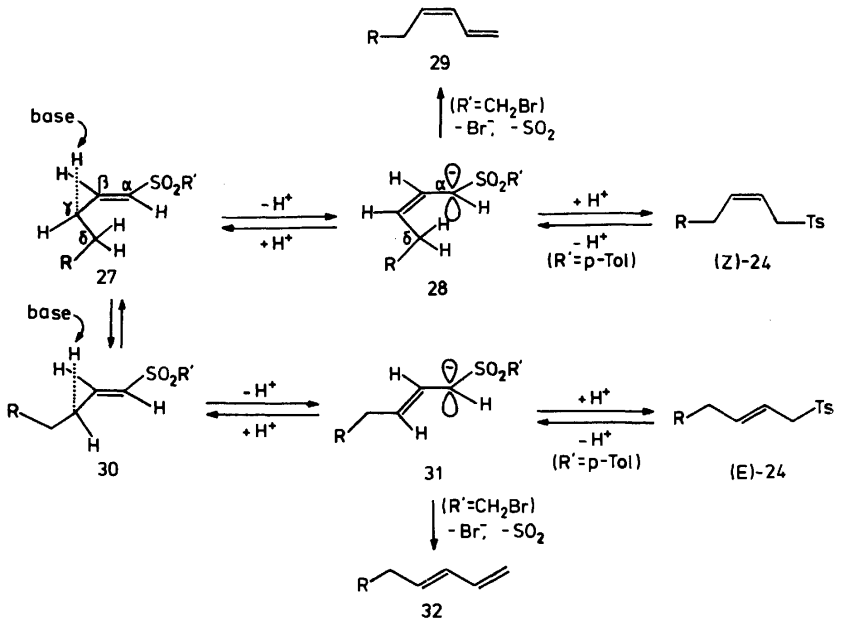
The question arised from the above experimental results is why (*E*)-**23** afford predominantly (*Z*)-**24** as a kinetically-controlled product. During the preparation of this manuscript, Block and his coworkers reported independently the similar results for the vinylogous Ramberg-Bäcklund reactions as shown in the following.[17)]



They attributed the stereoselectivity of the reaction to a stabilizing, attractive interaction between the developing negative charge at the α-position and the CH_2 group at the δ-position (a "*syn effect*"[18)]) favoring transition state **27** over **30** for deprotonation (Scheme 7).

Namely, these experimental results including ours suggest that the acidity of the protons at γ-position of vinylic sulfones varies remarkably in each conformation. We would like to propose to call such acidity of a proton chracteristic to each conformation "*Conformational Acidity.*" However, it should be noted that the anionic intermediate **31** is more stable than its (Z)-isomer **28** as can be seen in the above results, while it could not be observed in the Ramberg-Bäcklund reactions since the subsequent desulfonylation proceeded readily at low temperature.

On the other hand, (*Z*)-vinylic sulfone (**33**) and α-alkylated vinylic sulfones (**34a—c**) gave exclusively the corresponding (*E*)-allylic sulfones (**24d** and **35a—c**), respectively, as shown in Scheme 8 and Table 6. It may be due to the steric congestion which precludes



Scheme 7. A probable course of the conversion of (*E*)-vinylic sulfones (**23**=**27**, **30**) to the corresponding allylic sulfones (**24**).

the possibility of a stabilizing syn interaction between the α- and δ-position as being pointed out by Block et al.[17]

It is noteworthy that the Z-ratio of **24a** (R″=CH_3) is higher in the conversion of **23a** (R″=CH_3) than other cases (**23b—d** to **24b—d**) in Scheme 6. This may suggest that the syn interaction between the α- and δ-position is more effective when R″ is methyl group. Further, the reverse conversion of **24a** to **23a** may be retarded by the stabilization of the allylic structure owing to the hyperconjugation of methyl group with the double bond,[19] therefore, the initially formed (Z)-isomer may be retained better when R″ is methyl group than other cases.

Preparation of Allylic Sulfones from Aldehydes. The direct preparation of allylic sulfones from aldehyde was next investigated.

Posner and Brunelle reported the conversion of carbonyl substrates to vinylic sulfones using sulfonylmethylphosphonate carbanions.[20] They gen-

erated the carbanions with butyllithium in THF at −78 °C. On the other hand, we have established above the conversion of the vinylic sulfones to the corresponding allylic sulfones using DBU as a base catalyst. Therefore, the direct preparation of allylic sulfones from aldehydes seemed to be possible if the carbanion of sulfonylmethylphosphonate was generated with DBU itself. Actually, this reaction proceeded well with diethyl phenylsulfonylmethylphosphonate (**37**) and 2 or 3 equiv of DBU in acetonitrile at room temperature as shown in Table 7. The predominant formation of (*Z*)-allylic sulfones (**38a—e**) was observed when the reaction was quenched within a relatively short time (See the cases of **38a**). These results agree with the discussion on the stereochemistry described above since it is known that the present Horner-Wittig type reaction initially affords (*E*)-vinylic sulfones.[20] Similar reaction with ketones afforded neither vinylic sulfones nor allylic sulfones, but a small amount of reduced product, methyl phenyl sulfone, was obtained (3—4%) along with recovery of sulfonylmethylphosphonate (60—70%).

Attempts to prepare the allylic sulfones from aldehydes by Peterson olefination using phenyl trimethylsilylmethyl sulfone and DBU were unsuccessful.[21] Desilylated sulfone was obtained as a main product.

Experimental

All the melting points were determined with a micro melting apparatus (Yanagimoto-Seisakusho) and were uncorrected. The ^{1}H NMR and IR spectra were recorded on JEOL JNM-GX 400 (400 MHz) FT-NMR spectrometer and JASCO IRA-1 diffraction grating infrared spectrometer, respectively. The chemical shifts of NMR are reported in the δ scale relative to TMS as an internal standard.

Materials. All the solvents were distilled and stored over a drying agent. Thin-layer chromatography (TLC) was performed on Merck's silica gel 60 PF_{254} (Art. 7749).

Preparation of 1-Tosyl-2-phenylethene (3a) via Iodosulfonization in methanol. To a mixed solution of styrene (**1a**, 104 mg, 1 mmol) and sodium *p*-toluenesulfinate tetrahydrate (375 mg, 1.5 mmol) in methanol (2 ml) was added iodine (254 mg, 1.0 mmol) at room temperature with stirring. A lot of yellowish solid[22] precipitated immediately. The solvent was replaced by ethyl acetate after stirring for 15 min, and the solution was successively washed with water, aqueous $NaHCO_3$ containing a small amount of $NaHSO_3$, and brine, and dried over Na_2SO_4. The residue obtained by evaporation of the solvent was treated with Et_3N (202 mg, 2 mmol) in dry acetonitrile (2 ml) at room temperature for 15 min. The residue after removal of solvent was taken up in ethyl acetate and successively washed with 1 mol dm^{-3} HCl, aqueous $NaHCO_3$, and brine, and dried over Na_2SO_4. The solvent was evaporated in vacuo and the resulting residue was subjected to preparative TLC (solvent; hexane–AcOEt=5:2, v/v) to afford 229 mg of **3a** (89% yield) as a solid. Mp 120—121 °C (from ethanol, lit,[12] 120—121 °C). IR (KBr) 3032, 1602, 1586, 1442, 1296, 1134, 1076, 964, 800, 738 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.43 (s, 3H), 6.85 (d, 1H, *J*=15 Hz), 7.30—7.52 (m, 7H), 7.65 (d, 1H, *J*=15 Hz), 7.83 (d, 2H, *J*=8 Hz). Found: C, 69.80; H, 5.35%. Calcd for $C_{15}H_{14}O_2S$: C, 69.74; H, 5.46%.

Other vinylic sulfones (**3b—g**) were prepared in a similar manner.

3b: An oil; MS *m/z* 224 (M^+, 71%), 139 (100), 91, 41; IR (neat) 3016, 2908, 2848, 1606, 1580, 1436, 1302, 1130, 1072, 954, 798 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.92 (t, 3H of E and Z, *J*=7.5 Hz), 1.41—1.55 (m, 2H of E and Z), 2.16—2.24 (m, 2H of E), 2.43 (s, 3H of E and Z), 2.60—2.68 (m, 2H of Z), 6.19—6.35 (m, 2H of Z, 1H of E), 6.95 (dt, 1H of E, *J*=7, 15 Hz), 7.33 (d, 2H of E and Z, *J*=8 Hz), 7.76 (d, 2H of E, *J*=8 Hz), 7.80 (d, 2H of Z, *J*=8 Hz); E/Z=78/22.

3c: An oil; MS *m/z* 238 (M^+, 23%), 139 (100), 91, 41; IR (neat) 3024, 2908, 2842, 1606, 1582, 1440, 1304, 1136, 1076, 962, 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.89 (t, 3H of E and Z, *J*=7 Hz), 1.27—1.48 (m, 4H of E and Z), 2.19—2.26 (m, 2H of E), 2.43 (s, 3H of E and Z), 2.61—2.68 (m, 2H of Z), 6.18—6.35 (m, 2H of Z, 1H of E), 6.95 (dt, 1H of E, *J*=7, 15 Hz), 7.32 (d, 2H of E and Z, *J*=8 Hz), 7.75 (d, 2H of E, *J*=8 Hz), 7.79 (d, 2H of Z, *J*=8 Hz); E/Z=78/22.

3d: An oil; MS *m/z* 294 (M^+, 13%), 209, 157 (100), 139, 138, 96, 55; IR (neat) 3032, 2916, 2840, 1608, 1582, 1454, 1312, 1139, 1076, 960, 801 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=0.84—0.92 (m, 3H of E and Z), 1.25 (m, 12H of E and Z), 1.35—1.50 (m, 2H of E and Z), 2.17—2.26 (m, 2H of E), 2.43 (s, 3H of E and Z), 2.61—2.67 (m, 2H of Z), 6.18—6.35 (m, 2H of Z, 1H of E), 6.95 (dt, 1H of E, *J*=7, 15 Hz), 7.32 (d, 2H of E and Z, *J*=8 Hz), 7.75 (d, 2H of E, *J*=8 Hz), 7.79 (d, 2H of Z, *J*=8 Hz); E/Z=83/17.

3e: Mp 62—63 °C (from cyclohexane); IR (KBr) 3020, 1614, 1584, 1430, 1276, 1132, 1076, 800 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.87 (d, 3H, *J*=1 Hz), 2.14 (d, 3H, *J*=1 Hz), 2.43 (s, 3H), 6.17 (m, 1H, *J*=1 Hz), 7.33 (d, 2H, *J*=8 Hz), 7.78 (d, 2H, *J*=8 Hz). Found: C, 62.75; H, 6.72%. Calcd for $C_{11}H_{14}O_2S$: C, 62.83; H, 6.71%.

3f: Mp 65 °C (from cyclohxane, lit,[12] 66—67 °C); IR (KBr) 1610, 1582, 1428, 1286, 1136, 1062, 794 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.86 (s, 3H), 1.99 (s, 3H), 2.21 (s, 3H), 2.43 (s, 3H), 7.31 (d, 2H, *J*=8 Hz), 7.74 (d, 2H, *J*=8 Hz).

3g: Mp 81—82 °C (from ethanol, lit,[12] 81—82 °C); IR (KBr) 3018, 2906, 2842, 1624, 1580, 1434, 1270, 1128, 1082, 802 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.52—1.69 (m, 4H), 2.12—2.21 (m, 2H), 2.21—2.30 (m, 2H), 2.43 (s, 3H), 7.01—7.06 (m, 1H), 7.32 (d, 2H, *J*=8 Hz), 7.73 (d, 2H, *J*=8 Hz).

Preparation of 1-Tosyl-1-decene (3d) via Iodosulfonization in Ethyl Acetate and Water. To a heterogeneous mixture of *p*-$CH_3C_6H_4SOONa \cdot 4H_2O$ (375 mg, 1.5 mmol) in water (1 ml) and ethyl acetate (2 ml) were added 1-decene (**1d**, 140 mg, 1 mmol) and iodine (254 mg, 1 mmol) at room temperature with stirring. The dark brown color of the mixture diminished gradually. After stirring for 24 h, 20 ml of ethyl acetate was added. The organic phase was separated and washed successively with aqueous $NaHCO_3$ containing a small amount of $NaHSO_3$ and brine, and dried over Na_2SO_4. The residue obtained by evaporation of the solvent was treated with Et_3N to give **3d**, in a similar manner described for **3a**. Spectral data of **3d** is given above.

Other vinylic sulfones (**3h—j**) were prepared in a similar way.

3h: (E)- and (Z)-isomers were separated on preparative

TLC (solvent; hexane–AcOEt–Et_2O=10:1:1, v/v) and characterized based on the known deshielding of alkyl groups syn to the sulfonyl group in vinylic sulfones.[23] (*E*)-**3h**: Yield 63%. Mp 71—72 °C (from ethanol); IR (KBr) 2940, 2844, 1626, 1580, 1454, 1298, 1128, 1079, 804 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.05 (d, 6H, J=7 Hz), 1.82 (s, 3H), 2.43 (s, 3H), 2.49—2.61 (m, 1H), 6.70 (d, 1H, J=10 Hz), 7.32 (d, 2H, J=8 Hz), 7.72 (d, 2H, J=8 Hz). Found: C, 65.30; H, 7.76%. Calcd for $C_{13}H_{18}O_2S$: C, 65.51; H, 7.61%. (*Z*)-**3h**: Yield 20%. An oil; MS *m/z* 238 (M^+, 52%), 140, 139, 83, 82, 67 (100), 55; IR (neat) 2948, 2852, 1626, 1586, 1456, 1278, 1134, 1081, 804 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.98 (d, 6H, J=7 Hz), 1.94 (s, 3H), 2.44 (s, 3H), 3.61—3.74 (m, 1H), 5.74 (d, 1H, J=11 Hz), 7.33 (d, 2H, J=8 Hz), 7.76 (d, 2H, J=8 Hz).

3i: Mp 89—90 °C (from ethanol); IR (KBr) 3028, 2932, 2852, 1581, 1564, 1434, 1278, 1134, 1081, 806 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.94—1.02 (m, 1H), 1.07—1.15 (m, 1H), 1.21—1.28 (m, 1H), 1.49—1.56 (m, 1H), 1.62—1.71 (m, 1H), 1.71—1.83 (m, 1H), 2.44 (s, 3H), 3.05—3.12 (m, 1H), 3.12—3.17 (m, 1H), 6.90 (d, 1H, J=3 Hz), 7.32 (d, 2H, J=8 Hz), 7.77 (d, 2H, J=8 Hz). Found: C, 67.60; H, 6.56%. Calcd for $C_{14}H_{16}O_2S$: C, 67.71; H, 6.49%.

3j: An oil; MS *m/z* 304 (M^+, 18%), 165, 149 (100), 148, 133, 123, 108, 107 (100), 105, 91, 82 (100), 54; IR (neat) 3012, 2912, 1658, 1612, 1584, 1438, 1290, 1136, 1078, 806 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.77 (s, 3H), 2.16 (s, 3H), 2.33—2.56 (m, 4H), 2.45 (s, 3H), 2.69—2.81 (m, 1H), 6.21 (s, 1H), 6.68—6.76 (m, 1H), 7.35 (d, 2H, J=8 Hz), 7.78 (d, 2H, J=8 Hz).

Preparation of 1-Phenyl-1-tosylethene (7a) via Sulfonylmercuration. To a solution of styrene (**1a**, 104 mg, 1 mmol) in methanol (1.5 ml) and dichloromethane (0.7 ml) were added $HgCl_2$ (272 mg, 1 mmol) and sodium *p*-toluenesulfinate tetrahydrate (250 mg, 1 mmol) at room temperatute. After stirring for 1 d, the reaction mixture was diluted with ethyl acetate (ca. 15 ml) and the insoluble substances were filtered off through a Celite bed. The residue obtained by evaporation of solvent was treated with DBU (0.18 ml, 1.2 mmol) in dry THF (4 ml) at room temperature for 10 min. After replacing the solvent by ethyl acetate, the solution was successively washed with water and brine, and dried over Na_2SO_4, followed by evaporation of the solvent. The residue was subjected to preparative TLC (solvent; hexane–ethyl acetate=8:1, v/v) to afford 157 mg of **7a** (61% yield) as a colorless oil. MS *m/z* 258 (M^+, 13%), 139, 103 (100), 77; IR (neat) 3040, 2902, 1583, 1302, 1138, 1058, 800 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.36 (s, 3H), 5.92 (s, 1H), 6.60 (s, 1H), 7.16—7.37 (m, 7H), 7.56 (d, 2H, J=8 Hz).

Other 2-tosyl-1-alkene were prepared in a similar manner.

7b: An oil, MS *m/z* 224 (M^+, 61%), 157 (100), 139, 119, 92, 91 (100), 69, 68, 65, 41; IR (neat) 2946, 1582, 1439, 1300, 1161, 1128, 1073, 802 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.86 (t, 3H, J=7 Hz), 1.42—1.55 (m, 2H), 2.20 (t, 2H, J=8 Hz), 2.44 (s, 3H), 5.69 (s, 1H), 6.34 (s, 1H), 7.33 (d, 2H, J=8 Hz), 7.76 (d, 2H, J=8 Hz).

7c: An oil, MS *m/z* 238 (M^+, 100%), 197, 157 (100), 139 (100), 133 (100), 92 (100), 91 (100), 67, 55 (100), 41; IR (neat) 2951, 2863, 1587, 1448, 1305, 1130, 1075, 804 cm^{-1}, ^1H NMR ($CDCl_3$) δ=0.84 (t, 3H, J=7 Hz), 1.21—1.33 (m, 2H), 1.38—1.49 (m, 2H), 2.22 (t, 2H, J=7.5 Hz), 2.44 (s, 3H), 5.69 (s, 1H), 6.33 (s, 1H), 7.33 (d, 2H, J=8.5 Hz), 7.75 (d, 2H, J=8 Hz).

7d: An oil, MS *m/z* 294 (M^+, 1%), 197, 157 (100), 139, 138, 92, 55, 41; IR (neat) 2918, 2847, 1586, 1458, 1305, 1160, 1133, 1075, 803 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.86 (t, 3H, J=7 Hz), 1.12—1.33 (m, 10H), 1.38—1.50 (m, 2H), 2.22 (t, 2H, J=8 Hz), 2.44 (s, 3H), 5.69 (s, 1H), 6.33 (s, 1H), 7.32 (d, 2H, J=8.5 Hz), 7.75 (d, 2H, J=8 Hz).

7e: An oil, Ms *m/z* 286 (M^+, 78%), 181, 131 (100), 130 (100), 129 (100), 115, 92, 91 (100), 65; IR (neat) 3006, 2900, 1582, 1300, 1137, 1072, 802 cm^{-1}; ^1H NMR δ=2.44 (s, 3H), 2.54 (dd, 2H, J=7, 8 Hz), 2.77 (dd, 2H, J=7, 8 Hz), 5.65 (s, 1H), 6.35 (s, 1H), 7.03—7.39 (m, 7H), 7.75 (d, 2H, J=8 Hz).

Conversion of 1-Tosyl-1-pentene (3b) to 1-Tosyl-2-pentene (11b). To a solution of **3b** (138 mg, 0.62 mmol) in acetonitrile (2 ml) was added DBU (184 µl, 1.23 mmol) at room temperature. After being allowed to stand overnight, the solvent was replaced by ethyl acetate. The resulting solution was successively washed with 1 mol dm^{-3} HCl, aqueous $NaHCO_3$ and brine, followed by being dried over Na_2SO_4. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; hexane–ethyl acetate–ether=10:1:1, v/v) to afford 127 mg of **11b** as an oil. 400 MHz ^1H NMR spectrum showed that it was a mixture of (E)- and (Z)-isomers (E/Z=84/16) of **11b** contaminated with a small amount of **3b** (ca. 1%). Yield 91% (unseparable **3b** was reduced in the calculation of the yield). MS *m/z* 224 (M^+, 1%), 157, 69 (100), 68, 41; IR (neat) 3012, 2952, 1584, 1440, 1294, 1132, 1076, 958, 802 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.76 (t, 3H of Z, J=8 Hz), 0.91 (t, 3H of E, J=7.5 Hz), 1.73—1.83 (m, 2H of Z), 1.97—2.07 (m, 2H of E), 2.45 (s, 3H of E and Z), 3.72 (d, 2H of E, J=7 Hz), 3.83 (d, 2H of Z, J=8 Hz), 5.32—5.45 (m, 1H of E and Z), 5.55 (dt, 1H of E, J=7, 15 Hz), 5.71 (dt, 1H of Z, J=8, 11 Hz), 7.33 (d, 2H of E and Z, J=8 Hz), 7.73 (d, 2H of E, J=8 Hz), 7.76 (d, 2H of Z, J=8 Hz); E/Z=84/16.

3c and **3d** were also converted to **11c** and **11d**, respectively, in a similar manner.

11c: An oil; MS *m/z* 238 (M^+, 4%), 157 (100), 139, 92 (100), 91 (100), 83, 82 (100), 67 (100), 65, 55, 41 (100); IR (neat) 3012, 2944, 2912, 2852, 1584, 1444, 1306, 1134, 1076, 959, 802 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.75 (t, 3H of Z, J=7 Hz), 0.82 (t, 3H of E, J=7 Hz), 1.10—1.21 (m, 2H of Z), 1.25—1.36 (m, 2H of E), 1.69—1.77 (m, 2H of Z), 1.94—2.02 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, J=7 Hz), 3.83 (d, 2H of Z, J=8 Hz), 5.34—5.45 (m, 1H of E and Z), 5.51 (dt, 1H of E, J=7, 15 Hz), 5.71 (dt, 1H of Z, J=8, 11 Hz), 7.33 (d, 2H of E and Z, J=8 Hz), 7.73 (d, 2H of E, J=8 Hz), 7.76 (d, 2H of Z, J=8 Hz); E/Z=52/48. Recovery of **3c**: 2%.

11d: An oil, MS *m/z* 294 (M^+, 0.1%), 209, 157, 138, 97, 83 (100), 69, 55; IR (neat) 3012, 2908, 2836, 1584, 1448, 1310, 1132, 1078, 958, 804 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.82—0.93 (m, 3H of E and Z), 1.05—1.34 (m, 10H of E and Z), 1.69—1.78 (m, 2H of Z), 1.94—2.03 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, J=7 Hz), 3.83 (d, 2H of Z, J=8 Hz), 5.34—5.44 (m, 1H of E and Z), 5.51 (dt, 1H of E, J=7, 15 Hz), 5.71 (dt, 1H of Z, J=8, 11 Hz), 7.33 (d, 2H of E and Z, J=8 Hz), 7.72 (d, 2H of E, J=8 Hz), 7.75 (d, 2H of Z, J=8.5 Hz); E/Z=65/35. Recovery of **3d**: 3%.

Conversion of 2-Tosyl-1-pentene (7b) to 1-Tosyl-2-pentene (11b). To a solution of **7b** (84 mg, 0.38 mmol) in dioxane (2.5 ml) were added *p*-toluenesulfinic acid hydrate (*p*-$CH_3C_6H_4SOOH \cdot xH_2O$, 133 mg, ca. 0.76 mmol) and DBU (230 µl, 1.52 mmol) at room temperature. After refluxing for 5 h, the solvent was replaced by ethyl acetate.

The solution was successively washed with 1 mol dm^{-3} HCl, aqueous $NaHCO_3$, and brine, followed by being dried over Na_2SO_4. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; hexane–ethyl acetate=8:1, v/v) to afford **11b** as an oil. It was found to be a mixture of (E)- and (Z)-isomers (E/Z=81/19) from its ^1H NMR spectrum. Physical data of **11b—d** are given above.

Alkylation of 2-Tosyl-1-phenylethanone (13). A solution of **13** (685 mg, 2.5 mmol, mp 109—110 °C (from ethanol), prepared by the reaction of 2-bromo-1-phenylethanone and p-$CH_3C_6H_4SOONa \cdot 4H_2O$ in refluxing ethanol according to a general method[8c]) in DMF (8 ml) was added into a flask containing finely powdered dry K_2CO_3 (518 mg, 3.75 mmol) under nitrogen. After stirring for 1 h at room temperature, a solution of iodoethane (468 mg, 3.0 mmol) in DMF (2 ml) was added dropwise. The reaction mixture was quenched, after stirring for 9 h, by the addition of a buffer solution (pH 7) followed by evaporation of the solvent under reduced pressure. The residue was taken up in ethyl acetate and the resulting solution was washed with brine twice and dried over Na_2SO_4. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; hexane–ethyl acetate=5:1) to afford 119 mg of 2-tosyl-1-phenyl-1-butanone (**14a**, 79% yield) as a solid. Mp 72.0—72.5 °C (from hexane–ethanol); IR (KBr) 3048, 2970, 1668, 1585, 1440, 1344, 1310, 1296, 1284, 1262, 1139, 1078, 970, 805, 746, 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=7.5 Hz), 1.98—2.22 (m, 2H), 2.43 (s, 3H), 4.99 (dd, 1H, J=4, 11 Hz), 7.31 (d, 2H, J=8 Hz), 7.48 (dd, 2H, J=7, 8 Hz), 7.60 (t, 1H, J=7 Hz), 7.64 (d, 2H, J=8 Hz), 7.97 (d, 2H, J=8 Hz). Found: C, 67.23; H, 6.15%. Calcd for $C_{17}H_{18}O_3S$: C, 67.52; H, 6.00%.

In a similar manner, **14b** and **14c** were prepared.

14b: Mp 89—90 °C (from hexane/ethanol); IR (KBr) 3048, 2950, 1665, 1585, 1440, 1340, 1310, 1290, 1245, 1140, 1075, 950, 804, 742, 675 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, 3H, J=7.5 Hz), 1.26 (m, 2H), 1.96—2.13 (m, 2H), 2.44 (s, 3H), 5.07 (dd, 1H, J=4, 11 Hz), 7.31 (d, 2H, J=8 Hz), 7.48 (dd, 2H, J=7, 8 Hz), 7.60 (t, 1H, J=7 Hz), 7.64 (d, 2H, J=8 Hz), 7.98 (d, 2H, J=8 Hz). Found: C, 68.24; H, 6.39%. Calcd for $C_{18}H_{20}SO_3$: C, 68.33; H, 6.37%.

14c: Mp 78.5—79.5 °C (from hexane/ethanol); IR (KBr) 3044, 2952, 2920, 1665, 1584, 1438, 1336, 1302, 1295, 1138, 1074, 940, 800, 742, 678 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.81 (t, 3H, J=7 Hz), 1.08—1.31 (m, 8H), 1.96—2.14 (m, 2H), 2.43 (s, 3H), 5.05 (dd, 1H, J=4, 11 Hz), 7.31 (d, 2H, J=8 Hz), 7.48 (dd, 2H, J=7, 8 Hz), 7.61 (t, 1H, J=7 Hz), 7.64 (d, 2H, J=8 Hz), 7.96 (d, 2H, J=8 Hz). Found: C, 70.37; H, 7.43%. Calcd for $C_{21}H_{26}O_3S$: C, 70.36; H, 7.31%.

Synthesis of 2-Tosyl-1-butene (15a) via Deacylation. To a solution of lithium diisopropylamide (LDA, 0.74 mmol, prepared from diisopropylamine (80 mg, 0.79 mmol) and n-BuLi (hexane solution, 0.74 mmol) at −30 °C) in THF (3 ml) was added dropwise a solution of **14a** (211 mg, 0.7 mmol) in THF (7 ml) at −78 °C under nitrogen. After stirring for 30 min at −78 °C, a THF solution of excess amount of formaldehyde was added. The reaction mixture was gradually warmed up to room temperature and stirred overnight. After treatment with a buffer solution (pH 7), the insoluble substance was filtered off through a Celite bed, and the solvent was replaced by ethyl acetate. The resulting solution was washed with brine and dried over Na_2SO_4. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; hexane–ethyl acetate=5:1, v/v) to afford 139 mg of **15a** (95% yield) as a colorless solid. Mp 26—28 °C (crude); MS m/z 210 (M^+, 26%), 139 (100), 92, 55; IR (KBr) 2970, 1582, 1295, 1170, 1128, 1073, 942, 865, 800, 722 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.07 (t, 3H, J=7 Hz), 2.27 (dq, 2H, J=2, 7 Hz), 2.44 (s, 3H), 5.70 (t, 1H, J=2 Hz), 6.34 (s, 1H), 7.33 (d, 2H, J=8 Hz), 7.75 (d, 2H, J=8 Hz).

In a similar manner, **15b** and **15c** were prepared.

15b: An oil; MS m/z 224 (M^+, 61%), 157 (100), 139, 119, 92, 91 (100), 69, 68, 65, 41; IR (neat) 2956, 1584, 1442, 1302, 1162, 1130, 1080, 940, 802, 726, 701 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, 3H, J=7 Hz), 1.49 (m, 2H), 2.20 (m, 2H), 2.44 (s, 3H), 5.69 (t, 1H, J=2 Hz), 6.34 (s, 1H), 7.34 (d, 2H, J=8 Hz), 7.76 (d, 2H, J=8 Hz).

15c: An oil; MS m/z 266 (M^+, 10%), 197, 157 (100), 139 (100), 92 (100), 69, 55, 41; IR (neat) 2915, 2842, 1584, 1458, 1302, 1160, 1133, 1073, 940, 802, 727 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.84 (t, 3H, J=7 Hz), 1.14—1.30 (m, 6H), 1.38—1.48 (m, 2H), 2.21 (m, 2H), 2.44 (s, 3H), 5.69 (t, 1H, J=1.5 Hz), 6.34 (s, 1H), 7.33 (d, 2H, J=8 Hz), 7.75 (d, 2H, J=8 Hz).

The conversion of **15a—c** to **16a—c** was carried out in a similar manner described for the conversion of **7b** to **11b**.

16a: An oil; MS m/z 210 (M^+, 22%), 156 (100), 140, 92, 91 (100), 65, 55; IR (neat) 3025, 2920, 1585, 1315, 1135, 1080, 960, 810, 718 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.37 (dd, 3H of Z, J=2, 7 Hz), 1.68 (dd, 3H of E, J=1, 6 Hz), 2.45 (s, 3H of E and Z), 3.71 (d, 2H of E, J=7 Hz), 3.83 (d, 2H of Z, J=8 Hz), 5.37—5.48 (m, 1H of E and Z), 5.57 (dq, 1H of E, J=6.5, 15 Hz), 5.82 (dq, 1H of Z, J=7, 11 Hz), 7.34 (d, 2H of E and Z, J=8 Hz), 7.73 (d, 2H of E, J=8 Hz), 7.76 (d, 2H of Z, J=8 Hz); E/Z=72/28.

16b: An oil; MS m/z 224 (M^+, 1%), 157, 69 (100), 68, 41; IR (neat) 3020, 2947, 1583, 1305, 1134, 1078, 958, 802, 722 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.76 (t, 3H of Z, J=7.5 Hz), 0.91 (t, 3H of E, J=8 Hz), 1.78 (m, 2H of Z), 2.01 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, J=7.5 Hz), 3.82 (d, 2H of Z, J=8 Hz), 5.32—5.45 (m, 1H of E and Z), 5.55 (dt, 1H of E, J=7, 15 Hz), 5.71 (dt, 1H of Z, J=8, 11 Hz), 7.33 (d, 2H of E and Z, J=8 Hz), 7.73 (d, 2H of E, J=8 Hz), 7.76 (d, 2H of Z, J=8 Hz); E/Z=81/19.

16c: An oil; MS m/z 266 (M^+, 0.2%), 157, 110, 69 (100), 55, 41; IR (neat) 2915, 2842, 1587, 1458, 1310, 1135, 1080, 962, 804, 725 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.84 (t, 3H of Z, J=7 Hz), 0.87 (t, 3H of E, J=7 Hz), 1.05—1.40 (m, 6H of E and Z), 1.67—1.79 (m, 2H of Z), 1.92—2.07 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, J=7.5 Hz), 3.83 (d, 2H of Z, J=8 Hz), 5.33—5.44 (m, 1H of E and Z), 5.50 (dt, 1H of E, J=7, 15 Hz), 5.71 (dt, 1H of Z, J=8, 11 Hz), 7.33 (d, 2H of E and Z, J=8 Hz), 7.73 (d, 2H of E, J=8 Hz), 7.75 (d, 2H of Z, J=8 Hz); E/Z=79/21.

Preparation of 2-Tosyl-1-nonanol (18a). p-Tolyl octyl sulfone (**17a**, 134 mg, 0.50 mmol) was lithiated by the reaction with n-BuLi (hexane solution, 0.55 mmol) in THF (5 ml) at −78 °C for 1 h under nitrogen, followed by the addition of a THF solution of excess amount of formaldehyde at −78 °C. After a few minute, the mixture was quenched with a phosphate buffer solution (pH 7) and the insoluble substance was filtered off through a Celite bed. The residue after removal of the solvent was taken up in ethyl acetate. The organic layer was washed with brine and dried over Na_2SO_4. The residue obtained by evaporation of

the solvent was subjected to preparative TLC (solvent; benzene–ethyl acetate=20:1, v/v) to afford 102 mg of **18a** (68% yield) as an oil. MS *m/z* 299 (M^+ +1, 1%), 280, 157, 92 (100), 83 (100), 69 (100), 55; IR (neat) 3530, 2915, 2847, 1588, 1460, 1294, 1138, 1078, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85 (t, 3H, *J*=7 Hz), 1.11—1.49 (m, 10H), 1.49—1.64 (m, 1H), 1.68—1.79 (m, 1H), 2.47 (s, 3H), 2.98 (dd, 1H of OH, *J*=6, 7 Hz), 3.01—3.09 (m, 1H), 3.83—3.95 (m, 2H), 7.38 (d, 2H, *J*=8 Hz), 7.78 (d, 2H, *J*=8 Hz).

18b and **18c** were prepared in a similar manner.

18b: An oil; Ms *m/z* 326 (M^+, 0.4%), 308, 157, 97, 92 (100), 83, 69, 55; IR (neat) 3515, 2958, 2842, 1588, 1458, 1294, 1136, 1078, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, 3H, *J*=7 Hz), 1.08—1.48 (m, 14H), 1.48—1.62 (m, 1H), 1.68—1.79 (m, 1H), 2.47 (s, 3H), 2.99 (dd, 1H of OH, *J*=6, 7 Hz), 3.01—3.09 (m, 1H), 3.85—3.96 (m, 2H), 7.38 (d, 2H, *J*=8 Hz), 7.78 (d, 2H, *J*=8 Hz).

18c: Mp 49.5—50.5 °C (from hexane); MS *m/z* 340 (M^+, 1%), 322, 185, 157 (100), 111, 97, 92, 83, 69, 55; IR (KBr) 3524, 2905, 2840, 1584, 1455, 1270, 1130, 1075, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, *J*=7 Hz), 1.09—1.48 (m, 16H), 1.48—1.62 (m, 1H), 1.66—1.79 (m, 1H), 2.47 (s, 3H), 2.98 (t, 1H of OH, *J*=7 Hz), 3.00—3.09 (m, 1H), 3.83—3.95 (m, 2H), 7.38 (d, 2H, *J*=8.5 Hz), 7.78 (d, 2H, *J*=8.5 Hz). Found: C, 66.95; H, 9.74%. Calcd for $C_{19}H_{32}O_3S$: C, 67.02; H, 9.47%.

Preparation of 2-Tosyl-1-nonene (19a). To a solution of **18a** (64 mg, 0.215 mmol) and mesyl chloride (30 mg, 0.26 mmol) in dichloromethane (1 ml) was added triethylamine (36 µl, 0.26 mmol) at room temperature. After stirring for 30 min, the reaction mixture was cooled to 0 °C and additional 60 µl (0.43 mmol) of triethylamine was added, followed by stirring for 1.5 d. The solution diluted with ethyl acetate was successively washed with 1 mol dm^{-3} aqueous $NaHCO_3$, and brine, and dried over Na_2SO_4. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; benzene–ethyl acetate=30:1, v/v) to afford 56 mg of **19a** (93% yield) as a colorless oil. MS *m/z* 280 (M^+, 1%), 197, 157 (100), 139, 92, 69, 55, 41; IR (neat) 2920, 2850, 1588, 1308, 1162, 1077, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85 (t, 3H, *J*=7 Hz), 1.13—1.31 (m, 8H), 1.38—1.49 (m, 2H), 2.22 (t, 2H, *J*=8 Hz), 2.44 (s, 3H), 5.69 (s, 1H), 6.34 (s, 1H), 7.33 (d, 2H, *J*=8 Hz), 7.75 (d, 2H, *J*=8 Hz).

In a similar manner, **19b** and **19c** were prepared.

19b: An oil; MS *m/z* 308 (M^+, 1%), 197, 157 (100), 152, 139, 92, 55; IR (neat) 2920, 2850, 1588, 1458, 1308, 1160, 1133, 1076, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, 3H, *J*=7 Hz), 1.11—1.36 (m, 12H), 1.36—1.50 (m, 2H), 2.22 (t, 3H, *J*=8 Hz), 2.44 (s, 3H), 5.69 (s, 1H), 6.33 (s, 1H), 7.33 (d, 2H, *J*=8 Hz), 7.75 (d, 2H, *J*=8 Hz).

19c: An oil; MS *m/z* 322 (M^+, 1%), 197, 166, 157 (100), 139, 92, 55; IR (neat) 2922, 2849, 1590, 1460, 1310, 1162, 1134, 1078, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, *J*=7 Hz), 1.07—1.34 (m, 14H), 1.34—1.49 (m, 2H), 2.21 (t, 2H, *J*=8 Hz), 2.44 (s, 3H), 5.69 (s, 1H), 6.33 (s, 1H), 7.33 (d, 2H, *J*=8 Hz), 7.75 (d, 2H, *J*=8 Hz).

The conversion of **19a—c** to **20a—c** was carried out in a similar manner described for the conversion of **7b** to **11b**.

20a: An oil; MS *m/z* 280 (M^+, 0.2%), 157 (100), 124 (100), 83 (100), 69 (100), 55 (100), 41; IR (neat) 2918, 2845, 1588, 1458, 1314, 1138, 1082, 960, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.86 (t, 3H of Z, *J*=7 Hz), 0.88 (t, 3H of E, *J*=7 Hz), 0.98—1.36 (m, 8H of E and Z), 1.73 (m, 2H of Z), 1.99 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, *J*=7 Hz), 3.83 (d, 2H of Z, *J*=8 Hz), 5.33—5.44 (m, 1H of E and Z), 5.51 (dt, 1H of E, *J*=7, 15 Hz), 5.71 (dt, 1H of Z, *J*=7.5, 11 Hz), 7.33 (d, 2H of E and Z, *J*=8 Hz), 7.73 (d, 2H of E, *J*=8 Hz), 7.76 (d, 2H of Z, *J*=8 Hz); E/Z=80/20.

20b: An oil; MS *m/z* 308 (M^+, 0.2%), 209, 157 (100), 152, 97, 83, 69, 55; IR (neat) 2915, 2840, 1587, 1442, 1312, 1135, 1080, 960, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H of Z, *J*=7 Hz), 0.89 (t, 3H of E, *J*=7 Hz), 1.02—1.48 (m, 12H of E and Z), 1.73 (m, 2H of Z), 1.98 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, *J*=7 Hz), 3.83 (d, 2H of Z, *J*=8 Hz), 5.35—5.44 (m, 1H of E and Z), 5.51 (dt, 1H of E, *J*=7, 15.5 Hz), 5.71 (dt, 1H of Z, *J*=7.5, 11 Hz), 7.33 (d, 2H of E and Z, *J*=8 Hz), 7.73 (d, 2H of E, *J*=8 Hz), 7.76 (d, 2H of Z, *J*=8 Hz); E/Z=78/22.

20c: An oil; MS *m/z* 322 (M^+, 0.5%), 166 (100), 157 (100), 111, 97 (100), 83 (100), 69 (100), 55, 43; IR (neat) 2917, 2840, 1590, 1458, 1316, 1138, 1080, 962, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H of E and Z, *J*=7 Hz), 1.00—1.54 (m, 14H of E and Z), 1.72 (m, 2H of Z), 1.98 (m, 2H of E), 2.44 (s, 3H of E and Z), 3.72 (d, 2H of E, *J*=7 Hz), 3.83 (d, 2H of Z, *J*=8 Hz), 5.33—5.44 (m, 1H of E and Z), 5.51 (dt, 1H of E, *J*=7, 15 Hz), 5.70 (dt, 1H of Z, *J*=7.5, 11 Hz), 7.33 (d, 2H of E and Z, *J*=8 Hz), 7.72 (d, 2H of E, *J*=8 Hz), 7.75 (d, 2H of Z, *J*=8 Hz); E/Z=77/23.

Preparation of (*E*)-1-Tosyl-1-butene (23a). To a solution of LDA (2 mmol, prepared from diisopropylamine (280 µl, 2 mmol) and *n*-BuLi (hexane solution, 2 mmol) at −30 °C) in THF (7.5 ml) was added dropwise a THF (1.5 ml) solution of butyl *p*-tolyl sulfone (**21a**, 212 mg, 1 mmol) at −78 °C under nitrogen. After stirring for 1 h at −78 °C, a solution of diphenyl diselenide (343 mg, 1.1 mmol) in THF (1 ml) was added at −78 °C. The mixture was gradually warmed up to room temperature and stirred overnight. After quenching with a phosphate buffer solution (pH 7), the THF was evaporated. The product was extracted from the aqueous phase with ethyl acetate several times and the combined organic extracts were successively washed with aqueous $NaHCO_3$ and brine, and dried over Na_2SO_4. The solution was condensed into ca. 6 ml followed by the addition of 3 ml of THF. To the resulting homogeneous solution was added 30% of hydrogen peroxide (0.43 ml, 5 mmol) at 0 °C. After stirring for 1 h at 0 °C and for 2 h at room temperature, the mixture was treated with aqueous $NaHCO_3$ and the product was extracted with ethyl acetate, followed by being dried over Na_2SO_4. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; benzene–ethyl acetate=50:1, v/v) to afford 181 mg of **23a** (86% yield) as a colorless oil; MS *m/z* 210 (M^+, 29%), 139 (100), 92, 91, 51; IR (neat) 3040, 2960, 1612, 1586, 1448, 1310, 1139, 1079, 958, 808 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.07 (t, 3H, *J*=7.5 Hz), 2.22—2.32 (m, 2H), 2.44 (s, 3H), 6.29 (d, 1H, *J*=15 Hz), 7.01 (dt, 1H, *J*=6, 15 Hz), 7.33 (d, 2H, *J*=8.5 Hz), 7.76 (d, 2H, *J*=8.5 Hz).

In a similar manner, **23b—d** were prepared.

23b: An oil; MS *m/z* 266 (M^+, 7%), 183, 157 (100), 139 (100), 111, 110 (100), 92, 91, 81 (100), 69 (100), 55, 43, 41; IR (neat) 3036, 2920, 2849, 1588, 1458, 1318, 1140, 1082, 958, 802 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.86 (t, 3H, *J*=7 Hz), 1.18—1.37 (m, 6H), 1.37—1.51 (m, 2H), 2.17—2.26 (m, 2H), 2.43 (s, 3H), 6.29 (d, 1H, 15 Hz), 6.95 (dt, 1H, *J*=7, 15 Hz), 7.32 (d, 2H, *J*=8 Hz), 7.75 (d, 2H, *J*=8 Hz).

23c: An oil; MS *m/z* 294 (M^+, 23%), 209, 183, 157 (100), 139 (100), 138 (100), 96 (100), 83 (100), 82, 55, 43, 41; IR (neat) 3042, 2918, 2851, 1588, 1460, 1315, 1140, 1080, 962, 802 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, 3H, J=7 Hz), 1.16—1.37 (m, 10H), 1.37—1.61 (m, 2H), 2.17—2.26 (m, 2H), 2.43 (s, 3H), 6.29 (d, 2H, J=15 Hz), 6.95 (dt, 1H, J=7, 15 Hz), 7.32 (d, 2H, J=8 Hz), 7.75 (d, 2H, J=8 Hz).

23d: Mp 44 °C (from hexane); MS *m/z* 308 (M^+, 13%), 209, 157 (100), 152, 139, 96, 92, 82, 68, 55, 43; IR (KBr) 3034, 2918, 1582, 1458, 1280, 1132, 1075, 962, 797 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=7 Hz), 1.24 (broad s, 12H), 1.36—1.51 (m, 2H), 2.15—2.26 (m, 2H), 2.43 (s, 3H), 6.29 (d, 2H, J=15 Hz), 6.95 (dt, 1H, J=7, 15 Hz), 7.32 (d, 2H, J=8 Hz), 7.75 (d, 2H, J=8 Hz). Found: C, 69.90; H, 9.39%. Calcd for $C_{18}H_{28}O_2S$: C, 70.08; H, 9.15%.

The conversion of **23a—d** to **24a—d** was achieved in a similar manner described for **3b** to **11b**. Their physical data were already shown above, namely, those of **24a** were similar to those of **16a**, **24b** to **16c**, **24c** to **11d**, and **24d** to **20b** except only the ratios of E/Z on their ^1H NMR spectra, respectively.

Conversion of (*E*)-1-Tosyl-1-undecene (23d) to 1-Tosyl-2-undecene (24d) with *t*-BuOK. To a solution of *t*-BuOK (29 mg, 0.26 mmol) in *t*-BuOH (4 ml) was added a solution of (*E*)-**23d** (40 mg, 0.13 mmol) in *t*-BuOH (2 ml) at 30 °C with stirring. One-milliliter aliquots were quenched each time shown in Table 5 with 1 mol dm^{-3} HCl followed by the addition of ethyl acetate. The organic phase was separated and washed successively with aqueous $NaHCO_3$ and brine, and dried over Na_2SO_4. The residue obtained by evaporation of the solvent was dissolved in $CDCl_3$ and the resulting solution was passed through a small and short alumina column to dry and to remove insoluble substances. The ratios of products shown in Table 5 were determined by 400 MHz ^1H NMR spectra of the $CDCl_3$ solution thus obtained.

α-Alkylated vinylic sulfones (**34a—c**) were prepared according to the procedure described in the previous paper.[9c] In order to yield the pure (E)- and (Z)-isomers of **34a** and **34b**, their precursors, the 1-alkyl-2-(1-pyrrolidinyl)-alkyl *p*-tolyl sulfones, were separated into each diastereoisomer with preparative TLC prior to Cope elimination reaction. Physical data of **34a—c** are given below. (E)- and (Z)-isomers were characterized based on the known deshielding of alkyl group syn to the sulfonyl group in vinylic sulfones.[23] It was further confirmed by the measurement of NOE for each isomer.

(*E*)-**34a**: An oil; MS *m/z* 322 (M^+, 11%), 197, 166 (100), 157, 139, 69, 55; IR (neat) 2920, 2850, 1640, 1590, 1490, 1460, 1295, 1135, 1070, 805, 707 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=7 Hz), 1.20—1.37 (m, 12H), 1.43—1.54 (m, 2H), 1.81 (s, 3H), 2.14—2.20 (m, 2H), 2.43 (s, 3H), 6.87 (t, 1H, J=7.5 Hz), 7.31 (d, 2H, J=8 Hz), 7.73 (d, 2H, J=8 Hz).

(*Z*)-**34a**: An oil; MS *m/z* 322 (M^+, 25%), 223, 197, 166, 157 (100), 139, 69, 68, 55; IR (neat) 2920, 2850, 1634, 1590, 1490, 1460, 1310, 1135, 1075, 805, 702 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, 3H, J=7 Hz), 1.16—1.44 (m, 14H), 1.96 (s, 3H), 2.44 (s, 3H), 2.60—2.70 (m, 2H), 5.97 (t, 1H, J 7.5 Hz), 7.32 (d, 2H, J=8 Hz), 7.76 (d, 2H, J=8 Hz).

(*E*)-**34b**: An oil; MS *m/z* 350 (M^+, 12%), 194, 157 (100), 139, 119, 83, 69, 55; IR (neat) 2950, 2910, 2840, 1627, 1587, 1450, 1305, 1127, 1078, 803, 710 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.81—0.96 (m, 6H), 1.17—1.43 (m, 14H), 1.43—1.55 (m, 2H), 2.14—2.24 (m, 4H), 2.43 (s, 3H), 6.88 (t, 1H, J=7 Hz), 7.31 (d, 2H, J=8 Hz), 7.73 (d, 2H, J=8 Hz).

(*Z*)-**34b**: An oil; MS *m/z* 350 (M^+, 44%), 251, 157 (100), 139, 96, 82, 69, 67, 55; IR (neat) 2950, 2910, 2840, 1620, 1587, 1450, 1305, 1130, 1075, 803, 703 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85—0.97 (m, 6H), 1.15—1.41 (m, 14H), 1.45—1.58 (m, 2H), 2.27 (t, 2H, J=7.5 Hz), 2.43 (s, 3H), 2.57—2.66 (m, 2H), 5.96 (t, 1H, J=7.5 Hz), 7.31 (d, 2H, J=8 Hz), 7.76 (d, 2H, J=8 Hz).

34c (mixture of E- and Z-forms): An oil; MS *m/z* 336 (M^+, 35%), 237, 211, 180, 157 (100), 139, 82, 69, 55; IR (neat) 2910, 2840, 1625, 1587, 1480, 1450, 1303, 1125, 1075, 803, 701 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.84—0.96 (m, 6H of E and 3H of Z), 1.05—1.13 (t, 3H of Z, J=7 Hz), 1.16—1.41 (m, 14H of Z and 12H of E), 1.42—1.58 (m, 2H of E), 2.15—2.30 (m, 4H of E), 2.30—2.38 (m, 2H of Z), 2.43 (s, 3H of E and Z), 2.57—2.67 (m, 2H of Z), 5.95 (t, 1H of Z, J=7 Hz), 6.86 (t, 1H of E, J=7.5 Hz), 7.30—7.35 (m, 2H of E and Z), 7.72—7.79 (m, 2H of E and Z).

(*E*)-**34c**: An oil; MS *m/z* 336 (M^+, 9%), 211, 180, 157, 139, 97, 83, 69 (100), 57, 55; IR (neat) 2910, 2840, 1625, 1587, 1480, 1455, 1367, 1307, 1145, 1075, 802, 703 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.84—0.98 (m, 6H), 1.20—1.37 (m, 12H), 1.42—1.58 (m, 2H), 2.15—2.30 (m, 4H), 2.43 (s, 3H), 6.86 (t, 1H, J=7.5 Hz), 7.31 (d, 2H, J=8 Hz), 7.73 (d, 2H, J=8 Hz).

The conversion of **34a—c** to the corresponding allylic sulfones (**35a—c**) was carried out with *t*-BuOK in *t*-BuOH in a similar manner described for the conversion of **23d** to **24d**. Physical data of **35a—c** were shown below.

(*E*)-**35a**: An oil; CIMS *m/z* 323 (M^+ +1, 12%), 199, 197, 167 (100), 158, 157 (100), 111, 97 (100), 83, 69; IR (neat) 2920, 2850, 1650, 1590, 1450, 1310, 1140, 1085, 965, 807, 710 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.89 (t, 3H, J=7 Hz), 1.14—1.36 (m, 12H), 1.41 (d, 3H, J=7 Hz), 1.97 (q, 2H, J=7 Hz), 2.44 (s, 3H), 3.62 (quintet, 1H, J=7 Hz), 5.36 (dd, 1H, J=7, 15.5 Hz), 5.45 (dt, 1H, J=6.5, 15.5 Hz), 7.31 (d, 2H, J=8 Hz), 7.70 (d, 2H, J=8 Hz).

(*E*)-**35b**: An oil; MS *m/z* 350 (M^+, 0.1%), 195, 125, 111, 97, 83 (100), 69, 57, 55; IR (neat) 2920, 2850, 1905, 1760, 1650, 1590, 1460, 1310, 1140, 1081, 965, 807 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.85—0.96 (m, 6H), 1.13—1.36 (m, 13H), 1.36—1.53 (m, 1H), 1.55—1.70 (m, 1H), 1.96 (q, 2H, J=7 Hz), 2.00—2.10 (m, 1H), 2.44 (s, 3H), 3.38—3.47 (m, 1H), 5.17 (dd, 1H, J=9, 15.5 Hz), 5.39 (dt, 1H, J=7, 15.5 Hz), 7.30 (d, 2H, J=8 Hz), 7.69 (d, 2H, J=8 Hz).

(*E*)-**35c**: An oil; CIMS *m/z* 337 (M^+ +1, 20%), 199, 197, 181 (100), 158, 157 (100), 125, 111, 97, 83, 69; IR (neat) 2920, 2840, 1720, 1590, 1450, 1308, 1140, 1080, 960, 805 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H, J=7 Hz), 0.93 (t, 3H, J=7 Hz), 1.14—1.37 (m, 12H), 1.56—1.72 (m, 1H), 1.97 (q, 2H, J=7 Hz), 2.10—2.21 (m, 1H), 2.44 (s, 3H), 3.30—3.38 (m, 1H), 5.18 (dd, 1H, J=9, 15.5 Hz), 5.42 (dt, 1H, J=7, 15.5 Hz), 7.30 (d, 2H, J=8 Hz), 7.69 (d, 2H, J=8 Hz).

Preparation of 4-Phenylsulfonyl-2-methyl-2-butene (38e) from 2-Methylpropanal (36e). To a mixed solution of diethyl phenylsulfonylmethylphosphonate (**37**, 74 mg, 0.25 mmol) and DBU (114 mg, 0.75 mmol) in acetonitrile (1.5 ml) was added 22 mg of **36e** (0.3 mmol) at room temperature with stirring. After 12 h, the reaction mixture was quenched with a phosphate buffer solution (pH 7), followed by replacing the solvent by ethyl acetate. The resulting solution was washed with brine twice and dried over

$MgSO_4$. The residue obtained by evaporation of the solvent was subjected to preparative TLC (solvent; hexane–ethyl acetate=5:1, v/v) to afford 46 mg of **38e** (88% yield) as an oil; MS *m/z* 210 (M^+, 2%), 69 (100), 41; IR (neat) 3048, 2960, 2904, 1578, 1440, 1300, 1144, 1080, 894, 774, 730, 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.31 (s, 3H), 1.71 (s, 3H), 3.79 (d, 2H, J=8 Hz), 5.19 (m, 1H), 7.49—7.59 (m, 2H), 7.61—7.68 (m, 1H), 7.81—7.93 (m, 2H).

In a similar manner, **38a—d** were prepared. Their physical data are given below.

38a: An oil (contaminated with a small amount of vinylic sulfone (ca. 8%), which was reduced in the calculation of the yield of **38a**); CIMS *m/z* 272 (M^+, 100%), 142, 130 (100), 129, 91, 52; IR (neat) 3048, 3012, 2912, 1590, 1486, 1442, 1300, 1142, 1080, 965, 720, 692 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.13 (d, 2H of Z, J=7 Hz), 3.32 (d, 2H of E J=7 Hz), 3.77 (dd, 2H of E, J=0.5, 7 Hz), 3.95 (d, 2H of Z, J=8 Hz), 5.42—5.60 (m, 1H of E and Z), 5.65 (dt, 1H of E, J=7, 15 Hz), 5.90 (dt, 1H of Z, J=7, 11 Hz), 6.93 (d, 2H of Z, J=7 Hz), 7.00 (d, 2H of E, J=7 Hz), 7.08—7.33 (m, 3H of E and Z), 7.42—7.71 (m, 3H of E and Z), 7.77—7.98 (m, 2H of E and Z).

38b: An oil; CIMS *m/z* 282 (M^+ +2, 77%), 281 (M^+ +1, 100), 183, 143 (100), 139, 138, 83, 53; IR (neat) 3052, 3012, 2920, 2844, 1580, 1440, 1314, 1140, 1080, 962, 720, 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (t, 3H of Z, J=7 Hz), 0.88 (t, 3H of E, J=7 Hz), 0.96—1.36 (m, 10H of E and Z), 1.72 (m, 2H of Z), 1.99 (m, 2H of E), 3.74 (d, 2H of E, J=7 Hz), 3.85 (d, 2H of Z, J=8 Hz), 5.33—5.46 (m, 1H of E and Z), 5.50 (dt, 1H of E, J=7, 15 Hz), 5.71 (dt, 1H of Z, J=7, 11 Hz), 7.49—7.60 (m, 2H of E and Z), 7.60—7.69 (m, 2H of E and Z), 7.80—7.94 (m, 2H of E and Z).

38c: An oil; CIMS *m/z* 295 (M^+ +1, 56%), 183, 153 (100), 143 (100), 97, 83, 69, 53; IR (neat) 3048, 2912, 2840, 1576, 1438, 1310, 1138, 1080, 960, 720, 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.88 (t, 3H of Z, J=7 Hz), 0.89 (t, 3H of E, J=7 Hz), 0.98—1.36 (m, 12H of E and Z), 1.72 (m, 2H of Z), 1.98 (m, 2H of E), 3.74 (d, 2H of E, J=7 Hz), 3.85 (d, 2H of Z, J=8 Hz), 5.34—5.46 (m, 1H of E and Z), 5.50 (dt, 1H of E, J=7, 15 Hz), 5.72 (dt, 1H of Z, J=7, 11 Hz), 7.49—7.59 (m, 2H of E and Z), 7.60—7.69 (m, 1H of E and Z), 7.80—7.95 (m, 2H of E and Z).

(***E***)-**38d**: An oil; CIMS *m/z* 293 (M^+ +1, 62%), 183, 152, 151 (100), 143, 109, 95, 81, 69, 51; IR (neat) 3052, 2952, 2900, 1578, 1440, 1312, 1140, 1080, 962, 730, 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.87 (d, 3H, J=7 Hz), 1.19 (m, 2H), 1.56 (s, 3H), 1.67 (s, 3H), 1.82 (q, 2H, J=7.5 Hz), 2.09 (m, 1H), 3.69—3.82 (m, 2H), 5.01 (m, 1H), 5.30—5.42 (m, 2H, J of olefinic protons=15.5 Hz), 7.50—7.58 (m, 2H), 7.60—7.67 (m, 1H), 7.81—7.92 (m, 2H).

(***Z***)-**38d**: An oil (contaminated with a small amount of vinylic sulfone (ca. 5%), which was reduced in the calculation of the yield of **38d**); CIMS *m/z* 293 (M^+ +1, 100%), 152 (100), 151 (100), 150 (100), 149, 143 (100), 135, 109 (100), 107, 95, 83, 82 (100), 81, 69, 67, 53, 51; IR (neat) 3052, 2952, 2912, 1580, 1440, 1312, 1140, 1080, 886, 722, 680 cm^{-1}; ^1H NMR ($CDCl_3$) δ=0.66 (d, 3H, J=7 Hz), 0.98—1.11 (m, 1H), 1.13—1.27 (m, 1H), 1.54 (s, 3H), 1.66 (d, 3H, J=1 Hz), 1.73 (q, 2H, J=7.5 Hz), 2.02—2.16 (m, 1H), 3.71—3.82 (m, 1H), 3.85—3.95 (m, 1H), 4.95 (m, 1H), 5.31—5.41 (m, 1H), 5.47 (dd, 1H, J=10, 11 Hz), 7.48—7.58 (m, 2H), 7.58—7.69 (m, 1H), 7.82—7.96 (m, 2H).

Authors express their sincere thanks to Professor Shigeyuki Aono and Dr. Kiyoshi Nishikawa of this Institute for their helpful discussions.

$CH_3\cdots O$ Hydrogen Bond. Implications of Its Presence from the Substituent Effects on the Populations of Rotamers in 4-Substituted 9-Ethyl-1-methoxytriptycenes and 9-(Substituted Phenoxymethyl)-1,4-dimethyltriptycenes[1)]

Yoshio TAMURA, Gaku YAMAMOTO, and Michinori ŌKI*
Department of Chemistry, Faculty of Science, The University of Tokyo,

(Received October 13, 1986)

In the series of 4-substituted 9-ethyl-1-methoxytriptycenes, the populations of the *sc* conformer increase as the electron-density on the 1-methoxy-oxygen decreases. This trend was interpreted on the basis of steric repulsion which should increase as the electron density on the oxygen atom becomes high. In contrast, in the series of 9-(substituted phenoxymethyl)-1,4-dimethyltriptycenes, the high electron density on the aryloxy-oxygen favors the *sc* form. The stabilization of the *sc* form relative to the *ap* in the high electron density compounds in the latter series is attributed to the presence of $CH_3\cdots O$ hydrogen bond, since other factors like Coulombic interactions, van der Waals repulsions, and van der Waals attractions could be excluded from being the main factor for the stabilization.

Hydrogen bond is a very important phenomenon both in chemistry and in biology.[2)] Those which involve the OH and NH groups as hydrogen donors are well-documented. However, the hydrogen bond which involves the CH group as a hydrogen donor, though theoretically possible, is controversial at best, except some strong hydrogen donors like hydrogen cyanide, acetylene, and chloroform.[3)] It is a common practice to assume the presence of a hydrogen bond when two groups concerned are placed within the sum of their van der Waals radii in crystals.[4)] Nishio and Hirota have discussed the presence of this kind of interactions from the unusual populations of rotamers but their work is lacking convincing evidence.[5)] Allerhand and Schleyer investigated the presence of hydrogen bond involving the methyl group without success.[6)] As judged from the acidity of methyl groups, the electron-accepting ability of the methyl should be the lowest among the CH groups. And this makes it difficult to detect the hydrogen bond involving the methyl group as a hydrogen donor.

Molecular interactions are generally observable when one of various factors predominates. The factors may be charge-transfer interactions, Coulombic interactions both repulsive and attractive, van der Waals repulsions, and van der Waals attractions (dispersion forces).[3)] Since the charge trasfer interactions involving the methyl group are weak, the attractive forces due to charge transfer may well be cancelled by the strong van der Waals repulsive forces. This is cosidered to be the situation where we do not usually observe hydrogen bond in which the methyl group acts as a hydrogen donor.

1,9-Disubstituted triptycenes comprise a very interesting group of compounds because the substituents are placed well within the sum of the van der Waals radii, as judged from the molecular structures in crystals.[7–9)] That means that the 9-substituent cannot avoid the very strong van der Waals repulsions irrespective of their rotational positions including the otherwise stable staggered positions. In addition, this geometry will enhance the overlap of the atomic orbitals concerned. The fact that this laboratory was able to report the presence of weak molecular interactions such as charge-transfer interactions between n-electrons and π^*-systems of benzene rings,[10)] n-electrons and σ^*-systems of acyloxymethyl groups,[11)] and n-electrons and π^*-systems of various carbonyl moieties[5)] by taking advantage of the 1,9-disubstituted triptycenes owes to these particular steric situations.

We have suggested in some of the previous papers from this laboratory that there have been some phenomena that might be explained by the presence of $CH_3\cdots O$ hydrogen bond. Although the thickness of the π-system is considered to be much smaller than the van der Waals radius of a methyl group, both 9-allyl- (**1**) and 9-ethyl-1,4-dimethoxytriptycene (**2**) show the $\pm sc/ap$ value of ca. 0.7.[12–13)] Similarly, 1,4-dimethoxy-9-(1-methyl-2-propenyl)triptycene (**3**) shows *sc/ap* value of 0.72.[14)] Apparently the methyl group is smaller than the π-system in this case. Although it is possible to argue that these unusual population ratios of rotational isomers are caused by an unexpected instability of the conformation in which the vinyl group takes the *ap* position or the electronic repulsion between the π-system and the methoxy-oxygen is very strong, we cannot overlook a possibility that there are attractive interactions such as $CH_3\cdots O$ hydrogen bond.

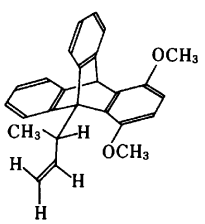
2



3

1-Substituted 9-(1-methoxyethyl)triptycenes (**4**) are another case that shows anomalous population ratios of rotamers. The *ap* rotamer becomes more favored than the statistical value of 2.0 when the 1-substituent is a methoxyl group whereas other substituents such as chloro, bromo, and methyl all disfavor the *ap* form to a large extent.[15] The results may be interpreted on one hand that the small bulkiness of the methoxyl group favors the *ap* form but on the other it is possible to assume that the $CH_3\cdots O$ hydrogen bond favors the *ap* form especially because all other substituents give small *sc*/*ap* values of 0.3—0.4. This large jump in populations might imply an attractive force in the *ap* form of the 1-methoxy compound.

In order to get further insight into the nature of the abnormal population ratios of these compounds, we have investigated the substituent effects in the population ratios, by introducing a substituent to the para position of the methoxyl group in 9-ethyl-1-methoxytriptycene (**10**) and to the para position (and in one case 3,4-positions) of the phenyl group in 9-(phenoxymethyl)-1,4-dimethyltriptycene (**16**). To the first approximation, it was expected that the lowering of the electron density on the oxygen atom should decrease the stability due to the charge-transfer interactions. The latter compounds behaved as expected, whereas the former did not. The results, however, support the presence of $CH_3\cdots O$ hydrogen bond, as will be discussed in this paper.

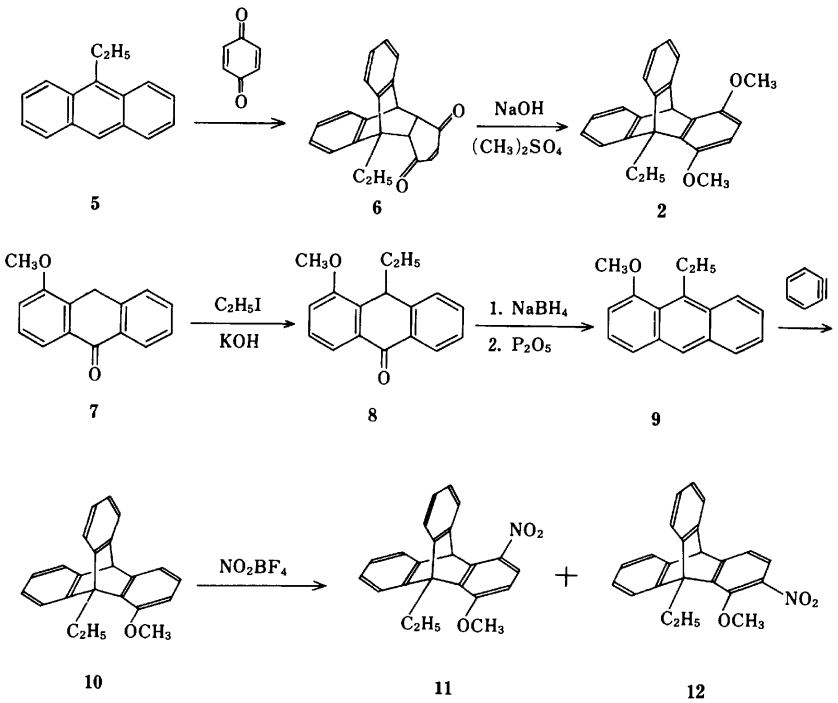
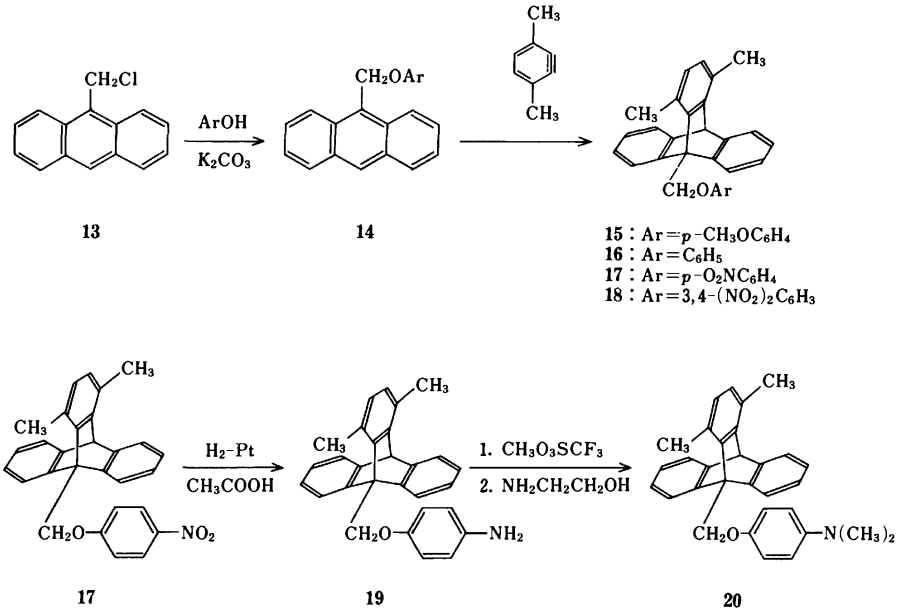
Synthesis and Determination of Populations

The synthetic routes for 4-substituted 9-ethyl-1-methoxytriptycenes and 9-(aryloxymethyl)-1,4-dimethyltriptycenes are shown in Schemes 1 and 2, respectively. 9-Ethyl-1,4-dimethoxytriptycene (**2**) had been prepared by treating 9-ethylanthracene with dimethoxybenzyne generated in situ by treating 2-chloro-1,4-dimethoxybenzene with phenylsodium.[12] However, the present method gave much better results including the yield and the ease of purification of the product. 9-Ethylanthracene (**5**) was heated with *p*-benzoquinone to produce the Diels–Alder adduct **6** which was then alternatively treated with aqueous sodium hydroxide and dimethyl sulfate to afford **2**. 4-Methoxy-9-anthrone (**7**) was ethylated with aqueous potassium hydroxide and ethyl iodide and the product **8** was converted to 9-ethyl-1-methoxyanthracene (**9**) by treatment with sodium tetrahydroborate and then with phosphorus pentaoxide. Treatment of the anthracene with benzyne generated from anthranilic acid afforded 9-ethyl-1-methoxytriptycene (**10**). Nitration of the triptycene (**10**) with nitronium tetrafluoroborate afforded a mixture of 2-nitro (**12**) and 4-nitro (**11**) de-



Scheme 1. Synthetic routes to 4-substituted 9-ethyl-1-methoxytriptycenes.

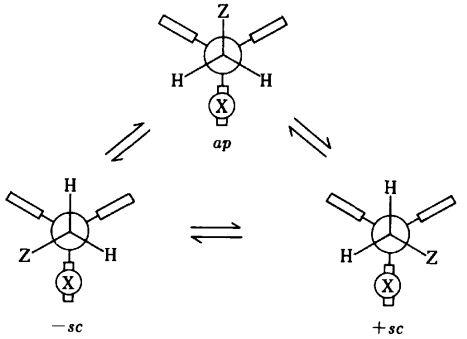


Scheme 2. Synthetic routes to 9-(aryloxymethyl)-1,4-dimethyltriptycenes.

rivatives which could be separated easily by chromatography. The structure of the 4-nitro compound was established by taking advantage of the chemical shift of 9-H in ^1H NMR spectroscopy. Whereas the 4-nitro compound (**11**) exhibits a large low-field shift of the 9-H signal, the 2-nitro compound **12** gives it at a normal range of 9-H signals of triptycenes.

9-(Aryloxymethyl)-1,4-dimethyltriptycenes (**15—18**) were preparad by treating 9-(aryloxymethyl)anthracene (**14**), which was synthesized by treatment of 9-(chloromethyl)anthracene (**13**) with substituted phenols in the presence of potassium carbonate, with 3,6-dimethylbenzyne which was generated from 3,6-dimethylanthranilic acid. 9-(Phenoxymethyl)anthracene had been prepared by treating 9-anthryldiazomethane with phenol,[16] but the present method gives much better results than the reported. 9-[4-(Dimethylamino)phenoxymethyl]-1,4-dimethyltriptycene (**20**) was prepared by reduction of 1,4-dimethyl-9-(4-nitrophenoxymethyl)triptycene (**17**), which was synthesized as above, to afford the amino compound (**19**). The amine (**19**) was then methylated to the corresponding quaternary ammonium salt with methyl triflate and then demethylated with 2-aminoethanol.

Population ratios of the rotational isomers were determined by integration of ^1H NMR spectra at 400 MHz obtained at low temperatures. Assignment of the rotamers was straightforward, because, as is seen in Scheme 3, the *ap* form should exhibit enanthiotopic methylene signal, a singlet, and the $\pm sc$ form diastereotopic, an AB quartet. In practice, however, the separation of the methylene signals was not always perfect to cause errors in integration. In those cases, methyl signals were used for the estimation of populations after completion of assignments by consulting the intensity with the methylene proton signals.



Scheme 3. Rotational circuit of 1,9-disubstituted triptycenes, where the 9-substituent is ZCH_2.

Results and Discussion

4-Substituted 9-Ethyl-1-methoxytriptycenes (2, 10, and 11). The population ratios obtained at ca. −40 °C with these compounds are shown in Table 1 and thermodynamic parameters for the $ap \rightleftarrows \pm sc$ processes in Table 2, where the populations of the $\pm sc$ form were divided by 2 in comparing the *ap* and the *sc* to accommodate the fact that the latter contains two degenerate positions.

The data in Table 1 are rather striking. Clearly the population of the *sc* form increases as the 4-substituent becomes more electron-withdrawing. Namely, the low electron-density on the 1-methoxy-oxygen favors the *sc* form. The changes in enthalpy and entropy were examined to find the possible cause for this phenomenon, but, as are shown in Table 2, rather small *r* values preclude any clear-cut conclusion

Table 1. Populations and Population Ratios of Rotamers of 4-Substituted 9-Ethyl-1-methoxytriptycenes at ca. −40 °C in $CDCl_3$

from the data. At least, however, the results imply that there are no abrupt abnormalities associated with the change in the 4-substituent. We may discuss the results in Table 1 by taking advantage of the factors which affect the populations of rotamers.

It is unlikely that the polarity of a molecule examined here changes according to the rotameric positions taken by the substituent, because the ethyl group is the only one which rotates: The methoxyl group(s) is expected to take a coplanar position with the benzene ring[17] with the methyl group away from the 9- or 10-carbon because of the steric effect. We may neglect that Coulombic interactions comprise a main factor which controls the populations of rotamers, because rotation of the ethyl group does not cause appreciable change in dipole–dipole interactions. Charge-transfer interactions between the methyl and the methoxy-oxygen cannot be the main factor either, because if it were the case, the *sc* form should be favored when the electron density on the methoxyl group is high. Dispersion forces are known to be proportional to polarizability and to ionization potential:[18] Whereas the former increases when the electron density of the methoxy-oxygen is high, the latter decreases under the circumstance. Thus dispersion forces should not play an important role here (vide infra).

Then the important factor seems to be the van der Waals repulsion. As the electron density on the 1-methoxy-oxygen becomes high, the effective bulkiness of the group increases, thus increasing the steric repulsion between the groups concerned. It is concluded that the repulsive forces rather than attractive forces are decisive in this case.

The opposite trend seen in the populations in 4-substituted 9-ethyl-1-methoxytriptycenes to that expected for the charge-transfer interactions between the methyl group of the 9-ethyl and the oxygen atom of the 1-methoxyl group prompted us to investigate another series of compounds. The idea was that the acidity of the methyl group in an ethyl may be too low to show significant interactions with the oxygen atom. Since the pK_a value of ethane is known to be much higher than toluene,[19] changing the methyl group from that in an ethyl to that in a toluene derivative should give better chances to observe the presence of the CH_3...O hydrogen bond. Thus we shifted to 9-(substituted phenoxymethyl)-1,4-dimethyltriptycenes.

9-(Substituted Phenoxymethyl)-1,4-dimethyltriptycenes (15—18 and 20). The data of populations and the thermodynamic parameters for the process $ap \rightleftarrows sc$ are given in Tables 3 and 4, respectively.

The data in Table 3 clearly show that the populations of the *sc* form increase as the electron density on the aryloxy-oxygen increases. The Hammett plot (Fig. 1) gives a fairly good linearity, the *r* factor being 0.983. The ρ value is −0.114, which is very small if we compare the value with normal reactions that take place at the α-position of the aryl group.[21] Close examination of the straight line reveals that the line does not pass the point for the unsubstituted compound and the plots form a concave curve. This together with the small ρ value will mean that the observed populations base on a delicate balance of attraction and repulsion, because if attractive force is enhanced by virtue of the high electron-density, the

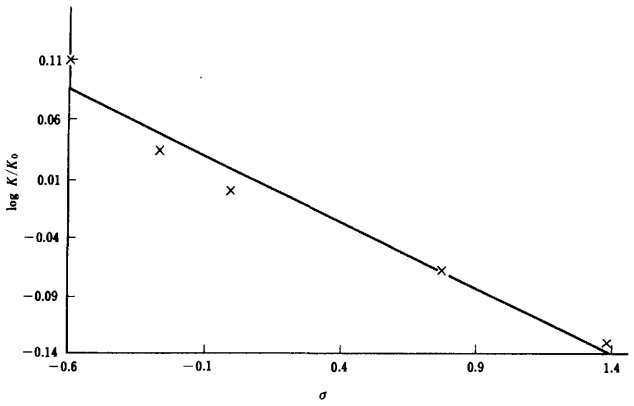

Fig. 1. The Hammett plot for the equilibrium constants of rotamers of 9-(aryloxymethyl)-1,4-dimethyltriptycenes.

same factor simultaneorsly enhances the repulsive forces.

The plot of log K vs. $1/T$ in this case affords better r factors than the case of 4-substituted 9-ethyl-1-methoxytriptycenes and shows the trend that the *sc* forms are more stabilized relative to the *ap* form as the electron-density on the aryloxy-oxygen becomes high. The data are again in conformity with the presence of attractive interactions between the 1-methyl group and the aryloxy-oxygen atom.

The above discussion all favors the presence of charge-transfer type interactions that stabilize the *sc* conformations. However, it may be better to confirm that we can reject possibilities that might favor the same conformation other than charge transfer. Steric repulsion may be excluded from the possibility, because, if it were the case, the *sc* forms in the compounds with an electron-rich oxygen should be disfavored because the high electron-density means the bulky oxygen atom. Coulombic interactions cannot be the main factor which controls the populations, because the only polar part of the molecule is the aryloxy group, that should not give much different electric interactions in different rotameric positions due to the fact that the other parts of the molecules are all hydrocarbons.

High electron density should enhance the polarizability of the oxygen atom and should lower the ionization potential. Since absolute values of these two factors are unknown, it is hard to exclude dispersion forces from the possibility of being a main factor which favors the *sc* conformation. However, since dispersion forces are inversely proportional to the sixth power of the distance concerned, enhanced dispersion forces must be more effective in the *sc* form than the *ap*. This should stabilize the *sc* form even in the 4-substituted 9-ethyl-1-methoxytriptycene series when the electron density of the methoxy-oxygen is high. Since the observed trend is just the opposite to the expectation from the dispersion forces in the said series, we conclude that the dispersion forces cannot be the main factor which controls the populations of the rotamers in the triptycenes. The results imply that, at least in triptycene series, when we compare the population ratios in a series of compounds, the effect of the dispersion forces may be disregarded from the main factor.

From the above results and discussion, we claim that we have observed the presence of CH_3···O hydrogen bond in the series of 9-(substituted phenoxymethyl)-1,4-dimethyltriptycenes. 1,9-Disubstituted triptycenes will continue to be a very convenient system in which we can find very weak molecular interactions that are impossible to find due to severe repulsions in other systems.

Experimental

^{1}H NMR Measurements. ^{1}H NMR spectra were recorded with a Varian EM390 instrument which operated at 90 MHz or with a JEOL GX400 which operated at 400 MHz. The data described in this experimental section are those obtained at 90 MHz at room temperature unless otherwise mentioned.

The assignment of the peaks observed at low temperature were performed by taking advantage of the population ratios and the coalescence phenomena. We assumed that the chemical shift differences for the 4-methoxy or 4-methyl protons should be smaller than those for the 1-methoxy or 1-methyl protons due to the anisotropy effect of the 9-substituent in the *sc* form. Since temperature variation measurements were not done for compounds **18** and **20**, the assignments of the methyl protons in them are tentative especially for the *sc* form.

Determination of Populations of the Rotamers. The ^{1}H NMR spectra at low temperatures were obtained with the use of the 400 MHz NMR machine. The indicated temperatures were calibrated by a thermocouple. The NMR data at low temperatures are summarized in Tables 5 and 6. For the determination of populations, the integrated intensities were obtained by cutting the chart papers and weighing the paper several times. The peaks for the integration were selected so that the best separation of the signals was observed. Signals used for the determination were those due to methyl protons for compounds **15**—**18** and **20** and methylene protons for compounds **2**, **10**, and **11**. The equilibrium data at various temperatures are given in Tables 7 and 8.

9-Ethyl-1,4-dimethoxytriptycene (2). A solution of 0.61 g (3.0 mmol) of 9-ethylanthracene (**5**)[22] and 1.60 g (14.8 mmol) of *p*-benzoquinone in 10 mL of acetonitrile was refluxed for 1 h. After cooling, the adduct **6**, which precipitated, was collected by filtration and washed with ether to remove unreacted *p*-benzoquinone. The residue was dissolved in 20 mL of dioxane and was treated alternatively with a solution of sodium hydroxide (3.00 g) in 30 mL of water and 15 mL of dimethyl sulfate under a nitrogen atmosphere. The reaction mixture was poured into 300 mL of water and the precipitate was collected. The product was purified by recrystallization from dichloromethane–hexane, the yield being 0.71 g (70%). Mp 193.5—195.5 °C (lit,[12] 179—181 °C).

	0.245 (−9.8)		

a) The observed population of the *sc* form was divided by 2 to compensate the degeneracy of the + and −*sc* forms.

Found: C, 84.34; H, 6.18%. Calcd for $C_{24}H_{22}O_2$: C, 84.18; H, 6.48%. ^1H NMR ($CDCl_3$) δ=1.54 (3H, t, J=6.6 Hz), 2.8—3.5 (2H, br), 3.67 (3H, s), 3.76 (3H, s), 5.81 (1H, s), 6.45 (2H, s), 6.8—7.6 (8H, m).

10-Ethyl-4-methoxy-9-anthrone (8). To a solution of 5.00 g (22.3 mmol) of 4-methoxy-9-anthrone (**7**)[23] and 34 g (0.22 mol) of methyl iodide in 130 mL of methanol, was added a solution of 1.34 g (24 mmol) of potassium hydroxide in 30 mL of methanol in 2.5 h. After stirring for 15 h, the mixture was poured into water and extracted with dichloromethane. The extract was dried over magnesium sulfate and the solvent was evaporated. The residue was chromatographed on silica gel (hexane–dichloromethane eluent) to give 0.61 g (11%) of 10-ethoxy-1-methoxyanthracene and then 3.11 g (55%) of 10-ethyl-4-methoxy-9-anthrone (**8**). ^1H NMR ($CDCl_3$) δ=0.40 (3H, t, J=9.0 Hz), 2.0 (2H, m), 3.93 (3H, s), 4.57 (1H, t, J=6.0 Hz), 7.0—8.4 (8H, m). This compound was directly used for the synthesis of 9-ethyl-1-methoxyanthracene (**9**).

The following ^1H NMR data ($CDCl_3$, δ) were recorded for 10-ethoxy-1-methoxyanthracene: 1.59 (3H, t, J=6.0 Hz), 4.03 (3H, s), 4.21 (2H, q, J=6.0 Hz), 6.67 (1H, d, J=6.0 Hz), 7.1—8.4 (6H, m), 8.61 (1H, s).

9-Ethyl-1-methoxyanthracene (9). To a refluxing solution of 2.55 g (10.1 mmol) of 10-ethyl-4-methoxyanthrone (**8**) in 100 mL of ethanol, was added a solution of 3.82 g (101 mmol) of sodium tetrahydroborate in 100 mL of 10% aqueous ethanol in 1 h. After heating for further 1 h, ethanol was removed by distillation and the mixture was poured into water. The mixture was extracted with dichloromethane and the extract was dried over magnesium sulfate. The solvent was evaporated and the residue was taken up in 250 mL of carbon tetrachloride. The solution was refluxed with 50 g of phosphorus pentaoxide for 2 h. After cooling the supernatant liquid was decanted and evaporated to give 2.29 g (96%) of almost pure 9-ethyl-1-methoxyanthracene (**9**). ^1H NMR ($CDCl_3$) δ=1.49 (3H, t, J=7.5Hz), 3.86 (2H, q, J=7.5 Hz), 4.02 (3H, s), 6.75 (1H, d, J=7.8 Hz), 7.2—8.8 (6H, m), 8.26 (1H, s). This compound was directly used for the synthesis of 9-ethyl-1-methoxytriptycene (**10**).

9-Ethyl-1-methoxytriptycene (10). To a boiling solution of 2.29 g (9.7 mmol) of 9-ethyl-1-methoxyanthracene (**9**) in 40 mL of dichloromethane, were added a solution of 2.04 g (15.0 mmol) of anthranilic acid in 40 mL of acetone and 2.60 g (22.2 mmol) of isopentyl nitrite in 40 mL of dichloromethane, from two funnels, in 3 h. After refluxing for further 30 min, the solvent was removed by distillation and the residue was submitted to chromatography on silica gel (hexane–dichloromethane eluent). The pure compound was obtained in 2.37 g (78%) yield after recrystallization from dichloromethane–hexane, mp 185—186 °C. Found: C, 88.30; H, 6.18%. Calcd for $C_{23}H_{20}O$: C, 88.42; H, 6.45%. ^1H NMR ($CDCl_3$) δ=1.54 (3H, t, J=6.3 Hz), 2.9—3.5 (2H, m), 3.66 (3H, s), 5.22 (1H, s), 6.48 (1H, dd, J=2.2, 7.8 Hz), 6.7—7.7 (10H, m).

Nitration of 9-Ethyl-1-methoxytriptycene (10). To a solution of 1.90 g (6.1 mmol) of **10** in 30 mL of acetonitrile, was added 7.33 g (5.5 mmol) of saturated solution (ca. 10%) of nitronium tetrafluoroborate in acetonitrile at −30 °C. The completion of the nitration was checked by TLC, and a few drops of the saturated solution of nitronium tetrafluoroborate were added if unreacted materials were detected. The mixture was poured into 500 mL of water and the precipitate was collected by filtration. After drying, the product was submitted to chromatography on silica gel (hexane–dichloromethane eluent). The desired 4-nitro compound **11** was eluted first, the yield being 0.32 g (15%). After recrystallization from dichloromethane–hexane, the pure sample melted at 260—261 °C. Found: C, 77.25; H, 5.23; N, 3.89%. Calcd for $C_{23}H_{19}NO_3$: C, 77.29; H, 5.36; N, 3.92%. ^1H NMR ($CDCl_3$) δ=1.55 (3H, t, J=5.7 Hz), 3.0—3.6 (2H, br), 3.81 (3H, s), 6.52 (1H, s), 6.54 and 7.62 (2H, ABq, J=10.2 Hz), 6.8—7.2 (8H, m).

The 2-nitro compound **12** was obtained in 0.11 g (5%) yield. Recrystallization from tetrahydrofuran–hexane afforded the pure sample, mp 235—236.5 °C. Found C, 77.38; H, 5.29; N, 3.83%. Calcd for $C_{23}H_{19}NO_3$: C, 77.29; H, 5.36; N, 3.92%. ^1H NMR ($CDCl_3$) δ=1.55 (3H, t, J=6 Hz), 3.30 (2H, q, J=6 Hz), 3.74 (3H, s), 5.33 (1H, s), 6.8—7.7 (10H, m).

9-(Aryloxymethyl)anthracenes (14). The following is a typical procedure for the syntheses of a series of compounds. Phenols were available from commercial sources, except for 3,4-dinitrophenol which was prepared according to the published procedure.[24]

A mixture of 415.7 mg (1.834 mmol) of 9-(chloromethyl)-anthracene (**13**),[25] 228.6 mg (2.429 mmol) of phenol, and 0.37 g (2.7 mmol) of potassium carbonate and 30 mL of acetone were refluxed for 48 h. After cooling, the precipitate was removed by filtration and the filtrate was poured into water. The mixture was extracted with dichloromethane and the extract was washed with aqueous sodium hydroxide. 9-(Phenoxymethyl)anthracene was obtained almost quantitatively.

These compounds were used directly for the syntheses of the corresponding triptycenes.

The following ^1H NMR data ($CDCl_3$, δ) were recorded (only aryl groups given for compounds **14**). Phenyl: 5.97 (2H, s), 6.8—8.5 (13H, m), 8.53 (1H, s). *p*-Methoxyphenyl: 3.77 (3H, s), 5.87 (2H, s), 6.86 and 7.04 (2H, ABq, J=9 Hz), 7.3—8.4 (8H, m), 8.48 (1H, s). *p*-Nitrophenyl: 6.05 (2H, s), 7.1—8.5 (12H, m), 8.54 (1H, s). 3,4-Dinitrophenyl: 6.11 (2H, s), 7.3—8.4 (11H, m), 8.60 (1H, s).

9-(Aryloxymethyl)-1,4-dimethyltriptycenes (15—18). The following is the typical procedure for the syntheses of the triptycenes. The results and analytical data are given in Table 9.

To a refluxing solution of 0.30 g (1.0 mmol) of 9-[(4-methoxyphenoxy)methyl]anthracene in 20 mL of dichloromethane, were added 0.66 g (4.0 mmol) of 3,6-dimethylanthranilic acid[26] in 40 mL of acetone and 1.14 g (9.7 mmol) of isopentyl nitrite in 40 mL of dichloromethane, from separate funnels, in 2 h. The whole was heated for further 30 min and the solvents were removed by distillation. The residue was submitted to chromatography on alumina (hexane–dichloromethane eluent). The product was recrystallized from tetrahydrofuran–hexane.

The following ^1H NMR data ($CDCl_3$, δ) were recorded except for the 3,4-dinitro compound, which was too sparingly soluble (only aryl groups given for compounds **15—17**). Phenyl: 2.57 (3H, s), 2.50 (3H, s), 5.66 (1H, s), 5.2—5.9 (2H, br), 6.64 and 6.72 (2H, ABq, J=7.8 Hz), 6.8—7.8 (12H, m). *p*-Methoxyphenyl: 2.57 (3H, s), 2.50 (3H, s),

Table 9. Yields, Melting Points, and Analytical Data of 9-(Aryloxymethyl)-1,4-dimethyltriptycenes

Compd	Yield	Mp θ_m/°C	Found			Calcd		
			C	H	N	C	H	N
15	60	216—217	86.13	6.16	—	86.09	6.26	—
16	61	176—176.5	89.84	6.15	—	89.65	6.23	—

3.82 (3H, s), 5.63 (1H, s), 5.3—6.0 (2H, br), 6.63 and 6.72 (2H, ABq, J=7.8 Hz), 6.8—7.8 (12H, m). *p*-Nitrophenyl: 2.55 (3H, s), 2.51 (3H, s), 5.89 (1H, s), 5.4—6.1 (2H, br), 6.64 and 6.74 (2H, ABq, J=8.0 Hz), 6.9—7.7 (10H, m), 8.35 (2H, d, J=9.0 Hz).

1,4-Dimethyl-9-[4-(dimethylamino)phenoxymethyl]triptycene (20). A solution of 97.0 mg (0.224 mmol) of 9-(4-nitrophenoxymethyl)-1,4-dimethyltriptycene (**17**) in 20 mL of acetic acid was shaken under a hydrogen atmosphere in the presence of 19.5 mg of platinum oxide for 19 h. The catalyst was removed by filtration and the filtrate was diluted with water. The mixture was neutralized with sodium hydrogencarbonate and extracted with dichloromethane. Evaporation of the solvent gave the almost pure amino compound **19**. ^{1}H NMR ($CDCl_3$) δ=2.55 (3H, s), 2.48 (3H, s), 3.89 (2H, br), 5.60 (1H, s), 5.6 (2H, br), 6.4—7.6 (14H, m).

To a solution of the amine (89 mg or 0.22 mmol) in 15 mL of dichloromethane, was added 73.4 mg (0.447 mmol) of methyl triflate in 5 mL of dichloromethane at room temperature under a nitrogen atmosphere, until the spot due to the starting amine was not detected in TLC. Water was added and the pH of the aqueous layer was adjusted to 7.0. The organic layer afforded a product which was practically insoluble in chloroform. The product was heated with 67 mg of 2-aminoethanol at 200 °C for 5 min and then poured into water. The precipitate was collected and recrystallized from tetrahydrofuran–hexane, mp 242—244 °C. The yield was 0.05 g (50%). Found: C, 86.23; H, 6.80; N, 2.97%. Calcd for $C_{31}H_{29}NO$: C, 86.27; H, 6.77; N, 3.25%. ^{1}H NMR ($CDCl_3$) δ=2.50 (3H, s), 2.57 (3H, s), 2.94 (6H, s), 5.63 (1H, s), 5.3—5.9 (2H, br), 6.63 and 6.72 (2H, ABq, J=8.4 Hz), 6.8—7.8 (12H, m).

The 400 MHz ^{1}H NMR spectra at low temperatures were measured at Institute for Molecular Science. We wish to thank Dr. Shigeru Murata of the Institute for technical assistance in the measurement.

Synthesis and Properties of Chiral Macrobicyclic and Macrotricyclic Cryptands Containing the *trans*-Tetrahydrofuran-2,5-diylbis(methylene) Subunit as the Chiral Center

Koichiro NAEMURA,* Yuji KANDA, Hiroshi IWASAKA, and Hiroaki CHIKAMATSU

(Received October 23, 1986)

The macrobicyclic and macrotricyclic cryptands containing the *trans*-tetrahydrofuran-2,5-diylbis(methylene) molecular framework as the chiral subunit were prepared in optically active forms. The enantiomer recognition property of the macrotricyclic tetracarboxamide (+)-**6** in transport of enantiomeric molecules was examined, and the cation-binding abilities of the macrotricyclic and macrobicyclic amines **7**, **10**, and **13** were also investigated.

Azamacropolycyclic polyethers (cryptands), as well as crown ethers, are of interest in host-guest chemistry. Various kinds of optically active crown ethers have been prepared and their chiral recognition behaviors have been extensively studied.[1] On the other hand, little synthesis of optically active cryptand have been reported, and chiral recognition property of the compound has been scarcely investigated.

Chiral macrotricyclic cryptands yield complexes by using a macrocyclic subunit as anchor site for binding a substrate. With primary ammonium salts, the NH_3^+-group binds directly to the macrocycle, and with alkali salts of organic anions, a cascade process is involved with first binding of the alkali cation followed by electrostatic pairing with the molecular anion. When the substrates are chiral, enantiomer recognition is expected to occur in both cases.[2]

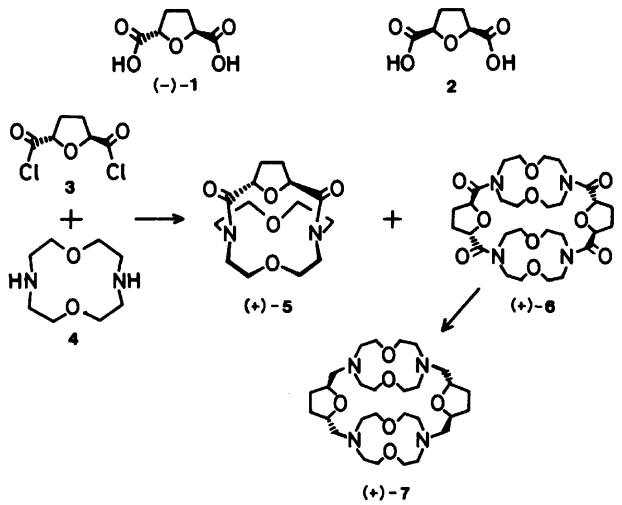
In our preceding papers,[3,4] we have reported the preparations and the enantiomer recognition properties of optically active crown ethers and open-chain polyethers which contained the *trans*-tetrahydrofuran-2,5-diylbis(methylene) subunit as the chiral center. Our continuing interest in chiral crown ethers and analogous compounds prompted us to prepare chiral macrotricyclic cryptand incorporating the *trans*-tetrahydrofuran-2,5-diylbis(methylene) subunit, and we present here our results on the syntheses and some properties of the chiral macrotricyclic and macrobicyclic cryptands.

Results and Discussion

One of our target compounds is the chiral cylindrical macrotricyclic cryptand containing two chiral centers, and Lehn and coworkers[2] have reported the synthesis of the cylindrical macrotricyclic tetracarboxamide by condensation of two molecules of the acid dichloride with two macrocyclic amine molecules.

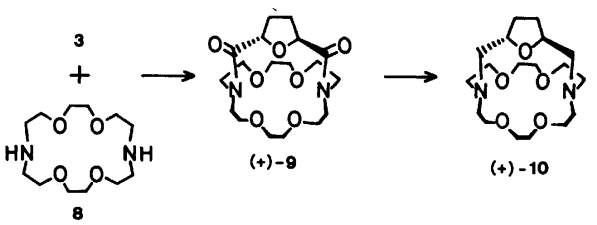
The synthetic strategy was to introduce the chiral centers by condensation of optically active acid dichloride with achiral macrocyclic amine. We previously reported the synthesis and the determination of absolute configuration of enantiomerically pure *trans*-tetrahydrofuran-2,5-dicarboxylic acid (**1**),[3] from which the chiral acid dichloride **3** was prepared. Treatment of (−)-(2*S*,5*S*)-**1**, $[\alpha]_D$ −5.4° (MeOH), with thionyl chloride gave the acid dichloride **3**, which was condensed with 1,7-diaza-12-crown-4 (**4**) in benzene in the presence of triethylamine under high dilution conditions.[5] Chromatography of the resulting mixture on alumina followed by recrystallization from benzene–hexane provided the desired macrotricyclic tetracarboxamide **6**, mp 240 °C (decomp), $[\alpha]_D$ +14.9° ($CHCl_3$), (26% yield) together with the macrobicyclic dicarboxamide **5**, mp 275 °C (decomp), $[\alpha]_D$ +41.0° ($CHCl_3$), (11% yield). The structures of these amides were proved by their mass spectra as well as elemental analyses and ^1H NMR spectra. The predominant formation of the macrotricyclic dimer **6** in condensation of **3** with **4** is rationalized by assuming that *trans*-tetrahydrofuran-2,5-dicarboxylic acid (**1**) contains diglycolic acid moiety.[2]

The reduction of (+)-**6** to the macrotricyclic tetramine **7** was carried out with lithium aluminium hydride in dry tetrahydrofuran (THF), and chromatography of the product on alumina afforded a 51% yield of **7**, $[\alpha]_D$ +32.5° ($CHCl_3$), as a colorless oil.

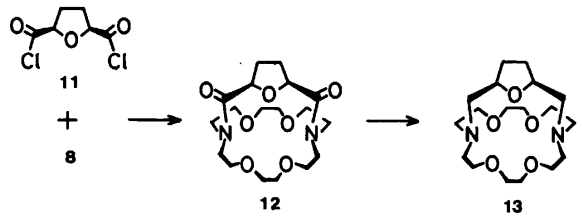


Next, we attempted to prepare the macrotricyclic cryptand, possessing the larger cavities than those of

(+)-**6**, by condensation of two molecules of **3** with two 1,10-diaza-18-crown-6 (**8**) molecules. Condensation of **3** with **8** in benzene was carried out by the same procedure described for the preparation of **6**. The product was chromatographed on alumina to give a 46% yield of the macrobicyclic dicarboxamide **9**, mp 203—205 °C, $[\alpha]_D$ +27.8° ($CHCl_3$), whose structure was also confirmed by the mass spectrum, and the cylindrical macrotricycle corresponding to **6** was not obtained. The dicarboxamide (+)-**9** was converted to the macrobicyclic diamine **10** by diborane reduction.[5] Refluxing of (+)-**9** with a freshly prepared diborane in dry THF gave the borane–amine adduct, which was hydrolyzed with 6M-hydrochloric acid (1 M=1 mol dm^{-3}) to afford the macrobicyclic diamine **10**, mp 190—192 °C, $[\alpha]_D$ +61.7° ($CHCl_3$), in 75% yield after recrystallization from hexane.



Finally, we prepared the macrobicyclic diamine incorporating achiral *cis*-tetrahydrofuran-2,5-diylbis-(methylene) residue. The acid dichloride **11** was obtained from *cis*-tetrahydrofuran-2,5-dicarboxylic acid (**2**) with thionyl chloride. Condensation of **11** with **8** under high dilution conditions followed by alumina column chromatography and recrystallization provided a 32% yield of **12**, mp 173—174 °C, and the cylindrical macrotricycle was not detected. Diborane reduction of **12** followed by hydrolysis with 6M-hydrochloric acid gave the achiral macrobicyclic diamine **13**, mp 208—209 °C, in 22% yield after recrystallization from hexane.



Chiral recognition property of the macrotricyclic tetracarboxamide (+)-**6** in transport of racemic primary ammonium cations; (±)-1,2-diphenylethylamine, (±)-2-aminotetralin and methyl (±)-phenylglycinate hydrochloride was examined and the results are given in Table 1.

The cryptand **6** has a higher enantiomer selectivity towards these guest molecules rather than 18-crown-6 and dibenzo-18-crown-6 derivatives incorporating the *trans*-tetrahydrofuran chiral center.[4] The cylindrical macrotricyclic cryptand (+)-**6** with D_2 symmetry contains two lateral and one central cavities.[6] Each lateral cavity possesses two chiral groups attached to nitrogen, and a large central cavity defined by the two macrocycles and the two bridges linking them incorporates two chiral subunits in the ring system. Both the lateral and the central cavities may bind NH_3^+-group, but in the complex formed by the binding of the substrate to the central cavity, the bound substrate may interact appreciably with the chiral center and therefore be subject to chiral discrimination.

Next, we studied extraction experiment for testing the chiral discrimination ability of the macrotricyclic amine **7** towards chiral molecular anion. Aqueous solution of potassium (±)-mandelate was extracted with a solution of (+)-**7** in $CDCl_3$. But, ^1H NMR spectrum of the organic layer obtained showed no signal due to the substrate. It appears that the molecular cavity of **7** is too small for inclusion of mandelate anion.

The macrobicyclic diamine **10** and **13** are analogues of cryptand 221[5] and possess the ethano bridge between C20 and C22 of the cryptand 221 molecular framework. We next turned our attention to the comparison of the cation-binding abilities of the macropolycyclic amines **7**, **10**, and **13** with that of

Table 2. Extraction of Alkali Metal Picrates

13	0.85	0.12	1.7	0.60	0.15

cryptand 221. The abilities were assessed by solvent extraction of aqueous solution of alkaline metal picrate with a chloroform solution containing cryptand. The results are summarized in Table 2.

As can be seen from Table 2, the alteration in the configuration of tetrahydrofuran moiety scarcely results in the variation in the cation-binding abilities of cryptands **10** and **13**. The striking difference between the cryptands **10** and **13** and the parent cryptand 221 is seen in their extractabilities for Cs^+ ion among alkali metal ions. The differences in extractabilities of three cryptands for the other alkali metal cations cannot be regarded as significant.

We also examined cation transport properties of **10** and **13** by using a chloroform liquid membrane system, and Table 3 lists the results.

Although potassium ion transport was most rapid in both cases, cryptands **10** and **13** hardly mediated transport of guest cations.

Experimental

Infrared spectral data were taken on a Hitachi 260-10 spectrophotometer, and ^{1}H NMR spectra were obtained from a JNM-MH-100 and a JNM-C-60. Chemical shifts are reported in parts per million (δ) down field from tetramethylsilane. Optical rotations were measured with a JASCO DIP-140 automatic polarimeter. Electronic spectral data were measured with a Hitachi 220A spectrophotometer and circular dichroism data were collected with a JASCO J-40 spectropolarimeter. Mass spectra were taken with a Hitachi RMS-4 spectrometer. Elemental analyses were determined on a Yanagimoto CHN-Corder, Type II. All melting and boiling points are uncorrected.

(2*S*,5*S*)-Tetrahydrofuran-2,5-dicarbonyl Dichloride (3). A mixture of (−)-(2*S*,5*S*)-tetrahydrofuran-2,5-dicarboxylic acid (**1**), $[\alpha]_D$ −5.4° (MeOH),[3] (1.50 g, 8.43 mmol) and thionyl chloride (10.5 g, 88.1 mmol) was stirred for 48 h at room temperature. The excess of thionyl chloride was evaporated under reduced pressure to give 1.60 g of **3**, which was used for the next reaction without further purification.

(+)-(3*S*,6*S*)-3,6-Epoxy-11,16-dioxa-1,8-diazabicyclo[6.5.5]-octadecane-2,7-dione (5) and (+)-(3*S*,6*S*,16*S*,19*S*)-3,6:16,19-Diepoxy-11,24,29,34-tetraoxa-1,8,10,21-tetraazatricyclo[20.5.5.5^{8,14}]-hexatriacontane-2,7,15,20-tetrone (6). The acid dichloride (**3**) (1.97 g, 10.0 mmol) and a mixture of 1,7-diaza-12-crown-4 (**4**)[5] (1.65 g, 9.48 mmol) and triethylamine (2.69 g, 26.6 mmol), each dissolved in 200 mL of dry benzene, were dripped over a period of 10.5 h from separate addition funnels into 400 mL of rapidly stirred dry benzene at room temperature. After the mixture was stirred for an additional 30 min, a precipitate was filtered off and the benzene was evaporated in vacuo. The residue was chromatographed on alumina. Fractions eluted with $CHCl_3$ gave 1.01 g of **5** (11% yield), which was recrystallized from benzene–hexane: mp 275 °C (decomp); $[\alpha]_D^{23}$ +41.0° (*c* 0.666, $CHCl_3$); IR (KBr) 1640, 1120, 1060 cm^{-1}; MS *m/z* 298 (M^+). Fractions eluted with $CHCl_3$–MeOH (95:5 v:v) afforded 2.35 g of **6** (26% yield), which was recrystallized from benzene–hexane: mp 240°C (decomp); $[\alpha]_D^{23}$ +14.9° (*c* 0.603, $CHCl_3$); IR (KBr) 1640, 1140, 1080, 1070 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=2.0—2.3 (8H, m, $-(CH_2)_2-$), 3.0—4.0 (32H, m, $-NCH_2CH_2O-$), 4.93 (4H, br s, CH); MS *m/z* 596 (M^+).

(+)-**5**: Found: C, 56.43; H, 7.34; N, 9.52%. Calcd for $C_{14}H_{22}O_5N_2$: C, 56.36; H, 7.34; N, 9.39%.

(+)-**6**: Found: C, 56.16; H, 7.30; N, 9.35%. Calcd for $C_{28}H_{44}O_{10}N_4$: C, 56.36; H, 7.34; N, 9.39%.

(+)-(3*S*,6*S*,16*S*,19*S*)-3,6:16,19-Diepoxy-11,24,29,34-tetraoxa-1,8,10,21-tetraazatricyclo[20.5.5.5^{8,14}]hexatriacontane (7). A solid $LiAlH_4$ (200 mg, 4.20 mmol) was added by portions to a solution of (+)-**6** (500 mg, 0.900 mmol) in 75 mL of dry THF at room temperature and then the mixture was refluxed for 16 h. To the chilled reaction mixture was slowly added 10% aqueous NaOH solution and a deposited solid was filtered off. The solvent was evaporated in vacuo and the residue was dissolved in 20 mL of $CHCl_3$. The organic solution was washed with water, dried over Na_2SO_4, and concentrated in vacuo. The residue was chromatographed on alumina, and fractions eluted with $CHCl_3$–MeOH (95:5 v:v) gave 230 mg of **7** (51% yield) as a colorless oil: $[\alpha]_D^{23}$ +32.5° (*c* 0.560, $CHCl_3$); ^{1}H NMR ($CDCl_3$) δ=1.4—2.2 (8H, m, $-(CH_2)_2-$), 2.6—2.9 (24H, m, $-NCH_2-$), 3.5 (16H, t, *J*=5 Hz, $-OCH_2-$), 3.9—4.2 (4H, m, CH). Found: C, 61.95; H, 9.50; N, 10.33%. Calcd for $C_{28}H_{52}O_6N_4$: C, 62.19; H, 9.69; N, 10.36%.

(+)-(20*S*,23*S*)-20,23-Epoxy-4,7,13,16-tetraoxa-1,10-diazabicyclo[8.8.6]tetracosane-19,24-dione (9). Condensation of **3** (2.39 g, 1.21 mmol) with 1,10-diaza-18-crown-6 (**8**);[5] (3.10 g, 11.2 mmol) was carried out by the same procedure described for the preparation of **5** and **6**. The product was chromatographed on alumina and fractions eluted with $CHCl_3$ gave 2.48 g of **9** (46% yield), which was recrystallized from benzene–hexane: Mp 203—205 °C; $[\alpha]_D^{22}$ +27.8° (*c* 0.410, $CHCl_3$); IR (KBr) 1660, 1110, 1060 cm^{-1}; MS *m/z* 386 (M^+). Found: C, 55.63; H, 7.89; N, 7.19%. Calcd for $C_{18}H_{30}O_7N_2$: C, 55.94; H, 7.83; N, 7.25%.

(+)-(20*S*,23*S*)-20,23-Epoxy-4,7,13,16-tetraoxa-1,10-diazabicyclo[8.8.6]tetracosane (10). To a solution of (+)-**9** (1.46 g, 3.00 mmol) in dry THF (20 mL) was added a freshly prepared solution of diborane (18 mmol) in 27 mL of dry THF at room temperature, and then the mixture was refluxed for 18 h. After cooling to room temperature, 3 mL of water was added to the mixture and the mixture was stirred for 1 h at room temperature. After the mixture was concentrated in vacuo, 70 mL of $CHCl_3$ was added to the residue and a deposited inorganic solid was filtered off. The solvent was evaporated in vacuo, and 50 mL of ether and 5 mL of 6M-HCl were added to the residue. After the mixture was stirred for 1 h at room temperature, the acidic aqueous layer was separated and the organic layer was extracted with water. The combined aqueous solutions were made alkaline with 25% aqueous NaOH solution and extracted with $CHCl_3$. The extract was dried over Na_2SO_4

and concentrated to give a solid, which was recrystallized from benzene–hexane to afford 785 mg of **10** (57% yield): Mp 190—192 °C; $[\alpha]_D^{23}$ +61.7° (*c* 0.505, $CHCl_3$); ^1H NMR ($CDCl_3$) δ=1.1—2.0 (4H, m, $-(CH_2)_2-$), 2.4—3.0 (12H, m, $-NCH_2-$), 3.1—3.8 (16H, m, $-OCH_2-$), 4.0—4.3 (2H, m, CH). Found: C, 60.15; H, 9.57; N, 7.80%. Calcd for $C_{18}H_{34}O_5N_2$: C, 60.30; H, 9.56; N, 7.82%.

***cis*-Tetrahydrofuran-2,5-dicarbonyl Dichloride (11).** By the same procedure described for the preparation of **3**, *cis*-tetrahydrofuran-2,5-dicarbonyl dichloride (**11**) (3.60 g) was prepared from *cis*-tetrahydrofuran-2,5-dicarboxylic acid (**2**)[7] (3.30 g, 0.0205 mol) and thionyl chloride (21.0 g, 0.176 mol). Without further purification, the product was used in the next reaction.

(20*S*,23*R*)-20,23-Epoxy-4,7,13,16-tetraoxa-1,10-diazabicyco-[8.8.6]tetracosane-19,24-dione (12). In the same manner described for the preparation of **5** and **6**, the acid dichloride **11** (1.20 g, 6.09 mmol) was condensed with 1,10-diaza-18-crown-6 (**8**) (1.55 g, 5.92 mmol), and the product was chromatographed on alumina. Fractions eluted with $CHCl_3$ provided 810 mg, of **12** (32% yield), which was recrystallized from benzene–hexane: Mp 173—174 °C; IR (KBr) 1650, 1120 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.7—2.2 (2H, m, $-(CH_2)_2-$), 2.3—3.2 (6H, m, $-(CH_2)_2-$ and $-NCH_2-$), 3.5—4.4 (20H, m, $-NCH_2-$ and $-OCH_2-$); MS *m/z* 386 (M^+). Found: C, 55.80; H, 7.86; N, 7.11%. Calcd for $C_{18}H_{30}O_7N_2$: C, 55.94; H, 7.83; N, 7.25%.

(20*S*,23*R*)-20,23-Epoxy-4,7,13,16-tetraoxa-1,10-diazabicyclo-[8.8.6]tetracosane (13). Treatment of **12** (650 mg, 1.68 mmol) with a solution of diborane (8.04 mmol) in dry THF followed by hydrolysis with 6M-HCl was carried out by the same procedure described for the preparation of **10**. The same workup described for **10** gave a solid which was recrystallized from hexane to provide 130 mg of **13** (22% yield): Mp 208—209 °C. Found: C, 60.18; H, 9.53; N, 7.80%. Calcd for $C_{18}H_{34}O_5N_2$: C, 60.30; H, 9.56; N, 7.82%.

Enantiomer Differential Transport. Enantiomer differential transport was carried out in a conventional apparatus which consisted of an outer cylindrical glass vessel (24.5 mm inner diameter) and a central glass tube (15.5 mm inner diameter). The 0.005 M $CHCl_3$ solution of the host separated the inner aqueous phase (0.1 M HCl) and the outer aqueous phase (0.08 M HCl) which contained $LiPF_6$ (0.4 M) and the racemic guest (0.04 M). The $CHCl_3$ layer was stirred at a constant speed (60 rpm) at 25±1 °C.

Cation Transport. The same apparatus described above was used. The $CHCl_3$ (5 mL) layer contained the cryptand (2.4×10^{-4} M) and the outer aqueous layer (5 mL) contained the metal picrate (2.4×10^{-4} M). The $CHCl_3$ layer was stirred at 25±1 °C.

Extraction Procedure. The aqueous solution (5 mL) of the metal picrate (2.4×10^{-4} M) and the $CHCl_3$ solution (5 mL) containing the host (2.4×10^{-4} M) were placed in a screw cap glass tube (30 mL) and the tube was shaken for 30 min at room temperature. Extraction of the picrate was followed by monitoring the absorbance at 357 nm of the aqueous phase.

A New Synthesis of Cyclic Ureas, Cyclic Urethanes, and a Quinazolinedione.[1] Selenium-Assisted Carbonylation of Aromatic Amines with Carbon Monoxide

Tohru YOSHIDA, Nobuaki KAMBE, Shinji MURAI, and Noboru SONODA*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 565
(Received November 4, 1986)

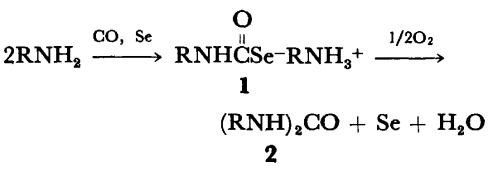
Five-, six-, and seven-membered cyclic ureas were synthesized in excellent yields from various aromatic diamines by reaction with carbon monoxide and a stoichiometric or excess amount of selenium in the presence of *N*-methylpyrrolidine. The carbonylation also proceeded using a catalytic amount of selenium in the presence of an oxidizing agent such as oxygen or dimethyl sulfoxide producing selectively the five- and six-membered cyclic ureas. In the case of 2-(2-aminoethyl)aniline under the catalytic conditions, intra- and intermolecular carbonylation competed resulting in the formation of a mixture of the seven-membered cyclic urea, 1,3,4,5-tetrahydro-2*H*-1,3-benzodiazepin-2-one and the acyclic urea, 1,3-bis[2-(2-aminophenyl)ethyl]-urea. The distribution ratio of these two products varied depending on the reaction conditions, but selective formation of the cyclic urea was attained only when a stoichiometric or excess amount of selenium was used. In addition to the above diamino compounds, 2-carbamoylaniline, 2-amino-3-pyridinol, and 2-(hydroxymethyl)-aniline also underwent similar carbonylation to give 2,4(1*H*,3*H*)-quinazolinedione, oxazolo[4,5-*b*]pyridin-2-(3*H*)-one, and 1,4-dihydro-2*H*-3,1-benzoxazin-2-one, respectively.

Many cyclic urea derivatives have been used as important precursors to pigments,[2] resins,[3] and bioactive compounds.[4] These cyclic ureas can be synthesized by intramolecular amination of in situ formed isocyanates via Hoffman, Curtius, or Lossen rearrangement,[5] or carbonylation of diamines using carbonylating reagents such as phosgene, ethyl chloroformate,[6] 1,1′-carbonyldiimidazole,[6] and 1,1′-[carbonylbis(oxy)]bis-2,5-pyrrolidinedione.[7]

In addition to these stoichiometric reactions, the catalytic *N*-carbonylation of diamines with carbon monoxide is an alternative approach to the synthesis of cyclic urea derivatives.[8] Although a number of studies on catalytic carbonylation of monoamines with carbon monoxide have been reported using a variety of transition metal complexes as the catalysts, these reaction often gave mixtures of urea, formamide, and oxamide.[9–15] The selectivity depends largely on the ligands as well as the metal used.[11] However, there are only two reports of the catalytic carbonylation of diamines: One uses $Mn_2(CO)_{10}$[16a] and the other $Ni(CO)_4$[16b]; selective formation of cyclic ureas has not been achieved using these two reaction systems.

Continuing an ongoing project on selenium-assisted carbonylation, we have established a convenient method for the synthesis of symmetrical ureas using a variety of amines which are reacted with carbon monoxide and oxygen in the presence of a catalytic amount of selenium under mild conditions.[17]

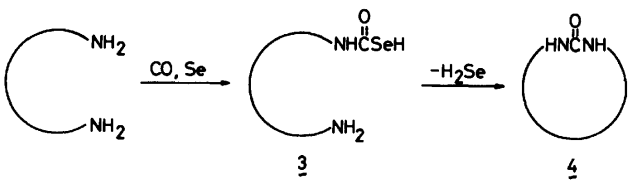
This catalytic reaction has been postulated[17a,b] to proceed via selenolcarbamate ammonium salt **1**[18] which undergoes aminolysis by the nucleophilic attack of a second amine molecule at the carbonyl carbon of **1** to form urea derivatives **2** in the presence of oxygen (Scheme 1). The intermediacy of the



Scheme 1.

selenolcarbamate **1** is strongly supported by the facts that the selenolcarbamate derived from piperidine was isolated[17a] and that the selenolcarbamate from diethylamine was trapped by alkyl halides to give alkyl selenolcarbamates.[17b]

We have expected that application of this reaction system to diamino compounds may provide a simple and convenient method for the synthesis of cyclic ureas **4**. In this paper, we will present full details of a study aimed at the selective formation of cyclic ureas from aromatic diamines by carbonylation with carbon monoxide using selenium (Scheme 2).[1]



Scheme 2.

Results and Discussion

Carbonylation of Aromatic Diamines with Carbon Monoxide Using Stoichiometric Amount of Selenium. We have shown that aliphatic amines react with carbon monoxide at room temperature in the presence of stoichiometric amount of selenium leading to the

selenolcarbamate **1**.[17a,b] Oxidation of **1** with oxygen afforded corresponding ureas in good yields.[17a] Alternatively, aromatic amines such as anilines were less reactive, and the reaction of aromatic amines required a tertiary amine as the base and higher reaction temperature.[17c]

A solution of *o*-phenylenediamine (**5**) was allowed to react at 100 °C with 31 kg cm^{-2} of carbon monoxide and a stoichiometric amount of selenium in the presence of *N*-methylpyrrolidine (NMP) in THF. The uptake of carbon monoxide ceased within 20 h. After the reaction was complete, the remaining carbon monoxide was purged and the mixture was stirred for 1 h under air to oxidize the resulting hydrogen selenide (see Scheme 2). The following workup gave an 89% yield of the cyclic urea **17**. Unreacted starting

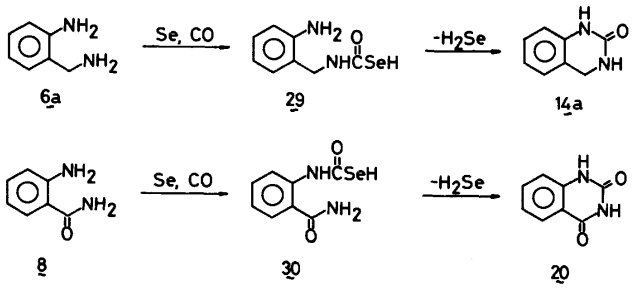
(J) Substrate (2.5 mmol), selenium (0.125 mmol), DMSO (2 mL), carbon monoxide (31 kg cm^{-2}), 100 °C, 20 h. b) See Table 2.

diamine was recoverd. When the reaction was carried out at 25 °C, only the starting material was recovered. In the absence of NMP, **5** gave **17** in 67% yield under similar conditions. This carbonylation was accelerated by using excess amounts of selenium. For example, when three-fold excess of selenium was used, **17** was obtained in 99% yield. Table 1 summarizes the results obtained when the reaction was carried out at 100 °C with 31 kg cm^{-2} of carbon monoxide and three-fold excess of selenium (conditions A-D in Table 1).

Other aniline derivatives having an aminoalkyl substituent in the ortho position **6a—c** and **7** underwent similar carbonylation to yield the corresponding cyclic ureas **18a—c** and **19** in good yields.

It should be noted that the carbamoyl nitrogen could be carbonylated under similar conditions as demonstrated by the reaction of 2-carbamoylaniline **8** in DMF (Entry 6 in Table 1). In this reaction, unreacted starting material was recovered. In THF, **8** did not react, probably due to the low solubility of **8** in THF.

The present carbonylation reaction is postulated to proceed via a selenolcarbamate intermediate formed by the reaction of the diamines with carbon monoxide and selenium (Scheme 3). The aliphatic amino group is more reactive than the aromatic one and may react faster with carbon monoxide in the presence of selenium, so that 2-(aminomethyl)aniline (**6a**) is preferentially converted to selenolcarbamate **29**.[19] In case of 2-carbamoylaniline **8**, the selenolcarbamate is formed at the site of the aromatic amino group, because of the low reactivity of the carbamoyl



Scheme 3.

nitrogen.

The intermediates **29** and **30** then undergo aminolysis by the intramolecular nucleophilic attack of the remaining NH_2 group to give the corresponding cyclic ureas **14a** and **20**, respectively, together with the formation of hydrogen selenide.

Naphthalene-, pyridine-, and pyrimidinediamines were also examined. The reaction of 1,2-, 2,3-, and 1,8-naphthalenediamine **10—12** under similar conditions gave rise to cyclic ureas **22—24**, respectively in good yields. Pyridine- and pyrimidinediamines **13**, **14**, and **16** which have the tertiary amino moiety in the aromatic ring underwent similar carbonylation even in the absence of NMP to give the corresponding cyclic ureas **25**, **26**, and **28** in good yields. In case of 2-amino-3-pyridinol **15**, the carbonylation reaction also proceeded without NMP to afford the corresponding cyclic urethane **27** in 87% yield.

Selenium-Catalyzed Carbonylation with Carbon Monoxide Using Oxidizing Agents. In addition to

the stoichiometric reaction described above, a similar carbonylation using a catalytic amount of selenium in the presence of an oxidizing agent was developed.[17a,c]

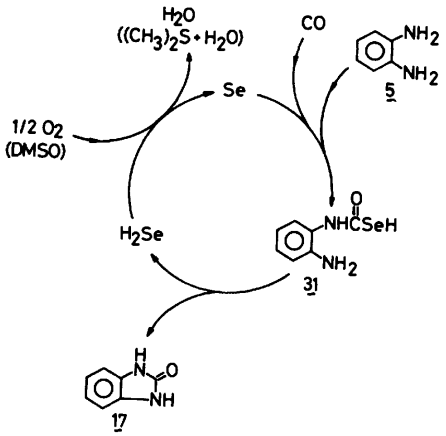
Reaction of *o*-phenylenediamine (**5**) was carried out at 100 °C using 0.05 equiv of selenium with 3 equiv of NMP under a gas mixture of carbon monoxide (29 kg cm^{-2}) and oxygen (2 kg cm^{-2}). After a similar workup as previously mentioned, the cyclic urea **17** was obtained in 99% yield. At room temperature **5** gave **17** in 77% yield.[20]

Other aromatic diamines **10**—**12** underwent intramolecular carbonylation catalytically in a similar manner to afford the corresponding cyclic compounds in good yields (Table 1). As described in the stoichiometric reactions, a tertiary amine was not required in the catalytic carbonylation of **13**—**16**. 2-Carbamoylaniline **8** and 2-amino-3-pyridinol **15** also afforded 2,4(1*H*,3*H*)-quinazolinedione **20** (20%) and **27** (71%).

This selenium-catalyzed carbonylation also proceeded using dimethyl sulfoxide[21] as the oxidizing agent instead of oxygen. Formation of dimethyl sulfide was confirmed by capillary gas chromatography and ^{1}H NMR.

Scheme 4 shows a plausible reaction path for this catalytic carbonylation under these reaction conditions.[22]

The catalytic carbonylation was found to proceed under much milder conditions in comparison with those of stoichiometric reactions.[20] For example, at room temperature under atmospheric pressure of a mixture of carbon monoxide and oxygen, 2-(aminomethyl)aniline **6a** and 2-(hydroxymethyl)aniline **9** were converted to the corresponding cyclic urea **18a** and urethane **21** in good yields, respectively, although the reaction using a stoichiometric amount of selenium in the absence of oxygen at room temperature resulted in the recovery of the starting materials. Under the catalytic conditions at room temperature in the presence of oxygen, 2-(2-aminoethyl)aniline (**7**) gave acyclic urea **33** (95%) together with a trace amount of cyclic urea **19** (<1%). In the stoichiometric reaction **19** was the sole product.



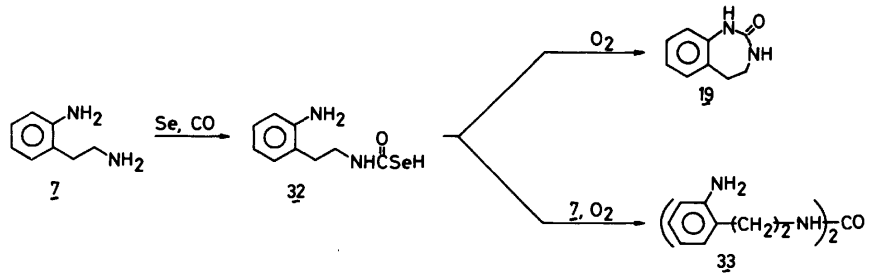
Scheme 4.

Selectivity between Intra- and Intermolecular Reactions of Selenium-Catalyzed Carbonylation of 2-(2-Aminoethyl)aniline (7). As mentioned above, intra- and intermolecular carbonylations competed in case of 2-(2-aminoethyl)aniline (**7**). Then we examined the effects of temperature, concentration, carbon monoxide and oxygen pressure, and amount of selenium used on the selectivity. The representative results were summarized in Table 2.

The cyclic urea **19** was preferentially formed under more dilute conditions (compare Entries 1, 6, and 7) and at higher temperatures (compare Entries 1, 2, and 3). The acyclic urea **33** was obtained selectively when the reaction was carried out at room temperature (Entries 3 and 4). Selective formation of cyclic urea **19** was attained only when a stoichiometric or excess amount of selenium was used (Entry 5).

These results are interpreted as follows. The aliphatic amino group of **7** is more nucleophilic than the aromatic amino group and reacts faster with selenium and carbon monoxide to form selenolcarbamate **32**. Therefore when a stoichiometric or excess amount of selenium is used, all of the aliphatic amino groups are converted rapidly to selenolcarbamate moieties which undergo intramolecular cyclization by the attack of the aromatic amino group.

On the other hand, in the catalytic reaction, there remains most of the starting material possessing the aliphatic amino group which can attack the carbamoyl carbon of **32** intermolecularly to form acyclic urea **33**. Thus, both intra- and intermolecular reactions take place competitively (Scheme 5).



Scheme 5.

NMP (0.79 mL, 7.5 mmol)

Experimental

Apparatus. Melting points were determined on a Yanagimoto HP-S2 and were uncorrected. ^{1}H NMR spectra were recorded on a Hitachi R-24B or a JEOL JNM-PS-100 with Me_4Si as an internal standard. ^{13}C NMR spectra were obtained on a JEOL FX-60s with Me_4Si as an internal standard. Infrared spectra were obtained on a Shimadzu IR-400. Mass spectra were recorded on a Hitachi Model RMU-6E. Gas chromatography were carried out on a Shimadzu GC-8A using a 0.2 mm×25 m fused silica capillary column CBP1-M25-025. Elemental analyses were performed on a Yanagimoto CHN-Corder MT-2.

Materials. THF was freshly distilled from sodium-benzophenone prior to use. DMF and DMSO were distilled from CaH_2. Metallic selenium (99.9%) and carbon monoxide (99.9%) were purchased from Nakarai Chemicals, Ltd. and Seitetsu Chem., Co., respectively. *N*-Methylpyrrolidine (NMP) was distilled from CaH_2. 2-(Aminomethyl)-aniline **6a**[23] and its derivatives **6b** and **6c**, and 2-(2-aminoethyl)aniline **7**[24] were prepared from nitriles following the procedures reported. All other starting materials were purchased from commercial sources and purified by distillation or recrystallization.

Carbonylation of *o*-Substituted Aromatic Diamines with Carbon Monoxide Using a Stoichiometric or Excess Amount of Selenium.

Formation of 2*H*-benzimidazol-2(3*H*)-one 17 as a Typical Experiment. *o*-Phenylenediamine (**5**) (270 mg, 2.5 mmol), selenium (592 mg, 7.5 mmol), NMP (0.79 mL, 7.5 mmol), and THF (10 mL) were placed in a 50 mL stainless-steel autoclave under a nitrogen atmosphere. Carbon monoxide (31 kg cm^{-2}) was introduced to the system, and the reaction vessel was heated to 100 °C with stirring. After 20 h, the apparatus was cooled to room temperature, and the remaining carbon monoxide was evacuated and the resulting mixture was stirred in the air for 1 h to oxidize resulting hydrogen selenide. The reaction mixture was extracted into THF (50 mL) by a Soxhlet extractor and the extract was evaporated in vacuo. The crude solid was recrystallized from THF–hexane to give 331 mg (99%) of **17**: Mp 299—300 °C (lit,[25] mp 300 °C); ^{1}H NMR (DMSO-d_6) δ=10.58 (br s, 2H), 7.02 (s, 4H); IR (KBr) 3025, 1715, 1020, 868, 714 cm^{-1}; MS *m/z* 134 (M$^+$). When a stoichiometric amount of selenium was used, **17** was obtained in 89% (295 mg) yield by a similar procedure.

Reactions under the same conditions and similar workup as described above gave cyclic ureas **18a—c**, **19**, and **21—23**.

3,4-Dihydro-2(1*H*)-quinazolinone (18a): 86%; mp 241—242 °C; ^{1}H NMR (DMDO-d_6) δ=9.08 (br s, 1H), 7.50—6.80 (m, 5H), 4.40 (s, 2H); IR (KBr) 3240, 1720, 1264, 740 cm^{-1}; MS *m/z* 148 (M$^+$). Found: C, 64.60; H, 5.20; N, 18.95. Calcd for $C_8H_8N_2O$: C, 64.85; H, 5.44; N, 18.92.

6-Methoxy-3,4-dihydro-2(1*H*)-quinazolinone (18b): 92%; mp 230—231 °C; ^{1}H NMR (DMSO-d_6) δ=8.81 (br s, 1H), 6.81 (s, 3H) 6.66 (br s, 1H), 4.32 (s, 2H), 3.71 (s, 3H); IR (KBr) 2970, 1660, 1031, 763 cm^{-1}; MS *m/z* 178 (M$^+$). Found: C, 60.28; H, 5.55; N, 15.60. Calcd for $C_9H_{10}N_2O_2$: C, 60.66; H, 5.66; N, 15.72.

6-Chloro-3,4-dihydro-2(1*H*)-quinazolinone (18c): 86%; mp 285—286 °C; ^{1}H NMR (DMSO-d_6) δ=9.38 (br s, 1H), 7.45—6.80 (m, 4H), 4.43 (s, 2H); IR (KBr) 3200, 1678, 1191, 802, 757 cm^{-1}; MS: *m/z* 182 (M$^+$). Found: C, 52.55; H, 3.77; N, 15.40. Calcd for $C_8H_7N_4ClO$: C, 52.62; H, 3.86; N, 15.34.

1,3,4,5-Tetrahydro-2*H*-1,3-benzodiazepin-2-one (19): 81%: mp 170.5—171 °C (lit,[26] mp 169—171 °C); ^{1}H NMR (DMSO-d_6) δ=8.90 (br s, 1H), 7.22—6.55 (m, 5H), 3.21 (m, 2H), 2.85 (m, 2H); IR (KBr) 3225, 1685, 1241, 750 cm^{-1}; MS *m/z* 162 (M$^+$).

2,4(1*H*,3*H*)-Quinazolinedione (20). A similar treatment of 2-carbamoylaniline (**8**) (340 mg, 2.5 mmol) with selenium (593 mg, 7.5 mmol), NMP (0.79 mL, 7.5 mmol) in DMF (10 mL) under a pressure of carbon monoxide (31 kg cm^{-2}), followed by a similar workup as described for the preparation of **17** afforded 85 mg (21%) of **20**: Mp >300 °C; ^{1}H NMR (DMSO-d_6) δ=11.50 (br s, 1H), 11.20 (br s, 1H), 8.07—6.59 (m, 4H); IR (KBr) 3200, 1704, 1141, 758, 683 cm^{-1}; MS *m/z* 162 (M$^+$). **20** showed the spectral data in complete accordance with those of the authentic sample (Aldrich).

1*H*-Naphth[1,2-*d*]imidazol-2(3*H*)-one (22): 98%; mp 347—347.5 °C; ^{1}H NMR (DMSO-d_6) δ=11.55 (br s, 1H), 10.75 (br s, 1H), 7.88—7.45 (m, 6H); IR (KBr) 3020, 1705, 787, 728 cm^{-1}; MS: *m/z* 184 (M$^+$). Found: C, 71.34; H, 4.41; N, 15.04. Calcd for $C_{11}H_8N_2O$: C, 71.73; H, 4.38; N, 15.21.

1*H*-Naphth[2,3-*d*]imidazol-2(3*H*)-one (23): 98%; mp >340 °C; ^{1}H NMR (DMSO-d_6) δ=10.65 (br s, 2H), 7.95—7.00 (m, 4H), 7.29 (s, 2H); IR (KBr) 3012, 1751, 825, 760, 700 cm^{-1}; MS *m/z* 184 (M$^+$). **23** showed the spectral data in complete accordance with the authentic sample.[27]

1*H*-Perimidin-2(3*H*)-one (24): 97%; mp >310 °C. ^{1}H NMR (DMSO-d_6) δ=10.11 (br s, 2H), 7.41—6.98 (m, 4H),

6.64—6.46 (m, 2H); IR (KBr) 3200, 1714, 813, 758 cm^{-1}; MS *m/z* 184 (M^+). **24** showed the spectral data in complete accordance with the authentic sample.[4b]

1*H*-Imidazo[4,5-*b*]pyridin-2(3*H*)-one (25). Treatment of 2,3-pyridinediamine (**13**) (546 mg, 5 mmol) with selenium (1.184 g, 15 mmol), in THF (10 mL) under pressure of carbon monoxide (31 kg cm^{-2}) at 100 °C for 20 h, followed by a similar workup as described for the preparation of **17** gave 660 mg (98%) of **21**: Mp 272—273 °C (lit,[28] mp 270—273 °C); ^1H NMR (DMSO-d_6) δ=10.99 (br s, 1H), 10.49 (br s, 1H), 6.74 (d, *J*=4.0 Hz, 1H), 7.56 (dd, *J*=4.0, 7.0 Hz, 1H), 7.06 (d, *J*=7.0 Hz, 1H); IR (KBr): 3000, 1685, 1459, 1107, 862, 714 cm^{-1}; MS: *m/z* 135(M^+).

1*H*-Imidazo[4,5-*c*]pyridin-2(3*H*)-one (26). Reaction of 3,4-pyridinediamine (14) (546 mg, 5 mmol) under the same conditions followed by a similar workup as described for the preparation of **25**, gave 648 mg (96%) of **26**: Mp 312—313 °C (lit,[29] mp 315 °C); ^1H NMR (DMSO-d_6) δ=11.57—10.09 (br, 2H), 8.33 (s, 1H), 8.32 (d, *J*=7.0 Hz, 1H), 7.20 (d, *J*=7.0 Hz, 1H); IR (KBr) 3000, 1710, 1227, 998, 905, 760, 697 cm^{-1}; MS *m/z* 135 (M^+).

Oxazolo[4,5-*b*]pyridin-2(3*H*)-one (27). 2-Amino-3-pyridinol (**15**) (550 mg, 5 mmol), selenium (1.184 g, 15 mmol), and DMSO (1 mL) was reacted under a pressure of carbon monoxide (31 kg cm^{-2}) at 100 °C for 20 h. The carbon monoxide and resulting dimethyl sulfide was evacuated through aqueous calcium hypochlorite solution. A similar workup as described for the preparation of **17** gave 517 mg (75%) of **27**: Mp 211—212 °C (lit,[29] 211—212 °C) ^1H NMR (DMSO-d_6) δ=10.31 (br s, 1H), 8.08 (d, *J*=5.0 Hz, 1H), 7.62 (d, *J*=7.0 Hz, 1H), 7.12 (dd, *J*=5.0, 7.0 Hz); IR (KBr) 3000, 2700, 1772, 1221, 791, 703 cm^{-1}; MS *m/z* 136 (M^+).

7*H*-Purin-8(9*H*)-one (28). Reaction of 4,5-pyrimidinediamine (**16**) (555 mg, 5 mmol) under the same conditions as described for the preparation of **27**, followed by a similar workup gave 682 mg (87%) of **28**: Mp >330 °C (lit,[30] 305—307 °C); ^1H NMR (DMSO) δ=11.76 (br s, 1H) 10.98 (br s, 1H), 8.54 (s, 1H), 8.04 (s, 1H); IR (KBr): 3050, 1730, 1459, 1107, 989, 714 cm^{-1}; MS *m/z* 136 (M^+). **28** showed the spectral data in complete accordance with the authentic sample.[30]

Carbonylation with Carbon Monoxide Using a Catalytic Amount of Selenium in the Presence of Oxygen. A typical experimental procedure is as follows. In a 50 mL stainless-steel autoclave, were placed *o*-phenylenediamine **5** (270 mg, 2.5 mmol), selenium (10 mg, 0.125 mmol), NMP (0.79 mL, 2.5 mmol), and THF (10 mL) under nitrogen atmosphere. The autoclave was charged with oxygen (2 kg cm^{-2}), and carbon monoxide (29 kg cm^{-2}) to the total pressure of 31 kg cm^{-2}. The reaction mixture was stirred at 100 °C for 20 h, and then cooled to room temperature. After evacuation of the remaining gas, the product was extracted into THF (50 mL) with a Soxhlet extractor. The solvent was evaporated in vacuo, and the residue was recrystallized from THF-hexane to give 328 mg (99%) of **17**.

The reactions of 2-carbamoylaniline (**8**), and 1,2-, 2,3-, 1,8-naphthalenediamine (**9—11**), were performed in a similar manner as exemplified by *o*-phenylenediamine (**5**).

Under similar conditions 1,2- and 3,4-pyridinediamine (**13**) and (**14**) (273 mg, 2.5 mmol) reacted with selenium (10 mg, 0.125 mmol), carbon monoxide (31 kg cm^{-2}), and oxygen (2 kg cm^{-2}) in the absence of NMP and gave **25** (98%, 327 mg) and **26** (96%, 324 mg), respectively. Similar reactions of 2-amino-3-pyridinol (**15**) (275 mg, 2.5 mmol), and 4,5-pyrimidinediamine (**16**) (278 mg, 2.5 mmol) in DMSO (1 mL) gave (**27**) (71%, 261 mg) and **28** (89%, 306 mg), respectively.

Catalytic Carbonylation under Atmospheric Pressure. A typical experimental procedure is as follows. In a three-necked 100 mL flask, were placed 2-(aminomethyl)aniline (**6a**) (305 mg, 2.5 mmol), selenium (10 mg, 0.125 mmol), NMP (0.79 mL, 7.5 mmol), and THF (10 mL) and carbon monoxide (4.5 mL min^{-1}) was bubbled into the reaction mixture at room temperature with stirring. All of metallic selenium reacted and a colorless homogeneous solution was obtained within 1 h. Oxygen (0.3 mL min^{-1}) was bubbled into the mixture, and after 3 h, the feed of carbon monoxide was stopped. The addition of oxygen was increased to 20 mL min^{-1}, and was continued for another 2 h. At this time, all of the selenium used was deposited. The product was extracted into THF (50 mL) with a Soxhlet extractor. The extract was evaporated in vacuo, and the residual solid was recrystallized from THF-hexane to give 315 mg (92%) of **18a**.

1,4-Dihydro-(2*H*)-3,1-benzoxazin-2-one (21). 2-(Hydroxymethyl)aniline(**9**) (307 mg. 2.5 mmol) was reacted under the same conditions as descrived above. A similar workup afforded 316 mg (85%) of **21**: Mp 118.5—119 °C (lit,[31] 118—120 °C); ^1H NMR ($CDCl_3$) δ=9.07 (br s, 1H), 7.67—6.43 (m, 4H), 5.40 (s, 2H); IR (KBr) 2980, 1701, 1446, 730 cm^{-1}; MS *m/z* 149 (M^+).

1,3-Bis[2-(2-aminophenyl)ethyl]urea (33). In a three-necked 50 mL flask, were placed 2-(2-aminoethyl)aniline (**7**) (340 mg, 2.5 mmol) selenium (10 mg, 0.125 mmol), NMP (0.79 mL, 7.5 mmol), and THF (5 mL). Carbon monoxide was bubbled (5 mL min^{-1}) into the reaction mixture at room temperature for 1 h. Oxygen was bubbled at a rate of 0.3 mL min^{-1} through the system for 3 h. The flow of carbon monoxide was then stopped, and the resulting mixture was stirred for another 1 h under oxygen. The selenium was filtered off and the solvent was evaporated in vacuo, and the residue was recrystallized from THF-pentane to afford 365 mg (95%) of **33**: Mp 103—104 °C; ^1H NMR ($CDCl_3$) δ=7.25—6.27 (m, 8H), 4.64 (br s, 2H), 3.39 (br s, 4H), 3.31 (t, *J*=7.6 Hz, 4H), 2.66 (t, *J*=7.6 Hz, 4H); ^{13}C NMR (DMSO-d_6) δ=162.74, 130.37, 127.57, 127.36, 123.38, 116.82, 115.31, 40.55, 40.12; IR (KBr) 3330, 2930, 1630, 1562, 1270, 1043, 752 cm^{-1}; MS *m/z* 298 (M^+). Found: C, 75.92; H, 7.53; N, 10.43. Calcd for $C_{17}H_{24}N_4O$: C, 76.09; H, 7.51; N, 10.44.

Catalytic Carbonylation with Carbon Monoxide Using a Catalytic Amount of Selenium in the Presence of Dimethyl Sulfoxide. In a 50 mL stainless-steel autoclave, were placed *o*-phenylenediamine (**5**) (270 mg, 2.5 mmol), selenium (10 mg, 0.125 mmol), DMSO (250 mg, 3.2 mmol), NMP (0.79 mL, 7.5 mmol), and THF (10 mL). The autoclave was charged with carbon monoxide (31 kg cm^{-2}) and the reaction was carried out at 100 °C for 20 h. The remaining carbon monoxide was purged, and the resulting mixture was analyzed by capillary gas chromatography, and the yield of dimethyl sulfide was found to be 85% (2.1 mmol) using octane as the internal standard. A similar workup gave **17** in 98% yield (328 mg).

In a similar manner, **8, 10, 12, 15,** and **16** were converted to **20, 22, 24, 27,** and **28**, respectively, in 23—98% yields.

This work was supported in part by a Grant-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

18) The intermediate, selenolcarbamic acid **1** may exist as the ammonium salt in the actual reaction mixture (Scheme 1). However, in the following Schemes 2—6, it will be shown in the free state for simplification.

19) In case of the carbonylation of 2-(aminomethyl)-aniline (**6a**), theoretical amount of carbon monoxide was absorbed at room temperature. Unfortunately, an attempt for the trapping of the corresponding selenolcarbamate with butyl iodide under nitrogen failed resulting in the formation of a mixture of cyclic urea **14a** and *N*-alkylated compounds of **14a**.

20) The fact that the intramolecular carbonylation of *o*-phenylendiamine (**5**) proceeded even at room temperature under catalytic conditions indicates that an alternative path may exist in the presence of oxygen. One of the possible paths is the intramolecular aminolysis of the corresponding diselenide which is formed in situ by the oxidation of the selenolcarbamate **31** with oxygen.[17c] An attempt for the isolation of the diselenide failed. In the absence of an oxidizing reagent (i.e., in the stoichiometric reaction), the cyclization via aminolysis of **31** may occur only at elevated temperatures to give **17** and hydrogen selenide (Scheme 4).

21) The use of dimethyl sulfoxide as an oxidizing agent rather than that of oxygen is recommended, because the limit of inflammablility of carbon monoxide in oxygen has large extent ranging from 15.5 to 93.9%. See, R. C. Wheast, "CRC Handbook of Chemistry and Physics," CRC Press, Inc. Boca Raton, Florida (1985), p. D-124.

There were investigated photochemical behaviors of 4-alkylated 1-benzyl-1,4-dihydronicotinamides (**1a—c**) having $R^1R^2C(OH)$ as the substituent (a: R^1=Ph and R^2=H; b: R^1=Ph and R^2=CF_3; c: R^1=*p*-NC-C_6H_4 and R^2=H). The direct photolysis of **1a—c** gave R^1R^2CO and the dimers of the dihydronicotinamide (BNA) fragment along with a minor amount of $[C_6H_5CH(OH)]_2$, being thus interpreted in terms of the homolysis between the $R^1R^2(OH)$ and BNA moieties. In the $[Ru(bpy)_3]^{2+}$-photosensitized reactions, it is suggested that **1a—c**$^{+\cdot}$ was generated as a key intermediate by electron transfer to excited $[Ru(bpy)_3]^{2+}$, undergoing a bond cleavage to give R^1R^2CO and the BNA· dimers. In the case of **1c**, however, $R^1R^2CH(OH)$ was formed, being attributed to a product from **1c**$^{-\cdot}$ that is formed by electron transfer from $[Ru(bpy)_3]^+$ to **1c**.

In previous papers,[2,3] we reported that the photosensitized reactions of 1-benzyl-1,4-dihydronicotinamide (BNAH), a typical NADH model, with either olefins or aromatic carbonyl compounds by $[Ru(bpy)_3]^{2+}$ (bpy=2,2′-bipyridine) yielded 1:1 adducts, new classes of 4-alkylated 1,4-dihydronicotinamides. These findings prompted us to investigate chemical behaviors of these adducts, since chemistry of 4-substituted 1,4-dihydronicotinamides has been of synthetic and biological significance.[4—7] We have found that the adducts with carbonyl compounds **1a—c** reveal interesting behaviors in either the direct photolysis or the photosensitization by $[Ru(bpy)_3]^{2+}$.

Experimental

Materials. The preparation and purification of BNAH[8] and $[Ru(bpy)_3Cl_2]\cdot 6H_2O$[9] were carried out according to the literature methods. The 4-alkylated dihydronicotinamides, **1a—c**, were obtained as 1:1 mixtures of the diastereoisomers by the $[Ru(bpy)_3]^{2+}$-photosensitized reactions of BNAH with benzaldehyde, 1,1,1-trifluoroacetophenone, and *p*-cyanobenzaldehyde as previously reported.[1,3] The diastereoisomers were separated by either repeated column chromatography on basic alumina or HPLC.[1] However, we confirmed that the photochemical behaviors of the isolated diastereoisomers are essentially identical with those of 1:1 mixtures. Therefore, we used 1:1-diastereoisomeric mixtures of **1a—c** in the present investigation. The other materials were obtained from Nakarai Chemicals and used after distillation and/or recrystallization.

Analytical Methods. The formation of **2**, **6c**, and 1,2-diphenyl-1,2-ethanediol was followed by GLC, whereas both the disappearance of **1a—c** and the formation of **3—5** were analyzed by HPLC. GLC was carried out on a Shimadzu GC-7A dual column instrument with flame-ionization detectors, and HPLC analysis were done on a Chemicosorb 7-ODS-H column using a Toyosoda CCPD dual pump coupled with a Yanaco M-315 spectromonitor working at 355 nm. A Hitachi 850 spectrofluorometer was used for luminescence-quenching experiments; deaerated solutions of the ruthenium complex (0.25 mM†) were photoexcited at 550 nm and intensities of the luminescence were monitored at 610 nm. Polarographic measurements were carried out for N_2-saturated water-free methanolic solutions containing **2a—c** (1 mM) and $NaClO_4$ (0.1 M) as the supporting electrolyte using an $Ag/AgNO_3$ reference electrode, a dropping mercury working electrode, and a Yanagimoto P-1100 potentiostat.

Direct Photolysis. A 3 cm^3-methanolic solution containing **1a—c** (50 mM) was bubbled with a gentle stream of Ar for 15 min and then irradiated with a high-pressure mercury lamp using a uranil glass filter (>330 nm) under cooling with water. The progress of the photoreactions was followed by GLC and HPLC.

Photosensitized Reactions by $[Ru(bpy)_3]^{2+}$. A 3 cm^3-methanolic solution containing **1a—c** (50 mM) and $[Ru(bpy)_3]^{2+}$ (1 mM) was bubbled with Ar for 15 min and then irradiated with a tungsten-halogen lamp using a solution filter of potassium chromate (20 g dm^{-3}), sodium nitrate (200 g dm^{-3}), and sodium hydroxide (6.7 g dm^{-3})(>470 nm)[2] under cooling with water. The progress of the reactions was followed by GLC and HPLC.

Results and Discussion

Direct Photolysis. Irradiation of a methanolic solution of **1a—c** (50 mM) at >330 nm mainly gave a carbonyl compound (**2a—c**) and the three isomeric dimers of 1-benzyl-3-carbamoyldihydro-4-pyridinyl radical, i.e. the 4,4′-bonded dimer (**3**), 4,6′-bonded dimer (**4**), and the diastereoisomer of **4** (**5**), as shown in Scheme 1. The dimers were isolated and identified by direct comparison with authentic samples,[10] while the other isomers could not be detected. In the case of **1a**, 1,2-diphenyl-1,2-ethanediol was formed in a 12% yield by GLC. Although the diol formation from **1b,c** can be presumed to occur, GLC and HPLC methods could not be used for the analysis.[11] In any case, moreover, we could not detect the alcohols, $R^1R^2CH(OH)$, nor the positional isomers of **1a—c** by extensive GLC and HPLC analyses. Table 1 summarizes yields of **2—5**.

These observations strongly suggest that the photoexcitation of **1a—c** results in a selective homolytic fission to generate a pair of $R^1R^2\dot{C}(OH)$ and the dihydropyridinyl radical (BNA·). The radical

a) For 3-cm³ methanolic solutions containing **1a**—**c** (0.05 M) irradiated at >330 nm. b) Based on **1a**—**c** consumed. c) 1,2-Diphenyl-1,2-ethanediol was formed in a 12% yield.

pair might diffuse apart out of a solvent cage in competition with the radical coupling regenerating **1a**—**c**. The free BNA· exclusively dimerizes to give **3**, **4**, and **5** in a kinetic controlled ratio. The predominant formation of **3** in the photolysis of **1b** appears to arise from a consequence of a secondary photoreaction, since irradiation of either **4** or **5** leads to the selective isomerization to **3** though the reverse photoisomerization does not occur.[12] On the other hand, the $R^1R^2\dot{C}(OH)$ are perhaps oxidized to **2a**—**c** by impurities and/or by unreclaimed reactions in competition with the dimerization. We attempted to detect other possible products arising from the $R^1R^2\dot{C}(OH)$ fragment, since yields of **2a**—**c** are lower than the combined yields of **3**—**5** in each case. However, we could not detect other definite products than those mentioned here. A possible mechanism is shown in Eqs. 1—6.

$$R^1R^2C(OH)\text{-BNA} \overset{h\nu}{\rightleftharpoons} \overline{R^1R^2\dot{C}(OH)\ \ BNA\cdot} \quad (1)$$

$$\overline{R^1R^2\dot{C}(OH)\ \ BNA\cdot} \longrightarrow R^1R^2\dot{C}(OH) + BNA\cdot \quad (2)$$

$$R^1R^2\dot{C}(OH) \xrightarrow[-H\cdot]{} R^1R^2C{=}O \quad (3)$$

$$2R^1R^2\dot{C}(OH) \longrightarrow R^1R^2C(OH)C(OH)R^1R^2 \quad (4)$$

$$R^1R^2\dot{C}(OH) \longrightarrow \text{Others} \quad (5)$$

$$2BNA\cdot \longrightarrow \mathbf{3} + \mathbf{4} + \mathbf{5} \quad (6)$$

It is of interest to note that the radical pair can be regarded as a mechanistic equivalent to a key intermediate that is involved in an ECE mechanism[13] proposed for the reduction of carbonyl compounds by BNAH in the dark as shown in Eqs. 7 and 8. According to this mechanism, BNA· could donate an electron to $Ph\dot{C}(OH)CF_3$ and *p*-$NCC_6H_4\dot{C}H(OH)$ since the reductions of trifluoroacetophenone and *p*-cyanobenzaldehyde by BNAH do occur in the dark to give the corresponding alcohols. However, the photolysis of either **1b** or **1c** did not afford the corresponding alcohols, thus indicating that BNA· is incapable of undergoing one-electron reduction of $R^1R^2\dot{C}(OH)$.[1,14]

Furthermore, the lack of the BNAH formation in the photolysis of **1a**—**c** suggests that transfer of a hydrogen-atom equivalent from $R^1R^2\dot{C}(OH)$ to BNA·, the reverse pathway of Eq. 7, is very unlikely to occur.

$$R^1R^2C{=}O + BNAH \rightleftharpoons$$

$$\overline{R^1R^2CO^{-}\cdot\ \ BNAH^{+}\cdot} \rightleftharpoons \overline{R^1R^2\dot{C}(OH)\ \ BNA\cdot} \quad (7)$$

$$\overline{R^1R^2\dot{C}(OH)\ \ BNA\cdot} \rightleftharpoons \overline{R^1R^2\bar{C}(OH)\ \ BNA^{+}} \xrightarrow{H^{+}} R^1R^2CH(OH) + BNA^{+} \quad (8)$$

Photosensitization by $[Ru(bpy)_3]^{2+}$. The photosensitized reactions of **1a**—**c** were carried out by the irradiation at >470 nm in order to achieve the selective photoexcitation of $[Ru(bpy)_3]^{2+}$. In the cases of **1a,b**, the results are similar to those of the direct photolysis with some differences in product ratios. The major products are again **2a,b**, and the BNA· dimers without the formation of BNAH and $R^1R^2CH(OH)$, and 1,2-diphenyl-1,2-ethanediol was also formed in a 13% yield in the case of **1a**.[11] Prominently, the photosensitized reaction of **1c** yielded *p*-cyanobenzyl alcohol (**6c**) in a 50% yield along with **2c** and the BNA· dimers, showing a sharp contrast to the lack of the alcohol formation in the direct photolysis. In this case, moreover, it is notable that the combined yield of **3**—**5** is significantly lower than that of **2c** and **6c** though BNAH is not formed, an observation contrary

Table 2. $[Ru(bpy)_3]^{2+}$-Photosensitized Reactions[a]

	1		Time	Convn.	Yield/%[b]				
	R^1	R^2	h	%	2	3	4	5	6

a) For 3-cm³ methanolic solutions containing **1a—c** (0.05 M) and $[Ru(bpy)_3Cl_2]\cdot 6H_2O$ (1 mM) irradiated at >470 nm. b) Based on **1a—c** consumed. c) 1,2-Diphenyl-1,2-ethanediol and hydrogen were detected in 13 and 2% yields respectively.

Table 3. Rate Constants for Quenching of $[Ru(bpy)_3]^{2+}$ Luminescence[a]

Quencher	$k_q\tau/M^{-1}$	k_q[b]$/M^{-1}\,s^{-1}$
1a	57	7.1×10^7
1b	17	2.1×10^7
1c	15	1.9×10^7
BNAH	120	1.5×10^8
DMT[c]	840	1.1×10^9
3	1700	2.1×10^9

a) Obtained from linear Stern-Volmer plots of the luminescence quenching for deaerated methanolic solutions. b) Calculated from the $k_q\tau$ values using $\tau=800$ ns at 20 °C in methanol.[2] c) *N,N*-Dimethyl-*p*-toluidine.

to those of the other cases. The results are summarized in Table 2 and in Scheme 1.

The luminescence of $[Ru(bpy)_3]^{2+}$ was quenched by **1a—c** at rate constants, which are significantly smaller than the quenching rate constant of BNAH and which decrease with increasing inductive effects of R^1 and/or R^2 as shown in Table 3. It is therefore reasonable to assume that electron transfer from **1a—c** to $[Ru(bpy)_3]^{2+}$ in the metal-to-ligand charge-transfer excited state occurs to initiate the photosensitized reactions (Eq. 9). Electron-withdrawing inductive effects of the aromatic rings and the trifluoromethyl group should weaken the electron-donating power of the dihydronicotinamide moiety of **1a—c** compared with BNAH.

$$\mathbf{1a—c} + [Ru(bpy)_3]^{2+} \overset{h\nu}{\rightleftharpoons} \mathbf{1a—c}^{+\cdot} + [Ru(bpy)_3]^{+} \quad (9)$$

The follow-up reaction of $\mathbf{1a—c}^{+\cdot}$ has two choices; one is the bond cleavage to yield **2a—c**, H^+, and BNA· (Eq. 10) and the other involves the formation of $R^1R^2\dot{C}(OH)$ and BNA^+ (Eq. 11). Although there is no unequivocal evidence supporting either or both of the two pathways, comparisons of reduction potentials between **2a—c** and BNA^+ in methanol might imply that Eq. 10 is thermodynamically more favorable than Eq. 11. The polarographic reduction waves of **2a** and **2c** in methanol appear at −1.86 and −1.52 V vs. Ag/Ag^+, respectively, which are more negative than the reduction wave of BNA^+ (−1.445 V).[1,15] Reduction waves of aromatic carbonyl compounds in the presence of a proton donor usually occur as the consequences arising from the formation of $R^1R^2\dot{C}$-(OH) by sequential electron-proton transfer to R^1R^2CO.[16] Therefore electron transfer from $R^1R^2\dot{C}$-(OH) to BNA^+ should be exothermic to yield **2a—c** and BNA· (Eq. 12).

$$\mathbf{1a—c}^{+\cdot} \longrightarrow R^1R^2CO + H^+ + BNA\cdot \quad (10)$$

$$\mathbf{1a—c}^{+\cdot} \longrightarrow R^1R^2\dot{C}(OH) + BNA^+ \quad (11)$$

$$R^1R^2\dot{C}(OH) + BNA^+ \xrightarrow[(\Delta G<0)]{} R^1R^2CO + H^+ + BNA\cdot \quad (12)$$

However, the formation of 1,2-diphenyl-1,2-ethanediol implies the intervention of $Ph\dot{C}H(OH)$. This can be easily interpreted by assuming the occurrence of electron transfer from $[Ru(bpy)_3]^+$ to **2a** (Eq. 13), which has already been discussed previously.[3] This might be a major origin for lower yields of **2a,b** compared with the BNA· dimers, provided that $\mathbf{2a,b}^{-\cdot}$ and $R^1R^2\dot{C}(OH)$ afford unreclaimed products even in part.

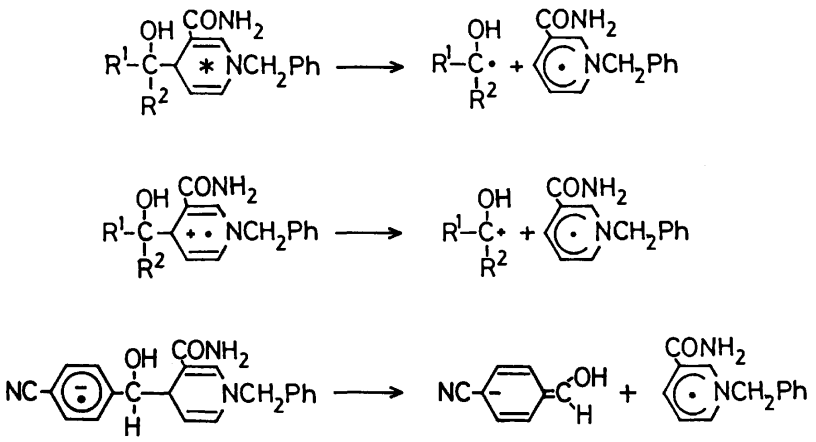
$$[Ru(bpy)_3]^+ + \mathbf{2a—c} \rightleftharpoons [Ru(bpy)_3]^{2+} + \mathbf{2a—c}^{-\cdot} \quad (13)$$

$$\mathbf{2a—c}^{-\cdot} + H^+ \longrightarrow R^1R^2\dot{C}(OH) \quad (14)$$

$$2R^1R^2\dot{C}(OH) \longrightarrow R^1R^2CH(OH)CH(OH)R^1R^2 \quad (15)$$

$$\mathbf{2a—c}\cdot \text{ and } R^1R^2\dot{C}(OH) \longrightarrow \text{Others} \quad (15')$$

The formation of **6c** is of particular interest with regard to the electron-transfer mechanism. In order to obtain further mechanistic insights, we carried out the $[Ru(bpy)_3]^{2+}$-photosensitized reactions of **1a—c** in the presence of BNAH or *N,N*-dimethyl-*p*-toluidine (DMT) in an equimolar amount, a concentration at which excited $[Ru(bpy)_3]^{2+}$ is exclusively quenched by BNAH or DMT (Table 3) via electron transfer (Eq. 16). Interestingly, the photosensitized reaction of **1c** in the presence of either BNAH or DMT selectively gave **6c** at a rate 3.7 or 2 times each more efficient than that in its absence, while **2c** was not formed at all. Furthermore, we could not detect BNAH in the photoreaction with DMT but **3**, **4**, and **5** though yields were not determined. In contrast, the photosensitized



Scheme 2.

reactions of **1a,b** in the presence of BNAH or DMT did not give the corresponding alcohols at all.

$$[Ru(bpy)_3]^{2+} + D \overset{h\nu}{\rightleftharpoons} [Ru(bpy)_3]^{+} + D^{+\cdot} \quad (16)$$
(D=BNAH or DMT)

$$[Ru(bpy)_3]^{+} + \mathbf{1c} \longrightarrow [Ru(bpy)_3]^{2+} + \mathbf{1c}^{-\cdot} \quad (17)$$

$$[Ru(bpy)_3]^{+} + \mathbf{1a,b} \dashrightarrow [Ru(bpy)_3]^{2+} + \mathbf{1a,b}^{-\cdot} \quad (18)$$

$$\mathbf{1c}^{-\cdot} + H^{+} \begin{cases} \longrightarrow p\text{-NC-C}_6\text{H}_4\text{-CH}_2\text{OH} + \text{BNA}\cdot & (19) \\ \dashrightarrow p\text{-NC-C}_6\text{H}_4\text{-}\dot{\text{C}}\text{H(OH)} + \text{BNAH} & (20) \end{cases}$$

On the basis of these observations, the formation of **6c** can be interpreted in terms of Eqs. 16, 17, and 19. A key pathway is the electron transfer from $[Ru(bpy)_3]^{+}$ to **1c**, in which the cyanophenyl group should be essential because of the electron-accepting nature. Since **3** is a much more efficient quencher of excited $[Ru(bpy)_3]^{2+}$ than either **1c** or BNAH (Table 3), it is expected that the BNA· dimers formed can also act as D in Eq. 16, being thus consumed during the photosensitized reaction of **1c**. This would be a reason for the lower yield of the BNA· dimers compared with the combined yield of **2c** and **6c** as shown in Table 2. On the other hand, $[Ru(bpy)_3]^{+}$ appears to be incapable of donating an electron to **1a,b** since the phenyl group has no extra electron-withdrawing substituent. The anion radical ($\mathbf{1c}^{-\cdot}$) thus formed undergoes a bond cleavage to give **6c** and BNA· in the presence of a proton donor. On the other hand, little participation of Eq. 20 can be expected, since both **2c** and BNAH were not formed in the photoreaction in the presence of DMT.

Summary

The present investigation exemplifies chemical bahaviors of photoexcited **1a—c**, the cation radicals, and the anion radical of **1c** as shown in Scheme 2. In the direct photolysis, the photoexcitation should be localized on the BNA moiety since it absorbs the incident light at >330 nm. This leads to the homolysis between the $R^1R^2\dot{C}(OH)$ and BNA moieties, while intramolecular electron transfer from the excited BNA chromophore to the R^1 group does perhaps not occur. Likewise, the positive charge of $\mathbf{1a—c}^{+\cdot}$ should be localized on the BNA chromophore, being apparently the driving force for the bond cleavage between $R^1R^2C(OH)$ and BNA. This is reminescent of the very acidic nature of $BNAH^{+\cdot}$.[17] On the other hand, the negative charge of $\mathbf{1c}^{-\cdot}$ should be localized on the *p*-cyanophenyl group, thus leading to the formation of *p*-cyanobenzyl alcohol. In any case, BNA· is commonly formed.

14) In a previous paper,[3] we reported that the $Ru(bpy)_3^{2+}$-photosensitized reactions of BNAH with **2b** and **2c** give the corresponding alcohols (**6c** and **6d**) as minor products. Although these observations would indicate the occurence of electron transfer from BNA· to $R_1R_2\dot{C}OH$, close analyses of the reactions[1] demonstrate that **6c** is not a primary product but a secondary one, perhaps from the $Ru(bpy)_3^{2+}$-photosensitized reduction of **1c** by BNAH as described in the present paper; see Eqs 16, 17, and 19. Furthermore, it was confirmed that the formation of **6b** is not photochemical but thermally arises from the reduction of **2b** by BNAH in the dark.

15) In polarography, **2b** shows no significant reduction wave in methanol because of the formation of the hemiacetal.[1]

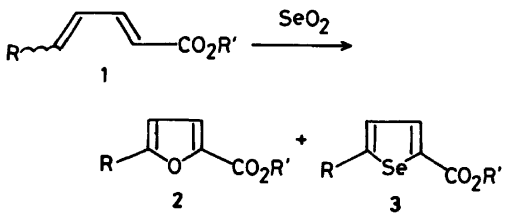
Oxidation of 2,4-Alkadienoic Esters with Selenium Dioxide. A New Synthesis of Furans and Selenophenes

Sadao Tsuboi, Shigetoshi Mimura, Shin-ichiro Ono, Kenji Watanabe, and Akira Takeda*
Department of Synthetic Chemistry, School of Engineering, Okayama University, Tsushima, Okayama 700
(Received November 4, 1986)

Direct oxidation of 2,4-alkadienoic esters with selenium dioxide gave 5-alkyl-2-furancarboxylic esters along with 5-alkyl-2-selenophenecarboxylic esters. Ethyl 5-methylfurancarboxylate was converted to 5-hydroxymethyl-2-furancarbaldehyde, a component of honey, via ethyl 5-bromomethyl-2-furancarboxylate (**5**) in good yield. The compound **5** was converted to (5-ethoxycarbonyl-2-furyl)methyl dimethyldithiocarbamate possessing fungicidal activity. Reaction of triphenylphosphonium salt of **5** with nonanal gave ethyl 5-(1-decenyl)-2-furancarboxylate (E/Z=88:12) in 86% yield. Ethyl 5-methyl-2-selenophenecarboxylate was also converted to ethyl 5-(1-decenyl)-2-selenophenecarboxylate (E/Z=7:3) in 30% total yield.

Selenium dioxide is a conventional and useful reagent for the oxidation of olefins to α,β-unsaturated ketones and allylic alcohols.[1] As our continuing interest in the chemistry of 2,4-alkadienoic esters **1**,[2] we carried out the oxidation of **1** with selenium dioxide.[3] Here we describe a novel synthesis of furans **2** and selenophenes **3** via the oxidation of **1** with selenium dioxide, as summarized below.



Oxidation of α,β-unsaturated carboxylic acids with SeO_2 gave a γ-acetoxy derivative[4] and an α,β-unsaturated γ-butyrolactone derivative.[5] However, oxidation of conjugated dienoic esters with SeO_2 is little known. Only the oxidation of methyl 3-(2,6,6-trimethyl-2-cyclohexenyl)-1-methyl-2-propenylideneacetate with SeO_2 in ethanol to give the corresponding 1- and 4-hydroxy-cyclohexenyl derivatives is reported.[6] Recently we reported a convenient synthesis of (2*E*,4*Z*)-alkadienoic esters.[2a,b] For its application to the syntheses of natural products, we oxidized some 2,4-alkadienoic esters **1** with SeO_2.

Oxidation of commercially available methyl (2*E*,4*E*)-2,4-hexadienoate (sorbate) (**1a**) with SeO_2 gave unexpectedly a mixture of methyl 5-methyl-2-furancarboxylate (**2a**) (56%) and methyl 5-methyl-2-selenophenecarboxylate (**3a**) (29%). Any trace amount of 6-hydroxy- or 6-oxosorbates which were expected to be produced could not be detected. To generalize the present synthesis, various kinds of 2,4-alkadienoic esters were oxidized with SeO_2 and the results are summarized in Table 1. Methyl (2*E*,4*Z*)-hexadienoate (**1b**) was also oxidized with SeO_2, giving an 1:1

Table 1. Oxidation of **1** with SeO_2

a) Geometries of **1a** and **1c** are (2*E*,4*E*), and those of others are (2*E*,4*Z*). b) Unless otherwise indicated, determined by ^1H NMR analysis after removal of polymerized products by short-path distillation or short column chromatography. c) Isolated yield.

mixture of **2a** and **3a** in good yields. Although the oxidation of ethyl (2*E*,4*Z*)-octadienoate (**1d**) with SeO_2 afforded furan **2c** (57%) and selenophene **3c** (29%), the yield in that of alkadienoates bearing a longer chain such as **1g** decreased.

Oxidations of **1a** with SeO_2 under various reaction conditions were conducted to optimize the yields, and the results were tabulated in Tables 2 and 3. Oxidation with 1—2 equiv of SeO_2 gave the best result. Most of the reaction gave the furan **2a** as a major product. However, the reaction in acetic acid afforded an 1:1 mixture of **2a** and **3a**.

Table 2. Oxidation of **1a** with a Various Amount of SeO_2[a]

Run	SeO_2 (equiv)	Yield/%[b] of Product	
		2a	**3a**
1	0.5	3[c]	0
2	1	60	20
3	2	52	30
4	5	13[d]	3[d]

a) Conducted in benzene at the reflux temperature for 6.5 h. b) Calculated by GLC analysis after purification by flash column chromatography. c) Starting material (**1a**) was recovered. d) Resinous materials were produced.

Table 3. Oxidation of **1a** with SeO_2 in Various Solvents[a]

Solvents	Reaction Time/h	Yield/%[b] of Products	
		2a	**3a**
Xylene	2.5	62	15
Toluene	4	56	8
Dioxane	4	50	25
Ethanol	1	66	2.4
Acetic Acid	4	32	32

a) SeO_2 (1.1 equiv) was used. b) Calculated by ^1H NMR analysis of a reaction mixture.

Structural determination was carried out on the basis of IR, NMR, and elemental analysis which were tabulated in Tables 4 and 5. IR spectra of furancarboxylates **2** showed characteristic absorptions at 1520, 1536, and 1600 cm^{-1}. On the other hand, IR spectra of selenophenecarboxylates **3** exhibited signals due to a selenophene ring at 1550, 1616, and 1640 cm^{-1}. Proton NMR spectra of **2a** showed two singlets at δ 2.36 and 3.78 and two doublets (J=3.2 Hz) at δ 6.00 and 6.92. Signals due to ring protons of selenophene **3** appeared at ca. δ 6.8 and 7.7 as two doublets (J= 3.7 Hz). Mass spectrum of **3a** showed characteristic signals of a selenium compound at m/z 204, 202, and 200.

To examine the synthetic utility of the product obtained by the present method, some chemical conversions of **2b** and **3b** were conducted representatively. Many natural products possessing 2,5-disubstituted furan rings have been reported.[7] The present synthesis will be useful for these compounds. For example, **2b** was successfully converted to 5-hydroxymethyl-2-furancarbaldehyde (**4**), a component of honey.[7a] The synthetic sequence are shown in Scheme 1. Furan **2b** was brominated with NBS to give ethyl 5-bromomethyl-2-furancarboxylate (**5**) in 85% yield which was subsequently hydrolyzed with aqueous $AgNO_3$ to ethyl 5-hydroxymethyl-2-furancarboxylate (**6**). After the alcohol **6** was converted to tetrahydropyranyl (THP) ether **7**, reduction of the latter with $LiAlH_4$ followed by oxidation with MnO_2 gave aldehyde **9** in good yield. Deprotection of THP

Table 4. Spectral Data of **2**

Compd	IR/cm^{-1}	^1H NMR (δ, CCl_4)

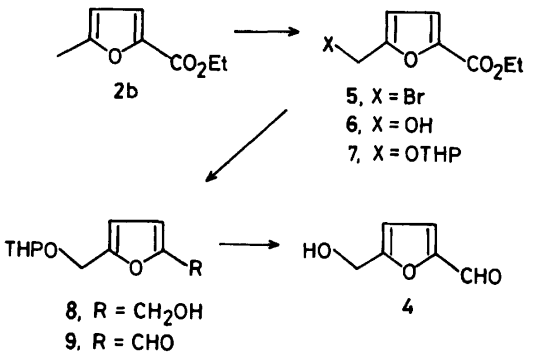
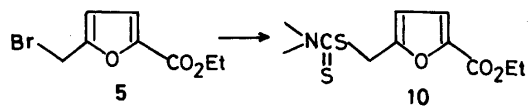
a) Known compound although spectral data are not reported; see Ref. 11.

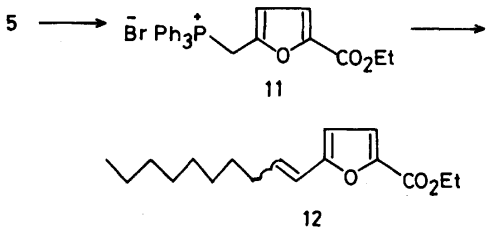


Scheme 1.

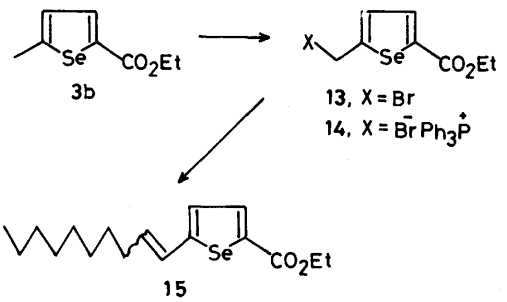
ether **9** with pyridinium *p*-toluenesufonate (PPTS) provided **4**[7a] in 21% yield from **7**. Pianka[8] has reported (5-ethoxycarbonyl-2-furyl)methyl dimethyldithiocarbamate (**10**) showed fungicidal activity. We prepared **10** in 65% yield by the reaction of **5** with sodium dimethyldithiocarbamate.



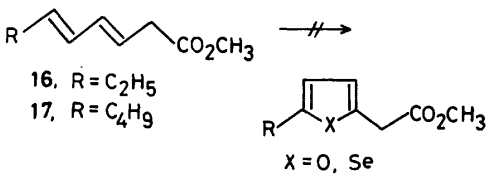
Furthermore, the bromide **5** was treated with triphenylphosphine to afford phosphonium salt **11**. The Wittig reaction of **11** with nonanal in the presence of butyllithium gave ethyl 5-(1-decenyl)-2-furancarboxylate (**12**) in 86% yield with the geometry of E/Z (88:12). Similarly, selenophenecarboxylate **3b** was also brominated with NBS to give bromide **13** in 71% yield. Reaction of **13** with triphenylphosphine



yielded triphenyl phosphonium salt **14**. Reaction of **14** with nonanal in the presence of butyllithium gave ethyl 5-(1-decenyl)-2-selenophenecarboxylate (**15**) in 85% yield with the geometry of E/Z (7:3).

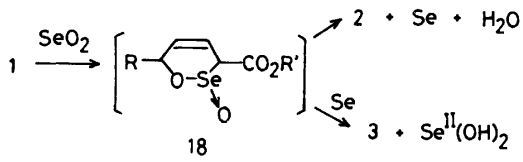


On the other hand, similar treatment of 3,5-alkadienoates such as methyl (3*E*,5*E*)-3,5-octadienoate (**16**) and methyl (3*E*,5*E*)-3,5-decadienoate (**17**) with



SeO_2 resulted in the recovery of the starting material. This fact shows that conjugated system between a diene and an ester group is required for the formation of furan and selenophene rings.

Although the accurate mechanism of the present reaction can not be clarified, the formation of **2** and **3** can be explained by the assumption of an intermediate **18** which is similar to the adduct of butadiene derivatives with SeO_2.[9] Thermal decomposition of **18** will give **2** along with selenium and water, and the reduction of **18** with selenium will give **3** and selenium(II) dihydroxide.



To our knowledge, syntheses of furans via the oxidation of alkadienes are quite few. Parthasarathy and Hort[10] reported the oxidative dehydrogenation of butadiene in the presence of silver ion to yield furan. But their methods required drastic conditions (258 °C[10a], 483 °C[10b]) and special techniques to control the reaction (4 second reaction[10a]). In particular, no reference was found on the use of selenium dioxide for furan synthesis from 2,4-alkadienoates **1**. The present method provides straightforwardly furans and selenophenes under comparatively mild conditions, and the simplicity makes it considerably attractive. Noteworthy is that this procedure for the synthesis of 5-methyl-2-selenophenecarboxylate is simpler than the previously reported one.[11]

Experimental

The melting and boiling points are uncorrected. Infrared (IR) spectra were obtained with a JASCO Model A-102 infrared spectrophotometer. ^1H NMR spectra (60 MHz) were recorded with a JEOL JNM-PMX60SI apparatus. ^1H NMR (100 MHz) and ^{13}C NMR spectra (25 MHz) were obtained with a JEOL JNM-FX100 apparatus using $CDCl_3$ as a solvent. All chemical shifts are reported in δ units downfield from internal Me_4Si, and J values are given in herz. Mass spectra were obtained with an ESCO EMD-05B apparatus. Column chromatography was accomplished using 100—200 mesh Wakogel C-200. Analytical determinations by GLC were performed on a Hitachi Model 163 gas chromatograph fitted with 10% Silicone SE-30 on Chromosorb W column (3 mm o.d.×1 m). Preparative GLC was performed on a Yanagimoto Model G-80 gas chromatogaph fitted with 10% Apiezone Grease L on Chromosorb W column (3 mm o.d.×1 m). High-performance liquid chromatography (HPLC) was obtained with a Yanagimoto liquid chromatograph L-2000.

All solvents and reagents were reagent grade, and solvents were dried according to the literature procedures.[12] Methyl sorbate and ethyl sorbate were distilled prior to use. Methyl (or ethyl) (2*E*,4*Z*)-2,4-alkadienoates (**1b** and **1d—g**) were prepared by the procedure reported previously.[2a,b]

Oxidation of 1 with SeO_2. The reaction was carried out under nitrogen at the reflux temperature of the solvent as shown in Table 1 until the starting material was consumed. The crude product was purified by column chromatography or preparative TLC. Spectral data and elemental analyses of **2**[13-15] and **3** are shown in Tables **4** and **5**. Representative procedures are detailed below.

Methyl 5-Methy-2-furancarboxylate (2a) and Methyl 5-Methyl-2-selenophenecarboxylate (3a). A mixture of **1a** (2 g, 15.9 mmol), SeO_2 (1.94 g, 17.5 mmol), and benzene (1 ml) was heated under reflux for 5 h with stirring. After filtration, the solvent was removed in vacuo. The residual oil was chromatographed on SiO_2 (hexane–ethyl acetate, 20:1) to give 2.18 g of a mixture of **2a**[13] (56% yield) and **3a** (29% yield) as an oil; **2a**/**3a** =57:43 by ^1H NMR analysis. Preparative TLC (SiO_2, hexane–ethyl acetate (4:1)) gave analytical samples, **2a** (R_f=0.52) and **3a** (R_f=0.61). Spectral and analytical data were shown in Tables 4 and 5.

Ethyl 5-Propyl-2-furancarboxylate (2d) and Ethyl 5-Propyl-2-selenophenecarboxylate (3d). A mixture of **1e** (0.10 g, 0.60 mmol), SeO_2 (0.1 g, 0.9 mmol), and xylene (0.5 ml) was heated under reflux for 2 h. The mixture was filtered off, and the solvent was removed in vacuo to give a brown oil. Flash column chromatography [SiO_2, hexane–ethyl acetate (4:1)] gave 85.3 mg of a mixture of **2d** (58%) and **3d** (15%) as an oil; **2d**/**3d**=74/26 by ^1H NMR analysis. Medium pressure liquid chromatography [SiO_2, hexane–ethyl acetate (4:1)] gave pure **2d** and **3d**: TLC analysis (SiO_2, hexane–ethyl acetate=4:1), **2d** (R_f=0.55) and **3d** (R_f=0.60).

Ethyl 5-Pentyl-2-furancarboxylate (2f) and Ethyl 5-Pentyl-2-selenophenecarboxylate (3f). A mixture of **1g** (1.0 g, 5.1 mmol), SeO_2 (0.85 g, 7.6 mmol), and xylene (10 ml) was heated under reflux for 20 h. After being mixed with celite, the mixture was filtered and the filtrate was concentrated in vacuo. The crude products were purified by column chromatography [SiO_2, hexane–ethyl acetate (30:1—0:1)] to give 0.179 g (17%) of **2f** and 43 mg (6.0%) of **3f**. Spectral and analytical data are shown in Tables 4 and 5.

Ethyl 5-Bromomethyl-2-furancarboxylate (5).[16] A mixture of **2b** (1.2 g, 7.8 mmol), NBS (1.52 g, 8.6 mmol), carbon tetrachloride (12 ml), and benzoyl peroxide (50 mg) was heated at the reflux temperature for 2 h. After filtration, the filtrate was concentrated to give 1.9 g of crude **5** which was distilled with a bulb-to-bulb distillation apparatus to afford 1.70 g (94%) of **5**:[16] Bp 120—140 °C (bath temp)/2 Torr (1 Torr=133.322 Pa); IR (neat)1720, 1590, 1535, 1520, 1300, 1221, 1145, 1020, 760 cm^{-}; ^1H NMR data were consistent with those reported.[16]

Ethyl 5-Hydroxymethyl-2-furancarboxylate (6).[17] To a mixture of **5** (0.15 g, 0.65 mmol), acetone (2.5 ml), and water (2.5 ml) was added $AgNO_3$ (0.267 g, 1.7 mmol). The mixture was stirred for 6 h at 22 °C, and then organic materials were extracted with ether. The combined extracts were washed with water, dried over $MgSO_4$ and concentrated. The crude product (111 mg) was purified by preparative TLC [SiO_2, hexane–ethyl acetate (2:1)] to give 33 mg (30%) of **6**:[17] R_f=0.13; IR (neat) 3500, 1730, 1600, 1550, 1540, 1320, 1225, 1160, 1038, 780 cm^{-1}; ^1H NMR (CCl_4) δ=1.35 (t, 3H, $CO_2CH_2C\underline{H}_3$), 3.50 (br s, 1H, OH), 4.25 (q, 2H, J=7 Hz, $CO_2C\underline{H}_2CH_3$), 4.55 (s, 2H, $C\underline{H}_2OH$), 6.30 (d, 1H, J=3.2 Hz,

=CHCH=CCO$_2$Et), 7.00 (d, 1H, J=3.2 Hz, CH=CCO$_2$Et).

Ethyl 5-Hydroxymethyl-2-furancarboxylate THP Ether (7). To a solution of **6** (64 mg, 0.38 mmol) and 3,4-dihydro-2*H*-pyran (34 mg, 0.4 mmol) in 0.2 ml of ether was added a catalytic amount of *p*-toluenesulfonic acid. The mixture was stirred for 90 min at room temperature, and then neutralized with NaHCO$_3$. After the mixture was filtered, washed with ether, and the filtrate was concentrated to give 74 mg (84%) of **7**: IR (neat) 1730, 1600, 1535, 1520, 1300, 1205, 1130, 1020 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.37 (t, 3H, J=7 Hz $CO_2CH_2CH_3$), 1.65 (br s, 6H, $3CH_3$), 3.55 (m, 2H, OCH_2), 4.28 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), 4.53 (d, 2H, J=3.5 Hz, THPOCH$_2$), 4.68 (m, 1H, >CHO), 6.33 (d, 2H, J=3.2 Hz, CHCH=C-CO$_2$Et), 7.00 (d, 2H, J=3.2 Hz, CH=C-CO$_2$Et).

2,5-Bis(hydroxymethyl)furan MonoTHP Ether (8). To a mixture of $LiAlH_4$ (11.4 mg, 0.30 mmol) and dry ether (2 ml) was added at −40 °C a solution of **7** (73 mg, 0.29 mmol) in 0.5 ml of dry ether. The mixture was stirred for 1 h at −40 °C. The mixture was worked up as shown in **6**, giving 52.8 mg (93%) of **8**: IR (neat) 3450, 1560, 1260, 1120, 1020, 800 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.0—2.0 (m, 6H, $3CH_2$), 3.0 (br s, 1H, OH), 3.5 (m, 2H, OCH_2CH_2), 4.38 (s, 2H, OCH_2), 4.45 (s, 2H, OCH_2C=), 4.61 (s, 1H, OCHO), 6.10 (s, 2H, 2CH=).

5-Hydroxymethyl-2-furancarbaldehyde THP Ether (9). To a mixture of activated MnO_2 (226 mg, 2.6 mmol), petroleum ether (2 ml), and diethyl ether (1 ml) was added a solution of **8** (50 mg, 0.26 mmol) in 1 ml of ether at room temperature. The mixture was stirred for 7d at room temperature and the organic materials were extracted with ether. The combined extract was washed with water, dried over $MgSO_4$. Removal of the solvent gave 70 mg of crude **9**: IR (neat) 1680, 1660, 1530, 1260, 1155, 1020, 965, 900, 815 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.6 (br s, 6H, $3CH_2$), 3.55 (m, 2H, CH_2O), 4.56 (d, 2H, J=3.5 Hz, OCH_2C=), 4.65 (m, 1H, OCHO), 6.41 (d, 2H, J=3.2 Hz, =CHCH=C-CHO), 7.10 (d, 2H, J=3.2 Hz, CH=C-CHO), 9.64 (s, 1H, CHO). Crude **9** was used for the next step without further purification.

5-Hydroxymethyl-2-furancarbaldehyde (4).[7a] To a solution of pyridinium *p*-toluenesulfonate[18] (6.6 mg, 0.03 mmol) in ethanol (1 ml) was added 70 mg (0.33 mmol) of crude **9**, and the mixture was stirred for 12 h at 55 °C. After removing the solvent, the residual oil (57 mg) was purified by preparative TLC [SiO_2, hexane-ethyl acetate (2:1)] to give 10 mg (21% yield from **6**) of **4**:[7a] IR (neat) 3440, 1680, 1530, 1195, 1020, 810, 780 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.66 (br s, 1H, OH), 4.77 (s, 2H, CH_2OH), 6.55 (d, 1H, J=3.2 Hz, CHCH=CCHO), 7.25 (d, 1H, J=3.2 Hz), 9.60 (s, 1H, CHO).

(5-Ethoxycarbonyl-2-furyl)methyl Dimethyldithiocarbamate (10).[8] To a solution of sodium dimethyldithiocarbamate (170 mg, 1.2 mmol) in methanol (2 ml) was added **5** (200 mg, 1.08 mol) at 0 °C with stirring. The mixture was stirred for 20 h at room temperature, and then poured into water. The organic materials were extracted with water, and dried over $MgSO_4$. Removal of the solvent gave 250 mg of crude **10**, which was purified by preparative TLC [SiO_2, hexane-ethyl acetate (4:1)] to yield 192 mg (65%) of **10**:[8] R_f=0.23; IR (neat) 1720, 1595, 1520, 1380, 1300, 1150, 1020, 980, 760 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.35 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 3.43 (s, 6H, $N(CH_3)_2$), 4.26 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), 4.58 (s, 2H, SCH_2), 6.39 (d, 1H, J=3.2 Hz, =CHCH=C-CO$_2$Et), 6.96 (d, 1H, J=3.2 Hz, CH=CO$_2$Et).

(5-Ethoxycarbonyl-2-furylmethyl)triphenylphosphonium Bromide (11). A mixture of triphenylphosphine (310 mg, 1.18 mmol), **5** (200 mg, 1.08 mmol), and benzene (2 ml) was stirred for 25 h at room temperature, and then filtered, washed with benzene, and dried in vacuo, giving 370 mg (74%) of **11**: Mp 194.5—195 °C; IR (KBr) 3450, 2900—2800, 1710, 1590, 1530, 1340, 1240, 1140, 760 cm^{-1}.

Ethyl 5-(1-Decenyl-2-furancarboxylate (12). To a solution of **11** (120 mg, 0.242 mmol) in dry THF (2 ml) was added dropwise 1.5 M† *n*-BuLi (0.162 ml, 0.242 mmol) at 0 °C with stirring under an atmosphere of nitrogen. After 30 min, nonanal (35 mg, 0.242 mmol) was added dropwise over 10 min, and the mixture was stirred for 30 min at 0 °C and for 4 h at room temperature. After being poured into ice water, the mixture was neutralized with dil HCl. The organic materials were extracted with ether, and the ethereal layer was washed with water, dried over $MgSO_4$, and concentrated. The residual oil (180 mg) was chromatographed on SiO_2 (hexane–ethyl acetate=40:1—0:1) to give 58 mg (86%) of **12**: IR (neat) 1730, 1650, 1580, 1500, 1380, 1300, 1200, 1010, 960, 760 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.7—1.6 (m, 18H, $CH_3(CH_2)_6$ and $CO_2CH_2CH_3$), 2.20 (m, 2H, CH_2CH=CH), 4.28 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), 6.12 (d, 1H, J=3.2 Hz, CHCH=C-CO$_2$Et), 6.97 (d, 1H, J=3.2 Hz, CH=C-CO$_2$Et). Found: C, 73.43; H, 9.56%. Calcd for $C_{17}H_{26}O_3$: C, 73.35; H, 9.41%. HPLC analysis [column, Unisil Q (10.7 mm o.d.×250 mm); eluent, hexane–ethyl acetate (20:1), 2.0 ml min^{-1}] showed two peaks at R_t17.6 and 20.2 min in an intensity ratio of 12:88. Each component was separated by preparative HPLC. The first fraction gave 5 mg of (*Z*)-**12**: IR (neat) 1730, 1720, 1640, 1502, 1300, 1020, 760 cm^{1}; ^{1}H NMR (CCl_4) δ=0.86 (t, 3H, J=5.5 Hz, CH_3), 1.28 (br s, 14H, $(CH_2)_7$), 1.32 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 2.45 (m, 2H, CH_2CH=CH), 4.22 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), 5.61 (td, 1H, J=6.3 and 11.0 Hz, CH_2CH=CH), 6.12 (d, 1H, J=11.0 Hz, CH=CH-furyl) 6.14 (d, 1H, J=3 Hz, CH=C-CO$_2$Et), 6.98 (d, 1H, J=3 Hz, =CH=C-CO$_2$Et), 6.98 (d, 1H, J=3 Hz, =CH-CH=C-CO$_2$Et). The second fraction gave 35 mg of (*E*)-**12**: IR (neat) 1730, 1720, 1660, 1580, 1505, 1300, 1022, 1110, 968, 770 cm^{-1}; ^{1}H NMR (CCl_4) δ=0.89 (t, 3H, J=5 Hz, CH_3), 1.30 (br s, 14H, $(CH_2)_7$), 1.32 (t, 3H, J=6Hz, $CO_2CH_2CH_3$), 2.15 (m 2H, CH_2CH=CH), 4.22 (q, 2H, J=8 Hz, $CO_2CH_2CH_3$), 6.03 (d, 1H, J=15 Hz, CH=C-CO$_2$Et), 6.42 (dt, 1H, J=5 and 15 Hz, CH_2CH=CH-), 6.08 (d, 1H, J=3 Hz, =CH-CH=C-CO$_2$Et), 6.93 (d, 1H, J=3 Hz, CH=C-CO$_2$Et).

Ethyl 5-Bromomethyl-2-selenophenecarboxylate (13). A mixed solution of **3b** (300 mg, 1.4 mmol), NBS (274 mg, 1.5 mmol), a catalytic amount of benzoyl peroxide and CCl_4 (3 ml) was heated under reflux for 10 h. The mixture was cooled and the precipitates were filtered off. Concentration of the filtrate gave 510 mg of crude products, which were purified by preparative TLC [SiO_2, hexane–ethyl acetate (4:1)] giving 90 mg of **3b** (R_f=0.59) and 290 mg (71%) of **13**: R_f=0.53; IR (neat) 1710, 1550, 1470, 1330, 1220, 1100, 1030, 1000, 750 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.35 (t, 3H, J=7 Hz, $CO_2CH_2CH_3$), 4.27 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$), 4.67 (s, 2H, CH_2Br), 7.18 (d, 1H, J=3.7 Hz, =CHCH=C-CO$_2$Et), 7.74 (d, 1H, J=3.7 Hz, CH=C-CO$_2$Et). Found: C, 32.55; H, 3.18%. Calcd for $C_8H_9BrO_2Se$: C, 32.46; H, 3.06%.

† 1 M=1 mol dm^{-3}.

(5-Ethoxycarbonyl-2-selenophenylmethyl)triphenylphosphonium Bromide (14). A mixture of **13** (200 mg, 0.86 mmol), triphenylphosphine (247 mg, 0.95 mmol), and benzene (2 ml) was heated at the reflux temperature for 20 h. The mixture was cooled and then filtered to afford 230 mg (50%) of **14** as white crystals: Mp 211—213 °C; IR (KBr) 1710, 1695, 1585, 1545, 1460, 1270, 1115, 1080, 745, 725 cm^{-1}.

Ethyl 5-(1-Decenyl)-2-selenophenecarboxylate (15). To a solution of **14** (190 mg, 0.34 mmol) in THF (2 ml), 1.5 M *n*-BuLi in hexane (0.20 ml, 0.34 mmol) was added at 0 °C. After 30 min nonanal (48 mg, 0.34 mmol) was added dropwise over 10 min, and the mixture was stirred for 30 min at 0 °C and for 6 h at room temperature and then worked up as shown in **12**, giving 180 mg of an oil. Preparative TLC [SiO_2, hexane–ethyl acetate(4:1)] gave 98 mg (85%) of **15**: R_f=0.62; E/Z=7:3; IR (neat) 1710, 1530, 1360, 1270, 1080, 945, 740 cm^{-1}; ^1H NMR (CCl_4) δ=0.7—0.8 (m, 18 Hz, $(CH_2)_6CH_3$ and $CO_2CH_2CH_3$), 2.20 (m, 2H, CH_2CH=CH), 4.24 (q, 2H, J=7 Hz, $CO_2CH_2CH_3$); 5.60 (dt, 0.3H, J=10 and 7Hz, CH_2CH=CH), 5.95 (dt, 0.7H, J=7 and 15 Hz, CH_2CH=CH), 6.42 (d, 0.7H, J=15 Hz, CH_2CH=CH), 6.48(d, 0.3H, J=10 Hz, CH_2CH=CH), 6.86 (d, 0.7 H, J=3.5 Hz CHCH=CCO_2Et), 6.98 (d, 0.3H, J=3.5 Hz, CHCH=C-CO_2), 7.68 (d, 0.7 H, J=3.5 Hz, CH=C-CO_2Et), 7.75 (d, 0.3H, J=3.5 Hz, CH=C-CO_2Me). Found: C, 59.61; H, 7.69%. Calcd for $C_{17}H_{26}O_2Se$: C, 59.82; H, 7.68%.

Treatment of Methyl (3*E*, 5*E*)-3,5-Octadienoate (16) with SeO_2. A mixture of **16** (49 mg, 0.32 mmol), SeO_2 (71 mg, 0.64 mmol), and xylene (2 ml) was heated under reflux for 3 h with stirring. After column chromatography [SiO_2, hexane–ethyl acetate(10:1)], the starting material **16** (30 mg) was recovered.

Treatment of Methyl (3*E*,5*E*)-3,5-Decadienoate (17) with SeO_2. A mixture of **17** (84 mg, 0.46 mmol), SeO_2 (102 mg, 0.92 mmol), and benzene (3 ml) was heated under reflux for 12 h with stirring. Column chromatography [SiO_2, hexane–ethyl acetate(10:1)] gave 52mg of the starting material **17**.

We thank Mr. Eiichiro Amano in our laboratory for elemental analyses.

Chemo- and Regioselective Reduction of Epoxides with Sodium Borohydride in Mixed Solvent Containing Methanol

Atsuhiro Ookawa, Hiroshi Hiratsuka, and Kenso Soai*
Department of Applied Chemistry, Faculty of Science, Science University of Tokyo, Shinjuku, Tokyo 162
(Received November 5, 1986)

Mono- and *gem*-disubstituted epoxides were reduced to more substituted alcohols in good to high yields (73—100%) and in high regioselectivities (89—100:11—0) by sodium borohydride in a mixed solvent of *t*-butyl alcohol-methanol or 1,2-dimethoxyethane-methanol. The reaction of disubstituted epoxide depends on the steric hindrance and the position of the substituents. Trisubstituted epoxides were not reduced by the present reducing system. The reactivity order of epoxides by the present reducing system was mono->2,2-di->2,3-di-≫trisubstituted epoxides. The chemoselectivity of the present reducing system is excellent. Thus, epoxides were selectively reduced in the presence of such reducible groups as carbamoyl, carboxyl, nitro, cyano, and bromo.

Epoxides are important synthetic intermediates,[1a] and their transformation reactions have been the subject of increasing interest in recent years.[1b] Among the many types of reactions involving epoxides, the reduction to alcohols by metal hydrides is one of the most fundamental reactions.[1b,2] Several kinds of metal hydrides[3] such as lithium aluminum hydride ($LiAlH_4$), lithium 9,9-dibutyl-9-borabicyclo[3.3.1]-nonane,[3f] lithium triethylhydroborate ($LiBHEt_3$)[4] and aluminum hydride are known to reduce epoxides.[3a-c] However, because of the poor chemoselectivities of most of these reducing agents, a selective reduction of epoxides can not usually be achieved in the presence of such reducible functional groups as carbamoyl, carboxyl, cyano, or halo. Regioselectivity and synthetic yield of lithium borohydride ($LiBH_4$) reduction of epoxides are low to moderate.[5]

Sodium borohydride ($NaBH_4$) is a mild chemoselective reducing reagent for ketones and aldehydes. It is generally accepted, however, that the reduction rate of epoxides with $NaBH_4$ is very slow.[3a-c] Exceptional epoxides, which are reported to be reduced with $NaBH_4$, contain neighboring functional groups which may in some way take part in the reduction.[6] To the best of our knowledge, no systematic study has been reported on the selective reduction of epoxides with $NaBH_4$.

We have studied chemoselective[7,8] and diastereoselective[9,10] reductions using $NaBH_4$ in a mixed solvent containing MeOH as one component, and chemoselective[11] and asymmetric[12] reductions using $LiBH_4$. In this paper, we describe a chemo- and regioselective reduction of epoxides with $NaBH_4$ in a mixed solvent containing MeOH.

Results and Discussion

We examined the effect of a solvent in the reduction of 2-phenyloxirane (**1a**) with $NaBH_4$. The reaction was carried out as follows. To a refluxing mixture of $NaBH_4$, **1a** and solvent, MeOH was added dropwise over a period of 1 h. Then, the reflux was continued for an additional 1 h. As shown in Table 1, the reaction in *t*-BuOH afforded 2-phenylethanol (**2a**) and 1-phenylethanol (**3a**) in 97% total yield with high regioselectivity (**2a**:**3a**=89:11). On the other hand, when a reduction was carried out in each single solvent (MeOH or *t*-BuOH), the yields of alcohols (**2a** and **3a**) dropped considerably to 33% (Table 1, Entries 1 and 2). Thus, the presence of a small amount of MeOH (about 5 molar equivalent to $NaBH_4$) in *t*-

BuOH was apparently effective to increase the chemical yields of **2a** and **3a**. 1,2-Dimethoxyethane (DME) was also a suitable co-solvent with MeOH for the reduction of **1a**. Reactions in such hydrocarbon solvents as benzene and hexane were very sluggish and showed low regioselectivities (Table 1, Entries 6 and 7).[13]

For one molar amount of monosubstituted oxirane, 2.5 molar amounts of $NaBH_4$ was sufficient to perform the reaction (Table 2, Entries 1—3). As to the amount of MeOH, about five molar amounts of MeOH to $NaBH_4$ were suitable for the reduction (Table 2, Entries 5—7). Thus, the optimum molar ratio was as follows: epoxide: $NaBH_4$: MeOH=1:2.5:12. Under the above conditions (in *t*-BuOH, molar ratio 1: $NaBH_4$: MeOH=1:2.5:12), aromatic and aliphatic monosubstituted epoxides (**1a** and **1b**) were reduced to the corresponding alcohols in 96—97% yields (Table 2, Entries 1 and 8). The reduction of 2-methyl-2-phenyloxirane (**1c**) proceeded with high regioselectivity; 2-phenyl-1-propanol (**2c**) was obtained as the sole product in 73% yield (Table 2, Entry 9). The reaction with 2,3-disubstituted oxirane was slower than that with 2,2-disubstituted one. A long reaction time was required for the reduction of cyclohexene oxide (**1d**) (Table 2, Entry 10).

One of the characteristic features of the present reducing system is chemoselectivity. Chemoselective or competitive reductions of **1a** in the presence of other functional groups such as carbamoyl, carboxyl, nitro or cyano are shown in Table 3. **1a** was reduced in good to high yields while other functional groups were not reduced (Table 3, Entries 1—3). The reduction of 2-(4-bromophenyl)oxirane proceeded to

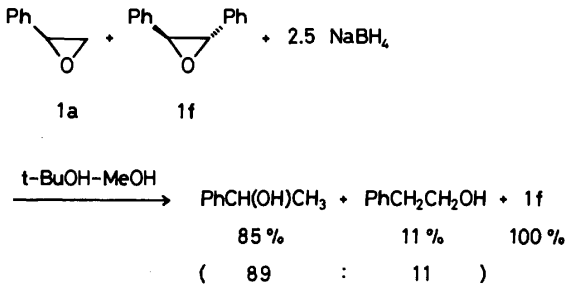
a) Data from Ref. 11. b) Data from Ref. 5.

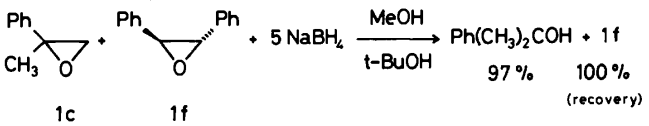
afford 2-(4-bromophenyl)ethanols in 100% yield (Table 3, Entry 4).

Another feature is high regioselectivity. Results are summarized in Table 4. Both aromatic and aliphatic epoxides were reduced with high regioselectivities (89—97:11—3) by $NaBH_4$-*t*-BuOH-MeOH (Table 4, Entries 2, 6, 8, and 10). The regioselectivities of $NaBH_4$ were higher than those of $LiBH_4$ (Entries 3, 4, 7, and 9). The regioselectivity was excellent in the reduction of **1a** with potassium borohydride (KBH_4)-MeOH-*t*-BuOH, although the chemical yield was low. The addition of MeOH caused an increace in the chemical yield and regioselectivity (Entries 1—4).

Though many reports have appeared regarding reductions of epoxide to alcohol, most of them (for example, $LiAlH_4$,[14] $LiBEt_3H$,[15] $LiAlH_4$-$AlCl_3$,[14]) reduce epoxides exceedingly rapidly, regardless of the structure of epoxide. In the competitive reduction of **1a** and *trans*-2,3-diphenyloxirane (**1f**) by a $NaBH_4$-*t*-BuOH-MeOH reducing system, **1a** was selectively reduced to **2a** and **3a** in 96% total yield, while **1f** was in 100% recovered. Thus, the present method can differentiate the structure of epoxides.



Furthermore, a competitive reduction between disubstituted epoxides was also performed. 2-Methyl-2-phenyloxirane (**1c**) was selectively reduced to 2-phenyl-2-propanol in 97% yield, while *trans*-2,3-disubstituted (**1f**) was quantitatively recovered.



Conclusion

The reduction of epoxides with $NaBH_4$ in a mixed solvent containing MeOH is of practical utility. The unique characteristic features of the present reducing system are exemplified by the regioselective and chemoselective reductions of epoxide in the presence of carbamoyl, carboxyl, nitro, cyano, bromo, and methoxyl groups and/or a structure selective reduction of the terminal epoxide in the presence of an internal one. A small amount of MeOH caused an increase in the reducing ability of $NaBH_4$ and the use of $NaBH_4$ in a *t*-BuOH-MeOH mixed solvent enabled the above-mentioned unique selective reduction.

Experimental

Melting and boiling points were uncorrected. IR spectra were recorded with a Hitachi 260-10 spectrophotometer. ^1H NMR spectra (60 MHz) were recorded using either a JEOL JNM-PMX-60 NMR spectrometer or a JEOL-PMX 60 SI NMR spectrometer. GLC analyses were carried out with a Shimadzu Gas Chromatograph (either model GC-4A

or model GC-4C). All of the reactions were run under an argon atmosphere. Organic extracts were dried over anhydrous sodium sulfate.

Materials Methanol and ethanol were stored, respectively, over 3A and 4A molecular sieves. *t*-Butyl alcohol (Kanto), sodium borohyride (Nakarai), potassium borohydride (Nakarai), and lithium borohydride (Wako) were used without further purification. 2-Phenyloxirane, *trans*-2,3-diphenyloxirane, α-methylstyrene and cyclohexene oxide were purchased from Aldrich. 2-Methyl-3-phenyloxirane was prepared by the method of Eliel et al.[14] Bp 49 °C/1.5 mmHg (lit,[14] 62 °C/2.3 mmHg)(1 mmHg=133.322 Pa). 2-(4-bromophenyl)oxirane and 2-(3-methoxyphenyl)-oxirane were prepared from the corresponding phenacyl bromide according to a procedure from the literature.[4] Other epoxides were synthesized by an oxidation of the corresponding olefin with *m*-chloroperbenzoic acid.[16] *trans*-2,3-Diphenyloxirane: Mp 68.2—70.0 °C (lit,[17] 65—67 °C). *cis*-2,3-Diphenyloxirane: Mp 38.2—39.O °C (lit,[18] 37—38 °C). 1-Methylcyclohexene oxide: Bp 58.0—58.4 °C/20 mmHg (lit,[18] 136—137 °C). 2-Methyl-3-phenyl-oxirane: Bp 115 °C/39 mmHg (bath temp). This oxirane was identified by ^{1}H NMR, compared to those of an authentic sample;[19] the ratio of cis/trans was determined by a GLC analysis.

Reduction of 2-Phenyloxirane (1a): To a refluxing mixture of $NaBH_4$ (0.095 g, 2.5 mmol) and **1a** (0.120 g, 1.0 mmol) in *t*-BuOH (4.0 ml), MeOH (0.5 ml) was added over a period of 1 h. After the reflux was continued for an additional 1 h, water and satd. aq. ammonium chloride were added to quench the reaction. Most of the solvent was evaporated under reduced pressure at an ambient temperature, and the residue was extracted with ether. An ethereal extract was dried, evaporated on a rotary evaporator and the residual oil was purified on silica gel TLC (dichloromethane–MeOH (10:1) as a developing solvent). A mixture of 1- and 2-phenylethanol was obtained in 93% yield (0.114 g).

Reduction of 2-Methyl-3-phenyloxirane (1g): Methanol (1.08 ml) was added dropwise to a refluxing mixture of 2-methyl-3-phenyloxirane (0.1465 g, 1.08 mmol), sodium borohydride (0.205 g, 5.42 mmol) and *t*-BuOH (6 ml) over a period of 1.5 h and the reflux was continued for additional 2.5 h. After cooling the mixture to room temperature, water, satd. aq ammonium chloride and ether were added. An organic layer was separated and an aq layer was extracted with dichloromethane. The combined organic layer was dried and evaporated. The residue was purified on silica-gel TLC (chloroform as developing solvent) to afford 1- and 2-phenylpropanols (**2g** and **3g**, 0.053 g, 36%). The recovery of **1g** was 63%. A GLC analysis showed that the ratio of alcohol (**2g**:**3g**) was 68:32. Analytical conditions were as follows; Shimadzu Gas chromatograph GC-4C model, OV-1 50 m capillary column, column temperature 120 °C, retention time, *trans*-**1g** (17.0 min), *cis*-**1g** (15.9 min); SE-30 25 m capillary column, column temp 95 °C, retention time, **2g** (7.1 min), **3g** (7.8 min).

Selective Reduction of 2-Phenyloxirane (1a) in the Presence of Nitrobenzene: Methanol (0.5 ml) was added dropwise to a mixture of **1a** (0.120 g, 1 mmol), nitrobenzene (0.123 g, 1 mmol), sodium borohydride (0.095 g, 2.5 mmol), and *t*-BuOH (4 ml) over a period of 1 h. The mixture was refluxed for an additional 1 h, cooled to room temperature, followed by the addition of water and MeOH. After evaporating most of the MeOH under reduced pressure, the mixture was extracted with dichloromethane. The extract was then dried and evaporated in vacuo. The residue was purified on silica-gel TLC (dichloromethane as developing solvent) to afford 1-phenyl- and 2-phenylethanol (0.111 g, 91% yield) and nitrobenzene (0.102 g, 83% recovery). A GLC analysis showed that the ratio of **2a** and **3a** was 89:11.

Structural Selective Reduction of 2-Phenyloxirane (1a) in the Presence of *trans*-2,3-Diphenyloxirane (1f): To a refluxing mixture of **1a** (0.118 g, 0.98 mmol), **1f** (0.193 g, 0.98 mmol), sodium borohydride (0.093 g, 2.46 mmol) and *t*-BuOH (6 ml), MeOH (0.5 ml) was added dropwise over a period of 1 h and the mixture was refluxed for additional 1 h. After quenching the reaction by the addition of water and satd. aq. ammonium chloride, the mixture was extracted with dichloromethane. The extract was dried and evaporated under reduced pressure. Purification on silica-gel TLC (benzene–chloroform=3:1 as developing solvent) afforded a mixture of **2a** and **3a** (0.115 g, 96% yield). ^{1}H NMR analyses of the mixture showed that the ratio of **2a** to **3a** was 89:11.

The present work was partially supported by a Grant from The Foundation "Hattori-Hokokai."

Photoresponsive Crown Ethers. 19. Photocontrol of Reversible Association-Dissociation Phenomena in "Tail(Ammonium)-Biting" Crown Ethers

Seiji SHINKAI,* Tohru YOSHIDA, Kiminori MIYAZAKI, and Osamu MANABE
Department of Industrial Chemistry, Faculty of Engineering, Nagasaki University, Nagasaki 852
(Received November 7, 1986)

The aggregation properties of photoresponsive crown ethers (**1**) having a crown ring and an ammonioalkyl (H_3N^+-$(CH_2)_n$-, n=4, 6, 10) group attached to the two sides of an azobenzene have been evaluated through the measurements of average molecular weights and electric conductance. Osmometric determination of average molecular weights established that all trans-isomers (*trans*-**1** (n=4, 6, 10)) form the pseudo-cyclic dimers due to intermolecular crown-ammonium complexation. Photoisomerized *cis*-**1** (n=6) and *cis*-**1** (n=10), which have been designed so that intramolecular "biting" of the ammonio group to the crown can occur upon photoisomerization, existed as the discrete monomers. On the other hand, *cis*-**1** (n=4), which cannot form the intramolecular "tail-biting" complex because of the short tetramethylene spacer, existed as the pseudo-cyclic dimer. This difference was well reflected by electric conductance: in **1** (n=6) and **1** (n=10), the conductance increased synchronously with trans-to-cis photoisomerization and decreased with cis-to-trans photoisomerization. Such a photoresponsive conductance change was scarcely detected for **1** (n=4). Furthermore, the additives which enforce dissociation of the dimeric species to the monomeric species suppressed the magnitude of the photoinduced conductance change. This is a novel example that the light energy is transmitted to the conductance change.

The development of photofunctional systems which change their chemical and physical properties in response to photoirradiation is currently a focal interest in the fields of biomimetic chemistry.[1] The photofunctional systems reported so far are related to the photocontrol of ion permeability,[2-6] solution pH,[7,8] membrane potentials,[9-12] polymer conformations,[13-16] binding to host molecules,[17-20] etc. In these intriguing fields, the purpose of our investigation has been to control the functions of a crown ether family by an on-off light switch, which would eventually lead to the photocontrol of ion-extraction and membrane transport.[1] Recently, we reported novel photoresponsive crown ethers (**1**) having a crown ether ring and an ammonioalkyl [-$(CH_2)_nNH_3^+$] group attached to the two sides of an azobenzene.[21] These photoresponsive crown ethers have been designed so that intramolecular "biting" of the crown to the tail(ammonium) group can only occur upon photoisomerization of the azobenzene segments to the cis-configuration (Scheme 1: Ts^-, *p*-toluenesulfonate). We found that this "tail-biting" really occurs in *cis*-**1** (n=6) and *cis*-**1** (n=10) but in *cis*-**1** (n=4) the tetramethylene spacer is too short to allow intramolecular "tail-biting".[21]

Through this study we noticed that *trans*-**1** might not be monomeric but form polymeric aggregates or pseudo-cyclic oligomers due to intermolecular crown$\cdots$ NH_3^+ complexation.[21] This idea arised from the fact that K^+ ion is transported across a liquid membrane against its concentration gradient from a basic aqueous phase to an acidic aqueous phase even in the dark although the transport efficiency is much improved by UV light irradiation.[21] This suggests that K^+ ion is released to the acidic aqueous phase because of the competitive binding with the ammonio group in *trans*-**1**.[22,23] Since the intramolecular crown-NH_3^+ complexation is sterically impossible in *trans*-**1**, this phenomenon can be rationalized only by the intermolecular crown-NH_3^+ complexation. If this is the case, UV light irradiation which mediates trans-to-cis isomerization of the azo segment and thus facilitates intramolecular "tail-biting" should enforce the dissociation of the intermolecular complex to the intramolecular one. To obtain an insight into the photoresponsive change in the aggregation properties of **1**, we assessed the effect of photoirradiation on the electric conductance and the average molecular weight. As a working hypothesis, we considered two possible aggregation modes, polymeric aggregates and pseudo-cyclic (e.g., dimeric) oligomers (Scheme 2). **2** and **3** were used as reference compounds.

Experimental

Materials. Preparations of 4′-[*p*-(4-aminobutoxy)phenylazo]benzo-18-crown-6, 4′-[*p*-(6-aminohexyloxy)phenylazo]-benzo-18-crown-6, and 4′-[*p*-(10-aminodecyloxy)phenylazo]-benzo-18-crown-6 were described previously.[21] Treatment of these amines with an equimolar amount of *p*-toluenesulfonic acid gave *trans*-**1** (n=4), *trans*-**1** (n=6), and *trans*-**1** (n=10), respectively, in quantitative yields.

4-(6-Aminohexyloxy)azobenzene. 4-Hydroxyazobenzene (5.38 g; 27.1 mmol) and *N*-(6-bromohexyl)phthalimide (8.18 g; 26.4 mmol) was heated at 100 °C in 150 ml of dimethyl sulfoxide in the presence of K_2CO_3 (1.92 g; 13.9 mmol). After 11 h, the reaction mixture was poured into excess water. The aqueous solution was extracted with chloroform, the chloroform solution being dried over Na_2SO_4. After filtration, the solution was evaporated in vacuo to dryness. The residue was washed with aqueous NaOH solution to remove unreacted 4-hydroxyazobenzene. Recrystallization of the orange powder from acetonitrile gave *N*-[6-[*p*-(phenylazo)phenoxy]hexyl]phthalimide: Mp 113—114 °C, yield 39%. IR (KBr) ν_{c-o-c} 1260 cm^{-1}; $\nu_{c=o}$ 1700 and 1770 cm^{-1}. Found: C, 73.64; H, 5.83; N, 9.92%. Calcd for $C_{26}H_{25}N_3O_3$: C, 73.05; H, 5.89; N, 9.38%.

Treatment of *N*-[6-[*p*-(phenylazo)phenoxyl]hexyl]phthalimide with hydrazine hydrate in ethanol gave 4-(6-aminohexyloxy)azobenzene. The method was described previously.[21] Mp 108—109 °C, yield 100%. It was very difficult to obtain good elemental analysis data because this compound readily absorbed CO_2 to form the carbonate. A similar behavior was observed previously for the free amines of **1**.[21] Found: C, 70.69; H, 7.66; N, 13.80%. Calcd for $C_{18}H_{23}N_3O \cdot 0.5H_2CO_3$: C, 70.87; H, 7.64; N, 13.65%. Treatment of 4-(6-aminohexyloxy)azobenzene with an equimolar amount of *p*-toluenesulfonic acid gave **2** in quantitative yield.

4′-(*p*-Hexyloxyphenylazo)benzo-18-crown-6 (3). Sodium salt of 4′-(*p*-hydroxyphenylazo)benzo-18-crown-6[21] (0.30 g; 0.66 mmol) and 1-bromohexane (0.88 g; 3.3 mmol) was heated at 100 °C in 50 ml of dimethyl sulfoxide in the presence of K_2CO_3 (0.2 g). The progress of the reaction was monitored by a TLC method (silica gel, chloroform–methanol (10:1 v/v)). After 5 h, the reaction mixture was poured into excess water. The aqueous solution was extracted with chloroform. After evaporating the chloroform solution to dryness, the residue was recrystallized from chloroform–ligroine; mp 115—117 °C, yield 50%. IR (KBr) ν_{c-o-c} 1120 and 1250 cm^{-1}; $\nu_{N=N}$ 1500 cm^{-1}. Found: C, 65.11; H, 7.92; N, 5.09%. Calcd for $C_{28}H_{40}N_2O_7$: C, 65.10; H, 7.80; N, 5.42%.

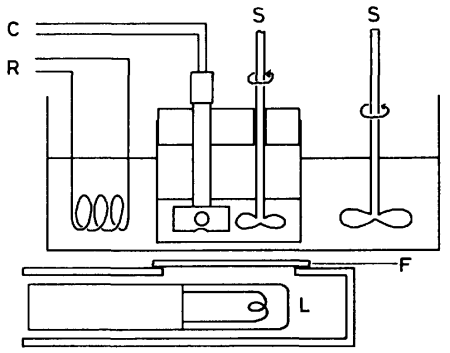

Fig. 1. Apparatus for measurements of the photo-induced conductance change. L: High-pressure Hg lamp, F: colored glass filter, S: stirrer, C: conductance electrode, R+ thermo-regulator.

Table 1. Average Aggregation Numbers (N_{av}) of *trans*-**1** and *cis*-**1**[a]

Crown ether	Concentration / g dm^{-3}	cis%[b]	N_{av}
trans-**1**(n=4)	0.370	—	2.3±0.3
cis-**1**(n=4)	0.370	76→53	2.3±0.2
trans-**1**(n=6)	0.380	—	2.3±0.2
cis-**1**(n=6)	0.380	85→80	1.1±0.1
trans-**1**(n=10)	0.410	—	1.9±0.1
cis-**1**(n=10)	0.410	72→50	1.2±0.1

a) 50 °C, 1-butanol. b) The values indicate the cis% before and after the measurement of vapor pressure.

Photoisomerization and Measurements of Electric Conductance. Trans-cis isomerization was carried out at 30 °C by using a 100W high-pressure Hg lamp with a colored glass filter: Toshiba UV-D35 ($330<\lambda<380$ nm) for UV light and Toshiba Y-46 ($\lambda>460$ nm) for visible light.

Conductance measurements were carried out at 30 °C by using an apparatus illustrated in Fig. 1. The containers for a thermostatted water-bath and a sample solution were made of transparent Pyrex glass. The sample solution was photoirradiated from the bottom of the water bath by a Hg lamp through a colored glass filter. In order to avoid the heat effect of the Hg lamp on electric conductance, both the water-bath and the sample solution were stirred effeciently.

Measurements of Average Molecular Weights. The average molecular weights (MW_{av}) of *trans*-**1** and *cis*-**1** were

determined by vapor pressure osmometry[24-26] (1-butanol at 50 °C). The apparatus (Corona, Type 117) was first calibrated by compound **2** and then used for the measurement of *trans*-**1**. On the other hand, the measurement of *cis*-**1** is more complicated: The 1-butanol solution of *trans*-**1** was irradiated by UV light and the cis% at the photostationary state was determined spectrophotometrically. This solution was immediately set up in the apparatus. After the measurement of MW_{av} (about 15 min), the cis% was determined again spectrophotometrically. The results are summarized in Table 1.

Results and Discussion

Osmometric Determination of MW_{av}. It is well-established that 18-crown-6 and its analogs can form stable complexes with ammonium cations, the stability being comparable with that of the K^+ complexes.[27-30] Thus, they are frequently employed as receptors to fix the ammonium moiety in guest molecules. The detailed studies have been reported by Sutherland, Lehn, and others.[27-34] For example, bis(crown ethers) and polymethylene-α,ω-diammonio cations can form pseudo-cyclic 1:1 complexes when the distance between the two crown systems is close to the distance between the two ammonium cations.[31-34] On the other hand, intermolecular, polymeric complexes result when the two crown systems are not located suitably to form pseudo-cyclic 1:1 complexes.[31,34]

It is sterically impossible for *trans*-**1** to form the intramolecular complex between the ammonium tail and the crown ring. Therefore, it should form either polymeric aggregates or pseudo-cyclic oligomers. In *cis*-**1**, on the other hand, examination of Corey-Pauling-Koltun models suggests that introduction of a proper spacer between the ammonium tail and the crown ring allows the intramolecular complexation and that the hexamethylene group optimizes the interaction. This means that *cis*-**1** (n=6) has the potential capability to form the intramolecular "tail-biting" complex.

The average aggregation numbers ($N_{av}=MW_{av}/MW$ of monomer) were calculated from MW_{av} determined by vapor pressure osmometry (Table 1). As the cis% at the photostationary state cannot be enhanced up to 100%, the N_{av} values for *cis*-**1** imply the cis-rich mixtures. It is clearly seen from Table 1 that all trans-forms give $N_{av}=2.0\pm0.3$. This suggests that they favorably form the pseudo-cyclic "dimers" but not the polymeric aggregates. It is not yet clear why the pseudo-cyclic dimers are more energetically-favorable than the polymeric aggregates. In the polymeric aggregates (Scheme 2) the terminal ammonium cation always remains uncomplexed. In contrast, the uncomplexed cation no longer exists in the cyclic forms. The polymeric aggregates may not be formed in the solution state because of this disadvantage.

When the trans-forms were photoisomerized to the corresponding cis-forms, the N_{av} values for **1** (n=6) and **1** (n=10) decreased very close to unity, 1.1±0.1. The finding supports that the cis-forms of **1** (n=6) and **1** (n=10) exist mainly as "monomers" in solution. In other words, the intramolecular "tail-biting" really occurs and the pseudo-cyclic dimers are dissociated into the discrete monomers. This is reasonably explained by the cis-configuration of the azo segment which facilitates the intramolecular "tail-biting" sterically. In contrast, the N_{av} for **1** (n=4) was scarcely affected by photoirradiation. The difference is readily ascribed to the incapability of *cis*-**1** (n=4) to bite at the intramolecular ammonium tail. One can conclude, therefore, that in **1** (n=4) not only the trans-form but also the cis-form should form the pseudo-cyclic dimers in solution.

Photoresponsive Conductance Change. Electric conductance is defined as a function of mobility of charged particles in solution. Therefore, it should reflect the photoinduced change in the molecular size. First, we examined the photoirradiation effect on **1** (n=6) in 1-butanol which was used for the determination of MW_{av} (Fig. 2). Very interestingly, the conductance (Λ=7.59 ohm^{-1} cm^2 mol^{-1} for *trans*-**1** (n=6)) increased on UV light irradiation ($330<\lambda$ 380 nm) and finally saturated at Λ=8.59 ohm^{-1} cm^2 mol^{-1} (cis 80%). On visible light irradiation (λ >460 nm) it decreased gradually and finaly reached the Λ value for *trans*- **1** (n=6). This process could be repeated several times by alternate irradiation of UV and visible light. We found, however, that the absolute Λ values in 1-butanol were affected sensitively by a small amount of concomitant water. On the other hand, the reproducible Λ values can be obtained when the concentration of 1-butanol was reduced by mixing with aprotic solvents. We thus employed a mixed solvent of *o*-dichlorobenzene-1-butanol=(9:1 v/v) for detailed examinations.

Figure 3 shows the effect of photoirradiation on cis% and conductance. Two curves were obtained by

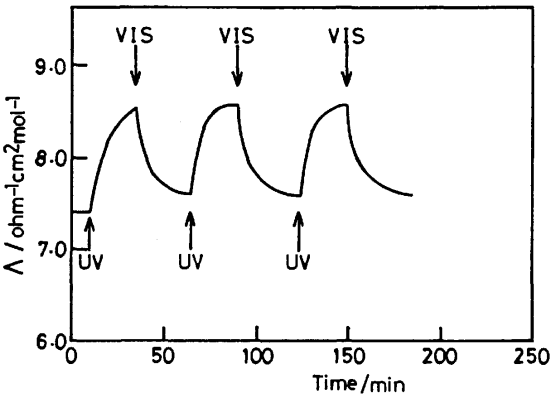

Fig. 2. Photoresponsive conductance change for **1**(n=6) in 1-butanol. [**1**(n=6)]=5.40×10^{-4} mol dm^{-3}.

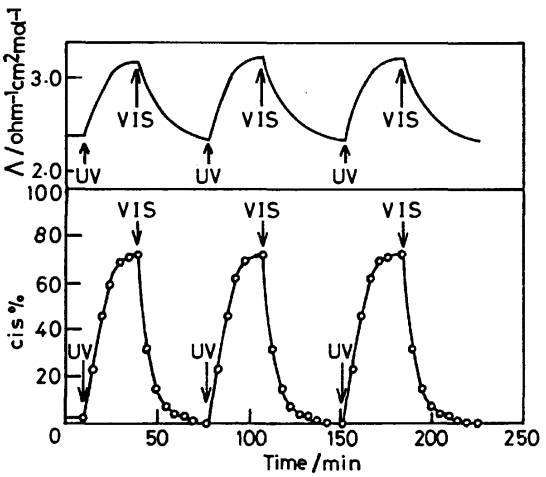

Fig. 3. Photoresponsive conductance change and cis% change for **1**(n=6) in o-dichlorobenzene-1-butanol=9:1 (v/v). [**1**(n=6)]=5.40×10^{-4} mol dm^{-3} for both conductance and cis% determination.

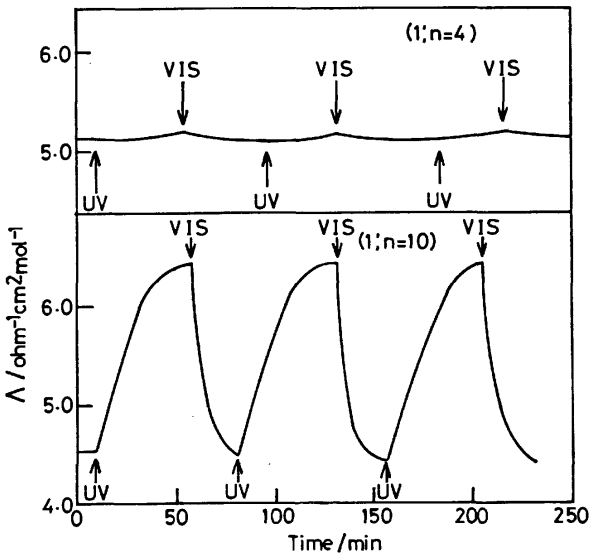

Fig. 4. Photoresponsive conductance change for **1**(n=4) and **1**(n=10) in o-dichlorobenzene-1-butanol=9:1 (v/v). [**1**(n=4)]=5.57×10^{-4} mol dm^{-3}, [**1**(n=10)=5.39×10^{-4} mol dm^{-3}.

using the same apparatus (Fig. 1) and the same conditions (see caption to Fig. 3). It is seen from Fig. 3 that two curves show excellent coincidence. Similar photoresponsiveness of both cis% and conductance was also observed for **1** (n=10) (Fig. 4: cis% is not illustrated here). The magnitude of the conductance change ($\Delta\Lambda$=2.00 ohm^{-1} cm^2 mol^{-1}) was somewhat greater than that for **1** (n=6) (0.85 ohm^{-1} cm^2 mol^{-1}). When visible light was not irradiated, the thermal cis-to-trans isomerization took place slowly. The first-order rate constants (k) determined at 30 °C by following the appearance of the absorption maxima of *trans*-(**1**) (364—368 nm)[21] were 2.39×10^{-5} s^{-1} for **1** (n=6) and 8.90×10^{-5} s^{-1} for **1** (n=10). The k values in the dark could be also determined by following the slow decrease in the conductance; k=2.30×10^{-5} s^{-1} for **1** (n=6) and 8.65×10^{-5} s^{-1} for **1** (n=10). Several lines of excellent coincidence between the spectroscopic data and the conductance data support that the conductance change is caused by the photoinduced trans-cis isomerization. In other words, the monomeric cis-forms have the Λ value higher than the dimeric trans-forms and two aggregation modes can be rever-

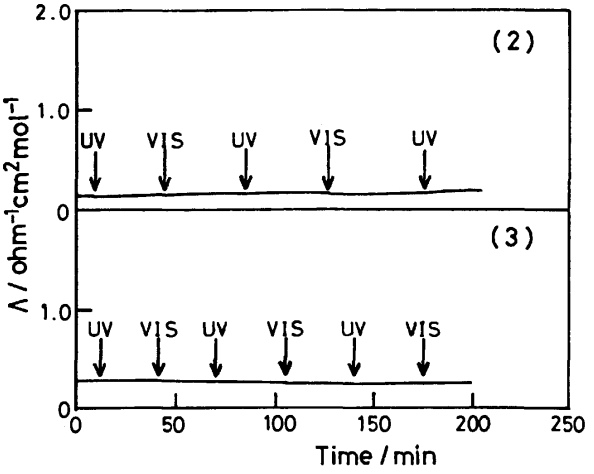

Fig. 5. Photoresponsive conductance change for **2** and **3** in o-dichlorobenzene-1-butanol=9:1 (v/v). [**2**]=5.45×10^{-4} mol dm^{-3}, [**3**]=5.36×10^{-4} mol dm^{-3}.

a) 30 °C, o-dichlorobenzene-1-butanol=9:1 (v/v). b) Electric conductance in the dark. c) Maximum electric conductance under UV light irradiation. cis% at the maximum conductance: 58% for **1**(n=4), 72% for **1**(n=6), and 78% for **1**(n=10). d) $\Delta\Lambda=\Lambda_{light}-\Lambda_{dark}$.

sibly interconverted by photoirradiation. The finding would be rationalized in terms of the difference in the mobility between the monomeric species and the dimeric species.

In contrast, the conductance change was scarcely detected for **1** (n=4) which could not form the "tail-biting" monomeric complex. Reference compounds, **2** and **3**, which have neither a crown ring nor an ammonium tail, showed no conductance change although the trans-cis photoisomerization really occurred in the conductance cell (maximum cis% under UV light irradiation, 51% for **2** and 58% for **3**: Fig. 5). As a summary of the foregoing results (Table 2), one can draw a conclusion that the photoinduced conductance change is observed only for the "tail-biting" crown ethers which can realize reversible interconversion between the monomeric form and the pseudo-cyclic, dimeric form.

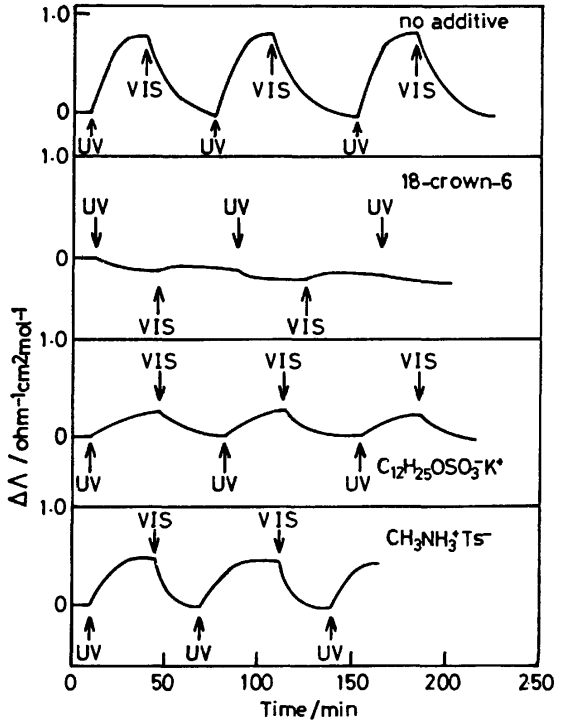

Fig. 6. Effect of additives on the photoresponsive conductance change for [**1**(n=6)] (5.40×10^{-4} mol dm^{-3}) in o-dichlorobenzene-1-butanol=9:1 (v/v). [18-Crown-6]=5.00×10^{-3} mol dm^{-3},[$C_{12}H_{25}OSO_3^-K^+$]=5.60×10^{-4} mol dm^{-3}, [$CH_3NH_3^+Ts^-$]=2.13×10^{-2} mol dm^{-3}.

Effects of Additives. In solvent extraction with **1** (n=6), we found that *trans*-**1** (n=6) can extract K^+ into the organic phase while *cis*-**1** (n=6) has almost no metal affinity.[21] On the other hand, the present study has established that both *trans*- and *cis*-**1** (n=6) form the complexes with the ammonio groups. The difference in the K^+ affinity should be related to the stability of the ammonium complexes: That is, the intermolecular ammonium cation in *trans*-**1** (n=6) can be replaced competitively by K^+, whereas the intramolecular ammonium-crown complex in *cis*-**1** (n=6) is so stable that the ammonium cation binds to the crown cavity in preference to K^+. This suggests that the added K^+ ion would selectively dissociate the dimeric aggregates of *trans*-**1** (n=6).

Figure 6 indicates the influence of K^+ and $CH_3NH_3^+$ on the photoresponsive wave of **1** (n=6). Separately, we confirmed that the cis% is scarcely affected by the addition of these ions. It is clearly seen from Fig. 6 that the photoresponsive wave for **1** (n=6) becomes significantly smaller in the presence of potassium dodecyl sulfate and methylammonium p-toluenesulfonate (Table 2). The finding suggests that these cations can dissociate the pseudo-cyclic dimers into the monomers through competitive binding to the crown cavity (Scheme 3).

Similar suppression of the conductance change can be induced by the additive which selectively interacts with the ammonio group. For instance, addition of 18-crown-6 effectively suppressed the photoinduced conductance change (Fig. 6). Conceivably, added 18-crown-6 competes with the crown ring in **1** for the ammonio group. As a result, the pseudo-cyclic dimers would be dissociated into the monomers.

Conclusions

The present study demonstrated that the conductance of the solution containing **1** (n=6) and **1** (n=10) changes reversibly in response to photoirradiation. The novel phenomenon is ascribed, on the basis of several lines of experimental evidence, to photo-induced association-dissociation phenomena in the "tail(ammonium)-biting" crown ethers. Since the conductance change is sensitively affected by added K^+, ammonium ions, etc., the concept may be applicable more generally to interdisciplinary fields between photochemistry and electrochemistry including sensors, membrane systems, etc.

Syntheses of 3-Deoxy-3-*C*-methyl-3-nitro-D- and L-glucosides and Their Denitrohydrogenation with Tributyltin Hydride

Sinichi OTANI* and Shiro HASHIMOTO
Department of Chemistry, College of Liberal Arts and Sciences, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606
(Received November 11, 1986)

Cyclization, with nitroethane in the presence of sodium methoxide, of the dialdehyde produced by periodate oxidation of methyl β-D-glucopyranoside and acetylation led to methyl 2,4,6-tri-*O*-acetyl-3-*C*-methyl-3-nitro-β-D- and -α-L-glucopyranoside (**1**, 12% and **2**, 8.8%). In the case of methyl α-D-glucopyranoside, products **3** (8.6%) and **4** (8.0%) were antipodes of **1** and **2**, respectively. Denitrohydrogenation of **1** or **3** with tributyltin hydride in toluene led to 3-deoxy-3-*C*-methyl-β-D-pyranosides (gluco, **5**, 61% and allo, **6**, 22%) or L-pyranosides (gluco, **9**, 65% and allo, **10**, 19%), respectively. This sequence of the reaction was a novel method for the syntheses of 3-deoxy-3-*C*-methyl-L-glucose and -L-allose. Denitrohydrogenation of **2** or **4** led to a mixture of 3-deoxy-3-*C*-methyl-α-L-pyranosides (allo, **7**, 39% and gluco, **8**, 41%) or mixture of 3-deoxy-3-*C*-methyl-α-D-pyranosides (allo, **11**, 38% and gluco, **12**, 41%), respectively. Methyl 2-*O*-acetyl-4,6-*O*-benzylidene-3-deoxy-3-nitro-β-D-glucopyranoside was denitrohydrogenated to the corresponding 3-deoxy sugar (**14**) in 68% yield.

Deoxy sugars are important constituents of some natural products, especially of antibiotics. The deoxy sugars may be prepared by the reduction of oxiranes with lithium aluminium hydride.[1] The most direct methods for preparing monodeoxy sugars are by homolytic replacement of a good leaving group modified from a hydroxyl group. Thiocarbonates,[2] *O*-alkyl thiobenzoates,[3] *O*-alkyl *S*-methyl dithiocarbonates,[3] [alkoxy(thiocarbonyl)]imidazolides,[3,4] dimethyl thiocarbamates,[5] trifluoromethanesulfonates[6] and thionocarbonates[7] were deoxygenated.

3-Deoxy-3-*C*-methylhexopyranosides were synthesized from 2,3-anhydro sugars and methyllithium[8] or methylmagnesium chloride,[9,10] from 3-oxo sugars by Wittig reaction and the following reduction,[11] from 3-deoxy-3-nitro-3-*C*-methyl sugar by electrochemical reduction,[12] and from 3-*O*-acetyl-3-*C*-methyl sugar by photoreduction.[13]

An efficient method became available for replacing the nitro group of secondary or tertiary nitro compounds by hydrogen using tributyltin hydride in refluxing benzene or toluene in the presence of azobisisobutyronitrile.[14—16] The reaction proceeds via free radical chain mechanism. The reduction was selective without affecting other functional groups such as chloro, cyano, alkoxycarbonyl, carbonyl, sulfinyl, sulfonyl, and carbon–carbon double bond.

Cyclization, with nitroethane or nitromethane in the presence of sodium methoxide, of the dialdehyde produced by periodate cleavage of methyl α- or β-D-glucopyranoside, led to 3-deoxy-3-nitro sugars.[17—20] In this paper the authors wish to report the synthesis of 3-deoxy-3-*C*-methyl-3-nitro-D- and -L-glucopyranosides and their denitrohydrogenation with tributyltin hydride.

Results and Discussion

Preparation of Nitro Sugars. Baer obtained crystalline mixture of methyl 3-deoxy-3-*C*-methyl-3-nitrohexopyranosides in 18—20% yield[17] from the dialdehyde, prepared by periodate oxidation of methyl α-D-glucopyranoside, and nitroethane in methanol in the presence of sodium methoxide. Catalytic hydrogenation of the product afforded two stereoisomeric amino glycosides, which were separated, acetylated, and hydrolysed to a pair of enantiomers of reducing amino sugars. The acetylated products were reported to be β-L-gluco (or allo) and α-D-gluco (or allo) derivatives. When a sequence of the above reaction was performed from methyl β-D-glucopyranoside, a set of nitrogeneous glycosides were obtained as the antipodes of the products from methyl α-D-glucopyranoside, having α-L-gluco (or allo) and β-D-gluco (or allo) configurations.[17]

The author acetylated crystalline cyclized products from the dialdehyde, prepared by periodate cleavage of methyl β-D-glucopyranoside, and nitroethane. The acetylated products were separated with a column of silica gel (benzene–ethyl acatate 4:1) to crystals **1** (12%) and a sirup **2** (8.8%) which were both levorotatory.

In ^{1}H NMR spectrum of **1** in $CDCl_3$, H-1, H-2, and H-4 appeared as doublets with $J_{1,2}$=7.9 Hz and $J_{4,5}$=10.1 Hz, indicating that these hydrogens were axial. Irradiation of the C–CH_3 induced nuclear Overhauser effect (NOE) to H-1 and H-5. Therefore, the C–CH_3 was axial. ^{13}C NMR spectrum showed C-1 at δ 100.5 and O–CH_3 at δ 57.0, indicating the presence of equatorial OCH_3.[21] Taking into account that **1** was levorotatory, **1** was methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-3-nitro-β-D-glucopyranoside.

^{1}H NMR spectrum of **2** in $CDCl_3$ showed C–CH_3 at δ 1.89. Irradiation of the C–CH_3 induced NOE to H-5 but not to H-1. Thus the C–CH_3 and O–CH_3 were axial and H-1 was equatorial. The doublet signal due to H-1 and H-2 with small splitting ($J_{1,2}$=4.3 Hz) in ^{1}H NMR and C-1 at δ 96.5 and OCH_3 at 56.0 ppm in ^{13}C NMR indicated the presence of axial OCH_3. $J_{4,5}$

(10.2 Hz) proved the diaxial H-4 and H-5 arrangement. Considering that **2** was levorotatory and that Baer obtained a pair of enantiomers of reducing amino sugars by catalytic hydrogenation,[17] **2** was methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-3-nitro-α-L-glucopyranoside.

When the above reaction sequence was performed with the dialdehyde from methyl α-D-glucopyranoside, acetylated products, crystals **3**, (8.6%) and a sirup **4**, (8.0%), were both dextrorotatory. NMR spectra of these products coincided with those of the products from methyl β-D-glucopyranoside. Therefore, **3** and **4** were methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-3-nitro-β-L-glucopyranoside and -α-D-glucopyranoside, antipodes of **1** and **2**, respectively.

All the products, **1**—**4**, had the nitro and the vicinal hydroxyl groups in equatorial orientation. In **2** and **3**, the epimerization was observed at C-1 and C-5, evidently owing to base-catalyzed epimerization of the starting dialdehydes.[20]

Denitrohydrogenation. The nitro group of tertiary or secondary nitro compounds is replaced by hydrogen with tributyltin hydride. Refluxing a mixture of a nitro compound, tributyltin hydride and azobisisobutyronitrile (AIBN) in benzene or toluene for 1—2 h in a stream of nitrogen gave the denitrohydrogenated product in good yield.[14]

$$RNO_2 + n\text{-}Bu_3SnH \longrightarrow RH + n\text{-}Bu_3SnONO$$

A mixture of **1**, tributyltin hydride and AIBN in toluene was boiled under reflux for 1.5 h in a stream of nitrogen. The solution was evaporated and chromatographed on a column of silica gel (benzene–ethyl acetate 4:1) to give levorotatory products, **5** (61%) and **6** (22%).

^{1}H NMR spectrum of **5** showed the presence of C–CH_3 (δ 0.92, doublet) and diaxial H-1 and H-2 ($J_{1,2}$=7.8 Hz). Signals of C-1 (δ 103.0) and OCH_3 (δ 56.6) in ^{13}C NMR supported the presence of equatorial OCH_3 and axial H-1. Signal of H-3 (sextet, $J_{2,3}$=$J_{3,4}$=10.6 Hz, $J_{3,Me}$=6.4 Hz) showed that H-3 and H-4 were axial. Consequently, **5** was methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-β-D-glucopyranoside.

^{13}C NMR spectrum of **6** showed axial C–CH_3 at δ 9.2, differing from equatorial C–CH_3 at δ 13.2 in **5**. Signal of H-3 (sextet, $J_{2,3}$=$J_{3,4}$=4.7 Hz, $J_{3,Me}$=7.2 Hz) showed that H-3 and C–CH_3 were equatorial and axial, respectively. $J_{1,2}$ (5.8 Hz) and $J_{4,5}$ (6.8 Hz) were rather small for diaxial protons. But C-1 at δ 99.2 and OMe at δ 56.5 in ^{13}C NMR supported the presence of axial H-1. Therefore, **6** was proved to be methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-β-D-allopyranoside. These results showed that the predominant product had an equatorial methyl in denitrohydrogenation.

Denitrohydrogenation of **3**, antipode of **1**, gave methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-β-L-glucopyranoside (**9**, 65%) and -allopyranoside (**10**, 19%). This reaction was proved to be a novel method for the syntheses of 3-deoxy-3-*C*-methyl-L-glucose and -L-allose.

Products of denitrohydrogenation of **2** were a levorotatory mixture of C-3 epimers with 51:49 ratio on the basis of the methyl peak of methoxyl group in ^{1}H NMR. Coupling constants of H-3, $J_{2,3}$ and $J_{3,4}$, were both 5.5 Hz for a minor product (**7**, 39%) and both 10.4 Hz for a major product **8** (41%). These showed that **7** and **8** had axial and equatorial C–CH_3, respectively. Consequently, **7** and **8** were methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-α-L-allopyranoside and -glucopyranoside, respectively. We could not find an appropriate developer for the separation of the mixture on TLC and on a column of silica gel. Similarly, denitrohydrogenation of **4**, antipode of **2**, gave a mixture of methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-α-D-allopyranoside (**11**, 38%) and -glucopyranoside (**12**, 41%) with the ratio of 48:52.

The stereochemistry of denitrohydrogenation was explained as follows. For the β-glycosides, intermediate C-3 radical was preferentialy attacked from axial direction by tributyltin hydride to form a product with equatorial methyl, for equatorial attack was sterically hindered with axial H-2 and H-4. For the α-glycosides, axial attack was considerably hindered with axial methoxyl group at C-1. Therefore, axial and equatorial attack occurred with the same difficulty.

The secondary nitro sugar, methyl 2-*O*-acetyl-4,6-*O*-benzylidene-3-deoxy-3-nitro-β-D-glucopyranoside (**13**), synthesized by cyclization of the dialdehyde from methyl β-D-glucopyranoside with nitromethane,[19] was denitrohydrogenated with tributyltin hydride to give methyl 2-*O*-acetyl-4,6-*O*-benzylidene-3-deoxy-β-D-glucopyranoside (**14**) in 68% yield. Secondary nitro compounds were generally denitrohydrogenated in lower yield than tertiary nitro compounds.[14]

Experimental

Melting points were measured in capillary tubes with a Yamato melting-point apparatus MP-21 and are uncorrected. Column chromatography was performed on

Wakogel C-200 (100—200 mesh). ^{1}H NMR spectra were recorded with a JEOL JNM-GX-400 spectrometer (400 MHz) and ^{13}C NMR spectra with a JEOL FX-90Q spectrometer (22.5 MHz) using tetramethylsilane as an internal standard in deuteriochloroform unless otherwise stated. Chemical shifts and coupling constants were recorded in δ and Hz units. TLC was performed on precoated HPTLC plates, silica gel 60 (E. Merck). Optical rotations were determined with a Jasco DIP-140 digital polarimeter.

Methyl 2,4,6-Tri-*O*-acetyl-3-deoxy-3-*C*-methyl-3-nitro-β-D-glucopyranoside (1) and -α-L-glucopyranoside (2). Methyl β-D-glucopyranoside (38.8 g) was oxidized with sodium periodate (85.6 g) to the sirupy colorless dialdehyde, which was treated with nitroethane in the presence of sodium methoxide in methanol to the crystalline product (12.3 g) according to Baer.[17] The crystalline product (10 g) in pyridine (180 ml) was acetylated with acetic anhydride (50 ml) overnight at room temperature. The reaction mixture was poured into water and extracted with chloroform. The extract was evaporated and treated with ethanol to crystals (**1**, 6.7 g). The mother liquor was evaporated and passed through a column of silica gel (60×5 cm, hexane–ethyl acetate 1:1). The additional crystalline **1**, (2.1 g) and a sirup **2**, (6.4 g) were obtained.

1: 8.8 g (12% yield from methyl β-D-glucopyranoside): Mp 124—125 °C; $[\alpha]_D^{22}$ −25.5° (*c* 1, chloroform); ^{1}H NMR δ=5.71 (H-4, 1H, d, $J_{4,5}$=10.1), 5.67 (H-2, 1H, d, $J_{1,2}$=7.9), 4.44 (H-1, 1H, d), 4.27 (H-6R, 1H, q, $J_{5,6R}$=4.6, $J_{6,6}$=12.4), 4.15 (H-6S, 1H, q, $J_{5,6S}$=2.8), 3.75 (H-5, 1H, octet), 3.51 (OMe, 3H, s) and 1.78 (CMe, 3H, s). NOE of H-1 (+12%) and H-5 (+12%) were measured by irradiation at δ 1.78. ^{13}C NMR δ=170.6, 168.2, 168.1 (C=OMe), 100.5 (C-1), 91.1 (C-3), 71.5, 71.4, 69.6 (C-2,4,5), 62.2 (C-6), 57.0 (OMe), 20.7, 20.5, 20.3 (CO<u>Me</u>), and 12.0 (C<u>Me</u>).

2: 6.4 g (8.8% yield from methyl β-D-glucopyranoside), $[\alpha]_D^{22}$ −96.7° (*c* 1, chloroform); ^{1}H NMR δ=5.63 (H-2, 1H, d, $J_{1,2}$=4.3), 5.58 (H-4, 1H, d, $J_{4,5}$=10.2), 5.11 (H-1, d), 4.31 (H-6S, 1H, q, $J_{5,6S}$=4.5, $J_{6,6}$=12.3), 4.11 (H-6R, 1H, q, $J_{5,6R}$=2.4), 3.94 (H-5, 1H, octet), 3.41 (OMe, 3H, s), and 1.89 (CMe, 3H, s). NOE of H-5 (+12%) was measured by irradiation at δ 1.89. ^{13}C NMR δ=170.5, 169.1, 168.3 (C=OMe), 96.5 (C-1), 91.2 (C-3), 71.2, 69.4, 66.2 (C-2,4,5), 61.8 (C-6), 56.0 (OMe), 20.6, 20.4, 20.2 (CO<u>Me</u>), and 13.1 (C<u>Me</u>).

Found: C, 46.28; H, 5.83; N, 3.61%. Calcd for $C_{14}H_{21}NO_{10}$: C, 46.28; H, 5.83; N, 3.86%.

Methyl 2,4,6-Tri-*O*-acetyl-3-deoxy-3-*C*-methyl-3-nitro-β-L-glucopyranoside (3) and -α-D-glucopyranoside (4). Methyl α-D-glucopyranoside (38.8 g) was oxidized with sodium periodate (85.6 g), and treated with nitroethane to crystals (7.9 g, 17% yield).[17] The crystalline product (5.9 g) was acetylated in a similar manner as the preceded procedure. Crystals (**3**, 4.7 g, 8.6% from methyl α-D-glucoside) and a sirup (**4**, 4.2 g, 8.0% from methyl α-D-glucoside) were obtained.

3: Mp 124—125 °C; $[\alpha]_D^{18}$ +29.0° (*c* 1, chloroform); ^{13}C NMR δ= 170.4, 168.1, 167.8 (C=OMe, each s), 100.8 (C-1, d), 91.3 (C-3, s), 71.9, 71.8, 70.1 (C-2,4,5, each d), 62.6 (C-6, t), 56.6 (OMe, q), 20.6, 20.3, 20.2 (CO<u>Me</u>, q), and 12.2 (C<u>Me</u>, q).

Found: C, 46.21; H, 5.81; N, 3.74%. Calcd for $C_{14}H_{21}NO_{10}$: C, 46.28; H, 5.83; N, 3.86%.

4: $[\alpha]_D^{22}$ +102° (*c* 1, chloroform); ^{13}C NMR δ=170.2, 168.9, 168.1 (C=OMe, each s), 96.8 (C-1, d), 91.5 (C-3, s), 71.6, 70.0, 66.6 (C-2,4,5, each d), 62.2 (C-6, t), 55.9 (OMe, q), 20.4, 20.2, 20.0 (CO<u>Me</u>, each q), and 13.2 (C<u>Me</u>, q).

Found: C, 45.98; H, 5.79; N, 3.86%. Calcd for $C_{14}H_{21}NO_{10}$: C, 46.28; H, 5.83; N, 3.86%.

Denitrohydrogenation of 1. A mixture of **1** (1.0 g, 2.7 mmol), tributyltin hydride (3 ml, 11 mmol), and AIBN solution (120 mg in 10 ml of toluene) in toluene (100 ml) was boiled under reflux.[14] A half an hour later, AIBN solution (60 mg in 5 ml of toluene) was added. Boiling under reflux for an hour, the solution was evaporated and chromatographed on a column of silica gel (60×3 cm, benzene–ethyl acetate 4:1). Methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-β-D-glucopyranoside (**5**, 0.52 g, 61%) and -allopyranoside (**6**, 0.19 g, 22%) were crystallized from ethanol and from hexane, respectively.

5: Mp 85 °C; $[\alpha]_D^{22}$ −39.7° (*c* 1, chloroform); ^{1}H NMR δ=4.79 (H-4, 1H, t, $J_{3,4}$=$J_{4,5}$=10.2), 4.70 (H-2, 1H, q, $J_{1,2}$=7.8, $J_{2,3}$=10.8), 4.34 (H-1, 1H, d), 4.23 (H-6R, 1H, q, $J_{5,6R}$=4.9, $J_{6,6}$=12.2), 4.10 (H-6S, 1H, q, $J_{5,6S}$=2.4), 3.63 (H-5, 1H, octet), 3.48 (OMe, 3H, s), 2.10, 2.09, 2.08 (3×COMe, 3×3H, each s), 1.91 (H-3, 1H, octet, $J_{3,Me}$=6.4), and 0.92 (CMe, 3H, d). ^{13}C NMR δ=170.7, 169.8 (overlapped) (C=OMe, each s), 103.0 (C-1, d), 74.6, 72.9, 70.4 (C-2,4,5, each d), 62.6 (C-6, t), 56.6 (OMe, q), 39.8 (C-3, d), 20.8, 20.7 (overlapped) (CO<u>Me</u>, q), and 13.6 (C<u>Me</u>, q).

Found: C, 52.60; H, 7.10%. Calcd for $C_{14}H_{22}O_8$: C, 52.82; H, 6.97%.

6: Mp 55 °C; $[\alpha]_D^{19}$ −35.5° (*c* 0.5, chloroform); ^{1}H NMR δ=4.94 (H-4, 1H, q, $J_{3,4}$=4.7, $J_{4,5}$=6.8), 4.82 (H-2, 1H, q, $J_{1,2}$=5.8, $J_{2,3}$=4.7), 4.60 (H-1, 1H, d), 4.25 (H-6, 2H, d, $J_{5,6}$=4.9), 3.98 (H-5, 1H, sextet), 3.45 (OMe, 3H, s), 2.66 (H-3, 1H, sextet, $J_{3,Me}$=7.2), 2.11, 2.090, 2.086 (3×COMe, 3×3H, each s), and 0.99 (CMe, 3H, d); ^{13}C NMR δ=170.7, 169.8, 169.7 (C=OMe, each s), 99.2 (C-1, d), 63.4 (C-5, t), 56.5 (OMe, q), 30.7 (C-3, d), 20.83, 20.75 (overlapped) (CO<u>Me</u>), and 9.2 (C<u>Me</u>, q).

Found: C, 52.71; H, 7.08%. Calcd for $C_{14}H_{22}O_8$: C, 52.82; H, 6.97%.

Denitrohydrogenation of 2. Compound **2** (1.0 g) was denitrohydrogenated in a similar manner as **1**. NMR spectra of the sirupy product (0.70 g, 80% yield) showed that it was a mixture of two components, methyl-2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-α-L-allopyranoside (**7**) and -glucopyranoside (**8**). According to the methyl peak of methoxyl group, components ratio **7**/**8** was 49/51. Separation of the components was unsuccessful on TLC and on a column of silica gel. $[\alpha]_D^{20}$ −114° (*c* 0.5, chloroform).

Found: C, 53.03; H, 7.20%. Calcd for $C_{14}H_{22}O_8$: C, 52.82; H, 6.97%.

7: ^{1}H NMR δ=4.94 (H-2, 1H, q, $J_{1,2}$=3.7, $J_{2,3}$=5.5), 4.94 (H-4, 1H, q, $J_{3,4}$=5.5, $J_{4,5}$=11.2), 4.65 (H-1, 1H, d), 4.29 (H-6R, 1H, q, $J_{5,6R}$=5.0, $J_{6,6}$=12.1), 4.17 (H-6S, 1H, q, $J_{5,6S}$=2.4), 4.07 (H-5, 1H, octet), 3.40 (OMe, 3H, s), 2.69 (H-3, 1H, q, $J_{3,Me}$=7.3), 2.12, 2.09, 2.08 (3×COMe, 3×3H, each s), and 1.12 (CMe, 3H, d). ^{13}C NMR δ=97.9 (C-1, d), 69.6, 68.4, 63.7 (C-2,4,5, each d), 62.6 (C-6, t), 55.5 (OMe, q), 33.3 (C-3, d), 20.9, 20.7 (overlapped) (CO<u>Me</u>, each q), and 8.51 (C<u>Me</u>, q). Signals of carbonyl carbons were appeared at 170.7, 170.3,

169.8, and 169.3, of which assignment to **7** or **8** was not determined.

8: ^{1}H NMR δ=4.83 (H-2, 1H, q, $J_{1,2}$=3.7, $J_{2,3}$=10.5), 4.78 (H-4, 1H, t, $J_{3,4}$=$J_{4,5}$=10.4), 4.62 (H-1, 1H, d), 4.22 (H-6R, 1H, q, $J_{5,6R}$=4.9, $J_{6,6}$=12.2), 4.05 (H-6S, 1H, q, $J_{5,6S}$=2.4), 3.88 (H-5, 1H, octet), 3.42 (OMe, 3H, s), 2.27 (H-3, 1H, sextet, $J_{3,Me}$=6.4), 2.12, 2.09, 2.07 (3×COMe, 3×3H, each s), and 0.92 (CMe, 3H, d); ^{13}C NMR δ=96.1 (C-1, d), 73.1, 70.5, 68.1 (C-2,4,5, each d), 62.9 (C-6, t), 55.2 (OMe, q), 34.9 (C-3, d), 20.9, 20.7 (overlapped) (COMe, each q), and 13.4 (CMe, q). Concerning signals of carbonyl carbons, see the data of **7**.

Denitrohydrogenation of 3. Compound **3** (1.0 g) was denitrohydrogenated in a similar manner as **1**. Methyl 2,4,6-tri-*O*-acetyl-3-deoxy-3-*C*-methyl-β-L-glucopyranoside (**9**, 0.57 g, 65%) and -allopyranoside (**10**, 0.17 g, 19%) were obtained.

Fluoride Ion-Induced Horner-Emmons Reaction of α-Silylalkylphosphonic Derivatives with Carbonyl Compounds

Takayuki KAWASHIMA,* Takafumi ISHII, and Naoki INAMOTO*
Department of Chemistry, Faculty of Science, The University of Tokyo,
Hongo, Bunkyo-ku, Tokyo 113
(Received November 12, 1986)

Dimethyl α-trimethylsilylbenzylphosphonate was allowed to react with carbonyl compounds in the presence of fluoride ion to give the corresponding olefins in fairly good yields. Use of CsF in tetrahydrofuran gave the best result. On the other hand, dimethyl trimethylsilylmethylphosphonate was allowed to react similarly with benzophenone to afford 1,1-diphenylethylene, dimethyl methylphosphonate, and dimethyl 2,2-diphenylethenylphosphonate. A similar result was obtained by using *O,O*-diethyl trimethylsilylmethylphosphonothioate. But, reaction of trimethylsilylmethylphosphonic bis(diethylamide) afforded only the protodesilylation product.

Since Si–F bond energy is high,[1] fluoride-induced desilylation has been utilized as a powerful tool for the generation of stabilized carbanions under neutral and relatively mild conditions.[2] The first application to the Wittig reaction was demonstrated by Vedejs and Martinez during the investigation on the generation and reaction of a carbanion stabilized by positively charged nitrogen, sulfur, or phosphorus.[3] Recently, this desilylation of α-silylalkylphosphonium salts has been studied in detail and shown to be a useful method for trisubstituted olefins by Bestmann and Bomhard.[4] If this fluoride ion-induced desilylation can be applied to α-silylalkylphosphonates, it is possible to undergo to Horner–Emmons reaction under neutral and mild conditions. A few of the results have already been described in a previous report.[5] In this paper we wish to report the detailed results.

Results and Discussion

Preparation of α-Trimethylsilylalkylphosphonic Derivatives 1. Dimethyl α-trimethylsilylbenzylphosphonate (**1a**) was prepared in 92% yield by α-lithiation of dimethyl benzylphosphonate (**2a**) and subsequent silylation with chlorotrimethylsilane.

$$X_2P(O)CH_2R \xrightarrow[2)\ Me_3SiCl]{1)\ BuLi} X_2P(O)CHRSiMe_3$$

2 **1**

a: R=Ph, X=OMe; b: R=H, X=OMe;
c: R=H, X=NEt_2

Dimethyl trimethylsilylmethylphosphonate (**1b**) was obtained similarly in 27% yield. The formation of dimethyl α,α-bis(trimethylsilyl)methylphosphonate could not be inhibited since the reaction was carried out under conditions where the quencher existed in more excess than the reactant (See Experimental). Very efficient distillation with a spinning band was necessary for removal of the by-product. According to the literature,[6] **1b** can be prepared by the Arbuzov reaction of trimethyl phosphite with trimethylsilylmethyl halide. Trimethylsilylmethylphosphonic bis(diethylamide) (**1c**) was also prepared in 43% yield by the same method as described above. *O,O*-Diethyl trimethylsilylmethylphosphonothioate (**1d**) was given in 74% yield by reaction of chlorodiethoxyphosphine with trimethylsilylmethylmagnesium chloride, followed by sulfurization.

$$(EtO)_2PCl + Me_3SiCH_2MgCl \longrightarrow \xrightarrow{S_8} (EtO)_2P(S)CH_2SiMe_3$$

Reaction of 1a with Benzaldehyde in the Presence of Various Fluoride Ion Sources. Dimethyl α-trimethylsilylbenzylphosphonate (**1a**) was allowed to react with benzaldehyde in tetrahydrofuran (THF) in the presence of various fluoride ion sources to give stilbene (**3a**) and a protodesilylation product, dimethyl benzylphosphonate (**2a**). The reaction proceeds as shown in the following scheme. The results are summarized in Table 1.

$$Me_3SiCHPhP(O)(OMe)_2 \xrightarrow[-Me_3SiF]{F^-}$$

$$^-CHPhP(O)(OMe)_2 \xrightarrow{H^+} PhCH_2P(O)(OMe)_2$$

2a

$$\downarrow PhCHO$$

$$PhCH{=}CHPh + (MeO)_2P(O)O^-$$

3a

When cesium fluoride dried freshly by a heat gun under vacuum was used, the best result was obtained. Use of acetonitrile as a solvent gave a similar result, but in toluene the reaction became very slow. Potassium fluoride was less effective even in the presence of 18-crown-6. On the other hand, ammonium fluorides could undergo desilylation efficiently even at room temperature, however, the

a) Isolated yields based on **1a**. b) By ^{1}H NMR analysis. c) Heated at 120 °C under vacuum. d) Dried by heating at 115 °C over P_2O_5 under vacuum. e) Dried by benzene azeotrope. f) Dried with molecular sieves 4A. g) Heated with a heat gun under vacuum. h) Heated at 120 °C over P_2O_5 under vacuum. i) Heated at 180 °C under vacuum. j) Commercially available one. k) Half mol equivalent of TBAF was used with molecular sieves 4A. l) Heated at 110 °C under vacuum.

yield of **3a** was rather poor. It seems to be due to the difficulty in drying because of its thermal instability and/or the existence of acidic hydrogens easily abstractable by the resulting carbanion. Considering that the yield of **3a** was less than 60% in spite of drying of tetrabutylammonium fluoride (TBAF) by various procedures such as absorption of water with molecular sieves 4A, removal of water as the benzene azeotrope and so on, the latter reason seems more likely.

It is interesting to point out that when metal fluorides were used only (*E*)-**3a** was obtained, while use of ammonium fluorides afforded a mixture of (*E*)- and (*Z*)-**3a** in a ratio of 90:10. In general the Horner–Emmons reaction using the phosphonates with substituents stabilizing carbanion at the α-position gives selectively thermodynamically more stable (*E*)-olefins through a reversible addition of the carbanion to the carbonyl compound at the first step of the reaction.[7] Therefore, it can reasonably be explained as follows: Ammonium cation makes counter anion more naked so that the second step of the reaction, cycloelimination of the phosphate ion, proceeds more readily to give kinetically (*Z*)-stilbene. Such an acceleration of the second step has been alternatively achieved by stabilizing a pentavalent intermediate by use of five-membered phosphonates[8] or electronegative group such as 2,2,2-trifluoroethyl.[9]

The following labeling experiment indicates that **1a** can not act as a proton source for the formation of **2a**, and that the resulting carbanion seems to be protonated by water which still remained in the system: A similar reaction using dimethyl α-deuterio-α-trimethylsilylbenzylphosphonate (**1a**-*d*) gave stilbene-*d* and dimethyl α-deuteriobenzylphosphonate (**2a**-*d*). No evidence was obtained for the formation of dimethyl α,α-dideuteriobenzylphosphonate. It can be concluded that the carbanion generated by desilylation does not abstract the α-proton of **1a**. Therefore, if water could be removed completely, the yield of the olefin is expected to increase.

The reaction can be followed by ^{31}P NMR spectroscopy. As the signal at δ_P 31.4 due to **1a** decreased gradually, the peak at δ_P 28.5 assignable to protodesilylation product **2a** appeared in a low intensity, but no peak of the phosphate ion could be observed around δ_P 0 except for use of TBAF, because of low solubility of metal phosphate.

Reactions of 1a with Other Carbonyl Compounds in the Presence of CsF. A mixture of **1a** and carbonyl compounds was refluxed overnight in THF in the presence of CsF to give the corresponding olefins in moderate yields. The results are shown in Table 2.

It is noteworthy that 1,2-diphenylpropene (**3c**) was obtained by reaction of **1a** with acetophenone in 67% yield, whereas the reaction using the lithio derivative caused mainly deprotonation of acetophenone and gave **3c** only in 8% yield, suggesting that the carbanion generated by the present desilylation is less basic than the lithio derivative. However, in the case of reactions with more easily enolizable carbonyl compounds such as cyclohexanone and isobutyraldehyde, the corresponding olefins were obtained in quite low yields. The latter result shows the limitation of the present reaction.

Determination of geometry of olefins was done by comparing their ^{1}H NMR spectra with those reported in the literature.[10,11] In the case of 3-methyl-1-phenyl-1-butene (**3e**) the upper field doublet due to the isopropyl group was assigned to Z-isomer based on shielding effect of benzene ring. This assignment is also supported by the fact that, on irradiating the minor peak due to the methine proton of the isopropyl group, the upper doublet became singlet and double doublet at δ 5.44 changed to a doublet with J=11.5 Hz, a typical vicinal coupling constant between the *Z*-protons. Considering that the Z-isomer formed predominantly in the case of **3c**, while the E-

isomer predominated over the Z-isomer in the case of **3e**, what determines stereochemistry of the olefin remains unclear.

Reaction of Dimethyl Trimethylsilylmethylphosphonate (1b) with Benzophenone in the Presence of CsF. A mixture of **1b**, benzophenone, and CsF in THF was refluxed for 1 d to afford 1,1-diphenylethylene (**3g**), dimethyl 2,2-diphenylethenylphosphonate (**4a**), and dimethyl methylphosphonate (**2b**) in 20, 30, and 50% yields, respectively. The following two mechanisms can be considered for the formation of **4a**: (i) Elimination of CsOH from the adduct **6** of the α-phosphinyl carbanion with benzophenone (Path a) and (ii) the Peterson reaction of α-trimethylsilyl-α-phosphinylmethylide anion (**7**) with benzophenone (Path b).[12]

$$(MeO)_2P(O)CH_2^-\ Cs^+ \xrightarrow{Ph_2C=O} (MeO)_2P(O)CH_2CPh_2O^-\ Cs^+ \quad \mathbf{6}$$

$$\xrightarrow[-CsOH]{} (MeO)_2P(O)CH{=}CPh_2 \quad \mathbf{4a} \qquad \text{(Path a)}$$

$$\mathbf{5} + \mathbf{1b} \longrightarrow \mathbf{2b} + Cs^+\ {}^-CH(SiMe_3)P(O)(OMe)_2 \quad \mathbf{7}$$

$$\xrightarrow{Ph_2C=O} (MeO)_2P(O)CH(SiMe_3)CPh_2O^-\ Cs^+ \quad \mathbf{8}$$

$$\xrightarrow[-Me_3SiOCs]{} (MeO)_2P(O)CH{=}CPh_2 \quad \mathbf{4a} \qquad \text{(Path b)}$$

In order to decide which mechanism is operative, an attempt to generate the intermediate β-oxido phosphonate (**6**) alternatively was done. Namely, dimethyl 2,2-diphenyl-2-(trimethylsiloxy)ethylphosphonate (**9**) was treated with CsF to afford 1,1-diphenylethylene (**3g**) in high yield and no 2,2-diphenylethenylphosphonate (**4**), indicating that path a can be ruled out. Therefore, the resulting carbanion **5** by desilylation may abstract a proton from **1b** in competition with an attack on a carbonyl compound to give α-silylalkylphosphonate carbanion (**7**) which undergoes the Peterson reaction with benzophenone to afford **3g**.

$$(MeO)_2P(O)CH_2CPh_2OSiMe_3 \xrightarrow[THF,\ reflux]{CsF} CH_2{=}CPh_2$$
$$\mathbf{9} \qquad\qquad \mathbf{3g}$$

It has been reported by Ando and Sekiguchi that dimethyl α-trimethylsilylalkylphosphonates such as **1b** are heated at 250 °C to give alkylidenedimethoxy(trimethylsiloxy)phosphoranes (**10**) through 1,3-silyl shift from carbon to oxygen atom, which undergo the Wittig-type olefination with carbonyl compounds.[13]

$$(MeO)_2P(O)CHRSiMe_3 \xrightarrow[O]{250\,^\circ C} (MeO)_2(Me_3SiO)P{=}CHR \quad \mathbf{10}$$

$$\xrightarrow{Ph_2C=O} RCH{=}CPh_2 + (MeO)_2P(O)OSiMe_3$$

From the fact that the thermal reaction of **1b** with benzophenone affords **3g** in good yield and no Peterson reaction product,[13] it can reasonably be concluded that methylenephosphorane (**10**), which was proposed as an intermediate in the above reaction, is less basic than the carbanion **7** formed by an attack of fluoride ion on **1b**.

Reaction using other trimethylsilylmethylphosphonic derivatives, trimethylsilylphosphonic bis(diethylamide) (**1c**) and *O,O*-diethyl trimethylsilylmethylphosphonothioate (**1d**), failed to raise the yield of the methylene derivative. Use of **1c** caused mainly protodesilylation because strong hygroscopic property of **1c** made it difficult to remove water. Use of **1d** gave a result similar to that for **1b**, and the yield of the olefin was also quite poor, in marked contrast to the fact that reaction of dimethyl lithiomethylphosphonothioate with carbonyl compounds gives the corresponding methylene derivatives in good yields.[14] Two phase reaction in the presence of phase-transfer catalyst does not work in this system, either.

Experimental

All melting points and boiling points are not corrected. ^{1}H NMR spectra were measured with a Varian EM-390 (90 MHz), a Hitachi R-24B (60 MHz), and a JEOL FX-90Q (90 MHz) spectrometers using tetramethylsilane (TMS) as internal standard. ^{13}C NMR spectra were taken with a JEOL FX-90Q (22.53 MHz) specrometer using TMS as internal standard. ^{31}P NMR spectra were recorded with a JEOL FX-90Q (36.28 MHz) spectrometer using 85% H_3PO_4 as external standard. Mass spectra were measured at 70 eV with a JEOL 300-D mass spectrometer.

Preparation of α-Trimethylsilylalkylphosphonic Derivatives 1. Dimethyl α-Trimethylsilylbenzylphosphonate (1a). Dimethyl benzylphosphonate (**2a**) was prepared as described previously.[15] To a solution of **2a** (18.3 g, 91.7 mmol) in THF (300 ml), distilled over benzophenone ketyl, was added butyllithium (commercially available, 1.5 M (1 M=1 mol dm^{-3}) solution in hexane, 101 mmol) at −78 °C under argon. After 5 min chlorotrimethylsilane (16.3 g, 150 mmol) was added to the reaction mixture. The solution was allowed to warm to room temperature. After neutralization with aq $NaHCO_3$ THF was removed under reduced pressure, then the residue was treated with water and dichloromethane. Organic layers were collected and aq solution was extracted four times with dichloromethane. All extracts were combined, dried over anhydrous $MgSO_4$, and then the solvent was evaporated to give a colorless oil which was distilled under vacuum to afford 22.9 g (92%) of **1a**. Bp 90—92 °C/0.05 Torr (1 Torr=133.322 Pa). ^{1}H NMR ($CDCl_3$) δ=0.11 (9H, s, Si(C$\underline{H}_3$)$_3$), 2.71 (1H, d, J=24.6 Hz, P-C$\underline{H}$-Si), 3.59 (3H, J=10.7 Hz, P(OC$\underline{H}_3$)(OCH′$_3$)), 3.66 (3H, d, J=11.0 Hz, P(OCH$_3$)(OC$\underline{H}$′$_3$)), and 7.2 (5H, br s, Ph). ^{13}C NMR ($CDCl_3$) δ_C=−1.35 (d, $^3J_{C,P}$=2.4 Hz, Si(C$\underline{H}_3$)$_3$), 36.84 (d, $^1J_{C,P}$=125.7 Hz, P-C$\underline{H}_2$Si), 51.78 (d, $^2J_{C,P}$=6.7 Hz, P(OC$\underline{H}_3$)(OC′H$_3$)), 52.98 (d, $^2J_{C,P}$=7.3 Hz, P(OCH$_3$)-(OC$\underline{H}$′$_3$)), 125.76 (d, $^5J_{C,P}$=2.4 Hz, para-C), 128.46 (d, $^3J_{C,P}$=1.8 Hz, ortho-C), 129.53 (d, $^4J_{C,P}$=8.5 Hz, meta-C), and 135.08 (d, $^2J_{C,P}$=7.3 Hz, ipso-C). ^{31}P NMR ($CDCl_3$) δ_P=31.4. MS m/z (rel intensity) 272 (M^+; 49), 257 (43), 167 (33), 151 (96), and 105 (100). Found: C, 53.04; H, 7.80%. Calcd for $C_{12}H_{21}O_3PSi$: C, 52.92; H, 7.77%.

Dimethyl α-Deuterio-α-trimethylsilylbenzylphosphonate (1a-*d*). To a solution of **1a** (2.1 g, 7.7 mmol) in 50 ml of THF was added n-BuLi (9.2 mmol) at −78 °C. After 5 min a solution of D_2O (0.55 g, 27.7 mmol) in THF (10 ml) was added to the reaction mixture. The reaction mixture was allowed to warm to room temperature, neutralized with aq NH_4Cl, and extracted with dichloromethane. After removal of the solvent the residue was distilled under vacuum with Kugelrohr to give 1.79 g (85%) of **1a**-*d*. Bp 100 °C/0.01 Torr. ^{1}H NMR ($CDCl_3$) δ=0.114 (9H, s, Si(C$\underline{H}_3$)$_3$), 3.55 (3H, d, $^3J_{H,P}$=10.8 Hz, P(OC$\underline{H}_3$)(OCH′$_3$)), 3.66 (3H, $^3J_{H,P}$= 11.0 Hz, P(OCH$_3$)(OC$\underline{H}$′$_3$)), and 7.24 (5H, br s, C$_6\underline{H}_5$). ^{31}P NMR ($CDCl_3$) δ_P=31.4. High resolution mass spectrum (HRMS) m/z Found: 273.1064. Calcd for $C_{12}H_{20}DO_3PSi$: 273.1061. D contents was estimated to be 98 and 87% by ^{1}H NMR and mass spectroscopies, respectively.

Dimethyl Trimethylsilylmethylphosphonate (1b). To a solution of dimethyl methylphosphonate (**2b**) (20.0 g, 160 mmol) in THF (200 ml) was added n-BuLi (176 mmol) at −78 °C. After 5 min chlorotrimethylsilane (34.7 g, 320 mmol) was added dropwise to the solution, the cooling bath was taken off. After aq $NaHCO_3$ was added, THF was evaporated, and the residue was extracted with dichloromethane. Organic layer was dried over anhydrous $MgSO_4$, then the solvent was evaporated to give 32.4 g of an equimolar mixture of **1b**, **2b**, and dimethyl α,α-bis(trimethylsilyl)methylphosphonate. Fractional distillation with a spinning band gave 8.42 g (27%) of **1b**. **1b**; bp 100 °C/12 Torr (lit,[6] 111—114 °C/21.5 Torr). ^{1}H NMR ($CDCl_3$) δ=0.1 (9H, s, Si(C$\underline{H}_3$)$_3$), 1.1 (2H, d, J=20 Hz, P-C$\underline{H}_2$), and 3.7 (6H, d, J=13 Hz, P(OC$\underline{H}_3$)$_2$). ^{13}C NMR ($CDCl_3$) δ_C=−0.42 (d, $^3J_{C,P}$=4.3 Hz, Si(C$\underline{H}_3$)$_3$), 13.65 (d, $^1J_{C,P}$=128.2 Hz, P-C$\underline{H}_2$), and 51.83 (d, $^2J_{C,P}$=6.7 Hz, (OC$\underline{H}_3$)$_2$). ^{31}P NMR ($CDCl_3$) δ_P=35.6.

Trimethylsilylmethylphosphonic bis(diethylamide) (1c). Methylphosphonic bis(diethylamide) (**2c**) was prepared by the Arbuzov reaction of ethoxybis(diethylamino)phosphine with iodomethane in 85.5% yield. Bp 120 °C/0.9 Torr. (lit,[16] bp 166 °C/33 Torr). To a solution of methylphosphonic bis(diethylamide) (0.4 ml, 1.88 mmol) in THF (10 ml) was added butyllithium (1.2 equiv) at −78 °C, and the mixture was allowed to warm to 0 °C. To a cooled solution of chlorotrimethylsilane (1.5 equiv) was added by means of a syringe the solution of α-lithio derivative of methylphosphonic bis(diethylamide) at −40 °C for 30 min. After stirring was continued overnight aq NH_4Cl was added, the organic layer was extracted with dichloromethane, dried over anhydrous $MgSO_4$. The solvent was evaporated to give colorless oil, which was distilled with Kugelrohr to give **1c** as a colorless oil in 43% yield. Bp 70 °C/0.03 Torr. ^{1}H NMR ($CDCl_3$) δ=0.16 (9H, s, Si(C$\underline{H}_3$)$_3$), 1.08 (12H, t, J=7.0 Hz, (N(CH$_2$C$\underline{H}_3$)$_2$)$_2$), 1.15 (2H, d, J=17.2 Hz, P-C$\underline{H}_2$), and 2.70—3.35 (8H, m, (N(C$\underline{H}_2$CH$_3$)$_2$)$_2$). ^{13}C NMR ($CDCl_3$) δ_C =0.36 (d, $^3J_{C,P}$=4.3 Hz, Si(C$\underline{H}_3$)$_3$), 14.44 (d, $^3J_{C,P}$=2.2 Hz, N(CH$_2$C$\underline{H}_3$)$_2$), 15.72 (d, $^1J_{C,P}$=106.4 Hz, P-C$\underline{H}_2$), and 39.05 (d, $^2J_{C,P}$=4.4 Hz, N(C$\underline{H}_2$CH$_3$)$_2$). ^{31}P NMR ($CDCl_3$) δ_P=35.41. HRMS m/z Found: 278.1952. Calcd for $C_{12}H_{31}N_2PSi$: 278.1942.

***O,O*-Diethyl Trimethylsilylmethylphosphonothioate (1d).** Diethoxychlorophosphine was prepared as described in a previous paper[16] in 40% yield, which was contaminated with about less than 8% of ethoxydichlorophosphine. Ten ml of trimethylsilylmethylmagnesium chloride solution, prepared from chloromethyltrimethylsilane (4.39 g, 35.8 mmol) and Mg (0.933 g, 38.4 mmol) in ether (27 ml), was added to a solution of diethoxychlorophosphine (1.64 g, 10.47 mmol) in ether (20 ml) with stirring at −78 °C under argon atmosphere, then dry excess amount of sulfur (0.4 g) was added by portions to the solution. The reaction mixture was allowed to warm to room temperature, the reaction was quenched by adding aq NH_4Cl. The organic layer was extracted with dichloromethane, dried over anhydrous $MgSO_4$. The solvent was removed under reduced pressure, and the residue was distilled fractionally under vaccum to give 1.869 g (74%) of **1d** as a colorless oil. Bp 115 °C/7 Torr. ^{1}H NMR ($CDCl_3$) δ=0.17 (9H, s, Si(C$\underline{H}_3$)$_3$), 1.29 (6H, t, J=7.1 Hz, (OCH$_2$C$\underline{H}_3$)$_2$), 1.53 (2H, d, J=20.0 Hz, P-C$\underline{H}_2$), and 3.75—4.42 (4H, m, (OC$\underline{H}_2$CH$_3$)$_2$). ^{13}C NMR ($CDCl_3$) δ_C=−0.12 (d, $^3J_{C,P}$=3.9 Hz, Si(C$\underline{H}_3$)$_3$), 16.19 (d, $^3J_{C,P}$=7.3 Hz, P(OCH$_2$C$\underline{H}_3$)$_2$), 25.47 (d, $^1J_{C,P}$=100.1 Hz, P-C$\underline{H}_2$), and 61.97 (d, $^2J_{C,P}$=6.8 Hz, P(OC$\underline{H}_2$CH$_3$)$_2$). ^{31}P NMR ($CDCl_3$) δ_P=97.80. HRMS: m/z Found: 240.0768. Calcd for

$C_8H_{21}O_2PSSi$: 240.0768.

Preparation of Dimethyl 2,2-Diphenyl-2-(trimethylsiloxy)-ethylphosphonate (9). To a solution of dimethyl methylphosphonate (**1b**) (1.74 g, 14 mmol) in THF (50 ml) was added dropwise *n*-BuLi (15.4 mmol) at −78 °C. After 5 min a solution of benzophenone (2.80 g, 15.4 mmol) in THF (5 ml) was added to the solution, and the reaction mixture was allowed to warm gradually to room temperature. After cooling the reaction mixture at −78 °C again was added chlorotrimethylsilane (2.28 g, 21 mmol) by means of a syringe. The reaction mixture was allowed to warm to room temperature and it was neutralized with aq $NaHCO_3$. After removal of the solvent the residue was treated with water, and extracted with dichloromethane. The extracts were dried over anhydrous $MgSO_4$ and the solvent was removed under reduced pressure to give crude **4**, which was recrystallized from hexane to afford 4.97 g (97%) of pure **9**. **9**: Mp 86—88 °C (hexane). ^1H NMR ($CDCl_3$) δ=−0.04 (9H, s, $Si(C\underline{H}_3)_3$), 3.05 (2H, d, J=19.6 Hz, $PC\underline{H}_2$), 3.42 (6H, d, J=11.0 Hz, $P(OC\underline{H}_3)_2$), and 7.1—7.3 (10H, m, 2×Ph). ^{31}P NMR ($CDCl_3$) δ_P=29.0. MS (70 eV) m/z (rel intensity) 378 (M^+; 2), 363 (59), 301 (33), and 255 (100). HRMS (70 eV) m/z Found: 378.1413. Calcd for $C_{19}H_{27}O_4PSi$: 378.1414. Found: C, 60.02; H, 7.07%. Reaction of 1a with Benzaldehyde in the Presence of CsF. 1) In a 30 ml two-necked flask was placed CsF (0.354 g, 2.33 mmol), dried at 120 °C under vacuum for 2 h. Into the flask were added benzaldehyde (0.24 ml, 2.37 mmol) and THF (10 ml) under argon atmosphere, and a solution of **1a** (0.708 g, 2.60 mmol) in THF (10 ml) was added to the mixture cooled at −19 °C. The reaction mixture was stirred at room temperature overnight, and refluxed for 40 min. Thin-layer chromatography (SiO_2, CCl_4) showed the existence of unreacted benzaldehyde and (*E*)-stilbene (**3a**). After evaporating the solvent the residue was treated with water and dichloromethane, and the organic layer was dried over anhydrous $MgSO_4$. The solvent was removed under reduced pressure to give 0.477 g of an oil, which was subjected to dry column chromatography (DCC)(SiO_2, CCl_4) to afford 0.13 g (32%) of (*E*)-**3a**. Identification of this compound was done by comparing its ^1H NMR spectrum with that previously reported[10] and R_f value with that of authentic sample.

2) A mixture of CsF (0.349 g, 2.3 mmol), which was dried overnight at 115 °C over phosphorus pentaoxide under vacuum, benzaldehyde (0.35 ml, 3.46 mmol), and **1a** (0.476 g, 1.75 mmol) in THF (20 ml) was stirred at room temperature for 2.5 h, and refluxed overnight. The work-up as described above gave a mixture of **2a**, unreacted benzaldehyde, and (*E*)-**3a**, which was subjected to DCC (SiO_2, CCl_4) to give 0.113 g (36%) of (*E*)-**3a** and 0.23 g (66%) of crude **2a**.

3) In a 30 ml two-necked flask were placed CsF (0.410 g, 2.70 mmol) and dry benzene (15 ml), and water was removed as an azeotrope with benzene. Into the flask were added THF (20 ml), benzaldehyde (0.210 g, 1.98 mmol), and **1a** (0.204 g, 0.75 mmol), the mixture was stirred overnight at 50 °C and refluxed for 2 h. The usual work-up gave 0.087 g (64%) of (*E*)-**3a**.

4) A mixture of CsF (0.340 g, 2.24 mmol) and molecular sieves 4A (1 g) was refluxed for 1 h in THF (20 ml). After cooling was added benzaldehyde (0.29 ml, 2.87 mmol) and **1a** (0.463 g, 1.70 mmol) to the suspension, and the reaction mixture was refluxed for 6 h. The usual work-up afforded (*E*)-**3a** in 52% yield.

5) In a 30 ml flask was placed CsF (0.347 g, 2.29 mmol) and dried by heating with a 400 W heat-gun under vacuum. After adding THF (20 ml), benzaldehyde (0.51 ml, 5.05 mmol), and **1a** (0.558 g, 2.05 mmol) the mixture was refluxed for 1 d, and was treated as described above. DCC (SiO_2, CCl_4) of the residue gave 0.311 g (85%) of (*E*)-**3a**.

6) CsF dried as described in 5) was used, the reaction was carried out in acetonitrile at 50 °C overnight, in toluene at 75 °C for 1 d plus at 90 °C for 12 h, and in 1,2-dimethoxyethane at room temperature for 6 h plus at reflux for 2.5 h to afford (*E*)-**3a** in 64, 60, and 51% yields after usual work-up, respectively.

Reaction of Dimethyl α-Deuterio-α-trimethylsilylbenzylphosphonate (1a-*d*) with Benzaldehyde in the Presence of CsF. Dimethyl α-deuterio-α-trimethylsilylbenzylphosphonate (**1a**-*d*) (0.625 g, 2.29 mmol) was allowed to react with benzaldehyde (0.740 g, 6.97 mmol) in the presence of CsF (0.896 g, 5.90 mmol) in THF (8 ml) as described above to give (*E*)-**3a**-*d* (0.29 g, 70%) and dimethyl α-deuteriobenzylphosphonate (**2a**-*d*) (0.15 g, 33%). (*E*)-**3a**-*d*: ^1H NMR ($CDCl_3$) δ=7.09 (1H, br s, -CD=C$\underline{H}$-) and 7.18—7.62 (10H, m, aromatic). HRMS m/z Found: 181.1007. Calcd for $C_{14}H_{11}D$: 181.1002. D contents was estimated to be 95% by the ^1H NMR spectrum. **2a**-*d*: ^1H NMR ($CDCl_3$) δ=3.16 (1H, br d, $^2J_{H,P}$=21.5 Hz, P-C$\underline{D}$H), 3.65 (6H, d, $^3J_{H,P}$=10.7 Hz, $P(OC\underline{H}_3)_2$), and 7.29 (5H, br s, aromatic). HRMS m/z Found: 201.0665. Calcd for $C_9H_{12}DO_3P$: 201.0665. D contents was estimated to be 95 and 86% by ^1H NMR and mass spectroscopies, respectively.

Reaction of 1a with Benzaldehyde in the Presence of Other Fluorides. 1) In a 30 ml two-necked flask was weighted potassium fluoride (0.14 g, 2.41 mmol), and it was dried at 120 °C over phosphorus pentaoxide under vacuum overnight. Drying was continued at 200 °C for additional 5 h. Into the flask were added benzaldehyde (0.41 ml, 4.06 mmol), THF (20 ml), and **1a** (0.409 g, 1.50 mmol), and the mixture was refluxed for 1 d. As the ^{31}P NMR showed that **1a** still remained in a significant amount, a trace of 18-crown-6 was added to the reaction mixture. After stirring at room temperature for 1 d the usual work-up gave 0.034 g (9.5%) of (*E*)-**3a**.

2) Freeze dry KF (0.67 g, 11.5 mmol), which was prepared according to the literature,[18] was dried at 180 °C under vacuum for 1 h in a 50 ml two-necked flask, and THF (40 ml), benzaldehyde (1.04 ml, 10.3 mmol), and **1a** (2.124 g, 7.80 mmol) were added into the flask, and then the mixture was refluxed for 2 d. (*E*)-Stilbene (**3a**) and crude **2a** were obtained in 40 and 69% yields after the usual work-up, respectively.

3) Reaction of **1a** (1.69 g, 6.20 mmol) with benzaldehyde (1.24 ml, 12.2 mmol) in the presence of freeze dry KF (0.71 g, 12.2 mmol) in refluxing acetonitrile (40 ml) afforded 0.58 g (57%) of (*E*)-**3a**.

4) To a solution of **1a** (0.43 g, 1.59 mmol) and benzaldehyde (0.32 ml, 3.18 mmol) in THF (18 ml) was added dropwise commercially available tetrabutylammonium fluoride (TBAF)(1 M THF solution, 1.91 ml) at room temperature. Stirring was continued for 2.5 h. In the ^{31}P NMR spectrum of the reaction mixture two peaks were

observed at δ_P=27.7 and 0.87 in almost same ratio, which can be assignable to the signals due to **2a** and tetrabutylammonium dimethyl phosphate, respectively. The usual work-up afforded a mixture of (*E*)- and (*Z*)-**3a** (0.168 g, 65%) and crude **2a** (0.128 g, 44%). The ratio of (*E*)- to (*Z*)-stilbene was determined to be 90:10 by ^{1}H NMR spectroscopy.[10]

5) A mixture of benzaldehyde (0.41 ml, 4.06 mmol), TBAF (1 ml, 1 mmol), and molecular sieves 4A (1 g) in THF (5 ml) was stirred overnight at room temperature. To the suspension was added a solution of **1a** (0.54 g, 1.98 mmol) in THF (15 ml), and the mixture was stirred for 3.5 h at room temperature. The usual work-up afforded (*E*)- and (*Z*)-**3a** (0.085 g, 26%) in the same ratio and crude **2a** (0.30 g, 80%).

6) A mixture of benzaldehyde (0.41 ml, 4.06 mmol), tetramethylammonium fluoride (TMAF) (0.372 g, 4.00 mmol), and **1a** (0.368 g, 1.35 mmol) in THF (15 ml) was stirred for 1.5 h at room temperature. The usual work-up gave (*E*)- and (*Z*)-**3a** in 30% yield. The ratio of (*E*)- and (*Z*)-**3a** was 90:10.

Reaction of Dimethyl α-Trimethylsilylbenzylphosphonate (1a) with Other Carbonyl Compounds in the Presence of CsF. Benzophenone. Cesium fluoride (0.410 g, 2.70 mmol) was dried in a 30 ml two-necked flask as described above, and a solution of dry benzophenone (0.729 g, 4.00 mmol) in THF (18 ml) and **1a** (0.518 g, 1.90 mmol) were added into the flask, and then the mixture was refluxed for 5 h and stirred at 50 °C overnight. The usual work-up gave a mixture (0.870 g) of 1,1,2-triphenylethylene (**3b**), **2a**, and unreacted benzophenone, which was subjected to DCC (SiO_2, CCl_4) to afford **3b** (0.385 g, 79%) as a viscous oil. ^{1}H NMR ($CDCl_3$) δ=6.87 (1H, s, C=C<u>H</u>Ph), 6.97 (5H, s, Ph), and 7.06—7.40 (10H, m, 2×Ph).

Acetophenone. In a 30 ml two-necked flask was weighted CsF (0.790 g, 5.20 mmol), dried as described above. After subsequent addition of acetophenone (0.49 ml, 4.21 mmol), THF (20 ml), and **1a** (0.490 g, 1.80 mmol), the mixture was refluxed overnight. The usual DCC (SiO_2, CCl_4) afforded a mixture of (*E*)- and (*Z*)-1,2-diphenylpropenes (**3c**) (0.234 g, 67%) as a colorless oil. (*E*)-**3c**: ^{1}H NMR ($CDCl_3$) δ=2.19 (3H, d, J=1.5 Hz, =CC<u>H</u>$_3$), 6.46 (1H, q, J=1.5 Hz, =C<u>H</u>Ph), and 6.90—7.62 (10H, m, Ph). (*Z*)-**3c**: ^{1}H NMR ($CDCl_3$) δ=2.26 (3H, d, J=1.2 Hz, =CC<u>H</u>$_3$), 6.83 (1H, q, J=1.2 Hz, =C<u>H</u>Ph), and 6.90—7.62 (10H, m, Ph). The ratio of (*E*)- and (*Z*)-**3c** was determined to be 1:3 from the integral ratio between the doublet at δ 2.26 due to E-isomer and the doublet at δ 2.19 due to Z-isomer.[11]

Cyclohexanone. In a 30 ml two necked flask was placed CsF (0.544 g, 3.65 mmol), and dried. Into the flask were added cyclohexanone (0.50 ml, 4.83 mmol), THF (20 ml), and **1a** (0.681 g, 2.50 mmol), and the mixture was refluxed for 5 h, and then it was stirred at 50 °C overnight. The residue obtained after the usual work-up was submitted to DCC (SiO_2, CCl_4) to give 0.146 g (35%) of benzylidenecyclohexane (**3d**). ^{1}H NMR ($CDCl_3$) δ=1.37—1.87 (6H, m, -CH_2-(C<u>H</u>$_2$)$_3$-CH_2-), 2.01—2.47 (4H, m, -C<u>H</u>$_2$-(CH_2)$_3$-C<u>H</u>$_2$-), 6.10 (1H, br s, =C<u>H</u>Ph), and 6.90—7.40 (5H, m, Ph).

Isobutyraldehyde. Cesium fluoride (0.55 g, 3.62 mmol) was dried, mixed with isobutyraldehyde (0.55 ml, 6.06 mmol), THF (30 ml), and **1a** (0.561 g, 2.06 mmol) and the mixture was refluxed for 5.5 h. The reaction mixture was treated as described above to give 0.535 g of an oil which was subjected to DCC (SiO_2, CCl_4) to afford a mixture of (*E*)- and (*Z*)-3-methyl-1-phenyl-1-butenes (**3e**) (0.10 g, 35%). (*E*)-**3e**: ^{1}H NMR ($CDCl_3$) δ=1.07 (6H, d, J=6.6 Hz, CH(C<u>H</u>$_3$)$_2$), 2.18—2.67 (1H, m, C<u>H</u>(CH_3)$_2$), 6.12 (1H, dd, J=5.4, 16 Hz, =C<u>H</u>CH(CH_3)$_2$), 6.36 (1H, d, J=16 Hz, =C<u>H</u>Ph), 6.9—7.6 (5H, m, Ph). (*Z*)-**3e**: ^{1}H NMR ($CDCl_3$) δ=1.02 (6H, d, J=6.6 Hz, CH(C<u>H</u>$_3$)$_2$), 2.67—3.14 (1H, m, C<u>H</u>(CH_3)$_2$), 5.44 (1H, dd, J=10.0, 11.5 Hz, =C<u>H</u>CH(CH_3)$_2$), 6.29 (1H, d, J=11.5 Hz, =C<u>H</u>Ph), and 6.9—7.6 (5H, m, Ph). The ratio of (*E*)- and (*Z*)-**3e** was determined to be 70:30 from the integral ratio of the doublet at δ 1.07 due to E-isomer to the doublet at δ 1.02 due to Z-isomer.

Cinnamaldehyde. A mixture of **1a** (0.675 g, 2.48 mmol), cinnamaldehyde (0.73 ml, 5.80 mmol), and CsF (0.75 g, 4.94 mmol) in THF (25 ml) was refluxed overnight. After removal of the solvent the residue was treated with water and extracted several times with dichloromethane. The extracts were combined, dried over anhydrous $MgSO_4$, and then the solvent was evaporated. The residue was subjected to DCC (SiO_2, CCl_4) to afford (*E*,*E*)-1,4-diphenyl-1,3-butadiene (**3f**) (0.326 g, 67%). Mp 151—152 °C (EtOH) (lit,[19] 152—153 °C).

Reaction of Trimethylsilylmethylphosphonic Derivatives (1b—d) with Benzophenone in the Presence of CsF. Dimethyl Trimethylsilymethylphosphonate (1b). A mixture of CsF (0.744 g, 4.90 mmol), dried as described above, benzophenone (1.35 g, 7.40 mmol), **1b** (0.420 g, 2.14 mmol), and THF (20 ml) was refluxed for 1 d with stirring. The usual work-up afforded 1,1-diphenylethylene (**3g**), dimethyl 2,2-diphenylethenylphosphonate (**4a**), and dimethyl methylphosphonate (**2b**) in 20, 30, and 50% yields, respectively. **4a**: ^{1}H NMR ($CDCl_3$) δ=3.49 (6H, d, J=11 Hz, P(OC<u>H</u>$_3$)$_2$), 6.18 (1H, d, J=15 Hz, =C<u>H</u>), and 7.3—7.5 (10H, m, 2×Ph). ^{31}P NMR ($CDCl_3$) δ_P=19.32. HRMS: *m/z* Found: 288.0913. Calcd for $C_{16}H_{17}O_3P$: 288.0914.

Trimethylsilylmethylphosphonic Bis(diethylamide) (1c). A mixture of CsF (0.559 g, 3.68 mmol), benzophenone (0.399 g, 2.19 mmol), and **1c** (0.381 g, 1.37 mmol) in THF (20 ml) was refluxed overnight to give methylphosphonic bis(diethylamide) (**2c**) almost quantitatively after usual work-up.

***O,O*-Diethyl Trimethylsilylmethylphosphonothioate (1d).** A mixture of CsF (0.577 g, 3.80 mmol), benzophenone (0.292 g, 1.60 mmol), and **1d** (0.250 g, 1.05 mmol) in THF (20 ml) was refluxed overnight. The usual work-up afforded **3g**, *O,O*-diethyl 2,2-diphenylethenylphosphonothioate (**4b**), and *O,O*-diethyl methylphosphonothioate (**2d**) in 30, 25, and 42% yields, respectively, from analysis of ^{1}H NMR and ^{31}P NMR spectra of the mixture. **4b**: Bp 175 °C/0.05 Torr. ^{1}H NMR ($CDCl_3$) δ=1.08 (6H, t, J=7.1 Hz, C<u>H</u>$_3$), 3.51—4.19 (4H, m, OC<u>H</u>$_2$), 6.36 (1H, d, J=20.3 Hz, =C<u>H</u>), 7.25 (5H, br s, Ph), and 7.35 (5H, br s, Ph). ^{31}P NMR ($CDCl_3$) δ_P=80.16. HRMS: *m/z* Found: 332.1008. Calcd for $C_{18}H_{21}O_2PS$: 332.1000.

Reaction of Dimethyl 2,2-Diphenyl-2-(trimethylsiloxy)-ethylphosphonate (9) with CsF. A mixture of CsF (0.749 g, 4.93 mmol) and **9** (0.867 g, 2.29 mmol) in THF (20 ml) was refluxed for 3 d. The usual work-up gave 1,1-diphenylethylene (0.351 g) in 85% yield.

Reaction of Dimethyl α-Lithiobenzylphosphonate with Acetophenone. To a solution of dimethyl benzylphosphonate (**2a**) (0.544 g, 2.72 mmol) in THF (20 ml) was added *n*-BuLi (2.0 ml, 1.64 M) at −78 °C. After 5 min a

solution of acetophenone (0.63 ml, 2.0 equiv) in THF (5 ml) was added to the solution at the same temperature and the reaction mixture was allowed to warm to room temperature, and then was stirred for 1 d. The usual work-up gave 0.856 g of crude mixture, which was chromatographed on silica gel (DCC, CCl_4) to give 0.043 g (8.1%) of **3c**.

The authors wish to express their thanks to Miss Toshiko Seki and Mrs. Kimiyo Saeki, who made the elemental analyses. They also thank to Shinetsu Kagaku Co. for a gift of chlorotrimethylsilane. The present work was partially supported by a Grant-in-Aid for Scientific Research No. 61540365 from the Ministry of Education, Science and Culture.

α,β-Epoxy Sulfoxides as Useful Intermediates in Organic Synthesis. X.[1] An Improved Synthesis of α,β-Unsaturated Carbonyl Compounds from Carbonyl Compounds with Carbon Homologation through α,β-Epoxy Sulfoxides

Tsuyoshi SATOH, Masayuki ITOH, Teruhiko OHARA, and Koji YAMAKAWA*
Faculty of Pharmaceutical Sciences, Science University of Tokyo,

(Received November 17, 1986)

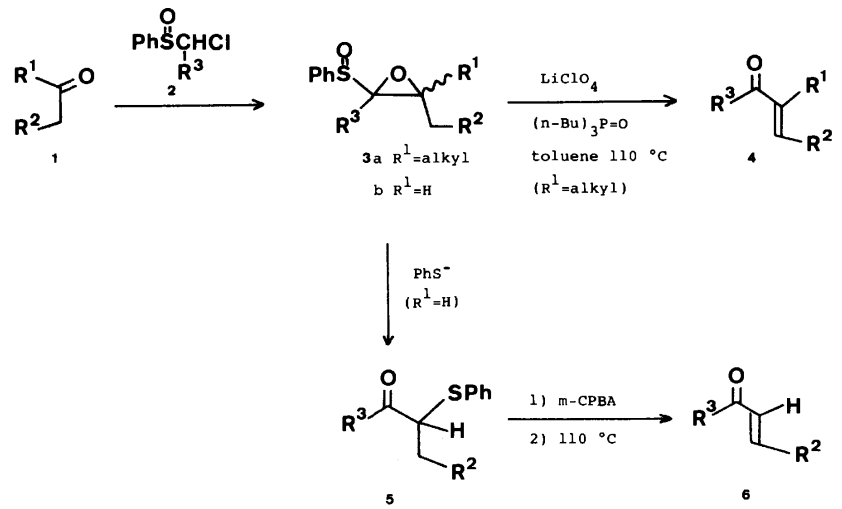
Treatment of the α,β-epoxy sulfoxides derived from **ketones** and chloromethyl phenyl sulfoxide or 1-chloroalkyl phenyl sulfoxides with lithium perchlorate in the presence of tributylphosphine oxide in toluene at 110 °C for about 1—3 h gave α,β-unsaturated aldehydes or α,β-unsaturated ketones in high yields. In contrast to these results, the α,β-epoxy sulfoxides derived from **aldehydes** did not give the desired α,β-unsaturated ketones. In this case, a sequential treatment of the α,β-epoxy sulfoxides with benzenethiolate and *m*-chloroperbenzoic acid afforded α-phenylsulfinylated ketones, which were heated in toluene at 110 °C to give the desired enones in good overall yields. The oxidation of the α,β-unsaturated aldehydes obtained by this method gave α,β-unsaturated carboxylic acids in high yields. These procedures afforded a new method for the synthesis of α,β-unsaturated carbonyl compounds, including α,β-unsaturated esters, from carbonyl compounds with carbon homologation.

The statement made by Roberts and Caserio[2] ("the chemistry of carbonyl compounds is virtually the backborn of synthetic organic chemistry") clearly indicates that carbonyl compounds, including α,β-unsaturated types, are of most importance in synthetic organic chemistry. Especially, α,β-unsaturated carbonyl compounds are quite useful in various synthetic reactions such as the Diels–Alder reaction[3] and Michael-type reactions.[4] Almost an uncountable numbers of methods for the preparation of carbonyl compounds have already been reported; however, as a consequence of the usefulness of carbonyl compounds, the exploration of a new procedure for their syntheses from readily available precursors is always welcome.

Recently, we reported[5] a new and useful method for the syntheses of various kinds of carbonyl compounds by the homologation of carbonyl compounds through α,β-epoxy sulfoxides (**3**). In the course of our studies on new synthetic method from carbonyl compounds **1** through α,β-epoxy sulfoxides (**3**)[6] we report here on a new and simple procedure for the synthesis of α,β-unsaturated ketones and α,β-unsaturated aldehydes from carbonyl compounds **1** with carbon homologation. These procedure are shown in Scheme 1.

Results and Discussion

A Synthesis of α,β-Unsaturated Ketones and α,β-Unsaturated Aldehydes from Ketones through α,β-Epoxy Sulfoxides. Before our first publication in 1984[7] only two kinds of synthetic methods through α,β-epoxy sulfoxides had been reported: One was a thermal reaction resulting in α,β-unsaturated carbonyl compounds,[8] and the other was a rearrangement of sulfinyl group with Lewis acids, such as $BF_3 \cdot Et_2O$, giving α-sulfinylated ketones.[9] These reactions, themselves, are quite interesting; unfortunately, the yields were not satisfactory for the

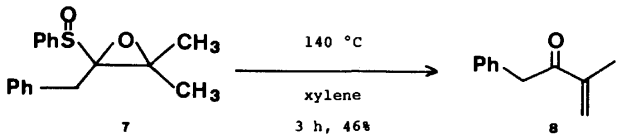


Scheme 1.

practical use in synthetic organic reactions. In fact, in our reexamination, upon heating in xylene at 140 °C for 3 h, the α,β-epoxy sulfoxide (**7**) gave a brown mixture in which the desired enone **8** was obtained in only 46% yield. On the other hand, a treatment of **7** with $BF_3 \cdot Et_2O$ in CH_2Cl_2 at room temperature for 4 h gave only a complex mixture.

We thought that a treatment of α,β-epoxy sulfoxides **3** with a weak Lewis acid under heating resulted in a sulfinyl group rearrangement followed by a thermal elimination of the rearranged sulfinyl group to afford the desired α,β-unsaturated carbonyl compounds under relatively mild conditions. First of all, we started to find the appropriate weak Lewis acid under heating (a temperature around refluxing benzene) by using the α,β-epoxy sulfoxide **7** as a substrate (Table 1). As shown in Table 1, aluminum, titanium, and magnesium alkoxides were not effective for this reaction; finally, lithium perchlorate in the presence of one equivalent of tributylphosphine oxide[10] was found to be quite effective for the desired reaction. This reaction was rather sluggish in refluxing benzene but in toluene at 110 °C the reaction took place quite smoothly and cleanly to afford the desired enone **8** in 74% yield. These conditions were used throughout this study.

The results of the preparation of α,β-unsaturated carbonyl compounds from ketones via α,β-epoxy sulfoxides upon a treatment with lithium perchlorate in toluene at 110 °C (the temperature of the oil bath used) are summarized in Table 2. The remarkable characteristics of the presented procedure are as follows: a) The yields are uniformly quite good except the result in Entry 8; b) the conditions were neutral, and the temperature of the reaction was much lower than that previously reported,[8] and the reaction time was less than 3 h; c) the reaction mixture was quite clean except the result in Entry 8; d) in Entry 8, though some by-products were observed, because of the mildness of the conditions, no double-bond migration giving conjugated divinyl ketone occured; e) usually, but not always, the reactions giving α,β-unsaturated aldehydes tended to proceed faster than those giving α,β-unsaturated ketones (Entries 10—14).



Scheme 2.

A Synthesis of α,β-Unsaturated Ketones from Aldehydes through α,β-Epoxy Sulfoxides. In contrast to the good results mentioned above a treatment of the α,β-epoxy sulfoxides **3b**, derived from aldehydes and **2**, with lithium perchlorate under the same conditions used above, did not give any good results. The reaction was very sluggish and prolonged heating resulted in a complex mixture. The reason for this results may be interpreted as being a stability problem involving a secondary carbocation[10] of the inter-

Table 1. Treatment of **7** with Weak Lewis Acid under Heating

Lewis Acid	Temp °C	Time	Enone **8**[a] %
$Al(OPr^i)_3$	83[b]	8 h	20

12	$[CH_3(CH_2)_3]_2CO$	H	1 h	 **19**	85
13		H	50 min	 **20**	98
14		H	2 h	 **21**[11]	88

a) Isolated purified yield after silica-gel column chromatography.

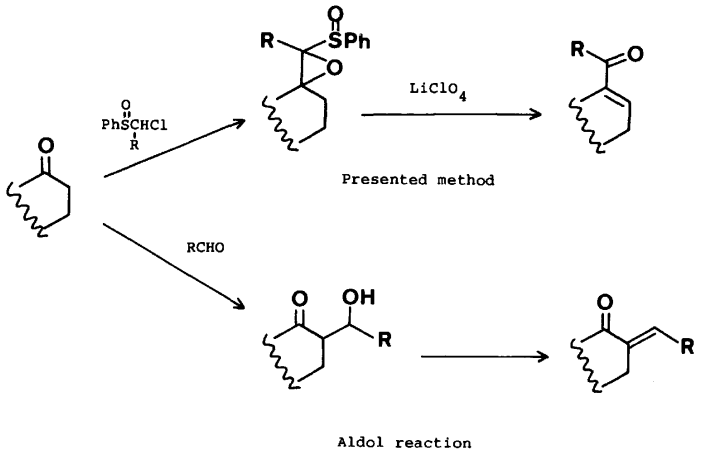
mediate (**22**). In the case of the α,β-epoxy sulfoxides derived from ketones, the cationic intermediate was tertiary, which may proceed to a rearrangement followed by a thermal elimination to afford α,β-unsaturated carbonyl compounds **4**. It is noteworthy that the α,β-epoxy sulfoxide having a phenyl group at the β position **24**, in which the carbocationic intermediate is thought to be stabilized by a phenyl ring, still did not give the rearranged product **25**.

This difficulty regarding the preparation of enones from α,β-epoxy sulfoxides could be overcome by taking another route (shown in Scheme 1). As already reported by us,[5b] the treatment of **3b** with benzenethiolate gave α-phenylthio ketones (**5**) in excellent yields. The sequential oxidation of **5** and the elimination of the resultant sulfoxide[12] must give the desired enone **6**.

Three example are listed in Table 3. Though two more steps were required, compared to the method described above, the overall yields from α,β-epoxy sulfoxides were equally good.

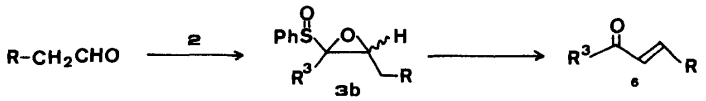
Here, we should like to describe the interesting characteristic of the presented procedure. As shown in Scheme 4, the famous aldol reaction affords α,β-unsaturated carbonyl compounds from carbonyl compounds with a carbon-chain elongation at the α-position of the carbonyl group. In contrast to this, the presented procedure gives α,β-unsaturated carbonyl compounds with a carbon-chain elongation from the carbonyl carbon itself.

An Application of This Method to a Synthesis of α,β-Unsaturated Esters from Ketones by One-Carbon Homologation. α,β-Unsaturated esters have received considerable attention for a long time in synthetic



Scheme 4.

Table 3. Preparation of α,β-Unsaturated Ketones from Aldehydes through α,β-Epoxy Sulfoxides



Entry	Aldehyde	R^3 in **2**	α,β-Unsaturated ketone	Yield[a] %
1	$CH_3(CH_2)_8CHO$	$PhCH_2$	 **26**	77
2	$PhCH_2CH_2CHO$	CH_3	 **27**	77
3	$CH_3(CH_2)_4CHO$		 **28**	88

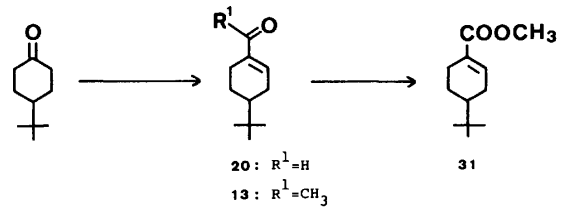
a) Three steps overall yield from the α,β-epoxy sulfoxide. The product was purified by silica-gel column chromatography.

organic chemistry. The Michael-type conjugate addition of various kinds of nucleophiles, especially carbon nucleophiles, to α,β-unsaturated esters is one of the most useful tools for constructing a carbon framework.[13] Recently, a diastereo- and/or enantioselective Michael addition of some enolates to α,β-unsaturated esters was also reported.[14] Several methods for the synthesis of saturated esters from ketones by one-carbon homologation have been reported;[15] however, very few methods for the synthesis of α,β-unsaturated ones from ketones by one-carbon homologation have been published.[16]

With the new method described above in hand, it was anticipated that the desired α,β-unsaturated ester, such as **31**, could be derived from α,β-unsaturated aldehyde **20** or α,β-unsaturated methyl ketone **13** by two types of oxidations: the oxidation of aldehydes to carboxylic acids[17] or the haloform-type oxidation of methyl ketone **13** to carboxylic acid.[18]

Several method for the oxidation of enals to α,β-unsaturated carboxylic acids have been reported;[17] we used the most recent method reported by Dalcanale and Montanari[17c] with a slight modification. The enal **20** was oxidized with sodium chlorite–hydrogen peroxide in *t*-butyl alcohol followed by methylation with diazomethane to afford the desired α,β-unsaturated ester **31** in 89% yield. Parallel to this reaction, several haloform-type oxidations[18] of the methyl ketone **13** were carried out, but it was found that the reaction were quite sluggish and gave only complex mixtures. Table 4 shows the results of the preparation of α,β-unsaturated esters from various kinds of ketones through the α,β-unsaturated aldehydes.

Beacuse of its overall simplicity and high overall yields, we believe that the presented procedure will prove valuable in the preparation of synthetically useful α,β-unsaturated carbonyl compounds.



Scheme 5.

Experimental

All melting points are uncorrected. Infrared (IR) spectra were measured directly on a NaCl plate or in KBr disks with a Hitachi 215 spectrometer. ^{1}H Nuclear magnetic resonance (NMR) spectra were measured in a $CDCl_3$ solution with a JOEL FX-100 spectrometer using Me_4Si as an internal standard. Ultraviolet (UV) spectra were measued in an EtOH solution with a Hitachi 200 spectrometer. Electron-impact mass spectra (MS) were obtained on a Hitachi M-80 double-focusing spectrometer at 70 eV by direct insertion. Silica-gel BW-127 ZH (Fuji-Devison) containing 2% fluoresence reagent 254 and quartz column were used for column chromatography and the products having UV absorption were detected by UV irradiation.

Table 4. Preparation of α,β-Unsaturated Esters from Ketones through α,β-Epoxy Sulfoxides and α,β-Unsaturated Aldehydes

Entry	Ketone	α,β-Unsaturated aldehyde/%[a]	α,β-Unsaturated ester	Yield[b] %
1	$CH_3(CH_2)_5\overset{O}{\overset{\|}{C}}(CH_2)_5CH_3$	**29** (91)	 **30**	95

α,β-Epoxy Sulfoxides. All α,β-epoxy sulfoxides, except the ones cited below, used in this study were prepared from carbonyl compounds and **2** (R^3=H or alkyl) through chlorohydrins nearly quantitative yields, which were reported previously.[5] α,β-Epoxy sulfoxides in Table 2; Entry 6: Colorless oil; IR (Neat) 1090, 1055 (SO) cm^{-1}; ^1H NMR δ=0.91 (9H, s), 1.30 (3H, s), 7.4—7.7 (5H, m); MS *m/z* (%) 307 ($[M+H]^+$, 0.7), 181 ($[M-PhSO]^+$, 64), 43 (100). Entry 7: Colorless prisms; mp 155—157 °C (AcOEt-hexane); IR (KBr) 1055 (SO) cm^{-1}; ^1H NMR δ=1.37 (3H, s), 2.97, 3.35, 3.47, 3.97 (each 1H, d, *J*=18 Hz), 7.21 (4H, bs), 7.40—7.75 (5H, m); Found: C, 71.74; H, 5.68; S, 11.43%. Calcd for $C_{17}H_{16}O_2S$: C, 71.80; H, 5.67; S, 11.25%. Entry 9: Colorless needles; mp 164—165 °C (hexane-MeOH); IR (KBr) 1055 (SO) cm^{-1}; ^1H NMR δ=0.66 (3H, s), 0.87 (6H, d, *J*=7 Hz), 0.98 (3H, d, *J*=7 Hz), 1.01 (3H, s), 1.28 (3H, s), 7.36—7.72 (5H, m); Found: C, 78.09; H, 10.25; S, 6.12%. Calcd for $C_{35}H_{54}O_2S$: C, 78.01; H, 10.10; S, 5.95%. Entry 11: Colorless oil; IR (neat) 1085, 1.40 (SO) cm^{-1}; ^1H NMR δ=1.32—2.24 (14H, m), 3.68 (1H, s), 7.4—7.7 (5H, m). Entry 12: Colorless oil: IR (neat) 1055 (SO) cm^{-1}; ^1H NMR δ=3.60 (1H, s), 7.3—7.8 (5H, m). Entry 13: Colorless crystals; mp 91—93 °C (recrystallized from EtOH); IR (KBr) 1050 (SO) cm^{-1}; ^1H NMR δ=0.91 (9H, s), 3.65 (1H, d, *J*=1 Hz), 7.40—7.70 (5H, m); MS *m/z* (%): 292 (M^+, 0.2), 167 ($[M-PhSO]^+$, 26), 126 (83), 57 (100); Found: C, 69.77; H, 8.39; S, 10.97%. Calcd for $C_{17}H_{24}O_2S$: C, 69.82; H, 8.27; S, 10.96%. Entry 14: Colorless needles; mp 97—98 °C (recrystallized from benzene-hexane); IR (KBr): 1085, 1045, 1040 (SO) cm^{-1}; ^1H NMR δ=1.10—2.32 (22H, m), 3.62 (1H, d, *J*=1 Hz), 7.38—7.76 (5H, m); MS *m/z* (%): 195 ($[M-PhSO]^+$, 26), 126 (100); Found: C, 71.40; H, 9.04; S, 10.14%. Calcd for $C_{19}H_{28}O_2S$: C, 71.21; H, 8.81; S, 10.00%. α,β-Epoxy sulfoxides in Table 3; Entry 1: Colorless oil; IR (neat) 1090, 1055 (SO) cm^{-1}; ^1H NMR δ=0.98 (3H, bt, *J*=6 Hz), 3.00, 3.05 (each 1H, d, *J*=16 Hz, benzyl-H), 3.70 (1H, t, *J*=6 Hz), 7.00—7.24, 7.36—7.64 (each 5H, m). Entry 2: Colorless oil; IR (neat) 1085, 1045 (SO) cm^{-1}; ^1H NMR δ=1.23 (3H, s), 3.61 (1H, t, *J*=7 Hz), 7.04—7.32, 7.38—7.70 (each 5H, m). α,β-Epoxy sulfoxide in Table 4; Entry 1: Coloress oil; IR (neat) 1055 (SO) cm^{-1}; ^1H NMR δ=3.65 (1H, s), 7.40—7.72 (5H, m); MS *m/z* (%): 211 ($[M-PhSO]^+$, 30), 126 (100).

3-Methyl-1-phenyl-3-buten-2-one (8). A solution of **7** (69 mg; 0.24 mmol) in xylene (3 ml) was heated at reflux for 3 h under N_2 atmosphere. The mixture was diluted with benzene and washed with sat. aq NH_4Cl. The solvent was evaporated and the residue was purified by silica-gel column chromatography (hexane:AcOEt=40:1) to give 18 mg (46%) of **8** as a pale yellow oil. IR (neat) 1670 (CO) cm^{-1}; ^1H NMR δ=1.87 (3H, m), 3.98 (2H, s), 5.79 (1H, m), 6.04 (1H, m), 7.0—7.4 (5H, m); UV λ_{max} 218 nm; MS *m/z* (%) 160 (M^+, 38), 91 ($[M-C_4H_5O]^+$, 59), 69 ($[M-PhCH_2]^+$, 100).

Treatment of 7 with Aluminum Isoproposide. Aluminum isopropoxide (161 mg; 0.79 mmol) was dissolved in 2 ml of isopropyl alcohol; to this was added a solution of **7** (120 mg; 0.42 mmol) in 1 ml of isopropyl alcohol and the reaction mixture was stirred and refluxed for 8 h. The reaction mixture was diluted with AcOEt and washed with sat. qa NH_4Cl. After the usual workup, the product was purified by silica-gel column chromatography to give 14 mg (20%) of **8** as a pale yellow oil.

General Procedure for the Preparation of α,β-Unsaturated Ketones and α,β-Unsaturated Aldehydes from α,β-Epoxy Sulfoxides. A typical procedure is described for a synthesis of 1-(1-cyclohexenyl)-2-phenylethanone (**9**). To a solution of $LiClO_4 \cdot 3H_2O$ (32 mg; 0.2 mmol) and $(n\text{-}Bu)_3PO$ (43.6 mg; 0.2 mmol) in 3 ml of toluene was added a solution of 2'-benzyl-2'-(phenylsulfinyl)spiro[cyclohexane-1,1'-oxirane][5a] (65 mg; 0.2 mmol) in 1 ml of toluene. The mixture was stirred and heated at 110 °C (the temperature of the oil bath used) under a N_2 atmosphere until all the α,β-epoxy sulfoxide was consumed (2.5 h). The solution was cooled to room temperature and diluted with benzene. The whole mixture was washed once with sat. aq NH_4Cl and dried over Na_2SO_4. The solvent was evaporated under reduced pressure and the reside was purified by silica-gel column chromatography (hexane:AcOEt=20:1) to give 39 mg (98%) of **9** as a colorless oil. IR (neat) 1685 (CO), 1640 (C=C) cm^{-1}; ^1H NMR δ=1.60 (4H, m), 2.23 (4H, m), 3.92 (2H, s), 6.98 (1H, m), 7.0—7.3 (5H, m); UV λ_{max} 233.5 nm; MS *m/z* (%): 200 (M^+, 4), 186 ($[M-CH_2]^+$, 5), 109 ($[M-PhCH_2]^+$, 100).

1-(1-Cyclohexenyl)-2-(4-methoxyphenyl)ethanone (10). Colorless needles (AcOEt-hexane); mp 106—108 °C; IR (KBr): 1675 (CO), 1645, 1625 (C=C) cm^{-1}; ^1H NMR δ=1.60 (4H, m), 2.22 (4H, m), 3.76 (3H, s), 3.86 (2H, s), 6.98 (1H, m, vinyl-H), 6.7—7.2 (4H, m); UV λ_{max} 228.5 nm; Found: C, 78.44; H, 7.99%. Calcd for $C_{15}H_{18}O_2$: C, 78.23; H, 7.88%.

1-(1-Cyclohexenyl)-1-heptanone (11). Colorless oil; IR (neat) 1675 (CO), 1645 (C=C) cm^{-1}; ^1H NMR δ=0.88 (3H, bt, *J*=7 Hz), 2.04—2.36 (4H, m), 2.60 (2H, t, *J*=8 Hz), 6.85 (1H, m, vinyl-H); UV λ_{max} 234 nm; MS *m/z* (%) 194 (M^+, 20), 124 ($[M-C_5H_{10}]^+$, 72), 109 ($[M-C_6H_{13}]^+$, 100); Found: *m/z* 194.1672. Calcd for $C_{13}H_{22}O$: M, 194.1669.

Cyclohexyl 1-Cyclohexenyl Ketone (12). Colorless oil; IR (neat) 1660 (CO), 1635 (C=C) cm^{-1}; ^1H NMR δ=6.83 (1H, m, vinyl-H), UV λ_{max} 234.5 nm; MS *m/z* (%) 192 (M^+, 21), 163 ($[M-C_2H_5]^+$, 3), 109 ($[M-C_6H_{11}]^+$, 100); Found: *m/z* 192.1524. Calcd for $C_{13}H_{20}O$: M, 192.1513.

1-Acetyl-1-(4-*t*-butyl)cyclohexene (13). Colorless oil; IR (neat) 1675 (CO), 1655 (C=C) cm^{-1}; ^1H NMR δ=0.89 (9H, s), 2.27 (3H, s), 6.86 (1H, m); UV λ_{max} 233.5 nm; MS *m/z* (%) 180 (M^+, 70), 165 ($[M-CH_3]^+$, 21), 123 ($[M-C_4H_9]^+$, 61), 43 (100).

2-Acetyl-1*H*-indene (14). Colorless crystals (Et_2O-hexane); mp 56—58 °C; IR (KBr) 1660 (CO) cm^{-1}; ^1H NMR δ=2.48 (3H, s), 3.64 2H, d, *J*=2 Hz), 7.20—7.62 (5H, m); UV λ_{max} 233, 239.5, 301 nm; MS *m/z* (%) 158 (M^+, 100), 143 ($[M-CH_3]^+$, 37), 115 ($[M-CH_3CO]^+$, 86).

3-(1-Oxo-3-butenyl)cholestene ($\Delta^{2,3}$-, $\Delta^{3,4}$-mixture) (15). Colorless oil; IR (neat) 1680 (CO), 1640 (C=C) cm^{-1}; ^1H NMR δ=3.43 (2H, m, CH_2=CH-C<u>H_2</u>CO-), 5.03 (1H, m, C<u>H_2</u>=CH-), 5.17 (1H, m, C<u>H_2</u>=CH-), 5.75—6.16 (1H, m, CH_2=C<u>H</u>-), 6.58 (bs, vinyl-H of 4-position), 6.75 (m, vinyl-H of 2-position); From these protones, the ratio of $\Delta^{2,3}$:$\Delta^{3,4}$ could be determined to be 5:6; UV λ_{max} 240 nm; MS *m/z* (%) 438 (M^+, 78), 397 ($[M-C_3H_5]^+$, 100); Found: *m/z* 438.3869. Calcd for $C_{31}H_{50}O$: M, 438.3859.

3-Acetylcholestene ($\Delta^{2,3}$-,$\Delta^{3,4}$-mixture) (16). Colorless solid; IR (neat) 1675 (CO), 1645 (C=C) cm^{-1}; ^1H NMR δ=2.27, 2.29 (each s, CH_3CO), 6,56 (bs, vinyl-H of 4-position); From these protones the ratio of $\Delta^{2,3}$:$\Delta^{3,4}$ could

be determined to be 4:5; UV λ_{max} 238 nm; MS *m/z* (%) 412 (M^+, 100), 397 ($[M-CH_3]^+$, 10), 369 ($[M-CH_3CO]^+$, 7); Found: *m/z* 412.3685. Calcd for $C_{29}H_{48}O$: M, 412.3702.

3-Formylcholestene ($\Delta^{2,3}$-, $\Delta^{3,4}$-mixture) (17). A mixture of $\Delta^{2,3}$- and $\Delta^{3,4}$-enal in a ratio of 2:5. Colorless solid; IR (KBr) 1680 (CO), 1655 (C=C) cm^{-1}; ^1H NMR δ=6.48 (bs, vinyl-H), 6.66 (m, vinyl-H), 9.36, 9.38 (each s, CHO); UV λ_{max} 233.5 nm; MS *m/z* (%) 398 (M^+, 100), 383 ($[M-CH_3]^+$, 13), 315 ($[M-C_5H_7O]^+$, 25); Found: *m/z* 398.3553. Calcd for $C_{28}H_{46}O$: M, 398.3546.

5-Formyl-4-nonene (19). Colorless oil; IR (neat) 2730 (CHO), 1700 (CO), 1650 (C=C) cm^{-1}; ^1H NMR δ=2.00—2.48 (4H, m), 6.41 (1H, t, *J*=7 Hz, vinyl-H), 9.32 (1H, s, CHO); UV λ_{max} 229.5 nm; MS *m/z* (%) 154 (M^+, 73), 139 ($[M-CH_3]^+$, 12), 125 ($[M-C_2H_5]^+$, 26), 111 ($[M-C_3H_7]^+$, 100).

4-*t*-Bultyl-1-cyclohexene-1-carbaldehyde (20). Colorless oil; IR (neat) 1690 (CO), 1650 (C=C) cm^{-1}; ^1H NMR δ=0.91 (9H, s), 6.78 (1H, m), 9.37 (1H, s); UV λ_{max} 231.5 nm; MS *m/z* (%) 166 (M^+, 18), 123 (21), 110 (71), 57 (100).

General Procedure for the Preparation of α,β-Unsaturated Ketones from the α,β-Epoxy Sulfoxides Derived from Aldehydes. A typical procedure is described for the synthesis of 1-phenyl-3-dodecen-2-one (**26**). To a solution of $NaBH_4$ (946 mg; 2.5 mmol) in 4 ml of EtOH was added diphenyl disulfide (273 mg; 1.25 mmol); the whole mixture was stirred and refluxed under a N_2 atmosphere for 30 min. The mixture was cooled to room temperature and to this was added 100 mg (0.26 mmol) of 2,3-epoxy-1-phenylsulfinyldodecane (the α,β-epoxy sulfoxide in Table 3, Entry 1); the reaction mixture was stirred at room temperature for 30 min. The reaction was quenched by adding sat. aq NH_4Cl and the EtOH was evaporated under vacuum and the residue was extracted with benzene-ether. The combined organic layer was washed once with sat. aq NH_4Cl, dried and concentrated. The residue was separated by silica-gel column chromatography to afford 98 mg (100%) of 1-phenyl-3-phenylthio-2-dodecanone as a colorless oil. IR (neat) 1705 (CO) cm^{-1}; ^1H NMR δ=0.88 (3H, bt, *J*=7 Hz), 3.67 (1H, t, *J*=7 Hz), 3.83, 3.84 (each 1H, d, *J*=16 Hz), 7.0—7.4 (10H, m). This α-phenylthio ketone (98 mg; 0.26 mmol) was dissolved in 4 ml of CH_2Cl_2 and the solution was cooled to −50 °C. To this was added *m*-CPBA (0.29 mmol) and after being stirred for 10 min, 10% aq NaOH (10 ml) was added. The whole mixture was extracted with CH_2Cl_2 and after the usual workup, the product was purified by silica-gel column chromatography to afford 99.6 mg (99%) of 1-phenyl-3-phenylsulfinyl-2-dodecanone as a colorless oil. IR (neat) 1705 (CO), 1045 (SO) cm^{-1}. This sulfoxide (57.7 mg; 0.15 mmol) was dissolved in 3 ml of toluene and the solution was refluxed under N_2 atmosphere for 15 min. The solvent was evaporated under reduced pressure and the residue was purified by silica-gel column chromatography to afford 30 mg (78%) of the desired enone **26** as a colorless oil. IR (neat) 1690, 1670 (CO), 1630 (C=C) cm^{-1}; ^1H NMR δ=0.88 (3H, bt, *J*=6 Hz), 2.00—2.32 (2H, m), 3.79 (2H, s), 6.09 (1H, dt, *J*=16, 1.5 Hz, vinyl-H), 6.88 (1H, dt, *J*=16, 7 Hz, vinyl-H), 7.04—7.40 (5H, m); UV λ_{max} 226.5 nm; MS *m/z* (%) 258 (M^+, 6), 188 ($[M-C_5H_{10}]^+$, 6), 167 ($[M-PhCH_2]^+$, 100); Found: *m/z* 258.1971. Calcd for $C_{18}H_{26}O$: M, 258.1981.

5-Phenyl-3-penten-2-one (27). α-Phenylthio ketone: Colorless oil; IR (neat) 1705 (CO) cm^{-1}; ^1H NMR δ=1.8—2.2 (2H, m), 2.24 (3H, s), 2.75 (2H, t, *J*=7 Hz), 3.55 (1H, t, *J*=7 Hz), 7.0—7.4 (10H, m); MS *m/z* (%) 270 (M^+, 24), 227 ($[M-CH_3CO]^+$, 4), 166 ($[M-C_8H_8]^+$, 42), 117 ($[M-C_8H_9OS]^+$, 100); Found: *m/z* 270.1090. Calcd for $C_{17}H_{18}OS$: M, 270.1077. α-Phenylsulfinylated ketone: Colorless oil; IR (neat) 1710 (CO), 1085, 1050 (SO) cm^{-1}. The enone **27**: Colorless oil; IR (neat) 1670 (CO), 1625 (C=C) cm^{-1}; ^1H NMR δ=2.23 (3H, s), 3.53 (2H, dd, *J*=7, 1.5 Hz), 6.03 (1H, dt, *J*=16, 1.5 Hz), 6.88 (1H, dt, *J*=16, 7 Hz), 7.0—7.4 (5H, m); UV λ_{max} 219 nm; MS *m/z* (%) 161 ($[M+H]^+$, 97), 126 (28), 117 ($[M-CH_3CO]^+$, 28), 91 ($[M-C_4H_5O]^+$, 100).

1-Cyclohexyl-2-hepten-1-one (28). α-Phenylthio ketone; see Ref. 5b. α-Phenylsulfinylated ketone: Colorless oil; IR (neat) 1700 (CO), 1085, 1050 (SO) cm^{-1}. The enone **28**: Colorless oil; IR (neat) 1695, 1670 (CO), 1635 (C=C) cm^{-1}; ^1H NMR δ=0.91 (3H, bt, *J*=6.5 Hz), 2.00—2.32 (2H, m), 2.54 (1H, m), 6.10 (1H, dt, *J*=15.5, 1.5 Hz), 6.82 (1H, dt, *J*=15.5, 7 Hz); UV λ_{max} 228.5 nm; MS *m/z* (%): 194 (M^+, 3), 137 ($[M-C_4H_9]^+$, 69), 111 ($[M-C_6H_{11}]^+$, 100); Found: *m/z* 194.1673. Calcd for $C_{13}H_{22}O$: M, 194.1670.

(*Z*)-7-Formyl-6-tridecene (29). Colorless oil; IR (neat) 1695 (CO), 1645 (C=C) cm^{-1}; ^1H NMR δ=0.90 (6H, m), 2.00—2.46 (4H, m), 6.40, (1H, t, *J*=7.5 Hz); UV λ_{max} 231.5 nm; MS *m/z* (%): 210 (M^+, 37), 167 (25), 155 (41), 141 (51), 113 (96), 43 (100).

General Procedure for the Preparation of α,β-Unsaturated Esters from α,β-Unsaturated Aldehydes. A typical procedure is described for the synthesis of 4-*t*-butyl-1-(methoxycarbonyl)cyclohexene (**31**). A solution of $NaClO_2$ (85%; 48 mg; 0.45 mmol) in 0.42 ml of H_2O was added dropwise over a period of 2 h to a stirred solution of **20** (49 mg; 0.3 mmol) in *t*-BuOH (0.5 ml), 10 mg of Na_2HPO_4 in 0.12 ml of H_2O and 35 μl of H_2O_2 (35%). The reaction mixture was vigorously stirred at room temperature for 20 h. The reaction was quenched by adding 6 mg of Na_2SO_3; the mixture was acidified with 10% HCl to pH 2 and the whole was extracted with ether. The combined ether layer was dried over Na_2SO_4 and the ether was evaporated. The residue, without further purification, was treated with slight excess CH_2N_2 in ether. The product was purified by silica-gel column chromatography with a mixture of hexane and AcOEt (50:1) as an eluent to give **31** (51 mg; 88%) as a colorless oil; IR (neat) 1720 (CO), 1655 (C=C), 1265 (COC) cm^{-1}; ^1H NMR δ=0.88 (9H, s), 3.70 (3H, s), 6.94 (1H, m); UV λ_{max} 220 nm; MS *m/z* (%) 196 (M^+, 31), 181 ($[M-CH_3]^+$, 6), 153 (19), 140 ($[M-C_4H_8]^+$, 100); Found: *m/z* 196.1455. Calcd for $C_{12}H_{20}O_2$: M, 196.1461.

(*Z*)-7-Methoxycarbonyl-6-tridecene (30). Colorless oil; IR (neat) 1715 (CO), 1640 (C=C), 1275, 1250 (COC) cm^{-1}; ^1H NMR δ=0.89 (6H, m), 2.0—2.4 (4H, m), 3.71 (3H, s), 6.69 (1H, t, *J*=7.5 HZ); UV λ_{max} 218 nm; MS *m/z* (%) 240 (M^+, 34), 209 ($[M-OCH_3]^+$, 9), 197 ($[M-C_3H_7]^+$, 13), 169 ($[M-C_5H_{11}]^+$, 100); Found: *m/z* 240.2092. Calcd for $C_{15}H_{28}O_2$: M, 240.2088.

The Ester 32. A mixture of $\Delta^{2,3}$- and $\Delta^{3,4}$-ester in a ratio of 2:5. Colorless solid; IR (KBr) 1715 (CO), 1675 (C=C), 1265, 1255, 1245 (COC); ^1H NMR δ=3.72 (3H, s), 6.68 (bs, vinyl-H), 6.08 (m, vinyl-H); UV λ_{max} 224 nm; MS *m/z* (%) 428 (M^+, 100), 413 ($[M-CH_3]^+$, 19), 315 (34); Found: *m/z* 428.3641. Calcd for $C_{29}H_{48}O_2$: M, 428.3651.

Photoinduced Substitution Reaction Initiated by Electron-Transfer. Photochemical Reaction of 2,3-Dichloro-1,4-naphthoquinone with Thiophenes

Kazuhiro MARUYAMA* and Hitoshi TAMIAKI
Department of Chemistry, Faculty of Science, Kyoto University, Kyoto 606
(Received November 18, 1986)

Photochemical reaction of 2,3-dichloro-1,4-naphthoquinone (**1**) with thiophenes **2** afforded 2-chloro-3-(2-thienyl)-1,4-naphthoquinones. The reaction might be initiated by the photoelectron transfer from **2** to **1**, resulting in the formation of combined products via recombination of the formed ion radicals $\mathbf{1}^{\cdot-}$ and $\mathbf{2}^{\cdot+}$ by accompanying elimination of chloro and hydro radicals. In the photoreaction, reactivity of **2** was estimated from the observed oxidation potentials of **2** and the calculated electron densities in $\mathbf{2}^{\cdot+}$.

Photoinduced reactions initiated by electron transfer are one of the recent topics. The reactions are attractive from the viewpoints of synthesis and mechanism in organic and bio-reactions.[1] We have already reported several photosubstitution reactions induced by photoelectron transfer; photochemical reactions of 2-halo-1,4-naphthoquinones with olefins[2] and olefin analogues[3] (Scheme 1). In this paper, we report the photoreaction of 2,3-dichloro-1,4-naphthoquinone (**1**) with thiophenes **2** to afford 2-chloro-3-(2-thienyl)-1,4-naphthoquinones **3** which are of interest as precursors of alkylated quinones,[4] and then discuss the reaction pathway.

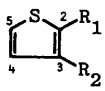
a) Anodic peak potential of **2**, error was within ±0.02 V, vs. ferrocene/ferrocenium ([**2**] = 10^{-3} mol dm^{-3}, [*n*-Bu_4NClO_4] = 0.1 mol dm^{-3}, in CH_2Cl_2, 100 mV s^{-1}, 24 °C). b) Adiabatic first ionization potential of **2**, data of Ref. 8. c) v_{rel} was the value of the initial rate in the formation of **3** relative to that in the formation of **3d** ([**1**] = 10^{-4} mol dm^{-3}, [**2**] = 10^{-3} mol dm^{-3}, in benzene, upon irradiation with light of 313 nm). d) All yields were based on consumed **1**, see Experimental part.

Results and Discussion

Photochemical reaction of quinone **1** with thiophenes **2** generally gave thienylquinones **3** (Table 1). Thiophenes **2a—g** successfully afforded **3a—g**, but the photoreaction of **2h—k** resulted in vain.[5] To explain reactivities of **2**, we tried to measure the oxidation potentials $E_{1/2}$ of **2**. All the thiophenes (**2**) were electrooxidized irreversibly,[6] and their anodic peak potentials E_{pa} are listed in Table 1. The order of their E_{pa} is supposed to be equal to that of their $E_{1/2}$ because the E_{pa} is nearly linear with the ionization potential I_P; $E_{pa}=0.501\ I_P-2.68$ (correlation coefficient =99.8%).[7] As shown in Table 1, thiophenes **2a—g** whose E_{pa} were smaller than 1.7 V reacted with **1** to give **3a—g**, and **2h—k** whose E_{pa} were greater than 1.7 V did not react. In the cases of 3-halothiophenes **2e—g**, the increase in their E_{pa} suppressed their reactivities v_{rel}, the value of the initial rate in the formation of **3** relative to that in the formation of **3d**. When **2d** was added to a benzene solution of **1**, a new absorption band (λ_{max}=422 nm, the formation constant K=0.08 dm^3 mol^{-1} at 22 °C[9]) appeared. In the ground state, thiophene **2d** formed apparently the charge-transfer (CT) complex with **1** absorbing light of wavelengths above 500 nm. Selective irradiation of the CT band (514.5 nm-irradiation, see Experimental part) led to the formation of **3d**. In the initial stage of the reaction, therefore, photoelectron transfer could occur from **2a—g** to **1**.

In order to understand the high regioselectivity in the reactions affording **3a—g** as well as less reactivity of 3-halothiophenes **2e—g**, we calculated the electron densities q in the cation radials of **2** ($\mathbf{2}^{\cdot+}$) formed by the photoelectron transfer process by using Hückel molecular orbital (HMO) method (Table 2). In the cases of **2a—d**, the substitution reaction occurred at the lowest q position. This position is the electron-poorest in $\mathbf{2}^{\cdot+}$, which must be attacked by the anion radical of **1** ($\mathbf{1}^{\cdot-}$) more easily than any other position. On the other hand, in the cases of 3-substituted thiophenes **2e—g**, the lowest q position is crowded with iodo, bromo, and chloro atoms on its neighbouring carbon atom. Such a situation could make attacking by the fairly bulky $\mathbf{1}^{\cdot-}$ difficult, so the substitution occurred at the second lowest q position sterically less hindered. The q values of C-5 atom in the cation radicals of 3-halothiophenes **2e—g** are over

Table 2. Calculated Electron Density q of $\mathbf{2}^{\cdot+}$ [a]



$\mathbf{2}^{\cdot+}$

R_1	R_2		C-2	C-3	C-4	C-5

a) HMO calculation (ω-technique), see Ref. 10. Parenthesis indicates the position which possesses no hydrogen.

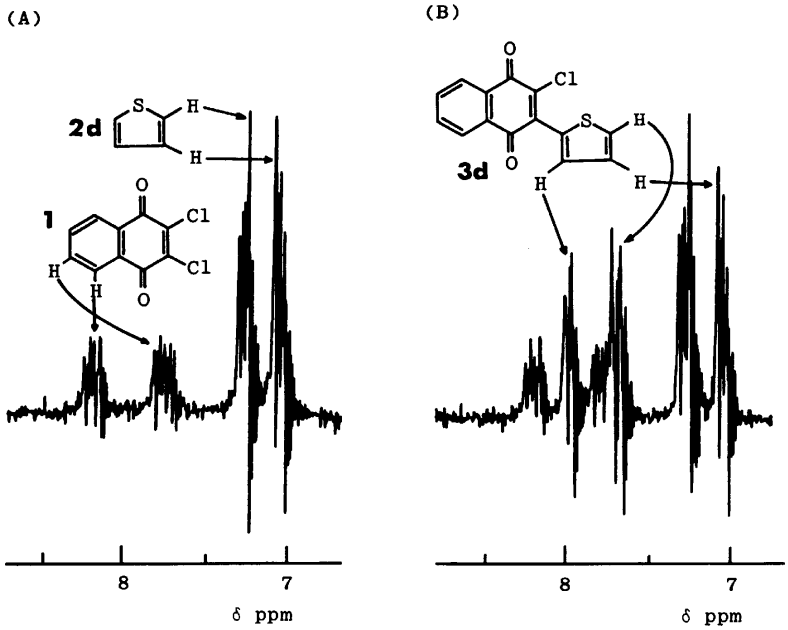

Fig. 1. ^{1}H NMR spectra observed in a CCl_4 solution of **1** and **2d**. (A) In the dark, (B) during irradiation.

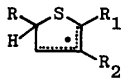
0.69 and greater than those of highly reactive thiophenes **2a—d**. So the relatively high q values of C-5 atom in $\mathbf{2e}^{\ddagger}$, $\mathbf{2f}^{\ddagger}$, and $\mathbf{2g}^{\ddagger}$ might suppress their reactivities. Thus, the experimental results could be clearly explained by simple HMO calculation.



4·

As shown in Fig. 1, in all the cases in which **3** were obtained except for **3a** and **3g**, photo-^{1}H CIDNP signals were observed at the protons in the thienyl moiety of **3**. The polarized patterns indicated that at least the structure of **4·** might exist in the course of the reaction and that all the radical pairs were in the triplet multiplicity.[11]

Under the conditions (see footnote a) in Table 1), the CT state in the ground state was much less than 1% (about 0.08% in **2d**) and the absorption at 313 nm was mainly due to quinone **1**. Upon irradiation with light of 313 nm, the local excitation of **1** was dominant and the CT excitation was negligible. Considering the fact that **1** photoreacted with various olefins via the triplet quenching mechanism,[12] the initially formed singlet excited state of **1** might immediately intersystem-cross to the triplet excited state, where it was quenched by **2** in the ground state to give the ion radical pair $^3(\mathbf{1}^{\cdot-}\cdots\mathbf{2}^{\ddagger})$. Above results lead us to the reaction mechanism in Scheme 2.

Experimental

Apparatus. All melting points were measured with a Yanagimoto micro melting point apparatus and were uncorrected. Ultraviolet and visible spectra were measured with a Shimadzu UV-200 spectrometer. Infrared spectra were measured with a JASCO IRA-1 spectrometer. Normal ^{1}H and ^{13}C NMR spectra were recorded on a JEOL JNM-FX400 instrument; chemical shifts (δ) are expressed in parts per million relative to tetramethylsilane. Mass spectra were measured with a JEOL JMS-DX-300 spectrometer. HPLC analyses were carried out with a Waters liquid chromatograph equipped with a LiChrosorb RP-18 column. The elemental analyses were performed at the Microanalysis Center of Kyoto University.

Materials. Reagent-grade solvents were simply distilled and used except otherwise noted. Quinone **1**, thiophenes **2b—d**, **2f**, and **2h—k** were commercially available and used after distillation. Thiohenes **2a**,[13] **2e**,[14] and **2g**[15] were synthesized according to the procedure in the literature.

Preparation of 2-Chloro-3-(2-thienyl)-1,4-naphthoquinones 3. General Procedure: A benzene solution (700 ml) of **1** (0.7 mmol) and 10 equiv of **2** (7 mmol) was irradiated with a high-pressure mercury arc lamp (300 W) through an aqueous $CuSO_4$ solution filter under argon atmosphere at room temperature. After irradiation for a suitable time (1 h for **3a—d** and **3g**, 3 h for **3e**, and 12 h for **3f**), the starting quinone **1**, thiophene **2**, and the photosubstituted product **3** were isolated by using flash column chromatography on silica gel with hexane and ether as eluents. Recrystallization from dichloromethane and hexane gave a pure sample. All yields were based on consumed **1**.

2-Chloro-3-(5-iodo-2-thienyl)-1,4-naphthoquinone (3a): 78% yield; red needles; mp 151.5—152 °C; UV ($CHCl_3$) 466 nm (ε 5450); IR (KBr) 1660 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=7.37 (1H, d, J=4 Hz, 4-H), 7.74 (1H, d, J=4 Hz, 3-H), 7.77—7.81 (2H, m), and 8.16—8.20 (2H, m); MS (70 eV) m/z (rel intensity) 400, 402 (M^+; 100, 34), 365 (M^+ −Cl; 45), 337 (M^+ −Cl−CO; 21), 273 and 275 (M^+ −I; 37, 18); Found: C, 41.76; H, 1.48; Cl, 8.87; I, 31.76%; M^+, 399.8822 and 401.8796. 2-Chloro-3-(2-thienyl)-1,4-naphthoquinone (3d): 57% yield; red prisms; mp 95 °C; UV ($CHCl_3$) 275 (ε 23000), 320 (50000), and 441 nm (4400); IR (KBr) 1670 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=7.22 (1H, dd, J=4 and 5 Hz, 4-H), 7.73 (1H, dd, J=1 and 5 Hz, 5-H), 7.75—7.79 (2H, m), 7.95 (1H, dd, J=1 and 4 Hz, 3-H), and 8.13—8.18 (2H, m); ^{13}C NMR ($CDCl_3$) δ=181.86 (s), 177.62 (s), 139.68 (s), 138.10 (s), 134.11 (d, C-3), 134.07 (d), 134.02 (d), 132.28 (d, C-5), 131.44 (s), 131.12 (s), 130.91 (s), 127.30 (d), 126.87 (d), and 126.57 (d, C-4); MS (70 eV) m/z (rel intensity) 276, 274 (M^+; 87, 37), 239 (M^+ −Cl; 100), and 211 (M^+ −Cl−CO; 30); Found: C, 60.96; H, 2.43; Cl, 12.78; S, 11.64%; M^+, 273.9856 and 275.9826. Calcd for $C_{14}H_7ClO_2S$: C, 61.21; H, 2.57; Cl, 12.90; S, 11.67%; M, 273.9855 and 275.9826.

2-Chloro-3-(4-iodo-2-thienyl)-1,4-naphthoquinone (3e): 17% yield; red needles; mp 141—143 °C; UV ($CHCl_3$) 444 nm (ε 4060); IR (KBr) 1670 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=7.77 (1H, d, J=1 Hz, 5-H), 7.78—7.82 (2H, m), 7.92 (1H, d, J=1 Hz, 3-H), and 8.16—8.22 (2H, m); MS (70 eV) m/z (rel intensity) 400, 402 (M^+; 100, 30), 365 (M^+ −Cl; 58), 337 (M^+ −Cl−CO; 25), 273, and 275 (M^+ −I; 12, 5); Found: m/z 399.8823 and 401.8791. Calcd for $C_{14}H_6ClIO_2S$: M, 399.8824 and 401.8794.

2-(4-Bromo-2-thienyl)-3-chloro-1,4-naphthoquinone (3f): 5% yield; orange needles; mp 125—127 °C; UV ($CHCl_3$) 433 nm (ε 3960); IR (KBr) 1670 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=7.61 (1H, d, J=1 Hz, 5-H), 7.78—7.82 (2H, m), 7.88 (1H, d, J=1 Hz, 3-H), and 8.16—8.21 (2H, m); MS (70 eV) m/z (rel intensity) 352, 354, 356 (M^+; 73, 100, 30), 317, 319 (M^+ −Cl; 69, 70), 289, 291 (M^+ −Cl−CO; 26, 27), 273, and 275 (M^+−Br; 12, 5); Found: m/z 351.8961, 353.8934, and 355.8916. Calcd for $C_{14}H_6BrClO_2S$: M, 351.8961, 353.8931, 353.8941, and 355.8912.

2-Chloro-3-(4-chloro-2-thienyl)-1,4-naphthoquinone (3g): 2% yield; red needles; mp 143—144 °C; UV ($CHCl_3$) 434 nm (ε 5730); IR (KBr) 1670 cm^{-1} (C=O); ^{1}H NMR ($CDCl_3$) δ=7.51 (1H, d, J=1.5 Hz, 5-H), 7.78—7.83 (2H, m), 7.84 (1H, d, J=1.5 Hz, 3-H), and 8.17—8.21 (2H, m); MS (70 eV) m/z (rel intensity) 308, 310, 312 (M^+; 75, 58, 11), 273, 275 (M^+ −Cl; 100, 35), 245, and 247 (M^+ −Cl−CO; 45, 16); Found: m/z 307.9465, 309.9438, and 311.9412. Calcd for $C_{14}H_6Cl_2O_2S$: M, 307.9466, 309.9436, and 311.9406.

Measurement of v_{rel}. A benzene solution (1 ml) of **1** (0.1 μmol) and **2** (1 μmol) was irradiated with light of 313 nm and sampled at an appropriate interval. The molar quantity of **3** was determined by measuring the area of HPL chromatogram (H_2O-MeOH=1/9) and plotted versus time. The initial rate in the formation of **3** was determined from a slope of the straight line. The value of v_{rel} was obtained by dividing each rate by the rate in the formation of **3d**.

Measurement of E_{pa} of Thiophenes 2. Electrochemical measurement was performed with PAR Model 174 polarographic analyzer, a standard H-cell, glassy carbon (working electrode), and a platinum wire (counter electrode). The solution was 10^{-3} mol dm^{-3} in **2**, in a 0.1 mol dm^{-3} tetrabutylammonium perchlorate-dried dichloromethane solution. All the cyclic voltammograms were recorded at 24 °C under single sweep conditions (scan rate; 100 mV s^{-1}). Anodic peak potentials were corrected vs. ferrocene/ ferrocenium. The peak potentials were measured with an error of ±0.02 V. It was necessary to repeat polishing of the electrode during the experiment, because thiophene polymers and others[6] were frequently adsorbed on the electrode surface.

Examination of CT Excitation. When thiophene **2d** was added to a benzene solution of quinone **1**, color of the solution was turned from pale yellow to pale orange, owing to the formation of the CT complex of **1** with **2d**. In a benzene solution, **1** had no absorption at wavelengths above 500 nm, but the CT complexes had the absorption in the region. For selective irradiation of the CT complex, NEC GLS 3300 Argon ion laser (514.5 nm, 1 W) was used. After irradiating a benzene solution of **1** and **2d** for a few minutes, **3d** was detected by thin-layer chromatography.

Observation of ^{1}H CIDNP Signals. Suitable amounts of **1** and **2** were dissolved in CCl_4, $CDCl_3$, or C_6D_6. The sample was irradiated in a Pyrex glass NMR sample tube with a high-pressure mercury arc projector lamp at room temperature and the ^{1}H NMR signals were recorded before, during, and after irradiation by a JEOL JNM-PS-100 instrument.

We thank Dr. Atsushi Terahara and Mr. Kohji Ichimori, Dr. Satoshi Okazaki and Mr. Kouichi Nozaki, and Mr. Ken Hosoya, Kyoto University, for their help on calculation, measurement of E_{pa}, and HPLC analyses.

Stereoselective Synthesis of (*E*)- or (*Z*)-α-Alkylidene-γ-butyrolactone from γ-Butyrolactone and Bis[ethoxy(thiocarbonyl)] Disulfide and Mechanistic Studies of the Effect of Metal Complexes on the Stereoselection

Syuichi MATSUI
Department of Industrial Chemistry, Fukui Technical College, Geshi, Sabae, Fukui 916
(Received November 25, 1986)

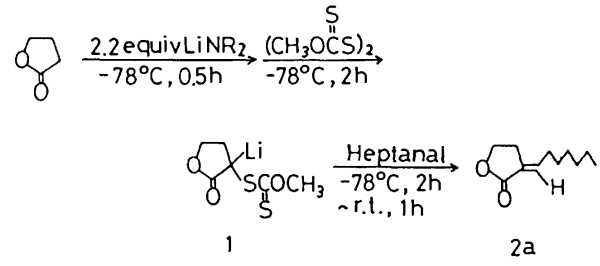
Treatment of γ-butyrolactone with bis[ethoxy(thiocarbonyl)] disulfide in the presence of 2.2 equiv of lithium diisopropylamide (LDA) produced lithium enolate of *O*-ethyl *S*-(tetrahydro-2-oxo-3-furanyl) dithiocarbonate, which reacted with an aldehyde to afford exclusively (*E*)-α-alkylidene-γ-butyrolactone. Interestingly, when the reaction was quenched below −20 °C or when it was carried out in the presence of metal complex such as zinc chloride, copper(I) iodide, or tributyltin chloride, (*Z*)-α-alkylidene-γ-butyrolactone was obtained as the major product. The stereoselectivity of this reaction was sensitive to the reaction temperature and the metal cation employed.

Much attention has been focused on the stereocontrolled synthesis of α-alkylidene-γ-butyrolactones (3-alkylidenedihydro-2(3*H*)-furanone) since these compounds serve as useful intermediates in organic synthesis[1] and constitute the biologically active natural products.[2] In particularly, the general stereoselective synthesis of (*Z*)-α-alkylidene-γ-butyrolactones has been attractive since these compounds can serve as important intermediate in the synthesis of obtusilactone isolated from *Lindela obtusiloba*[3] as cytotoxic natural product. Although several methods have been reported for the direct introduction of an alkylidene group to α position of a γ-butyrolactone.[2,4] there has been no general method for the stereoselective introduction. Recently, the stereoselective synthesis of (*E*)-α-alkylidene-γ-butyrolactones using the monoanion of *O*-ethyl *S*-(tetrahydro-2-oxo-3-furanyl) thiocarbonate, or the dianion of α-mercapto-γ-butyrolactone has been reported by Tanaka et al.[5a] (*E*)- or (*Z*)-α-Alkylidene-γ-butyrolactones can also be synthesized with high stereoselectivity, starting with easily available γ-butyrolactone and bis[methoxy-(thiocarbonyl)] disulfide.[5b] The observation that the presence of metal complex such as zinc chloride, copper(I) iodide, or tributyltin chloride causes a dramatic alternation in the stereoselectivity of the reaction is very interesting.

In this paper the mechanistic aspects of these reaction and the effect of metal complexes on the stereoselection are described in greater detail.

Results and Discussion

One Pot Synthesis of α-Alkylidene-γ-butyrolactones (2) from γ-Butyrolactone. Treatment of γ-butyrolactone with bis[methoxy(thiocarbonyl)] disulfide in the presence of 2.2 equiv of lithium amide at −78 °C in THF gave the lithium enolate **1** which reacted with heptanal to give exclusively (*E*)-α-heptylidene-γ-butyrolactone (**2a**). Among the various lithium amides examined, lithium diisopropylamide (LDA) is the most efficient base for converting γ-butyrolactone into the enolate **1** as shown in Table 1.



1 2a

Generality of this new methodology is apparent from the results summarized in Table 2. In all cases examined, (E)-isomers were obtained exclusively. The E/Z ratio of product **2** was determined in same manner as reported previously.[5a] For example, the ^{1}H NMR spectrum of **2a** shows the vinyl proton β to the carbonyl at δ 6.58 for (E)-isomer and at δ 6.06 for (Z)-isomer, respectively.[6] Integration showed a **96:4** mixture of (*E*)-**2a** and (*Z*)-**2a**, being identical with the ratio obtained by GLC analysis (E/Z=95/5). (Z)-Isomer could be readily separated from (E)-isomer, which eluted more slowly than (Z)-isomer.

Table 1. Effect of Lithium Amide in the Reaction of γ-Butyrolactone with Heptanal

Lithium amide	Yield[a] of **2a** %	E/Z[b]
$(i\text{-Pr})_2$NLi	65	96/4

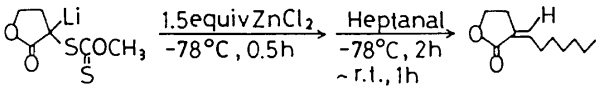
a) Isolated yields. b) Determined by ^1H NMR and GLPC analyses of the isolated product. c) Triethyl phosphite was added before adding carbonyl compound as a desulfurization agent. d) Ethyl bromide was added before adding carbonyl compound.

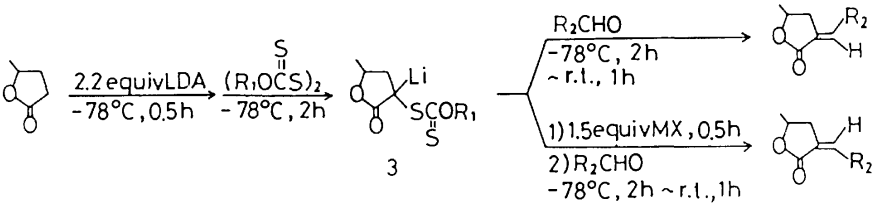
In contrast, when the reaction was carried out in the presence of metal complex such as anhydrous zinc chloride, copper(I) iodide, or tributyltin chloride, (*Z*)-α-alkylidene-γ-butyrolactone was obtained as the major product as shown in Table 3. For example, the reaction of the lithium enolate **1** with heptanal in the presence of 1.5 equiv of zinc chloride afforded predominantly (*Z*)-α-heptylidene-γ-butyrolactone in 68% (E/Z=17/83) isolated yield.



1 2a

As can be seen from the data listed in Tables 2 and 3, the alternation of substituent R of disulfide ROCSSCOR gave little significant improvement in the yield and the stereoselectivity of **2**. The effect of solvent on the yield and E/Z ratio of **2a** has been examined in the reaction of **1** with heptanal in the presence of 1.5 equiv of copper(I) iodide. The results (Table 4) indicate that among the solvents examined, tetrahydrofuran is the most efficient solvent for converting γ-butyrolactone into **2a** and the stereoselectivity of (*Z*)-**2a** is correlative with the solubility of metal complex in solvent.

One Pot Synthesis of α-Alkylidene-γ-valerolactone (4) from γ-Valerolactone. (*E*)- or (*Z*)-α-Alkylidene-γ-valerolactones (**4**) were also synthesized with high stereoselectivity according to the following route.



3 4

a) Isolated yields. b) Determined by ^1H NMR and GLPC analyses of the isolated product. c) Metal complex was added before treating with disulfide. d) Triethyl phosphite was added before adding carbonyl compound as a desulfurization agent. e) 100 ml of THF was used for the reaction of 20 mmol of γ-butyrolactone with aldehyde.

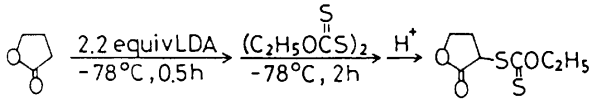
Table 4. Effect of Solvent on the Yields and E/Z Ratios of **2a**

Solvent	Yield[a] of **2a** %	E/Z[b]
THF	69	16/84[c]
THF	61	33/67[d]
DEE	0	—
DME	47	20/80[c]
THF-HMPA[e]	35	15/85[c]

a) Isolated yields. b) Determined by ^1H NMR and GLPC. c) 60 ml of solvent was used for the reaction of 20 mmol of γ-butyrolactone with heptanal. d) 40 ml of solvent was used for the reaction of 20 mmol of γ-butyrolactone with heptanal. e) A mixture of THF and HMPA (8 : 1, v/v) was used as a solvent.

The results were summarized in Table 5. Thus, the observations presented here represent a new and general method for the stereoselective introduction of alkylidene functionality on the α-position of γ-butyrolactone or γ-valerolactone by one pot procedure. These procedures are synthetically significant in respect of utilizing easily available γ-butyrolactone or γ-valerolactone as the starting material.

The Reaction of Lithium Enolate of *O*-Ethyl *S*-(tetrahydro-2-oxo-3-furanyl) Dithiocarbonate (5a) and Thiocarbonate (5b) with Carbonyl Compounds. When γ-butyrolactone was treated with bis[ethoxy(thiocarbonyl)] disulfide in the presence of 2.2 equiv of LDA at −78 °C for 2 h and followed by quenching with saturated aqueous ammonium chloride solution, *O*-ethyl *S*-(tetrahydro-2-oxo-3-furanyl) dithiocarbonate (**5a**) was obtained in 72% isolated yield.



5a

On the other hand, when the reaction was carried out in the presence of 1.1 equiv of LDA, lactone **6** was obtained in the place of **5a** as the major product in 41% (82% based on disulfide) isolated yield and γ-butyrolactone (37%) was recovered. The formation of **6** appears to involve a deprotonation of **5a**, followed by an attack toward disulfide.[7]

Table 5. Stereoselective Synthesis of α-Alkylidene-γ-valerolactones (**4**) from γ-Valerolactone and Carbonyl Compounds

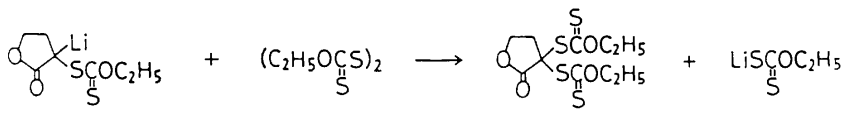
5a



6

Above observation suggests that the reaction of lithium enolate of γ-butyrolactone with aldehydes in the presence of bis[ethoxy(thiocarbonyl)] disulfide to give α-alkylidene-γ-butyrolactone (**2**) proceeds via *O*-ethyl *S*-(tetrahydro-2-oxo-3-furanyl) dithiocarbonate (**5a**) as intermediate. In this paper the author has examined the effect of the starting material **5a** or **5b**, the reaction temperature and time, and metal complex (MX) added on the yields and E/Z ratios of **2** produced in the following reactions, and studied the mechanistic aspects of these reactions.

The geometrical compositions of **2** obtained under various conditions are summarized in Table 6. When the reaction of lithium enolate **7** with aldehyde was carried out in the presence of metal complex (MX) such as $ZnCl_2$, CuI, or $(n\text{-Bu})_3SnCl$, (*Z*)-**2** was obtained as major product, whereas these reactions in the absence of metal cations other than Li^+ gave exclusively (*E*)-**2**. However, $MgBr_2$ was less effective. An increase in the proportion of (*Z*)-product using

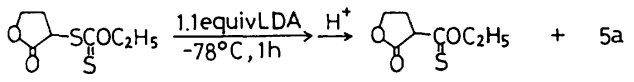
a) Isolated yields. b) Determined by ^1H NMR and GLPC analyses of the isolated product. c) Carbonyl compound was instantly added after **5a** was treated with 1.1 equiv of LDA for 1 min. d) Triethyl phosphite was added before adding carbonyl compound as a desulfurization agent. e) *n*-BuLi was used as a base and THF-HMPA (v/v, 16/1) was used as a co-solvent.

metal complex, but to a lesser extent than for **5a**, was also observed for the reaction of **5b** with aldehyde. Therefore, the common mechanism is taken into cosideration for the reactions of **5a** and **5b** with aldehyde to afford **2**.

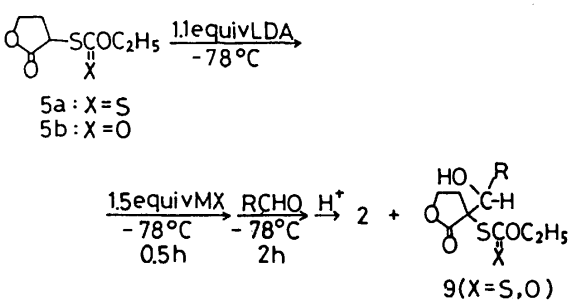
In order to examine the stability of lithium enolate **7a**, **5a** was treated with 1.1 equiv of LDA in THF at −78 °C for 1 h, and then quenched with saturated aqueous ammonium chloride solution. Upon work-up, lactone **8** was isolated in 18% yield in addition to 68% recovery of **5a**. The transformation of **7a** to **8** appears to involve the formation of a thiirane by intramolecular cyclization, followed by expulsion of sulfur.



5a 8

As is apparent from Table 6, when the treating time of **5a** with 1.1 equiv of LDA was shortened to 1 min from 1 h, the yield of **2a** was enhanced to 87% from 63% in the reaction of **5a** with heptanal. The result suggests that the self-rearrangement of lithium enolate **7a** takes place competitively.

The Generation of Aldol Adducts 9. As shown in Table 7, when the reactions of **7a** with aldehydes were carried out at −78 °C for 2 h and then quenched with dilute hydrochloric acid, aldol adduct **9** (X=S) were isolated in good yields but **2** was not detected.



On the other hand, in the reactiion of **7b** with butanal, **2e** was isolated in 23—28% yields but the aldol adduct (X=O) was little isolated. These results may be attributed to the difference in the amount of polarization between thiocarbonyl (C=S) and carbonyl group (C=O) of **9**, that is, in the reaction of **7a** with aldehydes, the small amount of polarization of thiocarbonyl group may reduce the rearrangement of the adduct **10** to **11** (described later).

The aldol adduct **9** should consist of a mixture of diastereomers (erythro and threo isomers).

The stereoselectivity of the resulting α-alkylidene-γ-butyrolactone (**2**) may be closely correlated with the stereo-structure of the aldol adduct **9** from which it is formed. The aldol adduct **9** was separated into the

a) Determined by ^1H NMR and GLPC analyses of the isolated product. b) Determined by ^1H NMR and MPLC (LiChroprep Si60 column, hexane-ethyl acetate eluent, Flow rate 1 ml min^{-1}). c) The reaction temperature was gradually raised to room temperature from −78 °C by removing cooling bath. d) The reaction temperature was immediately raised by dipping the reaction mixture in water bath maintained at 25 °C.

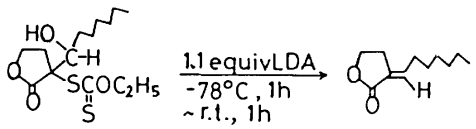
faster-eluting diastereomer and the slower-eluting diastereomer by column chromatography on silica gel with 3:1 hexane-ethyl acetate as eluent. The ^1H NMR spectrum of **9a** derived from heptanal shows the hydroxymethine proton at δ 3.70 for the faster-eluting isomer and at δ 4.04 for the slower-eluting isomer. The slightly major isomer resulting from the aldol condensation was in all instances the slower-eluting diastereomer which was assigned erythro form (**e-9**), whereas the slightly minor and mobile isomer was assigned threo form (**t-9**).[8] The stereochemical compositions (**e-9**/**t-9**) of the aldol adducts obtained from various aldehydes were determined by ^1H NMR and/or MPLC (medium-pressure liquid chromatography) system, and summarized in Table 7. These results show that the metal enolate of **5a** condensed with aldehydes to exhibit consistently low diastereoselectivity, regardless of the metal cation employed.

Effects of Reaction Temperature and Time. Effects of reaction temperature and time after adding aldehyde on the yields and stereoselectivities of **2** and **9** were next examined. These results under the various conditions were summarized in Table 8. When the reaction of **5a** with heptanal was carried out at −78 °C for 2 h and at −50 °C for 1 h, 58% of aldol adduct **9a** was isolated in addition to 26% of **2a**. Interestingly, the geometry selectivity of **2a** was Z-selective (E/Z=28/72) in spite of absence of metal cation other than Li^+. With only the lithium cation present, as the reaction temperature before quenching was raised gradually to 0 °C or above the yields and E-selectivity of **2a** increased. On the other hand, in the

presence of $ZnCl_2$ Z-selectivity of **2a** was observed even if the reaction temperature before quenching was raised gradually to room temperature. Next, in the reaction of **7a** with butanal at −78 °C, the effect of reaction time on the yields and the erythro/threo ratios of aldol adducts **9e** was examined but it was little observed. It is reasonable to consider that the aldol-type reacition of **7a** with an aldehyde is so rapid that the equilibrium described later is reached almost instantly.

The satisfactory yield of the aldol adduct **9** was obtained only at low temperature (−78 to −20 °C).

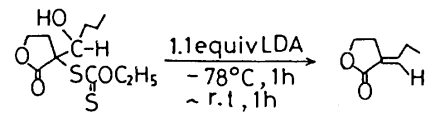
The Retro-Aldolization of 9. The results listed in Tables 7 and 8 predict the retro-aldolization of **9** to the lithium enolate **7a** and aldehyde, since the diastereomer ratios of aldol adducts **9** do not correspond to the E/Z ratios of the final product **2**. When the purified adduct **9a** (erythro/threo=45/55) was lithiated with 1.1 equiv of LDA at −78 °C, and followed by warming to room temperature, α-alkylidene-γ-butyrolactone (**2a**) was obtained in 73% (E/Z=94/6) isolated yield.



9a 2a

erythro/threo=45/55 73%(E/Z=94/6)

The same reaction for the adduct **9e** afforded (*E*)-**2e** with high stereoselectivity, regardless of the stereochemistry of **9e**.

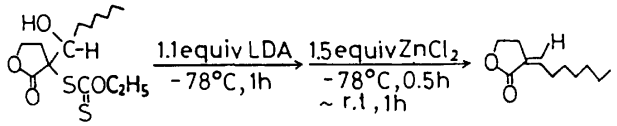


9e 2e

erythro/threo = 20/80 → 63%(E/Z=97/3)

=73/27 → 71%(E/Z=100/0)

On the other hand, when the same reaction for the nearly erythro **9a** (erythro/threo=91/9) was carried out in the presence of $ZnCl_2$, (*Z*)-**2a** was obtained as the major product (E/Z=27/73) in 78% isolated yield.

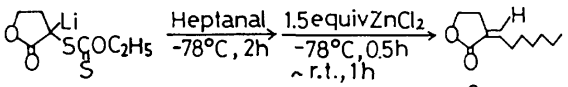


9a 2a

erythro/threo=91/9 78%

(E/Z=27/73)

Furthermore, in the reaction of **7a** with heptanal, even when $ZnCl_2$ was added after treating with heptanal at −78 °C for 2 h, (*Z*)-**2a** was obtained as major product as well as the results listed in Table 6.

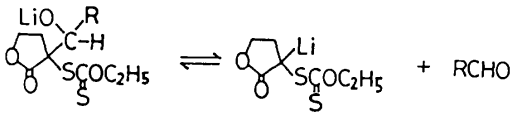


7a 2a

65%

(E/Z=22/78)

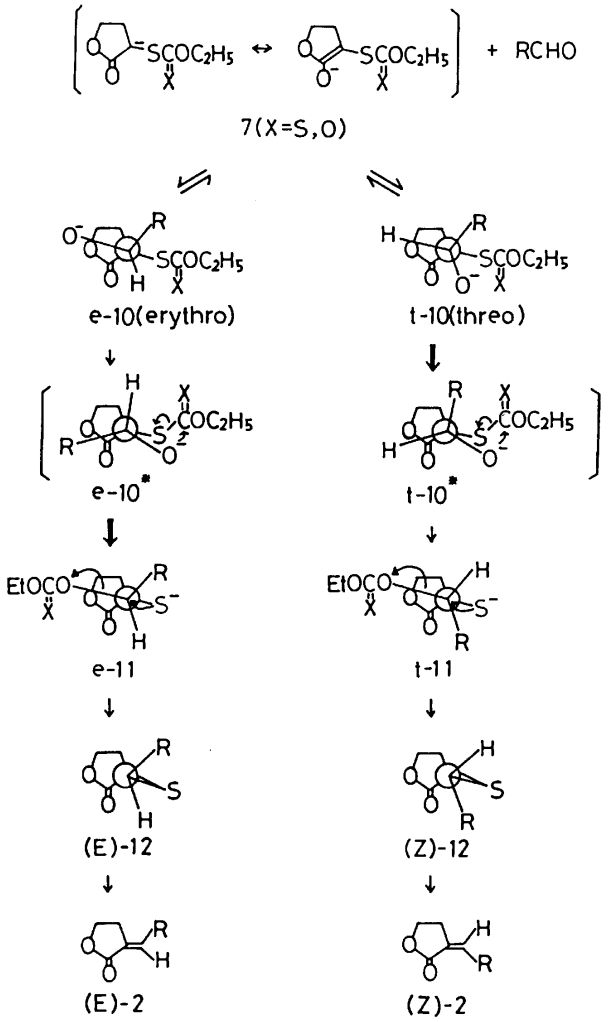
From these results, it is reasonable to consider that **10** is in equilibrium with **7a** as follows, and that the effect of the metal complex employed is exhibited in the conversion of the aldol adduct **10** to the final product **2**.



10 7a

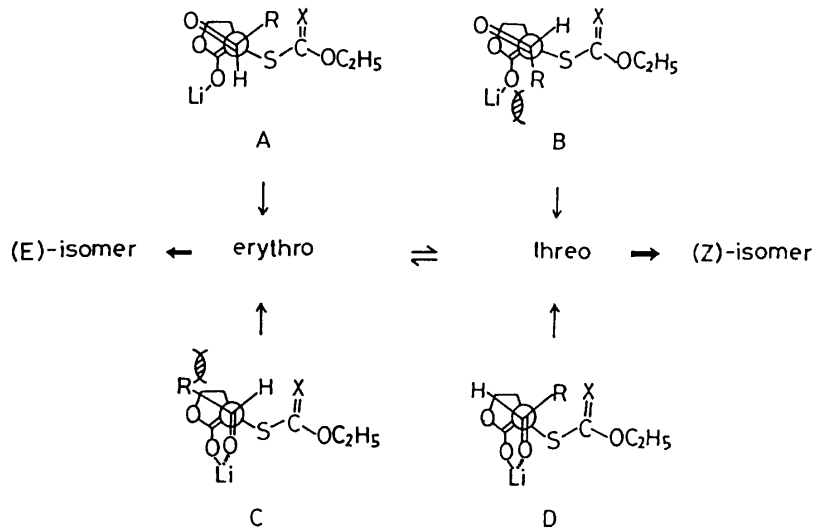
Mechanistic Aspects. As reported previously,[5a,9] it is reasonable to assume that the mechanism of this reaction involves aldol condensation of **7** with carbonyl compound, rearrangement of an adduct **10** to **11**, subsequent conversion of **11** to thiirane species **12**, and elimination of sulfur to give α-alkylidene-γ-butyrolactone (**2**) (Scheme 1). The equilibrium between (*E*)-**2** and (*Z*)-**2** was not observed even after allowding to stand at room temperature for several days. The elimination of sulfur from **12** to give **2** is explained by a stereospecific mechanism.[10] Furthermore, it is reasonable to consider that **e-11** is not in equilibrium with **t-11**, since, in both conformations, the intramolecular rearrangement of $\underset{\underset{X}{\|}}{COC_2H_5}$ group is already occured. Thus, the aldol adduct **e-10** (erythro) and **t-10** (threo) should convert to (*E*)- and (*Z*)-**2** stereospecifically, respectively. It is considered that the geometry of final product **2** is dependent on whether the aldol condensation proceeds via erythro or threo isomer as intermediate. However, as is apparent from Tables 7 and 8, the aldol-type reactions of **7** with aldehydes at low temperature have exhibited low diastereoselectivity regardless of metal cation employed. That is, the diastereomer ratio of aldol adduct **9** does not correspond to the geometry of **2**. It is documented that, in the kinetically controlled aldol-type reaction, the appearance of stereoselection is attributed to the form of the transition state.[8g,11] It is generally believed that, when an aldol-type reaction is carried out at relatively low temperature in ethereal solvent, even lithium enolate is satisfactory to stabilize the metal chelate.[8g,12] Recently, acyclic transition states have been also proposed to account for the erythro-selective aldol reaction with enol silyl ethers and acetals,[13] zirconium enolates,[14] and crotyltrialkyltins.[15] Furthermore, Heathcock et al. have reported that the reactions of lithium enolate of dioxolanones

with aldehydes occur through the conventional Zimmerman–Traxler transition state[16] with the hydrogen of the aldehyde RCHO, rather than the R group, over the face of the dioxolanone ring.[17] The transition state models **A, B, C,** and **D** were proposed for the reactions of **7** with aldehydes (Scheme 2).



Scheme 1.

It is reasonable to consider that , among four possible transition state models (Scheme 2), **A** leading to erythro isomer and **D** leading to threo isomer, in both which the lactone carbonyl group and R group of aldehyde RCHO are anti-oriented, must be favored for the steric reason. Thus, the aldol condensations of **7** with aldehydes under the kinetically controlled reaction conditions occur through the transition states **A** and **D**, giving consistently almost 1:1 mixture of diastereomers of **9**. In these reactions, the effect of metal complex added was little observed for the stereoselection of **9**. The results listed in Table 8 show that, even in the absence of metal cation other than Li^+, when the reaction of **7** with aldehyde was carried out below −20 °C (*Z*)-**2** was obtained as major product, while (*E*)-**2** was exclusively obtained when the reaction was quenched after warming to 0 °C or above. On the contrary, in the presence of metal cation such as Zn^{2+} or Cu^+, Z-selectivity of **2** was observed even when the reaction was quenched after warming to room temperature. The observations presented here can be rationalized by considering that a retro-aldolization of **10** to the starting materials is in competition with the rearrangement of **10** to **11**, that is, the reaction of **7** with aldehyde proceeds via erythro or threo isomer to give **2** is the thermodynamically controlled process, and that the erythro isomer **e-10** become energetically more favorable than the threo isomer **t-10** as the reaction temperature is raised. Since it seems that the cyclic transition state **D** can not be controlled by lithium coordination as the reaction temperature is raised to room temperature.[8g,12] In addition, in two possible stereoisomeric precursors (**e-**



Scheme 2.

11 and **t-11**) leading to **2** as shown in Scheme 1, if the conformer, in which the $OCOC_2H_5$ and S^- groups are

anti-periplanar, is favorable one for the subsequent intramolecular attack of S^- group and elimination of the $OCOC_2H_5$ species, the orientation of R group is

thus represented as **e-11** and **t-11**, respectively. The rearrangement reaction of **e-10** to **e-11** would proceed more smoothly than that of **t-10** to **t-11**, since the steric interaction between a bulky R group and a lactone carbonyl is minimized in **e-11**. On the other hand, the stereoisomer **t-11**, in which the alkyl and carbonyl group are gauche, would exhibit severe interactions. Thus, (*E*)-**2** predominates. However, if a metal complex such as $ZnCl_2$ or CuI is added, the reaction of **7** with aldehyde proceeds via threo isomer **t-10** to give (*Z*)-**2** as major product. Since the threo isomer **t-10**, which seems to exist as structure with the six-membered ring containing coordination to metal cation of an alcoholate anion and a lactone carbonyl oxygen, can become energetically more favorable than the more charged-separated erythro isomer **e-10**. Furthermore, the difference in rotational energy between the conformational conversion of **e-10** to **e-10*** and that of **t-10** to **t-10*** (Scheme 1) is proposed to account for the threo-selective reaction at low temperature (−78 to −20 °C) to give (*Z*)-**2**. That is, the rotation about C–C bond formed by the aldol-type reaction must occur, since the both conformations **e-10*** and **t-10***, in which an alcoholate anion and $SCOC_2H_5$ group are cis or gauche, are favorable for

the subsequent intramolecular attack of O^- group toward $SCOC_2H_5$ group. The conformational

conversion of **t-10** to **t-10*** must be energetically more favorable than that of **e-10** to **e-10*** for the steric interaction between a lactone carbonyl and an alcoholate anion coordinated to a metal cation or a bulky R group.

It is concluded that the stereoselectivity of α-alkylidene-γ-butyrolactone (**2**) results from the aldol-type reaction of **7** with aldehyde which takes a different course as functions of the metal cation employed and the reaction temperature. That is, in the presence of only Li^+, this reaction occurs through erythro adduct **e-10** leading to (*E*)-**2**, whereas the reaction occurs predominantly through threo adduct **t-10** leading to (*Z*)-**2** when it was quenched below −20 °C or when it was carried out in the presence of metal cation such as Zn^{2+}, Cu^+, or Sn^{4+}. Furthermore, the effect of the metal complex employed and the reaction temperature on the stereoselectivity of **2** is exhibited in the rearrangement reaction of aldol adduct **10** to **11**.

Experimental

General. All reactions were performed under a nitrogen atmosphere. The glassware was dried by flaming in a nitrogen stream. Tetrahydrofuran (THF) was dried by distillation from calcium hydride and by subsequent distillation from lithium aluminum hydride under a nitrogen atmosphere. Diisopropylamine were distilled from calcium hydride and stored over molecular sieves. Butyllithium was titrated by the Kofron's method[18] before use. γ-Butyrolactone, γ-valerolactone, triethyl phosphite, and carbonyl compounds were purified by distillation under a nitrogen atmosphere. Zinc chloride was successively fused under reduced pressure and then cooled under nitrogen. Copper(I) iodide and magnesium bromide was prepared by the reported procedure.[8g,19] Magnesium chloride and tributyltin chloride were obtained commercially. Diisopropoxytitanium dichloride and triisopropoxytitanium chloride were prepared from titanium tetrachloride and tetraisopropyl titanate by the Dijkgraaf's method.[20] *O*-Ethyl *S*-(tetrahydro-2-oxo-3-furanyl) dithiocarbonate (**5a**) and thiocarbonate (**5b**) were prepared by the reported procedure.[5a] Melting points were determined with a Yamato Kagaku melting point apparatus and are uncorrected. Boiling points were determined during distillation and are uncorrected. Infrared spectra were determined on a Hitachi Model 260-30 spectrophotometer. Nuclear magnetic resonance spectra were determined on a JEOLCO MH-100 spectrometer. Chemical shifts are given in δ units, part per million relative to tetramethylsilane as an internal standard. Carbon tetrachloride (CCl_4), chloroform-*d* ($CDCl_3$) and benzene-d_6 (C_6D_6) were used as solvent. Gas chromatograms were obtained using a Varian Aerograph Model 920 instrument with a 0.15 cm×120 cm glass column (20% Silicone DC-550 on Celite 545). Silica gel (Wakogel) of the size 100—300 mesh was used for column chromatography. Medium-pressure liquid chromatography (MPLC) was performed on a unit constructed from various commercial components.

Preparation of Disulfides. Bis[methoxy(thiocarbonyl)], bis[ethoxy(thiocarbonyl)], and bis[isopropoxy(thiocarbonyl)] disulfides were prepared by the reported procedure.[21]

Preparation of Bis[menthyl(thiocarbonyl)] Disulfide. To a solution of 6.26 g (40 mmol) of *l*-methol in 50 ml of THF was added dropwise 40 mmol of butyllithium at 0 °C. After stirring for 1 h, 3.2 ml (50 mmol) of carbon disulfide was added dropwise and the reaction mixture was stirred for 1 h. 5.06 g (20 mmol) of iodide in 40 ml of THF was then added dropwise and the reaction mixture was stirred for 1 h. To this was added 10 ml of saturated aqueous ammonium chloride solution and the mixture was extracted four times with ether. The ether extracts were washed with dilute aqueous sodium thiosulfate solution and saturated aqueous sodium chloride solution, dried on anhydrous sodium sulfate, and concentrated under reduced pressure. The recrystallization from ethanol gave 1.31 g (71%) of bis[menthyl(thiocarbonyl)] disulfide: Mp 94.0—95.0 °C; ^1H NMR (CCl_4) δ=5.20—5.48 (m, 2H, 2CHO), 2.04—2.25 (m, 2H, 2CH), 0.72—2.04 (m, 34H, 4CH, $6CH_2$, and $6CH_3$). IR (KBr pellet) 2950, 1050, 630 cm^{-1}. Found: C, 56.94; H, 8.31%. Calcd for $C_{22}H_{38}O_2S_4$: C, 57.10; H, 8.28%.

Reaction of Lithium Enolate of γ-Butyrolactone with Carbonyl Compounds. General Procedure: Lithium diisopropylamide (LDA) (44 mmol) was prepared as usual in 60 ml of THF at −78 °C. After 10 min, a solution of 1.72 g (20 mmol) of γ-butyrolactone in 5 ml of THF was added over a period of 3 min. After stirring for 1 h at −78 °C, a solution of 22 mmol of disulfide in 6 ml of THF was added over a period of 10 min and the reaction mixture was stirred for 2 h at −78 °C. To this was added dropwise a solution of 22 mmol of carbonyl compound in 6 ml of THF over a period of 10 min and the reaction mixture was stirred for 2 h at −78 °C. Usually, the reaction mixture was then warmed gradually to room temperature from −78 °C by removing the cooling bath and it was stirred for 1 h before quenching with saturated aqueous ammonium chloride solution (10 ml). It was then poured into dilute hydrochloric acid and extracted with ether (50 ml×4). The extracts were washed with saturated aqueous sodium chloride solution, dried on anhydrous sodium sulfate, and concentrated under reduced pressure. Product isolation and purification by silica-gel chromatography gave (*E*)-α-alkylidene-γ-butyrolactone as main product.

Reaction of Lithium Enolate of γ-Butyrolactone with Carbonyl Compounds Using Metal Complexes. The preparation of α-heptylidene-γ-butyrolactone (**2a**) using zinc chloride is given here as a typical experiment. To a solution of lithium enolate in THF produced by treatment of γ-butyrolactone with bis[methoxy(thiocarbonyl)] disulfide in the presence of 2.2 equiv of LDA was added a solution of 4.10 g (30 mmol) of zinc chloride in 30 ml of THF. After 30 min, a solution of 2.20 g (22 mmol) of heptanal in 3 ml of THF was added dropwise. After stirring at −78 °C for 2 h, the reaction mixture was warmed gradually to room temperature from −78 °C and it was stirred for 1 h before quenching with saturated aqueous ammonium chloride solution (10 ml). The usual work-up and the purification by silica-gel chromatography (hexane-benzene) gave 2.48 g (68%) of **2a**.

Physical Properties of α-Alkylidene-γ-butyrolactones. The analytical samples were obtained by silica-gel chromatography. The (E)- and (Z)-isomers of **2a** were separated by silica-gel chromatography using hexane-benzene as eluent, and were identified by comparison of ^{1}H NMR and IR spectra with corresponding data reported previously.[5]

(*Z*)-α-Heptylidene-γ-butyrolactone (2a): ^{1}H NMR (CCl_4) δ=6.06 (m, 1H, CH=C), 4.18 (t, *J*=7 Hz, 2H, CH_2O), 2.46—2.92 (m, 4H, $2CH_2$), 1.02—1.50 (m, 8H, $4CH_2$), 0.88 (m, 3H, CH_3). Reaction of Lithium Enolate of γ-Valerolactone with Carbonyl Compounds. The same procedure as above was employed, except using γ-valerolactone instead of γ-butyrolactone.

α-Heptylidene-γ-valerolactone (4a): (E)-Isomer: ^{1}H NMR (CCl_4) δ=6.46 (m, 1H, CH=C), 4.48 (m, 1H, CH-O-), 1.90—3.10 (m, 4H, $2CH_2$), 1.10—1.60 (m, 11H, CH_3 and $4CH_2$), 0.88 (m, 3H, CH_3). IR (neat) 1750 (COO), 1680 (CH=C) cm^{-1}. (Z)-Isomer: ^{1}H NMR (CCl_3) δ=6.02 (m, 1H, CH=C), 4.48 (m, 1H, CH-O-), 2.22—3.10 (m, 4H, $2CH_2$), 1.10—1.62 (m, 11H, CH_3 and $4CH_2$), 0.88 (m, 3H, CH_3). IR (neat) 1750 (COO), 1680 (CH=C) cm^{-1}. Found: C, 73.17; H, 10.40%. Calcd for $C_{12}H_{20}O_2$: C, 73.43; H, 10.27%.

α-Hexylidene-γ-valerolactone (4b): (E)-Isomer: ^{1}H NMR (CCl_4) δ=6.44 (m, 1H, CH=C), 4.50 (m, 1H, CH-O-), 1.98—3.06 (m, 4H, $2CH_2$), 1.00—1.56 (m, 9H, CH_3 and $3CH_2$), 0.88 (m, 3H, CH_3). IR (neat) 1750 (COO), 1670 (CH=C) cm^{-1}. Found: C, 72.40; H, 10.11%. Calcd for $C_{11}H_{18}O_2$: C, 72.49; H, 9.95%. (Z)-isomer: ^{1}H NMR (CCl_4) δ=5.94 (m, 1H, CH=C), 4.40 (m, 1H, CH-O-), 2.10—3.00 (m, 4H, $2CH_2$), 1.08—1.60 (m, 9H, CH_3 and $3CH_2$), 0.88 (m, 3H, CH_3). IR (neat) 1750 (COO), 1680 (CH=C) cm^{-1}.

α-(2-Methylbutylidene)-γ-valerolactone (4c): (E)-Isomer: ^{1}H NMR (CCl_4) δ=6.22 (dt, *J*=9.9, 2.7 Hz, 1H, CH=C), 4.52 (m, 1H, CH-O-), 2.00—3.20 (m, 3H, CH_2 and CH), 1.38 (d, *J*=7 Hz, 3H, CH_3), 1.05 (d, *J*=7 Hz, 3H, CH_3), 0.88 (m, 5H, CH_2 and CH_3). IR (neat); 1750 (COO), 1680 (CH=C) cm^{-1}. (Z)-Isomer: ^{1}H NMR (CCl_4) δ=5.72 (dt, *J*=9.8, 2.2 Hz, 1H, CH=C), 4.42 (m, 1H, CH-O-), 3.48 (m, 1H, CH), 2.20—3.20 (m, 2H, CH_2), 1.36 (d, *J*=7 Hz, 3H, CH_3), 0.97 (d, *J*=7 Hz, 3H, CH_3), 0.85 (m, 5H, CH_2 and CH_3). Found: C, 71.15; H, 9.70%. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%. IR (neat); 1750 (COO), 1670 (CH=C) cm^{-1}.

α-Pentylidene-γ-valerolactone (4d): (E)-Isomer: ^{1}H NMR (CCl_4) δ=6.50 (m, 1H, CH=C), 4.52 (m, 1H, CH-O-), 2.00—3.20 (m, 4H, $2CH_2$), 1.10—1.70 (m, 7H, CH_3 and $2CH_2$), 0.80—1.10 (m, 3H, CH_3). IR (neat) 1750 (COO), 1680 (CH=C) cm^{-1}. Found: C, 71.66; H, 9.70%. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%. (Z)-Isomer: ^{1}H NMR (CCl_4) δ=6.04 (m, 1H, CH=C), 4.48 (m, 1H, CH-O-), 2.20—3.20 (m, 4H, $2CH_2$), 1.20—1.60 (m, 7H, CH_3 and $2CH_2$), 0.90 (m, 3H, CH_3).

α-(2-Methylpropylidene)-γ-valerolactone (4e): (E)-Isomer: ^{1}H NMR (CCl_4) δ=6.20 (dt, *J*=9.3, 2.6 Hz, 1H, CH=C), 4.44 (m, 1H, CH-O-), 2.20—3.20 (m, 3H, CH_2 and CH), 1.35 (d, *J*=7 Hz, 3H, CH_3), 1.05 (d, *J*=7 Hz, 6H, $2CH_3$). IR (neat) 1750 (COO), 1680 (CH=C) cm^{-1}. Found: C, 70.03; H, 9.38%. Calcd for $C_9H_{14}O_2$: C, 70.10; H, 9.15%. (Z)-Isomer: ^{1}H NMR (CCl_4) δ=5.74 (dt, *J*=9.6, 2.1 Hz, 1H, CH=C), 4.42 (m, 1H, CH-O-), 3.66 (m, 1H, CH), 2.20—3.10 (m, 2H, CH_2), 1.34 (d, *J*=6 Hz, 3H, CH_3), 0.98 (d, *J*=7 Hz, 6H, $2CH_3$). IR (neat) 1750 (COO), 1670 (CH=C) cm^{-1}.

α-Butylidene-γ-valerolactone (4f): (E)-Isomer: ^{1}H NMR (CCl_4) δ=6.36 (m, 1H, CH=C), 4.42 (m, 1H, CH-O-), 1.96—3.00 (m, 4H, $2CH_2$), 1.28—1.60 (m, 5H, CH_2 and CH_3), 0.92 (t, *J*=7 Hz, 3H, CH_3). (Z)-Isomer: ^{1}H NMR (CCl_4) δ=5.96 (m, 1H, CH=C), 4.44 (m, 1H, CH-O-), 2.24—3.04 (m, 4H, $2CH_2$), 1.20—1.56 (m, 5H, CH_3 and CH_2), 0.90 (t, *J*=7 Hz, 3H, CH_3). IR (neat) 1750 (COO), 1680 (CH=C) cm^{-1}. Found: C, 69.95; H, 9.17%. Calcd for $C_9H_{14}O_2$: C, 70.10; H, 9.15%.

Reaction of γ-Butyrolactone with Bis[ethoxy(thiocarbonyl)] Disulfide. To a solution of lithium diisoprop-

ylamide (LDA) (44 mmol) in 60 ml of THF was added a solution of 1.72 g (20 mmol) of γ-butyrolactone in 5 ml of THF at −78 °C. After stirring for 1 h, a solution of 5.32 g (22 mmol) of bis[ethoxy(thiocarbonyl)] disulfide in 5 ml of THF was added and the reaction mixture was stirred at −78 °C for 2 h. The cooling bath was removed and the reaction mixture was quenched with 10 ml of saturated aqueous ammonium chloride solution. The usual work-up and the purification by silica-gel chromatography (benzene) gave 2.97 g (72%) of **5a**. The product was identified by comparison of the ^{1}H NMR spectrum and retention time of GLC with the correponding data from independently synthesized material described above.

On the other hand, the reaction of 20 mmol of γ-butyrolactone treated by 22 mmol of LDA with 22 mmol of bis[ethoxy(thiocarbonyl)] disulfide gave 2.67 g (41%) of **6**: Mp 130.5—131.5 °C. ^{1}H NMR ($CDCl_3$) δ=4.72 (q, *J*=7 Hz, 4H, $2CH_2O$), 4.58 (t, *J*=7 Hz, 2H, CH_2O), 3.21 (t, *J*=7 Hz, 2H, CH_2O), 1.50 (t, *J*=7 Hz, 6H, $2CH_3$). IR (KBr pellet) 2990, 1780 (COO), 1035 cm^{-1}. Found: C, 36.49; H, 3.98%. Calcd for $C_{10}H_{14}O_4S_4$: C, 36.79; H, 4.32%.

Reaction of Lithium Enolate of 5a or 5b with Carbonyl Compounds. The preparation of α-heptylidene-γ-butyrolactone from **5a** and heptanal is given here as a typical experiment. To a solution of lithium diisopropylamide (LDA) (22 mmol) in 60 ml of THF was added 4.13 g (20 mmol) of *O*-ethyl *S*-(tetrahydro-2-oxo-3-furanyl) dithiocarbonate (**5a**) at −78 °C. After 30 min, a solution of 2.51 g (22 mmol) of heptanal in 3 ml of THF was added over 2 min. After stirring at −78 °C for 2 h, the reaction mixture was warmed gradually to room temperature from −78 °C and it was stirred for 1 h before quenching with saturated aqueous ammonium chloride solution (10 ml). The usual work-up and the purification by silica-gel chromatography (benzene) gave 2.22 g (61%) of **2a**.

The procedure using butyllithium instead of LDA as base and THF-HMPA (v/v, 16/1) instead of THF as solvent was also employed for the reaction of lithium enolate of **5b** with carbonyl compounds.

(*Z*)-α-Benzylidene-γ-butyrolactone (2b): Mp 90.5—91.5 °C. ^{1}H NMR ($CDCl_3$) δ=7.50 (m, 2H, aromatic), 7.04 (m, 3H, aromatic), 6.70 (m, 1H, CH=C), 4.20 (t, *J*=7 Hz, 2H, CH_2O), 3.00 (m, 2H, CH_2). IR (KBr pellet); 1740 (COO), 1650 (CH=C) cm^{-1}. Found: C, 75.67; H, 5.88%. Calcd for $C_{11}H_{10}O_2$: C, 75.84; H, 5.79%.

(*Z*)-α-Hexylidene-γ-butyrolactone (2g): ^{1}H NMR (CCl_4) δ=6.22 (m, 1H, CH=C), 4.30 (t, *J*=7 Hz, 2H, CH_2O), 2.60—3.00 (m, 4H, $2CH_2$), 1.00—1.58 (m, 6H, $3CH_2$), 0.92 (m, 3H, CH_3). IR (neat) 1758 (COO), 1675 (CH=C) cm^{-1}. Found: C, 71.20; H, 9.65%. Calcd for $C_{10}H_{16}O_2$: C, 71.39; H, 9.59%.

Decomposition of Lithium Enolate 7a. The lithium enolate **7a** was prepared as usual from 4.13 g (20 mmol) of **5a** and 22 mmol of LDA in 60 ml of THF. After stirring at −78 °C for 1 h, the reaction mixture was quenched by adding 10 ml of saturated aqueous ammonium chloride solution. The usual work-up and the product isolation gave 2.81 g (68%) of **5a** and 0.63 g (18%) of α-[ethoxy(thiocarbonyl)]-γ-butyrolactone (**8**): ^{1}H NMR (CCl_4) δ=4.56 (q, *J*=7 Hz, 2H, CH_2O), 4.30 (m, 2H, CH_2O), 3.84 (t, *J*=7 Hz, 1H, CH), 2.72 (m, 2H, CH_2O), 1.44 (t, *J*=7 Hz, 3H, CH_3). Found: C, 47.88; H, 5.91%. Calcd for $C_7H_{10}O_3S$: C, 48.26; H, 5.79%.

Therefore, in the subsequent experiments carbonyl compound was instantly added after treating of **5a** with 1.1 equiv of LDA.

General Procedure for the Preparation of Aldol Adducts 9. To a solution of LDA (22 mmol) in 60 ml of THF was added 4.13 g (20 mmol) of **5a** at −78 °C. When the addition was complete, a solution of 22 mmol of carbonyl compound in 5 ml of THF was added and the reaction mixture was stirred at −78 °C for 2 h. The cooling bath was removed and the reaction mixture was poured into dilute hydrochloric acid, and extracted with ether (50×3 ml). The combined organic layer was washed twice with saturated aqueous sodium chloride solution, dried on anhydrous sodium sulfate, and concentrated under reduced pressure. The chromatography on silica gel (hexane-ethyl acetate 3:1) gave a purified but unseparated diastereomers **9** in high yields. The diastereomers were separated by MPLC system using hexane-ethyl acetate 3:1 as eluent, and the diastereomer ratios were determined.

α-(1-Hydroxyheptyl)-α-[ethoxy(thiocarbonyl)thio]-γ-butyrolactone (9a): Chromatography (hexane-ethyl acetate 3:1) afforded in 67% yield a 45:55 mixture of the faster eluting (assigned threo) and slower eluting (assigned erythro) isomers. The faster eluting diastereomer was obtained as a viscous oil: ^{1}H NMR ($CDCl_3$) δ=4.46 (q, *J*=7 Hz, 2H, CH_2O), 4.20 (m, 2H, CH_2O), 3.70 (bt, 1H, CH), 3.40 (bs, 1H, OH), 2.60 (m, 2H, CH_2), 1.08—1.60 (m, 13H, $5CH_2$ and CH_3), 0.70—0.88 (m, 3H, CH_3). IR (neat) 3402 (OH), 1740 (COO) cm^{-1}.

The slower eluting diastereomer was obtained as crystals: Mp 81.5—82.5 °C. ^{1}H NMR ($CDCl_3$) δ=4.64 (q, *J*=7 Hz, 2H, CH_2O), 4.36 (t, *J*=7 Hz, 2H, CH_2O), 4.04 (m, 1H, CH), 3.68 (bs, 1H, OH), 2.08—2.84 (m, 2H, CH_2O), 1.08—1.60 (m, 13H, $5CH_2$ and CH_3), 0.64—0.84 (m, 3H, CH_3). IR (KBr pellet) 3400 (OH), 1736 (COO) cm^{-1}. Found: C, 52.14; H, 7.17%. Calcd for $C_{14}H_{24}O_4S_2$: C, 52.47; H, 7.55%.

α-(1-Hydroxypropyl)-α-[ethoxy(thiocarbonyl)thio]-γ-butyrolactone (9d): Chromatography (hexane-ethyl acetate 2:1) afforded in 70% yield a 48:52 mixture of the faster eluting (assigned threo) and slower eluting (assigned erythro) isomers. The faster eluting diastereomer was obtained as a viscous oil: ^{1}H NMR ($CDCl_3$) δ=4.58 (q, *J*=7 Hz, 2H, CH_2O), 4.32 (t, *J*=7 Hz, 2H, CH_2O), 4.02 (m, 1H, CH), 3.44 (bs, 1H, OH), 2.12—2.96 (m, 2H, CH_2), 1.06—1.80 (m, 5H, CH_3 and CH_2), 1.02 (t, *J*=7 Hz, 3H, CH_3). IR (neat) 3500 (OH), 1770 (COO) cm^{-1}.

The slower-eluting diastereomer was obtained as a viscous oil: ^{1}H NMR ($CDCl_3$) δ=4.71 (q, *J*=7 Hz, 2H, CH_2O), 4.46 (t, *J*=7 Hz, 2H, CH_2O), 3.74—3.94 (m, 1H, CH), 3.89 (s, 1H, OH), 2.50—3.00 (m, 2H, CH_2), 1.20—1.80 (m, 5H, CH_2 and CH_3), 1.04 (t, *J*=7 Hz, 3H, CH_3). IR (neat) 3480 (OH), 1760 (COO) cm^{-1}. Found: C, 45.20; H, 5.98%. Calcd for $C_{10}H_{16}O_4S_2$: C, 45.43; H, 6.10%.

α-(1-Hydroxybutyl)-α-[ethoxy(thiocarbonyl)thio]-γ-butyrolactone (9e): Chromatography (hexane-ethyl acetate 3:1) afforded in 84% yield a 47:53 mixture of the faster eluting (assigned threo) and slower eluting (assigned erythro) isomers. The faster elutiong diastereomer was obtained as a viscous oil: ^{1}H NMR ($CDCl_3$) δ=4.72 (q, *J*=7 Hz, 2H, CH_2O), 4.44 (t, *J*=7 Hz, 2H, CH_2O), 4.16 (m, 1H, CH), 3.54 (bs, 1H, OH), 2.24—2.96 (m, 2H, CH_2), 1.08—1.64 (m, 7H, $2CH_2$ and CH_3), 0.64—1.08 (m, 3H,

CH_3). IR (neat) 3480 (OH), 1770 (COO) cm^{-1}.

The slower-eluting diastereomer was obtained as a viscous oil: ^1H NMR ($CDCl_3$) δ=4.74 (q, J=7 Hz, 2H, CH_2O), 4.46 (t, J=7 Hz, 2H, CH_2O), 3.78—4.24 (m, 2H, CH and OH), 2.30—3.00 (m, 2H, CH_2), 1.08—1.90 (m, 7H, $2CH_2$ and CH_3), 0.80—1.08 (m,3H, CH_3). IR (neat) 3480 (OH), 1760 (COO) cm^{-1}. Found: C, 47.41; H, 6.70%. Calcd for $C_{11}H_{18}O_4S_2$: C, 47.46; H, 6.52%.

Preparation of α-Heptylidene-γ-butyrolactone (2a) from α-(1-Hydroxyheptyl)-α-[ethoxy(thiocarbonyl)thio]-γ-butyrolactone (9a): Into a solution of 8.10 mmol of LDA in 15 ml of THF, 2.36 g (7.36 mmol) of **9a** in 6 ml of THF was added at −78 °C. After stirring at −78 °C for 1 h and then at room temperature for 2 h, the usual work-up and chromatographic isolation afforded 0.98 g (73%) of **2a**, which was identical by spectroscopic comparison with an authentic sample.

α-Butylidene-γ-butyrolactone (2e): The similar reactions utilizing 2.13 g (7.65 mmol) and 1.61 g (5.80 mmol) of **9e** gave 0.68 g (63%) and 0.58 g (71%) of **2e**, respectively.

Preparation of 2a from 9a Using $ZnCl_2$. Into a solution of 7.21 mmol of LDA in 15 ml of THF, 2.10 g (6.55 mmol) of **9a** in 6 ml of THF was added at −78 °C. After stirring at −78 °C for 1 h, 1.34 g (9.83 mmol) of zinc chloride in 9 ml of THF was added. After stirring at −78 °C for 30 min and then at room temperature for 2 h, the usual work-up and chromatographic isolation afforded 0.93 g (78%) of **2a**.

The author would like to thank Drs. Aritsune Kaji and Kazuhiko Tanaka, Department of Chemistry, Faculty of Science, Kyoto University, for their helpful discussion during this work.

Alkaline treatment of 1-[2-(substituted methylthio)vinyl]pyridinium bromides, readily obtainable from the *S*-alkylation of pyridinium 1-(thiocarbonyl)methylides with various alkyl bromides such as bromoacetonitrile, ethyl bromoacetate, and some phenacyl bromides, gave smoothly 1,9a-dihydropyrido[2,1-*c*][1,4]thiazine derivatives as almost isomeric mixtures. These dihydropyridothiazines are very unstable and decomposed rapidly at ordinary temperature, but by treating them with a dehydrogenating agent such as lead tetraacetate (LTA) or 2,3-dichloro-5,6-dicyano-*p*-benzoquinone (DDQ) at 0 °C the desulfurized and the rearranged aromatic indolizine derivatives were formed in moderate to good yields.

A compound having a planar cyclic $4n\pi$ system is very intriguing molecule because various interesting reactions to avoid the high energic state caused by its resonance destabilization can be expected. Our recent reports[1,2] showed that neutral pyrido[1,2-*d*][1,3,4]thiadiazines bearing a planar 12π system are 1,3,4-thiadiazinyl anion congeners[3] and undergo smoothly the desulfurization or the rearrangement to give the aromatized pyrazolo[1,5-*a*]pyridine derivatives in good yields. On the other hand, the extension of this reaction to its 1-deaza analogue gave only 1,9a-dihydropyrido[2,1-*c*][1,4]thiazine derivatives and did not afford the initially expected indolizine derivatives except a few examples.[4] All our attempts to obtain the corresponding aromatic indolizines from these primary bicyclo adducts in the presence or absence of various dehydrogenating agents at ordinary temperature were unsuccessful, but we found that the treatment of them with LTA and DDQ at the limited temperature (0 °C) afforded the expected indolizines in moderate to good yields. In this paper we wish to report convenient syntheses of 1,9a-dihydropyrido[2,1-*c*][1,4]thiazines and their dehydrogenative transformations to the desulfurized and the rearranged indolizine derivatives.

Results and Discussion

Preparations of 1,9a-Dihydropyrido[2,1-*c*][1,4]thiazines. The treatment of 1-[1-cyano-2-methylthio-2-(substituted methylthio)vinyl]pyridinium bromides **10**—**23**, obtainable quantitatively from the *S*-alkylations of the corresponding pyridinium (thiocarbonyl)-methylides **1** and **2** with bromoacetonitrile (**3**), ethyl bromoacetate (**4**), phenacyl bromide (**5**), *p*-chlorophenacyl bromide (**6**), *p*-bromophenacyl bromide (**7**), *p*-methylphenacyl bromide (**8**), and *p*-phenylphenacyl bromide (**9**), with 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU) in chloroform at 0 °C for 10 min afforded unstable yellow products **24**—**37** in 43—84% yields, respectively. Similar reactions of 1-[1-[1-(ethoxycarbonyl) and 1-benzoyl]-2-methylthio-2-(substituted methylthio)vinyl]pyridinium bromides **42**—**53** with DBU gave the corresponding compounds **54**—**65** in 39—89% yields and those of pyridinium bromides **68**—**78** possessing a methyl group at the 2-position yielded compounds **79**—**89** in 49—97% yields (Schemes 1 and 2). All products except **62**—**65**, **82**, **84**, and **86** were isomeric mixtures, and their isolatons other than **24a** were unsuccessful because of their thermal instability. These isomeric ratios (see Schemes 1 and 2) determined by their proton NMR (^{1}H NMR) spectra suggest the following inclinations for the substituent effect in these cyclization reactions: 1) In the adducts **24a,b**—**37a,b**, **54a,b**—**65a,b**, and **79a,b**—**89a,b** having 9a-hydrogen, the formations of the trans isomers (type b) increase with the increase of the steric hindrance of the substituent (R_2) derived from the alkylating agents **3**—**9**. 2) In the adducts **79c,d**—**89c,d** bearing a 9a-methyl group, the cis isomer (type c) is always predominant or exclusive. 3) The 2-methyl group of salts **68**—**78** does not cause large steric hinderance toward the cyclization at the 2-position. 4) When the group (R) is an ethoxycarbonyl and the substituent (R_2) is a bulky aroyl group, their cyclization reactions afford sole products **62b**—**65b**, **84b**, and **86b**, respectively.

The structures of compounds **24**—**37**, **54**—**65**, and **79**—**89**, were determined by their analytical and spectral inspections and by the mechanistic consideration of their transformations to indolizine derivatives. Adducts **24**, **25**, **28**—**37**, **54**—**56**, **59**, **61**—**65**, **79**, **80**, **83**—**86**, and **88** gave the satisfactory elemental analyses, though almost adducts of them were isomeric mixtures, and more evidently their ^{1}H NMR spectra (Table 1) supported our proposed 1,9a-dihydropyrido[2,1-*c*][1,4]-thiazine structure. For example, the spectrum of compound **24** indicated the proton signals due to the major isomer at δ 2.50 (3H, s, MeS), 4.02 (1H, d, J= 2.0 Hz, 1-H), 4.60 (1H, m, 9a-H), 4.99 (1H, br t, J=7.0 and 6.0 Hz, 7-H), 5.41 (1H, br q, J=10.0 and 4.0 Hz, 9-H), 6.21 (1H, br q, J=10.0 and 6.0 Hz, 8-H), and 6.72 (1H, br d, J=7.0 Hz, 6-H), together with weak proton

Scheme 2.

signals of the minor one appeared at δ 4.03 (1H, d, J=8.0 Hz, 1-H), 4.41 (1H, br q, J=8.0 and 4.0 Hz, 9a-H), and 6.45 (1H, br d, J=7.0 Hz, 6-H). The chemical shifts (δ 4.02—6.72) and the signal patterns of these skeletal protons indicated distinctly the presence of a nonaromatic 1,2-dihydropyridine moiety in **24**, and the presence of the two kinds of the 1-H signals coupled with 2.0 or 8.0 Hz showed that **24** was a cis and trans mixture at the 1- and 9a-positions. From the consideration of Karplus relationship between the coupling constant and the dihedral angle using Dreiding models, we concluded that the major isomer (its dihedral angle is about 60°) is *cis* (**24a**) and the other (its dihedral angle is about 180°) is *trans* (**24b**). The ^{1}H NMR spectrum of **79** obtained from the alkaline treatment of 2-methylpyridinium salt **68** exhibited four methyl proton singlets at δ 1.43, 1.54, 2.08, and 2.25, and a pair of the 6-proton signals at δ 6.54 (br d, J=7.0 Hz) and 6.82 (br d, J=7.0 Hz), together with two methylthio singlets (δ 2.50 and 2.57) and many undistinguishable multiplets in the range of δ 4.0—6.5. From these spectral data we also concluded that

a) The coupling constants are as follows: $J_{1,9a}$=2.0(cis) or 8.0(trans), $J_{6,7}$=7.0, $J_{7,8}$=6.0, $J_{8,9}$=10.0, $J_{9,9a}$=4.0, $J_{7,9}$=2.0, J_{Et}=7.0 Hz. b) Overlapped with the signals of the major isomer. c) Overlapped with the signals at δ 4.4—5.2. d) Overlapped with the signals at δ 4.3—5.2. e) Overlapped with the signals at δ 4.3—5.3. f) Overlapped with the signals at δ 3.9—4.7. g) Overlapped with each others at δ 1.0—1.6 and 4.0—4.7. h) 2.57 or 2.50 (s). i) Overlapped with each others at δ 3.7—6.5.

compound **79** consisted of both cis and trans mixtures of 6-methyl and 9a-methyl derivatives and both cyclization to 2- and 6-positions on the pyridine ring took place. In the same way the distinction between the cis isomer and the trans one in the 9a-methyl derivatives **79c,d**—**89c,d** were carried out by the comparisons of the chemical shifts (δ 6.75—6.90 for the cis isomers **79c**, **81c**, **83c**, **85c**, and **87c**—**89c**, and δ 6.54 for the trans isomer **79d**) of each 6-proton with those (δ 6.59—6.73 for the cis isomers **24a**—**37a** and δ 6.42—6.57 for the trans isomers **24b**—**37b**) of the 9a-H derivatives. These chemical shifts and the signal patterns were very similar to those of 4,4a-dihydropyrido[1,2-*d*][1,3,4]-thiadiazine derivatives synthesized earlier by us.[2b] Furthermore, the transformations of these compounds **24**—**37**, **54**—**65**, and **79**—**89** to the corresponding indolizine derivatives using a dehydrogenating agent supported strongly our proposed structures (See below).

Transformations to Indolizine Derivatives. Because of the thermal instability, the transformations from these dihydropyridothiazines to the corresponding indolizines did not take place except in compounds **26**, **27**, and **58**, and their treatment with an oxidizing or a dehydrogenating agent at a temperature over 0 °C resulted always in polymeric tars. Among many reagents examined for purpose of this transformation, we found that LTA and DDQ gave satisfactory results only when they were used at 0 °C. The reactions of dihydropyridothiazines **24**—**27** and **54**—**61** bearing a cyano or an ethoxycarbonyl group at the 1-position with LTA in tetrahydrofuran (THF) or with DDQ in chloroform in an ice bath afforded the desulfurized indolizines **90**—**101**, and those of compounds **28**—**37** and **62**—**65** having an aroyl group at that position with the same reagents gave the rearranged indolizines **102**—**115** in considerable yields. On the other hand, the reactions of dihydropyridothiazines **79**—**89**, synthesized from 2-methylpyridinium bromides **68**—**78**, with LTA or DDQ gave always only 5-methylindolizine derivatives **116**—**126** which were convertible from 9a-H adducts (types a and b), and did not afford any significant product which might be derived from 9a-methyl compounds (types c and d). The reaction of 1,4-dicyano adduct **79** with LTA, however, gave only 6-acetoxy-1,3-dicyano-5-methyl-2-methylthioindolizine **127** in very low yield (3%) instead of the expected 1,3-dicyano-5-methyl-2-methylthioindolizine **116**, while that of **79** with DDQ yielded normal product **116**. These results are summarized in Schemes 3 and 4. These dehydrogenating agents, LTA and DDQ, were effective to the same extent unless the substituents R and/or R_2 were an ethoxycarbonyl group, but, when the group(s) was so, the latter reagent was superior in the yield and the easy separation to the former.

The same indolizine derivatives could be also synthesized by adding directly DDQ to 1,9a-dihydropyridothiazines generated in situ from the alkaline treatment of the corresponding pyridinium salts (See Scheme 3). It was found that this method has high synthetic value because it can be carried out without the isolation of unstable dihydropyridothiazines.

In above reactions, the desulfurized indolizines **90**—

101 and **116—119** were always formed when R_2 was a cyano or an ethoxycarbonyl group, and the rearranged indolizines **102—115** and **120—126** were obtained whenever R_2 was an aroyl group. These substituent effects are all the same as those observed in the formations from 4,4a-dihydropyrido[1,2-*d*][1,3,4]thiadiazines to the desulfurized and rearranged pyrazolo-[1,5-*a*]pyridines.[1,2]

The structures of these indolizines **90—127** were determined mainly by their spectral and elementary analyses and in part by the comparison with authentic samples **94** (mp 142—143°C, Lit,[5] mp 139°C) and **96** (mp 143—144 °C, Lit,[5] mp 138—139 °C). In particular, the chemical shifts and signal patterns due to the skeletal protons in their ^{1}H NMR spectra (Table 2) were grossly similar to those of known indolizine derivatives prepared by us[6] and by other investigators.[5,7] The mass spectra of compounds **90**, **92**, **102**, **104**, **106**, **108**, and **110** gave molecular ion peaks at *m/z* 213, 260, 324, 360, 404, 338, and 401, respectively. On the other hand, the structure of unusual 6-acetoxyindolizine **127** was decided on the basis of the presences of a AB type signal coupled with 9.0 Hz (vicinal coupling) at δ 7.18 and 7.63 and of an acetoxy methyl signal at δ 2.41

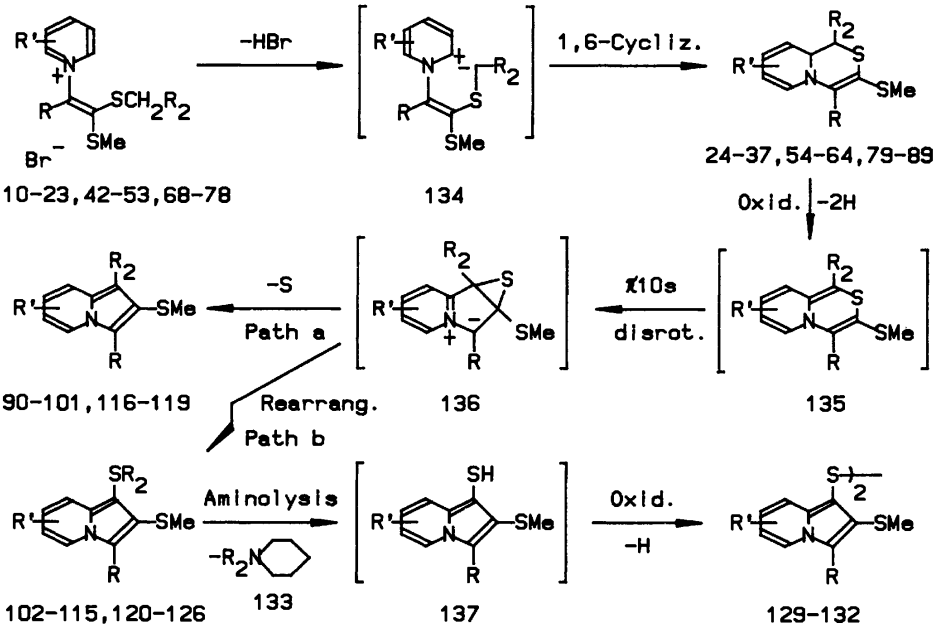
(s) and by the comparison of the chemical shifts of the pyridine protons in the ^{1}H NMR spectrum.

In order to obtain further evidences for the rearranged indolizine structure, the aminolysis of compounds **102**, **103**, **112**, and **113** with piperidine **128** were carried out in ethanol at the reflux temperature, and the corresponding disulfides **129—132** were obtained in good yields together with *N*-benzoylpiperidine **133** (Scheme 5). The structures of disulfides **129—132** were also determined by their IR and ^{1}H NMR spectral inspections in which the absence of the benzoyl group was clearly exhibited.

Reaction Mechanisms. Possible mechanisms for the reactions of pyridinium sals **10—23**, **42—53**, and **68—78** to desulfurized indolizines **90—101** and **116—119**, and rearranged indolizines **102—115** and **120—126** and of the rearranged indolizines to disulfides **129—132** are summarized in Scheme 6. This mechanisms are formally the same as those proposed to the reactions of a 1,3,4-thiadiazinyl anion by Schmidt et al.[3] and of a pyrido[1,2-*d*][1,3,4]thiadiazine by us.[1,2] In contrast with our previos works[1,2] for its aza-analogue, 1,9a-dihydropyrido[2,1-*c*][1,4]thiazine intermediates could be separated actually and the effect of dehydrogenating agents in the conversion from them to aromatic indolizines derivatives was confirmed distinctly. On the other hand, the lowness of the stereoselectivity and the regioselectivity in the 1,6-cyclizations of the zwitterionic species **134** to 1,9a-dihydropyrido[2,1-*c*][1,4]thiazines **24—37**, **54—65**, and **79—89** may be largely owing to the one plane and one anionic pyramidal approach (see Fig. 1) which undergoes less steric hindrance than the two plane approach as seen in normal cycloaddition reactions. The increase of the formation ratios of the trans isomers to cis isomers with the increase of the bulkiness of the group R_2 in the 9a-H adducts **24—37**, **54—65**, and **79a,b—89a,b** can be explained reasonably by considering the sterically less hindered conformation (**B**) in the transition state, and the predominance of the cis isomers in 9a-methyl adducts **79c,d—89c,d** can be understand similarly by thinking the larger steric hindrance of the 2-methyl group than that of the flat pyridine ring. Furthermore, the fact that the



Scheme 6.

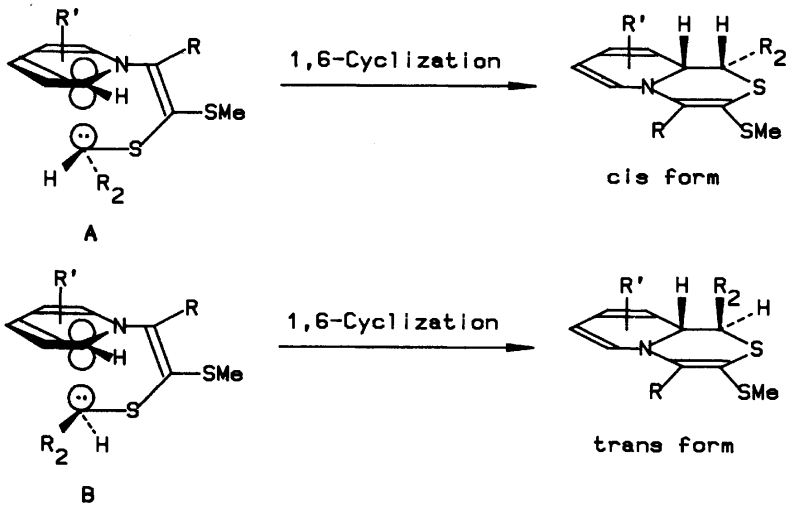


Fig. 1.

effect of the substituent R_2 in these reactions was all the same that as in the transformations of pyridothiadiazines to pyrazolo[1,5-*a*]pyridines suggests strongly a mechanistic similarity between these two reactions.

On the other hand, the mechanism for the formation of 6-acetoxyindolizine **127** is uncertain, but it may involve an attack of the acetoxyl radical generated from LTA onto the electron-rich sp^2 carbon in the pyridothiazine or indolizine intermediate.

Our reactions described here have a theoretical and practical values because only the desulfurizaion has been reported in the reaction of a 1,4-thiazinyl anion system[8] and the *S*-containing indolizine has been scarcely synthesized.[5,9]

Experimental

Melting points were measured with a Yanagimoto micro-melting point apparatus and are uncorrected. Microanalyses were carried out on a Perkin-Elmer 240 Elemental analyzer. The ^1H NMR spectra were determined with a Varian EM360A spectrometer in deuteriochloroform with tetramethylsilane as an internal standard. The chemical shifts are expressed in δ values. The IR spectra were taken with a Hitachi 260-10 Infrared spectrophotometer, and the mass specta with a JEOL LMS-01SG-2 mass spectrometer attached with a JEC-6 spectrocomputer.

Preparations of Pyridinium 1-(Thiocarbonyl)methylides. These pyridinium 1-(thiocarbonyl)methylides **1**, **2**, **38**—**41**, **66**, and **67** were synthesized from the alkaline treatment of

the corresponding pyridinium chlorides, carbon disulfide, and dimethyl sulfate according to the procedure described in the literature.[10] Some properties of new compounds **2** and **66** are as follows: **2**, 76%, yellow needles, mp 180—181 °C (from EtOH-$CHCl_3$), IR (KBr) 2165 (CN) and 1399 cm^{-1}. Found: C, 54.27; H, 4.52; N, 12.65%. Calcd for $C_{10}H_{10}N_2S_2$: C, 54.02; H, 4.53; N, 12.60%. **66**, 68%, yellow prisms, mp 145—146 °C (from EtOH-$CHCl_3$), IR (KBr) 2160 (CN) and 1385 cm^{-1}. Found: C, 53.96; H, 4.54; N,12.65. Calcd for $C_{10}H_{10}N_2S_2$: C, 54.02; H, 4.53; N, 12.60.

Preparations of Pyridinium Bromides. General Method. These pyridinium salts **10—23**, **42—53**, and **68—78** (2 mmol) were prepared in quantitatively yields from the reactions of the corresponding pyridinium methylides **1**, **2**, **38—41**, **66**, and **67** (2 mmol) with small excess of alkyl bromides **3—9** (2.4 mmol) in chloroform at room temperature for 1—10 d. After the evaporation of the solvent followed by the removal of an unaltered alkylating agent by washing them three times with 30 ml portions of ether, they were used immediately to the next reactions without further purification.

Preparations of 1,9a-Dihydropyrido[2,1-*c*][1,4]thiazines. General Method. To a chloroform solution (20 ml) of pyridinium bromide (2 mmol) DBU (0.380 g, 2.5 mmol) was added dropwise under stirring in an ice bath. The resulting dark red solution was kept for further 10 min at the temperature, and then concentrated immediately at reduced pressure at below 40 °C. The residue was quickly separated by short pass column chromatography (alumina, 1.7 cm diameter×7 cm long) using chloroform as an eluent. The chloroform layer was concentrated at reduced pressure without heating. The same column separation was repeated further two times. Recrystallizations of the resulting 1,9a-dihydropyrido[2,1-*c*][1,4]thiazines from chloroform-hexane in a freezer afforded pure samples.

The preparations of pure samples of compounds **26**, **27**, **57**, **58**, **81**, **82**, and **89** for analyses and the separations of the cis and trans mixtures were unsuccessful because of their thermal instability, but pure **24a** was isolated by the repeated recrystallization. Compounds **26**, **27**, and **58** were decomposed in a freezer to give the aromatized indolizines **92**, **93**, and **98** in 76, 66, and 15% yields, respectively.

Some data of these products are listed in Tables 1 and 3.

Preparations of Indolizines. General Method A. To a tetrahydrofuran solution (30 ml) of dihydropyridothiazine (1 mmol) LTA (0.443 g, 1 mmol) was added under stirring in an ice bath and the solution was stirred for further 6 h at the temperature. The resulting solution was filtered to remove insoluble substances and the filtrate was concentrated at reduced pressure. The residue was separated by column chromatography (alumina) using ether and then chloroform as eluents. The combined chloroform layer was concentrated and the recrystallization of the residue from chloroform-hexane gave the corresponding indolizine derivatives.

General Method B. DDQ (0.227 g, 1 mmol) as a dehydrogenating agent and chloroform as a solvent were

employed here instead of LTA and tetrahydrofuran in Method A. The same work-ups yielded the corresponding indolizines.

General Method C. To a chloroform solution (30 ml) of pyridinium bromide (2 mmol) DBU (0.380 g, 2.5 mmol) was added dropwise under stirring in an ice bath and the resulting dark red solution was stirred for further 10 min at the temperature. An equimolar amount of DDQ was added to the reaction mixture and the resulting solution was stirred for 6 h in an ice bath. The same work-ups described in Method A gave indolizine derivatives.

The treatment of dihydropyridothiazines with LTA or DDQ at over 0°C gave always polymeric tars, and those at below 0 °C required more prolonged reaction time (a week to a month). When LTA was used as a dehydrogenating agent in the preparations of indolizines **92—95**, **98—101**, **117—119**, **121**, and **123** possessing an ethoxycarbonyl groups, the isolations of their indolizines from the reaction mixtures were considerably troublesome due to the formation of polymeric tars with similar solubility.

These data were summarized in Tables 2 and 4.

Preparations of Disulfides. General Method. An ethanolic solution (30 ml) of 1-benzoylthioindolizine (1 mmol) and piperidine **128** (0.50 g, 5.9 mmol) was heated under reflux for 6 h, the resulting solution was cooled overnight in a freezer, the separated crystals were collected by filtration, and the recrystallization from ethanol afforded the corresponding disulfide. The concentration of the filtrate, followed by its column separation (alumina) gave 1-benzoylpiperidine **133** in very good yields (88—96%). The structure of compound **133** was determined by comparison with the authentic sample.[11]

Some data of these disulfides are as follows: **129**, 90%, yellow prisms, mp 190—193 °C, IR (KBr) 2199 cm^{-1} (CN), ^1H NMR ($CDCl_3$) δ=2.62 (6H, s, 2×SMe), 6.6—7.1 (6H, m, 6, 7, 8, 6′, 7′, and 8′-H), and 8.11 (2H, br d, J=7.0 Hz, 5 and 5′-H). Found: C, 54.54; H, 3.19; N, 13.03%. Calcd for $C_{20}H_{14}N_4S_4$: C, 54.77; H, 3.22; N, 12.77%. **130**, 90%, yellow needles, mp 206—207 °C, IR (KBr) 2190 cm^{-1} (CN), ^1H NMR, ($CDCl_3$) δ=2.24 (6H, s, 2×Me), 2.66 (6H, s, 2×SMe), 6.5—6.9 (4H, m, 6, 8, 6′, and 8′-H), and 7.99 (2H, d, J=7.0 Hz, 5 and 5′-H). Found: C, 56.54; H, 3.86; N, 12.28%. Calcd for $C_{22}H_{18}N_4S_4$: C, 56.62; H, 3.89; N, 12.01%. **131**, 73%, yellow needles, mp 120—121 °C, IR (KBr) 1681 cm^{-1} (CO), ^1H NMR ($CDCl_3$) δ=1.46 (6H, t, J=7.0 Hz, 2×$\underline{CH_3}CH_2O$), 2.59 (6H, s, 2×SMe), 4.47 (4H, q, J=7.0Hz, 2×$CH_3\underline{CH_2}O$), 6.5—7.1 (6H, m, 6, 7, 8, 6′, 7′, and 8′-H), and 9.31 (2H, m, 5 and 5′-H). Found: C, 54.10; H, 4.53; N, 5.43%. Calcd for $C_{24}H_{24}N_2O_4S_4$: C, 54.11; H, 4.54; N, 5.26%. **132**, 86%, yellow prisms, mp 141 °C, IR (KBr) 1664 cm^{-1} (CO), ^1H NMR ($CDCl_3$) δ=1.45 (6H, t, J=7.0 Hz, 2×$\underline{CH_3}CH_2O$), 2.01 (6H, s, 2×Me), 2.64 (6H, s, 2×SMe), 4.47 (4H, q, J=7.0 Hz, 2×$CH_3\underline{CH_2}O$), 6.47 (2H, br d, J=7.0 Hz, 6 and 6′-H), 6.51 (2H, br s, 8 and 8′-H), and 9.20 (2H, d, J=7.0 Hz, 5 and 5′-H). Found: C, 55.67; H, 4.92; N, 4.80%. Calcd for $C_{26}H_{28}N_2O_4S_4$: C, 55.69; H, 5.03; N, 5.00%.

In-beam EIMS and Molecular SIMS of Quaternary Ammonium Chlorides of Benzylamine Derivatives

Yasuo SHIDA,* Kazuo TSUJIMOTO,† Takashi IKEDA,† and Mamoru OHASHI*,†
Tokyo College of Pharmacy, Horinouchi 1432-1, Hachioji, Tokyo 192-03
†Department of Materials Science, The University of Electro-Communications, Chofu, Tokyo 182
(Received December 1, 1986)

The in-beam EIMS and SIMS of three quaternary ammonium chlorides of benzylamine derivatives have been examined, and their fragmentation processes have been clarified by means of the B/E costant and B^2/E constant linked scanning techniques. The B/E constant linked scan of the benzyltrimethylammonium ion (m/z 150) in the in-beam EIMS indicated a fragment ion at m/z 126 as a daughter ion. A substitution reaction between the m/z 150 ion and a chlorine atom in the first field free region is proposed. The characteristics of SIMS of those compounds were demonstrated in comparison with those of EIMS and the fragmentation processes of the salts upon Xe^+ bombardment were established based on the linked scanning techniques.

In order to test the suitability of the unified model for soft ionization proposed by Vestal[1] we have examined the matrix effects on the in-beam Electron Ionization Mass Spectrometry (EIMS) of quaternary ammonium salts.[2] During the course of this investigation we tried to clarify the fragmentation processes of those quaternary ammonium salts upon electron ionization (in-beam EI) and upon Xe^+ bombardment [molecular Secondary Ion Mass Spectrometry (SIMS)] on the basis of the B/E constant and the B^2/E constant linked scanning mass spectra. We found that the linked scans indicated the unusual behavior of the benzyltrimethylammonium ion in the in-beam EIMS. This article deals with the fragmentation processes of three quaternary ammonium salts of benzylamine derivatives upon electron impact and upon Xe^+ ion bombardment.

Experimental

The in-beam EIMS were taken with a Hitachi RMU-6 and a Hitachi M-80 spectrometers. The in-beam EIMS were obtaind with an electron energy of 70 eV (80 μA) and at a source temperature of 200 °C. Samples were introduced into the in-beam system with probe heating at 300 °C. The molecular SIMS were performed with a double focusing Hitachi M-80B spectrometer. Xenon was used as the primary ion source and was accelerated to 8 kV. In these studies the samples dissolved in glycerol matrix were applied to the stainless steel target for the molecular SIMS. The B/E constant and the B^2/E constant linked scanning techniques were applied to each spectrum.

Benzyltrimethylammonium chloride (**1**), benzyltriethylammonium chloride (**2**) and benzyldimethylphenylammonium chloride (**3**) were purchased from Tokyo Kasei Co. and used without further purification.

Results and Discussion

1. In-beam EIMS. Figure 1a shows the in-beam EIMS of **1**. The intact quaternary ammonium ion is observed at m/z 150 (C^+), and the fragment ions at m/z 135 (C^+–Me), 126 ($PhCH_2Cl^+$), 91 ($C_7H_7^+$) and 58 ($CH_2{=}NMe_2$) are also abundant. The fragment ion at m/z 126 must contain chlorine atom because of the relative abundance of the isotope peak at m/z 128, and must correspond to the molecular ion of benzyl chloride. This ion seems to come from a thermal SN-2 type reaction under the in-beam conditions producing benzyl chloride molecules followed by electron ionization. In order to confirm the origins of the ion at m/z 126 as well as the other fragment ions, we examined the B/E constant linked scan of the C^+ at m/z 150. Figure 2a represents its spectrum. As expected, the ions at m/z 135, 134, 91, and 58 are shown to be derived from C^+ in accorded with the general fragmentation of quaternary ammonium salts in the in-beam EI.[3-5]

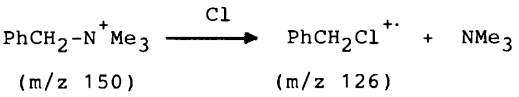
Surprisingly, this linked scan also indicates that the ion at m/z 126 is a daughter ion of C^+. The same technique showed that the m/z 126 ion is the parent ion of the m/z 91 ion, consistant with the structure of benzyl chloride. To ascertain the origin of the m/z 126 ion, we examined the B^2/E constant linked scan and found abroad weak peak around m/z 135 as the parent ion. Figure 3a shows the linked scanning spectrum. However, the B/E constant linked scan of m/z 135 ion did not show any peaks at m/z 126, but strong praks at m/z 91 and 58 as shown in Fig. 3b. If the ion at m/z 135 is the parent ion of m/z 126 ion, the fragmentation processes involving a charge exchange mechanism as shown in Scheme 1 may account for this unusual

$$\underset{(m/z\ 150)}{PhCH_2\text{-}N^+Me_3} \longrightarrow \underset{(m/z\ 135)}{PhCH_2\text{-}N^{+\cdot}Me_2} \xrightarrow{PhCH_2Cl} \underset{(m/z\ 126)}{PhCH_2Cl^{+\cdot}} + PhCH_2NMe_2$$

Scheme 1.

transition. However, it is hard to rationalize that collision between the *m/z* 135 ion and benzyl chloride transfers not only an electron but also the kinetic energy to each other.

The second possibility is a collision between the C^+ and a chlorine atom in the first field free region in accordance with the result of the *B/E* constant linked scan. Scheme 2 shows an example of the reaction. Since, under the in-beam conditions, large amounts of neutral species are vaporized in the ion source,[1] many



Scheme 2.

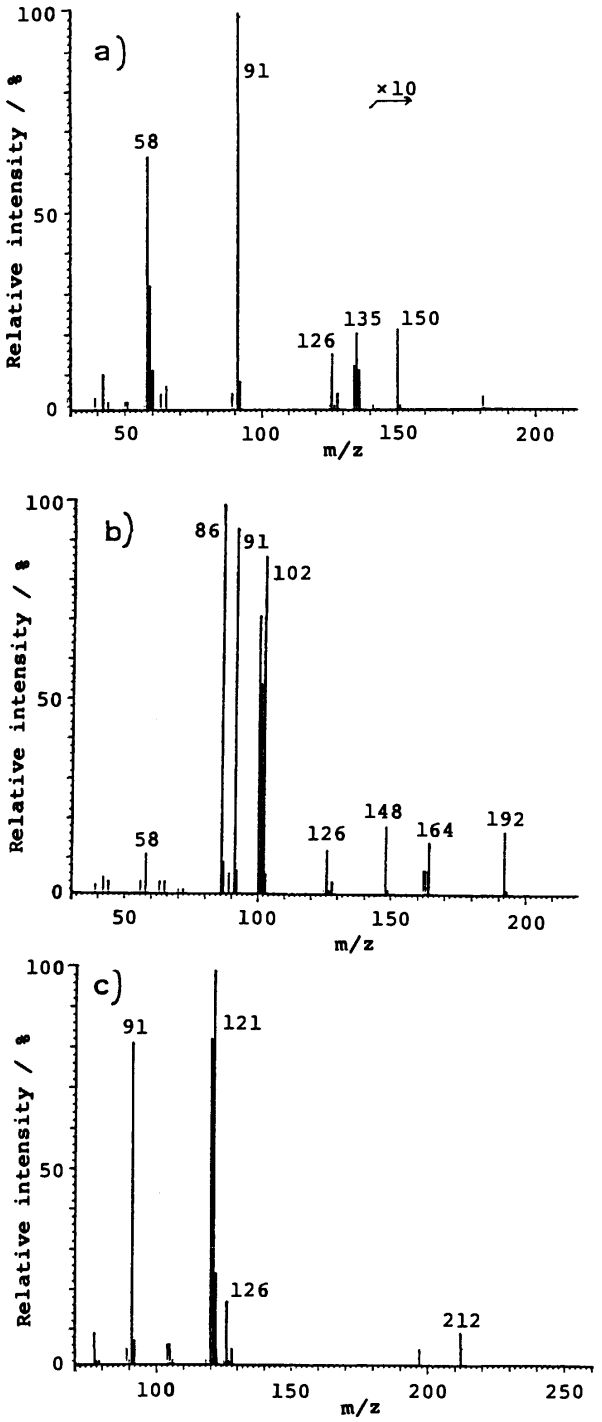


Fig. 1. In-beam EIMS of three quaternary ammonium chlorides of benzylamine derivatives.

ion-molecular reactions are also expected to happen in the first field free region. At this stage, the processes shown in Scheme 2 are reasonably conceivable. The third possibility is the so-called "artifact peak" discussed by Beynon et al.[6] Suppose that there are a parent ion m_1, a daughter ion m_2, and another ion m_3 formed in the source and fully accelerated, which then decomposes to give an ion m_4. The only necessary condition for the detection of m_4 in the B/E constant linked scanning spectra is as follows;

$$m_3=m_2^2/m_1,\ m_4=m_2m_3/m_1.$$

In our case, $m_1=150$ and $m_2=126$. Then substituting these values for the equations, we obtained $m_3=106$, $m_4=89$. However, we found no peak corresponding to those ions. Thus the possibility of the artifact peak is excluded. The fragmentation processes of the in-beam EIMS of **1** are summarized in Scheme 3.

The in-beam EIMS of **2** and **3** are shown in Figs. 1b and 1c, respectively. The B/E constant linked scanning spectra of each C^+ at m/z 192 or 212 are shown in Figs. 2b and 2c, respectively. Figures 2b and 2c also show the presence of benzyl chloride ion at m/z 126 and 128, but the linked scanning spectra do not. Thus we conclude that the unusual behavior of **1** in the B/E constant linked scan is not general, but very specific. The fragmentation processes of **2** and **3** upon in-beam EI are summarized in Scheme 4 and 5, respectively.

2. SIMS. Figures 4a—c show the glycerol assisted SIMS os **1, 2,** and **3**, respectively. The major fragment ions from the quaternary ammonium ion (C^+) are similar to those of the in-beam EIMS. Several major differences between the SIMS and the in-beam EIMS are also noticed: i.e., (1) the cluster ions of $(R_4N^+)_2Cl$ are observed in the SIMS but not in the in-beam EIMS, (2) the ions at m/z 126 and 128 due to the benzyl chloride molecular ion observed in the in-beam EIMS are absent in the SIMS, (3) the fragment ions having not only even electrons but also odd electrons are often observed in the in-beam EIMS but the ions carrying only even electrons are observed in the SIMS. For instance, in the SIMS spectrum of **2** (Fig. 4b), the peaks at m/z 163, 102, and 101 observed in the in-beam EIMS are absent, but the peaks at m/z 192, 162, 148, 100, 91, and 86 are commonly observed in both spectra. Similarly, in the case of **3**, the peaks at m/z 212, 121,

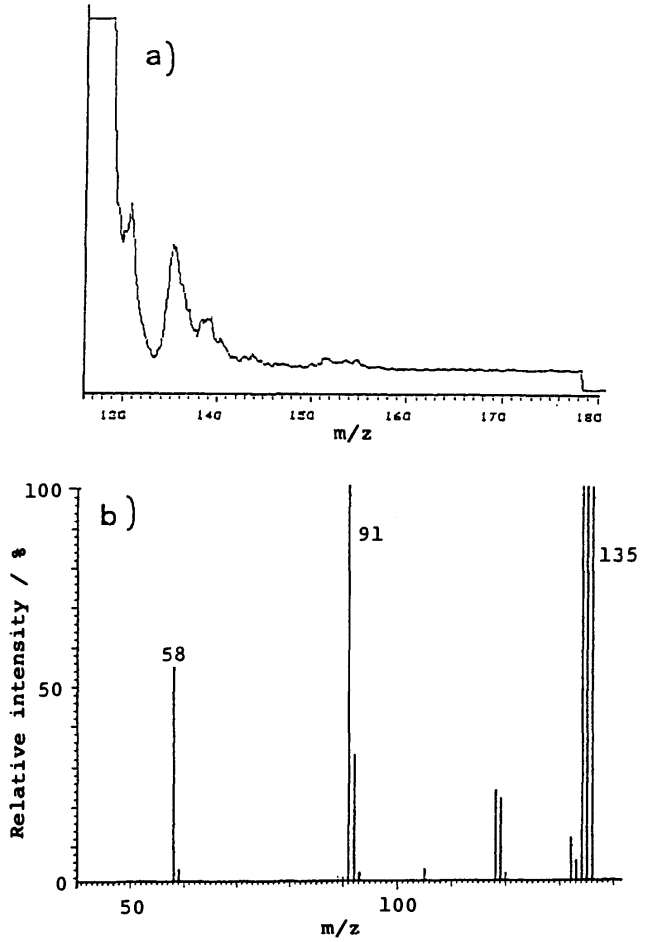

Fig. 3. a) B^2/E constant linked scanning spectrum of m/z 126 ion, and b) B/E constant linked scannining spectrum of m/z 135 ion of the in-beam EI spectrum of **1**.

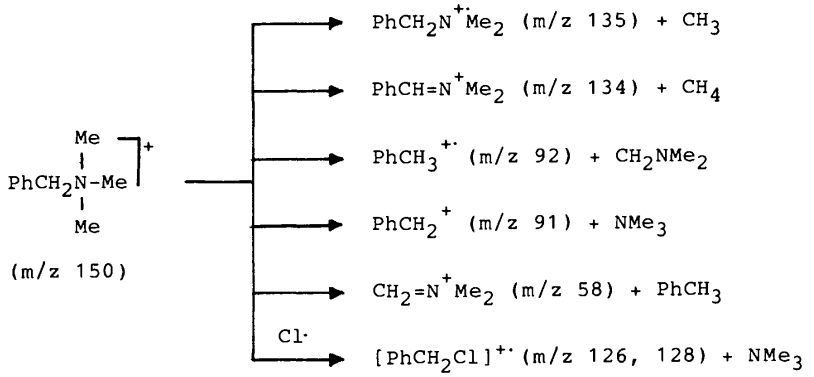

Scheme 3.

and 91 are common in both spectra, but strong peak at *m/z* 120 observed in the in-beam EIMS is absent in the SIMS.

The *B/E* constant and B^2/E constant linked scanning spectra of major peaks of **1** are shown in Figs. 5 and 6, respectively. On the basis of these spectra, the fragment processes of **1** are summarized as shown in Scheme 6: i.e., the cluster ion at *m/z* 335 forms only a C^+ ion at *m/z* 150, which decomposes to yield ions at *m/z* 134, 91, and 58 and the ion at *m/z* 134 also produces the *m/z* 91 ion.

Similarly, the fragmentation processes of **2** and **3** in the SIMS are also summarized in Scheme 7 and 8, respectively.

In conclusion we have clarified the characteristics of the in-beam EIMS and the SIMS of three quaternary

ammonium chlorides of benzylamine derivatives, and indicated the unusual behavior of benzyltrimethylammonium chloride in the *B/E* constant linked scanning spectra. Care must be taken for the interpretation of the *B/E* constant linked scanning spectra, considering the possibilities of the ion-molecular reactions in the first field free region in the in-beam EIMS.

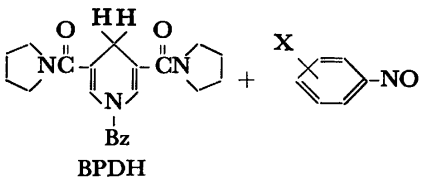
(Received December 1, 1986)

Metal ion catalyzed reduction of substituted nitrosobenzenes by 1-benzyl-3,5-bis(1-pyrrolidinylcarbonyl)-1,4-dihydropyridine (BPDH) in acetonitrile has been studied for seven bivalent metal ions. The reduction of *N*-methylacridinium salt (MA) has also been examined. In the former cases, it was found that the metal ions catalyze the reduction by forming a 1:1 complex with BPDH according to a Michaelis-Menten type saturation kinetics which allowed to derive the association constants, K_M, for the complexation and the second-order rate constants, k_2, for the reduction. A linear relationship was found between log k_2 and the ionization potentials of metal ions with a positive slope. A linear Hammett relationship was also observed between log k_2 and the Hammett σ constants with a positive ρ value for three metal ions. These results suggest that a bivalent metal ion is sandwiched between the BPDH and the substrate and acts as a Lewis acid to stabilize the incipient *N*-oxide anion of the substrate which is formed by hydride transfer in the transition state. In the cases of MA, all metal ions inhibited the reduction. Repulsion between the positive charges of the metal ion-BPDH complex and the substrate salt appears to be prevailing.

The role of zinc ion at the active site of alcohol dehydrogenase has attracted much attention in recent years.[1] Recent crystallographic and the related studies[2-5] have disclosed the following features for the structure of reactive ternary complex at the active site of the enzyme: (a) A zinc ion sits at the bottom of a hydrophobic pocket, (b) the oxygen atom of substrate is directly coordinated to the zinc ion, and (c) there is no direct contact between the zinc ion and the coenzyme. These features strongly suggest that the zinc ion performs as an electrophile to polarize the carbonyl group or to ionize the hydroxyl group of substrate.

In the model studies, it has also been observed that a bivalent metal ion such as Mg^{2+} or Zn^{2+} ion accelerates the rate of reduction of some carbonyl substrates,[6-22] and it has been considered that a metal ion may also polarize the substrate carbonyl group as a Lewis acid as in enzymic systems.[6-8,12,15] However, the role of a bivalent metal ion in model systems so far studied seems to be somewhat different from the one suggested for the above enzymic systems on the following grounds.[13-22] Namely, it has been demonstrated that a bivalent metal ion such as Mg^{2+} or Zn^{2+} ion forms a complex with the 1,4-dihydronicotinamide moiety of the reductants.[14-22] It has also been indicated that Mg^{2+} ion does not show any measurable complexation with such a substrate as ethyl benzoylformate, in spite of the rate acceleration.[16]

We have also been interested in the activation of model systems of NADH coenzyme by acids and metal ions. In our previous paper, we reported the carboxylic acid-catalyzed reduction of substituted nitrosobenzenes by BPDH in acetonitrile.[23,24] We proposed a mechanism that a carboxylic acid acts as a general acid by protonating the oxygen atom of nitroso group of the substrate in the transition state. The acid-catalyzed rate was faster for a substrate having a more electron-donating substituent. As a natural extension, we have now studied the metal ion-catalyzed reduction of substituted nitrosobenzenes (NB) by BPDH in acetonitrile (Eq. 1). We will describe in this paper that bivalent metal ion catalysis is much more efficient than carboxylic acid one and the rate is faster for a substrate having a more electron-withdrawing substituent, in contrast to the case of the above acid-catalysis.



BPDH (1)

Results

Products, Kinetic Analysis, and Metal Ion Catalysis. The reduction was carried out in anhydrous acetonitrile under nitrogen atmosphere. The substrate nitrosobenzenes were confirmed to be reduced to hydroxylamines quantitatively by HPLC analysis as described before.[23,24] The rates of reduction were followed spectrophotometrically by observing the decrease of absorbance at 355 nm due to the disappearence of BPDH. The rate of reduction was slow in the absence of metal ion. In the presence of a metal ion, the pseudo-first-order rate constant, k_{obsd} increased with increasing concentration of the metal ion according to a manner to obey a Michaelis-Men-

ten type saturation kinetics, as shown in Fig. 1. Here the metal ions were used as the perchlorates with water of crystallization. The results suggest the complexation of the metal ion with either BPDH or a nitrosobenzene, or both before the rate-limiting step. As for the substrate, it was observed that the rates (k_{obsd}) were first-order with respect to the concentration of the nitrosobenzene, as shown in Fig. 2. Therefore, the complexation between the substrate nitrosobenzene and the metal ion prior to the reduction seems to be unimportant.

It was confirmed spectrophotometrically that the complexation occurs between Zn^{2+} ion and BPDH. As shown in Fig. 3a, the absorption maximum of BPDH at 355 nm in the absence of metal ion shifts to a shorter wavelength of 320 nm in the presence of Zn^{2+} ion. The plots of absorbance change as a function of the Zn^{2+} ion concentration gave a saturation curve of Fig. 3b which indicates a complexation and fits nicely with the curve for Zn^{2+} ion in Fig. 1. Thus, it is likely that the rate acceleration by Zn^{2+} ion is due to the

complexation of BPDH with the Zn^{2+} ion. A similar correlation between the rate acceleration and the spectral change was also confirmed for the other metal ions. Furthermore, the rate of reduction was observed to be inhibited in the presence of water and this rate inhibition was perfectly parallel to the loss of complexation as shown in Fig. 4.

The saturation curves in Fig. 1 can be described by assuming a reaction scheme shown in Scheme 1 in which BPDH (DH) and a metal ion (M^{2+}) form a 1:1 complex ($DH \cdot M^{2+}$) with an association constant, K_M, and the complex reacts with the substrate (ArNO) with a second-order rate constants, k_2, to give the products, D^+ and $ArNHO^-$. Uncatalyzed rate (k_2') must also be taken into account, although its contribution to the total rate was negligible. The scheme leads to a rate equation shown by Eq. 1, and under the conditions of $[M]_T \gg [DH \cdot M]$, Eqs. 2 and 3 can be derived by an approximation, where $[DH]_T$ and $[M]_T$ are the total concentration BPDH and metal ion, respectively, and $[ArNO]_0$ is the initial concentration of substrate which is used in a large excess and taken to be constant under a pseudo-first-order conditions. Experimentally, the k_2 and K_M values were obtained as usual from the reciprocal plots of Eq. 4. The results are shown in Table 1.

$$\text{Rate} = k_{obsd}[DH]_T = k_2'[ArNO]_0[DH]_T + k_2[ArNO]_0[DH \cdot M^{2+}] \quad (1)$$

$$[DH \cdot M^{2+}] = \frac{K_M[M]_T[DH]_T}{1+K_M[M]_T} \quad ; \quad [M]_T \gg [DH \cdot M^{2+}] \quad (2)$$

$$k_{obsd} = k_0 + \frac{k_2K_M[ArNO]_0[M]_T}{1+K_M[M]_T} \quad ; \quad k_0 = k_2'[ArNO]_0 \quad (3)$$

$$\frac{1}{(k_{obsd}-k_0)} = \frac{1}{k_2[ArNO]_0} + \frac{1}{k_2K_M[ArNO]_0} \cdot \frac{1}{[M]_T} \quad (4)$$

$$DH + M^{2+} \overset{K_M}{\rightleftharpoons} DH \cdot M^{2+} \xrightarrow{k_2[ArNO]_0} D^+ + Ar\text{-}NHO^- + M^{2+}$$

$$DH + ArNO \xrightarrow{k_2'} D^+ + ArNHO^-$$

Scheme 1.

The k_2 and K_M values as the Functions of Ionization Potentials of Metal Ions. In Table 1 are shown the ionization potentials (I_P) of metal ions[25] in addition to the above k_2 and K_M values. It can be seen that there is a good linear relationship between I_P and $\log k_2$ values, as shown in Fig. 5. It indicates that a metal ion having a higher I_P is more active. In Fig. 6 is also shown a correlation between I_P and $\log K_M$ values. Although the correlation is not so good as in the case

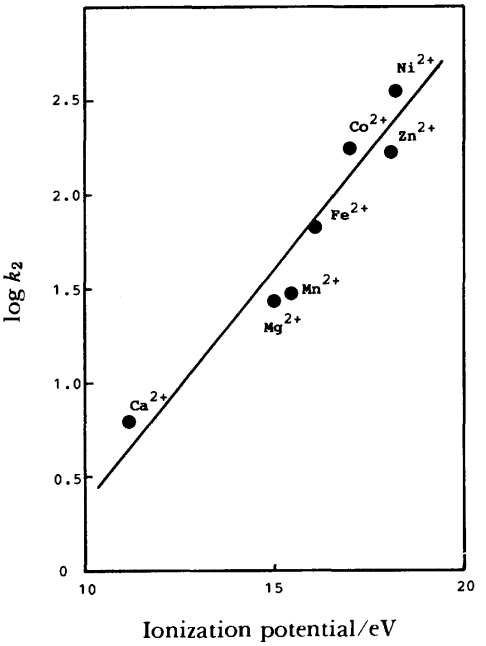

Fig. 5. Correlation between I_P and $\log k_2$.

of Fig. 5, there is a clear tendency that a metal ion having a lower I_P forms a stronger complex with the dihydropyridine (BPDH). The Table 1 also indicates that, at a high metal ion concentration, i.e., $K_M[M]_T \gg 1$, the observed reactivity (k_{obsd}) is governed by k_2 value (see Eq. 3) which is in the order of $Ni^{2+}>Co^{2+}>Zn^{2+}>Fe^{2+}>Mn^{2+}>Mg^{2+}>Ca^{2+}$, but at a low metal ion concentration, i.e., $K_M[M]_T \ll 1$, the reactivity is governed by k_2K_M which is in the order of $Zn^{2+}>Mn^{2+}>Co^{2+}>Fe^{2+}>Mg^{2+}>Ca^{2+}>Ni^{2+}$. It may be interesting that biologically important Zn^{2+} ion is the most active at a low metal ion concentration.

The Effects of Substrate-Substituents on the Rates. Figure 1 indicates that the rates of reaction (k_{obsd}) become saturated with the use of 3×10^{-3} M† of metal ion in the presence of 1×10^{-4} M of BPDH and 1×10^{-3} M of NB (X=H) for all the metal ions except for Ni^{2+} ion. For the other substituted NB's (X=*p*-CH_3 to *m*-CF_3), the rate saturation was also observed at the metal ion concentration of 3×10^{-3} M except for Ni^{2+} ion. Therefore, these saturated rates can be used as the substitutes of k_2 values (see Eq. 3) to examine the Hammett relationships. The results are shown in Table 2 and Fig. 7. A good linear relationship can be seen for each of the five metal ions. The ρ values

Table 3. Temperature Effect on the Second-Order Rate Constants for the Reduction of Nitrosobenzene by BPDH in the Presence of Metal Ions in Acetonitrile[a)]

	k_2 / s^{-1} mol^{-1} dm^3		
T	Zn^{2+}	Ni^{2+}	Mg^{2+}
5 °C	108	36.5	10.1
15 °C	131	51.1	18.5
25 °C	171	83.4	30.0
35 °C	206	109	39.7
ΔH^* / kJ mol^{-1}	13.0	23.9	30.0
ΔS^* / J K^{-1} mol^{-1}	152	121	109
$T\Delta S^*$ / kJ mol^{-1}	45.2	36.0	32.4

a) [BPDH] = 1 × 10^{-4} mol dm^{-3}, [C_6H_5NO] = 1 × 10^{-3} mol dm^{-3}, [metal ion] = 3 × 10^{-3} mol dm^{-3}.

obtained from the slopes of the straight lines are 0.76, 0.81, 0.89, 1.12, and 1.23 for Co^{2+}, Zn^{2+}, Ni^{2+}, Mn^{2+}, and Mg^{2+} ion, respectively. The ρ value for Ni^{2+} ion may be somewhat larger than that expected for the saturated rates. At any rate, these ρ values are all positive, indicating that the rate-determining k_2 step is assisted by an electron-withdrawing substituent on the substrate NB. It is also noticed that the ρ value is smaller for a more active metal ion.

Temperature Effects. The temperature effects on the above saturation rates were examined for three metal ions as shown in Table 3 and in Figs. 8 and 9. It may be seen that the weight of ΔH^* term to the total rate is relatively small as compared to the ΔS^* term, especially in the case of Zn^{2+} ion. A linear isokinetic relationship in Fig. 9 may indicate the mechanism of catalysis to be the same for these three metal ions.

Metal Ion Inhibition in the Reduction of *N*-Methylacridinium Cation (MA). As shown in Fig. 10, the reduction of MA ion by BPDH was found to be inhibited by all metal ions. The order of inhibition is $Ni^{2+}<Co^{2+}<Zn^{2+}<Fe^{2+}<Mn^{2+}<Mg^{2+}<Ca^{2+}$ and almost the same as in the order of the association constants between BPDH and metal ions shown in Table 1. It may be suggested that the inhibition is due to a charge repulsion between the positive charge of substrate salt and metal ion-BPDH complex.

Discussion

It has been established in the model studies of NADH coenzyme that the metal ions such as Zn^{2+} and Mg^{2+} enhance the rates of reduction of some carbonyl substrates.[6-22)] However, much remain to be clarified for the mechanism of metal ion catalysis. As mentioned in the introductory part, it has been proposed that a metal ion may polarize the substrate carbonyl group as a Lewis acid to facilitate the reduction.[6-8,12,15)] However, confusing facts for this idea are the spectral evidence for the complexation between a metal ion and the dihydropyridine moiety, but not between a metal ion and the substrate carbonyl group. Namely, the electronic absorption at around 350 nm due to the π-π^* transition of the dihydropyridine moiety undergoes a red shift on complexation with a metal ion.[9,14-16,18,19)] Two explanations were proposed for the modes of complexation. Ohno et al.

proposed a sandwich type complexation for the transition state of reduction in which Mg^{2+} ion is located between the dihydropyridine and the substrate based on the electronic and infrared spectra.[13,16,17] Gase et al., however, explained differently based on the ^{13}C NMR spectra that Mg^{2+} ion coordinates to the amide oxygen of 1-benzyl-1,4-dihydronicotinamide.[20] Hughes et al. also considered the complexation on the amide moiety based on the electronic[9] and ^{1}H and ^{13}C NMR[14] spectra.

The present BPDH was also found to show a strong complexation with a bivalent metal ion in dry acetonitrile as manifested from the changes of absorption spectra at around 355 nm (Fig. 3) and from the saturation kinetics (Fig. 1). Here it should be noticed that the spectral change was a blue shift of 355 nm absorption, in contrast to a red shift mentioned above. There may be two conceivable types of complexation which result in different spectral changes as illustrated in Fig. 11. One is the complexation on the amide-oxygen (a) which would result in a red shift because of the metal ion stabilization of an excited state. The other is the complexation on the dihydropyridine ring involving an enamine π-system (b) which would result in a blue shift because of the metal ion destabilization of an excited state.[21,22] The observed blue shift seems to conform to the latter possibility.

As shown in Table 1 and Fig. 6, there is a tendency that a metal ion having a lower I_P forms a stronger complex with BPDH. As for the transition metal ions, it can also be shown that the magnitude of $\log K_M$ increases linearly with increasing ionic radius of metal ion in the order of $Ni^{2+}<Co^{2+}<Zn^{2+}<Fe^{2+}<Mn^{2+}$. This order is contrary to that of commonly observed Irving-Williams series.[26] This order is also difficult to correlate with the softness parameters σ_p of Pearson and Mawby[27] and σ_A of Ahrland[28] proposed for these metal ions. On the other hand, the rates of exchange of hydrated water molecule of aqua complexes of metal ions are known to be in the order of $Ni^{2+}<Co^{2+}<Fe^{2+}<Mn^{2+}$,[29] similarly as in the above order. For further discussions, however, it is necessary to know the ligand-exchange equilibrium between the hydrated water and BPDH since in this study the hydrated metal ions were used.

It is well-known that the pK_a's of aqua complexes of metal ions are linearly correlated with the ionization potentials (I_P) of metal ions.[30] Namely, the acidity of hydrated water becomes stronger on a metal ion of higher I_P. Thus, a linear correlation between the k_2 and the I_P values in Fig. 5 strongly suggests that the k_2 step is facilitated by the stabilization of the incipient *N*-oxide anion formed as the proceeding of hydride transfer in the transition state. The postulated mechanism is illustrated in Fig. 12. The figure also indicates a concerted process in which the exchange of ligand on the metal ion occurs from the dihydropyridine to the anion of product hydroxylamine. In this mechanism, it is important to know whether a metal ion does polarize the substrate N=O double bond before the hydride transfer or not, which might be answerd by looking at the Hammett substituent effect. In Fig. 7, the Hammett ρ values were observed to be in a range 0.76—1.23 which indicates the k_2 step to be facilitated by an electron-withdrawing substituent of the substrate. On the other hand, we reported previously that the ρ values for uncatalyzed and the carboxylic acid-catalyzed rates are 1.35 and −0.93, respectively.[24] The present ρ values are thus very close to that of uncatalyzed rates, suggesting that, in the present metal ion-catalyzed reduction, the substrate NO bond is not perturbed much by metal ion before the hydride transfer. It should be noticed that a negative ρ value (−0.93) for the carboxylic acid-catalysis indicates the importance of protonation of NO group in the transition state. Thus, the metal ion catalysis is found to be quite different from the carboxylic acid catalysis in anhydrous acetonitrile.

A sandwich structure in Fig. 12 proposed for the ternary complex in the transition state appears to be similar to that proposed by Ohno et al. for the

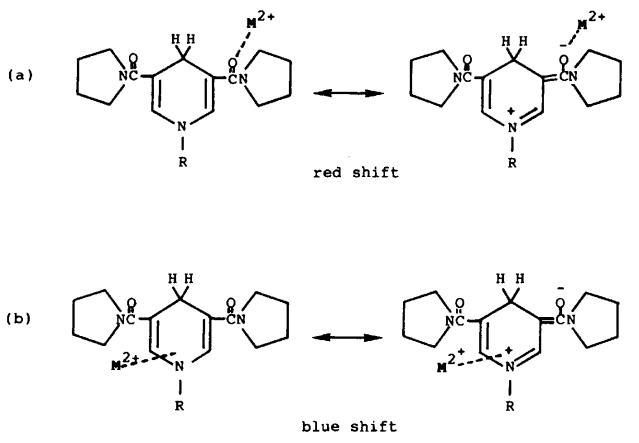

Fig. 11. Schematic illustration to explain a red shift (a) and blue shift (b) of electronic absorption at around 355 nm of BPDH on complexation with a metal ion.

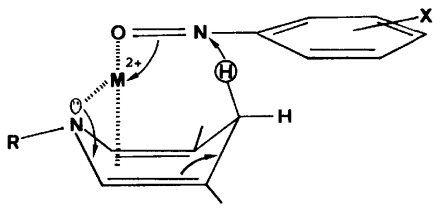

Fig. 12. Schematic illustration of the transition state for an M^{2+} ion-catalyzed reduction of substituted nitrosobenzene.

reduction of carbonyl substrate.[13,16,17] Important difference is that in the latter model electron movement occurs from the dihydropyridine to the substrate through the metal ion, in a reversed way as considered in the former case.

In Fig. 12, it is assumed that the hydrogen to be transferred is the pseudo axial one in the 4-position in the boat conformation of 1,4-dihydropyridine moiety. This assumption is based on a recent proposal that the axial hydrogen is more reactive than the equatorial one.[31] Finally, it must be mentioned that a metal coordination on the amide group may also explain most of the present results except the blue shift of electronic absorption on complexation.

In conclusion, the function of a metal ion seems to be dual in the present system: (a) to form a ternary complex, and (b) to facilitate the hydride transfer by stabilizing the incipient product anion. The two functions seem to be compensating to each other so that a metal ion such as Zn^{2+} ion having a proper balance in the two functions becomes the most active under certain conditions.

Experimental

Materials. Anhydrous acetonitrile was prepared by distilling over phosphorus pentoxide. Substituted nitrosobenzenes were prepared by the reduction of the corresponding commercially available nitrobenzenes with zinc powder as reported previously.[24] Metal ions were used as the perchlorates which were commercially available as special grade reagents.

1-Benzyl-3,5-bis(1-pyrrolidinylcarbonyl)-1,4-dihydropyridine (BPDH) was prepared according to a previous method, mp. 46 °C.[24]

Product analysis was performed for unsubstituted nitrosobenzene (X=H) by HPLC method as described before.[24]

Kinetics. The procedures were essentially the same as those reported previously.[24] In a 1 cm quartz UV cell stoppered with a rubber septum cover was placed a 3 mL acetonitrile solution of BPDH and the solution was well bubbled with acetonitrile saturated pure nitrogen gas through inserted needles. Stock solutions of nitrosobenzene and metal ion in acetonitrile were treated similarly. Then the quartz cell was mounted on a water-jacketed UV cell holder and nitrosobenzene and a metal ion stock solutions in water bath were kept at 25 °C for 15 min. The reaction was started by adding 10 μL each of the solution of nitrosobenzene and the metal ion in this order to the quartz cell by a Hamilton microsyringe. The rates of reduction were followed by monitoring the decrease of absorbance of BPDH at 355 nm. In most cases the reaction was carried out under pseudo-first-order conditions by using 10 molar excess of nitrosobenzene over BPDH.

Optically Active Polyamides Having (−)-Anti Head-to-Head Coumarin Dimer Component. 2. Chiroptical Property in the Film State

Yun CHEN, Kazuhiko SAIGO,* Noriyuki YONEZAWA, and Masaki HASEGAWA
Department of Synthetic Chemistry, Faculty of Engineering, The University of Tokyo, Bunkyo-ku, Tokyo 113
(Received December 6, 1986)

The chiroptical property of optically active polyamides (**3a—i**), derived from (−)-anti head-to-head coumarin dimer (**1**), was investigated by comparing their UV and circular dichroism (CD) spectra with those of the corresponding model diamides (**8a—i**) in the film state. The result suggests that the polyamides (**3a—c,g**) derived from acyclic aliphatic diamines, exist in a random conformation due to the flexibility of the diamine components. The polyamides (**3d,h**), consisting of piperazine, are assumed to be in a rod-like conformation, resulting from their rigid and fixed main chains. The polyamides (**3e,f,i**), prepared from aromatic diamines, show reversed and split Cotton effects at 270—300 nm in comparison with those of model diamides. This phenomenon is interpreted by the formation of an ordered conformation of macromolecular asymmetry.

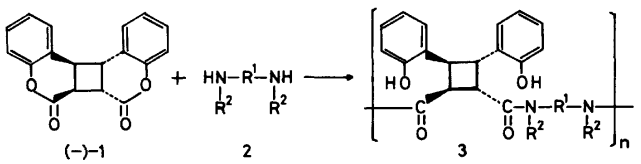
Recently, we have synthesized a series of optically active polyamides by the ring-opening polyaddition reaction of (—)-anti head-to-head coumarin dimer with diamines,[1,2] and have shown that these polyamides exist in a random or ordered conformation in solution depending on the medium and/or on the structure of diamine components.[1,2] For example, the polyamide, consisting of (—)-anti head-to-head coumarin dimer and 1,4-phenylenediamine components, exists in a random coil in *N,N*-dimethylacetamide solution, while in basic media it exists in an ordered conformation due to the electronic repulsion of the phenolate anions formed by the base. It is well-known that CD spectral study is very effective to investigate the chiroptical property of polypeptides in the film-state.[3,4] These observation and fact prompted us to disclose the conformations of the optically active polyamides in the film state, since it is considered to be possible that these polyamides form an ordered conformaion even in film state depending on the rigidity of the diamine component.

In this paper, we wish to report the chiroptical property of the optically active polyamides, derived from (—)-anti head-to-head coumarin dimer, in the film state on the basis of the comparison of their UV and CD spectra with those of the corresponding model diamides.

Results and Discussion

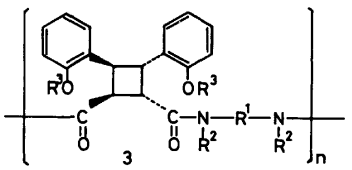
Synthesis of Optically Active Polyamides and Model Diamides. Optically active polyamides **3a—f** were synthesized by the ring-opening polyaddition reaction of (−)-anti head-to-head coumarin dimer **1** as described in detail in the literature.[2]

Optically active *O*-methylated polyamides **3g—i** were prepared by the interfacial polycondensation reaction of bis(acid chloride) **6** with diamines using benzyltriethylammonium chloride as a phase-transfer catalyst. The starting material **6** could be obtained from **1** by three steps as shown in the following Scheme 2.

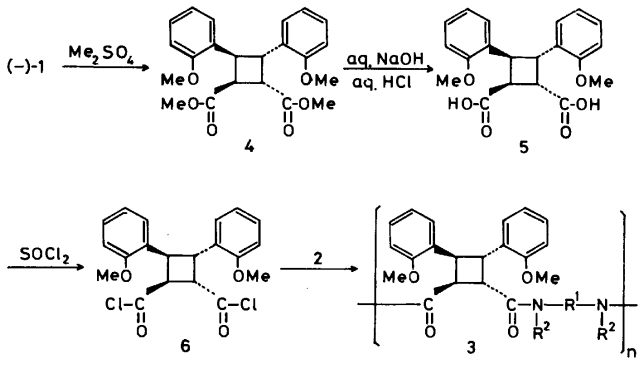


Scheme 1.

The notations for the optically active polyamides are as follows:



Polyamide	R^1	R^2	R^3	η_{inh}
3a	$-(CH_2)_6-$	H	H	0.88
3b	$-(CH_2)_6-$	CH_3	H	0.35
3c		H	H	0.63
3d			H	0.51
3e		H	H	0.36
3f		H	H	0.31
3g	$-(CH_2)_6-$	H	CH_3	1.01
3h			CH_3	1.00
3i		H	CH_3	0.50



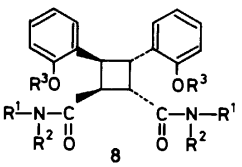
Scheme 2.

Similar to the ring-opening polyaddition reaction, the interfacial polycondensation also gave high-molecular-weight polyamides (η_{inh}=0.50—1.01 dl g^{-1}). These *O*-methylated polyamides showed no solubility in common organic solvents, but could dissolve in *m*-cresol, *N,N*-dimethylacetamide (DMAc), dimethyl sulfoxide (DMSO), *N*-methyl-2-pyrrolidone (NMP), and acetic acid very slowly.

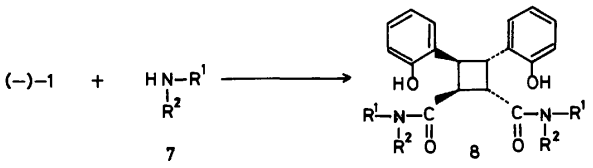
Model diamides **8a—f** were synthesized by ring-opening addition reaction as reported in the literature.[2] In order to study the influence of the extension of resonance on UV and CD spectra, model diamides **8e′, f′** were synthesized in a similar manner.

O-Methylated model diamides **8g—i** were synthesized by interfacial condensation without the phase-transfer catalyst.

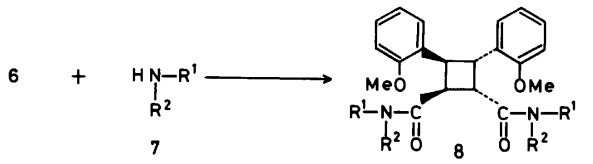
The notations for the model diamides are as follows:



Diamide	R^1	R^2	R^3
8a	$-(CH_2)_5CH_3$	H	H
8b	$-(CH_2)_5CH_3$	CH_3	H
8c	$-CH_2-C_6H_4-CH_3$	H	H
8d			H
8e		H	H
8e′		H	H
8f		H	H
8f′		H	H
8g	$-(CH_2)_5CH_3$	H	CH_3
8h			CH_3
8i		H	CH_3



Scheme 3.



Scheme 4.

Chiroptical Property in the Film State. Polyamide **3** was cast on the outside surface of a quartz cell and dried to give a clear and homogeneous thin film. In the case of model diamide **8**, a clear and homogeneous thin deposit could also be obtained with the exception of **8b**. The cast sample was found to be isotropic on the basis of the fact that UV and CD spectra, obtained by rotating the sample around the axis of the incident beam, were identical to each other.

It is known that the chiroptical property of synthetic polyamides can be investigated by comparing their CD spectra with those of the corresponding model diamides.[5] In general, the random conformation of the polymer results in weaker Cotton effect at about the same wavelength than that of the corresponding model diamide. In this study, we compared mainly the Cotton effects of the amide carbonyl and aromatic chromophores in polyamide **3** with those of model diamide **8**, respectively.

As listed in Table 1, model diamides **8a, c, d, g, h**, derived from aliphatic amines, show maximum absorption(s) at about 275 nm in their UV spectra, which apparently corresponds to the π-π^* transition of hydroxyphenyl group. In CD spectra, all of the model diamides show *negative* Cotton effects at about 235 and 275 nm. The former negative CD band may be assigned to a component of the split π-π^* transition due to an exciton coupling of amide carbonyl chromophore,[6] although a short-wavelength component of this split cannot be observed because of the limit of measurement. Moreover, the latter can be assigned to the π-π^* transition of the aromatic[2] chromophore.

In the case of model diamides **8e, f, i** derived from aromatic amines, their molar extinction coefficients are much larger than those of the model diamides derived from aliphatic amines. Negative CD bands of the amide carbonyl and aromatic chromophores in **8**, **f**, **i** appear at about 240 and 280 cm, respectively, namely, the CD bands red-shifted about 5 nm in

Table 1. Optical Properties of Model Diamides in the Film State

Diamide	UV spectra		CD spectra	
	ε	λ_{max}	$\Delta\varepsilon$	λ_{max}
8a	4780	273.2	−2.60	270.8
	4500	280.0	−7.92	236.0
8c	5150	275.0	−3.50	275.0
	4700	281.0	−9.02	235.0
8d	3820	280.0	−3.42	277.0
			−4.36	236.5
8g	3880	273.1	−1.93	270.0
	3780	280.0	−1.59	230.0
8h	4318	276.0	−3.79	274.0
			−11.14	235.5
8e	21700	249.0	−7.95	279.0
			−13.63	241.0
8e'	39000	272.0	−6.00	282.5
			−7.80	238.5
8f	24900	257.5	−10.33	279.0
			−19.25	238.5
8f'	59300	262.0	−7.25	282.5
			−9.08	241.0
8i	19700	251.3	−11.00	279.0
			−10.82	243.0

comparison with those of the aliphatic counterparts. These phenomena would be attributable to the resonance effect of the amide carbonyl chromophore with the aromatic amine residue and to the effect of the aromatic amine residue as an aromatic chromophore. Moreover, **8e'** and **8f'**, synthesized to clarify the influence of the extension of the resonance on CD spectra in the film state, show also only a little decrease and shift in CD bands, although they show an enhanced molar extinction coefficient in UV spectra.

From these facts, it is clear that the negative CD bands of model diamide **8** result simply from the chiral carbons of cyclobutane ring and that the extension of the resonance in the aromatic amine residue results only in a little decrease and shift of the CD bands.

The UV and CD spectra of polyamide **3a** and model diamide **8a** in the dry film state are shown in Fig. 1. The negative CD bands of **3a** at 230—240 and 260—280 nm are, as mentioned for model diamides, assigned to a component of the split π-π^* transition of the amide carbonyl chromophore and to the π-π^* transition of the hydroxyphenyl chromophore, respectively. Comparing the bands with those of **8a**, the former band shows enhanced intensity with a blue shift although the latter exhibits weaker intensity.

Similar enhanced intensity and blue shift of the CD band of polyamide at 230—240 nm in comparison with that of the corresponding model diamide were also

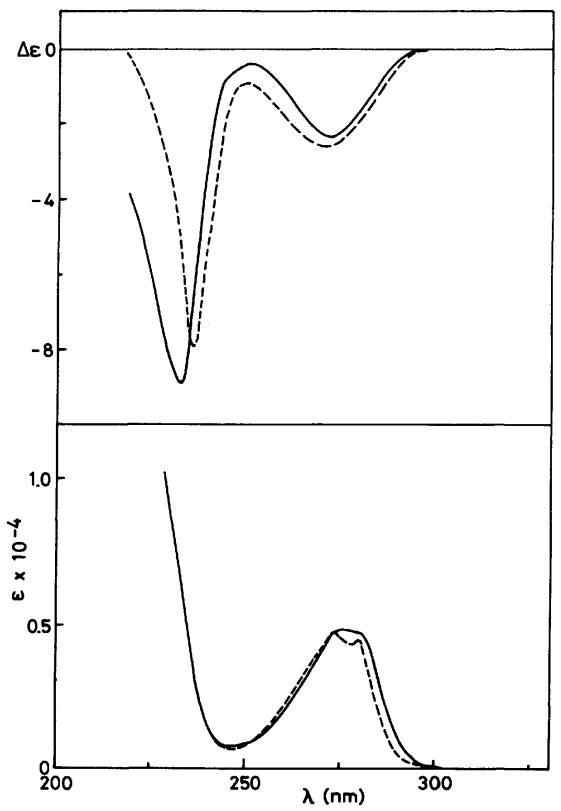


Fig. 1. CD and UV spectra of polyamde **3a** (——) and model diamide **8a** (------) in the film state.

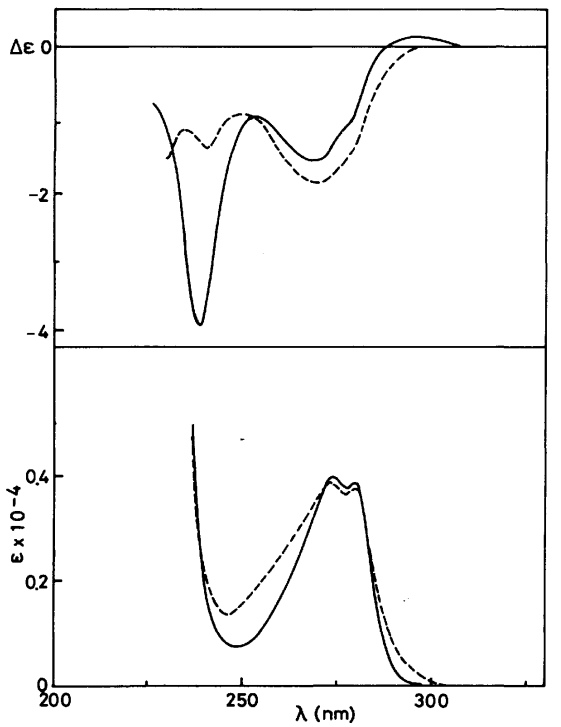

Fig. 2. CD and UV spectra of polyamide **3g** (——) and model diamide **8g** (------) in the film state.

observed for **3g**. Namely, *O*-methylated polyamide **3g** shows stronger CD band at ca. 240 nm than that of model diamide **8g**, while the band at 270 nm is weaker than that of **8g** as shown in Fig. 2.

Similarity in the CD shape between **3a** and **8a**, and between **3g** and **8g**, suggests that they possess similar conformational preference, resulting from the asymmetric cyclobutane ring. But the enhancement of the band at 230—240 nm indicates that **3a** and **3g** aggregate by the interaction between the amide groups, respectively, although **3a** and **3g** exist essentially in a random conformation.

In the case of polyamide **3c**, both negative CD bands are weaker in intensity than those of model diamide **8c** (Fig. 3). This is a typical phenomenon for a completely random conformation.[5] Then, **3c** would exist in a random conformation in the film state.

The preparation of the thin film of **8b** was not successful since it precipitated out and became opaque on drying. Then, the chiroptical study of polyamide **3b** could not be conducted by comparing directly the CD spectrum of **3b** with that of **8b**. But the CD spectrum is very similar to that of **3c**, indicating that **3b** exists in a random conformation in the film state. The random conformation would result from the flexibility of the diamine component and the lack of amide hydrogen.

Considering the structural difference between **3a**, **3b**, and **3g**, it would be concluded that the amide hydrogen plays an important role for macromolecular aggregation but the phenolic hydroxyl does not. The lack of aggregation in polyamide **3c** would be attributed to the steric crowd near by the amide group.

The CD bands of polyamides **3d** and **3h** at the wavelength shorter than 250 nm degenerate significantly in comparison with those of **8d** and **8h**, respectively, as shown in Figs. 4 and 5. The much smaller mean residue rotation and molecular circular dichroism of **3h** in DMAc than those of **8h**, similar to that observed between **3d** and **8d**,[1,2] indicate the existence of a rigid conformation of **3h** in DMAc. The Corey-Pauling-Koltun space-filling molecular models of **3d** and **3h** show that the diacid component is in a very tight conformation and that neither polymer main chain nor hydroxyphenyl (or methoxyphenyl) group in the side chain can rotate. On the basis of these observations, it seems possible to say that polyamides **3d** and **3h**, derived from piperazine, have a fixed rod-like conformation in the film state as well as in solution.

The film-state UV and CD spectra of polyamide **3e** and model diamides **8e**, **e'** are shown in Fig. 6. Model diamide **8e** shows normal negative CD bands at 235—245 and 270—285 nm, which can be assigned to a component of the split π-π^* transition of the amide carbonyl chromophore and the π-π^* transition of the

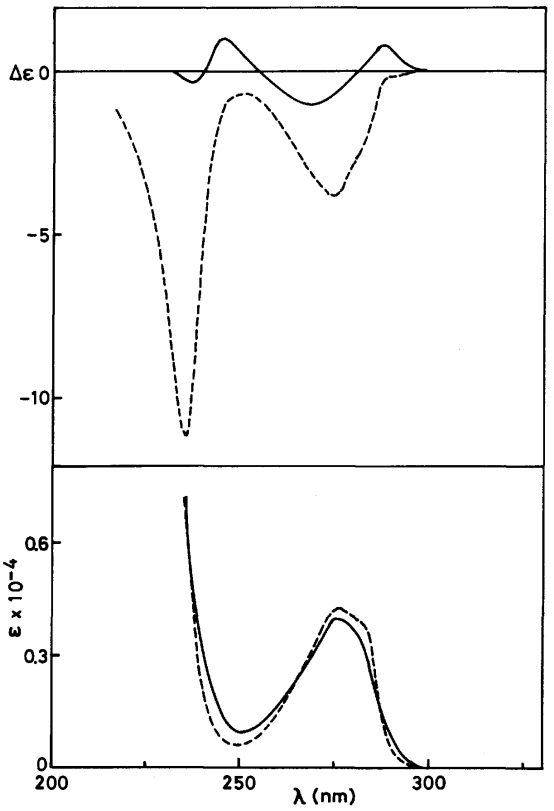

Fig. 5. CD and UV spectra of polyamide **3h** (——) and model diamide **8h** (------) in the film state.

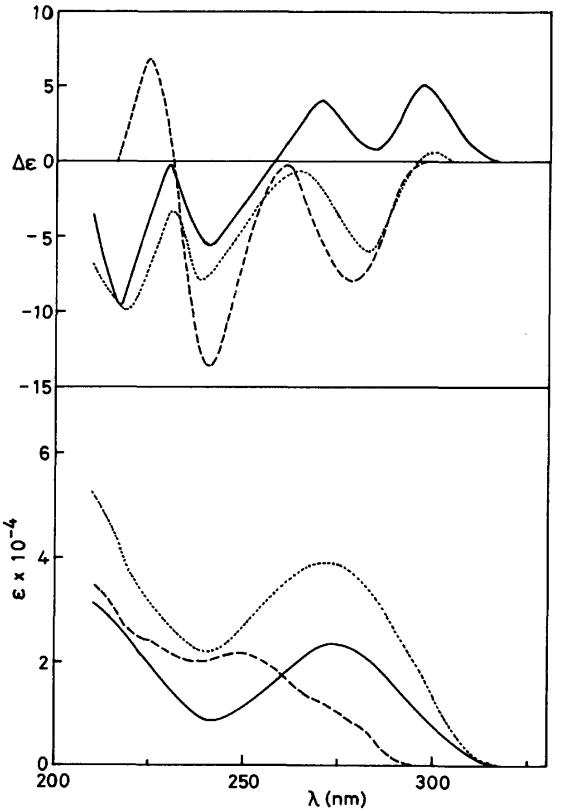

Fig. 6. CD and UV spectra of polyamide **3e** (——) and model diamide **8e** (------), **8e′** (·····) in the film state.

aromatic chromophore, respectively. The red shift and increased intensity of the UV absorption of **8e′** in comparison with that of **8e** would be attributed to the extension of its mesomeric region. But, this extension in **8e′** results only in a little decrease and shift of the CD bands at 235—245 and 270—285 nm. However, in the CD spectrum of **3e**, two *positive* CD bands appear at 265—275 and 290—302 nm in contrast to the *negative* bands of **8e** and **8e′** at 270—285 nm. These two positive CD bands would be attributed to the π–π^* transitions of 2-hydroxyphenyl group in the side chain and 1,4-phenylenediamine residue in the main chain. Then, the drastic difference is considered to result from a second ordered conformation, for which the aromatic residues in the main and side chains probably play an important role. Similar CD spectral change was observed for **3e** in DMAc on addition of 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU). The CD spectrum of **3e** in the film state is quite similar to that of **3e** in DMAc when DBU/hydroxyphenyl in the side chain is 2.[2] But, it is not so developed as observed in 0.2 M (1 M=1 mol dm^{-3}) NaOH, in which **3e** exists in a fully developed ordered conformaion.[2] This means that in the dry film state **3e** exists in an ordered conformation of macromolecular asymmetry though it is incomplete.

As shown in Fig. 7, *O*-methylated polyamide **3i**

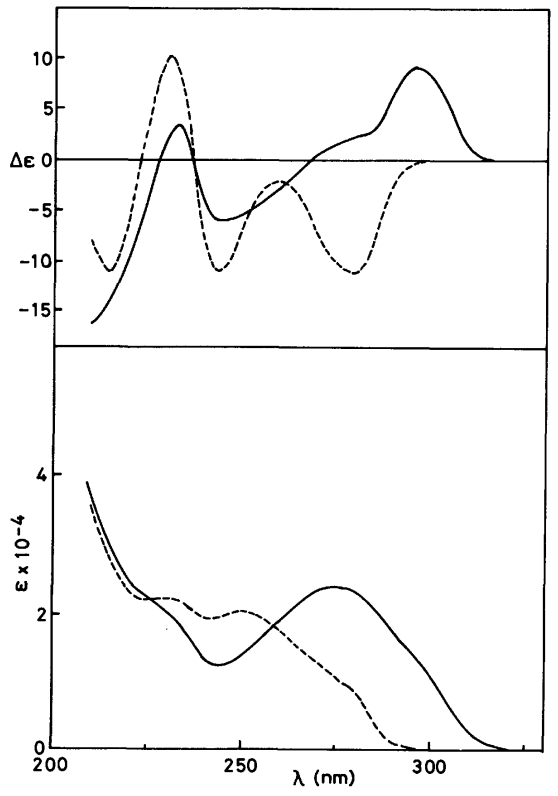

Fig. 7. CD and UV spectra of polyamide **3i** (——) and model diamide **8i** (------) in the film state.

shows CD bands similar to that of **3e**, i.e. the *positive* band at 290—300 nm with shoulder at 270—285 nm. This means that **3i** forms an ordered conformation similar to that of **3e** in spite of its lack of phenolic hydroxyl group in the side chain.

From these results, it is considered that the ordered conformation of **3e** and **3i** in the film state would be attributed to the hydrogen bonding of amide residue, which renders the polymer main chain taking a macromolecular asymmetry to release the strain.[7,8] To ascertain the contribution of the amide hydrogen to the ordered conformation, the preparation of the polyamide, consising of **1** and *N,N'*-dimethyl-1,4-phenylenediamine, was tried. But, the reaction gave only low-molecular-weight polyamide. Then, the contribution could not be demonstrated directly.

As shown in Fig. 8, the CD bands of **3f** at 255—300 nm tends to appear in *positive* region in contrast to those of negative bands of **8f** and **8f'**. This means that **3f** is also in an ordered conformation of macromolecular asymmetry, although this ordered conformation is less developed than that of **3e** due to the flexibility of the diphenyl ether linkage.

On the basis of these CD spectral studies, the following chiroptical property in the dry film state is concluded for polyamide **3**: Polyamides **3a**—c and **3g**, derived from acyclic aliphatic diamines, exist essentially in a random conformation due to the flexibility of the diamine components, but **3a** and **3g** show an aggregation phenomenon, for which the amide hydrogen is important. Polyamides **3d** and **3h**, derived from piperazine, have a fixed rod-like conformation due to their very rigid and tight main chain. Polyamides **3e**, **3f**, and **3i** exist in an ordered conformation of macromolecular asymmetry though it is incomplete. In the formation of the ordered conformation, the structure of the diamine component and the amide hydrogen play an important role. At present, these ordered conformations of **3e**, **3f**, and **3i** cannot be specified, but they possess the possibility to form a sheet and/or helical conformation in the dry film state. The chiroptical property of the polyamides in the film state is summarized in Table 2 with that in solution.[2]

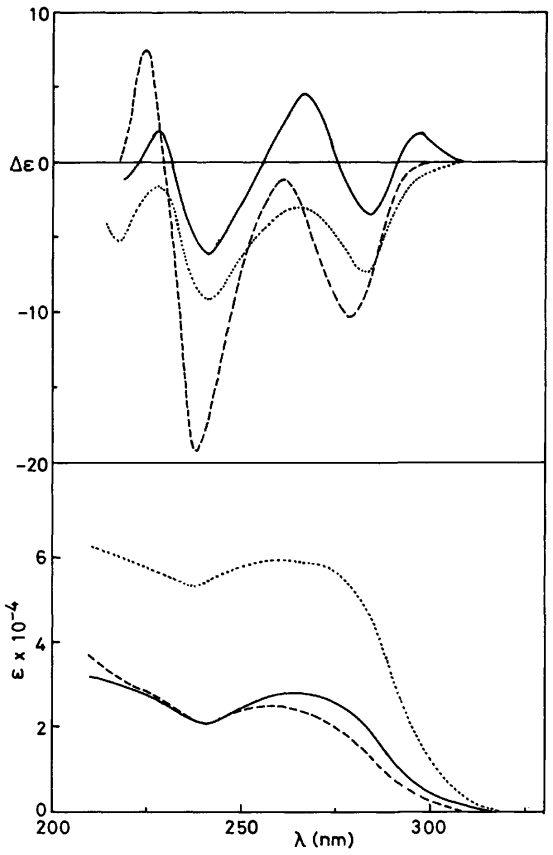

Fig. 8. CD and UV spectra of polyamide **3f** (——) and model diamide **8f** (------), **8f'** (·····) in the film state.

Table 2. Conformation of Polyamides **3a**—**i** in the Film State with that in Solution

Polyamide	In solution		Film state

a) Insoluble. b) The chiroptical property of *O*-methylated polyamides in DMAc was investigated in this work.

Experimental

Measurement. Melting points were determined on a Laboratory Devices Mel-Temp and are uncorrected. The IR spectra were obtained on a Jasco IR-810 spectrophotometer. ^{1}H NMR spectra were recorded with a Hitachi R-40 (90 MHz) spectrometer. The optical rotations were measured with a Jasco DIP-360 digital polarimeter at 20 °C in a 1.0 dm cell. The inherent viscosities of the polyamides were measured at 30 °C with an Ostwald viscometer at the concentration of 0.30 g dl^{-1}. The circular dichroism and UV spectra were measured on a Jasco J-500 spectropolarimeter and on a Shimadzu UV-260 spectrophotometer, respectively, at room temperature.

Materials. (−)-Anti head-to-head coumarin dimer (**1**) was obtained from the racemate by the diasteriomeric resolution method as reported in the previous paper.[9] Before use, **1** was recrystallized from benzene and dried at 60 °C in vacuo (ca. 2 mmHg) for 24 h: $[\alpha]_D$ −9.0° (*c* 1.00, benzene), almost 100% enantiomeric excess on the basis of

HPLC analysis of its diamide derivative with *S*-(−)-1-phenylethylamine.[10]

3,4-Bis(2-methoxyphenyl)-1,2-cyclobutanedicarbonyl Dichloride (6). To a solution of **1** (7.31 g, 25.0 mmol) in acetone/2.0 M NaOH (73 ml/150 ml) was added dropwise dimethyl sulfate (99.21 g, 786 mmol) in a period of one hour at room temperature. After stirring for 4 h at the temperature, acetone was evaporated, and the mixture was extracted with carbon tetrachloride (150 ml×3). The evaporation of the solvent to dryness gave an oily product. The purification of the crude product by silica-gel chromatography (eluent: hexane/ethyl acetate=60/40 (v/v)), followed by recrystallization from hexane/acetone, gave 6.00 g (63%) of dimethyl 3,4-bis(2-methoxyphenyl)-1,2-cyclobutanedicarboxylate (**4**): Mp 85.5—86.5 °C; $[\alpha]_D$ −169.8° (*c* 0.5, chloroform); IR (KBr) 1720, 1240, 1020, and 759 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.25 (6H, s), 3.77 (8H, s with shoulder), 4.75 (2H, pseudo d, *J*=8.0 Hz), and 6.5—7.2 (8H, m).

Found: C, 68.93; H, 6.40%. Calcd for $C_{22}H_{24}O_6$: C, 68,74; H, 6.29%.

Diester **4** (4.61 g, 12.0 mmol) was hydrolyzed in a solution of 1.0 M NaOH/MeOH (50 ml/25 ml) at 50 °C for 5 h, and then the solution was acidified with 1.0 M HCl after evaporation of methanol. The precipitates appeared were collected by filtration and recrystallized from water/ethanol to give 3.65 g (85%) of 3,4-bis(2-methoxyphenyl)-1,2-cyclobutanedicarboxylic acid (**5**): Mp 268.0—269.5 °C: $[\alpha]_D$ −121.2° (*c* 0.5, MeOH); IR (KBr) 2600, 1700, 1246, 1030, and 757 cm^{-1}; ^1H NMR (Me_2SO-d_6) δ=3.5 (2H, pseudo d, *J*=8.0 Hz), 4.6 (1H, pseudo d, *J*=8.0 Hz), 3.75 (6H, s), 6.4—7.2 (8H, m), and 11.75 (2H, s).

Found: C, 67.37; H, 5.65%. Calcd for $C_{20}H_{20}O_6$: C, 67.41; H, 5.66%.

Dicarboxylic acid **5** (3.65 g, 10.2 mmol) was refluxed in a mixture of thionyl chloride/benzene (75 ml/90 ml) for 2 h until the solution became clear. After evaporation of thionyl chloride and benzene, the residue was recrystallized from hexane to give 3.70 g (92%) of 3,4-bis(2-methoxyphenyl)-1,2-cyclobutanedicarbonyl dichloride (**6**): ^1H NMR ($CDCl_3$) δ=3.78 (6H, s), 4.2—4.7 (4H, m), and 6.5—7.3 (8H, m). Bis(acid chloride) **6** was immediately used in the interfacial synthesis of polyamides and model diamides without further purification

General Procedure for Synthesis of Polyamides 3. The synthesis of optically active polyamides **3a—f** by ring-opening polyaddition reaction has been described in the previous paper.[2]

O-Methylated polyamides **3g—i** were synthesized by the interfacial polycondensation reaction of **6** with the corresponding diamines as follows: To a solution of diamine (2.78 mmol) in 12 ml of 1.0 M NaOH was added 0.63 g of benzyltriethylammonium chloride (2.78 mmol) as a phase-transfer catalyst. Then, a chloroform solution (11 ml) of **6** (1.09 g, 2.78 mmol) was added to the aqueous solution at once under vigorous stirring at room temperature. The precipitates appeared were collected by filtration, washed successively with methanol and hot water, and dried in vacuo at 80 °C for 48 h.

Polyamide 3g: Yield 84%; η_{inh}=1.01 dl g^{-1} (*m*-cresol); $[\alpha]_D$ −70.3° (*c* 0.3, *m*-cresol); IR (KBr) 3500—3300, 3000—2800, 1645, 1525, 1247, 1024, and 755 cm^{-1}.

Found: C, 68.47; H, 6.97; N, 5.85%. Calcd for $(C_{26}H_{32}N_2O_4 \cdot H_2O)_n$:C, 68.70; H, 7.54; N, 6.16%.

Polyamide 3h: Yield 86%; η_{inh}=1.00 dl g^{-1} (DMAc); $[\alpha]_D$ −40.7° (*c* 0.3, DMAc); IR (KBr) 3600—3300, 3100—2800, 1630, 1243, 1028, and 755 cm^{-1}.

Found: C, 67.25; H, 6.25; N, 6.36%. Calcd for $(C_{24}H_{26}N_2O_4 \cdot H_2O)_n$: C, 67.90; H, 6.65; N, 6.60%.

Polyamide 3i: Yield 99%; η_{inh}=0.50 dl g^{-1} (DMAc); $[\alpha]_D$ +5.7° (*c* 0.3, DMAc); IR (KBr) 3600—3200, 3100—2800, 1668, 1545, 1245, 1026, and 755 cm^{-1}.

Found: C, 69.82; H,5.24; N, 6.07%. Calcd for $(C_{26}H_{24}N_2O_4 \cdot H_2O)_n$: C, 69.94; H, 5.87; N, 6.27%.

General Procedure for the Synthesis of Model Diamides 8. The synthesis of optically actically active diamides (**8a—f**) by ring-opening addition reaction has been reported in the previous paper.[2] Model diamides **8e′**, **8f′** were also synthesized by this method.

The general procedure for the synthesis of *O*-methylated model diamides **8g—i** by interfacial condensation reaction is described as follows: To a solution of amine (4.00 mmol) in 2.0 ml of 1.0 M NaOH was added dropwise a chloroform solution (2.0 ml) of **6** (0.16 g, 0.40 mmol) in a period of 5 min under vigorous stirring at room temperature. After stirring for additional 10 min, chloroform was evaporated, and the remaining solid mass was collected by filtration. The recrystallization gave the corresponding 3,4-bis(2-methoxyphenyl)-1,2-cyclobutanedicarboxamide (**8g—i**).

***N,N′*-Bis(4-acetylaminophenyl)-3,4-bis(2-hydroxyphenyl)-1,2-cyclobutanedicarboxamide (8e′)**: Light brown prism (EtOH-H_2O); yield 79%; mp 198 °C (decomp); $[\alpha]_D$ −131.4° (*c* 0.3, DMAc), −109.9° (*c* 0.3, 0.37 M NaOH); IR (KBr) 3600—2800, 1660, 1610, 1255, 1020, 940, 840, and 760 cm^{-1}; ^1H NMR (Me_2SO-d_6) δ=1.90 (6H, s), 3.81 (2H, pseudo d, *J*=8.0 Hz), 4.73 (2H, pseudo d, *J*=8.0 Hz), 6.4—7.5 (16H, m), 9.2—9.5 (4H, 2 peaks), and 9.61 (2H, s).

Preparation of Thin Films for Chiroptical Study. The thin films of the polyamides and model diamides were prepared by casting their solution (ca. 30 mg ml^{-1} DMAc) on the outside surface of a quartz cell (10×45×10 mm). The coated films were dried at ambient air and then in vacuo for 24 h at room temperature. The obtained thin films were at the concentration of ca. 10^{-4} repeating-unit mmol (or mmol) cm^{-2}. All CD spectra were given in $\Delta\varepsilon$, molecular circular dichroism, with cm^2/repeating-unit-mmol (or mmol) unit, which was calculated by the following equation:

$$\Delta\varepsilon = [\theta]/3300 \text{ and } \theta = 0.1 \times [\theta] \times m/MW$$

where MW is the repeating-unit molecular weight (or molecular weight) of the polyamide (or the model diamide); m is the sample weight per unit area (g cm^{-2}); θ is the measured ellipticity (deg); and $[\theta]$ is the molecular ellipticity (deg·$cm^2$$dmol^{-1}$).

Thin film were also cast on the outside surface of a cylindrical quartz cell [10×20 (o.d.) mm], and each CD measurement was repeated four times by rotating the sample cell by 45, 90, and 120 degrees from the first position around the axis of the incident light beam to give almost identical spectra.

Stereoelectronic Control in the Hydrolysis of RNA by Imidazole

Kazunari TAIRA*
Department of Chemistry, The Pennsylvania State University,
University Park, PA 16802, U.S.A.
(Received June 23, 1986)

The cleavage of poly(uridylic acid) by imidazole buffer was studied recently by Breslow and Labelle, and a bell-shaped profile was observed for the rate vs. buffer protonation state. The reaction, however, was kinetically first-order in buffer (R. Breslow and M. Labelle, *J. Am. Chem. Soc.*, **108**, 2655 (1986)). The sequential base-acid mechanism proposed by those authors is in agreement with the expectation based on the stereoelectronic effects. In addition, the alternative sequential acid-base mechanism, which could not be excluded on the basis of their kinetic data, may be excluded based on the stereoelectronic considerations.

The hydrolysis of RNA and simpler model compounds has been the subject of much investigation.[1-9] In the hydrolysis of both RNA[1,9] and a simpler phosphate diester, such as methyl 2-hydroxyethyl hydrogenphosphate,[5,6] the mechanistic sequence involves two steps: The formation of a five-membered cyclic phosphate via an intramolecular nucleophilic attack by the vicinal hydroxyl group with concomitant exocyclic cleavage, followed by the hydrolysis of the cyclic diester intermediate. The formation of a 2′,3′-cyclic diester suggests why RNA, which functions as a carrier of genetic information and thus has a high turnover rate, is capable of undergoing rapid degradation. On the other hand, DNA, which serves to store genetic information and from which the requisite 2′-hydroxyl group is absent, is resistant to hydrolysis.

The rate of hydrolysis of five-membered ring cyclic phosphate such as methyl ethylene phosphate (MEP) and ethylene hydrogenphosphate (EP) is 10^6 to 10^8 times faster than that of their acyclic analogues, trimethyl phosphate and dimethyl hydrogenphosphate, respectively. Westheimer and coworkers proposed that this rate acceleration was due to the energy released in going from a strained five-membered cyclic ester to a "strain-free" cyclic phosphorane transition state.[3] However, as pointed out by Gerlt et al.,[10] the amount of ring strain is insufficient to explain the total lowering of activation energy of the five-membered cyclic phosphates. Therefore, Gorenstein et al.[11-14] proposed, based upon molecular orbital calculations on the basic hydrolysis of model phosphate diesters, that a significant fraction of this difference in reactivity between five-membered cyclic phosphates and their acyclic counterparts comes from orbital stereoelectronic effects in the trigonal bipyramid transition state. Gorenstein and coworkers have provided

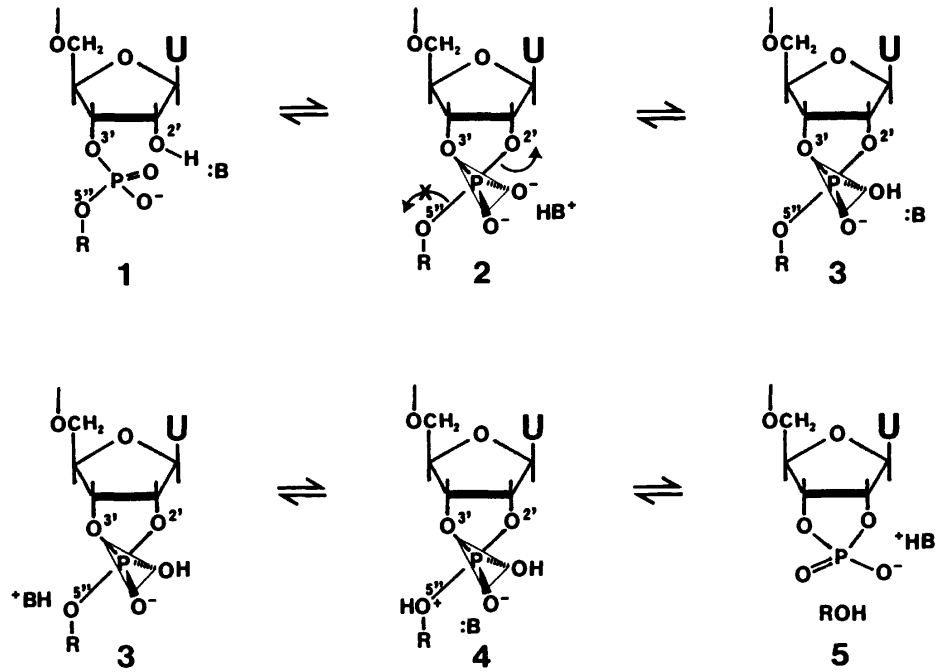

Fig. 1 Breslow and Labelle's mechanism for the hydrolysis of RNA by imidazole.[9] The equatorial positions are indicated by triangle planes.

* Present address: Fermentation Research Institute, Agency of Industrial Science & Technology, Yatabe-machi, Tsukuba Science City, Ibaraki 305.

theoretical justification[11-19] as well as experimental support[20-28] for these stereoelectronic effects.

Breslow and Labelle[9] recently investigated the hydrolysis of poly(uridylic acid) (poly-U) by imidazole buffers and proposed the sequential general base-acid catalysis mechanism, as shown in Fig. 1. In the first step, nucleophilic attack is catalyzed when the imidazole (:B) removes a proton from the 2′-hydroxyl group of **1**. The resulting more nucleophilic oxygen adds to phosphorus, and the temporarily formed imidazolium ion ($^+$BH) puts a proton back onto one of the equatorial phosphorus oxygens of **2** to generate intermediate **3**. In the reversal of this reaction, the same sequence runs backwards: The endocyclic cleavage of the phosphorane intermediate, **3**, occurs by deprotonation of **3** and eventual protonation of the leaving 2′-oxygen. However, in the forward direction, exocyclic cleavage takes place with the loss of 5′-oxygen of the next nucleotide by a process preferentially catalyzed by imidazolium ion ($^+$BH), but not by imidazole (:B). In the case of the imidazolium ion catalysis, a proton is added presumably to the leaving group first followed by proton removal from the phosphorus oxygen so that the final product monoanion, **5**, is formed.[9]

As Breslow and Labelle pointed out,[9] their mechanism is quite curious: The endocyclic cleavage of **3** (backward reaction) is catalyzed by a base (:B), however, the exocyclic cleavage of **3** (forward reaction) is catalyzed by an acid ($^+$HB). Furthermore, due to the well-known kinetic ambiguity, the alternative sequential acid-base mechanism, in which the formation of intermediate **3** is catalyzed by imidazolium ion ($^+$HB) and its forward decomposition is catalyzed by imidazole (:B), cannot be cxcluded on the basis of their kinetic data.

In this paper, we suggest that the mechanism proposed by Breslow and Labelle could be rationalized by the stereoelectronic effect. This explanation not only supports their mechanism, in which an imidazole catalyzes the endocyclic cleavage and an imidazolium ion catalyzes the exocyclic cleavage, but also uniquely excludes the alternative sequential general acid-base mechanism.

Discussion

Stereoelectronic Effects in the Hydrolysis of MEP. The role of orbital orientation in organic and enzymatic reactions has been of considerable interest over the last decade.[11-41] Deslongchamps and coworkers[29] in studying tetracovalent carbon species have demonstrated selective cleavage of bonds which are *trans*-antiperiplanar (app) to lone pairs on directly bonded oxygen and nitrogens. Molecular orbital calculations have provided theoretical justification for these stereoelectronic effects in tetracovalent carbon and phosphorus species and pentacovalent phosphoranes.[11-19,33-38] For example, in the cyclic transition state/intermediate, **8**, which corresponds to Breslow's intermediate, **2**, (the ribose ring portion is omitted) the two lone pairs on the equatorial ring oxygen are oriented partially antiperiplanar (app) to the axial ring ester bond, which corresponds to the phosphorus-(2′-oxygen) bond in **2**.

Thus, the stereoelectronic theory suggests that this app lone pair can significantly facilitate the endocyclic P—O ester bond cleavage. As Deslongchamps argues that a cleavage is stereoelectronically controlled when and only when **two** heteroatoms possess lone pair orbitals app to the departing bond,[29] the exocyclic cleavage (P–OR bond cleavage) can also be stereoelectronically assisted by the lone-pair orbitals on the **two** equatorial anionic oxygens (orbitals not shown in **8**). However, the endocyclic cleavage is still favored over the exocyclic cleavage because the endocyclic breakage is assisted by **all three** equatorial oxygen lone pairs, especially those on the equatorial ring-oxygen. Note that the equatorial ring oxygen lone-pairs (orbitals are shown in Scheme 1) of **8** are app **only** to the apical endocyclic ester bond and **not** to the exocyclic bond. Indeed, as Gorenstein argued earlier, in the five-membered-ring cyclic esters the ring constrained the lone pairs in a stereoelectronically favorable orientation while

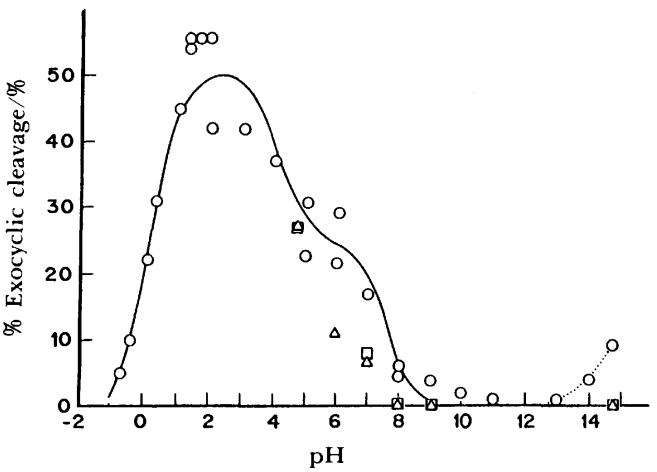

Fig. 2 Percentage exocyclic cleavage of methyl ehylene phosphate (○,△) and ethyl ethylene phosphate (□) vs. pH. Data from Kluger et al.[4] (○) and our own work (△, MEP; □, EEP).[6]

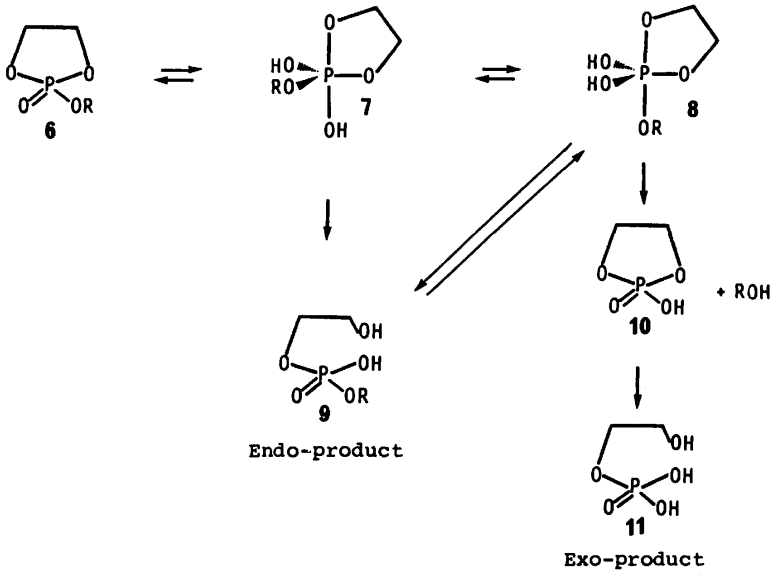

Fig. 3 Reaction paths for the formation of endocyclic and exocyclic cleavage products.

in the acyclic transition state, proper app lone pair overlap would require "freezing" of one or more rotational degrees of freedom about the ester bonds. It is thus significant that a considerable portion of the rate difference between cyclic and acyclic reactions is driven entropically.

However, a major difficulty with the stereoelectronic effect explanation for a portion of the rate acceleration was the observation of significant exocyclic cleavage (Fig. 2) in the hydrolysis of methyl ethylene phosphate (MEP) (Fig. 3).[3,4] As shown in Figures 2 and 3, hydrolysis of **6** (MEP) yielded not only the endocyclic cleavage product **9** but also as much as 1—50% of the exocyclic cleavage product **11**, formed by rapid hydrolysis of the initially formed ethylene hydrogenphosphate (EP), **10**. While the exocyclic cleavage in acid could be reconciled with the "reverse anomeric effect"[30] (see below), the 9 and 15% exocyclic cleavage in 5 and 10 M† alkali, respectively, was at odds with the stereoelectronic effect: Recall that the lone pairs on the ring oxygen are app only to the endocyclic bond (**8** in Scheme 1).

We carried out the hydrolysis of ethyl ethylene phosphate (EEP)[5] as well as MEP[24] at **low** concentration of ester in 5 M NaOH and analyzed the reaction products by phosphorus NMR instead of the earlier proton NMR and GC methodology.[4] We found that, compared with Kluger et al.'s earlier results,[4] there was much less (0±3% vs. the reported 9%) exocyclic cleavage product produced in the hydrolysis of MEP in 5 M NaOH. These results were consistent with the prediction of the stereoelectronic effect. However, recently Kluger and Thatcher[7,8] rechecked Kluger et al.'s earlier results[4] by proton NMR (and to a lesser extent by phosphorus NMR), employing **much higher** concentration of the starting ester. By monitoring the appearance of the methanol peak, they found that at strong alkaline conditions the fraction of "methanol" (which they equate with the exocyclic cleavage product) in fact appeared to increase to as much as 24% exocyclic cleavage in saturated NaOH (18.5 M) and 9.2% in 5.6 M NaOH.

However, Gorenstein et al. now report[41] that, in contrast to the claims of Kluger and Thatcher,[7,8] the increase in exocyclic cleavage product with increasing strong base is shown to arise from an artifactual sidereaction in the base-catalyzed hydrolysis of MEP. The initial product of endocyclic cleavage, methyl 2-hydroxyethyl hydrogenphosphate **9**, reacts with a second molecule of MEP **6**, when the reaction is carried out at **high** concentration of MEP, to yield a reactive "triester dimer" which subsequently releases methanol to yield a relatively stable "diester dimer": note that Kluger and Thatcher equate the amount of "methanol" with the exocyclic cleavage product. Although a small amount of exocyclic cleavage product is observed in strong alkali (<0.5%±1.5% for EEP and 2—4%±1.5% for MEP), these results are still completely consistent with arguments regarding stereoelectronic control in these reactions.[41]

In conclusion, a base-catalyzed hydrolysis of five-membered-ring cyclic phosphates, such as EEP and MEP, preferencially undergoes endocyclic cleavage. It is important to notice that, in Fig. 1, the endocyclic cleavage of **3** (backward reaction) occurs by a prior deprotonation of an equatorial oxygen (base catalysis).

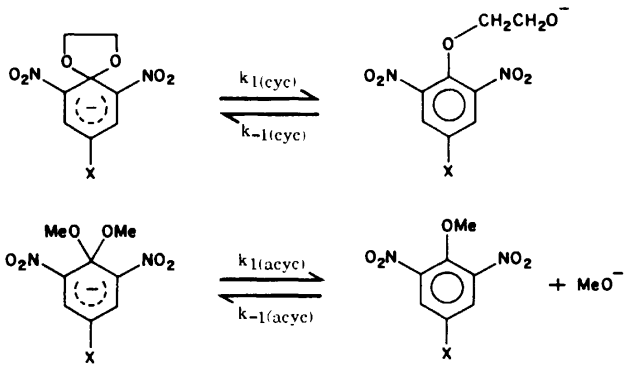


Scheme 4.

The Reverse Anomeric Effect. Electron-withdrawing substituents show a powerful preference for the axial position in 2-substituted tetrahydropyrans (ground state stereoelectronic effect or anomeric effect). However, groups such as *N*-alkylpyridinium appear to show a preference for the equatorial position, and there is evidence to suggest that this preference is stronger than the usual steric preferences found in cyclohexanes.[30] This reversed equatorial preference by protonated or positively charged substituents, which are even stronger electron-withdrawing groups, is called "the reverse anomeric effact." Although, to date, the origin of the reverse anomeric effect is not well understood, dipole moment interaction appears to operate, since the preference of imidazole for the equatorial position (**13**) in the equilibrium (**12**⇄**13**) of Scheme 2 is greater in more polar solvent and, when sufficient trifluoroacetic acid is added to the solvent ($CDCl_3$), only the isomer **14** with the imidazolium group equatorial exists.[30]

In the acid-catalyzed hydrolysis of MEP, the above-mentioned dipole moment arguments suggest that protonation on the exocyclic ester oxygen is favored over the endocyclic oxygen. This would thus favor exocyclic cleavage in acidic media (Scheme 3).

In strong acid, protonation of both exo- and endo-oxygens may be possible, in which case the mode of cleavage is again governed by the stereoelectronic effect (see Fig. 2).

In related systems, Bernasconi and Howard[42] thoroughly investigated the breakdown of spiro cyclic and acyclic Meisenheimer complexes derived from 1-(2-hydroxyethoxy)-2,6-dinitro-4-X-benzenes and 2,6-dinitro-4-X-anisoles, respectively, where X was Cl, CF_3, NO_2, or SO_2CF_3.

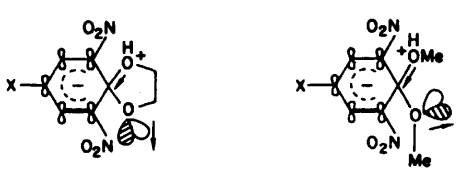
They concluded that the difference in intrinsic reactivity between the two families was quite large ($\Delta\Delta G^{\ddagger}=\Delta G^{\ddagger}[k_{1(acyc)}]-\Delta G^{\ddagger}[k_{1(cyc)}]=3.80$ to 5.34 kcal mol^{-1} (1 cal=4.184 J)) and this difference increased as the X substituent became more electron-withdrawing. The most likely cause for the difference in reactivity is of stereoelectronic origin. As described in the above-mentioned endocyclic cleavage of **8**, the orientation of the lone-pair orbitals on oxygen in the spiro cyclic complexes is such as to lead to n–σ^* overlap (app orientation) in the transition state. On the other hand, in the acyclic (1,1-dimethoxy-) complexes the orientation of the lone-pair orbitals does not lead to such overlap unless the complex first undergoes an unfavorable conformational change (Scheme 5).

The fact that $\Delta\Delta G^{\ddagger}$ increases with the electron-withdrawing strength of the X substituent supports this interpretation because the n–σ^* overlap leading to a transfer of electron density from the nonreacting oxygen into the antibonding orbital of the scissile bond becomes more important when a transfer of electron density from the benzene ring (p–σ^* type interaction) is less available because of an electron-withdrawing X group.

More importantly, the study of Bernasconi and Howard[42] further indicates that the difference in intrinsic reactivity is smaller for the acid-catalyzed compared to the noncatalyzed pathway, and this difference diminishes with increasing acidity of the catalyst. For the specific acid-catalyzed pathway the reactivity difference between the two families nearly disappears ($\Delta\Delta G^{\ddagger}$ spans a range ca. 0.09 to 0.2 kcal mol^{-1}). This means that in acidic media one does not observe much of a stereoelectronic effect. This indicates that for the acid-catalyzed lower activation-energy pathway a further lowering of the activation energy by the stereoelectronic effect becomes less important, compared to the noncatalyzed pathway. The breakdown behavior of these Meisenheimer complexes is very similar to that of the hydrolysis of EEP, MEP, and as well as RNA by imidazole: Under basic conditions the cyclic C(P)-O bond breaks (endocyclic cleavage) much faster than the acyclic C(P)-O bond (exocyclic cleavage), however, the exocyclic bond cleavage $k_{1(acyc)}$ starts to compete with the endocyclic bond cleavage $k_{1(cyc)}$ upon an increase in acidity of the medium, as shown by the percentage of exocyclic cleavage in Fig. 2.

Favored Protonation on 5′ Oxygen. If we use the above-mentioned dipole moment analysis in the protonation of the Meisenheimer complexes, it can easily be shown (Scheme 6) that protonation of the acyclic complexes is favored. This interpretation is consistent with Bernasconi and Howard's observation[42] of less negative ρ values and smaller Bronsted α values in the cyclic Meisenheimer complexes, indicating that less positive charge (H^+) has been transferred to the cyclic system than to the acyclic counterpart from the catalyst in the transition state.

The favorable protonation of the acyclic complexes is also consistent with the Hammond Postulate. In case of the breakdown of the cyclic complexes, one might expect an early transition state due to the intrinsically high reactivity of these compounds.[43] Because of the early transition state, the pK_{app} of the departing oxygen for the cyclic complexes would be low, and hence would not be subject to appreciable protonation. The acyclic complexes, on the other hand, would be less reactive than the cyclic counterparts, and in turn would have their transition states further along the reaction coordinate. Because of this later position on the reaction coordinate, one might expect the pK_{app} of the oxygens of the acyclic complexes to be higher than that of the cyclic counterparts and in turn more susceptible to transition state protonation. These predictions would lead to more positive ρ values and larger Bronsted α values in the acyclic families.



Scheme 6.

Similar argument would support our earlier analysis in that the exocyclic 5′ oxygen, in **3** (Fig. 1) or **8** (Scheme 1), is more susceptible to transition state protonation. In case of the exocyclic cleavage of the strain-free[3] intermediates, **3**, or **8**, one might expect a later transition state due to an increase in ring strain in the transition state in forming the five-membered cyclic diesters, **5** or **10**. The endocyclic cleavage, on the other hand, would not experience any increase in ring stain and therefore would have an earlier transition state, resulting in a less favorable protonation for the endocyclic 2′ oxygen.

Hydrolysis of RNA by Imidazole. The elegant work by Breslow and Labelle[9] has given us insight into a sequential catalytic mechanism for the hydrolysis of RNA by imidazole buffer. As they pointed out, their preferred mechanism (Fig. 1) is quite curious since, for the cleavage of the phosphorus-(2′-oxygen) bond (endocyclic cleavage) in **3**, the basic form of imidazole is utilized, whereas for the cleavage of the phosphorus-(5″-oxygen) bond (exocyclic cleavage) the conjugate acid form of imidazole acts as a catalyst. They pose the question: "*Why is it that loss of the C-5″ oxygen from intermediate* **3** *occurs by a prior protonation of the leaving group oxygen, while loss of the C-2′ oxygen from* **3** *occurs by a prior deprotonation of an oxygen on the phosphorus? If in the alternative slower path the loss of the 5″ oxygen can also occur with imidazole catalysis, and thus with a prior deprotonation, why is it that the prior protonation mechanism is not the best for the loss of C-2′ oxygen? It is hard to see a good reason for this mechanistic distinction* ...."

However, taken together with the observation, in the hydrolysis of MEP, that an endocyclic cleavage is preferred in basic media due to the stereoelectronic effect and an exocyclic cleavage becomes competitive in acidic media because protonation is more favorable on the exocyclic oxygen (the reverse anomeric effect), a similar analysis to the hydrolysis of RNA provides a capability for uniquely supporting the mechanism of Breslow and Labelle. The deprotonation of **3** by imidazole leads to **2**, which is equivalent to **8** in Scheme 1, resulting in stereoelectronically favorable P-(2′-O) bond cleavage. For the forward reaction, protonation is preferred on the exocyclic 5″-oxygen, leading to the loss of 5″ oxygen of the next nucleotide. Apparently, this analysis disfavors the kinetically equivalent alternative mechanism, a sequential general acid-base catalysis, since protonation is never favored on an endocyclic 2′-

oxygen and at the same time the stereoelectronic effect disfavors an exocyclic cleavage.

This mechanism may indeed be significant for the action of Ribonuclease.[9] At the active site of Ribonuclease, the basic imidazole of the enzyme (His-12) acts to remove the proton from the attacking 2′-hydroxyl group which then adds to phosphorus from the opposite side of the leaving 5″-OR group, leading to the in-line mechanism[44-46] intermediate, **2**. In order to shift the equilibrium toward the exocyclic cleavage, via the monoanion intermediate, **3**, the temporarily formed imidazolium ion (His-12) transfers its proton to one of the equatorial oxygens (the equatorial positions are indicated by a triangle plane in Fig. 1). Recall that without this proton transfer, the dianion intermediate, **2**, stereoelectronically favors the decomposition to the starting diester, **1**. The imidazolium ion of the enzyme (His-119) then acts to put a proton on the leaving 5″-oxygen atom, and indeed this is the preferred protonation site, as discussed in terms of the reverse anomeric effect as well as the Hammond Postulate.

It is important to realize that all the reaction steps discussed in the previous paragraph are also the chemically favored lower energy pathways (i.e., in-line over adjacent, endo- over exo-cleavage of the basic form of the intermediate, and 5′- over 2′-protonation). For the first transesterification step, the more electron-withdrawing 2′-oxygen and 5′-OR groups occupy the apical positions, as required by the preference rule,[3] leading to the in-line mechanism. The first stereochemical study of an enzymatic P–O bond cleavage was that of Usher, Eckstein, and their associates on pancreatic ribonuclease A.[44,45] They showed that each of the two P–O bond cleavage steps catalyzed by this enzyme proceeded with inversion of configuration at phosphorus (in-line mechanism). Presently, over thirty stereochemical studies of enzymatic substitution at phosphorus have been carried out.[46] There is as yet no indication of an adjacent mechanism which involves pseudorotatory rearrangements in pentavalent intermediates of enzymatic substitutions at phosphorus. All reactions studied to date are stereospecific, and the available data strongly supports the hypothesis that each enzymatic substitution at phosphorus proceeds by an in-line mechanism with inversion of configuration at phosphorus. Together with the probable involvement of the stereoelectronic and reverse anomeric effects in the action of Ribonuclease, this enzyme appears to take advantage of any energy lowering effects at each reaction steps (in-line over adjacent, endo-over exo-cleavage, 5′- over 2′-protonation, etc.), in accord with the "evolutionary perfection."[47]

In conclusion, as can be seen in Fig. 2, the mode of cleavage of MEP and EEP is pH-dependent: The exo- and endocyclic cleavages are preferred in acidic and basic media, respectively. Similarly, the exo- and endocyclic cleavages of the RNA intermediate, **3**, are catalyzed by the acidic and basic forms of imidazole, respectively. These observations are consistent with the arguments regarding the stereoelectronic effect and the reverse anomeric effect.

There is no way for the author to express his great appreciation to Prof. David G. Gorenstein then at University of Illinois/Chicago and presently at Purdue University and Prof. William L. Mock at University of Illinois/Chicago for their wonderful hospitality and guidance during the author's stay at UIC. Influence by these professors has greatly enhanced the author's interest in the role of orbital interactions in reaction mechanisms. The author wishes to express his appreciation for the support and understanding, in addition to an excellent tutelage, of Prof. Stephen J. Benkovic and Patricia Benkovic at Pennsylvania State University. This article is dedicated to the author's outstanding teachers: Professors S. J. Benkovic at Penn State, D. G. Gorenstein at Purdue, W. L. Mock at Univ. of Illinois, T. Koizumi at Toyama Medical and Pharmaceutical University, J. Sunamoto at Nagasaki University, E. Tsukamoto, A. Hamano, H. Nagasue at Sasebo Technical College, R. Tanaka at Kyushu University, and K. Furukawa at Fermentation Research Institute, Tsukuba. Lastly, the very helpful discussion and comments of the author's colleague, Dr. Robert J. Miller, are much appreciated.

Activation of Glassy Carbon Electrodes by Polishing with Ceramics Particles

Makoto AIHARA* and Masahiro KOMATSU†

Synopsis. Glassy carbon electrode polished with ceramics particles (TiB_2, SiC, and TiC) showed higher oxidation rate of ascorbic acid. The activation seems to depend on hardness of glassy carbon and ceramics particles and to be influenced by fresh edges formed on glassy carbon surface.

Glassy carbon electrode (GCE) has been used for voltammetry and amperometry. Renewal of glassy carbon (GC) is usually perfomed by polishing GC surface with an abrasive such as α-alumina. It was recently shown that an oxide (α-Al_2O_3, CeO_2, ZrO_2, etc.) dispersed on GC surface enhances the rate of electrochemical reaction of ascorbic acid and other compounds.[1-3] A model has been proposed to explain the enhancement. A porous thin layer of carbon embracing metal oxide particles adheres to the surface of base GC.[1-3] The current is enhanced due to additional current from an electroactive species in the porous layer. These studies are, however, limited to the experiments on metal oxides.

In this paper, activity of three types of glassy carbon electrode polished with ceramics particles (titanium boride (TiB_2), silicone carbide (SiC), and titanium carbide (TiC)) was investigated for oxidation of ascorbic acid by cyclic voltammetry.

Experimental

L-Ascorbic acid (Wako Pure Chem. Co.) was used without further purification. α-Al_2O_3 was obtained from Buehler Co. (Chicago), TiB_2 (particle size: 2 μm, hardness: 3200—3400 kg mm^{-2}) from Hermann C. Starck Co., SiC (particle size: 2 μm, hardness: 2700 kg mm^{-2}) from Fujimi Kenmazai Kogyo Co., and TiC (particle size: 2 μm, hardness: unknown[4]) from Japan New Metals Co. The supporting electrolyte was 0.1 M (1 M=1 mol dm^{-3}) phosphate buffer at pH 2.0. Twice distilled water was used throughout the experiments. Other chemicals used are of reagent grade.

Three types of GC (GC-10, GC-20, and GC-30, Tokai Carbon Co.) with a geometric area of 0.071 cm^2 were used. Each GC was polished succesively with α-Al_2O_3 of 1.0, 0.3, and 0.05 μm in diameter as a slurry with water, until a mirrorlike surface was obtained. After polishing, the electrode was washed with water for 15 min in an ultrasonic field. The each electrode was repolished with an aqueous slurry of an abrasive (TiB_2, SiC, or TiC) for 30 s on a polishing pad (Yanaco) under pressure and rinsed with water. The electrode was electrochemically examined immediately. GCE was deactivated by a polishing cloth.[5]

A Yanaco model VMA-010 cyclic voltammetric analyzer was employed for cyclic voltammetric measurements. The reference and counter electrodes were Ag/AgCl (Yanaco, MR-P3) and a Pt wire, respectively. The differential capacitance of GCE was evaluated from a.c. measurements with a Fuso phase sensitive amplifier.

Electrodes activated by polishing with the abrasives were immersed into a solution of 1×10^{-3} M ascorbic acid in 0.1 M phosphate buffer solution at pH 2.0 and cyclic voltammograms were recorded to examine the activity of GCE at a scan rate of 100 mV s^{-1}.

Table 1. Electrochemical Data for Ascorbic Acid Oxidation

GC	Abrasive	Size μm	E_{pa} V. vs. Ag/AgCl	$E_{pa/2}$ V. vs. Ag/AgCl	i_{pa}^*/i_{pd}
GC-10	TiC	2	0.257	0.190	0.90
	SiC	2	0.233	0.166	1.21
	TiB_2	2	0.216	0.159	1.40
	α-Al_2O_3	0.05	0.209	0.171	1.27
		0.3	0.205	0.160	1.40
		1.0	0.205	0.163	1.52
GC-20	TiC	2	0.185	0.155	1.87
	SiC	2	0.175	0.141	2.44
	TiB_2	2	0.171	0.139	2.50
	α-Al_2O_3	0.05	0.190	0.158	1.72
		0.3	0.176	0.144	2.07
		1.0	0.169	0.135	3.13
GC-30	TiC	2	0.181	0.155	2.02
	SiC	2	0.171	0.139	3.22
	TiB_2	2	0.171	0.139	3.80
	α-Al_2O_3	0.05	0.181	0.151	1.89
		0.3	0.179	0.141	2.43
		1.0	0.170	0.139	3.58

* i_{pa} is peak current value measured at about 10 s after polishing.

Results and Discussion

By preliminary experiments using GCE activated with α-Al_2O_3 (1.0, 0.3, and 0.05 μm in diameter) it was revealed that the enhancement of oxidation of ascorbic acid depends on the particle size of α-Al_2O_3 as shown in Table 1. In this study, GCE surface was activated by polishing it with ceramic particles(TiB_2, SiC, and TiC) with a same particle size of 2 μm.

Typical cyclic voltammograms of ascorbic acid solution in phosphate buffer are shown in Fig. 1. No cathodic wave was observed for deactivated and activated GCE. A broad oxidation wave was obtained at the deactivated GCE. The avarage of 20 peak potential (E_{pd}) values at deactivated GCE was 0.476 V vs. Ag/AgCl. Peak current (i_{pa}) was enhanced and peak potential (E_{pa}) shifted to a less positive potential by polishing GCE with seramics particles. Similar voltammetric behavior was observed at GCE activated with each of the ceramics. The results for oxidation of ascorbic acid are summarized in Table 1, indicating that the activation of ascorbic acid occurs at GCE activated with the ceramics particles. The presence of metal oxide particles dispersed on GC surface will not necessary for activation of ascorbic acid. The order of activation is TiB_2>SiC>TiC at the same type of GCE. TiB_2 is assumed to have the highest hardness in three abrasives examined. The results indicate that the activation depends on the hardness of ceramics particles at a constant particle size.

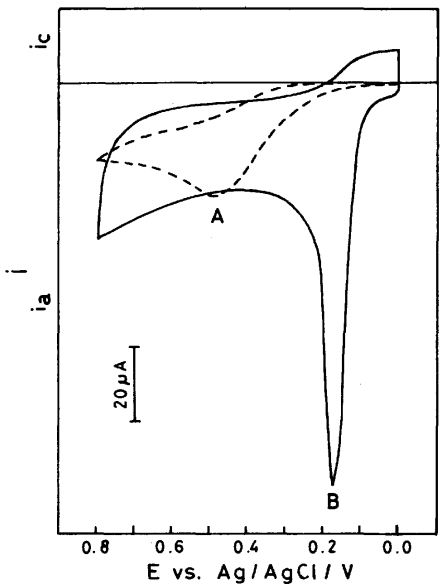

Fig. 1. Cyclic voltammograms of 1×10^{-3} M ascorbic acid at pH 2.0 at GC-30 GCE. Scan rate 0.1 V s^{-1}. (A): Deactivated by final polishing on a polishing cloth. (B): Activated by polishing with TiB_2.

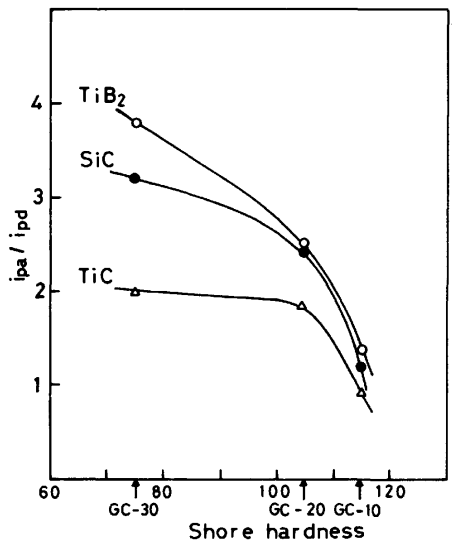

Fig. 2. Plots of the ratio of i_{pa} to i_{pd} versus the average Shore hardness of GC.

Figure 2 shows the relationship between the ratio of peak current at activated GCE(i_{pa}) to peak current at deactivated GCE (i_{pd}) and the average Shore hardness of GC. The order of oxidation activation for three types of GCE is GC-30>GC-20>GC-10. GC-30 GCE which has the lowest hardness shows the most enhanced oxidation of ascorbic acid. These results suggest that active edges are formed on carbon surface of GCE(GC-30) polished with TiB_2.

On the other hand, the differential capacitance at peak potential for deactivated GCE(GC-30) in ascorbic acid solution was 62 μF cm^{-2}. The values for GCE(GC-30) polished with TiB_2, SiC, and TiC were 570, 554, and 463 μF cm^{-2}, respectively. These values are seven to nine times greater than that for deactivated GCE and similar to that for edge orientation of pyrolytic graphite.[6] It is likely that ascorbic acid is adsorbed on fresh carbon edges. The activation of ascorbic acid oxidation will be ascribed to fresh carbon edges formed on GCE surface.

The authors wish to thank Dr. Minoru Nakamizo of Government Industrial Research Institute, Kyushu for valuable discussion. We also would like to thank Professor Eiichi Sekido and Assistant Professor Yoshitaka Masuda of Kobe University for double layer experiments. One of the authors(M. A.) was supported by a grant from Fukuoka Prefecture.

The Magnetic Properties of the Ammonium Chloride Adducts of Copper(II) Fluoroacetate and Copper(II) Bromoacetate

Shuji EMORI,* Nobuhide MORISHITA, and Yoneichiro MUTO
Department of Chemistry, Faculty of Science and Egineering, Saga University, Honjo-machi, Saga 840
(Received November 11, 1986)

Synopsis. Compounds of formula $Cu(XCH_2COO)_2 \cdot nACl$ (A=NH_4, CH_3NH_3, $(CH_3)_2NH_2$, $(CH_3)_4N$ and X=F, Br) have been prepared, and characterized by magnetic susceptibility and IR spectroscopy measurements. Factors affecting the magnetic moments of copper(II) salts of monosubstituted alkanoic acids are discussed.

Most copper(II) carboxylates have the familiar bridged copper(II) acetate monohydrate structure,[1,2] and their magnetic properties have been studied extensively to elucidate the factors which determine the magnitude of spin-exchange coupling between copper(II) ions.

According to the Edwards equation with 'hard' base and 'borderline' acid,[3] their stability constants depend primarily to the basicities of the carboxylato ligands. Therefore it seems likely that their magnetic properties relate to the acidities of their parent acids. Actually, in some series of dinuclear copper(II) carboxylates,[4-9] the magnetic moment tends to increase as the pK_a value of the parent acid decreases. This empirical relationship has been explained in terms of the inductive effect of the carboxylato substituents, and is supported by molecular orbital analyses.[10,11]

However, there exist a few exceptions; e.g., the room temperature-magnetic moments of copper(II) haloacetate hydrates[4] vary from 1.32 BM for fluoroacetate to 1.43, 1.54, and 1.49 BM for chloro-, bromo-, and iodoacetates, whereas the pK_a values of the parent acids are 2.66, 2.86, 2.90, and 3.17, respectively. Since the magnitude of the spin-exchange coupling in these hydrates may be affected by other factors, such as the intermolecular hydrogen bonds between the water molecules in the axial positions and the oxygen atoms of the carboxylato groups,[1,2] it is preferable to accumulate the magnetic data and to examine the general tendency for the compounds with the same axial ligands. We have prepared various ammonium chloride adducts of copper(II) fluoroacetate and copper(II) bromoacetate, and compared their magnetic data with those of other dinuclear copper(II) salts of monosubstituted alkanoic acids with chloride ions in the axial positions.

Compounds with a stoichiometry of $Cu(XCH_2COO)_2 \cdot nACl$, where X=F or Br and A=$NH_4$, CH_3NH_3, $(CH_3)_2NH_2$, or $(CH_3)_4N$, were prepared by a previously described method for the corresponding chloroacetates.[8] These compounds were obtained as green crystals.

The effective magnetic moments of these compounds (Table 1) were evaluated from the room-temperature magnetic susceptibilities, corrected for the diamagnetic contribution of the constituent atoms using Pascal constants[12] with a value of $N\alpha=60\times10^{-6}$ emu mol^{-1} (1 emu=$4\pi\times10^{-6}$ m^3).

For the methylammonium chloride adducts of copper(II) fluoroacetate and copper(II) bromoacetate, the temperature dependence of their magnetic susceptibilities was measured in the temperature range of 80—300 K to confirm their dinuclear structures. The results agreed well with the Bleaney-Bowers equation,[13] using the following parameters: $g=2.17$ and $2J=-359$ cm^{-1} for the fluoroacetate and $g=2.19$ and $2J=-300$ cm^{-1} for the bromoacetate, respectively. The IR spectra of the solid compounds show the characteristic bands in the ranges 1450—1460 and 1625—1660 cm^{-1} connected with symmetric and unsymmetric COO stretching vibrations of the carboxyl groups.[14]

Table 1. Analytical Data and Effective Magnetic Moments at 20 °C

Compound	Found (Calcd)/%					μ_{eff}/BM
	Cu	Cl	C	H	N	
$Cu(BrCH_2COO)_2 \cdot 3/2NH_4Cl$	15.07 (15.14)	12.33 (12.67)	11.45 (11.45)	2.46 (2.40)	5.01 (5.01)	1.40
$Cu(BrCH_2COO)_2 \cdot CH_3NH_3Cl$	15.80 (15.62)	8.85 (8.71)	14.84 (14.76)	2.53 (2.48)	3.26 (3.44)	1.41
$Cu(BrCH_2COO)_2 \cdot (CH_3)_2NH_2Cl$	15.02 (15.10)	8.33 (8.42)	17.09 (17.12)	2.81 (2.87)	3.09 (3.33)	1.43
$Cu(FCH_2COO)_2 \cdot 2NH_4Cl$	19.59 (19.58)	21.77 (21.84)	14.77 (14.80)	3.67 (3.73)	8.44 (8.63)	1.29
$Cu(FCH_2COO)_2 \cdot CH_3NH_3Cl$	21.59 (22.29)	12.34 (12.42)	20.77 (21.06)	3.65 (3.53)	4.95 (4.91)	1.27
$Cu(FCH_2COO)_2 \cdot (CH_3)_2NH_2Cl$	20.90 (21.24)	12.42 (11.85)	23.88 (24.09)	3.96 (4.04)	4.59 (4.68)	1.26
$Cu(FCH_2COO)_2 \cdot (CH_3)_4NCl$	19.88 (19.42)	10.81 (10.83)	29.09 (29.37)	4.92 (4.93)	4.18 (4.28)	1.28

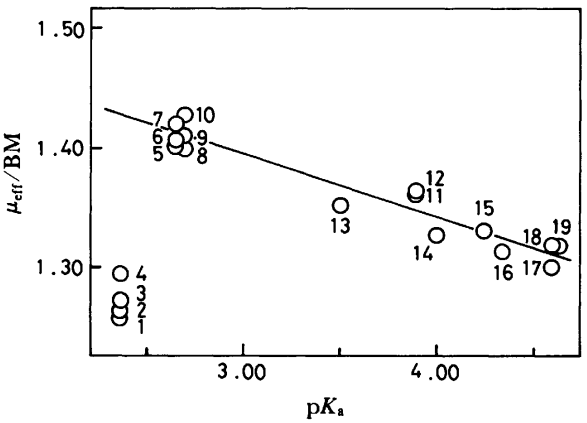

Fig. 1. The magnetic monent at 20 °C plotted against the pK_a value of the parent carboxylic acid for the copper(II) salts of monosubstituted alkanoic acids with chloride ions in the axial positions; the fluoroacetates (**1**—**4**), the chloroacetates (**5**—**7**),[8] the bromoacetates (**8**—**10**), the 3-chloropropionates (**11**, **12**),[15] the ω-ammonioalkanoates (**13**—**16**),[9] the butyrates (**17**, **18**),[15] and the propionate (**19**).[15]

The magnetic and IR spectral data indicate that the present compounds have the bridged dinuclear structure similar to copper(II) acetate monohydrate.[1,2]

In order to examine the correlation between the room-temperature magnetic moment of dinuclear copper(II) carboxyate and the pK_a value of its parent acid, the data for the present compounds, together with those of other dinuclear copper(II) salts of monosubstituted alkanoic acids with chloride ions in the axial positions, are plotted in Fig. 1. The magnetic moments of the chloroacetates[8] were corrected for the difference of room temperature by use of the Bleaney-Bowers equation[13] with g=2.15. As can be seen from Fig. 1, the magnetic moments of the fluoroacetates are much smaller than those expected from the pK_a value of fluoroacetic acid. However, except for fluoroacetates, there is a linear relation between these magnetic moments and the pK_a values of the parent acids in the range of those measurements. The best line has a slope of −0.052 BM and the intercept of 1.31$_8$ BM at pK_a=4.56 (the pK_a value of acetic acid). The variation of single-triplet separation values (e.g.,$-2J$=278, 300, and 320 cm^{-1} for the dimethylammonium chloride adduct of copper(II) chloroacetate,[8] the methylammonium chloride adduct of copper(II) bromoacetate, and the copper(II) chloride compound with 4-aminobutyric acid,[9] respectively) is consistent with this general trend, and agrees well with the molecular orbital analyses.[10,11]

It is still unclear why the magnetic data for the fluoroacetates deviate from the general trend. Porter and Doedens have pointed out that there is an apparent relationship between the singlet-triplet separation values and the group polarizabilities of the carboxlato substituents.[16] However the ordering for the above-mentioned $-2J$ values is contrary to the proposal that lower $-2J$ values are associated with increasing group polarizabilities. From the study of ^{19}F NMR in the series of fluorochloromethanes,[17] it is known that the fluorine nuclei are shielded in the opposite manner from that predicted by electronegativity considerations. In order to explain these anomalous chemical shifts, Gutowsky and Hoffman have suggested the use of higher energy orbitals in the hybridized orbitals of atoms attached to fluorine atoms.[18] This idea may explain the small magnetic moment observed for the present fluoroacetates, because the higher energy orbitals interact more strongly with the electronic system of neighboring carboxylato group, through which spin-exchange coupling between copper(II) ions operates. However, the elucidation of cause and mechanism depends upon future multilateral studies.

Structure of Protonated Products of Potassium 1-(Dimethylamino)naphthylide

Akira Oku* and Yukio Homoto
Department of Chemistry, Kyoto Institute of Technology, Matsugasaki, Sakyo-ku, Kyoto 606
(Received December 8, 1986)

Synopsis. Potassium 1-(dimethylamino)naphthylide (K^+DMAN^-) was protonated by aqueous THF and the structures of protonated products (overall yield of three isomeric products was almost quantitative) were analyzed by ^1H NMR and their 2D-NOE correlation. Products were 1-(dimethylamino)-5,8-dihydronaphthalene (major product, 88%), 7,8-dihydro- (9%), and 5,6-dihydro-isomer (3%). Deducing from the structures, the protonation pathway as well as the spin distribution in K^+DMAN^- is discussed.

Potassium 1-(dimethylamino)naphthylide radical anion (abbreviated as K^+DMAN^-) has recently been appearing in literatures as a useful reductant instead of parent naphthylide[1,2] because of the ease with which DMAN and its derivatives can be removed from the reaction mixture by the workup with aqueous acid, and which enables easy product analysis as well as the accomplishment of synthetic purposes. Although $DMAN^-$ can be used in diverse ways,[3-6] it seemed strange to us that the structure of the most common workup products from $DMAN^-$, i.e., dihydro-DMAN (abbreviated as DMAN-H_2), has not yet been elucidated. Since $DMAN^-$ is an unsymmetrically substituted naphthalene radical anion, the structural analysis of its protonated products will also afford information for the spin distribution in this radical anion. We report here the structural elucidation of protonated products of $DMAN^-$.

When a THF solution of K^+DMAN^-, prepared from potassium metal and DMAN in THF under a nitrogen atmosphere (60% of the initially charged DMAN was active), was treated at −70 °C with aqueous THF, a mixture of isomeric 1-(dimethylamino)dihydronaphthalenes (DMAN-H_2) was obtained besides DMAN. The most likely protonation mechanism is:[7]

$$[DMAN^-] + H_2O \longrightarrow [DMAN\text{-}H_1]^\cdot + OH^- \quad (1)$$

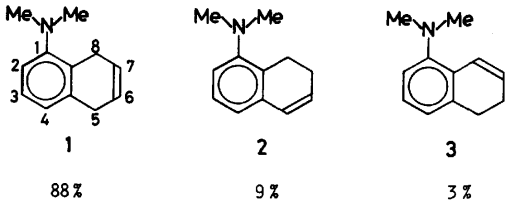
$$[DMAN\text{-}H_1]^\cdot + [DMAN^-] \longrightarrow [DMAN\text{-}H_1]^- + DMAN \quad (2)$$

$$[DMAN\text{-}H_1]^- + H_2O \longrightarrow DMAN\text{-}H_2 + OH^- \quad (3)$$

$$2[K^+DMAN^-] + 2H_2O \longrightarrow 2DMAN + 2KOH + H_2. \quad (4)$$

According to Eqs. 1—3, one mol each of DMAN and DMAN-H_2 should be produced from two moles of $DMAN^-$. In fact, the protonation mixture was analyzed by VPC to be consisting of DMAN (retention time, t_r=23.74 min) and three other products **1** (t_r=22.87 min), **2** and **3** (t_r=21.27 min) in the ratio DMAN/**1**/**2**/**3**=67/29/3/1.[8] Taking into account that the titrated concentration of active K^+DMAN^- before protonation was 60% based on the initially charged DMAN, the calculated (theoretical) product distribution based upon this correction should be DMAN/DMAN-H_2=70/30,[9] which agrees well with the observed distribution DMAN/(**1**+**2**+**3**)=67/33. Consequently, it is concluded that active K^+DMAN^- was transformed almost quantitatively into dihydronaphthalenes **1**, **2**, and **3** (corrected yields: **1**=88%, **2**=9%, **3**=3%). The participation of a reduction process (Eq. 4)[10] which may partially account for the production of DMAN is thus negligible.

Product **1** and a mixture of **2** and **3** were separated and purified by column as well as by VPC. The mass spectral analysis of both **1** and the mixture of **2** and **3** showed M^+ (m/z)=173 which agrees with DMAN-H_2. The ^1H NMR spectra of these products showed the same proton ratio of *N*-methyl/Ar-H/(aliphatic+olefinic)=6/3/6, indicating that the protonation took place mainly on the unsubstituted ring. Three structures which agree with the above observations are shown below.

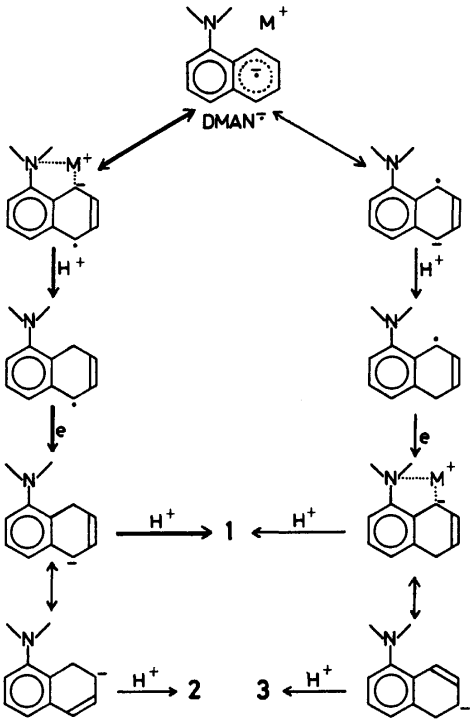


1 88% **2** 9% **3** 3%

The structure of the major product was determined to be **1** by its ^1H NMR spectrum: Two sets of methylene protons with roughly the same chemical shift are appearing at δ 3.26 as doublets, and two olefinic protons at δ 5.93 as a doublet.

Structural determination of **2** and **3** was somewhat complicated because their separation was possible only by the use of a capillary column (OV-101 30 m, ΔR_f=0.03, isomer ratio=3/1) and their ^1H NMR spectra are almost identical: *N*-Methyl protons are appearing as two singlets at δ 2.61 and 2.65 (ratio 1:3), and β-methylene protons between 2.16—2.33, benzylic α-methylene protons at δ 2.68 (partially overlapping *N*-methyls), β-olefinic methines at δ 6.0, α-olefinic methines at δ 7.0 (overlapping aromatic protons, identified by the irradiation at δ 6.06).

To determine which isomer predominates in the mixture of **2** and **3**, a two-dimensional Nuclear Overhauser Effect (2D-NOE) correlation diagram was taken.[11] The expected NOE between *N*-methyl (δ 2.65) and α-methylene protons (δ 2.68) of **2** was indecipherable due to the mutual overlapping of their signals. However, an appreciable correlation between *N*-methyl (δ 2.65) and β-methylene protons (δ 2.20) was observed. By a molecular model analysis it is shown that protons of *N*-methyls and 7-methylene group of **2** stay within the interproton distance of 2.4—2.6 Å, whereas those of *N*-methyls and 6-



Scheme 1.

methylene group of **3** stay more apart. This observation supports at least the presence of isomer **2**. In addition, the anticipated strong correlation between methyls (δ 2.61) and 8-methine proton (δ 7.0) of **3** appeared only weakly. Although 2D-NOE measurements are generally considered not so reliable for quantitative analysis, yet the above results reasonably lead us to conclude that isomer **2** predominates over the other isomer **3** (isomer ratio **2**/**3**=3 by VPC).

Structures and the product distribution both provide information for solving the major channel of the protonation mechanism (Scheme 1). First of all, the protonation takes place exclusively on the unsubstituted ring of $DMAN^-$. This may be due to the spin distribution which is greatly shifted toward the unsubstituted half of the molecule. Second, the peri-position spatially adjacent to the dimethylamino group in $DMAN^-$ is predominantly protonated. This selectivity can be explained in terms of both the stability of benzylic carbanion intermediates and the coordination effect between the alkali metal cation and the nitrogen atom.

Experimental

General. 1-(Dimethylamino)naphthalene (DMAN) was commercially available and was purified by distillation before use. ^1H NMR spectra and homonuclear NOE correlated 2D-NMR were taken on Varian XL 200 spectrometer equipped with a 2D-NOE program. Mass spectra were taken on Hitachi M-80A spectrometer. For the VPC analysis Shimazu GC-9A was used.

Preparation and Determination of K^+DMAN^-. A THF solution of K^+DMAN^- was prepared under a nitrogen atmosphere by mixing 2.0 g (0.05 gram atom) of potassium metal and 8.6 g (0.05 mol) of DMAN in 100 mL of THF at 0 °C. The concentration of active radical anion was determined to be 0.30 dm^{-3} according to the titration method reported previously.[12]

Reaction and Workup Procedures. The radical anion solution prepared above was cooled to 0 °C, to which was slowly added dropwise a 5:1 mixture (20 cm^3) of THF and water. The reaction mixture was warmed up to 20 °C and was extracted with diethyl ether. After drying over anhydrous Na_2SO_4 and concentrating the ethereal solution, the product mixture was analyzed by VPC (packed column Apiezon Grease-L 2 m; fused silica capillary column OV-101 0.5 mm×30 m). Results are described in the main text.

^1H NMR Spectra of 1-(Dimethylamino)-5,8-dihydronaphthalene (5,8-Dihydro-DMAN, 1). δ=2.67 (6H, s, 2Me); 3.26 (4H, d, CH_2, $J(5,6)=J(8,7)=1.0$ Hz); 5.93 (2H, bs, -CH=, $J(6,5)=J(7,8)=1.0$ Hz); 6.85 (1H, dd, ArH(4), $J(4,3)=7.6$, $J(4,2)=1.0$ Hz); 6.95 (1H, dd, ArH(2), $J(2,3)=7.6$, $J(2,4)=1.0$ Hz); 7.14 (1H, t, ArH(3), $J(3,2)=J(3,4)=7.6$ Hz). Mass spectrum M^+ (m/z)=173. Anal. Calcd for $C_{12}H_{15}N$: C, 83.19; H, 8.73; N, 8.08%. Found: C, 83.03; H, 8.98; N, 7.87%.

^1H NMR Spectra of a Mixture of 7,8-Dihydro-DMAN (2) and 5,6-Dihydro-DMAN (3). δ=2.20 (2H, m, 7-CH_2 of **2** and 6-CH_2 of **3**, $J(7,8)=8.0$ Hz); 2.61 (s, Me's of **3**) and 2.65 (s, Me's of **2**), total integration of 2.61 plus 2.65 is equivalent to 6H; 2.68 (2H, bt, 8-CH_2 of **2** and 5-CH_2 of **3**, $J(8,7)$ of **2**=$J(5,6)$ of **3**=8.0 Hz); 6.00 (1H, dt, 6-CH= of **2** and 7-CH= of **3**, $J(6,7)$ of **2**=$J(7,6)$ of **3**=4.4 Hz, $J(6,5)$ of **2**=$J(7,8)$ of **3**=10.0 Hz); 6.74 (1H, d, 5-CH= of **2**, $J(5,6)$ of **2**=10.0 Hz); 6.73 (1H, d, ArH(4) of **2** and **3**, $J(4,3)$ of **2** and **3**=7.6 Hz); 6.81 (1H, d, ArH(2) of **2** and **3**, $J(2,3)=7.6$ Hz); 7.00 (1H, t, ArH(3) of **2** and **3**, $J(3,4)=J(3,2)=7.6$ Hz); 8-CH= of **3** may be hidden near 7.0. Mass spectrum M^+ (m/z)=173. Anal. Found: C, 83.07; H, 9.05; N, 7.78%.

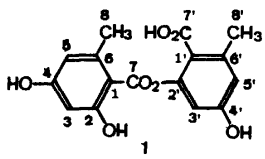
Chemical Studies on the Lichen. I. The Structure of Isolecanoric Acid, a New *ortho*-Depside Isolated from *Parmelia tinctorum* Despr.

Atsushi SAKURAI* and Yohko GOTO
Department of Chemistry, Faculty of Science, Shizuoka University, Ohya, Shizuoka 422
(Received December 15, 1986)

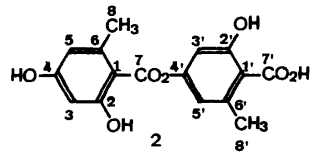
Synopsis. A new *ortho*-depside, isolecanoric acid was isolated from *Parmelia tinctorum* Despr. and 2-(2,4-dihydroxy-6-methylbenzoyloxy)-4-hydroxy-6-methylbenzoic acid was assigned to this substance from studies on the hydrolysis products and from analyses of the ^1H and ^{13}C NMR spectra. This substance is the first *ortho*-depside isolated from the genus Lichen.

Lichens produce many unusual secondary metabolites ("lichen substance") hardly found in other plants.[1] The major phenolic substances, among them are divided into classes of *meta*-depside, *para*-depside, depsidone, etc, but *ortho*-depside has not been isolated. From a lichen, *Parmelia tinctorum* Despr. (Umenoki-goke in Japanese) *para*-depsides, atranolin and lecanoric acid have been isolated.[2]

In our studies on the constituents of *Parmelicaeae* we found the presence of a new depside in *P. tinctorum* Despr. besides them and named it isolecanoric acid (**1**). In this paper we wish to report the isolation and structure of **1**.



1



2 8'

The lichen which occurred on stone walls was collected and extracted with acetone followed by reextraction with methanol. The later extract was subjected to chromatography on a column of Sephadex LH-20 eluting with methanol. The last effluent gave **1** as colorless powder, mp >300 °C (colored at 220 °C) in 0.03% yield from wet plant. Compound **1** is optically inactive and from its elemental analyses was suggested the formula $C_{16}H_{14}O_7$. The UV spectrum of **1** in ethanol shows the absorption maxima at 211, 269, and 303 nm, which was similar to that of lecanoric acid (**2**) in the spectral pattern.[2]

The ^1H NMR spectrum of **1** in a mixture of $CDCl_3$ and CD_3OD shows the small difference in the chemical shifts as compared with that of **2**.[3] And the spectrum of **1** shows the signals ascribed to two aromatic methyl protons at δ 2.56 (3H, s) and 2.62 (3H, s), and to the protons attached to two 1,2,3,5-tetrasubstituted benzene rings at δ 6.22 (1H, d, J=2 Hz) and 6.30 (1H, d, J=2 Hz), and 6.48 (1H, d, J=2.1 Hz) and 6.54 (1H, d, J=2.1 Hz).

Treatment of **1** with diazomethane in methanol gave a tetramethyl derivative of **1** as colorless needles, mp 154—155 °C [MS (20 eV): M^+ 374], and its ^1H NMR spectrum in $CDCl_3$ shows the signals ascribed to three methoxyl groups and to one

Table 1. Carbon-13 NMR Chemical Shifts of **1**, **2**, **3**, and **4** in DMSO-d_6

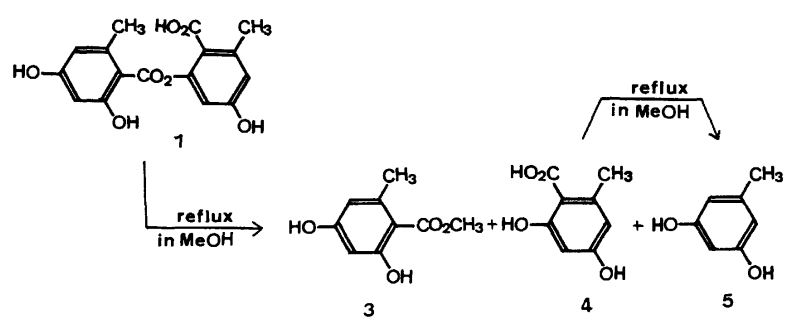
In parts per million downfield from tetramethylsilane. Values bearing the same superscript may be interchanged.



Scheme 1.

methoxycarbonyl group at δ 3.82 (6H, s), 3.86 (3H, s), and 3.90 (3H, s).

After having been refluxed in methanol followed by separation with a column of Sephadex LH-20 in the same manner as described above, compound **1** gave methyl orsellinate (**3**) and orsellinic acid (**4**) in a molar ratio of ca. 1:1 and a trace amount of orcinol (**5**).[4] Since **4** gives **5** by further treatment with boiled methanol, compound **5** should be formed by decarboxylation of **4** after methanolysis of **1**.

In the ^{13}C NMR spectra of **1**, **2**, **3**, and **4** in DMSO-d_6 as shown in Table 1, the signals ascribed to the carbons at the left hand of **1** (C-1—C-8) show the good agreement with those of **2**, whereas the signals at the right hand (C-1′—C-8′) show a little difference between **1** and **2**. The 2′-carbon bearing a benzoyloxy group in **1** appears at a field higher by 10.7 ppm than that of **4**, and 1′-, 3′-, and 5′-carbons in **1** (*ortho*- and *para*-potitions to C-2′) appear at fields lower by 11.3, 6.5, and 1.6 ppm respectively than those of **4**. The 4′-carbon in **2** appears at a field higher by 11.9 ppm than that of **4**, and 1′-, 3′-, and 5′-carbons in **2** appear at fields lower by 11.0, 6.9, and 4.0 ppm respectively than those of **4**. These results indicate that the ester bond in **1** should be linked at the 2′-position.

These ^1H NMR and ^{13}C NMR spectral data and all experimental results described above support the structure of isolecanoric acid (**1**) to be 2-(2,4-dihydroxy-6-methylbenzoyloxy)-4-hydroxy-6-methylbenzoic acid.

Compound **1** is the first *ortho*-depside isolated from the genus Lichen. Moreover we found the presence of **1** in *P. clavurifera* Räs. (Matsuge-goke in Japanese)[5] as a minor constituents with **2**.

Experimental

All melting points are uncorrected. The ^1H NMR spectra were measured with a Varian EM-390 90 MHz NMR spectrometer. The ^{13}C NMR spectra were measured with a JEOL JNM-PFT-60 NMR spectrometer at 15.04 MHz. Chemical shifts were expressed by δ value (ppm) from tetramethylsilane as internal standard. The IR spectra were measured with a Hitachi EPI-G3 spectrophotometer and the UV spectra were measured with a JASCO UVIDEC-510 spectrophotometer.

Isolation of Isolecanoric Acid (1). The lichen (300 g) which occurred on stone walls was collected and extracted with acetone (1500 cm^3) followed by reextraction with methanol (1500 cm^3) at room temperature for a week. The later extract was condensed to a syrup under reduced pressure and the syrup was subjected to chromatography on a column of Sephadex LH-20 (3.5×120 cm) eluting with methanol. The last effluent gave **1** as colorless powder after recrystallization from methanol: Mp >300 °C (colored at 220 °C); yield, 90 mg (0.03% from wet plant); UV (EtOH) 211 (log ε 4.56), 269 (4.21), and 303 nm (3.99); ^1H NMR (CD_3OD–$CDCl_3$) δ=2.56 (3H, s, Ar–CH_3), 2.62 (3H, s, Ar–CH_3), 6.22 (1H, d, J=2 Hz, Ar–H), 6.30 (1H, d, J=2 Hz, Ar–H), 6.48 (1H, d, J=2.1 Hz, Ar–H), and 6.54 (1H, d, J=2.1 Hz, Ar–H); ^{13}C NMR (DMSO-d_6) δ=21.7 (q), 23.0 (q), 107.6 (s), 110.1 (d), 112.5 (d), 116.3 (s), 140.3 (s), 142.2 (s), 151.1 (s), 160.7 (s), 161.4 (s), 165.6 (s), 167.6 (s), and 171.8 (s). Found: C, 58.93; H, 4.78%. Calcd for $C_{16}H_{14}O_7 \cdot 0.5H_2O$: C, 58.72; H, 4.63%.

Treatment of **1** (10 mg) in methanol (10 cm^3) with an ether solution containing diazomethane followed by chromatography through silica gel with hexane–ethyl acetate (4:1) afforded a tetramethyl derivative of **1** as colorless needles after recrystallization from acetone–hexane: Mp 154—155 °C; yield, 4 mg; MS (20 eV): M^+ 374; ^1H NMR ($CDCl_3$) δ=2.30 (3H, s, Ar–CH_3), 2.42 (3H, s, Ar–CH_3), 3.82 (6H, s, OCH_3), 3.86 (3H, s, OCH_3), 3.90 (3H, s, OCH_3), 6.37 (2H, s, Ar–H), and 6.67 (2H, brs, Ar–H). Found: m/z 374.1374. Calcd for $C_{20}H_{22}O_7$: M, 374.1365.

Methanolysis of 1. Compound **1** (44 mg) was dissolved in methanol (50 cm^3) and the solution was refluxed for 20 h. The mixture was concentrated and was subjected to chromatography on a column of Sephadex LH-20 in the same manner as described above, and afforded methyl orsellinate (**3**) (23 mg; mp 142—144 °C), orsellinic acid (**4**) (22 mg; mp 180—183 °C), and orcinol (**5**) (*ca.* 2 mg; mp 104—106 °C). Further treatment of **4** with boiled methanol gave **5**. These substances **3**, **4**, and **5** were proved to be identical with authentic samples which were prepared by methanolysis of lecanoric acid (**2**) in the same manner.

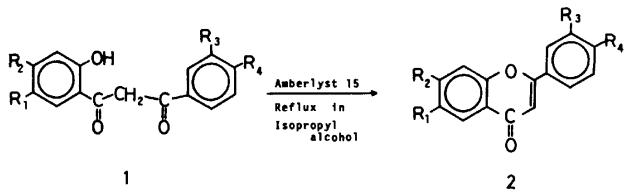
(Received December 12, 1986)

Synopsis. Flavone was prepared from 1-(2-hydroxyphenyl)-3-phenyl-1,3-propanedione by using nonaqueous cation-exchange resin in a nearly quantitative yield. Of several reaction media, isopropyl alcohol gave the best result. Eight substituted flavones were also synthesized from the corresponding diketones in satisfactory yields.

Organic syntheses using ion-exchange resins have long been known, which are exemplified by esterification of acids and alcohols,[1] addition of acids to olefins,[2] Knoevenagel condensation,[3] and von Pechmann reaction.[4] Recently, the utilization of ion-exchange resins is in rapid progress. The use of the resin as catalyst has the following advantages: (1) Products can be stripped of catalyst resin simply by filtering reaction mixtures; (2) the resin can be recovered simply by filtration; (3) it is possible to minimize side reactions. But, hitherto, only few examples using ion-exchange resin have been known in the field of flavonoid synthesis. On the other hand, Baker-Venkataraman's method[5] is one of the best known procedures of a number of synthetic methods for flavones. In this method flavone (**2a**) is usually prepared by intramolecular dehydration, followed by cyclization, of 1-(2-hydroxyphenyl)-3-phenyl-1,3-propanedione (**1a**) with sulfuric acid in glacial acetic acid; **1a** is obtained from *o*-(benzoyloxy)acetophenone by the Baker-Venkataraman transformation.



1 2

Now we attempted this cyclization by using a nonaqueous cation-exchange resin, Amberlyst 15, instead of sulfuric acid, and succeeded in obtaining satisfactory results. In this work, flavones (**2**) were also obtained in high yields by very simple procedures and under comparatively mild conditions. When a mixture of **1a** and a resin in a solvent was heated at the reflux temperature for several hours, a crude product was obtained almost quantitatively simply by filtering off the resin.

Reactions were carried out in benzene, chloroform, acetonitrile, or isopropyl alcohol. The results obtained are summarized in Table 1. We avoided using glacial acetic acid as the reaction medium, because its boiling point is close to the limiting temperature for the use of Amberlyst 15 (120 °C). The reactions were monitored by means of TLC analyses, and were taken as finished when the spot of starting material disappeared or when no change was observed in spots of substrate and product for more than three hours. In the case of chloroform, the reaction did not finish even after 27 h.

Amberlyst 15 is a macroreticular (MR) sulfonic acid type cation-exchange resin and has a huge network structure. When this kind of resin is used as an organic reaction catalyst, the key point is the rate of diffusion of substrate into the network of resin. The best yield of **2a** in the case of isopropyl alcohol may be due to the facility of the diffusion of substrate into the resin. Furthermore, it is remarkable that solvents having a comparatively high dielectric constant give high yields of **2a**. In those solvents the exchange groups in the resin might get more activated than in low dielectric solvents.

The total capacity of Amberlyst 15 is 4.6—5.0 meq/g-R, and accordingly one gram of resin is formally equivalent to ca. 5 mmol of substrate. But it is considered that in this reaction the resin acts as a catalyst for the substrate. This was confirmed by the following experimental result: When a recovered resin was used again for the same reaction without any regenerating treatment, **2a** reappeared and its yield did not extremely decrease (crude 90% and pure 75%; 3 h), although degradation of the resin was observed to

Table 1. Yields of Flavone (**2a**) and Reaction Times in Four Solvents[a]

Solvent[b]	Reaction Time / h	Yield[c] / %
Benzene	14	65[d]
Chloroform	>27	79[d]
Acetonitrile	6	83
Isopropyl alcohol	4	90

a) Substrate: 3.0 g (12.5 mmol); resin: 3.0 g (15.0 meq). b) 80 ml. c) Isolated yield. d) Isolated by column chromatography.

Table 2. Influence of Reaction Composion on the Yield of Flavone (**2a**) in Isopropyl Alcohol[a]

Composion (**1a** : Resin)	Reaction Time / h	Isolated Yield / %
1 : 0.33	14.5	90
1 : 1.20	4	90[b]
1 : 1.43	4	91
1 : 2.64	3	92
1 : 5.0	3	90

a) Solvent: 30 ml. b) From the value in Table 1.

Table 3. Reaction Times and Yields of Mono- or Disubstituted Flavones (**2b—i**) in Isopropyl Alcohol in the Presence of Amberlyst 15

Product No.	R_1	R_2	R_3	R_4	Reaction Time h	Isolated Yield %
2b	H	OCH_3	H	H	8.5	80
2c	H	H	H	OCH_3	2.5	78
2d	H	H	OCH_3	H	8	85
2e	H	OCH_3	OCH_3	H	19	83
2f	H	H	H	Cl	9	80
2g	H	H	Br	H	19.5	67
2h	CH_3	H	H	H	5	90
2i	H	CH_3	H	H	6	83

some extent.

In search for the optimum reaction conditions, reactions were repeated in isopropyl alcohol with several compositions of **1a** and resin. The results are shown in Table 2. Although there is not a great difference in the yield caused by changing the reaction composition, it can be concluded from the viewpoint of reaction time and economy that nearly equivalent composition of substrate and resin is optimum.

Eight mono- or disubstituted flavones (**2b—i**) were also prepared from the corresponding diketones (**1b—i**) by the same procedure. The results obtained are summerized in Table 3. Syntheses of a few 2′-substituted derivatives were also attempted in vain. This may be due to the steric hindrance by the introduction of the 2′-substituent close to the reaction center. From the results in Table 3, this method may be regarded as a general synthetic procedure for the flavones except the above-mentioned examples.

Thus we believe that this reaction allows a facile preparation of flavones, although the behavior of the substrate and product molecules in the network structure of the resin is not clear at present.

Experimental

All melting points were uncorrected. ^{1}H NMR spectra were obtained with a Hitachi R-22 (90 MHz) spectrometer by using tetramethylsilane as an internal standard. Physical data of isolated flavones agreed with those of independently synthesized authentic samples, which have already been reported.[6]

Materials. Solvents were of commercially available grade and were purified by ordinary procedures before use. Amberlyst 15 (Rohm and Haas Co., Ltd., U. S. A.) was employed without any treatment. Diketones were prepared according to known procedures,[5] and were identified on the basis of values in literatures[7] except for the following derivatives.

1-(2-Hydroxyphenyl)-3-(3-methoxyphenyl)-1,3-propanedione (1d): Mp 85.0—86.0 °C; ^{1}H NMR (CCl_4) δ=3.82 (3H, s, 3-OCH_3), 6.76 (2H, s, -CH_2-), 6.79—7.72 (8H, m, Aromatic), and 11.77 (1H, s, 2-OH). Found: C, 71.05; H, 5.10%. Calcd for $C_{16}H_{14}O_4$: C, 71.10; H, 5.22%.

1-(2-Hydroxy-4-methoxyphenyl)-3-(3-methoxyphenyl)-1,3-propanedione (1e): Mp 102.0—103.0 °C; ^{1}H NMR (CCl_4) δ=3.78 (3H, s, 4-OCH_3), 3.80 (3H, s, 3-OCH_3), 6.56 (2H, s, -CH_2-), 6.27—7.59 (7H, m, Aromatic), and 12.22 (1H, s, 2-OH). Found: C, 67.95; H, 5.30%. Calcd for $C_{17}H_{16}O_5$: C, 67.99; H, 5.37%.

1-(2-Hydroxyphenyl)-3-(3-bromophenyl)-1,3-propanedione (1g): Mp 115.0—116.0 °C; ^{1}H NMR (CCl_4) δ=6.71 (2H, s, -CH_2-), 6.81—8.00 (8H, m, Aromatic), and 11.71 (1H, s, 2-OH). Found: C, 56.48; H, 3.50; Br, 25.01%. Calcd for $C_{15}H_{11}O_3Br$: C, 56.45; H, 3.47; Br, 25.04%.

1-(2-Hydroxy-5-methylphenyl)-3-phenyl-1,3-propanedione (1h): Mp 88.0—91.0 °C; ^{1}H NMR ($CDCl_3$) δ=2.32 (3H, s, 5-CH_3), 6.79 (2H, s, -CH_2-), 6.83—7.98 (8H, m, Aromatic), and 11.86 (1H, s, 2-OH). Found: C, 75.54, H, 5.61%. Calcd for $C_{16}H_{14}O_3$: C, 75.58; H, 5.55%.

1-(2-Hydroxy-4-methylphenyl)-3-phenyl-1,3-propandione (1i): Mp 83.0—84.5 °C; ^{1}H NMR (CCl_4) δ=2.30 (3H, s, 4-CH_3), 6.68 (2H, s, -CH_2-), 6.51—7.89 (8H, m, Aromatic), and 11.82 (1H, s, 2-OH). Found: C, 75.60; H, 5.50%. Calcd for $C_{16}H_{14}O_3$: C, 75.58; H, 5.55%.

General Procedure. In a 50 ml conical flask equipped with a reflux condenser, a mixture of diketone (3.0 g, 12.5 mmol) and resin (3.0 g, 15.0 meq) was placed. Then isopropyl alcohol (30 ml) was added and the flask was heated on a hot plate for several hours under reflux with magnetic stirring. During the reaction, trace amounts of the reaction solution were withdrawn at hourly intervals with a glass capillary and subjected to TLC analyses. When the reaction was taken as finished, the flask was cooled to room temperature and had 20 ml chloroform added. Then the resin was filtered off and washed with a small amount of chloroform. The solvent of filtrate was removed by using an evaporator and the residue was dried overnight in a desicator under reduced pressure. Then the pure product was obtained by recrystallization from hexane or ligroine and benzene.

^{1}H and ^{19}F NMR Spectra of Some Fluorocyclobutane Derivatives

Kensuke TAKAHASHI,* Hiroshi KIMOTO,† and Hiroshige MURAMATSU†
Department of Applied Chemistry, Nagoya Institute of Technology, Gokiso-cho, Showa-ku, Nagoya 466
†Government Industrial Research Institute, Nagoya, Hiratemachi, Kita-ku, Nagoya 462
(Received October 2, 1986)

Synopsis. ^{1}H and ^{19}F NMR spectra were observed at 60.00 and 56.46 MHz, respectively, for ten 1,1,2,2-tetrahalo-1,2,2a,7a-tetrahydro-7*H*-cyclobut[*a*]inden-7-ones. NMR parameters, thus obtained, are discussed in connection with molecular structures and properties. The structures were partly confirmed by NOE measurements. The signs of all coupling constants observed for six compounds were determined by a selective decoupling technique (except for one with a small magnitude). A deshielding effect of the carbonyl group to a particular ^{19}F atom has also been obtained; it is useful for a structural determination.

Although many fluorocyclobutanes have been synthesized by the thermal cycloaddition of fluoroolefines, only a few NMR spectral parameters of cyclobutanes have been reported.[1] Recently, we obtained several title compounds by the photocycloaddition of indene to chlorofluoroethylenes as a part of studies on the syntheses of fluorine-containing fused polycyclic compounds.[2] During these studies, ^{1}H and ^{19}F NMR spectral data were found to be potentially useful in determining the structures of the compounds. Therefore, we wish to report on some NMR data in this article in order to contribute to the structural determination of similar compounds. This article makes clear that the configuration between fluorine and proton can be ascertained by NOE measurements. The signs of several fluorine-proton and fluorine-fluorine coupling constants were also determined relative to the vicinal proton-proton coupling constants.

Experimental

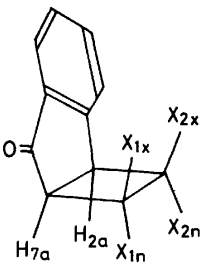
All ^{1}H and ^{19}F NMR spectra were recorded on a Hitachi R-20B spectrometer at a probe temperature (31.5 °C). ^{19}F and ^{1}H selective decoupling and tickling experiments were performed with the aid of a R-201SD decoupler, a R-209PA power amplifier, and a MG-514C synthesizer(Anritsu Electric Co., Ltd).

Chemical shifts were measured at 60 and 56.46 MHz for ^{1}H and ^{19}F nuclei, respectively; accuracies were within 0.2 Hz for ^{1}H and 0.4 Hz for ^{19}F measurements. All iterative calculations of the spectral analyses were carried out with a Hitachi-8450 computer system using a modification of LAOCN3 program.[3]

Samples of the title cyclobutane derivatives were synthesized from chlorofluoroethylenes and indene and the preparative methods were published.[2] The samples were dissolved in CCl_4 or $CDCl_3$ with small amounts of TMS and C_6F_6 served as internal references for ^{1}H and ^{19}F spectra, respectively. All sample solutions were degassed by the freeze-pump-thaw technique and sealed in 5-mm NMR sample tubes under vacuum.

Results and Discussion

The compounds studied are shown in Table 1;



X= F or Cl

Scheme 1.

Table 1. ^{1}H and ^{19}F Chemical Shifts of Fluorocyclobutanes in Carbon Tetrachloride

Compound No.	Conc. wt%	Chemical Shift/ppm

a) Uncertain because **5** could not be isolated. b) The sample contains **8** in the amount of 40%. c) In $CDCl_3$ solution.

Scheme 1 shows the numberings of positions (x=exo and n=endo). The NMR spectral parameters obtained from iterative refinements are shown in Tables 1 and 2. The parameters for compound **5** could not be obtained since the sample was impure.

^{1}H and ^{19}F Chemical Shifts. As shown in Table 1, the ^{1}H chemical shifts fall in a narrow range. The H_{2a} chemical shifts are always larger than those of H_{7a}. ^{19}F chemical shifts show a range of variations. The ranges of the chemical shifts for H_{2a}, H_{7a}, F_{1x}, F_{1n}, F_{2x}, and F_{2n} are about 0.18, 0.28, 16.95, 23.1, 17.9, and 9.9 ppm, respectively. The range is larger for H_{7a} than for H_{2a}; among fluorine nuclei, the F_{1n} shows the largest variation and the F_{2n} shows the smallest. The introduction of a chlorine atom instead of a fluorine atom caused a shielding effect for the fluorine chemical shift. This tendency is contrary to the strong inductive effect of fluorine, and is interpreted by the magnetic anisotropy effect of the chlorine atom.

When a carbonyl group was introduced to the 7-position of a precursor hydrocarbon, a large effect was observed on the ^{19}F chemical shifts of F_{1x}. The effect on the chemical shift of F_{1x} amounts to about 10 ppm while that of F_{1n} is smaller than 2.5 ppm in magnitude. This deshielding of F_{1x} is ascribed to a magnetic anisotropy effect of the 7-positioned carbonyl group; it seems to be useful for assigning of the F_{1x} signal. The observed chemical-shift displacements of F_{1x} and F_{1n} are given in Table 3. The values for F_{1x} are about 9.5 ppm. However, those for the F_{1n} are separated into two groups: one group falls at about 0.5 ppm and the other is at about −2.5 ppm. Compounds **2** and **6**, which belong to the latter group, have a trans-dichloro configuration. These chlorine atoms seem to contribute to the displacement.

Spin-Spin Coupling Constants. The coupling constants obtained from the spectral analyses of the compounds studied (except for **5** and **10**) are given in Table 2. Among the values, the relative signs of the coupling constants were determined by using selective decoupling and tickling techniques (except for the values for **8** and **9**). Typical decoupled spectra of **1** are given in Fig. 1 as examples. The upfield doublet of H_{2a} was decoupled when the upfield doublet of F_{1x} was irradiated as shown in Fig. 1C. The result shows that the $^3J_{2a7a}$ and the $^3J_{7a1x}$ of **1** have the same sign. The sign of $^4J_{2a1x}$ of **7** could not be determined because of its small magnitude. From the values given in Table 2, the signs of $^2J_{FF}$, $^3J_{HF}$, and $^4J_{HF}$ are positive, while those of $^3J_{FF}$ are negative. The values of fluorine-proton and fluorine-fluorine coupling constants vary largely in magnitude, while the vicinal proton coupling constants are almost constant. Therefore, care should be taken for the use of the coupling constants in order to determine the structures of the samples. For example, $^3J_{2a2x}$ of **4** and **6** and the $^3J_{2a2n}$ of **7** and **9** vary largely in magnitude.

NOE Enhancement. NOE observations can give valuable informations for structural determination.[4] The results of the present investigation are shown in Table 4. The signals of the H_{7a} of **2** and **6** increase in intensity by about 15% when the F_{1n} resonance is irradiated; for H_{2a}, irradiation of the F_{2n} resonance is effective. The results are consistent both with the structures determined from other chemical and physical properties and with the relative positions of the atoms shown in Scheme 1.

(Received December 8, 1986)

Synopsis. The crystal structure of trichloroacetamide has been determined by the single crystal X-ray diffraction method. Intermolecular contacts have been found to be responsible for the inequivalent reorientations of the CCl_3 groups of two crystallographically-independent molecules in the crystal.

It is well-known that CCl_3 groups in organic compounds undergo reorientations around the C_3 axis in crystalline state.[1] For several trichloromethyl derivatives, the magnitudes of the potential barrier height hindering the reorientation (V_0) have been determined by means of pulsed ^{35}Cl NQR method.[2-6] Chlorine NQR studies on trichloroacetamide (TCAA) indicated that the asymmetric unit of the crystal contains two independent CCl_3 groups with relatively different V_0 values (20.1 and 46.8 kJ mol^{-1}).[6,7] The origin of this difference has been unknown. Besides, our preliminary thermal analysis by a differential scanning calorimeter (DSC) showed that TCAA has a peculiar phase transition. Because of these reasons we decided to carry out the crystal structure analysis of TCAA.

Experimental

Recrystallizations of commercial trichloroacetamide (Nakarai Chemicals, LTD.) from diethyl ether gave colorless plate crystals (mp 415 K by DSC). A crystal with approximate dimensions of 0.5×0.4×0.3 mm^3 was used for the X-ray measurements. The unit cell parameters and intensities were measured on a Rigaku AFC-5 automatic four circle diffractometer with graphite-monochromatized Mo-K_α radiation. 1562 reflections within the range $2\theta<55°$ were collected by the ω-2θ scan technique. The ω scan width, scan rate and back ground counting time at both ends of a scan were $\omega=(1.4+0.35\tan\theta)°$, 8° min^{-1}, and 5.0 s, respectively. Lorentz and polarizetion corrections were made. Independent 1340 reflections with $|F_o|>3\sigma(F_o)$ were used in structure analysis. The structure was solved by the direct method (MULTAN 78)[8] and refined by the block-diagonal least-squares method (HBLS-V) with anisotropic temperature factors.[9] The function minimized was $\Sigma w(|F_o|-|F_c|)^2$. All the hydrogen atoms were found in the difference Fourier map and included in the refinement with isotropic temperature factors. The final R value was 0.058 (R_w=0.068). The weighting scheme adopted at the final stage was w=1.0 for $|F_o|\leq10.0$ and $w=[1.0+0.096(|F_o|-10.0)]^{-1}$ for $|F_o|>10.0$. Atomic scattering factors were taken from International Tables for X-Ray Crystallography.[10] The computations were carried out on an ACOS-1000 computer at Kobe University. Final atomic parameters are listed in Table 1.[11]

Crystal data: $C_2H_2Cl_3NO$, M=162.4, monoclinic, $P2_1$, a=10.415(2), b=5.785(1), c=10.182(2) Å, β=107.61° (2), Z=4, D_c=1.845 Mg m^{-3}, D_m=1.82 Mg^{-3}, μ=1.5 mm^{-1}, F(000)=320.

Results and Discussion

In accordance with the prediction of the NQR work,[7] the asymmetric unit of the crystal of TCAA contains two independent molecules (designated as Molecule A and B) shown in Fig. 1 (ORTEP-drawings).[12] The bond lengths, bond angles, and dihedral angles are listed in Table 2. The values of bond lengths and angles are comparable with those found in several amides.[13-17]

An ORTEP drawing of the crystal structure is shown in Fig. 2. A pair of N-H···O hydrogen bonds of lengths 2.982 and 3.019 Å couples Molecule A and B to form a dimer. Interestingly, the two molecules are related by a local two-fold axis. Each molecule of a dimer is also connected by other kinds of hydrogen bonds of lengths 2.915 and 2.957 Å to its nearest neighbors in the c direction. This results in a two-dimensional system of hydrogen bonds similar to those found in tetradecanamide and decanamide.[16,17]

The gross feature of the solid is determined by van der Waals contacts of chlorine atoms in CCl_3 groups on both sides of the layer.

The crystal and molecular structures of TCAA suggest that the observed difference in V_0 is attributable to intermolecular contacts between CCl_3 groups and their neighboring atoms. Then, by rotating the group around its C_3 axis, we calculated the atom-atom potential energy (U) as a function of rotation angle (ϕ) on the basis of the following function[18]

$$U = \Sigma\varepsilon_i(2.90\times 10^5 \exp(-12.50/P_i) - 2.25P_i^6)$$

where P_i stands for the sum of van der Waals radii (Σr_i^*) divided by the distance (r_i) between interacting centers. The values of van der Waals radii and ε_i were taken from Ref. 19.

The results of the calculations shown in Fig. 3 indicate that the intermolecular Cl···Cl interactions dominate to determine the magnitude of the potential, and that the value of $V_0=U_{max}-U_{min}$ of Molecule A is considerably larger than that of Molecule B. These findings are consistent with the result of the NQR study. However, for both Molecule A and B, the calculated V_0 values are twice as high as the observed ones. Unfortunately, the discussion on the magnitude of V_0 will be artificial, because it depends strongly on the choice of van der Waals radius of chlorine atom.

As seen in Table 1, the magnitudes of the tem-

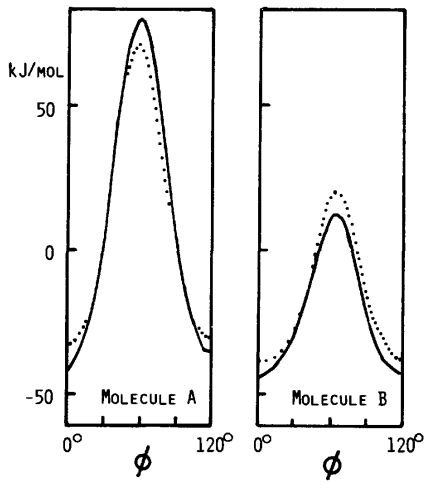

Fig. 3. Calculated atom-atom potential curves of CCl_3 groups in trichloroacetamide crystal as a function of rotation angle (ϕ), where the orientation with ϕ=0 corresponds to the structure determined by the present X-ray work. ——: Including interactions with all atoms within 4.1 Å (twice of the van der Waals radius of chlorine atom); ·····: including interactions only with chlorine atoms within 4.1 Å.

perature factor (B_{eq}) for Cl atoms in Molecule B are considerably larger than those in Molecule A. Moreover, the thermal ellipsoids of Cl atoms of Molecule B indicate the ease of the reorientation of the CCl_3 group around the C_3 axis (see Fig. 2). Thus, the CCl_3 group with the higher V_0 value may be assigned to Molecule A, although a complete assignment should be done by the Zeeman NQR study on a single crystal.

(Received May 20, 1986)

Synopsis. The crystal structure of the title complex was determined by X-ray diffraction: Orthorhombic, space group $C222_1$, a=20.553(2) Å, b=11.210(1) Å, c=8.980(2) Å, and Z=4. The structure was solved by the direct method and was refined anisotropically by the full-matrix least-squares method: R was 0.062 for 1206 observed reflections. The $[Cu(bpy)_2]^+$ cation has a pseudo-tetrahedral arrangement (average Cu–N=2.021 Å). The interligand dihedral angle in $[Cu(bpy)_2]^+$, 75.2°, differs significantly from that previously reported $[Cu(1,10\text{-phenanthroline})_2]ClO_4$ (49.9°).

2,2′-Bipyridine(bpy) and 1,10-phenanthroline (phen) are bidentate ligands, whose π acceptor capability significantly contributes to the stabilization of their low valent metal complexes.[1,2] Regarding their complexation, it is interesting to compare these ligands with 2,9-dimethyl-1,10-phenanthroline (dmp) and 6,6′-dimethyl-2,2′-bipyridine (dmbp). Four-coordinate copper(I) cations tend to favor a regular tetrahedral arrangement[3] due to its d^{10} configuration. The interligand dihedral angles, between the mean planes defined by the metal ion and each set of bidentate nitrogen atoms, were 80.2° and 85.7° for $[Cu(dmp)_2]^+$,[4,5] and 80.7° for $[Cu(dmbp)_2]^+$,[6] indicating a pseudo-tetrahedral geometry. Recently, two interesting structures, $[Cu(phen)_2]ClO_4$ and $[Cu(phen)_2][CuBr_2]$, have been reported,[7] whose interligand dihedral angles were 49.9° and 76.8°, respectively. Although both structures have the same $[Cu(phen)_2]^+$ unit, these two angles are quite different. In the case of the $[Cu(bpy)_2]^+$ cation, the question arose as to how large is the interligand dihedral angle. In order to answer this question, an X-ray structural determination of $[Cu(bpy)_2]ClO_4$ was carried out.

Experimental

Preparations. $[Cu(bpy)_2]ClO_4$ was synthesized in the following way.[8] Under a nitrogen atmosphere, an 8-ml methanol solution of bpy(80 mM) (1 M=1 mol dm^{-3}) was added to tetrakis(acetonitrile)copper(I) perchlorate (40 mM) and stirred at 298 K. Brown prism-like crystals suitable for diffraction studies were grown from this solution in a sealed tube at 273 K.

Crystal Data. $C_{20}N_4H_{16}Cu$, ClO_4, $F.W.$ 475.35, orthorhombic, space group $C222_1$ (No. 20, systematic absences, hkl: $h+k=2n+1$ and $00l$: $l=2n+1$), a=20.553(2), b=11.210 (1), c=8.980(2) Å, D_c=1.526 g cm^{-3} for Z=4.

A crystal with approximate dimensions of 0.15×0.15×0.20 mm^3 was mounted on a Rigaku AFC-6B four-circle diffractometer with graphite-monochromatized Cu $K\alpha$ radiation ($\bar{\lambda}$=1.54178 Å). The intensity data were collected at 296 K in the θ–2θ scan mode with a 1.2° scan width, $2\theta_{max}$ of 120° ($-22\leq h\leq 22$, $0\leq k\leq 12$, $0\leq l\leq 10$), and scan rate of 4° min^{-1}. They were converted to $|F_o|$ data in the usual manner. An absorption correction was not applied (μ=2.98 mm^{-1}). Of the 1834 measured reflections, 1206 were observed ($|F_o|>3\sigma(F_o)$), where $\sigma(F_o)$ is the standard deviation estimated by countig statistics.

Structure Solution and Refinement. The structure was solved by a direct method (*MULTAN* 78),[9] and refined by full-matrix least-squares calculations with anisotropic thermal parameters, including isotropic H atoms located on a difference Fourier synthesis. The final R and R_w values were 0.062 and 0.060, respectively. The atomic parameters of non-hydrogen atoms are given in Table 1.#

The atomic scattering factors[10] and anomalous dispersion[11] terms for all atoms were obtained from International Tables for X-Ray Crystallography, Vol. IV. All computation were performed on a FACOM M-382 computer at the Data Processing Center, Kyoto University using the program system KPPXRAY.[12]

Results and Discussion

The view of the cation in Fig. 1 shows that the central copper atom, with a pseudo-tetrahedral geometry, is coordinated to two bpy molecules via the pyridine nitrogens. Selected bond lengths and angles are also given in Fig. 1. A perchlorate anion does not coordi-

a) Equivalent isotropic temperature factor defined by Hamilton.[20]

Tables of thermal parameters of non-hydrogen atoms, fractional coordinates of hydrogen atoms, and the observed and calculated structure factors are being kept at the Chemical Society of Japan, Document No. 8734.

nate to the copper because the closest Cu···O contact is 5.26 Å. The bpy ligand is planar within 0.04 Å, with the twisting about the Cl-C6 bond (dihedral angle is 2.2°). The Cu-N lengths are slightly shorter than that of $[Cu(dmbp)_2]BF_4$,[6] indicating that the steric interaction between copper atom and methyl group is unexpectedly little. On the other hand, a steric effect of the methyl group has been found in $[Cu(phen)_2]^+$ and $[Cu(dmp)_2]^+$, and the Cu-N length for the former is clearly shorter than that for the latter (Table 2). The interligand dihedral angle, α, of the present complex is of particular interest. The angle 75.2° is slightly smaller (by 5.7°) than that in $[Cu(dmbp)_2]^+$, and an apparent difference between two complexes is not appreciated; this indicates that there are no marked substituent effects. Table 2 shows that α of $[Cu(phen)_2]NO_3$ differs by 27° from that of $[Cu(phen)_2][CuBr_2]$.

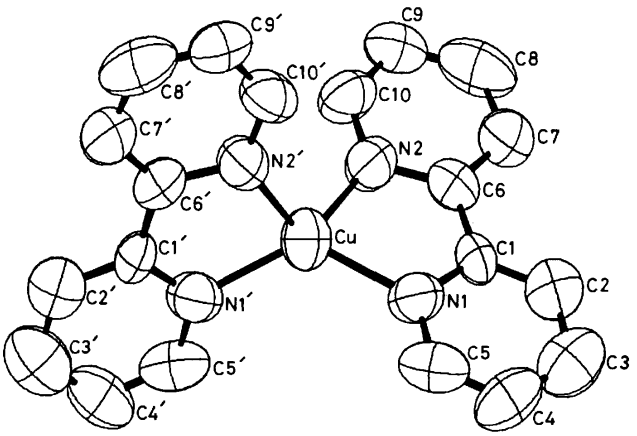

Fig. 1. View of the $[Cu(bpy)_2]^+$ cation. Thermal ellipsoids are drawn at 50% probability level: Hydrogen atoms are omitted. The labeling scheme used for the atom in the molecule is also shown. The primed atom notes the atom translated by two-fold axis. Selected bond lengths (Å) and angles (deg.) are as follows: Cu-N1=2.020(9); Cu-N2=2.021 (11); Cl-C6=1.440(15); Cl-N1=1.325(14); C6-N2= 1.385(15); N1-Cu-N1′=127.1(4); N1-Cu-N2′=131.3 (4); N1-Cu-N2=81.5(4); N2-Cu-N2′=109.7(4); C6-Cl-N1=115.9(9); Cl-C6-N2=116.5(9); Cu-N1-Cl= 114.2(8); Cu-N1-C5=127.3(8); Cu-N2-C6=111.4(8); Cu-N2-C10=130.3(9).

The small angle for the former is not necessarily due to a counter anion because of no coordination of the anion; the angle is associated with the intermolecular interaction from a crystal packing, rather than the intramolecular interaction inherent in copper(I). The α of 49.9° is close to that of a copper(II) complex, $[Cu(bpy)_2]^{2+}$.[14] In the copper(II) complex, the small angle α is reasonable since the copper(II) cation prefers a near square-planar structure to a tetrahedral one.[15] According to Table 2, α for the methyl complex, $[Cu(dmbp)_2]^+$, is about 81°, larger by ca. 6° than that for methyl group-free complexes. On the other hand, it is surprising to find that α for $[Cu(tmbp)_2]^+$ is smaller than that for the present complex in spite of the dmbp analog.[16] These facts suggest that α for tetrahedral copper(I) complexes with the bidentate ligand *in the solid state* depends on the crystal packing dominating over the steric effect of methyl groups. The effect of the methyl group should be considered, especially in the case of a square-planar arrangement, rather than a tetrahedral arrangement. The near neighboring methyl groups probably play an important role in inhibiting the deformation toward a square-planar geometry. This role is advantageous for copper(I) complexes. In fact, dmp favors a copper(I) ion rather than a copper(II) ion: the stability con-

stant $10^{19.1}$ of $[Cu(dmp)_2]^+$ is very much larger than that, $10^{11.7}$, of $[Cu(dmp)_2]^{2+}$.[17] This is also well-illustrated in terms of the redox properties of the copper complexes of dmp and dmbp since both $[Cu(dmp)_2]^+$ and $[Cu(dmbp)_2]^+$ have higher redox potentials of copper than the corresponding complexes without methyl substituents (Table 2).[1,18,19] These facts indicate that the steric interaction of the methyl groups in the 2 and 9 positions of phen and in the 6 and 6′ positions of bpy favor the tetrahedral geometry of the copper(I) complex *in solution* since there is no effect owing to closed packing, forcing the copper(II) complex to avoid a square planar geometry.

13) The electron-density distribution of the oxygen atoms of the ClO_4^- ion was much diffuse with the shortening of the Cl–O bond lengths (1.30—1.36 Å), but the configuration of the ClO_4^- ion was evidently indicative of tetrahedral type. The large distribution will be interpreted as static disorder rather than thermal motion. This indicates rather weak interaction between $[Cu(bpy)]_2^+$ cation and ClO_4^- anion.

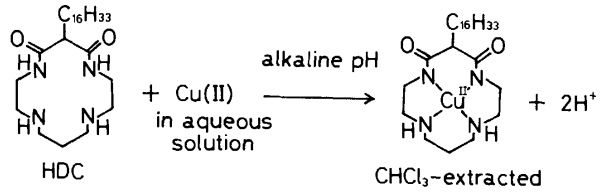
(Received December 8, 1986)

Synopsis. The flow manifold described permits suction-flow liquid-liquid extraction of copper(II) in a discrete aqueous sample as its macrocyclic dioxotetramine (6-hexadecyl-1,4,8,11-tetraazacyclotetradecane-5,7-dione, HDC) chelate into chloroform. The organic extract is successively fed into the inductively coupled plasma by a peristaltic pump. The detection limit is 1.5 ng cm^{-3} copper(II) and the relative standard deviation is 2.2% (n=10) for 100 ng cm^{-3} copper(II).

The chemical properties of macrocyclic polyamines have received much attention in recent years.[1] However their applications to chemical analysis have been limited.[2] Kimura et al.[3] recently synthesized HDC and found that it selectively encloses copper(II) with simultaneous deprotonation of two amides as a neutral 1 : 1 complex in alkaline pH and is potentially useful for the separation of copper(II) by solvent extraction.



This paper demonstrates an analytical application of HDC as a chelating agent for copper(II) to an on-line liquid-liquid extraction for the inductively coupled plasma atomic emission spectrometry (ICPAES) of copper. The limiting factors for the extraction and the ICPAES were investigated to obtain the maximum sensitivity of copper, and the technique was applied to the analysis of some biological samples.

Experimental

Apparatus and Reagents. A Kyoto Koken Model UOP-1S ICP atomic emission spectrometer was used. The flow system comprised a Teflon suction cup,[4] a 6-channel variable-speed peristaltic pump (Tokyo Rikakikai Model MP-3), T-joints, a segmentor, a Teflon extraction coil (1 mm i.d., 2 m long) and a phase separator (4 mm i.d., 40 mm horizontal long, 60 mm vertical long). The phase separator was made up of a T-piece glass fitting into which a Teflon fiber string was inserted at one of the bends.[5] As for the pump tubing, Acidflex (Technicon Corp.) for chloroform and Tygon (Norton Co.) for aqueous solutions were used. The inner diameters of the tubing for sample, HDC, buffer, and chloroform were 2.4, 1.6, 1.6, and 1.6 mm, respectively. The other parts of the flow system were made of 1-mm i.d. Teflon tubing. The assembly is shown in Fig. 1.

HDC was prepared by refluxing dimethyl hexadecylmalonate and 3,7-diazanonane-1,9-diamine in methanol (25% yield, mp 113°C from methanol-benzene).[3] A solution of the chelating agent [5.0×10^{-4} M (1 M=1 mol dm^{-3})] was prepared by dissolving HDC in dilute hydrochloric acid and diluting with water. A 1000 μg cm^{-3} copper(II) standard stock solution was prepared by dissolving 0.500 g of copper metal (99.999%) in dilute hydrochloric acid diluting to 500 cm^3 with water. Solutions of suitable concentrations were prepared by dilution. A 1000 μg cm^{-3} nickel(II) solution was prepared by dissolving 0.500 g of nickel metal

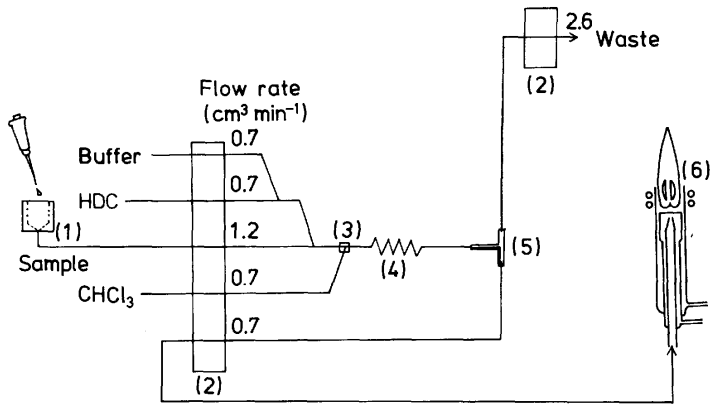


Fig. 1. Flow diagram for extraction of copper(II) with HDC into chloroform.

(99.999%) in dilute hydrochloric acid and diluting to 500 cm^3 with water. A borate buffer solution (1 M, pH 9) was prepared by mixing boric acid and sodium hydroxide. Chloroform was used without further purification.

Recommended Procedure for Copper Determination. A sample solution ([Cu(II)]$\lesssim$500 ng cm^{-3}) in which nickel(II) had been added in the concentration of 30 μg cm^{-3}, usually 2 cm^3, was added to the suction cup from a Pipetman P-5000 (Gilson International). As shown in Fig. 1, the sample was sucked into the mixture of the HDC and the buffer solutions, and with chloroform in the segmentor. The segmented solution was carried into the extraction coil and the phase separator. The organic extract was introduced by the peristaltic pump into the nebulizer of the ICP spectrometer. The transient Cu I 324.754-nm emission signal at an observation height of 13 mm above load coil was recorded on a strip-chart recorder, and the peak height was measured. The optimum argon gas flow rates for the ICP were 12 dm^3 min^{-1} of plasma gas, 1.0 dm^3 min^{-1} of auxiliary gas and 0.325 dm^3 min^{-1} of nebulizer gas.

Results and Discussion

The effect of pH on the extraction was investigated, keeping the other variables in the recommended procedure constant. The HDC-copper(II) complex was confirmed to be quantitatively extracted into chloroform in the pH 8—14; a pH 9 borate buffer solution (1 M) was used throughout. Under the conditions, the pH of the sample solution had to be above ca. 0.8 to obtain a maximum and constant intensity.

It is interesting to note that the extraction rate of copper(II) was much accelerated by addition of nickel(II). When a 1-mm i.d. and 2-m long Teflon extraction coil was used and nickel(II) was absent in the aqueous phase, the recovery of copper(II) was no more than about 50%. However, in the presence of nickel(II) of more than 60-fold amounts of copper(II), the extraction of copper(II) was confirmed to be complete even with the same length of the extraction coil. The behavior of nickel(II) is not understood as yet and awaits further investigation.

The volume of sample taken in the suction cup was varied by using the volume-adjustable pipet. Figure 2 shows some typical signals obtained with different volumes of a 100 ng cm^{-3} copper(II) solution at a time constant for the electronic circuit of 10 s. Variation of the time constant had no appreciable effect on the sensitivity provided that it was in the range 3—10 s. However, the signal became noisy at the smaller time constant. The best reproducibility was obtained at 10 s. The peak height was proportional to the volume added up to about 3 cm^3 and thereafter was constant. A 2-cm^3 sample plug showed ca. 80% of the plateau intensity. This volume seems to be a good compromise between high sensitivity and the practical requirements of high sampling rate and low reagent consumption.

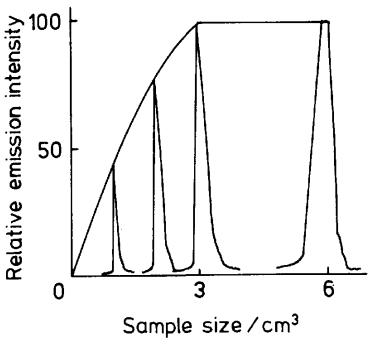

Fig. 2. Recorder tracings obtained with various sample volumes. Copper(II): 100 ng cm^{-3}.

Table 1. Determination of Copper in Human Organs[a)]

Sample	Copper found/μg g^{-1}	
	Present method	GF-AAS[b)]
Liver 3374	9.3±0.2	9.7±0.2
Liver 3355	4.8±0.1	4.7±0.1
Liver 3308	4.2±0.2	4.5±0.2

Kidney 3354	4.0±0.1	3.8±0.3

a) Wet base. b) Mean±av. dev., 2 results.

Under the recommended procedure, a linear calibration graph was obtained for up to 500 ng cm^{-3} copper(II). The detection limit (S/N=3) was 1.5 ng cm^{-3} copper. The detection limit is about 11-fold better than that obtained by direct aspiration of the aqueous solution. The improvement is attributed not only to the preconcentration of copper by extraction, but also to the enhancement effect of chloroform.[6] The relative standard deviation for 10 replicate measurements was 2.2% for 100 ng cm^{-3} copper(II) and the sample throughput was 25 h^{-1}.

The interferences of large amounts of alkali and alkaline earth metal salts could be avoided by the extraction. Most other metal ions such as cobalt(II), nickel(II), zinc(II), cadmium(II), tin(II), antimony(III), mercury(II), lead(II), and bismuth(III) did not interfere with the determination of copper when present in 200-fold amounts of 100 ng cm^{-3} copper(II). Interferences were encountered only with aluminum(III), chromium(III), and ion(III); the maximum permissible amounts within 10% error of these species were 91-, 45-, and 32-fold, respectively. The interferences may arise from metal hydrolysis during the extraction process of copper(II) under the alkaline condition.

The reliability of the present method was examined by comparing the analytical results of some human organ samples with those obtained by the graphite-furnace atomic absorption spectrometry (GF-AAS) combined with dithizone-carbon tetrachloride batch-extraction.[7] The samples were prepared by digesting in Teflon beakers with nitric acid and perchloric acid on a hot plate. As Table 1 shows, the data are in good agreement with each other.

The authors wish to express their thanks to Professor Mitsuo Kiboku of Kinki University and Dr. Koji Kirimoto of Kure National Hospital for providing the human organ samples.

Synthesis, Properties, and Crystal and Molecular Structure of Diaquatetrakis(thiocyanato)cobalt(II)mercury(II)-2-pyrrolidone (1/2), $[CoHg(SCN)_4(H_2O)_2]\cdot 2C_4H_7NO$

Synopsis. The title inclusion compound, which has a new-type "double decker" host skeleton, has been obtained, and its crystal and molecular structure has been determined by the X-ray diffraction technique using its single crystal. 2-Pyrrolidone molecules are not directly coordinated to any metal atoms, but are hydrogen-bonded with coordinated water-oxygen atoms in the two-dimensional polymer planes of $[CoHg(SCN)_4(H_2O)_2]_n$. In the complex polymer, each pair of adjacent Hg(4S(SCN) four-coordinated in a tetrahedral geometry) and Co(4N(SCN), 2O(water, trans) six-coordinated in an octahedral geometry) atoms are bridged with a thiocyanate (SCN) ion. Such two types of networks are spread approximately parallel to the (010) plane at 1/4 and 3/4 heights, and the included Lewis base molecule layers are also doubled. Compared with the previously reported single-layer host skeleton of $[CoHg(SCN)_4(H_2O)_2]\cdot 2L$ (L=Lewis base), the present one is short in its inter-complex layer distance, in spite of the analogous size of the included molecule. The crystallographic data are: orthorhombic, space group $P2_1nb$, a=12.004(4), b=15.330(5), c=11.985(4) Å, and Z=4. The final R value was 0.054.

Previously, the present authors[1,2] have reported about the crystal structures of some adducts of tetrakis(thiocyanato) cobalt(II)mercury(II), $CoHg(SCN)_4$ (**1**), with the general formula of $CoHg(SCN)_4(H_2O)_2\cdot 2L$ (L=*N*,*N*-dimethylacetamide (dma), (**2**)[1] or *N*-methyl-2-pyrrolidone (mpd) (**3**).[2] These complexes were found to be a new type of inclusion compound in which the Lewis bases were not coordinated to any metal atoms directly, but were kept between the two-dimensional polymeric planar networks only by the hydrogen bondings. The cage structure of **2** and **3** are almost the same.

In this line of research, the title complex was obtained. From the preliminary test, its crystal system and the unit cell size were found to be different from those of **2** and **3**. Expecting to find a new type of structure of the inclusion compound, we have investigated the crystal and molecular structures of this complex by means of the X-ray diffraction method, using its single-crystal.

Experimental

Synthesis of Diaquatetrakis(thiocyanato)cobalt(II)mercury(II)-2-pyrrolidone(1/2), $CoHg(SCN)_4(H_2O)_2\cdot 2pd$ (4). The crystalline powder of **1** (1.0 g, 2.0 mmol) was dissolved into 2-pyrrolidone (pd) (10 cm³), and 20 cm³ of water was added to the solution. The mixture was left standing for several days; thereby the red-brown crystals of **4** were deposited. They were filtered off and dried over silica gel. Yield: 0.8 g, 57%. Anal. Found: Co, 8.22; C, 20.75; H, 2.76; N, 12.33%. Calcd for $CoHgC_{12}H_{18}N_6O_4S_4$: Co, 8.44; C, 20.65; H, 2.60; N, 12.04%.

X-Ray Structure Analysis. A crystal of **4** with the dimensions of 0.3×0.3×0.12 mm³ was used for the intensity measurement. Crystallographic data: $CoHgC_{12}H_{18}N_6O_4S_4$ $F.W.$=698.10, orthorhombic, with the space group of $P2_1nb$, a=12.004(4), b=15.330(5), c=11.985(4) Å, U=2205.5(11) Å³, Z=4, D_m=2.07(3) Mg m⁻³, D_x=2.07 Mg m⁻³, μ(Mo $K\alpha$)=8.28 mm⁻¹. Reflections within a range of $3°<2\theta<60°$ were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer, with graphite-monochromated Mo $K\alpha$ radiation, the ω-2θ scan technique was employed (scan speed, 4° min⁻¹ in θ; scan width, 1.12+0.5tanθ°). Of the 3564 independent reflections measured, 1841 $|F_o|>3\sigma(|F_o|)$ reflections were used for the structure determination. The intensities were corrected for the Lorentz and polarization factors as well as for the absorption. The last correction was made using a numerical Gaussian integration.[3] The structure was solved by the heavy atom method. The final R value obtained by applying the anisotropic temperature parameters was 0.054.[4] As the R value for the structure with an inversed chirality was 0.059, the value was not adopted.

All the calculations were carried out on a HITAC M-680H computer apparatus at the Computer Center of the University of Tokyo, using the local version of the UNICS program system.[5] The atomic scattering factors were taken from Ref. 6.

Other Measurements. The infrared absorption spectra were obtained by means of a Hitachi EPI-G3 grating infrared spectrophotometer using mineral oil and hexachloro-1,3-butadiene mull. The magnetic moment of the solid sample was measured at 20 °C using a Gouy balance.

Results and Discussion

The selected bond-lengths and bond angles, and also some interatomic distances, are shown in Table 1.[7] A perspective drawing of the complex around a cobalt atom, together with the hydrogen bondings between the neighboring cobalt atoms along the b-axis, is shown in Fig. 1. The projection of the structure along the b-axis is shown in Fig. 2.

Each mercury atom is coordinated tetrahedrally to four SCN sulfur atoms. The cobalt atom is six-coordinated and is in an octahedral geometry, where four SCN nitrogen atoms are ligated equatorially, and two water oxygen atoms, axially, approximately from the b-axis directions. The bond lengths of Hg–S, Co–O, and Co–N (on the average, 2.536, 2.089, and 2.12 Å respectively) are not much different from the respective sums of Shannon's ionic radii: Hg–S, 2.80; Co–O, 2.00; and Co–N, 2.11 Å.[8] Both of the bond angles, Co–N–C (169° on the average) and N–C–S (177° on the average) deviate a little from 180°.

As is shown in Fig. 1, both kinds of pd molecules

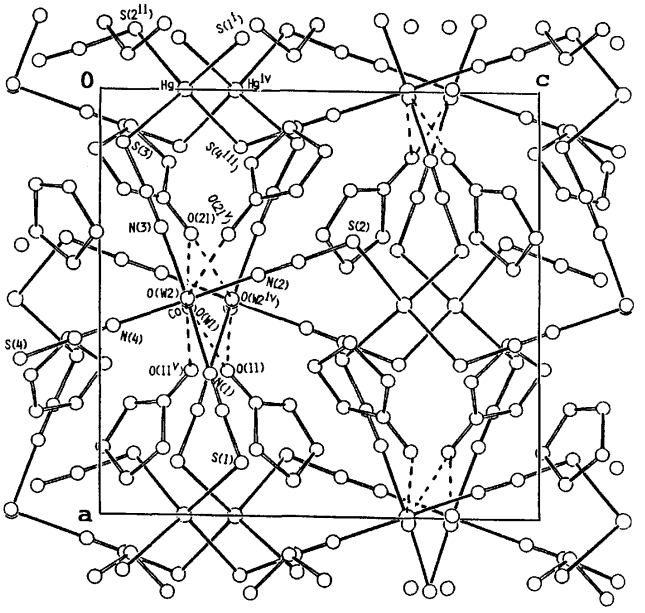

Fig. 2. The projection of the unit cell of the complex to the (010) plane.

are linked by hydrogen-bondings to the water oxygen atoms, which are ligated to the cobalt atoms. As is shown in Fig. 2, two mercury(II), two cobalt(II), and four SCN ions make a sixteen-membered ring which organizes the unit of the two-dimensional network of the polymeric complex and which is about the same as those of **2** and **3**.

The 1/4 of the ac face of the unit cell of **4** is 35.97 Å^2, while those of **2** and **3** (1/4 of the ab face) are 36.75 and 36.17 Å^2 respectively. Therefore, the areas of this sixteen-membered rings (exactly, the projections to the average plane) are approximately the same.

However, the crystal structures **2** or **3**, and **4** are very different with each other. In the cases of **2** and **3**, the network of the complex as well as the base molecule layer spread parallel to the ab-plane, and the separation of the plane corresponds with the c-axis length: 7.985 Å in **2** and 8.097 Å in **3** respectively. On the other hand, there are two such networks in the **4**

Table 2. Infrared Absorption Data of **1**, mpd, **3**, pd, and **4** (in σ/cm^{-1})

1[1]	mpd[9]	**3**	pd[9]	**4**	Tentative Assignment
		3360 (s)		3290 (s)	ν(O-H)
			3240 (w)	3400 (w)	ν(N-H)
	2895 (m)	2950 (m)	2940 (m)	2980 (m)	ν(C-H)
2150 (s)		2140 (s)		2140 (s)	ν(CN)
		1650 (m)		1655 (m)	δ(HOH)
	1682 (s)	1640 (s)	1687 (s)	1640 (s)	ν(CO)
720 (s)		730 (m)		720 (m)	ν(CS)
470 (s)		460 (s)		470 (m)	δ(SCN)
447 (s)		440 (s)		445 (m)	δ(SCN)

1, $CoHg(SCN)_4$; **3**, $CoHg(SCN)_4(H_2O)_2 \cdot 2mpd$; **4**, $CoHg(SCN)_4(H_2O)_2 \cdot 2pd$.

complex, approximately 1/4 and 3/4 in height respectively, parallel to the (0 1 0) plane. Therefore, the separation of the network plane is a half of the b-axis length, 7.665 Å, which is much shorter than those of **2** and **3**. On both network layers, the respective metal atomic positions deviated only a little, approximately in the c-axis direction, from each other. However, the positions of the pd molecules in the two intervals are very different. Each pd molecule exists in a interval space where the top and bottom walls are concave, while the space between the convexed walls is vacant. Thus, the filled and empty intervals are laid alternately, perpendicular to the plane. This is probably the main cause of the shorter inter-layer distance of this complex.

If we define the cage volumes of this type of inclusion compound by the unit-cell volume divided by the number of the included base molecule, they are 292 and 296 $Å^3$ in the cases of **2** and **3** respectively. On the other hand, the volume of the **4** complex is $2205.5/8=276$ $Å^3$, which is smaller than the former two, showing the more compact packing in this complex.

Some infrared spectral data are shown in Table 2. When the wavenumbers of the peaks of **4** are compared with those of the free-ligand molecules,[9] its ν(C=O) peak is found to be red-shifted by 40—50 cm^{-1}. Such a red shift has also been observed in the spectra of **3** as well as **2**,[1] and it is considered to be due to the strong hydrogen bonds between the Lewis-base molecule and the ligating water molecules. The hydrogen bondings are manifested by the ν(O-H) at high frequencies, too.[10] The ν(N-H) of **4** is shifted from 3240 (free pd) to 3400 cm^{-1} as a result of the release from mutual hydrogen bondings in the free ligand molecules.[11] The wavenumbers of the bands caused by the SCN ions of **1**, **2**,[1] **3**, and **4** are not very different from one another.

The magnetic moment of **4** is about 5.05 BM at 20 °C, about the same as that of **3**, 4.98 BM (1 BM=$9.274078(36)\times10^{-24}$ JT^{-1}). These are typical values for the cobalt(II) ion in the octahedral geometry.

The Relationships between the Formation Constants of 2,2′-Bipyridine Metal(II) Complexes and the Donor Numbers of Solvents

Yuriko Abe* and Goro Wada†
Graduate Division of Human Culture and Faculty of Science,† Nara Women's University, Nara 630
(Received September 29, 1986)

Synopsis. The complex formation constants of cobalt(II) or zinc(II) with 2,2′-bipyridine (bpy) were determined spectrophotometrically in various solvents. The values of $\log K_1$, $\log K_2$, and $\log K_3$ for the Co(II) complexes obtained were 4.06±0.06, 3.09±0.04, and 1.15±0.02 respectively in dimethyl sulfoxide, while those of $\log K_1$ for the Zn(II)–bpy complexes were 6.27±0.10, 4.14±0.01, 4.71±0.03, and 3.44±0.12 in trimethyl phosphate, *N,N*-dimethylformamide, *N,N*-dimethylacetamide, and dimethyl sulfoxide respectively. It was found that the linear relationships hold between logarithms of the formation constants of the bpy complexes and the donor numbers of the solvents when both the solvated metal ions and the bpy complexes are octahedral in the solvents.

In recent years, studies of the solvent effects on the chemical reactions have been extensively reported.[1-3] However, there are few quantitative equilibrium data to account for the solvent effects for the first transition metal complexes.[1,4,5]

In this study, we determined spectrophotometrically the complex formation constants of cobalt(II) or zinc(II) with 2,2′-bipyridine (bpy) in dimethyl sulfoxide (DMSO), trimethyl phosphate (TMP), *N,N*-dimethylformamide (DMF), and *N,N*-dimethylacetamide (DMA) for the purpose of clarifying the solvent effects on the chemical equilibria. The linear relationship between the logarithms of the complex formation constants and the donor numbers of the solvents will be discussed on the basis of the experimental data.

Experimental

Materials and Preparations. DMSO and DMF of a guaranteed reagent grade were purified as has been described elsewhere.[6,7] TMP and DMA were distilled under a reduced pressure of nitrogen, after having been dried with 5A molecular sieves. 2,2′-Bipyridine was recrystallized from a hexane solution. Solvated complexes of the metal ions $[M(s)_6](ClO_4)_2$ (M=Co(II) or Zn(II), and s=dmso, dmf, or dma) were synthesized by methods similar to those of $[M(hmpa)_4](ClO_4)_2$:[8] hydrated metal perchlorate was treated with a large excess of 2,2-dimethoxypropane for one hour with stirring. At the end of the dehydration period, a slight excess of the solvent was added. After several minutes, a large excess of anhydrous ether was added, and then the precipitate was filtered. They were dried in a vaccum desiccator. Solvated Zn(II) perchlorate in TMP was prepared as follows: hydrated Zn(II) perchlorate was dissolved in TMP, where 5A molecular sieves were present for the purpose of dehydration. After standing overnight, 5A molecular sieves were removed from the solution. Portions of stock solutions of these metal perchlorates were taken to analyze the metal ion concentrations by the spectrophotometric methods already reported.[9] The bpy complex solutions were prepared by mixing aliquots of the stock solutions of metal perchlorates with those of the bpy solution. The ionic strength was kept at I=0.06 M (mol dm^{-3}) with sodium perchlorate.

Apparatus. The absorptivities of complex solutions were measured by using a Shimadzu Spectrophotometer, Model UV-200S, with a thermostated cell compartment. The temperature was kept at 25±0.1 °C.

Results and Discussion

The value of the first formation constant, $K_1=[[M(bpy)]^{2+}]/[M^{2+}][bpy]$, for the Co(II)–bpy complex in DMSO, and those for the Zn(II)–bpy complexes in DMSO, DMF, DMA, and TMP were obtained by the use of Job's curves.[10,11] The value of the second formation constant, $K_2=[[M(bpy)_2]^{2+}]/[[M(bpy)]^{2+}][bpy]$, and that of the third formation constant, $K_3=[[M(bpy)_3]^{2+}]/[[M(bpy)_2]^{2+}][bpy]$, for the Co(II)–bpy complex in DMSO were obtained by the linear relationship method.[10,11] The results are summarized in Table 1, together with the results in hexamethylphosphoric triamide (HMPA) and those for the Mn(II)–bpy complex previously reported.[11-13] The $\log K$ values decrease roughly in accordance with the increase in the donor number (D) of the solvents, except for the K_1 and K_2 values for the Co(II)–bpy complexes and for the K_1 value for the Mn(II)–bpy complex in HMPA, as shown in Table 1.

It is accepted that, in solvents such as water, methanol, DMSO, and DMF, the solvated ions of first transition metals are mostly octahedral.[14-16] On the other hand, we have already reported that, in HMPA, they prefer the tetrahedral configurations to the octahedral ones since the HMPA molecule is very bulky as compared with the molecules of the other solvents.[9,11] Therefore in all the solvents used here other than in HMPA, $[M(s)_6]^{2+}$ (M(II)=Mn(II), Co(II), or Zn(II), s=solvent) is octahedral.[14-16] Their bpy complexes are probably be octahedral also, for the bpy ligand gives a stronger ligand field than the solvents. Nevertheless, $[Zn(hmpa)_6]^{2+}$, $[Zn(hmpa)_4(bpy)]^{2+}$, and $[Co(hmpa)_2(bpy)_2]^{2+}$ in HMPA are octahedral, in contrast with the tetrahedral configurations of $[M(hmpa)_4]^{2+}$ and $[M(hmpa)_2(bpy)]^{2+}$ (M(II)=Mn(II) or Co(II)).[9,11] Therefore, when the octahedral–octahedral equilibria are established in the solvents, the linear relationship can be said to hold roughly between $\log K$ vs. D as shown in Table 1. The deviation from the linearity in HMPA may be due to the establishment of a tetrahedral–tetrahedral or tetrahedral–octahedral equilibrium, in consequence of the steric hindrance caused by the bulkiness of the HMPA molecule in the coordination sphere.[11]

When bpy coordinates to a metal ion, the metal ion liberates two solvent molecules from the coordination sphere. Therefore, the true formation constant should

be $K_{x+1}[s]^2$ rather than $K_{x+1}=[[M(bpy)_{x+1}]^{2+}]/[[M(bpy)_x]^{2+}][bpy]$ (x=0, 1, or 2) in an octahedral-octahedral equilibrium, where [s] is the molar concentration of the solvent. Since the [s] values are not equal to each other for various solvents, the plots of log $K_{x+1}[s]^2$ *vs.* D are probably more reasonable than those of log K_{x+1}. Figure 1 shows the plots of log $K_{x+1}[s]^2$ *vs.* D. The linearity for the K_1 of the Zn(II)-bpy complex corresponding to the octahedral-octahedral equilibria in all solvents is improved from that in Table 1.

When octahedral-octahedral equilibria hold in various solvents, the following linear equation is given:

$$\log K[s]^2 = \alpha D + \text{const.} \quad (1)$$

where α is the slope of the straight line. Moreover, the following equation holds in the solvents:

$$-RT \ln K[s]^2 = \Delta H - T\Delta S \quad (2)$$

It is considered that the ΔS values of the equilibria in various solvents are roughly equal, because one bpy molecule is taken in, and two solvent molecules are liberated in each reaction. Thus, the changes in the K values upon changing solvents are due mainly to the changes in the ΔH values upon changing solvents, which depend upon the properties of the solvent; the bond strength between the metal ion and the solvent in the coordination sphere increases with the increase in the basicities of the solvents. The donor number is a measure of the basicity of the solvent, being equal to the heat of the reaction between $SbCl_5$ and the solvent in 1,2-dichloroethane.[2] All the solvents used in the present study coordinate with the oxygen atom to the first transition metal ion, with no back donation in the coordination. Thus, it is considered that Eq. 1 might hold for the metal ion in various solvents in octahedral-octahedral equilibria.

It has been reported that, in the cases of halide (X^-), the stabilities of $[Co(X)_4]^{2-}$ are affected by both the donor number and the acceptor number of the solvents.[2] However, since bpy is electrically neutral and the solvation to bpy occurs more weakly than that to the Cl^- ion, the acceptor number is not important here.

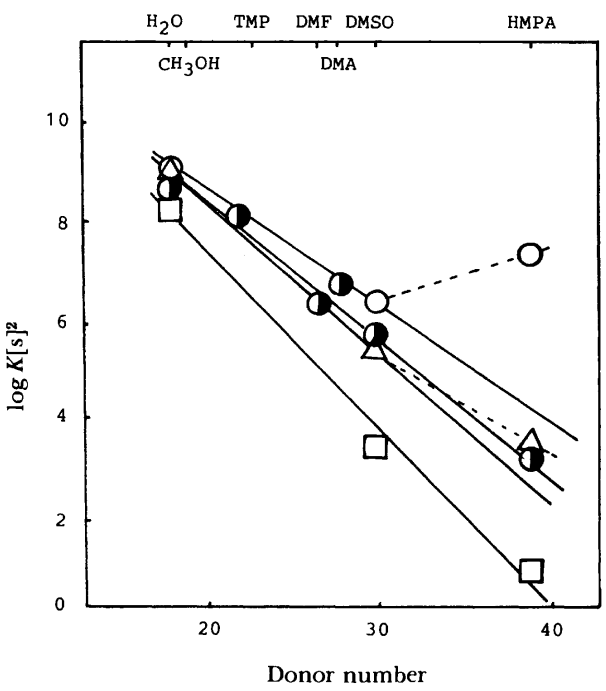

Fig. 1. Linear relations of log $K[s]^2$ vs. donor numbers in various solvents. For Co(II)-bpy complexes, (○): log $K_1[s]^2$, (△): log $K_2[s]^2$, (□): log $K_3[s]^2$. In HMPA, the value of log K_2 is plotted since the tetrahedral-octahedral equilibrium holds at the second step. For Zn(II)-bpy complexes, (◑): log $K_1[s]^2$.

In conclusion, log $K[s]^2$ is linear with respect to the donor number only when the solvation to the ligand is weak and the octahedral-octahedral equilibria hold in the solvents, as is shown in Fig. 1.

Preparation and Structure of {Bis(3-aminopropyl)amine}(*r*-1, *c*-3, *c*-5-cyclohexanetriamine)cobalt(III) Complex

Minoru Ishii,* Michiko Umehara, and Masayoshi Nakahara
Department of Chemistry, College of Science, Rikkyo (St. Paul's) University, Nishiikebukuro 3, Toshima-ku, Tokyo 171
(Received August 8, 1986)

Synopsis. {Bis(3-aminopropyl)amine}(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)cobalt(III) complex was prepared and the crystal structure of its iodide has been analyzed by X-ray diffraction. The complex cation has a facial configuration and an exo-type of N(secondary)-H bond orientation in bis(3-aminopropyl)amine. There is only a little distortion in the octahedron of this complex cation.

Although the complexes of five-membered rings of diethylenetriamine (dien) ligand have been extensively studied, reports on those of six-membered ring bis(aminopropyl)amine (dpt) are relatively few.

In a previous paper, the authors described the preparation of *mer*-$[Co(dpt)_2]^{3+}$ complex and the resolution to their optical isomers.[1] We also reported the structure of a bis-type complex of *r*-1,*c*-3,*c*-5-cyclohexanetriamine (chta), which takes a facial position and forms six-membered rings.[2]

The title complex, which is the mixed complex of chta and dpt, has necessary a facial geometry and exo and endo isomers in dpt as shown in Fig. 1.

In this paper, the authors will report the preparation of {bis(3-aminopropyl)amine}(*r*-1,*c*-3,*c*-5-cyclohexanetriamine)cobalt(III) complex, $[Co(chta)(dpt)]^{3+}$, and the crystal structure of its iodide.

Experimental

Preparation. To 80 mg of finely ground $[CoCl_3(chta)]$,[3] 5 ml of dpt solution (45 mg dpt/ml ethanol) was added, and the solution was stirred for 5 h on a water bath. The reddish-orange solution was diluted with a small amount of water and filtered to remove unreacted materials. The filtrate was poured into a column (ϕ 40 mm, h 300 mm) containing SP-Sephadex C-25 resin of Na^+ form. After the column was washed with 1 dm^3 water, elution was carried out with 1.0 mol dm^{-3} hydrochloric acid. A faster red layer and a slower reddish-orange layer descended. The reddish-orange fraction was concentrated to a small volume by an evaporator at 35 °C. With addition of ethanol to this solution, orange powders were obtained. Yield 21 mg (18%). Found: C, 32.50; H, 7.49; N, 18.87%. Calcd for $CoCl_{12}N_6H_{32}Cl_3 \cdot H_2O$: C, 32.48; H, 7.72; N, 18.94%. Absorption maxima of ligand field bands and their extinction coefficients are as follows: ,20300 cm^{-1} (log ε=1.90), 28300 cm^{-1} (log ε=1.94). The crystal for X-ray analysis was grown from an aqueous solution, after the chloride was converted into iodide with an I^- form anion-exchange resin.

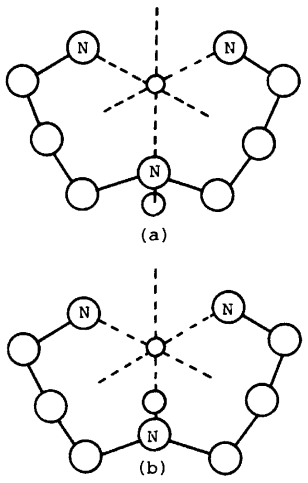

Fig. 1. Coordination mode of bis(3-aminopropyl)-amine. (a) exo (b) endo.

Crystal Structure Determination. The crystal data are as follows: $[Co(chta)(dpt)]I_3 \cdot H_2O$, $CoC_{12}N_6H_{32}I_3 \cdot H_2O$, $F.W.$= 818.09, monoclinic, space group $P2/a$,[4] a=23.424(7), b=12.079(3), c=9.761(3) Å, β=123.93(11)°, V=2291.6(1) Å^3, D_x=2.03 Mg m^{-3}, D_m=2.05 Mg m^{-3}, Z=4. A polyhedral crystal of approximately spherical shape with the radius of 0.5 mm was used for the X-ray intensity measurement. The intensity was measured on a Rigaku AFC-5 four-circle diffractometer (Keio University) with graphite-monochromated Mo $K\alpha_1$ radiation (λ=0.7093 Å) up to 2θ of 55°. The θ-2θ scan technique was employed. Independent 4482 reflections with $|F_o|>3\sigma(|F_o|)$ were used for structure determination. Corrections were made for the Lorentz and polarization factors, but no correction for absorption and extinction was applied. The structure was analyzed by the Patterson method by means of UNICS.[5] The calculation was carried out on a UNIVAC 1100 computer at Rikkyo University Computer Center. Scattering factors were taken from International Tables for X-ray Crystallography.[6] The refinement was carried out using the block-diagonal least-squares program HBLS IV based on $\Sigma w(|F_o|-k|F_c|)^2$, w=1, with anisotropic thermal parameters for nonhydrogen atoms and isotropic ones for hydrogen atoms. Fifteen among thirty-two hydrogen atoms (except those of the water molecule) were found from different synthesis. The remaining seventeen hydrogen atoms were located at sites calculated by assuming a tetrahedral geometry around C and N and fixed bond lengths. The atomic and thermal parameters of the complex are given in Table 1.[7] The R and R_2 values were 4.09 and 4.60%, respectively. A perspective drawing of the complex cation is shown in Fig. 2.

Results and Discussion

The chta and dpt ligands coordinate with six nitrogen atoms from above and below cobalt atom to form an octahedral complex. Each ligand spreads across a face of the octahedron, that is, it coordinates in facial positions as expected. In the dpt chelate, N-(secondary)-H (N(5)-H) bond orientation has apparently an exo-type (Fig. 1-(a)). In the chta chelate, triplet six-membered chelate rings have stable chair-

conformation. In contrast to this, the double fused six-membered dpt chelate rings take chair and skew-boat conformations (Fig. 3) which are the same as that observed in *s-fac*-[Co(dien)(dpt)](S_2O_6)(ClO_4)·H_2O.[8] There is a little difference in the Co–N distances between chta and dpt chelates in the $[Co(chta)(dpt)]^{3+}$ complex, but these values agree with the results obtained for the complex having six-membered chelate rings[9] (Table 2). The N–Co–N angles in the chelate rings are close to 90° (Table 3), distinct from other complexes containing facial type dpt (for example, in *s-fac*-$[Co(dien)(dpt)]^{3+}$,[8] 96.2°, 87.9°, and 92.5°, in *u-fac*-$[Co(dien)(dpt)]^{3+}$,[10] 96.6°, 88.7°, and 90.5°, and in $[Co_2(OH)_3(dpt)_2]^{3+}$,[11] 95.5°, 98.4°, and 93.1°) and comparable to those of chta complex (in $[Co(chta)_2]^{3+}$,[2] 90.1°, 90.0°, and 89.9°). The trans N–Co–N angles are slightly smaller than 180° and the non-chelate N–Co–N angles are slightly larger or smaller than 90°. These facts indicate that six nitrogen atoms form a slightly distorted octahedron around cobalt atom; the axis perpendicular to facial plane of octahedron elongates. In the complexes containing dpt, *s-fac*-,[8] *mer*-,[12] *u-fac*-$[Co(dien)(dpt)]^{3+}$,[10] and *mer*-$[Co(dpt)_2]^{3+}$,[13] there exists a considerable deviation from 90° in their N–Co–N angles of six-membered chelate rings. However, in the title complex, $[Co(chta)(dpt)]^{3+}$, the octahedral configuration is retained. It is known that chta ligands in $[Co(chta)_2]^{3+}$ [2] form a robust octahedron with cobalt atom. It seems that the particular structure of the title dpt complex is due to combination of dpt with chta and that distortion is fairly reduced by soft conformation of six-membered dpt chelate rings to retain octahedra of CoN_6 chromophores.

The Molecular Structure of (+)$_{589}$-β_2-(3-Methyl-2-iminobutanoato) ((2*S*,10*S*)-4,8-diazaundecane-2,10-diamine)cobalt(III) Perchlorate: α-Imino Acidato Complex

(Received December 25, 1986)

Synopsis. The crystal structure of (+)$_{589}$-β_2-(3-methyl-2-iminobutanoato)((2*S*,10*S*)-4,8-diazaundecane-2,10-diamine)cobalt(III) perchlorate has been determined by the single-crystal X-ray diffraction method. The complex ion adopts *Λ*-β_2 configuration, and it has the Co–N(imine) bond length of 1.90 Å, which is shorter than the Co–N(amine) bond lengths. The chelate ring of the 2-imino carboxylato is planar.

α-Imino acids (2-imino carboxylic acids) chelated to a metal ion are stable in an aqueous solution, while free α-imino acids are subject to be hydrolyzed. The syntheses and properties of cobalt(III) complexes of α-imino acids have been reported.[1–3] It reacts with nucleophile on its α-carbon, while it reacts with electrophile on its β-carbon and imino nitrogen. These facts make this ligand a useful building block for the synthesis of α-amino acid derivatives.

Recently, we obtained α-imino acidato Co(III) complexes by the dehydrogenation of the corresponding α-amino acidato complexes: The reaction of the [Co(α-amino acidato)(tetraamine)]$(ClO_4)_2$ complex with potassium permanganate gave a dehydrogenated product [Co(α-imino acidato)(tetraamine)]-$(ClO_4)_2$.[2] Asymmetric addition of a nucleophile to the imino carbon atom of α-imino acidate ligand can be expected, when optically active tetraamine ligand is employed. Since the tetraamine ligand seems to have a significant influence on the stereoselectivity, the structure of the complex is important, but the structure of the simple α-imino acidato complex has not yet been determined, as far as we know.[4] In this paper, we wish to report the X-ray structure determination of the molecular structure of (+)$_{598}$-β_2-[Co(oval)(2,10-Me_2-2,3,2-tet)]$(ClO_4)_2$.[5]

Experimental

(+)$_{598}$-β_2-[Co(oval)(2,10-Me_2-2,3,2-tet)]$(ClO_4)_2$ was prepared in a manner similar to that described previously.[3] Red crystals were obtained by crystallization from an aqueous solution. Found: C, 30.03; H, 5.78; N, 12.23%. Calcd for $C_{14}H_{32}Cl_2CoN_5O_{10}$: C, 30.01; H, 5.76; N, 12.50%.

The crystal used in the data collection was a red needle with the approximate dimentions of 0.1×0.05×0.05 mm^3. The diffraction data were measured on a Rigakudenki AFC-5R diffractometer using Mo *Kα* radiation monochromated by graphite (*λ* 0.7107 Å). Within the range of $2\theta<60°$, 1729 independent reflections with $|F_o| \geqq 2.5\sigma(F_o)$ were obtained. The intensities were corrected for Lorentz and polarization effects.

Crystal data for $C_{14}H_{32}Cl_2CoN_5O_{10}$: *F.W.*=560.3; Orthorhombic; $P2_12_12_1$; a=14.743(4), b=15.165(3), c=10.568(2) Å; V=2362.7(10) Å^3; Z=4; D_m=1.565 g cm^{-3}; D_x=1.575 g cm^{-3}; μ=10.07 cm^{-1}.

The structure was solved by the heavy-atom method and refined by a full-matrix least-squares method with anisotropic temperature factors for non-H atoms (for hydrogen atoms isotropically). The final discrepancy factors were $R=\Sigma||F_o|-|F_c||/\Sigma|F_o|=0.062$ and $R_w=[\Sigma w(|F_o|-|F_c|)^2/\Sigma w|F_o|^2]^{1/2}=0.060$ with a weighting scheme, $1/w=a|F_o|^2+b|F_o|+c$, were a, b, and c were calculated automatically. The absolute configuration of the whole complex ion was determined by the known absolute configuration of the asymmetric carbon atoms. All the hydrogen atoms except those of the terminal methyl groups of the isopropyl group were located and refined. The atomic scattering factors and the corrections for anomalous dispersion of Co, Cl, O, N, and C were taken from the literature.[6] Final positional and thermal parameters for non-hydrogen atoms are listed in Table 1.[7]

All the calculations were carried out on a HITAC M200H computer at the Computer Center of the Institute for Molecular Science and a HITAC M280H computer at the Computer Center of the University of Tokyo with Universal Program System UNICS-III.[8]

Results and Discussion

The observed structure of the complex ion (+)$_{589}$-[Co(oval)(2,10-Me_2-2,3,2-tet)]$^{2+}$ is shown in Fig. 1. The

tetraamine ligand and the α-imino acidato are coordinated to a cobalt ion in the cis-β_2 geometry.[10] The absolute configuration of the complex ion deduced from the known absolute configuration of the asymmetric carbon atoms of the tetraamine ligand is Λ. The geomtry around metal ion showed no change during the oxidation reaction. The electronic and circular dichroism (CD) spectra are shown in Fig. 2. The CD spectrum in a neutral solution showed a positive Cotton effect corresponding to the first absorption band, which is consistent with the absolute configuration. The solution showed characteristic

changes of the electronic and CD spectra on basification because of the dissociation of the imino proton.[3]

Selected bond lengths and bond angles are given in Table 2 and 3, respectively. The bond length between the imino nitrogen atom and cobalt atom, Co–N(5) is 1.90(1) Å, which is shorter than the average of other Co–N bond lengths (1.97 Å). This value is similar to the Co–N(imine) bond lengths of the α-imino acidato Co(III) complex reported previously.[4] The bond angle N(5)–Co–O(1) (82.7(4)°) is smaller than that of α-amino acidato chelate ring, and, therefore, is more strained. The bond length C(10)–N(5) (1.29(1) Å) is consistent with that expected for a C=N bond.[4]

The chelate ring of the α-imino acidate moiety is planar as expected (Fig. 3). The deviations from the least-squares plane through the five atoms are within 0.0030 Å.[11]

The isopropyl group appeared to be a *t*-butyl group, due to disordering in the crystal. Its conformation was gauche to the carboxylato group.

The authors are grateful to Prof. Sadao Yoshikawa of the University of Tokyo for helpful discussion, and to Drs. Takehiko Mori and Tamotsu Inabe of the Institute for Molecular Science for kindly collecting the diffracting data. This work was partly supported by a Grant-in-Aid for Scientific Research No. 60750810 from the Ministry of Education, Science and Culture.

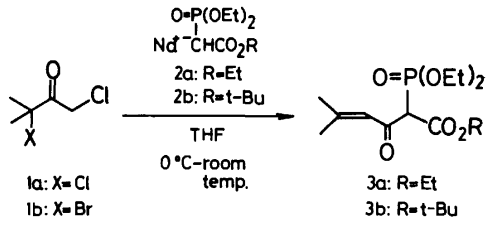
Favorskii-Type Rearrangement of α,α'-Dihalo Ketones Induced by Enolates of (Diethoxyphosphinyl)acetic Esters and Its Application to the Synthesis of α,α'-Divinyl Ketones

Takashi SAKAI,* Eiichiro AMANO, Kazuyoshi MIYATA, Masanori UTAKA, and Akira TAKEDA
Department of Synthetic Chemistry, School of Engineering, Okayama University, Tsushima, Okayama 700
(Received October 16, 1986)

Synopsis. A Favorskii-type rearrangement of 1,3-dihalo-3-methyl-2-butanone with enolate of ethyl (diethoxyphosphinyl)acetate or *t*-butyl (diethoxyphosphinyl)acetate gave ethyl 2-(diethoxyphosphinyl)-5-methyl-3-oxo-4-hexenoate (**3a**) or its *t*-butyl ester (**3b**). Compound **3b** was applied to the preparation of (*E*)-5-methyl-1-(*p*-tolyl)-1,4-hexadien-3-one and diethyl (4-methyl-2-oxo-3-pentenyl)phosphonate, which are the important intermediates for natural product syntheses.

Recently, we have made considerable efforts[1a-d] to extend the base of the Favorskii rearrangement[2] to carbanions such as enolates of malonic ester and (phenylsulfonyl)acetic ester. In a preceding paper,[1d] we reported that sodium enolates of β-keto esters reacted with 1,3-dihalo-3-methyl-2-butanone to give dihydro-4-pyrone derivatives via the Favorskii-type rearrangement. In this paper, we elucidate that the reaction is adaptable to enolates of (diethoxyphosphinyl)acetic esters, giving α-(diethoxyphosphinyl) β-keto esters (**3a,b**) in good yields. Products having a phosphinyl-functionality were utilized for the preparation of α,α'-divinyl ketones.

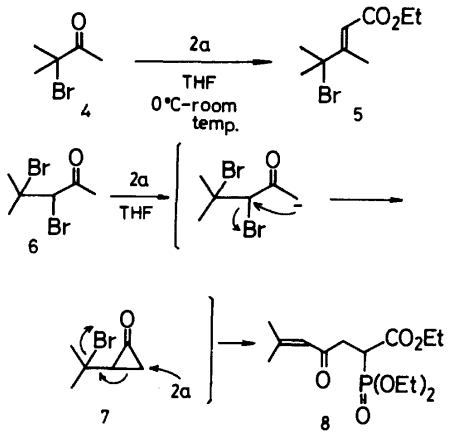
A reaction of 1,3-dichloro-3-methyl-2-butanone (**1a**) with sodium enolate of ethyl (diethoxyphosphinyl)-acetate (**2a**) in THF at room temperature gave ethyl 2-(diethoxyphosphinyl)-5-methyl-3-oxo-4-hexenoate (**3a**) in 42% yield (Scheme 1). The yield was improved up to 79% by using 3-bromo-1-chloro-3-methyl-2-butanone (**1b**). The *t*-butyl ester **3b** was similarly obtained in 36% yield from **1a** or in 81% yield from **1b**. The reaction can be explained in parallel with that described previously.[1d]



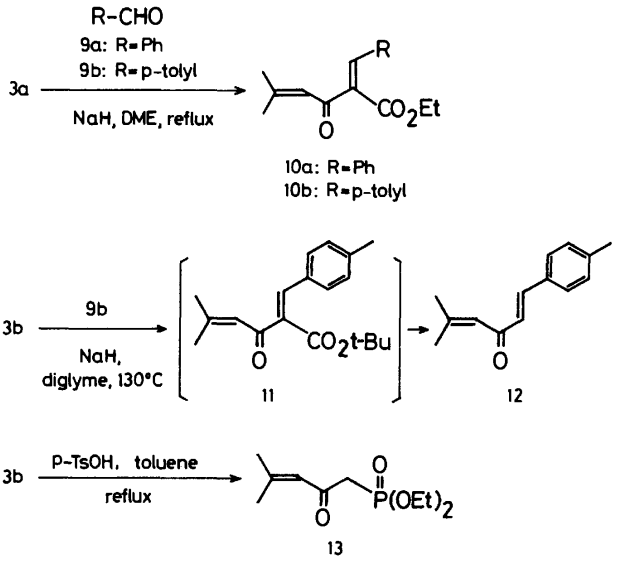
Scheme 1.

Attempts to apply the above reaction to 3-bromo-3-methyl-2-butanone (**4**) and 3,4-dibromo-4-methyl-2-pentanone (**6**) resulted in giving **5** (43% yield) and **8** (41% yield), respectively (Scheme 2). The formation of **8** suggests to us that the enolate **2a** may attack C-3 methylene carbon, instead of the carbonyl carbon, of the cyclopropanone intermediate **7**, which is produced under the basic conditions in a manner similar to the conventional Favorskii rearrangement.[2] It is interesting that the mode of the ring cleavage[3] of **7** is in marked contrast to that of the Favorskii rearrangement although a further investigation is required to confirm the mechanism.

The Horner–Wadmorth–Emmons reaction of sodium



Scheme 2.



Scheme 3.

enolate derived from **3a** with benzaldehyde (**9a**) was carried out in refluxing 1,2-dimethoxyethane (DME), giving α-benzylidenation product **10a** in 31% yield[4] (Scheme 3). A similar reaction with *p*-tolualdehyde (**9b**) gave **10b** in only 17% yield.[4] On the other hand, sodium enolate derived from **3b** was allowed to react with aldehyde **9b** at an elevated temperature (130 °C) in diglyme to give (*E*)-5-methyl-1-(*p*-tolyl)-1,4-hexadien-3-one (**12**) in 47% yield. In this case, deesterification of **11** may have occurred thermally[5] in the course of the reaction. Furthermore, the treatment of **3b** with a catalytic amount of *p*-toluenesulfonic acid in refluxing toluene gave (4-methyl-2-oxo-3-pentenyl)-phosphonate (**13**) in 78% yield. Compounds **12** and **13** are the important intermediates for the syntheses of *ar*-turmerone[1d,6] and related sesquiterpenes.[7]

Experimental

IR spectra were taken on a JASCO Model A-102 spectrometer. ^{1}H NMR spectra (60 MHz) were measured with a JEOL Model JNM-60 SI spectrometer by using Me_4Si as an internal standard. Preparative TLC was carried out on silica gel (Kieselgel 60 PF_{254}, Merck A. G. Darmstadt).

Materials: 1,3-Dichloro-3-methyl-2-butanone (**1a**)[8] was prepared by chlorination of 3-methyl-2-butanone with 2.4 equiv of sulfuryl chloride. 3-Bromo-3-methyl-2-butanone (**4**)[9] was prepared by bromination of the starting ketone with *N*-bromosuccinimide. 3-Bromo-1-chloro-3-methyl-2-butanone (**1b**)[10] was obtained by chlorination of **4** with sulfuryl chloride. (Diethoxyphosphinyl)acetates **2a**[11] and **2b**[12] were prepared by the reported procedures.

Ethyl 2-(Diethoxyphosphinyl)-5-methyl-3-oxo-4-hexenoate (3a). To a suspension of NaH (48 mg, 2 mmol) in THF (6 ml) was added a solution of ethyl (diethoxyphosphinyl)-acetate (448 mg, 2 mmol) in THF (2 ml); stirring was continued at room temperature for 2 h. To this was added **1b** (199 mg, 1 mmol) with stirring during an additional 48 h at room temperature. The mixture was poured into water and acidified with 10% HCl. The organic layer was extracted with ether, washed with aqueous $NaHCO_3$ and brine, dried ($MgSO_4$), and concentrated. The residue was purified by preparative TLC on silica gel (hexane–acetone, 3:1) to give 242 mg (79%) of **3a**: IR (neat) 1740, 1693, 1620, and 1555 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.32 (9H, t, *J*=7 Hz), 1.96 (3H, d, *J*=1.5 Hz), 2.14 (3H, d, *J*=1.2 Hz), 3.74—4.36 (6.77H, m), 6.32 (0.77H, m), 6.79 (0.23H, m), 14.65 (0.23H, br s, enol OH). Found: C, 50.87; H, 7.64%. Calcd for $C_{13}H_{23}O_6P$: C, 50.98; H, 7.57%.

A similar reaction of **1a** with **2a** gave **3a** in 42% yield.

***t*-Butyl 2-(Diethoxyphosphinyl)-5-methyl-3-oxo-4-hexenoate (3b).** A similar reaction of **1a** and **1b** with sodium enolate of *t*-butyl (diethoxyphosphinyl)acetate (**2b**) gave **3b** in 36% and 81% yields, respectively. **3b**: IR (neat) 1730, 1690, 1620, and 1555 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.31 (6H, t, *J*=7 Hz), 1.45 (9H, s), 1.93 (3H, br s), 2.09 (3H, br s), 3.67—4.36 (4.8H, m), 6.30 (0.2H, m), 6.73 (0.8H, m), 13.90 (0.2H, br s, enol OH). Found: C, 53.97; H. 8.06%. Calcd for $C_{15}H_{27}O_6P$: C, 53.89; H, 8.18%.

Ethyl (*E*)-4-Bromo-3,4-dimethyl-2-pentenoate (5):[13] 43% yield after purification by column chromatography (hexane–ether, 30:1); IR (neat) 1725 and 1640 cm^{-1}, ^{1}H NMR (CCl_4) δ=1.28 (3H, t, *J*=7 Hz), 1.93 (6H, s), 2.36 (3H, s), 4.11 (2H, q, *J*=7 Hz), 5.85 (1H, m).

Ethyl 2-(Diethoxyphosphinyl)-6-methyl-4-oxo-5-heptenoate (8). To a mixture of mesityl oxide (98.1 mg, 1.0 mmol), $NaHCO_3$ (35 mg, 0.42 mmol), and ether (1 ml), was added bromine (159 mg, 1.0 mmol) dropwise; the mixture was stirred for 2 h. The resulting ether solution of 3,4-dibromo-4-methyl-2-pentanone (**6**)[14] was slowly introduced to a suspension of **2a** which was prepared from ethyl (diethoxyphosphinyl)acetate (448 mg, 2.0 mmol) and NaH (48 mg, 2 mmol) in THF (2 ml) in a manner similar to that described above. After being stirred for 21 h at room temperature, the usual work up of the mixture gave 128 mg (41%) of **8** after purification by preparative TLC (hexane–acetone, 4:1; twice development, R_f=0.16—0.26). **8**: IR (neat) 1740, 1695, and 1625 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.28, 1.30, 1.32 (each with 3H, t, *J*=7 Hz), 1.88 (3H, br s), 2.10 (3H, br s), 2.7—3.7 (3H, m), 4.13 (6H, q, *J*=7 Hz), 6.02 (1H, m). Found: C, 52.43; H, 7.93%. Calcd for $C_{14}H_{25}O_6P$: C, 52.50; H, 7.87%.

Ethyl 2-Benzylidene-5-methyl-3-oxo-4-hexenoate (10a). To a suspension of NaH (72 mg, 3 mmol) in DME (3 ml) was added a solution of ester **3a** (918 mg, 3 mmol) and benzaldehyde (**9a**) (501 mg, 3.6 mmol) in DME (4 ml). The mixture was stirred for 1 h at room temperature and then for an additional 3 h under reflux. It was poured into water and acidified with 10% HCl. The organic layer was extracted with ether, washed with brine, dried ($MgSO_4$), and concentrated. The residual oil was purified by preparative TLC (hexane–acetone, 3:1) to give 240 mg (31%) of **10a**: IR (neat) 1720, 1705, 1672, and 1618 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.30 (3H, t, *J*=7 Hz), 1.84 (2.2H, br s), 1.95 (0.8H, br s), 2.17 (3H, br s), 4.20 (2H, q, *J*=7 Hz), 5.92 (0.7H, m), 6.20 (0.3H, m), 7.26 (5H, m), 7.40 (0.3H, s), 7.47 (0.7H, s). Found: C, 74.46; H, 6.94%. Calcd for $C_{16}H_{18}O_3$: C, 74.40; H, 7.02%.

Ethyl 5-Methyl-3-oxo-2-(*p*-tolylmethylene)-4-hexenoate (10b). A similar reaction of **3a** with *p*-tolualdehyde (**9b**) gave **10b** (17%): IR (neat) 1719, 1670, and 1610 cm^{-1}; ^{1}H NMR ($CDCl_3$) δ=1.27 (3H, t, *J*=7 Hz), 1.83 (1.7H, s), 1.94 (1.3H, s), 2.18 (3H, br s), 2.33 (3H, s), 4.21 (1.1H, q, *J*=7 Hz), 4.28 (0.9H, q, *J*=7 Hz), 6.02 (0.56H, m), 6.27 (0.44H, m), 6.9—7.4 (4H, m), 7.43 (0.44H, s), 7.51 (0.56H, s). Found: C, 75.16; H, 7.34%. Calcd for $C_{17}H_{20}O_3$: C, 74.97; H, 7.40%.

(*E*)-5-Methyl-1-(*p*-tolyl)-1,4-hexadien-3-one (12). A similar reaction of enolate of **3b** with **9b** was carried out in diglyme at 130 °C for 16 h. The crude product was purified by preparative TLC (hexane–acetone, 3:1) to afford **12** (47%), whose ^{1}H NMR spectral data were identical with those reported.[6]

Diethyl (4-Methyl-2-oxo-3-pentenyl)phosphonate (13). A mixture of **3b** (131 mg, 0.39 mmol), *p*-toluensulfonic acid (40 mg, 0.23 mmol), and toluene (3 ml) was stirred for 3.5 h under reflux. The cooled mixture was washed with aqueous $NaHCO_3$ and water. The organic layer was separated and the aqueous layer was extracted with ether. The combined organic layer was dried ($MgSO_4$) and then concentrated. Distillation of the crude product [bp 100—105 °C (0.3 mm Hg) (1 mmHg=133.322 Pa)] gave **13** (89 mg, 78%): IR (neat) 1680, 1620, and 1255 cm^{-1}; ^{1}H NMR (CCl_4) δ=1.33 (6H, t, *J*=7 Hz), 1.93 (3H, br s), 2.13 (3H, br s), 2.88 (2H, d, *J*=22 Hz), 3.97 and 4.11 (each with 2H, q, *J*=7 Hz), 6.20 (1H, m). Found: C, 59.25; H, 9.53%. Calcd for $C_{10}H_{19}O_2P$: C, 59.39; H, 9.47%. These spectral data are consistent with those of the corresponding dimethyl ester.[6a]

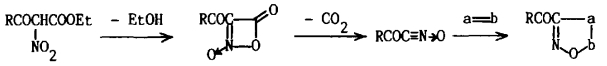
(Received November 28, 1986)

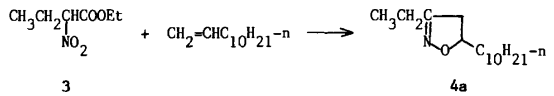
Synopsis. 3-Alkyl-2-isoxazolines and 3-alkylisoxazole were prepared by thermolysis of ethyl 2-nitroalkanoates at about 230 °C in the presence of dipolarophiles.

1,3-Dipolar cycloaddition reactions using nitrile oxides are one of versatile methods for the preparation of five-membered heterocycles. A variety of preparative methods for nitrile oxides are known so far.[1-12] Recently, we reported[10,11] the thermolysis of nitromalonates (**1**) and the mono anilides (**2**) at 160—170 °C to give nitrile oxides effectively, which could be trapped by a variey of dipolarophiles as cycloadducts



1 : R = OEt
2 : R = NHAr

in high yields. Although ethyl 2-nitrobutanoate (**3**) remained unchanged under similar reaction conditions,[11] a thermolysis of **3** under more vigorous thermal conditions in the presence of dipolarophiles did give cycloadducts. For example, a mixture of **3** and 1-dodecene in an appropriate solvent was heated to reflux for several hours under nitrogen and the following work-up of the reaction mixture gave a desired cycloadduct, 5-decyl-3-ethyl-2-isoxazoline (**4a**), in yields shown in Table 1. It was found from the



3 4a

Table that the yield of **4a** was not so varied from the employment of an excess of the dipolarophile and was effectively affected by the reaction temperature. Though a considerable amount of both substrates was recovered from the reaction mixture of Runs 1—4 and 6—8, none of **3** could be recovered from the reaction mixture of Run 5 in which formation of a considerable amount of tarry material was observed. Although the optimum reaction conditions were not yet attained, the best yield (48%) of the cycloadduct (**4a**) obtained is comparable with that by Mukaiyama method.[5]

Table 2. Yields and Melting Points of the Cycloadducts (**4**, **6**, **8**, and **9**)[a]

Adduct	R^2	R^3	Yield / %	Mp(θ_m/°C) (Bp(θ_b/°C)/mmHg)
4a	H	$C_{10}H_{21}$-*n*	48	(130—135/0.3)
4b	H	C_8H_{17}-*n*	43	(110—115/0.2)
4c	H	$C_{12}H_{25}$-*n*	37	33—34[b]
4d	H	$C_{14}H_{29}$-*n*	21	41—43
4e	$-(CH_2)_{10}-$		20	(128—135/0.2)
4f	H	$CH_2C_6H_4OCH_3$-*p*	34	(166—170/0.4)
4g	H	$CH_2OC_6H_4NO_2$-*p*	10	83—85[b]
4h	$COOCH_3$	$COOCH_3$	10	(110—115/0.3)[b]
4i	Ph	Ph	25	(140—145/0.5)
4j	CH_3	$C_6H_4OCH_3$-*p*	24	(144—149/0.4)
6a	H	$C_{10}H_{21}$-*n*	12	(130—136/0.6)
6b	H	C_8H_{17}-*n*	5	(110—115/0.5)
6c	H	$C_{12}H_{25}$-*n*	28	(145—151/0.4)
6e	$-(CH_2)_{10}-$		8	(137—140/0.4)
6f	H	$CH_2C_6H_4OCH_3$-*p*	15	(158—165/0.4)
8a	H	$C_{10}H_{21}$-*n*	33	(160—167/0.4)
8b	H	C_8H_{17}-*n*	30	(110—115/0.6)
8c	H	$C_{12}H_{25}$-*n*	39	34—36
8e	$-(CH_2)_{10}-$		20	(165—173/0.4)
8f	H	$CH_2C_6H_4OCH_3$-*p*	33	(160—165/0.4)
9	H	C_8H_{17}-*n*	14	(83—91/0.2)

a) Satisfactory microanalyses are obtained (C, H, N: ±0.25%). b) Lit, mp; **4c**: 35—36 °C,[7] **4g**: 83—85 °C,[7] **4h**: 83 °C/0.3 mmHg.[12] [1 mmHg=133.322 Pa].

Table 1. The Reaction of **3** with 1-Dodecene

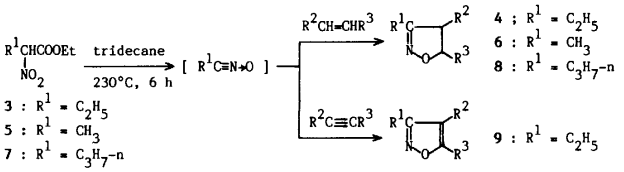
Run No.	Molar ratio of **3**: 1-dodecene	Solvent	Reaction temperature[a]	Reaction time	Yield of **4a**[b]	Recovery of **3**
1	1 : 1	Mesitylene	164 °C	6 h	0%	>90%
2	1 : 1	Decalin	190 °C	6 h	trace	>90%
3	1 : 1	Tridecane	234 °C	3 h	31%	50%
4	1 : 1	Tridecane	234 °C	6 h	48%	40%
5	1 : 1	Tridecane	234 °C	12 h	40%	0%
6	1 : 1	Tetradecane	254 °C	4.5 h	42%	38%
7	1 : 2	None	213 °C	3 h	25%	57%
8	1 : 2	None	213 °C	6 h	42%	45%

a) The boiling point of the solvent is shown except for the cases of Runs 7 and 8, in which that of 1-dodecene is shown. b) Yields were calculated on the basis of **3** used.

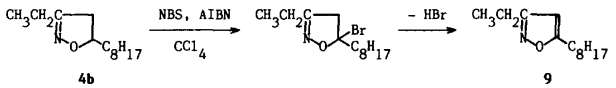
The results of the reaction of **3** with some dipolarophiles under similar conditions such as Run 4 in Table 1 were summarized in Table 2 along with those obtained by the reactions using ethyl 2-nitropropanoate (**5**) or ethyl 2-nitropentanoate (**7**) instead of **3**. In cases using **5**, yields of the desired cycloadducts (**6**) were generally lower than those from **3** or **7**. This results may be ascribed to the nature of the boiling point (195 °C) of **5**, lower than those (>230 °C) of **3** and **7**.

Table 3. ^{1}H NMR Spectral Data of the Cycloadducts (**4**, **6**, **8**, and **9**)

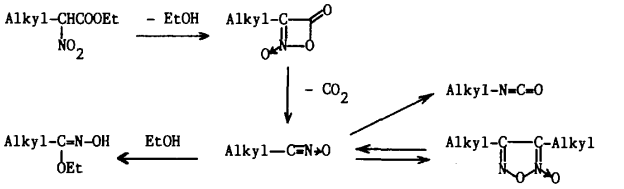
Adduct	^{1}H NMR, ppm (in $CDCl_3$)
4a	0.9 (t, 3H, J=7), 1.15 (t, 3H, J=7), 1.1—1.8 (m, 18H), 2.35(q, 2H, J=7), 2.45(dd, 1H, J= 8, 16), 3.0(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
4b	0.85(t, 3H, J=7), 1.15(t, 3H, J=7), 1.0—1.7 (m, 14H), 2.33(q, 2H, J=7), 2.45(dd, 1H, J= 8, 16), 3.0(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
4d	0.9 (t, 3H, J=7), 1.16 (t, 3H, J=7), 1.0—1.8 (m, 26H), 2.35(q, 2H, J=7), 2.45(dd, 1H, J= 8, 16), 3.0(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
4e	1.17 (t, 3H, J=7), 1.1—1.8 (m, 20H), 2.3 (q, 2H, J=7), 2.6—3.2(m, 1H), 4.2—4.7(m, 1H).
4f	1.1(t, 3H, J=7), 2.3(q, 2H, J=7), 2.5—3.2(m, 4H), 3.8(s, 3H), 4.5—5.0(m, 1H), 6.83(d, 2H, J=9), 7.17(d, 2H, J=7).
4i	1.05 (t, 3H, J=7), 1.9—2.45 (m, 2H), 4.17 (d, 1H, J=7), 5.4(d, 1H, J=7), 7.3(brs, 10H).
4j	1.05(t, 3H, J=7), 1.25(d, 3H, J=7), 1.9—2.6 (m, 2H), 2.7—3.4(m, 1H), 3.8(s, 3H), 4.95(d, 1H, J=9), 7.0(d, 2H, J=9), 7.3(d, 2H, J=9).
6a	0.9(t, 3H, J=7), 1.0—1.7(m, 18H), 1.95(s, 3H), 2.47(dd, 1H, J=8, 16), 2.95(dd, 1H, J=10, 16), 4.0—4.7(m, 1H).
6b	0.9(t, 3H, J=7), 1.0—1.7(m, 14H), 1.95(s, 3H), 2.47(dd, 1H, J=8, 16), 2.95(dd, 1H, J=10, 16), 4.0—4.7(m, 1H).
6c	0.9(t, 3H, J=7), 1.0—1.7(m, 22H), 1.97(s, 3H), 2.45(dd, 1H, J=8, 16), 3.0(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
6e	1.0—1.8(m, 20H), 1.95(s, 3H), 2.6—3.1(m, 1H), 4.2—4.7(m, 1H).
6f	1.93(s, 3H), 2.3—3.2(m, 4H), 3.77(s, 3H), 4.4—5.0 (m, 1H), 6.8(d, 2H, J=9), 7.15 (d, 2H, J=9).
8a	0.9 (t, 3H, J=7), 0.97 (t, 3H, J=7), 1.1—1.9 (m, 20H), 2.3(t, 2H, J=7), 2.47 (dd, 1H, J= 8, 16), 2.97(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
8b	0.9 (t, 3H, J=7), 0.96 (t, 3H, J=7), 1.1—1.9 (m, 16H), 2.3(t, 2H, J=7), 2.47 (dd, 1H, J= 8, 16), 2.97(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
8c	0.9 (t, 3H, J=7), 0.96 (t, 3H, J=7), 1.1—1.9 (m, 24H), 2.3(t, 2H, J=7), 2.47 (dd, 1H, J= 8, 16), 2.97(dd, 1H, J=10, 16), 4.1—4.7(m, 1H).
8e	0.9(t, 3H, J=7), 1.0—1.9(m, 22H), 2.25(t, 2H, J=7), 2.6—3.1(m, 1H), 4.2—4.7(m, 1H).
8f	0.9 (t, 3H, J=7), 1.5 (hexet, 2H, J=7), 2.3(t, 2H, J=7), 2.5—3.2 (m, 4H), 3.77(s, 3H), 4.5—5.0(m, 1H), 6.8(d, 2H, J=9), 7.15(d, 2H, J=9).
9	0.9(t, 3H, J=7), 1.0—1.5(m, 15H), 2.6(q, 2H, J=7), 2.67(t, 2H, J=7), 5.8(s, 1H).



The structure of the cycloadducts (**4**, **6**, **8**, and **9**) were assigned on the basis of elemental, MS, NMR, and IR spectral analyses (see Table 3). The assignment of the structure (**4c**, **4g**, and **4h**) was further supported by comparison of the physical properties with those of authentic specimens prepared according to literatures.[7,12] The structure of **9** was supported by the evidence that the physical properties of **9** agreed with those of the specimen prepared by dehydrogenation of **4b** with *N*-bromosuccinimide.[13]



Gradual evolution of carbon dioxide and ethanol was observed in the course of the reactions. From these evidences, one of the probable mechanism of the formation of the isoxazolines and isoxazole may be explained on the basis of the formation of nitrile oxide intermediate from the decomposition of ethyl 2-nitroalkanoates though we failed to isolate 3,4-dialkylfurazan 2-oxides, a dimer of the nitrile oxide, from the decomposition of those in the absence of dipolarophiles. This results may be explained as follows: a reverse reaction of the furazan 2-oxides to nitrile oxide has been known to be possible under the reaction temperature,[14] and consequently, the nitrile oxide is consumed by irreversible reactions such as the rearrangement to isocyanates or the reaction with ethanol giving ethyl hydroximic acid which, then,



undergo further transformations such as decomposition, polymerization, and reaction with ethanol and/or the staring material to give complex tarry materials under the conditions, though we failed to isolate any compound that supports this mechanism from the tarry mixture. The lower yields of the cycloadducts (**4**, **6**, **8**, and **9**) from **3**, **5**, or **7** than those from **1** or **2** can be ascribed to the result of the difficulty of thermolysis of **3**, **5**, and **7** into nitrile oxides. In other words, the introduction of electron-withdrawing group such as carbalkoxy and carbamoyl groups at α-position of ethyl nitroacetate promotes the tautomerization to the corresponding aci-nitro isomers and,

consequently, intramolecular condensation and the following decarboxylation giving nitrile oxides are accelerated.

Experimental

Measurements. Melting and boiling points are all uncorrected. ^{1}H NMR spectra were recorded on Varian T-60A instrument with TMS as an internal standard; chemical shifts are given in δ-units and coupling constants (J) are in herz units: s=singlet; d=doublet; t=triplet; m=multiplet; brs=broad singlet.

Materials. Ethyl 2-nitroalkanoates (**3, 5,** and **7**) were prepared according to the method described in literature.[15] The other chemicals were of commercial origin and were used without further purification.
