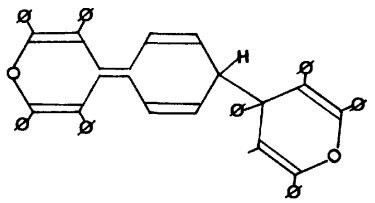
Configuration of Dimer. All dimers mentioned above may be expected to be formed through the σ bonding between the carbons at 4-position of each radical in the light of the configuration of the dimers of 2,4,6-trimethyl- and 2,3,5,6-tetraphenylpyranyl radicals. In practice, it is possible to assemble the dimers of σ-bonding configuration for **1**, **2**, and **4** with a Corey-Pauling-Kolton (CPK) space filling molecular models, though the dimer for **1** or **2** which has a substituent larger than a hydrogen atom at 3-position carbon is highly strained. As to the dimer for **3** and **5**, however, it is absolutely impossible to construct them with the CPK molecular model because of the large steric hindrance of phenyl groups both 3- and 5-position in the pyrylium or thiopyrylium ring. The apparent temperature effects on the intensity of the radical absorbances at 490 (for **3**) and 470 nm (for **5**) are similar to that for 1-alkyl-4-carbomethoxy pyridinyl radical,[11] where the intensity of the absorbance at ca. 640 nm increases with decreasing the temperature, due to a charge-transfer complex formation between two pyridinyl radicals.

In our case, however, the amounts of these pyranyl and thiopyranyl radicals are confirmed to increase with lowering the temperature by the ESR measurement. The absorption in visible region is not the charge-transfer band but the monomer radical band in comparison with those of radicals for **1**, **2**, **4**, and other pyrylium salts.[5] Thus, a potential energy of a radical and a dimer vs. the reaction coordinate diagram is considered to be different between the equilibrium for ordinary pyrylium salts and that for **3** and **5**. Taking into account the large steric hindrance of phenyl groups, it is reasonable that the potential energies of the radicals of **3** and **5** are lower than that of the dimers. Moreover, the dimers for **3** and **5** may not have the tight σ bonding at 4-position carbon of the radical. Then, two possible structures of the dimer are considered. One is **6** in which one radical attacks a benzene ring of another radical in 4-position carbon, analogous to the case of the dimerization of triphenylmethyl radical.[12] It is possible to make the molecule of **6** with CPK model. The other is the ordinary dimer configuration with a σ bonding at 4-position carbon, not tight but very loose bonding taking into account the flexibility of the pyrylium or thiopyrylium ring.



6

The authors wish to thank Prof. Yoshizo Suzuki for supplying the pyrylium salts. We are also indebted to Dr. Kazuaki Shimada for his help in taking NMR spectra.

The Hypervirial Condition in the Hückel Model

Makoto ISIHARA
Department of General Education, Shotoku-Gakuen Women's Junior College, Nakauzura 1-38, Gifu 500
(Received March 1, 1989)

This paper analyzes a fundamental aspect of the Hückel model through the hyperviral theorem. The analysis leads to the condition to be satisfied by bond orders and site electron densities as a set of linear equations. The condition, named the hypervirial condition, is common to all the eigenstates of the Hückel model Hamiltonian and brings information on a sort of detailed balance in electron distribution. The hypervirial and the symmetry conditions are related to each other, being consistent but not fully equivalent. Examination of the relation between the two conditions results in the concept of the "intrinsic" hypervirial condition that remains nontrivial with the symmetry condition fulfilled. Several examples provide various expressions obtainable from the hypervirial condition to facilitate understanding the nature of the condition. A few features of the hypervirial condition for alternant systems are mentioned.

The Hückel medel[1,2] is one of the simplest independent-particle models in the electronic structure theory of molecules and has been extensively used and investigated since the dawn of quantum chemistry.[3] The model will never lose its value in studies on molecular electronic structures particularly of conjugated systems, at least as a qualitative guide. We should regard the Hückel model as a tool of sketching out some essentials of the behavior of electrons in molecules rather than a crude approximation to real systems.

Nowadays we have no practical difficulty at all in "solving" the Hückel model numerically for individual systems except for extreme cases. With the Hückel matrix given, or usually with a pertinent set of geometrical parameters inputted, the computer immediately prints out molecular orbitals, their energies, electron densities, bond orders, and so on. This does not mean, however, that nothing remains to be explored in the world of the Hückel model. Above all, significant is to investigate the general characteristics of the model itself which might be hardly revealed through individual numerical calculations. In fact, for example, various graph-theoretical approaches[4] and the propagator formalism[5] as well as Coulson and Longuet-Higgins' formalism[6] have enriched our recognition on the Hückel model soundly.

What is intended in this paper is not to propose a novel far-reaching methodology but only to analyze a certain fundamental aspect of the Hückel model through the hypervirial theorem.[7] Still, the author believes that this must advance our understanding of the Hückel model.

We have the six sections below: the first is the preliminary section where basic definitions are introduced on the Hamiltonian, bond orders, and so on. In the second section the hypervirial condition upon bond orders and site electron densities are derived from the hypervirial theorem. The third section describes the symmetry condition in the language of permutation group theory, outlining the relation between the hypervirial and the symmetry conditions. The fourth section concerns the intrinsic hypervirial condition that remains nontrivial with the symmetry condition fulfilled. Several illustrative examples follow in the subsequent section. The last section touches upon the hypervirial condition for alternant systems.

Preliminaries

Suppose an electronic system of m sites. Denote the set $\{1,\cdots,m\}$ of the sites by M and the set $\{\uparrow,\downarrow\}$ of the one-electron spin states by Ω. The Hückel model assumes that the system has the $2m$ one-electron quantum states $\{r\mu\}$ specified by the site $r\in M$ and the spin $\mu\in\Omega$[8] and that the creators $\{a^\dagger_{r\mu}\}$ and the annihilators $\{a_{r\mu}\}$ for the one-electron quantum states $\{r\mu\}$ fulfil the canonical anticommutation relation. The Hückel model Hamiltonian H is defined with the creators and the annihilators as

$$H=\sum_{r,s\in M} b_{rs}\,(a^\dagger_{r\uparrow}a_{s\uparrow}+a^\dagger_{r\downarrow}a_{s\downarrow}), \tag{1}$$

where $\{b_{rs}\}$ are the components of what is called the Hückel matrix. Assume that the Hückel matrix B is real symmetric, which makes the model transparent without serious loss of physical contents. The matrix is almost always simplified further.

Designate the two ordered pairs of different sites $r,s\in M$ as rs and sr. Let L denote the set of all the pairs composed of different sites of M. Call the pair rs the connected pair if the sites r and s are bonded, noting that the word "bonded" is used here with regard to the site framework but not to the electronic structure considered. Denote the subset of L that consists of all the connected pairs by Y and the complementary subset by $\overline{Y}$. Let us refer to the model with the simplification

$$b_{rs}=\begin{cases}\beta_{rs} & (rs\in Y)\\ 0 & (rs\in\overline{Y})\end{cases} \tag{2}$$

as the semisimple Hückel model[9] and to the model with the more popular simplification

$$b_{rs} = \begin{cases} \alpha & (r=s) \\ \beta & (rs\in Y) \\ 0 & (rs\in\overline{Y}) \end{cases} \tag{3}$$

as the simple Hückel model.

The most informative quantities of definite physical meaning in the Hückel model are electron densities $\{q_r\}$ on sites and bond orders $\{p_{rs}\}$ between sites.[10] Let us call them p-densities generically for convenience' sake, often designating q_r as p_{rr}. Although p-densities are defined originally in terms of Hückel orbital coefficients, we can generalize the definition quite naturally. Put

$$\begin{cases} \rho_{\mu rs} = (a^\dagger_{r\mu}a_{s\mu} + a^\dagger_{s\mu}a_{r\mu})/2 \\ \zeta_{\mu rs} = -\,\mathrm{i}\,(a^\dagger_{r\mu}a_{s\mu} - a^\dagger_{s\mu}a_{r\mu})/2 \end{cases} \quad (r,s\in M;\ \mu\in\Omega) \tag{4}$$

and define

$$\begin{cases} p_{\mu rs} = \langle|\rho_{\mu rs}|\rangle \\ z_{\mu rs} = \langle|\zeta_{\mu rs}|\rangle \end{cases} \quad (r,s\in M;\ \mu\in\Omega) \tag{5}$$

for each eigenstate $|\rangle$ of H. We can define p-densities by

$$p_{rs} = \langle|(\rho_{\uparrow rs} + \rho_{\downarrow rs})|\rangle = p_{\uparrow rs} + p_{\downarrow rs} \qquad (r,s\in M). \tag{6}$$

The matrix P of the component $\{p_{rs}\}$ is real symmetric necessarily. Let us call the matrix the p-density matrix.[11]

Hypervirial Condition

The hypervirial theorem affirms that any eigenstate $|E\rangle$ of the Hamiltonian $\hat{H}$ of a system fulfils

$$\langle E|[\hat{H}, \hat{A}]|E\rangle = 0 \tag{7}$$

for any linear operator $\hat{A}$ of the system. Since the Hückel model has the one-body Hamiltonian conserving the spin, essential is the one-body hypervirial theorem[12]

$$\langle|[H, a^\dagger_{r\mu}a_{s\mu}]|\rangle = 0 \qquad (r,s\in M;\ \mu\in\Omega), \tag{8}$$

which is rewritten by calculating the commutator as

$$\sum_{t\in M}(b_{rt}\langle|a^\dagger_{t\mu}a_{s\mu}|\rangle - \langle|a^\dagger_{r\mu}a_{t\mu}|\rangle\, b_{ts}) = 0 \qquad (r,s\in M;\ \mu\in\Omega). \tag{9}$$

Thus, we find that the combination corresponding to

$$\langle|[H, \mathrm{i}\zeta_{\mu rs}]|\rangle = 0 \qquad (r<s\in M;\ \mu\in\Omega) \tag{10}$$

suffices to give the linear equations for $\{p_{\mu rs}\}$

$$\sum_{t\in M}(b_{rt}p_{\mu ts} - p_{\mu rt}b_{ts}) = 0 \qquad (r<s\in M;\ \mu\in\Omega). \tag{11}$$

Here, the case of $r>s$ is excluded because the equation for rs is essentially identical with that for sr; the case of $r=s$, giving nothing, is also excluded. By virtue of the linearity the same equations hold for $\{p_{rs}\}$. Let us refer to the equations the hypervirial relationships and shorten "hypervirial relationship" to "HVR" from now on.

We can take the other combination independent of the above one. The combination corresponding to

$$\langle|[H, \mathrm{i}\rho_{\mu rs}]|\rangle = 0 \qquad (r\leqq s\in M;\ \mu\in\Omega) \tag{12}$$

leads to the linear equations for $\{z_{\mu rs}\}$

$$\sum_{t\in M}(b_{rt}z_{\mu ts} - z_{\mu rt}b_{ts}) = 0 \qquad (r\leqq s\in M;\ \mu\in\Omega). \tag{13}$$

However, after all, these equations do not give more than the reality condition

$$z_{\mu rs} = 0 \qquad (r,s\in M;\ \mu\in\Omega), \tag{14}$$

which is a natural consequence of the reality assumption of the Hückel matrix.

To return, regarding the HVRs for p-densities as a condition imposed upon p-densities, call it the hypervirial condition, which is abbreviated as the HVC in the following. The HVC can be expressed compactly in the matrix form as[13,14]

$$[B, P] = 0. \tag{15}$$

In particular, for the simple Hückel model, we have

$$[J, P] = 0 \tag{16}$$

with the adjacency matrix J.[15,16] Bear it in mind that the HVC is common to all the eigenstates of H without regard to the number of electrons contained. Say, by supposing the one-electron eigenstate, p-densities in the HVC are read as the p-densities due to one Hückel orbital. With the number n of electrons fixed, we have the number condition

$$n = \sum_{r\in M} p_{rr} \tag{17}$$

as a condition independent of the HVC. Then, the HVC plus the number condition is common to all the n-electron eigenstates of H.

Now let n_μ denote the number of μ-spin electrons in a system. When $n_\uparrow$ and $n_\downarrow$ differ, each of the HVCs upon $\{p_{\uparrow rs}\}$ and upon $\{p_{\downarrow rs}\}$ becomes meaningful under the number conditions for n_μ's.[17] However, as long as we do not substitute numbers for n_μ's, the condition upon $\{p_{\mu rs}\}$ is identical with that upon p-densities in the form of equations. In what follows, the condition upon p-densities is treated representatively; it is enough to affix the subscript "$\uparrow$" or "$\downarrow$" (or "μ") to "p"

and "n" for the others.

A little arrangement of terms in HVRs is preferable, particulary for practical purposes. Putting

$$d_{rs} = b_{rs}(q_r - q_s), \tag{18}$$

$$e_{rs} = (b_{rr} - b_{ss})\, p_{rs}, \tag{19}$$

and

$$f_r^s = \sum_{t \neq r,s} b_{rt} p_{ts}, \tag{20}$$

we write the HVR for rs as

$$e_{rs} + f_r^s - f_s^r = d_{rs}. \tag{21}$$

The left side concerns only bond orders, while the right does site electron densities. Note that d_{rs} and e_{rs} are antisymmetric for the interchange of r and s, but that f_r^s and f_s^r differ in general. We can leave d_{rs} and e_{rs} out of account, respectively, for $b_{rs}=0$ and for $b_{rr}=b_{ss}$. Let C_r^s be the set of sites adjacent to r other than s. Note that C_s^r differs from C_r^s in general. For the semisimple Hückel model, the summation in f_r^s runs over C_r^s and the term d_{rs} vanishes unless rs is a connected pair. In particular, the simple Hückel model has the exquisitely simple HVRs independent of values of α and β;

$$\tilde{f}_r^s - \tilde{f}_s^r = \tilde{d}_{rs} \tag{22}$$

with

$$\tilde{f}_r^s = \sum_{t \in C_r^s} p_{ts} \tag{23}$$

and

$$\tilde{d}_{rs} = \begin{cases} q_r - q_s & (rs \in Y) \\ 0 & (rs \in \overline{Y}). \end{cases} \tag{24}$$

Table 1 is an adequate dictionary for a diagrammatic representation of HVRs for the semisimple Hückel model, which can be used for the simple Hückel model with trivial translation. The diagrammatic representation will be found quite useful for writing out HVRs for individual systems. It may help us conceive the physical meaning of HVRs.

It is obvious that the HVC brings information on a sort of detailed balance in electron distribution in a system. Some portion of the balance is, however, often ascribable to the symmetry of the system. The number N_h of independent HVRs is given by

$$N_h \leqq m(m-1)/2. \tag{25}$$

Table 1. Diagrammatic Representation of HVRs for the Semisimple Hückel Model[a]

Term	Diagram	
	For adjacent rs	For nonadjacent rs
f_r^s		e_{rs}		
d_{rs}		

a) Read f_r^s as $\tilde{f}_r^s$ and d_{rs} as $\tilde{d}_{rs}$ with all β's unity for the simple Hückel model, which has no term corresponding to e_{rs}.

The equality holds only for systems of no "spatial" symmetry at all. The symmetry condition often makes some HVRs trivial, while the HVC often contains some part of the symmetry condition. Let us proceed with this problem.

Symmetry Condition

The symmetry of molecular systems is to be treated generally through the point group.[18] However, it is pertinent and rather essential for the present purpose to consider the symmetry of the Hückel matrix with permutation groups.[19] Let S_m be the symmetric group on M and designate the element consequent on the action of $x \in S_m$ on $r \in M$ simply as xr. Let G, a subgroup of S_m, be the permutation group consisting of all the permutations $\{x\}$ that keep the Hückel matrix B invariant in the sense that

$$b_{xrxs} = b_{rs} \qquad (r,s \in M). \tag{26}$$

The permutation group G carries the characteristics of the symmetry of B which fully reflects the symmetry of a system in the Hückel model.

Here, tentatively, the state $|\rangle$ is said to be faithful if it fulfils

$$\langle|\rho_{\mu xrxs}|\rangle = \langle|\rho_{\mu rs}|\rangle \quad (r,s \in M;\ \mu \in \Omega)\ (x \in G). \tag{27}$$

Any nondegenerate eigenstate of H is easily proved to be faithful. For degenerate eigenstates, however, relevant choice is required for the eigenstates to be faithful. Arbitrary configurations composed of Hückel orbitals cannot necessarily lead us to faithful states, even if they are eigenstates of H. Only faithful eigenstates are natural and satisfactory as stationary states of an entire system.[10,20] Let us confine ourselves to faithful eigenstates when the permutational symmetry is considered.

Two elements $r,s \in M$ are said to be transitive if there exists $x \in G$ satisfying $s = xr$. The transitivity is an equivalence relation and gives the classification of M

$$M = \Gamma_1 + \cdots + \Gamma_v \tag{28}$$

with $\{\Gamma_i\}$ the equivalence classes, which are called the orbits on M.[21] Let V denote the set $\{1,\cdots,v\}$ of the subscripts of the orbits. Likewise, two elements $rs,tu \in L$ are said to be transitive if there exists $x \in G$ satisfying $tu = xrxs$. We have the classification of L

$$L = \Lambda_1 + \cdots + \Lambda_w \tag{29}$$

with $\{\Lambda_i\}$ the orbits on L. Denote the set $\{1,\cdots,w\}$ of the subscripts by W. The orbit on M and that on L are often called the site orbit and the pair orbit, respectively. The number of elements contained in an orbit is conventionally called the length of the orbit. Using the concept of orbits, we can write the permutational symmetry condition as

$$\begin{cases} q_r = q_s & (r,s \in \Gamma_i) \qquad (\text{each } i \in V) \\ p_{rs} = p_{tu} & (rs,tu \in \Lambda_i) \qquad (\text{each } i \in W). \end{cases} \tag{30}$$

Note that this does not always reproduce the transpositional symmetry inherent in bond orders completely.[22] The modifier "permutational" stands for this fact. The symmetry condition is abbreviated as the SC in the following.

Let us define the subset Δ_i of L, which is said to be dual with Λ_i, as

$$\Delta_i = \{rs \mid sr \in \Lambda_i\} \qquad (i \in W). \tag{31}$$

Evidently, the subset Δ_i is a pair orbit, identical or disjoint with Λ_i. The pair orbit Λ_i is said to be selfdual if identical with Δ_i, and nonselfdual otherwise. Let w° be the number of selfdual orbits plus half the number of nonselfdual ones. Arranging the subscripts of pair orbits relevantly, we can make the w° "pseudorbits"[23]

$$\Theta_i = \Lambda_i \cup \Delta_i \qquad (i \in W^\circ = \{1,\cdots,w^\circ\}). \tag{32}$$

constitute L. The pseudorbits enable us to incorporate the transpositional symmetry into the SC;

$$\begin{cases} q_r = q_s & (r,s \in \Gamma_i) \qquad (\text{each } i \in V) \\ p_{rs} = p_{tu} & (rs,tu \in \Theta_i) \qquad (\text{each } i \in W^\circ). \end{cases} \tag{33}$$

For the number N_p of symmetry-independent p-densities, we have

$$N_p = v + w^\circ \tag{34}$$

immediately from this.

To see the general relation between the HVC and the SC, let us use the matrix notation, denoting the permutation matrix corresponding to $x \in G$ by X. The transpositional symmetry is always presupposed here; we can identify the SC with the permutational SC. What serves the purpose is the Lie–Jacobi identity

$$[[B, P], X] + [[P, X], B] + [[X, B], P] = 0 \quad (x \in G), \tag{35}$$

which is reduced by the invariance of B to

$$[[B, P], X] = [[X, P], B] \qquad (x \in G), \tag{36}$$

showing the consistency of the HVC and the SC immediately. If the HVC is presupposed, we have

$$[[X, P], B] = 0 \qquad (x \in G). \tag{37}$$

Clearly, this cannot make all $[X, P]$'s for $x \in G$ vanish in general. On the other hand, with the SC presupposed, we have

$$[[B, P], X] = 0 \qquad (x \in G). \tag{38}$$

This assures that $[B, P]$ has the same permutational symmetry as B and P, but does not suffice to reproduce the HVC in general. The next section will clarify what follows upon the HVC from the presupposed SC in some detail.

Group theory is ready to provide some interesting results about the number of site orbits, that of pair orbits, lengths of them, and so on. However, let us skip the subject now, which is of rather mathematical interest. Actually, it is not difficult to check site orbits and pair orbits for a given system, usually much easier than to find the permutation group itself.

Intrinsic Hypervirial Condition

Because the SC is quite simple and much more accessible than the HVC, we suppose that the SC is fulfilled prior to the HVC in taking account of both. Let us refer to the HVR left nontrivial with the SC fulfilled as the intrinsic HVR and name the condition consisting of intrinsic HVRs the intrinsic HVC. The reason why we treat the SC using the concept of orbits is that the concept is advantageous for describing the intrinsic HVC.

For two arbitrary elements rs and $r's'$ of a pair orbit, we always have the permutation $x \in G$ that fulfils $r'=xr$ and $s'=xs$. Hence, noting

$$\sum_{t \in M} b_{rt} p_{ts} = \sum_{t \in M} b_{r'xt} p_{xts'} = \sum_{t \in M} b_{r't} p_{ts'}, \tag{39}$$

we find that the HVR for $r's'$ is identical with that for rs. Since the HVRs for rs and for sr are essentially identical, we can conclude that each pseudorbit corresponds to its HVR, whether the HVR is intrinsic or not. This neat result, mentioned in the preceding section already, is not all that follow from the presupposed SC.

Let rs be an arbitrary element of a selfdual orbit. Then, there exists the permutation $x \in G$ that fulfils $x(rs)=sr$. Since this means $xr=s$ and $xs=r$, we have

$$\sum_{t \in M} b_{rt} p_{ts} = \sum_{t \in M} b_{sxt} p_{xtr} = \sum_{t \in M} b_{st} p_{tr}, \tag{40}$$

which makes the HVR for rs trivial. Thus, the intrinsic HVC contains no HVRs for selfdual orbits. This is the most crucial result that is also fundamental for writing out intrinsic HVRs for individual systems.

To outline locations of selfdual and nonselfdual orbits in L, it is suitable to define the region L_{ij} as

$$L_{ij} = \{rs \in L \mid r \in \Gamma_i;\ s \in \Gamma_j\} \qquad (i,j \in V). \tag{41}$$

Let us refer to L_{ij} as the diagonal region if $i=j$ and as the off-diagonal region otherwise. Diagonal regions are defined for site orbits of length more than unity. We readily find that no orbit spreads over separate regions and that no orbit in off-diagonal regions is selfdual. Hence, orbits in off-diagonal regions are to correspond to intrinsic HVRs. Since orbits in the off-diagonal region L_{ji} are dual with orbits in L_{ij}, we have only to consider off-diagonal regions for $i<j$. On the other hand, orbits in diagonal regions are almost exclusively selfdual and scarcely lead to intrinsic HVRs. Roughly speaking, as the symmetry of a system becomes lower, we have more intrinsic HVRs.

Actually, it is never laborious to check whether a site pair belongs to a selfdual orbit or not; yet, as to orbits in diagonal regions, the following cases are worth noting.

(1) If the length of an orbit Γ_i is two, then L_{ii} is a selfdual orbit in itself.

(2) Let Γ_i be an orbit of length $|\Gamma_i|$ more than two. If there exists no other site orbit of the same length as $|\Gamma_i|$, then all the orbits in L_{ii} are selfdual.

(3) As a corollary of the above, if we have only one orbit on M, that is, if M itself is an orbit, then all the pair orbits are selfdual.

The proofs of these are omitted, but it will be easy to comprehend them by supposing relevant configurations of sites.

Now assume that we have more than one orbits Γ_i's of the same length more than two. Of course, it is probable for orbits in L_{ii}'s to be selfdual. However, if G is a cyclic group of order more than two, it is possible for orbits in L_{ii}'s to be nonselfdual. Then, HVRs for orbits in different L_{ii}'s are, moreover, not all independent of each other. Such a case is very exceptional and not discussed here in further detail. Instead, a typical example is shown in Fig. 1, which will be enough to understand when exceptional cases occur.

Consider the number N_p° of p-densities left independent with both of the SC and the HVC fulfilled. Put exceptional cases aside for brevity. The number of intrinsic HVRs is equal to that of pseudorbits in off-diagonal regions, so that, using the number N' of pseudorbits in diagonal regions, we have

$$N_p^\circ = v + N'. \tag{42}$$

Let N_i' denote the number of pseudorbits in the

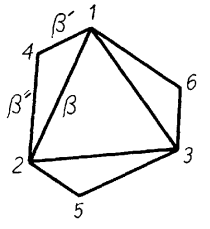

Fig. 1. Nonselfdual orbits in diagonal regions: $\Gamma_1=\{1,2,3\}$, $\Gamma_2=\{4,5,6\}$, $\Delta_1=\{12,23,31\}$, $L_{11}=\Delta_1+\Delta_1$, and so on.

diagonal region for an orbit Γ_i of length $|\Gamma_i|$. The obvious, rough estimate

$$N_i' \leqq |\Gamma_i| - 1 \qquad (i \in V) \tag{43}$$

leads to

$$N' = \sum_{i \in V} N_i' \leqq m - v \tag{44}$$

and gives

$$N_p^\circ \leqq m. \tag{45}$$

If $|\Gamma_1|$ is more than two and if G contains a cyclic group of order $|\Gamma_1|$, then we have the better estimate

$$N_1' \leqq [|\Gamma_1|/2], \tag{46}$$

where $[\cdots]$ is Gauß' symbol. This can improve the estimate for N_p° considerably for systems of high symmetry.

The discussion in this section may be too crude from a mathematical point of view; there is plenty of room for refinement. Nevertheless, the results obtained here is adequate to work with the intrinsic HVC practically.

Illustrative Examples

What the HVC implies will be understood well through working on several examples. Some hints as to when and how to utilize the HVC may also be obtained. The best way for writing out HVRs for individual systems (without computers) is probably to use the diagrammatic repesentation over so-called structure formulas. Although the diagrammatic method needs neither the Hückel matrix nor the p-density matrix written explicitly, most of the following examples have expressions of the matrices for the sake of clarity, half of the off-diagonal components being often omitted to avoid useless complexity.

Simple Systems. The simplest example that has the intrinsic HVC is the asymmetric two-site system shown in Fig. 2 (a). Put

$$B = \begin{pmatrix} \alpha & \beta \\ \beta & \alpha' \end{pmatrix} \tag{47}$$

and

$$P = \begin{pmatrix} q & p \\ p & q' \end{pmatrix}. \tag{48}$$

The nonselfdual orbit {12} corresponds to the intrinsic HVR

$$(\alpha - \alpha')\,p = \beta\,(q - q'), \tag{49}$$

which means that the bond order is proportional to the difference between the electron densities on the two sites with the proportionality constant $\beta/(\alpha-\alpha')$. If $\beta=0$, then we have $p=0$ for $\alpha' \neq \alpha$. If we put $\alpha'=\alpha$, the HVR becomes $q'=q$ for nonvanishing β. Then, the HVR is not intrinsic, contained in the SC.

The three-site chain system is another instructive simple example. Let the middle site be the third one, as shown in Fig. 2 (b). The semisimple Hückel model for the system has

$$B = \begin{pmatrix} \alpha & 0 & \beta \\ 0 & \alpha'' & \beta'' \\ \beta & \beta'' & \alpha' \end{pmatrix} \tag{50}$$

and

$$P = \begin{pmatrix} q & p' & p \\ p' & q'' & p'' \\ p & p'' & q' \end{pmatrix}. \tag{51}$$

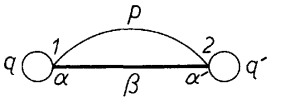
The three HVRs for the pairs 12, 13, and 23 are

$$\begin{cases} (\alpha - \alpha'')\,p' + \beta p'' - \beta'' p = 0 \\ (\alpha - \alpha')\,p - \beta'' p' = \beta\,(q - q') \\ (\alpha'' - \alpha')\,p'' - \beta p' = \beta''\,(q'' - q'). \end{cases} \tag{52}$$

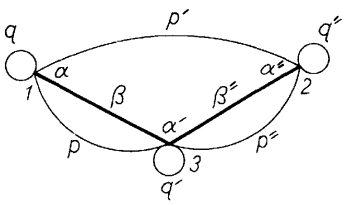
The case of $\alpha''=\alpha$ lets the first HVR mean

$$p/\beta = p''/\beta'', \tag{53}$$

which is ready to give $p''=p$ for $\beta''=\beta$. Really, assume that $\beta''=\beta$ besides $\alpha''=\alpha$. Then, the two site orbits $\Gamma_1=\{1,2\}$ and $\Gamma_2=\{3\}$ follow immediately. The diagonal region L_{11} contains only one selfdual orbit $\Lambda_1=\{12,21\}$; the off-diagonal region L_{12} does only one nonselfdual orbit $\Lambda_2=\{13,23\}$. We have the SC that



(a)



(b)

Fig. 2. Simple systems.

$q''=q$ and $p''=p$. Intrinsic is only the HVR for Λ_2

$$q - ((\alpha - \alpha')/\beta)p = q' - p', \tag{54}$$

which is reduced further to

$$q = q' - p' \tag{55}$$

in the simple Hückel model.

A Theorem on Invariants in Chains. It will be suitable to mention here a general theorem for chains in the simple Hückel model. Only bifurcation sites being aside, the theorem is valid for any chain part of arbitrary systems. The term "chain part" should be taken here in a broad sense; a chain part is able to have no end site or to be a part of a ring. The theorem is explained in Figs. 3 and 4.

Let K be the set of nonterminal sites $\{1,\cdots,k\}$ in a chain and q_r be the electron density on the site $r\in K$. Each site of K has two adjacent sites; let p_r denote the bond order between the two sites adjacent to r. Define the modified electron density $\tilde{q}_r$ on the site r as

$$\tilde{q}_r = q_r - p_r \qquad (r\in K). \tag{56}$$

Then, the HVC leads us to the invariance of the modified site electron density in the chain;

$$\tilde{q}_r = \tilde{q}_s \qquad (r,s\in K). \tag{57}$$

Moreover, if the chain has an end site, we have

$$\tilde{q}_r = q_0 \qquad (r\in K), \tag{58}$$

where q_0 is the electron density on the end site. Of course, this can be paraphrased into the invariance of the modified site electron density in the chain by the natural definition $\tilde{q}_0=q_0$. Thus, we can assign a unique modified site electron density to a chain.

This theorem holds for any eigenstate of H, whether faithful or not, without regard to the number of electrons or the alternant symmetry. Hence, we may regard the theorem as a generalization of Coulson-Rushbrooke's theorem,[24] as far as chain parts are concerned. Unfortunately, the bifurcation site prevents us from defining the modified electron density on the site uniquely. If we intend to sustain the invariance of the modified site electron density including bifurcation sites, it seems to be inevitable to assign a few direction-dependent modified electron densities to bifurcation sites.

We can generalize the theorem into "the invariance of the modified p-density in a chain" directly. The modified bond order between adjacent sites is definable for chains containing more than one sites apart from bifurcation sites. Here, use single letters $\{1,\cdots,\tau\}$ for nonterminal connected pairs in a chain. Denote the set by T, each pair of which has two adjacent sites. Let p_ξ be the bond order for the pair $\xi\in T$ and p'_ξ be that between the two sites adjacent to ξ. Then, it follows from the HVC that the modified bond order

$$\tilde{p}_\xi = p_\xi - p'_\xi \qquad (\xi\in T) \tag{59}$$

is invariant in the chain;

$$\tilde{p}_\xi = \tilde{p}_\eta \qquad (\xi,\eta\in T). \tag{60}$$

If the chain has an end connected pair, we have

$$\tilde{p}_\xi = p_0 \qquad (\xi\in T) \tag{61}$$

with the bond order p_0 for the end connected pair. It is

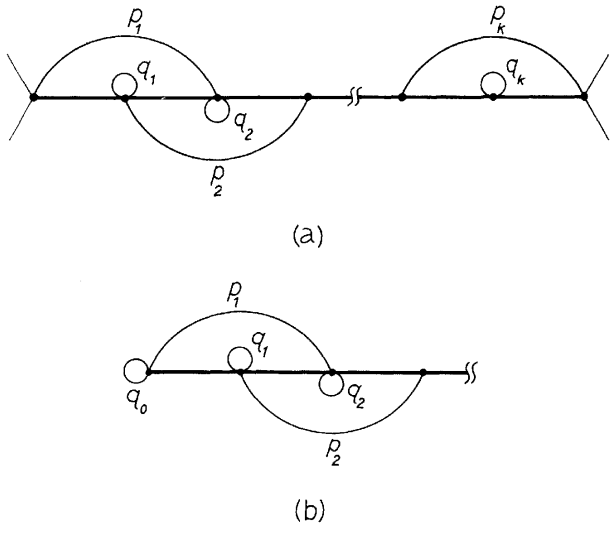


Fig. 3. The invariance of the modified site electron density in a chain: (a) $\tilde{q}_1=\tilde{q}_2=\cdots=\tilde{q}_k$ with $\tilde{q}_r=q_r-p_r$, (b) $\tilde{q}_0=\tilde{q}_1=\tilde{q}_2=\cdots$ with $\tilde{q}_0=q_0$.

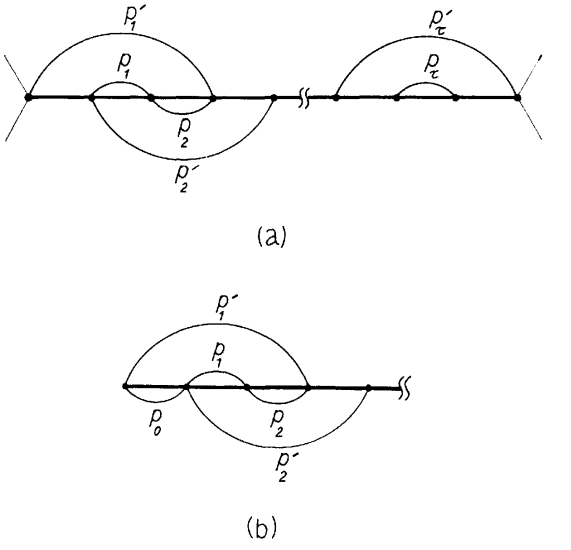

Fig. 4. The invariance of the modified bond order between adjacent sites in a chain: (a) $\tilde{p}_1=\tilde{p}_2=\cdots=\tilde{p}_\tau$ with $\tilde{p}_\xi=p_\xi-p'_\xi$, (b) $\tilde{p}_0=\tilde{p}_1=\tilde{p}_2=\cdots$ with $\tilde{p}_0=p_0$.

easy to apply the above treatment to bond orders between sites distant in a chain, with defining modified bond orders relevantly.

Consider the bond order p_e between the two end sites of a chain. Successive applications of the above theorem for modified p-densities enable us to connect p_e with other two p-densities in a simple way as follows. For even-membered chains, use the bond order p for the central connected pair and the bond order p' for the connected pair adjacent to it; for odd-membered chains, use the electron density q on the central site and the electron density q' on the site adjacent to it. Then, we have

$$\begin{cases} p_e = p - p' & \text{(even-membered)} \\ p_e = q - q' & \text{(odd-membered).} \end{cases} \tag{62}$$

Figure 5 shows a few representatives with the notation.

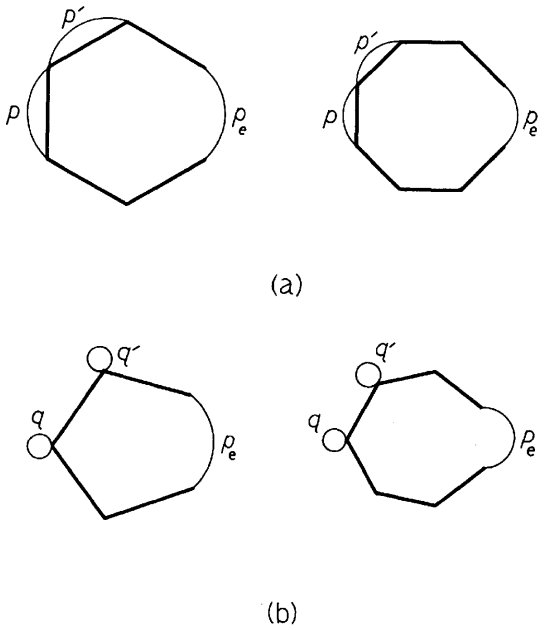

Fig. 5. The bond order between the two ends of a chain: (a) $p_e=p-p'$, (b) $p_e=q-q'$.

Systems of a Ring with a Site Attached. Let us take the simple Hückel model for the system shown in Fig. 6 (a), which is appropriate for practice-minded readers to master handling HVRs. Putting

$$B = \begin{pmatrix} \alpha & \beta & \beta & 0 \\ & \alpha & \beta & 0 \\ & & \alpha & \beta \\ & & & \alpha \end{pmatrix} \tag{63}$$

and

$$P = \begin{pmatrix} q & p & p' & p'' \\ & q & p' & p'' \\ & & q' & p^\circ \\ & & & q^\circ \end{pmatrix}, \tag{64}$$

we have the three site orbits $\Gamma_1=\{1,2\}$, $\Gamma_2=\{3\}$, and $\Gamma_3=\{4\}$. Each of the three off-diagonal regions L_{12}, L_{13}, and L_{23} is a nonselfdual orbit in itself, so that the intrinsic HVRs are

$$\begin{cases} p' - p - p'' = q - q' \\ p^\circ + p'' - p' = 0 \\ 2p'' = q' - q^\circ. \end{cases} \tag{65}$$

Now let us express p', p°, and p'' in terms of the other p-densities q, q', q°, and p. Then, we have

$$p' = p + q - (q' + q^\circ)/2, \tag{66}$$

$$p^\circ = p + q - q', \tag{67}$$

and

$$p'' = (q' - q^\circ)/2. \tag{68}$$

Further, the number condition

$$n = 2q + q' + q^\circ \tag{69}$$

can eliminate, say, q', from these. Using the "excess electron densities on sites"

$$\begin{cases} \underline{q} = q - n/4 \\ \underline{q}^\circ = q^\circ - n/4, \end{cases} \tag{70}$$

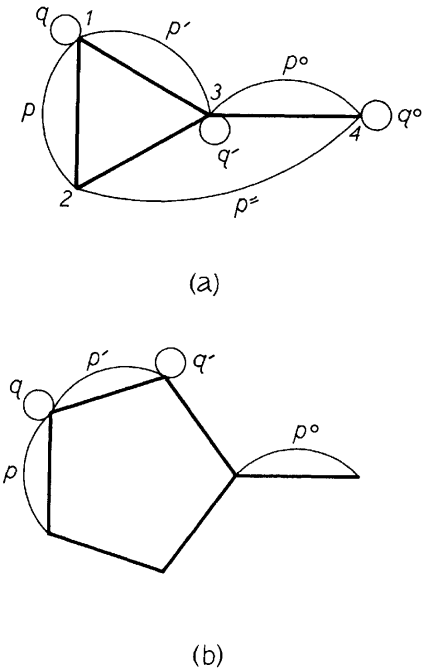

Fig. 6. Systms of a ring with a site attached.

we obtain

$$p' = p + 2\underline{q}, \tag{71}$$

$$p^\circ = p + 3\underline{q} + \underline{q}^\circ, \tag{72}$$

and

$$p'' = -\underline{q} - \underline{q}^\circ. \tag{73}$$

When we take account of the number condition, the concept of excess electron densities on sites is useful in general.

Another system similar to this is shown in Fig. 6 (b) together with the notation used below. Treating the system within the simple Hückel model, we have the four site orbits $\Gamma_1=\{1,2\}$, $\Gamma_2=\{3,4\}$, $\Gamma_3=\{5\}$, and $\Gamma_4=\{6\}$. The off-diagonal region L_{12} contains two nonselfdual orbits, while each of L_{13}, L_{14}, L_{23}, L_{24}, and L_{34} is a nonselfdual orbit in itself. Thus the intrinsic HVC consists of seven HVRs expressed in terms of thirteen p-densities. Here, let us only show a few expressions for p°, without writing the HVRs explicitly. It is easy to derive

$$p^\circ = p' + q - q' \tag{74}$$

from the HVRs. As another expression, say, we have

$$p^\circ = p + 2\underline{q} + \underline{q}', \tag{75}$$

using the number condition.

Systems of a Site over a Ring. Consider the six-site system composed of a pentagonal ring and an additional site over the ring. See Fig. 7. Assuming the five-fold axis, put

$$B = \begin{vmatrix} \alpha^\circ & \beta^\circ & 0 & 0 & \beta^\circ & \beta \\ & \alpha^\circ & \beta^\circ & 0 & 0 & \beta \\ & & \alpha^\circ & \beta^\circ & 0 & \beta \\ & & & \alpha^\circ & \beta^\circ & \beta \\ & & & & \alpha^\circ & \beta \\ & & & & & \alpha' \end{vmatrix} \tag{76}$$

and

$$P = \begin{vmatrix} q^\circ & p_1^\circ & p_2^\circ & p_2^\circ & p_1^\circ & p \\ & q^\circ & p_1^\circ & p_2^\circ & p_2^\circ & p \\ & & q^\circ & p_1^\circ & p_2^\circ & p \\ & & & q^\circ & p_1^\circ & p \\ & & & & q^\circ & p \\ & & & & & q' \end{vmatrix}. \tag{77}$$

Since the site orbits are $\Gamma_1=\{1,\cdots,5\}$ and $\Gamma_2=\{6\}$, we have only one off-diagonal region L_{12}, which is a nonselfdual orbit in itself and gives one HVR. If we define α and q for the ring by

$$\alpha = \alpha^\circ + 2\beta^\circ \tag{78}$$

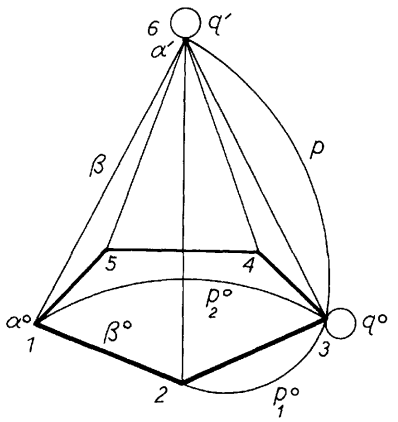

Fig. 7. A site over a pentagonal ring.

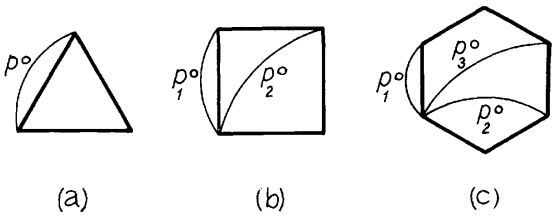

Fig. 8. Ξ's for polygonal rings: (a) $\Xi=2p^\circ$, (b) $\Xi=2p_1^\circ+p_2^\circ$, (c) $\Xi=2p_1^\circ+2p_2^\circ+p_3^\circ$.

and

$$q = q^\circ + \Xi \tag{79}$$

with

$$\Xi = 2p_1^\circ + 2p_2^\circ, \tag{80}$$

we can write the HVR in the same form as that for the asymmetric two-site system as

$$(\alpha - \alpha')p = \beta(q - q'). \tag{81}$$

However, there exists the qualitative difference between them that arises from the contents of α and q. Only when either $(\alpha-\alpha')$ or $(q-q')$ is negative, we have positive p under negative β. Further, for $|p|$ not to be negligible, it is necessary that $|\alpha-\alpha'|$ is comparable with or smaller than $|\beta|$. The contents of α and q are thus significant.

Even if a pentagonal ring is replaced with another polygonal ring of m° sites, we have a HVR of the same form as the above by reading Ξ as the sum of $m^\circ-1$ bond orders between one site and the others of the polygonal ring. A few Ξ's are given in Fig. 8.

Interacting Subsystems. Suppose the six-site system composed of the four- and the two-site chain subsystems interacting with each other. See Fig. 9. The system provides a simple example suggesting some applicability of the HVC to problems on reactivity. Adopting the simple Hückel model in the subsystems and assuming the reflection symmetry, we have

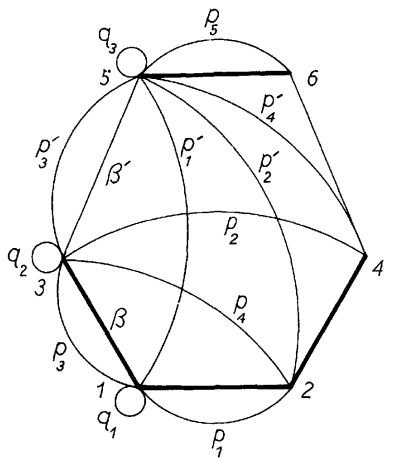

Fig. 9. Interacting four- and two-site subsystems.

$$B = \begin{vmatrix} \alpha & \beta & \beta & 0 & 0 & 0 \\ & \alpha & 0 & \beta & 0 & 0 \\ & & \alpha & 0 & \beta' & 0 \\ & & & \alpha & 0 & \beta' \\ & & & & \alpha & \beta \\ & & & & & \alpha \end{vmatrix} \tag{82}$$

and

$$P = \begin{vmatrix} q_1 & p_1 & p_3 & p_4 & p_1' & p_2' \\ & q_1 & p_4 & p_3 & p_2' & p_1' \\ & & q_2 & p_2 & p_3' & p_4' \\ & & & q_2 & p_4' & p_3' \\ & & & & q_3 & p_5 \\ & & & & & q_3 \end{vmatrix}. \tag{83}$$

The site orbits are $\Gamma_1=\{1,2\}$, $\Gamma_2=\{3,4\}$, and $\Gamma_3=\{5,6\}$; each of L_{12}, L_{13}, and L_{23} contains two nonselfdual orbits. Thus, we have the six HVRs

$$\begin{cases} p_4 - \lambda p_1' = q_1 - q_2 \\ p_2 + p_3 - p_1 - \lambda p_2' = 0 \\ p_3' - \lambda p_3 = 0 \\ p_4' - \lambda p_4 = 0 \\ p_1' - p_4' = \lambda (q_2 - q_3) \\ p_2' - p_3' + \lambda (p_5 - p_2) = 0, \end{cases} \tag{84}$$

where

$$\lambda = \beta'/\beta \tag{85}$$

is regarded as standing for the strength of the interaction between the subsystems. The HVRs allow us to express the four intersubsystem bond orders p_1', p_2', p_3', and p_4' in terms of six relevant intrasubsystem p-densities.

If we use the electron densities q_1, q_2, and q_3 and the intrasubsystem bond orders p_1, p_3, and p_5 between adjacent sites, then we have

$$p_1' = \lambda (1 - \lambda^2)^{-1}(q_1 - q_3), \tag{86}$$

$$p_2' = \lambda (1 - \lambda^2)^{-1}(p_1 - p_5), \tag{87}$$

$$p_3' = \lambda p_3, \tag{88}$$

and

$$p_4' = \lambda (1 - \lambda^2)^{-1} q_1 - \lambda q_2 - \lambda^3 (1 - \lambda^2)^{-1} q_3. \tag{89}$$

The third equation for p_3' is crucial. Let β be negative and p_3 be positive. If $|\beta'|$ is small, then $|p_3'|$ will be small necessarily. The sign of p_3' is, however, opposite to that of β'. This means that $|p_3'|$ can be enlarged in "positive feedback" with $|\beta'|$. Another remarkable point is that p_1' and p_4' are, respectively, closely related to the inter- and intra-subsystem differences between the electron densities. This stands out in the approximate expressions

$$p_1' \simeq \lambda (q_1 - q_3) \tag{90}$$

and

$$p_4' \simeq \lambda (q_1 - q_2) \tag{91}$$

for the weak interaction $|\lambda| \ll 1$.

It is, of course, possible to use other intrasubsystem p-densities than the above. Say, we can rewrite p_3' as

$$p_3' = \lambda (1 - \lambda^2)^{-1} p_1 - \lambda p_2 - \lambda^3 (1 - \lambda^2)^{-1} p_5$$

$$\simeq \lambda (p_1 - p_2) \tag{92}$$

using p_1, p_2, and p_5.

Generally speaking, we should derive the most advisable expression from HVRs to our purpose. As far as the expression is reasonably simple, we will find its physical meaning, aside from whether or not our intuition is able to draw some image about the meaning.

The Hypervirial Condition for Alternant Systems

Many conjugated systems have the alternant symmetry, which leads to the outstanding consequences for the m-electron ground state of an m-site system, Coulson-Rushbrooke's theorem and others.[24,25] It is never futile to mention the HVC for alternant systems specially. For the assignment of starred and unstrarred sites, follow the convention.

Let $M^\star$ and $M^\odot$ be the subsets of M that consist of all the starred sites and all the unstarred sites, respectively. The Hückel matrix of the alternant symmetry has the components

$$b_{rs}=\begin{cases}\delta_{rs}\alpha & (r,s\in M^{\star}\text{ or }r,s\in M^{\odot})\\ \begin{cases}\beta_{rs} & (rs\in Y)\\ 0 & (rs\in\overline{Y})\end{cases} & \begin{pmatrix}r\in M^{\star},\ s\in M^{\odot}\\ \text{or}\\ r\in M^{\odot},\ s\in M^{\star}\end{pmatrix}\end{cases}. \tag{93}$$

Let us use the symbols

$$p_{rs}=\begin{cases}p^{\star}_{rs} & (r,s\in M^{\star})\\ p^{\odot}_{rs} & (r,s\in M^{\odot})\\ p^{\times}_{rs} & (r\in M^{\star},s\in M^{\odot}\text{ or }r\in M^{\odot},s\in M^{\star})\end{cases} \tag{94}$$

distinctively. The set C^s_r contains only either starred or unstarred sites. Let us affix "$\star$" or "$\odot$" to C^s_r to show the attribute of the sites contained therein. It is readily found that the HVC includes the following three classes of HVRs.

$$\sum_{t\in C^s_r\odot}(\beta_{rt}p^{\times}_{ts}-p^{\times}_{rt}\beta_{ts})=0 \qquad (r<s\in M^{\star}), \tag{95}$$

$$\sum_{t\in C^s_r\star}(\beta_{rt}p^{\times}_{ts}-p^{\times}_{rt}\beta_{ts})=0 \qquad (r<s\in M^{\odot}), \tag{96}$$

and

$$\sum_{t\in C^s_r\odot}\beta_{rt}p^{\odot}_{ts}-\sum_{t\in C^s_r\star}p^{\star}_{rt}\beta_{ts}=d_{rs} \qquad (r\in M^{\star},\ s\in M^{\odot}) \tag{97}$$

with

$$d_{rs}=\begin{cases}\beta_{rs}(p^{\star}_{rr}-p^{\odot}_{ss}) & (rs\in Y)\\ 0 & (rs\in\overline{Y}).\end{cases} \tag{98}$$

The primary feature is that $\{p^{\star}_{rs},\ p^{\odot}_{rs}\}$ and $\{p^{\times}_{rs}\}$ enter the HVRs separately. In particular, the first and the second classes concern only the bond orders $\{p^{\times}_{rs}\}$ without regard to any site electron density. Note that, so far, the state is not specified.

Now let us confine ourselves to the m-electron ground state. The well-known two consequences of the alternant symmetry[24,26]

$$\begin{cases}p^{\star}_{rr}=1 & (r\in M^{\star})\\ p^{\odot}_{rr}=1 & (r\in M^{\odot})\end{cases} \tag{99}$$

and

$$\begin{cases}p^{\star}_{rs}=0 & (r\neq s\in M^{\star})\\ p^{\odot}_{rs}=0 & (r\neq s\in M^{\odot})\end{cases} \tag{100}$$

are related to each other through the third class of HVRs, forming an "admissible solution" of the HVRs. Since the rest is only $\{p^{\times}_{rs}\}$, the first and the second classes of HVRs can be utilized for determining them directly with some auxiliary conditions. As a matter of fact, the main condition used by Hall in his method of determining bond orders in alternant systems is really the HVRs.[27] Although he said nothing about the hypervirial theorem there, his method is an interesting application of the HVC.[28]

7) J. O. Hirschfelder, *J. Chem. Phys.*, **33**, 1462 (1961), in which the hypervirial theorem originated. Recently an excellent monograph on this theorem was published: F. M. Fernández and E. A. Castro, "Hypervirial Theorems," Springer-Verlag, Berlin (1987), which has a useful bibliography every chaper. S. T. Epstein, "The Variation Method in Quantum Chemistry," Academic Press, New York (1974) includes a neat description of the hypervirial theorem and several theorems related to it.

8) The word "spin" is used in place of "one-electron spin state" for brevity, which will cause no confusion.

9) Do not take the word "bonded" too literally in defining the connected pair. Then, the semisimple Hückel model is, actually, the most general Hückel model.

10) C. A. Coulson, *Proc. R. Soc. London, Ser. A,* **169**, 413 (1939) and the references cited therein.

11) Without the diagonal components, it would be proper to call this matrix the bond order matrix. Really, this matrix is a kind of density matrices, but the term "density matrix" is so variously used that it is preferable to prefix "*p*" the prevalent symbol for the bond order. Hence the generic name "*p*-density."

12) M. Isihara, *Bull. Chem. Soc. Jpn.*, **54**, 3312 (1981).

13) We can also state that the product *BP* is real symmetric, since both of *B* and *P* are real symmetric.

14) Hückel orbitals do not appear at all throughout the present treatment. Derivation via the orbitals is, of course, possible. However, the derivation seems to be inevitably less general in the specification of the state and to leave the physical ground of the HVC obscure.

15) The adjacency matrix is what Ruedenberg named the topological matrix; K. Ruedenberg, *J. Chem. Phys.*, **22**, 1878 (1954).

16) In some sense, we may say that the HVC in the simple Hückel model depends only on the adjacency, but this should be never misunderstood to mean that bond orders between nonadjacent sites are superfluous.

17) M. Isihara, *Bull. Chem. Soc. Jpn.*, **58**, 2472 (1985); **59**, 3963 (1986).

18) The point group is described in many books on molecular orbital theory. As a standard monograph, F. A. Cotton, "Chemical Applications of Group Theory," John Wiley & Sons, New York (1963).

19) The use of permutation groups is prevalent in constructing spin eigenfunctions for many-electron systems. As another interesting application of permutation groups in quantum chemistry, H. C. Longuet-Higgins, *Mol. Phys.*, **6**, 445 (1963).

20) G. W. Wheland, *Proc. R. Soc. London, Ser. A*, **164**, 397 (1938).

21) For the transitivity, the orbit, and other concepts related to them, consult the literature on group theory, particularly on permutation groups.

22) Say, suppose *G* to be the group consisting of only the identity or a cyclic group of order more than two.

23) A pseudorbit corresponds to an orbit obtained by ignoring the order in site pairs. If only the SC were considered, the nonordered pair would be used from the outset.

24) C. A. Coulson and G. S. Rushbrooke, *Proc. Camb. Phil. Soc.*, **36**, 193 (1940); H. C. Longuet-Higgins, *J. Chem. Phys.*, **18**, 265 (1950).

25) The classical studies cited in Ref. 24 were followed by various developments; for example, A. D. McLachlan, *Mol. Phys.*, **2**, 271 (1959); J. Koutecký, *J. Chem. Phys.*, **44**, 3702 (1966). See also Ref. 4.

26) Note that the state is assumed to be faithful.

27) G. G. Hall, *Proc. R. Soc. London, Ser. A*, **229**, 254 (1955); K. Ruedenberg, *J. Chem. Phys.*, **29**, 1232 (1958).

28) The HVC in the Hückel model seems to have drawn no attention somewhy, at least explicitly. The reason may include the confusion of the HVC with the reality condition or, paradoxically, the tractability of the Hückel orbital theory.

Chelate Stability Constants of *N*-(*o*-Hydroxybenzyl)iminodiacetic Acid (HBIDA) with Yttrium and Lanthanoid Ions

Chelate stability constants of *N*-(*o*-hydroxybenzyl)iminodiacetic acid with yttrium and some lanthanoid ions (M^{3+}) were determined by the potentiometric method at 25 °C and at an ionic strength of 0.1 with potassium nitrate. The computation of the titration data indicated that four kinds of complexes, ML, ML_2^{3-}, $M(HL)^+$, and $M(HL)_2^-$ (except for thulium and lutetium) were formed on each metal ion and the values of the stability constants increased with the increase of atomic number of the element. The values found for the stability constants of yttrium complexes are between those for gadolinium and terbium ions.

It has been reported that *N*-(*o*-hydroxybenzyl)-iminodiacetic acid (HBIDA, H_3L) is a tetradentate chelating ligand in which the phenolic oxygen, in addition to the iminodiacetate group, can coordinate to metal ions such as iron(III), copper(II), nickel(II), zinc(II), and cobalt(II), and their stability constants have also been reported.[1] However, no stability constants have been reported on the HBIDA complexes with lanthanoid and yttrium ions. The chelate stability constants of many amine-*N*-polycarboxylic acids[2] including iminodiacetic acid (IDA)[3] with trivalent lanthanoid ions including yttrium have now been measured to understand the factors which influence the formation and stability of the lanthanoid ion complexes.[4]

It is interesting to study the complexes formation of the ligands which have phenolic oxygen as an additional coordination site such as HBIDA with lanthanoid ions. Accordingly, complex formation of HBIDA with lanthanoid ions has been investigated and their stability constants discussed in comparison with those for IDA and other amine-*N*-polycarboxylic acids.

Experimental

The HBIDA employed was synthesized according to Harris et al.[1] The crude product was recrystallized more than five times from water, and the purity of the final product was checked by elemental analyses, NMR spectrum and molecular weight determination by alkalimetry. The stock solutions of the metal ions were prepared from analytical grade metal nitrates or oxides and were standardized by direct EDTA titration using the appropriate indicator.[5] The 35 cm^3 of the solution containing 0.1 mmol of HBIDA and 0.05 mmol of metal ion was titrated with 0.1 M (1 M=1 mol dm^{-3}) carbonate-free potassium hydroxide solution, and the free hydrogen ion concentration was measured with a Denkikagaku Keiki IOC-10 pH meter by a procedure similar to that described in a previous report.[6] During the titrations, the solutions were kept under a nitrogen atmosphere, at 25±0.5 °C and at an ionic strength of 0.1 with potassium nitrate.

The ultraviolet absorption spectra of the 2×10^{-4} M of ligand solutions were measured at $p[H^+]=11-12.5$ in 1 cm-length quartz cell using a Shimadzu UV-180 spectrophotometer. During the measurements, the sample solutions were kept at 25±0.5 °C and at an ionic strength of 0.1 with potassium nitrate.

Results and Discussion

From the titration data of the ligand in the absence of metal ion, the two final protonation constants were calculated directly using a computer program SUPERQUAD.[7] The first protonation constant was determined by the spectrophotometric method. The following values; $\log K^H_1=11.94$, $\log K^H_2=8.15$, and $\log K^H_3=2.34$, were obtained, respectively. These values were in good agreements with those reported by Harris et al.[1] and were used in the calculations of the stability constants of the metal complexes

The titration data for the 1:2 metal to ligand systems were also analyzed by the use of the same program. The computer calculations indicated the formation of the following complexes, ML, ML_2^{3-}, MLH^+, and $ML_2H_2^-$ (except for thulium and lutetium) and evaluated the values of their stability constants. The results are summarized in Table 1, in which β functions are defined as follows.

$$\beta_1 = [ML]/[M^{3+}][L^{3-}], \quad \beta_2 = [ML_2^{3-}]/[M^{3+}][L^{3-}]^2,$$
$$\beta_{M(LH)} = [M(LH)^+]/[M^{3+}][LH^{2-}] \quad \text{and}$$
$$\beta_{M(LH)_2} = [M(LH)_2^-]/[M^{3+}][LH^{2-}]^2.$$

The value of the stability constant of the 1:1 HBIDA complexes, $\log \beta_1$, increases with an increase in the atomic number of the lanthanoid ions, starting from the first element (11.65 for lanthanum) to the last element (14.87 for lutetium) as shown in Table 1. This stability trend suggests that the HBIDA belongs to the ligand of the first group according to Moeller et al.[4] who have pointed out that the ligand such as IDA and nitrilotriacetic acid (NTA) belonged to the first group. NTA is a well known tetradentate ligand which coordinates to a metal ion with three carboxylate-oxygen atoms and an amino-nitrogen atom, and its stability constants with lanthanoid ions have been reported.[8] The stability constants for the 1:1 HBIDA

Table 1. The Stability Constants, β_n and $\beta_{M(LH)_n}$ (n=1, 2), of HBIDA Complexes of Lanthanoid and Yttrium Ions (25 °C, I=0.1 with KNO_3)

Metal ions	log β_1[a]	log β_2	log $\beta_{M(LH)}$	log $\beta_{M(LH)_2}$

Lu	14.87(0.01)	27.76(0.01)	6.71(0.02)	

a) Values in parentheses are standard deviations.

complexes are higher than those for the NTA complexes, the increments being 1.29 with the lanthanum- and 2.38 with the lutetium complex, in log unit.

On the other hand, the values for the stability constants of the 1:1 HBIDA complexes are about twice as large as those of the 1:1 IDA complexes, in log unit.[3] Since IDA binds to a metal ion as a tridentate ligand in the 1:1 normal complexes, the increase in the stability constants of the HBIDA is likely to be due to the tetradentate nature of the ligand. Such a coordination has been reported on some divalent metal complexes, such as with nickel(II) and zinc(II).[1]

As to the overall stability constants of the 1:2 metal to ligand complexes of HBIDA, log β_2, the value also increases with an increase in the atomic number of the elements, starting from lanthanum (19.67) to lutetium (27.76). It was found from these values that the second stepwise stability constants $K_{ML_2}=[ML_2^{3-}]/[ML][L^{3-}]$ were in a range of 8.02 (lanthanum) to 12.89 (lutetium) in log unit. Such an increase in the values of the second stepwise constants of the 1:2 complexes with an increase in atomic number of lanthanoid ions is common to the complexes by complexane-type or related ligands. Such a trend has been also found in the values of the second stepwise stability constants of the 1:2 metal to IDA complexes in which no steric hindrance due to the coordinated ligands has been found.[3] This suggests that no steric hindrance occurs between the two ligands in the 1:2 HBIDA complexes as in the case of the IDA complexes.[3] The corresponding value for the 1:2 yttrium complex is found in between those for gadolinium and terbium as in the case of the 1:1 complex.

The stability constant of the protonated 1:1 HBIDA complex, log $\beta_{M(LH)}$, also increases with the increase in the atomic number of the element. The value for the yttrium complex is again found in lie between the values for the gadolinium and terbium complexes as in the case of the nonprotonated complexes. These values are smaller than those of the 1:1 IDA complexes, indicating that, in the protonated 1:1 metal to HBIDA complex, the phenolate oxygen is not involved in the coordination, but is protonated to form a free phenol group. Eventually, HBIDA is likely to behave as tridentate ligand.

Concerning the overall stability constant of the protonated 1:2 HBIDA complex, the values for log $\beta_{M(LH)_2}$ are higher than those of the 1:2 IDA complexes for the lighter lanthanoid group.[3] However, the increments decrease with an increase in the atomic number of the elements; both values become almost same at holmium, then, the values for the IDA complex becoming higher than those for the HBIDA only after the erbium complex. These results suggest that the diprotonated 1:2 HBIDA complexes of the lighter lanthanoid ions are unusually stable, if one remembers that the stabilities of the protonated 1:1 HBIDA complexes are lower than those of the 1:1 IDA complexes. The second stepwise stability constant of the diprotonated 1:2 HBIDA complex ($K_{M(LH)_2}=[M(LH)_2^-]/[M(LH)^+][LH^{2-}]$) was found to be 5.92 in log units at lanthanum from Table 1. This value is higher by 0.97 log units than the value for the first constant. The value for the second stepwise constant becomes smaller with the increasing atomic number of the lanthanoid elements, but it is still in a similar level of the first ones at erbium and at ytterbium. These rather high values for the overall stability constants of the diprotonated 1:2 HBIDA complex seem to be exceptional, if one remembers that the second stepwise stability constant does not generally exceed that of the first one. In the case of the transition metal complexes of HBIDA, the values for the second stepwise stability constants are 65.0 and 63.1 per cent of the first ones, for cobalt(II) and zinc(II), respectively. Thus,

the unusually high values for the diprotonated 1:2 HBIDA complex are peculiar to the lanthanoid ions, and may be partly due to hydrogen bonding between two free phenol groups of the coordinated HBIDA. In the case of the transition metal complexes, the ionic radii are too small to allow the formation of such hydrogen bonding.

Thermotropic Behavior of Proteins and Acylated Proteins in Monolayers

Tomoyoshi MITA
Department of Natural Science, Osaka Women's University,
Daisen-cho, Sakai, Osaka 590
(Received December 19, 1988)

In order to obtain information concerning the effect of proteins on the thermotropic properties of biological membranes, the temperature-dependences of monolayers of different proteins and some acyl derivatives of bovine serum albumin (BSA) have been investigated. The hydrophobic proteins such as hemoglobin, β-lactoglobulin, and β-casein formed dilute monolayers, whereas the hydrophilic proteins such as cytochrome C and lysozyme formed concentrated monolayers. BSA showed an intermediate isotherm between those of dilute and concentrated films. The monolayers of BSA, cytochrome C, and lysozyme were gradually expanded with increasing temperatures. However, the temperature-dependences of the monolayers of hemoglobin, β-lactoglobulin, β-casein, and acyl derivatives were significantly different from those of the monolayers of hydrophilic proteins. In detail, the monolayers of hemoglobin and β-lactoglobulin formed the most compact structures around 20 °C and 30 °C, respectively, while the monolayers of β-casein formed the most expanded structure around 30 °C. In addition, the monolayers of acetyl and propionyl derivatives formed the most compact structures around 30 °C. These results suggest that the hydrophobicity of protein is an important factor relating to thermal stability of proteins in monolayers.

Lipids and proteins are the main constituents of biological membranes. One of the major concerns in membrane biology is to understand how lipids and proteins interact with each other and how such interaction affects the properties of both lipids and proteins in membranes.

Membrane properties are sensitive to environmental influences such as temperature. From this viewpoint, the protozoan *Tetrahymena pyriformis* has been used as the model system for investigating molecular mechanisms involved in cellular acclimation to environmental temperature extremes.[1-3] Furthermore, the effects of lipids on the thermotropic properties of biological membranes have been investigated extensively.[4-11] However, the interpretation of such studies may be complicated by the present lack of detailed information concerning the effect of proteins on the thermotropic properties of biological membranes. One way to gain detailed insight into the molecular aspects of such interactions may be to investigate the thermotropic properties of proteins in membranes.

Because of the strongly amphipathic nature of protein, the change to an extended conformation in which the protein molecule lowers the Gibbs energy of the system by maximizing contact of nonpolar side chains with the nonpolar phase, within steric limitations, is understandable.[12] In biological membranes, integral proteins penetrate the hydrocarbon region (hydrophobic), while peripheral proteins are located adjacent the outer or inner surface (hydrophilic) of the membranes. The integral proteins are arranged in such a manner that their polar groups are either exposed to the aqueous environment or associated electrostatically with the hydrophilic groups of membrane, while nonpolar parts of the protein maintain contact with the inner hydrophobic region.[13] From this viewpoint, Jähnig[14] has analyzed the factors that effect the thermodynamics of the partitioning of proteins between aqueous and membrane phases, and demonstrated that the hydrophobic effect provides the main driving force for insertion into the membrane.

In order to model the physical properties of biological membranes, artificial bilayers such as vesicle, planar bilayers such as black lipid membrane, and monolayers are often used. Although the monolayer does not completely mimic the specific environments of cell membrane surfaces, the study of spread monolayers offers useful insights into the surface conformational behavior of proteins.[15] Another advantage of using a monolayer technique is that the orientation of the protein molecules at the interface is understood precisely and the area occupied by each molecule can be determined over wide limits by careful compression of the film.

With this in mind, the author started the current work to estimate the thermotropic behavior of different native proteins in monolayers. Although the proteins used were not membrane bound but water soluble, they were chosen because of their well-known amino acid sequences and three dimensional structures. On the other hand, the hydrophobicity of proteins can be converted by the technique of selective chemical modification. For example, acylation of lysine side chains in proteins is not only the modification leading to loss of charge, but the reaction leading to significant increase of hydrophobicity. Therefore some acyl derivatives of protein have been used as a model for investigating the hydrophobic effect.[16] The present work also intends to investigate the contributions of hydrophobic effects of proteins in membranes through measurements of the temperature-dependence of monolayers of some acylated proteins.

Experimental

Chemicals. All chemicals were of the highest purity available, used without further purification. Water was distilled once, passed through a mixed ion bed exchanger, and redistilled.

Proteins. The following proteins of high purity were used in this study as obtained from the suppliers: Bovine serum albumin (BSA), bovine hemoglobin (2×crystallized), horse cytochrome C (Type III), β-casein, and β-lactoglobulin (contain variant A and B) were from Sigma Chemical Co., lysozyme (6×crystallized) was a product of Seikagaku Kogyo Co. (Japan).

Acylation of the Proteins. For this study the acetyl, propionyl, butyryl, and palmitoyl derivatives of BSA were prepared by the method of Fraenkel-Conrat.[17] Satisfactory compounds were obtained by reacting with appropriate anhydride in 50% saturated sodium acetate solution at 0 °C. Acetylation required 1 h, whereas propionylation and butyrylation required 2 h. The palmitoyl derivative was prepared by reacting BSA in 50% saturated sodium acetate solution with palmitic anhydride dissolved in ethanol, at 50 °C.[18] Palmitoylation required 10 min. The reaction mixtures were exhaustively dialyzed against water to remove excess reagent. The palmitoyl derivative was then washed with diethyl ether to remove unreactive palmitic anhydride. These derivatives were isolated by lyophilization.

Extent of Acylation. The extent of acylation of BSA was measured by the loss of ninhydrin-positive color in the derivatives compared to BSA.[19]

Apparatus. A Kyowa's surface pressure apparatus (Kyowa Surface Science Co.) was used. The film balance is fully automated and provide with continuous recording of surface pressure versus film area. The inside dimensions of the Teflon-coated trough were 70×14×0.5 cm.

Spreading Solvents. A 50% 1-propanol containing 0.5 mol dm^{-3} sodium acetate was employed as a spreading solvent for BSA, hemoglobin, β-casein, cytochrome C, and lysozyme. Acidic chloroform-methanol (2:1 v:v with 1 cm^3 concd HCl/250 cm^3 solvent)[20] was used for β-lactoglobulin, acetyl-BSA, and propionyl-BSA. A 50% 1-propanol containing 0.05 mol·dm^{-3} sodium carbonate was used for butyryl-BSA and palmitoyl-BSA. These solutions were stored in the refrigerator and used after about 24 h. Comparison of spreading solvents was made by spreading BSA from a 50% 1-propanol containing 0.5 mol·dm^{-3} sodium acetate. No difference was found in the surface pressure-area isotherm.

Surface Pressure. Surface pessure was measured by the Wilhelmy method, using a roughened glass plate. The films were compressed by the moveable Teflon barrier. In the experiments reported below, no buffer was used, in order to provide a very simple subphase. The water was poured into the trough to a height of 1—2 mm above the rim. The surface of the substrate was cleaned by moving the Teflon barrier from one side of the trough to the other. The cleaning of the surface was repeated until the surface pressure of the substrate did not exceed 0.2 mN·m^{-1}. Constant temperature were controlled by running water in the trough surrounded by a water jacket and regulated by a Cool Mate (TE-105 M, Toyo Seisakusho Co.) circulation bath. The temperature was monitored below and as close as possible to the surface of the water phase. The monolayers were made on the surface by using a microsyringe (Hamilton Co.). For the surface pressure-area (π-A) isotherms, exactly 0.05 mg of protein was spread from a 0.05% solution onto an area of 897 cm^2. Monolayer spreading was made by the direct application of numerous small drops (≈0.0006 cm^3) of spreading solution to the surface of the substrate. A time interval of 30 min was allowed for the equilibration of the monolayer before it was compressed. The π-A isotherms for proteins were made by using a compression velocity of 0.0567 $m^2 \cdot mg^{-1} \cdot min^{-1}$. Each part of the experiment was replicated at least three times and then averaged.

Results

Unlike the common substances studied as insoluble monolayers, quantitative spreading of water soluble proteins requires that none is able to dissolve into the bulk solution and diffuse away. For this purpose, two techniques are developed.[21] One is achieved by allowing a very thin layer of the solution to flow down a glass rod before reaching the water surface, this was just introduced by Trurnit.[22] Another satisfactory quantitative spreading technique is also achieved by the direct application of small drops of protein solution which is prepared with 50% 1-propanol containing 0.5 mol·dm^{-3} sodium acetate, as introduced by Ställberg and Teorell.[23] A comparison of the two spreading techniques was made using lysozyme. No difference was found between the two techniques, and the latter was used in this study.

Characteristics of Protein Monolayers at an Air-Water Interface. The wide variety of surface behavior exhibited by proteins at the air-water interface is illustrated by the properties of β-casein, hemoglobin, β-lactoglobulin, BSA, cytochrome C, and lysozyme. Figure 1 shows the π-A isotherms obtained at 25 °C for monolayers of the six proteins spread on water. β-

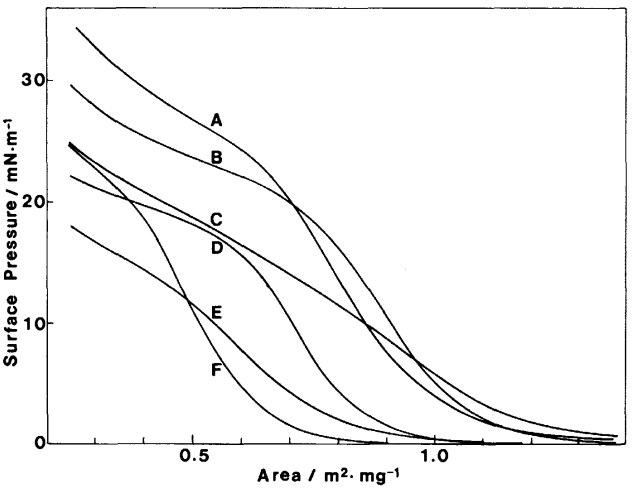

Fig. 1. π-A isotherms for monolayers of different proteins spread on water at 25 °C. A) β-Lactoglobulin, B) hemoglobin, C) β-casein, D) BSA, E) cytochrome C, F) lysozyme.

Table 1. Some Structural Parameters, Ratio of Polar to Apolar Amino Acid Residues, and Hydrophobicity Parameters for Various Proteins

Protein	Polar-apolar ratio	Hydrophobicity parameter, $H\phi_{ave}$ /kJ·res.$^{-1}$	Helix content (%)	SS bond content per molecule	Molecular weight
β-Casein	0.86	5.57	10	0	23000
Hemoglobin	1.09	4.65	75	0	64500
β-Lactoglobulin	1.28	4.98	55	2	18400
BSA	1.63	4.35	55	17	66300
Cytochrome C	2.04	4.23	45	0	11700
Lysozyme	2.26	4.06	35	4	14300

Casein, hemoglobin, and β-lactoglobulin formed dilute monolayers, whereas cytochrome C and lysozyme formed concentrated films. BSA showed an isotherm intermediate between those of the dilute and concentrated films. Dilute protein monolayers are supposed to be completely unfolded molecules, whereas concentrated films are considered to contain incompletely unfolded molecules.[24]

Some structural parameters of these proteins are summarized in Table 1, together with the ratio of polar to apolar amino acid residues and the hydrophobicity parameter. The values of the ratio of polar to apolar amino acids were estimated by Hatch's theory.[25] Proteins with a large proportion of apolar residues exhibit the lower values of the ratio of polar to apolar amino acids (below 1.5). The hydrophobicity parameter, the average hydrophobicity ($H\phi_{ave}$), is based on Tanford's Gibbs energies to transfer the amino acid side chains from an organic environment to an aqueous environment.[26] This was calculated by Bigelow's theory.[27] Proteins with high hydrophobicity exhibit the higher values of $H\phi_{ave}$ (over 4.6 kJ·res.$^{-1}$). It is clear from Fig. 1 and Table 1 that proteins such as β-casein, hemoglobin, and β-lactoglobulin, with either a high content of apolar residues or high hydrophobicity, unfold more easily than proteins such as cytochrome C and lysozyme, with either a low content of apolar amino acids or low hydrophobicity.

Effect of Temperature on Various Protein Monolayers at an Air-Water Interface. The π-A isotherms for various protein monolayers over a range of temperature 10—40 °C are shown in Figs. 2—7. Figures 2—4 show the isotherms for the monolayers of BSA, cytochrome C, and lysozyme spread on water at different temperatures, respectively. These monolayers gradually expanded with increasing temperature. Figures 5—7 show the isotherms for the monolayers of hemoglobin, β-lactoglobulin, and β-casein spread on water at different temperatures, respectively. The temperature-dependences of the monolayers of these proteins were considerably smaller than those of the monolayers of hydrophilic proteins such as BSA, cytochrome C, and lysozyme over the whole temperature range measured. Figure 8 shows the plots of area as a function of temperatures for various protein monolayers at (a)

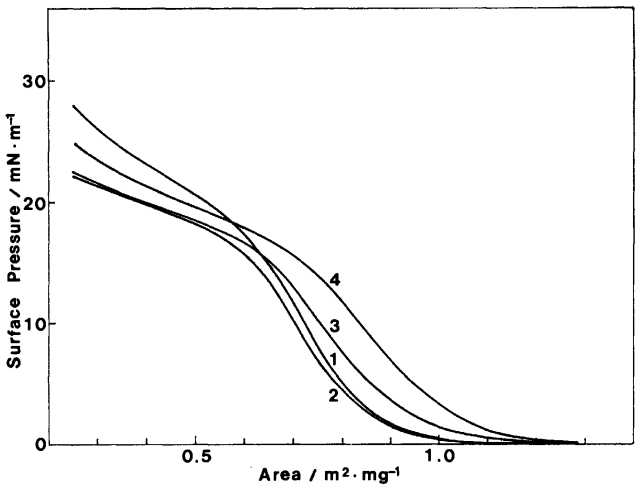

Fig. 2. π-A isotherms for BSA monolayer at different temperatures. Isotherm temperatures are numbered with increasing temperatures: 1) 12.9 °C, 2) 23.1 °C, 3) 33.5 °C, 4) 43.0 °C.

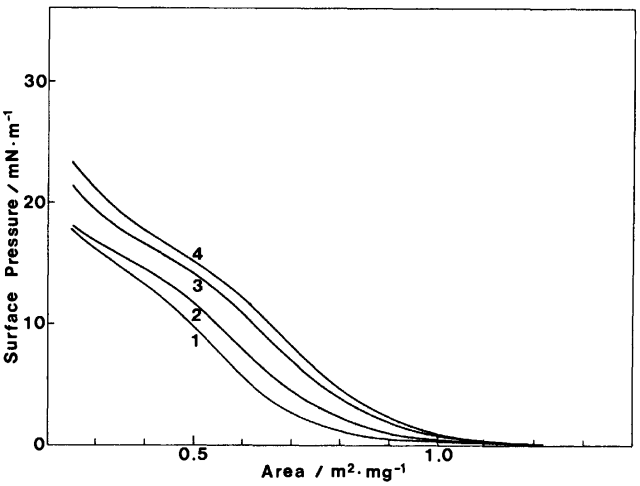

Fig. 3. π-A isotherms for cytochrome C monolayer at different temperatures. 1) 11.9 °C, 2) 24.1 °C, 3) 32.8 °C, 4) 41.0 °C.

π=5 mN·m^{-1} and (b) π=15 mN·m^{-1}, derived from Figs. 2—7. The result indicates that BSA, cytochrome C, and lysozyme at the interface exhibit the extended conformations with increasing temperatures, while

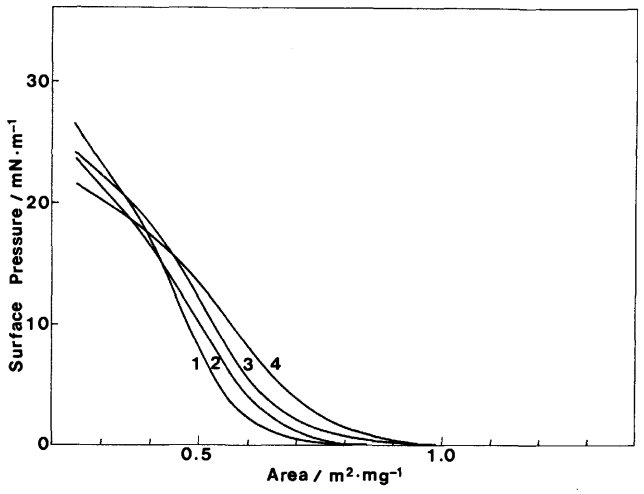

Fig. 4. π-A isotherms for lysozyme monolayer at different temperatures. 1) 10.6°C, 2) 15.4°C, 3) 25.1°C, 4) 34.5°C.

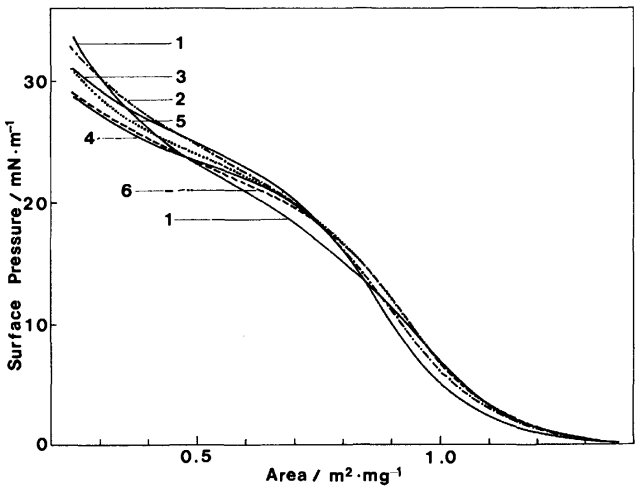

Fig. 5. π-A isotherms for hemoglobin monolayer at different temperatures. 1) 7.2°C, 2) 11.2°C, 3) 19.8°C, 4) 24.4°C, 5) 32.7°C, 6) 41.8°C.

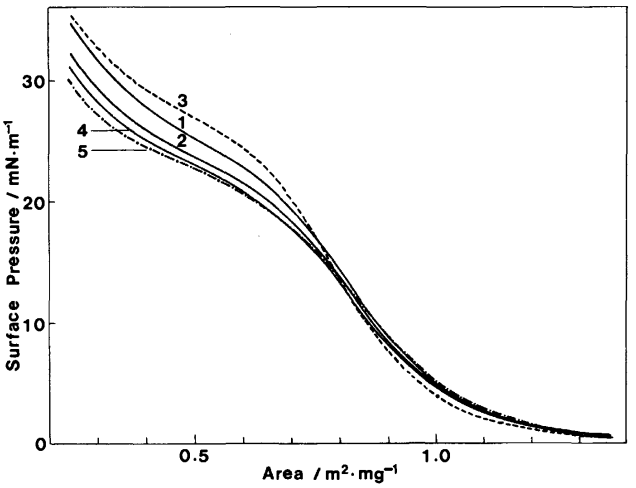

Fig. 6. π-A isotherms for β-lactoglobulin monolayer at different temperatures. 1) 11.6°C, 2) 16.3°C, 3) 26.7°C, 4) 39.8°C, 5) 45.9°C.

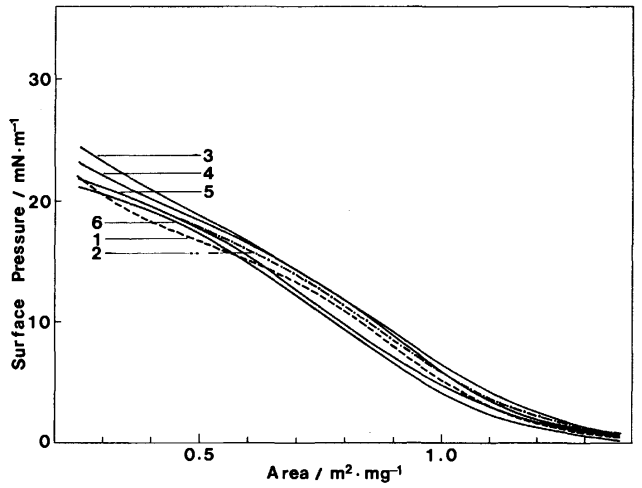

Fig. 7. π-A isotherms for β-casein monolayer at different temperatures. 1) 9.5°C, 2) 16.6°C, 3) 24.5°C, 4) 29.4°C, 5) 36.8°C, 6) 39.5°C.

hemoglobin and β-lactoglobulin at the interface exhibit the most compact conformations around 20 °C and 30 °C, respectively, and β-casein exhibits the most extended conformation around 30 °C.

Characteristics of Monolayers of BSA and Its Derivatives at an Air-Water Interface. On acylation the amino groups involved were principally the ε-NH_2 of the lysines and the terminal amino group of the protein.[16] Tanford[26] has shown that the Gibbs energy change to be expected when methylene or methyl groups are transferred from organic solvent to water is +3.06 kJ·mol^{-1} at 25 °C. By using this value, acylated lysines, i.e., acetyl, propionyl, butyryl, and palmitoyl lysines were assigned hydrophobicities of 15.3, 18.4, 21.4, and 64.1 kJ·mol^{-1}, respectively. $H\phi_{ave}$ is the total hydrophobicity divided by the number of residues.[27] $H\phi_{ave}$ of acyl derivatives of BSA in this way could be calculated. Table 2 shows the extent of substitution of amino acid residues and $H\phi_{ave}$ of BSA and its derivatives.

Figure 9 shows the isotherms obtained at 25 °C for monolayers of BSA and its derivatives spread on water. An interesting feature of these isotherms is the expansion as the length of alkyl side chain on the modifying acyl group was increased up to n=2 (propionyl) but the condensation as it was further increased up to n=15 (palmitoyl), compared to the isotherm of BSA.

Effect of Temperature on Monolayers of Acyl Derivatives of BSA at an Air-Water Interface. The π-A isotherms for the monolayers of acyl derivatives of BSA over a range of temperature 10—40 °C are shown

Table 2. Degree of Substitution of Amino Acid Residues and Hydrophobicity Parameters for BSA and Its Derivatives

BSA and its derivative	Degree of substitution of amino acid residue (%)	Hydrophobicity parameter, $H\phi_{ave}$/kJ·res.$^{-1}$
BSA	—	4.35
Acetyl-BSA	66.9	4.98
Propionyl-BSA	67.4	5.19
Butyryl-BSA	63.9	5.36
Palmitoyl-BSA	98.5	10.17

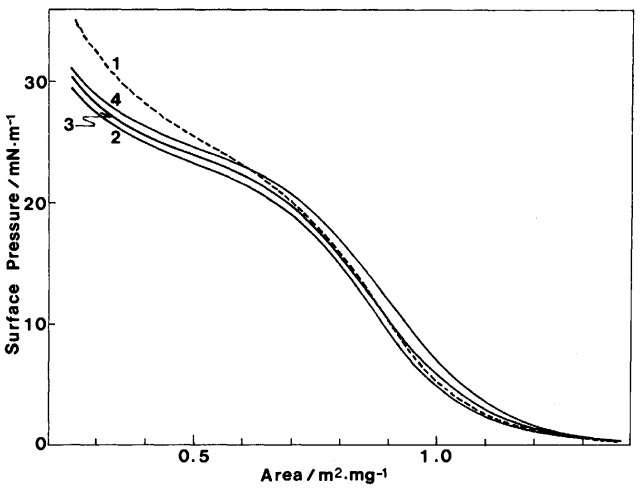

Fig. 11. π-A isotherms for propionyl-BSA monolayer at different temperatures. 1) 11.1°C, 2) 24.0 °C, 3) 35.1°C, 4) 41.3°C.

in Figs. 10—13. Figures 10 and 11 show the isotherms for acetyl-BSA and propionyl-BSA monolayers spread on water at different temperatures, respectively. The isotherms of their derivatives showed a decremental shift with increasing temperatures up to 30 °C but an incremental one with increasing temperatures above 30 °C, indicating that the temperature-dependences of their derivatives were essentially different from that of BSA in Fig. 5. Figures 12 and 13 show the isotherms for butyryl-BSA and palmitoyl-BSA monolayers spread

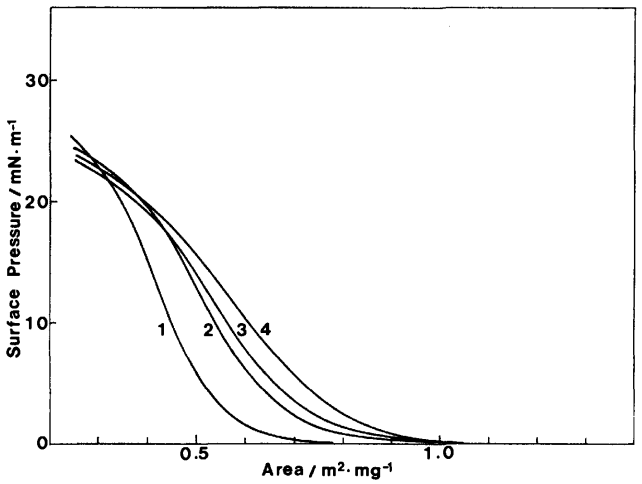

Fig. 12. π-A isotherms for butyryl-BSA monolayer at different temperatures. 1) 8.6°C, 2) 23.6°C, 3) 30.9°C, 4) 42.9°C.

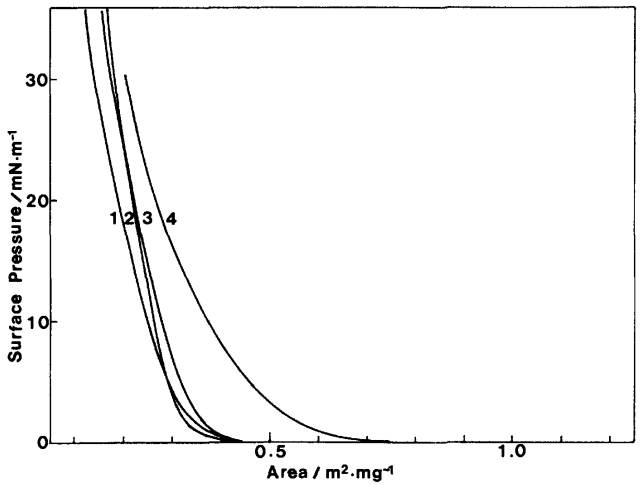

Fig. 13. π-A isotherms for palmitoyl-BSA monolayer at different temperatures. 1) 12.5°C, 2) 23.0°C, 3) 32.5°C, 4) 42.2°C.

on water at different temperatures. These monolayers were gradually expanded with increasing temperatures, although the hydrophobicities of their derivatives were higher than those of acetyl and propionyl derivatives. Figure 14 shows the plots of area as a function of temperature for the monolayers of BSA and its derivatives at (a) π=5 mN·m^{-1} and (b) π=15 mN·m^{-1}, derived from Figs. 2 and 10—13. The result indicates that acetyl and propionyl derivatives at the interface exhibit the most compact conformations around 30°C, while that butyryl and palmitoyl derivatives exhibit the extended conformations with increasing temperatures.

Discussion

It is assumed that proteins at an air-water interface lose their tertiary structure. They exist in extended

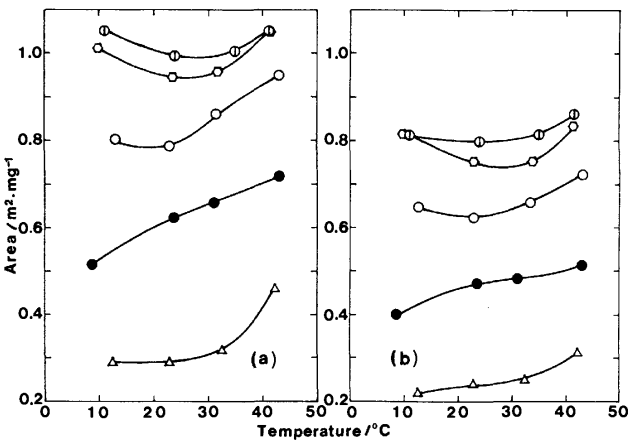

Fig. 14. Plots of area as a function of temperature for monolayers of BSA and its derivatives at (a) π=5 mN·m^{-1} and (b) π=15 mN·m^{-1}, derived from Figs. 2 and 10—13. ○, BSA; ○, acetyl-BSA; ⊕, propionyl-BSA; ●, butyryl-BSA; △, palmitoyl-BSA.

conformations with hydrophobic domains oriented at the interface and hydrophilic domains directed toward the aqueous phase. However, the unfolding of a protein molecule at the interface is not infinite but within steric limitations such as intramolecular disulfide bonding. Accordingly, the unfolding of proteins at the interface is considered as follows. The hydrophobic proteins such as β-casein, hemoglobin, and β-lactoglobulin unfold more easily than the hydrophilic proteins such as cytochrome C and lysozyme. Particularly, β-casein is a flexible more or less random coil molecule without any disulfide bond and with a low helix content, while lysozyme is a rigid globular molecule, the peptide chain being crosslinked by four disulfide bonds (Table 1). In this way, the degree of unfolding may be influenced not only by the hydrophobicity but by the flexibility of the molecule. Similar results have been obtained by Evans et al.,[16] Birdi,[28] and Graham and Phillips.[29]

Privalov et al.[30-33] has extensively studied the stability of the native conformation of proteins in an aqueous phase. The stability of the protein is usually described in terms of the denaturation Gibbs energy for the unfolded and native conformations. That is, the Gibbs energy of protein unfolding, $\Delta G^u(T)$, can be expressed as

$$\Delta G^u(T) = \Delta H^u(T) - T\,\Delta S^u(T) \qquad (1)$$

where $\Delta H^u(T)$ and $\Delta S^u(T)$ are the net change of enthalpy and entropy of protein unfolding, respectively. $\Delta G^u(T)$ is generally shown as a function of temperature. According to Privalov and Khechinashvili,[30] $\Delta G^u(T)$~T curves for lysozyme and ribonuclease decrease steeply with increasing temperatures, respectively. However, $\Delta G^u(T)$~T curves for myoglobin and trypsin

inhibitor have the maximum values at about 30 °C and decrease again with decreasing temperatures, indicating so-called cold denaturation.[34] A similar result has been obtained by Ooi and Oobatake.[35] The extent of protein unfolding may be correlated to the Gibbs function as follows. The native protein progressively unfolds with diminishing the Gibbs energy. In this way, the hydrophilic proteins such as lysozyme (see Table 1) and ribonuclease (polar–apolar ratio of 2.64, average hydrophobicity of 3.68 kJ·res.$^{-1}$) tends to unfold with increasing temperatures, while the hydrophobic proteins such as myoglobin (polar–apolar ratio of 1.26, average hydrophobicity of 4.84 kJ·res.$^{-1}$) and trypsin inhibitor (polar–apolar ratio of 1.57, average hydrophobicity of 4.94 kJ·res.$^{-1}$) aquire the most compact structures around 30 °C.

The thermodynamics of protein adsorption at an interface has been noted by MacRitchie,[36] indicating that the entropy gain due to hydrophobic domains is the dominant factor governing protein adsorption at an interface. Therefore, the above phenomenon in the aqueous phase would apply to protein unfolding at the interface, i.e., the temperature-dependence of unfolding of protein in membranes would be dependent on the degree of hydrophobicity of the protein. The hydrophilic proteins such as BSA, cytochrome C, and lysozyme at the interface exhibited the extended conformations with increasing temperatures (Figs. 2—4 and 8). In addition, the hydrophobic proteins such as hemoglobin and β-lactoglobulin at the interface exhibited the most compact conformations around 20 °C and 30 °C, respectively (Figs. 5, 6, and 8). It is particularly interesting that hemoglobin which is similar to myoglobin in structure and function exhibits the behavior of cold denaturation at the interface. These results suggest that Privalov's thermodynamics may be applied to the mechanisms of protein unfolding not only in the aqueous phase but also at an interface.

However, the thermotropic behavior of β-casein monolayer is in conflict with the above consideration. This may be explained as follows. The decrease in the Gibbs energy is attributed to a hydration effect due to hydrated water around the protein molecule.[35] In this sense, the hydration effect of the protein at the interface will be diminished compared to that of the protein in the aqueous phase. β-Casein, a flexible more or less random coil molecule, may exist in a completely extended conformation with its hydrophobic domains oriented at the interface and its hydrophilic domains directed toward the aqueous phase. Accordingly the thermotropic behavior of β-casein at the interface may be significantly different from that of β-casein in the aqueous phase.

The above speculation was confirmed by investigating the thermotropic behavior of monolayers of acyl derivatives of BSA. The monolayers of acetyl-BSA and propionyl-BSA, where the hydrophobic domains were introduced by acylation of the lysine side chains, were more expanded than that of unmodified BSA (Fig. 9). Furthermore, the isotherms for the acetyl and propionyl derivatives showed distinct decremental shifts with increasing temperatures up to 30 °C, but an incremental one with further increasing temperatures, i.e., these derivatives exhibited the most compact conformations at the interface around 30 °C (Figs. 10, 11, and 14).

On the other hand, the monolayers of butyryl and palmitoyl derivatives, where the hydrophobicities were higher than those of acetyl and propionyl derivatives, were more condensed than that of unmodified BSA. In addition, the monolayers of the butyryl and palmitoyl derivatives were simply expanded with increasing temperatures, despite their significantly high hydrophobicities (Figs. 12—14, Table 2). Particularly, both the shape of the isotherm and the temperature-dependence of the monolayer of the palmitoyl derivative were similar to those of dipalmitoylphosphatidylcholine (DPPC). Phillips[4] has discussed the temperature-dependence of lipid monolayers in the following terms. When the hydrocarbon chains are sufficiently long, condensed monolayers are formed, whereas with shorter chains, liquid-expanded films occur. When the temperature is greater than the phase transition temperature T_c (41 °C in the case of DPPC), the monolayer is completely expanded and the π–A isotherm does not show an intermediate region. When the temperature is considerably lower than T_c, the monolayer will be fully condensed. At intermediate temperatures, the π–A isotherms show the well-pronounced change of slope due to the onset of two-dimensional crystallization. It is seen from Fig. 12 and Table 2 that the apparent area occupied per palmitoyl side chain in the monolayer of palmitoyl-BSA is 7.0×10^{-19} m^2 at 23 °C. When DPPC is spread on water, the area per molecule in the monolayer is about 4.8×10^{-19} m^2 below T_c.[4] Since palmitoyl side chains therefore comprise about 34% of the total area at the air–water interface, the thermotropic behavior of the palmitoyl side chains will become pronounced rather than that of hydrophobic domains in protein.

In conclusion, the results obtained in this study suggest that the hydrophobicity of the protein is the dominant factor determining the thermal stability of proteins in monolayers. This study is being continued to obtain further information about the hydrophobic effect of proteins in membranes through the measurements of the temperature-dependence on mixed monolayers constituted of proteins and lipids.

The skillful technical assistance of Misses Junko Hata, Kyoko Morikawa, Sizuko Nomura, and Kana Tabata is gratefully acknowledged.

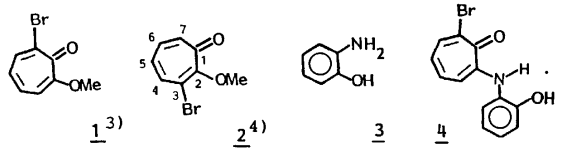
(Received January 5, 1989)

The reaction of 6-bromocyclohepta[*b*][1,4]benzoxazine (**19**) and *o*-aminophenol (**3**) was studied and compared with that of 3-bromo-2-methoxytropone (**2**) with **3**. 14H-[1,4]Benzoxazino[3′,2′:3,4]cyclohepta[1,2-*b*]-[1,4]benzoxazine, 10-(*o*-hydroxyanilino)cyclohepta[*b*][1,4]benzoxazine (**D**), 1- and 4-formylphenoxazines and their Schiff bases (**C** and **X**) were obtained in very good yields by modifying the conditions of the reaction of **19** with **3**. Structures of **D**, **C**, and their isomers were determined and the possible reaction pathways for the formation of various products are discussed.

We have reported that the reaction of 2-bromo-7-methoxytropone (**1**) and 3-bromo-2-methoxytropone (**2**) with *o*-aminophenol (**3**) in refluxing acetic acid gave quite different results: while **1** afforded mainly 2-bromo-7-(*o*-hydroxyanilino)tropone (**4**) besides small amounts of two by-products (compounds **A** and **B**, vide infra),[3] the reaction of **2** turned out to be very



1[3] 2[4] 3 4

complex, giving various colorful products, which were easily separated by preparative silica-gel TLC and conveniently named compounds **A**—**L** according to their decreasing R_f-values.[4] The structures of most of these compounds (**A**, **B**, **F**, **G**, **J**, and **L**) were determined by spectroscopy, as shown in Chart 1. Among them, compounds **5** (**G**) and **6** (**J**) were 1:1 condensation products, whereas compounds **10** (**A**), **7** (**B**), **C**, **D**, **9** (**F**), and **8** (**L**) were 1:2 condensation products; compound **B** was a secondary product from compound **C** (see below). Compound **D** (**15**, Scheme 1) changed to compound **A** (**10**) by autoxidation, while compound **C** (**18**, Scheme 1) gradually decomposed to compound **B** (**7**) on heating in methanol.[4] However, since **C** and **D** were not isolated as pure materials, we could not determine their exact structures at that time.

8 (L) 9 (F) 10 (A)

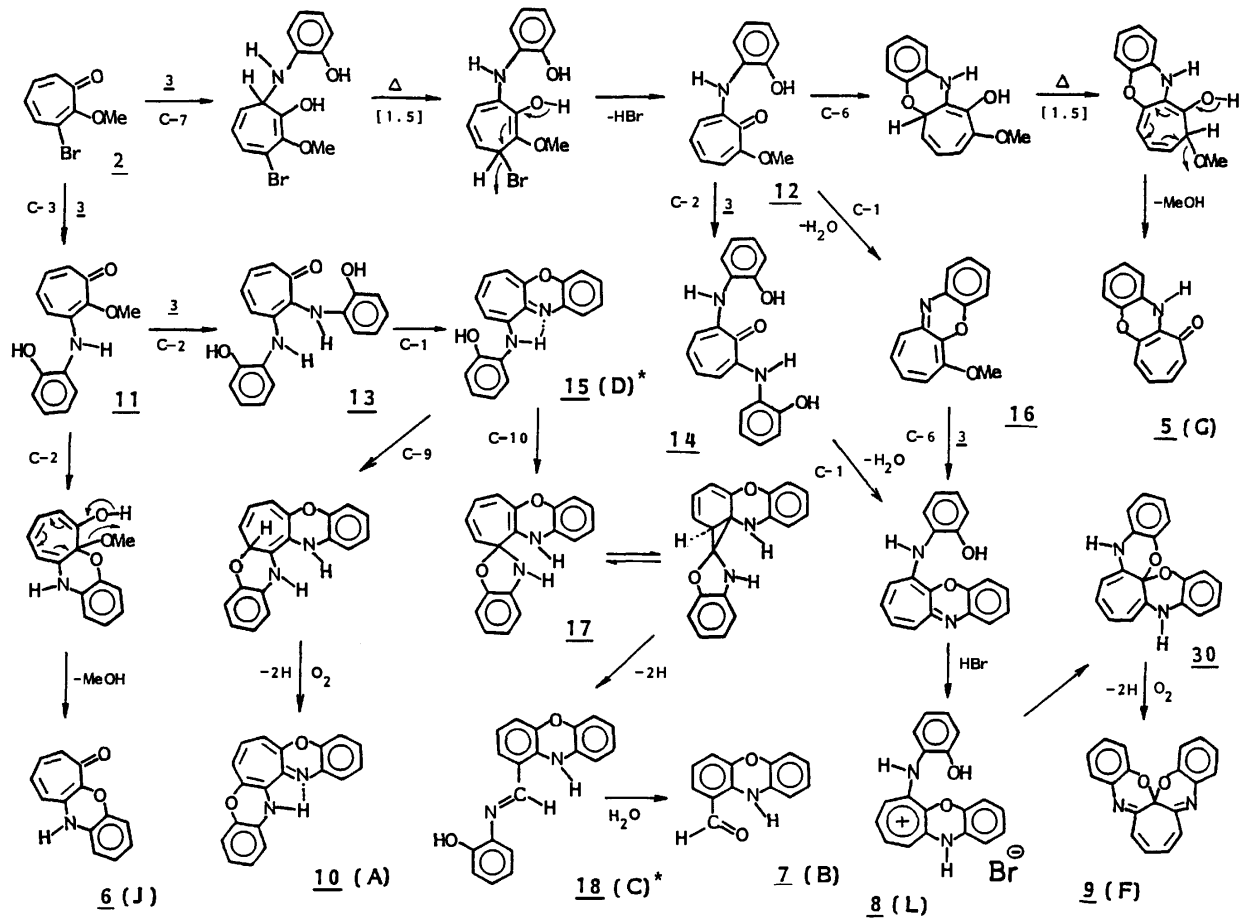
Chart 1.

Meanwhile, we were able to resolve the chiral acetal **9** (**F**) and its derivatives into their optical antipodes and to determine their absolute configurations by an X-ray method[5] and by theoretical calculations of their CD spectral data.[6]

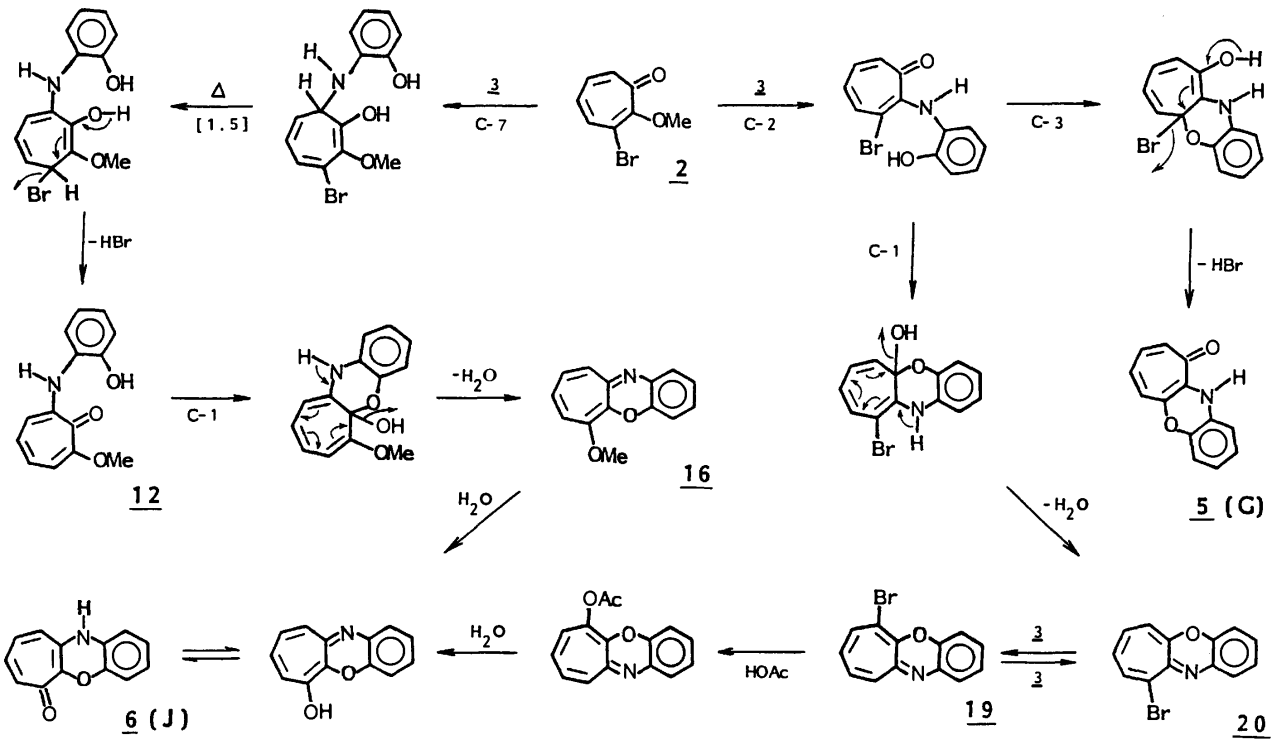
It has generally been recognized that the course of various reactions of troponoids are often extremely sensitive towards a slight structural difference of both substrates and reagents, as well as the reaction conditions employed (solvent and concentration, temperature, and with or without catalyst, etc.).[2,5] However, the considerable difference between the reactions of two isomers (**1** and **2**) with **3** under the same conditions was far beyond our expectation.

At that time, we considered that the methoxyl group at C-2 of **2** would be very inactive to the nucleophilic replacement due to steric interferences (between carbonyl and bromine atom), and we believed that 1:1 condensation products (**J** and **G**) had been produced via **11** (normal substitution at C-3) and **12** (cine substitution at C-7). On the other hand, compounds **D**, **A** (**10**), **C**, and **B** (**7**) were thought to be formed through a common intermediate, **15**, via 2,3-disubstituted product **13** followed by an oxidative ring closure to **10**, and a rearrangement to **18** and **7** via spirooxazole **17**. The possible pathways proposed then are summarized in Scheme 1; however, we did not have any positive proof of the intermediates for each products.

Takase and his coworkers found[8] that the treatment of **2** and morpholine or pyrrolidine first afforded two monosubstitution products (normal and cine at C-3 and C-7, respectively), and then the 2,3- and 2,7-disubstituted products. However, differing from the above-mentioned case, the most preferable site of substitution of **2** with arylamine has recently been found by us to be the C-2 and then C-7 positions.[9] We have also found that the bromine atoms on a cyclohepta[*b*][1,4]benzoxazine ring are easily saponified by warm acetic acid to give cyclohepta[*b*][1,4]-



Scheme 1.[4] * Structure of these compounds were determined in this paper.



Scheme 2.

benzoxazines.[10] Therefore, the formation of 1:1 condensation products should now be formulated, as in Scheme 2.

In this paper, we would like to describe the reaction of 6-bromocyclohepta [*b*][1,4]benzoxazine (**19**) with **3** and *p*-anisidine along with a reexamination of the reactions of **2** with **3**, to obtain useful information about these very complex reactions of the special heterocyclic tropylium system.

Results and Discussion

Reaction of 2 with 3. To obtain uselful information about the formation sequence of various products from **2** and **3** and to confirm the structures of intermediates for these compounds, we first reexamined the reaction in refluxing acetic acid by periodically checking the reactant with the reversed-phase high-pressured liquid chromatography (HPLC) equipped with a stopped-flow UV-spectrometer. An example of the chromatograph of the reaction mixture heated at 120 °C for 30 min is shown in Fig. 1a. Each peak was characterized by the stopped-flow UV-visible spectra as well as MS after separation and the assignment of the main peaks was made as follows: peaks 1 (**L**), 3(**3**), 5(**J**), 8 (**2** and **H**[1]), and 10 (**G**). When the heating was continued for several hours, peaks 11 — 16 began to appear at a retention time (RT) of 20—50 min, as seen in their amplified figures in Fig. 1b. Peaks 12, 13, and 14 were identified by TLC and UV to be compounds **C**, **D**, and **B** (**7**), respectively.

After heating **2** and **3** in acetic acid for 60 min, the reaction mixture was separated by HPLC (Fig. 1b) and we obtained small amounts of compounds **C** and **D**. Compound **D** ($C_{19}H_{14}N_2O_2$, reddish-brown needles, mp 135—138 °C decomp) was quantitatively converted into **10** (**A**, $C_{19}H_{12}N_2O_2$) by silica-gel TLC eluted with benzene. Orange-colored compound **C** (mp 158—160 °C, $C_{19}H_{14}N_2O_2$), which gradually degraded to **7** (**B**) on heating or standing in methanol, was therefore thougth to be a Schiff base (**18**) of **7**. Upon the addition of a trace of dil sulfuric acid the methanolic solution of **C** instantly became deep purple red and then discolored after 10—20 seconds, giving HPLC peaks due to **7** and oxidative dimer **H**[1] (**22**),[7] but only a trace amount of **3**; we found that **22** was, however, not produced when the experiment was conducted under nitrogen.

Since the quantity of pure compounds **C** and **D** were not sufficient for their structural studies, we then studied the reaction of **3** with **19** as an analogue of the possible reaction intermediates, **16** and **20**, under various conditions.

Reaction of 19 and 3. Under Acidic Conditions. On heating **19** with **3** in acetic acid at 120 °C for 1.5 h and after careful separation of the reaction mixture, compounds **L** (**8**, 55%), **D** (25%), the rearranged product **B** (**7**, ca. 10%), and a trace amount of compound **A** were isolated. Compound **D** was assigned to have the structure of 10-(*o*-hydroxyanilino)-cyclohepta[*b*][1,4]benzoxazine (**15**), based on the evidence of the spectral data; the AA'BB' singal pattern of the four protons on the seven-membered ring in the ^{1}H NMR spectrum should be noted (see Experimental part). Pure **15** is stable as crystals, but its methanolic solution was autoxidized rapidly in the presence of a weak base or an acid to give a quantitative yield of **10** (**A**, Scheme 3). Hydroperoxyl radical (HOO·), which is expected to be liberated when **15** (**D**) is autoxidized to **10** (**A**) [and **8** (**L**) to **9** (**F**)], would induce oxidation of **3** to the dehydro dimer **22**. As a consequence, **22** always accompanies, as one of the products, in the reaction of this series. **10** exists as a symmetrical and almost planar hydrogen bonded form, as shown by X-ray crystallography,[11] and does not open its benzoxazine ring, even upon heating with methanolic

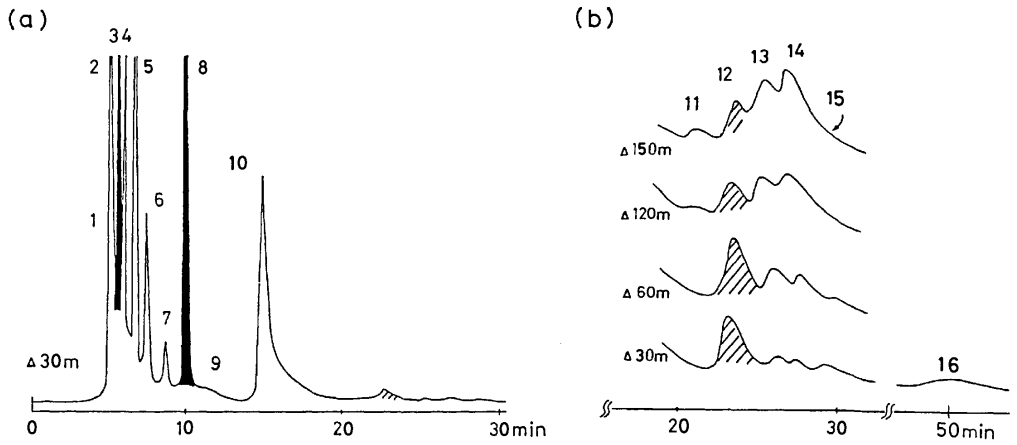


Fig. 1. Time-dependent HPLC chromatograms of the reaction of **2** and **3** in AcOH at 120 °C for 30 minutes.

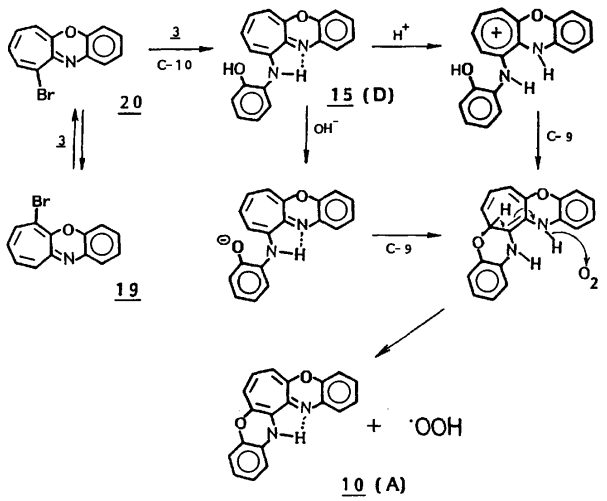

Scheme 3.

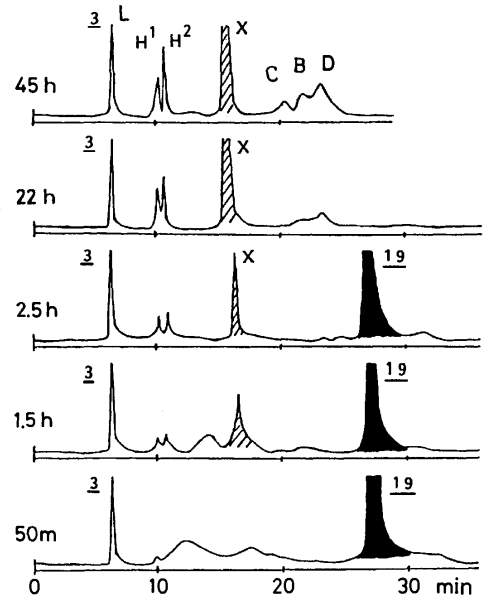

Fig. 2. Time-dependent HPLC chromatograms of the reaction of **19** and **3** in MeOH at room temp in the presence of DABCO.

alkali. We could not obtain its *N*-methyl or *N*-acetyl derivative by ordinary method, presumably because of the strong intramolecular hydrogen bonding.

Under Basic Conditions. Since compound **C** was extremely unstable in dil mineral acid, we then examined the reaction of **19** with **3** at room temperature in methanol containing an equivalent of 1,4-diazabicyclo[2.2.2]octane (DABCO) in order to neutralize HBr produced during the reaction; the time-dependent HPLC chromatograms are shown in Fig. 2. Many initially observed peaks became simplified after a few hours. Then, peaks of **3** (RT, 6 min), **22** (H^1, RT, 10.5 min), H^2 (RT, 11 min), and **X** (RT, 16 min) as well as weak peaks of **8** (**L**), **C**, **7** (**B**), and **15** (**D**)

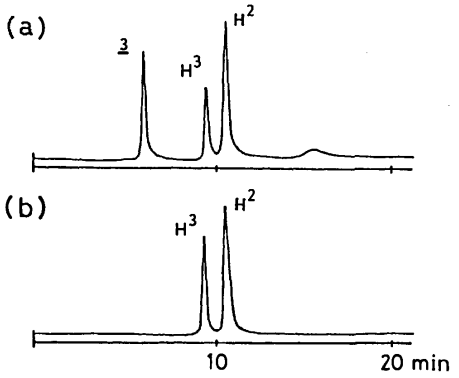

Fig. 3. (a) HPLC chromatograms of compound **X** in MeOH containing a trace amount of dil sulfuric acid. (b) HPLC chromatograms of compound H^2 in MeOH containing a trace amount of dil sulfuric acid.

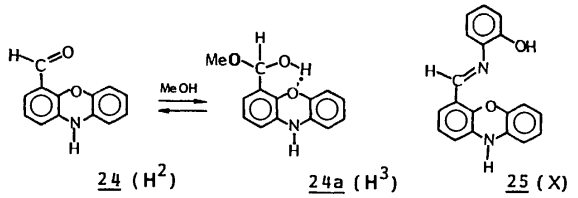
remained unchanged; unknown peak **X** corresponding to the main peak gradually crystallized out. Compound **X** (yellow needles, mp 210—211 °C) showed IR absorbance maxima at 3350 and 1618 cm^{-1} due to NH and C=N, respectively, exhibited ^1H NMR (DMSO-d_6) signals at δ 8.85, 8.75, and 8.27 due to OH, NH, and HC=N, respectively, and was identified to be an isomer of compound **C** by MS. The addition of a small amount of dil sulfuric acid to compound **X** dissolved in methanol, resulting in the production of a deep purple color, quickly followed by a complete bleaching of the solution. This solution was found to consist of three components: **3**, H^2 (RT, 11 min), and H^3 (RT, 9.8 min) by HPLC (Fig. 3a). Compound H^2 (yellow needles, mp 186—187 °C) isolated by TLC, showed IR absorbance maxima at 3250 (NH) and at 2840, 2780, and 1675 cm^{-1} (CHO), and exhibited ^1H NMR (acetone-d_6) signals at δ 10.36 (CHO), 7.61 (NH), and 7.02 (1 benzene ring proton adjacent to CHO). These data and the results of the X-ray analysis[12] indicate that compound H^2 is 4-formylphenoxazine (**24**), an isomer of **7** (**B**). Compound H^3 [UV λ_{max} (MeOH) 236 and 318 nm] was partly produced from **24** [UV λ_{max} (MeOH) 228, 276, 313, and 416 nm, (MeOH+6 M HCl) 236 and 318 nm] in MeOH by the addition of a small amount of dil sulfuric aicd (Fig. 3b). The compound isolated from peak H^3 showed the same HPLC retention time (11 min) and MS of **24**, suggesting that H^3 would be the hemiacetal **24a**, which is stabilized somewhat by hydrogen bonding with the *O*-atom of heterocyclic ring.



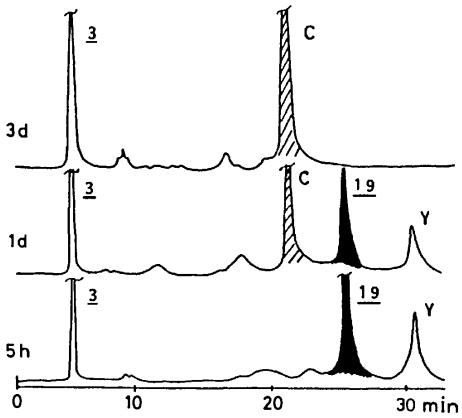


Fig. 4. Time-dependent HPLC chromatograms of the reaction of **19** and **3** in MeOH at 5 °C.

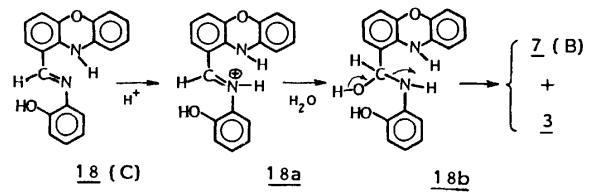
Under Neutral Conditions. Since we unexpectedly obtained the Schiff base **25** instead of the Schiff base of **7**(**B**) in the presence of DABCO, reactions of **19** and **3** in MeOH at 5 °C were performed without the base and were periodically monitored by HPLC. As shown in Fig. 4, a peak of compound **Y** (see later) appears first, and compound **C** increased as **Y** and **19** decreased among the reaction mixture. Almost no other products [e.g. **7** (**B**), **10** (**A**), **15** (**D**)] were observed in this case, even upon standing for 3 days. The product corresponding to the main peak of compound **C** gradually crystallized out in high yield. The IR spectrum of compound **C** showed OH and NH absorptions at 3470 and 3200 cm^{-1}, respectively. The ^1H NMR spectrum consisted of a proton signal of the benzene ring adjacent to the C=N group (δ 6.88, dd, J=8 and 2 Hz) and the signals at δ 9.78, 8.50, and 6.05 due to OH, HC=N, and NH groups, respectively. Taken together with the results of high-resolution MS, compound **C** was unambiguously identified as being the Schiff base **18** of 1-formylphenoxazine (**7**). A complete assignment for the ^1H NMR signals was made by using a decoupling technique; the result is described in the Experimental section.

When this reaction of **19** with **3** is studied using greater amounts for preparative purposes, we obtained about 70% yield of **18** (**C**), besides a 20% yield of **15** (**D**) and a trace amount of the ring-opened product **4**.[3] It is noted that the yields of **15** and **18** highyl depend on the reaction conditions employed; for example, at 50 °C a 30% yield of **18** and 50% of **15** were produced along with 10% of **4**. The temporary deep-violet color observed when trace acid was added to the soltion of **18** is considered to be due to the formation of a cyanine dye-type iminium salt of the Schiff base **18**, (or its 4-isomer in the case of **24**). This was followed by facile hydrolysis to produce **7** (or **24**) and **3** (Scheme 4). As for **Y**, we later identified it[13] to be a 10-bromo compound **20** produced by an unpercedented inter-

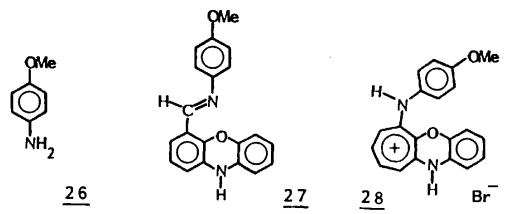


Scheme 4.

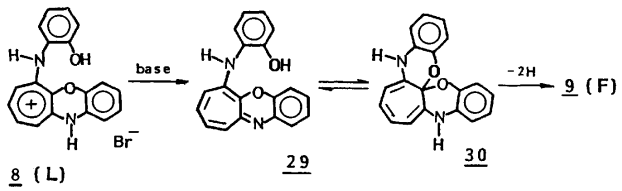
molecular heterocyclic exchange reaction between **19** and **3**. Isomers **19** and **20** are shown in the presence of **3** to exist in solution at equilibrium, as shown in Scheme 2.

From its structure, we first considered[2] that **15** was formed from 6-bromo compound **19** by cine substitution at C-10 followed by [1,5]hydrogen-shift. However, this assumption became doubtful because **15** was produced from **19** and **3**, even at low temperature (described before). Indeed, a recent study of the reaction of 10-bromo compound **20** with arylamine has confirmed that **15** is the normal substitution product of **20** with **3** (Scheme 3).[14]

To clarify the reason why two different Schiff bases, **18** and **25**, are produced from **19** and **3**, in the absence or presence of base (DABCO), we examined the reaction of **19** with the *p*-anisidine (**26**) having no OH group at the *o*-position. Upon standing a methanolic



solution of **19** and **26**, we obtained, besides some ring-opened compound **4**, mainly rearranged 4-formylphenoxazine (**24**, 65%) which was produced by the hydrolysis of Schiff base **27**. Upon heating at 50 °C, a 57% yield of 6-substituted cations **28**, 38% fo **24** and some anilinotropone **4** were obtained. The addition of DABCO or acetic acid to the methanolic solution of **19** and **26** did not change the result, and no C-10 substituted compound (**D**-type) and 1-formylphenoxazine (**7**) were formed. However, an almost quantitative yield of **28** was obtained upon refluxing **19** and **26** in acetic acid. Compound **28** (reddish-brown needles, mp >300 °C), which exhibited a UV spectrum very similar to that of **8** (**L**), was assigned to have a structure of 6-(*p*-methoxyanilino)cyclohepta[*b*][1,4]benzoxazine hydrobromide on the basis of spectral data (see Experimental part). From this evidence, and also from the structure of **9** (**F**), **8** (**L**) is obviously the normal substitution product derived from **3** and **19** and stabilized as the HBr salt. 6-(*o*-Hydroxyanilino)cyclohepta-[*b*][1,4]benzoxazine (**29**) was obtained as a yellowish-

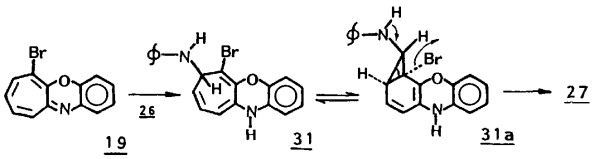


Scheme 5.

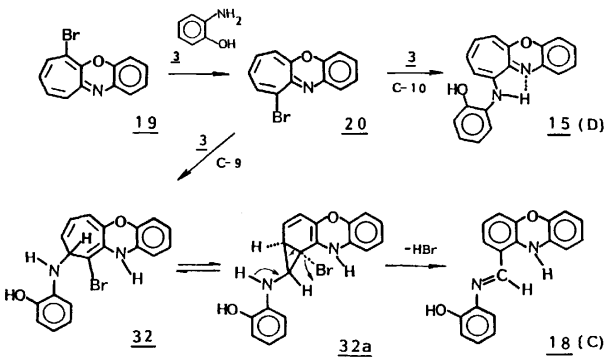
brown solid by neutralizing the salt **8**. However, it was very unstable in open air and was easily dehydrogenated to give stable dehydro acetal **9** (**F**) via acetal **30** (Scheme 5).

These results indicate that the presence of an OH group at ortho to the anilino nitrogen is essential to produce **7**, **10**, **15**, and **18**. Since the rearranged product **18** was produced by the reaction of **19** and **3** in neutral or even weakly acidic conditions, and also from its structure, we first speculated[4] that the spiroxazole intermediate **17** produced from **15** by ring closue at C-10 rearranged to Schiff base **18** via norcaradiene form (in Scheme 1).

However, we later confirmed that **15** (**D**) did not yield the rearranged product under various conditions. Therefore, the formation of Schiff base **27** (**X**-type) from **19** and *p*-anisidine (**26**) must have proceeded by the attack of the arylamine at C-7 (to give **31**), followed by rearrangement via norcaradiene **31a** shown in Scheme 6. The production of **25** (and **24**) from **19** and **3** in the presence of a base can be similarly interpreted, since the heterocycle exchange reaction[13] of **19** to **20** is significantly retarded by a base. These pieces of evidence indicate that **15** (**D**) and **18** (**C**) are not derived directly from 6-bromo compound **19** by a cine



Scheme 6.



Scheme 7.

substitution at C-10, but instead, are produced from the exchanged 10-bromo compound **20** by normal substitution at C-10 (for **15**) and by an attack at C-9 (for **18**), as illustrated in Scheme 7.

Thus, the unusually complex nature of the reaction of **19** and **3** was finally unveiled by the discovery of the novel and facile heterocycle-exchange reaction between the substrate and the reagent,[13] details of which will be reported elsewhere.

Experimental

Melting points were determined with a Yanagimoto MP-3S and are uncorrected. The IR and electronic spectra were measured by using a Shimadzu IR-450 and a Shimadzu UV-202 spectrometer, respectively; the UV spectra in acid or alkali solutions were taken after adding a few drops of 6 M HCl or 6 M NaOH (1 M=1 mol dm^{-3}) to the sample solution. The ^{1}H NMR spectra were measured in $CDCl_3$ (unless otherwise specified) with a JEOL JNM-PS/PFT (100 MHz) or a JEOL JNM-GX270 (270 MHz) spectrometer using TMS as the internal standard. The assignments of all signals were made by empoloying a first-order analysis with the aid of a decoupling technique. The mass spectra were taken on a JEOL JMS-DX300 mass spectrometer and a Shimadzu LKB 9000 GC-mass spectrometer at 70 eV. The HPLC was carried out with Hitachi gel #3011 with MeOH–hexane (9:1) as the solvent. The centrifugal chromatography was performed with a Hitachi CLC-5 instrument in a Fuji silica gel layer (KT-2151, 3 mm thickness) using benzene as an eluent. TLC analyses were carried out with Merck Kieselgel 60F-254 plate.

Reaction of 3-Bromo-2-methoxytropone (2) with *o*-Aminophenol (3). a) At 120 °C: A solution of 167 mg (0.78 mmol) of **2** and 127 mg (1.17 mmol) of **3** in 5 cm^3 of acetic acid was heated at 120 °C for 1 h and then evaporated in vacuo. The residue was preliminarily separated into four fractions by means of silica-gel column with benzene–MeOH (20:1) as the eluent. Each fraction was carefully separated by preparative HPLC with Hitachi gel #3019 using MeOH–hexane (9:1) or TLC with silica gel 60F-254 (0.25 mm, Merck) using benzene–MeOH (10:1) as the eluent, giving compounds **A**[4] (10 mg, 4% yield), **B**[4] (7 mg, 4% yield), **C** (see below, 3 mg, 1% yield), **D** (see below, 2 mg, 1% yield), **G**[4] (35 mg, 21% yield), **J**[4] (16 mg, 10% yield), and **L**[4] (82 mg, 28% yield), besides the recovered **2** (30 mg, 20%).

b) At 60 °C: A solution of 30 mg (0.14 mol) of **2** and 30 mg (0.28 mmol) of **3** in 3 cm^3 of methanol was heated at 60 °C for 5 h, followed by the same work-up procedures mentioned above, giving 2 mg (5%) of **G**, besides the recovered **2** (25 mg, 85%).

c) At 80 °C: Procedures similar to the those at 60 °C were employed. Thus, a solution of 20 mg (0.1 mol) of **2** and 20 mg (0.2 mmol) of **3** was heated in 2 cm^3 of 1-butanol at 80 °C for 3 h, giving 4 mg (20%) of **G** and a small amount of **J**, besides the recovered **2** (15 mg, 75%).

Reaction of 6-Bromocyclohepta[*b*][1,4]benzoxazine (19) and *o*-Aminophenol (3). A. Under Acidic Conditions: A solution of 50 mg (0.2 mmol) of **19** and 30 mg (0.3 mmol) of **3** in 2 cm^3 of acetic acid was heated at 120 °C for 1 h. The solvent was evaporated in vacuo and the residue was chromatographed in a column of silica gel with benzene,

giving 40 mg (55%) of compounds **L**, 15 mg (25%) of **D**, 4 mg (10%) of **B**, and a trace amount of **A**.

B. Under Basic Conditions: A solution of 20 mg (0.07 mmol) of **19**, 12 mg (0.11 mmol) of **3**, and 14 mg (0.11 mmol) of DABCO in 2 cm^3 of methanol was allowed to stand for 1 d at room temp. After cooling, the ppt was filtered off and recrystallized from methanol to give 14 mg (64%) of compound **X** (see below). The above filtrate was a mixture of compounds **A, B, C, D, H¹, H²** (see below), **4**[3] and **L** (by TLC, HPLC, and UV).

C. Under Neutral Conditions: a) Similar procedures for acidic conditions were followed. Thus, 30 mg (0.11 mmol) of **19** with 22 mg (0.22 mmol) of **3** in 2 cm^3 of methanol was heated at 50 °C for 3 h, giving 18 mg (50%) of compounds **D**, 10 mg (30%) of **C**, and 3 mg (10%) of **4**.

b) Similar procedures for basic conditions were followed. Thus, a soluion of 22 mg (0.08 mmol) of **19** and 13 mg (0.12 mmol) of **3** in 1 cm^3 of methanol was kept at 5 °C (refrigerator) for 3 d, giving 17 mg (70%) of **C**, 4 mg (15%) of **D**, and a small amount of **4**.

Compound C, Schiff Base of 1-Formylphenoxazine (18): Orange needles; mp 158 — 160 °C (from benzene); UV λ_{max} (MeOH) 227 (log ε 4.56), 279 (4.07), 327 (4.03), 344[sh] (3.98), 363[sh] (3.82), and 430 nm (3.88), (MeOH+6 M NaOH) 226 (log ε 4.63), 275 (4.17), 315 (3.84), and 407 nm (4.00); IR (KBr) 3470 (NH) and 1615 cm^{-1} (C=N); ^{1}H NMR (270 MHz) δ=9.78 (1H, br, OH), 8.50 (1H, s, HC=N), 7.20 (1H, td, J=8.0 and 1.7 Hz, H-4′), 7.07 (1H, dd, J=8.0 and 1.7 Hz, H-6′), 7.03 (1H, dd, J=8.0 and 1.7 Hz, H-3′), 6.95 (1H, td, J=8.0 and 1.7 Hz, H-5′), 6.88 (1H, dd, J=7.5 and 2.1 Hz, H-2), 6.72 (1H, td, J=7.5 and 2.0 Hz, H-8), 6.64 (4H, m, H-3,4,7,9), 6.40 (1H, dd, J=7.5 and 2.0 Hz, H-6), and 6.05 (1H, br, NH); ^{13}C NMR (67.8 MHz) δ (off resonance)=162.7 (d, HC=N), 150.1 (s), 144.1 (s), 143.8 (s), 137.4 (s), 134.5 (s) 130.0 (s), 128.2 (d), 127.9 (d), 123.9 (d), 122.4 (d), 120.9 (d), 119.5 (d), 117.6 (d), 117.2 (d), 117.1 (s), 115.6 (d), 115.2 (d), and 114.3 (d).

Found: m/z 302.1090. Calcd for $C_{19}H_{14}N_2O_2$: M, 302.1054.

Hydrolysis of C: To a solution of **C** (20 mg, 0.07 mmol) in methanol (2 cm^3) was added a trace of dil sulfuric acid. Then, the mixture, which instantly became deep purple red and then discolored after 10 — 20 seconds, was evaporated in vacuo. The residue was neutralized with aq $NaHCO_3$ and extrated with benzene.

The extracts were combined, dried (Na_2SO_4) and evaporated in vacuo. The residue was chromatogrphed on silica gel thin-layer plates with benzene as the eluent, followed by recrystallization from benzene, giving **B** and **3** in almost quantitative yields.

Compound D, 10-(*o*-Hydroxyanilino)cyclohepata[*b*][1,4]-benzoxazine (15): Reddish brown needles (from MeOH); mp 135 — 138 °C (decomp); UVλ_{max} (MeOH) 233 (log ε 4.30), 265 (4.34), 311[sh] (3.99), and 467 nm (4.08), (MeOH+6 M HCl) 220 (log ε 4.34), 265 (4.35), 273 (4.36), 303 (4.08), 451[sh] (3.91), and 499 nm (3.91); IR (KBr) 3350 (OH), 3250 (NH), and 1600 cm^{-1} (C=N); ^{1}H NMR (270 MHz) δ=9.86 (1H, br, OH), 8.58 (1H, br, NH), 7.24 (1H, dd, J=7.5 and 1.6 Hz, H-6′), 7.06 (1H, td, J=8 and 2 Hz, H-3′), 6.86 (1H, td, J=8 and 2 Hz, H-5′), 6.79 (3H, m, H-1,2,3), 6.53 (1H, m, J=8 and 2 Hz, H-4), 6.34 (2H, m, H-6,9), and 6.14 (2H, m, H-7,8).

Found: m/z 302.1080. Calcd for $C_{19}H_{14}N_2O_2$: M, 302.1054.

Conversion of D into A: a) A solution of 2 mg of **D** in 2 cm^3 of methanol was allowed to stand for 2 d at room temp. After removing the solvent in vacuo, the residue was recrystallized from hexane, giving **A** in an almost quantitative yield.

b) A solution of 1 mg of **D** in 2 cm^3 of methanol containing a drop of 6 M NaOH was allowed to stand for 3 h at room temp. After removal of the solvent in vacuo, the residue was chromatographed in a column of silica gel with benzene as the eluent, giving **A**.

Compound H², 4-Formylphenoxazine (24): Yellow needles (from MeOH); mp 186 — 187 °C (decomp); UV λ_{max} (MeOH) 228 (log ε 4.53), 236[sh] (4.44), 276 (3.90), 313 (3.81), and 416 nm (3.43), (MeOH+6 M HCl) 236 (log ε 4.57), and 318 nm (3.94); IR (KBr) 3260 (NH), 2840, 2780, and 1675 cm^{-1} (CHO); ^{1}H NMR (270 MHz, acetone-d_6) δ=10.36 (1H, s, CHO), 7.61 (1H, br, NH), 7.02 (1H, dd, J=8 and 2 Hz, H-3), 6.81 (1H, t, J=8 Hz, H-2), 6.76 (2H, m, H-7,9), 6.71 (1H, dd, J=8 and 2 Hz, H-1), 6.27 (1H, td, J=8 and 2 Hz, H-8), and 6.54 (1H, dd, J=8 and 2 Hz, H-6); ^{13}C NMR (67.8 MHz, acetone-d_6) δ (off resonance)=188.2 (d, CHO), 147.6 (s), 143.3 (s), 134.3 (s), 132.7 (s), 125.4 (d), 124.3 (d), 121.9 (d), 118.8 (d), 118.7 (d), 116.4 (d), and 114.5 (d).

Found: m/z 211.0658. Calcd for $C_{13}H_9NO_2$: M, 211.0633.

Compound H³, 4-Formylphenoxazine Hemiacetal (24a): To a solution of compound **X** (1 mg) in methanol (0.5 cm^3) was added a trace of dil sulfuric acid. After 10 min at room temp, the solution was found to be a mixture of **3** (RT, 6 min), **H²** (RT, 11 min), and **H³** (RT, 9.8 min) by means of reversed-phase HPLC and UV absorptions. The compound isolated from peak **H³** showed the same RT (11 min by repeated HPLC) and MS (M^+, 211) as those of **24**.

Compound X, Schiff Base of 4-Formylphenoxazine (25): Yellow needles; mp 210 — 211 °C decomp (from MeOH); UV λ_{max} (MeOH) 230 (log ε 4.73), 285 (4.14), 324 (4.11), 353[sh] (4.05), and 425 nm (3.44), (MeOH+6 M NaOH) 230 (log ε 4.76), 271 (4.23), 315[sh] (3.98), and 399 nm (3.88); IR (KBr) 3350 (NH) and 1618 cm^{-1} (C=N); ^{1}H NMR (270 MHz) δ=9.05 (1H, s, HC=N), 7.48 (1H, dd, J=8 and 2 Hz, H-3), 7.34 (1H, dd, J=8 and 2 Hz, H-6′), 7.21 (1H, td, J=8 and 2 Hz, H-4′), 7.01 (1H, dd, J=8 and 2 Hz, H-3′), 6.93 (1H, td, J=8 and 2 Hz, H-5′), 6.82 (1H, t, J=8 Hz, H-2), 6.74 — 6.82 (2H, m, H-7,9), 6.71 (1H, td, J=8 and 2 Hz, H-8), 6.48 (1H, dd, J=8 and 2 Hz, H-1), 6.43 (1H, dd, J=8 and 2 Hz, H-6), and 5.26 (1H, br, NH); (100 MHz, DMSO-d_6) δ=8.85, 8.75, and 8.27 (3H, s, NH, OH, and HC=N, respectively), 7.37 (1H, dd, J=8.0 and 2.0 Hz, H-3), 6.4 — 7.4 (10H, m, others).

Found: m/z 302.1041. Calcd for $C_{19}H_{14}N_2O_2$: M, 302.1054.

Hydrolysis of X: Similar procedures for compound **C** were followed. Thus, 50 mg (0.17 mmol) of compound **X** in 5 cm^3 of methanol gave **3** and 33 mg (94%) of **H²**.

Reaction of 19 with *p*-Anisidine (26). a) At Room Temperature: A solution of 50 mg (0.18 mmol) of **19** and 30 mg (0.28 mmol) of **26** in 2 cm^3 of methanol was stirred for 1 d at room temp. After removal of the solvent, the residue was chromatographed in a column of silica gel with benzene–methanol (50:1) as the eluent, giving 11 mg (20%) of **28** and 25 mg (65%) of **H²**, along with a small amount of ring-opened compound **4**.

b) At 50 °C: A solution of 42 mg (0.15 mmol) of **19** and 28 mg (0.23 mmol) of **26** in 2 cm^3 of methanol was heated at 50 °C for 3 h, followed by the same work-up procedures as above, giving 35 mg (57%) of **28**, 12 mg (38%) of **H²**, and a small amount of **4**.

c) **At 120 °C:** The procedures similar to those at 50 °C were employed. Thus, 30 mg (0.11 mmol) of **19** and 20 mg (0.18 mmol) of **26** were heated in 2 cm^3 of methanol at 120 °C for 1 h, giving 26 mg (75%) of **28**, 4 mg (15%) of **H²**, and a small amount of **4**.

6-(*p*-Methoxyanilino)cyclohepta[*b*][1,4]benzoxazine (28): Reddish brown needles (from methanol); mp >300 °C (decomp); UV λ_{max}(MeOH) 234, 268, 300, and 428 nm, (MeOH+6 M NaOH) 238, 304, 451, 480^{sh}, and 630 nm; ^{1}H NMR (270 MHz, CD_3OD) δ=7.23 (2H, m, H-2′,6′), 7.08 (2H, m, H-3′, 5′), 6.98—7.20 (3H, m, H-8,9,10), 6.85—6.95 (3H, m, H-1,2,3), 6.38 (1H, m, H-7), 6.61 (1H, m, H-4), and 3.85 (3H, s, OCH_3).

Found: *m/z* 316.1217. Calcd for $C_{20}H_{16}N_2O_2$: M, 316.1211.

We thank Professor Hiroshi Yamamoto (Okayama Univ.) for helpful discussions. We also thank Professor Yoichi Iitaka and Mrs. Hikaru Nakamura (Tokyo Univ.) for their kindly performing X-ray analyses for Compounds **10** and **24**.

Stereoselective Synthesis of 2,4-Diamino Acids by Asymmetric Hydrogenation

Nam Gyu PARK, Sannamu LEE,* Hiroshi MAEDA,† Haruhiko AOYAGI, and Tetsuo KATO††
Laboratory of Biochemistry, Faculty of Science, Kyushu University 33, Higashi-ku, Fukuoka 812
(Received February 4, 1989)

A stereoselective synthesis of unusual basic amino acids, ornithine, 2,4-diaminopentanoic acid, and 2,4-diamino-6-methylheptanoic acid, was achieved by the hydrogenation of cyclic α,β-dehydro dipeptides obtained by the condensation of cyclo(-Gly-L(or D)-aminoacyl-) and protected linear or chiral amino aldehydes. The degree of chiral induction greatly depended on the bulkiness of the side chains of α,β-dehydro amino acids. The R_f values on paper chromatography of (2*S*,4*S* or 2*R*,4*S*)-diaminopentanoic acid prepared by the present method were different from the reported values of a compound which had been obtained from metabolic products of *Clostridium sticklandii* and estimated to be 2,4-diaminopentanoic acid.

In any study on the design, synthesis and structure-function of bioactive peptides, the use of unusual amino acids as starting materials is often important. We have established a synthetic method of optically active α-amino acids by asymmetric hydrogenation of cyclic α,β-dehydro dipeptides and successfully prepared lots of α-amino acids.[1-4] However, the method was applied only for the preparation of neutral amino acids. It seems interesting how the chiral induction in hydrogenation would be influenced by a functional and/or chiral side chain in cyclic α,β-dehydro dipeptides. We selected in the present study ornithine (**3**) with a functional side chain, and 2,4-diaminopentanoic acid (**1**) and 2,4-diamino-6-methylheptanoic acid (**2**) with a chiral side chain as target materials (Fig. 1).

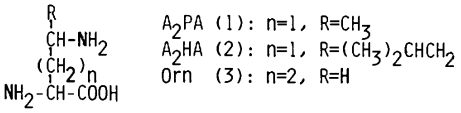

Fig. 1. Structure of synthetic amino acids.

Among compounds **1**—**3**, **1** was reported to be a metabolic intermediate in the an aerobic oxidation of ornithine in *Clostridium sticklandii*.[5] The structure was estimated merely from the behavior on paper chromatography and the metabolic pathway because of the scarce presence of the intermediate in the cells. Since the isolation and identification of the intermediate have not yet been carried out, its chemical and optical identification is attractive. Compound **2** was previously synthesized as a diastereoisomer by catalytic hydrogenation of ethyl 3-propyl-5-pyrazolinecarboxylate, but not obtained as an optically active one.[6] Hence, the stereoselective synthesis of the optically active diastereoisomer is also of interest.

Results and Discussion

The synthetic route for **1** and **2** is shown in Fig. 2. We previously reported that when L-amino acid[7] was used in cyclic α,β-dehydro dipeptide as a chiral source,

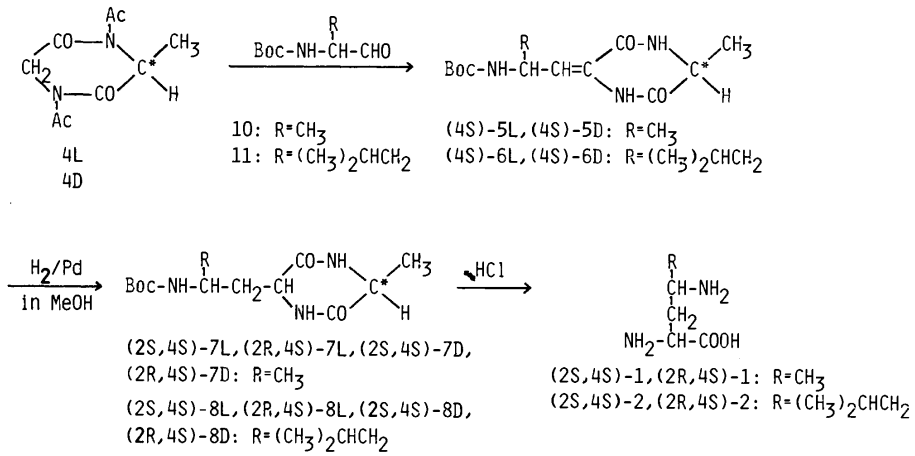

Fig. 2. Synthetic route for 2,4-diamino acids (**1** and **2**).

† Present address: Nippon Mining Co., Ltd., Toda 355.
†† Present address: Kumamoto Institute of Technology, Kumamoto 860.

asymmetric hydrogenation exclusively gave L-amino acid.[1] If the asymmetric hydrogenation of cyclic α,β-dehydro dipeptides (**5** and **6**) proceeds stereospecifically, it is able to synthesize stereoselectively two optical isomers of **1** and those of **2**, respectively, via the condensation of **4L** and **4D** with the protected (2*S*)-2-amino aldehyde (**10** or **11**) followed by hydrogenation. As an asymmetric source, we chose neutral L- or D-alanine because of the easy separation of alanine from basic amino acids, i.e., final products.

In the synthesis of **1**, the condensation of **4L** with Boc-(2*S*)-alaninal (**10**)[8] in the presence of *t*-BuOK[9] gave cyclic acetyl-α,β-dehydro dipeptide, which was then deacetylated by the action of 1-(2-aminoethyl)-piperazine to afford cyclic α,β-dehydro dipeptide, (4*S*)-**5L**. A mixture of (2*S*,4*S*)-**7L** and (2*R*,4*S*)-**7L** was obtained by hydrogenation of (4*S*)-**5L** in the presence of Pd-black. In order to determine the formation ratio of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1**, the hydrogenated mixture was subjected to acid hydrolysis and then amino acid analysis. The elution pattern of the hydrolysate is shown in Fig. 3. The stereochemistry in this amino acid was deduced as follows: the main product should be (2*S*,4*S*)-**1**, based on the previously proposed mechanism for the asymmetric hydrogenation of cyclic α,β-dehydro dipeptides.[1] The peak ratio of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** in the hydrolysate was 3:2. The color yield of the purified optical isomers, (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1**, for ninhydrin was determined to be ca.1:1. Thus, the chiral induction of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** in hydrogenation was calculated to be 3:2, as shown in Table 1. After the isomers were separated with AG 50WX8 using a sodium citrate buffer (pH 5.28) as an eluent, the final products were purified by recrystallization. Their purity was confirmed by thin-layer chromatography and elemental analysis. The preparation of **1** from (4*S*)-**5D** was also carried out similarly (Fig. 2). The use of **4D** instead of **4L** gave highly stereoselectively (2*R*,4*S*)-**1** (Table 1). Compound **2** was obtained from **4L** or **4D** and Boc-(2*S*)-leucinal (**11**)[8] in the same manner as described above. The ^{1}H NMR spectra of (4*S*)-**6L** and (4*S*)-**6D** obtained (Fig. 4) showed that the signal peaks corresponding to each functional group were observed. It is suggested that the *Z*- or *E*-isomer was formed stereoselectively without racemization in the condensation reaction. To determine the geometric isomers of *Z*- or *E*-isomer, we measured the NOESY spectrum by 2D NMR spectroscopy. The correlation between the amide proton of piperazinedione (–C=C–NH–) and proton of asymmetric carbon (–N–CH–C=) in the NOESY spectrum indicates that these proton are closely located. Consequently, (4*S*)-**6L** and (4*S*)-**6D** are not *E*-isomer but *Z*-isomer. Compounds (4*S*)-**5L** and (4*S*)-**5D** also showed NMR spectra similar to those of (4*S*)-**6L** and (4*S*)-**6D**, respectively (data not shown). Compounds (4*S*)-**6L** and (4*S*)-**6D** were not obtained in good yields. The low yields can probably be attributable to slow reaction, because the TLC of the reaction mixture showed main spots of the product and the starting materials, including some minor spots. The condensation of **4L** with **11** gave selectively (2*S*,4*S*)-2,4-diamino-6-methylheptanoic acid (**2**). In the case of **4D**, the product was a mixture of (2*S*,4*S*)-**2** and (2*R*,4*S*)-**2**, although the formation of (2*R*,4*S*)-**2** was fairly preferential. In the case of **3**, Boc-3-aminopropionaldehyde was obtained from Boc-3-amino-1-propanol by oxidation with pyridium dichromate,[10] and diethylamine was used instead of 1-(2-aminoethyl)piperazine in the step of deacetylation. Compound **3** was obtained in good optical yield from cyclo(-ΔOrn(Boc)-L-Ala-) (**9**), which was derived from **4L** and Boc-3-aminopropionaldehyde.

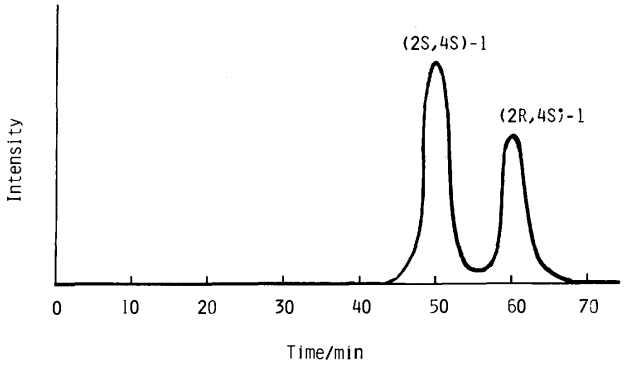

Fig. 3. Elution pattern of A_2PA.

We previously presented a presumptive mechanism on the asymmetric hydrogenation of cyclic α,β-dehydro dipeptide; the rigid planar structure of cyclic α,β-dehydro dipeptide, which is induced when the peptide is absorbed on the catalyst, has an important effect on asymmetric hydrogenation.[11] However, if there is a group which makes adsorption of the ring structure on the catalyst disadvantageous, the chiral induction in hydrogenation will decrease. The fact that L-ornithine (**3**) was obtained in good optical yield indicates that, when L-alanine was used as a chiral source, the

Table 1. Chiral Induction in Hydrogenation of Cyclic Dehydrodipeptides

Cyclic dehydrodipeptide	Amino acid	Chiral induction
(4*S*)-**5L**	A_2PA	3:2 (2*S*,4*S*:2*R*,4*S*)
(4*S*)-**5D**	A_2PA	1:5 (2*S*,4*S*:2*R*,4*S*)
(4*S*)-**6L**	A_2HA	95:5 (2*S*,4*S*:2*R*,4*S*)
(4*S*)-**6D**	A_2HA	2:3 (2*S*,4*S*:2*R*,4*S*)

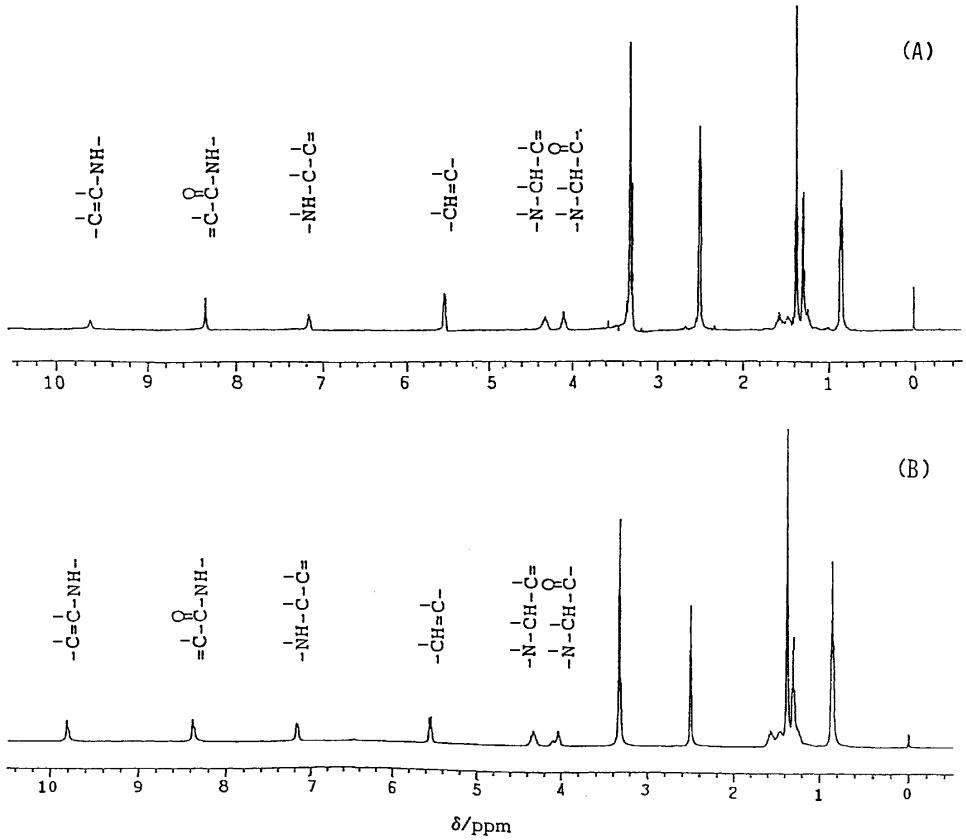

Fig. 4. ^{1}H NMR spectra of dehydro compounds (4*S*)-**6L** (A) and (4*S*)-**6D** (B).

Table 2. Comparison of the Chromatographic Property of Synthetic Compounds **1**, L-Ornithine, and Reported Compound[a)]

Solvent	(2*S*,4*S*)-**1**	(2*R*,4*S*)-**1**	L-Orn	Reported compound	L-Orn
MeOH:H_2O:pyridine (20:5:1)	0.08	0.12	0.13	0.46[b)]	0.16[b)]
1-Propanol:pyridine:H_2O (1:1:1)	0.10	0.22	0.23	0.42[b)]	0.22[b)]

a) Paper chromatography was carried out on Whatmann 3MM paper. b) Cited from Ref. 5.

adsorption of the urethane group on a catalytic surface had no effect on the optical yield. In the case of (4*S*)-**5L**, (4*S*)-**5D**, and (4*S*)-**6D**, the optical yields were relatively low. It is considered from the CPK model that free rotation between β- and γ-carbon atoms in the dehydro moiety is hindered because of collision of urethane NH and α-NH in the dehydroamino acid residue. Consequently, the side chain (CH_3 or $(CH_3)_2CHCH_2$) and the Boc group project to the upper and lower side, respectively, of the piperazinedione ring or vice versa. This indicates that the extent of chiral induction is not necessarily determined only by the methyl side chain in the Ala residue, i.e., chiral source. Interestingly, (4*S*)-**6L** could be highly selectively hydrogenated, although we can not now explain the reason.

The R_f values on paper chromatography of synthetic (2*S*,4*S*)-**1** and (2*S*,4*R*)-**1** were quite different from those of the reported compound which was estimated previously as 2,4-diaminopentanoic acid (see Table 2). Therefore, the structure of the metabolic intermediate should be reexamined. To date, the intermediates in the similar reactions in the lysine fermentation have been identified as 3,6-diaminohexanoic acid (β-lysine),[12] 3,5-diaminohexanoic acid,[13,14] and 5-amino-3-oxohexanoic acid.[15] Another amino acid has been tentatively identified as 2,5-diaminohexanoic acid.[16]

We tried to develop our asymmetric synthesis for the preparation of unusual basic amino acids. Further work along this line is in progress in order to obtain stereoselectively complicated amino acid, such as ones containing two or more asymmetric centers.

Experimental

Thin-layer chromatography was performed on silica gel G (Merck) with the following solvent systems: R_f^1 *n*-BuOH–AcOH–pyridine–H_2O (4:1:1:2, v/v); R_f^2, $CHCl_3$–MeOH (5:1, v/v); R_f^3, $CHCl_3$–EtOAc (1:1, v/v); R_f^4, *n*-BuOH–AcOH–H_2O (1:1:2, v/v). Optical rotations were measured on a Union high-sensitivity polarimeter PM-71. Amino acid analyses were performed with a Hitachi KLA-5 amino acid analyzer after the hydrolysis in 6 M HCl (1 M=1 mol dm^{-3}) in sealed tubes at 110 °C for 24 h. ^1H NMR spectra were determined at 25 °C with JEOL JNN-GX-400 spectrometer (400 MHz) using Me_4Si as the internal standard in DMSO-d_6.

Cyclo(-Ac-Gly-Ac-L-Ala-) (4L) and Cyclo(-Ac-Gly-Ac-D-Ala-) (4D). Compound **4L** and **4D** were synthesized by the same procedure as that described in the literature.[1]

Cyclo(-ΔA$_2$PA(Boc)-L-Ala-) ((4S)-5L). To a chilled solution of **4L** (2.2 g, 10.5 mmol) in DMF (15 ml) were added a solution of *t*-BuOK (1.2 g, 10.5 mmol) in *t*-BuOH (20 ml) and **10** (1.82 g, 10.5 mmol)[8] at 0 °C. The mixture was stirred at 0 °C for 2 h and at 25 °C for 3 h. After evaporation in vacuo, the residue was dissolved in EtOAc, washed with water, dried over Na_2SO_4 and evaporated. Oily cyclo(-ΔA$_2$PA-N-Ac-L-Ala-) was dissolved in DMF (5 ml), and to the solution was added 1-(2-aminoethyl)piperazine (2.6 ml) at 0 °C. The solution was stirred at 0 °C for 1 h and at 25 °C for 2 h and evaporated in vacuo. The residue was dissolved in EtOAc, washed with 10% citric acid and aq. NaCl, dried over Na_2SO_4 and evaporated. The residual oil was crystallized by the addition of MeOH–ether. Yield, 600 mg (28%); mp 215—220 °C; $[\alpha]_D^{20}$ +106° (*c* 1.0, MeOH); R_f^2 0.73. Found: C, 54.81; H, 7.34; N, 14.70%. Calcd for $C_{13}H_{21}O_4N_3$: C, 55.11; H, 7.47; N, 14.83%. Compound (4*S*)-**5D** was prepared similarly from **4D** and **10**. Yield, 59%; mp 210—214 °C; $[\alpha]_D^{20}$ +104° (*c* 1.0, MeOH); R_f^2 0.68. Found: C, 55.22; H, 7.47; N, 14.55%.

Cyclo(-ΔA$_2$HA(Boc)-L-Ala-) ((4S)-6L). Compound (4*S*)-**6L** was synthesized by the same procedure as that described above using **4L** (1.7 g, 7.9 mmol) and **11** (2.36 g, 10.5 mmol).[8] Yield, 475 mg (19%); mp 187—191 °C; $[\alpha]_D^{20}$ +106° (*c* 1.0, MeOH); R_f^3 0.34. Found: C, 58.66; H, 8.39; N, 12.65%. Calcd for $C_{16}H_{27}O_4N_3$: C, 59.06; H, 8.39; N, 12.91%. Compound (4*S*)-**6D** was prepared similarly from **4D** and **11**. Yield 19%; mp 179—185 °C; $[\alpha]_D^{20}$ +108° (*c* 1.0, MeOH); R_f^3 0.33. Found: C, 58.78; H, 8.39; N, 12.76%.

Cyclo(-A$_2$PA(Boc)-L-Ala-). Compound (4*S*)-**5L** (567 mg, 2 mmol) was dissolved in MeOH (20 ml) and hydrogenated at 1 atm pressure of H_2 in the presence of Pd black (20 mg) for 5 h at 25 °C. The filtrate was evaporated and the residue was crystallized by the addition of ether–petroleum ether. The hydrogenated compound was observed to show two spots by R_f^3, owing to the presence of diastereomers ((2*S*, 4*S*)-**7L** and (2*R*,4*S*)-**7L**). Yield of the diastereomers, 525 mg (92%), R_f^3 0.27 and 0.15. Cyclo(-A$_2$PA(Boc)-D-Ala-) was prepared similarly. Yield of the diastereomers ((2*S*,4*S*)-**7D** plus (2*R*,4*S*)-**7D**), 90%; R_f^3 0.25 and 0.15.

Cyclo(-A$_2$HA(Boc)-L-Ala-). This compound was synthesized by the same procedure as described above using (4*S*)-**6L** (423 mg, 1.3 mmol). The yield of the diastereomers ((2*S*, 4*S*)-**8L** plus (2*R*,4*S*)-**8L**), 362 mg (85%); R_f^3 0.38 and 0.36. Cyclo(-A$_2$HA(Boc)-D-Ala-) was prepared similarly. The yield of the diastereomers ((2*S*,4*S*)-**8D** plus (2*R*,4*S*)-**8D**) was 93%; R_f^3 0.37 and 0.34.

2,4-Diaminopentanoic Acid ((2*S*,4*S*)-1 and (2*R*,4*S*)-1). Cyclo(-A$_2$PA(Boc)-L-Ala-) (428 mg, 1.5 mmol) was hydrolyzed with 6 M HCl at 110 °C for 24 h. The solution was evaporated several times by the addition of water. The residue dissolved in water was put on a column of Dowex 50WX8 (200—400 mesh, H^+ form). The column was washed with water, 1 M pyridine, and eluted with 2 M aq. ammonia. The eluate was evaporated several times by the addition of water. The enantiomeric ratio of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** was determined using a portion of the residue as 3:2 with an amino acid analyzer. The yield of (2*S*,4*S*)-**1** plus (2*R*,4*S*)-**1** was 172 mg (87%); R_f^1 0.33 and 0.25. The ratio of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** from cyclo(-A$_2$PA(Boc)-D-Ala-) was 1:5. The yield of (2*S*,4*S*)-**1** plus (2*R*,4*S*)-**1** in a 1.5 mmol scale was 163 mg (82%); R_f^1 0.33 and 0.25. The residue was solidified from H_2O–acetone as its monohydrochloride by the addition of an equivalent hydrochloric acid.

2,4-Diamino-6-methylheptanoic Acid ((2*S*,4*S*)-2 and (2*R*, 4*S*)-2). Hydrolysis of cyclo(-A$_2$HA(Boc)-L-Ala-) and cyclo(-A$_2$HA(Boc)-D-Ala-) (327 mg, 1 mmol each) was performed by the same procedure as that described above. The ratios of (2*S*,4*S*)-**2** and (2*R*,4*S*)-**2** were determined as 95:5 from cyclo(-A$_2$HA(Boc)-L-Ala-) and 2:3 from cyclo(-A$_2$HA(Boc)-D-Ala-), respectively. Yields of (2*S*,4*S*)-**2** plus (2*R*,4*S*)-**2** from cyclo(-A$_2$HA(Boc)-L-Ala-) and from cyclo(-A$_2$HA(Boc)-D-Ala-) were 194 mg (92%) and 169 mg (80%), respectively; R_f^1 0.64 and 0.25.

Separation of (2*S*,4*S*)-1 and (2*R*,4*S*)-1. Diastereomeric 2,4-diaminopentanoic acid (**1**) from cyclo(-A$_2$PA(Boc)-L-Ala-) (68 mg 0.4 mmol) was separated into its diastereoisomers by chromatography using a colum (1.8×150 cm) of AG 50WX8 (200—400 mesh, H^+ from). Diastereomers were eluted with a 0.35 M sodium citrate buffer of pH 5.28. The component of the fraction from 1850 to 2000 ml was confirmed to be (2*S*,4*S*)-**1** and that of the fraction from 2300 to 2450 ml to be (2*R*,4*S*)-**1**, using an amino acid analyzer. Each of the fractions containing (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** was concentrated. The concentrated solution was desalted using Dowex 50WX8 (200—400 mesh, H^+ form). After washing with water, the basic amino acid was eluted with 2 M aq. ammonia. The eluate was evaporated several times in order to remove excess ammonia by the addition of water. The residue was recrystallized from H_2O–acetone as its monohydrochloride. Recoveries of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1** were 32 mg (77%) and 16 mg (59%), respectively. (2*S*,4*S*)-**1**; mp 185—191 °C (decomp); $[\alpha]_D^{20}$ +7.2° (*c* 0.3, H_2O); R_f^1 0.33. Found: C, 35.90; H, 7.65; N, 16.21%. Calcd for $C_6H_{12}O_2N_2 \cdot HCl$: C, 35.61; H, 7.77; N, 16.61%. (2*R*,4*S*)-**1**; mp 198—202 °C (decomp); $[\alpha]_D^{20}$ −5.0° (*c* 1.0, H_2O); R_f^1 0.25. Found: C, 35.77; H, 7.78; N, 16.03%. Diastereomeric **1** (68 mg, 0.4 mmol) from cyclo(-A$_2$PA(Boc)-D-Ala-) was also treated similarly. Recoveries of (2*S*,4*S*)-**1** and (2*R*,4*S*)-**1**, 6 mg (45%) and 40 mg (72%).

Separation of (2*S*,4*S*)-2 and (2*R*,4*S*)-2. Diastereoisomeric 2,4-diamino-6-methylheptanoic acid from cyclo(-A$_2$HA(Boc)-L-Ala-) (105 mg, 0.5 mmol) was separated into its diastereoisomers by chromatography using a column (1×30 cm) of AG 50WX8 (200—400 mesh, H^+ form). Diastereoisomers were eluted with a 0.35 M sodium citrate buffer of pH 5.28. The component of the fraction from 350 to 500 ml was

confirmed to be (2*S*,4*S*)-**2**, and that of the fraction from 650 ml to 800 ml to be (2*R*,4*S*)-**2**, and worked up as described above. Recoveries of (2*S*,4*S*)-**2** and (2*R*,4*S*)-**2** were 82 mg (82%) and 4 mg (74%), respectively. (2*S*,4*S*)-**2**; mp 235—240 °C (decomp); $[\alpha]_D^{20}$ +7.6° (*c* 0.5, H_2O); R_f^1 0.63. Found: C, 45.28; H, 9.02; N, 13.30%. Calcd for $C_8H_{18}O_2N_2 \cdot HCl$: C, 45.60; H, 9.09; N, 13.30%. (2*R*,4*S*)-**2**; mp 245—248 °C (decomp); $[\alpha]_D^{20}$ −5.3° (*c* 0.5, H_2O); R_f^1 0.55. Found: C, 45.35; H, 9.25; N, 13.15%. Diastereomeric **2** (105 mg) from cyclo(-A_2HA(Boc)-D-Ala-) was also treated similarly. Recoveries of (2*S*,4*S*)-**2** and (2*R*,4*S*)-**2** were 32 mg (76%) and 53 mg (83%), respectively.

Cyclo(-ΔOrn(Boc)-L-Ala-) (9). To a solution of Boc-$NH(CH_2)_3OH$ (9.58 g, 54.7 mmol) in CH_2Cl_2 (200 ml) was added pyridium dichromate (43.76 g, 109 mmol). The mixture was stirred at room temperature for 24 h. After evaporation in vacuo, the residue dissolved in EtOAc was put on a column of silica gel and the portion containing aldehyde was collected. After evaporation in vacuo, crude aldehyde (6.31 g, 12.2 mmol) was obtained. To a solution of crude aldehyde in DMF (40 ml) were added a solution of *t*-BuOK (1.64 g, 12.2 mmol) in *t*-BuOH (30 ml) and **4L** (2.63 g, 12.2 mmol) at 0 °C. The mixture was stirred at 0 °C for 2 h, at 25 °C for 24 h and evaporated in vacuo. The residue was dissolved in EtOAc, washed with water, dried over Na_2SO_4 and evaporated. The residue was dissolved in DMF (6 ml) and was added to $NH_2NH_2 \cdot H_2O$ (0.97 ml, 12.2 mmol). The mixture was stirred at 25 °C for 2 h and evaporated. The residue was crystallized by the addition of ether. Yield, 1.85 g (54%); mp 233—235 °C; $[\alpha]_D^{20}$ −12.4° (*c* 1.0, DMF); R_f^2 0.69. Found: C, 55.03; H, 7.56; N, 14.78%. Calcd for $C_{13}H_{21}O_4N_3$: C, 55.11; H, 7.47; N, 14.83%.

Cyclo(-Orn(Boc)-L-Ala-). This compound was synthesized from **9** (220 mg, 0.78 mmol) by the same procedure as described for the preparation of cyclo(-A_2PA(Boc)-L-Ala-). The yield was 208 mg (94%).

L-Ornithine (3). The hydrolysis of cyclo(-Orn(Boc)-L-Ala-) (460 mg, 1.6 mmol) was performed by the same procedure described for the preparation of **1**. This compound was confirmed to be L-Orn, as compared with authentic L-Orn by thin-layer chromatography and polarimetry. The yield was 130 mg (62%); R_f^1 0.03, R_f^4 0.54; $[\alpha]_D^{20}$ +17.1° (*c* 1.0, H_2O) (lit,[17] $[\alpha]_D^{20}$ +16.8° (*c* 1, H_2O)).

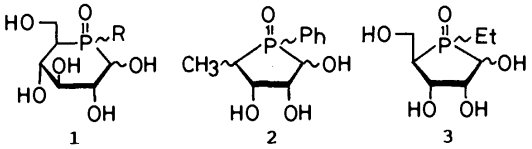
Synthesis and Structural Analysis of 4-Deoxy-4-(hydroxyphosphinyl and phenylphosphinyl)-D-ribofuranoses

Tadashi HANAYA and Hiroshi YAMAMOTO*
Department of Chemistry, Faculty of Science, Okayama University,
Tsushima, Okayama 700
(Received February 13, 1989)

Methyl 2,3-*O*-isopropylidene-β-D-ribopyranoside gave efficiently (in 4 steps) methyl 4-deoxy-4-[dimethoxyphosphinyl and (methoxy)phenylphosphinyl]-2,3-*O*-isopropylidene-β-D-ribopyranosides (ca. 30% overall yield). These were led (in 2—3 steps) to the title compounds and then converted into 1,2,3,5-tetra-*O*-acetyl-4-deoxy-4-(methoxyphosphinyl and phenylphosphinyl)-D-ribofuranoses, whose structures and $^3T_2$ (and $^2T_3$) conformations were established by spectroscopy.

Various sugar analogues possessing a phosphorus atom in place of oxygen in the hemiacetal ring have been prepared in recent years;[1-6] e.g., 5-deoxy-5-phosphinyl-D-glucopyranoses (**1**).[4,7] These compounds are of interest in view of their physicochemical properties as well as potential biological activity.[1] As for analogues of D-ribose type, 4,5-dideoxy-4-(phenylphosphinyl)- (**2**)[8] and 4-deoxy-4-(ethylphosphinyl)-D-ribofuranoses (**3**)[3] have been synthesized in lengthy steps as a mixture with their L-lyxofuranose analogues (particularly in the case of **2**). We wish to report herein our detailed studies on synthesis and structural analysis of D-ribofuranose analogues having a hydroxyphosphinyl group in the ring,[9] as well as of those having PO(Ph) as a representative arylphosphinyl group in the ring. Although PO(OH)-in-ring sugar analogues were usually found more difficult to prepare than those having an alkyl- or arylphosphinyl group in the ring,[1,3,10] both 4-deoxy-4-(hydroxyphosphinyl and phenylphosphinyl)-D-ribofuranoses have become available in almost comparably good yield. The present synthesis also clarifies the ambiguity that existed in the previous synthetic schemes concerning the epimerization caused by hydride reduction of some intermediates.[4,7]



Results and Discussion

For synthesis of the D-ribofuranose analogues **3**,[3] methyl 2,3-*O*-isopropylidene-α-L-lyxopyranoside (**5**, prepared,[3,11] with some difficulty, from D-galacturonic acid **4** in 4 steps) was used as the precursor of the preparation of the starting material, (methyl 2,3-*O*-isopropylidene-β-D-*erythro*-pentopyranosid)-4-ulose (**6**)[3] (Scheme 1). However, we have now found it more convenient to utilize instead methyl 2,3-*O*-isopropylidene-β-D-ribopyranoside (**7**) for preparation of **6**, because **7** is readily available in quantities, though along with the chromatographically separable 3,4-*O*-isopropylidene isomer, from D-ribose in 2 steps.[12] Oxidation of **7** with pyridinium chlorochromate (PCC) in dichloromethane in the presence of Molecular Sieves (3A) now furnished **6** more effectively than the previous oxidation procedure for **5** (see Scheme 1).

Compound **6** was then converted into the tosylhydrazones **8a,b**[3] (as a 4:1 mixture of *Z* and *E* isomers) in 95% yield. This in turn was treated with an excess of dimethyl phosphonate in the presence of trifluoromethanesulfonic acid at 25 °C for 5 h, giving the (4*S*)-phosphonate **9** (56% isolated yield) and the (4*R*)-epimer **10** (10%), together with minor proportions of by-products **11** (10%), **12** (4%), and **13** (1.5%). These compounds were chromatographically separable, and their structural and conformational assignments (see Scheme 2) were made on the basis of spectral data (in particular by ^{1}H NMR, see the complete assignments given in the Experimental section). For distinction between the two major products **9** and **10**, the following characteristic δ, ^3J, and ^4J values of their ^{1}H NMR data were taken into consideration: δ 4.85 (H-1), $J_{1,2}$=4.7 Hz, and $J_{2,P}$=1.2 Hz for **9** (predominantly in $^1C_4$ form) and δ 4.17 (H-1), $J_{1,2}$=7.2 Hz, and $J_{3,5e}$=1.5 Hz for **10** ($^4C_1$). Among the minor products, **11** was readily protected again with 2,2-dimethoxypropane to

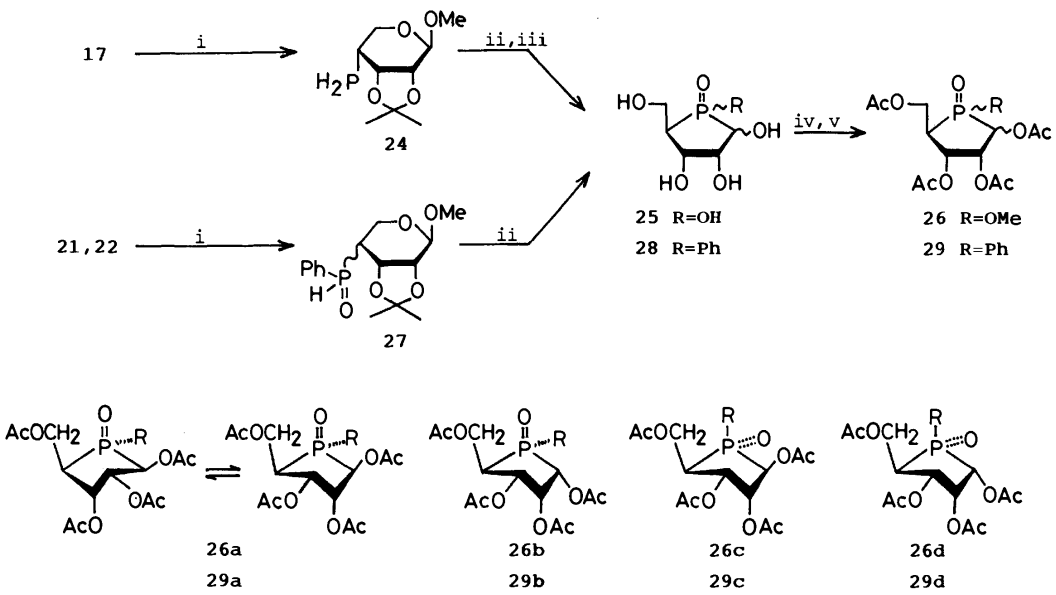
reproduce the above 2,3-*O*-isopropylidene compounds **9** and **10**.

Similarly, the addition of methyl phenylphosphinate to **8a,b** took place smoothly, affording (4*S*)-phosphinates **14a,b** (60% yield) and (4*R*)-epimers **15a,b** (6%), together with the deprotected products **16** (9%), each being a mixture of inseparable, two diastereomers due to asymmetry of the phosphorus atom. Their structures and the preferred conformations shown in Scheme 2 were established as described above (for **9**—**11**); note that no minor products corresponding to **12** and **13** were obtained in this case. This is the first time that both epimers of the phosphonate or phosphinate addition products have been isolated and characterized in this type of synthetic scheme for the sugar ring-C–P bond formation.[1]

Reductive removal of the tosylhydrazino group from these addition products were then studied in detail. Thus, upon treatment of the major (4*S*)-epimer **9** with sodium borohydride in THF at 25 °C for 12 h, it was found that methyl 4-deoxyl-4-(dimethoxyphosphinyl)-2,3-*O*-isopropylidene-β-D-ribopyranoside (**17**) and α-L-lyxopyranoside (**18**) were produced in a ratio of 85:15, respectively (Scheme 3). When the minor (4*R*)-epimer **10** was subjected to the same reduction, **17** and **18** were obtained notably in almost the same ratio as above. The structural assignments of these C-4 epimers were based on their spectral data (see the Experimental section); the following characteristic ^1H NMR data in particular served for clear distinction between them, δ 4.37 (H-1), $J_{3,4}$=3.0 Hz, and $J_{3,5e}$=0.8 Hz for **17** ($^4C_1$) vs. δ 4.79 (H-1), $J_{1,5e}$=2.0 Hz, $J_{2,P}$=1.6 Hz, and $J_{3,4}$=8.4 Hz for **18** ($^1C_4$). Besides **17** and **18**, a minor proportion of detosylated hydrazino compounds **19** (12%) and **20** (7%) were produced from **9** and **10**, respectively. By the analysis of the NMR data, all of these compounds (**17**—**20**) are most likely to have conformations (in $CDCl_3$) in which the phosphonate group is predominantly linked equatorially (see Scheme 3).

Similar results were obtained for the reductive cleavage of 4-deoxy-4-[(methoxy)phenylphosphinyl] compounds **14** and **15**, thus either of these compounds providing the D-ribopyranosides **21a,b** and L-lyxopyranosides **22a,b** in a ratio of 88:12, besides a minor amount (7% yield) of hydrazino compounds **23** consisting of a ca. 1:7 mixture of (4*R*)- and (4*S*)-epimers (Scheme 3). Furthermore, the borohydride reduction of a pure epimer **15a**, which was the only crystalline compound among the four diastereomers **14a,b** and **15a,b**, was found to give the same ratio (88:12) of two pure diastereomers **21a** and **22a**, together with a minor proportion of a pure (4*R*)-4-hydrazino-epimer **23a**; note that no other isomers **21b** and **22b** were produced from **15a**. These results therefore indicated that an epimerization took place at C-4 (but not at the P atom) during the borohydride



Scheme 4. Synthesis and Conformations of **26** and **29**. i, SDMA/benzene. ii, 0.5 M HCl-*i*PrOH. iii, aq H_2O_2. iv, CH_2N_2/MeOH–DMSO. v, Ac_2O–Pyridine.

reduction of all of these hydrazino compounds **9**, **10**, **14**, and **15**, resulting in the formation of the major products **17** and **21a,b** presumably through a thermodynamically controlled process.

The D-ribose type precursor **17** was then reduced with an excess (3 equiv) of sodium dihydrobis(2-methoxyethoxy)aluminate (SDMA)[13] in benzene at 5 °C for 1 h, giving solely methyl 4-deoxy-2,3-*O*-isopropylidene-4-phosphino-β-D-ribopyranoside **24** (Scheme 4); it should be noticed that no epimerization occurred at C-4 of **17** with SDMA (see below), in contrast to the equilibration (at C-5) observed in the case of 5-deoxy-5-[ethyl(methoxy)phosphinyl]-α-D-*xylo*-hexofuranoses to give predominantly 5-deoxy-5-(ethylphosphinyl)-L-idopyranoses.[5c]

The extremely air-sensitive compound **24** was promptly hydrolyzed under argon with mineral acid at 90 °C for 1 h to effect deprotection and the subsequent ring transposition. Oxidation of the resulting air-sensitive[10] phosphinediyl-in-ring compound with hydrogen peroxide at 25 °C for 1 d afforded 4-deoxy-4-(hydroxyphosphinyl)-D-ribofuranoses (**25**). For isolation and characterization, **25** were converted into its 4-(methoxyphosphinyl) tetraacetates **26** by the usual method (in 17% overall yield from **17**) (see Scheme 4). Rechromatography of **26** in a column of silica gel with 19:1 ethyl acetate–ethanol as the eluant afforded pure 1,2,3,5-tetra-*O*-acetyl-4-deoxy-4-[(*R*)-methoxyphosphinyl]-β-D-ribofuranose (**26a**, 6.3% yield from **17**), its α-anomer **26b** (3.3% yield), and the 4-[(*S*)-*P*]-β-isomer **26c** (2.8%), and its α-anomer **26d** (1.7%). Structures of **26a—d** were established by the analysis of their spectral data (Experimental section) and the approximate conformations of these isomers shown in Scheme 4 were derived from the analysis of 500 MHz ^{1}H NMR spectra (see below). The fact that the products **26a—d** were all D-ribofuranose configuration proved that no epimerization actually took place at C-4 of **26** during the SDMA reduction to yield **24**.

The conversion of 4-[(methoxy)phenylphosphinyl] compounds **21** and **22** into the corresponding PO(Ph)-in-ring D-ribofuranose analogues **28** was conducted by the same procedures described above. Namely, the SDMA reduction of **21** (or **22**) gave the 4-(phenylphosphinyl)-β-D-*erythro*-pentopyranoside **27**, which was then treated with dilute acid to provide predominantly 4-deoxy-4-(phenylphosphinyl)-D-ribofuranoses (**28**). Characterization of **28** was made as the 4-deoxy-4-(phenylphosphinyl) tetraacetates **29a—d** (see Scheme 4) as described above for **26a—d**.

^{1}H NMR Spectral Analysis of Tetra-*O*-acetyl-4-deoxy-4-(methoxy- and phenylphosphinyl)-D-ribofuranoses (26a—d and 29a—d). For the structural assignments of these new products, the chemical shift of each proton signal and the dependence of $^2J_{H,P}$, $^3J_{H,P}$, $^3J_{H,H}$, and $^4J_{H,H}$ values on their dihedral angles were carefully taken into consideration; the precise parameters obtained at 500 MHz for these compounds are summarized in Table 1. Some characteristic features of **26** and **29** are discussed here in detail, although in many cases they closely resemble those of the previously obtained **2** and **3**.

(1) The orientation of the ring P=O group can be established by the δ values of H-4 in combination with

a) The assignments of acetoxyl groups may have to be interchanged. b) J Values for P-Ph: $J_{P,o}$=12.5, $J_{P,m}$=3.5, $J_{P,p}$=1.5, $J_{o,p}$=7.8, $J_{m,p}$=7.5, and $J_{o,p}$=1.5 Hz. Compounds **29b—d** show similar J values.

the $J_{4,P}$ values. In the present study, a slightly upfield shift of these signals with a smaller $J_{4,P}$ value† is observed for **26a,b** and **29a,b**, thus showing an almost trans relationship between H-4 and the ring P=O for these compounds. The cis or gauche relationship for **26c,d** and **29c,d** was confirmed by the large $J_{4,P}$ values.† The anomeric orientation of C-1 is similarly derived from the magnitudes of δ values of H-1 and the $J_{1,P}$ values as well as the presence of $J_{1,4}$. Namely, a relatively large values of δ and $J_{1,P}$† for H-1 of **26b,c** and **29b,c** indicate the cis (or gauche) relationship of the H-1 and P=O groups, whereas the small $J_{1,P}$ values† point out an almost trans relationship for **26a,d** and **29a,d**. The presence of a small long-range W-coupling ($J_{1,4}$) observed for **26a,c** and **29a,c** indicates the β-configuration of H-1. Therefore, combination of these data readily permits unambiguous establishment of the configurations of H-1 as well as ring-phosphorus atom of aldopentofuranoses.

(2) Compounds **26b—d** and **29b—d** have a large $J_{2,P}$ values and small $J_{3,P}$ and thus are considered to exist preponderantly in the E_2 (or readily variable $^3T_2$) conformation. The concurrent differences in the δ values of H-2 (larger) and H-3 (smaller) further support their respective quasi-equatorial and quasi-axial orientation. Compounds **26a** and **29a** have rather close magnitudes of $J_{2,P}$ and $J_{3,P}$ and the δ values of H-2 and H-3. This suggests an averaging between the interconverting $^3T_2$ and $^2T_3$ conformations with a slight tendency towards $^3T_2$ and $^2T_3$ form (respectively for **26a** and **29a**), judging from the magnitudes of the corresponding δ and J values. The conformations of these P-in-ring D-ribofuranoses are of interest in view of the reported monocyclic furanoid derivatives including many nucleosides and nucleotides which are regarded as existing as rapidly interconverting conformation in solution, favoring puckering the C-2–C-3 region of the furanoid ring.[14]

The present findings are believed to have clearly proved the equilibrated epimerization caused by the hydride reagents in favor of the formation of the key intermediate methyl 4-deoxy-4-phosphinyl-β-D-ribopyranosides, as well as to have established an efficient synthetic scheme for preparation of D-ribofuranose analogues having various kinds of phosphinyl or phosphino group in the hemiacetal ring. The extension of this work including improvement of the yields of the ring-transposition steps and preparation of D-ribofuranose analogues having various other kinds of *P*-substituents, as well as biological evaluation of the compounds, is in progress.

Experimental

Melting points were determined with a Yanagimoto MP-S3 instrument and were uncorrected. All reactions were monitored by TLC (Merck silica gel 60F, 0.25 mm) with (*A*) AcOEt, (*B*) 1:1 AcOEt-hexane, (*C*) 19:1 AcOEt-EtOH, and (*D*) 5:3:1 2-propanol-AcOEt-water as the eluant; components were detected by exposing the plates to UV light and/or by spraying them with 20% sulfuric acid-ethanol, with subsequent heating. Column chromatography was

† For these features, an exception lies in the parameters for the methoxyphosphinyl compounds **26a—d**, having intermediate, close magnitudes of $J_{1,P}$ and $J_{4,P}$. These unusual parameters have also been observed for per-*O*-acetyl-5-deoxy-5-(methoxyphosphinyl)-D-xylo-[10] and D-gluco-pyranoses.[4]

performed by Wako C-200 silica gel. The ^{1}H NMR spectra were measured in $CDCl_3$ (unless otherwise specified) with a Hitachi R-600 (60 MHz) or Varian VXR-500 instrument (500 MHz, the CS-NMR Lab., Okayama Univ.) at 27 °C. Chemical shifts (at 500 MHz unless otherwise stated) were recorded as δ values relative to tetramethylsilane as the internal standard. The assignments of all signals were made by employing a first-order analysis with the aid of decoupling technique and, when necessary, the parameters were confirmed by a computer-assisted simulation analysis. The mass spectra (EI, unless otherwise specified) were taken on a Shimadzu LKB-9000 low-resolution or a JEOL JMX-HX100 high-resolution instrument and were given in terms of *m/z* (rel intensity) compared with the base peak.

(Methyl 2,3-*O*-Isopropylidene-β-D-*erythro*-pentopyranosid)-4-ulose[3] (6). To a stirred suspension of finely powdered Molecular Sieves 3A (20 g) and PCC (10.0 g, 46.4 mmol) in dry CH_2Cl_2 (150 cm^3) was added a soln of **7**[12] (4.29 g, 21.0 mmol) in dry CH_2Cl_2 (50 cm^3) at 0 °C. The mixture was stirred at 20 °C for 4 h and then 2-propanol (5 cm^3) was added at 0 °C. The mixture was stirred at 20 °C for 2 h, triturated with ether (500 cm^3) for 2 h, and the ppt was filtered off through activated carbon. The filtrate was evaporated in vacuo and the residue was purified by short-pass chromatography with 2:1 AcOEt–hexane as an eluant, giving **6** as a colorless syrup (3.98 g, 94%, lit,[3] 74% from **5**): R_f=0.60 (*B*); ^{1}H NMR[15] δ=1.37, 1.51 (3H each, 2s, CMe_2), 3.47 (3H, s, MeO-1), 4.13, 4.18 (1H each, 2d, $J_{5,5'}$=16.8 Hz, H-5,5′), 4.41 (1H, d, $J_{2,3}$=6.8 Hz, H-3), 4.42 (1H, dd, $J_{1,2}$=0.8 Hz, H-2), and 4.78 (1H, br s, H-1).

(Methyl 2,3-*O*-Isopropylidene-β-D-*erythro*-pentopyranosid)-4-ulose (*Z*)- and (*E*)-4-Tosylhydrazones[3] (8a,b). A slightly modified procedure was employed to give a better yield of the product. Thus, to a soln of **6** (3.94 g, 19.5 mmol) in absolute methanol (100 cm^3) was added tosylhydrazine (4.00 g, 21.5 mmol) under stirring at room temp. After 6 h, the mixture was evaporated in vacuo. The residue was diluted with CH_2Cl_2, washed with dil HCl, aq $NaHCO_3$, and then with water. The organic layer was dried (Na_2SO_4) and evaporated in vacuo. The residue was purified by column chromatography with 1:1 AcOEt–hexane, giving **8** as a colorless amorphous solid (6.84 g, 95%): R_f=0.50 (**8a**), 0.42 (**8b**) (*B*) (4:1, lit,[3] 91% yield, 1:1); ^{1}H NMR[15] for **8a** (*Z*) δ=1.05, 1.33 (3H each, 2s, CMe_2), 2.41 (3H, s, MeC_6-S), 3.41 (3H, s, MeO-1), 4.06, 4.20 (1H each, 2d, $J_{5,5'}$=14.8 Hz, H-5,5′), 4.13 (1H, dd, $J_{2,3}$=5.8, $J_{1,2}$=0.8 Hz, H-2), 4.83 (1H, d, H-3), 4.87 (1H, br s, H-1), 7.28, 7.80 (2H each, 2br d, J=8.4 Hz, C_6H_4-S), and 9.69 (1H, br s, NH); for **8b** (*E*) δ=1.32, 1.45 (3H each, 2s, CMe_2), 2.43 (3H, s, MeC_6-S), 3.34 (3H, s, MeO-1), 4.16 (1H, br d, $J_{2,3}$=7.4 Hz, H-2), 4.26 (2H, s, H-5,5′), 4.55 (1H, br s, H-1), 4.67 (1H, d, H-3), 7.31, 7.83 (2H each, 2br d, J=8.3 Hz, C_6H_4-S), and 7.61 (1H, br s, NH), for the reasoning behind the respective assignments of *Z* and *E* isomers to **8a** and **8b**, see Ref. 16.

Methyl (4*R* and 4*S*)-4-Deoxy-4-(dimethoxyphosphinyl)-4-(2-tosylhydrazino)-β-D-*erythro*-pentopyranosides (9—13). To a mixture of **8** (1.28 g, 3.76 mmol) and dimethyl phosphinate (3.30 g, 30.0 mmol) was added trifluoromethanesulfonic acid (0.100 cm^3, 1.13 mmol) at 0 °C under argon, followed by stirring at 25 °C for 5 h. The mixture was diluted with CH_2Cl_2, washed with saturated aq $NaHCO_3$ and then with water, dried (Na_2SO_4), and evaporated in vacuo. The residue was chromatographed on a silica-gel column with 2:1 AcOEt–hexane (which was gradually changed to AcOEt), giving **9—13**.

9 [(4*S*)-2,3-*O*-Isopropylidene-epimer]: Colorless syrup (1.01 g, 56%); R_f=0.33 (*A*); ^{1}H NMR δ=1.32, 1.35 (3H each, 2s, CMe_2), 2.42 (3H, s, MeC_6-S), 3.47 (3H, s, MeO-1), 3.77, 3.84 [3H each, 2d, J_{POMe}=10.7, 10.5 Hz, P(OMe)$_2$], 3.88 (1H, dd, $J_{5e,5a}$=12.6, $J_{5a,P}$=7.0 Hz, H-5a), 4.03 (1H, ddd, $J_{2,3}$=6.7, $J_{1,2}$=4.7, $J_{2,P}$=1.2 Hz, H-2), 4.14 (1H, dd, $J_{5e,P}$=11.4 Hz, H-5e), 4.30 (1H, br s, NH-4), 4.59 (1H, dd, $J_{3,P}$=8.5 Hz, H-3), 4.85 (1H, d, H-1), 6.40 (1H, br s, TsNH), and 7.30, 7.80 (2H each, 2br d, J=8.1 Hz, C_6H_4-S); MS *m/z* 480 (M^+; 0.7), 465 (7), 325 (7), 293 (10), 221 (30), 207 (29), 193 (100), 178 (30), 165 (51), 137 (27), 109 (46), and 91 (55).

Found: *m/z* 480.1341. Calcd for $C_{18}H_{29}N_2O_9PS$: M, 480.1331.

10 [(4*R*)-2,3-*O*-Isopropylidene-epimer]: Colorless needles (178 mg, 10%); R_f=0.23 (*A*); mp 156—157 °C (from AcOEt–hexane); ^{1}H NMR δ=1.33, 1.51 (3H each, 2s, CMe_2), 2.42 (3H, s, MeC_6-S), 3.47 (3H, s, MeO-1), 3.70 (1H, dt, $J_{5e,5a}$=12.9, $J_{5e,P}$=1.6, $J_{3,5e}$=1.5 Hz, H-5e), 3.76, 3.83 [3H each, 2d, J_{POMe}=10.8, 10.9 Hz, P(OMe)$_2$], 3.88 (1H, dd, $J_{1,2}$=7.2, $J_{2,3}$=5.1 Hz, H-2), 3.92 (1H, dd, $J_{5a,P}$=1.9 Hz, H-5a), 3.95 (1H, br s, NH-4), 4.17 (1H, d, H-1), 4.36 (1H, ddd, $J_{3,P}$=3.5 Hz, H-3), 6.58 (1H, br s, TsNH), and 7.32, 7.79 (2H each, 2br d, J=8.2 Hz, C_6H_4-S); MS *m/z* 465 ($M-CH_3$; 0.8), 325 (1.5), 293 (14), 281 (30), 221 (59), 207 (39), 178 (72), 165 (40), 149 (58), 109 (90), and 91 (100).

11: Pale yellow syrup (165 mg, 10%); R_f=0.15—0.08 (*A*); ^{1}H NMR (60 MHz) δ=2.40 (3H, s, MeC_6-S), 3.47 (3H, s, MeO-1), 3.0—3.6 (2H, m, HO-2,3), 3.77, 3.82 [3H each, 2d, J_{POMe}=11.0 Hz, P(OMe)$_2$], 3.7—4.6 (5H, m, H-2,3,5,5′, NH-4), 4.70 (1H, br d, $J_{1,2}$=3.0 Hz, H-1), 6.9—7.2 (1H, m, TsNH), and 7.30, 7.84 (2H each, 2d, J=8.1 Hz, C_6H_4-S).

12 [(4*S*)-3-*O*:4-*N*-Isopropylidene-isomer]: Colorless prisms (68 mg, 4%); R_f=0.28 (*A*); mp 153—154 °C (from AcOEt); ^{1}H NMR δ=0.62, 1.33 (3H each, 2s, CMe_2), 2.33 (1H, br s, HO-2), 2.42 (3H, s, MeC_6-S), 3.46 (3H, s, MeO-1), 3.68 (1H, dd, $J_{1,2}$=6.5, $J_{2,3}$=3.0 Hz, H-2), 3.78, 3.97 [3H each, 2d, J_{POMe}=10.9, 11.0 Hz, P(OMe)$_2$], 3.80 (1H, dd, $J_{5e,5a}$=12.5, $J_{5a,P}$=3.5 Hz, H-5a), 4.06 (1H, dd, $J_{5e,P}$=4.2 Hz, H-5e), 4.52 (1H, d, H-1), 4.61 (1H, dd, $J_{3,P}$=15.6 Hz, H-3), 7.23 (1H, br s, TsNH), and 7.30, 7.82 (2H each, 2br d, J=8.3 Hz, C_6H_4-S); MS *m/z* 465 ($M-CH_3$; 2.5), 433 (2), 325 (2), 295 (3), 207 (32), 189 (55), 178 (55), 149 (58), 109 (60), and 91 (100).

Found: *m/z* 465.1120. Calcd for $C_{17}H_{26}N_2O_9PS$: $M-CH_3$, 465.1097.

13 [(4*R*)-4-(2-*O*-*Cyclo*-methoxyphosphinyl)-isomer]: Colorless prisms (23 mg, 1.5%); mp 202—204 °C decomp (from AcOEt); R_f=0.10 (*A*); ^{1}H NMR (in 9:1 $CDCl_3$–DMSO-d_6) δ=2.35 (3H, s, MeC_6-S), 2.50 (1H, br s, HO-3), 3.31 (3H, s, MeO-1), 3.71 (3H, d, J_{POMe}=11.1 Hz, POMe), 3.81 (1H, dd, $J_{5a,P}$=22.6, $J_{5e,5a}$=11.6 Hz, H-5a), 3.84 (1H, dd, $J_{5e,P}$=5.0 Hz, H-5e), 4.25 (1H, br s, NH-4), 4.34 (1H, dd, $J_{2,P}$=20.0, $J_{1,2}$=2.5, $J_{2,3}\simeq$0 Hz, H-2), 4.41 (1H, d, $J_{3,P}$=28.3 Hz, H-3), 4.71 (1H, d, $J_{1,2}$=2.5 Hz, H-1), 7.23, 7.69 (2H each, 2br d, J=8.2 Hz, C_6H_4-S), and 7.88 (1H, br s, TsNH).

Compound **11** (165 mg) was stirred at 25 °C for 8 h in 2,2-dimethoxypropane (5 cm^3) containing 4 M hydrochloric acid (1 M=1 mol dm^{-3}) in 1,4-dioxane (0.1 cm^3). The soln was neutralized with anhyd $NaHCO_3$, filtered, and evaporated in vacuo. The residue was purified by column chromatog-

raphy, giving **9** and **10** (153 mg in total, 85%).

Methyl (4*R* and 4*S*)-4-Deoxy-4-[(*R* and *S*)-(methoxy)-phenylphosphinyl]-4-(2-tosylhydrazino)-β-D-*erythro*-pentopyranosides (14—16). By the use of the same procedures as those for preparation of **9** and **10**, compound **8** (820 mg, 2.21 mmol) was treated with methyl phenylphosphinate (2.70 g, 17.3 mmol) and trifluoromethanesulfonic acid (0.060 cm^3, 0.68 mmol) at 20 °C for 10 h. Purification by column chromatography gave **14—16**.

14a,b {(4*S*)-2,3-*O*-Isopropylidene-4-[(*R* and *S*)-*P*]-diastereomers}: Colorless syrup (698 mg, 60%, a 2:1 mixture of **14a** and **14b**); R_f=0.50—0.46 (*A*); ^{1}H NMR for **14a** δ=1.23, 1.37 (3H each, 2s, CMe_2), 2.39 (3H, s, MeC_6-S), 3.43 (3H, s, MeO-1), 3.69 (3H, d, J_{POMe}=10.8 Hz, POMe), 3.79 (1H, dd, $J_{5c,5a}$=12.8, $J_{5a,P}$=7.5 Hz, H-5a), 3.86 (1H, dd, $J_{2,3}$=6.8, $J_{1,2}$=4.9 Hz, H-2), 3.94 (1H, dd, $J_{5c,P}$=10.7 Hz, H-5e), 4.35 (1H, dd, $J_{3,P}$=9.2 Hz, H-3), 4.58 (1H, br s, NH-4), 4.87 (1H, d, H-1), 6.62 (1H, br s, TsNH), 7.22, 7.71 (2H each, 2br d, *J*=8.3 Hz, C_6H_4-S), 7.49 [2H, m, $J_{o,m}$=7.6, $J_{m,p}$=7.3, $J_{P,m}$=3.6 Hz, Ph(*m*)], 7.63 [1H, m, $J_{o,p}$=$J_{P,p}$=1.5 Hz, Ph(*p*)], and 7.76 [2H, m, $J_{P,o}$=11.4 Hz, Ph(*o*)], for **14b** δ=1.36, 1.42 (3H each, 2s, CMe_2), 2.39 (3H, s, MeC_6-S), 3.47 (3H, s, MeO-1), 3.52 (1H, dd, $J_{5c,5a}$=12.8, $J_{5a,P}$=9.0 Hz, H-5a), 3.67 (3H, d, J_{POMe}=10.9 Hz, POMe), 3.74 (1H, dd, $J_{5c,P}$=14.9 Hz, H-5e), 4.06 (1H, dd, $J_{2,3}$=6.4, $J_{1,2}$=5.3 Hz, H-2), 4.58 (1H, br s, NH-4), 4.59 (1H, d, H-1), 4.75 (1H, dd, $J_{3,P}$=7.5 Hz, H-3), 6.52 (1H, br s, TsNH), 7.20, 7.61 (2H each, 2br d, *J*=8.3 Hz, C_6H_4-S), 7.53 [2H, m, Ph(*m*)], 7.65 [1H, m, Ph(*p*)], and 7.76 [2H, m, Ph(*o*)].

15a,b {(4*R*)-2,3-*O*-Isopropylidene-4-[(*R* and *S*)-*P*]-diastereomers}: Colorless syrup (70.3 mg, 6.3%), recrystallization of the syrup from AcOEt–hexane yielded **15a** (50.3 mg) as colorless needles, mp 172—173 °C; R_f=0.30 (*A*); ^{1}H NMR for **15a** δ=1.20, 1.43 (3H each, 2s, CMe_2), 2.40 (3H, s, MeC_6-S), 3.41 (3H, s, MeO-1), 3.59 (1H, dd, $J_{5c,5a}$=12.8, $J_{5a,P}$=2.2 Hz, H-5a), 3.65 (1H, dt, $J_{5c,P}$=1.0, $J_{3,5c}$=0.8 Hz, H-5e), 3.74 (3H, d, J_{POMe}=11.1 Hz, POMe), 3.99 (1H, dd, $J_{1,2}$=7.3, $J_{2,3}$=5.0 Hz, H-2), 4.03 (1H, d, H-1), 4.19 (1H, ddd, $J_{3,P}$=1.3, $J_{3,5e}$=0.8 Hz, H-3), 4.27 (1H, br s, NH-4), 6.83 (1H, br s, TsNH), 7.27, 7.75 (2H each, 2d, *J*=8.3 Hz, C_6H_4-S), 7.48 [2H, m, Ph(*m*)], 7.60 [1H, m, Ph(*p*)], and 7.84 [2H, m, Ph(*o*)]; MS *m/z* 511 ($M-CH_3$; 0.8), 371 (2.2), 327 (13), 263 (13), 224 (56), 195 (32), 183 (48), 155 (100), 141 (32), and 91 (47).

16: Pale yellow syrup (96 mg, 9%); R_f=0.22—0.10 (*A*); ^{1}H NMR (60 MHz) δ=2.40 (3H, s, MeC_6-S), 3.30, 3.33 (3H each, 2s, MeO-1), 3.3—3.6 (2H, m, HO-2,3), 3.58, 3.68 (3H each, 2d, J_{POMe}=11.1 Hz, POMe), 3.7—4.65 (5H, m, H-2,3,5,5′, NH-4), 4.65—4.80 (1H, m, H-1) 6.8—7.1 (1H, m, TsNH), and 7.20—8.05 (9H, m, C_6H_4-S, C_6H_5-P).

Compound **16** (96 mg) was converted into **14** and **15** (84 mg in total, 80%) by the same procedures for **11**.

Methyl 4-Deoxy-4-(dimethoxyphosphinyl)-2,3-*O*-isopropylidene-β-D-ribo- (17), α-L-Lyxo- (18), (4*S*)-4-Hydrazino-β-D-*erythro*-pentopyranoside (19), and (4*R*)-Epimer (20). A. From 9. Sodium borohydride (140 mg, 3.70 mmol) was added to a soln of **9** (514 mg, 1.07 mmol) in dry THF (15 cm^3) at 0 °C. The mixture was stirred at 25 °C for 12 h. After evaporation of the solvent in vacuo, the residue was diluted with $CHCl_3$, and the ppt was filtered off through activated carbon. The filtrate was washed twice with water, dried (Na_2SO_4), and evapotated in vacuo. The residue was chromatographed on a silica-gel column with AcOEt as an eluant, giving **17—19**.

17: Colorless syrup (153 mg, 48%); R_f=0.35 (*A*); ^{1}H NMR δ=1.36, 1.51 (3H each, 2s, CMe_2), 2.72 (1H, dddd, $J_{4,P}$=23.8, $J_{4,5a}$=11.8, $J_{4,5e}$=5.5, $J_{3,4}$=3.0 Hz, H-4), 3.44 (1H, s, MeO-1), 3.72, 3.75 [3H each, 2d, J_{POMe}=11.1, 10.8 Hz, $P(OMe)_2$], 3.81 (1H, ddd, $J_{5c,5a}$=11.3, $J_{5a,P}$=4.3 Hz, H-5a), 3.90 (1H, dddd, $J_{5c,P}$=2.2, $J_{3,5e}$=0.8 Hz, H-5e), 3.90 (1H, dd, $J_{2,3}$=6.1, $J_{1,2}$=4.8 Hz, H-2), 4.37 (1H, d, H-1), and 4.60 (1H, ddd, $J_{3,P}$=3.0 Hz, H-3); MS *m/z* 281 ($M-CH_3$; 72), 265 (9), 238 (27), 221 (91), 207 (30), 179 (25), 149 (22), 137 (97), 127 (24), 110 (43), 100 (100), and 85 (39).

Found: *m/z* 281.0764. Calcd for $C_{10}H_{18}O_7P$: $M-CH_3$, 281.0790.

18: Colorless syrup (26.0 mg, 8.2%); R_f=0.38 (*A*); ^{1}H NMR δ=1.35, 1.53 (3H each, 2s, CMe_2), 2.35 (1H, br dtd, $J_{4,P}$=19.3, $J_{4,5a}$=8.9, $J_{3,4}$=8.4, $J_{4,5e}$=5.1 Hz, H-4), 3.40 (1H, s, MeO-1), 3.775, 3.78 [3H each, 2d, J_{POMe}=10.9, 10.8 Hz, $P(OMe)_2$], 3.79, 3.81 (1H each,§ H-5a,5e), 3.97 (1H, dt, $J_{2,3}$=5.0, $J_{1,2}$=1.9, $J_{2,P}$=1.6 Hz, H-2), 4.51 (1H, ddd, $J_{3,P}$=11.4 Hz, H-3), and 4.79 (1H, t, $J_{1,5e}$=2.0 Hz, H-1); MS *m/z* 296 (M^+; 0.5), 281 ($M-CH_3$; 12), 221 (39), 177 (41), 149 (25), 109 (57), 100 (100), and 85 (3).

Found: *m/z* 281.0760. Calcd for $C_{10}H_{18}O_7P$: $M-CH_3$, 281.0790.

19: Colorless needles (42.0 mg, 12%); mp 133—134 °C (from AcOEt–hexane); R_f=0.59 (*A*); ^{1}H NMR δ=1.37, 1.61 (3H each, 2s, Me_2C), 3.41 (3H, s, MeO-1), 3.87, 3.875 [3H each, 2d, J_{POMe}=10.5 Hz, $P(OMe)_2$], 3.65 (1H, dd, $J_{5a,5e}$=12.9, $J_{5a,P}$=12.3 Hz, H-5a), 3.92 (1H, ddd, $J_{5e,P}$=4.5, $J_{1,5e}$=1.0 Hz, H-5e), 3.95 (1H, m, HN-4), 4.05 (1H, ddd, $J_{2,3}$=6.3, $J_{1,2}$=3.0, $J_{2,P}$=1.0 Hz, H-2), 4.63 (1H, dd, $J_{3,P}$=9.3 Hz, H-3), 4.70 (1H, dd, H-1), and 5.98, 6.03 (1H each, 2m, H_2NN-4); MS *m/z* 326 (M^+; 59), 311 (11), 307 (11), 294 (27), 279 (12), 259 (10), 247 (17), 229 (35), 217 (79), 205 (21), 194 (31), 177 (51), 166 (100), 156 (23), 141 (29), 136 (34), 127 (61), 109 (71), 99 (68), and 80 (67).

Found: *m/z* 326.1235. Calcd for $C_{11}H_{23}N_2O_7P$: M, 326.1243.

B. From 10. The same procedures described above for the conversion of **9** were followed. Thus, **10** (160 mg) gave **17** (48.6 mg, 49%), **18** (8.7 mg, 9%), and **20** (7.5 mg, 7%) after purification by column chromatography.

20: Colorless syrup; R_f=0.57 (*A*); ^{1}H NMR δ=1.39, 1.55 (3H each, 2s, CMe_2), 3.52 (3H, s, MeO-1), 3.82, 3.93 [3H each, 2d, J_{POMe}=10.7 Hz, $P(OMe)_2$], 3.97 (1H, ddd, $J_{5a,5e}$=13.3, $J_{5e,P}$=2.2, $J_{3,5e}$=1.6 Hz, H-5e), 3.98 (1H, m, HN-4), 4.03 (1H, dd, $J_{2,3}$=5.5, $J_{1,2}$=4.7 Hz, H-2), 4.15 (1H, ddd, $J_{3,P}$=3.0 Hz, H-3), 4.48 (1H, d, H-1), and 5.47, 6.48 (1H each, 2m, H_2NN-4).

Methyl 4-Deoxy-2,3-*O*-isopropylidene-4-[(*R* and *S*)-(methoxy)phenylphosphinyl]-β-D-ribo- (21a,b), α-L-Lyxo- (22a,b), (4*R* and 4*S*)-4-Hydrazino-β-D-*erythro*-pentopyranosides (23), and (4*R*)-Epimer (23a). A. From 14 and 15. By the use of the same procedures as those for **9**, a 9:1 mixture of **14** and **15** (450 mg, 0.855 mmol) was treated with sodium borohydride (100 mg, 2.64 mmol) at 20 °C for 20 h, giving **21a**, **21b**, **22a,b**, and **23**, after separation by column chromatography.

21a: Colorless prisms (98.2 mg, 34%); R_f=0.34 (*A*); mp

§ Their splitting patterns uncertain because of overlapping with other signals.

126—127 °C (from AcOEt–hexane); ^{1}H NMR δ=1.30, 1.48 (3H each, 2s, CMe_2), 2.73 (1H, dddd, $J_{4,P}$=18.5, $J_{4,5a}$=11.7, $J_{4,5e}$=5.5, $J_{3,4}$=3.0 Hz, H-4), 3.44 (3H, s, MeO-1), 3.73 (3H, d, J_{POMe}=11.1 Hz, POMe), 3.80 (1H, t, $J_{2,3}$=5.9, $J_{1,2}$=5.2 Hz, H-2), 3.91 (1H, ddd, $J_{5e,5a}$=11.3, $J_{5a,P}$=3.8 Hz, H-5a), 3.98 (1H, ddt, $J_{5e,P}$=1.3, $J_{3,5e}$=1.2 Hz, H-5e), 4.30 (1H, dddd, $J_{2,3}$=5.9, $J_{3,P}$=3.9 Hz, H-3), 4.33 (1H, d, H-1), 7.48 [2H, m, Ph(*m*)], 7.57 [1H, m, Ph(*p*)], and 7.79 [2H, m, Ph(*o*)]; MS *m/z* 343 (M+1; 1.2), 327 (42), 311 (11), 284 (29), 225 (17), 195 (27), 183 (98), 173 (42), 155 (100), 141 (30), 128 (31), and 100 (95).

Found: *m/z* 327.0983. Calcd for $C_{15}H_{20}O_6P$: M−CH_3, 327.0997.

21b: Colorless syrup (57.2 mg, 20%); R_f=0.30 (*A*); ^{1}H NMR δ=1.31 (6H, s, CMe_2), 2.80 (1H, dddd, $J_{4,P}$=21.3, $J_{4,5a}$=12.0, $J_{4,5e}$=5.3, $J_{3,4}$=3.0 Hz, H-4), 3.43 (3H, s, MeO-1), 3.71 (3H, d, J_{POMe}=11.2 Hz, POMe), 3.75 (1H, ddd, $J_{5e,5a}$=10.9, $J_{5a,P}$=3.7 Hz, H-5a), 4.00 (1H, ddt, $J_{5e,P}$=1.3, $J_{3,5e}$=1.2 Hz, H-5e), 4.31 (1H, d, H-1), 4.55 (1H, dt, $J_{3,P}$=3.2 Hz, H-3), 7.48 [2H, m, Ph(*m*)], 7.57 [1H, m, Ph(*p*)], and 7.77 [1H, m, Ph(*o*)].

22a,b: Colorless syrup (21.0 mg, 7.2%, an inseparable 2:1 mixture of **22a** and **22b**); R_f=0.40 (*A*); ^{1}H NMR for **22a** δ=1.31, 1.39 (3H each, 2s, CMe_2), 2.43 (1H, dddd, $J_{4,P}$=13.0, $J_{4,5a}$=10.5, $J_{3,4}$=8.6, $J_{4,5e}$=4.4 Hz, H-4), 3.36 (3H, s, MeO-1), 3.61 (1H, dddd, $J_{5e,5a}$=12.1, $J_{5e,P}$=7.9, $J_{1,5e}$=1.5 Hz, H-5e), 3.71 (3H, d, J_{POMe}=11.2 Hz, POMe), 3.77 (1H, ddd, $J_{5a,P}$=3.5 Hz, H-5a), 3.93 (1H, dt, $J_{2,3}$=5.2, $J_{1,2}$=1.9, $J_{2,P}$=1.5 Hz, H-2), 4.65 (1H, ddd, $J_{3,P}$=10.7 Hz, H-3), 4.77 (1H, t, H-1), 7.49 [2H, m, $J_{o,m}$=7.5, $J_{m,p}$=7.3, $J_{P,m}$=3.5 Hz, Ph(*m*)], 7.57 [1H, m, $J_{o,p}$=$J_{P,p}$=1.5 Hz, Ph(*p*)], and 7.79 [2H, m, $J_{P,o}$=11.8 Hz, Ph(*o*)], for **22b** δ=1.23, 1.32 (3H each, 2s, CMe_2), 2.47 (1H, dddd, $J_{4,P}$=13.5, $J_{4,5a}$=10.5, $J_{3,4}$=9.1, $J_{4,5e}$=4.5 Hz, H-4), 3.54 (3H, s, MeO-1), 3.66 (3H, s, J_{POMe}=11.2 Hz, POMe), 3.70, 3.78 (1H each,§ H-5a,5e), 3.85 (1H, dt, $J_{2,3}$=5.2, $J_{1,2}$=1.8, $J_{2,P}$=1.5 Hz, H-2), 4.52 (1H, ddd, $J_{3,P}$=11.6 Hz, H-3), 4.79 (1H, t, $J_{1,5e}$=1.5 Hz, H-1), 7.49 [2H, m, Ph(*m*)], 7.57 [1H, m, Ph(*p*)], and 7.79 [2H, m, Ph(*o*)]; MS *m/z* 342 (M^+; 0.5), 327 (31), 311 (10), 267 (33), 225 (23), 209 (35), 195 (11), 183 (44), 173 (21), 155 (100), 128 (63), and 77 (41).

Found: *m/z* 327.0972. Calcd for $C_{15}H_{20}O_6P$: M−CH_3, 327.0997.

23: Colorless syrup (22.2 mg, 7.0%, a ca. 7:1 mixture of (4*S*) and (4*R*) epimers); R_f=0.55—0.50 (*A*); ^{1}H NMR (60 MHz) δ=1.26, 1.37, 1.43, 1.58 (6H, 4s, CMe_2), 3.35, 3.45, 3.48 (3H, 3s, MeO-3), 3.76, 3.81 (3H, d, J_{POMe}=10.8 Hz, POMe), 3.60—4.20 (3H, m, H-5,5′, NH-4), 4.20—4.95 (3H, m, H-1,2,3), 5.6—6.2 (2H, m, H_2NN-4), and 7.45—8.00 (5H, m, PPh).

B. From 15a. By the same procedures described above, **15a** (60.0 mg) was converted into **21a** (22.2 mg, 57%), **22a** (3.0 mg, 7.7%), and **23a** (2.5 mg, 5.9%).

23a: Colorless prisms, mp 169—170 °C (from AcOEt–hexane); R_f=0.50 (*A*); ^{1}H NMR δ=1.26, 1.28 (3H each, 2s, CMe_2), 3.48 (3H, s, MeO-3), 3.87 (1H, br d, $J_{5e,5a}$=13.3, $J_{5a,P}$=0.5 Hz, H-5a), 3.90 (3H, d, J_{POMe}=10.7 Hz, POMe), 3.93 (1H, ddd, $J_{2,3}$=5.5, $J_{3,P}$=2.9, $J_{3,5e}$=2.0 Hz, H-3), 4.02 (1H, t, $J_{1,2}$=5.8 Hz, H-2), 4.06 (1H, m, NH-4), 4.16 (1H, dt, $J_{5e,P}$=2.0 Hz, H-5e), 4.30 (1H, d, H-1), 5.32 (2H, br s, H_2NN-4), 7.49 [2H, m, $J_{o,m}$=7.8, $J_{m,p}$=7.6, $J_{P,m}$=3.6 Hz, Ph(*m*)], 7.61 [1H, m, $J_{m,p}$=1.5, $J_{P,p}$=1.3 Hz, Ph(*p*)], and 7.82 [2H, m, $J_{P,o}$=11.7 Hz, Ph(*o*)].

Methyl 4-Deoxy-2,3-*O*-isopropylidene-4-phosphino-β-D-ribopyranoside (24). To a soln of **17** (220 mg) in dry benzene (4 cm^3) was added, with stirring, a soln of SDMA[13] (70% in toluene, 0.65 cm^3, 3 equiv) in dry benzene (1 cm^3) in small portions at 5 °C under argon. The stirring was continued at this temp for 1 h. Then, water (0.5 cm^3) was added at 0 °C and the mixture was stirred for 30 min. The ppt was centrifuged and washed with several portions of benzene. The organic layers were combined and evaporated in vacuo, giving **24** as a colorless syrup: R_f=0.68 (*A*); MS *m/z* 221 (M+1; 59), 205 (15), 189 (12), 155 (38), 129 (26), 112 (45), 100 (55), and 43 (100); the specimen was not stable enough for ^{1}H NMR and other spectral measurements.

1,2,3,5-Tetra-*O*-acetyl-4-deoxy-4-[(*R* and *S*)-methoxyphosphinyl]-α,β-D-ribopyranoses (26a—d). The above syrup **24** was immediately dissolved in 2-propanol (2 cm^3) and 0.5 M hydrochloric acid (2 cm^3). The mixture was degassed with argon and then stirred at 90 °C for 1 h. After cooling, the reactant was neutralized by adding enough Amberlite IRA-45. The resin was filtered off and washed with water, and the filtrate was evaporated in vacuo. The residue was dissolved in water (2 cm^3), treated with 30% aq hydrogen peroxide (0.2 cm^3) at room temp for 1 d, and concentrated in vacuo to give crude 4-deoxy-4-(hydroxyphosphinyl)-D-ribofuranoses (**25**) as a colorless syrup: R_f=0.10 (*D*).

Compound **25** was methylated with ethereal diazomethane in 1:1 DMSO–MeOH (4 cm^3) at 0 °C. When the reaction mixture became turbid, it was concentrated in vacuo and repeatedly treated with ethereal diazomethane in the same mixed solvent. The solvent was evaporated in vacuo to give the 4-(methoxyphosphinyl) derivative [R_f=0.73 (*D*)]. This was acetylated with acetic anhydride (1.5 cm^3) in dry pyridine (3 cm^3), giving a mixture of tetraacetates **26a—d**, which were separated by column chromatography with a gradient eluant of 3:1 AcOEt–hexane→AcOEt→19:1 AcOEt–EtOH.

26a (4-[(*R*)-Methoxyphosphinyl]-β-isomer): Colorless syrup (17.8 mg, 6.3% yield from **17**); R_f=0.47 (*A*); ^{1}H NMR, see Table 1; MS *m/z* 380 (M^+; ≃0), 354 (0.6), 338 (2.1), 320 (0.8), 296 (32), 278 (19), 236 (24), 218 (15), 193 (16), 177 (42), 149 (31), 123 (21), and 43 (100).

Found: *m/z* 338.0748. Calcd for $C_{12}H_{19}O_9P$: M−CH_2CO, 338.0767.

26b (4-[(*R*)-*P*]-α-Isomer): Colorless syrup (9.3 mg, 3.3% yield from **17**); R_f=0.42 (*A*); ^{1}H NMR, see Table 1; MS *m/z* 381 (M+1; 3.8), 353 (1.8), 338 (4.3), 321 (1.9), 296 (90), 278 (41), 250 (40), 236 (74), 218 (35), 207 (40), 193 (52), 177 (100), 165 (50), 147 (47), 123 (68), and 43 (100).

Found: *m/z* 381.0952. Calcd for $C_{14}H_{22}O_{10}P$: M+1, 381.0951.

26c (4-[(*S*)-*P*]-β-Isomer): Colorless syrup (7.8 mg, 2.8% yield from **17**); R_f=0.40 (*A*); ^{1}H NMR, see Table 1.

26d (4-[(*S*)-*P*]-α-Isomer): Colorless syrup (4.8 mg, 1.7% yield from **17**); R_f=0.34 (*A*); ^{1}H NMR, see Table 1.

1,2,3,5-Tetra-*O*-acetyl-4-deoxy-4-[(*R* and *S*)-phenylphosphinyl]-α,β-D-ribopyranoses (29a—d). The procedures similar to those for **26** from **17** were employed. Thus, **21** (140 mg, 0.41 mmol) was treated with SDMA (0.25 cm^3, 0.85 mmol) at 5 °C for 1 h, giving phosphine oxide **27** as a colorless syrup: R_f=0.70 (*A*). This was refluxed with 1:1 ethanol–0.5 M HCl (4 cm^3, oxygen-free) for 3 h to afford **28** as colorless syrup: R_f=0.48 (*D*). This was acetylated with

Ac_2O–pyridine to give a mixture of **29a—d**, which were separated by column chromatography.

29a (4-[(*S*)-Phenylphosphinyl]-β-isomer): Colorless syrup (20.3 mg, 12% yield from **21**); R_f=0.41 (*A*); ^{1}H NMR, see Table 1; MS *m/z* 426 (M^+; ≃0), 342 (13), 324 (13), 256 (15), 185 (15), and 81 (100); FAB-MS (thioglycerol matrix, with xenon gas) *m/z* 427 (M+1; 100), 385 (21), 369 (53), 343 (13), 327 (10), 309 (16), 267 (11), 223 (14), and 207 (13).

Found: *m/z* 427.1187. Calcd for $C_{19}H_{24}O_9P$: M+1, 427.1158.

29b (4-[(*S*)-*P*]-α-Isomer): Colorless syrup (7.7 mg, 4.4% yield); R_f=0.36 (*A*); ^{1}H NMR, see Table 1.

29c (4-[(*R*)-*P*]-β-Isomer): Colorless syrup (10.9 mg, 6.3% yield); R_f=0.33 (*A*); ^{1}H NMR, see Table 1; MS, *m/z* 426 (M^+; ≃0), 368 (28), 341 (10), 282 (10), 256 (45), 236 (82), 185 (35), and 81 (100); FAB-MS (thioglycerol matrix, with xenon gas), 427 (M+1; 100), 385 (12), 367 (21), 343 (8), 325 (12), 309 (12), 282 (10), 265 (12), 230 (12), 223 (25), 205 (18), and 185 (46).

Found: *m/z* 427.1158. Calcd for $C_{19}H_{24}O_9P$: M+1, 427.1158.

29d (4-[(*R*)-*P*]-α-Isomer): Colorless syrup (5.0 mg, 2.9% yield); R_f=0.27 (*A*); ^{1}H NMR, see Table 1.

Besides these separated products, an inseparable mixture of unidentified products [R_f=0.35—0.20 (*A*), ca. 2% yield from **21**] was obtained, although they were speculated to be the L-lyxofuranose derivatives.

When a 9:1 mixture of **21** and **22** was subjected to the same procedures described above, **29a—d** were also obtained predominantly in similar yields to those described above.

We are grateful to Mr. Shin-ichi Takekuma (Kinki Univ., Osaka) for the measurement of mass spectra. The present work was partially supported by Grant-in-Aid for Scientific Research No. 63540500 from the Ministry of Education, Science and Culture.

Total Syntheses of (+)-Altholactone [(+)-Goniothalenol] and Three Stereocongeners and Their Cytotoxicity against Several Tumor Cell Lines[1)]

Yoshihide UENO, Kin-ichi TADANO,* Seiichiro OGAWA,*

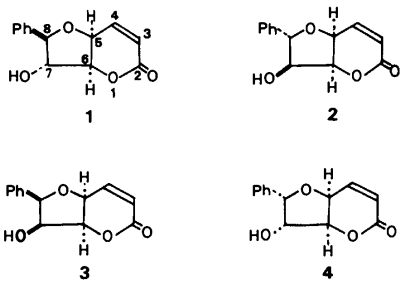
(Received March 4, 1989)

Enantiospecific total synthesis of (+)-altholactone [(+)-goniothalenol] (**1**), a novel tetrahydrofuropyran-5-one possessing significant cytotoxicity against several tumor cell lines, has been achieved by using L-arabinose as the redundant starting material. The pivotal tetrahydrofuran formation was realized by treatment of the diastereomeric mixture of (2*S*,3*R*)-4,5-epoxy-5-phenyl-1,2,3-pentanetriol 1,3-benzylidene acetals **8** and **8'** with silica gel. Simultaneous stereochemical inversion at C-4 and C-5 of the major cyclization product, *O*,*O'*-benzylidene derivative of (2*S*,3*R*,4*S*,5*S*)-2-(hydroxymethyl)-5-phenyltetrahydrofuran-3,4-diol (**11**), to the 2*S*,3*R*,4*R*,5*R* diastereomer **10** was achieved by hydroboration of (2*S*,3*S*)-3-hydroxy-2-(hydroxymethyl)-5-phenyl-2,3-dihydrofuran *O*,*O'*-benzylidene derivative (**18**) which derived from **11**. Pfitzner-Moffatt oxidation of **10** followed by $NaBH_4$ reduction gave the 2*S*,3*R*,4*S*,5*R* diastereomer **20** exclusively. Displacement of the triflate group in (2*S*,3*R*,4*S*,5*S*)-2-(hydroxymethyl)-5-phenyl-4-[(trifluoromethylsulfonyl)oxy]tetrahydrofuran-3-ol *O*,*O'*-benzylidene derivative (**21**) by acetate, which was prepared from **11**, furnished the 2*S*,3*R*,4*R*,5*S* diastereomer **22**. The total synthesis of **1** was completed by Collins oxidation of (2*S*,3*R*,4*R*,5*R*)-2-(hydroxymethyl)-3,4-bis(methoxymethoxy)-5-phenyltetrahydrofuran (**34**), which was prepared from **10**, and subsequent Witting olefination with (ethoxycarbonylmethylene)triphenylphosphorane followed by hydrolysis. By employing the analogous reaction sequence, compounds **11**, **20**, and **22** were efficiently converted into (+)-7,8-di-*epi*- (**2**), (+)-7-*epi*- (**3**), and (+)-8-*epi*-altholactone (**4**), respectively. The cytotoxicity of **1**—**4** against several tumor cell lines was examined.

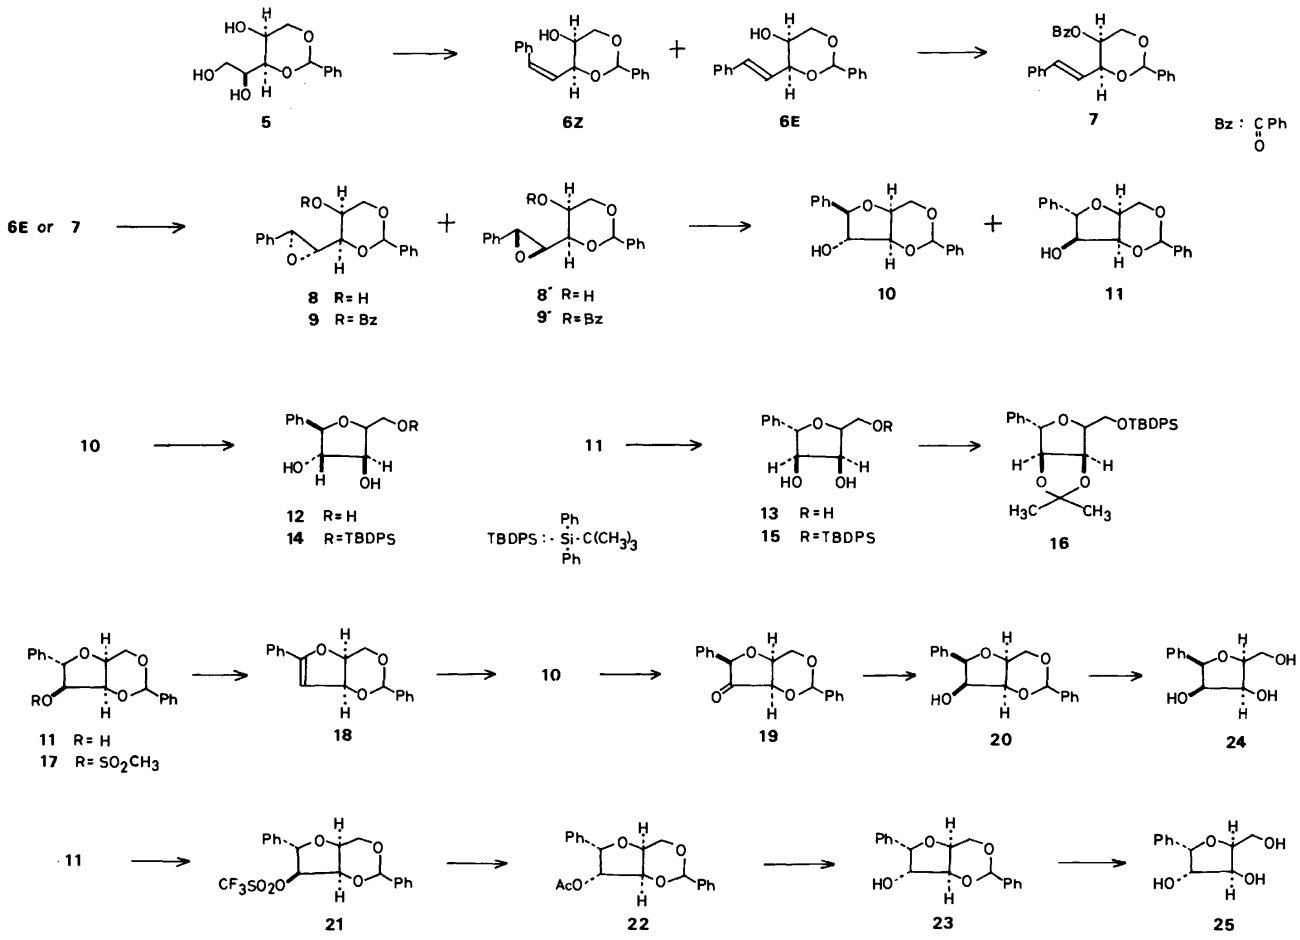
In 1977, Loder and Nearn reported the isolation of a novel tetrahydro-5*H*-furo[3,2-*b*]pyran-5-one derivative from the extracts of the bark of an unnamed *Polyathia* species (Annonaceae) and they named this natural product "altholactone".[2)] The relative configuration of altholactone was determined by means of spectral analyses of it and some derivatives, and the absolute configuration of natural (+)-enantiomer was tentatively assigned to be **1** based on correlation of the CD spectrum of it with those of the structurally defined natural α,β-unsaturated δ-lactones.[2)] Compound **1** was later isolated from the ethanolic extract of the stem bark of *Goniothalamus giganteus* (Annonaceae) by one of us (J. L. M.),[3)] and the proposed relative configuration was confirmed by the X-ray crystallographic analysis. This tetrahydrofuropyran-5-one **1** is known to possess bioactivities such as an antitumor activity against murine P388 leukemia in vivo at 45 mg/kg and shows lethality to brine shrimp (LC_{50} 234 μg ml^{-1}).[3)] As the structurally similar natural products to **1**, goniothalamin,[4)] goniodiol,[5)] goniotriol,[5)] dihydrokawain-5-ol,[6)] olguine,[7)] anamarine,[8)] and asperlin[9)] were isolated from some plants and a fungus. Some of them (goniothalamin, goniodiol, and goniotriol) were reported to have an asymmetric carbon atom with *S* configuration as δ-carbon of the α,β-unsaturated δ-lactone moiety. On the other hand, the same position of the other natural products was *R* configuration. These facts provoke much interest in the biosynthetic correlation of **1** to the other natural products. This structural uniqueness and biological importance of **1** prompted us to undertake the total synthesis of **1**. Very recently, two total syntheses of **1** and its (−)-enantiomer have been reported by Gesson and coworkers[10)] and by Gillhouley and Shing.[11)] In this article, we describe in detail our independent total syntheses of **1** and three stereocongeners, namely, (+)-7,8-di-*epi*- (**2**), (+)-7-*epi*- (**3**), and (+)-8-*epi*-altholactone (**4**).[12)] The cytotoxicity of **1**—**4** against several tumor cell lines was examined and the results are also described herein.



Results and Discussion

Syntheses of (+)-Altholactone (1) and Three Stereocongeners (2—4). As a starting material for the enantiospecific total synthesis of **1**, we chose the known 1,3-*O*-benzylidene-L-arabinitol (**5**) which was readily prepared from L-arabinose by a two-step reaction sequence.[13)] The C-2 and C-3 of **5** correspond to C-5 and C-6 (altholactone numbering) of **1**. Oxidative cleavage of the glycol in **5** with $NaIO_4$ in

aqueous MeOH and subsequent Wittig olefination with benzylidenetriphenylphosphorane, prepared by BuLi treatment of benzyltriphenylphosphonium chloride,[14] furnished a 1:3 mixture of **6Z** and **6E** in a combined yield of 84%. These geometrical isomers were cleanly separated by silica-gel chromatography. The *Z* isomer **6Z** was isomerized to **6E** in 81% yield by treatment wth thiophenol (PhSH) in refluxing benzene in the presence of 2,2′-azobis(2-methylpropanenitrile) (AIBN).[15] Epoxidation of **6E** with *m*-chloroperbenzoic acid (mCPBA) in refluxing CH_2Cl_2 provided an inseparable mixture of (*R*,*R*)- (**8**) and (*S*,*S*)-epoxides (**8′**). The ratio of **8** to **8′** could not be determined by its ^1H NMR spectral analysis. It was found that tetrahydrofuran formation took place partly during purification of the mixture of **8** and **8′** by silica-gel chromatography. Therefore, the mixture of **8** and **8′** in CH_2Cl_2 was kept standing with silica gel (30 to 40 multiple weight of **6E**) at room temperature for 25—35 h. As a result, the cyclization products **10** and **11** were obtained in 19% and 73% yields, respectively, after chromatographic separation on silica gel. From these results, the ratio of **8** to **8′** was estimated to be 1 to 3.8. The effect of the C-2 substituent on the epoxidation was next pursued. The benzoate **7** was prepared by the standard benzoylation of **6E**. Treatment of **7** with mCPBA in refluxing CH_2Cl_2 gave an inseparable mixture of **9** and **9′**. The benzoyl groups of this mixture were removed with sodium methoxide, and the resulting mixture of **8** and **8′** was treated with silica gel as described above. Compound **11** was obtained by crystallization of the reaction mixture in 83% yield. The other cyclization product **10** was obtained in 6% yield after silica-gel chromatography of the mother liquor. In consideration of the yields of **10** and **11**, the ratio of the epoxides **9** and **9′** was estimated to be 1 to 13.8.[16] By reason that the combined yield of **10** and **11** was sufficiently high, the silica-gel-promoted cyclization found in the present work is worthy to note.[17,18] The structures of **10** and **11** could not be determined unambiguously from their ^1H NMR spectra. However, these were established as follows. Hydrolysis of **10** and **11** with 1 M† HCl gave the debenzylidene derivatives **12** and **13**. The primary hydroxyl groups in **12** and **13** were silylated to give **14** and **15**. Treatment of **14** with 2,2-dimethoxypropane in the presence of 10-camphorsulfonic acid (CSA) resulted in a quantitative recovery of **14**. On the other hand, compound **15** was converted into the isopropylidene derivative **16** in 87% yield under the same reaction conditions. These results

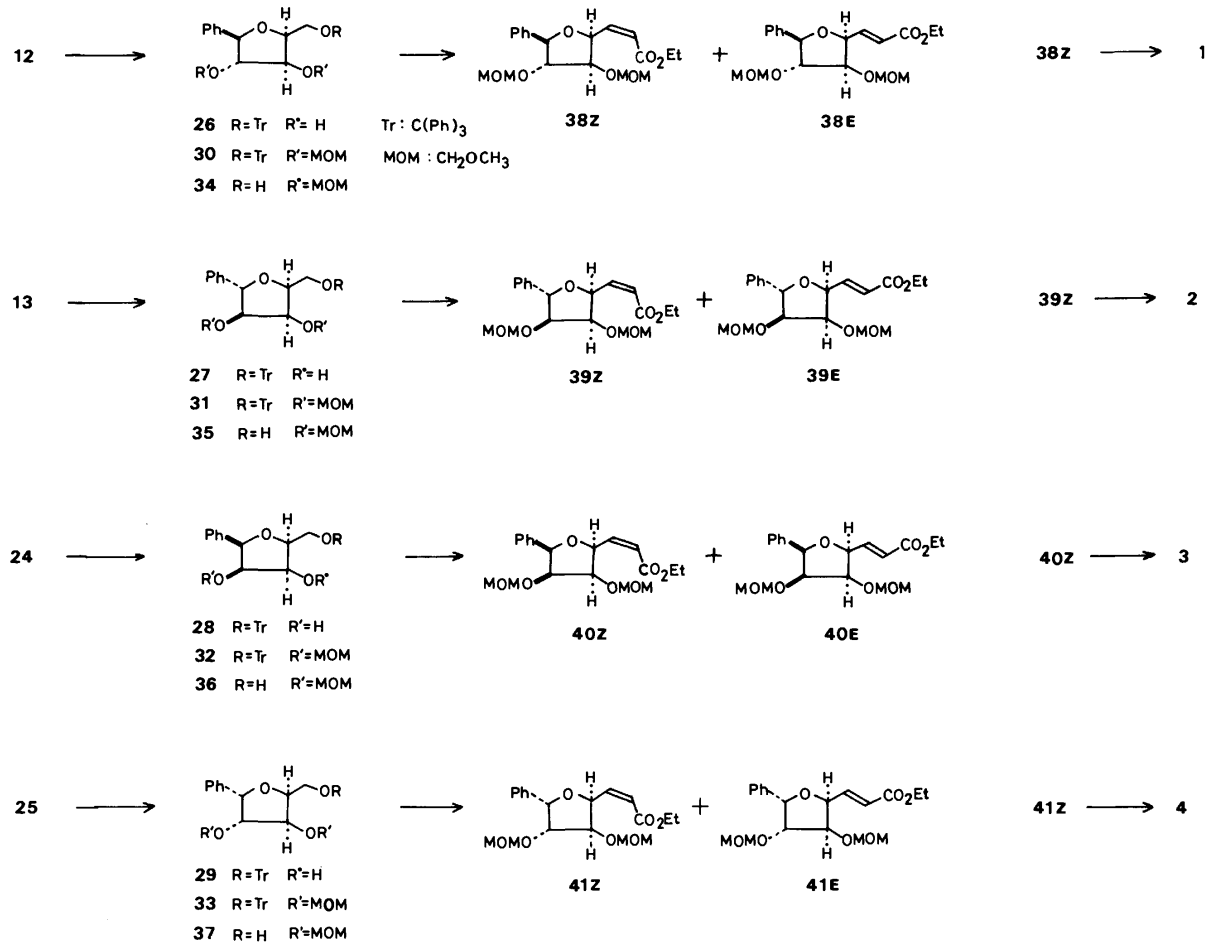


† 1 M=1 mol dm^{-3}.

reveal that relationship of the vicinal diols are trans for **14** and cis for **15**. The structures of **10** and **11** were established as depicted.

Unfortunately, the minor cyclization product **10** possesses all of the required asymmetric carbons. Therefore, the conversion of **11** into **10** was investigated. For this purpose, an introduction of a hydroxyl group at C-3 of a model such as **18** by hydroboration protocol was examined. The attack of borane to **18** was expected to proceed from the less hindered convex face. The dihydrofuran **18** was prepared as follows. Methanesulfonylation of **11** gave the mesylate **17**. Brief exposure of **17** to *t*-BuOK in refluxing THF resluted in the formation of **18** through elimination of methanesulfonic acid. As anticipated, the hydroboration of **18** with BH_3–THF complex in THF followed by oxidative work-up with H_2O_2 furnished **10** as a single product in 65% yield from **17**. Two other diastereomers **20** and **23**, the proper synthetic precursors for **3** and **4**, were prepared as follows. Pfitzner–Moffatt oxidation[19] of **10** gave **19** smoothly,[20] and $NaBH_4$ reduction of **19** gave **20** in 83% yield from **10**. The attack of the hydride occurred exclusively from the convex face of **19**. Trifluoromethanesulfonylation of **11** gave the triflate **21**. Displacement of the triflate group by acetate group in S_N2 fashion took place by heating of **21** in DMF with AcOK at 135 °C. The acetate **22** was obtained in 79% yield.[21] Deacetylation of **22** with sodium methoxide gave **23**. Direct displacement of the triflate group by hydroxyl group was achieved by treatment of **21** in DMF–DMSO with KO_2.[22] Compound **23** was obtained in 58% yield.

The remaining elaboration for the total synthesis of **1** from **12** was an introduction of 2-pyrone unit, and this was accomplished as follows. Selective tritylation of **12** gave the mono trityl ether **26** in 75% yield. The remaining hydroxyl groups were protected as methoxymethyl (MOM) ethers to provide **30** in 89% yield. Hydrolysis of **30** with *p*-TsOH provided the detritylated product **34**. Collins oxidation[23] of **34** followed by Wittig olefination of thus formed aldehyde[24] with (ethoxycarbonylmethylene)triphenylphosphorane in MeOH gave *Z* and *E* isomers of α,β-unsaturated esters **38Z** and **38E** in 62% and 9% yields, respectively. Finally, hydrolysis of **38Z** with 1 M HCl provided (+)-altholactone **1** as needles in 96% yield in consequence of deprotection of the MOM ethers followed by δ-lactonization. The ^1H (400 MHz) and ^{13}C (100 MHz) NMR spectra of synthetic **1** were identical with those of natural product. Mixed melting point of synthetic **1** (mp 113—114 °C) with natural **1** (mp 110 °C[3]) showed no depression (mmp 112—113 °C). Furthermore, the



specific rotation of synthetic **1** [$[\alpha]_D^{33}$ +180.8° (*c* 0.52, EtOH)] revealed that the absolute configuration of natural **1** [$[\alpha]_D^{20}$ +188°[2] and $[\alpha]_D^{25}$ +184.7°[3]] is 5*S*,6*R*, 7*R*,8*R*.

The syntheses of three stereocongeners **2**—**4** were accomplished by the virtually same reaction sequence described above. Debenzylidenation of **20** and **23** gave the triols **24** and **25**. By the sequence of tritylation, methoxymethylation, and detritylation, the triol **13** was converted into **35** in an overall yield of 51% via **27** (72%) and **31** (91%). Similarly, compound **24** was converted into **36** in an overall yield of 51% via **28** (79%) and **32** (90%). Also, compound **37** was obtained from **25** in an overall yield of 82% via **29** (93%) and **33** (94%). By the Collins oxidation followed by Wittig olefination, compounds **35**, **36**, and **37** were transformed to *Z* and *E* isomers of the α,β-unsaturated esters, **39Z** (58%) and **39E** (5%), **40Z** (72%) and **40E** (5%), and **41Z** (53%) and **41E** (4%). Hydrolysis of **39Z**, **40Z**, and **41Z** with 1 M HCl gave (+)-7,8-di-*epi*- (**2**), (+)-7-*epi*- (**3**), and (+)-8-*epi*-altholactone (**4**), in 78%, 79%, and 82% yields, respectively. The stereocongeners **2**—**4** were fully characterized by the spectral means. In addition, the synthesis of **3** has been reported very recently by Gillhouley and Shing.[11] The physical data of our synthetic **3** [mp 117—117.5 °C, $[\alpha]_D^{30}$ +23.0° (*c* 0.50, EtOH)] coincides well with those of the reported data [mp 121—123 °C, $[\alpha]_D^{22}$ +23.5° (*c* 0.4, EtOH)].

Cytotoxicity of (+)-Altholactone (1) and Three Stereocongeners (2—4). The cytotoxicity assays of **1**—**4** were carried out by using the following tumor cells: 9PS, a methylcholanthrene induced murine leukemia; 9KB, a human nasopharyngeal carcinoma; A-549, a human lung-cell cancer; MCF-7, a human breast cancer; HT-29, a human colon cancer. The ED_{50} values ($\mu g\ ml^{-1}$) of **1**—**4** are as follows. **1**: 9PS (2.01×10^{-1}), 9KB (3.03), A-549 (>10), MCF-7 (>10), HT-29 (2.49); **2**: 9PS (9.4×10^{-1}), 9KB (>10), A-549 (5.85), MCF-7 (4.7), HT-29 (4.7×10^{-1}); **3**: 9PS (1), 9KB (2.6), A-549 (4.6), MCF-7 (4.8), HT-29 (2.1); **4**: 9PS (9.5×10^{-1}), 9KB (>10), A-549 (>10), MCF-7 (>10), HT-29 (4.5). From these results, the level of cytotoxicity of **2**—**4** seems to be marginal. It appears that the 8-*epi* isomer **4** is less active than the other isomers, but **4** may be selectively active in the colon tumor. Meanwhile, the cytotoxicity of natural **1** was examined in detail at the National Cancer Institute. The cytotoxicity of **1** is quite potent (10^{-5} to 10^{-7} molar for IC_{50} values), and the results are listed in Table 1.

Experimental

General Procedures. Reactions were carried out at room temperature unless otherwise described. Melting points were determined with a Mitamura Riken micro melting points apparatus and are uncorrected. Specific rotations were measured with a Jasco DIP-4 polarimeter in a 10 mm cell. Column chromatography was performed on Silicagel 60 (Katayama Chemicals), flash column chromatography was performed on Wako C-300 (Wako Pure Chemicals), and thin-layer chromatography (TLC) was performed on a glass plate coated with Kieselgel 60 GF_{254} (Merck) followed by detection using UV light and/or charring with H_2SO_4. Preparative TLC (PTLC) was performed on a glass plate (20×20 cm) coated with Kieselgel PF_{254} (Merck), and compounds were extracted with CH_2Cl_2 or AcOEt. IR spectra were recorded with a Hitachi Model 225 (KBr) or with a Jasco Model A-202 (neat) spectrometer. ^1H NMR spectra at 90 MHz were recorded with a Varian EM-390 spectrometer, and ^1H NMR at 400 MHz and ^{13}C NMR at 100 MHz were recorded with a JEOL JNM-GX 400 FT NMR spectrometer with internal standard of Me_4Si. High-resolution mass spectra were obtained with a Hitachi Model M-80 spectrometer.

Benzene, dichloromethane (CH_2Cl_2), and *N*,*N*-dimethylformamide (DMF) were dried over CaH_2 and then distilled. Acetone was dried over $CaSO_4$ and then distilled. Pyridine was distilled over NaOH. Tetrahydrofuran (THF) was

distilled over $LiAlH_4$ and then over Na/benzophenone.

Glycol Cleavage of 5 and Successive Wittig Olefination with Benzylidenetriphenylphosphorane. (2*S*,3*S*,4*Z*)- and (2*S*,3*S*,4*E*)-1,3-*O*-Benzylidene-5-phenyl-4-pentene-1,2,3-triol (6Z and 6E). To a solution of **5** (15.0 g, 62.4 mmol) in methanol (350 ml) was added an aqueous solution (150 ml) of $NaIO_4$ (14.7 g, 68.6 mmol). This mixture was stirred for 30 min, and the resulting white solids were removed by filtration. The filtrate was concentrated in vacuo. The residue was partitioned between AcOEt (600 ml) and H_2O (150 ml). The aqueous phase was extracted with AcOEt (2×300 ml). The combined organic phases were dried (Na_2SO_4) and concentrated in vacuo to give an aldehyde, which was subjected to Wittig reaction directly. The Wittig reaction was carried out under an argon atmosphere. To a suspension of benzyltriphenylphosphonium chloride (48.2 g, 124 mmol) in THF (250 ml) was injected BuLi (1.60 M solution in hexane, 77.5 ml, 124 mmol). After being stirred for 1 h, a THF solution (50 ml) of the aldehyde above was added to the ylide solution. After being stirred for 1 h, 1% aqueous NH_4Cl solution (90 ml) and H_2O (300 ml) were added to the mixture. This aqueous mixture was extracted with AcOEt (3×450 ml). The organic phases were combined, dried (Na_2SO_4), and concentrated in vacuo. The residue was treated with a small amount of AcOEt, and insoluble materials were removed. The filtrate was concentrated in vacuo. Column chromatography of the residue (AcOEt/hexane 1:10) provided **6Z** (3.60 g, 21%) and **6E** (11.1 g, 63%). **6Z** as white crystals, mp 106—107 °C: R_f 0.73 (AcOEt/hexane 1:1): $[\alpha]_D^{23}$ −340° (*c* 1.05, $CHCl_3$); IR ν_{max}^{KBr} 3320, 1445, 1390, 1330, 1130, 1075 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.70—3.10 (br s, 1H), 3.37—3.67 (m, 1H), 4.12 (dq, 2H, *J*=1 and 11 Hz), 4.72 (d, 1H, *J*=9 Hz), 5.63 (s, 1H), 6.07 (dd, 1H, *J*=9 and 12 Hz), 6.79 (d, 1H, *J*=12 Hz), 7.25—7.65 (m, 10H). Found: C, 76.48; H, 6.56%. Calcd for $C_{18}H_{18}O_3$: C. 76.57; H, 6.43%. **6E** as white crystals, mp 109.5—110 °C: TLC R_f 0.65 (AcOEt/hexane 1:1); $[\alpha]_D^{22}$ +61.0° (*c* 1.51, $CHCl_3$); IR ν_{max}^{KBr} 3570, 2980, 1490, 1450, 1395, 1370, 1350, 1215, 1145, 1115, 1070 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.60—3.00 (br s, 1H), 3.43—3.73 (br s, 1H), 4.05, 4.19 (each dd, each 1H, *J*=1 and 12 Hz), 4.55 (d, 1H, *J*=6 Hz), 5.67 (s, 1H), 6.32 (dd, 1H, *J*=6 and 16.5 Hz), 6.75 (d, *J*=16.5 Hz, 1H), 7.17—7.67 (m, 10H). Found: C, 76.64; H, 6.42%. Calcd for $C_{18}H_{18}O_3$: C, 76.57; H, 6.43%.

Isomerization of 6Z to 6E. A mixture of **6Z** (3.60 g, 12.8 mmol), PhSH (0.66 ml, 6.4 mmol), and AIBN (420 mg, 2.56 mmol) in benzene (120 ml) was refluxed for 30 min. The mixture was then concentrated in vacuo. Pure **6E** (2.92 g, 81%) was obtained by flash column chromatography (AcOEt/hexane 1:10) of the residue.

Epoxidaion of 6E Followed by Treatment with Silica Gel. (2*S*,3*R*,4*R*,5*R*)- and (2*S*,3*R*,4*S*,5*S*)-2-(Hydroxymethyl)-5-phenyltetrahydrofuran-3,4-diol *O*,*O*′-Benzylidene Derivatives (10 and 11). A mixture of **6E** (1.62 g 5.74 mmol) and mCPBA (2.49 g, 14.4 mmol) in CH_2Cl_2 (30 ml) was refluxed for 30 min. The mixture was diluted with CH_2Cl_2 (120 ml) and washed with 20 wt% aqueous $Na_2S_2O_3$ (2×80 ml) and saturated aqueous $NaHCO_3$ (2×80 ml). The organic phase was dried (Na_2SO_4) and concentrated in vacuo to give an inseparable mixture of **8** and **8′** as amorphous solids, which was used in the next step without further purification. The mixture of **8** and **8′** was dissolved in CH_2Cl_2 (120 ml) and silica gel (60 g) was added. The mixture was kept standing for 36 h. Then the silica gel was removed by filtration, washed with CH_2Cl_2 (500 ml), AcOEt (500 ml), and EtOH (250 ml). The combined filtrate and washings were concentrated in vacuo. The residue was purified by flash column chromatography (AcOEt/$PhCH_3$ 1:40, 1:20, and 1:5 successively). From the fractions corresponding to R_f 0.46 (AcOEt/$PhCH_3$ 1:3), compound **11** (1.25 g, 73%) was obtained as crystals, mp 127—128 °C. From the fractions corresponding to R_f 0.21, compound **10** (124 mg) was obtained as crystals, mp 131—132 °C. The fractions corresponding to R_f 0.31 was also concentrated in vacuo to give uncyclized **8**. Thus obtained **8** was treated with silica gel (10 g) in CH_2Cl_2 (20 ml) for 6 days. Filtration and chromatographic purification as described above gave an additional **10** (208 mg, total 332 mg, 19%). **10**: $[\alpha]_D^{25}$ +28.4° (*c* 0.90, $CHCl_3$) IR ν_{max}^{KBr} 3430, 2910, 2880, 1450, 1390, 1335, 1245, 1210, 1125, 1080, 1055 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.30 (br s, 1H), 3.97—4.30 (m, 4H), 4.50 (d, 1H, *J*=12 Hz), 4.80 (d, 1H, *J*=2 Hz), 5.46 (s, 1H), 7.17—7.60 (m, 10H). Found: C, 72.62; H, 6.12%. Calcd for $C_{18}H_{18}O_4$: C, 72.47; H, 6.08%. **11**: $[\alpha]_D^{23}$ −11.3° (*c* 1.00, $CHCl_3$); IR ν_{max}^{KBr} 3420, 1450, 1390, 1360, 1215, 1150, 1095, 1050 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.50—2.75 (m, 1H), 3.97—4.60 (m, 5H), 5.01 (d, 1H, *J*=8 Hz), 5.59 (s, 1H), 7.23—7.67 (m, 10H). Found: C, 72.56; H, 6.11%. Calcd for $C_{18}H_{18}O_4$: C, 72.47; H, 6.08%.

(2*S*,3*S*,4*E*)-1,3-*O*-Benzylidene-2-*O*-benzoyl-5-phenyl-4-pentene-1,2,3-triol (7). To a stirred solution of **6E** (6.88 g, 24.4 mmol) in pyridine (180 ml) was added benzoyl chloride (9.26 ml, 78.1 mmol) at 0 °C. After being stirred for 20 h, the resulting crystals were removed by filtration. The filtrate was concentrated in vacuo. The residue was partitioned between CH_2Cl_2 (1500 ml) and saturated aqueous $NaHCO_3$ (500 ml). The organic phase was washed with saturated aqueous $NaHCO_3$ (500 ml) and H_2O (500 ml) successively. The organic phase was dried (Na_2SO_4) and concentrated in vacuo. The resulting crystals were recrystallized from AcOEt to give **7** (7.73 g). The mother liquor was concentrated and recrystallization of the residue gave an additional **7** (1.02 g, total 8.75 g, 93%), mp 164.5—165.5 °C: TLC R_f 0.69 (AcOEt/toluene 1:5), $[\alpha]_D^{22}$ +161° (*c* 1.19, $CHCl_3$); IR ν_{max}^{KBr} 2850, 1715, 1445, 1350, 1265, 1085 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=4.22, 4.51 (each d, each 1H, *J*=15 Hz), 4.75—4.90 (m, 1H), 5.07—5.20 (m, 1H), 5.75 (s, 1H), 6.26 (dd, 1H, *J*=6 and 16.5 Hz), 6.69 (d, 1H, *J*=16.5 Hz), 7.17—7.73, 8.07—8.30 (m, 15H). Found: C, 77.90; H, 5.86%. Calcd for $C_{25}H_{22}O_4$: C, 77.70; H, 5.74%.

Conversion of 7 into 10 and 11. Compound **7** (16.4 g, 42.2 mmol) in CH_2Cl_2 (200 ml) was oxidized with mCPBA (18.3 g, 106 mmol) under reflux for 2.5 h. After extractive workup as described in the case of **8** and **8′**, the mixture of **9** and **9′** was obtained. The mixture of **9** and **9′** was dissolved in MeOH (750 ml), and MeONa (1 M in MeOH, 63.6 ml, 63.6 mmol) was added. After being stirred for 2.5 h, the solution was neutralized with 1 M HCl and concentrated in vacuo. Extractive workup (AcOEt/H_2O) of the residue gave a mixture of **8** and **8′**, which was treated with silica gel (600 g, 32 h). Recrystallization of the concentrate of the reaction mixture from MeOH provided **11** (8.37 g). From the mother liquor, an additional **11** (2.13 g, total 10.5 g, 83%) and **10** (759 mg, 6%) were obtained by the similar chromatographic purification and retreatment with silica gel as described above. Compounds **10** and **11** from **6E** and those from **7** were identical in all respects.

Debenzylidenation of 10 and 11. (2*S*,3*R*,4*R*,5*R*)- and (2*S*,3*R*,4*S*,5*S*)-2-(Hydroxymethyl)-5-phenyltetrahydrofuran-3,4-diol (12 and 13). A solution of **10** (845 mg, 2.8 mmol) in a mixture of 1,4-dioxane (20 ml) and 1 M HCl (20 ml) was refluxed for 30 min. The mixture was neutralized with 4 M NaOH, then concentrated in vacuo. The residue was partitioned between AcOEt (40 ml) and water (50 ml). The organic phase was dried (Na_2SO_4) and concentrated. The residue was purified by silica-gel chromatography (AcOEt/hexane 2:3) to give **12** (529 mg, 89%) as a colorless oil: TLC R_f 0.41 (EtOH/$PhCH_3$ 1:4); $[\alpha]_D^{25}$ +24.4° (*c* 0.76, MeOH); IR ν_{max}^{neat} 3380, 2880, 1495, 1455, 1100, 1085 cm^{-1}; ^1H NMR (90 MHz, CD_3OD) δ=3.81—4.41 (m, 5H), 4.52 (d, 1H, *J*=6 Hz), 7.15—7.51 (m, 5H).

Compound **11** (850 mg) was converted into **13** (489 mg, 82%) as described in the preparation of **12** after chromatographic purification, mp 81.5—82.5 °C: TLC R_f 0.17 (EtOH/$PhCH_3$ 1:10); $[\alpha]_D^{29}$ −41.3° (*c* 1.15, MeOH); IR ν_{max}^{KBr} 3400, 2885, 1450, 1340, 1280, 1150 cm^{-1}; ^1H NMR (90 MHz, CD_3OD) δ=3.80—4.12 (m, 3H), 4.19—4.48 (m, 2H), 4.80 (d, 1H, *J*=7.5 Hz), 7.25—7.59 (m, 5H). Found: C, 62.88; H, 6.69%. Calcd for $C_{11}H_{14}O_4$: C, 62.84; H, 6.71%.

***t*-Butyldiphenylsilylation of 12 and 13. (2*S*,3*R*,4*R*,5*R*)- and (2*S*,3*R*,4*S*,5*S*)-2-[(*t*-Butyldiphenylsilyloxy)methyl]-5-phenyltetrahydrofuran-3,4-diol (14 and 15).** To a solution of **12** (10 mg, 0.05 mmol) in DMF (0.5 ml) were added *t*-butylchlorodiphenylsilane (0.015 ml, 0.06 mmol) and imidazole (8 mg, 0.12 mmol). After being stirred for 3.5 h, the silylating reagent (0.03 ml) and imidazole (16 mg) were added, and the mixture was stirred more 2 h. The mixture was concentrated in vacuo, and AcOEt (4 ml) was added to the residue. The insoluble materials were removed by filtration, and the filtrate was concentrated. The residue was purified by PTLC (EtOH/$PhCH_3$ 1:10) to give **14** (17 mg, 79%) as a colorless oil: TLC R_f 0.73 (EtOH/$PhCH_3$ 1:5); ^1H NMR (90 MHz, $CDCl_3$) δ=1.02 (s, 9H), 1.52—1.80, 2.39—2.72 (m, each 1H), 3.55—4.45 (m, 5H), 4.57 (d, 1H, *J*=6 Hz), 7.15—7.85 (m, 15H).

Analogously as described above, compound **13** (20 mg) was converted into **15** (37 mg, 85%). **15** as a colorless oil: TLC R_f 0.66 (AcOEt/hexane 1:2); $[\alpha]_D^{29}$ −31.5° (*c* 1.56, $CHCl_3$); IR ν_{max}^{neat} 3400, 2940, 2860, 1430, 1110 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.10 (s, 9H), 3.40—3.85 (m, 2H), 3.90—4.53 (m, 5H), 4.92 (d, 1H, *J*=6 Hz), 7.30—7.55, 7.65—7.89 (m, 15H).

Isopropylidenation of 15. A mixture of **15** (21 mg, 0.05 mmol), 2,2-dimethoxypropane (0.008 ml), and CSA (3 mg) in acetone (0.5 ml) was stirred for 2 h, and neutralized with saturated aqueous $NaHCO_3$, then concentrated. The residue was purified by PTLC (AcOEt/hexane 1:10) to give **16** (20 mg, 87%) as a pale yellow oil. **16**: TLC R_f 0.85 (AcOEt/hexane 1:4); $[\alpha]_D^{28}$ −4.3° (*c* 1.00, $CHCl_3$); IR ν_{max}^{neat} 2940, 1430, 1385, 1375, 1215, 1120 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.08 (s, 9H), 1.32, 1.45 (each s, 3H×2), 4.05 (s, 3H), 4.62—4.98 (m, 2H), 5.12 (s, 1H), 7.30—7.52, 7.62—7.82 (m, 15H).

(2*S*,3*R*,4*S*,5*S*)-2-(Hydroxymethyl)-4-[(methylsulfonyl)oxy]-5-phenyltetrahydrofuran-3-ol *O*,*O*′-Benzylidene Derivative (17). To a stirred solution of **11** (1.67 g, 5.6 mmol) in pyridine (35 ml) were added methanesulfonyl chloride (0.65 ml, 8.4 mmol) and DMAP (137 mg, 1.12 mmol). After being stirred for 2.5 h, the mixture was concentrated in vacuo. The residue was partitioned between CH_2Cl_2 (600 ml) and H_2O (200 ml). The organic phase was dried (Na_2SO_4) and concentrated in vacuo. The resulting crystals were recrystallized from AcOEt to give **17** (1.35 g). The mother liquor was concentrated, and the residue was purified by a silica-gel column chromatography (AcOEt/$PhCH_3$ 1:5) to give an additional **17** (0.58 g, total 1.93 g, 93%), mp 186—186.5 °C. **17**: TLC R_f 0.48 (AcOEt/$PhCH_3$ 1:3); $[\alpha]_D^{22}$ −75.2° (*c* 1.24, $CHCl_3$);IR ν_{max}^{KBr} 2920, 1410, 1350, 1175 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.83 (s, 3H), 4.00—4.57 (m, 3H), 4.75—5.03 (m, 2H), 5.37 (d, 1H, *J*=6 Hz), 5.58 (s, 1H), 7.30—7.68 (m, 10H). Found: C, 60.75; H, 5.51%. Calcd for $C_{19}H_{20}O_6S$: C, 60.62; H, 5.36%.

Elimination of the Mesyloxy Group in 17, Successive Hydroboration of the Dihydrofuran Derivative 18 Followed by Oxidative Work-up. Conversion of 17 into 10. A mixture of **17** (1.96 g, 5.21 mmol) and *t*-BuOK (2.04 g, 18.2 mmol) in THF (140 ml) was refluxed for 20 min under argon atmosphere. The reaction mixture was mainly consisted of the dihydrofuran **18**, and used directly without purification [**18**: ^1H NMR (90 MHz, $CDCl_3$) δ=4.05—4.45 (m, 2H), 4.70 (d, 1H, *J*=12.5 Hz), 5.00 (t, 1H, *J*=3 Hz), 5.47 (s, 1H), 5.66 (d, 1H, *J*=2.5 Hz), 7.22—7.80 (m, 5H)]. The mixture in THF obtained above was cooled to 0 °C, and BH_3–THF complex (1 M in THF, 31.3 ml, 31.3 mmol) was added. After being stirred for 1.5 h, 2 M aqueous NaOH (26 ml) and H_2O (30 ml) were added successively to the mixture. After being warmed to room temperature, H_2O_2 (35 wt% in H_2O, 28 ml) was added to the mixture which was stirred more 1.5 h. To the mixture was added saturated aqueous Na_2SO_3 (30 ml), and the mixture was stirred for 1 h. This was diluted with AcOEt (500 ml), washed with 0.1 M HCl (100 ml) and saturated aqueous $NaHCO_3$ (100 ml). The organic phase was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by repeated flash column chromatography (AcOEt/$PhCH_3$ 1:5) to give **10** (1.09 g 65%), which was identical with an authentic sample described above in all respects.

Pfitzner-Moffatt Oxidation of 10 and Successive $NaBH_4$ Reduction. (2*S*,3*R*,4*S*,5*R*)-2-(Hydroxymethyl)-5-phenyltetrahydrofuran-3,4-diol *O*,*O*′-Benzylidene Derivative (20). To a stirred solution of **10** (913 mg, 3.06 mmol) in benzene (85 ml) were added DMSO (1.31 ml, 18.4 mmol), pyridine (0.37 ml, 4.6 mmol), CF_3COOH (0.35 ml, 4.6 mmol), and dicyclohexylcarbodiimide (1.89 g, 9.2 mmol). After being stirred for 30 min, the resulting white solids were filtered off. The filtrate was diluted with AcOEt (500 ml), and this was washed with H_2O (100 ml). The organic phase was dried (Na_2SO_4) and concentrated in vacuo. To the residue was added a small amount of AcOEt, and the precipitates were filtered off. The filtrate was concentrated in vacuo to give crude tetrahydrofuranone **19**, which was reduced directly. The residue was dissolved in MeOH (20 ml), and $NaBH_4$ (174 mg, 4.6 mmol) was added. After being stirred for 1 h, the mixture was neutralized with Amberlite IR-120 (H^+). The resin was removed by filtration and washed with MeOH. The combined filtrate and washings were concentrated in vacuo. The residue was purified by flash column chromatography (AcOEt/$PhCH_3$ 1:20) to give **20** (758 mg, 83%) as white crystals, mp 121—122 °C. **20**: TLC R_f 0.43 (AcOEt/$PhCH_3$ 1:2); $[\alpha]_D^{27}$ +12.7° (*c* 1.42, $CHCl_3$); IR ν_{max}^{KBr} 3560, 2915, 1400, 1225, 1210, 1150, 1095, 1080, 1065 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.00 (br s, 1H), 3.92—4.01 (m, 1H), 4.18 (dd, 1H, *J*=2 and 13.5 Hz), 4.38 (dd, 1H, *J*=2 and

6 Hz), 4.55 (d, 1H, J=13.5 Hz), 4.54—4.96 (m, 1H), 5.20 (d, 1H, J=9 Hz), 5.53 (s, 1H), 7.25—7.77 (m, 10H). Found: C, 72.34; H, 6.06%. Calcd for $C_{18}H_{18}O_4$: C, 72.47; H, 6.08%.

Inversion of the Hydroxyl Group at C-4 in 11 via Triflate 21. (2*S*,3*R*,4*R*,5*S*)-4-Acetoxy-2-(hydroxymethyl)-5-phenyltetrahydrofuran-3-ol *O,O'*-Benzylidene Derivative (22). To a stirred solution of **11** (1.00 g, 3.35 mmol) in pyridine (20 ml) were added triethylamine (1.87 ml, 13.4 mmol) and trifluoromethanesulfonic anhydride (1.70 ml, 10.1 mmol) at −15 °C. After being stirred at −15 °C for 2 h, the mixture was concentrated in vacuo. The residue was partitioned between AcOEt (200 ml) and H_2O (100 ml). The organic phase was washed with saturated aqueous NaCl (2×100 ml), dried (Na_2SO_4), and concentrated in vacuo to give crude triflate **21**, which was rapidly passed through a silica-gel column by flash chromatography (AcOEt/hexane 1:10 then 1:5). The fractions having R_f 0.55 (AcOEt/hexane 1:2) were concentrated in vacuo to give **21** as a yellow solid (1.31 g). A mixture of **21** (1.31 g) and potassium acetate (1.49 g, 15.2 mmol) in DMF (26 ml) was heated at 135 °C for 1 h with stirring. After being cooled to room temperature, insoluble materials were removed by filtration. The filtrate was concentrated in vacuo. The residue was partitioned between AcOEt (200 ml) and H_2O (50 ml). The organic phase was washed with saturated aqueous NaCl (50 ml), dried (Na_2SO_4), and concentrated. The residue was purified by flash column chromatography (AcOEt/hexane 1:10 then 1:5) to give **22** (902 mg, 79%) as white crystals, mp 123—124 °C. **22**: TLC R_f 0.69 (AcOEt/hexane 1:2); $[\alpha]_D^{21}$ +16.9° (c 1.57, $CHCl_3$); IR ν_{max}^{KBr} 3060, 2920, 2900, 1740, 1370, 1240, 1140 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.72 (s, 3H), 4.05—4.35, 4.49—4.70 (each m, each 2H), 5.55 (s, 1H), 5.57—5.77 (m, 2H), 7.30—7.69 (m, 10H). Found: C, 70.29; H, 5.94%. Calcd for $C_{20}H_{20}O_5$: C, 70.57; H, 5.92%.

(2*S*,3*R*,4*R*,5*S*)-2-(Hydroxymethyl)-5-phenyltetrahydrofuran-3,4-diol *O,O*-Benzylidene Deriative (23). A mixture of **22** (1.97 g, 5.79 mmol) and MeONa (1 M in MeOH, 8.7 ml, 8.7 mmol) in MeOH (40 ml) was stirred for 30 min. The mixture was neutralized with Amberlite IR-120 (H^+), the resin was removed by filtration, washed with MeOH. The combined filtrate and washings were concentrated in vacuo. The residual crystals were recrystallized from toluene to give **23** (1.53 g). By silica-gel column chromatography of the concentrate of the mother liquor (AcOEt/hexane 1:10 then 1:4), an additional **23** (0.10 g, total 1.63 g, 94%) was obtained. **23** as white crystals, mp 154—155 °C: TLC R_f 0.49 (AcOEt/hexane 1:2); $[\alpha]_D^{23}$ +76.1° (c 1.43, $CHCl_3$); IR ν_{max}^{KBr} 3330, 2920, 1490, 1445, 1390, 1300, 1210, 1125, 1110, 1080, 1065 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.85 (br s, 1H), 4.02—4.69 (m, 5H), 5.54 (s, 1H), 5.61 (d, 1H, J=3 Hz), 7.30—7.67 (m, 10H). Found: C, 72.22; H, 6.08%. Calcd for $C_{18}H_{18}O_4$: C, 72.47; H, 6.08%.

Direct Preparation of 23 from 21 with KO_2. Compound **21** (20.0 mg), which was prepared from 17.8 mg of **11** as described above, was dissolved in DMSO-DMF (v/v 1/1, 1 ml). To the solution were added a solution of 18-crown-6 (55 mg) and KO_2 (13 mg) in DMSO-DMF (v/v 1/1, 1 ml). After being stirred for 30 min, the mixture was quenched with 5% aqueous $Na_2S_2O_3$ (5 ml). This aqueous solution was extracted with CH_2Cl_2 (4×10 ml). The combined extracts were dried (Na_2SO_4), and concentrated in vacuo. The residue was purified by PTLC (AcOEt/hexane 2:3) to give **23** (10.2 mg, 58% from **11**), which was identical with an authentic sample in all respects.

Debenzylidenation of 20 and 23. (2*S*,3*R*,4*S*,5*R*)- and (2*S*,3*R*,4*R*,5*S*)-2-(Hydroxymethyl)-5-phenyltetrahydrofuran-3,4-diol (24 and 25). By the analogous reaction conditions and work-up as described in the preparation of **12**, 836 mg of **20** was converted into debenzylidene derivative **24** (503 mg, 85%) as white crystals, mp 100.5—101 °C. **24**: TLC R_f 0.22 (EtOH/$PhCH_3$ 1:4); $[\alpha]_D^{28}$ −89.4° (c 1.50, MeOH); IR ν_{max}^{KBr} 3280, 1450, 1315, 1280, 1200, 1145, 1125, 1100, 1050 cm^{-1}; ^1H NMR (90 MHz, CD_3OD) δ=3.77—3.92 (m, 2H), 4.00—4.22 (m, 2H), 4.58 (dd, 1H, J=4.5 and 7.5 Hz), 4.85 (d, 1H, J=3 Hz), 7.25—7.55 (m, 5H). Found: C, 62.68; H, 6.63%. Calcd for $C_{11}H_{14}O_4$: C, 62.84; H, 6.71%.

Analogously, compound **23** (1.57 g) was debenzylidenated to give **25** (1.02 g, 92%) as white crystals, mp 100—101 °C. **25**: TLC R_f 0.31 (EtOH/$PhCH_3$ 1:5); $[\alpha]_D^{23}$ +94.0° (c 2.13, MeOH); IR ν_{max}^{KBr} 3440, 2930, 2880, 1480, 1450, 1285, 1260, 1200, 1070 cm^{-1}; ^1H NMR (90 MHz, CD_3OD) δ=3.80—4.00 (m, 2H), 4.08—4.54 (m, 3H), 5.23 (d, 1H, J=3 Hz), 7.21—7.56 (m, 5H). Found: C, 62.83; H, 6.67%. Calcd for $C_{11}H_{14}O_4$: C, 62.84; H, 6.71%.

Selective Tritylation of the Primary Hydroxyl Groups in 12, 13, 24, and 25. (2*S*,3*R*,4*R*,5*R*)-, (2*S*,3*R*,4*S*,5*S*)-, (2*S*,3*R*,4*S*,5*R*)-, and (2*S*,3*R*,4*R*,5*S*)-5-Phenyl-2-[(triphenylmethoxy)methyl]tetrahydrofuran-3,4-diol (26, 27, 28, and 29). To a solution of **12** (507 mg, 2.41 mmol) in pyridine (15 ml) were added triphenylmethyl chloride (1.01 g, 3.62 mmol) and DMAP (59 mg, 0.48 mmol). After being stirred at 90 °C for 8 h, the mixture was concentrated in vacuo. The residue was dissolved in AcOEt (400 ml) and washed with H_2O (2×100 ml). The organic phase was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by silica-gel column chromatography (AcOEt/hexane 1:2 containing 1% Et_3N, then EtOH/$PhCH_3$ 1:40) to give **26** (823 mg, 75%) as a pale yellow oil: TLC R_f 0.62 (EtOH/$PhCH_3$ 1:5 containing 1% Et_3N); $[\alpha]_D^{28}$ −26.9° (c 1.16, $CHCl_3$); IR ν_{max}^{neat} 3430, 3060, 3040, 2940, 2880, 1600, 1490, 1450, 1320, 1220, 1150, 1100 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.80—3.70 (m, 4H), 3.87—4.33 (m, 3H), 4.56 (d, 1H, J=6 Hz), 7.10—7.67 (m, 20H).

Analogously as described above, **13** (440 mg), **24** (500 mg), and **25** (967 mg) were converted into **27** (686 mg, 72%), **28** (851 mg, 79%), and **29** (1.94 g, 93%). **27** as a pale yellow oil: TLC R_f 0.70 (AcOEt/hexane 1:2); $[\alpha]_D^{29}$ −19.1° (c 1.10, $CHCl_3$); IR ν_{max}^{neat} 3410, 3100, 3070, 3045, 2870, 1600, 1495, 1450, 1400, 1325, 1220, 1155, 1080, 1045 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.57—3.29 (br s, 1H), 3.31—3.71 (m, 2H), 3.99 (dd, 1H, J=4.5 Hz and 7.5 Hz), 4.23—4.52 (m, 2H), 4.85 (d, 1H, J=7.5 Hz), 7.25—7.62 (m, 20H). **28** as a pale yellow oil: TLC R_f 0.37 (AcOEt/hexane 1:2 containing 1% Et_3N); $[\alpha]_D^{27}$ −71.1° (c 1.45, $CHCl_3$); IR ν_{max}^{neat} 3400, 3050, 3025, 2925, 2875, 1600, 1485, 1445, 1215, 1070 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.41—3.22 (br, 2H), 3.40, 3.72 (each dd, each 1H, J=4.5 and 10.5 Hz), 4.06—4.52 (m, 3H), 4.93 (d, 1H, J=4.5 Hz), 7.25—7.65 (m, 20H). **29** as a colorless foam: TLC R_f 0.66 (EtOH/$PhCH_3$ 1:5 containing 1% Et_3N); $[\alpha]_D^{23}$ +43.6° (c 2.05, $CHCl_3$); IR ν_{max}^{neat} 3450, 3055, 3025, 2930, 2875, 1600, 1490, 1445, 1220, 1180, 1150 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.45 (br s, 1H), 3.54 (d, 2H, J=6 Hz), 4.12—4.22 (m, 1H), 4.36—4.66 (m, 2H), 5.40 (d, 1H, J=3 Hz), 7.25—7.63 (m, 20H).

Methoxymethylation of Compounds 26, 27, 28, and 29. (2*S*,3*R*,4*R*,5*R*)-, (2*S*,3*R*,4*S*,5*S*)-, (2*S*,3*R*,4*S*,5*R*)-, and (2*S*,3*R*,4*R*,5*S*)-3,4-Bis(methoxymethoxy)-5-phenyl-2-[(triphenyl-

methoxy)methyl]tetrahydrofuran (30, 31, 32, and 33). To a solution of **26** (823 mg, 1.82 mmol) in THF (20 ml) were added *N,N*-diisopropylethylamine (19.0 ml, 109 mmol) and freshly distilled chloromethyl methyl ether (7.47 ml, 98.3 mmol). After being refluxed for 2 h under argon atmosphere, the mixture was diluted with AcOEt (500 ml). The solution was washed with H_2O (100 ml), saturated aqueous NaCl (100 ml), and then dried (Na_2SO_4), and concentrated in vacuo. The residue was purified by siliica-gel chromatography (AcOEt/hexane 1:40 containing 1% Et_3N) to give **30** (875 mg, 89%) as a pale yellow oil: TLC R_f 0.72 (AcOEt/$PhCH_3$ 1:5 containing 1% Et_3N); $[\alpha]_D^{28}$ +48.4° (*c* 1.21,$CHCl_3$); IR ν_{max}^{neat} 3060, 3040, 2950, 2900, 1600, 1495, 1450, 1215, 1150, 1100, 1080 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=3.02, 3.33 (each s, each 3H), 3.14—3.43 (m, 1H), 3.68 (dd, 1H, *J*=6 and 9 Hz), 3.88—4.93 (m, 6H), 4.13 (dd, 1H, *J*=3 and 9 Hz), 4.85 (d, 1H, *J*=3 Hz), 7.01—7.86 (m, 20H). Found: C, 75.86; H, 6.90%. Calcd for $C_{34}H_{36}O_6$: C, 75.53; H, 6.71%.

By the analogous procedure for the preparation of **30**, **27** (667 mg), **28** (822 mg), and **29** (1.88 g) were converted into **31** (726 mg, 91%), **32** (888 mg, 90%), and **33** (2.12 g, 94%). **31** as a pale yellow oil: TLC R_f 0.52 (AcOEt/hexane 1:5 containing 1% Et_3N); $[\alpha]_D^{29}$ −12.4° (*c* 1.58, $CHCl_3$); IR ν_{max}^{neat} 3075, 3050, 2960, 2910, 1600, 1500, 1460, 1225, 1160, 1080, 1060, 1035 cm^{-1}; ^1H NMR (90 MHz. $CDCl_3$) δ=3.06, 3.22 (each s, each 3H), 3.12—3.42, 3.50—3.72 (each m, 2H), 4.12 (dd, 1H, *J*=4.5 and 9 Hz, 1H), 4.30—4.78 (m, 6H), 4.83 (d, 1H. *J*=9 Hz), 7.15—7.69 (m, 20H). **32** as a pale yellow oil: TLC R_f 0.44 (AcOEt/hexane 1:3 containing 1% Et_3N); $[\alpha]_D^{26}$ + 11.6° (*c* 2.17, $CHCl_3$); IR ν_{max}^{neat} 3055, 3025, 2950, 2895, 1600, 1490, 1445, 1210, 1145, 1070, 1025 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.89, 3.20 (each s, each 3H), 3.30—3.85 (m, 2H), 4.02—4.60 (m, 6H), 5.00 (d, 1H, *J*=4.5 Hz), 7.18—7.70 (m, 20H). Found: C, 75.91; H, 6.74%. Calcd for $C_{34}H_{36}O_6$: C, 75.53; H, 6.71%. **33** as a pale yellow oil: TLC R_f 0.68 (AcOEt/$PhCH_3$ 1:4 containing 1% Et_3N); $[\alpha]_D^{24}$ +82.8° (*c* 2.42, $CHCl_3$); IR ν_{max}^{neat} 3060, 3040, 2950, 2900, 1600, 1490, 1445, 1220, 1150, 1110, 1070, 1035 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.94, 3.25 (each s, each 3H), 3.60 (dd, 1H, *J*=6 and 9 Hz), 4.10—4.80 (m, 8H), 5.15 (d, 1H, *J*=3 Hz), 7.20—7.68 (m, 20H).

Detritylation of 30, 31, 32, and 33. (2*S*,3*R*,4*R*,5*R*)-, (2*S*,3*R*,4*S*,5*S*)-, (2*S*,3*R*,4*S*,5*R*)-, and (2*S*,3*R*,4*R*,5*S*)-2-(Hydroxymethyl)-3,4-bis(methoxymethoxy)-5-phenyltetrahydrofuran (34, 35, 36, and 37). A solution of **30** (853 mg, 1.58 mmol) in a mixture of AcOEt (30 ml) and MeOH (30 ml) containing *p*-TsOH (monohydrate, 601 mg, 3.16 mmol) was stirred for 45 min. The mixture was neutralized with Et_3N and concentrated in vacuo. The residue was purified by silica-gel chromatography (AcOEt/$PhCH_3$ 1:3) to give **34** (440 mg, 94%) as a colorless oil. **34**: TLC R_f 0.30 (EtOH/$PhCH_3$ 1:10); $[\alpha]_D^{27}$ +66.3° (*c* 1.13, $CHCl_3$); IR ν_{max}^{neat} 3460, 2950, 2900, 1600, 1500, 1450, 1400, 1365, 1210, 1150, 1100, 1040, 1030 cm^{-1}; ^1H NMR (90 MHz) δ=2.45 (br s, 1H), 3.24 (s, 6H), 3.66—4.39 (m, 5H), 4.39—4.85 (m, 5H), 7.07—7.49 (m, 5H); MS *m/z* calcd for $C_{15}H_{21}O_6$ (M^+−H) 297.1336, observed 297.1329.

Analogously as described above, **31** (712 mg), **32** (839 mg), and **33** (2.12 g) were converted into **35** (306 mg, 78%), **36** (332 mg, 72%), and **37** (1.10 g, 94%). **35** as a colorless oil: TLC R_f 0.20 (AcOEt/hexane 1:2) $[\alpha]_D^{28}$ +5.2° (*c* 1.63, $CHCl_3$); IR ν_{max}^{neat} 3450, 2950, 2900, 1600, 1490, 1450, 1400, 1360, 1300, 1220, 1150, 1080, 1050, 1020 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.85 (br s, 1H), 3.15, 3.42 (each s, each 3H), 3.82 (d, 2H, *J*=6 Hz), 4.05 (dd, 1H, *J*=4.5 and 7.5 Hz), 4.24—4.78 (m, 6H), 4.93 (d, 1H, *J*=7.5 Hz), 7.18—7.46 (m, 5H) MS *m/z* calcd for $C_{15}H_{23}O_6$ (M^++H), 299.1493, observed 299.1497. **36** as a colorless oil: TLC R_f 0.12 (AcOEt/hexane 1:2); $[\alpha]_D^{26}$ +2.4° (*c* 1.52, $CHCl_3$); IR ν_{max}^{neat} 3470, 2950, 2900, 1600, 1500, 1460, 1370, 1260, 1220, 1155, 1030 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.90, 3.45 (each s, each 3H), 3.92 (d, 2H, *J*=4.5 Hz), 4.05—4.50, 4.61—4.85 (m, 7H), 5.00 (d, 1H, *J*=3 Hz), 7.58—7.86 (m, 5H). Found: C, 60.63; H, 7.51%. Calcd for $C_{15}H_{22}O_6$: C, 60.39; H, 7.43%. **37** as a colorless oil: TLC R_f 0.18 (AcOEt/hexane 1:2); $[\alpha]_D^{24}$ +89.3° (*c* 1.24, $CHCl_3$); IR ν_{max}^{neat} 3450, 2950, 2890, 1600, 1495, 1455, 1400, 1360, 1215, 1150, 1105, 1045 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=2.40 (br s, 1H), 2.98, 3.48 (each s, each 3H), 3.90 (dd, 2H,*J*=3 and 6 Hz), 4.1—4.59 (m, 5H), 4.75 (s, 2H), 5.25 (d, 1H, *J*=3.5 Hz), 7.22—7.52 (m, 5H).

Collins Oxidation of 34, 35, 36, and 37, and Successive Wittig Olefination with (Ethoxycarbonylmethylene)triphenylphosphorane. (2*S*,3*R*,4*R*,5*R*)-, (2*S*,3*R*,4*S*,5*S*)-, (2*S*,3*R*,4*S*,5*R*)-, and (2*S*,3*R*,4*R*,5*S*)-2-[(*Z*)- and (*E*)-2-(Ethoxycarbonyl)-ethenyl]-3,4-bis(methoxymethoxy)-5-phenyltetrahydrofuran (38Z and 38E, 39Z and 39E, and 40Z and 40E, and 41Z and 41E). The oxidation was carried out under argon atmosphere. To a mixture of pyridine (3.40 ml, 42.0 mmol) and CH_2Cl_2 (30 ml) was added CrO_3 (2.10 g, 21.0 mmol) at 0 °C. After being stirred for 13 h, a solution of **34** (418 mg, 1.40 mmol) in CH_2Cl_2 (5 ml) was added to the mixture. The mixture was stirred for 15 min, and applied on a short silica-gel column (12 g). The column was eluted with ether to give an aldehyde [R_f 0.46 (AcOEt/$PhCH_3$ 1:2)], which was subjected to the Wittig reaction. A mixture of the aldehyde obtained and (ethoxycarbonylmethylene)triphenylphosphorane (975 mg, 2.80 mmol) in MeOH (10 ml) was stirred for 30 min, and concentrated in vacuo. The residue was purified by flash chromatography (AcOEt/hexane 1:10 then 1:5) to give **38Z** (320 mg, 62%) and **38E** (47 mg, 9%). **38Z** as a colorless oil: TLC R_f 0.71 (AcOEt/$PhCH_3$ 1:2); $[\alpha]_D^{29}$ +176° (*c* 1.13, $CHCl_3$); IR ν_{max}^{neat} 3000, 2950, 2900, 1720, 1655, 1600, 1500, 1450, 1200, 1155, 1110 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.30 (t, 3H, *J*=7.5 Hz), 3.18, 3.35 (each s, each 3H), 4.06—4.21 (m, 1H), 4.18 (q, 2H, *J*=7.5 Hz), 4.42—4.85 (m, 6H), 5.43—5.61 (m, 1H), 5.92 (dd, 1H, *J*=1.5 and 12 Hz), 6.53 (dd, 1H, *J*=7.5 and 12 Hz), 7.23—7.55 (m, 5H). Found: C, 62.47; H, 7.10%. Calcd for $C_{19}H_{26}O_7$: C, 62.28; H, 7.15%. **38E** as a colorless oil: TLC R_f 0.62 (AcOEt/$PhCH_3$ 1:2); $[\alpha]_D^{30}$ +15.7° (*c* 0.96, $CHCl_3$); IR ν_{max}^{neat} 3000, 2950, 2900, 1720, 1665, 1600, 1500, 1470, 1455, 1370, 1305, 1265, 1220, 1180, 1155, 1105 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.30 (t, 3H, *J*=7.5 Hz), 3.22, 3.34 (each s, each 3H), 4.06—4.22 (m, 2H), 4.21 (q, 2H, *J*=7.5 Hz), 4.44—4.79 (m, 5H), 4.82 (d, 1H, *J*=4.5 Hz), 6.23 (dd, 1H, *J*=1.5 and 16.5 Hz), 7.08 (dd, 1H, *J*=6 and 16.5 Hz), 7.22—7.51 (m, 5H). Found: C, 61.99; H, 6.99%. Calcd for $C_{19}H_{26}O_7$: C, 62.28; H, 7.15%.

By the analogous reaction conditions and work-up described for preparation of 38Z and **38E**, **35** (264 mg), **36** (345 mg), and **37** (944 mg) were converted into **39Z** (188 mg, 58%) and **39E** (16 mg, 5%), **40Z** (305 mg, 72%) and **40E** (23 mg, 5%), and **41Z** (614 mg, 53%) and **41E** (46 mg, 4%). **39Z** as a colorless oil: TLC R_f 0.46 (AcOEt/hexane 1:4); $[\alpha]_D^{29}$ +34.5° (*c* 1.56, $CHCl_3$); IR ν_{max}^{neat} 3000, 2960, 2950, 2900, 2850, 1720, 1655, 1600 1500, 1470, 1460, 1420, 1400, 1310, 1200, 1160 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.30 (t, 3H, *J*=7.5 Hz), 3.11, 3.39 (each s, each 3H), 4.10—4.30 (m, 1H),

4.20 (q, 2H, J=7.5 Hz), 4.40—4.82 (m, 5H), 5.08 (d, 1H, J=7.5 Hz), 5.78—5.98 (m, 1H), 5.95 (dd, 1H, J=1 and 12 Hz), 6.50 (dd, 1H, J=7.5 and 12 Hz), 7.20—7.55 (m, 5H). Found: C, 62.18; H, 7.06%. Calcd for $C_{19}H_{26}O_7$: C, 62.28; H, 7.15%. **39E** as a colorless oil: TLC R_f 0.28 (AcOEt/hexane 1:4); $[\alpha]_D^{29}$ −17.6° (*c* 1.48, $CHCl_3$); IR ν_{max}^{neat} 3000, 2950, 2900, 2835, 1720, 1660, 1600, 1500, 1470, 1460, 1400, 1370, 1300, 1270, 1220, 1180, 1155, 1130 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.28 (t, 3H, J=7.5 Hz), 3.15, 3.40 (each s, each 3H), 4.17 (q, 2H, J=7.5 Hz), 4.10—4.82 (m, 6H), 4.82—5.05 (m, 1H), 5.00 (d, 1H, J=7.5 Hz), 6.11 (dd, 1H, J=1 and 16.5 Hz), 7.03 (dd, 1H, J=6 and 16.5 Hz), 7.30—7.57 (m, 5H). Found: C, 61.96; H, 7.02%. Calcd for $C_{19}H_{26}O_7$: C, 62.28; H, 7.15%. **40Z** as a colorless oil: TLC R_f 0.49 (AcOEt/hexane 1:3); $[\alpha]_D^{25}$ +6.8° (*c* 1.33, $CHCl_3$); IR ν_{max}^{neat} 2950, 2900, 1710, 1645, 1600, 1500, 1450, 1410, 1380, 1360, 1260, 1185, 1150 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.31 (t, 3H, J=7.5 Hz), 2.90, 3.39 (each s, each 3H), 4.20 (q, 2H, J=7.5 Hz), 4.30—4.82 (m, 6H), 5.05 (d, 1H, J=3 Hz), 5.82 (t, 1H, J=4.5 HZ), 5.98 (d, 1H, J=12 Hz), 6.66 (dd, 1H, J=4.5 and 12 Hz), 7.26—7.58 (m, 5H); MS *m/z* calcd for $C_{19}H_{26}O_7$ (M^+), 366.1676, observed, 366.1662. **40E** as a colorless oil: TLC R_f 0.30 (AcOEt/hexane 1:3); $[\alpha]_D^{25}$ −79.8° (*c* 1.42, $CHCl_3$); IR ν_{max}^{neat} 3000, 2950, 2900, 1720, 1660, 1600, 1500, 1450, 1370, 1300, 1270, 1250, 1215, 1150 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.32 (t, 3H, J=7.5 Hz), 2.90, 3.40 (each s, each 3H), 4.22 (q, 2H, J=7.5 Hz), 4.21—4.86 (m, 7H), 5.05 (d, 1H, J=3 Hz), 6.09 (d, 1H, J=15 Hz), 7.25 (dd, 1H, J=6 and 15 Hz), 7.32—7.56 (m, 5H); MS *m/z* calcd for $C_{19}H_{26}O_7$ (M^+) 366.1676, observed 366.1669. **41Z** as a colorless oil: TLC R_f 0.60 (AcOEt/hexane 1:2); $[\alpha]_D^{23}$ +161.8° (*c* 1.66, $CHCl_3$); IR ν_{max}^{neat} 2980, 2950, 2890, 1715, 1640, 1600, 1490, 1450, 1410, 1380, 1360, 1300, 1190, 1150 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ= 1.31 (t, 3H, J=7.5 Hz), 2.97, 3.40 (each s, each 3H), 4.22 (q, 2H, J=7.5 Hz), 4.18—4.73 (m, 6H), 5.40 (d, 1H, J=3.5 Hz), 5.80—6.00 (m, 1H), 5.95 (dd, 1H, J=1.5 and 12 Hz), 6.50 (dd, 1H, J=7.5 and 12 Hz), 7.27—7.58 (m, 5H); MS *m/z* calcd for $C_{19}H_{26}O_7$ (M^+) 366.1677, observed 366.1688. **41E** as a colorless oil: TLC R_f 0.51 (AcOEt/hexane 1:2); $[\alpha]_D^{23}$ +116.2° (*c* 1.79, $CHCl_3$); IR ν_{max}^{neat} 2980, 2950, 1720, 1660, 1600, 1500, 1455, 1370, 1300, 1260, 1215, 1180, 1150 cm^{-1}; ^1H NMR (90 MHz, $CDCl_3$) δ=1.30 (t, 3H, J=7.5 Hz), 2.95, 3.43 (each s, each 3H), 4.22 (q, 2H, J=7.5 Hz), 4.11—4.52 (m, 4H), 4.71 (d, 2H, J=3 Hz), 4.98—5.18 (m, 1H), 5.31 (d, 1H, J=3 Hz), 6.23 (dd, 1H, J=2.5 and 16.5 Hz), 7.11 (dd, 1H, J=5.5 and 16.5 Hz), 7.29—7.55 (m, 5H); MS *m/z* calcd for $C_{19}H_{26}O_7$,(M^+) 366.1677, observed 366.1667.

Demethoxymethylation of 38Z, 39Z, 40Z, and 41Z Accompanied by γ-Lactonization. (+)-Altholactone (1), (+)-7,8-Di-*epi*- (2), (+)-7-*epi*- (3), and (+)-8-*epi*-Altholactone (4). A solution of **38Z** (320 mg, 0.87 mmol) in a mixture of 1 M HCl (8 ml) and 1,4-dioxane (8 ml) was refluxed for 1 h and concentrated in vacuo. The residue was partitioned between AcOEt (100 ml) and saturated aqueous $NaHCO_3$ (30 ml). The organic phase was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash chromatography (AcOEt/hexane 1:2) to give **1** (195 mg, 96%) as needles, mp 113—114 °C: TLC R_f 0.40 (AcOEt/hexane 1:1); $[\alpha]_D^{33}$ +180.8° (*c* 0.52 EtOH); IR ν_{max}^{KBr} 3430, 3070, 3040, 2950, 2930, 2900, 1730, 1640, 1600, 1490, 1365, 1245, 1150, 1100, 1090 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ=2.66 (d, 1H, J=4.4 Hz), 4.45 (dd, 1H, J=2.4 and 5.9 Hz, after irradiation of the doublet at δ=2.66), 4.65 (1H, t, J=5.4 Hz), 4.74 (d, 1H, J=5.9 Hz), 4.95 (dd, 1H, J=2.4 and 5.4 Hz), 6.22 (d, 1H, J=10.2 Hz), 6.99 (dd, 1H, J=5.4 and 10.2 Hz), 7.29—7.36 (m, 5H) ^{13}C NMR (100 MHz, $CDCl_3$) δ=68.15 (d), 83.56 (d), 86.03 (d), 86.63 (d), 123.59 (d), 126.12 (d), 128.34 (d), 128.63 (d), 138.12 (s), 140.56 (d), 161.70 (s). Found: C, 67.24; H, 5.18%. Calcd for $C_{13}H_{12}O_4$: C, 67.23; H, 5.21%.

By the analogous procedure described for the preparation of **1**, **39Z** (164 mg), **40Z** (305 mg), and **41Z** (271 mg) were converted into **2** (81.5 mg, 78%), **3** (153 mg, 79%), and **4** (140 mg, 82%), respectively. **2** as a needles, mp 99—100 °C; TLC R_f 0.52 (AcOEt/hexane 1:1); $[\alpha]_D^{30}$ +74.1° (*c* 0.54, EtOH); IR ν_{max}^{KBr} 3430, 3080, 3050, 2945, 1730, 1645, 1610, 1500, 1460, 1400, 1255, 1170, 1130 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ=3.30 (d, 1H, J=6.4 Hz), 4.26 (dd, 1H, J=5.4 and 7.3 Hz, after irradiation of the doublet at δ=3.30), 4.78 (d, 1H, J=7.3 Hz), 4.88 (dd, 1H, J=4.4 and 5.9 Hz), 5.04 (dd, 1H, J=5.4 and 5.9 Hz), 6.20 (d, 1H, J=9.3 Hz), 6.87 (dd, 1H, J=4.4 and 9.3 Hz), 7.30—7.38 (m, 5H); ^{13}C NMR (100 MHz, $CDCl_3$) δ=67.73 (d), 78.32 (d), 78.51 (d), 83.30 (d), 122.95 (d), 125.69 (d), 128.27 (d), 128.62 (d), 138.47 (s), 141.77 (d), 161.23 (s). Found: C, 67.21; H, 5.20%. Calcd for $C_{13}H_{12}O_4$; C, 67.23; H, 5.21%. **3** as needles, mp 117—117.5 °C: TLC R_f 0.43 (AcOEt/hexane 1:1); $[\alpha]_D^{30}$ +23.0° (*c* 0.50, EtOH); IR ν_{max}^{KBr} 3380, 3050, 2940, 2880, 1710, 1635, 1600, 1480, 1400, 1345, 1280, 1245, 1200, 1155 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ=2.24 (d, 1H, J=5.9 Hz), 4.52 (t, 1H, J=4.4 Hz, after irradiation of the doublet at δ=2.24), 4.78 (ddd, 1H, J=1.0, 3.4, and 7.8 Hz), 5.06 (d, 1H, J=4.4 Hz), 5.22 (dd, 1H, J=4.4 and 7.8 Hz), 6.11 (dd, 1H, J=1.0 and 10.3 Hz), 6.85 (dd, 1H, J=3.4 and 10.3 Hz), 7.29—7.39 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) δ=67.23 (d), 73.70 (d), 79.69 (d), 80.72 (d), 121.56 (d), 126.90 (d), 128.32 (d), 128.44 (d), 135.28 (s), 141.70 (d), 161.21 (s). Found: C, 67.23; H, 5.40%. Calcd for $C_{13}H_{12}O_4$: C, 67.23; H, 5.21%. **4** as needles, mp 193.5—194 °C: TLC R_f 0.46 (AcOEt/hexane 1:1); $[\alpha]_D^{26}$ +224° (*c* 0.5, EtOH); IR ν_{max}^{KBr} 3440, 3060, 2940, 2920, 2860, 1700, 1635, 1600, 1490, 1450, 1385, 1355, 1325, 1260, 1255, 1195, 1160 cm^{-1}; ^1H NMR (400 MHz, $CDCl_3$) δ=1.66 (d, 1H, J=2.4 Hz), 4.50 (d, 1H, J=2.0 Hz, after irradiation of the doublet at δ 1.16), 4.88 (t 1H, J=4.9 Hz), 5.08 (dd, 1H, J=2.0 and 4.9 Hz), 5.35 (d, 1H, J=2.0 Hz), 6.20 (d, 1H, J=9.8 Hz), 7.00 (dd, 1H, J=4.9 and 9.8 Hz), 7.33—7.43 (m, 5H); ^{13}C NMR (100 MHz, $CDCl_3$) δ=68.13 (d), 77.89 (d), 83.54 (d), 84.25 (d), 123.08 (d), 126.62 (d), 128.62 (d), 128.89 (d), 134.72 (s), 140.59 (d), 161.01 (s). Found: C, 67.09; H, 5.43%. Calcd for $C_{13}H_{12}O_4$: C, 67.23; H, 5.21%.

We are grateful to Mr. Hisao Arita of Keio University for performing elemental analyses. Support for the biological assays was obtained from grant No. 30909 from the National Cancer Institute, and cytotoxicities were determined through the cooperation of the Cell Culture Laboratories, Purdue Cancer Research Center.

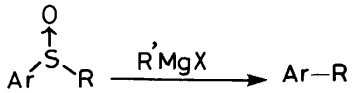
Synthesis and Reaction of 2,2′-Biquinolyl

Shoji WAKABAYASHI,* Yukihiro KUBO, Takashi TAKEDA, Jun-ichi UENISHI, and Shigeru OAE*
Department of Chemistry, Faculty of Science, Okayama University of Science, Ridai-cho, Okayama 700
(Received January 9, 1989)

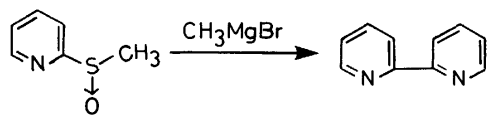
A title compound is readily prepared from methyl 2-quinolyl sulfoxide (**3**) with methylmagnesium bromide in excellent yield and an ipso addition of alkylmagnesium halides to 2,2′-biquinolyl (**4**) is also described.

Ligand coupling reaction of aryl sulfoxides with Grignard reagents has been developed by S. Oae and co-workers.[1] This reaction is interesting in not only mechanistic aspects[2] but also synthetic applicabilities for various types of benzyl-, allyl-, or aryl-substituted aromatic compounds.[3] Recently a formation of



Ar:Heteroaryl, Aryl
R :Benzyl, Allyl, Aryl
R':Alkyl

bi(heteroaryl) compounds has been reported in the reaction of alkyl pyridyl sulfoxides with alkyl Grignard reagents.[4] This homolytic coupling reaction was found by treating of methyl 2-pyridyl sulfoxide (**1**) with a primary alkyl Grignard reagent in ether or THF and resulted 2,2′-bipyridyl (**2**) in moderate yields.



1 2

In an extension of this study to obtain bi(heteroaryl) compounds, we would like to describe herein a facile preparation of 2,2′-biquinolyl (**4**) under very mild conditions and also the first example of an alkyl Grignard addition to **4**.

When methyl 2-quinolyl sulfoxide (**3**)[5] was treated with one equivalent of methylmagnesium bromide at room temperature in THF, the reaction completed instantaneously giving **4** exclusively in 90 to 98% yields. This reaction takes place even at lower temperatures. The reaction appears to complete in less than 20 s at −78 °C affording **4** in more than 90% yield. This remarkably high reaction rate is in contrast to that of the formation of **2**, which required about 10 hours to complete the reaction of **1** with methylmagnesium bromide at −78 °C. Approximately the formation of **4** is at least 10^3 faster than that of **2**. The compound **4** is currently used for a wide poupose of coating materials, chelating reagents and catalysts as a copper complex in the modern technological fields.[6]

Among the recent reports for the preparation of **4**, i.e., palladium-catalyzed coupling reaction,[7] nickel-catalyzed coupling reaction[8] or electrochemical reaction,[9] this preparative method offers several advantages such as the mildest reaction conditions, the shortest reaction time, the simple operation and also the high yield.

f, $CH_2=CHCH_2$-
g, $CH_2=CH(CH_3)CH$-

Another interesting aspect is that the reaction of the same substrate **3** with two equivalents of methylmagnesium bromide did not stop at the same stage of **4** but proceeded further. Eventualy 2-methyl-1,2-dihydro-2,2′-biquinolyl (**5a**) was isolated in 79% yield. This compound was identified by spectroscopic analysis. A mass spectrum has shown the molecular ion peak at 272 (*m/z*), which has lost a methyl group to give a base peak appearing at 257 (*m/z*). In a ^{1}H NMR spectrum a singlet peak at δ 1.83 for 3 protons indicates quaternary methyl group and a broad singlet of secondary amine proton appears at δ 5.01. A ^{13}C NMR spectrum has also supported this structure. Thus the spectrum shows the C-2 substituted methyl carbon at δ 30.84 and C-2 methine carbon at δ 59.15. These carbons appear as a quartet and a singlet

Table 1. Reaction of **3** with Grignard Reagents

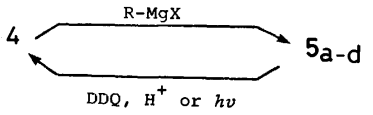
Grignard reagent	(equiv)	Products (yield/%)
CH_3MgBr	1.1	**4** (98)
	2.1	**5a** (79)
CH_3CH_2MgBr	2.1	**5b** (61)
$(CH_3)_2CHCH_2MgCl$	2.1	**5c** (77)
$(CH_3)_2CHMgCl$	2.1	**5d** (26)[a]
PhMgBr	2.1	**6e** (20) **4** (50)
$CH_2=CHCH_2MgCl$	2.1	**6f** (80)
$CH_2=CH(CH_3)CHMgCl$	2.1	**6g** (74)

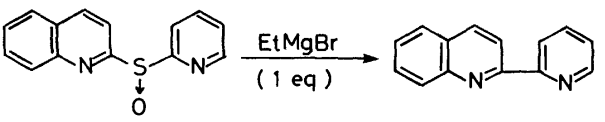
a) The major product was isopropyl 2-quinolyl sulfoxide in 61% yield.

respectively by a off-resonance experiment. In a IR spectrum an absorption of the secondary amine is observed at 3390 cm^{-1}.

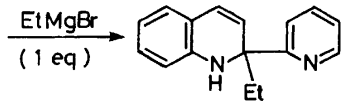
Table 1 lists the results in the reactions with several Grignard reagents. Ethyl-, isobutyl-, and isopropylmagnesium halides provided the corresponding C-2 alkyl-substituted products **5b**, **5c**, and **5d** in 61%, 77%, and 26% yields, respectively. In the case of isopropylmagnesium chloride the ligand-exchange product, isopropyl 2-quinolyl sulfoxide was obtained in 61% yield along with the desired product. The reaction of phenylmagnesium bromide gave none of **5e** but **4** as a major product and 2-phenylquinoline (**6e**)[10] as a minor product. Normal ligand-coupling reaction is predominant in the reaction of allyl- and (1-methyl-2-propenyl)magnesium chloride affording 2-allyl- and 2-(1-methyl-2-propenyl)quinolines **6f** and **6g**[11] along with unseparable isomeric α,β-unsaturated compounds in 80% and 74% yields.

The compound **5** have been confirmed to be formed from 2,2′-biquinolyl intermediate. In fact the reaction of **4** with one equivalent of alkylmagnesium halides such as methyl-, ethyl-, isobutyl-, and isopropylmagnesium halides, afforded exclusively the corresponding C-2 alkyl-substituted products, **5a**, **5b**, **5c**, and **5d** in 59%, 68%, 90%, and 39% yields, respectively. However the reaction with phenylmagnesium bromide and allylmagnesium chloride have shown to be totally unreacted. The products **5a—d** are considerably stable in frozen benzene at −20 °C for a month but are oxidized spontaneously at room temperature to **4** within a couple of days. Particularly, in the case of **5d** the transformation to **4** takes within a half day in $CDCl_3$ which is much faster than the others. Meanwhile, oxidation of **5a** with DDQ in benzene afforded **4** instantaneously at 0 °C. The half life time of **5a** in acidic ethanol containing 5% of *dl*-10-camphorsulfonic acid was 4 hours and that under the sunlight or ultraviolet irradiation was about a half hour in the same solvent. But no transformation was observed in a day in basic ethanol containing 5% of triethylamine.





7 8



9

Investigations of this addition[12] were carried out in other substrates. None of the corresponding C-2 alkyl-substituted pyridine and/or 1,2-dihydro-2,2′-bipyridyl has been detected in the reaction of **1** with methyl- or ethylmagnesium bromide even when the Grignard reagent has been used in a large excess. Meanwhile treatment of one equivalent of ethylmagnesium bromide with 2-pyridyl 2-quinolyl sulfoxide (**7**) has been found to give ligand-coupling product, 2-(2-pyridyl)quinoline (**8**) in 54% yield as a sole product, which upon treatment with another equivalent of ethylmagnesium bromide gave successively 2-ethyl-2-(2-pyridyl)-1,2-dihydroquinoline (**9**) in 35% yield. In the addition of ethylmagnesium bromide to 2-substituted quinolines **6e** or **6f**, only the starting materials were recovered quantitatively. All these observations reveal clearly that this Grignard addition is a substrate specific reaction to 2-(2-pyridyl and/or 2-quinolyl)-quinolines. The produced compound **9** as well as **5a—d** are structurally unique and are fairly stable at low temperature under inert atmosphere, but oxidized easily in certain conditions to give back to **8** and/or **4** quantitatively.

Experimental

Melting points were taken on Yanaco melting point apparatus and were uncorrected. Spectra were measured with the following instruments; ^1H and ^{13}C NMR: JEOL-GX400 (400 MHz and 100 MHz), low- and high-resolution MS: JEOL-JMS-303HF and IR: JASCO IRA-1. NMR spectra were obtained in $CDCl_3$ with tetramethylsilane as an internal standard. Mass spectra were obtained with a direct

inlet method at 70 eV by the Analytical Center of Okayama University of Science. Only strong and/or structurally important peaks are reported here for MS and IR. All reactions were carried out under Argon atmosphere. Solvents (THF and ether) for the reactions were freshly distilled over sodium benzophenone ketyl before the use. Methyl- and ethylmagnesium bromide were purchased from the Kanto Chemical Co. Other Grignard reagents were freshly prepared in dry ether or THF by the procedure in literatures.[13] Thin-layer chromatography (TLC) was carried out on 0.25 mm E. Merck precoated silica-gel plates (60F-254) and for silica-gel column chromatography Wako gel (C-200) was used.

Reactions of 3 with Grignard Reagents. To a stirred THF (3 ml) solution of **3** (1 mmol) was added Grignard reagent (1.1 mmol or 2.1 mmol) in THF or ether solution dropwise at room temperature. After 30 min reaction mixture was quenched with a saturated ammonium chloride solution (3 ml) and extracted with ether (50 ml). The ethereal layer was washed with water (2 ml) and brine (2 ml) and dried over $MgSO_4$. The solvent was removed and the residue was purified by column chromatography on silica gel.

6g:[11] Colorless oil, R_f=0.38 (10% ether in hexane); ^{1}H NMR δ=1.54 (3H, d, J=7.2 Hz), 3.85 (1H, m), 5.14 (1H, ddd, J=10.3, 1.6, 1.3 Hz), 5.19 (1H, ddd, J=17.4, 1.6, 1.3 Hz), 6.18 (1H, ddd, J=17.4, 10.3, 6.5 Hz), 7.32 (1H, d, J=8.5 Hz), 7.49 (1H, td, J=7.8, 1.0 Hz), 7.69 (1H, td, J=7.7, 1.8 Hz), 7.78 (1H, dd, J=7.9, 1.1 Hz), 8.07 (1H, d, J=8.0 Hz), 8.08 (1H, d, J=8.0 Hz).

2-Pyridyl 2-Quinolyl Sulfoxide (7). To a mixture of 2-chloroquinoline (2.945 g, 18 mmol) and 2-pyridinethiol (2.0 g, 18 mmol) in hexamethylphosphoric triamide (HMPA, 20 ml) was added pieced of sodium metal (414 mg, 18 mmol) by several portions and the mixture was heated at 80 °C with stirring. After 2 days it was quenched with water (20 ml) and extracted with ether (200 ml). The ethereal layer was washed with water (3 ml×5) and brine (3 ml) and dried over $MgSO_4$. The solvent was removed and the crude sulfide, R_f=0.23 (20% ether in hexane), was used for the next reaction without any purification. To a chloroform solution (15 ml) of the crude sulfide was added carefully m-chloroperbenzoic acid portionwise at room temperature and the reaction was monitored by TLC to check the starting material consumed. It was diluted with chloroform (100 ml) and washed with aq. sodium thiosulfate (6 ml×2), aq. sodium hydrogencarbonate (6 ml×2), water (6 ml), and brine (6 ml) and dried over $MgSO_4$. After removal of the solvent under reduced pressure the residue was purified by column chromatography on silica gel eluted with 60% ethyl acetate in hexane to give **7** (1.5 g) in 35% yield. Mp 86—87 °C (from benzene); ^{1}H NMR δ=7.30 (1H, m), 7.59 (1H, td, J=8.3, 1.6 Hz), 7.76 (1H, td, J=7.9, 0.7 Hz), 7.83 (1H, d, J=8.5 Hz), 7.86 (1H, td, J=7.7, 1.4 Hz), 8.04 (1H, dd, J=8.6, 1.1 Hz), 8.11 (1H, d, J=8.1 Hz), 8.21 (1H,

d, J=8.8 Hz), 8.30 (1H, d, J=8.8 Hz), 8.58 (1H, d, J=5.3 Hz); ^{13}C NMR δ=115.53 (d), 119.52 (d), 124.96 (d), 127.85 (d), 128.04 (d), 128.43 (s), 129.78 (d), 130.59 (d), 137.98 (d), 138.45 (d), 147.57 (s), 150.06 (d), 163.68 (s), 163.87 (s); IR ($CHCl_3$) 1060, 1580, 1590, 2960 cm^{-1}. Found: C, 66.18; H, 3.80; N, 11.00; S, 12.59%. Calcd for $C_{14}H_{10}N_2OS$: C, 66.12; H, 3.96; N, 11.02; S, 12.61%.

2-(2-Pyridyl)quinoline (8).[14] Methylmagnesium bromide (0.8 ml, 0.5 M solution in THF; 1 M=1 mol dm^{-3}) was dropped into **7** (94 mg, 0.36 mmol) in THF (4 ml) at room temperature. The mixture was stirred for 15 min at the same temperature. Then it was quenched with a saturated ammonium chloride solution (8 ml) and extracted with chloroform (40 ml). The organic layer was washed with water (2 ml×2) and brine (2 ml) and dried over $MgSO_4$. The solvent was removed and the residual oil was chromatographed on silica gel eluted with 25% ether in hexane to afford **8** (40 mg) in 54% yield. Mp 98 °C (from ethanol); R_f=0.20 (30% ether in hexane); ^{1}H NMR δ=7.36 (1H, td, J=6.4, 1.4 Hz), 7.56 (1H, td, J=7.1, 1.5 Hz), 7.74 (1H, dt, J=7.9, 1.5 Hz), 7.85 (1H, d, J=8.5 Hz), 7.88 (1H, td, J=7.3, 1.9 Hz), 8.19 (1H, d, J=8.7 Hz), 8.29 (1H, d, J=8.2 Hz), 8.56 (1H, d, J=8.2 Hz), 8.66 (1H, dd, J=8.1, 1.1 Hz), 8.75 (1H, ddd, J=4.7, 1.9, 1.1 Hz).

2-Ethyl-2-(2-pyridyl)-1,2-dihydroquinoline (9). To a stirred THF solution (3 ml) of **8** (58 mg, 0.28 mmol) was dropped ethylmagnesium bromide (0.34 ml, 1 M solution in THF) at room temperature. After 3 min it was quenched with a saturated ammonium chloride solution (3 ml) and extracted with chloroform (20 ml). The organic layer was washed with water (5 ml) and brine (5 ml) and dried over $MgSO_4$. The solvent was removed under reduced pressure and the residue was purified by silica-gel column chromatography eluted with 15% ether in hexane to give **9** as colorless oil (23 mg) in 35% yield. R_f=0.32 (30% ether in hexane); ^{1}H NMR δ=0.91 (3H, t, J=7.3 Hz), 1.98 (2H, qd, J=7.3, 0.7 Hz), 4.77 (1H, bs), 5.82 (1H, dd, J=9.9, 1.4 Hz), 6.50 (1H, d, J=9.9 Hz), 6.53 (1H, d, J=8.4 Hz), 6.55 (1H, td, J=7.3, 1.1 Hz), 6.87 (1H, dd, J=7.3, 1.1 Hz), 6.97 (1H, td, J=7.7, 1.5 Hz), 7.09 (1H, ddd, J=7.3, 4.8, 1.1 Hz), 7.42 (1H, ddd, J=7.0, 1.1, 0.7 Hz), 7.61 (1H, td, J=7.8, 1.8 Hz), 8.56 (1H, ddd, J=4.8, 1.8, 1.1 Hz); ^{13}C NMR δ=8.56 (q), 35.99 (t), 61.70 (s), 112.82 (d), 117.06 (d), 119.54 (s), 120.61 (d), 121.44 (d), 126.10 (d), 126.36 (d), 126.81 (d), 128.86 (d), 136.46 (d), 143.44 (s), 149.01 (d), 165.83 (s); MS m/z (rel intensity, %) 236 (M^+, 45), 208 (base), 158 (70), 143 (30), 128 (33), 104 (40), 77 (20); IR ($CHCl_3$) 1450, 1580, 1630, 2950, 3400 cm^{-1}. (Received February 20, 1989)

The anti/syn stereoselectivity in the metal hydride reductions of a series of substituted 3,4-dihydro-1,4-ethanonaphthalen-2(1*H*)-ones was studied. The observed steroselectivity sequence was found to be parallel with the homoconjugation sequence except for the case of 5,8-dimethoxy-substituted derivative: the portion of anti attack increases as the benzene ring becomes electron-rich. The results were rationalized by Cieplak's transition state model or by the nonclassical carboncation model. A special coordinated transition state was considered to explain the results for 5,8-dimethoxy-substituted compound.

Because of the homoconjugation interaction between the carbonyl group and the endocyclic double bond, bicyclo[2.2.2]oct-5-en-2-one has attracted considerable attention. This interaction has been investigated in terms of ^{13}C NMR,[1] PES,[2] and CD[3] studies. The homoconjugation interaction may also be revealed by chemical reactions especially by the stereoselectivity in nucleophilic additions. Hitherto, several experimental data in the nucleophilic additions toward this substrate have been reported. Metal hydrides such as sodium borohydride[4] or lithium aluminum hydride[5] are known to attack the carbonyl group predominantly from the anti side of the double bond, whereas Grignard reagents such as alkyl- or vinylmagnesium halides[6,7] mainly attack from the syn side. The origin of the stereoselectivity has not been considered in most cases. However, Snowden and co-workers speculated a steric factor in the Grignard reactions.[6] Brown and Muzzio considered a steric effect between attacking hydride and the π-electrons of C_5–C_6 double bond.[4] We have recently reported the anti/syn stereoselectivity of metal hydride reductions of a series of substituted 1,2,3,4-tetrahydro-1,4-methanonaphthalen-9-ones and have found that the electron-donating substituents on the benzene ring increase the portion of anti attack.[8] In order to know whether this substituent effect in bicyclic systems is general or not, we have extended our study to bicyclo[2.2.2]oct-5-en-2-one. In this paper, the metal hydride reductions of a series of substituted 3,4-dihydro-1,4-ethanonaphthalen-2(1*H*)-ones (**1a—e**) are investigated.

Results and Discussion

Stereochemistry of Anti- (2a—e) and Syn-Alcohols (3a—e). The reduction of substituted 3,4-dihydro-1,4-ethanonaphthalen-2(1*H*)-ones (**1a—e**) with various metal hydrides gave the corresponding anti- (**2a—e**) and syn-alcohols (**3a—e**) in high yields (>78%). The produced alcohols can be separated by preparative TLC or gas chromatography. In Table 1, the ^1H NMR data of the alcohols are listed. Among the methylene protons, the H_3-anti proton appears in the range of δ 2.2—2.4 as a d-d-d like multiplet for the anti-alcohols (**2a—e**) or a d-d-d pattern (typically, J=14, 9, and 3 Hz) for the syn-alcohols (**3a—e**). The H_3-syn proton and other four methylene protons appear in the higher field (δ 1.0—2.2) as multiplets. By addition of a NMR shift reagent, Eu(fod)$_3$, the H_3-syn proton of the syn-alcohols (**3a—e**) becomes separable as a multiplet having a geminal coupling of J=ca. 14 Hz from other methylene protons. The lower chemical shift of the H_3-syn proton compared with that of the H_3-anti proton is probably due to the anisotropic effect of the benzene ring.

Table 1 also summarizes the relative shift values (1.00 for H_1 proton in both alcohols) induced by Eu(fod)$_3$ for the H_3 and other protons. It is clear from the table that the H_3-anti proton of the anti-alcohols has a larger relative shift (1.0—1.2) than that of the syn-alcohols (0.5—0.6). The relative shifts for other protons are reasonable except for the large induced shifts of the aromatic and methoxyl protons of **2e** and **3e**, the large shifts being ascribed to the partial coordination of Eu(fod)$_3$ onto the methoxyl groups. However,this coordination would not much affect the shift of H_3-anti proton because of the relatively long distance between the H_3-anti proton and the coordinated metal center. The assigned stereochemistry is

a) All reactions were performed at 0 °C. b) Lithium tri-*t*-butoxyaluminum hydride. c) Bis(1,2-dimethylpropyl)borane (disiamylborane).

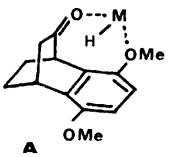
also in good accordance with the fact that the H_2-methine proton of the anti-alcohols has a lower chemical shift (δ ca. 3.9) than that (δ 4.1—4.2) of the syn-alcohols owing to the expectable anisotropy effect of the benzene ring. In our previous study,[8] we have observed that the syn-alcohols derived from a series of the related methanonaphthalen-9-ones have shorter GC retention time (OV-17) than the corresponding anti-alcohols. The GC retention time for these isomeric alcohols probably relates to their vapor pressure at the GC conditions. The higher vapor pressure of the syn alcohols can be expected from the possible intramolecular hydrogen bond between the hydroxyl group and the benzene π-bond. In the present system (**2a**—**e** and **3a**—**e**), the stereochemical assignment by this qualitative GC method resulted in a complete agreement with that from the NMR shift reagent study.

Stereoselective Metal Hydride Reductions of 1a—e. Table 2 shows the ratios of anti/syn-alcohols in the reductions using typical metal hydrides. Although some of these values differ only slightly and are nearly equal within the experimental error (±2%), there is apparently an overall trend that the portion of syn-alcohol (anti attack) increases in the sequence of **1a**⇄**b**→**d**⇄**c**→**e** in most cases despite of considerably different sizes and reactivities of the reagents. In particular, the reductions with sodium borohydride, diisobutylaluminum hydride, and bis(1,2-dimethylpropyl)borane (common name "disiamylborane" is used hereafter) follow this sequence. A small change in the sequence is observed with lithium aluminum hydride and diborane reductions. The anti/syn selectivity varies most widely in the reduction with disiamylborane. In this case, the main product is switched from the anti- to the syn-alcohol when the benzene ring becomes electron rich (**2a**/**3a**=73/27→**2e**/**3e**=27/73). Similar trends are observed for the reduction with diisobutylaluminum hydride, sodium borohydride, and diborane. With a very bulky

hydride, tri-*t*-butoxyaluminum hydride, the anti/syn ratio is almost constant (ca. 1:1) for **1a—e**; this result suggests that the electronic perturbation of the substituents is minimized for this bulky reagent and probably also suggests that the steric congestion in both the anti and syn sides would not be much different for **1a—e**.

Several comments on the results of Table 2 can be given. The selectivity is considerably dependent on the reagents for the each substrate; the anti/syn ratio varies from 40/60 (LAH in ether) to 84/16 (diborane in THF) for reduction of **1a**, from 35/65 (LAH in THF) to 90/10 (diborane in THF) for **1b**, from 13/87—15/85 (LAH in THF) to 54/46—65/35 (lithium tri-*t*-butoxyaluminum hydride in ether or diborane in THF) for **1c—e**. Among the reducing reagents used, the reductions with lithium aluminum hydride give the highest portion of anti attack for all the substrates. On the other hand, the reductions with borane reagents tend to produce the high portion of syn attack for **1a,b**. Although the reason for these selectivity change is not clear at present, it may relate with several factors such as the structure of reactive species,[9] the mode and degree of solvation,[9] Lewis acidity of the reagents,[10] and the ability of reagents for electron transfer.[11]

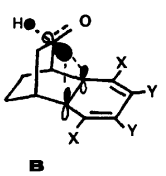
Obviously, the observed sequence of **1a≒b→d≒c→e** cannot be rationalized by steric effect of the substituents on the benzene ring. On the contrary, this sequence seems to be explicable by the electron-donating ability of the substituents on the benzene ring with the exception of **1d**. The electronic perturbation of the substituents to the reactive center would increase in the sequence of **1a→b→c→d→e**, in which methoxyl groups at C_6 and C_7 positions would have a larger electronic effect than those at C_5 and C_8 positions from the consideration of molecular orbitals of the benzo moieties. We have previously shown that the IR carbonyl stretching frequencies of a series of the related methanonaphthalenones are lined parallel with the electron donating ability of the benzene rings as well as the homoconjugation interaction.[8] The observed frequencies of the starting ketones (**1a—e**) follow the expected sequence [IR, ν_{CO} (cm^{-1}) in CCl_4; 1736 for **1a**, 1733 ($CDCl_3$) for **1b**, 1733 for **1c**, 1728 for **1d**, 1725 for **1e**]. Presumably, the deviation for **1d** in the sequence of stereoselectivity is due to the special coordination of the metal hydrides on the neighboring methoxyl group in the transition state as shown in structure **A** which would increase the portion of syn attack. As recognized from inspection of the molecular model, this type of coordination is much weak for **1e** and for the corresponding 1,2,3,4-tetrahydro-1,4-methano naphthalen-9-one derivatives in which such an anomalous effect was not observed in the metal hydride reductions,[8] because of the long distance between n-orbital of the carbonyl oxygen and the lone-pair electrons of the methoxyl group and because of the poor overlapping direction of these orbitals, respectively. Considering the above coordination factor for **1d**, we conclude that the variation of anti/syn stereoselectivity in the metal hydride reductions of **1a—e** is electronic in origin.



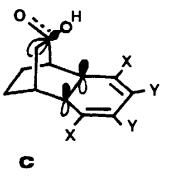
A

Several electronic factors in nucleophilic additions to cyclic ketones have been previously reported.[12,13] Among them, as we have pointed out in our previous report,[8] a qualitative transition state model developed by Cieplak seems to be attractive. Cieplak assumed that a newly formed bond between nucleophiles and carbonyl carbons is weak and intrinsically electron deficient in the transition state and therefore characterized as a low-lying antibonding σ^*-orbital.[10] In his model, the transition state can be stabilized by the interaction between the σ^*-orbital and electron-donating orbitals neighboring the carbonyl group, so that the favorable transition state is such that the nucleophiles approach to the carbonyl carbon from the anti side of donor orbital. More recently, le Noble and co-workers have reportd that the model developed by Cieplak reasonably explains the stereoselectivity in the reduction of a series of 5-substituted adamantanones.[14]

Application of Cieplak's model to our system gives satisfactory explanation. We show qualitative sketches of the transition states for the anti attack (**B**) and the syn attack (**C**). In the transition state **B**, the elec-

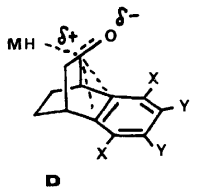


B



C

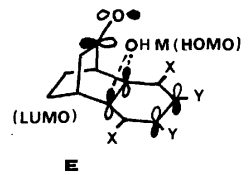
tron-deficient σ^*-orbital can be much stabilized by the bonding interaction with π-orbital of the benzene ring with a larger overlap of back side lobe of the σ^*-orbital. Electron donating substituents on the benzene ring would increase the stabilization gain in the transition state **B** and hence the anti attack. However, a similar explanation is afforded by the consideration of contribution of the nonclassical carbocation. As Cieplak pointed out, the incipient C-H bond is electron-deficient in nature, some positive charge remains on the carbonyl carbon with the greater extent than the ground state. When the benzene ring becomes electron-rich, the transition state for the anti attack would be stabilized as shown in **D**. Both the explanations are related to the stabilization



D

gain obtained by the HOMO-LUMO interaction between the benzene π-orbital and the p-orbital of the carbonyl carbon in the transition state. The interaction in the transition state must be parallel with that in the ground state (homoconjugation interaction).

Apart from the above explanations, it may be interesting to consider the role of secondary orbital interaction in the metal hydride reductions. As shown in **E**, incoming hydride would experience the antibonding repulsive secondary orbital interaction with



E

the benzene π-orbital. Although kinetic treatment was not investigated in this paper, this interaction predicts that the lower reactivity in the syn side should be observed as the benzene ring becomes electron-rich. In this context, Brown and Muzzio reported the rate study of sodium borohydride reduction of bicyclo[2.2.2]oct-5-en-2-one and its saturated analogue.[4] According to their study, the predominant anti attack is mainly due to the enhanced rate in the anti side. From this result, the antibonding secondary orbital interaction is not likely to be an origin of the stereoselectivity.

In summary, we have observed that the anti/syn stereoselectivity of a series of substituted 3,4-dihydro-1,4-ethano-naphthalen-2(1*H*)-ones is parallel with the homoconjugation interaction except for **1d**: the portion of anti attack increases as the benzene ring becomes electron-rich. A special coordinated transition state was considered to rationalize the results for **1d**. It should be noted that the variation of anti/syn stereoselectivity in the present system is considerably small when compared to the corresponding 1,2,3,4-tetrahydro-1,4-methanonaphthalen-9-one derivatives.[8] The reason would be simply due to the weaker interaction between the benzene π-orbital and the reactive center in **1a—e** in the transition state.

Experimental

General. Melting points were measured on a Mettler FP2 apparatus and are uncorrected. IR spectra were recorded with a Hitachi EPI-G3 grating spectrophotometer and wavenumbers were corrected with use of polystyrene film. The wavenumbers of the carbonyl stretching for **1a—e** were directly read from the spectrophotometer at their maximum absorptions. ^{1}H NMR spectra were obtained at 90 MHz on a JEOL FX-90Q or 100 MHz on a Varian XL-100. ^{13}C NMR spectra were taken with a JEOL FX-90Q (22.5 MHz). Mass spectra were measured on a JEOL JMS-01SG-2 mass spectrometer. GLC analysis were performed on a Hitachi 063 gas chromatography with a glass column packed with Silicone OV-17 (3%) on Chromosorb W AW DMCS (1 m). Column chromatography was carried out with Merck Kieselgel 60 and preparative TLC with Merck Kieselgel GF_{254} (Type 60). Lithium aluminum hydroide, sodium borohydride, lithium tri-*t*-butoxyaluminum hydride, and diisobutylaluminum hydride were commercial products. Diborane and disiamyborane were generated in situ prior to use.[15] Compounds **1a—d** were prepared according to the reported methods.[16] All the solvents were distilled before use.

Synthesis of 3,4-Dihydro-6,7-dimethoxy-1,4-ethanonaphthalen-2(1*H*)-one (1e). To a stirred solution of 280 mg (1.28 mmol) of 1,2,3,4-tetrahydro-6,7-dimethoxy-1,4-methanonaphthalen-9-one[8] in dichloromethane (6 cm^3) cooled at 0 °C under nitrogen, was sucessively added over 1 min boron trifluoride etherate (0.02 cm^3) and ethyl diazoacetate (217 mg, 1.90 mmol). After 4 h stirring at room temperature, the reaction mixture was treated with saturated aqueous sodium hydrogencarbonate (5 cm^3) and dichloromethane (20 cm^3). The separated organic layer was washed with brine (5 cm^3) and dried over magnesium sulfate. Purification with preparative TLC (hexane:ethyl acetate=3:1 (v/v)) gave 221 mg (57%) of a mixture of the syn and anti isomer (ca. 1:1 ratio) of the α-keto ester. The solution of 221 mg (0.727 mmol) of the α-keto ester in a mixture of dioxane (6 cm^3) and hydrochloric acid (2 mol dm^{-3}, 6 cm^3) was refluxed for 2 h. After cooling to room temperature, water (20 cm^3) was added and the mixture was extracted with ethyl acetate (20 cm^3) twice. The organic layer was dried over magnesium sulfate and evaporated under reduced pressure. The resulting crude α-keto carboxylic acid was dissolved in 4 cm^3 of *o*-dichlorobenzene and the solution was refluxed for 1 h under nitrogen atmosphere. The solvent was evaporated under reduced pressure. Purification with preparative TLC (hexane:ethyl acetate=3:1 (v/v)) gave 93 mg (53%) of **1e**: colorless prisms from hexane; mp 100—101 °C; IR (CCl_4) 2925, 2850, 1725, 1504, 1466, 1348, 1290, 1260, 1233, 1011 cm^{-1}; ^{1}H NMR (100 MHz, $CDCl_3$) δ=1.50—2.50 (m, 6H), 3.35 (m, 1H), 3.52 (m, 1H), 3.84 (s, 3H), 3.86 (s, 3H), 6.75 (s, 1H), 6.80 (s, 1H); ^{13}C NMR ($CDCl_3$) δ=23.55, 25.34, 36.25, 42.13, 52.02, 56.11, 108.22, 109.55, 128.29, 135.23, 148.01, 148.37, 211.51; MS (75 eV) *m/z* (%) 232 (M^+; 100), 204 (30), 190 (55), 189 (57). Found: C, 72.35; H, 7.01%. Calcd for $C_{14}H_{16}O_3$: C, 72.39; H, 6.94%.

Prototypical Procedure for Reductions with Lithium Aluminum Hydride. To a suspension of 20 mg (0.53 mmol) of lithium aluminum hydride in 5 cm^3 of dry ether under nitrogen at 0 °C was added dropwise over 2 min a solution of 100 mg (0.410 mmol) of **1a** in 5 cm^3 of dry ether. After 30 min, the reaction was quenched by addition of 0.08 cm^3 of water. The ether layer was dried over magnesium sulfate. Separation with preparative TLC (hexane:ethyl acetate=5:1 (v/v)) gave 38 mg of **2a** and 56 mg of **3a** in overall yield of 93% (**2a**:**3a**=40:60). The yields and product ratios for other derivatives were as follows, in ether: 93% (**2b**:**3b**=36:64) for **1b**, 81% (27:73) for **1c**, 90% (38:62) for **1d**,

and 99% (30:70) for **1e**, in THF: 79% (43:57) for **1a**, 87% (35:65) for **1b**, 85% (14:86) for **1c**, 95% (13:87) for **1d**, 85% (15:85) for **1e**. **2a**: colorless needles from hexane; mp 81—82 °C, IR (KBr) 3270, 2955, 1507, 1401, 1343, 1062, 1048, 1022, 1012, 1003, 952, 870, 819 cm^{-1}; ^1H NMR (100 MHz, $CDCl_3$) δ=1.05—2.15 (m, 6H), ca. 2.40 (m, 1H), 3.44 (m, 2H), 3.93 (m, 1H). Found: C, 58.43; H, 4.03%. Calcd for $C_{12}H_{10}OF_4$: C, 58.54; H, 4.09%. **3a**: colorless needles from hexane; mp 96—99 °C, IR (KBr) 3250, 1950, 1502, 1408, 1351, 1118, 1078, 1043, 1028, 935, 862, 832 cm^{-1}; ^1H NMR (100 MHz, $CDCl_3$) δ=1.05—1.90 (m, 6H), 2.25 (ddd, 1H, J=14.0, 9.0, and 3.0 Hz), 3.50 (m, 2H), 4.21 (m, 1H). Found: C, 58.72; H, 3.99%. Calcd for $C_{12}H_{10}F_4$: C, 58.58; H, 4.09%. **2b**: colorless needles from benzene-hexane; mp 138—141 °C, IR (KBr) 3300, 2950, 1394, 1380, 1340, 1279, 1224, 1172, 1078, 1050, 1010 cm^{-1}; ^1H NMR (100 MHz, $CDCl_3$) δ=1.05—2.15 (m, 6H), ca. 2.40 (m, 1H), 3.64 (m, 2H), 3.93 (m, 1H). Prototypical Procedure for Reduction with Diisobutylaluminum Hydride. To a solution of 100 mg (0.410 mmol) of **1a** in 10 cm^3 dry ether under nitrogen at 0 °C was dropwise a hexane solution (1.32 cm^3) of diisobutylaluminum hydride (2.30 mmol). After being stirred for 30 min at 0 °C, the mixture was treated with 2 cm^3 of ethanol, 8 cm^3 of aqueous hydrochloric acid (2 mol dm^{-3}), and 10 cm^3 of ether. The separated ether layer was washed with brine and dried over magnesium sulfate. The products were separated with preparative TLC (hexane:ethyl acetate=5:1 (v/v)) to give 50 mg of **2a** and 43 mg of **3a** in overall yield of 92% (**2a**:**3a**=54:46). The yields and the ratios of anti- and syn-alcohols were as follows; 93% (**2b**:**3b**=53:47) for **1b**, 93% (28:72) for **1c**, 89% (29:71) for **1d**, 89% (21:79) for **1e**.

Prototypical Procedure for Reductions with Lithium Tri-*t*-butoxyaluminum Hydride. To a suspension of 420 mg (1.65 mmol) of lithium tri-*t*-butoxyaluminum hydride in 5 cm^3 of dry ether under nitrogen at 0 °C was added a solution of 100 mg (0.410 mmol) of **1a** in dry ether (5 cm^3). After stirring overnight at 0 °C, the mixture was treated with 3 cm^3 of ethanol, 8 cm^3 of aqueous hydrochloric acid (2 mol dm^{-3}), and 10 cm^3 of ether. The separated ether layer was washed with brine, dried over magnesium sulfate. The products were purified with preparative TLC to give 47 mg of **2a** and 42 mg of **3a** in overall yield of 88% (**2a**:**3a**=53:47). The yields and rations of anti- and syn-alcohols were as follows, 91% (**2b**:**3b**=52:48) for **1b**, 94% (54:46) for **1c**, 98% (55:45) for **1d**, 93% (59:41) for **1e**.

Prototypical Procedure for Reductions with Diborane. To a suspension of 31 mg (0.82 mmol) of sodium borohydride in dry THF(10 cm^3) under nitrogen at 15—18 °C was added dropwise 0.13 cm^3 (1.0 mmol) of boron trifluoride etherate. After 30 min stirring, a solution of 100 mg (0.410 mmol) of **1a** in 5 cm^3 dry THF was added to the mixture and stirred for 30 min at 0 °C. The mixture was treated with 3 cm^3 of ethanol and 8 cm^3 of aqueous hydrochloric acid (2 mol dm^{-3}), and extracted with 15 cm^3 of ether twice. The ether layer was washed with brine and dried over magnesium sulfate. Separation with preparative TLC gave 62 mg of **2a** and 12 mg of **3a** in overall yield of 73% (**2a**:**3a**=84:16). The yields and ratios of anti- and syn-alcohols were as follows; 94% (**2b**:**3b**=90:10) for **1b**, 80% (52:48) for **1c**, 84% (65:35) for **1d**, 83% (45:55) for **1e**.

Prototypical Procedure for Reductions with Disiamylborane. To a suspension of 31 mg (0.82 mmol) of sodium borohydride and 0.21 cm^3 (2.0 mmol) of 2-methyl-2-butene in 10 cm^3 of dry diglyme under nitrogen at 0 °C was added 0.13 cm^3 (1.0 mmol) of boron trifluoride etherate. The mixture was stirred for 30 min at 0 °C. To this suspension was added over 2 min a solution of 100 mg (0.410 mmol) of **1a** in diglyme (5 cm^3) at 0 °C. After being stirred for 3 h, aqueous sodium hydroxide (3 mol dm^{-3}, 10 cm^3) and 30% aqueous hydrogen peroxide (8 cm^3) was added and the mixture was stirred overnight at room temperature. The mixture was treated with ice-water and extracted with 40 cm^3 of eter twice. The ether layer was washed with brine and dried over magnesium sulfate. Separation with preparative TLC gave 59 mg of **2a** and 22 mg of **3a** in overall yield of 80% (**2a**:**3a**=73:27). The yields and ratios of anti- and syn-alcohols were as follows; 78% (**2b**:**2b**=69:31) with 7% recovery of **1b**, 95% (37:63) for **1c**, 81% (40:60)for **1d**, 86% (27:73) for **1e**.

NMR Shift Reagent Study. The alcohols (**2a—e**, **3a—e**) were each dissolved in $CDCl_3$ (25—30 mg/ ca. 0.3 cm^3) in a NMR tube. The shift reagent, Eu(fod)$_3$, was weighed out and added into the solution four times in about 5 mg portions, and the ^1H NMR spectrum was measured each

time. The plots of the observed relative shift of each proton vs. the amount of added $Eu(fod)_3$ gave good straight lines. From the slope of each proton, the relative shift value was calculated.

Lanthanoid(III) Trichloride-Tin(II) Chloride Mediated Cycloaddition Reaction of α,α′-Dibromo Ketones with 1,3-Dienes or Enamines

Shin-ichi FUKUZAWA,* Masakazu FUKUSHIMA, Tatsuo FUJINAMI, and Shizuyoshi SAKAI
Department of Materials Science, Faculty of Engineering,

(Received February 25, 1989)

The reaction of α,α′-dibromo ketones with 1,3-dienes in the presence of $CeCl_3$–$SnCl_2$ in tetrahydrofuran is found to give the corresponding [3+4] cycloadduct in fair to good yields under mild conditions. Furan and cyclopentadiene serve as highly efficient receptors of the oxyallyl intermediate to give bicyclic cycloadducts. The reaction of 2,4-dibromo-3-pentanone with isoprene gives both [3+4] and [3+2] cycloadducts. [3+2] Cycloaddition proceeds similarly with enamines to afford 2-cyclopenten-1-ones after treatment with 3% ethanolic NaOH solution.

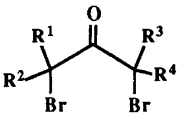
Organic synthesis using lanthanoid compounds has been of current interest.[1] Lanthanoid(III) trichloride ($LnCl_3$) has appeared to be one of the attractive reagent for organic synthesis. The combination with $NaBH_4$[2] or $LiAlH_4$[3] is efficient for 1,2-regioselective reduction of α,β-unsaturated carbonyl compounds, organic halides, and phosphine oxide. They can also be employed together with Grignard reagents or organolithium reagents for regio- and stereoselective alkylation of carbonyl compounds.[4] The characteristic of these reactions may be explained by the lanthanoid ion being a weak Lewis acid and having a high affinity for oxygen.[5] These combined reagents have recently been accepted into the repertoire of standard synthetic methodology. Lanthanoid(III) trichloride has been used as a Lewis acid catalyst for Friedel–Crafts reaction,[6] aldol reaction of silyl enol ether,[7] and ring opening reaction of oxirane.[8] Other trivalent lanthanoid reagents than $LnCl_3$ are also found to be useful for organic synthesis. For example, lanthanoid perchlorate and triflate are good catalyst for preparation of 4-substituted 2,6-dimethylpyrimidines from amines and nitriles.[9] Lanthanoid triflate can also be used with alkyllithium for the conversion of tertiary amines to ketones.[10] Lanthanoid tris[bis(trimethylsilyl)amide] has been developed for regioselective alkylation of epoxides with alkyllithium, where $LnCl_3$ poorly works.[11]

On the other hand, we previously reported a facile aldol synthesis from α-halo ketones and carbonyl compounds by using the combined reagent of $CeCl_3$–$SnCl_2$; a cerium enolate was assumed to be an intermediate.[12] The success of this reaction is due to activation of carbonyl group by cerium(III) ion promoting the reduction of the halogen group by $SnCl_2$. When we applied this combined reagent to a reaction of α,α′-dibromo ketone with furan and cyclopentadiene, the bicyclooctenones, i.e., [3+4] cycloadducts were produced in high yields. As α,α′-dibromo ketone has been recognized as a suitable building block for preparation of five- and seven-membered carbocycles by reaction with alkenes and 1,3-dienes, respectively,[13] the following reagents so far been developed for the reaction: Cu/NaI,[14] Zn/Cu,[15] Fe/graphite,[16] and $Fe_2(CO)_9$.[17] The former three reagents requires some activations and reaction system is heterogeneous. $Fe_2(CO)_9$ is toxic and expensive, and it requires long reaction time and high reaction temperature, although it appears to be an excellent reagent for both [3+4] and [3+2] cycloadditions. $CeCl_3$–$SnCl_2$ reagent can be more conveniently used for the cycloaddition reaction of some α,α′-dibromo ketones, and the reaction procedure is quite simple. The reaction is homogeneous, needs no activation, and is carried out at room temperature in the air. Both $CeCl_3$ and $SnCl_2$ are easily kept with a little care of moisture, non toxic, and inexpensive.

We would like to report here a facile [3+4] and [3+2] cycloaddition reaction of α,α′-dibromo ketones with 1,3-dienes and enamines by $CeCl_3$–$SnCl_2$, respectively.

Results and Discussion

Reaction of α,α′-Dibromo Ketones with Furans in the Presence of the Combined Reagent of $LnCl_3$–$SnCl_2$: The reaction of 2,4-dibromo-3-pentanone (**1**) with furan in tetrahydrofuran (THF) proceeded smoothly at 0 °C to room temperature to afford the cycloadduct (**4**) in good yield when the combined reagent of $CeCl_3$–$SnCl_2$ was employed. The results are shown in Table 1. One equivalent of $SnCl_2$ to **1** was sufficient for the reaction (Run 1), but an excess of $SnCl_2$ gave a more satisfactory yield of **4**; a three-fold excess of $SnCl_2$ was enough to obtain a reasonable



1; $R^1=R^3=Me$, $R^2=R^4=H$

2; $R^1=R^2=R^3=R^4=Me$

3; $R^1=R^2=Me$, $R^3=R^4=H$

Table 1. Cycloadduct Synthesis from **1** and Furan by $LnCl_3$-$SnCl_2$[a]

8;R^1=R^2=R^3=R^4=Me, R^5=R^6=H

result (Run 3). No reaction took place in the absence of either $CeCl_3$ or $SnCl_2$ (Run 5,8). The use of SnF_2 or $PbCl_2$ (lead and tin are both 4B element) instead of $SnCl_2$ results in no reaction with the recovery of starting **1**. It may be concluded that the combination of $CeCl_3$ and $SnCl_2$ is essential to the reaction. Cycloadduct **4** was a mixture of three stereoisomers with respect to the two methyl groups (**4a**, **4b**, and **4c**).[18] The isomer ratio was determined by ^1H NMR integration of the bridgehead protons and olefinic protons after addition of the shift reagent [Eu(dpm)$_3$] according to the literature.[17b] The isomer ratio did not change when the reaction was carried out for a longer time (Run 4), indicating that the isomerization in **4** was not involved in the system and the configuration must be determined at a cycloaddition step.

Other lanthanoid trichloride such as $LaCl_3$, $SmCl_3$, $EuCl_3$, and $ErCl_3$ can be used for the reaction; the yields and isomer ratios were virtually the same despite variation of the lanthanoid metal. For reasons of economy $CeCl_3$ was chosen for investigation.

The cycloadducts of **1** with the substituted furans such as 2-methylfuran and 2,5-dimethylfuran were also obtained as mixtures of two types of cis adducts in good yields, no trans isomers being produced. The reaction of the other dibromide (**2** and **3**) with furan similarly gave 1:1 adduct (**7** and **8**, respectively) in high yields. The results are summarized in Table 2 (Runs 2, 3, 7, and 10).

Reaction with Cyclopentadiene: The reaction of the dibromides with 1,3-dienes including furans are also shown in Table 2. The $CeCl_3$-$SnCl_2$ promoted the reaction of the dibromides (**1**—**3**) and cyclopentadiene gave the bicyclic ketones (**9**—**11**) in high yields (Runs 4, 8, 11). The cycloadduct derived from **1** was two types of cis adducts (**9a** and **9b**) in a ratio of **9a**:**9b**=72:28. No trans isomer was discernible in this reaction. The structural determination of the adduct was carried out by ^1H NMR by reference to the literature.

14

Reaction with Open-Chain 1,3-Dienes: Reaction of **1**—**3** with open-chain 1,3-dienes were examined by using 1,3-butadiene, isoprene, and 2,3-dimethyl-1,3-butadiene. With 2,3-dimethyl-1,3-butadiene the corresponding 4-cycloheptenones (**12**, **13**, **15**, and **16**) were obtained in moderate yields, but less than that with cyclic dienes (Table 2, Runs 5, 9, and 12). It is interesting that the reaction of **1** with isoprene gave **14** as [3+2] cycloadduct in addition to the expected [3+4] cycloadduct **13** (Run 6). A similar result is reported in the reaction of α-bromo silyl enol ether with isoprene.[18] Unfortunately, the cycloadduct with 1,3-butadiene could not be isolated and many products were formed. As a [3+2] cycloadduct with isoprene was obtained, we tried the reaction of **1** with monoalkenes such as styrene and α-methylstyrene, but results was no reaction.

Reaction with Enamines: Although the reaction of an α,α′-dibromo ketone with alkenes did not produce

[3+2] cycloadducts, the cycloadducts with activated alkenes such as enamines could be obtained. For example, when a mixture of **1** and 1-morpholinocyclopentane (**17**) were reacted in the presence of $CeCl_3$–$SnCl_2$ in THF at 0 °C and subsequently treated with 3% ethanolic NaOH, 2-cyclopenten-1-one (**21**) was produced in a moderate yield as a mixture of cis and trans isomers in a ratio of cis:trans=6:94. The other examples are given in Table 3.[20]

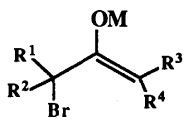
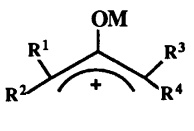
Reaction Mechanism: Treatment of **1** with 1 equiv of $CeCl_3$–$SnCl_2$ (1:1) followed by with D_2O in THF gave 2-bromo-4-deuterio-3-pentanone (**26**). This result may suggest that the first step of the reaction of α,α′-dibromo ketone with $CeCl_3$–$SnCl_2$ involves a single debromination just like a Reformatsky reaction to afford a corresponding cerium α-bromo enolate (**27a**).[12] The enolate **27a** suffers further elimination of bromide ion by way of S_N1 like reaction to give the oxyallyl cation (**28a**) which undergoes [3+4] and [3+2] cycloadditions with 1,3-dienes and enamines, respectively.[15b,17a] α-Halo silyl enol ether (**27b**) is an isolated metal α-halo enolate and has been designed for the synthetic equivalent of an oxyallyl cation.[19] Then the



27a;M=$CeCl_2$
27b;M=$SiMe_3$



28a; M=$CeCl_2$
28b;M=$SiMe_3$

plausible key intermediate of the oxyallyl cation seems to be the ceruim α-bromo enolate.

Experimental

^{1}H NMR spectra were recorded with Hitachi R-24 (60 MHz) and Hitachi R-600 (60 MHz) instrument in $CDCl_3$ solutions with $SiMe_4$ as an internal standard. IR spectra were taken with Shimadzu IR 410. GLC analyses were carried out by using a Shimadzu 8A apparatus on EGSS-X(3%)-Chromosorb-W(2 m) and Silicone DC QF-1(5%)-Chromosorb-W(2 m) columns (N_2 as carrier gas).

Frash column chromatography was performed by EYELA EF-10 apparatus by using Merck Kieselgel 60 (230—400 mesh) or Wako C-300. Preparative TLC separation was conducted using 20×20 cm glass plates coated with a 2.0 mm thick layer of Merck Kieselgel PF_{254} gipsphaltig.

Tetrahydrofuran was distilled from sodium benzophenone ketyl under nitrogen. Anhydrous $LaCl_3$, $CeCl_3$, $SmCl_3$, $EuCl_3$, and $ErCl_3$ were obtained by drying the commercial hydrate with $SOCl_2$.[13] Anhydrous tin(II) chloride was purchased from Wako Pure Chemicals Co. and further dried at 200 °C in vacuo before use.

α,α'-Dibromo ketones (**1**, **2**, and **3**) were prepared by a dibromination of the corresponding ketones with bromine in diethyl ether catalyzed by phosphorus tribromide.[15a] Furan, 2-methylfuran, and 2,5-dimethylfuran were distilled over potassium hydroxide. Cyclopentadiene was distilled by thermolysis of commercial dicyclopentadiene at 200 °C just prior to use. Enamines were prepared from the corresponding ketones and morpholine in the presence of a catalytic amount of *p*-toluenesulfonyl chloride in refluxing benzene.

Reaction of α,α'-Dibromo Ketones with 1,3-Dienes in the Presence of $CeCl_3$-$SnCl_2$. General Procedure: Anhydrous $CeCl_3$ (1.00 g, 4 mmol) and $SnCl_2$ (2.27 g, 12 mmol) were placed in a 50 cm^3 two-neck round bottom flask containing a magnetic stirrer bar. To this THF (10 cm^3) was introduced followed by addition of a mixture of α,α'-dibromo ketone (4 mmol) and 1,3-diene (12—40 mmol) in 5 cm^3 of THF at 0 °C with stirring. The mixture was stirred at 0 °C for 2 h and then at room temperature for additional 3 h. The solution was poured into diluted HCl, extracted with chloroform (20 cm^3×3), dried ($MgSO_4$), and evaporated under reduced pressure. The residue was passed through a short alumina column (2 cm×3 cm) eluted with chloroform to remove a polymeric product. Removal of the solvent by a rotary evaporator left the almost pure adduct by ^{1}H NMR analysis, which was further subjected to preparative TLC or flash column chromatography on silica gel (hexane–ethyl ehter=10:1 as eluent). All the cycloadducts were known compounds, then the identification and isomer ratio of the products were carried out by ^{1}H NMR and IR by reference to the literature.[15,17b] The spectra data of all the products were satisfied with the structure of the reported ones. The isomer ratio of the products, **4a**:**4b**:**4c**, **5a**:**5b**, and **6a**:**6b** were determined by ^{1}H NMR integration of the bridge head protons and olefinic protons with the shift reagent, Eu(dpm)$_3$.

Reaction of α,α'-Dibromo Ketone with Enamine by $CeCl_3$-$SnCl_2$: Anhydrous $CeCl_3$ (1.00 g, 4 mmol) and $SnCl_2$ (2.27 g, 12 mmol) were placed in a 50 cm^3 two-neck round bottom flask containing a magnetic stirrer bar. THF (10 cm^3) was introduced to the flask followed by addition of THF (5 cm^3) solution of α,α'-dibromo ketone (4 mmol) and enamine (12 mmol) at room temperature with stirring. The mixture was stirred at room temperature for 5 h, then diluted with ethyl acetate (50 cm^3), treated with saturated $NaHCO_3$ (30 cm^3), and filtered. The filtrate was washed with brine (30 cm^3×2), and dried ($MaSO_4$), After evaporation of the solvent the residue (the undeaminated adduct) was treated with 3% ethanolic NaOH solution (3 cm^3) at room temperature for 30 min. The solution was diluted with ethyl acetate (50 cm^3), neutralized with dilute HCl (20 cm^3), washed with brine (30 cm^3×2), then dried over $MgSO_4$. Evaporation of the solvent left a yellow oil which was passed through a short alumina column (2 cm×3 cm) with chloroform. The adduct (cyclopentenone derivative) was isolated by flash column chromatography on silica gel (hexane–ethyl acetate =10:1 as eluent). The cyclopentenone was obtained as a mixture of cis and trans (except for **24** and **25**). The stereoisomers was separated by preparative TLC (hexane–ethyl acetate=10:1). ^{1}H NMR and IR spectra of the products were identical with those of the reported ones.[17c] The isomer ratio was determined by GLC.

The Esterification of Carboxylic Acid with Alcohol over Hydrous Zirconium Oxide

Kyoko TAKAHASHI,* Makoto SHIBAGAKI, and Hajime MATSUSHITA
Life Science Research Laboratory, Japan Tobacco, Inc., 6-2 Umegaoka, Midori-ku, Yokohama, Kanagawa 227
(Received February 13, 1989)

The esterification of carboxylic acids with alcohols proceeded efficiently with hydrous zirconium oxide to give the corresponding esters in the vapor phase, in the liquid phase, and in an autoclave. The steric hindrance of carboxylic acids and alcohols affected the esterification by lowering the reactivity. With a rise in the reaction temperature, the conversion of the carboxylic acid increased. The dehydration of alcohols was prevented by using hydrous zirconium oxide in spite of the high reaction temperature. The reaction rate is first-order with respect to the concentration of the catalyst and an alcohol and is inversely proportional to that of the carboxylic acid. Transesterification also proceeded efficiently.

In our previous papers,[1-5] we reported that hydrous zirconium oxide has the catalytic activity for the reduction of aldehydes and ketones with 2-propanol and the amidation of carboxylic acid with amine. Since the hydrous zirconium oxide was expected to have affinities for both carboxylic acids and alcohols, the esterification of carboxylic acids with alcohols was carried out by the catalysis of the oxide.

In the esterification of carboxylic acids with alcohols, homogeneous catalysts, such as sulfulic acid and hydrochloric acid, are usually used. These methods, however, need tedious work-up procedures in the isolation of the products. Recently, heterogeneous catalysts, such as Nafion-H,[6] the zirconium oxide–sulfate ion,[7] the titanium oxide–sulfate ion,[8] heteropoly acids supported on carbon,[9] silica–alumina, zeolite HY,[10] cation-exchange resin, and niobic acid,[11] have been reported to be effective catalysts for the esterification. These are all solid acid or solid superacid catalysts, however, there is a fear of unfavorable side reactions such as dehydration because of the strong acidity of the catalyst. As heterogeneous catalysts for the esterification, titanium alkoxide and zirconium alkoxide supported on silica, alumina, or silica–alumina have also been reported.[12] The preparation of these catalysts is, however, troublesome.

The hydrous zirconium oxide consists of hard and translucent granules. According to the X-ray diffraction analysis, the oxide was shown to be amorphous. Esterification over hydrous zirconium oxide has the following advantages: 1) the hydrous zirconium oxide is easily prepared by the neutralization of an aqueous zirconium dichloride oxide solution; 2) the products can easily be isolated by filtering-off the catalyst and subsequently evaporating the solvent, because the catalyst is insoluble in any solvent; 3) the oxide is stable at room temperature in air, and 4) the oxide is not sensitive to air or water, and the esterification does not require water-free conditions.

In this paper, we wish to report that the hydrous zirconium oxide catalyzes the esterification of carboxylic acid with alcohol efficiently and that it also catalyzes the transesterification. These reactions were carried out in the vapor phase, in the liquid phase, and in an autoclave. The hydrous zirconium oxide does not have a strong acid strength on the surface, and such undesirable side reactions as dehydration can be avoided, unlike as in the cases of acid catalysts. The mechanism of esterification over hydrous zirconium oxide was also studied in vapor-phase reactions.

Experimental

Materials. Commercial reagents were used for the reaction without any further purification.

Hydrous Zirconium Oxide. To a solution of zirconium dichloride oxide ($ZrOCl_2 \cdot 8H_2O$)(200 g of a solid in 10 dm^3 of deionized water) we slowly added an aqueous solution of sodium hydroxide (1 mol dm^{-3}) at room temperature. Constant, gentle stirring was maintained, and the addition was continued until the pH of the resulting solution reached 6.80. The resulting product was filtered and washed free from chloride ions. The gel was spread on a glass plate and dried in air at room temperature for 10 h and then at 80 °C for 2 h. Fifty-four grams of hydrous zirconium oxide were obtained in the form of granules, which were subsequently heated at 300 °C for 5 h.

General Procedures for Vapor-Phase Reactions. The catalytic esterification was carried out in a glass-flow reactor (6.5 mm in diameter) with a fixed-bed catalyst: flow rate of nitrogen gas=60 cm^3 min^{-1}; catalyst=2.0 g, 24—60 mesh; reaction temperature=135—280 °C. A mixture of a carboxylic acid, an alcohol, and a hydrocarbon as an internal standard was fed into the reactor (5 or 10 cm^3 h^{-1}) by means of a microfeeder. In some cases, benzene was also added to dilute the reaction mixture. The activity and selectivity of the reaction were determined after the steady states has been reached. The products were then analyzed by gas chromatography (a capillary column PEG 20M 30 m). The products were identified by a comparison of their retention times with those of authentic samples.

General Procedures for Liquid-Phase Reaction. In a 25 cm^3 round-bottomed flask equipped with a reflux condenser we placed the catalyst (2.0 g), a carboxylic acid, an alcohol, and a hydrocarbon as an internal standard. The contents were then heated under a gentle reflux. In some reactions, toluene was added to the solution in order to raise the reaction temperature. In some cases, the reaction

mixture was placed in an oil bath kept at 77.0±0.1 °C. The reaction mixture was collected after 5 hours, and the products were analyzed by means of gas chromatography.

General Reaction Procedures in an Autoclave. In a 100-cm^3 autoclave were placed the catalyst (2.0 g), a carboxylic acid, an alcohol, and a hydrocarbon as an internal standard. The autoclave was then heated to the reaction temperature (130—240 °C) and kept there for 2 h. The analysis of the products was performed in a manner similar to described above.

Surface Acidity. The quantity of surface acidic sites was measured by the butylamine-titration method using various Hammett indicators.

Results and Discussion

Esterification in the Vapor Phase. The results of vapor-phase esterification of carboxylic acids with alcohols over hydrous zirconium oxide are listed in Table 1. The esterification of carboxylic acids, except for adamantanecarboxylic acid, with primary alcohols gave the corresponding esters in high yields (Entries 1—7). In the case of the reaction with secondary alcohols, the conversion of the carboxylic acid increased in this order: tertiary<secondary<primary. These results can be explained by the steric hindrance of the carboxylic acid (Entries 9—14). The esterification with tertiary alcohol gave the ester in a low yield (Entry 16). The esterification of cyclohexanecarboxylic acid with primary alcohol gave the ester in a higher yield than that with secondary alcohol (Entries 3 and 11). As has been described above, the steric hindrance of alcohols also affected the esterification. The higher the reaction temperature, the more carboxylic acid was consumed. The selectivity for the ester, however, was lowered, and the reaction gave the alcohol as a by-product of the reduction of the carboxylic acid (Entries 4 and 5). The selectivity for the ester was 100% in the esterification with benzyl alcohol at 150 °C (Entry 8).

Table 1. Esterification in the Vapor Phase over Hydrous Zirconium Oxide[a)]

Entry	Reactant		Temperature/°C	Conversion/%	Selectivity/%

Since the reaction with benzyl alcohol at 150 °C over Nafion H caused undesirable polymerization,[6] the hydrous zirconium oxide is superior to the superacid catalyst. Moreover, the hydrous zirconium oxide caused scarcely any dehydration of alcohols.

Transesterification in the Vapor Phase. The reactions of alcohols or carboxylic acids with ethyl acetate—that is, transesterification—were investigated by means of the catalysis of the hydrous zirconium oxide in the vapor phase. The transesterification, an useful method for the preparation of esters, needs water-free conditions; and it is used for the preparation of polyesters. The results of the reaction catalyzed by the hydrous zirconium oxide are listed in Table 2.

Generally, most of the alcohols were converted to the corresponding acetates in the transesterification with ethyl acetate; the selectivity of the reaction was very high in each case. Primary alcohols were more reactive than secondary ones, while tertiary ones were not efficiently reacted. In the case of menthol, the reactivity was lowered by its steric hindrance. The transesterification of carboxylic acids gave the esters in low yields.

Esterification in the Liquid Phase. The esterifications of carboxylic acids with alcohols over the hydrous zirconium oxide were investigated in the liquid phase; the results are listed in Table 3. The reactions were carried out at the reflux temperature of the solution. Most of the carboxylic acids were converted to the corresponding esters in high yields. In the esterification with primary alcohol, the reactivities increased in this order: tertiary carboxylic acid< secondary one<primary one, the same as in the vapor-phase reactions (Entries 1—7). The yields of the ester in the reactions with primary alcohols were higher than in those with secondary alcohol. The esterification of acetic acid with menthol gave the ester in a lower yield than that with cyclohexanol (Entries 9 and 10). The yield was, however, increased by adding toluene to the reaction mixture. This suggests that raising the reaction temperature enhanced the reactivity, even in the reaction of menthol (Entry 11). In the case of the reaction of salicylic acid with methanol, the corresponding methyl ester was obtained in a 13% yield (Entry 8). The low conversion of salicylic acid was explained by its strong adsorption, since the pK_a value of salicylic acid (2.98) was lower than that of the other carboxylic acid (ca. 4.8) shown in Table 3. This suggests that the reactivity was inhibited by the adsorption of carboxylic acid. In order to clarify the

difference in reactivity between carboxylic acids and between alcohols, the esterification was carried out at the same temperature (77 °C) in the liquid phase. The results are shown in Table 4. In the reaction of primary carboxylic acid with primary alcohol, the reactivity of the esterification was lowered according to the length of the carbon chain (Entries 1—3, and 5). In the reaction of secondary carboxylic acid with primary alcohol, the reaction of the carboxylic acid which possesed a methyl group at a α-position was lower than that of cyclohexane carboxylic acid. Further, the carboxylic acid which possesed a ethyl group in the α-position gave the ester in a lower yield. These results suggest that the steric hindrance of carboxylic acid affects the reaction. The esterification of tertiary carboxylic acid with primary alcohol gave the ester in a low yield because of the steric hindrance. In the case of benzoic acid, the reactivity was relatively low. This result was caused by the relatively low pK_a value (4.20) of benzoic acid, much as in the case of salicylic acid. The reactivities of alcohol increased in this order: tertiary alcohol<secondary one<primary one. The esterification in the liquid phase over hydrous zirconium oxide was affected by the steric hindrace of carboxylic acids and alcohols. Though the conversion in the liquid-phase esterification was lower than the vapor-phase reaction because of the lower reaction temperature, the selectivity was always 100%.

a) Catalyst: 2.0 g; carboxylic acid or alcohol: 2 mmol; ethyl acetate: 60 mmol; reaction for 5 h.

Transesterification in the Liquid Phase. The results of the transesterification of alcohols and carboxylic acids with ethyl acetate in the liquid phase are shown in Table 5. The tendency of the reactivities of several alcohols was similar to that in the vapor phase. The yield of the ester in the transesterification of primary alcohol was higher than that of the secondary one, and the reaction of carboxylic acid did not proceed. The selectivities of the esters were usually 100%.

Dependence on the Molar Ratio of Carboxylic Acid to Alcohol in Liquid-Phase Esterification. Table 6 shows the dependence on the molar ratio of acetic acid to ethyl alcohol in liquid-phase esterification. When either carboxylic acid or alcohol was used in excess, the ester was given efficiently. The reaction in even an equimolecular quantity of acetic acid and ethyl alcohol gave the ester in a 77% yield. The selectivity of the ester was always 100%.

Esterification in an Autoclave. It has been described that the reaction temperature affects the esterification over hydrous zirconium oxide. In order to obtain the ester in a higher yield, the esterification was carried out in an autoclave at a high temperature. The results are shown in Tables 7 and 8. The esterification in an autoclave gave the ester in a higher yield than that in a vapor-phase or liquid-phase reaction. The decarboxylation of salicylic acid and the dehydration of secondary and tertiary alcohol occurred slightly. It was learned that *t*-butyl alcohol could easily be dehydrated by using an acid catalyst at a high temperature. However, it was interesting that the esterification proceeded preferentially over hydrous zirconium oxide. The reaction of acetic acid with ethylene glycol and glycerol gave, selectively, the diacetate and triacetin respectively. Although the reaction of terephtalic acid gave both diacetate and monoacetate, the reactions of other dibasic acids and acid anhydrides gave the diesters selectively. By using an autoclave, the esterification of the polyhydric alcohol or dibasic acid over hydrous zirconium oxide proceeded effectively.

Transesterification in an Autoclave. Table 9 shows the results of the transesterification over hydrous zirconium oxide in an autoclave. The yields were higher than those in a vapor-phase or liquid-phase reaction. The conversion of carboxylic acid increased,

Amount/mol g^{-1}	0	8×10^{-6}	5×10^{-4}	1.4×10^{-3}

and the selectivity decreased, with the rise in the reaction temperature. The reaction with menthol gave the ester in a low yield because of its steric hindrance. Although the transesterification with carboxylic acid gave the ester in neither a vapor nor a liquid phase, it could proceed efficiently in an autoclave.

Durability of Hydrous Zirconium Oxide in Vapor-Phase Esterification. In order to estimate the durability of the hydrous zirconium oxide, the esterification of acetic acid with ethyl alcohol was carried out at 250 °C in the vapor phase. As a result, the catalytic activity of the hydrous zirconium oxide was kept for at least 170 h. This showed that the hydrous zirconium oxide is a durable heat-stable catalyst.

Surface Acidity. The findings on the surface acidity of the hydrous zirconium oxide are shown in Table 10. The acid amounts at $H_0 \leq -8.2$ and $H_0 \leq -5.6$ are 0 and 8×10^{-3} mmol·g^{-1} respectively. This shows that the hydrous zirconium oxide does not have as strong acid sites as the other solid acid catalysts. From the point of view of avoiding such side reactions as the dehydration of alcohols, low acidity is an advantage in an esterification catalyst. The hydrous zirconim oxide has the same activity for esterification as a superacid catalyst such as Nafion H. This suggests that the hydrous zirconium oxide is different from an acid catalyst. Most solid acids decrease in acidity upon the adsorption of water; however, it has been reported[13] that the niobic acid is not deactivated by the adsorption of water. Judging from the result of keeping its activity under an atmosphere of water vapor, the hydrous zirconium oxide might have a character similar to that of the niobic acid. However, the surface acidity of the hydrous zirconium oxide is lower than that of niobic acid.[11]

Dependence on the Catalyst Amount in a Vapor-Phase Reaction. For determining the order of catalyst amounts, the esterification rates of acetic acids with ethyl alcohol were measured over the range from 1.0 to 6.0 g of the catalyst. As a result, the esterification rates, r, were directly proportional to the amounts of the catalysts. Hence the rate, r, should be introduced as:

$$r = k\cdot[\text{cat.}], \quad (1)$$

where [cat.] and k are the concentration of the catalyst and the first-order rate constant respectively. Therefore, the specific rate, r_0, is:

$$r_0 = r/[\text{cat.}]. \quad (2)$$

Dependence on the Reaction Temperature in a Vapor-Phase Reaction. In order to investigate the

dependence on the reaction temperature, the esterifications of acetic acid with ethyl alcohol were carried out under the following two kinds of conditions: 1) the concentration of acetic acid, that of ethyl alcohol, the sample feed, and the temperature range were 2.77 mmol·cm^{-3}, 13.9 mmol·cm^{-3}, 10 cm^3·h^{-1}, and 120—220 °C respectively; 2) they were 6.66 mmol·cm^{-3}, 9.88 mmol·cm^{-3}, 5 cm^3·h^{-1}, and 135—250 °C respectively. Linear relationships between the natural logarithm of the specific rate vs. the reciprocal the absolute temperature, that is, the Arrhenius plot, were obtained in both cases. From the inclination of the lines, the activation energies were estimated to be, on the average, 12.4 kcal·mol^{-1}.

Dependence on the Alcohol Concentration in a Vapor-Phase Reaction. For determining the order of alcohol concentrations, the esterification rates of acetic acid with ethyl alcohol were measured under the following conditions: the concentration of acetic acid was constant at 1.53 mmol·cm^{-3}, the concentration of ethyl alcohol was changed in the range from 1.53 to 15.3 mmol·cm^{-3}, and benzene was added as a diluent to keep the volume of the reaction mixture constant. The correlation between the natural logarithm of the concentration of ethyl alcohol and that of the specific rate indicated that the order in alcohol concentrations was estimated to be first-order.

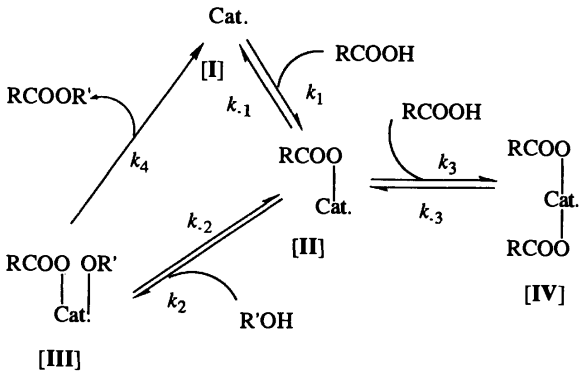
Dependence on the Carboxylic Acid Concentration in a Vapor-Phase Reaction. In order to investigate the dependence on the carboxylic acid concentration, the esterification of acetic acid with ethyl alcohol was carried out under the following conditions: the concentration of ethyl alcohol was constant at 7.65 mmol·cm^{-3}, the concentration of acetic acid was changed in the range from 0.918 to 2.55 mmol·cm^{-3}, and benzene was used as a diluent. The correlation between the natural logarithm of the concentration of acetic acid and that of the specific rate indicated that the reaction rate could be estimated to be of a minus first-order dependence on the concentration of acetic acid.

Kinetic Discussion in a Vapor-Phase Reaction. As has been described above, the reaction rate of the esterification over hydrous zirconium oxide in the vapor phase, r, is:

$$r = k' \cdot [\text{cat.}]^1 \cdot [\text{A}]^1 \cdot [\text{C}]^{-1}, \tag{3}$$

where k', [cat.], [A], and [C] are the rate constant, the concentration of the catalyst, that of ethanol, and that of acetic acid respectively. These results suggest that the rate-determining step is the step subsequent to the adsorption of the carboxylic acid and alcohol on the catalyst.

The result of the minus first-order dependence on the concentration of acetic acid suggests that acetic acid inhibits the reaction by adsorption on the surface of the hydrous zirconium oxide. We assume that the



Scheme 1.

mechanism of the esterification of carboxylic acid with alcohol over the hydrous zirconium oxide in the vapor phase is as is shown in the Scheme 1.

Based on the proposed scheme, the following equation was obtained by the use of the stationary-state method, while the esterification rate is expressed by:

$$r = \frac{k_1 \cdot k_2 \cdot k_4 \cdot [\text{A}] \cdot [\text{C}] \cdot [\text{cat.}]}{k_{-1} \cdot k_{-2} + k_1 \cdot k_2 \cdot [\text{C}] + k_1 \cdot k_2 \cdot [\text{A}] \cdot [\text{C}] + k_{-1} \cdot k_{-2} \cdot K_3 \cdot [\text{C}]^2 + k_4 \cdot B}$$

$$= \frac{k \cdot K_1 \cdot K_2 \cdot [\text{A}] \cdot [\text{C}] \cdot [\text{cat.}]}{1 + K_1 \cdot [\text{C}] + K_1 \cdot K_2 \cdot [\text{A}] \cdot [\text{C}] + K_1 \cdot K_3 \cdot [\text{C}]^2 + k \cdot B/(k_{-1} \cdot k_{-2})}, \tag{4}$$

$$(B = k_{-1} + k_2 \cdot [\text{A}] + k_1 \cdot [\text{C}] + k_{-1} \cdot k \cdot K_3 \cdot [\text{C}]^2)$$

where K_1, K_2, and k are k_1/k_{-1}, k_2/k_{-2}, and k_4 respectively. The kinetic results show that the last step constitutes the rate-determining step. Therefore, k is far less than k_n, and the rate equation can be rewritten as:

$$r \fallingdotseq \frac{k \cdot K_1 \cdot K_2 \cdot [\text{A}] \cdot [\text{C}] \cdot [\text{cat.}]}{1 + K_1 \cdot [\text{C}] + K_1 \cdot K_2 \cdot [\text{A}] \cdot [\text{C}] + K_1 \cdot K_3 \cdot [\text{C}]^2}. \tag{5}$$

Furthermore, the inhibition of the carboxylic acid suggests that k_3 is larger than k_{-3}— that is, $K_3 > K_n$; hence, the rate equation becomes:

$$r \fallingdotseq \frac{k \cdot K_1 \cdot K_2 \cdot [\text{A}] \cdot [\text{C}] \cdot [\text{cat.}]}{K_1 \cdot K_3 \cdot [\text{C}]^2} = \frac{k \cdot K_2 \cdot [\text{A}] \cdot [\text{cat.}]}{K_3 \cdot [\text{C}]}. \tag{6}$$

This equation apparently corresponds to Eq. 3, and the proposed scheme may be concluded to be reasonable.

Multi-Ionic Potential and Membrane Permeability Matrix. III. Diffusion and Concentration of Ions within Membrane Phase as a Controlling Factor to Ion Permselectivity

Kozue KAIBARA,* Hiroyoshi INOUE, and Toshio ARITOMI
Department of Chemistry, Faculty of Science, Kyushu University,
Hakozaki, Higashi-ku, Fukuoka 812
(Received February 15, 1989)

Membrane concentrations of cations in the NaCl-CsCl and NaCl-$CaCl_2$ systems with a highly selective cation-exchange membrane were measured under the extensive external electrolyte conditions. The modes of membrane/solution distribution and diffusion of cations, as a controlling factor to the membrane permselectivity, were correlated consistently with the electrochemical and cation flux data, as well as with the estimated membrane permselectivity parameters. The NaCl-CsCl uni-uni valent cation system was characterized well by the Na^+/Cs^+ concentration ratio of external solution, since the Na^+/Cs^+ concentration ratio in the membrane phase was related directly to the external ratio. Na^+/Cs^+ diffusion coefficient ratio varied from 0.5 to 3 with increasing external Na^+/Cs^+ concentration ratio from 1/100 to 100. While in the NaCl-$CaCl_2$ uni-bi valent cation system, the high and constant membrane concentration of Ca^{2+} regulated the transport process. The Na^+/Ca^{2+} diffusion coefficient ratio ranged from 0.5 to 500 with external Na^+/Ca^{2+} ratio from 1/100 to 100. Analyses on the phenomenological coefficients, describing the inter-cationic correlations within the membrane phase, as a function of the external cation concentration ratio were also carried out.

Selective ion transport processes across a charged-membrane are controlled, in general, by the modes of ionic migration within the membrane phase and by the profiles of ionic distribution between the membrane and external phases (see e.g., Refs. 1—3). Therefore, the phenomenological studies of the membrane transport process, such as the measurements of transmembrane potential, conductance, and ion flux, as well as the estimations of membrane transport parameters describing the permeability and selectivity to permeant ions, must be consistent with the results on the estimations of ionic behaviors within the membrane phase. The aim of the present experiments is to examine the conditions of permeant ions within the membrane phase and to correlate these results systematically with the results based on the linear phenomenological analyses in the multi-ionic transport systems with a cation-exchange membrane.[4,5] The substantial ion permselectivity of an ion-exchange membrane should be evaluated in the multiple counterion systems and the practical ion-exchange membrane related techniques are operated usually in a multi-ionic system as in the sea water condensation process (see e.g., Refs. 6—9). The present experiments are designed not only for the detailed phenomenological descriptions of the multi-ionic membrane transport process but also for the survey of a more efficient operating condition in the ion-exchange membrane-related processes.

Experimental

A typical highly selective cation-exchange membrane, CK-1,1.0t (Asahi Chemical Industry Co., Ltd.), was used throughout the present experiments. The basic physicochemical properties of the CK-1, 1.0t membrane were noted in earlier papers.[4,5,10] Electrolyte solutions were prepared from extra pure salts with twice-distilled water. All the measurements were carried out at regulated room temperature, 25±1 °C.

In the present experiments, the membrane properties were examined in NaCl-CsCl and NaCl-$CaCl_2$ systems, where the concentration of one of the electrolytes is varied from 10^{-1} to 10^{-3} mol dm^{-3} and that of the other electrolyte is kept constant at 10^{-1}, 10^{-2}, or 10^{-3} mol dm^{-3}. Then, the concentration ratios of the two kinds of external electrolytes ranged at 100—1/100. In case of the CK-1, 1.0t membrane, the previous experimental results on the single electrolyte systems indicated that the cation concentrations within the membrane phase are almost constant at below the external electrolyte concentration of around 5×10^{-1} mol dm^{-3} and, above this external concentration, rapid increases in the membrane cation concentration due to a drastic intrusion of Donnan adsorbed cations are observed.[10] Accordingly in the present experimental conditions, it is expected that the total cation concentrations in the membrane phase are kept at a constant level and that the effects of relative occupancy of respective cations for available membrane sites upon the membrane transport process can be examined systematically.

Membrane concentrations of the respective cations were measured by the following procedures. A piece of the CK-1, 1.0t membrane sample (0.1—0.2 g, ca.1 cm^2), preweighed at the reference conditions in which all the membrane samples were equilibrated sufficiently with 10^{-1} mol dm^{-3} NaCl solution, was immersed in the test aqueous solution with an appropriate electrolyte composition for 96 h to establish sufficiently an equilibrium condition of ions within the membrane phase. Then the test membrane sample, being wiped off the adhering electrolyte solution, was washed with distilled water for 72 h to extract Donnan adsorbed ions. It was required at least 50 h to elute stiffly adsorbed Donnan ions in the CK-1, 1.0t membrane. In the next step, remaining cations which are thought to be bound to ion-exchange sites were extracted perfectly by means of soaking the membrane sample into 1 mol dm^{-3} HCl solution for 24 h. Cation concentrations in the respective aqueous eluents were measured with an atomic absorption spectrophotometer (Hitachi 180-50) after the suitable dilution

steps and/or, in case of the bi-cationic systems, the appropriate treatments to prevent from the interference due to the coexisting cations. The Cs^+ concentrations were measured with addition of $CaCl_2$ into the eluent sample solutions to inhibit the ionizations of Cs and to increase the spectral intensities.

Electrochemical measurements to estimate the transmembrane potential and conductance data as well as intercompartmental cation flux measurements were described in earlier papers.[4,5] The experimental systems consisted of aqueous solution phases I and II separated by the membrane, one of which contains NaCl as electrolyte and the other, CsCl or $CaCl_2$. The concentration of one of the electrolytes in phase I was varied from 10^{-1} to 10^{-3} mol·dm^{-3} and that of the other electrolyte in phase II was kept constant at 10^{-1}, 10^{-2}, or 10^{-3} mol dm^{-3}. The respective electrolyte concentrations in phases I and II correspond to those in the systems for the membrane ion concentration measurements described above. As will be discussed in the later section, the membrane-electrolyte solution systems in the present study are close fairly to the cationic equilibrium condition, so the experimental data obtained from the two types of the systems, the binary (two counterion) systems equilibrated or separated with a cation-exchange membrane, are correlated well to each other.

Results and Discussion

Thermodynamic background for the analyses of the present membrane transport process can be summarized as follows. When Z_1-valent metal, M_1, and Z_2-valent metal M_2 in chloride form are dissolved in the aqueous phases I and II separated by the membrane phase, respectively, the fundamental linear phenomenological equation employing the membrane permeability matrix as a principal transport parameter is expressed as:[4,5]

$$\begin{bmatrix} J_{M_1} \\ J_{M_2} \\ J_{Cl} \end{bmatrix} = - \begin{bmatrix} P_{M_1\cdot M_1} & P_{M_1\cdot M_2} & P_{M\cdot Cl} \\ P_{M_2\cdot M_1} & P_{M_2\cdot M_2} & P_{M_2\cdot Cl} \\ P_{Cl\cdot M_1} & P_{Cl\cdot M_2} & P_{Cl\cdot Cl} \end{bmatrix} \begin{bmatrix} -a^{I}_{M_1}\exp(-Z_1FV/2RT) \\ a^{II}_{M_2}\exp(Z_2FV/2RT) \\ a^{II}_{Cl}\exp(-FV/2RT) - a^{I}_{Cl}\exp(FV/2RT) \end{bmatrix} \quad (1)$$

where J is the ionic flux, a is the activity, V is the membrane potential, F is the Faraday constant, R is the gas constant, and T is the absolute temperature; the subscripts M_1, M_2, and Cl refer to metal cations, M_1 and M_2, and chloride ion; the superscripts I and II indicate the solution phase. The 3×3 matrix in the right hand side of Eq. 1 is the membrane permeability matrix, of which elements represent the partial contributions of the inter-ionic correlations indicated by the subscript indices on the membrane transport processes. The respective matrix elements can be estimated based on the membrane potential, conductane, and ion flux data.[4,5] Since the electroconductive membrane permeabilities to metal cations M_1 and M_2 and to Cl^-, P_{M_1}, P_{M_2}, and P_{Cl}, are defined as a function of the membrane permeability matrix elements:

$$\begin{aligned} P_{M_1} &= P_{M_1\cdot M_2} + (Z_2P_{M_2\cdot M_1} - P_{Cl\cdot M_1})/Z_1 \\ P_{M_2} &= P_{M_2\cdot M_2} + (Z_1P_{M_1\cdot M_2} - P_{Cl\cdot M_2})/Z_2 \\ P_{Cl} &= P_{Cl\cdot Cl} - (Z_1P_{M_1\cdot Cl} + Z_2P_{M_2\cdot Cl}) \end{aligned} \quad (2)$$

the membrane electric current, I, is expressed as:

$$\begin{aligned} I &= F(Z_1J_{M_1} + Z_2J_{M_2} - J_{Cl}) \\ &= [FZ_1P_{M_1}a^{I}_{M_1}\exp(-Z_1FV/2RT) \\ &\quad - FZ_2P_{M_2}a^{II}_{M_2}\exp(Z_2FV/2RT)] \\ &\quad + FP_{Cl}[a^{II}_{Cl}\exp(-FV/2RT) - a^{I}_{Cl}\exp(FV/2RT)] \end{aligned} \quad (3)$$

The electroconductive membrane permeabilities to respective ions can be estimated directly from the electrochemical data such as the membrane potentials and conductances.[4,5,11]

Introducing the membrane permeability to whole cations, $P_{M_1\text{-}M_2}$, defined as:

$$P_{M_1\text{-}M_2} = (Z_1P_{M_1}Z_2P_{M_2})^{1/2}\exp[-(Z_1 - Z_2)FV/4RT] \quad (4)$$

the cationic component of membrane electric current, the term in the first brackets in Eq. 3, can be modified and the expression for the membrane electric current is reduced to:

$$\begin{aligned} I &= -2FP_{M_1\text{-}M_2}(a^{I}_{M_1}a^{II}_{M_2})^{1/2}\sinh[(Z_1 + Z_2)F(V - V_{M_1\text{-}M_2})/4RT] \\ &\quad + 2FP_{Cl}(a^{I}_{Cl}a^{II}_{Cl})^{1/2}\sinh[-F(V - V_{Cl})/2RT] \end{aligned} \quad (5)$$

where $V_{M_1\text{-}M_2}$ is the cationic equilibrium membrane potential, which corresponds to the Nernstian equilibrium potential for a single cationic system, and V_{Cl} is the Nernstian equilibrium membrane potential for Cl^-. The expression for $V_{M_1\text{-}M_2}$ is derived from Eq. 3 by introducing the conditions, I=0 and P_{Cl}=0 as:

$$V_{M_1\text{-}M_2} = -[2RT/(Z_1 + Z_2)F]\ln(Z_2P_{M_2}a^{II}_{M_2}/Z_1P_{M_1}a^{I}_{M_1}) \quad (6)$$

Equation 6 deduces that the linear relationships of $V_{M_1\text{-}M_2}$ with logarithmic $a^{I}_{M_1}$ correspond to the constant P_{M_1}/P_{M_2}. The transmembrane potential in the absence of electric current, V_0, is related to $V_{M_1\text{-}M_2}$ and V_{Cl} as:

$$V_0 = t_{M_1\text{-}M_2}V_{M_1\text{-}M_2} + t_{Cl}V_{Cl} \quad (7)$$

where $t_{M_1\text{-}M_2}$ and t_{Cl} are the transport numbers to the whole metal cations and Cl^-, respectively.

The membrane permselectivity to ions depends, in general, upon the membrane/solution distribution and migration speed of permeating ions.[1-3] The membrane permeability ratio of cations, P_{M_1}/P_{M_2}, can be expressed as:[4,12,13]

$$\frac{P_{M_1}}{P_{M_2}} = \frac{D^m_{M_1}}{D^m_{M_2}} \frac{C^m_{M_1,Total}/C^m_{M_2,Total}}{C^s_{M_1}/C^s_{M_2}} \quad (8)$$

where D^m is the diffusion coefficient of metal cation within the membrane phase and, C^m and C^s are the cation concentrations in the membrane phase and in the external solution, respectively. The total membrane concentration of metal cation M, $C^m_{M,Total}$, is the sum of two components of cation concentration within the membrane phase as:

$$C^m_{M,Total} = C^m_{M,H_2O} + C^m_{M,HCl} \quad (9)$$

where C^m_{M,H_2O} is the Donnan adsorbed component of metal cation M eluted with distilled water and $C^m_{M,HCl}$ is the site-bound component of metal cation M eluted with HCl solution as described in the experimental section. In the present study, changes in $C^m_{M,Total}$, C^m_{M,H_2O}, and $C^m_{M,HCl}$ for Na^+, Cs^+, and Ca^{2+} were measured as a function of the concentration and composition of external electrolyte solution. The respective components of the membrane cation concentrations are expressed in the unit of mol per kg of wet membrane sample in the reference conditions. Correlations of the membrane cation concentration with the membrane transport phenomena, such as the transmembrane potentials and ion fluxes, were examined systematically in the following part of this section.

C^m_{M,H_2O} and $C^m_{M,HCl}$ as a Function of the External Electrolyte Concentration. Figure 1 illustrates the Na^+ and Cs^+ concentrations within the CK-1, 1.0t membrane phase as a function of the external electrolyte concentration for the NaCl-CsCl systems, in which the concentration of NaCl or CsCl was varied from 10^{-1} to 10^{-3} mol dm^{-3} and that of the other electrolyte was kept constant at 10^{-2} mol dm^{-3}. As a result of the fact that 85—99% of Na^+ and more than 99% of Cs^+ were bound to the ion-exchange sites, the total site-bound cations, which should be constant and equivalent to the exchange capacity, came up to 98—99% of the total cations in the membrane phase, and accordingly Cl^- ions were almost perfectly excluded from the membrane phase. When the external NaCl and CsCl concentrations were the same, i.e., $C^s_{NaCl} = C^s_{CsCl} = 10^{-2}$ mol dm^{-3}, the concentration of the site-bound Cs^+ was as twice as that of the site-bound Na^+, so that $C^m_{Na,HCl}/C^m_{Cs,HCl} \cong 1/2$. Under the external condition, $C^s_{NaCl}/C^s_{CsCl} \cong 2.5$, the equivalent amounts of Na^+ and Cs^+ were bound to the ion-exchange sites, i.e., $C^m_{Na,HCl} = C^m_{Cs,HCl}$. The Donnan adsorbed cation component contained more Na^+ than Cs^+ in the external concentration range studied, for example, $C^m_{Na,H_2O}/C^m_{Cs,H_2O} \cong 1.4$ when $C^m_{NaCl} = C^s_{CsCl} = 10^{-2}$ mol dm^{-3} and $C^m_{Na,H_2O}/C^m_{Cs,H_2O} \cong 2$, when $C^s_{NaCl}/C^s_{CsCl} \cong 2.5$.

In case of the systems where Ca^{2+} permeates across the CK-1, 1.0t cation-exchange membrane, the membrane/solution distributions of Na^+ and Ca^+ were entirely different from those of Na^+ and Cs^+. Figure 2 summarizes the Donnan adsorbed and site-bound cation concentrations of Na^+ and Ca^{2+} for the

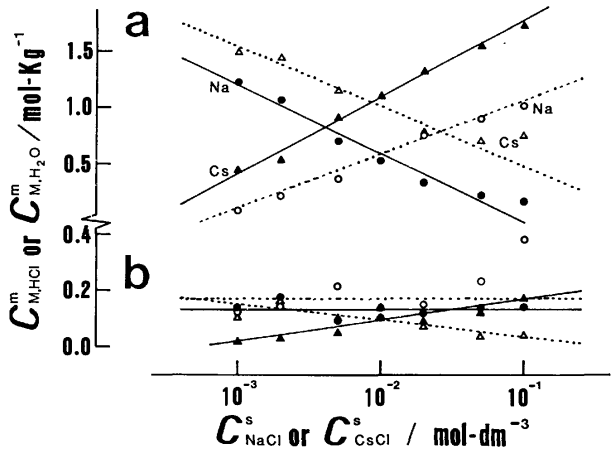

Fig. 1. Concentrations of the site-bound and Donnan adsorbed fractions of cations, Na^+ and Cs^+, in NaCl-CsCl systems. Concentrations within the membrane phase, $C^m_{M,HCl}$ and C^m_{M,H_2O}, as a function of the external electrolyte concentration, C^s_{NaCl} or C^s_{CsCl} equilibrated with the membrane phase. Upper frame a indicates $C^m_{M,HCl}$ and lower frame b indicates C^m_{M,H_2O}. ●: Na^+, ▲: Cs^+ in 10^{-2} mol dm^{-3} C^s_{NaCl} system. ○: Na^+, △: Cs^+ in 10^{-2} mol dm^{-3} C^s_{CsCl} system.

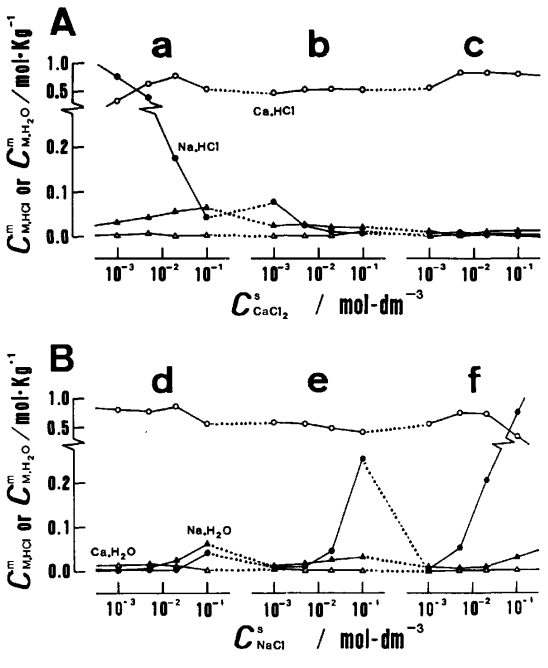

Fig. 2. Concentrations of the site-bound and Donnan adsorbed fractions of cations, Na^+ and Ca^{2+}, in NaCl-$CaCl_2$ systems. Concentrations within the membrane phase, $C^m_{M,HCl}$ and C^m_{M,H_2O}, as a function of the external electrolyte concentration, C^s_{NaCl} or $C^s_{CaCl_2}$. Constant C^s_{NaCl} system (A) and constant $C^s_{CaCl_2}$ system (B). C^s_{NaCl}, a: 10^{-1}; b: 10^{-2}; c: 10^{-3} mol dm^{-3}. $C^s_{CaCl_2}$, d: 10^{-1}; e: 10^{-2}; f: 10^{-3} mol dm^{-3}. ●: C^m_{NaHCl}, ○: $C^m_{Ca,HCl}$, ▲: C^m_{Na,H_2O}, △: C^m_{Ca,H_2O}.

NaCl–$CaCl_2$ systems, in which the external concentration of NaCl or $CaCl_2$ was varied from 10^{-1} to 10^{-3} mol dm^{-3} and that of the other electrolyte was kept constant at 10^{-1}, 10^{-2}, or 10^{-3} mol dm^{-3}. As can be seen in Fig. 2, the site-bound Ca^{2+} amounted to 97—99% of the total Ca^{2+} within the membrane phase keeps almost constant level. On the other hand, the site-bound Na^+ is varied from 15 to 96% of the total Na^+ in the membrane phase. In the external condition, $C^s_{NaCl}/C^s_{CaCl_2}<10$, the site-bound Ca^{2+} amounted to 80—98% of the total membrane cations. The concentrations of Donnan adsorbed Na^+ were 10 times larger than those of Ca^{2+}, when the external NaCl and $CaCl_2$ concentrations are the same, $C^s_{NaCl}=C^s_{CaCl_2}=$ 10^{-1}, 10^{-2}, or 10^{-3} mol dm^{-3}.

Membrane/Solution Distribution of Cations and Membrane Transport Phenomena. Quantitative and qualitative differences in the membrane/solution distribution of cations between the NaCl–CsCl and the NaCl–$CaCl_2$ systems cause characteristic and distinctive membrane transport phenomena in these systems. Figure 3 shows the correlations of the total cation concentration in the CK-1, 1.0t membrane (Fig. 3-C) with the membrane potential (Fig. 3-A) and inter-compartmental ion flux (Fig. 3-B) data for the NaCl–CsCl systems as a function of the external NaCl/CsCl concentration ratio. The total membrane concentrations of Na^+ and Cs^+, $C^m_{Na,Total}$ and $C^m_{Cs,Total}$, changed as the external Na^+ and Cs^+ concentrations, C^s_{NaCl} and C^s_{CsCl}, changed. $C^m_{Na,Total}$, was almost equal to $C^m_{Cs,Total}$ when $C^s_{NaCl}/C^s_{CsCl}=2.5$. These results indicate that the membrane affinities to Cs^+ are higher than those to Na^+. It is suggested that the higher membrane affinities to Cs^+ arise partly from accessibilities of Cs^+ to the fixed cation-exchange sites due to smaller hydrated radius of Cs^+ than that of Na^+. Under the external conditions where C^s_{NaCl}/C^s_{CsCl} ratios are lower than 1/10 or higher than 100, available exchange-sites were occupied by a large amount of Cs^+ or Na^+, respectively (see also Fig. 7-B).

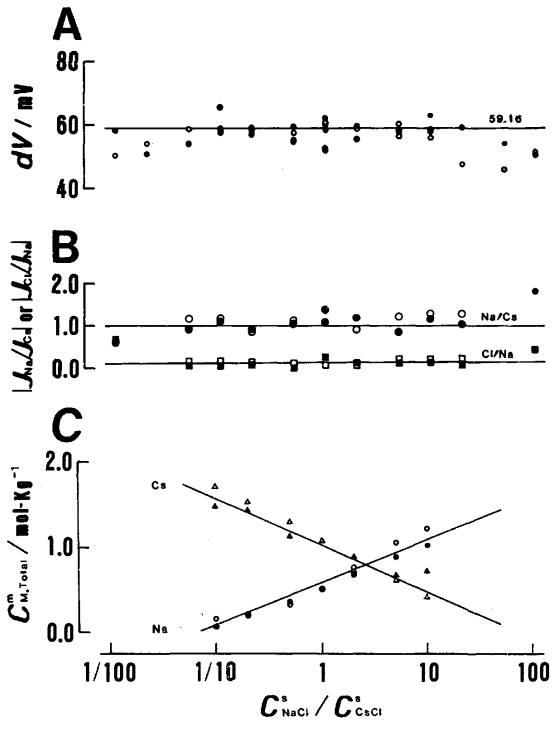

Fig. 3. Membrane potential gradient (for details see text), dV, inter-compartmental ionic flux ratio, $|J_{Na}/J_{Cs}|$ or $|J_{Cl}/J_{Na}|$, and total metal cation concentration within the membrane phase, $C^m_{Na,Total}$ or $C^m_{Cs,Total}$, as a function of external NaCl/CsCl concentration ratio, C^s_{NaCl}/C^s_{CsCl}. Closed and open marks indicate the constant C^s_{NaCl} and C^s_{CsCl} systems, respectively. These constant external electrolyte concentrations correspond to the constant electrolyte concentration in phase II separated from phase I by the membrane. In B, ● and ○: $|J_{Na}/J_{Cs}|$, ■ and □: $|J_{Cl}/J_{Na}|$. In C, ● and ○: $C^m_{Cs,Total}$, ▲ and △: $C^m_{Na,Total}$.

The transmembrane potential data are plotted as the gradient of the potential vs. logarithm of the mean electrolyte activity of phase I curve, dV ($=\Delta V/\Delta \log a^I_{M_1}$), in Fig. 3-A. It was suggested, on the basis of experimental results showing the almost perfect exclusion of Cl^- from the membrane phase, that the membrane process in the NaCl–CsCl system is controlled only by cations, Na^+ and Cs^+. In that case, the transmembrane potentials for the NaCl–CsCl systems are expected to be nearly equal to $V_{Na\text{-}Cs}$ and, accordingly, the estimated dV values should be close to 59.16 mV at 25 °C with the constant cationic permeability ratio, P_{Na}/P_{Cs}, as seen in Fig. 3-A (refer to Eq. 6). The inter-compartmental ion flux data also support these situations. As can be seen in Fig. 3-B, the Cl^- flux is suppressed at an extremely low level and the membrane transport process can be characterized by the Na^+ and Cs^+ fluxes in opposite directions with each other.

For the NaCl–$CaCl_2$ systems, the ideal uni- and bivalent cationic equilibrium potential, $V_{Na\text{-}Ca}$, is 39.44 mV at 25 °C as calculated from Eq. 6 with the constant P_{Na}/P_{Ca}. As can be seen in Fig. 4-A, the potential gradient dV values correspond to the ideal $V_{Na\text{-}Ca}$ values within the external electrolyte concentration range, $1/10<C^s_{NaCl}/C^s_{CaCl_2}<10$. However, the estimated dV values deviate positively or negatively in the external conditions where $C^s_{NaCl}/C^s_{CaCl_2}$ is higher than 10 or lower than 1/10, respectively. Corresponding to these transmembrane potential responses, the inter-compartmental ion fluxes varied in multiple modes. It is shown in Fig. 4-B that Cl^- flux is negligible in the range of $1/10<C^s_{NaCl}/C^s_{CaCl_2}<10$, so the Na^+ and Ca^{2+} fluxes flowing in opposite directions from each other control the transport processes across the CK-1, 1.0t cation-exchage membrane in the same manner as the above NaCl–CsCl systems are controlled only by Na^+ and Cs^+ fluxes. Out of this concentration range, the Na^+ and Cl^- fluxes increased with increasing relative concentration of external Na^+, whereas the Ca^{2+} and

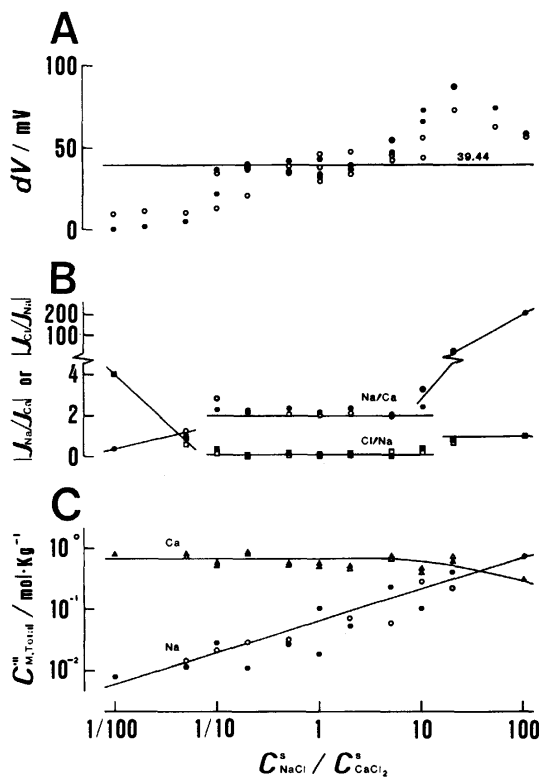

Fig. 4. Membrane potential gradient, dV, ionic flux ratio, $|J_{Na}/J_{Ca}|$ or $|J_{Cl}/J_{Na}|$, and total metal cation concentration within the membrane phase, $C^{m}_{Na,Total}$ or $C^{m}_{Ca,Total}$, as a function of the external NaCl/$CaCl_2$ concentration ratio, $C^{s}_{NaCl}/C^{s}_{CaCl_2}$. Closed and open marks indicate the constant C^{s}_{NaCl} and $C^{s}_{CaCl_2}$ systems, respectively. In B, ● and ○: $|J_{Na}/J_{Ca}|$, ■ and □: $|J_{Cl}/J_{Na}|$. In C, ● and ○: $C^{m}_{Na,Total}$, ▲ and △: $C^{m}_{Ca,Total}$.

Cl^- fluxes increased with decreasing Na^+ concentrations. It can be recognized that the ion transport processes of the NaCl-$CaCl_2$ system with a highly permselective cation-exchange membrane shift from the $CaCl_2$ transporting process ($J_{Ca}=(1/2)J_{Cl}$, $J_{Na}=0$), through the Na-Ca transporting process ($J_{Na}=-2J_{Ca}$, $J_{Cl}=0$), and finally to the NaCl transporting process ($J_{Na}=J_{Cl}$, $J_{Ca}=0$), as an increase in the relative Na^+ concentration of the external phase.

These membrane transport characteristics should be a reflex of the Na^+ and Ca^+ concentration profiles within the membrane phase plotted in Fig. 4-C. The total Ca^{2+} concentration in membrane, $C^{m}_{Ca,Total}$, was kept at high and constant level throughout the external concentration range studied, while the total Na^+ concentration within membrane, $C^{m}_{Na,Total}$, varied from a low level at 1/100 of $C^{m}_{Ca,Total}$ to high level comparable with $C^{m}_{Ca,Total}$, with the external Na^+ concentration change. In the limits of the $C^{m}_{Na,Total}/C^{m}_{Ca,Total}$ values from 1/20 ($C^{s}_{NaCl}/C^{s}_{CaCl_2}=1/10$) to 1/2 ($C^{s}_{NaCl}/C^{s}_{CaCl_2}=10$), the membrane process was controlled only by cations, Na^+ and Ca^{2+}. The Na^+ concentrations within the membrane phase increased with increasing external Na^+ concentrations, and finally reached at the same level as the membrane Ca^{2+} concentration when the external solution contained Na^+ in 30 times of Ca^{2+} concentration. The results given in Figs. 4-B and C suggest that, in the membrane utilizing techniques where the permeations of bivalent cation have to be avoided as far as possible, such as in the desalination process of sea water, the membrane concentration of bivalent cation should be kept, at least, not exceeding ca. 75% of the total membrane cations. Such a condition can be realized, in case of the CK-1, 1.0t cation-exchange membrane, by keeping the external bivalent cation concentrations at below 1/20 of the univalent cation concentrations.

Membrane/Solution Distribution of Cations and Membrane Transport Parameters. The ion concentration profiles within charged membrane phase, as an origin of the generation of a variety of the membrane transport phenomena, were discussed further in terms of the membrane transport parameters. As pointed out already, the NaCl-CsCl system with the CK-1, 1.0t membrane can be characterized as a cationic equilibrium system, in which the oppositely running Na^+ and Cs^+ fluxes with almost the same magnitudes were observed. And, accordingly the membrane potential responses are recognized as an ideal equilibrium potential for Na^+ and Cs^+ showing the linear relationships against the logarithmic external activity, $\log a^{I}_{M_I}$, with the slope of 59.16 mV predicted from Eq. 6. In these situations, the P_{Na}/P_{Cs} values calculated based on the electrochemical data are almost constant at 0.72 corresponding with the ideal value calculated based on Eq. 6 as shown in Fig. 5-A. A slight deviation of P_{Na}/P_{Cs} values from the ideal value was observed: the substantial negative and positive deviations were recognized in the higher and lower $C^{s}_{NaCl}/C^{s}_{CsCl}$ regions, respectively, where the gradient of the membrane potential vs. logarithmic activity curves decreases similarly as illustrated in Fig. 3-A. These results were caused partly from the Cl^- transport across the membrane at quite low levels.

On the other hand, the Cl^- transport process was involved considerably in the ion transport phenomena across the CK-1, 1.0t membrane for the NaCl-$CaCl_2$ system as discussed above. In Fig. 5-B1, the P_{Na}/P_{Ca} values estimated from the electrochemical data are plotted and compared with those, indicated by the solid curve, evaluated from Eq. 6 providing that the observed transmembrane potentials correspond to the cationic equilibrium potential $V_{Na\text{-}Ca}$. For the potential responses illustrated in Fig. 4-A, the P_{Na}/P_{Ca} values, calculated from Eq. 6 with the condition of $P_{Cl}=0$, no longer give a constant value for the whole concentration ranges studied. When the system was characterized by only the cation transport process, the constant P_{Na}/P_{Ca} values were obtained as in the NaCl-CsCl system. As can be seen in Fig. 5-B1, a large positive deviation of the P_{Na}/P_{Ca} values from those evaluated by Eq. 6 are observed in the system with high $C^{s}_{NaCl}/C^{s}_{CaCl_2}$ ratio,

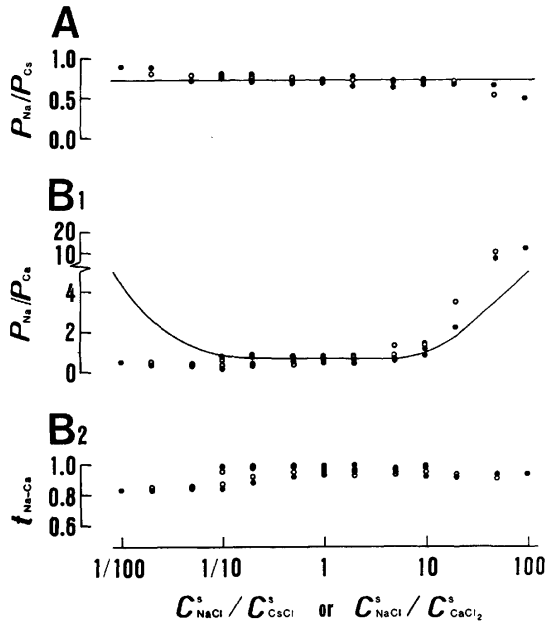

Fig. 5. Membrane permeability ratios, P_{Na}/P_{Cs} (A) and P_{Na}/P_{Ca} (B1), and transport number to whole cation, $t_{Na\text{-}Ca}$ (B2), as a function of the external NaCl/CsCl or NaCl/$CaCl_2$ concentration ratio, C^s_{NaCl}/C^s_{CsCl} or $C^s_{NaCl}/C^s_{CaCl_2}$. Closed marks indicate the constant C^s_{NaCl} system and open marks indicates the constant C^s_{CsCl} (A) or constant $C^s_{CaCl_2}$ (B1 and 2) systems.

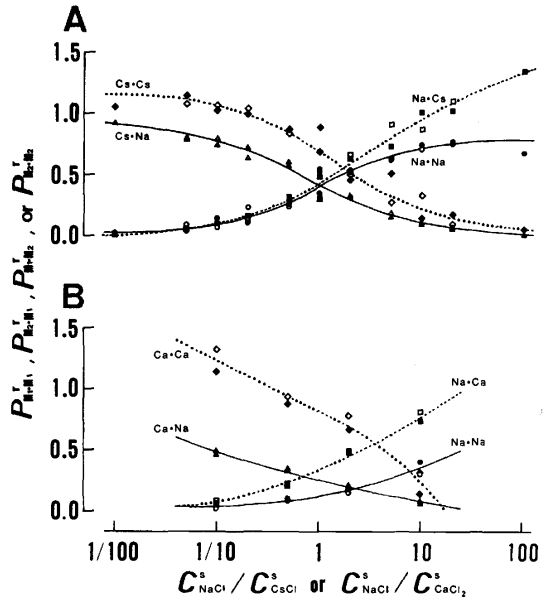

Fig. 6. Membrane permeability matrix elements as a function of the external electrolyte concentration ratio, C^s_{NaCl}/C^s_{CsCl} or $C^s_{NaCl}/C^s_{CaCl_2}$. Closed marks indicate the constant C^s_{NaCl} system and open marks indicate the constant C^s_{CsCl} (A) or constant $C^s_{CaCl_2}$ (B) systems. ● and ○: $P^r_{M_1\cdot M_1}$ ▲ and △: $P^r_{M_2\cdot M_1}$, and ■: and □ $P^r_{M_1\cdot M_2}$, ◆ and ◇: $P^r_{M_2\cdot M_2}$.

where the transport process can be characterized by the NaCl transport with small Ca^{2+} flux. On the other hand, in the low $C^s_{NaCl}/C^s_{CaCl_2}$ systems where the transport process can be characterized by the $CaCl_2$ transport with small Na^+ flux, the P_{Na}/P_{Ca} values kept at relatively constant level and a large negative deviation from the values based on Eq. 6 was observed. To examine further the influence of Cl^- permeation on the transport process across a cation-exchange membrane, the transport number to whole cation, Na^+ and Ca^+, $t_{Na\text{-}Ca}$, relative to t_{Cl} was evaluated in the NaCl-$CaCl_2$ systems. As shown in Fig. 5-B2, the $t_{Na\text{-}Ca}$ values decrease in these systems and there is a substantial effect of Cl^- transport on the cation transport.

When the membrane transport processes are controlled only by two cationic species, M_1 and M_2, the 3×3 membrane permeability matrix in Eq. 1 can be reduced to the 2×2 matrix describing the partial contributions of the inter-cationic correlations on the membrane process.[4,5] Figure 6 summarizes the elements of the 2×2 membrane permeability matrix for the NaCl-CsCl and NaCl-$CaCl_2$ systems estimated from the electrochemical and inter-compartmental ion flux data with the nonequilibrium thermodynamic relations discussed earlier. For the NaCl-$CaCl_2$ system, the permeability matrix element calculations were available only for the system in which Cl^- flux is negligible. In Fig. 6, the permeability matrix elements are plotted as a relative value against the membrane permeability to whole cation, $P_{M_1\text{-}M_2}$, as:

$$P^r_{M_1\cdot M_1} = P_{M_1\cdot M_1}/P_{M_1\text{-}M_2},\quad P^r_{M_1\cdot M_2} = P_{M_1\cdot M_2}/P_{M_1\text{-}M_2} \qquad (10)$$
$$P^r_{M_2\cdot M_1} = P_{M_2\cdot M_1}/P_{M_1\text{-}M_2},\quad P^r_{M_2\cdot M_2} = P_{M_2\cdot M_2}/P_{M_1\text{-}M_2}$$

Magnitudes of the membrane permeability matrix element driven by the electrochemical activity difference of some cations (see Eq. 1) increased with increasing relative concentration of those cations. The membrane permeability matrix representations including the Cl^- relating components were discussed in earlier papers of this series for the NaCl-$CaCl_2$ systems.[5]

Membrane/Solution Distribution and Diffusion of Cations within Membrane Phase. It has been an established concept based on the theoretical and experimental investigations of the membrane transport phenomena that the ion permselectivity of a charged membrane can be determined as a function of the migration speed of ions within the membrane phase and of the membrane/solution distribution coefficient of permeating ions. As a conclusion of the present experiments, the diffusion coefficient ratio of cations, $D^m_{M_1}/D^m_{M_2}$, and the cation concentration ratio, $C^m_{M_1,Total}/C^m_{M_2,Total}$, in the CK-1, 1.0t membrane phase are examined as a function of the external electrolyte concentration ratio, $C^s_{M_1Cl_1}/C^s_{M_2Cl_2}$. The results are summarized in Fig. 7. These two quantities are

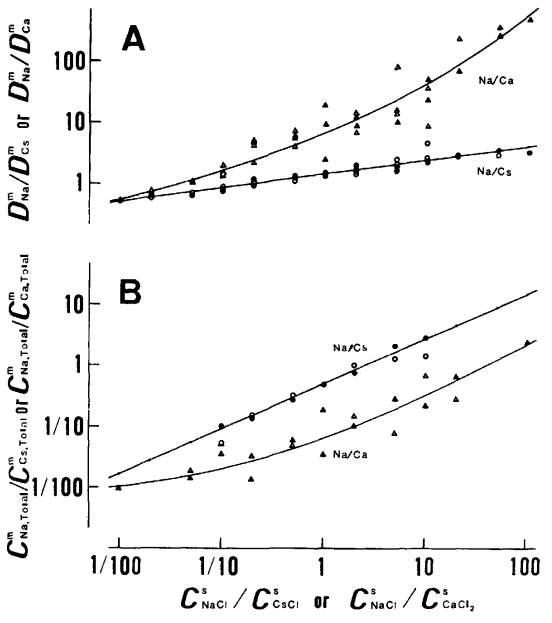

Fig. 7. Diffusivity ratio (A), D^m_{Na}/D^m_{Cs} or D^m_{Na}/D^m_{Ca}, and total cation concentration ratio (B), $C^m_{Na,Total}/C^m_{Cs,Total}$ or $C^m_{Na,Total}/C^m_{Ca,Total}$, within the membrane phase as a function of the external concentration ratio, C^s_{NaCl}/C^s_{CsCl} or $C^s_{NaCl}/C^s_{CaCl_2}$. Closed marks indicate the constant C^s_{NaCl} system and open marks indicate the constant C^s_{CsCl} or C^s_{CaCl} systems. ● and ○ refer to Na/Cs ratios, and, ▲ and △ refer to Na/Ca ratios.

important as a controlling factor to the membrane permselectivity in the multi-ionic systems. In case of the NaCl-CsCl system, in which all the permeating cations are univalent, the Na/Cs diffusivity ratio within the membrane phase was kept at an almost constant level, whereas the Na/Cs concentration ratio changed considerably corresponding with the changes in external Na/Cs concentration ratio. When bivalent cations were introduced as permeating species as in the NaCl-$CaCl_2$ system, the Na/Ca diffusivity ratio varied considerably, from 0.5 to 500, as compared with that of the NaCl-CsCl system. As mentioned before, at the upper or lower limilts of the Na/Ca diffusivity ratios, the systems were characterized by the NaCl or $CaCl_2$ transport process. Changes in the Na/Ca membrane concentration ratio within the membrane phase, on the other hand, were depressed to the limits not exceeding 100 times against the 10000 times changes in the external Na/Ca concentration ratio, from 1/100 to 100.

In the multi-ionic system with a highly permselective ion exchange membrane, the membrane transport process can be characterized as a function of the external electrolyte composition when the charges of counterions are the same. When the system contains the counterions with different charges, the membrane transport process tends to be controlled by the counterions with higher charges based on the monopolistic occupation of the available ion-exchange sites of membrane with multivalent counterions.

The authors wish to thank Asahi Chemical Industry Co., Ltd. for providing the ion-exchange membrane, CK-1, 1.0t, used in the present investigation. One of the authors (K. K.) is grateful to the Ministry of Education, Science and Culture for a Grant-in-Aid for Scientific Research on Priority Areas and to the Kurata Foundation for the research grant support.

(Received December 21, 1988)

The effects of the substituents in the Schiff-base *N*-salicylidene-*o*-aminophenol (SOAP) on the fluorescence of its aluminum complexes were investigated. *N,N'*-Disalicylideneethylenediamine (DSED) derivatives were used as aldehyde reagents for the condensation to prepare 25 different SOAP compounds, for these reagents can be conveniently hydrolyzed to yield salicylaldehyde derivatives. *o*-Aminophenol (OAP) derivatives were used as amine reagents for the SOAP compounds. A methoxyl group at the 4-position of the benzylidene group in the Schiff base and a sulfo group at the 5-position in the amine component increased the fluorescence intensity of the complex. The relationship between the fluorescence intensity and the structure of the complex was investigated by the Free-Wilson method of estimation, and good agreements were obtained between the experimental and the calculated values of the fluorescence intensities. The fluorometric determination procedure of aluminum was established by using 4,4'-dimethyl DSED and 4-sulfo OAP. Aluminum can be accurately determined in the range from 0.001 to 3 μg/25 ml under optimum conditions.

N-Salicylidene-*o*-aminophenol (SOAP) is an excellent fluorometric reagent for aluminum, gallium, and beryllium.[1-6] Derivatives of SOAP may have even better sensitivities than the parent compound. Several substituted SOAP have been examined in connection with the fluorometric determination of aluminum. Some SOAP derivatives, which have only one substituent group in the aldehyde or amine component, have been described in previous studies.[2-4] Only a few studies involving SOAP with two or more substituent groups have been performed,[7] however, except with alkyl derivatives.[5]

In the case of 2,2'-dihydroxyazobenzene, which has a structure analogous to the SOAP structure, some derivatives with two or three substituents have been synthesized, and several derivatives, such as Superchrome Garnet Y and Lumogallion, have been found to be excellent fluorometric reagents.[8-11] In the present paper, the fluorescence properties of aluminum complexes with 25 SOAP derivatives including several combinations of various substituent groups were systematically examined in order to establish the lower detection limits for the fluorometric determination of aluminum. The relationship between the fluorescence intensities and the structures of the aluminum complexes has been explained by means of the Free-Wilson method of estimation.[12] Furthermore, the fluorometric determination of aluminum has been established by using the most sensitive reagent, which is superior to the conventional one, *N*-salicylidene-2-aminophenol-4-sulfonic acid.[2]

Experimental

Apparatus. The fluorescence spectra and the intensity were measured with a Hitachi Model 204 fluorescence spectrophotometer fitted with a 150 W Xenon lamp. The absorption spectra were measured with a Shimadzu Model UV-200S double-beam spectrophotometer. A Toa pH Meter, Model HM-20E, was used for the pH measurements.

Reagents. Standard Solution of Aluminum: A stock solution of aluminum was prepared by dissolving 0.5038 g of aluminum (99.99%) with 20 ml of concentrated hydrochloric acid and then diluting the solution to 500 ml with water. The standard solution was prepared by suitable dilution with 0.1 M hydrochloric acid (1 M=1 mol dm^{-3}) from the stock solution.

***N,N'*-Disalicylideneethylenediamine (DSED) and Its Derivatives:** DSED and its derivatives were synthesized by the condensation of salicylaldehyde and its derivatives with ethylenediamine[8] and then characterized by means of elemental analysis, their melting points, and their IR spectra. These compounds were dissolved in *N,N*-dimethylformamide (DMF). The aldehydes, which were not commercially available, were prepared by the Duff reaction.[13]

***o*-Aminophenol (OAP) and Its Derivatives:** OAP (Wako Pure Chemical Industries, Ltd.) and its derivatives (Tokyo Kasei Kogyo Co., Ltd.) were purified by the method of Charles and Freiser.[14] These compounds were then dissolved in 0.1 M ammonia or DMF, containing ascorbic acid (6.0×10^{-2} M). These solutions are subject to oxidation, but were sufficiently stable for use over a period of 8 hours.

***N*-(2-Hydroxy-4-methylbenzylidene)-2-aminophenol-4-sulfonic Acid:** This compound was synthesized by the condensation of 2-hydroxy-4-methylbenzaldehyde with 2-aminophenol-4-sulfonic acid by the method of Freeman and White.[8] The product thus obtained was purified by repeated recrystallizations from ethanol containing activated charcoal.

Uranine Standard Solution: 0.1 g of uranine (Wako Pure Chemical Industries, Ltd.) was dissolved in 100 ml of water, after which the solution was diluted appropriately with

water to give solutions containing (5.0×10^{-2}—1.0) μg ml^{-1}. These solutions were employed as reference standards of the fluorescence in adjusting the sensitivity of the instrument.

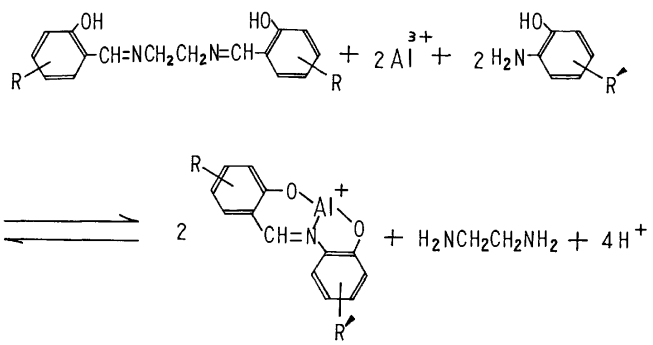
All the other reagents used were special-grade or equivalent.

General Procedure. To a sample solution containing an appropriate amount of aluminum ions, add 1 ml of a DSED-derivatives solution, 1 ml of an OAP-derivatives solution, and 1 ml of a 20% ammonium acetate solution. Adjust the pH to the required value with a diluted hydrochloric acid or an ammonia solution; then dilute the solution to 25 ml with water. After mixing thoroughly, warm the solution at 50 °C for 10 min and then cool to room temperature. Measure the fluorescence intensity at the optimum excitation and emission wavelengths, using an uranine solution as the reference standard.

As has been described by Yamamoto et al.,[15] the correction of the experimental fluorescence intensity for variations in photomultiplier response and the source intensity with the wavelength were not performed because the maximum excitation and emission wavelengths of this series of the complexes lay within a narrow region. The excitation and emission spectra and the maximum wavelengths of the complexes were the corrected values in the present paper.[16]

Results and Discussion

Formation of an Aluminum-Schiff Base Complex. According to the general procedure, DSED was hydrolyzed in an aqueous solution to liberate salicylaldehyde (SAL), which then reacted with aluminum and OAP to form a fluorescent Schiff-base complex (Scheme 1). Such a reaction had previously been utilized for the fluorometric determination of beryllium,[17] zinc,[18] aluminum,[19] and magnesium.[20] Although the same complex is formed when SOAP is used instead of DSED and OAP, the procedure in this study has the advantage that the most suitable concentrations of SAL and OAP can be selected in order to obtain the optimum fluorescence conditions, and so the fluorescence intensity of the reagent blank can be decreased.



Scheme 1.

In all cases, the fluorescence intensity of the aluminum complex required 80 min to reach its maximum at 20 °C, but readily reached its maximum intensity at 50 °C within 5 min. The fluorescence intensity is stable for at least 2 h.

The absorption spectra of the reagents alone indicated that a free Schiff base was not formed under the optimum conditions for the formation of the aluminum complex. This suggests a mechanism for this formation of the aluminum-Schiff base complex in which SAL and OAP first coordinate to the aluminum ion, thus forming a ternary chelate compound, this compound is then transformed into a Schiff-base complex by the kinetic template mechanism.[19-22]

The molar ratio of aluminum to ligand in the complex was determined fluorometrically by the continuous-variation method. The results indicate that the metal-ligand ratio is 1:1.

Fluorescence Properties of Aluminum-Schiff Base Complexes. The fluorescence properties of aluminum complexes with 25 SOAP derivatives were examined. Their fluorescence characteristics, as obtained under the optimum conditions, are summarized in Table 1.

Aluminum formed fluorescent complexes with a Schiff base in a weakly acidic solution. The optimum pH's for the fluorescence intensity were near pH 5. The optimum concentrations of DSED derivatives and OAP derivatives were about 1.5×10^{-4} M and ($2-5)\times10^{-4}$ M respectively in the final solution. The excitation and emission maxima of aluminum complexes occur at wavelengths of 395—420 nm and 485—535 nm respectively. Some typical excitation and emission spectra of aluminum complexes are shown in Fig. 2.

The fluorescence intensities of the aluminum complexes were markedly changed by the substituent groups on the Schiff base. A methoxyl group at the 4-position of the benzylidene group in the Schiff base (No. **3** in Table 1) and a sulfo group at the 5-position in the amine component (No. **9**) increased the fluorescence intensity of the complexes. These results were consistent with those reported by Morishige.[5] However, the combination of a methyl or a methoxyl group at the 4-position in the aldehyde component and a sulfo group at the 5-position in the amine component (No. **16** or **19**) further increased the fluorescence intensity. The fluorescence enhancement upon the introduction of these substituent groups was due to the increase in the molar absorptivity and the fluorescence quantum yield of its aluminum complex, as will be described below.

The relationship between the fluorescence intensity and the structure of the complex was investigated by means of the Free-Wilson method of estimation, which has been known as a mathematical technique describing the structure-biological activity relationships of a series of chemical analogs.[12] The mathematical model used is based upon the assump-

a) Al(III): 0.25 μg/25 ml (3.7×10^{-7} M). b) 70 div. vs. 0.5 μg ml^{-1} uranine (setting 405 nm/500 nm). c) Corrected value.

tion that the fluorescence intensity [I] in a series of analogs can be given as the sum of the "overall average" values (μ) and the contribution of each substituent [R]; i.e.,

$$\mu + \Sigma[R] = [I] \quad (1)$$

where [R] is the specific value determined by a substituent group at a certain position. Furthermore, the sum of [R] at each position is restricted to zero in this model; i.e.,

$$\Sigma[R] = 0 \quad \text{(at each position)}. \quad (2)$$

The application of this method of estimation to the fluorescence intensities of aluminum complexes of 9 SOAP derivatives, which have substituent groups at the 5-position on the benzylidene group in each component of the Schiff base, has been investigated by Yamamoto et al.[15] They reported that this method could be applied to that series of Schiff bases.

This method was applied to the experimental fluorescence intensities of a total of 25 aluminum complexes in our study. The μ and [R] values were calculated by means of multiple regression analysis using a computer. Then the calculated values were substituted into Eq. 1; the fluorescence intensity of each complex was thus obtained. The results are presented as the correlation of the calculated values with the experimental values of the fluorescence intensities in Fig. 1 (Key, O). Good agreements were obtained between these two values, with the relation of $y=1.00x+0.021$ and a correlation coefficient of 0.940. These results indicated that this method could also be applied to the series of Schiff bases which have substituent groups at the 4- and 5-positions in each component.

Moreover, the μ and [R] values were calculated by using the experimental values of 11 kinds of complexes which have only one substituent group in either the aldehyde or amine component of the Schiff base (μ;50.2, $[H]_{R^4}$;−5.4, $[CH_3]_{R^4}$;7.3, $[OCH_3]_{R^4}$;25.8, $[OH]_{R^4}$;4.8, $[H]_{R^5}$;2.1, $[CH_3]_{R^5}$;12.3, $[OH]_{R^5}$;−29.2, $[H]_{R^{4'}}$;−1.4, $[CH_3]_{R^{4'}}$;12.3, $[H]_{R^{5'}}$;−6.8, $[SO_3H]_{R^{5'}}$;47.9, $[COOH]_{R^{5'}}$;21.4, $[Cl]_{R^{5'}}$;−22.1). The fluorescence intensities of the complexes which have a combination of two substit-

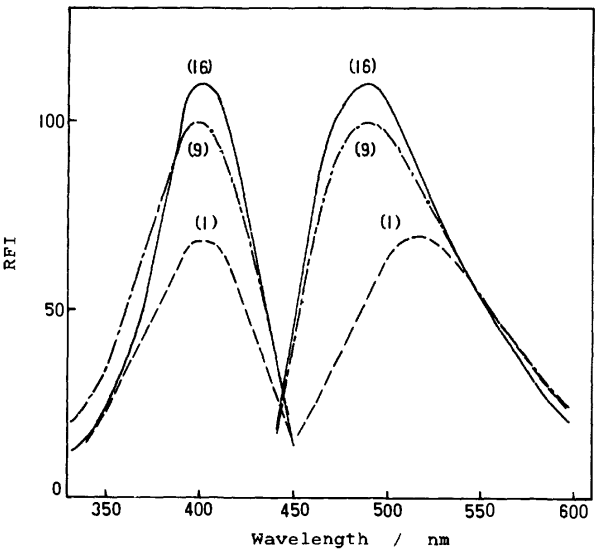

Fig. 2. Corrected excitation and emission spectra of aluminum complexes with Schiff bases; (1) SOAP (*N*-salicylidene-*o*-aminophenol), (9) *N*-salicylidene-2-aminophenol-4-sulfonic acid, (16) *N*-(2-hydroxy-4-methylbenzylidene)-2-aminophenol-4-sulfonic acid. Conditions for (1), (9), and (16); reference to Table 1.

uent groups were estimated by the use of the μ and [R] values obtained. As is shown in Fig. 1 (Key, Δ), a linear relationship was observed between the estimated and the experimental values, with the relation of $y=0.771x+20.1$ and a correlation coefficient of 0.917, except for the complexes which have a hydroxyl group at the 4-position in the amine component of the Schiff base (Nos. **12**, **13**, and **15**). These results suggest that, if the fluorescence intensities of several compounds among these series of Schiff base are experimentally measured, a better structure for the fluorometric reagent can be predicted by means of this method of estimation. In general, the combination of two substituent groups, both of which increase the fluorescence intensity, will provide a much stronger fluorescence. On the other hand, the combination of substituent groups, one of which increases the fluorescence intensity, while the other decreases it, will cause their properties to cancel each other out. The exception of the hydroxyl group at the 4-position in the amine component suggests that this group interacts with a substituent group in the aldehyde component to contribute to the fluorescence intensity.

The molar absorptivity (ε), the fluorescence quantum yield (ϕ_f), and the fluorescence sensitivity index (FSI) of the aluminum-SOAP complex (No. **1**) have been reported by Morishige (ε=20400, ϕ_f=0.205, and FSI=0.309).[4] The substitution of a sulfo group at the 5-position in the amine component (No. **9**) caused a remarkable increment in ϕ_f (0.802) and a slight decrement of ε (14100), so that FSI was raised to 0.653.[4] In this study a much higher FSI (0.766) was achieved by the combination of a methyl group and a sulfo group (No. **16**), where ϕ_f and ε were 0.810 and 18100 respectively.

Fluorometric Determination of Aluminum

Procedure I. The combination of *N,N'*-bis(4-methylsalicylidene)ethylenediamine [4,4'-dimethyl DSED] and 2-aminophenol-4-sulfonic acid [4-sulfo OAP], which form Complex No. **16** (in Table 1), was the most suitable reagent for the fluorometric determination of aluminum because of its high sensitivity and its reproducibility, with a low blank value. The analytical conditions were, therefore, investigated further.

The excitation and emission spectra of the aluminum complexes of these reagents are shown in Fig. 2. The optimum excitation and emission wavelengths are 400 (uncorrected value: 410) nm and 490 (480) nm respectively.

The effect of the pH on the fluorescence intensity is indicated in Fig. 3. The aluminum complex showed maximum fluorescence in the pH region of 5.1—5.5.

Figure 4 shows the effect of the concentration of the reagent at the optimum pH. The maximum fluorescence intensity was achieved with 1.4×10^{-4} M of 4,4'-dimethyl DSED and 3.2×10^{-4} M of 4-sulfo OAP in the final solution. These concentrations correspond to the addition of 1 ml of 0.1% 4,4'-dimethyl DSED and 1 ml of 0.15% 4-sulfo OAP in a 25-ml solution for the determination of aluminum.

0.1% 4,4'-dimethyl DSED dissolved in DMF was stable for over one month. 0.15% 4-sulfo OAP in a

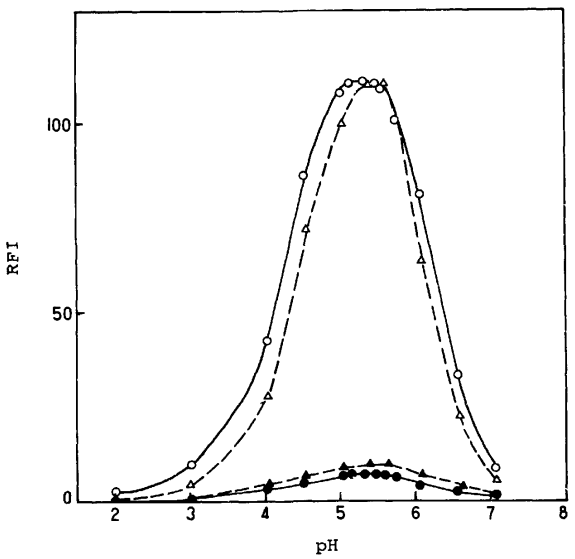

Fig. 3. Effect of pH on fluorescence intensity. Al(III): 0.25 μg/25 ml (3.7×10^{-7} M), Wavelength: 400 nm/490 nm, 70 div. vs. 0.5 μg ml^{-1} uranine (setting 405 nm/500 nm), Reagent: O; 4,4′-dimethyl DSED (1.4×10^{-4} M)+4-sulfo OAP (3.2×10^{-4} M): Δ; *N*-(2-hydroxy-4-methylbenzylidene)-2-aminophenol-4-sulfonic acid (4.8×10^{-4} M): ●; reagent blank of O: ▲; reagent blank of Δ.

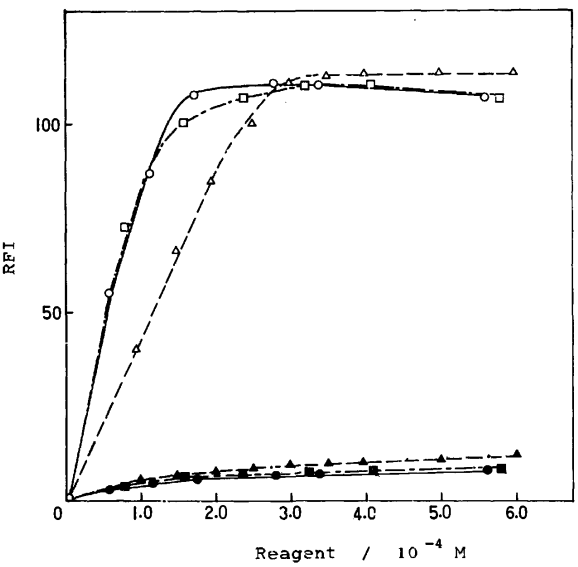

Fig. 4. Effect of concentration of 4,4′-dimethyl DSED (O), 4-sulfo OAP (□) and *N*-(2-hydroxy-4-methylbenzylidene)-2-aminophenol-4-sulfonic acid (Δ) on fluorescence intensity. Al(III): 0.25 μg/25 ml (3.7×10^{-7} M), pH: 5.3, Wavelength: 400 nm/490 nm, 70 div. vs. 0.5 μg ml^{-1} uranine (setting 405 nm/500 nm), O: containing 4-sulfo OAP (3.2×10^{-4} M): □: containing 4,4′-dimethyl DSED (1.4×10^{-4} M), ●: reagent blank of O: ■: reagent blank of □, ▲: reagent blank of Δ.

0.1 M ammonia solution containing ascorbic acid (6.0×10^{-2} M) was stable for use over a period of 24 h, while this solution without ascorbic acid was subject to oxidation and exhibited a brown color. This solution should, therefore, be made up daily.

According to the general procedure, aluminum can be determined in the range from 0.001 to 3 μg/25 ml with a relative error of 3% under optimum conditions, as has been described above.

The effects of diverse ions were also studied. The following cations in 100-fold excesses did not interfere with the determination of aluminum: silver(I), arsenic(III), barium(II), boron(III), cadmium(II), calcium(II), magnesium(II), manganese(II), mercury(II), molybdenum(VI), thallium(I), and zinc(II). Cobalt(II), chromium(VI), copper(II), indium(III), iron(II), iron(III), and nickel(II) caused negative errors in 10-fold excesses. Beryllium(II) and gallium(III) in 10-fold excesses did not interfere at all.

Procedure II. As has been mentioned, the same complex is formed by using only the Schiff base [i.e., *N*-(2-hydroxy-4-methylbenzylidene)-2-aminophenol-4-sulfonic acid] instead of those two components. Another procedure was also investigated by using the Schiff base as a fluorometric reagent, because the Schiff base in a DMF solution is more stable than 4-sulfo OAP.

The excitation and emission spectra, and the optimum wavelengths of the aluminum complex with this reagent, were just the same as those obtained by Procedure I.

The effect of the pH on the fluorescence intensity is indicated in Fig. 3. The aluminum complex showed its maximum fluorescence at pH 5.3—5.5.

Various amounts of a 0.075% (2.4×10^{-3} M) Schiff-base solution were added to a solution containing 0.25 μg of aluminum, after which the fluorescence intensity was measured at the optimum pH. As is shown in Fig. 4, 4.8×10^{-4} M is adequate. This concentration is equivalent to the addition of 5 ml of a 0.075% reagent solution in 25 ml for the procedure of determining aluminum. The 0.075% reagent solution is stable for over one month.

Aluminum can be determined in the same range as in Procedure I, i.e., from 0.001 to 3 μg/25 ml.

The authors are very grateful to Dr. Yoshimoto Abe, Faculty of Science and Technology, Science University of Tokyo, for his helpful discussions.

A Resonance Raman Study of Polymeric Thiolato Cobalt(III) Complexes: Possible Bridging Modes

Kan KANAMORI,* Sonomi INO, Yumiko MIZUNO, Isao KANESAKA, Kiyoyasu KAWAI, and Jinsai HIDAKA†
Department of Chemistry, Faculty of Science, Toyama University, Gofuku, Toyama 930
†Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received January 13, 1989)

The resonance Raman spectra of polymeric $Co^{III}\{SCH_2CH(NH_2)COOH\text{-}S\}_3$ and $Na_3Co^{III}(SCH_2COO\text{-}S)_3$ complexes were investigated. The complexes gave two totally symmetric Co–S stretchings, indicating the presence of two different Co–S–Co bridging modes in the complexes. Possible bridging modes are discussed in relation to their structures.

Schubert[1] first obtained the red H_3Co(cysteinato)$_3$ complex, which is insoluble in acids and water, but soluble in alkali to give cherry-red solutions. Neville and Gorin[2] and Gorin and Spessard[3] proposed that, in this complex, both thiolato and carboxylato groups are coordinated to cobalt(III). However, when the complex was reinvestigated by McCormick and Gorin,[4] they concluded, on the basis of the infrared spectra, that the complex is polymeric and consists only of thiolate bridges. Similar polymeric complexes have been prepared with hexanethiol,[4] 3-mercaptopropionate,[4] 2-mercaptoethanol,[5] mercaptoacetate,[6] and ethyl mercaptoacetate.[6] However, no difinitive data have been reported so far concerning the bridging mode in the polymeric thiolato complexes. We here wish to present the first report on the bridging mode of the polymeric thiolato cobalt(III) complexes, as studied by means of the resonance Raman spectra.

Experimental

Preparation. The polymeric complexes, $Co\{SCH_2CH(NH_2)COOH\text{-}S\}_3$[1] and $Na_3Co(SCH_2COO\text{-}S)_3$,[6] and the trinuclear complex, $K_3[Co\{Co(SCH_2CH(NH_2)COO\text{-}N,S)_3\}_2]$,[7] were prepared according to the methods in the literature and were identified by means of their electronic-absorption spectra.

Measurements. The samples used for Raman measurements were in the form of aqueous solutions or disks. The disks were spun to avoid thermal decomposition induced by laser illumination. The Raman spectra were recorded on a JASCO R-800 laser Raman spectrophotometer. Excitation profiles were obtained by using the laser lines of a Spectra Physics 164 Ar^+ laser (514.5, 501.7, 496.5, 488.0, 476.5, 465.8, and 457.9 nm) and of a Coherent Radiation model CR599 dye laser employing Rhodamine 6G dye (610.0, 588.0, and 567.8 nm). The laser power was below 100 mW for solid samples. The spectral band width was set at 5 cm^{-1}. The Raman intensities were measured relative to the totally symmetric S–O stretching mode of the potassium sulfate incorporated in the sample. Corrections of the observed intensity were applied to the fourth power of the wavenumber of scattered radiation and the instrumental response. The intensities were averaged over more than three measurements.

Results and Discussion

Raman Spectra. A polymeric complex, $Co(SCH_2CH(NH_2)COOH\text{-}S)_3$, gives very intense Raman bands in the 200—500 cm^{-1} region and some very weak bands in the 600—1000 cm^{-1} region in the solid state with 488.0-nm excitation. An alkaline solution of the complex gives essentially the same spectrum as that obtained in the solid state, indicating that the polymeric structure is retained also in the solution. Figure 1 shows the polarized resonance Raman spectra in the 200—500 cm^{-1} region of the complex in a 0.1 mol dm^{-3} NaOH solution. The depolarization ratios of the 406-, 341-, 280-, and 220-cm^{-1} bands are all near to 1/3; ρ=0.34, 0.33, 0.31, and 0.32 respectively. Thus, all these bands can reasonably be assigned to totally symmetric

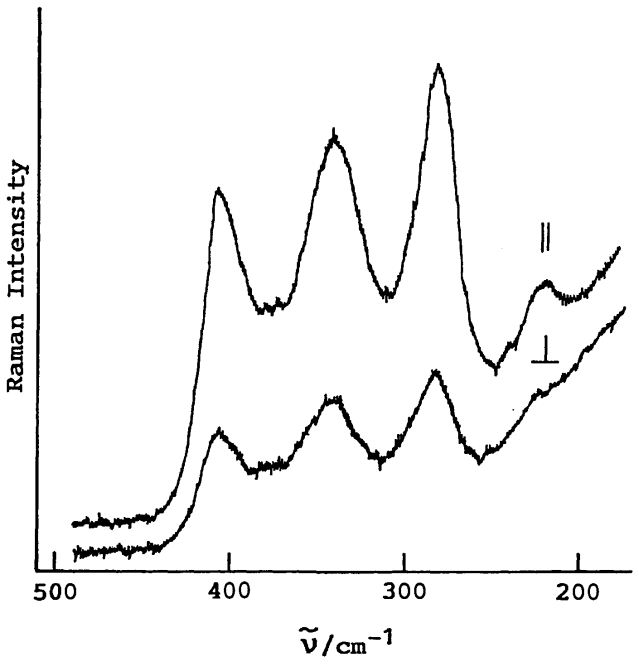

Fig. 1. Polarized resonance Raman spectra of polymeric tris(cysteinato-*S*)cobalt(III) in 0.1 mol dm^{-3} NaOH solution with 488.0-nm excitation (500 mW).

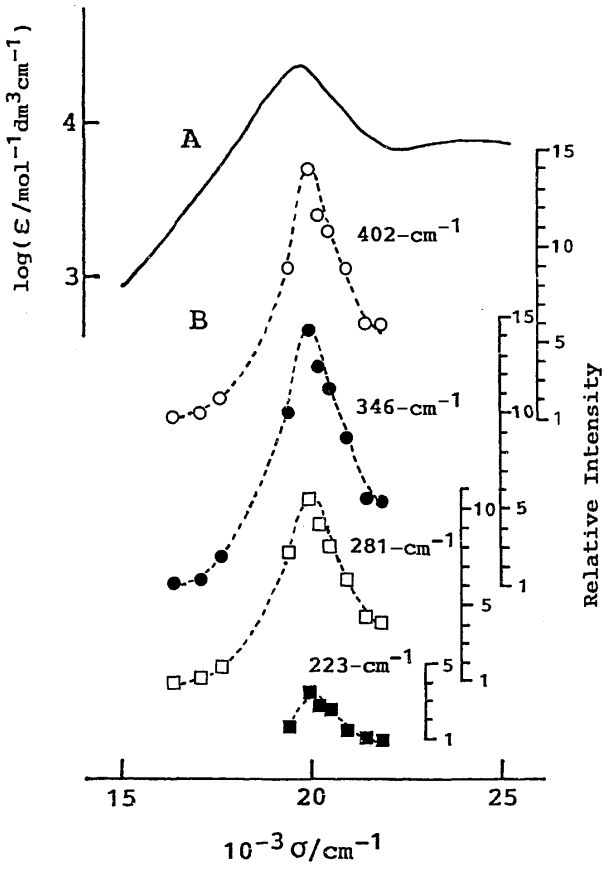

Fig. 2. Electronic absorption spectrum of polymeric tris(cysteinato-*S*)cobalt(III) in 0.1 mol dm^{-3} NaOH solution and the excitation profiles of the 402-, 346-, 281-, and 223-cm^{-1} bands in the solid state.

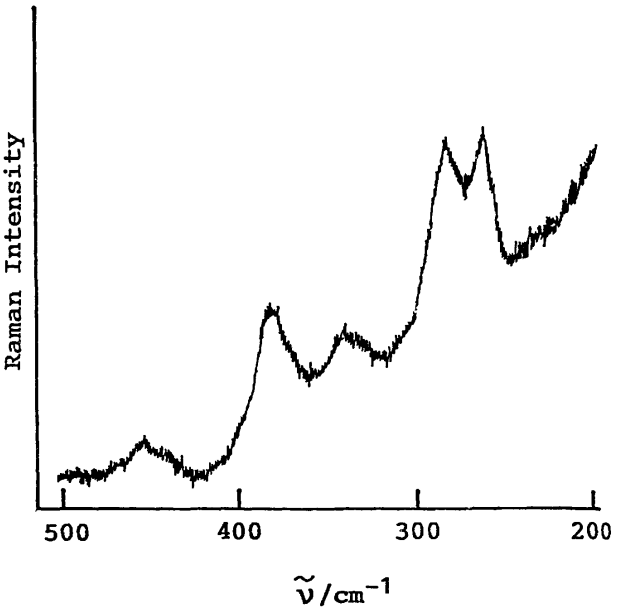

Fig. 3. Resonance Raman spectra of polymeric $Na_3Co(SCH_2COO\text{-}S)_3$ in aqueous solution with 514.5-nm excitation (150 mW).

modes. The depolarization ratios, 1/3, under these resonance condition correspond well with those expected for an electronic transition between the nondegenerate states of symmetries lower than cubic, but still not very low.[8]

Figure 2-A shows the electronic absorption spectrum of the $Co(SCH_2CH(NH_2)COOH\text{-}S)_3$ complex in an alkaline solution. The electronic absorption band at 19600 cm^{-1} has been assigned to the charge-transfer transition between the cobalt(III) and bridging sulfur because of its high intensity.[6] This charge-transfer-band position corresponds well with those of the charge-transfer bands of the trinuclear complexes containing sulfur bridges, such as $[Co\{Co(SCH_2CH_2NH_2)_3\}_2]^{3+}$[9] and $[Co\{Co(SCH_2CH(NH_2)COO\text{-}N,S)_3\}_2]^{3-}$.[10,11]

The excitation profiles of the four bands (402, 346, 281, and 223 cm^{-1}) of the polymeric $Co(SCH_2CH(NH_2)\text{-}COOH\text{-}S)_3$ complex were obtained for the solid sample, because the solid sample gives more intense Raman bands than does the solution; the results are shown in Fig. 2-B. The excitation profiles of the four bands reach their maxima at 20500 cm^{-1}, close to the electronic absorption maximum at 19600 cm^{-1}, indicating that the resonant transition is a charge-transfer one between the cobalt(III) and bridging sulfur.

When the electron giving rise to a resonant transition is localized on the coordinating atom, an intense resonance enhancement can not be expected for intraligand vibrational modes. The resonant transition of the present polymeric thiolato complexes is just such a case. Therefore, all the four resonance-enhanced Raman bands observed for each polymeric thiolato complex should be assigned to the vibrational modes of the Co–S moiety and not to the intraligand modes—that is, they should be assigned to the Co–S stretchings and Co–S–Co or S–Co–S bendings.

Figure 3 illustrates the resonance Raman spectrum in an aqueous solution of the polymeric $Co(SCH_2\text{-}COO\text{-}S)_3^{3-}$. $Na_3Co(SCH_2COO\text{-}S)_3$ and $Co(SCH_2COOH\text{-}S)_3$ in the solid state give practically the same spectra. The four bands in the 200—400 cm^{-1} region can be assigned to modes similar to those observed for the polymeric $Co(SCH_2CH(NH_2)COOH\text{-}S)_3$ in the corresponding region, since all the bands are polarized and since the excitation profiles of the bands reach their maxima at ca. 20000 cm^{-1}.

Bands characteristic of metal-sulfur stretchings have been observed in the region of 300—400 cm^{-1}.[12] For the trinuclear μ-S complex, $[Co\{Co(SCH_2CH_2NH_2)_3\}_2]^{3+}$, the Co–S stretchings have been assigned to the 358- and 345-cm^{-1} bands, and the bendings, to the 278- and 262-cm^{-1} bands.[9] We observed the Co–S stretching at 370 cm^{-1} and the bendings at 301 and 258 cm^{-1} for $K_3[Co\{Co(SCH_2CH(NH_2)COO\text{-}N,S)_3\}_2]$. On the basis of the assignment for the trinuclear complexes and the measurement of the depolarization ratios, the bands at

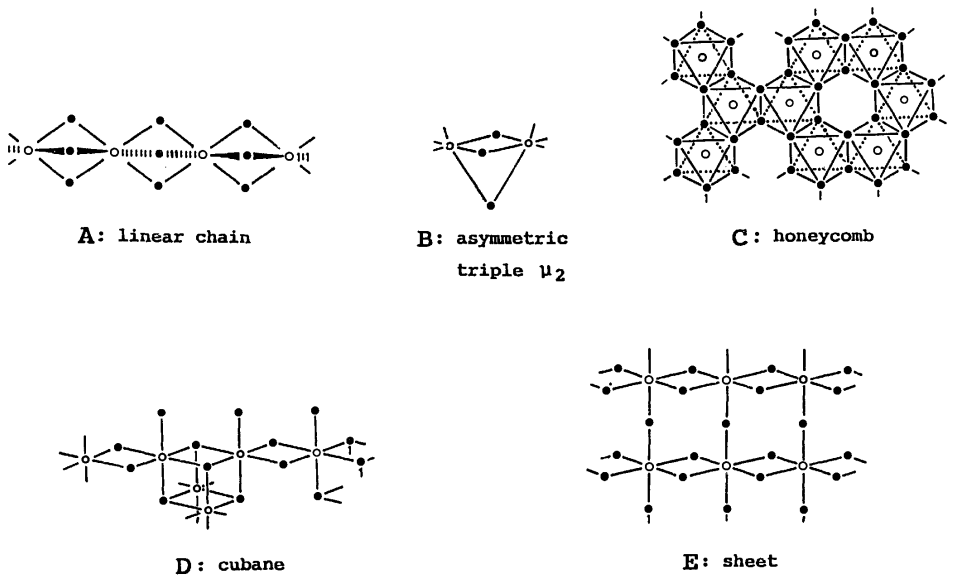

Fig. 4. Possible bridging modes of polymeric Co(S-R)$_3$ complex (● and O denote sulfur and cobalt atom, respectively).

402 and 346 cm^{-1} of the polymeric Co(SCH$_2$CH(NH$_2$)-COOH-*S*)$_3$ complex can be assigned to the totally symmetric Co–S stretchings, and the bands at 281 and 223 cm^{-1}, to the totally symmetric bending modes. Similarly, the bands at 379 and 339 cm^{-1} of the polymeric Na$_3$Co(SCH$_2$COO-*S*)$_3$ complex can be assigned to the totally symmetric Co–S stretchings, and those at 281 and 262 cm^{-1}, to the totally symmetric bendings.

It is noted that, on going from the polymeric Co(SCH$_2$CH(NH$_2$)COOH-*S*)$_3$ to the polymeric Na$_3$Co-(SCH$_2$COO-*S*)$_3$, the band at 402 cm^{-1} shifts to lower wavenumbers, and the band at 223 cm^{-1}, to higher wavenumbers, while the other two bands remain at almost the same position. This spectral behavior may suggest that, in these complexes, there are two types of bridging modes and that the bridging geometry (Co–S bond length and/or Co–S–Co angle) of one of them is affected by the nature (probably the bulkiness) of pendant group, while the other is not. A change in the bridging geometry would result in the frequency shift of the Co–S stretching and the Co–S–Co bending.

The weak band at 453 cm^{-1} of the polymeric Na$_3$Co(SCH$_2$COO-*S*)$_3$ complex can not be assigned at present. The position is, however, somewhat higher for a Co–S stretching band.

Possible Bridging Modes. Figure 4 shows possible bridging modes for the present polymeric thiolato complexes, Co(S-R)$_3$. It is well-known that thiolates can take a variety of bridging modes because of the flexibility of the sulfur bridging. For example, the M–S–M angles are ca. 60° in [(Me$_2$S)Cl$_2$W(SEt)$_3$WCl$_2$-(SMe$_2$)][13] while they are ca. 140° in [Fe$_3$(SPh)$_3$Cl$_6$]$^{3-}$.[14] Though these facts allow us to apply a variety of bridging modes to the present polymeric thiolato complex, the present results of the totally symmetric Co–S stretchings restrict the possibility of the bridging mode as follows!

(A) The linear chain structure with two triple μ_2-bridges proposed by McCormick and Gorin[4] has been found in the trinuclear complexes, [Co{Co(SCH$_2$CH$_2$-NH$_2$-*N*,*S*)$_3$}$_2$]$^{3+}$ [15] and [Co{Co(SCH$_2$CH(NH$_2$)COO-*N*,*S*)$_3$}$_2$]$^{3-}$.[10] This structure is, however, inconsistent with the present Raman results, because the structure gives only one totally symmetric Co–S stretching band if the triple μ_2-bridge is symmetric.

(B) An asymmetric triple μ_2-bridge caused by the elongation of an M–S–M moiety has been found in low-symmetry mixed-ligand complexes such as [Re$_2$-(SC$_6$H$_4$Me)$_7$(NO)$_2$]$^-$.[16] A lowering of the symmetry of the triple μ_2-bridge caused by this kind of distortion gives two totally symmetric Co–S stretchings. This distortion, however, seems to be unlikely in the present polymeric complexes, with only one kind of ligand, as in [Co{Co(SCH$_2$CH$_2$NH$_2$-*N*,*S*)$_3$}$_2$]$^{3+}$ [15] and [Co{Co-(SCH$_2$CH(NH$_2$)COO-*N*,*S*)$_3$}$_2$]$^{3-}$.[10]

(C) A honeycomb structure with three double μ_2-bridges such as [Co{(OH)$_2$Co(en)$_2$}$_3$]$^{6+}$ [17] is also inconsistent with the Raman results for the same reason as has been mentioned in (A).

(D) Structure **D** containing a cubane structure has three μ_3-bridging thiolates, one double μ_2-bridging thiolate, and one nonbridging thiolate. A cubane structure with thiolato-bridges has also been found in [Re$_4$(CO)$_{12}$(SMe)$_4$].[18] For Structure **D**, the three Co–S(μ_3) bonds are not equivalent; that is, two of them are trans to the Co–S(μ_2) bond, while one is trans to the Co–S (nonbridging) bond. Thus, this structure should give three totally symmetric Co–S(bridging)

stretchings (two Co-S(μ_3) stretchings and one Co-S(μ_2) stretching).

(E) The sheet structure proposed by McCormick and Gorin[4] consists of two different μ_2-bridging modes—namely, two double μ_2-bridges and two single μ_2-bridges. Structure **E** gives two totally symmetric Co-S stretchings. Such greatly different Co-S-Co bridging modes are probable causes of the appreciable difference in the wavenumbers of the two Co-S stretchings of the present polymeric thiolato complexes. In conclusion, the present polymeric thiolato cobalt(III) complexes are highly likely to have the sheet structure **E**.

Solvent Extraction of Thallium(I) Picrate into Benzene with Mixtures of Crown Ethers and Tributyl Phosphate

Yasuyuki TAKEDA
Department of Chemistry, Faculty of Science, Chiba University, Yayoi-cho, Chiba 260
(Received December 27, 1988)

Synopsis. Thallium(I) picrate was extracted into benzene at 25 °C with crown ether (15-crown-5 (15C5) and benzo-15-crown-5 (B15C5)) and/or tributyl phosphate (TBP). The crown ether complex with thallium picrate (1:1:1) accepts one TBP molecule. The thallium picrate complex with B15C5 and TBP is more stable than the corresponding 15C5 complex in benzene.

Solvent extraction of metal ions by crown compounds is widely studied in various fields.[1] Numerous basic data about extraction process have been reported to date, and furthermore, crown compounds have been used as extraction reagents for separation and determination of metal ions, particularly alkali and alkaline earth metal ions.

There are many factors which influence extractability and extraction-selectivity of crown compounds for metal ions; namely, (1) distribution of a crown compound itself, (2) stability of a crown compound complex with a metal ion in an aqueous solution, (3) extraction of a crown compound complex with a metal ion, (4) a counter anion which forms an ion pair with a cationic crown compound complex, (5) diluent, (6) coexisting species in an aqueous phase, (7) coexisting another ligand in an organic phase, and (8) structure of a crown compound. As for the factor (7), extractability of crown ethers for alkali and alkaline earth metal ions is enhanced by the addition of donor solvents such as tributyl phosphate (TBP), trioctylphosphine oxide, and bis(2-ethylhexyl)hydrogenphosphate.[1,2] This synergistic increase is due to the fact that crown ether–metal ion complexes form adducts with the donor solvents. The stoichiometry of the adduct complex with an alkali metal ion is metal ion:crown ether:donor solvent=1:1:1.[1,2]

In the present work, since scarcely any data on synergistic extractions of crown ether–Tl^+ complexes with donor solvents have been reported, extraction of thallium(I) picrate was conducted in the presence of crown ether and/or TBP at 25 °C between benzene and water. Compositions of the extracted complexes and adduct-formation constants in benzene have been determined. The synergistic extraction-behavior of Tl^+ was compared with that of Rb^+, which is a s-block element and nearly equal to Tl^+ in size. The crown ethers used in this study were 15-crown-5 (15C5) and benzo-15-crown-5 (B15C5). Their cavities (0.85—1.1 Å[1] (radius)) are smaller than Tl^+.

Experimental

Materials. 15-Crown-5 (Nisso Co., Ltd.) and analytical-grade TBP (Wako Pure Chemicals, Ltd.) were used without further purification. Benzo-15-crown-5 (Merck Japan Ltd.) was dissolved in heptane, and filtered while hot. It was recrystallized from heptane twice and, prior to use, dried at 40 °C in vacuo. The purity of $TlNO_3$ and concentrations of picric acid solutions were determined by EDTA and alkaline titrations, respectively. Analytical-grade benzene was washed twice with distilled water.

Procedure. All the experiments were conducted at 25±0.2 °C. The experimental procedures were similar to those in the previous paper.[2] Concentrations of $TlNO_3$, picric acid, TBP, 15C5, and B15C5 were 4.2×10^{-5}—4.2×10^{-3}, 4.4×10^{-4}—4.9×10^{-3}, 8.0×10^{-2}—9.7×10^{-1}, $(1.4—2.9)\times10^{-2}$, and 6.5×10^{-4}—1.6×10^{-1} mol dm^{-3}, respectively. All the extractions were carried out in the pH range of 1.9—5.7. Concentrations of thallium(I) extracted into benzene phase were determined by atomic absorption spectrometry.

Results and Discussion

Equilibrium constants can be defined by the following equations:

$$K_{ex}(MLL'A) = [MLL'A]_o[H^+]/[M^+][L]_o[L']_o[HA]_o, \quad (1)$$

$$K_{D,L} = [L]_o/[L], \quad (2)$$

$$K_{ex}(HA) = [HA]_o/[H^+][A^-], \quad (3)$$

$$K_{MLL'A,o} = [MLL'A]_o/[MLA]_o[L']_o, \quad (4)$$

where the subscript "o" and the lack of a subscript refer to the organic and the aqueous phase, respectively; M^+, A^-, L, and L′ denote a monovalent metal ion, a picrate ion, crown ether, and another neutral ligand, respectively. All the activity coefficients of chemical species have been assumed as unity. The $K_{ex}(HA)$

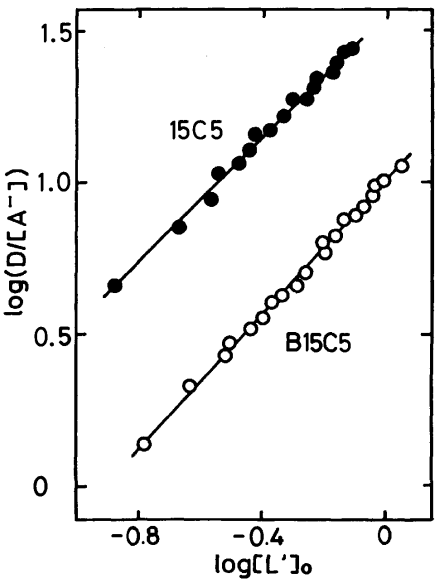

Fig. 1. Plots of $\log(D/[A^-])$ vs. $\log[L']_o$ for 15C5- and B15C5-TBP systems.

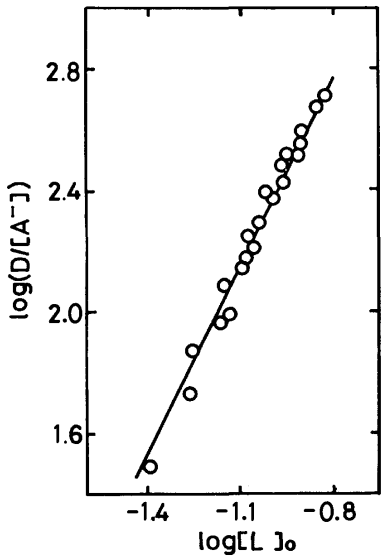

Fig. 2. Plots of $\log(D/[A^-])$ vs. $\log[L]_o$ for the B15C5 system.

value was spectrophotometrically determined to be 247.

When both L and L′ is in the benzene phase, the distribution ratio (D) is represented by

$$D = [MLL'A]_o/[M^+]. \quad (5)$$

Substitution of Eqs. 1 and 3 into Eq. 5 gives

$$D = K_{ex}(MLL'A)K_{ex}(HA)[L]_o[L']_o[A^-]. \quad (6)$$

$\log(D/[A^-])$ vs. $\log[L']_o$ plots for 15C5- and B15C5-TBP systems are shown in Fig. 1. The plots for 15C5 and B15C5 in Fig. 1 have a slope of 1. $\log(D/[A^-])$ vs. $\log[L]_o$ plots for the 15C5- and B15C5-TBP systems were similar (a straight line with a slope of 1), and so have been omitted. $\log(D/[A^-])$ vs. $\log[L]_o$ plots for the B15C5 system in Fig. 2 show a straight line with a slope of 2, where L=L′=B15C5. This indicates that B15C5 forms a 2:1 complex with Tl^+. Thus, K_{ex}(MLL′A) can be described by Eq. 1. When L′=TBP, the value of $[L']_o$ in Eq. 6 was supposed to be nearly equal to that of $[L']_t$, and those of $[L]_o$ and $[A^-]$ were calculated from Eqs. 7 and 8 respectively:

$$[L]_o = ([L]_t - [MLL'A]_o - [MLA]_o)/(1 + K_{D,L}^{-1}), \quad (7)$$

$$[A^-] = ([HA]_t - [M]_{o,t})/\{1 + (K_{HA} + K_{ex}(HA))[H^+]\}, \quad (8)$$

where the subscript "t", $[M]_{o,t}$, and K_{HA} denote the total concentration, the total concentration of thallium in the organic phase, and the association constant of picric acid (K_{HA}=1.9[5][3]). When both L and L′ are B15C5, values of $[B15C5]_o$ and $[A^-]$ in Eq. 6 were calculated from Eqs. 9 and 8, respectively:

$$[L]_o = ([L]_t - 2[M]_{o,t})/\{1 + K_{D,L}^{-1} - K_{ex}(HA)K_{ex}(MLA)[M^+][A^-]\}, \quad (9)$$

where $K_{ex}(MLA) = [MLA]_o[H^+]/[M^+][L]_o[HA]_o$ (K_{ex}(MLA)=6.9[4]) and $[M^+] = [M]_t - [M]_{o,t}$. The equilibrium constants obtained from these data are summarized in Table 1.

Table 1. Equilibrium Constants at 25 °C

$K_{D,L}$		15C5 0.15[6][5]		B15C5 20[6]	
		L	L′	Tl^+	Rb^+
$\log K_{ex}$(MLL′A)	15C5	TBP		1.58	0.56[7]
	B15C5	TBP		1.17	0.37[6]
	B15C5	B15C5		1.95	1.22[6]
$\log K_{MLL'A,o}$[a]	15C5	TBP		0.17	0.81[7]
	B15C5	TBP		0.33	1.32[6]
	B15C5	B15C5		1.11	2.17[6]

a) $K_{MLL'A,o} = [MLL'A]_o/[MLA]_o[L']_o$.

By way of example, for the crown ether-TBP mixed system, D values of Tl(I) are 4.6×10^{-3} ($[15C5]_t = 2.9\times10^{-2}$ M (1 M=1 mol dm^{-3}), $[Tl]_t = 2.0\times10^{-3}$ M, $[HA]_t = 5.6\times10^{-4}$ M, $[TBP]_t = 3.2\times10^{-1}$ M) and 2.1×10^{-3} ($[B15C5]_t = 4.0\times10^{-3}$ M, $[Tl]_t = 2.0\times10^{-3}$ M, $[HA]_t = 4.5\times10^{-4}$ M, $[TBP]_t = 3.3\times10^{-1}$ M). This shows that only a slight amount of Tl(I) ((0.2—0.5)%) is extracted into a benzene phase.

Ionic radius of Tl^+ (1.50 Å[8]) is nearly equal to that of Rb^+ (1.49 Å[8]). Thallium(I), however, is much more extracted into benzene than Rb^+ with mixtures of crown ether and TBP. Mixtures of 15C5 and TBP are more effective for extraction of Tl^+ than those of B15C5 and TBP.

The crown ether complex with thallium picrate (1:1:1) accepts one TBP molecule. From the structure of the crown ether complex with Tl^+ held in the cavity, a picrate anion- and a TBP molecule-contact are possible in respective directions perpendicular to the plane of the ring.

$K_{MLL'A,o}$ designates adduct-formation constant of a MLA complex with L′ in a benzene solution. It is seen from $\log K_{MLL'A,o}$ values in Table 1 that extractability of Tl^+ is slightly enhanced by the addition of TBP. Since Tl^+ and Rb^+ have nearly equal sizes, 15C5 and B15C5 complexes with Tl^+ are expected to be similar in size and shape to those with Rb^+, respectively; in addition, free energy of hydration of Tl^+ (343 kJ mol^{-1} [9]) is much the same as that of Rb^+ (320 kJ mol^{-1} [9]); however, $\log K_{MLL'A,o}$ values of Tl^+ are relatively smaller than those of Rb^+. This cannot clearly be explained at the present time.

When L′=TBP, $\log K_{MLL'A,o}$ value of Tl^+ for B15C5 is larger than that for 15C5. The same tendency was observed for Rb^+ and Cs^+.[6] Benzo-15-crown-5 has two aromatic ether oxygen atoms. It thus appears that electron density in the B15C5 cavity is lower than that in the 15C5 cavity. Consequently, surface charge density of an exposed part of the metal ion trapped in the cavity may be lower for 15C5 than for B15C5. This is responsible for the larger $\log K_{MLL'A,o}$ value of B15C5 than that of 15C5. A Tl(B15C5)$_2$A complex is more stable than a Tl(B15C5)(TBP)A complex in a benzene solution. This may be attributed to the fact that B15C5 has more donor oxygen atoms than TBP.

The Crystal and Molecular Structures of Bis[1,2-bis(methylthio)vinylenedithio]-tetrathiafulvalene (TMTVT)

Hideyuki NAKANO, Takashi NOGAMI,* Yasuhiko SHIROTA, Shigeharu HARADA, and Nobutami KASAI

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565

(Received January 5, 1989)

Synopsis. An X-ray crystal structure analysis of the title molecule (TMTVT) was made. The central portion of tetrathio-TTF was shown to be almost planar, and the outer portions of the two bis(methylthio)vinylenes are bent toward opposite directions each other. TMTVT molecules form a columnar stack toward the *c*-axis with equal intermolecular spacings.

Bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) is known to give several ambient presssure organic superconductors.[1] The most characteristic feature of BEDT-TTF salts is their two-dimensional electrical properties, which arise from S····S contacts that are shorter than the van der Waals distance between adjacent donor molecules in the crystal.[2] This crystal structure results in a suppression of a Peierls transition inherent in a one-dimensional system. TTF derivatives possessing multi-chalcogen atoms are attractive donor molecules, because they are expected to give complexes which are highly conductive down to low temperatures; this is a prerequisite for realizing organic superconductors. We have synthesized several TTF derivatives possessing eight or twelve chalcogen atoms.[3-7] This paper reports on an X-ray crystal structure analysis of bis[1,2-bis(methylthio)vinylenedithio]-tetrathiafulvalene (TMTVT) which has the largest number of sulfur atoms (twelve)[5] in the TTF-derivatives ever known.

Experimental

$C_{14}H_{12}S_{12}$, M 565.04, monoclinic, space group $P2_1/n$, a=7.939(1), b=28.302(2), c=5.067(1) Å, β=95.74(1)°, V=1132.8(2) Å^3, D_c=1.657 g cm^{-3} for Z=2. The crystal used had a needle shape with 0.04×0.16×0.46 mm^3. Reflection intensities were measured by the θ-2θ scan technique up to 2θ=120° on a Rigaku rotating anode four-circle diffractometer using nickel-filtered Cu $K\alpha$ radiation. The scan rate was 4° min^{-1} and the scan width $\Delta\theta$=(1.4+0.15 tan θ)°. Backgrounds were counted for 3 s at both ends of each scan. No significant intensity decay of the standard reflections, which were measured after every 100 reflections, was detected. Of the 1997 reflections measured, 1564 were observed ($|F_o|>2\sigma(F_o)$). The usual Lorentz and polarization corrections were applied, but no absorption correction was made [μ(Cu $K\alpha$)=102.8 cm^{-1}].

Structure Solution and Refinement

The structure was solved by a direct method (*MULTAN* 78),[8] and was refined anisotropically by a block-diagonal least-squares procedure (*HBLS* V).[9] The function minimized was $\sum\omega(\Delta F)^2$. The weighting function used in the final stage of the refinement was $\omega=[\sigma^2(F_o)-0.0826|F_o|+0.0166|F_o|^2]^{-1}$. The hydrogen atoms could not be found on a D-map, which is probably due to either the rotation or the large amplitude of vibration of the methyl group. Therefore, the hydrogen atoms were not included in the final refinement. Atomic scattering factors were taken from those of International Tables for X-Ray Crystallography.[10] The final R index was 0.091. The atomic coordinates and equivalent isotropic temperature factors[11] are given in Table 1.† Bond lengths and bond angles are shown in Fig. 1, and the crystal structures in Figs. 2 and 3.

Results and Discussion

The TMTVT molecules are on the centers of symmetry. The central tetrathio-TTF portion of the TMTVT molecule is approximately planar; this plane is almost perpendicular to the b-c plane. Two bis(methylthio)vinylene portions at both ends of the molecule are bent toward opposite directions from each other (Fig. 1(b)). Both BEDT-TTF[14] and bis(vinylenedithio)tetrathiafulvalene (VT)[15] possess planar structures only at the central tetrathioethylene portion. Comparing the molecular structure of TMTVT with those of BEDT-TTF and VT, the central planar portion is extended more widely in the former molecule. The crystal structure is characterized by a face-to-face stack of TMTVT molecules toward the c-axis with equal intermolecular spacings (Fig. 2(a)). The interplanar distance between adjacent molecules is 3.53 Å. S····S contacts [3.700(3) Å] almost equal to the van der Waals radius (3.7 Å) are found between methylthio groups of TMTVT molecules belonging to the adjacent stacks [S(5)(x,y,z)····S(6)

† Tables of anisotropic thermal parameters and observed and calculated structure factors are kept at the Chemical Society of Japan, Document No. 8880.

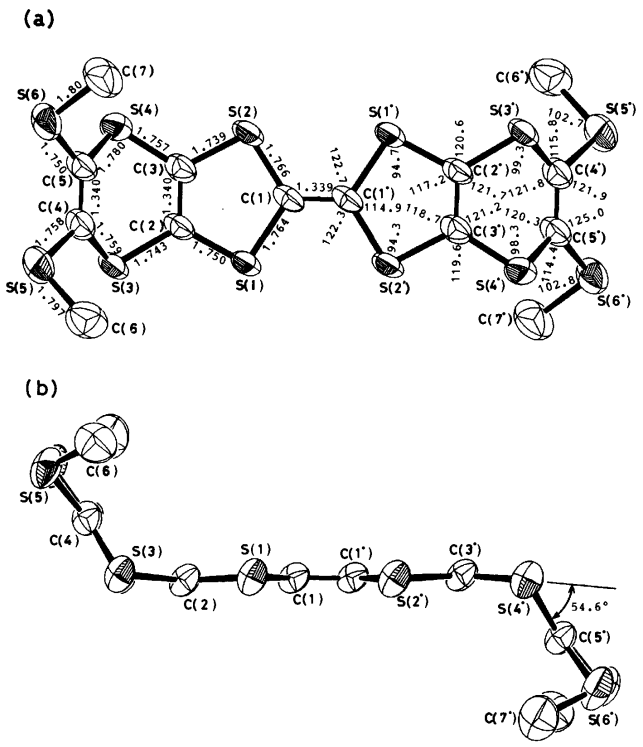

Fig. 1. Molecular structure of TMTVT.[12] (a) Over view, (b) side view. Nonhydrogen atoms are drawn as thermal ellipsoids with 50% probability level. Estimated standard deviations of the bond lengths and angles are 0.005—0.01 Å and 0.3—0.4°, respectively.

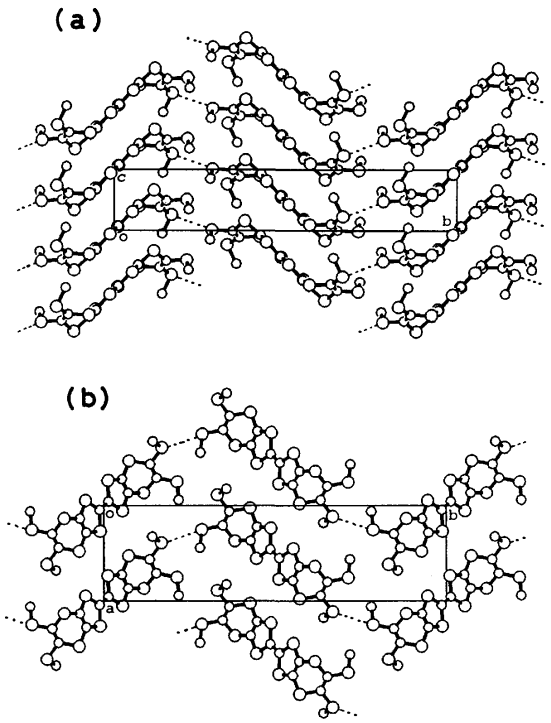

Fig. 2. Crystal structure of TMTVT[13] projected along the *a* axis (a) and the *c* axis (b). Dotted line indicates intermolecular S····S contact almost equal to the van der Waals distance (3.7 Å).

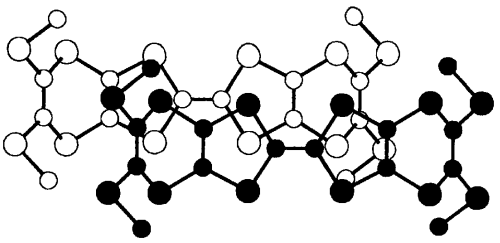

Fig. 3. Overlap of two TMTVT molecules.[13]

$(-0.5+x,0.5-y,-0.5+z)$], and are shown by dotted lines in Fig. 2. All of the other S····S distances are longer than the van der Waals radius. Figure 2(b) shows a side-by-side arrangement of molecules of equal height. All of the side-by-side S····S distances are longer than the van der Waals radius, unlike the cases of BEDT-TTF salts.[2] Figure 3 shows the overlap of two TMTVT molecules projected normal to the molecular plane. The two molecules shift with each other in order to avoid direct overlap of carbon and sulfur atoms between them.

We are grateful for Protein Engineering Center, Institute for Protein Research, Osaka University, for the use of the diffractometer and ACOS S850 computer.

Synopsis. The molecular structure of a novel Schiff base complex, [*N,N'*-ethylenebis(1-phenyl-2-imino-1-butanonato)]-(acetonitrile)manganese(III) perchlorate has been determined by X-ray diffraction method. The molecule has an elongated octahedral geometry around the metal atom.

A number of studies have been reported on the crystal structures of *N,N'*-bis(1-methyl-3-oxobutylidene)ethylenediamine type Schiff base complexes of transition metals such as Cu(II), Co(II), and V(II).[1] The chemical behavior of the Schiff base complexes of Mn(III) has also been paid attention because of important roles in some biochemical processes, e.g. in manganesesuperoxide dismutase[2,3] and pseudocatalase[4] which are known to contain Mn(III) ions. The structure of Mn(III) complex, [Mn(acen)Cl] containing a tetradentate *N,N'*-ethylenebis(4-imino-2-pentanonato) ligand (abbreviated to acen and formerly called *N,N'*-ethylenebis(acetylacetone iminato)), has been determined by X-ray analysis.[5] In this paper we describe the preparation and molecular structure of a novel Mn(III) Schiff base complex, [Mn(bzacen)(CH_3CN)(ClO_4)] containing a similar tetradentate *N,N'*-ethylenebis(1-phenyl-2-imino-1-butanonato) ligand (abbreviated to bzacen and formerly called *N,N'*-ethylenebis(benzoylacetone iminato)).

Experimental

The Schiff base, H_2bzacen and $Mn(C_2H_3O_2)_3\cdot 2H_2O$ were prepared as described previously.[6,7] A mixture of H_2bzacen and $Mn(C_2H_3O_2)_3\cdot 2H_2O$ was refluxed in 2-propanol for 3 h. The resulting precipitate was washed with 2-propanol and dissolved in methanol, to which aqueous solution of sodium perchlorate was added. Red thin-plate crystals were obtained by recrystallization from a mixed solution of benzene and acetonitrile.

Crystal Data. [$Mn(C_{22}H_{22}O_2N_2)(CH_3CN)(ClO_4)$], M=541.44, orthorhombic, space group *Pnma*, a=9.077(1), b=15.563(1), c=17.205(2)Å, U=2430.5 Å^3, Z=4, D_c=1.48 g cm^{-3}, D_m=1.49 g cm^{-3}, μ(Mo $K\alpha$)=7.3 cm^{-1}.

A well-shaped crystal was mounted on an Enraf-Nonius CAD4 diffractometer. Accurate unit-cell parameters were determined by the least-squares fit of 2θ values of 25 strong reflections. Integrated intensities were collected by the θ-2θ scan technique with the scan rate of 5.5° min^{-1} and the scan width of $\Delta 2\theta=(1.2+0.7\tan\theta)°$. The scan was repeated with a slower rate for weak reflections. A total of 2552 independent reflections was obtained within $2°<2\theta<52°$. Intensity data were corrected for usual Lp effects but absorption and extinction corretions were ignored.

The structure was solved by the heavy atom method. The systematic absences suggested that the possible space group is either *Pnma* or $Pn2_1a$. When the space group is assumed as

a) As defined by Hamilton.[10]

Pnma considering the molecular symmetry of the present complex, the structure was reasonably solved. All the nonhydrogen atoms were refined anisotropically and the hydrogen atoms except for those of the methyl group were included in the structure factor calculation. The refinement of structure was carried out by the block-diagonal least-squares procedures using the *HBLS*-V program.[8] The final refinement converged the R and R_w factors to 0.084 and 0.106 for 999 observed reflections ($|F_o|>3\,\sigma(|F_o|)$), respectively. The weighting scheme used is $w=(\sigma^2+a|F_o|+b|F_o|^2)^{-1}$ where a and b used in the final refinement cycles are 0.2237 and 0.0003, respectively. The atomic scattering factors were taken from the International Tables for X-ray Crystallography.[9] The final atomic parameters are listed in Table 1.†

Results and Discussion

The molecular structure of the title complex is shown in Fig. 1 together with atomic numbering system. Bond distances and angles are listed in Table 2. During the course of the structure analysis, both ClO_4 anion and the CH_3CN solvent molecule were found to be coordinated to the Mn(III) atom. The molecule has crystallographic C_s symmetry, in which the Mn(III) atom is located onto a mirror plane together with atoms of two axial ligands, Cl, O(1A), O(2A), C(1S), C(2S), and N(1S).

The coordination geometry around the Mn(III) atom is elongated octahedral as expected for a high spin d^4 metal ion due to the Jahn-Teller effet. In the equatorial plane, the tetradentate bzacen ligand is coordinated to the metal atom with bond distances of Mn–O=1.889(9) and Mn–N=1.955(10) Å, which agree with the average values of the similar complex.[5] The bond distances between the Mn(III) atom and the axial ligands, Mn–O(1A)[2.44(2) Å] and Mn–N(1S)[2.47(2) Å] are about 0.5 Å longer than the corresponding distances between the metal and the bzacen ligand in the equatorial plane. The ClO_4 anion and CH_3CN molecule are semi-coordinated to the metal atom from

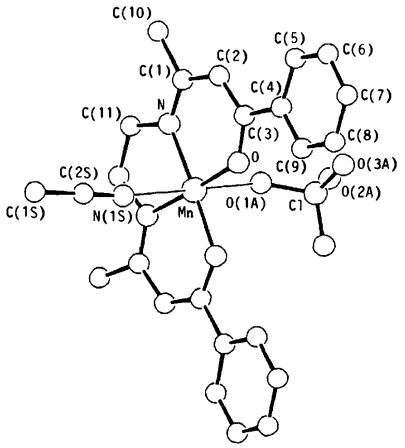

Fig. 1. The molecular structure of [Mn(bzacen)-(CH_3CN)(ClO_4)] together with atomic numbering system.

† The tables for anisotropic temperature factors of nonhydrogen atoms, for atomic coordinates of hydrogen atoms, and for observed and calculated structure factors are deposited as Document No. 8882 at the Office of the Editor of Bull. Chem. Soc. Jpn.

both apical sites. This six-coordinate octahedral geometry in the present complex is in contrast with the five-coordinate square-pyramidal structure in [Mn(acen)Cl].[5] The coordination ability of the solvent molecule may affect the resulted structure of the present complex.

Bond distances and angles in the chelate ligand agree within experimental errors, with the values reported hitherto in the similar complexes.[1,5] As observed in the tetradentate acen ligand in Schiff base complexes, the delocalization of double bonds within the N–C(1)–C(2)–C(3)–O chelate ring is also observed in this bzacen ligand. The bridging CH_2–CH_2 bond distance in this ligand, C(11)–C(11′)=1.43(4) Å is somewhat shorter than the expected value. Similar shortened CH_2–CH_2 distances observed in the acen ligand were reported in the Mn(III)[5] and V(IV)[11] complexes [1.40(1) and 1.42(3) Å, respectively].

All the atoms except for two phenyl groups in the bzacen ligand are coplanar with the Mn(III) atom, the maximum atomic deviation from the least-squares plane being 0.03 Å. The plane of the phenyl group is also almost included in the co-plane of the chelate atoms of the bzacen ligand. The dihedral angle between these two planes is only 6.8°.

(Received February 18, 1989)

Synopsis. The rates of adsorption and desorption during co-adsorption process of CO and H_2 on the Ni polycrystalline surface were measured. The desorption rate of CO(a) was enhanced by the presence of CO(g) or H_2(g) in the gas phase. The desorption rate of adsorbed hydrogen was accelerated by CO(g) but not by H_2(g).

A series of our previous works on the adsorption process of CO

$$\mathrm{CO(g)} \underset{v_-}{\overset{v_+}{\rightleftarrows}} \mathrm{CO(a)} \qquad (1)$$

on several group-VIII metal surfaces has shown that the absolute desorption rate v_- is almost proportional to the ambient CO pressure while the adsorption is actually proceeding.[1-6] There is a great enhancing contribution by gas-phase molecules to the desorption rate process—"adsorption-assisted desorption"(AAD)—besides the thermal desorption.

This time we took the same approach for co-adsorption of CO and H_2 on nickel polycrystalline surfaces. Adsorption of CO and H_2 on group-VIII metal surfaces was investigated in relation with the mechanism of methanation etc.[7-14] However there are few cases in which the dynamics of adsorption and desorption were mesured while the adsorption process is actually going on. We studied adsorption-desorption kinetics of the co-adsorption of CO and H_2 on Ni polycrystalline surfaces during the adsorption process.

The adsorption rate v_+ and the desorption rate v_- of CO and H_2 are mathematically divided into 16 components as functions of the surface concentration of CO(a) and H(a), N_{CO} and N_H, and the gas-phase pressures P_{CO} and P_{H_2}. For example, the important components of the desorption rate of CO are:

$$\begin{aligned} v^{CO}_- = {} & v^{CO}_-(N_{CO}) && \text{: thermal desorption} \\ & + v^{CO}_-(N_{CO}, P_{CO}) && \text{: AAD} \\ & + v^{CO}_-(N_{CO}, P_{H_2}) && \text{: cross desorption by } H_2\text{(g)} \\ & + v^{CO}_-(N_{CO}, N_H) && \text{: surface effect by H(a)} \\ & + (12 \text{ other components}) && \end{aligned} \qquad (2)$$

where each $v^{CO}_-(*,*)$ falls zero when any one of the variables inside parentheses is zero.

The values of those components are obtained by measuring the amounts of the surface species as functions of time. Each component is distinguished by gas-switching technique between corresponding molecules. This technique is the extended version of the "isotope-jump method".[1] The rates are calculated from the change of the surface concentrations of the adsorbates measured by the flash desorption at each point of time. We expected changes in the rate of desorption of H(a) by CO(g), and vice versa, as well as ADD of CO and H_2. We call these phenomena the "cross desorption". It is distinguished from ADD, in which the desorption of the surface species is enhanced by the same species in the gas phase. In this paper we mainly mention about the desorption processes. The adsorption rates were difficult to measures precisely enough in some cases.

Experimental

Experiments were performed in an ultrahigh vacuum apparatus equipped with a mass spectrometer (MS), a sample temperature programmer, an Auger electron spectrometer, etc.[1] Several pieces of Ni foil (0.03 mm thickness, 1.4 cm^2 total area) were used as the samples. The surfaces were cleaned by Ar ion bombardment and annealing. The gas samples were $^{12}C^{16}O$, $^{12}C^{18}O$, H_2 and D_2 obtained from commercial vessels. The procedures of gas-switching experiments were as follows. Details in calibration and calculation procedures are describe elsewhere.[1]

(1) Clean up the surface by flashing up to 800 K.
(2) Keep the sample at the desired temperature/K.
(3) At time $t=0$, start introducing Gas 1 (the species to leave on the surface) at the desired pressure P_1/Pa.
(4) At time $t=t_1$, stop introducing Gas 1, and, at the same time, start introducing Gas 2 (The gas-phase species) at pressure P_2/Pa.
(5) At time $t=t_1+t_2$, flash the sample and record the flash-desorption trace of the desired species by MS.

For each pair of Gases 1 and 2, measurements were done at various T, P_1, P_2, t_1, and t_2, and the surface concentrations of Gases 1 and 2 (N_{CO} and N_H/N_D/molecules·cm^{-2}) were obtained from the peak ares of flash desorption in (5).

The obtained surface concentrations N's were plotted as functions of t_2 with fixed T, P, and t_1. These t_2–N curves were numerically curve-fitted to exponential functions, and the differerential conefficients at $t=t_1+0$ were calculated. These differential coefficients i.e. the slopes of the tangents at the right side of t_1 are the rates of adsorption of the "Gas 2" species, and the rates of desorption (negatively signed) of the "Gas 1" species. In some cases precise determination of adsorption rate was not possible because of the background gas pressure. We mainly focussed on the desorption rates.

Results and Discussion

1. Gas 1=$^{12}C^{18}O$, Gas 2=$^{12}C^{16}O$ {$v^{CO}_\pm(N_{CO}, P_{CO})$}. The kinetics of absorption of CO without H_2(g) were

examined. We can measure the absolute rates of adsorption and desorption of CO by distinguishing Gases 1 and 2 using isotope-labelled molcules. The absolute rates of adsorption and desorption are dependent on the surface concentration N_{CO} and the gas-phase pressure P_{CO}.[4] The absolute adsorption rate $v^{CO}{}_+$ is a nonlinear function of N_{CO} and proportional to P_{CO}. The initial adsorption rate ($v^{CO}{}_+$ when $N_{CO}=0$) is independent of the temperature T between 329 K and 394 K. The desorption rate $v^{CO}{}_-$ is greatly affected by the gas-phase pressure of CO:

$$v^{CO}{}_- = \mu_{CO} N_{CO} = (\mu_{CO}{}^0 + k_{CO} P_{CO}) N_{CO}. \quad (3)$$

Figure 1 shows the rate constant μ_{CO} as a function of P_{CO} and T. The rate constant at $P_{CO}=0$, $\mu_{CO}{}^0$, corresponds to the thermal desorption process, the pressure-dependent part of the rate constant is proportional to P_{CO}. We call this kind of kinetics "adsorption-assisted desorption (AAD)".[1-6] So far we have proposed several models to elucidate the mechanism of acceleration of the desorption by the effect of the gas phase.[14]

2. Gas 1=D_2, Gas 2=H_2{$v^{H_2}{}_\pm(N_H, P_{H_2})$}. Whether AAD is applicable for gases other than CO is an attractive question.[15,16] The absolute rates of adsorption and desorption of H_2 only were measured in the same manner as CO by using H_2 and D_2. The species desorbed by flash desorption procedure are H_2, HD, and D_2. The amounts of H(a) and D(a) were calculated by summing the areas of those three peaks. The absolute adsorption rate $v^{H_2}{}_+$ was a nonlinear function of N_D and proportional to P_{H_2}. It decreased with increasing temperature T. Figure 2 shows the absolute desorption rate $v^D{}_-$ as a function of N_D and P_{H_2}. It is approximately proporitional to $(N_D)^2$ in the high coverage region. $v^D{}_-$ did not change when the pressure P_{H_2} changed. Namely, AAD did not occur in the case of H_2 on Ni.

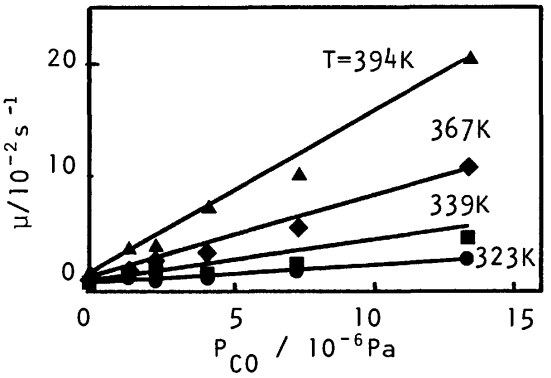

Fig. 1. The absolute desorption rate constant of CO, μ, as a function of pressure P_{CO} and temperature T.

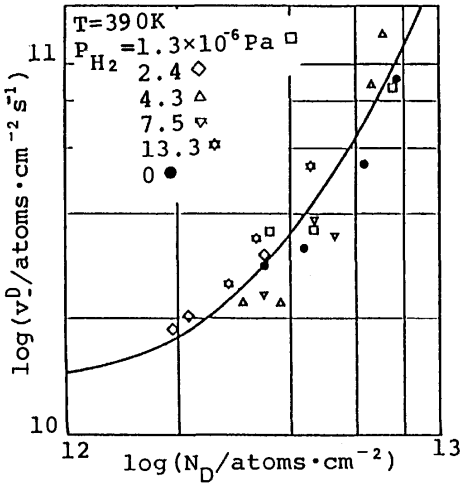

Fig. 2. The absolute desorption rate of D(a), $v^D{}_-$, as a function of the surface concentration N_D and pressure P_{H_2}.

3. Gas 1=CO, Gas 2=H_2{$v^{H_2}{}_+(N_{CO}, P_{H_2})$ and $v^{CO}{}_-(N_{CO}, P_{H_2})$}. If Gas 2 is a different chemical species from Gas 1, we see the effects of the adlayer of Gas 1 on the adsorption of Gas 2, and the effects of Gas 2 in the gas phase on the desorption from the adlayer of Gas 1. Replacement of the adsorbates in the equilibrium condition is trivial and well recognized. We observe the effects of the gas phase molecules on the desorption kinetics. In the present case the gas-phase species is H_2, and the adlayer species is CO. It was difficult to calculate $v^{H_2}{}_+$ precisely, as the amount of H(a) was suppressed by coexistence fo CO. The adsorption step of H_2(g) ($v^{H_2}{}_+$) was strongly poisoned by CO(a).

The desorption of CO(a) was weakly enhanced by H_2(g). Figure 3 shows CO(a) (N_{CO}) decreasing after the gas phase was switched to H_2. It decreased a little bit faster at $P_{H_2}=1.3\times10^{-4}$ Pa than a $P_{H_2}=0$, i.e. $v^{CO}{}_-(N_{CO}, P_{H_2})>0$. The "cross desorption" of CO(a) by H_2(g) was demonstrated in this experiment.

4. Gas 1=D_2, Gas 2=CO{$v^{CO}{}_+(N_D, P_{CO})$ and $v_-(N_D, P_{CO})$}. The reverse case of 3. was examined. The adsorption rate of CO was almost indifferent of the surface concentration of D(a) at temperatures higher than 329 K. The result was almost the same as the data of the absolute adsorption rate.[5]

Figure 4 shows the desorption rate of D, $v^D{}_-$, as a function of N_D and P_{CO}. In Fig. 4, $v^D{}_-$ is fitted to second-order functions of N_D, that is,

$$v^D{}_- = \mu_D (N_D)^2 \quad (4)$$

Cross desorption of D(a) by CO(g) is obvious in this

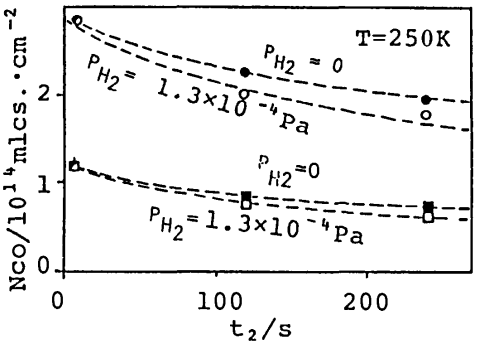

Fig. 3. The surface concentration of CO(a), N_{CO}, as a function of time t_2 with ambient H_2 molecules at pressure P_{H_2} for two initial N_{CO}'s.

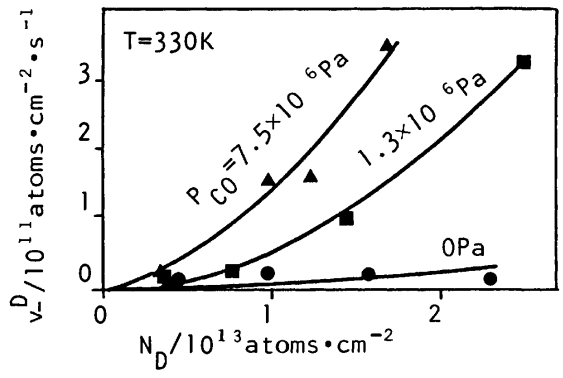

Fig. 4. The desorption rate of D(a), v^D_-, as a function of the surface concentration of D(a), N_D, and pressure of CO, P_{CO}.

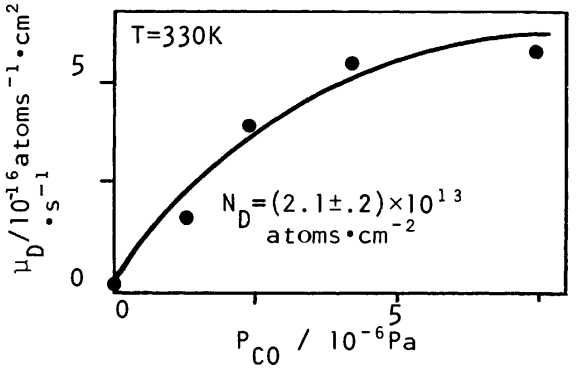

Fig. 5. The 2nd-order rate constant of D(a), μ_D, as a function of CO pressure P_{CO}.

case. Figure 5 shows P_{CO}-dependence of the second-order rate constant μ_D of v^D_-. It is curve fitted to

$$\mu_D = \mu_D^0 + k_{D,CO}P_{CO}^{0.74}. \quad (5)$$

The heat of adsorption of CO is larger than that of H_2.[17] If there is a direct energy-transfer process between adsorbates upon adsorption of CO, desorption of H(a) can be accelerated by CO, but not by H_2.

5. Gas 1=D_2 and CO, Gas 2=Vacuum {$v^D_-(N_D, N_{CO})$ and $v^{CO}_-(N_D, N_{CO})$}. This experiment was done to distinguish the effect of the gas-phase molecules from that of the adsorbed molecules. The desorption of molecules into vacuum indicates the effects of one adsorbed species to the other adsorbed species. Figure 6 shows the second-order rate constant μ_D of D(a) when N_D was constant and N_{CO} was varied. μ_D was not significantly changed by N_{CO}, namely, the desorption of CO did not depend on the surface concentration of D(a) at the same temperature.

To summarize, we observed the acceleration of desorption of a surface species by the same species in the gas phase—adsorption-assited desorption— of CO

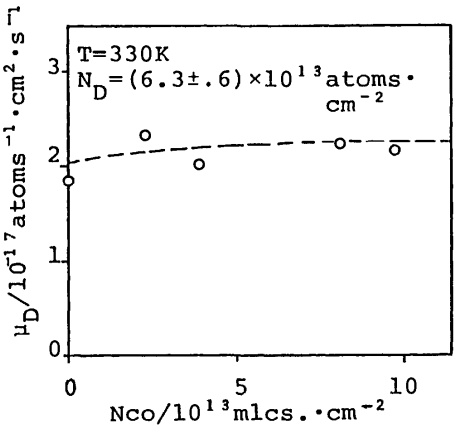

Fig. 6. The 2nd-order desorption rate constant of D(a), μ_D, as a function of the surface concentration of CO(a), N_{CO}. This measurement was done without ambient gas molecules.

but not of H_2. The adsorption of CO(g) is indifferent of the presence of H_2(g) or H(a), and desorption of CO(a) is weakly promoted by H_2(g). Adsorption of H_2 is poisoned by CO(a), and desorption of H(a) is accelerated by CO(g). The acceleration of desorption of H(a) is not due to the surface interaction with CO(a), but to the interaction between CO(g) and H(a) when CO reaches the surface.

A Flow-Through Detector Based on the Photoelectrochemical Reaction of an Anthraquinone-2,6-disulfonate Dianion/ Cationic Perfluoro Polymer Complex

Naoyoshi EGASHIRA,* Toshirou FUJISAWA, and Kazuya OHGA*
Department of Environmental Chemistry and Engineering, Faculty of Engineering, Oita University, 700 Dannoharu, Oita 870-11
(Received December 22, 1988)

Synopsis. A glassy carbon electrode modified with an anthraquinone-2,6-disulfonate dianion/cationic perfluoro polymer complex was used as the working electrode of a flow-through detector based on a photoelectrochemical reaction. Several α-amino acids gave anodic photocurrents. The photocurrent-peak area of proline increased linearly with the concentration in the range of 0.5—10 mmol dm^{-3} and the detection limit (S/N=2) was 5×10^{-5} mol dm^{-3}.

In a previous paper,[1] we reported a new electrochemical flow-through detector which was equipped with a working electrode modified with polystyrene having pendant anthraquinone groups. The principle of detection proposed involves photochemical reduction of the anthraquinone moiety by analytes and electrochemical oxidation of the resulting reduced form of the anthraquinone on the electrode to give an anodic current. The detector has the advantage of permitting direct analyses of α-amino acids and amines which are undetectable by conventional electrochemical detectors without pretreatment.[2,3] However, a dimethyl sulfoxide solution that is rarely used for HPLC analysis of amino acids was required as the mobile phase because of the hydrophobicity of the polymer used. In the present paper, we described a modified electrode favorable for an aqueous mobile phase using a hydrophilic polymer, a complex (Fig. 1) formed from a cationic perfluoro polymer (CPF) and disodium anthraquinone-2,6-disulfonate (ADS).

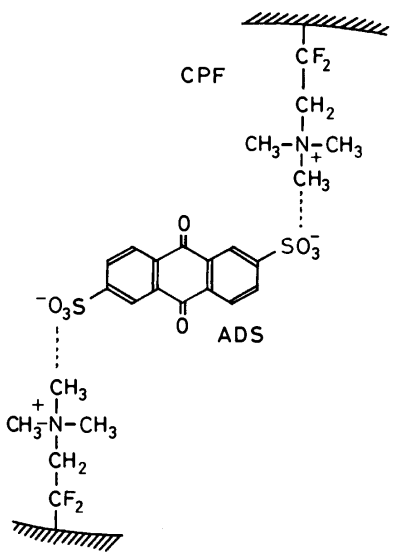

Fig. 1. CPF/ADS complex.

Experimental

A CPF film (Toyo Soda Co.) was finely cut and mixed with H_2O/CH_3OH/2-propanol (volume ratio, 1:1:1).[4] The mixture was refluxed with stirring at 70 °C for 36 h and filtered. The concentration of CPF in the filtrate was estimated to be 0.84 mg cm^{-3} on evaporating the solvent and weighing the remaining CPF. A given amount of ADS was added to 1 cm^3 of the CPF solution to yield a complex solution.

A glassy carbon disk (Tokai Carbon GC-30S) of 0.6 cm in diameter was coated with 0.1 cm^3 of the complex solution and dried under reduced pressure. The polymer-film thickness of the modified electrode obtained was evaluated to be about 3 μm with an Ono Sokki DG-215 digital dial gauge having a spindle. The flow-through cell used was the same as reported previously[1] and was equipped with a glass window (Corning) to cut off light of wavelengths shorter than 310 nm. The light source was a 500-W xenon lamp (Shimadzu). The light intensity was estimated to be 3.2 μW cm^{-2} with a Tokyo Kougaku Kikai UVR-365 exposure meter which responds to light from 310 to 400 nm. The modified electrode, a platinum plate (0.15 cm^2), and a Ag/AgCl electrode were employed as the working, counter, and reference electrodes, respectively. A potential of 0.2 V was imposed on the working electrode in order to reoxidize the reduced form of ADS. A N_2-bubbled phosphate buffer solution (0.1 mol dm^{-3}, pH 11) was allowed to flow through the cell at a rate of 1.0 cm^3 min^{-1}

Results and Discussion

The cyclic voltammogram of the modified electrode showed reversible redox peaks around −0.6 V as shown in Fig. 2, indicating that the electrode can be used effectively to detect the reduced form of ADS. A potential difference between the redox peaks of about 0.2 V was larger than those for electroactive species immobilized on electrodes in the form of monolayers,[5] probably because of an uncompensated ohmic resistance of the polymer film.[6] A maximum anodic peak current was obtained with a film prepared from 1.2 mg of ADS and 1 cm^3 of the CPF solution; further addition of ADS to the CPF solution did not significantly increase the photocurrent, as is described below.

Figure 3 shows the anodic photocurrents resulting from the intermittent injection (20 mm^3) of a buffer solution of proline (1 mmol dm^{-3}) into the cell. The peak area of the current was found to be reproducible at about ±3% and to increase linearly with the concentration of proline in the range of 0.5—10 mmol dm^{-3} (Fig. 4). The detection limit was 5×10^{-5} mol dm^{-3} (S/N=2) comparable to that of a differential refractive index detector.[7]

Other α-amino acids also gave photocurrent peaks,

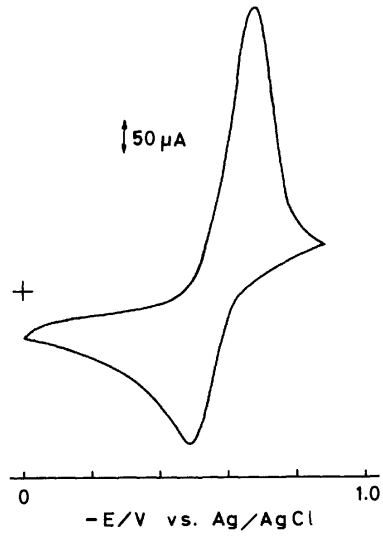

Fig. 2. Cyclic voltammogram of a modified electrode (area: 0.283 cm^2) with a CPF/ADS complex in 0.1 mol dm^{-3} phosphate buffer (pH 11). The sweep rate was 0.1 V s^{-1} and the weight ratio of ADS to CPF was 1.4.

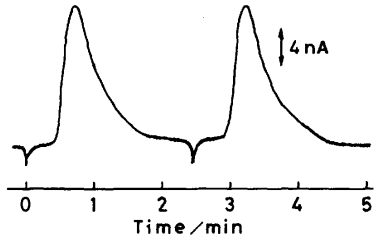

Fig. 3. Photocurrent response of the modified electrode (ADS/CPF weight ratio=1.4) induced by intermittent injection of proline (10 mmol dm^{-3}, 20 mm^3).

though the currents were lower than that of proline: The peak areas of methionine, lysine, histidine, and valine were 0.14, 0.14, 0.10, and 0.04 μC, respectively, when the same molar quantities as that of proline (0.2 μmol, 0.33 μC) were injected. In addition, it is important to note here that dark currents were not observed for these amino acids. These results suggest

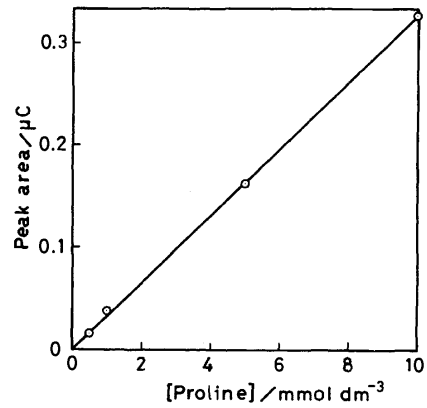

Fig. 4. A calibration curve of the peak area vs. the concentration of proline. Injection volume was 20 mm^3.

that the CPF/ADS-modified electrode is applicable to HPLC analysis of such electroinactive amino acids with aqueous mobile phases.

The proline peak area was unchanged for about 7 h after an initial unstable period (2 h), but subsequently, decreased gradually, probably owing to loss of ADS from the complex. Thus, the development of a more stable photoresponsive polymer would be required for this type of detector to have long life.

The present work was partially supported by a Grant-in-Aid for Scientific Research No. 62750768 from the Ministry of Education, Science and Culture.

Effect of 2,2′-Bipyridine on Nickel(II)-Halide Interactions within Their Ternary Complexes in *N,N*-Dimethylformamide

Shin-ichi ISHIGURO* and Kazuhiko OZUTSUMI†
Department of Electronic Chemistry, Tokyo Institute of Technology at Nagatsuta, Midori-ku, Yokohama 227
(Received February 20, 1989)

Synopsis. The formation of ternary (2,2′-bipyridine)-bromonickel(II) complexes has been studied by calorimetry in *N,N*-dimethylformamide containing 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a constant ionic medium at 25 °C. The data are well explained in terms of the formation of $[NiBr(bpy)]^+$ and $[NiBr(bpy)_2]^+$ (bpy=2,2′-bipyridine), and their formation constants, enthalpies and entropies were determined. It is elucidated that the affinities of Br^- as well as Cl^- ions to $[Ni(bpy)]^{2+}$ and $[Ni(bpy)_2]^{2+}$ are enhanced almost to the same extent over Ni^{2+}. The enhancement is ascribed mainly to an increase in entropies upon complexation in both Ni^{II}–Cl^-–bpy and Ni^{II}–Br^-–bpy systems.

Affinities of halide ions to a metal ion change depending on the solvent.[1] Ligating anions or molecules to a metal ion in ternary systems also influence the affinities of halide ions.[2] In the ternary Ni^{II}–Cl^-–bpy (bpy=2,2′-bipyridine) system the formation of $[NiCl(bpy)]^+$, $[NiCl_2(bpy)]$, $[NiCl(bpy)_2]^+$, and $[NiCl_2(bpy)_2]$ has been proposed in DMF.[3] It is found that the log K_1 value for the formation of $[MCl]^+$ is appreciably larger for M=$[Ni(bpy)]^{2+}$ or $[Ni(bpy)_2]^{2+}$ than for Ni^{2+}. Furthermore, the enhanced complexation is essentially due to the increased entropies and the corresponding enthalpies remain rather constant. Relative affinities among halide ions to nickel(II) ion may be of interest in view of hard and soft acids and bases. Therefore, we examined the complexation equilibria in the Ni^{II}–Br^-–bpy system in DMF by calorimetry at 25 °C, and the result was compared with that in the Ni^{II}–Cl^-–bpy system.

Results and Discussion

Calorimetric titration curves obtained in the ternary Ni^{II}–Br^-–bpy system are depicted in Fig. 1. The heat of reaction q measured at each titration point is normalized with the volume of the titrant added δv and the concentration of the ligand ions in the titrant $C_{X,tit}$, and the term $-q/(\delta v C_{X,tit})$ is plotted against C_X/C_M, where C_X and C_M denote the total concentrations of the bromide and metal ions, respectively, in solution. As seen in Table 1 the formation of various sets of ternary $[NiBr_p(bpy)_q]^{(2-p)+}$ complexes was assumed along with the relevant binary complexes. Analyzed on the basis of the known thermodynamic parameters for the binary 2,2′-bipyridine[3] and bromo[4] complexes of nickel(II), the titration curves in Fig. 1 are finally explained in terms of the formation of $[NiBr(bpy)]^+$ and $[NiBr(bpy)_2]^+$ (case A in Table 1). The solid lines in Fig. 1, calculated using the constants for case A in Table 1, well reproduce the experimental points. It is elucidated that the formation of $[NiBr_2(bpy)]$ and $[NiBr_2(bpy)_2]$ is practically negligible in contrast to that of the corresponding $[NiCl_2(bpy)]$ and $[NiCl_2(bpy)_2]$ complexes.[3] It is also noted that the formation of $[NiBr_2]$ is virtually negligible in DMF.[4]

In Table 2 are compared the thermodynamic parameters for the formation of $[MX]^+$ (X=Cl, Br and M=Ni^{2+}, $[Ni(bpy)]^{2+}$, $[Ni(bpy)_2]^{2+}$). We see from Table 2 that for $[Ni(bpy)]^{2+}$ as well as $[Ni(bpy)_2]^{2+}$ the log K_1(Br) value is smaller than the log K_1(Cl) value, and the decrement is to an almost similar extent to that for Ni^{2+}. The ΔH_1°(Br) value is larger than the ΔH_1°(Cl) value for $[Ni(bpy)]^{2+}$ as well as $[Ni(bpy)_2]^{2+}$, and the increment is also to an almost similar extent to the value for Ni^{2+}. On the othen hand, practically the

	Br	82[c]	102	95

a) Ref. 6. b) Ref. 3. c) Ref. 4.

same ΔS°_1 values for Cl and Br are found for all the M ions. These results imply that the Ni^{II}–X^- (X=Cl, Br) interactions are not appreciably influenced by the coordination of 2,2′-bipyridine molecules to the nickel(II) ion, in other words, the coordination of 2,2′-bipyridine molecules to nickel(II) ion does not change virtually the hard and soft nature of the nickel(II) ion.

With regard to the bromo complexes the $\log K_1$ value for $[Ni(bpy)]^{2+}$ is larger than that for Ni^{2+}. The value for $[Ni(bpy)_2]^{2+}$ is also larger than that for Ni^{2+}. The larger $\log K_1$ values are ascribed mainly to the increased entropies upon complexation, and the change in the corresponding enthalpies is rather small. The same conclusion has been obtained for X=Cl. Consequently, the entropy increase seems to be independent of the kind and nature of halide ions. Nickel(II) ion and its binary 2,2′-bipyridine complexes are solvated to form six-coordinated $[Ni(dmf)_6]^{2+}$, $[Ni(bpy)(dmf)_4]^{2+}$ and $[Ni(bpy)_2(dmf)_2]^{2+}$ in DMF. Therefore, a specific or steric intermolecular bpy–dmf interaction might occur in $[Ni(bpy)(dmf)_4]^{2+}$ and $[Ni(bpy)_2(dmf)_2]^{2+}$, which is expected to lead to the entropy increase for $[Ni(bpy)]^{2+}$ and $[Ni(bpy)_2]^{2+}$.

Experimental

Reagents. Chemicals used were prepared or purified as described elsewhere.[3]

Measurements. Calorimetric measurements were carried out using an on-line controlled calorimetry system.[5] Varying concentrations of nickel(II) perchlorate 2,2′-bipyridine solutions (40 cm^3) containing 0.16 mol dm^{-3} $(C_2H_5)_4NClO_4$ as a constant ionic medium were titrated with a 0.16 mol dm^{-3} $(C_2H_5)_4NBr$ solution. The detailed procedure of the measurements is described elsewhere.[3]

Photoreaction of (*E*)-1-Mesityl-2-(2,4,6-tri-*t*-butylphenyl)diphosphene

Masaaki YOSHIFUJI,*,† Takahiro SATO, and Naoki INAMOTO
Department of Chemistry, Faculty of Science, The University of Tokyo, Hongo, Tokyo 113
(Received September 20, 1988)

Synopsis. Photoirradiation of (*E*)-1-mesityl-2-(2,4,6-tri-*t*-butylphenyl)diphosphene gave 1,2-bis(2,4,6-tri-*t*-butylphenyl)diphosphene via a cyclotetraphosphane.

In connection with our study on the photolysis of such organophosphorus compounds in low coordination states as listed below (**1**—**4**),[1,2a,3,4] an unsymmetrical diphosphene was prepared[5] and was irradiated with a mercury lamp.[6] In order to observe *E*/*Z* isomerization around the P=P double bond (**5**⇄**6**) which had been observed for a symmetrical diphosphene **2** (**2**⇄**7**),[2a,7] or the ligand **5** on the metal carbonyls (**1**),[1] (*E*)-1-mesityl-2-(2,4,6-tri-*t*-butylphenyl)diphosphene (**5**) was dissolved in tetrahydrofuran (THF) and was irradiated at −40 °C, monitoring by the ^{31}P NMR at −56 °C at an appropriate time interval. Figure 1 shows some selected ^{31}P NMR spectra during the photolysis through a Pyrex filter. The starting diphosphene **5**, which gives an AB quartet[5] at low field, however, afforded the symmetrical (*E*)-diphosphene **2**,[2b] on irradiation, together with the *Z*-isomer **7**,[2a,7] giving their signals at δ_P 488.3 and δ_P 367.7, respectively. The peaks due to **2** and **7** increased on long irradiation while the complicated but symmetrical signals appeared at around δ_P 0 to −50 which did not correspond to **6**. The spectrum was simulated by the parameters of AA'BB' spin system given in Table 1 as cyclotetraphosphane (**8**), a head-to-head dimer of the starting diphosphene **5**. Figure 2 shows the simulated spectrum by LAOCOON 3.

The photolysis of 1-(pentamethylcyclopentadienyl)-

Table 1. ^{31}P NMR Parameters of **8**

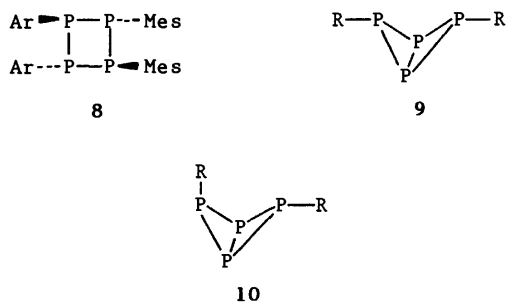

Scheme 3.

2-(2,4,6-tri-*t*-butylphenyl)diphosphene was recently reported by Jutzi and Meyer indicating the intermediacy of cyclotetraphosphanes for the formation of the symmetrical diphosphene **2** and/or bicyclo[1.1.0]tetraphosphanes like **9** or **10**.[8] Our results also suggested that an intermediate **8** decomposed to **2** followed by photo-equilibrium of **2** to **7**.

The whole process apparently resembles to a metathesis of olefins,[9] but in the present case, the other part of dimesityldiphosphene was not observed, probably because of its instability. At higher field there were observed some unknown peaks, however, it should be noted that we were not able to detect either **6**, **9**, or **10**.

In conclusion, it seems likely that photolysis of diphosphenes, depending upon the substituents and irradiation conditions, gives dimerization, cleavage, and *E*/*Z* isomerization.

Experimental

Preparation of (*E*)-1-Mesityl-2-(2,4,6-tri-*t*-butylphenyl)diphosphene (5). The diphosphene **5** was prepared according to the method described before.[5]

Photolysis of the Diphosphene 5. The diphosphene **5** (183.7 mg, 0.431 mmol) was dissolved in 1 ml of THF in an NMR sample tube of 10 mmϕ under argon and the sample was irradiated through a 2 mm thick Pyrex filter with a Riko 100-W medium-pressure mercury lamp at −40 °C. The irradiated sample was monitored by ^{31}P NMR at −56 °C at a certain time interval. Some ^{31}P NMR spectra taken at 36.3 MHz were shown in Fig. 1. The similar results were obtained after irradiation over a period of 1 h without the Pyrex filter at −75 °C. Attempts to isolate **8** failed.

Simulation of ^{31}P NMR Spectrum. The signals were analyzed as the AA'BB' spin system by a modified version of LAOCOON 3 program. The parameters were listed in Table 1 and the simulated spectrum was shown in Fig. 2.

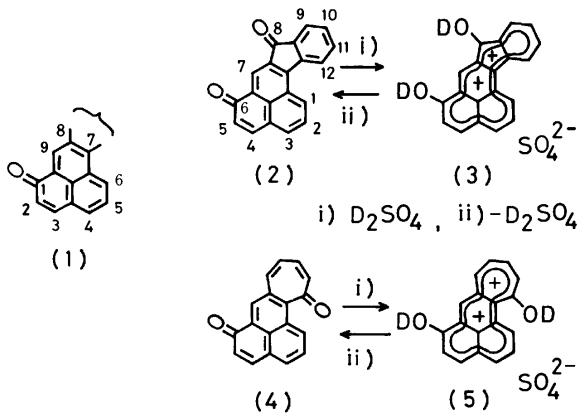
(Received October 15, 1988)

Synopsis. Convenient and general syntheses of condensed phenalenones with various ring systems fused at the 7 and 8-positions are described together with the synthesis of indeno[1,2-*a*]phenalene-6,8-dione (quinone) and the formation of its di-cationic species in strong acidic media.

Although many types of condensed phenalenones have been actively studied,[1] there have been few general methods for their synthesis. Other condensed phenalenones such as those having fused rings at 7- and 8-positions have remained to be investigated.[2] In the course of our synthetic study of such new systems we devised a new convenient and general method for the synthesis of condensed phenalenones (**1**). Further the title cationic species (**3**) generated from quinone (**2**) is of interest regarding its tropicity, since the structurally related dication (**5**) generated from cyclohepta[*a*]phenalene-6,12-dione (**4**) was found to show diatropicity[3] in spite of the 16-π epectron system.

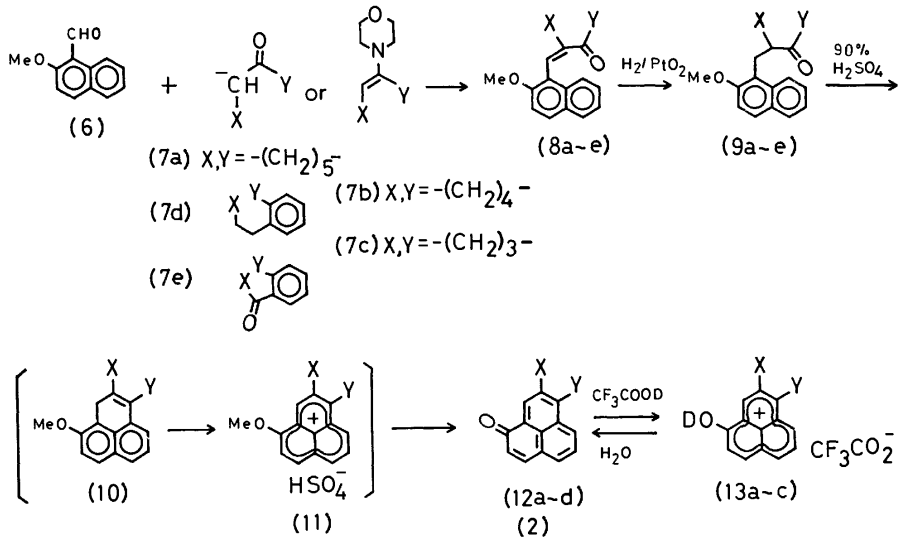


(1) (2) (3) (4) (5)

The reaction of cycloheptanone (**7a**) with one equivalent of 1-formyl-2-methoxynaphthalene (**6**) in the presence of sodium methoxide in dry tetrahydrofuran (THF) under reflux for 3.5 h gave an α,β-unsaturated ketone (**8a**) as pale yellow needles in 90% yield. The direct cyclodehydration of **8a** by 90% sulfuric acid (H_2SO_4) at 45 °C for 25 min provided an expected phenalenone derivative (**12a**) as yellow needles, but in very low yield. The alternative method was next employed. The catalytic hydrogenation of **8a** with H_2/PtO_2 at 2.7 atm for 3 h gave a saturated ketone (**9a**) as pale yellow oil almost quantitatively. This was subjected cyclodehydration under similar conditions without further pruification to give **12a** in 60% yield. This cyclization might have proceeded through the cationic species **11** generated by oxidation of cyclodehydrated product **10** with H_2SO_4.[4] For the synthesis of systems fused with five and six membered ring, the enamines **7b** and **7c** were used instead of ketones to avoid double condensation of **6** with cyclic ketones. The compounds **8b** and **8c** were obtained in 75% and 76% yield, respectively, by the reaction of **7**, and **7c** with **6** in toluene under reflux for 5 h follwed by hydrolysis. Then similar treatment as above furnished phenalenone derivatives **12b** and **12c** in 60% and 35% yield, respectively, via saturated ketones **9b** and **9c**, and cationic intermediates **11**.

The IR spectra showed that the absorption band of a carbonyl group shifted to larger wavenumber in the order of **12a**, **12b**, and **12c**. This suggests that the contribution of the dipolar structure decreases in this order. The same tendency was observed in the ^1H NMR spectra; the ^1H NMR singals of the phenalenone moiety slightly shifted up-field in the same order. In the UV spectra also, the bathochromic shifts (hexane to ethanol) of longest absorption maxima of these compounds decreases as the fused ring size decreases. These indicate that the increased strain in the fused ring diminishes the contribution of the dipolar structure. These compounds generated the cationic species **13a**, **13b**, and **13c** in a strong acid such as trifluoroacetic acid, as confirmed by the spectral evidences especially from the ^1H NMR and UV spectroscopy. The ^1H NMR signals of these cationic species showed the down field shifts by ca. 1 ppm. However, the electronic state of the cationic species does not seem to be greatly affected by the size of the fused ring, as is deduced from the similarity of their chemical shift values. In the UV spectra, the longest absorption maxima of these compounds shifted to longer wavelength by 30—50 nm as compared with those of phenalenones.

The syntheses of **12d** and the title new quinone **2** were similarly achieved as shown in the scheme. The structures of these compounds, including the synthetic intermediates, were determined spectroscopically and by elemental analysis. It is noted that the IR spectrum of **2** showed the characteristic absorption band of a carbonyl group in a five-membered ring at 1708 cm^{-1}. The dicationic species **3** generated by dissolving **2** in strong acid was confirmed by the UV and ^1H NMR spectra. In the UV spectrum, the larger shift of the longest wavelength absorption band of **3** (about 100 nm) compared to the above-mentioned condensed penalenones (about 50 nm) suggests the generation of a dicationic species. Unfortunately, because of its low solubility in various solvents such as DMSO, DMF, and $CDCl_3$, the ^{13}C NMR spectrum of **2** could not be obtained. However, the ^1H chemical shifts of **2** in D_2SO_4 showed that all protons of both the phenalenone moiety and the indenone moiety were shifted to low field by 0.70 ppm and 0.38 ppm, respectively, (av. 0.57 ppm) compared to those of **2** in $CDCl_3$. The down field shifts of the



indenone moiety could not be interpreted only by the deshielding effect of the monocation generated in the phenalenone moiety, but it should be considered as due to the generation of the dicationic species. Then, it is to be noted that the protons of the phenalenone moiety of **3** (av. 8.70 ppm) in D_2SO_4 resonated at higher field than those of the dicationic species **5** (av. 9.15 ppm) by 0.45 ppm. This might be interpreted by some contribution of a paratropic rather than the diatropic character expected for 18-π electrons, in accord with the case of the dicationic species of cyclohepta[*a*]-phenalene-6,12-dione **5**[2] in which the diatropic character was observed in spite of its 16-π electronic system.[3]

Experimental

All melting points are uncorrected. The ^1H NMR spectra were taken on a Hitachi R-24 (60 MHz) and on a JEOL-FX 90 (90 MHz) spectrometers, in chloroform-*d* (TMS as internal standard) trifluoroacetic acid-*d* (TMS), and deuteriosulfuric acid (dichloromethane as internal standard). The ^{13}C NMR spectra were taken on a JEOL-FX 90 (23 MHz) spectrometer, in chloroform-*d* (TMS as internal standard) and trifluoroacetic acid-*d* (TMS). The mass spectra were taken on a JEOL-OISG-2 mass spectrometer. The UV and IR spectra were taken on a Hitachi EPS-3T spectrometer and on a IR-810 spectrometer, respectively.

The Following Procedures a) and b) Are Representative for the Preparation of Condensed Compounds 8a, 8b, 8c, 8d, and 8e. a) Condensation of Cyclic Ketones with 1-Formyl-2-methoxynaphthalene 6. To a solution of 3.00 g (16 mmol) of **6** and 1.80 g (16 mmol) of **7a** in 30 mL of anhydrous THF 0.90 g (16 mmol) of sodium methoxide was added and refluxed for 3 h. After cooling the solution was poured onto dil. hydrochloric acid (HCl) and extracted three times with 20 mL of ether. The combined organic layer was washed with water and brine, and dried over anhydrous $MgSO_4$. After removal of the solvent in vacuo, the residue was chromatographed on silica gel to give 4.32 g (90%) of **8a**, from benzene elution.

8a; pale yellow oil; IR (film) 3027w, 1665vs, 1250s, 926m, 788m, 730m cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.70—7.50 (m, 4H), 7.40—7.10 (m, 4H), 3.78 (s, 3H, -OMe), 2.60 (m, 2H), 2.30 (m, 2H), 1.60 (m, 6H); MS *m/z* 280 (M^+, 100%), and HRMS Found: 280.1461, Calcd for $C_{19}H_{20}O_2$: 280.1461.

8d; pale yellow needles (recrystallized from hexane); mp 72—74 °C; IR (KBr) 3060w, 1670vs, 1610m, 1258vs, 740m, 706m cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.70 (m, 1H), 8.75—7.10 (m, 6H), 3.81 (s, 3H, -OMe), 2.70 (m, 2H), 2.58 (m, 2H); MS *m/z* 314 (M^+, 100%); Anal. ($C_{22}H_{18}O_2$) C, H.

8e; (56%); orange needles (recrystallized from hexane and dichloromethane); mp 218—219 °C; IR (KBr) 3055w, 2925w, 1680vs, 1615s, 1248vs, 725m cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.18 (s, 1H), 7.90—7.00 (m, 10H), 3.75 (s, 3H, -OMe), MS *m/z* 294 (M^+, 100%); Anal. ($C_{21}H_{14}O_3$) C, H.

b) **Condensation Reaction of Enamines with 6.** The mixture of 2.30 g (13.5 mmol) of **6** and 2.35 g (13.5 mmol) of *N*-cyclohexenylmorpholine **7b** in 15 mL of dry toluene was refluxed for 12 h. The cooled reaction mixture was added to 10 mL of 3 M-HCl solution and refluxed for 30 min. The resulting mixture was extracted with ether (15 mL×3). The combined organic layer was washed with water and brine three times each, and dried over anhydrous $MgSO_4$. After removal of the solvent, the residue was chromatographed on silica gel to give 4.45 g (76%) of pale yellow solid of **8b** from benzene elution, and recrystallized from hexane.

8b; pale yellow needles; mp 107—109 °C; IR (KBr) 3045w, 2850w, 1680vs, 1615s, 1245vs, 800m, 740m cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.70 (m, 7H), 3.26 (s, 3H, -OMe), 2.50—2.00 (m, 4H), 1.95—1.40 (m, 4H), MS *m/z* 266 (M^+, 28%), 236 (100%); Anal. ($C_{18}H_{18}O_2$) C, H.

Similarly **8c** was obtained in 74% yield; pale yellow needles hexane); mp 97—98.5 °C; IR (KBr) 3050w, 1710vs, 1610m, 780m cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.80—7.60 (m, 4H), 7.50—7.15 (m, 3H), 3.84 (s, 3H, -OMe), 2.42 (t, *J*=7.2 Hz, 2H), 2.40 (t, *J*=7.2 Hz, 2H), MS *m/z* 252 (M^+, 20%), 221 (100%); Anal. ($C_{17}H_{16}O_2$) C, H.

General Procedure for the Catalytic Hydrogenation of α,β-Unsaturated Ketones and the Following Cyclodehydration Reaction. To a solution of ca. 15 mmol of the unsaturated ketone in excess of ten times its weight of ethyl acetate (ca. 50—60 mL) a catalytic amount of platinum dioxide (ca. 1 mg) was added and hydrogenated under medium pressure (2.7—3.0 atm) of hydrogen at room temperature for 3.5 h. The resulting mixture was filtered and concentrated under reduced pressure to give the hydrogenated product. The resulting residue was added to about ten times its weight of 90% sulfuric acid and stirred at 45 °C for 25 min in an oil bath. The mixture was poured onto a large excess (ca. ten times of weights) of ice-water, and extracted with dichloromethane (50 mL×3). The combined organic layer was washed three times with water and brine, and dried over anhydr. $MgSO_4$.

After removal of the solvent, the residure was chromatographed on silica gel to give phenalenone derivatives from dichloromethane eluent; These were recrystallized from hexane.

9a; pale yellow oil; IR (film) 3050w, 2930w, 1730vs, 1690s, 1250s, 938m, 800m, 745m cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.60—6.90 (m, 6H), 3.75 (s, 3H, -OMe), 3.40—3.15 (m, 3H), 2.80—2.35 (m, 4H), 1.80—1.40 (m, 6H); MS *m/z* 282 (M^+, 100%), 141 (98%), HRMS Found: 282.1635, Calcd for $C_{19}H_{22}O_2$: 282.1620.

9b; pale yellow oil; IR (film) 3050w, 3000w, 1700vs, 1620m, 1590s, 1150m, 802m, 749m cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.05—7.00 (m, 6H), 3.80 (s, 3H), 3.50 (m, 1H), 2.50—1.50 (m, 10H), MS *m/z* 270 (M^+, 100%); HRMS Found: 268.1421, Calcd for $C_{18}H_{20}O_2$: 268.1460.

9c; pale yellow oil; IR (film) 3060w, 2940w, 1736vs, 1625s, 1255vs, 1160s, 810m, 750m cm^{-1}; ^1H NMR ($CDCl_3$) δ=7.95 (d, *J*=8.8 Hz, 1H), 7.70 (m, 2H), 7.55—7.18 (m, 3H), 3.88 (s, 3H, -OMe), 3.52 (dd, *J*=4.8 and 14.0 Hz, 1H), 3.10 (dd, *J*=12.0 and 14.0 Hz, 1H), 2.60—2.10 (m, 3H), 2.0—1.50 (m, 4H); MS *m/z* 252 (M^+, 35%), 171 (100%); HRMS Found: 252.1296, Calcd for $C_{17}H_{18}O_2$: 252.13404.

9d; pale yellow needles (hexane); mp 110—111 °C; IR (KBr) 3025w, 1662vs, 1608s, 1240vs, 796m, 732m cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.02 (m, 2H), 7.70 (m, 2H), 7.25 (m, 6H), 3.85 (m, 1H), 3.83 (s, 3H, -OMe), 3.22 (dd, *J*=12.0 and 16.0 Hz, 1H), 2.80 (m, 3H), 1.94 (m, 2H), MS *m/z* 316 (M^+, 100%); Anal. ($C_{22}H_{20}O_2$) C, H.

9e; pale yellow needles (hexane); mp 169—172 °C; IR (KBr) 3040w, 2920vs, 1721s, 1685vs, 1238vs, 1066s, 786m, 720 cm^{-1}; ^1H NMR ($CDCl_3$) δ=8.02—7.63 (m, 6H), 7.55—7.10 (m, 4H), 3.77 (s, 3H, -OMe), 3.61 (d, *J*=6.2 Hz, 2H), 3.33 (dd, *J*=6.2 and 8.6 Hz, 1H), MS *m/z* 316 (M^+, 100%); Anal. Oxovanadium(V)-Induced Ring-Opening Oxygenation of Cyclic Ketones in Alcohol

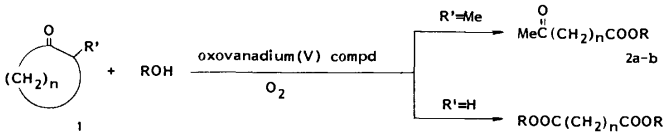
Toshikazu HIRAO,* Makoto MORI, and Yoshiki OHSHIRO*
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received November 7, 1988)

Synopsis. Cyclic ketones underwent ring-opening oxygenation on treatment with $VO(OEt)Cl_2$ in alcohol under oxygen to give the corresponding keto ester or diesters depending on the substituent at 2-position. This system was applicable to a catalytic reaction.

Higher oxidation state species of transition metals induce effective oxidative transformations. Vanadium compounds including oxovanadium ones have been known to be useful in oxidation. Their utilization is, however, limited mostly in acidic water,[1] which reduces the synthetic versatility. We herein describe that oxovanadium(V) ethoxides are sufficiently used in the ring-opening oxygenation reactions of cyclic ketones in alcohol.

2-Methylcyclohexanone (**1a**) was oxidized to ethyl 6-oxoheptanoate (**2a**) on treatment with the solution of $VO(OEt)_3$ or $VO(OEt)Cl_2$ in ethanol under oxygen. The regioselective bond cleavage between carbonyl carbon and 2-carbon was observed without formation of the regioisomer (Eq. 1). Molecular oxygen was introduced effectively in this system to form the carbonyl function since only a trace amount of the keto ester **2a** was obtained under nitrogen. Reaction in methanol led to the predominant formation of the corresponding



(1)

methyl ester **2b** with a small amount of **2a**, suggesting that the alkoxyl group is derived from the solvent. The reactivities of vanadium compounds were found to depend on their substituents; $VO(acac)_2$ and $V(acac)_3$ were less active than $VO(OEt)Cl_2$. $VO(OEt)Cl_2$ worked well with cyclohexanone (**1c**) as listed in Table 1, but use of $VO(OEt)_3$ gave a poor yield of diethyl adipate (**2c**) under the same conditions. The similar difference in reactivities was also observed in oxygenation of unsubstituted cyclic ketones such as cycloheptanone (**1d**) and cyclooctanone (**1e**). It is assumed to be due to the high Lewis acidity of $VO(OEt)Cl_2$.

In contrast, substitution with chloro group at 2-position of cyclohexanone resulted in the facile oxidation with either $VO(OEt)_3$ or $VO(OEt)Cl_2$ giving the same diester **2c** as obtained from cyclohexanone (Eq. 2, Table 1).

Table 1. Vanadium-Induced Oxygenation Reactions

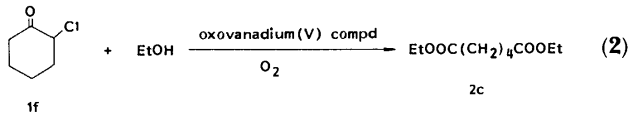
1	Vanadium Compd[a]	ROH, R	Time/h	2	Yield/%
(**1a**)	$VO(OEt)Cl_2$	Et	3	$MeC(=O)(CH_2)_4COOEt$ (**2a**)	52
1a	$VO(OEt)Cl_2$	Et	3[b]	**2a**	3
1a	$VO(OEt)_3$	Et	22	**2a**	50
1a	$VO(OEt)_3$	Me	30	$MeC(=O)(CH_2)_4COOMe$ (**2b**)	60[c]
1a	$VO(acac)_2$	Et	30	**2a**	30
1a	$V(acac)_3$	Et	30	**2a**	19
(**1c**)	$VO(OEt)Cl_2$[d]	Et	30	$EtOOC(CH_2)_4COOEt$ (**2c**)	64
1c	$VO(OEt)_3$	Et	30	**2c**	3
(**1d**)	$VO(OEt)Cl_2$	Et	30	$EtOOC(CH_2)_5COOEt$ (**2d**)	40
1d	$VO(OEt)_3$	Et	30	**2d**	Trace
(**1e**)	$VO(OEt)Cl_2$	Et	20	$EtOOC(CH_2)_6COOEt$ (**2e**)	35
1e	$VO(OEt)_3$	Et	11	**2e**	0
(**1f**)	$VO(OEt)Cl_2$	Et	3	**2a**	46
1f	$VO(OEt)_3$	Et	11	**2a**	57

a) Vanadium compound (1.0 equiv) was used unless otherwise stated. b) Reaction was carried out under nitrogen. c) The keto ester **2a** was obtained in 7% yield. d) $VO(OEt)Cl_2$ (1.25 equiv) was used.

Table 2. Oxovanadium(V)-Catalyzed Oxygenation Reactions[a)]

1	Oxovanadium Compd/equiv		Time/h	2	Yield/%
1a	$VO(OEt)Cl_2$	0.2	10	**2a**	50
1a	$VO(OEt)Cl_2$	0.05	30	**2a**	53
1a	$VO(OEt)_3$	0.2	11	**2a**	3
1c	$VO(OEt)Cl_2$	0.2	60	**2c**	30
1f	$VO(OEt)Cl_2$	0.2	10	**2c**	52

a) Reactions were carried out in ethanol.



(2)

Another interesting feature should be noted that a catalytic system was achieved by use of $VO(OEt)Cl_2$ under oxygen (Eq. 3). Some results are summarized in Table 2, showing that 0.05 mol equiv of $VO(OEt)Cl_2$ were enough for the oxygenation reaction. An active oxovanadium species seems to be regenerated in situ. With $VO(OEt)_3$ employed, however, such a catalytic cycle was not observed under the similar conditions.

(3)

Although the reaction mechanism has not been elucidated yet, one of the plausible paths is figured out as follows. Oxovanadium(V) ethoxide is assumed to work as a Lewis acid to generate the thermodynamically stable enolate, which is considerd to undergo the similar oxygenation reaction as reported.[1,2)]

The chemistry of transition metal enolates recently draws much attention because it has been scarcely explored despite valuable intermediates in organic syntheses.[3)] Considering oxovanadium(V) ethoxides as Lewis acids with oxidation ability, the above-mentioned ring-opening oxygenation reaction is considered to present such an example.

Experimental

^1H NMR spectra were measured on JEOL JNM-FX90Q spectrometer; IR spectra were measured using Hitachi 270-30 spectrometer. Mass spectra were determined by the electron impact method on Hitachi RMV-6E. $VO(OEt)Cl_2$ was prepared from $VOCl_3$ and an equimolar amount of ethanol with bubbling nitrogen into the hexane solution at room temperature and distilled under the reduced pressure (bp 36—38 °C/1 mmHg†). $VO(OEt)_3$ was supplied from Shinko Chemical Co., Ltd. Ketones and alcohols were purified according to usual methods.

† 1 mm Hg=133.322 Pa.

The Representative Procedure for the Oxovanadium(V)-Induced Oxygenation Reaction of 1. To a solution of 2-methylcyclohexanone (**1a**, 0.224 g, 2.0 mmol) in ethanol (2 mL) was added $VO(OEt)Cl_2$ (0.366 g, 2.0 mmol) at room temperature. The mixture was stirred at reflux under oxygen (1 atm, gasbag) for 3 h. Saturated aqueous $NaHCO_3$ solution (30 mL) was added to the resultant mixture, which was extracted with ether (5×30 mL). The combined ethereal solution was washed with saturated aqueous NH_4Cl solution (10 mL) and then water (10 mL), dried over Na_2SO_4, and concentrated. The yield of ethyl 6-oxoheptanoate (**2a**) was determined by GLC (52% yield, PEG 20M 10%, 2.1 m column, 200 °C). If necessary, the residue was chromatographed on silica-gel column to give **2a**. The reactions of other cyclic ketones and 2-chlorocyclohexanone (**1f**) were carried out in the similar way as mentioned above. The reaction conditions are listed in Table 1. These products were identified by comparison of spectral data with those of the authentic samples.[4)]

The Oxovanadium(V)-Catalyzed Oxygenation Reaction of 1. The amount of $VO(OEt)Cl_2$ was reduced in the catalytic reactions as shown in Table 2. The procedure is similar as described in the stoichiometric reactions.

This study was partly supported with Grant-in-Aid for Special Project Research from the Ministry of Education, Science and Culture.

On the Reaction of *N*-Vinyliminophosphoranes with 2,4,6-Cyclooctatrienone. Intermediate Formation of 8-Azabicyclo-[5.3.1]undeca-2,4,7,9-tetraene Ring System[1)]

Makoto NITTA* and Nobuhiro KANOMATA
Department of Chemistry, School of Science and Engineering, Waseda University, Shinjuku-ku, Tokyo 169
(Received November 12, 1988)

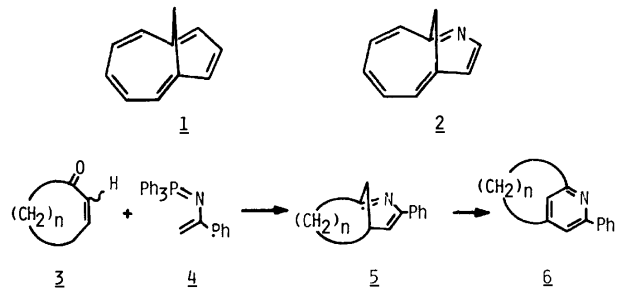
Synopsis. The reaction of *N*-(1-phenylvinyl)iminotriphenylphosphorane and of *N*-(1,3,5-cycloheptatrienyl)iminotributylphosphorane with 2,4,6-cyclooctatrienone gave an intermediacy of 8-azabicyclo[5.3.1]undeca-2,4,7,9-tetraene derivatives, which underwent an intramolecular Diels–Alder reaction to construct a tetracyclic ring system.

The 1,6-methano[10]annulenes[2,3)] and their nitrogen analogues[4,5)] have been widely investigated by Vogel et al. and have been recognized as aromatic compounds in terms of their chemical and spectroscopic properties. The synthesis of 1,5-methano[10]-annulene (**1**)[6,7)] was accomplished via two different routes, and the ^{1}H NMR clarified that the diamagnetic ring current is induced in this system, despite the expected differences in the pi-bond torsion between the two isomeric annulenes. However, no synthetic entry into 8-azabicyclo[5.3.1]undeca-1,3,5,7,9-pentaene (**2**), which is an analogue of **1**, has appeared. Thus, we attempted the synthesis of the 8-azabicyclo[5.3.1]undeca-2,4,7,9-tetraene skeleton, the dehydrogenation of which was expected to give the ring system, **2**.

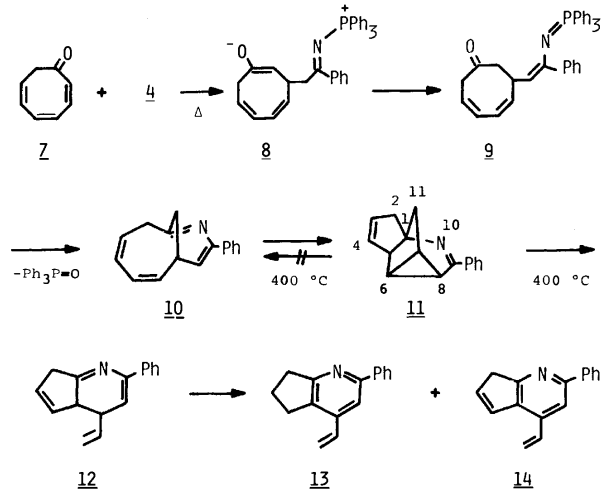
Our synthetic strategy is based upon utilizing *N*-vinyliminophosphoranes, which are very convenient synthones for constructing various heterocyclic ring systems.[8–13)] Among these synthetic reactions, *N*-(1-phenylvinyl)iminotriphenylphosphorane (**4**) reacted with a series of cyclic α,β-unsaturated ketones **3** to give [*n*](2,4)pyridinophane derivatives (**6**, n=6—9), as shown in Scheme 1.[12)] Therefore, the preparation of an 8-azabicyclo[5.3.1]undeca-2,4,7,9-tetraene ring system by using *N*-vinyliminophosphoranes, **4** and *N*-(1,3,5-cycloheptatrienyl)iminotributylphosphorane (**15**), with 2,4,6-cyclooctatrienone seemed to be promising.

The reaction of **7**[14)] and **4**[9,11)] in anhydrous 1,2-dimethylbenzene under reflux for 15 h gave 9-phenyl-10-azatetracyclo[5.3.1.0.^{1,5}0^{6,8}]undeca-3,9-diene (**11**) in 47% yield (Scheme 2). The formation of **11** can be reasonably explained as follows.[12)] The Michael addition of **4** to the β-carbon atom of **7** gives **8**, the hydrogen transfer of which gives **9**. The intramolecular aza-Wittig reaction of **9** is expected to give **10**. However, compound **10** seems to be labile under reaction conditions and underwent an intramolecular Diels–Alder reaction to give **11**. The thermal lability of **10** to give **11** is reminiscent of the thermal reactivity of bicyclo[5.3.1]undeca-2,4,7,9-tetraene, the C_2=C_3 double bond and diene system in which are located appropriate for the Diels–Alder reaction.[6a)] The assignments of ^{1}H and ^{13}C resonances of **11** are accomplished by 2D ^{1}H NMR and 2D ^{1}H–^{13}C NMR analysis. Considering the ^{1}H NMR spectrum, a pair of methylene protons (11-H_2) appears at δ 1.93 and δ 0.85, which is shielded by the C=N double bond. The remaining signals appear at δ 1.93—1.99 (5-H, 6-H, and 7-H), δ 2.56 (8-H), δ 2.66 and 2.85 (a pair of methylene protons, 2-H_2) δ 5.76 and 5.79 (a pair of vinyl protons, 3-H and 4-H), and δ 7.39 and 7.38 (phenyl group). The ^{1}H NMR and ^{13}C NMR (see Experimental) characteristics are in good accordance with the proposed structure of **11**. Since we could not succeed in isolating the intermediate **10**, we tried a retro Diels–Alder reaction of **11** to **10**. However, the flash pyrolysis of **11** at 400 °C afforded 6,7-dihydro-2-phenyl-4-vinyl-5*H*-cyclopenta[*b*]pyridine (**13**) and 2-phenyl-4-vinyl-7*H*-cyclopenta[*b*]pyridine (**14**) in 22 and 4% yield, respectively. The spectral data of **13** and **14** supported the structures (see Experimental). The formation of **13** and **14** is explained by retro Diels–Alder reaction including methylene bridge, a typical Cope rearrangement of tricyclo[3.2.1.0^{2,7}]oct-3-ene system,[15)] to result in the formation of an intermediate **12** followed by hydrogen transfer or dehydrogenation (Scheme 2).

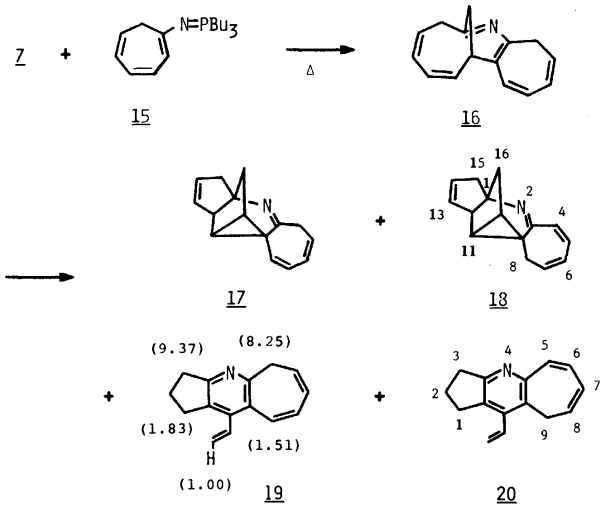
Similarly, the reaction of **9** with *N*-(1,3,5-cycloheptatrienyl)iminotributylphosphorane (**15**)[13)] in anhydrous bromobenzene under reflux afforded a mixture of 2-



Scheme 1.



Scheme 2.



Scheme 3.

azapentacyclo[8.5.1.0.^{1,12}0.^{3,9}0^{9,11}]hexadeca-2,5,7,13-tetraene (**17**) (35%), 2-azapentacyclo[8.5.1.0.^{1,12}0.^{3,9}0^{9,11}]-hexadeca-2,4,6,13-tetraene (**18**) (35%), 1,2,3,5-tetrahydro-10-vinylcyclohepta[*b*]cyclopenta[*e*]pyridine (**19**) (5%), and 1,2,3,9-tetrahydro-10-vinylcyclohepta[*b*]cyclopenta-[*e*]pyridine (**20**) (1.4%), via the possible intermediate **16** (Scheme 3). Although the isolation of both **17** and **18** was unsuccessful, compound **18** was isolated in pure form in the thermal reaction of a mixture of **17** and **18** (vide infra). The ^{1}H NMR spectrum of **18** exhibited signals of a shielded methylene proton (16-H) at δ 0.65, which is located over the C=N double bond, a pair of methylene protons (15-H$_2$) at δ 2.55 and 2.70, two vinyl protons (13-H and 14-H) at δ 5.69, and four protons (10-H, 11-H, 12-H, and 16-H) at δ 1.50—1.90. The chemical shifts and the coupling patterns of these signals are similar to the corresponding signals of **11**. The remaining signals on the cycloheptadiene moiety for **18** appear at δ 6.48 (4-H), δ 6.20 (5-H), and δ 5.99 (6-H and 7-H), in addition to the signals of a pair of methylene protons at δ 2.23 and 2.29 (8-H$_2$). The assigned ^{1}H NMR and ^{13}C NMR (see Experimental) characteristics are in good accordance with the proposed structure **18**. On the other hand, the ^{1}H NMR signals corresponding to **17** were read from the spectrum of a mixture of **17** and **18**. The signals of a shielded methylene proton (16-H) appearing at δ 0.73, three methine protons (10-H, 11-H, and 12-H) and a methylene proton (16-H) at δ 1.47—2.07, a pair of methylene protons (15-H$_2$) at δ 2.37—2.77, and a pair of vinyl protons (13-H and 14-H) appearing at around δ 5.71 are suggestive of a skeleton similar to **18**. Furthermore, two methylene protons appearing at δ 3.00—3.20 and four vinyl protons (5-H, 6-H, 7-H, and 8-H) appearing at δ 5.30—6.55 are suggestive of the cycloheptadiene moiety. A characteristic difference between **17** and **18** is the chemical shifts of methylene protons in their cycloheptadiene rings. The fact that the methylene signals (4-H$_2$) of **17** appear at lower field than those (8-H$_2$) of **18** is ascribed to a deshielding effect of the nitrogen atom which is close to 4-H$_2$ in **17**. The ^{1}H NMR and ^{13}C NMR (assigned in Experimental) spectra of **19** and **20** revealed that they have a cycloheptatriene ring fused on the pyridine ring. The methylene protons in the cycloheptatriene rings of **19** (δ 3.19) and **20** (δ 2.97), and the pseudo-contact ^{1}H NMR spectra of **19** obtained by using Eu(fod)$_3$ unequivocally supported the structures. The relative down-field shifts of the δ's of typical protons are given in parentheses in the structural formula **19**. Compound **18** could be derived from 1,5-hydrogen shift of **17**. The independent thermal reaction of a 1/1 mixture of **17** and **18** in bromobenzene under reflux gave **19** and **20**, in addition to **18**. The pathways for the formation of **19** and **20** can be expalined by a Cope rearrangement of **17** and **18**, as in the case of **11**. The thermal isomerization reaction of **19** in refluxing bromobenzene also occurred to give **20**, thus suggesting the interconversion between **19** and **20**.

The smallest cyclic α,β-unsaturated ketone which reacted with *N*-vinyliminophosphoranes is cyclononenone, giving [6](2,4)pyridinophane (Scheme 1).[12] We have clarified here that the *N*-vinyliminophosphoranes, **4** and **15**, actually react with 8-membered ketone **7** to form constrained intermediates, 8-azabicyclo[5.3.1]undeca-2,4,7,9-tetraene derivatives **10** and **16**.

Experimental

The IR spectra were recorded on a Shimadzu IR-400 spectrometer. The ^{1}H NMR spectra were recorded on a Hitachi R-24 or on a Hitachi R-90H spectrometer. The ^{13}C NMR spectra were recorded on a Hitachi R-90H or on a JEOL GSX400 spectrometer. The 2D ^{1}H NMR and 2D ^{1}H–^{13}C NMR experiments were performed on a JEOL GSX400 spectrometer. The chemical shifts are given in ppm (δ) relative to the internal SiMe$_4$ standard. The mass and high-resolution mass spectral studies were conducted using Shimadzu GCMS QP-1000 and JEOL JMS-DX300 spectrometers. The desired 2,4,6-cyclooctatrienone (**7**),[14] *N*-(1-phenylvinyl)iminotriphenylphosphorane (**4**)[9,11] and *N*-(1,3,5-cycloheptatrienyl)iminotributylphosphorane (**15**)[13] were prepared by the methods described in the literature. All the reactions were carried out under a dry nitrogen atmosphere.

Reaction of 7 with 4. A solution of **7** (60 mg, 0.50 mmol) and **4** (284 mg, 0.75 mmol) in anhydrous 1,2-dimethylbenzene (5 cm^3) was refluxed for 15 h. After the solvent was evaporated, the residue was separated by TLC on silica gel using benzene–ethyl acetate (10/1) as a developer to give **11** (52 mg, 47%), triphenylphosphine oxide (120 mg, 58%) and acetophenone (12 mg, 13%) which arise from the hydrolysis of **4**. For **11**: Mp 44—47 °C; IR (CCl_4), 3059, 2930, 2860, 1592, 1562, 1494, 1446, 1383, 1351, 1292, 1256, 1196, 1182, 1156, 1122, 1106, 1096, 1070, 1022, 992, 936, 842 cm^{-1}; ^{1}H NMR ($CDCl_3$), δ=0.85 (1H, dd, J=11.0, 1.0 Hz), 1.93 (1H, dd, J=11.0, 2.0 Hz), 1.93—1.99 (3H, m), 2.56 (1H, t, J=7.5 Hz), 2.66 (1H, ddd, J=16.0, 2.5, 1.2 Hz), 2.85 (1H, ddd, J=16.0, 2.5, 1.6 Hz), 5.76 (1H, dtd, J=6.1, 2.5, 1.6 Hz), 5.79 (1H, ddt, J=6.1, 2.5, 1.2 Hz), 7.39 (3H, m), 7.83 (2H, m); ^{13}C NMR ($CDCl_3$), δ=18.9 (d, 6-C or 7-C), 19.3 (d, 7-C or 6-C), 20.9 (d, 8-C), 31.4 (t, 11-C), 40.3 (t, 2-C), 50.9 (d, 5-C), 71.1 (s, 1-C), 126.1 (2C, d, Ph), 128.1 (2C, d, Ph), 129.2 (d, Ph), 129.8 (d, 3-C or 4-C), 131.5 (d, 4-C or 3-C), 139.2 (s, Ph), 167.0 (s, 9-C); MS, *m/z* (rel intensity), 221 (M^+, 68), 220 (100). Found: *m/z* 221.1219. Calcd for $C_{16}H_{15}N$: M, 221.1204.

Thermal Reaction of 11. A solution of **11** (100 mg, 0.45 mmol) in anhydrous benzene (20 cm^3) was passed through a Pyrex column (15 mm×120 mm) containing glass beads (ϕ=2 mm) preheated at 400 °C under a nitrogen stream (flow rate=20 cm^3 min^{-1}). After concentration of the

collected pyrolysate, the resulting residue was separated by TLC on alumina using hexane–ether (4/1) to give **13** (22 mg, 22%) and **14** (4 mg, 4%). For **13**: Yellow oil; IR (CCl_4), 3067, 2960, 2848, 1593, 1581, 1565, 1500, 1461, 1443, 1430, 1388, 1337, 1224, 1031, 990, 924, 877, 694 cm^{-1}; ^1H NMR ($CDCl_3$), δ=2.14 (2H, tt, J=8.1, 7.9 Hz), 2.99 (2H, t, J=7.9 Hz), 3.08 (2H, t, J=8.1 Hz), 5.50 (1H, dd, J=11.0, 1.1 Hz), 5.90 (1H, dd, J=17.6, 1.1 Hz), 6.76 (1H, dd, J=17.6, 11.0 Hz), 7.29—7.49 (4H, m), 7.89—8.00 (2H, m); ^{13}C NMR ($CDCl_3$), δ=22.8 (t, 6-C), 29.5 (t, 5-C), 34.4 (t, 7-C), 114.4 (d, 3-C), 118.9 (t, $=CH_2$), 126.8 (2C, d, Ph), 128.2 (d, Ph), 128.4 (2C, d, Ph), 132.6 (s, 4a-C), 133.6 (d, -CH=), 139.9 (s, Ph), 141.0 (s, 4-C), 156.2 (s, 2-C), 166.4 (s, 7a-C); MS, m/z (rel intensity), 221 (M^+, 75), 220 (100). Found: m/z 221.1199. Calcd for $C_{16}H_{15}N$: M, 221.1204. For **14**: Yellow oil; IR (CCl_4), 3071, 2930, 1593, 1502, 1461, 1433, 1378, 1226, 1027, 988, 922, 874, 693 cm^{-1}; ^1H NMR (CCl_4), δ=3.48 (2H, m), 5.50 (1H, dd, J=11.0, 1.2 Hz), 5.94 (1H, dd, J=16.8, 1.2 Hz), 6.85 (1H, dd, J=16.8, 11.0 Hz), 6.93—7.67 (6H, m), 7.85—8.08 (2H, m); MS, m/z (rel intensity), 219 (M^+, 100). Found: m/z 219.1050. Calcd for $C_{16}H_{13}N$: M, 219.1048.

Reaction of 7 with 15. A solution of **7** (600 mg, 5.00 mmol) and **15** (2.30 g, 7.50 mmol) in anhydrous bromobenzene (20 cm^3) was heated under reflux for 3 h. After the solvent was evaporated, the resulting residue was separated by column chromatography on silica gel. The fractions eluted with benzene–ethyl acetate (9/1) afforded a mixture of **19** and **20** (98 mg, 9%). The fractions eluted with benzene–ethyl acetate (8/2) afforded a mixture of **17** and **18** (741 mg, 71%) in a ratio of 1/1. The mixture of **19** and **20** was separated by TLC on alumina using hexane–ether (4/1) as developer. The first band from the TLC plates contained **19** (53 mg, 5%). The second band contained **20** (15 mg, 1.4%). For **18**: Oil; IR (CCl_4), 3035, 2931, 2855, 1600, 1551, 1442, 1427, 1345, 1294, 1180, 1114, 940, 894, 880 cm^{-1}; ^1H NMR ($CDCl_3$), δ=0.65 (1H, d, J=11.4 Hz), 1.50—1.90 (4H, m), 2.23 (1H, dd, J=14.9, 5.9 Hz), 2.29 (1H, dd, J=14.9, 5.7 Hz), 2.55 (1H, d, J=16.3 Hz), 2.70 (1H, dd, J=16.3, 3.1 Hz), 5.69 (2H, m), 5.99 (2H, m), 6.20 (1H, dd, J=11.6, 4.8 Hz); ^{13}C NMR ($CDCl_3$), δ=25.4 (d, 10-C or 11-C), 25.7 (d, 11-C or 10-C), 30.2 (t, 8-C), 31.1 (t, 16-C) 37.3 (s, 9-C), 39.9 (t, 15-C), 50.4 (d, 12-C), 72.0 (s, 1-C), 127.7 (d, 7-C), 129.6 (d, 14-C), 130.8 (d, 6-C) 131.4 (d, 13-C), 132.0 (d, 5-C), 133.5 (d, 4-C), 170.0 (s, 3-C); MS, m/z (rel intensity), 209 (M^+, 48), 208 (100). Found: m/z 209.1195. Calcd for $C_{15}H_{15}N$: M, 209.1204. The ^1H NMR signals for **17** was read from the spectrum of a mixture of **17** and **18** as follows: δ=0.73 (1H, d, J=11.0 Hz), 1.47—2.07 (4H, m), 2.37—2.77 (2H, m), 3.00—3.20 (2H, m), 5.71 (2H, m), 5.30—6.55 (4H, m). For **19**: Oil; IR (CCl_4), 3083, 3031, 2882, 2856, 2847, 1622, 1584, 1559, 1542, 1427, 1402, 1384, 1366, 1242, 1212, 1162, 998, 933, 850 cm^{-1}; ^1H NMR ($CDCl_3$), δ=2.06 (2H, tt, J=7.9, 7.7 Hz), 2.90 (2H, t, J=7.7 Hz), 3.00 (2H, t, J=7.9 Hz), 3.19 (2H, d, J=6.6 Hz), 5.52 (1H, dd, J=17.6, 1.7 Hz), 5.64 (1H, dd, J=11.6, 1.7 Hz), 5.84 (1H, dt, J=9.7, 6.6 Hz), 6.11 (1H, dd, J=9.7, 4.8 Hz), 6.53 (1H, dd, J=11.7, 4.8 Hz), 6.80 (1H, dd, J=17.6, 11.6 Hz), 7.11 (1H, d, J=11.7 Hz); ^{13}C NMR ($CDCl_3$), δ=23.2 (t, 2-C), 30.5 (t, 1-C), 34.4 (t, 3-C), 37.5 (t, 5-C), 121.9 (t, $=CH_2$), 125.0 (s, 9a-C), 125.7 (d, 6-C), 126.9 (d, 7-C), 128.4 (d, 8-C), 128.7 (d, 9-C), 131.8 (s, 10a-C), 132.7 (d, -CH=), 139.8 (s, 10-C), 153.8 (s, 4a-C), 165.7 (s, 3a-C); MS, m/z (rel intensity), 209 (M^+, 100). Found: m/z 209.1211. Calcd for $C_{15}H_{15}N$: M, 209.1204. For **20**: Oil; IR (CCl_4), 3083, 3031, 2891, 2858, 2846, 1622, 1581, 1542, 1432, 1381, 1182, 992, 930 cm^{-1}; ^1H NMR ($CDCl_3$), δ=2.08 (2H, quint, J=7.3 Hz), 2.95 (2H, t, J=7.3 Hz), 2.97 (2H, d, J=6.7 Hz), 3.01 (2H, t, J=7.3 Hz), 5.51 (1H, dd, J=17.6, 1.5 Hz), 5.65 (1H, dd, J=11.6, 1.5 Hz), 5.81 (1H, dt, J=9.7, 6.7 Hz), 6.16 (1H, dd, J=9.7, 5.3 Hz), 6.65 (1H, dd, J=11.6, 5.3 Hz), 6.88 (1H, dd, J=17.6, 11.6 Hz), 7.30 (1H, d, J=11.6 Hz); ^{13}C NMR ($CDCl_3$), δ=23.4 (2-C), 27.8 (9-C), 30.9 (1-C), 34.2 (3-C), 121.3 ($=CH_2$), 124.5 (9a-C), 126.4 (8-C), 126.8 (7-C), 129.9 (6-C), 132.7 (-CH=), 134.5 (5-C), 134.8 (10a-C), 139.4 (10-C), 153.0 (4a-C), 162.4 (3a-C); MS, m/z (rel intensity), 209 (M^+, 100). Found: m/z 209.1189. Calcd for $C_{15}H_{15}N$: M, 209.1204.

Thermal Reaction of 17 and 18. A 1/1 mixture of **17** and **18** (209 mg, 1.00 mmol) in anhydrous bromobenzene (10 cm^3) was heated under reflux for 3 h. The reaction mixture was then concentrated and separated by column chromatography on silica gel using benzene–ethyl acetate (10/1) as eluent to give a mixture of **19** and **20** (8 mg, 4%), in addition to **18** (39 mg, 19%).

Thermal Reaction of 19. A solution of **19** (35 mg, 0.167 mmol) in anhydrous bromobenzene (3 cm^3) was heated under reflux for 3 h. After solvent removal in vacuo, the resulting residue was separated by TLC on alumina using hexane–ether (8/1) as a developer to give **19** (21 mg, 60%) and **20** (7 mg, 20%).

Enhanced Cyclization of *N*-Benzyloxycarbonyl-*N*-substituted Dipeptide Methyl Esters with Ammonia

Katsuhiro KAWASHIRO,* Kazuhisa NISHIGUCHI, and Ikuo KUROSAKA
Department of Chemical Science and Technology, Faculty of Engineering, The University of Tokushima, Minamijosanjima, Tokushima 770
(Received November 18, 1988)

Synopsis. Cyclization of *N,N'*-[*N*-(benzyloxycarbonyl)(Z)-iminobis(methylenecarbonyl)]bis[glycine] dimethyl ester to the hydantoin derivative took place easily under mild ammonolysis conditions. Replacement of Z by *p*-methoxybenzyloxycarbonyl also led to the cyclization. Influence of different substituent groups on the cyclization was studied with some *N*-Z-dipeptide methyl esters.

The benzyloxycarbonyl (Z) has been used frequently in peptide synthesis as an amino-protecting group. However, elimination of Z has been reported in some instances. For example, some *N*-Z-peptide esters give hydantoins or urea derivatives with the loss of benzyl alcohol by alkaline saponification, where glycine is next to N-terminal residue.[1-3] In addition, *N*-Z-dipeptide esters carrying glycine as C-terminus were converted to 3-(carbamoylmethyl)hydantoins, when the side chain of the N-terminal amino acid is rather large such as benzyl, 2-(methylthio)ethyl, or isobutyl group.[4,5] The present study concerns enhanced cyclization of *N*-Z- and *N*-*p*-methoxybenzyloxycarbonyl (Z(OMe))-*N*-substituted glycylglycine methyl esters with ammonia.

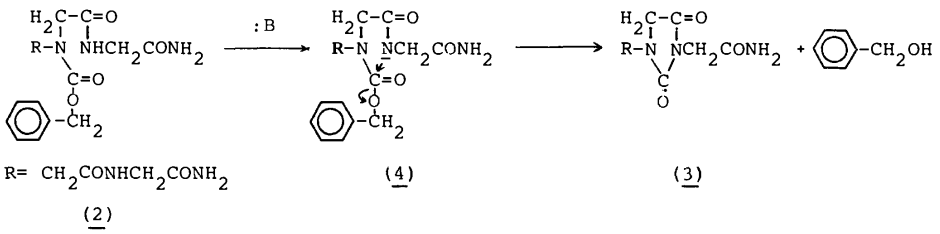
Results and Discussion

In an attempt to obtain *N,N'*-[*N*-Z-iminobis(methylenecarbonyl)]bis[glycinamide] (**2**), the corresponding dimethyl ester (**1**) was subjected to ammonolysis in methanol (MeOH) containing dry ammonia (ca. 6 M) (1 M=1 mol dm^{-3}) at room temperature for 24 h. Contrary to expectation, the product was soluble in water, ^{1}H and ^{13}C NMR spectra of which no longer showed signals characteristic of phenyl group. The amino acid analysis of the acid hydrolyzate revealed the presence of glycine and ammonia in a molar ratio of 1:2, and the absence of iminodiacetic acid (IDAA). The findings suggested that cyclization with a loss of Z group took place during the ammonolysis. The ^{1}H NMR spectrum was well consistent with a cyclic structure, 3-(carbamoylmethyl)-1-(carbamoylmethylaminocarbonylmethyl)hydantoin (**3**). The signals could be assigned as follows: A doublet at δ=3.66 is ascribed to NHCH_2 protons; three singlets at 3.94, 4.02, and 4.07 to the three CH_2, respectively; a pair of singlet at 7.08 and 7.35 to $CONH_2$; a pair of singlet at 7.22 and 7.56 to $CONH_2$; a triplet at 8.32 to NH.

For further identification of the product, the acid hydrolyzate was trimethylsilylated with *N,O*-bis(trimethylsilyl)(TMS)-trifluoroacetamide (BSTFA) and then analyzed by the gas chromatography-mass spectrometry (GC-MS). On GC, two peaks eluted: The first peak was identified as an *N,N,O*-tri-TMS derivative of glycine. In the mass spectrum of the second peak, the molecular (M^+) and M−15 (CH_3) ions were observed at *m/z* 360 and 345, respectively, indicating that this compound is the *O,O'*-di-TMS derivative of 1,3-bis(carboxymethyl)hydantoin (mol. wt.=360). Thus the ammonolysis product was confirmed not to be the linear diamide (**2**), but the cyclic amide (hydantoin derivative, **3**).

As shown in Scheme 1, ring closure to **3** involves proton abstraction from nitrogen of the peptide bonds of **2**. Then, the resulting anion (**4**) attacks the carbonyl carbon of the Z group, giving **3** along with the benzyloxyde anion. The ring closure is completed when the benzyloxyde anion abstracts a proton from the conjugate acid BH^+ forming benzyl alcohol. The hydantoin ring is not opened by the excess of ammonia because of its weak basicity.[6] The time course of the ammonolysis at room temperature was followed by HPLC. Benzyl alcohol and **3** were the final products. In contrast, **2** was found to be an intermediate product, which disappeared completely in 8 h.

When Z(OMe) was used as an *N*-protecting group (**5**) instead of Z, the cyclization also took place, but that was not the case for *t*-butoxycarbonyl (Boc) group (**6**); in the latter instance, the *N*-protected linear diamide (**7**) was obtained. This difference can be explained in terms of the nature of the *N*-protecting groups. The phenyl group of Z and Z(OMe) stabilizes the benzyloxyde-type anion by electron-withdrawing, leading to the cyclization. In contrast, the *t*-butyl group of Boc makes the corresponding anion very unstable by electron-repelling, and it consequently prevents the cyclization.



Scheme 1. A possible mechanism for cyclization.

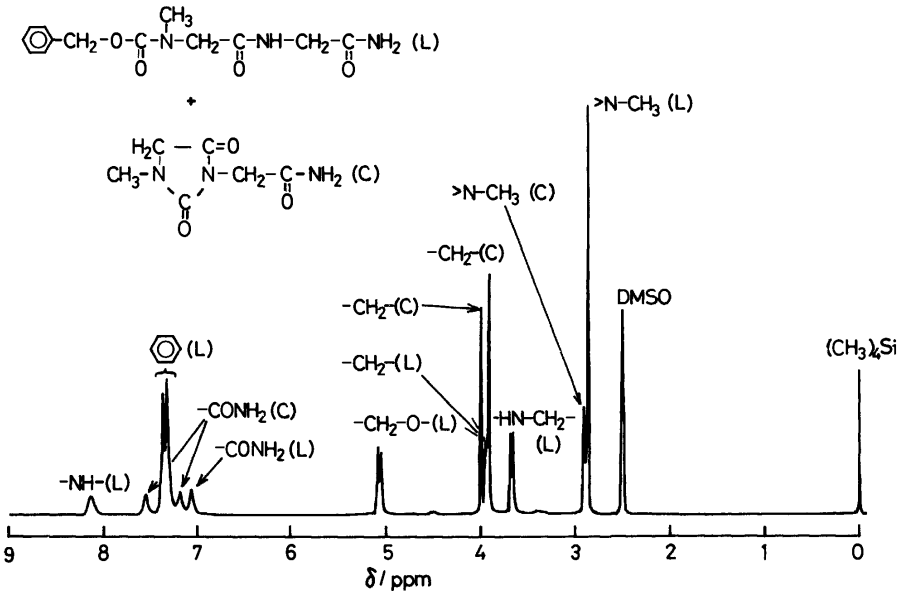


Fig. 1. ^{1}H NMR spectrum for the ammonolysis product of **9**.

Table 1. Results of the Ammonolysis of *N*-Z-dipeptide Methyl Esters

Parent ester	Ratio of the product	
	Linear amide	Cyclic amide
Z-DL-Ala-Gly-OMe (**8**)	100	—
Z-Sar-Gly-OMe (**9**)	54	46
Z-CEGly-Gly-OMe (**10**)	40	60
Z-CEAla-Gly-OMe (**11**)	8	92
Z-CEGly-DL-Ala-OMe (**12**)	100	—
Z(OMe)-CEGly-Gly-OMe (**13**)[a)]	60	40

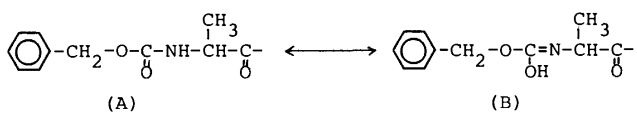
a) *N*-Z(OMe) derivative.

In order to investigate the influence of different substituent groups, some *N*-Z-dipeptide methyl esters were subjected to ammonolysis at room temperature for 24 h (Table 1). The NH of peptide bond was allowed to be free, because this NH plays an important role in the cyclization (Scheme 1). The ratio between linear and cyclic amides in the products was determined by the ^{1}H NMR spectroscopy.

Figure 1 shows the ^{1}H NMR spectrum for the ammonolysis product of Z-Sar-Gly-OMe (**9**). The absence of singlet at δ=3.6 indicated that ammonolysis of the ester was completed under these conditions. From the comparison of the spectrum (Fig. 1) with that of authentic Z-Sar-Gly-NH_2, the signals marked as L were assigned to the linear amide. But one of the two signals of $CONH_2$ overlaps with phenyl protons of Z. The remaining signals marked as C were well consistent with the cyclic amide, 3-(carbamoylmethyl)-1-methylhydantoin (**14**) as follows: A singlet at δ=2.91 was ascribed to NCH_3 protons; a singlet at 3.91 to CH_2; a singlet at 3.99 to CH_2; a pair of singlets at 7.19 and 7.55 to $CONH_2$. In this instance, the ratio of the two amides was determined by comparing the integrated value of CH_2O protons at δ=5.04 and 5.08 (linear amide) with that of NCH_3 at δ=2.87 and 2.91 (both amides). The formation of **14** was also confirmed by GC-MS after trimethylsilylation of the hydrolyzate of the reaction mixture.

As can be seen in Fig. 1, the absorption of the phenyl and CH_2O protons appeared like a doublet, respectively, thouth they must be singlets normally. For example, these two appeared as singlets for Z-Gly-Gly-NH_2. However, we found that **9** also exhibited such a signal splitting in the 200 MHz spectrum. Therefore, it seems plausible to consider that the signal splitting is due to the presence of the two conformational isomers in a DMSO solution of *N*-Z-*N*-substituted glycylglycine methyl esters and amides. In the 60 MHz spectra, such a signal splitting was not observed because of low resolution.

Table 1 presents the results of the ammonolysis. As we expected, the cyclization was not observed for Z-Gly-Gly-OMe and Z-DL-Ala-Gly-OMe (**8**), which carry no *N*-substituent groups. On the other hand, *N*-Z-*N*-substituted dipeptide esters having glycine residue as C-terminus were generally prone to ring closure. For example, **9** gave a mixture of the linear and cyclic amides in a ratio of 54:46, while its isomer **8** yielded only the normal linear amide. This difference could be explained in terms of the resonance effect. The contribution of resonance structure B increases the electron density on the carbonyl carbon of Z, so



(A) (B)

that the amide anion cannot attack it (Scheme 1). In contrast, such resonance is no longer possible with *N*-Z-*N*-substituted dipeptide esters, the carbonyl carbons of which remain electron-lacking.

The cyclization seems to depend on the nature of the *N*-substituent groups. For example, the extent of the cyclization of Z-CEGly-Gly-OMe[7] (**10**) was higher than that of **9**. This finding could be explained in terms of the difference in electron-repelling ability of the two substituent groups, CH_2CH_2CN and CH_3; the latter repels electron more strongly than the former, increasing electron density of the carbonyl carbon of Z of **9**. The substitution on α-carbon of the N-terminal glycine enhanced the cyclization significantly, as shown for Z-CEAla-Gly-OMe[7] (**11**). In contrast, the substitution on α-carbon of the C-terminal glycine prevented the cyclization completely, as shown for Z-CEGly-DL-Ala-OMe (**12**). This finding indicates that glycine residue carrying a reactive amino group must be present as C-terminus for the cyclization, because the hydantoin is a secondary amide, the diacyl derivative of C-terminal amino acid.

As we can expect, the corresponding *N*-Z(OMe)-dipeptides were also found to cyclize under the ammonolysis conditions. In the instance of Z(OMe)-CEGly-Gly-OMe (**13**), the extent of the cyclization was comparable with that of the corresponding *N*-Z derivative (**10**).

In conclusion, a special care in ammonolysis of *N*-Z- and *N*-Z(OMe)-*N*-substituted dipeptide esters was suggested. Such cyclization, however, will provide a convenient method for the synthesis of 1,3-disubstituted hydantoins.

Experimental

All the melting points determined by a Yanagimoto micro-melting point apparatus were not corrected. ^1H NMR spectra were obtained by a JEOL FX-200 (FT 200 MHz) spectrometer using tetramethylsilane as an internal reference. GC-MS was carried out as previously reported[8] to give 20 eV spectra. HPLC was carried out by a JASCO 880 pump connected with a JASCO 875 UV monitor (column, Finepak SIL C_{18}).

***N*-Protected IDAAs.** Introduction of Z, Z(OMe), and *t*-Boc to IDAA was carried out using Z-Cl,[9] MZ-SDP,[9] and Boc-SDP,[9] respectively, according to the conventional methods.

Z-IDAA: Yield 73%; mp 82—84 °C. Anal. ($C_{12}H_{13}NO_6$) C, H, N.

Z(OMe)-IDAA: Yield 85%; mp 121—122 °C. Anal. ($C_{13}H_{15}NO_7$) H, C, N.

***t*-Boc-IDAA:** Yield 65%; mp 117—120 °C. Anal. ($C_9H_{15}NO_6$) C, H, N.

***N*-Protected IDAA Disuccinimido Esters.** These were prepared by the dicyclohexylcarbodiimide method.

Z-IDAA Disuccinimido Ester: Yield 93%; mp 178—181 °C. Anal. ($C_{20}H_{19}N_3O_{10}$) C, H, N.

Z(OMe)-IDAA Disuccinimido Ester: Yield 64%; mp 201—203 °C. Found: C, 51.03; H, 4.44; N, 8.96%. Calcd for $C_{21}H_{21}N_3O_{11}$: C, 51.33; H, 4.31; N, 8.55%.

***t*-Boc-IDAA Disuccinimido Ester:** Yield 96%; mp 171—174 °C. Anal. ($C_{17}H_{21}N_3O_{10}$) C, H, N.

***N,N'*-[*N*-Protected Iminobis(methylenecarbonyl)]bis[glycine] Dimethyl Esters.** These were prepared by coupling of the *N*-protected IDAA disuccinimido ester with glycine methyl ester.

Z-N($CH_2CONHCH_2COOCH_3$)$_2$ (1): Yield 51%; mp 89—92 °C. Anal. ($C_{18}H_{23}N_3O_8$) C, H, N.

Z(OMe)-N($CH_2CONHCH_2COOCH_3$)$_2$ (5): Yield 53%; mp 82—84 °C. Anal. ($C_{19}H_{25}N_3O_9$) C, H, N.

***t*-Boc-N($CH_2CONHCH_2COOCH_3$)$_2$ (6):** Yield 50%; mp 120—123 °C. Anal. ($C_{15}H_{25}N_3O_8$) C, H, N.

Ammonolysis of 1, 5, and 6. The *N*-protected ester (1 g) was dissolved in MeOH (5 ml) and then 50 ml of MeOH containing dry NH_3 (ca. 6 M) was added. After standing at room temperature for 24 h, the solution was evaporated to dryness and then the residue was recrystallized. The time course of **1** was followed with HPLC by analyzing the aliquots of the reaction mixture at appropriate intervals.

Ammonolysis of 1: Yield 56%; mp 209—211 °C. Anal. ($C_9H_{13}N_5O_5$ (cyclic amide)) C, H, N.

Ammonolysis of 5: Yield 65%; mp 207—209 °C. Found: C, 39.98; H, 4.80; N, 25.34%. Calcd for $C_9H_{13}N_5O_5$ (cyclic amide): C, 39.86; H, 4.83; N, 25.82%.

Ammonolysis of 6: Yield 90%; mp 87—90 °C. Anal. ($C_{13}H_{23}N_5O_6$ (linear amide)) C, H, N. The amino acid analysis of the hydrolyzate revealed the presence of glycine and IDAA in a molar ratio of 2:1.

***N*-Z- and *N*-Z(OMe)-dipeptide Methyl Esters.** Compounds **8**—**13** were prepared by the conventional method of peptide synthesis. The elemental analyses were well agreed with the calculated values except **12**. Melting points were as follows: Z-DL-Ala-Gly-OMe (**8**), 74—76 °C; Z-Sar-Gly-OMe (**9**), 74—77 °C; Z-CEGly-Gly-OMe (**10**), 60—63 °C; Z-CEAla-Gly-OMe (**11**), 103—105 °C; Z-CEGly-DL-Ala-OMe (**12**), oil; Z(OMe)-CEGly-Gly-OMe (**13**), 83—85 °C.

Ammonolysis of *N*-Z- and *N*-Z(OMe)-dipeptide Methyl Esters. The ester (1 g) was dissolved in MeOH (6 ml) and then 50 ml of MeOH containing dry NH_3 (ca. 6 M) was added. After ammonolysis at room temperature for 24 h, the solution was evaporated to dryness with a rotary evaporator. The residue was dried in vacuum. A part of the residue was dissolved in DMSO-d_6 and ^1H NMR spectra were obtained.

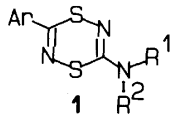
Decomposition Reaction of 3-Aryl-6-disubstituted Amino-1,4,2,5-dithiadiazines in the Solid State

Katsumi YONEMOTO* and Isao SHIBUYA
National Chemical Laboratory for Industry, Tsukuba, Ibaraki 305
(Received December 3, 1988)

Synopsis. 3-Diethylamino-6-phenyl-1,4,2,5-dithiadiazine, on standing in air at room temperature, decomposed to afford 5-diethylamino-3-phenyl- and 3,5-bis(diethylamino)-1,2,4-thiadiazoles, whereas in the melt and in solution it was remarkably stable. With increasing bulkiness of substituents (Ar and/or NR_2) in 1,4,2,5-dithiadiazines, their stability in the solid state clearly enhanced. Some interstack interactions in the crystal seem to favor the decomposition.

The chemistry of 1,4-dithiins[1] and their aza analogues, 1,4,2-dithiazines,[2] interesting 8π-electron ring systems, has been extensively studied. Higher aza-analogous ring systems, 1,4,2,5-[3] and 1,4,2,6-dithiadiazine isomers,[4] were prepared as diaryl derivatives for the first time in 1984 by two independent groups. Thermal and photochemical decompositions of 3,5-diphenyl-1,4,2,6-dithiadiazine were reported.[4] We have recently prepared unsymmetrically substituted 1,4,2,5-dithiadiazines through a ring expansion of the corresponding 1,4,2-dithiazolium salts by incorporating one nitrogen atom using *N*-unsubstituted sulfenamides[5] or an I_2–NH_3 system.[6] We now report on the stability and decomposition of 3-aryl-6-(disubstituted amino)-1,4,2,5-dithiadiazines (**1**) in the solid state.



1

Results and Discussion

Some of 3-aryl-6-(disubstituted amino)-1,4,2,5-dithiadiazines, when allowed to stand in air at room temperature, gradually decomposed to give a colorless oil, in contrast to the high stability of 3,6-diaryl-1,4,2,5-dithiadiazines under similar conditions.[3] The decomposition was monitored by following the color fading of yellow crystal and by TLC. Decomposition times, as required for crystalline compounds to be completely decomposed, are listed in Table 1. In the melt and in solution, on the contrary, dithiadiazines **1** were all remarkably stable. For example, compound **1c** was completely recovered after a week in the melt at 76 °C (>mp 71.5 °C) and after a few months in CH_2Cl_2, MeCN, or EtOH. Thus the stability of **1** depends markedly on the phases.

1,4,2,5-Dithiadiazines, which, if planar, would show the 8π-antiaromatic character, actually assume a boat-like conformation[3b,5] common to 1,4-dithiins,[1] which accounts for the thermal stability of the electron rich π-system. The authors speculate that the boat-shaped structure (characterized especially by the fold angle of hetero-ring and the bulkiness of substituents) will have an effect on the mode of stacking with varying intermolecular interactions which either favors or disfavors the observed decomposition, and that the close intermolecular contact in crystal will result in an increase in the fold angle to instabilize the dithiadiazine ring system itself.

Based on the above speculation, the stability of **1** is expected to be dependent on the electron-donating nature of disubstituted amino groups, which seems to be related to the fold angle. The stability of **1a—f** bearing different disubstituted amino groups and the same phenyl group at the C-3 and C-6 positions, respectively, was examined (Entries 1—6). The electron-donating ability of disubstituted amino groups can be estimated from the basicity of the corresponding secondary amines, and accordingly the data are arranged in the decreasing order of pK_a values.[7] However, there is no correlation between the stability of **1** and the electron-donating ability of substituents.

In order to obtain additional information concerning the electron density on the ring carbons C-3 and C-6, ^{13}C NMR spectra were measured. The chemical shifts for ring carbon bearing Ph and that bearing NR_2 are clearly dependent on the nature of disubstituted amino groups, but bear no correlation to the stability of **1**.

We turn our attention to the steric effect of substituents. It can be seen from Entries 1—6 that **1b, e,** and **f** bearing rather bulky substituents, diisopropylamino, morpholino, and *N*-methylphenylamino groups, respectively, are stable, whereas **1c** and **1d** bearing the smaller diethylamino and dimethylamino groups, respectively, have lower stability. The introduction of methoxyl or chloro group on the para-position of the phenyl group in **1a** enhanced the stability of crystal (Entries 7 and 8). Furthermore, the substitution of bulky aryl groups for the phenyl group in **1c**, with the small diethylamino group at the other position kept intact, also tends to retard the decomposition (Entries 10—14).

From the above results, the difference in stability among **1** in the solid state proved to be ascribable to the steric effect of substituents at the C-3 and C-6 positions rather than to their electronic effect.

In order to obtain further information on the decomposition, we examined products attributable to decomposition fragments; the results are presented in Table 2. Compound **1c** decomposed in the solid state to afford 5-diethylamino-3-phenyl-1,2,4-thiadiazole (**2a**) and 3,5-bis(diethylamino)-1,2,4-thiadiazole (**3a**), together with considerable amounts of benzonitrile and elemental sulfur. The formation of **2a** is rationalized by thermal elimination of sulfur (position 1 in **1c**) from the unstable 8π-electron ring system to

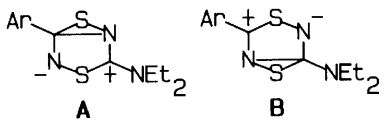
afford the more stable 6π-electron one. Such a sulfur extrusion is common to 6-membered 8π-electron ring systems such as 1,4-dithiins[1b,c] and 1,4,2-dithiazines.[2] On the other hand, the formation of **3a** is unique and requires a more complex pathway, because two diethylamino groups are introduced on the 1,2,4-thiadiazole ring. Although 3,5-diphenyl-1,2,4-thiadiazole was not formed, one other product was separated by TLC in a trace amount. It seems to be 3-diethylamino-5-phenyl-1,2,4-thiadiazole, an isomer of **2a**, merely because of the presence of the molecular ion peak at *m/z* 233 (100%) in mass spectrum. The selectivity of the sulfur extrusion can be interpreted in terms of considerable contribution of valence isomer **A** leading to **2a**, compared with **B**, owing to the higher electron-donating ability of diethylamino group than that of phenyl group. Other unstable dithiadiazines **1d**, **j**, and n also decomposed to afford **3** as a main product.



A **B**

Compound **1c**, which is stable in the melt, decomposed at higher temperature. When heated at 200 °C for 30 min, **1c** was completely decomposed to afford a black oil comprised of **2a** (21%) and **3a** (28%). A 1:1 solid mixture of **1c** and Ph_3P, which was prepared by evaporation of their CH_2Cl_2 solution and allowed to stand in air, slowly decomposed to afford **2a** in 44% yield as a main product and a small amount of **3a**, with triphenylphosphine sulfide formed as expected. It was further found that the stable derivative **1f** also decomposed when heated at 200 °C for 2 h to give the corresponding two 1,2,4-thiadiazole deriva-

tives **2c** and **3c** in low yields.

Information concerning the solid state structure of unstable derivatives has been difficult to obtain. However, an X-ray analysis of stable 3-(*p*-chlorophenyl)-6-morpholino-1,4,2,5-dithiadiazine was successfully performed in our previous work.[5] Direct overlapping occurs between the dithiadiazine rings (head to head with an S···S′ separation of 4.06 Å), but the formation of **3** cannot be directly predicted by the molecular orientation. At present, we believe that this decomposition proceeds much faster in the geometrically fixed crystal in which some interstack interactions favor unimolecular and bimolecular decompositions leading to **2** and **3**, respectively. For detailed interpretation of the mechanism for the formation of **3**, further investigations are needed. This decomposition is also attractive as an alternative synthetic method for 3,5-bis(disubstituted amino)-1,2,4-thiadiazoles, which are limitedly accessible by other methods.[8] Further studies on the decomposition in solution, including photolysis, are in progress.

Experimental

^{1}H and ^{13}C NMR spectra were recorded on a Hitachi R-40 and a JEOL FX-90A spectrometer, respectively, in $CDCl_3$, using TMS as an internal standard. Two-dimensional $^1J_{CH}$ shift-correlation spectra and long-range ($^nJ_{CH}$) shift-correlation spectra (COLOC) were recorded on a Bruker AC 200P spectrometer at 50.13 MHz for ^{13}C. Mass spectra were taken on a Hewlett Packard 5995A spectrometer by the electron impact ionizing technique at 70 eV.

3-Aryl-6-(disubstituted amino)-1,4,2,5-dithiadiazines **1** were prepared from the corresponding 1,4,2-dithiazolium salts using our reported procedures, and recrystallized from appropriate solvents (MeCN–ether, CH_2Cl_2–hexane, etc.).[5,6]

Decomposition Reaction of 1. Decomposition reactions of **1** (1 mmol) were carried out in the solid state at room temperature or in the melt at 200 °C. Decomposition times are listed in Tables 1 and 2. Crude products were purified by preparative TLC on silica gel. Their yields are presented in Table 2.

Insolubilizing Studies of Water-Soluble Poly(Lys Tyr) by Tyrosinase[1)]

Akira NAGAI and Hiroyuki YAMAMOTO*
Institute of High Polymer Research, Faculty of Textile Science and Technology, Shinshu University, Ueda 386
(Received December 8, 1988)

Synopsis. Insolubilization of water-soluble synthetic poly(Lys Tyr) was examined using tyrosinase in water and simulated seawater systems. Tyrosinase oxidized tyrosine aromatic nuclei, causing intermolecular crosslinking reactions. The salinity, system pH and α-chymotrypsin are considered to play roles in the insolubilizing reaction.

It has been widely observed in both sea and fresh water that water-soluble proteins normally remain insoluble or surface adhesive in biological systems. Lindner et al.[2)] proposed a mechanism called auto-crosslinking to explain the adhesive properties of proteins secreted by barnacles and mussels. Auto-crosslinking occurs between tyrosyl residues of protein side-chains and the free amino or other reactive groups of other protein molecules with a phenolase enzyme forming an intermolecular crosslink. In this mechanism an oxidase enzyme secreted from byssus and enzyme glands of *Mytilus edulis* plays an initial primary role in protein insolubilization, followed by adhesion.[3,4)] Oxidase also participates in arthropods and chicken-egg shell hardening on land.[5)] These adhesive and hardening phenomena, however, consist of many complex factors, and the auto-crosslinking mechanism described above has not yet been confirmed in a simple protein model.

We have investigated the polymer chemistry of some polypeptide models of *Mytilus edulis*, barnacle, silkworm and caddisworm.[6–9)] This report describes insolubilizing experiments on synthetic poly(Lys Tyr) using tyrosinase in the presence of activator α-chymotrypsin.

Experimental

Poly(Lys[1] Tyr[1]) (hydrobromide, molecular weight 90000), tyrosinase and α-chymotrypsin were purchased from Sigma. Simulated sea water was produced according to the analytical values of six major inorganic salts (NaCl, $MgCl_2$, Na_2SO_4, $CaCl_2$, KCl, and $NaHCO_3$).[10)] The viscosity of poly(Lys Tyr) with and without an enzyme was measured using an Ubbelohde viscometer at 25 °C in both fresh water and seawater. The absorption spectra was measured using a spectrophotometer (Jasco UVIDEC-1).

Results and Discussion

Poly(Lys Tyr) is soluble in fresh water but not in real and simulated seawater. It can, however, be solubilized when the salt concentration is less than 20% of real seawater, with a pH of less than 9. The viscometric characteristics of poly(Lys Tyr) in water and simulated seawater (20% concentration) with and without tyrosinase are depicted in Fig. 1. A slight decrease in the specific viscosity of the polypeptide was found in water. In 20% seawater poly(Lys Tyr), with and without tyrosinase, increases its viscosity to similar levels within 20 h to a 4-fold maximum after 2 days. This increase is attributable to a hydrophobic stacking of tyrosine aromatic nuclei in the polypeptide side chains. After 20 h the poly(Lys Tyr) solution with tyrosinase exhibited a pale brownish purple color. In the tyrosinase free system, however, a white precipitate developed after 70 h. When α-chymotrypsin is added to a poly(Lys Tyr) solution containing tyrosinase, the

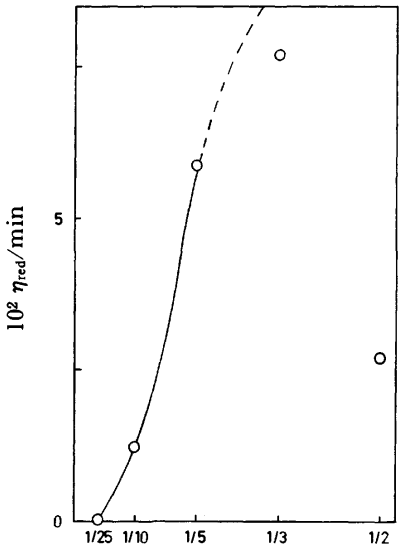

Fig. 4. Effect of salinity on viscosity change of poly(Lys Tyr) in simulated seawater. --- Turbidity observed in freshly prepared solution.

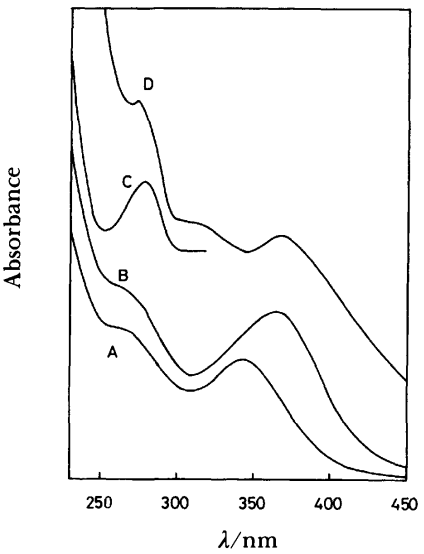

Fig. 5. Absorption spectra of products of poly(Lys Tyr) and model compounds. (A) Boc-L-Dopa quinone and (B) crosslinked Boc-L-Dopa quinone-α-Boc-L-lysine in water-alcohol (1:1 v/v);(C) poly(Lys Tyr) in simulated seawater; (D) 8 mol dm^{-3} HCl solution of partially hydrolyzates from the reaction of poly(Lys, Tyr), tyrosinase and α-chymotrypsin.

viscosity increases rapidly for up to 45 min and a precipitate may be observed by naked eye after 50 min in 20% sea water; the viscosity thereafter gradually decreases to 100 min (Fig. 2). The complex results shown in Figs. 1 and 2 suggest that a system containing poly(Lys Tyr), tyrosinase, and α-chymotrypsin in seawater acts as an auto-crosslinking model. α-Chymotrypsin is believed to cleave the polypeptide at its Tyr sites and to accelerate oxidation at the polypeptide terminals by tyrosinase, followed by the formation of intermolecular crosslinks.

The effects of pH on the viscosity change are depicted in Fig. 3. The viscosity of poly(Lys Tyr) in the presence of tyrosinase slowly decreased in water (pH 6.5) over 4 days. Tyrosinase in seawater induces a minor pH independent of the increase in the viscosity. The presence of both tyrosinase and α-chymotrypsin in seawater is associated with maximum pH-dependent viscosity changes, at around pH 6.5. The effect of salinity levels in this system at pH 6.5 is depicted in Fig. 4. No change in the viscosity was observed in 4% simulated seawater; increasing the salinity accelerated the viscosity change to a maximum level at 20% simulated seawater. At above 33% seawater concentration the hydrophobic stacking effect between Tyr residues predominates, causing a rapid visible precipitation, as described in the explanation of results in Fig. 1.

Absorption spectroscopy was selected to monitor the reaction in the investigation of the auto-crosslink mechanism. A low molecular weight *t*-butoxycarbonyl (Boc)-L-β-3,4-dihydroxyphenyl-α-alanine (Dopa) quinone-α-Boc-L-lysine model system was prepared to confirm the explanation given for the results of Figs. 2—4 (the synthesis will be described elsewhere). The absorption spectra of Boc-Dopa quinone, Boc-L-Dopa quinone-α-Boc-L-lysine, poly(Lys Tyr) and crosslinked poly(Lys Tyr) containing tyrosinase and α-chymotrypsin in aqueous media are depicted in Fig. 5. The absorption spectra of Boc-L-Dopa quinone (curve A) exhibited an absorption band at 340 nm and a shoulder at around 270 nm. To this solution was added α-Boc-L-lysine (no absorption in the 230—450 nm wavelength range). The development rate of the new absorption band at 360—365 nm due to the

crosslink reaction was gradual and slowed down after overnight (curve B). Poly(Lys Tyr) exhibits an absorption peak at 275 nm (curve C). The addition of tyrosinase and α-chymotrypsin to the poly(Lys Tyr) solution caused a rapid 275-nm spectroscopic change (decrease) in seawater and turbidity after about 4 min, while the same system in water exhibited a much slower change. The precipitated materials were collected by centrifugation and partially hydrolyzed by an 8 mol dm^{-3} HCl solution for 3 days at 50 °C, while becoming a clear solution. Curve D in Fig. 5 exhibits an absorption band at 360—365 nm which agreed with the absorption result of curve B of the crosslinked model compound.

From the above-mentioned results, the oxidase enzyme tyrosinase was found to catalyze a succesive reaction from phenol to catechol and, finally, to *o*-quinone in both fresh water and seawater. The oxidation reaction is much faster toward tyrosine than toward tyrosine copolymer. α-Chymotrypsin, thought to exist in the integument and to act as a kind of activator of prephenoloxidase, randomly digests the tyrosine copolymer at aromatic residues and accelerates oxidation by tyrosinase, followed by rapid precipitate formation due to intermolecular crosslinking. This may be a possible insolubilizing mechanism of adhesive proteins in water systems.

The present work was partly supported by a Grant-in-Aid for Scientific Research (No. 61490014) from the Ministry of Education, Science and Culture.

Solubilization of Hemin in Neutral and Acidic Aqueous Solutions by Forming Complexes with Water-Soluble Macromolecules

Isamu INAMURA,* Masayuki ISSHIKI, and Takeo ARAKI
Department of Chemistry, Faculty of Science, Shimane University, Matsue 690
(Received December 13, 1988)

Synopsis. Hemin was solubilized in neutral and acidic aqueous solutions by complexing with poly(*N*-vinylpyrrolidone) (PVP), polyethylene glycol (PEG), poly(vinyl alcohol) (PVA) and dextran. In neutral aqueous solutions, hemin in the PVP, PEG, and PVA complexes was monomeric and that in the dextran complex was dimeric. The effects of pH and ultraviolet (UV) irradiation on the spectroscopic properties of the complexes were examined.

It is well-known that hemin is soluble in organic solvents, alkaline aqueous solutions, and aqueous detergent micelles, but insoluble in neutral and acidic aqueous solutions.[1-3] Nishida et al.[4] reported that in alkaline aqueous solutions the aggregated ferroheme (ferroprotoporphyrin IX) and ferroheme·pyridine complex dissociated into the monomers upon the addition of water-soluble macromolecules.

We have recently succeeded in solubilizing hemin in neutral and acidic aqueous solutions by means of water-soluble linear polymers of PVP, PEG, PVA, and dextran. The properties of hemin in aqueous macromolecular solutions were investigated by comparing its absorption spectra with those of hemin in dimethyl sulfoxide (DMSO), an aqueous NaOH solution, and an aqueous Triton X-100 solution.

Experimental

Materials. Hemin (chlorohemin) manufactured by Eastman Kodak Co. was used without further purification. PVP (molecular weight (mol wt), 40000) and PEG (mol wt, 20000) were purchased from Kishida Chemical Co., Ltd. PVA (PVA-117: mol wt, 77000, degree of saponification, 98.5 mol%) was kindly donated by Kuraray Co., Ltd. Dextran (mol wt, 75000) was purchased from Wako Pure Chemical Industries, Ltd. PVP, PEG, PVA, and dextran were purified by reprecipitation of them in solvent-nonsolvent, namely in water-acetone, benzene-petroleum ether, water-methanol, and water-ethanol, respectively.

Method for Solubilization of Hemin in Neutral and Acidic Aqueous Solutions. Solid hemin (0.5 mg) was added to an aqueous macromolecular paste (PVP, PEG, and dextran, 33%; PVA, 15%) containing 1.0 g polymer and gently stirred. The mixture was added by 0.3 ml of 28% aqueous ammonia and stirred gently, resulting in hemin being dissolved. It was then evaporated to a hemin-polymer film under reduced pressure at room temperature. A small amount of water was added onto the film, and stirred gently at room temperature (PVP, PEG, and dextran films) or 100 °C (PVA film) until a paste was formed. The paste was diluted with water to a given concentration, resulting in a neutral aqueous macromolecular solution of hemin.

Acidic aqueous macromolecular solutions of hemin were obtained by the addition of concentrated hydrochloric acid to the neutral aqueous solutions.

Hemin was also dissolved in an aqueous Triton X-100 solution in a similar way by using aqueous ammonia.

Analytical Methods. The absorption spectra at room temperature were measured with a double-beam spectrophotometer, UVIDEC-510 (Japan Spectroscopic Co., Ltd.).

Photobleaching of Hemin. Photobleaching experiments were carried out under ultraviolet (UV) light. UV irradiation was performed with a fluorescence lamp (Mitsubishi GL-15) placed 10 cm from a quartz cuvette containing the hemin solution. The photodegradation (%) of hemin was calculated by dividing the absorbance after UV irradiation by that before irradiation. The wavelengths used to monitor the photodegradation were those of the absorption maxima of Soret bands.

Results and Discussion

There have been several suggestions that a sharp

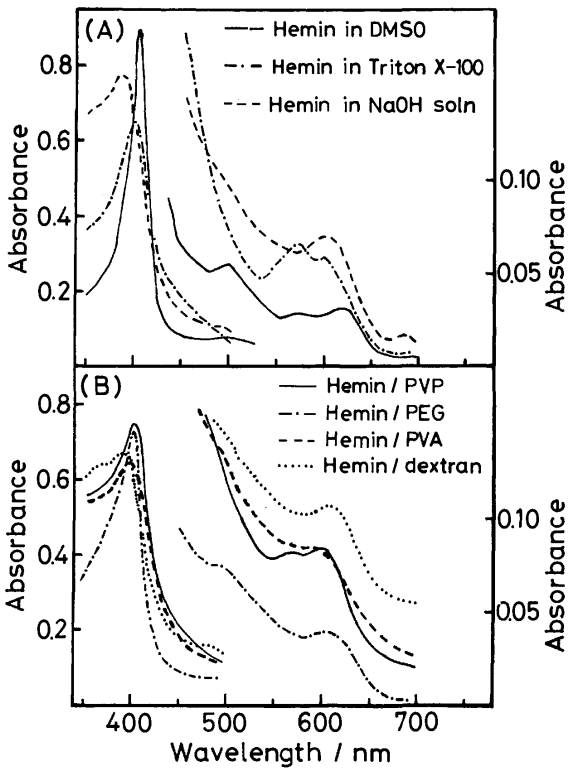

Fig. 1. Absorption spectra of hemin in different states. (A) hemin dissolved in various solvents: ——, hemin in DMSO (hemin, 5.1×10^{-6} mol dm^{-3}); —·—·—, hemin in an aqueous Triton X-100 solution (hemin, 1.0×10^{-5} mol dm^{-3}; Triton X-100, 1.0%, pH 5.7); ---, hemin in an aqueous NaOH solution (hemin, 1.5×10^{-5} mol dm^{-3}; pH 10.4). (B) hemin-macromolecular complexes in water: ——, hemin-PVP complex (hemin, 1.53×10^{-5} mol dm^{-3}; pH 7.5); —·—·—, hemin-PEG complex (hemin, 1.0×10^{-5} mol dm^{-3}; pH 7.1); ---, hemin-PVA complex (hemin, 1.6×10^{-5} mol dm^{-3}; pH 6.3); ·····, hemin-dextran complex (hemin, 1.3×10^{-5} mol dm^{-3}; pH 7.5).

single Soret band corresponds to monomeric ferriheme (ferriprotoporphyrin IX), whereas a doublet shows the presence of dimers.[1,5] Further, the absorption spectra of ferriheme are considered to depend on the species bound to iron at the fifth and sixth positions.[1]

Figure 1-(A) shows the absorption spectra of hemin dissolved in various solvents. The absorption maxima were as follows: 405, 498, 575, and 623 nm for hemin in DMSO; 401, 573, and 600 nm for hemin in an aqueous Triton X-100 solution; 360, 388, 500, and 603 nm for hemin in an aqueous NaOH solution. It is generally considered that hemin is monomeric in DMSO[1] and aqueous Triton X-100 solutions,[2,3] and dimeric[6] in aqueous NaOH solutions.[2]

Hemin was dissolved in neutral aqueous solutions by means of water-soluble linear polymers of PVP, PEG, PVA, and dextran. The resulting solutions gave the absorption spectra of hemin shown in Fig. 1-(B). Since hemin itself is insoluble in neutral aqueous solutions,[1-3] it can be inferred that the linear polymers complexed with hemin, resulting in the solubilization of hemin in neutral aqueous solutions. The polymers probably bound hemin within a random coil of the chain.

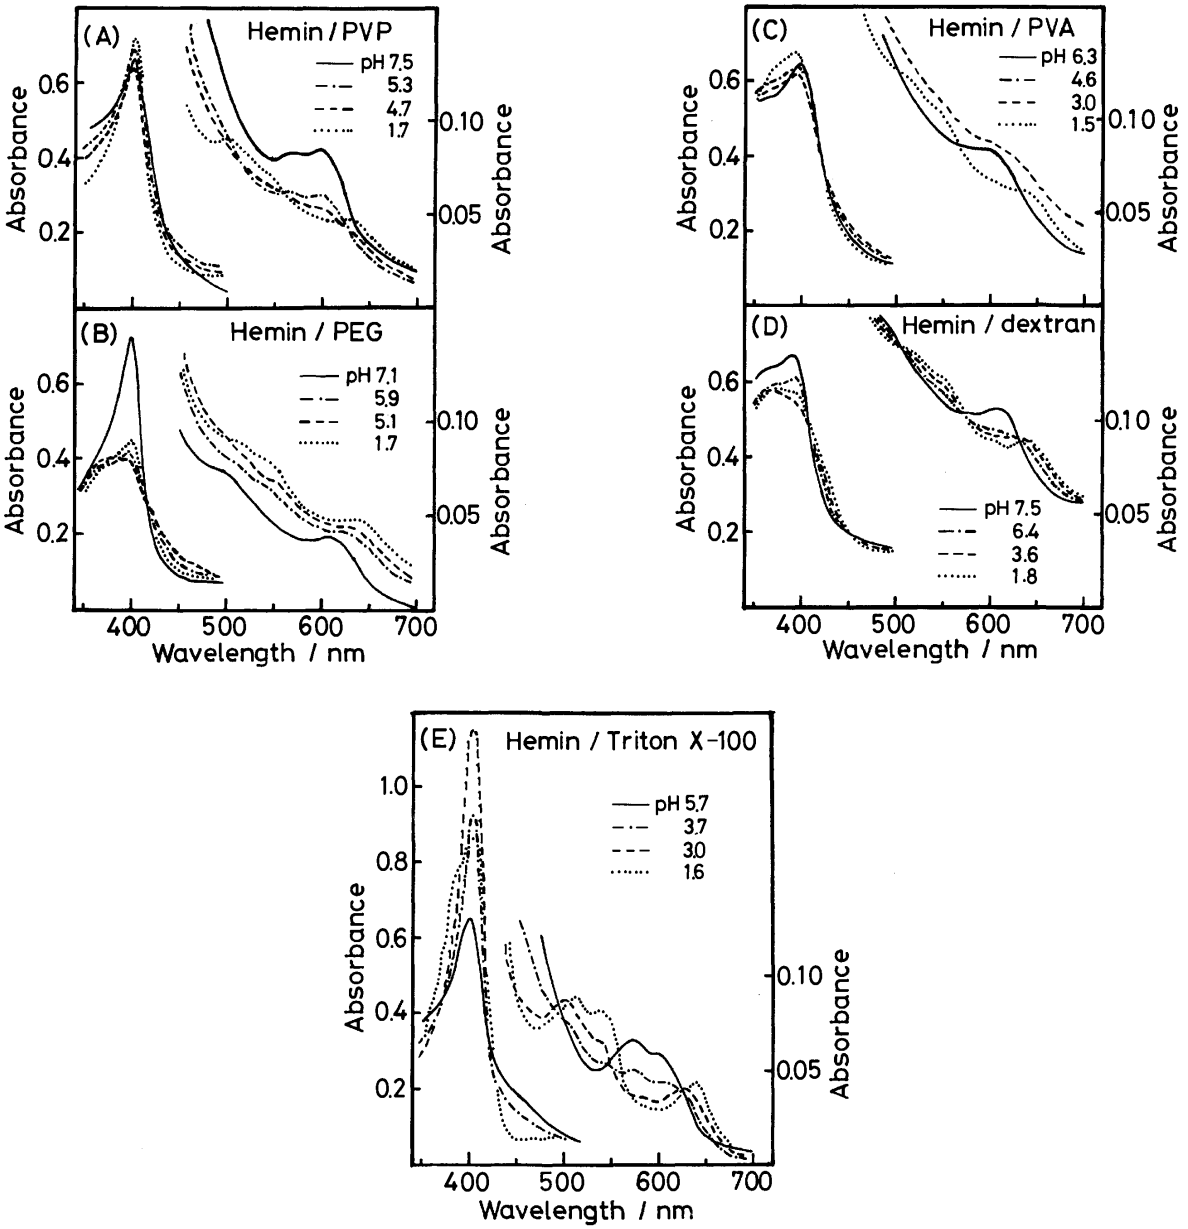

Fig. 2. Dependence on pH of absorption spectra for hemin in different states. The concentrations of hemin were the same as in Fig. 1. (A) hemin-PVP complex in water, (B) hemin-PEG complex in water, (C) hemin-PVA complex in water, (D) hemin-dextran complex in water, (E) hemin in an aqueous Triton X-100 (1.0%) solution.

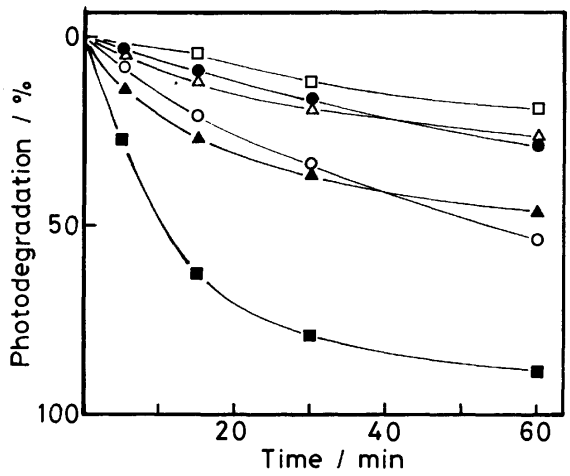

Fig. 3. Photodegradation of hemin in different states by irradiation of UV light. The wavelengths monitoring the photodegradation were those of absorption maxima of Soret bands. The concentrations of hemin were the same as in Fig. 1. ○, hemin-PVP complex in water (pH 7.5); ▲, hemin-PEG complex in water (pH 6.9); ●, hemin-PVA complex in water (pH 7.1); △, hemin-dextran complex in water (pH 7.5); □, hemin in aqueous Triton X-100 (1.3%) solution (pH 6.5); ■, hemin in DMSO.

The absorption maxima for the hemin-macromolecular complexes in neutral aqueous solutions (Fig. 1-(B)) were as follows: 401, 568, and 600 nm for PVP complex; 400, 490, and 608 nm for PEG complex; 398 and 600 nm for PVA complex; 365, 389, and 608 nm for dextran complex. The PVP, PEG, and PVA complexes have a sharp single Soret band which resembled, in both shape and position, that of hemin in DMSO and the aqueous Triton X-100 solution. However, the dextran complex had a double Soret band similar to that of hemin in an aqueous NaOH solution. On the other hand, the Q-bands of the PVP and PEG complexes resembled those of hemin in the aqueous Triton X-100 solution and DMSO, respectively. The Q-bands of the dextran complex were similar to those of hemin in the aqueous NaOH solution. From these results, it can be inferred that hemin in the PVP, PEG, and PVA complexes is monomeric and that in the dextran complex it is dimeric.

Figure 2 shows the dependence on pH of the absorption spectra of hemin in different states. The pH-dependence of the Soret bands of the hemin-macromolecular complexes markedly depended on the polymer species. The Soret bands of the PVP complex became narrower as the pH decreased, as well as those of hemin in the aqueous Triton X-100 solution. The Soret band of the PEG and PVA complexes became broader with decreasing pH, and the Soret band of the PEG complex was largely decreased in intensity, even at pH 5.9. In the case of the dextran complex, as the pH decreased the intensity of the Soret band at 365 nm became larger than that at 389 nm. From these results it is considered that the monomeric hemin in the PVP complex was stable even in acidic aqueous solutions, but that in the PEG and PVA complexes was unstable and probably changed into a dimer or aggregates under acidic conditions.

The pH-dependence of the Q-bands for the hemin-macromolecular complexes hardly depended on the polymer species, as shown in Fig. 2. At the lowest pH, three new peaks were observed at similar positions for each complex: that is, at 500, 540, and 628 nm for PVP complex; at 500, 548, and 640 nm for PEG complex; at 510, 545, and 640 nm for PVA complex; at 515, 550, and 638 nm for dextran complex. For hemin in the aqueous Triton X-100 solution, the pH-dependence of the Q-bands were clearly observed, showing it to be similar to that for the hemin-macromolecular complexes. That is, at the lowest pH (1.6), three new peaks appeared at 510, 541, and 640 nm. The appearance of three new peaks for all of the samples implies that upon adding hydrochloric acid to neutral aqueous solutions of hemin to lower the pH (see Experimental section), the chloro ligand bound to iron gradually increases in the presence of excess of Cl^- ions.[1)]

Figure 3 shows the photodegradation of hemin in different states upon irradiation of UV light. It was found that hemin in macromolecular complexes in neutral aqueous solutions was more stable against UV irradiation than that in DMSO. The rates of photodegradation of hemin in macromolecular complexes depended on the polymer species. That is, hemin in the PVA and dextran complexes was photodegraded more slowly than that in the PVP and PEG complexes. Hemin in the aqueous Triton X-100 solution was more stable against UV irradiation than that in macromolecular complexes.

From the above results it can be inferred that in neutral aqueous solutions the carbonyl group of PVP and ether oxygen of PEG have a stronger coordinating power to iron of hemin than the hydroxyl group of PVA and dextran. Ether oxygen of PEG, however, probably loses its strong coordinating power in acidic aqueous solutions.

(Received January 11, 1989)

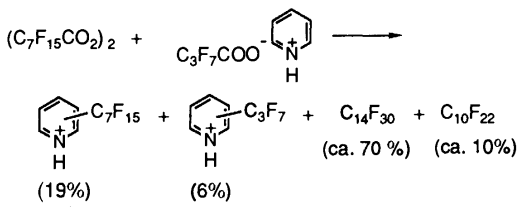
Synopsis. Bis(perfluoroalkanoyl) peroxide ($(R_FCO_2)_2$) suffered a nucleophilic displacement with perfluoroalkanoate ($R_F'CO_2^-$) to give new mixed peroxide ($R_F(CO)OO(CO)R_F'$). When thiophene was reacted with bis(perfluoroalkanoyl) peroxide in the presence of pyridinium perfluoroalkanoate, not only the perfluoroalkyl group (R_F) of the peroxide, but also perfluoroalkyl group (R_F') of perfluoroalkanoate, was introduced into thiophene.

The O–O bonds of diacyl peroxides are usually weak and homolytic cleavages take place easily. On the other hand, diacyl peroxides, especially which have strong electron-withdrawing groups, also react as electrophiles in the presence of nucleophiles such as amines, sulfides, or electron-rich benzenes.[1] We have been studying the reactions of bis(perfluoroalkanoyl) peroxides (**1**) and found three types of reactions: (1) a homolytic cleavage of the O–O bond, (2) electron transfer from substrate to the peroxide, and (3) a nucleophilic reaction on the O–O bond of the peroxide.[2] Due to the strong electron-withdrawing fluoroalkyl groups peroxide **1** easily suffered electron transfers or nucleophilic attacks. In the course of the study we found that perfluoroalkanoate ($R_F'COO^-$) attacked bis(perfluoroalkanoyl) peroxide ($(R_FCOO)_2$) to give new mixed peroxide ($R_F(CO)OO(CO)R_F'$); the results will be described herein.

$C_nF_{2n+1}\overset{\overset{O}{\|}}{C}OO\overset{\overset{O}{\|}}{C}C_nF_{2n+1}$

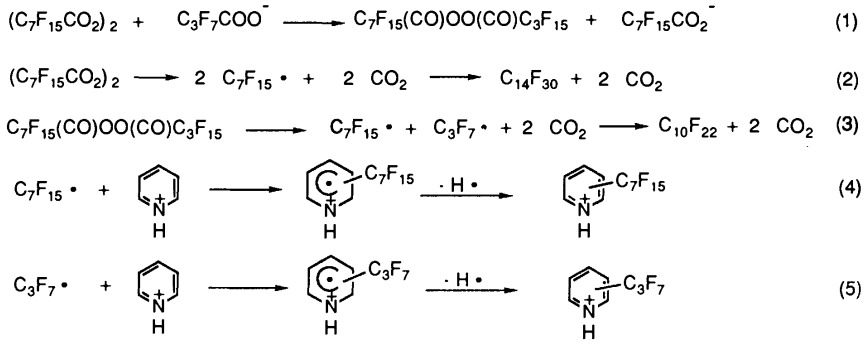
n = 1 (1a), n = 3 (1b), n = 7 (1c)

In the reaction of pyridinium perfluorobutyrate with **1c**, not only perfluoroheptylpyridines but also perfluoropropylpyridines were formed. Both perfluorodecane ($C_{10}F_{22}$) and perfluorotetradecane ($C_{14}F_{30}$) were also detected as coupling products of perfluoroalkyl radicals by GC-MS.



In order to explain these results, we propose the exchange of the perfluoroheptanoyloxy group in **1c** with perfluorobutyrate to give mixed diacyl peroxide and perfluoroheptanoate, as shown in Scheme 1 (Eq. 1). Peroxide **1c** decomposes homolytically to give perfluorotetradecane via a perfluoroheptyl radical (Eq. 2 in Scheme 1). The mixed peroxide also decomposes to perfluoroheptyl and perfluoropropyl radicals and perfluorododecane is produced as a coupling product (Eq. 3 in Scheme 1). The cage escaped perfluoroheptyl or perfluoropropyl radical attacks the pyridinium salt to give perfluoroheptyl- or perfluorpropylpyridine (Eqs. 4 and 5 in Scheme 1).[3] This is the first example of a nucleophilic displacement of the carboxy group in diacyl peroxide with another carboxylate to give new mixed peroxide (as far as we know,[4]), whereas a nucleophilic displacement with carbanions[5,6] or halide anions[7] has in general been well-investigated.

We have reported that peroxide **1** reacts with an electron-rich substrate to give a perfluoroalkylated compound via electron transfer from the substrate to **1**.[2,3] Thus, if a nucleophilic displacement of peroxide **1** with perfluoroalkanoate while affording mixed peroxide occurs, the perfluoroalkyl group of the pyridinium perfluoralkanoate should be introduced into the substrate when **1** reacts with an electron-rich substrate in the presence of pyridinium perfluoroalkanoate. Since we have thoroughly studied the perfluoroalkylation of thiophene,[3,8] we chose thiophene



Scheme 1.

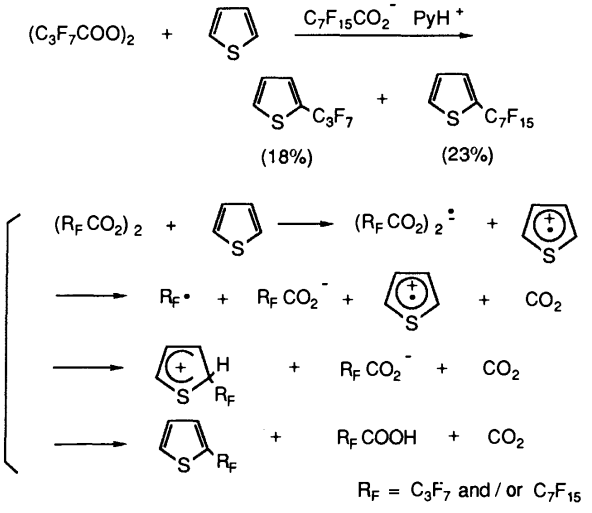

Scheme 2.

as the substrate for an examination of perfluoroalkylation using this method.

Peroxide **1b** was reacted with pyridinium perfluorooctanoate at 0°C for 1 h and then thiophene was added. The resulting solution was further kept at 40 °C for an additional 3 h under vacuum conditions. As expected, 2-(perfluoroheptyl)thiophene was obtained in a yield of 23% in addition to 2-(perfluoropropyl)thiophene in 18% yield, as shown in Scheme 2. The ratio of perfluoropropylthiophene and perfluoroheptylthiophene remained unaltered, even when **1b** and pyridinium perfluorooctanoate was reacted for more than 1 h; then, thiophene was added. Similarly, reactions of **1** with thiophene in the presence of some pyridinium perfluoroalkanoate were performed under various conditions; the results are summarized in Table 1.

In the reaction of thiophene with **1c** in the presence of pyridinium perfluorobutyrate, the perfluoropropyl group was introduced into thiophene. The ratio of perfluoroheptylthiophene and perfluoropropylthiophene was almost the same as that obtained from a reaction system of **1b** and pyridinium perfluorooctanoate (Table 1, Runs **1** and **2**). This means that in the reaction systems of peroxide **1** and pyridinium perfluoroalkanoate, equilibrium as shown below must be attained:

$$(C_3F_7CO_2)_2 + C_7F_{15}CO_2^- \rightleftharpoons C_3F_7(CO)OO(CO)C_7F_{15} + C_3F_7CO_2^-$$

$$C_3F_7(CO)OO(CO)C_7F_{15} + C_7F_{15}CO_2^- \rightleftharpoons (C_7F_{15}CO_2)_2 + C_3F_7CO_2^-$$

Thus, perfluoroheptylthiophene is expected to be obtained selectively when a large excess of pyridinium perfluorooctanoate per **1b** is used. However, the total yield of perfluoroalkylated thiophenes decreased upon increasing the amounts of the pyridinium salt, whereas the ratio of perfluoroheptylthiophene per perfluoropropylthiophene increased (Table 1, Runs **1**, **3**, and **4**). Perfluoroalkylations of thiophene with **1b** or **1c** proceeded almost quantitatively (Table 1, Runs **5** and **6**); however, in the reaction of thiophene with **1** in the presence of pyridinium salt, the total yield of perfluoroalkylthiophenes was about 40%, as shown in Table 1, Runs **1** and **2**. The low yields of perfluoroalkylthiophenes in these reaction systems may not be attributed to the homolytic decomposition of **1** during the exchange reaction of **1** with perfluoroalkanoate, because the homolytic decomposition of **1b** or **1c** does not occur at 0 °C for 1 h. However, it was reported that a N-lone pair of amine attacked nucleophilically the O–O bond of **1b** to decompose the peroxide rapidly, even at 0 °C.[3)] Probably, peroxide **1** reacted with free pyridine which was liberated from the pyridinium salt during the exchange reaction; thus, the yield of perfluoroalkylated thiophene in the presence of pyridinium salt might have been decreased, especially when the amount of pyridinium salt was increased.

By choosing the peroxide, the ratio of perfluoroheptylthiophene per total yield of perfluoroalkylated thiophenes could be increased; the ratio of perfluoroheptylthiophene per total yield was larger in a reaction using **1a** as the peroxide than in one using **1b** (Table 1, Runs **1** and **7**). Peroxide **1a** might suffer a nucleophilic displacement with perfluoroalkanoate more easily than **1b**.

It is very interesting from the view of synthetic chemistry that the perfluoroalkyl group of pyridinium

perfluoralkanoate is introduced into thiophene. We have been studying the synthesis of the diacyl peroxides which contain perfluoroalkyl groups. However, we have not succeeded in the synthesis of the diacyl peroxides which contain perfluoroalkyl chains longer than perfluoroheptyl. We therefore tried to prepare perfluorononylthiophene in a reaction of thiophene with pyridinium perfluorododecanoate in the presence of **1b** (Table 1, Run **8**). Although the yield of the perfluorononylthiophene was not sufficient, the perfluorononyl group could be introduced into thiophene without the synthesis of bis(perfluorododecanoyl) peroxide.

Perfluoroalkylation with peroxide **1** was shown to be a useful and effective method in our previous papers.[2,3,8] In this paper we show that the perfluoroalkyl group can be introduced into thiophene, even if the corresponding peroxide can not be synthesized.

Experimental

^{1}H NMR spectra were taken with a JEOL JNM PMX 60si (60MHz) spectrometer. ^{13}C NMR spectra were taken with a JEOL JNM Fx90Q FTNMR spectrometer. IR spectra were recorded on a Hitachi 260-10 spectrometer. Gas chromatography was performed by a Hitachi 163 or 263-30 gas chromatograph with a SE-30 (10%) 1 m stainless-steel column. Gel-permeation chromatography was performed by means of a JAI Model LC-08 liquid chromatograph equipped with JAIGEL-1H columns (20 ϕ×600 mm×2) and using chloroform as an eluent. Mass spectra were obtained with JEOL JMS DX-300 spectrometer by an electron-impact (EI) ionization technique at 70 eV.

Materials. The syntheses of bis(perfluoroalkanoyl) peroxides were described in the literature.[3,9] These peroxides were used as solutions of Freon 113 without isolation. Pyridinium perfluoroalkanoates were prepared from pyridine with the corresponding perfluoroalkanoic acids. Pyridinium perfluorobutyrate (mp 56—58 °C (from ether)), pyridinium perfluorooctanoate (mp 69—70 °C (from ether)), and pyridinium perfluorododencanoate (mp 101—103 °C (from ether)).

Reaction of Pyridinium Perfluorobutyrate with Bis(perfluorooctanoyl) Peroxide. A solution containing 2 mmol of bis(perfluorooctanoyl) peroxide and 1 mmol of pyridinium perfluorobutyrate in 25 ml of Freon 113 in a degassed sealed tube was kept at 40 °C for 5 h. The solution was then washed with 20 ml of 5% NaOH and 20ml of water. The organic layer was analyzed by GC-MS.

Reaction of Thiophene with Pyridinium Perfluoroalkanoate in the Presence of Peroxide. The reaction was typically performed as follows. A solution containing 0.5 mmol of **1b** and 1.0 mmol of pyridinium perfluorooctanoate in 5 ml of Freon 113 was stirred for 1 h in an ice bath, and then 1.0 mmol of thiophene was added. The resulting mixture was degassed and kept at 40 °C for 3 h in a sealed tube. The reaction mixture was chromatographed over silica gel (Wakogel C-60) using ether as an eluent in order to remove the pyridinium salt and acid. The yields of the perfluoroalkylated thiophene were determined by GC using chlorobenzene as an internal standard. Perfluoropropylthiophene and perfluoroheptylthiophene were isolated using gel-permeation chromatography.

Reaction of Thiophene with 1c without Pyridinium Salt. A solution containing 2 mmol of **1c** and 4 mmol of thiophene in 25 ml Freon 113 was degassed and kept at 40 °C for 3 h in a sealed tube. The solution was washed with 20 ml of water and the organic layer was analyzed by GC-MS. The yield of perfluoroheptylthiophene was determined by GC using chlorobenzene as an internal standard.

2-Pentadecafluoroheptylthiophene; ^{1}H NMR($CDCl_3$) δ= 7.17 (1H), 7.4—7.6 (2H); ^{13}C NMR ($CDCl_3$) δ=127.5(C5), 130.3 (C4), 130.8 (C3); IR 1360 (CF_3), 1220 (CF_2) cm^{-1}; MS *m/z* 452 (M^+); Exact MS: *m/z* 451.9765, Calcd for $C_{11}H_3F_{15}S$: 451.9717.

2-(Nonadecafluorononyl)thiophene; ^{1}H NMR ($CDCl_3$) δ=7.00 (1H), 7.2—7.5 (2H); ^{13}C NMR ($CDCl_3$) δ=127.4 (C5), 130.2 (C4), 130.6 (C3); IR 1360 (CF_3), 1200 (CF_2) cm^{-1}; MS *m/z* 552 (M^+); Exact MS: *m/z* 551.9664, Calcd for $C_{13}H_3F_{19}S$: 551.9652.

The spectral data for 2-(heptafluoropropyl)thiophene was reported in the literature.[3]

Synthesis of Novel 10-Se-3 Type Selenatetraazapentalene Derivatives with a Hypervalent Selenium

Noboru MATSUMURA,* Masaaki TOMURA, and (the late) Shigeo YONEDA
Department of Applied Chemistry, College of Engineering, University of Osaka Prefecture, Sakai, Osaka 591
(Received February 4, 1989)

Synopsis. Novel selenatetraazapentalene derivatives, 2,3-disubstituted 6,7-dihydro-5*H*-2a-selena(2*a*-Se^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione, were synthesized by a convenient one-pot reaction using the lithium selenoureide/phenacyl chloride/alkyl isothiocyanate system in good yields.

Chemistry of 1,6,6a-trithia(6*a*-S^{IV})pentalene and analogous compounds has attracted much attention because of their unusual electronic structure, and many 6a-thia(S^{IV})pentalene derivatives containing 10π-electrons in the framework were synthesized.[1] We have recently reported that 12π-thiatetraazapentalene derivatives having π-hypervalent sulfur and two thiocarbonyl groups in the frameworks are synthesized by a convenient one-pot reaction using the lithium thioureide/phenacyl chloride/alkyl isothiocyanate system.[2] However, compounds of this type have not been so well-investigated to date.[3] For a detailed study of the physical and chemical properties of this 12π-tetraazapentalene derivatives, we have tried a synthesis of 12π-selenatetraazapentalenes having a hypervalent selenium (10-Se-3 type).

In this paper, we report the synthesis of 2,3-disubstituted 6,7-dihydro-5*H*-2a-selena(2*a*-Se^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithione (**4**) and its spectral characterization.

Results and Discussion

The 6-membered-ring selenourea (**2**) was prepared by the reaction of *S*,*S*′-dimethyl dithioselenocarbonate (**1**)[4] with 1,3-propanediamine. The reaction was carried out in tetrahydrofuran (THF) at room temperature for 1 h under argon, and further purification with flash-chromatography afforded cyclic selenourea **2** in 35% yield. Selenourea **2** was slightly unstable and colored to red gradually under the atmosphere.

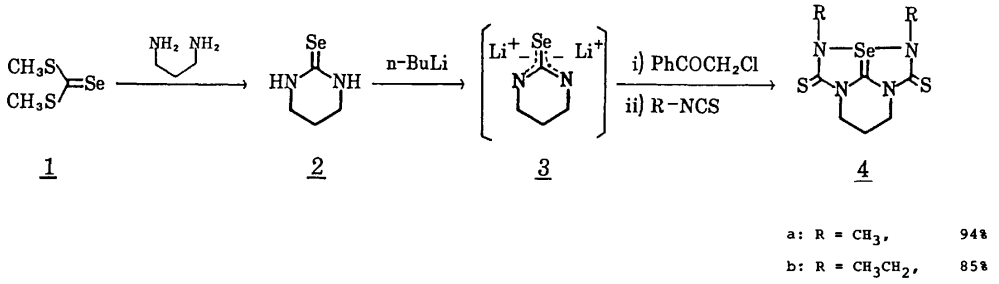
Synthetic reaction of selenatetraazapentalene derivatives **4** was carried out under the same conditions which were used in the synthesis of 10-S-3 type thiatetraazapentalenes.[2] Selenourea **2** was treated with two molar equivalents of butyllithium in THF at 0 °C for 1 h under argon. The resulting dianion (**3**) was allowed to react with a molar equivalent of phenacyl chloride under reflux for 1 h. After cooling to room temperature, a solution of alkyl isothiocyanate (R=CH_3, CH_3CH_2, or CH_2=$CHCH_2$; three times molar quantity of **2**) in THF was added, and the reaction mixture was stirred at room temperature for 20 h. Usual workup and purification gave selenatetraazapentalene derivatives **4a—c** in poor yields (7—12%). It is considered that the poor yields of **4** are due to the thermolability of the dianion **3**. Therefore, the reaction of the dianion **3** with phenacyl chloride was carried out at room temperature. Consequently, the yields of 10-Se-3 type selenatetraazapentalene derivatives **4** have risen remarkably. Scheme 1 shows the reaction pathway for the formation of **4** and the yields of products.

Compounds **4** are considerably stable in air. UV spectra of **4a—c** in acetonitrile show a strong absorption band near 260 nm, and there is no absorption band in the visible region. The structure of **4** was determined by IR, ^{1}H NMR, ^{13}C NMR, mass spectra, and elemental analyses.

Experimental

General. Melting points were determined on a Yanagimoto MP-S3 melting point apparatus and were uncorrected. ^{1}H and ^{13}C NMR spectra were obtained using a JEOL JNM-GX270 spectrometer. Chemical shifts are reported in ppm from TMS as an internal standard and are given in δ units. The IR and UV spectra were determined on a Hitachi 215 Grating infrared spectrometer and Shimadzu UV-265 spectrometer, respectively. Mass spectra were obtained with a Shimadzu LKB-9000 instrument equipped with a solid injector; the ionizing voltage was 70 eV. Purifications of products were conducted by column chromatography on silica gel (Wakogel C-300).

3,4,5,6-Tetrahydro-2(1*H*)-pyrimidineselenone (2). 1,3-Propanediamine (2.87 mmol) was added dropwise to a solution of *S*,*S*′-dimethyl dithioselenocarbonate (**1**) (1.89 mmol) in 30 ml of tetrahydrofuran (THF) at room temperature



Scheme 1.

under argon. The reaction mixture was stirred under the same conditions for 1 h. After THF was evaporated, the residue was flash-chromatographed on silica gel (chloroform:ethyl acetate=3:1 as an eluent) to give 108 mg of **2** in 35% yield. Reprecipitation from hexane and then recrystallization from methanol afforded pure **2** as a colorless solid: mp 198—201 °C (decomp); IR (KBr) 3180 (NH), 2940, 1560, 1315, and 1205 cm^{-1}; ^1H NMR ($CDCl_3$) δ=1.99 (m, 2H, $NCH_2\underline{CH_2}CH_2N$), 3.31 (d of t, 4H, J=2.0 and 6.0 Hz, $NC\underline{H_2}CH_2C\underline{H_2}N$), and 7.06 (br, 2H, NH); MS m/z (rel intensity) 166 (M^++2; 18), 164 (M^+, based on ^{80}Se isotope peak; 100), 162 (M^+−2; 48), 149 (8), 116 (26), 84 (24), and 83 (25). The microanalysis (C, H, N) was in satisfactory agreement with the calculated value within ±0.5%.

Typical Procedure for the Synthesis of 4. To a cooled THF solution (0 °C, 25 ml) of **2** (94 mg, 0.58 mmol) was added a hexane solution of butyllithium (1.25 mmol) with stirring at 0 °C under argon, and the mixture was stirred for 1 h under the same conditions. To the resulting dianion **3** was added dropwise a THF solution (5 ml) of phenacyl chloride (0.58 mmol). After stirring at room temperature for 1 h under argon, a solution of methyl isothiocyanate (1.74 mmol) in THF (5 ml) was added, and the reaction mixture was stirred under the same conditions for 20 h. After THF was evaporatd, the residue was poured into an aqueous ammonium chloride. The solution was extracted with chloroform, and the extract was washed with water, dried over anhydrous Na_2SO_4, and condensed under reduced pressure. Flash-chromatography of the residue on silica gel using chloroform as an eluent gave 167 mg (94%) of **4a** as a colorless solid. Recrystalization from hexane–chloroform afforded a pure sample.

2,3-Dimethyl-6,7-dihydro-5*H*-2a-selena(2*a*-*Se*^{IV})-2,3,4a,7a-tetraazacyclopent[*cd*]indene-1,4(2*H*,3*H*)-dithoine (4a). Mp 213—216 °C (decomp); IR (KBr) 2930, 1575, 1535, 1500, 1185, and 1110 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.36 (m, 2H, $NCH_2\underline{CH_2}CH_2N$), 3.32 (s, 6H, 2×$CH_3$), and 4.49 (t, 4H, J=6.0 Hz, $N\underline{CH_2}CH_2C\underline{H_2}N$); ^{13}C NMR ($CDCl_3$) δ=20.28, 33.52, 46.48, 159.21, and 171.13; UV (CH_3CN) 213 (log ε 4.23), 259 (4.41), ca. 290 (sh, 3.85), and 325 nm (3.56); MS m/z (rel intensity) 237 (3), 235 (M^+-CH_3NCS, based on ^{80}Se isotope peak; 10), 233 (4), 193 (3), 122 (4), 97 (8), 73 (100), 72 (55), and 69 (29). (Received February 6, 1989)

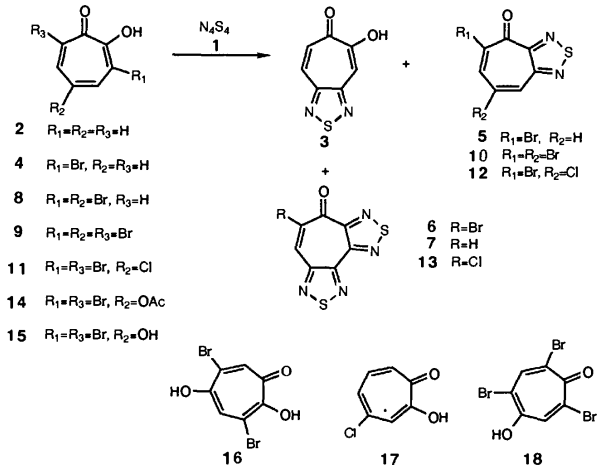
Synopsis. The reactions of tropolones with tetrasulfur tetranitride gave 4*H*-cyclohepta[*c*][1,2,5]thiadiazol-4-ones, 6*H*-cyclohepta[*c*][1,2,5]thiadiazol-6-one, and 7*H*-cyclohepta[1,2-*c*:3,4-*c'*]bis[1,2,5]thiadiazol-7-ones (9—56% yields) in one step. The yields of the products were not improved so much under high pressure and by the addition of a radical initiator.

Recently, we reported the reactions of tetrasulfur tetranitride (**1**) with alkyl- and alkylhalogeno phenols to give 2,1,3-benzothiadiazoles in a one-step procedure.[1] From the reactions of **1** with bromocatechols and bromoresorcinols, benzobis- and benzotris[1,2,5]thiadiazoles were prepared.[2] Dihydroxynaphthalene derivatives also gave the corresponding naphtho[1,2,5]thiadiazoles.[3] The 1,2,5-thiadiazole ring system was converted by reduction to 1,2-diamino-, 1,2,3,4-tetraamino-, and hexaaminobenzenes[2] and also used as a building unit for preparation of electron acceptors and electron donors.[4,5] In these regards, since the reaction of **1** was limited to benzenoids, we extended the reaction of **1** to troponoids to prepare new heterocyclic troponoids.

When a toluene solution of tropolone (**2**) and **1** was refluxed for 9 h, a single product (**3**) was obtained after silica-gel chromatography. The ^{1}H NMR spectrum of **3** showed three olefinic proton signals, a singlet at δ=7.76 and an *AB* quartet with a large magnitude of vicinal spin–spin coupling constant (J=12.5 Hz) at δ=7.29 and 8.10, confirming that the seven-membered ring is maintained. Therefore, the structure of **3** can be identified to be 5-hydroxy-6*H*-cyclohepta[*c*][1,2,5]-thiadiazol-6-one. Since we had previously experienced that the yields of thiadiazoles are frequently improved by the use of halogeno derivatives,[1] we then turned our attention to reactions with halogeno tropolones. In contrary to **2**, the reaction with 3-bromotropolone (**4**) was somewhat complicated and gave three products (**5**—**7**), of which **5** was a 1:1-condensation product and the others were 2:1-condensates. The NMR spectrum of **5** showed two doublet signals at δ=8.14 (J=9.5 Hz)



Scheme 1.

Table 1. Reaction Conditions and Product Yields of Tropolones with **1**

Substrate (Ratio)	Temp/°C	Press/bar	Time/h	Additive	Products/% 5	6	7	10
4 (1:1)	110	1	14	—	4	2	26	
4 (1:2)	110	1	10	—	8	7	25	
4 (1:2.6)	110	1	10	—	11	9	18	
4 (1:3)	110	1	14	V-40		15	28	
4 (1:3)	110	1	48	—		14	26	
4 (1:5)	110	1	21	V-40	10	6	16	
4 (1:5)	110	1	21	—	2	2	10

9 (1:3)	110	1	48	—		44		

and 7.78 (J=11.7 Hz) and a doublet of doublets signal at 6.81. For the bromine-containing minor product, **6**, a singlet signal appeared at δ=8.84, while the bromine-free product, **7**, showed an AB quartet (J=13.0 Hz). The yields of **6** and **7** were improved to some extent when **1** was used in excess. The results are summarized in Table 1. Compounds **6** and **7** were also obtained from the reactions of 3,5-dibromotropolone (**8**) with **1** in 24 and 22% yields, respectively. From 3,5,7-tribromotropolone (**9**), another bromine-containing 1:1-condensate (**10**) was obtained in 21% yield together with **6** in 35% yield. Similarly, 3,7-dibromo-5-chlorotropolone (**11**) gave a dihalogeno 1:1-condensate (**12**) and an unseparable mixture of **6** and a chlorine-containing product (**13**). The results concerning the reaction of **9** with **1** under various conditions are tabulated in Table 1.

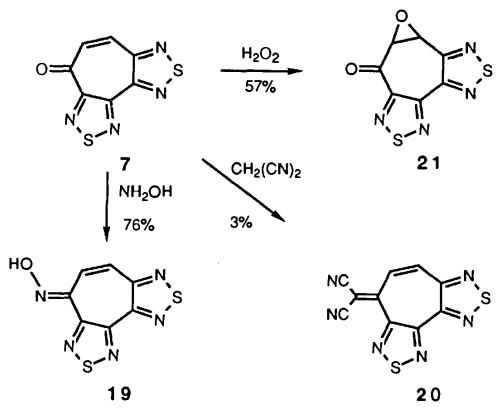
As shown in Table 1, the yields of products did not show much improvement, either under a high pressure of 3000 bar or by the addition of V-40, a radical initiator.

Furthermore, reactions with five halotroponoids (**14**—**18**) were carried out. No identified product has, however, been detected.

As an extention, the preparation of the tris[1,2,5]-thiadiazole derivative was investigated. No expected product was obtained from the reactions of **6** and **7** with **1** under similar conditions.

To check the reactivity of the carbonyl group of **7**, a couple of reactions with carbonyl reagents were attempted: Treatment with hydroxylamine hydrochloride and malononitrile afforded condensates (**19** and **20**) in 76 and 3% yields, respectively. The reaction of the carbonyl group in **7** with a bulky dicyanomethylene group was sterically unfavorable.

In order to introduce oxygen functions into the seven-membered conjugated system, the hydrogen peroxide-oxidation of **7** was carried out, and the epoxide (**21**) was obtained in 57% yield. However, an attempt to convert the epoxide to a hydroxy ketone, corresponding "tropolone", has so far been unsuccessful.



Scheme 2.

Although the yields of condensates between tropolones and tetrasulfur tetranitride were not high, the present method was valuable with respect to a one-step procedure for new heterocyclic troponoids.

Experimental

Reaction of Tropolone (2) with 1. A toluene solution (10 cm³) of **2** (174 mg) and **1** (287 mg) was stirred at room temperature for 1 h and refluxed for 9 h. The mixture was cooled and the solvent was evaporated. The residue was chromatographed on a silica-gel column to give 17.1 mg (9%) of **3** and 43.8 mg (25%) of **2**.

3: Brownish crystals (benzene), mp 146—148 °C (decomp); ^{1}H NMR[6] δ=7.29 (1H, d, J=12.5 Hz), 7.76 (1H, s), 8.10 (1H, d, J=12.5 Hz), and 8.10 (1H, s): ^{13}C NMR δ=108.2, 129.9, 132.7, 154.7, 155.0, 157.1, and 181.0; IR (KBr) 3290, 1632, 1592, 927, 883, 875, and 857 cm^{-1}; MS m/z (%) 180 (M^+, 41), 152 (base), 124 (40), 97 (17), 80 (21), 71 (15), and 52 (33).

Found: m/z 179.9992. Calcd for $C_7H_4N_2O_2S$: M, 179.9993.

Reaction of 3-Bromotropolone (4) with 1. a) A toluene solution (8 cm³) of **4** (150 mg) and **1** (166 mg) was refluxed for 14 h. The mixture was purified by silica-gel chromatography to give 7.8 mg (4%) of **5**, 4.3 mg (2%) of **6**, and 43.3 mg (26%) of **7**.

5: Pale yellow crystals (methanol), mp 160—161 °C (decomp); ^{1}H NMR δ=6.81 (1H, dd, J=11.7, 9.5 Hz), 7.78 (1H, d, J=11.7 Hz), and 8.14 (1H, d, J=9.5 Hz); ^{13}C NMR δ=126.5, 128.8, 135.9, 138.8, 155.7, 157.5, and 172.3; IR (KBr) 1637, 1615, 880, 845 and 815 cm^{-1}; UV (MeOH) 222 (ε 11900, sh), 231.6 (12800), 266.8 (11000), 301 (2200, sh), and 370.8 nm (6300); MS m/z (%) 244 (M^++2, 89), 242 (M^+, 87), 216 (61), 214 (57), 163 (23), 135 (base), 108 (24), 76 (24), and 50 (19).

b) A toluene solution (150 cm³) of **4** (1.04 g) and **1** (4.76 g) was refluxed for 48 h. Silica-gel chromatography gave 248 mg (16%) of **6** and 356 mg (31%) of **7**.

Reaction of 3,5-Dibromotropolone (8) with 1. A toluene solution (15 cm³) of **8** (68.8 mg) and **1** (136 mg) was refluxed for 12 h to give 18.2 mg (24%) of **6** and 12 mg (22%) of **7**.

Reaction of 3,5,7-Tribromotropolone (9) with 1. a) A toluene solution (7 cm³) of **9** (193 mg) and **1** (219 mg) was refluxed for 7.5 h. Silica-gel chromatography gave 37.2 mg (21%) of **10** and 57.9 mg (35%) of **6**.

10: Yellow crystals (benzene), mp 194—196 °C (decomp); ^{1}H NMR δ=8.20 (1H, d, J=1.8 Hz) and 8.37 (1H, d, J=1.8 Hz); ^{13}C NMR δ=122.6, 130.3, 134.7, 142.5, 144.0, 156.0, and 171.5; IR (KBr) 1639, 920, 880, and 850 cm^{-1}; UV (MeOH) 212.0 (ε 15100), 232.4 (17000), 268.0 (16000), 308 (2500, sh), and 375.2 nm (7500); MS m/z (%) 324 (M^++4, 53), 322 (M^++2, base), 320 (M^+, 50), 296 (32), 294 (63), 292 (31), 215 (45), 213 (44), 150 (58), 134 (34), 76 (26), 57 (30), and 50 (25).

Found: C, 26.39; H, 0.72; N, 8.51%. Calcd for $C_7H_2N_2OSBr_2$: C, 26.11; H, 0.63; N, 8.70%.

b) A toluene solution (8 cm^3) of **9** (50.1 mg) and **1** (79 mg) was heated at 100 °C for 10 h under 3000 bar. Silica-gel chromatography gave 20 mg (47%) of **6**.

Reaction of 3,7-Dibromo-5-chlorotropolone (11) with 1. A toluene solution (10 cm^3) of **11** (203 mg) and **1** (264 mg) was refluxed for 9 h. Silica-gel chromatography of the mixture gave 41.8 mg (23%) of **12** and 46.2 mg of a mixture of **6** (21%) and **13** (9%).

12: Brown needles (benzene), mp 134—136 °C (decomp); ^1H NMR δ=7.97 (1H, d, J=1.8 Hz) and 8.23 (1H, d, J=1.8 Hz); IR (KBr) 1640, 1600, 1360, 930, 880, and 855 cm^{-1}; MS m/z (%) 280 (M^++4, 28), 278 (M^++2, base), 276 (M^+, 72), 252 (19), 250 (61), 248 (46), 234 (11), 232 (15), 171 (23), 169 (63), and 50 (21).

Found: m/z 275.8781 (M^+), 277.8772 (M^++2), and 279.8710 (M^++4). Calcd for $C_7H_2N_2OClBr$: 275.8760 (M), 277.8740 (M+2), and 279.8710 (M+4).

Attempted Reactions of Halotroponoids (14+18) with 1. A toluene solution of a halotroponoid and **1** was refluxed for 9 h. No expected product was detected.

Reaction of 6 with 1. A toluene solution (4 cm^3) of **6** (10 mg) and **1** (9.2 mg) was refluxed for 11 h. Compound **6** (10 mg) was recovered unchanged.

Reaction of 7 with 1. A toluene solution (8 cm^3) of **7** (13.6 mg) and **1** (13.5 mg) was refluxed for 13 h. Compound **7** (13.4 mg) was recovered unchanged.

Reaction of 7 with Hydroxylamine Hydrochloride. To an ethanol solution (3 cm^3) of **7** (20.2 mg) was added an aqueous solution (3 cm^3) of hydroxylamine hydrochloride (6.9 mg) in the presence of AcONa (12.7 mg) and the mixture was refluxed for 5.5 h. The solvent was evaporated and the residue was washed with water to give 16.4 mg (76%) of **19**.

19: Yellow crystals (diethyl ether), mp 194-197 °C (decomp); IR (KBr) 3342, 3246, 1627, 1032, and 953 cm^{-1}; MS m/z (%) 237 (M^+, base) and 207 (61).

Found: m/z 236.9782. Calcd for $C_7H_3N_5OS_2$: M, 236.9779.

Reaction of 7 with Malononitrile. To an anhydrous dichloromethane solution (7 cm^3) of **7** (78.3 mg) and malononitrile (34.9 mg) were added $TiCl_4$ (0.2 cm^3) and then anhydrous pyridine (0.3 cm^3) at 0 °C. The mixture was stirred at room temperature for 5 h. The mixture was diluted with a 10% aqueous HCl solution and extracted with AcOEt. After evaporating the solvent, the residue was purified by silica-gel chromatography to give 2.6 mg (3%) of **20**.

20: Yellow crystals (benzene), mp 188—190 °C (decomp); ^1H NMR δ=7.51 (1H, d, J=12.8 Hz) and 7.70 (1H, d, J=12.8 Hz); IR (KBr) 2216, 1615, and 1526 cm^{-1}; UV (MeOH) 208.8 (ε13400), 265 (6200, sh), 271.2 (6700), 308.0 (9400), 351 (8400, sh), 366 (9300, sh), and 387.2 nm (10300); MS m/z (%) 270 (M^+, base), 244 (12), 218 (9), 85 (11), 83 (24), and 63 (10).

Found: m/z 269.9786. Calcd for $C_{10}H_2N_6S_2$: M, 269.9782.

Epoxidation of 7. To an anhydrous DMSO solution (5 cm^3) of **7** (50.6 mg) were added 35% H_2O_2 (2 cm^3) and (n-Bu)$_4$NF (115 mg) and the mixture was stirred at room temperature for 13 h. The mixture was poured into water and extracted with AcOEt. Silica-gel chromatography of the residue gave 30.9 mg (57%) of **21**.

21: Colorless crystals (chloroform-hexane), mp 177—178 °C; ^1H NMR δ=4.44 (1H, d, J=4.4 Hz) and 5.02 (1H, d, J=4.4 Hz); ^{13}C NMR δ=55.2, 64.5, 149.1, 150.5, 154.7, 155.0, and 188.7; IR (KBr) 1703, 1030, 885, 842, and 819 cm^{-1}; MS m/z (%) 238 (M^+, 11), 210 (10), 138 (10), 86 (34), 71 (30), 58 (47), and 46 (base).

Found: C, 35.28; H, 0.76; N, 23.46%. Calcd for $C_7H_2N_4O_2S_2$: C, 35.29; H, 0.85; N, 23.52%.

Synopsis. A stoichiometry for the reductive dehalogenation of an organic halide with carbonylferrates was established: One mol of the halide was quantitatively reduced with the carbonylferrates derived from 0.2 mol of pentacarbonyliron(0) and 2 mol of cathodically-generated tetramethylammonium methoxide. The dehalogenation was also examined using a variety of halides under the stoichiometric reaction conditions.

Organic synthetic chemistry using transition metal carbonyls has been extensively developed.[1] Particularly, pentacarbonyliron(0) [$Fe(CO)_5$] has been favorably used because of its relatively low toxicity and price.[2] Pentacarbonyliron(0) itself has a reducing power and can be used as a unique reducing reagent. For instance, it reduces selectively vinyl chlorides, enol acetates and α,β-unsaturated aldehydes to the corresponding olefins, but the reduction requires undesirable reaction conditions such as high temperature, long reaction time and the use of large excess amounts of $Fe(CO)_5$, and product yields are not high.[3] On the other hand, alkali metal tetracarbonylferrates [$M_2Fe(CO)_4$ and $MHFe(CO)_4$; M=K, Na], which can be conveniently prepared, mostly in situ, from $Fe(CO)_5$ and alkali metal hydroxides (NaOH, KOH), have stronger reducing powers and can be used for the selective hydrogenation of α,β-unsaturated compounds[1-6] and for the selective dehalogenation of α-halo ketones at room temperature.[7] However, in all the reactions, more than one mol of $Fe(CO)_5$ (or the tetracarbonylferrates) to one mol of the substrates must be used to obtain reasonable or high product yields. Exceptionally, Takegami et al.[8] reported that one mol of allyl chloride could be reductively dechlorinated with 0.33 mol of $K_2Fe(CO)_4$ to give 0.63 mol of propylene and 0.06 mol of 1,5-hexadiene. If the reaction were completed, this fact would suggest that 0.5 mol of $K_2Fe(CO)_4$ is stoichiometrically consumed to dechlorinate 1 mol of the chloride. However, there was no evidence for the completion of the reaction. Collman et al.[9] made a kinetic and mechanistic study on oxidative addition of alkyl halides to $Na_2Fe(CO)_4$ and proposed a two-electron S_N2-type mechanism with no detectable competing one-electron halogen atom abstraction and/or radical chain mechanism,[10] but did not mention stoichiometry of the reductive dehalogenation reaction which occurs successively to the oxidative addition. Moreover, although the stoichiometry of formation reaction of the ferrates has been established,[11-13] in the in situ preparation of the ferrates used actually as reducing reagents, 0.5 mol of NaOH to 1 mol of $Fe(CO)_5$ was used in a case[4] while 3 mol of KOH in another one.[7]

In this work, an overall stoichiometry for the reductive debromination of an organic bromide was established, and then the dehalogenation of a variety of halides was examined under the stoichiometric reaction conditions.

Results and Discussion

Establishment of Stoichiometry. For a stoichiometric study it is desired that a reaction completes under given reaction conditions within an experimental time scale used. However, the reductive dehalogenation with sodium and potassium ferrates does not seem to proceed at reaction rates enoughly high to perform successfully the stoichiometric study because of low product yields and/or long reaction times.[7,8] For instance, 1 mol of 2-bromocamphor,[7] which was selected as a substrate in this work, reacted with $KHFe(CO)_4$ prepared from 1 mol of $Fe(CO)_5$ and 3 mol of KOH, in a 1,2-dimethoxyethane–ethanol mixture for a few days at room temperature to give camphor in only 59%. Generally, the reactivity of anion reagents is enhanced by weakening interaction with their counter cations. In fact, the oxidative addition of alkyl halides to $Na_2Fe(CO)_4$ is accelerated by using crown ethers, cryptands and highly nucleophilic solvents, or by replacing the counter cation (Na^+) by quaternary ammonium cations.[9] Ferrates and their analogues can be also prepared using alkali metal alkoxides instead of NaOH and KOH.[14,15] In this work, a quanternary ammonium alkoxide was used.

Preparation of anion reagents with onium counter cations from the corresponding alkali metal salts is mostly troublesome and not practical, since the use of expensive crown ethers and onium fluorides is required in an ordinary method. Phase-transfer catalysts also are not always applicable owing to the impossibility of realizing anhydrous reaction conditions. On the other hand, cathodic reduction of a certain kind of organic compounds can easily generate anionic species with onium counter cations, when onium salts are used as supporting electrolytes. Previously,[16-19] it was confirmed that anionic species generated cathodically from alcohols, carboxylic acids, carbon acids and amides in nonaqueous cathodic solutions containing quaternary ammonium salt supporting electrolytes are much more reactive bases than those generated using alkali metal salt electrolytes. In this work, methanol solutions of tetramethylammonium methoxide ($Me_4N^{+\cdot\cdot-}OMe$) in various concentrations could be prepared by electrolyzing a methanol solution of Me_4NCl at various amounts of charge passed in a divided cell. One mol of the methoxide is formed by passing 1 F (1 F=96484.56 C) of charge, according to the following equation:

Table 1. Reductive Dehalogenation of Halides under the Stoichiometric Conditions[a]

Run	Halide	Yield[b]/%	By-product (Yield/%)
1	Octyl iodide	68	
2	Cyclohexyl iodide	58	
3	1-Bromo-2-phenylethane	5	Styrene (90)
4	1-Bromo-1-phenylethane	30	2,3-Diphenylbutane (15)
5	*meso*-1,2-Dibromo-1,2-diphenylethane	0	*trans*-Stilbene (86)
6	Tripenylmethyl bromide	50	Methyl triphenylmethyl ether (33)
7	Phenacyl bromide	82	Methyl phenacyl ether (trace)
8	*p*-Bromophenacyl bromide	78	
9	3-Bromocamphor	91	

a) See the text. b) For the corresponding normal dehalogenation products.

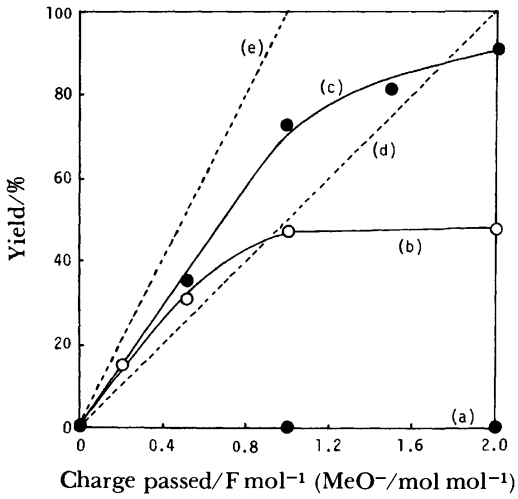

Fig. 1. Relationship between camphor yield and amount of charge passed (methoxide) in the reductive debromination of 3-bromocamphor. (a) 0, (b) 0.1, and (c) 0.2 mol of $Fe(CO)_5$ to 1 mol of 3-bromocamphor, and theoretical lines for (d) two-electron and (e) one-electron reduction.

$$MeOH + e \xrightarrow{Me_4NCl} Me_4N^+ \cdot^- OMe + \frac{1}{2}H_2$$

To the cathodic solution electrolyzed at a prescribed amount of charge between 0 to 2.0 F mol^{-1} of 3-bromocamphor, which correspond to 0 to 2.0 mol of methoxide/mol of 3-bromocamphor, was added a prescribed amount of $Fe(CO)_5$ (0 to 0.2 mol/mol of 3-bromocamphor) and then α-bromocamphor itself. The reaction mixture was stirred for 3 h at room temperature. A longer reaction time did not result in any detectable increase in the yield of camphor.

As shown in Fig. 1, the debromination of 3-bromocamphor did not occur with neither $Fe(CO)_5$ nor methoxide [see (a)]. When 0.1 mol of $Fe(CO)_5$ to 1 mol of 3-bromocamphor was used, the yield of camphor reached to ca. 50% at 1.0 F of charge (corresponding to 1.0 mol of cathodically-generated methoxide) per 1 mol of 3-bromocamphor and no increase was observed at a larger amount (2.0 F) of charge [see (b)]. On the other hand, the yield approximated to 100% at 2.0 F using 0.2 mol of $Fe(CO)_5$ [see (c)]. These facts suggest that 3-bromocamphor is debrominated to camphor by overall two-electron reduction which consumes stoichiometrically 0.2 mol of $Fe(CO)_5$ and 2 mol of methoxide, and consequently a stoichiometry for the reactants and camphor formed can be formulated as follows:

$$R\text{-}Br + \frac{1}{5}Fe(CO)_5 + 2\,MeO^- \xrightarrow{H^+} R\text{-}H + [X]$$

R-Br and R-H: 3-bromocamphor and camphor, respectively
H^+: Proton from water added in work-up procedure
[X]: A mixture of unknown products

Composition of [X], which should consist of iron and bromine compounds and probably CO_2,[20] has remained unknown, because products other than camphor were not analyzed. Therefore, at present it is difficult to discuss reaction mechanism in detail.

It is interesting that curves (b) and (c) at amounts of charge smaller than 1.0 and 2.0 F, respectively, lie in an area between straight lines (d) and (e) which indicate theoretical yields in the two- and one-electron reductions, respectively (see Fig. 1), though the overall reaction is the two-electron reduction as descrived above. This fact suggests that the one-electron reduction occurs concurrently with the two-electron reduction under conditions where amounts smaller than 10 mol of methoxide to 1 mol of $Fe(CO)_5$, or that an iron complex with more reducing capacity is formed under such conditions. Concerning the latter, it should be noted that contribution of the reduction with the zero-valent iron of $Fe(CO)_5$ is negligibly small to explain reasonably increases in the capacity.

Reductive Dehalogenation of a Variety of Halides under the Stoichiometric Conditions. The establishment of stoichiometry for the starting compounds is practically useful for performing efficiently the reductive dehalogenation from a synthetic aspect, though the reaction mechamism has not been clarified. Table 1 shows results of the dehalogenation of a variety of halides under the stoichiometric conditions where 1 mol of halides, 0.2 mol of $Fe(CO)_5$ and 2 mol of methoxide were used.

As shown in Table 1, most of iodides and bromides used could be dehalogenated using a much smaller amount of $Fe(CO)_5$ than that reported in previous papers[4-8] to give the corresponding products in good or high yields. Alkyl chlorides were hardly dechlorinated.[9] Bromobenzene also could not be debrominated.

Some types of side reactions occurred. The normal debromination of 1-bromo-2-phenylethane was almost completely suppressed due to predominant occurrence

of hydrogen bromide elimination with base, and consequently the main product was styrene (Run 3). The side reaction of a benzyl bromide seems to proceed mainly by a one-electron reduction process via the corresponding benzyl radical intermediate (Run 4). Although *meso*-1,2-dibromo-1,2-diphenylethane has two bromine atoms at the benzyl position and also gave exclusively *trans*-stilbene which is apparently a one-electron reduction product, the reaction mechanism is not necessarily rationalized by the one electron-transfer process (Run 5).[21] The formation of methyl ethers as by-products may be owing to direct nucleophilic reaction of methoxide with bromides (Runs 6, 7).

Instead of methanol, ethanol, ethanethiol, 2-propanol, phenol, and acetic acid were also used as sources of cathodically-generated bases, but they did not give any satisfactory results except for ethanol.

Experimental

Chemicals used were commercially available.

A typical experimental procedure was as follows: A methanol solution (10 cm^3 as either a catholyte or an anolyte) containing Me_4NCl (0.4 mol dm^{-3}) as a supporting electrolyte was galvanostatically electrolyzed at 1 A dm^{-2} of cathodic current density under a nitrogen atmosphere at room temperature in a divided cell. The cathode and anode were platinum plates. After a prescribed amount of charge was passed, a prescribed amount of $Fe(CO)_5$ was added to the catholyte. After allowed to stand for 15 min, a halide (1 mmol) was added. The reaction mixture was stirred for 3 h at room temperature under a nitrogen atmosphere, and then poured into a 1% hydrochloric acid solution. The resulting mixture was repeatedly extracted with ether and the combined ethereal extract was washed with a 1% sodium hydrogencarbonate solution and water, and then was dried over anhydrous sodium sulfate. The ethereal solution obtained thus was subjected to gas chromatography (PEG 20M column, 60—170 °C) for product analysis. The products were also separated by thin layer chromatography (Silica gel, hexane).

(Received February 7, 1989)

Synopsis. 2-Methylsulfonylmethyl-3,4,5-trimethoxybenzyl methyl ether was synthesized in 4 steps from methyl 3,4,5-trimethoxybenzoate, confirming the structure of the natural phenol.

We recently reported the isolation of 3,4,5-trihydroxybenzyl methyl ether (**1**) and 2-methylsulfonylmethyl-3,4,5-trihydroxybenzyl methyl ether (**2**) from the red alga *Grateloupia filicina* (Wulfen) J. Agardh.[1] Both of the compounds showed moderate antibacterial activity against *Bacillus substilis*. Described here is our attempted approach to the unique sulfone (**2**), resulting in the synthesis of its trimethyl derivative (**11**). The complete identity of synthetic **11** and the derivative from the natural product denied the possibility of another structure (**3**) for the sulfone.

3,4,5-Trimethoxybenzyl alcohol was treated with sodium hydride and methyl iodide to give a methyl ether (**4**), whose spectral and physical properties were identical with those of the derivative from the natural phenol (**1**). Compound **4** was exposed to chloromethyl methyl sulfide and tin(IV) chloride,[2] giving not the desired sulfide (**9**) but the chloride (**5**) as a major product. Under the same conditions, however, methyl 3,4,5-trimethoxybenzoate (**6**) could be converted smoothly to sulfide (**7**) in 70% yield. **7** was reduced with lithium aluminum hydride to alcohol (**8**). In contrast to the preparation of **4**, treatment of **8** with methyl iodide and sodium hydride produced many compounds containing low yield of the desired methyl ether (**9**). When **8** was heated in refluxing methanol in the presence of *p*-toluenesulfonic acid,[3] **9** was obtained in 53% yield,[4] accompanied by the pentamethoxy compound (**10**). Oxidation of the sulfide (**9**) proceeded cleanly with excess *m*-chloroperbenzoic acid, affording the sulfone (**11**).

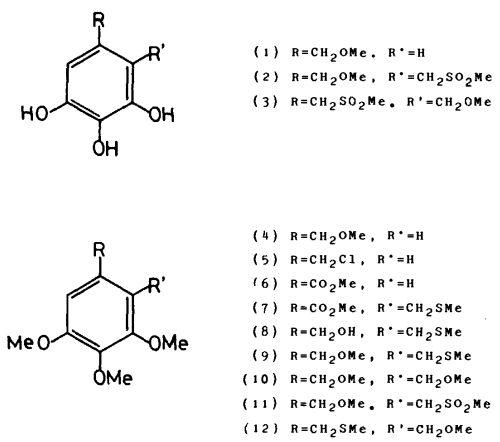

Fig 1.

The last stage toward **2** in our plan was the cleavage of all of the methyl ether on **11** and selective methylation of the benzylic hydroxyl group. Unfortunately, all trials for demethylation of **11** were unsuccessful despite use of various conditions using boron tribromide,[5] aluminum chloride–ethanethiol[6] and sodium iodide–chlorotrimethylsilane.[7]

To confirm the structure of **2**, then, natural phenol was converted to **11** with methyl iodide and sodium hydride. The spectral and physical properties of synthetic **11** and the derivative from the natural product were identical in all respects.

Experimental

3,4,5-Trimethoxybenzyl Methyl Ether (4). To a solution of 3,4,5-trimethoxybenzyl alcohol (973 mg, 4.91 mmol) in dry THF (80 ml), was added sodium hydride (60% suspension, 245 mg, 6.13 mmol) and methyl iodide (3.49 ml, 56.1 mmol) at room temperature. After stirring for 12 h, aqueous ammonium chloride was added to the mixture and THF was evaporated. The aqueous residue was extracted with ether and the organic layer was dried (Na_2SO_4) and evaporated. Column chromatography on silica gel using ethyl acetate–hexane (1:1) gave **4** (885 mg, 93%) as an oil. IR ($CHCl_3$) ν 1593, 1503, 1035 cm^{-1}; ^1H NMR ($CDCl_3$) δ=3.41 (3H, s, $CH_2O\underline{CH_3}$), 3.85 (3H, s, OCH_3, 4 position), 3.87 (6H, s, OCH_3, 3 and 5 position), 4.40 (2H, s, $\underline{CH_2}OCH_3$), 6.60 (2H, s, aromatic). Found: *m/z* 212.1048. Calcd for $C_{11}H_{16}O_4$: M, 212.1048.

Methylation of the Natural Phenol (1). To a solution of the phenol (**1**) (18.3 mg, 0.107 mmol) in THF (2 ml), was added sodium hydride (60% suspension, 40 mg, 1.0 mmol), methyl iodide (0.5 ml, 8 mmol), and dimethyl sulfoxide (1 ml) as a cosolvent. After refluxing overnight, water and ethyl acetate was added to the mixture. The organic layer was dried ($MgSO_4$) and evaporated to give the crude product. Purification by preparative TLC using ethyl acetate–benzene (1:2) gave **4** (15.0 mg, 66%) as an oil. The IR, ^1H NMR, mass spectrum and the R_f value of TLC in various solvent system were identical with those of the synthetic sample.

Methyl 2-Methylthiomethyl-3,4,5-trimethoxybenzoate (7). To a solution of methyl 3,4,5-trimethoxybenzoate (**6**) (1.152 g, 5.10 mmol) and chloromethyl methyl sulfide (0.55 ml, 6.6 mmol) in dry dichloromethane (15 ml), was added tin(IV) chloride (0.19 ml, 1.6 mmol) at 0°C. Another portions of tin(IV) chloride (0.19 ml and 0.10 ml, 2.5 mmol totally) was added to the mixture, while the reaction was carried out at room temperature for 7 h. After addition of aqueous sodium hydogencarbonate, the organic layer was dried (Na_2SO_4) and evaporated. The crude product was purified by column chro-

matography on silica gel using ethyl acetate–hexane (1:3—1:1) as eluent to give **7** (1.098 g, 70%) as an oil. IR ($CHCl_3$) ν 1717 cm^{-1} (ester CO); ^1H NMR ($CDCl_3$), δ=2.03 (3H, s, SCH_3), 3.85 (3H, s, OCH_3), 3.88 (9H, s, OCH_3), 4.09 (2H, s, SCH_2–), 7.20 (1H, s, aromatic); MS *m/z* (rel intensity) 286 (26, M^+), 255 (6), 239 (100), 224 (15), 179 (7). Found: *m/z* 286.0888 Calcd for $C_{13}H_{18}O_5$: M, 286.0876.

2-Methylthiomethyl-3,4,5-trimethoxybenzyl Alcohol (8). To a suspension of lithium aluminum hydride (233 mg, 6.14 mmol) in dry ehter (30 ml), was added a solution of **7** (1.057 g, 3.70 mmol) in ehter (5 ml) at 0°C. After stirring at room temperature for 2 h and destroying the excess hydride with ethyl acetate, 10% aqueous sodium hydroxide was added until white aluminum oxide separates. The organic layer was dried (Na_2SO_4) and evaporated. Purification by column chromatography on silica gel using ethyl acetate–hexane (1:1) as eluent gave **8** (835 mg, 87%) as an oil. IR ($CHCl_3$) ν 3426 cm^{-1} (alcohol); ^1H NMR ($CDCl_3$) δ=2.07 (3H, s, SCH_3), 3.78—3.88 (9H, OCH_3), 4.63 (2H, bd, J=3.5 Hz, CH_2OH), 6.74 (1H, s, aromatic); MS *m/z* (rel intensity) 258 (3, M^+), 211 (100), 196 (22), 181 (14), 152 (16), 61 (7). Found: *m/z* 258.0976 (M^+). Calcd for $C_{12}H_{18}O_4S$: M, 258.0926.

2-Methylthiomethyl-3,4,5-trimethoxybenzyl Methyl Ether (9). A solution of **8** (90.2 mg, 0.35 mmol) and *p*-toluenesulfonic acid (7 mg, 0.04 mmol) in methanol (5 ml) was refluxed for 6 h. After addition of aqueous sodium hydrogencarbonate, methanol was evaporated and the aqueous residue was extracted with ether. The organic layer was dried (Na_2SO_4) and evaporated. The crude product was chromatographed on silica gel using ethyl acetate–hexane (1:3) as eluent to give **9** (50.1 mg, 53%) as an oil. IR ($CHCl_3$) ν 1124 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.05 (3H, s, SCH_3), 3.38 (3H, s, $CH_2O\underline{CH_3}$), 3.74—3.87 (11H, $\underline{CH_2}S$ and three OCH_3), 4.48 (2H, s, $\underline{CH_2}OCH_3$), 6.64 (1H, s, aromatic); MS *m/z* (rel intensity) 272 (1, M^+), 224 (100), 209 (20), 195 (99), 180 (14). Found: *m/z* 272.1079. Calcd for $C_{13}H_{20}O_4S$: M, 272.1081.

2-Methylsulfonylmethyl-3,4,5-trimethoxybenzyl Methyl Ether (11). To a solution of **9** (282 mg, 1.04 mmol) in dry dichloromethane (10 ml), was added sodium hydrogencarbonate (342 mg, 4.07 mmol) and then *m*-chloroperbenzoic acid (710 mg, 4.10 mmol) at room temperature. After stirring for 2 h, aqueous sodium sulfite, aqueous sodium hydrogencarbonate and dichloromethan was added to the mixture. The organic layer was dried (Na_2SO_4) and evaporated. Purification by column chromatography on silica gel using ethyl acetate–hexane (1:1) as eluent gave **11** (207 mg, 66%) as solid, which was recrystallized from ether. Mp 94.5—96.5°C; IR ($CHCl_3$) ν 1600, 1499, 1461, 1412, 1310, 1197, 1127 cm^{-1}; ^1H NMR ($CDCl_3$) δ=2.80 (3H, s, SO_2CH_3), 3.40 (3H, s, $CH_2O\underline{CH_3}$), 3.83, 3.87, 3.93 (each 3H, s, OCH_3), 4.44, 4.57 (each 2H, s, CH_2S and CH_2O) 6.77 (1H, s, aromatic); MS *m/z* (rel intensity) 304 (2, M^+), 225 (48), 195 (100), 180 (13). Found: *m/z* 304.1017. Calcd for $C_{13}H_{20}O_6S$: M, 304.0980.

Methylation of 2-Methylsulfonylmethyl-3,4,5-trihydroxybenzyl Methyl Ether (2). A solution of **2** (2.5 mg, 0.0095 mmol) in THF (0.5 ml) was treated with sodium hydride (60% suspension in mineral oil, 2 mg, 0.05 mmol) and methyl iodide (0.2 ml, 5 mmol) for 24 h at room temperature, and refluxed overnight. Aqueous ammonium chloride was added to the mixture, which was extracted with dichloromethane and the organic layer was dried (Na_2SO_4) and evaporated. Preparative TLC on silica gel using ethyl acetate–hexane (1:1) as solvent gave **11** (0.7 mg, 24%). The IR, ^1H NMR, mass spectra, the GC retention time, and the R_f value of TLC in various solvent system were identical with those of the synthetic sample.

Shift References in High-Resolution Solid-State NMR

Shigenobu HAYASHI* and Kikuko HAYAMIZU
National Chemical Laboratory for Industry, Tsukuba, Ibaraki 305
(Received February 7, 1989)

Synopsis. The high-resolution solid-state ^{13}C, ^{29}Si, ^{31}P, ^{23}Na, ^{27}Al, and ^{11}B NMR spectra of several compounds have been measured using magic-angle sample spinning. Their isotropic chemical-shift values have been determined accurately to use as shift references in solid-state NMR; this makes comparison between literature shift data possible.

High-resolution solid-state NMR has been widely used for such lighter nuclides as ^{13}C, ^{29}Si, and ^{3}P in the solid state.[1] By using this technique, chemical shifts in solids can be determined accurately, and nonequivalent sites can sometimes be distinguished.

The chemical shift can be expressed as the deviation of the resonance frequency with respect to reference materials. For example, tetramethylsilane (TMS) is universally used as an internal shift reference in liquid-state ^{13}C, ^{1}H, and ^{29}Si NMR. On the other hand, in solid-state NMR, an external reference is used instead of an internal reference. A correction of the bulk magnetic susceptibility is, however, necessary in the case of an external reference, though it is not discussed in the present work.

For the reference materials in solid-state NMR, the following properties are desirable:

(1) The central peak is very sharp under magic-angle sample spinning (MAS).

(2) The material contains a large amount of the observed nuclei, thus making the detection easy.

(3) For the $I \geqq 1$ spins, the crystal symmetry is very high, and so the spins have no electric-field gradient. This means that the center transition ($m=1/2 \leftrightarrow -1/2$) has neither broadening nor a shift caused by the second-order quadrupole effect.

(4) The compounds are available commercially.

(5) The spin-lattice relaxation time of the observed nucleus (or of the proton when the cross-polarization technique is used) is short enough.

(6) The materials are stable in air.

(7) The materials can be used for the set-up of the spectrometer. This means that solid materials are preferable.

Various second-reference materials have been used,[2] but their bases are sometimes ambiguous or have not been described explicitly. While the magnetic field was relatively low, any difference in the second-reference materials was little trouble since the resolution in high-resolution solid-state NMR was not so good as in liquid-state NMR. However, in the high-field NMR instruments recently developed the resolution is sometimes comparable to that in liquid-state NMR, and the chemical shift can be determined very accurately. The use of different second-reference materials might, therefore, now cause some deviation in shift values.

The aim of this paper is to present data on several materials which can be used as second references. This would enable us to compare literature data. We have measured the high-resolution solid-state ^{13}C, ^{29}Si, ^{31}P, ^{23}Na, ^{27}Al, and ^{11}B NMR spectra of several compounds and have determined the isotropic chemical shift accurately.

Experimental

The compounds were available commercially. High-resolution solid-state NMR spectra were measured by the use of a Bruker MSL400 pulsed spectrometer at room temperature. The probe was doubly tuned to the observed nucleus and proton, being capable of proton-dipolar decoupling and cross-polarization if necessary. The magic-angle sample-spinning technique[3] was used to determine the isotropic chemical shift accurately. The spinning rate of the rotor was changed between 2 and 4 kHz; typically, 4 kHz was used. A JEOL FX200 pulsed spectrometer was also used, and the values obtained by the two spectrometers agreed within the limits of experimental error. The static magnetic fields were 9.40 and 4.69 T for MSL400 and FX200 respectively. Since the precision and reproducibility were somewhat better in MSL400, the results obtained by the use of MSL400 will be described here. The higher-frequency shift is expressed as positive.

Results and Discussion

Table 1 summarizes the chemical-shift values of the compounds studied in this work, including the first-reference materials. For practical purposes, materials widely used in liquid-state NMR were selected as the first-reference materials and no correction of the bulk magnetic susceptibility was performed. The experimental errors in Table 1 reflect the reproducibility of the measurements carried out in this work.

^{13}C. The first-reference compound is tetramethylsilane (TMS). It is difficult to deal with neat TMS because of its low boiling point, and the TMS solution might include the solvent effect on the shift. Experimentally, no sharp resonance line of neat TMS was observed in this work. Adamantane, glycine, and hexamethylbenzene have been used as the second-reference compounds. Especially for adamantane, Earl and VanderHart,[4] have measured the chemical shift precisely, getting the value of 29.50±0.10 ppm with respect to TMS. This value is adapted in the present paper, since to our knowledge, this is the most reliable value available at present. VanderHart[5] has also reported field-dependent ^{13}C chemical shifts in solids, among which adamantane shows a field-independent chemical shift. The chemical shifts of glycine and hexamethylbenzene obtained in the present work are given in Table 1.

^{29}Si. The first-reference compound is, again, TMS; TMS is not adequate for routine use for the same reasons as in the case of ^{13}C. The second-reference compounds used are 3-(trimethylsilyl)propionic-d_4 acid sodium salt (TSPA: $(CH_3)_3Si(CD_2)_2COONa$), hexa-

Table 1. Chemical Shifts

Nuclei	Compounds	Chemical shifts (ppm)	
^{13}C	Tetramethylsilane	(0)[a]	
	Adamantane	38.55±0.02	29.50[b]
	Glycine	176.50±0.03	43.70±0.05
	Hexamethylbenzene	132.15±0.03	17.21±0.05
^{29}Si	Tetramethylsilane	(0)[a]	
	3-(trimethylsilyl)propionic-d_4 acid Na salt (TSPA)	1.50[b]	
	Hexamethylcyclotrisiloxane	−9.68±0.05	
	Silicone rubber (Poly(dimethylsiloxane))	−22.42±0.05	
	Hexamethyldisiloxane	6.56±0.05	
^{31}P	85% H_3PO_4	0[b]	
	$(NH_4)_2HPO_4$	1.33±0.02	
	$NH_4H_2PO_4$	1.00±0.03	
^{23}Na	1M NaCl aqueous solution	0[b]	
	NaCl	7.21±0.03	
	NaBr	5.04±0.02	
	NaI	−3.25±0.06	
^{27}Al	1M $AlCl_3$ aqueous solution	0[b]	
	$NaAlO_2$	79.33±0.15	
^{11}B	$(C_2H_5)_2O \cdot BF_3$	0[b]	
	BPO_4	−3.60±0.03	
	$NaBH_4$	−42.06±0.02	

a) This value was not checked in the present work. b) This value is assumed in the present work; therefore, it has no experimental error.

methylcyclotrisiloxane (HMCTS), silicone rubber (poly(dimethylsiloxane)), and hexamethyldisiloxane (HMDS). Among these, TSPA is assumed to have a chemical shift of 1.50 ppm in this work, though there is no clear basis for this assumption. The chemical shifts of $(CH_3)_3Si(CH_2)_3COOH$ (1.54 ppm) and $(CH_3)_3Si(CH_2)_4COOH$ (1.53 ppm)[6] might form a basis. However, the obtained values of HMCTS (−9.68 ppm), silicone rubber (−22.42 ppm), and HMDS (6.56 ppm) are reasonable considering the values in the literature.[6] The error in the value of TSPA is considered to be less than 0.10 ppm, although the shift of TSPA should be related to TMS experimentally.

^{31}P. The first-reference material is 85% H_3PO_4. $(NH_4)_2HPO_4$ (1.33 ppm) and $NH_4H_2PO_4$ (1.00 ppm), which have no crystalline waters, can be used as the second-reference compounds. Some inorganic phosphates contain crystalline waters and/or they are hygroscopic, which influence the chemical shift.

^{23}Na. The first-reference material is a 1M NaCl aqueous solution (1M=1 mol dm^{-3}). NaCl (7.21 ppm), NaBr (5.04 ppm), and NaI (−3.25 ppm) can be the second-reference compounds.

^{27}Al. The first-reference material is a 1 M $AlCl_3$ aqueous solution. $NaAlO_2$ (79.33 ppm) can be the second-reference compound.

^{11}B. The first-reference compound is $(C_2H_5)_2O \cdot BF_3$ (diethyl ether-boron trifluoride (1/1)). This compound is a strong Lewis acid, and it is very reactive. The use of second-reference compounds, such as anhydrous BPO_4 (−3.60 ppm) and $NaBH_4$ (−42.06 ppm), is preferable.

When chemical shifts in solid and liquid states are compared, some problems are left unsolved, as has been pointed above and as will be described below. In the cases of ^{13}C and ^{29}Si, conversions to the TMS reference could not be checked in the present paper, although the ^{13}C reference has previously been checked by Earl and VanderHart.[3] The effect of the bulk magnetic susceptibility should always be taken into consideration when the chemical shifts are discussed in detail.

However, for practical purposes, the determination of a chemical shift by using the external reference described above is sufficient. The shift value can easily be corrected when more reliable reference data are obtained. In order to make this later correction possible, though, it is strongly recommended that the reference materials actually used should be explicitly described in the paper.

The Crystal and Molecular Structures of Tetraethylammonium [Tetraaquatetrakis(isothiocyanato)neodymate(III) and europate(III)], $[(C_2H_5)_4N][M(NCS)_4(H_2O)_4]$, (M=Nd, Eu)

Akira OUCHI
Department of Chemistry, College of Arts and Sciences, The University of Tokyo, Komaba, Meguro-ku, Tokyo 153
(Received December 1, 1988)

Synopsis. The crystal and molecular structures of the title new complexes were determined by means of a single-crystal X-ray diffraction method. The crystals of the neodymium(III) complex, $NdC_{12}H_{28}N_5O_4S_4$, F. W. 578.87, are triclinic, space group $P\bar{1}$, a=14.13(2), b=15.39(1), c=12.92(1) Å, α=106.81(8), β=114.70(9), γ=90.09(10)°, U=2418(5) Å^3, Z=4, D_m=1.57(3), D_x=1.59 g cm^{-3}, μ(Mo $K\alpha$)=25.22 cm^{-1}. The isomorphous europium(III) complex was also obtained: a=14.069(9), b=15.328(9), c=12.865(9) Å, α=106.98(5), β=114.57(5), γ=90.07(6)°, U=2390(3) Å^3, D_m=1.60(3), D_x=1.63 g cm^{-3}, μ(Mo $K\alpha$)=30.04 cm^{-1}. Two crystallographically independent neodymium(III) atoms in a unit cell have approximately the same coordination geometry: square antiprism 4*O*,4*N*-octa-coodination. A pair of the O atoms as well as N atoms are in cis positions on the top square and in trans positions on the bottom square of each polyhedron, where the lines connecting both pairs of the N atoms on both squares are approximately parallel.

The structures of metal thiocyanato complexes have already been actively investigated.[1,2] Among them, the lanthanoid complexes are interesting because of their specific coordination number (for example, six in tetrabutylammonium salts, $[(C_4H_9)_4N]_3[M(SCN)_6]$[3]), and of their coordination geometry (for example, cubic in $[(C_2H_5)_4N]_4[M(SCN)_7(H_2O)]$ (**1**)[4]).

In this line of the study, we obtained another types of lanthanoid thiocyanato complexes (shown in the title), $[(C_2H_5)_4N][Nd(SCN)_4(H_2O)_4]$ (**2**), and the isomorphous europium(III) complex (**3**). It is very interesting that when using almost the same starting solution, crystals of **2** were obtained when this solution was kept in benzene vapor, while crystals of **1** were obtained when it was kept over silica gel. Although the structures of the complexes $K_4[M(SCN)_4(H_2O)_4]\cdot(SCN)_3\cdot nH_2O$ (M=Nd) (**4**), Eu (**5**)) have already been reported,[5] they are double salts in which, moreover, the counter cation is K^+: the coordination geometry of the anionic complexes is much affected by the kinds of counter cations.[6-8] We therefore examinted the structures of **2** and **3** by the single-crystal X-ray diffraction technique.

Experimental

Synthesis of Tetraethylammonium [Tetraaquatetrakis(isothiocyanato)neodymate(III)] (2). Neodymiun and tetraethylammonium thiocyanates were obtained as reported previously.[4] Into a methanolic solution (15 cm^3) containing 1.0 mmol of $Nd(SCN)_3$ and 0.2 cm^3 of water, 0.80 g (4.3 mmol) of $[(C_2H_5)_4N](SCN)$ was dissolved and left standing in a desiccator over benzene for several weeks: crystals of **2** were deposited. Yield: 0.46 g (0.80 mmol, 80%). The europium complex (**3**) was also obtained by the same technique and almost in the same yield. Attempts to synthesize types of La and the Pr complexes by this technique failed. Calcd for $MC_{12}H_{28}N_5S_4O_4$: M=Nd, Nd, 24.92; C, 24.90; H, 4.88; N, 12.10%; M=Eu, Eu, 25.91; C, 24.57; H, 4.81; N, 11.94%. Found: M=Nd, Nd, 24.98; C, 25.15; H, 5.05; N, 12.12%; M=Eu, Eu, 25.85; C, 24.57; H, 4.75; N, 11.78%.

Single Crystal X-Ray Structure Analysis. The crystal of **2** used for a structure analysis was pale violet in color, and parallelepiped in shape (0.30×0.30×0.28 mm^3); that of **3** was colorless and in a similar shape (0.29×0.29×0.29 mm^3). The intensities in the range $3<2\theta<50°$ (2θ) were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer using graphite monochromated Mo $K\alpha$ radiation (λ= 0.71073 Å) by means of a ω-2θ scan technique (scan speed, 4° min^{-1} (ω); scan width (ω), 1.07+0.35tanθ° for **2**, and 1.15+0.35tanθ° for **3**). The intensities were corrected for Lorentz and polarization factors, but not for absorption or extinction. Of 8576 independent intensities collected, 6453 reflections with $|F_o|>3\sigma(|F_o|)$ were used for the structure determination of **2**, and 6438 in 8465 reflections for that of **3**.

All calculations were carried out on a HITAC M-682H computer at the Computer Center of the University of Tokyo using a local version of the UNICS program.[9] The scattering factors were taken from Ref. 10.

The structure of **2** was solved by the heavy-atom method, and the positional and thermal parameters were refined by a block-diagonal least-squares method. No hydrogen atom was included in the structure factor calculations. The structure of **3** was refined in the same way, starting from the final values of **2**. At the final stage of the refinement, the shifts of the parameters were less than one third of the corresponding standard deviations. The final R values applying anisotropic temperature factors were 0.040 (R_w=0.052) for **2**, and 0.055 (R_w=0.061) for **3**.[11]

If only complex anions were considered, the centers of symmetry of the crystal exist at the middle points of both pairs of the respective kinds of complex metal atoms, Nd(1) and Nd(2). The tetraethylammonium ions centered by the N(3) atoms are also distributed so as to take the same positions as the centers of symmetry. On the other hand, the central nitrogen atoms, N(4) and N(5), of the other two kinds of tetraethylammonium ions exist just at the centers of symmetry. As these cations were found not to be cetrosymmetric, we had to assume that the respective eight ethyl carbon atoms around each central nitrogen atom were disordered at two positions with equal occupancy factors. On the calculation, the positions of the N(4) and N(5) atoms were fixed at 0.5, 0.5, 0.5 and 0.5, 0, 0.5, respectively.

Results and Disccusion

Selected bond lenghts of **2** and **3** are shown in Table 1. A perspective drawing of a complex centered by the Nd(1) atom is shown Fig. 1, and a projection of the unit cell of the neodymium complex along the c-axis is shown in Fig. 2.[1]

There are two kinds of crystallographically independent complexes; however, they are approximately in the same form. All the complexes are in a square-

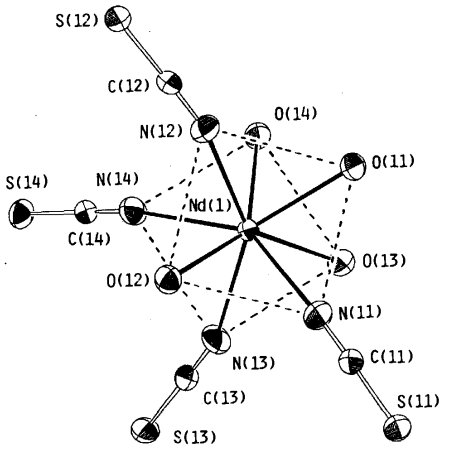

Fig. 1. Perspective drawing of the neodymium(III) complex anion centered by Nd(1) atom, with the numbering scheme of the atoms: 30% probability ellipsoids are shown for the atoms in the figure.

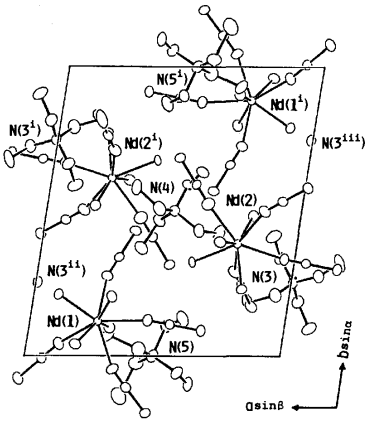

Fig. 2. A projection of the unit-cell of the neodymium(III) complex along c-axis. The numbering of the metal and the tetraethylammonium nitrogen atoms are also shown. Only one in possible two arrangements are shown for the tetraethylammonium carbon atoms around the N(4) and N(5) atoms, respectively. The carbon atoms around the N(3ⁱⁱ) and N(3ⁱⁱⁱ) atoms are not shown. Key to the symmetry operations: i, 1−x, 1−y, 1−z; ii, 1+x, y, z; iii, −x, 1−y, 1−z.

antiprism 4*N*,4*O*-octa-coordination. On a top square of each coordination polyhedron, the two N atoms as well as the two O atoms take a cis configuration, respectively, while on the bottom square they take a trans configuration: the lines through two N atoms on the respective faces are approximately parallel. The mean squares planes of the respective four atoms at the apexes of the top and the bottom squares of each coordination polyhedron are nearly parallel (dihedral angles are: 3.5, 3.2° for **2**, and 2.7, 3.1° for **3**). As shown in Table 1, the M-N and the M-O bond lengths of **2** and **3** are distributed over a relatively wide range, and the longest or shortest members are not always the same in both complexes.

The average of the eight bond lengths are: **2**, Nd-N, 2.500 (2.486(11)—2.504(8)); Nd-O, 2.473 (2.454(7)—2.493(9)) Å; **3**, Eu-N, 2.456 (2.445(9)—2.470(10)); Eu-O, 2.421 (2.392(9)—2.444 (12)) Å. These M-N(SCN) and M-O(H_2O) bond lengths are not much different from the corresponding ones of the related compounds.[4,5,13] However, as mentioned above, in **2** and **3** the average M-O bond length is a little shorter than the average M-N length in each complex. This tendency is also found in the tetramethylammonium salts, $[(CH_3)_4N]_3[M(SCN)_6(CH_3OH)(H_2O)]$, (M=La through Er), which are also in the square antiprism coordination geometry.[13] On the other hand, in **4** and **5**, although the anionic complexes have the same chemical composition and the coordination geometry, their M-O(H_2O) is reported to be longer than M-N(SCN) in each complex.[5] Probably this fact is caused by the types of counter cations. Since the tetramethyl- and tetraethylammonium ions are surrounded by hydrocarbon groups, they are less polar than the potassium ions.

The average M-N-C and N-C-S angles are: **2**, 163.4 (158.4(9)—170.5(5)) and 178.8 (177.3(6)—179.5(7))°; **3**, 164.3 (157.6(14)—171.6(8)) and 178.2 (176.8(10)—178.8(11))°, respectively.

In the crystals of **2** and **3** the metal atoms are arranged approximately on lines parallel to the b-axis (intersecting the ac-plane at about 0.25, 0, 0, and 0.75, 0, 0). The dihedral angles between the top or the bottom square planes of the coordination polyhedrons and the ab-plane are small (**2**, 10.4—14.2; **3**, 10.9—14.0°). The N atoms of the counter cations are also arranged approximately on lines parallel to the b-axis, intersecting the ac-plane at about 0, 0, 0.5 and 0.5, 0, 0.5). Thus, in the crystal, the layers of the anions and the cations are piled alternately along the a-axis as well as c-axis.

CIDEP Study of the Photoreduction of Aromatic Ketones with Alkoxides in Alcohols

Keishi OHARA, Hisao MURAI, and Keiji KUWATA*
Department of Chemistry, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received November 9, 1988)

The photoreductions of xanthone and benzophenone with alkoxides in several alcohols were studied by observing CIDEP. The total emission spectra, observed after the photoexcitation, were assigned to the ketone anion radicals having TM spin polarization. The dependence of the spectral line width upon alkoxides indicates the existence of a hyperfine interaction between the ketone anion radical and the alkali metal cation, even in the early stage of the photochemical reaction in an alcoholic media. A careful analysis of the spectral pattern leads to the conclusion that the counter radical of the ketone anion interacting as a geminate pair which is responsible for the RPM polarization, is other than a methoxyl radical in these systems.

ESR studies on the aromatic ketone anions formed by the reduction with alkali metals in ethereal solvents proved the properties of ion pairs between the ketone anion radicals and the alkali metal cations.[1-4] The phenomenon of an 'atom transfer' in the electron-transfer process has also been shown.[5] On the other hand, the photoreduction of aromatic ketones has been investigated in several systems extensively.[6,7] Alkoxides are known to be one of the good reducing agents used in the photoreaction of aromatic ketones in alcoholic media. The primary steps in this photochemical reaction, especially concerning the behavior of the alkali metal cation and the alkoxyl radical, are of great interest, but few studies on this problem has been reported.[1]

The studies on CIDEP (chemically induced dynamic electron polarization) provide information about the primary steps of photochemical reactions, and are powerful tools for studying the reaction dynamics. The time-resolved study of the CIDEP spectra provides information about the chemical exchange and/or electron spin exchange reactions which induce the relaxation processes.[8]

In the present paper, the CIDEP investigation of the photoreduction of aromatic ketones, xanthone (9-xanthenone), and benzophenone (diphenylmethanone), with alkoxides in several alcohols is presented. New information concerning the presence of a weak interaction between the ketone anions and the alkali metal cations in alcoholic media in the early stage of the photochemical reaction is given. To our knowledge, this paper represents the first CIDEP investigation on the ion pairs formed in the photochemical reaction of aromatic ketones and alkoxides in alcoholic solvents.

Experimental

Xanthone and benzophenone were recrystallized repeatedly from acetone. A sodium methoxide ($NaOCH_3$), 28% methanol solution provided by Wako Pure Chemical Industries, Ltd., was used as received. Potassium methoxide ($KOCH_3$) as ca. 10% methanol solution was prepared by the reaction of potassium metal and methanol. The solvents used in this experiment were ethanol, 2-propanol, cyclohexanol, and a 1 : 1 (v/v) mixture of cyclohexanol and isobutyl alcohol (2-methyl-1-propanol). Commercially available special-grade alcohols provided by Wako Pure Chemical Industries, Ltd. were used as received. Throughout most of the present experiment, the concentrations of xanthone and benzophenone were 0.01 and 0.1 mol dm^{-3}, respectively, unless otherwise noted. The mixing ratio of a methanol solution of alkoxide and the other alcoholic solvents was 1 : 9 in volume in most cases. The concentrations of $NaOCH_3$ and $KOCH_3$ in the solution used in the experiment were ca. 0.5 and 0.1 mol dm^{-3}, respectively. The solutions were deoxygenated by bubbling with pure nitrogen gas prior to the CIDEP measurements.

A nitrogen gas laser (λ=337.1 nm, 5 mJ/pulse) was used for the photoexcitation with a repetition rate of 7.5 Hz. Steady-state ESR was observed by an X-band ESR spectrometer using 100-kHz field modulation during the pulsed laser excitation. The CIDEP spectra were measured by a modified X-band ESR spectrometer (time resolution of 60 ns) for the time-resolved measurement using no field modulation. A boxcar integrator was used to record the time-resolved ESR spectra at several fixed gate times after the laser pulse. The gate width of the boxcar integrator was 0.2 or 0.5 μs. The steady-state ESR and CIDEP measurements were carried out at room temperature. The solutions were flowed at a constant rate of ca. 25 ml h^{-1} through a flat quartz cell of 0.3-mm depth in an ESR cavity of TE_{011} mode. The details were similar to those reported before.[9,10]

Results and Discussion

(I) Xanthone. Figure 1 shows typical results of the steady-state ESR spectra observed during the in situ laser photolysis in the systems of xanthone/$NaOCH_3$ and xanthone/$KOCH_3$ in the mixture of cyclohexanol and isobutyl alcohol (HB). These spectra were assigned to xanthone anion radical from their hyperfine structure (hfs). Other radical species could not be detected. The hyperfine coupling constants (hfc) were in good agreement with those reported in the literature.[11] The line width of the spectra observed using $NaOCH_3$ was much broader than those observed using $KOCH_3$. The change in the concentration of

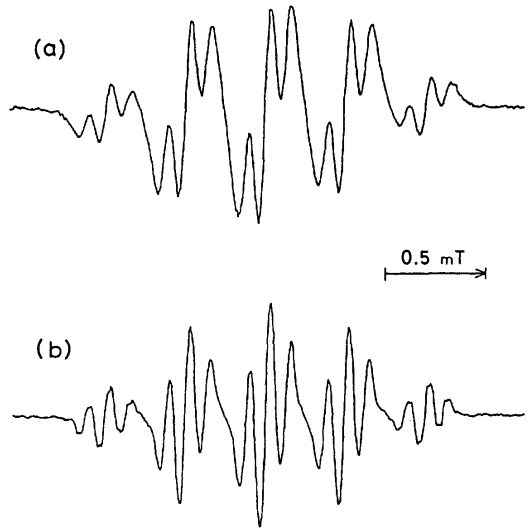

Fig. 1. Steady state ESR spectra observed during the in situ laser photolysis of (a) xanthone/$NaOCH_3$ and (b) xanthone/$KOCH_3$ in HB.

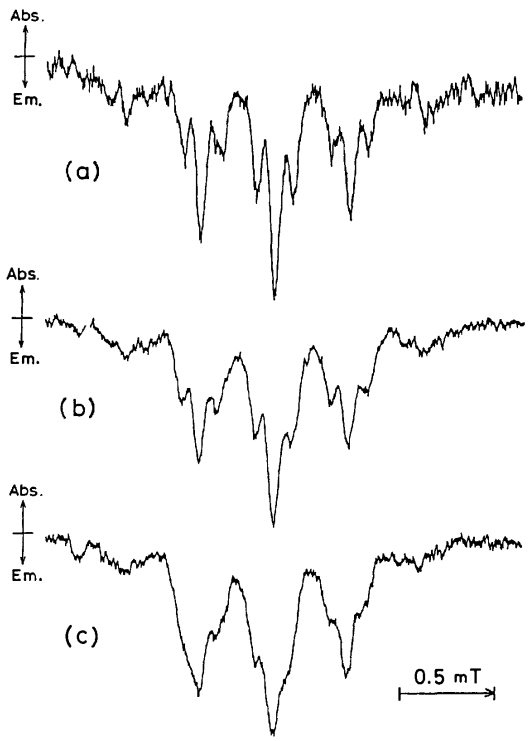

Fig. 2. Time resolved ESR spectra observed in the systems of xanthone and $NaOCH_3$ (a) in ethanol, (b) in 2-propanol and (c) in HB with the gate opening time from 1.0 to 1.2 μs after the laser pulse.

xanthone and alkoxides did not affect the respective spectral patterns and the line width, though it did affect the signal intensities. These results imply the existence of a certain interaction which affects the line width of the ESR spectra between the alkali metal cation and the radical anion in alcoholic media. The line width of the spectra observed using $NaOCH_3$ drastically varied with the solvent alcohol. This effect also appeared weakly in a system containing $KOCH_3$.

Figure 2 shows the time-resolved ESR spectra observed in a system of xanthone and $NaOCH_3$ in various alcohols with the gate opening time from 1.0 to 1.2 μs after the laser pulse. In all the time-resolved ESR spectra shown in the present paper, the downward signals show the microwave emission. These spectra were assigned to the xanthone anion radical; other radical species could not be detected. The spectral hfs were the same as those observed in the steady-state ESR.

The total emission pattern of these spectra clearly shows the feature of the triplet mechanism (TM) of CIDEP; namely, the photochemical reaction is much faster than the spin-lattice relaxation process of the spin polarized triplet state of precursor xanthone. The intensity of hyperfine (hf) lines in the lower field was slightly stronger than that of the corresponding $|M_I|$ lines in the higher field. This fact suggests a slight superposition of emission on the lower-field side and absorption on the higher-field side (E/A pattern), which is due to the radical pair mechanism (RPM) between the geminately produced radicals. The CIDEP signals decayed in some tens of microseconds, depending upon the experimental conditions. This signal decay does not reflect the chemical reaction but, rather, CIDEP relaxation, since the steady state ESR measurement provides the equilibrated spectrum of the anion radical. The line width of the CIDEP spectra varied with the solvent. It became broader with an increase in the molecular weight of the alcohols used in this experiment.

Figure 3 shows the CIDEP spectra observed using

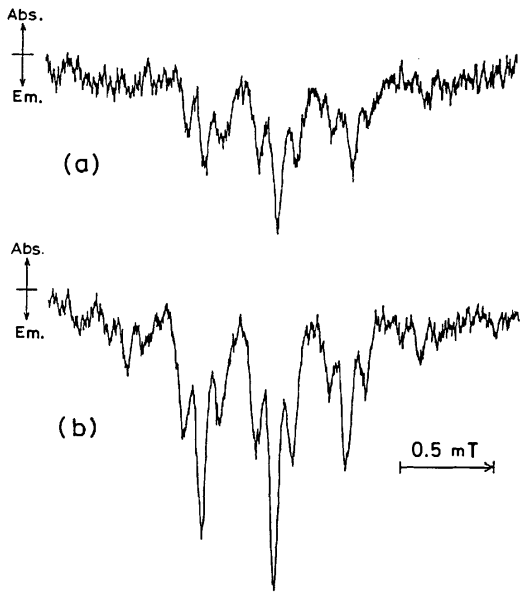

Fig. 3. Time resolved ESR spectra observed in the systems of xanthone and $KOCH_3$ (a) in 2-propanol and (b) in HB with the gate opening time from 1.0 to 1.2 μs after the laser pulse.

$KOCH_3$ in 2-propanol and HB. The spectral hfs and the total emission pattern are almost the same as those observed using $NaOCH_3$. The line width observed in this system is much sharper than that observed in the system containing $NaOCH_3$, as it is clearly demonstrated by comparing Figs. 2 and 3. The solvent effect on the line width, similar to the system of $NaOCH_3$, also appeared weakly. The dependence of the line width upon the solvents and alkoxides observed in the CIDEP study is similar to the result of the steady-state ESR observation described above. Even immediately (0.1 μs) after the photoexcitation, the CIDEP spectra were essentially identical to those observed in the later region, except for the line width. This line-broadening in the early period usually occurs in CIDEP measurements.[12,13] These results clearly demonstrate that the same interaction as that observed in the steady-state ESR takes place even in the period earlier than 10^{-7}s after the photoexcitation.

The photoreduction of xanthone with alkoxides can be represented as follows:

$$Xn+h\nu \longrightarrow Xn(S_1)^* \xrightarrow{ISC} Xn(T_1)^* \quad (1)$$

$$Xn(T_1)^* + MOCH_3 \longrightarrow Xn^{\cdot-} + M^+ + {}^{\cdot}OCH_3, \quad (2)$$

where M denotes alkali metal and the asterisks represent the electronic excited states. Xanthone is excited by a laser pulse to the excited singlet state (S_1), and the spin-selective intersystem crossing (ISC) induces spin polarization in the triplet state (T_1): namely, the uppermost spin-sublevel is exclusively populated.[14,15] This excited triplet state reacts with alkoxides very quickly while the spin polarization is conserved. Therefore, the product anion radical, preserving the spin polarization, shows the total emission spectra. This xanthone anion radical and the alkali metal cation form the ion pair soon after the photochemical reaction in the alcoholic solvents. This ion-pair formation is considered to be analogous to that reported in the system of alkali metal reduction of aromatic ketones in ethereal solvents.[1-3] Although the methoxyl radical carrying TM spin polarization may be produced by this photoreduction, we could not detect this particular radical. Alcohol radicals which may be produced by a secondary reaction of this radical were not observed either. The failure to detect these radical species may be explained by the rapid relaxation of the spin polarization of the methoxyl radical.

The line width of these CIDEP spectra is considered to be caused by a hyperfine interaction between the alkali metal cation and the radical anion; therefore, the hfc of sodium nuclei is larger than that of potassium. This is analogous to the results in an ethereal solution, reported in the literature.[1,2,11] However, this hyperfine interaction in alcoholic solvents is much weaker than that in ethereal solvents. Thus, the solvent effect on the line width may also be explained by a variation of the hyperfine interaction, possibly due to the polarity of the solvent. This means that the hyperfine interaction between the radical anion and the alkali metal cation becomes stronger with a decrease in the polarity of the solvent.

The existence of the paramagnetic dimer of ketone anion radicals was reported,[16] which might obscure the hfs of the ESR spectrum. In the present experiment, however, this contribution to the line width may be negligible since the concentration of radicals in our observing systems, probably less than 10^{-4} mol dm^{-3}, was scarce enough not to form the dimer.

In ordinary steady-state ESR, the variation of spin-spin relaxation time by electron transfer between radical species and its parent molecule is one of the causes of line-broadening. In the time-resolved ESR studies, however, it is known that such an exchange reaction sensitively affects the time evolution of the CIDEP spectrum.[8,13,17] In the presence of the electron-transfer process, the effective relaxation time of CIDEP signals is dependent upon the line degeneracy D_i, microwave field strength ω_1, and the concentration of parent molecule $[A]$. The apparent spin-spin and spin-lattice relaxation times (T_{2i}^{ET} and T_{1i}^{ET}) for a line i at low ω_1 are as follows:

$$\frac{1}{T_{2i}^{ET}} = \frac{1}{T_2} + \frac{(D - D_i)}{D} k_{ET}[A] \quad (3)$$

and

$$\frac{1}{T_{1i}^{ET}} = \frac{1}{T_1} + \omega_1^2 \left(\frac{1}{T_{2i}^{ET}} - \frac{1}{T_1}\right)^{-1} \quad (4)$$

where D is the total line degeneracy and k_{ET} is the rate constant of the electron-transfer reaction.

The CIDEP spectra observed in systems of $NaOCH_3$ with xanthone of different concentrations and by shifting the gate opening time of the boxcar integrator are shown in Fig. 4. The hfs of spectra, its total emission pattern and the line width were not seriously affected by the concentration of xanthone and the gate-opening time. On the other hand, the observable spin-lattice relaxation time of the spin polarization on each hf line was different. The center line of the respective triplet ones of the spectra decayed faster than its neighboring lines. This result can be considered to demonstrate the dependence of the effective relaxation times upon the line degeneracy.

The concentration dependence of the signal decay is clearly demonstrated by a comparison of Figs. 4a and 4b. The observed decay rate of the CIDEP signals increases with a decrease in the concentration of xanthone. This may be explained by the term $k_{ET}[A]$, which affects the observed values of the relaxation time in Eqs. 3 and 4. A system using potassium methoxide provided similar results.

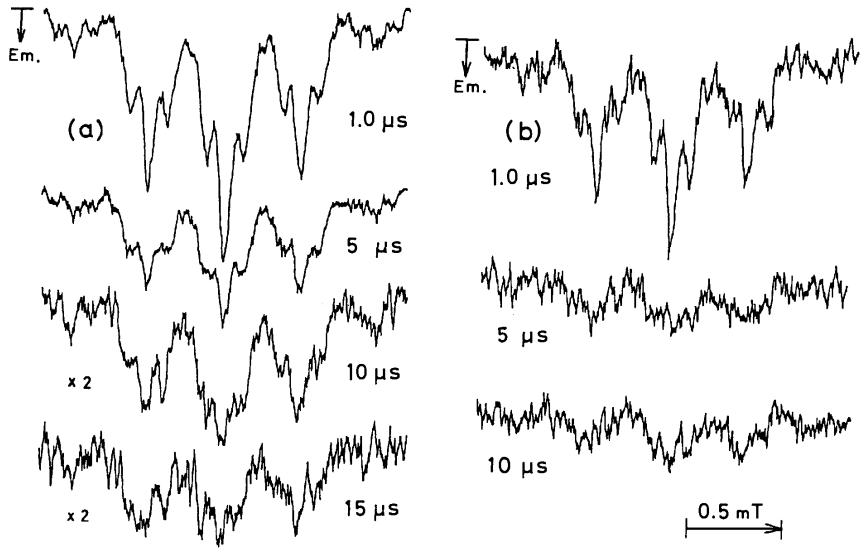

Fig. 4. Time evolution of CIDEP spectra observed by shifting gate opening time (fixed gate width of 0.5 μs) of the boxcar integrator in the system of xanthone/$NaOCH_3$ in 2-propanol. The concentration of xanthone is (a) 6.9×10^{-3} mol dm^{-3} and (b) 1.9×10^{-3} mol dm^{-3}.

These results seem to suggest that the electron-transfer reaction from a xanthone anion radical to its parent molecule takes place. The rate of the electron-transfer reaction is reported to be slow (k_{ET} is ca. 10^7 $mol^{-1}\,dm^3\,s^{-1}$) in the case of fluorenone anion radical in alcoholic media.[18] If this value is adopted in the present system, the contribution of the electron-transfer reaction to the result shown in Fig. 4 is thought not to be very significant. On the other hand, the excitation by the attenuated laser light provided data concerning a fast decay, compared with the one excited by intense light. This result suggests that the concentration of radicals also affects the apparent decay rate of the spin polarization: that is, the relaxation mechanism such as the electron spin-exchange reaction must also be taken into account in this particular system. In this case, the apparent relaxation rate of hf line i may also be expressed in an identical form to that used in Eqs. 3, where the spin-exchange rate and the radical concentration must be used, instead of k_{ET} and $[A]$,[13] respectively.

After all, it was suggested that the spin-exchange reaction between anion radicals and the electron transfer from the xanthone anion radical to its parent molecule takes place in the early period after photoreduction, and the interaction of the ion pair continues

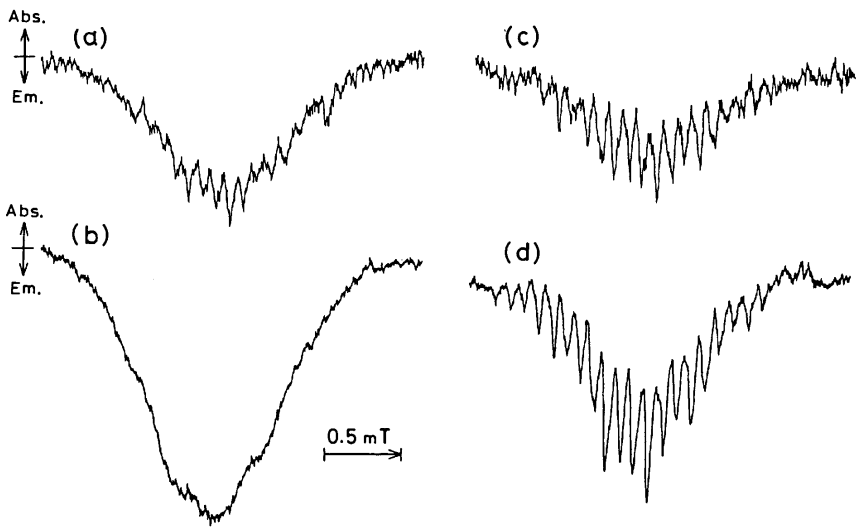

Fig. 5. Time resolved ESR spectra observed by the photoreduction of benzophenone with alkoxides in various alcohols with gate opening time from 1.0 to 1.2 μs. (a) $NaOCH_3$/2-propanol, (b) $NaOCH_3$/HB, (c) $KOCH_3$/2-propanol, and (d) $KOCH_3$/HB.

during these processes. The transfer of the alkali metal cation takes place along with the electron-transfer reaction, which is known as an 'atom transfer'.[5]

(II) Benzophenone. Figure 5 shows the CIDEP spectra observed in the photolysis of benzophenone instead of xanthone in alcoholic solvents containing $NaOCH_3$ or $KOCH_3$. These spectra, having a total emission pattern of TM, are assigned to benzophenone anion radical by an analysis of the hfs,[1,2] which clearly appeared in the system of potassium methoxide. No other species, such as the alcohol radical, was detected. The spectral change with the solvent and the alkoxide showed a similar tendency to that observed using xanthone. The change in the concentration of benzophenone did not affect the spectral pattern or line width seriously, though the decay of the signal became fast upon diluting the concentration. This situation was also the same as that observed using xanthone. Steady-state ESR measurements also provided an ordinary ESR spectrum of the anion radical during the laser photolysis. Consequently, the photochemical primary reaction and successive processes in the system of benzophenone are very similar to those of xanthone: namely, there exists a hyperfine interaction between the benzophenone anion and the alkali metal cation; solvation also affects the interaction.

Concerning the contribution of RPM to the total emission spectra observed in both xanthone and benzophenone systems, a unique and important feature of this reaction is obtained. Usually, RPM provides the E/A character by S-T_0 mixing of the two geminately produced radicals having nearly the same g-value. In the present experimental systems, the counter radical of the ketone anion is predicted to be a methoxyl radical which must be produced in the early stage of this reaction. The methoxyl radical is known to have a larger g-value,[19,20] g_{iso}=2.029,[21] while the ketone anion radicals have a g-value of 2.0036,[22] which is close to that of a free electron. This larger difference of the g-values almost gives a symmetrical total absorption spectrum of the ketone anion through S-T_0 mixing.[23-25]

The simulated CIDEP spectra of the ketone anion radical of pure TM polarization and of pure RPM regarding the above-mentioned assumption in the case of benzophenone, are shown in Figs. 6a and 6b, respectively. The hfc of A(o)=0.280 mT, A(m)=0.100 mT, A(p)=0.354 mT and the line width of 0.030 mT (FWHM) are employed for the anion radical. These hfc values, which are obtained from the observed CIDEP spectrum, are in good agreement with those reported before.[1,2] In order to reproduce the observed spectra of the distorted total emission pattern, the contribution of TM must be slightly stronger than that of RPM. This situation hardly takes place due to the following two reasons. The signal intensity might be very weak owing to a cancellation of the emission and absorption components under the condition assumed above, though the observed signal intensity was almost comparable with the ordinary TM spectrum observed in several systems. Secondly, since the spin-lattice relaxation of triplet ketones competes with its chemical reactions, the spectral pattern could be sensitively influenced by such experimental

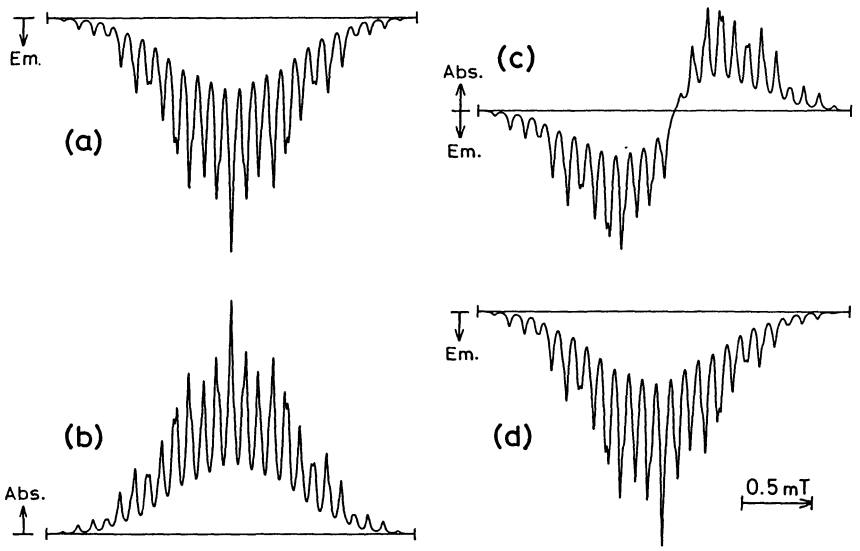

Fig. 6. Simulated CIDEP spectra of benzophenone anion radical in the cases of (a) pure TM, (b) pure RPM assuming the counter radical is methoxyl radical having a hfc of 5.2 mT,[19] and (c) pure RPM assuming the counter radical is methanol radical having a g-factor of 2.0032 and hfc's of A_{CH}=1.75 mT and A_{OH}=0.100 mT.[26] (d) Mixed spectrum of 80% of (a) and 20% of (c), whose intensities are normalized previously.

conditions as the viscosity of the solution or the concentration of solutes, though no such effect has been observed.

Figure 6c shows the simulated CIDEP spectrum of pure RPM obtained by assuming an alcohol radical (hydroxymethyl radical) as the counter one. Figure 6d shows the hybrid spectrum of Figs. 6a and 6c, where the predominant contribution of TM is assumed. In the system of xanthone, similar results were obtained by simulation. Therefore, it was tentatively concluded that the counter radical interacting as a geminate pair is not methoxyl but, perhaps an alcohol radical such as the hydroxymethyl radical produced by a secondary reaction with the solvent or by a fast isomerization of the methoxyl radical.[20] The lifetime of the methoxyl radical would be shorter than the time required for S-T_0 mixing (10^{-9}—10^{-7} s).[23-25]

In conclusion, the photoreduction of xanthone and benzophenone in alcoholic solvents was investigated by CIDEP. The product anion radical and the alkali metal cation form the ion pair soon after the photochemical reaction. The time-resolved ESR study demonstrated that the hyperfine interaction of the ion pair exists, even in the early stage of the photoreaction. It was also suggested that the electron spin-exchange process between the ketone anion radicals possibly occurs along with an electron-transfer reaction. The E/A distortion component of the total emission spectrum could be explained by the contribution of the geminate pair RPM; also, the counter radical of the anion radical of ketones in the geminate cage was shown to be other than the alkoxyl radical.

(Received November 9, 1988)

The solvent effect on the hydrogen bonds between guanine and cytosine and between hypoxanthine and cytosine was studied by means of solution calorimetry and ab initio MO calculations. The experimental enthalpy changes for guanine-cytosine and hypoxanthine-cytosine systems in aqueous solution were estimated to be about −10 and −14 kJ mol^{-1}, respectively. In order to explain these experimental results, the electronic structures of hydrated bases and hydrated base pairs were calculated, assuming two types of hydration schemes. In the first type, it was expected that the complementary base pairs were destabilized in aqueous solution. In the second type, the stabilization energies in aqueous solution were calculated to be −11.9 kJ mol^{-1} for the hydrated guanine-cytosine system and −18.5 kJ mol^{-1} for hypoxanthine-cytosine one, respectively, which agreed with the experimental results. This suggests that water molecules bound to base pairs contribute to the stabilization/destabilization of hydrogen bonds between bases. The present calculation showed the possibility of C-H$^{\delta+}$···O hydrogen-bond formation between the complementary base pair and H_2O.

It is well-known that deoxyribonucleic acid (DNA) is a macromolecule with a double-stranded helical structure formed by a complementary interaction between purine and pyrimidine bases,[1] bringing about a helix-coil transition by a change in the environmental conditions, such as pH, ionic strength, or temperature.[2]

In previous papers,[3,4] in order to clarify the stabilization scheme of DNA molecule in aqueous solution, the enthalpy changes of duplex formations by an equimolar mixture of poly(riboguanylic acid)-(poly(G)) with poly(ribocytidylic acid) (poly(C)), and of poly(riboinosinic acid)(poly(I)) with poly(C) solutions with a 0.1 mol dm^{-3} Tris-HCl buffer solution at pH 7.60 were measured using LKB batch-type microcalorimeter at 298.15 K. Poly(I) contains hypoxanthine, which is a deamino analogue of guanine. We reported that the enthalpy changes accompanying duplex formation were about −9 kJ (mol of base pair)$^{-1}$ for the poly(G)·poly(C) duplex, and about −21 kJ (mol of base pair)$^{-1}$ for the poly(I)·poly(C) duplex, respectively. The estimated enthalpy changes between polynucleotides may correspond to the total energy containing various types of interactions such as the hydrogen bonding between bases, the solvent effect of water, the stacking effect, conformational change, and the dissociation of self-associated poly(G) and poly(I).[3-19] Especially, the hydrogen bonds between bases may mainly contribute to both the stability and conformation of polynucleotides.

Recently,[20] we reported on theoretical and experimental studies concerning the Watson-Crick and the Hoogsteen pairs of adenine-uracil hydrogen-bonded systems, and pointed out that not only the hydrogen bonding between bases, but also the solvent effect of water played an important role in the stability of base pairs in aqueous solution.

Clementi and Corongiu[19] investigated theoretically the hydration schemes of guanine, cytosine, and the guanine-cytosine pair by means of isoenergy contour map analysis and Monte Carlo simulations.

In the present study, in order to elucidate the solvent effect of water on the stability of a base pair, the energies of nonhydrated and hydrated complementary base pairs (Watson-Crick pairing) of guanine with cytosine and of hypoxanthine with cytosine were calculated by an ab initio MO method, by assuming two types of hydration schemes. These results were compared with the results of solution calorimetric experiments.

Experimental

9-Methylguanine, cytosine (Cyt), and hypoxanthine (Hyp) were purchased from Tokyo Kasei Kogyo Co., Ltd., Japan, and used without further purification. 9-Methylguanine, instead of guanine (Gua), was used because of the requirement of higher solubility in aqueous solution.

Water was purified by an ordinary method,[21] and finally distilled by the use of a long column.

A 0.1 mol dm^{-3} Tris-HCl (tris(hydroxymethyl)aminomethane-hydrochloric acid) solution was used as the buffer solution (pH 7.0).

In this study, an LKB batch-type microcalorimeter was used (described in a previous paper[22]). The measured temperature was 298.15±0.005 K. For measurements of the heat of mixing, equal volumes (about 2 ml) of 5×10^{-4} mol dm^{-3} Gua or Hyp and Cyt solutions were mixed.

Calculations

Ab initio MO calculations were carried out with IMSPACK[23] and GAUSSIAN 80[24] programs using STO-3G minimal basis set.[25] The geometry of Hyp was optimized (see Fig. 1). The geometries of Gua and Cyt were taken from Del Bene[26] and Matsushita et al.[27] respectively.

†† Present address: Mitsui Petrochemical Industries, Ltd., Iwakuni, Yamaguchi 740.

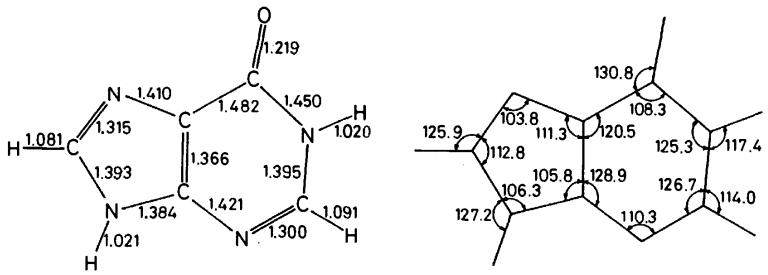

Fig. 1. The optimized structure of Hyp. Units are angstroms and degrees.

Since the hydrogen bond is much weaker than the usual covalent bond, it is expected that the geometries of bases might be almost unchanged by hydrogen-bond formation. Therefore, we optimized only the hydrogen-bonding regions of the nonhydrated base pairs, and the hydrated bases and base pairs.

For the calculation of intermolecular interaction energy, an extended basis set, such as 4-31G or 6-31G*, is recommended. However, since the number of basis sets for hydrogen-bonded systems in the present work was very large, the STO-3G minimal basis set was used. The purpose of this work was to perform both comparative and qualitative studies of the effects of hydrogen bonding and hydration on the physicochemical properties of DNA. For this purpose, the STO-3G minimal basis set proved to be useful.

Results and Discussion

Hydrogen-Bonding Interactions of Gua with Cyt and of Hyp with Cyt. Since it is well-known experimentally that Watson-Crick pairing is the most stable structure in possible hydrogen-bonding schemes of Gua with Cyt,[28] we calculated this type of base pair. The Watson-Crick pairing of Hyp with Cyt was also calculated. The optimized geometric parameters for the hydrogen-bonding region of Gua-Cyt and Hyp-Cyt pairs are shown in Fig. 2, together with the experimental values of the 9-ethylguanine-1-methylcytosine pair determined by X-ray diffraction crystallography (in parenthesis[28]). As can be seen in Fig. 2a, the calculated intermolecular distances are somewhat underestimated. This is a general tendency as long as one uses STO-3G minimal basis set.

The calculated results of the hydrogen-bonding energies (E_{HB}), the magnitude of the charge transfer from pyrimidine to purine bases (Δq), and dipole moments (μ) for Gua-Cyt and Hyp-Cyt pairs are summarized in Table 1, together with the vector sum of the dipole moments of monomers (μ_{SUM}). As can be seen in Table 1, E_{HB} was estimated to be −111.3

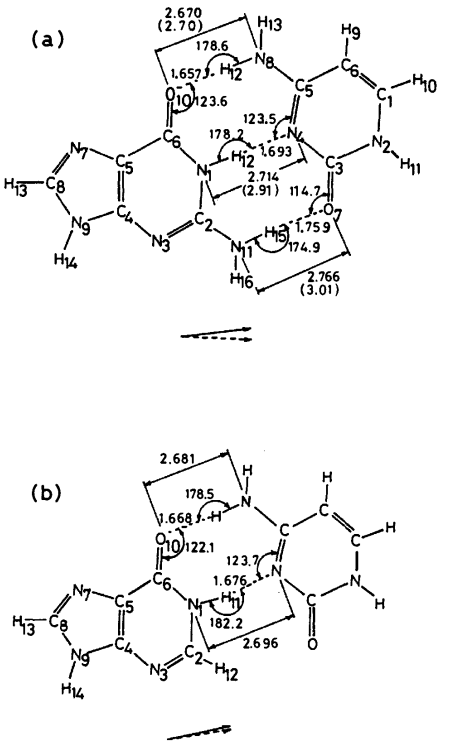

Fig. 2. The optimized geometric parameters of (a) Gua-Cyt and (b) Hyp-Cyt pairs. Units are angstroms and degrees. The solid and broken arrows show the direction of dipole moments for base pairs and of the vector sum of dipole moments for monomers, respectively.

Table 1. The Calculated Results of the Hydrogen-Bonding Energies, E_{HB}, the Magnitude of the Charge Transfer from Pyrimidine to Purine Bases, Δq, Dipole Moments of Base Pairs, μ, and the Vector Sum of Dipole Moments of Monomers, μ_{SUM}, for Gua-Cyt and Hyp-Cyt Pairs

	E_{HB}/kJ mol^{-1}	Δq/e[a]	μ[b]/Debye	μ_{SUM}[b]/Debye
Gua-Cyt pair	−111.3	0.06	6.53	4.78
Hyp-Cyt pair	−82.4	0.02	4.13	3.11

a) e=−1.6×10^{-19} C. b) The direction refers to Fig. 2.

kJ mol^{-1} for Gua-Cyt pair and −82.4 kJ mol^{-1} for Hyp-Cyt one, respectively. Hereafter, we call the hydrogen bonds between the complementary bases the internal hydrogen bonds. Therefore, E_{HB} is the energy of the internal hydrogen bonds. The calculated result for the Gua-Cyt pair is comparable with the experimental one reported by Yanson et al. ($\Delta H°$=−87.9 kJ mol^{-1})[6,7] and with the calculated one by Forner et al. (E_{HB}=−124.1 kJ mol^{-1}).[8] Since the calculated dipole moment of the Gua-Cyt pair is larger than that of the Hyp-Cyt one, it is expected that in a polar solvent, the Gua-Cyt pair may be more stable than that of Hyp-Cyt due to a dipole-dipole interaction between solute and solvent molecules.

In order to obtain informations concerning the nature of the internal hydrogen bonds of Gua-Cyt and Hyp-Cyt pairs, the calculated hydrogen-bonding energies were decomposed into physically meaningful energy components such as the electrostatic (E_{ES}), the exchange repulsion (E_{EX}), the polarization (E_{PL}), and the charge-transfer (E_{CT}) energies, according to the Kitaura-Morokuma method.[29] The results are summarized in Table 2, where $E_{CT(X\to Y)}$ and $E_{CT(Y\to X)}$ refer to the charge-transfer interaction energies from Gua and Hyp to Cyt, respectively. As can be seen in Table 2, the dominant energy components for both Gua-Cyt and Hyp-Cyt pairs are the electrostatic and the charge-transfer interactions, as in the usual hydrogen-bonded systems.[30]

It should be noted that for the Hyp-Cyt pair, $E_{CT(Y\to X)}$ (−50.6 kJ mol^{-1}) is almost the same as $E_{CT(X\to Y)}$ (−49.8 kJ mol^{-1}), though the Gua-Cyt pair, $E_{CT(Y\to X)}$ (−88.3 kJ mol^{-1}), is much larger than $E_{CT(X\to Y)}$ (−51.5 kJ mol^{-1}). This result is because in the Gua-Cyt pair, two hydrogen bonds (N_1-H_{12}···N_4 and N_{11}-H_{15}···O_7) contribute to $E_{CT(Y\to X)}$, while only one hydrogen bond (O_{10}···H_{12}-N_8) contributes to $E_{CT(X\to Y)}$. On the other hand, in the Hyp-Cyt pair, one hydrogen bond (O_{10}···H_{12}-N_8) contributes to $E_{CT(X\to Y)}$ and one hydrogen bond (N_1-H_{11}···N_4) to $E_{CT(Y\to X)}$.

Table 2. Hydrogen-Bonding Energies and Their Components for the Gua-Cyt and Hyp-Cyt Pairs

		Gua-Cyt pair /kJ mol^{-1}	Hyp-Cyt pair /kJ mol^{-1}
E_{HB}		−111.3	−82.4
E_{ES}		−141.0	−112.1
E_{EX}		212.5	166.5
E_{PL}		−13.0	−9.2
E_{CT}		−140.2	−101.3
E_{CT}	$E_{CT(X\to Y)}$[a]	−51.5	−49.8
	$E_{CT(Y\to X)}$[a]	−88.3	−50.6

a) X refers to Gua for Gua-Cyt pair and to Hyp for Hyp-Cyt one. Y refers to Cyt.

The Results of Calorimetric Measurements

The heats of mixing of Gua and Cyt solutions and Hyp and Cyt solutions were measured using an LKB batch-type microcalorimeter at 298.15±0.005 K. The experimental results were exothermic, suggesting that the mixed systems were stabilized by complementary base-pair formation, if we assumed that the heat of dilution of each base was negligible.

The obtained results are summarized in Table 3, together with the $\Delta H°$-values reported by other investigators.[5-7] As can be seen in Table 3, it is of interest to note that the stability ($\Delta H°=H°$(base pair A-B)−$H°$(base A)−$H°$(base B)) of the Gua-Cyt system decreases with an increase in the polarity of solvents. From the point of view of a dipole-dipole interaction,

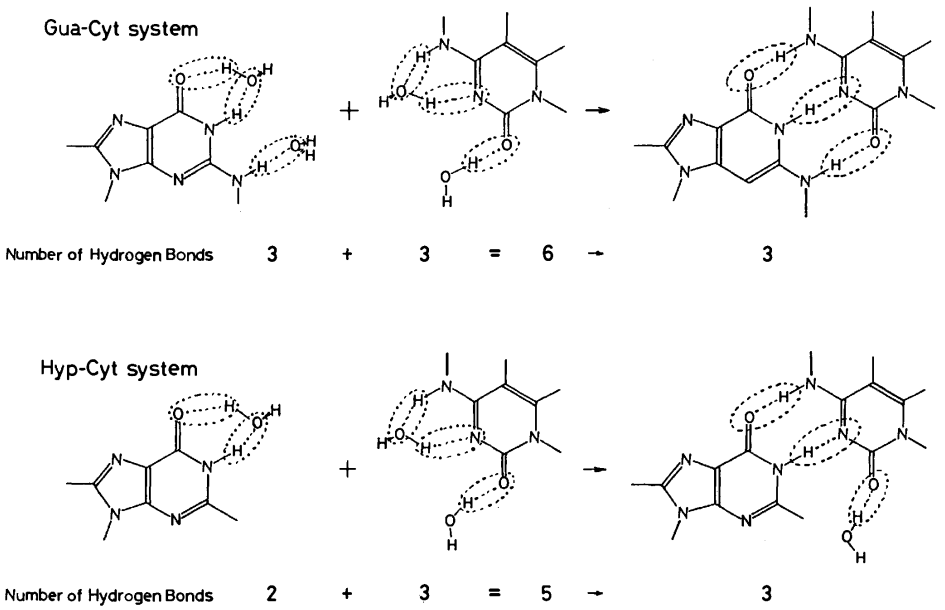

Table 3. Experimental Enthalpy Changes of the Hydrogen-Bond Formation between Gua and Cyt and between Hyp and Cyt

Solvent	Enthalpy change, ΔH° /kJ (mol base pair)$^{-1}$		Ref.
	Gua-Cyt pair	Hyp-Cyt pair	
H_2O[a]	−10	−14	This work
$CHCl_3$[b]	−42—−48	−38	5
Gas phase	−87.9		6,7

a) The concentration of 5×10^{-4} mol dm^{-3}. b) Guanosine and Cytisine for Gua-Cyt pair, and 2′,3′-*O*-benzylidine-5′-*O*-tritylinosine and cytisine for Hyp-Cyt pair.

the stability of complementary base pairs is expected to increase with an increase in the polarity of solvents, and also with an increase in the dipole moment of the base pair. Actually, in $CHCl_3$ solutions, the Gua-Cyt system (calculated dipole moment μ=6.53 Debye) is more stable than the Hyp-Cyt system (μ=4.13 Debye) (see Table 3). Therefore, the decrease of stability in the aqueous solution comes from destabilization due to the dehydration of a hydrated base in the process forming a base pair. That is, in the Gua-Cyt system, the number of hydrogen bonds decreases from six to three(hydrated four H_2O molecules are removed and three internal hydrogen bonds are formed in Gua-Cyt pair), while in the Hyp-Cyt system, the number of hydrogen bonds decreases from five to three (see figure given below). As a result, the stability of the base pair in aqueous solution is reversed; that is, the order of stability is Hyp-Cyt pair>Gua-Cyt pair.

Hydration Effect on the Internal Hydrogen Bonds of Gua-Cyt and Hyp-Cyt Pairs. In order to elucidate the hydration effect on the stability of internal hydrogen bonds of the complementary base pair, hydrated bases and base pairs were calculated by ab initio MO methods, by assuming various degrees of hydration.

To consider possible hydration schemes for Gua, Hyp, and Cyt, the net charges (Mulliken population of atoms) were calculated. The results are shown in Fig. 3. As can be seen, there are eight hydrogen-bonding sites (proton donating or accepting site) in Gua and six sites in Hyp and Cyt, respectively, at which hydration is possible. We distinguish the hydrogen-bonding site and the hydration region. The possible hydration regions of bases are shown in Fig. 3. There are five hydration regions ((A)—(E)) in Gua, four regions ((F)—(I)) in Hyp, and four regions ((J)—(M)) in Cyt.

At the hydration regions, two types of hydration schemes are possible. The first type is as follows. Since each proton-donating or -accepting site in a base can bind with one H_2O molecule, two H_2O molecules can be coordinated at each bay-like region (A), (C), (D), (H), (I), (J), or (L) shown in Fig. 3. In this case,

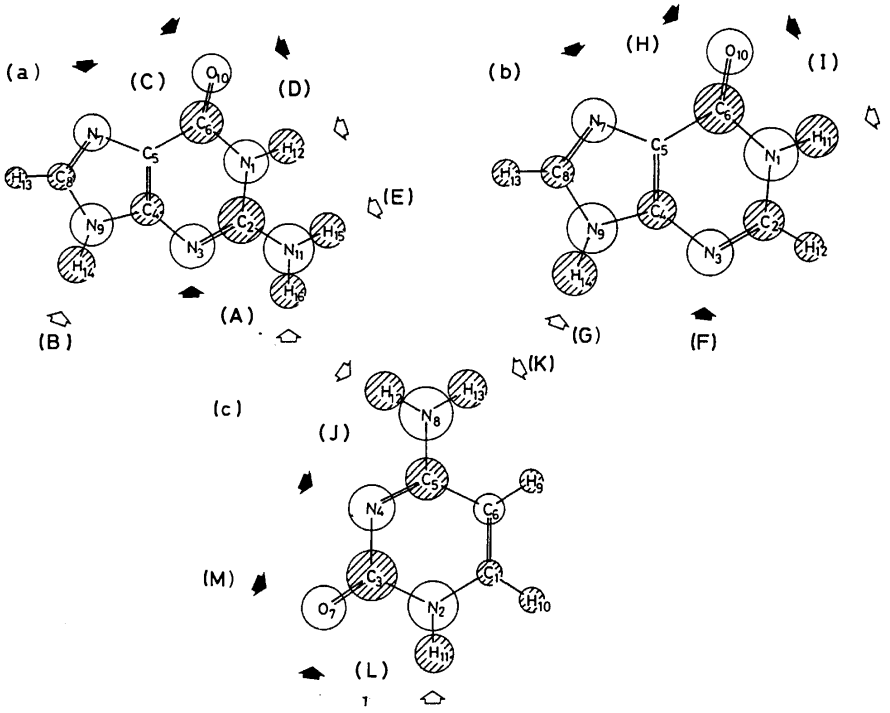

Fig. 3. The net charges of (a) Gua, (b) Hyp, and (c) Cyt. The open and shaded circles represent the negative and positive net charges, respectively. The area of the circle shows the relative magnitude of the net charge. The open and shaded arrows indicate the location of proton donating and accepting sites. The uppercase alphabetical letters represent the hydration regions.

there are some interactions between hydrated H_2O's in these regions, such as hydrogen bonding, dipole-dipole interactions and steric hindrance. Therefore, we optimized each hydrogen-bonding moiety of hydrated bases. At other regions ((B), (E), (F), (G), (K), and (M)), one H_2O molecule is coordinated. Furthermore, there are some direct interactions between hydration regions (A) and (B), between (D) and (E), between (F) and (G), and between (J) and (M). Thus, geometry optimization was performed at these regions simultaneously. The calculated results are shown in Figs. 4a, b, and c.

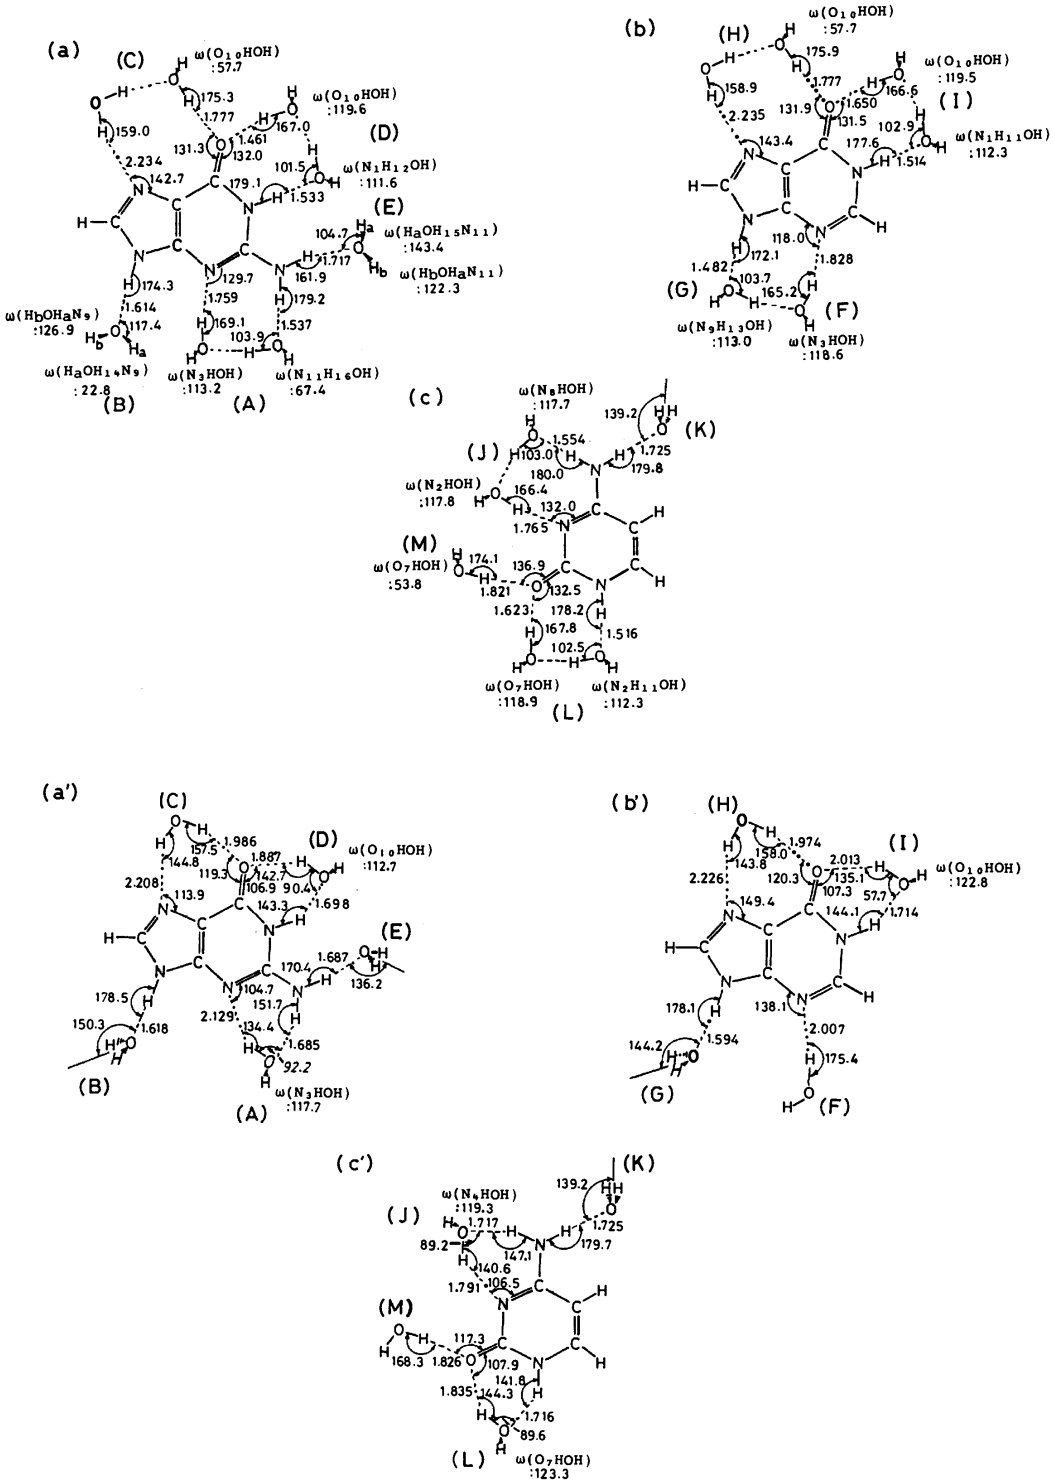

Fig. 4. The optimized geometric parameters of (a) and (a′) hydrated Gua, (b) and (b′) hydrated Hyp, and (c) and (c′) hydrated Cyt. Units are angstroms and degrees. Dihedral angles are given as follows; for an example, the dihedral angle between N_3-H-O and H-O-H planes at region (A) in the hydrated Gua(figure a′) is given by $\omega(N_3HOH)$: 117.7.

In the second type of hydration scheme, one H_2O molecule is bound between proton-donating and -accepting sites in each bay- like region shown in Figs. 4a′, b′, and c′. Optimized geometric parameters are shown n Figs. 4a′, b′, and c′.

The hydration scheme of Gua shown in Fig. 4a′ is rather similar to that of Pullman et al.[12] and that of Clementi and Corongiu.[19] The hydration scheme of Cyt, shown in Fig. 4c′, is similar to that of Clementi and Corongiu calculated by Monte Calro simulations.[19] However, it is somewhat different from that of Pullman et al.[12]

The electron density changes due to internal hydrogen-bond formation of Gua-Cyt and Hyp-Cyt pairs were calculated (Fig. 5). As can be seen in Fig. 5, it is of interest to note that the charge densities on the H_9 and H_{10} atoms of the C-H bonds of Cyt in the Gua-Cyt pair and those on the H_{12} atom of the C-H bond of Hyp, and H_9 and H_{10} atoms of Cyt in the Hyp-Cyt pair considerably decreased by the formation

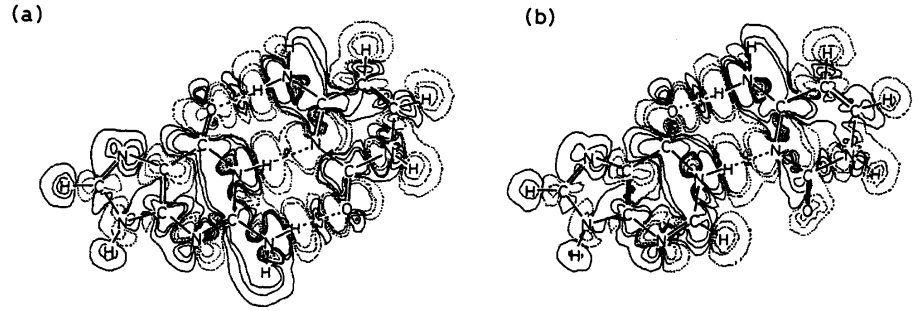

Fig. 5. The electron density changes due to the hydrogen-bond formation of (a) Gua-Cyt and (b) Hyp-Cyt pairs. Full and dotted lines indicate the density increase and decrease, respectively. The values of these lines are ±0.0001, ±0.0005, and ±0.001 (Bohr)$^{-3}$, successively.

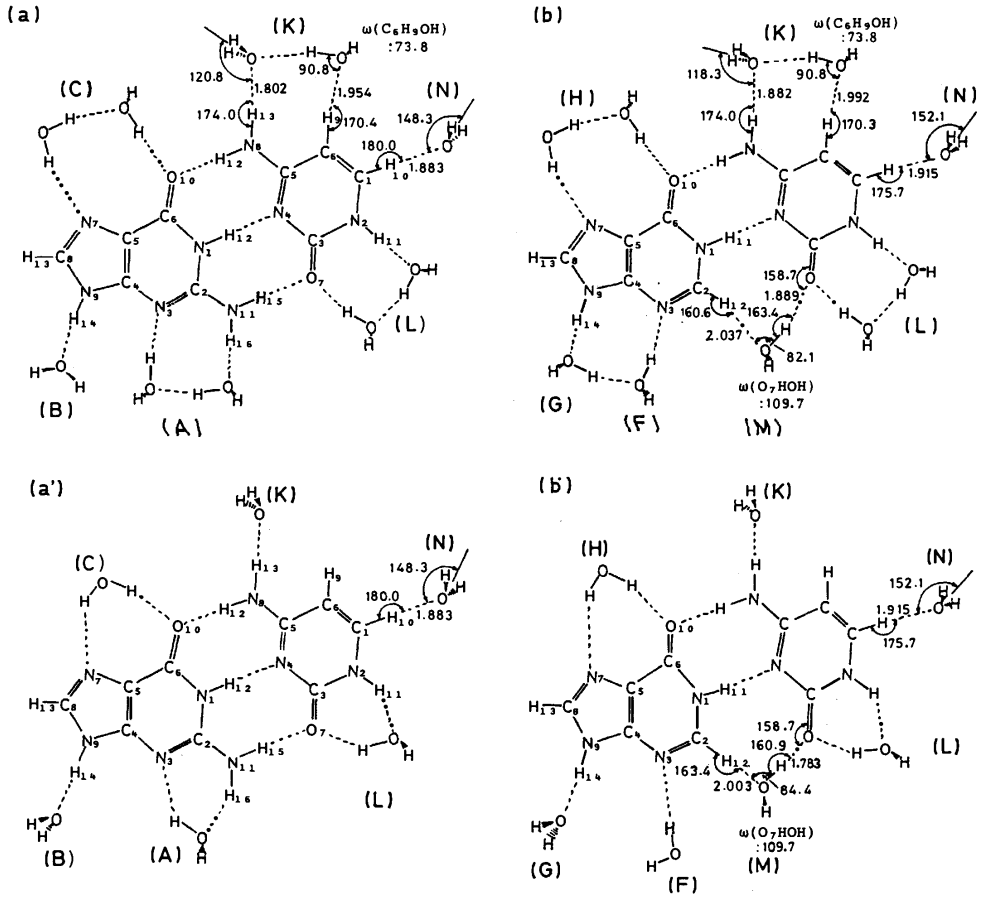

Fig. 6. The hydration schemes and optimized geometric parameters between base pair and water molecule of (a) and (a′) Gua-Cyt and (b) and (b′) Hyp-Cyt pairs. Units are angstroms and degrees.

of internal hydrogen bonds. Therefore, these hydrogen atoms come to have unusual, positive net charges. This result expects an unusual C-$H^{\delta+}$···O hydrogen-bond formation with H_2O at H_{12} of Hyp in the Hyp-Cyt pair. Also, there is a possibility of a similar type hydrogen bonding between H_2O and C_6-H_9 or C_1-H_{10} of Cyt in both Gua-Cyt and Hyp-Cyt pairs.

In order to investigate this type of interesting C-$H^{\delta+}$···O hydrogen bonding, we carried out ab initio MO calculations, while assuming various possible hydration schemes (Figs. 6a, b, a′, and b′). The optimized geometrical parameters are shown in these figures. Our result shows that C-$H^{\delta+}$···O hydrogen bonds are possible in both Gua-Cyt and Hyp-Cyt pairs.

Goldblum et al. investigated the hydration scheme of the Gua-Cyt pair using an overlap multipole procedure.[11] However, their scheme is somewhat different from ours. On the other hand, the hydration scheme of the Gua-Cyt pair shown in Fig. 6a is rather similar to that of Clementi and Corongiu studied by Monte Carlo simulations.[19]

In order to estimate the effect of hydration on the internal hydrogen bonds of complementary base pairs, Gua-Cyt and Hyp-Cyt pairs with various degrees of hydration were calculated. The calculated results are summarized in Table 4. For the Gua-Cyt pair, the internal hydrogen bonds are stabilized by hydration at regions (C), (K), and (N), but destabilized by that at regions (A), (B), and (L) in both hydration schemes (Figs. 6a and 6a′). Especially, H_2O molecules which arehydrated to an amino group (region (A)) brought about a significant destabilization of internal hydrogen bonds of the Gua-Cyt pair. It is of interest to note that the same result was also found in the hydration to the amino group of the adenine-uracil pair.[20] On the other hand, for the Hyp-Cyt pair, hydration at regions (H), (K), (N), and (M) causes a stabilization of the internal hydrogen bonds, while that at region (L) brings about destabilization in both hydration schemes (Figs. 6b and 6b′).

When all of the possible donating and accepting sites are hydrated, the Hyp-Cyt pair is considerably stabilized, while the Gua-Cyt pair is slightly destabilized (see Table 4). This result can be explained as follows: The charge-transfer interaction at the internal hydrogen bonds of the Gua-Cyt pair is weakened, while that of the Hyp-Cyt pair is strengthened, due to a change in the HOMO and LUMO energies by hydration. Both the Gua-Cyt and Hyp-Cyt pairs are stabilized by C-$H^{\delta+}$···O hydrogen-bond formation.

The experimental results show that the enthalpy changes due to complementary base-pair formation in aqueous solution were rather small compared with those in $CHCl_3$ or the gas phase. As mentioned in the previous section, this is due to destabilization by the dehydration of hydrated bases in the process of complementary base-pair formation.

In order to explain the experimental results quantitatively, the energy differences between the hydrated bases and base pairs were evaluated by the following energy cycles. For the first type of hydration scheme

Table 4. The Calculated Hydrogen-Bonding Energies between Hydrated Gua and Cyt, and between Hydrated Hyp and Cyt for Various Hydration

Gua-Cyt pair			Hyp-Cyt pair		
Region[a]	E_{HB} / kJ mol^{-1}	ΔE_{HB}[b] / kJ mol^{-1}	Region[a]	E_{HB} / kJ mol^{-1}	ΔE_{HB}[c] / kJ mol^{-1}
Nonhydrated	−111.3		Nonhydrated	−82.4	
(Hydration schemes shown in Figs. 6a and b)

a) Refer to Fig. 6. b) $\Delta E_{HB}=E_{HB}-(-111.3)$. c) $\Delta E_{HB}=E_{HB}-(-82.4)$. d) The values contain the C-$H^{\delta+}$···O hydrogen-bonding energies.

of the Gua-Cyt system (Fig. 6a), the energy cycle (Cycle 1) can be expressed as follows:

$$\begin{array}{ccc} (\text{Gua} + 8\text{H}_2\text{O}) & \xrightarrow[\Delta E_1]{} & (\text{Gua-8H}_2\text{O}) \\ + & & + \\ (\text{Cyt} + 6\text{H}_2\text{O}) & \xrightarrow[\Delta E_2]{} & (\text{Cyt-6H}_2\text{O}) \\ \downarrow \Delta E_5 & & \downarrow \Delta E_3 \\ (\text{Gua-Cyt} + 14\text{H}_2\text{O}) & \xrightarrow[\Delta E_4]{} & (5\text{H}_2\text{O-Gua-Cyt-5H}_2\text{O}) + 2(\text{H}_2\text{O})_2 \end{array}$$

For the second type hydration scheme (Fig. 6a'), it (Cycle II) can be expressed as follows:

$$\begin{array}{ccc} (\text{Gua} + 5\text{H}_2\text{O}) & \xrightarrow[\Delta E_1]{} & (\text{Gua-5H}_2\text{O}) \\ + & & + \\ (\text{Cyt} + 4\text{H}_2\text{O}) & \xrightarrow[\Delta E_2]{} & (\text{Cyt-4H}_2\text{O}) \\ \downarrow \Delta E_5 & & \downarrow \Delta E_3 \\ (\text{Gua-Cyt} + 9\text{H}_2\text{O}) & \xrightarrow[\Delta E_4]{} & (3\text{H}_2\text{O-Gua-Cyt-3H}_2\text{O}) + \frac{3}{2}(\text{H}_2\text{O})_2 \end{array}$$

Similarly, for the first type hydration scheme of the Hyp-Cyt system (Fig. 6b), it (Cycle III) is represented as follows:

$$\begin{array}{ccc} (\text{Hyp} + 6\text{H}_2\text{O}) & \xrightarrow[\Delta E_1]{} & (\text{Hyp-6H}_2\text{O}) \\ + & & + \\ (\text{Cyt} + 6\text{H}_2\text{O}) & \xrightarrow[\Delta E_2]{} & (\text{Cyt-6H}_2\text{O}) \\ \downarrow \Delta E_5 & & \downarrow \Delta E_3 \\ (\text{Hyp-Cyt} + 12\text{H}_2\text{O}) & \xrightarrow[\Delta E_4]{} & (4\text{H}_2\text{O-Hyp-Cyt-5H}_2\text{O}) + (\text{H}_2\text{O})_2 \\ & & \quad \diagdown \text{H}_2\text{O} \diagup \end{array}$$

For the second type of hydration scheme (Fig. 6b'), it (Cycle IV) is given by

$$\begin{array}{ccc} (\text{Hyp} + 4\text{H}_2\text{O}) & \xrightarrow[\Delta E_1]{} & (\text{Hyp-4H}_2\text{O}) \\ + & & + \\ (\text{Cyt} + 4\text{H}_2\text{O}) & \xrightarrow[\Delta E_2]{} & (\text{Cyt-4H}_2\text{O}) \\ \downarrow \Delta E_5 & & \downarrow \Delta E_3 \\ (\text{Hyp-Cyt} + 8\text{H}_2\text{O}) & \xrightarrow[\Delta E_4]{} & (3\text{H}_2\text{O-Hyp-Cyt-3H}_2\text{O}) + \frac{1}{2}(\text{H}_2\text{O})_2 \\ & & \quad \diagdown \text{H}_2\text{O} \diagup \end{array}$$

where, it was assumed that the removed H_2O molecules formed the dimer. The dimerization energy was calculated to be -21.3 kJ mol^{-1}.

The calculated values are summarized follows:

Cycle I: $\Delta E_1 = -373.8$ kJ mol^{-1}
$\Delta E_2 = -287.4$ kJ mol^{-1}
$\Delta E_4 = -445.2$ kJ mol^{-1}
$\Delta E_5 = -111.3$ kJ mol^{-1}

Table 5. The Calculated Energy Differences by Hydrogen-Bond Formation between Hydrated Gua and Cyt and between Hydrated Hyp and Cyt, and the Experimental Enthalpy Changes in Aqueous Solution

	ΔE_3[a]	ΔE_3[b]	$\Delta H°$[c]
	kJ mol^{-1}	kJ mol^{-1}	kJ mol^{-1}
Gua-Cyt pair	+104.7(Cycle I)	−11.9(Cycle II)	−10
Hyp-Cyt pair	+97.5(Cycle III)	−18.5(Cycle IV)	−14

a) The first type of hydration schemes. b) The second type of hydration schemes. c) Data from calorimetric experiment (see Table 3).

Cycle II: $\Delta E_1 = -191.1$ kJ mol^{-1}
$\Delta E_2 = -144.4$ kJ mol^{-1}
$\Delta E_4 = -236.1$ kJ mol^{-1}
$\Delta E_5 = -111.3$ kJ mol^{-1}

Cycle III: $\Delta E_1 = -305.9$ kJ mol^{-1}
$\Delta E_2 = -287.4$ kJ mol^{-1}
$\Delta E_4 = -413.4$ kJ mol^{-1}
$\Delta E_5 = -82.4$ kJ mol^{-1}

Cycle IV: $\Delta E_1 = -138.7$ kJ mol^{-1}
$\Delta E_2 = -144.4$ kJ mol^{-1}
$\Delta E_4 = -219.2$ kJ mol^{-1}
$\Delta E_5 = -82.4$ kJ mol^{-1}

ΔE_5 is equal to E_{HB} (the internal hydrogen-bonding energy of complementary base pair in vacuo). The values are given in Table 1. Comparing the hydration energy of Gua with that of Hyp in both Cycles (ΔE_1), we can see that the hydrated Gua is more stable than the hydrated Hyp. This is due to the existance of an amino group at which stable hydration occurs.

ΔE_3 is the energy difference, which may correspond to the mixing process in the calorimetric experiment. It can be estimated by using the energies in the energy cycles mentioned above. The obtained results are summarized in Table 5, together with the $\Delta H°$-values determined from calorimetric experiments. The magnitudes of the calculated energy differences (ΔE_3), based on Cycles II and IV, are in good agreement with the experimental enthalpy change, while those based on Cycles I and III disagree with the experiment. It is of interest to note that the order of the ΔE_3-values of hydrated Gua-Cyt and Hyp-Cyt pairs in both energy cycles agrees with that of the experimental $\Delta H°$-values.

Conclusions

Stabilization due to the formation of hydrogen bonds between Gua and Cyt and between Hyp and Cyt in vacuo and in aqueous solution was investigated by means of ab initio MO calculations and solution calorimetry.

The calculated hydrogen-bonding energies in vacuo were -111.3 kJ mol^{-1} for the Gua-Cyt pair and -82.4 kJ mol^{-1} for Hyp-Cyt, respectively. Thus, the Gua-Cyt pair was more stable than the Hyp-Cyt pair in vacuo. The main contributions to the internal hydrogen bonds of Gua-Cyt and Hyp-Cyt pairs were both electrostatic and charge-transfer interactions. For the Gua-Cyt pair, the charge transfer from Cyt to Gua through the hydrogen bonds was larger than that from Gua to Cyt. Since the dipole moment of the Gua-Cyt pair was larger than that of Hyp-Cyt, the Gua-Cyt pair was expected to be more stable than the Hyp-Cyt pair in a polar solvent because of the stabilization due to the dipole-dipole interaction between solute and solvent. This expectation agreed with the experiments concerning $CHCl_3$ solutions. However, the calorimetric measurement showed that in aqueous solution, the Hyp-Cyt pair was more stable than Gua-Cyt. That is, the enthalpy changes of the association of Gua with Cyt and of Hyp with Cyt in aqueous solution were estimated to be -10 kJ mol^{-1} for the Gua-Cyt system and -14 kJ mol^{-1} for the Hyp-Cyt system by using a solution microcalorimeter.

In order to explain this result, we carried out ab initio MO calculations of hydrated bases and base pairs, by assuming two types of hydration schemes. Using the energy cycles, we estimated the energies corresponding to the experimental heats of mixing (ΔE_3). The calculated ΔE_3's based on the second type hydration scheme agreed with the experiments. Thus, the expermental results for aqueous solutions could be explained by dehydration in the course of complementary base-pair formation.

From the calculated results, it was shown that there was a possibility of C-H$^{\delta+}$···O hydrogen-bond formation between a H_2O molecule and a base pair. Furthermore, it was indicated that a H_2O molecule bound to an amino group of Gua destabilized the internal hydrogen bonds of complementary base pairs, however, that to the amino group of Cyt stabilized the internal hydrogen bonds.

In conclusion, the present work showed that hydration/dehydration had an important effect on the stability of the complementary base pair.

We are grateful to the Computer Center of the Institute for Molecular Science for the use of HITAC M-680H and S-820/80 computers. This work was partly supported by the Grant-in-Aid for Scientific Research (No. 62470013) from the Ministry of Education, Science and Culture.

(Received November 19, 1988)

The relationship between the chemical structure and the cyclic adenosine monophosphate phosphodiesterase inhibitory activity was studied regarding forty-eight flavones, thirty-five flavanones, and six isoflavones by using the ^{13}C NMR chemical shift averaged over all aromatic carbons in a compound. The average value of potent ^{13}C chemical shifts over the aromatic carbons active flavonoids (IC_{50} 0.6—20.0 $\times 10^{-5}$ M/L) are within the range from δ 133.5 to δ 135.7, but those of the inactive flavonoids and the weak active flavonoids are not within this range. This means that the averaged ^{13}C chemical shift becomes an "index" for testing the inhibitory activity. Further, the above relationship was proposed as a means for conveniently determining the inhibitory activity.

3′,5′-Cyclic adenosine monophosphate (cAMP) phosphodiesterase (PDE) inhibition can be used as a screening agent to detect physiologically active compounds.[1] It is known that there is a close relationship between the inhibition of PDE in vitro among 158 therapeutic agents tested for PDE inhibition and the physiological activity in vivo.[2-6] Moreover, many flavonoids have been identified as having a potent inhibitory activity on cAMP PDE.[7-10] These results indicate that the PDE inhibitors might have a variety of physiological activities. However, it takes a long time to determine such physiological activities using the conventional method. Thus, it has been important to develop a simple method.

We studied the relationship between the inhibitory activity on cAMP PDE of flavonoids and the averaged ^{13}C NMR chemical shifts (δ_{av}) for all carbons in the ring structures of these compounds. We also clarified whether or not the averaged ^{13}C NMR chemical shift is useful for studying the cAMP PDE inhibitory activity and using its relationship as a simple method for determining physiological activities. The averaged ^{13}C NMR chemical shifts employed in this work reflect the electronic structure and electronic states of the molecules[11,12] which may govern the mechanism of the inhibitory activity. As shown in the theory of ^{13}C shielding in aromatic hydrocarbons,[13] the chemical shift δ of each carbon can be expressed as $\delta \propto 1/\Delta E \cdot Q$, where ΔE is the averaged excitation energy, and Q is a function of the electron density and bond order of a molecule.

The averaged excitation energy is assumed to be a constant for the aromatic compounds considered here.[11]

Thus, we expect that the averaged ^{13}C NMR chemical shift is a measure of the inhibitory activity.

Experimental

Authentic samples were used in the tests for the evaluation of the inhibitory activity on cAMP phosphodiesterase which had been isolated or prepared during structural studies.[1,8,14] (Tables 1, 2, and 3), (Fig. 1 (a), (b), and (c)). Cyclic AMP PDE inhibitory activity was assayed by the method described in a previous paper.[14]

The ^{13}C NMR spectra were recorded with Fourier transform spectrometers (JEOL JNM FX-90 Q, JEOL JNM GX-270 and JEOL JNM GX-400) operating at 22.5, 67.5, and 100.4 MHz, respectively, at room temperature. Dimethyl-d_6 sulfoxide was used as a solvent. The concentration of the samples was 2—10% (w/v). The chemical shifts were expressed in ppm relative to tetramethylsilane (TMS).

Results and Discussion

The averaged ^{13}C NMR chemical shifts (δ_{av}) over all the ring carbons of flavonoids and 50% inhibitory concentrations (IC_{50})cAMP PDE inhibitory activities of these samples are shown in Tables 1, 2, and 3. The compounds listed in these tables can be divided into three groups: potent inhibitory groups (IC_{50}=0.6—20.0$\times 10^{-5}$ M/L and δ_{av}=133.5—135.7), weak inhibitory groups (IC_{50}=20.1—35.3$\times 10^{-5}$M/L and $\delta_{av} \leqq$ 133.5), and inactive groups ($IC_{50} \geqq 35.3 \times 10^{-5}$ M/L$\geqq$135.7). The relationship between the δ_{av} of the individual compound and the IC_{50} value in the cAMP PDE inhibition is shown in Fig. 2. As can be seen from this figure, it is found that there is a correlation between IC_{50} and δ_{av} in the range from 133.5 to 135.7 . This means that δ_{av} can be used to discern whether the

compounds being considered are potent inhibitors or not. Thirty flavones compounds **1**, **3**, **4**, **6**, **7**, **8**, **10**, **12**, **13**, **19**, **20**, **22**, **23**, **28**, **29**, **30**, **31**, **33**, **34**, **35**, **36**, **37**, **38**, **39**, **40**, **42**, **45**, **46**, **47**, and **48** have potent cAMP PDE inhibitory activity,[8] and their averaged chemical shifts are within the range δ 133.5 to 135.7. The δ_{av} values for the remaining eleven compounds **2**, **14**, **15**, **16**, **17**, **18**, **24**, **25**, **26**, **27**, and **44** are smaller than 133.5, while those for compounds **32** and **41** are larger than 135.7. The thirteen compounds, except for **32**

a) The δ_{av} of the individual compounds having no prenyl groups. b) The δ_{av} of the individual compounds having prenyl groups or having no prenyl groups and isoflavones.

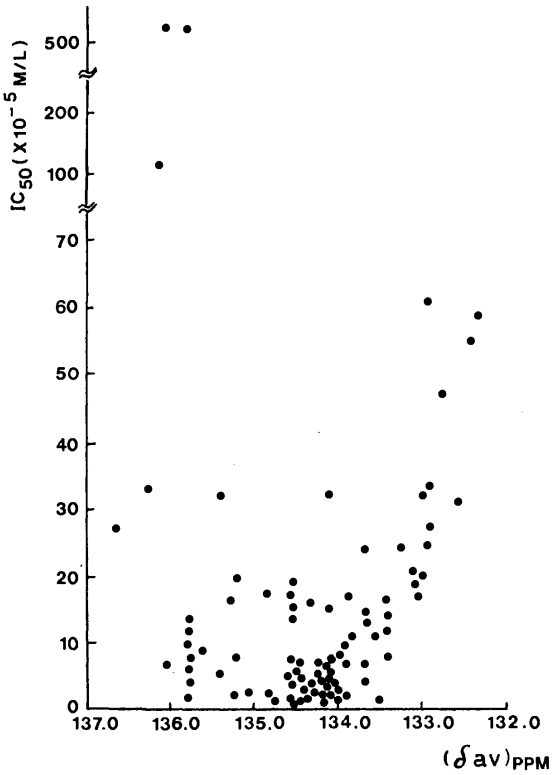

Fig. 2. The relationship between the averaged ^{13}C NMR chemical shifts (δ_{av}) of flavones and their cAMP PDE inhibitory activity IC_{50}.

and **41**, have a large IC_{50} value (>20.1) and, thus, inactive property. The δ_{av} value of **43** is slightly lower than 133.5, suggesting that this compound has a strong cAMP PDE inhibitory activity.

The values of δ_{av} for **5**, **11**, and **21** are within the range 133.5—135.7; thus, these compounds can be expected to be in the potent inhibitory group. However, the values of IC_{50} for **5**, **11**, and **21** are not contained in the potent inhibitory group. This means that it is not easy to exactly determine the borderline region.

Next, we consider the effect of the substituent group of the compounds on the relationship between the cAMP PDE inhibitory activity and δ_{av}. When the hydroxyl group or methoxyl group is substituted at the C-5, 7 or 4′-positions on an aromatic ring of compounds **14**, **15**, and **16**, their cAMP PDE inhibitory activity is detected slightly or not and the values of δ_{av} are smaller than 133.5. When the methoxyl group is substituted at the C-6 position on an aromatic ring in compounds **4**, **19**, **20**, **23**, **34**, and **35**, the increase in cAMP PDE inhibitory activity can be recognized[8] and the δ_{av} values are within the range 133.5—135.7. When the hydroxyl group, methoxyl group or *o*-glucosyl group is substituted at the C-5, 7, 3′ or 4′-positions on an aromatic ring of compounds **24**, **25**, **26**, and **27**, the cAMP PDE inhibitory activity is detected slightly or not and the values of δ_{av} are smaller than 133.5. However, when the methoxyl group or *o*-rhamnosyl group is substituted at the C-3 position on the aromatic ring of compounds **45** and **46**, the increase in cAMP PDE inhibitory activity can be recognized and the δ_{av} values are within the range 133.5—135.7. Eleven flavanones compounds **51**, **56**, **57**, **58**, **59**, **73**, **74**, **75**, **79**, **82**, and **83** have potent cAMP PDE inhibitory activity.[9] However, as can be seen from Table 2, the δ_{av} value of compounds having no prenyl, geranyl and lavandulyl group **51**, **56**, **57**, **58**, **59**, **79**, and **80**, are within the range 135.9—136.5, beyond the range 133.5—135.7.

On the other hand, in the case of having a prenyl group, it has been found that the value of δ_{av} for compounds **49**, **50**, **54**, **76**, **77**, **78**, and **81** are within the range 133.5—135.7, having a prenyl group.

It is considered that the prenyl group is a factor for having the cAMP PDE inhibitory activity, from the result of using the averaged value of the ^{13}C NMR chemical shift.

Flavanones derivatives[9] having no prenyl groups **52**, **53**, **60**, **62**, **63**, **64**, **65**, **66**, **69**, **70**, **71**, and **72** have a potent cAMP PDE inhibitory activity, and the δ_{av} values are within the range 133.5 to 135.7, as well as flavones. Compounds **55**, **61**, and **67** can be expected to be inactive groups or weak inhibitory group; the values of δ_{av} are larger than 135.7. Similary, concerning isoflavone derivatives, compounds **86**, **87**, **88**, and **89** showed potent cAMP PDE inhibitory activity.

The δ_{av} values of compounds **84** and **85** are smaller than 133.5. Therefore, these can be expected to be a weak inhibitory group or an inactive group.

Finally, we conclude the following. The cAMP PDE inhibitory activity for flavonoids can be examined from the averaged ^{13}C NMR chemical shift over all ring carbons. Further, it can be suggested that it is very useful to use this approach for drug design.

^{15}N nuclear magnetic resonance spectra were measured for $[CoX(^{15}NH_3]^{n+}$ ($X=CN^-$, $^{15}NH_3$, H_2O, and Br^-) and *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$ ($X_2=(CN^-)_2$, $(NO_2^-)_2$, en-^{15}N,^{15}N, ox^{2-}, and $(H_2O)_2$; en-^{15}N,^{15}N and ox^{2-} represent the ^{15}N-enriched ethylenediamine and oxalate ion, respectively). Two sharp signals of ^{15}N NMR were observed for $[CoX(^{15}NH_3)_5]^{n+}$ except for the cases of $X=^{15}NH_3$ and NO_2^-. The signals of ^{15}N NMR in *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$, were assigned on the basis of the selectively proton irradiated spectra at frequencies which had been already assigned to each amino proton. The chemical shifts of ^{15}N NMR are correlated to the Co-N bond strength; it is expected that the stronger is the Co-N bond, the greater is the shift of the ^{15}N NMR signal to a higher field. When we express $[CoX(^{15}NH_3)_5]^{n+}$ and *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$ as $[CoXN_5]^{n+}$ and *cis*-$[CoX_2N_4]^{n+}$, the effect on the ^{15}N NMR chemical shifts by the substituent X is roughly additive.

One of the authors (Y.N.) has been able to semi-quantitatively explain the behaviors of the ^1H NMR chemical shifts in $[CoX(NH_3)_5]^{n+}$ by assuming that the induced ^1H NMR chemical shifts by changing X are mainly due to a change in the magnetic anisotropy of the Co(III) ion.[2-4] However, there were some descrepancies between the calculated and observed values. They were significantly large for the protons of NH_3 trans to X in complexes with $X=CN^-$ and NO_2^-. The chemical shift of the observed signals to higher fields than the calculated ones might be caused by increased electron densities on the trans ammine protons induced by the large inductive effects of X. The H-D exchange rates of the ammine protons were related to their acidity.[5] The trans ammine protons exchange more slowly than the cis ones with $X=CN^-$ and NO_2^-.[5] On the other hand, though the trans ammine protons exchange faster than the cis ones with $X=H_2O$, Cl^-, and Br^-, there has been no evidence of decreased electron densities of the trans ammine protons in the ^1H NMR chemical shifts.[4] ^1H NMR chemical shifts of ammine protons are easily affected by the solvent; in contrast, though, it has been reported that the chemical shifts of the NMR signals of ^{15}N directly bound to cobalt(III) are hardly affected by the solvent.[6] It is, therefore, expected that information concerning the Co-N bond strength and the acidity of ammine protons can be obtained from ^{15}N NMR chemical shifts with no solvent effect.

Lehman and Fung measured the ^{15}N NMR for $[CoX(^{15}NH_3)_5]^{n+}$ by the use of the INDOR technique, and then erroneously assigned the ^1H NMR chemical shift signals.[7] Thus, we doubted the shift directions of the ^{15}N NMR signals since their assignments of the ^{15}N NMR signals depended upon those of the proton signals.[7] The ^{14}N NMR signals of the same samples were also measured by Herbison-Evans and Richards.[8] The signals of $[Co(H_2O)(NH_3)_5]^{3+}$ and $[CoCl(NH_3)_5]^{2+}$ were single and the shift values were lower than that of $[Co(NH_3)_6]^{3+}$. It was one aim of the present work to determine the correct ^{15}N shift values of $[CoX(^{15}NH_3)_5]^{n+}$ relative to that of $[Co(^{15}NH_3)_6]^{3+}$ by directly observing the ^{15}N NMR signals. Furthermore, it would be interesting to find out whether the effect of substituent X_2 on the chemical shifts of ^{15}N NMR signals in *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$ is additive or not.

Experimental

Materials. The $[CoX(^{15}NH_3)_5](NO_3^-)_n$ ($X=NO_2^-$, $^{15}NH_3$, H_2O, and Br^-) and the *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$ ($X_2=(CN^-)_2$, $(NO_2^-)_2$, en-^{15}N,^{15}N, ox^{2-}, and $(H_2O)_2$) were synthesized according to the well-established methods.[9] The $[Co(CN)(NH_3)_5](ClO_4)_2$ containing $^{15}NH_3$ was synthesized by the method of Sibert.[10] The en-^{15}N,$^{15}N\cdot 2HCl$ and $^{15}NH_3$ were obtained from British Oxygen Co., Ltd., and their ^{15}N contents were 98 and 99.5%, respectively. Ligands diluted 30 to 40% of ^{15}N were used in all preparations of the complexes.

Equipments and Measurements. About 200 mg of each complex was dissolved in 1.5 ml of DMSO-d_6 in a 10-mmϕ tube and 1000—10000 transients were accumulated for $[CoX(^{15}NH_3)_5]^{n+}$. About 100 mg was dissolved in 1.5 ml of a DCl-D_2O solution (pD=2) in a 10-mmϕ tube and 1000—10000 transients were accumulated for *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$. *cis*-$[Co(H_2O)_2(en\text{-}^{15}N,^{15}N)_2]^{3+}$ was dissolved in CF_3COOD. ^{15}N NMR spectra were recorded on a JEOL PFT-100 pulsed Fourier transform NMR spectrometer operated at 10.1 MHz. Only that of $[Co(en\text{-}^{15}N,^{15}N)_3]^{3+}$ (Fig. 2) was measured for a 0.1 M aqueous solution (1M=1 mol dm^{-3}) on a JEOL JNM-FX60 spectrometer at 6.06 MHz (204000 repetitions). $Na^{15}NO_2$ or $Na^{15}NO_3$ was used as an external reference of ^{15}N NMR signals.

Results

Hexaammine- and Pentaamminecobalt(III) Complexes. The ^{15}N resonance spectra of $[CoX(^{15}NH_3)_5]^{n+}$ (X=CN^-, NO_2^-, $^{15}NH_3$, H_2O, and Br^-) are shown in Fig. 1. The ^{59}Co resonance spectra have already been measured for several Co(III) complexes.[11] By comparing ^{15}N and ^{59}Co NMR spectra, it was found that the broader is the line of the ^{59}Co NMR signal, the sharper is the line of ^{15}N NMR signal of $^{15}NH_3$ group directly bound to Co(III) ion. The ^{15}N NMR signal of $[Co(^{15}NH_3)_6]^{3+}$ is broad and complicated. This is due to coupling between the ^{15}N and ^{59}Co nuclei, resulting in the slow quadrupolar relaxation rate of the nuclear magnetic moment of ^{59}Co under high symmetry around the ^{59}Co nucleous.[12] In $[CoX(^{15}NH_3)_5]^{n+}$ the resonance signal of ^{15}N trans to X was distinguished from that of the cis on the basis of their intensities. The chemical shift values are given in Table 1. We erroneously reported the shift value of $[Co(^{15}NH_3)_6]^{3+}$ in a previous report,[1] taking the signal position of the impurity. In the present study, the central position of the broad signal was adopted as the correct shift value.[12] It can be seen from Table 1 that the ^{15}N NMR signal of the trans $^{15}NH_3$ of $[CoX(^{15}NH_3)_5]^{n+}$ appears at a higher field from that of $[Co(^{15}NH_3)_6]^{3+}$ and the cis one at a lower field with X=H_2O, Cl^-, and Br^-. In contrast, the trans $^{15}NH_3$ with X=CN^- gives an ^{15}N signal at a lower field and a cis one at a higher field. The ^{15}N NMR signals of $[Co(NO_2)(^{15}NH_3)_5]^{2+}$ were broad and not clearly separated.

Table 1. ^{15}N NMR Shift Values in $[CoX(^{15}NH_3)_5]^{n+}$ Relative to That of $[Co(^{15}NH_3)_6]^{3+}$

X	Trans	Cis
CN^-	−23.9	1.7
NO_2^- [b]	−11	−16
NH_3	0.0[a]	0.0[a]
H_2O	20.7	−5.5
Cl^- [c]	8.6	−6.2
Br^-	2.8	−3.0

a) The shift value (418.2 ppm) of $[Co(^{15}NH_3)_6]^{3+}$ as a standard of $^{15}NO_3^-$ was calculated from that as a standard of $^{15}NO_2^-$. b) The ^{15}N resonance signals of $[Co(NO_2)(^{15}NH_3)_5]^{2+}$ were not as sharp as that of the other $[CoX(^{15}NH_3)_5]^{n+}$ complexes as shown in Fig. 1. Therefore, the appropriate shift positions were given, which differ to some extent from those in Part I.[1] c) The values are from Ref. 7. The chemical shift values were recalculated considering the difference of 6.5 ppm between the present and the literature values of $[Co(^{15}NH_3)_6]^{3+}$.

Table 2. ^{15}N NMR Shift Values in *cis*-$[CoX_2(en\text{-}^{15}N, ^{15}N)_2]^{n+}$ Relative to That of $[Co(en\text{-}^{15}N,^{15}N)_3]^{3+}$

X_2	Trans	Cis
$(CN^-)_2$	−16.6	4.0
$(NO_2^-)_2$	−2.8	−2.8
en	0.0[a]	0.0[a]
ox^{2-}	8.1	−8.9
$(H_2O)_2$	9.4	−8.0

a) The shift value (392.0 ppm) of $[Co(en\text{-}^{15}N,^{15}N)_3]^{3+}$ was calculated from that as a standard of $^{15}NO_2^-$.

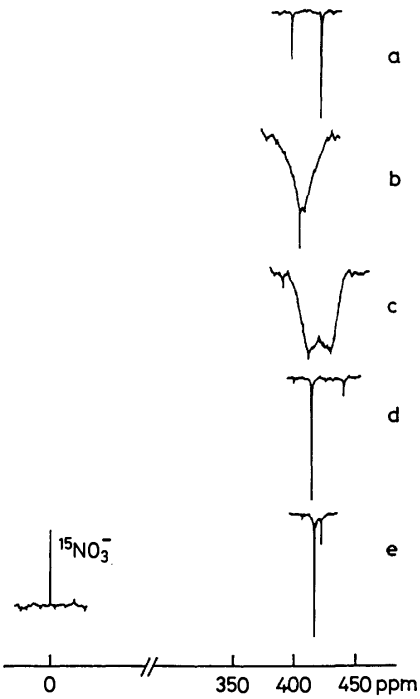

Fig. 1. ^{15}N NMR spectra of (a) $[Co(CN)(^{15}NH_3)_5]^{2+}$, (b) $[Co(NO_2)(^{15}NH_3)_5]^{2+}$, (c) $[Co(^{15}NH_3)_6]^{3+}$, (d) $[Co(H_2O)(^{15}NH_3)_5]^{3+}$, and (e) $[CoBr(^{15}NH_3)_5]^{2+}$.

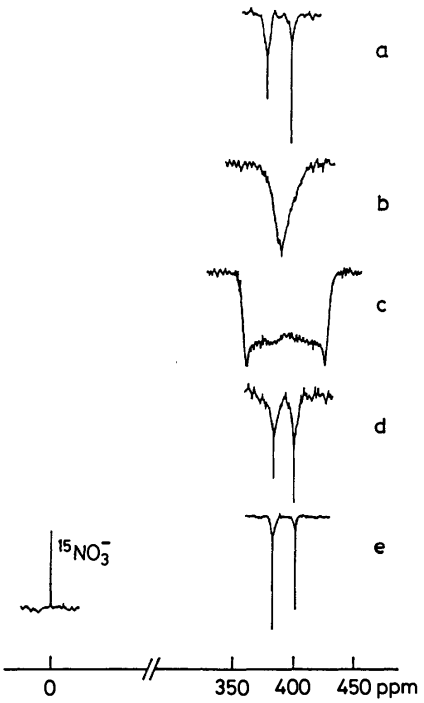

Fig. 2. ^{15}N NMR spectra of (a) *cis*-$[Co(CN)_2(en\text{-}^{15}N, ^{15}N)_2]^+$, (b) *cis*-$[Co(NO_2)_2(en\text{-}^{15}N,^{15}N)_2]^+$, (c) $[Co(en\text{-}^{15}N,^{15}N)_3]^{3+}$, (d) $[Co(ox)(en\text{-}^{15}N,^{15}N)_2]^+$, and (e) *cis*-$[Co(H_2O)_2(en\text{-}^{15}N,^{15}N)_2]^{3+}$.

Tris- and *cis*-Bis(ethylenediamine)cobalt(III) Complexes. The ^{15}N NMR spectra of the *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$ ($X_2=(CN^-)_2$, $(NO_2^-)_2$, en-^{15}N,^{15}N, ox^{2-}, and $(H_2O)_2$) are shown in Fig. 2. The observed shift values are given in Table 2. The ^{15}N NMR signal of $[Co(en\text{-}^{15}N,^{15}N)_3]^{3+}$ was very broad for the same reason as that of $[Co(^{15}NH_3)_6]^{3+}$.[12] The central position of the signal was adopted as its chemical shift value. Each of the two ^{15}N NMR signals of $[Co(ox)(en\text{-}^{15}N,^{15}N)_2]^+$ could be assigned on the basis of the spectra selectively irradiated at the resonance frequency of amino protons,[5,13] as shown in Fig. 3. The intensity of the ^{15}N NMR signal in a lower field was more strongly enhanced when the amino proton signal at −5.1 ppm (-NH_2 cis to X) was irradiated, as shown in Fig. 3c. Thus, the ^{15}N NMR signal in the lower field corresponds to that of the amino group cis to O^- in $X_2=ox^{2-}$. Accordingly, the ^{15}N NMR signal in the higher field should correspond to that of the amino group trans to O^-; this was ascertained from selective irradiation, as shown in Fig. 3d. In contrast, the selectively proton-decoupled ^{15}N NMR spectra of *cis*-$[Co(CN)_2(en\text{-}^{15}N,^{15}N)_2]^+$ revealed that the lower-field signal corresponds to that of the amino group trans to CN^-, and the higher-field signal to the cis one. These findings were also confirmed regarding the proton spectra selectively irradiated at ^{15}N NMR signal frequencies, based on the fact that the ^{1}H NMR signal in a higher field was that of the amino group cis to CN^- in $X_2=(CN^-)_2$.[5,13-15] The ^{15}N NMR signal for *cis*-$[Co(NO_2)_2(en\text{-}^{15}N,^{15}N)_2]^+$ was not clearly separated, being broader than that in $[Co(NO_2)(^{15}NH_3)_5]^{2+}$, as shown in Fig. 2b.

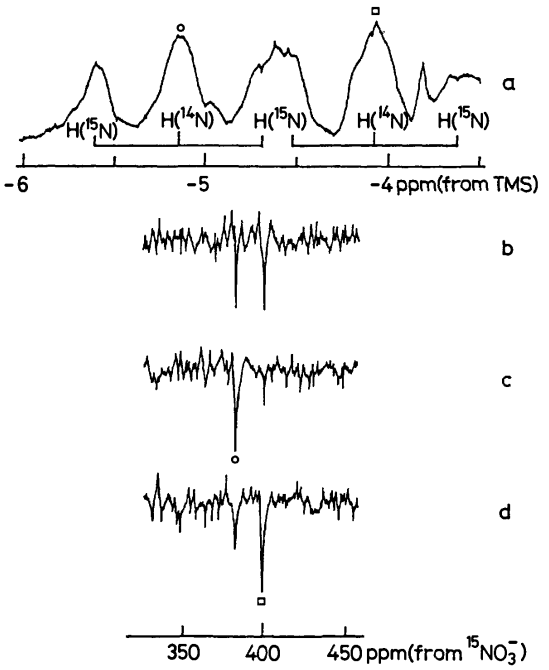

Fig. 3. (a) ^{1}H NMR spectrum of the amino group in $[Co(ox)(en\text{-}^{15}N,^{15}N)_2]^+$ at 99.5 MHz, (b) Proton noise decoupled ^{15}N NMR spectrum at 10.1 MHz, (c) ^{15}N NMR spectrum selectively irradiated at the frequency of the amino proton cis to O^- (at −5.1 ppm), (d) ^{15}N NMR spectrum selectively irradiated at the frequency of the amino proton trans to O^- (at −4.2 ppm).

Discussion

Generally, the magnetic shielding constant consists of three terms, as follows:

$$\sigma=\sigma_D+\sigma_P+\sigma_L, \quad (1)$$

where σ_D and σ_P are diamagnetic and paramagnetic terms, respectively, due to the electron of the observed atom; σ_L is the long-range magnetic term due to the other atoms in the molecule.[16] Solvent effects are not considered in this equation.

Hexaammine- and Pentaamminecobalt(III) Complexes. In the present case, the chemical shift induced by the magnetic anisotropy of the Co(III) ion may be the dominant part in σ_L. As shown in Eqs. 7 and 8 of Ref. 4, the ^{15}N NMR chemical shift induced by the Co(III) ion of $^{15}NH_3$ in $[CoX(^{15}NH_3)_5]^{n+}$ can be expressed relative to that of $[Co(^{15}NH_3)_6]^{3+}$, as follows:

$$\sigma_L=[\sigma(NH_3)-\sigma(X)]/3R^3\langle r^{-3}\rangle \text{ for trans } (\theta=0)$$

and

$$\sigma_L=-[\sigma(NH_3)-\sigma(X)]/6R^3\langle r^{-3}\rangle \text{ for cis } (\theta'=0),$$

where parameters $\sigma(NH_3)$ and $\sigma(X)$ are the paramagnetic shielding constants of ^{59}Co contributed by ligands NH_3 and X, respectively.[3,4] The relevant quantities used in the present study, except for R (adopted 2 Å as Co-N bond length[17]), have already been presented in Refs. 3 and 4. Subtracting the calculated σ_L from the observed σ, $\sigma_D+\sigma_P$ are obtained from Eq. 1. These values are given in Table 3. The contributions of σ_L are less than about 2 ppm and $\sigma_D+\sigma_P$ plays a main role in the ^{15}N NMR chemical shifts for $[CoX(^{15}NH_3)_5]^{n+}$, whereas σ_L does the same in the ^{1}H NMR chemical shifts. The ^{14}N NMR spectra of free NH_3 and $[Co(NH_3)_6]^{3+}$ were measured in liquid by Herbison-Evans and Richards and later by Bramley et al.[8,18] The chemical shift due to complex formation was to a higher field (about 50 ppm in Ref. 8 and a bout 130 ppm in Ref. 18). In their reports, the ^{14}N NMR chemical shift was mainly caused by the

Table 3. ^{15}N NMR Shift Values, σ_L and $(\sigma_D+\sigma_P)$ in $[CoX(^{15}NH_3)_5]^{n+}$ Relative to That of $[Co(^{15}NH_3)_6]^{3+}$

	σ_L		$(\sigma_D+\sigma_P)$	
X	Trans	Cis	Trans	Cis
CN^-	−2.3	1.1	−21.6	0.6
NH_3	0.0	0.0	0.0	0.0
H_2O	1.5	−0.8	19.2	−4.7
Cl^-	1.2	−0.6	7.4	−5.6
Br^-	1.0	−0.5	1.8	−2.5

magnetically-susceptible nonbonding paired electrons of NH_3 (σ_P). Regarding complex formation, these are constrained largely between the metal and nitrogen atoms as a bonding electron pair, and are considerably less susceptible to the magnetic field; thus, they contribute less to the nitrogen σ_P part in Ramsay's formula.[16] We calculated a higher shift value (70 ppm), based on the same ideas presented in Refs. 8 and 18.[19]

The contribution of NH_3 makes the hydrogens acidic; therefore, the protons can possibly be exchanged with those (deuterons) in the solution. For $[CoX(NH_3)_5]^{n+}$ complexes with X=H_2O, Cl^-, Br^-, or other weaker ligands than NH_3 in the spectrochemical series, it has been considered that the H-D exchange rates of the protons of NH_3 trans to X are faster than that of the cis ones.[5,21,25] With X=CN^-, the case is inverse.[5,21] With X=NO_2^-, the ^1H NMR signal did not split to each of the trans and cis signals of NH_3. Sakaguchi et al. have speculated from plots of the an H-D exchange rates that the protons of the trans NH_3 undergo an H-D exchange more slowly than that of the cis group (with X=CN^- and NO_2^-).[5] It could be said that the protons of NH_3 (trans or cis to X), whose ^{15}N NMR signal shifts to a higher field than another, undergo an H-D exchange faster than those of another NH_3 in $[CoX(NH_3)_5]^{n+}$. With X=Cl^-, the higher-field shift of the ^{15}N NMR signal of NH_3 trans to Cl^- corresponds to a faster H-D exchange rate of the protons. It can be seen from Table 3 that if X is a weaker ligand than $^{15}NH_3$ in the spectrochemical series, the ^{15}N NMR signal of $^{15}NH_3$ trans to X shifts to a higher field from that in X=NH_3 and cis signal to a lower field. Provided that the higher the magnetic field of ^{15}N NMR signal, the faster the H-D exchange rate of ammine protons and the stronger the Co-N bond, the shift directions are consistent with the findings of the H-D exchange rate of NH_3.[5,21] The lower-field shift of the ^{15}N NMR signal of the trans $^{15}NH_3$ in $[Co(CN)(^{15}NH_3)]^{2+}$ corresponds to a decrease in the H-D exchange rate of ammine protons trans to CN^-.[5,21,25] In the process of the synthesis of $[Co(CN)(NH_3)_5]^{2+}$, ^{15}N was introduced in the last step, as shown below:

$$[Co(CN)(NH_3)_4(H_2O)]^{2+} + {}^{15}NH_3 + {}^{15}NH_4Cl \rightarrow [Co(CN)(^{15}NH_3)_n(NH_3)_{5-n}]^{2+} + HCl.$$

The ^1H NMR signal of the last product is shown in Fig. 4. It can be seen from Fig. 4 that the NH_3 trans to CN^- was much more substituted by $^{15}NH_3$ than the cis. It may be considered that the lower-field shift of the ^{15}N NMR signal, the decrease in the H-D exchange rate, and the weakened Co-N bond strength for the NH_3 trans to CN^- are caused by the same origin, i.e., an inductive trans effect of CN^-. Similar phenomena have been observed by Halpern et al. in the synthesis of *trans*-$[Co(^{15}NH_3)(SO_3)(NH_3)_4]^+$, where the NH_3 trans to SO_3^{2-} was mostly substituted by

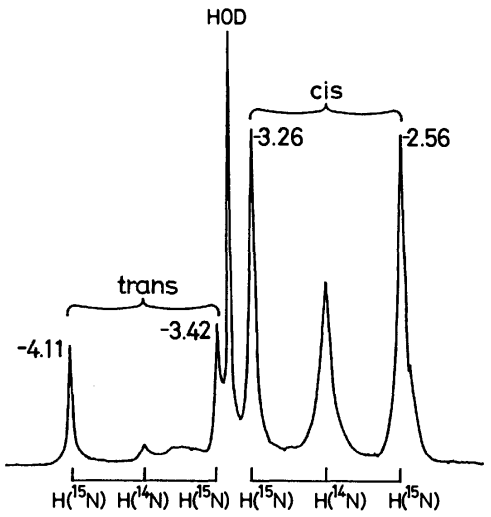

Fig. 4. ^1H NMR spectrum of $[Co(CN)(^{15}NH_3)_n(NH_3)_{5-n}]^{2+}$ in DMSO-d_6. Shift values are ppm from an external reference (TMS). Coupling constants, $^1J_{NH}$ are 68 and 70 Hz for trans and cis NH_3 respectively (measured at 99.5 MHz).

$^{15}NH_3$, though the cis NH_3 was not. It was caused by a marked trans-labilizing influence of the S bonded sulfito ligand.[22]

As mentioned above, the shift direction of ^{15}N NMR signals of trans and cis $^{15}NH_3$ in $[CoX(NH_3)_5]^{n+}$ are correlated to the H-D exchange rates and the Co-N bond strengths, though the relation can not be quantitatively interpreted at present.

The ^{14}N NMR signals are broad owing to a quadrupolar relaxation of ^{14}N nucleous; the ^{14}N NMR signals were inseparable from each of the trans and cis signals. The ^{15}N NMR signals were separated into two sharp signals without problems related to the quadrupolar relaxation of ^{15}N nucleous (Fig. 1), except for X=NO_2^- and $^{15}NH_3$. These exceptions are due to coupling between the ^{15}N and ^{59}Co nuclei. The lower-field shifts of ^{14}N NMR signals for X=H_2O and Cl^- from $[Co(^{14}NH_3)_6]^{3+}$ in Ref. 8. represent the weighted mean values of one trans and four cis shifts of the corresponding ^{15}N signals.

Tris- and *cis*-Bis(ethylenediamine)cobalt(III) Complexes. The ^{15}N NMR shift value of $[Co(en\text{-}^{15}N,{}^{15}N)_3]^{3+}$ was obtained from the central position of the broad signal. In *cis*-$[CoX_2(en\text{-}^{15}N,{}^{15}N)_2]^{n+}$ with X_2=ox^{2-}, CO_3^{2-} (weaker ligands than en), the higher-field shifts of the ^1H NMR signals of the trans amino protons are consistent with the theory of anisotropy of Co(III) ion.[3,13] The assignment of the NMR signals and the H-D exchange in *cis*-$[CoX_2(en\text{-}^{15}N,{}^{15}N)_2]^{n+}$ have been studied in more detail by Nakazawa et al.,[14] where one half of the trans aminoproton signals undergoes a large counterion-dependent shift in DMSO-d_6; it is therefore assigned to the trans hydrogens directed approximately parallel to the molecular two-fold axis of the complexes with X_2=$(CN^-)_2$,

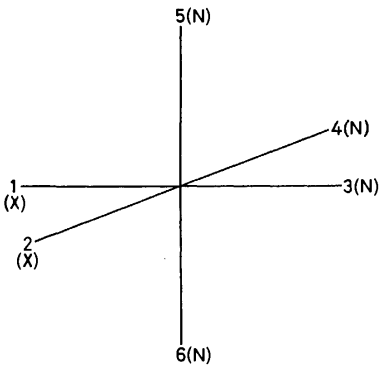

Fig. 5. Framework of *cis*-$[CoX_2N_4]^{n+}$ with numbering of ligating atoms.

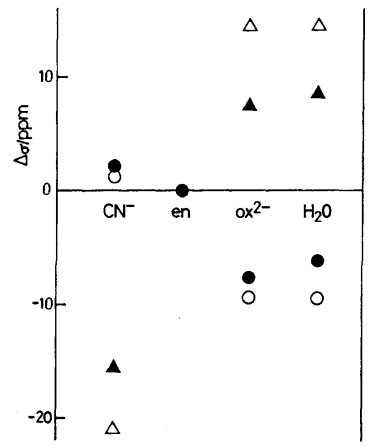

Fig. 6. Plots of ^{15}N NMR shift values $(\sigma_D+\sigma_P)$ of $-^{15}NH_2$ in *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$. Circles and triangles are for cis and trans to X, respectively (open for calculated; solid for observed (Table 4)). The calculated values are $\{(\sigma_D+\sigma_P)(trans)+(\sigma_D+\sigma_P)(cis)\}$ and $\{(\sigma_D+\sigma_P)(cis)\times 2\}$ (Table 3), for trans and cis ^{15}N to X, respectively (see text). The calculated value for the aqua complex was also used for the oxalato one.

$(NO_2^-)_2$, $acac^-$, ox^{2-}, and mal^{2-}. On the other hand, we found that upon deuteration of amino protons, the noise-decoupled NMR signal of the ^{13}C adjacent to the deuterated amino nitrogen shifted by about 0.15 ppm per substituted deuteron to a higher field.[15] The lower-field signal of the $^{13}C\{^1H\}$NMR spectrum in *cis*-$[Co(CN)_2(en)_2]^+$ splits at first; this has already been assigned to that of the ^{13}C adjacent to the $-NH_2$ cis to CN^-.[23] Thus, the amino protons cis to CN^- were deuterated first, and the adjacent ^{13}C NMR signal shifted to a higher field in acidified D_2O. This result is different from that found by Nakazawa et al.

Assignments of ^{15}N NMR signals were confirmed by the selective irradiation of the ^{1}H NMR signals of $-^{15}NH_2$. Accordingly, the assignments of the ^{1}H NMR signals of $-NH_2$ are very important for the assignment of the ^{15}N NMR signals. The results for $X_2=(NO_2^-)_2$ and ox^{2-} were the same as those by Nakazawa et al. and might also be similar for $X_2=acac^-$ and mal^{2-}.

Table 4. ^{15}N NMR Shift Values, σ_L and $(\sigma_D+\sigma_P)$ in *cis*-$[CoX_2(en\text{-}^{15}N,^{15}N)_2]^{n+}$ Relative to That of $[Co(en\text{-}^{15}N,^{15}N)_3]^{3+}$

	σ_L		$(\sigma_D+\sigma_P)$	
X_2	Trans	Cis	Trans	Cis
$(CN^-)_2$	−1.0	1.9	−15.6	2.1
en	0.0	0.0	0.0	0.0
ox^{2-}	0.6	−1.2	7.5	−7.7
$(H_2O)_2$	0.9	−1.8	8.5	−6.2

The additivity of the effect of the substituent X on the ^{15}N NMR chemical shifts was examined in the aforementioned $[CoXN_5]^{n+}$- and *cis*-$[CoX_2N_4]^{n+}$-type complexes, as shown below. The effect is separated into two parts: trans and cis. Each can be easily obtained from experimental data for $[CoXN_5]^{n+}$ complexes. On the basis of this data, the ^{15}N MMR shift values for *cis*-$[CoX_2N_4]^{n+}$ complexes can be estimated. The framework of *cis*-$[CoX_2N_4]^{n+}$ is shown with numbering of ligating atoms in Fig. 5. The trans nitrogen atoms located at positions 3 and 4 are subject to a trans effect from one X and a cis effect from another X. The cis nitrogen atoms at positions 5 and 6 are subject to only a cis effect from X at positions 1 and 2. The calculated values are shown along with the observed ones (Table 4) in Fig. 6. It seems to be roughly additive between the trans and the cis effects, thus postulated to be separately caused by ligand X on the ^{15}N NMR chemical shifts.

A Complex Generated in a Cationic Surfactant-Aromatic Additive System

Hirotaka HIRATA,* Yumi KANDA, and Yuko SAKAIGUCHI
Niigata College of Pharmacy, Department of Physical Chemistry, 2-13-5, Kamishin'eicho, Niigata 950-21
(Received December 23, 1988)

Aqueous binary solutions of hexadecyltrimethylammonium bromide (HTAB) and *o*-iodophenol (OIPh) exhibit remarkable viscoelasticity. From the centrifuged sediment of such a solution a *crystalline* product was isolated on long standing. Elementary analysis of the *crystals* for C, H, and N gave an estimated composition consistent with a one-to-one molar ratio of the two substances. Comparisons with DSC and IR measurements on the *crystal* and equimolar mechanical mixtures suggested that a *crystalline* complex was formed characterized by low thermal stability.

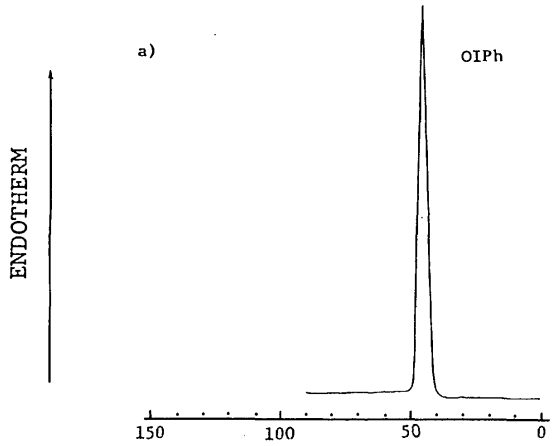
By electron microscopy we have recently identified elongated rod like micelles in several cationic surfactants such as HTAB or *N*-hexadecylpyridinium bromide on treatment with some aromatic derivatives.[1-3] These solutions often exhibit high viscoelasticity and spinnability. We have established that the viscoelasticity in solution arises from a cobweb-like entanglement of the elongated rod shaped micelles.[3]

Other investigators accumulated informations about the cause of the solution behaviors over the extensive areas,[4,5] but little is yet known about the condition suitable for the generation of such gigantic micelles in solution containing quaternary ammonium cationic surfactants and aromatic compounds, though there has been speculation about the interactions taking place in such systems.[6]

In the sediment centrifuged from HTAB/OIPh aqueous solutions after long standing we have isolated a *crystalline* product. This material exhibits strong viscoelasticity and spinnability when dissolved in water and appeared to be a complex of HTAB and OIPh. Elementary analysis, differential scanning calorimetry (DSC) and infrared spectroscopy (IR) of the *crystals* have been carried out.

Results and Discussion

The *crystals* are prismatic with average size about 1 mm×3mm. They exhibt lateral cleavage streaks and a granular structure.



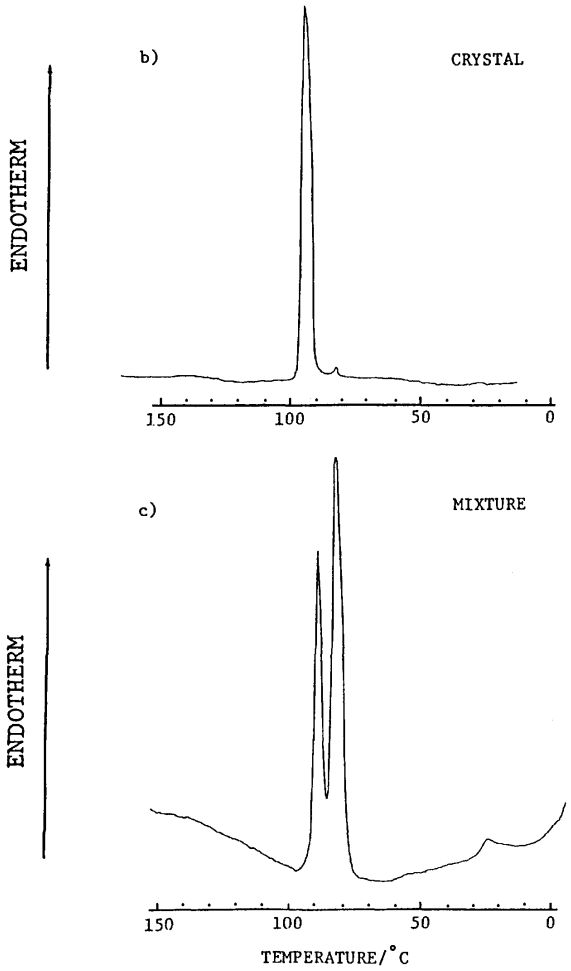


Fig. 1. The thermogram in DSC of a) OIPh, b) *crystal*, and c) the mechanical mixture of one-to-one molar ratio of HTAB and OIPh.

Table 1. The Results of the Elementary Analysis of the *Crystal* Obtained from the Sediment Solution of the HTAB/OIPh System

	Content	
	Observed	Calculated[a]
C (%)	51.28	51.37
H (%)	8.10	8.05
N (%)	2.48	2.40

a) The values are those which supposed to be composed of HTAB and OIPh in the molar ratio of unity.

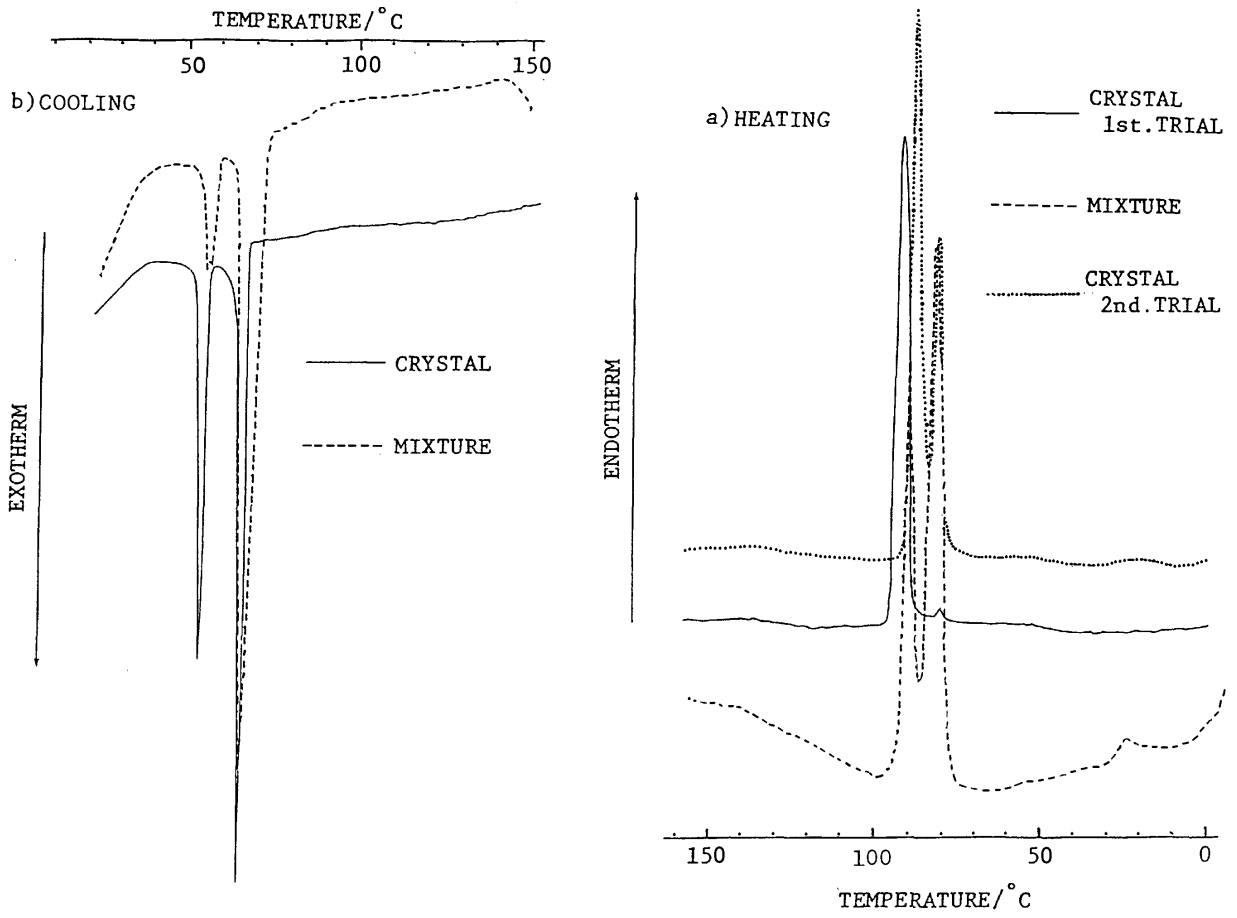

Fig. 2. The thermograms in DSC of the *crystal* and the mechanical mixture in one-to-one molar ratio, a) a comparison of the profiles in the repeated trial upon the first heating of the *crystal* with the second one and with the profile of the mixture. In the mixture the profile was not changed depending on the repetition, b) a comparison of the cooling profile of the *crystal* with that of the mechanical mixture.

Elementary analyses of the washed and dried material for C, H, and N are given in Table 1. These are in good accord with the values expected for each component and suggest a one-to-one molar complex formation. From the elementary analysis some anticipation of containing water hydrated was denied after a treatment of a one overnight drying before analysis. But it appeared for the *crystals* to occlude some water in the initial stage of having just been taken out of the sediment solution, because the *crystals* decreased their weight by about 20% during a one ovenight evacuation at room temperature. The fact was also supported in the thermal analyses (see below).

Microscopic examination at ×40 of a small *crystal* immersed in water showed a swollen profile domain surrounding the *crystal*. On touching the swollen region with a needle tip the region changed abruptly to a heavy viscoelastic solution. This observation seems to be very important to deduce the molecular weight of the *crystalline* species and the relation of the solution behaviors to the gigantic micellar figures observed in the electron micrographs.

In Fig. 1 the DSC's of the *crystals* and the equimolar simple mechanical mixtures of the single component constituents are compared. In this respect the behavior of the *crystal* and the equimolar mixture both differ from each other, i.e. OIPh only shows a characteristic endotherm at 42.3 °C corresponding to its solid to liquid phase transition. HTAB was assumed to have a very high temperature transition near 235—237 °C.[7]

All thermal behaviors can be compared with the observations under a polarizing microscope. The single endotherm of the *crystal* at 94.5 °C corresponds to a solid-smectic phase change observed as the disappearance of the sharp crystal edge seen under the microscope. The as yet uncharacterized smectic phase persists to considerably higher temperatures in accord with that no other peaks are observed in the DSC above 94.5 °C. Microscope image changes are also observed at temperatures consistent with the endothermal peaks in the DSC diagrams. Judged from their fluidity the phase transitions would appear to be due to smectic changes.

On subsequent cyclic thermal changes the endothermal peak profile of the *crystal* separated into a doublet at 83.0 °C and 88.0 °C (Fig. 2a) after the first cycle, but subsequent cycles produced no further change. In

the cooling stage the exothermal profile for the *crystal* was identical with that of the equimolar mixture. (Fig. 2b) This would suggest that there is a thermally induced dissociation of the complex. On the contrary, on a second heating cycle of the mixture changes occur in the thermogram which approaches that of the *crystal*. No restoration of the initial peak profile of the *crystal* DSC may also be explained by the fact that the *crystal* is a high molecular weight entity which would be difficult to restore the original crystal lattice during such a rapid cooling. From this we infer that the HTAB/OIPh *crystalline* complex has an equilibrium point towards the components. In reversal a system of components readily deviates to the complex side.

Some effects of moisture are observed in the thermogram of the *crystal*. After several DSC cycles a specimen left overnight in moist air exhibited other peaks in the low temperature region (Fig. 3). These can be attributed to water retained in the crystal lattice. Exposure to moisture increased the *crystal* weight by about 1% and restored the initial state after several DSC cycles with decrease of those peaks of the moisture origin. This suggests that the HTAB/OIPh complex can accomodate some water of hydration.

Figure 4 shows the IR spectra of the *crystal* and the equimolar mixture. There are significant differences between 1400 and 700 cm^{-1} due to additional bands in

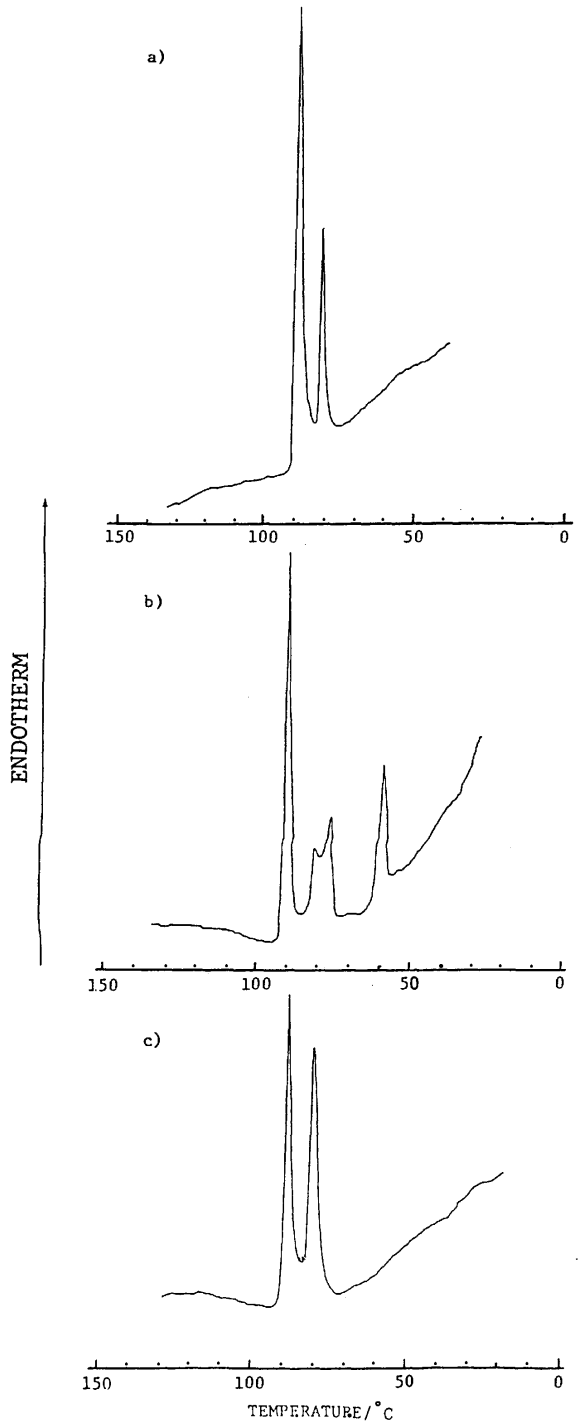

Fig. 3. The effect of the water hydrated on the *crystal* DSC, a) before moistened after several repeated trials, b) one-over-night moistened specimen, and c) after the second trial of the moistened specimen. In the succesive trials the profiles were almost not changed any more.

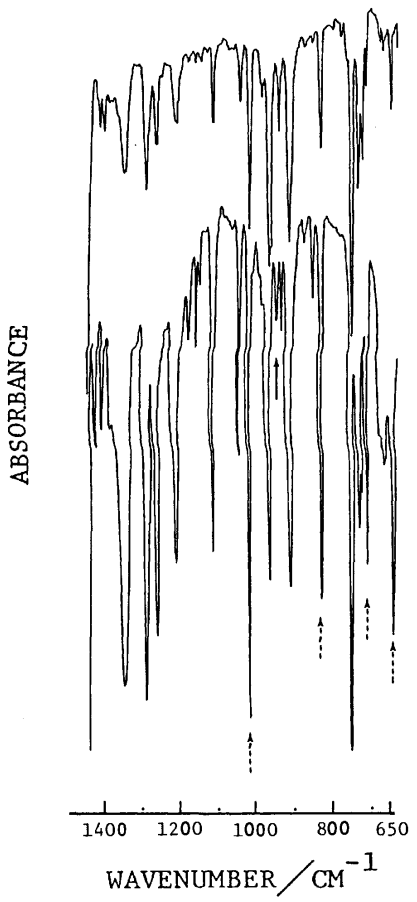

Fig. 4. The IR absorption spectra of the *crystal* (below) and the mechanical mixture in one-to-one molar ratio (above). ↑ shows a newly splitted doublet band, observed in the *crystal*, from a singlet band of the mechanical mixture. ↕ shows the remarkably increased bands in the *crystal* compared with those of the mechanical mixture.

the spectrum of the *crystal*. There are also some notable intensity reversals. New bands occur at 931 cm^{-1} and 938 cm^{-1}; these would appear to result from a splitting of the 938 cm^{-1} band. Intensity reversals are noted in four regions (Fig. 4). These would appear to involve a nearly 4-fold enhancement in the intensity for the *crystal*. From these we infer that there are changes on the skeletal motions of the benzene nucleus of OIPh. This may be associated with a difference of the surrounding field in the *crystal* and the equimolar mixture.

From these differences in the DSC's and IR spectra of the *crystal* and the equimolar mixture we may deduce that the interactions between the aromatic and quaternary ammonium groups is not very great and that the complex formation and dissociation can easily be induced by heat.

X-Ray analysis of the *crystalline* species is currently in progress revealing the crystal structure is *Pnn*2 orthorhombic with lattice constants a=8.722 Å, b=39.954 Å, c=8.404 Å, $\alpha=\beta=\gamma=90°$ with a unit cell volume of V=2928.6 $Å^3$. Some structural aspects of the *crystal* have also been known.[8] Further work is under way to refine these data to ascertain the exact structure of the complex *crystal* with particular consideration to the interaction of the materials, the large elongated micelle structure and the behavior of the solutions.

We are indebted for the elementary analysis to the members of the Assay Laboratory of the Protein Research Institute of Osaka University.

Experimental

HTAB was used after one recrystallization of commercially available material from an acetone-methanol mixture. OIPh was of pure reagent grade, used as purchased. The sediment solutions of HTAB/OIPh were obtained by centrifugal separation at 60000 rpm for 1 h. using a Hitachi SPC85H centrifuge. The DSC measurements were carried out using a Rigaku Denki Co. Low Temperature Differential Scanning Calorimeter. Since the profile shift of the thermogram was considerable in repeated runs, especially following the initial heating, the cycles were always repeated on a way of a heating-after-cooling cycle. The rate of temperature scan was maintained at 10 K m^{-1} in both directions. IR measurements were made on a Hitachi 260-10 Infrared Spectrometer. The spectra were measured as KBr disks.

Physicochemical Properties of Polyacrylates Containing Tetraphenylporphinatocobalt(II) and Chloro(tetraphenylporphinato)iron(III) as Side Chains

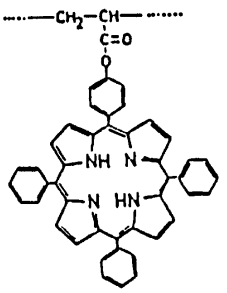
Mikiharu KAMACHI,* Mahito SHIBASAKA, Atushi KAJIWARA, Wasuke MORI,† and Michihiko KISHITA†
Department of Macromolecular Science, Faculty of Science, Osaka University, Toyonaka, Osaka 560
†Department of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560
(Received January 10, 1989)

Polyacrylates containing tetraphenylporphinatocobalt(II) (TPP-Co(II)) and chloro(tetraphenylporphinato)iron(III) (TPP-Fe(III)Cl) as side chains were prepared. Their physicochemical properties were investigated by UV-visible spectroscopy, ESR spectroscopy, and magnetic susceptibility (χ_M) measurement. In comparison of the visible spectra of polymers with those of the corresponding monomers, hypochromism of the Soret band and some of Q bands was observed in both polymers. In the measurements of ESR spectra, hyperfine splitting constants and anisotropic g-values of TPP-Co(II) or -Fe(III)Cl moieties bound to the polymers were somewhat different from those of TPP-Co(II) and -Fe(III)Cl, respectively. These differences in spectroscopic behavior suggest that there are some interactions between porphinatometal ion moieties in the polymers. The values of χ_M for the polymers containing TPP-Co(II) were found to obey the Curie-Weiss law with θ=190 K, which was explained in terms not only of spin-orbit interaction of the Co(II) ion but also antiferromagnetic interaction among the Co(II) ions. The magnetic moment of the TPP-Co(II) moiety bound to the polymer is smaller than that of TPP-Co(II), indicating occurrence of an antiferromagnetic interaction between Co(II) ions in the polymer. The values of χ_M for polymers containing TPP-Fe(III)Cl were found to obey the Curie-Weiss law with θ=20 K. This can be explained in terms of the presence of antiferromagnetically-interacting sites. From the experimental results, it is concluded that the antiferromagnetic interaction between TPP-metal ions bound to the polymer is larger than that of the corresponding TPP-metal ions. Molecular oxygen is adsorbed to polyAOTPP-Co(II) and 5-(4-propanoyloxyphenyl)-10,15,20-triphenylporphinatocobalt(II) (POTPP-Co(II)) below 180 K. Magnetic susceptibility measurement and ESR study show that molecular oxygen is bound to the Co(II) ion by chemisorption whose binding energy is 24 kJ M^{-1}.

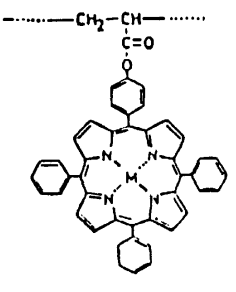
Many studies of physicochemical properties of tetraphenylporphinatometal ions have been reported.[1-5] However, there have been few studies of polymers containing metalloporphins in the side chain, although the polymers seem to have interesting and unusual properties caused by an aggregate of porphin moieties.[6,7] To our knowledge, no homoplymerization of vinyl compounds containing porphin moieties in the side chains has been reported except for our papers.[8] Recently, we succeeded in the preparation of this type of polymer by radical polymerization of 5-(4-acryloyloxyphenyl)-10,15,20-triphenylporphine (AOTPP).[8]

In the course of our study of the magnetic properties of polymers containing paramagnetic species in the side chain,[9-12] we found that polyacrylates containing tetraphenylporphinatosilver(II) (TPP-Ag(II)) have strong antiferromagnetic interactions.[9] Since cobalt(II) and iron(III) which are composed of electronic configurations of d^7 and d^5, respectively, have a possibility of multiplet state, and hence have the potential of leading to ferromagnetic substances,[13,14] polyacrylates containing tetraphenylporphinato-Co(II) or -Fe(III)Cl (TPP-Co(II) or -Fe(III)Cl) as side chains were prepared and their magnetic properties were investigated. They showed antiferromagnetic behavior, contrary to expectation.

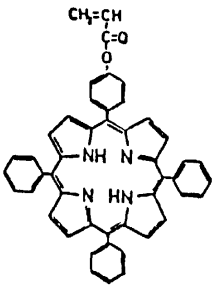
In this paper, we present the results of the preparation and the spectroscopy of the polymers (polyAOTPP-Co(II) and -Fe(III)Cl), as well as their magnetic properties. The antiferromagnetic behavior observed in the polymers is ascribable to the electronic interaction between the TPP-metal moieties bound to the polymers, which was found by UV-visible and ESR spectroscopy. In addition, adsorption of molecular oxygen on polyAOTPP-Co(II) is considered.



PolyAOTPP



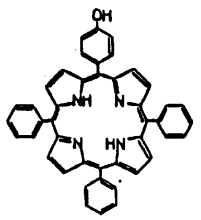
PolyAOTPP-M
M: Co(II) or Fe(III)Cl



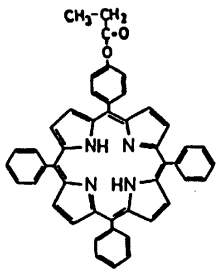
AOTPP

Experimental

Materials. Solvents were purified by distillation under nitrogen atmosphere. 5-(4-Acryloyloxyphenyl)-10,15,20-triphenylporphine (AOTPP) and its polymer (poly(AOTPP)) were prepared as described previously.[8] The molecular weight of the polymer was determined to be 80000—100000 by GPC measurements.[8] 5,10,15,20-Tetraphenylporphine (TPP) was synthesized according to Alder et al.[15] Tetraphenylporphinatocobalt(II) was prepared according to Bucher et al.[16] in 96% yield. Chlorotetraphenylporphinatoiron(III) was prepared according to Maricondi et al.[17] in 64.8%. 5-(4-Hydroxyphenyl)-10,15,20-triphenylporphine (HOTPP) was prepared by the method described previously.[8]



HOTPP



POTPP

5-(4-Propanoyloxyphenyl)-10,15,20-triphenylporphine (POTPP) was prepared by adding propanoyl chloride to a THF solution of HOTPP and triethylamine. The crude product was purified by column chromatography, followed by repeated recrystallization from chloroform-methanol. Yield 90%.

Found: C, 82.07; H, 5.04; N, 8.13%

Calcd for $C_{47}H_{35}N_4O_2$: C, 82.07; H, 5.13; N, 8.15%

5-(4-Propyloyloxyphenyl)-10,15,20-triphenylporphinatocobalt(II) [POTPP-Co(II)] was prepared as follows: POTPP (0.61g) and cobalt(II) (0.30 g) acetylacetonate were dissolved in 100 ml chloroform. The solution was refluxed for 1 h and chloroform was removed by a rotatory evaporator. The product was purified by repeated precipitation from chloroform-methanol. The content of Co(II) was determined by flame spectrometric analysis.

Found: C, 76.22; H, 4.47; N, 7.64; Co, 7.6%

Calcd for $C_{47}H_{33}N_4O_2Co$: C, 75.80; H, 4.47; N, 7.52; Co; 7.91%.

Poly[5-(4-acryloyloxyphenyl)-10,15,20-triphenylporphinatocobalt(II): Poly(AOTPP) (0.40 g) and cobalt(II) acetylacetonate (0.40 g) were dissolved in 100 ml THF. The solution was refluxed for 24 h and THF was removed by a rotatory evaporator. During the reflux, the reaction was followed by taking visible spectra of the solution at different times. Chloroform was added to the residue to dissolve the polymer, and the polymer was isolated by precipitation with methanol and purified by repeated precipitations from chloroform-methanol. The precipitated polymer was isolated by centrifugation and dried in vacuo overnight. The content of Co(II) was determined to be 74 mol% of the TPP-moiety by flame spectrometric analysis.

Poly[chloro-5-(4-acryloyloxyphenyl)-10,15,20-triphenylporphinatoiron(III)Cl]: poly(AOTPP) (0.25 g) and iron(III) chloride (0.14 g) was mixed in 100 ml of toluene containing 5 ml of methanol. The mixture was refluxed for 24 h and filtered to remove unreacted iron(III) chloride. The filtrate was washed with water. The polymer was isolated from the organic layer by evaporation, dried in vacuo, dissolved in benzene, and reprecipitated with ethanol. The polymer was purified by repeated precipitation from benzene-ethanol. The precipitated polymer was isolated by filtration, and dried in vacuo overnight. Yield 0.27 g.

The content of Fe(III) ions was determined to be 92 mol% of the TPP-moiety by flame spectrometric analysis.

Measurements. UV-visible spectra were recorded on a Hitachi 124 spectrophotometer. IR spectra were recorded on a JASC DS-402G spectrophotometer.

ESR spectra were measured with a JEOL Model JES FE 1X ESR spectrometer with 100 kHz modulation. A TE_{011} mode cylindrical cavity with a variable temperature adaptor (ES-UCT-2AX) was used. The temperature was controlled by a variable temperature control unit (ES-VT-3A). ESR measurements at 77 K were carried out using an insertion-type liquid nitrogen Dewar, a tip of which is made of doublefold Suprasil tubes. The *g*-values were estimated using MnO as a standard sample which was provided by JEOL.

Gram magnetic susceptibility (χ_g) was determined by the Gouy method at room temperature. Water was used as a standard sample for χ_g. The value of χ_g for water was found to be -0.727×10^{-6} cgs emu, being in agreement with the established value. The temperature dependence of χ_g was determined by the Faraday method, using a Cahn RH electric balance in a temperature range from 4 K to 300 K. The molar magnetic susceptibilities (χ_M) were corrected by the following equation to remove diamagnetic contributions from the ligand

$$\chi_M=\chi_g\times M-\chi_{dia}$$

where M is molecular weight of TPP-metal or monomer unit of the polymer, and χ_{dia} for TPP-Co(II), TPP-Fe(III)Cl, polyAOTPP-Co(II), and polyAOTPP-Fe(III)Cl were calculated to be -521×10^{-6}, -542×10^{-6}, -498×10^{-6}, and -418×10^{-6} cgs emu, respectively. The effective magnetic moment (μ_{eff}) was calculated from the following equation:

$$\mu_{eff}=2.33\sqrt{\chi_M\cdot T}$$

The amount of molecular oxygen absorped was determined from the difference in the weight of samples before and after O_2 gas was introduced into the system.

Results and Discussion

UV-Visible Spectra. UV-visible spectra of TPP-Co(II) and polyAOTPP-Co(II) are shown in Fig. 1. Both compounds have the Soret band at 411 nm and Q bands in the region from 500 to 700 nm, as shown in the spectra of metalloporphins.[8] The wavelength of the Soret band of polyAOTPP-Co(II) is similar to that of TPP-Co(II), but the molecular extinction coefficient (ε) of polyAOTPP-Co(II) is smaller than that of TPP-Co(II). Q bands of polyAOTPP-Co(II) are broader than those of TPP-Co(II). Close examination of the spectra shows that at 530 nm the value of ε

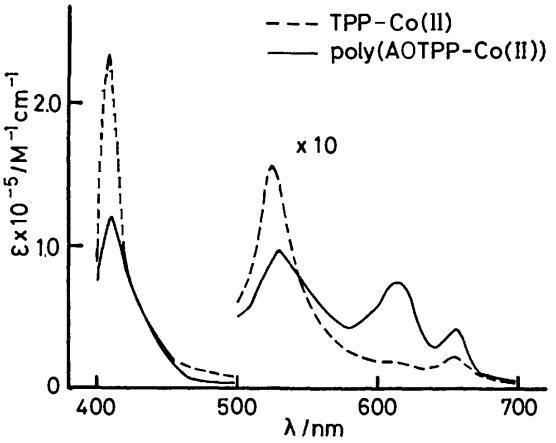


Fig. 1. Visible spectra of TPP-Co(II) and polyAOTPP-Co(II) in chloroform at room temperature. (----) TPP-Co(II), and (——) polyAOTPP-Co(II).

of polyAOTPP-Co(II) is smaller than that of TPP-Co(II), and that at 670 nm the former is larger than the latter. In addition, at 610 nm a stronger and broader absorption band is more clearly observed in spectrum of polyAOTPP-Co(II). The UV-visible spectrum of 5-(4-propanoyloxyphenyl)-10,15,20-triphenylporphinatocobalt(II) (POTPP-Co(II)) was measured to study the influence of the ethoxycarbonyl group bound to the TPP on the spectrum. Since the spectrum of POTPP is almost the same as that of TPP except for the slight change in λ_{max} and ε, the presence of the ethoxycarbonyl group is not considered to be an important factor for the difference in molecular extinction coefficients of the absorption bands between TPP-Co(II) and polyAOTPP-Co(II). The case where all the metal ions incorporated into the polymer are not bound to the TPP moieties might be considered as the origin of this difference. However, IR absorption bands due to TPP-Co(II) moieties of the polymer was almost the same as those of TPP-Co(II). Moreover, the local structure around a Co(II) ion in TPP-Co(II) and polyAOTPP-Co(II) was investigated by the EXAFS method. A Co(II)-N distance was determined to be 2.1 Å in polyAOTPP-Co(II), being consistent with 2.1 Å in TPP-Co(II).[18] This result shows that Co(II) ions incorporated into the polymer are mostly bound to the TPP moieties as TPP-Co(II). Therefore, the difference in the absorption bands between polyAOTPP-Co(II) and AOTPP-Co(II) is reasonably ascribed to the hypochromism and the hyperchromism, which suggests that there are some interactions between TPP-Co(II) moieties in the polymer.[19] It has been usually considered that there is no stacking between TPP rings because of steric repulsion by the phenyl groups.[20] Recently, however, the presence of interaction due to close approach of the two porphin rings has been found in porphin dimers in organic solvents[21] and in aqueous solution of tetrakis(4-sulfophenyl)porphin,[22] and the change in the values of ε has been explained in terms of an exciton coupling model.[7] Bulky TPP moieties bound to a polymer chain are possibly forced into some interactions due to their close approach.

UV-visible spectra of TPP-Fe(III)Cl and polyAOTPPFe(III)Cl are shown in Fig. 2. The values of ε of the Soret band (416 nm) and the absorption band at 515 nm are smaller in polyAOTPP-Fe(III)Cl than in TPP-Fe(III)Cl. The absorption band at 653 nm of polyAOTPP-Fe(III)Cl is stronger and is shifted 3 nm to longer wavelength than the corresponding band of TPP-Fe(III)Cl. In addition, an absorption near 558 nm is observed in polyAOTPPFe(III)Cl. The observed spectroscopic absorption feature of polyAOTPP-Fe(III)Cl is similar to that of polyAOTPP-Co(II), suggesting the presence of exciton coupling between porphin moieties in a polymer chain.

ESR Spectra of Polycrystalline State. Figure 3 shows the ESR spectra of the powdered samples of

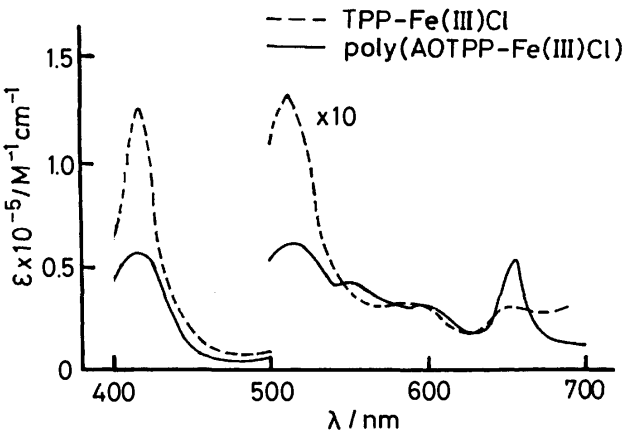

Fig. 2. Visible spectra of TPP-Fe(III)Cl and polyAOTPP-Fe(III)Cl in chloroform at room temperature. (----) TPP-Fe(III)Cl and (——) polyAOTPP-Fe(III)Cl.

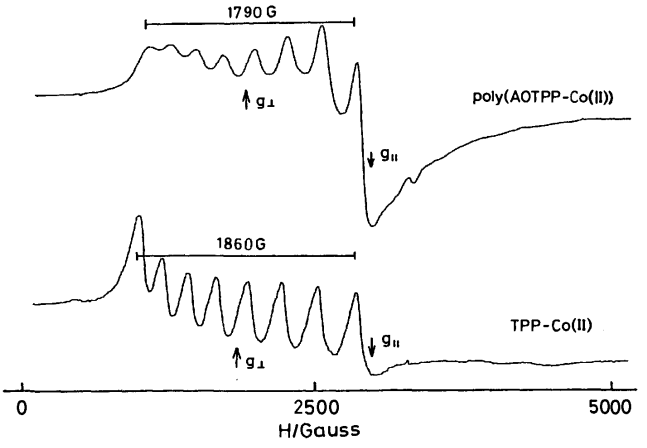

Fig. 3. ESR spectra of TPP-Co(II) and polyAOTPP-Co(II) powders in vacuo at 77 K.

TPP-Co(II) and polyAOTPP-Co(II) in vacuo at 77 K. The spectrum of TPP-Co(II) is similar to those of cobalt(II) phthalocyanine[23] 5,10,15,20-tetrakis(*p*-methylphenyl)porphinatocobalt(II).[24] These spectra are composed of two anisotropic resonance lines ($g_{//}$ and $g_{\perp}$) with an anisotropic magnetic interaction between an unpaired electron and a cobalt nucleus of spin $I=7/2$. The spectrum can be interpreted by the following spin Hamiltonian reflecting the axial symmetry:[23]

$$H=\beta[g_{//}H_zS_z+g_{\perp}(H_xS_x+H_yS_y)]+AS_zI_z+B(S_xI_x+S_yI_y) \quad (1)$$

where A and B are the cobalt nuclear hyperfine interaction constants.

The low-field set of 8 intense lines shows that the resonance lines are not equally spaced and their hyperfine splitting constants increase from 194 to 310 (1G=10^{-4} T) with increasing magnetic field. The progressive hyperfine splitting can be explained in terms of the anisotropic resonance condition with substantial second-order interactions as follow:[23]
For the direction pararell to the magnetic field,

$$H_{//}=(H_0/g_{//})-(AM_I/g_{//})-B^2[I(I+1)-M_I^2](2g_{//}H_0)^{-1}. \quad (2)$$

For the direction perpendicular to the magnetic field,

$$H_{\perp}=(H_0/g_{\perp})-(BM_I/g_{\perp})-(A^2+B^2)[I(I+1)-M_I^2](4g_{\perp}H_0)^{-1}. \quad (3)$$

The high-field set of lines that belong to $g_{//}$ also should be theoretically composed of eight lines. However, the signals of this set were much weaker, being detected as five lines by increasing the amplification of the spectrometer. The remaining three lines are hidden by the strong $g_{\perp}$ resonances. The four hyperfine splitting constants estimated from the five lines are unequal and larger than 300 G. This spectrum is almost the same as that of 5,10,15,20-tetrakis(*p*-methylphenyl)porphinatocobalt(II).[24] The spin Hamiltonian parameters were determined to be $g_{//}=1.80$, $g_{\perp}=3.59$, $A=197\times10^{-4}$ cm^{-1}, and $B=395\times10^{-4}$ cm^{-1} by the same method as Refs. 22 and 23. The deviation from the free electron value of $g=2.0023$ implies that spin-orbit interactions are operative in the Co(II)-TPP molecule.

The ESR spectrum of polyAOTPP-Co(II) shows the superposition of anisotropic resonance lines about $g=2.0$ on the spectrum similar to that of TPP-Co(II). Although accurate g-values of the former are not clear because of the low resolution of the spectrum, the values of $g_{//}$ and $g_{\perp}$ estimated approximately from the maximum and minimum of the spectrum seems to be 2.2 and 2.0, respectively. This anisotropic spectrum is similar to that of reduced vitamin B_{12} which is five-coordinated owing to the attachment of 5,6-dimethylbenzimidazole.[25] The presence of the five-coordinated TPP-Co(II) moieties in polyAOTPP-Co(II) seems to be in accord with the finding of UV-visible spectroscopy that TPP-moieties bound to a polymer chain are forced to make some interaction. The spectrum similar to that of TPP-Co(II) is composed of the low-field set of 8 intense lines whose hyperfine splitting constants increase from 178 to 306 G with increasing magnetic field, and the weaker high-field set which could be observed as 5 peaks, whose hyperfine splitting constants changes from 303 to 430 G, by increasing the amplification. The remaining three lines are hidden by the low field set of $g_{//}$ with stronger intensities. The respective 8 lines in the lower-field set of polyAOTPP-Co(II) are broader than the corresponding lines of TPP-Co(II), and hyperfine splitting constants of the former are smaller than those of the latter. The comparison of these spectra shows that there is an exchange interaction between TPP-Co(II) moieties in polyAOTPP-Co(II),[26] which explains the difference in the temperature dependence of χ_M and μ_{eff} between polyAOTPP-Co(II) and TPP-Co(II) in the section of magnetic properties.

Figure 4 shows the ESR spectra of the powdered samples of TPP-Fe(III)Cl and PolyAOTPP-Fe(III)Cl in vacuo at 77 K. The resonance lines of TPP-Fe(III)Cl were observed at $g=6.4$ and $g=2.0$, being typical of d^5-high spin Fe(III)Cl complexes.[27] The ESR spectrum of polyAOTPP-Fe(III)Cl is similar to that of TPP-Fe(III)Cl except for the broadening of the signal at $g=6.0$ and the increase in the intensity of the resonance line at $g=2.0$. The difference in the line width and the signal intensity between polyAOTPP-Fe(III)Cl and Fe(III)Cl seems to be consistent with the presence of an exchange interaction between TPP-Fe(III)Cl moieties in the polymer, which was observed by measurement of the temperature dependence of χ_M and μ_{eff} in the next section.

Magnetic Properties. The temperature dependence of χ_M^{-1} and μ_{eff} is shown in Fig. 5. The straight line for the χ_M^{-1}-temperature relationship intersects

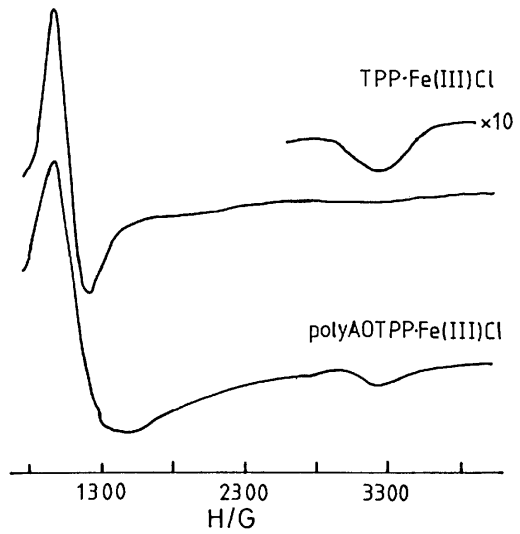

Fig. 4. ESR spectra of TPP-Fe(III)Cl and polyAOTPP-Fe(III)Cl powders in vacuo at 77 K.

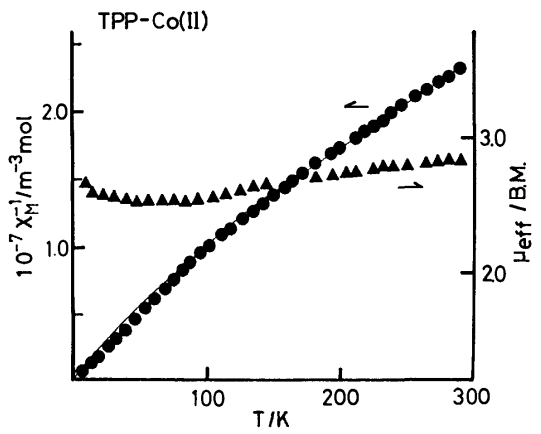

Fig. 5. Temperature dependence of χ_M^{-1} and of TPP-CO(II). (——) Calculated line.

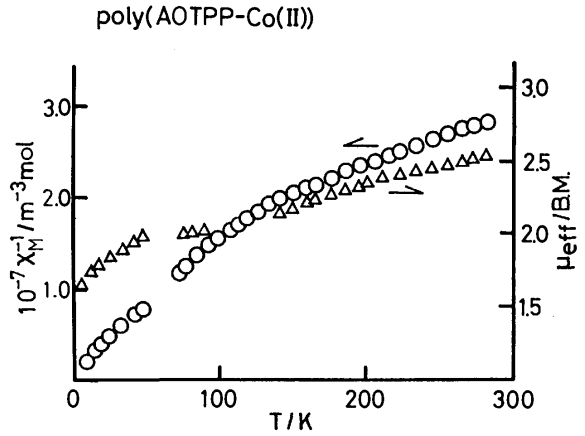

Fig. 6. Temperature dependence of χ_M^{-1} and of polyAOTPP-Co(II).

the ordinate above the origin, indicating that χ_M obeys the Curie-Weise law ($\chi_M=C/(T-\theta)$) with $\theta=-45$ K. This result suggests an antiferromagnetic interaction between TPP-Co(II) molecules each of which has an unpaired electron because of low spin d^7 configuration.[28] If the deviation from the Curie law ($\chi_M=C/T$) is due to the antiferromagnetic interaction the magnetic moment estimated from χ_M should be lower than the spin-only value of 1.73 B.M.[29] The magnetic moment observed at room temperature is 2.83 B.M., being larger than the spin-only value. This rather large value of the magnetic moment leads to the supposition that incomplete quenching of the orbital moment takes place in TPP-Co(II) because of low spin d^7 configuration and results in an anisotropic magnetic susceptibility ($g_{//}$ and $g_\perp$) due to the spin-orbit interaction.[30] Accordingly, the deviation of the temperature dependence of χ_M^{-1} from the Curie law is probably caused by the anisotropic magnetic susceptibility. Anisotropic susceptibilities are estimated by Eqs. 4 and 5:[30,31]

$$\chi_{//} = \frac{N\beta^2}{kT} \tag{4}$$

$$\chi_\perp = \frac{N\beta^2}{4kT}\left(2+\frac{6\lambda}{\Delta E}\right)^2 + \frac{3N\beta^2}{\Delta E+\lambda/2} + \frac{3N\beta^2}{\Delta E+\lambda/2} \tag{5}$$

where λ is a spin-orbit coupling constant, ΔE transition energy, N Avogadro's number, B Bohr magneton, k Boltzmann constant, and T temperature.

The value of ΔE is determined by Eq. 6 on the assumption[32] that λ is 400 cm^{-1}, which is 75% of that for the free Co(II) ion.

$$\Delta E = \frac{6\lambda}{g_\perp - g_e} \tag{6}$$

where the $g_\perp$ value was determined to be 3.32 from ESR spectra. From Eq. 6, ΔE was estimated to be 1800 cm^{-1}. Anisotropic magnetic susceptibilities at various temperatures were calculated from Eqs. 5 and 6 by using these ΔE and λ various.[31] Average magnetic susceptibilities χ at various temperature were calculated from Eq. 7 using $\chi_{//}$ and $\chi_\perp$.

$$\chi = \frac{1}{3}\chi_{//} + \frac{2}{3}\chi_\perp \tag{7}$$

The temperature dependence of the average magnetic susceptibility is in agreement with the experimental data shown Fig. 5. Therefore, the temperature dependence of χ_M is mainly ascribed to the spin-orbit coupling of Co(II) itself rather than the antiferromagnetic interaction between TPP-Co(II) molecules.

PolyAOTPP-Co(II): The temperature dependences of χ_M^{-1} and μ_{eff} of polyAOTPP-Co(II) are shown in Fig. 6. The straight line covering the high temperature range of the χ_M^{-1}-temperature relation intersects above the origin, indicating that χ_M obeys the Curie-Weiss law with $\theta=-190$ K. The magnetic moment of polyAOTPP-Co(II) was 2.58 BM, being smaller than that of TPP-Co(II)(2.83 BM). Moreover, the former decreased more markedly with lowering the temperature than the latter. This result shows that the antiferromagnetic interaction as well as anisotropic susceptibilities caused by the spin-orbital coupling should be involved in the magnetic behavior of polyAOTPP-Co(II). Accordingly, the temperature-dependence of magnetic susceptibility involving both factors was estimated. The theoretical temperature dependence χ_M^{-1} was found to be in better agreement with the experimental data by using the spin-spin interaction between three Co(II) ions rather than two Co(II) ions. Equations 4 and 5 were corrected by taking into account an antiferromagnetic interaction between three Co(II) ions as in Eqs. 8 and 9:[33]

$$\chi_{//} = \frac{N\beta^2}{3kT}\frac{\exp(3x)+5}{\exp(3x)+1} \tag{8}$$

$$\chi_\perp = \frac{1}{3}\frac{N\beta^2}{3kT}\left(2+\frac{6\lambda}{\Delta E}\right)\frac{\exp(3x)+5}{\exp(3x)+1} + \frac{3N\beta^2}{\Delta E+\lambda/2} + \frac{3N\beta^2}{\Delta E-\lambda/2} \tag{9}$$

where $x=-J/kT$.

In this calculation, λ and ΔE were assumed to be the same as those used in Eqs. 4 and 5, because the remarkable wavelength changes in these values between TPP and poly AOTPP was not found in UV-visible absorption and g values in ESR, respectively. The temperature dependence of the average $\bar{\chi}$ was estimated by using various coupling constants for antiferromagnetic interaction. Results are shown in Fig. 7. The best fit between theoretical and experimental curves was obtained with $J=-45$ cm^{-1}. Since polyAOTPP-Co(II) is considered to have various sites of different J values, this $J=-45$ cm^{-1} is an average of various J values.

TPP-Fe(III)Cl and PolyAOTPP-Fe(III)Cl: The temperature dependences of χ_M^{-1} and μ_{eff} of TPP-Fe(III)Cl are shown in Fig. 8. The straight line for the χ_m^{-1}-temperature relationship intersects the ordinate above the origin, indicating that χ_M obeys the Curie-Weiss law with $\theta=-11$ K. Since the ESR spectrum of TPP-Fe(III)Cl shows the high-spin d^5 config-

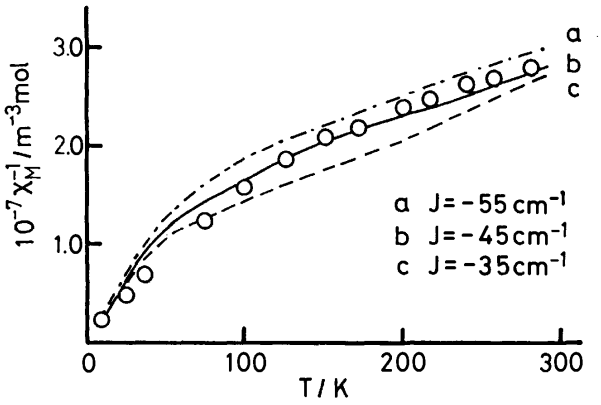

Fig. 7. Theoretical curves for the temperature dependence of the magnetic susceptibility of polyAOTPP-Co(II) with various antiferromagnetic interaction. $J=-55$ cm^{-1}, (b) $J=-45$ cm^{-1}, (c) $J=-35$ cm^{-1}.

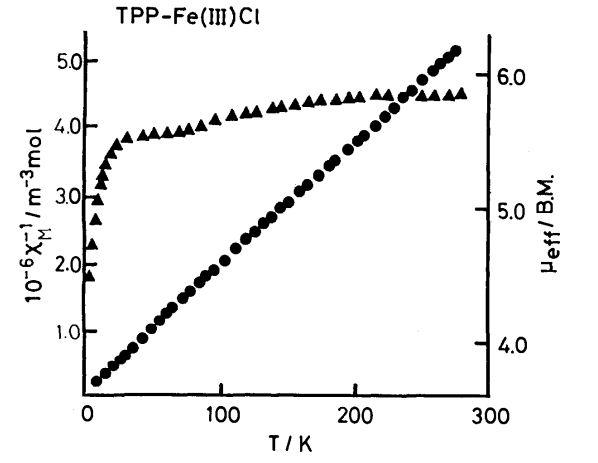

Fig. 8. Temperature dependence of χ_M^{-1} and μ_{eff} of TPP-Fe(III)Cl.

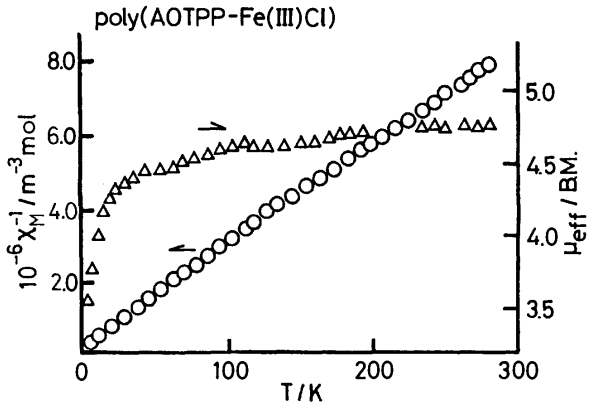

Fig. 9. Temperature dependence of χ_M^{-1} and μ_{eff} of polyAOTPP-Fe(III)Cl.

uration, anisotropic magnetic susceptibility due to the spin-orbit coupling interaction might be reasonably removed from the origin of deviation of the temperature dependence of χ_M^{-1} from the Curie law. Accordingly, the deviation is ascribed to the antiferromagnetic interaction. The magnetic moment of 5.82 B.M. is smaller than 5.92 B.M. of the spin-only value of d^5-high spin configuratic,[33] supporting that there are weak antiferromagnetic interaction.

The temperature dependences of χ_M^{-1} and μ_{eff} of polyAOTPP-Fe(III)Cl are shown in Fig. 9. The straight line for χ_M^{-1}-temperature relation intersects above the origin, indicating that χ_M^{-1} obeys the Curie-Weiss law with $\theta=-20$ K. The magnetic moment of polyAOTPP-Fe(III)Cl was 4.90 B.M. at room temperature, being smaller than that of TPP-Fe(III)Cl. Since TPP-Fe(III)Cl moieties bound to a polymer chain are considered to have various antiferromagnetically interacting sites, the temperature dependence of χ_M was apparently simulated by Eq. 10 derived for paramagnetic compound with exchange interaction of J on the assumption of the two paramagnetic sites with J_1 and J_2 as primary approximation.[34]

$$\chi_M=\sum_i\left(\frac{P_iNg^2\beta^2}{kT}\right)\frac{55+30x^{10}+14x^{18}+5x^{14}+x^{18}}{11+9x^{10}+7x^{18}+5x^{14}+3x^{18}+x^{30}} \quad (10)$$

where $x=\exp(-J_i/kT)$ and P_i indicates molar fraction of site occupancy with J_i.

The temperature dependence of χ_M^{-1} for polyAOTPP-FeCl(III)Cl was best simulated using the ratio of $P_1:P_2=42:58$ for the sites with $J_1=-50$ cm^{-1} and $J_2=0$ cm^{-1}, respectively. The reason why polyAOTPP-Fe(III)Cl has larger antiferromagnetic interaction than TPP-Fe(III)Cl might be ascribed to the fact that the porphin moieties are forced to collect near the chain.

Oxygen Adsorption of PolyAOTPPCo(II). The temperature dependences of χ_M^{-1} and μ_{eff} of TPP-Co(II) and polyAOTPP-Co(II) under 20 mmHg (1 mmHg≈133.322 Pa) of O_2 are shown in Figs. 10

and 11, respectively. These temperature dependences of χ_M^{-1} and μ_{eff} of TPP-Co(II) were not different from those in the absence of O_2, indicating that there is no special interaction between O_2 and the Co(II) ion.

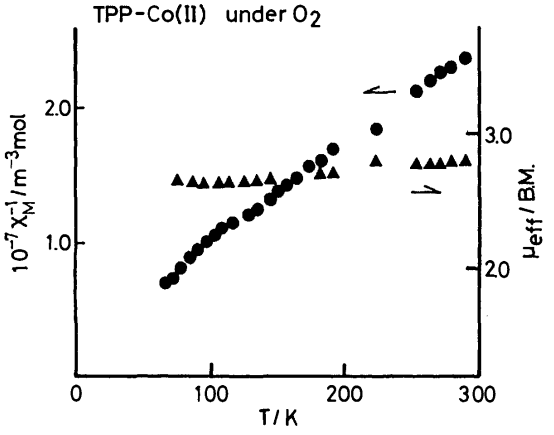

Fig. 10. Temperature dependence of χ_M^{-1} and μ_{eff} of TPP-Co(II) in the presence of molecular oxygen.

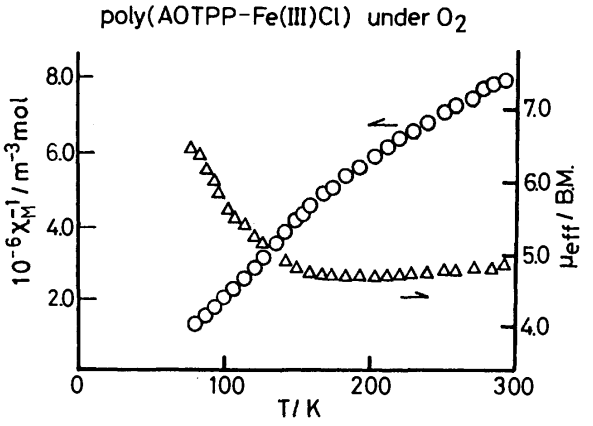

Fig. 11. Temperature dependence of χ_M^{-1} and μ_{eff} of polyAOTPP-Co(II) in the presence of molecular oxygen.

The temperature dependences of χ_M^{-1} and μ_{eff} of polyAOTPP-Co(II) under 20 mmHg O_2 was not different from those in the absence of O_2 at temperatures higher than 250 K, but they were markedly different from that in the absence of O_2 below 200 K (Fig. 6). Magnetic moment μ_{eff} increased from 2.5 BM to 3.3 BM with lowering the temperature from 180 K to 70 K. In order to make clear the origin of the abnormal behavior of the magnetic susceptibility under O_2 at low temperature, the O_2 pressure dependence of weight at 77 K was measured at various pressures of O_2 using a magnetic balance. The weight increased on increasing the pressure of O_2, and became a limiting value at pressures higher than 70 mmHg, in which the ratio of O_2 to Co(II) ion is almost 1.0. The pressure dependence of the adsorbed O_2 shows a Langmuir type isotherm curve. This result shows that there is special interaction between Co(II) and O_2. The ESR spectrum of polyAOTPP-Co(II) was measured in the presence of O_2 and compared with that in vacuum, as shown in Fig. 12. The ESR spectrum of polyAOTPP-Co(II) under O_2 shows the appearence of a new absorption band at 3350 G (g=2.01) in addition to that in the absence of O_2. The intensity of the new resonance line increased on lowering the temperature. Similar ESR spectra have been observed in oxygen-containing samples of tetrakis(*p*-methylphenyl)-porphine and tetrakis(*p*-methoxyphenyl)porphine in toluene-glass with *N*-substituted imidazole and amine,[24] and have been ascribed to the O_2 adduct prepared by chemical adsorption of O_2 on five-coordinated amine-Co(II) complex.[24,35] Since the ESR spectrum of polyAOTPP-Co(II) in vacuo showed the presence of the five-coordinated TPP-Co(II) moieties, the new resonance line at 3350 gauss in the presence of O_2 can reasonably be ascribed to the O_2 adduct of the TPP-Co(II) moiety. For an understanding of the strength of the adsorption of O_2,

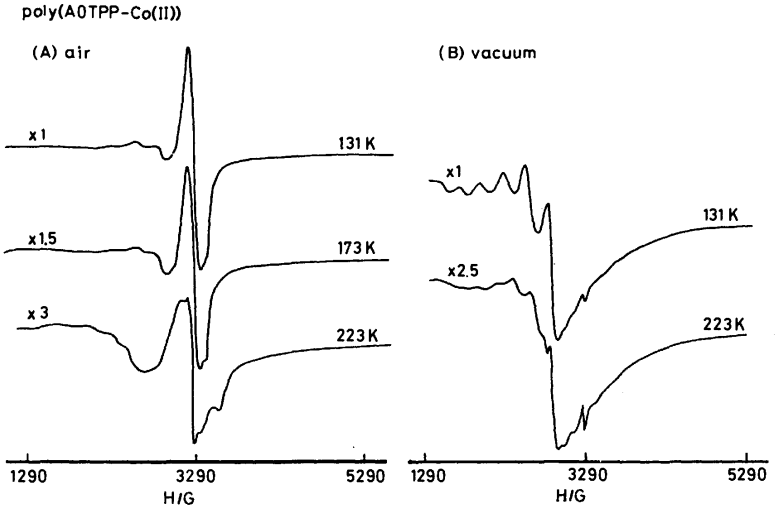

Fig. 12. ESR spectrum of polyAOTPP-Co(II) under molecular oxygen at 77 K.

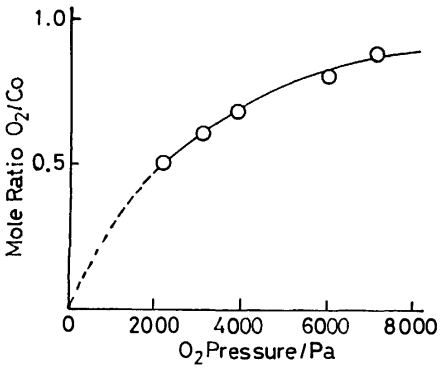

Fig. 13 Oxygen adsorption of polyAOTPP-Co(II) as a function of oxgen pressure at 77 K. (——) Eye-guided line.

the oxygen-pressure dependence of weight of polyAOTPP-Co(II) was measured at various temperatures under 20 mmHg of O_2. The weight of O_2 adsorbed depended on the temperature and reversibly changed on varying the temperature. Therefore, the following relation is considered on the adsorption.

$$\mathrm{Co(II)\cdots O_2} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \mathrm{Co(II)} + \mathrm{O_2} \tag{11}$$

$$k = \frac{k_1}{k_{-1}} = \frac{[\mathrm{Co(II)}][\mathrm{O_2}]}{[\mathrm{Co(II)}\cdots\mathrm{O_2}]} = \frac{[\mathrm{Co(II)}]\,P_{\mathrm{O_2}}}{[\mathrm{Co(II)}\cdots\mathrm{O_2}]} \tag{12}$$

Since the amount of oxygen adsorbed is estimated to be less than 3% of total O_2 of the measuring system even if the TPP-Co(II) moieties adsorb completely O_2, P_{O_2} can resonably be regarded as constant in all experiments. The temperature dependence of K/P_{O_2} is regarded as that of K. Thus, the binding energy for O_2-adsorption was estimated to be 24 kJ mol^{-1} from the temperature dependence of K/P_{O_2}, which corresponds to the chemical adsorption.

Similarly, POTPP-Co(II) adsorbs O_2. Since TPP-Co(II) does not adsorb O_2, it is assumed that the ester group plays an important role for the chemical adsorption of O_2.

The authors would like to express their sincere appreciation to professor Shun-ichi Nozakura, Osaka University, for his encouragement. This work was partly supported by a Grant-in-Aid for Scientific Research on Priority Area "Macromolecule-Complexes (No. 62612001)" from the Ministry of Education, Science and Culture.

ESR Studies on Chain Transfer Reactions: Rate Constants for the Reactions of Model Radicals of Polystyrene Growing Chain Ends with Tetrahalomethanes and Thiophenols

Yoko KUWAE and Mikiharu KAMACHI*
Department of Macromolecular Science, Faculty of Science, Osaka University, Toyonaka, Osaka 560
(Received January 28, 1989)

The absolute rate constants for reactions of the model radicals of the growing chain ends of styrene and methacrylonitrile with tetrahalomethanes and thiophenols were determined by spin-trapping methods using ESR spectroscopy. The model radicals were produced by the photodecomposition of 1,1′-diphenylazoethane and 2,2′-azobisisobutyronitrile. In the case of the styrene model radical, the rate constants for the halogen abstraction reaction from CBr_4, $CBrCl_3$, and CCl_4 were 1.1×10^7, 2.0×10^6, and 1.1×10^5 $M^{-1}s^{-1}$, respectively, and increased with increasing electron affinity of tetrahalomethanes. The rate constants for the hydrogen abstraction reaction from thiophenols were of the order 10^6 $M^{-1}s^{-1}$, independent of the electron-donating and -accepting properties of the para substituents. In the case of the methacrylonitrile model radical, the rate constants for the halogen abstraction reaction from CBr_4 and $CBrCl_3$ were 1.1×10^5 and 4.5×10^3 $M^{-1}s^{-1}$, respectively. The rate constants for the hydrogen abstraction reaction from thiophenols with $-CH_3$, -H, and -Cl substituent in the para position were 4.5×10^4, 2.7×10^4, and 1.7×10^4 $M^{-1}s^{-1}$, respectively. The rate constants decreased with increasing the electron-withdrawing power of the substituent.

It has been well-known that tetrahalomethanes and thiol derivatives are strong chain-transfer reagents for the radical polymerization of styrene.[1,2] Although the chain-transfer constants (C_s) have been determined by the Mayo equation,[1] the values of C_s reported for strong chain-transfer reagents, such as CBr_4 and $CBrCl_3$, have varied over two orders of magnitude.[3-6] From a study of the dependence of C_s on the extent of polymerization, Thomson and Walter[6] pointed out the fact that this deviation is mainly due to the effect of a rapid removal of the transfer reagents on the degree of polymerization, since most of the strong transfer reagents are considered to be consumed at 0.5—0.7% conversion and the subsequent reaction probably similar to bulk polymerization. Since it is difficult to accurately estimate C_s for strong chain-transfer reagents by the Mayo equation, the value of C_s should be evaluated under the conditions where it is not influenced by the extent of polymerization.

Recently, we reported on a method for determining the absolute rate constants of model radicals of the propagating chain ends with tetrahalomethane using a spin-trapping ESR method.[12] In the present work, we applied this method to the halogen- and hydrogen-abstraction of the α-methylbenzyl radical (CH_3-$\dot{C}HC_6H_5$), which is a model radical for the polystyrene end, from tetrahalomethanes and thiophenols.

The absolute rate constant, k_{trs}, provides more direct information concerning the mechanism of the chain-transfer reaction than C_s. An understanding of the mechanism of the chain-transfer reaction to strong transfer reagents possibly provides important information concerning the chemical properties of the propagating radical and the radical reaction control, such as the transformation of a radical reaction to an ionic reaction through the complex formation or electron transfer of the propagating radical to additives. In this paper, therefore, we determined the absolute rate constants for hydrogen abstraction of the 1-cyano-1-methylethyl radical (an electropositive radical) from thiophenols and reevaluated k_x for halogen-abstraction reactions of this radical from halomethanes. Additionally, these rate constants were compared with the corresponding ones of the α-methylbenzyl radical.

Experimental

Materials. 1,1′-Diphenylazoethane was prepared according to the oxidation of the corresponding hydrazine derivatives. 2-(*t*-Butylthio)acrylonitrile was prepared by Viehe's method.[14] Thiophenols, commercially available, were purified by distillation or recrystallization. Azobisisobutyronitrile (AIBN) and tetrahalomethanes were purified as described previously.[12]

The ESR spectra were recorded on a Japan Electron Optics Laboratory Model JES-FE 1X ESR spectrometer under irradiation with a 500-W high-pressure mercury lamp (Ushio 500) at 80 °C. The temperature in the cavity of the ESR spectrometer was controlled with a variable temperature accessory (ES-VT-3A). The simulation for the overlap of two adducts was carried out using a JEOL ESR simulation program (0398) operating on a EC 6 computer.

A solution of an azocompound (2.0×10^{-2}—1.0×10^{-1} M; 1M=1 mol dm^{-3}), a trapping reagent (6.4×10^{-1}—6.4×10^{-3} M), and a transfer reagent (0.9—7.8×10^{-2}M) in toluene was put into a sample tube equipped with an ESR cell (spectrocil 3 mm) in the side arm, degassed by repeated melting and freezing under vacuum, and then sealed. The UV spectra were measured on a Hitachi 124 UV-visible spectrometer. Ionization potentials were measured by photoelectron spectroscopy with calibration by xenon as an internal standard (IP 12.130 eV).

An estimation of the kinetic parameter was carried out by a computer calculation using a nonlinear least-square method, whose program was Sals II written by Nakagawa et al. (Tokyo University).

Results

Addition Reaction of α-Methylbenzyl Radical to 2-(*t*-Butylthio)acrylonitrile. Figure 1 shows the ESR spectrum observed under irradiation of a mixture of 1,1′-diphenylazoethane and 2-(*t*-butylthio)acrylonitrile, a spin-trapping reagent (T). The ESR spectrum of a triplet of triplets of doublets with hyperfine splitting constants of 1.1, 0.28, and 0.08 mT, respectively, was reasonably assigned to the adduct of the model radical of the polystyrene propagating end to T.[12,14] The change in the ESR spectrum with the reaction time showed that the concentration of the adduct became stationary within several minutes after irradiation. The signal due to the α-methylbenzyl radicals (M·) could not be detected, indicating that the stationary concentration of M· was negligibly small, as compared with that of the adduct (MT·). Therefore, the bimolecular self-termination of M· was not taken into account in the kinetic treatment. Thus, the reactions are shown in Eqs. 1 to 4:

$$\text{M-N=N-M} \xrightarrow{I} \text{M}\cdot \qquad I\text{: Rate} \qquad (1)$$

$$\text{M}\cdot + \text{T} \xrightarrow{k_1} \text{MT}\cdot \qquad (2)$$

$$\text{MT}\cdot + \text{M}\cdot \xrightarrow{k_2} \text{product} \qquad (3)$$

$$\text{MT}\cdot + \text{MT}\cdot \xrightarrow{k_3} \text{product} \qquad (4)$$

The assumption of the steady state for the concentrations of M· and MT· leads to

$$[\text{T}] = \frac{k_2}{k_2} \frac{[\text{MT}\cdot](1+k_3/I[\text{MT}\cdot]^2)}{(1-k_3/I[\text{MT}\cdot]^2)}. \qquad (5)$$

The relation between the stationary concentration of MT· and T is shown in Fig 2. Ratios k_2/k_1 and k_3/I were determined from Eq. 5 by a computation using the data shown in Fig. 2: results are shown in Table 1,

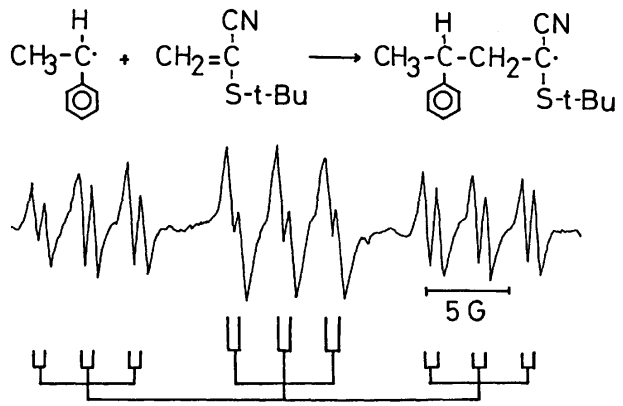

Fig. 1. ESR spectrum observed on irradiation of a mixture of 1,1′-diphenylazoethane and 2-(*t*-butylthio)acrylonitrile (T) in toluene at 80 °C. [1,1′-diphenylazoethane]=5×10⁻² M and [T]=0.64 M.

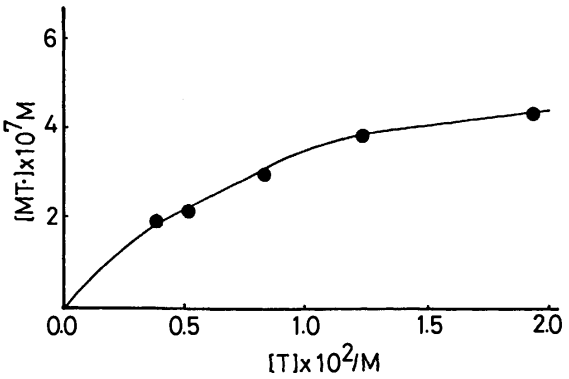

Fig. 2. Relation between MT· and T concentrations at 80 °C. [1,1′-diphenylazoethane]=5.0×10⁻² M.

along with data for AIBN. The value of k_3/I for the reaction of 1,1′-diphenylazoethane is larger than that of AIBN. The difference is probably due to the difference in *I*.

Halogen- and Hydrogen-Abstraction Reaction of the Model Radical from Tetrahalomethanes and Thiophenols. The intensity of the ESR spectra of the adducts (MT· and RT·) was much lower in the absence of UV light irradiation at 80 °C than that under UV irradiation. Accordingly, the adducts obtained thermally were neglected in the kinetic study under UV light irradiation. Figure 3 shows a typical example

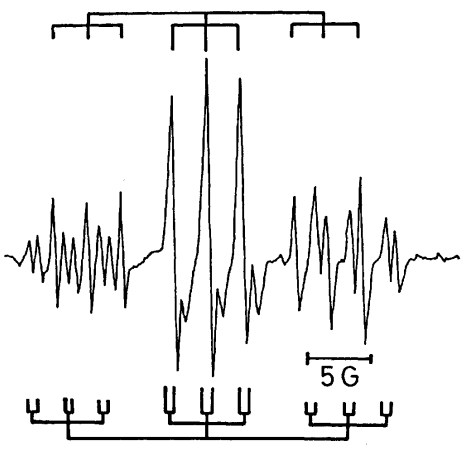

Fig. 3. ESR spectrum observed on the UV irradiation of a mixture of azo compound, thiophenol, and T in toluene at 80 °C. [1,1′-diphenylazoethane]=8.0×10⁻² M, [thiophenol]=8.0×10⁻² M, and [T]=0.32 M.

of the ESR spectra observed upon irradiating a mixture of thiophenol, 1,1′-diphenylazoethane, and T. The spectrum (Fig. 3) showed an overlap of a triplet of triplets of doublets and a triplet of triplets, which were reasonably assigned to the adducts of the α-methylbenzyl radical and the sulfur-centered radical produced from thiophenol,[12,14] respectively. An overlap of two kinds of a triplet of triplets was observed in a mixture of thiophenol, AIBN, and T, which was assigned to the adducts of the 1-cyano-1-methylethyl radical and the sulfur-centered radical. Similar spectra were observed in mixtures of azo compounds, tetrahalomethane and T.[12] The hyperfine splitting constants of the adducts are shown in Table 2. The reactions are shown in the following schemes:

$$M\text{-}N{=}N\text{-}M \xrightarrow{I} M\cdot \quad (1)$$

$$M\cdot + T \xrightarrow{k_1} MT\cdot \quad (2)$$

$$M\cdot + RX \xrightarrow{k_x} MX + R\cdot \quad (6)$$

$$R\cdot + T \xrightarrow{k_{1x}} RT\cdot \quad (7)$$

$$RT\cdot + RT\cdot \xrightarrow{k_3} RTTR \quad (8)$$

$$RT\cdot + MT\cdot \xrightarrow{k_3} RTTM \quad (9)$$

$$MT\cdot + MT\cdot \xrightarrow{k_3} MTTM \quad (10)$$

Since M· and R· were not observed in the ESR spectra, the self-coupling reactions of these radicals were not taken into account. The stationary state treatment on R·, RT·, and MT· yields

$$\frac{[RT\cdot]}{[MT\cdot]} = \frac{k_{1x}[R\cdot][T]}{k_1[M\cdot][T]} = \frac{k_x[RX]}{k_1[T]}. \quad (11)$$

A typical example of a plot of [RT·]/[MT·] vs. the concentrations of transfer reagents is shown in Fig. 4. A linear relation was observed, the ratio, k_x/k_1, being calculated from the slope. Results are shown in Tables 3 and 4. Since the kinetic parameters obtained so far were k_x/k_1, k_2/k_1, and k_3/I, the absolute rate constants of each elementary process could not be directly estimated. If k_2 can be evaluated, k_1 could be estimated from k_2/k_1, and then k_x from k_x/k_1 using the obtained k_1. However, it is hard to directly measure the cross-coupling rate constant (k_2). If self-coupling reactions of M· and MT· are determined, the rate constants of a cross-coupling reaction can generally be estimated as the geometrical mean of the self coupling constants:

$$k_2 = (k_3 k_M)^{1/2}, \quad (12)$$

where k_M and k_3 are the rate constants for the self-coupling reactions of M· and MT·, respectively.

The k_M's for $CH_3\dot{C}HC_6H_5$ and $(CH_3)_2\dot{C}CN$ have already been reported to be 4.7×10^9 $M^{-1}s^{-1}$ [15] and 8×10^9 $M^{-1}s^{-1}$,[16] respectively. We determined k_3 to be $6.5\pm3\times10^8$ $M^{-1}s^{-1}$ as an average of data for 5 radicals estimated in a previous paper.[12] Accordingly, k_2's for these reactions were estimated from Eq. 12, being

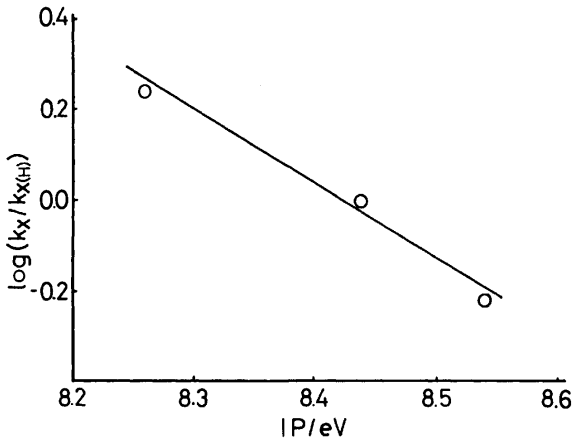

Fig. 5. Relation between rate constants and ionization potentials of thiophenols in the hydrogen abstraction reactions of $(CH_3)_2\dot{C}CN$ from the S-H bonds.

5.5×10^9 M^{-1} s^{-1} and 4.2×10^9 M^{-1} s^{-1} for $CH_3\dot{C}HC_6H_5$ and $(CH_3)_2\dot{C}CN$, respectively. Then, the k_1's were estimated from k_1/k_2 and the k_x's from k_x/k_1 (Table 5). It can be seen that the k_x's for reactions between $CH_3\dot{C}HC_6H_5$ and tetrahalomethanes decreased in the order $CBr_4>CBrCl_3>CCl_4$: k_x of $CH_3\dot{C}HC_6H_5$ with CBr_4 was 6 and 10^2 times as large as those with $CBrCl_3$ and CCl_4, respectively. A similar trend in k_x for the halogen-abstraction reaction of $(CH_3)_2\dot{C}CN$ from tetrahalomethanes was observed (Table 5). The k_x's for the reaction of $CH_3\dot{C}HC_6H_5$ with CBr_4 and $CBrCl_3$ were about 50 and 200 times as large as those of $(CH_3)_2\dot{C}CN$ with the corresponding tetrahalomethanes, respectively.

In the case of thiophenols, k_x's of $CH_3\dot{C}HC_6H_5$ were in order of 10^7, being independent of the nature of para substituents (Table 6), while k_x's of $(CH_3)_2\dot{C}CN$ were in the order of 10^5 and decreased with electron-accepting substituents. The value of $\ln k_x$ for $(CH_3)_2\dot{C}CN$ was linearly correlated with the ionization potential of thiophenols (Fig. 5).

Discussion

To our knowledge, the absolute rate constants for the halogen-abstraction reaction of carbon radicals from tetrahalomethanes have been reported for only a few radicals, such as the methyl, *t*-butyl,[17] and phenyl radicals.[18,19] Therefore, we could not check the reliability of our data by comparison with other data. The k_x's for the halogen-abstraction reaction of the phenyl radical from CBr_4 and CCl_4 have been reported to be 5×10^9 [19] and 5.8×10^6 M^{-1} s^{-1},[18] respectively, two orders of magnitude larger than the corresponding k_x of $CH_3\dot{C}HC_6H_5$, (Table 5). This difference can reasonably be explained by the lower reactivity of $CH_3\dot{C}HC_6H_5$ due to resonance stabilization than that of the phenyl radical. The k_x's for the halogen abstraction reactions of $CH_3\cdot$, $(CH_3)_3C\cdot$, and $(CH_3)_2\dot{C}OCH_2CH_3$ from CCl_4 have been reported to be 3.35×10^2 (80 °C),[7] 4.9×10^4 (30 °C),[17] and 1.0×10^8 M^{-1} s^{-1},[20] respectively. The k_x of $CH_3\dot{C}HC_6H_5$ from CCl_4 is larger than that of $\cdot CH_3$, and less than that of $(CH_3)_2\dot{C}OCH_2CH_3$. The k_x of $CH_3\dot{C}HC_6H_5$ at 80 °C is twice as large as that for $(CH_3)_3\dot{C}$ at 30 °C. When the k_x of the latter radical at 80 °C is calculated on the assumption that its activation energy is 13.8 kJ mol^{-1},[17] it is estimated to be 1.06×10^5 M^{-1} s^{-1}, being of the same order as the k_x for the former. The k_x for the halogen abstraction reaction of carbon radicals has been found to be of the following order:

$$(CH_3)_2\dot{C}OCH_2CH_3>\dot{C}(CH_3)_3=CH_3\dot{C}HC_6H_5>\dot{C}H_3.$$

This order seems to be correlated with the electron-donating property of the α-substituents. These results show that our method for the determination of the rate constant of the halogen-abstraction reaction leads to reasonable rate constants. However, when the k_x's of $(CH_3)\dot{C}HC_6H_5$ were compared with the corresponding k_{trs}'s which were calculated from k_p and C_s's for the radical polymerization of styrene, a remarkable difference between k_x and k_{trs} was found (Table 5).

The determination of C_s has usually been carried out using the Mayo equation:[21]

$$1/P_n = 1/P_{n0} + C_s[S]/[M], \quad (13)$$

where P_n and P_{n0} are the number degree of polymerization of the polymer produced in the presence and absence of transfer reagents[S], respectively; [S]/[M] is

the molar ratio of the transfer reagent to the monomer. Thomas et al.[6] pointed out the fact that C_s in a CBr_4-styrene system was dependent on the extent of polymerization: C_s was 420 in the extent of polymerization to 0.5%, and 2.1 when the reaction was performed to 5% conversion. In addition, an accurate determination of the number average degree of polymerization is necessary for an accurate determination of C_s. Since a significant loss of low-molecular-weight polymer obtained in the low extent of polymerization leads to an overestimation of P_n, the C_s obtained by the Mayo equation seems to be smaller than the true value.

When thiophenols were used as chain-transfer reagents, the k_x's for the hydrogen-abstraction reactions of the styrene model radical from thiophenols was of the 10^6 order of magnitude, being consistent regarding the order of magnitude with the rate constant for the hydrogen abstraction of benzyl radical from thiophenol at 80 °C, which was estimated from the rate constant at 25 °C and the activation energy.[22,23] In addition, our results show that the k_x's is one order smaller than its halogen abstraction rate constant from CBr_4.[24] Since the C_s's of thiophenol derivatives have been reported to be one or two orders smaller than that of CBr_4[24] in the radical polymerization of styrene, the k_x for the hydrogen abstraction of α-methylbenzyl radical from thiophenol seems to be reasonable. To our knowledge, only a few absolute rate constants for the hydrogen abstraction of carbon radicals from thiophenol have been reported: The k_x's of the hydrogen-abstraction of phenyl, butyl, octyl, isopropyl, and *t*-butyl radicals from thiophenol are 1.9×10^9,[18] 1.36×10^8,[23] 9.2×10^7,[23] 1.05×10^8,[23] and $8.0\times10^7=1.47\times10^8$ [23] $M^{-1}s^{-1}$, respectively. These values are one or two orders of magnitude larger than the k_x of $CH_3\dot{C}HC_6H_5$. This styrene model radical is considered to be less reactive than phenyl radical and alkyl radicals, since the former radical is more stabilized through a delocalization of unpaired electron than the latter radicals. Accordingly, the difference in the rate constants between the model radicals and the others can be reasonably explained on the basis of the stabilization of the radical.

The k_x of $(CH_3)_2\dot{C}CN$ with thiophenols were an order of magnitude of 10^2 smaller than that of $CH_3\dot{C}HC_6H_5$, being dependent on the nature of the substituent binding to the benzene ring of thiophenol: the larger the electron-donating property of the substituent, the larger the k_x. The values of $\ln k_x$ were linearly correlated with the ionization potential of thiophenols. This result suggests the possibility that the hydrogen abstraction of $(CH_3)_2\dot{C}CN$ from thiophenol takes place through electron transfer or the charge-transfer complex of the radical. The k_x for the halogen abstraction of the styrene model radical from thiophenols might be too large for the substituent effect to be observed.

In conclusion, the rate constants for the halogen-abstraction reaction of the model radicals from tetrahalomethanes decreased in the order

$$CBr_4 > CBrCl_3 > CCl_4.$$

The rate constants (k_x) obtained by this method were larger than the corresponding chain-transfer rate constants (k_{trs}) calculated from the largest C_s and propagation rate constants of styrene (k_p).[12] This difference between k_x and k_{trs} can possibly be ascribed to an underestimation of C_s due to the removal of a fraction of a lower molecular weight polymer in the determination of the C_s values. In benzenethiols, the hydrogen-abstraction rate constants of the styrene model radical were an order of magnitude of 10^7, being independent of the substituents which were introduced in the para-positions of the aromatic ring; however, the rate constants of the methacrylonitrile model radical were an order of magnitude of 10^4, and decreased with increasing the electron-accepting power of the substituent.

Shock Tube Studies of the H_2-O_2 Reaction by Atomic Resonance Absorption Spectroscopy

Tohru KOIKE
Department of Chemistry, National Defense Academy, Hashirimizu, Yokosuka 239
(Received January 24, 1989)

The increases of O-atoms and of H-atoms in the reaction between H_2 and O_2 in shock waves were measured over the temperature range of 1000—1400 K by atomic resonance absorption spectroscopy. The induction times of the absorptions by these two species were evaluated and computer modeling was carried out to reproduce these values. As one of the initiations of the H_2-O_2 reaction, $H_2+O_2=H+HO_2$ was found to play an important role in the progress of the reaction. The rate constant of this reaction was evaluated as: $k=4.1\times10^{16}$ exp(−285 kJ/RT) $cm^3 \cdot mol^{-1} \cdot s^{-1}$.

The reaction of H_2-O_2 in shock waves has been studied in a wide temperature range by many researchers and is well-known to proceed through chain initiations, chain branchings, and chain terminations. Although reliable rate constants are proposed for most of the important elementary reactions of each step,[1] some of them are still controversial.

Atomic resonance absorption spectroscopy (ARAS) is very sensitive and concentrations of O-atoms and H-atoms of about 10^{-12} mol·cm^{-3} can be detected. Most of the studies by ARAS have been made to clarify the reaction of reactants highly diluted in Ar, e.g., ppm order. Two points could be given for the advantage in using the ARAS under such experimental conditions. One is that the reactions intended to measure should not be affected by secondary reactions. The other is that temperature variation by the progress of the reaction could be almost avoided. Detailed reviews of shock tube studies using this technique have recently been given by Just.[2]

ARAS has also been applied to the kinetic study of the H_2-O_2 reaction by Pamidimukkala and Skinner in the temperature range of 1919—2781 K[3] and by Frank and Just in the temperature range of 1700—2500 K.[4] They measured the test gas mixtures of $H_2/N_2O/Ar$ with or without O_2. Since the reaction mechanisms are specifically devised to explain the experimental result thus obtained, some of the elementraty reactions which are important under ordinary conditions are excluded from the reaction mechanisms.

We also applied ARAS to the H_2-O_2 reaction at lower temperatures than those of these two studies. Due to the slowness of growth rates of O- and H-atoms under such conditions at lower temperatures, these atoms are produced only in small amounts. We had to use test gas mixtures of rather higher concentrations of reactants than those previously used for ARAS. Thus, we could study the early stages of the reaction and could obtain the rate constant of $H_2+O_2=HO_2+H$.

Experimental

The test section of the rectangular shock tube used in a former study[5] on incident shock waves was reconstructed so as to be applicable to the ARAS measurements as follows.

Observation windows were located 3.3 m down-stream from the diaphragm section. Two of the 4 observation windows, made of MgF_2, had two vacuum tight flanges for the ARAS. A quartz tube was connected perpendicularly to one of the windows. A rotary pump was used to let gas mixtures of H_2 or O_2 diluted in He by 1% flow at 2 Torr (1 Torr ≈ 133.322 Pa) through the quartz tube. A microwave generator (Raytheon, PGM10×1) was used to discharge the gas mixture and the emissions were used as the light source of the ARAS. For the other window, a vacuum-UV-monochromator (Minuteman, 302-VM, dispersion=40 nm mm^{-1}) was located to isolate the desired emission lines centered at 121.6 nm for the Lyman-α line of H-atoms and at 130.5 nm for the O-triplet line of O-atoms. The VUV monochromator having entrance and exit slits of 1 mm width was evacuated to about 5×10^{-4} Torr using a rotary pump combined with a liquid-N_2 trap. A solar blind photomultiplier (Hamamatu, R-1459) was used as a detector. The signals from the detector were fed into an operational amplifier, and then, recorded on a digital oscilloscope (Iwatsu, DS-6121) combined with an XY-recorder.

The test section of the shock tube was evacuated to less than 10^{-5} Torr before each run. Gases for the test gas were 99.999% pure H_2, 99.999% pure O_2, and 99.999% pure Ar and were used without further purification. The compositions of the two test gases prepared are shown in the footnote of Fig. 3.

A trial run with a test gas of pure Ar was carried out and it was confirmed that no appreciable absorption was observed under the present experimental conditions. With regard to the absorptions of test gas mixtures of O_2/Ar and H_2O/Ar in the present temperature range, only small absorptions at the shock front attributable to O_2 and H_2O were observed.

Results and Discussion

Figure 1 is a sample oscillogram exhibiting the time profile of the absorption at 130.5 nm. The absorption occurs immediately after the shock arrival to the observation window; it holds a plateau value and then increases exponentially to a high value. From the oscillograms, the absorption at the shock front and the induction times, τ, defined as the time interval between the shock arrival to the observation window

Octagonals: $H_2/O_2/Ar=1.1/5.8/93.1$.
Lines through each data point show least squares fit. Computer modeling was done to reproduce these lines.

and the foot of the exponential absorption rise, were evaluated.

The absorption at the shock front can be attributed to the absorption by O_2, since the absorption by H_2 is reported to be negligible.[4] Figure 2 shows the absorptivity, a, evaluated from the absorption as: $a=\ln(I_0/I)/(d[O_2])$, where I_0=incident light intensity. I=transmitted light intensity at the shock front, and d=optical path length. There seems to be no temperature dependence for the a values at 130.5 nm. The a values of O_2 for the Lyman-α line at 121.6 nm are also shown in the figure. These a values are smaller than those at 130.5 nm and are seen to increase with temperature. The thick lines are extrapolated values from the reported ones[4] obtained at much higher temperatures than the present. It is seen that the present values and the extrapolated values are close to each other. Thus, the present optical system can be considered to be working well.

Figure 3 shows the temperature dependence of τ evaluated from the absorption time profile at 130.5 nm. It is seen that the temperature dependence of τ is almost the same for the two mixtures investigated. As for the absolute value of τ, it gets smaller with larger concentration of O_2. The lines are the least-squares fit for the data points.

The results shown in Fig. 3 were subjected to interpretation by computer modeling. The induction times by modeling were evaluated from the time profile of the modeled O-atom concentration, i.e., the reaction time when the concentration value reaches 1.66×10^{-12} mol·cm^{-3} for the O-atom was assumed to correspond to the induction time.[4]

The computer program used in modeling is the same one as was used in the former study.[5] In the modeling, numerical integration is carried out by taking into account both the forward and reverse rates of each elementary reaction, and the reverse rate constants are calculated from the forward rate constants combined with equilibrium constants based on appropriate thermochemical data.[6]

Warnatz et al.[1,7] has recently reviewed the reaction mechanism of H_2-O_2 and recommended the rate constants of Reactions 2—11 which are valid over the temperature range of 1000—2500 K as shown in Table

Table 1. Reaction Mechanism and Rate Constant
$k=A\,T^n \exp(-E/RT)$
(mol, cm, s, and J units)

Reaction	A	n	E	W[a]	PS	FJ
1) $H_2+O_2=H+HO_2$	4.1 +16[b]	0	2.85+5	*		
2) $H_2+AR=H+H+Ar$	2.2 +14	0	4.0 +5	*	*	*
3) $O_2+AR=O+O+Ar$	1.2 +14	0	4.5 +5	*	*	*
4) $H+O_2=OH+O$	1.22+17	−0.91	6.91+4	*	*	*
5) $O+H_2=OH+H$	1.5 + 7	2.0	3.16+4	*	*	*
6) $OH+H_2=H_2O+H$	1. + 8	1.6	1.38+4	*	*	*
7) $H+O_2+AR=HO_2+Ar$	7. +17	−0.8	0	*	*	
8) $OH+OH=H_2O+O$	1.5 + 9	1.14	0	*	*	
9) $H+HO_2=OH+OH$	1.5 +14	0	4.2 +3	*		
10) $OH+HO_2=H_2O+O_2$	2. +13	0	0	*		
11) $O+HO_2=OH+O_2$	2. +13	0	0	*		

a) The reactions designated by * in the last three columns are those adopted by Warnatz (W), Pamidimukkala and Skinner (PS), and Frank and Just (FJ). b) The number after + exhibits an index for 10.

1. We tried to reproduce the τ values in Fig. 3 by computer modeling adopting his mechanism. As for the rate constant of Reaction 1, we adopted the value of the reverse direction, k_{-1}, recommended also by Warnatz.[1] It was found that the τ values by modeling thus carried out are larger than those measured. The present τ values could not also be reproduced using the two reaction mechanisms which are in accordance with the results by ARAS,[3,4] as described above. It can be pointed out that the two reaction mechanisms are for much higher temperatures than the present. Any of the reactions, which are important in the present lower temperature range, are expected to be ignored or treated to have a small role in their reaction mechanisms. As for the test gas mixtures measured by ARAS, N_2O was used as oxidizer with or without O_2. Since the concentration of O_2 seems to be small in the mixtures without O_2, chain termination, Reaction 7, was not taken into account in the reaction mechanism by Frank and Just.[4] With regard to the initiation reactions, $H_2+O_2=OH+OH$ was taken into account by Frank and Just.[4] In the reaction mechanism proposed by Warnatz, the reverse reaction of $H+HO_2=H_2+O_2$, Reaction 1, can also be a chain initiation. He did not, however, specify the kind of product of Reaction 1. Among the three reaction mechanisms considered, the mechanism giving the closest τ values in Fig. 3 is that of Frank and Just.[4] Since rate constants of important reactions are not so different from each other over the present temperature range, such a discrepancy between the values by experiment and those by modeling could be attributed to whether appropriate initiation reactions were taken into account in the reaction mechanism.

We accepted the rate constants by Warnatz[1] and assumed Reaction 1 to be one of the chain initiations in the H_2-O_2 reaction. The rate of the reaction having a four-center path, $H_2+O_2=OH+OH$, can be considered to be small,[8] since this reaction has much higher activation energy than Reaction 1 does. Then, we only changed the k value of Reaction 1 so as to be in accord with the least squares lines in Fig. 3 and finally we succeeded in modeling them with the following value for k_1.

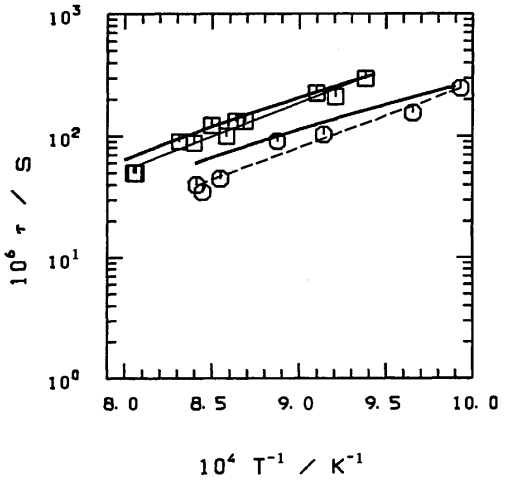

Fig. 4. τ obtained at 121.6 nm vs. $10^4/T$.
Symbols are the same as those in Fig. 3.
Lines through each data point show least squares fit. Thick lines show the values by computer modeling using the reaction mechanism in Table 1.

$$k_1=4.1\times10^{16}\exp(-285\ \mathrm{kJ}/RT)\ \mathrm{cm^3\cdot mol^{-1}\cdot s^{-1}}$$

The reaction mechanism of the 11 elementary reactions shown in Table 1 is the conclusion of this study and the lines in Fig. 3 are the results of modeling, which agree well with the experiment.

Figure 4 shows the relation between the τ values of the absorption by H-atoms and $10^4/T$. Since the absorption by H-atoms is larger than that by O-atoms, the temperatures of the data points are seen to be shifted to a lower region than those by O-atoms shown in Fig. 3. The two thin lines are least-squares fits to the data points. The thick lines are obtained by computer modeling using the reaction mechanism in

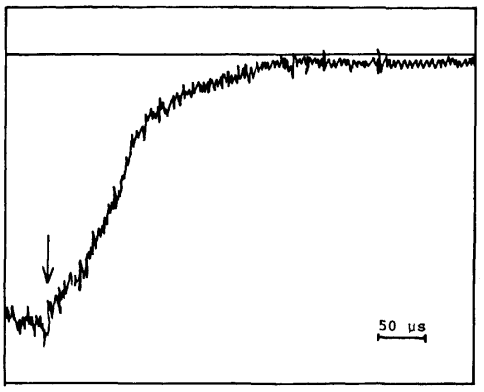

Fig. 5. A sample oscillogram showing the absorption at 121.6 nm by H-atoms.
Test gas: $H_2/O_2/Ar=4.8/1/94.2$
$P_1=20$ Torr, $T_2=1288$ K
The upper line shows the zero-level of the incident light intensity. The arrow shows the shock front.

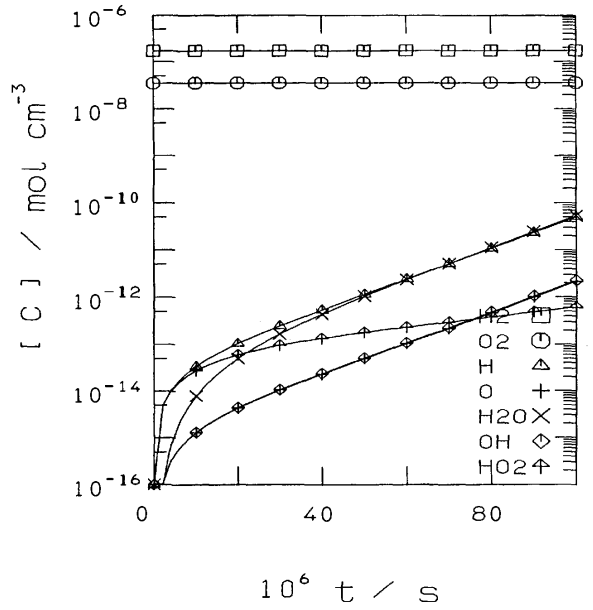

Fig. 6. Computer modeling for the absorption profile shown in Fig. 5.
It is seen that the concentration of H-atoms at 50 μs is above the threshold value of 8.3×10^{-13} mol·cm^{-3}.

Table 1. The threshold value of the H-atoms was assumed to be 8.3×10^{-13} mol·cm^{-3}.[4] Although the relation between experiment and modeling is seen to be good for most the cases, a complete agreement between them was not established.

We could obtain an agreement of the τ values between experiment and modeling for O-atoms and H-atoms as above. Therefore, it can be concluded that the threshold values of concentrations of these two species[4] assumed for modeling are appropriate in the present case.

Figure 5 is an oscillogram showing the absorption of the Lyman-α line obtained at much higher temperatures than that of Fig. 1. The absorption at 50 μs (lab. time) is seen to occur and can be attributed to H-atoms. We compared this with the result by computer modeling using the reaction mechanism in Table 1 under the same experimental conditions of Fig. 5. The concentration profiles of each species thus obtained are shown in Fig. 6. It is seen that the concentration of H-atoms at 50 μs is larger than the threshold value of 8.3×10^{-13} mol·cm^{-3}. If a smaller value was assigned for the k_1, the concentration at 50 μs obtained by modeling fell below the value of the detection limit. The absorption by H-atoms at 50 μs must be unobservable in this case. Therefore, it is confirmable also on the basis of such a degree of absorption that Reaction 1 plays an important role as a chain initiation in the reaction mechanism of H_2-O_2.

It should be pointed out that the present k_1 does not agree with literature values.[1,9] Baulch et al.[9] recommended the k_1 value. The present k_1 is larger than their value extrapolated to the temperature range of this study by almost one order. With regard to the extrapolated k_1 value derived from the k_{-1} by Warnatz,[1] it does not accord with the value in Table 1 either. These literature values are considered to be valid below 1000 K, though not in the present temperature range.

It is also seen from Fig. 6 that the concentrations of reactants, H_2 and O_2, do virtually remain constant even if the reaction passes through the time τ. In accordance with this figure, modeling also indicates that the reaction temperature does not change at all and equals that of the shock front. Such experimental conditions of a constant temperature above 1000 K with very small concentrations of H- and O-atoms continuing a few hundred μs may give a reaction environment to study reactions between such atoms and any interesting species. Therefore, it can be inferred that this study might have introduced a new way of shock tube research using ARAS.

The author wishes to thank Prof. Kihei Morinaga, National Defense Academy, for his useful discussions and continuous encouragement throughout this work. The author wishes also to thank important comments of reviewers concerning the initiation step of the H_2-O_2 reaction.

Gel Filtration Chromatographic Study of Micellar Growth of Polyethylene Glycol Dodecyl Ethers

Noriaki FUNASAKI,* Sakae HADA, and Saburo NEYA
Kyoto Pharmaceutical University, Yamashina-ku, Kyoto 607
(Received February 4, 1989)

The aggregation properties of polyethylene glycol dodecyl ethers ($C_{12}E_n$; n=4, 5, and 8) are investigated with frontal gel (Sephadex G-200 and Sephacryl S-500) filtration chromatography (GFC) at 25 °C. At the trailing boundary of derivative GFC patterns for $C_{12}E_5$, unusual two peaks of micelles appear together with a peak of monomer. These micellar peaks are assigned to two types of micelle, viz., large (R_h=30 nm) and small (R_h=5 nm) micelles. As the $C_{12}E_5$ concentration is increased, the peak height for the large micelle increases more rapidly than that for the small micelle. Analysis of the centroid elution volume data by asymptotic theory reveals that the large micelle is the hexamer of the small micelle. This conclusion is supported by computer simulations of the GFC patterns, based on plate theory. In the derivative pattern of the trailing boundary for $C_{12}E_8$, the micellar peak becomes sharper and shifts to larger elution volume side, with increasing concentration. This pattern is well simulated with the assumption of linear concentration dependence of the micellar elution volume. Micelle size of $C_{12}E_8$ appears to remain constant. For $C_{12}E_4$, which is hydrophobically adsorbed on the gels, huge micelles coexist with a small amount of large micelles (R_h=33 nm).

In spite of the large amount of research that has been carried out by using a number of experimental techniques, it is still a matter of controversy if the aggregation number of nonionic surfactant micelles increases or not with increasing surfactant concentration.[1-17] For polyethylene glycol dodecyl ethers ($C_{12}E_n$) at 25 °C, Tanford et al. reported that micellar growth occurs only at $n \leqq 6$.[1] Hexaethylene glycol dodecyl ether ($C_{12}E_6$) has therefore become one of the most extensively investigated nonionic surfactants.[2] Experimental techniques applied for investigations of pentaethylene glycol ($C_{12}E_5$) and octaethylene glycol ($C_{12}E_8$) dodecyl ethers include static (SLS)[3-8] and dynamic (DLS)[7-9] light scattering, nuclear magnetic resonance (NMR),[8-10] static (SNS)[11,12] and dynamic (DNS)[11] neutron scattering, fluorescence decay (FD),[13] fluorescence quenching (FQ),[13] sedimentation velocity (SV), viscosity (VIS),[1,6] gel filtration chromatography (GFC),[1] electron paramagnetic resonance (EPR),[14,15] vapor pressure osmometry (VPO),[16] and electric birefringence.[17] There is general agreement that the $C_{12}E_8$ micelle little grows at 25 °C, but the contradiction remains unsolved for $C_{12}E_5$. For $C_{12}E_5$, EPR[14] and VPO[16] data were interpreted as showing that the $C_{12}E_5$ micelle remains small independently of concentration, whereas SLS[4,5,8,9] and NMR[8] data suggested that $C_{12}E_5$ micelles are polydisperse and increase with increasing concentration.

Two models for micellar growth have been proposed. One is multiple equilibrium model, which assumes that size of large micelles are highly polydisperse and increases with increasing concentration.[18] The second is secondary aggregation model, which assumes that size of large micelles is almost monodisperse and remains constant independently of concentration.[1,2,8,19] The former model denies the presence of the second critical micelle concentration, whereas the latter predicts it.[19]

The advantage of GFC as well as SV over other techniques is to separate mixtures different in size. For the quantitative analysis of GFC patterns for self-associating systems, the large sample size (frontal) method is generally used.[2,20] The small sample size (zonal) method showed that the $C_{12}E_8$ micelle does not grow with increasing concentration at 25 °C.[1] The $C_{12}E_6$ micelle was investigated by both the zonal and frontal methods. The zonal method showed that this micelle grows.[1] The frontal method showed that small and large micelles coexist in equilibrium with each other.[2]

In this work, we investigate aggregation behavior of $C_{12}E_5$, $C_{12}E_8$, and tetraethylene glycol dodecyl ether ($C_{12}E_4$) by the frontal GFC method at 25 °C. In the derivative elution pattern, only one micellar peak is observed for $C_{12}E_8$, whereas two separate micellar peaks are present for $C_{12}E_5$ and $C_{12}E_4$. These results will be analyzed by the asymptotic and plate theories that we have already developed.[2,20]

Theoretical Basis

Secondary Aggregation Model for Micellar Growth. Multiple equilibrium model, which takes into consideration all aggregated species, will be formally the most comprehensive theory for micelle formation.[18] Secondary aggregation model,[19] which will be described below, may be regarded as a special case of this theory.

A small micelle may be formed from m_1 monomers as follows:

$$\underset{C_1}{m_1 \text{ monomers}} \overset{K_1}{\rightleftarrows} \underset{C_2}{\text{small micelle}} \tag{1}$$

and

$$K_1 = C_2/C_1^{m_1}. \tag{2}$$

A large micelle may be formed by the aggregation of m_2 small micelles:

$$m_2 \text{ small micelles} \underset{C_2}{\overset{K_2}{\rightleftarrows}} \underset{C_3}{\text{large micelle}} \quad (3)$$

and

$$K_2=C_3/C_2^{m_2}. \quad (4)$$

The total concentration C_0 of surfactant may be written as

$$C_0=C_1+C_2+C_3, \quad (5)$$

where all concentrations are expressed on a monomer basis. When m_1 is very large, we can use the approximation of C_1=cmc.

GFC Patterns for Micellar Systems. According to asymptotic theory,[2,20] the centroid volume V_c is defined as

$$V_c=\int_0^{C_0} V\mathrm{d}C/C_0, \quad (6)$$

where V represents the volume flow through the column since introduction of the sample's leading edge. For the above system, V_c can be written as

$$V_c=(C_1V_1+C_2V_2+C_3V_3)/C_0, \quad (7)$$

where V_1, V_2, and V_3 denote the elution volumes of the monomer, the small micelle, and the large micelle, respectively. By using the approximation of C_1=cmc, one can obtain

$$C_2=[C_0(V_c-V_3)+\mathrm{cmc}(V_3-V_1)]/(V_2-V_3) \quad (8)$$

and

$$C_3=[C_0(V_2-V_c)+\mathrm{cmc}(V_1-V_2)]/(V_2-V_3). \quad (9)$$

By using Eqs. 4, 8, and 9, we can determine m_2 and K_2 from GFC elution volume data.

A gel column may be regarded to consist of n successive plates, and each plate is composed of the stationary gel phase and the mobile aqueous phase. This plate theory has been reported for micellar systems in detail.[20] The void volume V_0 and the number n of plates are required for computer-simulation based on this theory. The derivative elution curve provides more detailed information than the original curve.[2,20] For the above micellar system, the plate theory can simulate the derivative pattern.[2,20]

Experimental

Materials. Homogeneous samples of $C_{12}E_8$, $C_{12}E_5$, and $C_{12}E_4$ were obtained from Nikko Chemicals. The purities of these samples were determined to be 99% or more by a Shimadzu GC-8A gas chromatograph. Sephadex G-200 and Sephacryl S-500 were purchased from Pharmacia Fine Chemicals. Blue dextran used for the determination of the void volume was obtained from Pharmacia. Proteins (Sigma) and beads (Dow Chemical Co.) whose hydrodynamic radii R_h (nm) are known were used for the determination of R_h's of micelles; R_h=1.9 (whale myoglobin type II), R_h=3.5 (bovine serum albumin), R_h=4.6 (yeast alcohol dehydrogenase), R_h=8.5 (thyroglobulin), R_h=10.7 (fibrinogen), and R_h=19 (polystyrene carboxylate modified beads). The ion-exchanged water was twice distilled and degassed before use.

Methods. The four columns shown in Table 1 were used, and the flow rate (cm^3h^{-1}) for each column is 6 (A), 8 (B), 24 (C), and 2.3 (D). The temperature of all columns was controlled at 25±0.2 °C. A sample or eluent was charged with a mini-pump. A large volume of sample over the total gel volume V_t was charged so that a plateau region might appear on the elution curve. Elution was monitored continuously with a refractive index monitor and recorded with a Shimadzu Chromatopac C-R1B data processor, except for column D. For the column D experiments the eluate was collected with a fraction collector and the concentration of $C_{12}E_4$ in each fraction was determined by gas chromatography. The refractive index of surfactant solution showed an approximately linear relationship with concentration. When necessary, a correction was made by using the calibration relationship. The derivative of an elution curve was obtained from slopes at appropriate intervals of V. The experimental procedure of GFC has already been reported in detail.[2]

Computer Simulation. Plate theory was used for simulation of the elution curve and its derivative. The equilibria of micellization and partition of a surfactant between the mobile and stationary phases were assumed to be established instantaneously. The simulation procedure has been reported elsewhere.[2,20]

Results and Discussion

$C_{12}E_5$. The dashed line in Fig. 1a shows a typical elution curve in the trailing boundary region for $C_{12}E_5$ (C_0=1.531 mmol dm^{-3}). Since a large amount of a sample was charged, the concentration of $C_{12}E_5$ in the first plateau region was equal to that of the charged sample. The concentration of $C_{12}E_5$ in the second plateau region is close to the cmc values (mmol dm^{-3}), 0.06[21] and 0.064,[22] as we have already predicted theoretically for micellar systems.[20] The derivative of this elution curve (solid line) shows three maxima and two minima. This pattern is unusual, since all GFC derivative patterns reported up to now have only two maxima due to the monomer and the micelle. The first largest peak (V_{3p}) has an elution volume close to the void volume, and therefore, this may be assigned to a large micelle. The last peak (V_{1p}) has a normal elution volume close to the total volume V_t of column A (Table 1). The second peak (V_{2p}) may be due to a small micelle.

To confirm this unusual result, we carried out a similar experiment on column B. As Fig. 1b shows, a very similar derivative pattern was obtained on column B. The first peak appeared near the void volume of column B (Table 1), and the size and shape of the second peak due to a small micelle are close to those on column A, when the difference in V_t between columns A and B is taken into consideration.

Figure 2 shows the derivative pattern for $C_{12}E_5$ as a function of C_0, obtained on column A. The positions of the three peaks little changed with C_0. The

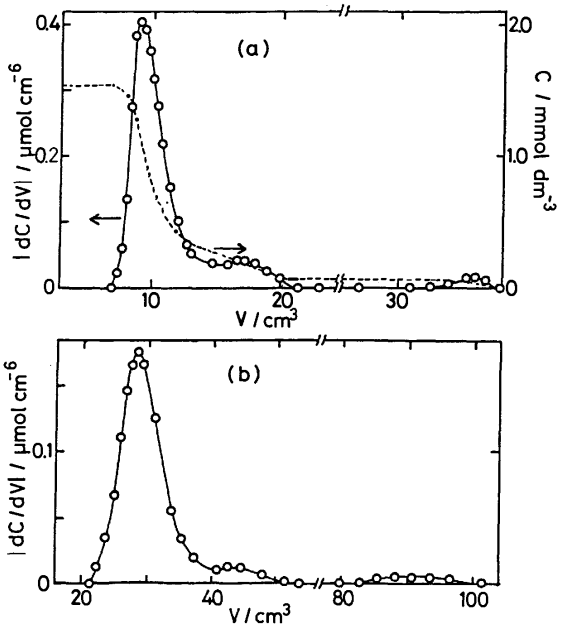

Fig. 1. Elution curve (dashed line) and its derivative (solid line) for $C_{12}E_5$ under two experimental conditions: on column A at C_0=1.5313 mmol dm^{-3} (a) and on column B at C_0=1.530 mmol dm^{-3} (b).

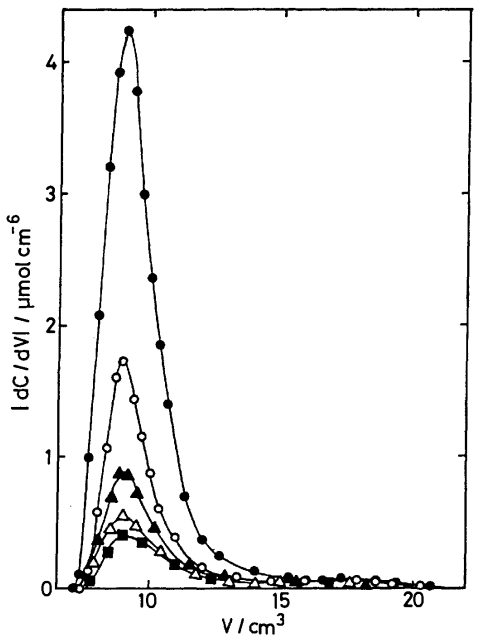

Fig. 2. Derivative elution curves for $C_{12}E_5$ on column A at five charged concentrations (C_0/ mmol dm^{-3}): 1.5313 (■); 1.8829 (△); 2.5676 (▲); 4.2537 (○); 10.6343 (●). The monomer region is omitted.

Table 1. Characteristics of the Columns Used

Column	Gel	Total volume	Void volume	Surfactant
		cm^3	cm^3	
A	G-200	30.2	9.5	$C_{12}E_5$
B	G-200	84.4	30.2	$C_{12}E_5$, $C_{12}E_8$
C	S-500	28.9	9.2[a]	$C_{12}E_4$, $C_{12}E_5$
D	G-200	31.2	9.8	$C_{12}E_4$

a) Estimated as the total volume multiplied by 0.32.

a) Estimated from V_2 for the small micelle. b) Estimated from the micellar peak for the large micelle by using column C.

height of the monomer peak remained unchanged with C_0, whereas those of the small and large micelles increased with increasing C_0 little and markedly, respectively.

Table 2 summarizes the literature values of m and R_h in dilute solution at 25 °C. These m values are very large, and consequently we can use the phase separation approximation, C_1=cmc. The simplest model which may apply to the results shown in Fig. 2 is the secondary aggregation model described in the Theoretical Basis section. Substitution of Eqs. 8 and 9 into Eq. 4 yields

$$\log[C_0(V_2-V_c)+\mathrm{cmc}(V_1-V_2)]=m_2\log[C_0(V_c-V_3)+\mathrm{cmc}(V_3-V_1)]+\log K-(m_2-1)\log(V_2-V_3) \quad (10)$$

The V_c value can be determined from both the leading and trailing boundaries of a frontal elution curve. Since these V_c values were close, we used the average of them. The centroid volumes, V_2 and V_3, of the small and large micelles are expected to be close to the corresponding peak volumes, V_{2p} and V_{3p}. The difference in V between the centroid and the peak stems from both asymmetry of the peak and the concentration dependence of the peak position. Furthermore V_1 should be close to V_c at infinite dilution, whereas V_3 should be close to V_c at infinite concentration. By employing values of V_1=35.5 cm^3, V_2=17.0 cm^3, V_3=9.5 cm^3, and cmc=0.06 mmol dm^{-3}, we plotted the V_c data on column A according to Eq. 10 in Fig. 3. By the least-squares method, we obtained values of m_2=6.04 and K_2=6.25 (mmol dm^{-3})$^{-5.04}$. From this m_2 value we can suggest that the large micelle of $C_{12}E_5$ is the hexamer of the small micelle.

Computer Simulation of GFC Patterns for $C_{12}E_5$. The computer simulation of GFC patterns based on plate theory has become a useful tool for investigating

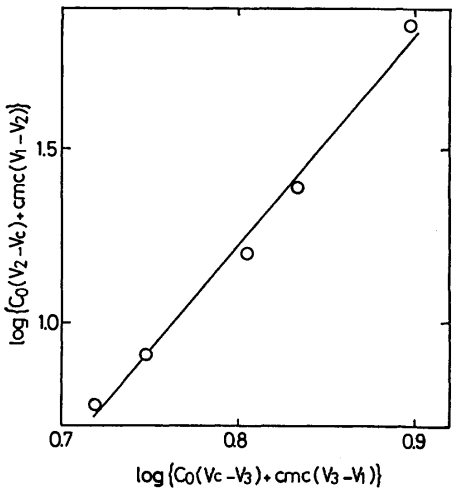

Fig. 3. Centroid volume data plotted according to Eq. 10 for $C_{12}E_5$ by using values of V_1=35.5 cm^3, V_2=17.0 cm^3, V_3=9.5 cm^3, and cmc=0.06 mmol dm^{-3}.

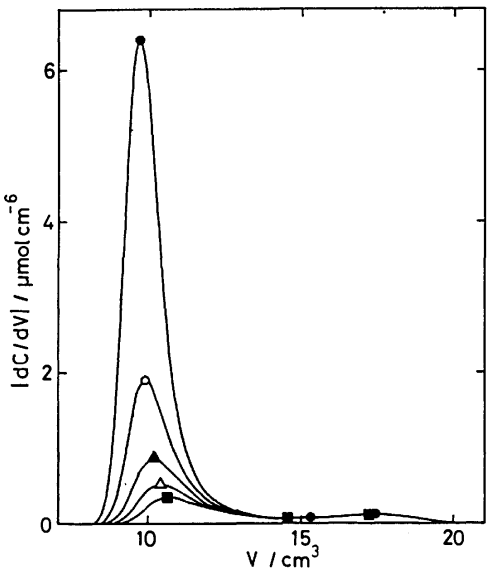

Fig. 4. Computer-simulated derivative patterns for $C_{12}E_5$ at the concentrations corresponding to Fig. 2. Input data used for the simulation: n=100, V_0=7.0 cm^3, V_1=35.5 cm^3, V_2=17.0 cm^3, V_3=9.5 cm^3, m_2=6, K_2=6.25 (mmol dm^{-3})$^{-5}$, and cmc=0.06 mmol dm^{-3}.

the aggregation properties of surfactants.[2,20,23] Taking into the literature m values (Table 2), we used values of m_1=500 and m_2=6. The elution volumes estimated above, V_1=35.5 cm^3, V_2=17.0 cm^3, and V_3=9.5 cm^3 were also used below. A K_1 value of 5×10^{606} (mmol dm^{-3})$^{-499}$ were estimated from the equation,[20] K_1=cmc$^{1-m_1}$/($2m_1$), by using cmc=0.06 mmol dm^{-3} and m_1=500. A K_2 values of 6.25 (mmol dm^{-3})$^{-5}$ were used. As fitting parameters, we used V_0=7.0 cm^3 and n=100. Figure 4 shows the computer simulated GFC patterns of $C_{12}E_5$, corresponding to the experimental ones (Fig. 2). Very close patterns were obtained by using cmc=0.06 mmol dm^{-3} (phase separation model), without using the m_1 and K_1 values, though they are not shown.

In Fig. 4 two peaks for small and large micelles are reproduced. This result differs from that of $C_{12}E_6$; the GFC derivative patterns for $C_{12}E_6$ had only one peak for the micelle, and the micellar elution volume decreased markedly with increasing C_0.[2] These different patterns can be ascribed to the difference in m_2; m_2=6 for $C_{12}E_5$ and m_2=2 for $C_{12}E_6$. The computer simulations based on plate theory correspond to the experimental GFC patterns for these surfactants. Furthermore we recall that asymptotic theory predicts only one peak at m=2 and two peaks at $m\geqq3$ for the monomer-m-mer system.[20] For the small micelle, both the observed and simulated values of V_{2p} slightly increased with increasing C_0, but the height simulated is larger than the observed one. For the large micelle, the simulated V_{3p} value decreased with increasing C_0 more rapidly than the observed one. Considering the inaccuracies in both experiment and theory, we did not attempt further improvements of fitting.

The hydrodynamic radius R_h of a species can be estimated from its elution volume V_e by using a calibration relationship between R_h and V_e for the proteins described in the Experimental section. For the small micelle of $C_{12}E_5$, we obtained values of R_h=5.0 nm (C_0=1.531 mmol dm^{-3}, on column A) and R_h=5.3 nm (C_0=1.530 mmol dm^{-3}, on column B) from their V_{2p} values, and a value of R_h=4.9 nm from V_2=17.0 cm^3. For the large micelle of $C_{12}E_5$, we could not determine the R_h value from the Sephadex G-200 data,since V_{3p} and V_3 were close to the exclusion limit of R_h for this gel. By using column C (Sephacryl S-500), we estimated a value of R_h=30 nm (C_0=9.816 mmol dm^{-3}).

$C_{12}E_8$. For $C_{12}E_8$ at 25 °C, there is general agreement that the micelle size little changes with C_0.[1,3,6-13,16]

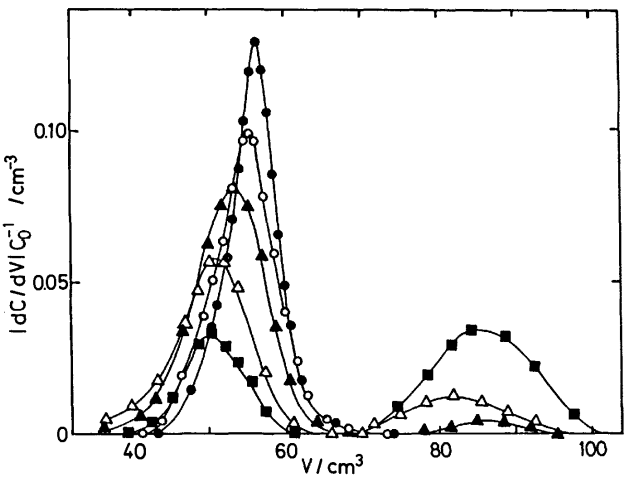

Fig. 5. Reduced derivative patterns for $C_{12}E_8$ at five charged concentrations (C_0/mmol dm^{-3}): 0.164 (■); 0.329 (△); 0.986 (▲); 21.655 (○); 42.336 (●).

Table 3 summarizes the literature values of m and R_h in dilute solution at 25 °C. The derivative patterns for $C_{12}E_8$ at the trailing boundary are shown in Fig. 5, where the ordinate is divided by C_0 for representing the GFC data in a wide range of C_0. As expected, there appeared a single peak of the micelle. As we have shown theoretically, the concentration dependence of the micellar peak V_{mp} is rather complicated;[24] when m is large enough, like $C_{12}E_5$, V_{mp} increases slightly with increasing C_0. The increase of V_{mp} shown in Fig. 5 is much larger than that predicted by plate theory. Furthermore the peak height of the micelle should be roughly proportional to C_0 at high concentrations, and consequently the peak divided by C_0 should have a constant height. As Fig. 5 shows, the micellar peak at C_0=42.336 mmol dm^{-3} is higher than that at C_0=21.655 mmol dm^{-3}. Though the reason has not yet been clarified, the peak position V_p sometimes increases with increasing C_0.[25] Then, as C_0 increases, the leading peak becomes broader, whereas the trailing peak becomes sharper.[20,26] These tendencies have been explained on the basis of plate theory for a nonassociable protein.[26] Values of cmc were reported to be 0.11[22] and 0.07 mmol dm^{-3}.[27]

Taking into consideration the above-mentioned results, we computer-simulated the derivative curve by using the following values; V_0=5.0 cm^3, V_1=83.8 cm^3, V_2=0.0822C_0+51.93 cm^3, and cmc=0.10 mmol dm^{-3}. The derivative patterns thus computed are shown by dashed lines. The solid lines were computed by using the mass action model; values of m=100 and K=4.9×10^{96} (mmol dm^{-3})$^{-99}$ were used instead of the cmc value (phase separation model). Though the difference between the solid and dashed lines is minor, the solid line is closer to the observed value than the dashed line. These computed patterns well reproduce the observed results (Fig. 5). Therefore, the increase of the micellar elution volume does not reflect true changes in micelle size.

The R_h value for the $C_{12}E_8$ micelle might be estimated to be 3.8 nm from the V_{2p} value at C_0=42.336 mmol dm^{-3}. For the monomer-m-mer system we have shown that the elution volume at infinite concentration corresponds to the true R_h value for the m-mer.[24] Therefore "true" R_h value for the $C_{12}E_8$ micelle may be smaller than 3.8 nm, as have been reported by other workers (Table 3).

$C_{12}E_4$. For $C_{12}E_4$ at 25 °C, values of cmc=0.04,[28] 0.046,[16] and 0.064[22] mmol dm^{-3} and R_h=180 nm (SLS)[29] have been reported. On two columns, columns C and D, we investigated the GFC patterns of $C_{12}E_4$. In the elution pattern of this surfactant, the concentration at the first plateau region was smaller than the initially charged concentration C_0, as shown in Figs. 7a (Sephadex G-200) and 7b (Sephacryl S-500). For the both columns the concentration at the second plateau region was close to the cmc and the V_1 value was much larger than the V_t value (Table 1). The

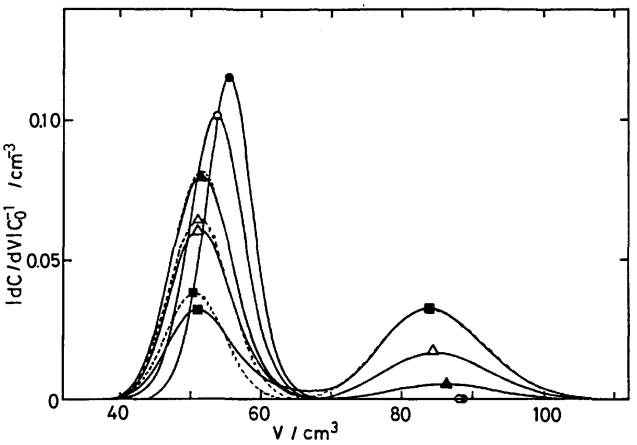

Fig. 6. Computer-simulated reduced derivative patterns for $C_{12}E_8$ at the five concentrations corresponding to Fig. 5. Input data used for the simulation according to two models: for mass action model (solid lines), n=120, V_0=5.0 cm^3, V_1=83.8 cm^3, V_2=0.0822C_0+51.93 cm^3, m=100, and K=4.9×10^{96} (mmol dm^{-3})$^{-99}$; for phase separation model (dashed lines), cmc=0.10 mmol dm^{-3} and the same values of n, V_0, V_1, and V_2.

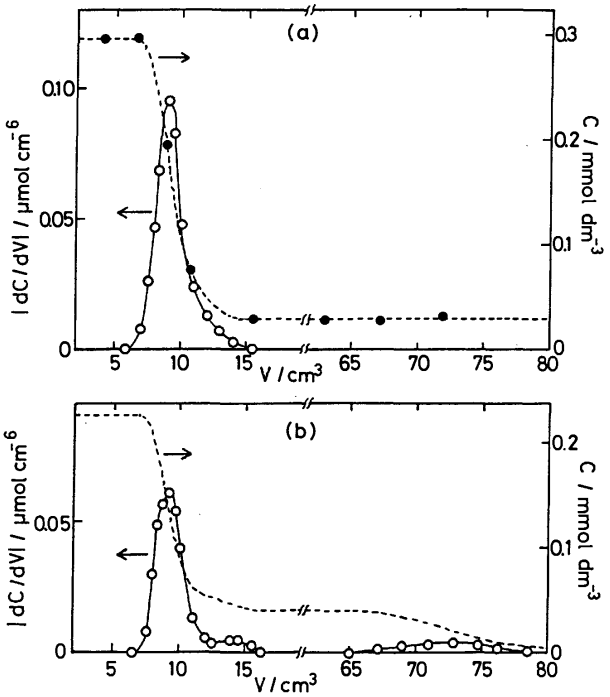

Fig. 7. Elution curves (dashed lines) and their derivatives (solid lines) for $C_{12}E_4$ under two experimental conditions: column D and C_0=0.508 mmol dm^{-3} (a); column C and C_0=0.276 mmol dm^{-3} (b).

latter fact indicates that the $C_{12}E_4$ monomer is adsorbed on the gels. This adsorption is ascribed to the hydrophobicity of $C_{12}E_4$. The reason for the reduction of concentration in eluate below C_0 may be ascribed to the adsorption or the clogging of huge micelles of $C_{12}E_4$ to the gel network. On Sephacryl S-500, the large peak appeared near the void volume

a) Estimated from the micellar peak shown in Fig. 5. The "true" value is expected to be smaller.

(Table 1) and the small peak has a value of R_h=33 nm. On Sephadex G-200, a single peak appeared near the void volume of this column, since all micelles of $C_{12}E_4$ are too large as compared with the gel pores.

Micellar Growth of Polyethylene Glycol Dodecyl Ethers at 25 °C. As Table 2 shows, VPO and EPR data on $C_{12}E_5$ have been interpreted as showing that small micelles form independently of C_0 above the cmc.[14,16] On the other hand, the NMR and SLS data (Table 2) suggested that large micelles form and grow with increasing C_0.[4,5,8-10] A similar controversy continues for $C_{12}E_6$.[2]

Our present and previous researches clearly showed that micellar size of $C_{12}E_4$, $C_{12}E_5$, $C_{12}E_6$, and $C_{12}E_8$ increases with a decrease of the polyoxyethylene chain length and with increasing C_0 except for $C_{12}E_8$ this result is consistent with others.[1,3,6-13,16] However our result on $C_{12}E_8$ does not show that smaller micelles do not form at very low concentrations, especially near the cmc. Very small m values have been reported, as shown in Table 3.[6,16] This discrepancy in m may stem from the difference in the extrapolation procedure of low concentration data to the cmc.

Our GFC data on $C_{12}E_5$ clearly indicate that small micelles coexist with large micelles. This result was analyzed in terms of the secondary aggregation model, viz., by assuming that sizes of these micelles are independent of C_0. This assumption may be valid in the concentration range which we investigated (C_0= 1.53—10.4 mmol dm^{-3}). Outside this range, smaller or larger micelles may form.

The molecular lengths of $C_{12}E_4$, $C_{12}E_5$, and $C_{12}E_8$ in the most stretched conformation are 3.2 nm, 3.5 nm, and 4.4 nm, respectively. From comparison between these values and R_h's, the $C_{12}E_8$ micelle is almost spherical and all the $C_{12}E_4$ and $C_{12}E_5$ micelles are nonspherical (probably rodlike).

The most important conclusion in this work is that the small and large micelles coexist for $C_{12}E_4$ and $C_{12}E_5$.

List of Symbols.

C_0; Total concentration of surfactant on a monomer basis
C_1; Monomer concentration of surfactant
C_2; Concentration of small micelles on a monomer basis
C_3; Concentration of large micelles on a monomer basis
K_1; Equilibrium constant of formation of small micelles from monomers
K_2; Equilibrium constant of formation of large micelles from small micelles
m; Number of monomers in a micelle
m_1; Number of monomers in a small micelle
m_2; Number of small micelles in a large micelle
n; Number of plates or number of oxyethylene units
V_0; Void volume
V_1; Centroid elution volume of monomers
V_2; Centroid elution volume of small micelles
V_3; Centroid elution volume of large micelles
V_c; Overall centroid elution volume
V_t; Total volume of gel bed
V_{1p}; Peak position of monomers in the derivative pattern
V_{2p}; Peak position of small micelles in the derivative pattern
V_{3p}; Peak position of large micelles in the derivative pattern

Studies on the Area-Temperature Isobars of Insoluble Monolayers at the Air/Water Interface. I. Development of a Microcomputer-Controlled Instrument for Measuring Precise Area-Temperature Isobars[1)]

Teiji KATO,* Tatsushi WAKANA, Katsunori OHSHIMA, and Katsuhiro SUZUKI
Department of Applied Chemistry, Faculty of Engineering, Utsunomiya University, 2753, Ishii-machi, Utsunomiya 321
(Received February 25, 1989)

A microcomputer-controlled instrument for measuring precise area-temperature (A-T) isobars of insoluble monolayers at the air/water interface was developed. To obtain precise A-T isobars, leakage or dissolution of film material must be checked. Before starting A-T isobar measurements, area or structural relaxations must be completed. A-T isobars of monolayers of cadmium eicosanoate, L-α-dipalmitoyl phosphatidylcholine (DPPC), trioctadecanoyl glyceride (TOG), and *cis*-9-octadecen-1-ol were measured. Precise A-T isobars can afford two-dimensional isobaric thermal expansivities of insoluble monolayers by differentiation with respect to temperature. The thermal expansivities were evaluated as around 9.0×10^{-4} K^{-1} for condensed monolayers and around 30×10^{-4} K^{-1} for liquid-expanded monolayers.

According to Crisp or Gaines,[2)] the number of degrees of freedom of a system of an insoluble monolayer on the water surface is given by the following equation,

$$F=C^{B}+C^{S}-P^{B}-q+3, \quad (1)$$

where F=number of degrees of freedom, C^{B}=number of components in bulk and equilibrated throughout the system, C^{S}=number of components confined to the surface, P^{B}=number of bulk phases, and q=number of surface phases in equilibrium with one another. In the derivation of the phase rule, it was assumed that film material should be confined completely to the surface phase and neither dissolution nor vaporization of film material should occur.

In the case of a single component monolayer, as $C^{S}=1$, $C^{B}=2$ (water and gas) and $P^{B}=2$ (a liquid and a gas phase), the number of degrees of freedom of the system is given as follows:

$$F=2+1-2-q+3=4-q. \quad (2)$$

There are three degrees of freedom when the monolayer consists of one surface phase. They are external pressure (three-dimensional), temperature and surface pressure (two-dimensional). Since experiments on insoluble monolayers are usually performed under atmospheric pressure, external pressure is dealt with not as a variable but rather as a constant (fixed to the atmospheric pressure). There is another experimental variable used usually, i.e., molecular area which can be changed by moving barriers confining the insoluble monolayer. There are three ways to take two variables from three, and there are three types of experiments on insoluble monolayers. The first is the surface pressure-area (π-A) isotherm where surface pressure is measured as a function of the molecular area, keeping temperature constant. The second is the area-temperature (A-T) isobar where the molecular area is measured as a function of temperature, keeping surface pressure constant. The third is the surface pressure-temperature (π-T) isochore or isoarea where surface pressure is measured as a function of temperature, keeping molecular area constant. π-A isotherms are the most popular and the most widely used thermodynamic measurements of insoluble monolayers. But it is very difficult to measure precise A-T isobars or π-T isochores because dissolution of film material into the subphase water or leakage of the film material through corners of barriers, even in a very small amount, will introduce fatal errors to the results. There are only a few papers reporting A-T isobars,[3,4)] and no reports on π-T isochores.

This paper reports development of a micromputer-controlled instrument for measuring A-T isobars of insoluble monolayers at the air/water interface and discusses procedures to obtain precise A-T isobars using this instrument. A-T isobars of some amphiphilic materials were measured with this instrument and two-dimensional isobaric thermal expansivities calculated from the isobars are also reported.

Experimental

Materials. L-α-Dipalmitoylphosphatidylcholine (DPPC, synthetic, 99+%), trioctadecanoyl glyceride (TOG, 99%) eicosanoic acid (99%), and *cis*-9-octadecen-1-ol (99%) were purchased from Sigma Chemicals and were used as film materials without further purification. Spectro-grade benzene, hexane, chloroform, ethanol, and methanol were used as spreading solvents. They were purchased from Wako Chemicals and were used without further rectification. Water for subphase was distilled using an all Pyrex distillation apparatus. Guaranteed grade sulfuric acid (Wako Chemicals) was used to adjust pH of the subphase water. Guaranteed grade cadmium acetate (Wako Chemicals) was used to prepare 10^{-3} M (1M=1 mol dm^{-3}) subphase for monolayers of eicosanoic acid.

Instrumentation. Figure 1 shows a block diagram of the instrument developed. Signals from two Wilhelmy-type surface balances and sheath platinum wire resistance thermometers were A/D converted and inputed into a 16-bit microcomputer (PC-286V, Epson). The microcomputer

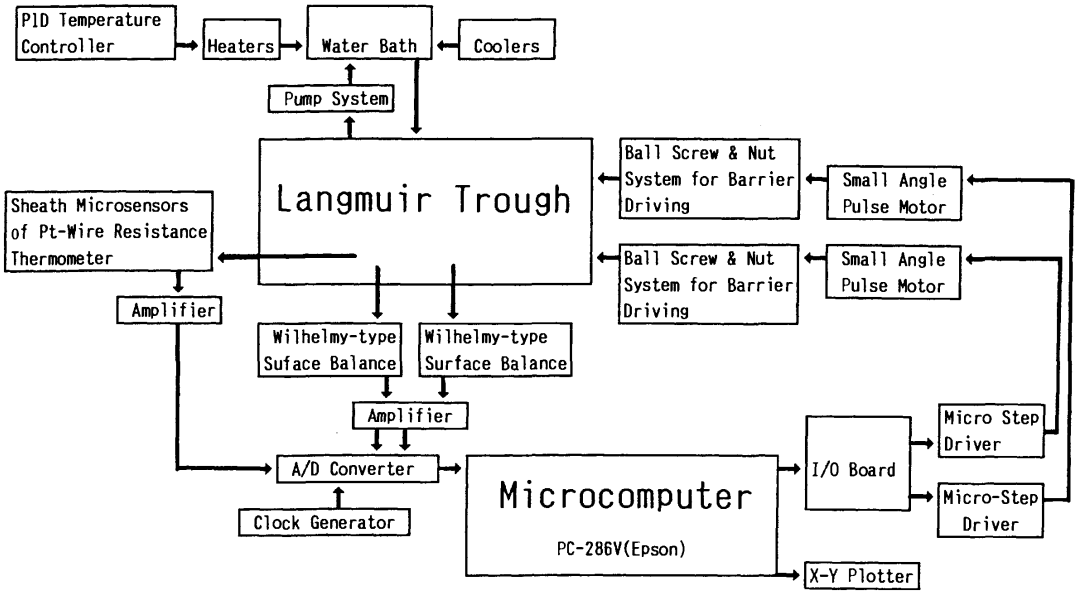

Fig. 1. Block diagram of the instrument.

feedback-controlled the monolayer surface pressure and maintained it strictly constant, based on the signals from the two surface balances by the method stated below. Temperature of subphase water was changed by circulating temperature controlled water from a water bath, which was equipped with control-heaters and coolers, through in a double-bottomed Langmuir trough. The monolayer temperature was measured with thin sheath microsensors of platinum wire resistance thermometers (sheath diameter=0.5 mm, element wire diameter=50 μm, 100 ohm), whose vertical position could be finely adjusted using a rack-and-pinion device.

The surface pressure of a monolayer must be strictly constant during an A-T isobar measurement. But it is difficult to keep it constant, based on signals from a single Wilhelmy-type surface balance because the zero-point of the balance itself changes with changing temperature of the subphase water. There are three reasons for drift of the zero point of the surface balance with changing temperature, i.e., changes of surface tension and density of subphase water, change of position of water surface by evaporation, and change of the dimensions of the Langmuir trough itself by thermal expansion. To overcome these difficulties, this instrument was equipped with two Wilhelmy-type surface balances; one was located in the monolayer-covered water area and another was in the clean water area. The microcomputer feedback-controlled positions of two barriers confining the monolayer through an I/O and a control boards (SMBMP, San-ei Electric Co., Ltd.), micro-step drivers (FD-5500WS, San-ei Electric Co., Ltd.), small-angle pulse motors (Vexta, Oriental Motors Co., Ltd.) and ball-screw and nut systems, to maintain the difference of outputs of the two surface balances constant. By this means, all causes of the zero-point drift of the surface balances with changing temperature could be cancelled completely and the pressure could be kept strictly constant during A-T isobar measurements. Four control parameters (the trigger interval, the real-time smoothing number, the surface compressibility of a monolayer and the feedback gain) were also used to control the surface pressure precisely.[5] Pressure fluctuation during the A-T isobar measurements was controlled within ± 0.15 mN m^{-1} in general. The spreading technique of monolayers restricted reproducibility in the molecular area of the A-T isobars and it was $\pm 1.0\%$ but the fluctuation in area during measurements was ± 0.001 nm^2 molecule^{-1} at most. These fluctuations were much less than those reported in previous A-T isobar measurements.[3]

A very shallow-type Langmuir trough was constructed using long rectangular rods of Teflon on a double-bottomed brass base which was coated with a thin pressure-sensitive Teflon adhesive sheet (inside dimensions of the trough, 80×16×0.4 cm). Only 600 ml of subphase water was required for the reason that the heat capacity of the system should be as small as possible to effect temperature change of the system rapidly.

Leakage and/or dissolution of the monolayers introduces serious errors into the A-T isobar. It is difficult to prevent leakage of monolayers at higher surface pressures and at higher temperatures by conventional rectangular barriers. The barriers used for this instrument were made from Teflon and have recesses of 1.5 mm depth in both ends to fit the inside width of the rims of the Langmuir trough (Fig. 2 (a)). Moreover, the barriers were equipped with flexible Teflon sheet-made skirts at the four corners of the recesses which slided smoothly without leakage of film molecules even when the temperature of the system changed widely (Fig. 2 (b) and (c)).

Dissolution of film material must be also avoided. Since film dissolution is a rate process and is accelerated by increasing temperature, the time that the film material is at high temperature must be short. Thus, the rates of temperature rising and lowering should be as high as possible to minimize the effect of dissolution. In this instrument, the maximum rate of temperature change was about 2 °C min^{-1} on average. Dissolution of film material can be checked by comparing an A-T isobar obtained at temperature rising with one at temperature lowering. If the two isobars coincide well with one other, we can confirm that there was no leakage or dissolution of the film material during measurement.

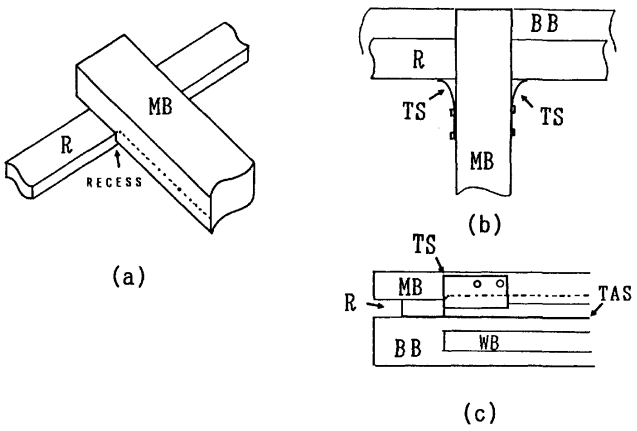

Fig. 2. Structure of the barriers used. (a) Fitness of the recesses of the barriers with rims of the Langmuir trough. (b) Top view of the barrier with flexible Teflon sheet-made skirts which slide smoothly against rims of the Langmuir trough. (c) Side view of the barrier and the trough. Precise A-T isobars can afford two-dimensional isobaric thermal expansivities by differentiation with respect to temperature. If there is no phase transition of the film material in the temperature range measured, the isobar will appear as a straight line as a whole, and hence it is easy to calculate the thermal expansivity by numerical differentiation with respect to temperature using linear regression analysis. If there are some phase transitions, the A-T isobar has some kinks. Correlation factors of the linear regression analysis are also calculated. All results are finally sent to an X-Y plotter for drawing normalized figures.

Results and Discussion

Dissolution. Figure 3 shows A-T isobars of DPPC at 40 mN m^{-1} exhibiting the effect of partial dissolution at higher temperature. The monolayer of DPPC was spread from a mixed solvent solution of hexane and ethanol (9:1 in volume) on pH 2 water. A Cloehn microsyringe of a gas-tight type which was connected to a synchronous motor-driven micrometer was used to administer the desired quantity of the spreading solution. The temperature was raised up to 45 °C at a rate of 2 °C min^{-1} and was kept constant there for 40 min, then lowered to 10 °C at the same rate. A phase transition begins at 42 °C. Dissolution of DPPC molecules occurred at the higher temperature and the A-T isobar measured under temperature lowering shifted downward about 4% in molecular area. The two isobars, however, were almost parallel below 42 °C, and this means that dissolution may be neglected in this temperature span.

Many of the A-T isobars of film materials forming stable insoluble monolayers could be measured up to about 45 °C without taking into account the dissolution under the conditions of this high rate of temperature change.

Area or Structural Relaxation. Figure 4 shows A-T isobars of an eicosanoic acid monolayer at 10 mN m^{-1} on water containing 10^{-3} M cadmium acetate. The monolayer was spread from a benzene solution. There are two isobars shown in the figure. Curves (a) and (b) are isobars measured with the temperature rising and lowering, respectively. The discrepancy between isobars (a) and (b) shows an area-relaxation effect of the monolayer.

An insoluble monolayer after just being compressed to a certain high pressure at low temperatures is in some unstable state and exhibits a tendency to relax to a more stable closed-packed state with time. The relaxation time depends on many factors, such as temperature, surface pressure, pH or ion types in the subphase etc. In general, the relaxation time is very long at low temperatures and at high pressures. Moreover, the relaxation takes longer time in a solid state than in a liquid state. Cadmium eicosanoate

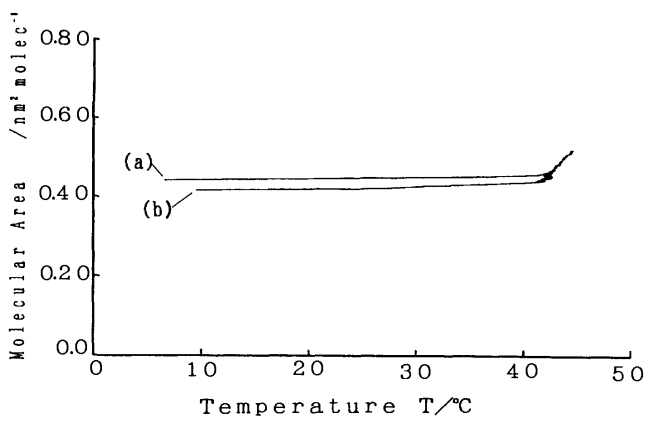

Fig. 3. A-T isobars of DPPC at 40 mN m^{-1} showing partial dissolution of the film material. (a) A-T isobar of DPPC measured at temperature rising. (b) A-T isobar of DPPC measured at temperature lowering, after keeping at 45 °C for 40 min.

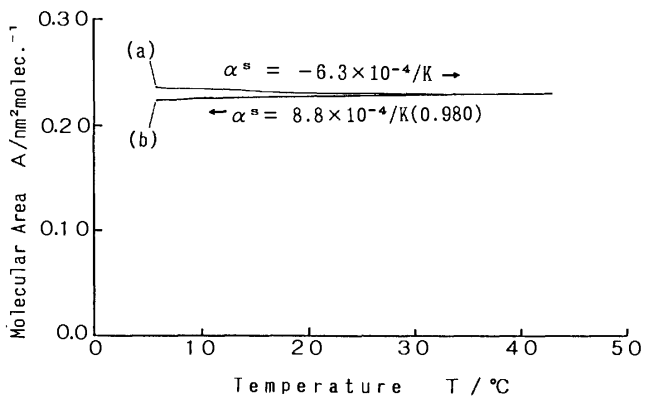

Fig. 4. A-T isobars of an eicosanoic acid monolayer at 10 mN m^{-1} on 10^{-3} M cadmium acetate showing the "thermally stimulated area relaxation" effect. (a) A-T isobar measured with the first rising of temperature without "isobaric thermal treatment." (b) A-T isobar measured with the temperature lowering. (See text.)

(see Fig. 4) is in a solid state in monolayers at 10 mN m^{-1}, and it takes very long time to relax especially at the starting low temperature of the A-T isobar measurement. The relaxation time becomes shorter as the temperature increases, and curve (a) gradually approaches curve (b) which exhibits no relaxation effect. It can be considered that curve (b) shows the true isobar of a cadmium eicosanoate monolayer under these conditions. The thermal expansivity calculated from isobar (a) was negative as shown in Fig 4. Curve (a) shows a "temperature accelerated" or "thermally stimulated" area relaxation process of the insoluble monolayer.

It is very interesting to point out that the discrepancy of the isobars (a) and (b) at 6 °C, about 5% in molecular area, corresponds well to the "hole" area detected by electron microscopic observation of monolayers of long-chain acids and their barium salts.[6] From the results shown in Fig. 4, it can be inferred that such "holes" in monolayers will disappear by "isobaric thermal treatment" up to a certain high temperature.

To eliminate the relaxation effect from A-T isobar measurements, we adopted the following experimental procedures: A monolayer is spread and is compressed to some constant pressure at room temperature. Then, the temperature of the system is raised to a certain high value where the relaxation time is very short, followed by lowering of the temperature to the starting point of the A-T isobar measurement, keeping pressure constant through out the whole time. The maximum temperature of the "isobaric thermal treatment" depends on the film material, the constant pressure and other experimental conditions. A-T isobars shown hereafter were measured with the procedures stated above, and it was checked that there was no significant leakage or dissolution of film material during measurement.

A-T Isobars of Some Typical Insoluble Monolayers. Figure 5 shows A-T isobars of a cadmium eicosanoate monolayer under the same conditions as those shown in Fig. 4. The relaxation effect disappeared and the two isobars, (a) and (b), coincided well with each other, except the part above 20 °C where isobar (b) showed a small undulation. The minimum surface compressibility of the monolayer at 9.8 °C was 1.0×10^{-3} m mN^{-1} which was a very small value corresponding to that of a solid state. The two-dimensional isobaric thermal expansivities and the correlation factors for the two isobars were calculated as 9.0×10^{-4} K^{-1} (0.998) and 9.9×10^{-4} K^{-1} (0.974) respectively.

Figure 6 shows an A-T isobar of a trioctadecanoyl glyceride monolayer which was spread from a benzene solution on pH 3 subphase (20 mN m^{-1}). The material has three hydrophobic long chains and forms very stable insoluble monolayers. The minimum surface compressibility at 6.4 °C was as small as 1.5×10^{-3} m mN^{-1}, corresponding to a value of a solid state. The monolayer exhibits no phase transition at 20 mN m^{-1} in the temperature span measured and the curve looks like a straight line. The two-dimensional thermal expansivity and the correlation factor calculated from the isobar were 9.0×10^{-4} K^{-1}

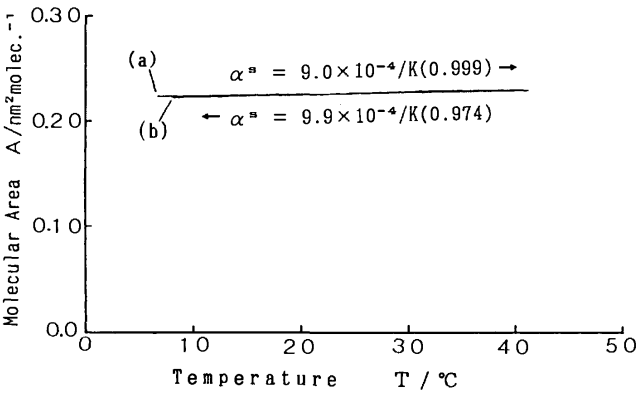

Fig. 5. A-T isobars of an eicosanoic acid monolayer which was measured following the procedures described in the text to eliminate the relaxation effect. Other experimental conditions are the same as those shown in Fig. 4. (a) An A-T isobar measured at temperature rising. (b) An A-T isobar measured at temperature lowering.

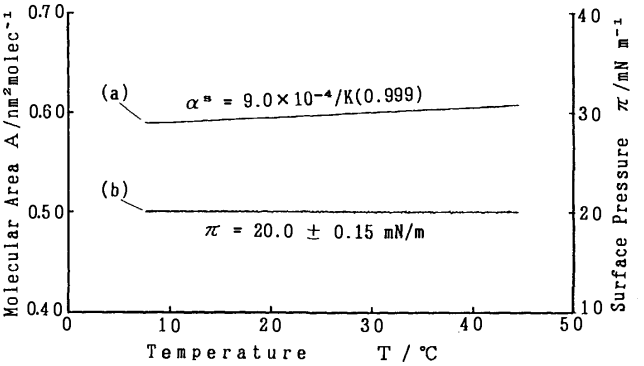

Fig. 6. (a) An A-T isobar of a TOG monolayer on pH 3 subphase at 20 mN m^{-1} measured at temperature rising, and (b) surface pressure fluctuation.

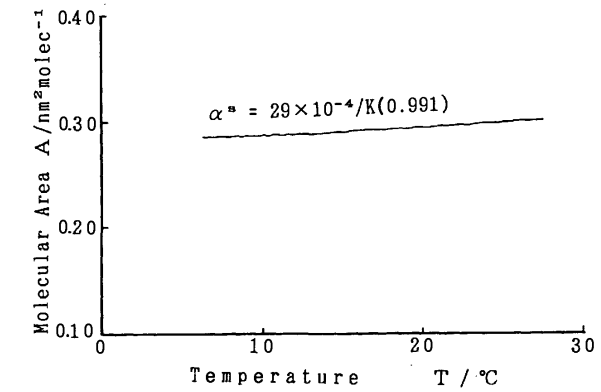

Fig. 7. An A-T isobar of an *cis*-9-octadecen-1-ol monolayer on distilled water at 15 mN m^{-1}.

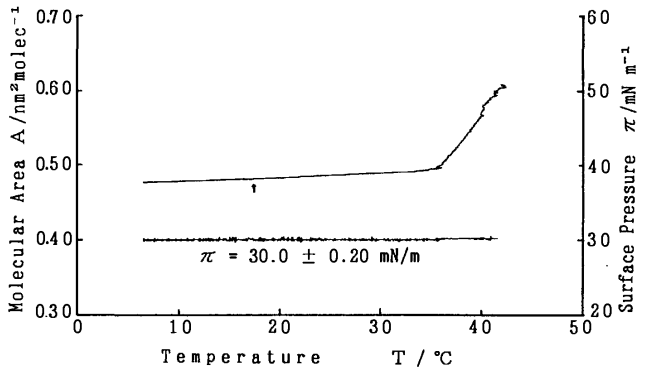

Fig. 8. An A-T isobar of a DPPC monolayer on pH 3 subphase at 30 mN m^{-1}. The isobar shows two phase transitions. The second-order one is detected at 18 °C and the "first-order" one at above 36 °C. The pressure was controlled strictly at 30.0±0.20 mN m^{-1} in spite of the existence of phase transitions.

and 0.999, respectively. The surface pressure fluctuation is also shown in the figure. In spite of the wide range of temperature change, it can be seen that pressure was controlled at 20.0±0.15 mN m^{-1} during the A-T isobar measurements.

Figure 7 shows an A-T isobar of a *cis*-9-octadecen-1-ol monolayer at 15 mN m^{-1} spread from a benzene solution on distilled water. This material has a cis-unsaturation in the middle of the hydrophobic chain and forms a typical liquid-expanded monolayer. As the solubility of this material in water is much larger than that of the corresponding saturated material, measurement was stopped at about 27 °C to reduce dissolution. A small relaxation effect was observed in the low temperature region of the isobar. The two-dimensional thermal expansivity of the liquid-expanded monolayer was calculated from the isobar data except at the low temperature region as 29×10^{-4} K^{-1} (0.991) which is much larger than those obtained for monolayers in a condensed state.

Figure 8 shows an A-T isobar of a DPPC monolayer at 30 mN m^{-1} on pH 3 subphase as well as the pressure fluctuation during the measurement. This material also forms stable insoluble monolayers but exhibits two phase transitions, one appears as a slight inflection at 18 °C (pointed by an upward arrow) and the other appears at 35 °C as a large stepwise change in molecular area as seen from the figure. In spite of the fact that the monolayer exhibits a phase transition with accompanying large area change, it can be seen that the surface pressure was kept constant at 30.0±0.20 mN m^{-1}. It can be considered that the phase transition detected at 18 °C corresponds to the second-order from phase IV (crystalline, non tilted) to phase III (crystalline, tilted) of DPPC.[3] Two-dimensional thermal expansivities of the condensed state below and above this transition were 9.0×10^{-4} K^{-1} (0.980) and 1.3×10^{-3} K^{-1} (0.995), respectively. The transition at the higher temperature corresponds to the first-order one from phase III to phase II (anisotropic fluid). Thermodynamics predicts that a first-order phase transition should appear as a vertical line in an A-T isobar. In practice, however, the A-T isobar in the transition region is not vertical but slanted. This may be because the molecular processes involved in the transition require some time to complete or the transition has a second-order character by approaching a critical point of the coexisting region of phase II and III as pointed out by Albrecht.[3]

Conclusion

A computer-controlled instrument for measuring A-T isobars of insoluble monolayers at the air/water interface was developed. By adopting a double surface balance system, the pressure could be controlled within ±0.15 mN m^{-1} using four control parameters. To obtain precise A-T isobars, it must be checked that there is no significant dissolution of film material into the subphase or no leakage of the material as shown by the agreement of two isobars measured at temperature rising and lowering. Before starting measurements, structural or area relaxations after compression must also be completed at a certain high temperature. In relation to the relaxation processes, the "isobaric thermal treatment" technique was proposed to densify insoluble monolayers, and this treatment will be a powerful tool to obtain dense and "defect-free" LB films.

Precise A-T isobars can afford two-dimensional isobaric thermal expansivities of insoluble monolayers that have never been reported. The thermal expansivities are about 30×10^{-4} K^{-1} for monolayers in the liquid-expanded state and about 10×10^{-4} K^{-1} for monolayers in the condensed states. A-T isobars will play important roles, together with the π-A isotherms, in considering physical properties or polymorphism of insoluble monolayers at the air/water interface.

Solution Properties of Sodium Perfluoroalkanoates. Heats of Solution, Viscosity *B* Coefficients, and Surface Tensions

Kunio TAMAKI,* Yoko ŌHARA, and Sumiko WATANABE
Department of Chemistry, Yokohama City University, Kanazawa-ku, Yokohama 236
(Received March 13, 1989)

The heats of solution, the viscosity *B* coefficients, and the surface activities of sodium perfluoroalkanoates, $F(CF_2)_nCOONa$, n=1—4, 6, 7), in water were measured. The changes in the heat capacity for dissolution in water, ΔC_p^∞, calculated from the heats of solution at 15, 25, and 35 °C, were positive for the salts, and the ΔC_p^∞ values increased with an increase in n. The increment in the ΔC_p^∞ values per CF_2 group was 93 J K^{-1} mol^{-1}. The viscosity *B* coefficients increased with the chain length at a definite temperature, and the increment in the viscosity *B* coefficients per CF_2 group was 0.119 dm^3 mol^{-1} at 25 °C. Further, the viscosity *B* coefficients for all the salts decreased with the increase in the temperature between 15 and 35 °C. Traube factors, as obtained from the surface tensions, were found to be 3.0 for the homologs from C_2 salt to C_7 salt. The results are discussed in comparison with those of sodium alkanoates, $H(CH_2)_nCOONa$.

The behavior of homologous organic monovalent anions, such as alkyl sulfates,[1,2] alkanesulfonates,[3] and dialkyl phosphates,[4] in water were discussed in previous papers. Perfluoroalkanoates are other organic monovalent anions. It is well-known that perfluoroalkanoic acids are considerably more hydrophobic than alkanoic acids. This stronger hydrophobicity of perfluorocarbon compounds leads to a greater lowering of the surface tensions[5] and to lower critical micelle concentration values[6] when compared to hydrocarbon compounds of the same chain length. In the present paper, experimental results will be reported on the temperature dependence of the heats of solution and the viscosity *B* coefficients, and on the surface active properties in water at 25 °C for the homologs of sodium perfluoroalkanoates ($F(CF_2)_nCOONa$, which will be abbreviated as f-C_n). The results will be discussed in comparison with those for homologs of sodium alkanoates ($H(CH_2)_nCOONa$, which will be abbreviated as C_n).

Experimental

Homologs of f-C_n were prepared by the neutralization of the corresponding perfluoroalkanoic acids (97—99%) with a solution of sodium hydroxide, after which the water was evaporated to dryness; the salts were purified several times by recrystallization from benzene-ethanol solutions. The salts of f-C_1 and f-C_2 were hygroscopic; all the salts were dried in vacuo at room temperature for several days, and the molecular weights were checked by means of volumetric analysis. A known amount of a sample was dissolved in water and passed through an ion-exchange resin in the hydrogen form; the eluent was titrated with a standard NaOH solution. It was found that the obtained samples have no water of crystallization. The homologs of C_n were commercial samples. The salts of C_1 and C_2 were used as received. The other C_n samples were purified by recrystallization from ethanol. All the salts were dried in vacuo at 100 °C for several days. The water was triply distilled.

The heats of solution were measured at 15, 25, and 35 °C using a twin isoperibol calorimeter, TIC-2C, of the Tokyo Riko Co., Ltd., by a method similar to that described in a previous paper.[3]

The viscosities were measured at 15, 25, and 35 °C using an automatic viscometer of the Shibayama Scientific Co., Ltd. The densities were measured using a vibrating-tube densimeter, twin-type SS-D-200, of the Shibayama Scientific Co., Ltd. The details of the procedure were described in a previous paper.[3] The electric conductivities were measured with an LCR meter, AG-4301B, of the Ando Electric Co., Ltd., using a frequency of 1000 Hz.

The surface tensions were measured at 25°C by means of the Wilhelmy method using a CBVP-A3 tensiometer of the Kyowa Kaimenkagaku Co., Ltd.

Results and Discussion

Heats of Solution. Heat-of-solution measurements were carried out in the concentration range of $(1.8—3.6)\times10^{-3}$ mol dm^{-3} (below the critical micelle concentrations). In this concentration range, any dependence of the heat of solution on the concentration is within the limit of experimental error, so the average of three or more measurements has been taken as the heat of solution at an infinite dilution ΔH_s^∞. The ΔH_s^∞ values of f-C_n salts in water are listed in Table 1. The results from the ΔH_s^∞ values were then used to calculate the change in the heat capacity for dissolution at an infinite dilution, ΔC_p^∞:

$$\Delta C_p^\infty = d\Delta H_s^\infty/dT, \quad (1)$$

where T is the temperature. The ΔC_p^∞ values obtained at 25 °C are also listed in Table 1.

The sign and magnitude of ΔC_p^∞ can be taken as a relative measure of the structural effect upon the solvent water.[7,8] The ΔC_p^∞ values of common salts indicate negative values, whereas the ΔC_p^∞ values of hydrophobic solutes indicate positive values. As may be seen in Table 1, the ΔC_p^∞ signs of the f-C_n salts are all positive, indicating that these salts behave as structure-makers in water. Figure 1 shows an approximate linear relation between the ΔC_p^∞ values and the number of carbon atoms in the perfluoroalkyl chain, n; the average increment in the ΔC_p^∞ values per

CF_2 group is 93 J K^{-1} mol^{-1}. The ΔC_p^∞ values for C_n salts in the temperature range of 25—35 °C, reported by Chaula and Ahluwalia,[9] are also included in Fig. 1. The average increment in ΔC_p^∞ per CH_2 group was reported as 59 J K^{-1} mol^{-1}. Therefore, the increment in the ΔC_p^∞ value per CF_2 group is about 1.6 times that of the CH_2 group.

The Viscosity *B* Coefficients. The viscosity of an aqueous solution of an electrolyte, η, for concentrations up to about 0.1 mol dm^{-3} can be represented by the Jones-Dole equation:[10]

$$\eta/\eta_0 = 1 + Ac^{1/2} + Bc, \quad (2)$$

where η_0 is the viscosity of water, c is the molar concentration, A is a constant related to ion-ion interaction, and B is the viscosity B coefficient. The A constant was interpreted theoretically by Falkenhagen and Vernon;[11] it can be calculated using the data of the limiting equivalent conductivities of the salt, the cation, and the anion. Equation 2 may be converted to:

$$\eta/\eta_0 - 1 - Ac^{1/2} = Bc. \quad (3)$$

When the left-hand side of Eq. 3, using the calculated values of A is plotted against c, the viscosity B coefficient is obtained as the slope of a straight line. The limiting molar conductivities required for the calculation of the A values in Eq. 3 for f-C_n salts were obtained from the measurements of the electric conductivities for aqueous solutions of these salts. The $Ac^{1/2}$ factor in Eq. 3 is relatively small, and the A values are insensitive to the variation in the temperature in the range of 15—35 °C, therefore, the values of A calculated using the limiting molar conductivities at 25 °C were also used for the A values at 15 and 35 °C. The A values for C_n salts were calculated from the limiting molar conductivities in the literature.[12] For example, Fig. 2 shows the results of the plotting of Eq. 3 for the f-C_n series at 25 °C. For each salt, the measurements were carried out in the concentration range below the critical micelle concentration. The values of A and B are listed in Table 2. The viscosities of the C_n salts at 25 °C were reported in a previous paper.[13] In this work, the temperature dependence of the viscosity B coefficients for the C_n series (n=1—7) were reinvestigated by means of a more elaborate method; the B values thus obtained are also included in Table 2. The viscosity B coefficient is related to the ion-solvent interaction and to the size and shape

of the ion, and it is highly specific for the electrolyte and the temperature.[14]

The B values of both homologous series of salts are found to increase with the chain length at a definite temperature. The average increment in the B values per CF_2 group for the f-C_n series is larger than the increment in the B values per CH_2 group for C_n; the values are 0.119 dm^3mol^{-1} per CF_2 group and 0.074 dm^3mol^{-1} per CH_2 group at 25 °C.

The temperature dependence of the B values may be regarded as an index of the solute-solvent interaction; the B values increase with the temperature for a solvent-structure-breaking salt, while they decrease with the temperature for a solvent-structure-making solute.[15] For both the homologous organic salts, it may be seen in Table 2 that the B values decrease as the temperature is raised from 15 to 35 °C; these salts behave as structure-making salts in the water phase. The B values of electrolytes are determined by adding the individual contributions of the ions. Fortunately, the B value of sodium ion is insensitive to the temperature.[16] Therefore, the temperature dependences of the viscosity B coefficients of the sodium salts of both series of organic acids discussed above conveniently reflect the nature of the organic anions, and both $F(CF_2)_nCOO^-$ and $H(CH_2)_nCOO^-$ anions are structure-making ions. The temperature dependence of the viscosity B coefficients at 25 °C, dB/dT, are also listed in Table 2. Previous experimental results of dB/dT are available for C_1(−0.0022 $dm^3mol^{-1}K^{-1}$), C_2(−0.0025 $dm^3mol^{-1}K^{-1}$), and C_3(−0.0028 $dm^3mol^{-1}K^{-1}$).[17] As is evident in Table 2, the dB/dT values for the f-C_n series are smaller than those for the C_n series with the same number of carbon atoms. In Fig. 3 the dB/dT values are plotted against n; the dB/dT values decrease with the number of carbon atoms in the perfluoroalkyl or alkyl chains of both series of salts; this means that the hydrophobic hydration

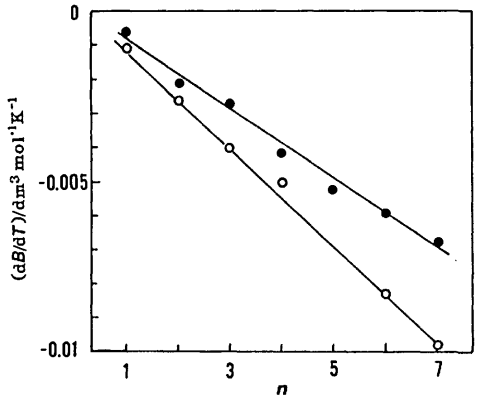

Fig. 3. Plots of dB/dT against n at 25 °C. ○, $F(CF_2)_nCOONa$; ●, $H(CH_2)_nCOONa$.

increase with the length of the chains. The average value of dB/dT per CF_2 group is −0.00144 $dm^3mol^{-1}K^{-1}$, while the value per CH_2 group is −0.00102 $dm^3mol^{-1}K^{-1}$. These values reflect the stronger hydrophobic nature of the f-C_n series than that of the C_n series.

Surface Tensions. Figure 4 shows the surface tensions, γ, of aqueous solutions of the f-C_n series as a function of the logarithmus of the molar concentration at 25 °C. It may be seen that all the salts reduce the surface tension of pure water. The shape of the surface tension-versus-concentration curve for an organic salt in aqueous solutions is considered to give a rough criterion of the behavior of the salt in water; common salt raises the surface tension of water, whereas hydrophobic salt reduces it.[18] Thus, f-C_n salts are excellent hydrophobic structure-makers in water. On the other hand, the surface tensions of aqeous solutions of the C_n series have been reported in the literature;[19] C_1 salt raises the surface tensions of pure water, whereas C_2 and higher homologous salts reduce

Table 3. Traube Factors, K, for $F(CF_2)_nCOONa$

n	γ=60 mN m^{-1}		γ=50 mN m^{-1}		γ=40 mN m^{-1}

the surface tension of water. Therefore, the surface-active properties of the f-C_n series are much more higher than those of the C_n series.

In addition, the critical micelle concentrations can be estimated from the surface-tension-versus-concentration curves in Fig. 4; the values are 0.030 mol dm^{-3} for f-C_7 salt, 0.080 mol dm^{-3} for f-C_6 salt, and 0.55 mol dm^{-3} for f-C_4 salt. However, the critical micelle concentration becomes obscure for f-C_3 salt.

It may be found in Fig. 4 that the concentrations required for an equal lowering of the surface tension diminish by a constant factor for an additional CF_2 group in the perfluorocarbon chain. This is in accord with Traube's rule, which is expressed as;

$$C_n/C_{n+1}=K, \tag{4}$$

where C_n and C_{n+1} are, respectively, the concentrations for successive members of the series with n and $n+1$ CF_2 groups at an equal lowering of the surface tension; K is termed the Traube factor. The values of K obtained from Fig. 4 are summarized in Table 3. It may be seen in Table 3 that the Traube factors are about 3.0 for the homologs from f-C_2 salt to f-C_7 salt. In a previous paper,[20] for homologous strong electrolytes K was derived as:

$$K=\exp(-\Delta G/2RT), \tag{5}$$

where ΔG is the free energy of the adsorption of the CF_2 or CH_2 group from water to the surface, R is the gas constant, and T is the temperature. By the substitution of K=3.0 at 25 °C into Eq. 5, ΔG becomes −5.4 kJ mol^{-1}. This value is comparable to those in the literature: −5.4 kJ mol^{-1} reported by Phillips[21] and −5.9 kJ mol^{-1} reported by Davies and Rideal.[22]

The authors wish to thank Dr. Yujin Tabata, Nihon Surfactant Ind. Co., Ltd., for generous donation of the perfluoroalkanoic acids.

Adsolubilization Behavior of Dyes Caused by Mixed Surfactant Bilayers Formed on Alumina

Kunio Esumi,* Yuichi Sakamoto, Tetsuya Nagahama, and Kenjiro Meguro
Department of Applied Chemistry and Institute of Colloid and Interface Science, Science University of Tokyo, Kagurazaka, Shinjuku-ku, Tokyo 162
(Received March 24, 1989)

The adsolubilization of dyes (yellow OB and azobenzene) was performed on mixed bilayers consisting of anionic and nonionic surfactants formed on α-alumina. The adsolubilization capacity of the two dyes increased with the increase in the concentration of the dyes solubilized in the supernatant. The mixed bilayer consisting of anionic hydrocarbon (lithium dodecyl sulfate) and nonionic hydrocarbon surfactants (polyoxyethylene nonylphenyl ether) showed a greater adsolubilization capacity than that consisting of anionic fluorocarbon (lithium perfluorooctanesulfonate) and nonionic hydrocarbon surfactants. Further, the adsolubilization capacity of the dyes was affected by the oxyethylene chain length of the nonionic hydrocarbon surfactant in the mixed bilayer.

The solubilized amounts of solubilizates depend on the kinds of surfactants. Generally, the order of solubilization capacity, i.e., the moles of hydrocarbons and polar compounds solubilized per mole of surfactant, appears to be as follows: nonionics>cationics>anionics for surfactants with the same hydrophobic chain length.[1-3] The solubilization behavior by mixed micelles of anionic and nonionic surfactants has also been investigated;[4-7] Muto et al.[8] reported, from their comparisons of ideal and observed solubilized amounts, that the ratio of observed solubilized amounts to ideal amounts of yellow OB and azobenzene decreases when two surfactants are mixed, while it decreases with an increase in the difference of the moles of solubilizates per mole of surfactant between two surfactants in the mixed systems.

On the other hand, the structure of a surfactant adsorbed layer on particles has been characterized by using a fluorescence technique, ESR, and Raman spectroscopy.[9-11] Chandar et al.[9] demonstrated that the adsorbed layer of sodium dodecyl sulfate at the alumina-water interface is similar to that in hemimicellization. Esumi et al.[12,13] reported on mixed surfactant bilayers consisting of hydrocarbon and fluorocarbon surfactants formed on ferric hydrosol and alumina. The microenvironmental properties of these mixed bilayers were studied on the alumina by means of the fluorescence-probing method. However, this fluorescence-probing method could not be used for ferric hydrosol because of the large scattering by the sol alone. Such adsorbed surfactants of micelle-like surfactant aggregates are called admicelles.[14] When micelles incorporate other molecules into their structure, it is called solubilization: here, incorporation by admicelles will be referred to as adsolubilization.[15]

Recently, we found[16] that some alcohols are adsolubilized more efficiently into anionic surfactant bilayers formed on alumina than they are solubilized into the micelles. Thus, it is interesting to compare the solubilization behavior into a micelle system to the adsolubilization into the surfactant bilayer on particles, since they seem to have similar properties.

In this work, the adsolubilization of yellow OB and azobenzene into single and mixed surfactant bilayers formed on α-alumina is investigated by measuring the amounts of the dyes adsolubilized.

Experimental

Materials. Lithium perfluorooctanesulfonate (LiFOS) and lithium dodecyl sulfate (LiDS) were synthesized.[17] LiFOS was purified by repeated crystallizations from dioxane after extraction with ethanol, and LiDS with ethanol together, and with a mixture of hexane and 2-propanol. The purity of these samples was confirmed by elemental analyses and by the lack of a minimum in the surface tension. The polyoxyethylene nonylphenyl ethers (NP7.5 and NP20) were supplied by the Nikko Chemicals Co., Ltd.; each number of the NP indicates the average oxyethylene chain length in the molecule. These NPs were used without further purification. The yellow OB and azobenzene were obtained from the Tokyo Kasei Co. and were used as received.

The alumina used was α-alumina of a 99.995% purity, supplied by Showa Denko K. K. The specific surface area, determined from the nitrogen-gas adsorption at −196 °C, was 10.1 $m^2 g^{-1}$ The average particle diameter was 500 nm, as determined by means of a particle analyzer based on photon correlation spectroscopy (Autosizer Model 700, Malvern Co., Ltd.).

Methods and Measurements. An aqueous surfactant solution required to form a bilayer was placed in contact with 0.3 g of alumina. A series of solutions was prepared, containing various concentrations of yellow OB or azobenzene solubilized in surfactant solutions. Then, these solutions containing solubilizates were added to the suspensions. After attaining the equilibrium of adsolubilization, the suspension was centrifuged. The concentration of dyes solubilized in the supernatant was determined using a UV spectrophotometer (200 A, Hitachi Co.).

The amount of solubilizates adsolubilized was determined from the difference between the concentrations before and

after the adsolubilization. Similarly, the amounts of solubilizates solubilized in micelles in the absence of alumina were determined. The amounts of anionic surfactants adsorbed were determined by means of an isotachophoretic analyzer (IP-3A, Shimadzu Ltd.), while those of nonionic surfactants, which have an absorption band at 275 nm, were determined by means of a UV spectrophotometer.

All the experiments were performed at 25 °C and at pH 3.5, which was adjusted by the use of nitric acid. In order to keep the ionic strength constant, 10 mmol dm^{-3} of lithium nitrate was used.

Calorimetric measurements were made with a Multi micro calorimeter MMC-5111 (Tokyo Rico Co., Ltd.), in which the reaction vessel was immersed in a thermostatted bath maintained at 25±0.05 °C. The enthalpies of the formation of surfactant bilayers on the alumina were determined by breaking glass ampoules containing flocculated alumina in an LiDS or LiFOS aqueous solution into NP aqueous solutions. Correction was made for the heat change associated with the breaking of the ampoules and with mixing of the surfactant aqueous solutions.

Results and Discussion

When LiFOS or LiDS is adsorbed on positively charged alumina, the alumina flocculates. In this study, it is found that the optimum flocculation concentration for alumina is 1 mmol dm^{-3} for both LiFOS and LiDS. On the addition more than 0.6 mmol dm^{-3} of NPs to the optimum flocculated alumina, the alumina becomes redispersed. This redispersion process has been interpreted as being caused by the formation of a mixed bilayer[12,18,19] on the alumina in such a manner that the NP molecule is adsorbed on the LiFOS or LiDS-covered alumina, with its hydrophilic groups oriented towards the liquid phase. Thus, the mixed bilayer of LiFOS and NP is formed by the interaction between the hydrocarbon chains of NP and the fluorocarbon chains of LiFOS, while that of LiDS and NP is formed by the interaction between the hydrocarbon chains of NP and of LiDS. The redispersion state was confirmed by measuring the particle size of alumina; it was found to be about 500 nm. The interior environment in the mixed bilayer thus formed appears to have properties similar to those in mixed micelles.

Figure 1 shows the adsolubilization capacity for yellow OB in the mixed bilayers on the alumina. Here, the additive concentration of NPs was 1 mmol dm^{-3}. The adsolubilization capacity for yellow OB is expressed by dividing the amount of the yellow OB adsolubilized per unit of weight of the alumina by the total amounts of surfactants adsorbed per unit of weight of the alumina. Table 1 tabulates the amounts of surfactants adsorbed in the mixed bilayers. It can be seen that the amount of NP decreases with an increase in the oxyethylene chain lengths of NP for both LiDS-NP and LiFOS-NP

Table 1. Amounts of Surfactants Adsorbed in Mixed Bilayers

System	Amount adsorbed ($\times 10^{-5}$ mol g^{-1})			
	LiFOS	LiDS	NP	Total
LiFOS-NP7.5	1.62	—	2.30	3.92
LiDS-NP7.5	—	1.98	3.20	5.18
LiFOS-NP20	1.62	—	1.80	3.42
LiDS-NP20	—	1.98	2.20	4.18

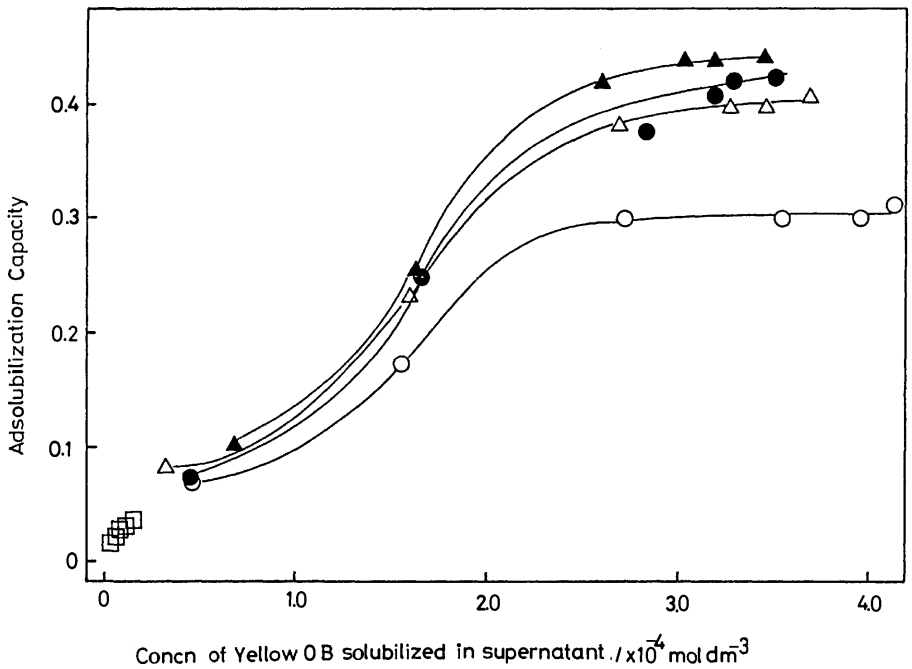

Fig. 1. Adsolubilization capacity for yellow OB in bilayers on alumina as a concentration of yellow OB solubilized in supernatant: (△) LiDS-NP7.5; (○) LiFOS-NP7.5; (▲) LiDS-NP20; (●) LiFOS-NP20; (□) LiDS-LiDS.

systems, and that the total amount of surfactant is greater for the LiDS-NP system than for the LiFOS-NP system with the same oxyethylene chain length of NP. The adsolubilization capacities for yellow OB in the mixed bilayers increase with an increase in the concentration of yellow OB solubilized in the supernatant; they appear to approach 0.5 except for the LiFOS-NP7.5 system. This indicates that the incorporation of yellow OB occurs systematically with the mixed bilayer (ratio of yellow OB : NP : LiDS or LiFOS=1 : 1 :1). These results also show that the systems containing NP20 have a higher adsolubilization capacity than those containing NP7.5, and that the LiDS-NP systems also have a higher adsolubilization than do the LiFOS-NP systems with the same ethylene oxide chain length of NP.

These differences may be attributed to the location of the adsolubilization site of yellow OB and to the magnitude of the hydrocarbon chain-hydrocarbon chain interaction and the hydrocarbon chain-fluorocarbon chain interaction of the surfactants. That is, generally it may be said that yellow OB is soluble in the poly(oxyethylene) shell of nonionic surfactant micelles and in the hydrocarbon core of anionic surfactant micelles.[20] In the mixed bilayers, since yellow OB is considered to be adsolubilized mainly in the poly(oxyethylene) chains of NP, the adsolubilization capacity of a system containing NP20 is greater than that of a system containing NP7.5. The difference in the adsolubilization capacity between the LiFOS-NP20 and LiDS-NP20 systems is small, however, probaly because of the less significant contributions from the hydrocarbon chain-hydrocarbon chain and hydrocarbon chain-fluorocarbon chain interactions. On the other hand, in the systems containing NP7.5, the adsolubilization capacity for yellow OB in the LiDS-NP7.5 system is greater than that in the LiFOS-NP7.5 system. This is presumably caused by the difference in the magnitudes of the hydrocarbon chain-hydrocarbon chain interaction and the hydrocarbon chain-fluorocarbon chain interaction of the surfactants.

Actually, from the measurement of the enthalpy of formation of a mixed bilayer, the enthalpy of the LiDS-NP7.5 system (-17.3 kJ mol^{-1}) was found to be greater than that of the LiFOS-NP7.5 system (-14.1 kJ mol^{-1}). This result supports the view that the hydrocarbon chain-hydrocarbon chain interaction of the LiDS-NP7.5 system is much stronger than the hydrocarbon chain-fluorocarbon chain interaction of the LiFOS-NP7.5 system. Mukerjee[21] has also pointed out that the hydrocarbon-hydrocarbon interaction is more favorable than the hydrocarbon-fluorocarbon interaction.

Further, the adsolubilization capacities for yellow OB in the single bilayers of LiDS and of LiFOS were measured in order to compare them with those in the mixed bilayers. However, the adsolubilization capacity for yellow OB in the LiFOS bilayer was too small to detect, as was to be expected from the amount of yellow OB solubilized in the LiFOS micelle.[8] The adsolubilization capacity for yellow OB in the LiDS bilayer (Fig. 1) is considerably smaller than that in the

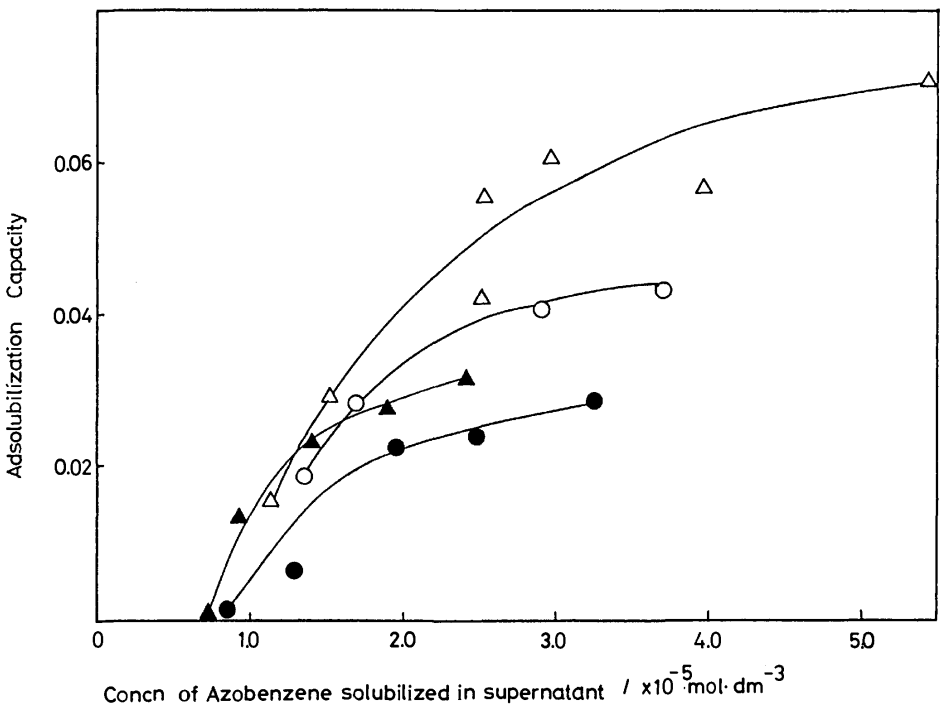

Fig. 2. Adsolubilization capacity for azobenzene in bilayers on alumina as a concentration of azobenzene solubilized in supernatant: (△) LiDS-NP7.5; (○) LiFOS-NP7.5; (▲) LiDS-NP20; (●) LiFOS-NP20.

mixed bilayers, suggesting that the hydrocarbon core in the LiDS bilayer has a very low adsolubilization capacity for yellow OB. This result corresponds with the low solubilization capacity for yellow OB in SDS micelles.[8] It is noteworthy that the adsolubilization capacities for yellow OB in the mixed bilayers are large compared to the solubilization capacity for yellow OB in the micelles; the solubilization capacities of NP7.5 and NP20 for yellow OB are 0.20 and 0.12 respectively.

The adsolubilization of azobenzene, which is soluble in the deep region of the poly(oxyethylene) shell for nonionic surfactant micelles, in the hydrocarbon core for the anionic surfactant micelles, and in both regions for mixed micelles,[22] was undertaken. Figure 2 shows the adsolubilization capacity for azobenzene in the LiDS-NP and LiFOS-NP systems. The adsolubilization capacity for azobenzene in the respective bilayers of LiDS and LiFOS was not large enough to measure. It is apparent, however, that the adsolubilization capacity for azobenzene in the LiDS-NP system is greater than that for the LiFOS-NP system, indicating that the adsolubilization of azobenzene is less favorable in the hydrocarbon chain-fluorocarbon chain layer for the LiFOS-NP system than in the hydrocarbon chain-hydrocarbon chain layer for the LiDS-NP system. This result emphasizes the aversion of aromatic compounds for fluorocarbon chains previously noted by the present authors.[17,23,24] The adsolubilization capacity for azobenzene decreased with the increase in the oxyethylene chain length of NP, contrary to the case of yellow OB. This result is presumably associated with the hydrophobic interactions in the bilayers; these interactions will increase with a decrease in the oxyethylene chain length of NP. This difference is also supported by the fact that the solubilization capacity for azobenzene in NP7.5 is greater than that for azobenzene in NP20. As well as yellow OB, the adsolubilization capacity for azobenzene in the mixed bilayers is greater than the solubilization capacity for azobenzene in NP7.5 and NP20; their capacities are 3.79×10^{-3} in NP7.5 and 3.44×10^{-3} in NP20 respectively.

In order to describe adsolubilization behavior using two solubilizates, we employed a partition coefficient K of the solubilizate between the bilayer and the

Table 2. Partition Coefficients of Yellow OB and Azobenzene in Bilayers

	327	1300		
	351	1200		

aqueous phases. The partition coefficient K is defined by Eq. 1:

$$K = \frac{S_{AC}}{S_W} \quad (1)$$

where S_{AC} is the adsolubilization capacity for dyes in the bilayer phase, and S_W, the concentration of dyes solubilized in the supernatant. These K values are tabulated in Table 2. The order in the magnitude of K for yellow OB is roughly as follows: LiDS-LiDS> LiDS-NP7.5, LiDS-NP20, and LiFOS-NP20> LiFOS-NP7.5. On the other hand, the K values for azobenzene are almost the same in all the systems except for the LiFOS-NP20 system. Wu et al.[15] reported that the partition coefficient of styrene into an SDS bilayer on alumina is around 300. This value is low compared with that for the dyes used here because they used ethanol to increase the solubility of styrene in an aqueous solution. For the adsolubilization of 1-hexanol and heptafluoro-1-butanol into the respective bilayers of LiDS and LiFOS,[16] the partition coefficient was obtained in the range between 100 and 500. The present data show that water-insoluble dyes, such as yellow OB and azobenzene, are adsolubilized more efficiently in the bilayers than are styrene and the two alcohols. Furthermore, it is noteworthy that, compared to the K values between micelles and bilayers, the efficiency of incorporation for water-insoluble compounds in the bilayers is significantly greater than that in micelles.[8]

The above results lead to the conclusion that water-insoluble dyes are adsolubilized into surfactant bilayers formed on the alumina, where the adsolubilization capacity of the mixed bilayer is greater for the LiDS-NP system than for the LiFOS-NP system. Further, in the mixed bilayers of the LiDS-NP and LiFOS-NP systems, the adsolubilization capacity for yellow OB increases with an increase in the oxyethylene chain length of NP, whereas that for azobenzene decrease with an increase in the oxyethylene chain length of NP. These phenomena are presumably associated with the different locations of the dyes in the mixed bilayers. The adsolubilization capacity for yellow OB and azobenzene in the bilayers is considerably greater than the solubilization capacity in the corresponding micelles.

Adsorption at Water/Air Interface and Micelle Formation of Decylammonium Bromide and Decylammonium Chloride Mixture

Hitoshi MATSUKI,* Naoko ANDO, Makoto ARATONO, and Kinsi MOTOMURA
Department of Chemistry, Faculty of Science, Kyushu University 33, Fukuoka 812
(Received April 12, 1989)

The surface tension of the aqueous solution of decylammonium bromide (DeAB) and decylammonium chloride (DeAC) mixture was measured as a function of the total molality and composition of surfactants at 298.15 K under atmospheric pressure. By applying the thermodynamic equations derived previously to the experimental results, the compositions in the mixed adsorbed film and mixed micelle were evaluated. It was found that the adsorbed film and micelle are rich in DeAB, which is more surface active than DeAC, compared with the aqueous solution. Further, the DeAB and DeAC molecules were concluded to mix ideally in the states of the adsorbed film and micelle. On the other hand, the compositions were compared with those of dodecylammonium chloride (DAC)-DeAC mixture at the critical micelle concentration (cmc). The discrepancy between the compositions was proved to be related closely to the differences between the cmc's and between the surface tension values at the cmc of pure surfactants.

The miscibility of surfactants in adsorbed films and micelles has been clarified thermodynamically by use of the excess thermodynamic quantities defined with reference to dividing planes and the two-dimensional phase diagrams representing the relation between the compositions of surfactants in the aqueous solution, adsorbed film, and micelle.[1-5] In the previous paper, the adsorbed film and micelle of dodecylammonium chloride (DAC)-decylammonium chloride (DeAC) mixture have been investigated by measuring the surface tension of the aqueous solution;[1,4] the difference of the surfactant ions has been shown to produce a considerable effect on the adsorption and micelle formation.

It is now important to examine the miscibility of surfactants having different counter ions in the adsorbed films and micelles, because the densities of aqueous solutions,[6-9] the micelle aggregation numbers,[10] and the surface activities[11,12] of surfactants are greatly dependent on the counter ion. In the present study, we adopt the decylammonium bromide (DeAB)-DeAC mixture. The surface tension of the aqueous solution is measured as a function of the total concentration and composition of the surfactants in the neighborhood of the critical micelle concentration (cmc) at constant temperature under atmospheric pressure. The results are compared with those of the DAC-DeAC system at the cmc.

Experimental

Decylammonium bromide was prepared from decylamine (Tokyo Kasei's guaranteed reagent) and hydrobromic acid (Nacalai Tesque's guaranteed reagent) and recrystallized five times from ethanol. Decylammonium chloride was prepared and purified by the method described previously.[1] The purity of the surfactants was checked by observing the absence of a minimum on the surface tension vs. concentration curves. Water was triply distilled from dilute alkaline permanganate solution.

The surface tension of aqueous solutions was measured by the drop volume technique described previously.[13] The error estimated for the value of surface tension was less than 0.05 mN m^{-1}. The measurements were carried out at the temperature kept constant at 298.15 K by immersing the cell in a thermostat under atmospheric pressure.

Results and Discussion

It has been shown that the total molality and composition of a surfactant mixture in the aqueous solution are appropriate for the variables to provide information concerning the adsorption behavior and micelle formation of the mixture at constant temperature T and pressure p.[1-5] Here the total molality and composition are defined respectively by

$$m = m_1 + m_2 \quad (1)$$

and

$$X_2 = m_2/m, \quad (2)$$

where m_i is the molality of surfactant i and the component 2 refers to DeAC. The surface tension γ was measured as a function of m at several X_2 values at 298.15 K under atmospheric pressure.

Figure 1 shows the variation in γ with m. It is seen

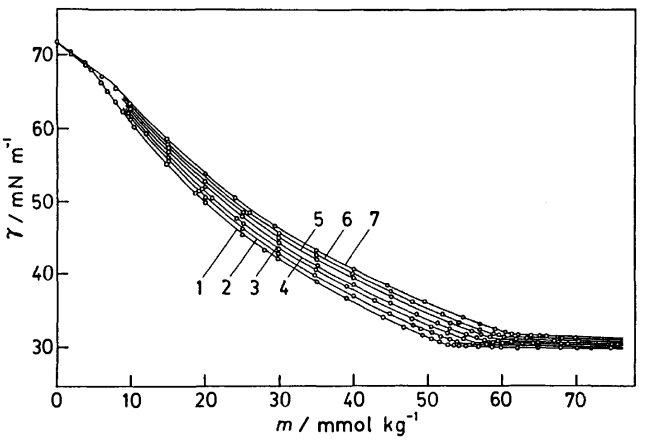

Fig. 1. Surface tension vs. total molality curves at constant composition: (1) X_2=0; (2) 0.299; (3) 0.500; (4) 0.650; (5) 0.800; (6) 0.900; (7) 1.

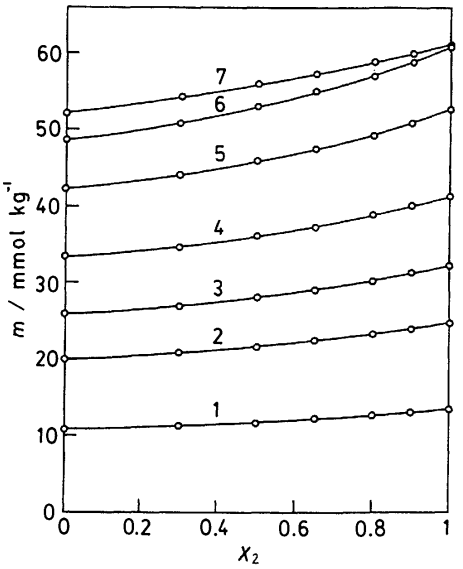

Fig. 3. Total molality vs. composition curves at constant surface tension: (1) γ=60 mN m^{-1}; (2) 50; (3) 45; (4) 40; (5) 35; (6) 32; (7) cmc vs. X_2.

that the value of γ decreases with increasing m and in the range of concentration above the cmc it does slightly and linearly. Further, the curve seems to have a distinct break point at the concentration corresponding to the cmc. By picking up the γ values at a concentration below the cmc from Fig. 1, the γ vs. X_2 curve is obtained and depicted together with the surface tension at the cmc γ^{cmc} vs. X_2 curve in Fig. 2. It is seen that the curves deviate slightly downward from the straight line connecting the γ values of pure DeAB and DeAC. Further, the m vs. X_2 curve at constant γ can also be obtained from Fig. 1; it is shown together with the cmc vs. X_2 curve in Fig. 3. We can find that the shape of the curve is convex downward at a low surface tension value though linear at a high one.

Let us first deal with the adsorption behavior of the surfactant mixture. According to the thermodynamics of adsorption of ionic surfactant mixtures developed previously,[1,2] the surface tension can be written as a function of m and X_2 at a concentration below the cmc at constant T and p:

$$d\gamma = -2(RT\Gamma^{H}/m)dm - [RT\Gamma^{H}(X_2^{H}-X_2)/X_1X_2]dX_2, \quad (3)$$

where the total surface density of surfactants Γ^{H} and the composition of DeAC in the mixed adsorbed film X_2^{H} are defined respectively by

$$\Gamma^{H} = \Gamma_1^{H} + \Gamma_2^{H} \quad (4)$$

and

$$X_2^{H} = \Gamma_2^{H}/\Gamma^{H} \quad (5)$$

Here Γ_i^{H} is the surface excess number of moles of surfactant i with reference to the two dividing planes making the surface excess numbers of moles of air and water zero.[14,15]

The value of Γ^{H} is evaluated by applying the following equation derived from Eq. 3 to the γ vs. m curve given in Fig. 1:

$$\Gamma^{H} = -(m/2RT)(\partial\gamma/\partial m)_{T,p,X_2}. \quad (6)$$

The Γ^{H} value is plotted against m at constant X_2 in Fig. 4; it is observed to increase with increasing m and approach the saturated value at a concentration near the cmc. It should be noted that the discontinuous change in Γ^{H} at a low concentration corresponds to the phase transition in the adsorbed film.[16]

It is apparent from Eq. 3 that there are two approaches to the evaluation of the composition in

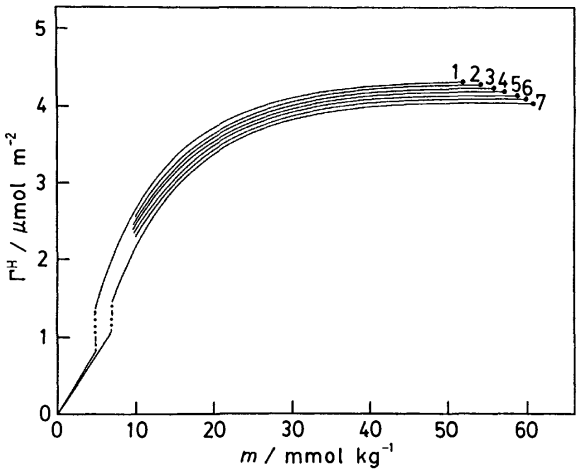

Fig. 4. Total surface density vs. total molality curves at constant composition: (1) X_2=0; (2) 0.299; (3) 0.500; (4) 0.650; (5) 0.800; (6) 0.900; (7) 1; (●) total surface density at the cmc $\Gamma^{H,cmc}$.

the mixed adsorbed film; one is the application of the equation

$$X_2^H = X_2 - (X_1X_2/RT\Gamma^H)(\partial\gamma/\partial X_2)_{T,p,m} \quad (7)$$

to the γ vs. X_2 curve at constant T, p, and m shown in Fig. 2 and the other is the application of the equation

$$X_2^H = X_2 - 2(X_1X_2/m)(\partial m/\partial X_2)_{T,p,\gamma} \quad (8)$$

to the m vs. X_2 curve at constant T, p, and γ shown in Fig. 3. The X_2^H values are presented in the forms of γ vs. X_2^H and m vs. X_2^H curves respectively in Figs. 5 and 6, where the corresponding γ vs. X_2 and m vs. X_2 curves are also depicted. It is seen that the value of X_2^H is smaller than that of X_2; that is, the mixed adsorbed film is enriched with DeAB, which has a smaller γ value than DeAC, over the whole range of composition. Taking account of the difference in chemical structure between DeAB and DeAC, the counter ion is said to have some effect on the adsorption behavior of surfactant ion. However, it is found that the composition difference $X_2-X_2^H$ is small compared with that of the DAC-DeAC system which is characterized by the different surfactant ion and the same counter ion.[1,4] Furthermore, the m vs. X_2^H curve seems not to deviate appreciably from the line connecting the m values of the pure surfactants. These findings indicate that the DeAB and DeAC molecules mix almost ideally in the adsorbed film.

Now let us consider the mixed micelle formation of surfactants. The thermodynamic equation describing the behavior of the mixed micelle at the cmc at constant T and p is[3]

$$-2(RT/\mathrm{cmc})\mathrm{dcmc} - [RT(X_2^M - X_2)/X_1X_2]\mathrm{d}X_2 = 0, \quad (9)$$

where X_2^M is the composition of DeAC in the mixed micelle defined by

$$X_2^M = N_2^M/(N_1^M + N_2^M), \quad (10)$$

where N_i^M is the number of molecules of surfactant i in one mixed micelle particle defined with regard to the spherical dividing surface which makes the excess number of moles of water zero. From Eq. 9, we can derive the relation between X_2^M and the derivative of the cmc with respect to X_2:

$$X_2^M = X_2 - 2(X_1X_2/\mathrm{cmc})(\partial\mathrm{cmc}/\partial X_2)_{T,p}. \quad (11)$$

The X_2^M value obtained from the cmc vs. X_2 curve shown in Fig. 3 is expressed in the form of the cmc vs. X_2^M curve in Fig. 7, where the cmc vs. X_2 curve is also drawn. It is seen that the population of DeAC in the mixed micelle is smaller than that in the solution although the difference between them is small. Sim-

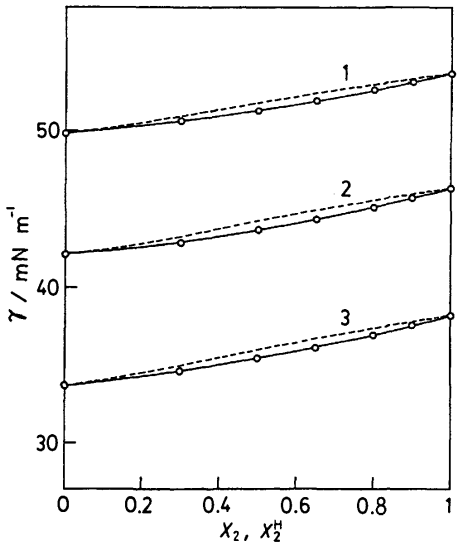

Fig. 5. Surface tension vs. composition curves at constant total molality: (1) m=20 mmol kg^{-1}; (2) 30; (3) 45; (——) X_2; (----) X_2^H.

ilar behavior was observed in the case of the potassium dodecyl sulfate-sodium dodecyl sulfate system.[3] Therefore, we may say that the DeAB and DeAC molecules mix ideally in the micelle as those in the adsorbed film.

Further, the X_2^H value at the cmc $X_2^{H,cmc}$ can be calculated by use of the composition dependence of the γ^{cmc} shown in Fig. 2 and the relation

$$X_2^{H,cmc} = X_2^M - (X_1X_2/RT\Gamma^{H,cmc})(\partial\gamma^{cmc}/\partial X_2)_{T,p}, \quad (12)$$

which is derived by combining Eq. 3 at the cmc with Eq. 9. Here $\Gamma^{H,cmc}$ is the total surface density of surfactants at the cmc represented by the closed circle in Fig. 4. The value of $X_2^{H,cmc}$ is shown in the form of the γ^{cmc} vs. $X_2^{H,cmc}$ plot in Fig. 8 and also in the form of the cmc vs. $X_2^{H,cmc}$ plot in Fig. 7. Comparing the values of $X_2^{H,cmc}$ and X_2^M, we notice that the micelle is slightly rich in DeAC compared with the adsorbed film. Since the difference between the values are small, however, it may be concluded that the miscibility of surfactants in the micelle is similar to that in the adsorbed film. This fact gives support to our view that the behavior of surfactants in the micelle resembles thermodynamically that in the adsorbed film.[4,17]

Finally, it is useful to compare the relation between the compositions in the aqueous solution, adsorbed film, and micelle of the DeAB-DeAC mixture with that of the DAC-DeAC mixture at the cmc. The cmc vs. composition curves are drawn in Fig. 9. It is clearly seen that the diagram of the DeAB-DeAC system is extremely thin compared with that of the DAC-DeAC system. To visualize the difference between the two systems quantitatively, the $X_2-X_2^M$, $X_2-X_2^{H,cmc}$, and $X_2^{H,cmc}-X_2^M$ values are plotted against X_2 in Fig. 10. Both the adsorbed film and the micelle are seen to be enriched with the surfactant which has the lower γ^{cmc} and cmc values. However, the $X_2-X_2^M$ and $X_2-X_2^{H,cmc}$ values of the DeAB-DeAC mixture are much smaller than those of the DAC-DeAC mixture; this may be attributable to a small difference in cmc between the constituents of the former mixture. On the other hand, the $X_2^{H,cmc}-X_2^M$ values of both the mixtures seem not to be different from each other, which arises from the fact that their differences in γ^{cmc}

between the constituents are comparable.

Further information about the miscibility of surfactants in the adsorbed film and micelle will be provided by examining the mixture of surfactants without a common ion.

(Received September 26, 1988)

The effects of temperature on the extraction of zinc(II) and cadmium(II) complexes with 8-quinolinol (HQ) and 2-methyl-8-quinolinol (HR) into three different types of organic solvents whose boiling points are relatively high were studied. 1) In the case of 1,1,2,2-tetrachloroethane (TCE), the extraction equilibrium can be written as follows (except for that of zinc with 2-methyl-8-quinolinol):

$$2M^{2+} + 6HQ_{(o)} + X^- \rightleftarrows M_2Q_3(HQ)_3^+{}_{(o)} + X^-{}_{(o)} + 3H^+,$$

where X^- refers to various inorganic anions. An ion-pair of the binuclear complex (complex ion pair) dissociates into a complex cation and an inorganic anion in the organic phase. The distribution ratios decrease remarkably with an increase in temperature. 2) In the 1-octanol (S) extraction system, zinc and cadmium are extracted as solvent-adducts, such as $MQ_2 \cdot S_2$. The distribution ratios are almost constant with a change in temperature. 3) In the *p*-xylene extraction system, a hydrated metal complex, $MQ_2 \cdot 2H_2O$, may precipitate and be deposited at the interface of both phases, except for the extraction of zinc with 2-methyl-8-quinolinol. 4) The zinc complexes of 2-methyl-8-quinolinol are extracted into TCE and *p*-xylene as anhydrous complexes, such as MR_2. The distribution ratios increase with an increase in temperature. Moreover, zinc can be separated from cadmium at high temperatures using 2-methyl-8-quinolinol and TCE.

Numerous studies have been conducted regarding the various factors affecting the solvent extraction of metal chelate. A few thermodynamic studies have been carried out. In these studies, however, measurements were conducted in the low-temperature region, below 50 °C, since volatile organic solvents, such as chloroform and benzene, were used.[1-5] As previously reported,[6-8] we studied the temperature effects on the extraction of 8-quinolinol, itself, and its divalent metal chelates into several organic solvents whose boiling points are relatively high over the temperature range 10 to 90 °C.

In this study the effects of temperature on the extraction behavior of zinc and cadmium with 8-quinolinol and 2-methyl-8-quinolinol between water and three different organic solvents were investigated with regard to the extraction mechanism. The organic solvents used were 1,1,2,2-tetrachloroethane, 1-octanol, and *p*-xylene, which were chosen as homologues of chloroform, 1-butanol, and benzene, respectively. The results for 2-methyl-8-quinolinol were compared with those for 8-quinolinol. Moreover, in order to corroborate the dissociation of the binuclear complex in TCE, the conductivities of the extract into TCE were measured.

Experimental

Reagents. Commercially available 8-quinolinol was purified by recrystallization from ethanol after steam distillation. A ^{65}Zn solution (1 mCi) was obtained from the Japan Radioisotope Association. Sodium salts of perchlorate, nitrate and chloride and other chemicals were all of analytical grade.

Apparatus. Extraction was carried out in a cylindrical glass tube with a magnetic stirrer in a water bath. The temperature was controlled by a thermoregulator to ±0.1 °C. A JASCO Ubest-30 spectrophotometer was used for the determination of 2-methyl-8-quinolinol. The concentration of zinc was determined by measuring the γ-radioactivity of aliquots of both aqueous and organic phases with a Packard Auto-Gamma 5100 single-channel pulse-height analyzer. Cadmium in both the phases was determined by a Nippon Jarrel Ash 8200 atomic absorption spectrophotometer equipped with a Nippon Jarrel Ash FLA 100 graphite furnace atomizer. For pH measurements, a Hitachi-Horiba M-5 pH meter equipped with a glass-calomel electrode pair for high-temperature work was used.

The conductivity measurements were carried out at 25.00±0.01 °C with a Yokogawa Hewlett Packard bridge, Type BV-Z-13B and a Yanagimoto conductivity cell, Type C.

Procedures. Partition of 2-Methyl-8-quinolinol: Equal (25 ml) volumes of the TCE solution containing a known concentration of 2-methyl-8-quinolinol and an aqueous solution pre-saturated with TCE were shaken in a constant-temperature bath for 3 h. The aqueous phase was adjusted to pH 8 with a borate buffer solution, and to an ionic strength of 0.1 with sodium perchlorate. After equilibration, the phases were immediately separated and cooled to room temperature. An aliquot of the aqueous phase was extracted into chloroform, while an aliquot of the organic phase was dissolved into chloroform. Then, the concentrations of 2-methyl-8-quinolinol were determined by measuring its UV absorbance at 312 nm.

Extraction Procedure: A 30 ml portion of a buffered zinc or cadmium solution was stirred with a 10 ml portion of 8-

quinolinol or 2-methyl-8-quinolinol solution of organic solvents standing in a constant-temperature bath for 30 min, which was found to be adequate for the attainment of distribution equilibrium. The pH of the initial aqueous solution was adjusted to the desired value with a small amount of an acetic acid-acetate buffer solution. Also, the ionic strength of the aqueous solution was adjusted to 0.1 with sodium salts.

The pH value of the aqueous phase, measured in situ after stirring, was taken as the equilibrium pH value. After phase separation, the concentration of zinc was determined by measuring the γ-radioactivity of aliquots of both phases with a single-channel pulse-height analyzer. In the case of cadmium, the concentration of cadmium in the aqueos phase was immediately determined with an atomic absorption spectrophotometer; the organic phase was analyzed after back extracting into a nitric acid solution. In each case, the volume of the aqueous phase was corrected for temperature with the values of the water density given in the Smithsonian tables; the volumes of the organic phases were corrected for temperature with experimentally determined density functions. Thus, the density at any temperature employed could be calculated using the following formulae: $1.597-1.562\times10^{-3}$ ($t-20$) for 1,1,2,2-tetrachloroethane, $0.8610-8.783\times10^{-4}$($t-20$) for *p*-xylene, and $0.8256-7.415\times10^{-4}$ ($t-20$) for 1-octanol, where temperature is in degrees centigrade.

All the extraction experiments were carried out below pH 5.5, since metal ions could be adsorbed on the wall of a glass container or the interface of both phases at higher pH.

Results and Discussion

Extraction of Zinc and Cadmium Complexes of 8-Quinolinol into TCE in the Presence of Several Inorganic Anions. The extraction of the zinc 8-quinolinol complex has been reported by several investigators.[9-14] A number of different species thought to have been extracted into the chloroform have been proposed: for example, $ZnQ_2HQ\cdot H_2O$,[9] $ZnQ_2(HQ)_2$,[10,11] and $ZnQ_2HQ\cdot S$,[12] where S represents the organic solvent. Furthermore, Oki et al.[13] and Sekido et al.,[14,15] have reported that an ionic association complex having the composition $Zn_2Q_3(HQ)_3{}^+ClO_4{}^-$ is extracted into chloroform from a zinc solution containing perchlorate ion.

Four types of plots were analyzed in order to determine the composition of zinc chelate under various conditions: $\log D$ vs. $\log[HQ]_0$, $\log D$ vs. pH, $\log D$ vs. $\log[X^-]$, and $\log D$ vs. $\log[Zn]_T$ at constant conditions for all the other factors, respectively. Herer, D is the distribution ratio of zinc; $[HQ]_o$, the concentration of 8-quinolinol in the organic phase; $[X^-]$, the concentration of inorganic anions in the aqueous phase; and $[Zn]_T$, the total concentration of zinc, respectively. Plots of $\log D$ vs. $\log[HQ]_0$ at 20 °C in the presence of perchlorate and chloride ions are shown in Fig. 1. It seems that three 8-quinolinol molecules combine with one zinc ion in these extraction systems, since all curves have solpes of 3. The curves in Fig. 2 show the relationship between $\log D$ and the pH at various

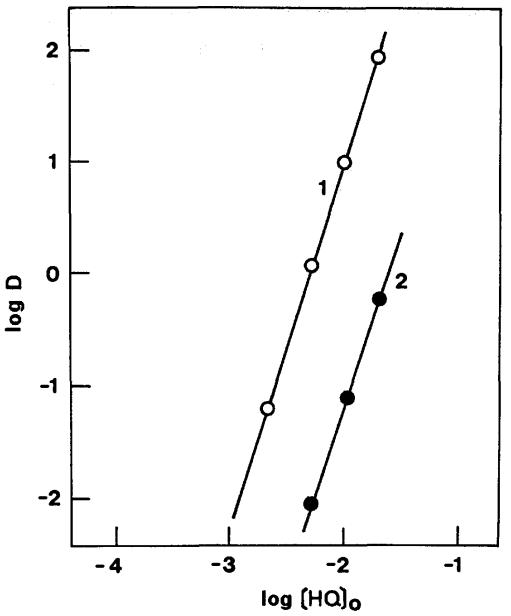

Fig. 1. Effects of 8-quinolinol concentration on the distribution ratio of zinc between TCE and water in the presence of perchlorate and chloride at 20 °C. $[Zn]_T=10^{-6}$ M, 0.09 M salts+0.01 M (AcOH-AcONa buffer) pH 5.0, 1; $NaClO_4$, 2; NaCl.

temperatures. The curves have slopes of 1.5 for the perchlorate system in the temperature range 20 to 80 °C and for the chloride system at 20 °C, as indicated by solid circles. In these systems it is supposed that one and a half hydrogen ions dissociate from three molecules of 8-quinolinol to form a chelate in the aqueous phase. In other words, three molecules of 8-

quinolinol and one and half molecules of hydrogen ions apparently combine with one zinc ion. In Fig. 3 values of log D are plotted against log[X^-]. In the perchlorate and chloride systems, the slopes of curves (1) and (2) both equal 0.5 at pH 5.0. This phenomenon is not accidental at pH 5.0, but also holds at different pH. It seems that half a molecule of anion apparently attaches itself to one zinc molecule in these systems. The curves in Fig. 4 show the relationship between log D and log$[Zn]_T$ in the perchlorate and chloride systems. The curves have slopes of nearly 0, though log D values increase only slightly as the concentration of zinc increases. The fact that log D is independent of the concentration of zinc has been considered to indicate that a mononuclear complex is the predominant zinc species in the organic phase.[13] However, if a mononuclear complex were the predominant species, unusual ionic dissociation of the binuclear complex in the organic phase must be assumed as follows, since the apparent composition of this complex is $ZnQ_3H_{3/2}X_{1/2}$ from above results:

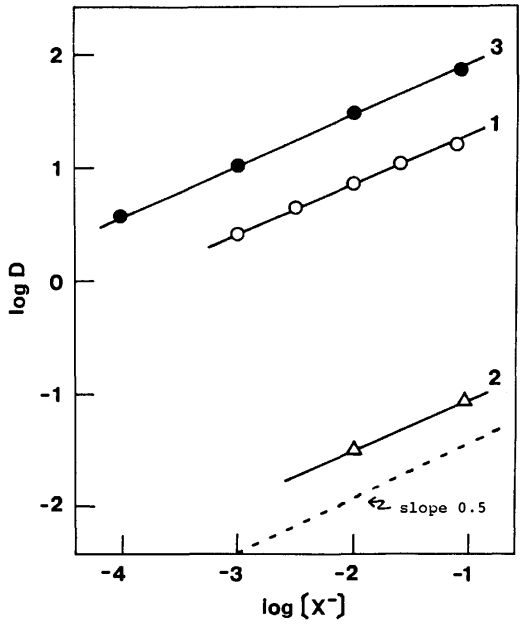

Fig. 3. Effects of concentration of inorganic anions on the distribution ratio of zinc between TCE and water at 20 °C.
$[HQ]_o=10^{-2}$ M, pH 5.0, 1; $NaClO_4$ system, 2; NaCl system, 3; $[HQ]_o=10^{-1}$ M, pH 3.8, $NaClO_4$ system.

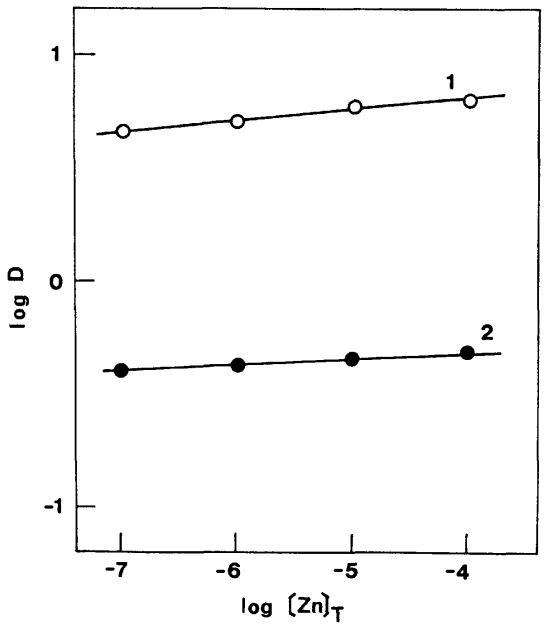

Fig. 4. Effects of metal concentration on the distribution ratio of zinc between TCE and water at 20 °C.
$[HQ]_o=2\times10^{-2}$ M, 1; $NaClO_4$ system, pH 4.0, 2; NaCl system, pH 4.8.

$$Zn_2Q_6H_3X_{(o)} \rightleftarrows ZnQ_3H_2^+{}_{(o)} + ZnQ_3HX^-{}_{(o)}, \quad (1)$$

where subscript o refers to the species in the organic phase.

Then, if the binuclear complex almost dissociates in the organic phase,

$$Zn_2Q_6H_3X_{(o)} \rightleftarrows Zn_2Q_6H_3^+{}_{(o)} + X^-{}_{(o)}, \quad (2)$$

the distribution ratio of zinc between the organic and aqueous phases in the acidic media would be given by following equation, since the simple zinc ion is the predominant zinc species in the aqueous phase:

$$D = \frac{2[Zn_2Q_6H_3^+]_o}{[Zn^{2+}]} \quad (3)$$

The extraction equation can be written as

$$2Zn^{2+} + 6HQ_{(o)} + X^- \rightleftarrows Zn_2Q_3(HQ)_3^+{}_{(o)} + X^-{}_{(o)} + 3H^+. \quad (4)$$

The extraction constant is

$$K_{ex} = \frac{[Zn_2Q_3(HQ)_3^+]_o[X^-]_o[H^+]^3}{[Zn^{2+}]^2[HQ]_o^6[X^-]} \quad (5)$$

In order to keep the electrical neutrality in the organic phase, $[Zn_2Q_3(HQ)_3^+]_o=[X^-]_o$, Eq. 5 can be transformed into

$$K_{ex} = \frac{[Zn_2Q_3(HQ)_3^+]_o^2[H^+]^3}{[Zn^{2+}]^2[HQ]_o^6[X^-]} \quad (6)$$

The distribution ratio, D can be given as

$$D = 2K_{ex}^{1/2}[HQ]_o^3[H^+]^{-3/2}[X^-]^{1/2}. \quad (7)$$

This equation means that plots of log D vs. log$[HQ]_o$ show a slope of 3, plots of log D vs. pH a slope of 1.5 and plots of log D vs. log[X^-] a slope of 0.5. Thus, the assumption that the ion pair of the binuclear complex would dissociate in the organic phase agrees well with the experimental results.

The dissociation of ion-associated complexes in an organic solvent with a dielectric constant that is relatively high, such as nitrobenzene (34.8), has already been reported. However, the dielectric constant of

TCE is 8.2 (at 20 °C). In order to corroborate the dissociation of the binuclear complex in TCE, the conductivities (Λ) of the extract into TCE in the presence of perchlorate or chloride were measured at 25 °C. The zinc concentration was varied from 10^{-5} to 10^{-3} M (1 M=1 mol dm^{-3}). Plots of Λ vs. $\sqrt{C}$ of zinc chelate of 8-quinolinol extracted into TCE are shown in Fig. 5. The limiting equivalent conductivities (Λ_0) can be calculated from the equation as follows:

$$\Lambda_0 = \frac{0.820|Z_i|}{\eta r_s}, \quad (8)$$

where η is the viscosity of the organic solvent and r_s is the Stokes radius. η of TCE at 25 °C is 1.60. The ionic radii of perchlorate and chloride are 2.4 Å[16] and 1.67 Å.[17] The ionic radius of the complex cation, $Zn_2Q_6H_3^+$, was estimated to be 8.7 Å by assuming it is 1.5-times larger than that of the simple chelate, ZnQ_2 (5.8 Å).[18] The dissociation constants were calculated to be 5.04×10^{-6} and 2.67×10^{-6}, respectively, from the degrees of dissociation ($\alpha=\Lambda/\Lambda_0$). Therefore, at a zinc concentration of 10^{-6} M, where the extraction experiment was carried out, it is considered that 98 and 77% of the ion pair of the binuclear zinc complexes could dissociate in TCE when in the presence of perchlorate and chloride, respectively. The results of conductivity measurements endorse the assumption that the ion pair of the binuclear complex dissociates into a complex cation and an inorganic anion in TCE.

The extraction behavior of cadmium chelate of 8-quinolinol into TCE is similar to that of the zinc chelate. The binuclear complex also dissociates in the organic phase as

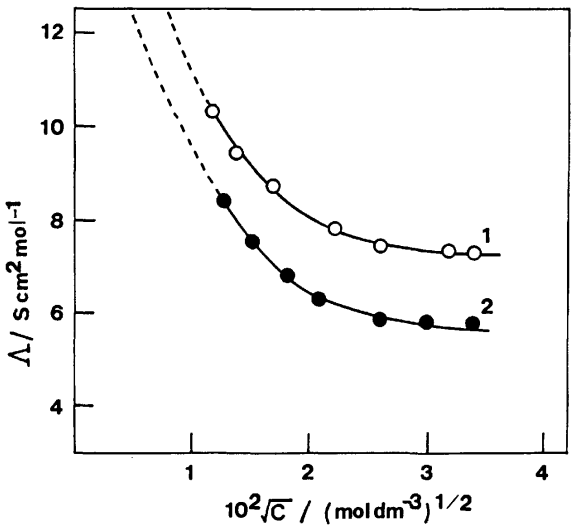

Fig. 5. Λ vs. $\sqrt{C}$ plots of zinc chelate of 8-quinolinol extracted into TCE at 25 °C.
1; $NaClO_4$ system, 2; NaCl system.

$$2Cd^{2+}+6HQ_{(o)}+X^- \rightleftarrows Cd_2Q_3(HQ)_3^+{}_{(o)}+X^-{}_{(o)}+3H^+. \quad (9)$$

The slopes of the plots of log D vs. log $[HQ]_o$, log D vs. pH and log D vs. log $[X^-]$ are 3, 1.5, and 0.5, respectively.

Plots of log D vs. $1/T$ for zinc and cadmium in the presence of perchlorate and chloride ions are shown in Fig. 6. The distribution ratios decrease remarkably with an increase in temperature for both zinc and cadmium. The curves for cadmium are linear up to fairly high temperatures, even for the chloride system, when compared to that of zinc. The changes of the slope of log D vs. $1/T$ suggest that the extracted species at high-temperature ranges are different from those at low-temperature ranges. This is supported by the fact that the slopes of the plots of log D vs. log $[HQ]_o$ in the zinc extraction system become smaller than 3 at high temperatures, especially for smaller anions, such as chloride and sulfate.[7] At high temperatures, the extraction of anhydrous chelate ZnQ_2 may occur in a manner similar to the 2-methyl-8-quinolinol system (as stated below). In the case of cadmium, a stable ion-associated compound is formed even in the chloride system at high temperatures because the ionic radius of the complex cation for cadmium is larger than that for zinc.

Extraction of Zinc and Cadmium with 2-Methyl-8-quinolinol into TCE in the Presence of Several Inorganic Anions. Since the chemical nature of 2-methyl-8-quinolinol is similar to that of 8-quinolinol, a large difference in the extraction behaviors of metal ions between both the ligands is not observed in most cases. In some cases, however, the structures of complexes with 2-methyl-8-quinolinol are quite different from those with 8-quinolinol, probably due to a steric hindrance effect of the methyl group, although this is debatable.[19]

The extraction of zinc and cadmium with 2-methyl-8-quinolinol into TCE in the presence of perchlorate and chloride ions was studied at various temperatures for a comparison with that with 8-quinolinol.

Plots of log D vs. variables such as pH, the concentrations of 2-methyl-8-quinolinol and concentrations of inorganic anions were obtained in order to determine the stoichiometry of the extracted species. The slopes of log D vs. pH, log D vs. log$[HR]_o$ and log D vs. log$[X^-]$ are 1.5, 3, and 0.5, respectively. Additionally, plots of log D vs. log$[Cd]_T$ are constant in the cadmium concentration range 10^{-6} M to 10^{-4} M. Therefore, the extraction behavior of the cadmium chelate of 2-methyl-8-quinolinol into TCE is similar to those of zinc and cadmium chelates of 8-quinolinol into TCE.

Hence, the extraction equation can be given as

$$2Cd^{2+} + 6HR_{(o)} + X^- \rightleftarrows Cd_2R_3(HR)_3^+{}_{(o)} + X^-{}_{(o)} + 3H^+. \quad (10)$$

The extraction behavior of zinc-2-methyl-8-quinolinol chelate into TCE is unlike the case of cadmium. The slopes of log D vs. pH are 2 at each temperature. The plots of log D vs. log$[HR]_o$ at a constant pH are linear with a slope of 2. The distribution ration of zinc are uneffected by the kind of inorganic anion involved. Thus, it can be concluded that only a single species, the simple 1 : 2 chelate, ZnR_2, is present in TCE. The overall raction can be represented by

$$Zn^{2+} + 2HR \rightleftarrows ZnR_2 + 2H^+. \quad (11)$$

In Fig. 7, the values of log D at pH 5.5 are plotted against the reciprocal of temperature for zinc and cadmium. In the case of cadmium, the distribution ratios decrease remarkably with an increase in temperature for perchlorate and chloride. The trend is similar to those of zinc and cadmium chelates of 8-quinolinol into TCE. However, in the case of zinc, the distribution ratios increase with an increase in temperature. The opposite effect is noted in the cases of cadmium and zinc with 8-quinolinol. These results indicate that the difference in distribution ratios of zinc and cadmium can be enhanced at high temperatures. Hence, solvent extraction with 2-methyl-8-quinolinol at high temperatures can be applied to the separation of zinc and cadmium in aqueous samples.

The principal difference between 8-quinolinol and

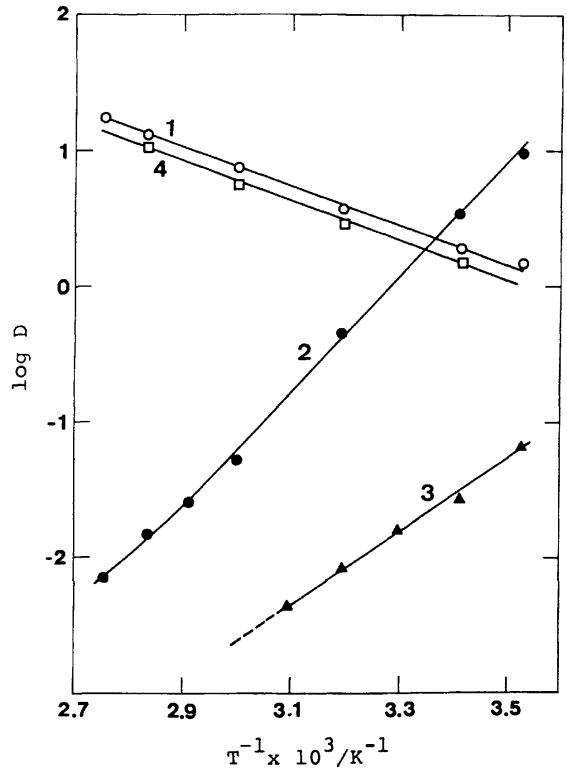

Fig. 7. Effects of temperature on the distribution ratio of zinc and cadmium with 2-methyl-8-quinolinol between TCE (or p-xylene) and water. pH 5.5, solvent=TCE, 1; Zn , $[HR]_o=5\times10^{-2}$ M, 2; Cd, $NaClO_4$ system, $[HR]_o=10^{-1}$ M, 3; Cd, NaCl system 4; solvent=p-xylene, Zn, $[HR]_o=2\times10^{-1}$ M.

2-methyl-8-quinolinol in the extraction of zinc into TCE is that the former forms a self-adduct complex whereas the latter forms a simple 1 : 2 complex. In the case of cadmium, both the ligands form self-adduct complexes, probably because the ionic radius of cadmium (0.97 Å) is larger than that of zinc (0.74 Å).

Extraction of Zinc and Cadmium with 8-Quinolinol and 2-Methyl-8-quinolinol into p-Xylene. In the 8-quinolinol extraction system, the precipitation of zinc and cadmium chelates occur even in the low-pH range. Therefore, a detailed investigation concerning the temperature effects was omitted. The total γ-activities of ^{65}Zn in both the aqueous and organic phases suddenly decrease above pH 4.5 after 10 min of shaking. At pH 5.0, about 20% of zinc disappears after 1 min of shaking, and almost all zinc in both phases disappears after 20 min of shaking. These phenomena indicate that the hydrated chelate $ZnQ_2{\cdot}2H_2O$ may precipitate and be deposited at the interface of both phases.

In the 2-methyl-8-quinolinol extraction system, no zinc in either phase disappears. This indicates that the 2-position methyl group not only interrupts the formation of a self-adduct complex of zinc, but also makes the dehydration of the zinc chelate easy. The extraction of zinc with 2-methyl-8-quinolinol into p-

xylene was evaluated by a slope analysis. The results showed that the zinc chelate of 2-methyl-8-quinolinol is extracted into *p*-xylene as a simple 1:2 complex, ZnQ_2, similar to the case of the extraction of the zinc chelate of 2-methyl-8-quinolinol into TCE. The distribution ratios increase with an increase in temperature, as shown in Fig. 7. Similar effects are noted in zinc extraction with 2-methyl-8-quinolinol into TCE.

Extraction of Zinc and Cadmium with 8-Quinolinol or 2-Methyl-8-quinolinol into 1-Octanol. According to the report of Schweitzer et al.,[1] when 1-butanol is used as an extracting solvent, the zinc chelate of 8-quinolinol is extracted as a solvent-adduct compound, $ZnQ_2 \cdot S_2$ (S is an alcohol molecule). In the case of a 1-octanol extraction system, the extraction mechanism of zinc and cadmium with 8-quinolinol or 2-methyl-8-quinolinol is similar to the case of 1-butanol. The slopes of log *D* vs. log[HQ(or HR)]$_o$ exhibit a linear range with a slope of 2. Additionally, the plots of log *D* vs. log[S]$_o$, when 1-octanol is dissolved in hexane, give a straight line of slope 2. These results suggest that the extracted species in octanol is a solvent-adduct compound, $MQ_2 \cdot S_2$ or $MR_2 \cdot S_2$. Temperature effects on the distribution ratios of zinc and cadmium with 8-quinolinol and 2-methyl-8-quinolinol are shown in Fig. 8. The distribution ratios are almost constant with a change in temperature.

Thermodynamic Parameters. The thermodynamic parameters for the distribution of 8-quinolinol[6] and 2-methyl-8-quinolinol between organic solvents and water are listed in Table 1. The values of log K_{DR} (K_{DR} is the distribution constant of reagent) for TCE, which have not been reported, are of a similar order to those for chloroform.[20,21] In all cases the ΔH values are negative and the ΔS values are positive. Hence, the fact that 8-quinolinol and 2-methyl-8-quinolinol are more soluble in organic solvents such as TCE, *p*-xylene, and 1-octanol than in water is due to the favorable contributions of both enthalpy and entropy. All the values of ΔH for the distribution processes of 8-quinolinol and 2-methyl-8-quinolinol are smaller than the values of the hydrogen-bond energy (10 to 25

kJ mol^{-1}).

The thermodynamic parameters for the extraction of zinc and cadmium with 8-quinolinol and 2-methyl-8-quinolinol into TCE, *p*-xylene, and 1-octanol are summarized in Tables 2 and 3.

In a series of the ion-associated complexes of zinc and cadmium, the values of ΔH are largely negative, which shows that the extraction of the complex ion pair is an exothermic reaction. The order of their ΔH values correlates with their extractability. Thus, the larger is the size of an inorganic anion or metal ion, the larger is the absolute values of ΔH. The values ΔS are also largely negative and proportional to those of ΔH in the ion-associated complex series of metals and inorganic anions. This is generally the trend observed in the thermodynamics of ion-pair extraction, indicating that the exothermic property is partly compensated with the term of ΔS. The values of ΔH for the extraction of cadmium with 2-methyl-8-quinolinol are similar to those of cadmium with 8-quinolinol in the presence of perchlorate and chloride. The extraction mechanism of cadmium with 2-methyl-8-quinolinol is similar to that of cadmium with 8-quinolinol.

The extraction of zinc with 2-methyl-8-quinolinol into TCE and *p*-xylene is an endothermic reaction, unlike the extraction of zinc with 8-quinolinol into TCE. It has been reported that this behavior is characteristic of chelating reactions in which the water molecules of the inner-coordination sphere of the metal ion are displaced by the chelating reagent.[22] The extraction constant (K_{ex}) of zinc with 2-methyl-8-quinolinol into TCE and *p*-xylene is a composite of the chelate formation constant, β_2, and its distribution constant, K_{DC}, as well as of the reagent acid-dissociation constant, K_a, and its distribution constant, K_{DR}: $K_{ex}=\beta_2 K_{DC} K_a^2 / K_{DR}^2$. β_2 and K_a are independent of the organic solvent. Therefore, the difference in the extraction constant between TCE and *p*-xylene can be related to the difference in the product, $K_{DC}K_{DR}^{-2}$. The values of ΔH for extraction constants are both 33.5 kJ mol^{-1} for TCE and *p*-xylene. It is conceivable that the difference in the ΔH values for the distribution coefficients of 2-methyl-8-quinolinol between TCE and *p*-xylene would be small, since the difference in the ΔH values for those of 8-quinolinol between both the solvents is also small (Table 1). Therefore, it is considered that the value of ΔH for the distribution constant of the zinc chelate with 2-methyl-8-quinolinol into TCE is almost the same as that into *p*-xylene. This means that the distribution of ZnR_2 into the organic phase is controlled by its own dehydration. The minute difference in the ΔG values between the TCE and *p*-xylene system is attributed to the ΔS term, probably due to the solvent-adduct ability of TCE with zinc chelates. The ΔH values for solvent-adduct systems are quite small, being close to zero.

Solvent Effect on the Liquid-Liquid Partition of 21*H*,23*H*-Porphine between Various Organic Solvents and Acidic Aqueous Solutions

Yoshito WAKUI,† Hisanori IMURA, and Nobuo SUZUKI*
Department of Chemistry, Faculty of Science, Tohoku University, Sendai 980
(Received December 16, 1988)

The liquid-liquid partition equilibrium of 21*H*,23*H*-porphine has been investigated at 25 °C. Organic phases were heptane, dodecane, carbon tetrachloride, benzene, toluene, chloroform, dichloromethane, and 1-octanol. The acidic aqueous phases were 5×10^{-2}—5×10^{-1} M hydrochloric acid. Porphine is present in such acidic solutions as a diprotonated form and no dimerization was found in any of the systems. The organic solvent effect on the partition coefficient of porphine is discussed with the aid of regular solution theory, and the solubility parameter of porphine is estimated as 10.7±0.6 $cal^{1/2}$ $cm^{-3/2}$.

Porphyrin and related derivatives are important compounds in biochemistry and geochemistry. In relation with chemical separation and natural migration of these porphyrin compounds, a systematic study on the solution behavior of porphyrins and their metal chelates is desirable. However, little is known about the solubility and the liquid-liquid partition of these porphyrin compounds. The solution behavior of a solute is governed by the physicochemical nature of the solute and solvents. The liquid-liquid partition of various organic solutes including metal β-diketonate complexes has been systematically studied and elucidated with the aid of regular solution theory and the scaled particle theory.[1-6]

In the present study, we have prepared high purity 21*H*,23*H*-porphine, which is the simplest porphyrin compound, having no substituent group. We have investigated its partition equilibria between various organic solvents and acidic aqueous solutions. The solvent effect is quantitatively discussed with the aid of regular solution theory.

Experimental

Materials. 2-Pyrrolecarbaldehyde (99% purity, Aldrich) was used as purchased. Carbon tetrachloride, chloroform, and dichloromethane were of spectroscopic grade (Spectrosol, Dojindo Lab.), and chloroform was used after washing several times with redistilled water. Other organic solvents were of guaranteed reagent grade and purified by ordinary methods.[7]

Hydrochloric acid was of analytical reagent grade (Wako Co.). The acid solutions were standardized with sodium carbonate (primary standard, Asahi glass Co.).

Unless otherwise stated, reagents used were of guaranteed reagent grade.

Preparation and Purification of 21*H*,23*H*-Porphine. 21*H*,23*H*-Porphine was synthesized by the method of Longo et al.,[8] and purified by a method modified somewhat from those of Rothemund[9] and Krol.[10] 2-(Hydroxymethyl)pyrrole, a starting material for synthesis of porphine, was prepared by reduction of 2-pyrrolecarbaldehyde with sodium borohydride according to the literature.[11] A crude product of porphine was obtained by keeping the dilute solution of 2-(hydroxymethyl)pyrrole in ethylbenzene at 100±2 °C with stirring. The ethylbenzene solution after reaction was fed into a silica-gel column (Kicselgel 60 HR, Merck) and eluted with benzene. The benzene solution obtained was washed with 50% (v/v) acetic acid and then 0.35% (w/v) hydrochloric acid. Porphine was extracted from benzene to 5% (w/v) hydrochloric acid. The aqueous solution was neutralized with a saturated sodium acetate solution and shaken with benzene to extract porphine. After washing with water, the benzene solution was concentrated with a rotary evaporator, and methanol was added to crystallize the porphine. A dark auburn crystalline product was filtered and dried over phosphorus pentaoxide in vacuo at 120 °C. Identification of the product was accomplished by C, H, N analysis, mass spectroscopy, proton magnetic resonance spectroscopy, and electronic absorption spectroscopy. The purity was also checked with high-performance liquid chromatography (column, LiChrosorb RP-18; mobile phase, acetone:acetonitrile:water=25:200:11.3; detection wavelength, 395 nm) and found to be more than 99%.

Apparatus. Absorbance of a solution was measured with a spectrophotometer (UVIDEC-2, JASCO). To prevent adsorption of porphine onto the wall of the glassware including volumetric flasks, and the quartz cell in the absorbance measurement, they were treated with dimethyldichlorosilane before use.

The extraction vial was shaken with a mechanical shaker at about 350 strokes per min. The density of the porphine solution was measured with a digital precision density meter (Anton Paar DMA-50). All experiments were carried out in a thermostated room at 25±0.5 °C.

Partition Experiments. An organic solvent and an acidic aqueous solution were preequilibrated to each other. A certain volume of the organic solution of porphine in 10^{-7}—10^{-4} M (1 M=1 mol dm^{-3}) was shaken with the acidic aqueous solution for 5—60 min and centrifuged. The ionic strength of an acidic aqueous solution was kept at 0.50 M with sodium chloride. The distribution ratio (D) of porphine which was the ratio of the total concentration of porphine in the organic phase to that in the aqueous phase was determined from the absorbance of the organic phases before (A_i) and after (A) shaking; $D=(V_a/V_0)A/(A_i-A)$, where V_a and V_0 are volume of the aqueous and the organic phase respectively. To ascertain achievement of the partition equilibrium, porphine was dissolved in an acidic aqueous solution and shaken with the organic solvent. The distribution ratio determined from the absorbance of the

† Present address: Government Industrial Research Institute, Tohoku, Nigatake, Sendai 983.

a) Soret band. b) Q Band was also used for the partition measurement. c) 0.5 M hydrochloric acid.

equilibrated aqueous phases is in good agreement with that obtained above. The wavelengths used for the absorbance measurement in different organic solvents are shown in Table 1. Lambert-Beer's rule was confirmed in the absorbance range of 0.13—0.67 in benzene and the acidic aqueous solution.

Density Measurement. The partial molar volume of porphine was calculated from the densities of porphine solutions in varying concentrations. The solubility of porphine in various organic solvents was remarkably low. A sufficient solubility of porphine to measure the difference in the density of the solution was obtained using only pyridine as a solvent. The concentration range of porphine was 4×10^{-4}—2×10^{-3} M. The uncertainty in the density measurement was within $\pm1\times10^{-5}$ g cm^{-3}.

Results and Discussion

Partition Equilibrium. Porphine (denoted as H_2A) is a nitrogen base and its partition between an organic phase and an acidic aqueous phase can be represented by the following equilibria.

$$H_2A + nH^+ \rightleftarrows H_{n+2}A^{n+} \qquad K_n = \frac{[H_{n+2}A^{n+}]}{[H_2A][H^+]^n}, \quad (1)$$

$$H_2A \rightleftarrows H_2A_o \qquad P = \frac{[H_2A]_o}{[H_2A]}, \quad (2)$$

where K_n and P are the overall protonation constant and the partition coefficient, respectively. The subscript o refers to the organic phase. Dimerization of porphine in the organic and aqueous phases is negligible under the present experimental conditions of sufficiently low concentration of porphine (vide infra). The distribution ratio of porphine is given by

$$D = \frac{[H_2A]_o}{[H_2A] + [H_3A^+] + [H_4A^{2+}] + \cdots + [H_{n+2}A^{n+}]}. \quad (3)$$

If a single species of protonated porphine is present in the aqueous phase, the distribution ratio can be written as

a) Equilibrium concentration in benzene phase. b) Equilibrium concentration in aqueous phase.

$$D = \frac{P}{K_n[H^+]^n}. \quad (4)$$

The dependence of the distribution ratio of porphine on the hydrogen ion concentration and the solute concentration was investigated in detail in the benzene system. The plots of $\log D$ as a function of $\log[H^+]$ are shown in Fig. 1, together with those for other solvents. The plots for benzene give a straight line with a slope of 2.0 which is determined by the least squares method, and those for other solvents also give the slope of 2.0±0.1. These demonstrate that only a single species of diprotonated porphine, H_4A^{2+}, is present in the acidic aqueous solution of 5×10^{-2}—5×10^{-1} M H^+. The effect of the porphine concentration on the partition equilibrium was investigated, that is, the distribution ratios of porphine with various initial concentrations were determined at different hydrogen ion concentrations. In Table 2, the

results are expressed as the product of two constants of P and K_2^{-1} calculated from Eq. 4 by knowing n=2. A constant value of 0.69±0.03 is obtained over a wide range of porphine concentration, and this supports no dimerization of porphine in either phase.

The values of $\log P \cdot K_2^{-1}$ for different solvents are listed in Table 3. The value increases in the following order; heptane<dodecane<1-octanol<carbon tetrachloride<benzene≈toluene<chloroform≈dichloromethane. As the protonation constant K_2 is not influenced by the organic solvents, the difference in these values is directly proportional to those in the partition coefficients P for the organic solvents.

Partial Molar Volume of Porphine. The partial molar volume is one of the important physical measures in solution chemistry, but no data for porphine and related compounds have yet been reported. In this paper, the partial molar volume of porphine is measured and used in the calculation based on regular solution theory. The partial molar volume of porphine is calculated from the relation between the mean molar volume obtained from the density measurement, V_m, and the molar fraction of porphine, X_2,

$$V_m = \overline{V}_1 + (\overline{V}_2 - \overline{V}_1)X_2 \quad (5)$$

where $\overline{V}_1$ and $\overline{V}_2$ refer to the partial molar volumes of solvent and solute. The plots for Eq. 5 are shown in Fig. 2. The equation, $\overline{V}_m$=(80.4±0.002)+(155.3±15.3)X_2, was obtained by the least squares method, and the partial molar volume of porphine, $\overline{V}_2$=236±15 cm^3 mol^{-1} (95% confidence limit), was determined.

Solvent Effect on Partition Coefficient. The activity coefficient of a nonelectrolyte solute, γ_s, can be expressed on the basis of regular solution theory.[12]

$$\ln \gamma_s = \frac{V_s}{RT}(\delta_1^2 + \delta_s^2 - 2\delta_1\delta_s), \quad (6)$$

where V and δ are the molar volume and solubility parameters respectively, and the subscripts 1 and s denote solvent and solute, respectively. Since the activily of a solute in the organic phase is equal to that in the aqueous phase in partition equilibrium, the partition coefficient of a solute expressed as a molar fraction, P^X, is related to the activity coefficient;

$$P^X = \frac{X_{s,o}}{X_{s,a}} = \frac{\gamma_{s,a}}{\gamma_{s,o}}, \quad (7)$$

where X is the molar fraction and the subscript a denotes the aqueous phase. From Eqs. 6 and 7, the following equation can be derived,

$$\frac{RT}{V_s}\ln P^X + \delta_o^2 = 2\delta_s\delta_o + \frac{RT}{V_s}\ln \gamma_{s,a} - \delta_s^2. \quad (8)$$

Substituting Eq. 4 (as n=2) into Eq. 8, we obtain.

$$\frac{RT}{V_s}(\ln D^X + 2\ln[H^+]) + \delta_o^2 = 2\delta_s\delta_o + \frac{RT}{V_s}\left(\ln \gamma_{s,a} - \ln K_2 - \frac{V_s\delta_s^2}{RT}\right), \quad (9)$$

where D^X is the distribution ratio expressed as a molar fraction. Since the second term of the right hand side of Eq. 9 is independent of the organic solvent, the plots of the left hand side against the solubility

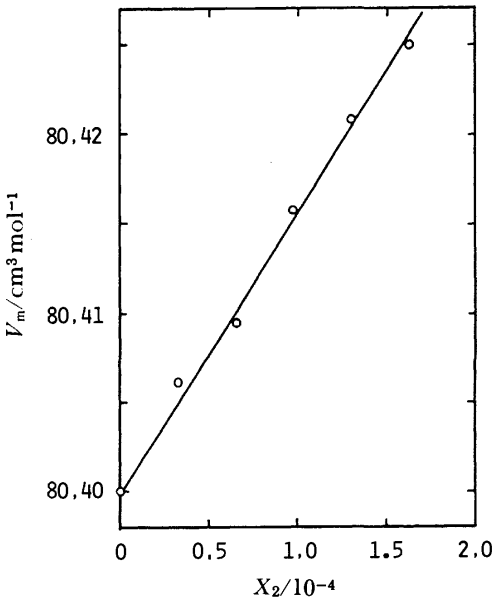

Fig. 2. Linear relationship between the mean molar volume of porphine solution in pyridine (V_m) and the molar fraction of porphine (X_2).

a) Calculated from the heat of vaporization of the solvent.[7] b) From the literature.[15] c) From Eq. 4, expressed in molar fraction. d) From Eq. 9 (see text).

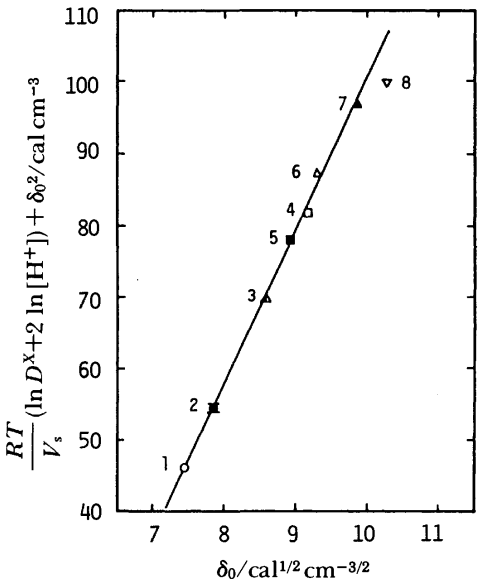

Fig. 3. Evaluation of the solvent effect of partition coefficient of porphine based on the regular solution theory. The numbers refer to those in Table 3.

parameter of the organic solvent, δ_0, should give a straight line, and the solubility parameter of porphine, δ_s, can be calculated from the slope. The $V_s$is replaced by the partial molar volume of porphine determined above. Even if the V_s value changes by 10% to larger or smaller values, it has an influence on the δ_s value of less than 3%. The solubility parameter of the organic solvent is calculated from the heat of vaporization of solvent at 25 °C.[7]

As shown in Fig. 3, the plots give a good linear relationship for heptane, dodecane, benzene, toluene, carbon tetrachloride, chloroform, and dichloromethane. Hence, these organic solutions of porphine may be designated regular solutions. The solubility parameter of porphine is calculated to be 10.7±0.6 cal$^{1/2}$ cm$^{-3/2}$ (95% confidence limit, 1 cal$^{1/2}$ cm$^{-3/2}$= 2.0455 J$^{1/2}$ cm$^{-3/2}$) by the least squares method of the plots for seven nonpolar solvents. This value is close to those of heterocyclic amines such as pyridine (10.7 cal$^{1/2}$ cm$^{-3/2}$) and quinoline (10.8 cal$^{1/2}$ cm$^{-3/2}$) which are calculated from the heat of vaporization of the pure liquid.[13]

The plot for 1-octanol is lower than the straight line drawn here. Considering that a direct solvation of 1-octanol to porphine possibly accompany a positive deviation, this negative deviation may be attributed to a peculiar behavior of a self-associated solvent such as 1-octanol which is refer to a larger δ_0 of 1-octanol (δ_0=10.2 cal$^{1/2}$ cm$^{-3/2}$). In other words it is unreasonable to treat the 1-octanol system strictly as a regular solution. It is interesting to note that chloroform does not cause any deviation in Fig. 3. This must be compared with a previous research of the solvent effect on the partition coefficient of heterocyclic amine such as 1,10-phenanthroline,[14] where a linear relationship expressed as Eq. 8 was again clear for heptane, cyclohexane, carbon tetrachloride, and benzene, but a large positive deviation was observed for chloroform. This was attributed to a specific interaction such as hydrogen bonding, between phenanthroline and chloroform. These results suggest that the nitrogen atoms in porphine hardly hydrogen bond with proton donors such as chloroform and 1-octanol.

The log $P^X \cdot K_2^{-1}$ for each solvent was calculated from Eq. 9 by knowing the second term of the right hand side from the intercept in Fig. 3. Table 3 shows that the calculated values are in good agreement, except for 1-octanol, with those obtained experimentally from D^X and [H$^+$] by Eq. 4. The log $P^X \cdot K_2^{-1}$ value for other nonpolar solvents can be calculated in this manner.

At present, P^X and/or K_2 can not be determined independently due to their high partition coefficient and the low solubility of porphine in the aqueous solvent. However the solvent effect on the liquid-liquid partition of the mother compound porphine can be quantitatively evaluated. This may be valuable information in understanding the solution behavior of porphyrin compounds.

(Received January 5, 1989)

$Cu(hfac)_2(5\text{-}Hmpz)_4$ (**1**) and $Cu(hfac)_2(5\text{-}Hmpz)$ (**2**) (Hhfac=1,1,1,5,5,5-hexafluoro-2,4-pentanedione; 5-Hmpz=5-methyl-1*H*-pyrazole) have been prepared by the stoichiometric reactions of $Cu(hfac)_2$ with 3-methyl-1*H*-pyrazole in petroleum ether. The structures of **1** and **2** have been determined by X-ray analyses. Crystal data for **1**: triclinic, $P\bar{1}$, a=9.531(1), b=10.286(2), c=8.891(2) Å, α=95.85(2), β=95.52(2), γ=85.41(1)°, V=860.9(3) Å^3, Z=1, and R=0.061. Crystal data for **2**: triclinic, $P\bar{1}$, a=9.647(6), b=12.075(9), c=9.130(5) Å, α=107.43(5), β=99.30(5), γ=87.20(6)°, V=1001.3(12) Å^3, Z=2, and R=0.064. In **1**, the geometry about each copper atom is approximately that of a tetragonal bipyramid, with four nitrogen atoms from 5-Hmpz molecules in the equatorial plane and two oxygen atoms from each hfac ligand in the axial positions. Each of the uncoordinated oxygen atoms of hfac ligands is intramolecularly hydrogen-bonded with two imino groups of adjacent 5-Hmpz molecules. In IR spectra, the split bands of ν_{C-O} were observed at 1648 and 1659 cm^{-1}. In **2**, each copper atom is approximately in an environment of a tetragonal pyramid, with an oxygen atom from a hfac ligand at the apex and a nitrogen atom from a 5-Hmpz molecule in the basal plane. The copper atom is located slightly above the plane. The split bands of ν_{C-O} were observed at 1644, 1662, 1669 cm^{-1}. An interpretation of the observed IR spectral bands is proposed.

Diazoles have both a pyridine-type nitrogen and a pyrrole-type nitrogen (imino group) in the same molecule, and they can react bifunctionally with many metal ions or Lewis acids giving a variety of products.[1,2] We have reported that the reaction of bis(nonfluorinated β-diketonato)copper(II) with diazoles gave diazole adducts and/or μ-diazolato complexes.[3] However, the reactions of diazoles with bis-(fluorinated β-diketonato)copper(II) have scarcely been investigated. It is well known that bis(fluorinated β-diketonato)copper(II) is a strong Lewis acid and reacts with unidentate nitrogen heterocycles, e.g., pyridine, substituted pyridines, quinoline, etc., producing 1:1 and/or 1:2 adducts.[4] However, the structures of these adducts have not been fully elucidated. For several adducts of $Cu(hfac)_2$ with bidentate ligands having nitrogen donors, X-ray analyses have been made. For example, adducts with 2,2′-bipyridine (bpy),[5] 1,4-diazabicyclo[2.2.2]octane (ted),[6] pyrazine (pyz),[7] 1,8-bis(dimethylamino)naphthalene,[8] and *N*,*N*-dimethylethylenediamine (dmed)[9] have been isolated and their structures determined. It has been observed that, of these adducts, only the last one cited above, $Cu(hfac)_2(dmed)_2$, contains unidentate hfac ligands. We have prepared the 1:4 and 1:1 adducts of $Cu(hfac)_2$ with 3-methyl-1*H*-pyrazole and here we discuss their structures in relation to the hydrogen bonds and spectral properties.

Experimental

Materials. Bis(1,1,1,5,5,5-hexafluoro-2,4-pentanedionato)-copper(II) was prepared by the reported method.[10] 3-Methyl-1*H*-pyrazole (Tokyo Kasei) was used without further purification.

Preparation of the Complexes. $Cu(hfac)_2(5\text{-}Hmpz)_4$: $Cu(hfac)_2$ was warmed with four times molar quantities of 3-methyl-1*H*-pyrazole in petroleum ether under reflux for 1 h. After standing for several days, violet crystals were formed and dried in vacuo. Found: C, 38.56; H, 3.19; N, 13.93; Cu, 7.84%. Calcd for $C_{26}H_{26}N_8O_4F_{12}Cu$: C, 38.74; H, 3.25; N, 13.90; Cu, 7.88%.

$Cu(hfac)_2(5\text{-}Hmpz)$: $Cu(hfac)_2$ was warmed with an equimolar quantity of 3-methyl-1*H*-pyrazole in petroleum ether under reflux for 1 h. After cooling, a green precipitate was formed. It was filtered and recrystallized from petroleum ether. Found: C, 30.14; H, 1.46; N, 4.86%. Calcd for $C_{14}H_8N_2O_4F_{12}Cu$: C, 30.04; H, 1.44; N, 5.00%.

Spectral Measurement. IR spectra were recorded on a Hitachi Model 225 grating infrared spectrophotometer.

Crystal Structure Analysis. Lattice constants were first approximately determined from Weissenberg photographs obtained with Cu$K\alpha$ radiation. Crystallographic data of both adducts are listed in Table 1. The X-ray diffraction data were collected by use of an automated four-circle diffractometer, Rigaku AFC-5, with a graphite-monochromated Mo$K\alpha$ radiation (λ=0.71073 Å) up to 2θ=60°, the θ-2θ scan technique being employed. The diffraction intensities were monitored by five standard reflections for every 50 reflections recorded. No signs of decomposition of the crystals were observed. The usual corrections for Lorentz and polarization effects were made with both crystals, but no absorption correction was applied. Independent reflections with $|F_o| > 3\sigma(|F_o|)$, 2173 and 2915 reflections for **1** and **2**, respectively, were used for the structure determinations. Calculations were carried out on a FACOM M-360 computer at the Rikkyo University Computer Center using the UNICS-III[11] and ORTEP Programs.[12] The atomic-scattering factors including the

a) Isotropic temperature factor.

anomalous scattering factors were taken from Ref. 13 for nonhydrogen atoms and from Ref. 14 for hydrogen atom. The structures were solved by the heavy atom method, and refined by standard Patterson, Fourier, and block-diagonal least-squares techniques. The CF_3 groups are rotationally disordered about the C-C bonds. The greater uncertainty is reflected in the higher standard deviations for F(4) and F(6) in **1** and for F(2) and F(3) in **2**. The final R values were 0.061 for **1** and 0.064 for 2, respectively. The positions of all hydrogen atoms were determined from the difference Fourier map. The final atomic coordinates of both complexes are given in Tables 2 and 3, and the geometries of the metal coordination spheres in Tables 4 and 5.[15]

Results and Discussion

ORTEP projections of **1** are shown in Figs. 1a and 1b with the atomic numbering. The molecule has a center of symmetry. A copper atom lies in the center of a tetragonally distorted octahedron and is coordinated with the four nitrogen atoms from 5-Hmpz molecules in the equatorial plane and by two oxygen atoms from different hfac ligands in the axial positions.

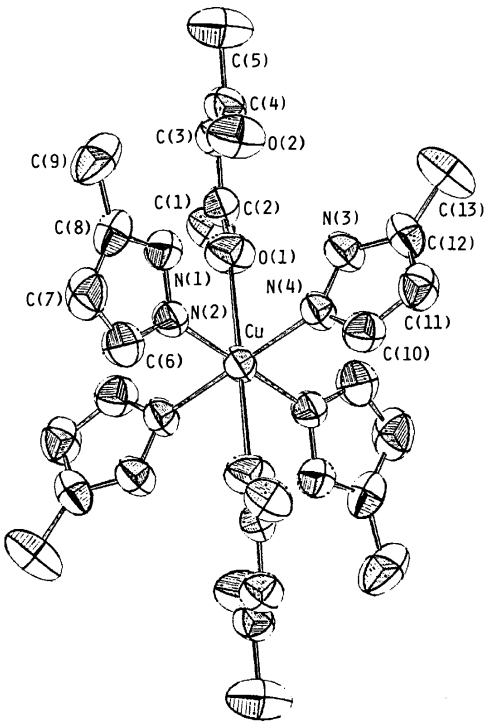

Fig. 1a. A perspective drawing of the structure of **1**, showing the numbering scheme of the atoms (50% probability thermal ellipsoids). Unlabeled atoms are related to labeled atoms by the inversion center. Fluorine atoms attached to C(1) and C(5) are omitted for clarity.

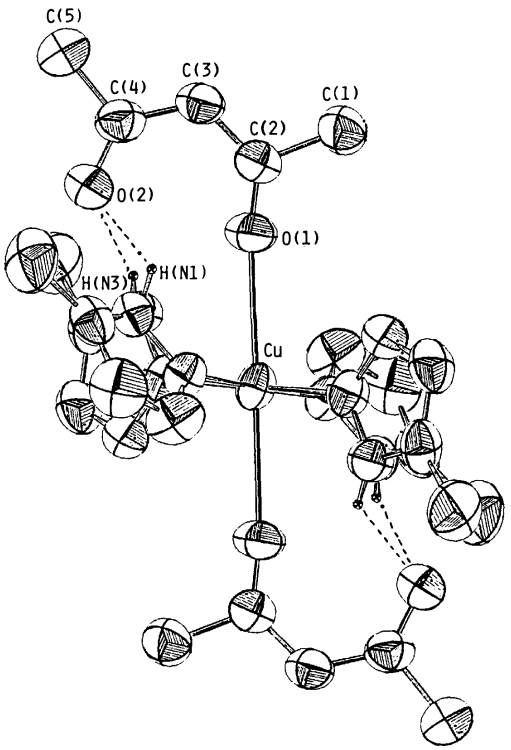

Fig. 1b. A perspective drawing of the molecular structure of **1**, showing the intramolecular hydrogen bonds. Only the H(N1) and H(N3) hydrogen atoms are shown.

The basic structure of **1** is rather similar to that of $Cu(hfac)_2(dmed)_2$, which also has a coordination of a tetragonal pyramid, with four nitrogen atoms in the equatorial plane and two oxygen atoms from unidentate hfac ligands at the apexes.

Another well-defined adduct with unidentate hfac ligand is Cu(acac)(hfac)(phen) (Hacac=2,4-pentanedione, phen=1,10-phenanthroline), which is five-coordinated, however, and an oxygen atom of hfac ligand is in the apical position of a tetragonal pyramid, the basal positions being occupied with two nitrogen atoms from a phen molecule and two oxygen atoms from an acac ligand.[16]

The 3-methyl-1*H*-pyrazole used as a starting material is found in the form of 5-Hmpz in the adduct, which is also the case with $[Cu_2F_2(3,5\text{-Hdmpz})_4(5\text{-Hmpz})_2](BF_4)_2$[17] (3,5-Hdmpz=3,5-dimethyl-1*H*-pyrazole). The 5-substituted form may be more favorable than the other tautomer, probably because

of the less steric crowding around the coordinating site.

Table 4 contains the selected bond lengths and bond angles in **1**. Also in Table 6, the bond lengths and bond angles of several adducts of bis(β-diketonato)-copper(II) in the literatures are summarized for comparison.

The Cu-O(1) distance (2.615(4) Å) is considerably longer than the corresponding Cu-O distances found in bis(2,4-pentanedionato)copper(II) or its adducts. For example, the average Cu-O bond lengths in planar Cu(hfac)$_2$ and cis-octahedral Cu(hfac)$_2$(py)$_2$[18] are 1.989(14) and 2.283(12) Å, respectively. In the case of the adducts containing unidentate hfac ligands, a comparably long Cu-O distance of 2.793(2) Å, and a some shorter Cu-O distance of 2.341(5) Å have been observed in Cu(hfac)$_2$(dmed)$_2$ and Cu(acac)(hfac)-(phen), respectively.

The hfac ligand is planar and has an approximate C_2 symmetry axis. The C(2)-O(1) and C(4)-O(2) distances are similar, i.e., 1.212(7) and 1.222(8) Å, respectively, and the C(2)-C(3) and C(3)-C(4) distances have nearly the same values of 1.395(8) and 1.385(9) Å, respectively.

These data suggest the complete delocalization of π-electrons in the hfac chelate ring. The C-O and C-C distances agree with the corresponding bond lengths in Cu(hfac)$_2$(dmed)$_2$ and Cu(acac)(hfac)(phen), and it has been discussed that these two adducts also have delocalized hfac rings.

As shown in Figs. 1a and 1b, the geometry of the unidentate hfac ligand in the molecule is unique in that Cu-O(1)-C(2) bond angle is exceptionally large (172.6(4)°), which is only comparable with the corresponding angle of 166.7(2)° in Cu(hfac)$_2$(dmed)$_2$. It is also of interest that the C_2 symmetry axis of hfac ligand is not perpendicular to the CuN_4 plane but is rather slanted against it, so that the coordinated O(1) atom lies nearer to the plane than the uncoordinated O(2) atom. The distances from the CuN_4 plane to O(1) and O(2) are 2.588(5) and 3.050(7) Å, respectively, while the Cu-O(2) distance is 4.414(5) Å. It may be reasonable that both in **1** and Cu(hfac)$_2$(dmed)$_2$, the geometry of the hfac ligands is stabilized by intramolecular hydrogen bonding. In Cu(hfac)$_2$(dmed)$_2$, the distances of the uncoordinated oxygen atom from the copper atom and from a NH_2-nitrogen atom of a dmed ligand are 4.226 Å and 2.995(3) Å, respectively. These values suggest that the uncoordinated oxygen atoms have no interaction with the copper atom and are intramolecularly hydrogen-bonded to the N atoms of the chelated dmed molecules.

Table 7. Distances O···N (l/Å) and Angles (ϕ/°) O···H-N of Hydrogen Bonds for **1**

O···N		O···H-N	
O(1)···N(3)	3.065(6)	O(1)···H(N3)-N(3)	125(4)
O(1)···N(1)	2.867(6)	O(1)···H(N1)-N(1)	132(5)
O(2)···N(3)	2.802(7)	O(2)···H(N3)-N(3)	157(4)
O(2)···N(1)	3.056(7)	O(2)···H(N1)-N(1)	133(5)

The data of several interactions between oxygen atoms and imino groups in **1** are summarized in Table 7. In Fig. 1b a perspective drawing of the structure of **1** is shown, indicating the hydrogen bonds. The uncoordinated oxygen atom forms intramolecular hydrogen bonds with adjacent two imino groups of the 5-Hmpz molecules. One bond is O(2)···H(N3)-N(3) and the other, probably a weaker one, is O(2)···H(N1)-N(1). In addition, it may be possible that a very weak hydrogen bond O(1)···H(N1)-N(1) is formed between the coordinated hfac oxygen atom and an imino group. The rather short distance of O(1)-H(N1) may favor the bond formation.

The Cu-N bond lengths have usual values, but it is interesting that the distances of adjacent Cu-N are not equal. Thus for Cu-N(2) and Cu-N(4), the bond lengths are 2.008(5) and 1.976(4) Å, respectively.

The planes of the coordinated 5-Hmpz molecules are slanted against the equatorial plane, so that the two imino groups are favorably located to form hydrogen bonds with an adjacent oxygen atom. The dihedral angle between the planes of the two adjacent 5-Hmpz molecules is 78.4°.

An ORTEP projection of adduct **2** is shown in Fig. 2. The molecule contains a five-coordinated copper ion, coordinated with two bidentate hfac ligands and a 5-Hmpz molecule.

The geometry is that of a tetragonal pyramid with an oxygen atom from a hfac ligand at the apex and nitrogen atom from a 5-Hmpz molecule in the basal plane. The copper atom is above the basal plane by 0.157(2) Å. This structure is similar to that of $Cu(acac)_2(4\text{-ampy})$ (4-ampy=4-aminopyridine), which is the only 1 : 1 adduct of bis(β-diketonato)copper(II) so far investigated by X-ray analysis.[19]

Table 5 contains the selected bond lengths and bond angles of **2**. The apical Cu-O(4) distance (2.196(5) Å) is greater than the basal Cu-O distances, the mean value of which is 1.950(12) Å. These values are comparable with the corresponding values of $Cu(acac)_2(4\text{-ampy})$.

Of the two hfac chelate rings, the one almost in the basal plane (ring 1) is different from the other (ring 2). In the ring 1, C(2)-C(3) and C(3)-C(4) distances as well as C(2)-O(1) and C(4)-O(2) distances are similar to each other. On the other hand, the other hfac chelate ring (ring 2) is distorted. The C(7)-C(8) and C(8)-C(9) distances are different from each other and so are the C(7)-O(3) and C(9)-O(4) distances. The alternation of long and short bond lengths in the

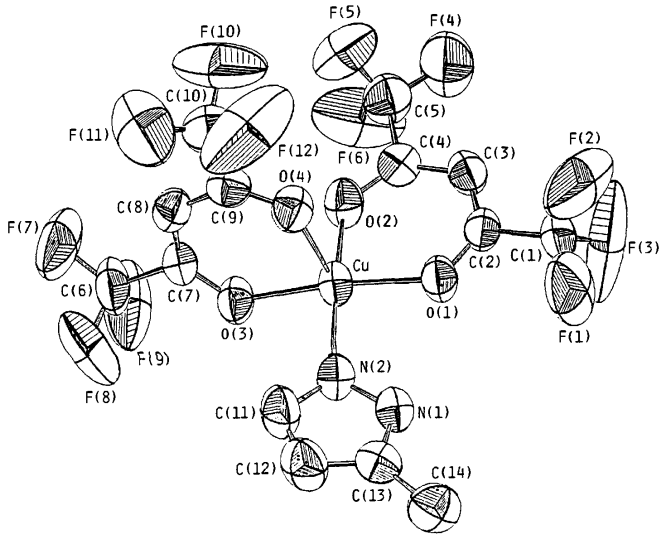

Fig. 2. A perspective drawing of the structure of **2**, showing the numbering scheme of the atoms (50% probability thermal ellipsoids).

β-diketonato chelate rings has been observed in the cis-octahedral adducts of $Cu(hfac)_2(py)_2$ and $Cu(hfac)_2(bpy)$. It has not been fully established that these facts may suggest the presence of a partially localized structure of hfac ligands.

The hfac rings are planar and dihedral angle of each hfac plane against O_3N plane is 1.53° and 78.2°. The angle between the two hfac planes is 76.8°.

Although the adducts **1** and **2** were prepared by stoichiometric reactions of $Cu(hfac)_2$ and 3-methyl-1*H*-pyrazole, the 1 : 2 adduct was not obtained by the similar method. The adduct **1** loses three molecules of 3-methyl-1*H*-pyrazole on standing for several weeks in the atmosphere, yielding **2**. This change may correspond to the bond formation by the uncoordinated carbonyls in **1**, displacing the 5-Hmpz molecules.

In Table 8, IR spectral data of **1** and **2** are listed. In general, the adduct formation of $Cu(hfac)_2$ and $Cu(tfac)_2$ (Htfac=1,1,1-trifluoro-2,4-pentanedione) weakens the Cu-O bonds, as evidenced by the shifts of the carbonyl stretching bands to the higher-frequency side from those observed for the parent complexes.[6,16,18,20]

Attempts have also been made to correlate the C-O bond lengths of the adducts to the ν_{C-O} frequencies at about 1650 cm^{-1} of IR spectra.[18] However, the approach to the bond types of the adducts by this way has not been fully attained.

The sharp band at 3424 cm^{-1} of **2** is definitely assignable to ν_{N-H} vibration of a free imino group. There is no interaction of hydrogen bonding, as it has been reported that, on making a hydrogen bond, the ν_{N-H} band shifts to lower-frequency side and line broadening occurs.[21] The O(1)-N(1) distance of 2.788(7) Å and O(1)···H(N1)-N(1) angle of 118(5)° may not be favorable for formation of a hydrogen bond. On the other hand, the spectrum of **1** has two broad bands in this region at 3270 cm^{-1} and at about 3200 cm^{-1}. Therefore these bands of **1** are assigned to the ν_{N-H} vibration of hydrogen-bonded imino groups.

The split ν_{N-H} bands may be indicative of the two different N-H···O hydrogen bonds described above.

Two separate bands with approximately equal intensities are observed in the IR spectrum of **1** at 1648 and 1659 cm^{-1}, which may be assigned to the ν_{C-O} vibrations of the coordinated and uncoordinated carbonyl groups, respectively.

Table 8. IR Spectral Data

Assignment	Adduct **1**	Adduct **2**	$Cu(hfac)_2$[22]
ν_{N-H}/cm^{-1}	3270(m)	3424(m)	
	ca. 3200(m, br)		
ν_{C-O}/cm^{-1}		1669(m)	
	1659(s)	1662(m)	
	1648(s)	1644(s)	1644(s)
		1615(w)	1614(w)
		1607(w)	

On the other hand, the spectra of **2** have three bands in carbonyl region at 1644, 1662, and 1669 cm^{-1} with approximate intensities of 2 : 1 : 1, respectively. For the adducts of bis(β-diketonato)metal(II) complexes, the splitting of a ν_{C-O} band in IR spectra has been reported only in the case of cis-octahedral Zn(hfac)$_2$(py)$_2$ observed at 1645 and 1660 cm^{-1},[18] which have been assigned to the stretching vibrations of carbonyls in the chelated hfac ligands with long and short C-O distances, respectively.

Thus far no information on the splitting of ν_{C-O} bands in the spectra of bis(β-diketonato)copper(II) adducts has been given. However, if the precise data are accumulated, the IR spectra may be of diagnostic help in predicting these structures of the adducts.

The authors are grateful to Ms. Michiko Umehara of Rikkyo University for the Weissenberg photograph techniques and Mr. Takayoshi Ozawa of this Institute for the elemental analysis.

(Received January 25, 1989)

The title new complexes were synthesized and their crystal and molecular structures were determined by the single-crystal X-ray diffraction method. The crystal form of $[(C_2H_5)_4N]_3[Yb(NCS)_6]\cdot(C_6H_6)$, for example, is monoclinic, space group $P2_1/c$, a=19.458(12), b=14.046(6), c=18.288(7) Å, β=91.28(4)°, Z=4, and the final R value obtained was 0.064. The other seven crystals are isomorphous with each other. The central metal atom is in an octahedral hexa-coordination geometry: six nitrogen atoms of isothiocyanate ions are ligated to each metal atom. Each solvent molecule is arranged betweeen each pair of neighboring metal atoms along the [1 $\bar{1}$ 0] axis in each crystal. The cations are arranged approximately between each pair of metal atoms along the [0 1 1], [0 $\bar{1}$ 1], and [1 1 0] axes, respectively. They were stable for more than a few weeks at room temperature; however, when heated at about 80—90 °C, their guest molecules were lost.

Although lanthanoids are hard elements[1] and they prefer to be coordinated to oxygen donor ligands,[2] the nitrogen atom of a thiocyanate ion (SCN) can be ligated to the metal atom. The M-N(NCS) bond is relatively weak in aqueous solution;[3] however, it is more stable in some organic solvents used for the solvent extraction of the metals.[4]

The crystal and molecular structures of the tetrabutylammonium hexakis(isothiocyanato)lanthanoidates (III) (M=Pr—Yb) have already been elucidated: six nitrogen atoms of NCS are ligated to the central metal atom in an octahedral geometry.[5] However its coordination number (6) is rather abnormal, since the preferred coordination number of lanthanoid complexes is eight or nine, although seven, ten, and to a less extent, the other numbers are also found in the other complexes. Coordination numbers of six or lower are found only in the complexes when the ligand is too massive to take higher coordination numbers; however, the SCN ion is not large.

In cases of some aqua-isothiocyanato mixed complexes, the coordination number of the central lanthanoid atoms is eight: $K_4[M(NCS)_4(H_2O)_4](SCN)_3\cdot nH_2O$ (M=Nd, Eu),[6] $[(C_2H_5)_4N]_4[M(NCS)_7(H_2O)]$ (M=La, Ce, Pr; Nd, Dy, Er),[7] and $[(CH_3)_4N]_3[M(NCS)_6(CH_3OH)(H_2O)]$ (M=La—Er)[8] are examples. Recently, we obtained some anhydrous isothiocyanato complexes of lanthanoids in which the metal atom is hepta-coordinated, such as $[(CH_3)_4N]_4[M(SCN)_7]$ (M=Dy, Er, Yb),[8] and $[(C_2H_5)_4N]_4[M(SCN)_7]\cdot C_6H_6$ (M=La, Pr).[9] The last example is regarded as being a kind of inclusion compound, since it has one benzene molecule per one metal atom in a crystal, and no bonding has been recognized between the molecule and the cations or anions. Therefore, it seemed to be interesting to find some other such type adducts of complexes of lanthanoids. We were able to synthesize the title new complexes, and have investigated their properties by the thermoanalytical technique as well as by infrared spectra. Moreover, their crystal and molecular structures were determined by the single-crystal X-ray diffraction technique.

Experimental

Synthesis of Tetraethylammonium [Hexakis(isothiocyanato)erbate(III)]·Benzene (1), the Isomorphous Benzene Adduct of Ytterbate(III) (2), and the Isomorphous Complexes Including Fluorobenzene (3,4), Toluene (5,6), or Chlorobenzene (7,8).§ The starting erbium(III) thiocyanate (in methanolic solution) and solid tetraethylammonium thiocyanate were obtained (as mentioned in a previous paper).[7] Into a methanolic solution (10 cm³) of erbium thiocyanate (1.0 mmol) tetraethylammonium thiocyanate (0.61 g, 3.2 mmol) was added and dissolved. To the solution, the ethanol-benzene mixture (1 : 1=v/v, 20 cm³) was added and the mixture was dried up using a rotary evaporator at about 80 °C. The dehydration process was repeated twice, and the residue was dissolved into 10 cm³ of methanol (GR grade reagent of Wako Pure Chemical Ind. Ltd.: it contains at most 0.2% of water). After a trace of insoluble matter was filtered off, the solution was left standing in the benzene-vapor moiety for several days. The precipitate was

§ Odd number ones are erbate, and even number ones are ytterbate.

separated, washed with a small portion of ethanol, and dried in a silica-gel desiccator overnight. Yield: 0.72 g (0.73 mmol, 73%). The isomorphous ytterbium complex (**2**) was obtained by almost the same technique.

The other six isomorphous adducts, the respective erbium (odd number ones) and ytterbium complexes (even number ones) including fluorobenzene, toluene, or chlorobenzene, were also synthesized by the same technique: keeping the starting solution in a desiccator over respective solvents.

In Table 1, are shown their elemental analyses and the numbering of the complexes. The yields of complexes **2**—**8**, starting from 1.0 mmol of the respective metal thiocyanates, are: **2**, 0.65 g, 66%; **3**, 0.83 g, 83%; **4**, 0.76 g, 75%; **5**, 0.55 g, 55%; **6**, 0.60 g, 60%; **7**, 0.50 g, 49%; and **8**, 0.45 g, 44%.

All of them are pale orange in color and are relatively stable: their crystals could be kept at room temperature for at least a few weeks without decomposition, although they lost their guests and became pulverized after a longer time. When they were kept in a stoppered bottle at about 6 °C or lower, they were stable for more than six months.

Attempts to synthesize the isomorphous complexes of dysprosium or of lighter lanthanoids, including any of the above-mentioned guests have not yet been successful.

X-Ray Structure Analysis. Crystallographic data of **1**—**8**, the size of the used crystal (approximately parallelepiped), and some experimental conditions for the X-ray structure analyses of **1**—**6** are listed in Table 2.

Reflections were collected on a Rigaku AFC-6A automated four-circle X-ray diffractometer, with graphite monochromated Mo$K\alpha$ radiation (λ=0.71073 Å), an ω-2θ scan technique being employed (scan speed 4° min^{-1}). The used crystals were coated with a cyanoacrylate resin to

prevent the escape of the guest; however, it was not necessary to seal the crystal in a glass capillary. During the intensity collection (about 5—7 days) a decrease in the standard reflection intensities was not recognized in the cases of complexes **1**—**4**, and less than 8% in the cases of the complexes **5** and **6**. The intensities were corrected for Lorentz and polarization factors, though no corrections were made for absorption.

Structure Determination. The structure of **2** was solved by the heavy-atom method. The positions of the metal and some sulfur atoms were deduced from the three-dimensional Patterson map, and the other atoms were located by successive Fourier syntheses. Their positional and thermal parameters were refined by a block-diagonal least-squares method. No hydrogen atom was included in the structure factor calculations.

It was found that several atoms have relatively large temperature factors, although this phenomenon had already been found for atoms loosely packed in the crystal in some other lanthanoid complexes.[10] Although the intensity measurement process was repeated for **2** using another crystal, the result was not improved: the temperature factors of some atoms were still very large. The occupancy factors of the atoms of the guest molecule were examined by a full-matrix least squares method; they converged to approximately 1.0.

After repeated refinement steps, some parameters were still moving over 3 times of their respective standard deviations, though their values almost converged. Therefore, at the final refinement steps, such parameters were fixed in the structure calculations.[13]

The structure of **1** was determined starting from the final parameters of **2**, and refined in a similar way.

The structures of **3** and **5** were obtained starting from the final parameters of **2**, and refined in a similar way. The positions of the fluorine atom of **3** and the methyl carbon atom of **5** were obtained from their difference synthesis maps. The structures of **4** and **6** were obtained starting from the final parameters of **3** and **5**, respectively, and their parameters were refined in the same way.

In **3** and **4**, from their difference synthesis map, the position of the fluorine atom was divided into two, F(1A) and F(1B), which were bonded to C(63) and C(66), respectively, with an equal occupancy factor.

In **5**, or **6**, from their difference synthesis maps, the position of the methyl carbon atom of toluene molecule was found to be not disordered, which is bonded to C(66).

All calculations were carried out on a HITAC M-682H computer at the Computer Center of the University of Tokyo, using a local version of the UNICS program.[11] The atomic scattering factors were taken from Ref. 12.

a) Numbers of the complexes (see Table 1). b) Average of the six values of the all SCN ions.

were obtained by means of a JASCO A-202 grating infrared spectrophotometer, using paraffin oil and hexachloro-1,3-butadiene mull. Simultaneous thermogravimetric (TG) and differential thermal analysis (DTA) were carried out with a Rigaku "Thermoflex" M-8075 using samples weighing about 10 mg, at a heating rate of 10 °C min^{-1} in air, with α-alumina used as a reference.

Results and Discussion

The final atomic coordinates and isotropic or equivalent isotropic temperature factors (B_{eq}/Å^2) of **2** are tabulated in Table 3; some selected bond lengths and bond angles of **1**—**6** are listed in Table 4. Perspective drawings of complex **2** around atoms Yb(1) and Yb(2) are shown in Figs. 1 and 2, and a projection of its unit cell along the b-axis in Fig. 3.[13]

In **2**, both of the crystallographically independent metal atoms, Yb(1) and Yb(2), are at the centers of symmetry, and are hexa-coordinated in an octahedral geometry: six nitrogen atoms of SCN ions are in coordination. The average M-N bond length is 2.28 Å (2.22—2.32 Å), which is a little shorter than the sum of the Shannon's crystal radii, 2.33Å.[14] The average bond angles, Yb-N-C and N-C-S, are 170 (167—175) and 176 (174—178)°, respectively.

Among the six coordinated SCN ions, four ions are situated approximately on a plane parallel to the ac-plane and are arranged approximately to [1 0 1] and [$\bar{1}$ 0 1]; the other two SCN ions are arranged approximately along the b-axis.

The tetraethylammonium ions around the N(41) and N(51) atoms are arranged approximately between each pair of neighboring metal atoms along [0 1 1] and [0 $\bar{1}$ 1]: the N(41) atoms are between the Yb(2)

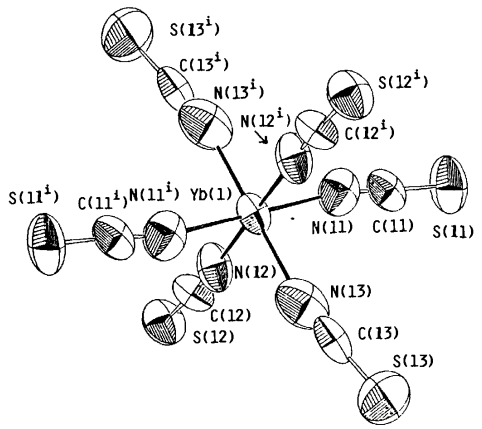

Fig. 1. Perspective drawing of tetraethylammonium [hexakis(isothiocyanato)ytterbate(III)]·benzene (**2**) around Yb(1) atom together with the numbering scheme of the atoms. Key to the symmetry operation: i, $-x$, $-y$, $-z$.

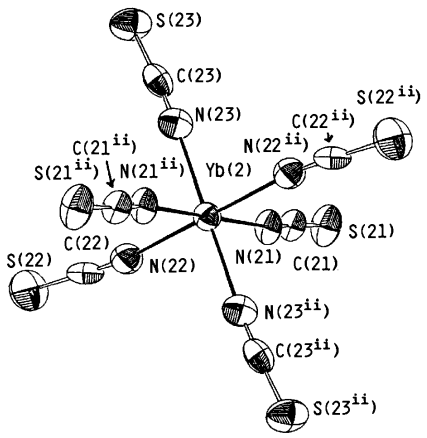

Fig. 2. Perspective drawing of tetraethylammonium [(hexakis(isothiocyanato)ytterbate(III)]·benzene (**2**) around Yb(2) atom together with the numbering scheme of the atoms. Key to the symmetry operation: i, 1−x, 1−y, −z.

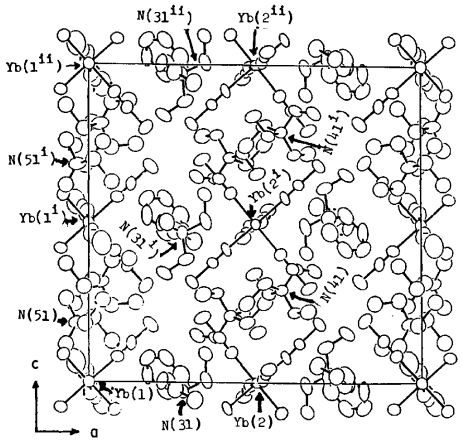

Fig. 3. Projection of the unit cell of tetraethylammonium [hexakis(isothiocyanato)ytterbate(III)]·benzene (**2**) along b-axis. The numbering scheme of some metal and ammonium nitrogen atoms are also shown. Key to the symmetry operations: i, *x*, 0.5−*y*, 0.5+*z*; ii, *x*, *y*, 1+*z*.

atoms, while the N(51) atoms are between the Yb(1) atoms. Another tetraethylammonium ion around the N(31) atom and the benzene molecule are arranged between each pair of Yb(1) and Yb(2) atoms along [1 1 0] and [$\bar{1}$ 1 0], respectively.

The structure of the isomorphous erbium complex (**1**) has essentially the same structure as **2**, although the average Er-N bond length is 2.31 Å (2.27(2)—2.33(2) Å) which is longer than the corresponding length of **2**, due to the longer metal crystal radii (the sum of the Shannon's crystal radii of Er-N is 2.35 Å). The reported Er-N(SCN) bond length of $[Er(SCN)_6]^{3-}$ ion in its tetrabutylammonium salt is 2.34(2) Å, which is a little longer than that of **1**.[5] Other than the metal ionic size and, consequently, the M-N bond lengths and the unit-cell volume, the structures of **1** and **2** are approximately the same.

We can compare with each other the relative volumes (where the organic molecules are included) from their unit-cell volumes of the same metal complexes, ytterbium ones: the unit-cell volumes of **2**, **4**, **6**, and **8** are 4998(4), 5032(9), 5118(4), and 5121(5) Å^3, respectively. Therefore, the space for the guest is expanded a little, depending on the increase in the volume of the guest molecule.

Although the unit cell of each erbium complex is a little larger than that of the corresponding ytterbium complex, almost no difference could be recognized between the thermal properties of the corresponding adducts of both metals (as shown in the later part of this paper). However, the same type inclusion compounds of dysprosium or smaller atomic number lanthanoids were not obtained. The formation of this kind of adduct is likely only for a limited range of sizes of the complex: the distance between the cations and anions should be kept to an appropriate value.

Qualitatively, we guess that, in cases of the isothiocyanato complexes of lanthanoids, when the organic groups of the cations are sufficiently large to supply enough non-polar moiety in the crystal, the coordinated SCN ions, which also contain a non-polar part (sulfur and carbon atoms), are capable of moving around their regular positions. As a result, the SCN ions are sufficiently bulky to be in hexa-coordination to lanthanoid metals. The structure of $[(C_4H_9)_4N]_3[M(NCS)_6]$ can be explained in terms this hypothesis. In cases of the present complexes, although the ethyl group of the cation is not sufficiently large, the central metal atom is relatively small (Er or Yb); moreover, some non-polar hydrocarbon or halohydrocarbon molecules are included. As a result, the SCN ions assume an octahedral geometry.

In infrared absorption spectra of the complexes **1**—**8**, the bands due to the N-bonded SCN ion appear in the same region as the other metal complexes:[15] ν(CN), 2050(s); ν(CS), 730(shoulder, partly overlapped with the peak of the cation); δ(SCN), 480 cm^{-1}. The bands due to the tetraethylammonium ion are commonly found in the specta of **1**—**8**, at about 1490(s), 1440(s), 1395(s), 1364(m), 1170(s), 1052(m), 997(s), 780(s), and 720(m) cm^{-1}. The peak of the mode of the out-of-plane deformation of the benzene ring is characteristic to complexes **1**—**8**, and is useful for identifying whether the complex really includes a guest or not. The peaks of **1** and **2** appear at 687 cm^{-1}, which is a liitle blue shifted from that of the free benzene (673 cm^{-1}). Such a shift in the peak of a guest molecules around 680—690 cm^{-1} was not observed in the spectra of **3**—**8**. The peaks of the guests in the infrared spectra are as follows: **3** and **4**, 683, 750, 805, 899, 1220, 1500, and 1598 cm^{-1}; **5** and **6**, 460, 693, 722, 1030, and 1080 cm^{-1}; and **7** and **8**, 682, 701, 1022, 1085, 1450, 1481, and 1584 cm^{-1} peaks, respectively. None of them shift much from the peak wavenumbers of the respective free guests.

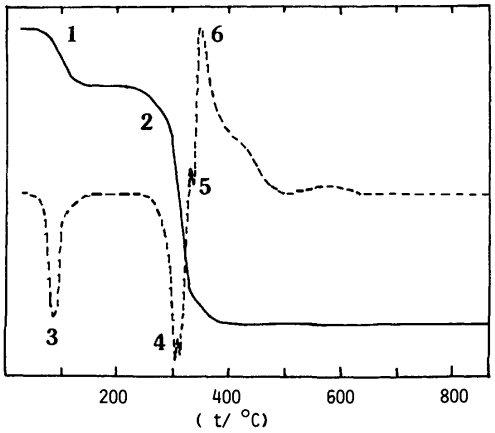

Fig. 4. TG(——) and DTA(----) curves of tetraethylammonium [hexakis(isothiocyanato)ytterbate(III)]·benzene (**2**). Mass loss of TG was taken downward and the exothermic change of DTA was taken upward. The temperature corresponding with the points numbered from **1** to **6** of the runs with the complexes **1**, **2**, **4**, **6**, and **8** are shown in Table 5.

Table 5. Thermal Analytical Data of the Complexes

Complex	1[b]	2[b]	3[b]	4[b]	5[b]	6[b]	R[c]
1[a]	81	297	93	303, 312	333	351	22
2[a]	88	285	99	304, 315	330	353	22
4[a]	82	288	94	305		330	24
6[a]	81	288	91	311	335	351	20
8[a]	83	285	95	302		343	23

a) Complexes shown in Table 1. b) The points shown in Fig. 4 (the temperatures in the table are shown in the unit of (t/°C)). c) The weight of residue after heating the samples up to 1000 °C (shown in weight %).

The simultaneous TG-DTA curves of complex **2** is shown in Fig. 4. The general feature of the curves of the other complexes are almost the same. The corresponding temperatures at points **1**—**6** shown in Fig. 4 (of the complexes **1**, **2**, **4**, **6**, and **8**) are listed in Table 5.

From these results, it was shown that when the temperature was increased, all kinds of guest molecules in them were removed at about 80—90 °C: no serious difference was found between their degradation temperatures. The change was found to be endothermic from their DTA curves, and the mass loss of this step of each complex approximately coincided with the molecular weight of each guest.

Between the first and second mass-loss steps, the vacant cage structure, $[(C_2H_5)_4N]_3[M(NCS)_6]$ (M=Er, Yb), was thought to be stable. In the respective infrared spectra of the residues after heating complexes **1**—**8**, about 2—5 h at 110 °C, the peaks of the guests completely disappeared, while the peaks of the SCN^- and $[(C_2H_5)_4N]^+$ ions were retained almost in the same wavenumber region. Each mass loss by this heating process also corresponded approximately with the weight of the included guest calculated from its formula.

At about 280—290 °C the complexes decomposed by one-step degradation, as shown by the TG curve; however, it consists of several complicated endo- and exothermic steps, judging from their DTA curves.

After the second step of decomposition, no specific changes were observed on the TG and DTA curves, and the residues after being heated to 1000 °C were mainly the respective metal oxides.

The authors wish to thank Shin-Etsu Chemical Ind. Co., Ltd., for presenting us with highly pure lanthanoid oxides.

Selective Fluorimetric Determination of Trace Amounts of Cobalt(II) with the System of Fluorescein-Hydrogen Peroxide-Tiron†

Itsuo MORI,* Yoshikazu FUJITA, Yoshihiro NAKAHASHI, Kinuko IKUTA, and Keiji KATO
Osaka University of Pharmaceutical Sciences, Matsubara-shi, Osaka 580
(Received February 27, 1989)

The decomposition reactions of fluorescein (Fl) or its halo derivatives in the basic region were systematically investigated in the presence of an oxidizing agent such as hydrogen peroxide and/or a metal ion such as cobalt(II) and/or catalytic agent such as tiron as an activator. Moreover, a highly selective spectrophotofluorimetric method for the determination of trace amounts of cobalt(II) was established by measuring the difference in relative fluorescence intensities (ΔF) between Fl-tiron-hydrogen peroxide and Fl-tiron-hydrogen peroxide-cobalt(II) solutions at an emission wavelength of 510 nm, with an excitation wavelength of 490 nm (the calibration graph was linear in the range of 0—6 ng cobalt(II) per 25 cm^3). The applications to the assay of cobalt in cyanocobalamine (vitamin B_{12}) preparations and its eye drops were also investigated, the results were relatively good.

For the spectrophotometric determination of trace amounts of cobalt(II), various kinetic and catalytic reactions between diphenol compounds, such as Pyrogallol Red (PR), phenylfluorone (Phfl), *o*-hydroxyhydroquinonephthalein (Qnph), and cobalt(II), in the presence of an oxidizing agent such as hydrogen peroxide have been investigated.[1-5] In this paper, we investigated the use of fluorescein (Fl) as a fluorescence reagent for the spectrofluorometric determination of trace metal ions; firstly, the fluorescence reactions among Fl or its halo derivatives and an oxidizing agent, such as hydrogen peroxide and/or metal ions such as cobalt(II) were systematically investigated; secondly, a fluorimetric method for the determination of trace amounts of cobalt(II) using the fluorescence reaction (fluorescence-quenching) among trace amounts of cobalt(II), Fl, tiron and hydrogen peroxide in the basic region was proposed and applied to the assay of cyanocobalamine (vitamin B_{12}) preparations.

Experimental

Apparatus and Reagents. Fluorescence-intensity measurements were made on a Shimadzu Model RF-540 spectrofluorophometer using 10-mm silica cells and a xenon arc source. A Hitachi-Horiba model F-8 pH meter, equipped with glass and a calomel combined electrode, was used for all the pH measurements.

Deionized water was used throughout. All reagents were of an analytical reagent grade. A stock solution of cobalt(II) (1.0×10^{-2} mol dm^3) was prepared by dissolving cobalt chloride in water, correcting by chelatometry,[6] and a 5.0×10^{-4} mol dm^{-3} cobalt(II) working solution was prepared by the suitable dilution of the stock solution just before use. Fl, its halo-derivative solution (1.0×10^{-3} mol dm^{-3}), and a 0.3% tiron solution were prepared by dissolving, respectively, Fl, its halo-derivatives[7,8] (highly purified Fl derivatives by recrystallization), and tiron in methanol. A 1.0% hydrogen peroxide solution was prepared by the dilution of a 30% hydrogen peroxide solution (Mitsubishi-Edogawa Chemical Co., Ltd.).

Standard Procedure. To each series of 30-cm^3 Erlenmyer flask, add an aliquot of a solution containing between 0 and 6.0 ng of cobalt(II). Add 2.0 cm^3 of a 1 M sodium hydroxide solution (1M=1 mol dm^{-3}), 1.0 cm^3 of a 1.0% hydrogen peroxide solution, 1.0 cm^3 of a 3.0% tiron solution, and 1.0 cm^3 of a 1.0×10^{-3} mol dm^{-3} Fl solution, and dilute to 10.0 cm^3 volume with water. A reflux condenser is attached, and the mixed solution (Solution A, Fl/cobalt(II)/tiron/hydrogen peroxide solution) is heated for 45 min together with Solution B (Fl/tiron/hydrogen peroxide solution), after with Solutions A and B are diluted to a 25-cm^3 volume with water. Measure the difference in fluorescence intensities (ΔF) between Solutions A and B at the emission wavelength of 510 nm with the excitation wavelength of 490 nm.

Results and Discussion

Fluorescence-Quenching Reaction between Fluorescein or Its Derivatives and Hydrogen Peroxide, and the Effects of Metal Ions and Oxidizing Agents. Firstly, the decomposition reactions of Fl and its halo derivatives, such as 2,7-dichlorofluorescein (2,7-Cl_2Fl), 3′,4′,5′,6′-tetrachlorofluorescein (3′,4′,5′,6′-Cl_4Fl), 2,4,5,7-tetrachloro-, 2,4,5,7-tetrabromo-, or 2,4,5,7-tetraiodofluorescein (2,4,5,7-Cl_4Fl, 2,4,5,7-Br_4Fl, 2,4,5,7-I_4Fl), in the presence of hydrogen peroxide as an oxidizing agent were systematically investigated by heating at 60 °C under various pH areas. As is shown in Table 1, the decomposition reactions (fluorescence-quenching) were obvious in basic media; all these halo-Fl derivatives except Fl and 3,4,5,6-Cl_4 Fl were easily decomposed[7,8] and then converted to non-fluorescence substances, but these fluorescence intensities were relatively small, unstable and varied widely in value (93%—108%). On the other hand, the fluorescence intensity of 3,4,5,6-Cl_4Fl was very stable, and it was not entirely decomposed by hydrogen peroxide. Fl was slightly decomposed by an oxidation reaction in the presence of hydrogen

peroxide, and its fluorescence reaction could easily be reproduced (97.5%—102.4%). Thus, because Fl has an appropriate stability and decomposed property for an oxidation-destruction reaction using hydrogen peroxide, and because the subsequent purification of Fl[7,8] was very easy, Fl was used as a fluorescence reagent for further investigations.

Secondly, the enhancement effect of such metal-ions as cobalt(II), iron(III), manganese(II), and copper(II) by the fluorescence-quenching reaction on the Fl used was systematically investigated. As is shown in Table 2, the difference in fluorescence intensity (ΔF) between Solution A (Fl/hydrogen peroxide/metal ions solution) and Solution B (Fl/hydrogen peroxide solution) was largest and showes most clearly in the presence of trace amounts of cobalt(II). That is, the amounts of ΔF in the presence of cobalt(II) was about 60-times that of ΔF in the presence of nickel(II) (ratio of inhibition of fluorescence-quenching; rates of relative fluorescence intensity on {(Fl-hydrogen peroxide-metal ion)−(Fl-hydrogen peroxide)}/(Fl-hydrogen peroxide), using a correction of the coexisting metal-ion concentration (ratio of fl.Int.), 20.042 for cobalt(II) vs. 0.355 for nickel(II)), the fluorescence-decomposition reaction of Fl was inhibited in proportion to the coexisting cobalt(II) concentrations.

Thirdly, the effect of the oxidizing agent was investigated in the oxidation and decomposition reactions of Fl; sodium hypochlorite, hydrogen peroxide, sodium nitrite, potassium iodate, chloramine B, potassium peroxodisulfate, etc. were used as oxidizing agents. The use of 1.0—2.0 cm^3 of a 1.0% hydrogen peroxide solution as an oxidating agent gave a large and reproducible ΔF. Although the quenching reaction was influenced by the amounts of hydrogen peroxide, further investigation was carried by using Fl and, finally, 0.04% hydrogen peroxide.

Effect of Activator. In this decomposition reaction of Fl, the fluorescence intensity of Fl-hydrogen peroxide-cobalt(II) system remained in the basic medium was significantly enhanced by the coexistence of a biphenol organic reagent, such as tiron, pyrocatechol, or gallic acid, as is shown in Table 3. In measuring the difference in fluorescence intensities the best results were produced using tiron as an activator; the optimum tiron concentration was 0.1—0.3% in the final solution. The inhibition phenomena of fluorescence-quenching (=difference in fluorescence intensities between Solution A (Fl/hydrogen peroxide/tiron/cobalt(II) solution) and Solution B (Fl/hydrogen peroxide/tiron solution)) were larger and more obvious than in the absence of a tiron-quenching ratio (difference in relative fluorescence intensities between Solutions A and B against the

Table 3. Effects of Activators on Fluorescence-Quenching Reaction

Activators	Procedure A R.fl. Int./% 510 nm		Procedure A Ratio of R.fl. Int.[a] at 510 nm	Procedure B Ratio of R.fl. Int.[a] at 510 nm
	Fl-H_2O_2	Fl-H_2O_2-Co(II)		
—	16.8	34.8	1.071	0.102
Tiron	17.1	61.8	2.614	4.051

Luminol	17.4	35.3	1.029	0.10
Resorcinol	17.9	34.7	0.939	0.10
Phenol	16.3	38.2	1.344	0.10
Glycerol	19.4	32.9	0.696	0.10
Gallic acid	30.0	65.4	1.180	0.10
Phenylalanine	22.1	39.8	0.801	0.10
Norepinephrine	23.0	64.5	1.804	0.10

Procedure A—Co(II) taken: 8.0×10^{-9} mol dm^{-3}; activator: 4.0×10^{-4} mol dm^{-3}; hydrogen peroxide: 0.03%; NaOH: 0.08 M; Fl: 4.0×10^{-5} mol dm^{-3}. Procedure B—Co(II) taken: 2.0×10^{-9} mol dm^{-3}; activator: 0.14%; hydrogen peroxide: 0.04%; NaOH: 0.08 M; Fl: 4.0×10^{-5} mol dm^{-3}; Ex: 490 nm; at heating on reflux for 45 min.

a) Rate of R.fl. Int. on {(Fl-H_2O_2-Co(II)-activator)—(Fl-H_2O_2-activator)}/(Fl-H_2O_2-activator).

relative fluorescence intensity of Solution B); they were 4.051 (in the presence of tiron) and 1.021 (without tiron), while the rates of fl.Int. were 810.2 (in the presence of tiron) and 20.042 (without tiron) for 40.0×10^{-8} mol dm^{-3} cobalt(II)). Thus, the fluorescence-quenching among Fl, hydrogen peroxide, and cobalt(II) in the presence of tiron gave the largest value. That is, the apparent fluorescence-quenching reaction in the presence of cobalt(II) and tiron was about 40-times that in the absence of tiron, and about 300-times that with copper(II) alone; rates of fl.Int.: 810.2 for cobalt(II), 4.490 for copper(II). The maximum and almost costant value was obtained by using a final tiron concentration of 0.2%—0.1%; for the analytical procedure, a final tiron concentration of 0.14% was used.

Fluorometry of Cobalt(II). Fluorescence Spectra. Figure 1 shows the excitation spectrum of the Fl solution and the emission spectra of Fl-hydrogen peroxide and Fl-hydrogen peroxide-cobalt(II) solutions after heating reactions at reflux for 45 min on basic media. The excitation spectrum of the Fl-hydrogen peroxide solution showed an excitation band with a maximum at 490 nm when an emission wavelength at 510 nm was used and an emission band at 510 nm when an excitation wavelength at 490 nm was used. Also, ΔF at 510 nm was proportional to the concentration of trace cobalt(II).

Effect of Concentration of Alkali. The quenching phenomena were recognized over a wide basical range; a maximum and almost constant ΔF value was obtained in a basic medium of a 0.02—0.5 M NaOH final solution under the optima excitation and emission wavelengths (Ex 490 nm, Em 510 nm). Although the elution of metal-ions from the glassware

—×—: {Fl-H_2O_2-Co(II)-tiron} soln (Co(II) 1.0×10^{-9}M.

was presumed, a final concentration of 0.08 M NaOH was selected for the recommended procedure for the assay of cobalt(II).

Effect of Fl Concentration. As the fluorescence-quenching is influenced by the purity of Fl, previously highly purified Fl was used. The effect of the Fl concentration was then considered. The best result was produced by using 1.0—1.5 cm^3 of a 1.0×10^{-3} mol dm^{-3} Fl (highly purified by recrystallization from Fl acetyl compound) methanol solution per 25 cm^3; a final solution of 4.0×10^{-5} mol dm^{-3} Fl was used for further investigations.

Effects of Temperature and Time. The effect of the temperature was studied at 50 °C, 60 °C, 80 °C, and 100 °C. An inhibition of the fluorescence-quenching was observed when the temperature was increased; the maximum quenching was obtained at reflux on a hotplate. The maximum quenching phenomenon was obtained by heating at reflux for 30 min or less, the fluorescence intensity was thereafter kept constant for longer than 60 min. Therefore, a standing time of 45 min using reflux heating was selected for the standard procedure. Although the coexistence effect of surfactants (nonionic, anionic, and cationic) was investigated, no enhancement effect at all was observed.

Calibration Graph. The calibration graph of cobalt(II) was linear over the range from 0 to 6 ng cobalt(II)/25 cm^3. For 3 ng of cobalt(II) in 25 cm^3, the coefficient of variation, as estimated from 5 replicates, was 2.5%.

Effect of Diverse Ions. The influences of diverse ions on the determination of 2.9 ng of cobalt(II) upon the use of the fluorescence reaction of a Fl-hydrogen peroxide-tiron-cobalt(II) system were also examined. The tolerance limit was taken as the amount that caused about a ±3% error in the fluorescence intensity. The coexistence of numerous metal-ions besides iron(III), manganese(II), copper(II), and nickel(II) did not interfere at all. That is, the coexistence of iron(III) gave a positive error when present in a 400-fold excess over cobalt(II), and the coexistence of copper(II), manganese(II), or nickel(II) also gave a positive error when present in a 50-fold excess over cobalt(II). On the other hand, the coexistence of almost any anion did not interfere, though the cyanide ion gave a negative error when present in a 40-fold excess over cobalt(II). The results are given in Table 4.

Mechanism of Fluorescence-Quenching Reaction. Although further investigation is necessary, the fluorescence-quenching reaction among Fl, hydrogen peroxide, cobalt(II), and tiron was estimated. Firstly, the oxidation and decompostion reaction of Fl by hydrogen peroxide was catalytically enhanced by the presence of small amounts of cobalt(II). Secondly, by the coexistence of tiron as an activator, the total amounts of hydrogen peroxide as an oxidation agent decreased following a reaction between tiron and hydrogen peroxide, or one of tiron, hydrogen peroxide, and cobalt(II). Then the R.fl.Int. of the Fl-hydrogen peroxide-tiron-cobalt(II) solution was found to be proportional to the amounts of cobalt(II); the total hydrogen peroxide concentration was less than the reference solution (Fl/hydrogen peroxide/tiron solution). Thus, the fluorescence-quenching reaction was recognized.

Table 4. Effects of Foreign Ions

Foreign ion	Added			Rate of R.fl. Int.[a)]	Recovery /%
	as	μg/25 cm^3	Mole ratio

a) Average recoveries from five determinations; cobalt(II) taken—2.9 ng/25 cm^3. b) Japanese Pharmacopoeia XI. c) Prepared sample.

Application. To verify the usefulness of the recommended procedure, the proposed method was applied to the determination of cobalt in cyanocobalamine (vitamin B_{12}) and also in some eye-drop and synthetic pharmaceutical preparations containing vitamin B_{12}. As is shown in Table 5, which gives the recovery data for 3—4 replicates of each sample, the results were relatively good. By using a reflux heating procedure on a hotplate, the proposed method does not require a preliminary decomposition procedure, and it is very simple, rapid, and selective.

In conclusion, the proposed method for the spectrophotometric determination of cobalt(II) based on the fluorescence-quenching of Fl by coexisting hydrogen peroxide, tiron, and cobalt(II) is simpler, more sensitive, and more reproducible than previous reported methods.[2,4,5,9-11] It works by means of a reaction between such organic reagents as Pyrogallol Red, Pyrocatechol Violet, and tiron and an oxidizing agent. The proposed method is very selective and excellent in its effect on foreign ions. Moreover, for the assay of cobalt containing organo compounds such as cyanocobalamine, the proposed method does not require any particular preparatory procedures; organo compounds are decomposed by standard procedures and their fluorescence is quenched well.

Solvent Influence on the Circular Dichroism Spectrum of Potassium Ethylenediaminetetraacetatocobaltate(III)

Toshiaki TAURA
Department of Chemistry, University of Aichi Prefecture,
Takadacho 3-28, Mizuho-ku, Nagoya 467
(Received February 2, 1989)

The circular dichroism (CD) spectrum of optically active potassium ethylenediaminetetraacetatocobaltate(III), (+)-K[Co(edta)]·$2H_2O$, was measured in water and a variety of organic solvents: ethylene glycol, methanol, formamide, ethanol, 2-propanol, chloroform, nitromethane, dichloromethane, dimethyl sulfoxide, acetonitrile, *N*,*N*-dimethylformamide, benzonitrile, *N*,*N*-dimethylacetamide, and acetone. The spectra in organic solvents were obtained for the solutions of the complex anion, which were prepared by the addition of a macrobicyclic polyether, cryptand 222. It was found that the peak positions and intensities of the CD bands are markedly influenced by the solvent molecules and this solvent influence on the peak position is linearly correlated to the influence on the corresponding first d-d absorption spectrum. Therefore, the solvent influence on the CD spectrum of this complex is suggested to be caused by the change in the d-d transition energy of this Co(III) complex anion. Furthermore, the positions and intensities of the CD peaks were also correlated with the electrophilic ability (the acceptor number: *AN*) and the bulk polarity (the dielectric constant) of the solvent, respectively. It is proposed that the inherent CD spectrum of $[Co(edta)]^-$ that is not solvated could be estimated on the basis of this correlation.

In the field of coordination chemistry, the circular dichroism (CD) spectra of metal complexes, especially cobalt(III) complexes, have been utilized to determine their absolute configuration around the central metal ions.[1] This is because the CD spectra in the d-d transition region are mainly dependent on the configuration of the metal complex, though these are affected to some extent by the conformation of the chelating ligand or the so-called vicinal effect from the ligand asymmetry. However, the CD spectra are sometimes influenced drastically by the outersphere interaction with the counter ion and the solvent molecule. Therefore, one can not obtain any decisive conclusion about the absolute configuration of the complex ion if the influence of the outersphere interaction is not made clear. The influence of the counter ion has so far been investigated for many cobalt(III) complexes:[2] $[Co(en)_3]^{3+}$ (en=ethylenediamine) and other cationic Co(III) complexes; the counter ions are oxoacid anions (PO_4^{3-}, SO_4^{2-}, etc.) and some dicarboxylates. As for the influence of the solvent, only a few systematic studies would appear to have been made on the circular dichroism of optically active metal complexes. Concerning the solvent influence on the CD spectra two reasons have so far been proposed. Bosnich and Harrowfield[3] reported that the CD spectra of cobalt(III) complexes of *trans*-$[Co(N)_4(X)_2]^+$ are markedly solvent-dependent, where $(N)_4$ refers to chiral quadridentate amines. In their first paper, they suggested that *trans*-(*R*,*R*)-[Co(3,2,3-tet)$(N_3)_2$]ClO_4(3,2,3-tet=$NH_2(CH_2)_3NH(CH_2)_2NH(CH_2)_3NH_2$) changed the sign of the CD peak in the longest wavelength region and this is due to the change of the chelate-ring conformation. By contrast, Hawkins et al.[4] investigated the CD and proton NMR spectra of some *trans*-$[Co(R\text{-pn})_2(X)_2]^{n+}$ and related complexes in a variety of solvents (*R*-pn=(*R*)-1,2-propanediamine). They ascribed the solvent dependence of the CD spectra to the stereoselective hydrogen bonding that is formed between the equatorial amino hydrogens of the complex cation and the solvent molecules, leading to the induction of the new asymmetry on the coordinated nitrogens. Thus, in both these two investigations it was proposed that the main factors of this solvent influence on the CD are the change of the chelate-ring conformation and the vicinal effect caused by the asymmetry induction on the coordinated nitrogens.

On the other hand, it has been found that the peak position of the first d-d absorption band is considerably influenced by solvent molecules when the absorption spectrum of K[Co(edta)]·$2H_2O$ was obtained in several organic solvents;[5] the complex is solubilized by the addition of a macrocyclic polyether, 18-crown-6 ether and cryptand 222.[6] This phenomenon makes us expect that the CD spectrum of this complex shows a fairly intensive solvent dependence. This complex anion, $[Co(edta)]^-$, has no amino hydrogens in the ligand and seems to have no flexible chelate rings leading to the drastic conformational change. Therefore, this should be a type of complex different from those considered in the above literature.

From this viewpoint, we have observed the CD spectra of optically active potassium ethylenediaminetetraacetatocobaltate(III) in a variety of solvents in order to elucidate how the CD of this complex is influenced by the solvent. The peak positions and intensities in each solvent are examined on the basis of the corresponding peak positions in the d-d absorption spectra, the dielectric constants and the acceptor numbers of solvents; the last parameter was proposed by Mayer et al. as a means of estimating the electrophilic ability of the solvents.[7] Thereafter, we have tried to obtain the inherent CD spectrum of

$[Co(edta)]^-$ without the contribution of the outersphere interactions.

Experimental

Materials. $K[Co(edta)]\cdot 2H_2O$ was prepared and resolved into two enantiomers $(+)_{546}$- and $(-)_{546}$-$K[Co(edta)]\cdot 2H_2O$[8] by using $(-)$-$[Co(NO_2)_2(en)_2]Br$[9] which was resolved by potassium antimony (*R,R*)-tartrate. The purity of these complexes was checked by spectroscopic methods: 580 nm (−1.72) and 500 nm (+0.77) for (+)-isomer from the less soluble diastereomeric salt [lit,[10] 578 nm (+1.50) and 504 nm (−0.76) for (−)-isomer]. Cryptand 222 was purchased from Merck Co. The organic solvents were of the purest grade commercially available and were used without further purification. The solvents used here are as follows: water, ethylene glycol, methanol, formamide, ethanol, 2-propanol, chloroform, nitromethane, dichloromethane, dimethyl sulfoxide, acetonitrile, *N,N*-dimethylformamide, benzonitrile, *N,N*-dimethylacetamide, and acetone.

Measurements. The circular dichroism (CD) spectra were recorded at ambient temperature[11] on the solutions of $(+)$-$K[Co(edta)]\cdot 2H_2O$ ($(1.00—1.50)\times 10^{-3}$ mol dm^{-3}) for water, and for organic solvents containing cryptand 222 (the 1.5 times concentration). A JASCO J-40CS recording spectropolarimeter with a 1-cm cell was used for the CD measurements. The CD spectra are not influenced by the addition of various amounts of cryptand 222 or by a change of the concentration of the cobalt(III) complex.[12] Furthermore, the slight amount of hydrate water ($(2.00—3.00)\times 10^{-3}$ mol dm^{-3}) were not a problem because the CD spectrum of the anhydrous salt of this complex shows only a minor change (within experimental error) in the solvents of acetonitrile and chloroform.

Results and Discussion

The CD spectra of $(+)_{546}$-$K[Co(edta)]\cdot 2H_2O$ (edta= $^-OOCCH_2(^-OOCCH_2)NCH_2CH_2N(CH_2COO^-)$-$CH_2COO^-$) in water and in chloroform are shown in Fig. 1. It is obvious that these CD spectra are very different from one another in the position and intensity of the peak. In both solvents, the CD spectra of this complex apparently have two components in the first d-d transition region (440—700 nm): a A_2 component of minus sign in the longer wavelength region and a B_2 or B_1 component (overlapped) of plus sign in the shorter wavelength region. (The assignment of the CD peaks has been made for the complex of C_2 symmetry near to the C_{2v} limit by McCaffery et al.[13] and the assignment of $[Co(edta)]^-$ has been carried out by Douglas et al.[10]) The peak positions of both components appear in a longer wavelength region in chloroform than in water. The intensity of the A_2 component is greater in water but that of the B_2 or B_1 component is slightly smaller in water than in chloroform. As the $[Co(edta)]^-$ anion is inert and stable in these solvents, this difference in CD is due to the outersphere interaction between the complex anion and solvent molecules.[14,15]

a) *AN* refers to the acceptor number of the solvent.

All data of the peak positions and intensities of the CD obtained are presented in Table 1 for a variety of solvents: H_2O, ethylene glycol (EG), methanol (CH_3OH), formamide (FA), ethanol (C_2H_5OH), 2-propanol (i-C_3H_7OH), chloroform ($CHCl_3$), nitromethane (CH_3NO_2), dichloromethane (CH_2Cl_2), dimethyl sulfoxide (Me_2SO), acetonitrile (CH_3CN), *N,N*-dimethylformamide (DMF), benzonitrile (C_6H_5CN), *N,N*-dimethylacetamide (DMA), and acetone (Me_2CO). This table also includes the acceptor numbers (*AN*) and the dielectric constants of solvents.

Correlation between the Peak Positions in CD and Absorption Spectra. At first we consider the correlation between the peak positions (λ_{max}(CD)) in the CD spectra and the peak positions (λ_{max}(ABS)) in the first d-d absorption spectra.[16] In Fig. 2, are plotted the λ_{max}(CD) values of the A_2 component against the λ_{max}(ABS) values[5] of the first d-d transition band in the corresponding solvents: H_2O, EG, CH_3OH, FA, C_2H_5OH, i-C_3H_7OH, $CHCl_3$, CH_3NO_2, CH_2Cl_2, Me_2SO, CH_3CN, DMF, C_6H_5CN, DMA, and Me_2CO. This figure indicates a linear correlation between these two values. Figure 3, in which the same plot for the B_2 or B_1 component is shown, suggests that the λ_{max}(CD) values are also linearly correlated to the λ_{max}(ABS) values. Therefore, the solvent dependence of the peak position of the CD in the first d-d transition region is completely due to the change in the d-d transition energy of this complex anion.

In the works of Bosnich and Hawkins, it seems that there is no such correlation between the peak positions in CD and absorption spectra. This is because the newly induced ligand asymmetry and the change

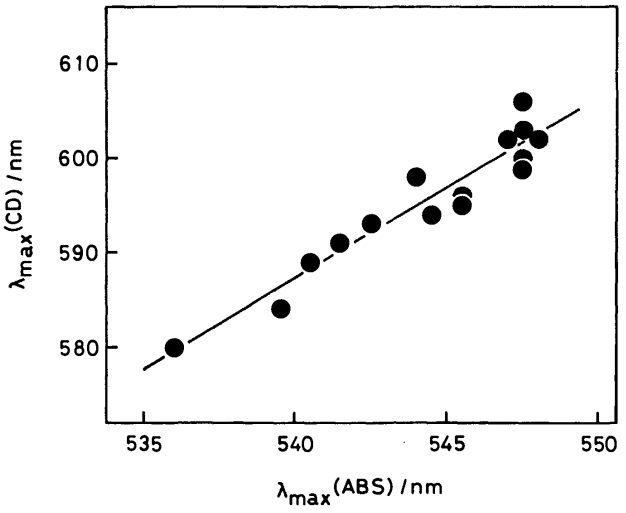

Fig. 2. The correlation between the peak positions (λ_{max}(CD): λ_1 in Table 1) of the A_2 component in the CD spectrum and the peak positions (λ_{max}(ABS)) of the first d-d absorption band in a variety of solvents. The data are plotted for the solvents presented in Table 1; the slope is 1.916 and the correlation coefficient is 0.955. The values of the peak positions of absorption bands are taken from Ref. 5.

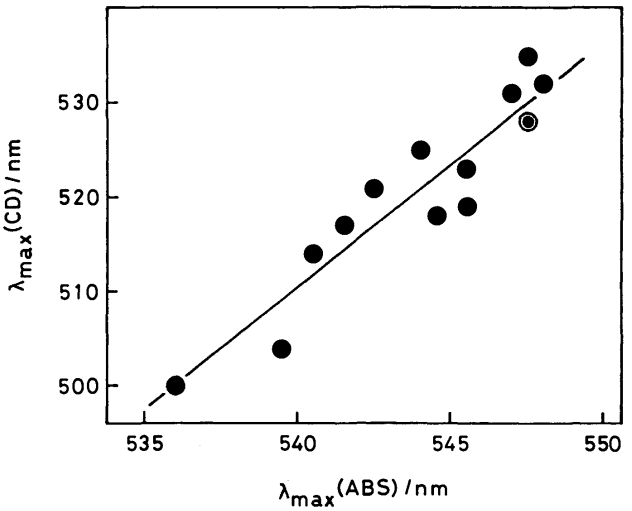

Fig. 3. The correlation between the peak positions (λ_{max}(CD): λ_2 in Table 1) of the B_2 or B_1 component in the CD spectrum and the peak positions (λ_{max}(ABS)) of the first d-d absorption band in a variety of solvents. The data are plotted for the solvents presented in Table 1; the slope is 2.586 and the correlation coefficient is 0.937. The values for absorption bands are from Ref. 5.

of the ligand conformation do not influence the absorption spectra in this way. Therefore, this suggests that the solvent influence is not generated from these two factors.

Correlation between the Peak Positions in CD and the Acceptor Numbers of Solvents. Furthermore, in order to elucidate the origin of this CD change more clearly, this solvent dependence is examined on the basis of the acceptor numbers (*AN*) that are proposed as a measure of estimating the electrophilic ability of solvents. In Table 1, it is apparent that λ_{max}(CD) (in later sections λ_{max} is used in place of λ_{max}(CD)) values are shifted to the shorter wavelength region as the acceptor number (*AN*) increases. The acceptor number indicates that the solvent bearing the large *AN* value is a strong electron acceptor. Therefore, solvent molecules interact strongly with the anion like $[Co(edta)]^-$ if the solvent bears a large value of the acceptor number. This interaction has already been investigated by the carbon-13 NMR studies.[15] It was reported in this NMR study that protic solvents bearing large *AN* values interact with negatively charged carboxyl groups of $[Co(edta)]^-$ through the hydrogen bonding between solvent hydrogens and carboxyl oxygens of the complex anion. Further, the solvent influence on the carbon-13 NMR chemical shift is rationalized by the electron-withdrawing effect caused by the hydrogen-bond formation. Accordingly, the CD change, which is due to the change of the d-d transition energy, is also supposed to be attributed to this hydrogen-bond formation between solvent molecules and $[Co(edta)]^-$ and to the electron-withdrawing effect. The correlation between this hydrogen bond-

ing and the change in the electronic state of the complex has now been studied by MO calculation.[5b] Then, the contribution of the solvent interaction to the peak positions of CD will be estimated quantitatively.

In Figs. 4 and 5, are plotted the λ_{max} values of the A_2 and B_2 or B_1 (abbreviated as B later on) components against the acceptor numbers of solvents. These figures indicate that the plots of λ_{max} give straight lines (the correlation coefficients are 0.821 and 0.801, respectively). The linearities of the lines suggest that the λ_{max} values in some solvent can be approximately estimated by using the acceptor number of the solvent. If the complex anion is hypothetically free from the solvation in hexane that bears the *AN* value of zero, the peak positions of the $[Co(edta)]^-$ anion that is not solvated could then be obtained by the extrapolations of these lines. The λ_{max} values of A_2 and B components in the solvent are calculated by the following equations (error bars are for one standard deviation):

$$\lambda_{max}(A_2) = \lambda_{max}^{\circ}(A_2) - (0.47 \pm 0.09) \times AN$$

$$\lambda_{max}(B) = \lambda_{max}^{\circ}(B) - (0.63 \pm 0.14) \times AN$$

where $\lambda_{max}^{\circ}(A_2)$, $\lambda_{max}^{\circ}(B)$, and *AN* refer to the peak positions ($\lambda_{max}^{\circ}(A_2)=608\pm3$ nm and $\lambda_{max}^{\circ}(B)=539\pm4$ nm determined by a linear least-squares analysis) in hexane as a standard solvent (*AN*=0) and the acceptor number of the solvent, respectively. The first terms in these equations could correspond to the inherent peak positions of the A_2 and B components for $[Co(edta)]^-$ that is not solvated and the second terms to the electron-withdrawing effect that is attributed to solvating molecules. Therefore, we could separate the inherent peak positions from the contributions of the solvent molecules.

The second terms in these equations are slightly different from each other (the coefficients are −0.47 for λ_{max} (A_2) and −0.63 λ_{max} (B), respectively). Though the origin of this slight difference is not clear, these terms should be in principle the same because stereoselective solvation does not exist in this system, as has been shown in the carbon-13 NMR study.[15] The solvent molecules interact equivalently with the four (axial and equatorial) carboxyl oxygens.

Correlation between the Intensities in CD and the Dielectric Constants of Solvents. One of the most interesting results in this work is the correlation between the intensities in CD and the dielectric constants of the solvents. The intensities of the CD peaks are varied from one solvent to another in Table

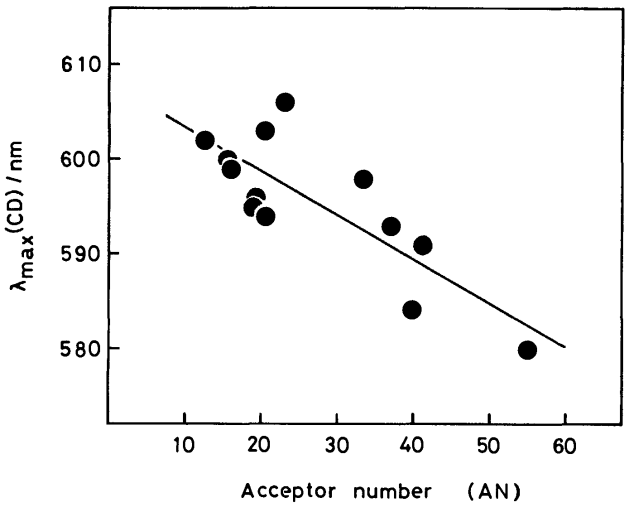

Fig. 4. The correlation between the peak positions (λ_{max}(CD): λ_1 in Table 1) of the A_2 component and the acceptor numbers (*AN*) of the solvents. The data are plotted for the solvents except for ethylene glycol (EG) presented in Table 1.

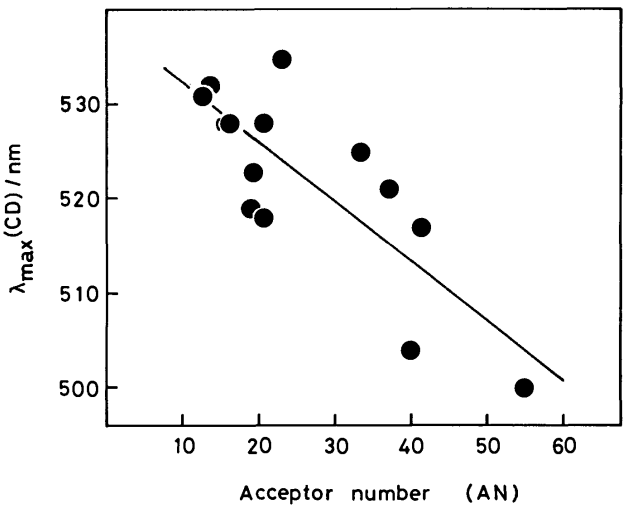

Fig. 5. The correlation between the peak positions (λ_{max}(CD): λ_2 in Table 1) of the B_2 or B_1 component and the acceptor numbers (*AN*) of the solvents. The data are plotted for the solvents except for ethylene glycol (EG) presented in Table 1.

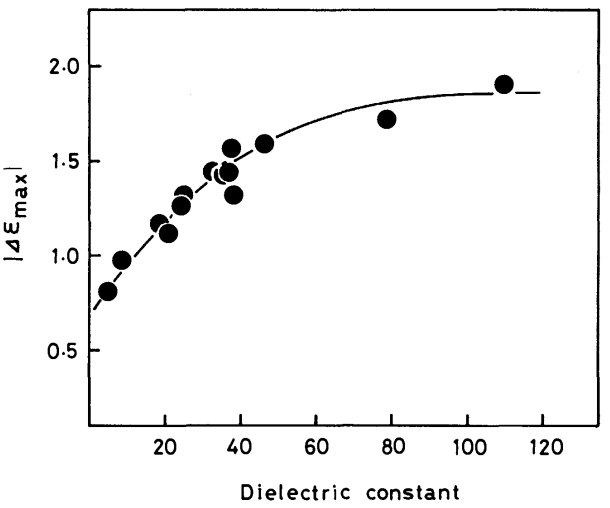

Fig. 6. The correlation between the intensities ($|\Delta\varepsilon_{max}|$: the absolute values of $\Delta\varepsilon_1$ in Table 1) of the A_2 component and the dielectric constants of the solvents.

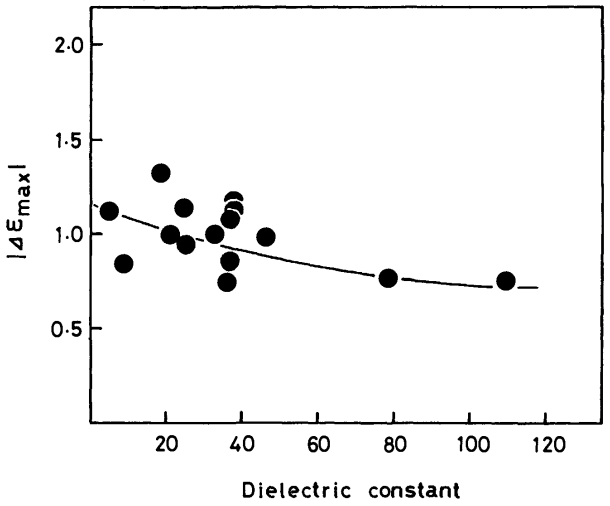

Fig. 7. The correlation between the intensities ($|\Delta\varepsilon_{max}|$: the absolute values of $\Delta\varepsilon_2$ in Table 1) of the B_2 or B_1 component and the dielectric constants of the solvents.

1. This variation is found to be correlated to the polarities of solvents, indicated by the dielectric constant. In Figs. 6 and 7, the intensities of the A_2 and B components are plotted against the dielectric constants of the solvents. The intensity of the B component does not drastically vary in this series of solvents. (The larger deviation of the plot in Fig. 7 is probably because this CD band contains two components B_2 and B_1.) In contrast to this component, the CD intensity of the A_2 component increases markedly and continuously as the dielectric constant of the solvent increases (Fig. 6). This A_2 component of the CD of $[Co(edta)]^-$ is assigned by McCaffery et al. and Douglas et al. The transition for the A_2 component is polarized along the C_2 axis of the complex, which is illustrated in Fig. 8. The electric dipole moment of this complex also extends along the C_2 direction, and so the polarization of the complex along this direction could increase more because of the polar environment of a large dielectric constant around the complex anion. Though a theoretical interpretation for the change of the rotational strength according to the dielectric constant of the solvent could not be suggested, it is probable that the rotational strength of the transition component A_2 polarized along the direction

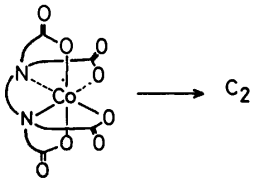

Fig. 8. The direction of the polarization for the A_2 transition and of the electric dipole moment of $[Co(edta)]^-$. The absolute configuration corresponds to the $(+)_{546}$-isomer that is used in this work.

of the dipole increases as the polarization of the complex along this direction increases.

We can confirm this result by considering the datum for formamide. This is one of the solvents bearing a dielectric constant larger than that of water. The dielectric constant of formamide (109.5) is much greater than that of water (78.5). In Fig. 6 one can clearly observe that the intensity of the A_2 component in formamide is much greater than the intensity in water.

It can be concluded that the intensity of the A_2 component which appears in the longest wavelength region increases as the dielectric constant corresponding to the bulk polarity of the solvent increases though the correlation is not linear.

From this correlation, we can tentatively estimate the intensities of the A_2 and B_2 or B_1(B) components in the hypothetical environment of the dielectric constant zero. These values are −0.70 (±10% error) for the A_2 and +1.15 (±20% error) for the B, which are evaluated by the extrapolation of the plots in Figs. 6 and 7. It is certain that, generally speaking, the solvent influence on the CD intensity depends not only on the dielectric constant but also on other solvent properties, ex. refractive indices. In this case the CD-intensity variation seems to depend mainly on the dielectric constants of the solvents.

Conclusion

The solvent influence on the circular dichroism spectrum of $[Co(edta)]^-$ has been rationalized by examining the correlation between the peak positions of the CD spectra and the acceptor numbers, and the correlation between the intensities of the CD bands and the dielectric constants of the solvents. Based on this rationalization, the CD spectrum was divided into the inherent CD and the contribution of the solvent influence. Eventually, the inherent CD spectrum of optically active $[Co(edta)]^-$ that is not solvated could be proposed. The peak positions and intensities for $(+)_{546}$-isomer are 608±3 nm (−0.70) and 539±4 nm (+1.15) [obsd.: 580 nm (−1.72) and 500 nm (+0.77) in water].

The author wishes to thank Prof. J. Fujita for the use of a JASCO J-40CS recording spectropolarimeter at Nagoya University.

9) F. P. Dwyer and F. L. Garvan, *Inorg. Synth.*, **6**, 195 (1960).

10) B. E. Douglas, R. A. Haines, and J. G. Brushmiller, *Inorg. Chem.*, **2**, 1194 (1963).

11) The temperature for the measurement is 23—25 °C. The CD spectrum was measured more than twice. The peak position was the same within experimental error (±1 nm) and the intensity was reproduced within ±3% of random errors. Therefore, the CD spectrum is not dependent on the temperature under the conditions used here.

12) It seems that there is no influence of the ion association with K^+ or the $K^+ \cdot$ C222 complex on the CD spectra of the $[Co(edta)]^-$ anion, where C222 refers to cryptand 222.

13) A. J. McCaffery, S. F. Mason, and B. J. Norman, *J. Chem. Soc.*, **1965**, 5094.

14) The absorption and CD spectra in the solvents did not show the time dependence during the measurements.

15) T. Taura, *Inorg. Chem.*, **27**, 2845 (1988).

16) The plot of the wavenumbers (cm^{-1}) of the peak positions against the acceptor number also gives the straight line. The intercepts and correlation coefficients are quite similar to those obtained from the plots of the wavelengths (nm). The intercept and correlation coefficient are 16440±80 cm^{-1} (608 nm) and 0.820 for the A_2 component and 18550±150 cm^{-1} (539 nm) and 0.801 for the B component, respectively.

Substituent Group Electronic Effects on Inversion and Proton-Exchange Rates at Chiral Nitrogen Centers for a Series of Bis(β-diketonato)-(*N*-methylethylenediamine)cobalt(III) Complexes

Guilin MA, Masaaki KOJIMA, and Junnosuke FUJITA*

(Received April 3, 1989)

The rates of the base-catalyzed proton exchange (deuteration, k_D) and inversion (epimerization, k_{ep}) at chiral nitrogen centers of $[Co(Xacac)_2(Me\text{-}en)]^+$ (Xacac: NO_2acac=3-nitro-2,4-pentanedionate, Clacac=3-chloro-2,4-pentanedionate, CH_3acac=3-methyl-2,4-pentanedionate; Me-en=*N*-methylethylenediamine) in aqueous solutions have been measured at 34.0 °C, and the results were compared with one another and with those of the corresponding acac complex (acac=2,4-pentanedionate) in order to investigate the substituent influence on the rates. The k_D and k_{ep} values of the NO_2acac complex are ca. 10^4 and ca. 10^6 times, respectively, larger than those of the CH_3acac complex. The effect of substituents is electronic and the Hammett relationship was found to hold for both deuteration and epimerization rates. The reduction (Co^{3+}/Co^{2+}) half-wave potential, $E_{1/2}$ obtained by rotating glassy carbon electrode voltammetry increases from −0.59 V (vs. SCE) for the CH_3acac complex to −0.08 V for the NO_2acac complex. A linear dependence was observed between $E_{1/2}$ and the Hammett parameter.

The kinetics of inversion and proton exchange at chiral secondary amine nitrogen centers of metal complexes have been studied extensively.[1] However, factors influencing the rates are not clear yet. In a previous paper,[2] we measured the rates of base-catalyzed epimerization and deuteration of $[Co(acac \text{ or } ox)_2(Me\text{-}en)]^{+or-}$ (ox=oxalate ion), and found that the rates of the uninegative ox complex are greater than those of the unipositive acac complex. The results indicate that the rates are largely affected by the electronic effect of coexisting ligands rather than the number of positive charges on the complex.[3]

In order to investigate the electronic effect on the rates of proton exchange and inversion in more detail, we have prepared a series of $[Co(Xacac)_2(Me\text{-}en)]^+$, in which the hydrogen atom at the 3-position of the acac ligand is replaced by a methyl, chloro, or nitro group.

Experimental

The $[Co(acac)_2(Me\text{-}en)]^+$ complex was prepared and separated into the two racemic pairs of diastereomers, *Λ*(*R*)*Δ*(*S*) and *Λ*(*S*)*Δ*(*R*), as described previously.[4]

[Co(CH_3acac)$_3$]. To a solution of $CoCl_2 \cdot 6H_2O$ (5 g, 21 mmol) in water (5 cm^3) was added 30% H_2O_2 (7.5 cm^3). This solution was added to an ice-cold slurry of $KHCO_3$ (15 g) in water (15 cm^3) with stirring. The resulting green solution of $[Co(CO_3)_3]^{3-}$[5] was filtered. To the filtrate was added 3-methyl-2,4-pentanedione[6] (7.2 g, 63 mmol) and the mixture was heated at 40 °C for 1.5 h to yield a green solid. The product was collected by filtration, washed with water, and recrystallized from chloroform by adding petroleum ether. Yield: 4.0 g. The ^{1}H NMR spectrum in $CDCl_3$ was identical with that reported by Brown et al.[7]

***Λ*(*R*)*Δ*(*S*)- and *Λ*(*S*)*Δ*(*R*)-[Co(CH_3acac)$_2$(Me-en)]ClO_4.** Active charcoal (0.2 g) and a solution of Me-en (0.244 g, 3.3 mmol) in methanol (20 cm^3) were added to a solution of [Co(CH_3acac)$_3$] (1.2 g, 3.0 mmol) in methanol (80 cm^3). The mixture was stirred for 45 min and then filtered. The purple filtrate was diluted with water (1 dm^3), and applied on a column (φ3 cm×20 cm) of SP-Sephadex C-25. By elution with 0.05 mol dm^{-3} NaCl, a purple and a red (probably $[Co(CH_3acac)(Me\text{-}en)_2]^{2+}$) band developed in this order. The eluate containing the purple band was collected and evaporated to a small volume under reduced pressure. To the concentrate sodium perchlorate was added to yield purple crystals, which were recrystallized from water (60 °C). Yield: 0.4 g. The crystals were a mixture of the two isomers, and they were separated by a column chromatographic method. About 0.15 g of the mixture was dissolved in water and the solution was applied on a column (φ2.2 cm×50 cm) of SE-Toyopearl HW-40[8] (fine). A recycling chromatographic technique with an eluent of 0.05 mol dm^{-3} NaCl was employed. After two times of recycling, two isomers, *Λ*(*R*)*Δ*(*S*) and *Λ*(*S*)*Δ*(*R*) were eluted separately in this order. From each eluate the perchlorate of the isomer was obtained by the same method as that described above. Found for the *Λ*(*R*)*Δ*(*S*)-isomer: C, 39.22; H, 6.12; N, 6.09%. Found for the *Λ*(*S*)*Δ*(*R*)-isomer: C, 39.36; H, 6.14; N, 6.18%. Calcd for $C_{15}H_{28}N_2O_8ClCo$: C, 39.27; H, 6.15; N, 6.11%.

***Λ*(*R*)*Δ*(*S*)- and *Λ*(*S*)*Δ*(*R*)-[Co(Clacac)$_2$(Me-en)]ClO_4.** These complexes were prepared by chlorination of the corresponding isomers of $[Co(acac)_2(Me\text{-}en)]ClO_4$ with *N*-chlorosuccinimide by a method similar to that for [Co(Clacac)-(en)$_2$]$(ClO_4)_2$[9] (en=ethylenediamine). To a suspension of *Λ*(*R*)*Δ*(*S*)-$[Co(acac)_2(Me\text{-}en)]ClO_4 \cdot 0.5H_2O$ (0.66 g, 1.54 mmol) in 0.01 mol dm^{-3} $HClO_4$ (8 cm^3) was added *N*-chlorosuccinimide (0.49 g, 3.67 mmol) little by little, and the mixture was stirred for 30 min at 50 °C. After cooling, the purple product was collected by filtration, and recrystallized from 0.01 mol dm^{-3}$HClO_4$. Yield: 0.26 g. The *Λ*(*S*)*Δ*(*R*)-isomer was obtained from *Λ*(*S*)*Δ*(*R*)-$[Co(acac)_2(Me\text{-}en)]ClO_4$ by the same method. Found for the *Λ*(*R*)*Δ*(*S*)-isomer: C, 31.14; H, 4.43; N, 5.57%. Found for the *Λ*(*S*)*Δ*(*R*)-isomer: C, 31.10; H, 4.40; N, 5.59%. Calcd for $C_{13}H_{22}N_2Cl_3CoO_8$: C, 31.25; H, 4.44; N, 5.61%.

***Λ*(*R*)*Δ*(*S*)- and *Λ*(*S*)*Δ*(*R*)-[Co(NO_2acac)$_2$(Me-en)]ClO_4.** These complexes were prepared by nitration of the corresponding isomers of $[Co(acac)_2(Me\text{-}en)]ClO_4$ in a manner similar to that for [Co(NO_2acac)$_3$].[10] A mixture of finely ground $Cu(NO_3)_2 \cdot 3H_2O$ (1.93 g, 8.0 mmol) and acetic anhydride (60 cm^3) was stirred for 15 min at 0 °C. To the slurry was added *Λ*(*R*)*Δ*(*S*)-$[Co(acac)_2(Me\text{-}en)]ClO_4 \cdot 0.5H_2O$ (0.6 g, 1.4 mmol).

The mixture was stirred for 3 h at 0 °C, and then for 1 h at room temperature. The blue solution was mixed with water (90 g) and ice (90 g), and the mixture was evaporated to a small volume under reduced pressure. To the concentrate was added sodium perchlorate to yield purple crystals. They were collected by filtration and recrystallized from 0.01 mol dm^{-3} $HClO_4$. Yield: 0.4 g. The $\Lambda(S)\Delta(R)$-isomer was obtained from $\Lambda(S)\Delta(R)$-[Co(acac)$_2$(Me-en)]ClO_4 by the same method. Found for the $\Lambda(R)\Delta(S)$-isomer: C, 30.29; H, 4.22; N, 10.76%. Found for the $\Lambda(S)\Delta(R)$-isomer: C, 29.86; H, 4.25; N, 10.83%. Calcd for $C_{13}H_{22}N_4ClCoO_{12}$: C, 29.99; H, 4.26; N, 10.76%.

Measurements. Absorption and ^{1}H NMR spectra were measured on a Hitachi 323 spectrophotometer and a Hitachi R-90H spectrometer, respectively. Electrochemical measurements were performed at 24 °C by using a Fuso HECS 321B potential sweep unit. Rotating disk experiments were carried out on a three-electrode system composed of glassy carbon rotating disk (2000 rev min^{-1}), platinum wire, and saturated calomel electrodes as the working, auxiliary, and reference electrodes, respectively. KCl was used as the supporting electrolyte at 0.1 mol dm^{-3} concentration.

Deuteration Studies. The rates of deuteration at the chiral amine nitrogen centers of the Clacac and CH_3acac complexes were measured in a phosphate buffer, pD 4.8—6.2 and pD 7.7—9.2, respectively at 34.0 °C, while those of the NO_2acac complex in a phthalate buffer (pD 2.4—3.1) at 34.0 °C. The empirical formula, pD=pH meter reading +0.4, was used to calculate [OD$^-$].[11] The complex perchlorates were converted into the more soluble chlorides with a Dowex 1X8 anion exchanger in the chloride form. The deuteration rates were followed by monitoring signal changes in the ^{1}H NMR spectra. The N-CH_3 doublet signal becomes a singlet by deuteration. All rates were followed for at least two half-lives. From the spectral changes, pseudo-first-order rate constants for deuteration, $k_{D(obsd)}$ were obtained as described previously.[12] For each complex, the $k_{D(obsd)}/[OD^-](=k_D)$ values are constant at 34.0 °C in the pD range measured, indicating that the reaction is first order in [OD$^-$]. Thus, the rate law was the same as that obtained previously for other amine complexes, $R=k_D$[complex][OD$^-$].[1]

Epimerization Studies. The rates of epimerization of the NO_2acac and the Clacac complexes were measured in a phosphate buffer (pH 6.4—7.2) and a borate buffer (pH 9.1—10.2), respectively, while that of the CH_3acac complex in 0.1 mol dm^{-3} NaOH (pH 12.6 at 34.0 °C) and a saturated aqueous solution of $Ca(OH)_2$ (pH 12.1 at 34.0 °C). The rates were followed by the same method as described previously.[12-14] It involves separation of two isomers of the complexes by a high-performance liquid chromatographic method. Analysis of chromatograms changed with reaction time gives the pseudo-first-order rate constant, $k_{ep(obsd)}$. The rate law for the epimerization reaction was the same as that for racemization (epimerization) of other chiral amine complexes, $R=k_{ep}$[complex][OH$^-$].[1] The runs starting from either of the isomers gave the same result within the experimental error. From these observations, the reaction can be expressed as

$$\Lambda(S)\Delta(R) \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \Lambda(R)\Delta(S).$$

The forward and reverse second-order rate constants, k_1 and k_{-1} were obtained from k_{ep} ($k_{ep}=k_1+k_{-1}$) and the equilibrium constant ($K_{eq}=k_1/k_{-1}$).

Results and Discussion

Preparation and Characterization of the Complexes. The [Co(CH_3acac)$_2$(Me-en)]$^+$ complex was prepared by the reaction of [Co(CH_3acac)$_3$] with Me-en in the presence of active charcoal. Four stereoisomers, $\Lambda(R)$, $\Lambda(S)$, $\Delta(R)$, and $\Delta(S)$ are possible for the complex (Fig. 1). The isomers were separated into two racemic pairs of the diastereomers, $\Lambda(R)\Delta(S)$ and $\Lambda(S)\Delta(R)$ by column chromatography on SE-Toyopearl. The structures of the isomers were assigned from the chemical shift of the *N*-methyl group in ^{1}H NMR spectra taking a shielding effect by the CH_3acac chelate ring into consideration; an isomer which shows a doublet attributable to the *N*-methyl group at a higher magnetic field is assigned to the $\Lambda(S)\Delta(R)$ isomer (Fig. 1 and Table 1). The isomers ($\Lambda(R)\Delta(S)$ and $\Lambda(S)\Delta(R)$) of [Co(Clacac)$_2$(Me-en)]$^+$ and [Co(NO_2acac)$_2$(Me-en)]$^+$ were prepared by chlorination and nitration, respectively of the corresponding isomers of [Co(acac)$_2$(Me-en)]$^+$. The configurations of the parent complexes remained unchanged as verified by the ^{1}H NMR spectra.

The distributions of the isomers at equilibrium (34 °C) were analyzed by the reversed-phase high-performance liquid chromatographic technique, and the results are given in Table 1. The difference in stability is very small between the isomers for each complex. Table 1 also gives the absorption spectral data for the [Co(Xacac)$_2$(Me-en)]$^+$ complexes, and the spectra are shown in Fig. 2. The $\Lambda(S)\Delta(R)$ isomers, in which the *N*-methyl group is situated over one of the Xacac chelate rings exhibit the first d-d absorption

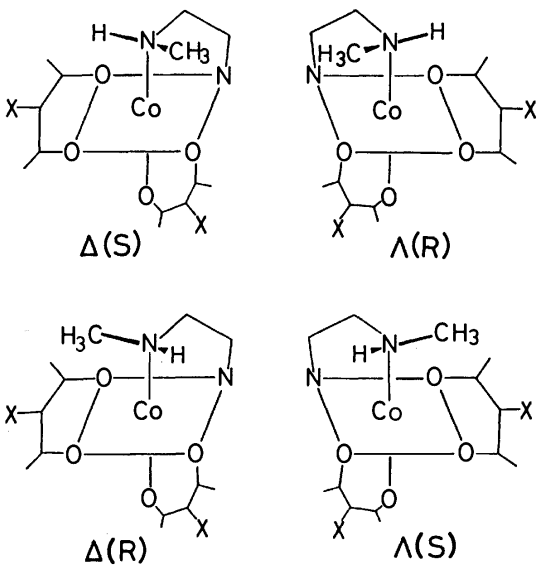

Fig. 1. The four stereoisomers of [Co(Xacac)$_2$(Me-en)]$^+$.

a) In D_2O-DCl. b) In D_2O. c) In 0.01 mol dm^{-3} $HClO_4$.

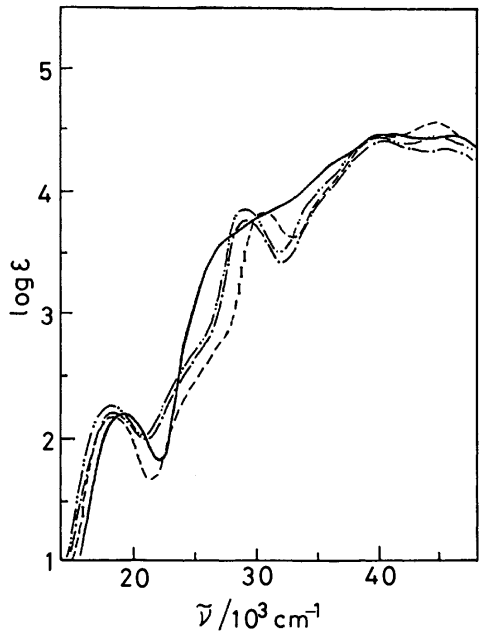

Fig. 2. Absorption spectra of $\Lambda(S)\Delta(R)$-[Co(Xacac)$_2$-(Me-en)]$^+$ in 0.01 mol dm^{-3} HCl, Xacac=NO_2acac (——), Clacac (—·—), acac (----), and CH_3acac (—··—).

band at lower energy than that of the $\Lambda(R)\Delta(S)$ isomers. The first absorption band shifts to lower energy as Xacac is changed from NO_2acac through Clacac and acac to CH_3acac. The shift will be related with the electronic effect of the X substituent on acac, since no steric interaction seems to occur among the X substituent and other ligands.

Electrochemistry and ^{1}H NMR Spectra. Electrochemistry is very useful for measuring electronic effects of substituents on the ligand in metal complexes. Rotating glassy carbon electrode voltammograms of the [Co(Xacac)$_2$(Me-en)]$^+$ complexes were measured in 0.1 mol dm^{-3} KCl vs. a saturated calomel electrode (SCE), and the results are summarized in Table 2. The complexes show a quasi-reversible reduction wave assignable to the Co^{3+}/Co^{2+} couple. The half-wave potentials ($E_{1/2}$ values) range from −0.08 V to −0.59 V. The difference in $E_{1/2}$ between the isomers is small in each complex. The $E_{1/2}$'s are plotted as a function of the Hammett σ_p parameter for the X substituent in [Co(Xacac)$_2$(Me-en)]$^+$ (Fig.3). A linear relationship between them indicates that the electronic effect of a substituent at the 3-position of the acac ligand is transmitted through the ligand to the metal ion in these complexes. It has been demonstrated that polarographic reduction potentials of Cr(III) and Ru(III) β-diketonates correlate well with the substituent electronic effects as measured by Hammett substituent effects.[15,16]

If the electronic effect is transmitted further to the amine nitrogen atoms, it should be reflected on the properties of the amine group. This is especially true for ^{1}H NMR spectroscopy, where an increase

Table 2. Electrochemical Data for the Reduction of [Co(Xacac)$_2$(Me-en)]$^+$ (vs. SCE) at 24 °C[a]

Xacac	Substituent parameter/σ_p	Isomer	$E_{1/2}$/V	$\lvert E_{3/4}-E_{1/4}\rvert$/V[b]
NO_2acac[c]	+0.78	$\Lambda(S)\Delta(R)$	−0.08	0.095
		$\Lambda(R)\Delta(S)$	−0.08	0.095
Clacac	+0.23	$\Lambda(S)\Delta(R)$	−0.28	0.095
		$\Lambda(R)\Delta(S)$	−0.27	0.095
acac	0	$\Lambda(S)\Delta(R)$	−0.47	0.100
		$\Lambda(R)\Delta(S)$	−0.47	0.105

		$\Lambda(R)\Delta(S)$	−0.56	0.100

a) By glassy carbon rotating disk experiments (in water containing 0.1 mol dm^{-3} KCl with a 0.01 V s^{-1} scan rate; 2000 rev min^{-1}). b) $E_{3/4}$ and $E_{1/4}$ are potentials at three-fourth and one-fourth of the limiting current value, respectively. c) Adjusted to pH 4 with dil $HClO_4$.

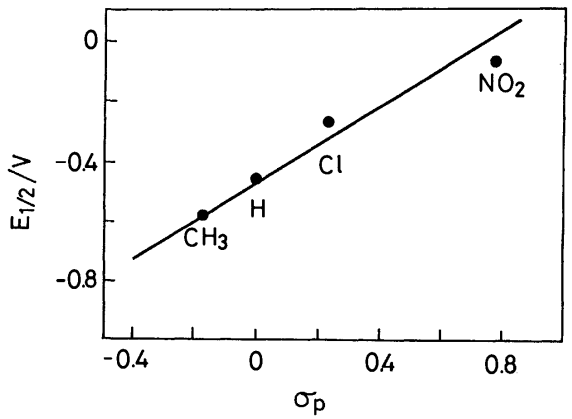

Fig. 3. Plot of the reduction half-wave potentials ($E_{1/2}$) vs. the Hammett parameter σ_p for $[Co(Xacac)_2(Me\text{-}en)]^+$ (Xacac=NO_2acac, Clacac, acac, and CH_3acac).

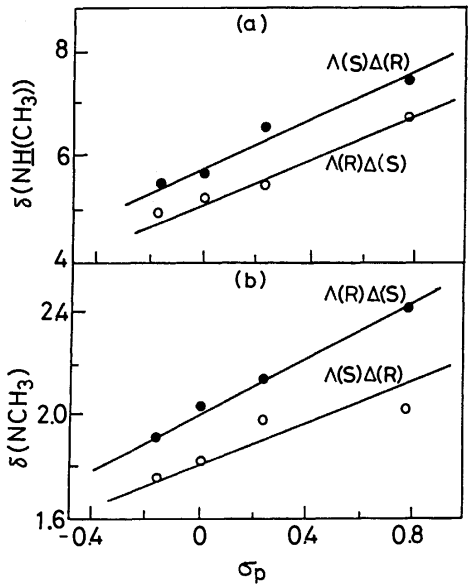

Fig. 4. Correlation of the ^1H NMR chemical shifts with the Hammett parameter, σ_p: $\delta(N\underline{H}(CH_3))$ vs. σ_p (a) and $\delta(NCH_3)$ vs. σ_p (b).

(decrease) in electron density on a particular proton will lead to a high (low) field shift for that proton. The chemical shift data of the $N\underline{H}(CH_3)$ and NCH_3 indicate this electronic effect (Table 1). For example, the $N\underline{H}(CH_3)$ signal of $\Lambda(S)\Delta(R)$-$[Co(NO_2acac)_2(Me\text{-}en)]^+$ is shifted 1.95 ppm downfield from its position in the spectrum of the corresponding CH_3acac complex. The nitro group withdraws electron density from the *N*-methyl nitrogen atom to cause the downfield shift of the amine proton signal. Plots of the chemical shifts of the $N\underline{H}(CH_3)$ and NCH_3 protons vs. the Hammett substituent constants (σ_p) were linear (Fig. 4).

Deuteration and Eqimerization Reactions. Table 3 gives the rate constants for deuteration, k_D at chiral nitrogen centers of the $[Co(Xacac)_2(Me\text{-}en)]^+$ complexes. The k_D value of the NO_2acac complex is ca. 10^4 times as large as that of the CH_3acac complex. A decrease in electron density on the amine nitrogen should labilize the hydrogen to promote H-D exchange. A linear relationship holds as shown in Fig. 5, where the logarithms of the deuteration rate constants for the Xacac complexes relative to that for the acac complex are plotted against the Hammett σ_p values. Although such a Hammett relationship has been reported to hold for deuteration of $[Co(Xacac)_2(en)]^+$ (Xacac=NO_2acac, Bracac, acac) in a D_2O-DMSO-d_6 mixture (weight ratio 1 : 3.9), the NO_2acac complex was deuterated faster than the acac complex only by a factor of 12.[16] The factor of the present Me-en complex in D_2O is 1600.

The rate constants for epimerization, k_{ep} of the $[Co(Xacac)_2(Me\text{-}en)]^+$ complexes are given in Table 3. Electronic contributions of the X substituents induce pronounced effect on the rates. For example, the epimerization rate of the NO_2acac complex is ca. 10^6 times greater than that of the CH_3acac complex. There also exists a linear Hammett relationship as

Table 3. A Comparison of Data for the Deuteration and Inversion at Chiral Nitrogen Centers of $[Co(Xacac)_2(Me\text{-}en)]^+$ at 34.0 °C

Xacac	Isomer	$k_D/M^{-1}s^{-1}$ [b]	$k_{ep}/M^{-1}s^{-1}$	(k_1 or k_{-1})/$M^{-1}s^{-1}$	r=(k_1 or k_{-1})/k_D

$$\Lambda(R)\text{-}[Co(Xacac)_2(^-N(CH_3)CH_2CH_2NH_2)] + H_2O \underset{k'-H^+}{\overset{k'+H^+}{\rightleftharpoons}} \Lambda(R)\text{-}[Co(Xacac)_2(NH(CH_3)CH_2CH_2NH_2)]^+ + OH^- \quad (3)$$

The actual rate of inversion of the amido complex is k_i (k'_i) and is pH independent.[19] The measured rate constant for epimerization (k_{ep}) is pH dependent since the rate depends on the amount of amido complex present. The ratio, $r=(k_1$ or $k_{-1})/k_D$, which is determined by partitioning the deprotonated intermediate between inversion and reprotonation, becomes a direct measure of the actual rate of inversion if the reprotonation rate is constant (diffusion controlled). This is the case when the pK_a values of $[Co(Xacac)_2(Me\text{-}en)]^+$ exceed 14, as has been estimated for other cobalt(III)-amine complexes.[1,20] A plot of $\log(r^X/r^H)$ against σ_p is found to be linear (reaction constant $\rho=+2.2$), where r^X and r^H denote the r values of the Xacac and acac complexes, respectively (Fig. 6).

The selenium atom of a selenide (RSeR′) ligand becomes chiral on coordination to a metal ion. We have studied the inversion at the selenium atom in $[Co(Xacac)_2(CH_3SeCH_2CH_2NH_2)]^+$ and found that the Hammett relationship holds for the rates of the Clacac, acac, and CH_3acac complexes, where the reaction constant ρ is -2.9, a negative value.[21] The first step of inversion at a chiral nitrogen center will be the abstraction of the coordinated secondary amine proton by OH^- to yield a pyramidal center (Eq. 1).

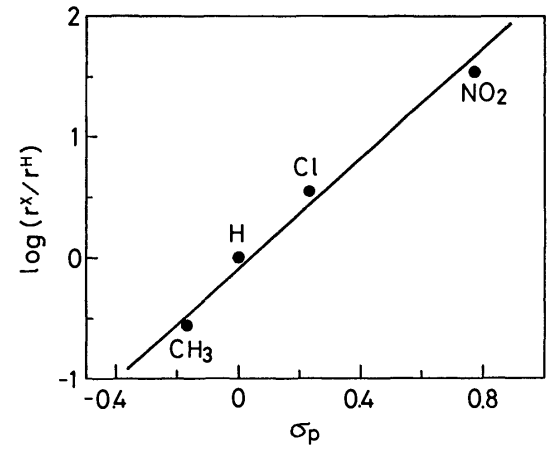

Fig. 6. Plot of $\log(r^X/r^H)$ vs. the Hammett σ_p for $[Co(Xacac)_2(Me\text{-}en)]^+$.

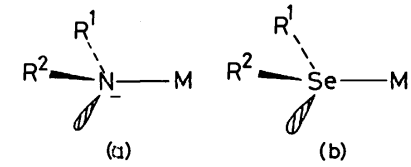

Fig. 7. Structures of the pyramidal amide intermediate (a) and the coordinated selenide (b).

The structure of the pyramidal amide intermediate will be similar to that of the coordinated selenide (Fig. 7), but inverse electronic effect was found. For a pyramidal atomic inversion, it is usually observed that an electronegative substituent on the central atom decreases the rate of inversion.[22] The Se inversion of the cobalt-selenides is the case.

The reason for the inverse electronic effect of the N inversion of $[Co(Xacac)_2(Me\text{-}en)]^+$ is difficult to explain. The cobalt-amide intermediates possess a formal negative charge on nitrogen, and the electronic effect of the charge might play an important role in controlling the stereochemistry to affect the inversion rate. The importance of electrostatic effect (electron repulsion effect) as a rate-controlling factor for an atomic inversion was pointed out by Anet et al.[23] They studied the rates of the N inversion of $(CH_2)_2NX$ and those of the C inversion of R_2C^-X. The effect of the group X on the negatively charged carbanion system was found to differ from that on the neutral aziridine system. The lack of correlation between the two systems was ascribed to the difference in electrostatic effect between them. A similar discussion might be made for the cobalt-amide intermediates, since they are isoelectronic with cobalt-selenides as carbanions are with amines.

Use of Polyoxetane Resin-Supported Quaternary Onium Salts as a Polymeric Phase-Transfer Catalyst for Preparing Ethers from Hydroxy Compounds and Alkyl Halides

(Received December 23, 1988)

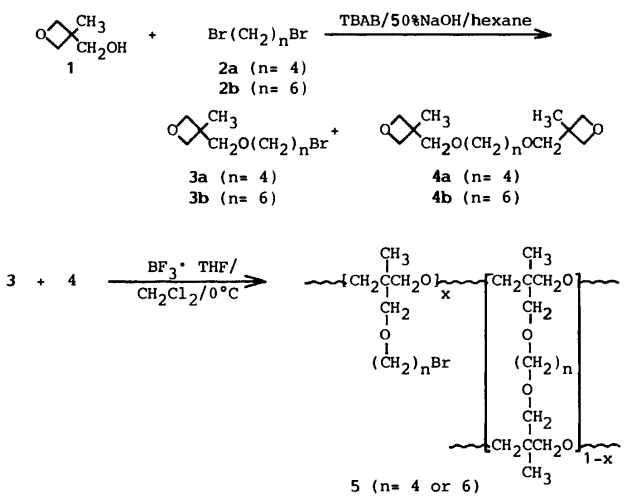
As a polymer support for preparing polymeric phase-transfer catalysts (PTC), soft, moderately polar polyoxetane resins were employed which were synthesized by a cationic ring-opening copolymerization of oxetanes $Br(CH_2)_nOCH_2$-X with bisoxetanes X-$CH_2O(CH_2)_nOCH_2$-X, where X=3-methyl-3-oxetanyl and n=4 or 6. In a few cases of those polymerizations, 3-(2-oxadecyl)-3-methyloxetane was used as a comonomer with a lipophilic pendant. The terminal bromine of the pendant groups of such polyoxetane resins was quaternized with tributylamine or tributylphosphine in DMF in order to examine the phase-transfer catalyzing ability of the resultant quaternary onium bromides in the etherification reaction between alkyl halides and alcohols or phenols. These reactions gave the desired products in fairly good yields within reaction periods of 1—3 h, indicating that the catalytic activities of those PTCs are comparable to that of tetrabutylammonium bromide. A fairly high catalytic activity of the polymeric PTC was observed at each of ten stages in a process using the polymeric PTC repeatedly for the etherification reaction of 3-hydroxymethyl-3-methyloxetane with 1,4-dibromobutane.

It has recently been increasingly recognized that synthetic polymers can be conveniently used in organic syntheses as reagents, catalysts, membranes, and substances with other various functionalities.[1,2] The polymeric phase-transfer catalyst (PTC) has attracted the attention of investigators who have hoped to readily obtain novel and important organic compounds by a simple work-up of a reaction mixture and to use the catalyst repeatedly after easily recovering it. Hereby, the use of various polymeric PTCs in organic syntheses has been reviewed.[1-6]

In the preparation of the polymeric PTCs, insoluble cross-linked polystyrenes have been widely used as polymeric supports for anchoring a catalytic group to the support. These polymeric supports have not always been used advantageously in organic syntheses using polar or ionic reagents and solvents, due to the low polarity of the polystyrene support. Furthermore, the movability of the catalytic group, which is anchored to hard (or unflexible) polymer matrices of the polystyrene support, would be more or less restricted, exerting an entropically unfavorable influence on the catalytic behavior. The catalytic activity of PTC was enhanced upon introducing a moderately long spacer between the catalytic group and the polymer matrix;[7] owing to the existence of such a long spacer, the catalytic group was kept apart from sterically crowded polymer matrices. In order to improve such undesirable qualities of the polymeric support as hardness (or unflexibility), low polarity, and low hydrophilicity, polyoxiranes have also been chosen as soft, polar, or hydrophilic segments in block and graft polymers.[8-12] Particularly, poly(oxyethylene) (POE) has often been successfully applied not only to the segments mentioned above, but also to catalysts and ionophors, which realize their functions via a cooperative action of the ether oxygen.[13-16]

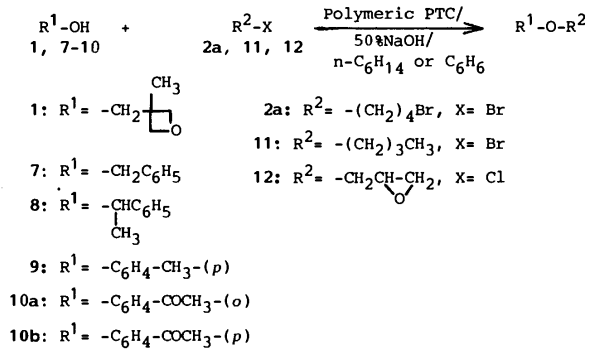
In our previous papers, we reported facile syntheses of oxetanes **3a** and **3b** carrying ω-bromo-2-oxapolymethylene side chains at the C-3 position of an oxetane ring, of bisoxetanes **4a** and **4b** being as a cross-linking agent, and of soft, moderately polar polyoxetane resins **5** by a cationic ring-opening copolymerization of those oxetanes.[17] We also briefly reported a fairly high catalytic activity of a polymeric PTC, which was prepared by quaternizing the pendant bromide of a polyoxetane resin with tributylamine (**6**), on the etherification reaction between the alcohol **1** and the dibromide **2a**.[18]

Thus, polyoxetane resins are thought to be very promising as a polymeric support. So far, there has been no investigation concerning the phase-transfer



Scheme 1.

catalysis using such polyoxetane resin-supported onium salts as a PTC, although polystyrene resin-supported PTCs have often been employed in various reactions of organic synthesis.[1-5] In this article, our investigation results are described in more detail concerning the application of polyoxetane resins to the polymeric support of PTCs for readily preparing several ethers from hydroxy compounds and alkyl halides.



Scheme 2.

Experimental

Materials. Oxetanes **3a** and **3b**, bisoxetanes **4a** and **4b**, and 3-(2-oxadecyl)-3-methyloxetane (**13**) were prepared by the phase-transfer catalytic reaction according to a method reported by us previously.[17] The hydroxy compounds **7**—**10**, the alkyl halides, **2a**, **2b**, **11**, and **12**, and tetrabutylammonium bromide (TBAB) were used without further purification of commercially available reagents. 1-Benzyloxy-4-bromobutane (**24**), 1-benzyloxybutane (**25**),[19] 1-(1-phenylethoxy)butane (**26**), benzyl 2,3-epoxypropyl ether (**27**),[20] 2,3-epoxypropyl 1-phenylethyl ether (**28**),[20] 1-(*p*-methylphenoxy)butane (**29**),[21] 1-(*o*- and *p*-acetylphenoxy)-4-bromobutanes (**30a** and **30b**), and 1,4-bis(*o*- and *p*-acetylphenoxy)butanes (**31a** and **31b**) were prepared by a phase-transfer catalytic reaction of the appropriate alcohol or phenol with the halide in the presence of TBAB, and were employed to draw calibration curves of the gas chromatography (GC) determination. IR and ^{1}H NMR spectra confirmed structures of these compounds.

24: bp 79—80 °C (14.7 Pa); IR(neat) 3075, 3040, 1600, 1580, 735, and 695 (monosubstituted benzene), and 1100 cm^{-1} (aliphatic ether); ^{1}H NMR($CDCl_3$) δ=1.6—2.2 [4H, m, $OCH_2(C\underline{H}_2)_2CH_2Br$], 3.42, 3.48 [each 2H, each bt, $C\underline{H}_2(CH_2)_2C\underline{H}_2Br$], 4.48 (2H, s, OCH_2Ar), and 7.33 (5H, m, ArH).

Found: C, 54.23; H, 6.19; Br, 32.83%. Calcd for $C_{11}H_{15}BrO$: C, 54.33; H, 6.23; Br, 32.86%.

26: bp 93—94 °C (0.31 kPa); IR(neat) 3075, 3040, 1600, 1500, 760, and 700 (monosubstituted benzene), and 1100 cm^{-1} (aliphatic ether).

30a: bp 132.5 °C (26.7 Pa); IR(neat) 3075, 3040, 1595, 1575, 1480, and 750 (1,2-disubstituted benzene), 1670 (C=O), and 1240 cm^{-1} (aromatic ether); ^{1}H NMR($CDCl_3$) δ=1.7—2.3 [4H, m, $OCH_2(C\underline{H}_2)_2CH_2Br$], 2.58 (3H, s, $COCH_3$), 3.2—3.7 (2H, bt, CH_2Br), 3.8—4.3 (2H, bt, CH_2OAr), 6.7—7.9 (4H, m, ArH).

Found: C, 73.29; H, 6.77%. Calcd for $C_{20}H_{22}O_4$: C, 73.59; H, 6.81%.

31b: mp 146.0—147.5 °C (acetone); IR(KBr) 1595, 1579, 1500, and 1465 (1,4-disubstituted benzene), 1670 (C=O), and 1240 cm^{-1} (aryl ether); ^{1}H NMR($CDCl_3$) δ=1.8—2.3 [4H, m, $(C\underline{H}_2)_2CH_2OAr$)], 2.56 (6H, s, $COCH_3$), 3.9—4.3 (4H, m, CH_2OAr), and 6.8—8.2 (8H, quartet-like, ArH).

Found: C, 73.60; H, 6.76%. Calcd for $C_{20}H_{22}O_4$: C, 73.59; H, 6.81%.

The polyoxetane resins with the pendant bromide were made by the copolymerization of **3a** or **3b** with **4a** or **4b**, and, if necessary, **13** in dichloromethane (DCM) at 0 °C with boron trifluoride (BF_3)-tetrahydrofuran (THF) complex (0.5% to total mole of the oxetane ring) as an initiator, as described by us previously.[17] The seven polymeric PTCs were prepared by heating a polyoxetane-supported bromide with a threefold molar excess of tributylamine (**6**) or -phosphine (**14**) in DMF at 100 °C for 10 h. The polymeric catalyst was filtered, washed successively with methanol and ether, and dried at 80 °C under reduced pressure of 27 Pa for 6 h.

Phase-Transfer Catalytic Reaction between Hydroxy Compounds and Alkyl Halides. In a round-bottomed flask there were placed a polymeric PTC, a hydroxy compound, an alkyl halide, and an internal standard of GC analysis. A 50% aqueous sodium hydroxide (NaOH) solution and hexane as a solvent were added into the mixture of reactants with ice-cooling. This was heated under reflux with efficiently stirring by means of a magnetic or mechanical stirrer. At every desired time, the mixture was cooled below 5 °C and an aliquot of the organic layer was withdrawn into a microsyringe to determine the product yield by GC. In a reaction on a preparative scale using 10 g of **1**, water (300 cm^3) was added into the resulting mixture below 5 °C after an appropriate reaction time. This was transferred to a separatory funnel to extract the product with ether. An aqueous layer was discarded as thoroughly as possible and the remainder was filtered to separate the polymeric catalyst. The polymer was washed successively with water, ether, and methanol. Here, methanol was successfully used to rinse the funnel. The organic layer of the filtrate was dried over Na_2SO_4 and distilled to give the products. In the examination of the repeated use of the polymeric PTC, the polymer collected by filtration was employed during the next stage of the process, using it repeatedly in the reaction between **1** and **2a** after or without drying the polymeric PTC.

Measurement. GC analysis of the products was performed in a Shimadzu GC 8A apparatus: glass column (3.2ϕ×1 m) packed with Silicone High Vacuum Grease

(30%)/Celite (80—100 mesh); carrier gas, He (66 cm^3 min^{-1}); temp, 140 or 210 °C. The IR spectra were recorded on a JASCO A-202 spectrometer, and on a ^1H NMR 60 (Hitachi R-24B) or 100 MHz instrument (JEOL FX-100S) using $CDCl_3$ as a solvent and TMS as an internal standard. A differential scanning calorimetry (DSC) measurement was carried out in a DSC/560 (Daini Seikohsha) at a heating rate of 20 °C min^{-1} for a sample in air.

Results and Discussion

Preparation of Polyoxetane Resin-Supported PTCs. The polyoxetane supports **15-I**, **16-I**, **17-I**, **18-I**, **19-I**, and **20-I** carrying a bromide at the pendant spacer end were prepared by cationic ring-opening copolymerization of **3** with **4**. All cross-linked polyoxetanes, thus obtained, were white elastic polymers insoluble in the ordinary organic solvents used, although the homopolymers from **3a** and **3b** were viscous materials with number-average molecular weight ($\bar{M}_n$) 3300—5500 and soluble in the ordinary solvents.[17] In a few cases of the above polymerization, **13** was used as a comonomer with a lipophilic pendant group. Those oxetane derivatives showed IR absorption bands due to a cyclic ether linkage at 980 and 835 cm^{-1}; however, these bands disappeared in the IR spectra of the polymers.[17] The pendant bromide of the supports was quaternized by heating with **6** or **14** in DMF at 100 °C to obtain the polymeric PTCs **15-II** to **20-II** carrying an onium bromide at the pendant spacer end. The polymeric PTCs, so obtained, are listed in Table 1. The mole fractions of the monomeric units (x, y, and z) in a starting polymer are assumed to be identical, respectively, with those in monomers charged in the copolymerization. The content of the onium bromide was calculated on the basis of nitrogen or phosphorus content determined by elemental analysis. IR spectra of the quaternized polymers indicated a considerably strong, broad band around 3400 cm^{-1}, even after drying the polymer at 60 °C for 8 h in vacuo, suggesting that the onium salt may adsorb molecules of water rigidly. For the present, to roughly estimate the mole fraction k of the monomeric unit with the pendant onium salt in a PTC, the k value was calculated on the basis of the nitrogen or phosphorus content and mole fractions x, y, and z in the dried PTC.

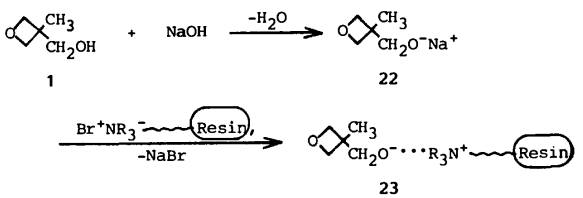
a) **1**, 1.99 mmol; **2a**, 5.98 mmol; *n*-$C_{16}H_{34}$ (internal standard of GC determination), 1.07 mmol; 50% NaOH, 2.8 g; hexane, 2.0 cm^3; at reflux temperature. b) Mol% of the onium bromide to **1**. c) Benzene was used as a solvent. d) **1** and **2a** were charged at a molar ratio of 1 : 1. e) 0.5 mol of ether oxygen of **21a**, **21b**, or POE 400 was used per one mole of **1**.

transfer catalytic reaction of **1** with **2a** using each of the several polymeric PTCs in 50% NaOH and an organic solvent at 70 °C. As shown in Fig. 1, a rate of the formation of **3a** decreased with an decrease in the amount of **16-IIa** from 2.7 to 0.1 mol% to **1**. A fairly good yield of 67% for **3a** was reached, even in the presence of only 0.1 mol% of the ammonium salt of polymeric PTC, although a prolonged reaction time of 4 h was required. When 1.1 to 2.7 mol% of the pendant ammonium salt was used, the formation rates of **3a** are almost comparable to the reaction rate in the presence of 1.7 mol% of TBAB. However, **3a** was formed very slowly in the absence of the catalyst. Similarly, in the presence of each polymeric PTC other than **16-IIa**, a sufficient yield of **3a** or **4a** as a main product was achieved within a few hours (Table 2). The formation of the main product depended on a **2a**/**1** molar ratio of 3.0 or 1.0. The catalytic activity of the phosphonium bromide of **16-IIb** was somewhat higher than that of the corresponding ammonium bromide of **16-IIa** and seemed to be comparable to the catalytic activity of TBAB. It is generally known that quaternary phosphonium salts act as PTC more effectively than the ammonium analogues (vide infra).

Effect of the Polyether Network: Regarding the reaction using a polymeric PTC at a **2a**/**1** mole ratio of 3.0, **4a** was formed in lower yields than that with TBAB, suggesting that it is somewhat difficult to form **4a** from substrate **3a**, which has a bulkier substituent than **2a**, and the nucleophile **1** at the S_N2 reaction stage crowded with polymer matrices. In our previous investigation of the preparation of oxetane derivatives under the phase-transfer catalytic conditions using TBAB in 50% NaOH and an organic solvent, it was found that hexane and ether were suitable solvents for such synthesis, while the catalysis of TBAB in benzene gave **3a** in a lower yield by about 13% than in hexane.[17] However, the yield of **3a** with **15-II**, in spite of using benzene as a solvent, was comparable to the yield of **3a** formed by the reaction in a hexane solvent, indicating that an aliphatic ether structure of the polyoxetane backbone of polymeric PTC plays an important role upon the above catalysis as the so-called "solid phase cosolvent" for the production of **3a** in higher yield.[22] The polyoxetane resin with a pendant onium salt spread in the form of oily or gelatinous particles over the interface between organic and aqueous layers; this aspect was clearly observed when the reaction mixture was permitted to stand in a reactor. On the other hand, the ether network of such polyoxetanes as **21a** and **21b** was hardly swellable in water and somewhat swellable in such organic solvents as ether, chloroform, and benzene, although the level of swellability of the polyether network itself in such solvents was not quite so remarkable as that of the polymeric PTC. The remarkable swelling of the polyoxetane support in the phase-transfer catalysis is attributable to the hydrophilicity of the pendant onium salt as well as to an expanding ability of the soft or elastic cross-linked network containing the ether linkage abundantly. Such a formation of the oily or gelatinous particles due to the swelling of the polymeric PTC has been not observed in the case of using the hard or rigid network of the cross-linked polystyrene support with the pendant onium salt. The ether network of **21a** and **21b** could hardly conduct the phase-transfer catalytic reaction of **1** with **2a**, since the relationships between the reaction time and the product yield are almost similar to that for the reaction in the absence of a PTC (Table 2). POE with a molecular weight of 400 showed a fairly high catalytic activity in the above-mentioned reaction, owing to a cooperative action of ether oxygens of POE. The ether network itself of the polyoxetane support can probably not efficiently solvate the sodium alkoxide **22** (which is generated from **1** and concentrated NaOH) via cooperative action analogous to that of POE, although an ether network of **21a** seems to have the slight ability to transfer the



Scheme 4.

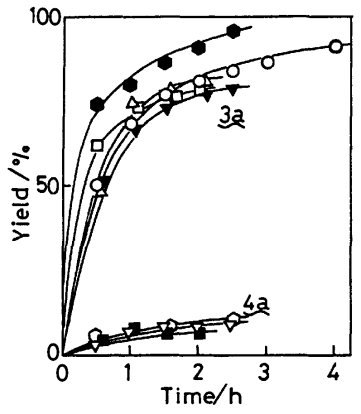


Fig. 2. Influence of the cross-linking agent and of the spacer length on yields of **3a** (▼, △, □, ○, ●) and **4a** (▽, ■, ○) in the phase-transfer catalytic reaction at a **1**/**2a** mole ratio of 1:3. PTC, mole fraction of **4a** or **4b** in a polymeric support, and mol% of an ammonium group to **1**: (▼, ▽) **15-II**, 0.10, 3.0; (△) **16-IIa**, 0.30, 1.1; (□, ■) **16-IIa**, 0.30, 2.7; (○) **17-II**, 0.50, 1.1; (●, ○) **20-II**, 0.21, 3.0.

ionic species **22** from an aqueous layer to an organic one.

Effects of the Cross-Linking Level and the Spacer: In Fig. 2, in comparisons of the PTCs used in a similar amount of the ammonium group between **16-IIa** and **17-II** (each 1.1 mol% to **1**), and **15-II** and **16-IIa** (each about 3 mol% to **1**), their apparent catalytic activities are taken to be comparable to each other, in spite of the order **15-II**>**16-IIa**>**17-II** for the *k* value and the inverted order for the *z* value. These results are interesting since, in general, the catalytic activity of a polymeric catalyst is considered to be lowered by decreasing the loading of a catalytic group and by increasing the mole fraction of the cross-linking agent in a polymeric support. Furthermore, the formation rate of **3a** is also hardly influenced by varying the amount of the ammonium group from 1.1 to 3.0% molar respect to **1**, as shown in the use of **16-IIa**, suggesting that an optimum amount of the catalytic group lies in a range 1 to 3 mol% to **1** (also see Figs. 1 and 4). When the pendant ammonium group of a PTC acts as a countercation accompanying an alkoxide anion of **22** into an organic layer, access of the accompanied alkoxide anion to each other, due to a local assembly of the ammonium group in the PTC, is undesired because of an electrostatic and/or a steric repulsion between the counteranions. Such a locally increased concentration of the ammonium group is realized by increasing the *k* value and/or the amount of the PTC used. A limited amount of the assembling ammonium group acts effectively as the countercation accompanying the alkoxide anion, particularly when using PTCs with high loading (or high *k* values).

It is concluded, therefore, that the *k* and *z* values have little influence on the catalytic activity of the PTC based on a polyoxetane support. Thus, the yield of **3a** reached a range of 76—80% within 2 h in every case of using the polymeric PTCs with cross-linking levels of 10, 30, and 50 mol%. Even the polymeric PTC with a 50 mol% cross-linking level swelled sufficiently under applied phase-transfer catalytic conditions. These results suggest that polyether networks with cross-linking levels of up to 50 mol% are soft (or elastic) and swellable enough for their use as a polymeric support of the PTC, being a contrast to the widely employed polystyrene supports containing only a few mol% of divinylbenzene as a cross-linking agent; use of PTCs with higher divinylbenzene contents frequently leads to remarkably lower product yields or requires hard reaction conditions to obtain a fairly good product yield.

The somewhat improved yields of **3a** were obtained by lengthening the spacer by an ethylene unit in both the side chain and cross-linking agent of a polymeric PTC, as shown in each comparison between **15-II** and **20-II**, and between **16-IIa** and **20-II** (each about 3 mol% to **1**). **20-II** gave a slightly higher yield of **3a** than **15-II** and **16-IIa** within the same reaction time, although **20-II** has a lower *k* and higher *z* values than **15-II**, and a higher *k* and lower *z* values than **16-IIa**. However, the loading and cross-linking levels of these PTCs are taken to be unimportant here (as mentioned above). Presumably, a longer spacer of the cross-linking agent causes the network to expand more sufficiently, and a longer spacer of the side chain causes the catalytic group to be located more apart from the crowded polymer matrices. It has also been reported that lengthening an alkyl chain between polymer matrices and a terminal onium group of the side chain significantly improves the yield of *O*-alkylated product in a phase-transfer catalytic reaction of 2-naphthol with benzyl bromide.[1,7]

Effect of the Lipophilic Pendant Group: Furthermore, in designing a polymer which is effective for a phase-transfer catalysis, it is important to find an optimum with respect to the relative content of the hydrophilic and lipophilic groups in a polymer. At the S_N2 reaction stage of the phase-transfer catalysis, it is required to create lipophilic domains dissolving the organic substrate to be allowed to react with the nucleophile which is transferred in the form of **23** from the aqueous phase to the organic phase. On the other hand, hydrophilic domains are required to stabilize ionic species of **23** transferred into the polymer matrices. The interesting behavior of water was also reported with respect to the mechanism of phase-transfer catalysis.[23,24] Thus, the polymeric PTCs **18-II** and **19-II** were employed to examine an effect of the lipophilic octyl group on the catalytic activity (Fig. 3). Use of the polymeric PTC **18-II** with 17 mol% of the monomeric unit **13** did not indicate the appreciable improvement of the catalytic activity, as compared with that of **16-IIa** with no octyl group, assuming use

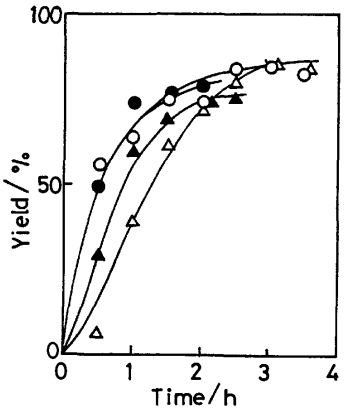

Fig. 3. Influence of a lipophilic unit **13** on a yield of **3a** in the phase-transfer catalytic reaction at a **1**/**2a** molar ratio of 1 : 3. PTC, mole fraction of **13**, and mol% of an ammonium group to **1**: (●) **16-IIa**, 0, 1.1; (▲) **16-IIa**, 0, 0.3; (○) **18-II**, 0.17, 0.7; (△) **19-II**, 0.50, 0.3.

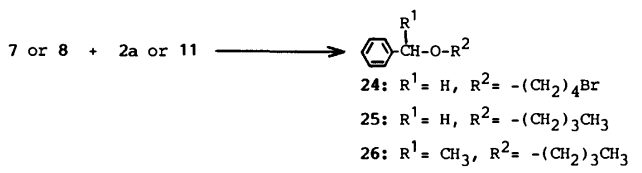
of the similar amount of the ammonium group to each other for these PTCs (0.7 and 1.1 mol% to **1**, respectively). However, as shown obviously in a comparison between phase-transfer catalytic reactions using quaternary ammonium salts of **16-IIa** and **19-II** in 0.3% molar respect to **1**, a lower rate was observed in the formation of **3a** in the presence of **19-II**, which is considered to have an almost comparable content of lipophilic domains relative to **16-IIa** since the lipophilic character of a PTC support is realized not only by the pendant octyl group but also by hydrocarbon chains in the spacers of the monomeric units **3a** and **3b**, some bromine atoms of which are converted into the terminal quaternary onium bromide to act as a catalytic group, and of the cross-linking agent units **4a** and **4b**. When a PTC support has considerably high content of the monomeric unit **13**, the polymeric PTC must consequently contain the catalytic group in its low content. Such a catalytic group is apt to be surrounded with lipophilic hydrocarbon chains which are abundantly present in the pendants and cross-linkages of the PTC support. Probably, the octyl pendant of polymeric PTCs with considerably high contents of the monomeric **13** behaved as a somewhat sterically hindering group and/or as a lipophilic group, which is undesirable for the hydrophilic alcohol **1** (or its alkoxide ion **23**). The high contents of monomeric units having such long alkyl groups are not required virtually for preparing polymeric PTCs of the reaction using hydrophilic reactants. At this time, however, it is difficult to describe whether the existence of a lower content of the monomeric unit **13** in a polymeric PTC is required to design a polymeric PTC having an optimum relative content of the hydrophilic and lipophilic domains. This problem should be clarified by further investigations of the design of various functional polymers.



Scheme 5.

Preparation of the Other Ether Compounds by the Phase-Transfer Catalysis Using a Polymeric PTC: The onium salts attached to the polyoxetane resins were effective for the phase-transfer catalysis between aralkyl alcohols **7** or **8**, and alkyl bromide **2a** or **11** (Figs. 4—6). The catalytic activities of **16-IIa** and **16-IIb** were comparable to that of TBAB in producing **25** under the same reaction conditions (Fig. 4). When 1-phenylethanol (**8**) was used in place of **7**, the considerably prolonged reaction time was required to obtain a

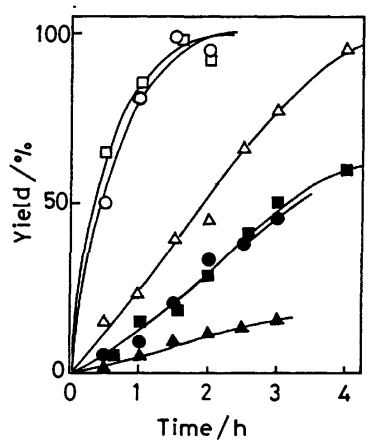

Fig. 7. Time-yield curves for **27** (○, △, □) and **28** (●, ▲, ■) at a **7** or **8**/**17** molar ratio of 1:3 in hexane-50% NaOH. PTC, mol% of an ammonium group to **1**, and reaction temperature: (○, ●) **16-IIa**, 3.5, reflux; (△, ▲) **16-IIb**, 3.4, 25 °C; (□, ■) **16-IIb**, 3.3, reflux.

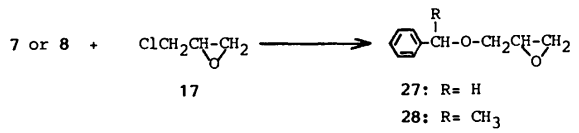
satisfactory yield of **26** in every case using the polymeric PTC or TBAB, probably due to the steric hindrance of methyl group toward the nucleophilic reaction of **8** (Fig. 5). The glycidyl ethers **27** and **28** were also produced by the phase-transfer catalytic reaction of **7** or **8** with epichlorohydrin (**17**) in ether at 25 °C or reflux temperature in the presence of the polymeric PTC (Fig. 7). The phase-transfer catalysis of **7** with **17** at reflux temperature gave **27** in satisfactory yield, while **28** was given in much lower yield by a reaction of **8** with **17** under the influence of a steric hindrance of the benzylic methyl group. Mouzin et al. have prepared various glycidyl ethers by the phase-transfer catalytic reaction of alcohols with **17** in the presence of tetrabutylammonium hydrogensulfate without a solvent, and have recommended a reaction temperature of up to 25 °C for the reaction conditions.[20] In our results, the yields of **28** by a 2 h-reaction in the presence of **16-IIb** were lower by 40—60% than those of **27** under the same reaction conditions, while at the most 20% for the difference of yield between **27** and **28** was reported by Mouzin and his coworkers. The lower yield of **28** obtained by using the polymeric PTC seems to be ascribable to the formation of a sterically hindered reaction stage involving a benzylic methyl group of **8** and the bulky polymer matrices.



Scheme 6.

An *O*-alkylation of phenols was also examined by reactions of phenols with alkyl bromides using the polymeric PTC under the phase-transfer catalytic conditions (Table 3). The catalytic activity of the polymeric PTC was fairly high, as compared to that of TBAB with respect to the formation of those *O*-alkylated products. The reaction of **10a** with **2a** in the presence of **15-II** gave the monosubstituted product **30a** almost exclusively, although in the other

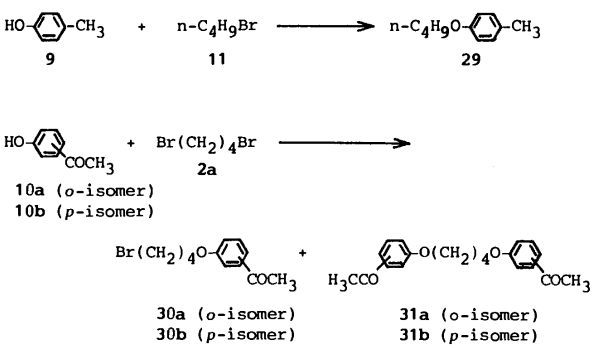

Scheme 7.

reactions in the presence of the polymeric PTC or TBAB the mono-, **30a** or **30b**, and the disubstituted products, **31a** or **31b**, were formed in a ratio of about 95 : 5, regardless of using either an ortho- or para-isomer. It is also thought that the acetyl substituent at the ortho position appreciably influenced the formation of **31a** via the further reaction of **30a** with **10a** in the sterically crowded matrices of the polymeric PTC.

Repeated Use of the Polymeric PTC: The catalytic activity of polymeric PTC **15-II** was examined in a process using the PTC repeatedly in the reaction between **1** and **2a** at the mole ratio of 3.0 in 50% NaOH and hexane. The considerably high phase-transfer catalyzing ability of **15-II** was obviously shown at each of ten stages in the process (Table 4). The reaction rate was enhanced by increasing the concentrations of the reactants (or by decreasing a volume of hexane). When a dried PTC was used, a somewhat longer reaction period was required to obtain a satisfactory yield (75—85%) of **3a**, as compared with that in the use of a wet PTC. This indicates the requirement of a certain period for swelling the dried matrices with the organic and aqueous mediums used in the present catalysis.

		4a:	3.6	7.3	8.5	9.4		

a) **1**, 19.9 mmol; **2a**, 58.7 mmol; polymeric PTC used on the reaction at the 1st stage, 0.33 g by dry weight of **15-II** (3.0 mol% to **1**); *n*-$C_{16}H_{34}$, 1.35 mmol; 50% NaOH, 26 g; at reflux temperature. b) A wet polymeric PTC was used. c) 0.27 g of dried **15-II** was recovered after the reaction at the 8th stage and, subsequently, was reused at this stage.

The unchanged pendant bromide of the polymeric PTC may be converted into the corresponding ether linkage by a phase-transfer catalytic reaction with the hydroxy compound used as the reactant, although the structural change of the pendant group was not confirmed in the present study. This problem is taken to be unimportant since the high catalytic activity was maintained during the experiment of the repeated use of polymeric PTC. The polymeric PTC was easily separated from a reaction mixture by filtration and reused at the next stage of the phase-transfer reaction after or without drying the PTC. A loss of 18% by weight of the dry catalytic PTC initially used was observed before reusing the PTC at the 9th stage, corresponding to an about 97% recovery of PTC per each stage.

The present polymeric PTCs were also proved to be useful for the ether synthesis on a preparative scale. The reaction of 10 g of **1** with three equivalents of **2a** in hexane in the presence of **17-II** in only 0.1% molar respect to **1** gave pure **3a** in a 74% isolated yield. **27** was isolated in a 85% yield by a reaction of 10 g of **7** with **17** in ether in the presence of **16-IIb** in 0.4 mol% of phosphonium salt to **7**.

Influence of the Reaction Temperature: The reaction temperature should be kept in a range of 70 to

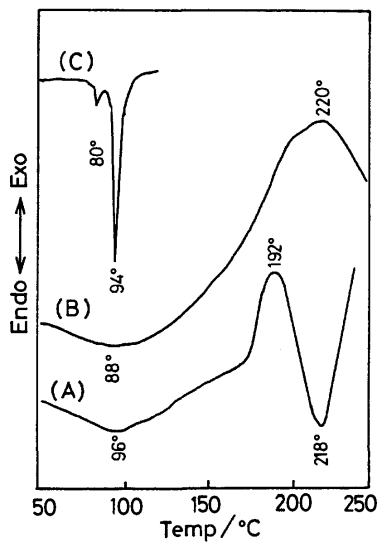

Fig. 8. DSC curves for polymeric PTCs **16-IIa** (A) and **16-IIb** (B), and TBAB (C).

80 °C in using the present polymeric PTCs. At lower temperatures the ether product was formed slowly, presumably requiring a prolonged reaction time to obtain a satisfactory yield. When those PTCs were used at temperatures above 100 °C, their catalytic activities decreased with the reaction time and, consequently, the reuse of the polymer as PTC became virtually impossible. Figure 8 shows the results of DSC measurements for the polymeric PTCs **16-IIa** and **16-IIb**, and TBAB. Probably due to a thermal decomposition, the quaternary ammonium-containing **16-IIa** begins to behave exothermally around 100 °C after indicating an endothermal peak at about 96 °C, which corresponds to a melting point of 94 °C for TBAB. The quaternary phosphonium-containing **16-IIb**, which has an exothermal peak at 220 °C, is taken to be somewhat more thermally stable than **16-IIa** with an exothermal peak at 192 °C. These results are compatible with those obtained for quaternary onium salts with low molecular weights.[25]

In this paper we have demonstrated one of the applications of polyoxetane resins to a polymeric support for preparing functionalized polyethers. It is thus concluded that quaternary onium salts based on a soft, moderately polar polyoxetane support are useful polymeric PTCs for the facile synthesis of ethers.

Nucleophilic Substitution Reactions of Alkyl Halides by Using New Polymer-Supported Reagents Containing Hemin

Kiyoshi SAITO and Kaoru HARADA*
Department of Chemistry, University of Tsukuba, Tsukuba, Ibaraki 305
(Received January 5, 1989)

A new polymer reagent consisting of hemin, divinylbenzene, and 2-methyl-5-vinylpyridine was synthesized by suspension copolymerization. Substitution reactions of primary, secondary, and tertiary alkyl halides with the hemin copolymer combined with cyanide, azide, and thiocyanate ions were given satisfactory yields. This reaction mechanism was revealed to be a S_Ni type on the basis of stereochemical study. The hemin copolymer was not only a polymer-supported reagent with functional capabilities, but also served to separate the product from the reaction mixture.

Ferri-protoporphyrin IX chloride (hemin) is a kind of tetrapyrrole derivative containing a large π-electron system and shows aromatic property. The axial coordination site of porphyrin is an interesting reaction field for various organic reactions. Recently, catalytic oxidation and epoxidation using metalloporphyrin complexs have revealed that the reactions take place on the coordination site of the metalloporphyrin.[1] However, studies on the reaction using ligands other than oxygen have not been reported to the best of our knowledge. Methemoglobin or ferrihemoglobin, in which the heme-ion carries an extra positive charge, has been found to have high affinity for cyanide ion.[2] We have synthesized beads shape hemin containing copolymer by suspension copolymerization[3] in order to prevent the stacking of hemin. It has been shown that the copolymer functions as a cyanide ion exchanger.[3] In this study we would like to describe the application of the hemin copolymer combined with various ligands as a polymer-supported reagent, for nucleophilic substitution in nonaqueous solvents. The use of crown ether as a phase transfer catalyst and of commercial anion-exchange resin as a polymer reagent for nucleophilic substitution in nonaqueous system has been reported.[4-7] In these systems, the mechanism of the reaction is of the S_N2 type. The nucleophilic substitution using Amberlyst A26 (**2**), was reported previously in a nonaqueous system.[5] The polymer investigated in this study is a copolymer consisting of hemin, divinylbenzene (DVB), and 2-methyl-5-vinylpyridine (MVP) (**1**). Figure 1 shows the difference in the binding of the nucleophile at the ion exchange site of **1** and **2**. In **2**, the nucleophile is combined with electrostatic interaction. On the other hand, in **1**, the chemical bonding of the nucleophile with the central iron has both electrostatic and also coordination properties.

Experimental

Synthesis of Hemin Copolymer (1) by Suspension Polymerization:[3] All the monomers used were as described previously.[3] The suspension polymerization was carried out with a standard apparatus for suspension polymerization.

Adsorption Experiment with Cyanide Ion: Copolymer **1** (chloride form, 0.155—0.189 g) was stirred in 50 ml $Na_2B_4O_5$-KH_2PO_4 buffer solution (pH 9; ionic strength 0.1) containing different amounts of KCN (2.14×10^{-4}—2.14×10^{-2} mol dm^{-3}). Detailed procedures of the experiments have been described previously.[3] **Azide Ion:** Copolymer **1** (chloride form, 0.155—0.189 g) was stirred for 12 h in water (50 ml) containing different amounts of NaN_3 (2.14×10^{-4}—2.14×10^{-2} mol dm^{-3}). The azide ion concentration of the supernatant was measured by the method of Labruto and Randisi.[8] **Thiocyanate Ion:** Copolymer **1** (chloride form, 0.155—0.189 g) was stirred for 12 h in water (50 ml) containing different amounts of KSCN (2.14×10^{-4}—2.14×10^{-2} mol dm^{-3}). The thiocyanate ion concentration

of the supernatant was measured by the method of Kruse and Mellon.[9]

Polymer-Supported Reagents (CN, N_3, SCN-Modified Hemin Copolymer): Copolymer **1** (chloride form, 10.0 g) was stirred for 12 h with potassium cyanide (7.0 g) or sodium azide (7.0 g) or potassium thiocyanate (10.0 g) in water (100 ml). The treated resin was filtered off and washed successively with water, methanol, and acetone before drying under reduced pressure at 60 °C.

To estimate the molar quantity of the nucleophile combined with the hemin copolymer, the prepared polymer-supported reagent was packed in a column (40 cm×10 mm diameter) and the nucleophile was eluted with 0.5 M NaOH.

CN, N_3, SCN-Bound Amberlyst A26:[5] Amberlyst A26 (chloride form, 100 g) was stirred for 6 h with potassium cyanide (42 g) or sodium azide (42 g) or potassium thiocyanate (60 g) in water (400 ml). The resin was filtered off and washed successively with water, tetrahydrofuran, and ether before drying under reduced pressure at 40 °C.

Substitution Reactions. The typical procedure of the substitution reaction is as follows: a mixture of halide (1 mmol), **1**-supported anion or **2**-supported anion (1 mmol), and benzene (30 ml) was stirred and heated at 60 °C or 80 °C for 10 h. The resin was filtered off and washed successively with benzene (10 ml×2) and ether (10 ml×2) (the ether was used for washing to elute the substitution product completely). The chemical yields were determined by GC analysis in comparison with authentic samples. The product was confirmed by IR and ^{1}H NMR spectrometry.

Synthesis of Optically Active α-Bromo Acid Methyl Ester. Optically active α-bromo acids were prepared from (*R*)- or (*S*)-amino acids in the usual way as follows: (*S*)-(−)-leucine (10 g, 76 mmol) in cold 3 M H_2SO_4 (300 ml; 1M=1 mol dm^{-3}), containing potassium bromide (55 g, 6 mol equiv) was treated with sodium nitrite (15 g, 2.7 mol equiv) at 0 °C for 0.5 h. The solution was kept at 0 °C for 1 h and then stirred for 1 h with ether (150 ml). The layers were separated and the aqueous solution was extracted with ether. The combined organic solution was dried ($MgSO_4$) and evaporated. After distillation of the crude product, 9.2 g (62%) of purified (*S*)-2-bromo-4-methylpentanoic acid was obtained, bp 97—98 °C (33.33 Pa); $[\alpha]_D^{20}$−33.4° (*c* 2, methanol), lit, $[\alpha]_D^{27}$−34° (methanol).[10] Esterification of the acid with diazomethane gave (−)-methyl-(*S*)-2-bromo-4-methylpentanoate, bp 50 °C (267 Pa). All optical purities of (*R*)- or (*S*)-α-bromo acids were determined by polarimeter before esterification with diazomethane.

(*R*)-2-Bromo propanoic acid, $[\alpha]_D^{22}$+27.3° (*c* 2, methanol), 84% e.e., lit, $[\alpha]_D^{23}$+32.4±3.6° (*c* 0.49, methanol);[16] (*S*)-2-bromo propanoic acid $[\alpha]_D^{22}$−24.5° (*c* 2, methanol), 89% e.e., lit, $[\alpha]_D^{27}$−27.6° (methanol);[10] (*R*)-2-bromo-3-phenylpropanoic acid, $[\alpha]_D^{22}$+10.4° (*c* 2, methanol), 100% e.e., lit, $[\alpha]_D^{20}$+9.0°;[17] (*S*)-2-bromo-3-phenylpropanoic acid, $[\alpha]_D^{22}$ −10.7° (*c* 2, methanol), 100% e.e., lit, $[\alpha]_D^{25}$−10.0° (*c* 2, methanol);[18] (*R*)-2-bromo-4-methylpentanoic acid, $[\alpha]_D^{22}$ +37.8° (*c* 2, methanol), 99% e.e., lit, $[\alpha]_D^{22}$+38.2±1.8° (*c* 2, methanol);[19] (*R*)-2-bromo-3-methylbutanoic acid, $[\alpha]_D^{22}$ +16.1° (*c* 2, methanol), 100% e.e., lit, $[\alpha]_D^{25}$+15.5 (methanol);[20] (*S*)-2-bromo-3-methylbutanoic acid, $[\alpha]_D^{22}$ −17.2° (*c* 2, methanol), 100% e.e., lit, $[\alpha]_D^{27}$−16.8° (methanol).[10]

Characterization of the Substituted Product. After substitution of the optically active α-bromo acid methyl ester with N_3-modified **1**, the resulting α-azido acid methyl ester was hydrogenated over 5% or 20%-Pd/C in the usual manner to form the α-amino acid methyl ester. A 5 mg sample of the α-amino acid methyl ester in 20 ml of 3 M HCl in *i*-PrOH was heated at 100 °C (30 min). The reaction mixture was evaporated under vacuum and the residue was dissolved in 20 ml of dichloromethane. The solution was cooled by using a Dry Ice-acetone bath and 4 ml of trifluoroacetic anhydride (TFAA) was added. The solution was warmed to room temprature, and allowed to stand for 1 h. The reaction mixture was evaporated under vacuum, the residue was dissolved in dichloromethane, and the enantiomeric excess (e.e.) was determined by GC analysis using a chiral stationary phase (Chirasil-Val III).[11]

ESR Spectra. The interaction between the substituted product (R-CN, R-N_3, R-SCN) and the hemin group in copolymer **1** was characterized by electron spin resonance (ESR) spectroscopy which was made at liquid nitrogen temperature with a JEOL-8 JES-FELX spectrometer.

Separation Experiment. The substitution reaction using hemin copolymer **1** was stopped at 65% yield and the reaction mixture containing **1** was packed in a column. After unreacted substrate was compleatly removed by elution with benzene, the reaction product was eluted with ether.

Results and Discussion

Adsorption Experiment. The coordination sphere around the central iron of the hemin in the copolymer was characterized by ESR spectroscopy.[3] The spectrum indicated the five-coordinated high spin type of ferri-porphyrin characterized by ESR signal with g=6.[3] On the other hand, the axial coordination number of N_3^- and SCN^- ions was close to one, as estimated from the results of adsorption experiments similar to those described previously.[3] These results could indicate that the hemin copolymer **1** contains hemin in which the fifth coordination site of the iron(III) is occupied with the MVP residue, and N_3^- and SCN^- ions bind to the sixth coodination position.

Substitution Reactions. The results are summarized in Table 1. The yields of the resulting nitrile, azide, or thiocyanate from halides are high, and by-products were not detected in the reaction mixture, even though the results described here were obtained by using equimolar reagents. Commercial anion-exchange resins have also been used as the polymer-reagent in substitution reactions involving cyanide ion.[4-6] However these commercial resins were not very active in the substitution reaction. Secondary halides gave the corresponding nitriles in low yields, and tertiary halides did not give any substitution products (Table 2). Previously, trimethylacetnitrile has been prepared by dehydration of trimethylacetamide[12] or by addition reaction of HCN to isobutene.[13] The substitution reaction of *t*-butyl bromide with KCN in DMSO did not give the corresponding nitrile but yielded the elimination product (Table 2).[14]

After the substitution reaction, it was found that most of the products were adsorbed onto the hemin site in the resin. The adsorbed products could easily be desorbed with ether or hexane.

The polymer reagent described in this paper is much more effective than the commercial anion-exchange resins, probably because the cyanide ion is adsorbed at the hemin site in **1** with ionic as well as with coordination bond. Taking this point into account, the substitution reaction of cinnamyl bromide with thiocyanate ion was investigated (Table 3). Harrison and Hodge have described this reaction using **2**-supported thiocyanate[5] (Table 3). They reported that the initial product of the reaction between **2**-supported thiocyanate and cinnamyl bromide was cinnamyl thiocyanate, but after prolonged reaction time the product rearranged to isothiocyanate.[5] In our reaction, however the only product obtained by the substitution reaction was cinnamyl thiocyanate under the same reaction conditions as Ref. 5). Therefore, the rearrangement of the initial product was prevented by the coordination of the product on the hemin site.

a) 80 °C, 6 h.

ESR Spectra. From the results described above, it can be assumed that some interaction exist between the product and the hemin residue under the reaction conditions. This interaction could be confirmed by ESR spectrometry (Fig. 2). Figure 2 shows the change of spectral pattern of butyl thiocyanate with **1**. In Fig. 2, (a) and (b) were measured before and after adsorption of the thiocyanate using a 1 : 2 mixture of the thiocyanate and benzene, and these are in accord with those of high- and low-spin Fe(III)-porphyrins, respectively. Spectrum (c) was obtained after desorp-

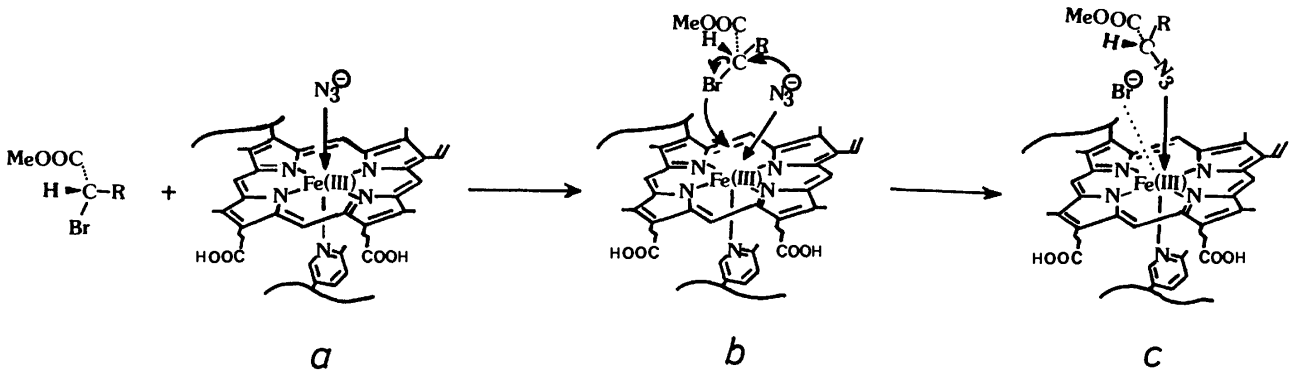
tion of the thiocyanate with hexane, and the pattern agrees with that of high-spin as it was before. The same spectral changes were observed in all of the substitution products. These results indicate that the interaction of the substitution product to the hemin site is coordination bond.

Reaction Mechanism. Taking into account the results mentioned above, it could be contemplated that these reactions proceed in the vicinity of the sixth coordination site of hemin residue in **1**. And the hemin site in the polymer reagent could not only be an ion exchange site, but also an excellent reaction field in the nucleophilic substitution. In order to further investigate this point, we have carried out stereochemical studies under the same conditions in which various optically active α-bromo acid methyl esters were used. The chemical pathway from the preparation of the substrate to the final product is shown in Scheme 1. Table 4 shows the optical purity (O.P.) of the α-bromo acid, the chemical yield (C.Y.) of α-azido acid methyl ester, the enantiomeric excess (e.e.) of the derivatized amino acid, and real retention of configuration in the substitution reaction (e.e./O.P.). As is evident from Table 4, this substitution reaction proceeded almost quantitatively, and the results of the substitution reaction agreed with these of the reaction proceed with S_Ni mechanism, with e.e./O.P. of approximately 100%.[21] In contrast with our results, the yields of the substitution products using azide bound **2**, and NaN_3 in the presence of crown ethers[13] (Table 4) were both low and the configurations of the products were inverted under the same conditions we used.

The interaction between substitution product, α-azido acid methyl ester, and the hemin residue in copolymer **1** was confirmed by ESR spectrometry.



Scheme 2. A possible reaction pathway of the nucleophilic substitution of optically active α-bromo acid methyl ester with N_3^- ion combined with **1** in benzene at 60 °C.

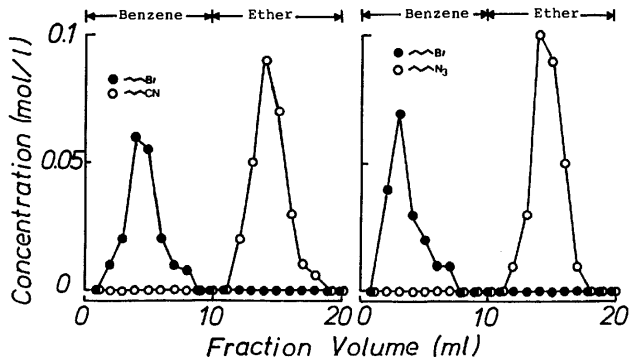


Fig. 3. Column separations of substitution reaction mixtures with **1**.

The same spectral changes were observed as shown in Fig. 2.

The mechanism of nucleophilic substitution reaction in this study could be explained as shown in Scheme 2. The nucleophile is adsorbed onto 6th coodination site of hemin in resin **1** on the basis of the coordination number of CN^-, N_3^-, and SCN^- (n=1)[3] and ESR spectra[3] (Scheme 2, *a*). It can be concluded from the results of ESR spectroscopic analysis (Fig. 2) (Scheme 2, *c*), that most of the reaction products are coordinated to the hemin site after substitution reaction. Taking into consideration the facts that (i) the substituted products were obtained from tertiary alkyl bromide in benzene; (ii) cinnamyl thiocyanate was produced in high yield; (iii) the reactions using optically active substrates proceeded with complete retention of configuration; it could be interpreted that the reaction is a S_Ni type substitution reaction (Scheme 2, *b*).

Column Separation. Copolymer **1** is not only a polymer-supported reagent with functional capability, but also serves to separate the product from the reaction mixture. The products were coordinated to hemin sites in the reaction solvent and could be desorbed easily with hexane or ether. Therefore, the separation characteristics of **1** were further investigated by using the column. The substitution reaction was stopped at 65% yield and the reaction mixture adsorbed in **1** was packed in a column. Figure 4 shows a typical column separation of the substrate (●) and the reaction product (○). When the reaction mixture was packed and eluted through a column with benzene (●), only the substrate(1-bromobutane) was in the eluent. The adsorbed reaction product (valeronitrile or butyl azide) was eluted almost completely with ether (recovery ca. 99 %).

Mass Spectrum and Thermal Behavior in Solid State of *N,N*-Di(1-hydroxyalkyl)-2-imidazolidinone

Choichiro SHIMASAKI,* Kyoko NAKAJIMA, Yuka SUGIMORI, Eiichi TSUKURIMICHI, and Toshiaki YOSHIMURA
Faculty of Engineering, Toyama University, Gofuku, Toyama 930
(Received January 12, 1989)

1,3-Bis(1-hydroxyalkyl)-2-imidazolidinones (**1**) were prepared by the reaction of imidazolidinone with propyl-, butyl-, isobutylaldehyde. They were unstable and moisture-sensitive substances, except for 1,3-bis(1-hydroxybutyl)-2-imidazolidinone (**1c**). In the decomposition by the electron impact of **1** and the dimer of **1c**, the molecular ion peak of **1** was not detected. The fragmentation of the imidazolidinone ring was considered to take place after a successive cleavage of the two side chains of **1**. The pyrolysis reaction of **1** was found to be a thermal decomposition via a molten state after a condensation reaction. The order of the pyrolysis was calculated on the basis of DSC curves. The condensation stage for **1c** apparently obeyed 1/2-order kinetics. From the dependence of the velocity on the temperature in DTA and the thermogravimetric analysis, the activation energy of decomposition was calculated; the value for the former was 67 and the latter 73 kJ mol^{-1}. The mechanism of pyrolysis was supported by the results of the IR spectrum and chemical analysis.

The derivatives of 2-imidazolidinone (**2**) have many advantages over any other substituted ureas. Furthermore, **2** has two active imino groups similar to the amino groups of urea. Compound **2** cannot produce compounds which have an intermolecular ether formation, such as tetrahydro-4*H*-1,3,5-oxadiazin-4-one. If **1** is cured at a certain temperature, the curing process must be similar to those of the main chain formation for the urea resin. The thermal decomposition of 1-hydroxyalkyl-2-imidazolidinone was previously reported by the present authors.[1] In this work, the decomposition study was extended to 1,3-bis(1-hydroxyalkyl)-2-imidazolidinone. The present authors investigated the condensation reaction of **1c** under no alkaline and acid catalyst conditions by IR, ^{1}H and ^{13}C NMR measurements. DSC and DTA are useful tools for measuring the thermally induced conformation transition of macromolecules as well as the polymerization process. An application of DSC and DTA to the study of polymerization provides information for kinetic data, such as the activation parameter.

Experimental

Materials. Compound **2**, ethanol, and methanol were of reagent grade and were used without further purification. The propionaldehyde, butyraldehyde, and isobutyraldehyde were distilled before use.

Preparation of Sample. 1,3-Bis(1-hydroxypropyl)-2-imidazolidinone (**1a**) was prepared according to the reported method for methylolurea.[2] The general procedure was as follows. *N*-(Hydroxymethyl)urea (**2** 21.5g (0.25 mol)) was suspended in 10 ml of ethanol under a nitrogen atmosphere. The ethanol solution was kept at pH 11 with a 8 M-NaOH aqueous solution (1 M=1 mol dm^{-3}) as the catalyst. After being stirred for 15 min, 35 ml of propionaldehyde was added dropwise to this suspension, which was kept under 15 °C by ice. White crude crystals were filtered with suction and dried in a desiccator. Recrystallization from chloroform gave white needle crystals of **1a**. 1,3-Bis(1-hydroxybutyl)-2-imidazolidinone (**1b**), and 1,3-di(1-hydroxy-2-methylpropyl)-2-imidazolidinone (**1c**) were prepared in a manner similar to **1a** by using 45 ml of butyr- or isobutyraldehyde and 10 ml of methanol.

Measurements. Elemental analyses of samples were carried out by using a Hitachi C,H,N-analyzer-026 at the Toyama Medical and Pharmacy University. IR spectra of samples were recorded on a Nipponbunko IR-810 using the KBr-disc method. The ^{1}H and ^{13}C NMR spectra of each solution was taken on a JNM-FX-90-FT-NMR instrument. A TMS was used as a reference. **1c** was dissolved in a deuterated dimethyl sulfoxide solution, and **1a**, **1b**, and **2** in a deuterated chloroform solution. A mass spectrum of each sample was taken with an ionization potential of 20 eV using a JEOL-JMS-D300 by EI method. Samples were heated in air using α-Al_2O_3 as reference by a Rigakudenki TG-DSC apparatus and Rigakudenki CN8078B2 (High Temperature Type) TG-DTA apparatus. DSC measurements were performed without using a reference by a Dupont 1090 DSC instrument.

Results and Discussion

Synthesis of 1. The physical properties of **1** are summarized in Table 1; the results from elemental analyses give the same values as those calculated. Most characteristic absorption in the IR spectra of **1** were identical. Only the absorption of **1** due to ν_{OH} (chelation) at about 3200 cm^{-1} was different among the three substrates. This absorption peak appears in the spectra of **1a**, **1b**, but not in **1c**. This result shows that only **1a** and **1b** have intramolecular hydrogen bonds. Figure 1 shows the possible schema A and B for the hydrogen bonding. From the fact that **1a** and **1b** decompose at lower temperatures than **1c**, it is suggested that *N*-(1-hydroxyalkyl)-2-imidazolidinone was formed by an elimination of aldehyde, provided that **1** has a structure of B. The absorption in the area 1680 cm^{-1} is sharp and shown in a single peak due to $\nu_{C=O}$. The absorption intensity of $\nu_{C=O}$ increases with increasing length of the side chain in **1**. In the mass spectra of **1**, the parent peak is not detected, but the peak of

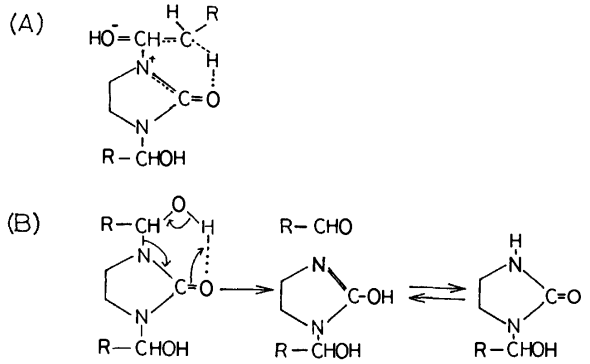

Fig. 1. Structure of A and B for **1**.

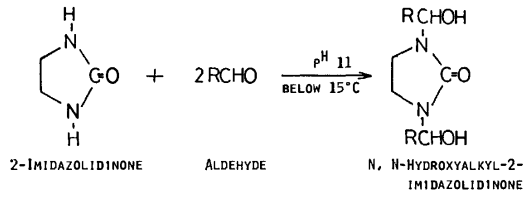

Scheme 1.

$(M-2H_2O)^+$ is detected as a base peak. The analytical and spectroscopic data in Table 1 indicate that the structure of **1** is the same as that proposed in Scheme 1.

The Fragmentation Mechanism for 1. The main cleavage mechanism for **1a** and **1b** is shown in Figs. 2 and 3, respectively. The molecular ion peak for both samples could not be detected. A very characteristic peak in both samples is the $(M-2H_2O)^+$ peak, which is the base peak. The elimination of the methyl group arises from one substituent group which is

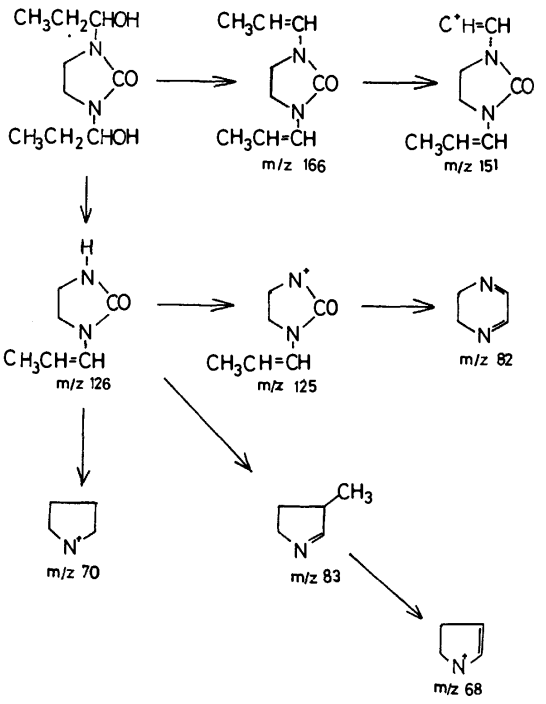

Fig. 2. The main cleavage mechanism for **1a**.

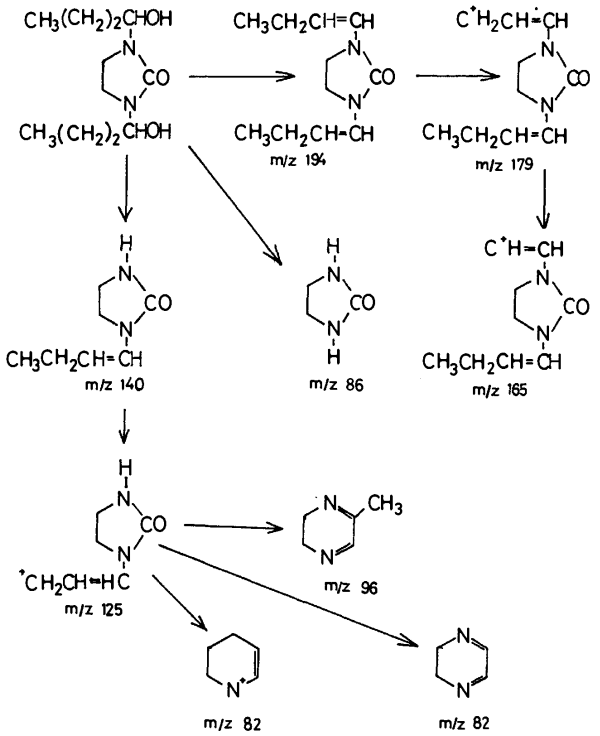

Fig. 3. The main cleavage mechanism for **1b**.

present in the base peak. The peaks at m/z 151 and 179 for **1a** and **1b** are the results of the ions from those base peaks. Although small in size, the peaks at m/z 126 and 140 for **1a** and **1b**, respectively, are due to a fragment ion resulting from the loss of aldehyde and water from the two substituent groups. The peak at m/z 125 appeared in both samples. In **1a**, this peak is due to the fragment ion resulting from the loss of the 1-hydroxypropyl group and water from the two substituent groups. In **1b**, this peak is due to the fragment ion resulting from the loss of propionaldehyde, water, and ethyl group from the two substituent groups. The peak due to the formyl group (m/z 58 or 72) and that due to the hydroxyl group (m/z 59) have been detected. From the fragment ion peaks at m/z 126 and 125, the functional group such as a carbonyl group, cyanic acid, and methyl group seems to be eliminated easily. In addition, the peak due to the elimination of two formyl groups (m/z 86) for both samples is also detected.

Figure 4 shows the detailed cleavage mechanism from the starting fragment ion at m/z 125 of **1b**. There are three cleavage patterns: I, II, and III. Considering the high resolution for the identification of the atomic content of the ions, it was concluded that fragmentation in I and II occurred through the loss of the carbonyl group, while III followed from the loss of HNCO (cyanic acid); the former fragmentation ion is

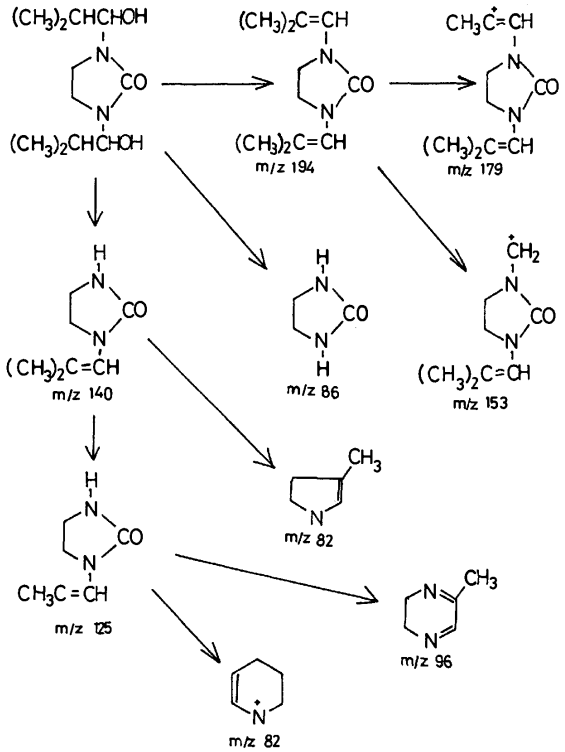

Fig. 5. The main cleavage mechanism for **1c**.

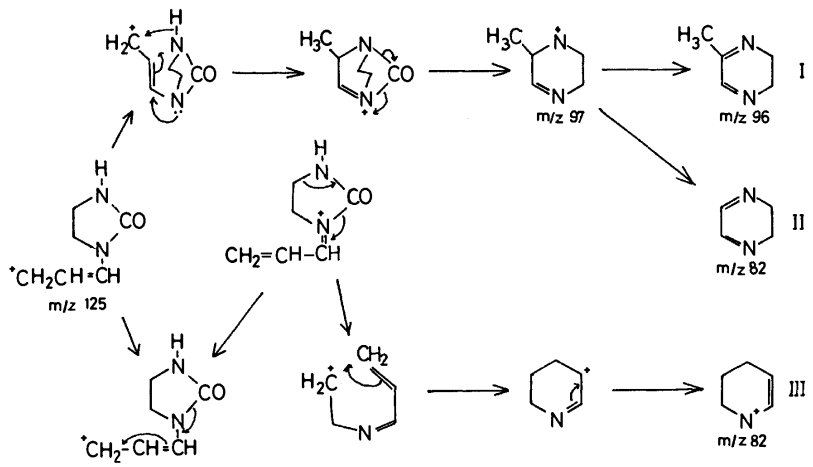

Fig. 4. The detailed cleavage mechanism for **1b**.

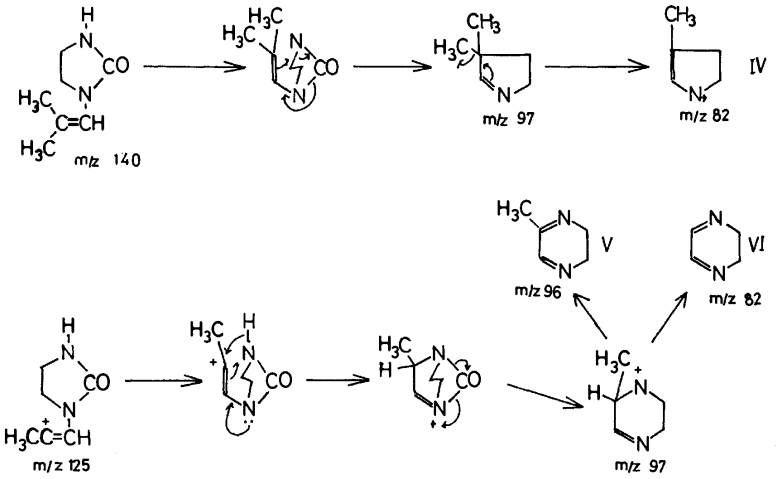

Fig. 6. The detailed cleavage mechanism for **1c**.

due to $C_5H_9N_2$ at m/z 97, the latter is C_5H_8N at m/z 82. The difference of cleavage patterns in I and II was confirmed by evidence from the high-resolution mass spectrum at m/z 96 and 82, which corresponds to fragment ions $C_5H_8N_2$ and $C_4H_6N_2$, respectively. These fragment ions are formed by the loss of proton and methyl groups from the ion at m/z 97.

The main cleavage mechanism for **1c** is shown in Fig. 5. The fragment ion detecting in **1c** is similar to that obtained for **1b**. Figure 6 shows the detailed cleavage mechanism from the starting fragment ions at m/z 140 and 125. Also, there are three cleavage patterns, such as IV, V, and VI. The IV cleavage pattern is confirmed from the fact that the fragment ions, $C_6H_{11}N$ (m/z 97) and HCNO (m/z 43) were detected, and, furthermore, the ion resulting from the loss of methyl group in the former fragment ion at m/z 97 was identified. The V and VI cleavage patterns are similar to I and II in Fig. 4, respectively.

Thermal Analysis. Figure 7 shows TG-DSC curves for **1**. These DSC curves exhibited an endothermic and an exothermic peak. The endothermic peak is attributed to both molten and condensation for **1**. However, the exothermic peaks for **1** are not always clear over a wide temperature range. The TG curve shows that the pyrolysis process for **1** takes place in two stages. In Fig. 7, the first plateau of the TG curve is probably due to a condensation of **1** to a dimer compound. The other plateau corresponds to a thermal degradation and a decomposition reaction. The TG-DSC measurement for **1c** was carried out at five heating rates from 0.625 to 20 °C min^{-1}. Figure 8 shows the DSC curves of **1c**. As shown in Fig. 8, both, the primary and secondary peak of the DSC curves shifted to higher temperature as the heating rate increased. At a heating rate of less than 10 °C min^{-1}, a new sharp peak appears in the area of 130 °C between the primary and secondary peak. **1c** melts rapidly at 132 °C. According to this fact, this sharp peak may be due to a molten stage. However, the

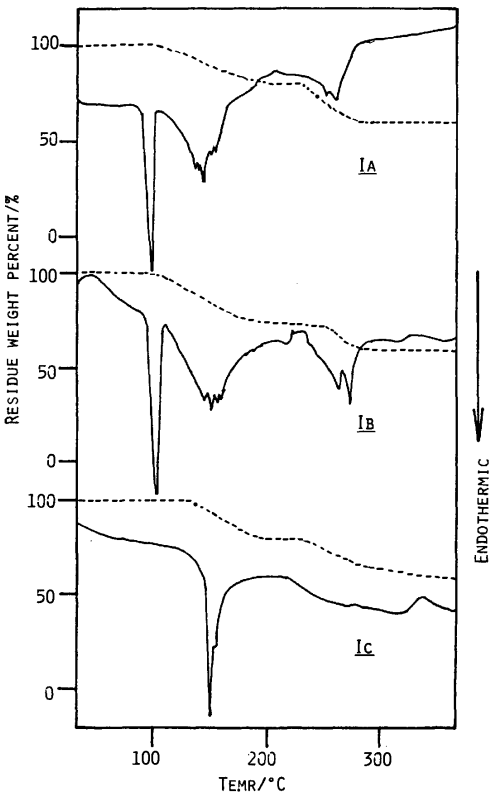

Fig. 7. TG-DSC curves for **1**.

fraction of the residual weight around 130 °C has a value approximated to that of the (molecular weight of **2**)/(molecular weight of **1c**) ratios. Since the melting point of **2** is 131 °C, this molten stage may not be due to the melting point for the eutectic mixture, but for **2**. Furthermore, TG-DTA measurement for **1c** was carried out at the heating rate from 2 to 10 °C min^{-1}. Both the primary and secondary peaks of the DTA curves shifted to higher temperatures with an increase in the heating rate, similarly to the DSC curves.

Kinetic Discussion for 1c. The kinetic discussion

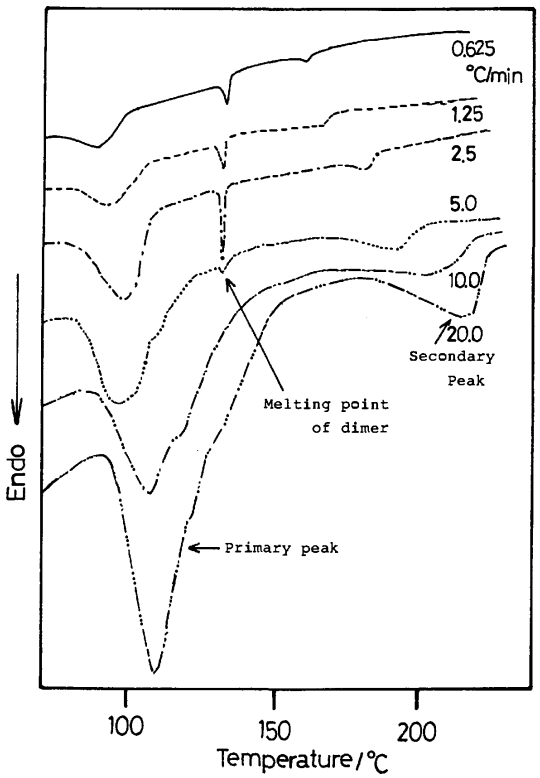

Fig. 8. DSC curves for **1c** at various heating rates.

is carried out in terms of the thermal analysis. Two methods for obtaining kinetic parameters from TG-DTA curves were applied. These methods are based on the general form of kinetic formulae and are applicable to general types of relation governed by a single activation energy. One method by Ozawa[3] utilizes the linear relation between the reciprocal of the absolute temperature and a definite fraction of the weight loss and the heating rate in TG curves in order to estimate the activation energy. The other method by Kissinger[4] requires information concerning both the temperature of the maximum peak and the heating rate in DTA curves; the Kissinger's plot is made for an apparent activation energy. According to Ozawa's method in thermal analysis, we carried out observations of the change in TG curves by different heating rates (ϕ). In each definite fraction of weight loss (θ), this method utilizes a linear relation between the reciprocal of the absolute temperature and the ordinal logarithm of the heating rate. The structural quantity is assumed to change the following ordinary reaction kinetics:

$$\theta = \Delta E/\phi R \cdot \rho(\Delta E/RT), \tag{1}$$

where ΔE and R are the activation energy and the gas constant, respectively. Also,

$$\log \rho(y) \simeq -2.315 - 0.4567y \quad (20<y<60). \tag{2}$$

Thus,

$$\log\phi_1 + 0.4567\Delta E/RT_1 = \log\phi_2 + 0.4567\Delta E/RT_2 = \cdots\cdots . \tag{3}$$

When an ordinary logarithm for a heating rate in Eq. 1 as the abscissa and the reciprocal of the absolute temperature as the ordinate is plotted, we obtained a straight line. From the gradient of this straight line, corresponding to $-0.4567\Delta E/R$, the activation energy was obtained.

It is evident, therefore, that the variation of the peak maximum for DTA curve can be expressed by means of an equation of the form

$$-\Delta E/R = \Delta \log(\phi/T_m^2)/\Delta(1/T_m), \tag{4}$$

where ϕ stands for the heating rate; ΔE, for the activation energy; T_m, for the temperature of the DTA-maximum; and R, for the gas constant. This method utilizes the linear relation between the $\Delta(1/T_m)$ and

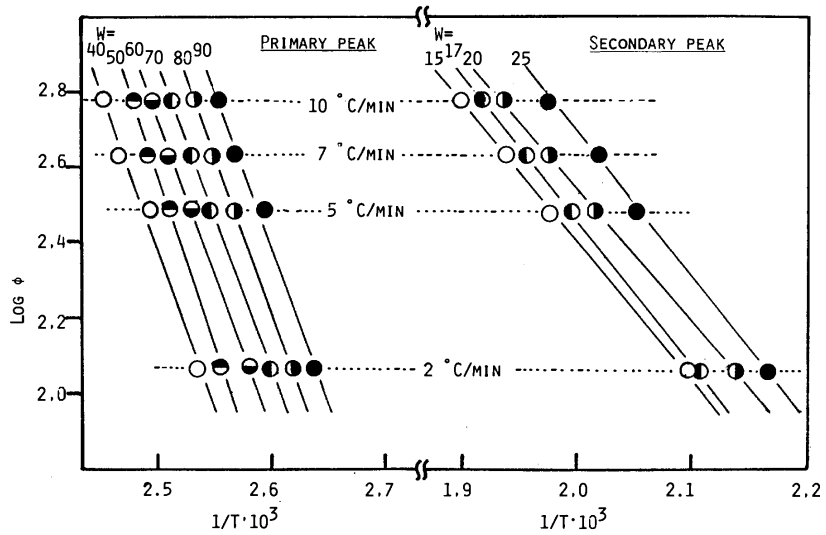

Fig. 9. Plots of logarithms of heating rate versus the reciprocal of absolute temperature for given conversation of pyrolysis of **1c**.

$\Delta\log(\phi/T_m^2)$. For these TG and DTA curves, Ozawa's or Kissinger's plots of **1c** were linear. Figures 9 and 10 show the results of these plots. Table 2 shows the values of the activation energy which was calculated from these plots.

Next, a kinetic study was carried out in terms of McGhie method.[5] DSC measurements were carried out over the temperature range 105—120 °C by a method in which the sample was hermetically sealed in an aluminum pan and in a DSC cell using an isothermal mode. Figure 11 shows typical isothermal condensation curves for **1c**. This kinetic study of the pyrolysis process of **1c** was carried out for the shaded parts with the same heat quantity. The 1/2-order kinetics plot of $2\times[a^{1/2}-(a-x)^{1/2}]$ vs. $t-t_0$ for each curve is linear, where a is the area under a given isothermal curve, and x is the fractional area up to time t. Figure 12 shows these plots for isothermal reactions of four samples at 106, 111, 116, 122 °C. The data have been normalized with respect to time by plotting the time after an induction period of t_0. Thus, each isothermal curve yielded two important quantities, t_0 and k. The kinetic data for the condensation of **1c** are summarized in Table 3.

Thermal Condensation of 1c. The thermal condensation of **1c** was considered from the results of IR spectra, ^{1}H and ^{13}C NMR spectra, mass spectra, and elemental analysis. **1c** was heated for various times under isothermal, or at various temperatures, under a nitrogen atmosphere in a thermostat. The IR spectra of the condensation product for **1c** show that the absorption due to ν_{C-O} at about 1100 cm^{-1} decreases in intensity. When the heating time was changed, the

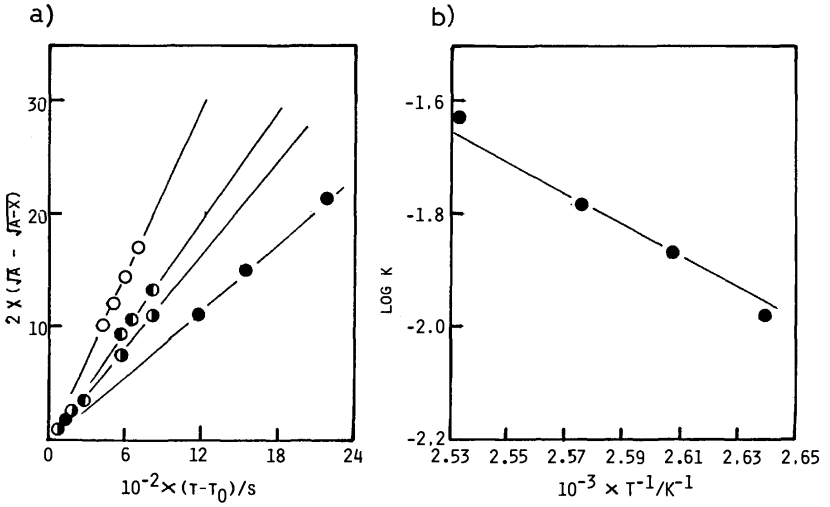

Fig. 12. a) 1/2 order kinetic plots of $2\times[a^{1/2}-(a-x)^{1/2}]$ vs. $t-t_0$ for the isothermal polycondensation of **1c**. b) Arrehenius plots of the 1/2 order kinetic constant for the polycondensation of **1c**.

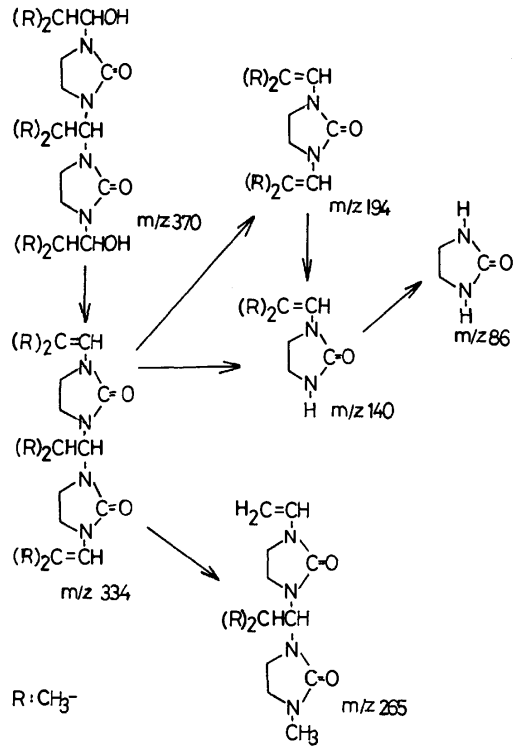

Fig. 13. Main fragmentation for dimer of **1c**.

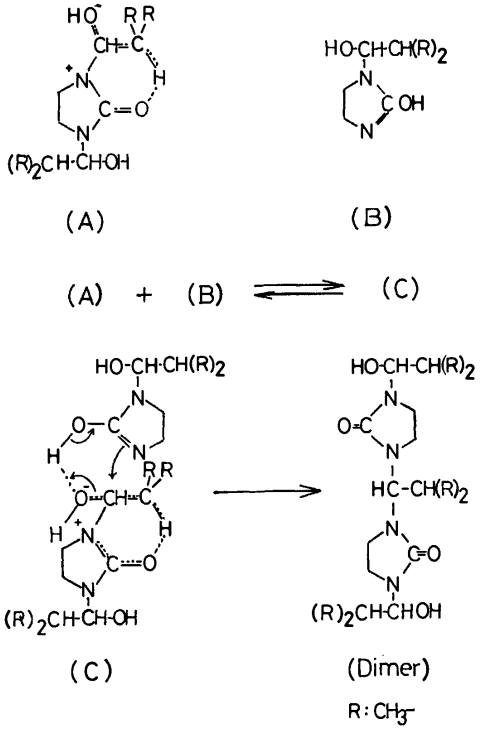

Fig. 14. The dimerization process for **1c**.

absorption peak due to $\nu_{C=O}$ at about 1680 cm^{-1} shifted to larger wavenumber with increasing time. The peak due to $\nu_{C=O}$ shifted at 1700 cm^{-1} after heating it for 5 h. The absorption peak due to ν_{OH} decreased in intensity with increasing heating time. On the other hand, when the temperature was changed, the heating product at 110 °C showed similar changes after 5 h. Also, the absorption peak due to ν_{NH} in the neighborhood of 3400 cm^{-1} appears at 145 °C. From these results it seems that both dehydration and condensation occur simultaneously for the thermal reaction of **1c**. The ^{13}C NMR spectra of **1c** shows that the signal at δ 159.923, due to the carbonyl group, separates into two signals, and that the signal due to the α-carbon atom attached to the hydroxyl group splits into three parts after condensation. These results show that the formation process of the dimer seemed to be dehydration after intermolecular hydrogen bonding. In the ^1H NMR spectra of **1c** and its condensation product, it was observed that the signal due to the hydroxyl group disappeared after condensation. The mass spectra of the condensation products also support this dimer

formation. There are no peaks due to trimer or oligomer in these mass spectra. The observed fragment ions in the mass spectra of the condensation products support the main fragmentation mechanism of the dimer in the case of **1c**. In the mass spectra after heating for 5 h, a peak at m/z 334 was detected. This peak is due to the fragmentation ion peak which is formed by the loss of two moles of water from molecular ion (M^+). The peak due to a molecular ion which is a dimer of **1c** was not detected. The maximum mass number ion peak obtained for these mass spectra, was the peak at m/z 265. The obtained fragment ion peak was cleared by considering the high-resolution mass spectra for an identification of the atomic content of the ions. Figure 13 shows the main cleavage mechanism of the dimer in the case of **1c**.

Reaction Mechanism for Thermal Condensation of 1c in Solid State. The possible structure of intermediates formed during the activated state in the course of the dimerization process for **1c** is the activated complex (A) and the enol type (B), like lactim in Fig. 14. The presence of (A) was confirmed by ESR measurements[1] in the case of 1-mono(1-hydroxyalkyl)-2-imidazolidinone; (B) gave no direct evidence concerning its existence in the solid state. In the molten state, however, the (B) had likewise been formed in the case of cyanuric acid. By a comparison of structures (A) and (B), the hydroxyl group of (A) was easier to eliminate than that of (B). In the next step, the activated complex (C) (Fig. 14) was formed from (A) and (B). It is expected for **1c** that the DSC measurement was taken in order to obtain information regarding the formation of (C) to the dimer. From these results, it is clear that (A), (B), and (C) are formed during the induction period.

We wish to thank Miss Misao Shinoda for the Mass spectra and Mr. Yoshiharu Yoneyama for NMR measurements. We thank Prof. Shigeya Takeuchi for good advice regarding DSC measurements.

Copper(I) Salt Catalyzed Reaction of 1,1,1-Trichloro-2,2,2-trifluoroethane with Trimethylsilyl Enol Ethers. A Convenient Synthesis of β-Chloro-β-(trifluoromethyl) α,β-Unsaturated Carbonyl Compounds

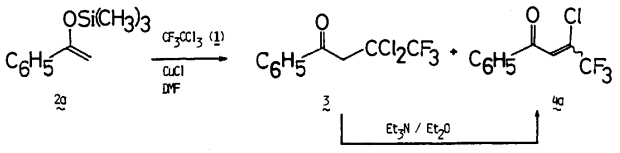
Takashi Okano, Toru Uekawa, and Shoji Eguchi*
Institute of Applied Organic Chemistry, Faculty of Engineering,
Nagoya University, Chikusa-ku, Nagoya 464-01
(Received January 23, 1989)

β-Chloro-β-(trifluoromethyl) α,β-unsaturated carbonyl compounds were obtained by the reaction of trimethylsilyl enol ethers with CF_3CCl_3 and CuCl, followed by dehydrochlorination with triethylamine or DBN. Aromatic enol ethers gave moderate to good yields of the chloro(trifluoromethyl)methylene ketone derivatives but aliphatic enol ethers and silyl ketene acetal gave only lower yields.

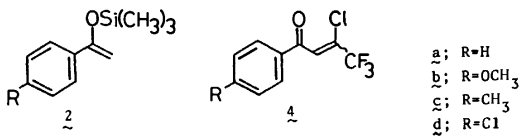
Synthetic methods for the preparation of trifluoromethyl-substituted organic compounds have drawn considerable interest recently because of their remarkable biological activity.[1] As one of versatile and economical reagents, 1,1,1-trichloro-2,2,2-trifluoroethane (**1**) has been utilized extensively to effect polyhaloalkylmetal addition to carbonyl compounds.[2,3] On the other hand, the addition of polyhalocarbons to carbon-carbon double bonds is known to be catalyzed effectively by copper chloride-2-aminoethanol redox system.[4] The successful addition of polyhalocarbons to trimethylsilyl enol ethers catalyzed by copper(I) chloride to afford β-halo α,β-unsaturated ketones has been reported also by Murai et al.[5] In spite of these pioneering works, the scope and limit of the Cu(I) catalyzed addition reaction of polyfluorinated **1** with silyl enol ethers seem to be yet unclarified. We report here the Cu(I) catalyzed addition reaction of **1** with various types of trimethylsilyl enol ethers, that provides a convenient regiospecific route to β-chloro-β-(trifluoromethyl) α,β-unsaturated ketones.[6] These compounds seem to be difficult to prepare regiospecifically by enol chlorination route of 1-trifluoromethyl-1,3-diketones. The reaction of 1-trifluoromethyl-3-aryl- or -3-alkyl-1,3-diketones with thionyl chloride has been reported to afford a regioisomeric mixture of the corresponding enol chlorides or only undesired α-chloromethylene ketone derivatives.[7]

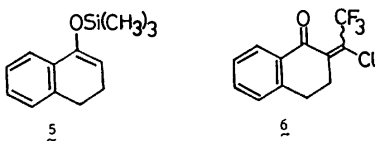
Results and Discussion

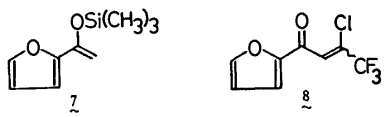
Since dichloromethylenation of acetophenone trimethylsilyl enol ether (**2a**) with CCl_4 in the presence of CuCl was reported by Murai et al.,[5] we examined first the reaction of **2a** with two equivalent of CF_3CCl_3 (**1**). In the presence of a catalytic amount of CuCl (0.1 equivalent), the reaction in DMF (*N*,*N*-dimethylformamide) at 80 °C afforded a mixture of saturated ketone **3** and dehydrochlorinated ketone **4a** (*E* : *Z* ratio was 10 : 90). Since **3** and **4a** were not readily separable, the mixture was treated with triethylamine at room temperature to complete the dehydrochlorination, affording **4a** in 23% yield. The *E* : *Z* ratio of **4a** was 10 : 90 as determined ^{19}F NMR data. A strong anisotropic effect for the carbonyl bond to CF_3 group was observed for *E*-isomer **4a**-*E* (δ 13.56 for **4a**-*E* and 8.65 for **4a**-*Z*, CF_3COOH as an external standard).[8,9]

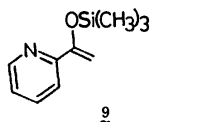


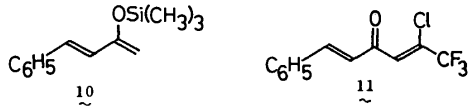
Scheme 1.

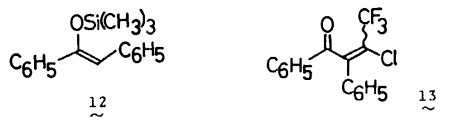


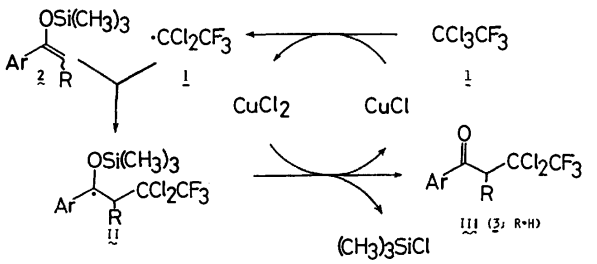












Scheme 2.

As outlined in Scheme 2, the reaction mechanism may involve one-electron transfer from CuCl to CF_3CCl_3 to afford a radical intermediate, $CF_3CCl_2\cdot$ (**I**). Following the addition of the β-position of the electron-rich silyl enol ether **2** to form benzyl radical **II**, oxidative desilylation with Cu(II) cation yields saturated ketone **3**. A partial dehydrochlorination of the primary product **3** under the reaction conditions gives unsaturated ketone **4**.

The use of large excess of **1** (20-fold equivalent) as well as equimolar CuCl along with addition of 4A Molecular Sieves to trap liberated HCl[10] raised the yield upon dehydrochlorination with triethylamine to 52%. DMF has been predicted as the most favorable solvent for electron transfer reactions,[11] in fact, no other solvent such as acetonitrile, dioxane, ethanol, nor pyridine gave better results.

Under the reaction conditions mentioned above, various silyl enol ethers were converted into unsaturated ketones with a β-trifluoromethyl group (Table 1).[12]

Table 1. β-Chloro-β-(trifluoromethyl) α,β-Unsaturated Carbonyl Compounds from Trimethylsilyl Enol Ethers and CF_3CCl_3

Entry	Silyl enol ether	Product	Reaction time/h	Yield (%)[a]	*Z*:*E*

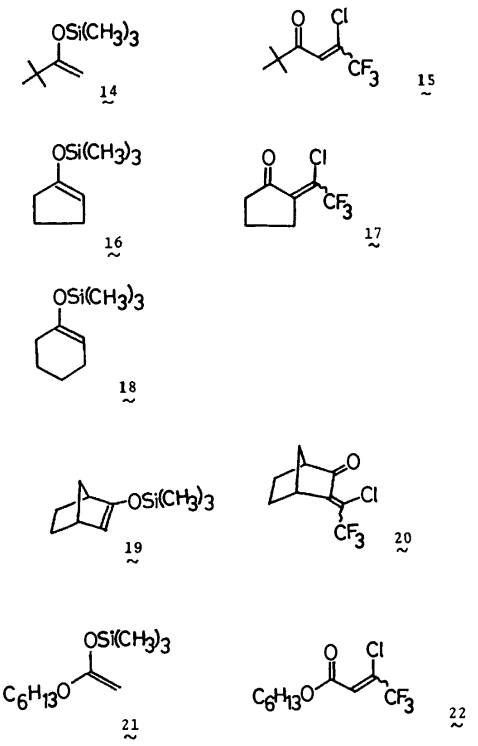
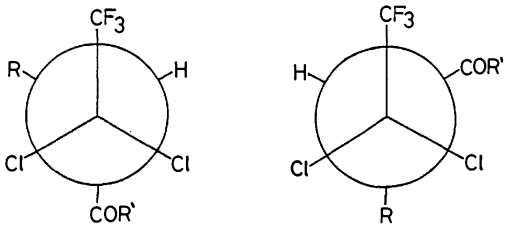
11	**16**	**17**	5	21(39)[d]	88:12
12	**18**	—	36	0[e]	—
13	**19**	**20**	7.5	32[c]	58:42
14	**21**	**22**	3	15	79:21

a) Isolated yield. b) A complex mixture was obtained. c) 1,5-Diazabicyclo[4. 3. 0]non-5-ene was used in dehydrochlorination. d) GLC yield determined by addition of adamantane as an internal standard; see Experimental. e) Cyclohexanone was a major product.



Aromatic ketone derivatives **4b—d** and **6** were obtained in moderate yields from the corresponding silyl enol ethers **2b—d** and **5**. Among heterocyclic enol ethers **7** and **9**, **7** gave furyl ketone **8** in 70 % yield, but pyridyl enol ether **9** afforded only a complex mixture due to the side reactions between CuCl and the pyridine moiety. Even in the case of conjugated silyl enol ether **10** which can generate a stable allyl radical intermediate, dienone **11** was obtained in 59% yield. Since $CF_3CCl_2\cdot$ radical is a bulky intermediate, sterically hindered substrates such as the diphenyl derivative **12** are unfortunately less reactive, affording the corresponding enones only in lower yields.

In contrast to aromatic enol ethers, alkyl or alicyclic enol ethers **18** and **21**, except sterically favorable methylene derivative **14** or strained cyclic enol ethers **16** and **19**, were not suitable substrates for this reaction because of the relative instability of the radical intermediates involved. Pinacolone silyl enol ether (**14**) gave *t*-butyl ketone **15** in 15% yield based on GLC. Silyloxycyclopentene (**16**) and silyloxynorbornene (**19**) gave α-[chloro(trifluoromethyl)methylene] ketones **17**



IV V

and **20** in lower yields. However, less strained silyloxycyclohexene (**18**) was unreactive under the reaction conditions except by slow hydrolysis to form cyclohexanone.[13] It is notable that benzo-fused derivative **5** is a suitable substrate in which a cyclohexadiene subunit is involved. Ketene silyl acetal **21** also gave unsaturated ester **22** in a low yield.

In the elimination step, triethylamine was effective in the most cases, but the more basic 1,5-diazabicyclo-[4.3.0]non-5-ene (DBN) was needed to obtain sterically hindered ketones **13** and **20**. The stereoselectivity of the elimination depends on the structure of the saturated intermediate **III** (Scheme 2). The *E*:*Z* isomer ratio was not changed before and after the triethylacetyl compounds, **2a—d**, **7**, **10**, **14**, and **21**, and cyclopentene **16** and **19** gave *Z*-isomers as major products via anti-elimination of HCl from the more stable via anti-elimination of HCl from the more stable conformers **IV** (R=H- or $-CH_2-$) where R'CO- group and CF_3- group are antiperiplanar. However, **5** and **12** gave *E*-isomers as major products. The increased repulsion between α-R group (R=$-CH_2-$ or Ph-) and CF_3 group destabilizes **IV** relative to conformer **V** affording *E*-isomers via anti-dehydrochlorination.[14]

In conclusion, CF_3CCl_3 (**1**) was found to be a convenient trifluoromethyl-containing synthon for methylenation of various silyl enol ethers, with some limitations in the applicable substrates. The resulting chlorinated unsaturated carbonyl compounds have synthetic potential for other transformations to trifluoromethyl-containing organic compounds.[15]

Experimental

All the melting points were taken on a Yanagimoto micromelting point hot stage apparatus and are uncorrected. ^1H NMR spectra were recorded on a JEOL JNM-FX-60 FT NMR spectrometer at 60 MHz and on A JEOL JNM-GX-500 FT NMR spectrometer at 500 MHz in $CDCl_3$. ^{19}F NMR spectra were recorded on a Hitachi R-20 instrument at 56.45 MHz in $CDCl_3$. Chemical shifts were reported in parts per million (δ) relative to Me_4Si as an internal standard for ^1H and to CF_3COOH as an external standard for ^{19}F. IR spectra were obtained on a JASCO IRA-1 spectrometer. Mass spectra (MS) were obtained on a ESCO EMD-05B mass spectrometer at 70 eV. Microanalyses were performed with a Perkin-Elmer 240B elemental analyzer. GLC analyses were carried out by using a Shimadzu GC-14A gas chromatograph on a 2 m packed column with OV-17 as stationary phase. Silyl enol ethers were prepared by ordinary methods; trimethylsilylation of lithium enolate prepared from a ketone or an ester with LDA, or by the reactions of ketones with chlorotrimethylsilane and triethylamine in DMF.

Preparation of β-Chloro-β-(trifluoromethyl) α,β-Unsaturated Ketones. A Typical Method: 3-Chloro-4,4,4-trifluoro-1-phenyl-2-buten-1-one (4a): A mixture of **2a** (192 mg, 1.00 mmol), **1** (3.82 g, 20.0 mmol), CuCl (49 mg, 1.0 mmol), and 4A Molecular Sieves (1.00 g) in anhydrous DMF (2 ml) was refluxed under nitrogen atmosphere for 3 h, and then Molecular Sieves were removed by filtration. To the filtrate was added Et_2O (50 ml) and saturated aqueous NaCl (50 ml). After separation of organic layer, the aqueous layer was extracted with Et_2O. The extracts were combined and dried (Na_2SO_4). After removal of the solvent by distillation, the residue was purified on a short silica gel (Fuji-Davison BW-300) column (1:1 hexane-CH_2Cl_2). The resultant mixture of **3** and **4a** (153 mg) was dissolved in Et_2O (2 ml) and triethylamine (110 mg, 1.00 mmol) was added. The mixture was stirred at room temperature overnight. The solvent was evaporated and the residue was chromatographed on a silica gel column (1:1 hexane-CH_2Cl_2) to give **4a** as pale yellow oil; 120 mg (52%); ^1H NMR ($CDCl_3$) δ=8.0—7.3 (m, 5H) and 7.44 (m, 1H); ^{19}F NMR ($CDCl_3$) δ=13.56 (s, 0.10F) and 8.65 (s, 0.90F); IR(neat) 3060, 1680, 1624, 1602, 1580, 1450, 1276, 1224, 1190, and 1150 cm^{-1}; MS *m/z* (rel intensity) 236(M^++2, 5), 234(M^+, 16), 206(8), 105(100), 77(94), 51(68), and 50(20). Found: C, 51.30; H, 2.48%. Calcd for $C_{10}H_6ClF_3O$: C, 51.20; H, 2.58%.

3-Chloro-4,4,4-trifluoro-1-(4-methoxyphenyl)-2-buten-1-one (4b). As described above, a mixture of **2b** (455 mg, 2.05 mmol), **1** (7.67 g, 40.9 mmol), CuCl (203 mg, 2.05 mmol), 4A Molecular Sieves (2.0 g) in DMF (3 ml) was treated and workup gave **4b** as pale yellow oil; 232 mg (44%); ^1H NMR($CDCl_3$) δ=7.91 (d, 2H, *J*=9.0 Hz), 7.39 (m, 1H), 6.98 (d, 2H, *J*=9.0 Hz), and 3.90 (s,3H); ^{19}F NMR($CDCl_3$) δ=13.70 (s, 0.08F) and 8.88 (s, 0.92F); IR(neat) 3045, 3020, 2970, 2945, 2840, 1678, 1600, 1576, 1514, 1460, 1444, 1422, 1260, 1236, 1184, 1168, and 1150 cm^{-1}; MS *m/z* 266(M^++2, 9), 264(M^+, 27), 236(19), 135(100), 107(19), 92(31), 77(40), 64(25), 63(31), 51(11), and 50(20). Found: C, 50.01; H, 2.96%. Calcd for $C_{11}H_8ClF_3O_2$: C, 49.92; H, 3.05%.

3-Chloro-4,4,4-trifluoro-1-(4-methylphenyl)-2-buten-1-one (4c). As described above, a mixture of **2c** (491 mg, 2.38 mmol), **1** (8.92 g, 47.6 mmol), CuCl (236 mg, 2.38 mmol), and 4A Molecular Sieves (2.38 g) in DMF (2 ml) was treated and workup gave **4c** as pale yellow oil; 237 mg (49%); ^1H NMR($CDCl_3$) δ=7.83 (d, 2H, *J*=8.2 Hz), 7.41 (m, 1H), 7.31 (d, 2H, *J*=8.2 Hz), and 2.44 (s, 3H); ^{19}F NMR($CDCl_3$) δ=14.30 (s, 0.07F) and 8.94 (s, 0.93F); IR(neat) 3050, 1678, 1602, 1576, 1408, 1280, 1270, 1230, 1180, and 1150 cm^{-1}; MS *m/z* 250(M^++2, 7), 248(M^+, 21), 220(10), 119(100), 91(64), 89 (12), 65(39), 63(21), 51(17), and 50(12). Found: C, 53.07; H, 3.26%. Calcd for $C_{11}H_8ClF_3O$: C, 53.14; H, 3.24%.

3-Chloro-4,4,4-trifluoro-1-(4-chlorophenyl)-2-buten-1-one (4d). As described above, a mixture of **2d** (548 mg, 2.41 mmol), **1** (9.02 g, 48.1 mmol), CuCl (238 mg, 2.40 mmol), and 4A Molecular Sieves (2.40 g) in DMF (3 ml) was treated and workup gave **4d** as pale yellow oil; 353 mg (55%); ^1H NMR($CDCl_3$) δ=7.88 (d, 2H, *J*=9.0 Hz), 7.53 (d, 2H, *J*=9.0 Hz), and 7.41 (m, 1H); ^{19}F NMR($CDCl_3$) δ=13.78 (s, 0.07F) and 8.94 (s, 0.93F); IR(neat) 3110, 3080, 1682, 1624, 1596, 1576, 1494, 1402, 1280, 1224, 1190, and 1156 cm^{-1}; MS *m/z* 272(M^++4, 3), 270(M^++2, 20), 268(M^+, 27), 242(12), 240 (19), 157(14), 141(30), 139(100), 113(13), 111(54), 86(35), 84(52), 76(17), 75(70), 74(17), 51(26), and 50(52). Found: C, 44.75; H, 1.76%. Calcd for $C_{10}H_5ClF_3O$: C, 44.64; H, 1.87%.

3,4-Dihydro-2-(1-chloro-2,2,2-trifluoroethylidene)-1(2*H*)-naphthalenone (6). As described above, a mixture of **5** (531 mg, 2.43 mmol), **1** (9.11 g, 48.6 mmol), CuCl (241 mg, 2.43 mmol), and 4A Molecular Sieves (2.40 g) in DMF (3 ml) was treated and workup gave **6** as pale yellow oil; 309 mg (49 %); ^1H NMR (500 MHz)($CDCl_3$) δ=8.096 (dd, 0.70H, *J*=7.9 and

1.2 Hz), 8.036 (dd, 0.30H, J=7.5 and 1.2 Hz), 7.533 (td, 1H, J=7.5 and 1.2 Hz), 7.377 (t, 1H, J=7.5 Hz), and 7.269 (d, J=7.5 Hz); ^{19}F NMR($CDCl_3$) δ=19.09 (s, 0.30F) and 17.83 (s, 0.70F); IR(neat) 3070, 3030, 2980, 2910, 1684, 1600, 1480, 1454, 1432, 1370, 1300, 1268, 1240, 1222, 1206, 1180, 1162, and 1132 cm^{-1}; MS m/z 262(M^++2, 17), 260(M^+, 53), 234(21), 232 (60), 225(20), 197(42), 187(54), 146(16), 128(52), 127(17), 118(37), 91(19), 90(100), 99(78), 88(12), 78(12), 77(32), 76(20), 75(28), 74(15), 73(25), 65(12), 64(37), 63(81), 62(28), 57(12), 51(89), and 50(58). Found: C, 55.24; H, 3.13%. Calcd for $C_{12}H_8ClF_3O$: C, 55.30; H, 3.09%.

3-Chloro-4,4,4-trifluoro-1-(2-furyl)-2-buten-1-one (8). As described above, a mixture of **7** (557 mg, 3.06 mmol), **1** (11.45 g, 61.1 mmol), CuCl (303 mg, 3.06 mmol), and 4A Molecular Sieves (3.01 g) in DMF (2 ml) was treated and workup gave **8** as a pale yellow solid; 447 mg (70%); mp 54—56 °C; ^{1}H NMR($CDCl_3$) δ=7.66 (m, 1H), 7.51 (s, 1H), 7.32 (d, 1H, J=3.7Hz), and 6.61 (dd, 1H, J=3.7 and 1.5 Hz); ^{19}F NMR($CDCl_3$) δ=12.58 (s, 0.03F) and 7.25 (s, 0.97F); IR(KBr) 3280, 3140, 3070, 1672, 1626, 1562, 1466, 1395, 1342, 1290, 1275, 1244, 1206, 1164, and 1150 cm^{-1}; MS m/z 226(M^++2, 10), 224(M^+, 27), 198(10), 196(30), 157(11), 95(100), and 69(25). Found: C, 42.76; H, 1.83%. Calcd for $C_8H_4ClF_3O_2$: C, 42.79; H, 1.80%.

(1*E*,4*Z*)-5-Chloro-6,6,6-trifluoro-1-phenyl-1,4-hexadien-3-one (11). As described above, a mixture of **10** (446 mg, 2.04 mmol), **1** (3.75 g, 20.0 mmol), CuCl (198 mg, 2.00 mmol), and 4A Molecular Sieves (2.00 g) in DMF (3 ml) was treated and workup gave **11** as a pale yellow solid; 314 mg (59%); Mp<30 °C; ^{1}H NMR($CDCl_3$) δ=7.65 (d, 1H, J=16.4 Hz), 7.3—7.9 (m, 5H), 7.17 (m, 1H), and 6.88 (d, 1H, J=16.4Hz); ^{19}F NMR($CDCl_3$) δ=8.79(s); IR(KBr) 3070, 3060, 1660, 1640, 1630, 1600, 1580, 1500, 1456, 1336, 1300, 1274, 1200, 1174, and 1140 cm^{-1}; MS m/z 262(M^++2, 18), 260(M^+, 49), 259(76), 197 (14), 157(10), 131(35), 128(15), 103(74), 102(22), 78(13), 77(100), 76(13), 75(18), 63(32), 51(38), and 50(38). Found: C, 55.20; H, 3.09%. Calcd for $C_{12}H_8ClF_3O$: C, 55.30; H, 3.09%.

3-Chloro-4,4,4-trifluoro-1,2-diphenyl-2-buten-1-one (13). As described above, a mixture of **12** (329 mg, 1.23 mmol), **1** (4.61 g, 24.6 mmol), CuCl (122 mg, 1.23 mmol), and 4A Molecular Sieves (1.23 g) in DMF (2 ml) was treated and after treatment with DBN (153 mg, 1.23 mmol) in Et_2O (3 ml), workup gave **13** as a colorless solid; 55 mg (14%); Mp 43—45 °C; ^{1}H NMR (500 MHz) ($CDCl_3$) δ=8.008 (d, 0.88H, J=7.9 Hz), 7.944 (d, 0.12H, J=7.3 Hz), 7.624 (t, 0.88H, J=7.3 Hz), 7.577 (t, 0.12H, J=7.3 Hz), and 7.45—7.33(m, 5H); ^{19}F NMR($CDCl_3$) δ=16.83 (s, 0.88F) and 14.05 (s, 0.12F); IR(KBr) 3060, 1678, 1598, 1580, 1492, 1450, 1300, 1250, 1184, and 1140 cm^{-1}; MS m/z 312(M^++2, 2), 310(M^+, 5), 106(14), 105(100), 77(50), 51(33), and 50(20). Found: C, 62.10; H, 3.52%. Calcd for $C_{16}H_{10}ClF_3O$: C, 61.85; H, 3.24%.

5-Chloro-6,6,6-trifluoro-2,2-dimethyl-4-hexen-3-one (15). As described above, a mixture of **14** (437 mg, 2.54 mmol), **1** (9.52 g, 50.8 mmol), CuCl (251 mg, 2.54 mmol), and 4A Molecular Sieves (2.5 g) in DMF (3 ml) was treated and workup gave **15** as colorless oil; 65 mg (12%); ^{1}H NMR($CDCl_3$) δ=7.21 (d, 1H, J=0.9 Hz) and 1.20 (s, 9H); ^{19}F NMR($CDCl_3$) δ=12.61 (s, 0.12F) and 7.43 (s, 0.88F); IR(neat) 2970, 2940, 2910, 2860, 1704, 1622, 1474, 1464, 1390, 1364, 1280, 1246, 1180, and 1150 cm^{-1}; MS m/z 157($M^+-C_4H_9$, 3),[16] 101(25), 59(100), 57(63), and 56(50). Found: C, 44.49; H, 4.96%. Calcd for $C_8H_{10}ClF_3O$: C, 44.78; H, 4.70%.

2-(1-Chloro-2,2,2-trifluoroethylidene)cyclopentanone (17). As described above, a mixture of **16** (160 mg, 1.02 mmol), **1** (3.77 g, 20.1 mmol), CuCl (101 mg, 1.02 mmol), and 4A Molecular Sieves (1.03 g) in DMF (2 ml) was treated and workup gave **17** as pale yellow oil; 41 mg (21%); ^{1}H NMR (500 MHz)($CDCl_3$) δ=3.100 (tq, 0.88H, J=7.1 and 3.3 Hz), 2.915 (tq, 0.12H, J=7.5 and 2.8 Hz), 2.551 (t, 0.12H, J=7.8 Hz), 2.479 (t, 0.88H, J=8.0 Hz), and 2.08—1.96 (m, 1H); ^{19}F NMR($CDCl_3$) δ=18.09 (t, 0.12F, J=3 Hz) and 14.19 (t, 0.88F, J=3 Hz); IR(neat) 2960, 2890, 1750, 1636, 1476, 1456, 1296, 1280, 1220, 1200, 1184, 1176, and 1150 cm^{-1}; MS m/z 200(M^++2, 2), 198(M^+, 6), 149(31), 97(10), 85(14), 83(15), 81(11), 73 (18), 71(25), 70(12), 69(25), 67(11), 65(11), 57(67), 56(24), 55(51), 53(11), 51(12), and 41(100). Found: C, 42.27; H, 2.98%. Calcd for $C_7H_6ClF_3O$: C, 42.34; H, 3.05%.

3-(1-Chloro-2,2,2-trifluoroethylidene)bicyclo[2.2.1]-heptan-2-one (20). As described above, a mixture of **19** (435 mg, 2.39 mmol), **1** (8.94 g, 47.7 mmol), CuCl (236 mg, 2.38 mmol), and 4A Molecular Sieves (2.40 g) in DMF (3 ml) was treated and after treatment with DBN (297 mg, 2.39 mmol) in THF (2 ml), workup gave **20** as pale yellow oil; 170 mg (32%); ^{1}H NMR($CDCl_3$) δ=3.5—4.0 (m, 2H), 2.7—3.0 (m, 2H), and 1.3—2.3 (m, 6H); ^{19}F NMR($CDCl_3$) δ=14.32 (s, 0.42F) and 11.99 (s, 0.58F); IR(neat) 2960, 2890, 1750, 1636, 1476, 1456, 1296, 1280, 1220, 1184, 1176, and 1150 cm^{-1}; MS m/z 226(M^++2, 9), 224(M^+, 25), 196(35), 161(79), 141(54), 91(46), 85(13), 79(40), 77(18), 75(25), 69(18), 68 (70), 67(100), 66(79), 63(27), 55(63), 54(13), 53(20), and 51(38). Found: C, 48.12; H, 3.58%. Calcd for $C_9H_8ClF_3O$: C, 48.13; H, 3.59%.

Hexyl 3-Chloro-4,4,4-trifluoro-2-butenoate (22). As described above, a mixture of **21** (131 mg, 0.61 mmol), **1** (2.27 g, 12.1 mmol), CuCl (60 mg, 0.61 mmol), and 4A Molecular Sieves (0.6 g) in DMF (3 ml) was treated and workup gave **22** as pale yellow oil; 24 mg (15%); ^{1}H NMR($CDCl_3$) δ=6.67 (d, 1H, J=0.7 Hz), 4.16 (t, 2H, J=7 Hz), and 1.1—0.7 (m, 11H); ^{19}F NMR ($CDCl_3$) δ=7.48 (s, 0.21F) and 7.13 (s, 0.79F); IR(neat) 3070, 2960, 2930, 2860, 1740, 1658, 1464, 1380, 1320, 1280, 1254, 1186, and 1140 cm^{-1}; MS m/z 223(M^+—Cl, 0.5),[16] 215(0.6), 201(1), 159(25), 157(78), 84(52), 83(18), 69(43), 55(100), and 54(48). Found: C, 46.25; H, 5.61%. Calcd for $C_{10}H_{14}ClF_3O_2$: C, 46.43; H, 5.46%.

Determination of GLC Yields: After the elimination reaction, a comparable amount of adamantane was added to the ethereal solution as an internal standard before the final workup, and then the mixture was analyzed on a GLC by comparison of relative sensitivity with an authentic sample of an *E*- and *Z*-mixture.

Addition of 9-Diazofluorene to Unsubstituted and Chloro-Substituted 1,4-Benzoquinones. A Comparison with the Addition of Diphenyldiazomethane

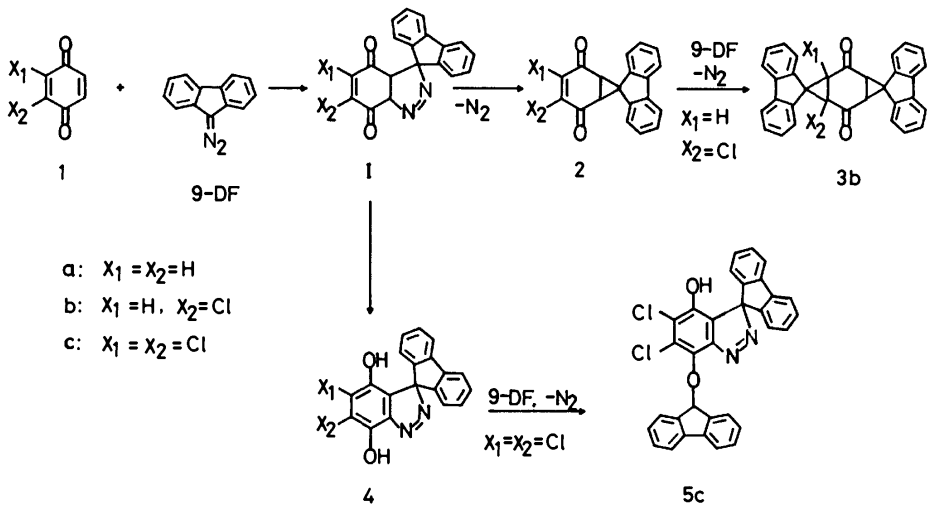
Takumi OSHIMA* and Toshikazu NAGAI
Institute of Chemistry, College of General Education, Osaka University, Toyonaka, Osaka 560
(Received February 4, 1989)

Unsubstituted 1,4-benzoquinone (**1a**) reacted at the C=C double bond with 9-diazofluorene (9-DF) to give norcarene dione **2a** and 4,7-dihydroxy-3*H*-indazole **4a**. Similarly, the reaction of 2-chloro-1,4-benzoquinone (**1b**) with 9-DF yielded norcarene dione **2b** and 4,7-dihydroxy-3*H*-indazole **4b**, together with tricyclic dione **3b**. 2,3-dichloro-1,4-benzoquinone (**1c**) and 9-DF produced norcarene dione **2c**, 4,7-dihydroxy-3*H*-indazole **4c**, and its fluorenyl ether **5c**. Reactions of 2,5- and 2,6-dichloro- and trichloro-1,4-benzoquinones (**1d**, **1e**, and **1f**) with 9-DF provided norcarene diones **2d**, **2e**, and **2f** and tricyclic diones **3d** and **3e**, respectively. On the other hand, tetrachloro-1,4-benzoquinone (**1g**) converted 9-DF into 9,9′-bifluorenylidene possibly via a 1 : 1 betaine intermediate arising from the C=O double bond addition. These results were markedly different from those of the previous diphenyldiazomethane reactions and are discussed in terms of structural changes of these diazoalkanes.

Since the early pioneering work by Pechmann for the addition of diazomethane to 1,4-benzoquinone,[1] the addition chemistry of diazoalkanes to quinones has received the continuing interest of several workers from synthetic and mechanistic points of view.[2] The products of these reactions are strongly dependent on the electronic and structural natures of these substrates. We previously reported that the reactions of diphenyldiazomethane (DDM) with unsubstituted and variously chloro-substituted 1,4-benzoquinones proceed through the addition to the quinonoid C=C or C=O double bonds, giving 4,7-dihydroxy-3*H*-indazoles, cyclopropane derivatives, or 1 : 1 betaine intermediates.[3] The addition modes varied with the numbers and with the substitution patterns of the chloro substituents. The unsubstituted quinone reacted only at the C=C double bond,[4] while the chlorinated quinones successively raised the proportion of the C=O addition with the increasing Cl substituents.[3] An extreme example is tetrachloro-1,4-benzoquinone, which reacted only at the C=O double bond.[5] We now report on an extended investigation of the reaction of planar 9-diazofluorene (9-DF) with a series of chloro-substituted 1,4-benzoquinones, especially focusing attention on the effects of the structural change of the diazoalkanes on the modes of additions.

Results and Discussion

In 1955, Horner and Lingnau reported that the reaction of 9-DF with 1,4-benzoquinone (**1a**) gives 90% 4,7-dihydroxy-3*H*-indazole **4a** on standing for a long time, together with a small amount of nitrogen-free norcarene dione **2a** (2%).[6] About twenty years later, Shechter et al. attained a high yield (73%) of **2a** when the reaction was carried out in refluxing benzene.[7] These products appear to be given by way of dipolar addition, followed by two competitive processes; dienolization and nitrogen release of the primary adduct pyrazoline **I** (Scheme 1.)



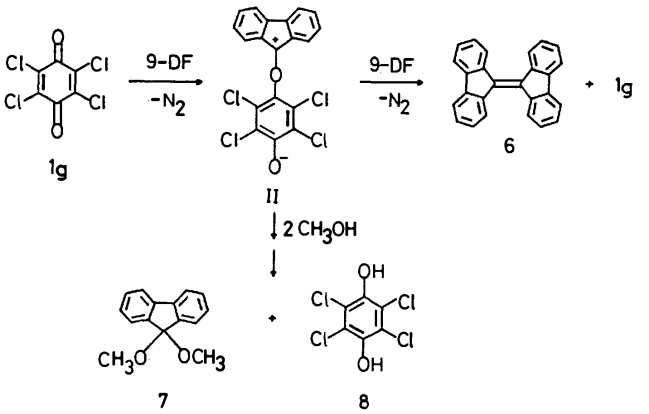
Scheme 1.

In contrast to Horner's result, but close to that of Shechter, the present equimolar reaction of 9-DF and **1a** yielded **2a** (61%) as a major product, even at 25 °C along with a moderate amount of **4a** (34%). An elevation of the reaction temperature to 60 °C moved the competing processes to the nitrogen release, as found in the yields of **2a** (77%) and **4a** (20%). A similar trend of accerelating the nitrogen release has been noticed for the previous reaction of diphenyldiazomethane (DDM) with **1a**.[3] The DDM reaction, which exclusively produced several dienolization products at 25 °C, gave rise to the corresponding norcarene dione in 12% yield at 80 °C.

The reaction of 2-chloro-1,4-benzoquinone (**1b**) with 9-DF at 25 °C gave tricyclic dione **3b** (13%), together with norcarene dione **2b** (50%) and 4,7-dihydroxy-3*H*-indazole **4b** (22%). The diadduct **3b** is the secondary product arising from a further additon of 9-DF to the resulting **2b**, as confirmed by a treatment of 9-DF with **2b**. The stereochemistry of **3b** is unknown, partly because of the very low solubility in common solvents. However, **3b** was shown to be not a mixture of stereoisomers by a careful HPLC measurement. We tentatively assign the stereochemically pure **3b** to be the anti-form since the syn-configuration suffers a considerable steric repulsion between the fluorenylidene ring protons, as estimated from its molecular model.[8] The monoadduct **2b** offered coupled NMR peaks with a narrow range of δ 3.4—3.5 assignable to the two nonequivalent bridgehead protons in bicyclo[4.1.0]hept-3-ene-2,5-dione system, indicating that the addition took place at the unchlorinated C=C bond of **1b**. Evidently, this site selectivity may be ascribed to the steric repulsive effects exerted by the Cl substituent, because the MNDO calculation[9] rather predicts an opposite addition to the chlorinated C=C bond, as previously described in the case of DDM reactions.[3]

2,3-Dichloro-1,4-benzoquinone (**1c**) also reacted at the unchlorinated C=C bond and brought about a significant increase in dienolization products, **4c** (56%) and **5c** (10%), relative to norcarene dione **2c** (18%). This appears to be performed by the two meta- and para-directing Cl (electron-withdrawing) substituents, cooperatively capable of activating the migrating protons. The formation of fluorenyl ether **5c** of **4c** only for this case is also attributable to the two chloro substituents which increse the acidity of phenolic OH of **4c** to react with 9-DF. Such etherification was quite usual in the DDM reactions, where considerable amounts of benzhydryl ethers of the corresponding 4,7-dihydroxy-3*H*-indazoles were provided not only for **1c** but also for unchlorinated **1a** and monochlorinated **1b**.[3] Primarily, the lower nucleophilicity of 9-DF compared to DDM may be due to the conjugation between the diazo and planar dibenzocyclopentadienylidene moieties.[10]

Escaping dienolization owing to the lack of the unsubstituted C=C bonds, 2,5- and 2,6-dichloro-1,4-benzoquinones (**1d** and **1e**), and trichloro-1,4-benzoquinone (**1f**) gave norcarene diones, **2d** (80%), **2e** (10%), and **2f** (97%) and tricyclic diones, **3d**(8%) and **3e** (42%), respectively (Scheme 2). Compounds **3d** and **3e** seem to have a stable anti-form in analogy with **3b**. Rather surprising is the abnormally high yield of secondary product **3e** for the case of *m*-dichlorinated **1e**. This implies that the resulting **2e** tends to react with 9-DF much faster than does the parent quinone **1e**. Indeed, the second-order rate constant (k= 7.00×10^{-3}/s^{-1} mol^{-1}, 30 °C, in benzene) of the addition of 9-DF to **2e** was about 5-times larger than that of the addition to **1e** (1.31×10^{-3}). The intriguing behavior of **1e** was also noted for the DDM reactions, where only this quinone yielded a small amount of tricyclic dione in the ordinary conditions.[3] No explanation for these unusual results can be offered at the present



Scheme 3.

Scheme 2.

time.

As expected from the complete blocking of both of the C=C double bonds with the Cl substituents, tetrachloro-1,4-benzoquinone (**1g**) gave no norcarene dione with 9-DF as well as the reaction with DDM[5] but, rather, very slowly converted it into 9,9′-bifluorenylidene (**6**) at 25 °C.[10] However, refluxing an equimolar solution of 9-DF and **1g** in benzene (1.30×10^{-2} mol dm^{-3}) for ten hours provided an almost quantitative yield of **6** with a substantial recovery of **1g** (Scheme 3). This observation, combined with the fact that only 16% 9-DF underwent spontaneous decomposition to give **6** in an identical refluxing time (by HPLC), substantiates some certain participation of quinone **1g**, even in this accelerated condition. The formation of the dimeric olefin is suggestive of a carbenic process involving fluorenylidene (Fl).[11] An attempt was made to capture the possible carbene intermediate by adding 10 equiv excess of methanol. This trapping experiment at 80 °C still provided **6** in 90% yield, together with a small amount of fluorenone dimethyl acetal (**7**, 7%) and tetrachlorohydroquinone (**8**, 5%). The **7** and **8** can be regarded as arising from a redoxical acetalization of a 1 : 1 betaine intermediate II by considering that the reaction of DDM with **1g**[5] and 2,3-dichloro-5,6-dicyanobenzoquinone (DDQ)[12] proceeds through similar intermediates and affords benzophenone dimethyl acetal in high yield when methanol is introduced. However, the absence of fluorenyl methyl ether, a well-known methanol adduct with Fl,[13] does not bear out the carbene mechanism for the formation of a large amount of **6**. Here, it should be remembered that **1g** converted phenyldiazomethane into stilbene by way of a 1 : 1 betaine intermediate, like II.[14] Moreover, a very recent investigation of the reaction of 9-DF with DDQ revealed that this system also provides a small amount of **6** along with the norcarene dione at ordinary temperature.[15] The mechanistic interpretation for the formation of **6** rests on the 1 : 1 betaine intermediate. Accordingly, we believe that the most plausible pathway providing **6** likewise involves the betaine **II** as a key intermediate, as formulated in Scheme 3. Incidentally, a marked difference in the chemical behavior between DDM and 9-DF betaines is noticiable. The DDM betaines derived from **1g** and DDQ tended to polymerize to poly(hydroquinone benzhydryl ether)s and were well-collapsed by the addition of methanol to benzophenone dimethyl acetal and hydroquinones.[5,12] On the other hand, the possible 9-DF betaines did not polymerize but, rather, underwent a further attack of another molecule of 9-DF to produce dimeric olefin **6**.

Thus, the present 9-DF reactions were apparently different from the previous DDM reactions in that the former diazoalkane exhibited only C=C additions, with one exception of the C=O addition for tetrachlorinated **1g**. However, the latter one significantly increased the C=O additions with increasing the Cl substituents of quinones as follows: **1a**, 0%; **1b**, 9%; **1c**, 12%; **1d**, 51%; **1e**, 50%; **1f**, 60%; **1g**, 100%.[3] To explain the outstanding difference, we suggest that the most important effect of replacing the twisted diphenyl groups with the planar biphenyl-2,2′-diyl one at the diazo-carbon is to change the structural properties of the diazoalkanes so that the 9-DF can more easily approach the intrinsically reactive C=C double bonds than DDM. That 9-DF reactions furnished diadducts in fair yields for quinones **1b**, **1d**, and **1e** also attributable to such structural framework of 9-DF by which the less-repulsive access to the C=C double bonds of the monoadducts will be achieved. The gradual variation of the DDM reactions to the C=O additions in going from **1a** to **1g**, therefore, may be rationalized as a result of avoiding the increasing steric repulsion caused when the nonplanar DDM approaches the C=C double bonds with increasing Cl substituents. These steric considerations may also well explain the change of the addition modes of 9-DF and DDM toward DDQ. 9-DF preponderantly added to the C=C double bond having the CN substituents to give norcarene dione,[15] while DDM provided no such cycloadduct but instead afforded the product due to the C=O addition[12] in a manner similar to the reaction with **1g**.[5] The present 9-DF reactions are also characterized by providing large amounts of nitrogen-released cycloadducts for quinones **1a—c** in contrast to the DDM reactions. This is partly because the fluorenylidene structure, which resonates with the cleaving C(3)-N(2) bond much better than the diphenylmethylene one, would facilitate the loss of nitrogen from the pyrazoline adducts (**I**).

Experimental

The IR, NMR, and mass spectra were taken with a Perkin Elmer 983G, a Varian EM 390, a JEOL GSX 400, and a Hitachi RMU 6E spectrometers, respectively.

Materials. The 9-diazofluorene (9-DF) was prepared by the oxidation of 9-fluorenone hydrazone with yellow mercury oxide[16] in ether and purified by recrystallization from ether; mp 94—95 °C. All quinones were provided and purified as described elsewhere.[3] Benzene was refluxed over lithium aluminium hydride and fractionated.

Spiro[fluorene-9,7′-[3′]norcarene]-2′,5′-dione (2a) and Spiro[3*H*-indazole-3,9′-fluorene]-4,7-diol (4a). A solution of **1a** (250 mg, 2.31 mmol) and 9-DF (444 mg, 2.31 mmol) in benzene (5 ml) was stored for 6 h at 25 °C. The precipitate was filtered, washed with ether (10 ml×2), and then with acetone (10 ml×2) to give analytically pure **2a** (305 mg, 48.5%). Recrystallization from a large volume of benzene yielded yellow needles: mp 256—257 °C, (lit,[6] 256 °C; lit,[7] 263—264 °C); IR(KBr) 1666, 1447, 734 cm^{-1}; ^{1}H NMR($CDCl_3$) δ=3.33 (s, 2H, cyclopropyl H), 6.8—7.9 (m, 10H, vinyl H+aromatic H); MS, *m/z* 272(M^+). Anal. ($C_{19}H_{12}O_2$) C, H. The filtrate and the washing were combined and concentrated to dryness. The solid residue was chromatographed on silica gel to provide a second crop of **2a** (75 mg, 12%) with benzene as an eluent. Further elution

with benzene-ether (1 : 1) gave **4a** (235 mg, 34%); yellow crystals (from acetone), mp 250 °C (decomp) (lit,[6] 252 °C); IR(KBr) 3416, 3238, 1447, 1275, 748 cm^{-1}; ^1H NMR (acetone-d_6) δ=6.5—8.0 (m, 10H, aromatic H), 7.65 (s, 1H, OH, exchangeable with CD_3OD), 9.17 (s, 1H, OH, exchangeable with CD_3OD); MS, m/z 300(M^+). Anal. ($C_{19}H_{12}O_2N_2$) C, H, N.

In a separated experiment, equimolar **1a** (2.31 mmol) and 9-DF in benzene (5 ml) were allowed to react for 3 h at 60 °C. The **2a** (485 mg, 77%) and **4a** (140 mg, 20%) were obtained on the same work-up treatment as above.

3′-Chlorospiro[fluorene-9,7′-[3′]norcarene]-2′,5′-dione (2b), 1′-Chlorodispiro[fluorene-9,4′-tricyclo[5.1.0.0^{3,5}]octane-8′,9″-fluorene]-2′,6′-dione (3b), and 5-Chlorospiro[3*H*-indazole-3,9′-fluorene]-4,7-diol (4b). A solution of **1b** (740 mg, 5.19 mmol) and 9-DF (1.00 g, 5.21 mmol) in benzene (15 ml) was allowed to stand for 6 h at 25 °C. The white solid formed was filtered and washed with acetone (10 ml×2) to give analytically pure **3b** (320 mg, 13%): mp 218—220 °C; IR(KBr) 1691, 1447, 1229, 734 cm^{-1}. The NMR of **3b** could not be determined because of its insolubility in common solvents. MS, m/z 470 (M^+). Anal.($C_{32}H_{19}O_2Cl$) C, H. The filtrate and the washing were combined and evaporated to dryness. The solid residue was chromatographed on silica gel. Elution with hexane-benzene (1 : 3) yielded the recovered **1b** (90 mg). Further elution produced **2b** (795 mg, 50%) with benzene and **4b** (88 mg, 5%) with benzene-ether (1 : 1). Recrystallization of **2b** from benzene gave yellow prisms: mp 210—220 °C; IR(KBr) 1685, 1665, 736 cm^{-1}; ^1H NMR($CDCl_3$) δ=3.43 (d×d, J=7.3 and 1.5 Hz, 1H, cyclopropyl H), 3.49 (d, J=7.3 Hz, 1H, cyclopropyl H), 6.9—7.9 (m, 9H, vinyl H+aromatic H); MS, m/z 306 (M^+). Anal.($C_{19}H_{11}O_2Cl$) C, H. Recrystallization of **4b** from benzene-ether mixture provided yellow plates: mp 210 °C (decomp); IR(KBr) 3264, 1446, 1226, 750 cm^{-1}; ^1H NMR($CDCl_3$) δ=4.83 (s, 1H, OH, exchangeable with CD_3OD), 6.6—7.9 (m, 9H, aromatic H), 8.00 (s, 1H, OH, exchangeable with CD_3OD); MS, m/z 334 (M^+). Anal.($C_{19}H_{11}O_2N_2Cl$) C, H, N.

In a separate experiment, monoadduct **2b** (31 mg, 0.1 mmol) in benzene (1 ml) was allowed to react with excess 9-DF (96 mg, 0.5 mmol) for 1 d at 25 °C. Diadduct **3b** was obtained in 90% yield.

3′,4′-Dichlorospiro[fluorene-9,7′-[3′]norcarene]-2′,5′-dione (2c), 5,6-Dichlorospiro[3*H*-indazole-3,9′-fluorene]-4,7-diol (4c), and 5,6-Dichloro-7-(9-fluorenyloxy)spiro[3*H*-indazole-3,9′-fluoren]-4-ol (5c). A solution of **1c** (330 mg, 1.86 mmol) and 9-DF (360 mg, 1.88 mmol) in benzene (5 ml) was stored for 3 h at 25 °C. The solvent was evaporated and the solid residue was chromatographed on silica gel. Elution with hexane-benzene (2 : 1) provided the recovered **1c** (30 mg) and **2c** (111 mg, 18%): mp 209—210 °C, yellow plates (from benzene); IR(KBr) 1687, 1555, 1079, 739 cm^{-1}; ^1H NMR($CDCl_3$) δ=3.55 (s, 2H, cyclopropyl H), 6.8—7.8 (m, 8H, aromatic H); MS, m/z 340 (M^+). Anal. ($C_{19}H_{10}O_2Cl_2$) C, H. Further elution with benzene gave **5c** (103 mg, 10%): mp 200 °C (decomp), pale yellow prisms (from chloroform); IR(KBr) 3437, 1435, 1197, 739 cm^{-1}; ^1H NMR($CDCl_3$) δ=5.13 (s, 1H, OH, exchangeable with CD_3OD), 6.7—8.0 (m, 17H, methine+aromatic H); MS, m/z 532 (M^+). Anal. ($C_{32}H_{18}O_2N_2Cl_2$) C, H, N. Finally, **4c** (386 mg, 56%) was eluted with benzene-ether (3 : 1). Recrystallization of **4c** from hexane-ether mixture yielded yellow needles: mp 215 °C (decomp); IR(KBr) 3424, 1449, 1083, 750 cm^{-1}; ^1H NMR(acetone-d_6) δ=6.6—8.0 (m, 8H, aromatic H), 7.87 (s, 1H, OH, exchangeable with CD_3OD), 10.1 (s, 1H, OH, exchangeable with CD_3OD); MS, m/z 368 (M^+). Anal. ($C_{19}H_{10}O_2N_2Cl_2$) C, H, N.

1′,4′-Dichlorospiro[fluorene-9,7′-[3′]norcarene]-2′,5′-dione (2d) and 1′,4′-Dichlorodispiro[fluorene-9,4′-tricyclo-[5.1.0.0^{3,5}]octane-8′,9″-fluorene]-2′,6′-dione (3d). A solution of **1d** (660 mg, 3.73 mmol) and 9-DF (720 mg, 3.75 mmol) in benzene (20 ml) was stored for 1 d at 25 °C. The solid formed was filtered and washed with benzene (5 ml×2) to leave analytically pure **3d** (154 mg, 8%): mp>350 °C; IR(KBr) 1698, 1443, 1286, 736 cm^{-1}. The NMR of **3d** could not be taken because of its insolubitity. MS, m/z 504 (M^+). Anal. ($C_{32}H_{18}O_2Cl_2$) C, H. The filtrate and the washing were combined and concentrated to give yellow crystals of **2d** (990 mg, 78%): mp 126—127 °C, pale yellow prisms (from benzene); IR(KBr) 1681, 1579, 989, 729 cm^{-1}; ^1H NMR($CDCl_3$) δ=3.77 (s, 1H, cyclopropyl H), 7.19 (s, 1H, vinyl H), 7.1—7.9 (m, 8H, aromatic H); MS, m/z 340 (M^+). Anal. ($C_{19}H_{10}O_2Cl_2$) C, H.

1′,3′-Dichlorospiro[fluorene-9,7′-[3′]norcarene]-2′,5′-dione (2e) and 1′,3′-Dichlorospiro[fluorene-9,4′-tricyclo-[5.1.0.0^{3,5}]octane-8′,9″-fluorene]-2′,6′-dione (3e). A solution of **1e** (1.00 g, 5.65 mmol) and 9-DF (1.08 g, 5.62 mmol) in benzene (20 ml) was stored for 6 h at 25 °C. The solid formed was filtered and washed with benzene (5 ml×2) and acetone (5 ml×2) to leave analytically pure **3e** (1.20 g, 42%) as a pale-yellow powder: mp>350 °C; IR(KBr) 1711, 1448, 1216, 741 cm^{-1}. The NMR of **3e** could not be taken because of its insolubility. MS, m/z 504(M^+). Anal. ($C_{32}H_{18}O_2Cl_2$) C, H. The filtrate and the washing were concentrated and chromatographed on silica gel. After elution of the recovered **1d** (0.39 g) with hexane-benzene (2 : 1), the **2e** (245 mg, 13%) was obtained with benzene. Recrystallization with hexane-benzene mixture produced yellow prisms: mp 127—129 °C IR(KBr) 1699, 1666, 1589, 1263, 1058, 721 cm^{-1}; ^1H NMR($CDCl_3$) δ=3.67(d, J=1.50 Hz, 1H, cyclopropyl H), 7.0—7.8 (m, 9H, vinyl H+aromatic H); MS, m/z 340 (M^+). Anal. ($C_{19}H_{10}O_2Cl_2$) C, H.

In separate experiments, solutions of **1e** (300 mg, 1.69 mmol) and 9-DF (650 mg, 3.38 mmol) in benzene (5ml) and of **2e**(100 mg, 0.294 mmol) and 9-DF (57 mg, 0.297 mmol) in benzene (3ml) were allowed to react as above. Both reactions provided 1 : 2 adduct **3e** in more than 96% yield.

The kinetic reactions were carried out in the presence of 30- (for **1e**) and 12-fold (for **2e**) molar excess of 9-DF ($3.6—7.7\times10^{-2}$ mol dm^{-3}) to permit a pseudo-first-order kinetic treatment. The rates were determined by following the relative decrease of **1e** and **2e** with respect to *p*-cyanobenzaldehyde and solvent benzene as internal standards, respectively, with a Hitachi 655A-12 HPLC instrument equipped with a Hitachi D-2000 chromato-integrator. The HPLC conditions using a Radial Pak cartridge C18(Waters Associates, Inc.) are as follows; 1 ml min^{-1}, eluents: 30% (for **1e**) and 20% aqueous methanol (v/v) (for **2e**), UV-detector wavelength: 254 and 273 nm for **1e** and **2e**, respectively.

1′,3′,4′-Trichlorospiro[fluorene-9,7′-[3′]norcarene]-2′,5′-dione (2f). A solution of **1f** (600 mg, 2.84 mmol) and 9-DF (545 mg, 2.84 mmol) in benzene (10 ml) was stored at 25 °C for 3 d. The solid formed was filtered and washed with benzene (5 ml×3) to give **2f** (980 mg, 92%): mp 210 °C (decomp), orange granulates (from acetone); IR(KBr) 1692,

1225, 1088, 729 cm^{-1}; ^1H NMR(acetone-d_6) δ=4.18 (s, 1H, cyclopropyl H), 6.7—7.8(m, 8H, aromatic H); MS, *m/z* 374 (M^+). Anal. ($C_{19}H_9O_2Cl_3$) C, H. The filtrate was chromatographed on silica gel to yield a second crop of **2f** (53 mg, 5%) with benzene as an eluent.

Reaction of 9-DF with Tetrachloro-1,4-benzoquione (1g) with or without Added Methanol. A solution of 9-DF (0.50 g, 2.6 mmol) and **1g** (0.64 g, 2.6 mmol) in benzene (20 ml) was refluxed for 10 h. The solvent was evaporated and the dark-red residue was washed with ether (10 ml×3) to give recovered **1g** (0.45 g, 70%). The ether solution was concentrated to dryness and subjected to silica-gel chromatography. Elution with hexane-benzene (1 : 4 v/v) yielded 9,9′-bifluorenylidene (**6**, 415 mg, 97%) and the second crop of **1g** (0.18 g, 28%).

As a trapping experiment, a solution of 9-DF (0.50 g), **1g** (0.64 g), and 10 equiv of methanol (0.83 g) in benzene (20 ml) was refluxed for 10 h. The same work-up as above recovered **1g** (0.40 g, 62.5%). The washing ether was evaporated and the dark-red residue was immediately submitted for NMR measurement. The singlet at δ 3.30 ($CDCl_3$), which was only one signal detectable in a field higher than δ 7.0 was assigned to the CH_3O groups of fluorenone dimethyl acetal (**7**) by comparison with spectrum of authentic sample[17] as well as chemical proof being hydrolyzed to fluorenone upon treatment with dilute hydrochloric acid. The absolute yield of acetal **7** (7%) was determined by the integral ratio with 1,1,1,2-tetrachloroethane (δ=4.20) as an internal standard. After a complete hydrolysis of acetal, the reaction product on chromatography over silica gel gave **6** (385 mg, 90%), the second crop of recovered **1g** (175 mg, 27%), and fluorenone (30 mg, 6%) with 5—30% benzene in hexane and tetrachlorohydroquinone (**8**, 30 mg, 5%) with 5% ether in benzene.

Oxidation Using Quaternary Ammonium Polyhalides. III.[1] An Effective Oxidation of Alcohols and Ethers by the Use of Benzyltrimethylammonium Tribromide

Shoji KAJIGAESHI,* Hiroshi KAWAMUKAI, and Shizuo FUJISAKI
Department of Industrial Chemistry, Faculty of Engineering, Yamaguchi University, Tokiwadai, Ube 755
(Received February 10, 1989)

The reaction of primary alcohols or simple ethers and α,ω-diols or cyclic ethers with a stoichiometric amount of benzyltrimethylammonium tribromide (BTMA Br_3) in carbon tetrachloride in the presence of Na_2HPO_4 aq or in acetic acid in the presence of CH_3CO_2Na aq at 60—70 °C gave dimeric esters and lactones respectively in good yields. The reaction of secondary alcohols with 1 equiv of BTMA Br_3 in the presence of a buffer at 60 °C gave ketones.

The dimeric esterification of primary alcohols **1** has been presented in several reports. For example, bromine-potassium bromate in water,[2] sodium dichromate-sulfuric acid,[3] sodium hypochlorite in acetic acid,[4] calcium hypochlorite in acetonitrile-acetic acid,[5] and sodium bromite ($NaBrO_2$) in acetic acid[6] have been used for the dimeric esterification of **1**. Dimeric esters **3** can be obtained by bubbling oxygen into a solution of **1** in acetic acid in the presence of cobalt acetate bromide.[7] Reduced copper-[8] and ruthenium-[9] catalyzed transformation of **1** to **3** have also been reported. The treatment of tributylstannyl alkoxides by NBS in carbon tetrachloride affords **3**.[10] We have recently reported that **1** can be converted into **3** by the use of sodium bromate in the presence of a catalytic amount of hadrobromic acid.[11]

Methods for the oxidative esterification of simple ethers **2** have also been described in the literature (Refs. 5 and 11).

Silver carbonate on Celite[12] and the ruthenium catalyst[9] has been used for the intramolecular oxidative lactonization of α,ω-diols **4**. Compounds **4** have also been oxidized to lactones **6** by sodium bromite in aqueous acetic acid[6] and by sodium bromate in 47% hydrobromic acid.[11] Bromine in an aqueous acetate buffer at pH 5 acts as an oxidant for the cleavage of THF to afford γ-butyrolactone.[13]

There are a number of methods concerning the oxidation of secondary alcohols **7** to ketones **8**. Several methods have been shown in the literature (Refs. 4, 10, and 11).

During the course of our investigation of the utility of benzyltrimethylammonium tribromide (BTMA Br_3) as a brominating agent,[14] we have now found that BTMA Br_3 is also an effective oxidizing agent.[15] In this paper, we wish to report on the oxidation of alcohols and ethers using BTMA Br_3 in the presence of such buffer as aqueous Na_2HPO_4 or CH_3CO_2Na.

Results and Discussion

The reaction of **1** or **2** with a calculated amount of BTMA Br_3 in carbon tetrachloride-water in the presence of Na_2HPO_4 at 60 °C gave **3** in good yields. In

Table 1. Oxidation of Primary Alcohols **1** and Simple Ethers **2** with BTMA Br_3 in the Presence of aq Na_2HPO_4[a] (in CCl_4 at 60 °C)

Run	Substrate 1 or 2	BTMA Br_3/ Substrate	Reaction time/h	Product 3	Yield[b]/ %
1	CH_3CH_2OH	1.1	7	$CH_3CO_2CH_2CH_3$	11[c]
2	$CH_3(CH_2)_2OH$	1.1	5.5	$CH_3CH_2CO_2(CH_2)_2CH_3$	52[c]
3	$CH_3(CH_2)_3OH$	1.1	4.5	$CH_3(CH_2)_2CO_2(CH_2)_3CH_3$	55[c]
4	$(CH_3)_2CHCH_2OH$	1.1	12	$(CH_3)_2CHCO_2CH_2CH(CH_3)_2$	80
5	$CH_3(CH_2)_4OH$	1.1	3.5	$CH_3(CH_2)_3CO_2(CH_2)_4CH_3$	84
6	$(CH_3)_2CH(CH_2)_2OH$	1.1	5	$(CH_3)_2CHCH_2CO_2(CH_2)_2CH(CH_3)_2$	77
7	$CH_3(CH_2)_5OH$	1.1	5	$CH_3(CH_2)_4CO_2(CH_2)_5CH_3$	96
8	$(C_2H_5)_2CHCH_2OH$	1.1	24	$(C_2H_5)_2CHCO_2CH_2CH(C_2H_5)_2$	69

10	$CH_3(CH_2)_{11}OH$	1.1	4	$CH_3(CH_2)_{10}CO_2(CH_2)_{11}CH_3$	91
11	Ph-CH_2OH	1.1	5	Ph-CHO	89
12	Ph-CH_2CH_2OH	1.1	4	Ph-$CH_2CO_2CH_2CH_2$-Ph	23[d]
13	$[CH_3(CH_2)_2]_2O$	2.2	3	$CH_3(CH_2)_2CO_2(CH_2)_3CH_3$	33
14	$[CH_3(CH_2)_5]_2O$	2.2	5	$CH_3(CH_2)_4CO_2(CH_2)_5CH_3$	78
15		4.4	14	$CH_3(CH_2)_4CO_2(CH_2)_5CH_3$	90
16	$(Ph\text{-}CH_2)_2O$	2.2	10.5	Ph-CHO	63

a) About a 2 equiv of Na_2HPO_4 to BTMA Br_3 was used. b) Yield of isolated product. c) The exact yield was not calculated due to the volatility of the product, but a significant conversion was indicated by the IR and ^1H NMR analyses. d) Yield was based on ^1H NMR.

Table 2. Lactonization of α,ω-Diols **4** and Cyclic Ethers **5** with BTMA Br_3 in the Preesence of a Buffer

Run	Substrate **4** or **5**	BTMA Br_3/ Substrate	Reaction conditions			Product **6**	Yield[a]/ %
			Temp/°C	Time/h	Buffer (Solvent)		
1	$HO-(CH_2)_4-OH$	2.1	70	5.5	Na_2HPO_4[b] (CCl_4)		60
2	$HO-(CH_2)_5-OH$	2.1	70	2.5	CH_3CO_2Na[c] (CH_3CO_2H)		49
3	$HO-(CH_2)_6-OH$	2.1	70	2.5	Na_2HPO_4[b] (CCl_4)	Mixture[d]	—
4		2.1	70	4	CH_3CO_2Na[c] (CH_3CO_2H)	Mixture[d]	—
5		2.1	60	4.5	Na_2HPO_4[b] (CCl_4)		55
6		2.1	60	10	Na_2HPO_4[b] (THF)		67[e]
7		2.1	70	8.5	CH_3CO_2Na[c] (CH_3CO_2H)		13

a) Yield of isolated product. b) About a 2 equiv of Na_2HPO_4 to BTMA Br_3 was used. c) About a 4 equiv of CH_3CO_2Na to BTMA Br_3 was used. d) The mixture of ε-caprolactone, a linear ester from 2 molecules of $HO-(CH_2)_6-OH$, and a polyester was confirmed by its ^1H NMR spectrum. e) The yield was obtained on the basis of the BTMA Br_3 used.

the absence of Na_2HPO_4, however, the reaction proceeded slowly and gave **3** in low yields. In the case of benzyl alcohol, the only oxidation product was benzaldehyde. The results are summarized in Table 1.

It is reasonable to assume that BTMA Br_3 can be dissociated by water as is shown in Eq. 1;[16]

$$\text{BTMA } Br_3 + H_2O \rightleftarrows \text{BTMA Br} + \text{HOBr} + \text{HBr}. \quad (1)$$

The hypobromous acid thus produced may act as the major active oxidizing species and may convert alcohols into esters as follows;

$$\underset{\mathbf{1}}{2\,R\text{-}CH_2OH} + 2\,\text{HOBr} \longrightarrow \underset{\mathbf{3}}{R\text{-}CO_2CH_2R} + 2\,H_2O + 2\,\text{HBr}. \quad (2)$$

Overall:

$$\underset{\mathbf{1}}{2\,R\text{-}CH_2OH} + 2\,\text{BTMA } Br_3 \longrightarrow \underset{\mathbf{3}}{RCO_2CH_2R} + 2\,\text{BTMA Br} + 4\,\text{HBr}. \quad (3)$$

In the case of ethers:

$$\underset{\mathbf{2}}{R\text{-}CH_2OCH_2R} + 2\,\text{BTMA } Br_3 + H_2O \longrightarrow \underset{\mathbf{3}}{R\text{-}CO_2CH_2R} + 2\,\text{BTMA Br} + 4\,\text{HBr}. \quad (4)$$

Generated hydrobromic acid can be removed by the Na_2HPO_4 which has been added previously:

$$HBr + Na_2HPO_4 \longrightarrow NaH_2PO_4 + NaBr \quad (5)$$

Thus, the equilibrium in Eq. 1 lies to the right, and the reaction (Eqs. 3 and 4) should proceed smoothly. In practice, a 2 equiv of Na_2HPO_4 to BTMA Br_3 was used.[17] Our experimental results agreed stoichiometrically with these equations, 3 and 4.

The reaction of **4** or cyclic ethers **5** with a stoichiometric amount of BTMA Br_3 in carbon tetrachloride or in acetic acid in the presence of aqueous Na_2HPO_4 or CH_3CO_2Na respectively at 60—70 °C gave **6**. The results are summarized in Table 2. The reactions can be presented in the following equations:

$$\underset{\mathbf{4}}{HO\text{-}(CH_2)_n\text{-}OH} + 2\,\text{BTMA } Br_3 \longrightarrow \underset{\mathbf{6}}{\text{  }} + 2\,\text{BTMA Br} + 4\,\text{HBr}. \quad (6)$$

$$\underset{\mathbf{5}}{\text{  }} + 2\,\text{BTMA } Br_3 + H_2O \longrightarrow \mathbf{6} + 2\,\text{BTMA Br} + 4\,\text{HBr}. \quad (7)$$

The ring cleavage of **5** should occur first in the case of the reaction of **5** with BTMA Br_3.

The oxidation of **7** with an equimolar amount of BTMA Br_3 in the presence of a buffer (CH_3CO_2Na aq in acetic acid or Na_2HPO_4 aq in carbon tetrachloride) at 60 °C afforded the corresponding **8** in good yields. The results are summarized in Table 3.

Table 3. Oxidation of Secondary Alcohols **7** with BTMA Br_3 in the Presence of a Buffer (at 60 °C)

Run	Substrate **7**	BTMA Br_3/ Substrate	Reaction conditions: Temp/ °C	Time/ h	Buffer (Solvent)	Product **8**	Yield[a]/ %
1	CH_3CH_2-CH-$(CH_2)_2CH_3$ (OH)	1.1	60	2	CH_3CO_2Na[b] (CH_3CO_2H)	CH_3CH_2-C-$(CH_2)_2CH_3$ (O)	80
2		1.1	60	3	Na_2HPO_4[c] (CCl_4)	Mixture	—
3	$CH_3(CH_2)_5$-CH-CH_3 (OH)	1.1	60	2	CH_3CO_2Na[b] (CH_3CO_2H)	$CH_3(CH_2)_5$-C-CH_3 (O)	98
4	Ph-CH-CH_3 (OH)	1.1	50	2	CH_3CO_2Na[b] (CH_3CO_2H)	Ph-C-CH_3 (O)	87

9		1.1	60	15	Na_2HPO_4[c] (CCl_4)	Ph-C-Ph (O)	100
10	Ph-C(=O)-CH(OH)-Ph	1.1	60	10.5	CH_3CO_2Na[b] (CH_3CO_2H)	Ph-C(=O)-C(=O)-Ph	83
11		1.1	60	11	Na_2HPO_4[c] (CCl_4)	Ph-C(=O)-C(=O)-Ph	64
12		1.1	60	15	CH_3CO_2Na[b] (CH_3CO_2H)		23
13		2.1	60	24	Na_2HPO_4[c] (CCl_4)		100
14		1.1	60	15	Na_2HPO_4[c] (CCl_4)		73
15		1.1	60	12	Na_2HPO_4[c] ($CHCl_3$)		89

a) Yield of isolated product. b) About a 4 equiv of CH_3CO_2Na to BTMA Br_3 was used. c) About a 2 equiv of Na_2HPO_4 to BTMA Br_3 was used. d) A mixture of acetophenone, α-bromoacetophenone, and the starting material, e) a mixture of cyclopentanone, 2-bromocyclopentanone, and the starting material, and f) a mixture of cyclohexanone, 2-bromocyclohexanone, and the starting material, were confirmed by mean of their respective ^1H NMR spectra.

$$\underset{\text{OH}}{\text{R-CH-R}^1} + \text{BTMA Br}_3 \quad \textbf{7}$$

$$\longrightarrow \underset{\text{O}}{\text{R-C-R}^1} + \text{BTMA Br} + 2\,\text{HBr} \quad (8)$$

$$\textbf{8}$$

We believe that, although other procedures for the esterification of primary alcohols and ethers, the lactonization of α,ω-diols and cyclic ethers, and the oxidation of secondary alcohols have been reported, our methods are more effective because of their ease, simplicity, mildness of conditions, and good product yields.

Experimental

Preparation of Ester from Alcohol. Typical Procedure (Run 9 in Table 1): To a solution of 1-octanol (1.30 g, 10 mmol) in carbon tetrachloride (10 ml) we added BTMA Br_3 (4.29 g, 11 mmol) and a solution of $Na_2HPO_4 \cdot 12\ H_2O$ (9.31 g, 26 mmol) in water (10 ml). The reaction mixture was stirred for 8.5 h at 60 °C until the initial orange color faded. The solution was then cooled to room temperature and treated with a 20% aqueous solution of $NaHSO_3$ (10 ml). The organic layer was separated and washed with water (100 ml), dried over $MgSO_4$, and evaporated in vacuo to give octyl octanoate as a colorless oil; yield: 1.27 g (99%), bp 153.5 °C/7 mmHg (lit,[18] bp 305.9 °C/760 mmHg; 1 mmHg≈133.322 Pa).

Preparation of Ester from Simple Ether. Typical Procedure (Run 14 in Table 1): To a solution of dihexyl ether (0.94 g, 5 mmol) in carbon tetrachloride (10 ml) we added BTMA Br_3 (4.29 g, 11 mmol) and a solution of $Na_2HPO_4 \cdot 12H_2O$ (8.60 g, 24 mmol) in water (10 ml). The reaction mixture was then stirred for 5 h at 60 °C until the initial orange color faded. The solution was cooled to room temperature and was worked up as has been described above for the preparation of octyl octanoate to give hexyl hexanoate as a colorless oil; yield: 0.78 g (78%), bp 238—240 °C/760 mmHg (lit,[19] bp 245.6 °C/760 mmHg).

Praparation of Lactone from α,ω-Diol. Typical Procedure (Run 1 in Table 2): To a solution of 1,4-butanediol (0.90 g, 10 mmol) in carbon tetrachloride (10 ml) we added BTMA Br_3 (8.19 g, 21 mmol) and a solution of $Na_2HPO_4 \cdot 12\ H_2O$ (16.41 g, 46 mmol) in water (20 ml). The reaction mixture was stirred for 5.5 h at 70 °C until the initial orange color faded, and then cooled to room temperature. To the mixture we added 20% $NaHSO_3$ aq (10 ml) and then a saturated Na_2CO_3 solution was added until the solution had been made alkaline enough. The reaction mixture was extracted with CH_2Cl_2 (10 ml×4), and ether (50 ml) was added to the CH_2Cl_2 solution in order to precipitate BTMA Br, which was insoluble in ether. The mixture was then filtered, and the filtrate was dried over $MgSO_4$ and evaporated in vacuo to give γ-butyrolactone as a colorless oil; yield: 0.52 g (60%), bp 205 °C/760 mmHg (lit,[20] bp 50—55 °C/3 mmHg).

Preparation of Lactone from Cyclic Ether. Typical Procedure (Run 5 in Table 2): To a solution of THF (0.72 g, 10 mmol) in carbon tetrachloride (10 ml) we added BTMA Br_3 (8.19 g, 21 mmol) and a solution of $Na_2HPO_4 \cdot 12\ H_2O$ (15.04 g, 42 mmol) in water (20 ml). The reaction mixture was stirred for 4.5 h at 60 °C until the initial orange color faded and was then worked up as has been described above to give γ-butyrolactone as a colorless oil; yield: 0.47 g (55%), bp 199 °C/760 mmHg (lit, [20] bp 50—55 °C/3 mmHg).

Preparation of Ketone from Secondary Alcohol. Typical Procedure (Run 3 in Table 3): To a solution of 2-octanol (1.31 g, 10 mmol) in acetic acid (2 ml) we added BTMA Br_3 (3.90 g, 10 mmol) and a solution of $CH_3CO_2Na \cdot 3\ H_2O$ (5.72 g, 42 mmol) in water (20 ml). The reaction mixture was stirred for 2 h at 60 °C until the initial orange color had faded and then cooled to room temperature. To the mixture we added 20% $NaHSO_3$ aq (10 ml); a saturated Na_2CO_3 solution was then added until the solution had been made alkaline enough. The organic layer was separated and washed with water (100 ml), dried over $MgSO_4$, and evaporated in vacuo to give 2-octanone as a colorless oil; yield: 1.25 g (98%), bp 175 °C/760 mmHg (lit,[21] 172 °C/760 mmHg).

A Model Study of Rhodopsin Regeneration in Visual Cell. Photoisomerization of all-trans Retinal in Phosphatidylcholine Vesicles

Hiroshi TANIE, Katsunori OHBA, Minoru SAKURAI,*
Yoshio INOUE, and Riichiro CHÛJÔ
Department of Biomolecular Engineering, Tokyo Institute of Technology, O-okayama 2-chome, Meguroku, Tokyo 152
(Received January 31, 1989)

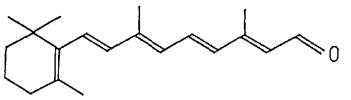
The photochemical behavior has been investigated for all-trans retinal in egg york phosphatidylcholine(EPC) vesicles and dipalmitoylphosphatidylcholine (DPPC) vesicles. In EPC vesicles, 10% of all-trans isomer is isomerized to 11-cis one upon direct irradiation of 15 W-fluorescence light for 180 min. In organic solvents the photoisomerization of all-trans isomer is induced depending on the dielectric constant of solvent. The distributions of retinal isomers in EPC vesicles is similar to those obtained in less polar solvents, such as diethyl ether. Significant difference is not recognized between the distributions of retinal isomers in DPPC vesicles at the above and below T_c. These results indicate that photoisomerization of retinal in PC vesicles is dominated by the electric properties of enviroment of retinal rather than the packing effect of PC membrane.

The vertebrate rhodopsin is embedded in the disk membrane of the rod outer segment (ROS) of a photoreceptor cell. Rhodopsin consists of an apoprotein opsin and a chromophore 11-cis retinal bound to opsin via protonated Schiff base linkage with a side chain of a lysine residue (e.g. Lys^{296} in bovine rhodopsin[1]). The illumination of rhodopsin leads to the isomerization of the 11-cis to all-trans form and finally to the release of the all-trans isomer from opsin.[2-5] Owing to poor solubility of retinal to water the released retinal possibly remains in the disk membrane, which is mainly composed of phosphatidylcholine (PC) and phosphatidylethanolamine (PE). Since PE has an amino group, retinal can form Schiff base with PE in the disk membrane. It has been reported that in the final stage of rhodopsin bleaching (metarhodopsin III) the populations of free, lipid-bound and protein-bound retinal are 34, 15, and 51%, respectively.[6] Although the metabolic pathway of the released retinal remains unclear, a possible one is that it is utilized for the rhodopsin regeneration. In order for rhodopsin regeneration to proceed all-trans retinal should be reisomerized to 11-cis form. When rhodopsin is partially bleached, photochemical reisomerization of the released retinal occurs in the disk membrane.[7] A mechanism for the above process has been proposed by Shichi and Somers[8,9] that the released all-trans retinal is reisomerized photochemically to 11-cis form as protonated retinal-PE Schiff base. This mechasnism is based on the following experimental data: (a) the bleached ROS complex shows an absorption maximum at 458 nm that is similar to the absorption maximum of protonated retinal-PE Schiff base, (b) 450—460 nm light covering the absorption maximum of 458 nm is the most effective on the formation of rhodopsin and (c) the formation of rhodopsin is markedly reduced by partial delipidation and restored by the addition of PE. According to an another report[7] the reisomerization probably occurs photochemically as free retinal, too.

On the other hand it has been reported that retinal-incorporated egg york PC vesicles are damaged by the singlet oxygen produced by the light absorption of retianl.[10-12] In acetonitrile retinal is also damaged by singlet oxygen.[13] Hence, in the disk membrane retinal may be damaged together with membrane by photochemically produced singlet oxygen.

In order to clarify the mechanisms of these reactions in which the released all-trans retinal participates, the photochemical behavior must be investigated for retinal in membrane. Many studies have been reported on photochemical isomerization of all-trans retinal in organic solvents using HPLC (high-performance liquid chromatography) the formation of 11-cis isomer increases with an increases of the polarity of solvents, and the formation of 11-cis isomer increases with an increase of the polarity of solvents, and the formation of 11-cis isomer seems to be reduced by the viscosity of solvents. The data obtained in solution are insufficient to understand the photochemical behavior in the disk membrane since membrane has some characteristics different from solvents i.e., (a) the microscopic inhomogeneity in electric properties arising from the water-hydrocarbon interface and (b) the packing effect of alkyl chains of phospholipids. There have been some reports on the photoisomerization of retinal in organized systems such as micells and membrane.[15,16] However, these reports disconcerned the regeneration process of rhodopsin.

In this report the experiments are designed in order to extract and clarify the effect of the above two factors, namely the inhomogeneity in environment and the packing effect on the photoisomerization of



all-trans retinal

retinal. Sonicated PC vesicle is used as a model of the disk membrane, and all-trans retinal is photoisomerized in it. We shall indicate that the significant amount of 11-cis retinal is photochemically produced in the model membrane system.

Experimental

Materials. Vitamin A was purchased from Riken Vitamin Co. Ltd. All-trans retinal was crystallized by oxidation of vitamin A with manganese dioxide in petroleum ether. Egg york phosphatidylcholine (EPC) and dipalmitoyl phosphatidylcholine (DPPC) were purchased from Sigma Chemical Co. All solvents used in the experiments were guaranteed grade.

Preparation of Vesicles. Chloroform solution of retinal and phospholipids, EPC, or DPPC were evaporated, giving a dry thin film. Molar ratio of retinal and PC was 1:5. Phospholipid dispersions were prepared by the addition of 50 mM KCl aqueous solution (1 M=1 mol dm^{-3}) to the dry film and subsequent shaking. The dispersions were then sonicated for 20 min under cooling by ice/water with Ultrasonic Disruptor Model UR-200P (Tomy Seiko Co., Ltd., frequency 20 kHz, output power 200 W). The resultant vesicle solutions were centrifuged at 15000 rpm for 40 min to remove multilayer vesicles and metallic titanium fragments from sonicator's microtip.

Photoisomerization of Retinal in Phospholipids. Irradiation was carried out under 15 W-fluorescence light for an appropriate duration. A 15 W-fluorescence lamp is used as a light source, due to relatively close distribution of wave length compared with that of sun light. 5 cm^3 methanol and 5 cm^3 1,2-dichloroethane were added to the sample and the suspensions were centrifuged at 10000 rpm for 2 min. The lower layer was collected and the organic solvent was removed by evaporation, followed by dissolving to solvent for HPLC. The samples were filtrated through the membrane milipore filters. The HPLC analysis were performed using Waters Model-590 HPLC, with a μ-porasil column (3.9 mm×30cm) under the conditions of flow rate 2.0 cm^3 min^{-1}, 6% diethyl ether/hexane (v/v) as a eluent, and 365 nm UV detection. The eluent and samples used were filtrated through membrane milipore filters before use.

The Photoisomerization of Retinal in Organic Solvents. Retinal was dissolved into the organic solvent used until the absorbance of the solution reached about 2. Irradiation is carried out under 15 W-fluorescence light for 90 min. After irradiation the solvents were removed by evaporation, followed by redissolved to solvent for HPLC. The HPLC analyses were similarly performed to the above procedure.

DSC Experiments. Retinal incorporated vesicles were prepared as mentioned above. Sample was injected into a small volume pan and the characteristics were recorded on DSC 10 (Seiko I&E) with heating rate of 0.5 °C min^{-1}.

All manipulations were performed under red dim light except the photoisomerization procedures.

Results

Estimation of Retinal Photo-Damage in EPC Vesicles. In Fig. 1 is shown the HPLC chromatogram of extract from retinal/EPC vesicles irradiated for 40 h. The peakes appearing in the retention time range of 4 to 10 min correspond to configurational isomers of retinal. Additional three broad peakes were found in the retention time range of 15 to 40 min. One of the three peaks found just before 20 min increases with the duration of irradiation. The identification of this peak has not been performed in particular. The hemiacetal isomer of 5,8-peroxyretinal is one of possible candidates, because 5,8-peroxyretinal is produced by the photoisomerization of all-trans retinal in aerated solution,[13] and easily isomerized to the hemiacetal isomer.[17] An absorption coefficient was reported for hemiacetal isomer of 5,8-peroxyretinal ($\varepsilon_{320\ nm}$=33000 in hexane[17]). This value was used in order to estimate the extent of oxidation.[16] According to the estimation, only 3% of retinal is damaged (converted to other compounds) during irradiation for 3 h. During irradiation for 40 h the damaging of retinal increased up to 13%.

Determination of Optimum Irradiation Time. In Fig. 2 the fractional populations of retinal isomers were plotted against a function of photo-irradiation

time. Fig. 2 indicates that the populations of retinal isomers approaches gradually to those at 40 h. In order to minimize the retinal damaging and to approach populations close to those in the photoequilibrium state, we determined the best irradiation time to be 180 min.

α-Tocopherol is well-known as a scavenger of singlet oxygen in biomembranes.[18-20] Retinal was photoisomerized in α-tocopherol/EPC vesicles. In Fig. 2 are shown the results for 180 min irradiation. The similarity of these two distributions of isomers obtained in the absence and in the presence of α-tocopherol indicates that the oxidation of retinal inaffects the isomerization behavior of retinyl polyene during irradiation for 180 min.

Photoisomerization of Retinal in EPC Vesicles. In Table 1 are summerized the populations of retinal isomers formed during direct irradiation (upper) and dark incubation (lower) in EPC vesicles. The isomerization time is 180 min in each case. Upon irradiation for 180 min in EPC vesicles 13-cis, 11-cis, and 9-cis isomers are formed with the populations of 33, 10, and 9%, respectively. 11-cis Isomer (important in rhodopsin regeneration) is formed less than 13-cis isomer. On the other hand, upon dark incubation for 180 min 11-cis and 9-cis isomers are not formed but only 13-cis isomer is formed with the population of 2.4%. No formation of 11-cis isomer is consistent with an earlier report.[21] It is noted that only under the irradiation conditions, 11-cis isomer can be formed.

Photoisomerization of Retinal in Organic Solvents. In Table 2 are summerized the populations of retinal isomers in the photostationary state in various organic solvents. By monitoring the change of the UV absorbance, it is confirmed that the photostationary state is attained by irradiation of 90 min. In order to investigate the dependence of isomer populations on the polarity of solvent, various types of solvents were selected so as to cover the wide range of the dielectric constants. In hexane 13-cis and 9-cis isomers were formed with the populations of 26 and 3%, repectively. 11-cis Isomer was not formed upon irradiation in hexane. In the solvents with relatively low dielectric constants, 4 to 6, 11-cis isomer is less formed than 13-cis isomer. In diehtyl ether, for example, 13-cis, 11-cis, and 9-cis isomers are formed with the populations of 37, 7, and 6%, respectively. In the solvents with relatively high dielectric constants, 30 to 40, 11-cis isomer is more formed than other cis isomers. In methanol, for example, 13-cis, 11-cis, and 9-cis isomers are formed with the populations of 15, 36, and 12%, respectively. On the basis of the relative population of 11-cis isomer against other cis isomers, we can classify the isomer distributions in those solvents into three types, named type A, type B, and type C (see the last column of Table 2). Type A is characterized as no formation of 11-cis isomer. Type B is characterized as the cis isomer formtions in the order of 13-cis>11-cis>9-cis. And type C is characterized as the preferencial formation of 11-cis isomer among cis ones. According to this classification, the formation of 11-cis isomer increases in the order of type A<type B<type C. We, therefore, found a good correlation between the distributions and the polarity (dielectric constant) of the solvents. That is to say, the relative

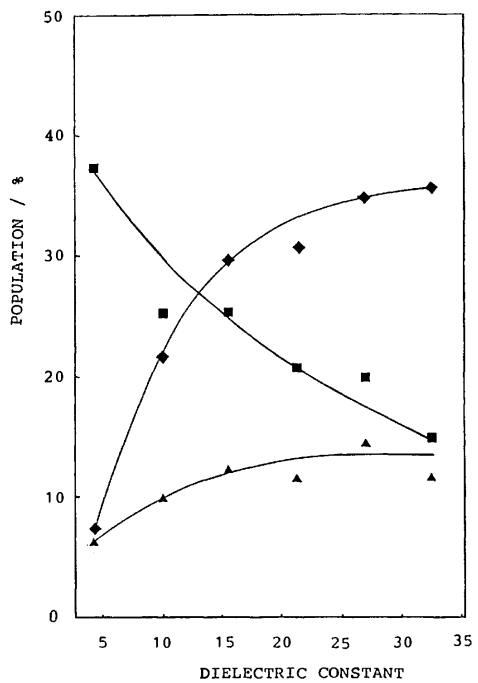

Fig. 3. The dielectric-constant dependence of the populations of retinal isomers formed in diethyl ether/methanol mixture (at room temperature); ■ 13-cis, ◆ 11-cis, ▲ 9-cis.

population of 11-cis retianl increases with an increase of the polarity of the environments.

Photoisomerization of Retinal in Diethyl Ether-Methanol Mixture. In order to confirm the polarity dependence of distributions of cis isomers, we used diethyl ether-methanol mixtures as the solvents for the isomerization reaction. In Fig. 3 the populations of cis isomers are plotted against the dielectric constants of solvents. The dielectric constans are calculated on the basis of linear combination of those of two components. In Fig. 3 is shown that with an increase in the dielectric constant the population of the 11-cis isomer increases while that of 13-cis isomer decreases. Irrespective of solvent composition, the 9-cis isomer is smaller than both 11-cis and 13-cis isomers. At low dielectric constants, 4 to 10, the population of 11-cis isomer is smaller than that of 13-cis isomer, and thus the isomer distributions is classified into the type B. At relatively higher dielectric constants, 15 to 33, the order of the formation of 11-cis and 13-cis isomers is altered and the isomer distributions is classified into the type C. These findings are confirmations for the correlation between the polarity of solvent and the distributions of retianl isomers.

We attempt to apply the above classification to the isomer distributions resulting from the photoisomerization of retinal in EPC vesicles (Table 1, upper). The isomer distribution in EPC vesicles can be assigned to one of these three types defined the above, namely, type B. Since the isomer distribution in EPC vesicles is comparable to those obtained in solutions of less polar solvents, especially in diethyl ether, we can suppose that the photoisomerization of retinal in EPC vesicles is also dominated by the polarity of its surrounding environment, and that retinal receives photon in an apolar region, such as hydrocarbon core of the vesicles.

Photoisomerization of Retinal in DPPC Vesicles. The gel-liquid crystal phase transition temperature T_c was measured for retinal-containing DPPC vesicles. From DSC (differencial scanning calorimetry) chromatogram, T_c of retinal/DPPC vesicles (molar ratio 1 : 5) was determined to be 37.7 °C. The T_c obtained here is lower by ca. 4.5 °C than that of pure DPPC vesicles, 41.2 °C. The lowering of T_c induced by incorporation of retinal is consistent with a previous report.[22]

In Table 3 are summerized the populations of retinal isomers formed during irradiation for 180 min in DPPC vesicles. In order to investigate the effect of mobility of lipids on isomerization process, irradiation were carried out at the temperatures above and below T_c, 51 °C and 24 °C, respectively. In the liquid crystal state (above T_c), 13-cis, 11-cis, and 9-cis isomers are formed with the populations of 36, 5, and 10%, respectively. In the gel state (below T_c), 13-cis, 11-cis, and 9-cis isomers are formed with the populations of 32, 5, and 10%, respectively. Both distributions at these two temperatures correspond to the medium type between A and B. No significant difference is recognized between the distributions formed at these two different temperatures. These findings indicate that the photoisomerization of retinal is inaffected by the change in the packing effect depending on the state of alkyl chain.

Table 3. Populations of Retinal Isomers Formed by Irradiation in DPPC Vesicles

Temperature /°C	Isomer formed/%				
	13-cis	11-cis	9-cis	7-cis	All-trans
51 (above T_c)	36.4	4.6	10.2	Trace	48.8
24 (below T_c)	32.4	5.3	11.9	Trace	50.3

Discussion

In the final stage of the rhodopsin bleaching, the major fraction of the retinal molecules released from opsin dissociates into free form in the disk membrane.[6] Thus, if these retinals are isomerized to 11-cis form and subsequently bind to opsin, the significant amount of rhodopsin is expected to be regenerated. It has been reported that second step (binding to opsin) in the regeneration process proceeds efficiently in the disk membrane.[9] The efficiency of rhodopsin regeneration, therefore, depends on that of the first step (isomerization to 11-cis isomer), which can be estimated from the present data. Irradiation experiments were carried out using the usual light source (15 W-fluorescence light), which does not contain the light of ultraviolet region (<400 nm). The present results indicate that under the irradiation of visible rays all-trans isomer (λ_{max}=387 nm) is efficiently isomerized to cis isomers in lipid membrane. Consequently, 10% of the all-trans is isomerized to 11-cis and simultaneously the comparable amount of 9-cis is produced. 9-cis Isomer can also bind with opsin, giving isorhodopsin. On the other hand, during dark incubation, 9- and 11-cis isomers are not produced in the lipid membrane. These results suggest that the significant amount of natural pigments can be regenerated through the light adaption of the disk membrane containing the bleached rhodopsin.

The population of 11-cis (10%) obtained here are inconsistent with that (0.3%) appearing elsewhere.[14] The origin of this discrepancy may be attributable to the difference in irradiation intensity. 400 W-mercury lamp was used in Ref.13. Stronger irradiation may induce various side reactions involving the formation of epoxyretinal.

The isomer distribution in EPC vesicles is similar to those in the medium of relatively lower dielectric constant. This finding suggests that the photoisomerization behavior of retinal in EPC vesicles is mainly controlled by electric properties of its environment. And the principal moiety of the retinal molecule should be located in a hydrophobic region of

EPC vesicles. In nonpolar solvent such as hexane 11-cis isomer is, however, not formed. Thus in EPC vesicles the retinyl polyene must be partially exposed to the polar region of EPC vesicles. Probably the -C=O group of retinal is in contact with the polar head groups of lipids. Such a location and orientation of retinal are consistent with the results of ESR[23] and NMR[15,24] studies on retinal-vesicles and -micelles systems. However, on the basis of the present results, the inhomogeneity of polarity in EPC vesicles is not necessarily important for the control of the photoisomerization pathway of retinal. Rather, the idea of the average polarity of the environment is sufficient to explain the observed isomer distribution.

No significant difference appearing in the isomer distributions in DPPC vesicles at above and below T_c. This finding suggests directly that the change in the packing effect induced by the phase transition of lipid inaffects the photoisomerization behavior of retinal. This is consistent with the fact that the trend of the isomer distribution is not largely different from that observed in solution. The incorporation of retinal into vesicles causes to increase lipid-lipid distance, leading to the decrease in the cooperativity of lipid molecules. This is supported by the facts that the incorporation of retinal leads to increasing the proton permiation,[25] broadening of the DSC transition[22] and lowering of the Tc of DPPC vesicles.[22] The weakening of the packing facilitates the isomerization of retinal, which may inaffects in lipid packing.

The isomer distribution attained in EPC vesicles is compared with that in DPPC vesicles. The formation of 11-cis in DPPC vesicles are smaller than in EPC vesicles, and the formation of 9-cis and 13-cis isomers in DPPC are larger than those in EPC vesicles. As indicated in Fig. 3 in the medium of lower dielectric constant (ca. 10), the populations of these isomers dramatically changes in the region of dielectric constant. In other words, the slight variation of the environment causes the largely different isomer populations in a lower dielectric medium. EPC and DPPC are different in the spiecies of fatty acid chains, indicating variation of the dielectric properties of hydrophobic core of membrane, and in the extent of retinal penetration. This is the main origin of the observed difference in the isomer distribution between EPC and DPPC vesicles.

In summary, we used the PC vesicles as a model of disk membrane. In EPC vesicles 10% of 11-cis retinal are formed by irradiation of 15 W-fluorescence light. Since 11-cis isomer is not formed during dark incubation, photoisomerization process is effective to form 11-cis isomer. On the other hand, the photoisomerization data in organic solvents are useful to explain the photoisomerization in EPC vesicles, and to estimate the environment of retinal in PC vesicles.

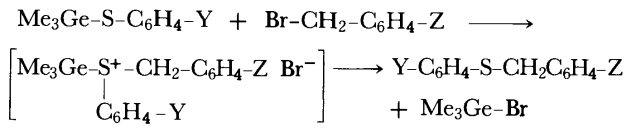
Mechanism of the Reaction of (Arylthio)trimethylgermanes with 1-Aryl-1-bromoethanes—Kinetic and Stereochemical Studies—

Seizi KOZUKA,* Takemi NITTA, Shoji TAMURA, and Waichiro TAGAKI
Department of Applied Chemistry, Faculty of Engineering, Osaka City University, Sugimoto 3-chome, Sumiyoshi, Osaka 558
(Received February 22, 1989)

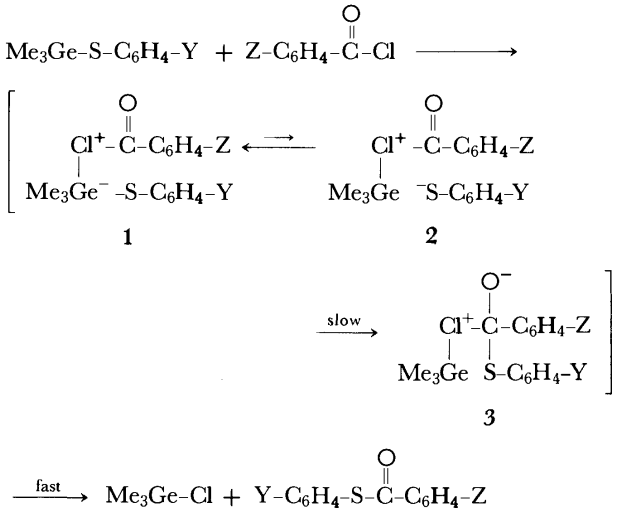
Kinetic and stereochemical studies have been conducted on the reaction of (arylthio)trimethylgermanes with 1-aryl-1-bromoethanes. The reaction has been found to obey a first-order kinetic equation. The rates of the reaction of the substituted arylethanes were well-correlated with σ^+ constants. Optically active 1-bromo-1-phenylethane gave racemic phenyl 1-phenylethyl sulfide by the reaction with trimethyl(phenylthio)germane. An S_N1 ionization of 1-aryl-1-bromoethanes has been suggested as the reaction mechanism.

We have reported a kinetic study on the reaction of (arylthio)trimethylgermanes with benzyl bromides giving aryl benzyl sulfides and bromotrimethylgermane.[1] The reaction obeyed a second-order kinetic equation and gave apparently negative ρ value due to the substituents on the arylthio group. Accordingly, a nucleophilic attack of the sulfur atom on the benzylic carbon atom has been suggested as the reaction mechanism (Scheme 1).



Scheme 1.

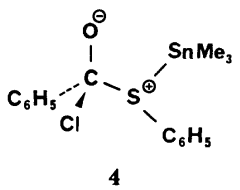
A quite different kinetic aspect was observed for the reaction of (arylthio)trimethylgermanes with aroyl chlorides.[2] The reaction also obeyed a second-order kinetic equation, however, quite different in the substituent effects. Namely, positive ρ values were observed for both due to the substituents on the arylthio moiety and to the substituents on the aroyl group. These substituent effects together with the observed large solvent effects on the rate of the reaction were well-rationalized in terms of 5-coordinated process involving unfavorable equilibrium formation of the intermediate **2** which was followed by rate-determining attack of the arenethiolate ion on the carbonyl carbon atom (Scheme 2).[2]



Scheme 2.

The difference in their mechanisms of those two reactions was explained in terms of different steric requirements of the reactants. Benzyl bromide can accept a bimolecular nucleophilic attack even by such bulky nucleophiles as (arylthio)trimethylgermanes. On the other hand, aroyl halides involve addition intermediates during the course of a nucleophilic addition-elimination process and hence hardly accept attack of a bulky nucleophile like the arylthiogermanes. Thus, the reaction with aroyl chlorides proceeds by another process, i.e., 5-coordination of the metal atom.[1]

The same concept can be applied to rationalizing mechanistic difference in the analogous reactions. It is quite natural that the reaction of (arylthio)trimethylstannanes, a compound bearing longer metal-sulfur bond than that of germanium-sulfur, with benzyl halides proceeds by a nucleophilic attack.[3] The longer stannyl-sulfur bond provides a room for a bimolecular nucleophilic process in the reaction even with aroyl chlorides which demands more space for the nucleophilic attack forming an intermediate **4**,



4

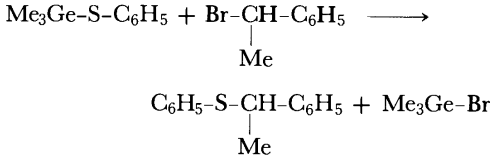
than that required for benzylic substrate.[4] On the contrary, (arylthio)trimethylsilanes can only undergo the 5-coordination process in the reaction even with phenacyl bromide which has been known as one of the most reactive substrates for S_N2 reactions.[5]

Based on these considerations, the length of germanium-sulfur bond in (arylthio)trimethylgermanes is critical which allows to proceed a bimolecular nucleophilic process in the reaction with benzyl halides.

An increment of some steric hindrance on benzyl halides may cause the change of the reaction mechanism from the bimolecular nucleophilic process to another, i.e., 5-coordination process. Thus, we have tried the reaction of (arylthio)trimethylgermanes with benzyl bromides bearing a methyl group at the α-position, that is 1-aryl-1-bromoethanes. Another possible mechanism would be the S_N1 process since the bromoalkane undergoes a facile unimolecular ionization.

Results and Discussion

Trimethyl(phenylthio)germane (247 mg, 1.27 mmol) was allowed to react with an equimolar amount of 1-bromo-1-phenylethane (235 mg, 1.27 mmol) at 100 °C for 41 h. The ^{1}H NMR spectrum of the reaction mixture showed signals only corresponding to the products although prolonged heating after completion of the reaction resulted in formation of some amount of unidentified side-product which might form from thermolysis of the product. Bromotrimethylgermane and phenyl 1-phenylethyl sulfide were isolated from the reaction mixture and characterized. Thus, the present reaction appeared to be a quite similar reaction in the type of the products with those of the reaction with benzyl halides[3] as shown in Scheme 3.



Scheme 3.

The reaction was carried out in a solvent with a small excess amount of the bromide. This is typical kinetic conditions for second-order reactions. The reaction was monitored by observing ^{1}H NMR trimethyl signals of the starting germane (δ=0.47) and the product, bromotrimethylgermane (δ=0.85). The rate constant was obtained by least-squares calculation of relative intensity of the trimethyl signals at time intervals. The second-order kinetic equation, each first-order in respective to the two reactants, failed to reveal linear kinetic plot. On the other hand, the first-order equation in respective to the concentration of the bromoethane gave a satisfactory result up to more than 90% completion. The result suggests the first-order reaction dependent only on the concentration of the bromoethane. The first-order dependency was also confirmed by the kinetic experiments with various concentrations of the phenylthiogermane. The rate constants thus obtained were nearly identical regardless of the different concentrations of the phenylthiogermane. Thus, the reaction was found to be of a first-order dependent only on the concentration of 1-bromo-1-phenylethane even under typical second-order reaction conditions. Accordingly, it is quite natural that the effect of the substituents (Y) of the arylthio group on the rate of the reaction appeared insignificant. These results are shown in Table 1.

Table 1 also contains activation parameters and the solvent effects on the rates of the reaction. The observed entropy of activation values are negative but these results do not contradict with the unimolecular ionization mechanism. The values observed for the analogous reactions of this type involving bimolecular nucleophilic or 5-coordination process as their mechanisms have been known much more negative than those observed for the present study in various solvents.[6] The values presently observed suggest looser transition state for the reaction than those proceeding bimolecular mechanisms. The smaller negative entropy of activations in absolute values in more polar solvents, shown in Table 1, are in accordance with the unimolecular ionization although it is difficult to explain why they are still negative. Substantially smaller enthalpy values observed in polar solvents suggest an ionic process for the present reaction and is in line with the large solvent effect.

Contrary to insignificant substituent effect of the arylthio group (Y), the substituents on 1-aryl-1-bromoethanes (Z) affect largely the rates of the reaction. The results are given in Table 2. Linear Hammett plots were obtained with σ^+ constants giving large negative ρ values for both the reactions in benzonitrile and anisole, although they are slightly curved upward as shown in Fig. 1. The effects of Z in both the solvents are nearly comparable with those of the unimolecular ionization of benzylic substrate.[7] The small upward deviations of the plots for the electron-withdrawing substituents may be explained by the minor contribution of a bimolecular nucleophilic substitution. The unimolecular ionization would become more unfavorable with the electron-withdrawing substituents and the bimolecular nucleophilic process would contribute more.

Table 2. First-Order Rate Constants for the Reaction of $Me_3GeSC_6H_5$ (0.262 mol dm^{-3}) with Z-$C_6H_4CH(Me)Br$ (0.318 mol dm^{-3})

Solvent	Temp/°C	Z	$k_1\times10^5$/s^{-1}	γ[a]
C_6H_5CN	70	*p*-Me	5.27±0.49	0.998

C_6H_5OMe	130	*m*-Cl	0.30±0.03	0.992

a) Correlation coefficient of the kinetic plot.

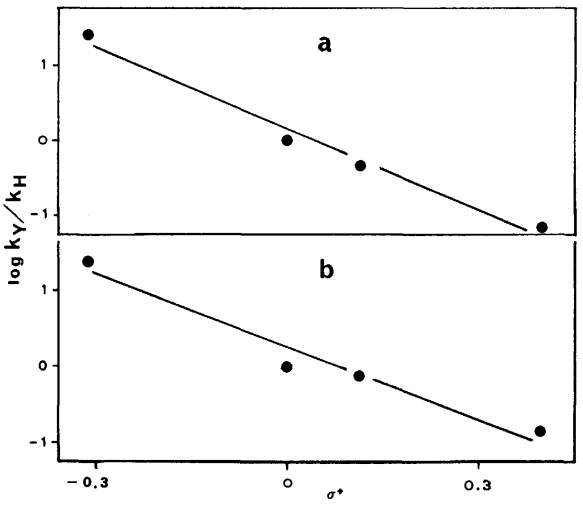

Fig. 1. Plots of the rate constants of the reactions of $Me_3GeSC_6H_5$ with Z-$C_6H_4CH(Me)Br$ against σ^+ constants, (a) in benzonitrile, (b) in anisole.

In a control experiment, 1-bromo-1-phenylethane was heated in the presence of 2,6-lutidine, instead of the thiogermane, in benzonitrile under the same reaction conditions used for the kinetic experiments. Styrene was obtained in about 70% yield which is quite comparable with the conversion of the reaction with the thiogermane under the same reaction conditions (65%) as shown in Scheme 4. The unimolecular ionization of the bromoethane has been confirmed under the kinetic conditions.

$$C_6H_5CH(Me)Br \ (318\ mmol\ dm^{-3}) \xrightarrow[110°C,\ 3.75\ h,\ in\ benzonitrile]{2,6\text{-lutidine (382 mmol dm}^{-3})} C_6H_5CH{=}CH_2 \quad (70\%\ yield)$$

Scheme 4.

Optically active (+)-1-bromo-1-phenylethane was allowed to react with an equimolar amount of trimethyl(phenylthio)germane. Phenyl 1-phenylethyl sulfide thus obtained was found to be racemized nearly completely (Scheme 5). This is conclusive evidence supporting a unimolecular ionization of the bromoethane.

$$Me_3GeSC_6H_5 + (+)\text{-}C_6H_5C^*H(Me)Br\ (40\%\ ee) \xrightarrow[100°C,\ 41\ h]{} C_6H_5C^*H(Me)SC_6H_5 \quad (51\%\ yield,\ 1.2\%\ ee)$$

Scheme 5.

All the results obtained in the present study suggest a mechanism involving unimolecular ionization of 1-aryl-1-bromoethanes at the rate-determining step (rds) for the reaction (Scheme 6). The present study, however, does not rule out minor contribution of a bimolecular nucleophilic process especially for the reaction with the 1-aryl-1-bromoethanes bearing electron-withdrawing substituents.

Among the three possible mechanisms mentioned earlier, the unimolecular ionization of 1-bromo-1-phenylethane has been confirmed in the present reaction. Although our hypothesis of the steric control

$$C_6H_5CH(Me)Br \xrightarrow{rds} [C_6H_5C^+H(Me)\ Br^-] \xrightarrow{Me_3GeSC_6H_5} C_6H_5CH(Me)SC_6H_5 + Me_3GeBr$$

Scheme 6.

on the reaction mechanism could not be clarified by the present study, this study revealed a first example of an S_N1 reaction for the reaction of the compounds bearing IVb atom-VIb atom bonds as summarized in Table 3. The particular mechanism is undoubtedly due to the nature of the substrate, 1-aryl-1-bromoethanes which easily undergoes unimolecular ionization. The present reaction is also an example of S_N1 reaction under unusual reaction conditions for the process. Most of the S_N1 reactions have been known to proceed with large excess of nucleophiles in polar media, or nucleophiles as the solvents.

It is interesting to note here, the halogen-exchange reaction of 1-bromo-1-phenylethane with mercury(II) thiocyanate in dibutyl ether at 0 °C giving thiocyanate. The mechanism has been suggested as the unimolecular ionization standing on the racemization of optically active 1-phenylethyl moiety during the reaction.[8] This is another unimolecular nucleophilic reaction under abnormal reaction conditions for the process. The reaction, however, may better be explained by initial association of 1-bromo-1-phenylethane with the salt followed by ionization of the formed complex or mercury(II) salt-assisted ionization of the reactant. 1-Bromo-1-phenylethane is fairly stable in nonpolar media below room temperatures in the absence of the salt. Kinetic study on the halogen-exchange reaction is desired to clarify the possible complexation of the bromoethane with mercury(II) salts. However, it is difficult to determine kinetic order of the salts because of their limited solubility in the solvent. On the other hand, no dependency of concentration of the nucleophile on the rate of the reaction has been confirmed in the present study. In this connection, the present reaction is not only a first example of S_N1 reaction of the compounds bearing IVb atom-VIb atom bonds with haloalkanes but also a unique unimolecular nucleophilic substitution proceeding with a small amount of nucleophile in nonpolar media.

Experimental

Materials. Solvents were dried and distilled. Substituted 1-bromo-1-phenylethanes were prepared by reduction of the corresponding acetophenones.[9] Commercially available optically active (−)-1-phenylethanol was brominated with PBr_3 obtaining (+)-1-bromo-1-phenylethane.[10] Preparation of (arylthio)trimethylgermanes was reported previously.[2]

Product Analysis. Trimethyl(phenythio)germane (0.25 g, 1.3×10^{-3} mol) was heated with an equimolar amount of 1-bromo-1-phenylethane (0.24 g, 1.3×10^{-3} mol) in a sealed tube at 100 °C for 41 h. ^{1}H NMR analysis of the reaction mixture showed only signals due to bromotrimethylgermane (δ 0.85, s, 9H) and phenyl 1-phenylethyl sulfide (δ 1.60, d, 3H; 4.30, q, 1H; 7.20, broad, 10H) and small amounts of the remaining reactants. The conversion was 85%. Bromotrimethylgermane was isolated by distillation (bp 113—114 °C, 84.2% yield). Phenyl 1-phenylethyl sulfide was isolated from the residue by column chromatography on silica gel with hexane as the eluent (0.14 g, 51.4% yield). The reaction of optically active compound was carried out similarly. Rotations ($[\alpha]_D$) of the starting 1-bromo-1-phenylethane and obtained phenyl 1-phenylethyl sulfide were, +69.0 ° (ethanol, c 2.35, 40.3% ee) and −9.04 ° (ethanol, c 0.55), respectively. Optical purity of the sulfide was determined by converting to the corresponding sulfone,[11] −1.14 ° (methanol, c 0.39, 1.2% ee).

Kinetics. The kinetic procedure was essentially the same to that previously reported.[1] Initial concentrations were 0.262 and 0.318 mol dm^{-3} for the thiogermane and the bromoethane, respectively.

The Reaction of 1-Bromo-1-phenylethane in the Absence of the Thiogermane. A mixture of 1-bromo-1-phenylethane (0.294 g, 0.318 mol dm^{-3}) and 2,6-lutidine (0.204 g, 0.382 mol dm^{-3}) in benzonitrile (0.50 cm^3) was sealed in a glass tube and heated at 110±0.1 °C for 3.75 h. After heating, the precipitated salt was filtered off. Styrene was identified by the pattern of its olefinic protons in the ^{1}H NMR spectrum of the filtrate and the yield was estimated by intensity of the signals relative to that of the remaining 1-bromo-1-phenylethane.

Syntheses of Cholesta-5,7-diene-3β,25-diol and Cholesta-5,7-diene-1α,3β,25-triol

Yoji TACHIBANA,* Shinji YOKOYAMA, and Masahiro TSUJI
Central Research Laboratory, Nisshin Flour Milling Co., Ltd.,
Tsurugaoka, Ooimachi, Irumagun, Saitama 354
(Received February 25, 1989)

Adducts of 3β-acetoxy- and 1α,3β-diacetoxy-23,24-dinorchola-5,7-dien-22-al (**7** and **14**) with 4-phenyl-3*H*-1,2,4-triazole-3,5-dione prepared by the ozonolysis of the corresponding adducts of ergosteryl acetate and 1α-acetoxyergosteryl acetate were transformed into 22-bromo-3β-tetrahydropyranyloxy- and 22-iodo-1α,3β-bis-(tetrahydropyranyloxy)-23,24-dinorchola-5,7-diene (**11** and **26**). The halide derivatives (**11** and **26**) were coupled with 2-methyl-4-phenylsulfonyl-2-(tetrahydropyranyloxy)butane (**6**) to afford 23-phenylsulfonyl-3β,25-bis(tetrahydropyranyloxy)- and 23-phenylsulfonyl-1α,3β,25-tris(tetrahydropyranyloxy)cholesta-5,7-diene (**12** and **27**). The reductive desulfonylation and deprotection of the tetrahydropyranyl group of **12** and **27** provided the title compounds, cholesta-5,7-diene-3β,25-diol (**1**) and cholesta-5,7-diene-1α,3β,25-triol (**2**).

It has been reported that vitamin D_3 must be metabolized to 25-hydroxyvitamin D_3 (25-OH-D_3) in the liver, and subsequently to 1α,25-dihydroxyvitamin D_3 (25-$(OH)_2$-D_3) in the kidney, before eliciting its hormonal activity.[1] Many workers have reported the syntheses of cholesta-5,7-diene-3β,25-diol (**1**)[2] and cholesta-5,7-diene-1α,3β,25-triol (**2**),[3-5] the precursors of 25-(OH)-D_3 and 1α,25-$(OH)_2$-D_3. Concerning the syntheses of **1** and **2**, any process of preparing them utilizing cholest-5-ene-3β,25-diol[6] and cholest-5-ene-1α,3β,25-triol[7] as key intermediates generally gives poor yields of **1** and **2** due to the side reactions involving the formation of a considerable amount of undesired 4,6-diene isomers.

We previously reported the synthesis of 1α-acetoxyergosteryl acetate (**3**) and 1α-hydroxyergosterol (**4**).[8] The C-22 aldehyde or alcohol readily obtainable from **3** and **4** seemed to be a good synthon for the preparation of 1α-hydroxylated steroidal 5,7-diene derivatives. In the present paper, the alternative syntheses of **1** and **2**, by the coupling of the corresponding steroidal 5,7-diene part and the side chain moiety, is described.

We first examined the synthesis of **1**. The C 5 synthon to constitute C (23)—C (27) side chain part was prepared as shown in Scheme 1. Methyl phenyl sulfone was treated with 2,2-dimethyloxirane in the presence of sodium hydride to give phenylsulfonyl alcohol (**5**). The hydroxyl group of **5** was protected as a tetrahydropyranyl ether (**6**) in the usual manner.

Ergosterol was converted into the known C-22 aldehyde (**7**) via route involving the protection of the 5,7-diene with 4-phenyl-3*H*-1,2,4-triazole-3,5-dione (PTAD) and ozonolysis according to the procedure described by Barton et al.[9] The aldehyde (**7**) was reduced with $LiAlH_4$ to afford the diol (**8**), which was treated with an equimolar amount of *p*-toluenesulfonyl chloride to give C-22 tosylate (**9**) selectively. After the hydroxyl group of **9** was protected as a tetrahydropyranyl ether, the resulting **10** was converted to C-22 bromide (**11**) by treatment with lithium bromide.[10] The bromide (**11**) was condensed with

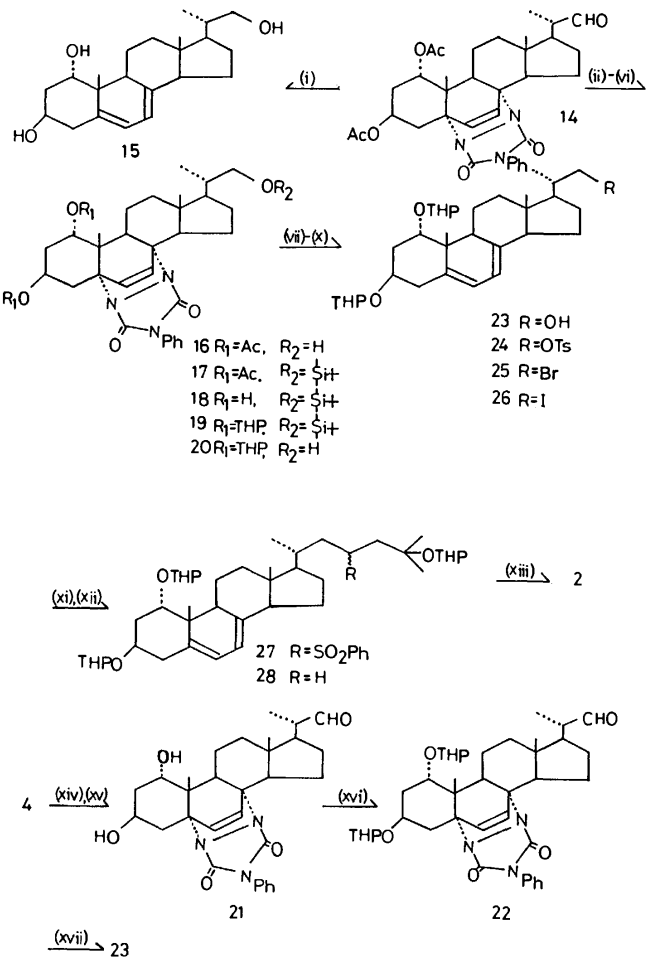

Scheme 3. (i) $LiAlH_4$, (ii) $NaBH_4$, (iii) *t*-$BuMe_2SiCl$-imidazole, (iv) KOH/EtOH, (v) DHP-PPTS, (vi) Bu_4NF/THF, (vii) $LiAlH_4$, (viii) TsCl-Py, (ix) LiBr-Li_2CO_3, (x) NaI, (xi) BuLi/**6**, (xii) Na-Hg, (xiii) PPTS/EtOH, (xiv) 4-Phenyl-3*H*-1,2,4-triazole-3,5-dione (xv) O_3-Me_2S, (xvi) DHP-PPTS, (xvii) $LiAlH_4$.

the C 5 alcohol derivative (**6**) in the presence of BuLi to provide the 23-phenylsulfonyl derivative (**12**). The deprotection of the tetrahydropyranyl group of **12** under acidic conditions, followed by the reductive desulfonylation[11] of the diol (**13**) with sodium amalgum led to the target compound (**1**) (Scheme 2).

In a manner similar to that described above, the synthesis of **2** was achieved as outlined in Scheme 3. The C-22 aldehyde (**14**) was synthesized by the ozonolysis of the adduct of **3** with PTAD.[12] As described in the synthesis of **1**, we attempted the selective tosylation for the hydroxyl group (at C-22) of the triol (**15**) prepared by the reduction of the aldehyde (**14**) with $LiAlH_4$. However, in contrast to the tosylation of **8**, the reaction of **15** with *p*-toluenesulfonyl chloride gave mixtures. Thus, the aldehyde (**14**) was subjected to reduction with $NaBH_4$ to produce the C-22 alcohol (**16**). The acetyl groups of **16** seemed to be unstable under the basic conditions employed here, and therefore, they were converted to tetrahydropyranyl groups as follows.[13] The protection of the hydroxyl group at C-22 as *t*-butyldimethylsilyl ether and the successive hydrolysis of the acetyl groups afforded the 1,3-diol (**18**). The protection of the hydroxyl groups of **18** as tetrahydropyranyl ether followed by the removal of the *t*-butyldimethylsilyl group with Bu_4NF provided the C-22 alcohol (**20**). The alcohol (**20**) was then treated with $LiAlH_4$ to give bis(tetrahydropyranyloxy) C-22 alcohol (**23**).

Alternatively, the alcohol (**23**) was obtained from 1α-hydroxyergosterol (**4**). The Diels-Alder adduct of **4** with PTAD was ozonized to yield the C-22 aldehyde (**21**). No epimerization of **21** (at C-20) was observed at this stage.[9] The protection of the 1,3-diol of **21** as tetrahydropyranyl ether and the subsequent reduction with $LiAlH_4$ produced the 5,7-diene (**23**). Subsequently, the alcohol (**23**) was reacted with *p*-toluenesulfonyl chloride to afford C-22 tosylate (**24**). The bromide (**25**) derived from **24** proved to be rather unreactive toward **6**. Accordingly, the tosylate (**24**) was converted to the corresponding iodide (**26**) by means of reaction with sodium iodide in boiling acetone.[13]

The iodide (**26**) was condensed with the sulfone (**6**) under the same conditions described above to yield the 23-phenylsulfonyl derivative (**27**). The reductive elimination of the phenylsulfonyl group with Na-Hg and the subsequent cleavage of the tetrahydropyranyl groups furnished the desired compound, cholesta-5,7-diene-1α,3β,25-triol (**2**).

Since 1α-hydroxylated C-22 alcohol (**23**) is obtainable from 1α-acetoxyergosteryl acetate or 1α-hydroxyergosterol, the procedure described here will provide a convenient synthetic method for the preparation of 1α-hydroxylated provitamin D derivatives.

Experimental

Melting points are uncorrected. UV spectra were taken on a Hitachi 320 spectrometer. ^1H NMR spectra were recorded in $CDCl_3$ on a JEOL JNF-FX200 spectrometer with TMS as an internal standard. Mass spectra were measured on a Hitachi M-80 mass spectrometer. Solvents were removed under reduced pressure.

2-Methyl-4-phenylsulfonyl-2-(tetrahydropyranyloxy)-butane (6). A dimethyl sulfoxide solution (70 ml) containing methyl phenyl sulfone (21.8 g) and sodium hydride (3.4 g) was heated at 70 °C for 1.5 h and then the solution was diluted with tetrahydrofuran (THF) (70 ml). To the solution, isobutylene oxide (14.0 g) in 35 ml of THF was added dropwise at 0 °C. The mixture was allowed to react for 3 h at 0 °C. After THF was removed, the residue was extracted with benzene. The benzene solution was washed with brine, dried over sodium sulfate and concentrated to dryness. The residue was purified by silica-gel chromatography. Elution with ethyl acetate/hexane (1/4, v/v) gave 2-methyl-4-phenylsulfonyl-2-butanol (**5**).[11] 20.7 g (65%).

A dichloromethane solution (250 ml) of **5** (8.0 g), dihydropyran (4.4 g), and pyridinium *p*-toluenesulfonate

(PPTS) (0.9 g) was reacted at room temperature for 6 h. The solution was washed with brine, dried (sodium sulfate) and evaporated. The residue was crystallized from ethyl acetate to afford **6**. 8.3 g (76%); mp 80—82 °C (lit,[11] 84—85 °C).

23,24-Dinorchola-5,7-diene-3β,22-diol (8). To a THF (60 ml) solution of $LiAlH_4$ (3.0 g) was added dropwise the solution of **7** (2.9 g in 50 ml of THF). The mixture was refluxed for 3 h. After decomposition of the excess $LiAlH_4$ with water, the solution was filtered on Celite. The residue after the evaporation of THF was crystallized from chloroform-methanol to yield **8**. 1.3 g (73%); mp 195—197 °C; *m/z* 330 (M^+); ^1H NMR δ=5.40, 5.58 (2H, m, H-6, H-7), 3.65 (2H, m, H-22), 3.40 (1H, m, H-3). Found: C, 79.65; H, 10.40%. Calcd for $C_{22}H_{34}O_2$; C, 79.95; H, 10.37%.

23,24-Dinorchola-5,7-diene-3β,22-diol 22-*p*-Toluenesulfonate (9). **8** (740 mg) and *p*-toluenesulfonyl chloride (635 mg) in a pyridine solution (10 ml) were reacted at room temperature for 6 h. The solution was then extracted with chloroform, washed with 10% hydrochloric acid, brine, and saturated sodium bicarbonate, dried (sodium sulfate), and evaporated. The residue was purified by means of chromatography on silica gel. Elution with chloroform/hexane (3/2, v/v) and crystallization of the crude product from ethyl acetate-hexane afforded **9**. 650 mg (60%); mp 163—165 °C; *m/z* 484 (M^+), 466 (M^+-H_2O); ^1H NMR δ=7.79 (2H d, *J*=8.4 Hz, aryl), 7.34 (2H, d, *J*=8.4 Hz, aryl), 5.56, 5.38 (2H, m, H-6, H-7), 3.97 (1H, m, H-22), 3.81 (1H, m, H-22), 3.64 (1H, m, H-3), 2.45 (3H, s, CH_3 (tosyl)). Found: C, 71.56; H, 8.49%. Calcd for $C_{29}H_{40}O_4S$: C, 71.70; H, 8.52%.

3β-Tetrahydropyranyloxy-23,24-dinorchola-5,7-dien-22-ol *p*-Toluenesulfonate (10). The tosylate (**9**) (600 mg) was dissolved in dichloromethane (10 ml). Dihydropyran (155 mg) and PPTS (30 mg) were added to the solution and the mixture was stirred at room temperature for 4 h. The solution was washed with brine and dried (sodium sulfate). The residue after the evaporation of solvent was crystallized from methanol to afford **10**. 470 mg (67%); mp 148—149 °C; *m/z* 568 (M^+), 484 (M^+—DHP); ^1H NMR δ=7.79 (2H, d, *J*=8.4 Hz, aryl), 7.34 (2H, d, *J*=8.4 Hz, aryl), 5.35, 5.55 (2H, m, H-6, H-7), 4.70 (1H, m, CH(THP)), 3.90 (1H, m, CH_2(THP)), 3.82, 3.70 (2H, m, H-22), 3.50 (1H, m, CH_2(THP)), 2.45 (3H, s, CH_3 (tosyl)). Found: C, 71.49; H, 8.48%. Calcd for $C_{34}H_{48}O_5S$: C, 71.79; H, 8.48%.

22-Bromo-3β-tetrahydropyranyloxy-23,24-dinorchola-5,7-diene (11). A *N,N*-dimethylformamide solution (5 ml) of the tosylate (**10**) (470 mg), lithium carbonate (58 mg) and lithium bromide (330 mg) was heated at 70 °C for 1 h. The mixture was extracted with chloroform, washed with brine, dried (sodium sulfate) and concentrated to dryness. The residue was chromatographed on silica gel (eluted with 5% ethyl acetate in hexane) to yield, **11**. 305 mg (77%); mp 146—149 °C (crystallized from ethyl acetate). ^1H NMR δ=5.37, 5.55 (2H, m, H-6, H-7), 4.75 (1H, m, CH(THP)), 3.81 (1H, m, CH_2 (THP)), 3.63 (1H, m, H-3), 3.52 (2H, m, H-22, CH_2(THP)), 3.36 (1H, m, H-22). Found: C, 67.67; H, 8.63%. Calcd for $C_{27}H_{41}O_2Br$: C, 67.91; H, 8.65%.

23-(Phenylsulfonyl)cholesta-5,7-diene-3β,25-diol (13). The sulfone derivative (**6**) (213 mg) was dissolved in THF (5 ml) and cooled to −20 °C. To the solution, was added dropwise 10% BuLi hexane solution (0.4 ml) and then the mixture was reacted with stirring at −20 °C for 1 h. To the solution was added the 22-bromide (**11**) (65 mg) in a mixture solution of HMPA (0.1 ml) and THF (0.5 ml). The mixture solution was stirred at −20 °C for 3 h. After the addition of sat ammonium chloride, the mixture was extracted with chloroform, washed with brine, dried (sodium sulfate) and evaporated. The residue was purified by chromatography on silica gel. Elution with 10% ethyl acetate in hexane afforded (**12**) (100 mg). The crude product was dissolved in ethanol (5 ml) and PPTS (16 mg) was added. The mixture solution was reacted at 50 °C for 3 h and extracted with chloroform. The solution was washed with brine, dried (sodium sulfate) and concentrated to dryness. The residue was chromatographed on silica gel (eluted with 20% ethyl acetate in hexane) to give **13**. 38 mg (51%) (amorphous powder); *m/z* 540 (M^+); ^1H NMR δ=7.91—7.95 (2H, m, aryl), 7.54—7.70 (2H, m, aryl), 5.57, 5.35 (2H, m, H-6, H-7), 3.70 (1H, m, H-3), 3.45 (1H, m, H-23).

Cholesta-5,7-diene-3β,25-diol (1). A solution of the sulfone derivative (**13**) (38 mg) in methanol (15 ml) saturated with Na_2HPO_4 was treated with 5% Na-Hg (2.5 g) at 35 °C for 4 h. After the separation of Hg by filtration, the solution was extracted with chloroform, washed with brine, and dried (sodium sulfate). Evaporation of the solvent left solid, which was crystallized from chloroform-hexane to provide **1**. 14 mg (50%); mp 182—183 °C. (lit,[2] 185—187 °C). UV λ_{max} 282 nm (ε=11900, ethanol).

22-Hydroxy-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-23,24-dinorchol-6-ene-1α,3β-diol 1,3-Diacetate (16). To a ethanol solution (10 ml) of sodium borohydride (0.6 g) was added a solution of **14** (2.0 g) in chloroform (50 ml) and the mixture was reacted with stirring at 0 °C for 30 min. The solution was washed with 50% acetic acid, sat sodium hydrogencarbonate and brine, dried (sodium sulfate) and evaporated. Crystallization of the residue from chloroform-hexane afforded **16**. 1.8 g, (90%); mp 196—198 °C; *m/z* 370 (M^+—triazolidine—CH_3COOH); ^1H NMR δ=7.26—7.52 (5H, m, aryl), 6.45, 6.34 (2H, ABq, *J*=8.0 Hz, H-6, H-7), 5.91 (1H, m, H-3), 5.11 (1H, brs, H-1), 3.21—3.38 (2H, m, H-22), 2.01, 2.03 (6H, s, $COCH_3$). Found: C, 66.94; H, 7.15; N, 6.82%. Calcd for $C_{34}H_{43}O_7N_3$: C, 67.42; H, 7.15; N, 6.94%.

22-(*t*-Butyldimethylsilyloxy)-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-23,24-dinorchol-6-ene-1α,3β-diol 1,3-Diacetate (17). To a solution of **16** (1.8 g) in *N,N*-dimethylformamide (5 ml) was added *t*-butyldimethylsilyl chloride (0.9 g) and imidazole (0.9 g). The mixture was warmed at 40 °C for 30 min and extracted with ether, washed with brine and evaporated. Purification on silica gel (eluted with ethyl acetate/hexane (3/7, v/v)) afforded **17**. 1.8 g (amorphous powder) (84%); *m/z* 484 (M^+—triazolidine—CH_3COOH); ^1H NMR δ=7.25—7.52 (5H, m, aryl), 6.45, 6.32 (2H, ABq, *J*=8.0 Hz, H-6, H-7), 5.88 (1H, m, H-3), 5.12 (1H, brs, H-1), 3.58 (1H, m, H-9), 3.28 (2H, m, H-22), 2.01, 2.03 (6H, s, $COCH_3$).

22-(*t*-Butyldimethylsilyloxy)-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazoline-1,2-diyl)-23,24-dinorchol-6-ene-1α,3β-diol (18). A methanol solution (50 ml) of **17** (1.7 g) and potassium carbonate (0.4 g) was heated at 60 °C for 1 h. After methanol was removed, the residue was extracted with chloroform, washed with brine and concentrated. The residue was crystallized from methanol-benzene to provide **18**. 1.3 g (85%); mp 222—224 °C; *m/z* 460 (M^+—triazolidine); ^1H NMR δ=7.23—7.39 (5H, m, aryl), 6.35, 6.18 (2H, ABq,

J=8.0 Hz, H-6, H-7), 4.80 (1H, m, H-3), 3.69 (1H, brs, H-1), 3.61 (1H, m, H-9), 3.05—3.29 (2H, m, H-22). Found: C, 67.50; H, 8.50; N, 6.36%. Calcd for $C_{36}H_{53}N_3O_5Si$: C, 67.97; H, 8.41; N, 6.61%.

22-(*t*-Butyldimethylsilyloxy)-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazoline-1,2-diyl)-1α,3β-bis(tetrahydropyranyloxy)-23,24-dinorchol-6-ene (19). The bis(silyl ether) (**18**) (1.2 g) was dissolved in dichloromethane (20 ml). To the solution, dihydropyran (350 mg) and PPTS (70 mg) were added. The mixture solution was reacted under reflux for 4 h. The solution was washed with brine, dried (sodium sulfate) and evaporated. The residue was purified by silica-gel chromatography. Elution with ethyl acetate/hexane (1/4, v/v) gave **19** as an amorphous powder. 1.1 g (75%); m/z 442 (M^+−triazolidine−2DHP−H_2O); ^{1}H NMR δ=7.20—7.50 (5H, m, aryl), 6.35, 6.49 (2H, ABq, J=8.0 Hz, H-6, H-7), 4.85 (2H, s, CH(THP)), 4.95 (1H, m, H-3), 3.40—3.92 (7H, m, CH_2(THP), H-1, H-9, H-22), 3.15—3.28 (1H, m, H-22). Found: C, 68.47; H, 8.65; N, 5.16%. Calcd for $C_{46}H_{70}N_3O_7$: C, 68.60; H, 8.78; N, 5.22%.

5α,8α-(4-Phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-1α,3β-bis(tetrahydropyranyloxy)-23,24-dinorchol-6-en-22-ol (20). To a THF solution (50 ml) of **19** (1.0 g) was added 2.5 ml of 1 M (1 mol dm^{-3}) tetrabutylammonium fluoride THF solution. The solution was stirred at room temp for 2 h and then extracted with ethyl acetate, washed with brine and evaporated. The residue was chromatographed on silica gel. Elution with ethyl acetate/hexane (3/7, v/v) afforded **20** (amorphous solid). 0.8 g (95%); m/z 514 (M^+−triazolidine); ^{1}H NMR δ=7.21—7.49 (5H, m, aryl), 6.29, 6.43 (2H, ABq, J=8.0 Hz, H-6, H-7), 4.79—4.86 (2H, m, CH(THP)), 3.90 (2H, m, CH_2(THP)), 3.30—3.76 (6H, m, H-1, H-9, H-22, CH_2(THP)).

1α,3β-Dihydroxy-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-23,24-dinorchol-6-en-22-al (21). 1α-Hydroxyergosterol (**4**) (270 mg) was dissolved in acetone (50 ml). To the solution was added PTAD by portion until the red color of the solution persisted. Removal of solvent and crystallization from acetone afforded 1α-hydroxy-5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl) ergosterol. 270 mg (87%); mp 237—238 °C; m/z 412 (M^+−triazolidine); ^{1}H NMR δ=7.28—7.41 (5H, m, aryl), 6.23, 6.39 (2H, m, H-6, H-7), 5.20 (2H, m, H-22, H-23), 4.84 (1H, m, H-3), 3.80 (1H, m, H-1). Found: C, 73.42; H, 8.38; N, 6.93%. Calcd for $C_{36}H_{49}O_4N_3$: C, 73.56; H, 8.40; N, 7.15%.

A 1% pyridine-dichloromethane solution (150 ml) of the adduct (200 mg) was ozonized at −60 °C (ozonizer E0-301, Okano Works Ltd.) until almost all the starting material was consumed (monitored by thin-layer chromatography). After argon gas was passed through the vessel, dimethyl sulfide (1 ml) was added. The solution was warmed slowly to room temperature, washed with brine, dried (sodium sulfate) and evaporated. The residue was chromatographed on silica gel. Elution with ethyl acetate/chloroform (1/4, v/v) gave **21** (amorphous powder) 140 mg (79%); m/z 344 (M^+−triazolidine); ^{1}H NMR δ=9.57 (1H, d, J=3.4 Hz, H-22), 7.29—7.40 (5H, m, aryl), 6.24, 6.36 (2H, ABq, J=8.1 Hz, H-6, H-7), 4.76 (1H, m, H-3), 3.76 (1H, m, H-1).

5α,8α-(4-Phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-1α,3β-bis(tetrahydropyranyloxy)-23,24-dinorchol-6-en-22-al (22). To a solution of the 22-aldehyde (**21**) (135 mg) in dichloromethane (10 ml) were added dihydropyran (108 mg) and PPTS (20 mg). The mixture was allowed to react at room temperature for 12 h. The solution was washed with brine, dried (sodium sulfate) and evaporated. The residue was purified by silica-gel chromatography (eluted with ethyl acetate/hexane (1/9, v/v)) to provide **22** ((108 mg (61%)) along with 5α,8α-(4-phenyl-3,5-dioxo-1,2,4-triazolidine-1,2-diyl)-3β-tetrahydropyranyloxy-23,24-dinorchol-6-en-22-al (42 mg (20%)). m/z 326 (M^+−triazolidine−2DHP−H_2O); ^{1}H NMR δ=9.56 (1H, d, J=3.4 Hz, H-22), 7.30—7.45 (5H, m, aryl), 6.36 (2H, m, H-6, H-7), 4.92 (1H, m, H-3), 4.80—4.85 (2H, m, CH(THP)), 3.89 (2H, m, CH_2(THP)), 3.70 (1H, brs, H-1), 3.50 (2H, m, CH_2(THP)).

1α,3β-Bis(tetrahydropyranyloxy)-23,24-dinorchola-5,7-dien-22-ol (23). (a) (from **20**). A THF solution containing $LiAlH_4$ (0.7 g) was added dropwise the THF solution (50 ml) of **20** (0.7 g). The mixture was reacted under reflux for 1 h. After decomposition of excess $LiAlH_4$, the solution was filtered on Celite. The solution was concentrated and the residue was extracted with ethyl acetate. The solution was washed with brine and evaporated. The residue was purified by silica-gel chromatography. Elution with ethyl acetate/hexane (1/3, v/v) gave **23** (amorphous powder). 0.5 g (95%); ^{1}H NMR δ=5.37, 5.64 (2H, m, H-6, H-7), 4.65—4.80 (2H, m, CH(THP)), 4.13 (1H, m, H-3), 3.89 (2H, m, CH_2(THP)), 3.75 (1H, brs, H-1), 3.65 (1H, m, H-22), 3.52—3.88 (3H, m, CH_2(THP), H-22).

(b) (from **22**). To a THF solution (20 ml) of $LiAlH_4$ (300 mg) was added **22** (100 mg) in THF (20 ml). The mixture was refluxed with stirring for 1 h. After the decomposition of the excess $LiAlH_4$, the solution was filtered on Celite. After the removal of the solvent, the residue was extracted with ethyl acetate. The solution was washed with brine, dried (sodium sulfate) and evaporated. The residue was chromatographed on silica gel. Elution with ethyl acetate/chloroform (1/9, v/v) yielded **23**. 48 mg (63%); the ^{1}H NMR spectrum agreed with that of **23** obtained from **20**.

22-Iodo-1α,3β-bis(tetrahydropyranyloxy)-23,24-dinorchola-5,7-diene (26). To a pyridine solution (5 ml) of **23** (400 mg) was added *p*-toluenesulfonyl chloride (600 mg). The mixture was reacted with stirring at room temperature for 1 h. The solution was extracted with ether, washed with 10% hydrochloric acid, sodium hydrogencarbonate and brine and dried (sodium sulfate). After evaporation of ether, the residue was purified on silica gel. Elution with ethyl acetate/hexane (1/9, v/v) provided 1α,3β-bis(tetrahydropyranyloxy)-23,24-dinorchola-5,7-dien-22-ol *p*-toluenesulfonate (**24**). 450 mg (89%); ^{1}H NMR δ=7.29 (2H, d, J=8.0 Hz, aryl), 7.24 (2H, d, J=8.0 Hz, aryl), 5.35, 5.63 (2H, m, H-6, H-7), 4.68—4.80 (2H, m, CH(THP)), 4.15 (1H, m, H-3), 3.75—4.05 (7H, m, H-1, H-22, CH_2(THP)), 2.25 (3H, s, CH_3(tosyl)).

An acetone solution (5 ml) of the tosylate (**24**) (400 mg) and sodium iodide (540 mg) was heated under reflux for 1 h. The residue after evaporation of acetone was chromatographed on silica gel (eluted ethyl acetate/hexane (1/9, v/v) to give **26** (amorphous powder). 324 mg (85%); m/z 624 (M^+), 540 (M^+−DHP); ^{1}H NMR δ=5.36, 5.64 (2H, m, H-6, H-7), 4.67—4.78 (2H, m, CH(THP)), 4.12 (1H, m, H-3), 3.80—3.98 (2H, m, CH_2(THP)), 3.75 (1H, brs, H-1), 2.45—2.67 (2H, m, CH_2(THP)), 2.20—2.40 (2H, m, H-22). Found: C, 60.99; H, 7.62%; Calcd for $C_{32}H_{49}IO_4$; C, 61.52; H, 7.92%.

23-Phenylsulfonyl-1α,3β,25-tris(tetrahydropyranyloxy)-cholesta-5,7-diene (27). A THF solution (10 ml) of **6** (910

mg) was cooled −20 °C. To the solution was added dropwise a 10% BuLi hexane solution (1.8 ml). The mixture was stirred at −20 °C for 30 min. To the mixture solution was added dropwise a solution of **26** (570 mg in 5 ml of THF and 0.5 ml of HMPA). The mixture was allowed to react for 30 min at −20 °C and for 1 h at 0 °C. After the reaction was stopped by adding sat. ammonium chloride, the mixture was extracted with ethyl acetate, washed with brine, dried (sodium sulfate) and evaporated. The residue was purified by chromatography on silica gel. Elution with ethyl acetate/hexane (1/4, v/v) yielded **27**. 700 mg (95%); *m/z* 706 (M^+−DHP−H_2O; ^{1}H NMR δ=7.50—7.97 (5H, m, aryl), 5.35, 5.62 (2H, m, H-6, H-7), 4.81 (3H, brs, CH(THP)), 4.14 (1H, m, H-3), 3.80—4.00 (3H, m, CH_2(THP)), 3.76 (1H, brs, H-1), 3.35—3.50 (3H, m, CH_2(THP)).

1α,3β,25-Tris(tetrahydropyranyloxy)cholesta-5,7-diene (28). A methanol solution (60 ml) (saturated with Na_2HPO_4) of **27** (700 mg) was treated with 5% Na-Hg (8.0 g) at room temperature for 6 h. After Hg was removed by filtration on Celite, the mixture was extracted with ether and washed with brine. The residue after evaporation of ether was chromatographed on silica gel. Elution with ethyl acetate/hexane (1/9, v/v) afforded **28**. 520 mg (90%); *m/z* 584 (M^+−DHP); ^{1}H NMR δ=5.36, 5.64 (2H, m, H-6 H-7), 4.69 (3H, m, CH(THP)), 4.12 (1H, m, H-3) 3.91 (3H, m, CH_2(THP)), 3.74 (1H, brs, H-1), 3.46 (3H, m, CH_2(THP)).

Cholesta-5,7-diene-1α,3β,25-triol (2). A mixture of **28** (400 mg) and PPTS (24 mg) in ethanol (6 ml) was heated at 55 °C for 4 h. The solution was extracted with ether, washed with brine and dried (sodium sulfate). The residue after evaporation of ether was purified by chromatography on silica gel. Elution with ethyl acetate/chloroform (1/3, v/v) gave the crude **2**, which was crystallized from ether-hexane to provide **2** as colorless needles. 205 mg (82%); mp 207—208 °C (lit,[3] 211—213 °C); UV λ_{max} 282 nm (ε=11800, ethanol).

The Synthesis of 4,5-Ethylenedithio-4′,5′-vinylenedithiotetrathiafulvalene (EVT) and Its Methyl and Dimethyl Derivatives (EMVT, EDMVT), and the Molecular and Crystal Structures of EVT

Hideyuki NAKANO, Kenji MIYAWAKI, Takashi NOGAMI,* Yasuhiko SHIROTA, Shigeharu HARADA, and Nobutami KASAI
Department of Applied Chemistry, Faculty of Engineering, Osaka University, Yamadaoka, Suita, Osaka 565
(Received March 8, 1989)

New donor molecules, 4,5-ethylenedithio-4′,5′-vinylenedithiotetrathiafulvalene (EVT) and its methyl and dimethyl derivatives (EMVT and EDMVT), were synthesized for the study of conducting organic salts. They are unsymmetrical TTF derivatives possessing moieties of both BEDT-TTF and bis(vinylenedithio)tetrathiafulvalene (VT) or its methyl and dimethyl derivatives. Their oxidation potentials were measured and then compared with those of the related donor molecules. The X-ray crystal structure analysis of EVT revealed that its molecular and crystal structures are very close to that of BEDT-TTF.

BEDT-TTF salts have given a variety of organic superconductors, and the superconducting transition temperature has now been raised to 10.4 K or 11.1 K in $(BEDT\text{-}TTF)_2Cu(SCN)_2$.[1] The crystal structures of the BEDT-TTF salts exhibit sulfur-sulfur networks shorter than the van der Waals distance among donor sites.[2] This crystal structure is believed to be effective for suppressing the Peierls transition inherent in a one-dimensional system. The donor molecules possessing molecular structures similar to BEDT-TTF are interesting, because they can be expected to give highly conducting organic complexes even at low temperatures. The replacement of the ethylene group of BEDT-TTF with vinylene group is one of the most attractive strategies in this regard. Thus, we synthesized bis(vinylenedithio)tetrathiafulvalene (VT) and its dimethyl and tetramethyl derivatives (DMVT and TMVT respectively).[3] Detailed electrical and structural studies of VT_2PF_6 revealed that this salt exhibits a quasi-one-dimensional electrical property and that a metal-insulator (M-I) transition occurs around 180 K.[4] Several VT-salts also showed an M-I transition,[5] probably due to the one-dimensional nature. Therefore, we have synthesized new unsymmetrical TTF-derivatives, EVT, EMVT, and EDMVT, which possess moieties of both BEDT-TTF and VT or its methyl and dimethyl derivatives, in the hope that they might give two-dimensional conducting salts. Here, EVT, EMVT, and EDMVT stand for 4,5-ethylenedithio-4′,5′-vinylenedithiotetrathiafulvalene, 4,5-ethylenedithio-4′,5′-(methylvinylenedithio)tetrathiafulvalene, and 4,5-ethylenedithio-4′,5′-(dimethylvinylenedithio)tetrathiafulvalene respectively.[6] The molecular and crystal structures of EVT are also reported.

Experimental

4,5-Ethylenedithio-4′,5′-vinylenedithiotetrathiafulvalene (EVT). To a mixture of 4,5-ethylenedithio-1,3-dithiole-2-thione (1.0 g, 4.45 mmol)[7] and 4,5-vinylenedithio-1,3-dithiol-2-one (0.92 g, 4.45 mmol),[3] we added triethyl phosphite (20 ml), which had been distilled freshly. The temperature of the solution was gradually elevated to 110 °C with stirring under a nitrogen atmosphere; thereafter, it was stirred for another 2 h at 110 °C. After cooling to room temperature, the precipitate was collected, washed with methyl alcohol, and dried under a vacuum. The crude product was chromatographed on a silica-gel column, using carbon disulflde as an eluent; the second main fraction gave almost pure EVT (0.75 g, 44%). Recrystallization from benzene gave reddish orange needle crystals. Mp 218°C (decomp). MS m/z 382 (M^+). Calcd for $C_{10}H_6S_8$: C, 31.39; H, 1.58; S, 67.03%. Found: C, 31.74; H, 1.57; S, 66.74%. ^1H NMR (CS_2) δ=3.25 (4H, s), 6.47 (2H, s). UV λ_{max}^{THF} ($\log\varepsilon$) 318.4 nm (4.33), 344.4 nm (4.24).

4,5-Ethylenedithio-4′,5′-(methylvinylenedithio)tetrathiafulvalene (EMVT) and 4,5-Ethylenedithio-4′,5′-(dimethylvinylenedithio)tetrathiafulvalene (EDMVT). EMVT and EDMVT were synthesized under reaction conditions similar as those described for EVT. 4,5-Methylvinylenedithio-1,3-dithiol-2-one[3] and 4,5-dimethylvinylenedithio-1,3-dithiol-2-one[3] were, therefore, used instead of 4,5-vinylenedithio-1,3-dithiol-2-one for the synthesis of EMVT and EDMVT respectively. EMVT: yield, 61%. orange needles. Mp 210 °C (decomp). MS m/z 396 (M^+). Calcd for $C_{11}H_8S_8$: C, 33.30; H, 2.03; S, 64.66%. Found: C, 33.40; H, 1.89; S, 64.39%. ^1H NMR (CS_2) δ=2.12 (3H, s), 3.26 (4H, s), 6.02 (1H, s). UV λ_{max}^{THF} ($\log\varepsilon$) 318.0 nm (4.12), 346.0 nm (4.02).

EDMVT: yield, 49%. yellow needles. Mp 217 °C (decomp). MS m/z 410 (M^+). Calcd for $C_{12}H_{10}S_8$: C, 35.09; H, 2.45; S, 62.45%. Found: C, 35.08; H, 2.30; S, 62.35%. ^1H NMR (CS_2) δ=2.30 (6H, s), 3.28 (4H, s). UV λ_{max}^{THF} ($\log\varepsilon$) 318.4 nm (4.15), 346.8 nm (4.06).

Determination of Molecular and Crystal Structures of EVT. $C_{10}H_6S_8$, M=382.68, monoclinic, space group $P2_1/n$, a=6.563(1), b=13.507(8), c=15.866(8) Å, β=93.47(2)°, V=1404(1) Å^3, D_c=1.80 g cm^{-3} for Z=4. The crystal used had a needle shape with approximate dimensions of 0.19×0.60×0.18 mm^3. The reflection intensities were measured by the θ-2θ scan technique up to 2θ=55° on a Rigaku AFC-4 four-circle diffractometer, using Mo $K\alpha$ radiation (λ=0.70926 Å). The scan rate was 4° min^{-1}, and the scan width, $\Delta\theta$=(1.20+0.5 tanθ)°. Backgrounds were counted for 3 s at both ends of a scan. No significant intensity decay of the standard reflections, which were measured after every 100 reflections, was detected. Of the 3513 reflections mea-

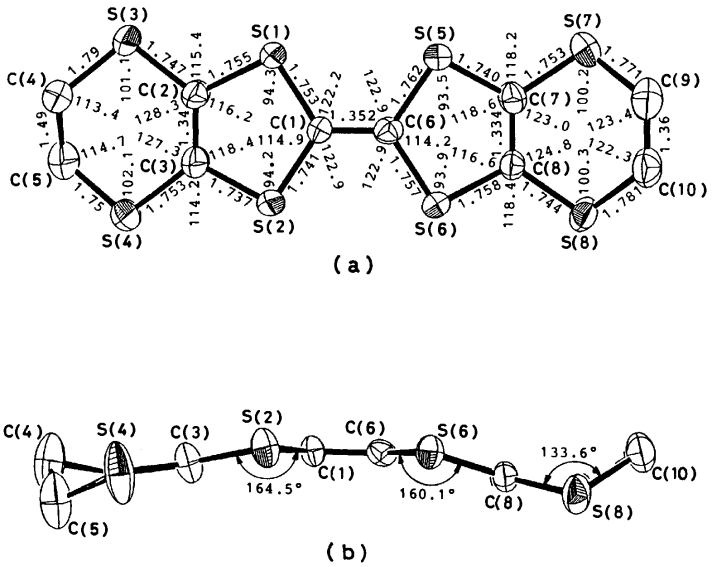

Fig. 1. Molecular structure of EVT.[14] (a) Over view, (b) side view. Nonhydrogen atoms are drawn as thermal ellipsoids with 50% probability level. Estimated standard deviations of the bond lengths and angles are 0.006—0.02 Å and 0.3—0.7° respectively.

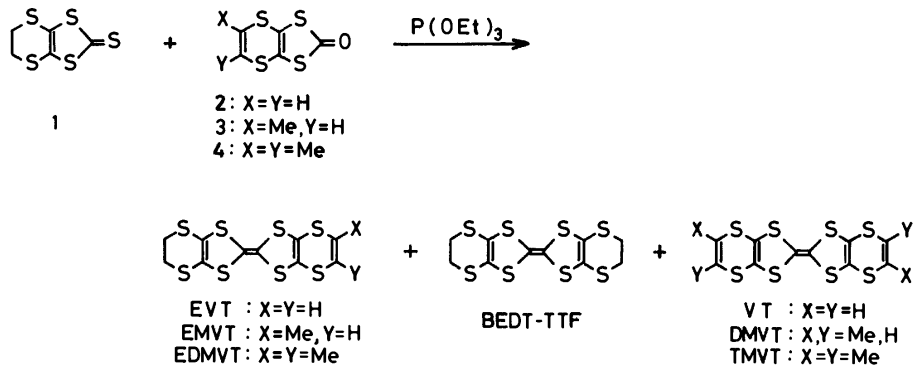
sured, the number of reflections observed was 2517 ($|F_o|>2\sigma(F_o)$). The usual Lorentz and polarization corrections were applied, but no absorption correction was made [μ(Mo$K\alpha$)=11.9 cm^{-1}].

The structure was solved by the direct method (*MULTAN* 78)[8] and was refined anisotropically by a block-diagonal least-squares procedure (*HBLS* V).[9] The hydrogen atoms could not be found on a D-map, probably because of their large thermal motion. Therefore, the hydrogen atoms were omitted in the final refinement. The function minimized was $\sum\omega(\Delta F)^2$. The weighting function used in the final stage of the refinement was $\omega=[\sigma^2(F_o)+0.0654|F_o|+0.0005|F_o|^2]^{-1}$. The atomic scattering factors were taken from those of the International Tables for X-Ray Crystallography.[10] The final R index was 0.070. The atomic coordinates of nonhydrogen atoms with equivalent isotropic temperature factors[11] are given in Table 1.[12] The bond lengths and bond angles are shown in Fig. 1.

Results and Discussion

Synthesis and Oxidation Potentials of EVT, EMVT, and EDMVT. The cross-coupling reaction of 4,5-ethylenedithio-1,3-dithiole-2-thione (**1**)[7] and 4,5-vinylenedithio-1,3-dithiol-2-one (**2**)[3] or its methyl (**3**) or dimethyl derivatives (**4**)[3] gave EVT, EMVT, or



Scheme 1.

TMVT[a)]	0.80	

a) Ref 3.

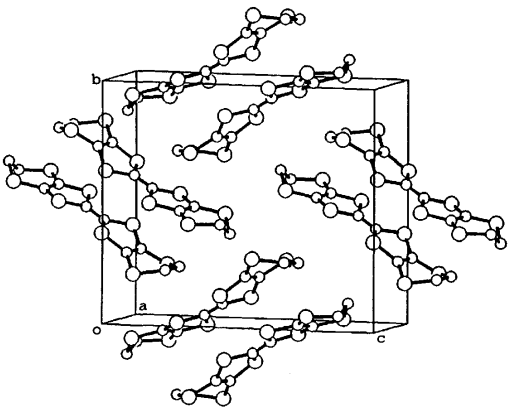

Fig. 2. Crystal structure of EVT.[15)]

EDMVT as the main product (Scheme 1). Self-coupling products (BEDT-TTF and VT or DMVT or TMVT) were always found as minor products. The amount of the cross-coupling product was usually more than 70% of the total coupling products. It is fortunate that, although the reaction products have similar molecular structures, the cross-coupling product can easily be separated from the self-coupling products by means of silica-gel chromatography, using carbon disulfide as the eluent. The absence of the self-coupling products in the purified EVT, EMVT, and EDMVT was confirmed by a study of the mass spectra. The coupling reaction of a mixture of **1** and 4,5-vinylenedithio-1,3-dithiole-2-thione[3)] in triethyl phosphite gave BEDT-TTF as the main product. Thus, **2** should be used instead of its thiocarbonyl derivative in order to obtain EVT.

The cyclic voltammetries of EVT, EMVT, and EDMVT were measured for THF solutions by using tetrabutylammonium perchlorate as the electrolyte and platinum plates as electrodes. Table 2 summarizes their half-wave oxidation potentials (vs. SCE), together with those of BEDT-TTF, VT, DMVT, and TMVT for the sake of comparison.[3)] EVT, EMVT, and EDMVT gave only one redox wave. Since the oxidation potentials of BEDT-TTF, VT, DMVT, and TMVT have been found to be in the order of BEDT-TTF<DMVT≈TMVT<VT,[3)] the following order of the oxidation potentials is predicted: BEDT-TTF< EVT<VT, BEDT-TTF<EMVT<DMVT, BEDT-TTF<EDMVT<TMVT. Table 2 shows that the prediction is satisfied for these new donor molecules.

The electrochemical crystallization of EVT was made for I_3-, PF_6-, AsF_6-, and IBr_2-salts. Their electrical conductivities at 0 °C were 184 $S\,cm^{-1}$ (I_3-salt), 0.76 $S\,cm^{-1}$ (PF_6-salt), 0.17 $S\,cm^{-1}$ (AsF_6-salt), and 4.2 $S\,cm^{-1}$ (IBr_2-salt). The temperature dependence of their electrical conductivities showed semiconducting behavior.

Molecular and Crystal Structures of EVT. The EVT molecule is not planar (Fig. 1(b)). The central portion of tetrathio-substituted ethylene is almost planar, but the outer parts are all bent in the same direction. This molecular structure is much closer to that of BEDT-TTF[13)] than to that of VT; the outer parts of VT are bent in the opposite directions.[4)] The pair-by-pair arrangement of EVT molecules, related by a center of symmetry, is shown in Fig. 2. The molecular arrangement is very close to that found in the BEDT-TTF crystal.[13)] The mode of overlapping of the paired molecules is shown in Fig. 3. The mode of the overlapping of the two molecules is also very close to that of BEDT-TTF.[13)] Several intermolecular S···S distances [S(5)(x,y,z)···S(6)($-x,-y,1-z$) (=3.588(3) Å), S(1)(x,y,z)···S(4)($-1+x,y,z$)(=3.431(4) Å), S(3)(x,y,z)···S(4)($-1+x,y,z$)(=3.516(4) Å), and S(7)

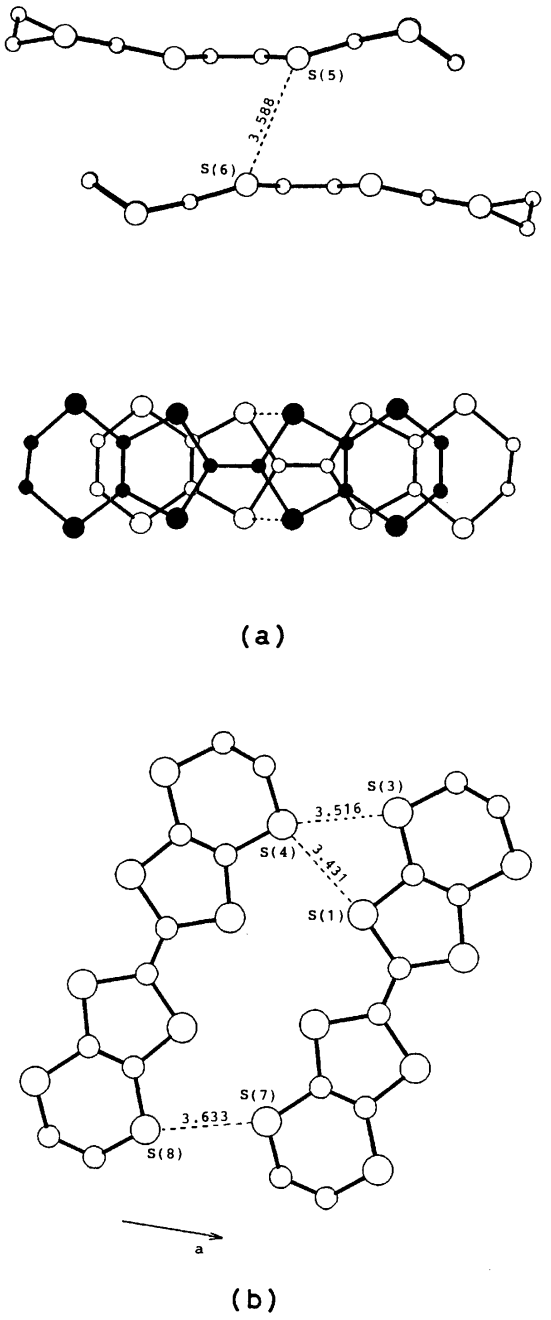

Fig. 3. (a) The mode of overlapping of the paired EVT molecules.[15] The dotted lines indicate the S···S contacts shorter than van der Waals distance (3.7 Å). (b) Molecular arrangememt along the *a* axis.[15]

(x,y,z)····S(8) $(-1+x,y,z)$(=3.633(3) Å)] are shorter than the van der Waals distance (3.7 Å) (Figs. 3(a) and 3(b)).

We are grateful to the Protein Engineering Center, Institute for Protein Research, Osaka University, for the use of the ACOS S850 computer.

Preparation of 3,6-Disubstituted Pyridazines from 3-Thiapentane-1,5-diones via 2,7-Dihydro-1,4,5-thiadiazepines

Juzo NAKAYAMA,* Toru KONISHI, Akihiko ISHII, and Masamatsu HOSHINO
Department of Chemistry, Faculty of Science, Saitama University, Urawa, Saitama 338
(Received March 18, 1989)

A series of 3-thiapentane-1,5-diones condense with hydrazine in the presence of a catalytic amount of *p*-toluenesulfonic acid in refluxing ethanol to give 2,7-dihydro-1,4,5-thiadiazepines in excellent yields. Thermal decomposition of the latter compounds in refluxing diethylene glycol affords the corresponding pyridazines in high yields with evolution of hydrogen sulfide. The above procedure is generally applicable to the preparation of a wide variety of 3,6-disubstituted pyridazines which are of structural interest and otherwise difficult to prepare.

In recent years we have been investigating the synthesis using 3-thia- and 3-selenapentane-1,5-diones as the starting materials.[1,2] In this connection, we were interested in the reports by Loudon and Young[3] and by Ajello.[4] The former group reports that the thermolysis of 2,7-dihydro-3,6-diphenyl-1,4,5-thiadiazepine (**2a**), obtainable by condensation of 1,5-diphenyl-3-thiapentane-1,5-dione (**1a**) with hydrazine, affords 3,6-diphenylpyridazine (**3a**) with evolution of hydrogen sulfide. The latter author also describes the formation of **3a** by thermolysis of 2,7-dihydro-3,6-diphenyl-1,4,5-selenadiazepine (**5a**) obtainable from 1,5-diphenyl-3-selenapentane-1,5-dione (**4a**). These reactions apparently seem to provide promising routes to substituted pyridazines. Their synthetic utility, however, has not been fully explored. We therefore planned to establish the generality of the above synthesis. We have chosen 3-thiapentane-1,5-diones (**1**) as the starting material since a wide variety of **1** are readily obtainable. Although 3-selenapentane-1,5-diones had become readily obtainable,[2a] the use of these compounds was abandoned because thermolysis of 2,7-dihydro-1,4,5-selenadiazepines might evolve highly toxic hydrogen selenide. Thus, herein we report the general synthesis of 3,6-disubstituted pyridazines (**3**) from **1** via 2,7-dihydro-1,4,5-thiadiazepines (**2**).

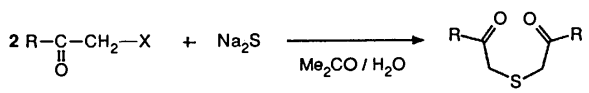
Results and Discussion

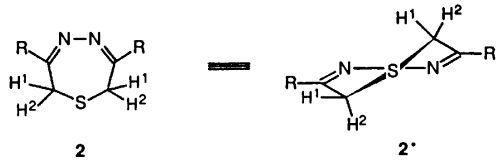
3-Thiapentane-1,5-diones (**1**) are easily prepared in good yields by adding an aqueous solution of sodium sulfide to a stirred and ice-cooled solution of an α-halo ketone in acetone.[5] Some α-halo ketones are commercial sources and were used as purchased and the others were prepared by bromination of the corresponding methyl ketones.[6] The yields of **1** thus obtained are summarized in the Scheme 1.



1

2,7-Dihydro-1,4,5-thiadiazepines (**2**) were obtained by condensation of **1** with hydrazine. The best results are generally attained by heating **1** with 1.6 equiv of hydrazine monohydrate in refluxing ethanol in the presence of a catalytic amount of *p*-toluenesulfonic acid (TsOH). Only **2g** was prepared by condensation in hot acetic acid. Reaction conditions and the yields of **2** are also summarized in the Scheme 1.

Sataty has shown that some 2,7-dihydro-1,4,5-thiadiazepines exist in a skew-boat conformation in solutions.[7] Actually, in the ^{1}H NMR spectra determined in deuteriochloroform as the solvent at 27 °C, the methylene protons of every **2** appear as AB quartet with J=12—13 Hz. These observations show that all of **2** exist in the skew-boat conformation **2'**, which results in the chemical shift non-equivalence of the methylene protons H^1 and H^2, in solutions around room temperature. The doublets of compounds **2h**—**j** appear as rather broad signals. This suggests that the ring inversion of these compounds occurs to some extent, while that of the other compounds are slow enough on the ^{1}H NMR time scale at room temperature.



2 **2'**

Conversion of **2** to the corresponding 3,6-disubstituted pyridazines **3** was cleanly attained by heating **2** in refluxing diethylene glycol. The evolution of hydrogen sulfide was observed in every case during the reaction. Reaction conditions and the yields of **3**

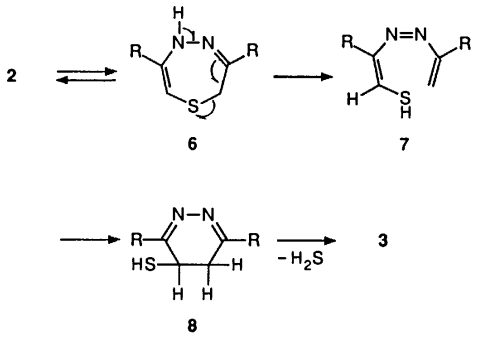
Scheme 1.

thus prepared are summarized in the Scheme 1.

As to the mechanism of the above thermolysis, the followings seem plausible. When **2** were heated in a highly polar solvent diethylene glycol, they probably partly tautomerize to the amino forms **6**, although we could not obtain the evidence for the existence of **6** by ^{1}H NMR and IR spectra determined in deuteriochloroform and carbon tetrachloride, respectively, at room temperature. Then **6** should undergo the carbon (sp^3)-sulfur bond cleavage to lead to the heterotrienes **7**, which in turn undergo electrocyclic ring closure to afford the heterocycles **8**. Finally **8** aromatize to give the final products **3** with loss of hydrogen sulfide.[8]



The synthetic method of **3** described above is convenient from the following points of view.

a) The standard method of synthesis of the pyridazine ring involves the action of hydrazine on 1,4-dicarbonyl compounds or their equivalent.[9] The preparation of 1,4-dicarbonyl compounds, however, often requires tedious or sophisticated procedures. In the present case, the starting **1** are readily obtainable.

b) None of the steps in the present synthesis requires any expensive reagents or special techniques. Work-up procedure is also simple and good overall yields are attained.

c) The method provides the synthesis of pyridazines which are of interest as the starting compounds for the preparation of conducting materials (**3g—j**).

d) The method allows the preparation of pyridazines having highly bulky groups such as *t*-butyl and 1-adamantyl (**3k** and **31**).

Experimental

General. Melting points were determined on a MEL-TEMP capillary tube apparatus and are uncorrected. ^{1}H NMR spectra were recorded on a JEOL PMX-60, a JEOL FX-90Q, or a Bruker AM-400 spectrometer and ^{13}C NMR spectra on a JEOL FX-90Q or on a Bruker AM-400 spectrometer. Chemical shifts are expressed in parts per million from tetramethylsilane as an internal standard. Mass spectra were measured on a Shimadzu QP-1000 spectrometer with ionization energy of 70 or 20 eV. High resolution mass spectra were determined on a JEOL DX-303 spectrometer. IR spectra were taken on a Hitachi 270-50 spectrometer. UV spectra were recorded on a Hitachi 340 spectrometer. Column chromatography was conducted using E. Merck silica gel 60 (70—230 mesh). Sodium sulfide enneahydrate, hydrazine monohydrate, and diethylene glycol are commercial sources and were used as purchased.

Elemental analyses were performed by Analytical Center of Saitama University, for which we thank Professor M. Sato and his staff.

General Procedure for the Preparation of 3-Thiapentane-1,5-diones (1). A solution of sodium sulfide enneahydrate (5 mmol) in 10 ml of water was added to a stirred and ice-cooled solution of an α-halo ketone (10 mmol) in an appropriate amount of acetone (20—60 ml). After completion of the addition, the mixture was warmed to room temperature and stirred for a few hours. The resulting crystalline precipitate was collected by filtration, washed with water and then with a small amount of cold methanol or ethanol, and recrystallized from an appropriate solvent. In the case of the crystalline precipitate being not separated or separated only in a small amount, the mixture was concentrated and the resulting precipitate was treated as described above.

2-Bromo-, 2-bromo-4′-methyl-, 2-bromo-4′-methoxy-, 2-bromo- 4′-chloro-, 2,4′-dibromo-, and 2-bromo-4′-phenylacetophenones, 2-bromo-2′-acetonaphthone (bromomethyl 2-naphthyl ketone), and 1-adamantyl bromomethyl ketone are commercial sources and were used as purchased. 2-(Bromoacetyl)thiophene, 2-(bromoacetyl)-5-chlorothiophene, and bromomethyl *t*-butyl ketone were obtained by bromination of commercially available 2-acetylthiophene, 2-acetyl-5-chlorothiophene, and *t*-butyl methyl ketone, respectively.[6] 2-(Bromoacetyl)-5-bromothiophene was synthesized by bromination of 2-acetyl-5-bromothiophene which is obtainable from 2-acetylthiophene.

1,5-Diphenyl-3-thiapentane-1,5-dione (**1a**),[5] 1,5-bis(4-methylphenyl)-3-thiapentane-1,5-dione (**1b**),[5] 1,5-bis(4-methoxyphenyl)-3-thiapentane-1,5-dione (**1c**),[5] 1,5-bis(4-chlorophenyl)-3-thiapentane-1,5-dione (**1d**),[5] 1,5-bis(4-bromophenyl)-3-thiapentane-1,5-dione (**1e**),[5] 1,5-di-2-naphthyl-3-thiapentane-1,5-dione (**1f**),[1a] 1,5-di-2-thienyl-3-thiapentane-1,5-dione (**1h**),[5] and 1,5-di-*t*-butyl-3-thiapentane-1,5-dione (**1k**)[5] are known compounds.

The following **1** are new compounds.

1,5-Di-4-biphenyl-3-thiapentane-1,5-dione (1g): mp 178—179 °C; white crystals from benzene; ^{1}H NMR ($CDCl_3$) δ=4.03 (4H, s, CH_2), 7.4—8.1 (18H, m); ^{13}C NMR ($CDCl_3$) δ=37.67, 127.27, 128.30, 128.95, 129.22, 134.21, 139.73, 146.24, 193.75; IR(KBr) 1678 cm^{-1} (C=O). Anal. ($C_{28}H_{22}O_2S$) C, H.

1,5-Bis(5-chloro-2-thienyl)-3-thiapentane-1,5-dione (1i): mp 96—97 °C; pale yellow crystals from ethanol; ^{1}H NMR ($CDCl_3$) δ=3.82 (4H, s, CH_2), 6.97 (2H, d, *J*=4 Hz), 7.57 (2H, d, *J*=4 Hz); ^{13}C NMR ($CDCl_3$) δ=36.97, 127.71, 132.69, 140.44, 140.87, 186.27. Anal. ($C_{12}H_8Cl_2O_2S_3$) C, H.

1,5-Bis(5-bromo-2-thienyl)-3-thiapentane-1,5-dione (1j): mp 113—114 °C; pale yellow crystals from carbon tetrachloride; ^{1}H NMR ($CDCl_3$) δ=3.82 (4H, s, CH_2), 7.11 (2H, d, *J*=4 Hz), 7.50 (2H, d, *J*=4 Hz); ^{13}C NMR ($CDCl_3$) δ=37.13, 123.59, 131.28, 133.12, 143.74, 186.05. Anal. ($C_{12}H_8Br_2O_2S_3$) C, H.

1,5-Di-1-adamantyl-3-thiapentane-1,5-dione (1l): mp 81—82 °C; white crystals from methanol; ^{1}H NMR ($CDCl_3$) δ=1.62—2.05 (30H, m), 3.49 (4H, broad s, CH_2); IR (KBr)

1704, 1678 cm^{-1} (C=O). Anal. ($C_{24}H_{34}O_2S$) C, H.

General Procedure for the Preparation of 2,7-Dihydro-1,4,5-thiadiazepines (2). A mixture of a 3-thiapentane-1,5-dione (**1**; 10 mmol) and hydrazine monohydrate (16 mmol) in ethanol (50—100 ml) containing *p*-toluenesulfonic acid monohydrate (ca. 10 mg) was heated under reflux until the starting sulfide had disappeared. The mixture was cooled to room temperature and the resulting crystalline precipitate was collected by filtration, washed with a small amount of cold ethanol, and recrystallized from an appropriate solvent.

Only compound **2g** was prepared by heating **1g** (5 mmol) and hydrazine monohydrate (8 mmol) in acetic acid (150 ml) at 95 °C for 2 h.

3,6-Diphenyl-2,7-dihydro-1,4,5-thiadiazepine (2a): mp 181—182 °C (lit,[3] mp 174—175 °C); white fine needles from ethanol; ^1H NMR ($CDCl_3$) δ=3.22 (2H, d, J=12 Hz), 3.54 (2H, d, J=12 Hz), 7.21—7.43 (6H, m), 7.69—7.81 (4H, m); ^{13}C NMR ($CDCl_3$) δ=26.46, 127.17, 128.79, 130.15, 135.18, 151.65.

3,6-Bis(4-methylphenyl)-2,7-dihydro-1,4,5-thiadiazepine (2b): mp 206—207 °C (lit,[3] mp 215 °C); white crystals from carbon tetrachloride; ^1H NMR ($CDCl_3$) δ=2.41 (6H, s), 3.33 (2H, d, J=13 Hz), 3.64 (2H, d, J=13 Hz), 7.27 (4H, d, J=8 Hz), 7.79 (4H, d, J=8 Hz); ^{13}C NMR ($CDCl_3$) δ=21.31, 26.35, 127.06, 129.50, 132.42, 140.33, 151.54.

3,6-Bis(4-methoxyphenyl)-2,7-dihydro-1,4,5-thiadiazepine (2c): mp 214—215 °C; white needles from benzene; ^1H NMR ($CDCl_3$) δ=3.31 (2H, d, J=13 Hz), 3.61 (2H, d, J=13 Hz), 3.87 (6H, s), 6.97 (4H, d, J=9 Hz), 7.84 (4H, d, J=9 Hz); ^{13}C NMR ($CDCl_3$) δ=26.29, 55.44, 114.27, 127.76, 128.63, 151.27, 161.30; IR (Nujol) 1600, 1546, 1506, 1302, 1254, 1176, 1018, 842 cm^{-1}; UV/Vis (CH_2Cl_2) 282 (ε=18000), 316 nm (sh, 15000). Anal. ($C_{18}H_{18}N_2O_2S$) C, H, N.

3,6-Bis(4-chlorophenyl)-2,7-dihydro-1,4,5-thiadiazepine (2d): mp 195—196 °C; white needles from carbon tetrachloride; ^1H NMR ($CDCl_3$)δ=3.20 (2H, d, J=13 Hz), 3.68 (2H, d, J=13 Hz), 7.43 (4H, d, J=9 Hz), 7.83 (4H, d J=9 Hz); ^{13}C NMR ($CDCl_3$) δ=26.29, 128.41, 129.06, 133.40, 136.38, 150.62; IR (Nujol) 1650, 1592, 1492, 1318, 1090, 1008, 896, 832 cm^{-1}; UV/Vis (CH_2Cl_2) 276 (ε=17000), 316 nm (9200). Anal. ($C_{16}H_{12}Cl_2N_2S$) C, H, N.

3,6-Bis(4-bromophenyl)-2,7-dihydro-1,4,5-thiadiazepine (2e): mp 208—209 °C (lit,[3] mp 202 °C); white fine needles from ethanol; ^1H NMR ($CDCl_3$) δ=3.29 (2H, d, J=13 Hz), 3.62 (2H, d, J=13 Hz), 7.58 (4H, d, J=8.5 Hz), 7.76 (4H, d, J=8.5 Hz); ^{13}C NMR ($CDCl_3$) δ=26.29, 128.57, 132.04, 133.83, 143.37, 150.68.

3,6-Di-2-naphthyl-2,7-dihydro-1,4,5-thiadiazepine (2f): mp 223—224 °C; white needles from carbon tetrachloride; ^1H NMR ($CDCl_3$) δ=3.57 (2H, d, J=13 Hz), 3.80 (2H, d, J=13 Hz), 7.52—7.57 (4H, m), 7.87—7.95 (6H, m), 8.14—8.17 (2H, m), 8.28 (2H, s); IR (Nujol) 1598, 1550, 1316, 1150, 858, 822, 748 cm^{-1}; UV/Vis (CH_2Cl_2) 264 (ε=33000), 316 nm (sh, 16000). HRMS Found: m/z 366.1193. Calcd for $C_{24}H_{18}N_2S$: M, 366.1191.

3,6-Di-4-biphenylyl-2,7-dihydro-1,4,5-thiadiazepine (2g): mp 267 °C (decomp); white crystals from chloroform ^1H NMR ($CDCl_3$) δ=3.51 (2H, d, J=13 Hz), 3.65 (2H, d, J=13 Hz), 7.40—8.05 (18H, m); IR (KBr) 1604, 1572, 1488, 1438, 1326, 844, 762, 734, 688 cm^{-1}; UV/Vis (CH_2Cl_2) 296 (ε=36000), 322 nm (sh, 34000). HRMS Found: m/z 418.1501. Calcd for $C_{28}H_{22}N_2S$: M, 418.1503.

3,6-Di-2-thienyl-2,7-dihydro-1,4,5-thiadiazepine (2h): mp 198—199 °C; pale yellow crystals from benzene/hexane; ^1H NMR ($CDCl_3$) δ=3.47 (2H, d, J=13 Hz), 3.62 (2H, d, J=13 Hz), 7.04—7.14 (2H, m), 7.36—7.50 (4H, m); ^{13}C NMR ($CDCl_3$) δ=26.83, 127.54, 129.71, 139.79, 148.13; IR (KBr) 3072, 1556, 1438, 1310, 1148, 1058, 1016, 856 cm^{-1}; UV/Vis (CH_2Cl_2) 276 (ε=15000), 318 nm (14000); MS m/z 278 (M^+). Anal. ($C_{12}H_{10}N_2S_3$) C, H, N.

3,6-Bis(5-chloro-2-thienyl)-2,7-dihydro-1,4,5-thiadiazepine (2i): mp 209—210 °C; pale yellow crystals from ethanol; ^1H NMR ($CDCl_3$) δ=3.41 (2H, d, J=12.5 Hz), 3.55 (2H, d, J=12.5 Hz), 6.91 (2H, d, J=4 Hz), 7.14 (2H, d, J=4 Hz); IR (Nujol) 1558, 1528, 1324, 1214, 1008, 816, 726, 698 cm^{-1}. UV/Vis (CH_2Cl_2) 294 (ε=14000), 348 nm (19000); MS m/z, M^+ (relative intensity) 346 (100), 347 (15), 348 (70), 349 (11), 350 (21). Anal. ($C_{12}H_8Cl_2N_2S_3$) C, H, N.

3,6-Bis(5-bromo-2-thienyl)-2,7-dihydro-1,4,5-thiadiazepine (2j): mp 180 °C (decomp); pale yellow crystals from benzene; ^1H NMR ($CDCl_3$) δ=3.24 (2H, d, J=13 Hz), 3.78 (2H, d, J=13 Hz), 7.05 (2H, d, J=4 Hz), 7.11 (2H, d, J=4 Hz); IR (Nujol) 3092, 1558, 1436, 1320, 1214, 1070, 1018, 982, 818 cm^{-1} UV/Vis (CH_2Cl_2) 296 (ε=19000), 345 nm (25000). HRMS Found: m/z 435.8229. Calcd for $C_{12}H_8{}^{79}Br^{81}BrN_2S_3$: M, 435.8196.

3,6-Di-*t*-butyl-2,7-dihydro-1,4,5-thiadiazepine (2k): mp 144—145 °C; white flakes from ethanol; ^1H NMR ($CDCl_3$) δ=1.26 (18H, s), 2.86 (2H, d, J=12 Hz), 3.02 (2H, d, J=12 Hz); ^{13}C NMR ($CDCl_3$) δ=23.75, 28.03, 37.83, 160.54; IR (KBr) 2976, 2924, 1590, 1462, 1422, 1360, 1176, 1070, 904, 720 cm^{-1}. Anal. ($C_{12}H_{22}N_2S$) C, H, N.

3,6-Di-1-adamantyl-2,7-dihydro-1,4,5-thiadiazepine (2l): mp 271—272 °C; white prisms from benzene/hexane; ^1H NMR ($CDCl_3$) δ=1.60—2.05 (30H, m), 2.88 (2H, d, J=12 Hz), 3.02 (2H, d, J=12Hz); ^{13}C NMR ($CDCl_3$) δ=22.95, 29.19, 36.71, 39.80, 40.09, 160.79; IR (KBr) 2904, 2848, 1582, 1450, 1342, 1280, 1250, 1100, 1028, 838 cm^{-1}; UV/Vis (CH_2Cl_2) 268 nm (ε=20000); MS m/z 382 (M^+). Anal. ($C_{24}H_{34}N_2S$) C, H, N.

General Procedure for the Preparation of 3,6-Disubstituted Pyridazines (3) from 2,7-Dihydro-1,4,5-thiadiazepines (2). A suspension of a 2,7-dihydro-1,4,5-thiadiazepine (**2**, 1 mmol) in diethylene glycol (10 ml) was heated under reflux until the starting **1** had been completely consumed (for the time of refluxing, see the Scheme 1). The evolution of hydrogen sulfide during the reaction was observed in every case. The mixture was cooled to room temperature and the resulting crystalline precipitate of **3** was collected by filtration, washed with a small amount of cold methanol or ethanol, and recrystallized from an appropriate solvent. The original filtrate and washings were combined, diluted with water, and extracted with dichloromethane. The extract was purified by column chromatography on silica gel to give an additional amount of **3**.

3,6-Diphenylpyridazine (3a): mp 222—223 °C (lit,[3] mp 222 °C; ^1H NMR ($CDCl_3$) δ=7.40—8.20 (10H, m), 7.87 (2H, s); ^{13}C NMR ($CDCl_3$) δ=126.62, 128.30, 129.01, 136.21, 138.54, 157.67.

3,6-Bis(4-methylphenyl)pyridazine (3b): mp 231—232 °C (lit,[3] mp 236 °C); ^1H NMR ($CDCl_3$) δ=2.43 (6H, s), 7.33 (4H, d, J=8 Hz), 7.86 (2H, s), 8.04 (4H, d, J=8 Hz) ^{13}C NMR ($CDCl_3$) δ=21.25, 123.75, 126.73, 129.71, 133.45, 140.06, 157.34.

3,6-Bis(4-methoxyphenyl)pyridazine (3c): mp 238—240 °C (lit,[10] mp 235 °C); ^1H NMR ($CDCl_3$) δ=3.89 (6H, s),

7.06 (4H, d, J=9 Hz), 7.83 (2H, s), 8.11 (4H, d, J=9 Hz).

3,6-Bis(4-chlorophenyl)pyridazine (3d): mp 265—267 °C (lit,[11] mp 264 °C; ^{1}H NMR ($CDCl_3$) δ=7.52 (4H, d, J=9 Hz), 7.91 (2H, s), 8.11 (4H, d, J=9 Hz).

3,6-Bis(4-bromophenyl)pyridazine (3e): mp 285—286 °C (lit,[3] mp 288 °C); ^{1}H NMR ($CDCl_3$) δ=7.68 (4H, d, J=9 Hz), 7.91 (2H, s), 8.04 (4H, d, J=9 Hz).

3,6-Di-2-naphthylpyridazine (3f): mp 280—281 °C; pale yellow crystals from 1,2-dichloroethane; ^{1}H NMR ($CDCl_3$) δ=7.56—7.58 (4H, m), 7.92—7.94 (2H, m), 7.99—8.05 (4H, m), 8.15 (2H, s), 8.36—8.39 (2H, m), 8.67 (2H, s). HRMS Found: m/z 332.1311. Calcd for $C_{24}H_{16}N_2$: M, 332.1314.

3,6-Di-4-biphenylylpyridazine (3g): mp 357—359 °C; white powder (purified by sublimation at 345—350 °C/0.01 Torr); ^{1}H NMR ($CDCl_3$) δ=7.38—8.26 (18H, m), 8.01 (2H, s); IR (KBr) 1584, 1486, 1418, 1166, 1040, 1002, 828, 758, 718, 682, 582, 472 cm^{-1}. Anal. ($C_{28}H_{20}N_2$) C, H, N.

3,6-Di-2-thienylpyridazine (3h): mp 181—182 °C (lit,[12] mp 175—176 °C); ^{1}H NMR ($CDCl_3$) δ=7.13 (2H, dd, J=5, 4 Hz), 7.47 (2H, dd, J=5, 1 Hz), 7.63 (2H, dd, J=4, 1 Hz), 7.71 (2H, s).

3,6-Bis(5-chloro-2-thienyl)pyridazine (3i): mp>300 °C (decomp); yellow crystals from benzene; IR (KBr) 1554, 1444, 1122, 1014, 838, 788, 530, 456 cm^{-1}; MS m/z, M^+ (relative intensity) 312 (100), 314 (85), 316 (25). Anal. ($C_{12}H_6Cl_2N_2S_2$) C, H, N.

3,6-Bis(5-bromo-2-thienyl)pyridazine (3j): mp>300 °C (decomp): yelllow crystals from benzene; IR (KBr) 1552, 1436, 1122, 838, 790, 746, 586 cm^{-1}. HRMS Found: m/z 401.8309. Calcd for $C_{12}H_6{}^{79}Br^{81}BrN_2S_2$: M, 401.8318.

3,6-Di-*t*-butylpyridazine (3k): mp 179—180 °C; white crystals from pentane; ^{1}H NMR ($CDCl_3$) δ=1.44 (18H, s), 7.44 (2H, s); ^{13}C NMR ($CDCl_3$) δ=30.00, 36.53, 123.10, 167.58; IR (KBr) 2972, 1588, 1538, 1482, 1366, 1152, 1038, 872 cm^{-1}. Anal. ($C_{12}H_{20}N_2$) C, H.

3,6-Di-1-adamantylpyridazine (3l): mp 278—280 °C; white crystals from methanol; ^{1}H NMR ($CDCl_3$) δ=1.61—2.08 (30H, m), 7.37 (2H, s); ^{13}C NMR ($CDCl_3$) δ=28.68, 36.70, 38.16, 41.73, 122.72, 167.25; IR (KBr) 2904, 2848, 1582, 1452, 1422, 1312, 1056, 810 cm^{-1}. Anal. ($C_{24}H_{32}N_2$) C, H, N.

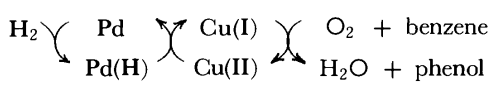
Catalytic Oxygenation of Benzene. Catalyst Design and Its Performance

Atsutaka KUNAI,* Takayuki WANI, Yasushi UEHARA, Fumiaki IWASAKI, Yasushi KURODA, Sotaro ITO, and Kazuo SASAKI
Department of Applied Chemistry, Faculty of Engineering, Hiroshima University, Shitami, Saijo-cho, Higashi-Hiroshima 724
(Received March 18, 1989)

A catalyst system for oxygenation reaction of benzene has been discussed. The catalyst system is composed of Pd and Cu species and operates in neat benzene under ambient conditions by feeding hydrogen and oxygen to the system. By selecting the reaction conditions properly, either phenol or benzoquinone is obtained as the major product.

There is a strong demand in the chemical industry to produce phenol or phenolic compounds in much more efficient ways.[1] Undoubtedly, the most efficient process currently operating in the chemical industry is the "Cumene Process." This process, however, necessitates multi-step operations throughout the whole process and accompanies by-production of equimolar amount of acetone. If benzene is directly converted to phenols without any by-product under moderate conditions, a great benefit will be brought about.

Many reactions are known which lead to phenol from benzene.[1,2] They are, however, too much basic[3-6] to be used for the practical purpose or require severe reaction conditions[7,8] and/or expensive chemical reagents.[7,9] In this paper, we report the nature and the performance of some new solid catalysts developed for the one-step production of phenol.



Scheme 1.

The catalyst system is basically composed of Pd and Cu species and operates in neat benzene under ambient conditions by feeding hydrogen and oxygen gases. The reaction sequence occurring in this system may be expressed as in Scheme 1, where palladium mediates electron transfer from hydrogen to copper(II) ions. The copper(I) ions thus produced activate dioxygen to produce phenol. Furthermore, the main product can be altered at will from phenol to *p*-benzoquinone if the reaction conditions are slightly modified. It should be noted that no effective catalyst has been known so far for the direct conversion of benzene to benzoquinone.

Experimental

Catalyst Preparation. The solid catalysts examined in this study were prepared in three different ways. **Catalyst A:** $PdCl_2$ (0.5 mmol), Cu(II) salt (10 mmol), and silica gel (10 g, Merck No. 9385, 230—400 mesh ASTM) were added to water (30 cm^3) altogether and exposed to ultrasonic wave for 90 min. The resultant mixture was heated to dryness on a steam bath under gentle agitation. **Catalyst B:** $PdCl_2$ was first dissolved in dil HCl (30 cm^3) and Cu(II) salt and silica gel were then added to the solution. The mixture was dried in the same way as described in the catalyst A. **Catalyst C:** A mixture of $PdCl_2$ and silica gel in water was stirred at 60 °C for 2 h to disperse the Pd salt on the silica surface. Copper(II) sulfate was then loaded on it. The mixture was dried in the same manner as described above.

Oxidation of Benzene. Experiments under atmospheric conditions were conducted in an Erlenmeyer flask (50 cm^3) equipped with two gas inlets and one outlet. A mixture of benzene (20 cm^3) and the catalyst (2 g) was taken in the flask and shaken in a thermostated bath at 25 °C at the rate of 140 times/min with 30 mm stroke under atmospheric pressure. The reacting gases were fed to the flask in two different modes. **(1) Simultaneous gas feeding:** During the whole reaction, both hydrogen and oxygen were passed through the flask simultaneously. **(2) Alternate gas feeding:** Gases in the flask were first replaced with hydrogen and shaken for a desired time. Hydrogen was then switched to either air or pure oxygen and the flask was again shaken. This alternate gas feeding was repeated several times in some experiments.

Experiments under pressurized conditions were carried out in a glass-made autoclave equipped with a mechanical stirrer by applying the alternate gas-feeding.

Product Analysis. During the reaction, a small amount of sample was taken up periodically for HPLC analysis. The products were analyzed by using Merck Lichrosorb RP-18 (10×250 mm) as the stationary phase and a solution of acetonitrile–phosphate buffer of pH 3.5 (1 : 3) as the eluent.

Results and Discussion

1. Catalyst Design. The solid catalyst designed in this study is basically composed of 2 mmol of copper(II) sulfate and a catalytic amount of palladium chloride (0.1 mmol) supported on 2 g of silica. By feeding hydrogen, $PdCl_2$ is reduced to metallic Pd.

As for the role of copper species in the oxidation of benzene, we have already demonstrated that, in aqueous acid solutions, low valent copper ions activate dioxygen to generate hydroxyl radicals (Eqs. 1 and 2), which react with benzene to yield phenolic compound (Eq. 3).[10-13]

$$O_2 + 2Cu^+ + 2H^+ \longrightarrow H_2O_2 + 2Cu^{2+} \quad (1)$$

Table 1. Catalytic Oxidation of Benzene by Simultaneous Feeding of Hydrogen and Oxygen[a)]

Reaction time/h	0.5	1	2	3	4	5	6	7	8	9
PhOH/μmol	4.7	15	48	77	114	141	167	183	205	229

a) The reaction was carried out using the catalyst C by simultaneous feeding of H_2 and O_2.

Table 2. Effect of Oxidation Time on the Phenol Yield[a)]

Oxidation time/min	5	10	15	20	25	30
PhOH/μmol	18.2	18.6	19.5	19.3	19.6	19.8

a) The reaction was carried out using the catalyst C by alternate feeding of H_2 and O_2. The oxidation started after the catalyst had been treated under H_2 for 90 min.

$$H_2O_2 + Cu^+ + H^+ \longrightarrow \cdot OH + Cu^{2+} + H_2O \quad (2)$$

$$\cdot OH + C_6H_6 + Cu^{2+} \longrightarrow C_6H_5OH + Cu^+ + H^+ \quad (3)$$

Since Cu(I) ions are consumed during the reaction, it is necessary to recycle Cu(I) ions by some suitable means in order to set up a continuous reaction system. This may be performed by using hydrogen as the reducing agent when certain metal catalyst is present in the system. Palladium seemed to be the best candidate among such catalysts (Eq. 4).[14)]

$$2\,Cu^{2+} + H_2 \xrightarrow{Pd} 2\,Cu^+ + 2\,H^+ \quad (4)$$

The overall stoichiometry of the reactions expressed by Eqs. 1—4 can simply be summarized as in Eq. 5 for phenol or in Eq. 6 for benzoquinone. It is interesting to see that the overall reaction of this system resembles in some sense the reactions catalyzed by oxygenase, where dioxygen is activated by some electron-transfer systems to be incorporated in organic substrates. The equations predict that either phenol or benzoquinone will be produced continuously by feeding both hydrogen and oxygen.

$$C_6H_6 + H_2 + O_2 \longrightarrow C_6H_5OH + H_2O \quad (5)$$

$$C_6H_6 + H_2 + 2\,O_2 \longrightarrow C_6H_4O_2 + 2\,H_2O \quad (6)$$

2. Reactions with Catalysts Made from $CuSO_4$. As will be described in the later section, counter ions of copper salts in the catalyst show a definite effect on the reaction pathways. In this section, the nature of the catalyst made from $CuSO_4$ is discussed.

At first, the catalytic oxidation of benzene was conducted by feeding hydrogen and oxygen simultaneously at 25 °C for 9 h. Table 1 shows results obtained with the catalyst C. As is seen in the table, phenol accumulates steadily with increasing reaction time except for the initial period of the reaction, indicating that the catalytic cycle supposed in Scheme 1 is effectively operating. The anomaly appearing in the initial stage may be due to the reduction of Pd(II) to Pd(0).

The simultaneous gas feeding has a definite risk of explosion. We accordingly examined the performance of the alternate gas feeding, where the catalyst may be activated to produce Cu(I) ions in the stage of hydrogen and benzene may be oxidized in the stage of oxygen. The latter method has an additional merit to present separately the behaviors of the catalyst during each stage of hydrogen and oxygen. The results shown in Table 2 were given by using the catalyst C, which was treated with hydrogen for 90 min. The yields of phenol were almost unchanged while the oxidation time was varied from 5 to 30 min,

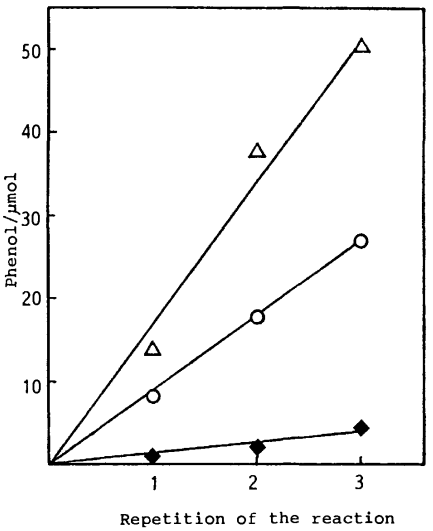


Fig. 1. Effect of reduction time on the phenol yield. The reactions were carried out using catalyst C by applying alternate feeding of H_2 and O_2. Symbols stand for the reduction time of 15 (◆), 30 (○), and 90 (△) min, respectively. Oxidation time was fixed at 5 min.

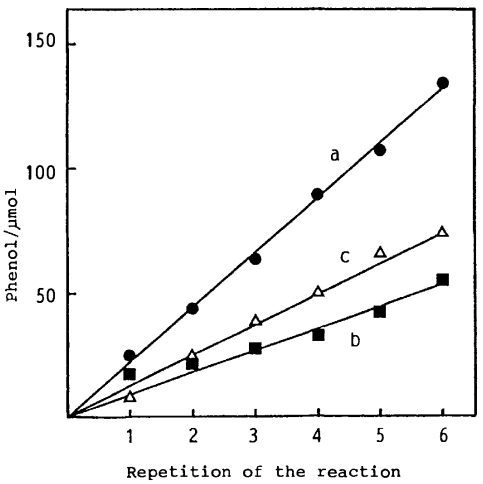

Fig. 2. Effect of preparation methods on the catalyst performance. The reactions were carried out in the same manner as described in Table 3 except that hydrogen reduction (30 min) and air-oxidation (30 min) were applied in each reaction cycle. Symbols stand for the catalysts of type A (●), B (■), and C (△), respectively.

Table 3. Effect of Catalyst Composition on the Phenol Yield[a)]

Run	Catalyst composition			Additive	Product
	SiO_2/g	$CuSO_4$/mmol	$PdCl_2$/mmol	CH_3COOH/g	Phenol/μmol
1	2	2	0.1	1	83
2	2	2	0.1	0	51
3	2	2	0.2	0	50
4	2	2	0	1	0
5	2	2	0	0	0
6	2	0	0.1	1	3
7	2	0	0.1	0	Trace
8	0	2	0.1	1	Trace
9	0	2	0.1	0	Trace
10	2	2	b)	0	4
11	c)	2	0.1	0	5

a) The reactions were performed using the catalysts corresponding to type A by applying alternate feeding of H_2 for 2 h and air for 1 h. In Runs 8 and 9, powdery mixture of $CuSO_4$ and $PdCl_2$ were used without support. b) H_2PtCl_6 (0.1 mmol) was used instead of $PdCl_2$. c) Alumina (2 g) was used instead of silica.

indicating that the time for 5 min must be enough to complete the oxidation.

In order to see the behavior of catalyst activation under hydrogen atmosphere, the time of hydrogen treatment was varied while the oxidation time was fixed at 5 min. The same process was repeated up to 3 times for each reaction. Results obtained were plotted in Fig. 1, which indicated that the catalyst activation with hydrogen was rather a slower step and the activation was still insufficient even after 90 min.

It should be noted that the preparation method of the catalysts affects the catalyst performance appreciably. This is shown in Fig. 2, where hydrogen and air were fed alternately by a period of every 30 min and the hydrogen/air cycle was repeated 6 times. Lines a, b, and c in the figure stand for results obtained with the catalysts A, B, and C, respectively. Undoubtedly, the catalyst A gave the best result among the three catalysts tested. The rate of phenol production with the catalyst A amounted to 22 μmol per cycle, compared with the corresponding rates of the catalysts B and C (9 μmol and 13 μmol, respectively).

The catalyst A was prepared by using ultrasonic wave for dispersing Pd salt on the silica surface instead of mechanical stirring which was employed for the catalyst C. The different performance appearing in the figure may be attributed to the size and distribution of the catalyst components, particularly of Pd. Superiority of using ultrasonic wave is doubtless.

In contrast, the performance of the catalyst B was the worst among the three. In order to ensure the complete dissolution of $PdCl_2$, this catalyst was prepared by dissolving $PdCl_2$ with a small amount of dil HCl. The worst performance is probably caused by excess chloride ions left in the catalyst.

Results in Table 3 prove that each catalyst component fills its own role in the catalytic cycle. In experiments for this table, the catalysts corresponding to type A were first activated with hydrogen for 2 h and then used for air-oxidation of benzene for 1 h. It is clearly indicated that, as far as the alternate gas feeding is concerned, the best performance is obtained only when Pd and Cu species are both loaded on the silica surface (Runs 1 to 3).[15)]

When $PdCl_2$ was replaced by H_2PtCl_6 (Run 10), phenol was certainly produced, but the yield was low. The catalyst composed of Pd alone produced only a trace amount of phenol (Runs 6 and 7). The absence of silica support seriously decreased the catalyst activity (Runs 8 and 9). When alumina was used instead of silica (Run 11), the yield of phenol decreased markedly, indicating that the supporting material should be hydrophilic and acid-resistant. Silica appears to satisfy these requirements. On the other hand, the inefficiency of alumina catalyst may be attributed to the degradation of alumina surface with sulfuric acid liberated during the reduction of Cu(II) salt.[16)]

3. Effect of Counter Ion in Cu Salts. Previous studies have shown that phenol and hydroquinone are formed competitively from the same intermediate, hydroxycyclohexadienyl radical (Eq. 7).[13)] The product selectivity was quite sensitive to the pH value of aqueous solution.[12)] Phenol predominated in solutions of lower pH, but the relative yield of hydroquinone to phenol (HQ/P) increased markedly with the increase in pH. At about pH=3.5, the HQ/P ratio became 2.5.

$$\cdot OH + C_6H_6 \longrightarrow \cdot C_6H_6OH \begin{cases} \longrightarrow \text{Phenol} \\ \longrightarrow \text{HQ} \end{cases} \quad (7)$$

In the present case, the solution phase is neat benzene and the acidity control in it seems difficult. There is, however, a possibility of controlling the acidity over the surface of the solid catalyst used here.

Table 4. Oxidation of Benzene with Catalysts Made from Various Cu Salts[a)]

Cu salt of	PhOH/μmol	BQ/μmol	Cu salt of	PhOH/μmol	BQ/μmol
SO_4^{2-}	51	5.2	PO_4^{3-}[b)]	40	0.1
Cl^-	0	0	AcO^-	0.4	0
NO_3^-	32	2.2	AcO^-[c)]	34	7.3
ClO_4^-	64	1.0			

a) The reaction was carried out in the same manner as Table 3. b) Phosphoric acid (0.85g) was also loaded onto the support. c) Acetic acid (2 g) was dissolved into benzene.

Table 5. Effect of Oxygen Pressure on the Product Selectivity[a)]

Cu salt	AcOH/vol%	Ratio of BQ/PhOH (Total products/μmol)			
		air, 1 atm	O_2, 1 atm	O_2, 3 atm[b)]	O_2, 6 atm[b)]
$Cu(OAc)_2$	2.5	—	0.79 (47.1)	1.50 (29.6)	—
	5.0	0.16 (24.6)	0.63 (44.2)	1.53 (57.6)	1.39 (29.6)
	10.0	0.20 (41.0)	0.61 (62.6)	0.84 (45.8)	—
	20.0	—	0.45 (43.4)	—	—
$CuSO_4$	0	0.10 (56.2)	0.11 (37.0)	0.12 (70.6)	—
	10.0	0.01 (31.2)	0.15 (39.0)	—	—

a) The reactions were carried out in the same manner as Table 3. b) Hydrogen reduction was also done under the same pressure.

During the stage of catalyst activation with hydrogen, copper(II) salt, CuX_2, is reduced to CuX and liberates free acid, HX (Eq. 8). Accordingly, we can expect that the acid strength of HX affects the fate of the intermediate species.

$$2\,CuX_2 + H_2 \longrightarrow 2\,CuX + 2\,HX \qquad (8)$$

This point was examined using several copper(II) salts as listed in Table 4. Reactions were conducted with the catalysts of type A in the same manner as noted on the margin of Table 3.

For salts of strong acid, sulfate, nitrate, and perchlorate, the reaction proceeded to produce 30—50 μmol of phenol. In contrast, no reaction was observed in the case of chloride. This is because initial activation of $PdCl_2$ to Pd(0) did not occur as was confirmed by visual observation.

In the case of acetate salt, when no particular treatment was applied, hydrogen reduction of Cu(II) to Cu(I) ions was extremely slow leading to a very low yield of phenol. For accelerating the reaction, addition of free acid was found to be effective. In fact when a small amount of acetic acid was added deliberately to benzene, the reaction proceeded at a reasonable rate. The yield of benzoquinone was still minor.

It is interesting to see that, however, the relative yield of *p*-benzoquinone vs. phenol (Q/P) increases in the following order: $ClO_4^- < NO_3^- < SO_4^{2-} < AcO^-$: the sequence being in accordance with the decreasing acid strength of their corresponding free acids.

In the case of phosphate salt, the yield of quinone is exceptionally low. In this case, phosphoric acid was used and impregnated onto the silica support during the process of catalyst preparation, because the phosphate salt was hardly soluble in water. Regarding this, it should be noted that the silica surface modified with phosphoric acid exhibits a strong acidity. In fact, the Hammett's H_0 function of the modified surface is said to be comparable with that of sulfuric acid.[17)]

4. Alteration of Product Selectivity. In the foregoing section, it has been indicated that the control of surface acidity permitted alteration of the product selectivity: Q/P varies from 0.02 in perchlorate case to 0.21 in acetate case. This tendency may be amplified by increasing oxygen concentration, since benzoquinone comes from the adduct of hydroxycyclohexadienyl radical with dioxygen.[11)] This point was investigated with the use of the acetate catalyst made by procedure A. Results are summarized in Table 5.

The data of the acetate catalyst indicate that the product ratio is sensitive to the oxygen pressure in the surrounding gas. As far as the oxygen source was ordinary air, the product ratio, Q/P, was only 0.21 even in the highest case. At 5% level of acetic acid added deliberately, the value increased from 0.16 to 1.53 corresponding to the change of oxygen pressure from 0.2 (air) to 3 atm, respectively. At 6 atm, the value tended to saturate. An addition of acetic acid was necessary for accelerating the reaction rate. As the data indicated, however, excess addition of it seemed to affect the Q/P ratio negatively.

In Table 5, are also shown the data for the sulfate catalyst for comparison. The Q/P ratio, in this case, never exceeded 0.15 even if pressurized oxygen was supplied. This clearly indicates that oxygen effect saturates below 1 atm when Cu salt is of a strong acid. In other words, the choice of counter ion is quite important for the effective performance of the diox-

ygenation reaction of benzene. The effect of counter ion is in agreement with our previous observation, where we have found that the pressure effect is pH dependent and saturates at low level at lower pH.[12]

Seemingly complicated effects of oxygen pressure, acid concentration, and counter ion in Cu salt are a reflection of multivariable nature of the reaction system. The highest value attained here, ca. Q/P=1.5, seems rather low, but we believe that the value will be improved by further modification of the reaction conditions.

The catalyst system described above has several advantages. Firstly, the reaction can be performed under very mild conditions and hence the total selectivity of oxygenated products, phenol and benzoquinone, is quite high. No other product is detected in the reaction mixture. Secondly, the catalyst preparation is simple and the catalysts having the same activity are always obtained. Thirdly, benzene can directly react with catalysts without any use of solvents. This fact leads to an additional advantage, i.e. the extremely simple isolation of the reaction products. Finally, either phenol or benzoquinone can be selectively obtained at will by a slight modification of the reaction conditions. With the use of the copper perchlorate catalyst, phenol is almost exclusively produced regardless of other conditions. Air is sufficient as the oxygen source. On the other hand, benzoquinone is obtained as the major product when the copper acetate system is employed in combination with the use of slightly pressurized oxygen.

Total Synthesis of Erythronolide A[1)]

Masaya NAKATA,* Masayuki ARAI, Katsuhiko TOMOOKA,
Naoki OHSAWA, and Mitsuhiro KINOSHITA*
Department of Applied Chemistry, Faculty of Science and Technology, Keio University,
Hiyoshi, Kohoku-ku, Yokohama 223
(Received March 29, 1989)

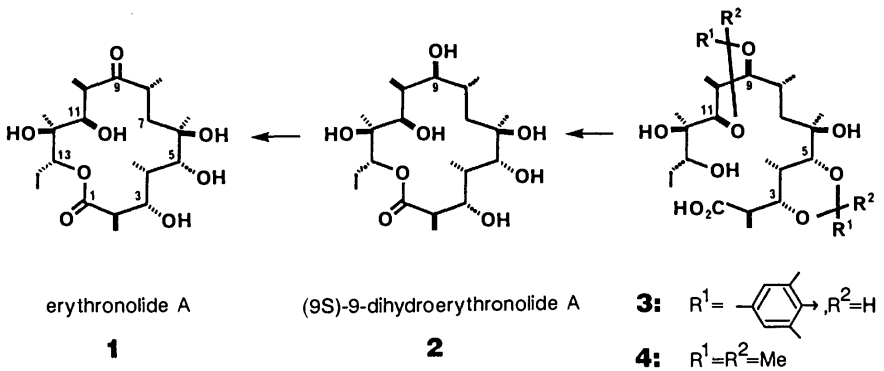
The enantiospecific total synthesis of erythronolide A (**1**) through (9*S*)-9-deoxo-9-hydroxyerythronolide A (**2**) from the chiral C1—C6, C7—C9, and C10—C13 synthetic segments is described. The C10—C13 segment, (3*R*,4*R*,5*R*)-5-*O*-benzyl-2-iodo-3,4-*O*-isopropylidene-4-methyl-1-heptene-3,4,5-triol (**11**) was synthesized in 16 steps and an 8.3% overall yield from D-ribose. The C7—C9 segment, (*S*)-(+)-2-(2-bromo-1-methylethyl)-1,3-dioxolane (**47**) was prepared from methyl (*S*)-(+)-3-hydroxy-2-methylpropionate in 8 steps and a 49% overall yield. The coupling of the Grignard reagent, prepared from magnesium and **47**, and the C1—C6 segment, 3,5,7-tri-*O*-benzyl-1,4,6-trideoxy-4,6-di-*C*-methyl-*keto*-L-*ido*-2-heptulose (**13**), afforded 5,7,9-tri-*O*-benzyl-2,3,6,8-tetradeoxy-2,4,6,8-tetra-*C*-methyl-L-*threo*-L-*ido*-nonose ethylene acetal (**48**) and its C4-epimer in 79% and 8% yields, respectively. 5,7,9-Tri-*O*-benzyl-4-*O*-*t*-butyldimethylsilyl-2,3,6,8-tetradeoxy-2,4,6,8-tetra-*C*-methyl-L-*threo*-L-*ido*-nonose (**12**), derived from **48**, was subjected to coupling reaction with the lithium reagent prepared from **11** to afford about 5 : 1 excess of the "Cram" product **50**. The homogeneous hydrogenation of **50** with [ClRh(Ph$_3$P)$_3$] gave 1,3,5,13-tetra-*O*-benzyl-6-*O*-*t*-butyldimethylsilyl-2,4,7,8,10,14,15-heptadeoxy-11,12-*O*-isopropylidene-2,4,6,8,10,12-hexa-*C*-methyl-D-*arabino*-D-*gluco*-L-*ido*-pentadecitol (**54**) and its C10-epimer in 41% and 7% yields from **12**, respectively. The conversion of **54** to **2** was accomplished by a sequence of reactions including the Corey-Nicolaou lactonization method in a 17% overall yield. Selective 3,5-*O*-benzylidenation of **2** followed by PCC oxidation and debenzylidenation gave **1** in 52% yield.

During the last decade, the total syntheses of various types of macrolide antibiotics have been achieved and well documented.[2)] Of these macrolides, erythromycin A is an extremely important 14-membered macrolide antibiotic.

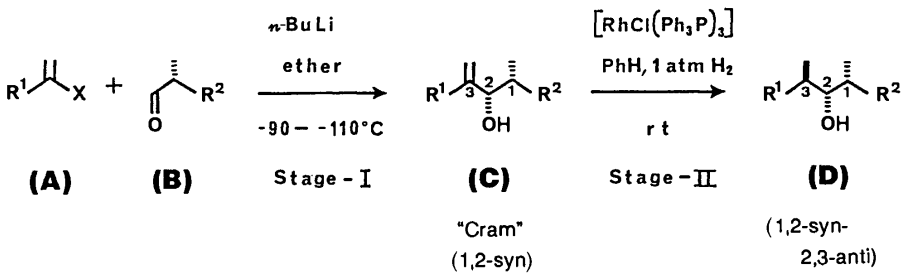
The only total synthesis of erythromycin A has been accomplished by Woodward and collaborators.[3)] After the first completion of the total synthesis of erythronolide A, aglycone of erythromycin A, by Corey et al. in 1979,[4)] several groups have succeeded in the synthesis of erythronolide A or the key intermediate carbamate in Woodward's total synthesis of erythromycin A.[5)] We wish to report in this full account[6)] the details of the total synthesis of erythronolide A.

Synthetic Strategy. We chose (9*S*)-9-deoxo-9-hydroxyerythronolide A (**2**) as a synthetic precursor of erythronolide A (**1**) by anticipating that the former could be converted into the latter through straightforward short steps (Scheme 1). Moreover, in the previous syntheses of erythronolide A,[4,5)] **2** has never been utilized as a practical synthetic precursor. The first crucial step for the synthesis of **2** should be the macrolactonization of the suitably protected seco-acid. In that sense, Woodward et al.[3)] had investigated extensively the structure-reactivity relationships of the lactonization. They concluded that *S*-configuration at C9 and cyclic protecting groups at C3/C5 and C9/C11 are required for efficient lactonization. Indeed, they realized good yield of lactonization of the naturally derived (9*S*)-9-hydroxy seco-acid 3,5 : 9,11-bis(cyclic acetal) derivative **3** by the Corey-Nicolaou method.[7)] By this fact, we thought the diacetonide **4** would be also a good precursor for the Corey-Nicolaou macrolactonization method, giving **2**.

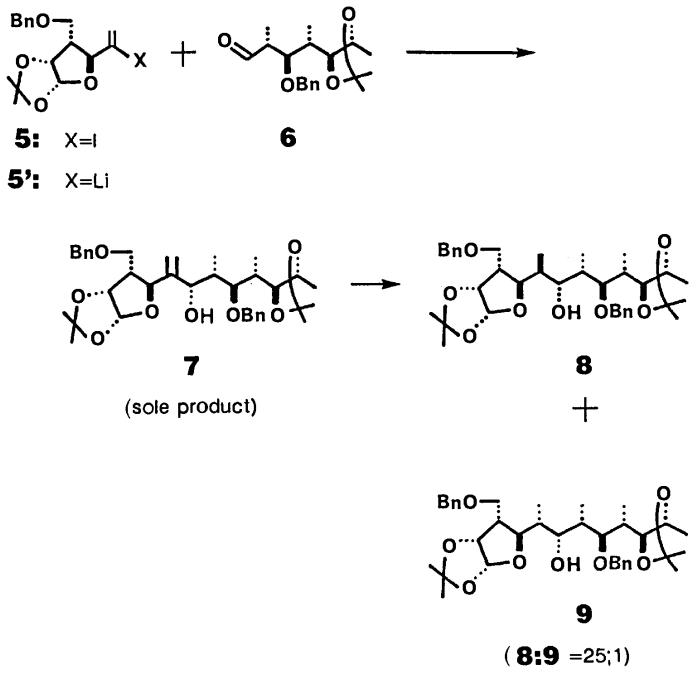
The next crucial step should be the effectively stereocontrolled enantiospecific synthesis of the key intermediate **4**. This seemed to be solved by the synthetic plan which was guided by our "two-stage coupling process."



Scheme 1.



Scheme 2.

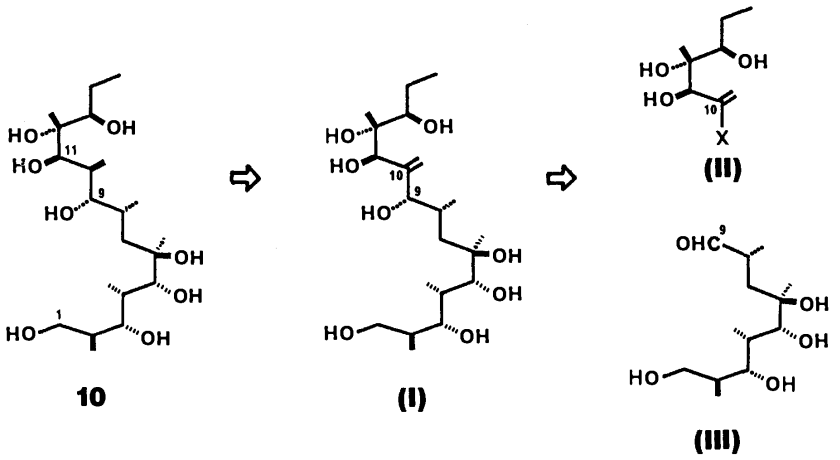


Scheme 3.

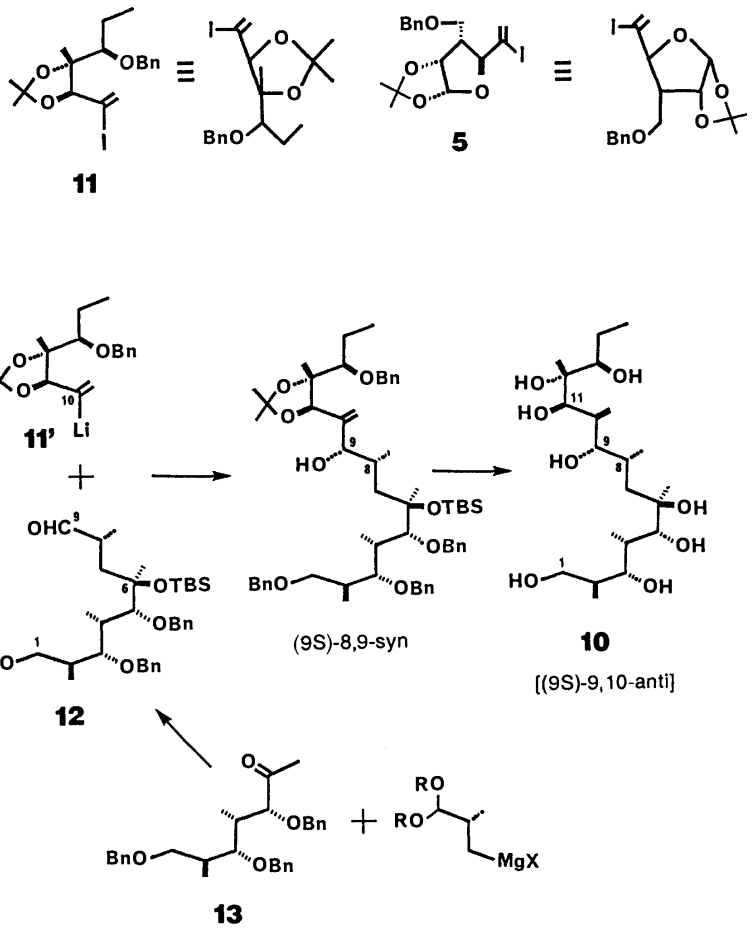
This new coupling process consists of two consecutive reaction stages (Scheme 2). The first stage is the "Cram (1,2-syn)" selective coupling reaction of a chiral vinyl halide (**A**) with a chiral α-methyl aldehyde (**B**) and the second one is the highly 2,3-anti-selective homogeneous hydrogenation of the major Cram type intermediary coupling product (**C**) with Wilkinson's catalyst. Consequently, the coupling of (**A**) and (**B**) by this process affords preferencially the final product (**D**) with 1,2-syn-2,3-anti configuration. In fact, this process was practicable in the enantiospecific synthesis of the ansa-chain portion of rifamycin W.[8] One example is showen in Scheme 3. The reaction of the chiral vinyllithium reagent **5'** prepared from the vinyl iodide **5** and the chiral (2*R*)-2-methyl aldehyde **6** gave a sole coupling product **7** (61% yield), which was subsequently hydrogenated homogeneously to give the anti-product **8** (95% yield) and the syn-product **9** (3.8% yield).

We can see in the polyol **10**, which is the hypothetical precursor of **4**, the three consecutive carbon chain (C8 to C10) having a 1,2-syn-2,3-anti configuration (Scheme 4). Therefore, a "two-stage coupling process" disconnection of the C9–C10 bond affords two subunits, **II** and **III**, through the vinylidene compound **I**. As the perspective view of the strategic vinyl iodide **11**, corresponding to the suitablly protected subunit **II**, seemed to be similar to that of **5** (Scheme 5), the reaction of the vinyllithium reagent **11'**, prepared from **11**, and (2*R*)-2-methyl aldehyde **12**, corresponding to the subunit **III**, would provide predominantly the "Cram" type of (9*S*)-8,9-syn-product, which could be homogeneously hydrogenated to produce selectively the (9*S*)-9,10-anti-product convertible into the desired polyol **10**. The aldehyde **12**, with the desired C6 chiral center, would be formed predominantly by the α-chelation controlled addition reaction,[9] of an appropriately protected chiral Grignard reagent to the chiral methyl ketone **13**,[10] which was previously synthesized in our laboratories as a versatile C1—C6 segment of **1**.

Preparation of Vinyl Iodide 11. The acetonide **14**[11] was obtained in 83% yield by treatment of D-ribose in acetone with 2,2-dimethoxypropane and a catalytic



Scheme 4.



Scheme 5.

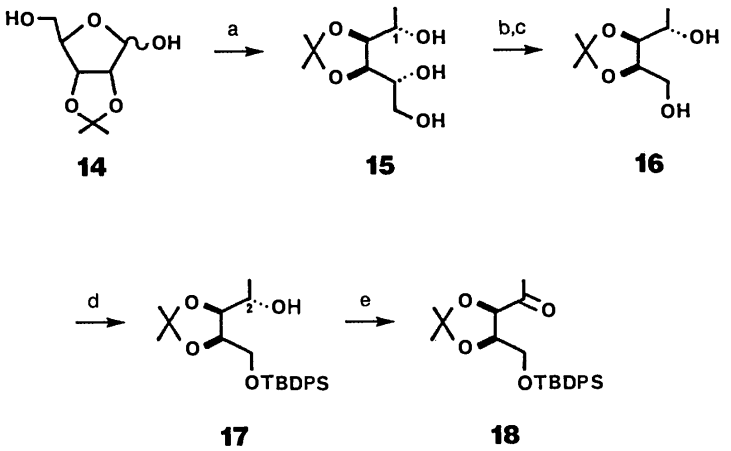
amount of H_2SO_4 (Scheme 6). The Grignard reaction of **14** with excess methylmagnesium iodide in diethyl ether afforded the alcohol **15** as a sole product in 73% yield. Regardless of the configuration at the newly formed Cl-stereocenter, the alcohol **15** can be used in the synthetic route since at a later stage this alcohol function is oxidized to a methyl ketone. We determined, however, its Cl-configuration (vide infra).

Oxidative cleavage of the glycol function in **15** with $NaIO_4$ followed by $LiAlH_4$ reduction of the resulting aldehyde afforded the alcohol **16** in 97.5% yield, whose primary alcohol was protected as its *t*-butyldiphenylsilyl (TBDPS) ether **17** (97%). Oxidation of **17** with PCC provided the methyl ketone **18** in a quantitative yield.

Since the attempts of 2-*O*-benzylation of **17** for the

purpose of straightforward determination of its (2*S*)-configuration was unsuccessful, the C2-epimer **19** was prepared (57%) along with **17** (28%) by $LiAlH_4$ reduction of **18** (Scheme 7). The 2-*O*-benzylation of **19** followed by removal of the silyl ether protecting group afforded the alcohol **20** in 91% yield. After treatment of **20** with aqueous acetic acid, the resulting triol was oxidized successively with $NaIO_4$ and CrO_3 to afford (*R*)-(+)-2-benzyloxypropionic acid **21**. The acid **21** was proved to be the enantiomer of the reported (*S*)-(−)-2-benzyloxypropionic acid[12] (see Experimental section).

The chelation controlled Grignard reaction of **18** with vinylmagnesium bromide in THF provided the products **22** and **23** in 94% yield as a 77:1 mixture of epimers (^1H NMR). Silica-gel chromatography separated **22** (85%) and **22**+**23** (8%; 5.7:1 mixture in favor of **22**) (Scheme 8). The (2*R*)-configuration of



Scheme 6. (a) MeMgI, ether; (b) $NaIO_4$, aq acetone; (c) $LiAlH_4$, THF; (d) TBDPSCl, imidazole, DMF; (e) PCC, MS 3AP, CH_2Cl_2.

22 was confirmed by the following manner. Reduction of double bond followed by $ZnBr_2$-promoted acetonide migration afforded **24**. After removal of the silyl ether protecting group, the diol was oxidized successively with $NaIO_4$ and KIO to give the carboxylic acid **25**, which was proved to be the epimer of **26**[13] by comparing optical rotation and ^1H NMR spectrum.

Ozonolysis of **22** followed by addition of ethylmagnesium bromide to the resulting aldehyde gave a ca. 1.6 : 1 mixture of the desired **27** and its epimer **28** in 63.5% combined yield. Since chromatographic separation of **27** and **28** was quite difficult, the isomeric

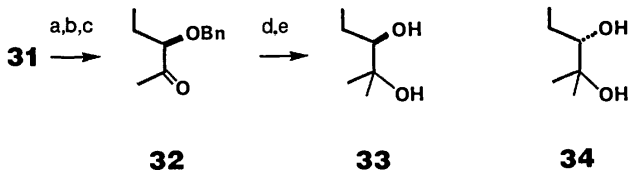
35

ratio was assumed based on the isolated yields of the chromatographycally separable products, **29** and **30**, obtained by desilylation of the epimeric mixture.

Direct *O*-benzylation of the mixture, **27** and **28**, with NaH and benzyl bromide in THF afforded fortunately only one isomeric *O*-benzyl derivative **31** (55%), and a 1 : 4.9 mixture of **27** and **28** was recovered (28%). The (3*R*)-configuration of **31** was confirmed by the following manner (Scheme 9). After desilylation of **31**,



32 **33** **34**

Scheme 9. (a) TBAF, THF; (b) 50% AcOH, 115 °C; (c) $NaIO_4$, aq acetone; (d) MeMgI, ether; (e) H_2/Pd, *t*-BuOH.

acidic hydrolysis of acetonide protecting group followed by $NaIO_4$ oxidation gave methyl ketone **32**. The Grignard reaction of **32** with methylmagnesium iodide followed by debenzylation gave the diol **33**. This diol (*R*)-(+)-**33** was proved to be the enantiomer of the reported (*S*)-(−)-**34**.[14] From this result, the configurations of the compounds **27**—**31** were established as depicted.

The aforesaid unchanged epimeric mixture in favor of the (3*S*)-epimer **28** was converted into the ketone **35** by DMSO-oxidation in 90% yield. $LiAlH_4$ reduction of **35** in diethyl ether at −78 °C gave a 5 : 1 epimeric mixture in preponderance of **27**, which was again benzylated to afford **31** in 55% yield from **35**; the total yield of **31** from **22** amounted to 43.8%. Brief exposure of **31** to 0.5 equiv of $FeCl_3$ in acetone led to the isomeric acetonide **36** (95%), which was desilylated to give **37** in 92% yield. Oxidative cleavage of the glycol function in **37** with $NaIO_4$ followed by successive treatment of the resulting aldehyde with methylmagnesium iodide and PCC provided the methyl ketone **38** in a 92% overall yield, which was converted through its hydrazone into the vinyl iodide **11** according to the improved procedure of Barton et al.[15] (Scheme 10).

Preparation of Aldehyde 12. With the chiral vinyl iodide **11**, C10—C13 segment of **1**, in hand, we turned our attention to the synthesis of the second requisite **12**, C1—C9 segment of **1**. For the purpose of synthesizing **12** from the previously prepared C1—C6 segment **13**,[10] an adequate C7—C9 segment had first to be inquired. After many unsuccessful attempts, the

most adequate synthetic segment was found to be (*S*)-(+)-2-(2-bromo-1-methylethyl)-1,3-dioxolane **47**.

As detailed below (Scheme 11), **47** was efficiently constructed from the known aldehyde **44**,[16] which in turn was prepared from the commercially available methyl (*S*)-(+)-3-hydroxy-2-methylpropionate **39**. Tritylation of **39** followed by $LiAlH_4$ reduction of the resulting unpurified **40** gave the alcohol **41**. Benzylation of **41** with NaH and benzyl bromide in THF gave **42**, which was hydrolyzed with Amberlyst 15 in methanol to afford the alcohol **43**. Swern oxidation of **43** gave the aldehyde **44**, which was directly acetalized with ethylene glycol and *p*-toluenesulfonic acid in acetonitrile to provide **45**. After hydrogenolysis of **45**, the resulting alcohol **46** was transformed into the desired bromide **47** by treating with ethyl bromid-triphenylphosphine and diethyl azodicarboxylate[17] in THF in a 49% overall yield from **39**.

The methyl ketone **13** was treated in diethyl ether with an excess Grignard reagent prepared from 13 equiv of magnesium and 4.3 equiv of **47** to afford the alcohol **48** and its C4-epimer in 79% and 8% isolated yield, respectively (Scheme 12). The configuration at the newly formed C4-stereocenter was assumed to be (*R*) by considering the α-chelation controlled Grignard addition reaction,[9] and established at a later stage. Thus obtained **48** was silylated with *t*-butyldimethylsilyl triflate (TBSOTf) and 2,6-lutidine in CH_2Cl_2 to give **49** in 89% yield. The last step in the synthesis of the aldehyde **12** was to remove the acetal protecting group in **49**. This transformation proved to be troublesome to some extent. Among a wide variety of conditions employed, tin(II) chloride-acetone combination gave satisfactory yield of **12** (72%).

Preparation of Polyol Derivative 56. The stage was now set for us to examine the feasibility of the stereocontrolled coupling between **11** and **12** (Scheme 13). A 1.9 M ethereal solution (1 M=1 mol dm^{-3}) of **11** (3 equiv) was lithiated with 3 equiv of butyllithium at −100 °C for 15 min under argon. To this solution was added a 0.3 M etherial solution of **12** (1 equiv) and stirred at −100 °C for 1 h. Quenching with saturated aqueous NH_4Cl followed by chromatographic isolation afforded the major coupling product **50** (ca. 50%

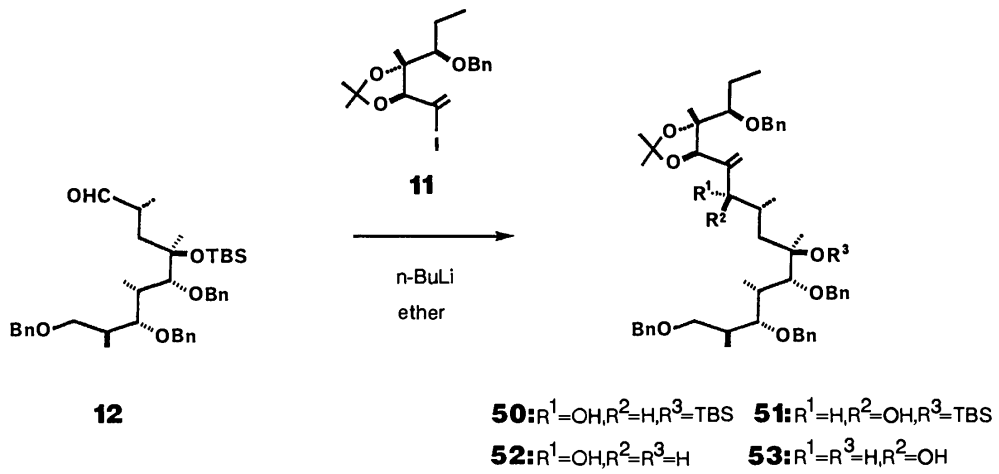
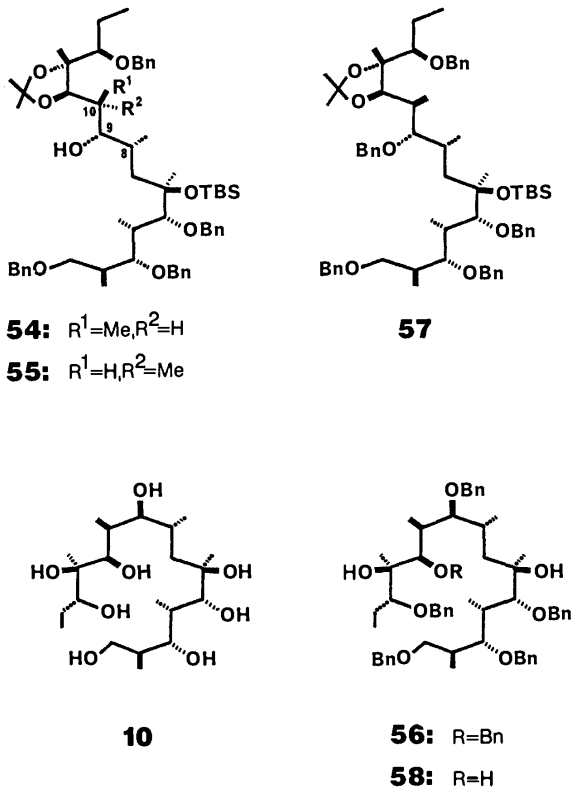


Scheme 13.

yield from **12**) contaminated with a by-product, probably one of the by-products originated from **11**, and the pure minor one **51** (10% yield from **12**). The yield of **50** was assumed based on the yield of **51** and on a ratio (5 : 1) of the corresponding separable desilylation products (**52** and **53**), derived from the crude mixture of **50** and **51**. The next step was homogeneous hydrogenation of the desired Cram type coupling product **50**. Usually this type of reaction is carried out smoothly at room temperature and 1 atm H_2 in benzene solution with 0.25 equiv of [ClRh(Ph_3P)$_3$] as catalyst for several hours.[8] However, hydrogenation of **50** under the usual conditions was very slow. After several experiments, we found that the crude **50** was homogeneously hydrogenated in benezene with 0.25 equiv of [ClRh(Ph_3P)$_3$] under 50 atm H_2 at 24 °C for 5 d to afford **54** 41% from **12**) and its C10-epimer **55** (7% from **12**). Hydrogenation of **50** was also carried out using [Rh(NBD(DIPHO-4)]BF_4[18] instead of the Wilkinson's catalyst, but no improvements in the reaction rate and the isomeric ratio were observed. The configuration of **54** was confirmed by the following manner. After desilylation and deacetonization of **54** with 46% aqueous HF-acetonitrile, the resulting alcohol was benzylated with 4 equiv of benzyl chloride and 8 equiv of KOH in DMF at 24 °C for 5 h to give **56** in 81% yield. Direct benzylation of **54** gave **57** in 84% yield. On the other hand, $LiAlH_4$ reduction of the naturally derived **2**[19,20] gave **10** in 72% yield, which was benzylated to afford **56** and **58**. The ratio of **56** and **58** depended on the reaction conditions used for benzylation (see Experimental section).

Acetonization of **58** followed by silylation provided **57**. The synthetic **56** and **57** were spectroscopically and chromatographycally identical with the corresponding materials obtained by the aforesaid transformations starting from naturally derived **2**. Consequently the structure showed for **48**, **49**, **12**, **50**, **54**, and **55** were determined and the anti-selectiveity in homo-



geneous hydrogenation of the "Cram" product **50** was also confirmed.

Preparation of Erythronolide A. Having thus prepared the polyol derivative **56**, which has the entire chiral sequence of (9*S*)-9-deoxo-9-hydroxyerythronolide A (**2**) in the proper absolute configuration, attention was directed toward the facile transformation of **56** into **2**. Protection of the tertiary alcohol function of **56** with triethylsilyl triflate and 2,6-lutidine provided all protected polyol **59** in 93% yield. Hydrogenolysis of **59** over palladium-black in ethanol furnished **60**. After the protection of the primary alcohol function of **60** with TBDPSCl and imidazole,

selective acetonization[4] of the resulting **61** with 2-methoxypropene and pyridinium *p*-toluenesulfonate (PPTS) in CH_2Cl_2 afforded the desired 3,5:9,11-

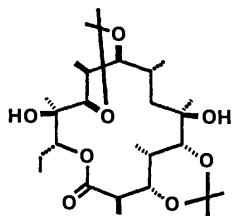
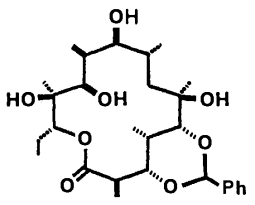
diacetonide **62** in 64% yield from **59**. The standard acetylation of **62** followed by desilylation of the acetate **63** with tetrabutylammonium fluoride (TBAF) in THF at 60 °C furnished **64** in 70% yield from **62**. Oxidation of **64** with 4 equiv of PDC in the presence of 3A Molecular Sieves in DMF afforded the acid **65**, which was deacetylated with 1-M NaOH-dioxane (1:1) to give the seco-acid 3,5:9,11-diacetonide **4** in 82% yield. Treatment of **4** with 1.5 equiv of triphenylphosphine and 1.5 equiv of di-(2-pyridyl) disulfide in THF yielded the 2-pyridinethiol ester, which was purified by silica-gel column chromatography (95% yield). This ester was subjected to lactonization by the modified Corey-Nicolaou method[7] using toluene instead of xylene to give the intramolecular cyclization product **66** in 65% yield. The protected lactone **66** was treated with 50% aqueous acetic acid to afford (9*S*)-9-deoxo-9-hydroxyerythronolide A (**2**) in quantitative yield. The synthetic sample of **2** was identical in all respects with a sample of the naturally derived **2**.[20] The overall yield of **2** from **56** was 21.1% in 11 steps.

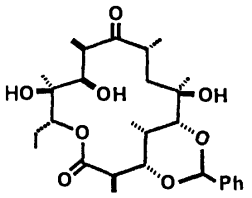
The lactone **2** was led to **1** by the straightforward transformation. Selective 3,5-*O*-benzylidenation[3] of **2** with benzaldehyde dimethyl acetal and 10-camphorsulfonic acid (CSA) in CH_2Cl_2 gave **67** in 80% yield. Selective oxidation[21] of **67** followed by



66



67



68

hydrogenolysis of the resulting ketone **68** with palladium-black in methanol furnished erythronolide A (**1**) in 66% yield. The synthetic sample of **1** was identical in all respects with naturally derived erythronolide A.[22]

Thus the new synthetic route to erythlonolide A through (9*S*)-9-deoxo-9-hydroxyerythronolide A from **13** was completed.

Experimental

Melting points were determined on a micro hot-stage Yanaco MP-S3 and were uncorrected. Optical rotations were measured on a JASCO DIP-360 photoelectric polarimeter in chloroform unless otherwise noted. IR spectra were recorded on a Hitachi Perkin-Elmer 225 spectrometer and ^1H NMR spectra on either a Varian EM-390 or a Bruker WM 250 spectrometer in $CDCl_3$ using TMS as internal standard. Mass spectra were recorded on Hitachi M-80 mass spectrometer. Silica-gel TLC and column chromatography were performed on Merck TLC 60F-254 and Merck Kieselgel 60, respectively. In general, organic solvents were purified and dried by the appropriate procedure, and evaporation and concentration were carried out under reduced pressure below 30 °C, unless otherwise noted.

2,3-*O*-Isopropylidene-D-ribofuranose (14).[11] To a stirred solution of D-ribose (25.0 g, 0.167 mol) and 2,2-dimethoxypropane (21.5 ml, 0.175 mol) in dry acetone (500 ml) at 0 °C was added concd H_2SO_4 (0.025 ml). After being stirred in a refrigerator (5 °C) for 20 h, the reaction mixture was neutralized with solid Na_2CO_3 and the insoluble materials were filtered off and washed with acetone. The combined filtrate and washings were concentrated. The residue was chromatographed on silica gel (1.6 kg) with 10:1 chloroform-methanol to afford **14** [26.2 g, 83%; R_f=0.39 (10:1 chloroform-methanol)] as a practically pure pale yellow syrup and 3,4-*O*-isopropylidene-D-ribopyranose [1.70 g, 5.5%; R_f=0.26 (10:1 chloroform-methanol)] as colorless needles.

2,3-*O*-Isopropylidene-1-*C*-methyl-D-allitol (15). To a stirred solution of methylmagnesium iodide [prepared from 33.5 g 1.38 mol) of magnesium powder and 94.3 ml (1.51 mol) of iodomethane] in dry diethyl ether (1050 ml) at 0 °C was added dropwise a solution of **14** (26.2 g, 0.138 mol) in dry diethyl ether (524 ml). The reaction mixture was stirred at 23 °C for 3.5 h. Saturated aqueous NH_4Cl (100 ml) was added to the ice-cooled reaction mixture. The phases were separated and the aqueous layer was thoroughly extracted with ethyl acetate. The combined organic layers were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (1.7 kg) with 1 : 4 benzene-ethyl acetate to afford **15** (26.5 g, 73%) as colorless crystals and 2.20 g (7.9%) of **14** was recovered: R_f=0.28 (1 : 4 benzene-ethyl acetate); mp 72—73 °C (needles, ether-hexane); $[\alpha]_D^{15}$ +27.5° (*c* 1.00); ^{1}H NMR (90 MHz) δ=1.32 (3H, d, 1-Me, J=6.0 Hz), 1.35 and 1.39 (each 3H, each s, CMe_2), 3.3—4.9 (9H, m).

Found: C, 52.64; H, 8.59%. Calcd for $C_9H_{18}O_5$: C, 52.41; H, 8.80%.

1-Deoxy-3,4-*O*-isopropylidene-D-ribitol (16). To a stirred solution of **15** (19.0 g, 0.0921 mol) in acetone (380 ml) at 0 °C was added dropwise a solution of $NaIO_4$ (59.1 g, 0.276 mol) in water (590 ml). The reaction mixture was stirred at 24 °C for 1 h. Acetone was removed under reduced pressure and the aqueous layer was extracted with ethyl acetate. The combined organic layers were washed with saturated aqueous NaCl, dried, and concentrated. The residue (16.0 g) was dissolved in dry THF (640 ml) and then cooled to 0 °C. To this was added portionwise $LiAlH_4$ (3.83 g, 0.101 mol) and the reaction mixture was stirred at 20 °C for 20 min. Wet diethyl ether (300 ml) and water (200 ml) were added carefully to the ice-cooled reaction mixture and the insoluble materials were filtered through Celite and washed with ethyl acetate. The combined filtrate and washings were concentrated and the residue was chromatographed on silica gel (330 g) with 1 : 1 benzene-ethyl acetate to afford **16** (15.8 g, 97.5%) as colorless crystals: R_f=0.34 (1 : 1 benzene-ethyl acetate); mp 47—49 °C (cubes, ether-petroleum ether); ^{1}H NMR (90 MHz) δ=1.31 (3H, d, 3×H-1, J=6.0 Hz), 1.34 and 1.39 (each 3H, each s, CMe_2), 2.90—3.60 (2H, br, 2×OH), 4.26 (1H, dq, H-2, $J_{2,3}$=7.2 Hz).

Found: C, 54.64; H, 8.93%. Calcd for $C_8H_{16}O_4$: C, 54.53; H, 9.15%.

5-*O*-(*t*-Butyldimethylsilyl)-1-deoxy-3,4-*O*-isopropylidene-D-ribitol (17). To a stirred solution of **16** (15.7 g, 89.1 mmol) in dry DMF (157 ml) were added at 0 °C imidazole (7.87 g, 116 mmol) and *t*-butylchlorodiphenylsilane (27.8 ml, 107 mmol). The reaction mixture was stirred at 24 °C for 2 h 40 min. The reaction mixture was poured into cold water (150 ml) and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (1.5 kg) with 25 : 1 benzene-ethyl acetate to afford **17** (35.6 g, 97%) as a colorless syrup: R_f=0.41 (25:1 benzene-ethyl acetate); $[\alpha]_D^{19}$ +8.0°, $[\alpha]_{365}^{19}$ +29° (*c* 1.12); ^{1}H NMR (90 MHz) δ=1.07 (9H, s, *t*-Bu), 1.28 and 1.30 (each 3H, each s, CMe_2), 1.34 (3H, d, 3×H-1, J=7.0 Hz), 3.58 (1H, dd, H-5, J_{gem}=10.2 and $J_{4,5}$=3.9 Hz), 3.81 (1H, d, H-5′, $J_{4,5'}$=0 Hz), 3.95—4.5 (4H, m), 7.3—7.8 (10H, m, 2×Ph).

Found: C, 69.24; H, 8.05%. Calcd for $C_{24}H_{34}O_4Si$: C, 69.52; H, 8.27%.

5-*O*-(*t*-Butyldiphenylsilyl)-1-deoxy-3,4-*O*-isopropylidene-*keto*-D-*erythro*-2-pentulose (18). To a stirred suspension of PCC (71.7 g, 332 mmol) and Molecular Sieves 3A powder (MS3AP) (83.1 g) in dry CH_2Cl_2 (208 ml) was added dropwise at 0 °C a solution of **17** (34.5 g, 83.2 mmol) in dry CH_2Cl_2 (138 ml). After 2 h at 22 °C, the reaction mixture was diluted with diethyl ether (200 ml) and the resulting suspension was transferred to a column filled with silica gel (930 g). The column was eluted with diethyl ether and the eluant was concentrated to give practically pure sample of **18** (34.3 g, 100%) as a pale yellow syrup. A portion of this was chromatographed on silica gel with 40 : 1 benzene-ethyl acetate to afford an analytically pure sample of **18**: R_f=0.55 (25 : 1 benzene-ethyl acetate); $[\alpha]_D^{22}$ +49.0° (*c* 0.97); IR ($CHCl_3$) 1712 cm^{-1}; ^{1}H NMR (90 MHz) δ=1.03 (9H, s, *t*-Bu), 1.37 and 1.57 (each 3H, each s, CMe_2), 2.27 (3H, s, 3×H-1), 3.72 (2H, d, 2×H-5, $J_{4,5}$=3.0 Hz), 4.30—4.60 (2H, m), 7.3—7.8 (10H, m, 2×Ph).

Found: C, 69.60; H, 7.63%. Calcd for $C_{24}H_{32}O_4Si$: C, 69.87; H, 7.82%.

$LiAlH_4$ Reduction of 18: To a stirred suspension of $LiAlH_4$ (50.0 mg, 1.32 mmol) in dry diethyl ether (1 ml) at −78 °C was added a solution of **18** (543 mg, 1.32 mmol) in dry diethyl ether (5.4 ml). After 2 h at −78 °C, wet diethyl ether was added to the reaction mixture. The insoluble materials were filtered through Celite and washed with ethyl acetate. The combined filtrate and washings were concentrated and the residue was chromatographed on silica gel (40 g) with 25 : 1 benzene-ethyl acetate to afford **17** (154 mg, 28%) and **19** (313 mg, 57%) as colorless syrups. **19**: R_f=0.27 (25 : 1 benzene-ethyl acetate); $[\alpha]_D^{20}$ 0°, $[\alpha]_{365}^{20}$ +15° (*c* 1.01); ^{1}H NMR (90 MHz) δ=1.08 (9H, s, *t*-Bu), 1.27 (3H, d, 3×H-1, J=4.5 Hz), 1.35 and 1.43 (each 3H, each s, CMe_2), 2.62 (1H, d, OH, J=3.0 Hz), 3.6—4.3 (5H, m), 7.3—7.8 (10H, m, 2×Ph).

Found: C, 69.80; H, 8.21%. Calcd for $C_{24}H_{34}O_4Si$: C, 69.52; H, 8.27%.

Transformation of 19 to (*R*)-2-Benzyloxypropinoic Acid (21). To a stirred solution of **19** (122 mg, 0.294 mmol) in dry THF (0.61 ml) at 0 °C was added NaH (19 mg, 0.44 mmol; 55% dispersion in mineral oil). After 0.5 h at room temperature, the mixture was cooled to 0 °C and benzyl bromide (0.052 ml, 0.44 mmol) was added. After being stirred at room temperature for 8 h, ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried and concentrated. The crude residual syrup (148 mg) was dissolved in THF (1.5 ml) and cooled to 0 °C. 1M solution of TBAF in THF (0.585 ml) was added to the above solution. After 2 h at 0 °C, ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (2.5 g) with 3 : 1 toluene-ethyl acetate to afford **20** (70.7 mg, 91% from **19**) as a colorless syrup, which was dissolved in 75% aqueous acetic acid (1.4 ml) and the mixture was heated at 80 °C for 10 h. The reaction mixture was concentrated and the residual triol (60.1 mg) was dissolved in acetone (1.4 ml) and cooled to 0 °C. A solution of $NaIO_4$ (125 mg, 0.584 mmol) in water (1.25 ml) was added and the mixture was stirred at 24 °C for 3 h. Acetone was removed under reduced pressure (50 mmHg; 1 mmHg≈133.322 Pa, 0 °C) and the aqueous phase was extracted with diethyl ether. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (0.5 g) with

6:1 hexane-ethyl acetate to afford (*R*)-2-benzyloxypropanal (43.6 mg, 100%) as a colorless syrup [^{1}H NMR (90 MHz) δ=1.31 (3H, d, 3×H-3, J=6.9 Hz), 3.88 (1H, dq, H-2, J=1.5 and 6.9 Hz) , 4.63 (2H, s, OC$\underline{H}_2$Ph), 7.37 (5H, s, Ph), and 9.69 (1H, d, CHO, J=1.5 Hz)]. This aldehyde (43.6 mg) was dissolved in a solution of CrO_3 in acetic acid and pyridine (3.5 ml; prepared from 1 g of CrO_3, 30 ml of acetic acid, and 1 ml of pyridine). After 3 h at 23 °C, ice-water was added and the mixture was extracted with diethyl ether. The etracts were washed with saturated aqueous $KHSO_4$, NaCl, dried, and concentrated (0 °C, 50 mmHg). The residue was chromatographed on silica gal (5 g) with 30:10:1 hexane-ethyl acetate-acetic acid to afford **21** (24.0 mg, 50% from **20**) as a colorless syrup: R_f=0.21 (30:10:1 hexane-ethyl acetate-acetic acid); $[\alpha]_D^{18}$ +54°, $[\alpha]_{546}^{18}$ +85° (*c* 2.30, benzene) [(*S*)-(−)-2-benzyloxypropionic acid: $[\alpha]_{546}$ −78.6° (*c* 2.3, benzene)[12]]; ^{1}H NMR (90 MHz) δ=1.47 (3H, d, 3×H-3, J=7.2 Hz), 4.12 (1H, q, H-2, J=7.2 Hz), 4.52 and 4.71 (each 1H, ABq, J=12.0 Hz), 7.37 (5H, s, Ph), and 8.0—8.4 (1H, br, COOH).

5-*O*-(*t*-Butyldiphenylsilyl)-1-deoxy-3,4-*O*-isopropylidene-2-*C*-vinyl-D-ribitol (22) and arabinitol (23). To a stirred solution of vinylmagnesium bromide [prepared from 343 mg (14.1 mmol) of magnesium powder and 0.99 ml (14.0 mmol) of vinyl bromide] in dry THF (36 ml) at 0 °C was added dropwise a solution of **18** (582 mg, 1.41 mmol) in dry THF (12 ml). After 3 h at room temperature, water was carefully added to the ice-cooled reaction mixture. The insoluble materials were filtered through Celite and washed with ethyl acetate. The combined filtrate and washings were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (50 g) with 10:1 hexane-ethyl acetate to afford **22** (527 mg, 85%) and a mixture of **22** and **23** (50 mg, 8.0%) as colorless syrups. The ratio of **22** and **23** of this mixture by ^{1}H NMR was 5.7:1. Therefore, the ratio of **22** and **23** was 77:1. **22**: R_f=0.37 (10:1 hexane-ethyl acetate); $[\alpha]_D^{24}$ +32.5° (*c* 1.00); ^{1}H NMR (90 MHz) δ=1.06 (9H, s, *t*-Bu), 1.30, 1.35, and 1.37 (each 3H, each s, 3×Me), 3.54 (1H, dd, H-5, $J_{4,5}$=3.6 and J_{gem}=10.5 Hz), 3.95—4.4 (4H, m) , 5.12 (1H, dd, C=CH (cis) J=1.8 and 10.5 Hz), 5.52 (1H, dd, C=CH (trans), J=1.8 and 17.7 Hz), 6.36 (1H, dd, C$\underline{H}$=CH$_2$), and 7.3—7.75 (10H, m, 2×Ph) [^{1}H NMR (90 MHz) of the mixture of **22** and **23** showed the following additional peaks; 5.06 (dd, C=CH) (cis), J=1.8 and 10.5 Hz), 5.31 (dd, C=CH (trans), J=1.8 and 17.7 Hz), 5.98 (dd, C$\underline{H}$=CH$_2$), which were attributed to **23**].

Found: C, 70.27; H, 8.05%. Calcd for $C_{26}H_{36}O_4Si$: C, 70.55; H, 8.20%.

Transformation of 22 to (4*S*,5*R*)-(−)-5-Ethyl-2,2,5-trimethyl-1,3-dioxolane-4-carboxylic Acid (25). A mixture of **22** (147 mg, 0.334 mmol), [ClRh(Ph$_3$P)$_3$] (61.8 mg, 0.668 mmol), and benzene (7.4 ml) was stirred at 23 °C for 4 h under atmospheric pressure of H_2. The reaction mixture was concentrated and the residue was passed through Florisil (11 g) with diethyl ether. The eluant was concentrated to give a colorless syrup (137 mg, 93%) [R_f=0.47 (10:1 toluene-ethyl acetate); ^{1}H NMR (90 MHz) δ=0.96 (3H, t, J=7.5 Hz), 1.08 (9H, s, *t*-Bu), 1.28, 1.32, and 1.37 (each 3H, each s, 3×Me), 1.71 (2H, q), 3.33 (1H, s, OH), 3.59 (1H, dd, J=3.9 and 10.2 Hz), 3.9—4.35 (3H, m), and 7.3—7.8 (10H, m, 2×Ph)]. To a stirred solution of this syrup (130 mg, 0.294 mmol) in dry CH_2Cl_2 (1.3 ml) was added $ZnBr_2$ (66.4 mg, 0.295 mmol) at 0 °C and the mixture was stirred at 0 °C for 2 h. Saturated aqueous Na_2CO_3 solution was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (15 g) with 20:1 toluene-ethyl acetate to afford **24** (108 mg, 83%) as a colorless syrup [R_f=0.44 (30:1 toluene-acetone); ^{1}H NMR (90 MHz) δ=1.00 (3H, t, J=7.5 Hz), 1.09 (9H, s, *t*-Bu), 1.24, 1.30, and 1.36 (each 3H, each s, 3×Me), 1.50—1.85 (2H, m), 2.48 (1H, d, OH, J=5.7 Hz), 3.6—3.95 (4H, m), and 7.3—7.8 (10H, m, 2×Ph)]. To a stirred solution of **24** (104 mg, 0.235 mmol) in dry THF (1.0 ml) was added at 0 °C TBAF (0.47 ml). After 1.5 h at 0 °C, ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatagraphed on silica gel (5 g) with 3.5:1 chloroform-acetone to give a colorless syrup (47.8 mg, 99%) [R_f=0.48 (1:3 toluene-ethyl acetate); ^{1}H NMR (90 MHz) δ=0.98 (3H, t, J=7.5 Hz), 1.23, 1.33, and 1.40 (each 3H, each s, 3×Me), 1.5—1.85 (2H, m), 2.5—2.85 (2H, br, 2×OH), 3.6—4.0 (4H, m)]. To a stirred solution of this syrup (45.6 mg, 0.223 mmol) in acetone (1.4 ml) was added at 0 °C a solution of $NaIO_4$ (95.5 mg, 0.446 mmol) in water (1 ml). After 1 h at 26 °C, acetone was removed by evaporation and the residue was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated to afford an aldehyde (12.0 mg, 31%; the low yield might be attributed to the volatility of the sample.) as a colorless syrup [R_f=0.76 (3:1 chloroform-acetone); ^{1}H NMR (90 MHz) δ=0.98 (3H, t, J=7.5 Hz), 1.16, 1.38, and 1.54 (each 3H, each s, 3×Me), 1.5—1.85 (2H, m), 4.12 (1H, d, J=2.0 Hz), and 9.75 (1H, d, J=2.0 Hz)]. To a solution of this aldehyde (12.0 mg, 0.070 mmol) in dioxane (0.3 ml) were added at 27 °C water (0.1 ml), K_2CO_3 (60.9 mg, 0.44 mmol), a solution of $KHCO_3$ (44.2 mg, 0.44 mmol) in water (0.49 ml), iodine (52.0 mg, 0.200 mmol), and a solution of KI (68.6 mg, 0.41 mmol) in water (0.06 ml), successively. After 2 h at 27 °C, solid $Na_2S_2O_3$ (102 mg, 0.41 mmol) was added and the mixture was extracted with diethyl ether. The aqueous phase was acidified (pH 2—3) with 10% aqueous H_2SO_4 under ice-cooling and immediately extracted with chloroform. The extracts were washed with saturated aqueous NaCl, dried, and concentrated to afford almost pure sample of **25** (6.8 mg, 52%) as colorless crystals: R_f=0.30 (80:5:1 chloroform-ethanol-acetic acid); $[\alpha]_D^{18}$ −27°, (*c* 0.84), ^{1}H NMR 90 MHz) δ=1.02 (3H, t, J=7.5 Hz), 1.22, 1.39, and 1.54 (each 3H, each s, 3×Me), 1.6—2.0 (2H, m), 4.43 (1H, s), and 8.2—8.65 (1H, br, COOH). The ^{1}H NMR of the authentic (+)-**26**[13] [$[\alpha]_D^{20}$ +26°, (*c* 0.84)] was identical with the above one.

3-*O*-Benzyl-7-*O*-(*t*-butyldiphenylsilyl)-1,2-dideoxy-5,6-*O*-isopropylidene-4-*C*-methyl-D-*manno*-heptitol (31). A solution of **22** (0.850 g, 1.93 mmol) in dry CH_2Cl_2 (43 ml) was stirred at −78 °C under bubbling with ca. 2% O_3 in O_2 (4300 ml, ca. 3.8 mmol). Dimethyl sulfide (1.42 ml, 19.3 mmol) was added and the mixture was warmed gradually to room temperature. The mixture was washed with water and saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (130 g) with 5:1 hexane-ethyl acetate to afford an aldehyde (0.620 g, 73%) as a colorless syrup [^{1}H NMR (90 MHz) δ=1.09 (9H, s), 1.29 (3H, s), 1.37 (3H, s), 1.40 (3H, s), 9.81 (1H, s)]. To a stirred solution of ethylmagnesium bromide [prepared from magnesium powder (0.27 g, 11 mmol) and ethyl bromide (0.84 ml, 11 mmol) in dry diethyl ether (19 ml) at 0 °C was added a

solution of the above aldehyde (0.620 g, 1.40 mmol) in dry diethyl ether (19 ml). After 1.5 h at room temperature, $Na_2SO_4 \cdot 10H_2O$ was added carefully to the ice-cooled reaction mixture. The insoluble materials were filtered through Celite and washed with ethyl acetate. The combined filtrate and washings were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (35 g) with 4:1 hexane-ethyl acetate to afford an inseparable mixture of **27** and **28** (0.580 g, 88%) as a colorless syrup. To a solution of the above mixture in dry THF (2.9 ml) were added at 0 °C NaH (65 mg, 2.70 mmol) and benzyl bromide (0.22 ml, 1.84 mmol) and the mixture was stirred at 21 °C for 4 h. Ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (28 g) with 20:1 hexane-ethyl acetate to afford **31** (380 mg, 55%) as a colorless syrup. The column was further eluted with 4:1 hexane-ethyl acetate to afford a mixture of **27** and **28** (162 mg, 28%). **31**: R_f=0.43 (6:1 hexane-ethyl acetate); $[\alpha]_D^{29}$ +7.5°, $[\alpha]_{365}^{29}$ +27.5° (*c* 1.00); ^{1}H NMR (90 MHz) δ=1.08 (12H, s, *t*-Bu involving 3×H-1), 1.29 and 1.39 (6H and 3H, each s, 4-Me and CMe_2), 1.5—2.1 (2H, m), 3.5—4.5 (6H, m), 4.72 (2H, s, $OC\underline{H}_2Ph$), and 7.2—8.0 (15H, m, 3×Ph).

Found: C, 72.27; H, 8.09%. Calcd for $C_{34}H_{46}O_5Si$: C, 72.56; H, 8.24%.

Desilylation of a Mixture of 27 and 28. (a) The mixture of **27** and **28** (12.4 mg, 0.0262 mmol) obtained from the Grignard reaction was dissolved in THF (0.124 ml) and solution of 1 M TBAF in THF (0.053 ml) was added under ice-cooling. After 1 h at 0 °C, ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (0.75 g) with 25:1 chloroform-methanol to afford **29** (3.6 mg, 59%) and **30** (2.3 mg, 37%) as colorless syrups. **29**: R_f=0.45 (25:1 chloroform-methanol); ^{1}H NMR (90 MHz) δ=1.0—1.3 (6H, m), 1.26, 1.37, and 1.49 (each 3H, each s, 4-Me and CMe_2). **30**: R_f=0.36 (25:1 chloroform-methanol); ^{1}H NMR (90 MHz) δ=0.9—1.2 (6H, m), 1.22, 1.37, and 1.49 (each 3H, each s, 4-Me and CMe_2).

(b) The mixture of **27** and **28** recovered after the benzylation reaction was desilylated as in the case of (a) to afford **29** and **30** in a ratio of 1:4.9.

(c) The mixture of **27** and **28** prepared from ketone **35** by $LiAlH_4$ reduction (vide infra) was desilylated as in the case of (a) to afford **29** and **30** in a ratio of 5:1.

Transformation of 31 to (*R*)-2-Methylpentane-2,3-diol (33). 1 M TBAF in THF (0.314 ml) was added to a stirred, ice-cooled solution of **31** (88.5 mg, 0.157 mmol), in dry THF (0.89 ml). After 1 h at 0 °C, ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (5 g) with 1:1 hexane-ethyl acetate to afford a diol (49.1 mg, 96%) as colorless needles [mp 94.5—100.5 °C; R_f=0.15 (3:1, hexane-ethyl acetate); ^{1}H NMR (90 MHz) δ=1.04 (3H, t, 3×H-1, *J*=7.2 Hz), 1.23 (3H, s, 4-Me), 1.35 and 1.52 (each 3H, each s, CMe_2), 1.5—2.0 (2H, m), 2.6—2.9 (2H, br, 2×OH), 3.47 (1H, dd, H-3, *J*=3.6 and 9.0 Hz), 3.7—3.85 (2H, m), 4.21 (1H, dt, H-6, $J_{6,7}$=6.0 Hz), 4.41 (1H, d, H-5, $J_{5,6}$=6.0 Hz), 4.68 (1H, s, $OC\underline{H}_2Ph$), and 7.35 (5H, s, Ph)]. A mixture of the above diol (45.0 mg, 0.139 mmol) and 50% aqueous acetic acid (0.9 ml) was heated at 115 °C for 2 h, then concentrated. The residue was chromatographed on silica gel (6 g) with 10:1 chloroform-methanol to afford a tetrol (37.5 mg, 95%) as colorless needles [mp 88—89.5 °C; R_f=0.19 (1:3 hexane-ethyl acetate); $[\alpha]_D^{24}$ +75° (*c* 1.00); ^{1}H NMR (90 MHz) δ=1.10 (3H, t, 3×H-1, *J*=7.0 Hz), 1.23 (3H, s, 4-Me), 1.5—1.9 (3H, m), 2.7—3.0 (2H, br, 2×OH), 3.4—3.9 (6H, m), 4.64 and 4.76 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=10.5 Hz), and 7.35 (5H, s, Ph)]. A solution of $NaIO_4$ (65.3 mg, 0.305 mmol) in water (0.65 ml) was added to a stirred, ice-cooled solution of the above tetrol (26.3 mg, 0.0925 mmol) in acetone (0.53 ml). After 1.5 h at room temperature, the reaction mixture was filtered and the filtrate was concentrated. The residue was chromatographed on silica gel (1 g) with 30:1 toluene-ethyl acetate to afford **32** (14.9 mg, 84%) as a colorless syrup [^{1}H NMR (90 MHz) δ=0.95 (3H, t, 3×H-5, *J*=7.0 Hz), 1.68 (2H, dq, 2×H-4, $J_{3,4}=J_{4,5}$=7.0 Hz), 2.17 (3H, s, 3×H-1), 3.71 (1H, t, H-3), 4.47 and 4.60 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=12.0 Hz), and 7.38 (5H, s, Ph)]. A solution of **32** (13.4 mg, 0.0697 mmol) in dry diethyl ether (0.27 ml) was added to a solution of methylmagnesium iodide [prepared from magnesium powder (20.3 mg, 0.836 mmol) and iodomethane (0.0564 ml, 0.906 mmol)] in dry diethyl ether (0.58 ml) under ice-cooling. After 2 h at 20 °C, saturated aqueous NH_4Cl was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (1 g) with 10:1 benzene-ethyl acetate to afford (*R*)-3-benzyloxy-2-methyl-2-pentanol (13.1 mg, 90%) as a colorless syrup [R_f=0.19 (20:1 benzene-ethyl acetate); $[\alpha]_D^{19}$ −7.7°, $[\alpha]_{365}^{19}$ −25.5° (*c* 0.98); ^{1}H NMR (90 MHz) δ=1.04 (3H, t, 3×H-5, *J*=6.3 Hz), 1.15 and 1.20 (each s, each 3H, 2-Me and 3×H-1), 1.4—1.8 (2H, m), 2.18 (1H, s, OH), 3.12 (1H, dd, H-3, *J*=4.5 and 6. 0 Hz), 4.61 and 4.73 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=10.5 Hz), and 7.35 (5H, s, Ph); Found: C, 74.72; H, 9.45%. Calcd for $C_{13}H_{20}O_2$: C, 74.96; H, 9.68%]. A mixture of the above alcohol (13.0 mg, 0.0624 mmol), palladium black, and *t*-BuOH (0.3 ml) was stirred at 28 °C for 0.5 h under bubbling with H_2. Catalyst was filtered off and the filtrate was concentrated to afford **33** (7.4 mg, 100%) as a colorless syrup: R_f=0.40 (10:1 chloroform-methanol); $[\alpha]_D^{18.5}$ +27.3° (*c* 1.10, ether); ^{1}H NMR (90 MHz) δ=1.03 (3H, t, 3×H-5, *J*=6.0 Hz), 1.15 and 1.20 (each 3H, each s, 3×H-1 and 2-Me), 2.45—2.65 (2H, br, 2×OH), 3.28 (1H, dd, H-3, *J*=3.0 and 9.0 Hz). The product **33** was proved to be the enantiomer of **34** by comparing its optical rotation with that of **34** [$[\alpha]_D$ −32.6° (*c* 1.10, diethyl ether)].[14]

7-*O*-(*t*-Butyldiphenylsilyl)-1,2-dideoxy-5,6-*O*-isopropylidene-4-*C*-methyl-*keto*-D-*arabino*-3-heptulose (35). To a mixture of **27** and **28** (0.720 g, 1.52 mmol), dry benzene (5 ml), dry DMSO (1.17 ml, 16.4 mmol), and dry pyridine (0.117 ml, 1.45 mmol) at 0 °C were successively added trifluoroacetic acid (0.062 ml, 0.81 mmol) and a solution of DCC (952 mg, 4.61 mmol) in dry benzene (3.24 ml). After 5 h at room temperature, the reaction mixture was filtered and the filtrate was washed with saturated aqueous $KHSO_4$, $NaHCO_3$, and NaCl solutions, dried, and concentrated. The residue was chromatographed on silica gel (85 g) with 10:1 pet. ether-diethyl ether to afford **35** (650 mg, 90%) as a colorless syrup: R_f=0.53 (10:1 toluene-ethyl acetate); $[\alpha]_D^{29}$ 0°, $[\alpha]_{365}^{29}$ −17.5° (*c* 1.00); IR (0.15 M in $CHCl_3$) 1713 cm^{-1}; ^{1}H NMR (90 MHz) δ=1.06 (3H, t, 3×H-1, *J*=7.5 Hz), 1.08

(9H, s, *t*-Bu), 1.27 and 1.36 (3H and 6H, each s, 4-Me and CMe_2), 2.69 (2H, q, 2×H-2), 3.65—4.45 (5H, m), and 7.3—7.85 (10H, m, 2×Ph).

Found: C, 68.68; H, 8.06%. Calcd for $C_{27}H_{38}O_5Si$: C, 68.90; H, 8.14%.

$LiAlH_4$ Reduction of 35 and Benzylation of the Resulting Mixture of 27 and 28. To a stirred suspension of $LiAlH_4$ (104 mg, 2.74 mmol) in dry diethyl ether (2.0 ml) at −78 °C was added a solution of **35** (1.25 g, 2.66 mmol) in dry diethyl ether (12 ml). After 2 h at −78 °C, wet diethyl ether was added to the reaction mixture and the mixture was warmed to room temperature. The insoluble materials were filtered off through Celite and washed with ethyl acetate. The combined filtrate and washings were concentrated and the residue was chromatographed on silica gel (35 g) with 6:1 toluene-ethyl acetate to afford a mixture of **27** and **28** (1.05 g, 83.6%). To a solution of this mixture in dry THF (5.3 ml) at 0 °C was added NaH (213 mg, 4.89 mmol, 55% dispersion in mineral oil). The mixture was stirred at 21 °C for 0.5 h. Benzyl bromide (0.40 ml, 3.36 mmol) was added to the above ice-cooled suspension and the mixture was stirred at 21 °C for 4.5 h. Ice was added and the mixture was extracted with ethyl acetate and the extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (120 g) with 20:1 hexane-ethyl acetate to afford **31** (845 mg, 68%) as a colorless syrup.

3-*O*-Benzyl-7-*O*-(*t*-butyldiphenylsilyl)-1,2-dideoxy-4,5-*O*-isopropylidene-4-*C*-methyl-D-*manno*-heptitol (36). To a stirred solution of **31** (1.47 g, 2.61 mmol) in dry acetone (37 ml) at 0 °C was added a solution of $FeCl_3$ (212 mg, 1.31 mmol) in dry acetone (7.4 ml). After 1 h at 29 °C, saturated aqueous $NaHCO_3$ was added to the reaction mixture. The insoluble materials were filtered through Celite and washed with ethyl acetate. The filtrate and washings were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (75 g) with 100:1 toluene-acetone to afford **36** (1.39 g, 95%) as a colorless syrup: R_f=0.49 (60:1 toluene-ethyl acetate); $[\alpha]_D^{26}$ −17.5° (*c* 1.00); ^{1}H NMR (90 MHz) δ=1.06 (3H, t, 3×H-1, *J*=7.4 Hz), 1.08 (9H, s, *t*-Bu), 1.25 (3H, s, 4-Me), 1.31 and 1.36 (each 3H, each s, CMe_2), 1.73 (2H, q, 2×H-2), 3.38 (1H, dd, H-3, *J*=6.3 and 5.7 Hz), 3.6—4.25 (5H, m), 4.67 (2H, s, $OC\underline{H}_2Ph$), and 7.25—7.85 (15H, m, 3×Ph).

Found: C, 72.84; H, 8.11%. Calcd for $C_{34}H_{46}O_5Si$: C, 72.56; H, 8.24%.

3-*O*-Benzyl-1,2-dideoxy-4,5-isopropylidene-4-methyl-D-*manno*-heptitol (37). To a stirred solution of **36** (1.30 g, 2.31 mmol) in THF (13 ml) at 0 °C was added 1 M TBAF in THF (4.6 ml). After 1 h at 0 °C, ice was added and the mixture was extracted with chloroform. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (50 g) with 2:1 hexane-ethyl acetate to afford **37** (691 mg, 92%) as a colorless syrup: R_f=0.23 (6:1 hexane-ethyl acetate); $[\alpha]_D^{22}$ −45.0° (*c* 1.00); ^{1}H NMR (90 MHz) δ=1.10 (3H, t, 3×H-1, *J*=7.5 Hz), 1.23, 1.30, and 1.40 (each 3H, each s, 4-Me and CMe_2), 1.6—2.1 (3H, m, 2×H-2 and OH), 3.34 (1H, dd, H-3, *J*=5.5 and 5.5 Hz), 3.55—4.30 (5H, m), 4.53 and 4.76 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=10.8 Hz), 7.39 (5H, s, Ph).

Found: C, 66.52; H, 8.60%. Calcd for $C_{18}H_{24}O_5$: C, 66.64; H, 8.70%.

5-*O*-Benzyl-1,6,7-trideoxy-3,4-*O*-isopropylidene-4-*C*-methyl-keto-D-*arabino*-2-heptulose (38). To a solution of **37** (723 mg, 2.23 mmol) in acetone (14.5 ml) at 0 °C was added a solution of $NaIO_4$ (524 mg, 2.45 mmol) in water (5.2 ml). After 3 h at 27 °C, acetone was removed by evaporation and the residue was extracted with $CHCl_3$. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residual aldehyde [652 mg, 100%; ^{1}H NMR (90 MHz) δ=4.45 (1H, s, H-2), 9.63 (1H, s, CHO)] was dissolved in dry diethyl ether (13 ml) and added to a stirred solution of methylmagnesium iodide [prepared from magnesium powder (0.54 g, 22 mmol) and iodomethane (1.53 ml, 24.6 mmol)] in dry diethyl ether (28 ml) under ice-cooling. After 2 h at 27 °C, $Na_2SO_4 \cdot 10H_2O$ was added to the ice-cooled reaction mixture and the insoluble materials were filtered off through Celite and washed with $CHCl_3$. The filtrate and washings were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (70 g) with 6:1 hexane-ethyl acetate to afford **fr.1** (91.7 mg, 13.3%) and **fr.2** (531 mg, 77.3%) as colorless syrups, both of which are the desired alcohol: R_f=0.58 (fr. 1), 0.40 (fr.2) (4:1 hexane-ethyl acetate). This epimeric mixture (623 mg, 2.02 mmol) was dissolved in dry CH_2Cl_2 (2.5 ml) and added to a stirred suspension of PCC (1.72 g, 8.07 mmol), MS 3AP (2.02 g) in dry CH_2Cl_2 (5.0 ml) at 0 °C. The reaction mixture was stirred at 25 °C for 1.5 h. Diethyl ether (5 ml) was added and the suspension was transferred to a column filled with silica gel (23 g). The column was eluted with diethyl ether and the eluant was concentrated to give **38** (607 mg, 98%) as a colorless syrup: R_f=0.61 (6:1 hexane-ethyl acetate); $[\alpha]_D^{21}$ 0°, $[\alpha]_{365}^{21}$ +25.0° (*c* 1.00); IR ($CHCl_3$) 1720 cm^{-1}; ^{1}H NMR (90 MHz) δ=1.00 (3H, t, 3×H-7, *J*=7.0 Hz), 1.14 (3H s, 4-Me), 1.35 and 1.53 (each 3H, each s, CMe_2), 1.4—1.85 (2H, m), 2.23 (3H, s, 3×H-1), 3.38 (1H, dd, H-5, *J*=4.8 and 8.4 Hz), 4.51 (1H, s, H-3), 4.63 and 4.78 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=11.4 Hz), and 7.33 (5H, s, Ph).

Found: C, 70.44; H, 8.42%. Calcd for $C_{18}H_{26}O_4$: C, 70.56; H, 8.55%.

5-*O*-Benzyl-1,2,6,7-tetradeoxy-2-iodo-3,4-*O*-isopropylidene-4-*C*-methyl-D-*arabino*-1-heptenitol (11). To a stirred solution of **38** (520 mg, 1.70 mmol) in ethanol (0.58 ml) were added triethylamine (2.01 ml, 14.4 mmol) and $NH_2NH_2 \cdot H_2O$ (0.33 ml, 6.8 mmol). After 1 h at 70 °C, the reaction mixture was cooled to room temperature and diluted with CH_2Cl_2. The mixture was washed with water, saturated aqueous NaCl, dried, and concentrated. The residual pale yellow syrup (544 mg, 100%) was dissolved in dry toluene (19 ml) and added at 0 °C to a mixture of iodine (946 mg, 3.73 mmol), 1,1,3,3-tetramethylguanidine (10.6 ml, 84.5 mmol), and dry toluene (5.5 ml). After 0.5 h at 0 °C, the reaction mixture was diluted with diethyl ether, washed with saturated aqueous $Na_2S_2O_3$, 10% aqueous citric acid, and saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (26 g) with 50:50:1 hexane-toluene-ethyl acetate to afford **11** (389 mg, 55%) as a colorless syrup: R_f=0.74 (6:1 hexane-ethyl acetate); $[\alpha]_D^{18.5}$ 0°, $[\alpha]_{365}^{18.5}$ −11.2° (*c* 1.12); ^{1}H NMR (90 MHz) δ=1.04 (3H, t, 3×H-7, *J*=7.2 Hz), 1.29 (3H, s, 4-Me), 1.37 and 1.52 (each 3H, each s, CMe_2), 1.55—1.7 (2H, m), 3.56 (1H, t, H-5, *J*=6.0 Hz), 4.52 (1H, s, H-3), 4.70 (2H, s, $OC\underline{H}_2Ph$), 6.08 and 6.62 (each 1H, each d, 2×H-1, *J*<1.0 Hz), and 7.32 (5H, s, Ph).

Found: C, 51.65; H, 5.87; I, 30.75%. Calcd for $C_{18}H_{25}O_3I$: C, 51.93; H, 6.05; I, 30.48%.

Methyl (*S*)-(+)-2-Methyl-3-triphenylmethoxypropionate

(40). A mixture of methyl (*S*)-(+)-3-hydroxy-2-methylpropionate (**39**) (2.00 g, 16.9 mmol), triphenylmethyl chloride (4.96 g, 17.8 mmol), triethylamine (3.54 ml, 25.4 mmol), DMAP (103 mg, 0.85 mmol), and dry CH_2Cl_2 (20 ml) was stirred at 23 °C for 15 h. The reaction mixture was poured into 50% aqueous NH_4Cl (20 ml). The phases were separated, and the aqueous layer was extracted with CH_2Cl_2 (20 ml×2). The combined organic layers were washed with saturated aqueous NaCl (20 ml), dried, and concentrated to give crude crystals (6.49 g, 100% up) of **40**, which was used without any further purification. A portion of this was chromatographed on silica gel with toluene to afford an analytically pure sample of **40**: mp 100—101 °C; R_f=0.38 (toluene); $[\alpha]_D^{31}$ +19.6° (*c* 1.00); IR (KBr) 1726 cm^{-1}; ^1H NMR (90 MHz) δ=1.13 (3H, d, 2-Me, *J*=6.6 Hz), 2.5—2.9 (1H, m, H-2), 3.05—3.45 (2H, m, 2×H-3), 3.70 (3H, s, OMe), and 7.1—7.55 (15H, m, Tr).

Found: C, 80.05; H, 6.78%. Calcd for $C_{24}H_{24}O_3$: C, 79.97; H, 6.71%.

(*R*)-(+)-2-Methyl-3-triphenylmethoxypropanol (41). To a stirred solution of the crude **40** (6.19 g) in dry THF (62 ml) at 0 °C was added $LiAlH_4$ (0.65 g, 17 mmol). After 50 min at room temperature, water (0.65 ml), 15% aqueous NaOH (0.65 ml), and water (1.95 ml) were added successively to the cooled (0 °C) reaction mixture. The insoluble materials were filtered off with Celite and washed with diethyl ether. The filtrate and washings were concentrated and the residue was chromatographed on silica gel (220 g) with 9:1 toluene-ethyl acetate to give **41** (4.89 g, 86% from **39**) as a pale yellow syrup, which on standing crystallized. An analytical sample was obtained by recrystallization from ethyl acetate-hexane: mp 74—76 °C; R_f=0.13 (8:1 hexane-acetone); $[\alpha]_D^{29}$ +28.4° (*c* 1.00); ^1H NMR (90 MHz) δ=0.84 (3H, d, 2-Me, *J*=6.9 Hz), 1.8—2.3 (1H, m), 2.21 (1H, d, OH, *J*=5.7 Hz), 2.9—3.35 (2H, m), 3.58 (2H, dd, 2×H-1, *J*=5.7 Hz), and 7.15—7.55 (15H, m, Tr).

Found: C, 82.59; H, 7.38%. Calcd for $C_{23}H_{24}O_2$: C, 83.10; H, 7.28%.

(*R*)-(−)-2-(2-Benzyloxy-1-methylethyl)-1,3-dioxolane (45). To a stirred solution of **41** (1.50 g, 4.51 mmol) in dry THF (15 ml) at 0 °C was added NaH (0.394 g, 9.02 mmol, 55% dispersion in mineral oil). After 1 h at room temperature, benzyl bromide (1.07 ml. 9.02 mmol) was added to the mixture under ice-cooling. The new mixture was heated under reflux (70 °C) for 2 h. The reaction mixture was cooled to 0 °C and ethanol (0.53 ml) was added and the mixture was stirred for 1 h. Cold water (20 ml) was added and extracted with diethyl ether. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (100 g) with 50:1 hexane-acetone to give a practically pure sample of **42** (1.91 g, 100%) as a pale yellow syrup [R_f=0.32 (50:1 hexane-acetone); $[\alpha]_D^{33}$ +4.3°, $[\alpha]_{365}^{33}$ +14.8° (*c* 0.88)]. This sample (1.73 g, 4.09 mmol) was dissolved in methanol (17.3 ml) and Amberlyst 15 (123 mg) was added. The mixture was heated at 50 °C for 3.5 h under vigorous stirring. The reaction mixture was filtered off and washed with methanol. The filtrate and washings were concentrated and the residue was chromatographed on silica gel (21 g) with 3.5:1 benzene-ethyl acetate to give **43** (612 mg, 83% from **41**) as a colorless syrup [R_f=0.32 (3.5:1 benezene-ethyl acetate); $[\alpha]_D^{33}$ −15.6° (*c* 1.37) [lit,[16] $[\alpha]_D$ −11.3° (*c* 16.05)]]. A solution of DMSO (0.469 ml, 6.61 mmol) in dry CH_2Cl_2 (1.2 ml) was added to a solution of oxalyl chloride (0.434 ml, 4.97 mmol) in dry CH_2Cl_2 (12 ml) at −78 °C under argon. After 3 min, a solution of **43** (551 mg, 3.06 mmol) in dry CH_2Cl_2 (3.6 ml) was added dropwise and the resulting suspension was stirred at −78 °C for 15 min. After addition of triethylamine (2.31 ml, 16.6 mmol), the mixture was gradually warmed to 0 °C for a period of 20 min. A mixture of 4:1 benzene-ether and water was added to the reaction mixture and phases were separated. The aqueous phase was extracted with 4:1 benzene-ether and the combined organic layers were washed with saturated aqueous NaCl, dried, and concentrated. The residual colorless aldehyde **44** was used without any further purification [R_f=0.64 (5:1 toluene-ethyl acetate) $[\alpha]_D^{33}$ −28.0° (*c* 1.40), [lit, [16] $[\alpha]_D$ −28° (*c* 1.40)]]. To a stirred mixture of **44** (514 mg, 2.88 mmol), ethylene glycol (1.60 ml, 28.8 mmol), and dry acetonitrile (5.14 ml) at 0 °C was added *p*-toluenesulfonic acid (45.1 mg, 0.288 mmol). After 35 h at 21 °C, the reaction mixture was poured into saturated aqueous $NaHCO_3$. The mixture was extracted with CH_2Cl_2 and the extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (30 g) with 15:1 toluene-ethyl acetate to give **45** (630 mg, 98%) as a colorless syrup: R_f=0.52 (10:1 toluene-ethyl acetate) $[\alpha]_D^{17}$ −3°, $[\alpha]_{365}^{17}$ +9° (*c* 0.81); ^1H NMR (90 MHz) δ=1.00 (3H, d, 2-Me, *J*=6.5 Hz), 1.85—2.3 (1H, m), 3.3—3.7 (2H, m) 3.7—4.0 (4H, m, OCH_2CH_2O), 4.52 (2H, s, OCH_2Ph), 4.86 (1H, d, H-1, $J_{1,2}$=5.4 Hz), 7.33 (5H, s, Ph).

Found: C, 70.15; H, 8.35%. Calcd for $C_{13}H_{18}O_3$: C, 70.25; H, 8.16%.

(*R*)-(−)-2-(2-Hydroxy-1-methylethyl)-1,3-dioxolane (46). A mixture of **45** (8.60 g, 38.7 mmol), palladium black, and methanol (86 ml) was vigorously stirred at room temperature for 1 h under bubbling with H_2. The catalyst was filtered off and washed with methanol. The filtrate and washings were concentrated to afford **46** (5.11 g, 100%) which was distilled under reduced pressure to give pure **46** (4.51 g, 88%) as a colorless oil: bp 69—71 °C (4 mmHg); $[\alpha]_D^{18}$ −6°, $[\alpha]_{365}^{18}$ −16.5° (*c* 1.21); ^1H NMR (90 MHz) δ=0.96 (3H, d, 2-Me, *J*=7.5 Hz), 1.8—2.2 (1H, m), 2.6—2.85 (1H, br t, OH), 3.5—3.8 (2H, m), 3.8—4.15 (4H, m, OCH_2CH_2O), and 4.77 (1H, d, H-1, $J_{1,2}$=7.3 Hz).

Found: C, 54.76; H 9.06%. Calcd for $C_6H_{12}O_3$: C, 54.53; H, 9.15%.

(*S*)-(+)-2-(2-Bromo-1-methylethyl)-1,3-dioxolane (47). To a stirred solution of **46** (970 mg, 7.34 mmol) and triphenylphosphine (2.89 g, 11.0 mmol) in dry THF (9.7 ml) at −5 °C was added dropwise diethyl azodicarboxylate (1.70 ml, 11.0 mmol). After 5 min at −5 °C, ethyl bromide (0.822 ml, 11.0 mmol) was added and the mixture was stirred at 20 °C for 2 h. The reaction mixture was concentrated under reduced pressure (120 mmHg) and the residue was chromatographed on silica gel (100 g) with 10:1 hexane-ethyl acetate to afford an oil (1.10 g, 77%) which was distilled to give a pure **47** (903 mg, 63%) as a colorless oil: bp 54—56 °C (3 mmHg); $[\alpha]_D^{16}$ +3°, $[\alpha]_{365}^{16}$ +11° (*c* 1.15); ^1H NMR (90 MHz) δ=1.09 (3H, d, 2-Me, *J*=6.5 Hz), 1.9—2.2 (1H, m), 3.29—3.4 (each 1H, each dd, H-3 and 3′, $J_{3,3'}$=9.3, $J_{2,3}$=7.0, and $J_{2,3'}$=4.5 Hz), 3.93 (1H, br s, OCH_2CH_2O), and 4.71 (1H, d, H-1, $J_{1,2}$=5.5 Hz).

Found: C, 37.10; H, 5.49; Br, 40.68%. Calcd for $C_6H_{11}O_2Br$: C, 36.95; H, 5.68; Br, 40.96%.

5,7,9-Tri-*O*-benzyl-2,3,6,8-tetradeoxy-2,4,6,8-tetra-*C*-methyl-L-*threo*-L-*ido*-nonose Ethylene Acetal (48) and Its C-4 Epimer. To a stirred suspension of magnesium powder

(687 mg, 28.3 mmol) in dry diethyl ether (50.5 ml) was added at room temperature 1,2-dibromoethane (0.244 ml, 2.83 mmol). After 0.5 h at room temperature, **47** (1.84 g, 9.43 mmol) in dry diethyl ether (92 ml) was added and the new mixture was stirred at room temperature for 1 h. To this was added **13** (1.01 g, 2.19 mmol) in dry diethyl ether (5.05 ml) and the mixture was stirred at room temperature for 2 h. Ice was added and the insoluble materials were filtered off with Celite and washed with ethyl acetate. The filtrate and washings were separated and the aqueous phase was extracted with ethyl acetate. The combined organic layers were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (200 g) with 7:1 hexane-acetone to afford **48** (999 mg, 79%) and its C4-epimer (101 mg, 8.0%) as colorless syrups.

48: R_f=0.41 (15:1 benzene-acetone); $[\alpha]_D^{16}$ +3°, $[\alpha]_{365}^{16}$ +20° (*c* 0.64); ^{1}H NMR (90 MHz) δ=0.9—1.3 (12H, m), 1.5—2.5 (5H, m), 3.3—3.8 (5H, m), 3.8—4.1 (4H, m, $OC\underline{H}_2C\underline{H}_2O$), 4.56 and 4.67 (each 2H, each s, 2×$OC\underline{H}_2Ph$), 4.5—4.95 (3H, m, H-1, $OC\underline{H}_2Ph$), and 7.3—7.6 (15H, m, 3×Ph).

Found: C, 74.71; H, 8.44%. Calcd for $C_{36}H_{48}O$: C, 74.97; H, 8.38%.

C4-epimer of **48**: R_f=0.34 (15:1 benzene-acetone); ^{1}H NMR (90 MHz) δ=0.9—1.3 (12H, m, 4×Me), 1.4—2.7 (6H, m), 3.35—4.15 (8H, m), 4.53 and 4.59 (each 2H, each s, 2×$OC\underline{H}_2Ph$), 4.4—5.15 (3H, m, H-1 and $OC\underline{H}_2Ph$), and 7.3—7.6 (15H, m, 3×Ph).

5,7,9-Tri-*O*-benzyl-4-*O*-*t*-butyldimethylsilyl-2,3,6,8-tetradeoxy-2,4,6,8-tetra-*C*-methyl-L-*threo*-L-*ido*-nonose Ethylene Acetal (49). To a solution of **48** (1.06 g, 1.84 mmol), 2,6-lutidine (0.852 ml, 7.31 mmol) in dry CH_2Cl_2 (10.6 ml) was added at 0 °C TBDMSOTf (1.27 ml, 5.53 mmol). After 2 h standing at 25 °C, ice was added and the mixture was extracted with CH_2Cl_2. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (50 g) with 8:1 hexane-ethyl acetate to give **49** (1.13 g, 89%) as a colorless syrup: R_f=0.67 (3:1 hexane-ethyl acetate); $[\alpha]_D^{16}$ +0°, $[\alpha]_{365}^{16}$ +8° (*c* 0.64); ^{1}H NMR (90 MHz) δ=(9H, s, *t*-Bu), 0.8—1.15 (9H, m, 2, 6, and 8-Me), 1.35 (3H, s, 4-Me), 1.5—2.5 (5H, m), 3.26 (1H, d, *J*=2. 1 Hz), 3.4—3.7 (3H, m), 3.8—4.1 (5H, m, $OC\underline{H}_2C\underline{H}_2O$+1H), 4.56 and 4.65 (each 2H, each s, 2×$OC\underline{H}_2Ph$), 4.4—4.95 (3H, m, H-1, and $OC\underline{H}_2Ph$), and 7.3—7.55 (15H, m, 3×Ph).

1,3,5,13-Tetra-*O*-benzyl-6-*O*-*t*-butyldimethylsilyl-2,4,7,8,10,14,15-heptadeoxy-11,12-*O*-isopropylidene-2,4,6,8,12-penta-*C*-methyl-10-*C*-methylene-D-*erythro*-L-*ido*-L-*ido*-pentadecitol (50) and Its D-*erythro*-L-*ido*-L-*altro* Epimer 51. To a solution of **49** (406 mg, 0.588 mmol) in dry acetone (20 ml) was added $SnCl_2$ (112 mg, 0.588 mmol) and the mixture was stirred at 26 °C for 19 h. The reaction mixture was poured into a cold saturated aqueous $NaHCO_3$ and extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (200 g) with 100:1 toluene-acetone to afford **12** (275 mg, 72%) as a colorless syrup [R_f=0.53 (8:1 hexane-ethyl acetate)]. To a cooled (−100 °C), stirred solution of **11** (531 mg, 1.28 mmol) in dry diethyl ether (0.667 ml) was added 1.38 M butyllithium in hexane (0.924 ml, 1.28 mmol) and the mixture was stirred at −100 °C for 15 min. To this was added the above aldehyde **12** (275 mg, 0.425 mmol) in dry diethyl ether (1.38 ml) and the mixture was stirred at −100 °C for 1 h. The reaction mixture was quenched with saturated aqueous NH_4Cl and extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (80 g) with 25:1 toluene-ethyl acetate to afford **11** (32% recovered), and a mixture of **50**, **51**, and impurities (0.45 g). This mixture was re-chromatographed on silica gel (50 g) with 10:1 hexane-ethyl acetate to afford **50**+impurities (252 mg) and **51** (40.1 mg, 10%). This impure **50** was directly used to the next step. **50**: R_f=0.38 (25:1 toluene-acetone); ^{1}H NMR (250 MHz) δ=0.09 and 0.10 (each 3H, each s, $SiMe_2$), 0.88 (9H, s, *t*-Bu, containing one of the doublets of three methyls), 0.95—1.05 (9H, one t and two d, 3×Me), 1.14, 1.32, and 1.48 (3H, 6H, and 3H, each s, 4×Me), 1.55—1.8 (3H, m), 1.8—2.0 (1H, m), 2.01 (1H, br d, OH, *J*=3.8 Hz), 2.1—2.35 (2H, m), 3.19 (1H, d, *J*=1.8 Hz), 3.25—3.6 (4H, m), 3.92 (1H, br t, H-9, *J*=3.8 Hz), 4.3—4.75 (9H, m), 5.33 and 5.47 (each 1H, each s), and 7.1—7.35 (20H, m), and some impurities' peaks. **51**: R_f=0.36 (25:1 toluene-acetone); $[\alpha]_D^{34}$ −6.5°, $[\alpha]_{365}^{34}$ −17.1° (*c* 1.00); ^{1}H NMR (250 MHz) δ=0.11 and 0.13 (each 3H, each s, $SiMe_2$), 0.88 (9H, s, *t*-Bu), 0.93, 1.04, and 1.06 (each 3H, each d, 2, 4, and 8-Me, *J*=6.8, 6.8, and 6.8 Hz), 1.03 (3H, t, 14-Me, *J*=7.5 Hz), 1.13, 1.30, 1.36, and 1.44 (each 3H, each s, 4×Me), 1.6—2.35 (7H, m), 3.21 (1H, d, *J*=2.0 Hz), 3.35 (1H, dd, *J*=6.8 and 9.0 Hz), 3.4—3.55 (3H, m), 4.05 (1H, br, H-9), 4.34 and 4.73 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=12.5 Hz), 4.45 and 4.48 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=12.5 Hz), 4.53 and 4.58 (each 1H, ABq, $OC\underline{H}_2Ph$, *J*=11.3 Hz), 4.62 (2H, s, $OC\underline{H}_2Ph$), 4.71 (1H, s, H-11), 5.16 and 5.31 (each 1H, each s, $C{=}C\underline{H}_2$), and 7.1—7.35 (20H, m, 4×Ph).

Desilylation of the Coupling Products. The crude coupling products (220 mg) containing **50**, **51**, and impurities were dissolved in THF (4.4 ml) and to this was added 1 M solution of TBAF in THF (0.47 ml). After 2 h at 25 °C, ice-water was added and the mixture was extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried and concentrated. The residue was chromatographed on silica gel (35 g) with 5:1 hexane-ethyl acetate to afford **52** (63.5 mg) and **53** (12.1 mg). **52**: R_f=0.36 (5:1 hexane-ethyl acetate); ^{1}H NMR (250 MHz) δ=0.82 (3H, d, *J*=7.0 Hz), 0.99 (3H, d, *J*=7.0 Hz), 1.01 (3H, t, *J*=7.0 Hz), 1.08 (3H, d, *J*=7.0 Hz), 1.11, 1.15, 1.36, and 1.50 (each 3H, each s, 4×Me), 1.55—2.3 (7H, m), 2.65—2.95 (2H, br), 3.15 (1H, d, *J*=2.3 Hz), 3.35—3.65 (4H, m), 4.25—4.75 (10H, m), 5.41 and 5.52 (each 1H, each s), and 7.2—7.35 (20H, m). **53**: R_f=0.31 (5:1 hexane-ethyl acetate); ^{1}H NMR (250 MHz) δ=0.86 (3H, d, *J*=6.3 Hz), 0.91 (3H, d, *J*=6.8 Hz), 0.98 (3H, t, *J*=74 Hz), 1.02 (3H, d, *J*=7.3 Hz), 1.06, 1.08, 1.28, and 1.41 (each 3H, each s, 4×Me), 1.5—2.25 (7H, m), 2.9—3.15 (2H, br), 3.25—3.45 (3H, m), 3.5—3.6 (2H, m), 4.3—4.7 (10H, m), 5.29 and 5.40 (each 1H, each s), and 7.15—7.35 (20H, m).

1,3,5,13-Tetra-*O*-benzyl-6-*O*-*t*-butyldimethylsilyl-2,4,7,8,10,14,15-heptadeoxy-11,12-*O*-isopropylidene-2,4,6,8,10,12-hexa-*C*-methyl-D-*arabino*-D-*gluco*-L-*ido*-pentadecitol (54) and Its D-*arabino*-L-*ido*-L-*ido* Epimer 55. A mixture of **50** (61.9 mg; contaminated with impurity), $[ClRh(PPh_3)_3]$, and degassed benzene (3.1 ml) was placed in autoclave and stirred under 50 kg cm^{-2} at 24 °C for 5 d. The reaction mixture was concentrated and the residue was passed through Florisil (100—200 mesh, 2 g) with ether and again concentrated. The residue was chromatographed on silica

gel (6 g) with 100:1 toluene-acetone to afford **54** (39.9 mg, 41% from **12**) and **55** (6.5 mg, 7% from **12**) as colorless syrups.

54: R_f=0.67 (6:1 hexane-ethyl acetate); ^{1}H NMR (250 MHz) δ=0.12 and 0.13 (each 3H, each s, $SiMe_2$), 0.86 (9H, s, *t*-Bu), 0.62, 0.89, 1.02, 1.03, and 1.06 (each 3H, each d, 5×Me, J=7.0, 7.0, 7.5, 7.3, and 6.8 Hz), 1.02 (3H, t, 14-Me, J=7.5 Hz), 1.22, 1.33, 1.34, and 1.42 (each 3H, each s, 4-Me), 1.5—2.35 (8H, m), 3.19 (1H, d, J=1.5 Hz), 3.32 (1H, dd, J=7.3 and 4.0 Hz), 3.34 (1H, dd, J=7.3 and 10.0 Hz), 3.4—3.55 (3H, m), 4.11 and 4.71 (each 1H, ABq, $OC\underline{H}_2Ph$, J=12.5 Hz), 4.45 and 4.48 (each 1H, ABq, $OC\underline{H}_2Ph$, J=12.5 Hz), 4.53 (1H, d, J=0.5 Hz), 4.53 and 4.60 (each 1H, ABq, $OC\underline{H}_2Ph$, J=11.3 Hz), 4.63 and 4.71 (each 1H, ABq, $OC\underline{H}_2Ph$, J=12.5 Hz), and 7.1—7.35 (20H, m, 4×Ph).

55: R_f=0.60 (6:1 hexane-ethyl acetate); ^{1}H NMR (250 MHz) δ=0.08 (6H, s, $SiMe_2$), 0.87 (9H, s, *t*-Bu), 0.85—1.10 (15H, m, 5×Me), 1.20, 1.31, 1.39, and 1.43 (each 3H, each 5, 4×Me), 1.5—2.35 (8H, m), 3.07(1H, dd, J=11.3 and 6.0 Hz), 3.2—3.55 (7H, m), 4.35—4.75 (8H, m), and 7.15—7.35 (20H, m, 4×Ph).

1,3,5,9,11,13-Hexa-*O*-benzyl-2,4,7,8,10,14,15-heptadeoxy-2,4,6,8,10,12-hexa-*C*-methyl-D-*arabino*-D-*gluco*-L-*ido*-pentadecitol (56) and Its 11-Debenzylated Product 58. (a) To a stirred solution of **10** (1.69 g, 3.98 mmol) in dry DMF (68 ml) at 0 °C was added freshly powdered KOH (7.11 g, 127 mmol) and the mixture was stirred at 22 °C for 1 h. To this was added benzyl chloride (7.32 ml, 63.7 mmol) at 0 °C and the mixture was stirred at 22 °C for 6.5 h. Ice-water was added and the mixture was extracted with ethyl acetate and the extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (299 g) with 5:1 hexane-acetone to afford **56** (2.24 g, 58%), **58** (74 mg, 2%), and a mixture of partially benzylated products (1.12 g) as colorless syrups.

56: R_f=0.44 (5:1 hexane-acetone); $[\alpha]_D^{29}$ +7.1°, $[\alpha]_{365}^{29}$ +22.2° (*c* 0.90); ^{1}H NMR (250 MHz) δ=0.93 (3H, d, J=7.5 Hz), 0.97 (3H, t, 14-Me, J=7.5 Hz), 1.01 (3H, d, J=7.3 Hz), 1.07 (3H, d, J=7.0 Hz), 1.11 (3H, d, J=7.0 Hz), 1.17 and 1.21 (each 3H, each s, 6- and 12-Me), 1.39 (1H, dd, H-7′, $J_{7',8}$=5.0, $J_{7,7'}$=13.8 Hz), 1.57 (1H, ddq, H-14, $J_{14,15}$=$J_{13,14}$=7.5, $J_{14,14'}$=15.0 Hz), 1.76 (1H, ddq, H-14′, $J_{14',15}$=7.5, $J_{13,14'}$=3.8 Hz), 1.88 (1H, dd, H-7, $J_{7,7'}$=13.8, $J_{7,8}$=5.0 Hz), 2.0—2.3 (4H, m), 2.55 and 2.65 (each 1H, each s, 2×OH), 3.18 (1H, d, H-11, $J_{10,11}$=1.5 Hz), 3.30 (1H, dd, H-13), 3.33 (1H, dd, H-1, $J_{1,1'}$=9.3 and $J_{1,2}$=5.3 Hz), 3.43 (1H, dd, H-1′, $J_{1',2}$=9.3 Hz), 3.5—3.6 (2H, m, H-3 and 9), 4.04 (1H, d, H-5, $J_{4,5}$=0.5 Hz), 4.35—4.8 (12H, m, 6×$OC\underline{H}_2Ph$), and 7.15—7.35 (30H, m, 6×Ph).

Found: C, 78.65; H, 8.30%. Calcd for $C_{63}H_{80}O_8$: C, 78.39; H, 8.35%.

58: R_f=0.39 (5:1 hexane-acetone) $[\alpha]_D^{23}$ +15.0°, $[\alpha]_{365}^{23}$ +45.6° (*c* 1.00); ^{1}H NMR (90 MHz, characteristic peaks only), δ=2.34, 3.07, and 3.70 (each br s, each 1H, 3×OH), 4.4—4.8 (10H, m, 5×$OC\underline{H}_2Ph$), and 7.15—7.4 (25H, m, 5×Ph).

Found: C, 76.60; H, 8.39%. Calcd for $C_{56}H_{74}O_8$: C, 76.85; H, 8.52%.

(b) Treatment of a mixture of **10** (667 mg, 1.57 mmol), benzyl chloride (2.89 ml, 25.1 mmol), powdered KOH (2.82 g, 50.3 mmol), and DMF (10 ml) in a sonicator (65 W, 48 kHz) at room temperature for 3.5 h yielded **58** (436 mg, 29%), **56** (346 mg, 23%), and a mixture of partially benzylated products (844 mg).

1,3,5,9,13-Penta-*O*-benzyl-6-*O*-*t*-butyldimethylsilyl-2,4,7,8,10,14,15-heptadeoxy-11,12-*O*-isopropylidene-2,4,6,8,10,12-hexa-*C*-methyl-D-*arabino*-D-*gluco*-L-*ido*-pentadecitol (57). (a) To a stirred solution of **58** (276 mg, 0.315 mmol) and 2,2-dimethoxypropane (0.194 ml, 1.57 mmol) in dry acetone (5.51 ml) was added at 0 °C a 1 v/v% solution of concd H_2SO_4 in dry acetone (0.0276 ml). After 2.5 h at 20 °C, the mixtuere was neutralized with solid Na_2CO_3 and insoluble materials were filtered off and the filtrate was concentrated and chromatographed on silica gel (9 g) with 50:1 CH_2Cl_2-ethyl acetate to afford the acetonide (271 mg, 94%) as a clorless syrup [R_f=0.44 (5:1 hexane-ethyl acetate); $[\alpha]_D^{25}$ −6.2°, $[\alpha]_{365}^{25}$ −24.6° (*c* 100); Found: C, 77.19; H, 8.41%. Calcd for $C_{59}H_{78}O_8$: C, 77.43; H, 8.59%.]. To a stirred solution of this (247 mg, 0.270 mmol) in dry CH_2Cl_2 (0.27 ml) was added 2,6-lutidine (0.126 ml, 1.08 mmol) and cooled to 0 °C. To this was added TBDMSOTf (0.186 ml, 0.809 mmol) and the mixture was stirred at 20 °C for 2.5 h. Ice-water was added and the mixture was extracted with CH_2Cl_2. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (30 g) with 30:1 hexane-acetone to afford **57** (264 mg, 95%) as a colorless syrup: R_f=0.69 (4:1 hexane-ethyl acetate); $[\alpha]_D^{28}$ +10.4°, $[\alpha]_{365}^{28}$ +37.4° (*c* 1.00); ^{1}H NMR (250 MHz) δ=0.07 and 0.09 (each s, each 3H, $SiMe_2$), 0.83 (3H, d, J=6.8 Hz), 0.88 (9H, s, *t*-Bu), 0.89 (3H, t, 3×H-15, J=7.5 Hz), 0.95 (3H, d, J=6.5 Hz), 1.01 (3H, d, J=7.3 Hz), 1.03 (3H, d, J=7.5 Hz), 1.21, 1.36, and 1.46 (3H, 6H, and 3H, each s), 1.5—2.4 (8H, m), 3. 13 (1H, dd, J=6.3 and 6.3 Hz), 3.19 (1H, d, J=2.0 Hz), 3.25—3.55 (4H, m), 4.3—4.75 (11H, m, 5×$OC\underline{H}_2Ph$ and 1H), and 7.15—7.35 (25H, m, 5×Ph).

Found: C, 75.66; H, 8.86%. Calcd for $C_{65}H_{92}O_8Si$; C, 75.83; H, 9.01%.

(b) To a solution of **54** (17.2 mg, 0.0183 mmol) in dry DMF (0.86 ml) was added at 0 °C powdered KOH (2.1 mg, 0.037 mmol) and the mixture was stirred at 24 °C for 1 h. To this was added benzyl chloride (0.0042 ml, 0.037 mmol) at 0 °C and the mixture was stirred at 24 °C for 4 h. After work-up, the residue was chromatographed on silica gel (1 g) with 5:1 hexane-acetone to afford **57** (15.9 mg, 84%) as a coloress syrup. This synthetic sample of **57** was identical with naturally derived **57** by ^{1}H NMR, $[\alpha]_D$, and TLC.

Transformation of 54 to 56. **54** (23.9 mg, 0.0254 mmol) was dissolved in 1:2 (v/v) mixture of 46% aqueous HF-acetonitrile (0.72 ml) and the solution was stirred at 24 °C for 1 h. Water was added and the mixture was extracted with CH_2Cl_2. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (1 g) with 4:1 toluene-ethyl acetate to give a diol (18.9 mg, 95%) as a colorless syrup. 17.0 mg (0.0216 mmol) of this was dissolved in dry DMF (0.85 ml) and cooled to 0 °C. To this was added powdered KOH (9.7 mg, 0.17 mmol) and the mixture was stirred at 24 °C for 1 h. This mixture was cooled to 0 °C and benzyl chloride (0.0099 ml, 0.086 mmol) was added. The new mixture was stirred at 24 °C for 5 h. After work-up, the residue was chromatographed on silica gel (1.5 g) with 5:1 hexane-ethyl acetate to give **56** (17.9 mg, 81% from **54**) as a colorless syrup. This synthetic sample of **56** was identical with naturally derived **56** by ^{1}H NMR (250 MHz), $[\alpha]_D$, and TLC.

1,3,5,9,11,13-Hexa-*O*-benzyl-2,4,7,8,10,14,15-heptadeoxy-2,4,6,8,10,12-hexa-*C*-methyl-6,12-di-*O*-triethylsilyl-D-*arabino*-

D-*gluco*-L-*ido*-pentadecitol (**59**). To a stirred mixture of **56** (669 mg, 0.693 mmol), 2,6-lutidine (0.305 ml, 2.77 mmol), and dry CH_2Cl_2 (13.4 ml) was added at 0 °C triethylsilyl trifluoromethanesulfonate (0.426 ml, 2.08 mmol). After 1.5 h at 23 °C, ice-water was added and the mixture was extracted with CH_2Cl_2. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (40 g) with 30 : 1 hexane-ethyl acetate to give **59** (766 mg, 93%) as a colorless syrup: R_f=0.64 (5 : 1 hexane-acetone); $[\alpha]_D^{30}$ +19.4° (*c* 1.00); ^{1}H NMR (250 MHz) δ=0.5—0.7 (12H, m, 6×SiC$\underline{H}_2$Me), 0.82 (3H, t, 3×H-15, *J*=7.5 Hz), 0.85—1.0 (24H, m, 6×SiCH$_2\underline{Me}$, 8- and 10-Me), 1.01 (3H, d, 4-Me, *J*=7.0 Hz), 1.02 (3H, d, 2-Me, *J*=7.0 Hz), 1.31 and 1.33 (each 3H, each s, 6- and 12-Me), 1.4—1.95 (5H, m), 1.95—2.15 (1H, m, H-8), 2.15—2.4 (2H, m, H-2 and 4), 3.15—3.25 (3H, m, H-9, 11, and 13), 3.33 (1H, dd, H-1, J_{gem}=9.5, and $J_{1,2}$=7.0 Hz), 3.47 (1H, dd, H-1′, $J_{1',2}$=7.3 Hz), 3.51 (1H, dd, H-3, *J*=3.8, and 5.5 Hz), 3.78 (1H, s, H-5, $J_{4,5}$=0 Hz), 4.3—4.95 (12H, m, 6×OC$\underline{H}_2$Ph), and 7.15—7.4 (30H, m, 6×Ph).

Found: C, 75.21; H, 9.01%. Calcd for $C_{75}H_{108}O_8Si_2$: C, 75.46; H, 9.12%.

1-*O*-*t*-Butyldiphenylsilyl-2,4,7,8,10,14,15-heptadeoxy-3,5:9,11-di-*O*-isopropylidene-2,4,6,8,10,12-hexa-*C*-methyl-6,12-di-*O*-triethylsilyl-D-*arabino*-D-*gluco*-L-*ido*-pentadecitol (62). A mixture of **59** (100 mg, 0.0839 mmol), palladium black, and ethanol (2.0 ml) was stirred at 20 °C for 0.5 h under bubbling with H_2, and the suspension was filtered. The filtrate was evaporated and the residue was chromatographed on silica gel (10 g) with 3 : 1 hexane-acetone to afford **60** (50.3 mg, 92%) as colorless foam. 46.6 mg (0.0714 mmol) of this sample was dissolved in dry DMF (4.66 ml) and imidazole (19.4 mg, 0.285 mmol) was added. This mixture was cooled to 0 °C and TBDPSCl (0.0742 ml, 0.285 mmol) was added and the new mixture was stirred at 25 °C for 3 h. The reaction mixture was poured into ice-water and extracted with ethyl acetate. The extracts were washed with saturated aqueous NaCl, dried, and concentrated. The residue was chromatographed on silica gel (10 g) with 4 : 1 toluene-ethyl acetate to give **61** (52.1 mg, 82%) as a colorless syrup [R_f=0.51 (3 : 1 hexane-acetone); ^{1}H NMR (90 MHz) δ=0.5—0.8 (12H, m, 6×SiC$\underline{H}_2$Me), 0.8—1.15 (33H, m, 11×Me), 1.05 (9H, s, *t*-Bu), 1.17 (6H, s), 1.25—2.1 (8H, m), 2.75 (1H, d, OH, *J*=8.3 Hz), 3.00 (1H, d, OH, *J*=6.8 Hz), 3.13 (1H, d, OH, *J*=6.5 Hz), 3.30 and 3.60 (each 1H, each s, 2×OH), 3.25—3.9 (6H, m), 4.15 (1H, d, *J*=11.3 Hz), and 7.25—7.75 (10H, m, 2×Ph)]. 42.3 mg (0.0474 mmol) of this sample was dissolved in dry CH_2Cl_2 (0.85 ml) and 2-methoxypropene (0.025 ml, 0.24 mmol) was added. The mixture was cooled to 0 °C and PPTS (1.2 mg, 0.0047 mmol) was added and the new mixture was stirred at 25 °C for 3 h. The reaction mixture was neutralized with solid Na_2CO_3 and insoluble materials were filtered off. The filtrate was concentrated and the residue was chromatographed on silica gel (5 g) with 50 : 1 toluene-ethyl acetate to afford **62** (39.2 mg, 85%) as colorless foam: R_f=0.78 (8 : 1 hexane-ethyl acetate); $[\alpha]_D^{29}$ +31.2°, (*c* 1.00); ^{1}H NMR (250 MHz) δ=0.45—0.7 (12H, m, 6×SiC$\underline{H}_2$Me), 0.8—1.1 (33H, m, 11×Me), 1.05 (9H, s, *t*-Bu), 1.17, 1.22, 1.27, 1.28, 1.40, and 1.41 (each 3H, each s, 6×Me), 1.50—2.0 (9H, m), 3.18 (1H, dd, *J*=1.5 and 7.0 Hz), 3.47 (1H, dd, *J*=10.3 and 6.0 Hz), 3.5—3.8 (5H, m), 7.1—7.25 and 7.35—7.55 (6H and 4H, m, 2×Ph).

3,5:9,11-Di-*O*-isopropylidene-(9*S*)-9-deoxo-9-hydroxy-erythronolide A (66). To a stirred suspension of PDC (188 mg, 0.499 mmol) and MS 3AP (125 mg) in dry CH_2Cl_2 (0.55 ml) was added at 0 °C a solution of **64** (68.2 mg, 0.125 mmol) in dry CH_2Cl_2 (0.27 ml). After 4 h at 22 °C, the reaction mixture was diluted with diethyl ether (0.5 ml) and the suspension was transferred to a column filled with silica gel (1 g). The column was eluted with diethyl ether and the eluant was concentrated. The residue was chromatographed on silica gel (2 g) with 60 : 20 : 1 hexane-ethyl acetate-acetic acid to afford **65** (59.2 mg, 85%) as a colorless syrup [R_f=0.48 (50 : 50 : 1 hexane-ethyl acetate-acetic acid); ^{1}H NMR (90 MHz, representitatives only) δ=2.07 (3H, s, OAc), 2.60 (1H, m), 3.28 (1H, dd, *J*=2.4 and 6.0 Hz), 3.52 (1H, d, *J*=1.5 Hz), 3.63 (1H, d, *J*=3.8 Hz), 3.83 (1H, dd, *J*=2.3 and 9.8 Hz), and 4.90 (1H, dd, H-13, *J*=3.8 and 9.0 Hz)]. This was dissolved in 1,4-dioxane (0. 13 ml) and 1 M aqueous NaOH (0.126 ml) was added. After 2 h at 23 °C, the reaction mixture was neutralised with CG 50 and filtered. The filtrate was concentrated and the residue was chromatographed on silica gel (2 g) with 2 : 1 hexane-acetone to afford **4** (52.4 mg, 96%) as a colorless syrup [R_f=0.23 (30 : 10 : 1 hexane-acetone-acetic acid)]. This was dissolved in dry THF (1.04 ml) and triphenylphosphine (39.4 mg, 0.150 mmol) and di-(2-pyridyl) disulfide (33.1 mg, 0.150 mmol) were added and stirred at 22 °C for 8 h. After concentration, the residue was chromatographed on silica gel (6.5 g) with 1 : 1 hexane-ethyl acetate to afford pyridyl ester of **4** (58.3 mg, 95%) as a colorless syrup, which was dissolved in dry toluene (5.83 ml) and this solution was slowly added to a refluxing dry toluene (41.2 ml) with

syringe pump during a period of 10 h under argon. After further 14 h standing at 110 °C, the mixture was concentrated and the residue was chromatographed on silica gel (3 g) with 5 : 1 hexane-acetone to afford **66** (31.0 mg, 65%) as a clorless foam: R_f=0.61 (3 : 1 hexane-acetone); $[\alpha]_D^{33}$ +12.1°, $[\alpha]_{365}^{33}$ +40.0° (*c* 0.66); IR ($CHCl_3$) 1720 cm^{-1}; ^1H NMR (250 MHz) δ=0.84 (3H, t, 14-Me, *J*=7.5 Hz), 1.01 (3H, d, 4-Me, *J*=6.8 Hz), 1.14 and 1.23 (each 3H, each s, 6- and 12-Me), 1.18 (3H, d, 2-Me), 1.24 (3H, d, 10-Me), 1.28 (3H, d, 8-Me, *J*=6.0 Hz), 1.46, 1.48, and 1.49 (3H, 6H, and 3H, each s, 2×CMe_2), 1.5—1.65 (3H, m, H-4, 7′, and 14′), 1.82 (1H, dq, H-10, *J*=7.3, $J_{9,10}$=0, and $J_{10,11}$=1.8 Hz), 1.94 (1H, ddq, H-14, *J*=7.5, $J_{14,14'}$=14.8, and $J_{13,14}$=2.5 Hz), 2.05—2.25 (3H, m, H-7, 8, and OH), 2.75 (1H, dq, H-2, $J_{2,3}$=10.8, and $J_{2,Me}$=6.5 Hz), 2.96 (1H, s, OH), 3.12 (1H, d, H-9, $J_{8,9}$=11.0 Hz), 3.60 (1H, d, H-11), 3.78 (1H, dd, H-3, $J_{3,4}$=1.0 Hz), 3.97 (1H, d, H-5, $J_{4,5}$=1.5 Hz), and 5.06 (1H, dd, H-3, $J_{13,14'}$=11.3 Hz).

Found: *m/z*, 485.3110. Calcd for $C_{26}H_{45}O_8$: M^+−Me, 485.3111.

(9*S*)-9-Deoxo-9-hydroxyerythronolide A (2). A mixture of **66** (69.4 mg, 0.139 mmol) and 50% aqueous acetic acid (1.39 ml) was stirred at 24 °C for 4 h. After concentration, the residual sample of **2** (58.3 mg, 100%) was recrystallised from acetone-hexane to afford a pure sample of **2**. This sample was identical in all respects [mp, TLC, ^1H NMR (250 MHz), and $[\alpha]_D$], with a sample of **2** prepared by the literature procedure.[20]

Data of 2: R_f=0.15 (3 : 1 hexane-ethyl acetate); mp 203—206 °C (acetone-hexane) [lit,[20a] 185—187 °C, lit,[20b] 199—200°C, mp of **2** prepared by the method of lit,:[20b]: 202—205 °C (acetone-hexane)]; $[\alpha]_D^{27}$ +9.5°, $[\alpha]_{365}^{27}$ +24.7° (*c* 2.00, MeOH) lit,[20a] $[\alpha]_D^{27}$ +9.5° (*c* 2.00, MeOH), lit,[20b] $[\alpha]_D^{25}$ +9.5° (*c* 2.00, MeOH), $[\alpha]_D$ of **2** prepared by the method of lit,:[20b] $[\alpha]_D^{30}$ +9.5°, $[\alpha]_{365}^{30}$ +24.1° (*c* 200, MeOH)]; ^1H NMR (250 MHz) δ=0.90 (3H, t, 3×H-15, *J*=7.3 Hz), 1.04 (3H, d, 4-Me, *J*=7.5 Hz), 1.05 (3H, s), 1.24 (3H, s), 1.24 (3H, d, 10-Me, *J*=7.3 Hz), 1.29 (6H, d, 2- and 8-Me, *J*=7.0 Hz) 1.2—1.35 (1H, m, H-7), 1.42 (1H, dd, H-7′, $J_{7,7'}$=15.0 and $J_{7',8}$=2.5 Hz), 1.45—1.65 (3H, m, H-4, 8, and 14), 1.95 (1H, ddq, H-14′, $J_{13,14'}$=2.3, $J_{14,14'}$=14.5 and $J_{14',Me}$=7.3 Hz), 2.0—2.1 (1H, m, H-10), 2.07 (1H, br s, OH), 2.63 (1H, br s, OH), 2.79 (1H, dq, H-2, $J_{2,3}$=10.3 and $J_{2,Me}$=7.0 Hz), 2.97 (1H, ddd, H-9, *J*=2.3, 9.0, and $J_{9,OH}$=9.0 Hz), 3.13 (1H, br s, OH), 3.48 (1H, dd, H-11, $J_{10,11}$=1.0 and $J_{11,OH}$=4.3 Hz), 3.57 (1H, d, 9-OH, *J*=9.0 Hz), 3.63 (1H, br s, OH), 3.85 (1H, d, H-3, $J_{2,3}$=10.3 and $J_{3,4}$=0 Hz), 3.95 (1H, br s, H-5, $J_{4,5}$=0 Hz), 4.30 (1H, d, 11-OH, *J*=4.3 Hz), and 4.64 (1H, dd, H-13).

Found: C, 59.73; H, 9.30%. Calcd for $C_{21}H_{40}O_8$: C, 59.98; H, 9.59%.

Erythronolide A (1). To a stirred mixture of **2** (37.6 mg, 0.0894 mmol), benzaldehyde dimethyl acetal (0.067 ml, 0.45 mmol), and dry CH_2Cl_2 (1.88 ml) was added at 0 °C CSA (2.1 mg, 0.0089 mmol). After 24 h at 0 °C, solid Na_2CO_3 was added and the insoluble materials were filtered off. The filtrate was concentrated and the residue was chromatographed on silica gel (9 g) with 3 : 2 hexane-ethyl acetate to afford **67** (36.5 mg, 80%) as colorless needles [R_f=0.68 (2 : 1 hexane-acetone); $[\alpha]_D^{26}$ +5.4°, $[\alpha]_{365}^{26}$ +11.2° (*c* 1.00); mp 128—130 °C (acetone-hexane); IR ($CHCl_3$) 1728 cm^{-1}; ^1H NMR (250 MHz) δ=0.87 (3H, t, 14-Me, *J*=7.5 Hz), 1.13 and 1.31 (each 3H, each s, 6- and 12-Me), 1.15 (3H, d, 4-Me, *J*=7.0 Hz), 1.24 (3H, d, 10-Me, *J*=7.3 Hz), 1.27 (3H, d, 2-Me, *J*=7.7 Hz), 1.32 (3H, d, 8-Me, *J*=7.5 Hz), 1.4—2.1 (7H, m), 2.41 (1H, br, 12-OH), 2.81 (1H, d, 9-OH, *J*=4.5 Hz), 2.91 (1H, dq, H-2, $J_{2,3}$=10.8 Hz), 3.1—3.2 (1H, m, H-9) , 3.14 (1H, s, 6-OH), 3.73 (1H, br s, H-11, $J_{10,11}$<1.0 Hz), 3.79 (1H, dd, H-3, $J_{3,4}$=1.0 Hz), 3.96 (1H, d, H-5, $J_{4,5}$=1.0 Hz), 4.26 (1H, d, 11-OH, *J*=1.6 Hz), 5.13 (1H, dd, H-13, $J_{13,14}$=2.3 and $J_{13,14}$=11.0 Hz), 5.65 (1H, s, $OC\underline{H}_2Ph$), 7.35—7.45 and 7.45—7.55 (3H and 2H, each m, Ph)]. A solution of this sample **67** (19.5 mg, 0.0383 mmol) in dry CH_2Cl_2 (0.078 ml) was added to a stirred suspension of PCC (132 mg, 0.613 mmol), MS 3AP (153 mg), and dry CH_2Cl_2 (0.38 ml) at 0 °C. After 0.5 h at 0 °C, the reaction mixture was diluted with diethyl ether (0.5 ml) and the suspension was transferred to a column filled with silica gel (1 g). The column was eluted with diethyl ether and the eluant was concentrated. The residue was chromatogaphed on silica gel (1 g) with 1 : 1 hexane-ethyl acetate to afford **68** (15.6 mg, 80%) as a colorless syrup [R_f=0.60 (2 : 1 toluene-acetone); $[\alpha]_D^{22}$ −36.6°, (*c* 1.00, MeOH); IR ($CHCl_3$) 1705 cm^{-1}; ^1H NMR (250 MHz) δ=0.90 (3H, t, 3×H-15, *J*=7.5 Hz), 1.10 (3H, s), 1.18 (3H, d, 4-Me, *J*=7.5 Hz) , 1.21 (3H, d, 10-Me, *J*=7.5 Hz), 1.25 (3H, s), 1.28 (3H d, 2-Me, *J*=6.5 Hz), 1.34 (3H, d, 8-Me, *J*=6.0 Hz), 1.59 (1H, ddq, H-14, $J_{13,14}$=10.3 and $J_{14,14'}$=14.8 Hz), 1.71 (2H, d, 2×H-7, $J_{7,8}$=7.3 Hz), 1.78 (1H, ddq, H-4, $J_{3,4}$=1.0 and $J_{4,5}$=1.3 Hz), 1.97 (1H, ddq, H-14′, $J_{13,14'}$=2.0 Hz), 2.31 (1H, br, OH), 2.60 (1H, br s, OH), 2.85—3.1 (3H, m), 3.29 (1H, d, 11-OH, *J*=5.0 Hz), 3.76 (1H, dd, H-11, *J*=5.0 and 5.0 Hz), 3.83 (1 H, dd, H-3, $J_{2,3}$=10.3 Hz), 4.01 (1H, d, H-5), 4.88 (1H, dd, H-13, *J*=2.0 and 10.3 Hz), 5.68 (1H, s, $OC\underline{H}_2Ph$), 7.3—7.45 and 7.45—7.55 (3H and 2H, m, Ph)]. A mixture of this sample **68** (23.5 mg, 0.0464 mmol), palladium black, and MeOH (0.71 ml) was stirred at 25 °C for 0.5 h under bubbling with H_2, and the suspension was filtered. The filtrate was concentrated and the residue was chromatographed on silica gel (1 g) with 2 : 1 toluene-acetone to afford **1** (15.9 mg, 82%) as colorless needles. The synthetic sample of **1** proved to be identical with the naturally derived erythronolide A[22] by spectroscopic means and mixed mp measurement: R_f=0.23 (2 : 1 hexane-acetone); mp 170—172 °C (acetone-hexane) [lit,[22] mp 172—173 °C, lit,[4] 168—172 °C, mp of **1** prepared by the method of lit,[22] 170—172 °C]; mix. mp 170—172 °C; $[\alpha]_D^{28}$ −36.7° (*c* 0.90, MeOH) [lit,[4] $[\alpha]_D^{25}$ −37° (*c* 0.90, MeOH) $[\alpha]_D$ of **1** prepared by the method of lit,:[22] −37.3° (*c* 0.90, MeOH)]; IR ($CHCl_3$) 1743 cm^{-1}; ^1H NMR (250 MHz) δ=0.85 (3H, t, 3×H-15, *J*=7.5 Hz), 1.01 (3H, d, 4-Me, *J*=7.3 Hz), 1.16 (3H, d, 10-Me, *J*=7.3 Hz), 1.17 (3H, s), 1.19 (3H, d, *J*=6.5 Hz), 1.24 (3H, d, *J*=6.5 Hz), 1.36 (3H, s), 1.4—1.6 (2H, m), 1.8—2.05 (3H, m), 2.48 (1H, s, OH), 2.6—2.8 (2H, m), 2.84 (1H, d, OH, *J*=3.8 Hz), 3.07 (1H, br q, H-10, $J_{10,11}$=0 Hz), 3.13 (2H, br s, 2×OH), 3.55—3.7 (2H, m), 3.81 (1H, br s, H-11, $J_{11,OH}$=0 Hz), 3.93 (1H, d, OH, *J*=2.5 Hz), and 5.04 (1H, dd, H-13, $J_{13,14}$=2.3 and $J_{13,14'}$=10.8 Hz). After addition of D_2O, the signals of H-5, H-3, and H-11 changed to 3.56 (d, $J_{4,5}$=2.5 Hz), 3.62 (d, $J_{3,4}$=0 and $J_{2,3}$=10.5 Hz), and 3.81 (d, $J_{10,11}$=1.0 Hz), respectively.

Found: C, 60.20; H, 8.86%. Calcd for $C_{21}H_{38}O_8$: C, 60.27; H, 9.15%.

We are gratefull to Prof. Sumio Umezawa, Institute of Bioorganic Chemistry, and the late Prof. Hamao Umezawa, Institute of Microbial Chemistry for their generous support of our program. Financial support by the Ministry of Education, Science, and Culture (Grant-in-Aid for Special Research) and by the Japan

Antibiotics Research Association Research Grant are deeply acknowledged. We are also indebted to Mr. Saburo Nakada, Keio University, for elemental analyses, Miss Yoshiko Koyama, Institute of Bioorganic Chemistry, for 250 MHz ^{1}H NMR spectral analyses, and Mr. Koichi Inoshita for his technical assistance.

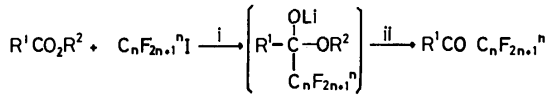
Preparation of Perfluoroalkyl Ketones by the Reaction of Perfluoroalkyllithiums with Esters

Hidemitsu UNO,* Yasukazu SHIRAISHI, and Hitomi SUZUKI*,†
Advanced Instrumentation Center for Chemical Analysis, Department of Chemistry, Faculty of Science, Ehime University, Bunkyo-cho 2-5, Matuyama 790
(Received April 27, 1989)

A variety of esters react with perfluoroalkyllithiums in situ generated from perfluoroalkyl iodides and methyllithium to give perfluoroalkyl ketones in good yields. Perfluoroalkyllithiums add to α, β-unsaturated esters only in the 1,2-addition mode even in the presence of copper salt. Exception was observed in the reaction with maleates where perfluoroalkylated succinic esters and normal 1,2-addition products are obtained in comparable amounts.

In recent years increasing attention has been paid to perfluoroalkyl-containing substances because of their unique properties which are not observed for fluorine-free partners. Straight chain perfluoroalkylalkanes are reported to form two different kinds of micelles depending on solvents[1] and to crystallize as a smetic liquid crystal.[2] Methodology for the introduction of the perfluoroalkyl group into a molecule[3] is, however, as yet far from maturity which makes a target compound often difficult to access. One of the important problems involved therein is thermal instability of perfluoroalkyl Grignard and lithium reagents which easily suffer β-elimination.[4] Thus, most efforts have been placed on the activation of thermally more stable reagents such as perfluoroalkylzinc[5] and -copper.[6] Unfortunately, these reagents, can not be successfully used for the perfluoroalkylation of unactivated esters due to their low nucleophilicity. Gassman and his co-worker have reported that pentafluoroethyllithium was conveniently generated from a metal halogen exchange reaction of pentafluoroethyl iodide with methyllithium at −78 °C and it reacted smoothly with aldehydes and ketones to give alcohols.[7] Gassman and our group have recently shown that this methodology can be extended to the preparation of perfluoroalkyl ketones from non-activated



Scheme 1. Reagents and conditions: i, MeLi-LiBr, ether, −78 °C, 1 h. ii, H^+.

esters (Scheme 1).[8-10] During the course of examining the scope of preparative utility of perfluoroalkyllithiums, we have also found the reaction with maleic esters affords perfluoroalkylsuccinates, which may be considered as a potential building block for synthesis of perfluoroalkyl-bearing cyclic compounds. In this paper, we report the full results of our study on the reaction of perfluoroalkyllithiums with various esters.

Results and Discussion

In situ generation of perfluoroalkyllithiums (1.1 equiv) by the reaction of perfluoroalkyl iodides with methyllithium in the presence of esters at −78 °C led to the formation of perfluoroalkyl ketones in good yields (Table 1). Addition of perfluoroalkyllithiums occurred only at the ester carbonyl group in the reactions with α,β-unsaturated esters and an α-bromo ester. It is noteworthy that methyl acrylate (**1l**) and methacrylate (**1m**) were also subject to 1,2-addition of the perfluoroalkyllithium reagent to give vinyl ketones (or hemiacetals) which could be easily isolated as the thiophenol-trapped compounds **14** and **15**, respectively. In the presence of methylcopper (1 equiv) and excess amounts of methyllithium (2 equiv), methyl cinnamate (**1b**) first underwent 1,2-addition of perfluoroalkyllithiums to form unsaturated ketones **4a—4c**, which then suffer 1,4-addition of methyllithium to afford saturated ketones **5a—5c**. In neither case bis-perfluoroalkylated compounds could be isolated in detectable amounts, which forms a marked contrast to the results obtained by Gassman and his co-worker.[10] This discrepancy may be rationalized by taking into account of the difference in amount and concentration of the lithium reagent employed. In order to obtain a perfluoroalkyl ketone, the use of a slightly excess of perfluoroalkyllithium is essential. When a large excess of perfluoroalkyllithium is used, the heat evolved during the generation of the lithium reagent will destroy the hemiacetal intermediate derived from the reagent and the ester. From this point of view, lower concentration of the reagent appears to be desirable, but it is not crucial as far as the reagents are satisfactorily soluble at low temperatures employed. We carried out the reaction by using 1.1 equiv of perfluorooctyl iodide (**2a**) to esters at 0.1 mol dm^{-3} concentration so as to keep them good soluble in ether at −78 °C. Under these conditions, the amount of methyllithium should be only in a slightly excess to the ester in order to prevent further reactions with perfluoroalkyllithium or methyllithium.

To get further insight into the reactivity of the reagents and regioselectivity of perfluoroalkylation, we conducted the reaction of perfluorooctyllithium with α,β-unsaturated diesters and the results are summarized in Table 2. Under the conditions employed (1.1 molar ratio of perfluorooctyllithium to esters), neither two perfluoroalkyl groups nor a pair of perfluoroalkyl and methyl groups could be introduced into molecules. The reaction with diethyl acetylenedicarboxylate (**1n**) gave the α-amino α,β-unsaturated ester **16**, which was presumably derived from 1,2-addition of perfluorooctyllithium followed by conjugate addition of ammonia generated upon quenching from aqueous ammonium chloride. When the reaction with **1n** was quenched with dilute hydrochloric acid, an intractable mixture was obtained. Perfluoroalkylation of diethyl azodicarboxylate (**1o**) occurred at the nitrogen atom to give *N*-perfluorooctyl-*N,N'*-hydrazinedicarboxylate **17** in 65% yield. From the reaction mixture diethyl *N*-methylhydrazine-*N,N'*-dicarboxylate (**18**) was also isolated in 18% yield. It is interesting to note that the reaction with the fumarate **1p** gave the trans γ-keto ester **19a** as a single product in 61% yield, while a similar reaction with the maleate **1q** produced the perfluorooctylsuccinate **20a** and an isomeric mixture of **19a** (*E*/*Z*=ca. 10/1) in comparable yields. Such Michael-type addition of a perfluoroalkylmetallic reagent is very rare.[11] In order to find

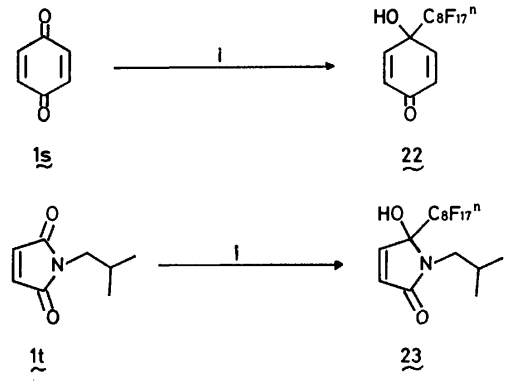

Scheme 2. Reagents and conditions: i, $C_8F_{17}{}^nI$, MeLi-LiBr, ether, −78 °C, 1 h.

additional examples, substrates with a cis-enedione structure similar to maleate were subjected to this perfluoroalkylation. The reactions of 1,4-benzoquinone (**1s**) and *N*-isobutylmaleimide (**1t**), however, resulted only in the expected formation of the quinol **22** and the lactam **23**, respectively (Scheme 2).

Since the formation of perfluoroalkylsuccinates appeared us to be quite interesting both from mechanistic and synthetic points of view, we examined the product selectivity for the reaction of dibutyl maleate under various conditions (Scheme 3 and Table 3). The important point is whether the perfluoroalkylsuccinate **20** will be formed by reactions with reagents other than perfluoroalkyllithium. Participation of perfluoroalkyl radical species could be ruled out because neither the formation of a radical addition product nor a marked change in the relative ratio of **19** and **20** was observed in the presence or absence of norbornene and styrene (Entries 30 and 31).[12] As the hypervalent iodine species such as Rf_2I^- were suggested to increase the stability of perfluoroalkyl anions,[13] we next examined whether such species play a role in determining the product distribution. The generation of perfluorobutyllithium from the metal-exchange reaction of the perfluorobutyl stannane **27** with methyllithium, in the presence of the maleate **1q**, led to the formation of both succinate **20c** and γ-keto ester **19c** in a ratio similar to that obtained from the reaction of the corresponding perfluoroalkyl iodide (Entry 32). In the reaction of **1q** using an excess of perfluorooctyl iodide (Entry 25), the ratio was also similar. Thus we may hold at present that the hypervalent perfluoroalkyl iodine species, even if they might exist, exsert little influence upon the partition between conjugate and 1,2-mode additions to maleates.

Perfluoroalkylation of the maleate **1q** in the presence of BF_3 is worthy to note (Entry 29). Proton and ^{13}C NMR analyses of the reaction mixture revealed the presence of three major products: **19b** (*Z*/*E*=>20/1), the succinate **20b**, and the hemiacetal[14] **24** (**19b** : **20b** : **24**=7 : 10 : 23). The hemiacetal structure of

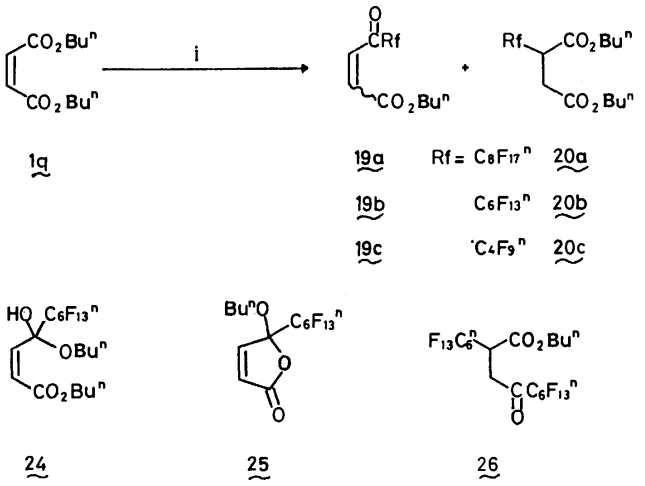
a) Isolated yield. b) Five equiv. to **1q**. c) Separation of **19** and **20** was not attempted. Numerals in parentheses refer to the ratios of 1,2- and 1,4-addition products in the crude reaction mixture estimated by NMR. d) Reaction temperature was −100 °C.



Scheme 3. Reagents and conditions: i, RfX, MeLi-LiBr, ether, −78 °C, 1 h.

24 was supported by the following observations: The NMR signals of **24** gradually disappeared as time passed. The signals of **19b** and 1-butanol became relatively stronger as compared with those of the succinate **20b** and new signals due to the lactone **25** appeared. After 3 days the reaction mixture was subjected to chromatographic separation to yield a mixture of **19b** (*Z*/*E*=6/5), **20b**, **25** (91%, **19b** : **20b** : **25**= 56 : 24 : 5), and a trace amount of the bisperfluorohexylated compound **26** (0.3%). Regiochemical assignment of **26** was based on the ^{13}C NMR absorptions of the ester carbonyl which appeared as double of doublets attributable to $^3J_{CF}$ coupling (6 and 3 Hz). The lactone **25** was isolated by GPC and its structure was confirmed by spectroscopic data. Thus in this reaction too, the 1,2-addition to one of the ester carbonyls was preferred to the conjugate addition. Coordination of BF_3 to the ester group would favor the 1,2-mode of addition of perfluoroalkyllithium[15] under these amphiphilic conditions.[16] The high yield and (*Z*)-stereoselectivity of **19b** may also reflect the stabilizing effect of BF_3 for the anion of the hemiacetal **24**.

Experimental

Melting points were measured with a Yanagimoto micro-melting point apparatus and are uncorrected. All distillation temperatures refer to the Kugelrohr bath temperature. Unless otherwise noted, all NMR spectra were observed with JEOL PMX-60 and GSX-270 spectrometers by using $CDCl_3$ as solvent, tetramethylsilane as an internal standard for ^1H and ^{13}C, and $CFCl_3$ for ^{19}F. Mass spectra were measured with a Hitachi M80LCAPI spectrometer under the following ionizing conditions: EI (20 eV) and CI (70 eV, methane as CI gas). IR spectra were recorded on a Hitachi 270-30 spectrophotometer. Column chromatography was carried out using Wakogel C-200. Preparative GPC was performed using JAI LC-08 with JAI-1H (20 mmID×60 cm) and JAI-2H (20 mmID×60 cm) columns. Diethyl ether was distilled from sodium benzophenone ketyl and stored over sodium wire. Dichloromethane was distilled from calcium hydride and stored over 4A Molecular Sieves. Esters and perfluoroalkyl iodides were purified by simple distillation. Methyllithium was titrated prior to use. Other commercially available materials were used without further purification. Perfluorobutyltributylstannane (**27**) was prepared according to a procedure similar to that used for pentafluoroethyltriallylstannane.[17]

Preparation of Perfluorobutyltributylstannane (27). To an ethereal solution (100 ml) of **2c** (5.19 g, 15 mmol) was added dropwise an ethereal solution of methyllithium-lithium bromide (10 mmol) at −90—−80 °C over 10 min. With an interval of 10 min tributylstannyl chloride (3.26 g, 10 mmol) in ether (10 ml) was added to the white suspension at −80 °C and the reaction mixture was allowed gradually to warm to room temperature with stirring. After 1 h the solvent was removed and the residual syrup was distilled under reduced pressure to give 2.05 g of **27** as a colorless oil (110—115 °C/0.15 mmHg††). The purity of **27** estimated by NMR was ca. 70%. Major contaminants were tributylmethylstannane (ca. 10%), tributylstannyl bromide (ca. 15%), and tributylstannyl chloride (ca. 5%). The product was used without further purification. **27**: ^1H NMR δ=0.92 (9H, t, J=7.3 Hz) and 1.15—1.70 (12H, m); ^{19}F NMR δ=−81.72 (3F, tt, J=9 and 4 Hz), −118.12 (2F, m, $J_{Sn\text{-}F}$=ca. 187 Hz), −119.22 (2F, m), and −126.53 (2F, br t, J=12 Hz); IR (neat) 2964s, 2924s, 1466m, 1348m, and 1300—1100vs cm^{-1}; MS (EI) m/z (rel intensity) 453 [M^+−Bu (^{120}Sn), 15%], 452 [M^+−Bu (^{119}Sn), 6], 451 [M^+−Bu (^{118}Sn), 12], 450 [M^+−Bu (^{117}Sn), 6], 449 [M^+−Bu (^{116}Sn), 6], 397 (4), 291 (100), 253 (71), and 235 (75).

General Procedure for Perfluoroalkylation of Esters. To an ethereal solution of **1** (1 mmol) and **2** (1.2 mmol) was added an ethereal solution of methyllithium-lithium bromide (1.1 mmol) at −78 °C during the course of 5 min and the mixture was stirred for 1 h at this temperature. The reaction was quenched by the addition of aqueous NH_4Cl and the product was extracted with ether. The organic phase was washed with brine, dried over Na_2SO_4, and evaporated. The residue was purified by column chromatography (hexane-CH_2Cl_2) and/or distillation.

Calcd for $C_{16}H_{21}O_4F_9$: C, 42.87; H, 4.72%).

Compound 21. (*E*)-Isomer: ^{1}H NMR δ=3.87 (3H, s), 7.05 (1H, d, J=15.6 Hz), and 7.45 (1H, d, J=15.6 Hz); ^{19}F NMR δ=81.32 (3F, tt, J=10 and 2 Hz), −121.48 (2F, t, J=12 Hz), −121.75 (2F, m), −122.40 (6F, m), −123.21 (2F, m), and −126.63 (2F, m); IR (neat) 2960m, 1730vs, 1316vs, and 1300—1100vs cm^{-1}; MS (CI) m/z (rel intensity) 533 (M^++1, 100%), 503 (7), 501 (8), 130 (9), 117 (9), and 113 (84).

(*Z*)-Isomer: ^{1}H NMR δ=3.82 (3H, s), 6.47 (1H, d, J=11.9 Hz), and 6.61 (1H, d J=11.9 Hz); ^{19}F NMR δ=−81.28 (3F, tt, J=10 and 2 Hz), −120.77 (2F, t, J=12 Hz), −121.48 (2F, m), −122.37 (4F, m), −122.68 (2F, m), −123.21 (2F, m), and −126.62 (2F, m); IR (KBr) 3090m, 1744vs, 1716vs, 1332vs, and 1300—1100vs cm^{-1}.

Reaction with 1,4-Benzoquinone. To a solution of **1s** (1.08 g, 10 mmol) and **2a** (5.46 g, 10 mmol) in ether (150 ml) was added an ethereal solution of methyllithium-lithium bromide (10 mmol) at −78 °C over 10 min. During the course of addition, the yellow solution gradually turned to a bluish purple suspension. After stirring for 1 h, the reaction was quenched with aqueous NH_4Cl. The organic phase was separated and the aqueous phase was extracted with ether. The combined extracts were washed with brine and dried over Na_2SO_4. The solvent was evaporated and the residue was chromatographed on silica gel ($CHCl_3$ as eluant). The fractions containing **22** was collected and concentrated to ca. 20 ml. Forced cooling of this concentrate followed by filtration gave 2.66 g (50%) of **22** as colorless crystals; mp 107—108 °C. ^{1}H NMR δ=1.59 (1H, br s), 6.43 (2H, d, J=10.1 Hz), and 6.91 (2H, d, J=10.1 Hz); ^{13}C NMR (acetone-d_6) δ=72.52 (tt, J=24 and 1 Hz), 100—125 (8 C), 132.28, 143.21 (m), and 184.99. ^{19}F NMR δ=−81.25 (3F, tt, J=10 and 2 Hz), −119.45 (4F, m), −122.0—−122.5 (6F, m), −123.17 (2F, m), and −126.58 (2F, m); IR (KBr) 3224m, 1674vs, 1628s, 1408s, 1392s, 1372s, 1330s, and 1300—1100vs cm^{-1}; MS (EI) m/z (rel intensity) 528 (M^+, 1%), 512 (1), 488 (3), 173 (8), 169 (2), 143 (9), and 109 (100) (Found: C, 31.87; 0.87%. Calcd for $C_{14}H_5O_2F_{17}$: C, 31.84; H, 0.95%).

Reaction with *N*-Isobutylmaleimide. To an ethereal solution (20 ml) of **1t** (153 mg, 1 mmol) and **2a** (546 mg, 1 mmol) was added an ethereal solution of methyllithium-lithium bromide (1 mmol) at −78 °C. After stirring for 30 min, the reaction was quenched with aqueous NH_4Cl. The reaction mixture was extracted with ethyl acetate. The organic extract was washed with brine and dried over Na_2SO_4. The solvent was evaporated and the residue was chromatographed on silica gel ($CHCl_3$ as eluant) to give 241 mg (42%) of **23** as colorless crystals; mp 122—123 °C; ^{1}H NMR δ=0.88 (6H, d, J=7.3 Hz), 2.21 (1H, m), 3.10 (1H, dd, J=14.3 and 8.2 Hz), 3.32 (1H, br s), 3.44 (1H, dd, J=14.3 and 7.0 Hz), 6.29 (1H, d, J=6.1 Hz), and 6.97 (1H, dt, J=6.1 and 2.7 Hz); ^{19}F NMR δ=−81.24 (3F, tt, J=10 and 2 Hz), −118.85 (1F, dm, J=280 Hz), −119.60 (1F, dm, J=285 Hz), −119.83 (1F, dm J=280 Hz), −121.29 (1 F, dm, J=285 Hz), −122.20 (6F, m), −123.18 (2F, m), and −126.58 (2F, m); IR (KBr) 3128s, 2964s, 1672vs, 1372s, and 1300—1100vs cm^{-1}; MS (EI) m/z (rel intensity) 573 (M^+, 7%), 530 (100), 518 (74), 501 (26), and 154 (53) (Found: C, 33.85; H, 2.16; N, 2.56%. Calcd for $C_{16}H_{12}NO_2F_{17}$: C, 33.52; H, 2.11; N, 2.44%).

Entry 29. To a solution of **1q** (1.14 g, 5 mmol), **2b** (2.68 g, 6 mmol), and $BF_3 \cdot OEt_2$ (0.65 ml, 5 mmol) was added an ethereal solution of methyllithium-lithium bromide (5.5 mmol) at −78 °C over 20 min. After stirring for 1 h, the reaction mixture was quenched by the addition of aqueous NH_4Cl. The ethereal layer was separated and the aqueous phase was extracted with ether. The combined organic

phase was washed with brine and dried over Na_2SO_4. Evaporation of the solvent gave 3.57 g of a reddish brown oil, of which NMR analysis showed the presence of **19b** ($Z/E \geqq 20/1$), **20b**, **24**, and a small amount of 1-butanol (**19b** : **20b** : **24**=7 : 10 : 23). Column chromatography of the crude oil on silica gel (hexane-CH_2Cl_2 as eluant) gave 0.013 g of **26** and 2.25 g of a mixture of **19b** (Z/E=6/5), **20b**, and **25** (**19b** : **20b** : **25**=56 : 24 : 5). Separation of these compounds was carried out by preparative GPC.

Compound 24. ^{1}H NMR (typical signals) δ=6.20 (1H, d, J=13.2 Hz), 6.30 (1H, br d, J=13.2 Hz), and 8.88 (1H, br s); ^{13}C NMR (typical signals) δ=97.62 (t, J=26 Hz), 125.59, 144.20, and 168.23.

Compound 25. ^{1}H NMR δ=0.91 (3H, t, J=7.3 Hz), 1.38 (2H, m), 1.60 (2H, m), 3.43 (1H, dt, J=8.9 and 6.3 Hz), 3.57 (1H, dt, J=8.9 and 6.3 Hz), 6.52 (1H, d, J=5.8 Hz), and 7.27 (1H, d, J=5.8 Hz); ^{19}F NMR δ=−81.35 (3F, tt, J=10 and 2 Hz), −118.75 (1F, dm, J=282 Hz), −120.77 (2F, m), −121.51 (1F, dm, J=282 Hz), −122.35 (2F, m), −123.18 (2F, m), and −126.62 (2F, m); ^{13}C NMR δ=13.41, 18.76, 31.07, 64.87, 106.86 (dd, J=30 and 28 Hz), 100—125 (6 C), 128.65, 147.36 (d, J=2 Hz), and 167.47; IR (neat) 2968m, 1816vs, 1620m, 1474m, 1366s, 1332s, and 1300—1100vs cm^{-1}; MS (CI) m/z (rel intensity) 475 (M^++1, 5%), 447 (11), 419 (100), 401 (64), and 383 (6).

Compound 26. ^{1}H NMR δ=0.94 (3H, t, J=7.3 Hz), 1.40 (2 H, m), 1.63 (2H, m), 3.20 (1H, dd, J=19.4 and 2.6 Hz), 3.60 (1H, dd, J=19.4 and 10.9 Hz), 3.79 (1H, m), and 4.20 (2H, m); ^{19}F NMR δ=−81.29 (6F, t, J=10 Hz), −112.0 (1F, dm, J=284 Hz), −113.3 (1F, dm, J=284 Hz), −120.49 (2F, t, J=12 Hz), −121.23 (2F, m), −121.98 (2F, m), −122.25 (2F, m), −122.60 (2F, m), −123.27 (4F, m), and −126.60 (4F, m); ^{13}C NMR δ=13.41, 18.81, 30.15, 34.67 (br), 43.11 (t, J=22 Hz), 66.77, 100—125 (12 C), 165.45 (dd, J=6 and 3 Hz), and 190.69 (t, J=27 Hz); IR (neat) 2968s, 1754vs, 1404m, 1348s, 1320s, and 1300—1100vs cm^{-1}; MS (CI) m/z (rel intensity) 796 (M^++2, 2%), 795 (M^++1, 3), 767 (9), 739 (30), 735 (69), 721 (100), 699 (40), 681 (23), 535 (18), and 479 (6).

Reaction of Perfluorobutyltributylstannane (27) with Dibutyl Maleate (1q). To an ethereal solution (10 ml) of **1q** (228 mg, 1 mmol) and **27** (815 mg, purity ca. 70%) was added an ethereal solution of methyllithium-lithium bromide (1.5 mmol) at −78 °C. After stirring for 1 h, the reaction mixture was quenched by the addition of aqueous NH_4Cl and extracted with ether. The extract was washed with brine and dried over Na_2SO_4. Evaporation of the solvent gave a pale yellow oil, of which NMR analysis revealed the presence of **19c** (E/Z=10/1), **20c** (**19c** : **20c**=2.1 : 1), and tributylmethylstannane. Chromatography of the crude oil on silica gel gave tributylmethylstannane (510 mg) and a mixture of **19c** and **20c** (**19c** : **20c**=33 : 10).

We thank Dr. Kazuhiro Shimokawa (Daikin Kogyo Co., Ltd.) for a gift of perfluoroalkyl iodides.

The Mechanism of Seasonal Variation in the Size Distributions of Atmospheric Chloride and Nitrate Aerosol in Tokyo

Hiroshi HARA,* Tsuyoshi KATO,†,†† and Hidetsuru MATSUSHITA
The Institute of Public Health, Shirokanedai 4-chome, Minato-ku, Tokyo 108
†Science University of Tokyo, Kagurazaka 1-chome, Shinjuku-ku, Tokyo 162
(Received December 19, 1988)

The volatility of ammonium chloride and nitrate was demonstrated to be responsible for the seasonal variation in size distributions that is the atmospheric fine-mode (<2 μm) chloride and nitrate aerosol were predominant in winter, but the coarse mode (>2 μm) was more pronounced in summer. An ion-balance examination and heating of winter aerosol samples demonstrated that fine-mode chloride and nitrate species are ammonium salts which are volatile at summer atmospheric temperatures. Both volatilized and unvolatilized concentrations of these chloride and nitrate species were determined both in winter and in summer to prove that the gas-solid interconversion took place in the atmosphere. The log-normal distributions of the ionic-component concentrations and the seasonal changes in the ionic composition of fine-mode aerosol were also discussed.

Chloride, like sulfate and nitrate[1,2] is one of the major ionic components of atmospheric aerosol. As yet, however, sufficient attention has not been paid to this component compared with sulfate and nitrate. Chloride has been considered to be of natural origin, such as sea spray and volcanic emission, whereas sulfate and nitrate have been studied in connection with photochemical air pollution and acid precipitation problems. Recently, however, the direct emission of hydrochloric acid associated with the burning of fossil fuels and of municipal refuse was noted, along with chlorine loss during the breakdown of seasalt by photoxidation with nitrogen dioxide along with aldehydes and through acidic displacement reactions.[3] Some of the HCl emitted into the atmosphere is expected to be transformed into ammonium chloride, which has been directly identified by means of X-ray diffraction analysis[4,5] or the IR spectrometry[6] of atmospheric aerosol, and has been speculated to exist in atmospheric aerosol on the basis of the observed seasonal trends in the chloride concentration[7,8] and in ammonium and nitrate losses from high-volume glass-fiber filters stored at room temperature.[9]

In the study of atmospheric aerosol, size distribution is a fundamental physicochemical parameter, like component concentrations, for the particle size is closely related to the source and restricts its aerodynamic behavior.[2,10,11] The size distribution of an aerosol mass is generally composed of fine (< 2 μm) and coarse (>2 μm) modes, with a distribution minimum at about 1—2 μm. The coarse-mode aerosol is directly emitted into the atmosphere, as seasalt aerosol and soil dust, for instance, whereas the fine is formed through gas-to-particle conversion, as sulfuric acid mist and automobile exhaust particles, for example. The fine- and coarse-mode concentrations are, however, essentially independent of each other.

Size-fractionated sampling and subsequent analysis has recently become a common procedure in aerosol chemistry. While there is a value in short term monitoring exercises, a full picture can only be drawn from data collected over lengthy periods.

On the basis of our June 1979—July 1982 observations in Tokyo, using an 8-stage Andersen sampler, we have discovered a seasonal variation in the size distribution of chloride aerosol and that the variation is air-temperature dependent.[7] The fine mode is predominant in winter, whereas the coarse is predominant in summer, which was comparable with the seasonal variation in the nitrate size distribution.[12,13] Similar seasonal changes have been noted in the U.S.[14] and England.[15]

We interpreted this variation as being due to the temperature dependence of the volatility of the chloride under the assumption that it was present as ammonium chloride.[7,8] A general review of this observation was given in a previous publication.[7]

This paper will report a further analysis of the data and experiments with collected aerosols in order to understand the variation mechanism of the distribution of chloride aerosol and to evaluate its significance in aerosol chemistry.

Experimental

The procedures have been described in detail elsewhere.[7,16] Aerosol was collected onto Teflon filters (Sumitomo Denko, Fluoropore FP 065) using an 8-stage Andersen sampler (Koritsu, KA-200P) on the rooftop (24 m) of the Institute of Public Health, about 3 km west of Tokyo Bay (Fig. 1). The water soluble components were extracted with an ion-chromatography eluent (0.0030 mol dm^{-3} $NaHCO_3$-0.0024 mol dm^{-3} Na_2CO_3) in an ultrasonic bath and were analyzed by two procedures: ion chromatography for chloride, nitrate, and sulfate (Dionex, System 10), and indophenol blue spectrophotometry for ammonium (Jasco, UV-1).[17]

Hydrochloric and nitric acids and ammonia in the atmosphere were sampled over the period from July, 1981, to February, 1982, with cellulose filters impregnated with

sodium carbonate, sodium chloride, and oxalic acid respectively.[17] Each of the gases was extracted with doubly-distilled water and determined by means of spectrophotometry: the mercury(II)-thiocyanate, the hydrazine-reduction, and the indophenol-blue methods for hydrogen chloride, nitric acid, and ammonia respectively.[17]

Results and Discussion

Temperature Dependence of the Fine Fraction. The size-distribution data were quantitatively analyzed as a function of the temperature. The distribution pattern was quantified by defining an index, "Fine Fraction" (FF), as $F/(F+C)$, where C and F represent the concentration sums of Stages 0—4 (coarse mode) and Stage 5 to the backup filter (fine mode), because the 50% effective cutoff diameters (ECD) for Stages 4 and 5 are 2.1 and 1.1 μm respectively.

Each value of FF was plotted as a function of the temperature for chloride and nitrate (Fig. 2) and for sulfate and ammonium (Fig. 3). The mean temperature in the sampling period was calculated from the daily mean data determined by the Meteorological Agency in Chiyoda-ku, 6.5 km northeast of the sampling site (Fig. 1). As is shown in Fig. 2, the FF's for chloride and nitrate were evidently temperature-dependent; they increased drastically with a decrease in the temperature. In contrast, sulfate and ammonium exhibited fine-mode-dominant distribution irrespective of the temperature (Fig. 3).

Temperature Dependence of Fine- and Coarse-Mode Concentrations. A high FF value will be a result either of a high fine-mode concentration or of a low coarse-mode one. The fine- and coarse-mode concentrations were plotted against the temperatures for chloride and nitrate. The fine-mode chloride concentration was temperature-dependent, similar to the FF for chloride (Fig. 4 (a)). However, coarse-mode chloride seemed to demonstrate the opposite temperature dependence, but with a narrower variation range than that of the fine mode (Fig. 4 (b)). The concentration slightly increased with the temperature. Similar features appeared in nitrate (Fig. 5(a) and (b)), where the fine-mode concentrations also controlled the size distribution. We interpret these data for both anions as indicating that, schematically, the fine-mode concentration decreased profoundly with the temperature, while the coarse-mode concentration increased when the temperature rose within a limited variation range compared with those of the fine mode.

No attempts seem to have been made to discuss the concentrations of either chloride and nitrate in each

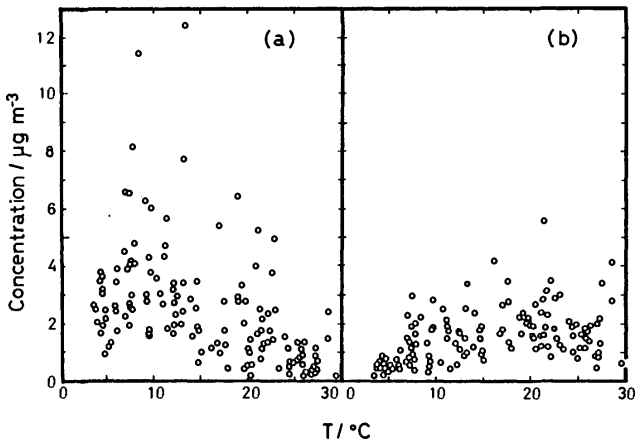

Fig. 4. Temperature dependence of (a) fine- and (b) coarse-mode chloride concentrations.

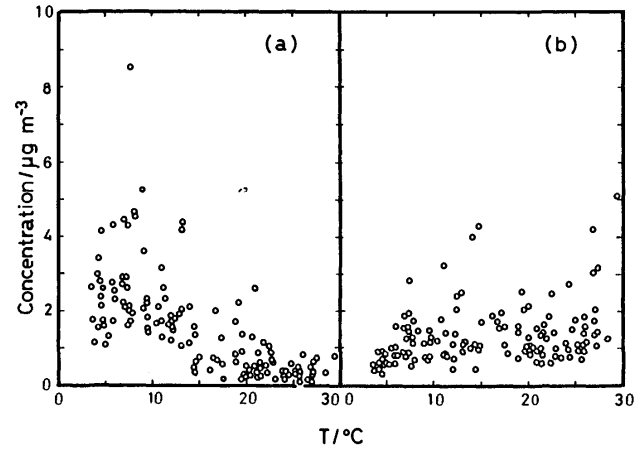

Fig. 5. Temperature dependence of (a) fine- and (b) coarse-mode nitrate concentrations.

mode in terms of the temperature, although it was pointed out nitrate aerosol shows a seasonal variation in its size distribution.

The temperature dependence of the coarse-mode chloride and nitrate will be explained in terms of both meteorology and chemistry on the assumption that those components originate from seasalt aerosol. The prevailing wind direction in Tokyo is northeast in winter and southwest in summer. Because of the location of Tokyo Bay relative to the sampling site (Fig. 1), the coarse-mode chloride is favored in the summer. Coarse-mode nitrate is attributed to the sodium nitrate[13,18] resulting from the chlorine-loss reaction:

$$NaCl + HNO_3 \longrightarrow NaNO_3 + HCl \quad (1)$$

Much more of the reactant, HNO_3, is photochemically formed in summer than in winter.

The temperature dependence of the fine mode will be discussed below.

Ion Balance. The next question is what is the chemical form of this fine-mode chloride responsible for the temperature dependence? In a previous paper,[7] we have speculated that this chloride is ammonium chloride, considering the reported identifications of this compound by means of IR spectrometry[6] and X-ray diffraction analysis.[5] Harrison and Pio[19] and Stevens et al.[20] also showed the ion-balance method, that ammonium chloride was one of the major compounds present in atmospheric aerosol. A similar analysis was applied to the present data.

Figure 6 is a plot of ammonium against the sum of the chloride, nitrate, and sulfate concentrations in the fine mode; the corresponding coarse-mode plot was not attempted because the sodium and calcium components, two major coarse-mode cations, were not determined in this study. The ion concentrations were expressed in units of μmol dm^{-3} to enable testing of the ion charge balance. Most of the points located on or slightly below the diagonal dotted 1 : 1 line were interpreted as corresponding to the condition in which all the anions cited were associated with ammonium ions.

The points falling below the line were attributable to the sulfuric acid and/or the ammoniumhydrogen sulfate, and possibly also to the sodium and calcium ions, which were not determined in this study. In some samples, a larger amount is obtained for ammonium than the three-anion sum. This may result from imprecision in analytical measurements, but in part it may also be due to the existence of organic salts of ammonium.

However, the data in Fig. 6 strongly suggest that the fine chloride and nitrate are in the form of the respective ammonium salts.

Simulation of Summer Temperatures. Another examination determined the chemical forms of fine-chloride and nitrate. Winter aerosol samples were subjected to heating in order to simulate summer

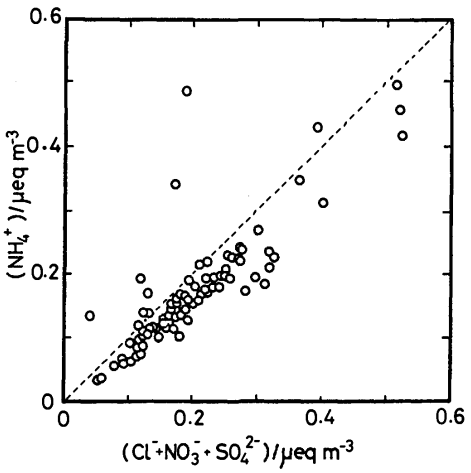

Fig. 6. Comparison of ammonium, and chloride, nitrate and sulfate concentrations in the fine mode on an equivalent basis.

temperature conditions. If the seasonal variation is derived from the temperature dependence of the gas-solid equilibria (Eqs. 2 and 3), the winter aerosol sample may be expected to exhibit a similar variation upon being heated to a summer temerature. Coarse- and fine-mode aerosol samples in winter were heated as follows. The filter at Stage 3 (50% ECD: 3.3 μm) and the backup filter were chosen to represent particles in the coarse- and fine-mode respectively. Filters with samples on were cut along a diagonal line into two equivalent parts. One part was directly subjected to the ion analysis as the reference. The other was heated, prior to the ion determination, in a temperature-controlled oven for 24 or 48 h at a typical summer temperature (between 25 and 30 °C).

Table 1 shows the ratio, C_a/C_b, of the concentrations after- (C_a) to before-heating (C_b), the subscripts a and b denote "after" and "before" respectively. For the coarse mode, the ratios were almost unity, which indicated that no vaporization took place at these temperatures. The coarse-mode ammonium was not determined because the concentration in this sample part was immeasurably small. In contrast, the fine-mode chloride, nitrate, and ammonium decreased in the C_a/C_b ratio, showing the vaporization losses of these ionic species. Nevertheless, the ratio of fine sulfate showed no appreciable change: $C_a/C_b=1.00\pm 0.06$.

For the fine mode, the ratio of the decreased amount of these anions to that of ammonium, $(\Delta Cl^- + \Delta NO_3^-)/\Delta NH_4^+$, was found to be 0.97 ± 0.12, essentially unity (Table 1). The fine-mode anionic species were concluded to form the respective ammonium salts: NH_4Cl, NH_4NO_3, $(NH_4)_2SO_4$, and their mixed salts, such as $(NH_4)_2SO_4\ nNH_4NO_3$ (n=1, 2).[5]

These findings show that fine-mode chloride, nitrate, and ammonium are highly volatile compared with the sulfate. Further, we interpret these results as indicating that the amount of species lost is in the form of NH_4Cl and NH_4NO_3 vapor. For the fine-mode ionic concentration of these winter samples, the averaged atmospheric concentration of ammonium (0.281 μequiv m^{-3}) agreed well with the averaged anion-sum (0.293 μequiv m^{-3}, where chloride: 0.090; nitrate: 0.077; sulfate: 0.126 μequiv m^{-3}).

Concentration Products of NH_3 and HCl, and NH_3 and HNO_3. Because both ammonium chloride and nitrate are volatile, hydrochloric and nitric acids volatalized from the fine-mode aerosol may be expected to exhibit complementary seasonal variations. However, the gaseous concentrations are restricted to the chemical equilibria, Eqs. 2 and 3:

$$NH_4Cl(s) \rightleftarrows NH_3(g) + HCl(g)\ K_2 \quad (2)$$

$$NH_4NO_3(s) \rightleftarrows NH_3(g) + HNO_3(g)\ K_3 \quad (3)$$

If these equilibria are attained in the atmosphere, the gas-concentration products, $P(NH_3)\cdot P(HCl)$ and $P(NH_3)\cdot P(HNO_3)$, should be equal to the equilibrium constants. The equilibrium constants for Eqs. 2 and 3 have been thermochemically calculated.[21-25]

In Fig. 7, the logarithm of the observed concentration products for NH_4Cl and NH_4NO_3 are plotted together with calculated and measured equilibrium constants, as a function of the reciprocal temperatures. The error bar corresponds to the assumed uncertainty of the gas concentration, 20% in either direction. The present plots agree very well with the predicted temperature dependences, K_2 and K_3, within the limits of experimental error. This agreement is encouraging.

The concentration product for NH_4Cl was found to be generally larger than that for NH_4NO_3; this was consistent with the fact that K_2 is larger than K_3, judging from both the calculated and measured vapor pressures.[21,24]

A number of groups have reported comparison of the observed NH_3-HCl[26-28] and NH_3-HNO_3[24,29-32] concentration products with calculations. For the NH_3-HNO_3 system, Hildermann et al.[31] have shown that measurements and theory are in good agreement for inland sites employing filter-based techniques without diffusion denuders. So far as we have sur-

Two Andersen samplers were simultaneously employed in March, 1981.

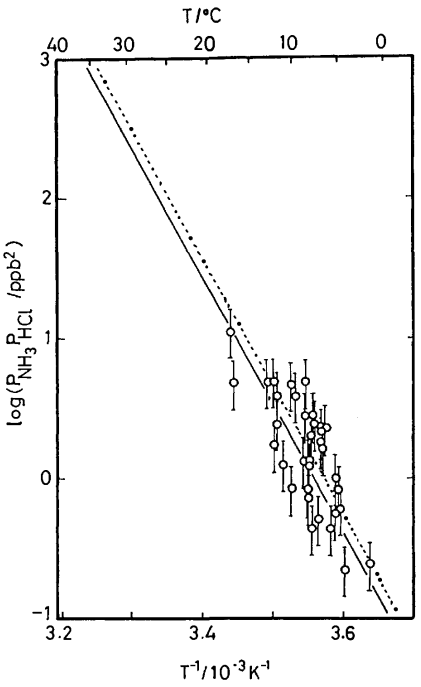

Fig. 7. Relationship between the measured NH_3–HCl products and ambient temperaute. The lines are calculated (——) and experimental (----) equilibrium constant, K_2.

veyed the literature, the other observational results exhibit considerable deviations in either direction from the predicted values even if the denuder method was applied to the nitric acid determinations. The magnitude of potential interference for the nitric acid measurement must be unequivocally determined in order to establish whether the equilibirum relationship, Eq. 3, holds in the atmosphere.

Theoretical models have been developed in consideration of several factors, such as the relative humidity[22,23,25] and such coexisting salts as $(NH_4)_2SO_4$.[25] Recently, however, Jaffe has pointed out potentially unwarranted confidence in the theoretical equilibrium constant.[35] If the free energy and enthalpy values are derived from the experimental equilibrium constants at temperatures well above the ambient conditions, as is the case for NH_4NO_3 (76—165 °C), the extrapolation of the calculated results on the basis of the thermodynamical vaules to ambient temperatures could lead to serious errors in the predicted concentration product.

The atmospheric concentration product in Eqs. 2 and 3 are still open to further discussion. Highly time-resolved observations and more sophisticated theoretical considerations based on reliable thermodynamical data are required to obtain quantitative explanations of these systems.[38–40]

***f*-Values.** In terms of the gas-particle distribution factor, defined as in Eq. 4, the involvement of the equilibria, Eqs. 2 and 3, in the seasonal-variation mechanism of the size-distribution was qualitatively examined. This factor was originally introduced by Grosjean and Friedlander[36] in examining carbonacious compounds, for the component, X, between the gas and aerosol phases as follows:

$$f(X)=P(X)/(G(X)+P(X)) \quad (4)$$

where $P(X)$ and $G(X)$ are the aerosol and gaseous concentrations, in $\mu g\,m^{-3}$ as X (Cl^- or NO_3^- in the fine mode or the corresponding gaseous form).

The temperature dependence of the values of this factor (the *f*-values) for chloride and nitrate species were examined over a wider range of temperature than that of the concentration products (Fig. 8). Over the range of 5—30 °C, the distribution factors decreased for both chloride and nitrate aerosol from near unity to zero with the temperature. This demonstrates that gaseous forms are favored in the summer period, while aerosol forms are favored in winter. These findings are in harmony with the above equilibria, Eqs. 2 and 3.

Tanaka et al.[28] undertook a similar investigation of gaseous and particulate chloride, nitrate, and ammonium species at a wooded park about 500 m from our institute in June, 1985, and February, 1986. The gas-particle distributions for chloride and nitrate were shown to be affected by the temperature in the same manner. Sasaki et al.[37] measured nitrate aerosol and nitric acid in four sites on the Kanto Plain from 28 to 30 July, 1983; they found that nitrate dominated over nitric acid as the temperature increased.

The restriction of the equilibria (Eqs. 2 and 3),

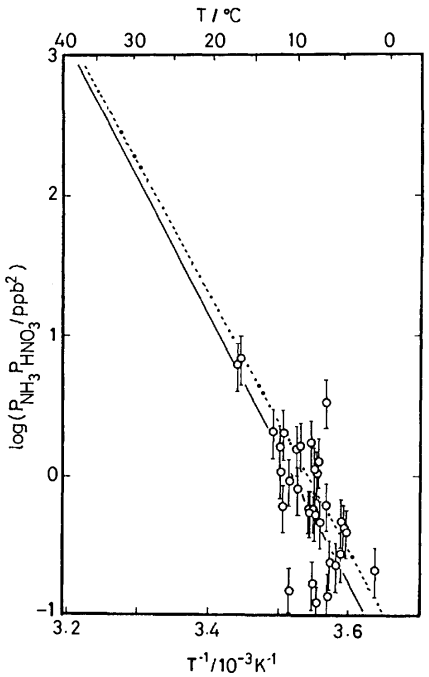

Fig. 8. Relationship between the measured NH_3–HNO_3 products and ambient temperaute. The lines are calculated (——) and experimental (----) equilibrium constant, K_3.

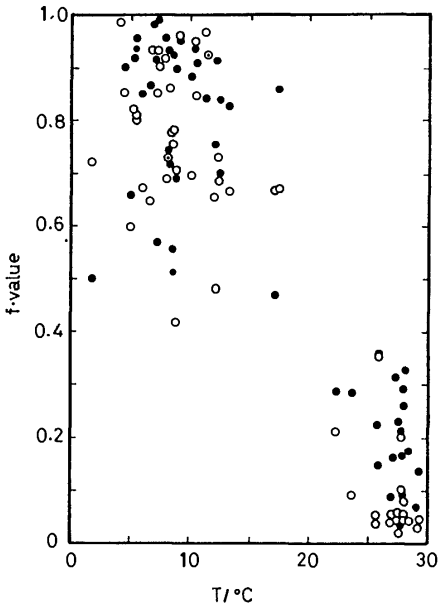

Fig. 9. Temperature dependence of *f*-values for chloride (O) and nitrate (●).

caused the seasonal variation over a wider range in the fine chloride and nitrate concentrations. In Tokyo, the range happens to be significantly both over and under the coase-mode concentrations; this results in our observed variation in the size distributions with the season.

Frequency Distributions. The cumulative distributions for the fine-, coarse-mode, and total concentrations of chloride, nitrate, sulfate, and ammonium aerosols are displayed in Fig. 9. The parameters approximated very closely to the log-normal distributions. Further, fine-mode chloride and nitrate showed bimodal distributions. This bimodal feature probably results from the temperature dependence of the equilibria, Eqs. 2 and 3.

Coarse nitrate and ammonium, as well as fine-mode chloride and nitrate, showed the bimodal distributions. A considerable change in the concentration level of fine chloride and nitrate (Figs. 4(a) and 5(a)) was observed at about 15 °C. At higher temperatures, the concentration level was rather lower than the level at lower temperatures. This change may be ascribed to the temperature dependence of the equilibria, Eqs. 2 and 3, which results in the bimodal distribution of the fine-chloride and nitrate concentrations. Although bimodal characteristics have also been observed for coarse nitrate and ammonium, no feasible explanation can as yet be offered for the distributional features of these species.

Anionic Composition of Coarse and Fine Aerosol. The relative molar-contributions of the three anions were obtained for fine and coarse modes respectively, classified with respect to the temperature (Fig. 10). In both modes, chloride was demonstrated to be a significant component.

For the fine mode, the relative composition depended dramatically upon the temperature. Chloride contributed 45% of the anions at temperatures below 5 °C. Nitrate exhibited a similar, but not so obvious, dependence. Sulfate contributed more as the temperature increased.

For the coarse mode, on the other hand, the composition was rather invariant with the temperature: chloride always constituted nearly half of the anions. Coarse chloride and nitrate are usually considered to be of seasalt origin and to result from the chlorine-loss reaction, Eq. 1, respectively. If the molar ratio of sulfate to chloride of the seawater (0.0517) is conserved throughout its transport as a seasalt particle, the seasalt sulfate was evaluated as contributing one-third of

Studies on the Electrochemical Behavior of Thiadiazole Derivatives. Electroreduction of 2-Benzoylamino-5-[cyanoaryl-hydrazonomethyl]-1,3,4-thiadiazoles

H. M. Fahmy,* M. Abdel Azzem,† M. Abdul Wahab, N. Abdel Fattah, and M. A. Aboutabl
Chemistry Department, Faculty of Science, Cairo University, Egypt
†El Monoufia University, Egypt
(Received June 13, 1988)

The electrochemical behavior of some 1,3,4-thiadiazole derivatives substituted at C_5 (carbon number five in thiadiazole ring) with a hydrazono group has been studied at a dropping mercury electrode (DME) in different pH values. Controlled potential electrolysis (CPE) in alkaline medium, cyclic voltammetry (CV), ultraviolet spectra (UV) and pK_a studies confirmed the proposed mechanism.

Literature scanning revealed that very little has been reported on the electroreduction of derivatives containing the thiadiazole ring structure. The results showed with no evidence or supports that the waves exhibited by these derivatives are due to the ring attack.[1-3] Furthermore, our laboratory investigated recently the electroreduction of a series of thiadiazole derivatives[4,5] substituted by an activated olefinic double bond where a Ziegler-Throp reaction[6] took place in which the hetero ring was unaffected. In a program aiming to study the electrochemical behavior of thiadiazole derivatives, it was found of interest to report the electroreduction of a series of 2-benzoylamino-5-[cyanoarylhydrazonomethyl]-1,3,4-thiadiazoles (**Ia—e**) together with a model compound namely 2-benzoylamino-5-cyanomethyl-1,3,4-thiadiazole (**II**) in order to increase data of such compounds to help in solving the conflicting results concerning the electroreactivity of this hetero ring which were proved to have pronounced medical and pharmaceutical activities.[7,8]

Experimental

(1) Organic Syntheses. (a) **2-Benzoylamino-5-cyanomethyl-1,3,4-thiadiazole (II)** was prepared according to literature[9] by refluxing a solution of 1-cyanoacetyl-4-benzoylthiosemicarbazide (1.0 g) in glacial acetic acid (30 ml) for five hours. The resulting solution was evaporated in vacuo and the remaining product was triturated with ethanol to give the solid product which was filtered off and recrystallized from acetic acid.

(b) 2-Benzoylamino-5-[cyanoarylhydrazonomethyl]-1,3,4-thiadiazoles (Ia—e) were prepared as follows: A solution of the appropriate aromatic diazonium salt (100 mmol) was added gradually to a cold solution of compound **II** (100 mmol) in ethanol (100 ml) and sodium acetate (13 g) with continuous stirring. The solid product thus formed was collected by filtration, washed with water, dried and finally crystallized from the appropriate solvent.

(2) Electrochemical Measurements. Polarograms were recorded with a Metrohm Polarecord E 506 with appropriate attachement E 505 using the Ag/10^{-2} M Ag^+ reference electrode and 10^{-4} M solutions in 50% by volume ethanolic Britton-Robinson buffers (1 M=1 mol dm^{-3}).[10] The capillary possessed the following characteristics in 0.1 M KNO_3 open circuit: t=3.9 s $drop^{-1}$, m=1.54 mg s^{-1} for h=52 cm. Cyclic voltammograms were recorded using a hanging drop mercury electrode (HDME) as working electrode with varying scan rates 50—800 mV s^{-1}. The pH-measurements were carried out with an Iskra Kranj pH-meter MA 5701.

(3) Spectrophotometric Measurements. Spectrophotometric measurements were carried out on a PYE Unicam 1800 spectrophotometer supplemented with a program controller automatic linear recording unit. The spectra were recorded on 4×10^{-5} M of the studied compound in 50% ethanolic Britton-Robinson buffer solutions. The pK_a were determined using the graphical correlation between pH and absorbance with their appropriate equations.[11]

(4) Preparative Electrolysis and Identification of the Resulting Products. The mercury pool electrolysis was carried out on 250 mg of the unsbstituted derivative in 200 ml 0.2 M NaOH due to the high insolubility of the compounds in acid media (BR acid mixture, dil HCl up to 2 M, H_2SO_4 up to 3.6 M and acetate buffer). By controlling the potential at −1.60 V vs. SCE, the current fell from 60 to 0.5 mA in ca. 4.5 hours of electrolysis. After complete electrolysis, the reaction mixture (pH=12.5) was acidified with concd HCl till pH≈1 at which the resulting compound began to precipitate. The product was filtered off and washed several times with hot ethanol (due to its insolubility in most solvents) to give a faint yellow compound of

mp=175 °C (yield ca. 60%) and identified as 2-benzoylamino-5-(α-aminocarboxymethyl)-1,3,4-thiadiazole. Azo dye test on the mother liquor gave a positive scarlet red color. IR of the resulting product (KBr) ν/cm^{-1}; 3460, 3240, 3030 (NH); 2900, 2760, 2700, 2640 (CH); 1660 (amide CO) (Fig. 1). ^1H NMR in DMSO: δ=4.08 (br., 1H, NH); 4.38 (1H, CH); 7.50 (6H, 3H aromatic protons and 3H, NH); 8.02 (2H, ortho-aromatic protons). ^1H NMR with D_2O: δ=4.38 (1H, CH); 7.50 (3H, aromatic protons); 8.02 (2H, ortho-aromatic protons). UV (in DMF) λ_{max} at 270, 372 nm respectively. Calcd: C, 47.4; H, 3.6; S, 11.5; N, 20.1; O, 17.2%. Found: C, 47.1; H, 5.0; S, 12.3; N, 18.8; O, 16.5%. MS m/z=278, 256, 212, 206, 195, 181, 151, and 110.

Results and Discussion

The polarograms of 10^{-4}M of **Ia**, taken as a typical example for the studied series **Ia—e**, are illustrated in Fig. 2. From the effect of mercury-height variation on i_l, cyclic voltammetry and routine analyses, it is found that each compound exhibits a four-electron diffusion-controlled irreversible wave A. This wave splits into two wavelets A_1 and A_2 of approximate

Scheme 1.

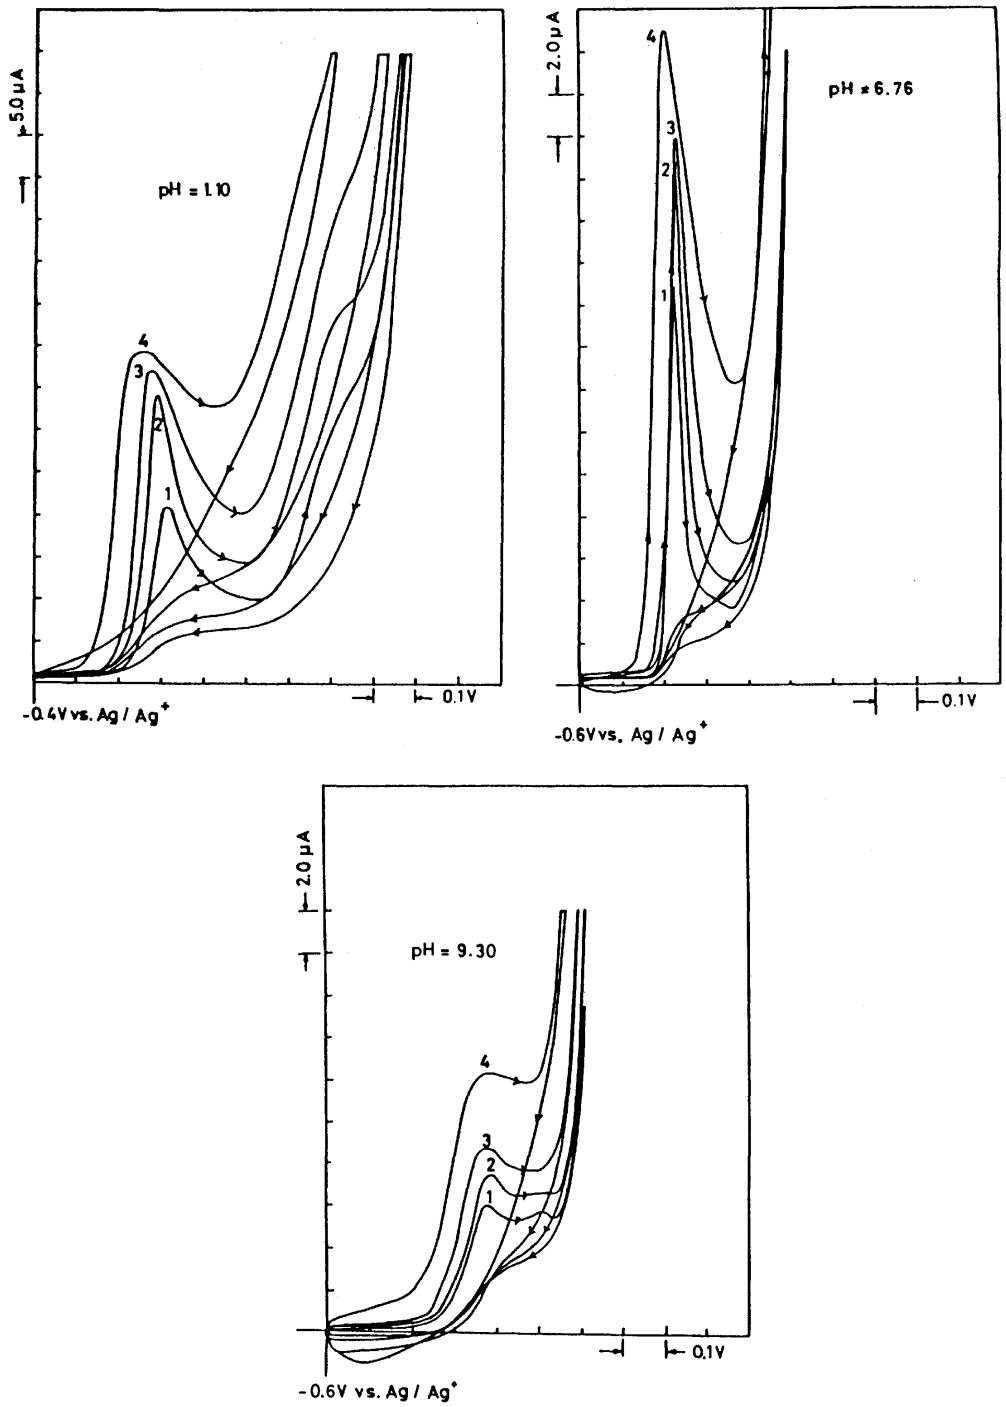

Fig. 6. Cyclic voltammograms of **Ia** at different pH values. 1; 50, 2; 100, 3; 200, 4; 500 mV s^{-1}.

The i_l-pH plot shows a moderate increase of i_l up to pH ca. 6 after which a weak dissociation curve appears in the pH range 6—8.5 followed again by a slight increase of i_l with increasing pH. In exception, compound **Ie** has revealed another four-electron wave. The less negative one was considered to correspond to the reduction of the NO_2 group into NHOH function. This assignment is based on the similar behavior of this wave with that reported for aromatic nitro compounds.[12]

Absorption Spectra of Compounds Ia—e and II. In solution of pH values 1.99—6.15 the absorption spectra of 4×10^{-5} M compound **Ia** are characterized by a strong band with λ_{max} at 396 and a weak one with λ_{max} at 290 nm. These are due to the absorption of the nonionized form liable to exist at low pH values. With increasing pH from 6.15 to 7.00 a red shift occurs giving rise to a band with λ_{max} at 404 nm and a shoulder at ca. 320 nm. As pH is further increased up to pH 8.85, the shoulder at 320 nm appears as a weak

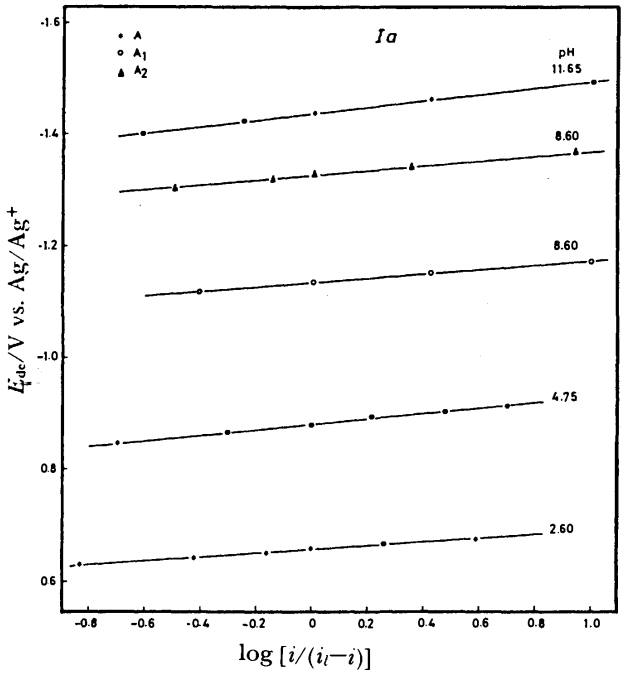

Fig. 7. Some representative logarithmic analysis plots for **Ia** at different pH values.

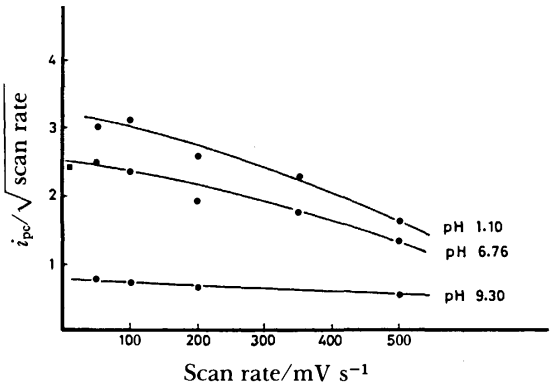

Fig. 8. Plots of the ratio of cathodic peak currents to the square roots of the scan rate as a function of the scan rate.

band at λ_{max}=322 nm. The shift of pH to the alkaline side is then accompanied by a red shift of the strong band as shown in Fig. 4. The absorption spectra are characterized by the presence of two isosbestic points at 304 and 346 nm in the pH range 1.99—8.85. The apparent ionization constant was calculated and the mean pK_a for each member is compiled in Table 1. The absorption spectra of model compound **II** showed one band at 270 nm in the pH range 1.99—6.15. At pH 6.15—11.76 the band is red-shifted acquiring λ_{max} at 310 nm. One isobestic point at 288 nm is observed throughout the whole pH range. Since all compounds **Ia—e** have practically constant pK_{a1} values ranging from 6.02 to 6.17 (cf. Table 1), it is clear that there is no dependence of ionization on the substituent effects. Hence, the ionizable center can be considered far from the aryl group, and this is confirmed by the fact that model compound **II** gave the same pK_a value (6.38). Therefore we can attribute the first pK_a to the ionization of the amide NH group (cf. Scheme 1). On the other hand, compounds **Ia—e** have another pK_{a2} depending mainly on the substituent effects as it is clear from the pK_a-σ correlation. Thus we can consider the pK_{a2} is due to hydrazono NH (cf. Scheme 1 and Fig. 5).

Mechanism of the Electrode Process. The behavior of wave A is in good agreement with the reported behavior of compounds containing the hydrazono linkage[13,14] and different from those containing the azo moiety.[15,16] This interpretation is confirmed by the fact that the wave corresponding to the reduction of the nitro moiety in compound **Ie** appeared before wave A.[17] Since the $E_{1/2}$ values of compounds **Ia—e** were pH-dependent and i_l-pH independent, it was concluded that both acidic and basic forms reach the electrode surface and are electroactive yielding the same product. Cyclic voltammograms at different pH values indicated that the processes are irreversible in nature (cf. Fig. 6) as confirmed by logarithmic analyses (cf. Table 2 and Fig. 7). It was shown that the relation between i_{pc} and $\sqrt{\nu}$ (where i_{pc} is the cathodic peak currents and ν is the scan rates) can be useful in deciding to which case in the Nicholson and Shain[18] classification a given process belongs. As is clear from Fig. 8 a CE mechanism takes place in acidic and neutral media which was confirmed by calculating $dE_{1/2}/d\,pH$ indicating that the protons are involved on the electrode reaction while it is an EC mechanism in alkaline medium. Based on the obtained results, one may propose Scheme 1 for the interpretation of these results. It is important to mention that it was difficult to carry out CPE in acidic medium due to the limited solubility of compounds **Ia—e**. Also, dianion **4** is stabilized through the spreading of the negative charge on the molecule. Finally we obtained compound **6** and not **5** due to the alkaline hydrolysis of the cyano group.[19]

The authors thanks Prof. M. R. H. Elmoghayar for providing the samples.

Alkylation of Toluene with 2-Propanol over Titania-Silica-Alumina Catalysts

K. V. C. Rao,* K. R. Sabu, and C. G. R. Nair†
Inter Disciplinary Research Group, Vikram Sarabhai Space Centre, Trivandrum-695022, India
†Department of Chemistry, University of Kerala, Trivandrum-695034, India
(Received July 11, 1988)

The alkylating activity of titania supported on silica-alumina has been reported earlier (V. G. Kumar, T. S. Shoba, and K. V. C. Rao, *Tetrahedron Lett.*, **26**, 3281 (1985)). Further investigations to synthesize such a catalyst with optimum alkylation activity resulted in the coprecipitation of the catalyst from a solution of pH 4—the test reaction selected being the alkylation of toluene with 2-propanol in a fixed bed tubular reactor. The product mixtures at different reaction times are analyzed to have a view on the variation of yields of different alkylated products with reaction time. The alkylated products are *o*-cymene, *p*-cymene, and diisopropyltoluenes (DIT). The presence of titania exerts a synergistic effect upon the alkylating activity of silica-alumina. Also the catalytic activity is governed by the physical characteristics of the catalyst like surface area and porosity. The trend of para-rich isomer distribution observed in the product mixture is attributed to the steric factors. It has been observed that *o*-cymene is formed at a constant rate whereas *p*-cymene formation decreased with reaction time. Increased formation of diisopropyltoluenes are observed with the passing of reaction time. Alkylation studies in the temperature range 165—240 °C have been done to find the effect of reaction temperature on the product distribution. Thus a decrease in the ortho to para molar ratio with increase in reaction temperature and increased formation of diisopropyltoluenes at lower temperatures are observed. No considerable reduction in the alkylation activity has been noticed up to five regeneration cycles.

Conventional catalysts like Lewis acids and mineral acids which are in use for the acid catalyzed alkylation reactions usually result in major corrosion problems due to large amounts of acid vapours.[1,2] Separation of the catalyst from the reaction products also poses difficulty in such homogeneous reactions. The introduction of solid acid catalysts like zeolites was a major breakthrough in alkylation chemistry.[2] Application of high-silica zeolites for alkylation process was realized commercially for the first time by Mobil/Badger[3] in 1980.[2] Crystalline aluminosilicate[4] and silica-alumina[5,6] were previously known to catalyze alkylation reactions. In addition, zeolites are modified by using alkaline earth metals[7] and Group IA,[8] Group IIIA,[9] and Group IVA[10] metals and are used for various alkylation reactions. The sulfates of metals like Zn, Al, Cd, Cu, and Ni supported on silica-alumina are used as catalysts in the alkylation of toluene with methanol of which zinc-sulfate supported on silica-alumina is the most active.[11] Silica-alumina,[12,13] reduced silica-alumina,[14] silica-alumina containing salts of Mn, Zn, Cr, Cu, Cd,[15] molecular sieves,[16] zeolites,[17,18] and rare-earth exchanged zeolites[19] are also used to alkylate benzene with ethylene.

Moreover, combinations of oxides of transition metals[20,21] alone or supported[22] on silica or silica-alumina are used for similar reactions. Certain supported systems like chromia/silica, molybdenum oxide on silica-alumina which are used for oligomerization and polymerization reactions respectively had indicated the utility of supported transition metal catalysts.[23–26] Incorporation of metal oxides may alter the catalytic activity and selectivity to different products.[27] A catalyst containing titanium oxide supported on silica-alumina was reported previously for the alkylation of different aromatic compounds.[28] A wide range of alkylating agents like alcohols, halides, and olefins have been used with this catalyst. The catalyst is reported to be regenerable also.

A systematic synthesis of Tisial catalysts and efficiency of these catalysts in the alkylation of toluene with 2-propanol has been reported in this paper. The catalytic activities of different Tisial catalysts are also compared with that of a synthetic silica-alumina sample. The effect of temperature on the catalytic activity of alkylation, the relative yields of different products and the regeneration studies of the catalyst have also been included.

Experimental

Sodium silicate (Scientific Chemicals), after dissolving in water, is filtered to remove any undissolved sediments. Aluminum sulfate used is of A.R. grade. Titanium tetrachloride is obtained from M/S Travancore Titanium Products, Chavara. Nitric acid and ammonia used are of chemically pure quality.

To an aqueous solution of sodium silicate (260 g dm^{-3} of distilled water) dilute nitric acid (1 : 1) is added at 90 °C under constant agitation, till the pH of the solution is reduced to one. The desired quantity of hot aluminum sulfate solution (333 g dm^{-3}) is added, followed by the addition of titanium tetrachloride (20 ml) under vigorous agitation. Ammonia solution is added slowly, till the required pH is attained. Precipitations are carried out at different pH's (2, 3, 4, 5, 6, 7, 8, and 9) and are designated as Tisial-2, Tisial-3, and so on. Silica-alumina catalyst is also synthesized at pH 4 without titania. The precipitates are washed with distilled water till free from sulfate ion and are extruded as pellets. These are dried at 120 °C for 12 h and sintered at 600 °C and used as catalysts for the

alkylation.

The silica to alumina molar ratio as well as titania contents of different catalysts determined by chemical analysis, and physical parameters such as pore volume, surface area etc., are included in Table 1.

The catalyst (25 g which corresponds to 60 ml in volume) is charged to a tubular glass reactor of 2.54 cm diameter. Provision is made to maintain the pre-catalyst, catalyst and post-catalyst zone temperatures at the desired levels. The reactor is fed under gravitational flow at a constant LHSV (liquid hourly space velocity) of 0.5 with a precalibrated capillary tube. The reaction products are collected by condensing the volatiles with chilled water. Samples are withdrawn from the bulk of the rection products at intervals of one hour and analyzed. The duration of each experiment is 7 h except for those done to study the effect of temperature on alkylation reaction, where it is 3 h. Toluene to 2-propanol molar ratio is kept at 3:1 in each experiment. To estimate the catalyst life for alkylation, the same catalyst (Tisial-5) is subjected to nine successive regenerations by passing air at the end of each experiment of 7 h at 600 °C.

Product mixtures are analyzed by gas chromatography in a Shimadzu GC-5A gas chromatograph. A stainless steel column (3 mm ϕ×2 m) packed with 5% SE 52 on Shimalite 60—80 mesh support is used under the experimental conditions of column temperature 120 °C, injection port temperature 220 °C, detector FID and carrier gas (Helium) flow rate of 60 cm^3 min^{-1}. A Shimadzu C-RIA data processor was used to calculate the peak areas. Products are found to be *p*-cymene (*p*-isopropyltoluene), *o*-cymene (*o*-isopropyltoluene), and three isomers of diisopropyltoluene (DIT). Percentage yields of alkylaromatics are calculated in the following way.

(i) For cymenes

$$\% \text{ Yield} = \frac{(\text{No of moles of cymene formed}) \times 100}{\text{No of moles of 2-propanol fed}}$$

(ii) For diisopropyltoluene (DIT):

$$\% \text{ Yield} = \frac{2 \times (\text{No of moles of DIT formed}) \times 100}{\text{No of moles of 2-propanol fed}}$$

Total Yield = (i) + (ii)

Products are also indentified by bp. Fractional distillation is done in a spinning band distillation column, B/R 36T; Option 3 (B. R. Instrument Coorporation, Maryland USA) at an rpm of 4000 and reflux ratio 20:1.

Results and Discussion

The extent of total conversion of 2-propanol to alkylaromatics over various Tisial and silica-alumina catalysts at 200 °C with reaction time is shown in Fig. 1. The conversion to *p*-cymene, *o*-cymene, and diisopropyltoluenes after the end of each hour of the experiment over Tisial-4 catalyst is given in Fig. 2.

Results of the study on regenerability and catalyst life is shown in Fig. 3.

Table 2 gives the mol% of 2-propanol converted to *o*-cymene and *p*-cymene over Tisial-4, Tisial-5, and silica-alumina catalysts.

The temperature dependence of alkylating activity

is investigated over Tisial-4 catalyst at different temperatures viz. 165, 180, 200, 220, and 240 °C (Table 3).

The distribution of different components in the product mixture at different temperatures is given in Table 4.

The percentage of titania content varied only mariginally with the pH of coprecipitation, whereas silica to alumina molar ratio decreased drastically from 47.6 (pH=2) to 9 (pH=5) (Table 1) and further increase in pH does not have much effect. Lower pH may be maximizing the silica precipitation whereas precipitation of aluminum hydroxide is favored by higher pH. The surface area and pore volume of the catalyst also indicate an increase up to pH 4 and further a decrease as is evidenced from Table 1. These two physical parameters are considerably diminished by precipitation at higher pH. The conversion of 2-propanol to alkylaromatics over different Tisial catalysts also showed an identical trend, where

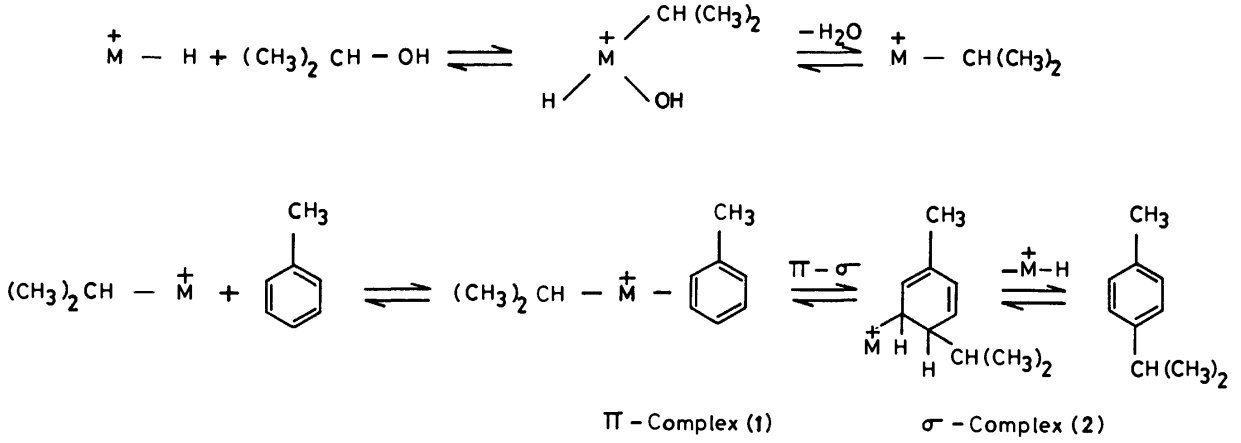
silica to alumina molar ratio of 16 (Tisial-4) appear to give optimum alkylation activity (Table 1 and Fig. 1). The comparison of the physicochemical characters as well as the activity for the alkylation of catalysts from Tisial-4 to Tisial-8 shows that the predominant factors governing the catalytic activity are the physical characteristics of the catalyst like surface area and pore volume, a higher value of which cause increased activity. However, the silica to alumina molar ratio also seems to be a controlling factor in the catalytic activity, which is evidenced by the lesser alkylating activity given by Tisial-2 and Tisial-3 with higher surface area and pore volume compared to Tisial-6 and Tisial-7 (Table 1 and Fig. 1).

The catalytic activity for the conversion of 2-propanol to alkylaromatics is much higher for Tisial-4 than for silica-alumina (Fig. 1). The surface area and pore volume for the latter are 135 $m^2 g^{-1}$ and 1.2 $cm^3 g^{-1}$ respectively and the corresponding values for Tisial-4 are 100 m^2 g^{-1} and 0.71 $cm^3 g^{-1}$ respectively. The silica to alumina molar ratio in both of these catalysts is 16. This reveals that the increased catalytic activity of Tisial-4 may be due to the presence of titania. When transition metal oxides are supported on silica-alumina, $\overset{+}{M}\cdots H$ species will be formed, where M is the transition metal.[28,29] These species initiate the alkylation reaction by the mechanism shown in Scheme 1.[28] The formation of the π-complex is possible because of the presence of low lying unoccupied d orbitals in the transition metal atom.[28,31] It may be presumed from the higher activity of the Tisial-4 catalyst that when titania is supported on silica-alumina, acid sites with suitable acid strength ($H_0 < +1.5$)[32] for the alkylation is increased. That is titania seems to exert a synergistic effect on silica-alumina.

Figure 1 also shows that the rate of formation of alkylaromatics remained constant with reaction time, for all the catalysts studied. In the product mixture the *p*-cymene content is more compared to *o*-cymene at a given time and the *o*-cymene concentration almost remained constant with reaction time. However, the rate of formation of *p*-cymene decreased with time and correspondingly the rate of formation of diisopropyltoluenes increased. This is illustrated in Fig. 2 by taking the case of Tisial-4. The trend of para-rich isomer may be due to the steric factors arising when the reacting species are adsorbed on adjoining sites.[33] Hence it can be assumed that the interaction between an adsorbed toluene molecule and the adsorbed alkylating moiety leads to the para isomer whereas the interaction of the latter with a free unadsorbed toluene in the gaseous state results in the ortho isomer. This also supports the observed lesser differences in the mol% of 2-propanol converted to *o*-cymene compared to that of *p*-cymene on Tisial-4, Tisial-5, and silica-alumina catalysts (Table 2). Also the simultaneous decrease of *p*-cymene and the increase of diisopropyltoluenes with time suggests that the *p*-cymene adsorbed is more prone to get further alkylated to produce diisopropyltoluenes. The results of the comparative study of Tisial-4 and silica-alumina show that the catalytic activity for the conversion of 2-propanol to alkylaromatics is increased by the presence of titania on silica-alumina.

Lesser amounts of alkyltoluenes are formed at temperatures lower than 200 °C. The optimum conversion of 2-propanol to alkylaromatics is observed at 200 °C (Table 3), above which it started decreasing. The increased conversion at 200 °C may be due to the effective diffusion of reactants into and the product molecules out from the pores of the catalyst.[34] The Lesser extent of formation of alkyltoluenes at temperatures 220 °C and 240 °C may be attributed to the possible formation of dealkylated product, namely toluene from the σ-complex (**2** of Scheme 1) by shifting the equilibrium. That is higher tempertures (>200 °C) favor the formation of toluene from the σ-complex, whereas lower temperatures give alkylated toluenes. This is inferred by the observation that the amount of unreacted toluene in the product mixture increased as the reaction temperature is increased



Scheme 1. The mechanism of alkylation catalyzed by transition metal oxide supported on silica-alumina.

beyond 200 °C (Table 4). Similarly, the dealkylation of formed cumene (isopropylbenzene) at temperatures >240 °C has also been observed by Baibuskii et al. over Y zeolite catalyst in the alkylation of benzene with propylene.[35]

In addition, the ortho isomer decreases marginally from 165 °C to 240 °C, while the para isomer shows an optimum at 200 °C (Table 3) and the ortho to para ratio decreases with increase of temperature. These observations are in line with those of alkylation reactions carried out on ion-exchanged zeolites.[32] Diisopropyltoluenes are formed in large amounts at lower temperatures (Table 3). This may be due to the high residence time of cymenes formed at lower temperatures resulting in further alkylation. In general, multialkylation may be favored at lower temperatures.[2]

Tisial-5 catalyst has been subjected to nine successive regenerations. The product pattern clearly indicate (Fig. 3) that alkylating activity of the catalyst is not appreciably affected by successive regenerations. This reveals that Tisial catalyst have sufficient active life for alkylation studies.

Conclusion

The silica-alumina supported titania catalysts are more active for the alkylation of toluene with 2-propanol than silica-alumina itself. Even in presence of titania, the physicochemical characteristics of the catalyst such as surface area, pore volume and silica to alumina molar ratio play a vital role in governing the catalytic activity. The Tisial catalyst co-precipitated from a solution of pH 4 has given the optimum conversion of 2-propanol to alkylaromatics. The para-rich isomer distribution can be attributed to steric factors. Multialkylation is found to be favoured at lower temperatures (<200 °C). The alkylating activity of the Tisial catalyst is not affected considerably by five successive regeneration cycles.

The authors gratefully acknowledge with thanks the support and encouragement given by Director, VSSC. They also acknowledge the help rendered by Dr. M. Rama Rao, Dr. V. G. Kumar, Mr. T. S. Radha Krishnan, Mr. S. Venkatachalam, and Mr. R. Natarajan for fruitful discussions. One of the authors (K. R. Sabu) acknowledges with gratitude the aid given to him by the U. G. C. in the form of a Junior Research Fellowship for carrying out this work.

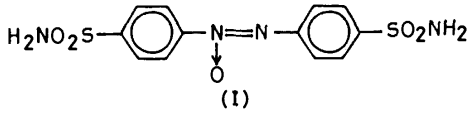
Electrochemical Behavior of Azoxybenzene-4,4′-disulfonamide at Pyrolytic Graphite Electrode

R. N. GOYAL* and Sandhya BHARGAVA
Department of Chemistry, University of Roorkee, Roorkee-247667, India
(Received August 29, 1988)

The electrochemical reduction of azoxybenzene-4,4′-disulfonamide has been studied in the Britton Robinson buffers of pH range 3.0—10.6 at a pyrolytic graphite electrode. The electroreduction was found to occur in a single well defined 4e, $4H^+$ peak. The hydrazo compound has been identified as the main product of the electrode reaction.

The studies on the electrochemical behavior of azo compounds has attracted considerable attention[1,2] in the last decade due to their application in dyes and pharmacy. Azoxy compounds on the other hand have not attracted considerable attention in spite of the importance of azoxy group in enhancing the antibiotic as well as antifungal nature of an organic compound.[3,4] A well-known azoxy antibiotic Elaiomycin has been found very effective in vitro but not in vivo against Mycobacterium tubercuiosis.[5] The other antibiotic LL-BH 872a, having an azoxy group, has been reported as a new antifungal agent.[6] In view of the importance of azoxy compounds in medicine, it was considered interesting to study the redox behavior of azoxybenzene-4,4′-disulfonamide (**I**) claimed as peroxodisulfate oxidation product of sulfanilamide.[7] Since oxidation products of sulfonamides have been suggested[8] responsible for their bacteriostatic action, it is expected that the electrochemical behavior of this compound would throw light on the metabolic pathway of the bacteriostatic action of sulfanilamide.



(I)

Experimental

Azoxybenzene-4,4′-disulfonamide was synthesized in the laboratory by the reported method[9] and its purity was ascertained by repeated crystallization, mp and TLC.

Equipments used for voltammetric and coulometric studies has been described elsewhere.[10] The UV spectral studies were carried out using Specord (C, Zeiss Zena) spectrophotometer. IR spectrum of the product was recorded on Beckmann IR-20 spectrophotometer. Thin-layer chromatography was carried out on silica Gel-G plates with benzene-methanol (80:20) as developer. The pyrolytic graphite electrode was prepared by the method reported earlier[11] and had an area ca. 2.0 mm^2. All potentials are referred to a saturated calomel electrode (SCE).

Chromatographic Procedure. For the identification of the product, about 8—10 mg of azoxybenzene-4,4′-disulfonamide was electroreduced at potentials more negative to peak 1c, in B. R. buffer of desired pH using a three compartment cell. A pyrolytic graphite plate (6×1 cm^2) was used as working electrode, cylinderical platinum gauze and SCE as the counter and reference electrodes respectively. The progress of electrolysis was monitored by recording cyclic voltammograms at different time intervals. The completely electrolyzed solution was transferred from the cell and lyophilized. The freeze-dried material was dissolved in 1—2 ml of distilled water and passed through a glass column packed with Sephadex G-10 (Sigma, bead size 40—120 μm) using doubly distilled water as eluant. This arrangement allowed separation of phosphate from the product. Fractions of 5 ml each were collected and their absorbance was monitored at 210 nm. The first peak to emerge out of the column (between volume 120—160 ml) was found to contain phosphate and rejected. The other peak between 200—230 ml was freeze-dried and analyzed by IR, melting point, and mass spectra.

The stock solution of compound **I** (2 mM; 1 M=1 mol dm^{-3}) was prepared in methanol (A. R.). The solutions for voltammetric studies were prepared by mixing 5.0 ml of azoxybenzene-4,4′-disulfonamide with 5.0 ml of B. R. buffers. The solutions were deaerated for 10—15 minutes and the curves were then recorded.

Results and Discussion

Linear sweep voltammetry of azoxybenzene-4,4′-disulfonamide at a scan rate of 10 mV s^{-1} exhibited a bump 1′c and a well defined reduction peak in B. R. buffers of pH range 3.0—10.6. The peak potential of the reduction peak was dependent on pH and shifted to more negative potential with increase in pH. The plot of E_p versus pH exhibited a break at around pH 6.8 (Fig. 1). The relationship between the peak potential and pH for the reduction peak (1c) is given by the equations:

$$E_p \text{ (pH 3.0—6.8)} = [-0.52-0.057 \text{ pH}] \text{ V vs. SCE}$$

$$E_p \text{ (pH 6.8—10.58)} = [-0.82-0.013 \text{ pH}] \text{ V vs. SCE}$$

Cyclic voltammetry of **I** at a scan rate of 100 mV s^{-1} exhibited a single reduction peak (1c) with a bump (1′c) in B. R. buffers of different pH when sweep was initiated in the negative direction. In the reverse sweep no peak was observed at pH<7.0. However, at pH>7.0 a bump closer to zero volt was occasionaly observed. Some of the typical cyclic voltammograms are presented in Fig. 2. The bump (1′c) was characterized as preadsorption peak due to strong adsorption

of the product by monitoring the relative height of adsorption response (1′c) to diffusion response (1c) with increase in the concentration of compound **I**.[12] It was interesting to observe that the ratio of peak currents for peaks 1′c/1c decreases with increase in concentration of compound **I** (Table 1) and thus indicated that peak 1′c is preadsorption peak due to strong adsorption of the product.[12] A further confirmation was made by recording cyclic voltammograms of **I** at different sweep rates. It was found that the ratio of 1′c/1c increases with increase in sweep rate (Table 2). Hence it was believed that peak 1′c is due to the strong adsorption of the product. The peak current function ($i_p/ACV^{1/2}$) for peak 1′c was also plotted against the sweep rate. It was observed that the peak current function increases with increase in sweep rate in the range 20—500 mV s^{-1} (Fig. 3), thereby further indicating peak 1′c due to strong adsorption.

The peak 1c was found to be diffusion controlled at low concentrations whereas at higher concentrations an indication of weak adsorption of the reactant was noticed. The peak current values (i_p) for the reduc-

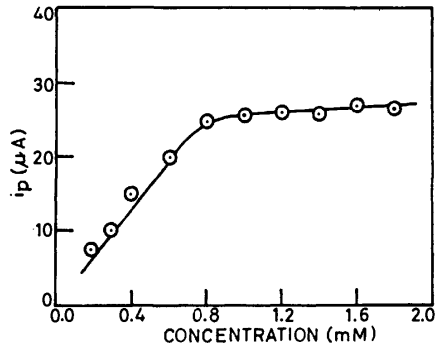

Fig. 4. Dependence of i_p on concentration for the reduction peak 1c at pH 7.26.

tion peak 1c increased linearly with increasing concentration of azoxybenzene-4,4′-disulfonamide upto a concentration of about 0.8 mM and at higher concentrations the peak current values had a tendency to become constant (Fig. 4). This behavior suggests complication due to the weak adsorption of the reactant.[13] Adsorption of the substrate at higher concentrations was further confirmed by the criteria proposed by Wopschall and Shain[14] for strong adsorption of product with weak adsorption of reactant. In such cases, at low scan rates (usually 10 to 500 mV s^{-1}) the adsorption peak current increases linearly with scan rate while diffusion peak current increases approximately as the square root of the sweep rate. A similar behavior was observed for peak 1′c and 1c in the case of azoxybenzene-4,4′-disulfonamide (Fig. 5). The strong adsorption of the product and the weak adsorption of reactant was further confirmed by plotting the ratio of adsorption (1′c) to diffusion (1c) peak current against $\sqrt{V}$. The dotted line shown in Fig. 6 indicates only adsorption of the product whereas the deviation of the observed behavior from straight line clearly pointed out that the reactant is weakly adsorbed and the product is strongly adsorbed in the present studies. This behavior is similar to that reported by Wopschall and Shain[15] for such systems.

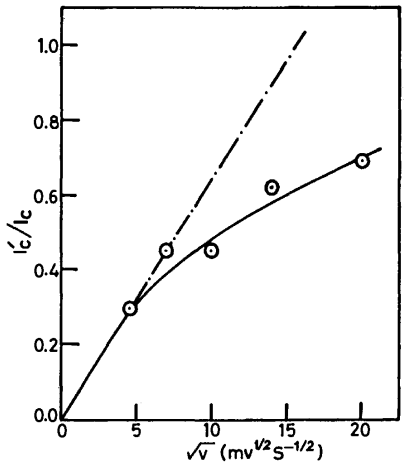

Fig. 6. Ratio of adsorption peak to diffusion peak (1′c/1c) as a function of square root of sweep rate. The dotted line indicates only adsorption of the product.

Table 3. Coulometric n-Values Observed for the Electroreduction of Azoxybenzene-4,4′-disulfonamide

pH	Potential V vs. SCE	Concn mM	Experimental n value[a]
3.08	0.9	0.5	4.12
	1.0	0.8	4.16
4.05	1.0	0.5	4.10
	1.0	0.8	3.88
5.06	1.1	0.5	3.92
6.03	1.1	0.5	4.16
	1.1	0.8	4.10

	1.1	0.8	3.90
10.58	1.1	0.5	4.04

a) Average of at least two replicate determination.

Controlled Potential Electrolysis. Controlled potential coulometry of azoxybenzene-4,4′-disulfonamide at pH values ranging from 3.0—10.58 at potentials more negative to peak 1c indicated that 4.0±0.1 electrons are transferred in the peak 1c process.

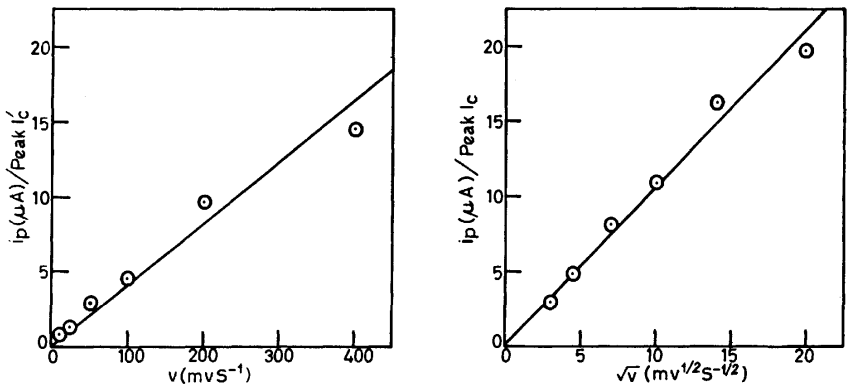

Fig. 5. Dependence of peak currents for peaks 1′c and 1c on V and $\sqrt{V}$ respectively.

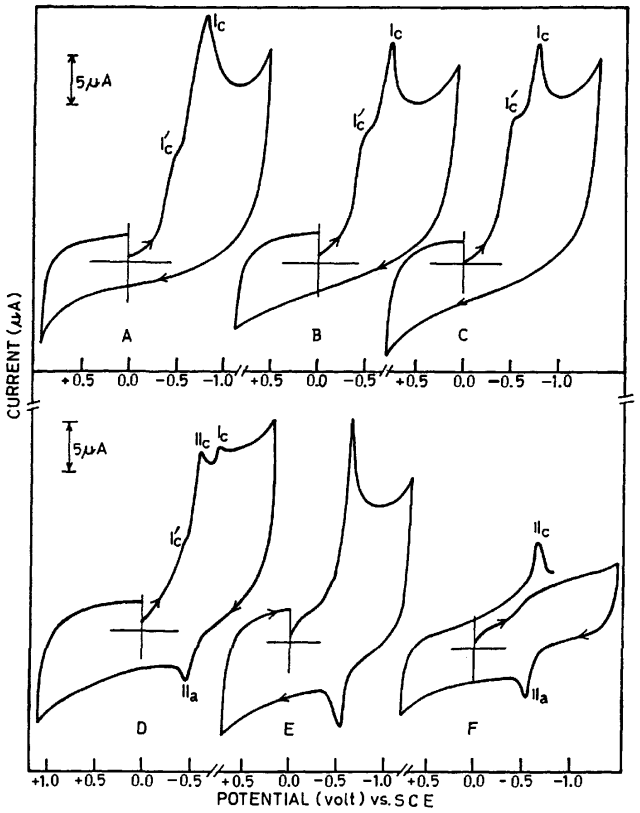

Fig. 7. Cyclic voltammograms of observed for 0.5 mM azoxybenzene-4,4′-disulfonamide undergoing electroreduction at −1.2 V. Curves were recorded at 0 (A), 10 (B), 30 (C), 60 (D), 90 (E), and 180 (F) min of electrolysis.

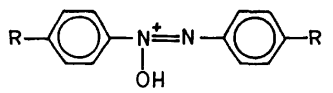
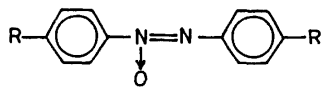
The values of n determined at various concentration of **I** and at different pH are presented in Table 3.

The progress of electrolysis was monitored by recording cyclic voltammograms at different time intervals. The cyclic voltammogram of azoxybenzene-4,4′-disulfonamide before electrolysis at pH 7.06 is presented by the curve A in Fig. 7. With progress of electrolysis reduction peak 1c decrease systematically whereas a new cathodic peak 11c starts appearing at a less negative potential after about 60 minutes of electrolysis. Peak 11c formed a quasi-reversible couple with peak 11a observed in subsequent sweep towards cathodic potentials. On further electrolysis, peak current for the redox couple 11c/11a increases. After about 3 h, peak 11c practically disappeared when sweep was initiated in negative direction. However, peak 11a was clearly observed and peak 11c was observed only in the second cycle (Fig. 5). The orange solution turned to colorless at the end of the electrolysis.

Spectral Studies. The UV/visible spectra of azoxybenzene-4,4′-disulfonamide were recorded in B. R. buffers in the pH range 3.08—10.58 to determine the pK_a. It was observed that compound **I** exhibits λ_{max} at 330 nm with a shoulder around 270 nm in the UV region and at 468 nm in the visible region below pH 6.03. In the pH range 6.03 to 7.07, the λ_{max} at longer wavelength shifted to 472 nm. At pH>7.07 the λ_{max} value was 480 nm. The absorbances at 350 and 472 nm were plotted against pH and gave an inflection point at around pH 6.8. Thus it is clear that below pH 6.8 compound **I** exists as a protonated species and at pH>6.8, it mainly exists as a neutral molecule. It is reported[16] that azoxy compounds are weak base and therefore protonation occurs on the oxygen atom. Hence the following species must exist in the solution.



below pK_a



above pK_a

The observed value of pK_a for azoxybenzene-4,4′-disulfonamide is in the range observed for azoxybenzene and a large number of substituted azoxybenzene.[17]

The progress of the electrolysis of azoxybenzene-4,4′-disulfonamide was also monitored by recording the spectral changes during the electrolysis. The UV spectrum of 0.05 mM azoxybenzene-4,4′-disulfonamide at pH 7.26 before electrolysis exhibited λ_{max} at

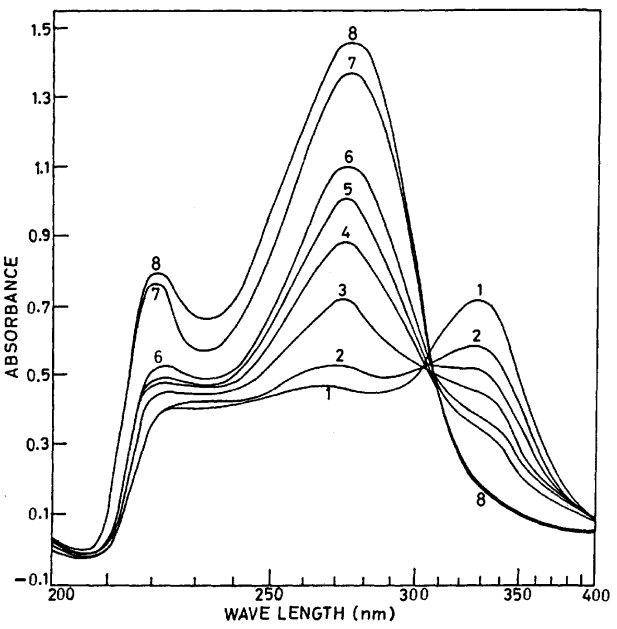


Fig. 8. Observed spectral changes for 0.5 mM azoxybenzene-4,4′-disulfonamide undergoing electroreduction at pH 7.26. Potential −1.2 V. Curves were recorded at 0 (1), 10 (2), 20 (3), 30 (4), 40 (5), 60 (6), 120 (7), and 180 (8) min of electrolysis.

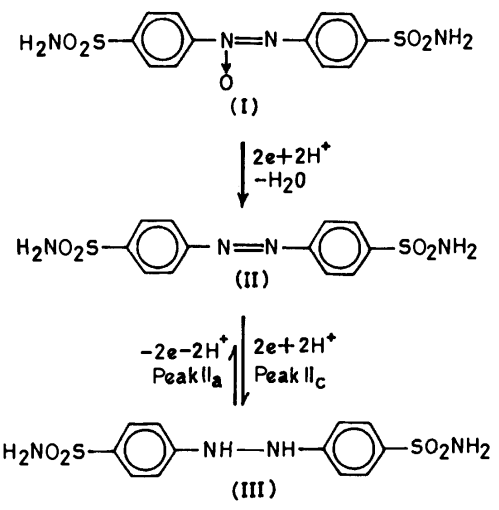
330 nm (Fig. 8, Curve 1). Application of a potential more negative to peak 1c, leads to decrease in absorbance at 330 nm and a systematic increase in absorbance in the region 250—300 and 210—225 nm. At the end of electrolysis a maximum at 276 nm and 220 nm was observed with isosbestic point at 310 nm. This clearly indicates that products of electroreduction of **I** absorbs at shorter wavelength in comparison to the starting material and hence π-chromophore system has been decreased. An almost similar behavior was observed at pH 3.08 and 10.58.

Characterization of the Product. In order to characterize the end product of the electrode reaction, the electrolysis was carried out at pH 3.08 and 7.26. The exhaustively electrolyzed solution was lyophilized and passed through a Sephadex column. The volume collected between 200—230 ml on freeze drying gave light yellow product which was analyzed by TLC, mp, IR, and mass spectra. TLC of the product exhibited only one spot with R_f=0.04 indicating thereby the formation of a single product during electroreduction of compound **I**. The product had a melting point of 158 °C. IR spectrum of azoxybenzene-4,4′-disulfonamide exhibited a strong band at 1450 cm^{-1} (N→O) in addition to other strong bands at 1610, 1400, 1320, 1300, 1245, 1080, 1010, and 910 cm^{-1}. The band at 1450 cm^{-1} disappeared in the product thereby clearly indicating that oxidation is occuring at N→O linkage. The mass spectrum of the product exhibited a clear molecular ion peak at 342. Some other high mass peaks were at 326 (7.3%); 325 (3.4%); 324 (1.1%); 262 (11.8%); 261 (7.3%); 260 (4.3%); 171 (17.1%); 170 (13.3%); 169 (9.2%). However, no attempt was made to explain the fragmentation pattern.

Redox Behavior. The experimental results indicate that reduction of azoxybenzene-4,4′-disulfonamide involves a 4e, $4H^+$ reaction to give a product which absorbs at a shorter wavelength in comparison with the starting material.

As there is no separation of peaks, it appears that 4e, $4H^+$ electrode reaction occurs in a single step. However, the formation of a quasi-reversible couple at the end of the electrolysis corresponding to azo derivative indicates that electrode reaction involves two 2e, $2H^+$ steps and since their potential is close to one another a single 4e, $4H^+$ step was observed in cyclic voltammetry. The following tentative mechanism can be suggested:

The first step in the reaction appears to be 2e, $2H^+$ reduction of azoxybenzene-4,4′-disulfonamide (**I**) to give azobenzene-4,4′-disulfonamide (**II**). As reduction of **II** is easier than **I**, it further reduces by taking 2e, $2H^+$ to give hydrazobenzene-4,4′-disulfonamide (**III**). Since the cleavage of N→O bond of azoxybenzene requires more negative potentials than electroreduction of the -N=N- bond in azobenzene,[18] therefore, **II** can not be formed as a stable intermediatory product and **III** is directly obtained (Scheme 1).



Scheme 1. Tentative mechanism proposed for the electroreduction of azoxybenzene-4,4′-disulfonamide.

To confirm whether the couple 11a/11c is due to the azohydrazobenzene-4,4′-disulfonamide system, cyclic voltammograms of azobenzene-4,4′-disulfonamide were recorded in buffers of different pH. The identical dE_p/dpH values clearly indicate that the redox couple 11a/11c is due to azobenzene-4,4′-disulfonamide. As hydrazobenzene-4,4′-disulfonamide (**III**) has less extensive π-conjugation system in comparison to **I**, the λ_{max} values in UV region shifted to shorter wavelengths.

Conclusion

It is apparent from the present studies that azoxybenzene-4,4′-disulfonamide is electroactive in nature and readily undergoes electroreduction in a 4e, $4H^+$ process to give hydrazo derivative as the final product. It has been suggested by Levitan et al.[19] that polarographic oxidation of sulfanilamide gives azoxybenzene-4,4′-disulfonamide together with other products. Since this compound is electroactive, it can undergo further reduction at higher negative potentials to give hydrazo compound as the ultimate product. Wawzonek[20] and others[21] have reported that electroreduction of azoxybenzene in acid media does not stop at hydrazo stage rather cleavage of NH-NH bond occurs to give aniline. However, in the present studies electroreduction of azoxybenzene-4,4′-disulfonamide gives hydrazo derivative as the final product. Thus it appears that the electron-withdrawing $-SO_2NH_2$ groups present in compound **I** inhibit the further reduction of -NH-NH- and only hydrazo product is formed. The nonreduction of -NH-NH- in presence of electron-withdrawing groups has been reported earlier by Florence[22] in azo/hydrazo benzene system. Azoxy compounds have also been reported to convert into azo compounds on prolonged electrolysis under controlled potential

conditions.[23] Hence it is possible that azoxy compound produced by polarographic oxidation of sulfanilamide converts to azo and then hydrazo product on prolonged electrolysis under controlled potential conditions.

Burton,[24] Mayer,[25] and others[26] have proposed that oxidation products of sulfonamides may partly be responsible for their antibacteria activity. Thus it is concluded that azoxybenzene-4,4′-disulfonamide, a suggested polarographic and chemical oxidation product of sulfanilamide is electroactive in nature and gives hydrazobenzene-4,4′-disulfonamide as the final product. Hence the redox behavior involved with compound **I** is most likely responsible for the bacteriostatic action of sulfanilamide.

The financal assistance for this work was provided by the Indian Council of Medical Research, New Delhi.

Environmental Effects on the Absorption and Fluorescence Spectral Characteristics of Benzimidazole-2-carboxylic Acid and Its Ester

Hemant K. SINHA and Sneh K. DOGRA*
Department of Chemistry, Indian Institute of Technology, Kanpur-208016, India
(Received September 5, 1988)

The absorption and fluorescence spectra of benzimidazole-2-carboxylic acid (BIA) and 5-chlorobenzimidazole-2-carboxylic acid (CBIA) have clearly indicated that benzimidazole (BI) ring and -COOH group are coplanar to each other and are held together in a rigid frame by intramolecular hydrogen-bonding. Dual fluorescence in observed in polar and hydrogen bonding solvents. The short wavelength fluorescence band is assigned to a structure where the -COOH group is perpendicular to the BI moiety and the long wavelength fluorescence band to the planar configuration. This is further manifested from the spectral characteristics of the ester of 5-chlorobenzimidazole-2-carboxylic acid (CBIM). Various prototropic reactions taking place in S_0 and S_1 states for all the three molecules are studied in the H_0/pH/H_- range of −10 to 16. All the dissociation constants are determined, both in the S_0 and S_1 states and are discussed.

In the early 1950's, it was discovered that 5,6-dimethyl-1-(α-D-ribofuranosyl)benzimidazole is an integral part of the structure of vitamin B_{12}.[1,2] These findings stimulated great interest in the chemistry of benzimidazoles and related compounds. Though a detailed study of the physicochemical properties of benzimidazole molecule is available, the similar study on the derivatives of benzimidazole (BI) has received attention only recently.[3-17] We have started to look into the spectral (both absorption and fluorescence) aspects of the various derivatives of BI in detail.[6-17]

The present study on 2-substituted carboxylic acids of benzimidazole has been carried out from the following point of views: (i) The spectral characteristics of the aromatic moiety are changed by the interaction of basic substituents. It has been found in some cases that -COOH group is coplanar to the aromatic ring both in S_0 and S_1 states,[18-20] whereas in some cases, this group is coplaner in S_1 state and not in S_0 state.[21-25] In the present case, besides the transition moment vector which tries to bring the -COOH group in plane with the aromatic moiety, chances are that intramolecular hydrogen bonding will be present and thus will affect the spectral properties. (ii) Due to the competition between the inter- and intramolecular hydrogen bonding in polar and protic solvents, chances are that different conformers may be present in different solvents or there may be equilibrium distribution of conformers in the polar and protic solvents. (iii) The study on the bifunctional molecules containing both electron-withdrawing and electron-withdrawing groups are very rare.[26,27] In our molecules, the two electron-withdrawing chromophores are tertiary nitrogen atom and the carboxyl group. We would like to see the effect of one group over the other as well as overall effect of the two groups on benzimidazole moiety. Thus the absorption and fluorescence spectra of these molecules have been studied in different solvents. pH dependent study has also been carried out to identify the various prototropic species present in the ground and excited singlet states. pK_a values of the various equilibrium reactions have been calculated in the ground and excited singlet states and are discussed. Ester of the corresponding acid has been employed in the above study to supplement our results.

Methods and Materials

5-Chloro-2-(trichloromethyl)benzimidazole (CTMBI) was obtained from Aldrich Chemical Company. It was hydrolyzed to 5-chlorobenzimidazole-2-carboxylic acid (CBIA) by 2 M sodium hydroxide solution (1 M=1 mol dm^{-3}) as suggested in the literature.[28] Similarly for the preparation of benzimidazole-2-carboxylic acid (BIA), 2-(trichloromethyl)-benzimidazole (TMBI) was synthesised by a reaction of *o*-phenylenediamine with methyl trichloroacetimidate (obtained from Aldrich Chemical Company) in acetic acid medium. Several attempts to isolate only 2-(trichloromethyl)benzimidazole (as suggested in the literature)[28] failed. This method has always resulted in a mixture of two products i.e. 2-(trichloromethyl)benzimidazole and bi(benzimidazole). Later these two compounds were separated by preparative thick-layer chromatography using Merck Silicagel G for thin-layer chromatography. The eluting solvent was a mixture of ethyl acetate and benzene in 1:1 (v/v) ratio. TMBI was then hydrolyzed to give the corresponding acid (BIA) as mentioned in the case of CBIA. Methyl ester of CBIA (CBIM) was prepared by refluxing CTMBI in methanol for 20 hours.[28] The purity of all the compounds was checked by noting the sharp melting point as well as by spectroscopic methods. The purity was also checked by fluorescence techniques i.e. by getting same fluorescence maxima when excited with different wavelengths.

The procedure used for purification of the solvents, preparation of the solutions and carrying out the calculations is the same as described in our recent papers.[29-33]

Results and Discussion

Effect of Solvents. The absorption and fluorescence spectra of BI, BIA, CBIA, and CBIM are depicted in Figs. 1 and 2 respectively. The relevant spectral data of BIA, CBIA, and CBIM are compiled in Tables

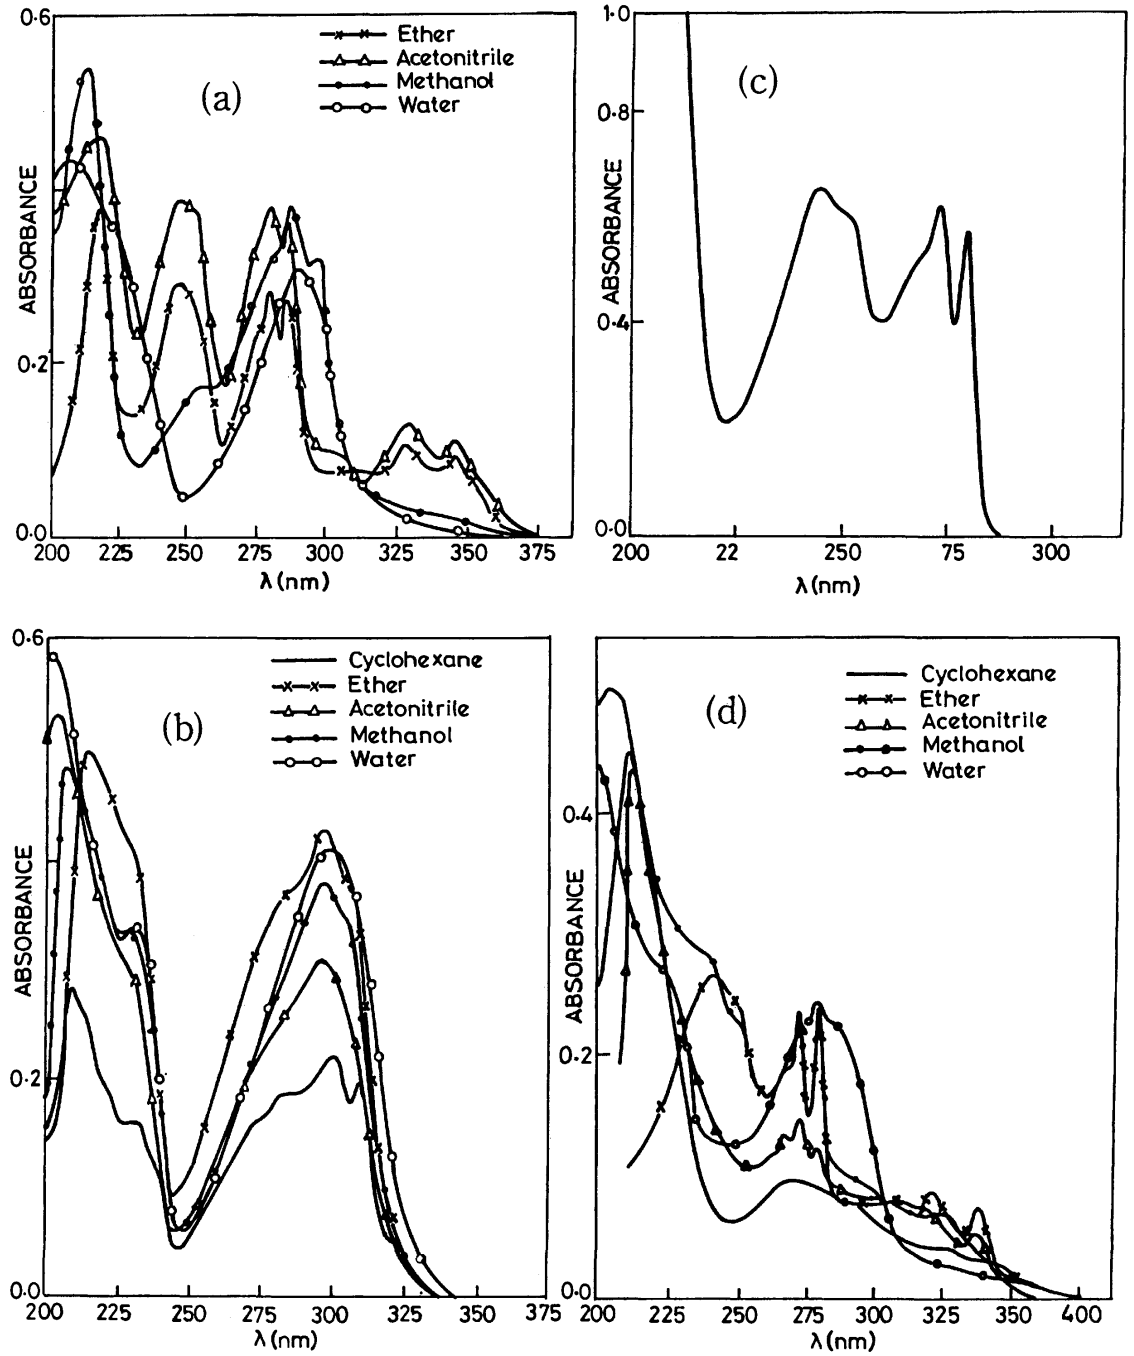

Fig. 1. Absorption spectra of (a) CBIA, (b) CBIM, (c) BI only in water and (d) BIA in different solvents at 298 K.

1 and 2. The absorption band maxima of all the three molecules are largely red-shifted as compared to BI.[34] Above 300 nm, the absorption band system of BIA and CBIA are nicely structured and weak with respect to other three band systems present below 300 nm, whereas in CBIM, this band system is broad and band maximum is close to 300 nm. The absorbance of this band system further decreases with the increase in polarity and hydrogen-bond-forming tendency of the solvents. The other band systems (ca. 280 nm, ca. 250 nm, and ca. 210 nm) are similar to BI. The absorption band maxima of all the band systems are nearly insensitive to the nature of the solvents.

Similar to the absorption spectra, the fluorescence spectra of BIA, CBIA, and CBIM are largely red-shifted as compared to BI.[34] The vibrational structure is observed in all the solvents with the exception of CBIM, where the vibrational structure is present only in cyclohexane. The vibrational frequencies observed in absorption and fluorescence spectra are the same i.e. 1100±50 cm^{-1} in CBIM and 1500±50 cm^{-1} in BIA and CBIA. Besides this, the fluorescence

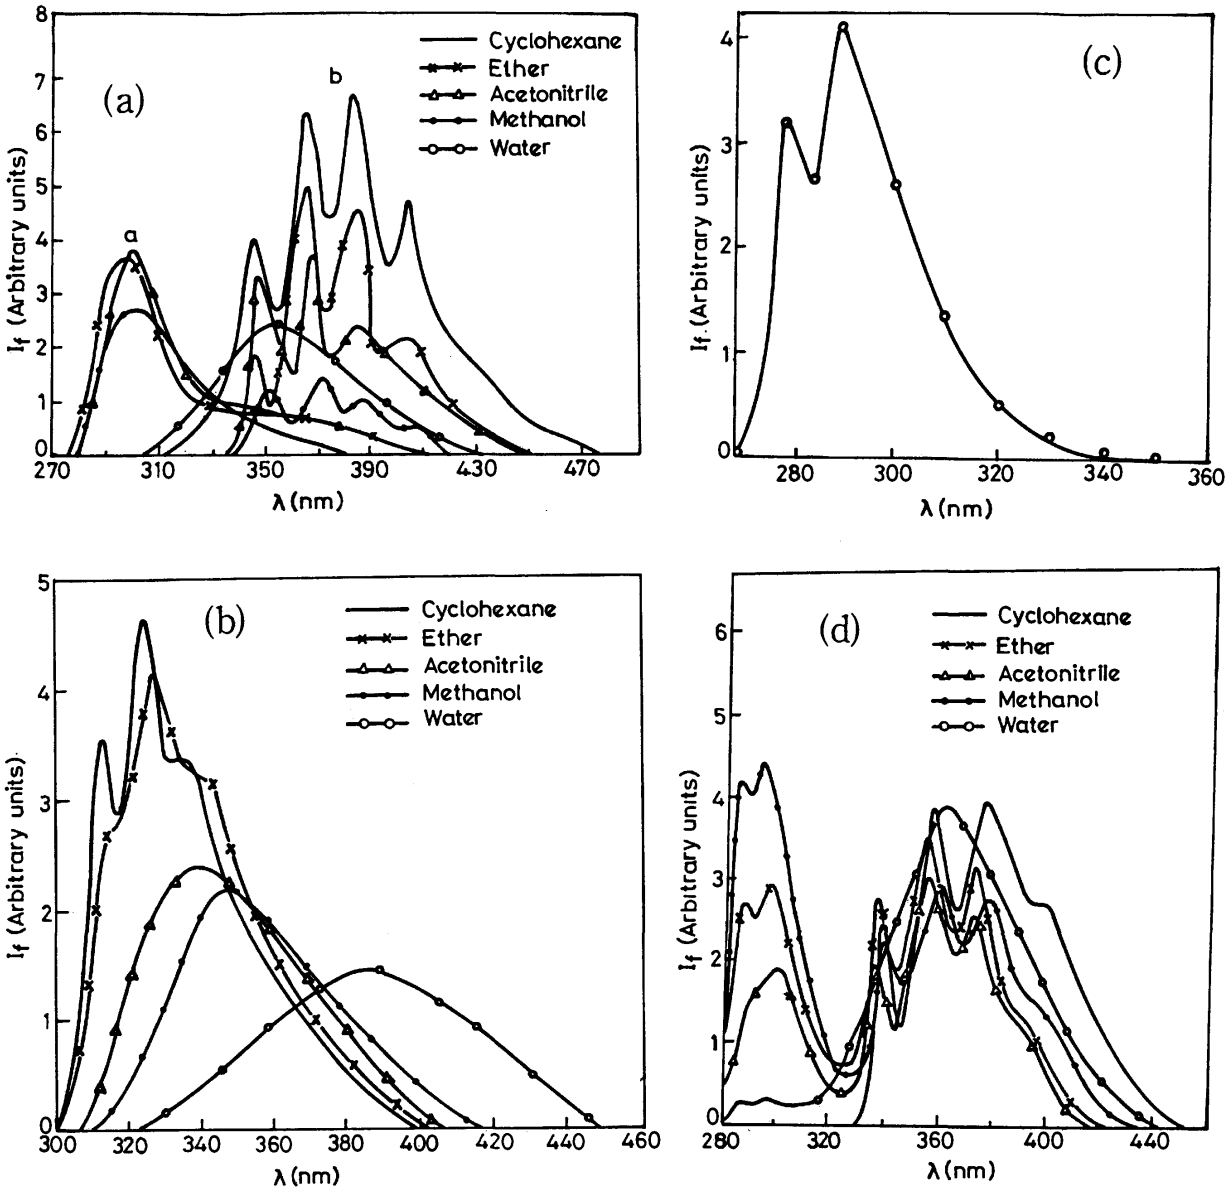

Fig. 2. Fluorescence spectra of (a) CBIA, (b) CBIM, (c) BI only in water and (d) BIA in different solvents at 298 K.

spectrum is not much separated from and makes mirror image with the absorption band.

Besides the structured long wavelength fluorescence (F_1), a second band system at ca. 300 nm is also observed in case of CBIA and BIA in all the solvents except cyclohexane. The excitation spectra recorded at 365 nm in all the solvents resemble the absorption spectra above 300 nm. However no useful information could be obtained from the excitation fluorescence spectra below 300 nm as the lamp intensity is very weak below 300 nm. Both the fluorescence band systems (F_1 and F_2) are hardly affected by varying the nature of solvents whereas that of CBIM shifts from 318 nm in cyclohexane to 390 nm in water.

Data of Tables 1 and 2 clearly indicate that the carboxyl group in these compounds is coplanar with the BI ring, both in the S_0 and S_1 states and hence extensive conjugation is observed. This behavior is similar to that observed in case of 4- and 5-indolecarboxylic acids[18,19] and different to many other carboxylic acids.[20,23,26,35] We suggest that the structured long wavelength absorption and fluorescence (F_1) from BIA and CBIA are due to the presence of intramolecularly hydrogen-bonded structure (**1**). This suggestion is based on the following facts. (i) The presence of intramolecular hydrogen bonding in BIA and CBIA leads to symmetrical structure. Presumably this will lead to the complete delocalization of π cloud

a) pH=12.

over the BI moiety and the -COOH group. This may result in small dipole moment. Because of this the effect of solvents on the spectral characteristics will be minimum. This is reflected by the data of Table 1. A similar behavior is also observed in case of bibenzimidazole.[36] Further the presence of five-menbered intramolecularly hydrogen-bonded structure in case of ninhydrin has been proposed by Dewar.[37] The same argument does not hold for CBIM, where the intramolecular hydrogen-bonding interaction with tertiary nitrogen atom is removed. Due to this, though the red shift is observed in the absorption spectrum of BI, it is not to that extent as noticed in case of BIA and CBIA. This is further manifested by the loss in the vibrational structure as well as the blue shift observed in the absorption spectrum of CBIM in polar and hydrogen-bonding solvents. This is due to the interaction of intermolecular hydrogen-bonding of the solvents with tertiary nitrogen atom and thus rotation of the -$COOCH_3$ group out of the plane of BI. (ii) The presence of long wavelength band due to the dimer formation (as observed in case of benzoic acid[38]) is rejected on the ground that the increase in the concentration of these acids does not affect the ratio of the absorbances of the two band system. Secondly, the observation of vibrational sturcture in such a loosely formed dimer is difficult to explain. (iii) The decrease in the absorbance of long wavelength absorption maxima in BIA and CBIA with increase in the proton donor/acceptor capacity of the solvents is due to the competition between the intra- and intermolecular hydrogen bonding and thereby shifting the equilibrium toward the open structure. The similar band system is also observed in the absorption spectrum of 2-(2-aminophenyl)benzimidazole,[12] which was broad and the ring formed due to intramolecular hydrogen bonding is a six member one. Observation of similar vibrational frequency in absorption and fluorescence spectra and the mirror image symmetry suggest that the molecular conjugation and the geometry of BIA and CBIA in S_1 state differ very little from that in S_0 state. The similar vibrational fre-

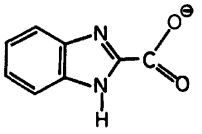
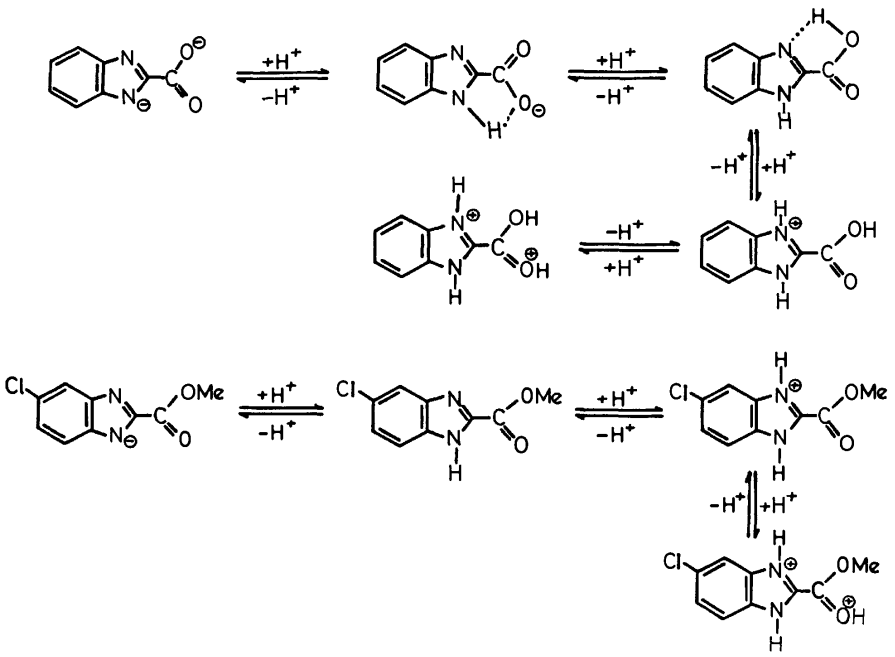
quency (ca. 1500 cm^{-1}) is also observed in the specturm of other 2-substituted benzimidazoles where the structure is rigid, for example, 2-(4-aminophenyl)-[11] and 2-(4-hydroxyphenyl)benzimidazoles.[15] The insensitivity of the fluorescence spectra of BIA and CBIA towards the nature of the solvents further extablishes the existence of rigid and symmetric structure (**1**) in the S_1 state. Since similar symmetric structure is not possible in CBIM, the vibrational structure is lost in more polar and protic solvents. Unlike absorption spectrum, the large red shift observed in the fluorescence spectrum of CBIA confirms the existence of manifold degeneracy of the excited singlet states of BI.[4,17,39] Both these molecules (CBIA and CBIM) contain electron-donating (Cl atom) in the benzene ring and electron-withdrawing group (-COOH or -COOMe) in the imidazole ring and thus will favor the charge transfer state to be of lowest energy. Whereas the effect of solvents on the fluorescence spectra has indicated that the π^* is the lowest energy state in CBIA and CT in CBIM. The presence of intramolecular hydrogen-bonding perturbations in CBIA may be responsible for inhibition of charge transfer from benzene to the carboxyl group. The migration of the charge density from the benzene ring towards the carboxylic acid group is further manifested from the low pK_a value of the protonation reaction of tertiary nitrogen atom (see later).

The fluorescence (F_2) spectrum closely resembles with that of parent BI molecule[34] or the monocation of the derivatives of BI where the CT transition is absent.[4,17] This fluorescence band can be assigned to the conformer where the -COOH group and BI ring are not coplanar (open strucure). Since only one fluorescence band (F_1) is observed in cyclohexane, it suggests that the open conformer is due to the competition between the intra- and intermolecular hydrogen bonding in polar and protic solvents. The following arguments can be given for rejecting the other possibility. (i) pK_a's of aromatic acids are close to 4,[40] whereas the pK_a for the protonation of tertiary nitrogen atom of BI is 5.53.[3] One can speculate the formation of zwitterion (**5**), with the carboxylato group perpendicular to the BI, both in S_0 and S_1 states. (ii) In our earlier paper,[39] it has been reported that the presence of strong electron-withdrawing groups (-CF_3, -CCl_3) at the 2-position decreases the pK_a value for the protonation reaction of the tertiary nitrogen atom to as low as ca. 1.0. In the present case, it is also expected that the pK_a for the same reaction of BIA and CBIA will also be low (ca. 0.5 see later). This is further confirmed by the similar value of pK_a (0.3) obtained for the prototropic reaction of CBIM, where the formation of zwitterion is not possible in this range of pH. (iii) The aromatic carboxylic acids are also stronger acids in nonpolar solvents as compared





Scheme 1. Various prototropic reactions of CBIA and CBIM in the ground and excited singlet states.

to that in aqueous medium. Complete absence of F_2 in cyclohexane rejects the possibility of a zwitterion.

Effect of Acid Concentration. The absorption and fluorescence spectral data of BIA, CBIA, and CBIM at various acid concentrations are compiled in Tables 1 and 2 respectively. Scheme 1 represents the various prototropic species of BIA and CBIM identified in the H_0/pH/H_- range of −10 to 16.

CBIM. At the extreme acid conditions, the species is a dication formed by protonating the carbonyl group and tertiary nitrogen atom. With decrease of acid concentration a blue-shift, blue-shift and red-shift observed in the absorption spectra of the dication of CBIM is consistent with the deprotonation of $-C\overset{OMe}{\underset{OH^+}{<}}$, $>\overset{+}{N}-H$ and >N-H groups respectively. The species formed are monocation, neutral and monoanion and the changes observed in the absorption spectra are consistent with the deprotonation reactions of various groups. On the other hand, dication is non-fluorescent, but the fluorescence specturm of monocation is blue-shifted, followed by a further blue shift under the above environments. The latter one is unusual because the deprotonation of >N-H group leads to red shift in the fluorescence spectrum of neutral species, as noticed in the absorption spectrum. This can be explained as follows. As said earlier, the lowest energy first excited singlet state of neutral CBIM is CT in character, because of the flow of charge from benzene ring to carboxyl group. In monoanion the presence of negative charge on $>N^-$ will inhibit the flow of charge towards the electron-withdrawing group and thus CT state will be destabilized. Similar behavior is also observed when strong electron-withdrawing groups (-CF_3, -CCl_3) are present at position-2.[39]

Table 3. pK_a and pK_a* of Various Prototropic Reactions of BIA, CBIA, and CBIM at 298 K

Equilibrium			pK_a*		
			pK_a	Abs	Flu
BIA					
Dication	⇌	Monocation	−5.0	−2.4	—

CBIM					
Dication	⇌	Monocation	−4.4	−3.2	—
Monocation	⇌	Neutral	0.3	0.8	2.9
Neutral	⇌	Monoanin	9.6	7.8	—

The pK_a values for the various prototropic reactions in S_0 state are calculated by using absorption spectral data and the values are listed in Table 3. The pK_a's for the monocation-neutral and neutral-monoanion equilibria are quite low as compared to those for BI (5.53[18] and 13.35).[41] This is because of the presence of electron-withdrawing -COOMe group, which decreases the charge densities at the tertiary nitrogen atom and the imino group. The pK_a values in the S_1 state are determined by using Forster cycle method[42] (whereever possible) and the fluorimetric titrations. The pK_a values for all the prototropic equilibria, determined from the fluorometric titrations agree

nicely with the pK_a values for the similar reactions in the ground state. This indicates that prototropic equilibria are not established in the S_1 state and could be due to the shorter lifetimes of the conjugate acid-base pairs. A similar behavior is observed in the protonation and deprotonation reactions of benzimidazoles.[17,39] Spectral changes do establish that the carbonyl group and tertiary nitrogen atom become stronger bases and >N-H becomes stronger acid on excitation to S_1 state.

BIA and CBIA. The nature of prototropic species formed in S_0 and S_1 states of BIA and CBIA in the H_0/pH/H_- range of −10 to 16 are the same i.e. in S_0 and S_1 states, dication, H_0 −2; monocation, H_0 −2 to pH 2; neutral, pH 2 to 4; monoanion, pH 4 to 11 and dianion, pH>11. This is also similar to the behavior of CBIM under the similar environments, with the following exceptions. (i) Monoanions in case of BIA and CBIA are formed by the deprotonation of -COOH group, as CBIM does not possess dissociated proton at pH≈4. pK_a for the neutal-monoanion equilibrium is consistent with the earlier results of carboxyl group.[43] (ii) A normal small red shift is observed in the absorption and fluorescence spectra when >NH group is deprotonated. This is because π^* state is the lowest excited singlet state in the monoanion and dianion of BIA and CBIA as compared to CBIM where CT is the lowest excited singlet state for the neutral and π^* is that for the monoanion. (iii) The pK_a value for the monoanion-dianion equilibrium (i.e. deprotonation of >N-H) of BIA (13.1) and CBIA (12.7) is higher than that for the CBIM (9.9). This could be due to the intramolecular hydrogen bond formed between the carboxylato group and the imino proton. A similar behavior is also observed in case of 2-(2-hydroxyphenyl)benzimidazole.[14]

Various prototropic reactions taking place in the complete range of −10 to 16 are depicted in the Scheme 1 and the pK_a values are compiled in Table 3.

Conclusion

The following conclusions can be arrived at from the above study: (i) The -COOH group in S_0 and S_1 states are coplanar with the BI moiety of CBIA and BIA. The -COOMe group of CBIM is better coplanar with the BI moiety in S_1 than S_0 state. (ii) Two conformers, one cyclic rigid and the other open structure, are present in case of BIA and CBIA. The latter is more favorable in the polar solvents. (iii) Charge transfer state is the emitting state in CBIM neutral species but π^* is the emitting state of monoanion of CBIM. In case of BIA and CBIA, the lowest excited state is of π^* character. (iv) The electron-withdrawing nature of -COOH/-COOMe group reduces the charge densities at the tertiary nitrogen atom and the imino group. This decreases the pK_a values for the protonation and deprotonation reactions.

The authors are thankful to the Department of Science and Technology, New Delhi, for the financial support to the project entitled "Proton Transfer Reactions in the Excited States".

Solvent and Electrode Kinetic Effects on Cathodic Reduction of $I_3^- + 2e \rightarrow 3I^-$ in Some Pure and Mixed Dipolar Aprotic Solvents†

Swapan BHATTACHARYA and Kiron K. KUNDU*
Physical Chemistry Laboratories, Jadavpur University, Calcutta 700032, India
(Received September 14, 1988)

Exchange current densities (i_0) of the redox reaction $I_3^- + 2e^- = 3I^-$ have been determined at 25 °C on platinum (Pt) and graphite (C) electrodes in acetonitrile (ACN), propylene carbonate (PC), *N*,*N*-dimethylformamide (DMF), and their binary mixtures by potentiostatic polarization studies under near equilibrium conditions. The studies in pure solvents have also been extended to 15 and 35 °C and also on platinized graphite (C)Pt electrode. The kinetic solvent effect data at 25 °C have been analyzed in the light of relative solvation of I_2 and transition state (TS) as reflected from the previously reported transfer free energies (ΔG_t°) of I_2 and that of TS derived therein for the respective solvent systems. The electrocatalytic activities of (C)Pt electrode in different solvent systems are found to be of the same order as that of Pt electrode possibly because of its large roughness factor. But the observed energies of activation (E_a) being of the order C≫C(Pt) ≈Pt suggest that graphite is intrinsically a weaker electrocatalyst than both the (C)Pt and Pt electrodes, which are however equivalent to each other so far as electrocatalytic activity is concerned. Moreover, while the electrocatalytic activity of Pt and (C)Pt electrodes is found to be in the order ACN > PC > DMF, that of C is ACN > DMF > PC, which have been ascribed to result from the differential adsorption propensities of the solvent molecules with respect to Pt and C surfaces respectively.

The electrode kinetics of $I_3^- - I^-$ redox couple had received wide interests[1-12] long since. It is chiefly because of its fairly reversible character in both aqueous[7-9] and various nonaqueous[1-6,10-12] solvents especially on Pt surface. This makes it a suitable reference electrode for the use of different electrochemical studies and also as a galvanic element in some potential primary and secondary batteries.[12-19] In fact its fairly high exchange current densities (i_0) on Pt-surface in some nonaqueous solvents led Coetzee and Gardner[20] to recommend it as a useful reference electrode in those solvents.

Although it is well-known that the degree of reversibility of an electrode depends on the nature of the solvent, electrode surface, temperature etc., relatively few work[20,21] have yet been reported on these aspects of this redox couple. This should have been useful particularly to understand the relative electrode kinetic behavior of this galvanic element to be used either as cathodes in some high energy rechargeable nonaqueous batteries or as the redox couple in some potential nonaqueous photoelectrochemical (PEC) cells.

True, exchange current densities of the I_3^-/I^- redox couple on Pt, steel and glassy carbon electrodes in some pure nonaqueous solvents are available in the literature.[20,21] But they are referred to the different conditions and concentrations, and measured by different techniques. Consequently, these are not amenable to the direct comparison is respect of solvent kinetic effect and of the electrocatalytic activity of the different electrodes, which in fact are vital for the search of the proper solvent and electrode to be used as the potential galvanic elements with increased efficiency either in the nonaqueous batteries[22-24] or in nonaqueous PEC cells.[8,23]

In a recent study[24] from this laboratory it has been observed that the efficiency of charging-discharging behavior of a potential rechargeable cell comprising I_3^-/I^- as a galvanic element, in dipolar aprotic solvents like ACN, PC, and DMF and their binary mixtures is better in some of these mixtures than in pure solvents. So, it was considered highly interesting and useful to make systematic studies on the thermodynamic and kinetic aspects of the involved galvanic reactions not only on the widely used Pt electrode but also on some cheaper electrode substrates. With this end in view in a recent paper[25a] we have reported the solvent effect on the relative E° values of I_3^-/I^-, I_2/I_3^-, and I_2/I^- redox couples and the formation constant (K_f) of I_3^- as per $I_2 + I^- \rightleftarrows I_3^-$ equilibrium, in terms of the solvation behavior of I_2, I^-, and I_3^- species. In another paper[25b] we have also reported the rate constant (k_s) values of the galvanic reaction:

$$3I^- \rightleftarrows I_3^- + 2e\,;\; 2I_3^- \rightleftarrows 3I_2 + 2e$$

on Pt electrode as determined by use of cyclic voltammetric technique. Both these reactions however exhibited quasi-equilibrium type cyclic voltammograms (CVG) in each of these solvent systems, and as a result the evolution of k_s values posed to be an involved problem.

In the present paper we are therefore reporting the exchange current densities (i_0) of the galvanic reaction: $I_3^- + 2e \rightleftarrows I_3^-$ as determined by potentiostatic polarization technique under near equilibrium conditions using both the costly Pt and the cheaper graphite carbon (C) electrodes in each of the solvent systems. Moreover, the studies in pure solvents have also been extended to two other temperatures viz. 15 and 35 °C and also with platinized graphite (C)Pt

† Presented in the National Seminar on Electrodics held in Central Electrochemical Research Institute, Karaikundi, Tamilnadu, India during July, 23—25, 1988.

electrode. It is hoped that the activation energies (E_a) of the reaction on different electrode substrates and in different pure solvents will help reflect the intrinsic electrocatalytic activities of the three electrode substrates viz. Pt, C, and (C)Pt and also their relative electrocatalytic behavior in the three dipolar aprotic solvents. Moreover, with a view to have a preliminary reflection about the solvent effect on the reaction mechanism attempts have also been made to take CV's of the reaction in those pure solvents.

Experimental

The solvents ACN (AR, BDH), DMF (E. Merck), and PC (Koch Light) were purified by the methods described earlier.[26,27] KI (GR, E. Merck) was dried by keeping it in vacuum desiccator for a week. I_2 (E. Merck) was purified by sublimation twice under vacuo.

Solvent mixtures were prepared by weight. Solutions of I^- and I_3^- of known strengths in a given solvent were prepared by mixing the appropriate amounts of the standard stock solutions of KI and I_2 in that solvent, the concentrations of which being checked by potentiometric titration with standard $AgNO_3$ solution and volumetric titration with standard thiosulfate solution respectvely.

The cell used in the polarization studies under near equilibrium conditions consists of a three electrode assembly of which the counter electrode is a Pt-foil electrode of 4 cm^2. The test and reference electrodes are either two identical Pt-foils [geometric area A=0.5 cm^2] or of two graphite/platinized graphite electrodes [A=0.1 cm^2]. The advantage of taking the two identical electrodes is that the potential difference between them in any given solution is zero in absence of any external source.[20] The reference electrode immersed in the test solutions is separated from the remainder by a glass cage ending with a fibre-tip similar to that described earlier.[20] In the case of cyclic voltammetric measurements, however, instead of using Pt or C, aqueous saturated calomel electrode SCE(W) was used as the reference electrode. Potentiostatic polarization and linear sweep cyclic voltammetric measurements were carried out with a standard Wenking ST 72 potentiostat along with a Wenking model VSG 72 voltage scan generator. A Houston Omnigraphic X-Y(t) recorder (model 2000) recorded the current and potential which have also been checked by a Kiethley digital electrometer (model 616).

The Pt-foils were pretreated with aqua regia and activated by burning in ethanol flame. Graphite electrodes taken from Nippo dry battery were boiled alternatively in concentrated HCl and hot water, and then dried. They were then covered with a plastic sheet inert to the test solution and the open portion was then polished by rubbing it with a fine file. Some of the graphite electrodes were platinized from 2% hexachloroplatinic acid solution (prepared with 2 M HCl solution; 1 M=1 mol dm^{-3}) using a current of 5 mA from a DB 300 constant current source (Galvanostat) for 30 minutes. The roughness factors of these electrodes were being known from a similar study[28] from this laboratory. The solutions were static at the time of measurements but shaken with a magnetic stirrer at the end of a single measurement, when the drifted voltage of the test electrode reverts back to its original equilibrium value within a time period of maximum five minutes. The initial equilibrium values however reached by about 0.5 hour. The steady state current at a given overpotential η has however reached within 10 minutes. No significant transient effect was observed except immediately after the onset of the over potential, when the rate of rise of current was relatively high. IR-drop was also found to be negligibly small as verified by altering the distance between the test and the reference electrodes even at the relatively high current drain condition. All the solutions were deoxygenated by passing O_2-free pure N_2 for about 15—20 minutes.

Cyclic voltammograms (CVG's) of 0.001 M I_2 solution in presence of 0.1 M $NaClO_4$ supporting electrolyte in water, DMF, ACN, and PC were taken on Pt electrodes with a scan rate of 50 mV s^{-1}. In polarization studies the solution consisted of I_3^- and I^- with a concentration $C_{I_3^-}=C_{I^-}$=0.05 M in those pure organic solvents as well as 25, 50, 75 wt% of their binary mixtures.

Results

A set of typical current (i)-overpotential (η) plots for the I_3^-/I^- redox couples in these solvent systems are shown in Fig. 1. The linear portions in near equilibrium regions are shown, beyond which they are curved. The plots for both Pt and C electrodes in different solvent systems are exactly similar in nature but different only in the extent of linear portions which usually increased with increased exchange current densities for different electrode-solvent pairs, indicating greater reversibility. Since very much low current (ca. 10^{-6} A) passed in the experimental near equilibrium condition (10 mV>η>−10 mV), the mass transfer polarization has been taken to be negligibly small. Moreover, the fact that a few measurements

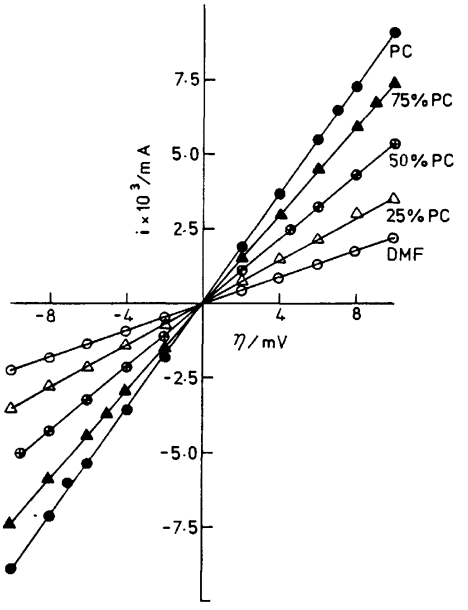

Fig. 1. Plots of $i\times10^3$/mA vs. η/mV for the cathodic solution of $I_3^-+2e^-\rightarrow3I^-$ on carbon electrodes in PC (●), 75% PC +25% DMF (▲), 50% PC +50% DMF (⊕), 25% PC +75% DMF (△), and DMF (○) solvents.

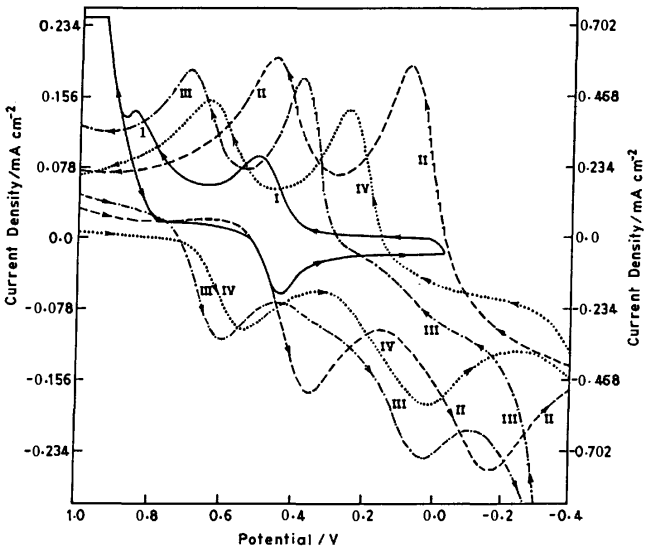

Fig. 2. Cyclic voltammograms of I_2 (10^{-3} M) solutions on platinum electrode. Reference electrode: saturated aqueous calomel. Solvents: H_2O (I) (current scale right hand side) (———), ACN (II) (---------), DMF (III) (—·—·—), PC (IV) (·····).

both at the static and stirring conditions of the solutions show no difference in the readings except some little fluctuations within tolerance limits, also appears to substantiate the above assumption.

The exchange current density (i_0) values for the reaction in different solvents have been determined by use of the Ohmic relation[29]

$$i_0 = \frac{RT\nu}{nF}(i/\eta)_{\eta\to 0} \qquad (1)$$

where i is the current, η is the overpotential, n is the number of electrons involved in the overall reaction, and ν is that in the rate-determining step (rds), which are taken to be 2 and 1 respectively.

In fact, although several mechanisms[20,21,29-33] have been proposed for the I_3^-/I^- system, none is without controversy. We therefore assumed, as Coetzee et al. did,[20] the widely accepted mechanism of Dane et al.[31]

$$I_3^- \rightleftarrows I_2 + I^-$$

$$I_2 + e^- \xrightarrow{\text{rds}} I_{ads} + I^-$$

$$I_{ads} + e^- \rightleftarrows I^-$$

Scheme 1.

for which $n=2$ and $\nu=1$. This is likely to be true in these solvent systems as well, as is evident from the similar behavior of CVG's in the solvents. As could be seen from Fig. 2, the observed CVG's exhibit two peaks in all the cosolvents including water, where the first peak is somewhat subdued. This kind of behavior has also been reported earlier in some of these cosolvents.[9,23] Thus the two peaks indicate that the reduction of I_2 takes place in two overall reactions

$$3I_2 + 2e = 2I_3^-$$

$$I_3^- + 2e = 3I^-$$

Scheme 2.

in all the cosolvent systems though at different potential regions because of the solvent effect on E° value.[26a] Notably, the peak currents (i_p) for both the reactions vary in the increasing order PC<DMF<ACN<H_2O whereas the peak potentials (E_p) vary in the order H_2O<DMF<PC<ACN. While the former order reflects relative kinetic solvent effect, the latter reveals the relative thermodynamic solvent effect of the reaction in the solvents concerned. Evidently, in H_2O the reactions are both thermodynamically and kinetically favorable, whereas in ACN although the reactions are not so much favorable thermodynamically, they are fairly so kinetically as compared to other cosolvents. Since the nature of CVG's for I_2-I_3^- and I_3^--I^-systems are nearly similar at least in all these organic solvents, their mechanisms are likely to be same in all the solvents concerned. This led us to believe, as Coetzee et al. did, that the widely accepted Dane et al.'s mechanism: Scheme 1 is also likely to be true in all these solvents.

Discussion

The values of the exchange current densities (i_0) in different solvent mixtures are presented in Table 1 and the variation of $RT \ln ({}_s i_0 / {}_r i_0)$ with cosolvent compo-

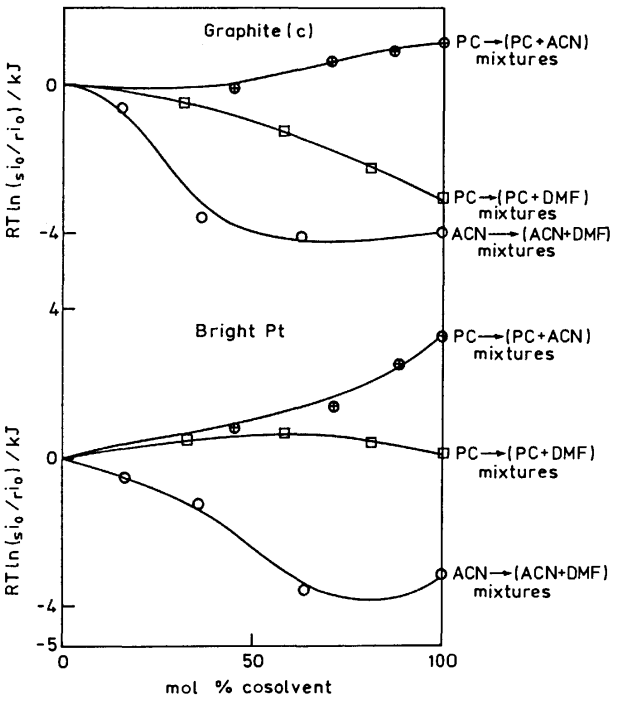

Fig. 3. Variation of $RT\ln({}_s i_0/{}_r i_0)$ against mol% cosolvent for the cathodic reduction of I_3^-+2e→3I^- on bright Pt and carbon C electrodes in PC→PC+ACN, PC→PC+DMF, and ACN→ ACN+DMF mixtures at 25 °C.

sition in Fig. 3, where subscripts s and r refer to the solvent and the assumed reference solvent respectively. In the cases of PC+ACN and ACN+DMF solvent systems, PC is the reference solvent and ACN and DMF are the cosolvents whereas in the case of ACN+DMF solvent system ACN is the reference solvent and DMF is the cosolvent. The results show a strong solvent dependence of i_0 values obtained for both types of electrodes: bright platinum (Pt) and graphite carbon (C), the highest value being almost 10 times greater than the lowest value. The order of the i_0 values of Pt electrode in different solvents follows the sequence: ACN≫DMF≈PC whereas that on C electrode is ACN>PC>DMF.

Moreover, from the data in Table 1 and in Fig. 3 it can be seen that in the case of Pt electrode while the i_0 values in PC-DMF solvent system remain more or less same with a slight maximum around 50 mol% DMF, those in PC-ACN solvent system increase almost monotonically with increase of cosolvent ACN and those in ACN-DMF system decrease monotonically upto 70 mol% of the cosolvent DMF beyond which there is an upward trend.

In the case of graphite electrode, although the behavior of $RT\ln({}_si_0/{}_ri_0)$-composition profiles in PC+ACN or ACN+DMF mixtures is nearly similar to those on Pt surface in the respective solvent systems, that for PC+DMF system takes a sharp downward trend right from zero percent DMF, instead of 50 mol% DMF observed in the case of Pt. Moreover, while the i_0 value in PC on C electrode remains nearly same as that on Pt electrode, this however gets increased with the addition of ACN and decreased with DMF. Evidently, rates of the electrode reaction are not only a function of the solvent properties but also on the electrode materials to some extent, as expected.

As the electrode reactions are multistep reactions, understanding of the solvent effect on electrode reactions, such as this, is an involved problem. This is because the reactions are not only guided by the solvated species involved in the different steps in Scheme 1 but also dependent on the coverage of the electrode by solvent molecules (θ_s). Besides, the solvent effect on the equilibrium potential $\Delta\phi_e$ involved in the expression for exchange current density (i_0):

$$i_0 = nF\vec{k}_s C_{I_2}\exp(-\beta\Delta\phi_e F/RT) \quad (2)$$

where $\vec{k}_s$ is the specific rate constant depending upon the solvent and the electrode surface, β the symmetry factor and other terms having usual significance, is also equally important. So, in order to see the true solvent effect let us examine the relative rates and solvation effect on the reactant I_2 in the rds and that of the transition state (TS) as obtained by use of the relation (3)

$$RT\ln({}_s\vec{k}_s/{}_r\vec{k}_s) = -\delta(\Delta G^{\neq}) = (-{}_s\Delta G^{\neq}) - (-{}_r\Delta G^{\neq}) = \Delta G_t^\circ(I_2) - \Delta G_t^\circ(TS) \quad (3)$$

which follows from the assumed rds as $I_2+e(M)\rightarrow$ TS→products and $RT\ln({}_s\vec{k}_s/{}_r\vec{k}_s)$ is related to $RT\ln({}_si_0/{}_ri_0)$ by Eq. A7 [vide appendix]. Here $\Delta G_t^\circ(i)$ stands for the transfer free energy of any species i from the standard state in the assumed reference solvent (r) to the standard state in the solvent (s) i.e. for the transfer process: i(r)→i(s). In Table 2 we present the values of transfer free energies of I_2 as obtained from a

previous paper[25a] and those of $-\delta(\Delta G^{\neq})$ as well as ΔG_t°(TS) as computed by use of Eq. 3 for both Pt and C electrodes and for all the three solvent systems, taking PC as the reference solvent in the PC+DMF and PC+ACN solvent systems and ACN in the ACN+DMF solvent system. Figures 4—6 depict the plots of $\Delta G_t^\circ(I_2)$, $[-\delta(\Delta G^{\neq})=RT\ln({}_s\vec{k}_s/{}_r\vec{k}_s)]$, ΔG_t°(TS), and $RT\ln({}_si_0/{}_ri_0)$ values as a function of the composition of the added cosolvent for both Pt and C electrodes.

From the plots of $RT\ln({}_s\vec{k}_s/{}_r\vec{k}_s)$ it may be noted that the values of the rate constant $\vec{k}_s$ of the reaction decrease as DMF or ACN is added to PC in PC+DMF and PC+ACN solvent systems respectively, but the values pass through a distinct minima when DMF is added to ACN in ACN+DMF solvent system. Notably, the actual values on Pt and C electrodes though

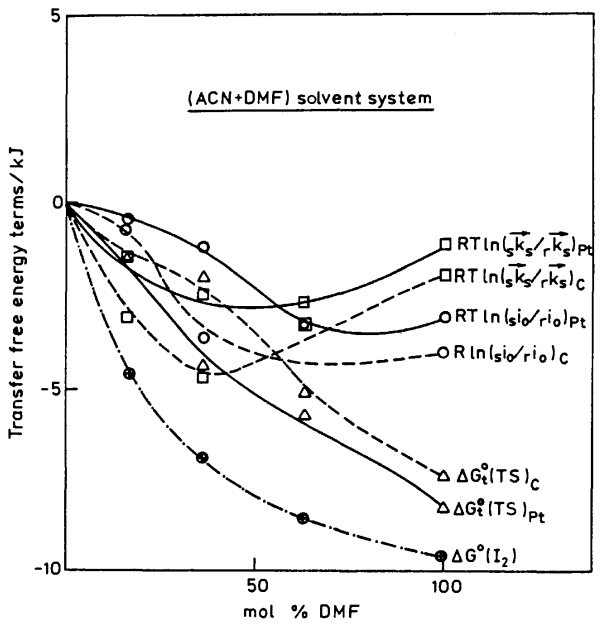

Fig. 6. Variation of $RT \ln ({}_s i_0/{}_r i_0)$ (○), $RT \ln ({}_s\vec{k}_s/{}_r\vec{k}_s)$ (□), ΔG_t° (I_2) (—·—·—), and ΔG_t° (TS) (△) for the cathodic reduction of $I_3^- + 2e^- \rightarrow 3I^-$ on Pt (solid lines) and graphite (C) (dotted lines) electrodes with mol% DMF in ACN→ACN+DMF solvent system.

differ appreciably, their overall behavior is more or less similar in nature in the respective solvents. Moreover, the relative behavior of $\vec{k}_s$ values is also fairly different from that of i_0 values in the respective solvents. Evidently, either the increasing solvation of the reactant I_2 in the rds or decreasing solvation of the transition state (TS) is responsible for the observed solvent effect on $\vec{k}_s$ values in these solvent systems.

Thus in PC+ACN solvent system as the cosolvent ACN is added to PC the solvation of I_2 hardly alters for $\Delta G_t^\circ(I_2)_{PC \rightarrow PC+ACN}$ remains nearly invariant, whereas the solvation of TS decreases to a large extent (see Fig. 4). And hence the decreased solvation of TS is responsible for the decreased rate constant values in the solvent system. The reason for decreased solvation of TS with increased ACN content may be attributed partly to the larger dipolar and dispersion interactions of TS with PC molecules compared to ACN molecules [μ_{PC}=4.98D, μ_{ACN}=3.92D; $\alpha_{PC}=8.56\times10^{-24}$ cm^3, $\alpha_{ACN}=4.41\times10^{-24}$ cm^3][25a] and partly to the smaller coverage θ_s and hence larger free surface $(1-\theta_s)$ in the case of PC molecules compared to the respective cases in the increased proportion of ACN molecules. This is because of the intrinsic structural and electronic configuration of the organic molecules. The decreased reaction rates on C surface compared to Pt surface seemingly result from the fact that a carbon atom with sp^2 electrons can usually be expected to undergo interaction with π-electron clouds of the donor -C≡N or >C=O groups of the solvent molecules. Moreover, as CH_3CN is smaller in size and bears greater thickness of the π-electron cloud than those of PC or DMF, it is expected to get adsorbed more on porous C electrode than bright Pt electrode.[34-36]

In PC+DMF solvent system, as DMF is added to PC the relative reaction rates get reduced on both the electrodes because of the pronounced solvation of I_2 molecules rather than the solvation of TS molecules which in fact get less solvated in the cases of both C and Pt electrodes at DMF rich compositions. Evidently, the effect of possible increased solvation of the TS by DMF molecules due to dispersion interactions[25a] is overcome by the superimposed effect of $(1-\theta_s)$ factors which seem to increase with DMF content and on C surface compared to Pt surface.

In ACN+DMF mixtures however, as DMF is added to ACN, the relative reaction rates, i.e. $RT \ln ({}_s\vec{k}_s/{}_r\vec{k}_s)$, are found to pass through a minimum in both the cases of Pt and C electrode surfaces. The observed variation of this is seemingly guided by the effect of pronounced solvation of I_2 molecules as opposed by the pronounced solvation of TS molecules which being larger in the case of Pt than on C surface, the relative profile for Pt lies above that for C. Since θ_{ACN} is likely to be greater than θ_{DMF}, solvation of TS through $(1-\theta_{org})$ is more in ACN-DMF mixtures than in ACN and this is again less on C surface than on Pt, thus resulting in the observed relative nature and positions of the profiles of relative rate constants on Pt and C surface in this solvent mixture. As the effect of temperature and the related energy of activation is expected to impart better reflection on the effect of electrode surfaces on the reaction rate, we may com-

Table 3. Logarithms of Exchange Current Densities at Different Temperatures and the Activation Energies (E_a)/kJ in the Different Solvents

3.354	3.62	3.48	3.87	4.20	4.00	5.02	4.24	3.90	4.49
3.245	3.55	3.44	3.71	4.10	3.97	4.11	4.09	3.83	4.25
Activation energy (E_a)/kJ mol^{-1}	8.5	8.4	32.0	16.2	16.2	13.5	26.6	26.2	44.4

pare the i_0 values at different temperatures at least for three pure solvents as presented in Table 3. A plot of log i_0 vs. T^{-1} for the reaction at a particular concentration of the reacting species yielded straight lines. The slopes of the lines yielded the E_a values as

$$E_a = -[\delta \ln {}_s i/\delta(T)^{-1}]_{c=\text{const.}} \quad (4)$$

The E_a values so obtained are presented in Table 3. From the perusal of E_a values it may be noted that E_a values for both bright Pt and C(Pt) electrodes are nearly equal to each other in the respective solvents whereas that on bare C electrode is fairly larger than those of both bright Pt and (C)Pt electrodes. This implies that (C)Pt electrode is as good as bright Pt electrode as the electrocatalyst for this reaction, whereas the bare C electrode is a much weaker electrocatalyst than either of the other two types of electrodes. The catalytic effect of Pt surface compared to C surface may be attributed[20] to the fact that sp^2 hybridized electrons of graphite C atom interacts more strongly with the nonbonding and π electrons of the O and N centers of the solvent molecules rather than with 5s electrons of I atom. This again seemingly indicates that the relative values of θ_s play an important role in dictating the relative catalytic activity of the electrode surfaces.

It may also be noted that E_a values on Pt and (C)Pt electrodes in the three solvents lie in the order ACN< PC<DMF, while that on C electrode is ACN< DMF<PC. In fact while the E_a values on Pt and (C)Pt electrodes and in the ratio ACN:PC: DMF=1:2:3, that on bare C electrode is 1:4:1.5. The strikingly larger E_a values on C surface in PC compared to other solvents apparently indicates that the differential propensities for adsorption of cosolvent molecules (θ_s) on C compared to Pt surface is possibly the dictating factor. But as is clear from our earlier discussion, just as for i_0 values, the solvent effect on E_a values as well should be an involved problem, as the latter is afterall computed from the temperature coefficient of i_0 values rather than that of $\vec{k}_s$ values, which should give a better reflection of the solvent effect on the involved kinetics of the reaction. But the limited knowledge on the temperature coefficients of $\Delta G_t^\circ(i)$ terms and hence the $\vec{k}_s$ values does not permit us to further examine the solvent effect on E_a values at this stage.

Thanks are due to the CSIR, Govt. of India for the financial assistance.

Appendix I

Consider the reaction scheme (Scheme A) for the overall reaction $I_3^- + 2e^- \rightleftarrows 3I^-$:

$$I_3^- \rightleftarrows I_2 + I^-$$
$$I_2 + e^- \xrightarrow{\text{rds}} I^- + I \qquad \text{Scheme A.}$$
$$I + e^- \rightleftarrows I^-$$

The exchange current i_0 is given by

$$i_0 = nF\vec{k}_s C_{I_2} \exp(-\beta\Delta\phi_e F/RT) \quad (A1)$$

where the terms have usual significance. Replacing C_{I_2} by $K_f C_{I_3^-}/C_{I^-}$ where K_f stands for the formation constant of $I_3^- : I_2 + I^- \rightleftarrows I_3^-$, we have

$$i_0 = nF\vec{k}_s \frac{I}{K_f}\frac{C_{I_3^-}}{C_{I^-}} \exp(-\beta\Delta\phi_e F/RT) \quad (A2)$$

If we consider the equantities of $\ln i_0$ in the solvent (s) relative to the reference solvent (r) and multiply both sides by RT we have

$$RT\ln({}_s i_0/{}_r i_0) = RT\ln\frac{\vec{{}_s k_s}}{\vec{{}_r k_s}} + RT\ln\frac{{}_r K_f}{{}_s K_f} + RT[\Delta\ln\frac{C_{I_3^-}}{C_{I^-}}] - \beta F[{}_s\Delta\phi_e^\circ - {}_r\Delta\phi_e^\circ] + \beta F\frac{RT}{2F}[\Delta\ln\frac{C^3_{I^-}}{C_{I_3^-}}] \quad (A3)$$

where Δ's stand for the differences of the respective quantities in the solvent(s) and the reference solvent (r).

Since K_f values are fairly large and comparable,[25a] from the experimental condition we have $C_{I_3^-} = C_{I^-} = 0.05$ M for all the solvents.

and hence, $\Delta\ln(C_{I_3^-}/C_{I^-}) = 0$, and $\Delta\ln(C^3_{I^-}/C_{I_3^-}) = 0$

Thus we have $RT\ln({}_s i_0/{}_r i_0) = RT\ln(\vec{{}_s k_s}/\vec{{}_r k_s}) + RT\ln({}_r K_f/{}_s K_f) - \beta F({}_s\Delta\phi_e^\circ - {}_r\Delta\phi_e^\circ)$. (A4)

If we express the second and third terms of Eq. A4 in terms of the involved transfer free energies, ΔG_t° of the species involved

$$RT\ln({}_r K_f/{}_s K_f) = \Delta G_t^\circ(I_3^-) - \Delta G_t^\circ(I_2) - \Delta G_t^\circ(I^-) \quad (A5)$$

and $$-\beta F({}_s\Delta\phi_e^\circ - {}_r\Delta\phi_e^\circ) = \frac{3}{4}\Delta G_t^\circ(I^-) - \frac{1}{4}\Delta G_t^\circ(I_3^-) \quad (A6)$$

if β is taken equal to 1/2.

Replacing these terms by transfer free energy terms Eq. A4 can be written as

$$RT\ln({}_s i_0/{}_r i_0) = RT\ln(\vec{{}_s k_s}/\vec{{}_r k_s}) + \frac{3}{4}\Delta G_t^\circ(I_3^-) - \Delta G_t^\circ(I_2) - \frac{1}{4}\Delta G_t^\circ(I^-) \quad (A7)$$

As the transfer free energies of I_2, I_3^-, and I^- are already known for the concerned solvent systems,[25a] $RT\ln({}_s k_s/{}_r k_s)$ values for the systems can be computed by using Eq. A7.

Compensation Effect in the Electrical Conduction Process in Polyene Incorporated Lipid Films

D. SARKAR and T. N. MISRA*
Department of Spectroscopy, Indian Association for the Cultivation of Science, Jadavpur, Calcutta 700032, India
(Received September 26, 1988)

Phosphatidylcholine films doped with polyenes show compensation behavior at low polyene concentration and follow a three constant semiconduction equation $\sigma_T=\sigma_0' \exp(E/kT_0) \exp(-E/kT)$, σ_0' and T_0 being constants for the lipid and the other parameters having their usual meanings. Consistent values of the constants σ_0' and T_0 obtained from various methods of evaluation suggest that the compensation effect has a physical origin. Significant change in the semiconduction activation energy of lipid film on various polyene doping suggests strong lipid-polyene interaction in the doped films.

In our earlier communications we have demonstrated the validity of the compensation rule in the electrical conduction process in some polyenes[1,2] and nucleic acid bases.[3,4] In polyenes, the semiconduction activation energy was varied by chemical vapour adsorption whereas in nucleic acid bases such variation was attained by doping with acridine dyes at low concentrations.

It has been shown that these organic semiconductors satisfy the three constant equation

$$\sigma_T=\sigma_0' \exp(E/kT_0) \exp(-E/kT) \quad (1)$$

where the preexponential factor σ_0 in the conventional expression has been replaced by $\sigma_0' \exp(E/kT_0)$. Here T_0 and σ_0' are constants for a specific material. The dependence of T_0 and σ_0' on the number of chemical double bonds,[5,6] donor and/or acceptor concentration in complexes,[3,4] molecular substituent groups[2] and molecular geometry[7] has been demonstrated. In Eq. 1 we have not used a half energy as was originally done by Rosenberg as localized states generally dominate in wide band gap materials like organic semiconductors and consequently it is more realistic to write down the activation energy according to the convention of extrinsic semiconduction.

However, some reported experimental results on compensation effect have often been criticized as these cover a narrow temperature range. Also the demonstrated compensation effect cover the Ohmic conduction region only. In pure and polyene doped phosphatidylcholine films sandwiched between a conducting SnO_2-coated glass and a stainless steel electrode, the conduction is known to be due to Schottky mechanism.[8] Also, this being a stable system, we have been able to cover a wider temperature range making the $\log \sigma_T$ vs. $1/T$ plots more meaningful in the context of compensation behavior. The result presented in this paper is therefore thought to add further credence to the physical origin of compensation effect.

Electrical conduction of model lipid membrane has been studied extensively in bilayers[9,10] and in thin films.[11,12] Light mediated electrical properties of some polyene incorporated bilayer lipid membranes have been studied extensively by Tien and his coworkers.[13-16] Dark conductive properties of the films was, however, neglected by them. This study is thought worthwhile also because the semiconductive properties of pure and polyene doped phosphatidylcholine, which is a major constituent of many cell membranes, is of significant relevance to olfactory transduction mechanism[17] where carotenoids incorporated in the olfactory cell membranes are thought to be the receptors of olfactory signals.

Experimental

Highly purified (99%) hydrogenated L-α-phosphatidylcholine (Egg lecithin) in powder form was obtained from Sigma Chemicals Co. U. K. High quality β-carotene, astacin, and vitamin A alcohol were obtained as gift from Hoffman La Roche Co. Switzerland. These materials, after checking purity by absorption spectroscopy, were used without any further purification. Each polyene was mixed with phosphatidylcholine in ca. 10^{-2} wt/wt concentration and ground repeatedly in a mortar till a uniform mixture was obtained. This mixed sample in powder form was taken in a sandwich cell configuration between a stainless steel and a SnO_2-coated glass electrode separated by a 2 mil (1 mil=0.0254 mm) thick Teflon spacer and pressed moderately to get a uniform thin film. The cell was then placed in a suitably designed conductivity chamber.[1] A dc voltage of 25 V across the electrodes was supplied from a dry battery pack. Currents were measured by an electrometer amplifier (model EA 815) of ECIL, India. Temperature measurements were made by a copper-constantan thermocouple and a panel meter (model 100) of HIL, India.

Results and Discussion

The semiconduction activation energies of all the samples were measured several times under vacuum (10^{-3} Torr; 1 Torr≈133.322 Pa) as well as in dry nitrogen atmosphere. All measurements gave consistent values. Almost the same values were obtained in vacuum and in dry nitrogen. The current-voltage characteristics of all the samples show Schottky behavior in the experimental voltage regime. The room temperature conductivity of the pure lipid

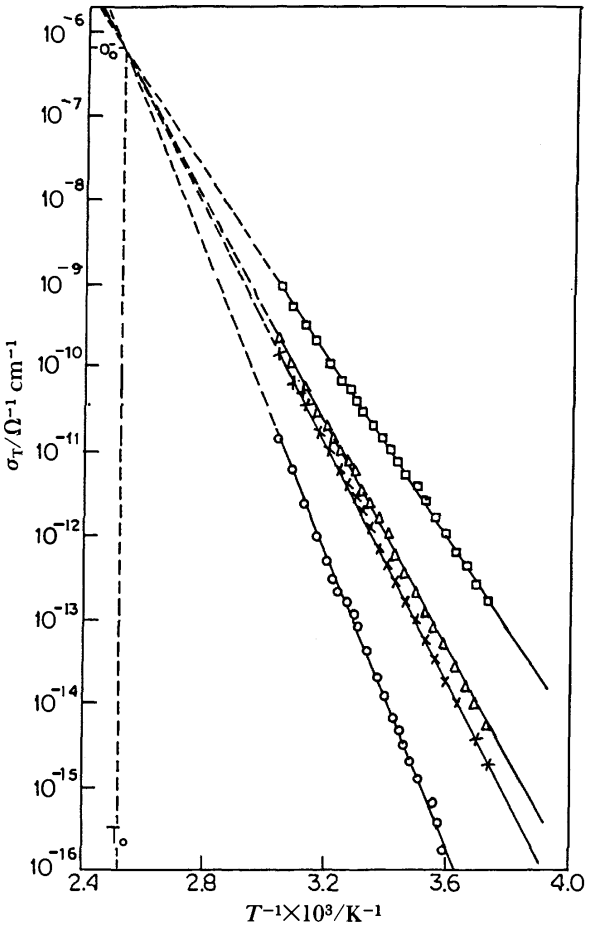

Fig. 1. The plot of $\log\sigma_T$ vs. $1/T$ for pure (—○—), β-carotene doped (—△—), vitamin A alcohol doped (—□—), and astacin doped (—×—) phosphatidylcholine films.

is ca. 10^{-13} $\Omega^{-1}cm^{-1}$. With polyene incorporation this value increases and the activation energy (which is 1.74 eV for the pure lipid) decreases. Such increase in conductivity of lipid films after polyene incorporation may be attributed to strong lipid-polyene interactions which may be of dipole-dipole,[18] hydrophobic or donor-acceptor[19] type. Donor-acceptor interactions increase the conductivity of lipid membrane on I_2 or water adsorption.[20]

In Fig. 1 we show $\log\sigma_T$ vs. $1/T$ plots for pure and β-carotene, astacin, and vitamin A alcohol doped lipid films. It is seen that the extrapolated lines in these plots intersect the ordinate at a wide variety of positions but they all pass approximately through a single point at a temperature T_0. This result is in conformity with Eq. 1. At the characteristic temperature T_0, the value of σ gives σ_0' value. For phosphatidylcholine, value of T_0 is 396.8 K and $\sigma_0'=7.5\times10^{-7}$ Ω^{-1} cm^{-1}. From Eq. 1 at any specific experimental temperature T_1, we get

$$\sigma(T_1)=\sigma_0' \exp(1/T_0-1/T_1)\,E/k \qquad (2)$$

$\sigma(T_1)$ will show different behavior with variation of E depending on whether $T_1>T_0$ or $T_1<T_0$. In our case $\sigma(T_1)$ increases with decreasing E as $T_1<T_0$.

Phosphatidycholine mixed with three different polyenes, β-carotene, astacin, and vitamin A alcohol has a distinct T_0 value. This result confirms our earlier observation[1,3] that T_0 is a molecular property of the semiconducting material.

Conpensation effect in the electrode limited conduction process has been discussed by Green.[21] He considered charge carrier injection at the semiconductor surface and showed that the preexponential factor in the standard semiconduction equation

$\sigma_T=\sigma_0 \exp(-E/kT)$ is given by

$$\sigma_0\approx n_0\left(\frac{kT}{h}\right)K \qquad (3)$$

where n_0 is the number of carriers available at the electrode and K is the transmission coefficient. If E is the energy obtained from the $\ln\sigma$ vs. $1/T$ plots and is small compared to the work-functions of the electrode and the semiconductor, then one gets

$$\ln K=A+BE+CE^2 \qquad (4)$$

where A; B, and C are some parameters. Neglecting the quadratic term

$$\log\sigma_0\approx C+C'E \qquad (5)$$

where C and C' are related to the parameters A and B. σ_0 represents the first two terms of Eq. 4. The compensation temperature T_0 of Eq. 4 is related to C' which in turn is related to the difference of the work functions of the electrode and the semiconductor and potential barrier width.

Roberts and Polanco[22] showed that for appropriate parameters, thermally assisted tunneling (TAT) yields the same shape of current voltage characteristics as in Schottky effect. It has been shown by Roberts[23] that for TAT, $\ln\sigma_{TAT}(max)$ vs. $1/T$ yields activation energy $E_{max}=\Phi-F_x$ where Φ is the potential barrier at the electrode-semiconductor interface and $F_x=(F/kT_x)^2$ $h^2/8m$ where F is the applied field and T_x is an arbitrary temperature. The curves at different F values pass through a focal point $T_0=(3/2)T_x$, where T_x is temperature corresponding to the average of the reciprocal temperatures through which experimental data points are collected. From Fig. 1, T_x=294 K and so the estimated T_0 value is 441 K. This is a value far beyond our experimental value which is ca. 400 K and is not within possible experimental error. Also for the TAT model proposed by Roberts,[23] the activation energy value should be temperature dependent and over an extended temperature range, the curves should deviate from the straight line. Our experimental results are at variance with this hypothesis. We therefore conclude that the thermally assisted tunneling model of Roberts cannot account for the obtained compensation effect in polyene doped lipid films.

True compensation effect is thought to arise from the existence of a linear relationship between the

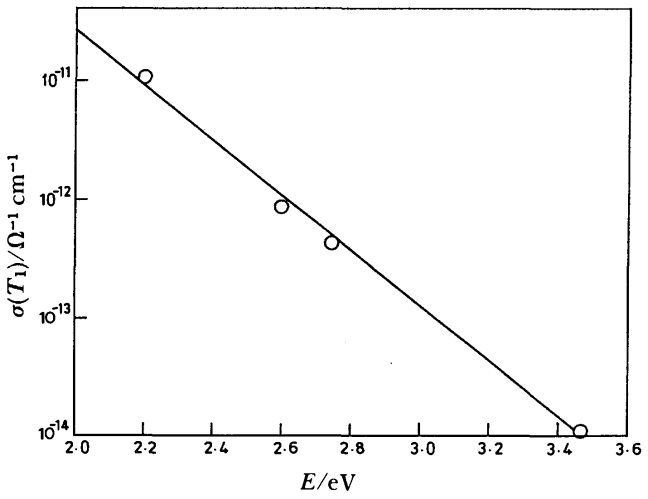

Fig. 2. The plot of $\log \sigma(T_1)$ vs. E at T_1=333.3 K for different polyene doped phosphatidylcholine films.

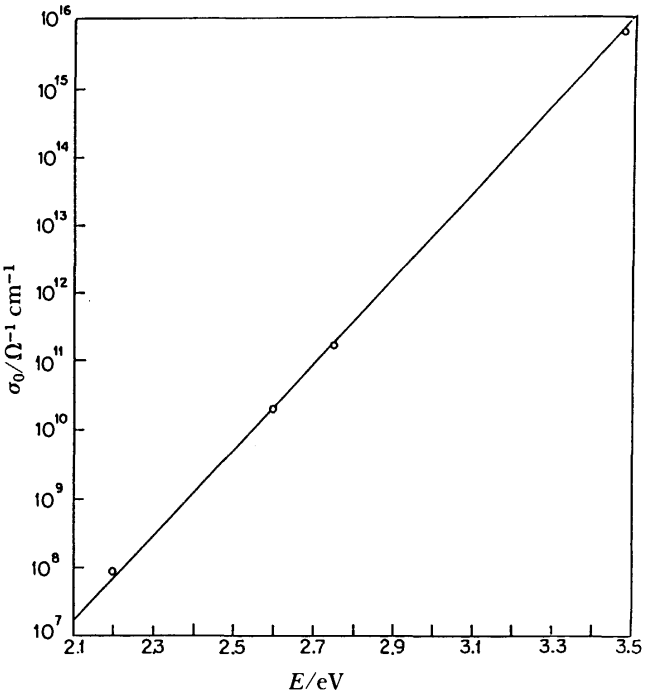

Fig. 3. The plot of $\log \sigma_0$ vs. E for different polyene doped phosphatidylcholine films.

activation energy and the activation entropy of the system. It has been pointed out by Johnston and Lyons[24] that if a true linear free energy relation (LFER) does hold for dark conduction. a physical relationship between σ_0 and E, $\log \sigma(T_1)$ vs. E must also be linear. In Fig. 2 we show such plot. T_0 and σ_0' are obtainable from the slopes and intercepts of these plots. These parameters can also be obtained from the plot of $\log \sigma_0$ vs. E as $\log \sigma_0 = \log \sigma_0' + E/kT_0$, σ_0 and E being experimentally measured. In Fig. 3 we show such plot. T_0 and σ_0' can be evaluated respectively from the slope and the intercept of this plot. In Table 1 we compare the values of T_0 and σ_0' obtained by various methods. The agreement is quite satisfactory. These results confirm that σ_0 and E are physically related and that T_0 has a physical origin. The meaning of T_0, however, remains unsettled. It has been established that T_0 is a molecular property of the semiconducting material.[25] In the theory based on rate process[26] T_0 has been attributed to the temperature at which the competing effects of energy and entropy balance each other.

Conclusion

The experimental results indicate that the compensation law is valid for electrical conduction process in various polyene doped phosphatidylcholine films where the conduction mechanism is electrode limited. Significant change in semiconduction activation energy of p lipid films on various polyene doping

Table 1. Comparison of T_0 and σ_0' Values of Pure and Various Polyene Doped Phosphatidylcholine Films

Different parameter	Phosphatidylcholine	Phosphatidylcholine+ β-carotene	Phosphatidylcholine+ astacin	Phosphatidylcholine+vitamin A alcohol
E/eV	1.74	1.30	1.38	1.10
$\sigma_T/\Omega^{-1}\,cm^{-1}$	1.20×10^{-13}	5.60×10^{-12}	3.00×10^{-12}	4.50×10^{-11}

Electrochemical Generation and Properties of the *p*-Dinitrobenzene Radical Anion in *N,N*-Dimethylformamide

Alexandra SAUER, Fritz WASGESTIAN,* and Ulrich NICKEL†
Institute of Inorganic Chemistry, University of Cologne, 5000 Cologne 41, Federal Republic of Germany
†Institute of Physical and Theoretical Chemistry, University of Erlangen-Nuremberg, Federal Republic of Germany
(Received October 17, 1988)

Potentiostatic reduction of *p*-dinitrobenzene in *N,N*-dimethylformamide yielded the anion radical. By careful exclusion of water and oxygen it was obtained free from by-products. It was stable for several hours at room temperature. Its UV-visible absorbance was determined in combination with polarographic analysis. The behavior towards water and oxygen is reported.

The electrochemical reduction of *p*-dinitrobenzene (pDNB) has been extensively studied. Polarography showed two reversible reduction waves, corresponding to the formation of the singly and doubly charged anions $pDNB^{\cdot-}$ and $pDNB^{2-}$.[1-9] In aqueous solution *p*-nitrophenylhydroxylamine (Hy) was the first long-lived reduction product.[10] In aprotic solvents, however, $pDNB^{\cdot-}$ was found to be stable. In DMF (*N,N*-dimethylformamide) it was obtained by potentiostatic reduction and characterized by ESR spectroscopy.[5,6]

The reaction of *p*-dinitrobenzene with OH^- yielded *p*-nitrophenoxide (pNP^-).[11-13] In the absence of oxygen both pNP^- and $pDNP^{\cdot-}$ were observed spectrophotometrically in DMSO (dimethyl sulfoxide).[13]

Compared to the characterization by ESR and electrochemical methods the electronic absorption spectrum of $pDNB^-$ is not so well-known. In aqueous solution the radical spectrum was obtained after pulse radiolysis.[14,15] $pDNB^-$ decayed fast with a second order rate constant of 3.3×10^8 $M^{-1}s^{-1}$ (1 M=1 mol dm^{-3}). In glassy solution in 2-methyltetrahydrofuran (MTHF) the radical was stable.[16] Its spectrum showed a pronounced vibrational fine structure. Recently a matrix molecule reorientation effect has been observed in the same solvent that blurred out the vibrational fine structure and caused a time dependent blue shift.[17] In aprotic solvents the *p*-dinitrobenzene radical ($pDNB^{\cdot-}$) is sufficiently stable to be studied by conventional techniques at room temperature.

Preparation of the radical by reaction with OH^- in aqueous DMSO was associated with the formation of $pNP^{\cdot-}$.[13] In the absorption spectrum pNP^- superimposed the bands around 430 nm. The absorption coefficient which Abe and Ikegami[13] used in their kinetic treatment differed by more than one order of magnitude from that in glassy solution in MTHF. Brown et al.[18] obtained the radical by chemical reduction with sodium in 1,2-dimethoxyethane. They reported the absorption spectrum assuming quantitative conversion. However, the presence of pNP^- could not be convincingly excluded. In our opinion another determination of the spectral characteristics, that is not disturbed by by-products or secondary reactions, is necessary.

Experimental

N,N-Dimethylformamide (DMF), Fluka ppa or Merck, Uvasol, was dried with anhydrous $CuSO_4$ and distilled. Solutions were deoxygenated by purging with dry

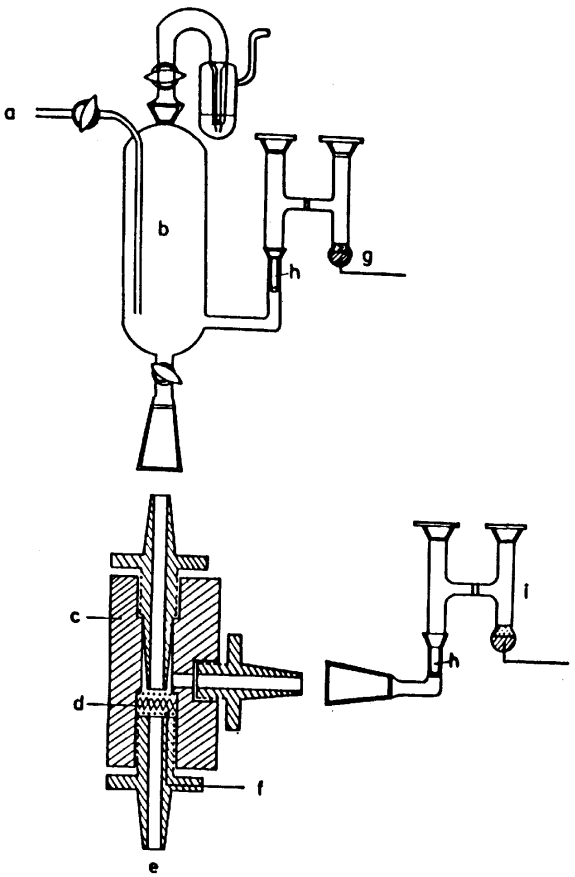

Fig. 1. Apparatus used for potentiostatic reduction of *p*-dinitrobenzene in DMF. a: argon entrance, b: vessel for stock solution, c: Teflon cell with working electrode, d: carbon fleece, e: exit to flow cell or ordinary spectrophotometric cell, f: Pt wire, g: counter electrode (SCE), h: agar-agar junction, i: reference electrode (SCE).

argon for 20 min. Supporting electrolytes were 0.1 M Bu_4NClO_4 (Fluka) or 0.1 M Et_4NClO_4 (Fluka). *p*-Dinitrobenzene (pDNB), Aldrich, was recrystallized from EtOH. For reasons of comparison the spectral data of *p*-nitrophenol (pNP) and *p*-nitrophenylhydroxylamine (Hy) were determined. pNP was obtained commercially (Merck), Hy was prepared according to literature.[19] Under our reaction conditions both were present in their base forms (pNP^- and Hy^-) with absorption maxima $\lambda(\varepsilon)$ [nm($l\,mol^{-1}\,cm^{-1}$)] at 432 (3.7×10^4) and 465; 485 (1.7×10^4); 520 sh, respectively. In the presence of pDNB the base form of the hydroxylamine formed an adduct with absorption at 500 (2×10^4). Absorption spectra were recorded on a Cary 2300 and a Uvikon 810 (Kontron). Polarograms were obtained by use of a potentiostat (HEKAelectronic PG 284) in combination with an xy-recorder (Servogor xy). The cathode was a dropping mercury electrode, the counter electrode a saturated calomel electrode (SCE), and the reference electrode was a Pt-electrode.

The apparatus used for the quantitative reduction is depicted in Fig. 1. The cathode was a carbon fleece contacted with a perfoliated gold foil. Counter and reference electrodes were SCEs separated from the solution by an agar-agar salt bridge. The use of a calomel electrode as counter electrode was advantageous, because its large mercury pool acted as reductant. By this means oxidation of the solvent was avoided. Voltage was supplied from a potentiostat (Wenking LB75 or 70TS1). The reductions were performed at flow rates of 0.5—0.8 ml min^{-1} and currents of 0.6—1 mA. After passing the fleece, the solution was directed either to a spectrophotometric flow cell or to the polarographic cell. After having recorded the polarogram, a sample of the solution was transferred to a spectrophotometric cell by use of a syringe and a hypodermic needle. During this operation the cell was standing in a flask that was flushed with argon. By the latter method polarographic as well as spectrophotometric analysis could be performed in the same solution.

Tandem cells were applied to study the effects of additives. These cells contained two separated compartments containing the reactants. By shaking the solutions could be mixed.

The spectral changes during oxidation were observed in ordinary spectrophotometer cells. Immediately after reduction the cells were transfered to the spectrophotometer. Recording was started approximately 1 min after reduction. The slowly penetrating air caused reaction.

The following absorptivity coefficients were used for the spectrophotometric analysis.

[nm]	[$M^{-1}\,cm^{-1}$]		
	$pDNB^{\cdot-}$	Hy	pNP^-
800	1.1×10^4	$\leqslant1.0\times10^2$	$\leqslant1.0\times10^2$
500	7.6×10^2	2.0×10^4	$\leqslant1.0\times10^2$
430	7.7×10^3	1.1×10^4	3.6×10^4

At first the radical concentration was determined from the absorbance at 800 nm. Then at 500 nm the concentration of *p*-nitrophenylhydroxylamine (pDNB-adduct) was obtained by subtracting the contribution by $pDNB^{\cdot-}$. Finally the concentration of pNP^- was obtained from the absorbance at 430 nm.

Results and Discussion

a) Potentiostatic Reduction and Quantitative Analysis. In DMF the polarographic reduction showed two reversible steps at −580 and −915 mV. SCE in reasonable agreement with literature.[1,4,5,8] The first reduction step led to the radical anion $pDNB^-$ and the second to $pDNB^{2-}$. Potentiostatic reduction at potentials between −600 and −900 mV only produced the single charged anion. Reduced solutions had the same ESR spectrum as previously reported for $pDNB^{\cdot-}$.[5,6]

Figure 2 shows polarograms of pDNB and its radical ion. If both species were present in solution, the oxidation current of the radical superimposed the reduction current of pDNB at the position of the first half wave potential. Their relative heights were a measure of the concentrations. In the absence of side reactions and assuming equal diffusion coefficients of pDNB and $pDNB^{\cdot-}$:

$$c(\text{pDNB}) = \frac{I_{red}}{I^0_{red}}\, c^0(\text{pDNB});$$

$$c(\text{pDNB}^{\cdot-}) = \frac{I_{ox}}{I^0_{red}}\, c^0(\text{pDNB}) \qquad (1)$$

where I^0_{red} and c^0(pDNB) are the reduction current and the pDNB concentration of the initial solution.

Table 1 presents a selection of our reduction experiments. The first set gives some preliminary results,

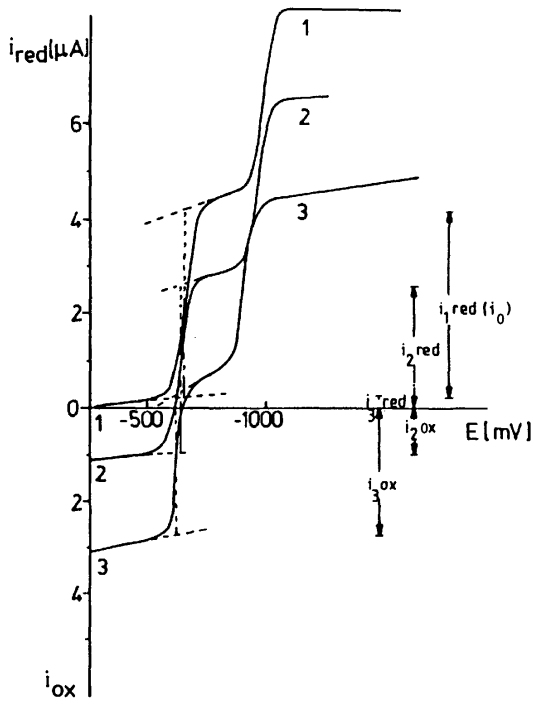

Fig. 2. Polarographic determination of pDNB and $pDNB^{\cdot-}$. 1: unreduced solution (1×10^{-3} M pDNB), 2: partly reduced solution (6×10^{-4} M pDNB. 3×10^{-4} M $pDNB^{\cdot-}$), 3: highly reduced solution (8×10^{-4} M $pDNB^{\cdot-}$).

a) In brackets concentrations determined polarographically after reduction. b) Radical concentrations determined at 750 nm.

where degassing was insufficient. The radical disappeared rather fast and pNP^- was formed. Whereas in well-degassed and carefully dried solutions the radical was stable for several hours. In those solutions the radical concentrations were determined polarographically. Set 2 compared the data with those obtained spectrophotometrically.

Solutions containing 5×10^{-4} M or less could be completely reduced potentiostatically. Immediately after reduction the solutions were practically free from by-products. The effect of the reduction potential is demonstrated in the last set. Potentials of −0.5 and −0.6 V did not cause reaction. At −0.7 V the pDNB was reduced but less than 50%. In this solution pNP^- was formed, whereas at −0.8 V the formation of pNP^- was negligible. At potentials sufficiently negative to produce the $pDNB^{2-}$ the hydroxylamine was found. In those solutions, where the pDNB was not completely reduced, the hydroxide ion, produced by electrolysis of traces of water or impurities of the electrolyte, led to substitution:[5]

$$RNO_2 + OH^- \longrightarrow ROH + NO_2^- \quad (2a)$$

$$ROH + OH^- \rightleftharpoons RO^- + H_2O \quad (2b)$$

$(R = O_2NC_6H_4)$

b) Spectral Characterization. From the electronic absorption spectrum recorded in combination with polarography (Fig. 3), the absorption coefficients were determined. By this procedure the spectrum was obtained without interference of pNP^- that overlaps the band at 400 nm.[13] Compared with the low-temperature spectrum in 2-methyltetrahydrofuran the bands are broadened and the vibrational fine structure has disappeared.

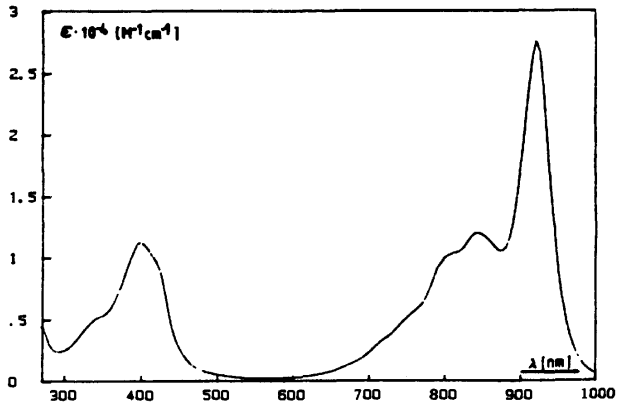

Fig. 3. UV-vis absorption spectrum of the *p*-dinitrobenzene radical anion. Avarage of 6 independent runs.

The absorbance is of the same order of magnitude as that in 2-methyltetrahydrofuran at low temperature. The spectral data estimated in Ref. 13 are obviously erroneous.

c) Reactivity of the Radical. The effect of additives was studied in the tandem cell. Dilution by DMF did not change the absorption spectrum. We regard this result as a proof that the system had no leakage. Addition of O_2 saturated DMF mainly reoxidized the radical. However, about 15% of the radical reacted to *p*-nitrophenoxide (pNP^-) probably with intermediate superoxide ions:

$$RNO_2^- + O_2 \longrightarrow RNO_2 + O_2^- \quad (3)$$

$$RNO_2^- + O_2^- \longrightarrow RO^- + NO_3^- \quad (4)$$

The reformed RNO_2 may also have reacted according to Eq. 2. The same percentage of pNP^- was also obtained after shaking in air.

The spectral changes during oxidation are shown in

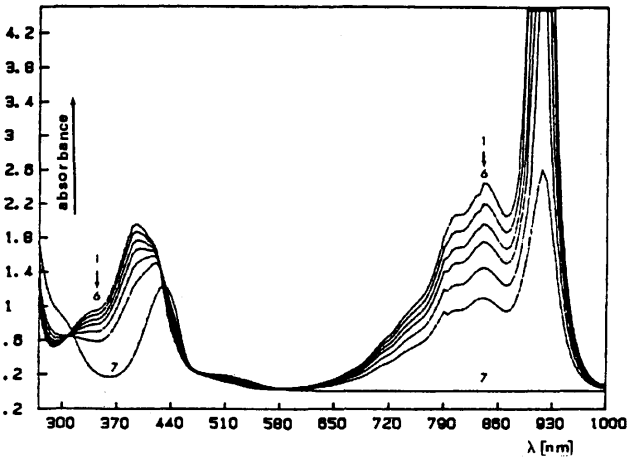

Fig. 4. Spectral changes during air oxidation of 1.7×10^{-4} M $pDNB^-$ 1: 0 min, 2: 5 min, 3: 15 min, 4: 26 min, 5: 47 min, 6: 83 min, 7: 18 h. Optical path length 1 cm, scan rate 5 nm s^{-1}, start at 1000 nm.

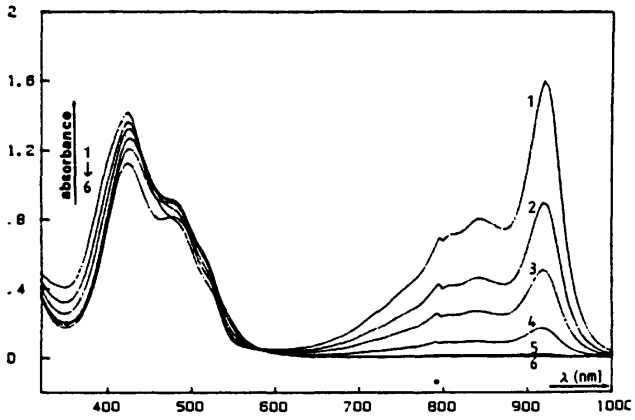

Fig. 5. Spectral changes during air oxidation of 1.2×10^{-4} M $pDNB^{\cdot-}$ in wet DMF (4 vol% H_2O). 1: 0 min, 2: 5 min, 3: 10 min, 4: 20 min, 5: 31 min, 6: 46 min. Pathlength 0.5 cm, other conditions as in Fig. 4.

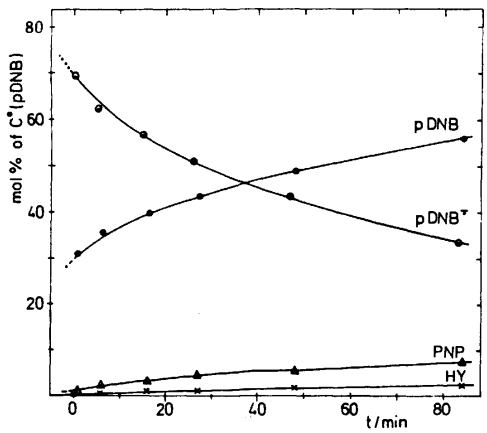

Fig. 6. Concentration changes during air oxidation of $pDNB^{\cdot-}$; analysis of data of Fig. 4; initial concentration of pDNB: 2.5×10^{-4} M.

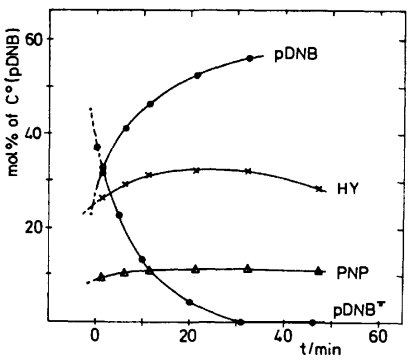

Fig. 7. Concentration changes during air oxidation of $pDNB^{\cdot-}$ in wet DMF; analysis of data of Fig. 5; initial concentration of pDNB 3.3×10^{-4} M.

Fig. 4. The disappearance of the radical caused the decrease of the band at 920 nm. In the 400 nm region the production of *p*-nitrophenoxide shifted the absorption maximum to 432 nm (absorption maximum of pNP^-). The curves pass through an isosbestic point at 310 nm although more than two components were present. However, the absorbance of pDNB, pNP^-, and $pDNB^{\cdot-}$ happens to be so similar at 310 nm that the minor contribution of pNP^- did not become evident. The reappearing pDNB produced the increase in absorbance at $\lambda<300$ nm. The weak absorbance at 510 nm was caused by traces of *p*-nitrophenylhydroxylamine which was present as an adduct of its base form with pDNB.

In wet DMF (4 vol% H_2O) the pattern was more complex (Fig. 5). The radical disappeared much faster; pNP^- and *p*-nitrophenylhydroxylamine (Hy) were produced in larger amounts. Initially, the hydroxylamine was formed as the base (absorption maximum at 480 nm), it reacted with pDNB forming the adduct with the absorption maximum at 500 nm.

Figures 6 and 7 show the kinetics in both systems. The remaining concentration of pDNB was determined from the sum of all the other known components. Figure 7 shows a decrease on hydroxylamine concentration that indicates the production of another compound. This could be *p*-nitronitrosobenzene which is formed by reaction of Hy with oxygen.[5] It does not absorb strongly in the visible region. Its intense absorption is found at 282 nm. For times longer than 30 min the sum analysis was not justified anymore. The radical decay was exponential in both solution.

We thank the "Deutsche Forschungsgemeinschaft" and the "Verband der Chemischen Industrie" for financial assistance.

Studies on Organomercury(II) Complexes of Maltol

Sangeeta BHATIA, Narender K. KAUSHIK,* and Gurvinder S. SODHI†
Department of Chemistry, University of Delhi, Delhi 110007, India
†Department of Chemistry, S. G. T. B. Khalsa College, University of Delhi, Delhi 110007, India
(Received May 24, 1988)

A number of organomercury(II) complexes involving maltol (**1**) of the type RHgL (**2**) [R=phenyl (C_6H_5), *o*-, *p*-hydroxyphenyl (*o*-, *p*-HOC_6H_4), *p*-acetoxyphenyl (*p*-$AcOC_6H_4$), 2-furyl (2-C_4H_3O); HL=maltol] have been synthesized and characterized. Conductance measurements indicate that the complexes are nonelectrolytes. From IR and UV studies, it is concluded that maltol acts as a bidentate ligand, coordinating to the mercury(II) ion through phenolic and carbonyl oxygen atoms. ^1H and ^{13}C NMR support the stoichiometry of the complexes. Fluorescence spectra have been recorded for *o*-, *p*-HOC_6H_4HgL complexes. For C_6H_4HgL, *p*-HOC_6H_4HgL, and *p*-$AcOC_6H_4HgL$ complexes, thermal studies (TG and DSC) have been carried out and relevant kinetic and thermodynamic parameters have been enumerated. In addition, the fragmentation pattern of the complexes has been analyzed on the basis of mass spectra.

During the course of our recent investigations on metal ion-biomolecule interactions, we have synthesized and characterized several organomercury(II) complexes and analyzed their biological activity.[1-6] The organomercury(II) purine complexes[3] were screened for C. N. S. activity; the isoniazid compounds[4] were tested for antitubercular activity; and the dithiocarbazate analogues[5] were examined for antifungal activity. To widen the scope of our investigations, we synthesized a few organomercury(II) complexes of maltol, an antibiotic substance and tested their antibacterial actvity.

Maltol (3-hydroxy-2-methyl-4*H*-pyran-4-one) (**1**) is found in the pine needles in the bark of larch. Since it is obtained as an alkaline degradation product of streptomycin salts,[7] its compounds exhibit considerable antibiotic activity. The interest in the metal complexes of maltol has arisen because of the following reasons. Firstly, since it is structurally related to flavones, the study of its complexes is expected to provide a model for the complexing properties of some naturally occurring keto-hydroxy systems. Secondly, the metal complexes of maltol possess relatively high stability owing to the formation of five membered chelate ring. Thirdly the metal complexes reveal a wide spectrum of antibacterial activity. It is expected that the antibiotic action of a drug is enhanced in the presence of metal ions, since the introduction of metal chelates in vivo prolongs the metabolism of the drug and leads to a more pronounced biological effect. In fact the present complexes have been found to be significantly active against *E. coli* and *P. pyocyanea* bacterial strains.

(2)

Experimental

The following instruments were used: Elico conductivity bridge, model CM-82 for conductivity measurements; Perkin-Elmer grating 621 spectrometer for IR spectra; Perkin-Elmer UV-visible spectrometer, model 554 for UV spectra; JEOL FX-200 spectrometer, for ^1H and ^{13}C NMR spectra; JASCO FP-550 spectrofluorometer for fluorescence studies; SETARAM G-70 thermoanalyzer for TG studies in air at a heating rate of 8° min^{-1}; Du Pont device for recording DSC curves up to 673 K at a heating rate of 8° min^{-1}. Mass spectra were recorded at Central Drug Research Institute, Lucknow (India).

Nitrobenzene was purified for conductance measurements by the method of Fay et al.[8] C_6H_5HgCl,[9] *o*-, *p*-HOC_6H_4HgCl,[10] *p*-$AcOC_6H_4HgCl$,[11] and 2-C_4H_3OHgCl[12] were prepared by standard methods. Maltol was purchased from Aldrich Chemical Co., Inc. USA.

Preparation of Complexes. A solution of RHgCl (0.05 mol) in 25 ml THF was added to a solution of maltol (0.05 mol) in 25 ml THF. The mixed solution was stirred for about 3 h at room temperature and filtered. The filtrate was evaporated under vacuum to one-fourth of its original volume and petroleum ether was added. The RHgL complexes separated out, which were filtered and dried. These were recrystallized from acetone solution by the addition of petroleum ether.

Results and Discussion

The complexes prepared are white in color and soluble in THF, DMSO, and acetone. The purity has been checked by elemental analyses, spectral studies and TLC. The conductance measured in 10^{-3} M (M=mol dm^{-3}) nitrobenzene solution (at 27 °C) was of the order of 0.5 Ω^{-1} cm^2 mol^{-1} for each of the complexes, indicating that they are nonelectrolytes. The results are summarised in Table 1.

Infrared Spectra. According to Katritzky and Jones[13] the absorption at 1660 cm^{-1} in maltol is assigned to ν(C=O) stretching frequency. This is lower than the conventional carbonyl stretching frequency partly because of the intramolecular hydrogen

Table 1. Analytical Data and Physical Characteristics

Complex	Decomp temp °C	$\Lambda/\Omega^{-1}cm^2mol^{-1}$	Found (Calcd)/% C	H	Hg

p-$AcOC_6H_4HgL$	148.6	138.1	122.2	150.7	122.2	138.1	149.1	146.2	177.8	113.9	155.2	27.2

bonding and partly due to the weakening of C=O bond by contributions from resonating structures. On complexation, this frequency is further lowered by ca. 45 cm^{-1}, indicating that C=O group is chelating. The ν(C=C) stretching frequency observed at 1580 cm^{-1} in case of the ligand is shifted to ca. 1560 cm^{-1} in complexes.[14]

In maltol, the band due to phenolic OH stretching occurs at 3200 cm^{-1} [15] and that due to δ(OH) at 1300 cm^{-1}.[14] These bands are absent in the spectra of the complexes, indicating the presence of metal-oxygen bond. A weak band at 450 cm^{-1} is attributed to ν(Hg-O) stretching vibrations.[16] The bands at 1290 and ca. 1220 cm^{-1} in case of ligand and complexes respectively are due to C-O-C stretching frequency.[15]

UV Spectra. The UV spectrum of maltol shows an intense band at 237 nm ($\log\varepsilon\approx6.7$) due to π-π^* absorption of chromophoric C=O group. This band is shifted to ca. 250 nm ($\log\varepsilon\approx6.1$) in case of the complexes. The shift in the absorption band due to carbonyl chromophore is attributed to the involvement of this group in complexation, thus supporting the conclusions drawn from IR studies.

^1H NMR Spectra. In ^1H NMR spectra, the following signals are attributed to the presence of maltol moiety in the complexes: δ 2.26 (s, 3H, CH_3 at C_2); δ 6.45 (d, 1H, H, J=6 Hz), 7.95 (d, 1H, H_6, J=6 Hz). The signal due to H_5 in free maltol absorbs at δ 6.30 (d, 1H, J=6 Hz). The downfield shift in case of metal complexes is due to involvement of carbonyl at C_4 in complexation. In the related kojic acid complexes,[6] the signals due to H_3 and H_6 absorb at ca. δ 6.93 and 8.05 respectively. In free kojic acid, the signal due to H_3 absorbs at δ 6.45 and that due to H_6 at δ 7.80. The downfield shift in these complexes is also attributed to the involvement of carbonyl at C_4 and hydroxyl at C_5 in complexation. The furyl group in the present complexes is identified by signals at δ 6.50 (d, 2H, J=10 Hz) and δ 7.52 (s, 1H).

^{13}C NMR Spectra. The C_4 carbonyl in pure maltol shows a resonance signal at δ 173.2 while the C_3 carbon absorbs at δ 143.2.[17] In metal complexes these signals appear at δ ca. 177.84 and 146.20 respectively. Thus, it is concluded that the complexes are formed by deprotonation of C_3 hydroxyl and chelation through C_4 carbonyl. In the ^{13}C NMR spectra of kojic acid the signals due to C_4 and C_5 appear at δ 174.61 and 145.82 respectively.[6] In the case of the complexes, the former signal is shifted to δ about 179.52 and the latter to δ about 148.71, indicating also that complexation involves C_4 carbonyl and deprotonated C_5 hydroxyl. In the present complexes, the C_2, C_5, and C_6 carbons absorb at δ ca. 149.25, 113.85, and 155.28 respectively. The methyl group at C_2 shows a resonance signal at δ ca. 27.20. The data are recorded in Table 2.

Fluorescence Studies. The o-, p-HOC_6H_4HgL complexes are fluorescent in nature. Hence their fluorescence spectra have been recorded. The absorption band is observed at 250 nm, while the emission band is at 500 nm. Thus in accordance with Franck-Condon principle and thermal relaxation of vibrational modes, the fluorescence spectra are observed on the red side of the absorption spectra in approximately mirror image relationship.[18] A slight distortion in the mirror image pattern arises due to the appearance of a weak band at 310 nm ($\log\varepsilon\approx1.5$), which is attributed to the forbidden transitions, $Hg6(^3P_1)\rightarrow Hg6(^1S_0)$

and $J=0\rightarrow J=0$.[17]

The spectra are free from antistokes effects. The pattern of the spectra follows Levschin's rule, indicating that the geometry of the excited state is similar to that of the ground state.[20] The quantum yield of fluorescence, ϕ_f, calculated by a relative method,[19] using anthracene as the reference are: *o*-HOC_6H_4HgL, 0.73; *p*-HOC_6H_4HgL, 0.72. Since the ϕ_f values show deviation from unity, it is inferred that fluorescence remains the dominant but not the exclusive mode of emission. The nonradiative modes are likely to be contributing to the emission process.

Thermal Studies. Thermogravimetric (TG) studies have been carried out for C_6H_5HgL, *p*-HOC_6H_4HgL, and *p*-$AcOC_6H_4HgL$ complexes. The weight loss in each case corresponds to the formation of HgO, which slowly volatilizes beyond 773 K. The order (n) and activation energy (E_a) for thermal decomposition reaction have been elucidated by the methods of Coats and Redfern.[21] The linearization curves are shown in Fig. 1.

The order of reaction in each case is one. A comparison of the activation energy data reveals that *p*-$AcOC_6H_4HgL$ complex has the lowest value of E_a. This may be explained on the basis of electron withdrawing effect of the acetoxyl group which weakens the R-Hg bond, making thermal degradation relatively easy. In case of *p*-HOC_6H_4HgL complex, the phenolic hydroxyl group is electron donating and the R-Hg bond is strengthened. Therefore the E_a value in this case is higher than in the unsubstituted C_6H_5HgL complex. That R-Hg bond cleavage is involved in the pyrolysis of the complexes is also indicated by the mass spectra, where peaks for $C_6H_5^+$, $HOC_6H_4^+$, and $AcOC_6H_4^+$ fragments have been observed.

The activation energy values of the present complexes are lower than those of the corresponding theophylline and theobromine analogues.[3] In the latter cases, the ligands are bound to the mercury(II) ion through nitrogen, which according to HSAB theory, is softer than oxygen. The soft mercury(II) ion thus forms a stronger bond with nitrogen than with oxygen. This makes thermal degradation of maltol complexes relatively easy and the reaction involves a lower value of E_a.

The apparent activation entropy,[22] $\Delta S^{\neq}$ has a positive value for all the complexes. The *p*-HOC_6H_4HgL complex has the highest value of $\Delta S^{\neq}$, while the *p*-$AcOC_6H_4HgL$ has the lowest. Hence, the former decomposes with greatest degree of randomness, while the latter with the least.

The TG data is supplemented by differential scanning calorimetry (DSC) studies. The thermal effects on DSC curves are endothermic in nature. The heat of reaction, ΔH has been enumerated from DSC curves. Thermal data are presented in Table 3.

Mass Spectra. The RHg^+, R^+, and Hg^+ ions dominate the mass spectra. The fragmentation pattern of

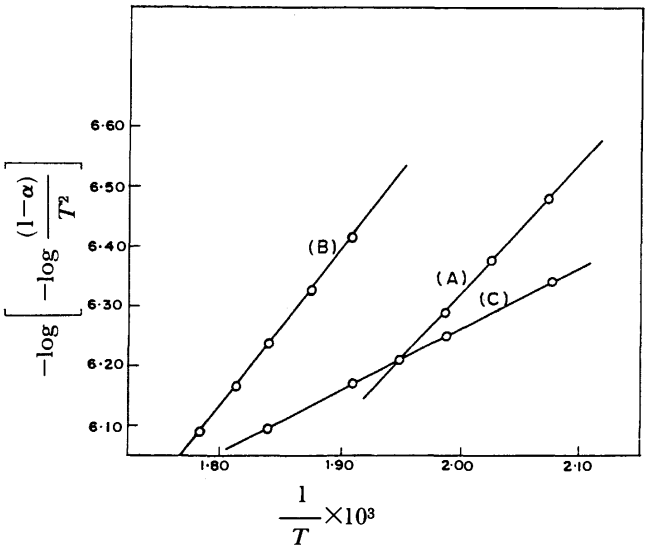

Fig. 1. Kinetic parameters from TG: (A) C_6H_5HgL, (B) *p*-HOC_6H_4HgL, (C) *p*-$AcOC_6H_4HgL$.

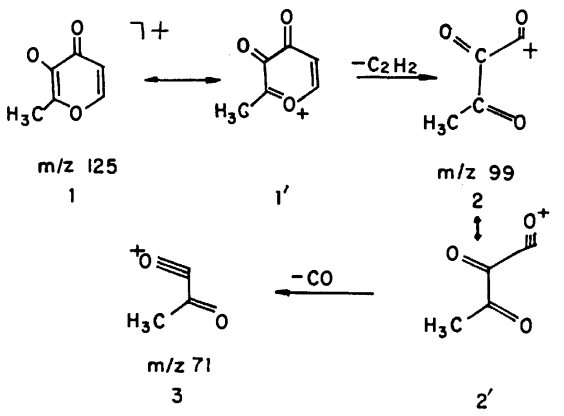

Scheme 1.

Table 3. Thermal Data

Complex	TG				DSC		
	Temp range / K	n	E_a / kJ mol^{-1}	$\Delta S^{\neq}$ / J deg^{-1} mol^{-1}	Thermal effect	T_{max} / K	ΔH / kJ mol^{-1}
C_6H_5HgL	453—523	1	42.46	29.59	Endothermic	495	108.92
p-HOC_6H_4HgL	453—573	1	50.99	38.99	Endothermic	518	128.92
p-$AcOC_6H_4HgL$	453—553	1	20.14	4.93	Endothermic	501	55.25

the RHg^+ portion is similar to that reported earlier.[4] The carbonium ion R^+ constitutes the base peak. The fragmentation of the ligand portion is shown in Scheme 1. The pattern is similar to that of 4-pyrone.[23] The molecular ion **1** (*m/z* 125) undergoes rearrangement to **1'** before losing C_2H_2. Fragment **2** (*m/z* 99) rearranges to **2'** and subsequently loses CO, resulting in fragment **3** (*m/z* 71).

Antibacterial Studies. The metal complexes have been tested against *E. coli* and *P. pyocyanea* bacterial strains using maltol as the standard for comparing the activity. The compounds were screened at two concentrations, 25 $\mu g\,ml^{-1}$ and 50 $\mu g\,ml^{-1}$. The inhibitory power of the complexes was greater than that of the control. The conpounds showed better inhibition at higher concentrations. At lower concentrations, the compounds were equally active against both bacterial strains. However, at higher concentrations, the order of activity against the two microorganisms was *P. pyocyanea*>*E. coli*. The C_6H_5HgL and *p*-$AcOC_6H_4HgL$ complexes were found to have higher activity than others.

One of the authors (G. S. S.) is thankful to the Indian National Science Academy, New Delhi for sanctioning bursary grant for a project of which the present work is a part.

Ortho Effects in Organic Molecules on Electron Impact 17-Parallel Oxygen Transfers from Nitro Group to Olefinic Double Bond and Sulfur in α-(*o*-Nitrophenylthio)cinnamic Acids

D. V. RAMANA,* N. SUNDARAM, and M. GEORGE
Department of Chemistry, Indian Institute of Technology, Madras 600036, India
(Received October 3, 1988)

An oxygen transfer from the nitro group to the olefinic double bond followed by a simple cleavage affords intense fragment corresponding to *o*-nitrosophenylthio cation at *m/z* 138 during the mass spectral fragmentations of α-(*o*-nitrophenylthio)cinnamic acid. Single and double oxygen transfers from the nitro group to sulfur lead to concerted ejections of [SO+CO_2] and [SO_2+CO_2] from the molecular ion of this compound. The mechanisms proposed for these processes are supported by high-resolution data, CID linked scan spectra, D-labelling, and chemical evidence.

The nitro group is known to interact very effectively with the ortho substituent in aromatic systems by transfering oxygen atoms to multiple bonds[1-4] or heteroatoms[5,6] present in the side chain on electron impact. Sulfur in the form of a thiocarbonyl[7,8] and a sulfide[9,10] is known to interact with the nitro group by accepting one or more oxygen atoms with subsequent expulsions of neutral molecules.[11] The electron impact mass spectra of α-(*o*-nitrophenylthio)cinnamic acid derivatives **1**—**8** (Scheme 1) were undertaken in this work in order to study the ortho interaction of the nitro group with the side chain containing sulfur and an olefinic double bond with a carboxyl group.

Results and Discussion

The base peak in the mass spectrum of α-(*o*-nitrophenylthio)cinnamic acid (**1**) is at *m/z* 138, having an elemental composition of C_6H_4NOS (138.00095) (Scheme 2, Tables 1 and 4). Furthermore, examination of the B/E linked scan spectrum of the molecular ion of **1** (Table 2) revealed that the ion at *m/z* 138 is directly formed from the molecular ion. An *o*-nitrosophenylthio cation structure is assigned to the ion at *m/z* 138. This hypothesis is confirmed

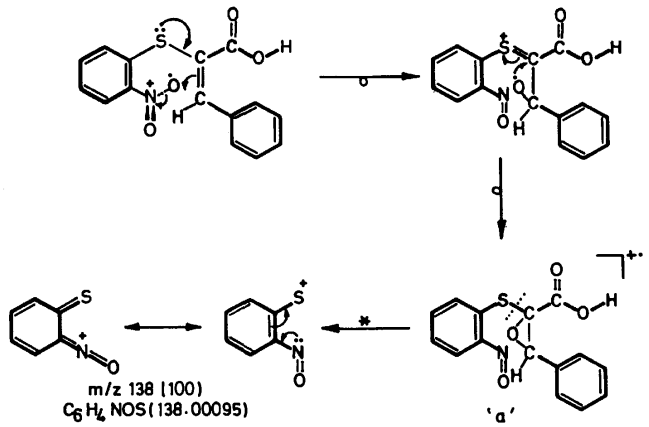
192	191 (100)	165 (82)	164 (29)					

The figures in parentheses indicate relative abundances of the ions.



Scheme 2.

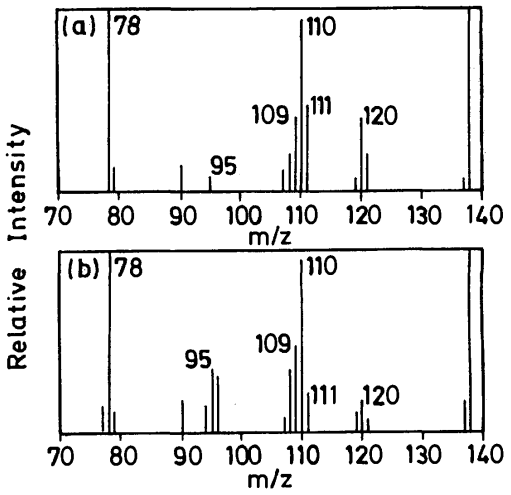


Fig. 1. CID B/E linked scan spectra of (a) m/z 138 of compound **1** and (b) m/z 138 of bis(*o*-nitrophenyl) disulfide.

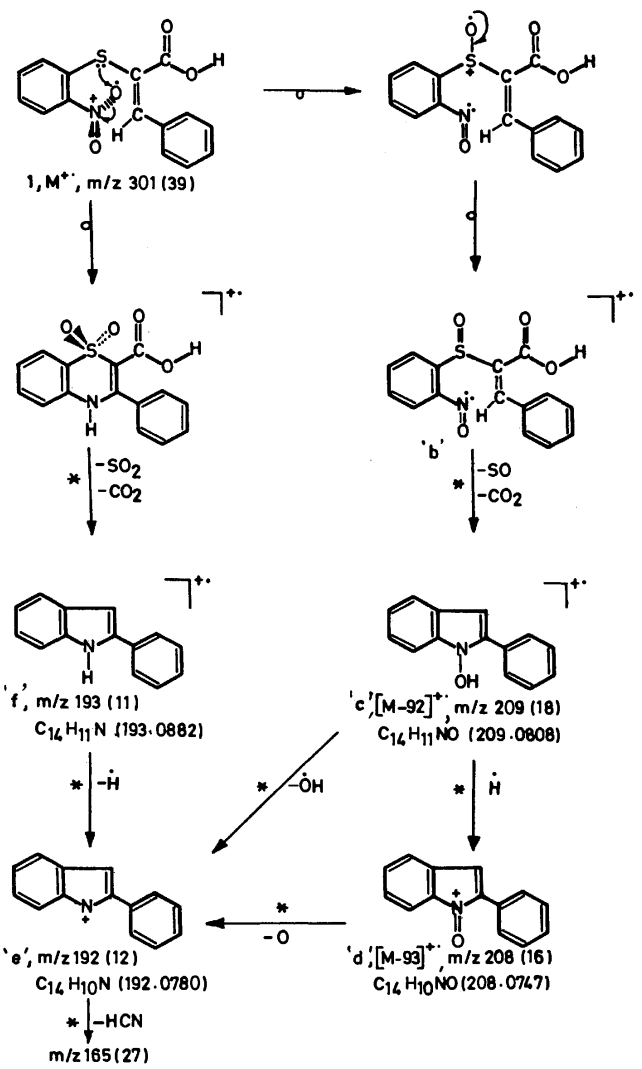

Scheme 3.

from the fact that the collision induced dissociation B/E linked scan spectrum of m/z 138 ion from compound **1** is identical with that of the ion at m/z 138 (Fig. 1) obtained from bis(*o*-nitrophenyl)disulfide, having *o*-nitrosophenylthio cation structure.[12]

Based on these observations, an oxygen transfer from the nitro group to the double bond in the side chain of compound **1** is envisaged for the formation of the rearranged molecular ion 'a' where a simple cleavage of the C-S bond affords the base peak in the spectrum at m/z 138 (Scheme 2). The proposed mechanism is further supported by the fact that the mass spectra of the substituted compounds **3** and **5**—**8** also have the base peaks at m/z 138 without any shifts (Table 1). Moreover, this ion is totally absent in the mass spectrum of the para isomer (**2**) (Table 1).

Single and double oxygen transfers from the nitro group to the sulfur in the side chain have also been

noticed in the mass specturm of compound **1** (Scheme 3). The single oxygen migration from the nitro group to sulfur leads to the rearranged molecular ion 'b'. Subsequent concerted ejection of SO and CO_2 from 'b' affords the ion 'c', $[M-92]^+$ at m/z 209 of 18% relative abundance. The extrusion of SO from 'b' can be visualized as the migration of the phenyl group from sulfur to the olefinic carbon followed by the expulsion of SO. Further loss of Ḣ from 'c' gives rise to an ion 'd' at m/z 208 (16) (Scheme 3). The elemental compositions $C_{14}H_{11}NO$ (209.0808) and $C_{14}H_{10}NO$ (208.0747) (Table 4) for 'c' and 'd' respectively obtained by high resolution technique, support the proposed elimination of SO and CO_2 from the molecular ion for the formation of 'c'. Both 'c' and 'd' lose ȮH and O respectively to give rise to a fragment 'e' at m/z 192.

The formation of 'e' at m/z 192 also takes place through another interesting parallel oxygen migration process. Initial double oxygen transfer from the nitro group to sulfur followed by concerted elimination of SO_2 and CO_2 directly from the molecular ion affords the interesting fragment ion 'f' at m/z 193 (11) (Scheme 3). An aryl migration from sulfur to the olefinic carbon after the initial double oxygen migration from the nitro group to sulfur can be proposed for the formation of 'f' $[M-SO_2]^{+\cdot}$. The expulsion of Ḣ from 'f' produces the ion 'e' at m/z 192. Also there is an evidence for the direct formation of 'e' from the molecular ion as seen in B/E linked scan spectrum of $M^{+\cdot}$ of **1** (Table 2). The elemental compositions $C_{14}H_{11}N$ (193.0882) and $C_{14}H_{10}N$ (192.0780) (Table 4) for 'f' and 'e' are in good agreement with the proposed elimination of SO_2 and CO_2 from the molecular ion for the formation of 'f'. The fragmentation pathways

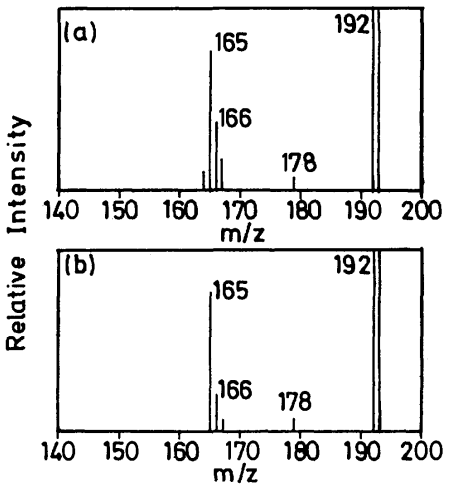

Fig. 2. CID B/E linked scan spectra of (a) ion 'f' and (b) m/z 193 from 2-phenylindole.

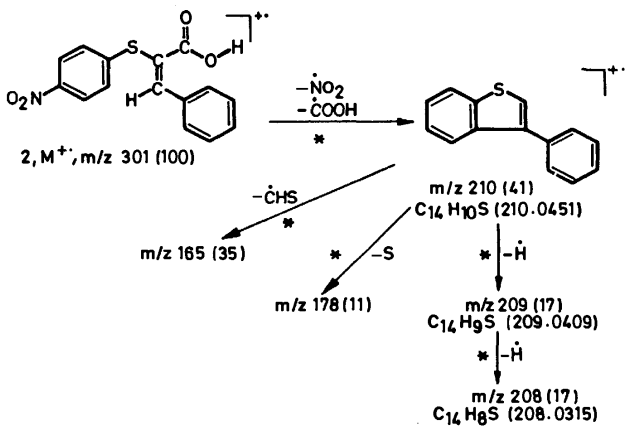
described in Scheme 2 are substantiated by linked scan B/E spectra of $M^{+\cdot}$, 'c', 'd', and 'e' (Table 2) of compound **1**. Similar single and double oxygen transfers from the nitro group to sulfur in the substituted compounds **5**—**8** lead to the formation of ions corresponding to 'c', 'd', 'f', and 'e' (Table 1). Also loss of substituent from 'e' in preference to loss of Ḣ leads to formation of the ion at m/z 208 and in turn to the formation of the fragment at m/z 192 in compounds **5**—**8** (Table 1).

A cyclic structure is proposed for 'c' from which the secondary fragmentations as observed in the mass spectrum of this compound are better explained. A 2-phenylindole structure is visualized for the ion 'f' at m/z 193 in compound **1**, instead of an open chain structure with an electron deficient nitrogen after the oxygen transfers. Evidence for the proposed structure for 'f' is obtained from the observation that the collision induced dissociation B/E linked scan spectrum of 'f' is identical with that of the molecular ion of 2-phenylindole (Fig. 2) taken as a reference compound. Furthermore the elemental compositions of



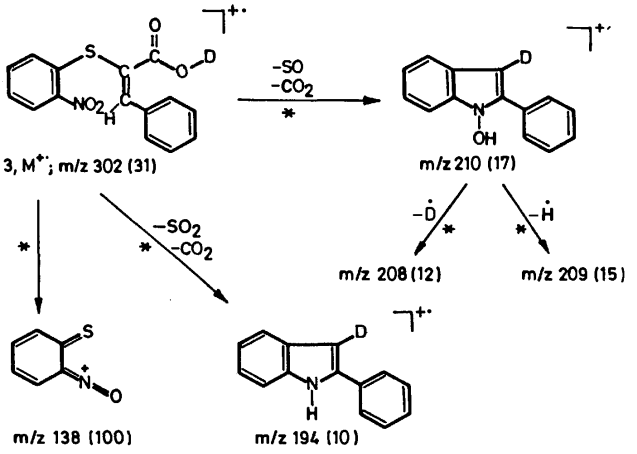
Scheme 4.

these ions as determined by the accurate mass measurements are also in agreement with those of the proposed structures.

However, the mass spectrum of the para isomer, **2**, also contains the peaks corresponding to $[M-92]^{+\cdot}$ and $[M-93]^{+}$ (Scheme 4) (Table 1). But the B/E linked scan spectra of $M^{+\cdot}$ and the abundant fragment ion at m/z 210 (Table 3) indicate that the mechanism of formation of the ions at m/z 209 and 208 in compound **2** is different from that noticed in compound **1**. A concerted elimination of $\dot{C}OOH$ and $\dot{N}O_2$ from the molecular ion affords the abundant ion at m/z 210. Two successive losses of $\dot{H}$ from the ion at m/z 210 produce the fragment ions at m/z 209 and m/z 208. The proposed mechanism is further supported by the elemental compositions $C_{14}H_{10}S$ (210.0451), $C_{14}H_9S$ (209.0409), and $C_{14}H_8S$ (208.0315) (Table 4) for the ions at m/z 210, 209, and 208 respectively.

Further evidence for the proposed ortho interactions are obtained from the mass spectra of deuterium analogues **3** and **4** (Scheme 4). The base peak in the mass spectrum of **3** is at m/z 138 since there is no involvement of the -COOH group in the formation of this ion. On the other hand, the concerted elimination of SO and CO_2 from the molecular ion affords the ion at m/z 210 which loses both $\dot{H}$ and $\dot{D}$ to give ions at m/z 209 and 208, respectively. Also the concerted ejection of SO_2 and CO_2 from the molecular ion of **3** produces an ion at m/z 194 (Scheme 5). These observations clearly indicate that the formation of 'c' and 'f' in compound **1** involves a decarboxylation process (elimination of SO and CO_2 or SO_2 and CO_2) and not an elimination of the $\dot{C}OOH$ as in the case of the para isomer, **2**. Moreover, the molecular ion of compound **4** undergoes, as expected, concerted expulsion of $\dot{N}O_2$ and $\dot{C}OOD$ giving rise to an abundant ion at m/z 210 as in compound **2** (Table 1).

It is evident from this study that the oxygen transfer to the olefinic double bond is more predominent, whereas the oxygen transfer to the sulfur is associated with the decarboxylation process.



Scheme 5.

Experimental

Compounds **1**,**2**, and **5**—**8** were prepared[13,14] by condensation reactions of (2-nitrophenylthio)acetic acid or (4-nitrophenylthio)acetic acid with the appropriate substituted benzaldehyde, according to the procedure reported in literature for the preparation of these compounds. Compounds **3** and **4** were synthesized by refluxing 50 mg each of **1** or **2** with one ml of D_2O for 120 h followed by usual work-up. The D-incorporation is found to be 76% in **3** and 62% in **4**. The purity of the compounds was checked by TLC and was characterized by IR and NMR spectral data.

The low-resolution spectra were taken on a Varian MAT CH-7 mass spectrometer. The spectra were run at 70 eV with an emission current of 100 μA. All the compounds were introduced into the mass spectrometer through the direct probe insertion at a probe temperature varying between 70 and 110 °C. The high-resolution data (at a resolution of 5000, 10% valley) were recorded on a Finnigan MAT 8230 mass spectrometer at an ionization energy of 70 eV and an acceleration voltage of 3 kV. The linked scan spectra were run on a Finnigan MAT 90 mass spectrometer.

One of the authors (MG) thands CSIR (India) for a fellowship. The authors thank R. S. I. C., I. I. T., Madras for the high-resolution data and Finnigan MAT Ltd., England for the linked scan spectra.

The Synthesis of *C*-Nucleoside Precursors. II.[1] Synthesis and Conformational Analysis of 3-(Pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazines[2]

Mohammed A. E. SHABAN* and Mamdouh A. M. TAHA
Department of Chemistry, Faculty of Science, Alexandria University, Alexandria, Egypt
(Received November 14, 1988)

Reaction of 1-hydrazino-4-phenylphthalazine with aldohexoses (D-galactose, D-glucose, D-mannose, and D-talose) and 6-deoxyaldohexoses (L-fucose and L-rhamnose) gave the colored *aldehydo*-sugar (4-phenyl-1-phthalazinyl)hydrazones or the colorless 3-(pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazines. The former can be cyclized to the latter by catalytic dehydrogenation. Structure elucidation of the prepared compounds was made on the basis of their various spectral properties. The *C*-nucleoside precursors were further characterized as their *O*-acetyl derivatives and the configurational-conformational correlation of these acetates was studied. Some of the prepared compounds were screened for insectidicidal, nematicidal, and herbicidal activities and found to be inactive. They showed, however, good corrosion inhibition of aluminium in acid solutions.

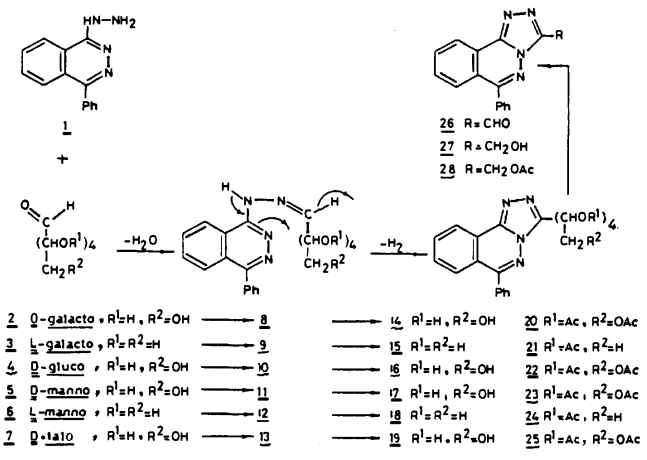
Since the isolation[3,4] of the first *C*-nucleoside pseudouridine in 1957 from yeast RNA, extensive research efforts have been aimed at the isolation and synthesis of newer members as well as of analogs.[5-8] Such efforts are rationalized in terms of the multifarious biological activities exhibited by these compounds mainly as a result of their close structural relationship to nucleosides. *C*-Nucleosides may be synthesized[9] by the approach involving carbon-to-carbon bond formation between the anomeric center of the sugar moiety and a preformed heterocycle or by stepwise construction of the heterocyclic system onto a properly functionalized glycosyl derivative with a fixed anomeric configuration.[10] Albeit yielding mixture of anomers, dehydrative cyclization of the polyhydroxyalkyl chains of heterocyclic compounds carrying polyhydroxyalkyl groups (acyclic *C*-nucleosides) offers a relatively simple approach for the synthesis of *C*-nucleosides.[11]

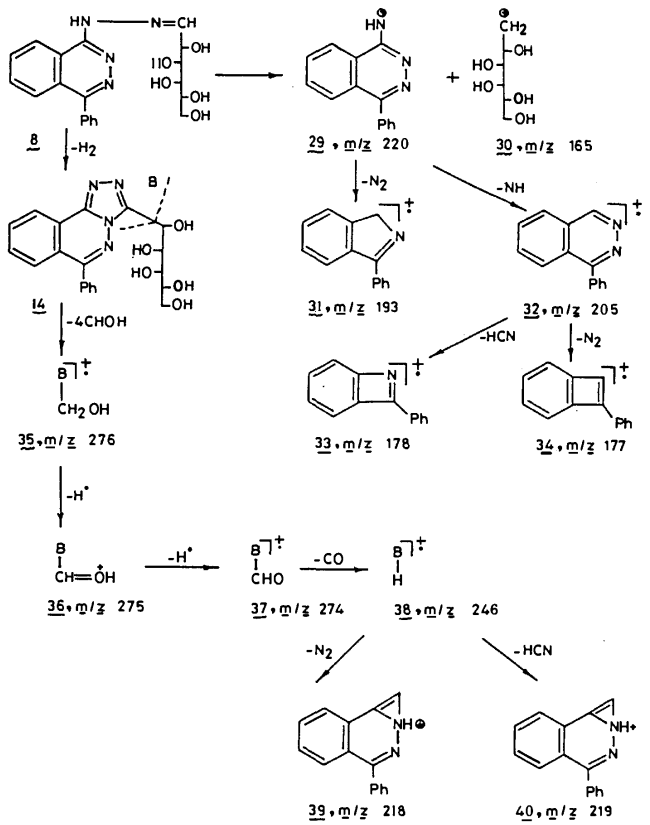
Continuing our work on the synthesis of polyhydroxyalkyl derivatives of heterocycles[12] and fused heterocycles[13,14] uesful as *C*-nucleoside precursors, we describe in this paper the synthesis of the title compounds. Hydrazinophthalazines are among the most medicinally useful hypotensive agents[15,16] which exert their effect as vasodilators by acting on the arteriolar smooth muscles. Studies have shown that Schiff bases[16] of hydrazinophthalazines as well as their cyclization products: 3-substituted 1,2,4-triazolo-[3,4-*a*]phthalazines,[17,18] also retain the hypotensive activity. Thus, 3-alkyl-1,2,4-triazolo[3,4-*a*]phthalazines were found[17] to be as potent as theophylline in inhibiting cyclic adenosine monophosphate phosphodiesterase and possess smooth muscle relaxant activity. Hydrazinophthalazines, however, are not without adverse effects[15] and search for less toxic derivatives thereof is highly desirable. We anticipated that *aldehydo*-sugar 1-phthalazinylhydrazones or their cyclized products 3-(pentahydroxypentyl)-1,2,4-triazolo[3,4-*a*]phthalazines may possess more potent hypotensive activity and less adverse effects since sugar moieties are expected to increase penetration of drugs into and secretion out of biological systems as a result of increasing their hydrophilicity.

Results and Discussion

The reaction of monosaccharides with 1-hydrazinophthalazine was first reported as early as 1954 by Menziani;[19,20] the products were erroneously ascribed 1-(1-phthalazinyl)-2-(glycosyl)hydrazine structures. In a previous publication[13] from this laboratory, this reaction was reinvestigated and the products were found to be either the colored (yellow to orange) *aldehydo*-sugar 1-phthalazinylhydrazones or the colorless 3-(polyhydroxyalkyl)-1,2,4-triazolo[3,4-*a*]-phthalazines. Rosenthal and Lee[21] synthesized the *C*-nucleoside 3-(β-D-ribofuranosyl)-1,2,4-triazolo[3,4-*a*]phthalazine by condensation of 2,5-anhydro-3,4,6-tri-*O*-benzoyl-D-allonic acid with 1-hydrazinophthalazine followed by removal of the *O*-benzoyl groups.

In the present investigation the aldohexoses D-galactose (**2**), D-glucose (**4**), D-mannose (**5**), and D-





Scheme 1.

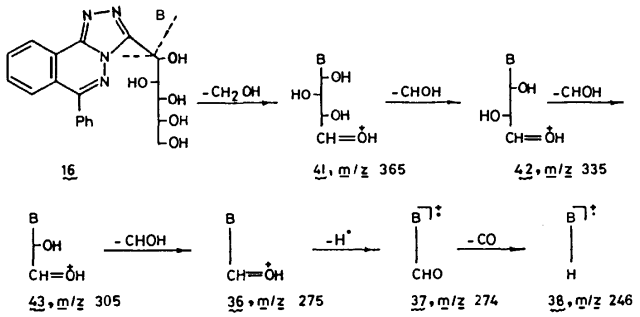
talose (**7**) as well as 6-deoxy-L-galactose (L-fucose, **3**) and 6-deoxy-L-mannose (L-rhamnose, **6**) were allowed to react with one molar equivalent of 1-hydrazino-4-phenylphthalazine[22,23] (**1**). The reaction products (**8** and **11**) of D-galactose and D-mannose were yellow and orange respectively while those (**16**, **19**, **15**, and **18**) of D-glucose, D-talose, L-fucose, and L-rhamnose were colorless.

The yellow product (**8**) of D-galactose had elemental analysis data agreeing with the monohydrate of the molecular formula $C_{20}H_{22}N_4O_5$. The IR spectrum of this product showed OH, NH, and C=N absorptions; its UV/visible spectrum revealed four maxima; and its ^{1}H NMR spectrum showed NH, CH=N, nine aromatic protons, and five OH signals. These data indicate that this product possesses the hydrazone structure: *aldehydo*-D-galactose (4-phenyl-1-phthalazinyl) hydrazone (**8**). The mass spectrum of **8** (see Scheme 1) did not show a molecular ion peak, yet revealed a fragmentation pattern consistent with the assigned structure. Cleavage of the hydrazono N-N bond gave the two fragments **29** (base peak, 100%) and **30** belonging to the phthalazine and sugar moieties respectively. Further cleavage of the heterocycle segment **29** gave fragments to which structures **31**—**34** were assigned on the basis of previous work[13,24-26] on similar systems.

The orange product obtained from the reaction of D-mannose (**5**) with 1-hydrazino-4-phenylphthalazine (**1**) gave analytical and spectral data similar to those obtained for hydrazone **8** and was, accordingly, assigned the structure of *aldehydo*-D-mannose (4-phenyl-1-phthalazinyl)hydrazone (**11**).

It was interesting to notice that repeated crystallization of the yellow hydrazone **8** gave a colorless product having different properties than those of the starting hydrazone. Thus, whereas **8** melted at 203—205 °C, the colorless product melted at 228—231 °C and the fingerprint region of their molecular spectra were substantially different. The UV/visible spectrum of the colorless product exhibited only two absorption maxima; the two other maxima which appeared in the spectrum of the hydrazone (**8**) were lacking. The ^{1}H NMR spectrum of the colorless product revealed the same number of aromatic and sugar chain protons as those of the parent hydrazone **8**, yet the azomethine and hydrazono protons (-CH=N-NH-) present in the spectrum of **8** were missing. In agreement with the ^{1}H NMR was the elemental analysis data which is compatible with the molecular formula $C_{20}H_{20}N_4O_5$; two hydrogens less than the starting hydrazone **8**. These data obviously indicated that repeated crystallization of **8** was accompanied by gradual thermal dehydrogenative cyclization until eventually transformed into the acyclic *C*-nucleoside 3-(D-*galacto*-pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]-phthalazine (**14**). This cyclization was carried out more efficiently under catalysis conditions by heating aqueous methanolic solutions of **8** with 10% palladium-on-charcoal whereupon **14** was obtained in high purity and excellent yield. Similarly, catalytic dehydrogenative cyclization of the orange *aldehydo*-D-mannose (4-phenyl-1-phthalazinyl)hydrozone (**11**) by heating its solution in aqueous methanol with 10% palladium-on-charcoal also gave the colorless 3-(D-*manno*-pentahydroxypentyl)-6-phenyl-1,2,4-triazolo-[3,4-*a*]phthalazine (**17**).

Reaction of D-glucose (**4**) with 1-hydrazino-4-phenylphthalazine (**1**) under the same conditions which were used for the reaction with D-galactose (**2**) and D-mannose (**5**) gave, unexpectedly, and a colorless product; the anticipated yellow hydrazone **10** has never been obtained. The ^{1}H NMR of this colorless product showed signals of the nine aromatic protons as well as the alditol chain protons; no azomethine or hydrazono proton signals (-CH=N-NH-) were present. The elemental analysis data agreed with the molecular formula $C_{20}H_{20}N_4O_5$ with two hydrogens less than the expected hydrazone **10**. These data would reconcile with the structure 3-(D-*gluco*-pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]-phthalazine (**16**). Thus, in contrast to D-galactose and D-mannose which gave the colored intermediate hydrazones, D-glucose directly gave the colorless cyclic triazolophthalazine. A plausible rationalization of this difference may be based upon the different solubilities of the intermediate hydrazones. The hydrazones (**8** and **11**) derived from D-galactose and D-



Scheme 2.

mannose were sparingly soluble enough to permit their separation while that (**10**) derived for D-glucose was soluble enough to remain in solution and, hence, undergoes thermal dehydrogenative cyclization to **16**. The mass spectrum of **16** did not reveal a molecular ion peak, yet showed the ($M-CH_2OH$) fragment (**41**, Scheme 2) which underwent sequential alditol chain fragmentation giving fragments **42**, **43**, and **36—38**. The B+30 fragment **36**, corresponding to the heterocyclic base carrying a protonated formyl group ($B-CHO^+H$), characteristic of [27] *C*-nucleosides appeared at *m/z* 275.

Similar to D-glucose (**4**), 1-hydrazino-4-phenylphthalazine (**1**) reacted with L-fucose (**3**), L-rhamnose (**6**), and D-talose (**7**) to give the corresponding colorless 3-(polyhydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]-phthalazine **15**, **18**, and **19** respectively.

Oxidative cleavage of the alditol chains of **14—19** with sodium periodate at room temperature gave 4-formyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**26**). Reduction of **26** with sodium borohydride gave 3-hydroxymethyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**27**). Acetylation of **27** gave 3-acetoxymethyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**28**). In their study on the pathogenesis of 1-hydrazinophthalazine-induced systemic lupus erythematosus, Zimmer et al.[28] synthesized 3-hydroxymethyl-1,2,4-triazolo[3,4-*a*]phthalazine and proved, by direct comparison, that it is a major metabolite found in the urine of hypertensive patients on treatment with this drug. 3-Hydroxymethyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**27**) may, therefore, be used for a imilar study.

For further characterization of the 3-polyhydroxypentyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazines (**14—19**) and in order to study the configurational-conformational correlations of their alditol chains, their per-*O*-acetyl derivatives were prepared by acetylation with acetic anhydride in the presence of pyridine. Out of the six prepared acetates, only three could be obtained in a crystalline form namely: 3-(D-*galacto*-1,2,3,4,5-pentaacetoxypentyl)- (**20**), 3-(D-*gluco*-1,2,3,4,5-pentaacetoxypentyl)- (**22**), and 3-(L-*galacto*-1,2,3,4-tetraacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**21**). The three other per-*O*-acetyl derivatives **23—25** having the D-*manno*-, 5-deoxy-L-*manno*-, and D-*talo*-pentitol configurations respectively were obtained as syrupy products. The IR spectra of the crystalline acetates (**20—22**) showed ester carbonyl absorptions and their ^{1}HNMR spectra revealed nine aromatic protons followed by the alditol chain protons signals (see Table 1). Among the alditol chain protons, H-1 resonated at the highest field due to electronic deshielding by the adjacent heterocyclic system.[29] Alditol H-2 resonated at the next lower field followed by H-3, H-4, H-5, and H-5′. These assignments were made on the basis of signal multiplicities and compared very well with those of acetylated alditol derivatives of 1,2,3-triazoles,[30] tetrazoles,[31] 1,3,4-oxadiazoles,[32] thiazoles,[33] and benzothiazoles.[34] Knowing[33,35–38] that the magnitude of vicinal proton-proton coupling constants of < 4 Hz correspond to protons having gauche orientation (dihedral angle ca. 60°) and that values of >7 Hz correspond to antiparallel orientation (dihedral angle

Table 1. Chemical Shifts[a] (δ) of the Alditol-Chain Protons of 3-(Polyacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazines in $CDCl_3$ at 90 MHz

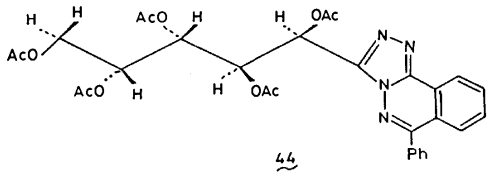
Compound	Configuration	$J_{1,2}$	$J_{2,3}$	$J_{3,4}$	$J_{4,5}$	$J_{4,5'}$	$J_{5,5''}$
20	D-*galacto*-	3	a)	a)	6	7.5	12
21	5-deoxy-L-*galacto*-	<3	9	4	7	—	—
22	D-*gluco*-	7.5	3	7.5	3	4.5	12

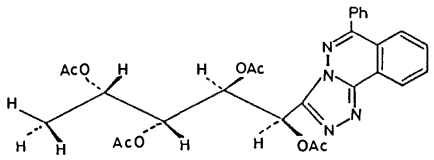
a) Unamenable to first order analysis due to overlapping of H-2 and H-3 signals.

ca. 180°), it is possible to predict the most favored conformations of compounds **20**, **21**, and **22** in terms of their observed coupling data (see Table 2).

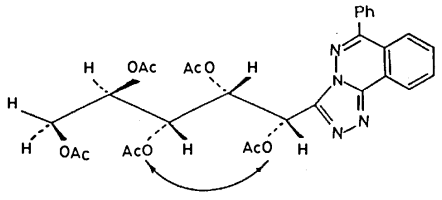
The small $J_{1,2}$ value (≤3 Hz) of the two *galacto*-pentitol derivatives: 3-(D-*galacto*-1,2,3,4,5-pentaacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**20**) and 3-(L-*galacto*-1,2,3,4-tetraacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**21**) indicates a gauche arrangement of H-1 and H-2. Like 2-methyl- and 2-phenyl-(D-*galacto*-1,2,3,4,5-pentaacetoxypentyl)-1,3,4-oxadiazoles[32] and penta-*O*-acetyl-D-galactitol,[39] the H-2 and H-3 signals of the D-*galacto*- derivative **20** were unamenable for analysis due to their overlapping. Fortunately, however, the H-2 and H-3 signals of the 5-deoxy-L-*galacto*- derivative **21** were not overlapping and the first-order analysis of the coupling constants was possible. The $J_{2,3}$ value of this derivative is large enough (9 Hz) to indicate exclusive antiparallel disposition of H-2 and H-3. On the other hand, the $J_{3,4}$ value of 4 Hz points out to the gauche relation of H-3 and H-4. These data are very compatible with the expected extended, planar, zigzag conformations **44** and **45** of **20** and **21** respectively in which the bulky heterocycle extends away from the acetylated alditol chain. These conformations are free of any unfavorable eclipsed 1,3-interactions and conform with those assigned[31-34] for other heterocyclic compounds with *galacto*-pentitol side chain.



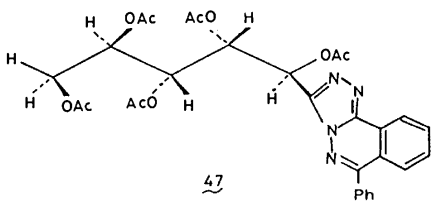
44



45



46



47

It would be expected that the extended, planar zigzag conformation **46** depicted for the 3-(D-*gluco*-1,2,3,4,5-pentaacetoxypentyl)-6-phenyl-1,2,4-triazolo-[3,4-*a*]phthalazine (**22**) represents a highly unfavorable situation owing to the dipolar eclipsed 1,3-interaction of the C-1 and C-3 acetoxyl groups. This expectation is, indeed, supported by the observed $J_{1,2}$ value (7.5 Hz); conformation **46** having H-1 and H-2 in a gauche arrangement would require a $J_{1,2}$ value of <4 Hz. Rotation about the C-1—heterocycle bond of **46** brings H-1 in the antiparallel orientation to H-2 and, therefore, mitigates the aforementioned 1,3-eclipsed interaction. This results in the formation of the "sickle" conformation **47** as a more favorable conformation of the D-*gluco*-derivative **22**. The observed $J_{2,3}$ and $J_{3,4}$ values (3 and 7.5 Hz respectively) are in congruence with the gauche and antiparallel dispositions of H-2–H-3 and H-3–H-4 respectively as depicted in the "sickle" conformation **47**.

Exploring some applications for the synthesized compounds, we have recently found[40,41] that 3-(D-*galacto*-pentahydroxypentyl)-6-phenyl-1,2,4-triazolo-[3,4-*a*]phthalazine (**16**) is a good inhibitor against the acid-corrosion of aluminium. Unfortunately however, compounds **8** and **11** showed no insecticidal activity when applied at the rate of 1000 ppm to the following insect species/host plant systems: mexican beet beetle (*Epilachna varivestis* Mulsant)/pinto bean (*Phaseolus vulgaris*); pea aphid (*Acyrthosiphon pisum* Harris)/fave bean (*Vicia faba*); southern armyworm (*Spodoptera eridania* Gramer)/pinto bean; and the two-spotted spider mite (*Tetranychus urticae*)/pinto bean.

Compounds **8** and **16** also showed no nematicidal activity at an application rate of 10 ppm against root-knot nematode (*Meloidogyne incognita*) hosted on cucumber (*Cucumis sativus*).

Compound **16** exhibited no herbicidal/plant growth regulation in the preemergence response and low activity (10—20%) in the post-emergence response screening when applied to the following test species: soybean (*Glycine max*, 20%); corn (*Zea mays*, 10%); wheat (*Triticum aestivum*, 10%); morningglory (*Ipomea spp*, 20%); velvetleaf (*Abutilon theophrasti*, 10%); barnyardgrass (*Echinochloa crus-galli*, 10%); and foxtail, green (*Setaria veridis*, 10%).

Experimental

General Methods. Melting points were determined with a Kofler block and are uncorrected. The infrared spectra (IR) were recorded for potassium bromide discs on a Unicam SP-1025 or Pye-Unicam SP-2000 spectrophotometers. Ultraviolet-visible spectra were recorded at ambient temper-

ature using a Unicam SP-1750 spectrophotometer. Proton magnetic resonance (^{1}H NMR) spectra were carried out at ambient temperature (ca. 25 °C) and at 90 MHz with a Varian EM-390 spectrometer for solutions in $CDCl_3$ or $(CD_3)_2SO$. Mass spectra were performed on an analytical system consisting of a Du Pont 21-419 mass spectrometer interfaced with a Du Pont 492-094 data-acquisition system. Follow up of the reactions and checking the homogeneity of the prepared compounds were made by performing thin-layer chromatography (TLC) on Silica gel G (Merck) precoated plates (layer thickness 0.25 mm) used without pretreatment. All the ratios of the solvent systems used were volume-to-volume (v/v); the distance of solvent travel was 5 cm, and the spots were detected by exposition to iodine vapour for a few minutes. All solvent evaporations were performed in a Buchi rotary evaporator under diminished pressure, with an outside bath temperature kept below 50 °C. Elemental microanalyses were performed in the Microanalysis Laboratory, Chemistry Department, Faculty of Science, Alexandria University using Perkin-Elmer Model PE-240 analyzer and in the Microanalysis Unit, Chemistry Department, Faculty of Science, Cairo Universtity.

***aldehydo*-D-Galactose(4-phenyl-1-phthalazinyl)hydrazone (8).** A solution of 1-hydrazino-4-phenylphthalazine (**1**, 1 g) in methanol (20 ml) was filtered through a fritted-glass funnel and added to a filtered solution of D-galactose (**2**, 0.8 g) in water (0.5 ml). The mixture was heated for 10 minutes on a boiling water bath and then kept for 24 hours at room temperature. The crystalline yellow product which separated, was filtered, washed several times with filtered methanol to give 1 g (59%) of **8** as yellow needles, mp 203—205 °C. All attempts to crystallize this hydrazone led to its transformation into the cyclic triazolophthalazine **14**. TLC in 1 : 1 chloroform-methanol, R_f: 0.52; $\lambda_{max}^{50\%EtOH}$ 338, 280, 240, and 212 nm, ($\log\varepsilon$: 4.61, 4.96, and 5.10); ν_{max}^{KBr} 3400 (broad, OH), 3300 (NH) and 1640 cm^{-1} (C=N); ^{1}H NMR $(CD_3)_2SO$: δ=12.15 (s, 1H, deuteratable, NH), 8.80 (d, 1H, CH=N), 8.75—7.40 (m, 9H, aromatic H), 4.82 (d, 1H, deuteratable, OH), 4.60 (m, 1H, alditol H), 4.40 (m, 2H, deuteratable, 2 OH) and 4.15 (m, 2H, deuteratable, 2 OH), the other protons together with the solvent absorption were congregated in a broad signal at δ 3.35.

Calcd for $C_{20}H_{22}N_4O_5 \cdot H_2O$: C, 57.69; H, 5.77; N, 13.46%. Found: C, 58.10; H, 5.60; N, 13.10%.

3-(D-*galacto*-Pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (14). Method (A): Attempted crystallization of *aldehydo*-D-galactose (4-phenyl-1-phthalazinyl)hydrazone (**8**) from water-methanol gave a gelatinous product which showed two spots on TLC (1 : 1 chloroform-methanol). One spot migrated at a rate similar to that of the parent hydrazone **8** (R_f: 0.52) and the other was slightly less polar (R_f: 0.55) and corresponds to that of **14**. Repeated crystallization from the same solvent caused the gradual transformation of **8** into **14** which crystallized from water-methanol as colorless needles, mp 228—231 °C; TLC in 1 : 1 chloroform-methanol, R_f: 0.55; $\lambda_{max}^{50\%EtOH}$ 244 and 212 nm ($\log\varepsilon$: 4.81 and 4.63); ν_{max}^{KBr} 3420 (broad, OH) and 1630 cm^{-1} (broad C=N); ^{1}H NMR $(CD_3)_2SO$: δ=8.75—7.37 (m, 9H, aromatic H), 5.37 (m, 2H, alditol H), 4.75 (d, 1H, deuteratable, OH), 4.40 (m, 1H, deuteratable, OH), 4.22 (d, 3H, deuteratable, 3 OH), and 3.75 (m, 2H, alditol H), the other protons together with the solvent absorption were gathered in a broad signal at δ=3.53.

Calcd for $C_{20}H_{20}N_4O_5$: C, 60.60; H, 5.09; N, 14.13%. Found: C, 60.10; H, 5.05; N, 14.74%.

Method (B): A solution of *aldehydo*-D-galactose (4-phenyl-1-phthalazinyl)hydrazone (**8**, 1 g) in a mixture of water (5 ml) and methanol (20 ml) was treated with 10% palladium-on-charcoal (0.5 g) and refluxed for 4 hours. The catalyst was filtered off on a layer of Celite and the filtrate was evaporated to dryness. Crystallization of the residue from water-methanol gave 0.7 g (70%) of **14**, mp and mixed mp 228—231 °C, having the same spectral properties as that obtained according to method (A).

3-(D-*galacto*-1,2,3,4,5-Pentaacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (20). 3-(D-*galacto*-Pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**14**, 1 g) was treated with pyridine (5 ml) and acetic anhydride (5 ml) for 24 hours at room temperature. The mixture was poured onto crushed ice and the product which separated was filtered, washed with water, and crystallized from methanol to give 0.9 g (59%) of **20**, mp 195—198 °C; TLC in 9 : 1 chloroform-methanol, R_f: 0.65; ν_{max}^{KBr} 1760 cm^{-1} (ester-carbonyl, *O*-acetyl groups); ^{1}H NMR ($CDCl_3$): δ=8.80—7.46 (m, 9H, aromatic H), 6.55 (d, 1H, alditol H-1), 5.68 (s, 2H, alditol H-2+H-3), 5.36 (m, 1H, alditol H-4), 4.28 (dd, 1H, alditol H-5), 3.92 (dd, 1H, alditol H-5′), 2.24, 2.13, 2.03 (3s, 3H each, 3 acetyl groups), and 1.98 (s, 6H, 2 acetyl groups).

Calcd for $C_{30}H_{30}N_4O_{10}$: C, 59.40, H, 4.99; N, 9.24%. Found: C, 59.85; H, 4.64; N, 9.67%.

3-(L-*galacto*-1,2,3,4-Tetrahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (15). A solution of 1-hydrazino-4-phenylphthalazine (**1**, 1 g) in methanol (20 ml) was added to a solution of 6-*deoxy*-L-galactose (L-fucose, **3**, 0.69 g) in the least amount of water (ca. 0.2 ml), and the mixture was heated for 20 minutes on a boiling water bath. The product, which separated after cooling was filtered, washed with chloroform and ether, and crystallized from water-methanol to give 0.9 g (56%) of **15**, mp 243—245 °C, TLC in 1 : 1 chloroform-methanol, R_f: 0.52; ν_{max}^{KBr} 3400 (boroad, OH) and 1625 cm^{-1} (C=N); ^{1}H NMR $(CD_3)_2SO$: δ=8.60—7.35 (m, 9H, aromatic H), 5.35 (m, 2H, alditol H), 4.68 (s, 1H, deuteratable, OH) and 1.06 (d, 3H, pentitol CH_3), the other protons and hydroxyl protons together with the solvent absorption were congregated in a broad signal at δ=3.45.

Calcd for $C_{20}H_{20}N_4O_4$: C, 63.16; H, 5.26; N, 14.74%. Found: C, 63.51; H, 5.30; N, 14.79%.

3-(L-*galacto*-1,2,3,4-Tetraacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (21). A solution of 3-(L-*galacto*-1,2,3,4-tetrahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]-phthalazine (**15**, 1 g) in pyridine (4 ml) was treated with acetic anhydride (4 ml) and kept at room temperature for 24 hours. The mixture was poured onto crushed ice and the product which separated was filtered, washed with water, and crystallized from methanol to give 0.6 g (42%) of **21**, mp 252—255 °C; TLC in 9 : 1 chloroform-methanol, R_f: 0.62; ν_{max}^{KBr} 1760 and 1745 cm^{-1} (ester-carbonyl, *O*-acetyl groups); ^{1}H NMR ($CDCl_3$): δ=8.80—7.47 (m, 9H, aromatic H), 6.58 (d, 1H, alditol H-1), 5.73 (dd, 1H, alditol H-2), 5.48 (dd, 1H, alditol H-3), 5.13 (m, 1H, alditol H-4), 2.20, 2.11, 1.92, 1.88 (4s, 3H each, 4 acetyl groups), and 1.16 (d, 3H, pentitol CH_3).

Calcd for $C_{28}H_{28}N_4O_8$: C, 61.31; H, 5.11; N, 10.22%. Found: C, 61.35; H, 5.29; N, 10.16%.

3-(D-*gluco*-Pentaacetoxypentyl)-6-phenyl-1,2,4-triazolo-[3,4-*a*]phthalazine (16). A solution of 1-hydrazino-4-phenylphthalazine (**1**, 1 g) in methanol (30 ml) was treated with a solution of D-glucose (**4**, 0.8 g) in the least amount of water (ca. 0.3 ml) and the mixture was heated for 15 minutes on a boiling water bath. The mixture was left to attain ambient temperature and the product which separated was filtered, washed with chloroform and ether, and crystallized from water-methanol to give 1 g (59.5%) of **16**, mp 245—247 °C; TLC in 1:1 chloroform-methanol R_f: 0.52; ν_{max}^{KBr} 3500, 3380 (OH) and 1550 cm^{-1} (C=N); ^1H NMR $(CD_3)_2SO$: δ=8.70—8.45 (m, 9H, aromatic H), 5.58 (d, 1H, deuteratable, O<u>H</u>), 5.30 (m, 1H, alditol H), 4.60 (m, 2H, deuteratable proton, O<u>H</u>+ undeuteratable proton, alditol H), and 4.28 (m, 3H, deuteratable, 3O<u>H</u>), the other protons together with the solvent absorption were congregated in a broad signal at δ=3.30.

Calcd for $C_{20}H_{20}N_4O_5$: C, 60.60; H, 5.09; N, 14.13%. Found: C, 60.68; H, 5.24; N, 13.99%.

3-(D-*gluco*-1,2,3,4,5-Pentaacetoxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (22). 3-(D-*gluco*-Pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**16**, 1 g) was treated with pyridine (5 ml) and acetic anhydride (5 ml) and kept at room temperature for 24 hours. The mixture was poured onto crushed ice (150 ml) and the product which separated was filtered, washed with water, and crystallized from methanol to give 0.9 g (59%) of **22**, mp 140—142 °C. TLC in 9:1 chloroform-methanol; R_f: 0.52, ν_{max}^{KBr} 1760 and 1745 cm^{-1} (ester-carbonyl, *O*-acetyl groups); ^1H NMR ($CDCl_3$): δ=8.80—7.48 (m, 9H, aromatic H), 6.63 (d, 1H, alditol H-1), 6.20 (dd, 1H, alditol H-2), 5.13 (m, 1H, alditol H-3+H-4), 4.15 (dd, 1H, alditol H-5), 3.87 (dd, 1H, alditol H-5′), 2.07 (s, 6H, 2 acetyl groups), 2.02, 1.88, and 1.75 (3s, 3H each, 3 acetyl groups).

Calcd for $C_{30}H_{30}N_4O_{10}$: C, 59.40; H, 4.99; N, 9.24%. Found: C, 59.30; H, 5.09; N, 9.40%.

***aldehydo*-D-Mannose (4-Phenyl-1-phthalazinyl)hydrazone (11).** A solution of 1-hydrazino-4-phenylphthalazine (**1**, 1 g) in methanol (30 ml) was added to a solution of D-mannose (**5**, 0.8 g) in the least amount of water (ca. 0.2 ml) and the mixture was heated for 15 minutes on a boiling water bath. The mixture was kept at ambient temperature for an overnight and the orange crystalline product which separated was filtered, washed with chloroform and ether. Crystallization from water-methanol gave 1 g (59%) of **11**, as orange plates, mp 195—198 °C; TLC in 1:1 chloroform-methanol, R_f: 0.43; $\lambda_{max}^{50\%EtOH}$ 350 and 284 nm (log ε: 2.39 and 2.70); ν_{max}^{KBr} 3430, 3350 (OH), 3280 (NH), 1640, 1610, and 1595 cm^{-1} (C=N); ^1H NMR $(CD_3)_2SO$: δ=12.15 (s, 1H, deuteratable, N<u>H</u>), 8.37 (m, 1H, aromatic H), 5.05 (d, 1H, deuteratable, O<u>H</u>), and 4.60—4.10 (m, 5H, 4 deuteratable protons, 4O<u>H</u>+undeuteratable proton, alditol H), the other protons together with the solvent absorption were gathered in a broad signal at δ=3.35.

Calcd for $C_{20}H_{22}N_4O_5 \cdot H_2O$: C, 57.69; H, 5.77; N, 13.46%. Found: C, 58.01; H, 5.52; N, 13.20%.

3-(D-*manno*-Pentahydroxypentyl)-6-phenyl-1,2,4-triazolo-[3,4-*a*]phthalazine (17). To solution of *aldehydo*-D-mannose (4-phenyl-1-phthalazinyl)hydrazone (**11**, 1 g) in a mixture of water (10 ml) and methanol (30 ml) 10% palladium-on-charcoal (0.5 g) was added and the mixture was refluxed for 3 hours. The catalyst was filtered off on a bed of Celite and the filtrate was evaporated to dryness. Crystallization of the residue from water-methanol gave 0.8 g (81%) of **17**, mp 198—202 °C; TLC in 1:1 chloroform-methanol, R_f: 0.60; $\lambda_{max}^{50\%EtOH}$ 246 nm (log ε: 3.51); ν_{max}^{KBr} 3350 (broad, OH) and 1650 cm^{-1} (broad, C=N); ^1H NMR $(CD_3)_2SO$: δ=8.68—7.42 (m, 9H, aromatic H), 5.70 (d, 1H, deuteratable, O<u>H</u>), 5.27 (m, 1H, alditol H), 4.40 (m, 5H, 4 deuteratable protons, 4O<u>H</u>+undeuteratable proton, alditol H), and 3.75 (m, 4H, alditol H).

Calcd for: $C_{20}H_{20}N_4O_5 \cdot 0.5H_2O$: C, 59.26; H, 5.19; N, 13.83%. Found: C, 59.66; H, 5.16; N, 13.51%.

Attempted Preparation of 23. Acetylation of 3-(D-*manno*-(pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]-phthalazine (**17**) with acetic anhydride in the presence of pyridine and processing of the reaction mixture as given for the preparation of **20** gave an uncrystallizable syrupy product.

3-(L-*manno*-1,2,3,4-Tetrahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (18). A solution of 1-hydrazino-4-phenylphthalazine (**1**, 1 g) in methanol (20 ml) was added to a solution of 6-deoxy-L-mannose (L-rhamnose **6**, 0.69 g) in the least amount of water (ca. 0.2 ml) and the mixture was heated for 15 minutes on a boiling water bath. The mixture was kept for an overnight at room temperature and the product which separated was filtered, washed with chloroform and ether, and crystallized from water-methanol to give 0.8 g (50%) of **18**, mp 150—154 °C; TLC in chloroform-methanol, R_f: 0.70; ν_{max}^{KBr} 3300 (broad, OH) and 1640 cm^{-1} (broad, C=N); ^1H NMR $(CD_3)_2SO$: δ=8.68—7.41 (m, 9H, aromatic H), 5.66 (s, 1H, deuteratable, O<u>H</u>), 5.25 (m, 1H, alditol H), and 1.18 (d, 3H, pentitol C<u>H</u>$_3$), the other protons and hydroxyl protons together with the solvent absorption were gathered in a broad signal at δ=3.80.

Calcd for $C_{20}H_{20}N_4O_4 \cdot H_2O$: C, 60.30; H, 5.50; N, 14.07%. Found: C, 60.87; H, 5.51; N, 13.71%.

Attempted Preparation of 24. Acetylation of **18** with acetic anhydride and pyridine yielded uncystallizable syrupy product.

3-(D-*talo*-Pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (19). A solution of 1-hydrazino-4-phenylphthalazine (**1**, 1 g) in methanol (20 ml) was treated with a solution of D-talose (**7**, 0.8 g) in the least amount of water (ca. 0.2 ml) and the mixture was heated for 15 minutes on a boiling water bath. The mixture was left to attain ambient temperature and the product which separated was filtered and washed with chloroform and ether. Crystallization from water-methanol gave 0.9 g (54%) of **19**, mp 238—240 °C; TLC in 1:1 chloroform-methanol, R_f: 0.54; ν_{max}^{KBr} 3580, 3260 (broad, OH), and 1620 cm^{-1} (C=N); ^1H NMR $(CD_3)_2SO$: δ=8.80—7.58 (m, 9H, aromatic H), 5.92 (m, 1H, deuteratable, O<u>H</u>), 5.45 (d, 1H, alditol H), 4.89 (d, 1H, deuteratable, O<u>H</u>), and 4.45 (m, 3H, 2 deuteratable protons, 2O<u>H</u>+undeuteratable proton, alditol H), the other protons and hydroxyl protons together with the solvent absorption were gathered in a broad siganl at δ=3.58

Calcd for $C_{20}H_{20}N_4O_5$: C, 60.60; H, 5.09; N, 14.13%. Found: C, 60. 32; H, 5.13; N, 14.01%.

Attempted Preparation of 25. Acetylation of **19** gave an uncrystallizable syrupy product.

3-Formyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (26). A suspension of any of the 3-(pentahydroxypentyl)-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**14—19**, 1 g) in distilled water (15 ml) was treated with a solution of sodium periodate (2.4 g) in distilled water (15 ml) and stirred for one

hour at room temperature. The product was filtered, washed with water, 10% sodium thiosulfate solution and water, and crystallized from methanol to give 0.4 g (57%) of **26**, mp 223—225 °C; TLC in 1 : 1 chloroform–methanol, R_f: 0.76; ν_{max}^{KBr} 1740 (CHO) and 1620 cm^{-1} (C=N); ^1H NMR $(CD_3)_2SO$: δ=10.37 (s, 1H, CHO), and 8.85—7.50 (m, 9H, aromatic H).

Calcd for $C_{16}H_{10}N_4O \cdot 0.5H_2O$: C, 67.85; H, 3.89%. Found: C, 67.64; H, 4.31%.

3-Hydroxymethyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (27). A solution of sodium borohydride (0.1 g) in water (5 ml) was dropwisely added to a suspension of 3-formyl-6-phenyl-1,2,4-triazolo[3,4,-*a*]phthalazine (**26**, 1 g) in water (10 ml) while stirring. The mixture was kept at room temperature for an overnight and then treated with a few drops of acetic acid. The product which separated was filtered, washed with water and crystallized from methanol to give 0.7 g (70%) of **27**, mp 248—250 °C; TLC in 1 : 1 chloroform–methanol, R_f: 0.78; ν_{max}^{KBr} 3300 (broad, OH) and 1620 cm^{-1} (C=N); ^1H NMR ($CDCl_3$): δ=8.85—7.50 (m, 9H, aromatic H), 5.25 (s, 2H, CH_2), and 2.48 (s, 1H, deuteratable, OH).

Calcd for $C_{16}H_{12}N_4O$: C, 69.57; H, 4.35%. Found: C, 69.40; H, 4.49%.

3-Acetoxymethyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (28). 3-Hydroxymethyl-6-phenyl-1,2,4-triazolo[3,4-*a*]phthalazine (**27**, 1 g) was treated with pyridine (2 ml) and acetic anhydride (2 ml) at room temperature for 24 hours. The mixture was poured onto crushed ice and then extracted with chloroform. The extract was successively washed with aqueous solutions of potassium hydrogensulfate (10%), saturated sodium hydrogencarbonate and water, and dried (Na_2SO_4). Evaporation of the solvent gave a syrup which crystallized from methanol to give 0.7 g (61%) of **28**, mp 195 °C; TLC in 9 : 1 chloroform–methanol, R_f: 0.52; ν_{max}^{KBr} 1760 cm^{-1} (ester-carbonyl, *O*-acetyl group); ^1H NMR ($CDCl_3$): δ=8.85—7.52 (m, 9H, aromatic H), 5.74 (s, 2H, CH_2) and 2.18 (s, 3H, acetyl group).

Calcd for $C_{18}H_{14}N_4O_2 \cdot 0.5H_2O$: C, 66.06; H, 4.59; N, 17.13%. Found: C, 66.46; H, 4.60; N, 16.90%.

Cluster Chemistry. Catalytic Behavior of $[H_2Ru_4(CO)_{12}]^{2-}$ in Reduction of Benzaldehyde and Nitrobenzene

Fumio WADA,* Masanori SHIMUTA, and Tsutomu MATSUDA
Department of Organic Syntheses, Faculty of Engineering,
Kyushu University, Hakozaki, Fukuoka 812
(Received January 26, 1989)

Synopsis. The dianion, $[H_2Ru_4(CO)_{12}]^{2-}$, showed excellent catalytic activity for the reduction of nitrobenzene, but not of benzaldehyde. In the presence of benzaldehyde under H_2 pressure, the dianion was converted to a new species of good catalytic activity, which is closely similar to a complex obtained from the reaction of $[H_2Ru_6(CO)_{18}]$ with DBU (1,8-diazabicyclo[5.4.0]undec-7-ene).

We previously reported that the reaction of $[HRu_3(CO)_{11}]^-$ (**I**) with DBU under H_2 pressure gave $[H_2Ru_4(CO)_{12}]^{2-}$ (**II**), which can act as a catalyst for the water gas shift reaction.[1a] Although the catalytic behavior of **I** has been studied in various reactions,[2] very little is known about that of **II**. In this paper we report on the catalytic activity of the dianion **II** in the reduction of benzaldehyde and nitrobenzene, compared with those of monoanionic hydrido ruthenium clusters, such as **I** and $[H_3Ru_4(CO)_{12}]^-$ (**III**). We also describe the formation of a new active catalyst from **II** (or $[H_2Ru_6(CO)_{18}]$ with DBU) in the benzaldehyde reduction.

Results and Discussion

The hydrido clusters (**I**, **II**, and **III**) used in this study are interconvertible, depending upon both the ratio of CO/H_2 under pressure of 10—30 kg cm^{-2} and the type of base used.[1b] Thus, reduction using these clusters must be carried out under conditions where only a desired anionic cluster acts as the main catalyst, as shown in Table 1.

Moreover, the substrates were shown to affect the interconversion. In the presence of benzaldehyde (or nitrobenzene), **II** was transformed into species **IV**, which can be prepared by a reaction of $[H_2Ru_6(CO)_{18}]$ with DBU; however, **II** in the presence of nitrobenzene was converted to an insoluble higher unclear cluster(s) under pure hydrogen pressure (20 kg cm^{-2}). Runs 2, 6, and 7 in Table 1, therefore, were carried out under hydrogen containing 10% of CO in order to prevent any transformation of **II** during reduction.

The complex **III** prepared from $[H_4Ru_4(CO)_{12}]$ and NEt_3 was stable, even in the presence of benzaldehyde under pure H_2 pressure.

Table 1 shows the results of the reduction together with the anionic hydrido clusters existing in each reaction system before and after reaction. The structures of these clusters were confirmed by a comparison of their IR spectra with those of authentic samples.[1] As can be seen in Table 1, the catalytic activity of **I** for benzaldehyde reduction was low (comparable to the result reported by Laine[2]), whereas **II** and **III** showed moderate activity (Runs 2 and 3, respectively). When benzaldehyde reduction with **II** was carried out under pure H_2 pressure (Run 1), **II** was easily changed to another species **IV** during the reduction, and a much higher conversion of benzaldehyde was observed, suggesting the increased catalytic activity of **IV**. Figure 1a shows the IR spectra of **IV** and complex **V** prepared in situ from $[H_2Ru_6(CO)_{18}]$ and DBU in methanol. Complex **V** is not the same as the known complex $[HRu_6(CO)_{18}]^-$ prepared by protonation of $[Ru_6(CO)_{18}]^{2-}$.[4] The ^{1}H NMR spectrum of **V** in CD_3OD shows two kinds of proton resonances at τ=29.3 (H_a) and 29.5 (H_b), and the intensity ratio of H_a/H_b is almost 1 : 1. At present, it is not yet clear whether species **V** is a single species or a mixture of two complexes. In view of the close similarity of complexes **IV** to **V** regarding their IR spectra, the catalytic activity of **V** was examined for benzaldehyde reduction. As expected, the result was comparable

a) Catalyst, 0.05 mmol; DBU, 0.5 ml; MeOH, 4.0 ml; substrate, 5.0 mmol; total pressure=20 kg cm^{-2}; 120±1 °C, 3 h. b) The existence of these anionic clusters was confirmed by IR except Run 1. c) The starting complex was **II**. d) NEt_3 and H_2O were used instead of DBU. e) NEt_3 instead of DBU was used. f) The starting complex was **V**.

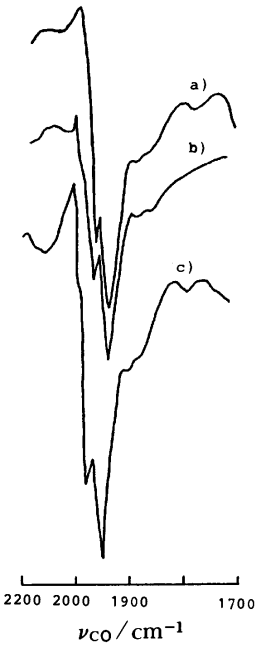

Fig. 1. IR spectrum in ν_{CO} region of the catalyst components after hydrogenation of benzaldehyde. a) **II** was used as a precursor under H_2 presure; b) the species **V** before reduction; c) after the reduction with **V**.

to that of **IV** (see Run 5), and the IR spectrum of the catalyst component in the ν_{CO} region shows that the starting complex **V** remains unchanged after reduction (see Fig. 1b and c). Unfortunately, many attempts to isolate **IV** have not yet been successful.

At present it is difficult to explain why species **IV** (or **V**) is so active for benzaldehyde reduction compared with other hydrido clusters, since the reactivity of the hydrogen atom in hydrido clusters does not always correspond to the hydridic character predicted from ^{1}H NMR.[5] A more detailed study is necessary in order to clarify the reactivity of **IV** (or **V**).

As mentioned above, the known anionic hydrido clusters (**I**, **II**, and **III**) are not good catalysts for benzaldehyde. The dianion **II**, however, acts as an excellent catalyst for nitrobenzene (Runs 6 and 7) under the same conditions (Run 2).[6] In the case of nitrobenzene reduction under pure H_2 pressure, **II** was readily converted not to **IV** but to higher nuclear cluster(s) which can be changed to **I** under CO pressure. This result suggests that the catalytic behavior of **II** in nitrobenzene reduction would be different from that of **II** in benzaldehyde reduction.

Experimental

The solvents and reagents used in this study were purified by distillation or recrystallization before use under N_2. All operations were carried out under a nitrogen atmosphere.

The typical reaction procedure was as follows. A catalyst solution (MeOH, 4 ml) containing only the desired anionic hydrido cluster (0.05 mmol) was previously prepared according to the methods described in the literature.[1] The catalyst solution (4 ml), benzaldehyde (or nitrobenzene) (5.0 mmol), and cyclohexanol (15 mmol) as an internal standard were placed in a 30 ml autoclave. Nitrogen in the autoclave was flushed three times with H_2, and then 20 kg cm^{-2} of H_2 (or a mixture of H_2 and CO) was charged. After the reaction at 120±1 °C for 3 h, the products were analyzed by GLC and the anionic clusters in the reaction mixture were identified by comparison of their IR spectra with those of authentic samples.[1]

Fluorescence Polarization Spectra along the Rotational Contour of the $10a_0^1$ Absorption Band of Pyrazine Vapor

Nobuhiro OHTA,* Osamu SEKIGUCHI,† and Takeshi TAKEMURA
Division of Chemistry, Research Institute of Applied Electricity, Hokkaido University, Sapporo 060
†Faculty of General Studies, Gunma University, Aramakimati, Maebashi, Gunma 371
(Received March 11, 1989)

Synopsis. Fluorescence polarization spectra for the $10a_0^1$ perpendicular absorption band belonging to the $S_0 \rightarrow S_1$ transition of pyrazine vapor have been obtained at room temperature. The spectra are well reproduced theoretically by considering the resonance fluorescence from fully resolved rotational levels in S_1 and by employing a symmetric top approximation.

Fluorescence emission from free rotating molecules was demonstrated to be largely polarized even in such larger molecules as pyrazine, pyrimidine and 1,3,5-triazine.[1] The analysis of the degree of polarization of fluorescence along the rotational contour of the parallel vibronic absorption bands of these azaaromatic compounds was shown to give a clue to understand the mechanism of the intramolecular vibrational redistribution within the singlet manifold.[2] Similarly, the polarization of ensemble-averaged fluorescence was shown by Nathanson and McClelland to be important to determine the extent of intramolecular vibration-rotation energy transfer.[3]

Terazima and Lim[4] reported that excitation of the $10a_0^1$ band of S_1 pyrazine, which lies at 383 cm^{-1} above the $S_0 \rightarrow S_1$ origin and exhibits a rotational contour of typical perpendicular bands,[5] leads to the appearance of fluorescence which is nearly completely depolarized in a jet, in contrast with the 0-0 band. They suggested that these results come from a strong mixing between fluorescence emissions induced by the parallel and perpendicular transitions, respectively, since these two emissions are expected to show an opposite behavior on polarization. On the other hand, Pratt and co-workers[6] proposed a different interpretation of the fluorescence depolarization for the $10a_0^1$ band, based on the phosphorescence excitation spectrum in the $S_0 \rightarrow T_1$ absorption region. The S_1 surface is well known to be distorted along the coordinate of the ν_{10a} vibration because of strong vibronic coupling with higher lying singlet states,[7] whereas vibronic coupling is not important in T_1 according to the $S_0 \rightarrow T_1$ spectrum. Thus, the potential curve of the ν_{10a} vibration is different in S_1 and T_1. Because of enhanced Franck-Condon factor as well as differences in the admixed $\pi\,\pi^*$ character, therefore, the S_1-T_1 spin orbit matrix element might be significantly larger for the levels involving ν_{10a} vibration. Pratt and co-workers suggested that such a mode specificity in the S_1-T_1 spin orbit interaction may induce a mode specificity in the fluorescence polarization, i.e., fluorescence depolarization occurs following excitation into the S_1 vibronic levels effectively coupled to the triplet levels.

In the present study, excitation polarization (EP) spectra of pyrazine along the rotational contour of the $10a_0^1$ perpendicular absorption band were obtained in a bulk gas by monitoring the parallel and perpendicular fluorescence bands with out-of-plane and in-plane transition moments, respectively.

Experimental

All the optical measurements were carried out at room temperature. The experimental apparatus and procedures are the same as reported in previous papers.[2] Briefly, the output frequency of a pulsed dye laser (Molecron DL14), pumped by a nitrogen laser (Molectron UV22), was doubled by a KDP crystal. The generated UV light, which is linearly polarized and used for excitation, has a repetition rate of 20 pps, a linewidth of ca. 0.5 cm^{-1} and a duration of ca. 3 ns.

The fluorescence emitted at right angles to the direction of propagation of the laser light for excitation was passed through a polarization analyzer and then through a scrambler. The emission was dispersed by a grating monochromator and detected by a photomultiplier. The intensities of the fluorescence polarized parallel and perpendicular to the polarization direction of the exciting light are denoted by $I_{/\!/}$ and $I_\perp$, respectively and the degree of polarization (P) is defined as $P=(I_{/\!/}-I_\perp)/(I_{/\!/}+I_\perp)$. The EP spectra along the rotational contour were obtained by combining two fluorescence excitation spectra obtained by monitoring $I_{/\!/}$ and $I_\perp$, separately.

Results and Discussion

Figure 1 shows the EP spectra of pyrazine along the rotational contour of the $10a_0^1$ band, together with the absorption spectrum. The sample pressure is 0.25 and 1.23 Torr (1 Torr=133.322 Pa) for the EP and absorption spectra, respectively. The EP spectra shown in Figs. 1(a) and 1(b) were obtained, respectively, by monitoring the fluorescence of parallel band of $10a_1^1 6a_0^1$ at 336 nm, and the perpendicular band of $10a_2^1$ at 339.8 nm with a spectral resolution of 0.2 nm.[7] The absorption band located at ca. 20 cm^{-1} higher than the $10a_0^1$ exhibits a parallel-type rotational contour and assigned as the $6a_0^1 16b_0^1$ bands.[8] The absorption spectrum of the $10a_0^1$ band exhibits a perpendicular-type rotational contour, and the rotational analysis was completed by Thakur and Innes.[5] The EP spectra shown in Figs. 1(a) and 1(b) are very different from each other, e.g., the P value near the origin is ca. −0.15 for the parallel fluorescence band, whereas P near the origin is ca. 0.1 for the perpendicular fluorescence band.

The EP spectra were simulated with a symmetric top approximation in the same manner as reported in the previous papers.[2] By assuming that wavefunction can be separated into a rotational part and a vibronic part, the intensity of the resonance fluorescence emitted from the optically prepared level is

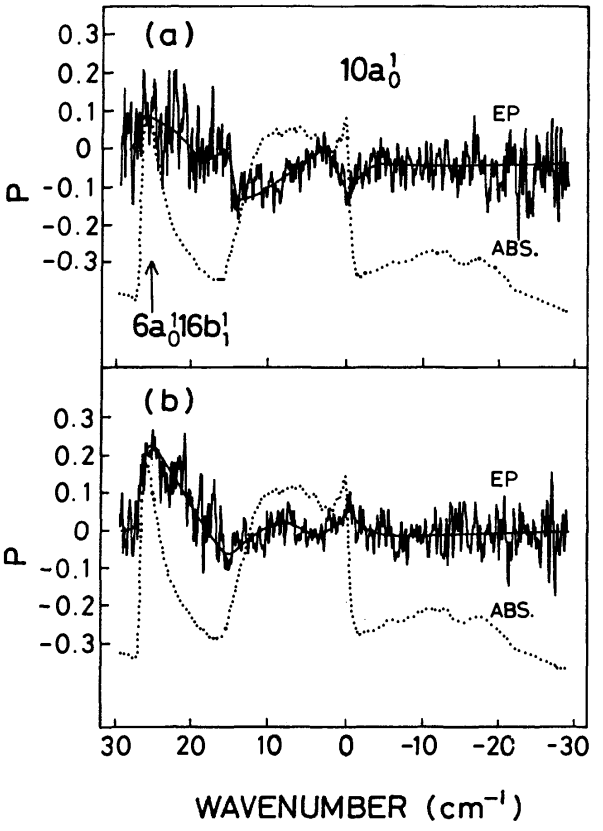

Fig. 1. Excitation polarization spectra of pyrazine vapor at 0.25 Torr along the rotational contour of the $10a_0^1$ band, obtained by monitoring the fluorescence at 336 nm (a) and at 339.8 nm (b). The dotted line represents the absorption spectrum. The band origin denoted by 0 is at 31258 cm^{-1}.[5] The absorption band lying at ~20 cm^{-1} above the $10a_0^1$ band is assigned as the $6a_0^1 16b_1^1$.[7]

given by

$$I \propto \nu_a \nu_e^4 \sum_{gg'} |M_g|^2 |M_{g'}|^2 f(JKJ'K'J''K'') \quad (1)$$

where

$$f(JKJ'K'J''K'') = (2J+1)^{-1} \times \sum_{MM'M''} |\langle J'K'M'|\Phi_{Fg}|JKM\rangle|^2 |\langle J''K''M''|\Phi_{Fg'}|J'K'M'\rangle|^2 \quad (2)$$

Here, ν_a, ν_e are the frequencies of the absorbed and emitted lights, respectively; M_g, $M_{g'}$ are the vibronic part of the dipole moment along the g and g' axes of the molecule-fixed Cartesian system, respectively; Φ_{Fg}, $\Phi_{F'g'}$ are the direction cosines between the F and g axes and between the F' and g' axes, respectively; $|JKM\rangle$, $|J'K'M'\rangle$ and $|J''K''M''\rangle$ represent the rotational wavefunctions of the initial, intermediate and final states, respectively. Note that F and F' represent the axes of the space-fixed Cartesian system in terms of which the radiation field is described. It is also noted that the polarization direction of the exciting light and the figure axis are regarded as X and z, respectively. Then, the fluorescence intensity at ν is given by

$$I(\nu) = \sum_{\nu_1 JKJ'K'J''K''} A(J'K') I g_{JK} P_{JK}(T) L(\nu - \nu_1) \quad (3)$$

where g_{JK}, $P_{JK}(T)$, $L(\nu-\nu_1)$ are the statistical weight, the Boltzman factor at a temperature of T, intensity of the exciting light at ν_a, respectively. ν_a is different from the excitation frequency ν of the maximum intensity by ν_1. A(J'K') is the factor to which fluorescence quantum yield is proportional.

With the relations M=M'=M'' and M=M'=M''±1 for the parallel and perpendicularly polarized fluorescence emissions, respectively,[9] the intensities of $I_{/\!/}(\nu)$ and $I_\perp(\nu)$ can be obtained from the above equations.

In the present experiments, the optical excitation was made for the perpendicular absorption band, i.e., g=x(y). The f values of Eq. 2 for F=F'=X and for F=X, F'=Y were evaluated for the individual rotational transitions of a symmetric top with the direction cosine matrix elements reported by Cross et al.[10] The EP spectra simulated for the parallel-type transition of emission, i.e., g'=z and for the perpendicular-type transition of emission, i.e., g'=x(y) are shown in Fig. 2, together with the simulated absorption spectrum. These spectra were obtained with the rotational constants: B''=0.20531 and C''=0.10249 in S_0 and B'=0.20322, and C'=0.10166 cm^{-1} in S_1.[5] Fluorescence emissions of pyrazine consist of fast and slow components.[11] In fact, the slow component occupies about 15% of the total fluorescence in intensity at 0.25 Torr for excitation into the $10a^1$. The quantum yield of the fast component is independent of the rotational level excited, whereas that of the slow component is nearly proportional to $(2J'+1)^{-1}$.[12] The simulated spectra shown in Figs. 2(a) and 2(b) were obtained by assuming that A(J'K') in Eq. 3 is constant, whereas the spectra in Figs. 2(c) and 2(d) were obtained by assuming that A(J'K') is $(2J'+1)^{-1}$.

Actually, the absorption spectrum is not well reproduced theoretically, as far as symmetric top approximation is employed. However, the EP spectra both for the parallel- and perpendicular-type fluorescence bands are reproduced very well by assuming a symmetric top approximation, as is seen in Figs. 1 and 2. In fact, Ray's parameter defined by $(2B-A-C)/(A-C)$ is 0.985 at the $10a^1$ level of S_1,[5] indicating that pyrazine is well regarded as an oblate symmetric top at this level. Accordingly, it is known that the EP spectra are not influenced by an asymmetry so severely as the absorption spectrum.

At several excitation positions along the rotational contour, the P value of each of the fast and slow components was evaluated by combining the total integrated intensity with the decays, both of which were obtained for each of $I_{/\!/}$ and $I_\perp$. However, a difference of P was not confirmed between the fast and slow components. These results are well understood from Fig. 2, i.e., the EP spectra simulated with the assumption that A(J'K') is constant are very similar to the spectra simulated with the assumption that A(J'K') is $(2J'+1)^{-1}$. It should be also noted that the EP spectrum for the $6a_0^1 16b_1^1$ band are very similar to those for the 0-0 band and that the observed spectra are similarly reproduced theoretically very well.[2]

Polarization property of fluorescence indicates that the emission whose intensity is proportional to $I_{/\!/}+2I_\perp$ must be monitored to obtain the true yield spectrum.

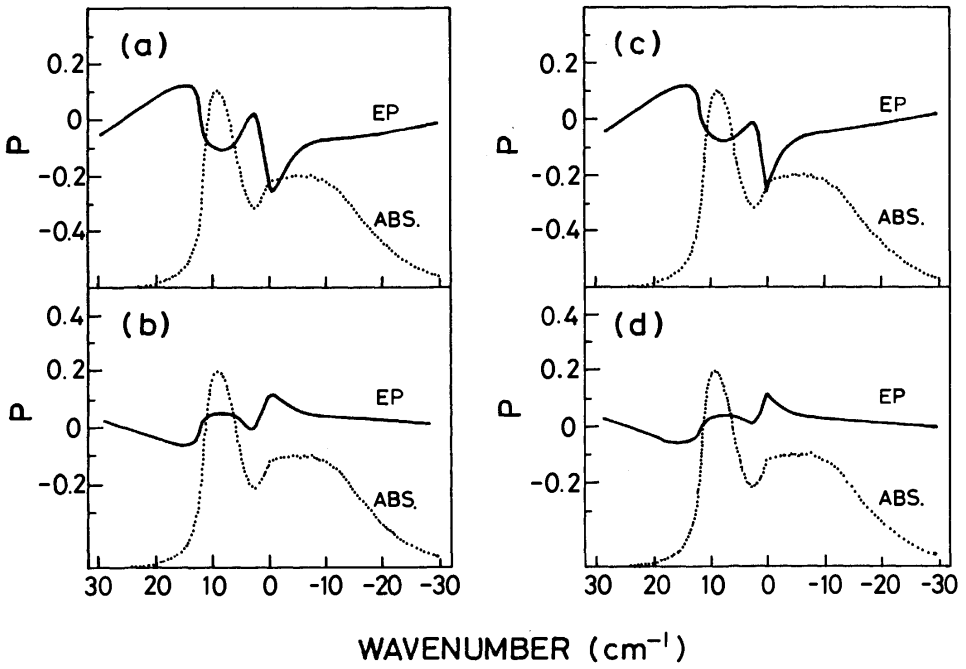

Fig. 2. Excitation polarization spectra at 298 K simulated for the $10a_0^1$ band of pyrazine according to Eqs. 1—3 with the following assumptions: (a) g=x(y), g'=z, and A(J'K') is constant; (b) g=x(y), g'=x(y), and A(J'K') is constant; (c) g=x(y), g'=z, and $A(J'K')=(2J'+1)^{-1}$; (d) g=x(y), g'=x(y), and $A(J'K')=(2J'+1)^{-1}$. The exciting light was assumed to have a triangle band-shape with a width (fwhm) of 0.5 cm^{-1}. Dotted line shows the simulated absorption spectra.

Previous conclusion for the $10a_0^1$ band that the fluorescence quantum yield of the fast component is nearly independent of the rotational level excited and that the yield of the slow fluorescence is proportional to $(2J'+1)^{-1}$ was derived from the yield spectra which were obtained without any polarization analyzer for emission.[12] The yield spectra obtained by setting the polarization analyzer for emission to the magic angle (54.7°), i.e., the observed fluorescence intensity corresponds to $I_{/\!/}+2I_{\perp}$, were confirmed to be very similar to the previous spectra. Fortunately, therefore, it is unnecessary to correct the previous conclusion concerning the excited rovibronic level dependence of the fluorescence quantum yield.

The EP spectra of pyrazine are well reproduced by considering the resonance fluorescence emitted from the individual rotational levels optically excited and by employing a symmetric top approximation, though the fluorescence consists of the fast and slow components which correspond to the dephasing decay and the population decay, respectively. Further, there is no evidence in the EP spectra that there is a mode specificity in the S_1-T_1 dynamics between the S_1 origin and the $10a^1$ level.

The authors thank Professor Emeritus Hiroaki Baba for his continuous encouragement. This work was partly supported by a Grant-in-Aid for Scientific Research on Priority Areas from the Ministry of Education, Science and Culture (No. 63606004).

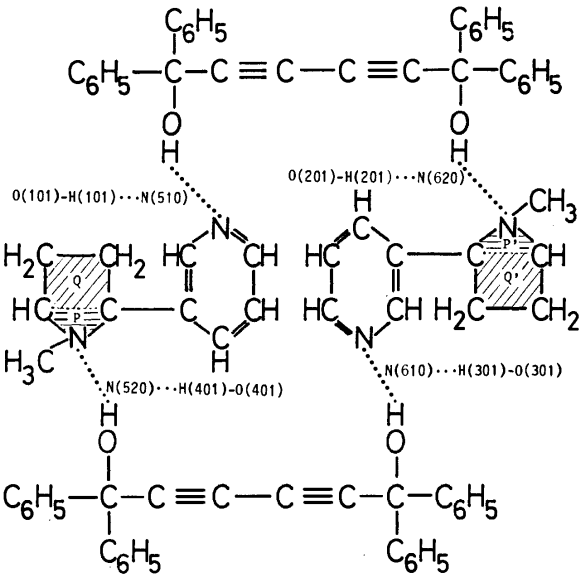
Synopsis. X-Ray crystal structure analysis of the title complex is described. $2(C_{30}H_{22}O_2),2(C_{10}H_{14}N_2)$, *F.W.* 1153.5, monoclinic, space group $P2_1$, a=28.913(2), b=12.353(1), c=9.340(1) Å, β=98.20(1)°, V=3301.7(6) Å^3, D_c=1.16 g cm^{-3} for Z=2. Two DD molceules are bound by two nicotine by four O-H···N hydrogen bonds to form a 2:2 complex. The crystal consists of these asymmetric 2:2 complexes.

Host-guest complexation method has been applied for the isolation of natural products.[1] Among them is the isolation of nicotine from tobacco leaves. In order to obtain structural informations on the complexation the crystal structure of the title 2:2 complex has been determined by means of X-ray diffraction.



Experimental

A crystal with approximate dimensions of 0.5×0.3×0.2 mm was mounted on a goniometer head attached to a Rigaku rotating anode four-circle diffractometer at the Institute for Protein Research, Osaka University. Intensity data were collected using nickel filtered Cu $K\alpha$ radiation by the θ-2θ scan technique up to 2θ=120°. The scan rate was 12° min^{-1} and the scan width $\Delta\theta$=(1.2+0.15 tanθ)°. Backgrounds were counted for 3 s at both ends of a scan. Three standard reflections measured after every 100 reflections to monitor the stability and orientation of the crystal showed slight change through the experiment. Of the 5175 reflections measured, number of reflections observed is 4640 ($|F_o|>2\sigma(F_o)$), where σ is the standard deviation obtained from the counting statistics). Usual Lorentz and polarization corrections were applied but absorption effect was ignored [μ(Cu $K\alpha$)=5.64 cm^{-1}].

Structure Solution and Refinement

The structure was established by the direct method. First the *MULTAN* 78[2] program was used to solve the structure. It seemed that all the non-hydrogen atoms of DD molecules and several non-hydrogen atoms of

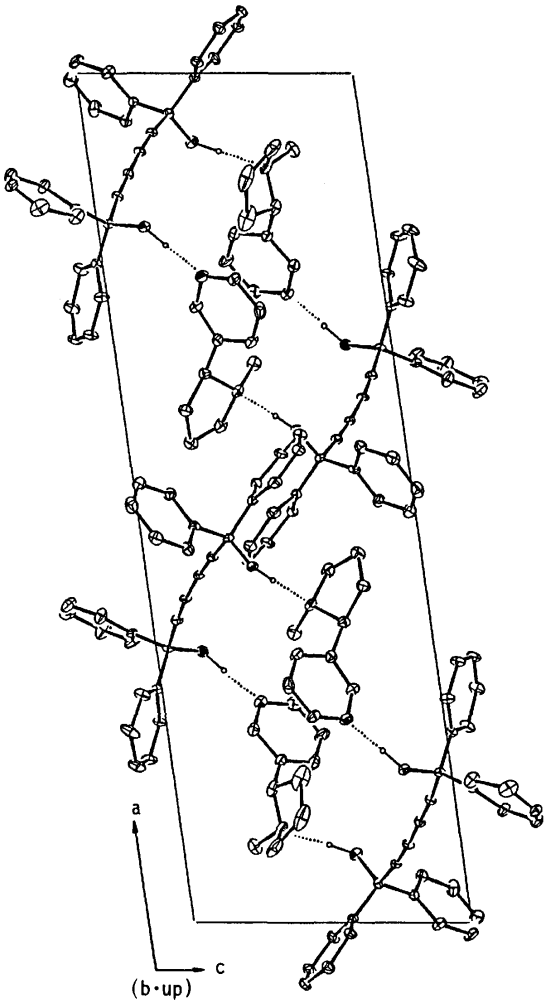


Fig. 1. Crystal structure projected along the b axis.[7] Non-hydrogen atoms are drawn as thermal ellipsoids with 10% probability level, and hydrogen atoms as spheres (B=1.0 Å). Hydrogen atoms not engaged in hydrogen bondings (shown by dotted lines) are omitted for clarity.

nicotine appeared on an E map, but the rest of non-hydrogen atoms of nicotine could not be located in spite of all possible efforts. The trial to solve the structure from the beginning by using the *SHELX-76*[3] program was successful. The structure was refined anisotropically by the least-squares procedure (*HBLS* V).[4] Hydrogen atoms except those of methyl groups were included in the refinements with isotropic temperature factors: R=0.063 for 4640 reflections ($|F_o|>2\sigma$). The function minimized in the refinement was $\sum w\Delta F^2$, and the weighting scheme used in the final stage of the refinement was $w=[\sigma^2(F_o)+0.01971|F_o|+0.00198|F_o|^2]^{-1}$. However, about one third of the hydrogen atoms could not be refined reasonably. All the hydrogen atoms refined were then relocated at the calculated positions, and the temperature factor of each hydrogen atom was assumed equal to the equivalent isotropic temperature factor of the non-hydrogen atom to which the hydrogen atom attached. Structure factor calculation gave the R value of 0.065. Atomic scattering factors used were taken from International Tables for X-Ray Crystallography.[6] Computations were done on an ACOS S930 computer at the Protein Engineering Center, Institute for Protein Research, Osaka University.

Final atomic parameters are given in Table 1.[††] Thermal parameters of atoms belong to the pyrrole ring of a nicotine molecule are fairly large. These might limit the accuracy of the result.

[††] Tables of anisotropic thermal parameters of non-hydrogen atoms, atomic parameters of hydrogen atoms, and observed and calculated structure factors are kept at the Chemical Society of Japan, Document No. 8890.

Results and Discussion

As seen in Fig. 1 the crystal is composed of a loose packing of 2:2 complex units of DD molecules with nicotine molecules. No close atomic contact less than 3.8 Å is observed between non-hydrogen atoms of adjacent complex units and also between those of pyridine rings of nicotine molecules in the complex unit.

The 2:2 complex has a sandwitch structure. The C-C≡C-C≡C-C backbone of each DD molecule bent inwardly in a small extent with the two hydroxyl groups inside and four phenyl groups outside. The two -C≡C- bond distances are 1.210(7) and 1.203(7) Å in one molecule and 1.190(7) and 1.191(7) Å in the other, whereas the central C-C distances in two molecules are 1.361(7) and 1.387(7) Å. All the bond angles on -C≡C-C≡C- linkages are slightly smaller than 180° [174.6(5), 177.2(6), 177.0(6), and 172.5(6)° in one molecule and 176.6(6), 174.9(6), 175.4(6), and 174.4(5)° in the other]. Two nicotine molecules are captured inside two DD molecules connected by four O-H···N hydrogen bonds. The nitrogen atom of the pyridine ring is bound to one of the hydroxyl groups of one DD by an approximately linear O-H···N hydrogen bond [O(101)···N(510)=2.806(7) and O(301)···N(610)=2.800 (8) Å]. The nitrogen atom of the pyrrole ring of the same nicotine molecule is also hydrogen bonded to the other hydroxyl group of the second DD [O(201)···N(620)=2.881(7) and O(401)···N(520)=2.930 (6) Å]. The pyrrole ring of nicotine takes an envelope form: the dihedral angle between planes defined by the nitrogen and two carbon atoms (Plane P or P′) and that made by the four carbon atoms(Plane Q or Q′) is 42.6(6) or 53.8(8)°. The pyridine ring and the Q plane (or Q′ plane) in the nicotine molecule makes approximately right angle [86.8(4) and 83.8(5)°]. Two pyridine rings of the different nicotine molecules are nearly parallel in the complex [dihedral angle: 7.9(3)°].

The present study was partially supported by a Grand-in-Aid for Scientific Research from the Ministry of Education, Science and Culture.

Synopsis. High-resolution solid-state ^{13}C CP/MAS NMR was applied to many cobalt(III) complexes, such as salicylato-, carbonato-, dichloro-, and dinitro(quadridentate amine)cobalt(III) complexes, $[CoL_2(\text{quadridentate amine})]^+$ (L: 1/2sal, $1/2CO_3$ Cl, NO_2; quadridentate amine: tren, trien, 2,3,2-tet, 3,2,3-tet, 3,3,3-tet). The signals of the methylene carbons of the coordinated quadridentate amine ligands in their complexes have been assigned to the center, NH_2- side, NH- side, and N- side methylene carbons. Also, the signals of the ring carbons of the coordinated salicylato ligand in their complexes have been assigned to the individual carbon atoms. It has been found that the signals of nonprotonated carbons (C-1, C-2, and C-7) of the coordinated salicylato ligand have been very high and that the ^{13}C CP/MAS NMR method is well-suited for studies of unstable compounds in solutions.

In the last decade, the high-resolution solid-state ^{13}C CP/MAS NMR method has been extensively applied to various organic materials.[2] This method has been proven to give very usuful information about the molecular structure and conformation of organic compounds,[3] the molecular motion of polymers,[4] and the rate processes in solids.[5] However, this method has not yet been adequately applied to the field of metal complexes. The present paper deals with the assignments of the ^{13}C NMR signals of the quadridentate amine and the ring carbons of the salicylato of $[CoL_2(\text{quadridentate amine})]^+$ (L: 1/2sal, $1/2CO_3$, Cl, NO_2; quadridentate amine: tren, trien, 2,3,2-tet, 3,2,3-tet, 3,3,3-tet) and deals with the application of the ^{13}C CP/MAS NMR method.

Experimental

Measurements. The ^{13}C CP/MAS NMR measurements were performed on a Bruker MSL high-power spectrometer operating at a field strength of 4.7 T, equipped with a double bearing (DB-MAS) and a variable-temperature probe unit. The resonance frequency was 50.323 MHz. A contact time of 2 ms was chosen, and the repetition time was 5 s. The 90° pulse width was typically 4 us for both ^{13}C and ^{1}H under cross-polarization conditions. The spectral width and data points were 30 kHz and 8 K points respectively. The spectra were usually obtained by the accumulation of from 300 to 500 FIDs, thus achieving a resonable signal-to-noise ratio for natural abundance samples. The ^{13}C chemical shifts were calibrated indirectly through external glycine-CO (δ=176.03; line width=15 Hz) relative to tetramethylsilane. The experimental errors of the ^{13}C chemical shift values were estimated to be within ±0.2 ppm. The alumina rotor with samples was spun at a rate of from 2500 to 3500 Hz with compressed dry air. Samples of ca. 150—250 mg were packed in the rotor. The ^{13}C NMR spectra in solutions were recorded with an FX-60 spectrometer (JEOL).

Preparation of Complexes. The $[Co(CO_3)(tren)]Cl \cdot 1.5H_2O$ (**1**), $[CoCl_2(tren)]Cl \cdot H_2O$ (**6**), $[Co(NO_2)_2(tren)]Cl$ (**11**), *cis*-α-$[Co(CO_3)(trien)]ClO_4 \cdot H_2O$ (**2**), *cis*-β-$[Co(CO_3)(trien)]Cl \cdot 1.5H_2O$ (**3**), *cis*-α-$[CoCl_2(trien)]Cl$ (**7**), *cis*-β-$[CoCl_2(trien)]Cl \cdot 0.5H_2O$ (**8**), *cis*-α-$[Co(NO_2)_2(trien)]Cl \cdot H_2O$ (**12**), *cis*-β-$[Co(NO_2)_2(trien)]NO_3$ (**13**), *cis*-β-$[Co(CO_3)(2,3,2\text{-tet})]Cl$ (**4**), *trans*-$[CoCl_2(2,3,2\text{-tet})]Cl \cdot 2.5H_2O$ (**9**), *cis*-β-$[Co(CO_3)(3,2,3\text{-tet})]Cl \cdot 3H_2O$ (**5**), and *trans*-$[CoCl_2(3,2,3\text{-tet})]Cl \cdot H_2O$ (**10**) were prepared according to previously published procedures.[6]

The *t*-$[Co(sal)(tren)]Cl \cdot H_2O$ (**14**), *p*-$[Co(sal)(tren)]Cl \cdot H_2O$ (**15**), *cis*-β_1-$[Co(sal)(trien)]Cl \cdot H_2O$ (**16**), *cis*-β_2-$[Co(sal)(trien)]Cl \cdot H_2O$ (**17**), *cis*-β_1-$[Co(sal)(2,3,2\text{-tet})]Cl \cdot H_2O$ (**18**), *cis*-β_2-$[Co(sal)(2,3,2\text{-tet})]Cl \cdot 2H_2O$ (**19**), *cis*-β_2-$[Co(sal)(3,2,3\text{-tet})]Cl \cdot 3H_2O$ (**20**), and *cis*-β_2-$[Co(sal)(3,3,3\text{-tet})]Cl \cdot H_2O$ (**21**) were also prepared according to previously published procedures.[7]

Abbreviations: tren: tris(2-aminoethyl)amine; trien: triethylenetetramine; 2,3,2-tet: 3,7-diazanonane-1,9-diamine; 3,2,3-tet: 4,7-diazadecane-1,10-diamine; 3,3,3-tet: 4,8-diazaundecane-1,11-diamine.

Results and Discussion

The coordinated quadridentate amine ligands of **1—3** exhibit the two ^{13}C CP/MAS NMR signals of the methylene carbons at δ=42—47 and 53—58, as is shown in Fig. 1. The signals at δ=42.2 and 56.3 of **1** have been assigned to the NH_2- side ($NH_2\mathbf{C}H_2\mathbf{C}H_2N$-) and N- side methylene carbons ($NH_2\mathbf{C}H_2\mathbf{C}H_2N$-) respectively of the coordinated tren ligand. The signals at δ=43—47 and 53—58 of **2** and **3** have been assigned to the NH_2- side and NH- side methylene carbons ($NH_2\mathbf{C}H_2\mathbf{C}H_2NH\mathbf{C}H_2$-) respectively. The signal of the NH_2- side methylene carbons of **2** is different from that of **3**; i.e., it is due to the configurations of cis-α and cis-β. The complexes **4** and **5** exhibit three signals of the methylene carbon at δ=22—29, 39—46, and 49—58. The signals at δ=39—46 and 49—58 were assigned to the NH_2- side and NH- side methylene carbons respectively by comparison with those of **1—3**. Accordingly, the signals at δ=22—29 are assigned to the center methylene carbons ($NH_n\mathbf{C}H_2\mathbf{C}H_2\mathbf{C}H_2NH$-, *n*: 1 or 2) of the coordinated quadridentate amine ligands. The signals of **3—5** are difficult to assign to the individual carbon atoms. However, the signals at δ=49.9 of **4** and at δ=49.8 of **5** are assigned to C-4 and C-6, and C-3 and C-7, methylene carbons[7c] respectively, because their methylene carbons are neighboring carbons of the center methylene carbons of C-2, C-5, or C-8. The signals at δ=

quadridentate amine

Standards: Glycine δ=42.9 and 43.8 for CH_2, δ=176.03 for ^{13}CO for solid-states; internal dioxane (δ=67.4) for solutions.
[ ]: The chemical shifts could not be assigned to the individual methylene carbon. a) Broad signal.

166—171 of **1**—**5** have been assigned to the coordinated carbonato carbons. The signals of the center, NH_2- side, NH- side, and N- side methylene carbons of the coordinated quadridentate amine ligands in **6**—**13** were assigned by comparison with those of **1**—**5**; these results are collected in Table 1. The signals at δ=20—28, ca. 37—46, ca. 47—53, and 60—61 of **14**—**21** were assigned to the center, NH_2- side, NH- side, and N- side methylene carbons of the coordinated quadridentate amine ligands respectively

by comparison with those of **1**—**13**. The salicylato carbon signals in the regions at δ=114—173 of the coordinated salicylato ligand have been assigned to the individual carbon atoms by comparison with those of **14**—**17**[7a,b] in solution; these results are collected in Table 1.

The chemical shifts of the center, NH_2- side, NH- side, and N- side methylene carbons of the coordinated quadridentate amine ligands of **1**—**13** are almost the same as those of **14**—**21**, and their chemical shifts are close to those in solutions, as is shown in Table 1 and Ref. 7. The methylene carbon signals can be affected by the electronic effect, the steric effect, the coordination number, or the configuration of the coordinated ligands in complexes; e.g., the NH_2- side and N- side methylene carbon signals of **1** appear at a higher field than those of **6** and **11**. The NH- side methylene carbon signals of **12** and **13** are very different from those of Complexes **2** and **3** and Complexes **7** and **8**. Also, the spectrum of **3** is different from that of **2**.

A difference between the ^{13}C CP/MAS NMR method and the ^{13}C NMR method was found in the signals of nonprotonated carbon and the measurements of unstable compounds in solutions: the signals of the C-1, C-2, and C-7 carbons (nonprotonated carbons) of the coordinated salicylato ligand have been very high, such as C-3, C-4, C-5, and C-6 carbons (protonated carbons), as is shown in Fig. 1. The ^{13}CNMR spectra of **2**, **7**, and **8** did not show the expected signals in solution, since they were changed to other species;[6b] e.g., the spectrum of **7** in solution is in agreement with that of $[Co(H_2O)_2(trien)]^{3+}$ (**22**). Also, the spectrum of **18**[7c] has not showed the expected signals, because **18** isomerizes to **19** in solution.

(Received January 13, 1989)

Synopsis. The Raman bands due to the totally symmetric ν(C-C)+ν(C-S) and ν(Co-S) modes of tris(dithiooxalato-*S,S*)cobaltate(III) exhibit resonance enhancements with excitation lines in the visible region. The resonance Raman excitation profiles of the two modes reveal the presence of a charge-transfer transition in the visible absorption spectrum of the complex.

The electronic structure of a transition metal complex with dithiooxalate (dto^{2-}: $C_2S_2O_2^{2-}$) has been a subject of interest because of the considerably delocalized π-orbital system of the ligand. The electronic spectral properties of planar divalent metal complexes with dto^{2-} were studied in several ways. For example, Kida et al.[1] reported the electronic absorption spectra of $[M(dto)_2]^{2-}$ (M=Ni(II), Pd(II), and Pt(II)). Latham et al. assigned the electronic absorption bands of the above-mentioned complexes on the basis of a molecular orbital treatment.[2] The visible absorption feature of $[Ni^{II}(dto)_2]^{2-}$ was investigated in detail by the use of Raman excitation profiles.[3] For octahedral trivalent metal complexes with dto^{2-}, Carlin and Canziani[4] investigated the visible absorption spectra of $[M(dto)_3]^{3-}$ (M=Cr(III), Co(III), and Fe(III)) and Hidaka and Douglas[5] discussed the circular dichroism spectra of $[M(dto)_3]^{3-}$ (M=Cr(III), Co(III), and Rh(III)). Two shoulders at 17000 and 21800 cm^{-1} of $[Co^{III}(dto)_3]^{3-}$ were assigned to the d-d transitions.[4,5] However, the absorption coefficient ($\log\varepsilon$=3.5) of the 21800-cm^{-1} band seems to be large for a Laporte-forbidden d-d transition, even if the d-d transitions are allowed to occur, to some extent, by orbital mixing (covalency) between the sulfur donor and cobalt(III). Here, we report the resonance Raman excitation profiles of $[Co^{III}(dto\text{-}S,S)_3]^{3-}$ as well as the property of absorption bands in the visible region. The application of the resonance Raman effect to the electronic absorption spectral study of transition metal complexes has been reviewed.[6]

Experimental

Preparation of Complexes. $CaK[Co^{III}(dto\text{-}S,S)_3]\cdot 6H_2O$ was prepared according to a method described in the literature[7] and was identified by its electronic absorption spectrum.

Measurements. Samples for Raman measurements were provided as disks containing an appropriate amount of K_2SO_4 (8 to 12 times of the complex in weight) as an intensity standard. Disks were spun in order to avoid thermal decomposition. Raman spectra were recorded on a JASCO R-800 laser Raman spectrophotometer using a Spectra Physics 164 Ar^+ laser (514.5, 501.7, 496.5, 488.0, 476.5, 465.8, and 457.9 nm) and a Coherent Radiation model CR599 dye laser employing Rhodamine 6G dye (632.8, 610.0, 588.0, and 567.8 nm). The laser power was below 100 mW. The spectral band width was set to 5 cm^{-1}. Intensity measurements were made relative to the totally symmetric S-O stretching of the sulfate incorpolated in the sample. Corrections of the observed intensity were applied to the fourth power of the wavenumber of scattered radiation and the instrumental response. Intensities were averaged over more than three measurements.

Electronic absorption spectra were measured with a Hitachi 220 spectrophotometer.

Results and Discussion

Figure 1 shows the resonance Raman spectrum of $CaK[Co^{III}(dto\text{-}S,S)_3]$. The band at 1113 cm^{-1} can be assigned to the ν(C-C)+ν(C-S) mode and the band at 349 cm^{-1} to the ν(Co-S) mode in comparison with the

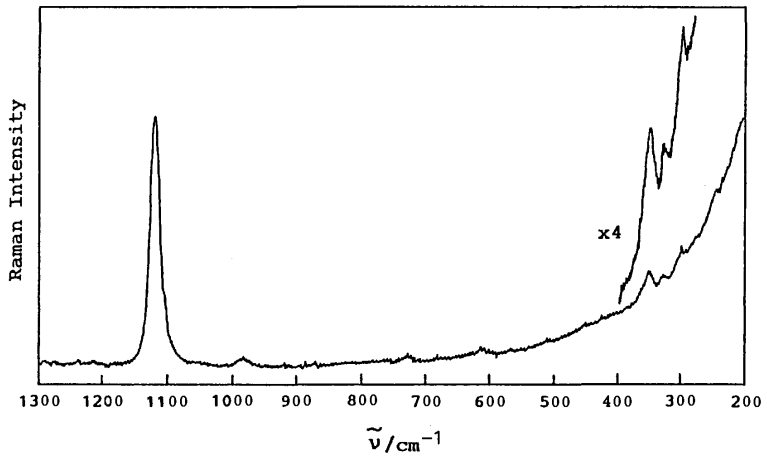

Fig. 1. Resonance Raman spectrum of $CaK[Co^{III}(dto\text{-}S,S)_3]$ (KBr disk, 488.0-nm excitation).

results of the normal coordinate analysis of $[Ni(dto\text{-}S,S)_2]^{2-}$,[3] where the ν(C-C)+ν(C-S) and ν_s(Ni-S) modes were assigned to the bands at 1085 and 317 cm^{-1}, respectively. The 1113-cm^{-1} band of $[Co^{III}(dto\text{-}S,S)_3]^{3-}$ is polarized in the solution Raman spectrum and can be assigned to the totally symmetric mode. The depolarization ratio of the 349-cm^{-1} band could not be determined precisely because of difficulty in observing the band of appropriate intensity in solution. This band, however, is the most intense band observed in the Co-S stretching region, and is reasonably assigned to the totally symmetric mode, since a totally symmetric metal-ligand stretching mode generally gives a far more intense Raman band than that of a non-totally symmetric mode as has been observed for the tris(chelate) complexes, $[Co^{III}(en)_3]^{3+}$ and $[Co^{III}(tn)_3]^{3+}$.[8]

Figure 2-A shows the visible absorption spectrum of $[Co^{III}(dto\text{-}S,S)_3]^{3-}$. The broad and unusually intense spectrum indicates that the d-d and charge-transfer transitions overlap each other. Low-energy metal-to-ligand charge-transfer transitions occur with high probability for complexes with dto^{2-} which have a low-energy π^*-orbital.[2]

Resonance Raman excitation profiles (that is, Raman intensities as a function of the excitation wavelength) have been successfully applied[3,9-13] to resolve overlapping absorption bands, especially those consisting of different types of transitions, such as d-d and charge-transfer transitions. This is because of the following features of resonance enhancements: (1) Excitation profiles are highly structured compared with electronic absorption spectra. (2) The extent of resonance enhancement greatly depends on the nature of resonant transitions. Resonance enhancement

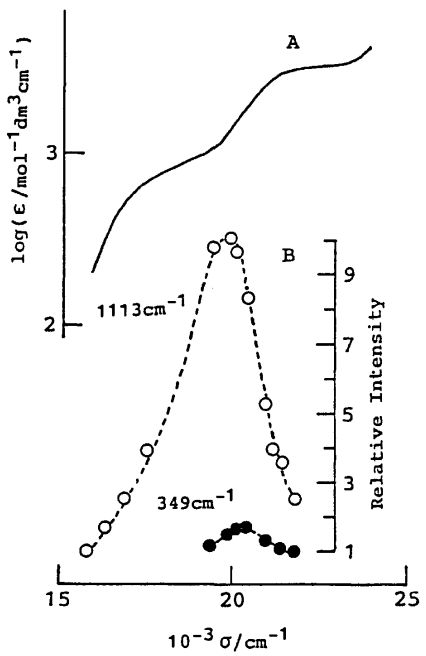

Fig. 2. A: Electronic absorption spectrum of $[Co^{III}(dto)_3]^{3-}$. B: Excitation profiles of the totally symmetric ν(C-C)+ν(C-S) and ν(Co-S). The weakest intensity was normalized to unity.

through an "A-type" interaction,[14] which concerns a single excited state, could hardly be expected within a Laporte-forbidden d-d transition.[15]

The strong resonance-enhancement was observed for the totally symmetric intra-ligand mode, ν(C-C)+ν(C-S), while the weak enhancement was observed for the totally symmetric metal-ligand mode, ν(Co-S).[16] The resonance-enhancement was not observed for the bands due to the non-totally symmetric modes. This observation indicates that the resonance-enhancement found in the present complex is the "A-type" which causes an intensity enhancement for the totally symmetric mode, but not for the non-totally symmetric mode. Therefore, the resonant transition must be a purely allowed transition, namely a charge-transfer transition. Figure 2-B illustrates the excitation profiles of the totally symmetric ν(C-C)+ν(C-S) and ν(Co-S) modes. The excitation profiles for both modes maximize at ca. 20000 cm^{-1}. This fact reveals that a charge-tansfer transition is situated at ca. 20000 cm^{-1} and overlaps with the two d-d transitions.

Coucouvanis and Piltingstrud[17] studied the absorption spectra of polynuclear complexes of the $[M(Ph_3P)_2]_3[M'(dto)_3]$-type (M=Cu(I), Ag(I); M'= Co(III), Al(III), Rh(III), and Cr(III)). They presumed that the band at ca. 20000 cm^{-1} of $[Co^{III}(dto)_3]^{3-}$ is due to a charge-transfer transition on the basis of the spectral change caused by the formation of an adduct with $[Cu^{I}(Ph_3P)_2]^{+}$. The present result is consistent with their suggestion.

Amorphous and Crystalline Peroxopolytungstic Acids Formed from Tungsten and Hydrogen Peroxide

Hiroshi OKAMOTO,*,† Akira ISHIKAWA, and Tetsuichi KUDO††
Central Research Laboratory, Hitachi, Ltd., P. O. Box 2, Kokubunji, Tokyo 185
(Received March 15, 1989)

Synopsis. Peroxopolytungstic acids, $WO_3 \cdot xH_2O_2 \cdot yH_2O$ ($0 \leqq x \leqq 1$), formed directly from tungsten and hydrogen peroxide are found to be crystalline or amorphous depending on x.

A tungsten powder dissolves vigorously in a hydrogen peroxide (H_2O_2) aqueous solution.[1,2] A systematic study on the products obtained from the aqueous solution with various peroxide ion (O_2^{2-}) to W molar ratio showed that an amorphous or crystalline solid of peroxopolytungstic acids could be obtained depending on the molar ratio. This note presents the synthesis for and some characteristics of various peroxopolytungstic acids formed directly from W and H_2O_2.

After W was dissolved in an H_2O_2 solution, the H_2O_2 in the solution was catalytically decomposed stepwise with a platinized platinum net, then the solution was dried under blown air at room temperature to leave solids. The peroxo content in the solids obtained by this way was related to the H_2O_2 concentration in the solution just before drying, as shown in Fig. 1. Here, the H_2O_2 and W concentrations in the original solutions were varied as shown in the figure legend. The H_2O_2 concentration in solutions and peroxo content in solids were determined by a titration using a $KMnO_4$ solution.

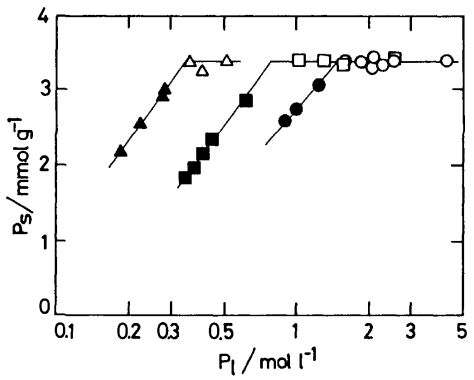

Fig. 1. Formation conditions for IPA and XW.
P_I: H_2O_2 concentration in the solution just before drying, P_s: Peroxo content in the obtained solids. Open symbols stand for XW and closed symbols for IPA. H_2O_2 and W concentrations in the starting solutions are 10 and 1.45 mol l^{-1} for circles, 5 and 0.79 mol l^{-1} for rectangles, and 1.7 and 0.35 mol l^{-1} for triangles.

† Present address: Advanced Research Laboratory, Hitachi, Ltd., P. O. Box 2, Kokubunji, Tokyo 185.
†† Present address: Institute of Industrial Science, University of Tokyo, 22-1 Roppongi 7 chome Minato-ku, Tokyo 106.

Despite decrease in the H_2O_2 concentration in the solution down to some value, the peroxo content for the solids remained constant at 3.39 ± 0.07 mmol g^{-1}. The solids were crystalline, which was confirmed by XRD. Some d-values are shown in Table 1. The crystal, XW, was insoluble in water or in an H_2O_2 solution. As H_2O_2 decomposition proceeded to pass through the point where a peroxide ion to tungsten molar ratio in the solution was approximately 1, an amorphous substance, IPA, was given instead of XW. A further decrease in H_2O_2 concentration in the solution allowed precipitation to take place, which is not shown in Fig. 1. The precipitate was amorphous. When the peroxo content in solid was decreased to 0, crystalline H_4WO_5 ($WO_3 \cdot 2H_2O$) was obtained.

To determine the composition for the solids, a thermal weight change was measured using TGA. The XW exhibited two discrete weight loss steps and finally changed to WO_3 at 398 °C. The first weight loss at approximately 110 °C caused XW to turn into another crystal, which we call XW′. Some d-values are shown in Table 1. The second weight loss at approximately 200 °C changed XW′ to an amorphous substance. On the the other hand, IPA showed indistinct weight loss steps and changed to WO_3 at 428 °C.

The peroxo content and the thermal weight change between rt and 500 °C gave the experimental formula as $WO_3 \cdot xH_2O_2 \cdot yH_2O$. It was found that XW had a maximum value of x, 0.97 ± 0.03, and a minimum value of y, 1.1 ± 0.1. Therefore, the formula for XW is thought to be basically $WO_3 \cdot H_2O_2 \cdot H_2O$. When $1 > x > 0$, $1.5 < y < 3.0$ and the peroxopolytungstic acids were amorphous IPA. The IPA with $1 > x \gtrsim 0.53$ was water-soluble, while the IPA with $0.53 \gtrsim x > 0$ was insoluble. For the extreme case of $x = 0$, the substance was $WO_3 \cdot 2H_2O$, as previously mentioned. Therefore, it follows that the substances formed directly from W and H_2O_2 are crystalline only for $x = 1$ or 0, while for $1 > x > 0$ they are amorphous, and phase sepa-

ration does not occur. The only water-soluble peroxopolytungstic acids are the IPA with $1>x\gtrsim0.53$.

A similar compositional analysis for XW', led to the formula for XW' being $WO_3 \cdot 0.94H_2O_2 \cdot 0.14H_2O$. However, the thermal changes from XW to XW' and from XW' to the amorphous substance were found to be time-dependent. Actually, the peroxo content for XW' decreased gradually with heating time and/or temperature increases. Therefore, an intermediate phase of XW' might have been mixed with some amorphous substance and XW fragments. Accordingly, the formula for XW' is supposed to be basically $WO_3 \cdot H_2O_2$.

Infrared and Raman spectra for IPA, XW, and XW' were very similar, as shown in Figs. 2 and 3, except for band sharpening and a small wavenumber shifting in the latter two. Although these small differences reflect differences in fine structures, the basic structure of IPA, XW, and XW' is concluded to be quite similar. Until now, all known coordination structures around W in peroxo containing polytungstic acid salts with a peroxo to W molar ratio=1, are octahedral with one corner of the octahedron at the center of the peroxo bond.[3,4] Therefore, IPA, XW, and XW' are supposed to have the same WO_7 pseudo-octahedral structure. By reference to the vibrational analyses[5,6] for $[Mo_6O_{19}]^{2-}$ and the Keggin structure such as $[SiW_{12}O_{40}]^{2-}$, IPA, XW, and XW' are considered to have both edge-shared and corner-shared pseudo-octahedral structures.

The Regioselective Side-Chain Lithiation of 2-Methyl-3-thiophenecarboxylic Acid

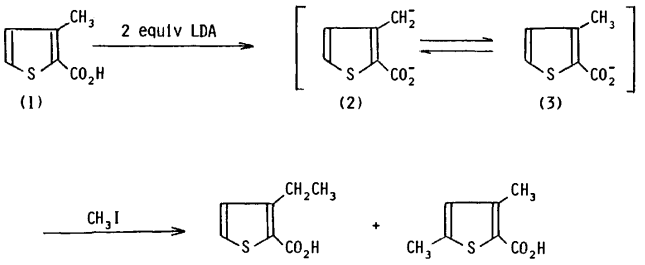
(Received November 29, 1988)

Synopsis. It was found that the dilithium salt (**5**), which was lithiated at the side-chain of 2-methyl-3-thiophenecarboxylic acid (**4**), was produced regioselectively by the reaction of **4** with lithium diisopropylamide (LDA). The reactions of **5** with alkyl halides resulted in the formation of 2-alkyl-3-thiophenecarboxylic acids (**7**). Further, δ-lactone derivatives (**11**) were obtained by the cyclization of the adducts (**10**) which were produced from **5** with aldehydes and ketones.

The side-chain metalation of thiophene derivatives has attracted considerable attention[1a-c] in terms of its usefulness for the synthesis of many types of the thiophene derivatives. However, the selectivity of the side-chain metalation of the thiophene derivatives is reported to be unsatisfactory because of the metalation of the thiophene nuclei. For example, Lee et al.[1c] reported that lithiation of 3-methyl-2-thiophenecarboxylic acid (**1**) with two equivalents of lithium diisopropylamide (LDA) and subsequent treatment with methyl iodide gave a mixture of the products which were formed from the dilithium salts of **2** and **3** respectively, in the ratio of 35 : 65 (Scheme 1).

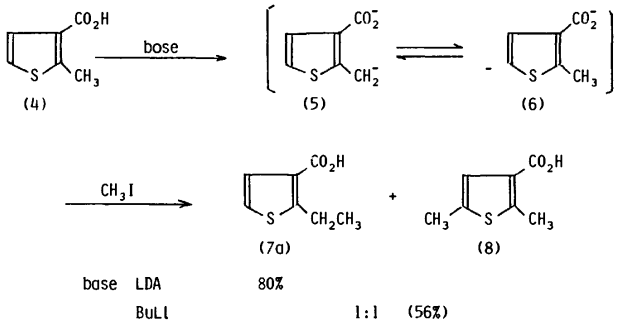


Scheme 1.

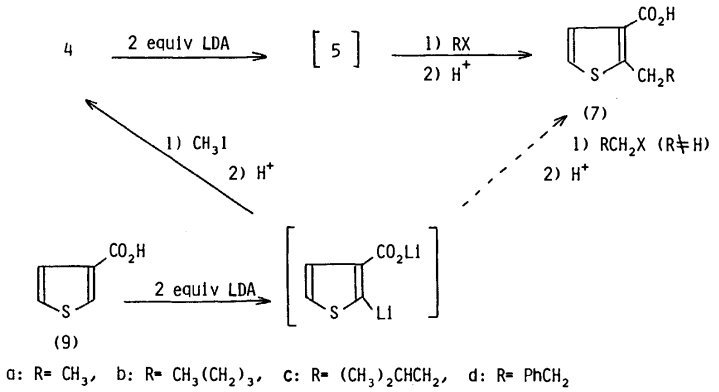
We report herein the selective side-chain lithiation of 2-methyl-3-thiophenecarboxylic acid (**4**) and some reactions of the resulting dilithium salt with electrophiles.

Results and Discussion

In the course of our studies on the Birch reduction of thiophene derivatvs,[2a,b] we examined the alkylation of 2-methyl-3-thiophenecarboxylic acid (**4**) and found the remarkably high regioselective side-chain lithiation of **4**. When the formation of a dilithium salt from **4** with two equivalents of lithium diisopropylamide (LDA) at −30 °C in THF was followed by alkylation with methyl iodide, 2-ethyl-3-thiophenecarboxylic acid (**7a**) was obtained in 80% yield without the formation of 2,5-dimethyl-3-thiophenecarboxylic acid (**8**). This result shows that the side-chain lithiation occurred selectively in sharp contrast to the reaction of 3-methyl-2-thiophenecarboxylic acid (**1**) with LDA. However, when butyllithium was used as the base instead of the LDA, regioselectivity was decreased and the mixture of **7a** and **8** was obtained in the ratio of 1 : 1. It is not clear at the present time why the selectivity of the lithiation is decreased by the use of the butyllithium.



. The reactions of the dilithium salt **5** with several alkyl halides were carried out to yield 2-alkyl-3-thiophenecarboxylic acids (**7**). The results are summarized in Table 1. These reactions may be useful



Scheme 2.

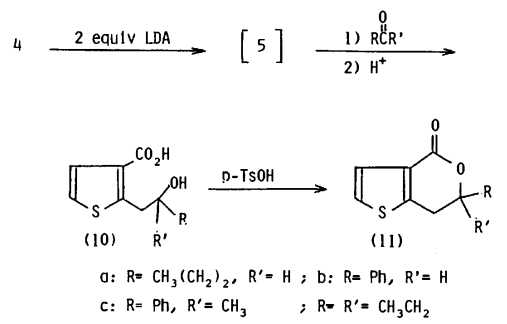


Table 1. Preparation of 2-Alkyl-3-thiophenecarboxylic Acid (**7**)

	R	Yields of **2**
7a	CH_3	80%
7b	$CH(CH_2)_3$	83%
7c	$(CH_3)_2CHCH_2$	70%
7d	$PhCH_2$	70%

Table 2. Preparation of 2-(2-Hydroxyalkyl)-3-thiophenecarboxylic Acid (**10**) and δ-Lactone Derivatives (**11**)

R	R'	Yields of **10** (%)		Yields of **11** (%)	
$CH_3(CH_2)_2$	H	**10a**	77	**11a**	86

because the yields of the reaction of dilithium salt of 3-thiophenecarboxylic acid (**9**) with alkyl halides are not satisfactory for the practical synthesis of **7**, except for the case of the methyl iodide[1b] (Scheme 2).

Furthermore, the reactions of dilithium salt **5** with aldehydes or ketones produced the adducts (**10**) which were easily cyclized to δ-lactone derivatives **11** in refluxing benzene in the presence of *p*-toluenesulfonic acid. The results are summarized in Table 2.

Experimental

Preparation of 2-Ethyl-3-thiophenecarboxylic Acid (7a). Into a solution of LDA in 20 ml of THF, prepared from diisopropylamine (3.60 g, 35.6 mmol) and butyllithium (36.0 mmol), a solution of 2-methyl-3-thiophenecarboxylic acid (**4**) (2.53 g, 17.8 mmol) in 5 ml of THF was added at −30 °C under nitrogen. After the reaction mixture had been stirred for 1 h at −30 °C, a solution of methyl iodide (2.53 g, 17.8 mmol) in 5 ml of THF was added and stirring was continued for 2.5 h at −30 °C. The reaction mixture was quenched with 10% hydrochloric acid and extracted with ether. The ethereal layer was washed with small amounts of sodium sulfite solution and dried over magnesium sulfate. After removal of the ether, the resulting residue was chromatographed on a silica-gel column. From the elution with benzene-ether (5 : 1), 2.24 g (80%) of 2-ethyl-3-thiophenecarboxylic acid (**7a**) was obtained, mp 58—60 °C.[3] IR (KBr): 3300—2300 cm^{-1} (CO_2H), 1660 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=1.47 (3H, t), 3.46 (2H, q), 7.33 (1H, d), 7.73 (1H, d), 11.6 (1H, brs); MS: *m/z* 156 (M^+).

2-Pentyl-3-thiophenecarboxylic acid (**7b**), 2-(3-methylbutyl)-3-thiophenecarboxylic acid (**7c**), and 2-(2-phenylethyl)-3-thiophenecarboxylic acid (**7d**) were obtained by the similar procedure from **4** and the corresponding alkyl bromides. Yields and spectral data are as follows:

7b: Yield 83%; mp 62.5—63 °C; IR (KBr): 3500—2350 cm^{-1} (CO_2H), 1690 cm^{-1} (C=O); ^1H NMR($CDCl_3$): δ=0.89 (3H, t), 1.24—1.88 (6H, m), 3.22 (2H, t), 7.02 (1H, d), 7.46 (1H, d), 11.1 (1H, brs); MS: *m/z* 198 (M^+).

7c: Yield 70%; mp 64.5—65 °C; IR (KBr): 3500—2400 cm^{-1} (CO_2H), 1680 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=0.95 (6H, d), 1.60 (3H, t), 3.22 (2H, t), 7.02 (1H, d), 7.46 (1H, d), 11.1 (1H, brs); MS: *m/z* 198 (M^+).

7d: Yield 70%; mp 96—97 °C; IR (KBr): 3500—2400 cm^{-1} (CO_2H), 1700 cm^{-1} (C=O); ^1H NMR($CDCl_3$): δ=2.86—3.11 (2H, m), 3.38—3.62 (2H, m), 7.02 (1H, d), 7.12—7.33 (5H, m), 7.46 (1H, d), 11.1 (1H, brs); MS: *m/z* 236 (M^+).

Preparation of 2-(2-Hydroxypentyl)-3-thiophenecarboxylic Acid (10a). Into a solution of LDA in 20 ml of THF, prepared from diisopropylamine (1.78 g, 17.6 mmol) and butyllithium (17.0 mmol), a solution of **4** (1.14 g, 8.0 mmol) in 5 ml of THF was added at −30 °C under nitrogen. The reaction mixture was stirred for 1 h at −30 °C. A solution of butanal (0.58 g, 8.1 mmol) in 5 ml of THF was added to the reaction mixture and the resulting mixture was stirred for 2 h at −30 °C. The reaction mixture was acidified with 10% hydrochloric acid and extracted with ether. The ethereal layer was washed with saturated sodium chloride solution and dried over magnesium sulfate. After removal of the ether, the resulting residue was chromatographed on a silica-gel column. From the elution with benzene-ether (5 : 1), 1.32 g (77%) of the acid **10a** was obtained, mp 73—75 °C. IR (KBr): 3400 cm^{-1} (OH), 3100—2300 cm^{-1} (CO_2H), 1660 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=0.73—1.87 (7H, m), 3.39 (1H, dd), 3.48 (1H, dd), 3.79—4.21 (1H, m), 7.1 (1H, brs), 7.30 (1H, d), 7.69 (1H, d); MS: *m/z* 194 (M^+-H_2O, $-H_2$). Found: C, 56.24; H, 6.84%. Calcd for $C_{10}H_{14}O_3S$: C, 56.04; H, 6.59%.

By a similar procedure, 2-(2-hydroxy-2-phenylethyl)-3-thiophenecarboxylic acid (**10b**), 2-(2-hydroxy-2-phenylpropyl)-3-thiophenecarboxylic acid (**10c**) and 2-(2-ethyl-2-hydroxybutyl)-3-thiophenecarboxylic acid (**10d**) were obtained from **4** and corresponding aldehydes or ketones. The yields, spectral and analytical data are as follows:

10b: Yield 63%; mp 143—148 °C; IR (KBr): 3300 cm^{-1} (OH), 3100—2300 cm^{-1} (CO_2H), 1690 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=3.36—4.03 (2H, m), 5.12 (1H, q), 7.26 (1H, d), 7.65 (1H, d), 7.36—7.81 (5H, m); MS: *m/z* 248 (M^+). Found: C, 62.74; H, 4.66%. Calcd for $C_{13}H_{12}O_3S$: C, 62.90; H, 4.58%.

10c: Yield 61%; mp 115—117 °C; IR (KBr): 3400—2400 cm^{-1} (CO_2H), 1660 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=1.60 (3H, s), 3.50 (1H, d), 3.78 (1H, d), 7.01 (1H, d), 7.17—7.56 (6H, m); MS: *m/z* 244 (M^+-H_2O). Found: C, 63.99; H, 5.44%. Calcd for $C_{14}H_{14}O_3S$: C, 64.11; H, 5.38%.

10d: Yield 81%; mp 95—97 °C; IR (KBr): 3400—2200 cm^{-1} (CO_2H), 1660 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=0.91 (6H, t), 1.54 (4H, q), 3.31 (2H, s), 7.09 (1H, d), 7.37 (1H, d); MS: *m/z* 210 (M^+-H_2O). Found: C, 57.65; H, 7.11%. Calcd for $C_{11}H_{16}O_3S$: C, 57.88; H, 7.07%.

Preparation of 6,7-Dihydro-6-propyl-4*H*-thieno[3,2-*c*]-pyran-4-one (11a). A solution of **10a** (1.16 g, 54.2 mmol) and a catalytic amount of *p*-toluenesulfonic acid in 100 ml of benzene was refluxed for 3 h with a water separating apparatus. The mixture was evaporated and the resulting residue was chromatographed on a silica-gel column. From the elution with benzene, 0.91 g (86%) of the pyrane **11a** was obtained as an oil. IR (NaCl): 1700 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=0.96 (3H, t), 1.31—2.04 (4H, m), 2.92—3.10 (2H, m), 4.42—4.76 (1H, m), 7.14 (1H, d), 7.41 (1H, d); MS: *m/z* 196 (M^+). Found: C, 61.38; H, 6.35%. Calcd for

$C_{10}H_{12}O_2S$: C, 61.21; H, 6.17%.

By a similar procedure, 6,7-dihydro-6-phenyl-4*H*-thieno-[3,2-*c*]pyran-4-one (**11b**), 6,7-dihydro-6-methyl-6-phenyl-4*H*-thieno[3,2-*c*]pyran-4-one (**11c**), and 6,6-diethyl-6,7-dihydro-4*H*-thieno[3,2-*c*]pyran-4-one (**11d**) were formed from the corresponding acids **10**. The yields, spectral and analytical data are as follows:

11b: Yield 87%; mp 130 °C; IR (KBr): 1700 cm^{-1}(C=O); ^1H NMR ($CDCl_3$): δ=3.33 (2H, d), 5.64 (1H, t), 7.20 (1H, d), 7.36—7.60 (6H, m); MS: *m/z* 230 (M^+). Found: C, 67.72; H, 4.27%. Calcd for $C_{13}H_{10}O_2S$: C, 67.82; H, 4.38%.

11c: Yield 94%; oil; IR (NaCl): 1700 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=1.64 (3H, s), 3.41 (1H, d), 3.67 (1H, d), 7.05 (1H, d), 7.20—7.53 (6H, m); MS: *m/z* 244 (M^+). Found: C, 68.66; H, 5.04%. Calcd for $C_{14}H_{12}O_2S$: C, 68.84; H, 4.95%.

11d: Yield 92%; oil; IR (NaCl): 1700 cm^{-1} (C=O); ^1H NMR ($CDCl_3$): δ=0.93 (6H, t), 1.86 (4H, q), 3.06 (2H, s), 7.14 (1H, d), 7.44 (1H, d); MS: *m/z* 210 (M^+). Found: C, 62.93; H, 6.88%. Calcd for $C_{11}H_{14}O_2S$: C, 62.84; H, 6.71%.

Synthesis of Five-Membered Cyclic Ketones Using Potassium Tetracarbonylferrate(2−)

Masakazu YAMASHITA,* Masaya UCHIDA, Haruyoshi TASHIKA, and Rikisaku SUEMITSU
Department of Applied Chemistry, Doshisha University, Kamikyo-ku, Kyoto 602
(Received January 11, 1989)

Synopsis. Various five-membered cyclic ketones were prepared from 1,4-dihaloalkanes and potassium tetracarbonylferrate(2−) in moderate to high yields. However, the yields of six- or seven-membered cyclic ketones from the corresponding dihalides were rather low.

The alkali metal tetracarbonylferrate(2−) $M_2Fe(CO)_4$ (M=Na, K) (**1**) is one of the most characteristic reagents and is used as a stoichiometric reagent in the synthesis of carbonyl compounds including ketones, aldehydes, carboxylic esters and amides via acylcarbonylferrates.[1] On the other hand, saturated and unsaturated five-membered cyclic ketones are important compounds that are not only included in a large number of biologically active natural products as a structural feature, but also as a precursor of lactones by Baeyer-Villiger oxidation. Therefore, undiminished efforts have been devoted to the synthesis of this moiety.[2]

In this paper we wish to report on a facile synthetic method of the five-membered cyclic ketones from 1,4-dihaloalkanes using tetracarbonylferrate (**1**) as a carbonylating agent.

Experimental

The IR spectra were recorded on a Hitachi 260-10 Infrared Spectrophotometer. The NMR spectra were measured on a Hitachi R-600 FT-NMR spectrometer at 60 MHz, using tetramethylsilane (δ=0.00) as an internal standard; chemical shifts are given in ppm. The mass spectra (MS) were determined on a Hitachi RM-50 GC-MS spectrometer. Analytical gas chromatography was carried out on a Yanagimoto G-8 gas chromatograph with a column of 10% Silicone gum SE-30 on Chromosorb and a Shimadzu GC-14A instrument using a Shimadzu capillary column HiCap CBP1-W12-100. The column chromatography was performed on Nakarai silica gel 60 (230—400 mesh).

Materials. Tetrahydrofuran (THF) was dried and deoxygenated by distillation from potassium-benzophenone under argon just before use. *N*-Methyl-2-pyrrolidone (NMP) was dried by distillation at reduced pressure and stored over 3A molecular sieves. Pentacarbonyliron (Strem Chemical Co.) was used without further purification. Potassium tri-s-butylhydroborate was purchased from the Aldrich Chemical Co. as a 1.0 M (1 M=1 mol dm^{-3}) THF solution under the trade name K-Selectride. 1,4-Dibromobutane, 1,5-dibromopentane, and 1,6-dibromohexane were commercial products of the highest available purity. *cis*-1,2-Bis(bromomethyl)cyclohexane, 1,2-bis(bromomethyl)-4-methylcyclohexane, *endo-cis*-2,3-bis(bromomethyl)bicyclo-[2.2.1]heptane, 1,4-dibromo-2-phenylbutane, 1-bromo-3-(bromomethyl)pentadecane, and 1,5-dibromo-3-phenylpentane were prepared from *cis*-1,2-cyclohexanedicarboxylic anhydride,[3,4] 4-methyl-*cis*-1,2-cyclohexanedicarboxylic anhydride,[3,4] *cis*-5-bicyclo[2.2.1]heptene-*endo*-2,3-dicarboxylic anhydride,[5] diethyl 2-phenylsuccinate,[3,6,7] dodecylsuccinic anhydride,[3,7] and diethyl 3-phenylglutarate,[6,8] respectively, by usual hydrogenation and the following bromination. Potassium tetracarbonylferrate (**1**) was prepared by a method mentioned in the literature.[9]

Synthesis of *cis*-Bicyclo[4.3.0]nonan-8-one. General Procedure. Reactions were conducted under an argon atmosphere. To the THF solution (13 ml) of 1.0 M potassium tri-*s*-butylhydroborate, 0.79 ml of pentacarbonyliron (6 mmol) was added, and the reaction mixture was refluxed for 4 h. After cooling, a supernatant solution was removed, and the resultant white solid was washed several times with hexane and dried by blowing argon through the flask. Then, 30 ml of NMP was injected and 1,2-bis-(bromomethyl)cyolohexane (5 mmol) was added. After stirring the mixture for 24 h at room temperature, the solution was diluted with ether, washed three times with saturated brine, and the organic layer was dried over anhydrous magnesium sulfate, filtered and concentrated. The residue was separated by column chromatography (hexane : dichloromethane : diethyl ether=5 : 1 : 1) to afford bicyclo[4.3.0]nonan-8-one as oil in 61% isolated yield.[10] IR (cm^{-1}): 2935, 1743, 1163. ^{1}H NMR ($CDCl_3$) (δ): 1.18—1.78 (m, 8H), 2.03—2.58 (m, 6H). MS (*m/z*): 138 (M^+).

Other cyclic ketones were synthesized following the general procedure described above.[10]

***cis*-3-Methylbicyclo[4.3.0]nonan-8-one.** Yield 60%. Oil. IR (cm^{-1}): 2930, 1748, 1162. ^{1}H NMR δ=0.90 (d, 3H, J=4.0 Hz), 1.00—1.95 (m, 7H), 1.95—2.75 (m, 6H). MS (*m/z*): 152 (M^+).

***endo*-Tricyclo[3.2.1.0^{2,6}]decan-4-one.** Yield 52%. Oil. IR (cm^{-1}): 2960, 1742, 1175. ^{1}H NMR δ=1.25—1.70 (m, 6H), 2.17—2.88 (m, 8H). MS (*m/z*): 150 (M^+).

3-Phenylcyclopentanone. Yield 58%. Oil. IR (cm^{-1}): 2975, 1750, 1290, 760, 700. ^{1}H NMR δ=1.30 (m, 2H), 2.22—2.77 (m, 4H), 3.40 (m, 1H), 7.28 (s, 5H). MS (*m/z*): 160 (M^+).

3-Dodecylcyclopentanone. Yield 60%. Oil. IR (cm^{-1}): 2940, 1750, 1475, 1162. ^{1}H NMR δ=0.90 (t, 3H, J=4.0 Hz), 1.20—1.40 (m, 25H), 1.95—2.42 (m, 4H). MS (*m/z*): 252 (M^+).

4-Phenylcyclohexanone. Yield 15%. Mp 78—80 °C. IR (cm^{-1}): 2940, 1710, 759, 699. ^{1}H NMR δ=1.80—2.30 (m, 4H), 2.38—2.75 (m, 5H), 7.28 (s, 5H). MS (*m/z*): 174 (M^+).

Results and Discussion

The various 1,4-dibromoalkanes reacted with potassium tetracarbonylferrate (**1**) in NMP to give the five-membered cyclic ketones in good isolated yield. The results of these reactions are listed in Table 1. However, the yields of six- or seven-membered cyclic ketones were rather low. This shows that it is difficult to cyclize intramolecularly. In fact, ω-bromo aldehydes (**2**) were obtained as by-products in these reactions.

The mechanism of these reactions is considered to be as follows (Scheme 1). First, an dibromoalkane reacts with (**1**) to afford an alkylcarbonylferrate (**4**), which transforms into an acylcarbonylferrate (**4**) with the solvent assisted migratory insertion of carbon monoxide. Intramolecular cyclization of the acylcar-

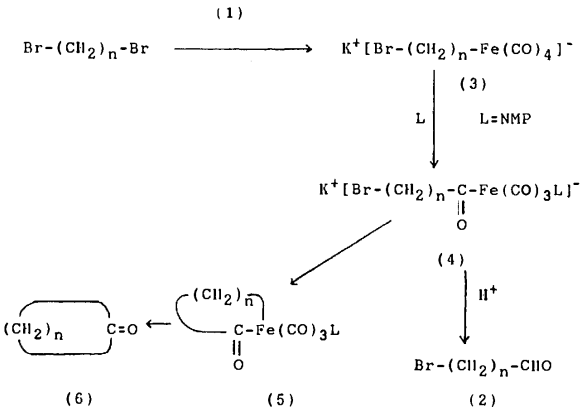
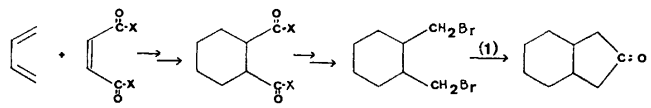


Scheme 1.

bonylferrate (**4**) leads to an acylalkyliron complex (**5**) which appears to collapse by reductive elimination to a cyclic ketone (**8**). In the reaction of (**1**) with 1,3-dibromopropane, the corresponding acylalkyliron complex (**5**) (n=3, L=triphenylphosphine) has been isolated as crystals.[11] The formation of ω-bromo aldehyde (**2**) is also considered to be derived from (**4**) by protonation in the work-up.[12]

By this method, five-membered cyclic ketones fused to the cyclohexane ring were prepared in good yields. The starting dibromoalkanes were easily prepared from the Diels-Alder adducts via hydrogenation and



bromination. Therefore, this method is considered to be useful in the synthesis of these cyclic ketone skeletons which appear widely in naturally occurring organic compounds.

Solubility and Coupling Reactivity of Protected Peptides in Highly Polar Solvents

Hisayuki MORII* and Kunihiro ICHIMURA
Research Institute for Polymers and Textiles, 1-1-4 Higashi, Tsukuba, Ibaraki 305
(Received January 20, 1989)

Synopsis. The solubility of protected peptides as well as the coupling rate was quantitatively examined in highly polar solvents. Symmetrical anhydrides in dimethyl sulfoxide (DMSO) containing *N,N*-dimethylformamide (DMF) or DMF solution of lithium chloride and diethyl phosphorocyanidate with triethylamine in DMSO-DMF were proved to be efficient coupling reagents for solid phase synthesis of hardly soluble peptides.

The demand for chemical synthesis of peptides is ever increasing in relation to peptides with non-natural sequences of amino acids. Kaiser et al. designed and synthesized non-natural amphiphilic peptides[1,2] possessing biological activities displayed by melittin and β-endorphin[3] whereas Ho et al. synthesized the 4-bundle helices[4] of peptides. However, syntheses of large peptides with regular sequences are often difficult probably because of the low solubility of the peptides. Narita et al. have investigated[5,6] the solubility and the conformation of the synthetic intermediates in organic solvents and suggested that the aggregation by the β-sheet formation causes the low solubility. In order to prevent the β-sheet formation, they recommended the use of *N*-substituted or α,α-disubstituted amino acid residues. However, when designed peptide sequence does not contain these residues destroying β-sheet structure, the use of highly polar solvents seems effective. Actually, DMF as well as DMF-DMSO[7] has been used in the fragment condensation to solubilize component peptides. DMF and NMP are also effective in the solid phase synthesis. Relatively high yields were obtained by using a DMF-DMSO mixed solvent.[4] The descriptions about the solubility of the protected peptides in highly polar solvents are qualitative in most papers and there are only few data available for the selection of coupling solvents.[8] During the course of our studies on non-natural long chain peptides, optimization of coupling conditions has been required. This paper deals with the more detailed examination of solubility of several types of peptides in highly polar solvents and the reactivity of several coupling reagents in these solvents.

Experimental

Materials[9] and Methods. The organic solvents were dried over Molecular Sieves 4A, and LiCl was dealt under dry conditions. TLC was performed on silica gel (Kieselgel $60F_{254}$, Merck). R_f values refer to the following solvent systems: R_f^1 ethyl acetate-MeOH (5:1 v/v), R_f^2 dioxane-MeOH (1:1), R_f^3 1-butanol-acetic acid-water (4:1:1), R_f^4 chloroform-MeOH (9:1). The optical rotations were determined with a Horiba SEPA-200 polarimeter at 24 °C. Elemental analyses were performed with a Yanaco MT-3 CHN Corder.

Synthesis. Boc-Asn-Asn-Phe-OBzl (Ia). This peptide was prepared stepwise by the standard solution technique.[10] R_f^2 0.86; R_f^3 0.80; R_f^4 0.10; $[\alpha]_D$ −11.3° (*c* 1.0, DMSO).

Boc-Asn-Asn-Phe-Ala-Asn-Asn-Phe-OBzl (Ib). This compound was prepared by the fragment condensation of Boc-Asn-Asn-Phe-OH with H-Ala-Asn-Asn-Phe-OBzl using WSC and HOBt. Mp 260—261 °C (decomp); $[\alpha]_D$ −20.6° (*c* 1.0, DMSO). Calcd for $C_{49}H_{63}N_{11}O_{14}\cdot H_2O$: C, 56.2; H, 6.3; N, 14.7%; Found: C, 56.0; H, 6.3; N, 15.1%.

Boc-Glu(OBzl)-Glu(OBzl)-Phe-Ala-Glu(OBzl)-Ala-Phe-Gly-OBzl (IIa). The peptide **IIa** was synthesized by a stepwise solid-phase procedure employing oxime resin described by Kaiser et al.[11] Mp 184—187 °C (decomp). Calcd for $C_{74}H_{86}N_8O_{17}\cdot H_2O$: C, 64.5; H, 6.4; N, 8.1%; Found: C, 64.5; H, 6.5; N, 8.1%.

Boc-Glu(OBzl)-Glu(OBzl)-Phe-Ala-Glu(OBzl)-Ala-Phe-Glu(OBzl)-Glu(OBzl)-Phe-Ala-Glu(OBzl)-Ala-Phe-Gly-OBzl (IIb). The fragment Boc-Glu(OBzl)-Glu(OBzl)-Phe-Ala-Glu(OBzl)-Ala-Phe-N_2H_3 was prepared by the cleavage of the heptapeptide resin with hydrazine according to the method of Kaiser et al.[11] Yield, 52%; R_f^1 0.78; R_f^2 0.86; R_f^4 0.58. Another fragment H-Glu(OBzl)-Glu(OBzl)-Phe-Ala-Glu(OBzl)-Ala-Phe-Gly-OBzl was obtained from compound **IIa** in 90% yield. The compound **IIb** was prepared with these two fragments according to the azide method. Mp 254—257 °C (decomp); $[\alpha]_D$ −5.0° (*c* 1.0, DMSO). Calcd for $C_{134}H_{153}N_{15}O_{30}\cdot 3H_2O$: C, 64.2; H, 6.4; N, 8.4%; Found: C, 64.4; H, 6.5; N, 8.8%.

Boc-Phe-Phe-Leu-Leu-Phe-Phe-Leu-Leu-Ala-OBzl (III). This compound was prepared in a similar manner as for the peptide **IIa**. Yield, 65%; mp 299—302 °C (decomp); $[\alpha]_D$ −23.2° (*c* 1.0, DMSO). Calcd for $C_{75}H_{101}N_9O_{12}\cdot H_2O$: C, 67.3; H, 7.8; N, 9.4%; Found: C, 67.6; H, 8.0; N, 9.5%.

To suppress racemization and side reactions in the fragment condensations, phenylalanine was chosen as C-terminus of carboxyl components. Little racemization was detected by ^1H NMR for compound **Ib**.

Solubility. The peptide was weighed precisely in a small tube and one or more drops of solvent was added to it. The suspension was stirred magnetically for one minute. By direct observation of the precipitant, it was judged whether an insoluble part was remained or not. The addition of the solvent and the judgement were repeated.

Determination of Coupling Rate. Five coupling reagents, i.e., DCC, HOBt-DCC, DEPC, DEPC-TEA, and symmetrical anhydride, were examined in the following way. Deprotected [4-(glycyloxymethyl)phenylacetamido]-methyl-resin (200 mg)[12] was placed in a test tube and suspended in a solvent. Boc-phenylalanine (2 equiv) was added subsequently. The coupling reaction was initiated with the addition of the coupling reagent such as DCC or DEPC. The reaction was pursued in 2.00 g of solvent. In the case of HOBt-DCC, HOBt (4 equiv) was added in advance. For DEPC-TEA, TEA was added one minute later after the addition of DEPC. Symmetrical anhydride was pre-formed with Boc-phenylalanine (4 equiv) and DCC (2 equiv) in dichloromethane and used as DMF solution. After specified times, the aliquots of the reaction mixture were removed and immediately washed with ethanol. The content of unreacted amino groups on the resin was deter-

mined by the method of Gisin,[13] which employs the salt formation with picric acid.

Results and Discussion

The amino acid residues in synthetic intermediates can be classified as follows: (i) unprotected residues which tend to form hydrogen bond, such as asparagine; (ii) hydrophilic residues with hydrophobic protecting groups; (iii) hydrophobic residues. The peptides **Ia** and **Ib** were designed to have an abundance of type-(i) residues. The peptides **IIa** and **IIb** were designed to be rich in type-(ii) residues and the peptide **III** was constructed with only type-(iii) residues. In common with the peptides **Ia—IIb** alanine and phenylalanine were used as the other residues.

The highly polar solvents such as HMPA, NMP, DMA, DMF, and DMSO are strong electron donors as well as strong electron acceptors on the basis of donor-acceptor concept.[14] HMPA is the strongest donor, and DMSO is the strongest acceptor among these solvents. Therefore, three representative solvents, i.e., HMPA, DMSO, and DMF, were examined in this study. DMF solution of LiCl was also examined because it is well-known as a good solvent for hydrogen-bonded compounds.

The characteristic solubility of the peptides in various solvent systems was obtained as shown in Fig. 1. The weights of peptide and solvent are represented as W_p and W_s, respectively. DMF has low solubilizing power for the peptides **Ia**, **Ib**, **IIb**, and **III**. These critical values of $\log(W_p/W_s)$ were in the range of -3 to -2. Only the peptide **IIa** was readily soluble in DMF. On the other hand, HMPA was a good solvent for the peptides **IIa**, **IIb**, and **III**. However, asparagine-rich peptides **Ia** and **Ib** had remarkably low solubility in HMPA. This result presumably relates to high donor character of HMPA. DMSO was quite a good solvent for the all peptides examined here. The critical values of $\log(W_p/W_s)$ were larger than -1.5. In comparison with the peptide **Ia** the peptide **Ib** had rather high solubility in DMSO in spite of the long chain length. This seems to be attributed to intramolecular hydrogen bonds.

DMF solution of LiCl was also a good solvent. The solubility of **Ib**, **IIa**, and **IIb** was comparable to that in DMSO. The peptides **Ia** and **III** were more soluble in DMF-LiCl than in DMSO. The solubility of these peptides was scarcely dependent on the content of LiCl in the range of 4% to 7%. In the mixed solvent systems, the solubility changes toward the mixing ratios were not simple. The peptide **III** had almost a constant solubility in DMF-HMPA system containing 0—80% of HMPA, though it had higher solubility in HMPA. It was also the case of DMF-DMSO system.

Further experiment suggested that the solubility in a mixed solvent depended on the order of mixing. For example, although the peptide **III** was insoluble in a mixture of DMF and DMSO at $W_p/W_s=10^{-2}$, the solubilization could be realized by dissolving it in pure DMSO at first and subsequently diluting with DMF to the same concentration. The procedure involving the devided addition of the solvents seems practically useful because mixed solvent systems give better coupling efficiency as described later.

For the solid-phase peptide synthesis, a rapid coupling reaction is desirable as a high efficiency can be achieved in a short time. Therefore, the coupling methods employing DCC, DCC-HOBt, DEPC, DEPC-TEA, and symmetrical anhydride were examined. The azide method and the pre-formed active ester methods were excluded because the former with diphenyl phosphorazidate was reported to be slower than DEPC method in DMF[15] and the latter reactions take place very slow in general.

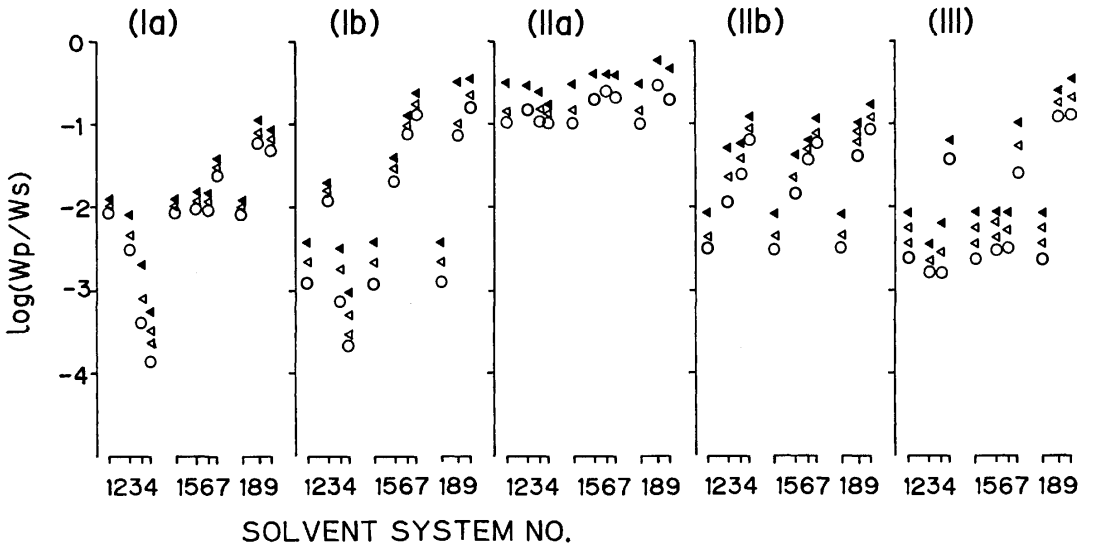

Fig. 1. Solubility of the peptides. The following solvent systems were used; 1: DMF, 2: HMPA-DMF (50 : 50 v/v), 3: HMPA-DMF (80 : 20), 4: HMPA, 5: DMSO-DMF (50 : 50), 6: DMSO-DMF (80 : 20), 7: DMSO, 8: DMF-LiCl (4%), 9: DMF-LiCl (7%). The open circles, the open triangles, and the closed triangles represent 'soluble', 'slightly insoluble', and 'apparantly insoluble', respectively.

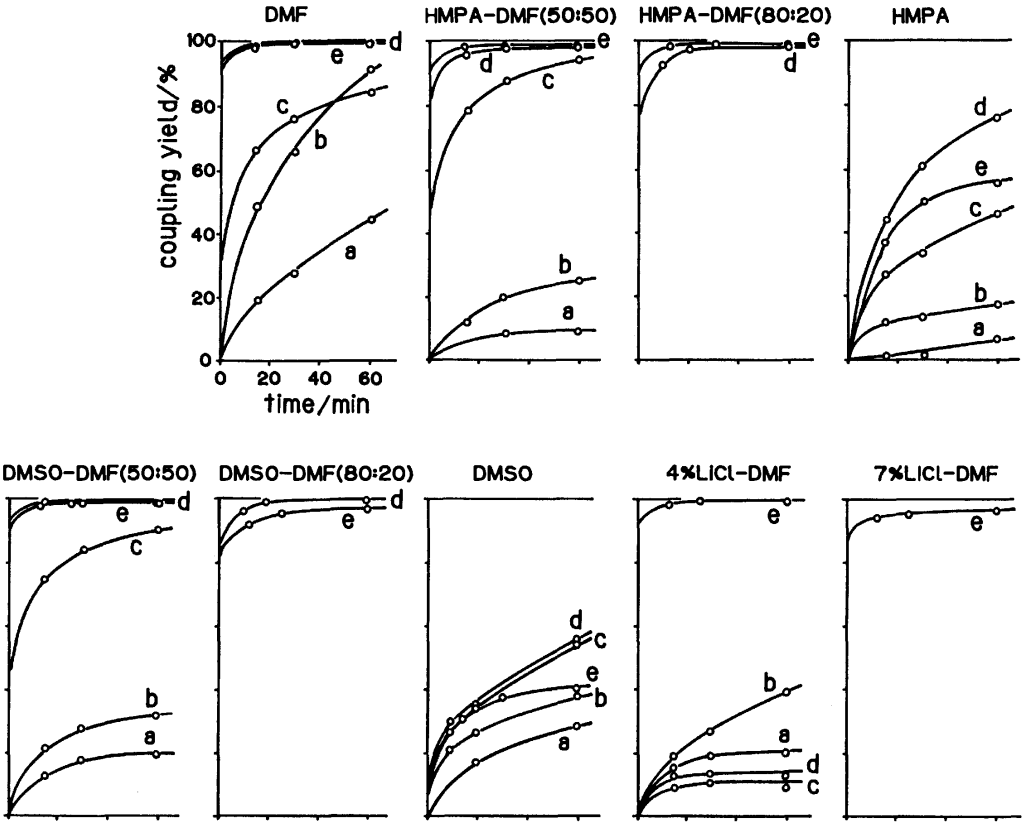

Fig. 2. Conversion curves of coupling reactions using DCC(a), DCC-HOBt(b), DEPC(c), DEPC-TEA(d) and symmetrical anhydride(e).

The conversion curves of those coupling reactions in various solvent systems are shown in Fig. 2. When DMF was used as a solvent, the coupling rate with DEPC-TEA and symmetrical anhydride were remarkably high. The result for DEPC-TEA is in line with the previous report.[15] On the other hand, DCC method is very slow. The coupling rates were considerably reduced for all the methods in HMPA as well as DMSO in comparison with those in DMF. This result means that the use of HMPA or DMSO alone is inadequete to realize both high solubilization and rapid coupling rate. Therefore, the coupling rates were examined in mixed solvent systems. In any mixed solvent containg DMF, the coupling reactions with DEPC-TEA and symmetrical anhydride method were as rapid as in DMF. The role of DMF seems to be essential for these rapid coupling reactions.

In conclusion, for the highly efficient synthesis of peptides the following methods can be recommended, i.e., symmetrical anhydride and DEPC-TEA in DMSO containing a small amount of DMF and the former method in DMF-LiCl.

Organic Photochemical Reactions. XXXII.[1] Photochemical Ring-Cleavage Reactions of 2,2-Diaryloxetanes in the Presence of Electron Donor

Kenichi NAKABAYASHI,† Shin FUJIMURA, Masahide YASUDA, and Kensuke SHIMA*
Department of Industrial Chemistry, Faculty of Engineering, Miyazaki University, Gakuen-Kibanadai, Miyazaki 889-21
(Received February 20, 1989)

Synopsis. Photochemical ring-cleavage reactions of 2,2-diaryloxetanes in the presence of triethylamine gave 1,1-diarylethenes selectively.

The cleavage of the oxetane ring has been studied in reactions with Brønsted acid or metal ion as well as in pyrolysis[2] or infrared multiphoton induced photolysis.[3] In these studies, the regiochemical control of ring cleavage has been an interesting subject. We previously reported that regioselective ring-cleavage reactions of 2,2-diaryloxetanes (**1**) into substituted benzophenone and alkene pairs are achieved by a photochemical electron transfer from **1** to a typical electron acceptor, such as aromatic nitriles.[1] Thus, the photochemical electron transfer has proved to be a useful method for the ring cleavage of oxetanes. Therefore, our attention was focused on the photochemical reaction of **1** in the presence of electron donors (Scheme 1).

Results and Discussion

Reaction Products. Photoreactions of **1** were carried out by irradiation in the presence of an electron donor at 254 nm. In attempts to find the optimum reaction conditions, the photoreaction of **1b** was carried out under various conditions. Hexane, cyclohexane, dibutyl ether, and tetrahydrofuran (THF) were found to be better solvents, since the photoreaction was relatively efficient, while methanol and acetonitrile were poor solvents (Table 1). As an electron donor, triethylamine (TEA) was better than the other amines tested (e.g. aliphatic or aromatic amines). Therefore, photochemical ring-cleavage reactions were performed with TEA in hexane throughout the present investigation.

Photochemical ring-cleavage reactions of **1a—d** in the presence of TEA gave the corresponding 1,1-diarylethene (**2**), while acetaldehyde or acetone was not detected by careful GLC analysis, though these compounds were expected as other products of the ring cleavage of **1**. The reaction products were unambiguously identified by direct comparisons with authentic samples which were prepared by acid-catalyzed fragmentation of the corresponding oxe-

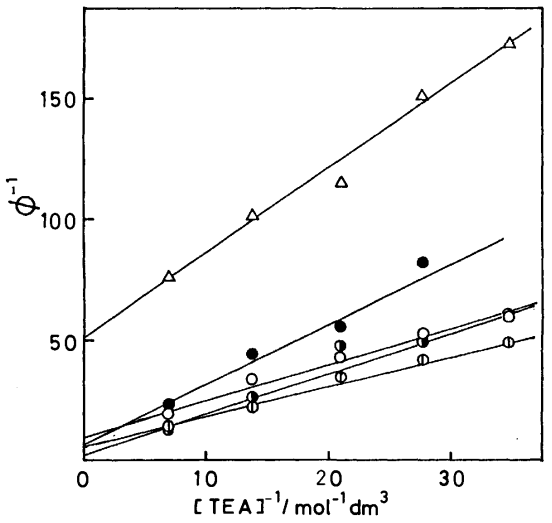

Fig. 1. Double-reciprocal plots of quantum yields vs. concentration of TEA for the photochemical ring-cleavage of **1a** (○), **1b** (◑), **1c** (◑), **1d** (●), and **1f** (△) in hexane.

† Present address: Department of Chemistry, Faculty of Education, Miyazaki University, Gakuen-Kibanadai, Miyazaki 889-21.

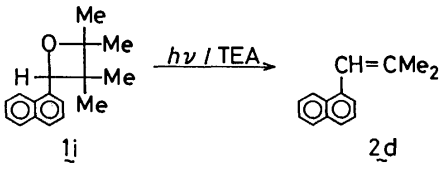
Table 2. Limiting Quantum Yields (ϕ^{∞}) in Photochemical Ring Cleavage of **1a—d, f** with TEA in Hexane

Oxetane	ϕ^{∞}
1a	0.09
1b	0.22
1c	0.31
1d	0.20
1f	0.02

tanes with *p*-toluenesulfonic acid. Substituted benzophenones and alkenes were not produced in the photoreaction. At low conversions (<5%), material balances were better than 90%, though other unreclaimed reactions increasingly occurred at higher conversions.

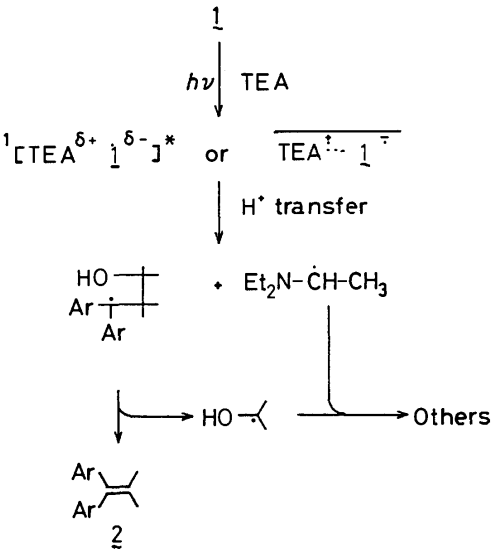
Quantum Yields. The formation of **2** increased linearly with the irradiation time up to 3% conversion. The formation of **2** increased with an increase in the concentration of TEA, but remarkably decreased at concentrations of TEA higher than 0.1 mol dm^{-3}. Since TEA has absorption at 254 nm in the UV spectrum, the absorption of incident light by TEA occurred to some extent. From the above-mentioned results, the photoexcitation of TEA would not bring about the ring-cleavage reactions of **1**. Therefore, the quantum yield (ϕ) for the formation of **2** at a given concentration of TEA was calculated on the basis of the light intensities absorbed by **1**. Thus, the quantum yields (ϕ) in various solvents were determined for the photochemical ring-cleavage reactions of **1b** (Table 1). Moreover, the limiting quantum yields (ϕ^{∞}) were determined by the usual double-reciprocal plots of ϕ vs. the concentration of TEA, for the photochemical ring-cleavage reactions of **1** in hexane (Fig. 1). The photochemical ring cleavage of **1a—d** proceeded in moderately high quantum yields, while those of **1f** occurred inefficiently. In the case of **1e, g, h**, no photochemical ring-cleavage occurred. The results are listed in Table 2.

Mechanism. No reaction occurred at all upon direct irradiation of **1** in the absence of TEA. The photochemical ring-cleavage of **1** occurred efficiently in nonpolar solvents, but proceeded inefficiently in polar solvents. Therefore, the exciplex formation between **1** and TEA can be assumed as being an initiation process, though no exciplex emission was observed in the cases of **1**-TEA pairs. An analogous 2,2,3,3-tetramethyl-4-(1-naphthyl)oxetane (**1i**) forms an emissive exciplex (λ_{max} 420 nm) with TEA in hexane; the photoreactions of **1i** with TEA gave 1-(1-naphthyl)-2-methylpropene (**2d**) (Scheme 2). Therefore, we assume a possible mechanism involving the exciplex formation followed by proton transfer from TEA to **1** in the exciplex or the ion pairs, as shown in Scheme 3. Similar mechanisms have been postulated for the photoreaction of aromatic hydrocarbons with TEA.[4] In a manner similar to that for acid-catalyzed fragmentation of oxetane ring, the protonated oxetane gives products (**2**) accompanying the formation of hydroxyalkyl radical which gives untractable materials. In polar solvents, the ion pair would dissociate into free ion radicals, and the inefficient photochemical ring-cleavage reactions would be attributed to the occurrence of unreclaimed reaction from free ion radicals.



1i 2d

Scheme 2.



Scheme 3.

In conclusion, it was found that photochemical ring-cleavage reactions of **1** in the presence of electron donors give the corresponding 1,1-diarylethenes selectively, in contrast with the photoreaction in the presence of electron acceptors[1] which affords substituted benzophenones and alkenes.

Experimental

Gas chromatography was performed on a Shimadzu GC-8A gas chromatograph using a 50 cm column of 2% OV-1 or 2% OV-17 on Chromosorb W. UV spectra and fluorescence spectra were obtained on a Hitachi 150-20 spectrometer or a Hitachi MPF-4 spectrometer, respectively.

Materials. Solvents were purified by usual methods.[5] Triethylamine was distilled before use. Preparation of oxetanes (**1**) were carried out by irradiation of benzene solution containing the substituted benzophenone or 1-naphthaldehyde and the alkene by high-pressure Hg lamp according to the procedure described in the previous paper.[1]

Photoreactions and Determination of Quantum Yields. Concentration of **1** were set in 0.01 mol dm^{-3} and concentration of TEA was variable between 0.03 and 0.144 mol dm^{-3}. Aliquot portions (4 cm^3) of reactant solutions and actinometer solutions were introduced into quartz tubes (8 mm, i.d.) and degassed by four freeze-pump-thaw cycles under high vacuum. Irradiation was carried out with an Eikosha EL-A 10 low-pressure Hg lamp using a "merry-go-round" turntable. Incident light intensity (I^0) was determined by the use of photocleavage reaction of 1,2,3,4-tetraphenyl-

cyclobutane to stilbene as an actinometer.[6] Quantum yields were calculated using light intensities (I) corrected by Eq. 1:

$$I = I^0 \varepsilon^1[\mathbf{1}]/(\varepsilon^1[\mathbf{1}] + \varepsilon^{TEA}[TEA]) \quad (1)$$

where ε^1 and ε^{TEA} represent molar extinction coefficient of **1** and TEA at 254 nm, respectively.

A Synthetic Route of 1,4,8-Trimethoxy-2-naphthalenecarbaldehyde via Duff Formylation of 4,8-Dimethoxy-1-naphthol[1)]

Yasuhiro TANOUE, Akira TERADA,* and Yasuyuki MATSUMOTO
Department of Chemistry, Kyushu Institute of Technology, Tobata, Kitakyushu, Fukuoka 804
(Received March 3, 1989)

Synopsis. A convenient route for preparing 1,4,8-trimethoxy-2-naphthalenecarbaldehyde was accomplished by the following: The starting material, 4,8-dimethoxy-1-naphthol, was prepared from 1,5-dimethoxynaphthalene through 1-bromo-4,8-dimethoxynaphthalene. Formylation of this naphthol and subsequent methylation gave 1,4,8-trimethoxy-2-naphthalenecarbaldehyde.

During the course of our synthetic studies of bioactive naphthoquinone derivatives, the entitled aldehyde, 1,4,8-trimethoxy-2-naphthalenecarbaldehyde (**3**) became one of the important intermediates. This compound was also a key intermediate in the syntheses of anthracycline system compounds[2)] and of 2-azanaphthacenequinone.[3)] This aldehyde **3** was first prepared as follows: i) Friedel-Crafts acylation of 2,5-dimethoxytoluene (**1**) with succinic anhydride, ii) Clemmensen reduction, then iii) cyclization gave a tetralone (**2**).[4)] Oxidation of **2** with 2,3-dichloro-5,6-dicyano-1,4-benzoquinone and methylation by trimethyl orthoformate gave **3**[2,3)] (Scheme 1).

Rapoport et al.[5)] have obtained 4,8-dimethoxy-1-naphthol (**5**) by the following process (Scheme 2). The naphthol **5** was conveniently used in the syntheses of 2-bromojuglone[5)] and of pyranonaphthoquinone.[6)] We will report here a synthetic method of 1,4,8-trimethoxy-2-naphthalenecarbaldehyde **3** via this naphthol **5** starting from 1,5-dimethoxynaphthalene (**4**).

Results and Discussion

We easily prepared the naphthol **5** from **4**; the process was as follows: i) Bromination of **4** and ii) oxidation of the organolithium compound, 1-lithio-4,8-dimethoxynaphthalene (Scheme 3).

Although two-equimolar bromination of **4** gave 4,8-dibromo-1,5-dimethoxynaphthalene,[7)] one molar-equivalent of bromine conveniently afforded 1-bromo-4,8-dimethoxynaphthalene (**6**) in 98% yield. Such a process as the direct lithiation of **4** using *n*-BuLi, treatment with butylmagnesium bromide, and oxidation to obtain **5** was unsuccessful. We attempted a direct hydrolysis of **6** using caustic alkali in the presence of Cu and Cu_2O; however, we still obtained unsatisfactory results. Finally, we tried a one-pot procedure, such as the lithiation of **6** by *n*-BuLi, treatment with *n*-BuMgBr, and oxidation to **5**.

Regarding the preparation of the final product **3** from **5**, the following two procedures were desirable:

(A) Formylation of 1,4,5-Trimethoxynaphthalene Leading to 3. Since we found that a trial formylation of 1,4-dimethoxynaphthalene (**7**) by a Vilsmeier reaction afforded 1,4-dimethoxy-2-naphthalenecarbaldehyde (**8**) in almost quantitative yield, the same procedure was carried out for 1,4,5-trimethoxynaphthalene (**9**) which was obtained by methylation of **5** with dimethyl sulfate. However, the yield of our required

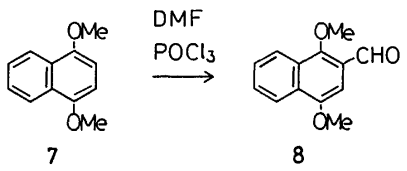
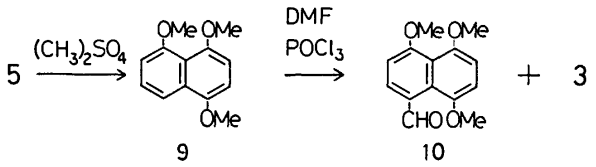


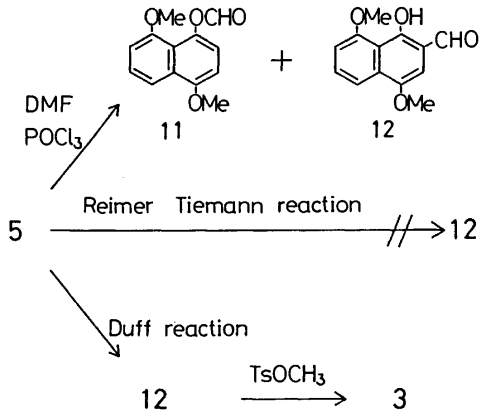


Scheme 4.

product (**3**) was slight (13%), and the main product was 4,5,8-trimethoxy-1-naphthalenecarbaldehyde (**10**) in 80% yield.

(B) Via Formylation of 5 to 1-Hydroxy-4,8-dimethoxy-2-naphthalenecarbaldehyde and Methylation to 3. Upon formylation the Vilsmeier reaction of **5** afforded mainly the formic ester (**11**) (62%) and the proposed 1-hydroxy-4,8-dimethoxy-2-naphthalenecarbaldehyde (**12**) was minor (24%). Another method, the Reimer-Tiemann reaction,[8] did not proceed. The Duff reaction[9] in acetic acid solvent resulted in 28% yield of **12**. The addition of an equimolar amount of *p*-toluenesulfonic acid monohydrate to this system resulted in a good yield of **12** (Scheme 5), though the reaction in trifluoro- and trichloroacetic acids gave only undesirable decomposition products (Table 1).

Methylation of **12** with methyl *p*-toluenesulfonate gave the final product **3** in 95% yield; with dimethyl sulfate the reaction was not satisfactory.



Scheme 5.

Experimental

Melting points were determined with a Yanagimoto micromelting point apparatus and were uncorrected. ^{1}H NMR spectra were taken on a JEOL JNM-60 in $CDCl_3$ using Me_4Si as an internal standard. Mass spectra and IR spectra were obtained with a JEOL DX-300 spectrometer, and a Hitachi 260-30 spectrometer, respectively. Column chromatography was carried out on silica gel (Wakogel C-200) or on alumina (Sumitomo, KCG-30) eluting with chloroform. Cu and Cu_2O powder of Wako Chemical Co. were used.

1-Bromo-4,8-dimethoxynaphthalene (6). Bromine (0.85 g, 5.3 mmol) in carbon tetrachloride (5 ml) was added dropwise to a solution of 1,5-dimethoxynaphthalene (**4**) (1.00 g, 5.3 mmol) in carbon tetrachloride (30 ml) at 70 °C. After stirring at 70 °C for 30 min, the solution was concentrated and the residue was chromatographed on silica gel to give 1.38 g (98%) of **6**. Recrystallization from hexane gave an analytical sample, mp 113—113.5 °C. IR (KBr) 1590, 1400, 1260, 1245, 1050, 800, and 740 cm^{-1}; ^{1}H NMR δ=3.94 (s, 6H, 2×OCH_3), 6.61 (d, J=8.4 Hz, 1H, ArH-2), 6.94 (dd, J=7.6 and 1.3 Hz, 1H, ArH-6), 7.32—7.46 (2d, J=8.4 and 7.6 Hz, 1H, ArH-7), 7.65 (d, J=8.4 Hz, 1H, ArH-3), 7.91 (dd, J=8.4 and 1.3 Hz, 1H, ArH-8); MS, m/z 268 (M^++2, 99.7%), 266 (M^+,100), 253 (48), 251 (49), 195 (26), 193 (28), and 115. Calcd for $C_{12}H_{11}O_2Br$: C, 53.96; H, 4.15%. Found: C, 53.07; H, 4.07%.

4,8-Dimethoxy-1-naphthol (5). A. Oxidation of the Lithium Compound of 6. A solution of **6** (0.20 g, 0.75 mmol) in tetrahydrofuran (10 ml) was cooled to −10 °C, and *n*-BuLi (1.20 ml, 1.87 mmol, 10 w/v % in hexane) was added and stirred at −10 °C for 1 h. To this system was added a solution of butylmagnesium bromide in tetrahydrofuran (Mg: 55 mg, 2.25 mmol; BuBr: 0.31 g, 2.25 mmol; THF: 10 ml) at −10 °C. After 40 min, dry oxygen was bubbled into the system for 1 h at such a rate as to keep the temperature

Table 1. Preparation of **12** from **5** by Duff Reaction

Entry	Solvent and catalyst	Condition		Yield/%
		Temp/ °C	Time/h	
1	CF_3COOH	85	3.5	0[a]
2	CCl_3COOH	95	1	0[a]
3	CH_3COOH	85	2	0[b]
4	CH_3COOH	Reflux	1	28
5	CH_3COOH, $TsOH\cdot H_2O$	Reflux	1	40
6	CH_3COOH, $TsOH\cdot H_2O$	Reflux	3	61
7	CH_3COOH, $TsOH\cdot H_2O$	Reflux	5	60
8	CH_3COOH, $TsOH\cdot H_2O$	Reflux	14	40

a) Decomposition product was obtained. b) Only starting material was recovered.
